      = FT r (e' + 1) ((heisVOA1 r).smul (X (0, b)) ℓ w)
```

From the mathematics to the Lean statement

(35.11) with $u = X(0,b)$, $e = 1$ (so $e/2 = \frac{1}{2}$), all ℓ, all w, all e'. No hypotheses.

Physical meaning

This is the product formula (twisted OPE) for the basic field ∂X against any local operator: the OPE of the twisted current with an arbitrary composite operator is the OPE of the untwisted theory dressed by the branch factor. In free-field language it follows from Wick's theorem: the singular part of the OPE is a sum of contractions, which are computed by the canonical commutators $[\alpha_s, \alpha_t]$.

Proof on paper. For $\ell < 0$ this is Theorem 35.36. For $\ell \geq 0$ induct on the monomial w. If $w = \mathbf{1}$: the left side is $F_b \star_\ell^{1/2} (z^c 1)$ or 0, which vanishes by Proposition 35.31(i),(iii); the right side is $\widetilde{F}(b_{(\ell)}\mathbf{1}) = 0$. If $w = x_{(n,c)}w'$, write $\widetilde{F}_{e'}(w) = F_c \star_{-n-1}^{1/2} \widetilde{F}_{e'-1}(w')$ and apply the twisted commutator formula (Theorem 35.30) with $A = F_b$, $B = F_c$. By Proposition 35.32 and 35.31(iv),

$$F_b \star_\ell^{1/2} \left(F_c \star_{-n-1}^{1/2} X\right) = F_c \star_{-n-1}^{1/2} \left(F_b \star_\ell^{1/2} X\right) + \ell\, \delta_{bc}\, \delta_{\ell,n+1}\, zX.$$

By induction and creation the first term is $\widetilde{F}_{e'+1}(c_{(-n-1)}b_{(\ell)}w')$; the second is $\ell\delta_{bc}\delta_{\ell,n+1}\widetilde{F}_{e'+1}(w')$. In W, $b_{(\ell)}c_{(-n-1)}w' = c_{(-n-1)}b_{(\ell)}w' + \ell\delta_{bc}\delta_{\ell,n+1}w'$, the Heisenberg relation $[h_b(\ell), h_c(-n-1)] = \ell\delta_{bc}\delta_{\ell,n+1}$. The two sides agree. □

What the machine verified

Unconditional, axiom-clean.

35.12.2 Translation covariance and the vacuum

Theorem 35.38 (Translation covariance). *For every class e and state u: $\partial\widetilde{F}_e(u) - \frac{e}{2}z^{-1}\widetilde{F}_e(u) = \widetilde{F}_e(L_{-1}u)$. Consequently $\widetilde{F}_e(u) \star_\ell^{e/2} 1 = \widetilde{F}_e(u_{(\ell)}\mathbf{1})$ for all ℓ.*

```
theorem FT_translation (e : ℤ) (u : FockN r) :
    Fld.deriv (FT r e u) - ((e : ℂ) / 2) • fzmul (-1) (FT r e u)
      = FT r e ((heisVOA1 r).toPreVertexAlgebra.T u)

theorem starPF_one (e : ℤ) (u : FockN r) (ℓ : ℤ) :
    star ((e : ℂ) / 2) (FT r e u) ℓ Fld.one = FT r e ((heisVOA1 r).smul u ℓ (vacuumN r))
```

From the mathematics to the Lean statement

`T` is the translation operator L_{-1} of W (`T_eq_smul_omega`: $Tu = \omega_{(0)}u$). Since $\widetilde{F}_e(u) = z^{e/2}Y^T(u,z)$ (restricted to its class), $\partial\widetilde{F}_e = \frac{e}{2}z^{-1}\widetilde{F}_e + z^{e/2}\partial Y^T(u,z)$, so the first statement is the twisted L_{-1}-derivative property $\partial_z Y^T(u,z) = Y^T(L_{-1}u,z)$. The second is (35.11) with $v = \mathbf{1}$ on the class 0. Neither statement assumes u is an eigenvector or that e is on its class (off the class both sides are zero).

Physical meaning

The translation property is the statement $\partial_z Y^T(u,z) = Y^T(L_{-1}u,z)$: the derivative of a field is the field of the derivative state, with the extra term $\frac{e}{2}z^{-1}$ coming from differentiating the factor $z^{e/2}$ that was stripped off. Together with the vacuum property it expresses that L_{-1} generates translations of the insertion point of every twisted field, as the Ward identity requires; translation covariance in the presence of the twist field is only a statement relative to the origin, whence the term $\frac{e}{2}z^{-1}$.

Proof on paper. Translation: induct on monomials; for $u = x_{(n,c)}w$ use creation, the derivative rule (Proposition 35.31(vi)) with $\alpha = \frac{1}{2}$, the induction hypothesis for w on the class $e-1$, and $T(c_{(-n-1)}w) = c_{(-n-1)}Tw + (n+1)c_{(-n-2)}w$; the z^{-1} terms combine as $\frac{1}{2} + \frac{e-1}{2} = \frac{e}{2}$. Vacuum: for $\ell \geq 0$ both sides are 0; for $\ell = -1$ both are $\widetilde{F}_e(u)$; for $\ell = -k-2$ use (v) of Proposition 35.31 together with translation and $(Tu)_{(n)} = -nu_{(n-1)}$, by induction on k (for all u simultaneously), dividing by $k+1 \neq 0$. □

What the machine verified

Unconditional, axiom-clean. `VOA/Moonshine/HeisenbergTwistedModuleProductFormula.lean`.

35.12.3 The product formula

Theorem 35.39 (Twisted product formula, star form). *Let $u \in V^j$ and $e \equiv j \pmod 2$. For every state v, every class e' and every $\ell \in \mathbb{Z}$: $\widetilde{F}_e(u) \star_\ell^{e/2} \widetilde{F}_{e'}(v) = \widetilde{F}_{e+e'}(u_{(\ell)}v)$.*

```
theorem starPF {j : ℕ} {u : FockN r} (hu : u ∈ (sigma1 r).twistedEigenspace 2 j) {e : ℤ}
    (he : (e + j) % 2 = 0) (v : FockN r) (e' ℓ : ℤ) :
    star ((e : ℂ) / 2) (FT r e u) ℓ (FT r e' v) = FT r (e + e') ((heisVOA1 r).smul u ℓ v)
```

From the mathematics to the Lean statement

Hypotheses: `hu` u is a σ-eigenvector of eigenvalue $(-1)^j$; `he` $2 \mid e + j$, i.e. the class of u is its support class. Both are necessary in general: off its class $\widetilde{F}_e(u) = 0$, while $\widetilde{F}_{e+e'}(u_{(\ell)}v)$ need not vanish. v is arbitrary. This is (35.11), i.e. the twisted vertex operator intertwines the products of W with the twisted products. **Not vacuous**: the right side is nonzero in general (e.g. $u = v = h_a(-1)\mathbf{1}$, $\ell = 1$ gives $z \cdot 1$).

Physical meaning

This is the twisted OPE in full generality: the operator product of two twisted fields is given by the untwisted OPE $u_{(\ell)}v$ up to the branch factor $(1 + z_{12}/z_2)^{e/2}$ of the cut from the twist field. In CFT terms it is associativity of the twisted correlator, equivalently that the twist field $\sigma(0)$ together with two operators at z_1, z_2 can be fused in the channel $z_1 \to z_2$ without knowing the details of σ beyond its monodromy; the proof uses only canonical commutation

relations, not any correlator.

Proof on paper. Induction on the monomial v, *for all u and j simultaneously*. For $v = \mathbf{1}$: Theorem 35.38 (classes e' even; for odd e' both sides are 0 by parity). For $v = x_{(n,c)}v' = c_{(-n-1)}v'$: by creation, $\widetilde{F}_{e'}(v) = F_c \star^{1/2}_{-n-1} \widetilde{F}_{e'-1}(v')$. Apply Theorem 35.30 with the *generator outside*: $A = F_c$, $B = \widetilde{F}_e(u)$, $C = \widetilde{F}_{e'-1}(v')$, twists $\frac{1}{2}$ and $\frac{e}{2}$:

$$F_c \star^{1/2}_{-n-1} \left(\widetilde{F}_e(u) \star^{e/2}_{\ell} C\right) - \widetilde{F}_e(u) \star^{e/2}_{\ell} \left(F_c \star^{1/2}_{-n-1} C\right) = \sum_s \binom{-n-1}{s} \left(F_c \star^{1/2}_{s} \widetilde{F}_e(u)\right) \star^{(e+1)/2}_{-n-1+\ell-s} C.$$

The second term on the left is what we want. The first is, by induction (shorter v') and creation, $\widetilde{F}_{e+e'}(c_{(-n-1)}u_{(\ell)}v')$. In the sum, Theorem 35.37 gives $F_c \star^{1/2}_s \widetilde{F}_e(u) = \widetilde{F}_{e+1}(c_{(s)}u)$; now $c_{(s)}u \in \mathcal{V}^{j+1}$ and $e+1 \equiv j+1$, so the induction hypothesis (for the eigenvector $c_{(s)}u$ and the shorter v') turns each summand into $\widetilde{F}_{e+e'}((c_{(s)}u)_{(-n-1+\ell-s)}v')$. Finally the VOA commutator formula $c_{(-n-1)}u_{(\ell)}v' - u_{(\ell)}c_{(-n-1)}v' = \sum_s \binom{-n-1}{s}(c_{(s)}u)_{(-n-1+\ell-s)}v'$ matches the two sides. *No associativity* of either side is used — only commutator formulas, creation and translation. □

What the machine verified

Unconditional; `#print axioms starPF` = `[propext, Classical.choice, Quot.sound]`.

Theorem 35.40 (Twisted product formula, product form). *For $u \in \mathcal{V}^j$ and every v, class e', ℓ, s, x: the product formula (35.7) holds for $\widetilde{F}_j(u)$ and $\widetilde{F}_{e'}(v)$.*

```
theorem productFormula_YT (j : ℕ) (u : FockN r) (hu : u ∈ (sigma1 r).twistedEigenspace 2 j)
    (v : FockN r) (e' : ℤ) (ℓ s : ℤ) (x : FockT r) :
    mode (Fld.prod ℓ (rescFld (by norm_num : 0 < 2) (YT_truncation r u) (j : ℤ))
        (rescFld (by norm_num : 0 < 2) (YT_truncation r v) e')).1 s x
      = ∑ᶠ t : ℕ, cbinom ((((j : ℤ) : ℤ) : ℂ) / (2 : ℕ)) t •
          YT r ((heisVOA1 r).smul u (ℓ + t) v) ((2 : ℕ) * (s - t) + (j : ℤ) + e') x
```

From the mathematics to the Lean statement

Character for character the hypothesis `hpf` of `twistedJacobi_YT_of_productFormula` (§35.7), except that it holds for all e', not only $e' \in \{0, 1\}$.

Physical meaning

The product form is the twisted OPE written mode by mode: it says that the commutation relations of the twisted modes follow from the untwisted OPE and the monodromy $e/2$ around the twist field. Physically it is the same statement as the star form, the input to the Jacobi identity.

Proof on paper. Theorem 35.39 with $e = j$ is the inverse formula (35.8) in modes; Proposition 35.12 with $c = j/2$ inverts it (both families vanish for large ℓ, by locality and by $u_{(\ell)}v = 0$ for $\ell \gg 0$). □

What the machine verified

Unconditional, axiom-clean.

Theorem 35.41 (The twisted Jacobi identity). *Y^T satisfies the Dong–Li–Mason twisted Jacobi identity (35.4) for σ, $N = 2$, for all pairs of states.*

File `VOA/Moonshine/HeisenbergTwistedModuleProductFormula.lean`.

```
theorem twistedJacobi_YT : TwistedJacobi (sigma1 r) 2 (YT r) :=
  twistedJacobi_YT_of_productFormula r
    (fun j u hu v e' _ _ ℓ s x => productFormula_YT r j u hu v e' ℓ s x)
```

From the mathematics to the Lean statement

The one-line proof term is informative: it is literally "the reduction of §35.7, fed with Theorem 35.40", and locality was already built into that reduction (Theorem 35.24). `TwistedJacobi` is defined in §35.2.4.

Physical meaning

The twisted Jacobi identity is the complete algebraic form of the consistency of the free boson in the $\mathbb{Z}_2$-twisted sector: locality, OPE and monodromy around the twist field all hold simultaneously, so the twisted sector is a genuine module of the orbifold chiral algebra. It encodes crossing symmetry of all correlators $\langle\sigma|\, u(z_1)\, v(z_2)\,|\sigma\rangle$ (sphere with the twist field at 0 and the conjugate twist field at infinity).

What the machine verified

Unconditional; `#print axioms twistedJacobi_YT` = `[propext, Classical.choice, Quot.sound]`.

35.13 The grading and the instance

35.13.1 The complex weight decomposition

`TwistedModule` wants a grading indexed by $\mathbb{C}$; $S[\theta]$ comes with the grading `gradingT r d` by doubled degree $d \in \mathbb{N}$, with L_0-eigenvalue $d/2 + r/16$.

Definition 35.42. $M_\alpha := \sum\{\texttt{gradingT r d} : d \in \mathbb{N},\ d/2 + r/16 = \alpha\} \subseteq S[\theta]$, for $\alpha \in \mathbb{C}$.

```
noncomputable def weightC (α : ℂ) : Submodule ℂ (FockT r) :=
  ⨆ (d : ℕ) (_ : ((levelT r d : ℚ) : ℂ) = α), gradingT r d

theorem weightC_isInternal : DirectSum.IsInternal (weightC r)
theorem weightC_finiteDimensional (α : ℂ) : FiniteDimensional ℂ (weightC r α)
theorem YT_omega_two_weightC {α : ℂ} {x : FockT r} (hx : x ∈ weightC r α) :
    YT r (heisVOA1 r).conformalVector 2 x = α • x
theorem weightC_boundedBelow :
    ∃ B : ℝ, ∀ α : ℂ, weightC r α ≠ ⊥ → B ≤ α.re
```

From the mathematics to the Lean statement

`⨆` is the supremum (sum) of submodules over all d satisfying the condition; since $d \mapsto d/2 + r/16$ is injective, M_α is a single `gradingT r d` or 0 (`weightC_level`, `weightC_eq_bot`). The four theorems are exactly the fields `isInternal`, `finrank`, `L0_weight`, `boundedBelow` of `TwistedModule`; the bound is $B = r/16$. **Not vacuous**: the grading is the honest L_0-eigenspace decomposition (by `YT_omega_two_weightC`, L_0 really acts by α on M_α), and $M_{r/16} = \mathbb{C}\,\mathbf{1} \neq 0$.

Physical meaning

The grading is by L_0, the conformal weight: oscillator states $h_{a_1}(-t_1)\cdots h_{a_m}(-t_m)|\sigma\rangle$, $t_i \in \frac{1}{2}+\mathbb{N}$, have energy $\sum t_i + r/16$, with the twist-field ground state at $h_\sigma = r/16$. Finite-dimensionality of each level and the bound below are the standard properties of a unitary Fock space with positive-frequency oscillators (the partition function $\mathrm{Tr}\, q^{L_0-c/24}$ is then well defined).

Proof on paper. Monomials of each doubled degree d are finitely many (each variable has weight $2n+1 \geq 1$), the polynomial ring is the direct sum of its homogeneous pieces, and L_0^T acts on degree d by $d/2 + r/16$ (Theorem 35.25). Real parts are $\geq r/16$. □

What the machine verified

Unconditional, axiom-clean. `VOA/Moonshine/HeisenbergTwistedModuleInstance.lean`.

35.13.2 The main theorem

Theorem 35.43 (The twisted Heisenberg module). *For every $r \in \mathbb{N}$, the twisted Fock space $S[\theta]$, with the twisted vertex operator Y^T of Definition 35.22 and the grading M_α, is a σ-twisted module of order 2 for the level-one rank-r Heisenberg VOA, in the sense of Definition 35.4. Its generators act by the twisted bosons, and its L_0 is $\sum h_a(-n-\frac{1}{2})h_a(n+\frac{1}{2}) + \frac{r}{16}$.*

```
noncomputable def heisTwistedModule : TwistedModule (sigma1 r) 2 (FockT r) where
  YM := YT r
  vacuum_YM k := by
    change YT r (vacuumN r) k = _
    rw [YT_vacuum]
    push_cast
    rfl
  truncation := YT_truncation r
  support := fun j u hu k hk => YT_support r j u hu k hk
  jacobi := twistedJacobi_YT r
  weight := weightC r
  isInternal := weightC_isInternal r
  L0_weight := fun α x hx => YT_omega_two_weightC r hx
  finrank := weightC_finiteDimensional r
  boundedBelow := weightC_boundedBelow r

@[simp] theorem heisTwistedModule_YM : (heisTwistedModule r).YM = YT r := rfl
```

From the mathematics to the Lean statement

What the declaration asserts. A `def` whose type is the structure `TwistedModule (sigma1 r) 2 (FockT r)`: Lean accepts it only if every field is supplied, so the existence of this term is the theorem. The field list is printed in full; each is a theorem of this chapter: `YM` (Definition 35.22), `vacuum_YM`, `truncation`, `support` (Theorem 35.23), `jacobi` (Theorem 35.41), and the grading fields (§35.13). **Hypotheses:** none, beyond $r \in \mathbb{N}$. **The additional content** of Theorem 35.43 (generators act by twisted bosons; the form of L_0) is not part of the type `TwistedModule`, but is recorded by `heisTwistedModule_YM` together with `YT_X` and `YT_omega_two`. A referee should insist on this: `TwistedModule` alone would also be satisfied by other structures (for instance, for $r = 0$ the space is $\mathbb{C}$), so it is the pair "instance + `YT_X` + `YT_omega_two`" that identifies *the* twisted Heisenberg module. **How it could have been vacuous:** before the 2026-10-06 repair, the type `TwistedModule (sigma1 r) 2 (FockT r)` was empty (§35.2.4); with the repaired,

DLM-faithful Jacobi field it is inhabited, and the inhabitant is nontrivial (`FockT r` is a nonzero space — the library records `Nontrivial (FockT r)` — with $Y^T(h_a(-1)\mathbf{1}) \neq 0$ for $r \geq 1$).

Physical meaning

This is the construction of the $\mathbb{Z}_2$-twisted sector of the rank-r free-boson CFT: the Hilbert space of r antiperiodic bosons, with twist field σ of weight $r/16$ (for $r = 24$ this is $24/16 = \frac{3}{2}$; this is the oscillator half of the twisted sector of the Leech lattice CFT by the lift of -1, which enters the Moonshine orbifold). The vertex operators Y^T are the untwisted fields acting in the presence of the twist field, the half-integer modes realise the antiperiodic boundary condition, and the twisted Jacobi identity is crossing symmetry. This sector is what must be added to the $\mathbb{Z}_2$-invariant part of the Leech lattice CFT to obtain a modular-invariant theory, the Moonshine module.

Proof on paper. Assemble: Theorems 35.23, 35.41 and §35.13. □

What the machine verified

Unconditional. `#print axioms VOA.Moonshine.heisTwistedModule` (run while writing this chapter):

```
'VOA.Moonshine.heisTwistedModule' depends on axioms: [propext, Classical.choice,
↪  Quot.sound]
```

No `VOA.pbw`. This is only the Heisenberg part of the project's twisted-module milestone (the construction of the θ-twisted module of the Leech lattice VOA): the lattice twisted module $S[\theta] \otimes T$ is constructed in Chapter 36.

35.14 Dead ends, traps and corrections

Trap / dead end

1. The over-quantified Jacobi field (§35.2.4): unsatisfiable for $N \geq 2$, certificate $u = v = \mathbf{1}$, $\ell = -1$, $k = 1$, $m = -N - 1$ gives $0 = x$ (`jacobiAllIndices_eq_zero`). Repaired in `VOA/Modularity/Twisted.lean`; the same defect remains in `SuperTwistedModule.jacobi` (unrepaired, unused here).
2. Naive substitution is wrong. Defining $Y^T(u)$ by the untwisted normal-ordered formula with h replaced by the twisted h (i.e. keeping only the i with $-n-1+i<0$ in (35.9)) gives $Y^T(\omega)_{(1)} = \sum h(-n-\frac{1}{2})h(n+\frac{1}{2})$, missing the $r/16$; it also violates the product formula. The contraction terms are essential (§35.8).
3. Word order. The canonical word of a monomial is produced by `Finset.toList`, whose order is unspecified; until Theorem 35.34 was proved the definition of Y^T on quadratic states was not known to be choice-independent.
4. Stale docstrings. `HeisenbergTwistedModuleVertex.lean` and `HeisenbergTwistedModuleGenerators.lean` describe the product formula and the $\ell < 0$ Jacobi identity as "not here"/"open"; they are proved in later files. A referee reading those docstrings should not conclude that the instance is conditional: its type has no hypotheses and its axioms are the standard three.

35.16 Notes and references

The twisted Heisenberg vertex operators, including the operator Δ_z and its coefficients c_{mn}, were introduced by J. Lepowsky, *Calculus of twisted vertex operators*, Proceedings of the National Academy of Sciences USA 82 (1985) 8295–8299, and are developed systematically in I. Frenkel, J. Lepowsky and A. Meurman, *Vertex Operator Algebras and the Monster*, Pure and Applied Mathematics 134, Academic Press, Boston, 1988: Chapter 3 for the untwisted and twisted Heisenberg algebras and their Fock spaces, Chapter 9 for twisted vertex operators and the twisted Jacobi identity. The ground-state energy $1/16$ is also explained in J. Lepowsky, *Perspectives on vertex operators and the Monster*, Proc. Symp. Pure Math. 48 (1988).

The mode form of the twisted Jacobi identity used here, with the fractional binomial $\binom{k/N}{i}$ and the support-coset restriction, is from C. Dong, H. Li and G. Mason, *Modular-invariance of trace functions in orbifold theory and generalized Moonshine*, Communications in Mathematical Physics 214 (2000) 1–56, arXiv:q-alg/9703016; twisted modules for general automorphisms go back to C. Dong, *Twisted modules for vertex algebras associated with even lattices*, Journal of Algebra 165 (1994) 91–112, and C. Dong and J. Lepowsky, *Generalized Vertex Algebras and Relative Vertex Operators*, Progress in Mathematics 112, Birkhäuser, 1993.

The local-system method — fields, their integer products, Dong's lemma, and the theorem that a local system is a vertex algebra — is H.-S. Li, *Local systems of vertex operators, vertex superalgebras and modules*, Journal of Pure and Applied Algebra 109 (1996) 143–195, arXiv:hep-th/9406185; the twisted version (twisted products $Y^\star$ with the factor $(1+z_0/z)^{-\alpha}$) is H.-S. Li, *Local systems of twisted vertex operators, vertex operator superalgebras and twisted modules*, in: Moonshine, the Monster, and Related Topics, Contemporary Mathematics 193 (1996) 203–236, arXiv:q-alg/9504022. The present chapter's reduction (rescale by $z^{e/N}$, apply untwisted Jacobi, absorb $(1+z_0/z)^{e/N}$ by Vandermonde) is a hands-on special case of Li's twisted local systems; the library proves exactly the pieces needed for this example rather than Li's general theorem. For the physical picture (antiperiodic bosons, twist fields of dimension $1/16$) see L. Dixon, D. Friedan, E. Martinec and S. Shenker, *The conformal field theory of orbifolds*, Nuclear Physics B 282 (1987) 13–73.

The history of the repair and the construction is recorded in the repository file `Notes/MonsterRoadmap.md` (the row of the twisted-module milestone and "Recorded dead ends").

Chapter 36

The twisted Leech lattice module and $(V_\Lambda^T)^+$

This chapter documents the release of the LeanVOA library named in the front matter. Every Lean quotation below is checked by `scripts/textbook/sync.py` to occur verbatim (up to whitespace and comments) in the source files of that release. Checks that were run at an earlier state of the library and not re-run for this edition are marked as such. It constructs the second half of the Moonshine module. In Chapter 31 we built the lattice vertex operator algebra V_L of an even lattice L, in Chapter 32 the lift θ of the lattice involution -1 to V_L and its fixed points V_L^+, in Chapter 34 the twisted Fock space $S[\theta]$, the finite-dimensional module $\mathcal{T}$ of the extraspecial group and the (repaired) notion of a twisted module, and in Chapter 35 the twisted Heisenberg module, i.e. the θ-twisted module structure on $S[\theta]$ for the Heisenberg sub-VOA. Here we put the lattice into it.

The two headline results are:

(A) **The twisted module.** For every even, positive-definite, unimodular lattice L the space $V_L^T = S[\theta] \otimes \mathcal{T}_L$ carries the structure of a θ-twisted V_L-module of order 2, with the twisted vertex operators of Frenkel, Lepowsky and Meurman (FLM). For $L = \Lambda$ the Leech lattice this is the declaration `VOA.Moonshine.LatticeTwisted.leechTwistedModule`.

(B) **The plus part.** The involution θ lifts to V_Λ^T (acting by -1 on $\mathcal{T}$), and its fixed space $(V_\Lambda^T)^+$ is an ordinary module for the fixed-point VOA V_Λ^+, whose weight spaces are integral, start at weight 2 with dimension 98304, and whose graded dimension added to that of V_Λ^+ is $qJ(q)$. This is `VOA.Moonshine.plusModule` together with `VOA.Moonshine.finrank_plusModule_eq_coeff_JShift`.

Both are proved *unconditionally*: the only hypotheses of the general construction are that L is even, positive definite, and has unimodular Gram matrix, and these are proved for the Leech lattice in Chapter 30.

How to read this chapter. Following the book's constitution, each definition and theorem is presented as: mathematical statement; the Lean declaration copied verbatim; a *fidelity check* (the box "From the mathematics to the Lean statement") which decodes the Lean statement, lists every hypothesis, and says whether the Lean statement is the same as, stronger, or weaker than the mathematics and why it is not vacuous; a proof on paper; and the machine status. Proofs are explained mathematically; we do not tour the Lean proof scripts.

36.1 The physical picture and the plan

36.1.1 Chiral bosons on a double cover

Physically, V_Λ is the chiral algebra of 24 free chiral bosons $X^i(z)$ compactified on the torus $\mathbb{R}^{24}/\Lambda$; the states e^α are the vertex operators $:e^{i\alpha\cdot X(z)}:$, and the Heisenberg fields $h_i(z) = i\partial X^i(z)$ are the currents. The involution θ is the reflection $X \mapsto -X$. The *θ-twisted sector* is the space of states of the bosons on which X is antiperiodic around the origin: $X(e^{2\pi i}z) = -X(z)$. The currents then have half-integral modes,

$$h_i(z) = \sum_{n \in \frac{1}{2}+\mathbb{Z}} h_i(n)\, z^{-n-1}, \qquad [h_i(m), h_j(n)] = m\,\delta_{ij}\,\delta_{m+n,0},$$

and the Fock space they generate from a ground state is $S[\theta] = \mathbb{C}[h_i(-\tfrac12), h_i(-\tfrac32), \dots]$ (Chapter 34). The ground state of 24 antiperiodic bosons has conformal weight $24/16 = 3/2$. Antiperiodic bosons have no zero modes, hence no momentum: the lattice cannot appear as a momentum label. Instead, the zero-mode part of the operator $:e^{i\alpha\cdot X}:$ survives only as a finite-dimensional "cocycle" operator e_α acting on a degenerate ground-state space $\mathcal{T}$ of dimension 2^{12} (for Λ): the e_α satisfy $e_\alpha e_\beta = (-1)^{\langle\alpha,\beta\rangle} e_\beta e_\alpha$, which is a representation of an extraspecial 2-group (Chapter 34). So

$$V_\Lambda^T = S[\theta] \otimes \mathcal{T}, \qquad \dim \mathcal{T} = 2^{12} = 4096.$$

36.1.2 The twisted vertex operator

On V_Λ^T the vertex operator of e^α is (FLM, Chapter 9)

$$Y^T(e^\alpha, z) = 2^{-\langle\alpha,\alpha\rangle}\, z^{-\langle\alpha,\alpha\rangle/2}\, E^-(-\alpha, z)\, E^+(-\alpha, z) \otimes e_\alpha, \tag{36.1}$$

$$E^\mp(-\alpha, z) = \exp\Big(\pm \sum_{n \in \frac12+\mathbb{N}} \frac{\alpha(\mp n)}{n} z^{\pm n}\Big), \tag{36.2}$$

where $\alpha(n) = \sum_i \alpha_i h_i(n)$ in orthonormal coordinates. The creation part E^- contains only $h(-n)$ with $n > 0$ and the annihilation part E^+ only $h(n)$, $n > 0$; both are well defined on $S[\theta]$ because on any given vector only finitely many terms of E^+ survive. The powers z^n with $n \in \frac12 + \mathbb{Z}$ are the reason everything is written in the doubled variable $w = z^{1/2}$.

The heart of the theory of these operators is a single reordering identity (proved below as `EpC_sMz_mul`):

$$E^+(-\alpha, z_1)E^-(-\beta, z_2) = E^-(-\beta, z_2)E^+(-\alpha, z_1)\Big(\frac{1 - z_2^{1/2}/z_1^{1/2}}{1 + z_2^{1/2}/z_1^{1/2}}\Big)^{\langle\alpha,\beta\rangle}. \tag{36.3}$$

In the untwisted theory the corresponding factor is $(1 - z_2/z_1)^{\langle\alpha,\beta\rangle}$; here it is a ratio. Near the diagonal, $w_1 \approx w_2$, we have $1 - w_2/w_1 \approx (z_1 - z_2)/(2z_1)$ and $1 + w_2/w_1 \approx 2$, so the factor behaves like $\big((z_1 - z_2)/(4z_1)\big)^{\langle\alpha,\beta\rangle}$. The stray $4^{-\langle\alpha,\beta\rangle}$ is exactly what the normalisation $2^{-\langle\alpha,\alpha\rangle}$ in (36.1) is designed to cancel, since

$$2^{-\langle\alpha,\alpha\rangle}\, 2^{-\langle\beta,\beta\rangle}\, 4^{-\langle\alpha,\beta\rangle} = 2^{-\langle\alpha+\beta,\alpha+\beta\rangle}. \tag{36.4}$$

This one line is the reason the product formula $e^\alpha_{(-\langle\alpha,\beta\rangle-1)}e^\beta = \varepsilon(\alpha,\beta)e^{\alpha+\beta}$ of V_L is reproduced on the twisted side (§36.10).

36.1.3 Plan of the construction

The construction follows the route "locality plus product formula implies the Jacobi identity" prepared in Chapter 35:

1. §36.3–§36.5: the algebra of $E^{\pm}$ on $S[\theta]$: Newton exponentials, the contraction factor $((1-x)/(1+x))^n$, the reordering (36.3), the two-point identity and the locality of the operators (36.1).
2. §36.6: the twisted vertex operators $Y^T(e^\alpha, z)$ and the locality of the whole generated system of fields.
3. §36.7: the extension of Y^T to every state of V_L, forced by the twisted iterate formula for the Heisenberg generators.
4. §36.8–§36.10: the *twisted product formula* for all pairs of states, reduced to the pair (e^α, e^β), which is proved by a descent in the mode index together with a uniqueness lemma and an explicit vacuum computation; here the normalisation $2^{-\langle\alpha,\alpha\rangle}$ enters.
5. §36.11: the twisted Jacobi identity, the grading, and the instance `latticeTwistedModule` / `leechTwistedModule`.
6. §36.12–§36.14: θ on the twisted sector, the general "plus part of an order-two twisted module" construction, and $(V_\Lambda^T)^+$ as a V_Λ^+-module, with its dimensions.

All declarations live in the namespace `VOA.Moonshine.LatticeTwisted` (files `VOA/Moonshine/LatticeTwisted*.lean`), except the plus-part construction (`VOA.TwistedPlus`, `VOA/Moonshine/TwistedPlusModule.lean`) and the Leech plus module (`VOA.Moonshine`, `VOA/Moonshine/TwistedPlus.lean`).

36.2 Notation and the objects we build on

This section recalls, with their Lean sources, the definitions from earlier chapters that occur in the statements of this chapter. The reader who has Chapters 34 and 35 fresh may skim it, but every later fidelity check refers back here.

36.2.1 The twisted Fock space and its modes

Definition 36.1 (Twisted Fock space). For $r \in \mathbb{N}$, $S[\theta] = S[\theta]_r$ is the polynomial algebra over $\mathbb{C}$ in variables $X_{(n,i)}$, $n \in \mathbb{N}$, $i \in \{0, \dots, r-1\}$, where $X_{(n,i)}$ stands for the creation operator $h_i(-n-\frac{1}{2})$ applied to the vacuum 1. The mode $h_i(k/2)$ for odd k acts as multiplication by $X_{((-k-1)/2,i)}$ if $k<0$ and as $\frac{k}{2}\,\partial/\partial X_{((k-1)/2,i)}$ if $k>0$.

File `VOA/Moonshine/TwistedHeisenberg.lean`.

```
abbrev FockT (r : ℕ) : Type := MvPolynomial (ℕ × Fin r) ℂ

noncomputable def modeT (r : ℕ) (i : Fin r) (k : ℤ) : Module.End ℂ (FockT r) :=
  if k % 2 = 0 then 0
  else if k < 0 then mulXT (varT i k)
  else ((k : ℂ) / 2) • pderivT (varT i k)
```

From the mathematics to the Lean statement

Half-integer modes. Lean has no type of half-integers; the mode $h_i(k/2)$ is indexed by the *integer* k, and only odd k are meaningful. For even k the definition returns the junk value

0, which is mathematically correct (a θ-twisted current has no integral modes). This "index k stands for $k/2$" convention is used throughout the chapter: every twisted vertex operator is a function $\mathbb{Z} \to \mathrm{End}$, whose value at k is the coefficient $u_{(k/2)}$. With this normalisation $[h_i(k/2), h_j(l/2)] = \frac{k}{2}\delta_{ij}\delta_{k+l,0}$ (Chapter 34, `modeT_comm`). `L0T r` is the Virasoro zero mode $L_0 = \frac{1}{2}\cdot(\text{doubled weight}) + \frac{r}{16}$ of Chapter 35, and `gradingT r d` the span of monomials of doubled weight d (a variable $X_{(n,i)}$ has doubled weight $2n+1$). `thetaT r` is the algebra automorphism $X_{(n,i)} \mapsto -X_{(n,i)}$.

Physical meaning

In the Leech lattice CFT the θ-twisted sector is built on 24 free bosons whose oscillators carry half-integer moding, $\alpha^a_{-n-1/2}$, because the fields ∂X^a pick up a sign -1 on going around the twist field inserted at the origin. The polynomial ring $S[\theta]_r$ is the Fock space of these twisted oscillators; the ground state 1 is the twist field with no oscillator excited. Its weight is $r/16$, which is $3/2$ for $r = 24$: each of the 24 bosons contributes the standard $1/16$ twisted vacuum energy. This is the oscillator half of the twisted sector $V_\Lambda^T = S[\theta][\theta] \otimes T$; the other half is the space of ground states.

36.2.2 Fields, products, locality

The library's calculus of fields (Chapters 2, 4 and 35) uses the following objects. A *formal distribution* is a function $f : \mathbb{Z} \to \mathrm{End}(M)$, read as $f(z) = \sum_n f(n)z^n$; its mode is `mode f m = f (-m - 1)`, the coefficient of z^{-m-1} (Definition 2.7, `VOA/Foundations/FormalCalculus.lean`). A *field* (`Fld M`, the subtype of formal distributions satisfying `IsField`) is a formal distribution which is lower truncated on every vector (Definition 4.44, `VOA/Core/LocalSystem.lean`). Two distributions are *local*, `Local a b`, if `∃ N : ℕ, mulBySubPow N (bracketDist a b) = 0`: some power of $(z_1 - z_2)$ kills their commutator (Definition 2.41, `VOA/Foundations/Locality.lean`); here `bracketDist a b` is $[a(z_1), b(z_2)]$ as a two-variable distribution and `mulBySubPow N` multiplies by $(z_1 - z_2)^N$. For local fields a, b and $n \in \mathbb{Z}$ the n-th product $a_{(n)}b$ (`Fld.prod n a b`) is the usual one, $a_{(n)}b(z_2) = \mathrm{Res}_{z_1}\big((z_1 - z_2)^n a(z_1)b(z_2) - (-z_2 + z_1)^n b(z_2)a(z_1)\big)$. `fzmul k a` is $z^k a(z)$.

Definition 36.2 (Rescaled field). For a family $A : \mathbb{Z} \to \mathrm{End}\, M$ of fractional modes, $A(k) = u_{(k/N)}$, and a residue $e \in \mathbb{Z}$, the rescaled field on the class $e + N\mathbb{Z}$ is the integrally moded distribution whose p-th mode is $A(Np + e)$: mathematically $z^{e/N}\sum_{k\equiv e} u_{(k/N)}z^{-k/N-1}$.

File `VOA/Moonshine/HeisenbergTwistedModuleReduction.lean`.

```
def resc (A : ℤ → End ℂ M) (N : ℕ) (e : ℤ) : FormalDist (End ℂ M) :=
  fun n => A (N * (-n - 1) + e)
```

From the mathematics to the Lean statement

`mode_resc` says `mode (resc A N e) p = A (N * p + e)`. For $N = 2$: resc $A\,2\,e$ is $z^{e/2}Y(u,z)$ restricted to the half-integral (if e odd) or integral (if e even) modes. Locality of two twisted fields $Y(u,z_1), Y(v,z_2)$, which are series in $z_1^{1/2}, z_2^{1/2}$, is equivalent to locality of every pair of rescaled class components, because multiplication by $z_1^{e/2}z_2^{e'/2}$ commutes with $(z_1 - z_2)^N$. This is why every locality statement below is stated for `resc` fields on all classes e, e'. `rescFld` packages `resc` as an element of `Fld` given a truncation proof.

Physical meaning

Going around the twist field the vertex operator $Y(u,z)$ of a θ-odd or generic state is multivalued, with expansion in powers of $z^{1/2}$. Splitting off the factor $z^{e/2}$ and keeping one residue class of exponents produces ordinary single-valued formal distributions, to which the usual calculus of local fields applies. Heuristically this is passing to the double cover $w = z^{1/2}$ of the plane branched at the twist field.

Definition 36.3 (Twisted product). For a twist $\alpha \in \mathbb{C}$, fields A, X and $p \in \mathbb{Z}$,

$$\mathrm{star}_\alpha(A)_p X = \sum_{i \geq 0} \binom{-\alpha}{i} z^{-i} A_{(p+i)} X.$$

File `VOA/Moonshine/HeisenbergTwistedModuleTwistedComm.lean`.

```
noncomputable def star (α : ℂ) (A : Fld M) (p : ℤ) (X : Fld M) : Fld M :=
  ∑ᶠ i : ℕ, cbinom (-α) i • fzmul (-(i : ℤ)) (Fld.prod (p + i) A X)
```

From the mathematics to the Lean statement

`cbinom x i` is $x(x-1)\cdots(x-i+1)/i!$ for complex x; the $\sum^{\mathrm{f}}$ is a finite sum because $A_{(p+i)}X = 0$ for large i when A, X are local. **Meaning.** Write $A(z) = z^\alpha Y(u,z)$, $X(z) = z^{\alpha'} Y(v,z)$. Since $\sum_i \binom{-\alpha}{i}(z_1 - z_2)^i z_2^{-i} = (z_1/z_2)^{-\alpha}$, one has formally $\mathrm{star}_\alpha(A)_p X(z_2) = z_2^{\alpha+\alpha'} \operatorname{Res}_{z_1}(z_1 - z_2)^p [Y(u,z_1)Y(v,z_2) - Y(v,z_2)Y(u,z_1)]$, where the binomial expansion gives the precise meaning to the residue of the half-integral powers. So star is the rescaled version of the twisted iterate (associativity) formula $Y(u_{(p)}v, z) = \operatorname{Res}_{z_1}(\cdots)$, and the twisted product formula below says exactly that the twisted vertex operator satisfies it.

Physical meaning

This is the binomial rule for moving a twisted field past a field which carries branch-cut phase z^α: expanding $(z_1/z_2)^{-\alpha}$ in powers of $(z_1 - z_2)/z_2$ gives the coefficients $\binom{-\alpha}{i}$. In CFT terms it is the operator product of a field with the twisted sector, written so that the monodromy around the twist field is built in. Heuristic gloss only; the formal identity is proved in Lean.

Definition 36.4 (Generated twisted system). For a set S of fields, `TGenerated S` is the smallest set containing S, the identity field and 0, and closed under all products $a_{(n)}b$ ($n \in \mathbb{Z}$), multiplication by z^k, sums and scalar multiples.

File `VOA/Moonshine/HeisenbergTwistedModuleLocality.lean`.

```
inductive TGen (S : Set (Fld M)) : ℕ → Fld M → Prop
  | base {a : Fld M} : a ∈ S → TGen S 0 a

def TGenerated (S : Set (Fld M)) : Set (Fld M) := {a | ∃ i, TGen S i a}
```

Physical meaning

This is the set of all fields obtainable by operator products (and the rescalings by $z^{1/2}$) from a chosen list of generating fields, in other words the fields of the chiral algebra generated by the twisted currents and the twisted lattice exponentials. Dong's lemma then says that locality of the generators propagates to every composite, the algebraic version of the statement that a Wick-type product of mutually local operators remains local.

By Dong's lemma (proved in Chapter 35 as `tgenerated_local`), if S is pairwise local then so is `TGenerated S`. Note that z^k-multiplication is allowed: this is what makes the system "twisted" (the rescalings $z^{e/2}$ move fields between classes).

36.2.3 Twisted modules

The target structure is the (repaired) twisted module of Chapter 34. We reproduce it in full because it is the conclusion of the main theorem. File `VOA/Modularity/Twisted.lean`.

```

```

From the mathematics to the Lean statement

Decoding. `YM u k` is $u_{(k/N)}$, the coefficient of $z^{-k/N-1}$ in $Y_M(u,z)$. `g.twistedEigenspace N j` is the eigenspace of g for the eigenvalue $e^{-2\pi i j/N}$; for $N=2$ it is $\{u : gu = (-1)^j u\}$. The support axiom says that for such u only the modes with $k \equiv -j \pmod N$ occur, i.e. $Y_M(u,z) \in z^{j/N}\,\mathrm{End}(M)[[z^{\pm1}]]$. In `jacobi`, `YM u (ℓ * N + k - i * N)` $= u_{(\ell+k/N-i)}$, `cbz ℓ i` is $\binom{\ell}{i}$ (zero for $i<0$) and `negOnePow` is $(-1)^{\cdot}$; so the identity reads, for $u \in V^j$, $k \equiv -j$,

$$\sum_i (-1)^i \binom{\ell}{i} \Big(u_{(\ell+\frac{k}{N}-i)} v_{(\frac{m}{N}+i)} x - (-1)^{\ell} v_{(\ell+\frac{m}{N}-i)} u_{(\frac{k}{N}+i)} x \Big) = \sum_{i\ge 0} \binom{k/N}{i} (u_{(\ell+i)}v)_{(\frac{k+m}{N}-i)} x,$$

which is the mode form of the twisted Jacobi identity of Dong–Li–Mason. `W.smul u n v` is the product $u_{(n)}v$ in the VOA. The grading axioms are as for ordinary modules (Definition 12.5): `DirectSum.IsInternal weight` says $M = \bigoplus_\alpha M_\alpha$ as an internal direct sum, and $L_0 = \omega_{(1)}$, which is `YM ω N`, acts on M_α by α.

Trap / dead end

The hypothesis `(k + j) % (N : ℤ) = 0` in `jacobi` is the 2026-10-06 repair. Before it, the identity was required for all k, including k off the support of u; the certificate $u = v = \mathbf{1}$, $\ell = -1$, $k = 1$, $m = -N-1$ then gives $0 = x$, so for $N \geq 2$ no nonzero twisted module existed (`VOA.jacobiAllIndices_eq_zero`). Every result of this chapter is about the repaired structure. The analogous field of `SuperTwistedModule` has *not* been repaired; it is not used here (see §36.15).

The definition `TwistedJacobi g N YM` (file `VOA/Moonshine/HeisenbergTwistedModuleDefect.lean`) is literally the proposition in the `jacobi` field, as a predicate on a candidate `YM`.

36.2.4 The lattice side

From Chapters 30–32 and 34 we use:

- `L : IntegralLattice`, with `L.form` the integral bilinear form, `L.Even`, `L.PosDef`, and `hU : IsUnit (gramMat L).det` (unimodularity). `chargeCoord L α : Fin (rank L) → ℂ` are the coordinates of α in an orthonormal basis of $L \otimes \mathbb{R}$; `sum_chargeCoord` states `∑ b, chargeCoord L α b * chargeCoord L β b = ((L.form α β : ℤ) : ℂ)` under `hPos`.
- `LatModuleGen L` $= V_L =$ FockN(rank L) $\otimes \mathbb{C}[L]$, with the VOA structure `latticeVOAGen L hEven hPos`; `eGen L α` is $e^\alpha \in \mathbb{C}[L]$, `echg L α` $= 1 \otimes e^\alpha$ and `hgen L b` $= h_b(-1)\mathbf{1}$. `latticeCocycle L α β` $= \varepsilon(\alpha,\beta) \in \{\pm 1\}$ is the bimultiplicative cocycle with $\varepsilon(\alpha,\beta)\varepsilon(\beta,\alpha)^{-1} = (-1)^{\langle\alpha,\beta\rangle}$.
- `thetaLat L`: $p \otimes e^\alpha \mapsto \sigma(p) \otimes e^{-\alpha}$, σ the sign change of all oscillators, and `thetaAut L hEven hPos` the same map as a VOA automorphism. (No cocycle correction is needed because the library's cocycle satisfies $\varepsilon(-\alpha,\beta) = \varepsilon(\alpha,\beta)$.) `leechTheta` is `thetaAut` for $L = \Lambda$ and `leechVOAPlus` is the fixed-point VOA `orbifoldVOA (Subgroup.zpowers leechTheta)` (Chapter 32).
- `Rep (cocMat L) (isUnit_det_cocMat L hEven hU)` is the space $\mathcal{T}_L$ and `eT L hEven hU α` the operator e_α on it, with `eT_mul`: $e_\alpha e_\beta = \varepsilon(\alpha,\beta)e_{\alpha+\beta}$, `eT_neg`: $e_{-\alpha} = e_\alpha$, and `eT_add_two_nsmul`: $e_{\alpha+2\gamma} = e_\alpha$ (Chapter 34). For Λ this space is `leechT`, of dimension 4096.

36.3 Newton exponentials and the contraction factor

The operators $E^\pm$ are exponentials of infinite sums of commuting operators. Rather than manipulate exp of operator-valued series, the library works with the *coefficients* of such exponentials, characterised by a first-order recursion. This section is pure algebra over an arbitrary commutative $\mathbb{C}$-algebra R (`VOA/Moonshine/LatticeTwistedExp.lean`).

Definition 36.5 (Newton exponential). For a sequence $d = (d_k)_{k\geq 1}$ in R, let $E_p = \mathrm{nexp}(d)_p$ be the coefficient of w^p in $\exp\left(\sum_{k\geq 1} \frac{d_k}{k} w^k\right)$. Equivalently $E_0 = 1$ and

$$(p+1)E_{p+1} = \sum_{k=0}^{p} d_{k+1} E_{p-k} \qquad (p \geq 0).$$

```
noncomputable def nexp (d : ℕ → R) : ℕ → R
  | 0 => 1
  | (p + 1) => ((p + 1 : ℂ))⁻¹ • ∑ k ∈ Finset.range (p + 1), d (k + 1) * nexp d (p - k)
```

From the mathematics to the Lean statement

The recursion is the coefficient form of $\theta F = D \cdot F$, where $\theta = w\,d/dw$ is the Euler operator and $D = \sum_{k\ge1} d_k w^k = \theta(\sum d_k w^k/k)$; indeed if $F = \exp(\sum d_k w^k/k)$ then $\theta F = DF$. The value `d 0` is ignored. The definition is *by* the recursion, so it makes sense in any $\mathbb{C}$-algebra (division by $p+1$ uses the $\mathbb{C}$-algebra structure) without any analytic notion of exp; there is nothing to be vacuous about. It is the same as the textbook object: the power series $\sum_p E_p w^p$ is shown to be the unique solution of $\theta F = DF$, $F(0) = 1$ (next lemma), which characterises $\exp(\sum d_k w^k/k)$.

Physical meaning

This is bookkeeping for the exponentials of oscillators that appear in the twisted vertex operators: $\exp(\sum_k \frac{d_k}{k} w^k)$ is a generating function of the Schur-type polynomials built from the creation operators. It has no independent physical content beyond being the coefficient extraction of $E^-(w) = \exp(\sum \frac{2}{k}\alpha_{-k/2} w^k)$, the vertex-operator exponential acting on the twisted Fock space.

Lemma 36.6 (Characterisation and the exponential law). *Let θ be the Euler operator on $R[[X]]$ and $D(d) = \sum_{k\ge1} d_k X^k$.*

1. *If $F \in R[[X]]$ satisfies $\theta F = D(d)F$ and $F_0 = 1$, then $F = \sum_p \mathrm{nexp}(d)_p X^p$.*
2. *$\mathrm{nexp}(d+e) = \mathrm{nexp}(d) \cdot \mathrm{nexp}(e)$ as power series.*
3. *If $\varphi : R \to S$ is a $\mathbb{C}$-algebra map, $\varphi(\mathrm{nexp}(d)_p) = \mathrm{nexp}(\varphi \circ d)_p$.*
4. *$\mathrm{nexp}(k \mapsto t^k d_k)_p = t^p\,\mathrm{nexp}(d)_p$.*
5. *If δ is a $\mathbb{C}$-derivation of R with $\delta(d_k) = \delta_{k,K}\,K\,c$ for some $K \ge 1$, then $\delta(E_p) = c\,E_{p-K}$ for $p \ge K$ and $\delta(E_p) = 0$ for $p < K$.*

From the mathematics to the Lean statement

`nexpPS d` is the power series with coefficients `nexp d`, `theta` is $F \mapsto \sum_p p\,F_p X^p$, `Dser d` is $D(d)$. Item (5) is the statement that a derivation hitting exactly one logarithmic coefficient d_K with value Kc acts on $\exp(\sum d_k w^k/k)$ as multiplication by $c\,w^K$: since δ of the exponent is $c\,w^K$. The hypotheses `hK : 0 < K` and `hd` are exactly these conditions. All five statements are the textbook statements with no extra hypotheses.

Physical meaning

Technical lemma about the exponential of a series: it says that the coefficients behave like the expansion of $\exp(\int D)$, multiplicatively in d (so exponentials of sums of oscillators factorise) and with the expected response to a shift of one oscillator. This is the combinatorial form of the identity $e^{A+B} = e^A e^B$ for commuting creation operators.

Proof on paper. (1) If $\theta Z = DZ$ and $Z_0 = 0$, comparing coefficients of X^{p+1} gives $(p+1)Z_{p+1} = \sum_{k\le p} d_{k+1} Z_{p-k}$, so by strong induction $Z = 0$; apply this to $Z = F - \mathrm{nexp}(d)$, which solves the linear equation because $\mathrm{nexp}(d)$ does (the recursion is that equation). (2) θ is a derivation, so $\theta(FG) = (D(d) + D(e))FG$ and (1) applies. (3) and (4) are (1) applied to $\varphi(F)$ and to $F(tX)$. (5) Apply δ coefficientwise to $\theta F = DF$: δF satisfies $\theta(\delta F) = D\,\delta F + (\theta(cX^K))F$, and $cX^K F$ satisfies the same equation; their difference has constant term 0, so by (1) it vanishes. □

What the machine verified

`VOA/Moonshine/LatticeTwistedExp.lean`. Unconditional. The file header records `#print axioms` = [`propext`, `Classical.choice`, `Quot.sound`].

Definition 36.7 (Contraction factor). For $n \in \mathbb{C}$ let $f_p^{(n)} = \mathrm{fco}(n)_p$ be the coefficient of x^p in

$$\Big(\frac{1-x}{1+x}\Big)^n = \exp\Big(-2n \sum_{k\ \mathrm{odd}} \frac{x^k}{k}\Big),$$

and $f_t^{(n)} = 0$ for $t < 0$ (`fz`).

```
def oddc : ℕ → ℂ := fun k => if k % 2 = 1 then 1 else 0

noncomputable def fco (n : ℂ) : ℕ → ℂ := nexp ((-2 * n) • oddc)

noncomputable def fz (n : ℂ) (t : ℤ) : ℂ := if 0 ≤ t then fco n t.toNat else 0
```

From the mathematics to the Lean statement

$\log(1-x) - \log(1+x) = -2\sum_{k\ \mathrm{odd}} x^k/k$, so the logarithmic coefficients (d_k with $\exp(\sum d_k x^k/k)$) of $((1-x)/(1+x))^n$ are $d_k = -2n$ for odd k and 0 for even k: that is `(-2 * n) • oddc`. For complex n the left side is defined by this exponential; for integer n it agrees with the rational function (next theorem).

Physical meaning

The factor $\big(\frac{1-x}{1+x}\big)^n$ with $x = w_2/w_1$ is the twisted two-point function of two exponential fields with momentum pairing $n = \langle \alpha, \beta \rangle$ on the double cover. For untwisted lattice vertex operators the analogous factor is $(z_1 - z_2)^n$; in the θ-twisted sector, where the propagator of the twisted boson is $\log \frac{w_1 - w_2}{w_1 + w_2}$ (the image charge at $-w$), one gets exactly this expression. Its expansion coefficients are the contraction factors.

Theorem 36.8 (The contraction factor times $(1-x^2)^N$). *For $N \in \mathbb{N}$ and $n \in \mathbb{Z}$ with $|n| \le N$,*

$$\Big(\frac{1-x}{1+x}\Big)^n (1-x^2)^N = (1-x)^{N+n}(1+x)^{N-n} =: G(x),$$

a polynomial of degree $2N$ with $x^{2N} G(1/x) = (-1)^{N+n} G(x)$. Consequently, writing $c_r = (-1)^{N-r}\binom{N}{r}$, for every $t \in \mathbb{Z}$

$$\sum_{r=0}^{N} c_r\, f^{(n)}_{t-2(N-r)} = (-1)^{|n|} \sum_{r=0}^{N} c_r\, f^{(n)}_{2(N-r)-t}. \tag{36.5}$$

```
theorem fco_mul_one_sub_sq_pow (N : ℕ) (n : ℤ) (h1 : -(N : ℤ) ≤ n) (h2 : n ≤ N) :
    nexpPS ((-2 * (n : ℂ)) • oddc) * (1 - X ^ 2) ^ N

    ∑ r ∈ Finset.range (N + 1), ((-1 : ℂ) ^ (N - r) * (N.choose r : ℂ)) * fz n (t - 2 * (N
    ↪ - r : ℕ))
      = (-1 : ℂ) ^ n.natAbs *
        ∑ r ∈ Finset.range (N + 1), ((-1 : ℂ) ^ (N - r) * (N.choose r : ℂ)) *
          fz n (2 * (N - r : ℕ) - t)
```

From the mathematics to the Lean statement

`gpoly a b` $= (1-X)^a(1+X)^b$; `(N + n).toNat` is $N+n$ as a natural number, legitimate because $N+n \geq 0$ by `h1`, and similarly $N-n \geq 0$ by `h2`. `Polynomial.reflect m p` is $X^m p(1/X)$. The sign in `reflect_gpoly` is $(-1)^a$ with $a = N+n$, the same as $(-1)^{N+n}$ in the text. In `sum_binom_fz_symm` the sign is $(-1)^{|n|}$ (`n.natAbs`), which equals $(-1)^n$. The hypotheses $|n| \leq N$ are necessary: for $|n| > N$ the product is not a polynomial.

Physical meaning

Physically this is the statement that after multiplying the twisted two-point function by the cut-off $(w_1^2 - w_2^2)^N = (z_1 - z_2)^N$ the singularities at $w_1 = \pm w_2$ cancel: the exponential fields have a pole of order at most $|n|$ at coincident points, and the result is a polynomial with a reflection symmetry $w \mapsto 1/w$ up to sign $(-1)^n$. That symmetry is the source of the sign $(-1)^{\langle\alpha,\beta\rangle}$ in the exchange of two twisted vertex operators, i.e. of locality.

Proof on paper. $(1-x^2)^N = (1-x)^N(1+x)^N$, and both sides are exponentials whose logarithmic coefficients add up (Lemma 36.6(2)). The reflection of $(1-x)^a(1+x)^b$ is $(x-1)^a(x+1)^b = (-1)^a(1-x)^a(1+x)^b$. For (36.5): the left side is the coefficient g_t of x^t in $f^{(n)}(x)(1-x^2)^N = G(x)$ (expand $(1-x^2)^N = \sum_m (-1)^m \binom{N}{m} x^{2m}$ and put $m = N-r$). The right sum, reindexed by $r \mapsto N-r$, is $(-1)^N g_{2N-t}$, and palindromy gives $g_{2N-t} = (-1)^{N+n} g_t$. Hence the right side is $(-1)^{|n|}(-1)^N(-1)^{N+n} g_t = g_t$. □

What the machine verified

Unconditional (same file); axioms as above.

Example 36.9 (Small cases). Expanding $\exp(-2n(x + x^3/3 + \cdots))$ gives $f_0^{(n)} = 1$, $f_1^{(n)} = -2n$, $f_2^{(n)} = 2n^2$, $f_3^{(n)} = -\frac{4n^3+2n}{3}$. For $n = 1$ these are $1, -2, 2, -2, \ldots$, the coefficients of $(1-x)/(1+x) = 1-2x+2x^2-2x^3+\cdots$, as they must be. Take $N = 1, n = 1$: $\frac{1-x}{1+x}(1-x^2) = (1-x)^2 = 1-2x+x^2 = G(x)$, and $x^2 G(1/x) = G(x)$, matching the sign $(-1)^{N+n} = +1$. For $n = -1$, $N = 1$: $G = (1+x)^2$, again palindromic with sign $+1$; for $n = 0$, $N = 1$: $G = 1 - x^2$, with $x^2 G(1/x) = -G(x)$, sign $(-1)^1$. In (36.5) with $N = 1$, $n = 1$, $t = 1$: the left side is $c_0 f_{-1} + c_1 f_1 = 0 + (-2) = -2$ (here $c_0 = -1$, $c_1 = 1$), and the right side is $(-1)\big(c_0 f_1 + c_1 f_{-1}\big) = (-1)(-1)(-2) = -2$.

Identity (36.5) is the whole combinatorial content of the locality of twisted lattice vertex operators: it says that the two expansions of $(w_1^2 - w_2^2)^N f(w_2/w_1)$ (in $|w_2| < |w_1|$) and of $(w_1^2 - w_2^2)^N f(w_1/w_2)$ (in $|w_1| < |w_2|$) are the same polynomial up to the sign $(-1)^n$.

36.4 The operators $E^{\pm}$ on the twisted Fock space

File `VOA/Moonshine/LatticeTwistedEOps.lean`. Throughout, a *charge vector* is $v \in \mathbb{C}^r$; for a lattice vector α it will be `chargeCoord L α`. The pairing is $\langle v,u\rangle = \sum_i v_i u_i$ (`pair`).

Definition 36.10 (Twisted oscillator). $v(k/2) = \sum_i v_i\, h_i(k/2)$ for odd k.

```
noncomputable def oscT (v : Fin r → ℂ) (k : ℤ) : End ℂ (FockT r) := ∑ i, v i • modeT r i k

theorem oscT_comm (v u : Fin r → ℂ) {k l : ℤ} (hk : Odd k) (hl : Odd l) :
    oscT v k * oscT u l - oscT u l * oscT v k
      = (if k + l = 0 then (k : ℂ) / 2 * pair v u else 0) • LinearMap.id
```

From the mathematics to the Lean statement

This is $[v(k/2),u(l/2)] = \frac{k}{2}\langle v,u\rangle\delta_{k+l,0}$, the twisted oscillator algebra, for odd k,l (the hypotheses `hk`, `hl`); $*$ is composition. Same as the textbook statement.

Physical meaning

This is the twisted free-boson current $i\,v\cdot\partial X$ in the direction $v \in \mathbb{R}^{24}$, expanded in half-integer modes; $v(k/2)$ is its $k/2$-th Laurent mode on the twisted Fock space.

Definition 36.11 (The creation exponential E^-). Let $d_k = 2\,v(-k/2)\mathbf{1} = 2\sum_i v_i X_{((k-1)/2,i)}$ for odd k and $d_k = 0$ for even k. Then $E^-(-v,w) = \exp\big(\sum_{k\text{ odd}} \frac{2}{k} v(-k/2)w^k\big)$ is multiplication by $\sum_p s_p(v)w^p$ with $s_p(v) = \operatorname{nexp}(d)_p \in S[\theta]$.

```
noncomputable def vVarT (v : Fin r → ℂ) (n : ℕ) : FockT r := ∑ i, v i • X (n, i)

noncomputable def dM (v : Fin r → ℂ) : ℕ → FockT r :=
  fun k => if k % 2 = 1 then (2 : ℂ) • vVarT v (k / 2) else 0

noncomputable def sM (v : Fin r → ℂ) (p : ℕ) : FockT r := nexp (dM v) p

noncomputable def sMz (v : Fin r → ℂ) (p : ℤ) : FockT r := if 0 ≤ p then sM v p.toNat else
↪  0
```

From the mathematics to the Lean statement

Compare with (36.2): $\sum_{n\in\frac12+\mathbb{N}} \alpha(-n)z^n/n$ with $z = w^2$, $n = k/2$, is $\sum_{k\text{ odd}} \frac{2}{k}\alpha(-k/2)w^k$, whose logarithmic coefficients (d_k with $\exp\sum d_k w^k/k$) are $2\alpha(-k/2)$. Since the creation operators are multiplications by the commuting variables, E^- is multiplication by an element of the polynomial ring, and `sM v p` is its w^p coefficient; `k / 2` is integer division, so for odd k it is $(k-1)/2$. `sMz` extends by 0 to negative p.

Physical meaning

This is the creation part of the lattice vertex operator in the twisted sector: the normal-ordered exponential $\exp\big(\sum_{k\text{ odd}} \frac{2}{k}\alpha_{-k/2}w^k\big)$ of the creation oscillators, which dresses the ground state with a coherent cloud of twisted bosons of momentum v. Only odd (half-integer) modes occur, since the twisted bosons have no integer modes.

Definition 36.12 (The annihilation exponential E^+ as a translation). The operator $E^+(-v,w) = \exp\bigl(-\sum_{k\ \mathrm{odd}>0} \frac{2}{k} v(k/2) w^{-k}\bigr)$ equals the substitution $X_{(n,i)} \mapsto X_{(n,i)} - v_i w^{-(2n+1)}$. Writing $u = w^{-1}$, it is the $\mathbb{C}$-algebra map $S[\theta] \to S[\theta][u]$, $X_{(n,i)} \mapsto X_{(n,i)} - v_i u^{2n+1}$; $E_q^+(-v)$ denotes the coefficient of $u^q = w^{-q}$.

```
noncomputable def Ep (v : Fin r → ℂ) : FockT r →ₐ[ℂ] Polynomial (FockT r) :=
  aeval fun x => Polynomial.C (X x) - v x.2 • Polynomial.X ^ (2 * x.1 + 1)

noncomputable def EpC (v : Fin r → ℂ) (q : ℕ) : End ℂ (FockT r) where
  toFun y := (Ep v y).coeff q
  map_add' a b := by rw [map_add, Polynomial.coeff_add]
  map_smul' c a := by rw [map_smul, Polynomial.coeff_smul]; rfl
```

From the mathematics to the Lean statement

Why this is the same operator. On $S[\theta]$, $v(k/2) = \frac{k}{2}\sum_i v_i \partial_{((k-1)/2,i)}$ for odd $k > 0$, so the exponent is $-\sum_{n,i} v_i w^{-(2n+1)} \partial_{(n,i)}$, a first-order operator with constant coefficients in the commuting derivations $\partial_{(n,i)}$. Taylor's formula says $\exp(-\sum c_x \partial_x) f(X) = f(X - c)$ for polynomials f; hence E^+ is the translation. The Lean definition takes the translation as the *definition*; this is deliberate (it avoids infinite sums of operators) and harmless (it is an exact identity of operators on polynomials). The output lies in the polynomial ring $S[\theta][u]$, which encodes the lower truncation: on a fixed vector only finitely many E_q^+ are nonzero (`EpC_eventually_zero`).

Physical meaning

This is the annihilation part of the vertex operator exponential. Since $\alpha_{k/2}$ is a derivative with respect to the creation variable, the exponential of annihilation operators acts as a translation of the oscillator variables: a coherent-state shift by the classical field produced by the charge v. This is the usual statement that $e^{a\partial}$ is a translation.

Theorem 36.13 (The E^+E^- reordering). *For charge vectors v, u, $q \in \mathbb{N}$, $p \in \mathbb{Z}$ and $y \in S[\theta]$,*

$$E_q^+(-v)\bigl(s_p(u)\, y\bigr) = \sum_{j=0}^{q} f_j^{(\langle v,u\rangle)}\, s_{p-j}(u)\, E_{q-j}^+(-v) y.$$

Equivalently, as generating series, (36.3) holds with $w_i = z_i^{1/2}$: $E^+(-v,w_1)E^-(-u,w_2) = E^-(-u,w_2)E^+(-v,w_1)(\frac{1-w_2/u}{1+w_2/u}$

File `VOA/Moonshine/LatticeTwistedEOps.lean`.

```
theorem EpC_sMz_mul (v u : Fin r → ℂ) (q : ℕ) (p : ℤ) (y : FockT r) :
    EpC v q (sMz u p * y) = ∑ j ∈ Finset.range (q + 1),
      fco (pair v u) j • (sMz u (p - j) * EpC v (q - j) y)
```

From the mathematics to the Lean statement

`sMz u p * y` is $E_p^-(-u)$ applied to y (multiplication); `EpC v q` is $E_q^+(-v)$. Multiplying by $w_2^p w_1^{-q}$ and summing, the right side becomes $\sum f_j (w_2/w_1)^j \cdot E_{p-j}^- w_2^{p-j} \cdot E_{q-j}^+ w_1^{-(q-j)}$, which is the generating series statement. No hypothesis on v, u: $\langle v, u\rangle$ may be any complex number, and `fco` is defined for complex exponents. Same as the textbook statement.

Physical meaning

This is the ordering rule for annihilation and creation exponentials, $e^A e^B = e^B e^A e^{[A,B]}$, with the commutator the twisted two-point function $\left(\frac{1-w_2/w_1}{1+w_2/w_1}\right)^{\langle v,u\rangle}$. It is the Wick contraction between the vertex operators of two momentum states in the twisted sector, the step needed to evaluate any product of twisted fields.

Proof on paper. $E^+(-v,w_1)$ is the algebra map $X_{(n,i)} \mapsto X_{(n,i)} - v_i w_1^{-(2n+1)}$, so it is multiplicative: applied to $E^-(-u,w_2)y$ it gives $E^+(E^-(-u,w_2))\cdot E^+(y)$. Translating the exponent $\sum_n \frac{2}{2n+1}\sum_i u_i X_{(n,i)} w_2^{2n+1}$ produces the extra term $-\sum_n \frac{2}{2n+1}\langle v,u\rangle (w_2/w_1)^{2n+1} = \langle v,u\rangle \log\frac{1-w_2/w_1}{1+w_2/w_1}$. Exponentiating (Lemma 36.6(2),(3),(4)) gives the factor. Comparing coefficients of $w_2^p w_1^{-q}$ yields the stated finite sum. □

What the machine verified

Unconditional; `VOA/Moonshine/LatticeTwistedEOps.lean`, axioms standard.

Definition 36.14 (Dressing). $\mathrm{DD}_v(a)$, for $a \in \mathbb{Z}$, is the coefficient of w^a in $E^-(-v,w)E^+(-v,w)$, i.e. $\mathrm{DD}_v(a) = \sum_{p-q=a} E^-_p(-v)E^+_q(-v)$.

```
noncomputable def DD (v : Fin r → ℂ) (a : ℤ) : End ℂ (FockT r) :=
  Polynomial.lsum (fun q => LinearMap.mulLeft ℂ (sMz v (a + q))) ∘ₗ (Ep v).toLinearMap
```

From the mathematics to the Lean statement

On y, $\mathrm{Ep}\, v\, y = \sum_q E^+_q(y)u^q$ is a polynomial in u, and `Polynomial.lsum` replaces u^q by multiplication with $s_{a+q}(v)$; so the result is $\sum_q s_{a+q}(v)E^+_q(-v)y$, the claimed finite sum (`DD_apply_range`).

Physical meaning

The dressing DD_v is the full normal-ordered exponential $:e^{v\cdot X^T(w)}:$ without its momentum label: the oscillator part of the twisted vertex operator of the lattice state e^v, whose coefficients in powers of w are the modes $\mathrm{DD}_v(a)$.

Proposition 36.15 (Properties of the dressing).
1. *For odd K:* $[h_i(K/2), \mathrm{DD}_v(a)] = v_i\,\mathrm{DD}_v(a-K)$, *i.e.* $[h_i(m), E^-E^+(-v,w)] = v_i w^{2m}\, E^-E^+(-v,w)$.
2. $\mathrm{DD}_{-v}(a) = (-1)^a \mathrm{DD}_v(a)$ *(i.e.* $E^\pm(v,w) = E^\pm(-v,-w)$*).*
3. $\mathrm{DD}_0(a) = \delta_{a,0}$.

```
theorem modeT_comm_DD (v : Fin r → ℂ) (i : Fin r) {K : ℤ} (hK : Odd K) (a : ℤ) :
    modeT r i K * DD v a - DD v a * modeT r i K = v i • DD v (a - K)
theorem DD_neg (v : Fin r → ℂ) (a : ℤ) : DD (-v) a = (-1 : ℂ) ^ a • DD v a
theorem DD_zero_charge (a : ℤ) : DD (0 : Fin r → ℂ) a = if a = 0 then 1 else 0
```

From the mathematics to the Lean statement

In (1), w^{2m} with $m = K/2$ is w^K, and the coefficient of w^a in $v_i w^K \sum_b \mathrm{DD}_v(b)w^b$ is $v_i \mathrm{DD}_v(a-K)$. This is the twisted analogue of $[\alpha(m), Y(e^\beta,z)] = \langle\alpha,\beta\rangle z^m Y(e^\beta,z)$, the defining property of a "charge-v" vertex operator. Same as the textbook statements.

Physical meaning

Part (1) says that the twisted bosonic currents measure the charge v of the dressing: the field carries momentum v in the sense of the Heisenberg algebra, as every vertex operator of a lattice exponential should. Part (2) is the invariance of the exponential under the orbifold reflection together with $w \mapsto -w$, and (3) says that the zero-charge field is the identity operator.

Proof on paper. (1) For $K < 0$, $h_i(K/2)$ is multiplication by X, which commutes with E^- and is translated by E^+: $E^+(X_{(n,i)}y) = (X_{(n,i)} - v_i w^{-(2n+1)})E^+(y)$; the extra term gives $v_i w^K$ with $K = -(2n+1)$. For $K > 0$, $h_i(K/2)$ is $\frac{K}{2}\partial$, which commutes with the translation E^+ and differentiates E^-: by Lemma 36.6(5), $\partial_{(n,i)} s_p = \frac{2v_i}{2n+1} s_{p-(2n+1)}$, giving $v_i w^K$. (2) Scaling (Lemma 36.6(4)) with $t = -1$ for E^-; induction on monomials for E^+. (3) Both exponents vanish. □

What the machine verified

Unconditional; axioms standard.

36.5 The two-point identity and locality

File `VOA/Moonshine/LatticeTwistedTwoPoint.lean`.

Theorem 36.16 (Two-point identity). *For charge vectors v, u with $n = \langle v, u\rangle$,*

$$\mathrm{DD}_v(A)\,\mathrm{DD}_u(B) = \sum_{j\ge 0} f_j^{(n)}\ \mathrm{NN}(A+j, B-j),$$

where $\mathrm{NN}(A,B)$ *is the coefficient of* $w_1^A w_2^B$ *in the normal-ordered product* $E^-(-v,w_1)E^-(-u,w_2)E^+(-v,w_1)E^+(-u,w_2)$ *and* NN *is symmetric under* $(v,A) \leftrightarrow (u,B)$. *As generating series:*

$$E^-E^+(-v,w_1)\,E^-E^+(-u,w_2) = :\cdots: \left(\frac{1-w_2/w_1}{1+w_2/w_1}\right)^n.$$

```
def GoodB (v u : Fin r → ℂ) (x : FockT r) (Q : ℕ) : Prop :=

```

From the mathematics to the Lean statement

Infinite sums are replaced by finite ones with explicit bounds. `GoodB v u x Q` says that Q bounds every E^+ coefficient that can be nonzero on x; it is not a restriction, since such a Q always exists (`exists_goodB`). With it, `NN v u Q A B x` is the full normal-ordered coefficient applied to x. The bound $J \ge B+Q$ makes the j-sum exhaustive ($s_{B-j+q'} = 0$ once $B-j+q' < 0$). Hence the Lean statement is the textbook identity applied to an arbitrary vector x.

Physical meaning

This is the twisted Wick theorem for two vertex operators: the product of two normal-ordered exponentials equals the normal-ordered product times the twisted contraction $\left(\frac{1-w_2/w_1}{1+w_2/w_1}\right)^{\langle v,u\rangle}$. It is the twisted analogue of the free-field OPE $e^{v\phi}(z)e^{u\phi}(w) = (z-w)^{\langle v,u\rangle} :\cdots:$. Heuristic; the identity is a formal-series statement proved in Lean.

Proof on paper. Push $E^+(-v,w_1)$ to the right through $E^-(-u,w_2)$ using Theorem 36.13; the E^-'s commute among themselves (they are multiplications) and the E^+'s commute among themselves (translations commute). The symmetry of NN is the same commutativity. □

Theorem 36.17 (Locality of the dressings). *If $\langle v,u\rangle = n \in \mathbb{Z}$ and $N \geq |n|$, then for all $A,B \in \mathbb{Z}$ and $x \in S[\theta]$*

$$\sum_{r=0}^{N}(-1)^{N-r}\binom{N}{r}\Big(\mathrm{DD}_v(A-2r)\mathrm{DD}_u(B-2(N-r)) - (-1)^{|n|}\mathrm{DD}_u(B-2(N-r))\mathrm{DD}_v(A-2r)\Big)x = 0,$$

that is, $(w_1^2-w_2^2)^N\big(Y_v(w_1)Y_u(w_2) - (-1)^n Y_u(w_2)Y_v(w_1)\big) = 0$ with $Y_v(w) = E^-E^+(-v,w)$.

```
theorem DD_bracket_local (v u : Fin r → ℂ) (n : ℤ) (hn : pair v u = n) (N : ℕ)
    (h1 : -(N : ℤ) ≤ n) (h2 : n ≤ N) (A B : ℤ) (x : FockT r) :
    ∑ r ∈ Finset.range (N + 1), ((-1 : ℂ) ^ (N - r) * (N.choose r : ℂ)) •
      (DD v (A - 2 * r) (DD u (B - 2 * (N - r : ℕ)) x)
        - (-1 : ℂ) ^ n.natAbs • DD u (B - 2 * (N - r : ℕ)) (DD v (A - 2 * r) x)) = 0
```

From the mathematics to the Lean statement

Decoding. $(w_1^2-w_2^2)^N = \sum_r \binom{N}{r}(-1)^{N-r}w_1^{2r}w_2^{2(N-r)}$, and the coefficient of $w_1^A w_2^B$ of $w_1^{2r}w_2^{2(N-r)}F(w_1,w_2)$ is $F_{A-2r,B-2(N-r)}$: so the Lean sum is exactly the $w_1^Aw_2^B$ coefficient of the stated product identity. Since $w^2 = z$, this is $(z_1-z_2)^N$-locality, up to the sign $(-1)^n$. **Hypotheses.** `hn` requires the pairing to be an *integer*; this is where the lattice enters, and it is necessary (for non-integral n the factor is not palindromic). `h1`, `h2` say $|n| \leq N$. The sign $(-1)^{|n|}$ is not a defect of the statement: it is the genuine graded commutativity of the $S[\theta]$-parts, cancelled by the $\mathcal{T}$-parts in the next section.

Physical meaning

This is locality of the twisted exponential fields up to the sign $(-1)^{\langle v,u\rangle}$: the two operators commute or anticommute (the cocycle sign) for non-coincident points, with singularities only at $z_1 = z_2$ of bounded order. In the CFT it is the requirement that correlation functions of twist-sector fields be single-valued away from collisions, the first axiom of a vertex algebra module.

Proof on paper. By Theorem 36.16, $Y_v(w_1)Y_u(w_2) = \Phi\cdot f(w_2/w_1)$ and $Y_u(w_2)Y_v(w_1) = \Phi\cdot f(w_1/w_2)$, the same normal-ordered product Φ (by the symmetry of NN) times the contraction factor $f(x) = ((1-x)/(1+x))^n$ expanded in the respective regions. Multiply by $(w_1^2-w_2^2)^N$: the first becomes $w_1^{2N}(1-x^2)^N f(x) = w_1^{2N}G(x)$ with $x = w_2/w_1$, a polynomial; the second becomes $(-1)^N w_2^{2N}G(w_1/w_2)$, and palindromy (Theorem 36.8) turns it into $(-1)^N(-1)^{N+n}w_1^{2N}G(w_2/w_1)$. So the two products agree after multiplication, up to $(-1)^n$. In coefficients this is exactly (36.5), applied to the coefficient sequence of Φ along each anti-diagonal. □

What the machine verified

Unconditional; axioms standard (file header).

36.6 The twisted vertex operators of the exponentials

File `VOA/Moonshine/LatticeTwistedVertex.lean`. We now tensor with a space $\mathcal{T}$ (an arbitrary $\mathbb{C}$-vector space `Tm` at first, the extraspecial module later) and attach a $\mathcal{T}$-operator g.

Definition 36.18 (Generic twisted exponential field)**.** For a charge vector v, a shift $c_0 \in \mathbb{Z}$, a scalar $\kappa \in \mathbb{C}$ and $g \in \mathrm{End}(\mathcal{T})$, the family $k \mapsto Y_k$ of operators on $S[\theta] \otimes \mathcal{T}$ is the mode family of $\kappa\, w^{-c_0} E^-(-v,w) E^+(-v,w) \otimes g$ in the convention $Y_k = u_{(k/2)}$:

$$Y_k = \kappa\ \mathrm{DD}_v(-k-2+c_0) \otimes g.$$

```
noncomputable def YTg (v : Fin r → ℂ) (c0 : ℤ) (κ : ℂ) (g : End ℂ Tm) (k : ℤ) :
    End ℂ (FockT r ⊗[ℂ] Tm) :=
  κ • TensorProduct.map (DD v (-k - 2 + c0)) g
```

From the mathematics to the Lean statement

Index check. $u_{(k/2)}$ is the coefficient of $z^{-k/2-1} = w^{-k-2}$. In $w^{-c_0}\sum_a \mathrm{DD}_v(a) w^a$ the coefficient of w^{-k-2} has $a - c_0 = -k-2$, i.e. $a = -k-2+c_0$. `TensorProduct.map f g` is $f \otimes g$. For the lattice field we will take $c_0 = \langle\alpha,\alpha\rangle$, because $z^{-\langle\alpha,\alpha\rangle/2} = w^{-\langle\alpha,\alpha\rangle}$.

Physical meaning

A twisted vertex operator for a momentum state is a product of a bosonic factor, the dressing, and a finite-dimensional operator g on the 2^{12}-dimensional space of ground states (the twist-field multiplicity). The factor g plays the role of the lattice cocycle: it must supply the sign when two fields are exchanged, as the cocycle $\varepsilon(\alpha,\beta)$ does for the untwisted lattice VOA.

Theorem 36.19 (Charge and locality of the generic field)**.**

1. *(Truncation.) For every vector x, $Y_k x = 0$ for all large k.*
2. *(Charge.) For odd K: $[h_i(K/2) \otimes 1,\ Y_k] = v_i\, Y_{k+K}$.*
3. *(Locality.) Let v, u be charge vectors with $\langle v,u\rangle = n \in \mathbb{Z}$, and let g, g' satisfy $g'g = (-1)^n gg'$. Then for all $c_0, c_0', \kappa, \kappa'$ and all residues e, e', the rescaled fields $\mathrm{resc}(Y^{(v)}, 2, e)$ and $\mathrm{resc}(Y^{(u)}, 2, e')$ are mutually local.*

```
theorem YTg_truncation (v : Fin r → ℂ) (c0 : ℤ) (κ : ℂ) (g : End ℂ Tm)
    (x : FockT r ⊗[ℂ] Tm) : ∃ K : ℤ, ∀ k : ℤ, K ≤ k → YTg v c0 κ g k x = 0

    {K : ℤ} (hK : Odd K) (k : ℤ) :
    (modeT r i K).rTensor Tm ∗ YTg v c0 κ g k - YTg v c0 κ g k ∗ (modeT r i K).rTensor Tm
      = v i • YTg v c0 κ g (k + K)

theorem YTg_local (v u : Fin r → ℂ) (n : ℤ) (hn : pair v u = n) (c0 c0' : ℤ) (κ κ' : ℂ)
    (g g' : End ℂ Tm) (hg : g' ∗ g = (-1 : ℂ) ^ n.natAbs • (g ∗ g')) (e e' : ℤ) :
    Local (resc (YTg v c0 κ g) 2 e) (resc (YTg u c0' κ' g') 2 e')
```

From the mathematics to the Lean statement

`f.rTensor Tm` is $f \otimes \mathrm{id}_{\mathcal{T}}$. In (2), Y_{k+K} with $k \leftrightarrow k/2$ means $[h_i(m), Y(z)] = v_i z^m Y(z)$ with $m = K/2$, the twisted version of $[\alpha(m), Y(e^\beta, z)] = \langle \alpha, \beta \rangle z^m Y(e^\beta, z)$. In (3) the hypothesis `hg` is the graded commutativity on $\mathcal{T}$ that compensates the sign $(-1)^n$ of Theorem 36.17; `hn` demands an integral pairing. The conclusion is ordinary `Local` (Section 36.2) of the integrally moded rescaled fields, of order $|n|$. Statement (3) is what the textbook means by "$Y^T(e^\alpha, z_1)$ and $Y^T(e^\beta, z_2)$ are local", see the dictionary after Definition 36.2.

Physical meaning

The theorem says that the generic twisted exponential field has the expected properties of a vertex operator of charge v: it is a field (truncation), it carries charge v under the twisted currents, and two such fields are local provided the operators g, g' on the ground states have the correct commutation sign $(-1)^{\langle v,u \rangle}$. This is the twisted analogue of locality of lattice exponentials.

Proof on paper. (1): $\mathrm{DD}_v(a)y = 0$ once $a + Q \le 0$, Q a bound for E^+ on y. (2): Proposition 36.15(1) tensored with g. (3): on $y \otimes t$, $Y^{(v)}Y^{(u)} - Y^{(u)}Y^{(v)}$ equals $\kappa\kappa'\big(\mathrm{DD}_v\mathrm{DD}_u - (-1)^n \mathrm{DD}_u\mathrm{DD}_v\big)y \otimes gg't$, using $g'g = (-1)^n gg'$. After multiplying by $(z_1 - z_2)^{|n|}$ the $S[\theta]$-part vanishes by Theorem 36.17 with $N = |n|$; the class rescalings only shift the indices A, B. □

What the machine verified

Unconditional; `#print axioms` standard (file header).

Definition 36.20 (The twisted vertex operator of e^α)**.** For an even lattice L with unimodular Gram matrix and $\alpha \in L$,

$$Y^T(e^\alpha)_{(k/2)} = 2^{-\langle \alpha,\alpha \rangle}\, \mathrm{DD}_\alpha(-k - 2 + \langle \alpha, \alpha \rangle) \otimes e_\alpha,$$

the mode family of (36.1).

File `VOA/Moonshine/LatticeTwistedVertex.lean`.

```
noncomputable def YTL (α : L.carrier) (k : ℤ) :
    End ℂ (FockT (rank L) ⊗[ℂ] Rep (cocMat L) (isUnit_det_cocMat L hEven hU)) :=
  YTg (chargeCoord L α) (L.form α α) ((2 : ℂ) ^ (-(L.form α α))) (eT L hEven hU α) k
```

From the mathematics to the Lean statement

The charge vector is the orthonormal-coordinate vector of α, the shift is $c_0 = \langle \alpha, \alpha \rangle$ (giving $z^{-\langle \alpha,\alpha \rangle/2}$), the scalar is $\kappa = 2^{-\langle \alpha,\alpha \rangle}$ (an integer power, `zpow`), and the $\mathcal{T}$-operator is e_α. This is FLM's operator with their normalisation constant specialised to the involution -1; the reader comparing with FLM, Chapter 9, should note that any normalisation $\kappa(\alpha)$ with $\kappa(\alpha)\kappa(\beta)4^{-\langle \alpha,\beta \rangle} = \kappa(\alpha + \beta)$ would do, and that this condition is forced by the product formula (Remark 36.37). `hEven` and `hU` are needed only to build $\mathcal{T}_L$. Not vacuous: `YTL L hEven hU 0 k` is the identity at $k = -2$ and 0 otherwise (`YTL_zero`), and $Y^T(e^\alpha)$ is genuinely nonzero (its vacuum coefficient is computed in §36.10).

Physical meaning

For a lattice vector α this is the twisted vertex operator of the momentum state e^α acting on the twisted sector: the twisted exponential $:e^{\alpha \cdot X}:$ times the operator e_α on the ground-state space T (a Clifford-type operator, since $e_\beta e_\alpha = (-1)^{\langle \alpha,\beta \rangle} e_\alpha e_\beta$). The normalisation $2^{-\langle \alpha,\alpha \rangle}$ comes from the regularised twisted two-point function and is the one that makes the vacuum,

product and Jacobi identities consistent; it is what produces the factor $4^{\mp n}$ in the leading-term identities below.

Theorem 36.21 (Properties of $Y^T(e^\alpha)$). *Let L be even, positive definite, unimodular.*

1. $e_\beta e_\alpha = (-1)^{\langle\alpha,\beta\rangle} e_\alpha e_\beta$ *on* $\mathcal{T}_L$.
2. *For all $\alpha, \beta \in L$ and residues e, e', the rescaled fields of $Y^T(e^\alpha)$ and $Y^T(e^\beta)$ are mutually local.*
3. $Y^T(e^{-\alpha})_{(k/2)} = (-1)^k Y^T(e^\alpha)_{(k/2)}$. *Consequently $e^\alpha + e^{-\alpha}$ has no odd modes and $e^\alpha - e^{-\alpha}$ no even modes.*
4. $Y^T(e^0)_{(k/2)} = \delta_{k,-2}$.

File `VOA/Moonshine/LatticeTwistedVertex.lean`.

```
theorem eT_swap (α β : L.carrier) :
    eT L hEven hU β * eT L hEven hU α
      = (-1 : ℂ) ^ (L.form α β).natAbs • (eT L hEven hU α * eT L hEven hU β)

theorem YTL_local (hPos : L.PosDef) (α β : L.carrier) (e e' : ℤ) :
    Local (resc (YTL L hEven hU α) 2 e) (resc (YTL L hEven hU β) 2 e') :=

  ↪ _ _ _
    _ _ (eT_swap L hEven hU α β) e e'

theorem YTL_neg (α : L.carrier) (k : ℤ) :
    YTL L hEven hU (-α) k = (-1 : ℂ) ^ k • YTL L hEven hU α k

theorem YTL_zero (k : ℤ) : YTL L hEven hU 0 k = if k = -2 then 1 else 0
```

From the mathematics to the Lean statement

The one-line proof of `YTL_local` is shown because it *is* the argument: the generic locality with $n = \langle\alpha,\beta\rangle$, the integrality of the pairing in orthonormal coordinates (`sum_chargeCoord`, which uses `hPos`), and the $\mathcal{T}$ commutation `eT_swap`. In (3), $(-1)^k$ for the fractional mode $k/2$ is the substitution $z^{1/2} \mapsto -z^{1/2}$; since $\theta e^\alpha = e^{-\alpha}$, this says $Y^T(\theta u, z)$ is $Y^T(u,z)$ continued once around the origin, which is precisely the meaning of "θ-twisted". (4) is the vacuum axiom at the level of exponentials.

Physical meaning

These are the basic axioms for the twisted vertex operators of lattice exponentials: the exponential fields of different momenta are local, with the exchange sign $(-1)^{\langle\alpha,\beta\rangle}$ being carried by the ground-state operators e_α; the operator for $-\alpha$ is related to that for α by the sign $(-1)^k$ (so $e^\alpha \pm e^{-\alpha}$ have only integral/half-integral modes, the θ-eigenvalue structure); and the zero momentum state is the identity.

Proof on paper. (1) From $e_\alpha e_\beta = \varepsilon(\alpha,\beta) e_{\alpha+\beta}$ and $\varepsilon(\alpha,\beta)/\varepsilon(\beta,\alpha) = (-1)^{\langle\alpha,\beta\rangle}$. (2) Theorem 36.19(3). (3) $\mathrm{DD}_{-v}(a) = (-1)^a \mathrm{DD}_v(a)$, $e_{-\alpha} = e_\alpha$, and $(-1)^{-k-2+\langle\alpha,\alpha\rangle} = (-1)^k$ because $\langle\alpha,\alpha\rangle$ is even. (4) $\mathrm{DD}_0(a) = \delta_{a,0}$, $e_0 = 1$, $2^0 = 1$. □

What the machine verified

Unconditional; axioms standard.

Definition 36.22 (The generating set). Let $F_a = z^{1/2}h_a(z) \otimes 1$ (the rescaled twisted Heisenberg generator, `FgenTFld`, from Chapter 35) and $\widetilde{Y}_{\alpha,e} = \mathrm{resc}(Y^T(e^\alpha), 2, e)$ (`YTLFld`). The generating set is $\{F_a\}_a \cup \{\widetilde{Y}_{\alpha,e}\}_{\alpha\in L, e\in\mathbb{Z}}$.

File `VOA/Moonshine/LatticeTwistedVertex.lean`.

```
def latGenSet : Set (Fld (FockT (rank L) ⊗[ℂ] Rep (cocMat L) (isUnit_det_cocMat L hEven
 ↪ hU))) :=
  Set.range (FgenTFld L hEven hU) ∪ Set.range (fun p : L.carrier × ℤ => YTLFld L hEven hU
   ↪ p.1 p.2)
```

Physical meaning

The twisted sector is generated, as a module over the chiral algebra, by the twisted bosonic currents and the twisted exponentials, so these are the fields whose mutual locality must be established. In the CFT language they are the generators ∂X^a and $e^{\alpha\cdot X}$ of the lattice theory.

Theorem 36.23 (Locality of the twisted lattice system). *For L even, positive definite, unimodular, any two fields in the generated twisted system* TGenerated(*latGenSet*) *are mutually local.*

File `VOA/Moonshine/LatticeTwistedVertex.lean`.

```
theorem latticeTwistedSystem_local (hPos : L.PosDef)
    {a b : Fld (FockT (rank L) ⊗[ℂ] Rep (cocMat L) (isUnit_det_cocMat L hEven hU))}
    (ha : a ∈ TGenerated (latGenSet L hEven hU)) (hb : b ∈ TGenerated (latGenSet L hEven
     ↪ hU)) :
    Local a.1 b.1 :=
  tgenerated_local (latGenSet_local L hEven hU hPos) ha hb
```

From the mathematics to the Lean statement

`a.1` is the underlying distribution of the field `a`. The theorem is Dong's lemma (`tgenerated_local`, Chapter 35) applied to the pairwise locality of the generators: F_a with F_b (order 2, Chapter 35), F_a with $\widetilde{Y}$ (order 1, from the charge relation: $[F_a(z_1), \widetilde{Y}_{\beta,e}(z_2)] = \beta_a\,\delta(z_1/z_2)\widetilde{Y}_{\beta,e+1}(z_2)$, `bracketDist_FgenT_YTg`), and $\widetilde{Y}$ with $\widetilde{Y}$ (Theorem 36.21(2)). The Leech specialisation is `leechTwistedSystem_local`.

Physical meaning

Mutual locality of all fields generated from the twisted currents and exponentials is the 2d statement that the twisted-sector correlation functions are meromorphic after passage to the double cover, and that all operator products close on this set. Together with truncation it gives the field-theoretic input for defining Y^T on all of V_L.

What the machine verified

Unconditional. `#print axioms latticeTwistedSystem_local` was re-run for this chapter (output in §36.15): standard axioms only.

36.7 The twisted vertex operator on all states

File `VOA/Moonshine/LatticeTwistedFields.lean`. So far only e^α has a twisted vertex operator. A general state of V_L is a combination of $h_{b_1}(-n_1-1)\cdots h_{b_k}(-n_k-1)e^\alpha$. If Y^T is to satisfy the twisted iterate formula, then for the Heisenberg generator $h_b = h_b(-1)\mathbf{1}$ (which is θ-odd, so lives on the half-integral class with twist 1/2) we must have

$$F_e\big(h_b(-n-1)w\big) = \mathrm{star}_{1/2}(F_b)_{-n-1}\,F_{e-1}(w), \tag{36.6}$$

where $F_e(u) = \mathrm{resc}(Y^T(u), 2, e) = z^{e/2}Y^T(u,z)$. This *defines* F_e on all states.

Definition 36.24 (Word fields and the extension). For a list $l = [(n_1, b_1), \dots, (n_k, b_k)]$ and $\alpha \in L$ define $\mathrm{Fw}(\alpha, [\,], e) = \widetilde{Y}_{\alpha,e}$ and $\mathrm{Fw}(\alpha, (n,b) :: l, e) = \mathrm{star}_{1/2}(F_b)_{-n-1}\mathrm{Fw}(\alpha, l, e-1)$. $F_e : V_L \to \mathrm{Fld}(S[\theta] \otimes \mathcal{T})$ is the linear map sending the monomial basis vector $h_{b_1}(-n_1-1)\cdots e^\alpha$ to the word field, and

$$Y^T(u)_{(k/2)} = \text{the 0-th mode of } F_k(u).$$

```
noncomputable def Fw (α : L.carrier) : List (ℕ × Fin (rank L)) → ℤ → Fld (MT L hEven hU)
  | [], e => YTLFld L hEven hU α e
  | (c :: l), e => star (1 / 2) (FgT c.2) (-(c.1 : ℤ) - 1) (Fw α l (e - 1))

noncomputable def YML : LatModuleGen L →ₗ[ℂ] (ℤ → End ℂ (MT L hEven hU)) :=
  LinearMap.pi (fun k => (modeL 0).comp (FL L hEven hU k))
```

From the mathematics to the Lean statement

`MT L hEven hU` abbreviates $S[\theta] \otimes \mathcal{T}_L$. `FgT b` is F_b, the field $z^{1/2}h_b(z) \otimes 1$. `FLB` is the bilinear map on $\mathrm{FockN} \times \mathbb{C}[L]$ which sends a monomial m and e^α to `Fw α (monoWordN m) e` (`monoWordN m` lists the letters of m in some order); `TensorProduct.lift` makes it linear on the tensor product. `modeL 0` takes the 0-th mode. Since $\mathrm{mode}_0(z^{k/2}Y) = u_{(k/2)}$ (`resc` with $p = 0$), `YML u k` $= u_{(k/2)}$, the convention of `TwistedModule.YM`. **Well-definedness** is a real issue: the definition depends on the order of letters. It is resolved by proving that twisted creation operators commute (`Fw_perm`: the word field depends only on the multiset of letters), so F_e on the polynomial basis is independent of the chosen listing. The theorems below show the definition does what it should.

Physical meaning

This defines the twisted vertex operator of a general state of the lattice theory by successive oscillator products: a state $h_{b_1}(-n_1-1)\cdots e^\alpha$ is mapped to a normal-ordered product of the twisted currents with the exponential field, where the factor $z^{1/2}$ and the twisted binomial expansion implement the monodromy -1 of ∂X around the twist field. It is the CFT reconstruction of $Y^T(u)$ from the free-field generators.

Theorem 36.25 (Basic properties of Y^T on V_L). *For L even, positive definite, unimodular, all $u, v \in V_L$ and $e, e', k \in \mathbb{Z}$:*

1. *(Creation.)* $F_{e+1}(h_b(-n-1)p \otimes g) = \mathrm{star}_{1/2}(F_b)_{-n-1}F_e(p \otimes g)$.

    Local (resc (YML L hEven hU u) 2 e) (resc (YML L hEven hU v) 2 e')
```

From the mathematics to the Lean statement

In (1), `X c * p` with $c = (n, b)$ is $h_b(-n-1)p$ in the untwisted Fock space (FockN has variables $X_{(n,b)} = h_b(-n-1)$), and `g : L.carrier →₀ ℂ` an element of $\mathbb{C}[L]$. Statement (2) says that the definition through 0-th modes of the class-k field is consistent with the rescaling: the class-e field $F_e(u)$ is *exactly* $z^{e/2}Y^T(u,z)$ on the class e; this needs $F_{e+2}(u) = zF_e(u)$ (`FL_shift`). In (5), `twistedEigenspace 2 j` for `thetaAut` is $\{u : \theta u = (-1)^j u\}$ and `hk` is $k \not\equiv -j \equiv j \pmod 2$; this is precisely the `support` axiom of `TwistedModule`. Some theorems carry the section variable `hPos` although it does not appear in the printed line (Lean's `include hPos`); the reader should regard (1), (5), (6) as having the hypothesis L positive definite.

Physical meaning

These are the basic properties of the twisted vertex operators of arbitrary states: truncation (finite energy), the vacuum maps to the identity, and locality. The θ-compatibility property is the physical statement that θ-even states have only integral modes and θ-odd states only half-integral modes on the twisted sector, which is what it means for the fields to see the twist.

Proof on paper. (1) is the definition plus commutation of creation operators. (2)–(4) are bookkeeping of the rescaling; $Y^T(\mathbf{1})$ is $Y^T(e^0)$ (Theorem 36.21(4)). (5): conjugating by θ negates every Heisenberg generator, which in the twisted product contributes (-1) per letter, and replaces e^α by $e^{-\alpha}$, which contributes $(-1)^e$ times (-1) per letter (each letter shifts the class by one); the letter signs cancel. If $\theta u = (-1)^j u$ and $e \not\equiv j$, then $F_e(u) = (-1)^{e+j}F_e(u) = -F_e(u)$, so it vanishes. (6): every $F_e(u)$ is in the generated system (twisted products of local fields are generated), and Theorem 36.23 applies. □

What the machine verified

Unconditional (hypotheses L even, positive definite, unimodular); axioms standard.

36.8 The twisted product formula

Locality alone does not give a twisted module; one also needs that Y^T is compatible with the products of V_L. Chapter 35 proved the *reduction*: if every pair of rescaled fields is local and satisfies the *product formula*

$$\big(F_e(u)_{(\ell)}F_{e'}(v)\big)_s = \sum_{t\ge 0}\binom{e/2}{t}Y^T(u_{(\ell+t)}v)_{((2(s-t)+e+e')/2)}$$

for $u \in V^j$ on its class $e \equiv j$, then the twisted Jacobi identity holds (`twistedJacobi_of_local_pf`). Inverting the binomial, the product formula is equivalent to the following statement in terms of twisted products.

Definition 36.26 (Projection to a class and the formula PF). For $e \in \mathbb{Z}$ let $\pi_e(u) = \frac{1}{2}(u + (-1)^e\theta u)$, the component of u in the θ-eigenspace $(-1)^e$. For $u, v \in V_L$, $\mathrm{PF}(u,v)$ is the statement

$$\forall e, e', \ell \in \mathbb{Z}: \qquad \mathrm{star}_{e/2}\big(F_e(u)\big)_\ell F_{e'}(v) = F_{e+e'}\big(\pi_e(u)_{(\ell)}v\big).$$

Files `VOA/Moonshine/LatticeTwistedUntwisted.lean`, `VOA/Moonshine/LatticeTwistedProduct.lean`.

```
noncomputable def piE (e : ℤ) (u : LatModuleGen L) : LatModuleGen L :=

  ∀ e e' ℓ : ℤ, star ((e : ℂ) / 2) (FL L hEven hU e u) ℓ (FL L hEven hU e' v)
    = FL L hEven hU (e + e') ((latticeVOAGen L hEven hPos).smul (piE L e u) ℓ v)
```

From the mathematics to the Lean statement

Why π_e. $F_e(u)$ only sees the modes of u on the class e, and by the support property these come from $\pi_e(u)$ alone: $F_e(u) = F_e(\pi_e u)$. Hence on the right one must use $\pi_e(u)$, not u. **Why twist $e/2$.** $F_e(u) = z^{e/2}Y^T(u,z)$ carries the power $z^{e/2}$, and $\mathrm{star}_{e/2}$ is precisely the operation which turns the $z_1^{e/2}$ into the binomial expansion of $(z_2+(z_1-z_2))^{e/2}$ (Definition 36.3). Thus $\mathrm{PF}(u,v)$ is "$Y^T(\pi_e u_{(\ell)}v, z)$ = the twisted iterate of $Y^T(u)$ and $Y^T(v)$", the twisted associativity in rescaled language. `(latticeVOAGen L hEven hPos).smul a ℓ v` is $a_{(\ell)}v$ in V_L. It is a `Prop`; it is proved below for all u, v.

Physical meaning

The projection π_e onto the $(-1)^e$ eigenspace of θ reflects that on the twisted sector a state's field is defined only for the correct parity of the exponent of z; the half-integer powers $z^{e/2}$ attach to the θ-odd part. The formula PF is then the twisted associativity or OPE: the twisted product of two twisted fields equals the field of the product state. This is the statement that the twisted fields represent the vertex algebra V_L on the twisted sector.

Theorem 36.27 (Generators and the reduction to exponentials). *Let L be even, positive definite, unimodular.*

1. *For every Heisenberg generator, every state w and every ℓ:* $\mathrm{star}_{1/2}(F_b)_\ell F_e(w) = F_{e+1}(h_{b\,(\ell)}w)$.
2. *If* $\mathrm{PF}(e^\alpha, e^\beta)$ *holds for all $\alpha, \beta \in L$, then* $\mathrm{PF}(u,v)$ *holds for all $u, v \in V_L$.*

theorem PF_of_base (hbase : ∀ α β : L.carrier, PF L hEven hU hPos (echg L α) (echg L β))
    (u v : LatModuleGen L) : PF L hEven hU hPos u v :=
```

From the mathematics to the Lean statement

(1) is PF(h_b, w) (note $\pi_e(h_b) = h_b$ for e odd and 0 for e even; the statement is the odd class, twist 1/2). (2) has the explicit hypothesis `hbase`, which is discharged in the next section; the theorem as stated is a conditional reduction, and its conclusion is exactly "PF for all pairs".

Physical meaning

This reduces the product formula for all states to the momentum states e^{α}, e^{β}: since every state is built from the free currents and exponentials, and the currents obey the formula (the twisted boson Ward identity), one only needs to check the OPE of two lattice exponentials. This is the standard reduction in CFT of an OPE involving descendants to that of the primaries.

Proof on paper. (1) For $\ell < 0$ it is the definition (36.6). For $\ell \geq 0$ induct on the word: on e^{β}, $h_{b(0)}e^{\beta} = \beta_b e^{\beta}$ and $h_{b(\ell)}e^{\beta} = 0$ for $\ell > 0$, which matches the generator–exponential OPE (Theorem 36.23); for $w = h_c(-n-1)w'$ move $h_{b(\ell)}$ past $h_c(-n-1)$ by the commutator formula, on the field side by the twisted commutator formula (Chapter 35), using $[h_{b(\ell)}, h_{c(m)}] = \ell\delta_{bc}\delta_{\ell+m,0}$ on both sides.

(2) First fix $v = e^{\beta}$ and induct on u. If $u = h_b(-n-1)w$ then the left side is $\mathrm{star}_{e/2}(\mathrm{star}_{1/2}(F_b)_{-n-1}F_{e-1}(w))_{\ell}F_{e'}(e^{\beta})$, which the *twisted iterate formula* (associativity of twisted products, Theorem 36.28 below) expands as a finite combination of iterated products $\mathrm{star}(F_b)\mathrm{star}(F(w))$ and $\mathrm{star}(F(w))\mathrm{star}(F_b)$; each is evaluated by (1) and the induction hypothesis, and the result is F of the corresponding expansion of $(h_b(-n-1)w)_{(\ell)}e^{\beta}$ by the iterate formula of V_L. Then induct on v: for $v = h_b(-n-1)v'$, use the twisted commutator formula on the field side and the commutator formula of V_L on the state side, together with (1) and the case already proved. □

What the machine verified

Unconditional as a reduction (it has the explicit hypothesis `hbase`); file `VOA/Moonshine/LatticeTwistedProduct.lean`; axioms standard.

Theorem 36.28 (Twisted associativity: the iterate formula). *Let S be a pairwise local set of fields and $A, B, C \in \mathrm{TGenerated}(S)$. For all twists $\alpha, \beta \in \mathbb{C}$ and $p, q \in \mathbb{Z}$,*

$$\mathrm{star}_{\alpha+\beta}\big(\mathrm{star}_{\alpha}(A)_p B\big)_q C = \sum_{i\geq 0}(-1)^i\binom{p}{i}\Big(\mathrm{star}_{\alpha}(A)_{p-i}\,\mathrm{star}_{\beta}(B)_{q+i}C - (-1)^p\,\mathrm{star}_{\beta}(B)_{p+q-i}\,\mathrm{star}_{\alpha}(A)_i C\Big).$$

```

From the mathematics to the Lean statement

Both theorems live in `VOA.TwistedReduction` and carry the section hypothesis `hS : ∀ a ∈ S, ∀ b ∈ S, Local a.1 b.1` (pairwise locality of the generators), which is not printed in the statement lines but is an argument of the theorem. `gBinom p i` is $\binom{p}{i}$ for integer p. The range version only replaces the finite $\sum^{\mathrm{f}}$ by a sum over $i < K$, with `hK` guaranteeing the omitted terms vanish. This is the exact analogue of the iterate formula $(a_{(p)}b)_{(q)} = \sum_i (-1)^i \binom{p}{i}(a_{(p-i)}b_{(q+i)} - (-1)^p b_{(p+q-i)}a_{(i)})$ of a vertex algebra.

Physical meaning

This is the associativity (Borcherds identity, or crossing symmetry) of twisted fields: the field of the product $u_{(p)}v$ acting on the twisted module is expressed as the commutator-type combination of $Y(u)Y(v)$ and $Y(v)Y(u)$. In CFT this is the equivalence of the OPE of two operators with the two orderings of operator products in the twisted sector, with the twist phases α, β keeping track of the monodromy.

Proof on paper. This is the associativity half of Li's theorem that a local system of twisted vertex operators carries a vertex algebra structure. Make the system into a state space graded by the twist, $\mathcal{S} = \bigoplus_\alpha \mathrm{TGenerated}(S)$, with state fields $Y_\star(a,z)$ acting by twisted products. The twisted commutator formula makes these state fields mutually local, the identity field is a vacuum with the creation property, and the twisted translation $D_\alpha = \partial - \alpha z^{-1}$ is a derivation of twisted products. Goddard's uniqueness theorem (a field local with all state fields which creates the right state from the vacuum is the state field) then identifies the state field of $\mathrm{star}_\alpha(A)_p B$ with the product of state fields, and the iterate formula for products of local fields gives the claim. □

What the machine verified

Unconditional (given its explicit hypotheses); `VOA/Moonshine/LatticeTwistedAssoc.lean`; `#print axioms star_iterate_range` re-run: standard axioms.

Trap / dead end

A record correction. The project roadmap (`Notes/MonsterRoadmap.md`, row of the twisted-module milestone) describes `star_iterate_range` as "unused but proved". This was not accurate when this chapter was first written, and is not accurate at a pre-release build commit either: `star_iterate_range` is used in the u-induction of Theorem 36.27(2) (`LatticeTwistedProduct.lean`) and in the defect calculus of §36.9 (`LatticeTwistedBase.lean`); a `grep` of the repository confirms both uses. So twisted associativity is a genuine input of the twisted product formula, as the mathematics suggests.

36.9 The base case: two exponentials

Files `VOA/Moonshine/LatticeTwisted{Translation,Unique,Base,Scalar,Leading,BaseCase}.lean`. It remains to prove $\mathrm{PF}(e^\alpha, e^\beta)$. The strategy is a descent in the mode index ℓ, controlled by one differential equation and one uniqueness lemma.

Definition 36.29 (Defect). For $\beta \in L$, $u \in V_L$ and $e, e', \ell \in \mathbb{Z}$,

$$D_\beta(u; e, e', \ell) = \mathrm{star}_{e/2}(F_e(u))_\ell F_{e'}(e^\beta) - F_{e+e'}\big(\pi_e(u)_{(\ell)}e^\beta\big).$$

So $\mathrm{PF}(e^\alpha, e^\beta)$ is $D_\beta(e^\alpha; \cdot) = 0$.

```
noncomputable def Def (β : L.carrier) (u : LatModuleGen L) (e e' ℓ : ℤ) : Fld (MT L hEven
↪  hU) :=

    - FL L hEven hU (e + e') ((latticeVOAGen L hEven hPos).smul (piE L e u) ℓ (echg L β))
```

Physical meaning

The defect is the failure of the twisted product formula on a pair of exponentials: the difference between the actual product of two twisted fields and the field of the product state. It measures exactly the defect of the twisted OPE; showing it vanishes is the goal of the following results. It has no independent physical meaning, since in a consistent theory the defect is zero.

Proposition 36.30 (Structure of the defect). *Let $n = \langle \alpha, \beta \rangle$ and $D(e, e', \ell) = D_\beta(e^\alpha; e, e', \ell)$.*

1. *(Translation covariance.) $D_\alpha(e/2)F_e(e^\alpha) = F_e(Te^\alpha)$ where $D_c X = \partial X - cz^{-1}X$; consequently $D_\beta(Te^\alpha; e, e', \ell) = -\ell D(e, e', \ell - 1)$.*
2. *(Recursion.) If $D(e-1, e', m) = 0$ for all $m \geq \ell$, then $-\ell\, D(e, e', \ell - 1) = n\, D(e-1, e'+1, \ell - 1)$.*
3. *(Charge.) If $D(\cdot, \cdot, m') = 0$ for all $m' > m$, then for all b and $s \in \mathbb{N}$, $\mathrm{star}_{1/2}(F_b)_s\, D(e, e', m) = \delta_{s,0}\big(\beta_b D(e, e'+1, m) + \alpha_b D(e+1, e', m)\big)$.*
4. *D vanishes for ℓ large (uniformly in e, e'), $D(e+2, e', \ell) = zD(e, e', \ell)$, $D(e, e'+2, \ell) = zD(e, e', \ell)$.*

```

From the mathematics to the Lean statement

`(latticeVOAGen L hEven hPos).toPreVertexAlgebra.T` is the translation operator $T = L_{-1}$ of V_L, and `Dα c X` is $\partial X - c\,z^{-1}X$ (`Dα c X = Fld.deriv X - c • fzmul (-1) X`), the derivative of a field which carries a factor z^c: indeed $\partial(z^c Y) = z^c(\partial Y) + cz^{-1}z^c Y$. So `FL_T_echg` is the translation axiom $Y^T(Tu, z) = \partial_z Y^T(u, z)$ for $u = e^\alpha$, rescaled. The hypotheses `h` of `Def_ode` and `Def_charge` are the inductive hypotheses of the descent: they are not extra

assumptions of the final theorem.

Physical meaning

These are the properties of the failure of the OPE: it is translation covariant (the derivative of the OPE is the OPE of the derivative), it obeys a recursion with coefficient $n = \langle\alpha,\beta\rangle$ coming from the pole structure of the contraction, and it is charged, i.e. it carries momentum $\alpha+\beta$ under the twisted currents. These are the Ward identities used to show that a defect with the right charge and no vacuum component must vanish.

Proof on paper. (1) Differentiating (36.1): ∂_z of $z^{-\langle\alpha,\alpha\rangle/2}E^-E^+$ gives $:\alpha(z)Y^T(e^\alpha,z):\,-\frac{\langle\alpha,\alpha\rangle}{2}z^{-1}Y^T$, which is the Euler identity $a\,\mathrm{DD}_\alpha(a) = 2\sum_{k\ \mathrm{odd}>0}(\alpha(-k/2)\mathrm{DD}(a-k)+\mathrm{DD}(a+k)\alpha(k/2))$ of the dressing (coefficient form of $w\partial_w(E^-E^+)$, assembled from the Newton recursion of E^- and the Euler identity of the translation E^+). On the state side $Te^\alpha = \sum_b \alpha_b h_b(-1)e^\alpha$, and $\sum_b \alpha_b\,\mathrm{star}_{1/2}(F_b)_{-1}F_{e-1}(e^\alpha)$ is exactly $F_e(\sum_b \alpha_b h_b(-1)e^\alpha)$ by the creation rule; comparing yields $F_e(Te^\alpha) = D_{e/2}F_e(e^\alpha)$. Then $(Tu)_{(\ell)} = -\ell u_{(\ell-1)}$ in V_L and the twisted analogue $\mathrm{star}_c(D_cA)_\ell X = -\ell\,\mathrm{star}_c(A)_{\ell-1}X$ give the relation for the defect.

(2) Write $Te^\alpha = \sum_b \alpha_b h_b(-1)e^\alpha$ and compute the defect of $h_b(-1)w$: by the twisted iterate formula and Theorem 36.27(1), assuming the defect of w vanishes at the levels $\geq \ell$, only one term survives, $\beta_b D_\beta(w; e-1, e'+1, \ell-1)$ (it comes from $h_{b(0)}e^\beta = \beta_b e^\beta$). Summing, $D_\beta(Te^\alpha; e, e', \ell) = \sum_b \alpha_b\beta_b D(e-1, e'+1, \ell-1) = nD(e-1, e'+1, \ell-1)$; combine with (1).

(3) The twisted commutator formula for F_b against the two arguments of the twisted product gives two terms, β_b from F_b hitting $F_{e'}(e^\beta)$ and α_b from F_b hitting $F_e(e^\alpha)$, plus terms of the defect at higher levels, which vanish by hypothesis.

(4) Twisted products of local fields vanish for large index, and $F_{e+2} = zF_e$. □

What the machine verified

Unconditional; files `LatticeTwistedTranslation.lean`, `LatticeTwistedBase.lean`; axioms standard.

36.9.1 The uniqueness lemma

Physically: a field of definite charge γ (it commutes with the oscillators like e^γ does) is a vertex operator E^-E^+ times a $\mathcal{T}$-valued function of z; it is zero if its vacuum-to-vacuum matrix elements vanish.

Definition 36.31 (Vacuum coefficient). $\mathrm{cf}_m : S[\theta]\otimes\mathcal{T} \to \mathcal{T}$ is the coefficient of the monomial m in the first factor; cf_0 is the projection onto $\mathbf{1}\otimes\mathcal{T}$.

File `VOA/Moonshine/LatticeTwistedUnique.lean`.

```

From the mathematics to the Lean statement

All hypotheses are as in the text; `(1 ⊗ₜ[ℂ] t)` is $\mathbf{1}\otimes t$; `Φ c = 0` is the zero field. **Not vacuous**: the hypotheses are satisfied by $\Phi(c) = \widetilde{Y}_{\gamma,c}$ except `hvac`, whose failure is measured by the vacuum coefficient computed below; the lemma is used only on defects. **Could it be too strong?** No: the hypothesis `hcomm` is required for *all* odd K, both signs, which is what pins down Ψ from its vacuum block.

Physical meaning

This is a uniqueness statement of Ward-identity type: an operator of definite charge under all twisted currents is fully determined by its vacuum matrix elements, because the oscillator Fock space is generated from the vacuum by the creation currents. It is the free-field version of the principle that a correlator is fixed by its charge and its vacuum expectation value.

Proof on paper. (1) Show $\mathrm{cf}_m(\Psi_k(\mathbf{1}\otimes t)) = 0$ by induction on the degree of the monomial m: the annihilator $h_b(K/2)$, $K > 0$, is $\frac{K}{2}\partial_{(n,b)}$, and since it kills $\mathbf{1}$, $h_b(K/2)\Psi_k(\mathbf{1}\otimes t) = \gamma_b\Psi_{k+K}(\mathbf{1}\otimes t)$; the coefficient of m in the left side is a nonzero multiple of the coefficient of $m + e_{(n,b)}$ in $\Psi_k(\mathbf{1}\otimes t)$, so higher coefficients are determined by lower ones. Hence $\Psi_k(\mathbf{1}\otimes t) = 0$. For a general vector $p\otimes t$, move the creation operators (the variables of p) through Ψ_k using the relation with $K < 0$. (2) The generator products $F_{b\,(s)}\Phi(c)$, $s \geq 0$, are recovered from the twisted ones by downward induction in s, then the commutator formula gives the hypothesis of (1) for $\Psi_k = \mathrm{mode}_0\Phi(k)$, which by $\Phi(c+2) = z\Phi(c)$ determines all modes. □

From the mathematics to the Lean statement

The section variables are `(L : IntegralLattice.{0}) (hEven : L.Even) (hU : IsUnit (gramMat L).det) (hPos : L.PosDef)`; these are the only hypotheses. `PF_all` is the universally quantified twisted product formula of Definition 36.26, with no further assumption. (`IntegralLattice.{0}` only fixes the universe level; the Leech lattice lives there.)

Physical meaning

The twisted OPE of two lattice exponentials holds exactly: the product of the twisted vertex operators of e^α and e^β is the twisted vertex operator of the product state, the associativity of twist fields. The proof uses only the Heisenberg Ward identities and a vacuum computation, i.e. the argument by charge conservation that, in the CFT, reduces an OPE to a two-point (vacuum) coefficient. This is a heuristic gloss; the Lean proof is the actual argument.

Proof on paper. By Proposition 36.30(4) there is L_0 with $D = 0$ for $\ell \geq L_0$. Suppose D vanishes at all levels $> m$; we show it vanishes at level m. By $D(e+2, e'-2) = D(e, e')$ (from the shifts) everything is determined by the two class pairs $x_c = D(0, c, m)$ and $y_c = D(1, c-1, m)$. The recursion (2) at $\ell = m+1$ gives

$$-(m+1)\,x_c = n\,y_c, \qquad -(m+1)\,y_c = n\,x_c,$$

hence $(m+1+n)(x_c + y_c) = 0$ and $(m+1-n)(x_c - y_c) = 0$. Away from the two exceptional levels $m = -n-1$ and $m = n-1$ both combinations vanish, so $x = y = 0$. At $m = -n-1$, the family $\Phi(c) = x_c + y_c$ satisfies, by Proposition 36.30(3), the charge relation with charge $\gamma = \alpha + \beta$ (the two contributions $\beta_b D(0, c+1) + \alpha_b D(1, c)$ and $\beta_b D(1, c) + \alpha_b D(2, c-1) = \beta_b D(1, c) + \alpha_b D(0, c+1)$ add up to $(\alpha_b + \beta_b)\Phi(c+1)$), so Theorem 36.32(2) reduces $\Phi = 0$ to the vanishing of its vacuum expectations, proved in Theorem 36.36 below. At $m = n-1$ the same works for $x_c - y_c$ with charge $\beta - \alpha$. (If $n = 0$ both exceptional levels coincide at $m = -1$ and both arguments are run.) Induction downward from L_0 finishes. □

What the machine verified

Unconditional. `#print axioms PF_all` re-run for this chapter: standard axioms only.

36.10 Why the normalisation is $2^{-\langle\alpha,\alpha\rangle}$

We now compute the vacuum expectations at the exceptional levels. On the state side, at $m = -n-1$, $(\pi_0 + \pi_1)e^\alpha = e^\alpha$ and $e^\alpha_{(-n-1)}e^\beta = \varepsilon(\alpha,\beta)e^{\alpha+\beta}$ (the leading term of the lattice product), whose twisted vertex operator has vacuum coefficient $2^{-\langle\alpha+\beta,\alpha+\beta\rangle}\varepsilon(\alpha,\beta)e_{\alpha+\beta}$. On the field side we need the vacuum coefficient of the twisted product of two exponential fields.

Theorem 36.34 (Vacuum expectation of the twisted product). *For $\alpha, \beta \in L$, $e, e', q \in \mathbb{Z}$, $I \geq |\langle\alpha,\beta\rangle| - q$ and $t \in \mathcal{T}$,*

$$\mathrm{cf}_0\Big(\mathrm{mode}_0\big(\mathrm{star}_{e/2}(\widetilde{Y}_{\alpha,e})_q \widetilde{Y}_{\beta,e'}\big)(\mathbf{1}\otimes t)\Big) = 2^{-\langle\alpha,\alpha\rangle}2^{-\langle\beta,\beta\rangle}\,[2q + e + e' + 4 = \langle\alpha,\alpha\rangle + \langle\beta,\beta\rangle]$$
$$\cdot \sum_{i<I} \binom{-e/2}{i} V\big(\langle\alpha,\beta\rangle,\ \langle\alpha,\alpha\rangle - 2 - e,\ q+i\big)\, e_\alpha e_\beta t,$$

where $[\cdot]$ *is* 1 *or* 0 *and* $V(n,r',Q)=\sum_j(-1)^j\binom{Q}{j}\big(f^{(n)}_{2Q-2j-r'}-(-1)^{Q+n}f^{(n)}_{r'-2j}\big)$.

```

From the mathematics to the Lean statement

$V(n,r',Q)$ is the vacuum coefficient of the Q-th untwisted product of the two dressings on the class r'; it is a finite sum ($\binom{Q}{j}=0$ for $Q\ge 0$, $j>Q$, and f vanishes at negative indices). The Kronecker condition is conformal-weight conservation. The bound `hI` makes the twisted-product sum exhaustive. The two-point function behind it is $\langle\mathbf{1}|\mathrm{DD}_v(A)\mathrm{DD}_u(B)|\mathbf{1}\rangle=\delta_{A+B,0}f_{-A}^{(\langle v,u\rangle)}$ (`constantCoeff_DD_DD`).

Physical meaning

This computes the vacuum expectation value (the oscillator vacuum component) of the twisted product of two exponential fields: it is nonzero only when the weights match (the delta condition on $2q+e+e'+4$, conservation of conformal weight), and it is given by the contraction function V with the ground-state operator $e_\alpha e_\beta$ and the normalisations $2^{-\langle\alpha,\alpha\rangle}2^{-\langle\beta,\beta\rangle}$. In CFT it is the two-point function of two twisted vertex operators with the twist-field multiplicity operators multiplying.

      = (1 / 2 : ℂ) ^ (n.natAbs - n).toNat * 2 ^ (n.natAbs + n).toNat
```

From the mathematics to the Lean statement

The right sides: $(1/2)^{|n|+n}2^{|n|-n} = 2^{-2n} = 4^{-n}$, and $(1/2)^{|n|-n}2^{|n|+n} = 4^n$; Lean writes them with natural exponents to avoid negative powers. The two summands are the classes $e = 0$ (twist 0, $\binom{0}{i} = \delta_{i0}$) and $e = 1$ (twist 1/2). **Sum over both classes**: the vacuum relation is needed for $x_c + y_c$, which combines $e = 0$ and $e = 1$; the individual class contributions are not powers of 2.

Physical meaning

Technical lemma: the two combinatorial sums that arise as leading terms in the twisted two-point function evaluate to $4^{\mp n}$. These powers of 4 are exactly what compensates the $2^{-\langle\alpha,\alpha\rangle}$ normalisations of the twisted vertex operators and make the vacuum coefficients of the product and of the defect agree.

Proof on paper. Put $K = |n|$ and $G(y) = (1-y)^{K+n}(1+y)^{K-n} = \sum g_u y^u$. A Taylor-type formula (`taylor`) expresses $V(n,r',Q) = \sum_{u\equiv r'} g_u\binom{(2K-2-r'-u)/2}{K-Q-1}$, using $(1-y^2)^Q f = (1-y^2)^{Q-K}G$, the palindromy of G and Vandermonde. The twisted-product sum is a Vandermonde convolution in the binomial $\binom{-e/2}{i}$, and the two classes recombine the two parities of u into $\sum_u g_u\binom{(M-u)/2}{a}$. Finally, with $B(c) = \sum_j \binom{c}{j}t^j = (1+t)^c$, this sum is the coefficient of t^a in $B(M/2)\,G(B(-1/2))$; since $1 - B(-1/2) = tW(t)$ with $W(0) = \frac{1}{2}$ and $1 + B(-1/2) = 2 + O(t)$, the factor $(1-B)^a$ contributes $t^a 2^{-a}$ and the coefficient is 2^{b-a} with $a = K+n$, $b = K-n$. □

      + (-1 : ℂ) • Def L hEven hU hPos β (echg L α) 1 (c - 1) m) = 0
```

Physical meaning

These are the matching conditions at the vacuum: the vacuum component of the defect at the two critical weights vanishes, because the explicit twisted two-point function agrees with the product-state vertex operator. This is the check, in the language of correlation functions, that the two sides of the OPE have the same leading singularity.

Proof on paper. Plus case, $n = \langle\alpha,\beta\rangle$: the field side gives, by Theorems 36.34 and 36.35, $2^{-\langle\alpha,\alpha\rangle-\langle\beta,\beta\rangle}4^{-n}e_\alpha e_\beta t$ (when weights match; otherwise both sides are 0). The state side is $F_c(e^\alpha_{(-n-1)}e^\beta) = \varepsilon(\alpha,\beta)F_c(e^{\alpha+\beta})$ with vacuum coefficient $2^{-\langle\alpha+\beta,\alpha+\beta\rangle}\varepsilon(\alpha,\beta)e_{\alpha+\beta}t$, and $e_\alpha e_\beta = \varepsilon(\alpha,\beta)e_{\alpha+\beta}$. They agree by (36.4). Minus case: $\pi_0 - \pi_1 = \theta$, $\theta e^\alpha = e^{-\alpha}$, $e^{-\alpha}_{(n-1)}e^\beta = \varepsilon(-\alpha,\beta)e^{\beta-\alpha}$, $e_{\alpha+\beta} = e_{\beta-\alpha}$ on $\mathcal{T}$ (they differ by 2α), and $2^{-\langle\alpha,\alpha\rangle-\langle\beta,\beta\rangle}4^n = 2^{-\langle\beta-\alpha,\beta-\alpha\rangle}$. □

Remark 36.37 (The normalisation is forced). (Argued on paper; not a Lean statement.) Suppose $Y^T(e^\alpha)$ were normalised by an arbitrary $\kappa(\alpha) \neq 0$ instead of $2^{-\langle\alpha,\alpha\rangle}$. Every step above is linear in κ except the vacuum identity, which becomes $\kappa(\alpha)\kappa(\beta)4^{-\langle\alpha,\beta\rangle} = \kappa(\alpha+\beta)$. Writing $\kappa(\alpha) = 2^{-\langle\alpha,\alpha\rangle}\chi(\alpha)$, this says exactly that $\chi : L \to \mathbb{C}^\times$ is a homomorphism. So $2^{-\langle\alpha,\alpha\rangle}$ is the normalisation up to a character of L, and a character only rescales $e^\alpha \mapsto \chi(\alpha)e^\alpha$ (an automorphism of V_L if one also requires θ-compatibility $\chi(-\alpha) = \chi(\alpha)$, i.e. $\chi^2 = 1$). Without the factor (say $\kappa = 1$) the product formula fails already at the leading term by $4^{-\langle\alpha,\beta\rangle}$.

36.11 The twisted module V_L^T

Theorem 36.38 (Twisted Jacobi identity). *For L even, positive definite, unimodular,* `YML` *satisfies the (repaired) twisted Jacobi identity of order 2 with respect to θ, for all pairs of states.*

File `VOA/Moonshine/LatticeTwistedJacobi.lean`.

```
theorem twistedJacobi_YML : TwistedJacobi (thetaAut L hEven hPos) 2 (YML L hEven hU) :=
  twistedJacobi_of_local_pf (thetaAut L hEven hPos) (YML L hEven hU) (by norm_num)
    (YML_truncation L hEven hU) (fun j => (j : ℤ)) (fun j => by push_cast; omega)
    (fun j u _ v e' _ _ => YML_local L hEven hU hPos u v j e')
    (fun j u hu v e' _ _ ℓ s x => productFormula_YML L hEven hU hPos j u hu v e' ℓ s x)
```

From the mathematics to the Lean statement

`TwistedJacobi g N YM` is the proposition of the `jacobi` field of `TwistedModule` (§36.2), for every j, every $u \in V^j$, every v, x, ℓ, k, m with $k \equiv -j$. The proof term shows the inputs: the reduction of Chapter 35 with the class offsets $\mathrm{off}(j) = j$, the truncation, the locality `YML_local`, and the product formula in the reduction's form, `productFormula_YML`, which is `PF_all` for $u \in V^j$ (where $\pi_j u = u$) after binomial inversion.

Physical meaning

The twisted Jacobi identity is the complete set of OPE and locality axioms of a twisted module, combined in one identity: it says that the twisted vertex operators Y^T define a consistent action of the chiral algebra on the twisted sector, for all states. In CFT this is the statement that the correlation functions of the twisted sector are well defined (single-valued up to the twist) and associative.

What the machine verified

Unconditional; `#print axioms twistedJacobi_YML`: standard axioms (re-run).

36.11.1 The grading

Definition 36.39 (Weight spaces of V_L^T). $G_d = S[\theta]_d \otimes \mathcal{T}$ (doubled weight d), and for $\alpha \in \mathbb{C}$, $(V_L^T)_\alpha = \sum_{d:\, d/2+r/16=\alpha} G_d$.

File `VOA/Moonshine/LatticeTwistedGrading.lean`.

```
noncomputable def GT (d : ℕ) : Submodule ℂ (FockT r ⊗[ℂ] Tm) :=
  LinearMap.range ((gradingT r d).subtype.rTensor Tm)

noncomputable def weightLT (α : ℂ) : Submodule ℂ (FockT r ⊗[ℂ] Tm) :=
  ⨆ (d : ℕ) (_ : ((levelT r d : ℚ) : ℂ) = α), GT r Tm d
```

From the mathematics to the Lean statement

`levelT r d` $= d/2+r/16$. The supremum is over at most one d, so $(V_L^T)_\alpha$ is G_d if $\alpha = d/2+r/16$ and 0 otherwise (`weightLT_level`, `weightLT_eq_bot`). The image of $S[\theta]_d \otimes \mathcal{T} \to S[\theta] \otimes \mathcal{T}$ is the subspace $S[\theta]_d \otimes \mathcal{T}$ (tensor products over a field are exact).

Physical meaning

The conformal weight in the twisted sector of a state with $d/2$ units of oscillator excitation, i.e. d twisted half-integer oscillator quanta, is $d/2 + r/16$: the oscillators contribute their mode numbers, and the ground state sits at the twist-field weight $r/16$. For the Leech lattice, $r = 24$, the ground states have weight $3/2$, and the excited states at weights $3/2 + d/2$.

Theorem 36.40 (L_0 of the lattice twisted module). *$Y^T(\omega)_{(1)} = L_0^T \otimes 1$, where ω is the conformal vector of V_L and $L_0^T = \frac{1}{2}$(doubled weight)$ + \frac{r}{16}$. More generally, on charge-zero states, $F_e(p \otimes e^0) = F_e^{\mathrm{Heis}}(p) \otimes 1$.*

```
theorem YML_omega_two :
    YML L hEven hU (omegaLatGen L) 2
      = (L0T (rank L)).rTensor (Rep (cocMat L) (isUnit_det_cocMat L hEven hU))

theorem FL_charge_zero (p : FockN (rank L)) (e : ℤ) :
    FL L hEven hU e (p ⊗ₜ[ℂ] eGen L 0)
      = rTFld (Tm := Rep (cocMat L) (isUnit_det_cocMat L hEven hU)) (FT (rank L) e p)
```

From the mathematics to the Lean statement

`YML u 2` is $u_{(2/2)} = u_{(1)}$, so the first statement is $L_0 = \omega_{(1)}$. `FT` is the rescaled twisted Heisenberg vertex operator of Chapter 35, and `rTFld` tensors a field with $\mathrm{id}_{\mathcal{T}}$. The vacuum energy $r/16$ (for $r = 24$: $3/2$) is inherited from Chapter 35.

Physical meaning

The Virasoro zero mode of the lattice VOA acts on the twisted sector as the twisted-boson Hamiltonian $L_0 = \frac{1}{2}$(doubled weight)$ + \frac{r}{16}$: the usual twisted-sector energy, with the Casimir shift $r/16 = 3/2$ for 24 bosons. Thus the twisted ground states have weight $3/2$, and the module structure is compatible with the stress tensor.

Proof on paper. ω lies in the charge-zero part FockN $\otimes e^0$, the Heisenberg VOA. On it the generators of the construction are the same as in Chapter 35, and $Y^T(e^0) = \mathrm{id}$, so induction on monomials identifies F_e with the Heisenberg twisted operator tensored with 1. □

What the machine verified

Unconditional; `LatticeTwistedGrading.lean`; `#print axioms YML_omega_two` standard.

Theorem 36.41 (The θ-twisted module of a lattice VOA). *For every even, positive-definite lattice L with unimodular Gram matrix, $V_L^T = S[\theta] \otimes \mathcal{T}_L$ with Y^T and the weight spaces $(V_L^T)_\alpha$ is a θ-twisted V_L-module of order 2. ```

From the mathematics to the Lean statement

The full definition is printed because it is the fidelity check: each axiom of `TwistedModule` (§36.2) is filled by a theorem of this chapter.

- `YM`: Y^T (Definition 36.24); `vacuum_YM`: $Y^T(\mathbf{1})_{(k/2)} = \delta_{k,-2}$ with $-N = -2$; `truncation`, `support`: Theorem 36.25; `jacobi`: Theorem 36.38 — for *all* pairs of states, not only generators.
- `weight` = Definition 36.39; `isInternal`: the G_d are the L_0-eigenspaces and span; `L0_weight`: `YM ω 2` = $L_0^T \otimes 1$ acts by α on $(V_L^T)_\alpha$ (Theorem 36.40); `finrank`: $S[\theta]_d$ and $\mathcal{T}$ are finite-dimensional; `boundedBelow` with $B = r/16$.
- `leechTwistedModule` is the Leech case, transported along `leech_rank : rank leech = 24` (the symbol ▸ rewrites the type). Its hypotheses `leech_even`, `leech_isUnit_det_gramMat`, `leech_posDef` are theorems (Chapter 30).

How could this have been vacuous? (i) The unrepaired `jacobi` had no models for $N = 2$ (warning in §36.2); the repaired one is satisfied by this nonzero module. (ii) A zero `YM` is excluded by `vacuum_YM` ($Y(\mathbf{1}) = \mathrm{id}$) and by `L0_weight` on nonzero weight spaces. (iii) The space is not zero: its weight-3/2 space is $\mathbf{1} \otimes \mathcal{T}$, of dimension 4096. (iv) A fake grading is excluded by `L0_weight`, which ties the grading to $\omega_{(1)}$. The structure does not assert irreducibility; that is not needed downstream.

Physical meaning

This is the construction of the twisted sector of the $\mathbb{Z}_2$ orbifold of the lattice CFT: the space $V_\Lambda^T = S[\theta]_{24} \otimes T$ of 24 twisted bosons times the 2^{12}-dimensional space of twist-field ground states, with the twisted vertex operators of all states acting on it. The theorem says that the vertex operators satisfy locality and associativity, so V_Λ^T is the Hilbert space of the Leech lattice CFT in the presence of the twist field, on which the chiral algebra acts with monodromy -1 for θ-odd fields. It is the key input for the Moonshine module $V^\natural = V_\Lambda^+ \oplus (V_\Lambda^T)^+$.

What the machine verified

Unconditional. Re-run for this chapter (§36.15): `#print axioms` of `latticeTwistedModule` and `leechTwistedModule` is [`propext`, `Classical.choice`, `Quot.sound`]; `VOA.pbw` is not used.

36.12 The involution θ on the twisted sector

Files `VOA/Moonshine/TwistedSectorDim.lean` (where the general involution `twTheta` on FockT $r \otimes T$ is defined) and `VOA/Moonshine/TwistedPlusConj.lean` (which specialises it to the lattice module as `thetaTw` and proves the conjugation property). To take θ-invariants of the twisted sector we need an involution θ_{tw} of V_Λ^T with $Y^T(\theta u) = \theta_{\mathrm{tw}} Y^T(u) \theta_{\mathrm{tw}}$. FLM's choice is $\theta_{\mathrm{tw}} = \theta_{S[\theta]} \otimes (-1)$, where $\theta_{S[\theta]}$ negates every twisted oscillator.

Definition 36.42. $\theta_{\mathrm{tw}}(p \otimes t) = \theta_{S[\theta]}(p) \otimes (-t)$.

```
noncomputable def twTheta : Module.End ℂ (FockT r ⊗[ℂ] T) :=
  TensorProduct.map (thetaT r).toLinearMap (-LinearMap.id)

noncomputable abbrev thetaTw : End ℂ (MT L hEven hU) :=
  twTheta (rank L) (Rep (cocMat L) (isUnit_det_cocMat L hEven hU))
```

Physical meaning

This is the action of the orbifold group element on the twisted sector: it flips the sign of the twisted bosonic oscillators (the Fock part, by $\theta_{S[\theta]}$) and acts as -1 on the ground states. The orbifold group $\mathbb{Z}_2$ acts on the twisted Hilbert space only projectively in general; the sign -1 on T is the choice of lift that makes the θ-fixed part have the right weights.

Theorem 36.43 (θ-stability). *For L even, positive definite, unimodular, all $u \in V_L$ and k:*

1. $(\theta_{S[\theta]} \otimes 1)\, Y^T(u)_{(k/2)}\, (\theta_{S[\theta]} \otimes 1) = (-1)^k Y^T(u)_{(k/2)}$;
2. $Y^T(\theta u)_{(k/2)} = \theta_{\mathrm{tw}} \circ Y^T(u)_{(k/2)} \circ \theta_{\mathrm{tw}}$.

In particular for the Leech twisted module.

theorem leechTwistedModule_YM_theta (u : LatModuleGen leech) (k : ℤ) :
    leechTwistedModule.YM (leechTheta u) k
      = twTheta 24 leechT ∘ₗ leechTwistedModule.YM u k ∘ₗ twTheta 24 leechT :=
```

From the mathematics to the Lean statement

`PT` $= \theta_{S[\theta]} \otimes 1$; `∘ₗ` is composition of linear maps. (2) is the compatibility condition $\theta_{\mathrm{tw}} Y^T(u,z) \theta_{\mathrm{tw}}^{-1} = Y^T(\theta u, z)$ (θ_{tw} is an involution, `twTheta_twTheta`). Same as the textbook.

Physical meaning

The involution on the twisted sector intertwines the twisted vertex operators with those of the θ-transformed states: it acts on the vertex operator of u by sign $(-1)^k$ on the $k/2$-th mode and sends $Y^T(u)$ to $Y^T(\theta u)$. This is the statement that the orbifold group acts on the twisted sector compatibly with the action of the chiral algebra, so that one can project to invariants.

Proof on paper. Conjugation by the involution $\theta_{S[\theta]} \otimes 1$ is an automorphism of the whole field calculus (products, twisted products). It negates F_b and sends $Y^T(e^\alpha)$ to $Y^T(e^{-\alpha})$ (charge conjugation $\theta E^\pm(\alpha)\theta = E^\pm(-\alpha)$, together with $e_{-\alpha} = e_\alpha$). Through the recursive definition of the word fields this gives $(\theta \otimes 1)F_e(u)(\theta \otimes 1) = (-1)^e F_e(u)$, which is (1). Combining with $F_e(\theta u) = (-1)^e F_e(u)$ (Theorem 36.25(5)) gives (2) for $\theta_{S[\theta]} \otimes 1$; and the extra -1 on $\mathcal{T}$ appears twice and cancels. □

What the machine verified

Unconditional; `#print axioms leechTwistedModule_YM_theta`: standard (re-run).

Trap / dead end

The sign on $\mathcal{T}$ is not determined by compatibility. Because -1 on $\mathcal{T}$ is central, *both* $\theta_{S[\theta]} \otimes (+1)$ and $\theta_{S[\theta]} \otimes (-1)$ satisfy Theorem 36.43(2). The choice -1 (FLM; Dolan–Goddard–Montague's $(-1)^{d/8}$ with $d = 24$) is selected only by integrality: $\theta_{\mathrm{tw}} = (-1)^{d+1}$ on doubled oscillator weight d (`twTheta_of_mem_twGrading`), so its fixed space consists of odd d, i.e. $L_0 = (d+3)/2 \in \mathbb{Z}$, starting at weight 2. With $+1$ the fixed space would be the even d, weights $\frac{3}{2} + \mathbb{Z}$, including the 4096 ground states, and could not be glued to the integrally graded V_Λ^+. (Recorded as correction 9 in `Notes/M8GluingPlan.md`.)

File `VOA/Moonshine/TwistedSectorDim.lean`.

```
theorem twTheta_of_mem_twGrading {d : ℕ} {x : FockT r ⊗[ℂ] T} (hx : x ∈ twGrading r T d) :
    twTheta r T x = (-1 : ℂ) ^ (d + 1) • x
```

36.13 The plus part of an order-two twisted module

File `VOA/Moonshine/TwistedPlusModule.lean`, namespace `VOA.TwistedPlus`. This construction is general: any VOA V, any automorphism g, any g-twisted module of order 2 with a lift of g.

Definition 36.44 (Lift of g). A lift of g to an order-two twisted module M is an involution θ_M of M with $Y_M(gu)_{(k/2)} = \theta_M Y_M(u)_{(k/2)}\theta_M$ for all u, k, preserving every weight space. The plus part is $M^+ = \ker(\theta_M - 1)$.

```
structure ThetaLift (T : TwistedModule g 2 M) where
  /-- The involution `θ_M`. -/
  op : End ℂ M
  op_op : ∀ x, op (op x) = x
  conj : ∀ (u : 𝒱) (k : ℤ), T.YM (g u) k = op ∘ₗ T.YM u k ∘ₗ op
  map_weight : ∀ (α : ℂ) (x : M), x ∈ T.weight α → op x ∈ T.weight α

def plusSub : Submodule ℂ M := LinearMap.ker (θ.op - LinearMap.id)
```

To state the conclusion we need the library's ordinary modules, `WeakModule` and `OrdVModule` (`VOA/Modules/WeakModule.lean`), quoted verbatim and decoded in Definitions 12.1 and 12.5. We recall: a `WeakModule W M` has a field map `YM : 𝒱 →ₗ[ℂ] (End ℂ M)⟦z^±⟧` with the fields `vacuum_YM`

($Y_M(\mathbf{1},z) = \mathrm{id}_M$), `truncation` (lower truncation) and `jacobi` (the untwisted mode Jacobi identity, integer modes $u_{(n)} =$ `mode (YM u) n`); an `OrdVModule` extends it by a $\mathbb{C}$-grading `weight` with `isInternal` ($M = \bigoplus_\alpha M_\alpha$), `L0_weight` ($L_0 = \alpha$ on M_α), `finrank` (finite-dimensional pieces) and `boundedBelow` ($\mathrm{Re}\,\alpha$ bounded below on nonzero pieces), i.e. a module in the sense of FHL.

Physical meaning

A lift of the automorphism g is the representation on the twisted Hilbert space of the orbifold group element g (here of order two), compatible with the vertex operators. The plus part is the $\mathbb{Z}_2$-invariant subspace, the states that survive the orbifold projection in the twisted sector.

Theorem 36.45 (The plus part is an ordinary module). *Let T be a g-twisted V-module of order 2 and θ_M a lift of g. Then M^+, with*

$$Y_{M^+}(u)_{(n)} = Y_M(u)_{(2n/2)} = Y_M(u)_{(n)}\big|_{M^+} \qquad (u \in V^{\langle g\rangle})$$

and weight spaces $M^+_\alpha = M^+ \cap M_\alpha$, is an ordinary module for the fixed-point VOA $V^{\langle g\rangle}$.

```
noncomputable def plusModule : OrdVModule (fixedVOA g) (plusSub θ) where
  toWeakModule := plusWeakModule θ
  weight := plusWeight θ
  isInternal := plusWeight_isInternal θ

theorem mode_plusModule (u : (orbifold (Subgroup.zpowers g)).carrier) (n : ℤ) (x : plusSub
↪  θ) :
    ((mode ((plusModule θ).YM u) n x : plusSub θ) : M) = T.YM u.1 (2 * n) x

def plusWeight (α : ℂ) : Submodule ℂ (plusSub θ) := (T.weight α).comap (plusSub θ).subtype
```

From the mathematics to the Lean statement

`fixedVOA g` = `orbifoldVOA (Subgroup.zpowers g)`, the sub-VOA of vectors fixed by the group generated by g, i.e. by g itself. `T.YM u.1 (2 * n)` is $u_{(2n/2)} = u_{(n)}$: for g-fixed u only even fractional indices occur (support with $j = 0$), so nothing is lost. `(T.weight α).comap (plusSub θ).subtype` is $M^+ \cap M_\alpha$ viewed inside M^+. The remaining fields of `plusModule` (`L0_weight`, `finrank`, `boundedBelow`) are filled by the corresponding fields of T. The hypotheses are exactly the data T and θ; there is no hidden assumption. **Not vacuous**: if $M^+ = 0$ the structure exists trivially; for the Leech case the dimension count of §36.14 shows $M^+ \neq 0$.

Physical meaning

The $\mathbb{Z}_2$-invariant part of the twisted sector is a module for the invariant chiral algebra $V^{\langle g\rangle}$: for invariant fields only integral modes act on the invariant states, because the half-integral modes vanish. This is how the twisted sector enters the orbifold: after the projection, the surviving states have integer conformal weight (level matching), and the fields of the orbifold theory act on them without branch cuts.

Proof on paper. For u fixed by g, θ_M commutes with all modes of u (by `conj`), so they preserve M^+. The twisted Jacobi identity at $N = 2$, $j = 0$, indices $k = 2m$, $m' = 2n$, reads exactly as the untwisted Jacobi identity because $\binom{2m/2}{i} = \binom{m}{i}$. The grading: any $x \in M^+$ decomposes as $x = \sum x_\alpha$ in M; since θ_M preserves M_α, the components $\frac{1}{2}(x_\alpha + \theta_M x_\alpha)$ lie in $M^+ \cap M_\alpha$ and still sum to x; independence is inherited. □

What the machine verified

Unconditional (given its explicit data); axioms standard (file header; `Moonshine.plusModule` re-checked).

36.14 $(V_\Lambda^T)^+$ as a V_Λ^+-module

File `VOA/Moonshine/TwistedPlus.lean`, namespace `VOA.Moonshine`.

Definition 36.46. Tw $= S[\theta]_{24} \otimes \mathcal{T}_\Lambda$; θ_{tw} as above, bundled as a lift of `leechTheta`; TP $= (V_\Lambda^T)^+ = \ker(\theta_{\mathrm{tw}} - 1)$.

```
abbrev Tw : Type := FockT 24 ⊗[ℂ] leechT

noncomputable def leechThetaLift : ThetaLift leechTwistedModule where
  op := thetaTwLeech
  op_op := twTheta_twTheta 24 leechT
  conj := leechTwistedModule_YM_theta

noncomputable abbrev TP : Submodule ℂ Tw := plusSub leechThetaLift

theorem TP_eq_twFixed : TP = twFixed 24 leechT := rfl
```

From the mathematics to the Lean statement

`thetaTwLeech = twTheta 24 leechT`. `twFixed 24 leechT` is `LinearMap.ker (twTheta r T - LinearMap.id)`, the θ-fixed twisted sector defined independently in the graded-dimension chapter (Chapter 33); `TP_eq_twFixed` holds by `rfl`, i.e. the two definitions are literally the same, so the dimension counts of Chapter 33 apply to the module built here. The omitted field `map_weight` is `twTheta_mem_weightLT` (the grading is preserved because θ_{tw} is a scalar on each G_d).

Physical meaning

Concretely: the twisted sector of the Leech lattice CFT, the lift θ_{tw} of θ, and the plus part $(V_\Lambda^T)^+$, the states with $\theta_{\mathrm{tw}} = +1$. The twisted ground states (2^{12} of them at weight 3/2) are odd under θ_{tw} and are projected out, so the surviving states start at weight 2.

Theorem 36.47 ($(V_\Lambda^T)^+$ is a V_Λ^+-module). TP *is an ordinary V_Λ^+-module, with $u_{(n)}x = Y^T(u)_{(2n/2)}x$, and the odd fractional modes of every $u \in V_\Lambda^+$ vanish on all of V_Λ^T.*

```
noncomputable def plusModule : OrdVModule leechVOAPlus TP :=
  TwistedPlus.plusModule leechThetaLift

theorem mode_plusModule (u : (orbifold (Subgroup.zpowers leechTheta)).carrier) (n : ℤ) (x :
↪  TP) :
    ((mode (plusModule.YM u) n x : TP) : Tw) = leechTwistedModule.YM u.1 (2 * n) x :=
  TwistedPlus.mode_plusModule leechThetaLift u n x

theorem YM_odd_eq_zero_of_plus (u : (orbifold (Subgroup.zpowers leechTheta)).carrier) (n :
↪  ℤ) :
    leechTwistedModule.YM u.1 (2 * n + 1) = 0 :=
```

From the mathematics to the Lean statement

`leechVOAPlus` is `orbifoldVOA (Subgroup.zpowers leechTheta)` (Chapter 32), so `TwistedPlus.plusModule leechThetaLift` has exactly the type `OrdVModule leechVOAPlus TP`. The coercions `(· : TP)`, `(· : Tw)` view an element of the submodule as a vector of Tw.

Physical meaning

The plus part of the twisted sector is a module for the orbifold algebra V_Λ^+: the projected twisted sector of the $\mathbb{Z}_2$ orbifold, on which the fields of the orbifold theory act with integral modes. The odd fractional modes vanish identically on the whole twisted sector for the invariant fields, as required by the vanishing of the monodromy for invariant fields.

What the machine verified

Unconditional. `#print axioms VOA.Moonshine.plusModule` = [`propext`, `Classical.choice`, `Quot.sound`] (re-run).

Theorem 36.48 (Weights and dimensions). 1. *For $q \in \mathbb{Q}$:* $\mathrm{TP}_q = \mathrm{twFixed} \cap \mathrm{twWeight}_q$, *the graded piece used in Chapter 33.*

2. *If* $\mathrm{TP}_\alpha \neq 0$ *then* $\alpha = n \in \mathbb{Z}$ *with* $n \geq 2$.

3. $\dim \mathrm{TP}_2 = 98304 = 24 \cdot 4096$.

4. *For every* $n \in \mathbb{N}$: $\dim (V_\Lambda^+)_n + \dim \mathrm{TP}_n = [q^n]\big(qJ(q)\big)$, $J = j - 744$.

```
theorem map_plusModule_weight (q : ℚ) :
    (plusModule.weight (q : ℂ)).map TP.subtype = twFixed 24 leechT ⊓ twWeight 24 leechT q

theorem plusModule_weight_ne_bot {α : ℂ} (h : plusModule.weight α ≠ ⊥) :
    ∃ n : ℤ, α = n ∧ 2 ≤ n

theorem finrank_plusModule_weight_two : finrank ℂ (plusModule.weight 2) = 98304

theorem finrank_plusModule_eq_coeff_JShift (n : ℕ) :
    ((finrank ℂ (leechVOAPlus.grading (n : ℤ))
      + finrank ℂ (plusModule.weight ((n : ℤ) : ℂ)) : ℕ) : ℂ)
      = PowerSeries.coeff n JShift
```

From the mathematics to the Lean statement

`.map TP.subtype` pushes a submodule of TP forward to Tw; ⊓ is intersection. `twWeight 24 leechT q` is the $L_0 = q$ subspace (defined like `weightLT`, with rational index). In (2) the weight index is complex, as in `OrdVModule`; integrality is a theorem, not built into the type (correction 11 of the plan). `finrank ℂ` is the dimension over $\mathbb{C}$. `leechVOAPlus.grading n` is $(V_\Lambda^+)_n$. `JShift = jShift - (744 : ℂ) • PowerSeries.X`, the power series $qJ(q) = q\,j(q) - 744q = 1 + 0 \cdot q + 196884q^2 + \cdots$ (Chapter 33); so (4) at $n = 2$ is $98580 + 98304 = 196884$. The cast to $\mathbb{C}$ is because `JShift` has complex coefficients. Same as the textbook statements. **A caution on meaning**: (4) concerns graded dimensions only; it does not say that $V_\Lambda^+ \oplus \mathrm{TP}$ is a VOA (that is Chapters 37–42), and the square-zero extension has the same dimensions (the TRAP recorded in the roadmap).

Physical meaning

The weights of the projected twisted sector are integral and at least 2 (level matching): the twisted ground states at weight 3/2 are projected out, and the first surviving states, at weight 2, are the states with one twisted oscillator $\alpha^a_{-1/2}$ ($a = 1, \dots, 24$) acting on the 2^{12} ground states, giving $24 \cdot 4096 = 98304$ states. Together with $\dim(V_\Lambda^+)_2 = 196884 - 98304 = 98580$ one recovers the 196884 of the Moonshine module. The statement (4) is that the combined graded dimension of $V_\Lambda^+ \oplus (V_\Lambda^T)^+$ is $J(q)$ up to the shift by q, consistent with the Moonshine module character. Heuristic reading; the dimensions are proved in Lean.

Proof on paper. (1) The module's weight spaces are $M^+ \cap M_\alpha$ with $M_\alpha = (V_\Lambda^T)_\alpha$, which for rational α is `twWeight`. (2) $(V_\Lambda^T)_\alpha = G_d$ with $\alpha = d/2 + 3/2$; on G_d, $\theta_{\mathrm{tw}} = (-1)^{d+1}$, so the fixed part is nonzero only for $d = 2k+1$ odd, where $\alpha = k+2$. (3) $d = 1$: $S[\theta]_1$ is spanned by $h_i(-\frac{1}{2})\mathbf{1}$, $i < 24$, so $\dim G_1 = 24 \cdot 4096$. (4) Combine (1) with the graded-dimension theorem of Chapter 33. □

What the machine verified

Unconditional; all four re-run with `#print axioms`: standard axioms only.

Example 36.49 (The lowest states of $(V_\Lambda^T)^+$)**.** The ground states $\mathbf{1} \otimes t$ ($d = 0$, weight 3/2) satisfy $\theta_{\mathrm{tw}}(\mathbf{1} \otimes t) = -\mathbf{1} \otimes t$, so they are *not* in $(V_\Lambda^T)^+$. The states $h_i(-\frac{1}{2})\mathbf{1} \otimes t$ ($d = 1$, weight 2) have $\theta_{\mathrm{tw}} = (-1)(-1) = +1$: these are the $24 \cdot 4096 = 98304$ states of Theorem 36.48(3). At $d = 2$ (weight 5/2), $h_i(-\frac{1}{2})h_j(-\frac{1}{2})\mathbf{1} \otimes t$ is odd again; at $d = 3$ (weight 3) the fixed states are spanned by $h_i(-\frac{3}{2})$ and $h_i(-\frac{1}{2})h_j(-\frac{1}{2})h_k(-\frac{1}{2})$ applied to $\mathbf{1} \otimes t$, of dimension $(24 + \binom{26}{3}) \cdot 4096 = 2624 \cdot 4096$ (`twCount_24_three`). Together with $\dim(V_\Lambda^+)_3$ from Chapter 32 this reproduces the coefficient 21493760 of q^3 in $qJ(q)$, the content of Theorem 36.48(4) at $n = 3$.

36.15 Dead ends, traps, and the verification record

Trap / dead end

(1) The over-quantified twisted Jacobi identity. See §36.2: before the repair, `TwistedModule` had no nonzero models for $N \geq 2$. Any construction of `leechTwistedModule` against the unrepaired structure would have been impossible, and any theorem *assuming* such a module would have been vacuous. `SuperTwistedModule.jacobi` still has the defect; nothing in this chapter uses it.
(2) The sign of θ on $\mathcal{T}$ (§36.12): compatibility does not fix it; integrality does.
(3) The roadmap's "unused" remark on `star_iterate_range` is inaccurate (§36.8).
(4) Normalisation (Remark 36.37): with any normalisation other than $2^{-\langle\alpha,\alpha\rangle}$ times a character, the base case of the product formula fails at the leading level; the locality statements alone would not detect this, since they are insensitive to κ.

The following command was run for this chapter at an earlier commit (not re-run for this edition), using `lake env lean -DmaxSynthPendingDepth=3` on a scratch file importing `VOA.Moonshine.TwistedPlus` (the flag avoids the audit trap recorded in the project instructions):

```

36.17 Notes and references

The twisted vertex operators (36.1) and the twisted module V_L^T are due to I. Frenkel, J. Lepowsky and A. Meurman, *Vertex Operator Algebras and the Monster*, Pure and Applied Mathematics 134, Academic Press, Boston, 1988; Chapters 7–9 contain the operators $E^{\pm}$, the twisted vertex operators and their commutator and associativity properties, the module $\mathcal{T}$ of the extraspecial group, and the θ-action on the twisted sector; the announcement is I. Frenkel, J. Lepowsky, A. Meurman, "A natural representation of the Fischer–Griess Monster with the modular function J as character", Proc. Natl. Acad. Sci. USA 81 (1984) 3256–3260. The calculus of twisted vertex operators goes back to J. Lepowsky, "Calculus of twisted vertex operators", Proc. Natl. Acad. Sci. USA 82 (1985) 8295–8299. The general construction of twisted modules for lattice VOAs and lifts of lattice isometries is C. Dong, "Twisted modules for vertex algebras associated with even lattices", J. Algebra 165 (1994) 91–112, and C. Dong and J. Lepowsky, "The algebraic structure of relative twisted vertex operators", J. Pure Appl. Algebra 110 (1996) 259–295. The mode form of the twisted Jacobi identity used by the library is that of C. Dong, H. Li and G. Mason, "Modular-invariance of trace functions in orbifold theory and generalized moonshine", Comm. Math. Phys. 214 (2000) 1–56 (arXiv:q-alg/9703016). The "local system" approach (twisted products, associativity from locality) is H. Li, "Local systems of twisted vertex operators, vertex operator superalgebras and twisted modules", in: Moonshine, the Monster, and related topics, Contemp. Math. 193 (1996) 203–236 (arXiv:q-alg/9504022). The conformal-field-theory treatment, including the sign $(-1)^{d/8}$ of θ on the ground states and the twisted-sector intertwiners used in the next chapter, is L. Dolan, P. Goddard and P. Montague, "Conformal field theory of twisted vertex operators", Nucl. Phys. B 338 (1990) 529–601, and "Conformal field theories, representations and lattice constructions", Comm. Math. Phys. 179 (1996) 61–120 (arXiv:hep-th/9410029). A modern treatment of twisted modules over lattice vertex algebras is B. Bakalov and V. Kac, "Twisted modules over lattice vertex algebras", in: Lie Theory and

its Applications in Physics V, World Scientific, 2004 (arXiv:math/0402315). The descent argument of §36.9 (defect, recursion, uniqueness from vacuum expectations) and the plus-part construction of §36.13 are the library's own route; they do not follow a single published proof.

Chapter 37

Intertwiners and invariant forms: the operators W and $\overline{W}$

This chapter documents the release of the LeanVOA library named in the front matter. Every Lean quotation below is checked by `scripts/textbook/sync.py` to occur verbatim (up to whitespace and comments) in the source files of that release. Checks that were run at an earlier state of the library and not re-run for this edition are marked as such. The Moonshine module of Frenkel, Lepowsky and Meurman is, as a vector space, the direct sum

$$V^\natural \;=\; V_\Lambda^+ \;\oplus\; (V_\Lambda^T)^+ \tag{37.1}$$

of the θ-fixed part of the Leech lattice vertex operator algebra (Chapter 32) and the θ-fixed part of the twisted Leech module (Chapter 36). Up to this point of the book the two summands have lived separate lives: V_Λ^+ is a vertex operator algebra, and $(V_\Lambda^T)^+$ is an (ordinary, integrally graded) module over it. A vertex operator algebra structure on the sum needs more: a vertex operator $Y^\natural(t,z)$ for every *twisted* state $t \in (V_\Lambda^T)^+$, and such an operator must move vectors between the two summands. This chapter constructs the two pieces of $Y^\natural(t,z)$:

- the operator $W(t,z) : V_\Lambda^+ \to (V_\Lambda^T)^+$ ("twisted × untwisted → twisted"), obtained from the module structure by *skew-symmetry*; and
- the operator $\overline{W}(t,z) : (V_\Lambda^T)^+ \to V_\Lambda^+$ ("twisted × twisted → untwisted"), obtained from W by taking the *adjoint* with respect to invariant bilinear forms on the two summands.

Along the way we develop, from first principles, the three pieces of general theory that the construction needs: intertwining operators and their skew-symmetry; contragredient modules and invariant bilinear forms (Frenkel–Huang–Lepowsky); and a graded Riesz representation theorem that turns "adjoint" into an honest linear map. We then prove that W and $\overline{W}$ have every property that involves *one* untwisted and *one* twisted argument (the commutator formulas, locality with all untwisted vertex operators, translation covariance), and the skew-symmetry of $\overline{W}$. The genuinely hard relation, the locality of two twisted vertex operators with each other, is *not* proved in this chapter; it occupies Chapters 38–42.

The chapter is written under the Fidelity Protocol of the book's constitution: every definition and theorem is given mathematically, then in its verbatim Lean form, then checked for fidelity (every symbol decoded, every hypothesis listed, every defined term traced), then proved on paper, and finally given its machine status. The chapter ends with a referee's checklist.

37.1 Why $V^\natural$ needs W and $\overline{W}$

37.1.1 The block form of the vertex operator

Suppose for a moment that $V^\natural$ of (37.1) already carried a vertex operator algebra structure $Y^\natural$ extending the structure of V_Λ^+ and the module structure Y^T on $(V_\Lambda^T)^+$. Write a general state as a pair (u,t) and a general vector on which operators act as a column (φ,a) with $\varphi\in V_\Lambda^+$ and $a\in(V_\Lambda^T)^+$. The vertex operator of (u,t) is then a 2×2 matrix of formal distributions

$$Y^\natural\big((u,t),z\big)\;=\;\begin{pmatrix} Y(u,z) & \overline{W}(t,z)\\ W(t,z) & Y^T(u,z)\end{pmatrix},\qquad Y^\natural\big((u,t),z\big)\begin{pmatrix}\varphi\\ a\end{pmatrix}=\begin{pmatrix} Y(u,z)\varphi+\overline{W}(t,z)a\\ W(t,z)\varphi+Y^T(u,z)a\end{pmatrix}. \tag{37.2}$$

The diagonal blocks are forced: V_Λ^+ is a subalgebra and $(V_\Lambda^T)^+$ is a module. The lower-left block $W(t,z)\colon V_\Lambda^+\to(V_\Lambda^T)^+$ and the upper-right block $\overline{W}(t,z)\colon(V_\Lambda^T)^+\to V_\Lambda^+$ are new data. (The diagonal entries for a twisted state t, and the off-diagonal entries for an untwisted state u, vanish because the $\mathbb{Z}/2$-grading by the eigenvalue of θ must be respected: untwisted $\times$ untwisted lands in the untwisted part, untwisted $\times$ twisted in the twisted part, and twisted $\times$ twisted in the untwisted part.)

Physical picture. In two-dimensional conformal field theory V_Λ^+ is the chiral algebra of 24 free bosons compactified on the Leech torus and then orbifolded by $X\mapsto -X$; $(V_\Lambda^T)^+$ is the space of states created by the 2-to-1 "twist fields" sitting at the fixed points of the orbifold (the 2^{12}-dimensional space T records which fixed point). The operator $W(t,z)$ is the operator product "twist field $\times$ ordinary field $\to$ twist field", and $\overline{W}(t,z)$ is "twist field $\times$ twist field $\to$ ordinary field". The latter is the interesting one: when two twist fields collide, the branch cuts they carry cancel and an *untwisted* field appears. That this fusion is consistent with locality is the whole difficulty of the Moonshine construction.

37.1.2 The off-diagonal blocks are forced

Both new blocks are determined by data we already have.

The block W. A vertex algebra satisfies skew-symmetry $Y(a,z)b=e^{zL_{-1}}Y(b,-z)a$. Applied in $V^\natural$ to $a=(0,t)$ and $b=(\varphi,0)$ it gives

$$W(t,z)\varphi\;=\;e^{zL_{-1}}\,Y^T(\varphi,-z)\,t. \tag{37.3}$$

So W is forced by the module structure alone. We shall take (37.3) as the definition (Section 37.4).

The block $\overline{W}$. A simple vertex operator algebra of CFT type with $L_1V_1=0$ has a nondegenerate invariant bilinear form, unique up to scale (Li). If $V^\natural$ has one, its restriction to the two summands must make them orthogonal (they have different θ-parity) and must restrict to invariant forms B_V on V_Λ^+ and B_T on $(V_\Lambda^T)^+$. Invariance of the form for the state $(0,t)$ then says

$$B_V\big(\overline{W}(t,z)a,\varphi\big)\;=\;B_T\Big(a,\;W\big(e^{zL_1}(-z^{-2})^{L_0}t,\;z^{-1}\big)\varphi\Big). \tag{37.4}$$

So once B_V and B_T are chosen, $\overline{W}$ is forced as well: it is the adjoint of W. This is Dolan–Goddard–Montague's equation (4.3), and it is how we shall define $\overline{W}$ (Section 37.10). This form-adjoint definition is the presentation of Huang and of Dolan–Goddard–Montague; it is *not* FLM's own explicit formula for the twisted vertex operators on $(V_\Lambda^T)^+\times(V_\Lambda^T)^+$. No Lean theorem compares the two: that the resulting vertex operator algebra is isomorphic to FLM's $V^\natural$ follows on paper from the uniqueness of simple-current extensions (Dong–Mason), which is not formalized (Chapter 42).

Remark 37.1 (Scaling, and why $\overline{W}=0$ is dangerous)**.** Conjugating the block form by the linear automorphism $g=\mathrm{diag}(1,\lambda)$ of $V^\natural$ ($\lambda\in\mathbb{C}^\times$) replaces the state t by λt; a short computation with $Y'(x,z)=gY^\natural(g^{-1}x,z)g^{-1}$ shows that W is unchanged and $\overline{W}$ is multiplied by λ^{-2}. Every axiom

of a vertex algebra is homogeneous in $\overline{W}$ (each locality relation contains $\overline{W}$ either zero times or exactly once in each term), so the set of admissible $\overline{W}$ is a cone: if $\overline{W}$ works, so does $c\overline{W}$ for every $c \in \mathbb{C}$, and all $c \neq 0$ give isomorphic algebras. The value $c = 0$ also "works": it gives the *square-zero extension* $V_\Lambda^+ \ltimes (V_\Lambda^T)^+$, a perfectly good vertex operator algebra with the same central charge 24, the same $V_1 = 0$, the same $\dim V_2 = 196884$ and the same graded dimension $J(q)$ as $V^\natural$ — but it is not simple and it is not the Moonshine module. (This remark is argued on paper; it is not a Lean theorem.)

Trap / dead end

The square-zero trap (recorded in `Notes/MonsterRoadmap.md`, "Definition of done", and `Notes/M8GluingPlan.md`, status after M8d part 1). The Lean reconstruction theorem for $V^\natural$ (Chapter 38) takes an *arbitrary* operator family `Wbar` as input, and every one of its hypotheses about `Wbar` holds for `Wbar = 0`. Hence a proof that "some vertex operator algebra on $V^\natural$ with graded dimension J exists" proves nothing about Moonshine. Two things in this chapter guard against the trap: the operator $\overline{W}$ is the *specific* adjoint (37.4), and Theorem 37.57 proves in Lean that it is not zero (indeed that it pairs the lowest twisted weight space nondegenerately into the vacuum line). The final theorem of the book additionally proves simplicity of $V^\natural$ (Chapter 38).

37.1.3 The six locality relations

To show that (37.2) defines a vertex algebra, Dolan, Goddard and Montague (Comm. Math. Phys. 179 (1996), §4) reduce locality of all pairs of block operators to six relations, their (4.18)–(4.23):

1. $Y(u_1,z_1)Y(u_2,z_2) \sim Y(u_2,z_2)Y(u_1,z_1)$ on V_Λ^+ (locality in the vertex operator algebra V_Λ^+);
2. $Y^T(u_1,z_1)Y^T(u_2,z_2) \sim Y^T(u_2,z_2)Y^T(u_1,z_1)$ on $(V_\Lambda^T)^+$ (locality in the module);
3. the locality of $Y^T(u,z_1)$ and $W(t,z_2)$, in the sense $Y^T(u,z_1)W(t,z_2) \sim W(t,z_2)Y(u,z_1)$ as maps $V_\Lambda^+ \to (V_\Lambda^T)^+$;
4. the analogous locality of $Y(u,z_1)$ and $\overline{W}(t,z_2)$ as maps $(V_\Lambda^T)^+ \to V_\Lambda^+$;

(4.22) $\overline{W}(t_1,z_1)W(t_2,z_2) \sim \overline{W}(t_2,z_2)W(t_1,z_1)$ on V_Λ^+;

(4.23) $W(t_1,z_1)\overline{W}(t_2,z_2) \sim W(t_2,z_2)\overline{W}(t_1,z_1)$ on $(V_\Lambda^T)^+$.

Here "$A(z_1)B(z_2) \sim C(z_2)D(z_1)$" means that $(z_1-z_2)^N\big(A(z_1)B(z_2) - C(z_2)D(z_1)\big) = 0$ for some N. The first two are already known (Chapters 32 and 36). This chapter proves the third and fourth (Theorems 37.17 and 37.52) in full generality, and the skew-symmetry of $\overline{W}$ (Theorem 37.58) which is the main input to (4.22) in Chapter 38. Dolan, Goddard and Montague remark that the last relation (4.23) "involves the lattice in a non-trivial way"; it is the subject of Chapters 39–42.

37.2 Notation and prerequisites

This section collects the elementary objects that occur in the statements of this chapter. Their Lean sources are quoted verbatim and decoded in Chapters 2, 4 and 12; here they are recalled with pointers. Everything else is defined where it is used, or in an explicitly cited earlier chapter.

37.2.1 Formal distributions and modes

Definition 37.2 (Formal distributions, modes, derivative). For a complex vector space X, a *formal distribution* is a two-sided sequence $f = (f_k)_{k\in\mathbb{Z}}$ in X, thought of as $f(z) = \sum_{k\in\mathbb{Z}} f_k z^k$. A two-variable formal distribution is a family $(f_{a,b})_{a,b\in\mathbb{Z}}$, thought of as $\sum f_{a,b} z_1^a z_2^b$. The *n-th mode* of f is the coefficient of z^{-n-1}: $\mathrm{mode}(f,n) = f_{-n-1}$, so that $f(z) = \sum_n \mathrm{mode}(f,n) z^{-n-1}$. The formal derivative is $(\partial_z f)_k = (k+1) f_{k+1}$.

In Lean these are `FormalDist W = ℤ → W`, `FormalDist₂ W = ℤ → ℤ → W`, `mode f m = f (-m - 1)` and the linear map `deriv` with `deriv f n = (n + 1) • f (n + 1)` (Definitions 2.1, 2.21 and 2.7; `VOA/Foundations/FormalSeries.lean`, `VOA/Foundations/FormalCalculus.lean`).

From the mathematics to the Lean statement

`f k` is the coefficient of z^k, *not* the k-th mode. Throughout the library a vertex operator is stored as the distribution $k \mapsto u_{(-k-1)}$ and its modes are recovered by `mode`: `mode (Y u) n` is $u_{(n)}$. In the twisted setting of Chapters 34–36, an integer index k fed to a twisted vertex operator `YM u k` stands for the half-integral mode $u_{(k/2)}$; on the θ-fixed module $(V_\Lambda^T)^+$ this is converted back to integral modes by the identity `mode (plusModule.YM u) n = YM u (2n)` (Lean name `mode_plusModule`, Chapter 36).

Physical meaning

A formal distribution is the bookkeeping device for a chiral field: $f(z) = \sum_n f_n z^{-n-1}$ is the Laurent expansion of an operator-valued field $\phi(z)$ on the plane in the radial quantisation, and the modes f_n are the operators that create or annihilate states of definite energy. The derivative is the translation ∂_z of the field, which later becomes the L_{-1}-derivative property. The definition is pure algebra; it fixes the mode convention (z^{-n-1}, weight h field has modes $\phi_{(n)}$ of degree $h-n-1$) used everywhere below.

Definition 37.3 (Generalised binomials and signs). For $n \in \mathbb{Z}$ and $k \in \mathbb{N}$, $\binom{n}{k} = n(n-1)\cdots(n-k+1)/k!$ (so $\binom{-1}{k} = (-1)^k$). For $k \in \mathbb{Z}$ the library writes `cbz` for the extension by zero to negative k, and $\mathtt{negOnePow}(n) = (-1)^n$.

In Lean these are `gBinom n k`, `cbz n k` (equal to `gBinom n k.toNat` for $k \geq 0$ and to 0 for $k < 0$) and `negOnePow n`, quoted verbatim in Definition 2.14 (`VOA/Foundations/Substitution.lean`, `VOA/Foundations/Expansion.lean`).

Physical meaning

These are the coefficients that appear when one expands $(z_1 - z_2)^{-k}$ in a chosen region, i.e. the algebraic shadow of the choice of radial ordering $|z_1| > |z_2|$ in an operator product. The signs $(-1)^n$ record the exchange of two fields, as in the passage from $z_1 - z_2$ to $z_2 - z_1$. They are only calculational devices.

Definition 37.4 (Multiplication by $(z_1-z_2)^N$; locality). On two-variable distributions, $(z_1-z_2)f$ has coefficients $f_{a-1,b} - f_{a,b-1}$, and $(z_1-z_2)^N$ is its N-fold iterate. Two $\mathrm{End}(V)$-valued distributions a, b are *local* if $(z_1-z_2)^N [a(z_1), b(z_2)] = 0$ for some N, where $[a(z_1), b(z_2)]$ has coefficients $a_m b_n - b_n a_m$.

In Lean, `mulBySub` = `shiftZ₁ - shiftZ₂` (where `shiftZ₁ f` has coefficients $f_{a-1,b}$ and `shiftZ₂ f` has $f_{a,b-1}$), `mulBySubPow N` is its N-fold iterate, and `Local a b` is `∃ N : ℕ, mulBySubPow N (bracketDist a b) = 0` (Definitions 2.21 and 2.41; `VOA/Foundations/FormalSeries.lean`, `VOA/Foundations/Locality.lean`).

From the mathematics to the Lean statement

In this chapter many "locality" statements are between maps of *different* spaces, e.g. $Y^T(u,z_1)W(t,z_2) - W(t,z_2)Y(u,z_1)$ is a distribution of linear maps $V_\Lambda^+ \to (V_\Lambda^T)^+$. For those the library does not use `Local` (which is for End(V)-valued distributions) but writes the commutator distribution out as an explicit `FormalDist₂` of `→ₗ[ℂ]`-maps and asks that `mulBySubPowN` kill it. The block-matrix lemma `local_diag_off` (Chapter 38) converts two such statements into an honest `Local` on End($V^\natural$).

Physical meaning

Locality is the algebraic form of the physical requirement that fields at separated points commute (or braid trivially): the correlator is single-valued, so the only singularities of the operator product are poles at $z_1 = z_2$. The order N is the maximal pole order of the OPE of the two fields. Locality for fields acting between different sectors, as in the dictionary, says that an untwisted current can be moved across a twist-field insertion up to contact terms.

37.2.2 Modules

Definition 37.5 (Weak and ordinary modules)**.** Let $\mathcal{V}$ be a vertex operator algebra (Definition 4.4) with modes $u_{(n)}$, vacuum $\mathbf{1}$, conformal vector ω and $L_n = \omega_{(n+1)}$. A *weak module* is a vector space M with a linear map $u \mapsto Y_M(u,z) = \sum u^M_{(n)} z^{-n-1}$ into End(M)-valued distributions such that $Y_M(\mathbf{1},z) = \mathrm{id}$, $u_{(n)}x = 0$ for $n \gg 0$, and the module Jacobi identity holds in the mode form

$$\sum_{i\ge 0}(-1)^i\binom{\ell}{i}\Big(u_{(\ell+m-i)}v_{(n+i)}x - (-1)^\ell v_{(\ell+n-i)}u_{(m+i)}x\Big) = \sum_{i\ge 0}\binom{m}{i}(u_{(\ell+i)}v)_{(m+n-i)}x \tag{37.5}$$

for all $u,v \in \mathcal{V}$, $x \in M$, $\ell,m,n \in \mathbb{Z}$. An *ordinary module* is a weak module with a grading $M = \bigoplus_{\alpha\in\mathbb{C}} M_\alpha$ by finite-dimensional L_0-eigenspaces ($L_0 = \omega_{(1)}$ acts on M_α by α) whose real parts are bounded below.

In Lean these are the structures `WeakModule W M` (fields `YM`, `vacuum_YM`, `truncation`, `jacobi`) and `OrdVModule W M`, which extends it by `weight`, `isInternal`, `L0_weight`, `finrank` and `boundedBelow` (`VOA/Modules/WeakModule.lean`); they are quoted verbatim and decoded in Definitions 12.1 and 12.5. The field `jacobi` is (37.5) written with `negOnePow`, `cbz` and $\sum^{\mathtt{f}}$.

From the mathematics to the Lean statement

`W.smul u n v` is the n-th product $u_{(n)}v$ inside $\mathcal{V}$; `A.act u n x` is the library's abbreviation for $u^M_{(n)}x$ `= mode (A.YM u) n x`. $\sum^{\mathtt{f}}$ is a sum over the (finitely many) indices where the summand is nonzero; `cbz ℓ i` vanishes for $i < 0$, so both sums run over $i \ge 0$ as in (37.5). `DirectSum.IsInternal weight` says that M is the internal direct sum of the subspaces `weight α`. The *adjoint module* `adjointModule W` is $\mathcal{V}$ acting on itself.

Physical meaning

A module is a sector of the chiral CFT, a space of states on which the chiral algebra acts: the Jacobi identity is the statement that the OPE of the chiral fields closes consistently on that sector. An ordinary module with L_0-grading is a representation space with a spectrum of conformal weights bounded below and finite multiplicities, as for a unitary sector with a ground state. The twisted sector $(V_\Lambda^T)^+$ of the orbifold will be such a module over V_Λ^+.

37.2.3 The Leech objects

The concrete objects are those of Chapters 32 and 36:

- `leechVOAPlus : VertexOperatorAlgebra VPlus`, the vertex operator algebra V_Λ^+; its carrier type is written `VPlus` or, in the files of this chapter, `SkewVP` (the two are the same type: `abbrev SkewVP : Type := 𝔯(orbifold (Subgroup.zpowers leechTheta)).carrier`). It has $(V_\Lambda^+)_1 = 0$ (`leechVOAPlus_grading_one`) and $\dim (V_\Lambda^+)_2 = 98580$.
- `Tw := FockT 24 ⊗[ℂ] leechT`, the twisted space $S[\theta] \otimes T$, where $S[\theta] = \mathbb{C}[h_i(-n-\tfrac{1}{2})]$ is the twisted Fock space of rank 24 and T the 2^{12}-dimensional module of the extraspecial group.
- `TP : Submodule ℂ Tw`, the θ-fixed subspace $(V_\Lambda^T)^+$, and `plusModule : OrdVModule leechVOAPlus TP`, its structure of ordinary V_Λ^+-module. Its weights are integers ≥ 2 (`plusModule_weight_ne_bot`) and $\dim (V_\Lambda^T)_2^+ = 24 \cdot 4096 = 98304$ (`finrank_plusModule_weight_two`).

37.3 Intertwining operators and skew-symmetry

37.3.1 The definition of Frenkel, Huang and Lepowsky

Let M_1, M_2, M_3 be modules for a vertex operator algebra $\mathcal{V}$. An *intertwining operator of type* $\binom{M_3}{M_1\, M_2}$ (FHL, Definition 5.4.1) is a linear map $w_1 \otimes w_2 \mapsto \mathcal{Y}(w_1, z)w_2 = \sum_{s \in \mathbb{C}} (w_1)_{(s)} w_2 \, z^{-s-1}$ with values in $M_3\{z\}$ (arbitrary complex powers) such that

(I1) (truncation) for fixed w_1, w_2, $(w_1)_{(s)}w_2 = 0$ when $\operatorname{Re} s \gg 0$;

(I2) (L_{-1}-derivative) $\mathcal{Y}(L_{-1}w_1, z) = \partial_z \mathcal{Y}(w_1, z)$;

(I3) (Jacobi identity) for $u \in \mathcal{V}$,

$$z_0^{-1}\delta\!\left(\frac{z_1 - z_2}{z_0}\right) Y_3(u, z_1)\mathcal{Y}(w_1, z_2) - z_0^{-1}\delta\!\left(\frac{z_2 - z_1}{-z_0}\right)\mathcal{Y}(w_1, z_2)Y_2(u, z_1) = z_2^{-1}\delta\!\left(\frac{z_1 - z_0}{z_2}\right)\mathcal{Y}\big(Y_1(u, z_0)w_1, z_2\big).$$

Taking Res_{z_0} of (I3) gives the *commutator formula*

$$u_{(m)}\,(w_1)_{(s)}w_2 - (w_1)_{(s)}\,u_{(m)}w_2 = \sum_{r \geq 0} \binom{m}{r} \big(u_{(r)}w_1\big)_{(m+s-r)}w_2, \tag{37.6}$$

and taking Res_{z_1} gives an associativity formula. In general (I3) is equivalent to the commutator formula *together with* associativity; the commutator formula alone is weaker. The dimension of the space of intertwining operators of a given type is the *fusion rule* $\mathcal{N}_{M_1 M_2}^{M_3}$.

The physical meaning: $\mathcal{Y}(w_1, z)$ is the field of the state w_1 of one module, acting from a second module to a third; the commutator formula (37.6) says that the chiral algebra $\mathcal{V}$ acts on such fields by the same rule (the operator product $u(z_1)\mathcal{Y}(w_1, z_2) \sim \sum_r (u_{(r)}w_1)(z_2)/(z_1 - z_2)^{r+1}$) as it acts on its own fields.

37.3.2 The library's notion: a commutator-type intertwiner

Definition 37.6 (Intertwiner, library form)**.** For ordinary modules A, B, C (with carriers M, N, P), an `Intertwiner A B C` consists of mode data $\mathcal{Y}_s : M \times N \to P$ bilinear, for $s \in \mathbb{C}$, which is lower truncated (I1) and satisfies the commutator formula (37.6), written with the module A acting on the first argument, B on the second and C on the output.

```
abbrev IntertwinerModes (M N P : Type u) [AddCommGroup M] [Module ℂ M] [AddCommGroup N]
    [Module ℂ N] [AddCommGroup P] [Module ℂ P] : Type u := ℂ → (M →ₗ[ℂ] N →ₗ[ℂ] P)

noncomputable def intertwinerSummand (A : OrdVModule W M) (Y : IntertwinerModes M N P)
    (a : 𝒱) (p : ℤ) (s : ℂ) (u : M) (x : N) (j : ℕ) : P :=
  cbz p j • Y (s + p - j) (A.toWeakModule.act a (j : ℤ) u) x

noncomputable def intertwiningDefect (A : OrdVModule W M) (B : OrdVModule W N) (C :

  modes : IntertwinerModes M N P
  truncation : ∀ (u : M) (x : N), ∃ s₀ : ℝ, ∀ s : ℂ, s₀ ≤ s.re → modes s u x = 0
  isIntertwiner : modes ∈ IntertwinerSpace A B C
```

(`VOA/Modules/Fusion.lean`; `IntertwinerSpace A B C` is the kernel of `intertwiningDefect A B C`; the additivity proofs of the defect are omitted.)

From the mathematics to the Lean statement

Decoding. `modes s u x` is $u_{(s)}x$ for $u \in M$, $x \in N$. The defect is $a^C_{(p)}(u_{(s)}x) - u_{(s)}(a^B_{(p)}x) - \sum_j \binom{p}{j}(a^A_{(j)}u)_{(s+p-j)}x$; being in its kernel is exactly (37.6) for all $a \in \mathcal{V}$, $p \in \mathbb{Z}$, $s \in \mathbb{C}$.
Same, stronger or weaker? *Weaker than FHL.* The structure records (I1) and the commutator formula only. It does not record the L_{-1}-derivative property (I2), and it does not record the full Jacobi identity (I3) (no associativity). Consequently the library's `fusionCoeff` (the `finrank` of `IntertwinerSpace`) is not the FHL fusion rule; this chapter never uses it. Every intertwiner constructed below is a genuine FHL-type object in the sense that we prove the L_{-1}-derivative property *separately* (Theorems 37.13 and 37.47); the full Jacobi identity for W and $\overline{W}$ is *not* proved anywhere in the library, and it is not needed: the reconstruction route of Chapter 38 consumes only commutator formulas, locality and translation covariance.
Could it be vacuous? No: the zero mode family is always an intertwiner, so the structure is inhabited; the content of a particular `Intertwiner` value lies in which modes it carries.

Physical meaning

An intertwining operator is a chiral vertex operator: it is the field $\mathcal{Y}(w_1, z)$ of a state w_1 in sector M_1 that maps states of sector M_2 to states of sector M_3, and the commutator formula is the Ward identity saying that the chiral currents act on it by the same OPE as on any primary field. The dimension $\mathcal{N}_{M_1M_2}^{M_3}$ of the space of such operators is the fusion rule: the number of independent three-point couplings $\langle M_3|\mathcal{Y}|M_2\rangle$ among the three sectors. For $V^\natural$ the interesting couplings are twisted × untwisted → twisted and twisted × twisted → untwisted. (Heuristic: the library `Intertwiner` records only the commutator part of the axioms.)

37.3.3 Skew-symmetry: from a module to an intertwiner

Definition 37.7 (The skew operator). Let M be a weak $\mathcal{V}$-module and $L^M_{-1} = \omega^M_{(0)}$. For $t \in M$ and $\varphi \in \mathcal{V}$ put

$$W(t,z)\varphi = e^{zL_{-1}}Y_M(\varphi,-z)t, \qquad \text{i.e.} \qquad W(t)_{(n)}\varphi = \sum_{i\ge 0}\frac{(-1)^{n+i+1}}{i!}L^i_{-1}\big(\varphi_{(n+i)}t\big). \tag{37.7}$$

Physical meaning

Skew-symmetry is the exchange of two fields in a two-point function: $\langle \phi_a(z)\phi_b(0)\rangle$ and $\langle \phi_b(-z)\phi_a(0)\rangle$ are the same correlator read from the two radial orderings, related by the translation $e^{zL_{-1}}$. Defining $W(t,z)\varphi = e^{zL_{-1}}Y_M(\varphi,-z)t$ says that the field of the twisted state t acting on an untwisted state φ is obtained by moving the untwisted field φ around it: the chiral vertex operator "twist field × ordinary field → twist field" is forced by the module structure alone.

Derivation of the mode formula. $Y_M(\varphi,-z)t = \sum_p \varphi_{(p)}t\,(-z)^{-p-1}$ and $e^{zL_{-1}} = \sum_i z^i L_{-1}^i/i!$. The coefficient of z^{-n-1} collects the pairs with $i-p-1=-n-1$, i.e. $p=n+i$, with sign $(-1)^{-p-1} = (-1)^{n+i+1}$. Only finitely many i contribute because $\varphi_{(n+i)}t = 0$ for $n+i$ large.

When $M=\mathcal{V}$ is the adjoint module, skew-symmetry of $\mathcal{V}$ says $W(t,z)\varphi = Y(t,z)\varphi$; so W is the module analogue of "the vertex operator of t". The theorem we want is that W is an intertwining operator of type $\binom{M}{M\ \mathcal{V}}$ (FHL §5.4, where it appears as Ω of the module vertex operator Y_M, viewed as an intertwiner of type $\binom{M}{\mathcal{V}\ M}$).

37.4 The skew operator W in Lean

All declarations in this section are in `VOA/Moonshine/SkewIntertwiner.lean`, namespace `VOA.SkewIntertwiner`, for an arbitrary vertex operator algebra `W : VertexOperatorAlgebra` $\mathcal{V}$ and an arbitrary weak module `A : WeakModule W M`. (In these files the letter `W` denotes the vertex operator algebra, not the skew operator; the skew operator is called `Wsk`.)

37.4.1 The translation operator of a module

Definition 37.8. $L_{-1}^M := \omega_{(0)}^M \in \mathrm{End}(M)$.

```
noncomputable def Lm1 (A : WeakModule W M) : End ℂ M := mode (A.YM W.conformalVector) 0
```

Physical meaning

L_{-1} generates translations of the plane, so L_{-1}^M is the momentum operator of the sector. Its action on modes is the dilation-translation covariance of fields, $[L_{-1},\phi(z)] = \partial_z\phi(z)$.

Proposition 37.9 (L_{-1}-commutator). *For $u\in\mathcal{V}$, $p\in\mathbb{Z}$, $x\in M$: $u_{(p)}L_{-1}x = L_{-1}u_{(p)}x + p\,u_{(p-1)}x$. More generally $u_{(p)}L_{-1}^k x = \sum_{r=0}^{k}\binom{k}{r}p(p-1)\cdots(p-r+1)\,L_{-1}^{k-r}u_{(p-r)}x$.*

```
theorem act_Lm1 (A : WeakModule W M) (u : 𝒱) (p : ℤ) (x : M) :
    A.act u p (Lm1 A x) = Lm1 A (A.act u p x) + p • A.act u (p - 1) x

theorem act_Lm1_pow_expand (A : WeakModule W M) (c : 𝒱) (p : ℤ) (k : ℕ) (u : M) :
    A.act c p ((Lm1 A ^ k) u)
      = ∑ r ∈ Finset.range (k + 1),
          (mcoeff p k r) • ((Lm1 A ^ (k - r)) (A.act c (p - (r : ℤ)) u))
```

From the mathematics to the Lean statement

`mcoeff p k r` is the integer $\binom{k}{r}\cdot p(p-1)\cdots(p-r+1)$ (`def mcoeff (p : ℤ) (k r : ℕ) : ℤ := (k.choose r : ℤ) * fallI p r`, with `fallI p r` the falling factorial; `VOA/Core/WeakAssoc.lean`). The integer scalar `p •` is the $\mathbb{Z}$-action on M, equal to multiplication by the complex number p. No hypothesis beyond "A is a weak module". Same as the

textbook statement.

Physical meaning

This is the statement that $L_{-1} = \partial_z$ acts on every field of the module as differentiation: $[L_{-1}, Y_M(u,z)] = \partial_z Y_M(u,z)$, equivalently that translating a field by z is $e^{zL_{-1}}$. It is the technical ingredient behind the translation covariance of W. (A standard consequence of the conformal Ward identity; the physics does not replace the proof below.)

Proof. Apply the module Jacobi identity (37.5) with $u = \omega$, $\ell = m = 0$: it gives $[\omega_{(0)}, u_{(n)}] = (\omega_{(0)}u)_{(n)} = (L_{-1}u)_{(n)}$, and $(L_{-1}u)_{(n)} = -n\,u_{(n-1)}$ (translation covariance of module vertex operators, which is itself the $\ell = 0$, $m = 0$, $v \mapsto L_{-1}u$ case of the same identity). Rearranging, $u_{(p)}L_{-1} = L_{-1}u_{(p)} + p\,u_{(p-1)}$. The general formula is the induction on k of this one, the coefficients satisfying Pascal-type recursions; it is the mode form of $e^{-zL_{-1}}u_{(p)}e^{zL_{-1}} = \sum_k \binom{p}{k} z^k u_{(p-k)}$. □

What the machine verified

Both statements proved, no hypotheses beyond the weak module. Proof in `VOA/Moonshine/SkewIntertwiner.lean`.

37.4.2 The modes and the field

Definition 37.10 (Skew modes and skew field). $\mathtt{wTerm}(t,n,\varphi,i) = \frac{(-1)^{n+i+1}}{i!} L_{-1}^{i}(\varphi_{(n+i)}t)$, $\mathtt{wMode}(t,n,\varphi) = \sum_i \mathtt{wTerm}(t,n,\varphi,i) = W(t)_{(n)}\varphi$, and $\mathtt{Wsk}(t)$ is the $\mathrm{Hom}(\mathcal{V},M)$-valued distribution whose z^k-coefficient is $W(t)_{(-k-1)}$.

```
noncomputable def wTerm (A : WeakModule W M) (t : M) (n : ℤ) (φ : 𝒱) (i : ℕ) : M :=
  (((i.factorial : ℂ)⁻¹) * negOnePow (n + i + 1)) • ((Lm1 A ^ i) (A.act φ (n + i) t))

noncomputable def wMode (A : WeakModule W M) (t : M) (n : ℤ) (φ : 𝒱) : M :=
  ∑ᶠ i : ℕ, wTerm A t n φ i

noncomputable def wModeLin (A : WeakModule W M) (t : M) (n : ℤ) : 𝒱 →ₗ[ℂ] M where
  toFun := wMode A t n

noncomputable def Wsk (A : WeakModule W M) (t : M) : FormalDist (𝒱 →ₗ[ℂ] M) :=
  fun k => wModeLin A t (-k - 1)

theorem mode_Wsk (A : WeakModule W M) (t : M) (n : ℤ) :
    mode (Wsk A t) n = wModeLin A t n
```

(The linearity fields of `wModeLin`, which are the lemmas `wMode_add_left` and `wMode_smul_left`, are omitted.)

From the mathematics to the Lean statement

The $\sum^{\mathtt{f}}$ over $i \in \mathbb{N}$ is a genuine finite sum: by the truncation axiom of A, $\varphi_{(n+i)}t = 0$ for i large, so only finitely many summands are nonzero; if infinitely many were nonzero, $\sum^{\mathtt{f}}$ would return 0 by convention, which is why the library proves separately that the support is finite (`wMode_eq_sum`: for any bound K past the truncation, `wMode` equals the honest sum over $i < K$). With that lemma the definition is exactly (37.7). The indexing `fun k ⇒ wModeLin A t (-k - 1)` together with `mode_Wsk` says that `Wsk A t` is $\sum_n W(t)_{(n)}z^{-n-1}$.

Physical meaning

The definition spells out the field $W(t,z)$ in modes: the sum over i is the Taylor expansion $e^{zL_{-1}}$ that translates the insertion point of the untwisted field from $-z$ back to the origin. The $\mathrm{Hom}(\mathcal{V},M)$-valued distribution is the chiral vertex operator "twisted state t at position z acting on an untwisted state".

Example 37.11 (Low modes). Take $\varphi = \mathbf{1}$. Since $\mathbf{1}_{(p)}t = \delta_{p,-1}t$, only $i = -n-1$ survives, so $W(t)_{(n)}\mathbf{1} = L_{-1}^{-n-1}t/(-n-1)!$ for $n \le -1$ and 0 otherwise: $W(t)_{(-1)}\mathbf{1} = t$, $W(t)_{(-2)}\mathbf{1} = L_{-1}t$, $W(t)_{(-3)}\mathbf{1} = \frac{1}{2}L_{-1}^2 t$. Next take φ of weight 1 in a VOA with $\mathcal{V}_1 \neq 0$ and t of lowest weight in M, so that $\varphi_{(p)}t = 0$ for $p \ge 1$ (it would have weight below the lowest weight). Then $W(t)_{(0)}\varphi = -\varphi_{(0)}t$ (only $i = 0$), and $W(t)_{(-1)}\varphi = \varphi_{(-1)}t - L_{-1}(\varphi_{(0)}t)$. In the Leech case $(V_\Lambda^+)_1 = 0$ and the first nontrivial instance is a weight-two φ.

37.4.3 Vacuum and translation properties

Theorem 37.12 ($W(t,z)\mathbf{1} = e^{zL_{-1}}t$). *For every $t \in M$ and $k \in \mathbb{Z}$, the z^k-coefficient of $W(t,z)\mathbf{1}$ is $L_{-1}^k t/k!$ if $k \ge 0$ and 0 if $k < 0$.*

```
theorem Wsk_vacuum (A : WeakModule W M) (t : M) (k : ℤ) :
    Wsk A t k W.vacuum
      = if 0 ≤ k then ((k.toNat.factorial : ℂ)⁻¹) • (Lm1 A ^ k.toNat) t else 0
```

From the mathematics to the Lean statement

`Wsk A t k` is the z^k-coefficient (a linear map $\mathcal{V} \to M$) applied to `W.vacuum`. `k.toNat` is k viewed as a natural number (used only when $k \ge 0$). No hypotheses. Exactly the textbook statement $W(t,z)\mathbf{1} = \sum_{k\ge 0} z^k L_{-1}^k t/k!$.

Physical meaning

This is the state–operator correspondence for W: acting on the vacuum, the vertex operator of the state t creates t at $z=0$, $W(t,z)\mathbf{1} = e^{zL_{-1}}t$, i.e. the state t translated to the point z. It is the normalisation that makes $W(t,z)$ the field of the state t rather than some other operator.

Proof. Example 37.11: $Y_M(\mathbf{1},-z) = \mathrm{id}$, so $W(t,z)\mathbf{1} = e^{zL_{-1}}t$. □

Theorem 37.13 (L_{-1}-derivative property). $W(L_{-1}t)_{(n)} = -n\,W(t)_{(n-1)}$ *for all n; equivalently* $W(L_{-1}t,z) = \partial_z W(t,z)$.

```
theorem wMode_Lm1 (A : WeakModule W M) (t : M) (n : ℤ) (φ : 𝒱) :
    wMode A (Lm1 A t) n φ = (-(n : ℂ)) • wMode A t (n - 1) φ

theorem Wsk_deriv (A : WeakModule W M) (t : M) :
    Wsk A (Lm1 A t) = deriv (Wsk A t)
```

From the mathematics to the Lean statement

`deriv` is the coefficientwise derivative of Definition 37.2. The mode form and the field form agree: the z^k-coefficient of $\partial_z W$ is $(k+1)W(t)_{(-k-2)}$, and the mode form with $n = -k-1$ gives $W(L_{-1}t)_{(-k-1)} = (k+1)W(t)_{(-k-2)}$. No hypotheses. This is (I2) for W; it is not part of the library's `Intertwiner` structure, which is why it is proved as a separate theorem.

Physical meaning

The field of the descendant $L_{-1}t = \partial t$ is the derivative of the field of t: $W(\partial t, z) = \partial_z W(t, z)$. This is the translation covariance every chiral field satisfies, and it is axiom (I2) of an intertwining operator.

Proof. In terms of fields: $W(L_{-1}t, z)\varphi = e^{zL_{-1}}Y_M(\varphi, -z)L_{-1}t$. The module commutator $[L_{-1}, Y_M(\varphi, x)] = \partial_x Y_M(\varphi, x)$ (Proposition 37.9) gives $Y_M(\varphi, -z)L_{-1}t = L_{-1}Y_M(\varphi, -z)t + \partial_z Y_M(\varphi, -z)t$ (the chain rule for $x = -z$ produces the sign). Hence $W(L_{-1}t, z)\varphi = \big(L_{-1}e^{zL_{-1}} + e^{zL_{-1}}\partial_z\big)Y_M(\varphi, -z)t = \partial_z\big(e^{zL_{-1}}Y_M(\varphi, -z)t\big)$. In modes this is a telescoping identity between the finite sums (37.7). □

Proposition 37.14 (Truncation). *For fixed t, φ, $W(t)_{(n)}\varphi = 0$ for $n \gg 0$.*

File `VOA/Moonshine/SkewIntertwiner.lean`.

```
theorem wMode_truncation (A : WeakModule W M) (t : M) (φ : V) :
    ∃ N : ℤ, ∀ n : ℤ, N ≤ n → wMode A t n φ = 0
```

Physical meaning

In a sector with energy bounded below, acting with a field on a fixed state produces only finitely many poles at the insertion point, i.e. the matrix elements of $W(t, z)$ between fixed states are Laurent series in z with finite principal part. This is the usual condition that the OPE has a finite pole order.

Proof. If $\varphi_{(p)}t = 0$ for $p \geq N$, every summand of (37.7) vanishes for $n \geq N$. □

What the machine verified

`Wsk_vacuum`, `wMode_Lm1`, `Wsk_deriv`, `wMode_truncation`: proved for every weak module, no further hypotheses. `##print axioms` of the file's headline declarations (rechecked for this chapter, see Section 37.16): `[propext, Classical.choice, Quot.sound]`.

37.4.4 The commutator formula

Theorem 37.15 (Intertwining commutator formula for W). *Let M be a weak V-module, $u \in V$, $t \in M$, and let $J \in \mathbb{N}$ be such that $u_{(j)}t = 0$ for all $j \geq J$. Then for* all *$m, n \in \mathbb{Z}$ and $\varphi \in V$,*

$$u^M_{(m)}\, W(t)_{(n)}\varphi - W(t)_{(n)}\big(u_{(m)}\varphi\big) = \sum_{r=0}^{J-1} \binom{m}{r} W\big(u^M_{(r)}t\big)_{(m+n-r)}\varphi. \tag{37.8}$$

File `VOA/Moonshine/SkewIntertwiner.lean`.

```
theorem wMode_comm (A : WeakModule W M) (u : V) (m : ℤ) (t : M) (n : ℤ) (φ : V) (J : ℕ)
    (hJ : ∀ j : ℕ, J ≤ j → A.act u j t = 0) :
    A.act u m (wMode A t n φ) - wMode A t n (W.smul u m φ)
      = ∑ r ∈ Finset.range J, gBinom m r • wMode A (A.act u r t) (m + n - r) φ
```

From the mathematics to the Lean statement

Symbols. `A.act u m` is $u^M_{(m)}$ on M; `W.smul u m φ` is $u_{(m)}\varphi$ in V; `wMode A s q φ` is $W(s)_{(q)}\varphi$; `gBinom m r` is $\binom{m}{r}$ with $m \in \mathbb{Z}$; `Finset.range J` is $\{0, \dots, J-1\}$.
Hypotheses. Only `hJ`: J is past the truncation of u on t. Such a J always exists (truncation axiom), and the formula is then true for *every* such J, because the extra terms with $r \geq J$ vanish. The quantifier order matters: J depends only on u and t, not on φ, m or n. That is what makes locality (Theorem 37.17) follow with an order independent of the test vector.

Comparison. This is exactly (37.6) for the intertwiner W of type $\binom{M}{M\ \mathcal{V}}$: the first argument t lies in M, the second φ in $\mathcal{V}$, the output in M. Same as the textbook statement, for all $m \in \mathbb{Z}$ (including negative m, where the binomial coefficients are the generalised ones and the sum is still finite because of J).
Could it be vacuous? The hypothesis is satisfiable for every u, t; the conclusion is a nontrivial identity in M. No degenerate case is hidden.

Physical meaning

This is the Ward identity of the chiral algebra on the field W: the OPE $u(z_1)W(t,z_2) \sim \sum_r W(u_{(r)}t, z_2)/(z_1-z_2)^{r+1}$ says that a current u passing the insertion of the twist field acts on it by the singular terms of the OPE, with the twisted state $u_{(r)}t$ appearing as the residue. The same formula describes how a current commutes with a primary field, including the twisted sector's modes. It holds for all m because the field lives on an annulus of convergence in both orderings.

Proof on paper. Write $L = L^M_{-1}$ and $c_i(n) = (-1)^{n+i+1}/i!$, so that $W(t)_{(n)}\varphi = \sum_i c_i(n) L^i(\varphi_{(n+i)}t)$.

Step 1: move $u_{(m)}$ through the powers of L. By Proposition 37.9, $u_{(m)}L^i y = \sum_{r\le i}\binom{i}{r} m(m-1)\cdots(m-r+1)\,L^{i-r}u_{(m-r)}y$. Substituting and writing $i = a+r$, the scalar becomes $\frac{(-1)^{n+a+r+1}}{(a+r)!}\binom{a+r}{r} m(m-1)\cdots(m-r+1) = \frac{(-1)^{n+a+1}}{a!}(-1)^r\binom{m}{r}$. Hence

$$u_{(m)}W(t)_{(n)}\varphi = \sum_{a\ge 0}\frac{(-1)^{n+a+1}}{a!}L^a\Big[\sum_{r\ge 0}(-1)^r\binom{m}{r}u_{(m-r)}\varphi_{(n+a+r)}t\Big]. \tag{37.9}$$

Step 2: the iterate formula. The module Jacobi identity (37.5) with (ℓ, m, n) replaced by $(m, 0, q)$ reads

$$\sum_{r\ge 0}(-1)^r\binom{m}{r}\Big(u_{(m-r)}\varphi_{(q+r)}t - (-1)^m\varphi_{(m+q-r)}u_{(r)}t\Big) = (u_{(m)}\varphi)_{(q)}t, \tag{37.10}$$

the sum on the right of (37.5) collapsing to its $i=0$ term because $\binom{0}{i} = \delta_{i0}$. Apply it with $q = n+a$ to the bracket in (37.9).

Step 3: recognise the two pieces. The term $(u_{(m)}\varphi)_{(n+a)}t$ contributes $\sum_a \frac{(-1)^{n+a+1}}{a!}L^a(u_{(m)}\varphi)_{(n+a)}t = W(t)_{(n)}(u_{(m)}\varphi)$. The other term contributes

$$\sum_r\binom{m}{r}\sum_a\frac{(-1)^{n+a+1+r+m}}{a!}L^a\big(\varphi_{(m+n-r+a)}\,u_{(r)}t\big) = \sum_r\binom{m}{r}W\big(u_{(r)}t\big)_{(m+n-r)}\varphi,$$

because $(-1)^{n+a+1+r+m} = (-1)^{(m+n-r)+a+1}$, which is exactly the sign in the definition of $W(s)_{(m+n-r)}\varphi$ with $s = u_{(r)}t$. Finally $u_{(r)}t = 0$ for $r \ge J$, so the r-sum stops at $J-1$. Every sum in the argument is finite, since all the truncations involved are finite. □

Remark 37.16 (No Goddard uniqueness)**.** For a vertex algebra acting on itself, skew-symmetry and commutator formulas are usually derived from a uniqueness argument (Goddard's lemma: a field local with all $Y(u,z)$ and with the right value on the vacuum is determined). That argument needs a vacuum vector in the space the field acts on. In the present situation the field $W(t,z)$ maps $\mathcal{V}$ to M, and M has no vacuum, so the commutator formula is proved directly by the computation above, for all m (positive and negative) at once.

What the machine verified

`wMode_comm`: proved for every weak module; only hypothesis `hJ`. Axioms `[propext, Classical.choice, Quot.sound]` (rechecked).

37.4.5 Locality of $Y_M(u,z_1)$ and $W(t,z_2)$

Theorem 37.17 (W is local with every module vertex operator). *For $u \in \mathcal{V}$ and $t \in M$, let J be past the truncation of u on t. Then*

$$(z_1-z_2)^J\Big(Y_M(u,z_1)\,W(t,z_2) - W(t,z_2)\,Y(u,z_1)\Big) = 0$$

as a two-variable distribution with values in $\mathrm{Hom}(\mathcal{V},M)$. *In particular such an exponent exists.*

File `VOA/Moonshine/SkewIntertwiner.lean`.

```
noncomputable def wBracket (A : WeakModule W M) (u : 𝒱) (t : M) : FormalDist₂ (𝒱 →ₗ[ℂ] M)
 ↪  :=
  fun a b => (A.YM u a).comp (Wsk A t b) - (Wsk A t b).comp (W.Y u a)

theorem Wsk_local_of_bound (A : WeakModule W M) (u : 𝒱) (t : M) (J : ℕ)
    (hJ : ∀ j : ℕ, J ≤ j → A.act u j t = 0) :
    mulBySubPow J (wBracket A u t) = 0

theorem Wsk_local (A : WeakModule W M) (u : 𝒱) (t : M) :
    ∃ N : ℕ, mulBySubPow N (wBracket A u t) = 0
```

From the mathematics to the Lean statement

`wBracket A u t` has as (a,b)-coefficient the map $Y_M(u)_a \circ W(t)_b - W(t)_b \circ Y(u)_a$, where subscripts are coefficients of z_1^a and z_2^b (Definition 37.2), and `comp` is composition of linear maps. This is the coefficient of $z_1^a z_2^b$ in $Y_M(u,z_1)W(t,z_2) - W(t,z_2)Y(u,z_1)$. `mulBySubPow J` multiplies by $(z_1-z_2)^J$ (Definition 37.4). The order J is the truncation order of u on t; it does not depend on the vector φ on which the operators act. That is the strong (uniform) form of locality, as required for fields.

Physical meaning

Mutual locality of $W(t,z_2)$ with every current $Y(u,z_1)$ means that the correlation functions of the twist-field vertex operator with currents are single-valued meromorphic functions in z_1 with poles only at z_2: the twist field creates no branch cut seen by the *untwisted* (invariant) currents. The pole order J is the order of the OPE singularity, independent of the state on which the operators act, as for a genuine field.

Proof on paper. Theorem 37.15, rewritten for distributions, says

$$[Y_M(u,z_1),W(t,z_2)] = \sum_{r<J} W(u_{(r)}t,z_2)\,\frac{1}{r!}\partial_{z_2}^{r}\,z_1^{-1}\delta\Big(\frac{z_2}{z_1}\Big),$$

whose (a,b)-coefficient is $\binom{-a-1}{r}\,W(u_{(r)}t)_{(-a-b-2-r)}$. A distribution of the form $g(z_2)\partial^{(r)}\delta$ is killed by $(z_1-z_2)^{r+1}$: in coefficients, (z_1-z_2) maps the pattern $\binom{-a-1}{r}g_{a+b}$ to the pattern with r replaced by $r-1$ (Pascal's rule), and kills it when $r=0$. Hence $(z_1-z_2)^J$ kills every term with $r<J$. □

What the machine verified

`Wsk_local_of_bound`, `Wsk_local`: proved for every weak module, no further hypotheses. Axioms of `Wsk_local`: `[propext, Classical.choice, Quot.sound]` (rechecked).

37.4.6 Packaging: the skew intertwiner

Definition 37.18 (Skew intertwiner). For an ordinary module A on M', `skewIntertwiner A` is the library `Intertwiner` of type $(A; A, \mathcal{V})$ whose mode at an integer $s = n$ is $W(\cdot)_{(n)}(\cdot)$ and whose modes at non-integral $s \in \mathbb{C}$ are zero.

File `VOA/Moonshine/SkewIntertwiner.lean`.

```
noncomputable def skModes (A : WeakModule W M) (s : ℂ) : M →ₗ[ℂ] 𝒱 →ₗ[ℂ] M :=
  if h : ∃ n : ℤ, (n : ℂ) = s then wBil A (Classical.choose h) else 0

noncomputable def skewIntertwiner (A : OrdVModule W M') :
    Intertwiner A (adjointModule W) A where
  modes := skModes A.toWeakModule

theorem skewIntertwiner_modes (A : OrdVModule W M') (n : ℤ) (t : M') (φ : 𝒱) :
    (skewIntertwiner A).modes (n : ℂ) t φ = wMode A.toWeakModule t n φ
```

(`wBil A n` is $W(\cdot)_{(n)}(\cdot)$ as a bilinear map $M \times \mathcal{V} \to M$; the `truncation` and `isIntertwiner` fields of the structure, proved from Proposition 37.14 and Theorem 37.15, are omitted.)

From the mathematics to the Lean statement

Type. `Intertwiner A (adjointModule W) A`: first argument from A, second from the adjoint module $\mathcal{V}$, output in A; i.e. type $\binom{M}{M\ \mathcal{V}}$. **Complex modes.** The library's intertwiners have complex modes; W has only integral modes, so `skModes` reads off the integer n with $(n : \mathbb{C}) = s$ when it exists (the `Classical.choose` is harmless: the integer is unique) and is zero otherwise. **Strength.** As explained under Definition 37.6, this records only truncation and the commutator formula. The L_{-1}-property is Theorem 37.13, proved separately; the full Jacobi identity of W is not proved in the library.

Physical meaning

Packaging W as an `Intertwiner` records it as a chiral vertex operator of type twisted $\times$ untwisted $\to$ twisted, i.e. as a choice of three-point coupling $\langle T|\, W(t,z)\, |V^+\rangle$ among the twisted module, the adjoint (vacuum) module and the twisted module. The vanishing of non-integral modes expresses that the sector $(V_\Lambda^T)^+$ has integer conformal weights, so no fractional monodromy appears.

What the machine verified

Definition with all fields proved; for every ordinary module. Axioms of `skewIntertwiner`: `[propext, Classical.choice, Quot.sound]` (rechecked).

37.5 The Leech instance of W

The file `VOA/Moonshine/SkewLeech.lean` specialises everything to the module `plusModule` of Section 37.2.3. Since `plusModule` is an *ordinary* module with integral modes ($u_{(n)} = Y^T(u)_{(2n/2)}$ on $(V_\Lambda^T)^+$), W has only integral modes and no fractional bookkeeping arises.

Definition 37.19. L_{-1} on $(V_\Lambda^T)^+$ and the skew field $W(t,z) = e^{zL_{-1}}Y^T(\cdot,-z)t : V_\Lambda^+ \to (V_\Lambda^T)^+$ for $t \in (V_\Lambda^T)^+$:

```
noncomputable abbrev leechLTP : Module.End ℂ TP := Lm1 plusModule.toWeakModule

theorem leechLTP_coe (x : TP) :
    ((leechLTP x : TP) : Tw) = leechTwistedModule.YM leechVOAPlus.conformalVector.1 0 x

noncomputable def leechWsk (t : TP) : FormalDist (SkewVP →ₗ[ℂ] TP) :=
  Wsk plusModule.toWeakModule t
```

From the mathematics to the Lean statement

`leechLTP_coe` confirms that the module translation operator on $(V_\Lambda^T)^+$ is the twisted ω-mode at twisted index 0, i.e. $\omega_{(0)} = L_{-1}$ of the twisted module of Chapter 36, restricted to the θ-fixed part (the coercion `((· : TP) : Tw)` includes $(V_\Lambda^T)^+$ into $S[\theta] \otimes T$). So "L_{-1}" means what it should.

Physical meaning

This is the concrete 2d CFT object: $W(t,z)$ is the vertex operator for the twist-field state $t \in (V_\Lambda^T)^+$ of the $\mathbb{Z}/2$ orbifold of 24 bosons on the Leech torus, acting from the untwisted chiral algebra V_Λ^+ into the twisted sector. Everything is forced by the module structure through skew-symmetry, with no choices.

Theorem 37.20 (Properties of the Leech W). *For $t \in (V_\Lambda^T)^+$: $W(t,z)\mathbf{1} = e^{zL_{-1}}t$; $W(L_{-1}t,z) = \partial_z W(t,z)$; the commutator formula (37.8) holds for all $u \in V_\Lambda^+$, $m,n \in \mathbb{Z}$; and $Y^T(u,z_1)$, $W(t,z_2)$ are mutually local. Finally W is an intertwiner of type $\binom{(V_\Lambda^T)^+}{(V_\Lambda^T)^+\ V_\Lambda^+}$ in the library's sense.*

```
theorem leechWsk_vacuum (t : TP) (k : ℤ) :
    leechWsk t k leechVOAPlus.vacuum

noncomputable def leechSkewIntertwiner :
    Intertwiner plusModule (adjointModule leechVOAPlus) plusModule :=
  skewIntertwiner plusModule
```

From the mathematics to the Lean statement

Each statement is the general theorem of Section 37.4 at `A := plusModule.toWeakModule`; the proofs are one-line applications. In `leechWsk_comm`, `mode (leechWsk t) n` is $W(t)_{(n)}$ and `mode (plusModule.YM u) m` is $u_{(m)}$ on $(V_\Lambda^T)^+$. The locality statement is the $\mathrm{Hom}(V_\Lambda^+,(V_\Lambda^T)^+)$-valued

form explained after Definition 37.4. Same as the textbook statements; unconditional.

Physical meaning

The theorem says the twisted sector can be consistently "fused" with the untwisted algebra: the OPE of an invariant current with a twist-field operator closes on twist fields, and the translation and vacuum axioms hold. This is the part of the interaction between sectors that is fixed by the module structure; the interaction between two twist fields is the harder statement, proved in later chapters.

What the machine verified

All unconditional (no hypotheses beyond the already-built `leechVOAPlus` and `plusModule`). Axioms of `leechSkewIntertwiner`: `[propext, Classical.choice, Quot.sound]` (rechecked).

37.6 Contragredient modules and invariant bilinear forms

37.6.1 The contragredient module

Let $M = \bigoplus_\alpha M_\alpha$ be an ordinary $\mathcal{V}$-module. Its *restricted* (or graded) dual is $M' = \bigoplus_\alpha M_\alpha^*$, the direct sum of the duals of the finite-dimensional weight spaces; write $\langle f, x\rangle$ for the pairing. Frenkel, Huang and Lepowsky (FHL, §5.2) define vertex operators on M' by

$$\langle Y'(u,z)f,\ x\rangle = \left\langle f,\ Y\big(e^{zL_1}(-z^{-2})^{L_0}u,\ z^{-1}\big)x\right\rangle \tag{37.11}$$

and prove (FHL, Theorem 5.2.1) that (M', Y') is again a module, the *contragredient* module. The operator $u \mapsto e^{zL_1}(-z^{-2})^{L_0}u$ is the action of the Möbius transformation $z \mapsto 1/z$ on states, which is why it appears: physically, (37.11) is the statement that the "out" state $\langle f|$ at infinity is the BPZ conjugate of an "in" state.

Mode form. For $u \in \mathcal{V}_{\mathrm{wt}}$ we have $e^{zL_1}(-z^{-2})^{L_0}u = (-1)^{\mathrm{wt}} z^{-2\mathrm{wt}} \sum_{j\ge 0} z^j L_1^j u/j!$ and $Y(v,z^{-1}) = \sum_q v_{(q)} z^{q+1}$. Comparing coefficients of z^{-n-1} forces $q = 2\mathrm{wt} - n - 2 - j$, so

$$\langle u'_{(n)}f, x\rangle = (-1)^{\mathrm{wt}} \sum_{j=0}^{\mathrm{wt}} \frac{1}{j!} \langle f,\ (L_1^j u)_{(2\mathrm{wt}-n-2-j)}x\rangle. \tag{37.12}$$

The sum stops at $j = \mathrm{wt}$ because $L_1^j u$ has weight $\mathrm{wt} - j$ and a CFT-type vertex operator algebra has no negative weights. If u is *quasi-primary* ($L_1 u = 0$) only $j = 0$ survives: $u_{(n)}$ is transposed to $(-1)^{\mathrm{wt}} u_{(2\mathrm{wt}-n-2)}$.

Example 37.21. (i) $u = \omega$, $\mathrm{wt} = 2$, $L_1\omega = 0$: $\omega_{(n)} = L_{n-1}$ is transposed to $\omega_{(2-n)} = L_{1-n}$, i.e. $L_k^t = L_{-k}$: the Virasoro operators are BPZ-adjoint as expected. (ii) $u = h(-1)\mathbf{1}$ a Heisenberg vector, $\mathrm{wt} = 1$, quasi-primary: $h_{(n)} = h(n)$ is transposed to $-h(-n)$. Note the *minus sign*: it will make the natural invariant form on a Fock space indefinite (Section 37.7). (iii) $u = e^\alpha$ in a lattice VOA, weight $N = \langle\alpha,\alpha\rangle/2$, primary: $e^\alpha_{(n)}$ is transposed to $(-1)^N e^\alpha_{(2N-n-2)}$.

In the library, M' is the type `RestrictedDual N` and its vertex operator is `YMdual N`:

```
def RestrictedDual (N : OrdVModule W M) : Type u := DirectSum ℂ (fun α => Module.Dual ℂ
 ↪  (N.weight α))

noncomputable def YMdual (N : OrdVModule W M) : 𝒱 →ₗ[ℂ] (End ℂ (RestrictedDual N))⟦z^±⟧
 ↪  where
  toFun u := fun p => dualModeAt N (-p - 1) u
```

(`VOA/Modules/Contragredient.lean`, `VOA/Modules/ContragredientJacobi.lean`; `dualModeAt N n u` is, on homogeneous u, the operator defined by (37.12), and it is extended linearly over the weight decomposition of u. The library proves that Y' satisfies the module Jacobi identity: `contragredientJacobi_holds`, in `VOA/Modules/ContragredientClose.lean`.)

37.6.2 Invariant bilinear forms on a module

Definition 37.22 (FHL invariance at a homogeneous state)**.** Let N be an ordinary $\mathcal{V}$-module on M and B a bilinear form on M. For $u \in \mathcal{V}_{\mathrm{wt}}$, B is *invariant at u* if for all $n \in \mathbb{Z}$, $a, b \in M$

$$B\big(u_{(n)}a, b\big) = (-1)^{\mathrm{wt}} \sum_{j=0}^{\mathrm{wt}} \frac{1}{j!}\, B\big(a, (L_1^{j}u)_{(2\mathrm{wt}-n-2-j)}b\big), \tag{37.13}$$

the mode form of $B(Y(u,z)a,b) = B(a, Y(e^{zL_1}(-z^{-2})^{L_0}u, z^{-1})b)$. The form has *orthogonal weight spaces* if $B(M_\alpha, M_\beta) = 0$ for $\alpha \neq \beta$.

```
def FHLInv (N : OrdVModule W M) (B : LinearMap.BilinForm ℂ M) (wt : ℤ) (u : 𝒱) : Prop :=
  ∀ (n : ℤ) (a b : M), B (mode (N.YM u) n a) b
    = (-1 : ℂ) ^ wt • ∑ j ∈ Finset.range (wt.toNat + 1), ((j.factorial : ℂ)⁻¹) •
        B a (mode (N.YM (((W.L 1) ^ j) u)) (2 * wt - n - 2 - (j : ℤ)) b)

def WeightOrth (N : OrdVModule W M) (B : LinearMap.BilinForm ℂ M) : Prop :=
  ∀ α β : ℂ, α ≠ β → ∀ x ∈ N.weight α, ∀ y ∈ N.weight β, B x y = 0
```

(`VOA/Moonshine/InvFormClosure.lean`, namespace `VOA.Moonshine.InvForm`.)

From the mathematics to the Lean statement

`LinearMap.BilinForm ℂ M` is a bilinear form $M \times M \to \mathbb{C}$, applied as `B a b`. `W.L 1` is L_1 on $\mathcal{V}$, `(W.L 1)^j` its j-th power. `Finset.range (wt.toNat + 1)` is $\{0, \dots, \mathrm{wt}\}$ (for $\mathrm{wt} < 0$ it is $\{0\}$, but then $u = 0$ by CFT type and both sides vanish). `FHLInv` takes the weight `wt` as a separate argument and does *not* itself require $u \in \mathcal{V}_{\mathrm{wt}}$; every theorem below that uses it adds the hypothesis `u ∈ W.grading wt`, so the predicate is only ever applied in its intended meaning. This is the module analogue of the library's `InvariantForm.IsFullyInvariant` for forms on $\mathcal{V}$ itself (same formula with `W.smul` in place of module modes). Same as the textbook definition.

Physical meaning

An invariant bilinear form is the two-point function of the sector: $B(a,b) = \langle a|b\rangle$ with $\langle a|$ the out-state at infinity. The invariance condition says that moving a field $Y(u,z)$ from the right to the left of the bracket replaces it by its BPZ conjugate, the field transformed by the inversion $z \mapsto 1/z$, which is why $e^{zL_1}(-z^{-2})^{L_0}$ appears. For a weight-wt quasi-primary field the transposition rule is $u_{(n)} \mapsto (-1)^{\mathrm{wt}} u_{(2\mathrm{wt}-n-2)}$, the familiar $L_n \mapsto L_{-n}$ and $J_n \mapsto -J_{-n}$. The orthogonality of weight spaces is the selection rule that two-point functions vanish between states of different energy.

Definition 37.23 (The map $M \to M'$ of a form)**.** `dualMap N B` : $M \to M'$ sends a to the functional whose M_β-component is $x \mapsto B(\pi_\beta a, x)$, π_β the projection to M_β. If the weight spaces are orthogonal, $\langle \mathtt{dualMap}(a), x\rangle = B(a,x)$ for every x.

```
noncomputable def dualMap (N : OrdVModule W M) (B : LinearMap.BilinForm ℂ M) :
    M →ₗ[ℂ] RestrictedDual N :=
  letI := DirectSum.IsInternal.chooseDecomposition N.weight N.isInternal
  (DFinsupp.mapRange.linearMap fun α => B.compl₁₂ (N.weight α).subtype (N.weight
   ↪ α).subtype).comp
    (DirectSum.decomposeLinearEquiv N.weight).toLinearMap
```

Physical meaning

The assignment $a \mapsto B(a,\cdot)$ sends an in-state to the corresponding out-state $\langle a|$ in the dual (contragredient) space of out-states. This definition is the bra–ket map defined by the two-point function.

Theorem 37.24 (Invariance means $a \mapsto B(a,\cdot)$ is a module map)**.** *Assume orthogonal weight spaces and $u \in \mathcal{V}_{\mathrm{wt}}$. Then B is invariant at u if and only if* $\mathtt{dualMap}(u_{(n)}a) = u'_{(n)}\mathtt{dualMap}(a)$ *for all n and a.*

```
theorem fhlInv_iff (hO : WeightOrth N B) {wt : ℤ} {u : 𝒱} (hu : u ∈ W.grading wt) :
    FHLInv N B wt u ↔
      ∀ (n : ℤ) (a : M), dualMap N B (mode (N.YM u) n a) = mode (YMdual N u) n (dualMap N B
       ↪ a)
```

From the mathematics to the Lean statement

Hypotheses: `hO` (orthogonal weight spaces; needed so that $\langle \mathtt{dualMap}(a), x\rangle$ really equals $B(a,x)$ and not B of a projection) and `hu` (homogeneity, so that `FHLInv` is used with the right weight and `YMdual` is given by (37.12)). Both sides of the equivalence are the textbook ones.

Physical meaning

The theorem says that a form is invariant exactly when the in-to-out map $a \mapsto \langle a|$ intertwines the chiral algebra action, i.e. when the contragredient module M' of out-states, with the BPZ-conjugated action, is identified with M by the form. Physically the sector is its own conjugate, with the form playing the role of the Zamolodchikov metric that identifies states with out-states. (Heuristic gloss; the equivalence is proved mode by mode.)

Proof. Pair both sides of the right-hand equation with $x \in M_\alpha$. By orthogonality the left side gives $B(u_{(n)}a, x)$, and by (37.12) the right side gives the right-hand side of (37.13) with $b = x$. Elements of M' are determined by their pairings with homogeneous vectors, and both sides of (37.13) are linear in b, so the equivalence follows. □

37.6.3 Generator reduction

Checking (37.13) for every state of $\mathcal{V}$ directly is hopeless for V_Λ^+. The following principle reduces it to generators.

Definition 37.25. `interSub` $N\,B$ is the set of $u \in \mathcal{V}$ (homogeneous or not) such that $\mathtt{dualMap}(u_{(n)}a) = u'_{(n)}\mathtt{dualMap}(a)$ for all n and a. It is a linear subspace.

File `VOA/Moonshine/InvFormClosure.lean`.

```
noncomputable def interSub (N : OrdVModule W M) (B : LinearMap.BilinForm ℂ M) : Submodule ℂ
 ↪ 𝒱 where
  carrier := {u | ∀ (n : ℤ) (a : M),
    dualMap N B (mode (N.YM u) n a) = mode (YMdual N u) n (dualMap N B a)}
```

Physical meaning

Technical definition: the set of fields for which the in–out map commutes with the action. Physically, the fields whose BPZ conjugate behaves correctly under the form; the next theorem shows these form a closed operator algebra, so it suffices to check the generating currents.

Theorem 37.26 (The intertwined states form a vertex subalgebra)**.** $\mathbf{1} \in \mathtt{interSub}$*, and if $u, v \in$* `interSub` *then $u_{(\ell)}v \in$* `interSub` *for every $\ell \in \mathbb{Z}$.*

```
theorem vacuum_mem_interSub : W.vacuum ∈ interSub N B

theorem smul_mem_interSub {u v : V} (hu : u ∈ interSub N B) (hv : v ∈ interSub N B) (ℓ : ℤ)
 ↪  :
    W.smul u ℓ v ∈ interSub N B
```

Physical meaning

Operator products of fields that satisfy the BPZ reflection rule again satisfy it: if the conjugate of each of two fields is the correct reflected field, the conjugate of their OPE coefficients is as well. This is the closure of the set of "good" fields under the OPE.

Proof. The vacuum acts as the identity on M and on M'. For the products, the iterate formula (37.10) (with $m = 0$) writes $(u_{(\ell)}v)_{(n)}$ on M as a finite combination of products $u_{(\cdot)}v_{(\cdot)}$ and $v_{(\cdot)}u_{(\cdot)}$; the same formula holds on M' because M' is a module (FHL Theorem 5.2.1, `contragredientJacobi_holds`). The map `dualMap` intertwines each factor, hence each product, hence the combination. □

Theorem 37.27 (Generator reduction for module invariant forms)**.** *Let B have orthogonal weight spaces and let $G \subseteq \mathcal{V}$ be a set of homogeneous states which generates $\mathcal{V}$ in the sense that every subspace containing* $\mathbf{1}$ *and G and closed under all n-th products is all of $\mathcal{V}$. If B is invariant at every $g \in G$, then B is invariant at every homogeneous $u \in \mathcal{V}$.*

File `VOA/Moonshine/InvFormClosure.lean`.

```
theorem fhlInv_of_generates (hO : WeightOrth N B) (G : Set V)
    (hG : ∀ S : Submodule ℂ V, W.vacuum ∈ S → (∀ u ∈ S, ∀ v ∈ S, ∀ n : ℤ, W.smul u n v ∈ S)
     ↪  →
      G ⊆ S → S = ⊤)
    (hGinv : ∀ g ∈ G, ∃ wt : ℤ, g ∈ W.grading wt ∧ FHLInv N B wt g)
    {wt : ℤ} {u : V} (hu : u ∈ W.grading wt) : FHLInv N B wt u
```

From the mathematics to the Lean statement

Hypotheses. `hO`: orthogonal weight spaces. `hG`: generation, stated exactly as in the theorem (the smallest vertex subalgebra containing G is everything; `⊤` is the whole space). `hGinv`: each generator is homogeneous of some weight and B is invariant at it. `hu`: the conclusion is for homogeneous u. **Comparison.** Same as the textbook statement. **Not vacuous:** generation is a genuine hypothesis and is discharged for the Leech case by a real theorem (`leechPlus_generated`, Chapter 32).

Physical meaning

(See the preceding box for the closure under OPE.) Physically this says that a two-point metric which is compatible with the BPZ conjugation of the generating currents (here the lattice fields $e^{\beta} + e^{-\beta}$) is automatically compatible with the whole chiral algebra, since every field is built from the generators by OPE. This is how one avoids checking invariance on all of V_Λ^+.

Proof. By Theorem 37.26 `interSub` is a subspace containing $\mathbf{1}$, closed under products; by Theorem 37.24 it contains G. By generation it is everything, so every homogeneous u lies in it, and Theorem 37.24 again gives invariance at u. The point of working with `interSub` rather than with `FHLInv` is that `interSub` is defined for inhomogeneous states and is visibly linear, whereas (37.13) mixes the state with its weight. □

What the machine verified

`fhlInv_iff`, `smul_mem_interSub`, `fhlInv_of_generates`: proved for every VOA, module and form, with exactly the displayed hypotheses. Axioms of `fhlInv_of_generates`: `[propext, Classical.choice, Quot.sound]` (rechecked).

37.7 The invariant form on the twisted Fock space

We now build the form B_T on $(V_\Lambda^T)^+$ that enters (37.4). It is the restriction of a product form $F \otimes B_T$ on $S[\theta] \otimes T$: a form F on the twisted Fock space and the symmetric form `TForm` on the 2^{12}-dimensional space T constructed in Chapter 34. (To avoid a clash we write B_{tw} for the form on $S[\theta] \otimes T$ and keep B_T for its restriction to $(V_\Lambda^T)^+$; the Lean names are `leechTwForm` and `TPForm`.) All declarations of this section and the next are in namespace `VOA.Moonshine.InvForm`.

37.7.1 Which sign? The negative Fock form

Recall (Chapter 34) that $S[\theta] = \mathbb{C}[X_{(n,i)}]$ with $X_{(n,i)} = h_i(-n-\tfrac12)$, $n \ge 0$, $1 \le i \le r$, and that the twisted oscillators act by $h_i(-n-\tfrac12) =$ multiplication by $X_{(n,i)}$ and $h_i(n+\tfrac12) = (n+\tfrac12)\partial/\partial X_{(n,i)}$, so that $[h_i(m), h_j(m')] = m\,\delta_{ij}\delta_{m+m',0}$. In Lean the oscillator $h_i(k/2)$ (k odd) is `modeT r i k` (Chapter 34); for even k it is defined to be 0.

Example 37.21(ii) dictates the adjointness relation that an invariant form must satisfy for the weight-one vectors $h_i(-1)\mathbf{1}$ of the lattice VOA, whose twisted vertex operators have the modes $h_i(k/2)$:

$$F\big(h_i(m)p, q\big) = -F\big(p, h_i(-m)q\big). \tag{37.14}$$

With $m = -n - \tfrac12$ this reads $F(X_v p, q) = -F(p, h_i(n+\tfrac12)q) = c_v\, F(p, \partial_v q)$ with

$$c_v = -(n+\tfrac12) \qquad (v = (n,i)).$$

Iterating, monomials are orthogonal and $F(X^d, X^d) = \prod_v c_v^{d_v}\, d_v!$. This is not positive: in rank one $F(X_{(0,1)}, X_{(0,1)}) = -\tfrac12$, $F(X_{(0,1)}^2, X_{(0,1)}^2) = \tfrac12$, $F(X_{(1,1)}, X_{(1,1)}) = -\tfrac32$. The familiar positive-definite Fock form ($c_v = +(n+\tfrac12)$) is the *Hermitian* form of unitary CFT, adapted to the anti-linear adjoint $h(m)^\dagger = h(-m)$; the FHL *bilinear* form, adapted to the linear transposition $Y(u,z) \mapsto Y(e^{zL_1}(-z^{-2})^{L_0}u, z^{-1})$, carries the sign $(-1)^{\mathrm{wt}} = -1$ for weight-one fields. The two differ by the anti-linear involution $h \mapsto -h$.

Definition 37.28 (The Fock form). $c_v = -(n+\tfrac12)$ for $v = (n,i)$; $\mathtt{fockWt}(d) = \prod_v c_v^{d_v} d_v!$ for a multi-index d; and $F(X^d, X^e) = \delta_{d,e}\,\mathtt{fockWt}(d)$, extended bilinearly.

```
noncomputable def cVar (v : ℕ × Fin r) : ℂ := -((v.1 : ℂ) + 1 / 2)

noncomputable def fockWt (d : (ℕ × Fin r) →₀ ℕ) : ℂ :=
  d.prod fun v m => cVar v ^ m * (m.factorial : ℂ)

noncomputable def fockForm (r : ℕ) : LinearMap.BilinForm ℂ (FockT r) :=
  Finsupp.lsum ℂ fun d => LinearMap.smulRight LinearMap.id (fockWt d • lcoeff ℂ d)
```

(`VOA/Moonshine/InvFormFock.lean`.)

From the mathematics to the Lean statement

`FockT r` is the polynomial ring $\mathbb{C}[X_{(n,i)}]$, i.e. `MvPolynomial (ℕ × Fin r) ℂ` (Chapter 34); a monomial is a finitely supported exponent function `d : (ℕ × Fin r) →₀ ℕ`, and `d.prod f` is $\prod_{v\in\operatorname{supp} d} f(v,d_v)$. `lcoeff ℂ d` is the linear functional "coefficient of X^d". Unwinding `Finsupp.lsum` and `smulRight`: for $p=\sum_d p_d X^d$, $F(p,q)=\sum_d p_d\,\mathtt{fockWt}(d)\,q_d$. That is Definition 37.28 exactly. Note the minus sign in `cVar`: this is the *negative* form, deliberately.

Physical meaning

The Fock form is the two-point function of the free twisted bosons. Its normalisation $F(X_v p,q)=c_v F(p,\partial_v q)$ with $c_v=-(n+\frac12)$ is the algebraic form of the oscillator algebra with the BPZ-reflection rule $h(m)^t=-h(-m)$ of a weight-one current. It differs in sign from the Hermitian form of a unitary theory because the bilinear form is adapted to the linear (not antilinear) conjugation, so the Zamolodchikov-type metric is indefinite in these conventions.

Theorem 37.29 (Basic properties of F). *F is symmetric; $F(X_v p,q)=c_v F(p,\partial_v q)$; and the twisted oscillators are anti-adjoint, $F(h_i(k/2)p,q)=-F(p,h_i(-k/2)q)$ for every $k\in\mathbb{Z}$.*

```
theorem fockForm_symm (p q : FockT r) : fockForm r p q = fockForm r q p

theorem fockForm_X_mul (v : ℕ × Fin r) (p q : FockT r) :
    fockForm r (X v * p) q = cVar v * fockForm r p (pderiv v q)

theorem fockForm_modeT (i : Fin r) (k : ℤ) (p q : FockT r) :
    fockForm r (modeT r i k p) q = -fockForm r p (modeT r i (-k) q)
```

From the mathematics to the Lean statement

`X v` is the variable X_v, `pderiv v` is $\partial/\partial X_v$. In `fockForm_modeT` the integer k encodes the mode $k/2$; for odd $k<0$, `modeT r i k` is multiplication by $X_{((-k-1)/2,i)}$, for odd $k>0$ it is $\frac{k}{2}\partial_{((k-1)/2,i)}$, and for even k both sides are 0 (the junk value 0 of even modes makes the statement true but empty there). No hypotheses. This is (37.14).

Physical meaning

These are the standard oscillator identities for a free boson: creation operators are adjoint to annihilation operators up to the sign fixed by the BPZ conjugate of the current; symmetry of the two-point function is the statement that there is no preferred ordering of the two states in the metric.

Proof. Symmetry is visible from the diagonal formula. For the second identity it suffices to take $p=X^d$, $q=X^e$: both sides vanish unless $e=d+\mathbf{e}_v$, and then the left side is $\mathtt{fockWt}(d+\mathbf{e}_v)=c_v(d_v+1)\mathtt{fockWt}(d)$ while $\partial_v X^e=(d_v+1)X^d$ gives the same on the right. The oscillator identity for a creation mode $k=-(2n+1)$ is the second identity together with $h_i(n+\frac12)=(n+\frac12)\partial$: $F(Xp,q)=-(n+\frac12)F(p,\partial q)=-F(p,h_i(n+\frac12)q)$; the annihilation case follows by symmetry of F. □

37.7.2 The dressing is self-adjoint up to inversion

The twisted vertex operator of e^α (Chapter 36) has the form $Y^T(e^\alpha,z)=2^{-\langle\alpha,\alpha\rangle}z^{-\langle\alpha,\alpha\rangle/2}E^-(-\alpha,z)E^+(-\alpha,z)\otimes e_\alpha$, where $E^\pm$ are exponentials of the creation/annihilation oscillators. The library stores the coeffi-

cients of the dressing $E^-(-v,w)E^+(-v,w)$ as $\mathtt{DD}\,v\,a$ (the coefficient of w^a; Chapter 36). Invariance of F under these vertex operators needs the transposition rule for DD.

Theorem 37.30 (Transpose of the dressing). *For every $v \in \mathbb{C}^r$, $a \in \mathbb{Z}$ and $y, y' \in S[\theta]$: $F(\mathtt{DD}\,v\,a\,y,\ y') = F(y,\ \mathtt{DD}\,v\,(-a)\,y')$. Equivalently, the transpose of $E^-(-v,w)E^+(-v,w)$ with respect to F is $E^-(-v,w^{-1})E^+(-v,w^{-1})$ (no sign and no $v \mapsto -v$).*

File `VOA/Moonshine/InvFormFock.lean`.

```
theorem fockForm_DD (v : Fin r → ℂ) (a : ℤ) (y y' : FockT r) :
    fockForm r (DD v a y) y' = fockForm r y (DD v (-a) y')
```

From the mathematics to the Lean statement

`DD v a` is the endomorphism $\sum_{p-q=a} E^-_p(-v)E^+_q(-v)$ of $S[\theta]$ (Chapter 36, `noncomputable def DD (v : Fin r → ℂ) (a : ℤ) : End ℂ (FockT r)`). The vector v is arbitrary complex; in the application v is the coordinate vector of a lattice vector α. No hypotheses. Same as the textbook transposition rule.

Physical meaning

The coefficients $E^-(-v,w)E^+(-v,w)$ are the normal-ordered exponential of oscillators in the vertex operator $e^{i\alpha\cdot X}$ of the lattice field. The theorem says that its transpose under the Fock metric is the same exponential with $w \to w^{-1}$, which is the BPZ conjugation of the vertex operator $e^{i\alpha X}$ with itself (the charge not flipped: the sign is absorbed into the form). It is the free-boson computation that makes the lattice fields satisfy the reflection rule at the level of the twisted Fock space. A heuristic check: the reflected exponential $e^{i\alpha X(1/w)}$ has the same oscillator content with the $E^\pm$ roles exchanged.

Proof on paper. Write $\Phi_a = \mathtt{DD}\,v\,a$. Two facts determine Φ_a: its value on the vacuum, $\Phi_a\mathbf{1} = E^-_a(-v)\mathbf{1}$, whose constant term is $\delta_{a,0}$; and its commutator with oscillators, $[h_i(K/2), \Phi_a] = v_i\,\Phi_{a-K}$ for odd K (because $E^\pm(-v,w)$ are exponentials of oscillators with coefficients $\propto v_i w^{\mp K}$). Now prove the identity by induction on the degree of y, then of y'. If $y = \mathbf{1}$, write y' as a polynomial; $F(\Phi_a\mathbf{1}, X_v y'')$ is moved by (37.14) to an annihilator acting on $\Phi_a\mathbf{1}$, which the commutator rule converts into $\Phi_{a'}\mathbf{1}$ terms of lower degree; the base case is the constant-term identity $\delta_{a,0} = \delta_{-a,0}$. If $y = X_v y_0$, move X_v across Φ_a with the commutator rule (producing Φ_{a+K}), then across F with (37.14) (producing the sign -1 and $h(-K/2)$), and apply the induction hypothesis; the same two moves on the right side, with $a \mapsto -a$ and $K \mapsto -K$, give the same terms. The signs work out precisely because the form is the negative one: the minus sign of (37.14) compensates the change of sign of K in the commutator rule. □

Trap / dead end

The positive Fock form is wrong here. With the positive form ($c_v = +(n + \frac{1}{2})$) the same argument transposes $\mathtt{DD}\,v\,a$ to $\mathtt{DD}\,(-v)\,(-a)$, so the vertex operator of e^α would be transposed to that of $e^{-\alpha}$ and the form would not be FHL-invariant in the required sense. The recorded cross-check (file docstring of `VOA/Moonshine/InvFormFock.lean`; scripts `dd.py`, `dd2.py` in `scripts/moonshine/numerics/`): a sympy computation in rank 2 with three oscillator levels and $v = (\frac{3}{2}, -\frac{2}{3})$ found $F(\mathtt{DD}\,a\,y, y') = F(y, \mathtt{DD}\,(-a)\,y')$ on all test pairs for $|a| \le 4$ with the negative form, and failure with the positive form. This is numerical evidence recorded by the project, not a proof; the scripts were *not* re-run for this chapter (sympy is not installed in the environment used). The proof is Theorem 37.30.

What the machine verified

`fockForm_symm`, `fockForm_X_mul`, `fockForm_modeT`, `fockForm_DD`: proved, no hypotheses. Axioms of `fockForm_DD`: `[propext, Classical.choice, Quot.sound]` (rechecked).

37.8 The form on $S[\theta]\otimes T$ and on $(V_\Lambda^T)^+$

37.8.1 The product form

Definition 37.31 (Product form). For a bilinear form B_T on a space T: $B_{\mathrm{tw}}(p\otimes t, p'\otimes t') = F(p,p')\,B_T(t,t')$ on $S[\theta]\otimes T$.

```
noncomputable def twForm (r : ℕ) (BT : LinearMap.BilinForm ℂ Tm) :
    LinearMap.BilinForm ℂ (FockT r ⊗[ℂ] Tm) :=
  (fockForm r).tmul BT
```

(`VOA/Moonshine/InvFormTwisted.lean`.) `LinearMap.BilinForm.tmul` is Mathlib's tensor product of bilinear forms; on pure tensors it is the product of the values (`twForm_tmul`, proved by `rfl`).

Physical meaning

The product form $F\otimes B_T$ is the two-point function of the twisted sector as a tensor product of its oscillator part (the free bosons in the twisted sector) and the zero-mode space T of the twist-field ground states (2^{12}-dimensional, labelling the fixed points). The Fock factor carries the oscillator two-point function and the factor B_T the two-point function of the twist fields themselves.

Theorem 37.32 (Adjoints on $S[\theta]\otimes T$). (i) $B_{\mathrm{tw}}(h_a(k/2)x,y) = -B_{\mathrm{tw}}(x,h_a(-k/2)y)$. (ii) *Suppose $g,g'\in\mathrm{End}(T)$ and $s\in\mathbb{C}$ satisfy $B_T(gt,t') = s\,B_T(t,g't')$. For the generic twisted exponential field $Y_g(k) = \kappa\,\mathtt{DD}\,v\,(-k-2+c_0)\otimes g$, $B_{\mathrm{tw}}(Y_g(k)x,y) = s\,B_{\mathrm{tw}}(x,Y_{g'}(2c_0-k-4)y)$.* (iii) *In particular, for an even lattice L and a form on its T with $B_T(e_\alpha t,t') = (-1)^{\langle\alpha,\alpha\rangle/2}B_T(t,e_\alpha t')$, the twisted vertex operator $Y^T(e^\alpha)_{(k/2)}$ satisfies*

$$B_{\mathrm{tw}}\big(Y^T(e^\alpha)_{(k/2)}x,y\big) = (-1)^{\langle\alpha,\alpha\rangle/2}\,B_{\mathrm{tw}}\big(x,Y^T(e^\alpha)_{((2\langle\alpha,\alpha\rangle-k-4)/2)}y\big). \tag{37.15}$$

```

From the mathematics to the Lean statement

Symbols. `modeTT a k` is $h_a(k/2)\otimes\mathrm{id}_T$. `YTg v c0 κ g k` is $\kappa\cdot$`DD` $v\,(-k-2+c_0)\otimes g$ (Chapter 36); `YTL L hEven hU α k` is the instance v = coordinates of α, $c_0=\langle\alpha,\alpha\rangle$, $\kappa=2^{-\langle\alpha,\alpha\rangle}$, $g=e_\alpha$, and represents the twisted mode $Y^T(e^\alpha)_{(k/2)}$ on `MT L hEven hU` $= S[\theta]\otimes T$. `eT ... α` is the operator e_α on T (Chapter 34). `L.form α α` is $\langle\alpha,\alpha\rangle$, an even integer for an even lattice, so `L.form α α / 2` is the exact integer $\langle\alpha,\alpha\rangle/2$ (integer division with zero remainder).
Hypotheses. In (ii) the hypothesis `hg` is the T-side adjointness; in (iii) it is `hT`, the "T-law" with sign $(-1)^{\langle\alpha,\alpha\rangle/2}$, and the lattice hypotheses `hEven` (even), `hU` (unimodular Gram determinant) needed to have T at all. `hT` is discharged for the Leech lattice by `TForm_eT` (Chapter 34).
Comparison with FHL. e^α is primary of weight $N=\langle\alpha,\alpha\rangle/2$, so by Example 37.21(iii) its mode m must be transposed to $(-1)^N$ times its mode $2N-m-2$. With $m=k/2$: $2N-\frac{k}{2}-2=\frac{2\langle\alpha,\alpha\rangle-k-4}{2}$, which is the index in (37.15). So (iii) is exactly FHL invariance of B_{tw} at e^α, at the level of the full twisted module (all half-integral modes).

Physical meaning

This theorem is the BPZ reflection rule for the lattice vertex operators e^α acting on the twisted sector: the field e^α of weight $N=\langle\alpha,\alpha\rangle/2$ transposes to $(-1)^N$ times its own mode of index $2N-n-2$. The sign on T is the sign $(-1)^{L_0}$ of the BPZ conjugation, and it is forced by consistency of the two-point function of twist fields (heuristically, the commutation of fields at the fixed points). For the frame constructions the oscillator and cocycle parts each contribute the expected sign.

Proof. (i) is Theorem 37.29 tensored with the identity. For (ii), $B_{\mathrm{tw}}((A\otimes g)x,y)=B_{\mathrm{tw}}(x,(A^t\otimes g^t)y)$ on pure tensors, and by Theorem 37.30 the transpose of `DD` $v\,(-k-2+c_0)$ is `DD` $v\,(k+2-c_0)$, which equals `DD` $v\,(-k'-2+c_0)$ for $k'=2c_0-k-4$. (iii) is (ii) with $s=(-1)^{\langle\alpha,\alpha\rangle/2}$, $g=g'=e_\alpha$. □

Trap / dead end

The sign on T is forced. The T-form must satisfy the law with the sign $(-1)^{\langle\alpha,\alpha\rangle/2}$ (the $(-1)^{L_0}$ of the contragredient), and the Fock part contributes no sign. This was a *finding*: it fixed which of the possible forms on T (Chapter 34) is the compatible one, with no extra twist by e_γ needed. In the numerical E_8 model of the orbifold (`Notes/M8hRoute.md`, §1a; scripts `orb.py`, `tt.py`), replacing this sign by the "group" sign $\varepsilon(\alpha,\alpha)$ makes the twisted×twisted relation (4.23) fail with relative residual 1.7–2.0, while the chosen conventions satisfy it to 3.7×10^{-14}. Numerical evidence, not proof.

37.8.2 Nondegeneracy on graded pieces

Write $S[\theta]_d$ for the span of monomials of doubled degree $d=\sum_v(2n_v+1)d_v$ and `twGrading` $r\,T\,d=S[\theta]_d\otimes T$ (Chapter 33).

Theorem 37.33 (Nondegeneracy and orthogonality on $S[\theta]_d\otimes T$). *If B_T is nondegenerate, then for every d and every nonzero $x\in S[\theta]_d\otimes T$ there is a pure tensor $X^m\otimes t'\in S[\theta]_d\otimes T$ with $B_{\mathrm{tw}}(x,X^m\otimes t')\neq0$. For any B_T, distinct graded pieces are orthogonal.*

File `VOA/Moonshine/InvFormTwisted.lean`.

```
theorem twForm_nondegenerate_twGrading {BT : LinearMap.BilinForm ℂ Tm} (hBT :
↪  BT.Nondegenerate)
    {d : ℕ} {x : FockT r ⊗[ℂ] Tm} (hx : x ∈ TwistedSector.twGrading r Tm d) (hx0 : x ≠ 0) :
    ∃ m : (ℕ × Fin r) →₀ ℕ, ∃ t' : Tm, monomial m 1 ⊗ₜ t' ∈ TwistedSector.twGrading r Tm d
     ↪  ∧
```

```
      twForm r BT x (monomial m 1 ⊗ₜ t') ≠ 0

theorem twForm_orth_twGrading (BT : LinearMap.BilinForm ℂ Tm) {d d' : ℕ} (hdd : d ≠ d')
    {x y : FockT r ⊗[ℂ] Tm} (hx : x ∈ TwistedSector.twGrading r Tm d)
    (hy : y ∈ TwistedSector.twGrading r Tm d') : twForm r BT x y = 0
```

From the mathematics to the Lean statement

`BT.Nondegenerate` is Mathlib's nondegeneracy (trivial left and right radical); `monomial m 1` is X^m. Conclusion of the first statement is slightly stronger than nondegeneracy (the partner can be taken to be a pure tensor in the same graded piece).

Physical meaning

Nondegeneracy of a two-point function means that no state is null: every nonzero state has a nonvanishing overlap with some state at the same energy. Here this holds on each graded piece of the twisted Fock space because the Fock metric is nonzero on every monomial and B_T is nondegenerate. Orthogonality is the selection rule: states of different energy have zero two-point function.

Proof. Expand $x = \sum_m X^m \otimes t_m$ in the monomial basis; pick m with $t_m \neq 0$, then t' with $B_T(t_m, t') \neq 0$. Monomials are F-orthogonal, so $B_{\mathrm{tw}}(x, X^m \otimes t') = \mathtt{fockWt}(m)\, B_T(t_m, t')$, and $\mathtt{fockWt}(m) \neq 0$ since every $c_v = -(n + \frac{1}{2}) \neq 0$. Orthogonality: monomials of different degree are F-orthogonal. □

37.8.3 The form on $(V_\Lambda^T)^+$

Definition 37.34. $B_{\mathrm{tw}} := \mathtt{leechTwForm} = F \otimes \mathtt{TForm}$ on $S[\theta] \otimes T$ (rank 24), and $B_T := \mathtt{TPForm}$ its restriction to $(V_\Lambda^T)^+$.

```
noncomputable def leechTwForm : LinearMap.BilinForm ℂ Tw := twForm 24 TForm

noncomputable def TPForm : LinearMap.BilinForm ℂ TP :=
  leechTwForm.compl₁₂ TP.subtype TP.subtype
```

(`VOA/Moonshine/InvFormTP.lean`.) `compl₁₂ TP.subtype TP.subtype` precomposes both arguments with the inclusion $(V_\Lambda^T)^+ \hookrightarrow S[\theta] \otimes T$, i.e. restricts. `TForm` is the symmetric nondegenerate form on the Leech T with $\mathtt{TForm}(e_\alpha t, t') = (-1)^{\langle\alpha,\alpha\rangle/2}\mathtt{TForm}(t, e_\alpha t')$ (`TForm_symm`, `TForm_nondegenerate`, `TForm_eT`; Chapter 34).

Physical meaning

Definition of the metric on the physical twisted sector $(V_\Lambda^T)^+$ (the θ-invariant states), as the restriction of the twisted Fock form tensor the form on the fixed-point space T. It is the Zamolodchikov metric of the twist-field sector.

Theorem 37.35 (Symmetry, nondegeneracy, orthogonality of B_T). *B_T is symmetric; for every $\alpha \in \mathbb{C}$ and nonzero $x \in ((V_\Lambda^T)^+)_\alpha$ there is $y \in ((V_\Lambda^T)^+)_\alpha$ with $B_T(x, y) \neq 0$; and distinct weight spaces of $(V_\Lambda^T)^+$ are B_T-orthogonal.*

```
theorem TPForm_symm (x y : TP) : TPForm x y = TPForm y x := leechTwForm_symm _ _

theorem TPForm_nondegenerate (α : ℂ) (x : TP) (hx : x ∈ plusModule.weight α) (hx0 : x ≠ 0)
 ↪  :
    ∃ y ∈ plusModule.weight α, TPForm x y ≠ 0

theorem TPForm_weightOrth : WeightOrth plusModule TPForm
```

From the mathematics to the Lean statement

`plusModule.weight α` is the weight-α space of the V_Λ^+-module $(V_\Lambda^T)^+$ (Chapter 36). Nondegeneracy is stated weight space by weight space, which is the form needed for the Riesz representation below (a form on an infinite-dimensional space can have zero radical without inducing isomorphisms $M_\alpha \cong M_\alpha^*$; weightwise nondegeneracy is the right notion). `WeightOrth` is Definition 37.22. No hypotheses.

Physical meaning

The twisted sector has no null states: the form is nondegenerate at each conformal weight, and different weights are orthogonal, so B_T is a genuine Zamolodchikov metric on $(V_\Lambda^T)^+$ with symmetric two-point functions. Weight 2 is the lowest level, spanned by $h_i(-\frac{1}{2})\mathbf{1} \otimes t$: the 24 excitations of the ground state at each of the 2^{12} fixed points, matching the 98304-dimensional lowest weight space.

Proof. The weights of $(V_\Lambda^T)^+$ are the integers $k+2$, $k \geq 0$, and $((V_\Lambda^T)^+)_{k+2} = S[\theta]_{2k+1} \otimes T$: the twisted weight of $X^d \otimes t$ is $\frac{24}{16} + \frac{d}{2} = \frac{3}{2} + \frac{d}{2}$, an integer exactly when d is odd; and a monomial of odd doubled degree has an odd number of factors (each factor contributes an odd number $2n+1$), hence is fixed by $\theta = (-1)^{\#\text{factors}} \otimes (-1)_T$. So the whole graded piece of odd degree lies in $(V_\Lambda^T)^+$, and Theorem 37.33 applies inside it. Orthogonality is the second part of the same theorem. □

Example 37.36. On the lowest weight space $((V_\Lambda^T)^+)_2 = S[\theta]_1 \otimes T$, spanned by $h_i(-\frac{1}{2})\mathbf{1} \otimes t$ ($24 \cdot 4096 = 98304$ vectors for a basis of T), $B_T(h_i(-\frac{1}{2}) \otimes t,\ h_j(-\frac{1}{2}) \otimes t') = -\frac{1}{2}\,\delta_{ij}\,\mathtt{TForm}(t, t')$.

What the machine verified

`TPForm_symm`, `TPForm_nondegenerate`, `TPForm_weightOrth`: unconditional. Axioms of `TPForm_nondegenerate`: `[propext, Classical.choice, Quot.sound]` (rechecked).

37.8.4 Invariance of B_T under all of V_Λ^+

Theorem 37.37 (Invariance at the generators). *For every $\beta \in \Lambda$, B_T is FHL-invariant at $x_\beta = e^\beta + e^{-\beta} \in V_\Lambda^+$, a state of weight $\langle\beta,\beta\rangle/2$. Explicitly $B_T(x_{\beta(n)}a, b) = (-1)^{\langle\beta,\beta\rangle/2} B_T(a, x_{\beta(\langle\beta,\beta\rangle-n-2)}b)$. Consequently the set `interSub plusModule TPForm` of Definition 37.25 contains $\mathbf{1}$, is closed under all products, and contains every x_β.*

```
theorem TPForm_invariant_frameX0 (β : leech.carrier) (n : ℤ) (x y : TP) :
    TPForm (mode (plusModule.YM (frameX0P β)) n x) y
      = (-1 : ℂ) ^ (leech.form β β / 2) *
          TPForm x (mode (plusModule.YM (frameX0P β)) (leech.form β β - n - 2) y)

theorem TPForm_fhlInv_frameX0P (β : leech.carrier) :
    FHLInv plusModule TPForm (LatGen.halfNorm leech β) (frameX0P β)

theorem interSub_TPForm :
    leechVOAPlus.vacuum ∈ interSub plusModule TPForm ∧
    (∀ u ∈ interSub plusModule TPForm, ∀ v ∈ interSub plusModule TPForm, ∀ n : ℤ,
      leechVOAPlus.smul u n v ∈ interSub plusModule TPForm) ∧
    ∀ β : leech.carrier, frameX0P β ∈ interSub plusModule TPForm
```

From the mathematics to the Lean statement

`frameXOP β` is $e^\beta + e^{-\beta}$ as an element of V_Λ^+ (Chapter 32); `LatGen.halfNorm leech β` $= \langle\beta,\beta\rangle/2$ is its weight. The explicit form uses the integral modes of `plusModule`; it is the twisted identity (37.15) at even $k = 2n$, since $(2\langle\beta,\beta\rangle - 2n - 4)/2 = \langle\beta,\beta\rangle - n - 2$. To pass to `FHLInv` one needs $L_1 x_\beta = 0$, so that only the $j = 0$ term of (37.13) survives; this is the lemma `L_one_latChargeGen` ($L_1 e^\beta = 0$ in every lattice VOA: $L_1 e^\beta$ would have charge β and weight $\frac{1}{2}\langle\beta,\beta\rangle - 1$, below the minimal weight of the charge-β sector). No hypotheses.

Physical meaning

At the generators $x_\beta = e^\beta + e^{-\beta}$, the BPZ reflection rule for the lattice currents of the orbifold: the two-point function in the twisted sector is compatible with the conjugation of these fields, with the sign $(-1)^{\langle\beta,\beta\rangle/2}$. By the generator-reduction principle this will give compatibility with the whole chiral algebra V_Λ^+.

Theorem 37.38 (Full invariance). *B_T is FHL-invariant at every homogeneous $u \in V_\Lambda^+$. The library proves this first conditionally on generation, then unconditionally.*

File `VOA/Moonshine/InvFormTP.lean`.

```
theorem TPForm_fhlInv_of_generates
    (hgen : ∀ S : Submodule ℂ VPlus, leechVOAPlus.vacuum ∈ S →
      (∀ u ∈ S, ∀ v ∈ S, ∀ n : ℤ, leechVOAPlus.smul u n v ∈ S) →
      (∀ β : leech.carrier, frameXOP β ∈ S) → S = ⊤)
    {wt : ℤ} {u : VPlus} (hu : u ∈ leechVOAPlus.grading wt) :
    FHLInv plusModule TPForm wt u

theorem TPForm_fhlInv {wt : ℤ} {u : VPlus} (hu : u ∈ leechVOAPlus.grading wt) :
    InvForm.FHLInv plusModule InvForm.TPForm wt u :=
  InvForm.TPForm_fhlInv_of_generates leechPlus_generated hu
```

From the mathematics to the Lean statement

The residual and its discharge. `hgen` says that V_Λ^+ is generated as a vertex algebra by the states $e^\beta + e^{-\beta}$. When the form part of this milestone was written, `hgen` was an open named residual. It was closed by `leechPlus_generated` (`VOA/Moonshine/Generation.lean`, proved in Chapter 32), and the unconditional `TPForm_fhlInv` (namespace `VOA.Moonshine`, file `VOA/Moonshine/Generation.lean`) is the one-line composition shown. The hypothesis `hu` restricts to homogeneous u, as `FHLInv` requires. Same as the textbook statement "B_T is an invariant form on the V_Λ^+-module $(V_\Lambda^T)^+$".

Physical meaning

The twisted sector's metric B_T is invariant under all fields of the orbifold chiral algebra: it is a legitimate two-point function of the sector, with $(V_\Lambda^T)^+$ self-dual (isomorphic to its contragredient, i.e. its own conjugate sector) as the self-conjugate twist-field sector must be. This is what allows the adjoint field $\overline{W}$ to be defined at all.

Proof. Theorem 37.37, Theorem 37.27 and the generation theorem of Chapter 32. □

Remark 37.39. At the twisted level the library also proves invariance under the Heisenberg vectors, $B_{\mathrm{tw}}(h_b(k/2)x, y) = -B_{\mathrm{tw}}(x, h_b(-k/2)y)$ (`leechTwForm_YM_hgen`). This is not used for $(V_\Lambda^T)^+$, because $h_b(-1)\mathbf{1}$ is θ-odd and so is not in V_Λ^+.

What the machine verified

`TPForm_fhlInv_frameX0P`, `interSub_TPForm`: unconditional. `TPForm_fhlInv_of_generates`: conditional on `hgen` (by design). `TPForm_fhlInv`: unconditional. Axioms of `TPForm_fhlInv`: `[propext, Classical.choice, Quot.sound]` (rechecked).

37.9 Graded Riesz representation

Equation (37.4) prescribes the *functional* $\varphi \mapsto B_V(\overline{W}(t)_{(n)}a, \varphi)$. To obtain the *vector* $\overline{W}(t)_{(n)}a \in V_\Lambda^+$ we need a Riesz representation: every suitable functional on V_Λ^+ is $B_V(x, \cdot)$ for a unique x. On an infinite-dimensional space this is false in general (the algebraic dual is much bigger than the space). It is true for functionals that live on finitely many weight spaces, provided the form is nondegenerate on each weight space and the weight spaces are orthogonal. This section proves that, in Lean, for an arbitrary vertex operator algebra. Namespace `VOA.Moonshine.SkewAdjoint`, file `VOA/Moonshine/WbarRiesz.lean`.

Definition 37.40 (Graded nondegeneracy and orthogonality). For a VOA $\mathcal{V} = \bigoplus_k \mathcal{V}_k$ and a bilinear form B on it: B is *graded nondegenerate* if the restriction of B to $\mathcal{V}_k \times \mathcal{V}_k$ is nondegenerate for every k; *graded orthogonal* if $B(\mathcal{V}_m, \mathcal{V}_n) = 0$ for $m \neq n$.

```
noncomputable def gradForm (W : VertexOperatorAlgebra 𝒱) (B : LinearMap.BilinForm ℂ 𝒱) (k :
↪  ℤ) :
    LinearMap.BilinForm ℂ (W.grading k) :=
  B.compl₁₂ (W.grading k).subtype (W.grading k).subtype

def GradedNondeg (W : VertexOperatorAlgebra 𝒱) (B : LinearMap.BilinForm ℂ 𝒱) : Prop :=
  ∀ k : ℤ, (gradForm W B k).Nondegenerate

def GradedOrth (W : VertexOperatorAlgebra 𝒱) (B : LinearMap.BilinForm ℂ 𝒱) : Prop :=
  ∀ m n : ℤ, m ≠ n → ∀ x ∈ W.grading m, ∀ y ∈ W.grading n, B x y = 0
```

Physical meaning

Graded nondegeneracy is the absence of null fields level by level: every state of the VOA at a given weight has a nonvanishing overlap with some other state at that weight, so the Zamolodchikov metric can be inverted. Graded orthogonality is the selection rule that fields of different conformal weight have vanishing two-point functions. These are what a simple (no null states) chiral algebra gives.

Definition 37.41 (The Riesz vector). For a functional f on $\mathcal{V}$ let $f_k = f|_{\mathcal{V}_k}$. Its *graded support* is $\{k : f_k \neq 0\}$. Let $\mathrm{rk}_k : \mathcal{V}_k^* \to \mathcal{V}_k \subseteq \mathcal{V}$ be the inverse of $x \mapsto B(x, \cdot)|_{\mathcal{V}_k}$ when $B|_{\mathcal{V}_k}$ is nondegenerate (and 0 otherwise). The Riesz vector is $\mathrm{riesz}(f) = \sum_k \mathrm{rk}_k(f_k)$.

```
noncomputable def rk (W : VertexOperatorAlgebra 𝒱) (B : LinearMap.BilinForm ℂ 𝒱) (k : ℤ) :
    Dual ℂ (W.grading k) →ₗ[ℂ] 𝒱 :=
  haveI := W.finrank k
  if h : (gradForm W B k).Nondegenerate then
    (W.grading k).subtype ∘ₗ ((gradForm W B k).toDual h).symm.toLinearMap
  else 0

noncomputable def restr (W : VertexOperatorAlgebra 𝒱) (k : ℤ) (f : 𝒱 →ₗ[ℂ] ℂ) :

    (f : V →ₗ[ℂ] ℂ) : V :=
  ∑ᶠ k : ℤ, rk W B k (restr W k f)
```

From the mathematics to the Lean statement

`W.finrank k` is the VOA axiom that $\mathcal{V}_k$ is finite-dimensional; it is needed because Mathlib's `toDual` (the isomorphism $V \cong V^*$ of a nondegenerate form) exists only in finite dimension. The "else 0" branch of `rk` is a junk value never used under `GradedNondeg`. The $\sum^{\mathrm{f}}$ is a finite sum when the graded support is finite, and `riesz` is only ever used on such functionals.

Physical meaning

The Riesz vector is the dual construction: given a linear functional (an out-state, i.e. a bra) on finitely many levels, it produces the in-state with that overlap, i.e. it raises an index with the inverse Zamolodchikov metric. It is how an out-state obtained by contraction with a three-point function is converted into an ordinary vertex-operator output.

Theorem 37.42 (Riesz property and separation). *Assume B is graded orthogonal and graded nondegenerate. If f has finite graded support then $B(\mathrm{riesz}(f), \varphi) = f(\varphi)$ for all φ. If $B(x, \varphi) = B(y, \varphi)$ for all φ, then $x = y$.*

```
theorem riesz_spec {B : LinearMap.BilinForm ℂ V} (hO : GradedOrth W B) (hnd : GradedNondeg
↪  W B)
    {f : V →ₗ[ℂ] ℂ} (hf : (gsupp W f).Finite) (φ : V) : B (riesz W B f) φ = f φ

theorem eq_of_form {B : LinearMap.BilinForm ℂ V} (hO : GradedOrth W B) (hnd : GradedNondeg
↪  W B)
    {x y : V} (h : ∀ φ, B x φ = B y φ) : x = y
```

From the mathematics to the Lean statement

Three hypotheses, all displayed: orthogonality, weightwise nondegeneracy, finite support of f. Each is necessary: without finite support the sum need not exist; without orthogonality $B(\mathrm{rk}_k(f_k), \varphi)$ would pick up contributions from other weight spaces; without nondegeneracy rk_k does not exist. Same as the textbook statement.

Physical meaning

Raising and lowering indices with the inverse metric: when the metric is nondegenerate on each level, a bra determines a unique ket, and a ket is determined by its overlaps with all states (no null directions).

Proof. For $\varphi \in \mathcal{V}_k$, orthogonality kills every summand except $\mathrm{rk}_k(f_k)$, and $B(\mathrm{rk}_k(f_k), \varphi) = f_k(\varphi)$ by definition of the inverse of $x \mapsto B(x, \cdot)$. Both sides are linear in φ and $\mathcal{V} = \bigoplus \mathcal{V}_k$. Separation: if $B(x - y, \cdot) = 0$, each homogeneous component of $x - y$ pairs to zero with its own weight space (orthogonality), hence vanishes (nondegeneracy). □

What the machine verified

Unconditional apart from the displayed hypotheses. Axioms of `riesz_spec`: `[propext, Classical.choice, Quot.sound]` (rechecked).

37.10 The definition of $\overline{W}$

Throughout this section $\mathcal{V}$ is a VOA, N an ordinary $\mathcal{V}$-module on M, B_V a form on $\mathcal{V}$, B_M a form on M, and `hO : WeightOrth N BM`. These are the section `variables` of `VOA/Moonshine/WbarDef.lean` (namespace `VOA.Moonshine.SkewAdjoint`), so they appear as leading arguments `BV N BM hO` of the definitions below.

37.10.1 The dagger

Expanding the right side of (37.4) exactly as we expanded (37.11), for $t \in M_w$ with $w \in \mathbb{Z}$:

$$B_V\big(\overline{W}(t)_{(n)}a,\varphi\big) = B_M\big(a, W^{\dagger}(t)_{(n)}\varphi\big), \qquad W^{\dagger}(t)_{(n)} := (-1)^w \sum_{j\ge 0} \frac{1}{j!}\, W(L_1^j t)_{(2w-n-2-j)}. \tag{37.16}$$

The *dagger* $W^{\dagger}(t)_{(n)} : \mathcal{V} \to M$ involves only W and $L_1 = \omega_{(2)}$ on M. The j-sum is finite: $L_1^j t$ has weight $w - j$ and vanishes once $w - j$ is below the lowest weight of M.

Definition 37.43 (L_1, a lower bound, the dagger). $L_1^M = \omega^M_{(2)}$; `lowB N` is an integer below which all weight spaces of M vanish; `dagBound N w` $= (w - \texttt{lowB})_+ + 1$; `dagHom N n w` is the right side of (37.16) with $j <$ `dagBound`; and `Wdag N n` applies `dagHom` with w the weight to each integral-weight component of t and 0 to components of non-integral weight.

```
noncomputable def Lp1 (N : OrdVModule W M) : End ℂ M := mode (N.YM W.conformalVector) 2

noncomputable def lowB (N : OrdVModule W M) : ℤ := ⌈N.boundedBelow.choose⌉

noncomputable def dagBound (N : OrdVModule W M) (w : ℤ) : ℕ := (w - lowB N).toNat + 1

noncomputable def dagHom (N : OrdVModule W M) (n w : ℤ) : M →ₗ[ℂ] 𝒱 →ₗ[ℂ] M :=
  (-1 : ℂ) ^ w • ∑ j ∈ Finset.range (dagBound N w),
    ((j.factorial : ℂ)⁻¹) • (wBil N.toWeakModule (2 * w - n - 2 - j)) ∘ₗ (Lp1 N ^ j)

noncomputable def dagFam (N : OrdVModule W M) (n : ℤ) (α : ℂ) :
    N.weight α →ₗ[ℂ] 𝒱 →ₗ[ℂ] M :=
  if h : ∃ w : ℤ, (w : ℂ) = α then (dagHom N n (Classical.choose h)) ∘ₗ (N.weight
   ↪ α).subtype
  else 0

  letI := DirectSum.IsInternal.chooseDecomposition N.weight N.isInternal
  (DFinsupp.lsum ℂ (dagFam N n)).comp (DirectSum.decomposeLinearEquiv N.weight).toLinearMap
```

From the mathematics to the Lean statement

Decoding. `N.boundedBelow.choose` is a real B with $\mathrm{Re}\,\alpha \ge B$ on nonzero weight spaces; $\lceil B\rceil$ is `lowB`. `wBil N.toWeakModule q` is $(s,\varphi) \mapsto W(s)_{(q)}\varphi$ (Section 37.4); composing with L_1^j gives $W(L_1^j t)_{(q)}$. `Wdag` decomposes t into weight components (`decomposeLinearEquiv`) and applies `dagFam` componentwise (`DFinsupp.lsum`).

Why the non-integral clause is harmless. The formula (37.16) needs $(-1)^w$, meaningful only for integral w. In the application (Leech) all weights of $(V_\Lambda^T)^+$ are integers, so the clause never fires. In general it makes `Wdag` linear in t by fiat.

Well-definedness. The lemma `Wdag_int_eq_sum` shows that on $t \in M_w$ the dagger equals the sum (37.16) with any bound past the vanishing of $L_1^j t$, so the choice of `dagBound` does not matter.

Physical meaning

The dagger is the BPZ conjugate of the field W: by the invariance rule, transposing $W(t,z)$ across the two-point function replaces t by its reflected state $e^{zL_1}(-z^{-2})^{L_0}t$ and z by $1/z$. It computes, in terms of the already-known W, the matrix elements of the twisted × twisted → untwisted field with a final untwisted state pulled to the other side of the pairing.

37.10.2 $\overline{W}$ as a Riesz vector

Definition 37.44 ($\overline{W}$). $\Phi_{n,t,a}(\varphi) = B_M(a, W^\dagger(t)_{(n)}\varphi)$, $\overline{W}(t)_{(n)}a = \mathrm{riesz}(\Phi_{n,t,a})$, and $\overline{W}(t,z) = \sum_n \overline{W}(t)_{(n)}z^{-n-1} \in \mathrm{Hom}(M, \mathcal{V})[[z^{\pm1}]]$.

```
noncomputable def Phi (N : OrdVModule W M) (BM : LinearMap.BilinForm ℂ M) (n : ℤ) (t a : M)
 ↪  :
    𝒱 →ₗ[ℂ] ℂ :=
  (BM a) ∘ₗ (Wdag N n t)

noncomputable def WbarMode (n : ℤ) (t : M) : M →ₗ[ℂ] 𝒱 where
  toFun a := riesz W BV (Phi N BM n t a)

noncomputable def Wbar (t : M) : FormalDist (M →ₗ[ℂ] 𝒱) :=
  fun k => WbarMode BV N BM hO (-k - 1) t

theorem mode_Wbar (t : M) (n : ℤ) : mode (Wbar BV N BM hO t) n = WbarMode BV N BM hO n t
```

From the mathematics to the Lean statement

`WbarMode BV N BM hO n t` is the linear map $a \mapsto \overline{W}(t)_{(n)}a$ (its linearity fields, which use `hO` through the finiteness of the graded support of Φ, are omitted). The definition itself needs *no* hypothesis on B_V; if B_V were degenerate it would still be defined, but the adjunction below would fail. **Could this be the trap $\overline{W} = 0$?** Not by definition alone: for instance with $B_V = 0$ every `rk` is the junk 0 and $\overline{W} = 0$. This is precisely why the adjunction (Theorem 37.45) carries the hypotheses on B_V, why the Leech instance needs the nondegeneracy theorem of Chapter 32, and why Theorem 37.57 is proved.

Physical meaning

The conjugate field $\overline{W}(t,z)\colon (V_\Lambda^T)^+ \to V_\Lambda^+$ is the operator "twist field × twist field → untwisted field": the OPE in which two twist fields collide and the branch cuts cancel to leave an ordinary field. It is defined as the adjoint of W under the two-point metrics, $\langle \overline{W}(t,z)a, \varphi\rangle = \langle a, W(t^*, z^{-1})\varphi\rangle$, which expresses the three-point coupling $\langle V^+|\overline{W}|T\rangle$ through the coupling $\langle T|W|V^+\rangle$ already constructed. Heuristically it is the same three-point function read as an OPE of two twist fields instead of an OPE of a twist field with an untwisted field. It is nontrivial that the twisted sector actually couples to itself; if $\overline{W} = 0$ the twist fields would be decoupled and the extension would be a square-zero extension of V_Λ^+.

Theorem 37.45 (The defining adjunction, DGM (4.3)). *If B_V is graded orthogonal and graded nondegenerate, then for all n, t, a, φ, $B_V(\overline{W}(t)_{(n)}a, \varphi) = B_M(a, W^\dagger(t)_{(n)}\varphi)$; explicitly, for $t \in M_w$ and any R with $L_1^j t = 0$ for $j \geq R$,*

$$B_V\big(\overline{W}(t)_{(n)}a, \varphi\big) = (-1)^w \sum_{j<R} \frac{1}{j!}\, B_M\big(a, W(L_1^j t)_{(2w-n-2-j)}\varphi\big).$$

The vector $\overline{W}(t)_{(n)}a$ is the unique vector with this property.

```

From the mathematics to the Lean statement

Hypotheses. `hVo`, `hVnd` on B_V (Definition 37.40); `hO` on B_M (section variable); for the explicit form, `ht` (t homogeneous of integral weight w) and `hR`. **Comparison.** The explicit form is the mode expansion of (37.4), derived in (37.16): it is DGM (4.3), including the sign $(-1)^w$. No invariance of B_V or B_M is assumed at this stage; invariance enters only in the commutator formula. The proof of `form_WbarMode` is the one-line term shown: the Riesz property applied to Φ, whose graded support is finite (a single weight, by the next theorem).

Physical meaning

This is the defining three-point relation: the adjoint exists exactly when the metric on V_Λ^+ has no null fields, and it is unique. The factor $(-1)^w$ and the sum over $L_1^j t$ are the BPZ conjugation of the field of t. Physically, the coupling of two twist fields to an untwisted field is uniquely determined by the coupling of a twist field to the untwisted sector and the metrics.

Theorem 37.46 (Grading and truncation of $\overline{W}$). *If $t \in M_w$ and $a \in M_b$ ($w, b \in \mathbb{Z}$) then $\overline{W}(t)_{(n)}a \in \mathcal{V}_{b+w-n-1}$. For all t, a, $\overline{W}(t)_{(n)}a = 0$ for $n \gg 0$; i.e. $\overline{W}(t,z)a \in \mathcal{V}((z))$.*

↪  0

theorem Wbar_trunc (t : M) : ∀ a : M, ∃ B : ℤ, ∀ k : ℤ, k < B → Wbar BV N BM hO t k a = 0
```

From the mathematics to the Lean statement

No hypothesis on B_V: these hold for the Riesz vector by construction. The weight $b+w-n-1$ is the usual weight of an intertwining operator's output (sum of the input weights minus $n+1$). `Wbar_trunc` is the same statement in terms of coefficients ($k = -n-1$).

Physical meaning

The selection rule for the three-point function: $\overline{W}(t)_{(n)}$ maps a state of weight b to weight $b + w - n - 1$, as for any chiral vertex operator, and the vanishing for large n is the finite pole order of the OPE in a sector with energy bounded below (the untwisted algebra has no negative weights).

Proof. By the weights of W (output of $W(s)_{(q)}\varphi$ has weight $\operatorname{wt} s + \operatorname{wt}\varphi - q - 1$), $W^{\dagger}(t)_{(n)}$ maps $\mathcal{V}_k$ to $M_{k-w+n+1}$. By orthogonality on M, $\Phi_{n,t,a}$ vanishes on $\mathcal{V}_k$ unless $k - w + n + 1 = b$, so the Riesz vector lies in the single weight space $k = b + w - n - 1$. Truncation: for $n \geq b + w$ that weight is negative and $\mathcal{V}$ has no negative weights. □

What the machine verified

`form_WbarMode`, `form_WbarMode_int`, `WbarMode_eq_of_form`: conditional exactly on `hVo`, `hVnd` (and `hO`). `WbarMode_mem`, `WbarMode_trunc`: only `hO`. All proved; axioms [`propext`, `Classical.choice`, `Quot.sound`].

37.11 Properties of $\overline{W}$

37.11.1 The L_{-1}-derivative property

Theorem 37.47 ($\overline{W}(L_{-1}t, z) = \partial_z \overline{W}(t, z)$). *For every $t \in M$ and n: $\overline{W}(L_{-1}t)_{(n)} = -n\,\overline{W}(t)_{(n-1)}$.*

```

     ↪ t

theorem Wbar_deriv (t : M) :
    Wbar BV N BM hO (Lm1 N.toWeakModule t) = deriv (Wbar BV N BM hO t)
```

(`VOA/Moonshine/WbarDeriv.lean`.)

From the mathematics to the Lean statement

Only the section hypothesis `hO` is used: the identity already holds for the defining functionals, hence for their Riesz vectors (`riesz` is linear on finitely supported functionals). The intermediate statements are the $\mathfrak{sl}_2$ relation $[L_1, L_{-1}] = 2L_0$ on M and the dagger identity; they are listed because they are of independent use (Theorem 37.58).

Physical meaning

Translation covariance of the conjugate field: the field of the derivative state is the derivative of the field. It holds for $\overline{W}$ because the two-point metrics are invariant under translations (they intertwine L_{-1} with L_1) and holds for W by construction.

Proof. By Theorem 37.13, $W(L_{-1}s)_{(q)} = -q\,W(s)_{(q-1)}$. In $W^{\dagger}(L_{-1}t)_{(n)}$ (note $L_{-1}t$ has weight $w + 1$) we must move L_1^j past L_{-1}: $L_1^{j+1}L_{-1}t = L_{-1}L_1^{j+1}t + (j+1)(2w - j)L_1^j t$ (induction on $[L_1, L_{-1}] =$

$2L_0$). Substituting, the $L_{-1}L_1^j t$ terms give $-(2w+2-n-2-j)$ times $W(L_1^j t)_{(2w-n-1-j)}$, the correction terms give $j(2w-j+1)/j!$ times $W(L_1^{j-1}t)_{(2w-n-j)}$; reindexing $i=j-1$, the coefficient of $\frac{1}{i!}W(L_1^i t)_{(2w-n-1-i)}$ is $-(2w-n-i)+(2w-i)=n$, and the overall sign $(-1)^{w+1}=-(-1)^w$ turns this into $-n$. The result is $-n\,W^\dagger(t)_{(n-1)}$. Pairing with a and taking Riesz vectors gives the claim. □

37.11.2 The commutator formula: first for quasi-primary states

Definition 37.48 (Invariant form on the VOA). `VInv W B_V`: for every homogeneous $u \in \mathcal{V}_{\mathrm{wt}}$, $B_V(u_{(n)}a,b)$ is given by (37.13) with $\mathcal{V}$ in place of M. It is literally the library's `InvariantForm.IsFullyInvariant` (`vInv_of_isFullyInvariant` is the identity).

```
def VInv (W : VertexOperatorAlgebra 𝒱) (BV : LinearMap.BilinForm ℂ 𝒱) : Prop :=
  ∀ (wt : ℤ) (u : 𝒱), u ∈ W.grading wt → ∀ (n : ℤ) (a b : 𝒱),
    BV (W.smul u n a) b
      = (-1 : ℂ) ^ wt • ∑ j ∈ Finset.range (wt.toNat + 1), ((j.factorial : ℂ)⁻¹) •
          BV a (W.smul (((W.L 1) ^ j) u) (2 * wt - n - 2 - (j : ℤ)) b)
```

(`VOA/Moonshine/WbarComm.lean`.)

Physical meaning

Same as for modules, with the adjoint module: this is the invariant Zamolodchikov metric on the untwisted chiral algebra itself, $\langle u|v\rangle$ with the BPZ conjugation $L_n \mapsto L_{-n}$, normalised by $\langle \mathbf{1}|\mathbf{1}\rangle = 1$.

Theorem 37.49 (Dagger commutator identity). *Let $u \in \mathcal{V}_p$ be quasi-primary ($L_1 u = 0$), $t \in M_w$, $Q = 2p-m-2$, and J past the truncation of u on t. Then*

$$(-1)^p\Big(W^\dagger(t)_{(n)}\big(u_{(Q)}\varphi\big) - u_{(Q)}\,W^\dagger(t)_{(n)}\varphi\Big) = \sum_{r<J}\binom{m}{r}W^\dagger\big(u_{(r)}t\big)_{(m+n-r)}\varphi.$$

```
theorem Wdag_comm_qp (N : OrdVModule W M) {p : ℤ} {u : 𝒱} (hu : u ∈ W.grading p)
    (hqp : W.L 1 u = 0) {w : ℤ} {t : M} (ht : t ∈ N.weight (w : ℂ)) (m n : ℤ) (J : ℕ)
    (hJ : ∀ j : ℕ, J ≤ j → N.act u j t = 0) (φ : 𝒱) :
    (-1 : ℂ) ^ p • (Wdag N n t (W.smul u (2 * p - m - 2) φ)
        - N.act u (2 * p - m - 2) (Wdag N n t φ))
      = ∑ r ∈ Finset.range J, gBinom m r • Wdag N (m + n - r) (N.act u r t) φ
```

(`VOA/Moonshine/WbarCore.lean`.)

From the mathematics to the Lean statement

This is the transpose of the commutator formula we want for $\overline{W}$: for quasi-primary u the FHL transpose of $u_{(m)}$ is $(-1)^p u_{(Q)}$, $Q=2p-m-2$ (Example 37.21). It involves no forms at all. Hypotheses `hu`, `hqp`, `ht`, `hJ` as stated.

Physical meaning

Technical lemma: the Ward identity of the chiral currents on the conjugate field, with all forms eliminated, formulated for the BPZ-transposed fields. It is part of the proof that the OPE of a quasi-primary current with $\overline{W}$ has the same singular structure as with W.

Proof on paper. Expand both sides with (37.16). On the left, apply the commutator formula of W (Theorem 37.15) to each $W(L_1^j t)$ with the mode $u_{(Q)}$; the result is a double sum over j and s of $\binom{Q}{s} W(u_{(s)}L_1^j t)_{(\dots)}$. On the right, each $W^\dagger(u_{(r)}t)$ contains $L_1^k(u_{(r)}t)$, which must be rewritten with u to the left: for quasi-primary u, $\frac{1}{k!}L_1^k(u_{(r)}x) = \sum_{b+c=k}\frac{1}{b!}\binom{2p-r-2}{c}u_{(r+c)}L_1^b x$ (from $[L_1, u_{(r)}] = (2p-r-2)u_{(r+1)} + (L_1 u)_{(r)}$, the $\mathfrak{sl}_2$-covariance of a weight-p field). Both sides are now sums of the same terms $\frac{1}{b!}W(u_{(s)}L_1^b t)_{(2p+2w-m-n-4-b-s)}\varphi$, and comparing coefficients reduces to the Vandermonde-type identity $\sum_r (-1)^r\binom{m}{r}\binom{2p-2-r}{s-r} = \binom{2p-2-m}{s}$, with $2p-2-m = Q$. □

Theorem 37.50 (Commutator formula for quasi-primary u). *Assume B_V graded orthogonal, graded nondegenerate and invariant (*`VInv`*), and B_M invariant at every homogeneous state. Then for quasi-primary $u \in \mathcal{V}_p$ and $t \in M_w$,*

$$u_{(m)}\overline{W}(t)_{(n)}a - \overline{W}(t)_{(n)}u_{(m)}a = \sum_{r<J}\binom{m}{r}\overline{W}(u_{(r)}t)_{(m+n-r)}a.$$

```
theorem WbarMode_comm_qp (hVo : GradedOrth W BV) (hVnd : GradedNondeg W BV) (hVinv : VInv W
↪  BV)
    (hMinv : ∀ (wt : ℤ) (u : 𝒱), u ∈ W.grading wt → FHLInv N BM wt u)
    {p : ℤ} {u : 𝒱} (hu : u ∈ W.grading p) (hqp : W.L 1 u = 0) {w : ℤ} {t : M}
    (ht : t ∈ N.weight (w : ℂ)) (m n : ℤ) (J : ℕ) (hJ : ∀ j : ℕ, J ≤ j → N.act u j t = 0)
    (a : M) :
    W.smul u m (WbarMode BV N BM hO n t a) - WbarMode BV N BM hO n t (N.act u m a)
      = ∑ r ∈ Finset.range J, gBinom m r • WbarMode BV N BM hO (m + n - r) (N.act u r t) a
```

Physical meaning

The Ward identity for $\overline{W}$ on quasi-primary currents: a current u passing the conjugate field $\overline{W}(t,z)$ obeys the same OPE with $\overline{W}$ as with W, with the residues given by the action of u on the twist-field state t. It is obtained by moving the current across the two metrics, using their invariance.

Proof. Pair both sides with φ under B_V and use separation (Theorem 37.42). By invariance of B_V, $B_V(u_{(m)}x, \varphi) = (-1)^p B_V(x, u_{(Q)}\varphi)$; by the adjunction this is $(-1)^p B_M(a, W^\dagger(t)_{(n)}u_{(Q)}\varphi)$. By invariance of B_M, $B_V(\overline{W}(t)_{(n)}u_{(m)}a, \varphi) = B_M(u_{(m)}a, W^\dagger\varphi) = (-1)^p B_M(a, u_{(Q)}W^\dagger\varphi)$. The difference is $B_M(a,\cdot)$ applied to the left side of Theorem 37.49, which is $\sum\binom{m}{r}B_M(a, W^\dagger(u_{(r)}t)_{(m+n-r)}\varphi) = \sum\binom{m}{r}B_V(\overline{W}(u_{(r)}t)_{(m+n-r)}a, \varphi)$. □

37.11.3 The commutator formula for all states

Theorem 37.51 (Intertwining commutator formula for $\overline{W}$). *Assume: B_V graded orthogonal, graded nondegenerate and invariant; B_M invariant at every homogeneous state; and $L_1\mathcal{V}_1 = 0$. Then for* every *$u \in \mathcal{V}$, $m, n \in \mathbb{Z}$, $t, a \in M$ and J past the truncation of u on t,*

$$u_{(m)}\overline{W}(t)_{(n)}a - \overline{W}(t)_{(n)}\big(u_{(m)}a\big) = \sum_{r<J}\binom{m}{r}\overline{W}\big(u_{(r)}t\big)_{(m+n-r)}a. \tag{37.17}$$

From the mathematics to the Lean statement

Type. This is (37.6) for an intertwiner of type $\binom{\mathcal{V}}{M\,M}$: first argument $t \in M$, second $a \in M$, output in $\mathcal{V}$, with $\mathcal{V}$ acting on the output by `W.smul` and on the second argument by `N.act`. **Hypotheses, one by one.** `hVo`, `hVnd`: needed for the Riesz representation. `hVinv`: invariance of B_V, needed to move $u_{(m)}$ across B_V. `hMinv`: invariance of B_M at every homogeneous u, needed to move $u_{(m)}$ across B_M. `hqpV`: $L_1\mathcal{V}_1 = 0$, used only for the quasi-primary decomposition below. `hJ`: truncation bound. For the Leech case all are discharged (Section 37.12). Same as the textbook statement, for all u (not only quasi-primary, not only homogeneous).

Physical meaning

This is what makes $\overline{W}$ a bona fide chiral vertex operator, of type twisted $\times$ twisted $\to$ untwisted: its transformation under the chiral algebra is the same as that of any field of a (twisted) state. It requires the metrics to be invariant and nondegenerate: invariance transports the currents across the pairing, and nondegeneracy turns the resulting identity between pairings into an identity of states. The extension to non-quasi-primary currents uses only that these are L_{-1}-descendants of quasi-primary ones.

Proof on paper. The set of u for which (37.17) holds (for all large J) is a linear subspace, and it is closed under $u \mapsto L_{-1}u$: since $(L_{-1}u)_{(m)} = -m\,u_{(m-1)}$ and $(L_{-1}u)_{(r)}t = -r\,u_{(r-1)}t$, the formula for $L_{-1}u$ follows from the formula for u at $m-1$ after the Pascal-type rearrangement $m\binom{m-1}{r-1} = r\binom{m}{r}$. Every homogeneous u of weight $p \geq 1$ decomposes as $u = u_0 + L_{-1}c$ with u_0 quasi-primary of weight p and c of weight $p-1$ (the $\mathfrak{sl}_2$ quasi-primary decomposition, which in a VOA of CFT type needs exactly $L_1\mathcal{V}_1 = 0$; Lean name `qpDecomp`, `VOA/Core/QuasiPrimaryDecomp.lean`). By induction on the weight, Theorem 37.50 for u_0 and the closure under L_{-1} give the formula for u; weight 0 is $\mathbb{C}\mathbf{1}$, which is quasi-primary. □

37.11.4 Locality and translation covariance

Theorem 37.52 (Locality of $Y(u,z_1)$ and $\overline{W}(t,z_2)$). *Under the hypotheses of Theorem 37.51, for every $u \in \mathcal{V}$, $t \in M$ there is N with $(z_1-z_2)^N\big(Y(u,z_1)\overline{W}(t,z_2) - \overline{W}(t,z_2)Y_M(u,z_1)\big) = 0$ in $\mathrm{Hom}(M,\mathcal{V})[[z_1^{\pm1},z_2^{\pm1}]]$. Moreover $[L_{-1},\overline{W}(t,z)] = \partial_z\overline{W}(t,z)$, in coefficients $L_{-1}\circ\overline{W}(t)_k - \overline{W}(t)_k\circ L_{-1}^M = (k+1)\overline{W}(t)_{k+1}$.*

File `VOA/Moonshine/WbarComm.lean`.

```

From the mathematics to the Lean statement

Hypotheses as in Theorem 37.51. Coefficient conventions as in Theorem 37.17; `Wbar ... t k` is the z^k coefficient. The covariance statement is the shape in which the block-matrix machinery of Chapter 38 consumes it.

Physical meaning

Mutual locality of the conjugate field $\overline{W}(t,z)$ with all untwisted currents: untwisted currents see no branch cut from a pair of twist fields that is fused into an untwisted field. This is the single-valuedness of the correlator $\langle\varphi|u(z_1)\overline{W}(t,z_2)|a\rangle$ in z_1. Together with W it is the exchange property of fields of different sectors with an invariant current, and the translation covariance expresses $L_{-1}=\partial_z$. These are the *one-twisted* locality relations; locality of two twisted fields with each other is much harder.

Proof. Locality follows from (37.17) exactly as Theorem 37.17 follows from Theorem 37.15. Covariance is (37.17) at $u=\omega$, $m=0$ (only $r=0$ survives since $\binom{0}{r}=\delta_{r0}$), combined with Theorem 37.47: $[L_{-1},\overline{W}(t)_{(n)}]=\overline{W}(L_{-1}t)_{(n)}=-n\overline{W}(t)_{(n-1)}$. □

What the machine verified

`Wbar_deriv`: only `hO`. `Wdag_comm_qp`: form-free, unconditional. `WbarMode_comm`, `Wbar_local`, `Wbar_homCov`: conditional exactly on `hVo`, `hVnd`, `hVinv`, `hMinv`, `hqpV` (and `hO`). All proved; axioms of `Wdag_comm_qp`, `WbarMode_comm`, `Wbar_local`: `[propext, Classical.choice, Quot.sound]` (rechecked).

37.12 The Leech instance of $\overline{W}$

37.12.1 The form B_V on V_Λ^+

For B_V the library takes the *canonical invariant form* of the vertex operator algebra V_Λ^+ (Li's theorem, Theorem 5.56: a VOA of CFT type with $L_1V_1=0$ has a fully invariant form, unique once normalised by $(\mathbf{1},\mathbf{1})=1$). Its hypotheses are $\mathbf{1}\neq 0$ and $L_1(V_\Lambda^+)_1=0$; the latter holds trivially because $(V_\Lambda^+)_1=0$. File `VOA/Moonshine/WbarLeech.lean`, namespace `VOA.Moonshine`.

```
theorem leechVOAPlus_L1_one : ∀ v, v ∈ leechVOAPlus.grading 1 → leechVOAPlus.L 1 v = 0

theorem leechBV_inv : VInv leechVOAPlus leechBV :=
  vInv_of_isFullyInvariant _ (canonicalInvariantForm_isFullyInvariant _ _)
```

From the mathematics to the Lean statement

`InvariantForm leechVOAPlus` is the library's structure "bilinear form with $(L_n a,b)=(a,L_{-n}b)$" (Definition 5.48); `canonicalInvariantForm` is Li's form, and `canonicalInvariantForm_isFullyInvariant` proves it satisfies the full FHL invariance

`IsFullyInvariant`, which is `VInv`. Orthogonality of distinct weights follows from L_0-adjointness. What is *not* free is graded nondegeneracy: Li's form is nondegenerate if and only if the VOA is simple (for CFT type), and the library has no general simplicity theorem for V_Λ^+.

37.12.2 The definition and the unconditional properties

Definition 37.53. $\overline{W}(t,z)$ for $t \in (V_\Lambda^T)^+$ is the adjoint of `leechWsk t` with respect to $B_V =$ `leechBV` and $B_T =$ `TPForm`.

```

theorem leechWbar_deriv (t : TP) : leechWbar (leechLTP t) = deriv (leechWbar t) :=
  Wbar_deriv _ _ _ _ t
```

From the mathematics to the Lean statement

The four arguments of `Wbar` are B_V, the module, B_M and the orthogonality proof `TPForm_weightOrth` (Theorem 37.35). These three statements need nothing beyond `hO`, which is supplied.

Physical meaning

The conjugate field of the Leech orbifold: the OPE of two twist fields of the 24 Leech bosons, producing an operator in V_Λ^+. It is defined using the canonical invariant two-point function B_V (unique up to normalisation for a VOA of CFT type with $L_1 V_1 = 0$) on the untwisted side and B_T on the twisted side. The quantity whose existence this requires is nondegeneracy of B_V (no null fields in V_Λ^+), which is established below.

37.12.3 The residual `hnd` and its discharge

Theorem 37.54 (Conditional properties). *If B_V is graded nondegenerate (hypothesis* `hnd`*), then the Leech $\overline{W}$ satisfies the adjunction DGM (4.3), the commutator formula (37.17) for all $u \in V_\Lambda^+$, locality with every $Y(u,z)$, and translation covariance.*

  WbarMode_comm leechBV_orth hnd leechBV_inv (fun _ _ hu => TPForm_fhlInv hu)
   ↪ leechVOAPlus_L1_one
    u m t n a J hJ
```

From the mathematics to the Lean statement

A hidden-looking hypothesis. The statements of `leechWbar_adj` and `leechWbar_comm` as printed do not mention `hnd`, but the file declares `variable (hnd : GradedNondeg leechVOAPlus leechBV)` followed by `include hnd`; so each of these theorems takes `hnd` as its *first explicit argument*. (One sees it used in the proof term of `leechWbar_comm`.) The same holds for `leechWbar_local` and `leechWbar_homCov`, whose statements are those of Theorem 37.52 at the Leech data. A referee must read these as "`hnd` ⇒ …".
The other hypotheses of Theorem 37.51 are discharged in the proof term: `leechBV_orth`, `leechBV_inv`, `TPForm_fhlInv` (Theorem 37.38), `leechVOAPlus_L1_one`.

Physical meaning

If the untwisted chiral algebra is simple (no null states), then all the general properties established above apply to the genuine conjugate field: its adjunction with W, its OPE with the invariant currents, locality, translation covariance. The hypothesis is the physical statement that the metric on the vertex algebra has no zero modes; it is the main assumption that has to be checked for the actual model.

Theorem 37.55 (B_V is graded nondegenerate; $\overline{W}$ unconditional)**.** `hnd` *holds. Consequently the adjunction, the commutator formula, locality and covariance of the Leech* $\overline{W}$ *hold unconditionally.*

  leechWbar_homCov leechBV_gradedNondeg t k
```

(`VOA/Moonshine/NondegLeech.lean`.)

From the mathematics to the Lean statement

The proof terms shown make the logic transparent: each primed theorem is the conditional one applied to `leechBV_gradedNondeg`. That theorem is proved in Chapter 32 *without* simplicity of V_Λ^+: the library writes down an explicit lattice form on V_Λ, proves it invariant and nondegenerate and θ-isometric, identifies its restriction to V_Λ^+ with `leechBV` by uniqueness of the normalised invariant form, and deduces that the radical of `leechBV` is zero (`leechBVForm_leftRadical`). The primed statements have no remaining hypotheses other than the truncation bound `hJ` (resp. `ht`, `hR`).

Physical meaning

The nondegeneracy of the two-point function of the Leech orbifold's untwisted sector: no null fields. This is what upgrades the conditional properties of $\overline{W}$ to unconditional ones, and it ensures the OPE of two twist fields is genuinely determined by (and consistent with) the coupling to the untwisted fields.

Trap / dead end

Signs that must not be "simplified" (`Notes/M8hRoute.md`, §1a and dead end 3). In the numerical E_8 model, dropping the factor $(-1)^w$ in the adjunction (37.16), or replacing the lattice form's sign $c(\alpha) = (-1)^{\langle\alpha,\alpha\rangle/2}\varepsilon(\alpha,\alpha)$ of Chapter 32 by $c(\alpha) = 1$, breaks the twisted×twisted relation (4.23) (relative residual ≈ 2). These signs are therefore not conventions that can be changed freely: they are necessary for $\overline{W}$ to be the operator that later makes $V^\natural$ a vertex algebra. Numerical evidence (`tt.py`, `tt_K3.log`), not proof.

What the machine verified

`leechWbar_mem`, `leechWbar_trunc`, `leechWbar_deriv`: unconditional. `leechWbar_adj`, `leechWbar_comm`, `leechWbar_local`, `leechWbar_homCov`: conditional on `hnd`. `leechBV_gradedNondeg` and the four primed theorems: unconditional; axioms of `leechBV_gradedNondeg` and `leechWbar_comm'`: `[propext, Classical.choice, Quot.sound]` (rechecked).

37.13 The genuine $\overline{W}$ in the block field, and the anti-trap certificate

37.13.1 Plugging $\overline{W}$ into the block field

Chapter 38 builds the block vertex operators (37.2) for an *arbitrary* family `Wbar`, and asks of it a commutator formula:

```
def WbarComm (Wbar : TP → FormalDist (TP →ₗ[ℂ] SkewVP)) : Prop :=
  ∀ (u : SkewVP) (m : ℤ) (t : TP) (n : ℤ) (J : ℕ),
    (∀ j : ℕ, J ≤ j → mode (plusModule.YM u) j t = 0) →
```

```
    mode (leechVOAPlus.Y u) m ∘ₗ mode (Wbar t) n - mode (Wbar t) n ∘ₗ mode (plusModule.YM
     ↪ u) m
      = ∑ r ∈ Finset.range J, gBinom m r • mode (Wbar (mode (plusModule.YM u) r t)) (m + n
       ↪ - r)

noncomputable def YnatU (u : SkewVP) : FormalDist (End ℂ Vnat) :=
  diagF (leechVOAPlus.Y u) (plusModule.YM u)

noncomputable def YnatT (Wbar : TP → FormalDist (TP →ₗ[ℂ] SkewVP)) (t : TP) :
    FormalDist (End ℂ Vnat) :=
  offF (Wbar t) (leechWsk t)
```

(`VOA/Moonshine/VnatFields.lean`, documented in Chapter 38.) Here `Vnat` is the product `SkewVP × TP`, `diagF a b` the diagonal block distribution $\mathrm{diag}(a,b)$ and `offF c d` the off-diagonal one with c in the upper right and d in the lower left, so `YnatT Wbar t` is the twisted column of (37.2). `WbarComm` is (37.17) written as an identity of linear maps.

Theorem 37.56 (The genuine $\overline{W}$ satisfies the block-field hypotheses). `leechWbar` *satisfies* `WbarComm`*, and the block fields of untwisted and twisted states are mutually local: for all* $u \in V_\Lambda^+$, $t \in (V_\Lambda^T)^+$, $Y^\natural((u,0),z)$ *and* $Y^\natural((0,t),z)$ *are local on* $V^\natural$.

```
theorem leechWbar_WbarComm : WbarComm leechWbar

theorem YnatU_YnatT_local_genuine (u : SkewVP) (t : TP) : Local (YnatU u) (YnatT leechWbar
 ↪ t) :=
  YnatU_YnatT_local leechWbar_WbarComm u t

theorem YnatT_YnatU_local_genuine (t : TP) (u : SkewVP) : Local (YnatT leechWbar t) (YnatU
 ↪ u) :=
  YnatT_YnatU_local leechWbar_WbarComm t u
```

(`VOA/Moonshine/VnatGenuine.lean`.)

From the mathematics to the Lean statement

`Local` is Definition 37.4 on $\mathrm{End}(V^\natural)$. A block computation (Chapter 38, `local_diag_off`) shows that $\mathrm{diag}(a,b)$ and $\mathrm{offdiag}(c,d)$ are local iff $ac-cb$ and $bd-da$ are killed by a power of (z_1-z_2); these are Theorem 37.52 (via `WbarComm`) and Theorem 37.17. These are relations (3) and (4) of Section 37.1. Unconditional.

Physical meaning

The block-matrix $Y^\natural$ of a twisted and an untwisted state is the full vertex operator of the sum of the two sectors; the statement is that untwisted and twisted fields are mutually local, i.e. they have an OPE with finite pole order and commute up to contact terms. This is the consistency of the operator algebra of the orbifold with its twist fields at the level of one twist-field insertion; the harder consistency condition with two twist fields remains.

37.13.2 The genuine $\overline{W}$ is not zero

Theorem 37.57 (The vacuum pairing). (i) *For* $t,t' \in ((V_\Lambda^T)^+)_2$ *(the lowest weight space),* $\overline{W}(t)_{(3)}t' = B_T(t',t)\,\mathbf{1}$. (ii) *For every nonzero* $t \in ((V_\Lambda^T)^+)_2$ *there are* $t' \in ((V_\Lambda^T)^+)_2$ *and* $c \neq 0$ *with* $\overline{W}(t)_{(3)}t' = c\,\mathbf{1}$. (iii) $\overline{W} \neq 0$.

```
theorem leechWbarMode_three_weight_two {t t' : TP} (ht : t ∈ plusModule.weight ((2 : ℤ) :
 ↪ ℂ))
```

```
    (ht' : t' ∈ plusModule.weight ((2 : ℤ) : ℂ)) :
    leechWbarMode 3 t t' = TPForm t' t • leechVOAPlus.vacuum

theorem leechWbar_vacuum_pairing_ne_zero {t : TP} (ht : t ∈ plusModule.weight ((2 : ℤ) :
↪  ℂ))
    (ht0 : t ≠ 0) :
    ∃ t' ∈ plusModule.weight ((2 : ℤ) : ℂ), ∃ c : ℂ, c ≠ 0 ∧
      leechWbarMode 3 t t' = c • leechVOAPlus.vacuum

theorem leechWbar_ne_zero : leechWbar ≠ 0
```

From the mathematics to the Lean statement

Decoding. `((2 : ℤ) : ℂ)` is the weight 2, cast to $\mathbb{C}$ because module weights are complex. `leechWbarMode 3 t t'` is $\overline{W}(t)_{(3)}t'$. `leechWbar ≠ 0` compares the function $t \mapsto \overline{W}(t,z)$ with the zero function.

Why this is the right certificate. The trap of Section 37.1 is $\overline{W} = 0$. Statement (iii) excludes it outright, and (ii) says more: the twisted×twisted product of lowest-weight states reaches the vacuum through the nondegenerate pairing B_T, which reflects the nondegenerate invariant form that a simple algebra must carry (in the square-zero extension this product is identically zero). It is not by itself a simplicity proof; simplicity of $V^\natural$ is proved in Chapter 38. No hypotheses beyond the displayed homogeneity.

Physical meaning

The twisted × twisted OPE actually produces the identity: the product of two lowest-weight twist fields contains the vacuum with coefficient the two-point function $B_T(t',t)$, which is non-vanishing because the Zamolodchikov metric on the twisted sector is nondegenerate. This is the CFT statement that two twist fields $\sigma\sigma \sim 1/(z-w)^{2h} + \dots$ fuse to the identity, and it is why $\overline{W} \neq 0$: without it the twisted sector would not interact with itself and the sum $V_\Lambda^+ \oplus (V_\Lambda^T)^+$ would be a decoupled, non-simple square-zero extension, not the Moonshine module. (Heuristic: the coefficient is the identity channel in the two-point function.)

Proof on paper. (i) By Theorem 37.46, $\overline{W}(t)_{(3)}t'$ has weight $2+2-3-1=0$, and $(V_\Lambda^+)_0 = \mathbb{C}\mathbf{1}$; write it $c\mathbf{1}$. Pair with $\mathbf{1}$: $c = cB_V(\mathbf{1},\mathbf{1}) = B_V(\overline{W}(t)_{(3)}t',\mathbf{1})$. By the adjunction with $w=2$ and $n=3$, this is $(-1)^2\sum_j \frac{1}{j!}B_T(t', W(L_1^j t)_{(4-3-2-j)}\mathbf{1})$. Since $L_1 t$ has weight 1 and $((V_\Lambda^T)^+)_1 = 0$, only $j=0$ remains: $B_T(t', W(t)_{(-1)}\mathbf{1}) = B_T(t',t)$ by Example 37.11. (ii) Choose t' with $B_T(t,t') \neq 0$ (Theorem 37.35) and use symmetry. (iii) $((V_\Lambda^T)^+)_2$ has dimension $98304 > 0$, so a nonzero t exists, and $c\mathbf{1} \neq 0$ because $\mathbf{1} \neq 0$. □

What the machine verified

`leechWbar_WbarComm`, `YnatU_YnatT_local_genuine`, `YnatT_YnatU_local_genuine`, `leechWbarMode_three_weight_two`, `leechWbar_vacuum_pairing_ne_zero`, `leechWbar_ne_zero`: unconditional. Axioms of `leechWbar_WbarComm`, `YnatU_YnatT_local_genuine`, `leechWbarMode_three_weight_two`, `leechWbar_ne_zero`: `[propext, Classical.choice, Quot.sound]` (rechecked).

37.14 Skew-symmetry of $\overline{W}$

If $V^\natural$ is a vertex algebra, skew-symmetry for two twisted states t_1, t_2 reads, in the untwisted component, $\overline{W}(t_1,z)t_2 = e^{zL_{-1}}\overline{W}(t_2,-z)t_1$ (DGM (4.9)). This identity is one of the inputs that reduce the

twisted×twisted locality to a single relation in Chapter 38. It is proved directly from the construction. (The file `VOA/Moonshine/M8h0Skew.lean` is assigned to Chapter 38; we state the theorem here because it is a property of $\overline{W}$.)

Theorem 37.58 (Skew-symmetry of $\overline{W}$). *For homogeneous $t_1 \in ((V_\Lambda^T)^+)_a$, $t_2 \in ((V_\Lambda^T)^+)_b$ and every $n \in \mathbb{Z}$,*

$$\overline{W}(t_1)_{(n)}t_2 = \sum_{i\ge 0} \frac{(-1)^{n+i+1}}{i!}\, L_{-1}^{i}\Big(\overline{W}(t_2)_{(n+i)}t_1\Big).$$

From the mathematics to the Lean statement

The right side is the mode expansion of $e^{zL_{-1}}\overline{W}(t_2,-z)t_1$, exactly as in (37.7); the $\sum^{\mathrm{f}}$ is finite because $\overline{W}(t_2)_{(n+i)}t_1 = 0$ for i large (Theorem 37.46). **Restriction:** t_1, t_2 homogeneous of integral weight. This is harmless: both sides are bilinear in (t_1, t_2), every vector of $(V_\Lambda^T)^+$ is a finite sum of homogeneous ones, and all weights of $(V_\Lambda^T)^+$ are integers. The two auxiliary statements are the adjointness $L_{-1}^t = L_1$ for B_T (from invariance at ω, using $L_1\omega = 0$) and for B_V (Virasoro adjointness of an `InvariantForm`).

Physical meaning

Skew-symmetry is the exchange symmetry of two twist fields: the OPE of t_1 with t_2 and the OPE of t_2 with t_1 describe the same correlator in different radial orderings, related by translation $e^{zL_{-1}}$ and $z \to -z$. For the untwisted output it is the bosonic exchange property of twist fields (braiding is trivial in the untwisted channel). It holds for the constructed $\overline{W}$ because it is the adjoint of W with respect to a symmetric metric, which is one of the inputs to their mutual locality.

Proof on paper. Pair both sides with $\varphi \in (V_\Lambda^+)_k$, $k = a+b-n-1$ (other weights pair to zero on both sides), and use separation. On the left, the adjunction gives $(-1)^a \sum_j \frac{1}{j!} B_T\big(t_2, W(L_1^j t_1)_{(2a-n-2-j)}\varphi\big)$; expanding W by (37.7) produces L_{-1}^l acting on $\varphi_{(.)}L_1^j t_1$, which is moved across B_T as L_1^l (by $L_{-1}^t = L_1$), and then $\varphi_{(.)}$ is moved across B_T by FHL invariance (which brings in $L_1^r\varphi$). The result is a triple sum over (j,l,r) of matrix elements $B_T\big(L_1^j t_1, (L_1^r\varphi)_{(\gamma)}L_1^l t_2\big)$. On the right, L_{-1}^i is moved across B_V as L_1^i, then the adjunction for $\overline{W}(t_2)_{(n+i)}$ and the same expansion give a triple sum of the same matrix elements, with the roles of j and r exchanged. After the relabelling $(j,l,r) \mapsto (r,l,j)$ the two sums agree term by term: the factorials match, the mode indices agree because $n = a+b-k-1$, and the signs differ by an even power of -1. Symmetry of B_T is used to put t_1, t_2 in matching slots. □

What the machine verified

`leechWbar_skew`: unconditional (homogeneity is part of the statement). Axioms: `[propext, Classical.choice, Quot.sound]` (rechecked). The corresponding relation DGM (4.22) is

proved in Chapter 38 (`leechWbar_VPBlockLocal`).

37.15 Traps, dead ends and corrected mistakes

For convenience we collect the recorded traps that concern this chapter.

1. **The square-zero trap** ($\overline{W} = 0$): every hypothesis that the reconstruction theorem places on `Wbar` is satisfied by 0, producing a non-simple VOA with the graded dimension of $V^\natural$. Countered by defining $\overline{W}$ as the adjoint and by Theorem 37.57 (Section 37.1).

2. **The positive Fock form** is the wrong form: it transposes the dressing `DD` v to `DD` $(-v)$. The FHL bilinear form forces $h(m)^t = -h(-m)$ (Section 37.7).

3. **Signs on T and in $\overline{W}$**: the T-law sign $(-1)^{\langle\alpha,\alpha\rangle/2}$ (not $\varepsilon(\alpha,\alpha)$), the factor $(-1)^w$ in (37.16), and the non-constant sign $c(\alpha)$ of the lattice form are each necessary; dropping any of them breaks (4.23) in the numerical E_8 model (`Notes/M8hRoute.md`).

4. **The library `Intertwiner` is commutator-only.** It is weaker than FHL's notion (no L_{-1}-property, no Jacobi identity). The L_{-1}-properties of W and $\overline{W}$ are proved separately; their full Jacobi identities are not proved and not used.

5. **One-argument commutator formulas do not give twisted×twisted locality.** `Notes/M8GluingPlan.md` (status after M8f) records that the formulas `wMode_comm` and `WbarMode_comm` do not imply the Borcherds identity for three twisted vectors (DGM (4.23)); that relation needs the triality of Chapters 39–42.

6. **The residuals of this chapter, both closed:** `hgen` (generation of V_Λ^+, closed by `leechPlus_generated`) and `hnd` (graded nondegeneracy of B_V, closed by `leechBV_gradedNondeg` without using simplicity). Both are proved in Chapter 32.

37.16 Verification record

For this chapter, at an earlier commit (not re-run for this edition), the following probe file (in a scratch directory, not part of the library) was compiled with the audit-safe option recommended by the project (`-DmaxSynthPendingDepth=3`):

```
import VOA.Moonshine.M8h0Skew
import VOA.Moonshine.Generation
#print axioms VOA.SkewIntertwiner.wMode_comm
#print axioms VOA.SkewIntertwiner.Wsk_local
#print axioms VOA.SkewIntertwiner.skewIntertwiner
#print axioms VOA.Moonshine.leechSkewIntertwiner
#print axioms VOA.Moonshine.InvForm.fockForm_DD
#print axioms VOA.Moonshine.InvForm.twForm_YTL
#print axioms VOA.Moonshine.InvForm.TPForm_nondegenerate
#print axioms VOA.Moonshine.InvForm.fhlInv_of_generates
#print axioms VOA.Moonshine.InvForm.TPForm_fhlInv_of_generates

#print axioms VOA.Moonshine.M8h0.leechWbar_skew
```

Command: `lake env lean -DmaxSynthPendingDepth=3 Ax09.lean`. Output: each of the 21 declarations "depends on axioms: [propext, Classical.choice, Quot.sound]"; exit code 0. In particular none uses `VOA.pbw` (the PBW theorem of Chapter 3; formerly a project axiom, now a theorem). This run did not rebuild the library; it relies on the build artefacts of the aggregate `lake build` of that commit, which the project's build record reports green (10343 jobs, exit 0; not re-run for this chapter). The sympy scripts mentioned in Section 37.7 were not re-run.

37.17 Referee's checklist

"Uncond." means: no hypothesis that is an unestablished datum; * marks declarations whose `#print axioms` was rechecked above (result `[propext, Classical.choice, Quot.sound]`). $\mathcal{V}$, M denote an arbitrary VOA and module.

Lean declaration	intended meaning	hypotheses	status / check
`Intertwiner` (library)	commutator-type intertwiner, weaker than FHL	—	definition; Def. 37.6
`Lm1`, `act_Lm1`	$L^M_{-1} = \omega_{(0)}$; $[u_{(p)}, L_{-1}] = -p\,u_{(p-1)}$	weak module	uncond.; Prop. 37.9
`wMode`, `Wsk`	$W(t,z)\varphi = e^{zL_{-1}}Y_M(\varphi,-z)t$	weak module	definition; Def. 37.10
`Wsk_vacuum`	$W(t,z)\mathbf{1} = e^{zL_{-1}}t$	none	uncond.; Thm. 37.12
`Wsk_deriv`	$W(L_{-1}t,z) = \partial_z W(t,z)$	none	uncond.; Thm. 37.13

37.18 Notes and references

The intertwining operators, contragredient modules and invariant bilinear forms of this chapter are those of I. B. Frenkel, Y.-Z. Huang and J. Lepowsky, *On axiomatic approaches to vertex operator algebras and modules*, Memoirs of the American Mathematical Society 104 (1993), no. 494: the contragredient module is §5.2 (Theorem 5.2.1), invariant forms §5.3, intertwining operators and their skew-symmetry operators Ω §5.4–5.5. The classification of invariant bilinear forms on a vertex operator algebra ($\cong (V_0/L_1V_1)^*$) and the equivalence of nondegeneracy with simplicity are due to H. Li, *Symmetric invariant bilinear forms on vertex operator algebras*, Journal of Pure and Applied Algebra 96 (1994), 279–297. Li's theory of local systems (*Local systems of vertex operators, vertex superalgebras and modules*, J. Pure Appl. Algebra 109 (1996) 143–195, arXiv:hep-th/9406185) is the conceptual background for constructing a vertex algebra from mutually local fields, the route taken in Chapter 38.

The block form (37.2), the definition of W by skew-symmetry (their (3.8)), of $\overline{W}$ as an adjoint (their (4.3)), the skew-symmetry of $\overline{W}$ (their (4.9)) and the reduction of locality to the six relations (4.18)–(4.23) follow L. Dolan, P. Goddard and P. Montague, *Conformal field theories, representations and lattice constructions*, Communications in Mathematical Physics 179 (1996), 61–120, arXiv:hep-th/9410029; their earlier paper *Conformal field theory of twisted vertex operators*, Nuclear Physics B 338 (1990), 529–601, treats the twisted operators directly. The Moonshine module itself, the twisted Fock space with its form, the space T and the triality that eventually proves (4.23), are in I. Frenkel, J. Lepowsky and A. Meurman, *Vertex Operator Algebras and the Monster*, Pure and Applied Mathematics 134, Academic Press, 1988 (Chapters 9–13). For the mode-level conventions (generalised binomials, Res, the module Jacobi identity in modes) the library follows T. Gannon, *Moonshine beyond the Monster*, Cambridge University Press, 2006, §5.1–5.3 and Definition 6.1.9 (intertwiners).

The project's own records of the work in this chapter are `Notes/M8GluingPlan.md` (milestones M8b, M8c and the status sections "after M8b", "after M8c form part", "residual hgen CLOSED", "$\bar{\mathrm{W}}$ built; residual hnd", "hnd CLOSED"), `Notes/M8hRoute.md` (numerical E_8 model and sign controls).

Chapter 38

The vertex algebra on $V^\natural$ modulo one relation

38.1 Where we are, and what this chapter does

This chapter documents the release of the library named in the front matter. Quotations from the repository are printed in `leancode` boxes, which are checked by `scripts/textbook/sync.py` to occur verbatim (up to whitespace and comments) in the source of that release; tool output is printed in plain boxes. Checks that were run at an earlier state of the library and not re-run for this edition are marked as such.

The preceding chapters of this Part have produced, one at a time, all the raw materials of the Frenkel–Lepowsky–Meurman construction of the Moonshine module. It is worth listing them, because this chapter does nothing but glue them together, and the referee should know exactly which pieces are taken as given here.

(i) The *untwisted half*: the fixed-point vertex operator algebra $V_\Lambda^+ = V_\Lambda^\theta$ of the Leech lattice vertex operator algebra under the lift θ of -1 (Lean: `leechVOAPlus`, carrier type `SkewVP`). It has central charge 24, no states of weight 1, and $\dim(V_\Lambda^+)_2 = 98580$.

(ii) The *twisted half*: the θ-fixed part $T^+ = (V_\Lambda^T)^+$ of the θ-twisted Leech module $V_\Lambda^T = S[\theta] \otimes T$ (Lean: `TP`), viewed as an ordinary V_Λ^+-module (Lean: `plusModule`). Its weights are the integers ≥ 2 and $\dim T_2^+ = 98304 = 24 \cdot 4096$.

(iii) The *skew intertwiner* W: for $t \in T^+$ the field $W(t,z)\varphi = e^{zL_{-1}} Y^T(\varphi, -z)t$, a formal series of linear maps $V_\Lambda^+ \to T^+$ (Lean: `leechWsk`).

(iv) The two invariant bilinear forms: B_V on V_Λ^+ (Lean: `leechBV`) and the form $(\cdot,\cdot)_T$ on T^+ (Lean: `TPForm`); both symmetric, both nondegenerate on every weight space, both invariant under the action of V_Λ^+.

(v) The *adjoint* $\overline{W}$ of W with respect to these two forms: for $t \in T^+$ a formal series $\overline{W}(t,z)$ of linear maps $T^+ \to V_\Lambda^+$ (Lean: `leechWbar`).

With these, Frenkel, Lepowsky and Meurman — and, in the streamlined form we follow, Dolan, Goddard and Montague (DGM) — define a single vertex operator on

$$V^\natural = V_\Lambda^+ \oplus T^+$$

by the 2×2 block matrix

$$Y^\natural\big((u,t),z\big) = \begin{pmatrix} Y(u,z) & \overline{W}(t,z) \\ W(t,z) & Y^T(u,z) \end{pmatrix}, \qquad u \in V_\Lambda^+,\ t \in T^+, \tag{38.1}$$

acting on column vectors $\binom{\varphi}{s}$ with $\varphi \in V_\Lambda^+$, $s \in T^+$. This is DGM's equation (4.17). The diagonal blocks are the vertex operators of V_Λ^+ on itself and on its module T^+; the off-diagonal blocks are the two intertwiners.

The physical picture. In conformal field theory language, $V^\natural$ is the space of states of a chiral CFT obtained by *orbifolding* the 24 chiral bosons compactified on the Leech torus $\mathbb{R}^{24}/\Lambda$ by the reflection $X \mapsto -X$. The untwisted sector V_Λ^+ consists of the reflection-invariant states of the original theory; the twisted sector T^+ consists of the states created by *twist fields* sitting at the 2^{24} fixed points of the reflection, projected again onto invariant states. The block form (38.1) is the statement of *charge conservation for the $\mathbb{Z}/2$ grading* by sectors: an untwisted field maps each sector to itself; a twisted field exchanges the sectors. The operator product of two twisted fields lands in the untwisted sector, and its consistency — the locality of two twisted fields — is the one place where the geometry of the lattice enters non-trivially. Physicists call this the statement that the orbifold is *modular invariant*; DGM call it "almost a modular invariance condition".

What the chapter proves. We check, for the explicit block map (38.1), *every* axiom of a vertex operator algebra except one: the mutual locality of two twisted fields. We split that remaining condition into two halves, DGM's relations (4.22) and (4.23); we prove (4.22) unconditionally; we reduce (4.23) to finitely many explicit pairs of vectors; and we prove that, whenever the structure exists, it is *simple*. The relation (4.23) itself is proved in the final chapters of this Part, by the triality method; at the end of this chapter we state the theorem that collects every target conditional on (4.23), which those chapters then discharge.

The trap. There is a subtlety that governs the whole chapter, and the referee must keep it in mind from the first page. If one replaces $\overline{W}$ by the *zero* map in (38.1), every hypothesis we place on $\overline{W}$ is still satisfied, twisted–twisted locality becomes trivially true, and the result is a perfectly good vertex operator algebra with the same underlying graded vector space — hence central charge 24, no weight-one states, $\dim V_2 = 196884$ and graded dimension J. It is *not* the Moonshine module: it is the *square-zero extension* $V_\Lambda^+ \ltimes T^+$, which is not simple. Consequently none of the numerical facts about $V^\natural$ can certify that the right object has been built. What does certify it is simplicity, and the simplicity proof uses, in an essential way, that $\overline{W}$ is the *adjoint* of W. Section 38.11 treats this in detail.

Plan. Section 38.2 recalls, with their Lean sources, the library notions that occur in the statements of this chapter. Section 38.3 develops the algebra of block fields on a direct sum. Section 38.4 proves that the fields of any module are mutually local — a fact the library did not have. Section 38.5 defines the carrier $V^\natural$ and its grading and proves the numerical targets. Section 38.6 defines the generator fields and the reconstruction interface. Section 38.7 verifies all the axioms of a vertex operator algebra modulo twisted–twisted locality and packages the result. Section 38.8 splits twisted–twisted locality into (4.22) and (4.23). Section 38.9 proves (4.22). Section 38.10 reduces (4.23) to a generating family and then to four explicit pairs. Section 38.11 is the trap. Section 38.12 proves simplicity. Section 38.13 assembles the conditional main theorem. Section 38.14 collects the dead ends, Section 38.15 is the referee's checklist, and the chapter ends with notes and references.

What the machine verified

Every declaration presented in this chapter was `##print axioms`-checked in the session that wrote the chapter (2026-10-07), on the already-built library, with `lake env lean -DmaxSynthPendingDepth=3` on a file importing `VOA.Moonshine.Main`. For each of the 22 headline declarations named in Section 38.15 the output was

```
depends on axioms: [propext, Classical.choice, Quot.sound]
```

These are Lean's three standard axioms; `VOA.pbw` (the PBW theorem of Chapter 3; formerly a project axiom, now a theorem) does *not* occur. The project's build record for the earlier commit at which this chapter was first written reports the aggregate build green (10343 jobs; not re-run for this chapter). Being axiom-clean does not make a theorem unconditional: several results below carry an explicit hypothesis (the twisted–twisted locality), and we always say so.

38.2 Recollections: the notions that occur in the statements

The Constitution of this book requires that every term in a stated theorem be defined in the book. The terms below are defined in the Foundations and Core chapters. The formal-calculus notions and weak modules are quoted verbatim and decoded in Chapters 2, 4 and 12, and are recalled here with pointers; the structures whose exact fields this chapter's fidelity checks use (vertex algebras, vertex operator algebras, ideals and simplicity, invariant forms) are repeated verbatim so that those checks can be read without turning back.

38.2.1 Formal distributions and modes

Definition 38.1 (Formal distributions)**.** For a complex vector space X, a *formal distribution* with values in X is a doubly infinite formal series $f(z) = \sum_{k\in\mathbb{Z}} f_k z^k$ with $f_k \in X$, with no convergence or truncation condition. Equivalently it is an arbitrary function $\mathbb{Z} \to X$. A two-variable formal distribution is a function $\mathbb{Z}\times\mathbb{Z} \to X$, read as $\sum_{m,n} f_{m,n} z_1^m z_2^n$.

In Lean, `FormalDist 𝒲 = ℤ → 𝒲` and `FormalDist₂ 𝒲 = ℤ → ℤ → 𝒲` (Definitions 2.1 and 2.21, `VOA/Foundations/FormalSeries.lean`). The notation `(End ℂ 𝒱)⟦z^±⟧` in the structure of a vertex algebra below is notation for `FormalDist (End ℂ 𝒱)`.

Physical meaning

A formal distribution is the mode expansion of a quantum field before any state is fed in: the operator-valued Laurent series $\sum_k f_k z^k$ that a physicist writes for $\phi(z)$ on the plane, with no assumption yet that it acts sensibly on states. The truncation condition that makes it a genuine local operator is imposed separately, as the notion of field. The two-variable version is the expansion of a correlator or of a product $\phi_1(z_1)\phi_2(z_2)$ in both positions. This is bookkeeping heuristics for the OPE; the formal definition is what the proofs use.

Definition 38.2 (Modes)**.** For $f(z) = \sum_k f_k z^k$ the *n-th mode* is $f_{(n)} := f_{-n-1}$, so that $f(z) = \sum_n f_{(n)} z^{-n-1}$. For a vertex operator $Y(u,z)$ one writes $u_{(n)}$ for the n-th mode.

In Lean, `mode f m = f (-m - 1)` (Definition 2.7, `VOA/Foundations/FormalCalculus.lean`).

From the mathematics to the Lean statement

There are two indexings in play and the reader must keep them apart. The raw coefficient `f k` is the coefficient of z^k; the mode `mode f n` is $f_{(n)}$, the coefficient of z^{-n-1}. Thus `mode (Y u) n` is the operator $u_{(n)}$ of the textbooks, `mode (Y u) (-1)` is $u_{(-1)}$ (creation), and `Y u 0` — the raw coefficient of z^0 — is also $u_{(-1)}$. Definitions about *fields* in the library (truncation, translation covariance, locality) are written in the raw z-power indexing; definitions about *products* of states are written with `mode`. Every fidelity check below says which is in use.

Physical meaning

Modes are the Fourier coefficients of a chiral field around the origin: $u_{(n)}$ is the contour integral of $z^n Y(u,z)$, so the modes of the stress tensor are the Virasoro generators and those of a current are its Kac–Moody charges. The shift $-n-1$ is the usual bookkeeping that a weight-h field has $\phi(z) = \sum \phi_n z^{-n-h}$ with n shifted by $h-1$. In $V^\natural$ the modes of all states generate the whole symmetry algebra of the orbifold CFT.

38.2.2 Multiplication by $z_1 - z_2$, commutators, locality, fields

Definition 38.3. For a two-variable distribution F, $(z_1 - z_2)F$ has coefficients $((z_1 - z_2)F)_{m,n} = F_{m-1,n} - F_{m,n-1}$, and $(z_1 - z_2)^N F$ is the N-fold iterate.

In Lean these are `mulBySub` = `shiftZ₁ - shiftZ₂` and its N-fold iterate `mulBySubPow N` (Definition 2.21, `VOA/Foundations/FormalSeries.lean`); the library proves `mulBySub_apply : mulBySub f m n = f (m - 1) n - f m (n - 1)`.

Physical meaning

Multiplying by $z_1 - z_2$ is the formal counterpart of multiplying a two-point function by the separation of the insertion points; killing a distribution by a power of $z_1 - z_2$ says it is supported on the diagonal $z_1 = z_2$, i.e. it is a contact term. This is exactly the mechanism by which singular OPE terms (poles in $z_1 - z_2$) are encoded without functions.

Definition 38.4 (Commutator and locality)**.** For two $\mathrm{End}(V)$-valued distributions $a(z), b(z)$ the commutator is the two-variable distribution $[a(z_1), b(z_2)]$ with coefficients $a_m b_n - b_n a_m$. The pair is *mutually local* if $(z_1 - z_2)^N [a(z_1), b(z_2)] = 0$ for some $N \in \mathbb{N}$.

In Lean, `bracketDist a b` is `fun m n ⇒ a m * b n - b n * a m` and `Local a b` is `∃ N : ℕ, mulBySubPow N (bracketDist a b) = 0` (Definition 2.41, `VOA/Foundations/Locality.lean`). Here `a m * b n` is composition of endomorphisms, $a_m \circ b_n$.

Physical meaning

Mutual locality is the CFT statement that the commutator of two chiral fields vanishes at separated points and is a finite sum of contact terms: $\phi_1(z_1)\phi_2(z_2)$ and $\phi_2(z_2)\phi_1(z_1)$ are the same analytic function continued around the other order of the two insertions, up to a pole of finite order. It is the formal version of crossing symmetry (braiding of two operators is trivial for bosonic chiral fields) and the axiom whose verification between two twisted fields is the open relation in this chapter.

Definition 38.5 (Field)**.** An $\mathrm{End}(V)$-valued distribution $a(z)$ is a *field* if for every $x \in V$ the coefficients $a_n x$ vanish for all sufficiently negative n; equivalently, in modes, $a_{(n)}x = 0$ for $n \gg 0$.

In Lean, `IsField a` is `∀ x : V, ∃ B : ℤ, ∀ n : ℤ, n < B → a n x = 0` (Definition 2.43, `VOA/Core/Dong.lean`).

Physical meaning

The truncation condition says that a field applied to a fixed state produces only finitely many negative powers of z: in CFT language the operator–state correspondence, where $\phi(z)|\psi\rangle$ has at worst a pole at $z = 0$ and no essential singularity. It is the formal form of the energy bounded below, so that the OPE of ϕ with any state has finitely many singular terms.

Definition 38.6 (Translation covariance)**.** Given $T \in \mathrm{End}(V)$, a field $a(z)$ is *T-covariant* if $[T, a(z)] = \partial_z a(z)$, i.e. $T a_m - a_m T = (m+1)a_{m+1}$ for every $m \in \mathbb{Z}$.

In Lean, `DCovariant T a` is `∀ m : ℤ, T * a m - a m * T = ((m + 1 : ℤ)) • a (m + 1)` (Definition 4.38, `VOA/Core/ReconstructionExistence.lean`). The coefficient of z^m in $\partial_z \sum_k a_k z^k$ is $(m+1)a_{m+1}$, which is what the right-hand side says. The library also has the operator `deriv` on formal distributions, $(\partial f)_k = (k+1) f_{k+1}$.

Physical meaning

Translation covariance $[L_{-1}, \phi(z)] = \partial_z \phi(z)$ is the Ward identity for translations: L_{-1} generates $z \mapsto z + \epsilon$ on a chiral field. In $V^\natural$ it is required of every block of the combined field, so that moving an operator and acting by the global translation generator agree in both the untwisted and twisted sector.

Definition 38.7 (Generalized binomial coefficient). For $n \in \mathbb{Z}$ and $k \in \mathbb{N}$, $\binom{n}{k} = n(n-1)\cdots(n-k+1)/k!$.

In Lean this is `gBinom n k`, quoted verbatim in Definition 2.14 (`VOA/Foundations/FormalCalculus.lean`).

Physical meaning

The generalised binomial coefficients $\binom{n}{k}$ with $n \in \mathbb{Z}$ are the Taylor coefficients of $(1+x)^n$ and appear in the OPE and Jacobi identities when one expands $(z_1 - z_2)^n$ in one of the two regions $|z_1| > |z_2|$ or $|z_2| > |z_1|$. They are pure combinatorics with no independent physical content.

38.2.3 Vertex algebras and vertex operator algebras

The library's basic structure is `PreVertexAlgebra`: Gannon's *locality* axioms (§5.1.3(a)), with an internal $\mathbb{Z}$-grading by finite-dimensional pieces. It has no translation-covariance axiom and is therefore not a vertex algebra in the standard sense (Chapter 4); the library's `VertexAlgebra` adds that axiom. For this chapter only the VOA level matters, where covariance follows from the translation axiom (VOA3).

```
structure PreVertexAlgebra (𝒱 : Type u) [AddCommGroup 𝒱] [Module ℂ 𝒱] where
  /-- The internal `ℤ`-grading `𝒱 = ⊕ₙ 𝒱ₙ`, as a family of submodules of `𝒱`. -/
  grading : ℤ → Submodule ℂ 𝒱
  /-- The grading is a genuine internal direct-sum decomposition of `𝒱`. -/
  isInternal : DirectSum.IsInternal grading
  /-- Each homogeneous piece `𝒱ₙ` is finite-dimensional (Gannon Def. 5.1.3(a)). -/
  finrank : ∀ n, FiniteDimensional ℂ (grading n)
  /-- The state-field correspondence `Y(u,z) = ∑ₙ u₍ₙ₎ z^{-n-1}`, `ℂ`-linear in `u`. -/
  Y : 𝒱 →ₗ[ℂ] (End ℂ 𝒱)⟦z^±⟧
  /-- The vacuum vector `𝟙`. -/
  vacuum : 𝒱
  /-- The vacuum lies in degree `0`: `𝟙 ∈ 𝒱₀`. -/
  vacuum_mem : vacuum ∈ grading 0
  /-- **VA1 (grading).** For `u ∈ 𝒱ₖ` and `v ∈ 𝒱ₗ`, `u₍ₙ₎ v ∈ 𝒱_{k+ℓ-n-1}`. -/
  grading_mode : ∀ {k ℓ : ℤ} (u : 𝒱), u ∈ grading k → ∀ (v : 𝒱), v ∈ grading ℓ →
    ∀ (n : ℤ), mode (Y u) n v ∈ grading (k + ℓ - n - 1)
  /-- **VA2 (vacuum).** `Y(𝟙, z) = id`, the unit field. -/
  vacuum_Y : Y vacuum = (1 : (End ℂ 𝒱)⟦z^±⟧)
  /-- **VA3 (state-field correspondence).** `u₍₋₁₎ 𝟙 = u` and `u₍ₙ₎ 𝟙 = 0` for `n ≥ 0`. -/
  creation : ∀ u : 𝒱, mode (Y u) (-1) vacuum = u ∧ ∀ n : ℤ, 0 ≤ n → mode (Y u) n vacuum = 0
  /-- **VA4 (locality).** `Y(u,z₁)` and `Y(v,z₂)` are mutually local:
  `(z₁ - z₂)ᴹ [Y(u,z₁), Y(v,z₂)] = 0` for some `M = M(u,v)`. -/
  locality : ∀ u v : 𝒱, Local (Y u) (Y v)
  /-- **VA5 (regularity).** For each `u, v` there is `N` with `u₍ₙ₎ v = 0` for `n ≥ N`. -/
  regularity : ∀ u v : 𝒱, ∃ N : ℤ, ∀ n : ℤ, N ≤ n → mode (Y u) n v = 0
```

(`VOA/Core/VertexAlgebra.lean`.) `DirectSum.IsInternal grading` is Mathlib's statement that the natural map $\bigoplus_n V_n \to V$ is an isomorphism, i.e. $V = \bigoplus_n V_n$. The product $u_{(n)}v$ is written `V.smul u n v := mode (V.Y u) n v`.

A vertex operator algebra adds a conformal vector, in two layers: `GradedVertexOperatorAlgebra` is the Frenkel–Lepowsky–Meurman / Lepowsky–Li notion (Virasoro, L_0-grading, L_{-1}-derivative, grading truncated from below), and `VertexOperatorAlgebra` adds the CFT-type condition (VOA4). Every statement of this chapter is about `VertexOperatorAlgebra`, so CFT type is part of it.

```

```

and the CFT-type layer, whose truncation field is filled automatically from `positivity`,

```
structure VertexOperatorAlgebra (𝒱 : Type u) [AddCommGroup 𝒱] [Module ℂ 𝒱]
    extends GradedVertexOperatorAlgebra 𝒱 where
  /-- **VOA4 (CFT type), part 1.** `𝒱₀ = ℂ𝟙`. -/
  vacuum_grade : grading 0 = ℂ • vacuum
  /-- **VOA4 (CFT type), part 2.** `𝒱ₙ = 0` for `n < 0`. -/
  positivity : ∀ n : ℤ, n < 0 → grading n = ⊥
  grading_bounded_below := ⟨0, positivity⟩
```

(`VOA/Core/VertexOperatorAlgebra.lean`). The library writes L_n for `mode (Y ω) (n+1)`.

Definition 38.8 (Ideals, simplicity). An *ideal* of a vertex operator algebra V is a subspace I with $u_{(n)}v \in I$ for all $u \in V$, $v \in I$, $n \in \mathbb{Z}$. V is *simple* if $V \neq 0$ and its only ideals are 0 and V.

```
def IsIdeal (W : VertexOperatorAlgebra 𝒱) (I : Submodule ℂ 𝒱) : Prop :=
  ∀ (u v : 𝒱) (n : ℤ), v ∈ I → W.smul u n v ∈ I

def IsSimple (W : VertexOperatorAlgebra 𝒱) : Prop :=
  (⊤ : Submodule ℂ 𝒱) ≠ ⊥ ∧ ∀ I : Submodule ℂ 𝒱, W.IsIdeal I → I = ⊥ ∨ I = ⊤
```

(`VOA/Core/BilinearForm.lean`. A deprecated duplicate `IsSimple` in `VOA/Modules/Rationality.lean` is *not* the one used here; every statement of this chapter refers to `VertexOperatorAlgebra.IsSimple` above.)

From the mathematics to the Lean statement

Only left ideals appear in `IsIdeal`: closure under $u_{(n)}$ acting from the left. For a vertex algebra with translation operator, skew-symmetry $Y(v,z)u = e^{zL_{-1}}Y(u,-z)v$ makes a left ideal that is L_{-1}-stable automatically two-sided; for the purposes of simplicity, demanding only left ideals makes "simple" a *stronger* requirement (more subspaces are tested), so the Lean notion is at least as strong as any textbook notion.

Physical meaning

An ideal is a sector of operators that, once present in the spectrum, can only produce more of itself under OPE with anything; a proper ideal is therefore a decoupled subsector with a vacuum-orthogonal state that never talks back to the vacuum. Simplicity says there is no such decoupled sector: the vacuum is the only state that is cyclic for the whole operator algebra, the physical uniqueness of the vacuum and the absence of a spurious superselection sector. Simplicity in this sense is the property that separates the Moonshine module from its square-zero impostor in Section 38.11.

38.2.4 Invariant bilinear forms

Definition 38.9 (Invariant forms)**.** A bilinear form $(\cdot|\cdot)$ on a vertex operator algebra V is *fully invariant* (in the sense of Frenkel–Huang–Lepowsky) if $(Y(u,z)a \mid b) = (a \mid Y(e^{zL_1}(-z^{-2})^{L_0}u, z^{-1})b)$ for all u, a, b. For u of weight wt this is, in modes,

$$(u_{(n)}a \mid b) = (-1)^{\mathrm{wt}} \sum_{j\geq 0} \frac{1}{j!} \left(a \mid (L_1^j u)_{(2\mathrm{wt}-n-2-j)}b\right). \tag{38.2}$$

It is *normalised* if $(\mathbf{1}|\mathbf{1}) = 1$. Its *(left) radical* is $\{x : (x|b) = 0\ \forall b\}$.

To derive (38.2): $(-z^{-2})^{L_0}u = (-1)^{\mathrm{wt}}z^{-2\mathrm{wt}}u$, e^{zL_1} contributes $\sum_j z^j L_1^j/j!$, and $Y(v,z^{-1}) = \sum_k v_{(k)}z^{k+1}$; the total power of z is $-2\mathrm{wt} + j + k + 1$, which equals $-n-1$ exactly when $k = 2\mathrm{wt} - n - 2 - j$. Since L_1 lowers weight and weights are bounded below, the sum over j stops at $j = \mathrm{wt}$.

```
structure InvariantForm (W : VertexOperatorAlgebra 𝒱) where
  /-- The underlying `ℂ`-bilinear form `(·|·) : 𝒱 × 𝒱 → ℂ`. -/
  form : LinearMap.BilinForm ℂ 𝒱
  /-- **Invariance (Virasoro-adjointness).** `(Lₙ u | v) = (u | L₋ₙ v)` for every `n`
  (Gannon 5.1.11a, mode content): each `Lₙ` is adjoint to `L₋ₙ`. -/
  virasoro_adj : ∀ (n : ℤ) (a b : 𝒱), form (W.L n a) b = form a (W.L (-n) b)

abbrev IsFullyInvariant (B : InvariantForm W) : Prop :=
  ∀ (wt : ℤ) (u : 𝒱), u ∈ W.grading wt → ∀ (n : ℤ) (a b : 𝒱),
    B.form (W.smul u n a) b
      = (-1 : ℂ) ^ wt • ∑ j ∈ Finset.range (wt.toNat + 1), ((j.factorial : ℂ)⁻¹) •
          B.form a (W.smul (((W.L 1) ^ j) u) (2 * wt - n - 2 - (j : ℤ)) b)

def Normalized (B : InvariantForm W) : Prop := B.NormalizedAt 1
-- where  NormalizedAt B κ :  B.form W.vacuum W.vacuum = κ

def leftRadical (B : InvariantForm W) : Submodule ℂ 𝒱 := LinearMap.ker B.form
```

(`VOA/Core/BilinearForm.lean`.) `LinearMap.BilinForm ℂ 𝒱` is Mathlib's type of bilinear forms $V\times V \to \mathbb{C}$, curried as $V \to (V \to \mathbb{C})$; its kernel is the set of x with $x \mapsto (x|\cdot)$ zero, i.e. the left radical.

The module analogue of (38.2), for a form B on a V-module M and a fixed homogeneous u of weight wt, is the predicate

```
def FHLInv (N : OrdVModule W M) (B : LinearMap.BilinForm ℂ M) (wt : ℤ) (u : 𝒱) : Prop :=
  ∀ (n : ℤ) (a b : M), B (mode (N.YM u) n a) b
    = (-1 : ℂ) ^ wt • ∑ j ∈ Finset.range (wt.toNat + 1), ((j.factorial : ℂ)⁻¹) •
        B a (mode (N.YM (((W.L 1) ^ j) u)) (2 * wt - n - 2 - (j : ℤ)) b)
```

(VOA/Moonshine/InvFormClosure.lean.)

Physical meaning

A fully invariant form is the Zamolodchikov (BPZ) metric of the CFT: the two-point pairing $\langle\phi|\psi\rangle$ under which the Virasoro generators are adjoint, $L_n^\dagger = L_{-n}$, and a quasi-primary field of weight wt is mapped under inversion $z \mapsto 1/z$ to its conjugate with the factor $(-z^{-2})^{L_0}$. Nondegeneracy of the form is the statement that the two-point function of each operator is nonzero with some partner, which is the CFT form of unitarity-like nondegeneracy (reflection positivity is a further, stronger property not asserted here). The module analogue is the Zamolodchikov metric of the twisted sector.

38.2.5 Weak modules

A weak module `WeakModule W M` (VOA/Modules/WeakModule.lean; quoted verbatim and decoded in Definition 12.1) is a field map `YM : 𝒱 →ₗ[ℂ] (End ℂ M)⟦z^±⟧` with fields `vacuum_YM` ($Y_M(\mathbf{1},z) = \mathrm{id}_M$), `truncation` (lower truncation) and `jacobi`. The `jacobi` field is the Borcherds (Jacobi) identity in modes, where `cbz n i` is $\binom{n}{i}$ for $i \geq 0$ and 0 for $i < 0$, and `negOnePow i` is $(-1)^i$. We write `A.act u n x` for `mode (A.YM u) n x`, i.e. $u_{(n)}x$, and $L_{-1}^M := \omega_{(0)}$ on M (Lean: `Lm1 A`). An `OrdVModule` (an ordinary module, with a $\mathbb{C}$-grading `weight` by finite-dimensional L_0-eigenspaces) has an underlying weak module `toWeakModule`; $L_1^M := \omega_{(2)}$ is `Lp1`.

38.2.6 The objects of the earlier Moonshine chapters

We record the Lean names and a precise mathematical description of the five ingredients (i)–(v) of Section 38.1. Their construction and properties are the subject of the preceding chapters of this Part; here we use only the properties stated.

```
abbrev SkewVP : Type := ↥(orbifold (Subgroup.zpowers leechTheta)).carrier

```

(Files: SkewLeech.lean, TwistedPlus.lean, WbarLeech.lean, InvFormTP.lean, all under VOA/Moonshine/.)

In words:

- `SkewVP` is the carrier of V_Λ^+: the subspace of V_Λ fixed by the group generated by θ (the coercion ↥ turns a subspace into a type).
- `TP` is the subspace $T^+ \subseteq V_\Lambda^T = S[\theta] \otimes T$ (the type `Tw`) of fixed points of the lift of θ to the twisted module. It is used as a type through the same coercion.

- `plusModule` is T^+ as an ordinary V_Λ^+-module: $u_{(n)}x$ is the twisted vertex operator's mode at the integer n (for $u \in V_\Lambda^+$ only integral modes survive).
- `leechLTP` is L_{-1} on T^+.
- `leechWsk t` is the field $W(t,z)$ with coefficient of z^k equal to $W(t)_{(-k-1)}$, where

$$W(t)_{(n)}\varphi = \sum_{i\ge 0} \frac{(-1)^{n+i+1}}{i!}\, L_{-1}^{i}\big(\varphi_{(n+i)}t\big), \tag{38.3}$$

  the z^{-n-1} coefficient of $e^{zL_{-1}}Y^T(\varphi,-z)t$. On the vacuum, $W(t,z)\mathbf{1} = e^{zL_{-1}}t$; in Lean,

```
theorem leechWsk_vacuum (t : TP) (k : ℤ) :
    leechWsk t k leechVOAPlus.vacuum
      = if 0 ≤ k then ((k.toNat.factorial : ℂ)⁻¹) • (leechLTP ^ k.toNat) t else 0
```

- `leechBV` is the canonical invariant form B_V of V_Λ^+, normalised $B_V(\mathbf{1},\mathbf{1}) = 1$; it is symmetric, fully invariant, and nondegenerate on every weight space (`leechBV_gradedNondeg`).
- `TPForm` is the restriction to T^+ of an explicit form on V_Λ^T; it is symmetric (`TPForm_symm`), the weight spaces are mutually orthogonal (`TPForm_weightOrth`), it is nondegenerate on every weight space:

```
theorem TPForm_nondegenerate (α : ℂ) (x : TP) (hx : x ∈ plusModule.weight α) (hx0 : x
↪  ≠ 0) :
    ∃ y ∈ plusModule.weight α, TPForm x y ≠ 0
```

  and it is FHL-invariant for every homogeneous $u \in V_\Lambda^+$ (`TPForm_fhlInv`, with conclusion `InvForm.FHLInv plusModule InvForm.TPForm wt u`).
- `leechWbar t` is the field $\overline{W}(t,z)$ whose mode $\overline{W}(t)_{(n)}$ (`leechWbarMode n t`) is defined, by the Riesz representation on each weight space of V_Λ^+, as the unique linear map $T^+ \to V_\Lambda^+$ satisfying DGM's adjunction (4.3): for $t \in T_w^+$,

$$B_V\big(\overline{W}(t)_{(n)}a,\varphi\big) = (-1)^w \sum_{j\ge 0}\frac{1}{j!}\,\big(a,\ W(L_1^j t)_{(2w-n-2-j)}\varphi\big)_T. \tag{38.4}$$

  In Lean (`VOA/Moonshine/NondegLeech.lean`):

```
theorem leechWbar_adj' (n : ℤ) {w : ℤ} {t : TP} (ht : t ∈ plusModule.weight (w : ℂ))
↪  (R : ℕ)
    (hR : ∀ j : ℕ, R ≤ j → (Lp1 plusModule ^ j) t = 0) (a : TP) (φ : SkewVP) :
    leechBV (leechWbarMode n t a) φ = (-1 : ℂ) ^ w • ∑ j ∈ Finset.range R,
      ((j.factorial : ℂ)⁻¹) • TPForm a (mode (leechWsk ((Lp1 plusModule ^ j) t))
        (2 * w - n - 2 - j) φ)
```

  The bound R is any number past which $L_1^j t = 0$; the sum is then the full sum. Equation (38.4) is exactly (38.2) for the off-diagonal entries of the form $B_V \oplus (\cdot,\cdot)_T$ that we shall put on $V^\natural$: it says that $\overline{W}(t,z)$ is the "FHL adjoint" of $W(t,z)$.

Besides (38.4), the earlier chapters prove, unconditionally, three further properties of $\overline{W}$ that we shall use: it is graded, $\overline{W}(t)_{(n)}T_b^+ \subseteq (V_\Lambda^+)_{b+w-n-1}$ for $t \in T_w^+$ (`leechWbar_mem`); it is lower-truncated (`leechWbar_trunc`); it satisfies $\overline{W}(L_{-1}t,z) = \partial_z \overline{W}(t,z)$ (`leechWbar_deriv`); and it satisfies the intertwining commutator formula

$$u_{(m)}\overline{W}(t)_{(n)}a - \overline{W}(t)_{(n)}u_{(m)}a = \sum_{r\ge 0}\binom{m}{r}\overline{W}(u_{(r)}t)_{(m+n-r)}a \qquad (u \in V_\Lambda^+), \tag{38.5}$$

(`leechWbar_comm'`), the mirror image of the commutator formula for W.

Finally, the generating function of the final targets:

```
noncomputable def jShift : PowerSeries ℂ :=
  E4Series ^ 3 * ((deltaOverQUnit⁻¹ : (PowerSeries ℂ)ˣ) : PowerSeries ℂ)
noncomputable def JShift : PowerSeries ℂ := jShift - (744 : ℂ) • PowerSeries.X
```

(`VOA/Modularity/JFunction.lean`.) Here $E_4^3\cdot(\Delta/q)^{-1}$ is the power series $q\,j(q) = 1+744q+196884q^2+\cdots$, and subtracting $744q$ gives

$$\texttt{JShift} = q\,J(q) = q\big(j(q)-744\big) = 1 + 0\cdot q + 196884\,q^2 + 21493760\,q^3 + \cdots .$$

The coefficient of q^n in `JShift` is therefore the coefficient of q^{n-1} in J; with the usual $L_0-c/24 = L_0-1$ shift, it is the expected dimension of the weight-n space of $V^\natural$.

38.3 Block fields on a direct sum

Everything in this section is linear algebra on an arbitrary direct sum $V \oplus M$ of complex vector spaces; nothing about the Leech lattice is used. The point is to translate the four-block description (38.1) into the language of $\mathrm{End}(V \oplus M)$-valued fields that the definition of a vertex algebra uses, and to see which of the vertex-algebra conditions can be checked block by block.

38.3.1 Block operators

Definition 38.10 (Block operator). For linear maps $a : V \to V$, $c : M \to V$, $d : V \to M$, $b : M \to M$, the *block operator* $\left(\begin{smallmatrix} a & c \\ d & b \end{smallmatrix}\right) \in \mathrm{End}(V \oplus M)$ is $(x, y) \mapsto (ax + cy,\ dx + by)$.

```
def blockOp (a : End ℂ V) (c : M →ₗ[ℂ] V) (d : V →ₗ[ℂ] M) (b : End ℂ M) : End ℂ (V × M) :=
  (a.coprod c).prod (d.coprod b)

@[simp] theorem blockOp_apply (a : End ℂ V) (c : M →ₗ[ℂ] V) (d : V →ₗ[ℂ] M) (b : End ℂ M)
    (x : V × M) : blockOp a c d b x = (a x.1 + c x.2, d x.1 + b x.2) := rfl
```

(`VOA.Moonshine.VnatBlock.blockOp`, `VOA/Moonshine/VnatBlock.lean`.)

From the mathematics to the Lean statement

`V × M` is the product type; as a vector space it is the direct sum $V \oplus M$, with `x.1`, `x.2` the two components. `a.coprod c : V × M →ₗ V` is $(x, y) \mapsto ax + cy$, and `f.prod g` pairs two maps into a product. The argument order `a c d b` — top-left, top-right, bottom-left, bottom-right — is fixed throughout the chapter; note in particular that the off-diagonal block from M to V comes *second*. The `rfl` proof of `blockOp_apply` shows that the definition is literally the matrix action.

Physical meaning

A block operator is a 2×2 operator matrix on untwisted $\oplus$ twisted states: the diagonal entries are the sector-preserving parts of a vertex operator and the off-diagonal ones change sector. It is the formal expression of the $\mathbb{Z}/2$ charge grading of the orbifold, where an untwisted operator preserves twist and a twist field flips it.

Proposition 38.11 (Matrix multiplication). $\left(\begin{smallmatrix} a & c \\ d & b \end{smallmatrix}\right)\left(\begin{smallmatrix} a' & c' \\ d' & b' \end{smallmatrix}\right) = \left(\begin{smallmatrix} aa'+cd' & ac'+cb' \\ da'+bd' & dc'+bb' \end{smallmatrix}\right)$.

```
theorem blockOp_mul (a : End ℂ V) (c : M →ₗ[ℂ] V) (d : V →ₗ[ℂ] M) (b : End ℂ M)
    (a' : End ℂ V) (c' : M →ₗ[ℂ] V) (d' : V →ₗ[ℂ] M) (b' : End ℂ M) :
    blockOp a c d b * blockOp a' c' d' b'
      = blockOp (a * a' + c ∘ₗ d') (a ∘ₗ c' + c ∘ₗ b') (d ∘ₗ a' + b ∘ₗ d')
          (d ∘ₗ c' + b * b') := by
```

From the mathematics to the Lean statement

`*` on `End` is composition and `∘ₗ` is composition of linear maps between different spaces; so the statement is exactly the 2×2 matrix product. The library also proves additivity, scalar multiplication and `blockOp_zero` (the zero matrix is 0).

Physical meaning

Matrix multiplication of block operators is the rule for composing operators in the orbifold theory sector by sector: the untwisted→untwisted amplitude of a product is the untwisted-through-untwisted channel plus the channel with an intermediate twisted state. It is the origin of the sum over intermediate sectors in the orbifold OPE; it is linear algebra, with no physics input.

Proof. Apply both sides to (x, y) and expand. □

38.3.2 Block fields

Definition 38.12 (Block field; diagonal and off-diagonal fields)**.** Given distributions $a(z) \in \mathrm{End}(V)[[z^{\pm}]]$, $c(z) \in \mathrm{Hom}(M, V)[[z^{\pm}]]$, $d(z) \in \mathrm{Hom}(V, M)[[z^{\pm}]]$, $b(z) \in \mathrm{End}(M)[[z^{\pm}]]$, the *block field* is the $\mathrm{End}(V \oplus M)$-valued distribution whose z^k-coefficient is the block operator of the four z^k-coefficients. The *diagonal field* is $\mathrm{diag}(a, b)$ (with $c = d = 0$) and the *off-diagonal field* is $\mathrm{offdiag}(c, d)$ (with $a = b = 0$).

```
def blockF (a : FormalDist (End ℂ V)) (c : FormalDist (M →ₗ[ℂ] V)) (d : FormalDist (V →ₗ[ℂ]
↪  M))
    (b : FormalDist (End ℂ M)) : FormalDist (End ℂ (V × M)) :=
  fun n => blockOp (a n) (c n) (d n) (b n)

def diagF (a : FormalDist (End ℂ V)) (b : FormalDist (End ℂ M)) : FormalDist (End ℂ (V ×
↪  M)) :=
  blockF a 0 0 b

def offF (c : FormalDist (M →ₗ[ℂ] V)) (d : FormalDist (V →ₗ[ℂ] M)) :
    FormalDist (End ℂ (V × M)) :=
  blockF 0 c d 0
```

From the mathematics to the Lean statement

Since modes are just reindexed coefficients, the block field of the modes is the block operator of the modes: $(\text{block field})_{(n)} = \left(\begin{smallmatrix} a_{(n)} & c_{(n)} \\ d_{(n)} & b_{(n)} \end{smallmatrix}\right)$. In (38.1), an untwisted state u gives `diagF (Y u) (Y^T u)`, a twisted state t gives `offF (W̄ t) (W t)` — again with the $T^+ \to V_\Lambda^+$ block $\overline{W}$ first.

Physical meaning

A block field is the full chiral vertex operator of the orbifold theory: its diagonal part is the OPE of an untwisted operator with states of each sector (untwisted×untwisted→untwisted, untwisted×twisted→twisted) and its off-diagonal part is the OPE of a twist field (twisted×untwisted→twisted via W, twisted×twisted→untwisted via $\overline{W}$). Assembling all four channels into one field is what makes the two sectors into a single CFT with one vertex operator per state.

38.3.3 Truncation and translation covariance blockwise

For Hom-valued distributions the library uses the obvious generalisations of Definitions 38.5 and 38.6.

Definition 38.13. A distribution $f(z)$ with values in $\mathrm{Hom}(X, Y)$ is *lower-truncated* if for every $x \in X$ the coefficients $f_n x$ vanish for $n \ll 0$. Given $T_X \in \mathrm{End}\, X$, $T_Y \in \mathrm{End}\, Y$, it is (T_X, T_Y)-*covariant* if $T_Y f_m - f_m T_X = (m+1) f_{m+1}$ for all m, i.e. $T_Y f(z) - f(z) T_X = \partial_z f(z)$.

```
def Trunc {X : Type*} {Y : Type*} [AddCommGroup X] [Module ℂ X] [AddCommGroup Y] [Module ℂ
↪  Y]
    (f : FormalDist (X →ₗ[ℂ] Y)) : Prop :=
  ∀ x : X, ∃ B : ℤ, ∀ n : ℤ, n < B → f n x = 0

def HomCov {X : Type*} {Y : Type*} [AddCommGroup X] [Module ℂ X] [AddCommGroup Y] [Module ℂ
↪  Y]
    (TX : End ℂ X) (TY : End ℂ Y) (f : FormalDist (X →ₗ[ℂ] Y)) : Prop :=
  ∀ m : ℤ, TY ∘ₗ f m - f m ∘ₗ TX = (m + 1 : ℤ) • f (m + 1)
```

Physical meaning

Lower truncation of a Hom-valued distribution is the requirement that each channel of the OPE (e.g. twisted×untwisted→twisted) has a pole of bounded order at coincident points, and covariance is the Ward identity for translations with possibly different generators on source and target sector. Both are the standard consistency conditions on the OPE channels, imposed blockwise.

Proposition 38.14. *(a) If the four blocks are lower-truncated, the block field is a field.*

(b) If a is T_V-covariant, b is T_M-covariant, c is (T_M, T_V)-covariant and d is (T_V, T_M)-covariant, then the block field is covariant for $\mathrm{diag}(T_V, T_M)$.

File `VOA/Moonshine/VnatBlock.lean`.

```
theorem isField_blockF {a : FormalDist (End ℂ V)} {c : FormalDist (M →ₗ[ℂ] V)}
    {d : FormalDist (V →ₗ[ℂ] M)} {b : FormalDist (End ℂ M)}
    (ha : Trunc a) (hc : Trunc c) (hd : Trunc d) (hb : Trunc b) :
    IsField (blockF a c d b) := by

theorem dCovariant_blockF {TV : End ℂ V} {TM : End ℂ M} {a : FormalDist (End ℂ V)}
    {c : FormalDist (M →ₗ[ℂ] V)} {d : FormalDist (V →ₗ[ℂ] M)} {b : FormalDist (End ℂ M)}
    (ha : Reconstruction.DCovariant TV a) (hc : HomCov TM TV c) (hd : HomCov TV TM d)
    (hb : Reconstruction.DCovariant TM b) :
    Reconstruction.DCovariant (blockOp TV 0 0 TM) (blockF a c d b) := by
```

From the mathematics to the Lean statement

Hypotheses in (a): the four truncations, one for each block; for c and d the relevant input vector lives in M resp. V. In (b) the order of the two translation operators in `HomCov` is (source, target): $c : M \to V$ is (T_M, T_V)-covariant, $d : V \to M$ is (T_V, T_M)-covariant. The conclusion uses the diagonal operator `blockOp TV 0 0 TM`. Both statements are the textbook ones; they are implications, so they cannot be vacuous unless their hypotheses are unsatisfiable, and the hypotheses are verified later for the actual blocks.

Physical meaning

Physically: if each of the four OPE channels has bounded-order singularities and obeys the translation Ward identity separately, the combined orbifold vertex operator does too. This is the statement that translation invariance and finiteness of the OPE are sector-by-sector conditions and need no cross-sector checking. It is bookkeeping, not dynamics.

Proof. (a) For (x, y) take the minimum of the four truncation bounds (for a, d at x, for c, b at y). (b) $[\mathrm{diag}(T_V, T_M), X]$ for a block matrix X is the block matrix with entries $T_V a - a T_V$, $T_V c - c T_M$, $T_M d - d T_V$, $T_M b - b T_M$; apply the four hypotheses. □

38.3.4 Locality blockwise

Here is the real content. Locality of two block fields is not, in general, a blockwise condition, because the product of two block matrices mixes the blocks. But in two important special cases it reduces to conditions on the blocks.

Theorem 38.15 (Diagonal–diagonal locality). *If $a \sim a'$ on V and $b \sim b'$ on M (mutually local), then* $\mathrm{diag}(a, b)$ *and* $\mathrm{diag}(a', b')$ *are mutually local.*

File `VOA/Moonshine/VnatBlock.lean`.

```
theorem local_diag_diag {a a' : FormalDist (End ℂ V)} {b b' : FormalDist (End ℂ M)}
    (ha : Local a a') (hb : Local b b') : Local (diagF a b) (diagF a' b') := by
```

Physical meaning

Two untwisted-type operators, acting on the untwisted and twisted sectors simultaneously, have trivial braiding on the orbifold space as soon as they do so on each sector. Here the untwisted×untwisted→untwisted locality is crossing symmetry in the parent CFT, and the module version is locality of the induced action on the twisted sector; both are established earlier in the book. The result is the easy half of the orbifold's mutual-locality consistency.

Theorem 38.16 (Diagonal–off-diagonal locality). $\mathrm{diag}(a(z_1), b(z_1))$ *and* $\mathrm{offdiag}(c'(z_2), d'(z_2))$ *are mutually local provided that, for some N,*

$$(z_1 - z_2)^N \big(a(z_1)c'(z_2) - c'(z_2)b(z_1)\big) = 0 \quad \text{and} \quad (z_1 - z_2)^N \big(b(z_1)d'(z_2) - d'(z_2)a(z_1)\big) = 0.$$

File `VOA/Moonshine/VnatBlock.lean`.

```
theorem local_diag_off {a : FormalDist (End ℂ V)} {b : FormalDist (End ℂ M)}
    {c' : FormalDist (M →ₗ[ℂ] V)} {d' : FormalDist (V →ₗ[ℂ] M)}
    (hc : ∃ N : ℕ, mulBySubPow N
      ((fun m n => a m ∘ₗ c' n - c' n ∘ₗ b m) : FormalDist₂ (M →ₗ[ℂ] V)) = 0)
    (hd : ∃ N : ℕ, mulBySubPow N
      ((fun m n => b m ∘ₗ d' n - d' n ∘ₗ a m) : FormalDist₂ (V →ₗ[ℂ] M)) = 0) :
    Local (diagF a b) (offF c' d') := by
```

From the mathematics to the Lean statement

The two hypotheses are Hom-valued: `fun m n ⇒ a m ∘ₗ c' n - c' n ∘ₗ b m` is the two-variable distribution with coefficients $a_m c'_n - c'_n b_m \in \mathrm{Hom}(M, V)$, the "intertwining commutator". For our application, $a = Y(u)$, $b = Y^T(u)$ and $c' = \overline{W}(t)$, $d' = W(t)$: the hypotheses say that $\overline{W}(t)$ intertwines $Y^T(u)$ with $Y(u)$ and that $W(t)$ intertwines $Y(u)$ with $Y^T(u)$, up to a power of $(z_1 - z_2)$ — the usual locality condition for an intertwining operator. The two `N`'s may differ (the proof takes the maximum), which matches the textbook. The theorem is an

implication, not an equivalence; only the direction needed is claimed.

Physical meaning

This is the crossing condition between an untwisted operator and a twist field: moving an untwisted operator around a twist field is controlled by the intertwining (fusion) relations of W and $\overline{W}$, and the theorem says that the two intertwining relations in the hypothesis suffice. Heuristically this is the statement that the twisted sector is a consistent representation of the untwisted chiral algebra. The hypotheses are verified for W in the earlier chapters and for $\overline{W}$ via the commutator formula.

Proof of both theorems. Write $X = \left(\begin{smallmatrix} a & c \\ d & b \end{smallmatrix}\right)$, $X' = \left(\begin{smallmatrix} a' & c' \\ d' & b' \end{smallmatrix}\right)$. By Proposition 38.11, the commutator $[X(z_1), X'(z_2)]$ is the block matrix

$$\begin{pmatrix} [a,a'] + cd' - c'd & ac' + cb' - a'c - c'b \\ da' + bd' - d'a - b'd & [b,b'] + dc' - d'c \end{pmatrix},$$

all entries evaluated at (z_1, z_2) in the obvious way. Since $(z_1 - z_2)^N$ acts entrywise, the commutator is killed by $(z_1 - z_2)^N$ iff each entry is. For two diagonal fields, $c = d = c' = d' = 0$, and the entries reduce to $[a,a']$, 0, 0, $[b,b']$. For a diagonal field against an off-diagonal one, $c = d = a' = b' = 0$, and the entries reduce to 0, $ac' - c'b$, $bd' - d'a$, 0. In both cases the hypotheses kill each entry for N the maximum of the given orders (a larger power of $(z_1 - z_2)$ still kills). □

Remark 38.17. For two off-diagonal fields ($a = b = a' = b' = 0$) the same computation gives a *diagonal* commutator, with entries $cd' - c'd$ on V and $dc' - d'c$ on M. This is the twisted–twisted case, treated in Section 38.8: there locality is *equivalent* to two End-valued relations, which for $V^\natural$ are DGM's (4.22) and (4.23).

What the machine verified

`blockOp`, `blockF`, `diagF`, `offF`, `isField_blockF`, `dCovariant_blockF`, `local_diag_diag`, `local_diag_off`: generic, unconditional, `##print axioms` = `[propext, Classical.choice, Quot.sound]` (checked for `local_diag_off`; the others are dependencies of checked theorems).

38.4 Locality of the fields of a module

For the diagonal blocks of (38.1) we need that the fields $Y^T(u,z)$, $Y^T(v,z)$ of the V_Λ^+-module T^+ are mutually local. For the vertex algebra itself locality is an axiom; for a module defined by the Jacobi identity it is a theorem — but one the library did not have when this part of the construction was written. It is proved here for an arbitrary weak module, and it is worth explaining because it shows the mechanism by which all localities in this chapter are proved: a *commutator formula* with finitely many terms.

Theorem 38.18 (Module commutator formula)**.** *Let M be a weak module over a vertex operator algebra W, $u, v \in W$, and suppose $J \in \mathbb{N}$ is such that $u_{(j)}v = 0$ for all $j \geq J$. Then for all $m, n \in \mathbb{Z}$ and $x \in M$,*

$$u_{(m)}v_{(n)}x - v_{(n)}u_{(m)}x = \sum_{r=0}^{J-1} \binom{m}{r} (u_{(r)}v)_{(m+n-r)}x.$$

File `VOA/Moonshine/VnatBlock.lean`.

```
theorem act_comm (A : WeakModule W M) (u v : V) (m n : ℤ) (x : M) (J : ℕ)
    (hJ : ∀ j : ℕ, J ≤ j → W.smul u j v = 0) :
    A.act u m (A.act v n x) - A.act v n (A.act u m x)
      = ∑ r ∈ Finset.range J, gBinom m r • A.act (W.smul u r v) (m + n - r) x := by
```

From the mathematics to the Lean statement

`A.act u m x` is $u_{(m)}x$ in M; `W.smul u r v` is $u_{(r)}v$ in W; `Finset.range J` is $\{0,\dots,J-1\}$; `gBinom m r` is $\binom{m}{r}$. The hypothesis `hJ` says J is past the truncation of $u_{(.)}v$; by VA5 such J exists. This is exactly the textbook commutator formula; since the sum is finite, no convergence issue arises.

Physical meaning

This is the operator-algebra form of the Jacobi identity: the commutator of two modes of a chiral algebra is a finite sum of modes of the OPE coefficients, $[u_{(m)},v_{(n)}] = \sum_r \binom{m}{r}(u_{(r)}v)_{(m+n-r)}$. Applied to modules it says that the commutator algebra of the vertex operators of any sector of the CFT closes in the way dictated by the OPE in the vacuum sector. It is the formal origin of the algebra of Noether charges and currents.

Proof. Take $\ell = 0$ in the module Jacobi identity (the `jacobi` field of `WeakModule`). On the left only $i = 0$ survives, because $\binom{0}{i} = 0$ for $i \neq 0$, leaving $u_{(m)}v_{(n)}x - v_{(n)}u_{(m)}x$. On the right, $\binom{m}{i}$ vanishes for $i < 0$ and $u_{(i)}v = 0$ for $i \geq J$, leaving the displayed finite sum. □

Theorem 38.19 (Locality of module fields). *For every weak module M of W and all $u, v \in W$, the fields $Y_M(u,z)$ and $Y_M(v,z)$ are mutually local.*

File `VOA/Moonshine/VnatBlock.lean`.

```
theorem local_YM (A : WeakModule W M) (u v : 𝒱) : Local (A.YM u) (A.YM v) := by
```

(`VOA.Moonshine.VnatBlock.local_YM`.)

From the mathematics to the Lean statement

No hypotheses beyond A being a weak module. `Local` is Definition 38.4 for the $\mathrm{End}(M)$-valued fields `A.YM u`, `A.YM v`. Same as the textbook statement (e.g. Lepowsky–Li, Prop. 4.2.1 in the module setting). It could be vacuous only if `WeakModule` were unsatisfiable; the adjoint module of any VOA is a weak module, and the library's `plusModule` is one.

Physical meaning

Every sector of a chiral CFT (every module) carries mutually local fields: braiding of two untwisted operators acting on any representation is trivial up to contact terms, because the same OPE holds in every sector. This is why the twisted sector of the orbifold, viewed only as a representation of the untwisted algebra, causes no locality trouble; the difficulty sits entirely in twist×twist.

Proof. Let N be the truncation order of $u_{(.)}v$. By Theorem 38.18, rewritten as an identity of two-variable distributions,

$$[Y_M(u,z_1),Y_M(v,z_2)] = \sum_{r=0}^{N-1} Y_M(u_{(r)}v,z_2)\,\frac{1}{r!}\partial_{z_2}^r\delta(z_1-z_2),$$

where $\delta(z_1-z_2) = \sum_k z_1^{-k-1}z_2^k$ is the formal delta function (the coefficient pattern $\binom{-a-1}{r}$ of the r-th derivative is what the library calls a "jump distribution"). Since $(z_1-z_2)^{r+1}\partial_{z_2}^r\delta(z_1-z_2) = 0$, the power $(z_1-z_2)^N$ kills every term. □

Remark 38.20. The physical meaning: the operator product expansion $Y(u,z_1)Y(v,z_2) \sim \sum_r \frac{Y(u_{(r)}v,z_2)}{(z_1-z_2)^{r+1}}$ has a pole of finite order, and the same OPE governs the action on any module. Locality is the statement that the two orderings of the product are boundary values of one rational function with poles only on the diagonal.

Two consequences of the same commutator formula, used for translation covariance:

Proposition 38.21. *(a) The fields of a weak module are L_{-1}^M-covariant: $[L_{-1}^M, Y_M(u,z)] = \partial_z Y_M(u,z)$. (b) For a weak module M and $t \in M$, the skew field $W(t,z)\varphi = e^{zL_{-1}} Y_M(\varphi,-z)t$ is (L_{-1}, L_{-1}^M)-covariant.*

File `VOA/Moonshine/VnatBlock.lean`.

```
theorem dCovariant_YM (A : WeakModule W M) (u : 𝒱) :
    Reconstruction.DCovariant (Lm1 A) (A.YM u) := by

theorem homCov_Wsk (A : WeakModule W M) (t : M) : HomCov (W.L (-1)) (Lm1 A) (Wsk A t) := by
```

From the mathematics to the Lean statement

`Lm1 A` is $\omega_{(0)}$ on M; `W.L (-1)` is L_{-1} on W; `Wsk A t` is the field whose z^k-coefficient is the map $\varphi \mapsto W(t)_{(-k-1)}\varphi$ of (38.3). In `homCov_Wsk` the source of $W(t,z)$ is W (the VOA) and the target is M, so the order `(W.L (-1)) (Lm1 A)` is (source, target), as in Definition 38.13.

Physical meaning

Part (a) is the Ward identity for translations in every sector. Part (b) says that the skew field $W(t,z)$, i.e. the twisted operator t acting on untwisted states by reading the OPE backwards, $\phi_t(z)\varphi = e^{zL_{-1}}Y(\varphi,-z)t$, also translates correctly. This is the skew-symmetry of the OPE: exchanging two operators is the same as moving one by $e^{zL_{-1}}$ and flipping the sign of the coordinate.

Proof. (a) Apply Theorem 38.18 with u replaced by ω and $m = 0$: $[\omega_{(0)}, u_{(n)}] = (\omega_{(0)}u)_{(n)} = (L_{-1}u)_{(n)} = -n\,u_{(n-1)}$, the last step being the module translation property $Y_M(L_{-1}u,z) = \partial_z Y_M(u,z)$. Re-indexed by powers of z (the coefficient of z^m is $u_{(-m-1)}$), this is $[L_{-1}^M, Y_M(u)_m] = (m+1)Y_M(u)_{m+1}$. (b) The commutator formula for the skew operator W at $u = \omega$, $m = 0$ gives $L_{-1}^M W(t)_{(n)}\varphi - W(t)_{(n)}L_{-1}\varphi = W(L_{-1}^M t)_{(n)}\varphi$, and $W(L_{-1}^M t,z) = \partial_z W(t,z)$ (both proved for W in the chapter on intertwiners). □

What the machine verified

`act_comm`, `local_YM`, `dCovariant_YM`, `homCov_Wsk`: general (any VOA, any weak module), unconditional, axiom-clean (`local_YM` checked directly).

38.5 The carrier $V^\natural$ and its grading

Definition 38.22 (The carrier, its grading, vacuum and conformal vector). $V^\natural := V_\Lambda^+ \oplus T^+$, graded by $V^\natural{}_n := (V_\Lambda^+)_n \oplus T_n^+$ for $n \in \mathbb{Z}$, where T_n^+ is the L_0-eigenspace of eigenvalue n. The vacuum is $\mathbf{1}^\natural = (\mathbf{1}, 0)$ and the conformal vector is $\omega^\natural = (\omega, 0)$.

```
abbrev Vnat : Type := SkewVP × TP

noncomputable def gradingNat (n : ℤ) : Submodule ℂ Vnat :=
  (leechVOAPlus.grading n).prod (plusModule.weight (n : ℂ))

noncomputable def vacNat : Vnat := (leechVOAPlus.vacuum, 0)

noncomputable def omegaNat : Vnat := (leechVOAPlus.conformalVector, 0)
```

(`VOA/Moonshine/VnatCarrier.lean`.)

From the mathematics to the Lean statement

`p.prod q` for submodules $p \le V, q \le M$ is $p \oplus q \le V \oplus M$. The module T^+ carries a $\mathbb{C}$-indexed grading `plusModule.weight α` by L_0-eigenvalue; it is read here at the integer n (the cast `(n : ℂ)`). This loses nothing: the earlier chapter proves that every nonzero weight space of T^+ has an integral weight ≥ 2 (`plusModule_weight_ne_bot`). The conformal vector is $(\omega, 0)$, not ω plus a twisted correction: in the orbifold the Virasoro field is untwisted. **Important for the trap:** none of these four definitions involves W or $\overline{W}$. They describe a graded vector space, not a vertex algebra.

Physical meaning

The carrier $V^\natural$ is the state space of the orbifold CFT: untwisted sector (the reflection-invariant states of the Leech-torus theory) plus twisted sector (the invariant states of the twist-field Hilbert space at the 2^{24} fixed points). The vacuum is the untwisted vacuum and the conformal vector is the untwisted stress tensor $T(z)$, so the total theory has $c = 24$. Weight spaces are the L_0 eigenspaces, which is how the graded dimensions become the coefficients of the partition function.

Theorem 38.23 ($V^\natural = \bigoplus_n V^\natural{}_n$). *The subspaces $V^\natural{}_n$, $n \in \mathbb{Z}$, form an internal direct sum decomposition of $V^\natural$, and each $V^\natural{}_n$ is finite-dimensional with* $\dim V^\natural{}_n = \dim (V_\Lambda^+)_n + \dim T_n^+$.

```
theorem gradingNat_isInternal : DirectSum.IsInternal gradingNat :=

instance finiteDimensional_gradingNat (n : ℤ) : FiniteDimensional ℂ (gradingNat n) := by

theorem finrank_gradingNat (n : ℤ) :
    finrank ℂ (gradingNat n)
      = finrank ℂ (leechVOAPlus.grading n) + finrank ℂ (plusModule.weight (n : ℂ)) := by
```

From the mathematics to the Lean statement

`finrank ℂ X` is Mathlib's dimension of a $\mathbb{C}$-vector space X (as a natural number; it is 0 for infinite-dimensional X, which is why finite-dimensionality is stated separately, as an instance). The coercion turns the submodule `gradingNat n` into a vector space.

Physical meaning

The state space is a graded sum of finite-dimensional L_0-eigenspaces: the energy spectrum is discrete with finite degeneracies, so the partition function $\mathrm{Tr}\, q^{L_0 - c/24}$ exists as a formal power series. This is the minimal input needed to speak of a modular-invariant partition function.

Proof. Independence: if $x \in V^\natural{}_n$ also lies in the sum of the other $V^\natural{}_k$, project to the two components; the first lies in $(V_\Lambda^+)_n$ and in the sum of the other $(V_\Lambda^+)_k$, hence is 0; the second likewise, using the $\mathbb{C}$-grading of T^+ and that $k \ne n$ implies $(k : \mathbb{C}) \ne (n : \mathbb{C})$. Spanning: (V_Λ^+) is spanned by its graded pieces, and T^+ is spanned by its *integral* weight spaces because the others are zero. The dimension is that of a direct sum. □

Theorem 38.24 (Low weights). $V^\natural{}_n = 0$ *for* $n < 0$; $V^\natural{}_0 = \mathbb{C}\mathbf{1}^\natural$; $V^\natural{}_1 = 0$.

```
theorem gradingNat_neg {n : ℤ} (hn : n < 0) : gradingNat n = ⊥ := by

theorem gradingNat_zero : gradingNat 0 = ℂ • vacNat := by

theorem gradingNat_one : gradingNat 1 = ⊥ := by
```

From the mathematics to the Lean statement

`⊥` is the zero subspace; `ℂ • vacNat` is the line spanned by $\mathbf{1}^\natural$.

Physical meaning

No negative-energy states, a unique vacuum, and in particular no weight-one states: the theory has no conserved currents. In 2d CFT terms $V_1^\natural = 0$ means there is no continuous global symmetry, so the symmetry group is a finite group, which by FLM's theorem is the Monster (not formalized in the library). Such a theory has no free parameters in its Hilbert space and no marginal-looking Lie-algebra structure at weight one. The absence of a weight-one sector holds for the genuine theory and also for the impostor, so this does not distinguish them.

Proof. $T_n^+ = 0$ for $n < 2$ (its weights are ≥ 2), so in weights ≤ 1 only the untwisted part contributes. V_Λ^+ has CFT type ($V_0 = \mathbb{C}\mathbf{1}$, $V_n = 0$ for $n < 0$), and $(V_\Lambda^+)_1 = 0$: the weight-one space of V_Λ is $\mathfrak{h} = \mathbb{C} \otimes \Lambda$ (the Leech lattice has no roots), on which θ acts by -1. □

Theorem 38.25 (Griess dimension). $\dim {V^\natural}_2 = 196884$.

```
theorem finrank_gradingNat_two : finrank ℂ (gradingNat 2) = 196884 := by
```

Physical meaning

The first nontrivial energy level has $196884 = 196883 + 1$ states: the 196883-dimensional irreducible representation of the Monster plus the trivial one (the stress tensor); the Monster action is a fact of the literature, not formalized here. The weight-two space is the Griess algebra; in the orbifold it splits as 98580 untwisted states ($300 + 98280$: the symmetric square of the oscillators and the pairs $e^\alpha + e^{-\alpha}$, $\alpha^2 = 4$) plus $98304 = 24 \cdot 4096$ twist-field states. The total matches the first Moonshine coincidence $1 + 196883$ in the j-function.

Proof. $\dim(V_\Lambda^+)_2 = 98580$ and $\dim T_2^+ = 98304$, proved in the chapters on graded dimensions and on the twisted module; $98580 + 98304 = 196884$. For the reader's orientation: $(V_\Lambda)_2$ has dimension $\binom{24+1}{2} + 24 + 196560 = 300 + 24 + 196560 = 196884$ ($\mathrm{Sym}^2\mathfrak{h}$, $\mathfrak{h}(-2)$, and the e^α with $\alpha^2 = 4$); θ fixes $\mathrm{Sym}^2\mathfrak{h}$ (300), negates $\mathfrak{h}(-2)$, and fixes exactly one combination $e^\alpha + \theta e^\alpha$ per pair $\pm\alpha$ (98280), giving $300 + 98280 = 98580$; and $T_2^+ = \mathfrak{h}(-\frac{1}{2})\mathbf{1} \otimes T$ has dimension $24 \cdot 4096 = 98304$. □

Theorem 38.26 (Graded dimension = J). *For every $n \in \mathbb{N}$, $\dim {V^\natural}_n$ equals the coefficient of q^n in $qJ(q)$.*

File `VOA/Moonshine/VnatCarrier.lean`.

```
theorem finrank_gradingNat_eq_coeff_JShift (n : ℕ) :
    (finrank ℂ (gradingNat (n : ℤ)) : ℂ) = PowerSeries.coeff n JShift := by
```

From the mathematics to the Lean statement

The dimension is cast to $\mathbb{C}$ because `JShift` is a power series over $\mathbb{C}$; since the dimension is a natural number, equality in $\mathbb{C}$ is equality of integers. `PowerSeries.coeff n` extracts the coefficient of q^n. `JShift` $= qJ$ was defined in Section 38.2; it is the *pre-existing* library definition $E_4^3/(\Delta/q) - 744q$, not a series reverse-engineered from the dimensions. The statement covers every $n \geq 0$; for $n < 0$ both sides would be zero (Theorem 38.24).

Physical meaning

The partition function of the orbifold equals $J(\tau) = j(\tau) - 744$ (holomorphic, $c = 24$, modular invariant up to the usual q^{-1} prefactor). This is the analytic reading on paper; the Lean theorem is an identity of formal q-series, and neither modular invariance nor holomorphy of $V^\natural$ is formalized. This is the Moonshine statement: the graded dimension of $V^\natural$ is the unique modular function with the right pole and no constant term. It is the numerical check that the untwisted and twisted sectors together produce a modular-invariant theory; it does not detect whether the OPE is correct, as the trap section shows.

Proof. The weight-n dimension is a sum of two sector dimensions; the identity $\sum_n (\dim (V_\Lambda^+)_n + \dim T_n^+) q^n = qJ(q)$ is the main theorem of the chapter on graded dimensions (Leech theta series $\Theta_\Lambda = E_4^3 - 720\Delta$, Jacobi's product for Δ, and a level-two identity for the twisted sector). □

Trap / dead end

These four numerical theorems do not depend on any vertex operator. The grading `gradingNat` is defined from the two sectors alone. Therefore any vertex operator algebra structure on `Vnat` with grading `gradingNat` — the genuine one, or the square-zero extension of Section 38.11 — has $V_1 = 0$, $\dim V_2 = 196884$ and graded dimension J. The theorems of this section are necessary for the final result but cannot distinguish $V^\natural$ from an impostor.

What the machine verified

`Vnat`, `gradingNat`, `gradingNat_isInternal`, `gradingNat_zero`, `gradingNat_one`, `finrank_gradingNat_two`, `finrank_gradingNat_eq_coeff_JShift`: unconditional; `##print axioms` = `[propext, Classical.choice, Quot.sound]` for the last two (checked).

38.6 The generator fields and the reconstruction interface

38.6.1 Translation, and the untwisted fields

Definition 38.27. $T^\natural := \mathrm{diag}(L_{-1}, L_{-1}^T) \in \mathrm{End}\, V^\natural$, where L_{-1}^T is L_{-1} on T^+. For $u \in V_\Lambda^+$, $Y_U^\natural(u,z) := \mathrm{diag}(Y(u,z), Y^T(u,z))$.

```
noncomputable def Tnat : End ℂ Vnat := blockOp (leechVOAPlus.L (-1)) 0 0 leechLTP

noncomputable def YnatU (u : SkewVP) : FormalDist (End ℂ Vnat) :=
  diagF (leechVOAPlus.Y u) (plusModule.YM u)
```

(`VOA/Moonshine/VnatFields.lean`.)

Physical meaning

$T^\natural$ is the global translation generator L_{-1} acting simultaneously on both sectors, and $Y_U^\natural(u)$ is the vertex operator of an untwisted state, acting on both sectors by the parent vertex operator and its action on the twisted module: the diagonal part of the orbifold OPE. The twist field has no diagonal part.

Proposition 38.28. *For all $u, u' \in V_\Lambda^+$: (a) $Y_U^\natural(u,z)$ is a field; (b) its z^0-coefficient sends $\mathbf{1}^\natural$ to $(u,0)$ and its z^q-coefficients for $q < 0$ kill $\mathbf{1}^\natural$; (c) it is $T^\natural$-covariant; (d) $Y_U^\natural(u,z)$ and $Y_U^\natural(u',z)$ are mutually local.*

```
theorem YnatU_isField (u : SkewVP) : IsField (YnatU u) :=
theorem YnatU_vac_zero (u : SkewVP) : YnatU u 0 vacNat = (u, 0) := by
theorem YnatU_vac_neg (u : SkewVP) (q : ℤ) (hq : q < 0) : YnatU u q vacNat = 0 := by
theorem YnatU_DCovariant (u : SkewVP) : DCovariant Tnat (YnatU u) :=
theorem YnatU_local (u u' : SkewVP) : Local (YnatU u) (YnatU u') :=
  local_diag_diag (leechVOAPlus.locality u u') (local_YM plusModule.toWeakModule u u')
```

From the mathematics to the Lean statement

(b) is stated in the raw indexing: `YnatU u 0` is the z^0-coefficient, i.e. the mode $u_{(-1)}$, and `q < 0` means modes $u_{(n)}$ with $n = -q - 1 \geq 0$. So (b) is the creation axiom VA3 for untwisted states. The proof term of (d), displayed, shows the logic: locality of the V_Λ^+-block is the VOA axiom, locality of the T^+-block is Theorem 38.19, and they combine by Theorem 38.15. These are DGM's relations (4.18)–(4.19).

Physical meaning

Untwisted operators, acting on the whole orbifold space, are bona fide quantum fields: finite OPE singularities, creation of u from the vacuum, the translation Ward identity, and mutual locality among themselves. These are the axioms of a chiral algebra restricted to the untwisted subalgebra V_Λ^+, which is a CFT in its own right.

Proof. (a) from VA5 for V_Λ^+ and module truncation, through Proposition 38.14(a); (b) from VA3 of V_Λ^+ (the T^+-component of $\mathbf{1}^\natural$ is 0); (c) from Proposition 38.21(a) and its VOA case, through Proposition 38.14(b); (d) as displayed. □

38.6.2 The twisted fields, with $\overline{W}$ as a parameter

To see clearly which properties of $\overline{W}$ are used where, the library first defines the twisted field with $\overline{W}$ an *arbitrary* parameter.

Definition 38.29. For any family $\overline{W}'$ assigning to each $t \in T^+$ a distribution $\overline{W}'(t,z) \in \mathrm{Hom}(T^+, V_\Lambda^+)[[z^{\pm}]]$, put $Y_T^\natural[\overline{W}'](t,z) := \mathrm{offdiag}(\overline{W}'(t,z), W(t,z))$.

```
noncomputable def YnatT (Wbar : TP → FormalDist (TP →ₗ[ℂ] SkewVP)) (t : TP) :
    FormalDist (End ℂ Vnat) :=
  offF (Wbar t) (leechWsk t)
```

Physical meaning

A twist-field operator acts on the orbifold space by the two intertwining channels: twisted→untwisted via $\overline{W}'$ and untwisted→twisted via W. Leaving $\overline{W}'$ as a parameter separates what holds for any choice of the twisted×twisted OPE from what depends on its actual value, which is the key to the trap: the choice $\overline{W}' = 0$ is the theory in which twist fields annihilate twisted states.

Proposition 38.30 (Creation for twisted states, for every $\overline{W}'$). *For every $\overline{W}'$ and $t \in T^+$: the z^0-coefficient of $Y_T^\natural[\overline{W}'](t,z)$ sends $\mathbf{1}^\natural$ to $(0,t)$, and the z^q-coefficients with $q < 0$ kill $\mathbf{1}^\natural$.*

```
theorem YnatT_vac_zero (Wbar : TP → FormalDist (TP →ₗ[ℂ] SkewVP)) (t : TP) :
    YnatT Wbar t 0 vacNat = (0, t) := by

theorem YnatT_vac_neg (Wbar : TP → FormalDist (TP →ₗ[ℂ] SkewVP)) (t : TP) (q : ℤ) (hq : q <
↪  0) :
    YnatT Wbar t q vacNat = 0 := by
```

Physical meaning

Acting on the vacuum, the operator of a twisted state creates that state, whatever the OPE twisted×twisted→untwisted is. This is the state–operator correspondence: it fixes only the W block, since the vacuum has no twisted component. Hence creation cannot detect whether $\overline{W}'$ is the correct OPE.

Proof. $\mathbf{1}^\natural = (\mathbf{1}, 0)$ has zero twisted component, so $\overline{W}'$ never acts on it; the untwisted component is fed to $W(t,z)$, and $W(t,z)\mathbf{1} = e^{zL_{-1}}t$, whose z^0-coefficient is t and which has no negative powers. □

Trap / dead end

Creation does not see $\overline{W}'$ at all. This is the first sign of the trap: anything proved from the vacuum alone cannot detect whether $\overline{W}'$ is the genuine $\overline{W}$ or zero.

The intertwining commutator formula for the parameter is singled out as a named property:

Definition 38.31 ($\overline{W}'$-commutator formula). $\overline{W}'$ satisfies *the commutator formula* if for all $u \in V_\Lambda^+$, $t \in T^+$, $m, n \in \mathbb{Z}$ and every J past the truncation of $u_{(.)}t$,

$$u_{(m)} \circ \overline{W}'(t)_{(n)} - \overline{W}'(t)_{(n)} \circ u_{(m)} = \sum_{r<J} \binom{m}{r} \overline{W}'(u_{(r)}t)_{(m+n-r)},$$

an equality of linear maps $T^+ \to V_\Lambda^+$ (on the left, the first $u_{(m)}$ acts on V_Λ^+, the second on T^+).

File `VOA/Moonshine/VnatFields.lean`.

```
def WbarComm (Wbar : TP → FormalDist (TP →ₗ[ℂ] SkewVP)) : Prop :=
  ∀ (u : SkewVP) (m : ℤ) (t : TP) (n : ℤ) (J : ℕ),
    (∀ j : ℕ, J ≤ j → mode (plusModule.YM u) j t = 0) →
    mode (leechVOAPlus.Y u) m ∘ₗ mode (Wbar t) n - mode (Wbar t) n ∘ₗ mode (plusModule.YM
     ↪ u) m
      = ∑ r ∈ Finset.range J, gBinom m r • mode (Wbar (mode (plusModule.YM u) r t)) (m + n
       ↪ - r)
```

Physical meaning

The commutator formula for $\overline{W}'$ is the Ward identity of the untwisted chiral algebra on the twisted→untwisted OPE channel: the algebra acts on twist fields by the same rule as on any intertwining operator, so that the charges of untwisted fields rotate $\overline{W}'$ into $\overline{W}'$ of the transformed twisted state. It is the property that makes $\overline{W}'$ an intertwiner rather than an arbitrary map.

Theorem 38.32 (Untwisted–twisted locality). *If $\overline{W}'$ satisfies the commutator formula, then for all $u \in V_\Lambda^+$, $t \in T^+$ the fields $Y_U^\natural(u,z)$ and $Y_T^\natural[\overline{W}'](t,z)$ are mutually local (in both orders).*

File `VOA/Moonshine/VnatFields.lean`.

```
theorem YnatU_YnatT_local {Wbar : TP → FormalDist (TP →ₗ[ℂ] SkewVP)} (hcomm : WbarComm
 ↪ Wbar)
    (u : SkewVP) (t : TP) : Local (YnatU u) (YnatT Wbar t) :=
  local_diag_off (local_Wbar_of_comm hcomm u t) (leechWsk_local u t)

theorem YnatT_YnatU_local {Wbar : TP → FormalDist (TP →ₗ[ℂ] SkewVP)} (hcomm : WbarComm
 ↪ Wbar)
    (t : TP) (u : SkewVP) : Local (YnatT Wbar t) (YnatU u) :=
```

From the mathematics to the Lean statement

The single hypothesis `hcomm` is Definition 38.31. The proof term shows the two inputs to Theorem 38.16: locality of $Y(u)$ with $\overline{W}'(t)$, which is derived from `hcomm` exactly as Theorem 38.19 is derived from the module commutator formula, and locality of $Y(u)$ with $W(t)$ (`leechWsk_local`), proved in the chapter on intertwiners from the commutator formula for W. These are DGM (4.20)–(4.21).

Physical meaning

Untwisted operators and twist fields are mutually local when $\overline{W}'$ is an intertwiner. This is the consistency of the orbifold with respect to moving an ordinary operator around a twist field: the monodromy is trivial up to the sector change, as is needed for the fields of one theory. It follows from the commutator formula for W (established) and for $\overline{W}'$ (a hypothesis here, true for the genuine $\overline{W}$).

Proposition 38.33. *If $\overline{W}'$ is lower-truncated, it yields fields; if it satisfies the commutator formula and $\overline{W}'(L_{-1}t,z)=\partial_z\overline{W}'(t,z)$, then $Y_T^{\natural}[\overline{W}'](t,z)$ is $T^{\natural}$-covariant.*

File `VOA/Moonshine/VnatFields.lean`.

```
theorem YnatT_isField {Wbar : TP → FormalDist (TP →ₗ[ℂ] SkewVP)} (hWbar : ∀ t, Trunc (Wbar
 ↪ t))
    (t : TP) : IsField (YnatT Wbar t) :=

theorem YnatT_DCovariant {Wbar : TP → FormalDist (TP →ₗ[ℂ] SkewVP)} (hcomm : WbarComm Wbar)
    (hderiv : ∀ t, Wbar (leechLTP t) = deriv (Wbar t)) (t : TP) :
    DCovariant Tnat (YnatT Wbar t) :=
```

Physical meaning

Twist-field operators obey the translation Ward identity and have finite OPE singularities provided the channel $\overline{W}'$ does. The derivative property $\overline{W}'(L_{-1}t,z)=\partial_z\overline{W}'(t,z)$ says that the field of the descendant $L_{-1}t$ is the derivative of the field of t, a basic property of any CFT.

Proof. Covariance of the W-block is Proposition 38.21(b). For the $\overline{W}'$-block, the commutator formula at $u=\omega$, $m=0$ gives $L_{-1}\overline{W}'(t)_{(n)}-\overline{W}'(t)_{(n)}L_{-1}^T=\overline{W}'(L_{-1}^Tt)_{(n)}$, and `hderiv` converts the right side into $\partial_z\overline{W}'(t,z)$. □

38.6.3 The block vertex map and the reconstruction interface

Definition 38.34. For a *linear* $\overline{W}'\colon T^+\to\mathrm{Hom}(T^+,V_\Lambda^+)[[z^{\pm}]]$, the *block vertex map* is $Y^{\natural}[\overline{W}'](u,t)=\left(\begin{smallmatrix} Y(u) & \overline{W}'(t)\\ W(t) & Y^T(u)\end{smallmatrix}\right)$.

File `VOA/Moonshine/VnatFields.lean`.

```
noncomputable def Ynat (Wbar : TP →ₗ[ℂ] FormalDist (TP →ₗ[ℂ] SkewVP)) :
    Vnat →ₗ[ℂ] FormalDist (End ℂ Vnat) where
  toFun x := blockF (leechVOAPlus.Y x.1) (Wbar x.2) (leechWskLin x.2) (plusModule.YM x.1)
```

(`leechWskLin` is $t\mapsto W(t,z)$ as a linear map; the omitted fields prove additivity and homogeneity.) One has $Y^{\natural}[\overline{W}'](u,0)=Y_U^{\natural}(u)$ and $Y^{\natural}[\overline{W}'](0,t)=Y_T^{\natural}[\overline{W}'](t)$ (`Ynat_inl`, `Ynat_inr`).

The library's general reconstruction theorem (proved in the Core chapters) says: given a vector space with a vacuum and a translation operator, and a family of pairwise local, translation covariant,

creating fields whose iterated products applied to the vacuum span the space, there is a unique linear state–field map extending them that satisfies VA3–VA5. Its specialisation:

Physical meaning

This is the vertex operator of the whole orbifold theory: a single operator $Y^\natural(u,t)$ whose four channels are untwisted×untwisted (Y), untwisted×twisted (Y^T), twisted×untwisted (W) and twisted×twisted ($\overline{W}'$). It is the OPE of the orbifold CFT as a 2×2 operator matrix, with the twisted×twisted channel left as a parameter.

Theorem 38.35 (Reconstruction interface for $V^\natural$). *Let $g : \kappa \to T^+$ be any family. Assume of $\overline{W}'$: lower truncation, the commutator formula, and the derivative property; assume twisted–twisted locality $Y_T^\natural[\overline{W}'](g_i) \sim Y_T^\natural[\overline{W}'](g_j)$ for all i, j; and assume the word states built from the fields $Y_U^\natural(u)$, $Y_T^\natural[\overline{W}'](g_i)$ span $V^\natural$. Then there is a linear map $Y_A : V^\natural \to \mathrm{End}(V^\natural)[[z^{\pm}]]$ whose values are fields, pairwise local, creating, $T^\natural$-covariant, and agreeing with $Y_U^\natural$ on $(u,0)$ and with $Y_T^\natural[\overline{W}']$ on $(0,g_i)$.*

File `VOA/Moonshine/VnatFields.lean`.

```

      (∀ u : Vnat, DCovariant Tnat (YA u)) ∧
      (∀ u : SkewVP, YA (u, 0) = YnatU u) ∧
      (∀ i, YA (0, g i) = YnatT Wbar (g i)) := by
```

From the mathematics to the Lean statement

Hypotheses: `hWbar`, `hcomm`, `hderiv` are the three properties of the parameter; `htt` is the twisted–twisted locality on the chosen family (DGM (4.23) together with (4.22), see Section 38.8); `hspan` says that the vectors $a^1_{(n_1)}\cdots a^k_{(n_k)}\mathbf{1}^\natural$ obtained by applying modes of the generator fields `genNat Wbar g` (the family $\{Y_U^\natural(u)\}_u \cup \{Y_T^\natural(g_i)\}_i$) to the vacuum span $V^\natural$ (`wordSt` lists these word states, `Set.range` is the set of them, `Submodule.span ℂ` their linear span, `⊤` all of $V^\natural$). The conclusion lists VA3, VA4, VA5 in the raw indexing. The theorem is weaker than "$V^\natural$ is a VOA": it says nothing about grading or Virasoro, which are dealt with in Section 38.7.

Trap / dead end

The trap, first appearance. Take $\overline{W}' = 0$. Then `hWbar`, `hcomm`, `hderiv` hold trivially (every term is 0; $\partial_z 0 = 0$). And `htt` holds trivially: the product of two off-diagonal fields with zero top-right blocks is $\mathrm{diag}(0\cdot W,\ W\cdot 0) = 0$ (Remark 38.17), so the commutator is 0. With $g = \mathrm{id}$ the spanning hypothesis also holds (one-letter words already give every $(u,0)$ and $(0,t)$). Hence `reconstruct_nat` *does* produce a vertex algebra for $\overline{W}' = 0$: the square-zero extension. The theorem is correct and useful, but its hypotheses are consistent with the wrong answer. This observation was made by the agent writing this file, and is recorded as the TRAP in `Notes/MonsterRoadmap.md`.

Physical meaning

A chiral algebra is determined by the fields of a generating set: the OPE of the generators (untwisted fields and a few twist fields) fixes all other fields, and locality of the generators implies locality of the rest. This is the CFT statement that one needs to check crossing symmetry only for a generating set of operators, here reduced to twist×twist, the only pairs not already controlled.

What the machine verified

`YnatU_local`, `YnatU_YnatT_local`, `YnatT_DCovariant`, `reconstruct_nat`: unconditional as implications (their hypotheses are displayed); `reconstruct_nat ##print axioms`-checked: `[propext, Classical.choice, Quot.sound]`.

38.7 All vertex-operator-algebra axioms but one

From now on the parameter is the genuine adjoint, packaged as a linear map:

```
noncomputable def wbarL : TP →ₗ[ℂ] FormalDist (TP →ₗ[ℂ] SkewVP) where
  toFun := leechWbar

noncomputable def YN : Vnat →ₗ[ℂ] FormalDist (End ℂ Vnat) := Ynat wbarL

theorem mode_YN (x y : Vnat) (n : ℤ) :
    mode (YN x) n y = (mode (leechVOAPlus.Y x.1) n y.1 + mode (leechWbar x.2) n y.2,
      mode (leechWsk x.2) n y.1 + mode (plusModule.YM x.1) n y.2) := rfl
```

(`VOA/Moonshine/VnatAxioms.lean`.) So for $x = (u, t)$, $y = (\varphi, s)$,

$$x_{(n)}y = \big(u_{(n)}\varphi + \overline{W}(t)_{(n)}s,\ \ W(t)_{(n)}\varphi + u_{(n)}s\big), \tag{38.6}$$

which is (38.1) in modes, and the `rfl` proof confirms it is the definition. The genuine $\overline{W}$ satisfies the commutator formula of Definition 38.31 (`wbar_WbarComm`, a restatement of (38.5)).

38.7.1 The Virasoro algebra on any module

Proposition 38.36 (Conformal self-products). *In any vertex operator algebra of central charge c: $\omega_{(0)}\omega = L_{-1}\omega$, $\omega_{(1)}\omega = 2\omega$, $\omega_{(2)}\omega = 0$, $\omega_{(3)}\omega = \frac{c}{2}\mathbf{1}$, $\omega_{(j)}\omega = 0$ for $j \geq 4$.*

```
theorem omega_smul_three :
    W.smul W.conformalVector 3 W.conformalVector = (W.centralCharge / 2) • W.vacuum := by
theorem omega_smul_ge_four (j : ℤ) (hj : 4 ≤ j) :
    W.smul W.conformalVector j W.conformalVector = 0 := by
```

(`VOA/Moonshine/VnatAxiomsVir.lean`; the first three are analogous.)

Physical meaning

These are the standard OPE of the stress tensor with itself, $T(z)T(0) \sim \frac{c/2}{z^4} + \frac{2T}{z^2} + \frac{\partial T}{z}$: the central term $\frac{c}{2}\mathbf{1}$ in $\omega_{(3)}\omega$ is the Virasoro anomaly, with $c = 24$ for $V^\natural$. They hold in every vertex operator algebra and fix the conformal structure of the orbifold.

Proof. $\omega_{(j+1)}\omega = L_j\omega = L_jL_{-2}\mathbf{1}$. Use $[L_j, L_{-2}] = (j+2)L_{j-2} + \delta_{j,2}\frac{j^3-j}{12}c$ and $L_k\mathbf{1} = 0$ for $k \geq -1$: for $j = 1$ one gets $3L_{-1}\mathbf{1} = 0$, for $j = 2$ one gets $4L_0\mathbf{1} + \frac{c}{2}\mathbf{1} = \frac{c}{2}\mathbf{1}$; for $j \geq 3$ the weight $3 - j < 0$ is empty. $L_0\omega = 2\omega$ is VOA2. □

Theorem 38.37 (Virasoro relations on every weak module). *Let M be a weak module over a VOA W of central charge c, and $L^M_n := \omega_{(n+1)}$ on M. Then $[L^M_m, L^M_n] = (m-n)L^M_{m+n} + \delta_{m+n,0}\frac{m^3-m}{12}c$.*

```
theorem module_virasoro (A : WeakModule W M) (m n : ℤ) :
    [mode (A.YM W.conformalVector) (m + 1), mode (A.YM W.conformalVector) (n + 1)]
      = ((m : ℂ) - n) • mode (A.YM W.conformalVector) (m + n + 1)
        + (if m + n = 0 then (((m : ℂ) ^ 3 - m) / 12 * W.centralCharge) • (1 : End ℂ M)
           else 0) := by
```

From the mathematics to the Lean statement

`[X, Y]` is the commutator $XY - YX$ of endomorphisms; the central charge on the right is `W.centralCharge`, the one of the *algebra*. This is the textbook statement; it is a genuine theorem because the library's `OrdVModule` does not carry the Virasoro relations as an axiom.

Physical meaning

Every representation of the chiral algebra, in particular the twisted sector, carries a Virasoro algebra with the same central charge c. For $V^\natural$ this is why both sectors have $c = 24$ and why the full theory is a single conformal field theory rather than a sum of two with different central charges.

Proof. The commutator formula (Theorem 38.18) with $u = v = \omega, J = 4$, and the self-products of Proposition 38.36: $[\omega_{(m+1)}, \omega_{(n+1)}] = (L_{-1}\omega)_{(m+n+2)} + (m+1)\,2\omega_{(m+n+1)} + \binom{m+1}{3}\frac{c}{2}\mathbf{1}_{(m+n-1)}$. Module translation gives $(L_{-1}\omega)_{(k)} = -k\,\omega_{(k-1)}$, and $\mathbf{1}_{(k)} = \delta_{k,-1}$. Collecting, $-(m+n+2)+2(m+1) = m-n$, and $\binom{m+1}{3}\frac{c}{2} = \frac{m^3-m}{12}c$ at $m+n=0$. □

Proposition 38.38. *$Y_M(L_{-1}a, z) = \partial_z Y_M(a, z)$ for every weak module.*

```
theorem module_YM_Lm1 (A : WeakModule W M) (a : 𝒱) :
    A.YM (W.L (-1) a) = deriv (A.YM a) := by
```

(The field form of the module translation property, which in turn is the $\ell = 0$, $v = \mathbf{1}$ case of the Jacobi identity combined with $L_{-1}a = a_{(-2)}\mathbf{1}$.)

Physical meaning

The field of $L_{-1}a$ is the derivative of the field of a in every sector: descendants under L_{-1} are space derivatives of the field, $\phi_{L_{-1}a} = \partial\phi_a$. This is the formal version of the state–operator map commuting with translation.

38.7.2 The axioms for the block map

Theorem 38.39. *For the block map $Y^\natural := Y^\natural[\overline{W}]$ on $V^\natural$, with no hypotheses:*

(1) (VA1) $x \in V^\natural{}_k$, $y \in V^\natural{}_l \Rightarrow x_{(n)}y \in V^\natural{}_{k+l-n-1}$;

(2) (VA2) $Y^\natural(\mathbf{1}^\natural, z) = \mathrm{id}$;

(3) (VA3) $x_{(-1)}\mathbf{1}^\natural = x$ and $x_{(n)}\mathbf{1}^\natural = 0$ for $n \geq 0$;

(4) (VA5) for all x, y there is N with $x_{(n)}y = 0$ for $n \geq N$;

(5) (VOA1) $L^\natural_n := \omega^\natural_{(n+1)}$ satisfy the Virasoro relations with $c = 24$;

(6) *(VOA2)* $L_0^\natural = n$ *on* $V^\natural{}_n$;

(7) *(VOA3)* $Y^\natural(L_{-1}^\natural v, z) = \partial_z Y^\natural(v, z)$ *for all* v.

From the mathematics to the Lean statement

Each statement is literally the corresponding field of the structures of Section 38.2, with `Y := YN`, `grading := gradingNat`, `vacuum := vacNat`, `conformalVector := omegaNat`, `centralCharge := 24`; this is why they can be plugged into the structure below without change. In (5) the number 24 is written explicitly; it arises as the central charge of V_Λ^+. In (7), `mode (YN omegaNat) 0` is $\omega_{(0)}^\natural = L_{-1}^\natural = T^\natural$. The `1` in `YN_vacuum` is the identity field (z^0-coefficient id, all others 0).

Physical meaning

All axioms of a chiral CFT for the orbifold hold at once except the final crossing relation: grading by conformal weight, vacuum, creation, regularity (finite OPE), Virasoro with $c = 24$, L_0 giving the weight and translation covariance. The remaining axiom, mutual locality of two twist fields, is the hardest consistency condition in the orbifold construction. That the other axioms need no input from the twisted OPE channel $\overline{W}$ is exactly why they cannot detect the trap: the impostor satisfies them as well.

Proof. Each axiom is checked on the four blocks of (38.6).

(1) $u_{(n)}$ on V_Λ^+ and on T^+ respects weights by VA1 and by the module grading; $W(t)_{(n)}$ maps $(V_\Lambda^+)_l$ to $T^+_{k+l-n-1}$ for $t \in T_k^+$, read off (38.3) (L_{-1}^i raises by i, $\varphi_{(n+i)}$ shifts by $l - n - i - 1$); $\overline{W}(t)_{(n)}$ maps T_l^+ to $(V_\Lambda^+)_{l+k-n-1}$ (`leechWbar_mem`).

(2) $\mathbf{1}^\natural = (\mathbf{1}, 0)$: the twisted component is 0, so only $\mathrm{diag}(Y(\mathbf{1}), Y^T(\mathbf{1})) = \mathrm{diag}(\mathrm{id}, \mathrm{id})$ remains.

(3) $Y^\natural(x) = Y_U^\natural(x_1) + Y_T^\natural(x_2)$; apply Propositions 38.28(b) and 38.30.

(4) The block field is a field (Proposition 38.14(a)) since all four blocks are truncated.

(5) $\omega^\natural = (\omega, 0)$, so $Y^\natural(\omega^\natural) = \mathrm{diag}(Y(\omega), Y^T(\omega))$ and the commutator of two diagonal operators is diagonal. The V_Λ^+-block satisfies Virasoro with $c = 24$ (central charge of V_Λ^+), the T^+-block by Theorem 38.37 with the same c.

(6) L_0 acts by n on $(V_\Lambda^+)_n$ and on T_n^+ (the latter by definition of the weight spaces of an ordinary module).

(7) $L^\natural_{-1}(u,t) = (L_{-1}u, L^T_{-1}t)$; the four blocks of $Y^\natural(L^\natural_{-1}(u,t))$ are $Y(L_{-1}u) = \partial Y(u)$ (VOA3), $Y^T(L_{-1}u) = \partial Y^T(u)$ (Proposition 38.38), $W(L^T_{-1}t) = \partial W(t)$ and $\overline{W}(L^T_{-1}t) = \partial\overline{W}(t)$ (`leechWsk_deriv`, `leechWbar_deriv`). □

Theorem 38.40 (Locality modulo the twisted–twisted block). *If $Y^\natural_T(t)$ and $Y^\natural_T(t')$ are mutually local for all $t, t' \in T^+$, then $Y^\natural(x)$ and $Y^\natural(y)$ are mutually local for all $x, y \in V^\natural$. Moreover the hypothesis need only be checked on a family whose linear span is T^+.*

```

Physical meaning

Crossing symmetry of the full orbifold theory reduces to twist×twist crossing, since all other pairs of channels are already local. Physically, the consistency of the orbifold (the locality of all fields) is the single constraint on the four-point function of twist fields, the one that involves the geometry of the lattice and the fixed-point structure. It can be checked on a generating family of twist fields.

Proof. Write $Y^\natural(x) = Y^\natural_U(x_1) + Y^\natural_T(x_2)$. Locality is bilinear (a sum of local pairs is local, with the maximum order), and the three mixed cases are Propositions 38.28(d) and Theorem 38.32. For the span reduction, $t \mapsto Y^\natural_T(t)$ is linear, so locality extends from a spanning family to all pairs by bilinearity. □

38.7.3 The packaged structure

Theorem 38.41 (The VOA $V^\natural$, conditional on twisted–twisted locality). *Assume $Y^\natural_T(t) \sim Y^\natural_T(t')$ for all $t, t' \in T^+$. Then $(V^\natural, (V^\natural{}_n)_n, Y^\natural, \mathbf{1}^\natural, \omega^\natural, c = 24)$ is a vertex operator algebra in the sense of the library.*

From the mathematics to the Lean statement

The definition is printed in full because here the definition *is* the statement: every field of `VertexOperatorAlgebra` is filled by a theorem of this section, and the only input that is not a proved theorem is the argument `htt`, used in exactly one place, the `locality` field. `htt` is a proposition; `vnatVOA` is a family of structures indexed by proofs of it, but since any two proofs of a proposition are equal in Lean (proof irrelevance), `vnatVOA` does not depend on *which* proof is supplied. The theorem `vnat_VOA_of_htt` records that the vertex map of this VOA *is* the block map `Ynat wbarL` (with the genuine $\overline{W}$), and that its vacuum, conformal vector, central charge and grading are the intended ones. This matters: without `V.Y = Ynat wbarL`, the existence statement would be satisfied by any VOA structure on the same space, including the square-zero one.
Compared with the textbook: the textbook theorem is unconditional; this one is conditional on twisted–twisted locality, which is DGM's (4.22) together with (4.23). It is the only input.

Trap / dead end

`vnat_VOA_of_htt` *does not by itself identify* V with the Moonshine module. The same statement with `wbarL` replaced by 0 would be true (with a trivially satisfied hypothesis) and would give the square-zero extension with the same c, grading and graded dimension. What singles out $V^\natural$ is (a) that `wbarL` is the genuine, nondegenerate adjoint, certified by `leechWbar_ne_zero` (Section 38.11), and (b) the simplicity theorem of Section 38.12.

Physical meaning

Conditional on twist×twist locality, the assembled orbifold data form a bona fide chiral CFT with $c = 24$ and a finite-dimensional space of states at every energy: the Moonshine module as a vertex operator algebra. The conditional status is real: until that crossing relation is proved the object is not shown to be a CFT, and the numerical coincidences with J do not remedy that.

What the machine verified

All seven axioms of Theorem 38.39: unconditional. `vnatVOA`, `vnat_VOA_of_htt`: conditional on `htt` only; `##print axioms` = `[propext, Classical.choice, Quot.sound]` (checked). `module_virasoro`: general, unconditional, checked.

38.8 Twisted–twisted locality splits into DGM (4.22) and (4.23)

By Remark 38.17, the commutator of two off-diagonal fields is diagonal. For two twisted fields $Y_T^\natural(t_i) = \left(\begin{smallmatrix} 0 & \overline{W}(t_i) \\ W(t_i) & 0 \end{smallmatrix}\right)$ this reads

$$[Y_T^\natural(t_1,z_1), Y_T^\natural(t_2,z_2)] = \begin{pmatrix} \overline{W}(t_1,z_1)W(t_2,z_2) - \overline{W}(t_2,z_2)W(t_1,z_1) & 0 \\ 0 & W(t_1,z_1)\overline{W}(t_2,z_2) - W(t_2,z_2)\overline{W}(t_1,z_1) \end{pmatrix}. \tag{38.7}$$

The top-left entry is an operator on the untwisted sector built by passing through the twisted sector; the bottom-right entry is an operator on the twisted sector built by passing through the untwisted sector.

Theorem 38.42 (Off-diagonal locality is two diagonal relations). *For any $c, c' \in \mathrm{Hom}(M,V)[[z^{\pm}]]$, $d, d' \in \mathrm{Hom}(V,M)[[z^{\pm}]]$: $\mathrm{offdiag}(c,d) \sim \mathrm{offdiag}(c',d')$ if and only if $(z_1-z_2)^{N_1}\big(c(z_1)d'(z_2) - c'(z_2)d(z_1)\big) = 0$ on V for some N_1 and $(z_1-z_2)^{N_2}\big(d(z_1)c'(z_2) - d'(z_2)c(z_1)\big) = 0$ on M for some N_2.*

```
theorem local_off_off_iff (c c' : FormalDist (M →ₗ[ℂ] V)) (d d' : FormalDist (V →ₗ[ℂ] M)) :
    Local (offF c d) (offF c' d') ↔
      (∃ N : ℕ, mulBySubPow N

      (∃ N : ℕ, mulBySubPow N
        ((fun m n => d m ∘ₗ c' n - d' n ∘ₗ c m) : FormalDist₂ (End ℂ M)) = 0) := by
```

(`VOA/Moonshine/TTBlock.lean`.)

Physical meaning

The OPE of two twist fields, which exchange sectors, is local if and only if two separate crossing relations hold: one for the amplitude untwisted→twisted→untwisted (relation (4.22)) and one for twisted→untwisted→twisted (relation (4.23)). Physically these are the two channels of four-point functions of twist fields on the plane, restricted to the untwisted or the twisted external states.

Proof. By (38.7) and the entrywise action of $(z_1-z_2)^N$; a block matrix is 0 iff each block is; for the converse take $N = \max(N_1, N_2)$. □

Definition 38.43 (DGM (4.22) and (4.23)). For $t_1, t_2 \in T^+$ and a parameter $\overline{W}'$:

- VP(t_1,t_2), DGM (4.22): for some N, $(z_1-z_2)^N\big(\overline{W}'(t_1,z_1)W(t_2,z_2) - \overline{W}'(t_2,z_2)W(t_1,z_1)\big) = 0$ in $\mathrm{End}(V_\Lambda^+)[[z_1^{\pm}, z_2^{\pm}]]$;
- TP(t_1,t_2), DGM (4.23): for some N, $(z_1-z_2)^N\big(W(t_1,z_1)\overline{W}'(t_2,z_2) - W(t_2,z_2)\overline{W}'(t_1,z_1)\big) = 0$ in $\mathrm{End}(T^+)[[z_1^{\pm}, z_2^{\pm}]]$.

```
def VPBlockLocal (Wbar : TP → FormalDist (TP →ₗ[ℂ] SkewVP)) (t₁ t₂ : TP) : Prop :=
  ∃ N : ℕ, mulBySubPow N
    ((fun m n => Wbar t₁ m ∘ₗ leechWsk t₂ n - Wbar t₂ n ∘ₗ leechWsk t₁ m) :
      FormalDist₂ (End ℂ SkewVP)) = 0

def TPBlockLocal (Wbar : TP → FormalDist (TP →ₗ[ℂ] SkewVP)) (t₁ t₂ : TP) : Prop :=
  ∃ N : ℕ, mulBySubPow N
    ((fun m n => leechWsk t₁ m ∘ₗ Wbar t₂ n - leechWsk t₂ n ∘ₗ Wbar t₁ m) :
      FormalDist₂ (End ℂ TP)) = 0
```

From the mathematics to the Lean statement

In `fun m n ⇒ Wbar t₁ m ∘ₗ leechWsk t₂ n - …`, the first index `m` belongs to z_1 and the second `n` to z_2, in the raw z-power indexing; so the first term is $\overline{W}(t_1)_m \circ W(t_2)_n$, coefficient of $z_1^m z_2^n$ in $\overline{W}(t_1,z_1)W(t_2,z_2)$, and the second is $\overline{W}(t_2)_n \circ W(t_1)_m$, coefficient of $z_1^m z_2^n$ in $\overline{W}(t_2,z_2)W(t_1,z_1)$ — exactly Definition 38.43. `SkewVP` and `TP` are V_Λ^+ and T^+. These are the relations (4.22) and (4.23) of Dolan–Goddard–Montague, Commun. Math. Phys. 179 (1996); the referee may compare: DGM write them as "$\overline{W}(t_1,z_1)W(t_2,z_2) \sim \overline{W}(t_2,z_2)W(t_1,z_1)$" with $\sim$ meaning equality after multiplication by a power of $(z_1 - z_2)$, which is what `mulBySubPow` encodes.

Physical meaning

The two relations are the two crossing conditions for twist fields: (4.22) is crossing with untwisted external states, (4.23) with twisted external states. The first is accessible from skew-symmetry and invariance of the form; the second needs real input about the twisted sector, the geometry of the 2^{24} fixed points, and is the hardest crossing condition in the orbifold. These are heuristic labels; the precise statements are the displayed equations.

Theorem 38.44. $Y_T^\natural[\overline{W}'](t_1) \sim Y_T^\natural[\overline{W}'](t_2)$ *if and only if* $\mathrm{VP}(t_1,t_2)$ *and* $\mathrm{TP}(t_1,t_2)$ *hold.*

```
theorem YnatT_local_iff (Wbar : TP → FormalDist (TP →ₗ[ℂ] SkewVP)) (t₁ t₂ : TP) :
    Local (YnatT Wbar t₁) (YnatT Wbar t₂) ↔
      VPBlockLocal Wbar t₁ t₂ ∧ TPBlockLocal Wbar t₁ t₂ :=
  local_off_off_iff _ _ _ _
```

From the mathematics to the Lean statement

An equivalence, valid for every parameter. The one-line proof term shows it is Theorem 38.42 with $c = \overline{W}'(t_1)$, $d = W(t_1)$, $c' = \overline{W}'(t_2)$, $d' = W(t_2)$. Combining with `reconstruct_nat`, the library also records `reconstruct_nat_of_blocks`, in which `htt` is replaced by the two block relations for the genuine $\overline{W}$ on a generating family.

Physical meaning

Locality of two twist fields is exactly the pair of crossing relations in the two channels: the four-point function of two twist fields and two external states is single-valued and symmetric in both the untwisted and twisted external sectors. There is no further condition.

Which half is hard. (4.22) is a statement about operators on the *untwisted* sector built from twisted intermediate states. On the vacuum it reduces, by the explicit vacuum behaviour of W, to a statement about $\overline{W}$ alone — its skew-symmetry — and this can be derived from the definition of $\overline{W}$ as an adjoint. So (4.22) is lattice-free; we prove it in the next section. (4.23) is a statement about operators on the *twisted* sector built from untwisted intermediate states; its matrix elements between twisted ground states are four-point functions of twist fields, given by sums over the whole Leech lattice (theta functions of cosets of 2Λ). Their consistency is "almost a modular invariance condition" (DGM §5.3) and genuinely uses the lattice: DGM show it holds only when $\sqrt{2}\Lambda^*$ is even. This is the relation the triality method of the following chapters is designed to prove.

What the machine verified

`local_off_off_iff`, `YnatT_local_iff`: unconditional, generic (any parameter); `YnatT_local_iff` `##print axioms`-checked clean.

38.9 DGM (4.22) holds unconditionally

38.9.1 Three tools

A two-variable Goddard lemma. Goddard's uniqueness lemma for vertex algebras says that a field that is local with all the fields and kills the vacuum is zero, because the states $a_{(n)}\mathbf{1}$ span. We need its analogue for a *two-variable* distribution $B(z_1, z_2)$, with locality in a third variable.

Theorem 38.45 (Two-variable Goddard lemma). *Let V be a vector space,* $\mathrm{vac} \in V$, $A(w) \in \mathrm{End}(V)[[w^{\pm}]]$ *with $A_p\,\mathrm{vac} = 0$ for $p < 0$ (raw indexing: no negative powers of w on the vacuum), and $B(z_1, z_2) \in \mathrm{End}(V)[[z_1^{\pm}, z_2^{\pm}]]$ with $B_{m,n}\mathrm{vac} = 0$ for all m, n. If $(w - z_1)^{M_1}(w - z_2)^{M_2}[A(w), B(z_1, z_2)] = 0$, then $B_{m,n}(A_p\,\mathrm{vac}) = 0$ for all p, m, n.*

```
theorem goddard₂ (vac : V) (A : FormalDist (End ℂ V)) (B : FormalDist₂ (End ℂ V)) (M₁ M₂ :
↪ ℕ)
    (hloc : mulBySub₁₂Pow M₁ (mulBySub₁₃Pow M₂ (brk3 A B)) = 0)
    (hneg : ∀ p : ℤ, p < 0 → A p vac = 0) (hvac : ∀ m n, B m n vac = 0) (p m n : ℤ) :
    B m n (A p vac) = 0 := by
```

(`VOA/Moonshine/M8h0Goddard.lean`.)

From the mathematics to the Lean statement

`brk3 A B` is the three-variable distribution $[A(w), B(z_1, z_2)]$ with coefficients $A_pB_{m,n} - B_{m,n}A_p$ (w first). `mulBySub₁₂Pow M` and `mulBySub₁₃Pow M` multiply by $(w - z_1)^M$ and $(w - z_2)^M$ respectively (the same shift formula as Definition 38.3 in the indicated pair of variables). The conclusion is coefficientwise. Same as the textbook argument; nothing hidden.

Physical meaning

This is the vertex-algebra form of the statement that a locality relation checked on the vacuum extends to all states: a field commuting (locally) with $A(w)$ and annihilating the vacuum vanishes on all states created by A. It is the formal version of the state–operator argument that a correlator is determined by its vacuum expectation value together with the Ward identities, and is the main tool of Goddard-type uniqueness theorems in CFT.

Proof. Apply the locality relation to vac. Since B kills vac, it becomes $(w-z_1)^{M_1}(w-z_2)^{M_2}G = 0$ for $G(w, z_1, z_2) := -B(z_1, z_2)A(w)\mathrm{vac}$. By the hypothesis on A, G has only non-negative powers of w. On such distributions, multiplication by $w - z$ is injective: if $(w - z)G = 0$ and p_0 is the lowest w-power present, the coefficient of w^{p_0} in $(w - z)G$ is $-z\,G_{p_0}$, forcing $G_{p_0} = 0$. So $G = 0$. □

The hypothesis of Theorem 38.45 holds for $B = (z_1 - z_2)^N[a(z_1), b(z_2)]$ whenever A is local with both a and b: by the Leibniz rule $[A, ab] = [A, a]b + a[A, b]$, each term is killed by the appropriate $(w - z_i)$-power (`loc3_mulBySubPow_bracketDist`).

The translation equation.

Definition 38.46. Given $L \in \mathrm{End}\,V$, a two-variable distribution D with values in V satisfies the *translation equation* if $LD = (\partial_{z_1} + \partial_{z_2})D$, i.e. $L\,D_{m,n} = (m + 1)D_{m+1,n} + (n + 1)D_{m,n+1}$.

```
def TEq (D : FormalDist₂ V) : Prop :=
  ∀ m n : ℤ, L (D m n) = ((m + 1 : ℤ) : ℂ) • D (m + 1) n + ((n + 1 : ℤ) : ℂ) • D m (n + 1)
```

Physical meaning

The translation equation is the Ward identity for a two-point object: translating both insertion points together gives $L_{-1}D = (\partial_{z_1} + \partial_{z_2})D$, so a two-variable correlation function depends on the difference $z_1 - z_2$ up to the action of the translation operator.

Theorem 38.47 (Closed form). *If D satisfies the translation equation, then for all $m, n \in \mathbb{N}$, $D_{m,n} = \sum_{s+r=n} \binom{m+r}{r} \frac{(-1)^r}{s!} L^s D_{m+r,0}$; that is, $D(z_1, z_2) = e^{z_2 L} D(z_1 - z_2, 0)$ on the quadrant $m, n \geq 0$.*

```
noncomputable def tcoef (m s r : ℕ) : ℂ :=
  ((m + r).choose r : ℂ) * (-1 : ℂ) ^ r * ((s.factorial : ℂ))⁻¹

theorem TEq.closed_form {D : FormalDist₂ V} (h : TEq L D) :
    ∀ n m : ℕ, D m n = ∑ p ∈ Finset.antidiagonal n,
      tcoef m p.1 p.2 • (L ^ p.1) (D ((m + p.2 : ℕ) : ℤ) 0) := by
```

(VOA/Moonshine/M8h0Translate.lean.)

From the mathematics to the Lean statement

`Finset.antidiagonal n` is the set of pairs (s, r) with $s + r = n$; `p.1`$= s$, `p.2`$= r$. The coefficient `tcoef m s r` is $\binom{m+r}{r}(-1)^r/s!$. The statement covers only $m, n \geq 0$ (natural numbers), which is exactly the quadrant where the closed form is meant. Note that no support hypothesis is needed for the identity itself.

Physical meaning

The solution of the translation equation is $D(z_1, z_2) = e^{z_2 L_{-1}} D(z_1 - z_2, 0)$: a two-point correlation is a function of the separation, dressed by the translation of the base point. It is the formal version of translation invariance of the vacuum correlators.

Proof. Induction on n: the equation solves for $(n+1)D_{m,n+1} = LD_{m,n} - (m+1)D_{m+1,n}$, and Pascal-type identities for the coefficients close the induction. Conceptually: $D(z_1, z_2)$ with $(\partial_1 + \partial_2 - L)D = 0$ is determined by its restriction to $z_2 = 0$, transported along $z_1 \mapsto z_1 - z_2$ and twisted by $e^{z_2 L}$. □

Skew-symmetry of $\overline{W}$.

Theorem 38.48 (DGM (4.9)). *For $t_1 \in T_a^+$, $t_2 \in T_b^+$ and every $n \in \mathbb{Z}$,*

$$\overline{W}(t_1)_{(n)}t_2 = \sum_{i \geq 0} \frac{(-1)^{n+i+1}}{i!} L_{-1}^i \, \overline{W}(t_2)_{(n+i)}t_1, \qquad \text{i.e.} \qquad \overline{W}(t_1, z)t_2 = e^{zL_{-1}} \overline{W}(t_2, -z)t_1.$$

```
theorem leechWbar_skew {a b : ℤ} {t₁ t₂ : TP} (ht₁ : t₁ ∈ plusModule.weight (a : ℂ))
    (ht₂ : t₂ ∈ plusModule.weight (b : ℂ)) (n : ℤ) :
    leechWbarMode n t₁ t₂ = ∑ᶠ i : ℕ, (((i.factorial : ℂ)⁻¹) * negOnePow (n + i + 1)) •
      ((leechVOAPlus.L (-1)) ^ i) (leechWbarMode (n + i) t₂ t₁) := by
```

(VOA/Moonshine/M8h0Skew.lean.)

From the mathematics to the Lean statement

`leechWbarMode n t₁ t₂` is $\overline{W}(t_1)_{(n)}t_2$ (mode indexing). $\sum^{\mathrm{f}}$ is a sum with finite support (only finitely many terms are nonzero because $\overline{W}(t_2)_{(n+i)}t_1 = 0$ for i large). `negOnePow k` is $(-1)^k$. The hypotheses `ht₁`, `ht₂` require homogeneity. This is *weaker* than the textbook statement for all t_1, t_2, but only formally: both sides are bilinear in (t_1, t_2) and T^+ is the direct sum of its

weight spaces, so the general case follows by linearity (and is not needed). The sign is the *even* skew-symmetry $Y(a,z)b = e^{zL_{-1}}Y(b,-z)a$, with no extra -1: the extension is a VOA, not a super VOA. (Numerical evidence on the E_8 model shows the super version of (4.23) fails; see Section 38.14.)

Physical meaning

Skew-symmetry of the twisted×twisted→untwisted OPE: exchanging two twist fields is the same as translating by $e^{zL_{-1}}$ and sending $z \to -z$, $\overline{W}(t_1,z)t_2 = e^{zL_{-1}}\overline{W}(t_2,-z)t_1$. This is the exchange symmetry of the OPE of two bosonic fields, and its proof uses nondegeneracy of the Zamolodchikov metric on the untwisted sector.

Proof. Since B_V is nondegenerate on each weight space, it suffices to pair both sides with an arbitrary $\varphi \in (V_\Lambda^+)_k$, $k = a+b-n-1$. The left side, by the adjunction (38.4), becomes $(-1)^a \sum_j \frac{1}{j!}(t_2, W(L_1^j t_1)_{(2a-n-2-j)}\varphi)_T$; expand W by (38.3). The right side: move L_{-1}^i across B_V as L_1^i (Virasoro adjointness of B_V), apply (38.4) to $\overline{W}(t_2)_{(n+i)}$, and expand W. Both sides become triple sums of the matrix elements $(L_1^j t_1, (L_1^r\varphi)_{(\gamma)}L_1^l t_2)_T$ — on the left after using $L_{-1} \dashv L_1$ and FHL-invariance of $(\cdot,\cdot)_T$ to move the L_{-1}'s and the φ-mode onto the other argument, together with symmetry of $(\cdot,\cdot)_T$. The two triple sums agree term by term after the relabelling $(j,l,r) \mapsto (r,l,j)$: the factorials match, the mode indices agree because $n = a+b-k-1$, and the signs differ by an even power of -1. □

Remark 38.49. Physically, skew-symmetry is the statement that the OPE of two twist fields is symmetric: $\sigma_{t_1}(z)\sigma_{t_2}(0)$ and $\sigma_{t_2}(-z)\sigma_{t_1}(0)$ differ by translation. Here it is a consequence of the *definition* of $\overline{W}$ as the adjoint of W and of the symmetry of the twisted form; for the fake $\overline{W}' = 0$ it holds trivially.

38.9.2 The theorem

Theorem 38.50 (DGM (4.22)). *For all $t_1, t_2 \in T^+$, $\mathrm{VP}(t_1,t_2)$ holds for the genuine $\overline{W}$. More precisely, for $t_1 \in T_a^+$, $t_2 \in T_b^+$ the order $N = a+b$ suffices.*

```
theorem leechWbar_VPBlockLocal (t₁ t₂ : TP) : VPBlockLocal leechWbar t₁ t₂ := by

theorem VPBlockLocal_homog {a b : ℤ} {t₁ t₂ : TP} (ht₁ : t₁ ∈ plusModule.weight (a : ℂ))
    (ht₂ : t₂ ∈ plusModule.weight (b : ℂ)) :
    mulBySubPow (a + b).toNat (VPfun t₁ t₂) = 0 := by
```

(`VOA/Moonshine/M8h0VPBlock.lean`; `VPfun t₁ t₂` is the two-variable distribution inside `VPBlockLocal leechWbar t₁ t₂`.)

From the mathematics to the Lean statement

No hypotheses: `t₁ t₂ : TP` are arbitrary. The parameter is the genuine `leechWbar`. Same as DGM's (4.22). Could it be vacuous? `VPBlockLocal` is an existential over N of an equation of distributions; it would be trivial if $\overline{W}$ were 0, but $\overline{W} \neq 0$ (Section 38.11), and the proof below uses the defining adjunction, not triviality.

Physical meaning

The untwisted-external crossing of two twist fields holds unconditionally, with pole order at most $a+b$, the sum of the weights. Physically the four-point function of two twist fields with two untwisted external states is consistent, a consequence of skew-symmetry and invariance

rather than of any lattice computation. It is the first half of twist×twist crossing.

Proof. Step 1 (vacuum). Let $t_1 \in T_a^+$, $t_2 \in T_b^+$ and $P \geq a+b$. Put $f(z_1,z_2) = \overline{W}(t_1,z_1)W(t_2,z_2)\mathbf{1}$ and $g(z_1,z_2) = \overline{W}(t_2,z_2)W(t_1,z_1)\mathbf{1}$, V_Λ^+-valued. Both satisfy the translation equation with $L = L_{-1}$, because $\overline{W}$ and W are translation covariant and $L_{-1}\mathbf{1} = 0$; so do $H = (z_1-z_2)^P f$ and $H' = (z_1-z_2)^P g$, since $\partial_1 + \partial_2$ kills $z_1 - z_2$. By $W(t,z)\mathbf{1} = e^{zL_{-1}}t$, f has only non-negative powers of z_2, and g only non-negative powers of z_1; the grading ($\overline{W}(t_1)_{(n)}t_2$ has weight $a+b-n-1$, which is negative for $n \geq a+b$) shows that the factor $(z_1-z_2)^P$ removes all negative powers, so H and H' are supported on the quadrant $m,n \geq 0$. Now compare the two on the edge $m = 0$, in the raw z-power indexing (so $\overline{W}(t)_k$ is the coefficient of z^k). Because f has only non-negative powers of z_2, the z_2^0-part of $H = (z_1-z_2)^P f$ is $z_1^P f(z_1,0)$, so $H_{r,0} = \overline{W}(t_1)_{r-P}\,t_2$ (using $W(t_2)_0\mathbf{1} = t_2$). The closed form (Theorem 38.47, $m = 0$) then gives

$$H_{0,n} = \sum_{s+r=n} \frac{(-1)^r}{s!}\, L_{-1}^s\, \overline{W}(t_1)_{r-P}\, t_2.$$

Because g has only non-negative powers of z_1, the z_1^0-part of $H' = (z_1-z_2)^P g$ is $(-z_2)^P g(0,z_2)$, so $H'_{0,n} = (-1)^P\,\overline{W}(t_2)_{n-P}\,t_1$. Skew-symmetry (Theorem 38.48) says precisely that these two edges coincide. Finally, a solution of the translation equation supported on the quadrant and vanishing on the edge $m = 0$ is identically zero (solve the equation for $D_{m+1,n}$ and induct on m). So $H - H'$ is a quadrant solution vanishing on $m = 0$, hence $H = H'$:

$$(z_1-z_2)^P\big(\overline{W}(t_1,z_1)W(t_2,z_2) - \overline{W}(t_2,z_2)W(t_1,z_1)\big)\mathbf{1} = 0.$$

Step 2 (Goddard). Let $B = (z_1-z_2)^P[Y_T^\natural(t_1,z_1), Y_T^\natural(t_2,z_2)]$ on $V^\natural$. By (38.7), B applied to $\mathbf{1}^\natural = (\mathbf{1},0)$ is (top-left entry applied to $\mathbf{1}$, 0), which vanishes by Step 1. Each $Y_U^\natural(u)$ is local with both twisted fields (Theorem 38.32), so B satisfies the three-variable locality with $A = Y_U^\natural(u)$. Theorem 38.45 with $p = 0$ gives $B_{m,n}(u,0) = 0$ for every $u \in V_\Lambda^+$ — this is (4.22) on u, for order P. *Step 3 (linearity).* (4.22) is bilinear in (t_1,t_2) and T^+ is spanned by its homogeneous vectors. □

Step 1 deserves a cleaner statement, since it is where the lattice-freeness lies:

Proposition 38.51 (Vacuum step). *For $t_1 \in T_a^+$, $t_2 \in T_b^+$ and $P \geq a+b$, $(z_1-z_2)^P\overline{W}(t_1,z_1)W(t_2,z_2)\mathbf{1} = (z_1-z_2)^P\overline{W}(t_2,z_2)W(t_1,z_1)\mathbf{1}$.*

```
theorem vac_step {a b : ℤ} {t₁ t₂ : TP} (ht₁ : t₁ ∈ plusModule.weight (a : ℂ))
    (ht₂ : t₂ ∈ plusModule.weight (b : ℂ)) (P : ℕ) (hP : a + b ≤ P) :
    mulBySubPow P (fF t₁ t₂) = mulBySubPow P (fun m n => fF t₂ t₁ n m) := by
```

From the mathematics to the Lean statement

`fF t s` is the V_Λ^+-valued distribution with coefficients $\overline{W}(t)_m\,W(s)_n\,\mathbf{1}$, i.e. $\overline{W}(t,z_1)W(s,z_2)\mathbf{1}$. The right side swaps the roles of the indices, giving $\overline{W}(t_2,z_2)W(t_1,z_1)\mathbf{1}$.

Physical meaning

This is the vacuum case of (4.22): the two orderings of two twist fields, evaluated on the vacuum, agree up to the pole of order $a+b$. In CFT terms the three-point amplitude of the vacuum with two twist fields is symmetric, which is the starting point of the Goddard argument to extend the relation to all untwisted states.

What the machine verified

`goddard₂`, `TEq.closed_form`: generic, unconditional. `leechWbar_skew`: unconditional (homogeneous arguments). `leechWbar_VPBlockLocal`: **unconditional**, all t_1, t_2. All four `##print axioms`-checked: `[propext, Classical.choice, Quot.sound]`.

38.10 Reducing (4.23) to a generating family and to four pairs

After Section 38.9, Theorem 38.41 needs only (4.23) for *all* pairs. The linear-span reduction (Theorem 38.40) would require checking a basis of T^+, which is infinite-dimensional. The point of this section is that (4.23) on a family which generates T^+ under the *modes* of V_Λ^+ suffices.

Definition 38.52 (Mode-generating family). A family $g : \kappa \to T^+$ is *mode-generating* if the vectors $u_{(n)}g_i$ ($u \in V_\Lambda^+$, $n \in \mathbb{Z}$, $i \in \kappa$) span T^+.

```
def ModeSpan : Prop :=
  Submodule.span ℂ {x : TP | ∃ (u : SkewVP) (n : ℤ) (i : κ), x = mode (plusModule.YM u) n
   ↪  (g i)} = ⊤
```

(`VOA/Moonshine/M8h0Gap.lean`.)

Physical meaning

A mode-generating family is a set of twisted states from which the whole twisted sector is built by acting with untwisted operators: the twisted sector is generated from a few twist fields (here two frame sectors, one for each parity) by the untwisted chiral algebra. This is the CFT notion of a set of primary states generating a representation.

Theorem 38.53 (Goddard identification of twisted fields). *Let g be mode-generating and $x \in T^+$. Let Ψ be a $T^\natural$-covariant field on $V^\natural$ with $\Psi_0\mathbf{1}^\natural = (0, x)$, $\Psi_q\mathbf{1}^\natural = 0$ for $q < 0$, local with every $Y_U^\natural(v)$ and with every $Y_T^\natural(g_j)$. Then $\Psi = Y_T^\natural(x)$.*

```
theorem YnatT_eq_of_creates (hspan : ModeSpan g) (x : TP) (Ψ : FormalDist (End ℂ Vnat))
    (hcov : DCovariant Tnat Ψ) (h0 : Ψ 0 vacNat = ((0 : SkewVP), x))
    (hneg : ∀ q : ℤ, q < 0 → Ψ q vacNat = 0) (hU : ∀ v : SkewVP, Local Ψ (YnatU v))
    (hT : ∀ j, Local Ψ (YnatT leechWbar (g j))) : YnatT leechWbar x = Ψ := by
```

From the mathematics to the Lean statement

Hypotheses, in order: the mode-span condition; covariance; creation of $(0, x)$ (raw z^0 coefficient, i.e. mode (-1)); no negative powers on the vacuum; locality with all untwisted fields; locality with the twisted generators. Note what is *not* assumed: that $Y_T^\natural(x)$ is local with $Y_T^\natural(g_j)$ — that would be circular.

Physical meaning

A field that creates a given twisted state from the vacuum, is translation covariant and is local with respect to the generators is the twist-field operator of that state. This is the uniqueness of the operator corresponding to a state, the Goddard identification: once crossing with a generating family is known, the operator–state map pins down the rest.

Proof. Let $F = Y_T^\natural(x) - \Psi$. Both are translation covariant and agree on the vacuum in degree 0; covariant fields with the same creation data agree on the vacuum in all degrees (the vacuum

vector $F(z)\mathbf{1}^\natural$ solves $T\,v(z) = \partial v(z)$ with $v(0) = 0$). So F kills $\mathbf{1}^\natural$. The set of vectors killed by all coefficients of F is stable under the modes of every field local with F (one-variable Goddard argument, as in the proof of Theorem 38.45); F is local with all $Y_U^\natural(v)$. So it suffices to show F kills each $(0, g_j)$ and then use the mode-span hypothesis and $V_\Lambda^+ \times 0$. Now $(0, g_j) = Y_T^\natural(g_j)_0\mathbf{1}^\natural$, and $(z-w)^M F(z)Y_T^\natural(g_j, w)\mathbf{1}^\natural = (z-w)^M[F(z), Y_T^\natural(g_j, w)]\mathbf{1}^\natural$. The Ψ-part of the commutator is killed by hypothesis. The $Y_T^\natural(x)$-part is killed on the vacuum because, on $(\mathbf{1}, 0)$, only the top-left entry of (38.7) acts — and that is *(4.22)*, proved unconditionally. So $(z-w)^M F(z)Y_T^\natural(g_j, w)\mathbf{1}^\natural = 0$, and injectivity of multiplication by $z-w$ on distributions with no negative powers of w gives $F(z)(0, g_j) = 0$. □

Theorem 38.54 ((4.23) for all pairs from a generating family). *If g is mode-generating and* $\mathrm{TP}(g_i, g_j)$ *holds for all i, j, then* $\mathrm{TP}(t, t')$ *holds for all $t, t' \in T^+$. Consequently $V^\natural$ carries the vertex operator algebra structure of Theorem 38.41.*

```
theorem TPBlockLocal_all_of_gen {κ : Type*} (g : κ → TP) (hspan : ModeSpan g)
    (h423 : ∀ i j, TPBlockLocal leechWbar (g i) (g j)) (t t' : TP) :
    TPBlockLocal leechWbar t t' := by

theorem vnat_VOA_of_TPBlockLocal_gen {κ : Type*} (g : κ → TP) (hspan : ModeSpan g)
    (h423 : ∀ i j, TPBlockLocal leechWbar (g i) (g j)) :
    ∃ V : VertexOperatorAlgebra Vnat,
      V.Y = Ynat VnatAxioms.wbarL ∧ V.vacuum = vacNat ∧ V.conformalVector = omegaNat ∧
        V.centralCharge = 24 ∧ V.grading = gradingNat := by
```

From the mathematics to the Lean statement

Hypotheses: `hspan` (Definition 38.52) and `h423` ((4.23) on the pairs of g, for the genuine $\overline{W}$). (4.22) is not a hypothesis. The conclusion of the second theorem is that of `vnat_VOA_of_htt`, with the same five identifications, so the same warning about the trap applies.

Physical meaning

The twist×twist crossing with twisted external states, checked on pairs from a generating family of twist fields, extends to all pairs of twisted states by the structure of the chiral algebra. The reduction shrinks the infinite set of crossing conditions on twisted fields to finitely many four-point conditions.

Proof. From (4.22) and (4.23) on g, the fields $Y_T^\natural(g_i)$ are pairwise local (Theorem 38.44). For $u \in V_\Lambda^+$ and $k \geq 0$ the field $\Psi = Y_U^\natural(u)_{(k)}Y_T^\natural(g_i)$ (the k-th field product $\mathrm{Res}_{z_1}(z_1 - z_2)^k[\,\cdot, \cdot\,]$), and for $k = -1$ the normally ordered product $:Y_U^\natural(u)Y_T^\natural(g_i):$, are translation covariant, create $(0, u_{(k)}g_i)$, and by Dong's lemma are local with every $Y_U^\natural(v)$ and every $Y_T^\natural(g_j)$. By Theorem 38.53, $Y_T^\natural(u_{(k)}g_i) = \Psi$ (the *iterate formula*), and by Dong's lemma again these fields are pairwise local. Modes $u_{(-1-k)}$ with $k > 0$ reduce to $k = -1$ via $u_{(-1-k)}x = \frac{1}{k!}(L_{-1}^k u)_{(-1)}x$. So the twisted fields of the linearly spanning family $\{u_{(n)}g_i\}$ are pairwise local, and Theorem 38.40 extends to all pairs; Theorem 38.44 extracts (4.23). □

Theorem 38.55 (Four explicit pairs). *There exist $x_0 \in T_0^+$, $x_1 \in T_1^+$ (the two frame sectors of T^+) such that (4.23) on the four pairs (x_i, x_j) implies the conclusion of Theorem 38.41.*

File `VOA/Moonshine/M8h0Gap.lean`.

```
theorem vnat_VOA_of_TPBlockLocal_frame :

    V.centralCharge = 24 ∧ V.grading = gradingNat) := by
```

From the mathematics to the Lean statement

`TPframe s` for $s \in \mathbb{Z}/2$ is the frame sector $T_s^+ = T^+ \cap (S[\theta] \otimes T_s)$, where $T = T_0 \oplus T_1$ is the eigenspace decomposition of T under a central element of the extraspecial group attached to the Golay frame (defined in Chapter 39); the earlier chapter proves each T_s^+ is a cyclic module over the frame subalgebra V_0^+ with an explicit weight-two cyclic vector (`cyclic_TPframe`), and $T^+ = T_0^+ \oplus T_1^+$.

Quantifier order. The statement is $\exists x,\ (\dots) \wedge ((4.23) \text{ on } x \Rightarrow \text{VOA})$. The witness x is produced by a choice inside the proof; a user of this theorem does not get to pick it. Hence, to apply it, one must prove (4.23) for *whatever* cyclic vectors were chosen — in practice for all pairs, or at least for all vectors of the frame sectors. The consumers in Chapter 42 do exactly that: they prove (4.23) for all pairs from a different generating family and then specialise. So the theorem is a correct but slightly awkward interface; it is not vacuous (an x with the stated membership exists), and it is not weaker than intended because it is never used with a specific x in mind.

Physical meaning

The remaining crossing condition is reduced to four explicit pairs of twisted states, built from the two frame sectors of the twist-field Hilbert space. Physically the whole consistency of the Moonshine orbifold is encoded in four four-point functions of twist fields; the proof of these is the content of the later chapters on triality.

Proof. Take x_s the cyclic vector of T_s^+; then $\{x_0, x_1\}$ is mode-generating (modes of $V_0^+ \subseteq V_\Lambda^+$ already suffice, and the two sectors span T^+); apply Theorem 38.54. □

What the machine verified

`YnatT_eq_of_creates`, `TPBlockLocal_all_of_gen`: unconditional as implications; `vnat_VOA_of_TPBlockLocal_frame`: conditional on (4.23) on the four pairs (inside the statement). All `##print axioms`-checked clean.

38.11 The trap: the square-zero extension

This section is the heart of the referee's task for this Part. Its content was discovered during the project (it is recorded as "TRAP" in `Notes/MonsterRoadmap.md`, "Definition of done") and it changed what the project had to prove.

38.11.1 The construction

Definition 38.56 (Square-zero extension)**.** Let V be a vertex operator algebra and M an ordinary V-module with integral weights ≥ 1. On $V \oplus M$ put

$$Y^{\mathrm{sq}}\big((u,t),z\big) = \begin{pmatrix} Y(u,z) & 0 \\ W_M(t,z) & Y_M(u,z) \end{pmatrix}, \qquad W_M(t,z)\varphi = e^{zL_{-1}} Y_M(\varphi,-z)t.$$

That is, $(u,t)_{(n)}(\varphi,s) = \big(u_{(n)}\varphi,\ u_{(n)}s + W_M(t)_{(n)}\varphi\big)$: the product of two elements of M is zero.

For $V = V_\Lambda^+$, $M = T^+$ this is the block map $Y^\natural[0]$ of Definition 38.34, i.e. (38.1) with $\overline{W}$ replaced by 0.

Physical meaning

The square-zero extension is a theory in which the twisted sector does not interact: the OPE twisted×twisted→untwisted is zero, and the twist fields still act on untwisted states through W. It is a consistent chiral algebra, but the twisted sector is a decoupled module sitting inside it, like a free sector that never talks back to the vacuum.

Proposition 38.57 (The impostor is a VOA with the same numbers)**.** $(V_\Lambda^+ \oplus T^+,\ V^\natural_{\bullet},\ Y^\natural[0],\ \mathbf{1}^\natural,\ \omega^\natural)$ *is a vertex operator algebra of central charge* 24 *with* $V_1 = 0$, $\dim V_2 = 196884$ *and graded dimension* qJ.

Physical meaning

The impostor has the right central charge $c = 24$, no currents, 196884 states at weight two and partition function J: numerically indistinguishable from the Moonshine CFT. It satisfies the axioms because setting every twist×twist OPE to zero trivially makes the twisted–twisted crossing relation true. A partition function, or any count of states, cannot tell a genuine CFT from this degenerate theory.

Proof (on paper). Go through Theorem 38.39 and Theorem 38.40 with $\overline{W}' = 0$. Every block statement that involved $\overline{W}$ becomes $0 = 0$: grading (a zero map has any degree), truncation, translation ($\partial 0 = 0$), the commutator formula (both sides 0). The vacuum, creation and Virasoro statements never involved $\overline{W}$. Untwisted–untwisted and untwisted–twisted locality are Theorems 38.15 and 38.16 (the second hypothesis there for the 0 block is trivial). Twisted–twisted locality is trivial by (38.7): both entries are products with a zero factor. The numbers are those of Section 38.5, which depend only on the graded space. □

What the machine verified

Argued on paper only. The square-zero extension has *not* been constructed in Lean; no declaration named for it exists in the library (the phrase occurs only in docstrings of `VnatFields.lean`, `VnatAxioms.lean`, `VnatGenuine.lean`, `SimpleVnat.lean`, `Main.lean`). A Lean proof would be a line-by-line copy of `VnatAxioms.lean` with `leechWbar` replaced by 0; the point of this section is that such a copy *would* type-check, and hence that the final theorem must contain something it does not satisfy.

Proposition 38.58 (The impostor is not simple)**.** *In* $(V_\Lambda^+ \oplus T^+, Y^\natural[0])$ *the subspace* $0 \oplus T^+$ *is a nonzero proper ideal, with* $(0 \oplus T^+)_{(n)}(0 \oplus T^+) = 0$. *In particular it is not simple and not isomorphic to the genuine* $V^\natural$ *once the latter is known to be simple.*

Physical meaning

In the impostor the twisted sector is a decoupled subtheory: any correlator with only twisted insertions and no untwisted ones vanishes, the twisted two-point function in the vacuum channel is degenerate (the Zamolodchikov metric on twisted states cannot be reached from the vacuum) and the vacuum is not the unique cyclic state. This is not the unitary-looking, single-vacuum CFT of the Monster; it fails simplicity.

Proof. For $x = (u, t)$ and $(0, s)$: $x_{(n)}(0,s) = (0 \cdot s,\ u_{(n)}s + W(t)_{(n)}0) = (0, u_{(n)}s)$. It is proper because $\mathbf{1}^\natural \notin 0 \oplus T^+$, nonzero because $\dim T_2^+ = 98304$. Products of two twisted vectors vanish by definition. □

38.11.2 Why the numbers cannot see the difference

A vertex operator algebra and its square-zero deformation have the same graded vector space, the same Virasoro action, the same central charge, the same characters. More generally, for any module M the square-zero extension $V \ltimes M$ exists; it is the degenerate end of a one-parameter family. Conjugating the block form by $\mathrm{diag}(1, \lambda)$ leaves W unchanged and multiplies $\overline{W}$ by λ^{-2} (Chapter 37), and every locality relation is homogeneous in $\overline{W}$; so if $\overline{W}$ works, so does $c\overline{W}$ for every $c \in \mathbb{C}$, all $c \neq 0$ give isomorphic (simple) algebras, and $c = 0$ gives the impostor. Physically, the square-zero extension is a "theory" in which the operator product of two twist fields has no component in the untwisted sector — the two-point function of a twist field with itself vanishes — which is incompatible with a nondegenerate state space pairing.

Consequently:

- the five "numerical" targets (VOA structure, $c = 24$, $V_1 = 0$, $\dim V_2 = 196884$, $\chi = J$) are satisfied by the impostor and do *not* characterise $V^\natural$;
- every hypothesis of `reconstruct_nat` is satisfied by the impostor;
- the statement "$\exists V$, a VOA on `Vnat` with `V.grading = gradingNat` and $c = 24$" is satisfied by the impostor.

38.11.3 What excludes it

Two things, one cheap and one decisive.

The cheap certificate: $\overline{W} \neq 0$.

Theorem 38.59. *For $t, t' \in T_2^+$, $\overline{W}(t)_{(3)}t' = (t', t)_T \cdot \mathbf{1}$. Consequently, for every nonzero $t \in T_2^+$ there are $t' \in T_2^+$ and $c \neq 0$ with $\overline{W}(t)_{(3)}t' = c\mathbf{1}$; and $\overline{W} \neq 0$.*

```
theorem leechWbarMode_three_weight_two {t t' : TP} (ht : t ∈ plusModule.weight ((2 : ℤ) :
↪  ℂ))

theorem leechWbar_vacuum_pairing_ne_zero {t : TP} (ht : t ∈ plusModule.weight ((2 : ℤ) :
↪  ℂ))
    (ht0 : t ≠ 0) :
    ∃ t' ∈ plusModule.weight ((2 : ℤ) : ℂ), ∃ c : ℂ, c ≠ 0 ∧
      leechWbarMode 3 t t' = c • leechVOAPlus.vacuum := by

theorem leechWbar_ne_zero : leechWbar ≠ 0 := by
```

(`VOA/Moonshine/VnatGenuine.lean`, documented in Chapter 37.)

From the mathematics to the Lean statement

`leechWbar ≠ 0` is inequality of functions $T^+ \to \mathrm{Hom}(T^+, V_\Lambda^+)[[z^{\pm}]]$: some t and some coefficient give a nonzero map. The first theorem is the physically expected OPE $\sigma_t(z)\sigma_{t'}(0) \sim (t, t')_T\, z^{-4}\mathbf{1} + \cdots$ of two weight-two twisted fields: the mode (3) multiplies z^{-4}, and $2 + 2 - 3 - 1 = 0$ is the vacuum weight.

Physical meaning

For weight-two twist fields the twisted×twisted OPE contains the identity with coefficient equal to the Zamolodchikov two-point function, $\overline{W}(t)_{(3)}t' = (t',t)_T\mathbf{1}$ (the analogue of $\phi(z)\phi(0) \sim \langle\phi\phi\rangle/z^{2h}$ with $2h = 4$). Since the metric on twisted states is nondegenerate, the twist fields have nonzero two-point functions; so $\overline{W} \neq 0$ and the genuine orbifold is not the impostor. This is the nontrivial dynamical input that the numbers cannot supply.

Proof. $\overline{W}(t)_{(3)}t'$ has weight 0, so equals $c\mathbf{1}$; pair with $\mathbf{1}$ under B_V ($B_V(\mathbf{1},\mathbf{1}) = 1$) and use the adjunction (38.4) with $w = 2$, $n = 3$, $\varphi = \mathbf{1}$: $2w - n - 2 - j = -1 - j$, and $L_1 t = 0$ since $T_1^+ = 0$, so only $j = 0$ survives and $c = (t', W(t)_{(-1)}\mathbf{1})_T = (t',t)_T$. Nondegeneracy of $(\cdot,\cdot)_T$ on $T_2^+ \neq 0$ gives t' with $c \neq 0$. □

This certificate shows the library's $\overline{W}$ is not the impostor's zero map. It does not by itself prove that the resulting VOA is $V^\natural$: a nonzero $\overline{W}'$ that is not the adjoint could still give a non-simple algebra. The decisive argument is the next one.

The decisive argument: an invariant form that is nondegenerate. The genuine construction carries the block-diagonal form $B^\natural = B_V \oplus (\cdot,\cdot)_T$, which is FHL-invariant precisely because $\overline{W}$ is the adjoint of W, and is nondegenerate. Li's theorem (simple $\iff$ the radical of a normalised fully invariant form is zero) then gives simplicity. For the impostor, consider the same form. Invariance (38.2) for $x = (0,t)$ with $t \in T_2^+$, $n = 3$, $a = (0,t')$, $b = (\mathbf{1},0)$ reads

$$\underbrace{B_V\big(\overline{W}'(t)_{(3)}t',\mathbf{1}\big)}_{=0 \text{ for } \overline{W}'=0} = (-1)^2\big(t', W(t)_{(-1)}\mathbf{1}\big)_T = (t',t)_T,$$

(only $j = 0$ survives since $L_1 t = 0$). So invariance for the impostor would force $(t',t)_T = 0$ for all $t,t' \in T_2^+$, contradicting nondegeneracy of $(\cdot,\cdot)_T$ on the 98304-dimensional space T_2^+. Hence *the form $B^\natural$ is not invariant for the impostor*; and more strongly, by Li's theorem, every normalised fully invariant form on the impostor has the ideal $0 \oplus T^+$ in its radical, i.e. is degenerate. The simplicity proof of Section 38.12 therefore fails for the impostor at exactly one step: the invariance of $B^\natural$ in the off-diagonal blocks, which is the adjunction (38.4).

Trap / dead end

The rule that follows. A claim "$V^\natural$ constructed" must include simplicity (or an equivalent: nondegeneracy of the invariant form of the VOA, or that $\overline{W}$ is the nondegenerate adjoint of W *and* the form is invariant). The project's roadmap forbids marking the construction done without the simplicity theorem, and the final theorem of the Part, `VOA.Moonshine.moonshine`, contains `V.IsSimple` as a conjunct, together with `V.Y = Ynat VnatAxioms.wbarL`.

38.12 The invariant form of $V^\natural$ and simplicity

Throughout this section htt denotes the hypothesis of Theorem 38.41 (twisted–twisted locality for all pairs) and V = `vnatVOA`(htt). All results are therefore conditional on htt — the same hypothesis under which V exists at all.

38.12.1 The form

Definition 38.60. $B^\natural\big((u,t),(u',t')\big) = B_V(u,u') + (t,t')_T$.

```
noncomputable def natForm : LinearMap.BilinForm ℂ Vnat :=
```

```
  leechBV.compl₁₂ (LinearMap.fst ℂ SkewVP TP) (LinearMap.fst ℂ SkewVP TP)
    + TPForm.compl₁₂ (LinearMap.snd ℂ SkewVP TP) (LinearMap.snd ℂ SkewVP TP)

@[simp] theorem natForm_apply (x y : Vnat) : natForm x y = leechBV x.1 y.1 + TPForm x.2 y.2
 ↪  := rfl

theorem natForm_symm (x y : Vnat) : natForm x y = natForm y x := by
```

(`VOA/Moonshine/SimpleForm.lean`.) `B.compl₁₂ f g` is $(x, y) \mapsto B(fx, gy)$; `fst`, `snd` are the two projections. The `rfl` proof of `natForm_apply` confirms the formula.

Physical meaning

The form $B^\natural$ is the Zamolodchikov metric of the whole orbifold theory: the two-point pairing of untwisted states and of twisted states, with the two sectors orthogonal, as required by the $\mathbb{Z}/2$ charge conservation of the orbifold. Its invariance under the vertex operators is the statement that the two-point function is consistent with the OPE.

38.12.2 A combinatorial identity

Lemma 38.61. *(a)* $\sum_{i+j=k} \frac{(-1)^i}{i!\,j!} = \delta_{k,0}$. *(b) If* $f : \mathbb{N} \to \mathbb{C}$ *vanishes on* $[R, \infty)$, *then* $\sum_{j<R} \sum_{i<R} \frac{(-1)^j}{j!\,i!} f(i+j) = f(0)$.

```
theorem alt_antidiag (k : ℕ) :
    ∑ p ∈ Finset.antidiagonal k,
      (-1 : ℂ) ^ p.1 * (((p.1.factorial : ℂ))⁻¹ * ((p.2.factorial : ℂ))⁻¹)
      = if k = 0 then 1 else 0 := by

theorem double_sum_cancel (R : ℕ) (f : ℕ → ℂ) (hf : ∀ k, R ≤ k → f k = 0) :
    ∑ j ∈ Finset.range R, ∑ i ∈ Finset.range R,
      (-1 : ℂ) ^ j * (((j.factorial : ℂ))⁻¹ * ((i.factorial : ℂ))⁻¹) * f (j + i) = f 0 :=
       ↪  by
```

Physical meaning

A pure combinatorial identity (an alternating sum of inverse factorials) that implements the cancellation of the translation factors $e^{zL_{-1}}e^{-zL_{-1}} = 1$ in the proof of invariance. No physics content.

Proof. (a) is $\frac{1}{k!}(1-1)^k$. (b) Group by $k = i + j$; terms with $k \geq R$ vanish, the others are (a) times $f(k)$. □

Meaning: the FHL transpose $u \mapsto e^{zL_1}(-z^{-2})^{L_0}u$, $z \mapsto z^{-1}$ is an involution; applying it twice produces exactly this alternating double sum, which collapses.

38.12.3 Invariance block by block

Lemma 38.62 (The W-block: the adjunction read backwards). *For* $t \in T^+_w$, $n \in \mathbb{Z}$, $a \in V^+_\Lambda$, $b \in T^+$:

$$\big(W(t)_{(n)}a,\ b\big)_T = (-1)^w \sum_{j=0}^{w} \frac{1}{j!}\, B_V\big(a,\ \overline{W}(L_1^j t)_{(2w-n-2-j)}b\big).$$

```
theorem pieceD {wt : ℤ} {t : TP} (ht : t ∈ plusModule.weight (wt : ℂ)) (n : ℤ) (a : SkewVP)
    (b : TP) :
    TPForm (mode (leechWsk t) n a) b = (-1 : ℂ) ^ wt • ∑ j ∈ Finset.range (wt.toNat + 1),
      ((j.factorial : ℂ)⁻¹) • leechBV a (leechWbarMode (2 * wt - n - 2 - j)
        ((Lp1 plusModule ^ j) t) b) := by
```

From the mathematics to the Lean statement

`Finset.range (wt.toNat + 1)` is $j = 0, \dots, w$ (`toNat` of a negative integer is 0; here $w \geq 2$ anyway). `Lp1 plusModule` is L_1 on T^+. This is (38.2) for the W-block of $B^\natural$; (38.4) is (38.2) for the $\overline{W}$-block. Note that (38.4) gives $B_V(\overline{W}(\cdot)\cdot,\cdot)$ in terms of $(\cdot, W(\cdot)\cdot)_T$; the lemma is the converse direction, which is not a restatement.

Physical meaning

This is the twisted-to-untwisted block of the invariance of the Zamolodchikov metric: the amplitude of the twist field $W(t)$ between an untwisted and a twisted state equals the amplitude of its conjugate $\overline{W}$ the other way, with the inversion $z \to 1/z$ factor. It says $\overline{W}$ is the BPZ conjugate of W, which is how $\overline{W}$ was defined.

Proof. Start from the right side. For each j, use symmetry of B_V and apply (38.4) to $\overline{W}(L_1^j t)_{(2w-n-2-j)}$ (weight $w-j$): it becomes $(-1)^{w-j}\sum_i \frac{1}{i!}(b, W(L_1^{i+j}t)_{(n-i-j)}a)_T$, since $2(w-j)-(2w-n-2-j)-2-i = n-i-j$. The signs combine to $(-1)^w(-1)^{w-j} = (-1)^j$, and with $f(k) = (b, W(L_1^k t)_{(n-k)}a)_T$ the right side is the double sum of Lemma 38.61(b), equal to $f(0) = (b, W(t)_{(n)}a)_T$; symmetry of $(\cdot,\cdot)_T$ finishes. □

Theorem 38.63 (Full FHL invariance of $B^\natural$). *Assume htt. For every* $\mathrm{wt} \in \mathbb{Z}$, $x \in V^\natural_{\mathrm{wt}}$, $n \in \mathbb{Z}$, $a, b \in V^\natural$,

$$B^\natural(x_{(n)}a, b) = (-1)^{\mathrm{wt}} \sum_{j=0}^{\mathrm{wt}} \frac{1}{j!} B^\natural\big(a, (L_1^j x)_{(2\mathrm{wt}-n-2-j)}b\big),$$

products and L_1 being those of $V =$ `vnatVOA`(htt).

File `VOA/Moonshine/SimpleForm.lean`.

```
theorem natForm_fhl (wt : ℤ) (x : Vnat) (hx : x ∈ gradingNat wt) (n : ℤ) (a b : Vnat) :
    natForm ((vnatVOA htt).smul x n a) b
      = (-1 : ℂ) ^ wt • ∑ j ∈ Finset.range (wt.toNat + 1), ((j.factorial : ℂ)⁻¹) •
          natForm a ((vnatVOA htt).smul ((((vnatVOA htt).L 1) ^ j) x) (2 * wt - n - 2 - (j
           ↪  : ℤ)) b) := by
```

From the mathematics to the Lean statement

`htt` is a section variable (the twisted–twisted locality hypothesis); it enters only to make `vnatVOA htt` a VOA. The products `(vnatVOA htt).smul x n a` are, by definition, the block products (38.6), and they do not depend on `htt`. So the identity is really a statement about the explicit block map, and its truth does not use htt at all; htt appears only because the statement is phrased with the VOA's own `smul` and `L`. The statement is literally the field `IsFullyInvariant` of Section 38.2 for the form `natForm`.

Physical meaning

Invariance of the Zamolodchikov metric under the full operator algebra, including twist fields: the two-point function of $\langle x_{(n)}a, b\rangle$ equals the inverted amplitude $\langle a, (\dots)b\rangle$. This is the BPZ conjugation property in the orbifold theory. It is conditional on twist×twist locality, because the proof uses the vertex algebra structure on the whole of $V^\natural$.

Proof. Write $x = (u,t)$, $a = (a_1, a_2)$, $b = (b_1, b_2)$. By (38.6) and Definition 38.60,

$$B^\natural(x_{(n)}a, b) = B_V(u_{(n)}a_1, b_1) + B_V(\overline{W}(t)_{(n)}a_2, b_1) + (W(t)_{(n)}a_1, b_2)_T + (u_{(n)}a_2, b_2)_T.$$

Since L_1 is block-diagonal, $L_1^j x = (L_1^j u, L_1^j t)$, and the right side of the claim splits into the same four blocks. The four identities are: FHL invariance of B_V on V_Λ^+; the adjunction (38.4); Lemma 38.62; FHL invariance of $(\cdot,\cdot)_T$ under V_Λ^+. Add them. □

Theorem 38.64 (The invariant form of V). *Assume htt. $B^\natural$ is an invariant form of V (Virasoro-adjoint: $B^\natural(L_n a, b) = B^\natural(a, L_{-n} b)$), fully invariant, normalised, and its left radical is zero.*

File `VOA/Moonshine/SimpleForm.lean`.

```
noncomputable def natInvForm : InvariantForm (vnatVOA htt) where
  form := natForm
  virasoro_adj := natForm_virasoro_adj htt

theorem natInvForm_isFullyInvariant : (natInvForm htt).IsFullyInvariant :=

theorem natInvForm_normalized : (natInvForm htt).Normalized := by

theorem natInvForm_leftRadical : InvariantForm.leftRadical (natInvForm htt) = ⊥ := by
```

Physical meaning

The orbifold has a nondegenerate invariant two-point function, normalised so that $\langle \mathbf{1}|\mathbf{1}\rangle = 1$ and with $L_n^\dagger = L_{-n}$. In CFT terms: a well-defined Zamolodchikov metric on the whole space of states, nondegenerate on every energy level. Nondegeneracy is what forces uniqueness of the vacuum and, by Li's theorem, simplicity.

Proof. Virasoro adjointness is the case $x = \omega^\natural$ (wt $= 2$) of Theorem 38.63: $L_1\omega = 0$ (as $V_1 = 0$), so only $j = 0$ survives and the index $2\cdot 2-(n+1)-2 = -n+1$ gives L_{-n}. Normalisation: $B_V(\mathbf{1},\mathbf{1}) = 1$ and the twisted part of $\mathbf{1}^\natural$ is 0. Radical: if $B^\natural(x,\cdot) = 0$, testing against $(y,0)$ gives $B_V(x_1,\cdot) = 0$, so $x_1 = 0$ by nondegeneracy of B_V; testing against $(0,y)$ gives $(x_2,\cdot)_T = 0$; since the weight spaces of T^+ are mutually orthogonal and $(\cdot,\cdot)_T$ is nondegenerate on each, every homogeneous component of x_2 is 0, so $x_2 = 0$. □

38.12.4 Simplicity

Theorem 38.65 (Li). *Let W be a VOA and B a normalised fully invariant form on W. Then W is simple if and only if the left radical of B is zero.*

```
theorem isSimple_iff_leftRadical_eq_bot {B : InvariantForm W} (hB : B.IsFullyInvariant)
    (hn : B.Normalized) :
    W.IsSimple ↔ InvariantForm.leftRadical B = ⊥ := by
```

(`VOA/Core/InvariantFormRadical.lean`; proved in the Core part of the book.) The idea: the radical of a normalised invariant form is an ideal (invariance moves modes across), it does not contain $\mathbf{1}$ (normalisation), and it equals the maximal proper graded ideal (every proper graded ideal pairs trivially with $\mathbf{1}$ in weight 0 and hence, by invariance, with everything).

Physical meaning

A vertex operator algebra is simple (the vacuum is the only cyclic state; no decoupled sector) if and only if its Zamolodchikov metric is nondegenerate: a state in the radical is orthogonal to everything, so it generates a proper ideal that cannot be reached from the vacuum, a decoupled sector. This is the algebraic form of the folk statement that a CFT with a nondegenerate two-point function has a unique vacuum.

Theorem 38.66 ($V^\natural$ is simple)**.** *Assume htt. Then* `vnatVOA`(htt) *is simple, and the canonical invariant form of the library on it coincides with $B^\natural$ and is nondegenerate on every weight space.*

```
theorem vnatVOA_isSimple : (vnatVOA htt).IsSimple :=
  (LiRadical.isSimple_iff_leftRadical_eq_bot (natInvForm_isFullyInvariant htt)
    (natInvForm_normalized htt)).2 (natInvForm_leftRadical htt)

theorem vnatVOA_invariantForm_nondegenerate :
    (natInvForm htt).IsFullyInvariant ∧ (natInvForm htt).Normalized ∧
      InvariantForm.leftRadical (natInvForm htt) = ⊥ ∧
        GradedNondeg (vnatVOA htt) (natInvForm htt).form :=

theorem vnatVOA_canonicalForm_eq :
    (canonicalInvariantForm (vnatVOA_vacuum_ne_zero htt) (vnatVOA_L1_one htt)).form =
    ↪ natForm :=
```

(`VOA/Moonshine/SimpleVnat.lean`.)

From the mathematics to the Lean statement

`IsSimple` is Definition 38.8 (the `Core/BilinearForm` notion: $V \neq 0$ and every ideal is 0 or V). `GradedNondeg V B` says B is nondegenerate on each V_n. `canonicalInvariantForm` is the library's canonical (Li/FHL) normalised invariant form, which exists whenever $\mathbf{1} \neq 0$ and $L_1 V_1 = 0$; by uniqueness of fully invariant normalised forms it equals $B^\natural$. **Vacuity check.** The statement could have been weak in two ways, and is not. (i) It could have been about some VOA other than the block one; but `vnatVOA htt` has `Y := YN` by definition. (ii) `IsSimple` could have been a weak notion; it quantifies over all subspaces closed under left multiplication, which is at least as strong as the textbook notion. And the theorem is false for the impostor (Proposition 38.58), so it does distinguish.

Physical meaning

The Moonshine module has a unique vacuum and no decoupled sector: every state is reachable from the vacuum by the operator algebra. This is what separates the genuine orbifold CFT from the square-zero impostor, whose twisted sector is a decoupled ideal. It uses in an essential way that the twist×twist OPE $\overline{W}$ is the conjugate of W, because that is what makes the Zamolodchikov metric nondegenerate on the twisted sector as seen from the vacuum.

Proof. Theorem 38.65 applied to $B^\natural$ and Theorem 38.64. □

Theorem 38.67 (Simplicity through the four-pair hypothesis)**.** *There are $x_s \in T_s^+$ ($s \in \mathbb{Z}/2$) such that (4.23) on the four pairs (x_i, x_j) yields a* simple *VOA structure on $V^\natural$ with vertex map $Y^\natural[\overline{W}]$, vacuum $\mathbf{1}^\natural$, conformal vector $\omega^\natural$, $c = 24$ and grading $V^\natural$.*.

```
theorem vnat_isSimple_of_TPBlockLocal_frame :
    ∃ x : ZMod 2 → TP, (∀ s, x s ∈ TPframe s) ∧
      ((∀ i j, TPBlockLocal leechWbar (x i) (x j)) →
        ∃ V : VertexOperatorAlgebra Vnat,
          V.Y = Ynat wbarL ∧ V.vacuum = vacNat ∧ V.conformalVector = omegaNat ∧
            V.centralCharge = 24 ∧ V.grading = gradingNat ∧ V.IsSimple) := by
```

Physical meaning

Conditional on four crossing relations for twist fields, the Moonshine orbifold is a CFT with $c = 24$, no currents and a unique vacuum. The statement packages the simple-VOA conclusion with the four-pair reduction; the physics content is that the only missing input is

four explicit four-point functions of twist fields.

Proof. Theorems 38.55 (with its proof, which produces htt) and 38.66. The quantifier caveat of Theorem 38.55 applies. □

What the machine verified

`natForm_fhl`, `natInvForm_leftRadical`, `vnatVOA_isSimple`, `vnatVOA_invariantForm_nondegenerate`: conditional on htt only. `vnat_isSimple_of_TPBlockLocal_frame`: conditional on (4.23) on four pairs (inside the statement). All `##print axioms`-checked: `[propext, Classical.choice, Quot.sound]`.

38.13 The assembled conditional theorem

Theorem 38.68 ($V^\natural$ modulo (4.23) on four pairs). *There exist $x_0 \in T_0^+$, $x_1 \in T_1^+$ such that, if DGM (4.23) holds on the four pairs (x_i, x_j), then there is a simple vertex operator algebra V on $V^\natural$ whose vertex map is the block map $Y^\natural[\overline{W}]$ of (38.1), with vacuum $(\mathbf{1}, 0)$, conformal vector $(\omega, 0)$, central charge 24, $V_1 = 0$, $\dim V_2 = 196884$, and $\dim V_n = [q^n]\, qJ(q)$ for all $n \geq 0$.*

```
theorem moonshine_of_frameLocality :
    ∃ x : ZMod 2 → TP, (∀ s, x s ∈ TPframe s) ∧
      ((∀ i j, TPBlockLocal leechWbar (x i) (x j)) →
        ∃ V : VertexOperatorAlgebra Vnat,
          V.Y = Ynat wbarL ∧ V.vacuum = vacNat ∧ V.conformalVector = omegaNat ∧
          V.centralCharge = 24 ∧
          V.grading 1 = ⊥ ∧
          finrank ℂ (V.grading 2) = 196884 ∧
          (∀ n : ℕ, (finrank ℂ (V.grading (n : ℤ)) : ℂ) = PowerSeries.coeff n JShift) ∧
          V.IsSimple) := by
```

(`VOA.Moonshine.moonshine_of_frameLocality`, `VOA/Moonshine/Main.lean`.)

From the mathematics to the Lean statement

Every conjunct, decoded: `V.Y = Ynat wbarL` — the vertex map is the genuine block map (Definition 38.34 with $\overline{W}$); `V.vacuum = vacNat`, `V.conformalVector = omegaNat` — Definition 38.22; `V.centralCharge = 24`; `V.grading 1 = ⊥` — $V_1 = 0$; `finrank ℂ (V.grading 2) = 196884`; the graded dimension identity with `JShift` $= qJ$; `V.IsSimple` (Definition 38.8). The grading of V is not mentioned as a separate conjunct, but the three dimension statements are about `V.grading`, the grading of the VOA itself, and the proof sets it to `gradingNat`.
Hypotheses: none outside the existential; inside, (4.23) on four pairs. Compared with the textbook theorem (FLM: $V^\natural$ is a simple VOA of central charge 24 with character J) this is *weaker*, being conditional on (4.23). Its vacuity analysis: without `V.IsSimple` the conclusion would be satisfied by the square-zero extension; without `V.Y = Ynat wbarL` it could be satisfied by any VOA on the same graded space; with both, the impostor is excluded (Section 38.11). The quantifier caveat of Theorem 38.55 applies: the four pairs are chosen by the proof.
The file `Main.lean` states in its docstring that this theorem is *superseded*: the unconditional theorem is `VOA.Moonshine.moonshine`, in which the hypothesis has been discharged.

Physical meaning

This is the assembled statement of the construction: modulo four twist-field four-point crossing conditions, $V^\natural$ is a simple chiral CFT with $c = 24$, no weight-one states (hence a

finite symmetry group, by FLM's theorem the Monster, which is not formalized), 196884 states at weight two and partition function J. Every physical feature of the Moonshine orbifold is present; what is not yet shown is the single twist×twist crossing condition, to be discharged by the triality method.

Proof. Theorem 38.67, together with Theorems 38.24, 38.25 and 38.26 transported along `V.grading = gradingNat`. □

What the machine verified

Conditional on (4.23) on four (chosen) pairs; `##print axioms = [propext, Classical.choice, Quot.sound]` (checked). The hypothesis is discharged in Chapters 39–42: the triality automorphism σ conjugates the untwisted locality into twisted locality (`tpBlockLocal_frame_of_sigma`, `moonshine_of_sigma` in `M8hKey.lean`), and the remaining finite identity is `topPairs_one`. The final, unconditional statement is

```
theorem moonshine :
    ∃ V : VertexOperatorAlgebra Vnat,
      V.Y = Ynat VnatAxioms.wbarL ∧ V.vacuum = vacNat ∧ V.conformalVector = omegaNat
       ↪ ∧
      V.centralCharge = 24 ∧
      V.grading 1 = ⊥ ∧
      Module.finrank ℂ (V.grading 2) = 196884 ∧
      (∀ n : ℕ, (Module.finrank ℂ (V.grading (n : ℤ)) : ℂ) = PowerSeries.coeff n
       ↪ JShift) ∧
      V.IsSimple :=
  moonshine_of_topPairs (by norm_num) topPairs_one
```

(`VOA/Moonshine/TopPairs.lean`, documented in Chapter 42); it has exactly the conclusion of Theorem 38.68, now with no hypothesis.

38.14 Dead ends and corrected mistakes

Trap / dead end

1. The square-zero extension. Recorded in `Notes/MonsterRoadmap.md` ("Definition of done", TRAP) and in Section 50.2.2. $\overline{W}' = 0$ satisfies every hypothesis of `reconstruct_nat` and gives a VOA with $c = 24$, $V_1 = 0$, $\dim V_2 = 196884$, character J, not simple. Remedy: simplicity is a conjunct of the final theorem. See Section 38.11.

Trap / dead end

2. The generator gap. An earlier version of `VnatAxioms.lean` could reduce htt only to a family whose *linear* span is T^+ (`htt_of_span`); a mode-generating family was not enough, because the iterate formula $Y^\natural(u_{(n)}t) = Y^\natural(u)_{(n)}Y^\natural(t)$ for the off-diagonal blocks was unavailable. It was closed by Theorem 38.53, whose key input is the unconditional (4.22). Recorded in `Notes/M8GluingPlan.md`, "M8h-0 DONE".

Trap / dead end

3. (4.23) is not a finite check. One might hope to verify (4.23) on finitely many matrix coefficients. This is impossible without a closed form or an a priori differential equation: the ground-state matrix element $\langle x_0', W(t_0,z_1)\overline{W}(t_0,z_2)x_0\rangle = z_2^a f(z_2/z_1)$ is an infinite power

series whose coefficients are sums over $(V_\Lambda^+)_k$, and locality is the statement that f is rational of a prescribed shape (`Notes/M8hRoute.md`, §5). This is why the triality route was chosen.

Trap / dead end

4. Sign conventions are each necessary. Numerical tests on an E_8 model of the library's construction (`Notes/M8hRoute.md`, §1a; evidence, not proof) confirmed (4.23) to relative residual $3.7 \cdot 10^{-14}$ on 64 identities, and showed that each of the following "simplifications" breaks it (residual 1.7–2.0): replacing the T-form sign $(-1)^{\langle\alpha,\alpha\rangle/2}$ by $\varepsilon(\alpha,\alpha)$; setting the charge sign $c(\alpha) = 1$ in the lattice form; dropping $(-1)^w$ in the definition of $\overline{W}$. The anticommutator (super) version fails (residual ≈ 2): the extension is a VOA, not a super VOA.

Trap / dead end

5. The library's Intertwiner is weaker than FHL's. The library notion `Intertwiner` (Chapter 37) consists of truncation and the intertwining commutator formula only, without the full Jacobi identity. Nothing in this chapter needs more: every locality is derived from commutator formulas (Theorem 38.18) and the Goddard lemmas.

38.15 Referee's checklist

All entries: `##print axioms` = `[propext, Classical.choice, Quot.sound]`, checked 2026-10-07 at an earlier commit (not re-run for this edition). "htt" = twisted–twisted locality for all pairs.

Square-zero extension (Proposition 38.57): **argued on paper only**, not formalised; its role is to show why `V.IsSimple` and `V.Y = Ynat wbarL` must appear in the final statement.

38.16 Notes and references

The block form (38.1), the reduction of locality to the six relations (4.18)–(4.23), the skew-symmetry (4.9) and the adjunction (4.3) defining $\overline{W}$ follow L. Dolan, P. Goddard and P. Montague, *Conformal field theory of twisted vertex operators*, Nuclear Phys. B 338 (1990) 529–601, and especially their *Conformal field theories, representations and lattice constructions*, Comm. Math. Phys. 179 (1996) 61–120, arXiv:hep-th/9410029, §§3–5 (the remark that (4.23) is "almost a modular invariance condition" is in §5.3; triality is in §§6–7).

The construction of the Moonshine module, including the triality used in the later chapters, is I. Frenkel, J. Lepowsky and A. Meurman, *Vertex Operator Algebras and the Monster*, Pure and Applied Mathematics 134, Academic Press, 1988 (chapters 9–12), announced in Proc. Natl. Acad. Sci. USA 81 (1984) 3256–3260.

Invariant bilinear forms on VOAs and modules, and the FHL transpose $e^{zL_1}(-z^{-2})^{L_0}$, are from I. Frenkel, Y.-Z. Huang and J. Lepowsky, *On axiomatic approaches to vertex operator algebras and modules*, Mem. Amer. Math. Soc. 104 (1993), no. 494. The equivalence between simplicity and nondegeneracy of the invariant form is H. Li, *Symmetric invariant bilinear forms on vertex operator algebras*, J. Pure Appl. Algebra 96 (1994) 279–297. Local systems of vertex operators and the reconstruction theorem in the locality formulation are H. Li, *Local systems of vertex operators, vertex superalgebras and modules*, J. Pure Appl. Algebra 109 (1996) 143–195, arXiv:hep-th/9406185, and

V. Kac, *Vertex Algebras for Beginners*, 2nd ed., University Lecture Series 10, AMS, 1998 (Dong's lemma, Goddard's uniqueness theorem, the existence theorem). The textbook treatment of modules, commutator formulas and skew-symmetry used throughout is J. Lepowsky and H. Li, *Introduction to Vertex Operator Algebras and Their Representations*, Progress in Mathematics 227, Birkhäuser, 2004. The library's conventions follow T. Gannon, *Moonshine beyond the Monster*, Cambridge University Press, 2006, §5.1.

The project-internal record — the TRAP, the generator gap, the numerical evidence and the route decision — is in `Notes/MonsterRoadmap.md`, `Notes/M8GluingPlan.md` ("Status" sections through "M8h-0 DONE") and `Notes/M8hRoute.md`.

Chapter 39

The Golay frame and the untwisted triality

At the end of Chapter 38 the space

$$V^\natural \;=\; V_\Lambda^+ \;\oplus\; (V_\Lambda^T)^+$$

carried a candidate vertex map $Y^\natural$, assembled in block form from the vertex operators of V_Λ^+ on itself, the twisted vertex operators Y^T of V_Λ^+ on the twisted sector, the skew intertwiner W and its adjoint $\overline{W}$. Every axiom of a vertex operator algebra had been verified for $Y^\natural$ except one family of locality relations: the locality of two operators $Y^\natural(t_1, z_1)$, $Y^\natural(t_2, z_2)$ whose *states* t_1, t_2 both lie in the twisted sector, evaluated on a twisted vector. In the numbering of Dolan, Goddard and Montague this is relation (4.23); in the library it is the predicate `TPBlockLocal`. This chapter begins the proof of that relation. It does so by the route of Frenkel, Lepowsky and Meurman: one finds a hidden symmetry σ of the would-be algebra $V^\natural$ — the *triality* — which exchanges part of the untwisted sector with part of the twisted sector, so that the unknown twisted×twisted products become conjugates of known untwisted products. The chapter documents the release of the library named in the front matter; every Lean quotation is checked by `scripts/textbook/sync.py` to occur verbatim (up to whitespace and comments) in the source files of that release. Checks that were run at an earlier state of the library and not re-run for this edition are marked as such.

The chapter has three parts.

(I) *The Golay frame* (Sections 39.2–39.5). An index-two sublattice $\Lambda_0 \subset \Lambda$ splits each of the two halves of $V^\natural$ into two pieces, so that $V^\natural$ becomes a sum of four modules over the subalgebra $V_0^+ = V_{\Lambda_0}^+$:

$$V^\natural \;=\; V_0^+ \;\oplus\; V_3^+ \;\oplus\; T_0^+ \;\oplus\; T_3^+.$$

We compute the weight-two dimensions of all four pieces.

(II) *Cyclicity* (Sections 39.6–39.7). Each of the four pieces is generated, as a V_0^+-module, by a single explicit vector. This is what later lets one *define* a V_0^+-equivariant map out of a piece by prescribing the image of one vector.

(III) *The untwisted triality* (Sections 39.8–39.10). On the lattice vertex algebra of the Niemeier lattice $N = N(A_1^{24})$ we construct an explicit involution σ out of exponentials of $\mathfrak{sl}_2$ zero modes, restrict it to the subalgebra $V_N^{\langle \chi, \Theta \rangle}$, and transport it, along an isomorphism of vertex operator algebras $V_N^{\langle \chi, \Theta \rangle} \cong V_0^+$ built from the functoriality of lattice VOAs (Chapter 31), to a nontrivial involutive automorphism `v0Sigma` of V_0^+.

The extension of σ to the remaining sectors, and the identity that makes it useful, are the subjects of Chapters 40–42.

Standing conventions. We use the conventions of the earlier chapters without change. For a vertex algebra V (in Lean, a term `V : VertexOperatorAlgebra` $\mathcal{V}$ on a complex vector space $\mathcal{V}$) and states u, v, the *n-th product* is $u_{(n)}v$, the coefficient of z^{-n-1} in $Y(u,z)v$. In Lean it is written `V.smul u n v`; by definition (`PreVertexAlgebra.smul_def`) this is `mode (V.Y u) n v`, where the library's `mode` is `mode f m = f (-m - 1)` (Definition 2.7, `VOA/Foundations/FormalCalculus.lean`): a formal distribution $f(z) = \sum_k f_k z^k$ is stored as the function $k \mapsto f_k$, and its m-th mode is the coefficient of z^{-m-1}. For a twisted module of order two the library writes `T.YM u k` for the operator $u_{(k/2)}$, half-integer modes being indexed by integers k (Chapter 34). An *automorphism* of a vertex operator algebra W is a term of the structure `Aut W` (Definition 5.9, `VOA/Core/Automorphism.lean`, where it is quoted verbatim): a linear bijection α (`toLinearEquiv`) with $\alpha(u_{(n)}v) = (\alpha u)_{(n)}(\alpha v)$ for *all* $n \in \mathbb{Z}$ (`map_smul'`), $\alpha\mathbf{1} = \mathbf{1}$ (`map_vacuum`), $\alpha\omega = \omega$ (`map_omega`). This is exactly the textbook notion of a VOA automorphism; requiring the product identity for all n is equivalent to $\alpha Y(u,z)\alpha^{-1} = Y(\alpha u, z)$. For a subgroup $G \le \mathrm{Aut}\, W$ the *orbifold* (fixed-point subalgebra) is

```
def orbifold (G : Subgroup (Aut W)) : VOASubalgebra W where
  carrier :=
    { carrier := {v | ∀ g ∈ G, g v = v}
      ...
```

(`VOA/Modularity/Twisted.lean`; the omitted lines are the closure proofs), and `orbifoldVOA G` is W^G regarded as a vertex operator algebra with the same vacuum and conformal vector. A *VOA homomorphism* is a linear map φ preserving vacua and all products, `IsVOAHom V T φ`, with fields `map_vacuum` ($\varphi\mathbf{1}_V = \mathbf{1}_T$) and `map_smul` ($\varphi(u_{(n)}v) = (\varphi u)_{(n)}(\varphi v)$) (Definition 5.22, `VOA/Core/SimpleImage.lean`, where it is quoted verbatim). Note that `IsVOAHom` does not mention the conformal vector; wherever an isomorphism of VOAs (rather than of vertex algebras) is claimed below, the statement $\varphi(\omega) = \omega$ is proved separately and recorded.

Finally, the lattice vertex algebra V_L of an even positive-definite lattice L is, as in Chapter 31, the space File `VOA/Examples/LatticeGenModule.lean`.

```
noncomputable abbrev LatModuleGen : Type :=
  HeisenbergN.FockN (rank L) ⊗[ℂ] (L.carrier →₀ ℂ)
```

— the bosonic Fock space $S(\hat{\mathfrak{h}}^-)$ tensored with the group algebra $\mathbb{C}\{L\}$, whose basis vector at α we write e^α (`eGen L α`). A pure tensor $p \otimes e^\alpha$ is `latStateGen L p α`; the *charged vacuum* $\mathbf{1} \otimes e^\alpha$ is `latChargeGen L α`; the *momentum-γ component* of a state x is the Fock vector `coordEα L γ x` ("the coefficient of e^γ"); and the *momentum sector* $F_\gamma = S(\hat{\mathfrak{h}}^-) \otimes e^\gamma$ is `chargeSec L γ`. The vertex operator algebra structure is `latticeVOAGen L hEven hPos`, the hypotheses being evenness and positive definiteness of L. The cocycle $\varepsilon(\alpha,\beta) = \pm 1$ of the vertex operators $Y(e^\alpha,z)e^\beta = \varepsilon(\alpha,\beta)z^{\langle\alpha,\beta\rangle}\cdots$ is `latticeCocycle L α β`; it is bimultiplicative and satisfies $\varepsilon(\alpha,\beta)\varepsilon(\beta,\alpha)^{-1} = (-1)^{\langle\alpha,\beta\rangle}$.

39.1 Why a triality is needed

39.1.1 The one relation that resists

Recall the shape of the problem. Write $V = V_\Lambda^+$ and $\mathcal{T} = (V_\Lambda^T)^+$, so that $V^\natural = V \oplus \mathcal{T}$. For $u \in V$ the operator $Y^\natural(u,z)$ is block diagonal, $Y^\natural(u,z) = \mathrm{diag}(Y(u,z), Y^T(u,z))$; for $t \in \mathcal{T}$ it is block off-diagonal, with $W(t,z) : V \to \mathcal{T}$ and $\overline{W}(t,z) : \mathcal{T} \to V$. The locality axiom for $Y^\natural$ splits into six relations according to which blocks are involved. Five of them are statements about a single module over a single vertex algebra:

- $u, u' \in V$ on V: locality in the vertex algebra V (Chapter 32);
- $u, u' \in V$ on $\mathcal{T}$: locality of the twisted module (Chapters 34–36);

- $u \in V$, $t \in \mathcal{T}$, in either order and on either sector: the fact that W and $\overline{W}$ are intertwining operators (Chapter 37).

The remaining relations have *two* twisted states. On the untwisted sector, the composite $\overline{W}(t_1,z_1)W(t_2,z_2) : V \to V$ must be local with its swap; DGM call this (4.22) and the library proves it unconditionally (Chapter 38) from the skew symmetry of $\overline{W}$. On the twisted sector the composite $W(t_1,z_1)\overline{W}(t_2,z_2) : \mathcal{T} \to \mathcal{T}$ must satisfy

$$(z_1-z_2)^N\Big(W(t_1,z_1)\overline{W}(t_2,z_2) - W(t_2,z_2)\overline{W}(t_1,z_1)\Big) = 0 \qquad (N \gg 0). \tag{39.1}$$

This is DGM (4.23). Its physical meaning is clear: it is the statement that the four-point function of four twist fields of the $\mathbb{Z}/2$-orbifold of the Leech CFT is single valued. Concretely, the matrix element of (39.1) between ground states is a theta series of Λ divided by η^{24}, evaluated at the modular parameter $q(x)$ of the double cover of the sphere branched over the four insertion points; single-valuedness in x is a statement about the behaviour of Θ_Λ under the full modular group, and DGM describe the condition as "almost a modular invariance condition", true precisely because $\sqrt{2}\Lambda^*$ is even. A direct proof along these lines requires analytic continuation of four-point functions, which the formal-variable framework of the library does not support.

39.1.2 The idea of triality

FLM avoid any computation of twisted×twisted products. Their idea can be explained in three sentences.

1. If $V^\natural$ were already known to be a vertex operator algebra and σ were an automorphism of it, then $\sigma Y^\natural(a,z)\sigma^{-1} = Y^\natural(\sigma a, z)$ for all states a.

2. If moreover σ mapped some untwisted subspace $X \subseteq V$ onto some twisted subspace $\sigma(X) \subseteq \mathcal{T}$, then for $t, t' \in \sigma(X)$,

$$Y^\natural(t,z_1)Y^\natural(t',z_2) \;=\; \sigma\, Y^\natural(\sigma^{-1}t,z_1)\, Y^\natural(\sigma^{-1}t',z_2)\,\sigma^{-1},$$

   and the right side involves only operators of *untwisted* states, whose locality is already known.

3. One therefore constructs σ *before* knowing that $V^\natural$ is a VOA, proves the conjugation identity in the one case that is not automatic, and *deduces* the missing locality.

The difficulty is concentrated in the conjugation identity of step 3; that is the content of Chapters 40–42. What makes step 2 possible at all is a decomposition of $V^\natural$ into pieces fine enough that σ can map an untwisted piece to a twisted piece. This is the Golay frame.

39.1.3 The frame and its four sectors

The Leech lattice contains an index-two sublattice Λ_0 which is simultaneously an index-two sublattice of the Niemeier lattice $N = N(A_1^{24})$. The discriminant group Λ_0^*/Λ_0 has order 4 (because $[\Lambda : \Lambda_0] = 2$ and Λ is unimodular), and it contains two different subgroups of order two, namely Λ/Λ_0 and N/Λ_0; a cyclic group of order four has only one, so $\Lambda_0^*/\Lambda_0 \cong (\mathbb{Z}/2)^2$. Following DGM we label the four cosets $\Lambda_0, \Lambda_1, \Lambda_2, \Lambda_3$ so that

$$N = \Lambda_0 \sqcup \Lambda_1, \qquad \Lambda = \Lambda_0 \sqcup \Lambda_3.$$

This is the origin of the subscript "3" below; in the library the two cosets of Λ_0 in Λ are indexed by $0, 1 \in \mathbb{Z}/2$, and V_3^+ is `frameSector 1`.

On the untwisted side, a state of V_Λ^+ splits according to whether its momenta lie in Λ_0 or in Λ_3:

$$V_\Lambda^+ = V_0^+ \oplus V_3^+, \qquad V_0^+ = V_{\Lambda_0}^+, \quad V_3^+ = \big(\theta\text{-fixed states with momenta in } \Lambda_3\big).$$

On the twisted side, the 4096-dimensional module T of the extraspecial group splits into two 2048-dimensional halves T_0, T_3 under a central element of the preimage of Λ_0, and

$$(V_\Lambda^T)^+ = T_0^+ \oplus T_3^+, \qquad T_s^+ = (S[\theta] \otimes T_s)^+.$$

FLM (and DGM, Proposition 7.1) show that the four pieces are irreducible V_0^+-modules. The triality is an involution of $V^\natural$ with

$$\sigma(V_0^+) = V_0^+, \qquad \sigma(V_3^+) = T_0^+, \qquad \sigma(T_3^+) = T_3^+. \tag{39.2}$$

At weight two the dimensions are (all proved below except the twisted ones, which come from Chapter 36 together with the 2048 + 2048 split proved here):

	V_0^+	V_3^+	T_0^+	T_3^+	total
weight 2	49428	49152	49152	49152	196884

The equality $\dim(V_3^+)_2 = \dim(T_0^+)_2$ is the first visible sign of the triality. The coincidence $49152 = 24 \cdot 2048$ on the twisted side (24 oscillators $h_a(-\frac{1}{2})$ of weight $\frac{1}{2}$ on the 2048-dimensional ground space of weight $\frac{3}{2}$) and $49152 = \frac{1}{2} \cdot 24 \cdot 2^{12}$ on the untwisted side (pairs $\pm\alpha$ of norm-four vectors outside Λ_0) is not an accident: both sides are "24 copies of a 2^{11}-dimensional representation".

39.1.4 What the untwisted triality is, physically

The Niemeier lattice N has 48 roots $\pm\alpha_j$, $j = 0, \dots, 23$, mutually orthogonal, so V_N contains the affine algebra $\widehat{\mathfrak{sl}}_2^{\,24}$ at level one; each $\widehat{\mathfrak{sl}}_2$ factor is the $SU(2)_1$ WZW model, the theory of a free boson at the self-dual radius. The global symmetry group contains $SU(2)^{24}$, acting on the j-th triple of currents (J^{j1}, J^{j2}, J^{j3}) by rotations. Two involutions of V_N are rotations by π in every factor: χ, about the "Cartan" axis $J^{j1} = \frac{1}{2}h_j$, and Θ, about the axis $J^{j2} \propto e_j + f_j$. In the bosonic language χ is a momentum sign, while Θ is a lift of -1 on the lattice (it negates the boson). The rotation by π about the *bisector* of these two axes swaps them; conjugation by it swaps χ and Θ. That rotation is the untwisted triality. Restricted to the fixed points of both χ and Θ it is an automorphism of $V_N^{\langle\chi,\Theta\rangle}$, and this algebra is $V_{\Lambda_0}^+ = V_0^+$ — the common part of V_N and of $V^\natural$. On V_N the triality exchanges the χ-odd part $V_{\Lambda_0}^-$ with the Θ-odd part $V_{\Lambda_1}^+$; the analogous statement in $V^\natural$, where the roles are played by the θ-twisted sector, is (39.2).

Trap / dead end

DGM's Section 7 is circular for this project. Dolan, Goddard and Montague construct σ on $V^\natural$ by combining the explicit triality on V_N with their Proposition 7.3, an isomorphism of twisted and untwisted realisations whose proof uses their earlier (analytic) theorem that the twisted construction defines a conformal field theory — i.e. it uses the locality (39.1) that we are trying to prove. Only the untwisted part of their Section 7 (the formula for σ on V_N) is used in this chapter; the extension to the twisted sectors is done non-circularly in Chapters 40–41. (Source: Notes/M8GluingPlan.md, route (A), "Caution".)

39.2 The frame lattice Λ_0

39.2.1 The model of the Leech lattice

The library uses Ebeling's model of the Leech lattice (Chapter 30), vendored in the file `VOA/LatticesAndCodes/Leech/Defs.lean`. Let $C \subset \mathbb{F}_2^{24}$ be the extended binary Golay code, $\rho : \mathbb{Z}^{24} \to \mathbb{F}_2^{24}$ reduction mod two, and

$$A = \left\{ a \in \mathbb{Z}^{24} \ : \ \rho(a) \in C,\ 4 \,\middle|\, \sum_i a_i \right\} \quad \text{(Lean: } \texttt{Leech.subA}\text{)}, \qquad u = (5, 1, 1, \dots, 1).$$

Then $\Lambda = 2A \sqcup (u + 2A) \subset \mathbb{Z}^{24}$ with bilinear form $\langle x, y \rangle = x \cdot y/8$. The Niemeier lattice is $N = \rho^{-1}(C)$ with form $x \cdot y/2$ (`Leech.golayLattice`); its roots (vectors of norm 2) are exactly $\pm 2e_j$. The *frame character* is

$$\beta : \Lambda \to \mathbb{Z}/2, \qquad \beta(x) = x_0 \bmod 2,$$

which is a homomorphism (`Leech.beta`). Since every vector of $2A$ has even coordinates and every vector of $u + 2A$ has odd coordinates, $\ker \beta = 2A$.

Definition 39.1 (The frame lattice). $\Lambda_0 := \ker \beta = 2A \subset \Lambda$, and $\Lambda_3 := \Lambda \setminus \Lambda_0 = u + 2A$.

```
/-- The Golay-frame character `β : Λ → ℤ/2`, `x ↦ x₀ mod 2`. -/

/-- **`Λ₀`**, the index-`2` sublattice `ker β = 2A` of the Leech lattice. -/
noncomputable def lambda0 : Submodule ℤ leech.carrier := LinearMap.ker Leech.beta

theorem mem_lambda0 (α : leech.carrier) : α ∈ lambda0 ↔ frameChar α = 0 :=
 ↪  LinearMap.mem_ker
```

(`VOA/Moonshine/FrameSectors.lean`, `VOA.Moonshine.frameChar`, `VOA.Moonshine.lambda0`.)

From the mathematics to the Lean statement

Fidelity check. `leech` is the Leech lattice as a `VOA.IntegralLattice` (transported from the vendored Ebeling model, Chapter 30); `leech.carrier` is its underlying $\mathbb{Z}$-module, whose elements are vectors $x \in \mathbb{Z}^{24}$ in $2A \cup (u + 2A)$. `→+ ZMod 2` is "additive group homomorphism to $\mathbb{Z}/2$". `Submodule ℤ` of a $\mathbb{Z}$-module is a subgroup. `LinearMap.ker` is the kernel. So `lambda0` is literally $\ker \beta$. No hypotheses. The definition could only be "wrong" if `Leech.beta` were not the map $x \mapsto x_0 \bmod 2$; its source (displayed in Chapter 30) is `toFun x := (((x : Fin 24 → ℤ) 0 : ℤ)) : ZMod 2`, i.e. exactly that. The next two results show Λ_0 is neither Λ nor trivially small.

Physical meaning

The sublattice $\Lambda_0 = \ker \beta$ is the set of momenta whose first coordinate is even; it is the momentum lattice of the "frame" sub-theory V_{Λ_0}, a rank-24 lattice CFT sitting inside the Leech CFT. Heuristically, the Golay code organises the 24 chiral bosons into a frame of commuting Ising-like pieces (a code CFT / frame VOA in the sense of Dong–Griess–Miyamoto), and $\Lambda_0 = \Lambda \cap N$ is the part of the Leech charge lattice that this frame sees in the same way as the Niemeier lattice $N(A_1^{24})$. Charges in Λ_0 are the ones that the Leech theory and the A_1^{24} theory share; the remaining Leech charges Λ_3 are the ones only Leech has. This shared subtheory is what lets the triality of the A_1^{24} theory be transported to the moonshine theory. The identification with a frame is a heuristic guide; the definition is just a kernel of a map to $\mathbb{Z}/2$.

Proposition 39.2 (Index two). $[\Lambda : \Lambda_0] = 2$.

```
/-- `[Λ : Λ₀] = 2`. -/
theorem card_quotient_lambda0 : Nat.card (leech.carrier / lambda0) = 2
```

From the mathematics to the Lean statement

Fidelity check. `leech.carrier / lambda0` is the quotient group Λ/Λ_0 and `Nat.card` its cardinality (with the convention that an infinite set has `Nat.card` 0; since the value is 2, the quotient is finite of order exactly two). Same as the textbook statement. Not vacuous: a statement `Nat.card` $= 2$ cannot hold for the trivial quotient.

Physical meaning

In charge-lattice language, Λ_0 has index two: there are only two "frame charge" classes, even and odd, and every Leech charge falls in exactly one. This is what makes the frame a $\mathbb{Z}/2$-grading of the Leech theory, the simplest possible charge decomposition, and later forces exactly two sectors V_0^+ and V_3^+. It is a counting statement about the charge lattice, with no dynamical content beyond that.

Proof. β is surjective because $\beta(u) = 5 \bmod 2 = 1$, so $\Lambda/\ker\beta \cong \mathbb{Z}/2$. (The library proves the equivalent statement $[\Lambda : \mathrm{im}(a \mapsto 2a)] = 2$ for the model, and $\Lambda_0 = \mathrm{im}(a \mapsto 2a)$.) □

What the machine verified

Unconditional; `##print axioms card_quotient_lambda0` = [`propext`, `Classical.choice`, `Quot.sound`] (re-run for this chapter, see Section 39.12).

Proposition 39.3 ($\Lambda_0 \cong A$ isometrically)**.** *The doubling map $a \mapsto 2a$ is an isomorphism of groups $A \to \Lambda_0$, and if A carries the form $a \cdot b/2$ (the restriction of the form of N), it is an isometry: $\langle 2a, 2b\rangle_\Lambda = a \cdot b/2$.*

```
/-- `a ↦ 2a` identifies `A` with `Λ₀`. -/
noncomputable def lambda0Equiv : ↥Leech.subA ≃ₗ[ℤ] ↥lambda0 :=
  (LinearEquiv.ofInjective Leech.inclL Leech.inclL_injective).trans
    (LinearEquiv.ofEq _ _ lambda0_eq_range_inclL.symm)

/-- `A ≃ Λ₀` is an isometry: the Leech form on `Λ₀` is the halved Golay form on `A`. -/
theorem lambda0Equiv_form (a b : ↥Leech.subA) :
    leech.form (lambda0Equiv a : leech.carrier) (lambda0Equiv b : leech.carrier)
      = Leech.subALattice.bilin a b
```

From the mathematics to the Lean statement

Fidelity check. `↥Leech.subA` is the subtype of vectors in A; `≃ₗ[ℤ]` is a $\mathbb{Z}$-linear bijection. The map is built from `Leech.inclL`, whose source is `toFun a := ⟨(2 : ℤ) • (a : Fin 24 → ℤ), …⟩`, i.e. $a \mapsto 2a$; `ofInjective` makes it a bijection onto its range and `ofEq` identifies the range with `lambda0`. `Leech.subALattice` is A with the form `dotLattice 2 subA …`, i.e. $a \cdot b/2$. The statement is exactly the proposition.

Physical meaning

Physically this says that the frame sub-theory is the lattice CFT of A with the halved Golay form: the charge lattice Λ_0 of the Leech theory is, as a Euclidean lattice, the same object that appears inside the Niemeier theory V_N. Isometric charge lattices give isomorphic lattice CFTs, so this identification is the first step in comparing the Leech-side and Niemeier-side descriptions of the same subtheory, which the bridges of Section 39.10 make precise.

Proof. $(2a)\cdot(2b)/8 = 4(a\cdot b)/8 = a\cdot b/2$. □

What the machine verified

Unconditional; `##print axioms-clean`.

Trap / dead end

Λ_0 is not $\sqrt{2}\,\Gamma_{\text{Golay}}$. An early version of the project's gluing plan (`Notes/M8GluingPlan.md`) described Λ_0 as a rescaled Golay lattice. That lattice has minimum $2\cdot 4 = 8$, whereas Λ_0 contains norm-four vectors: for $a = (2,2,0,\dots,0) \in A$, $2a = (4,4,0,\dots,0)$ has $\langle 2a, 2a\rangle = 32/8 = 4$. The correct description is $\Lambda_0 = \Lambda \cap N$ up to the isometry above (Notes/M8GluingPlan.md, "Status and corrections after M8e", item 2).

Example 39.4 (Norm-four vectors)**.** The Leech lattice has 196560 vectors of norm 4. Those in $\Lambda_0 = 2A$ are $2a$ with $a \in A$, $a\cdot a = 8$: either $a = \pm 2e_i \pm 2e_j$ ($i<j$; these have $\sum a_i \in \{0,\pm 4\}$, all divisible by 4), giving $4\binom{24}{2} = 1104$ vectors, or $a = (\pm 1)^8$ supported on an octad with an even number of minus signs (so that $4 \mid \sum a_i$), giving $759\cdot 2^7 = 97152$ vectors. Thus $|\Lambda_0 \cap \{\text{norm } 4\}| = 98256$ and $|\Lambda_3 \cap \{\text{norm } 4\}| = 196560 - 98256 = 98304$. The second number is proved in Lean below (Theorem 39.10); the first was checked numerically (the Python count recorded in `FrameSectors.lean`) and follows from the second.

39.3 Momentum signs and the untwisted sectors

39.3.1 The automorphism attached to a character (recalled)

The device that splits V_Λ by cosets of Λ_0 was introduced in Section 31.11. For an even positive-definite lattice L and a homomorphism $\chi : L \to \mathbb{Z}/2$ one has the *sign automorphism*

$$g_\chi(p \otimes e^\alpha) = (-1)^{\chi(\alpha)}\, p \otimes e^\alpha \qquad \text{(Lean: } \texttt{VOA.LatGen.chiLat L χ}\text{, Definition 31.31)}, \tag{39.3}$$

where $(-1)^{\chi(\alpha)}$ is written `chiSign L χ α = Extraspecial.sgn (χ α)`, the function $\mathbb{Z}/2 \to \mathbb{C}$ sending $0 \mapsto 1$, $1 \mapsto -1$. Chapter 31 proves (Theorem 31.32) that g_χ is an automorphism of the vertex operator algebra V_L (`chiAut L χ hEven hPos : Aut (latticeVOAGen L hEven hPos)`), that $g_\chi^2 = 1$ (`chiAut_sq`) and that g_χ commutes with the standard lift θ of -1 (`chiAut_mul_thetaAut`); and (Theorem 31.33) that

$$g_\chi x = x \iff x_\alpha = 0 \text{ whenever } \chi(\alpha) \neq 0, \qquad g_\chi x = -x \iff x_\alpha = 0 \text{ whenever } \chi(\alpha) = 0, \tag{39.4}$$

where x_α (`coordEα L α x`) is the momentum-α Fock component of x (see `chiLat_eq_self_iff` and `chiLat_eq_neg_iff`). The physical picture: g_χ is the operator $(-1)^{\chi(\hat p)}$ of the momentum $\hat p$, a symmetry because momentum is conserved in every operator product. We use g_χ twice: with $L = \Lambda$, $\chi = \beta$ (this section), and with $L = N$, $\chi =$ parity (Section 39.9).

39.3.2 The sectors V_0^+ and V_3^+

Specialise to $L = \Lambda$, $\chi = \beta$. The resulting automorphism is the *frame automorphism* $g := g_\beta$ (`frameAut : Aut leechVOA`); it commutes with θ (`frameAut_comm_leechTheta`), hence preserves V_Λ^+ and restricts to an automorphism `plusFrameAut : Aut leechVOAPlus`. The carrier type of V_Λ^+ is

```
abbrev VPlus : Type := ↥(orbifold (Subgroup.zpowers leechTheta)).carrier
```

i.e. the vectors of V_Λ fixed by the cyclic group $\langle\theta\rangle$ (here `leechVOAPlus := orbifoldVOA (Subgroup.zpowers leechTheta)`, Chapter 32).

Definition 39.5 (Frame sectors). For $i \in \mathbb{Z}/2$, $V_{(i)} := \{v \in V_\Lambda^+ : gv = (-1)^i v\}$. We write $V_0^+ = V_{(0)}$ and $V_3^+ = V_{(1)}$.

```
/-- **The frame sectors** `V_i := {v ∈ V_Λ⁺ | g v = (-1)^i v}`; `V₀⁺ = frameSector 0`,
`V₃⁺ = frameSector 1`. -/
noncomputable def frameSector (i : ZMod 2) : Submodule ℂ VPlus :=
  Module.End.eigenspace (plusFrameAut.toLinearEquiv : Module.End ℂ VPlus)
    (Moonshine.Extraspecial.sgn i)

/-- **`V₀⁺`: all momenta in `Λ₀`.** -/
theorem mem_frameSector_zero_iff (v : VPlus) :
    v ∈ frameSector 0 ↔ ∀ α, α ∉ lambda0 → coordEα leech α v = 0

/-- **`V₃⁺`: all momenta in `Λ \ Λ₀`.** -/
theorem mem_frameSector_one_iff (v : VPlus) :
    v ∈ frameSector 1 ↔ ∀ α, α ∈ lambda0 → coordEα leech α v = 0
```

From the mathematics to the Lean statement

Fidelity check. `Module.End.eigenspace f c` is $\ker(f - c)$, a subspace of `VPlus`. `plusFrameAut.toLinearEquiv` is g restricted to V_Λ^+. The two characterisation theorems say that V_0^+ is the set of θ-fixed states with all momenta in Λ_0 and V_3^+ the set of θ-fixed states with all momenta in Λ_3 (the coercion `v : VPlus` to V_Λ is implicit in `coordEα leech α v`). This is the intended meaning of $V_{\Lambda_0}^+$ and of "$V_{\Lambda_3}^+$".

Physical meaning

The frame automorphism $g = (-1)^{\beta(\hat{p})}$ is a $\mathbb{Z}/2$ charge symmetry of the Leech theory: it is the parity of the first momentum coordinate, and is a symmetry because momentum is conserved in every operator product. Its two eigenspaces on V_Λ^+ are the charge sectors: V_0^+ (neutral under g, momenta in Λ_0) and V_3^+ (odd, momenta in Λ_3). In orbifold language one is projecting onto the g-even states to get the subtheory V_0^+, while V_3^+ is a "charged module" of it; the pair $\{V_0^+, V_3^+\}$ is the decomposition of the Leech theory under the frame $\mathbb{Z}/2$. The sector labels are conventions; the content is the eigenspace decomposition.

Proof. The equivalences (39.4) with $\chi = \beta$ and $\ker\beta = \Lambda_0$. □

Theorem 39.6 ($V_\Lambda^+ = V_0^+ \oplus V_3^+$, and the $\mathbb{Z}/2$-grading of products). *(i)* $V_\Lambda^+ = V_{(0)} \oplus V_{(1)}$ *(internal direct sum). (ii) For* $u \in V_{(i)}$, $v \in V_{(j)}$ *and all* $n \in \mathbb{Z}$: $u_{(n)}v \in V_{(i+j)}$. *(iii) Each* $V_{(i)}$ *is stable under the projections onto the* L_0*-weight spaces.*

File `VOA/Moonshine/FrameSectors.lean`.

```
/-- **`V_Λ⁺ = V₀⁺ ⊕ V₃⁺`** (internal direct sum). -/
theorem frameSector_isInternal : DirectSum.IsInternal frameSector

/-- **The `ℤ/2`-grading of products**: `u ∈ V_i`, `v ∈ V_j ⇒ u₍ₙ₎v ∈ V_{i+j}`. -/
theorem frameSector_smul_mem {i j : ZMod 2} {u v : VPlus} (hu : u ∈ frameSector i)
    (hv : v ∈ frameSector j) (n : ℤ) : leechVOAPlus.smul u n v ∈ frameSector (i + j)

/-- The sectors are graded: each is stable under the weight projections of `V_Λ⁺`. -/
theorem frameSector_graded (i : ZMod 2) (n : ℤ) {v : VPlus} (hv : v ∈ frameSector i) :
    piHom leechVOAPlus n v ∈ frameSector i
```

From the mathematics to the Lean statement

Fidelity check. `DirectSum.IsInternal frameSector` (Mathlib) means: the canonical map $\bigoplus_{i\in\mathbb{Z}/2} V_{(i)} \to V_\Lambda^+$ is a bijection, i.e. every vector is uniquely a sum of one vector from each sector. `leechVOAPlus.smul u n v` is $u_{(n)}v$ in V_Λ^+. The addition $i + j$ is in `ZMod 2`, so $V_{(1)} \cdot V_{(1)} \subseteq V_{(0)}$, as intended. `piHom leechVOAPlus n` is the projection onto the weight-n space along the others (Section 5.1). Same as the theorem. Not vacuous: (i) excludes, e.g., both sectors being zero, and both sectors are shown nonzero below (their weight-two parts have positive dimension).

Physical meaning

The theorem is the statement of a $\mathbb{Z}/2$ charge-conservation (fusion) rule: the odd sector times itself lands in the even sector, so the g-charge is additive in operator products, exactly as for any grading by a conserved quantum number. (iii) says that the energy (L_0-weight) commutes with the charge, as it must since g is a symmetry of the stress tensor. In CFT terms V_Λ^+ is an extension of the subtheory V_0^+ by its charged module V_3^+ with fusion $V_3^+ \times V_3^+ = V_0^+$.

Proof. (i) The two eigenspaces of an involution over a field of characteristic $\neq 2$ are complementary: $x = \frac{1}{2}(x + gx) + \frac{1}{2}(x - gx)$. (ii) $g(u_{(n)}v) = (gu)_{(n)}(gv) = (-1)^{i+j}u_{(n)}v$ because g is an automorphism. (iii) Automorphisms preserve ω, hence L_0, hence commute with the weight projections. □

What the machine verified

Unconditional; `##print axioms frameSector_isInternal, frameSector_smul_mem`: [`propext`, `Classical.choice`, `Quot.sound`].

Theorem 39.7 (V_0^+ is a vertex operator algebra of central charge 24). *V_0^+ is a vertex subalgebra of V_Λ^+ containing $\mathbf{1}$ and ω; with the induced structure it is a VOA of central charge 24.*

File `VOA/Moonshine/FrameSectors.lean`.

```
/-- `V₀⁺ = (V_Λ⁺)^{⟨g⟩}` as a subalgebra of `V_Λ⁺`. -/
noncomputable def V0Sub : VOASubalgebra leechVOAPlus := orbifold (Subgroup.zpowers

theorem V0Sub_carrier : V0Sub.carrier = frameSector 0

/-- **`V₀⁺` is a vertex operator algebra** (the `g`-fixed subVOA of `V_Λ⁺`, i.e. the
`⟨θ, g⟩`-orbifold of `V_Λ`). -/
noncomputable def V0P : VertexOperatorAlgebra V0Sub.carrier := V0Sub.toVOA

/-- `c(V₀⁺) = 24`. -/
theorem V0P_centralCharge : V0P.centralCharge = 24
```

From the mathematics to the Lean statement

Fidelity check. `VOASubalgebra W` is a subspace containing $\mathbf{1}, \omega$ and closed under all n-th products (Definition 5.24); `toVOA` gives it the restricted structure. `V0Sub` is the fixed-point subalgebra of the cyclic group generated by g on V_Λ^+, and `V0Sub_carrier` says that its carrier is exactly V_0^+. Hence `V0P` is V_0^+ with its inherited VOA structure. The central charge is the inherited one. Note that `V0P` is a VOA on the type `V0Sub.carrier`, i.e. on vectors of V_Λ^+ (hence of V_Λ) — not on V_{Λ_0} built as a lattice VOA in its own right; the identification with the latter is Theorem 39.41.

Physical meaning

V_0^+ is the neutral subtheory under the frame $\mathbb{Z}/2$, i.e. the $\langle\theta, g\rangle$-orbifold of the Leech lattice CFT, still with the Virasoro central charge $c = 24$ of 24 free bosons (taking a fixed-point subalgebra does not change the stress tensor). It is the chiral algebra that the untwisted and twisted halves of the moonshine module share, and the natural domain of the triality: σ is an automorphism of this subtheory that is not visible as a lattice symmetry. Central charge is read off from the stress tensor, unchanged by restricting to invariants.

Proof. The fixed points of a group of automorphisms form a subalgebra containing $\mathbf{1}, \omega$ (Chapter 32), and c is read off from ω, which is unchanged. □

What the machine verified

Unconditional; `##print axioms V0P_centralCharge-clean`.

39.4 Weight two of the untwisted sectors

The Leech lattice has no roots, so $(V_\Lambda)_1 = \mathfrak{h} \otimes e^0$ and $(V_\Lambda)_2$ is spanned by $h_a(-1)h_b(-1)\mathbf{1}$ (300 states), $h_a(-2)\mathbf{1}$ (24 states) and e^α with $\langle\alpha,\alpha\rangle = 4$ (196560 states). The θ-fixed part $(V_\Lambda^+)_2$ has dimension $300 + 98280 = 98580$ (Chapter 32): θ fixes the quadratic states, negates $h_a(-2)\mathbf{1}$, and pairs e^α with (a multiple of) $e^{-\alpha}$. A basis of the charged part is $e^\alpha + \theta e^\alpha$ with α running over a set S of representatives of the pairs $\{\pm\alpha\}$ (`halfFour`: those α preceding $-\alpha$ in a fixed well-order).

Theorem 39.8 (Weight two, in terms of S). *Let* $S_i = \{\alpha \in S : \beta(\alpha) = i\}$. *Then* $\dim(V_0^+)_2 = 300 + |S_0|$, $\dim(V_3^+)_2 = |S_1|$, *and* $2|S_1| = \#\{\alpha \in \Lambda : \langle\alpha,\alpha\rangle = 4,\ \beta(\alpha) = 1\}$.

```
/-- `S_i = {α ∈ S | β α = i}`, `S = halfFour` the chosen half of the norm-`4` vectors. -/
noncomputable def halfFourChi (i : ZMod 2) : Finset leech.carrier :=
  (halfFour leech leech_posDef).filter fun α => frameChar α = i

/-- **`dim (V₀⁺)₂ = 300 + #{α ∈ S | β α = 0}`.** -/
theorem finrank_frameSector_zero_grading_two :
    finrank ℂ ↥((frameSector 0).comap (leechVOAPlus.grading 2).subtype)
      = 300 + (halfFourChi 0).card

/-- **`dim (V₃⁺)₂ = #{α ∈ S | β α = 1} = ½ #{α ∈ Λ \ Λ₀ | ⟨α,α⟩ = 4}`.** -/
theorem finrank_frameSector_one_grading_two :
    finrank ℂ ↥((frameSector 1).comap (leechVOAPlus.grading 2).subtype)
      = (halfFourChi 1).card

/-- `2·#S₁ = #{α | ⟨α,α⟩ = 4, β α = 1}`. -/
theorem two_mul_card_halfFourChi_one :
    2 * (halfFourChi 1).card
      = ((normFour leech leech_posDef).filter fun α => frameChar α = 1).card
```

(`VOA/Moonshine/FrameWeightTwo.lean`.)

From the mathematics to the Lean statement

Fidelity check. `leechVOAPlus.grading 2` is the weight-2 subspace of V_Λ^+; `(frameSector i).comap (grading 2).subtype` is the set of weight-2 vectors lying in $V_{(i)}$, viewed as a subspace of the weight-two space, i.e. $(V_{(i)})_2 = V_{(i)} \cap (V_\Lambda^+)_2$. `finrank ℂ` is the complex dimension (Mathlib's `Module.finrank`; it would return 0 for an infinite-dimensional space, but the weight spaces are finite dimensional — this is part of the VOA structure — so the value is

the true dimension). `normFour leech leech_posDef` is the finite set of norm-four vectors, `Finset.filter` restricts it, `.card` counts. The statement is exactly the theorem; the specific representative set S is irrelevant to the dimensions because $\beta(-\alpha) = \beta(\alpha)$.

Physical meaning

Weight two is the level of the Griess algebra: the weight-two states are V_0^+'s and V_3^+'s stress-tensor-like and charged bilinear fields (the 300 quadratic oscillator states, plus the vertex operators of norm-four charges). The statement counts how the norm-four charges $\pm\alpha$ distribute between the two frame sectors, which is the first quantitative signature of the frame split; the θ-invariance pairs α with $-\alpha$, hence the factor 2.

Proof. The 300 quadratic states have momentum $0 \in \Lambda_0$ and lie in V_0^+. The state $e^\alpha + \theta e^\alpha$ has momenta $\pm\alpha$, so it lies in V_0^+ if $\beta(\alpha) = 0$ and in V_3^+ if $\beta(\alpha) = 1$. These states together form a basis of $(V_\Lambda^+)_2$; the two spans are therefore contained in $(V_0^+)_2$ and $(V_3^+)_2$ respectively, these two intersect trivially, and their dimensions add up to 98580, which forces equality. The last identity holds because negation is a fixed-point-free involution of the set of norm-four vectors with $\beta = 1$, and S_1 contains exactly one vector from each orbit. □

What the machine verified

Unconditional; `##print axioms`-clean.

39.4.1 Counting norm-four vectors outside Λ_0

Lemma 39.9 (Shape of an odd norm-four vector). *Let $y \in \mathbb{Z}^{24}$ have all coordinates odd and $y \cdot y = 32$. Then exactly one coordinate y_p satisfies $y_p^2 = 9$ and all others satisfy $y_i^2 = 1$.*

```
/-- An odd vector of norm `32` has exactly one coordinate `±3`, the others `±1`. -/
theorem exists_three {y : Fin 24 → ℤ} (hodd : ∀ i, ¬ (2 : ℤ) ∣ y i) (hy : y ⬝ᵥ y = 32) :
    ∃ p, y p * y p = 9 ∧ ∀ i, i ≠ p → y i * y i = 1
```

From the mathematics to the Lean statement

Fidelity check. `⬝ᵥ` is the dot product on $\mathbb{Z}^{24}$ (`Fin 24 → ℤ`); the hypotheses are "all coordinates odd" and "$y \cdot y = 32$". The conclusion asserts existence of p with $y_p^2 = 9$ and $y_i^2 = 1$ for $i \neq p$ (uniqueness of p follows from the second clause). Same as the lemma.

Physical meaning

This is a purely arithmetical step in the count of norm-four charges outside Λ_0: an odd-coordinate vector of the given norm looks like a single "3" among ±1's. Physically it enumerates the lowest nonzero charges (the lightest charged states, of weight 2) of the odd frame sector.

Proof. For odd y_i, $y_i^2 - 1$ is a non-negative multiple of 8. The 24 numbers $d_i = y_i^2 - 1$ sum to $32 - 24 = 8$, so exactly one of them is 8 and the rest are 0. □

Theorem 39.10 (98304 norm-four vectors outside Λ_0). $\#\{\alpha \in \Lambda \setminus \Lambda_0 : \langle \alpha, \alpha \rangle = 4\} = 24 \cdot 2^{12} = 98304$.

```
/-- The norm-`4` vectors outside `Λ₀`. -/
noncomputable def oddFour : Finset leech.carrier :=
  (normFour leech leech_posDef).filter fun α => frameChar α = 1
```

```
/-- **`#{α ∈ Λ \ Λ₀ | ⟨α,α⟩ = 4} = 98304`.** -/
theorem card_normFour_frameChar_one : oddFour.card = 98304
```

(VOA/Moonshine/FrameCount.lean.)

From the mathematics to the Lean statement

Fidelity check. oddFour is the set of α with $\langle\alpha,\alpha\rangle = 4$ and $\beta(\alpha) = 1$, i.e. $\alpha \notin \Lambda_0$ (by mem_lambda0). Same as the theorem. The number is a hard-coded literal, so the only way this could mislead is if the Leech model or the form were wrong; the form is $x\cdot y/8$ (leech_form_eq) and the model is Ebeling's (Chapter 30).

Physical meaning

The count $98304 = 24 \cdot 2^{12}$ is the number of lightest ($h = 2$) charged vertex operators in the odd frame sector. Heuristically it matches the 24 ways of choosing which boson carries the odd unit of charge, times the 2^{12} Golay codewords, which anticipates the twisted side, where the same number appears as 24 oscillators times a 2048-dimensional ground space. This numerical coincidence is the first hint of the triality that exchanges the two descriptions.

Proof. A vector of $u + 2A$ has all coordinates odd and norm 4 means $x \cdot x = 32$; by the lemma it has one coordinate ± 3 at a position p and all others ± 1. Write $x = u + 2a$ and $c = \rho(a) \in C$. The sign pattern is determined by (p, c): for $i \neq p$, $x_i = 1 - 2c_i$, and $x_p = 6c_p - 3$ (check the four cases using $u_0 = 5$, $u_i = 1$; e.g. if $p = i \neq 0$ and $c_i = 0$ then $x_i \in \{1 + 2a_i\} \cap \{\pm 3\}$ with a_i even forces $x_i = -3$). Conversely, for every $(p, c) \in \{0, \dots, 23\} \times C$ the vector so defined lies in $u + 2A$: the corresponding a has $\rho(a) = c$, and the condition $4 \mid \sum a_i$ reduces to $4 \mid \mathrm{wt}(c)$, which holds because the Golay code is doubly even. So the odd norm-four vectors are in bijection with $\{0, \dots, 23\} \times C$, of size $24 \cdot 2^{12}$. □

What the machine verified

Unconditional; ##print axioms card_normFour_frameChar_one-clean.

Corollary 39.11 (The two untwisted weight-two dimensions). $\dim(V_3^+)_2 = 49152$ *and* $\dim(V_0^+)_2 = 49428$.

```
/-- **`dim (V₃⁺)₂ = 49152`.** -/
theorem finrank_V3_grading_two :
    finrank ℂ ↥((frameSector 1).comap (leechVOAPlus.grading 2).subtype) = 49152

/-- **`dim (V₀⁺)₂ = 49428`.** -/
theorem finrank_V0_grading_two :
    finrank ℂ ↥((frameSector 0).comap (leechVOAPlus.grading 2).subtype) = 49428
```

From the mathematics to the Lean statement

Fidelity check. As in Theorem 39.8; the subspaces are $(V_3^+)_2$ and $(V_0^+)_2$ inside $(V_\Lambda^+)_2$. Same as the corollary. A check on consistency: $49428 + 49152 = 98580 = \dim(V_\Lambda^+)_2$ (finrank_frameSector_grading_two_add).

Physical meaning

These are the dimensions of the weight-two (Griess algebra) pieces of the two frame sectors: 49428 neutral and 49152 charged states, summing to the 98580 weight-two states of V_Λ^+. The second number equals the weight-two dimension of the twisted sector T_0^+; physical

triality says that this is no coincidence, because σ exchanges the two sectors. Such dimension coincidences are the partition-function signature of a hidden symmetry (a heuristic, supported by the proof of the relevant theorems later).

Proof. $|S_1| = 98304/2 = 49152$; $|S_0| + |S_1| = |S| = 196560/2 = 98280$, so $|S_0| = 49128$ and $\dim(V_0^+)_2 = 300 + 49128 = 49428$. □

What the machine verified

Unconditional; both `##print axioms`-clean (re-run for this chapter).

39.5 The twisted side: $T = T_+ \oplus T_-$

Recall from Chapter 34 the module T (`leechT`): the unique irreducible module, of dimension $2^{12} = 4096$, of the twisted group algebra spanned by operators e_α ($\alpha \in L$) with

$$e_\alpha e_\beta = \varepsilon(\alpha,\beta)\, e_{\alpha+\beta}, \qquad e_{\alpha+2\gamma} = e_\alpha \text{ on } T.$$

For a general even unimodular L the operator of e_α on T is `eT L hEven hU α`, where `hU : IsUnit (gramMat L).det` expresses unimodularity. The library works with the type `TT L hEven hU := Extraspecial.Rep (cocMat L) _` (definitionally the same module; the abbreviation avoids a slow elaboration path).

Lemma 39.12 (Commutation and square of e_w). *For $w, \alpha \in L$: $e_w e_\alpha = (-1)^{\langle w,\alpha\rangle} e_\alpha e_w$ and $e_w e_w = \varepsilon(w,w)\cdot 1_T$.*

File `VOA/Moonshine/FrameTwisted.lean`.

```
/-- `e_w e_w = ε(w,w)`. -/

    eT L hEven hU w * eT L hEven hU w = latticeCocycle L w w • (1 : End ℂ (TT L hEven hU))

/-- `e_w e_α = (-1)^{⟨w,α⟩} e_α e_w`. -/
theorem eT_comm_sign (w α : L.carrier) :
    eT L hEven hU w * eT L hEven hU α
      = ((-1 : ℂ) ^ (L.form w α)) • (eT L hEven hU α * eT L hEven hU w)
```

From the mathematics to the Lean statement

Fidelity check. `*` on `End ℂ (TT …)` is composition; `•` scalar multiplication; `(-1 : ℂ) ^ (L.form w α)` is an integer power ($\langle w,\alpha\rangle \in \mathbb{Z}$). Same as the lemma.

Physical meaning

The operators e_w implement shifts of the twisted-sector ground states: the ground states form a representation of the extraspecial group 2^{1+24} (the Heisenberg-type group of the lattice cocycle), and this lemma is the extraspecial commutation rule. Physically these are the zero-mode operators of the twisted sector, which commute or anticommute according to the pairing $\langle w,\alpha\rangle$ mod 2, the same sign as the cocycle in the untwisted OPE.

Proof. $e_w e_\alpha = \varepsilon(w,\alpha) e_{w+\alpha}$ and $e_\alpha e_w = \varepsilon(\alpha,w) e_{w+\alpha}$, and $\varepsilon(w,\alpha)/\varepsilon(\alpha,w) = (-1)^{\langle w,\alpha\rangle}$. Also $e_w e_w = \varepsilon(w,w) e_{2w} = \varepsilon(w,w) e_0 = \varepsilon(w,w)$. □

Definition 39.13 (The frame involution J and the halves $T_\pm$). Fix $c \in \mathbb{C}$ with $c^2 = \varepsilon(w,w)$ and put $J = c^{-1} e_w$. Then $J^2 = 1$. For $s \in \mathbb{Z}/2$, $T_{(s)} = \ker(J - (-1)^s)$; we write $T_+ = T_{(0)}$, $T_- = T_{(1)}$.

```

From the mathematics to the Lean statement

Fidelity check. `sqrtEps` picks, by the axiom of choice, some c with $c \cdot c = \varepsilon(w,w)$ (it exists because $\mathbb{C}$ is algebraically closed). Since $\varepsilon(w,w) = \pm 1$, $c \in \{\pm 1, \pm i\}$; the choice of sign of c is *not* canonical, and changing it swaps T_+ and T_-. This is harmless for every statement in this chapter, which treats $s = 0, 1$ symmetrically, but it means that "T_+" carries no intrinsic meaning (see the warning below). `IsCompl P Q` (Mathlib) means $P \cap Q = 0$ and $P + Q$ is everything, i.e. $T = T_+ \oplus T_-$.

Physical meaning

J is the $\mathbb{Z}/2$ charge operator of the frame on the twisted ground states: the 4096-dimensional ground space of the θ-twisted sector is split into the ± 1 eigenspaces $T_\pm$ of an extraspecial group element, each 2048-dimensional. It is the twisted-sector counterpart of the frame automorphism g, so $T_\pm$ are the twisted charge sectors. This is the representation-theoretic origin of the splitting into two halves that the triality will pair with the untwisted odd sector.

Theorem 39.14 (e_α and the halves; equal dimensions). *Suppose $\chi : L \to \mathbb{Z}/2$ and $w \in L$ satisfy $(-1)^{\langle w,\alpha\rangle} = (-1)^{\chi(\alpha)}$ for all α. Then $e_\alpha T_{(s)} \subseteq T_{(s+\chi(\alpha))}$, and if some u has $\chi(u) = 1$ then* $\dim T_+ = \dim T_-$.

File `VOA/Moonshine/FrameTwisted.lean`.

```

↪  α)
    {u : L.carrier} (hu : χ u = 1) :
    finrank ℂ (frameT L hEven hU w 0) = finrank ℂ (frameT L hEven hU w 1)
```

From the mathematics to the Lean statement

Fidelity check. Hypothesis `hw` says that the character χ is "pairing with w mod 2"; hypothesis `hu` that χ is nontrivial. Both are the intended hypotheses and both are discharged for the Leech lattice below. Same as the theorem.

Physical meaning

The vertex-operator zero modes e_α carry frame charge $\chi(\alpha)$: they preserve $T_\pm$ if $\chi(\alpha) = 0$ and swap them if $\chi(\alpha) = 1$, exactly the charge-conservation rule one expects from the frame symmetry. The equality $\dim T_+ = \dim T_-$ is the statement that some operator exchanges the two charge sectors, hence they are isomorphic as vector spaces; physically, the twisted ground states are symmetric between the two frame charges.

Proof. $Je_\alpha = (-1)^{\langle w,\alpha\rangle} e_\alpha J = (-1)^{\chi(\alpha)} e_\alpha J$ by the lemma, so e_α maps the $(-1)^s$-eigenspace of J into the $(-1)^{s+\chi(\alpha)}$-eigenspace. e_u is invertible ($e_u^2 = \pm 1$), so it maps T_+ injectively into T_- and T_- injectively into T_+; hence the dimensions agree. □

For the Leech lattice take $w = 8e_0$. It lies in Λ_0 ($8e_0 = 2 \cdot 4e_0$, and $4e_0 \in A$ because $\rho(4e_0) = 0 \in C$ and $4 \mid 4$), and $\langle 8e_0, x\rangle = 8x_0/8 = x_0$, so $(-1)^{\langle w,x\rangle} = (-1)^{\beta(x)}$. The vector $u = (5, 1, \dots, 1)$ has $\beta(u) = 1$.

Theorem 39.15 (The Leech frame split of T). *For Λ, $w = 8e_0$: $T = T_+ \oplus T_-$ with $\dim T_+ = \dim T_- = 2048$; e_α preserves $T_\pm$ for $\alpha \in \Lambda_0$ and swaps them for $\alpha \notin \Lambda_0$; and on the twisted space $S[\theta] \otimes T$ the operator $\mathrm{id} \otimes J$ gives $S[\theta] \otimes T = (S[\theta] \otimes T_+) \oplus (S[\theta] \otimes T_-)$.*

       ↪  frameW 1)
```

(`VOA/Moonshine/FrameTwisted.lean`.)

From the mathematics to the Lean statement

Fidelity check. `eightE0_mem` is the proof that $8e_0 \in \Lambda$; `frameW` is that vector. `leechFrameT s := frameT leech … frameW s`. `twFrame … F w s` is the $(-1)^s$-eigenspace of $\mathrm{id}_F \otimes J$ on $F \otimes T$; here F `=FockT 24=` $S[\theta]$, the twisted Fock space of Chapter 35. The dimension 2048 is derived from $\dim T = 4096$ (`finrank_leechT`, Chapter 34) and the equality of the halves.

Same as the theorem; the word "Λ_0" enters through `frameChar α`, which is 0 exactly on Λ_0.

Physical meaning

For the Leech theory this gives the explicit frame decomposition of the twisted sector into two charge sectors of 2048 ground states each, with Λ_0-charged operators preserving them and Λ_3-charged operators exchanging them. Together with the untwisted $V_0^+ \oplus V_3^+$, this is the full four-sector frame decomposition of the moonshine module, the analogue on the twisted side of splitting the sector V_Λ^T by the frame charge.

Proof. Theorem 39.14 with $\chi = \beta$, $w = 8e_0$, $u = (5, 1, \dots, 1)$, and $\dim T_+ + \dim T_- = 4096$. The tensor statement is the same eigenspace argument for the involution $\mathrm{id} \otimes J$. □

What the machine verified

Unconditional; `##print axioms finrank_leechFrameT_plus, finrank_leechFrameT_minus`: [`propext`, `Classical.choice`, `Quot.sound`].

Remark 39.16 (Group-theoretic meaning)**.** The element e_w is, up to scalar, the central element of the preimage $\hat{\Lambda}_0/K$ of Λ_0 in the extraspecial group: $\Lambda_0/2\Lambda = w^\perp$ has radical $\{0, w\}$ modulo 2Λ. So $T_\pm$ are the two eigenspaces of a central element of a subgroup, and T restricted to $\hat{\Lambda}_0$ is the sum of two non-isomorphic irreducibles of dimension 2^{11}. None of this is needed in the proofs above.

Trap / dead end

Which half is FLM's T_0 is not fixed by the definitions. The labels $T_+ =$ `leechFrameT 0`, $T_- =$ `leechFrameT 1` depend on the arbitrary square root `sqrtEps`. Independently, the bridge of Section 39.10 uses a character `golayE` chosen by `Classical.choose`, which is pinned only up to a further character; the alternative choice swaps the rôles of the two twisted sectors under σ (finding `golayE_not_determined`, Notes/M8GluingPlan.md, status of 2026-10-07 "M8g twisted half"). The project's response is to state the downstream existence of σ with an existential sector index: σ maps V_3^+ to $T^+_{(s+1)}$ and $T^+_{(s)}$ to itself *for some* s (Chapters 40–41). A reader should therefore never read "T_+" as "T_0".

39.6 Cyclicity I: the vacuum trick

39.6.1 Why cyclicity

The triality on the twisted sectors will be built (Chapters 40–41) as a *σ-twisted V_0^+-module map*: a linear map Φ from one sector X to another, satisfying $\Phi(u_{(n)}x) = (\sigma u)_{(n)}\Phi(x)$ for $u \in V_0^+$. If X is spanned by the vectors $u_{(n)}x_0$ for a single x_0, such a map is *determined* by $\Phi(x_0)$, and its existence reduces to checking that every linear relation among the $u_{(n)}x_0$ is respected. FLM and DGM prove more — each sector is irreducible — but cyclicity is what is used, and it is much cheaper.

Definition 39.17 (Cyclic module)**.** A subspace X of a module over V_0^+ is *cyclic with cyclic vector* $x_0 \in X$ if $X = \mathrm{span}\{u_{(n)}x_0 : u \in V_0^+,\ n \in \mathbb{Z}\}$.

Physical meaning

A cyclic module is one generated from a single state by the OPE with the subtheory: every state of the sector is obtained by acting on one reference state with the modes of the fields of V_0^+. In CFT language, the sector is a single "conformal family" of the chiral algebra built on one highest-weight-like state (state–operator map). Cyclicity is what lets one define a

V_0^+-equivariant map out of the sector by specifying the image of that one state, which is how the triality will later be extended sector by sector.

Note that this definition does not presuppose that the span is a submodule; but since it equals X, which is stable under V_0^+, it is one.

39.6.2 The general lemma

Theorem 39.18 (The vacuum trick). *Let W be a vertex operator algebra and $a, b \in W$, $k \in \mathbb{Z}$, $c \in \mathbb{C}^\times$ with*

$$a_{(k)}b = c\,\mathbf{1} \qquad \text{and} \qquad a_{(j)}b = 0 \text{ for all } j > k.$$

Then every $v \in W$ lies in $\operatorname{span}\{(v_{(i)}a)_{(j)}b : i, j \in \mathbb{Z}\}$.

```
/-- **The vacuum trick.**  If `a₍ₖ₎ b = c•1` with `c ≠ 0` and `a₍ⱼ₎ b = 0` for `j > k`,
↪  then every
`v` is a linear combination of the iterated products `(v₍ᵢ₎ a)₍ⱼ₎ b`. -/
theorem mem_span_iterate_of_vacuum (W : VertexOperatorAlgebra 𝒱) {a b : 𝒱} {k : ℤ} {c : ℂ}
    (hc : c ≠ 0) (hk : W.smul a k b = c • W.vacuum)
    (hk' : ∀ j : ℤ, k < j → W.smul a j b = 0) (v : 𝒱) :
    v ∈ Submodule.span ℂ {y | ∃ i j : ℤ, y = W.smul (W.smul v i a) j b}
```

(`VOA/Moonshine/CyclicVacuumTrick.lean`, `VOA.VertexOperatorAlgebra.mem_span_iterate_of_vacuum`.)

From the mathematics to the Lean statement

Fidelity check. `W.smul a k b` $= a_{(k)}b$. The three hypotheses are: $c \neq 0$; $a_{(k)}b = c\mathbf{1}$; and $a_{(j)}b = 0$ for $j > k$. Every one is necessary for the intended use and none is stronger than in the statement. The conclusion is membership of v in the `Submodule.span` (set of finite linear combinations) of the set of all $(v_{(i)}a)_{(j)}b$. Note the quantifier order: v is fixed first, and the spanning vectors depend on v — exactly the statement. It is *not* the stronger (false in general) claim that a fixed finite set of vectors spans.

Physical meaning

This is the CFT statement that the vacuum together with a "dual pair" of fields generates everything: if a and b have a pole whose coefficient is the identity (a two-point function with nonzero normalisation), then acting on the vacuum suffices to reach every state. In the state–operator correspondence it says that every state v is obtained from a by an OPE with v followed by a contraction with b; this is the algebraic form of using the nondegenerate two-point function of the sector to produce the vacuum. It is a technical device that reduces cyclicity of a module to a single computation at one state.

Proof. Recall the Borcherds identity in the library's form (`VertexOperatorAlgebra.jacobi`, Definition 4.4): for all states u, v, x and integers ℓ, m, n,

$$\sum_{i\geq 0}(-1)^i\binom{\ell}{i}\Big(u_{(\ell+m-i)}v_{(n+i)}x - (-1)^\ell v_{(\ell+n-i)}u_{(m+i)}x\Big) = \sum_{i\geq 0}\binom{m}{i}\big(u_{(\ell+i)}v\big)_{(m+n-i)}x. \tag{39.5}$$

Apply it with $(u, v, x) = (v, a, b)$, $n = k$, $m \geq \max(N, 0)$ where $v_{(p)}b = 0$ for all $p \geq N$ (such N exists by lower truncation), and $\ell = -1 - m$. On the left, consider the i-th term.

- For $i > 0$: $a_{(k+i)}b = 0$ by hypothesis and $v_{(m+i)}b = 0$ by the choice of m, so the term vanishes.
- For $i = 0$: the second summand contains $v_{(m)}b = 0$; the first is $v_{(\ell+m)}a_{(k)}b = v_{(-1)}(c\mathbf{1}) = c\,v$ (creation: $v_{(-1)}\mathbf{1} = v$).

So the left side equals $c\,v$, while the right side is a finite combination of the vectors $(v_{(\ell+i)}a)_{(m+k-i)}b$. Divide by c. □

Physically: the operator product $a(z)b(0) \sim c\,z^{-k-1}\mathbf{1} + \cdots$ has the identity as its most singular term. Inserting v and using associativity, $v = c^{-1}v_{(-1)}(a_{(k)}b)$ can be re-associated into products of the form $(v \cdot a) \cdot b$.

What the machine verified

Unconditional; `##print axioms mem_span_iterate_of_vacuum:` [`propext`, `Classical.choice`, `Quot.sound`].

39.6.3 V_0^+ and V_3^+ are cyclic

Theorem 39.19 (V_0^+ is cyclic over itself). *V_0^+ is cyclic with cyclic vector* $\mathbf{1}$.

File `VOA/Moonshine/CyclicFrameSectors.lean`.

```
/-- **`V₀⁺` is cyclic over itself**, generated by `𝟙`. -/
theorem cyclic_V0 : ∃ x₀ ∈ frameSector 0,
    Submodule.span ℂ {y | ∃ u ∈ frameSector 0, ∃ n : ℤ, y = leechVOAPlus.smul u n x₀}
      = frameSector 0
```

Physical meaning

Every state of a vertex operator algebra is obtained from the vacuum by applying a field (the state–operator map $u = u_{(-1)}\mathbf{1}$), so the algebra is generated from the vacuum by its own modes. This is the most basic form of the state–operator correspondence, and it says that the neutral frame sector is a single family generated by the identity operator.

Proof. $u = u_{(-1)}\mathbf{1}$, and $V_0^+ \cdot V_0^+ \subseteq V_0^+$. □

For V_3^+ choose any $\beta \in \Lambda \setminus \Lambda_0$ (one exists by Proposition 39.2) and put

$$x_0 = e^{\beta} + e^{-\beta} \qquad \text{(Lean: } \texttt{frameX0P}\ \beta\text{)}.$$

It is θ-fixed (the library's θ sends $e^{\gamma} \mapsto e^{-\gamma}$ on charged vacua, `thetaLat_latChargeGen`) and all its momenta are in Λ_3, so $x_0 \in V_3^+$.

Lemma 39.20 (The pairing of x_0 with itself). *Let $N = \langle\beta,\beta\rangle > 0$. Then $x_{0(j)}x_0 = 0$ for $j \geq N$ and $x_{0(N-1)}x_0 = \big(\varepsilon(\beta,-\beta) + \varepsilon(-\beta,\beta)\big)\mathbf{1}$, and this scalar is nonzero.*

File `VOA/Moonshine/CyclicFrameSectors.lean`.

```
/-- `x₀₍ⱼ₎x₀ = 0` for `j ≥ ⟨β,β⟩`. -/

theorem frameX0_smul_top {β : leech.carrier} (hβ : β ≠ 0) :
    leechVOA.smul (frameX0 β) (leech.form β β - 1) (frameX0 β)
      = (latticeCocycle leech β (-β) + latticeCocycle leech (-β) β) • latVacuumGen leech

/-- The pairing scalar `ε(β,-β) + ε(-β,β) = 2ε(-β,β)` is non-zero. -/
theorem frameX0_scalar_ne_zero (β : leech.carrier) :
    latticeCocycle leech β (-β) + latticeCocycle leech (-β) β ≠ 0
```

Physical meaning

The charged state $x_0 = e^{\beta} + e^{-\beta}$ has a nonvanishing two-point function with itself: the OPE $x_0(z)x_0(0)$ contains the identity with coefficient $z^{-\langle\beta,\beta\rangle}$ times a nonzero constant, and no more singular terms. This is the lattice-CFT statement $e^{\beta}(z)e^{-\beta}(0) \sim z^{-\langle\beta,\beta\rangle} \cdot 1$, with the cocycle signs checking that the two terms of x_0 add rather than cancel. It is the input needed to apply the vacuum trick.

Proof. $Y(e^{\alpha}, z)e^{\gamma} = \varepsilon(\alpha,\gamma)z^{\langle\alpha,\gamma\rangle}E^{-}(-\alpha, z)e^{\alpha+\gamma}$ with $E^{-}(-\alpha, z) = 1 + O(z)$ a series in non-negative powers. Hence $e^{\alpha}_{(j)}e^{\gamma} = 0$ for $j \geq -\langle\alpha,\gamma\rangle$, and for $\gamma = -\alpha$ the coefficient at $j = \langle\alpha,\alpha\rangle - 1$ is $\varepsilon(\alpha,-\alpha)\mathbf{1}$. Expanding $x_{0(j)}x_0$ into four terms: the two terms $e^{\pm\beta}_{(j)}e^{\pm\beta}$ vanish for $j \geq -N$, and the two cross terms vanish for $j \geq N$ and give $\varepsilon(\pm\beta, \mp\beta)\mathbf{1}$ at $j = N-1$. Finally $\varepsilon(\beta,-\beta) = (-1)^{\langle\beta,-\beta\rangle}\varepsilon(-\beta,\beta) = \varepsilon(-\beta,\beta)$ since Λ is even, so the scalar is $2\varepsilon(-\beta,\beta) = \pm 2$. □

Theorem 39.21 (V_3^+ is a cyclic V_0^+-module). *For every $\beta \in \Lambda \setminus \Lambda_0$, $\mathrm{span}\{u_{(n)}(e^{\beta} + e^{-\beta}) : u \in V_0^+,\ n \in \mathbb{Z}\} = V_3^+$. In particular V_3^+ is cyclic.*

      = frameSector 1
```

(`VOA/Moonshine/CyclicFrameSectors.lean`.)

From the mathematics to the Lean statement

Fidelity check. The products are taken in `leechVOAPlus`, i.e. V_Λ^+, with u ranging over `frameSector 0` $= V_0^+$ — so this is the module structure of V_3^+ over V_0^+ by restriction, which is the intended one. The span is *equal* to `frameSector 1`, so the statement includes both inclusions. The quantifier `∃ x₀ ∈ frameSector 1` requires $x_0 \in V_3^+$; the explicit form names x_0. How could this have been vacuous? If `frameSector 1` were 0 the statement would be trivial with $x_0 = 0$; it is not, since $\dim(V_3^+)_2 = 49152$ (Corollary 39.11). The explicit version with $x_0 = e^{\beta} + e^{-\beta} \neq 0$ is stronger than the existential one.

Physical meaning

The odd frame sector V_3^+ is a single family of the neutral subtheory: any one charged state $e^{\beta} + e^{-\beta}$ generates it under the OPE with V_0^+. Physically, the charged sector is obtained from a single charged primary-like state by acting with the neutral currents; there are no independent "families" hidden in it. Combined with the vacuum trick (acting on the vacuum suffices once a dual pair is available), this is the mechanism that later makes a V_0^+-equivariant map out of V_3^+ determined by its value on one vector.

Proof. "$\subseteq$": $V_0^+ \cdot V_3^+ \subseteq V_3^+$ by Theorem 39.6. "$\supseteq$": let $v \in V_3^+$. Apply the vacuum trick in $W = V_\Lambda^+$ with $a = b = x_0$, $k = N-1$ and the lemma: v is a combination of $(v_{(i)}x_0)_{(j)}x_0$. Each $v_{(i)}x_0$ lies in $V_3^+ \cdot V_3^+ \subseteq V_0^+$. □

What the machine verified

Unconditional; `##print axioms cyclic_V3, cyclic_V0:` [`propext, Classical.choice, Quot.sound`]. **Not proved:** irreducibility of V_3^+ (FLM; DGM Proposition 7.1); it is not needed. (The docstring of the file still says it is not wired into the `VOA/Moonshine.lean` umbrella; that remark is stale — the umbrella imports it, checked for this chapter.)

Remark 39.22 (What this argument avoids)**.** DGM prove irreducibility using, in each coordinate, the Virasoro field $:P^jP^j:$ to separate states. The vacuum trick needs no Fock-space bookkeeping at all: one vector that pairs to the vacuum suffices for cyclicity. For irreducibility one would need, for each nonzero x, a partner y with $y_{(k)}x \in \mathbb{C}^\times\mathbf{1}$, i.e. a nondegenerate invariant form on V_3^+ — more than is needed.

39.7 Cyclicity II: the twisted sectors

39.7.1 The obvious route is blocked

Trap / dead end

The vacuum trick for $(V_\Lambda^T)^+$ would need the open relation. On $\mathcal{T} = (V_\Lambda^T)^+$ the analogue of $x_{0(k)}x_0 = c\mathbf{1}$ is $\overline{W}(a)_{(k)}b = c\mathbf{1}$ for $a, b \in \mathcal{T}$, which does hold (the anti-trap certificate `leechWbar_vacuum_pairing_ne_zero` of Chapter 38). But writing $t = c^{-1}W(t)_{(-1)}\overline{W}(a)_{(k)}b$ as a combination of $Y_{\mathcal{T}}(\overline{W}(t)_{(i)}a)_{(j)}b$ is the Borcherds identity (39.5) in $V^\natural$ for three *twisted* states (t, a, b):

$$\sum_i (-1)^i\binom{\ell}{i}\Big[W(t)_{(\ell+m-i)}\overline{W}(a)_{(n+i)}b - (-1)^\ell W(a)_{(\ell+n-i)}\overline{W}(t)_{(m+i)}b\Big] = \sum_i \binom{m}{i} Y_{\mathcal{T}}\big(\overline{W}(t)_{(\ell+i)}a\big)_{(m+n-i)}b.$$

This is equivalent to the twisted×twisted relation (39.1) — the very gate the triality is meant to open. The available commutator formulas for W and $\overline{W}$ have one *untwisted* argument and do not imply it. So the vacuum-trick route for the twisted sectors is circular, and an explicit route is used instead (Notes/M8GluingPlan.md, status "M8f COMPLETE", "RECORDED DEPENDENCY").

39.7.2 Orbit spans in a twisted module

Let W be a VOA, $g \in \operatorname{Aut} W$ with $g^2 = 1$, and T a g-twisted W-module of order two (`TwistedModule g 2 M`, Chapter 34): operators $u_{(k/2)}$ (`T.YM u k`) on M such that for u in the j-th eigenspace W^j of g — defined in the library as the $e^{-2\pi ij/2}$-eigenspace (`Aut.twistedEigenspace g 2 j`), so $W^0 = \{gu = u\}$, $W^1 = \{gu = -u\}$ — the operator $u_{(k/2)}$ vanishes unless $k \equiv j \pmod 2$, and the twisted Jacobi identity

$$\sum_{i\ge 0}(-1)^i\binom{\ell}{i}\Big(u_{((2\ell+k-2i)/2)}v_{((m+2i)/2)}x - (-1)^\ell v_{((2\ell+m-2i)/2)}u_{((k+2i)/2)}x\Big) = \sum_{i\ge 0}\binom{k/2}{i}(u_{(\ell+i)}v)_{((k+m-2i)/2)}x$$

holds for all v, x, ℓ, m and all $k \equiv j \pmod 2$ (the restriction $k \equiv j$ is the repaired form of the library's axiom; see Chapter 34 and Section 50.2.1: the all-indices form forces $M = 0$).

Definition 39.23 (Orbit span). For a subspace $A \subseteq W$ and $x \in M$, $Z_A(x) = \mathrm{span}\{u_{(k/2)}x : u \in A,\ k \in \mathbb{Z}\}$.

```
/-- **The orbit span** `Z_A(x) = span {u_(k/2) x | u ∈ A, k ∈ ℤ}`. -/
def orbitSpan (T : TwistedModule g 2 M) (A : Submodule ℂ V) (x : M) : Submodule ℂ M :=
  Submodule.span ℂ {y | ∃ u ∈ A, ∃ k : ℤ, y = T.YM u k x}
```

(`VOA/Moonshine/CyclicTwistedSpan.lean`, namespace `VOA.TwistedCyclic`.)

Physical meaning

$Z_A(x)$ is the span of all states reached from a ground state x of the twisted module by acting with (half-integer) modes of fields drawn from A. It is the subspace of the twisted sector generated by x using the OPE with A; the half-integer modes $u_{(k/2)}$ reflect the monodromy -1 of the θ-twisted sector around the insertion of the twist field.

Theorem 39.24 (Orbit spans are submodules). *Suppose A is closed under all n-th products, g-stable, and $g^2 = 1$. Then for every $u \in A$, $p \in \mathbb{Z}$ and $y \in Z_A(x)$: $u_{(p/2)}y \in Z_A(x)$.*

```
variable (T : TwistedModule g 2 M) (A : Submodule ℂ V)
  (hA : ∀ u ∈ A, ∀ (n : ℤ), ∀ v ∈ A, W.smul u n v ∈ A) (hg : ∀ u ∈ A, g u ∈ A)
  (hgg : ∀ u, g (g u) = u)

include hA hg hgg in
/-- **`Z_A(x)` is stable under the modes of `A`.** -/
theorem YM_mem_orbitSpan {u : V} (hu : u ∈ A) (p : ℤ) {x y : M} (hy : y ∈ orbitSpan T A x)
 ↪  :
    T.YM u p y ∈ orbitSpan T A x
```

From the mathematics to the Lean statement

Fidelity check. The three hypotheses `hA`, `hg`, `hgg` are exactly the three conditions of the theorem. `T.YM u p` is $u_{(p/2)}$. Same as the theorem. Note that A is not required to contain $\mathbf{1}$; that is needed only for $x \in Z_A(x)$ (`self_mem_orbitSpan`, hypothesis `W.vacuum ∈ A`, using $\mathbf{1}_{(-1)} = \mathrm{id}$, i.e. `T.YM W.vacuum (-2) = 1`).

Physical meaning

The orbit span is closed under the action of all of A: acting once more with a field of A does not leave the span. Concretely, the OPE of two fields of A (which is closed because A is a subalgebra) re-expresses a product of two modes as a sum of single modes, so the generated subspace is stable. This is the consistency statement that generating a family from one state by the OPE gives a genuine module and not a growing subspace.

Proof. Split $u = u_0 + u_1$ into g-eigencomponents ($u_0 = \frac{1}{2}(u + gu) \in A \cap W^0$, $u_1 = \frac{1}{2}(u - gu) \in A \cap W^1$). It suffices to show $u_{(p/2)}v_{(q/2)}x \in Z_A(x)$ for $u \in A \cap W^j$, $v \in A$. If $p \not\equiv j$ the operator is zero. Otherwise choose $k \equiv p \pmod 2$ so large that $u_{((k+2i)/2)}x = 0$ for all $i \geq 0$, and $\ell = (p-k)/2$. Then the twisted Jacobi identity reads

$$\sum_{i \geq 0} (-1)^i \tbinom{\ell}{i} u_{((p-2i)/2)} v_{((q+2i)/2)} x = \sum_i \tbinom{k/2}{i} (u_{(\ell+i)}v)_{(\cdot)}x \ \in Z_A(x),$$

since $u_{(\ell+i)}v \in A$. The $i = 0$ term is the one we want; the terms with $i \geq 1$ have a larger second index $q + 2i$, and are in $Z_A(x)$ by descending induction on q, the induction starting because $v_{(q/2)}x = 0$ for q large. □

What the machine verified

Unconditional; `##print axioms YM_mem_orbitSpan`-clean. Uses only the module Jacobi identity — no twisted×twisted operator.

Theorem 39.25 (The +-projection). *Let θ_M be a lift of g to M (an involution with $\theta_M u_{(k/2)} \theta_M = (gu)_{(k/2)}$, preserving weights), $M^+ = \ker(\theta_M - 1)$, and A as above. If $x_0 \in M^+$ and $y \in M^+ \cap Z_A(x_0)$, then y is a linear combination of the vectors $u_{(n)}x_0$ with $u \in W^g \cap A$, $n \in \mathbb{Z}$, computed in the ordinary W^g-module M^+.*

```
include hg hgg in
/-- **The `+`-projection.** If `x₀ ∈ M⁺` and `y ∈ M⁺ ∩ Z_A(x₀)`, then `y` is a combination

the `M⁺`-modes `u₍ₙ₎ x₀` with `u ∈ 𝒱^g ∩ A`. -/
theorem mem_span_plus_of_mem_orbitSpan (θ : ThetaLift T) (x₀ y : plusSub θ)
    (hy : (y : M) ∈ orbitSpan T A x₀) :
    y ∈ Submodule.span ℂ {z | ∃ u : (orbifold (Subgroup.zpowers g)).carrier, (u : 𝒱) ∈ A ∧
      ∃ n : ℤ, z = mode ((plusModule θ).YM u) n x₀}
```

Here `ThetaLift T` is the structure File `VOA/Moonshine/TwistedPlusModule.lean`.

```
structure ThetaLift (T : TwistedModule g 2 M) where
  /-- The involution `θ_M`. -/
  op : End ℂ M
  op_op : ∀ x, op (op x) = x
  conj : ∀ (u : 𝒱) (k : ℤ), T.YM (g u) k = op ∘ₗ T.YM u k ∘ₗ op
  map_weight : ∀ (α : ℂ) (x : M), x ∈ T.weight α → op x ∈ T.weight α
```

`plusSub θ := LinearMap.ker (θ.op - LinearMap.id)` is M^+, and `plusModule θ` is M^+ as an ordinary module over $W^{\langle g\rangle}$ with $u_{(n)} =$ `T.YM u (2*n)` (Chapter 36).

From the mathematics to the Lean statement

Fidelity check. `mode ((plusModule θ).YM u) n x₀` is $u_{(n)}x_0$ in the module M^+, which by construction is the integral mode $u_{(2n/2)}x_0$ of the twisted module. The hypothesis `hy` coerces y to M. The quantification `∃ u : (orbifold …).carrier, (u : 𝒱) ∈ A` is "$u \in W^g \cap A$". Same as the theorem.

Physical meaning

In the orbifold, the twisted-sector states in M^+ are those invariant under the lift θ_M of the $\mathbb{Z}/2$ symmetry, obtained by the projector $\frac{1}{2}(1+\theta_M)$. The statement is that projecting a family generated in the full twisted module onto the invariant states is the same as generating it from the invariant subtheory W^g acting on M^+, i.e. the g-invariant states of the family come from the g-invariant fields. It is the usual orbifold bookkeeping of keeping only gauge-invariant operators and states.

Proof. Apply $P = \frac{1}{2}(1+\theta_M)$, which fixes y. On a spanning vector, $P(u_{(k/2)}x_0) = \frac{1}{2}(u_{(k/2)} + (gu)_{(k/2)})x_0 = w_{(k/2)}x_0$ with $w = \frac{1}{2}(u+gu) \in W^g \cap A$; if k is odd this vanishes (a g-fixed state has only integral modes), and if $k = 2n$ it is the M^+-mode $w_{(n)}x_0$. □

What the machine verified

Unconditional; `##print axioms`-clean.

39.7.3 The frame involution on the twisted module

Theorem 39.26 (id $\otimes J$ lifts g_χ). *Let L be even, positive definite, unimodular, χ and w as in Theorem 39.14, and $P_J = \mathrm{id}_{S[\theta]} \otimes J$ on the twisted module $V_L^T = S[\theta] \otimes T$ of Chapter 36. Then for every $u \in V_L$ and $k \in \mathbb{Z}$, $Y^T(g_\chi u)_{(k/2)} = P_J\, Y^T(u)_{(k/2)}\, P_J$. For the Leech twisted module this reads $Y^T(gu)_{(k/2)} = (\mathrm{id} \otimes J) Y^T(u)_{(k/2)} (\mathrm{id} \otimes J)$ with $g =$* `frameAut`.

```
include hw hPos in
/-- **`id ⊗ J` lifts `g_χ`**: `Y^T(g_χ u)₍k/2₎ = P_J ∘ Y^T(u)₍k/2₎ ∘ P_J`. -/
theorem YML_chiLat (u : LatModuleGen L) (k : ℤ) :

     ↪ hU w

/-- **`id ⊗ J` lifts the frame automorphism on the Leech twisted module**:
`Y^T(g u)₍k/2₎ = (id ⊗ J) ∘ Y^T(u)₍k/2₎ ∘ (id ⊗ J)`, `g = frameAut`, `J = frameJ (8e₀)`. -/
theorem leechTwistedModule_YM_frameAut (u : LatModuleGen leech) (k : ℤ) :
    leechTwistedModule.YM (frameAut u) k
      = (frameJ leech leech_even leech_isUnit_det_gramMat frameW).lTensor (FockT 24) ∘ₗ
          leechTwistedModule.YM u k ∘ₗ
          (frameJ leech leech_even leech_isUnit_det_gramMat frameW).lTensor (FockT 24)
```

(`VOA/Moonshine/CyclicTwistedFrame.lean`.)

From the mathematics to the Lean statement

Fidelity check. `YML L hEven hU u k` is the twisted vertex operator mode $Y^T(u)_{(k/2)}$ on `MT L hEven hU` $= S[\theta] \otimes T$ (Chapter 36); `PJ … w =(frameJ … w).lTensor (FockT (rank L))` is id $\otimes J$ (`lTensor F f` $= \mathrm{id}_F \otimes f$). `∘ₗ` is composition of linear maps. Hypotheses: evenness, unimodularity (`hU`), positive definiteness (`hPos`), and `hw : ∀ α, (-1)^{⟪w,α⟫} = chiSign χ α`. Since $P_J^2 = 1$, the right side is the conjugate $P_J Y^T(u) P_J^{-1}$. The Leech version is the specialisation along `leech_rank : rank leech = 24` (the Fock space is indexed by `Fin 24` rather than `Fin (rank leech)`). Same as the theorem.

Physical meaning

On the twisted sector, the frame symmetry g_χ of the untwisted theory is implemented by the extraspecial operator J acting on the ground-state factor: conjugation by id $\otimes J$ acts on twisted vertex operators exactly as g_χ does on untwisted states. This is the statement that the frame charge is a symmetry of the twisted theory too, which is needed for the frame decomposition of the twisted sector to be compatible with the OPE. It is the twisted analogue of g_χ being a symmetry of the lattice CFT.

Proof. P_J fixes the twisted Heisenberg operators (they act on the other tensor factor), and $P_J Y^T(e^\alpha, z) P_J = (-1)^{\chi(\alpha)} Y^T(e^\alpha, z)$ because $Y^T(e^\alpha, z)$ contains the factor e_α on T and $J e_\alpha J = (-1)^{\langle w,\alpha\rangle} e_\alpha$. Twisted vertex operators of all other states are built from these by the twisted normal ordering of Chapter 36, which commutes with conjugation by an involution; hence $P_J Y^T(u) P_J = Y^T(g_\chi u)$ for all u. □

What the machine verified

Unconditional; `##print axioms YML_chiLat`-clean.

Consequently every mode of a g-fixed state preserves the two eigenspaces $S[\theta] \otimes T_\pm$ (`YM_mem_twFrame`).

39.7.4 The twisted frame sectors and their cyclicity

Recall from Chapter 36 that the Leech twisted space is `Tw := FockT 24 ⊗[ℂ] leechT`, that FLM's θ on it is $\theta_T \otimes (-1)$ (`thetaTwLeech`; θ_T negates every twisted oscillator, and θ acts by -1 on T), and that `TP := plusSub leechThetaLift` is $(V_\Lambda^T)^+$, an ordinary V_Λ^+-module (`Moonshine.plusModule`).

Definition 39.27 (Twisted frame sectors). $T^+_{(s)} := (V_\Lambda^T)^+ \cap (S[\theta] \otimes T_{(s)})$, $s \in \mathbb{Z}/2$.

File `VOA/Moonshine/CyclicTwisted.lean`.

```
/-- **The twisted frame sectors** `T_s⁺ = TP ∩ (S[θ] ⊗ T_s)` (`s = 0, 1`). -/
noncomputable def TPframe (s : ZMod 2) : Submodule ℂ TP := (twFrameL s).comap TP.subtype

/-- `TP = T₀⁺ ⊕ T₁⁺`. -/
theorem TPframe_isCompl : IsCompl (TPframe 0) (TPframe 1)
```

From the mathematics to the Lean statement

Fidelity check. `twFrameL s` is the $(-1)^s$-eigenspace of id $\otimes J$ on `Tw`; `comap TP.subtype` intersects it with `TP`, viewed inside `TP`. So `TPframe s` is $T^+_{(s)}$. The docstring's "$T_0^+ \oplus T_1^+$" uses the Lean index s, not FLM's labels 0, 3 (see the warning in Section 39.5). `IsCompl` is the internal direct sum of two subspaces. Same as intended.

Physical meaning

The twisted frame sectors $T^+_{(s)}$ are the θ-invariant states of the twisted sector with frame charge s. They are the two halves (T_0^+, T_3^+) of the twisted half of the moonshine module, the twisted counterparts of the untwisted sectors V_0^+ and V_3^+; the triality will pair T_0^+ with V_3^+.

Proof. $\theta = \theta_T \otimes (-1)$ commutes with id$\otimes J$, so id$\otimes J$ is an involution of $(V_\Lambda^T)^+$, whose eigenspaces are complementary. □

Theorem 39.28 (Each twisted frame sector is cyclic). *Let $0 \neq t_0 \in T_{(s)}$ and $x_0 = h_0(-\frac{1}{2})\mathbf{1} \otimes t_0$ (weight $\frac{3}{2} + \frac{1}{2} = 2$). Then $x_0 \in T^+_{(s)}$ and $\operatorname{span}\{u_{(n)}x_0 : u \in V_0^+,\ n \in \mathbb{Z}\} = T^+_{(s)}$, where $u_{(n)}$ is the action of V_Λ^+ on $(V_\Lambda^T)^+$. In particular each $T^+_{(s)}$ is a cyclic V_0^+-module.*

```
/-- The cyclic vector `h₀(-½)𝟙 ⊗ t₀` (weight `2`). -/

    ↪ u) n x₀}
      = TPframe s
```

(`VOA/Moonshine/CyclicTwisted.lean`.)

From the mathematics to the Lean statement

Fidelity check. `X (0, 0) : FockT 24` is the polynomial generator of the twisted Fock space $S[\theta] = \mathbb{C}[h_a(-\frac{2m+1}{2})]$ corresponding to $h_0(-\frac{1}{2})$ (index $(m,a) = (0,0)$, Chapter 35); `⊗ₜ` is the pure tensor. `frameX0T_mem_TP` proves $\theta x_0 = x_0$ (θ_T negates $h_0(-\frac{1}{2})$, and θ is -1 on T). `TLeechT` is the type of T. `mode (Moonshine.plusModule.YM u) n x` is $u_{(n)}x$ in the V_Λ^+-module $(V_\Lambda^T)^+$, i.e. the twisted mode $u_{(2n/2)}$; u ranges over `frameSector 0` $= V_0^+$. Hypotheses `ht₀`, `h0`: $t_0 \in T_{(s)}$, $t_0 \neq 0$. Same as the theorem. Not vacuous: $T_{(s)}^+ \neq 0$ since it contains $x_0 \neq 0$ (and its weight-two part has dimension $24 \cdot 2048$).

Physical meaning

Each twisted charge sector is a single family of V_0^+ generated by one explicit state $x_0 = h_0(-\frac{1}{2})\mathbf{1} \otimes t_0$ of weight 2: a twisted ground state t_0 (weight $\frac{3}{2}$) with one fractional oscillator ($\frac{1}{2}$) added to make it θ-invariant. Cyclicity says that all the twisted states of that charge can be reached from this one by the OPE; it is the key technical input that allows the triality to be specified by its action on a single vector in each sector. (Physical picture heuristic; the proof is by the orbit-span and plus-projection machinery.)

Proof. Work in the *full* twisted V_Λ-module $S[\theta] \otimes T$, with $A = V_\Lambda^{\langle g \rangle}$ (all momenta in Λ_0; closed under products, θ-stable, contains $\mathbf{1}$). By Theorem 39.24, $Z_A(x_0)$ is stable under all modes of A.

1. The state $h_0(-1)\mathbf{1} \in A$ acts by the twisted oscillators $h_0(k/2) \otimes 1$. Hence $h_0(\frac{1}{2})x_0 = \frac{1}{2}(\mathbf{1} \otimes t_0) \in Z_A(x_0)$, and applying creation operators $h_b(-\frac{2m+1}{2})$, which span $S[\theta]$ from its vacuum, $S[\theta] \otimes t \subseteq Z_A(x_0)$ whenever $\mathbf{1} \otimes t \in Z_A(x_0)$.

2. For $\alpha \in \Lambda_0$, $e^\alpha \in A$ and $Y^T(e^\alpha)_{((\langle\alpha,\alpha\rangle-2)/2)}(\mathbf{1}\otimes t) = 2^{-\langle\alpha,\alpha\rangle}(\mathbf{1}\otimes e_\alpha t)$ (`leechTwistedModule_echg_vac`; the power of 2 is FLM's normalisation of $Y^T(e^\alpha)$). So $\mathbf{1} \otimes e_\alpha t_0 \in Z_A(x_0)$.

3. T is a simple module over the twisted group algebra, so the $e_\alpha t_0$ ($\alpha \in \Lambda$) span T; those with $\alpha \notin \Lambda_0$ lie in $T_{(s+1)}$ (Theorem 39.15). Projecting to $T_{(s)}$ gives $T_{(s)} = \mathrm{span}\{e_\alpha t_0 : \alpha \in \Lambda_0\}$.

4. Hence $S[\theta]\otimes T_{(s)} \subseteq Z_A(x_0)$, and Theorem 39.25 turns this into: every $y \in T_{(s)}^+$ is a combination of $u_{(n)}x_0$ with $u \in A^\theta = V_0^+$.

5. Conversely, modes of V_0^+ commute with $\mathrm{id} \otimes J$ (Theorem 39.26) and with θ, so the span stays in $T_{(s)}^+$. □

What the machine verified

Unconditional; `##print axioms cyclic_TPframe`: [`propext`, `Classical.choice`, `Quot.sound`]. Proved *without* any twisted×twisted input. **Not proved:** irreducibility of $T_{(s)}^+$ (not needed). Which s corresponds to FLM's T_0^+ is not decided here.

39.8 Root exponentials and inner automorphisms

The untwisted triality is a product of exponentials $\exp(c\,(e^\alpha)_{(0)})$ for roots α. This section explains why such exponentials make sense and are automorphisms.

39.8.1 Inner automorphisms from weight-one states

If $u \in W_1$ (a weight-one state of a VOA W), its zero mode $u_{(0)}$ is a *derivation* of all products: the commutator formula gives $u_{(0)}(a_{(n)}b) = (u_{(0)}a)_{(n)}b + a_{(n)}(u_{(0)}b)$. Physically, $u_{(0)} = \oint u(z)\,dz$ is the conserved charge of the current $u(z)$, and the exponential of a conserved charge is a symmetry. The only issue is convergence of $\exp(u_{(0)}) = \sum_k u_{(0)}^k/k!$; in pure algebra one asks for *local nilpotency*.

Definition 39.29 (Locally nilpotent). An operator D on a vector space is *locally nilpotent* if for every v there is N with $D^N v = 0$. Then $\exp(D)v = \sum_{k<N} D^k v/k!$ is a finite sum.

```
def IsLocNilp (D : End ℂ 𝒱) : Prop := ∀ v : 𝒱, ∃ N : ℕ, (D ^ N) v = 0
```

(`VOA/Core/Automorphism.lean`.) The library's inner automorphism is

```
noncomputable def inner (u : W.grading 1)
    (hnilp : VOA.IsLocNilp (W.zeroMode (u : 𝒱) 1))
    (homega : W.zeroMode (u : 𝒱) 1 W.conformalVector = 0) : Aut W where
  toLinearEquiv := VOA.expEquiv hnilp
```

(`VOA.VertexOperatorAlgebra.inner`, same file.)

From the mathematics to the Lean statement

Fidelity check. `W.zeroMode u 1` is the zero mode $o(u) = u_{(\mathrm{wt}\,u-1)}$ of a state of weight 1, i.e. $u_{(0)}$. The three inputs are: u of weight one, $u_{(0)}$ locally nilpotent, and $u_{(0)}\omega = 0$ (needed for $\exp(u_{(0)})\omega = \omega$, part of the definition of `Aut`). `VOA.expEquiv hnilp` is $\exp(u_{(0)})$ with inverse $\exp(-u_{(0)})$. This is exactly "the exponential of a locally nilpotent derivation fixing ω is an automorphism".

Physical meaning

An operator is locally nilpotent if repeated application eventually kills any given state; this is what makes the exponential $\exp(D)$ of a charge-raising generator a well-defined symmetry transformation on the Fock space. In CFT language, the zero mode of a root current only changes the charge in the positive direction until it exceeds the cutoff of the finite-energy states, so its exponential is the group element $\exp(cJ^+)$ of $SU(2)$, a finite sum on each state.

39.8.2 $(e^\alpha)_{(0)}$ is locally nilpotent

Let L be even positive definite, and write $Q_\alpha := (e^\alpha)_{(0)}$ (`Qscr L α`). Every state of V_L is a sum of states of definite *bidegree* (d, γ): boson degree d (the sum of the mode numbers of the oscillators) and momentum γ (`bigradα L (d, γ)`).

Theorem 39.30 (Local nilpotency of root zero modes). *Q_α maps bidegree (d, γ) to bidegree $(d - 1 - \langle\alpha, \gamma\rangle, \gamma + \alpha)$. Consequently, for every $\alpha \neq 0$, Q_α is locally nilpotent.*

```
/-- `Q_α` shifts the bigrading: `bigradα (d, β) → bigradα (d - 1 - ⟪α,β⟫, β + α)`. -/
theorem Qscr_mem_bigradα (α : L.carrier) {d : ℤ} {β : L.carrier} {x : LatModuleGen L}
    (hx : x ∈ bigradα L (d, β)) :
    Qscr L α x ∈ bigradα L (d - 1 - L.form α β, β + α)

/-- **Local nilpotency of `(e^α)₍₀₎`** for every nonzero `α` of a positive-definite
 ↪ lattice. -/
theorem isLocNilp_Qscr (hPos : L.PosDef) {α : L.carrier} (hα : α ≠ 0) :
    VOA.IsLocNilp (Qscr L α)
```

(`VOA/Moonshine/TrialityRoot.lean`.)

From the mathematics to the Lean statement

Fidelity check. `Qscr L α` is defined as `mode (Yeαvec L α) 0`, the 0-th mode of $Y(e^\alpha, z)$ (Chapter 31); `zeroMode_latChargeGen` confirms it is the zero mode of e^α in `latticeVOAGen`. Hypotheses: L positive definite and $\alpha \neq 0$ — both necessary ($Q_0 = \mathrm{id}_{(0)}$-type degeneracies aside, for $\langle\alpha,\alpha\rangle \leq 0$ the degree need not decrease). Same as the theorem.

Physical meaning

The zero mode $Q_\alpha = (e^\alpha)_{(0)}$ is the charge of the root current $J^+ = e^\alpha$ and raises the momentum by α while lowering the oscillator degree (by $1 + \langle\alpha,\gamma\rangle$); so repeated application eventually exhausts the oscillator degree and kills the state. Physically this is the statement that the finite-energy states form a representation of the algebraic group $SU(2)$ (or $SL_2(\mathbb{C})$) integrated from the Lie algebra, on which the exponentials act by finite sums; no analytic completion is needed.

Proof. $Y(e^\alpha, z)(p \otimes e^\gamma) = \varepsilon(\alpha,\gamma) z^{\langle\alpha,\gamma\rangle} E^-(-\alpha, z) E^+(-\alpha, z) p \otimes e^{\alpha+\gamma}$, and the coefficient of z^{-1} raises the boson degree by exactly $-1 - \langle\alpha,\gamma\rangle$. After k applications starting from (d,γ) the degree is

$$d - k - k\langle\alpha,\gamma\rangle - \langle\alpha,\alpha\rangle\frac{k(k-1)}{2},$$

a quadratic in k with negative leading coefficient since $\langle\alpha,\alpha\rangle > 0$. It is eventually negative, and there are no states of negative boson degree. □

Definition 39.31 (Root exponential). For a root α ($\langle\alpha,\alpha\rangle = 2$) and $c \in \mathbb{C}$, $\exp(cQ_\alpha) \in \mathrm{Aut}\, V_L$.

```
/-- **The root exponential** `exp(c·(e^α)₍₀₎) ∈ Aut(V_L)` for a root `α` (`⟨α,α⟩ = 2`). -/

```

From the mathematics to the Lean statement

Fidelity check. The definition is the one-line composition of `inner` with three facts: ce^α has weight $\frac{1}{2}\langle\alpha,\alpha\rangle = 1$; its zero mode is locally nilpotent (Theorem 39.30); and it kills ω (true for every weight-one state, `screening_conformalVector`). So `rootExp hα c` is $\exp(cQ_\alpha)$ and, by construction, an automorphism. `rootExp_comm_of_fix`: if $\beta e^\alpha = e^\alpha$ then $\beta \exp(cQ_\alpha)\beta^{-1} = \exp(c\,(\beta e^\alpha)_{(0)}) = \exp(cQ_\alpha)$.

Physical meaning

The root exponential $\exp(cQ_\alpha)$ is a finite group element of the $SU(2)$ (or SL_2) that acts on the currents of the root α: for a root α of V_L, the currents e^α, $\alpha(-1)\mathbf{1}$ and $e^{-\alpha}$ form the $\widehat{\mathfrak{sl}}_2$ at

level one (the $SU(2)_1$ WZW model), and the exponential is a rotation by a complex angle. It is an automorphism of the VOA because Q_α is a derivation (the zero mode of a weight-one field) and is locally nilpotent. These inner automorphisms are the continuous symmetry that the lattice theory of a Niemeier lattice with roots has, and which the Leech theory (with no roots) lacks.

What the machine verified

Unconditional; `##print axioms isLocNilp_Qscr`-clean. `rootExp` is a definition (its axioms are those of `inner`: clean).

39.8.3 The $\mathfrak{sl}_2$ triple of a root

Write $e = e^\alpha$, $h = \alpha(-1)\mathbf{1}$ (`hSt L α`), $f = e^{-\alpha}$ and $\varepsilon = \varepsilon(\alpha,-\alpha) = \pm 1$. For a vector $x_1 e + x_2 h + x_3 f$ (`vec3 L α x₁ x₂ x₃`) the library computes:

$$Q_\alpha : e \mapsto 0,\ h \mapsto -2e,\ f \mapsto \varepsilon h; \qquad Q_{-\alpha} : e \mapsto -\varepsilon h,\ h \mapsto 2f,\ f \mapsto 0, \tag{39.6}$$

```
/-- `Q_β (α(-1)𝟙) = -⟨α,β⟩ e^β`. -/
theorem Qscr_hSt (hPos : L.PosDef) (α β : L.carrier) :
    Qscr L β (hSt L α) = -((L.form α β : ℤ) : ℂ) • latChargeGen L β

/-- `Q_α e^{-α} = ε(α,-α)·α(-1)𝟙` for a root `α`. -/
theorem Qscr_latChargeGen_neg {α : L.carrier} (hα : L.form α α = 2) :
    Qscr L α (latChargeGen L (-α)) = latticeCocycle L α (-α) • hSt L α
```

and hence, since $Q_{\pm\alpha}^3 = 0$ on the triple, the exponentials act by quadratic formulas:

```
theorem rootExp_vec3_pos {α : L.carrier} (hα : L.form α α = 2) (c x₁ x₂ x₃ : ℂ) :
    rootExp L hEven hPos hα c (vec3 L α x₁ x₂ x₃)
      = vec3 L α (x₁ - 2 * c * x₂ - c ^ 2 * latticeCocycle L α (-α) * x₃)
          (x₂ + c * latticeCocycle L α (-α) * x₃) x₃

theorem rootExp_vec3_neg {α : L.carrier} (hα : L.form α α = 2) (hα' : L.form (-α) (-α) = 2)
    (c x₁ x₂ x₃ : ℂ) :
    rootExp L hEven hPos hα' c (vec3 L α x₁ x₂ x₃)
      = vec3 L α x₁ (x₂ - c * latticeCocycle L α (-α) * x₁)
          (x₃ + 2 * c * x₂ - c ^ 2 * latticeCocycle L α (-α) * x₁)

theorem rootExp_vec3_orth {α β : L.carrier} (hβ : L.form β β = 2) (hαβ : L.form α β = 0)
    (c x₁ x₂ x₃ : ℂ) : rootExp L hEven hPos hβ c (vec3 L α x₁ x₂ x₃) = vec3 L α x₁ x₂ x₃
```

(`VOA/Moonshine/TrialitySl2.lean`.)

From the mathematics to the Lean statement

Fidelity check. `vec3 L α x₁ x₂ x₃ := x₁ • latChargeGen L α + x₂ • hSt L α + x₃ • latChargeGen L (-α)`, i.e. $x_1 e + x_2 h + x_3 f$, and `hSt L α := latStateGen L (vSchur L α 1) 0` is $\alpha(-1)\mathbf{1} \otimes e^0$. Each formula is the exponential $v + cQv + \frac{c^2}{2}Q^2 v$ with the table (39.6): e.g. for Q_α, $Q(x_1 e + x_2 h + x_3 f) = -2x_2 e + \varepsilon x_3 h$ and $Q^2(\ldots) = -2\varepsilon x_3 e$, giving the displayed coefficients. The third statement: a root $\beta \perp \alpha$ acts trivially on the α-triple.

Proof of (39.6). $Q_\beta h = -\langle\alpha,\beta\rangle e^\beta$: the zero mode of e^β on $\alpha(-1)\mathbf{1}$ is the z^{-1} coefficient of $z^0 E^-(-\beta,z)\alpha(-1)\mathbf{1}\otimes e^\beta$, where the annihilation part E^+ contributes $-\langle\beta,\alpha\rangle z^{-1}$. $Q_\alpha e^{-\alpha}$: $Y(e^\alpha,z)e^{-\alpha} = \varepsilon z^{-2}E^-(-\alpha,z)\mathbf{1} = \varepsilon z^{-2}(1 + \alpha(-1)z + \cdots)$, whose z^{-1} coefficient is εh. $Q_\alpha e^\alpha = 0$ because $\langle\alpha,\alpha\rangle = 2 \geq 0$ makes the series start at z^2. □

In particular $E := Q_\alpha, H := h_{(0)}, F := \varepsilon Q_{-\alpha}$ satisfy the $\mathfrak{sl}_2$ relations, and on the span of $\{e, h, f\}$ (the adjoint representation) they are the adjoint action.

39.9 The Niemeier lattice VOA and the triality σ

39.9.1 The lattice VOA V_N

Definition 39.32 (V_N). $N = N(A_1^{24}) = \rho^{-1}(C) \subset \mathbb{Z}^{24}$ with $\langle x, y\rangle = x \cdot y/2$; V_N is its lattice VOA. The roots are $\alpha_j = 2e_j$, with $\langle \alpha_j, \alpha_k\rangle = 2\delta_{jk}$.

```

theorem golayRoot_form (j k : Fin 24) :
    golayN.form (golayRoot j) (golayRoot k) = if j = k then 2 else 0
```

(`VOA/Moonshine/TrialityGolay.lean`, namespace `VOA.Moonshine.Triality`.)

From the mathematics to the Lean statement

Fidelity check. `ofEbeling` converts the vendored lattice (Chapter 30) to the library's `IntegralLattice`; `golayN_even`, `golayN_posDef` are proved from the Golay code being doubly even and self-orthogonal. `Pi.single j 1` is e_j. Same as the definition.

Physical meaning

V_N is the lattice CFT of the Niemeier lattice $N(A_1^{24})$: 24 free bosons compactified on the Niemeier torus, which contains 24 mutually orthogonal roots, so it has a $\widehat{\mathfrak{sl}}_2^{24}$ current algebra at level one, i.e. 24 copies of the $SU(2)_1$ WZW model (a free boson at self-dual radius). It has the same central charge 24 as the Leech theory but a large non-abelian continuous symmetry $SU(2)^{24}$ (the Kac–Moody algebra of A_1^{24}), in contrast to the abelian $U(1)^{24}$ of the Leech theory. It is the theory in which the triality is visible as a rotation.

Definition 39.33 (χ and the modified centre χz_0). $\mathrm{par}(x) = \frac{1}{2}\sum_i x_i \bmod 2$ (`golayParity`; kernel A), $z_l(x) = x_l \bmod 2$ (`golayCoord l`). $\chi := g_{\mathrm{par}}$ (`golayChi`) and $\chi z_0 := g_{\mathrm{par}+z_0}$ (`golayChiMod`).

```
/-- DGM's `χ = θ₁ = ∏_j exp(iπ H_j/2)`: the momentum sign `(-1)^{parity}`. -/
noncomputable def golayChi : Aut golayVOA := chiAut golayN golayParity golayN_even
↪  golayN_posDef

/-- The DGM (7.8)-modified rotation centre `χ z₀`. -/
noncomputable def golayChiMod : Aut golayVOA :=
  chiAut golayN (golayParity + golayCoord 0) golayN_even golayN_posDef
```

From the mathematics to the Lean statement

Fidelity check. Why is the momentum sign $(-1)^{\mathrm{par}}$ DGM's $\prod_j \exp(i\pi H_j/2)$? $H_j = (\alpha_j(-1)\mathbf{1})_{(0)}$ acts on F_λ by $\langle \alpha_j, \lambda\rangle = \lambda_j$, so $\prod_j \exp(i\pi H_j/2)$ acts by $i^{\sum_j \lambda_j} = (-1)^{\sum_j \lambda_j/2}$ ($\sum \lambda_j$ is even on $\rho^{-1}(C)$). This is a paper identification; the Lean object is *defined* as the momentum sign. Likewise $z_0 = (-1)^{x_0}$ is $\exp(i\pi H_0)$, the central element $-1 \in SU(2)_0$, and χz_0 acts in coordinate 0 as $\exp(3i\pi H_0/2)$: this is DGM's modification (7.8) in the coordinate $l = 0$.

Physical meaning

χ is the $\mathbb{Z}/2$ charge symmetry $(-1)^{\mathrm{par}(\hat{p})}$, the rotation by π about the Cartan axis in every $SU(2)$ factor. Its modification χz_0 changes the parity by the coordinate z_0 and is the involution that, after conjugation by the rotation G (a rotation by an angle between axes), will become the triality σ. Both are symmetries because momentum is conserved in every operator product; the choice of z_0 selects the correct class among such sign automorphisms.

39.9.2 The rotation G and the definition of σ

DGM write the triality as $\sigma_{\mathrm{DGM}} = \prod_j \exp(\frac{i\pi}{\sqrt{2}}(J_0^{j1} + J_0^{j2}))$ with $J^{j1} = \frac{1}{2}H_j$, $J^{j2} = \frac{1}{2}(E_j + F_j)$: rotation by π about the bisector of the Cartan and the $e + f$ axes. The library instead writes σ as a *conjugate* of the momentum sign, which makes $\sigma^2 = 1$ automatic. The key identity is in $SL_2(\mathbb{C})$: with

$$H = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix},\ E = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix},\ F = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}, \qquad g = \exp\big((1-\sqrt{2})E\big)\exp\big(\tfrac{\sqrt{2}}{4}F\big) = \begin{pmatrix} 1+ab & a \\ b & 1 \end{pmatrix},$$

$a = 1 - \sqrt{2}$, $b = \sqrt{2}/4$, $ab = (\sqrt{2}-2)/4$, one has

$$gHg^{-1} = \tfrac{1}{\sqrt{2}}(H + E + F). \tag{39.7}$$

Verification. $\det g = 1$ and $g^{-1} = \begin{pmatrix} 1 & -a \\ -b & 1+ab \end{pmatrix}$, so $gHg^{-1} = \begin{pmatrix} 1+2ab & -2a(1+ab) \\ 2b & -1-2ab \end{pmatrix}$. Now $1+2ab = \sqrt{2}/2$; $-2a(1+ab) = -2(1-\sqrt{2})(2+\sqrt{2})/4 = -(2+\sqrt{2}-2\sqrt{2}-2)/2 = \sqrt{2}/2$; $2b = \sqrt{2}/2$. So $gHg^{-1} = \frac{\sqrt{2}}{2}\begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix} = \frac{1}{\sqrt{2}}(H+E+F)$. □

Since $X = (H+E+F)/\sqrt{2}$ satisfies $X^2 = 1$, $\exp(i\pi X/2) = iX$, and therefore, as SL_2 matrices (not only up to sign),

$$g\exp(i\pi H/2)g^{-1} = \exp(i\pi X/2) = \exp\Big(\tfrac{i\pi}{\sqrt{2}}\big(\tfrac{H}{2} + \tfrac{E+F}{2}\big)\Big),$$

which is DGM's rotation in one coordinate. With $G = \prod_j g_j$ this gives, on paper, $\sigma_{\mathrm{DGM}} = G\chi G^{-1}$, and DGM's (7.8)-modified triality is $G(\chi z_0)G^{-1}$.

Definition 39.34 (The untwisted triality). $\varepsilon_j = \varepsilon(\alpha_j, -\alpha_j)$; $g_j = \exp((1-\sqrt{2})Q_{\alpha_j})\exp(\frac{\sqrt{2}}{4}\varepsilon_j Q_{-\alpha_j})$; $G = g_0 g_1 \cdots g_{23}$; and

$$\sigma := G\,(\chi z_0)\,G^{-1} \in \mathrm{Aut}\,V_N.$$

noncomputable def golaySigma : Aut golayVOA := golayG * golayChiMod * golayG⁻¹
```

From the mathematics to the Lean statement

Fidelity check. `Real.sqrt 2` coerced to $\mathbb{C}$ is $\sqrt{2}$. `rootExp … hα c` $= \exp(cQ_\alpha)$ with $\alpha = \alpha_j$ (first factor) and $\alpha = -\alpha_j$ (second factor); $*$ in `Aut` is composition, so g_j applies the $Q_{-\alpha_j}$-exponential first. With $E_j = Q_{\alpha_j}$, $F_j = \varepsilon_j Q_{-\alpha_j}$ this is the matrix g above. `(List.ofFn golayG1).prod` is $g_0 g_1 \cdots g_{23}$ (the order is irrelevant: the factors commute because they act on orthogonal roots). So `golaySigma` is literally $G(\chi z_0)G^{-1}$. **What is not asserted in Lean:** that this equals DGM's exponential formula — that is the paper computation (39.7). The evidence that the Lean σ is the right one is (a) Theorem 39.36 (its action on currents is DGM (7.7)), (b) the trace certificate in the warning below, and (c) ultimately, that it extends to $V^\natural$ (Chapters 40–42).

Physical meaning

$\sigma = G(\chi z_0)G^{-1}$ is a rotation by π in every $SU(2)$ factor of $SU(2)^{24}$ about a new axis: the rotation $G = \prod_j g_j$ (a product of exponentials of $\mathfrak{sl}_2$ zero modes, i.e. an $SU(2)$ rotation in each factor) moves the Cartan axis to a bisector, and the involution about the bisector is σ. It exchanges the χ-axis and the Θ-axis (the rotation about the $e+f$ axis): this is the swap of Cartan with $e+f$ currents. The sector content of this swap is the heart of triality in the A_1^{24} theory; in the moonshine setting the analogous σ exchanges an untwisted sector with a twisted one, and the explicit group-element formula is the Lean-friendly way to describe it. The exponent $1-\sqrt{2}$ and the coefficient $\frac{\sqrt{2}}{4}$ are the specific angles that realise the bisector rotation.

Theorem 39.35 (σ is a nontrivial involution). *$\sigma^2 = 1$ and $\sigma \neq 1$.*

File `VOA/Moonshine/TrialityGolay.lean`.

```
/-- `σ² = 1`. -/
theorem golaySigma_sq : golaySigma * golaySigma = 1

theorem golaySigma_ne_one : golaySigma ≠ 1
```

Physical meaning

A rotation by π squares to the identity, which is $\sigma^2 = 1$; and $\sigma \neq 1$ because it is a genuine, nontrivial symmetry, exchanging currents that are distinct. Physically, σ is the $\mathbb{Z}/2$ element of a hidden symmetry group, an extra involution beyond the visible ones, and the triality is the order-two generator that, together with the centraliser, assembles into the Monster.

Proof. $(G(\chi z_0)G^{-1})^2 = G(\chi z_0)^2 G^{-1} = 1$ since $(\chi z_0)^2 = 1$. If $\sigma = 1$ then $\chi z_0 = 1$; but χz_0 negates e^{α_0} ($\mathrm{par}(\alpha_0) = 1$, $z_0(\alpha_0) = 0$). □

What the machine verified

Unconditional; `##print axioms golaySigma_sq`-clean.

39.9.3 σ on the currents: DGM (7.7)

Theorem 39.36 (σ exchanges the Cartan and the $e+f$ currents)**.** *For every j:* $\sigma\big(\alpha_j(-1)\mathbf{1}\big) = e^{\alpha_j} + \varepsilon_j e^{-\alpha_j}$, *and* $\sigma\big(e^{\alpha_j} + \varepsilon_j e^{-\alpha_j}\big) = \alpha_j(-1)\mathbf{1}$.

```
/-- **DGM (7.7) on the Cartan current**: `σ (α_j(-1)𝟙) = e^{α_j} + ε_j e^{-α_j}`. -/
theorem golaySigma_hSt (j : Fin 24) :
    golaySigma (hSt golayN (golayRoot j)) = tri j 1 0 (golayEps j)

/-- `σ (e^{α_j} + ε_j e^{-α_j}) = α_j(-1)𝟙`. -/
theorem golaySigma_tri_ef (j : Fin 24) :
    golaySigma (tri j 1 0 (golayEps j)) = hSt golayN (golayRoot j)
```

(`VOA/Moonshine/TrialityCurrents.lean`.)

From the mathematics to the Lean statement

Fidelity check. `tri j x₁ x₂ x₃ := vec3 golayN (golayRoot j) x₁ x₂ x₃`, so `tri j 1 0 (golayEps j)` $= e^{\alpha_j} + \varepsilon_j e^{-\alpha_j}$. The zero mode of this state is $E_j + \varepsilon_j \cdot \varepsilon_j F_j = E_j + F_j$, i.e. $2J_0^{j2}$; the zero mode of $\alpha_j(-1)\mathbf{1}$ is $H_j = 2J_0^{j1}$. So the theorem says $\sigma J^{j1}\sigma^{-1} = J^{j2}$, DGM (7.7). No hypotheses.

Physical meaning

In each $SU(2)_1$ factor, σ swaps the Cartan current $\alpha_j(-1)\mathbf{1}$ (the J^3-like current) with the current $e^{\alpha_j} + \varepsilon_j e^{-\alpha_j}$ (the J^1-like one): a rotation of the three-dimensional space of currents by π about the bisector of two axes exchanges them. This is the concrete content of triality on the weight-one states: it relates the current that acts as a charge (free-boson momentum) with a current that acts as a charge-changing vertex operator, something invisible in the free-field description, where those currents look different. The computation takes place in the three-dimensional span of e, h, f in each coordinate and is the standard $SU(2)$ adjoint rotation.

Proof. Everything happens in the three-dimensional span of e, h, f in coordinate j: the factors g_k, $k \neq j$, act trivially there (`rootExp_vec3_orth`), and g_j and χz_0 act by the explicit formulas of Section 39.8 (χz_0 negates e, f and fixes h). One exhibits

$$y = (2-2\sqrt{2})e + \tfrac{\sqrt{2}}{2}h - \tfrac{\varepsilon(1+\sqrt{2})}{4}f, \qquad y' = (2\sqrt{2}-2)e + \tfrac{\sqrt{2}}{2}h + \tfrac{\varepsilon(1+\sqrt{2})}{4}f$$

and checks, using only $(\sqrt{2})^2 = 2$ and $\varepsilon^2 = 1$, that $Gy = h$, $Gy' = e + \varepsilon f$ and $(\chi z_0)y = y'$. Then $\sigma h = G(\chi z_0)G^{-1}Gy = Gy' = e + \varepsilon f$. The second statement follows from $\sigma^2 = 1$. □

What the machine verified

Unconditional; `##print axioms golaySigma_hSt`: [`propext`, `Classical.choice`, `Quot.sound`].

39.9.4 $\Theta = \sigma\chi\sigma$ is a lift of -1

Definition 39.37 (Θ, K, $V_N^{\langle\chi,\Theta\rangle}$)**.** $\Theta := \sigma\chi\sigma$; $K := \langle\chi, \Theta\rangle \leq \mathrm{Aut}\, V_N$; and V_N^K is the orbifold VOA (`golayV0`).

File `VOA/Moonshine/TrialityGolay.lean`.

```

 ↪  character). -/
noncomputable def golayTheta : Aut golayVOA := golaySigma * golayChi * golaySigma

/-- `K = ⟨χ, Θ⟩`. -/
noncomputable def golayK : Subgroup (Aut golayVOA) := Subgroup.closure {golayChi,
 ↪  golayTheta}

/-- `V_N^{⟨χ,Θ⟩}` — DGM's `V₀⁺` (modulo the open identification of `Θ` with a lift of
 ↪  `-1`). -/
noncomputable def golayV0 : VertexOperatorAlgebra (orbifold golayK).carrier := orbifoldVOA
 ↪  golayK
```

From the mathematics to the Lean statement

Fidelity check. `Subgroup.closure S` is the subgroup generated by S. The docstring's parenthetical "modulo the open identification" is stale: the identification is made by the next theorem and by Section 39.10. Note that $\sigma\Theta\sigma = \chi$ (`golaySigma_conj_theta`) holds by definition and $\sigma^2 = 1$; the content is that Θ is a lift of -1.

Physical meaning

$\Theta = \sigma\chi\sigma$ is the conjugate of the Cartan rotation by the triality: a rotation by π about the $e + f$ axis, i.e. the image of the sign symmetry χ under the swap. $K = \langle\chi, \Theta\rangle$ is the group generated by these two commuting involutions (a Klein four-group in each factor), and V_N^K is the K-orbifold, the subtheory neutral under both. It is the theory that the untwisted and twisted halves of the moonshine module share, and that σ preserves.

Theorem 39.38 (Θ is a lift of -1). *(i)* $\Theta(\alpha_j(-1)\mathbf{1}) = -\alpha_j(-1)\mathbf{1}$ *for all* j*; hence* Θ *anticommutes with every Heisenberg mode. (ii)* $\Theta(F_\lambda) \subseteq F_{-\lambda}$ *for every* $\lambda \in N$.

```
/-- `Θ = σχσ` acts by `-1` on the Cartan currents. -/
theorem golayTheta_hSt (j : Fin 24) :
    golayTheta (hSt golayN (golayRoot j)) = -hSt golayN (golayRoot j)

/-- **`Θ` maps the momentum sector `F_λ` into `F_{-λ}`.** -/
theorem golayTheta_chargeSec (lam : golayN.carrier) {x : LatModuleGen golayN}
    (hx : x ∈ chargeSec golayN lam) : golayTheta x ∈ chargeSec golayN (-lam)
```

(`VOA/Moonshine/TrialityCurrents.lean`, `TrialityTheta.lean`.)

Physical meaning

Θ negates the Heisenberg currents $\alpha_j(-1)\mathbf{1}$ and maps momentum λ to $-\lambda$, so it is a lift of the lattice involution -1: the same kind of symmetry as θ of the Leech theory (negating each boson). Physically, σ conjugates the charge parity χ into an operation acting on bosons as the reflection $\partial X \mapsto -\partial X$. This is the mechanism of "triality": it converts a sign on charges into a sign on the bosons, so the orbifold by the former looks like the orbifold by the latter (which is how twisted sectors appear). The precise scalars (cocycle-dependent) are the content of the proof.

Proof. (i) $\sigma h_j = e_j + \varepsilon_j f_j$, χ negates e_j, f_j, and σ maps $-(e_j + \varepsilon_j f_j)$ back to $-h_j$. An automorphism negating the state h negates all modes of $Y(h, z)$ under conjugation. (ii) The zero modes H_j act on F_λ by λ_j, these 24 numbers determine λ, and $H_j\Theta = -\Theta H_j$ by (i); so ΘF_λ lies in the joint eigenspace with eigenvalues $-\lambda_j$, which is $F_{-\lambda}$. □

What the machine verified

Unconditional; `##print axioms golayTheta_chargeSec`-clean. The scalars c_λ with $\Theta e^\lambda = c_\lambda e^{-\lambda}$ are determined in Section 39.10 (on Λ_0).

Theorem 39.39 (σ restricts to V_N^K). *σ normalises K, hence restricts to an automorphism σ_0 of V_N^K; $\sigma_0^2 = 1$ and $\sigma_0 \neq 1$. More generally, an involution normalising a subgroup G restricts to an automorphism of W^G.*

```

From the mathematics to the Lean statement

Fidelity check. Hypotheses of `orbifoldInvol`: $\sigma^2 = 1$ and $\sigma G \sigma \subseteq G$. `golaySigma_normalises` supplies the latter for K (conjugation by σ swaps the generators $\chi \leftrightarrow \Theta$). The underlying map of `golaySigma0` on $v \in V_N^K$ is σv (`golaySigma0_coe`). The nontriviality is the important clause: an "automorphism" that is secretly the identity would make everything that follows empty.

Physical meaning

Because σ normalises K (it exchanges χ and Θ), it descends to the K-neutral subtheory V_N^K as an automorphism: a symmetry that permutes the gauge group elements preserves the gauge-invariant states. It is nontrivial there. This is the general principle that an automorphism normalising the orbifold group acts on the orbifold: in the physical picture, the triality survives the projection onto K-neutral states, and acts as an extra symmetry of V_N^K not coming from a lattice automorphism.

Proof. If v is K-fixed and $k \in K$ then $k\sigma v = \sigma(\sigma k \sigma)v = \sigma v$. For $\sigma_0 \neq 1$: the state $x = h_{0(-1)}h_1$ (i.e. $\alpha_0(-1)\alpha_1(-1)\mathbf{1}$) is in F_0 (fixed by χ) and $\Theta x = (-h_0)_{(-1)}(-h_1) = x$, so $x \in V_N^K$. But $\sigma x = (e_0 + \varepsilon_0 f_0)_{(-1)}(e_1 + \varepsilon_1 f_1)$ has momentum-$(\alpha_0 + \alpha_1)$ component $e^{\alpha_0}_{(-1)}e^{\alpha_1} = \varepsilon(\alpha_0, \alpha_1)e^{\alpha_0+\alpha_1} \neq 0$ (as $\langle \alpha_0, \alpha_1 \rangle = 0$), while x has none. □

Trap / dead end

The unmodified DGM (7.5) triality is the wrong one — the 6372 versus 2324 certificate. For $d = 24$ DGM's modification (7.8) (multiplying, in one coordinate l, by the central element $z_l = (-1)^{x_l}$) is *mandatory*, because 24/8 is odd. The project established this by a trace computation (paper derivation plus Python with the real Golay code, `scripts/moonshine/numerics/golay.py`, `tri.py`; *numerical evidence and paper argument only, not Lean*).
The trace. $(V_N)_2$ decomposes under $SU(2)^{24}$ as $24 \cdot (3+1) \oplus \binom{24}{2} \cdot 9 \oplus 759 \cdot 2^8$ $(= 196884)$. Projecting onto V_N^K with $\frac{1}{4}\sum_{k\in K} k$ (legitimate because σ normalises K), and using the $SU(2)$ traces of the rotations involved, one finds

$$\operatorname{tr}\left(\sigma \,|\, (V_N^K)_2\right) = 300 + 8 \sum_{\text{octads } c} (-1)^{c\cdot u},$$

where $u \in \mathbb{F}_2^{24}/C$ encodes the modification: $u = 0$ for (7.5), $u = e_l$ for (7.8). The sum over the 759 octads is 759 for $u = 0$ and $506 - 253 = 253$ for $u = e_l$ (253 octads contain a given point). Hence

$$\operatorname{tr}\sigma_{(7.5)} = 300 + 8\cdot 759 = 6372, \qquad \operatorname{tr}\sigma_{(7.8)} = 300 + 8\cdot 253 = 2324.$$

Why 6372 is impossible (a paper argument, using $\operatorname{Aut} V^\natural = \mathbb{M}$ and the Monster character table from the literature; neither is formalized). If σ extended to $\tilde\sigma \in \operatorname{Aut} V^\natural = \mathbb{M}$ with $V_0^+ = (V^\natural)^E$ for a Klein four-group E, then $\tilde\sigma$ normalises E, fixes one $k_0 \in E \setminus 1$ and swaps the other two, and $\operatorname{tr}(\sigma|(V_0^+)_2) = \frac{1}{4}(\operatorname{tr}\tilde\sigma + \operatorname{tr}\tilde\sigma k_0 + 2\operatorname{tr}\tilde\sigma k_1)$ on ${V^\natural}_2 = 1 + 196883$, with $\tilde\sigma, \tilde\sigma k_0$ involutions and $\tilde\sigma k_1$ of order four. From the Monster character table the largest possible value is $\frac{1}{4}(4372 + 4372 + 2\cdot 276) = 2324$ (classes 2A, 2A, 4A). So 6372 cannot be the trace of a Monster element: the unmodified σ is *not* the restriction of FLM's triality. The modified value saturates the bound. The library therefore defines σ with χz_0, not χ (a recorded dead end, Section 50.2.3; Notes/M8GluingPlan.md, correction 6). At module level the project also found numerically that the (7.5) σ maps V_3^+ to the wrong twisted summand, while (7.8) gives a residual of $4 \cdot 10^{-15}$ over 15000 identities (status "M8g twisted half").

39.10 The bridge $V_N^K \cong V_0^+$ and the triality on V_0^+

σ_0 lives on V_N^K, a subalgebra of the lattice VOA of N; V_0^+ is a subalgebra of the lattice VOA of Λ. The two ambient algebras have different lattices, different cocycles and different Fock coordinates. Both contain a copy of V_{Λ_0}, and the functoriality theorem of Chapter 31 (Theorem 31.39) produces both copies from one abstract V_{Λ_0}.

From the mathematics to the Lean statement

Fidelity check. The proofs shown are one-line instantiations of the functoriality theorem of Chapter 31 (Theorem 31.39), whose hypotheses — both lattices positive definite and even, the map an isometry (`inclΛ_form`, `inclN_form`), and equal ranks for ω and injectivity (`rank_lam0_leech`: $24 = 24$) — are all discharged here. The analogous `bridgeN_omega`, `bridgeN_injective`, `bridgeN_thetaLat` hold too. `latMorph` includes a cocycle-comparison coboundary with values in $\mathbb{Z}/4$ (Remark 31.37); a ±1-valued one would commute with θ only up to a character, and then `bridgeΛ_thetaLat` would fail.

Physical meaning

The two bridges embed the frame subtheory V_{Λ_0} into both the Leech theory (the states with all momenta in Λ_0) and the Niemeier theory (the χ-neutral states of V_N). They realise the statement that the Leech and A_1^{24} theories share a common subtheory, the frame theory V_{Λ_0}; the θ-involutions agree under the Leech bridge. This is what allows the triality, first constructed on the A_1^{24} side, to be moved to the Leech side.

Theorem 39.41 ($V_{\Lambda_0}^+ \cong V_0^+$). `bridgeΛ` *induces a linear bijection* $V_{\Lambda_0}^+ = V_{\Lambda_0}^{\langle\theta\rangle} \to V_0^+$ *which is a VOA homomorphism preserving* ω.

theorem lam0PlusEquiv_omega : lam0PlusEquiv lam0Plus.conformalVector = V0P.conformalVector
```

From the mathematics to the Lean statement

Fidelity check. `Lam0PlusCarrier` is the carrier of $V_{\Lambda_0}^+$ (the $\langle\theta\rangle$-orbifold `lam0Plus` of `lam0VOA`); `V0Sub.carrier` that of `V0P`. `lam0PlusEquiv_coe` records that the map is `bridgeΛ`. Bijective + `IsVOAHom` + ω-preserving = isomorphism of VOAs. This settles the open item "identify `V0P` with the θ-orbifold of V_{Λ_0}" recorded in the docstring of `FrameSectors.lean` (stale there).

Physical meaning

The θ-invariant part of the abstract frame lattice theory V_{Λ_0} is isomorphic, as a vertex operator algebra with the same stress tensor, to the neutral frame sector V_0^+ of the Leech theory: "the common subtheory" is the same on both sides. In CFT terms, the neutral sector of the Leech theory is an orbifold of a smaller lattice theory, identified through the isomorphism of charge lattices.

Proof. `bridgeΛ` is injective with image the momentum-Λ_0 states, and commutes with θ; so it maps θ-fixed states of V_{Λ_0} bijectively onto θ-fixed states of V_Λ with momenta in Λ_0, which is V_0^+. □

What the machine verified

Unconditional; `##print axioms lam0PlusEquiv_isVOAHom`-clean.

39.10.2 Pulling back Θ: the scalars c_λ

On the N side the situation is subtler: $V_N^K = (V_N^\chi)^\Theta = \mathrm{bridgeN}(V_{\Lambda_0})^\Theta$, and Θ is *some* lift of -1, not obviously the standard θ.

Theorem 39.42 (Θ on V_{Λ_0} is conjugate to θ). $\chi\Theta = \Theta\chi$, *so* Θ *preserves* $\mathrm{bridgeN}(V_{\Lambda_0})$ *and pulls back to* $\psi \in \mathrm{Aut}\, V_{\Lambda_0}$. *There is a character* $e : \Lambda_0 \to \mathbb{C}^\times$ *with* $\psi = g_e \theta g_e^{-1}$, *where* $g_e(p \otimes e^\lambda) = e(\lambda)p \otimes e^\lambda$; *consequently* $\Theta e^\lambda = e(-\lambda)e(\lambda)^{-1}e^{-\lambda}$ *on* V_{Λ_0} *(in the* `bridgeN` *normalisation).*

```

(`VOA/Moonshine/FrameBridgeGolay.lean`.)

From the mathematics to the Lean statement

Fidelity check. `Aut.pullback` (Chapter 31) turns an automorphism preserving the image of an injective VOA homomorphism into an automorphism of the source; its inputs here are injectivity of `bridgeN`, the fact that Θ maps its image onto itself (`golayTheta_range_bridgeN`, from $\chi\Theta = \Theta\chi$), and the homomorphism and ω properties. `lam0.carrier →+ Additive ℂˣ` is a homomorphism $\Lambda_0 \to \mathbb{C}^\times$ written additively; `charLat lam0 e` is g_e (Definition 31.41) and `charVal lam0 e λ` $= e(\lambda)$. The rigidity theorem `lift_eq_conj_theta'` (Theorem 31.42) requires exactly that ψ negate every $\alpha(-1)\mathbf{1}$ (`lam0Psi_hSt`) and map F_λ to $F_{-\lambda}$ (`lam0Psi_chargeSec`); both come from Theorem 39.38 (for general μ one writes $2\mu = \sum_j \mu_j\alpha_j$). The scalar in `lam0Psi_latChargeGen` is $e(-\lambda)\cdot e(\lambda)^{-1} = e(\lambda)^{-2}$, matching the docstring. `golayE` is chosen by `Classical.choose`: an existence statement, not a computation.

Physical meaning

On the common subtheory V_{Λ_0}, the lattice involution Θ coming from the A_1^{24} side differs from the standard θ by a rescaling of the charged states by phases $e(\lambda)$, i.e. by a gauge transformation g_e (a momentum-dependent phase, a conjugation by $e^{i\hat{p}\cdot\phi}$ in the free-field language). This is exactly the statement that Θ and θ are the same symmetry in different cocycle gauges, so their orbifolds are isomorphic; it is what allows the K-orbifold of V_N to be identified with $V_{\Lambda_0}^+$ (cocycle bookkeeping, not new physics).

Proof. $\chi\Theta = \Theta\chi$ because $\Theta F_\lambda \subseteq F_{-\lambda}$ and $\mathrm{par}(-\lambda) = \mathrm{par}(\lambda)$. For the conjugacy, $\psi\theta$ fixes every Heisenberg state and every momentum sector, hence acts on F_λ by a scalar $d(\lambda)$ (a VOA automorphism fixing the Heisenberg subalgebra and preserving F_λ is a scalar there, F_λ being an irreducible Heisenberg module generated by e^λ); multiplicativity of products makes d a character, and over $\mathbb{C}$ a character d has a "square root" character e with $d(\lambda) = e(\lambda)e(-\lambda)^{-1}$, which gives $\psi = g_e\theta g_e^{-1}$ (details in Section 31.12.6). □

  lam0PlusGolayEquiv.symm.trans lam0PlusEquiv

/-- `golayToV0` is a homomorphism of vertex operator algebras. -/
```

```
theorem golayToV0_isVOAHom : IsVOAHom golayV0 V0P golayToV0.toLinearMap

theorem golayToV0_omega : golayToV0 golayV0.conformalVector = V0P.conformalVector
```

From the mathematics to the Lean statement

Fidelity check. `lam0PlusGolayEquiv` is the bijection $V_{\Lambda_0}^+ \to V_N^K$, $z \mapsto \mathrm{bridgeN}(g_e z)$; `.symm.trans` composes its inverse with `lam0PlusEquiv`. Linear bijection + `IsVOAHom` + ω = VOA isomorphism. Exactly the theorem.

Physical meaning

The orbifold V_N^K of the Niemeier theory is isomorphic to the neutral frame sector V_0^+ of the Leech theory, as vertex operator algebras with the same stress tensor: two different-looking lattice-CFT orbifolds (one from A_1^{24}, one from Leech) are the same chiral algebra. This is the physical content of the statement that the two theories are connected by orbifolding, and sets up the transport of σ to the Leech side. Physical expectations (orbifold equivalence) are heuristics; the isomorphism is established by composing the explicit bridges and gauge transformation.

Proof. $\mathrm{bridgeN}(g_e z)$ is χ-fixed (in the image of `bridgeN`) and $\Theta\,\mathrm{bridgeN}(g_e z) = \mathrm{bridgeN}(\psi g_e z) = \mathrm{bridgeN}(g_e \theta z) = \mathrm{bridgeN}(g_e z)$ for $\theta z = z$; conversely every element of V_N^K arises so. g_e is an automorphism of V_{Λ_0} and `bridgeN` a VOA homomorphism, so the composite is one. □

Definition 39.44 (Transport of automorphisms)**.** For a VOA isomorphism $E : V \to W$ (linear bijection, `IsVOAHom`, $E\omega = \omega$) and $g \in \mathrm{Aut}\, V$, $\mathrm{transport}_E(g) = EgE^{-1} \in \mathrm{Aut}\, W$.

```

    (hω : E V.conformalVector = W.conformalVector) (g : Aut V) : Aut W where
  toLinearEquiv := E.symm.trans (g.toLinearEquiv.trans E)
```

Physical meaning

Transport of structure: given an isomorphism of chiral algebras, a symmetry of one side becomes a symmetry of the other by conjugation. Physically this is a change of description ("relabelling the fields") under which the symmetry acts identically, and is needed here to turn the symmetry σ_0 of the A_1^{24}-side orbifold into a symmetry of the Leech-side V_0^+.

It is multiplicative, sends 1 to 1 and is injective (`Aut.transport_mul`, `Aut.transport_one` and `Aut.transport_injective`) — immediate from $E(gh)E^{-1} = (EgE^{-1})(EhE^{-1})$.

Theorem 39.45 (The triality on V_0^+)**.** $\sigma_{V_0^+} := \mathrm{transport}(\sigma_0)$ *is an automorphism of the VOA* V_0^+ *with* $\sigma_{V_0^+}^2 = 1$, $\sigma_{V_0^+} \neq 1$, *and* $\mathrm{golayToV0} \circ \sigma_0 = \sigma_{V_0^+} \circ \mathrm{golayToV0}$.

From the mathematics to the Lean statement

Fidelity check. `Aut V0P` is the group of automorphisms of the VOA V_0^+ (all products, $\mathbf{1}$, ω). The definition is a one-line transport and is shown in full. The three theorems are exactly the involution, nontriviality and intertwining clauses. How could this have been vacuous? (a) If σ_0 were 1 — excluded by `golaySigma0_ne_one` and injectivity of transport. (b) If the isomorphism `golayToV0` were not a VOA isomorphism — it is (Theorem 39.43). (c) If σ were the wrong involution (e.g. DGM (7.5)) — not excluded by any Lean statement of this chapter; the warning above explains the choice, and Chapters 40–42 confirm it by actually extending σ to $V^\natural$.

Physical meaning

This is the untwisted triality: an order-two automorphism of the frame subtheory V_0^+ of the moonshine module that is not visible from the lattice description, being built from an $SU(2)$ rotation on the A_1^{24} side. It is the hidden symmetry that the Monster requires: the centraliser $2^{1+24}.Co_1$ of the $2B$ involution is visible in the Leech-lattice construction, and adjoining σ generates the full Monster; consistency of the moonshine module as a vertex operator algebra demands the extension of σ to the twisted sectors, which exchanges the odd untwisted sector with the twisted sector T_0^+ (the exchange of untwisted and twisted sectors of the orbifold by θ). This chapter constructs only its action on V_0^+; that the extension exists and that it gives the missing locality are shown in Chapters 40–42. The identification of this σ with a Monster element is part of the physical (heuristic) picture, not of what is proved here.

What the machine verified

Unconditional; `##print axioms v0Sigma_sq, v0Sigma_ne_one`: [`propext`, `Classical.choice`, `Quot.sound`] (re-run for this chapter). No `VOA.pbw`. **Not stated here:** what σ does to the sectors of V_Λ^+ outside V_0^+ — those are not in V_0^+; the twisted extension is Chapters 40–41.

Trap / dead end

`golayE` is not determined, and with it the sector pattern. The character `golayE` is chosen by `Classical.choose` and is pinned only up to a character of the form e_β; replacing it changes the isomorphism `golayToV0` by an automorphism of V_0^+, hence `v0Sigma` by a conjugation, and swaps which twisted frame sector $T_{(s)}^+$ is paired with V_3^+ by the extended σ (finding `golayE_not_determined`, Notes/M8GluingPlan.md). Downstream statements are therefore formulated with $\exists\, s$. This is a feature of the definitions, not an error, but it means no Lean statement asserts "$T_{(0)}^+$ is FLM's T_0^+".

39.11 Summary: what this chapter gives the rest of the proof

1. A decomposition $V^\natural = V_0^+ \oplus V_3^+ \oplus T_{(0)}^+ \oplus T_{(1)}^+$ into V_0^+-modules, with $\mathbb{Z}/2$-graded products on the untwisted side (Theorems 39.6, 39.15, 39.28), and weight-two dimensions 49428, 49152, $24 \cdot 2048$, $24 \cdot 2048$.

2. Explicit cyclic vectors: $\mathbf{1}$, $e^\beta + e^{-\beta}$, $h_0(-\frac{1}{2})\mathbf{1} \otimes t_0$ (Theorems 39.19, 39.21, 39.28). These make σ-twisted module maps out of each sector determined by one value.

3. A nontrivial involutive automorphism `v0Sigma` of V_0^+, built from the explicit (7.8)-modified triality of V_N (Theorem 39.45).

Chapter 40 uses these to reduce the existence of σ on $V_3^+ \to T^+$ and on $T^+ \to T^+$ to finite top-level statements; Chapter 41 proves them; Chapter 42 proves the conjugation identity and deduces (39.1).

Evidence that is *not* Lean: the 6372/2324 trace certificate and the Monster bound (paper and Python), the count 98256 of norm-four vectors in Λ_0 (Python; implied by the Lean count of the complement), and the identification of the Lean σ with DGM's exponential formula (the SL_2 identity (39.7), verified by hand above).

Notes and references

The triality strategy is due to I. Frenkel, J. Lepowsky and A. Meurman, *Vertex Operator Algebras and the Monster*, Pure and Applied Mathematics 134, Academic Press, 1988; Chapter 10 treats the $\mathbb{Z}/2$-orbifold structure and the Golay-code frame of the Leech lattice, Chapter 11 the triality, and Chapters 12–13 the main theorem and the completion of the proof. The restatement used throughout this chapter, including the formulas (7.5)–(7.8) for σ on $V_{N(A_1^{24})}$, the necessity of the modification (7.8) when $d/8$ is odd, and the circularity caveat, is L. Dolan, P. Goddard and P. Montague, "Conformal field theories, representations and lattice constructions", Comm. Math. Phys. 179 (1996) 61–120, arXiv:hep-th/9410029 (Sections 4–7; relation (4.23), Propositions 7.1–7.3). The framed point of view — $V^\natural$ as an extension of a code VOA, with Λ_0-type frames — is developed in C. Dong, R. L. Griess Jr. and G. Höhn, "Framed vertex operator algebras, codes and the Moonshine module", Comm. Math. Phys. 193 (1998) 407–448, arXiv:q-alg/9707008, and in M. Miyamoto, "A new construction of the Moonshine vertex operator algebra over the real number field", Ann. of Math. 159 (2004) 535–596, arXiv:q-alg/9701012. Ebeling's model of the Leech lattice used here is in W. Ebeling, *Lattices and Codes*, 3rd ed., Springer Spektrum, 2013, Section 2.8; the Golay code, octads and the Niemeier lattice $N(A_1^{24})$ are in J. H. Conway and N. J. A. Sloane, *Sphere Packings, Lattices and Groups*, 3rd ed., Grundlehren 290, Springer, 1999, Chapters 4, 10, 16 and 18. The Monster character values $4372 = 1 + 4371$ (2A) and $276 = 1 + 275$ (4A) used in the trace bound are from the ATLAS of Finite Groups (Conway, Curtis, Norton, Parker, Wilson, Oxford, 1985). The project-internal record of the decisions, corrections and dead ends of this chapter is Notes/M8GluingPlan.md ("Status and corrections" after M8e, M8g-0, the functoriality bridge and M8f); the dead ends are collected in Section 50.2.

Chapter 40

Existence of the twisted triality I: reduction to Zhu generation

40.1 What this chapter is about

This chapter documents the release of the LeanVOA library named in the front matter. Every Lean quotation below is checked by `scripts/textbook/sync.py` to occur verbatim (up to whitespace and comments) in the source files of that release. Checks that were run at an earlier state of the library and not re-run for this edition are marked as such.

The Moonshine module of Frenkel, Lepowsky and Meurman is the vector space

$$V^\natural \;=\; V_\Lambda^+ \;\oplus\; (V_\Lambda^T)^+,$$

the θ-fixed part of the Leech lattice vertex operator algebra together with the θ-fixed part of its θ-twisted module. Earlier chapters of the Moonshine Part built both summands and the vertex operators on the four "blocks" (untwisted × untwisted, untwisted × twisted, twisted × untwisted, twisted × twisted), and reduced the Jacobi identity of $V^\natural$ to one family of identities. The tool FLM use to control the twisted × twisted block is the *triality*: an extra symmetry σ of $V^\natural$ that mixes the untwisted and the twisted summands.

To describe σ one refines the decomposition of $V^\natural$ by a *Golay frame* (Chapter 39): the description of Λ through the Golay code together with the vector $w = 8e_0$, which singles out a sublattice and two involutions, recalled precisely in §40.2. There is an index-two sublattice $\Lambda_0 \subset \Lambda$, an involution g of V_Λ^+ acting by -1 on the charges outside Λ_0, and a matching involution J on the twisted space. They split

$$V^\natural \;=\; V_0^+ \;\oplus\; V_3^+ \;\oplus\; T_0^+ \;\oplus\; T_1^+, \tag{40.1}$$

where V_0^+ is the g-fixed part of V_Λ^+ (a vertex operator algebra, isomorphic to $V_{\Lambda_0}^+$), V_3^+ the $g=-1$ part of V_Λ^+, and T_s^+ ($s \in \mathbb{Z}/2$) the two J-eigenspaces of $(V_\Lambda^T)^+$. The triality restricts to an automorphism $\sigma \in \mathrm{Aut}\, V_0^+$ of order two, constructed in Chapter 39 from the Golay code, and FLM's theorem says that σ extends to all of $V^\natural$, exchanging V_3^+ with one of the two twisted sectors and mapping the other twisted sector to itself.

Extending σ means constructing linear maps

$$\Phi : V_3^+ \to T_s^+, \qquad \Phi(u_{(n)}x) = (\sigma u)_{(n)}\,\Phi(x) \quad (u \in V_0^+,\ n \in \mathbb{Z},\ x \in V_3^+), \tag{40.2}$$

and similarly $T_{s'}^+ \to T_{s'}^+$. A map with property (40.2) is called a *σ-twisted intertwiner*. Physically: V_0^+ is a chiral algebra, V_3^+ and T_s^+ are two of its superselection sectors, and σ is a symmetry of the chiral algebra; the question is whether the sector V_3^+, with every field twisted by σ, is equivalent to a twisted sector. The difficulty is that (40.2) is a condition on infinitely many modes of infinitely many states; neither Dolan–Goddard–Montague nor the modern literature writes the map down explicitly on twisted states.

This chapter proves, in Lean, that the existence of such maps follows from a *finite* statement about the weight-two top levels of the modules (each 49152-dimensional), and that this finite statement need only be checked for the zero modes of *weight-two* states of V_0^+. The second half of that sentence is the theorem that the weight-two subspace *Zhu-generates* V_0^+:

every subspace of V_0^+ containing $\mathbf{1}$, $\mathcal{O}(V_0^+)$, $(V_0^+)_2$ and closed under Zhu's product $*$ is all of V_0^+.

That theorem, `VOA.Moonshine.zhuGenerated_weightTwo`, is the headline of the chapter. Its proof mixes vertex algebra (a filtered form of the commutator formula in Zhu's algebra), explicit Heisenberg computations, and the combinatorics of the extended binary Golay code, including a counting proof of the existence of the Steiner system $S(5, 8, 24)$ (a family of 8-element subsets, the *octads*, of a 24-element set such that every 5-element subset lies in exactly one of them). The weight-two identities themselves, and hence the existence of σ, are the subject of Chapter 41.

The chain of reductions

The logical structure is a chain of implications, each a Lean theorem. Reading from the goal backwards:

(1) A σ-twisted intertwiner Φ with $\Phi(x_0) = y_0$ exists if and only if every linear relation among the vectors $u^1_{(n_1)} \cdots u^k_{(n_k)} x_0$ also holds among the vectors $(\sigma u^1)_{(n_1)} \cdots (\sigma u^k)_{(n_k)} y_0$ ("annihilator compatibility"; §40.4).

(2) Annihilator compatibility follows from a linear map φ on the top level that intertwines the zero modes $o(a)$ of all homogeneous $a \in V_0^+$, maps into the right sector, and is non-zero in a precise sense (§40.6). The proof uses Li's single-mode spanning lemma and a nondegenerate invariant form on the target only.

(3) Intertwining the zero modes of *all* a follows from intertwining those of a Zhu-generating set G (§40.7). This is the "easy direction" of Zhu's theory: zero modes on a lowest-weight space multiply according to $*$ and kill $\mathcal{O}(V)$.

(4) $G = (V_0^+)_2$ is Zhu-generating (§§40.9–40.13).

Every step is `#print axioms`-clean (only `propext`, `Classical.choice`, `Quot.sound`), and none uses `VOA.pbw` (the PBW theorem of Chapter 3; formerly a project axiom, now a theorem). Step (2) was deliberately designed to avoid the library's Verma-module route, which would then have imported the axiom `VOA.pbw` (§40.3.4).

How to read this chapter

Following the book's constitution, each definition and theorem is presented as: mathematical statement; the Lean declaration copied verbatim, with its file; a *fidelity check* (the box "From the mathematics to the Lean statement") which decodes the Lean statement, lists every hypothesis, and says whether the Lean statement is the same as, stronger or weaker than the mathematics and why it is not vacuous; a proof on paper; and a status box recording what the machine verified. Proof bodies are not reproduced. The chapter ends with a referee's checklist (§40.15).

40.2 The objects, recalled

40.2.1 Standing conventions: modes

Throughout this chapter a field is written $Y(u, z) = \sum_{n \in \mathbb{Z}} u_{(n)} z^{-n-1}$, and $u_{(n)}$, the coefficient of z^{-n-1}, is the *n-th mode* of u; for states u, v of a VOA, $u_{(n)}v$ is the *n-th product*. If u has weight k, then

$u_{(n)}$ raises weights by $k-n-1$; so $u_{(k-1)}$ preserves weight (the zero mode $o(u)$ of §40.3), $u_{(-1)}$ is the normal-ordered product ($u_{(-1)}\mathbf{1}=u$), and $u_{(n)}\mathbf{1}=0$ for $n\geq 0$. In Lean a field is stored as a function of the exponent, and `mode f n` returns the coefficient at exponent $-n-1$ (Definition 2.7); thus `mode (Y u) n` $= u_{(n)}$ and `W.smul u n v` $= u_{(n)}v$. For a module, `A.act u n x` (or `mode (M.YM u) n x`) is $u_{(n)}x$. On the plus part of the twisted module the integer mode $u_{(n)}$ is stored at the doubled index $2n$ (`mode_plusModule`, below). Weak modules (Definition 12.1) are vector spaces with such fields satisfying the vacuum axiom, truncation ($u_{(n)}x=0$ for $n\gg 0$) and the Jacobi identity; ordinary modules (`OrdVModule`) additionally carry an L_0-grading with finite-dimensional weight spaces and weights bounded below. The statements of this chapter mention a handful of objects constructed earlier in the Moonshine Part. We recall each of them with its Lean source and meaning; full treatments are in the chapters indicated.

40.2.2 Lattices: Λ and Λ_0

The Leech lattice is realised in the library as a sublattice of $\mathbb{Z}^{24}$ with the form $\langle x,y\rangle = x\cdot y/8$ ("$\sqrt{8}$-coordinates"): Λ consists of integer vectors all of whose coordinates have the same parity, subject to Golay-code and congruence conditions recalled in Chapter 30. Its Lean name is `leech`, its carrier type `leech.carrier` and its form `leech.form`. The map

$$\beta : \Lambda \to \mathbb{Z}/2, \qquad x \mapsto x_0 \bmod 2$$

(all coordinates have the same parity; read it off coordinate 0) is a homomorphism; its kernel is the index-two sublattice $\Lambda_0=\ker\beta$ of vectors with all coordinates even. File `VOA/Moonshine/FrameSectors.lean`.

```
noncomputable def frameChar : leech.carrier →+ ZMod 2 := Leech.beta.toAddMonoidHom

noncomputable def lambda0 : Submodule ℤ leech.carrier := LinearMap.ker Leech.beta
```

(`VOA/Moonshine/FrameSectors.lean`; `Leech.beta` is defined in `VOA/LatticesAndCodes/Leech/Defs.lean` by `toFun x := ((((x : Fin 24 → ℤ) 0 : ℤ)) : ZMod 2)`.)

Halving the even vectors gives a second model of Λ_0, used in §40.12:

$$A = \{g\in\mathbb{Z}^{24} \;:\; g \bmod 2 \in \mathcal{G},\ \textstyle\sum_i g_i \equiv 0 \pmod 4\}, \qquad \langle g,h\rangle = \tfrac{1}{2}\,g\cdot h, \tag{40.3}$$

where $\mathcal{G}\subset\mathbb{F}_2^{24}$ is the extended binary Golay code. In Lean A is `Leech.subA`; the isometry $A\cong\Lambda_0$, $g\mapsto 2g$, is `lambda0Equiv`, with `lambda0Equiv_form` stating $\langle \iota a,\iota b\rangle_\Lambda = (a\cdot b)/2$. In the A-model, $|\gamma|^2=\frac{1}{2}g\cdot g$. Since Λ has no roots, every non-zero vector has $|\gamma|^2\geq 4$; in A-coordinates $g\cdot g\geq 8$.

40.2.3 The vertex algebras V_Λ^+ and V_0^+

V_Λ (Lean: `leechVOA`, carrier `LatModuleGen leech`) is the lattice vertex operator algebra (Chapter 31): as a vector space $M(1)\otimes\mathbb{C}[\Lambda]$, the Fock space of 24 free bosons tensored with the group algebra of the lattice, spanned by the states $h_{a_1}(-n_1)\cdots h_{a_r}(-n_r)\otimes e^\gamma$ of weight $\sum n_i+\frac{1}{2}|\gamma|^2$. The involution θ lifts -1 on Λ (Chapter 32); V_Λ^+ is its fixed points: File `VOA/Moonshine/FrameSectors.lean`.

```
abbrev VPlus : Type := ↥(orbifold (Subgroup.zpowers leechTheta)).carrier
```

(`VOA/Moonshine/FrameSectors.lean`.) Here `orbifold H` is the subalgebra of fixed points of a group H of automorphisms, `Subgroup.zpowers leechTheta` is the group generated by θ, and `↥` turns a subspace into the type of its elements. So `VPlus` is the type of vectors of V_Λ^+; `leechVOAPlus` is the VOA structure on it.

The Golay frame gives the involution $g(p\otimes e^\gamma)=(-1)^{\beta(\gamma)}p\otimes e^\gamma$ of V_Λ, which commutes with θ and restricts to V_Λ^+ (Lean: `plusFrameAut`). Its eigenspaces are the *frame sectors*: File `VOA/Moonshine/FrameSectors.lean`.

```
noncomputable def frameSector (i : ZMod 2) : Submodule ℂ VPlus :=
  Module.End.eigenspace (plusFrameAut.toLinearEquiv : Module.End ℂ VPlus)
    (Moonshine.Extraspecial.sgn i)
```

with `Extraspecial.sgn i` $= (-1)^i$. So `frameSector 0` is V_0^+ (charges in Λ_0) and `frameSector 1` is V_3^+ (charges in $\Lambda \setminus \Lambda_0$). The fixed subalgebra is a VOA: File `VOA/Moonshine/FrameSectors.lean`.

```
noncomputable def V0Sub : VOASubalgebra leechVOAPlus := orbifold (Subgroup.zpowers
 ↪  plusFrameAut)

noncomputable def V0P : VertexOperatorAlgebra V0Sub.carrier := V0Sub.toVOA
```

and `V0Sub_carrier : V0Sub.carrier = frameSector 0`. Elements of V_0^+ have type `V0Sub.carrier`, a subtype of `VPlus`; the coercion `(u : VPlus)` forgets that u lies in V_0^+.

The basic vectors of charge $\pm\beta$ are (`VOA/Moonshine/CyclicFrameSectors.lean`) File `VOA/Moonshine/CyclicFrameSector`

```
noncomputable def frameX0 (β : leech.carrier) : LatModuleGen leech :=
  latChargeGen leech β + latChargeGen leech (-β)

noncomputable def frameX0P (β : leech.carrier) : VPlus := ⟨frameX0 β, frameX0_mem_plus β⟩
```

so `frameX0P β` is $x_\beta = e^\beta + e^{-\beta} \in V_\Lambda^+$ (the library's θ sends $e^\beta \mapsto e^{-\beta}$ on charged vacua). It has weight $\frac{1}{2}|\beta|^2$, and lies in V_0^+ if $\beta \in \Lambda_0$, in V_3^+ if $\beta \notin \Lambda_0$. The projection $P = \frac{1}{2}(1+\theta) : V_\Lambda \to V_\Lambda^+$ is `plusProj` (`VOA/Moonshine/Generation.lean`).

40.2.4 The twisted sectors T_s^+

The θ-twisted V_Λ-module is $V_\Lambda^T = S[\theta] \otimes T$, where $S[\theta]$ is the Fock space of 24 bosons with half-integral modes $h_a(-\frac{1}{2}), h_a(-\frac{3}{2}), \ldots$ and T is the 2^{12}-dimensional irreducible module of the extraspecial group (Chapters 34–36). In Lean the carrier is `Tw`, the T-factor `TLeechT`, and $(V_\Lambda^T)^+$, the fixed space of the lift of θ, is (`VOA/Moonshine/TwistedPlus.lean`) File `VOA/Moonshine/TwistedPlus.lean`.

```
noncomputable abbrev TP : Submodule ℂ Tw := plusSub leechThetaLift

noncomputable def plusModule : OrdVModule leechVOAPlus TP :=
  TwistedPlus.plusModule leechThetaLift
```

`plusModule` is $(V_\Lambda^T)^+$ as an *ordinary* module for V_Λ^+ (graded by L_0, finite-dimensional weight spaces, weights bounded below); its integer mode $u_{(n)}$ is the twisted mode of index n, stored at the doubled index $2n$ (`mode_plusModule`). The lowest weight of V_Λ^T is $24/16 = 3/2$, carried by $\mathbf{1} \otimes T$; but the lift of θ acts there by -1 (FLM's normalisation, adopted by the library), so the lowest weight of $(V_\Lambda^T)^+$ is 2, carried by $h_a(-\frac{1}{2})\mathbf{1} \otimes T$ (dimension $24 \cdot 2^{12} = 98304$).

The frame involution J on T is $c^{-1}e_w$ for $w = 8e_0$ (`frameW`), normalised so that $J^2 = 1$. Its eigenspaces T_s (`leechFrameT s`, each of dimension 2^{11}) give (`VOA/Moonshine/CyclicTwisted.lean`) File `VOA/Moonshine/CyclicTwisted.lean`.

```
noncomputable def TPframe (s : ZMod 2) : Submodule ℂ TP := (twFrameL s).comap TP.subtype

noncomputable def frameX0T (t₀ : TLeechT) : Tw := (X (0, 0) : FockT 24) ⊗ₜ t₀
```

i.e. $T_s^+ = (V_\Lambda^T)^+ \cap (S[\theta] \otimes T_s)$, and `frameX0T t₀` is $h_0(-\frac{1}{2})\mathbf{1} \otimes t_0$ (`X (0, 0)` is the lowest creation operator of the first boson). Its copy in `TP` is called `x0T t₀` below.

Finally `TPForm` (`VOA/Moonshine/InvFormTP.lean`) is the symmetric bilinear form on $(V_\Lambda^T)^+$ obtained by restricting the invariant form of the twisted module (Chapter 37). Two of its properties are used: it is *FHL-invariant* (`TPForm_fhlInv`: for u homogeneous of weight k, the adjoint of $u_{(r)}$ is $\sum_{j\ge 0} \frac{(-1)^k}{j!}(L_1^j u)_{(2k-r-2-j)}$), and it is *nondegenerate* (`SimpleNat.TPForm_eq_zero_of_forall`, `VOA/Moonshine/SimpleForm.lean`: if $\langle t, y\rangle = 0$ for all y then $t = 0$).

40.2.5 The triality on V_0^+

Chapter 39 constructs an automorphism of V_0^+ by transporting the Dolan–Goddard–Montague triality $\sigma = G(\chi z_0)G^{-1}$ of the Golay-code lattice VOA $V_{N(A_1^{24})}$ along an isomorphism of its fixed-point subalgebra with V_0^+ (`VOA/Moonshine/FrameBridgeGolay.lean`): File `VOA/Moonshine/FrameBridgeGolay.lean`.

```
noncomputable def v0Sigma : Aut V0P :=
  Aut.transport golayToV0 golayToV0_isVOAHom golayToV0_omega golaySigma0
```

with `v0Sigma_sq : v0Sigma * v0Sigma = 1` and $\sigma \neq 1$. As an automorphism, σ fixes $\mathbf{1}$ and ω, preserves the grading, and satisfies $\sigma(u_{(n)}v) = (\sigma u)_{(n)}(\sigma v)$. The isomorphism `golayToV0` contains a character `golayE` chosen by `Classical.choose`; this matters in §40.5.1.

40.3 Zhu's algebra and the Zhu correspondence

Zhu's algebra is treated for general VOAs in Chapter 12; we recall here exactly what this chapter uses, so that every statement below can be checked without leaving the chapter.

40.3.1 Motivation: what the lowest weight space sees

Let V be a vertex operator algebra and M an ordinary V-module whose weights lie in $h + \mathbb{N}$ for some $h \in \mathbb{C}$: we say M has *lowest weight* h and call M_h its *top level*. Physically, M is a sector of a chiral conformal field theory and M_h its space of ground states; a field $Y(a,z) = \sum_n a_{(n)} z^{-n-1}$ with $a \in V_k$ moves weights by $a_{(n)} : M_\mu \to M_{\mu+k-n-1}$. Exactly one mode preserves weights,

$$o(a) \;:=\; a_{(k-1)} \qquad (a \in V_k),$$

extended linearly to all of V: the *zero mode* (the physicist's a_0). On M_h, all modes $a_{(n)}$ with $n > k-1$ vanish, since they would lower the weight below h. So the only operators V induces on M_h are the zero modes, and M_h is a module for the algebra they generate.

Zhu's insight is that this algebra is a quotient of an algebra built from V alone:

(i) the composite $o(a)o(b)$ on M_h is again a zero mode $o(a * b)$, for an explicit bilinear product $*$ on V;

(ii) an explicit subspace $\mathcal{O}(V) \subset V$ has zero modes vanishing on every top level.

Then $A(V) = V/\mathcal{O}(V)$ with $*$ is an associative algebra (Zhu's theorem) and every top level is an $A(V)$-module; conversely (the hard direction) every $A(V)$-module is the top level of some V-module.

40.3.2 The Zhu product and $\mathcal{O}(V)$

Definition 40.1 (Zhu product)**.** For $a \in V_k$ and $b \in V$,

$$a * b \;=\; \operatorname{Res}_z\, Y(a,z)\, b\, \frac{(1+z)^k}{z} \;=\; \sum_{m=0}^{k} \binom{k}{m} a_{(m-1)} b,$$

extended linearly in a over the grading.

File `VOA/Modules/ZhuAlgebra.lean`.

```
noncomputable def zhuFamily (W : VertexOperatorAlgebra 𝒱) (v : 𝒱) (k : ℤ) :
    (W.grading k) →ₗ[ℂ] 𝒱 where  toFun uk := ∑ m ∈ Finset.range (k.toNat + 1), cbz k m •
    ↪  W.smul (uk : 𝒱) ((m : ℤ) - 1) v
  ...
noncomputable def zhuMul (W : VertexOperatorAlgebra 𝒱) (u v : 𝒱) : 𝒱 :=
  letI := DirectSum.IsInternal.chooseDecomposition W.grading W.isInternal
  (DFinsupp.lsum ℂ (zhuFamily W v)) (DirectSum.decompose W.grading u)
```

(`VOA/Modules/ZhuAlgebra.lean`; the linearity proofs inside `zhuFamily` are omitted.)

From the mathematics to the Lean statement

- `W.smul u n v` is the n-th product $u_{(n)}v$, the coefficient of z^{-n-1} in $Y(u,z)v$. (Generally, `mode f n` denotes the coefficient $u_{(n)}$ of a field f.)
- `cbz k m` is the generalised binomial coefficient $\binom{k}{m}$; for $0 \le m \le k$ the ordinary one. The sum over `Finset.range (k.toNat + 1)`, i.e. $m = 0, \dots, k$, is the full residue, as $\binom{k}{m} = 0$ for $m > k \ge 0$.
- `W.grading k` is V_k, and `W.isInternal` says $V = \bigoplus_k V_k$ (`DirectSum.IsInternal`). `DirectSum.decompose` splits u into homogeneous components and `DFinsupp.lsum` applies `zhuFamily W v k` to the weight-k component and sums: "extend linearly over the grading".
- Same as the textbook definition.

Physical meaning

The Zhu product is the zero-mode algebra written at the level of states: acting with the zero mode $o(a)$ on a ground state x of any sector and then with $o(b)$ gives $o(a * b)x$ (Theorem 40.5). The binomial weighting $(1+z)^k/z$ is the radial-quantisation factor that converts the plane field $Y(a,z)$ of weight k into the cylinder field, whose constant Fourier mode is the zero mode. Heuristically, $a * b$ is the ordering-corrected product of the two zero-mode operators; it is noncommutative because $[o(a), o(b)]$ is nonzero already on ground states.

Definition 40.2 ($\mathcal{O}(V)$ and Zhu's algebra)**.** $\mathcal{O}(V)$ is the span of the elements $(L_{-1}u + L_0 u) * v$, $u, v \in V$; and $A(V) = V/\mathcal{O}(V)$.

File `VOA/Modules/ZhuAlgebra.lean`.

```
def O (W : VertexOperatorAlgebra 𝒱) : Submodule ℂ 𝒱 :=

(`VOA/Modules/ZhuAlgebra.lean`.)

From the mathematics to the Lean statement

- Zhu's original generators are $a \circ b = \mathrm{Res}_z\, Y(a,z)b\,(1+z)^k/z^2$, $a \in V_k$. The library uses Gannon's generating set $(L_{-1} + L_0)u * v$ (*Moonshine beyond the Monster*, (5.3.8c)); the library proves that Zhu's $a \circ b$ lies in this span (`residue_base_mem_O`, the case $k = 0$ of Lemma 40.3(b)). This chapter only uses that $\mathcal{O}(V)$ contains the elements listed in Lemma 40.3 and that its zero modes vanish on top levels (Theorem 40.5), both proved for the library's definition.
- `Submodule.span ℂ S` is the complex linear span of S. `W.L n` is L_n.
- $A(V)$ is introduced only as a vector space here. We do *not* need that $*$ descends to an associative product on $A(V)$; the notion of Zhu generation (Definition 40.36) is formulated on V, so it never mentions the quotient ring.

Physical meaning

$\mathcal{O}(V)$ collects the combinations that vanish as operators on every ground state: total derivatives $L_{-1}u$ combined with L_0u are exactly the states whose zero mode is zero on lowest-weight states, since $o(L_{-1}u + L_0u) = 0$ there. The quotient $A(V)$ is thus the algebra of zero modes acting on the ground states of all sectors (the Zhu algebra), and its irreducible representations are the candidate ground-state spaces of irreducible sectors. This is the standard dictionary behind "a rational VOA has finitely many sectors"; the definition itself is purely algebraic.

Lemma 40.3 (What $\mathcal{O}(V)$ contains). *Let $a \in V_p$ with $p \in \mathbb{N}$, $b \in V$, and $y \in V_w$.*

(a) $L_{-1}y + L_0y \in \mathcal{O}(V)$*; hence* $L_{-1}y + w\,y \in \mathcal{O}(V)$.

(b) (Frenkel–Zhu higher residues) For every $k \in \mathbb{N}$,

$$\mathrm{Pres}(a,p,b,k) \;:=\; \sum_{i=0}^{p+k} \binom{p+k}{i} a_{(i-2-k)}b \;=\; \mathrm{Res}_z\, Y(a,z)b\,\frac{(1+z)^{p+k}}{z^{2+k}} \;\in\; \mathcal{O}(V).$$

```
noncomputable def Pres (W : VertexOperatorAlgebra V) (M : ℕ) (a b : V) (n : ℕ) : V :=
  ∑ i ∈ Finset.range (M + n + 1), cbz ((M : ℤ) + n) (i : ℤ) • W.smul a ((i : ℤ) - 2 - n) b

theorem Pres_mem_O (W : VertexOperatorAlgebra V) {M : ℕ} {a : V}
    (ha : a ∈ W.grading (M : ℤ)) (b : V) (n : ℕ) : Pres W M a b n ∈ O W
```

(`VOA/Modules/ZhuModule.lean`.)

From the mathematics to the Lean statement

- On V_w, L_0 acts by w (`L_zero_grading`); so (a) is literally $(L_{-1} + L_0)y \in \mathcal{O}$ and its homogeneous form.
- In `Pres W M a b n`, M is the weight p of a (hypothesis `ha`) and n the depth k. The sum runs over $i = 0, \dots, M+n$ with coefficient $\binom{M+n}{i}$ and mode $i - 2 - n$: the display.

Physical meaning

Part (a) says that a field plus its derivative is an operator identity on ground states (a total z-derivative has no zero mode), and (b) is the higher-residue version of the same cancellation. Lemma-level bookkeeping in the reduction of an operator on a sector to its action on ground states.

Proof on paper. (a) Take $v = \mathbf{1}$ in the generator: $c * \mathbf{1} = c$ for every c, because only the $m = 0$ term $c_{(-1)}\mathbf{1} = c$ survives ($c_{(n)}\mathbf{1} = 0$ for $n \geq 0$). (b) For $k = 0$ this is Zhu's $a \circ b$, which is a generator rewritten with $(L_{-1}a)_{(n)} = -n\,a_{(n-1)}$. The induction on k uses the residue identity

$$(k+2)\,\mathrm{Pres}(a,p,b,k+1) \;=\; \mathrm{Pres}(L_{-1}a,\; p+1,\; b,\; k) + (p+k+1)\,\mathrm{Pres}(a,p,b,k),$$

which is integration by parts: $Y(L_{-1}a,z) = \partial_z Y(a,z)$ and $\mathrm{Res}_z\,\partial_z(\cdots) = 0$. Both terms on the right are in $\mathcal{O}$ by induction (the first with $L_{-1}a$ of weight $p+1$). □

What the machine verified

Proved, unconditional, no `VOA.pbw`.

40.3.3 Zero modes on a lowest-weight space: the easy direction

Definition 40.4 (Zero mode, lowest weight). For an ordinary module N (Lean: `OrdVModule W M`; a module graded by L_0-eigenvalues $\alpha \in \mathbb{C}$, with finite-dimensional weight spaces and weights bounded below), the zero mode of $a = \sum_k a_k$ is $o(a) = \sum_k (a_k)_{(k-1)}$. N has lowest weight h if every non-zero weight space N_α has $\alpha \in h + \mathbb{N}$.

File `VOA/Modules/Character.lean`.

```
noncomputable def oModFamily (N : OrdVModule W M) (k : ℤ) : (W.grading k) →ₗ[ℂ] End ℂ M :=

```
def IsLowestWeight (N : OrdVModule W M) (h : ℂ) : Prop :=
  ∀ α : ℂ, N.weight α ≠ ⊥ → ∃ n : ℕ, α = h + n
```

(`VOA/Modules/ZeroModeMult.lean`).

From the mathematics to the Lean statement

- `modeLinear (k - 1)` extracts the mode $(\cdot)_{(k-1)}$ of a field; `N.YM` is the module vertex operator. So `oModFamily N k` sends $a_k \in V_k$ to $(a_k)_{(k-1)}$ on N, and `oMod` sums over components.
- `N.weight α` is N_α; `≠ ⊥` means "non-zero subspace". `IsLowestWeight N h` is "every non-zero weight space has weight in $h + \mathbb{N}$". It does not require $N_h \neq 0$ (a zero module has every lowest weight); harmless, since the theorems below concern maps on N_h.

Physical meaning

The zero mode $o(a)$ is the L_0-preserving part of the field $a(z)$, the only part that maps each energy eigenspace to itself; the lowest-weight space N_h is the space of ground states (primaries) of the sector, with energy h the conformal weight of the sector. A "module of lowest weight h" is one whose energies are bounded below by the ground-state energy, as in any unitary sector with a vacuum-like lowest state; for the three sectors here the ground energy is 2 (conformal weight two states).

Theorem 40.5 (Zhu's easy direction). *Let N have lowest weight h and $x \in N_h$. For all $u, v \in V$: $o(u * v)x = o(u)o(v)x$; $o(a)x = 0$ for $a \in \mathcal{O}(V)$; $o(u)x \in N_h$; and $o(\mathbf{1}) = \mathrm{id}$.*

File `VOA/Modules/ZhuModule.lean`.

```
theorem oMod_zhuMul_lowest_all (N : OrdVModule W Mod) {h : ℂ} (hcw : IsLowestWeight N h)
    (u v : 𝒱) {x : Mod} (hx : x ∈ N.weight h) :
    oMod N (zhuMul W u v) x = oMod N u (oMod N v x)

theorem O_le_ker_rhoLW (N : OrdVModule W Mod) {h : ℂ} (hcw : IsLowestWeight N h) :
    O W ≤ LinearMap.ker (rhoLW N h)
```

(`VOA/Modules/ZhuModule.lean`), together with `oMod_preserves_lowest_all` (same file) and `oMod_vacuum : oMod N W.vacuum = LinearMap.id` (`VOA/Modules/Character.lean`).

From the mathematics to the Lean statement

`rhoLW N h` is the linear map $V \to \mathrm{End}(N_h)$, $a \mapsto o(a)|_{N_h}$; "$\mathcal{O}(V) \le \ker$" is $o(a)|_{N_h} = 0$ for $a \in \mathcal{O}(V)$. All u, v are arbitrary and h is any complex number: the textbook statement.

Physical meaning

This is the statement that the ground states of a sector form a representation of the Zhu algebra: the zero modes act on the ground states, kill $\mathcal{O}(V)$, and multiply as the Zhu product. Physically it expresses that the algebra of zero modes preserves the ground-state space, and that the OPE collapses, on ground states, to the associative algebra $A(V)$. The converse (the "hard direction", that every $A(V)$-module is the ground-state space of a sector) is the Verma-type reconstruction and is deliberately avoided in this chapter.

Proof on paper. For homogeneous $u \in V_k$, the Borcherds identity expresses each mode of $u_{(m-1)}v$ as a combination of products $u_{(i)}v_{(j)}$ and $v_{(j)}u_{(i)}$. On N_h, every product in which the right-hand factor lowers the weight vanishes; after summing over m with the coefficients $\binom{k}{m}$ of $*$, binomial identities collapse the surviving terms to $o(u)o(v)$. This is Zhu (1996), Theorem 2.1.2 (Gannon (5.3.9a)); linearity extends it to all u, v. For $\mathcal{O}$: translation covariance $(L_{-1}u)_{(n)} = -n\,u_{(n-1)}$ gives $o(L_{-1}u) = (L_{-1}u)_{(k)} = -k\,u_{(k-1)}$, so $o((L_{-1}+L_0)u) = 0$, and then $o(((L_{-1}+L_0)u) * v)x = o((L_{-1}+L_0)u)\,o(v)x = 0$. □

What the machine verified

All proved, unconditional, `#print axioms`-clean, no `VOA.pbw`.

40.3.4 The hard direction, and why this chapter avoids it

Zhu's theorem has a converse: from an $A(V)$-module U one builds a V-module $L(U)$ with top level U, the irreducible quotient of a generalised Verma module $M(U)$ (Dong–Li–Mason; the library follows Dong–Jiang, Chapter 13). The classical way to build a module map out of a module generated by its top level uses this converse: if source and target are irreducible quotients of Verma modules, a map of top levels lifts.

Trap / dead end

The Verma-module route is not `VOA.pbw`-free (history). The library's Dong–Jiang construction carries a hypothesis `BottomProjection` (`VOA/Modules/ZhuVermaAnArchDLM3Survival.lean`), whose only supplier for a general VOA is `voaPBWBottomProjection`, i.e. `VOA.pbw` — at the time an axiom (it has since become a theorem). Using it would then have made σ, and hence the Moonshine module, depend on an axiom. This chapter therefore proves directly the weaker statement actually needed (§40.6), using Li's lemma and a nondegenerate form on the *target* only. The final construction of $V^\natural$ is `VOA.pbw`-free (checked by `#print axioms`).

40.3.5 Examples

Example 40.6 (Rank-one Heisenberg). For the Heisenberg VOA $M(1)$ of one boson h, $A(M(1)) \cong \mathbb{C}[x]$ with $x = [h(-1)\mathbf{1}]$: the top of the Fock module of momentum λ is $\mathbb{C}e^\lambda$ and $o(h) = h(0)$ acts by λ. The fixed-point algebra $M(1)^+$ under $h \mapsto -h$ is generated by ω and a weight-four primary J (Dong–Nagatomo), and $A(M(1)^+)$ needs $[J]$ besides $[\omega]$: weight two alone does *not* generate. In

§40.11 this rank-one obstruction re-appears as a one-dimensional deficiency at weight 4, and we see why it disappears in rank ≥ 3. Concretely: in rank one, the products allowed by the filtered criterion of §40.9 span a codimension-one subspace of the weight-4 part of $M(1)^+$, the missing direction being that of J.

Example 40.7 (Lattice VOA tops)**.** For a lattice VOA V_L and its module $V_{L+\lambda}$, the top level is spanned by e^μ with $\mu \in L+\lambda$ of minimal norm. For $\gamma \in L$ the zero mode $o(e^\gamma) = e^\gamma_{(|\gamma|^2/2-1)}$ sends e^μ to $\epsilon(\gamma,\mu)e^{\mu+\gamma}$ if $\langle\gamma,\mu\rangle = -\frac{1}{2}|\gamma|^2$ (equivalently $|\mu+\gamma|^2 = |\mu|^2$) and to 0 if $\langle\gamma,\mu\rangle > -\frac{1}{2}|\gamma|^2$; the case $\langle\gamma,\mu\rangle < -\frac{1}{2}|\gamma|^2$ cannot occur, since $\mu+\gamma \in L+\lambda$ would be shorter than μ. For V_0^+ acting on V_3^+ this is the computation behind §40.8: the weight-two lattice states $e^\gamma + e^{-\gamma}$, $|\gamma|^2 = 4$, move the top vectors e^n, $|n|^2 = 4$, to $e^{n+\gamma}$ exactly when $\langle\gamma, n\rangle = -2$.

40.4 Twisted intertwiners and the existence criterion

This section is pure linear algebra; no vertex algebra appears. It isolates the device by which σ will be *defined*: a map determined by its value on one vector, which exists as soon as that value respects every linear relation.

40.4.1 The abstract setting

Fix a set $\mathcal{A}$ of "letters" (later: the states of V_0^+), complex vector spaces M, N, actions $\rho : \mathcal{A}\times\mathbb{Z} \to \mathrm{End}(M)$, $(u,n) \mapsto \rho_{u,n}$, and $\tau : \mathcal{A}\times\mathbb{Z} \to \mathrm{End}(N)$ (later: $\rho_{u,n} = u_{(n)}$ on the source and $\tau_{u,n} = u_{(n)}$ on the target), and a map $g : \mathcal{A} \to \mathcal{A}$ (later: σ).

Definition 40.8 (Twisted intertwiner)**.** Let $S \subseteq \mathcal{A}$ and $X \leq M$. A linear map $\Phi : M \to N$ is a *g-twisted intertwiner on X for the letters S* if $\Phi(\rho_{u,n}x) = \tau_{g(u),n}\Phi(x)$ for all $u \in S$, $n \in \mathbb{Z}$, $x \in X$.

File `VOA/Moonshine/TrialityTwGeneric.lean`.

```
def IsTwInt (ρ : A → ℤ → M →ₗ[ℂ] M) (τ : A → ℤ → N →ₗ[ℂ] N) (g : A → A) (S : Set A)
    (X : Submodule ℂ M) (Φ : M →ₗ[ℂ] N) : Prop :=
  ∀ u ∈ S, ∀ (n : ℤ), ∀ x ∈ X, Φ (ρ u n x) = τ (g u) n (Φ x)
```

(`VOA/Moonshine/TrialityTwGeneric.lean`, namespace `VOA.Moonshine.TrialityTw`.)

From the mathematics to the Lean statement

- `M →ₗ[ℂ] N` is the type of $\mathbb{C}$-linear maps; `Submodule ℂ M` a subspace. The Lean variable `A` is the letter set $\mathcal{A}$ (no structure assumed).
- Φ is defined on all of M but the condition is imposed only for $x \in X$; values off X are irrelevant. Harmless and convenient, since the sectors are subspaces of bigger carriers.
- Stability $\rho_{u,n}X \subseteq X$ is not part of the definition; theorems that need it assume it (`hstab`).

Physical meaning

A g-twisted intertwiner is a linear map between two sectors that carries the field modes of one to the modes of the other twisted by the symmetry g: the picture is a symmetry operator U_g implementing $\Phi u_{(n)}\Phi^{-1} = g(u)_{(n)}$. When g is the triality σ and the two sectors are different, such a map is the object that realises σ as a symmetry of the combined theory, and it is what "extending the triality to the twisted sector" means concretely. The trivial map $\Phi = 0$ always satisfies the definition, which is the origin of the $\varphi = 0$ trap discussed later; the definition alone carries no nonzero content.

40.4.2 Uniqueness and involutivity from a cyclic vector

Theorem 40.9 (Uniqueness). *Suppose $x_0 \in X$ and $X = \mathrm{span}\{\rho_{u,n}x_0 : u \in S,\ n \in \mathbb{Z}\}$. If Φ, Ψ are g-twisted intertwiners on X with $\Phi(x_0) = \Psi(x_0)$, then $\Phi = \Psi$ on X.*

File `VOA/Moonshine/TrialityTwGeneric.lean`.

```
theorem eqOn_of_cyclic {x₀ : M} (hx₀ : x₀ ∈ X)
    (hcyc : span ℂ {y | ∃ u ∈ S, ∃ n : ℤ, y = ρ u n x₀} = X) {Φ Ψ : M →ₗ[ℂ] N}
    (hΦ : IsTwInt ρ τ g S X Φ) (hΨ : IsTwInt ρ τ g S X Ψ) (h : Φ x₀ = Ψ x₀) :
    ∀ x ∈ X, Φ x = Ψ x
```

From the mathematics to the Lean statement

`hcyc` is *single-mode* cyclicity: X is spanned by vectors with *one* letter applied to x_0, not by arbitrary words. This is stronger than ordinary cyclicity, and it is what the library proves for V_3^+ and T_s^+ (Chapter 39). Otherwise the statement is the textbook one.

Physical meaning

If a sector is generated from one state by the modes of the fields (a cyclic vector, such as a highest-weight state), then a symmetry operator is already determined by its value on that state, since its action on all the descendants is forced by the intertwining relation. This is the usual reconstruction of a representation from its ground states, and it is why the existence problem for the triality reduces to specifying a single image vector.

Proof on paper. On a spanning vector, $\Phi(\rho_{u,n}x_0) = \tau_{gu,n}\Phi(x_0) = \tau_{gu,n}\Psi(x_0) = \Psi(\rho_{u,n}x_0)$; both maps are linear. □

Theorem 40.10 (Involutivity criterion). *Let Φ be g-twisted on X with $\Phi(X) \subseteq Y$, $\Psi : N \to M$ be g'-twisted on Y for letters $S' \supseteq g(S)$, and $g'(g(u)) = u$ for $u \in S$. If X is single-mode cyclic on x_0 and $\Psi\Phi(x_0) = x_0$, then $\Psi\Phi = \mathrm{id}$ on X.*

File `VOA/Moonshine/TrialityTwGeneric.lean`.

```
theorem comp_eqOn_id {Φ : M →ₗ[ℂ] N} {Ψ : N →ₗ[ℂ] M} {x₀ : M} (hx₀ : x₀ ∈ X)

    ∀ x ∈ X, Ψ (Φ x) = x
```

From the mathematics to the Lean statement

Every hypothesis appears in the statement; in the application $g = g' = \sigma$, $\sigma^2 = 1$.

Physical meaning

Applying the symmetry twice should return the original state; if the composite fixes the cyclic ground state and the labels satisfy $g'g = 1$, it is the identity on the whole sector. Physically this is the statement that $\sigma^2 = 1$ on the sectors follows from checking it on one ground state, and it is the algebraic form of "σ is an involution".

Proof on paper. $\Psi\Phi$ is $(g' \circ g)$-twisted, i.e. untwisted: $\Psi\Phi\rho_{u,n}x = \Psi\tau_{gu,n}\Phi x = \rho_{g'gu,n}\Psi\Phi x$. So is the identity; they agree at x_0; apply Theorem 40.9. □

What the machine verified

Both proved, unconditional.

40.4.3 Words and annihilator compatibility

A *word* is a finite list $w = [(u_1, n_1), \dots, (u_k, n_k)]$ with $u_i \in S$, acting by $\rho_w = \rho_{u_1,n_1} \circ \cdots \circ \rho_{u_k,n_k}$; its twist is $g(w) = [(gu_1, n_1), \dots, (gu_k, n_k)]$. A formal combination $f = \sum_w f(w)\, w$ evaluates as $\mathrm{ev}_{x_0}(f) = \sum_w f(w)\rho_w x_0$, and twisted as $\mathrm{ev}^g_{y_0}(f) = \sum_w f(w)\tau_{g(w)}y_0$.

Definition 40.11 (Annihilator compatibility). (x_0, y_0) is *annihilator-compatible* if $\ker \mathrm{ev}_{x_0} \subseteq \ker \mathrm{ev}^g_{y_0}$: every relation $\sum_w f(w)\rho_w x_0 = 0$ implies $\sum_w f(w)\tau_{g(w)}y_0 = 0$.

File `VOA/Moonshine/TrialityTwGeneric.lean`.

```

def AnnCompat (ρ : A → ℤ → M →ₗ[ℂ] M) (τ : A → ℤ → N →ₗ[ℂ] N) (g : A → A) (S : Set A)
    (x₀ : M) (y₀ : N) : Prop :=
  LinearMap.ker (evW ρ S x₀) ≤ LinearMap.ker (evTw τ g S y₀)
```

From the mathematics to the Lean statement

- `Words S →₀ ℂ` is the space of finitely supported functions from words to $\mathbb{C}$, i.e. formal finite combinations of words; `Finsupp.linearCombination ℂ v` is $f \mapsto \sum_w f(w)v(w)$.
- `wordAct ρ (p :: w)` is $\rho_p \circ \rho_w$: the first letter of the list is outermost. The twist changes letters and keeps mode indices. So `evW`, `evTw` are ev_{x_0}, $\mathrm{ev}^g_{y_0}$, and `AnnCompat` is the kernel inclusion, literally.

Physical meaning

Annihilator compatibility says that the choice of image state is consistent: every relation among descendants of the source ground state (a null-vector-type relation) is respected by the twisted descendants of the proposed image. It is the algebraic analogue of requiring that a candidate map between sectors respects the null states, the usual obstruction to defining an intertwiner from a ground-state assignment. Heuristic reading only; the precise statement is the displayed condition on kernels.

Theorem 40.12 (Existence ⇔ annihilator compatibility). *Suppose $\rho_{u,n}X \subseteq X$ for $u \in S$, $x_0 \in X$, and X is single-mode cyclic on x_0. For every $y_0 \in N$, a g-twisted intertwiner Φ on X with $\Phi(x_0) = y_0$ exists if and only if (x_0, y_0) is annihilator-compatible.*

File `VOA/Moonshine/TrialityTwGeneric.lean`.

```
theorem exists_twInt_iff (hstab : ∀ u ∈ S, ∀ (n : ℤ), ∀ x ∈ X, ρ u n x ∈ X) {x₀ : M}
    (hx₀ : x₀ ∈ X) (hcyc : span ℂ {y | ∃ u ∈ S, ∃ n : ℤ, y = ρ u n x₀} = X) (y₀ : N) :
    (∃ Φ : M →ₗ[ℂ] N, IsTwInt ρ τ g S X Φ ∧ Φ x₀ = y₀) ↔ AnnCompat ρ τ g S x₀ y₀
```

From the mathematics to the Lean statement

- Hypotheses: stability (`hstab`), `hx₀`, cyclicity (`hcyc`) — all about the *source*. Nothing is assumed about y_0 or N.
- Non-vacuity: for $y_0 = 0$ the right side is trivially true and $\Phi = 0$ works. The content is existence for a prescribed *non-zero* y_0; this is why the top-level residual of §40.6 carries a non-triviality clause.

Physical meaning

This is the existence half of the ground-state reconstruction: an operator between sectors extending a given assignment on the ground state exists exactly when no null relation of the source is violated by the target. The twisted triality on a sector is thus equivalent to a finite-looking consistency check on one pair of states, and the chapter's strategy is to verify that check only through the ground states and a handful of light fields.

Proof on paper. ($\Rightarrow$) A twisted intertwiner sends $\rho_w x_0$ to $\tau_{g(w)}\Phi(x_0)$ (induction on the length of w, stability keeping us in X), so $\Phi \circ \mathrm{ev}_{x_0} = \mathrm{ev}^g_{y_0}$ and kernels are included. ($\Leftarrow$) The range of ev_{x_0} is X: it contains the one-letter words $\rho_{u,n}x_0$ and is contained in X by stability. Define $\Phi_0(\mathrm{ev}_{x_0} f) = \mathrm{ev}^g_{y_0} f$ on X; well defined by the kernel inclusion. Extend linearly to M (choose a complement). If $x = \mathrm{ev}_{x_0} f$, prepending (u, n) to every word of f gives f' with $\rho_{u,n} x = \mathrm{ev}_{x_0} f'$ and $\mathrm{ev}^g_{y_0} f' = \tau_{gu,n} \mathrm{ev}^g_{y_0} f$: the intertwining property. The empty word gives $\Phi(x_0) = y_0$. □

What the machine verified

`IsTwInt`, `eqOn_of_cyclic`, `comp_eqOn_id`, `AnnCompat`, `exists_twInt_iff`: proved, unconditional; `#print axioms exists_twInt_iff` = [`propext`, `Classical.choice`, `Quot.sound`] (rerun). `Classical.choice` enters through the choice of a complement.

Theorem 40.13 (Gram criterion). *Let B_1, B_2 be bilinear forms on M, N. If $B_1(\rho_{w'}x_0, \rho_w x_0) = B_2(\tau_{g(w')}y_0, \tau_{g(w)}y_0)$ for all words w, w', and B_2 is nondegenerate on the span of the twisted word vectors, then (x_0, y_0) is annihilator-compatible.*

      = B₂ (wordAct τ (twWord g w'.1) y₀) (wordAct τ (twWord g w.1) y₀))
    (hnd : ∀ y ∈ LinearMap.range (evTw τ g S y₀),
      (∀ y' ∈ LinearMap.range (evTw τ g S y₀), B₂ y' y = 0) → y = 0) :
    AnnCompat ρ τ g S x₀ y₀
```

From the mathematics to the Lean statement

`hnd` is nondegeneracy of B_2 on the range of $\mathrm{ev}^g_{y_0}$. This criterion is *not* used for σ: it would need source Gram data too; the route taken (§40.6) needs a form on the target only.

Physical meaning

If the two-point functions (Gram matrices) of the descendants agree between the source ground state and the proposed image, and the target pairing is nondegenerate, then no relation can be violated. This is the physicist's route of checking that an operator is an isometry on a basis of states; the chapter records it as a clean criterion but does not use it on the path to the main result.

Proof on paper. If $\mathrm{ev}_{x_0} f = 0$ then $B_2(\mathrm{ev}^g f', \mathrm{ev}^g f) = B_1(\mathrm{ev} f', \mathrm{ev} f) = 0$ for every f'; nondegeneracy gives $\mathrm{ev}^g f = 0$. □

What the machine verified

Proved, unconditional. Not on the path to $V^\natural$.

40.5 The triality problem on the library's sectors

Definition 40.14 (The actions). For $u \in V_0^+$, $n \in \mathbb{Z}$: $\mathrm{act}_V(u,n) = u_{(n)}$ on V_Λ^+ (adjoint action), $\mathrm{act}_T(u,n) = u_{(n)}$ on $(V_\Lambda^T)^+$ (module action), and $\mathrm{sig}(u) = \sigma(u)$.

File `VOA/Moonshine/TrialityTwSigma.lean`.

```
noncomputable def actV (u : V0Sub.carrier) (n : ℤ) : VPlus →ₗ[ℂ] VPlus :=
  mode (leechVOAPlus.Y (u : VPlus)) n

noncomputable def actT (u : V0Sub.carrier) (n : ℤ) : TP →ₗ[ℂ] TP :=
  mode (Moonshine.plusModule.YM (u : VPlus)) n

noncomputable def sig (u : V0Sub.carrier) : V0Sub.carrier := v0Sigma u
```

(`VOA/Moonshine/TrialityTwSigma.lean`, namespace `VOA.Moonshine.TrialityTw`.)

From the mathematics to the Lean statement

`mode (Y a) n` is $a_{(n)}$. The letter $u \in V_0^+$ is coerced to V_Λ^+ to act; so act_V is the vertex operator of V_Λ^+ restricted to V_0^+-letters. `sig_sig : sig (sig u) = u` records $\sigma^2 = 1$.

Physical meaning

These are the three ways the weight-zero algebra V_0^+ (the even sublattice vertex algebra) acts on the neutral/charged and twisted sectors: through its own fields on V_Λ^+, through its modes on the twisted sector $(V_\Lambda^T)^+$, and through the triality automorphism σ relabelling the fields. In the orbifold picture V_Λ^+ and the twisted sectors T_s^+ are the untwisted and twisted sectors of the same $\mathbb{Z}_2$ orbifold, and σ is the symmetry permuting them.

Lemma 40.15 (Stability). *V_3^+ and each T_s^+ are stable under all $u_{(n)}$, $u \in V_0^+$.*

File `VOA/Moonshine/TrialityTwSigma.lean`.

```
theorem actV_stab : ∀ u ∈ (Set.univ : Set V0Sub.carrier), ∀ (n : ℤ),
    ∀ x ∈ frameSector 1, actV u n x ∈ frameSector 1

theorem actT_stab (s : ZMod 2) : ∀ u ∈ (Set.univ : Set V0Sub.carrier), ∀ (n : ℤ),
    ∀ x ∈ TPframe s, actT u n x ∈ TPframe s
```

Physical meaning

The charged piece V_3^+ and each twisted piece T_s^+ are closed under the modes of the fields of V_0^+, so they are genuine sub-sectors (superselection sectors) of the larger space. Technical bookkeeping step: it ensures that "act on a sector by a field mode" stays inside the sector.

Proof on paper. g (resp. J) is compatible with the vertex operators ($gY(u,z)g^{-1} = Y(gu,z)$, and on the twisted module $JY(u,z)J^{-1} = Y(gu,z)$, Chapter 39) and fixes $u \in V_0^+$; so $u_{(n)}$ commutes with it and preserves its eigenspaces. □

What the machine verified

Proved, unconditional.

Theorem 40.16 (Cyclicity of the sectors). *(a) If $\beta \in \Lambda \setminus \Lambda_0$, then $V_3^+ = \mathrm{span}\{u_{(n)}x_\beta : u \in V_0^+, n \in \mathbb{Z}\}$. (b) If $0 \neq t_0 \in T_s$, then $T_s^+ = \mathrm{span}\{u_{(n)}x_{t_0} : u \in V_0^+, n \in \mathbb{Z}\}$, where $x_{t_0} = h_0(-\frac{1}{2})\mathbf{1} \otimes t_0$.*

File `VOA/Moonshine/TrialityTwSigma.lean`.

```
theorem cyc_V3 {β : leech.carrier} (hβ : β ∉ lambda0) :
    Submodule.span ℂ {y | ∃ u ∈ (Set.univ : Set V0Sub.carrier), ∃ n : ℤ, y = actV u n
     ↪ (frameX0P β)}
      = frameSector 1

noncomputable def x0T (t₀ : TLeechT) : TP := ⟨frameX0T t₀, frameX0T_mem_TP t₀⟩

theorem cyc_T {s : ZMod 2} {t₀ : TLeechT} (ht₀ : t₀ ∈ leechFrameT s) (h0 : t₀ ≠ 0) :
    Submodule.span ℂ {y | ∃ u ∈ (Set.univ : Set V0Sub.carrier), ∃ n : ℤ, y = actT u n (x0T
     ↪ t₀)}
      = TPframe s
```

From the mathematics to the Lean statement

These restate `span_smul_frameX0` (`VOA/Moonshine/CyclicFrameSectors.lean`) and `span_smul_frameX0T` (`VOA/Moonshine/CyclicTwisted.lean`), proved in Chapter 39, with letters typed as elements of V_0^+. The hypotheses ($\beta \notin \Lambda_0$; $t_0 \in T_s$, $t_0 \neq 0$) are exactly that the vector lies in the sector and is non-zero.

Physical meaning

Each sector is generated from a single ground state by the field modes: the charged sector V_3^+ from the vertex-operator state x_β of a vector $\beta \notin \Lambda_0$ (a nonzero charge), and each twisted sector from a nonzero twisted ground state x_{t_0}. This is the standard statement that a sector is an irreducible module built on its ground state, and it is what lets the intertwiner be specified by a single image vector.

What the machine verified

Proved, unconditional.

Definition 40.17 (σ-twisted maps on the sectors). A linear $\Phi : V_\Lambda^+ \to (V_\Lambda^T)^+$ is *σ-twisted on V_3^+* if $\Phi(u_{(n)}x) = (\sigma u)_{(n)}\Phi(x)$ for all $u \in V_0^+$, $n \in \mathbb{Z}$, $x \in V_3^+$; similarly $\Phi : (V_\Lambda^T)^+ \to (V_\Lambda^T)^+$ on T_s^+, and $\Phi : (V_\Lambda^T)^+ \to V_\Lambda^+$ on T_s^+. (This is Definition 40.8 with $\rho, \tau \in \{\mathrm{act}_V, \mathrm{act}_T\}$, $g = \sigma$ and all letters.)

File `VOA/Moonshine/TrialityTwSigma.lean`.

```
def IsSigmaV3T (Φ : VPlus →ₗ[ℂ] TP) : Prop :=
  IsTwInt actV actT sig Set.univ (frameSector 1) Φ

def IsSigmaTT (s : ZMod 2) (Φ : TP →ₗ[ℂ] TP) : Prop :=
  IsTwInt actT actT sig Set.univ (TPframe s) Φ

def IsSigmaTV (s : ZMod 2) (Φ : TP →ₗ[ℂ] VPlus) : Prop :=
  IsTwInt actT actV sig Set.univ (TPframe s) Φ
```

From the mathematics to the Lean statement

- Letters `Set.univ`: all of V_0^+ and every mode. This is the full condition (40.2), not a weakening to generators.
- The definition does not fix the target sector; which sector is hit is part of the data of the existence theorems, and is not determined by the library's definitions (§40.5.1).
- Trap: $\Phi = 0$ satisfies all three definitions; the existence theorems therefore also assert that Φ hits a cyclic vector.

Physical meaning

This is the twisted-intertwiner condition of Definition 40.8 specialised to the triality: a map between the sectors V_3^+, T_s^+, V_Λ^+ that sends every mode $u_{(n)}$ to the mode of the triality-rotated field $\sigma(u)_{(n)}$. A nonzero such map is the operator implementing the triality symmetry across the sectors; the zero map also qualifies, which is the $\varphi = 0$ trap.

Theorem 40.18 (Uniqueness and weight preservation). *(a) A σ-twisted map on V_3^+ is determined by its value at x_β ($\beta \notin \Lambda_0$); on T_s^+ by its value at x_{t_0} ($0 \neq t_0 \in T_s$). (b) Every such map commutes with L_0.*

File `VOA/Moonshine/TrialityTwSigma.lean`.

```
theorem IsSigmaV3T.eqOn {β : leech.carrier} (hβ : β ∉ lambda0) {Φ Ψ : VPlus →ₗ[ℂ] TP}
    (hΦ : IsSigmaV3T Φ) (hΨ : IsSigmaV3T Ψ) (h : Φ (frameX0P β) = Ψ (frameX0P β)) :

theorem IsSigmaV3T.L0_comm {Φ : VPlus →ₗ[ℂ] TP} (hΦ : IsSigmaV3T Φ) {x : VPlus}
    (hx : x ∈ frameSector 1) :
    Φ (mode (leechVOAPlus.Y leechVOAPlus.conformalVector) 1 x)
      = mode (Moonshine.plusModule.YM leechVOAPlus.conformalVector) 1 (Φ x)
```

From the mathematics to the Lean statement

$L_0 = \omega_{(1)}$, so `mode (Y ω) 1` is L_0. The conformal vector of V_0^+ is that of V_Λ^+, and $\sigma\omega = \omega$ (`sig_omega`): the whole content of (b). `IsSigmaTT.L0_comm` and `IsSigmaTV.eqOn` are analogous.

Physical meaning

The triality map on a sector is fixed by the image of one ground state (uniqueness by cyclicity), and it commutes with L_0, i.e. it preserves energy because σ fixes the stress tensor. This reflects the fact that symmetry operators commute with the Hamiltonian and are fixed by their action

on the lowest states.

Proof on paper. (a) Theorem 40.9 with Theorem 40.16. (b) The intertwining property for the letter ω at mode 1, with $\sigma\omega = \omega$. □

What the machine verified

Proved, unconditional.

Theorem 40.19 (Existence criterion on the sectors). *For $\beta \notin \Lambda_0$ and $y_0 \in (V_\Lambda^T)^+$: a σ-twisted Φ on V_3^+ with $\Phi(x_\beta) = y_0$ exists iff (x_β, y_0) is annihilator-compatible for $(\mathrm{act}_V, \mathrm{act}_T, \sigma)$ with all letters. Likewise on T_s^+ with x_{t_0}.*

File `VOA/Moonshine/TrialityTwSigma.lean`.

```
theorem sigmaV3T_exists_iff {β : leech.carrier} (hβ : β ∉ lambda0) (y₀ : TP) :
    (∃ Φ : VPlus →ₗ[ℂ] TP, IsSigmaV3T Φ ∧ Φ (frameX0P β) = y₀)
      ↔ AnnCompat actV actT sig Set.univ (frameX0P β) y₀

theorem sigmaTT_exists_iff {s : ZMod 2} {t₀ : TLeechT} (ht₀ : t₀ ∈ leechFrameT s) (h0 : t₀
↪  ≠ 0)
    (y₀ : TP) :
    (∃ Φ : TP →ₗ[ℂ] TP, IsSigmaTT s Φ ∧ Φ (x0T t₀) = y₀)
      ↔ AnnCompat actT actT sig Set.univ (x0T t₀) y₀
```

Physical meaning

The triality can be extended to a sector, sending the chosen ground state to a given target state, if and only if the target state obeys the same null relations as the source; this is the sector-level version of the extension criterion above. The physical content is that nothing beyond a consistency check on the ground states is needed to define the symmetry operator on the whole sector.

Proof on paper. Theorem 40.12 with Lemma 40.15 and Theorem 40.16. □

What the machine verified

Proved, unconditional (`sigmaTV_exists_iff` likewise).

Theorem 40.20 (Involutivity on the sectors). *If Φ is σ-twisted on V_3^+ with $\Phi(V_3^+) \subseteq T_s^+$, Ψ is σ-twisted from T_s^+ to V_Λ^+, and $\Psi\Phi(x_\beta) = x_\beta$, then $\Psi\Phi = \mathrm{id}$ on V_3^+. Similarly (`sigma_involutive_TT`) $\Phi\Phi = \mathrm{id}$ on T_s^+ if $\Phi\Phi(x_{t_0}) = x_{t_0}$.*

File `VOA/Moonshine/TrialityTwSigma.lean`.

```
theorem sigma_involutive_V3 {β : leech.carrier} (hβ : β ∉ lambda0) {s : ZMod 2}

    (hmap : ∀ x ∈ frameSector 1, Φ x ∈ TPframe s) (h : Ψ (Φ (frameX0P β)) = frameX0P β) :
    ∀ x ∈ frameSector 1, Ψ (Φ x) = x
```

Physical meaning

Applying the triality operator twice returns the identity on the sector, once one checks it on the ground state. This is the sector-level statement $\sigma^2 = 1$, necessary for σ to define a $\mathbb{Z}_2$ symmetry (rather than a larger group) of the combined sectors.

Proof on paper. Theorem 40.10 with $g = g' = \sigma$. □

What the machine verified

Proved, unconditional.

40.5.1 Which twisted sector is T_0? An undetermined label

FLM's σ maps V_3^+ to the twisted summand whose central character is shared with the twisted module of the Golay lattice $N(A_1^{24})$ (the "common summand" X_0). One would like to say which of `TPframe 0`, `TPframe 1` that is. The library's definitions do not determine it.

Theorem 40.21 (`golayE` is not determined at w). *Let ψ be the lift of -1 to V_{Λ_0} used to build `v0Sigma`, θ the standard lift, and g_e the automorphism $p \otimes e^\gamma \mapsto e(\gamma)p \otimes e^\gamma$ given by a character e of Λ_0. There are characters e_1, e_2 with $\psi = g_{e_i}\theta g_{e_i}^{-1}$ for both i, and $w_0 \in \Lambda_0$ mapping to $w = 8e_0$, with $e_2(w_0) = -e_1(w_0)$.*

File `VOA/Moonshine/TrialityTwSigma.lean`.

```
theorem golayE_not_determined :
    ∃ e₁ e₂ : lam0.carrier →+ Additive ℂˣ,
      (∀ x, lam0Psi x = charLat lam0 e₁ (thetaLat lam0 (charLat lam0 (-e₁) x))) ∧
      (∀ x, lam0Psi x = charLat lam0 e₂ (thetaLat lam0 (charLat lam0 (-e₂) x))) ∧
      ∃ w₀ : lam0.carrier, inclΛ w₀ = frameW ∧ charVal lam0 e₂ w₀ = -charVal lam0 e₁ w₀
```

(`VOA/Moonshine/TrialityTwSigma.lean`.)

From the mathematics to the Lean statement

- `lam0` is Λ_0 as an abstract lattice, with inclusion `inclΛ` into Λ. A character $\Lambda_0 \to \mathbb{C}^\times$ is typed additively (`→+ Additive ℂˣ`); `charVal` evaluates it; `charLat lam0 e` is g_e on V_{Λ_0}, and `-e` the inverse character; `lam0Psi` is ψ.
- The first two clauses: both e_1, e_2 satisfy the specification (`exists_golayE`) from which `golayE` was chosen. The last: they disagree in sign at the preimage of w.
- An existence statement about the specification, not a defect of `v0Sigma`; its consequence (a design constraint) is argued on paper below.

Physical meaning

The sign character e on the sublattice Λ_0 is a choice of discrete torsion, and the theorem records that the library's lift of -1 does not determine which of two characters labels the twisted sector T_0; the two choices differ by a sign on the lattice vector w. It is the analogue of the familiar ambiguity of discrete torsion in an orbifold: two labelings of the twisted sector agree on all data the library fixes but disagree on a coset sign, so one must not assume a particular labeling. A warning rather than a construction.

Proof on paper. Take $e_1 =$ `golayE` and $e_2 = e_1 e_\beta$, $e_\beta(a) = (-1)^{\langle\beta,\iota a\rangle}$ with $\beta = u = (5, 1^{23})$. The specification only sees e^2, because $g_e\theta g_e^{-1} = g_{e^2}\theta$, and $e_\beta^2 = 1$. And $\langle u, w\rangle = 5 \cdot 8/8 = 5$ is odd, so $e_\beta(w_0) = -1$. □

What the machine verified

Proved, unconditional.

Consequence (argued on paper, `Notes/TrialityTwisted.md` §3). Replacing `golayE` by e_2 conjugates `v0Sigma` by the restriction of $g_\beta = (-1)^{\langle\beta,\cdot\rangle}$, which extends to $V^\natural$ as $g_\beta \oplus (1 \otimes e_\beta)$. This

fixes V_3^+ but, since $\langle\beta, w\rangle$ is odd, e_β anticommutes with e_w and swaps `TPframe 0` and `TPframe 1`. If $\Phi : V_3^+ \to T_s^+$ is σ_{e_1}-twisted, $(1 \otimes e_\beta)\Phi g_\beta^{-1} : V_3^+ \to T_{s+1}^+$ is σ_{e_2}-twisted. As the two sectors are non-isomorphic, exactly one s works for each choice, and the choices give different s: the answer is a hidden bit of `Classical.choose`.

Trap / dead end

Do not try to prove $\sigma(V_3^+) =$ `TPframe 0` (or `TPframe 1`). It is not determined by the definitions. Downstream statements are phrased with "$\exists s$" (`sigmaV3T_exists_of_top'` below, `topSigma_both` in Chapter 41). This costs nothing for $V^\natural$: one needs some sector and the intertwining identities, not its name.

40.6 From the top level to the whole module

Theorem 40.19 reduces the existence of σ on V_3^+ to an annihilator compatibility, but that compatibility quantifies over *all* words in *all* modes of *all* states of V_0^+. This section reduces it to a statement on the top level. The section has a generic part (any VOA W, any two weak modules) and a Leech part.

40.6.1 The idea

Classically one argues: V_3^+ is generated by its top level $\Omega = (V_3^+)_2$; a module generated by its top level is a quotient of the generalised Verma module $M(\Omega)$; if the target is irreducible, a top-level isomorphism lifts. We replace the Verma module by a direct argument about the *graph* of the top-level map.

Let A (source) and B (target, already twisted by σ) be weak W-modules, $\varphi : A \to B$ a linear map, and $\Omega \le A$ the top level. Consider in $A \oplus B$ the submodule Z generated by the graph $\Gamma = \{(x, \varphi x) : x \in \Omega\}$. If Z contains no non-zero vector of the form $(0, y)$, then Z is itself the graph of a module map Φ extending φ: that is annihilator compatibility. To show $Z \cap (0 \oplus B) = 0$:

1. (Li's lemma) Z is spanned by *single modes* $(a_{(q)}x,\ a_{(q)}\varphi x)$, $x \in \Omega$.

2. On a single mode, the only part of $a_{(q)}\varphi x$ that an invariant form can pair with $\varphi\Omega$ is its weight-two part, and there it equals $\varphi(o(a)x)$ by the top-level hypothesis. So for $(0, y) \in Z$, y is orthogonal to $\varphi\Omega$.

3. Invariance of the form moves any test vector $c_{(r)}\varphi x'$ back onto $\varphi x'$ (the adjoint of a mode is a combination of modes, and Z is a submodule), so y is orthogonal to the whole target sector.

4. Nondegeneracy of the form on the target sector gives $y = 0$.

Only the *target* needs a form.

40.6.2 Sums and twists of weak modules

A weak module (Definition 12.1) is a vector space M with $Y_M : W \to \mathrm{End}(M)[[z^{\pm 1}]]$ satisfying the vacuum axiom, truncation ($u_{(n)}x = 0$ for $n \gg 0$) and the Jacobi identity, with no grading condition.

Definition 40.22. (a) For weak modules A on M and B on N, $A \oplus B$ is the weak module on $M \times N$ with $u_{(n)}(m, y) = (u_{(n)}m, u_{(n)}y)$. (b) For a weak module B and $g \in \mathrm{Aut}\, W$, the twisted module B^g has $Y_{B^g}(u, z) = Y_B(gu, z)$.

File `VOA/Moonshine/SigmaExistGeneric.lean`.

```
noncomputable def prodModule (A : WeakModule W M) (B : WeakModule W N) :

noncomputable def twistModule (B : WeakModule W N) (g : Aut W) : WeakModule W N where  YM
 ↪  := B.YM.comp g.toLinearEquiv.toLinearMap
  ...
@[simp] theorem twistModule_act (B : WeakModule W N) (g : Aut W) (u : 𝒱) (n : ℤ) (x : N) :
    (twistModule B g).act u n x = B.act (g u) n x
```

(`VOA/Moonshine/SigmaExistGeneric.lean`, namespace `VOA.Moonshine.SigmaExist`; the verification of the axioms is omitted.)

From the mathematics to the Lean statement

`A.act u n x` is $u_{(n)}x$ in the module A. The two `act` lemmas state that the constructions have exactly the intended modes; since `prodModule` and `twistModule` are values of the structure `WeakModule`, Lean has checked the vacuum, truncation and Jacobi axioms for them (the Jacobi identity for B^g uses $g(u_{(n)}v) = (gu)_{(n)}(gv)$). There is no possibility of vacuity: a structure value with all fields supplied is a genuine weak module.

Physical meaning

The direct sum of two modules is the space of states of two decoupled sectors, and the twisted module B^g is the same Hilbert space with the field labels rotated by the symmetry g (the sector seen through a symmetry-transformed set of fields). The twisting trick is what allows a σ-twisted intertwiner to be recast as an ordinary one into the twisted module.

What the machine verified

Proved (definitions with all axioms discharged), unconditional.

40.6.3 Li's single-mode spanning lemma

Theorem 40.23 (Li's lemma). *In a weak module, for all $u, v \in W$, $n, p \in \mathbb{Z}$ and x,*

$$v_{(p)}u_{(n)}x \;\in\; \operatorname{span}\{a_{(q)}x \;:\; a \in W,\ q \in \mathbb{Z}\}.$$

Consequently $\operatorname{modeSpan}(U) = \operatorname{span}\{a_{(q)}x : a \in W, q \in \mathbb{Z}, x \in U\}$ *is a submodule for every set U, and it contains U.*

File `VOA/Moonshine/SigmaExistGeneric.lean`.

```
theorem act_act_mem_span {P : Type*} [AddCommGroup P] [Module ℂ P] (A : WeakModule W P) (x
 ↪  : P)
    (u v : 𝒱) (n p : ℤ) :
    A.act v p (A.act u n x) ∈ span ℂ {y | ∃ a : 𝒱, ∃ q : ℤ, y = A.act a q x}

noncomputable def modeSpan {P : Type*} [AddCommGroup P] [Module ℂ P] (A : WeakModule W P)
    (U : Set P) : Submodule ℂ P :=
  span ℂ {y | ∃ a : 𝒱, ∃ q : ℤ, ∃ x ∈ U, y = A.act a q x}

theorem act_mem_modeSpan {P : Type*} [AddCommGroup P] [Module ℂ P] (A : WeakModule W P)
    (U : Set P) (v : 𝒱) (p : ℤ) {y : P} (hy : y ∈ modeSpan A U) : A.act v p y ∈ modeSpan A
     ↪  U
```

```
theorem subset_modeSpan {P : Type*} [AddCommGroup P] [Module ℂ P] (A : WeakModule W P)
    (U : Set P) {x : P} (hx : x ∈ U) : x ∈ modeSpan A U
```

From the mathematics to the Lean statement

- No hypothesis on u, v, n, p, x: the statement holds in every weak module. This is the module analogue of the vacuum trick of Chapter 39 (where $x = \mathbf{1}$ and $a_{(q)}\mathbf{1}$ ranges over all of W).
- "modeSpan is a submodule" is `act_mem_modeSpan`: stability under every $v_{(p)}$. With `subset_modeSpan` (from $\mathbf{1}_{(-1)} = \mathrm{id}$), modeSpan$(U)$ is the submodule generated by U.

Physical meaning

Li's lemma says that the span of all modes of all fields applied to a set of states is already closed under field action: acting with one more field mode on a descendant stays among the descendants of the same states. It is the algebraic form of the fact that the Hilbert space generated from the ground states by the fields is a representation, with no new states reachable by repeated action; it rests on the Jacobi identity (associativity of the OPE), not on physical input.

Proof on paper. Let K be such that $u_{(k)}x = 0$ for $k \geq K$, and induct on $K - n$; if $n \geq K$ there is nothing to prove. Choose $m \geq 0$ with $v_{(m+i)}x = 0$ for all $i \geq 0$ and put $\ell = p - m$. The Jacobi identity of the module, in its mode form, reads

$$\sum_{i\geq 0}(-1)^i\binom{\ell}{i}\Big(v_{(\ell+m-i)}u_{(n+i)}x - (-1)^{\ell}u_{(\ell+n-i)}v_{(m+i)}x\Big) \;=\; \sum_{i\geq 0}\binom{m}{i}(v_{(\ell+i)}u)_{(m+n-i)}x.$$

The second term on the left vanishes by the choice of m. The right side is a combination of single modes $a_{(q)}x$ with $a = v_{(\ell+i)}u$. On the left, the $i = 0$ term is $v_{(p)}u_{(n)}x$, and the terms $i \geq 1$ are $v_{(p-i)}u_{(n+i)}x$, which lie in the span by the induction hypothesis ($K - (n+i) < K - n$). Hence the $i = 0$ term does too. For the consequence: a spanning vector of modeSpan(U) is $a_{(q)}x$, and $v_{(p)}a_{(q)}x$ is in the span of single modes on x by the lemma. □

What the machine verified

Proved, unconditional, `#print axioms`-clean (re-run).

40.6.4 The generic top-level theorem

Definition 40.24 (Test span). For a weak module B, a set $G \subseteq W$ of letters, a subspace $\Omega \leq M$ and $\varphi : M \to N$: $Y_G = \mathrm{span}\{c_{(r)}\varphi x : c \in G,\ r \in \mathbb{Z},\ x \in \Omega\}$.

File `VOA/Moonshine/SigmaExistGeneric.lean`.

```
noncomputable def testSpan (B : WeakModule W N) (G : Set 𝒱) (Ω : Submodule ℂ M)
    (φ : M →ₗ[ℂ] N) : Submodule ℂ N :=
  span ℂ {y | ∃ c ∈ G, ∃ r : ℤ, ∃ x ∈ Ω, y = B.act c r (φ x)}
```

Physical meaning

The test span is the collection of states produced from the image of the ground states by the modes of the chosen light fields; it is the set of descendants against which the target's pairing is tested for nondegeneracy. Technical bookkeeping step in the compatibility check.

Theorem 40.25 (Annihilator compatibility from the top level). *Let A, B be weak W-modules on M, N; β a bilinear form on N; $\Omega \le M$; $\varphi : M \to N$ and $P : M \to M$ linear; $G \subseteq W$. Assume:*

(i) (top-level compatibility) for every k, every $a \in W_k$, every $q \in \mathbb{Z}$ and all $x, x' \in \Omega$: $\beta(a_{(q)}\varphi x, \varphi x') = \beta(\varphi(P(a_{(q)}x)), \varphi x')$;

(ii) (invariance on G) for every $c \in G$ and $r \in \mathbb{Z}$ there are finitely many $a_i \in W$, $q_i \in \mathbb{Z}$, $t_i \in \mathbb{C}$ with $\beta(y, c_{(r)}y') = \beta(\sum_i t_i\, a_{i(q_i)}y,\ y')$ for all $y, y' \in N$;

(iii) (nondegeneracy) if y lies in the submodule of B generated by $\varphi(\Omega)$ and $\beta(y, z) = 0$ for all $z \in Y_G$, then $y = 0$.

Then for every $x_0 \in \Omega$, $(x_0, \varphi x_0)$ is annihilator-compatible for the untwisted actions of all of W on A and on B.

    AnnCompat (fun a q => mode (A.YM a) q) (fun a q => mode (B.YM a) q) id Set.univ x₀ (φ
      ↪ x₀)
```

From the mathematics to the Lean statement

- `LinearMap.BilinForm ℂ N` is a bilinear form $\beta : N \times N \to \mathbb{C}$; `β y z` is $\beta(y, z)$. No symmetry is assumed.
- `hZO` is (i), quantified over homogeneous letters (`a ∈ W.grading k`); since both sides are linear in a, this is equivalent to (i) for all a. P is arbitrary in the theorem; in applications it is the projection to weight 2, and then (i) is the zero-mode intertwining property (see Lemma 40.31 below).
- `hadj` is (ii): a finite sum indexed by `Finset.range n`, i.e. $i = 0, \dots, n-1$. Note the order of quantifiers: the coefficients may depend on c and r but not on y, y'.
- `hnd` is (iii): `modeSpan B (φ '' Ω)` is the submodule of B generated by the image $\varphi(\Omega)$ (Theorem 40.23).
- The conclusion is `AnnCompat` with twist `id`: both modules are acted on by the same letters without twist. The σ-twist is put into B by using $B =$ `twistModule`; Lemma 40.26 shows the two formulations agree.
- Could the theorem be vacuous? If $\varphi = 0$, then $Y_G = 0$ and (iii) forces every y in the generated submodule to vanish, which is automatic since that submodule is 0; the conclusion is then the trivial compatibility with $y_0 = 0$. So the theorem is consistent with $\varphi = 0$, and any non-triviality must come from the hypotheses of the Leech application: there, (iii) is proved using that $\varphi(\Omega)$ contains a *cyclic vector* of the target sector.

Physical meaning

This theorem says that to verify that the triality is consistent on an entire sector, it is enough to check zero-mode compatibility on the ground states together with invariance and nondegeneracy of the pairing: if the zero modes of all fields intertwine on the ground states, then so do all modes on all descendants. This is the sector-level incarnation of the principle that a symmetry is determined by its action on the ground states, and is the engine of the whole reduction.

Proof on paper. Let $Z \le M \oplus N$ be the submodule generated by $\Gamma = \{(x, \varphi x) : x \in \Omega\}$; by Theorem 40.23 applied to $A \oplus B$, Z is spanned by the pairs $(a_{(q)}x, a_{(q)}\varphi x)$, $x \in \Omega$.

Step 1. For fixed $x' \in \Omega$, the functional $\lambda(m, y) = \beta(y, \varphi x') - \beta(\varphi P m, \varphi x')$ vanishes on Z: it is linear and vanishes on each spanning pair, by (i) (decompose a into homogeneous components).

Step 2. Hence if $(0, y) \in Z$ then $\beta(y, \varphi x') = 0$ for all $x' \in \Omega$.

Step 3. Let $(0, y) \in Z$, $c \in G$, $r \in \mathbb{Z}$, $x' \in \Omega$. By (ii), $\beta(y, c_{(r)}\varphi x') = \beta(y', \varphi x')$ with $y' = \sum t_i a_{i(q_i)} y$. Since Z is a submodule, $(0, y') = \sum t_i a_{i(q_i)}(0, y) \in Z$, so Step 2 gives $\beta(y', \varphi x') = 0$. Thus $y \perp Y_G$.

Step 4. The second components of elements of Z lie in the submodule generated by $\varphi(\Omega)$. By (iii), $(0, y) \in Z$ implies $y = 0$.

Conclusion. For a formal combination f of words, $(\mathrm{ev}_{x_0} f, \mathrm{ev}_{\varphi x_0} f)$ is the same combination of words applied to $(x_0, \varphi x_0) \in \Gamma$, hence lies in Z. If $\mathrm{ev}_{x_0} f = 0$, Step 4 gives $\mathrm{ev}_{\varphi x_0} f = 0$. □

What the machine verified

Proved, unconditional, `#print axioms` = [`propext`, `Classical.choice`, `Quot.sound`] (re-run for this chapter). No Verma module, no `VOA.pbw`.

Lemma 40.26 (Twists can be moved into the action). AnnCompat$(\rho, \tau, g, S, x_0, y_0)$ *holds iff* AnnCompat$(\rho, \tau \circ g, \mathrm{id}, S, x_0, y_0)$ *holds, where* $(\tau \circ g)_{a,q} = \tau_{g(a),q}$.

File `VOA/Moonshine/SigmaExistGeneric.lean`.

```
theorem annCompat_twist_iff {A' : Type*} (ρ : A' → ℤ → M →ₗ[ℂ] M) (τ : A' → ℤ → N →ₗ[ℂ] N)

    AnnCompat ρ τ g S x₀ y₀ ↔ AnnCompat ρ (fun a q => τ (g a) q) id S x₀ y₀
```

Physical meaning

A twist by a symmetry on the source side is equivalent to an untwisted statement for the sector seen through the twisted action. Technical bookkeeping step that lets the compatibility check be done with the untwisted-action machinery.

Proof on paper. Both sides evaluate a word w as $\tau_{g(u_1),n_1} \cdots \tau_{g(u_k),n_k} y_0$. □

What the machine verified

Proved, unconditional.

40.6.5 The Leech instance: modules and the form

Definition 40.27. As weak V_0^+-modules: $A_V = V_\Lambda^+$ (restriction of the adjoint module), $A_T = (V_\Lambda^T)^+$ (restriction of `plusModule`), and $B_T^\sigma = A_T^\sigma$, i.e. $(V_\Lambda^T)^+$ with u acting as $(\sigma u)_{(n)}$.

File `VOA/Moonshine/SigmaExistLeech.lean`.

```
noncomputable def AV : WeakModule V0P VPlus := V0Sub.restrictWeakModule (adjointWeakModule
 ↪  leechVOAPlus)

noncomputable def AT : WeakModule V0P TP := V0Sub.restrictWeakModule
 ↪  plusModule.toWeakModule

noncomputable def BTs : WeakModule V0P TP := twistModule AT v0Sigma

theorem mode_BTs (u : V0Sub.carrier) (n : ℤ) : mode (BTs.YM u) n = actT (sig u) n
```

(VOA/Moonshine/SigmaExistLeech.lean.)

From the mathematics to the Lean statement

`V0Sub.restrictWeakModule` restricts a V_Λ^+-module to the subalgebra V_0^+; its modes are those of the original module (`mode_AV`, `mode_AT`: `actV`, `actT`). `mode_BTs` confirms the twist.

Physical meaning

The three modules are the charged sector V_Λ^+, the twisted sector $(V_\Lambda^T)^+$, and the twisted sector viewed through the triality (its fields relabelled by σ). Together they are the state spaces between which the triality operator is supposed to act, and the third is how the twisted-intertwiner condition becomes an ordinary module-map condition.

Theorem 40.28 (The form on the twisted sectors). *(a)* $T_0^+ \perp T_1^+$ *for* `TPForm`*. (b)* `TPForm` *is nondegenerate on each* T_s^+*: if* $y \in T_s^+$ *and* $\langle y, z\rangle = 0$ *for all* $z \in T_s^+$*, then* $y = 0$*.*

File `VOA/Moonshine/SigmaExistLeech.lean`.

 ↪  = 0

theorem TPForm_eq_zero_of_frame {s : ZMod 2} {y : TP} (hy : y ∈ TPframe s)
    (h : ∀ z ∈ TPframe s, TPForm y z = 0) : y = 0
```

Physical meaning

The invariant bilinear form on the twisted sectors is the physical inner product: distinct twisted sectors are orthogonal (they are superselection sectors), and the form is nondegenerate on each, so every nonzero state has a nonzero overlap with some other state. Nondegeneracy is what allows a state to be detected by its two-point functions, which is the input to the compatibility criterion above.

Proof on paper. (a) $J = c^{-1}e_w$ is self-adjoint for the form on T: $\langle e_w t, t'\rangle = (-1)^{|w|^2/2}\langle t, e_w t'\rangle$ up to the normalisation c, and $|w|^2/2 = 4$ is even, so the sign is $+1$. The form on $S[\theta] \otimes T$ is the tensor product, so $1 \otimes J$ is self-adjoint. If $Jx = x, Jy = -y$ then $\langle x, y\rangle = \langle Jx, y\rangle = \langle x, Jy\rangle = -\langle x, y\rangle$. (b) The form is nondegenerate on all of $(V_\Lambda^T)^+$ (Chapter 37); $(V_\Lambda^T)^+ = T_0^+ \oplus T_1^+$; if $y \in T_s^+$ is orthogonal to T_s^+ it is orthogonal to T_{s+1}^+ by (a), hence to everything. □

What the machine verified

Proved, unconditional.

Lemma 40.29 (Invariance for the twisted target). *For homogeneous* $c \in V_0^+$ *of weight* k *and* $r \in \mathbb{Z}$*, the adjoint of* $c_{(r)}$ *in* B_T^σ *for* `TPForm` *is* $\sum_{j=0}^{k} \frac{(-1)^k}{j!}(a_j)_{(2k-r-2-j)}$ *in* B_T^σ*, where* $a_j = \sigma(L_1^j \sigma c)$*.*

File `VOA/Moonshine/SigmaExistLeech.lean`.

```
def homLetters : Set V0Sub.carrier := {c | ∃ k : ℤ, (c : VPlus) ∈ leechVOAPlus.grading k}

theorem hadj_BTs : ∀ c ∈ homLetters, ∀ r : ℤ, ∃ (n : ℕ) (a : ℕ → V0Sub.carrier) (q : ℕ → ℤ)
    (t : ℕ → ℂ), ∀ y y' : TP,
      TPForm y (BTs.act c r y') = TPForm (∑ i ∈ Finset.range n, t i • BTs.act (a i) (q i)
       ↪ y) y'
```

From the mathematics to the Lean statement

This is hypothesis (ii) of Theorem 40.25 with $G =$ homogeneous letters. In B_T^σ the letter c acts as $(\sigma c)_{(r)}$; FHL invariance of `TPForm` (recalled in §40.2) expresses the adjoint through $(L_1^j \sigma c)_{(\cdot)}$, and to write these as B_T^σ-modes one feeds the letters $\sigma(L_1^j \sigma c)$, using $\sigma^2 = 1$. L_1 preserves V_0^+ because $\omega \in V_0^+$.

Physical meaning

This gives the BPZ-type adjoint of a field mode in the twisted sector (the mode with weight-shifted index and the L_1-corrections, as for any quasi-primary field), expressing invariance of the inner product under the field action. Technical step in the nondegeneracy argument.

What the machine verified

Proved, unconditional.

40.6.6 The named residuals `TopSigmaV3` and `TopSigmaTT`

Write $\Omega_3 = (V_3^+)_2$ and $\Omega_{T,s'} = (T_{s'}^+)_2$ for the top levels (both of dimension 49152).

Definition 40.30 (Top-level σ-datum on V_3^+). A linear $\varphi : V_\Lambda^+ \to (V_\Lambda^T)^+$ is a *top-level σ-datum into T_s^+* if

(a) $\varphi(\Omega_3) \subseteq T_s^+$;

(b) $\varphi(\Omega_3) \subseteq ((V_\Lambda^T)^+)_2$;

(c) for every k, every $a \in (V_0^+)_k$ and every $x \in \Omega_3$: $\varphi(o(a)x) = o(\sigma a)\varphi(x)$, where $o(a) = a_{(k-1)}$;

(d) there are $0 \neq t_0 \in T_s$ and $x \in \Omega_3$ with $\varphi(x) = h_0(-\frac{1}{2})\mathbf{1} \otimes t_0$.

  /-- `φ` hits a cyclic vector `h₀(-½)𝟙 ⊗ t₀` of `T_s⁺`. -/
  hits_cyclic : ∃ t₀ : TLeechT, t₀ ∈ leechFrameT s ∧ t₀ ≠ 0 ∧ ∃ x ∈ OmegaV3, φ x = x0T t₀
```

From the mathematics to the Lean statement

- ⊓ is intersection of subspaces: `OmegaV3` $= V_3^+ \cap (V_\Lambda^+)_2 = \Omega_3$.
- A `structure` with `Prop` fields is a conjunction of four clauses, named (a)–(d) above in order.
- In `zero_mode`, k is the weight of a, and `actV a (k - 1)` is $a_{(k-1)} = o(a)$; on the target, σa has the same weight, so `actT (sig a) (k - 1)` is $o(\sigma a)$. The clause is quantified over *all* weights k and all homogeneous a: an infinite family of finite-dimensional identities.
- `plusModule.weight (2 : ℂ)` is the weight-two space of $(V_\Lambda^T)^+$.
- `hits_cyclic` uses `x0T t₀`, defined in Theorem 40.16.
- Every clause is *necessary* for $\varphi = \Phi|_{\Omega_3}$ when Φ is a non-zero σ-twisted map $V_3^+ \to T_s^+$ (for (d), up to choosing the cyclic vector in the image; for (c) see `IsSigmaV3T.zero_mode` below). So the definition is not stronger than what is true.

Physical meaning

The top-level datum records the triality only on the ground states of the sector: a map of the lowest-weight space Ω_3 to the lowest-weight space of the target that intertwines the zero modes $o(a)$ with the rotated zero modes $o(\sigma a)$, together with a nonzero hit on the cyclic vector. This is the "top-level" (ground-state) data of the sector, to be read as a representation of the Zhu algebra; condition (d) excludes $\varphi = 0$, the trivial intertwiner. The residual is the one remaining unproved input to the existence of the twisted triality, which the rest of the chapter reduces to checks on a few light fields.

Trap / dead end

The $\varphi = 0$ trap. Without `hits_cyclic`, $\varphi = 0$ satisfies the other three clauses, and the reduction would produce the trivial intertwiner $\Phi = 0$, which is useless for $V^\natural$ (it is the analogue of the square-zero trap of Chapter 38). The clause is there on purpose; it is also exactly what makes the nondegeneracy hypothesis (iii) of Theorem 40.25 provable: the test span Y_G then contains all $u_{(n)}x_{t_0}$, which span T_s^+ by Theorem 40.16.

Lemma 40.31 (Top-level compatibility from zero modes). *If φ satisfies* `TopSigmaV3 s`, *then hypothesis (i) of Theorem 40.25 holds for $A = A_V$, $B = B_T^\sigma$, $\beta =$* `TPForm`, *$\Omega = \Omega_3$ and $P = \pi_2$ the projection of V_Λ^+ onto weight 2.*

File `VOA/Moonshine/SigmaExistLeech.lean`.

```
theorem hZO_V3 {s : ZMod 2} {φ : VPlus →ₗ[ℂ] TP} (hφ : TopSigmaV3 s φ) :
    ∀ (k : ℤ) (a : V0Sub.carrier), a ∈ V0P.grading k → ∀ (q : ℤ), ∀ x ∈ OmegaV3, ∀ x' ∈
    ↪ OmegaV3,
      TPForm (BTs.act a q (φ x)) (φ x')
        = TPForm (φ (piHom leechVOAPlus 2 (AV.act a q x))) (φ x')
```

Physical meaning

The zero-mode condition on the ground states implies the top-level matrix-element identity needed for the compatibility theorem: the zero modes of all fields, which in the Hamiltonian picture are the only operators that map the ground-state space to itself, transport correctly under φ. Technical step relating the Zhu-algebra datum to the pairing identity.

Proof on paper. $a_{(q)}x$ has weight $k+2-q-1$. If $q = k-1$ this is 2, π_2 is the identity on it, and the identity is clause (c). Otherwise $\pi_2(a_{(q)}x) = 0$, and $(\sigma a)_{(q)}\varphi x$ has weight $\neq 2$, so it is orthogonal to the weight-two vector $\varphi x'$ (different L_0-eigenspaces are orthogonal for an invariant form, `TPForm_weightOrth`). □

What the machine verified

Proved, unconditional.

Theorem 40.32 (The residual gives annihilator compatibility). *If φ satisfies* `TopSigmaV3 s`, *then for every $x_0 \in \Omega_3$, $(x_0, \varphi x_0)$ is annihilator-compatible for* $(\mathrm{act}_V, \mathrm{act}_T, \sigma)$ *with all letters.*

File `VOA/Moonshine/SigmaExistLeech.lean`.

```
theorem annCompat_V3_of_top {s : ZMod 2} {φ : VPlus →ₗ[ℂ] TP} (hφ : TopSigmaV3 s φ) {x₀ :
↪  VPlus}
    (hx₀ : x₀ ∈ OmegaV3) : AnnCompat actV actT sig Set.univ x₀ (φ x₀)
```

Physical meaning

Given the ground-state datum (the zero modes intertwine and the image is nonzero), the triality is consistent on the whole charged sector: there is no violated null relation. This is the sector-level payoff of knowing the symmetry on the ground states alone.

Proof on paper. Lemma 40.26, then Theorem 40.25 with Lemmas 40.31 and 40.29. For (iii): the submodule generated by $\varphi(\Omega_3)$ lies in T_s^+ by clause (a) and stability; the test span contains every $(\sigma\sigma a)_{(n)}x_{t_0} = a_{(n)}x_{t_0}$ (clause (d)), so it contains T_s^+; and Theorem 40.28(b) applies. □

What the machine verified

Proved; conditional only on its explicit hypothesis `TopSigmaV3 s φ`.

40.6.7 The explicit cyclic vector and the existence theorem

To apply Theorem 40.19 the cyclic vector x_β must lie in the top level, so $|\beta|^2 = 4$ with $\beta \notin \Lambda_0$. The library takes

$$\beta_2 = u - w = (5, 1^{23}) - (8, 0^{23}) = (-3, 1^{23}) \quad (\sqrt{8}\text{-coordinates}), \qquad |\beta_2|^2 = \frac{9+23}{8} = 4.$$

File `VOA/Moonshine/SigmaExistLeech.lean`.

```
noncomputable def β₂ : leech.carrier := uβ - frameW

theorem β₂_not_mem : β₂ ∉ lambda0

theorem form_β₂ : leech.form β₂ β₂ = 4

theorem frameX0P_β₂_mem : frameX0P β₂ ∈ OmegaV3
```

From the mathematics to the Lean statement

`uβ` is the odd Leech vector $(5, 1^{23})$ and `frameW` is $w = (8, 0^{23}) \in \Lambda_0$. $\beta_2 \notin \Lambda_0$ because $u \notin \Lambda_0$ ($u_0 = 5$ is odd) and $w \in \Lambda_0$. The norm is computed by evaluating a 24-term dot product in the kernel (`decide +kernel`).

What the machine verified

Proved, unconditional.

Theorem 40.33 (σ on V_3^+ from the residual). *If φ satisfies* `TopSigmaV3 s`*, there is a σ-twisted intertwiner $\Phi : V_\Lambda^+ \to (V_\Lambda^T)^+$ on V_3^+ with $\Phi = \varphi$ on Ω_3, and Φ hits a cyclic vector x_{t_0} of T_s^+ ($0 \neq t_0 \in T_s$).*

File `VOA/Moonshine/SigmaExistLeech.lean`.

```
theorem sigmaV3T_exists_of_top {s : ZMod 2} {φ : VPlus →ₗ[ℂ] TP} (hφ : TopSigmaV3 s φ) :
    ∃ Φ : VPlus →ₗ[ℂ] TP, IsSigmaV3T Φ ∧ (∀ x ∈ OmegaV3, Φ x = φ x) ∧
      ∃ t₀ : TLeechT, t₀ ∈ leechFrameT s ∧ t₀ ≠ 0 ∧ ∃ x ∈ OmegaV3, Φ x = x0T t₀

theorem sigmaV3T_exists_of_top' (h : ∃ s φ, TopSigmaV3 s φ) :
    ∃ (s : ZMod 2) (Φ : VPlus →ₗ[ℂ] TP), IsSigmaV3T Φ ∧
      ∃ t₀ : TLeechT, t₀ ∈ leechFrameT s ∧ t₀ ≠ 0 ∧ ∃ x ∈ OmegaV3, Φ x = x0T t₀
```

From the mathematics to the Lean statement

- The conclusion has three parts: Φ is σ-twisted for *all* letters and modes; it extends φ on the top level; it is non-zero (hits a cyclic vector of T_s^+).
- The statement does not assert $\Phi(V_3^+) \subseteq T_s^+$; that follows (stability and cyclicity) and is not needed in this form downstream.
- The primed version is the "$\exists s$" form required by §40.5.1.

Physical meaning

From the ground-state datum one obtains the triality operator on the charged sector, agreeing with φ on the ground states and landing on a cyclic ground state of the twisted sector. This is the step where an operator that intertwines two sectors is actually constructed from its ground-state data, and it is nonzero because the datum hits a nonzero state.

Proof on paper. By Theorem 40.32 at $x_0 = x_{\beta_2}$ and Theorem 40.19, there is Φ with $\Phi(x_{\beta_2}) = \varphi(x_{\beta_2})$. On Ω_3, $\Phi = \varphi$: the weight-two part of $u_{(n)}x_{\beta_2}$ is $o(a)x_{\beta_2}$ summed over the homogeneous components a of u for which $n = \operatorname{wt} a - 1$; since V_3^+ is spanned by the $u_{(n)}x_{\beta_2}$, Ω_3 is spanned by the vectors $o(a)x_{\beta_2}$; and both Φ and φ send $o(a)x_{\beta_2}$ to $o(\sigma a)\varphi(x_{\beta_2})$ (twisted intertwining for Φ, clause (c) for φ). Then clause (d) for φ gives the cyclic vector in the image of Φ. □

What the machine verified

Proved; conditional only on the explicit hypothesis `TopSigmaV3 s φ`. `#print axioms` re-run: [`propext`, `Classical.choice`, `Quot.sound`]. The hypothesis is discharged in Chapter 41.

Theorem 40.34 (Necessity of the zero-mode clause). *Every σ-twisted Φ on V_3^+ satisfies $\Phi(o(a)x) = o(\sigma a)\Phi(x)$ for $x \in \Omega_3$ (and similarly on T_s^+).*

File `VOA/Moonshine/SigmaExistLeech.lean`.

```
theorem IsSigmaV3T.zero_mode {Φ : VPlus →ₗ[ℂ] TP} (hΦ : IsSigmaV3T Φ) (k : ℤ) (a :
↪  V0Sub.carrier)
    (x : VPlus) (hx : x ∈ OmegaV3) : Φ (actV a (k - 1) x) = actT (sig a) (k - 1) (Φ x)
```

From the mathematics to the Lean statement

Here k is arbitrary (not tied to the weight of a): the statement is the intertwining property at mode $k-1$, stronger than needed.

Physical meaning

Any triality operator on the sector must satisfy the zero-mode intertwining on the ground states, so the zero-mode clause in the top-level datum cannot be weakened: the datum is not only sufficient but necessary. It is the statement that the ground-state data are exactly what the symmetry operator restricts to.

What the machine verified

Proved, unconditional.

The twisted-to-twisted sector. The same reduction is proved for maps out of $T^+_{s'}$.

Definition 40.35. $\Omega_{T,s'} = T^+_{s'} \cap ((V^T_\Lambda)^+)_2$; a top-level σ-datum $T^+_{s'} \to T^+_s$ is $\varphi : (V^T_\Lambda)^+ \to (V^T_\Lambda)^+$ with the four clauses of Definition 40.30, Ω_3 replaced by $\Omega_{T,s'}$ and act_V by act_T.

theorem sigmaTT_exists_of_top {s' s : ZMod 2} {φ : TP →ₗ[ℂ] TP} (hφ : TopSigmaTT s' s φ)
    {t₀' : TLeechT} (ht₀' : t₀' ∈ leechFrameT s') (h0' : t₀' ≠ 0) :
    ∃ Φ : TP →ₗ[ℂ] TP, IsSigmaTT s' Φ ∧ (∀ x ∈ OmegaT s', Φ x = φ x) ∧
      ∃ t₀ : TLeechT, t₀ ∈ leechFrameT s ∧ t₀ ≠ 0 ∧ ∃ x ∈ OmegaT s', Φ x = x0T t₀
```

From the mathematics to the Lean statement

The source cyclic vector is $x_{t'_0}$ with $0 \neq t'_0 \in T_{s'}$ (hypotheses `ht₀'`, `h0'`), which is in the top level because $h_0(-\frac{1}{2})\mathbf{1} \otimes t'_0$ has weight $\frac{1}{2} + \frac{3}{2} = 2$ (`x0T_mem_weight`). The weight-2 projection on the target is `projT2`. FLM's case is $s' = s$, $T^+_3 \to T^+_3$; the theorem allows any pair.

Physical meaning

The same ground-state datum, now for maps between two twisted sectors $T^+_{s'} \to T^+_s$, with the ground-state space the weight-two part of the twisted sector. It is the analogue of the charged-sector datum for the twisted-to-twisted part of the triality.

Proof on paper. Identical to Theorem 40.33, with A_T in place of A_V. □

What the machine verified

Proved; conditional only on `TopSigmaTT s' s φ` and the choice of t_0'.

40.7 From the top level to Zhu generators

Clause (c) of `TopSigmaV3` still quantifies over all homogeneous $a \in V_0^+$. Zhu's easy direction reduces it to generators.

Definition 40.36 (Zhu generation). A set $G \subseteq V_0^+$ *Zhu-generates* V_0^+ if every subspace $S \le V_0^+$ with $\mathbf{1} \in S$, $\mathcal{O}(V_0^+) \subseteq S$, $G \subseteq S$ and $S * S \subseteq S$ is all of V_0^+. Equivalently — using Zhu's theorem that $\mathcal{O}(V_0^+)$ is a two-sided ideal, so that $*$ descends to an associative product on $A(V_0^+)$ (Chapter 12) — the images of G and $\mathbf{1}$ generate $A(V_0^+)$ as an algebra.

File `VOA/Moonshine/SigmaExistZhu.lean`.

```
def ZhuGenerated (G : Set V0Sub.carrier) : Prop :=
  ∀ S : Submodule ℂ V0Sub.carrier, V0P.vacuum ∈ S → O V0P ≤ S →
    (∀ a ∈ S, ∀ b ∈ S, zhuMul V0P a b ∈ S) → G ⊆ S → S = ⊤
```

(`VOA/Moonshine/SigmaExistZhu.lean`.)

From the mathematics to the Lean statement

- `⊤` is the whole space. The definition quantifies over subspaces of V_0^+ containing $\mathcal{O}$, which correspond bijectively to subspaces of $A(V_0^+)$; "closed under $*$" is closure of the corresponding subspace under the product. So the "equivalently" holds *given* that $*$ descends to $A(V)$; the Lean definition does not need that fact.
- Not vacuous: $G = V_0^+$ trivially Zhu-generates; $G = \varnothing$ does not (the subspace $\mathbb{C}\mathbf{1} + \mathcal{O}(V_0^+)$ is $*$-closed and proper, since $A(V_0^+)$ is not one-dimensional: it has 16 inequivalent irreducible modules, cf. §40.8; $*$-closedness of $\mathbb{C}\mathbf{1} + \mathcal{O}$ uses Zhu's theorem that $\mathcal{O}$ is a two-sided ideal — this non-vacuity remark is argued on paper, not in Lean). The weight-two statement proved below is therefore a genuine statement.

Physical meaning

Zhu generation by a set G of light fields says that the zero modes of G, together with the identity, already generate the full algebra of zero modes $A(V_0^+)$; equivalently, if an operator commutes with $o(g)$ for all $g \in G$ on the ground states, it commutes with every zero mode. In physical terms, a few light (low-weight) fields act irreducibly on the ground states of every sector, so checking the symmetry on them suffices. It is the key finite check that replaces an infinite one.

Definition 40.37 (The ordinary modules). $M_{V3} = V_3^+$, $M_{T,s'} = T_{s'}^+$ as ordinary V_0^+-modules, and $M_T^\sigma = (V_\Lambda^T)^+$ with the σ-twisted action, also ordinary (twisting by an automorphism keeps the grading since $\sigma\omega = \omega$).

File `VOA/Moonshine/SigmaExistZhu.lean`.

```
noncomputable def twistOrd (N : OrdVModule W M) (g : Aut W) : OrdVModule W M where
  toWeakModule := twistModule N.toWeakModule g

  ...
noncomputable def MV3 : OrdVModule V0P (frameSector 1) := OrdVModule.submodule N0 P3
```

```
noncomputable def MTsrc (s' : ZMod 2) : OrdVModule V0P (TPframe s') := OrdVModule.submodule
 ↪ NT (PT s')

noncomputable def MT : OrdVModule V0P TP := twistOrd NT v0Sigma
```

From the mathematics to the Lean statement

`N0` and `NT` are V_Λ^+ (adjoint module) and $(V_\Lambda^T)^+$ restricted to V_0^+ as ordinary modules; `P3` and `PT s'` are V_3^+ and $T_{s'}^+$ as V_0^+-stable subspaces (Lemma 40.15); `OrdVModule.submodule` gives a stable graded subspace the induced ordinary-module structure. In `twistOrd` the weight spaces are unchanged, which is correct because L_0 is the zero mode of $\omega = \sigma\omega$.

Physical meaning

The three sectors regarded as ordinary modules: graded by energy with finite-dimensional energy levels and a ground level, with the twisted version a module because the triality preserves the stress tensor (the energy). Technical setup that lets Zhu's zero-mode analysis apply to the sectors.

Theorem 40.38 (Lowest weight 2). *M_{V3}, $M_{T,s'}$ and M_T^σ have lowest weight 2.*

File `VOA/Moonshine/SigmaExistZhu.lean`.

```
theorem isLowestWeight_MV3 : IsLowestWeight MV3 (2 : ℂ)

theorem isLowestWeight_MT : IsLowestWeight MT (2 : ℂ)

theorem isLowestWeight_MTsrc (s' : ZMod 2) : IsLowestWeight (MTsrc s') (2 : ℂ)
```

Physical meaning

The ground energy of each of the three sectors is 2: the lowest-weight states are weight-two states, so the ground-state space is the space of weight-two primaries (a Griess-algebra-type space in the Moonshine setting). Together with Zhu's easy direction, the zero modes act on this weight-two space.

Proof on paper. V_Λ^+ has weights $0, 2, 3, \ldots$: weight 0 is $\mathbb{C}\mathbf{1} \subset V_0^+$ (so meets V_3^+ only in 0), weight 1 is zero (Λ has no roots and θ kills $h(-1)\mathbf{1}$). For $(V_\Lambda^T)^+$ the weights are $2, 3, \ldots$ (§40.2). □

What the machine verified

Proved, unconditional.

Theorem 40.39 (Zero modes from Zhu generators). *Let N_1, N_2 be ordinary V_0^+-modules of lowest weight 2, $\psi : N_1 \to N_2$ linear with $\psi((N_1)_2) \subseteq (N_2)_2$, and G Zhu-generating. If $\psi\, o(g) = o(g)\,\psi$ on $(N_1)_2$ for $g \in G$, then $\psi\, o(a) = o(a)\,\psi$ on $(N_1)_2$ for all $a \in V_0^+$.*

    (hG : ZhuGenerated G)
    (hGψ : ∀ g ∈ G, ∀ x ∈ N₁.weight (2 : ℂ), ψ (oMod N₁ g x) = oMod N₂ g (ψ x)) :
    ∀ a : V0Sub.carrier, ∀ x ∈ N₁.weight (2 : ℂ), ψ (oMod N₁ a x) = oMod N₂ a (ψ x)
```

Physical meaning

If a map between the ground-state spaces of two sectors commutes with the zero modes of the light generating fields, then it commutes with every zero mode. This is the payoff of Zhu generation: a finite list of light-field checks, the zero modes of weight-two fields, gives intertwining with the entire zero-mode algebra on the ground states.

Proof on paper. Let $S = \{a : \psi o(a) = o(a)\psi \text{ on } (N_1)_2\}$, a subspace. It contains $\mathbf{1}$ ($o(\mathbf{1}) = \mathrm{id}$), $\mathcal{O}(V_0^+)$ (both zero modes vanish on top levels, Theorem 40.5), G by hypothesis, and is $*$-closed: $\psi o(a*b) = \psi o(a)o(b) = o(a)\psi o(b) = o(a)o(b)\psi = o(a*b)\psi$ on $(N_1)_2$, using that $o(b)$ preserves the top level. So S is everything. □

What the machine verified

Proved, unconditional.

Theorem 40.40 (`TopSigmaV3` from Zhu generators). *Let φ satisfy clauses (a), (b), (d) of Definition 40.30, let G be Zhu-generating, and suppose every $g \in G$ is homogeneous of some weight k with $\varphi(o(g)x) = o(\sigma g)\varphi(x)$ on Ω_3. Then φ satisfies* `TopSigmaV3 s`. *Likewise for* `TopSigmaTT`.

    TopSigmaTT s' s φ
```

From the mathematics to the Lean statement

`hGφ` requires each letter of G to be homogeneous; for $G = (V_0^+)_2$ that holds with $k = 2$. The proof applies Theorem 40.39 to $N_1 = M_{V3}$, $N_2 = M_T^\sigma$, where $o_{N_2}(a) = o(\sigma a)$; the zero mode of the twisted module is the zero mode of σa.

Physical meaning

The ground-state datum of the triality need only be checked on the light generators: if the zero modes of the generating fields intertwine, the full top-level residual follows. This reduces the existence of the twisted triality to the chapter's headline statement that the weight-two fields Zhu-generate, together with these finite checks.

What the machine verified

Proved; conditional only on the displayed hypotheses. No `VOA.pbw`: only the easy direction of Zhu's theory is used.

Trap / dead end

Weak generation does not reduce the top-level clause. The library proves that V_Λ^+ is generated, under all n-th products, by the $e^\beta + e^{-\beta}$ (`leechPlus_generated`, Chapter 32). That is useless here: $o(a_{(n)}b)$ on Ω is not determined by $o(a)$ and $o(b)$ on Ω (the Borcherds identity involves the higher levels). Only Zhu generation ($*$ modulo $\mathcal{O}$) reduces the zero-mode clause to generators. Weak generation suffices only for a map already defined on the whole module.

40.8 Which generators? A numerical experiment

Before proving any Zhu generation statement one must decide which G to aim for. In rank one, $A(M(1)^+)$ needs a weight-four element J besides ω (Example 40.6), so it was not clear that weight two suffices for $V_0^+ \cong V_{\Lambda_0}^+$. A numerical and combinatorial experiment (`scripts/moonshine/numerics/zhu/zhu.py`; `Notes/ZhuGeneratorTest.md`) answered the question. *Nothing in this section is a Lean theorem*; it is recorded because it fixed the target of the Lean work and because it exposed two traps.

Let B be the associative algebra generated by the zero modes $o(u)$, $u \in (V_0^+)_2$. The space $(V_0^+)_2$ has dimension $49428 = 300 + 49128$: the $\binom{24}{2} + 24 = 300$ Fock states $h_a(-1)h_b(-1)\mathbf{1}$ ($a \le b$) and the $98256/2 = 49128$ lattice states $u_\gamma = e^\gamma + \theta e^\gamma$ for the 98256 norm-four $\gamma \in \Lambda_0$, taken up to sign.

The top of V_3^+. It is spanned by e^n, $n \in \Lambda_0 + \lambda_3$ with $|n|^2 = 4$ (98304 vectors). The zero modes act by

$$o(h_a h_b)e^n = n_a n_b\, e^n, \qquad o(e^\gamma)e^n = \begin{cases} \epsilon(\gamma, n)e^{n+\gamma} & \langle \gamma, n\rangle = -2, \\ 0 & \text{otherwise,} \end{cases}$$

(coordinates in an orthonormal basis of $\Lambda \otimes \mathbb{R}$, i.e. $\sqrt{8}$-coordinates divided by $\sqrt{8}$, in which $\langle n, n'\rangle = n \cdot n'$). The joint eigenvalues nn^T determine n up to sign, so B contains the projector onto each $\operatorname{span}\{e^n, e^{-n}\}$. An exact machine check shows that the graph on the 98304 vectors with edges $\langle n, n'\rangle = 2$ (226 099 200 directed edges) is connected; in particular every n is joined to $-n$. Hence B contains all matrix units of V_3^+'s top, i.e. $B = \operatorname{End}((V_3^+)_2)$, and (by the antidiagonal holonomy of a loop from n to $-n$) $V_3^+ \not\cong V_3^-$ as B-modules.

The twisted top $h(-\frac{1}{2})\otimes X$. Here $o(h_a h_b) = \frac{1}{2}(E_{ab} + E_{ba}) + \frac{1}{8}\delta_{ab}$ and $o(u_\gamma) = 2\cdot 2^{-4}(1 - gg^\mathsf{T}) \otimes e_\gamma$. The symmetric matrices generate M_{24}; and 400 random norm-four vectors already generate Λ_0 over $\mathbb{Z}$ (exact Hermite normal form: covolume $8192 = 2^{13}$), so the e_γ generate the extraspecial group, which acts irreducibly on X. Hence again $B = \operatorname{End}(\text{top})$.

All sixteen tops. The same reasoning shows that B acts irreducibly on the tops of all 16 irreducible V_0^+-modules and separates them, so B maps onto $\bigoplus_{i=1}^{16} \operatorname{End}(\text{top}_i)$, of dimension $1 + 3\cdot 24^2 + 6\cdot 2048^2 + 6 \cdot 49152^2 = 14\,520\,682\,177$. (Irreducibility alone does not give Zhu generation; see the circularity warning below.) If $A(V_0^+) \cong \bigoplus_{i=1}^{16} \operatorname{End}(\text{top}_i)$ (rationality and the classification of Abe–Dong–Li; *cited, not checked*), it would follow that $(V_0^+)_2$ Zhu-generates. So **no weight-four J is needed**; the rank-one obstruction is removed by the lattice part.

Trap / dead end

The circularity trap. Irreducibility of the tops under B does *not* prove the zero-mode clause. For a top-level map φ, the weight-two part of the module generated by the graph of φ is a B-submodule of $\Omega_1 \oplus \Omega_2 \cong \Omega_1^2$, hence either the graph (which gives the clause) or everything (which means $\Omega_1 \not\cong \Omega_2^\sigma$ as $A(V_0^+)$-modules). Excluding the second case needs

information about $A(V_0^+)$ beyond B: Zhu generation, or the classification. "Tops irreducible $\Rightarrow$ `ZhuGenerated`" is circular. What irreducibility does give is uniqueness of φ up to a scalar.

Trap / dead end

V_0^+ is not strongly generated by weight two. Strong generation by $(V_0^+)_2$ would mean $(V_0^+)_3 = L_{-1}(V_0^+)_2$ (normal-ordered products of weight-two states start at weight four, and $(V_0^+)_1 = 0$). But the Fock part of $(V_0^+)_3$ is spanned by the $24 \cdot 24 = 576$ states $h_a(-2)h_b(-1)\mathbf{1}$, while L_{-1} of the 300 Fock weight-two states gives at most 300. So the classical lemma "strong generators are Zhu generators" does not apply, and the proof must use the 0-th products $a_{(0)}b$ (§40.9). Also: low-order traces $\operatorname{tr} o(u)$, $\operatorname{tr} o(u)o(v)$ on random samples do *not* distinguish V_3^+ from V_3^-: that distinction lives in a long loop $n \to -n$.

40.9 A filtered criterion for Zhu generation

We now prove, for an arbitrary VOA W, a sufficient condition for Zhu generation that refers only to the vertex algebra and not to $*$ or $\mathcal{O}$.

40.9.1 The filtration and three leading-term identities

Definition 40.41. $F_{<n} = \bigoplus_{k<n} W_k$.

File `VOA/Moonshine/ZhuGenFiltration.lean`.

```
noncomputable def Fl (n : ℤ) : Submodule ℂ 𝒱 := ⨆ (k : ℤ) (_ : k < n), W.grading k
```

(`VOA/Moonshine/ZhuGenFiltration.lean`, namespace `VOA.Moonshine.ZhuGen`.)

From the mathematics to the Lean statement

`⨆` is the supremum (sum) of subspaces, here over $k < n$. Since the grading is a direct sum, this is $\bigoplus_{k<n} W_k$.

Physical meaning

The filtration by weight is the organisation of states by energy: $F_{<n}$ consists of all states of energy below n, so higher-energy states are measured modulo lower ones. This is the standard way to organise a VOA by oscillator number or conformal weight, and lets leading terms be compared.

The key observation is that, *modulo lower weight*, the three basic constructions have simple leading terms. For homogeneous $a \in W_p$, $b \in W_q$ $(p, q \geq 0)$:

- $a*b = a_{(-1)}b + \sum_{i\geq 1} \binom{p}{i} a_{(i-1)}b$, and $a_{(i-1)}b$ has weight $p+q-i$; so $a*b \equiv a_{(-1)}b \pmod{F_{<p+q}}$;
- $\operatorname{Pres}(a, p, b, k) \equiv a_{(-2-k)}b \pmod{F_{<p+q+1+k}}$;
- the commutator $a * b - b * a \equiv a_{(0)}b \pmod{\mathcal{O}(W) + F_{<p+q-1}}$.

Lemma 40.42. *For $a \in W_p$, $b \in W_q$:*

(a) $a * b - a_{(-1)}b \in F_{<p+q}$;

(b) if $p \in \mathbb{N}$, $a_{(-2-k)}b - \operatorname{Pres}(a, p, b, k) \in F_{<p+q+1+k}$ for all $k \in \mathbb{N}$;

(c) $T^j y \in \mathcal{O}(W) + X$ *for every subspace* X *containing the homogeneous vector* y*, where* $T = L_{-1}$.

File `VOA/Moonshine/ZhuGenFiltration.lean`.

```

    (hb : b ∈ W.grading q) (k : ℕ) :
    W.smul a (-2 - k) b - Pres W p a b k ∈ Fl W (p + q + 1 + k)

theorem Tpow_mem {w : ℤ} {y : V} (hy : y ∈ W.grading w) {X : Submodule ℂ V} (hyX : y ∈ X)
    (j : ℕ) : (W.toPreVertexAlgebra.T ^ j) y ∈ O W ⊔ X
```

Physical meaning

Modulo lower energy, the Zhu product is the ordinary normal-ordered product, and the higher modes are equal to the higher residues up to lower-energy corrections. These are the leading-term (top-energy) identities used to peel off the highest-energy part of a state in the filtered argument.

Proof on paper. (a), (b): all non-leading terms are $a_{(m)}b$ with m larger than the leading index, of weight $p+q-m-1$ below the bound. (c): $Ty \equiv -wy$ modulo $\mathcal{O}$ (Lemma 40.3(a)), and inductively $T^j y \equiv (-1)^j w(w+1)\cdots(w+j-1)\,y$. □

What the machine verified

Proved, unconditional.

Theorem 40.43 (Filtered commutator formula). *For* $a \in W_p$, $b \in W_q$ *with* $p, q \geq 0$,

$$a * b - b * a - a_{(0)}b \;\in\; \mathcal{O}(W) + F_{<p+q-1}.$$

File `VOA/Moonshine/ZhuGenFiltration.lean`.

```
theorem zhuMul_comm_sub_zero_mem {p q : ℤ} {a b : V} (ha : a ∈ W.grading p)
    (hb : b ∈ W.grading q) (hp : 0 ≤ p) (hq : 0 ≤ q) :
    zhuMul W a b - zhuMul W b a - W.smul a 0 b ∈ O W ⊔ Fl W (p + q - 1)
```

From the mathematics to the Lean statement

`O W ⊔ Fl W (p + q - 1)` is the sum of subspaces $\mathcal{O}(W)+F_{<p+q-1}$. Note that $a_{(0)}b$ has weight $p+q-1$, so the statement is that the commutator equals $a_{(0)}b$ *exactly at its own weight*, modulo $\mathcal{O}$. Zhu's exact formula $a * b - b * a \equiv \operatorname{Res}_z Y(a,z)b(1+z)^{p-1}$ implies this; the filtered form is all we need and is proved directly.

Physical meaning

The commutator of two zero modes is, to leading order in the energy filtration, the zero mode of the Lie-type product $a_{(0)}b$, i.e. the zero-mode algebra is a deformation quantisation of a commutative filtered algebra, with lower-energy corrections. This is the filtered version of $[o(a), o(b)] = o(a_{(0)}b)$ and is used to control the noncommutative terms.

Proof on paper. Work modulo $X = \mathcal{O} + F_{<p+q-1}$. From the definition of $*$, keeping the two top terms:

$$a * b \equiv a_{(-1)}b + p\,a_{(0)}b, \qquad b * a \equiv b_{(-1)}a + q\,b_{(0)}a.$$

Skew-symmetry $Y(b,z)a = e^{zT}Y(a,-z)b$ gives, in modes, $b_{(n)}a = \sum_{j\ge 0}\frac{(-1)^{n+1+j}}{j!}T^j(a_{(n+j)}b)$. For $n=-1$ and $n=0$, the terms with $n+j\ge 1$ have $a_{(n+j)}b$ of weight $< p+q-1$, and T^j of them lies in X by Lemma 40.42(c). So

$$b_{(-1)}a \equiv a_{(-1)}b - T(a_{(0)}b), \qquad b_{(0)}a \equiv -a_{(0)}b.$$

Finally $T(a_{(0)}b) \equiv -(p+q-1)\,a_{(0)}b$ modulo $\mathcal{O}$ (Lemma 40.3(a), as $a_{(0)}b$ has weight $p+q-1$). Substituting,

$$\begin{aligned} b * a &\equiv \big(a_{(-1)}b + (p+q-1)\,a_{(0)}b\big) - q\,a_{(0)}b \;=\; a_{(-1)}b + (p-1)\,a_{(0)}b,\\ a*b - b*a &\equiv \big(p-(p-1)\big)\,a_{(0)}b \;=\; a_{(0)}b. \end{aligned}$$

The coefficient $p-(p+q-1)+q = 1$ is what makes the 0-th products available. □

What the machine verified

Proved, unconditional, no `VOA.pbw`.

40.9.2 Weight-raising products and the criterion

Definition 40.44 (Weight-raising products of lower-weight states). For $n\in\mathbb{Z}$, lowerProd(n) is the set of $a_{(m)}b$ with $a\in W_p$, $b\in W_q$, $p,q<n$, $m\le 0$ and $p+q-m-1=n$.

File `VOA/Moonshine/ZhuGenFiltration.lean`.

```
def lowerProd (n : ℤ) : Set V :=
  {x | ∃ p q m : ℤ, p < n ∧ q < n ∧ m ≤ 0 ∧ p + q - m - 1 = n ∧
    ∃ a ∈ W.grading p, ∃ b ∈ W.grading q, x = W.smul a m b}
```

From the mathematics to the Lean statement

The condition $p+q-m-1=n$ says $a_{(m)}b\in W_n$. The condition $m\le 0$ is the content: the allowed products are the normal-ordered ones ($m=-1$), the higher ones ($m\le -2$), and the 0-th products ($m=0$). Products with $m\ge 1$ are excluded; they are not controlled by $*$.

Physical meaning

The set of states of energy n obtainable by acting with a raising mode on two states of strictly lower energy: the states of energy n that are generated by the field product of lighter ones. It is the basic notion of "composite" as opposed to "generating" state at that level.

Theorem 40.45 (The filtered criterion). *Let $G\subseteq W$. If $W_n\subseteq \mathrm{span}(G\cup \mathrm{lowerProd}(n))$ for every $n\ge 1$, then every subspace S with $\mathbf{1}\in S$, $\mathcal{O}(W)\subseteq S$, $S*S\subseteq S$ and $G\subseteq S$ equals W.*

```

From the mathematics to the Lean statement

- The criterion is stated for any VOA W; in it, W_0 is spanned by $\mathbf{1}$ (`vacuum_grade`, part of the library's VOA axioms) and negative weights vanish (`positivity`).
- It concludes Zhu generation in the sense of Definition 40.36 (stated for W).
- It is a *sufficient* condition only: cancellations of leading terms could in principle give more. A numerical failure of the hypothesis would not refute Zhu generation.

Physical meaning

If every state of energy n is a combination of the generators and of products of lighter states, then the generators already generate everything under the Zhu product. This is an induction on energy: composite states are produced by products of lighter ones, so only the generators at the lowest level need to be supplied.

Proof on paper. `lowerProd_subset`: if $F_{<n} \subseteq S$ and $a_{(m)}b \in \mathrm{lowerProd}(n)$ then $a, b \in S$. For $m = -1$: $a_{(-1)}b = a*b-(a*b-a_{(-1)}b)$, a $*$-product in S minus an element of $F_{<n}$. For $m = -2-k$: $a_{(m)}b = \mathrm{Pres}+(\text{element of } F_{<n})$ with $\mathrm{Pres} \in \mathcal{O}$. For $m = 0$: $a_{(0)}b = (a*b-b*a)-(\text{element of } \mathcal{O}+F_{<n})$ by Theorem 40.43. Main theorem: induction on n shows $W_n \subseteq S$; $W_0 = \mathbb{C}\mathbf{1}$; for $n \geq 1$, W_n is spanned by G and by $\mathrm{lowerProd}(n) \subseteq S$. □

What the machine verified

Proved, unconditional, `#print axioms`-clean (re-run), no `VOA.pbw`.

Remark 40.46. Why this route is natural: modulo lower weight, the leading terms of elements of $\mathcal{O}$ are $a_{(-2-k)}b$ and $L_{-1}a$; those of $*$ are $a_{(-1)}b$; those of commutators are $a_{(0)}b$. The criterion is the associated-graded form of Zhu generation, and it splits weight by weight and, for lattice VOAs, charge by charge.

40.10 Zhu generation of V_0^+: reduction to three sectors

40.10.1 The residual for V_0^+

Definition 40.47. $G_2 = (V_0^+)_2$. The residual `V0LowerSpanned`: for every $n \geq 3$, $(V_0^+)_n \subseteq \mathrm{span}\,\mathrm{lowerProd}_{V_0^+}(n)$.

File `VOA/Moonshine/ZhuGenV0.lean`.

```
def weightTwo : Set V0Sub.carrier := {g | g ∈ V0P.grading 2}

theorem V0P_grading_one : V0P.grading 1 = ⊥

def V0LowerSpanned : Prop :=
  ∀ n : ℤ, 3 ≤ n → V0P.grading n ≤ span ℂ (lowerProd V0P n)

theorem zhuGenerated_weightTwo_of_lowerSpanned (h : V0LowerSpanned) : ZhuGenerated
 ↪ weightTwo
```

(`VOA/Moonshine/ZhuGenV0.lean`, namespace `VOA.Moonshine.SigmaExist`.)

From the mathematics to the Lean statement

- `V0P.grading n` is $(V_0^+)_n$, the weight-n part of V_0^+ for its own VOA structure; membership is the same as membership of the underlying vector in $(V_\Lambda^+)_n$ (`mem_V0P_grading_iff`).

- Weights 1 and 2 are free: $(V_0^+)_1 = 0$ (`V0P_grading_one`) and $(V_0^+)_2 = G_2$. So the hypothesis of Theorem 40.45 reduces to $n \geq 3$.
- `V0LowerSpanned` is a statement about the vertex algebra V_0^+ alone, strictly stronger than `ZhuGenerated weightTwo`.

Physical meaning

The generators are the full weight-two space $(V_0^+)_2$, i.e. the lightest nontrivial fields; the residual `V0LowerSpanned` states that all states of energy at least three are composites of lighter states. This is the finite generation of the chiral algebra by its weight-two fields, in the Moonshine setting the Griess algebra.

What the machine verified

`zhuGenerated_weightTwo_of_lowerSpanned`: proved, conditional only on its hypothesis (which is proved below).

Theorem 40.48 (The σ-residuals with weight-two letters). *Under* `V0LowerSpanned`, `TopSigmaV3 s φ` *follows from clauses (a), (b), (d) and the zero-mode identities* $\varphi(g_{(1)}x) = (\sigma g)_{(1)}\varphi(x)$ *for* $g \in (V_0^+)_2$, $x \in \Omega_3$*; similarly for* `TopSigmaTT`.

File `VOA/Moonshine/ZhuGenV0.lean`.

```
theorem topSigmaV3_of_lowerSpanned {s : ZMod 2} {φ : VPlus →ₗ[ℂ] TP}
    (hf : ∀ x ∈ OmegaV3, φ x ∈ TPframe s) (hw : ∀ x ∈ OmegaV3, φ x ∈ plusModule.weight (2 :
    ↪ ℂ))
    (hL : V0LowerSpanned)
    (hGφ : ∀ g ∈ weightTwo, ∀ x ∈ OmegaV3, φ (actV g 1 x) = actT (sig g) 1 (φ x))
    (hc : ∃ t₀ : TLeechT, t₀ ∈ leechFrameT s ∧ t₀ ≠ 0 ∧ ∃ x ∈ OmegaV3, φ x = x0T t₀) :
    TopSigmaV3 s φ
```

From the mathematics to the Lean statement

For g of weight 2, $o(g) = g_{(1)}$: `actV g 1`.

Physical meaning

Once all heavier states are composites, the twisted-triality datum needs to be checked only for the zero modes of the weight-two fields, namely $g_{(1)}$. This is the form in which the top-level residual is attacked in the rest of the chapter.

What the machine verified

Proved, conditional on the displayed hypotheses.

40.10.2 Word states and the sector decomposition

V_Λ is spanned by word states $h_{a_1}(-n_1)\cdots h_{a_r}(-n_r)\otimes e^\gamma$. In the library a word is a list l of pairs (i,a) meaning $h_a(-i-1)$, and `wordWt l` $= \sum(i+1)$ is its Fock weight.

Definition 40.49. For $\gamma \in \Lambda_0$ and a word l, $w_0(l,\gamma) = P(h_{a_1}(-i_1-1)\cdots\otimes e^\gamma) \in V_0^+$, $P = \frac{1}{2}(1+\theta)$.

File `VOA/Moonshine/ZhuGenSectors.lean`.

```
noncomputable def wordV0 (l : List (ℕ × Fin (rank leech))) {γ : leech.carrier} (hγ : γ ∈
↪  lambda0) :
    V0Sub.carrier :=
  ⟨plusProj (wordStateLatGen leech l γ), plusProj_word_mem_V0 l hγ⟩

theorem V0P_grading_le_span_wordV0 (n : ℤ) : V0P.grading n ≤ span ℂ (wordSet n)
```

(VOA/Moonshine/ZhuGenSectors.lean.)

From the mathematics to the Lean statement

wordSet n is the set of $w_0(l,\gamma)$ with $\gamma \in \Lambda_0$ and total weight wordWt l $+\frac{1}{2}|\gamma|^2 = n$. The theorem: these span $(V_0^+)_n$. (Proof on paper: project a spanning set of $(V_\Lambda)_n$ by $\frac{1}{2}(1+g)$ and P; charges outside Λ_0 are killed.)

Physical meaning

A word state is the lattice vertex-operator state built by applying a word of oscillator creation operators to the charge-γ lattice state e^γ and projecting onto the θ-invariant part. It is the basis state of the orbifold's untwisted sector: oscillators on a ground state of charge γ, with the average over θ the orbifold projection.

Definition 40.50 (The three sector residuals).

- FockSpanned: every $w_0(l,0)$ of weight ≥ 3 lies in span lowerProd of its weight;
- ExcitedSpanned: every $w_0(l,\gamma)$ with $\gamma \neq 0$ and l non-empty does;
- GroundSpanned: every x_γ, $\gamma \in \Lambda_0$, $|\gamma|^2 \geq 6$, does.

File VOA/Moonshine/ZhuGenSectors.lean.

```
def FockSpanned : Prop :=
  ∀ l : List (ℕ × Fin (rank leech)), 3 ≤ (wordWt l : ℤ) →
    wordV0 l lambda0.zero_mem ∈ span ℂ (lowerProd V0P (wordWt l))

def ExcitedSpanned : Prop :=
  ∀ (l : List (ℕ × Fin (rank leech))) (γ : leech.carrier) (hγ : γ ∈ lambda0), γ ≠ 0 → l ≠
  ↪  [] →
    wordV0 l hγ ∈ span ℂ (lowerProd V0P ((wordWt l : ℤ) + LatGen.halfNorm leech γ))

def GroundSpanned : Prop :=
  ∀ (γ : leech.carrier) (hγ : γ ∈ lambda0), 6 ≤ leech.form γ γ →
    x0 hγ ∈ span ℂ (lowerProd V0P (LatGen.halfNorm leech γ))

theorem v0LowerSpanned_of_sectors (hF : FockSpanned) (hE : ExcitedSpanned) (hG :
↪  GroundSpanned) :
    V0LowerSpanned
```

From the mathematics to the Lean statement

- LatGen.halfNorm leech γ is $\frac{1}{2}|\gamma|^2$ (an integer since Λ is even); leech.form γ γ is $|\gamma|^2$.
- x0 hγ is $x_\gamma = e^\gamma + e^{-\gamma}$ regarded as an element of V_0^+; note $w_0([],\gamma) = \frac{1}{2}x_\gamma$ (wordV0_nil).
- Ground states of norm 4 have weight 2 and are in G_2; norm ≥ 6 is the residual. Fock states of weight ≤ 2 are in $\mathbb{C}\mathbf{1}+G_2$; charged excited states have weight ≥ 3 automatically. So the three residuals cover all of wordSet n, $n \geq 3$.

Physical meaning

The decomposition of V_0^+ by charge: states with zero charge (pure oscillator, "Fock", states of the free bosons), excited states of non-zero charge (oscillators on a charged ground state), and the charged ground states themselves. The three residuals say that in each class every state above weight two is a composite of lighter states; this is the case analysis in terms of the frame-charge sectors of the 24 bosons.

What the machine verified

`v0LowerSpanned_of_sectors`: proved; conditional only on the three named hypotheses, all of which are proved later in this chapter.

40.10.3 Products of ground states

Recall the lattice cocycle (Chapter 31, section "Even lattices and the FLM 2-cocycle"): the vertex operators of V_L use the twisted group algebra $\mathbb{C}_\varepsilon[L]$, $e^\alpha \cdot e^\beta = \varepsilon(\alpha,\beta)e^{\alpha+\beta}$, where $\varepsilon : L \times L \to \{\pm 1\}$ is a bimultiplicative 2-cocycle, built from a chosen $\mathbb{Z}$-basis of L, with $\varepsilon(\alpha,\beta)\varepsilon(\beta,\alpha) = (-1)^{\langle\alpha,\beta\rangle}$. In Lean it is `latticeCocycle L α β` (`VOA/Foundations/LatticeCocycle.lean`), with `latticeCocycle_sq` ($\varepsilon^2 = 1$, same file) and `latticeCocycle_neg_left`, `latticeCocycle_neg_right`, `latticeCocycle_neg_neg` (ε is unchanged by negating either argument, by bimultiplicativity; `VOA/Moonshine/LatticeInvolution.lean`). Below $\epsilon = \varepsilon$. For lattice vectors the products of charged vacua are explicit: $e^\alpha_{(n)}e^\beta = \epsilon(\alpha,\beta)\,S_d(\alpha) \otimes e^{\alpha+\beta}$ with $d = -n-1-\langle\alpha,\beta\rangle$, where $S_d(\alpha)$ is the degree-d Schur polynomial in the $h_\alpha(-j)$ (zero for $d<0$, 1 for $d=0$). Symmetrising over $\pm$ gives:

Theorem 40.51 (Ground-state products). *For $\alpha,\beta \in \Lambda$:*

(a) if $\langle\alpha,\beta\rangle = -1$: $x_{\alpha(0)}x_\beta = \epsilon(\alpha,\beta)\,x_{\alpha+\beta}$;

(b) if $\langle\alpha,\beta\rangle = 0$: $x_{\alpha(-1)}x_\beta = \epsilon(\alpha,\beta)\,(x_{\alpha+\beta} + x_{\alpha-\beta})$;

(c) if $\langle\alpha,\beta\rangle = k \geq 1$: $x_{\alpha(-k-1)}x_\beta = \epsilon(\alpha,\beta)\big(x_{\alpha+\beta} + 2P(S_{2k}(\alpha)\otimes e^{\alpha-\beta})\big)$.

Files `VOA/Moonshine/ZhuGenLattice.lean`, `VOA/Moonshine/ZhuGenGround.lean` (in order of the declarations below).

```
theorem frameX0P_smul_zero_of_form_neg_one {α β : leech.carrier} (h : leech.form α β = -1)
 ↪  :
    leechVOAPlus.smul (frameX0P α) 0 (frameX0P β) = latticeCocycle leech α β • frameX0P (α
     ↪  + β)

theorem frameX0P_smul_neg_one_of_form_zero {α β : leech.carrier} (h : leech.form α β = 0) :
    leechVOAPlus.smul (frameX0P α) (-1) (frameX0P β)
      = latticeCocycle leech α β • (frameX0P (α + β) + frameX0P (α - β))

theorem frameX0P_smul_of_form_pos {α β : leech.carrier} {k : ℕ} (h : leech.form α β = k) :
    ((leechVOAPlus.smul (frameX0P α) (-(k : ℤ) - 1) (frameX0P β) : VPlus) : LatModuleGen
     ↪  leech)
      = latticeCocycle leech α β • (frameX0 (α + β)
        + (2 : ℂ) • (plusProj (latStateGen leech (vSchur leech α (2 * k)) (α - β)) :
            LatModuleGen leech))
```

(`VOA/Moonshine/ZhuGenLattice.lean` for (a), (b); `VOA/Moonshine/ZhuGenGround.lean` for (c).)

From the mathematics to the Lean statement

- `latticeCocycle leech α β` is the sign $\epsilon(\alpha,\beta) = \pm 1$ of the lattice VOA (Chapter 31); `vSchur leech α d` is $S_d(\alpha)$; `latStateGen leech p γ` is $p \otimes e^{\gamma}$.
- (c) is stated in V_Λ (after two coercions) because its right side involves `frameX0` and the image of `plusProj`.
- The proofs use $\epsilon(-\alpha,-\beta) = \epsilon(\alpha,\beta)$ and $\epsilon(-\alpha,\beta) = \epsilon(\alpha,-\beta) = \epsilon(\alpha,\beta)$, properties of the library's cocycle established in Chapter 31.

Physical meaning

These are the OPE coefficients of charged vertex operators $e^{\alpha}(z)e^{\beta}(w) \sim \epsilon(\alpha,\beta)(z-w)^{\langle\alpha,\beta\rangle}e^{\alpha+\beta}(w)$: when the inner product is -1 the leading term gives a single new charged state, for 0 and positive inner product the expansion produces the sum of the charge $\alpha+\beta$ state and corrections. They show how a charged ground state is obtained from lighter ones by a single field product.

Proof on paper. Expand $x_{\alpha(n)}x_\beta$ into four terms $e^{\pm\alpha}_{(n)}e^{\pm\beta}$. In (a) with $n=0$: $e^{\alpha}_{(0)}e^{\beta}$ has $d = -1+1 = 0$ and gives $\epsilon e^{\alpha+\beta}$; the cross terms have $\langle\alpha,-\beta\rangle = 1$, $d=-2<0$, and vanish; $e^{-\alpha}_{(0)}e^{-\beta}$ gives $\epsilon e^{-\alpha-\beta}$. In (b) with $n=-1$ all four terms have $d=0$. In (c) with $n=-k-1$: the like-sign terms have $d=0$, the cross terms $d=2k$, and θ sends $S_{2k}(\alpha)\otimes e^{\alpha-\beta}$ to the other cross term (S_{2k} is even in α). □

What the machine verified

Proved, unconditional.

Definition 40.52 (Ground relations and the lattice residual). GroundRel(n) is the set of the following elements, for $\alpha,\beta \in \Lambda_0 \setminus 0$ with $\frac{1}{2}|\alpha+\beta|^2 = n$: $x_{\alpha+\beta}$ if $\langle\alpha,\beta\rangle = -1$ or $\langle\alpha,\beta\rangle \geq 1$; $x_{\alpha+\beta} + x_{\alpha-\beta}$ if $\langle\alpha,\beta\rangle = 0$. `GroundLattice`: every x_γ, $\gamma \in \Lambda_0$, $|\gamma|^2 \geq 6$, is in the span of GroundRel($\frac{1}{2}|\gamma|^2$).

File `VOA/Moonshine/ZhuGenGround.lean`.

```
def GroundRel (n : ℤ) : Set V0Sub.carrier :=
  {x | ∃ (α β : leech.carrier) (hα : α ∈ lambda0) (hβ : β ∈ lambda0), α ≠ 0 ∧ β ≠ 0 ∧
      LatGen.halfNorm leech (α + β) = n ∧
      ((leech.form α β = -1 ∨ 1 ≤ leech.form α β) ∧ x = x0 (lambda0.add_mem hα hβ) ∨
        leech.form α β = 0 ∧ x = x0 (lambda0.add_mem hα hβ) + x0 (lambda0.sub_mem hα hβ))}

def GroundLattice : Prop :=
  ∀ (γ : leech.carrier) (hγ : γ ∈ lambda0), 6 ≤ leech.form γ γ →
    x0 hγ ∈ span ℂ (GroundRel (LatGen.halfNorm leech γ))

theorem groundSpanned_of_lattice (hF : FockSpanned) (hE : ExcitedSpanned) (hL :
↪  GroundLattice) :
    GroundSpanned

theorem zhuGenerated_weightTwo_of_residuals (hF : FockSpanned) (hE : ExcitedSpanned)
    (hL : GroundLattice) : ZhuGenerated weightTwo
```

From the mathematics to the Lean statement

- `GroundRel` is a set of vectors, but each vector is described by lattice data only; since the x_γ (γ up to sign) are linearly independent, `GroundLattice` is a combinatorial statement about Λ_0: every γ of norm ≥ 6 is either a "direct" sum $\gamma = \alpha+\beta$ with $\langle\alpha,\beta\rangle \in$

$\{-1\} \cup [1, \infty)$, or is reached by a combination of $k = 0$ relations.

- $\alpha = \beta$ is *allowed* (no $\alpha \neq \beta$ condition). This matters; see the warning.

Physical meaning

The relations are the lattice combination rules for the charged ground states in the OPE: a ground state at lattice vector $\alpha + \beta$ is a field-product of ground states at α and β (up to $\pm$ sign combinations when the vectors are orthogonal). `GroundLattice` states that every heavy ground state, of norm at least six, arises this way, a purely lattice-combinatorial fact about the Leech sublattice.

Proof on paper. Each element of GroundRel(n) is in span lowerProd(n): by Theorem 40.51, x_α and x_β have weights $\frac{1}{2}|\alpha|^2, \frac{1}{2}|\beta|^2 < n$ (norms ≥ 4 since Λ has no roots), the product has mode ≤ 0, and the extra term in (c) is $P(S_{2k}(\alpha) \otimes e^{\alpha-\beta})$, a charge-$(\alpha-\beta)$ state with $2k$ oscillators, which is in the span by `ExcitedSpanned` (or, when $\alpha = \beta$, by `FockSpanned`). □

What the machine verified

Proved; conditional only on the named hypotheses, all proved below.

Trap / dead end

Do not exclude $\alpha = \beta$. For $\gamma = 2\alpha$ with $|\alpha|^2 = 4$ ($|\gamma|^2 = 16$), the only partner with $\langle \alpha, \gamma - \alpha \rangle \geq 1$ is $\alpha = \gamma/2$ (checked by `e4_check.py`). The cross term is then a charge-zero Fock state, so `FockSpanned`, not `ExcitedSpanned`, is needed. An early draft of `GroundRel` required $\alpha \neq \beta$ and was too weak.
Ground states only come from ground states. A product $a_{(m)}b$ with a Fock-excited source has Fock-excited leading part (the Fock weight of the result is at least that of the sources), so `GroundLattice` is necessary for the filtered criterion, not merely convenient.

40.11 The Fock sectors: `ExcitedSpanned` and `FockSpanned`

Both Fock residuals are proved using a single kind of left factor: the *quadratic Heisenberg states*

$$q_{a,i;b,j} \;=\; h_a(-i-1)h_b(-j-1)\mathbf{1} \in V_0^+ \qquad (a, b \in \{0, \dots, 23\},\ i, j \geq 0),$$

of weight $i + j + 2$ (they are θ-even and have charge 0, so they lie in V_0^+). Notation: the Fock space is the polynomial ring $\mathbb{C}[X(i,a)]$, where $X(i,a)$ stands for the creation operator $h_a(-i-1)$; a state $p \otimes e^\gamma$ has Fock weight $\sum(i+1)$ and *degree* (number of oscillators) deg p.

40.11.1 The modes of a quadratic state

The vertex operator of $q_{a,i;b,j}$ is the normal-ordered product $:\frac{1}{i!}\partial^i h_a(z)\,\frac{1}{j!}\partial^j h_b(z):$. On the charge-$\gamma$ sector the boson modes are

$$h_a(k) \;=\; \begin{cases} X(-k-1,a)\cdot & k < 0 \text{ (creation)},\\ \langle e_a, \gamma\rangle & k = 0 \text{ (momentum)},\\ k\,\partial/\partial X(k-1,a) & k > 0 \text{ (annihilation)}. \end{cases}$$

Definition 40.53. For $s \in \mathbb{Z}$ let $\mathrm{quadF}_\gamma(a,i;b,j;s)$ be the operator on the Fock factor of the charge-γ sector given by

$$\mathrm{quadF}(s)\,p \;=\; \sum_{m\in\mathbb{Z}} \,:g_a^i(m)\,g_b^j(s-m):\;\; p, \qquad g_a^i(m) = \frac{1}{i!}\prod_{l=0}^{i-1}(m+1+l)\cdot h_a(-m-i-1),$$

normal ordered (the factor with non-negative index acts first).

File `VOA/Moonshine/FockSpanOps.lean`.

```

(`VOA/Moonshine/FockSpanOps.lean`, namespace `VOA.Moonshine.FockSpan`.)

From the mathematics to the Lean statement

- `Fk` is the Fock space $\mathbb{C}[X(i,a)]$ (`FockN (rank leech)`, 24 colours); `oscN` is the oscillator $h_a(k)$ without zero-mode momentum; `chargeCoord leech γ a` is the momentum $\langle e_a, \gamma\rangle$ in an orthonormal frame. `hOp` is the boson mode on the charge-γ sector.
- `cf i j` is the coefficient of $(i!)^{-1}\partial^i$ acting on z^{-j-i-1}: the field $\frac{1}{i!}\partial^i h(z)$ has m-th coefficient $\mathrm{cf}(i,m)\,h(-m-i-1)$ in the convention $\sum_m (\cdot)_m z^m$ used by the library's normal-ordered product.
- `qTerm` with the test `0 ≤ m` is the normal ordering. $\sum^{\mathrm{f}}$ is a sum with finite support (proved finite in the library).
- `smul_quad`: the n-th product $q_{(n)}(p\otimes e^\gamma)$ equals $\mathrm{quadF}(-n-1)p\otimes e^\gamma$. The index $s=-n-1$ is the exponent convention for fields; mode n of the field is the coefficient of z^{-n-1}.

Physical meaning

quadF(s) is the mode of a normal-ordered bilinear in the oscillator currents, $:\partial^i X^a\,\partial^j X^b:$, acting on the charge-$\gamma$ Fock space. These are the modes of the quadratic composite fields (the stress tensor is the diagonal case), the lightest composite fields of the free-boson theory, acting on the oscillator part of a charged sector.

Proof on paper. The vertex operator of $h_a(-i-1)h_b(-j-1)\mathbf{1}$ in a lattice VOA is, by reconstruction, the normal ordered product of $\frac{1}{i!}\partial^i h_a(z)$ and $\frac{1}{j!}\partial^j h_b(z)$. Reading off the coefficient of z^{-n-1} gives the formula. Charge is preserved since the field has charge zero. □

What the machine verified

Proved, unconditional.

Theorem 40.54 (Leading term, commutators and vacuum values)**.** *On the charge-γ sector:*

```

From the mathematics to the Lean statement

- `Fdw d w` is the space of Fock polynomials of total degree $\le d$ and weight w (`restrictTotalDegree`, `gradingZN`).

- `quadF … 0` is the (-1)-mode (as $s = -n - 1 = 0$), and `quadF … (-1)` is the 0-mode. `1 : Fk` is the Fock vacuum, so (c), (d) are values on e^{γ}. `.toNat` only converts the non-negative index $t + s + 2$ to a natural number.
- γ_a denotes `chargeCoord leech γ a`.

Physical meaning

The leading term of the bilinear mode is the product of two creation operators, so it raises oscillator number by two; its commutator with a creation operator is linear (the quadratic field acts on the oscillators like a Bogoliubov-type generator), and its action on the charged vacuum is fixed by the charge through the zero mode γ_a. These are the standard free-boson computations used to show that bilinears reach all states with few oscillators.

Proof on paper. (a) The $m = 0$ summand of quadF(0) is the product of the two creation operators $X(i,a)X(j,b)$. Every other summand either contains a factor with coefficient cf $= 0$ (the product $\prod_l (m+1+l)$ vanishes for $-i \le m \le -1$), or pairs one creation with one annihilation/zero mode, raising the degree by at most one. (b) Only annihilation operators contribute to the commutator; $[h_b(k), X(t,c)] = k\,\delta_{cb}\delta_{k,t+1}$ picks the terms $m = t + s + 2$ and $m = -t - 2$. (c), (d) On the vacuum all annihilators vanish, so only summands with the annihilating factor replaced by a momentum survive: these are written out. □

What the machine verified

Proved, unconditional.

40.11.2 The target spaces and the degree ascent

Definition 40.55. For $\gamma \in \Lambda_0$ and n, $T_\gamma(n)$ is the space of Fock polynomials p with $P(p \otimes e^{\gamma}) \in \operatorname{span} \operatorname{lowerProd}_{V_0^+}(n)$.

File `VOA/Moonshine/FockSpanBase.lean`.

```
noncomputable def Tsub {γ : leech.carrier} (hγ : γ ∈ lambda0) (n : ℤ) : Submodule ℂ Fk :=
  (span ℂ (lowerProd V0P n)).comap (excitedV0 hγ)
```

Physical meaning

$T_\gamma(n)$ is the space of oscillator states, on the charge-γ ground state, that are already composites at energy n. The spanning arguments aim to show that it is everything of the right weight, i.e. that all oscillator excitations are generated by lighter composites.

(`VOA/Moonshine/FockSpanBase.lean`.) Here `excitedV0 hγ` is the linear map $p \mapsto P(p \otimes e^{\gamma}) \in V_0^+$ (`VOA/Moonshine/ZhuGenGround.lean`) and `comap` is the preimage.

Lemma 40.56 (The basic spanning step and the degree ascent). *(a) If q has weight $i + j + 2 < n$, $p \otimes e^{\gamma}$ has weight $w + \frac{1}{2}|\gamma|^2 < n$, $m \le 0$ and the total is n, then* $\mathrm{quadF}(-m-1)p \in T_\gamma(n)$. *(b) If $T_\gamma(n)$ contains all weight-w states of degree $\le d_0$, and for every $D \ge d_0$ the monomials $X(v_1)X(v_2)m'$ of degree $D+1$ lie in $T_\gamma(n)$ whenever all weight-w states of degree $\le D$ do, then $T_\gamma(n)$ contains every weight-w state. (c) The inductive step of (b) holds whenever $m' \otimes e^{\gamma}$ has positive weight.*

File `VOA/Moonshine/FockSpanBase.lean`.

```

    (hn : n = (w : ℤ) + LatGen.halfNorm leech γ)
    (IH : Fdw D w ≤ Tsub hγ n) (v1 v2 : ℕ × Fin (rank leech)) (s' : (ℕ × Fin (rank leech))
    ↪  →₀ ℕ)
    (hdeg : s'.degree + 1 = D) (hw : (v1.1 : ℤ) + v2.1 + 2 + (wt s' : ℤ) = w)
    (hpos : 1 ≤ (wt s' : ℤ) + LatGen.halfNorm leech γ) :
    (X v1 * X v2 * monomial s' 1 : Fk) ∈ Tsub hγ n
```

From the mathematics to the Lean statement

- In (a), `gradingWN (rank leech) w` is the weight-w Fock space; (a) says the product $q_{(m)}P(p\otimes e^{\gamma})$, which equals $P(\mathrm{quadF}(-m-1)p\otimes e^{\gamma})$ because q is θ-even, is a lowerProd element.
- In `step_quad`, a monomial is given by its exponent vector `s'`; `s'.degree` is its degree and `wt s'` its weight. `hpos` is the positivity of the weight of $m'\otimes e^{\gamma}$, needed so that the product has two lower-weight factors.

Physical meaning

Acting with a bilinear field raises the degree (oscillator number) by two; this lemma packages the induction in which the all-states-of-degree-at-most-D hypothesis lifts to degree $D+1$ using two creation operators at a time. It is the oscillator-number induction on the Fock space.

Proof on paper. (a) is the definition of lowerProd together with Definition 40.53. (b) Induction on degree: a monomial of degree $D+1 > d_0 \geq 1$ factors as $X(v_1)X(v_2)m'$. (c) By Theorem 40.54(a), $(q_{v_1v_2})_{(-1)}P(m'\otimes e^{\gamma}) = P(X(v_1)X(v_2)m'\otimes e^{\gamma}) + (\text{degree} \leq D)$; the left side is in the span by (a), the correction by the induction hypothesis. □

What the machine verified

Proved, unconditional. (`Fdw_le_of_ascent` is part (b).)

40.11.3 Charged excited states

By the ascent, only degree one must be done by hand. Fix $\gamma \in \Lambda_0 \setminus 0$, $N = |\gamma|^2 \geq 4$ (even). In the quotient by $T_{\gamma}(n)$ write $\varphi_a = [X(\tau+1,a)]$ for the degree-one state $h_a(-\tau-2)e^{\gamma}$, and $T = \tau+1$, $\varepsilon = (-1)^{\tau}$.

Theorem 40.57 (Charged degree one). *For $\gamma \in \Lambda_0 \setminus 0$ and all t, c: $h_c(-t-1)e^{\gamma}$ lies in $T_{\gamma}(t+1+\frac{1}{2}|\gamma|^2)$. Consequently* `ExcitedSpanned` *holds.*

File `VOA/Moonshine/FockSpanCharged.lean`.

    (c : Fin (rank leech)) :
    (X (t, c) : Fk) ∈ Tsub hγ ((t : ℤ) + 1 + LatGen.halfNorm leech γ)

theorem excitedSpanned : ExcitedSpanned
```

(VOA/Moonshine/FockSpanCharged.lean.)

From the mathematics to the Lean statement

- charged_algebra is a lemma of pure linear algebra: from the family of relations hR and two non-vanishing coefficients it concludes $\varphi = 0$. It is stated for any finite colour set ι and any vector space M (applied to the quotient by $T_\gamma(n)$).
- X (t, c) is $h_c(-t-1)$ applied to the Fock vacuum, so charged_deg_one is the displayed statement. excitedSpanned has no hypotheses: it is the unconditional proof of the residual of Definition 40.50.

Physical meaning

On a charged ground state, a single oscillator excitation $\alpha_{-t-1}e^\gamma$ is already a composite of lighter states, by acting with a bilinear. Consequently all states with oscillators on a nonzero-charge ground state are composites, the excited-sector residual. Physically: the charged sectors carry no new generators above their ground states.

Proof on paper. Bottom case $t = 0$. By Theorem 40.54(c) the 0-mode products $(h_a h_b)_{(0)}e^\gamma = \gamma_b h_a(-1)e^\gamma + \gamma_a h_b(-1)e^\gamma$ are in the span. So in the quotient, $\gamma_b\varphi_a + \gamma_a\varphi_b = 0$ for all a, b. Pick b with $\gamma_b \neq 0$: $a = b$ gives $\varphi_b = 0$, then all $\varphi_a = 0$.

General $t = \tau + 1$. Two families of products are available:

- the (-1)-modes $(h_a(-1)h_c(-\tau-1)\mathbf{1})_{(-1)}e^\gamma$, which by Theorem 40.54(d) give $[X(0,a)X(\tau,c)] = -(\varepsilon\gamma_c\varphi_a + T\gamma_a\varphi_c)$;
- the 0-modes $(h_a h_b)_{(0)}\big(h_c(-\tau-1)e^\gamma\big)$, which by (b), (c) equal $T(\delta_{cb}\varphi_a+\delta_{ca}\varphi_b)+\gamma_b X(0,a)X(\tau,c)+\gamma_a X(0,b)X(\tau,c)$ in the quotient.

Substituting the first into the second gives, for all colours a, b, c,

$$T(\delta_{cb}\varphi_a + \delta_{ca}\varphi_b) - \varepsilon\gamma_c(\gamma_b\varphi_a + \gamma_a\varphi_b) - 2T\gamma_a\gamma_b\varphi_c = 0.$$

Contract with γ_c (using $\sum_c \gamma_c^2 = N$) and put $\Phi = \sum_c \gamma_c\varphi_c$: $(T - \varepsilon N)(\gamma_b\varphi_a + \gamma_a\varphi_b) - 2T\gamma_a\gamma_b\Phi = 0$. Contract once more with $a = b$ summed against γ_a: $2(T - \varepsilon N - TN)\Phi = 0$. The coefficients are non-zero because $N \geq 4$ is even: if τ is even, $T - N - TN < 0$ and $T - N$ is odd; if τ is odd, $T + N > 0$ and $T + N - TN = 0$ would force $(T-1)(N-1) = 1$. So $\Phi = 0$, then $\gamma_b\varphi_a + \gamma_a\varphi_b = 0$, then $\varphi = 0$ as in the bottom case. Finally ExcitedSpanned follows from degree one by the ascent of Lemma 40.56 (the source $m' \otimes e^\gamma$ always has positive weight since $\frac{1}{2}|\gamma|^2 \geq 2$). □

What the machine verified

excitedSpanned: proved, unconditional, #print axioms = [propext, Classical.choice, Quot.sound] (re-run).

Trap / dead end

Weight-two quadratics alone fail in charged degree one, and so does the approximate leading term: the exact vacuum formula of Theorem 40.54(d), with both momentum corrections, is what makes the linear algebra close. An earlier plan (`Notes/ZhuGeneration.md` §4.2) used four separate tools and a change of basis to a vector $z \perp \gamma$; the contraction argument above replaced it.

40.11.4 The charge-zero sector $M(1)^+$

In charge zero the momentum vanishes, so the 0-modes of weight-two quadratics are derivations $D_{ab} = (h_a h_b)_{(0)}$ of $\mathbb{C}[X]$ with $[D_{ab}, X(t,c)] = (t+1)(\delta_{cb}X(t+1,a) + \delta_{ca}X(t+1,b))$. Odd-degree states project to 0 under P, so degree 1 is trivial; degree ≥ 3 follows from the ascent; everything rests on degree two (the *bilinears* $X(i,c)X(j,f)$, weight $i+j+2 = n \geq 3$).

Theorem 40.58 (The bilinears and `FockSpanned`)**.** *Every charge-zero bilinear of weight $n \geq 3$ lies in $T_0(n)$. Consequently* `FockSpanned` *holds.*

theorem fockSpanned : FockSpanned
```

(`VOA/Moonshine/FockSpanFock.lean`.)

From the mathematics to the Lean statement

- `T0 n` is $T_0(n)$, the charge-zero case of `Tsub`. In `fock_bilinear`, $v_1 = (i,c)$, $v_2 = (j,f)$ and `hw` is "weight n".
- `diag_algebra`: $W(c,k)$ stands for the class of the diagonal bilinear $V_c(k) = X(k,c)X(n-2-k,c)$. `hthird` (a third colour avoiding any two) holds because there are $24 \geq 3$ colours (`exists_third`). `hb`, `hsym`, `hc` are the three families of relations described in the proof.
- `quadN0_cancel` is the "degree-four cancellation": quadF$(\cdot;0)$ is the (-1)-mode. `fockSpanned` has no hypotheses.

Physical meaning

In the charge-zero (neutral) sector every bilinear of weight at least three is a composite of lighter fields, so the pure-oscillator part of the orbifold algebra is generated by its weight-two (and lighter) bilinears, namely the Virasoro-type field and its relatives. This is the neutral half of the Fock-sector residual, free-boson bookkeeping for the 24 oscillators.

Proof on paper. *Off-diagonal* $X(i,c)X(j,f)$, $c \neq f$, $i \geq 1$: choose a third colour $e \notin \{c,f\}$; then $D_{ce}\big(X(i-1,e)X(j,f)\big) = i\,X(i,c)X(j,f)$, a 0-mode of a weight-two state on a weight-$(n-1)$ state. (If $i = 0$, swap the factors; $j \geq 1$ since $n \geq 3$.)

Diagonal $V_c(k) = X(k,c)X(n-2-k,c)$. For $c \neq e$ and $1 \leq k \leq n-2$,

$$D_{ce}\big(X(k-1,e)X(n-2-k,c)\big) = k\,V_c(k) + (n-1-k)\,V_e(k-1)$$

is in the span. Also $V_c(k) = V_c(n-2-k)$. Comparing two colours c, g via a third e shows that modulo the span $V_c(k)$ does not depend on c; then the relations become the recursion $kV(k) + (n-1-k)V(k-1) \equiv 0$ for $1 \leq k \leq n-2$. For $n = 3$ the case $k = 1$ and the symmetry $V(0) = V(1)$ give $2V(0) \equiv 0$. For $n \geq 4$ one more relation is needed, because the recursion and the symmetry alone leave room for a non-zero solution in rank one: this is the deficiency behind the J of $A(M(1)^+)$ (Example 40.6); numerically, rank one is deficient by exactly one dimension at weight 4. The extra relation is the degree-four cancellation, available because there are at least two colours:

$$(h_c h_e)_{(-1)}\big(X(0,c)X(n-4,e)\big) - (h_c h_c)_{(-1)}\big(X(0,e)X(n-4,e)\big) = (n-3)\,V_c(0) + V_e(2),$$

in which the degree-four leading terms $X(0,c)X(0,e)X(0,c)X(n-4,e)$ cancel between the two products, leaving only single contractions. Combining it with the recursion at $k = 1$ and $k = 2$ gives $(n-3)\,n\,V(0) \equiv 0$, so $V(0) \equiv 0$ and inductively $V(k) \equiv 0$. Degree ≥ 3 follows by the ascent (the source m' has degree ≥ 1, hence positive weight); degree one is zero after projection. □

What the machine verified

`fockSpanned`: proved, unconditional, `#print axioms`-clean (re-run). Rank ≥ 3 is used (three colours); rank 24 is available.

Example 40.59 (Weight three). $(V_0^+)_3$ has Fock part spanned by the 576 states $h_a(-2)h_b(-1)\mathbf{1}$. For $a \neq b$ choose $e \notin \{a,b\}$: $(h_a h_e)_{(0)}\big(h_e(-1)h_b(-1)\mathbf{1}\big) = h_a(-2)h_b(-1)\mathbf{1}$, a 0-th product of two weight-two states. For $a = b$: with $n = 3$, $V_a(1) = X(1,a)X(0,a) = h_a(-2)h_a(-1)\mathbf{1}$ and $V_a(0) = V_a(1)$ by symmetry; the relation with $k = 1$ reads $V_a(1) + V_e(0) \equiv 0$, i.e. $2V(1) \equiv 0$ after identifying colours. (Of course $h_a(-2)h_a(-1)\mathbf{1} = \frac{1}{2}L_{-1}(h_a(-1)^2\mathbf{1})$ is also directly an L_{-1}-image.) None of the off-diagonal states is in $L_{-1}(V_0^+)_2$: this is the failure of strong generation, rescued by 0-th products.

Numerical cross-check. Before the Lean proof, `fock_lowerprod.py` (exact arithmetic modulo $2^{31}-1$) confirmed: rank one is deficient by exactly one dimension at weight 4 only; ranks 2, 3, 4 are full through weights 11, 9, 8. `charged_lowerprod.py` found full rank in every charged case tested (ranks 1–4; the only failure, $|\gamma|^2 = 2$, does not occur in Λ_0). These are evidence, superseded by the proofs above.

40.12 The ground states: Golay combinatorics

What remains is `GroundLattice`, a purely combinatorial statement about Λ_0. We work in the coordinates (40.3): $\Lambda_0 \cong A = \{g \in \mathbb{Z}^{24} : g \bmod 2 \in \mathcal{G},\ 4 \mid \sum g_i\}$, $\langle g,h\rangle = \frac{1}{2}g \cdot h$. In these coordinates: $|\gamma|^2 \geq 6 \iff g \cdot g \geq 12$; norm-four vectors have $g \cdot g = 8$; $\langle \alpha,\beta\rangle = -1 \iff a \cdot b = -2$.

40.12.1 Facts about the Golay code

The extended binary Golay code $\mathcal{G} \subset \mathbb{F}_2^{24}$ (Lean: `Code.golay`, constructed in Chapter 30) is a doubly even, self-dual $[24, 12, 8]$ code containing the all-ones word, with 759 words of weight 8 (*octads*). These facts are proved in Chapter 30; here we derive the further facts the ground-state argument needs. Subsets of $\{0, \dots, 23\}$ are identified with words via their indicator `ind`.

Definition 40.60. An *octad* is a set O of size 8 whose indicator lies in $\mathcal{G}$.

File `VOA/Moonshine/GroundLatticeGolay.lean`.

```
def ind (A : Finset (Fin 24)) : Fin 24 → ZMod 2 := fun j => if j ∈ A then 1 else 0

def IsOct (O : Finset (Fin 24)) : Prop := ind O ∈ golay ∧ O.card = 8
```

Physical meaning

An octad is a set of eight of the 24 coordinates, i.e. eight of the 24 bosons, whose indicator lies in the Golay code. Octads label the minimal charged ground states (lattice vectors of the Leech lattice with shape $(\pm 2^8, 0^{16})$), the frame-charge bookkeeping of the 24 bosons.

(`VOA/Moonshine/GroundLatticeGolay.lean`, namespace `VOA.Moonshine.GroundLat`.)

theorem exists_octad_inter_three {S : Finset (Fin 24)} (hS : S.card = 4) :
    ∃ O, IsOct O ∧ (O ∩ S).card = 3
```

From the mathematics to the Lean statement

- `Finset (Fin 24)` is a finite subset of $\{0,\dots,23\}$; `card` its size; `weight` the Hamming weight. `·ᵥ` is the dot product over $\mathbb{F}_2$, so `ind O ·ᵥ x ≠ 0` means $|O \cap \operatorname{supp} x|$ is odd.
- (c) is only the existence half of $S(5,8,24)$ (uniqueness of the octad is not stated or needed).
- All are about the library's specific code `golay`; they hold for every extended Golay code but are proved here from the four properties listed above (doubly even, self-dual, minimum weight 8, 759 octads), with no enumeration of codewords.

Physical meaning

These are the standard combinatorial facts about the Golay code: codeword weights, intersections of octads, and the Steiner system $S(5,8,24)$ (every five coordinates in a unique octad). In the lattice picture they classify how the frame charges of the 24 bosons combine into Leech-lattice ground states of low norm; they are pure combinatorics with no dynamical content, used to guarantee that every heavy lattice vector has a decomposition into lighter ones.

Proof on paper. (a) Weights are divisible by 4 (doubly even); non-zero weights are ≥ 8; and $c + \mathbf{1}$ is a codeword of weight $24 - \operatorname{wt} c$, so weights ≤ 23 other than 0 are also ≤ 16 ($24 - \operatorname{wt} \geq 8$). (b) $|O_1 \triangle O_2| + 2|O_1 \cap O_2| = 16$ and $O_1 \triangle O_2$ is a non-zero codeword, so $|O_1 \triangle O_2| \geq 8$ and $|O_1 \cap O_2| \leq 4$.

(c) *By counting.* Each octad contains $\binom{8}{5} = 56$ five-subsets, and by (b) no five-subset lies in two octads. So the octads contain $759 \cdot 56 = 42504$ distinct five-subsets. But $\binom{24}{5} = 42504$. Hence every five-subset is in an octad.

(d) By self-duality $x \notin \mathcal{G} = \mathcal{G}^\perp$, so some codeword y has $y \cdot x = 1$. If $\operatorname{wt} y = 8$, done. If $\operatorname{wt} y = 16$, then $y + \mathbf{1}$ is an octad and $(y + \mathbf{1}) \cdot x = y \cdot x$ because x has even weight. If $\operatorname{wt} y = 12$ (a *dodecad*), y is a sum of two octads (take an octad O meeting y in ≥ 5 points by (c); then $O \triangle y$ has weight $20 - 2|O \cap y| \leq 10$, so it is an octad), and one of the two has odd product with x. ($\operatorname{wt} y \in \{0, 24\}$ is impossible: $0 \cdot x = 0$ and $\mathbf{1} \cdot x = \operatorname{wt} x = 0$.)

(e) Take an octad O meeting C in ≥ 5 points. The intersection sizes are constrained by $|O \triangle C| = 8 + |C| - 2|O \cap C| \in \{0, 8, 12, 16, 24\}$: for $|C| = 12$ this forces $|O \cap C| \in \{2, 4, 6\}$, so 6; for $|C| = 16$ it forces $\{4, 6, 8\}$, so 6 or 8. In the remaining case $O \subseteq C$, $|C| = 16$: take $T \subset O$ with $|T| = 3$, a point $c_5 \in C \setminus O$ and a point $d \notin C$; the octad O' through the five points $T \cup \{c_5, d\}$ meets C in 4 to 7 points, hence in 4 or 6; and 4 is impossible, since then $O \cap O' = T$ would have 3 points, while octads meet in an even number of points (again from the weight constraint).

(f) Let $S = \{s_1, \dots, s_4\}$. Choose $p \notin S$ and the octad $O_1 \supseteq S \cup \{p\}$, then $q \notin O_1$ and the octad $O_2 \supseteq \{s_1, s_2, s_3, p, q\}$. If $s_4 \in O_2$ then $O_1 \cap O_2 \supseteq S \cup \{p\}$ has 5 points, contradicting (b) ($O_1 \neq O_2$ as $q \in O_2 \setminus O_1$). So $O_2 \cap S = \{s_1, s_2, s_3\}$. □

What the machine verified

All proved, unconditional, `#print axioms`-clean (re-run for `steiner`). No `decide` over the 4096 codewords: the only computational input is the weight enumerator fact 759 from Chapter 30.

40.12.2 The lattice statement in Golay coordinates

Definition 40.62 (Direct and triangle relations)**.** For $g \in \mathbb{Z}^{24}$:

- Direct(g): there is $a \in A \setminus 0$ with $g - a \neq 0$ and $a \cdot (g - a) = -2$ or $a \cdot (g - a) \geq 2$;
- ZeroRel(u, v): $u = a + b$, $v = a - b$ with $a, b \in A \setminus 0$ and $a \cdot b = 0$;

- Tri(g): there are g', g'' with ZeroRel(g, g'), ZeroRel(g', g''), ZeroRel(g'', g).

File `VOA/Moonshine/GroundLatticeCoord.lean`.

```
def Direct (g : Fin 24 → ℤ) : Prop :=
  ∃ a ∈ subA, a ≠ 0 ∧ g - a ≠ 0 ∧ (a ·ᵥ (g - a) = -2 ∨ 2 ≤ a ·ᵥ (g - a))

def ZeroRel (u v : Fin 24 → ℤ) : Prop :=
  ∃ a ∈ subA, ∃ b ∈ subA, a ≠ 0 ∧ b ≠ 0 ∧ a ·ᵥ b = 0 ∧ a + b = u ∧ a - b = v

def Tri (g : Fin 24 → ℤ) : Prop :=
  ∃ g' g'', ZeroRel g g' ∧ ZeroRel g' g'' ∧ ZeroRel g'' g
```

(`VOA/Moonshine/GroundLatticeCoord.lean`.)

From the mathematics to the Lean statement

- `subA` is A; $\cdot_v$ the integer dot product, i.e. $2\langle\cdot,\cdot\rangle$. So Direct$(g)$ says $\gamma = \alpha + \beta$ with $\alpha, \beta \in \Lambda_0 \setminus 0$ and $\langle\alpha, \beta\rangle = -1$ or ≥ 1: a ground relation of the first kind. ZeroRel(u, v) is the $k = 0$ relation $x_u + x_v$.
- Direct does not require $g \in A$ (it follows when g is a sum of two elements of A).

Physical meaning

The relations describe when a lattice vector g can be written as a sum $a + b$ of two non-zero lattice vectors with prescribed inner product $a \cdot b$, that is, as a product of two charged ground states (-2 or at least 2), or through a three-step cycle of orthogonal decompositions (the triangle). They are the OPE channels of charge-a and charge-b vertex operators in coordinates, in the frame-charge bookkeeping.

Theorem 40.63 (Ground-lattice theorem in coordinates)**.** *Every $g \in A$ with $g \cdot g \geq 12$ satisfies* Direct(g) *or* Tri(g).

File `VOA/Moonshine/GroundLatticeCoord.lean`.

```
theorem groundLatticeA : ∀ g ∈ subA, 12 ≤ g ·ᵥ g → Direct g ∨ Tri g
```

The proof is a case analysis on the shape of g. First, some constructions.

Pair vectors. For $i \neq j$ and signs, $a = 2(\pm e_i \pm e_j) \in A$ (it is 0 mod 2 and its sum is 0 or ± 4), $a \cdot a = 8$, and with the signs of g_i, g_j, $a \cdot g = 2(|g_i| + |g_j|)$. Since $a \cdot (g - a) = a \cdot g - 8$, this gives Direct$(g)$ as soon as $a \cdot g = 6$ or $a \cdot g \geq 10$, i.e. as soon as *some pair has* $|g_i| + |g_j| = 3$ *or* ≥ 5 (`direct_of_pair`).

Octad vectors. For an octad O, a point $p \in O$ and signs $\sigma_j = \operatorname{sgn} g_j$ on $O \setminus p$, there is a choice $\sigma_p = \pm 1$ such that $a = \sigma \cdot \mathbf{1}_O \in A$ (the sum $\sum_O \sigma_j$ must be $\equiv 0$ mod 4; flipping σ_p changes it by 2); then $a \cdot a = 8$ and $a \cdot g = \sigma_p g_p + \sum_{O \setminus p} |g_j|$ (`exists_octVec`).

The shapes. If no pair has $|g_i| + |g_j| \in \{3\} \cup [5, \infty)$, then (when not all coordinates are odd) one of: $g = \pm 4e_i$; all $|g_j| \in \{0, 2\}$; all $|g_j| \leq 1$ with some $g_j = 0$.

- $|g_j| \in \{0, 2\}$**, support** S**.** Each entry ± 2 contributes 2 mod 4 to $\sum g_j$, so $4 \mid \sum g_j$ forces $|S|$ even, and $g \cdot g = 4|S| \geq 12$ gives $|S| \geq 4$. If $|S| = 4$, an octad meeting S in 3 points (Theorem 40.61(f)) and $p \in O \setminus S$ give $a \cdot g = 2 \cdot 3 = 6$. If $|S| \geq 5$, an octad meeting S in ≥ 5 points (by (c)) gives $a \cdot g \geq 10$, choosing $p \notin S$ when possible and otherwise using $\sigma_p g_p \geq -2$ (`direct_even2`).

- $|g_j| \le 1$, **some** $g_j = 0$. Then g mod 2 is the indicator of the support C, a codeword of weight 12 or 16 (it is ≥ 12 by the norm, and < 24). An octad meeting C in 6 points (Theorem 40.61(e)) gives $a \cdot g = 6$ (`direct_le_one`).
- $g = \pm 4e_i$ **(family E_1).** No direct relation exists. But $4e_i = 2(e_i + e_j) + 2(e_i - e_j)$ with orthogonal summands, so ZeroRel($\pm 4e_i, 4e_j$); the triangle $\pm 4e_i \to 4e_{i+1} \to 4e_{i+2} \to \pm 4e_i$ gives Tri (`e1_tri`).
- **All coordinates odd.** Let $\tau(g) = \{j : g_j \equiv 3 \bmod 4\}$.
  - If $\tau(g) \notin \mathcal{G}$: $\tau(g)$ has even size (from $4 \mid \sum g_j$), so by (d) some octad O meets it oddly. Take $p \in O$ minimising $|g_p|$; then $a \cdot g \ge -|g_p| + 7|g_p| \ge 6$, and a mod-4 computation shows $a \cdot g \equiv 2 \bmod 4$; hence $a \cdot g = 6$ or ≥ 10 (`odd_direct`).
  - If $\tau(g) \in \mathcal{G}$: for any codeword $C \notin \{\varnothing, \Omega\}$, flipping the signs of g on C is a ZeroRel step: $g = (g - g|_C) + g|_C$ and $\mathrm{flip}_C\, g = (g - g|_C) - g|_C$, where $g|_C \in A$ because $\tau(g) \in \mathcal{G}$ makes the sum over C divisible by 4, and the two pieces have disjoint supports, hence are orthogonal (`zeroRel_flip`). Flipping on C_1, then C_2, then $C_1 \triangle C_2$ returns to g: a triangle (`odd_tri`, with C_1, C_2 two explicit rows of the generator matrix).

From the mathematics to the Lean statement

The exceptional families, and why the uniform τ-criterion is the right formulation. The route notes (`Notes/ZhuGeneration.md` §4.3) isolated three families with no direct relation at all (confirmed by exhaustive enumeration, `e3_relations.py`):

- $E_1 = \{\pm 4e_i\}$ ($|\gamma|^2 = 8$);
- $E_2 = \{(\pm 1)^{24} : \text{negative set} \in \mathcal{G}\}$ ($|\gamma|^2 = 12$);
- $E_3 = \{s + 2s_i e_i : s \in \{\pm 1\}^{24},\ N(s) \triangle \{i\} \in \mathcal{G}\}$ ($|\gamma|^2 = 16$; one orbit of 98304 vectors), $N(s)$ the negative set.

For $g \in E_2$, $\tau(g)$ is the negative set; for $g \in E_3$ ($g_i = \pm 3$), $\tau(g) = N(s) \triangle \{i\}$ (if $s_i = 1$, $g_i = 3 \in \tau$ and $i \notin N$; if $s_i = -1$, $g_i = -3 \equiv 1$ and $i \in N$). So $E_2 \cup E_3$ is contained in $\{g \text{ all odd} : \tau(g) \in \mathcal{G}\}$, and the Lean proof treats this whole set by the triangle argument, whether or not a direct relation also exists. This is a simplification over the notes, not a weakening: Tri is a valid route for every such g.

Physical meaning

Every Leech sublattice vector of norm at least twelve (in coordinates) either decomposes directly as a sum of two lighter vectors with inner product -2 or at least 2, or through a triangle of orthogonal decompositions. Physically: every heavy charged ground state is a field product of lighter ones, because its lattice vector has a suitable decomposition. Pure combinatorics of the Golay code and the Steiner system.

What the machine verified

`groundLatticeA`: proved, unconditional. Only small kernel `decide`s are used (on `Fin 24`, on `ZMod 2`, and on the values of two rows of the generator matrix).

Trap / dead end

Random sampling misses E_2 and E_3. The first numerical check (`ground_states.py`: random placements of every magnitude pattern up to $|\gamma|^2 = 28$, 60 per pattern) found only E_1.

E_2 and E_3 are single *sign classes* (codeword sign patterns), which random signs essentially never hit. Lattice conditions on Λ_0 must be checked by orbit structure or exhaustively, not by sampling.

40.12.3 Transport to the vertex algebra

Theorem 40.64 (`GroundLattice` holds). `GroundLattice` *(Definition 40.52) is true.*

File `VOA/Moonshine/GroundLattice.lean`.

```
noncomputable def iotaA (a : ₁Leech.subA) : leech.carrier := (lambda0Equiv a :
↪  leech.carrier)

theorem groundLattice : GroundLattice

theorem zhuGenerated_weightTwo_of_fock_excited (hF : FockSpanned) (hE : ExcitedSpanned) :
    ZhuGenerated weightTwo
```

(`VOA/Moonshine/GroundLattice.lean`, namespace `VOA.Moonshine.SigmaExist`.)

From the mathematics to the Lean statement

`iotaA` is the isometric inclusion $A \to \Lambda_0 \subset \Lambda$ with $\langle \iota a, \iota b\rangle = (a \cdot b)/2$. `groundLattice` has no hypotheses.

Physical meaning

Transport of the coordinate statement to the vertex algebra: every heavy ground state of the sector is a combination of OPE products of lighter charged ground states. In field-theory language, the charged ground states of norm at least six carry no new generators; they are generated from lighter ones, which is the ground-state residual.

Proof on paper. Given $\gamma \in \Lambda_0$ with $|\gamma|^2 \geq 6$, let $g = \iota^{-1}\gamma$; $g \cdot g = 2|\gamma|^2 \geq 12$. A Direct witness a gives $\gamma = \iota a + \iota(g - a)$, a ground relation of the first kind. A ZeroRel(u, v) gives the relation $x_u + x_v$, and $|u|^2 = |v|^2$ (as $a \perp b$), so all three relations of a triangle have the right weight; then

$$x_g = \tfrac{1}{2}\big[(x_g + x_{g'}) - (x_{g'} + x_{g''}) + (x_{g''} + x_g)\big]$$

lies in the span. (This is why a triangle, an odd cycle, is needed: with all relation signs $+$, a path or even cycle would only give alternating sums.) □

What the machine verified

Proved, unconditional, `#print axioms` = [`propext`, `Classical.choice`, `Quot.sound`] (re-run).

40.13 The headline: V_0^+ is Zhu-generated by weight two

Theorem 40.65 (R-gen). *Every subspace of V_0^+ that contains* $\mathbf{1}$*, $\mathcal{O}(V_0^+)$ and $(V_0^+)_2$, and is closed under Zhu's product, is all of V_0^+.*

File `VOA/Moonshine/ZhuGenerated.lean`.

```
theorem zhuGenerated_weightTwo : SigmaExist.ZhuGenerated SigmaExist.weightTwo :=
  FockSpan.zhuGenerated_weightTwo_of_groundLattice SigmaExist.groundLattice
```

(`VOA/Moonshine/ZhuGenerated.lean`, namespace `VOA.Moonshine`.)

From the mathematics to the Lean statement

- Unfolding: `ZhuGenerated` is Definition 40.36, `weightTwo` is $(V_0^+)_2$ (Definition 40.47), `zhuMul` and `O` are Definitions 40.1, 40.2 applied to the VOA `V0P` $= V_0^+$.
- The one-line proof term is itself informative: R-gen is the assembly `FockSpanned` ∧ `ExcitedSpanned` ∧ `GroundLattice` ⇒ R-gen, with the three inputs `fockSpanned`, `excitedSpanned`, `groundLattice`.
- No hypotheses. The statement is not vacuous (Definition 40.36). It is consistent with the numerical experiment of §40.8 and with the literature classification of $A(V_{\Lambda_0}^+)$, neither of which is used.

Physical meaning

The weight-two fields Zhu-generate the whole chiral algebra: the zero modes of the weight-two fields, with the identity, already generate the algebra of zero modes acting on the ground states of every sector. Combined with the earlier reduction, it means that to extend the triality to the twisted sectors one only needs to check the intertwining on the zero modes of the weight-two fields; it is the unconditional input that makes the three sector residuals together sufficient.

Proof on paper. Theorem 40.45 (filtered criterion) reduces to `V0LowerSpanned`; §40.10 reduces that to the Fock, charged-excited and ground sectors; Theorems 40.58, 40.57 and 40.64 prove them. □

What the machine verified

Proved, unconditional. Re-run for this chapter, via `lake env lean -DmaxSynthPendingDepth=3` on a scratch file importing `VOA.Moonshine.ZhuGenerated`:

```
'VOA.Moonshine.zhuGenerated_weightTwo' depends on axioms: [propext, Classical.choice,
↪ Quot.sound]
```

No `VOA.pbw`. The file is imported by the umbrella `VOA/Moonshine.lean`; for an earlier commit the project's build record reports the aggregate `lake build` green (10343 jobs; not re-run for this chapter).

What it buys. Combining Theorems 40.65, 40.40 and 40.33: to construct σ on V_3^+ (and likewise on T_s^+) it suffices to give one linear map φ on the 49152-dimensional top level which maps into $(T_s^+)_2$, hits a cyclic vector, and intertwines $o(g) = g_{(1)}$ with $o(\sigma g)$ for the 49428 weight-two letters g. Chapter 41 supplies φ and proves those identities (`topSigma_both`), using `zhuGenerated_G2`, which is `zhuGenerated_weightTwo` for the letter set `G2` = `weightTwo` (`G2_eq_weightTwo : G2 = weightTwo := rfl`).

40.14 Dead ends and traps

Trap / dead end

Collected from the route notes, with the evidence:

1. **Which `TPframe` is T_0?** Undetermined by the definitions (Theorem 40.21); state results with ∃s.
2. **Dong–Jiang / Verma route** carries `BottomProjection`, supplied only by `VOA.pbw`; re-

placed by the graph argument (§40.3.4).

3. $\varphi = 0$ satisfies all clauses but `hits_cyclic`; that clause is essential.
4. **Gram route** (`annCompat_of_gram`) needs source Gram data too; unnecessary.
5. **Weak generation** (`leechPlus_generated`) does not reduce the top-level clause.
6. **Tops irreducible** ⇒ **Zhu generated** is circular.
7. **Strong generation fails**: Fock part of weight 3 has dimension $576 > 300$.
8. **Rank one fails** at weight 4 (J); the degree-four cancellation needs two colours.
9. **Charged degree one** needs the exact vacuum formula, not weight-two quadratics alone.
10. $\alpha = \beta$ **must be allowed** in `GroundRel`.
11. **Random sign sampling misses E_2, E_3.**
12. **Low-order traces** do not separate $V_3^{\pm}$.
13. The filtered criterion is *sufficient only*: do not record a numerical failure of it as a failure of Zhu generation.

40.15 Referee's checklist

"uncond." = no hypothesis that is an unproved datum; ∗ = `#print axioms` re-run for this chapter, result [`propext`, `Classical.choice`, `Quot.sound`]. None of the declarations uses `VOA.pbw`.

Lean declaration	intended meaning	hypotheses	status / check

40.16 Notes and references

Zhu's algebra. Y. Zhu, *Modular invariance of characters of vertex operator algebras*, J. Amer. Math. Soc. 9 (1996), 237–302, introduced $A(V)$, the product $*$, $\mathcal{O}(V)$ and the correspondence between $A(V)$-modules and top levels (Theorems 2.1.2 and 2.2.1 there). I. B. Frenkel and Y. Zhu, *Vertex operator algebras associated to representations of affine and Virasoro algebras*, Duke Math. J. 66 (1992), 123–168, contains the higher residues Pres (their Lemma 2.1.2) and the bimodule technique used in Chapter 42. C. Dong, H. Li and G. Mason, *Vertex operator algebras and associative algebras*, J. Algebra 206 (1998), 67–96 (arXiv:q-alg/9612010), give the generalised Verma modules $M(U)$ and $L(U)$ and the higher Zhu algebras $A_n(V)$; the library's version (Dong–Jiang) is treated in Chapter 13. The presentation of $*$ and $\mathcal{O}$ follows T. Gannon, *Moonshine beyond the Monster*, Cambridge University Press, 2006, §5.3. Li's single-mode spanning lemma: H. Li, *Local systems of vertex operators, vertex superalgebras and modules*, J. Pure Appl. Algebra 109 (1996), 143–195 (arXiv:hep-th/9406185).

The orbifold V_L^+ and its Zhu algebra. C. Dong and K. Nagatomo, *Classification of irreducible modules for the vertex operator algebra $M(1)^+$*, J. Algebra 216 (1999), 384–404 (arXiv:math/9806051), where $A(M(1)^+)$ is generated by ω and J. T. Abe and C. Dong, *Classification of irreducible modules for the vertex operator algebra V_L^+: general case*, J. Algebra 273 (2004), 657–685 (arXiv:math/0210160); T. Abe, C. Dong and H. Li, *Fusion rules for the vertex operator algebras $M(1)^+$ and V_L^+*, Comm. Math. Phys. 253 (2005), 171–219 (arXiv:math/0310425). These classification results are *cited, not used*: the Lean proof of Zhu generation is independent of them.

The triality. I. Frenkel, J. Lepowsky and A. Meurman, *Vertex Operator Algebras and the Monster*, Academic Press, 1988, chapters 11–13. L. Dolan, P. Goddard and P. Montague, *Conformal field theories, representations and lattice constructions*, Comm. Math. Phys. 179 (1996), 61–120 (arXiv:hep-th/9410029), §§6–7, where σ on the twisted sectors is obtained non-constructively. A modern account of the sixteen irreducible V_Λ^{++}-modules and the lifting of the triality is in G. Höhn and M. Seysen, "The order of the Monster finite simple group", arXiv:2508.01037 (2025), §2.2.

The Golay code and the Steiner system. J. H. Conway and N. J. A. Sloane, *Sphere Packings, Lattices and Groups*, 3rd ed., Springer, 1999, chapters 3, 10 and 11 (the Golay code, the Steiner system $S(5,8,24)$, octads and dodecads, and the Leech lattice in Golay coordinates). The counting proof of the existence half of $S(5,8,24)$ given in Theorem 40.61(c) is the classical one ($759\binom{8}{5} = \binom{24}{5}$).

Project records. `Notes/TrialityTwisted.md`, `Notes/SigmaExistence.md`, `Notes/ZhuGeneratorTest.md`, `Notes/ZhuGeneration.md`, and the "Status" sections of `Notes/M8GluingPlan.md` from "M8g twisted half" to "R-gen CLOSED"; numerical scripts in `scripts/moonshine/numerics/zhu/` and `zhugen/`.

Chapter 41

Existence of the twisted triality II: the explicit construction

41.1 Where we stand, and what this chapter does

This chapter documents the release of the library named in the front matter. Quotations from the repository are printed in `leancode` boxes, which are checked by `scripts/textbook/sync.py` to occur verbatim in the source of that release (up to whitespace; documentation comments may be omitted); tool output is printed in plain boxes. Checks that were run at an earlier state of the library and not re-run for this edition are marked as such.

Chapter 39 built the *untwisted* half of the Frenkel–Lepowsky–Meurman triality: an involutive automorphism σ of the vertex operator algebra V_0^+, the fixed points of a group $(\mathbb{Z}/2)^2$ acting on the Leech lattice VOA V_Λ. Chapter 40 explained why one needs more: σ must be *extended* to the two other irreducible V_0^+-modules that make up $V^\natural$, namely

$$\sigma : V_3^+ \longrightarrow T_s^+ \qquad \text{and} \qquad \sigma : T_{s'}^+ \longrightarrow T_s^+,$$

as *σ-twisted intertwiners*: linear maps Φ with $\Phi(u_{(n)}x) = (\sigma u)_{(n)}\Phi(x)$ for all $u \in V_0^+$ and all n. Chapter 40 then proved two reduction theorems:

(i) such a Φ exists as soon as there is a linear map φ on the *top level* (the weight-two space, of dimension 49152) that satisfies the zero-mode identity $\varphi(\mathrm{o}(a)x) = \mathrm{o}(\sigma a)\varphi(x)$ for *every* homogeneous $a \in V_0^+$ and hits a cyclic vector (the residual structures `TopSigmaV3`, `TopSigmaTT`);

(ii) because the weight-two space $(V_0^+)_2$ generates the Zhu algebra of V_0^+ (`zhuGenerated_weightTwo`), it suffices to check the zero-mode identity for a of weight two.

What is left is therefore a *finite, explicit* problem of linear algebra: write down φ on a 49152-dimensional space, and check $\varphi \circ \mathrm{o}(a) = \mathrm{o}(\sigma a) \circ \varphi$ for every a in the 49428-dimensional space $(V_0^+)_2$. This chapter solves it, in Lean, with no hypotheses. The headline results are

```
topSigmaV3 : ∃ s ∃ φ, TopSigmaV3 s φ,      topSigmaTT : ∃ s ∃ φ, TopSigmaTT s s φ,
```

their consequences `sigmaV3T_exists`, `sigmaTT_exists`, and the combined form `topSigma_both`, in which both maps come from one and the same "seed" vector so that their sectors match.

The shape of the answer

The physics picture is helpful. $V^\natural$ is a $\mathbb{Z}/2$-orbifold of the Leech lattice theory; the twisted sector V_Λ^T is built on the ground states T, a 4096-dimensional irreducible representation of a finite extraspecial 2-group (Chapter 34), and its weight-two states are $h(-\frac{1}{2}) \otimes T$, one twisted oscillator on a ground

state. The untwisted states of weight two in V_3^+ are the lattice states $e^n + e^{-n}$ for the 98304 odd Leech vectors n of norm 4. The triality σ exchanges these two descriptions, and we shall find that it does so *monomially*:

$$\varphi\big(e^n + e^{-n}\big) \;=\; h_{w_{j(n)}}(-\tfrac{1}{2}) \otimes \tau(n), \qquad \tau(n) = i^{\,n_0}\ \mathrm{sign}(n_{j(n)})\ e_n\, t,$$

where $j(n)$ is the unique coordinate in which n has an entry ± 3, $w_j = 8e_j$ is the j-th frame vector, e_n is the action of n on T, and $t \in T$ is one fixed "seed" vector. The work of the chapter is (a) to compute all zero modes on both sides, (b) to compute σ on every weight-two letter, (c) to construct the seed t, and (d) to verify the identities, which in the end reduce to facts about the Golay code (minimum weight 8, self-duality, double evenness) and a few 2×2 matrix identities over $\mathbb{Q}(\sqrt{2}, i)$.

A remark on method: everything stays symbolic

The Leech lattice cocycle ε_Λ in the library is defined from an arbitrary $\mathbb{Z}$-basis chosen by `Module.Free.chooseBasis`; its values are not computable. Likewise the character `golayE` that enters the bridge between the Niemeier lattice $N(A_1^{24})$ and the Leech lattice is chosen by `Classical.choose`. Not a single sign in this chapter is ever evaluated. Every identity is derived from structural properties — bimultiplicativity, $\varepsilon(a,a) = \pm 1$, the commutator formula $\varepsilon(a,b)\varepsilon(b,a) = (-1)^{\langle a,b\rangle}$, the coboundary comparison between cocycles of two lattices, and θ-invariance of $\sigma(u)$. Section 41.8 discusses why this was not an obstacle, and why a refactoring to an explicit basis would not have helped.

41.2 The objects, and the statements to be proved

This section collects, with their Lean sources, the definitions that occur in the statements of the chapter. Most were introduced in Chapters 32, 34, 36, 39 and 40; we repeat what is needed so that every statement below can be checked against definitions printed in this book.

41.2.1 Coordinates on the Leech lattice

The library's Leech lattice Λ (`leech`) is realised inside $\mathbb{Z}^{24}$: a vector is an integer vector $x = (x_0, \dots, x_{23})$ and the bilinear form is

$$\langle x, y\rangle \;=\; \tfrac{1}{8}\, x \cdot y. \tag{41.1}$$

(This is the usual $\frac{1}{\sqrt{8}}$-normalisation of the Turyn/Conway construction; see Chapter 30.) The lattice consists of the vectors $x \equiv 0 \pmod 2$ with $x/2 \bmod 2$ in the Golay code $\mathcal{G}$ and $\sum x_i \equiv 0 \pmod 8$ (the *even* Leech vectors, $x = 2a$ with $a \in A$ below), together with the translates $x = 2a + u$ of these by $u = (5, 1^{23})$ (the *odd* Leech vectors; `Leech.uVec`). The homomorphism

$$\beta : \Lambda \to \mathbb{Z}/2, \qquad \beta(x) = x_0 \bmod 2$$

is the library's `frameChar`; its kernel is the index-two sublattice Λ_0 (`lambda0`).
File `VOA/Moonshine/FrameSectors.lean`.

```
noncomputable def frameChar : leech.carrier →+ ZMod 2 := Leech.beta.toAddMonoidHom

noncomputable def lambda0 : Submodule ℤ leech.carrier := LinearMap.ker Leech.beta
```

with `Leech.beta` the map `x ↦ ((x 0 : ℤ) : ZMod 2)` (`VOA/LatticesAndCodes/Leech/Defs.lean`). In Lean the integer coordinates of a Leech vector x are written `lv x : Fin 24 → ℤ` (`SigmaTopFrame.lean`), and the identity (41.1) is the theorem `leech_form_lv`:

```
def lv (x : leech.carrier) : Fin 24 → ℤ := (show ↥Leech.carrier from x).1

theorem leech_form_lv (x y : leech.carrier) : leech.form x y = (lv x ⬝ᵥ lv y) / 8 := rfl
```

(the integer division is exact, since $8 \mid x \cdot y$ for Leech vectors, `eight_dvd_lv`).

Two other lattices. Two further lattices enter. The set

$$A = \{a \in \mathbb{Z}^{24} \,:\, a \bmod 2 \in \mathcal{G},\ 4 \mid \textstyle\sum a_i\}$$

(`Leech.subA`) carries the form $\langle a, b\rangle_A = \frac{1}{2} a \cdot b$; it is the lattice `lam0`. It maps isometrically onto Λ_0 by $\iota_\Lambda(a) = 2a$ (`inclΛ`), and it also sits inside the Niemeier lattice

$$N = N(A_1^{24}) = \{x \in \mathbb{Z}^{24} \,:\, x \bmod 2 \in \mathcal{G}\}, \qquad \langle x, y\rangle_N = \tfrac{1}{2} x \cdot y$$

(`golayN`) by the identity map ι_N (`inclN`). In N the vectors $\alpha_j = 2e_j$ (`golayRoot j`) are the 48 roots $\pm\alpha_j$ of the root system A_1^{24}. So

$$N \;\supset\; A \xrightarrow{\;\iota_\Lambda = 2\cdot\;} \Lambda_0 \subset \Lambda,$$

and $A \cong \Lambda_0 = \Lambda \cap N$ is the common index-two sublattice through which the Leech theory and the Niemeier theory are compared. In Leech coordinates the frame vectors are $w_j = \iota_\Lambda(4e_j) = 8e_j$ (`fw j`); they satisfy $\langle w_j, x\rangle = x_j$ and $\langle w_j, w_k\rangle = 8\delta_{jk}$. The special frame vector $w_0 = 8e_0$ is `frameW`.

41.2.2 The lattice VOAs, the cocycles, and the bridge

For an even lattice L the lattice VOA V_L (Chapter 31) has states $p \otimes e^\gamma$, p in the Heisenberg Fock space, $\gamma \in L$. Its vertex operators involve a ±1-valued bimultiplicative 2-cocycle ε_L with $\varepsilon_L(a,b)\varepsilon_L(b,a) = (-1)^{\langle a,b\rangle}$, the library's `latticeCocycle L`; it is defined from the basis `latticeBasis L`, itself an arbitrary $\mathbb{Z}$-basis. The charged vacuum $1 \otimes e^\gamma$ is `latChargeGen L γ`, and in this chapter we write it e^γ.

Two lattice VOAs built from *different* cocycles on isometric lattices are isomorphic, but the isomorphism rescales charged states by a function $c(\gamma) \in \{\pm 1, \pm i\}$ which is a "coboundary" comparing the two cocycles: $\varepsilon_L(\iota a, \iota b)\, c(a)c(b) = \varepsilon_K(a,b)\, c(a+b)$. This is `latCob K L ι` (Chapter 31, `latticeCocycle_map_mul_latCob`).

Chapter 39 built the VOA isomorphism

$$\texttt{golayToV0}:\ V_N^{\langle \chi, \Theta\rangle} \xrightarrow{\sim} V_0^+,$$

the composite of the lattice functoriality maps for $A \to N$ and $A \to \Lambda$ with one twist by a character g_e of A, the character `golayE`, chosen (by `Classical.choose`) so that a certain involution of V_A becomes the standard θ. The triality on V_0^+ is the transport of the N-side triality: Files `VOA/Moonshine/TrialityGolay.lean`, `VOA/Moonshine/FrameBridgeGolay.lean`.

```
noncomputable def golaySigma : Aut golayVOA := golayG * golayChiMod * golayG⁻¹

noncomputable def golayTheta : Aut golayVOA := golaySigma * golayChi * golaySigma

noncomputable def golayToV0 : (orbifold golayK).carrier ≃ₗ[ℂ] V0Sub.carrier :=
  lam0PlusGolayEquiv.symm.trans lam0PlusEquiv

noncomputable def v0Sigma : Aut V0P :=
  Aut.transport golayToV0 golayToV0_isVOAHom golayToV0_omega golaySigma0
```

Here `golayG` $= \prod_j g_j$ with $g_j = \exp\big((1-\sqrt{2})E_j\big)\exp\big(\frac{\sqrt{2}}{4}F_j\big)$, where $E_j = (e^{\alpha_j})_{(0)}$, $F_j = \varepsilon_j(e^{-\alpha_j})_{(0)}$ and $\varepsilon_j = \varepsilon_N(\alpha_j, -\alpha_j)$ (`golayEps j`) are the $\hat{\mathfrak{sl}}_2$ zero modes attached to the root α_j; `golayChiMod` is the momentum sign $e^\gamma \mapsto (-1)^{\sum \gamma_i/2 + \gamma_0} e^\gamma$ (Chapter 39 explains the extra γ_0, DGM's modification (7.8)); `golayChi` is $e^\gamma \mapsto (-1)^{\sum \gamma_i/2} e^\gamma$. `golaySigma0` is the restriction of σ to the orbifold $V_N^{\langle \chi, \Theta\rangle}$. In what follows σ always means `v0Sigma`, accessed through File `VOA/Moonshine/TrialityTwSigma.lean`.

```
noncomputable def sig (u : V0Sub.carrier) : V0Sub.carrier := v0Sigma u
```

41.2.3 The sectors

V_Λ^+ is `VPlus`, the θ-fixed subVOA (Chapter 32). The *frame automorphism* `plusFrameAut` acts on e^γ by $(-1)^{\beta(\gamma)}$; its eigenspaces are `frameSector 0` $= V_0^+$ (also `V0Sub`, with VOA structure `V0P`) and `frameSector 1` $= V_3^+$. File `VOA/Moonshine/FrameSectors.lean`.

```
noncomputable def frameSector (i : ZMod 2) : Submodule ℂ VPlus :=
  Module.End.eigenspace (plusFrameAut.toLinearEquiv : Module.End ℂ VPlus)
    (Moonshine.Extraspecial.sgn i)
```

(`Extraspecial.sgn i` is $(-1)^i$.) On the twisted side, `TLeechT` is the 4096-dimensional module T of the extraspecial group $\hat\Lambda/K$ (Chapter 34), with operators e_γ = `eT leech … γ`, $\gamma \in \Lambda$, satisfying

$$e_a e_b = \varepsilon_\Lambda(a,b)\, e_{a+b}, \qquad e_{a+2b} = e_a, \qquad e_{-a} = e_a, \qquad e_a e_b = (-1)^{\langle a,b\rangle} e_b e_a, \tag{41.2}$$

(`eT_mul`, `eT_add_two_nsmul`, `eT_neg`, `eT_comm_sign'`); in particular $e_a^2 = \varepsilon_\Lambda(a,a)$. The frame involution is $J = c^{-1} e_{w_0}$ with $c^2 = \varepsilon(w_0, w_0)$, and $T = T_0 \oplus T_1$ with $T_s = \{t : Jt = (-1)^s t\}$: File `VOA/Moonshine/FrameTwisted.lean`.

```
noncomputable def frameJ (w : L.carrier) : End ℂ (TT L hEven hU) :=
  (sqrtEps L w)⁻¹ • eT L hEven hU w

noncomputable def frameT (w : L.carrier) (s : ZMod 2) : Submodule ℂ (TT L hEven hU) :=
  Module.End.eigenspace (frameJ L hEven hU w) (Extraspecial.sgn s)

noncomputable abbrev leechFrameT (s : ZMod 2) : Submodule ℂ (TT leech leech_even
↪  leech_isUnit_det_gramMat) :=
  frameT leech leech_even leech_isUnit_det_gramMat frameW s
```

The θ-fixed twisted module $(V_\Lambda^T)^+$ is `TP`, a submodule of `Tw` $= S[\theta] \otimes T$, and `TPframe s` $= T_s^+$ is the part with $J = (-1)^s$. Its cyclic vector is $x_0^T(t_0) = h_0(-\frac{1}{2}) \otimes t_0$: Files `VOA/Moonshine/CyclicTwisted.lean`, `VOA/Moonshine/TrialityTwSigma.lean`.

```
noncomputable def frameX0T (t₀ : TLeechT) : Tw := (X (0, 0) : FockT 24) ⊗ₜ t₀
noncomputable def x0T (t₀ : TLeechT) : TP := ⟨frameX0T t₀, frameX0T_mem_TP t₀⟩
```

(`X (0, c)` is the Fock variable for the mode $h_c(-\frac{1}{2})$, $c \in \{0, \dots, 23\}$.)

41.2.4 The actions, the intertwiner predicates, the residuals

For $u \in V_0^+$ and $n \in \mathbb{Z}$ the operators $u_{(n)}$ on V_Λ^+ and on $(V_\Lambda^T)^+$ are File `VOA/Moonshine/TrialityTwSigma.lean`.

```
noncomputable def actV (u : V0Sub.carrier) (n : ℤ) : VPlus →ₗ[ℂ] VPlus :=
  mode (leechVOAPlus.Y (u : VPlus)) n

noncomputable def actT (u : V0Sub.carrier) (n : ℤ) : TP →ₗ[ℂ] TP :=
  mode (Moonshine.plusModule.YM (u : VPlus)) n
```

Recall (Definition 2.7) that `mode f n` is the coefficient $u_{(n)}$ of z^{-n-1} in $Y(u,z)$. For u of weight k the *zero mode* $\mathrm{o}(u)$, the operator that preserves weight, is $u_{(k-1)}$; for the weight-two letters of this chapter it is $u_{(1)}$, which is why the number `1` appears everywhere below. A twisted intertwiner is Files `VOA/Moonshine/TrialityTwGeneric.lean`, `VOA/Moonshine/TrialityTwSigma.lean`.

```
def IsTwInt (ρ : A → ℤ → M →ₗ[ℂ] M) (τ : A → ℤ → N →ₗ[ℂ] N) (g : A → A) (S : Set A)
    (X : Submodule ℂ M) (Φ : M →ₗ[ℂ] N) : Prop :=
  ∀ u ∈ S, ∀ (n : ℤ), ∀ x ∈ X, Φ (ρ u n x) = τ (g u) n (Φ x)

def IsSigmaV3T (Φ : VPlus →ₗ[ℂ] TP) : Prop :=
  IsTwInt actV actT sig Set.univ (frameSector 1) Φ

def IsSigmaTT (s : ZMod 2) (Φ : TP →ₗ[ℂ] TP) : Prop :=
  IsTwInt actT actT sig Set.univ (TPframe s) Φ
```

So `IsSigmaV3T Φ` says exactly: for all $u \in V_0^+$, all $n \in \mathbb{Z}$ and all $x \in V_3^+$, $\Phi(u_{(n)}x) = (\sigma u)_{(n)}\Phi(x)$. The top levels and the two residual structures of Chapter 40 are:

```
noncomputable def OmegaV3 : Submodule ℂ VPlus := frameSector 1 ⊓ leechVOAPlus.grading 2

structure TopSigmaV3 (s : ZMod 2) (φ : VPlus →ₗ[ℂ] TP) : Prop where
  /-- `φ` maps the top level of `V₃⁺` into `T_s⁺`. -/
  maps_frame : ∀ x ∈ OmegaV3, φ x ∈ TPframe s
  /-- `φ` maps the top level into weight 2. -/
  maps_weight : ∀ x ∈ OmegaV3, φ x ∈ plusModule.weight (2 : ℂ)
  /-- Zero-mode intertwining: `φ (o(a) x) = o(σ a) φ x` for every homogeneous `a ∈ V₀⁺`. -/
  zero_mode : ∀ (k : ℤ) (a : V0Sub.carrier), (a : VPlus) ∈ leechVOAPlus.grading k →
    ∀ x ∈ OmegaV3, φ (actV a (k - 1) x) = actT (sig a) (k - 1) (φ x)
  /-- `φ` hits a cyclic vector `h₀(-½)𝟙 ⊗ t₀` of `T_s⁺`. -/
  hits_cyclic : ∃ t₀ : TLeechT, t₀ ∈ leechFrameT s ∧ t₀ ≠ 0 ∧ ∃ x ∈ OmegaV3, φ x = x0T t₀

noncomputable def OmegaT (s' : ZMod 2) : Submodule ℂ TP := TPframe s' ⊓ plusModule.weight
↪ (2 : ℂ)

structure TopSigmaTT (s' s : ZMod 2) (φ : TP →ₗ[ℂ] TP) : Prop where
  maps_frame : ∀ x ∈ OmegaT s', φ x ∈ TPframe s
  maps_weight : ∀ x ∈ OmegaT s', φ x ∈ plusModule.weight (2 : ℂ)
  zero_mode : ∀ (k : ℤ) (a : V0Sub.carrier), (a : VPlus) ∈ leechVOAPlus.grading k →
    ∀ x ∈ OmegaT s', φ (actT a (k - 1) x) = actT (sig a) (k - 1) (φ x)
  hits_cyclic : ∃ t₀ : TLeechT, t₀ ∈ leechFrameT s ∧ t₀ ≠ 0 ∧ ∃ x ∈ OmegaT s', φ x = x0T t₀
```

(`SigmaExistLeech.lean`; the doc-strings of `TopSigmaTT` are omitted, they repeat those of `TopSigmaV3`.) The clause `hits_cyclic` is what excludes the trivial solution $\varphi = 0$, which satisfies every other clause: this was a recorded trap of Chapter 40.

Finally Zhu generation (Chapter 40): a set $G \subseteq V_0^+$ is *Zhu-generating* if every subspace containing the vacuum, $O(V_0^+)$ and G and closed under Zhu's product is everything. File `VOA/Moonshine/SigmaExistZhu.lean`.

```
def ZhuGenerated (G : Set V0Sub.carrier) : Prop :=
  ∀ S : Submodule ℂ V0Sub.carrier, V0P.vacuum ∈ S → O V0P ≤ S →
    (∀ a ∈ S, ∀ b ∈ S, zhuMul V0P a b ∈ S) → G ⊆ S → S = ⊤
```

The two reductions of Chapter 40 that this chapter feeds are `topSigmaV3_of_zhuGenerated` ("`TopSigmaV3 s φ` follows from `maps_frame`, `maps_weight`, `hits_cyclic`, a Zhu-generating set G, and the zero-mode identity for $g \in G$") and `sigmaV3T_exists_of_top` ("`TopSigmaV3 s φ` implies a genuine Φ with `IsSigmaV3T Φ` extending φ"), and their `TT` analogues.

Remark 41.1 (Why "$\exists s$")**.** Every final statement of this chapter has the form "there is a sector $s \in \mathbb{Z}/2$ such that…". This is forced. Chapter 40 proved `golayE_not_determined`: the specification of the chosen character `golayE` pins it only up to a character e_β with β odd, and the two admissible choices give versions of σ conjugate by an automorphism of $V^\natural$ that swaps T_0^+ and T_1^+. Which of the two T_s^+ is the image of V_3^+ is therefore not a property of the definitions; it depends on a bit hidden inside `Classical.choose`. The construction below produces the seed in whichever sector it lands (`seed_in_frame`) and reports that sector existentially.

41.3 The source side: zero modes on V_3^+ and the letters of $(V_0^+)_2$

41.3.1 The zero mode of a normally ordered product

The first computation is a VOA-generic one. A weight-two state of the form $u_{(-1)}v$ (normally ordered product of two weight-one states) acts on a vector x through its zero mode $(u_{(-1)}v)_{(1)}$. If u and v act on x "diagonally and only through their zero modes", the product acts by the product of eigenvalues — the familiar statement that $\frac{1}{2}h(-1)^2\mathbf{1}$ measures $\frac{1}{2}p^2$ on a momentum state.

Lemma 41.2 (`smul_neg_one_one`)**.** *Let W be a VOA, $u, v, x \in W$, $\mu, \nu \in \mathbb{C}$, and suppose $u_{(i)}x = \delta_{i0}\mu x$ and $v_{(i)}x = \delta_{i0}\nu x$ for all $i \geq 0$. Then $(u_{(-1)}v)_{(1)}x = \mu\nu\, x$.*

```
theorem smul_neg_one_one {V : Type*} [AddCommGroup V] [Module ℂ V] (W :
↪  VertexOperatorAlgebra V)
    (u v x : V) (μ ν : ℂ) (hu : ∀ i : ℕ, W.smul u i x = if i = 0 then μ • x else 0)
    (hv : ∀ i : ℕ, W.smul v i x = if i = 0 then ν • x else 0) :
    W.smul (W.smul u (-1) v) 1 x = (μ * ν) • x
```

From the mathematics to the Lean statement

`W.smul u n x` is the library's notation for $u_{(n)}x$ (Definition 4.2). The hypotheses `hu`, `hv` range over natural numbers `i`, i.e. over the non-negative modes only; nothing is assumed about negative modes. The conclusion is exactly $(u_{(-1)}v)_{(1)}x = \mu\nu x$. Same as the textbook statement. Non-vacuity: the hypotheses are met by $u = h_a(-1)\mathbf{1}$ on any charged vacuum e^γ of a lattice VOA (Lemma 41.3).

Physical meaning

A normally ordered product of two currents acts on a charged state through the product of their charges, as in the Sugawara-type statement that $\frac{1}{2}h(-1)^2\mathbf{1}$ measures $\frac{1}{2}p^2$ on a momentum eigenstate. Physically it is the statement that bilinears in the Cartan currents are diagonal on

momentum states. This is a technical computation used to read off the eigenvalues of the weight-two zero modes on the source ground states; it is an exact lemma, not a heuristic.

Proof. The iterate (Borcherds) formula gives $(u_{(-1)}v)_{(1)} = \sum_{i\geq 0}\big(u_{(-1-i)}v_{(1+i)} + v_{(-i)}u_{(i)}\big)$, with the second sum coming from $(-1)^{-1}$ times the reversed terms. Applied to x, every $v_{(1+i)}x$ vanishes $(1+i \geq 1)$, and in $v_{(-i)}u_{(i)}x$ only $i = 0$ survives, giving $v_{(0)}u_{(0)}x = \mu\nu x$. □

What the machine verified

Unconditional; `VOA/Moonshine/SigmaTopSource.lean`. Used only as a tool.

41.3.2 The letters

Fix the orthonormal coordinates $h_1, \dots, h_{24}$ of $\mathfrak{h} = \Lambda \otimes \mathbb{C}$ used by the library's Heisenberg algebra (an orthonormal basis obtained from the Gram matrix; not the Golay frame). Write γ_a for the a-th orthonormal coordinate of γ (`chargeCoord leech γ a`). The weight-two space of V_0^+ contains two kinds of states:

- the *Heisenberg letters* $q_{ab} = h_a(-1)h_b(-1)\mathbf{1}$ (`qV a b`), 300 linearly independent ones;
- the *lattice letters* $u_\gamma = e^{\gamma} + e^{-\gamma}$ (`lV γ hγ`) for $\gamma \in \Lambda_0$ of norm 4.

Both are θ-invariant and frame-even, i.e. lie in V_0^+. For the lattice letters the library uses one representative of each pair $\pm\gamma$: `halfFour` is the set of norm-four vectors γ with $\gamma \prec -\gamma$ for a fixed well-order $\prec$, and File `VOA/Moonshine/FrameWeightTwo.lean`.

```
noncomputable def halfFourChi (i : ZMod 2) : Finset leech.carrier :=
  (halfFour leech leech_posDef).filter fun α => frameChar α = i
```

S_0 =`halfFourChi 0` (49128 vectors, even) and S_1 =`halfFourChi 1` (49152 vectors, odd). The states

$$x_n = e^{n} + e^{-n} \in V_3^+ \qquad (n \in S_1)$$

(`frameX0P n`, with `frameX0 β = latChargeGen leech β + latChargeGen leech (-β)`) will be our basis of the top level of V_3^+.

Proposition 41.3 (source zero modes). *Let $n \in \Lambda$.*

(a) $\mathrm{o}(q_{ab})\,x_n = n_a n_b\, x_n$.

(b) If $\gamma \in \Lambda_0$, $n \notin \Lambda_0$ and both have norm 4, then $|\langle\gamma, n\rangle| \leq 2$ and

$$\mathrm{o}(u_\gamma)\,x_n = [\langle\gamma,n\rangle = -2]\,\varepsilon_\Lambda(\gamma,n)\,x_{\gamma+n} + [\langle\gamma,n\rangle = 2]\,\varepsilon_\Lambda(\gamma,-n)\,x_{\gamma-n}.$$

```

          ↪ 0)
```

From the mathematics to the Lean statement

Symbols. `actV g 1` is $g_{(1)}$, the zero mode of the weight-two letter g. `leech.form γ γ = 4` is "norm 4" in the convention $\langle\gamma,\gamma\rangle = 4$ (weight $\frac{1}{2}\langle\gamma,\gamma\rangle = 2$). Norm 4 is the minimal norm: Λ has no vectors of norm 2. **Hypotheses.** In (b), $\gamma \in \Lambda_0$ makes u_γ a letter of V_0^+, and $n \notin \Lambda_0$ makes x_n a state of V_3^+; the norms are those of weight-two states. In (a) no hypothesis on n is needed. **Fidelity.** The Lean statements are literally the textbook formulas; the Iverson brackets are `if … then … else 0`. **Could it be vacuous?** No: the hypotheses are satisfied by every pair (letter, basis vector) that occurs, e.g. $\gamma = 4e_0+4e_1$, $n = (-3,1^{23})$ up to the coordinate convention. The only caveat is that the cocycle signs are left symbolic (`latticeCocycle leech γ n`), which is also how the textbook formula is written.

Physical meaning

The states $x_n = e^n + e^{-n}$ are the lowest-weight (top-level) states of the untwisted sector, labelled by a norm-four momentum n of the Leech lattice. Part (a) says the Heisenberg bilinears $h_a(-1)h_b(-1)\mathbf{1}$ have zero modes that just measure the momentum components $n_a n_b$, i.e. they are diagonal charges. Part (b) says the lattice vertex operators $e^\gamma + e^{-\gamma}$ shift momentum by $\pm\gamma$ only when the inner product is ∓ 2, the standard momentum-conservation selection rule of a vertex-operator zero mode. These are the operators that σ must be made to intertwine, so this is the full list of what the source side does to ground states.

Proof. (a) On $e^{\pm n}$, $h_a(-1)\mathbf{1}$ acts only through its zero mode, with eigenvalue $\pm n_a$; Lemma 41.2 gives $(\pm n_a)(\pm n_b) = n_a n_b$ on both terms. (b) For lattice states the vertex operator gives $e^\gamma_{(m)}e^n = \varepsilon(\gamma,n)\,S_{-m-1-\langle\gamma,n\rangle}(\gamma)\,e^{\gamma+n}$, where S_k is the k-th elementary Schur polynomial in the modes $\gamma(-1),\gamma(-2),\dots$, and $S_k = 0$ for $k<0$. For $m=1$ the exponent is $-2-\langle\gamma,n\rangle$: the term vanishes if $\langle\gamma,n\rangle > -2$ and equals $\varepsilon(\gamma,n)e^{\gamma+n}$ if $\langle\gamma,n\rangle = -2$. The bound $|\langle\gamma,n\rangle| \le 2$ comes from $\|\gamma \pm n\|^2 = 8 \pm 2\langle\gamma,n\rangle \ge 4$ ($\gamma \pm n \neq 0$ because $\gamma \in \Lambda_0 \not\ni n$, and nonzero Leech vectors have norm ≥ 4). Expanding $(e^\gamma + e^{-\gamma})_{(1)}(e^n + e^{-n})$ into four terms and using $\varepsilon(-\gamma,-n) = \varepsilon(\gamma,n)$ and $\varepsilon(-\gamma,n) = \varepsilon(\gamma,-n)$ (bimultiplicativity and $\varepsilon = \pm 1$) gives the formula. □

What the machine verified

Unconditional; `SigmaTopSource.lean`; `##print axioms = [propext, Classical.choice, Quot.sound]` (stated in the file header; the headline results of the chapter, which depend on these, were re-checked in this writing, see §41.18).

So on V_3^+ the Heisenberg letters are *diagonal* and the lattice letters are *monomial* in the basis x_n. This is what makes the problem tractable.

41.3.3 Spanning

Proposition 41.4 (spanning sets). *(a)* $(V_3^+)_2 = \mathrm{span}\{x_n : n \in S_1\}$.

(b) $(V_0^+)_2 = \mathrm{span}\{q_{ab}\} + \mathrm{span}\{u_\gamma : \gamma \in S_0\}$.

```
theorem OmegaV3_le_span : OmegaV3 ≤ span ℂ (frameX0P '' (halfFourChi 1 : Set
↪  leech.carrier))

theorem grading_two_V0_le_span {g : VPlus} (hg : g ∈ frameSector 0) (h2 : g ∈
↪  leechVOAPlus.grading 2) :
    g ∈ span ℂ (Set.range (fun p : Fin (rank leech) × Fin (rank leech) => qP p.1 p.2)
      ∪ frameX0P '' (halfFourChi 0 : Set leech.carrier))

def G2 : Set V0Sub.carrier := {g | (g : VPlus) ∈ leechVOAPlus.grading 2}
```

From the mathematics to the Lean statement

`OmegaV3` is $(V_3^+)_2$ (frame sector 1 intersected with weight 2). `f '' S` is the image of a set; `span ℂ` the linear span; "$\leq$" between submodules is inclusion. Only the inclusion "$\subseteq$" is stated, which is the direction used; the reverse inclusion is `frameX0P_mem_OmegaV3` (each x_n lies in the top level). `qP a b` is q_{ab} viewed in V_Λ^+ (`qV` is the same state viewed in V_0^+). `G2` is the set of all weight-two elements of V_0^+ — the Zhu-generating set of Chapter 40.

Physical meaning

The weight-two layer of the untwisted sector is the space of the lowest-energy states of the odd part, and these two spanning sets say it is generated by the momentum states x_n over the odd norm-four vectors. On the other side, the weight-two fields are the quadratic currents plus the lattice vertex operators of the even norm-four vectors. This is the bookkeeping that lets us check a symmetry on a basis of states and a basis of fields; it is a purely technical completeness statement.

Proof. Weight two in V_Λ consists of the quadratic Fock states $p \otimes e^0$ (p of degree two: 300 states $h_a h_b$ and 24 states $h_a(-2)$), the states $h_a(-1) \otimes e^\gamma$ with $\|\gamma\|^2 = 2$ (none: no roots), and the 196560 charged vacua of norm 4. On the θ-fixed part the $h_a(-2)$ disappear (θ acts by -1) and the charged vacua pair up into $e^\gamma + e^{-\gamma}$. Splitting by β: frame-odd γ give $(V_3^+)_2$, frame-even γ and the Fock part give $(V_0^+)_2$. Both statements are then dimension counts against the dimensions 49152 and $300 + 49128 = 49428$ computed in Chapter 39 (`finrank_plusTwoChi`). □

What the machine verified

Unconditional; `SigmaTopSource.lean`.

41.3.4 Reduction of the zero-mode clause to letters and basis vectors

Definition 41.5 (`ZM`). For a linear map $\varphi : V_\Lambda^+ \to (V_\Lambda^T)^+$, a set X and a letter $g \in V_0^+$, `ZM φ X g` is the statement $\varphi(o(g)x) = o(\sigma g)\varphi(x)$ for all $x \in X$. `ZMT` is the same with source $(V_\Lambda^T)^+$.

File `VOA/Moonshine/SigmaTopTT.lean`.

```
def ZM (φ : VPlus →ₗ[ℂ] TP) (X : Set VPlus) (g : V0Sub.carrier) : Prop :=
  ∀ x ∈ X, φ (actV g 1 x) = actT (sig g) 1 (φ x)

def ZMT (φ : TP →ₗ[ℂ] TP) (X : Set TP) (g : V0Sub.carrier) : Prop :=
  ∀ x ∈ X, φ (actT g 1 x) = actT (sig g) 1 (φ x)
```

Physical meaning

This is the 2d CFT statement that a candidate map φ between two sectors is an intertwiner at one field: sending a state first and then acting with the light field g must agree with acting with the transformed field σg on the image state. In other words φ matches charges, the zero-mode eigenvalues of the field g on x and of σg on $\varphi(x)$. Requiring it for all weight-two fields is the discrete shadow of the Ward identity relating the two sectors. This is the basic compatibility condition that every later eigen-condition is a rewriting of.

Theorem 41.6 (basis reduction). *Let $\varphi : V_\Lambda^+ \to (V_\Lambda^T)^+$ be linear. Suppose $\varphi(o(g)x_n) = o(\sigma g)\varphi(x_n)$ for all $n \in S_1$ and all letters g of the form q_{ab} or u_γ ($\gamma \in S_0$). Then for every $g \in (V_0^+)_2$ there is k (namely $k = 2$) with g of weight k and $\varphi(g_{(k-1)}x) = (\sigma g)_{(k-1)}\varphi(x)$ for all $x \in (V_3^+)_2$.*

```
theorem hGφ_V3_of_basis (φ : VPlus →ₗ[ℂ] TP)
    (hQ : ∀ a b : Fin (rank leech), ∀ n ∈ halfFourChi 1,
      φ (actV (qV a b) 1 (frameX0P n)) = actT (sig (qV a b)) 1 (φ (frameX0P n)))
    (hL : ∀ γ ∈ halfFourChi 0, ∀ n ∈ halfFourChi 1,
      φ (actV (lV' γ) 1 (frameX0P n)) = actT (sig (lV' γ)) 1 (φ (frameX0P n))) :
    ∀ g ∈ G2, ∃ k : ℤ, (g : VPlus) ∈ leechVOAPlus.grading k ∧
      ∀ x ∈ OmegaV3, φ (actV g (k - 1) x) = actT (sig g) (k - 1) (φ x)
```

From the mathematics to the Lean statement

`lV' γ` is u_γ when $\gamma \in \Lambda_0$ and the junk value 0 otherwise (a total function is convenient; on $S_0 \subseteq \Lambda_0$ it is the genuine letter, `lV'_eq`). The conclusion has precisely the shape of the hypothesis `hGφ` of `topSigmaV3_of_zhuGenerated` with $G =$`G2`, which is why the existential $\exists k$ appears although $k = 2$. Same as the textbook statement.

Physical meaning

It is enough to test the intertwining property on a basis of ground states and a basis of light fields: the zero modes are linear in both the field and the state, so matching charges on the generators propagates to everything in the weight-two layer. Physically this is the familiar reduction of a symmetry check to checking the action on the generating currents and the lowest-energy states. It replaces an infinite family of conditions by finitely many (about 10^5) explicit ones; it is a technical reduction and carries no new physics.

Proof. The identity $\varphi\,\mathrm{o}(g) = \mathrm{o}(\sigma g)\varphi$ is linear in g (because σ and $g \mapsto g_{(1)}$ are linear) and linear in x. Proposition 41.4 gives spanning sets for both. □

What the machine verified

Unconditional; `SigmaTopSource.lean`. The analogous frame-form statements `hGφ_V3_of_frame`, `hGφ_TT_of_frame` (`SigmaTopTT.lean`) replace the abstract q_{ab} by the frame letters of §41.5.

41.4 The target side: zero modes on the twisted top level

The top level of $(V_\Lambda^T)^+$ is $h(-\frac{1}{2}) \otimes T$, of dimension $24 \cdot 4096$; the weight-two states $h_c(-\frac{1}{2}) \otimes t$ have conformal weight $\frac{24}{16} + \frac{1}{2} = 2$. On it we need the zero modes of q_{ab} and of e^α.

41.4.1 Twisted modes in Lean

The twisted module V_Λ^T is a θ-twisted module of period $N = 2$ (`TwistedModule leechTheta 2`, Chapter 34). Its vertex operator has half-integral modes, and the library stores the mode $u_{(k/2)}$ under the integer index k: `YM u k` is $u_{(k/2)}$. So the zero mode $u_{(1)}$ of a weight-two element is `YM u 2`, and on the θ-fixed part, which is an ordinary V_Λ^+-module, the ordinary mode $u_{(n)}$ is `YM u (2 * n)`; this is the theorem File `VOA/Moonshine/SigmaTopFrame.lean`.

```
theorem actT_coe (u : V0Sub.carrier) (n : ℤ) (y : TP) :
    ((actT u n y : TP) : Tw) = leechTwistedModule.YM ((u : VPlus) : LatModuleGen leech) (2
    ↪ * n) y
```

Proposition 41.7 (twisted zero modes). *On $h_c(-\frac{1}{2}) \otimes t$, $t \in T$:*

(a) $\mathrm{o}(h_a(-1)h_b(-1)\mathbf{1})\,(h_c \otimes t) = \big(\frac{1}{8}\delta_{ab}h_c + \frac{1}{2}\delta_{bc}h_a + \frac{1}{2}\delta_{ac}h_b\big) \otimes t$;

(b) for $\|\alpha\|^2 = 4$: $\mathrm{o}(e^\alpha)\,(h_c \otimes t) = 2^{-4}\big(h_c - 2\alpha_c\,\alpha(-\frac{1}{2})\big) \otimes e_\alpha t$;

(c) $\mathrm{o}(e^{-\alpha}) = \mathrm{o}(e^{\alpha})$ *on the twisted module (more generally on all even modes).*

File `VOA/Moonshine/SigmaTopTarget.lean`.

```
theorem YML_quadSt (a b c : Fin (rank L)) (t : Rep (cocMat L) (isUnit_det_cocMat L hEven
↪  hU)) :

          + (if b = c then (1 / 2 : ℂ) else 0) • X (0, a)
          + (if a = c then (1 / 2 : ℂ) else 0) • X (0, b)) ⊗ₜ t

theorem YML_echg_X (α : L.carrier) (hα : L.form α α = 4) (c : Fin (rank L))
    (t : Rep (cocMat L) (isUnit_det_cocMat L hEven hU)) :
    YML L hEven hU (echg L α) 2 ((X (0, c) : FockT (rank L)) ⊗ₜ t)
      = (2 : ℂ) ^ (-(4 : ℤ)) • ((X (0, c) - (2 * chargeCoord L α c) • vVarT (chargeCoord L
      ↪  α) 0)
          ⊗ₜ eT L hEven hU α t)

theorem YML_echg_neg_two (α : L.carrier) :
    YML L hEven hU (echg L (-α)) 2 = YML L hEven hU (echg L α) 2
```

From the mathematics to the Lean statement

These are stated for a general even unimodular positive-definite lattice L (`hEven`, `hU` = unimodularity, `hPos`); the Leech versions `leechYM_quad`, `leechYM_echg_X`, `leechYM_echg_neg_two` follow by transport along rank $\Lambda = 24$ (the casts `cc`, `chT` only renumber coordinates). `YML … u 2` is $u_{(1)}$, the zero mode, by the half-integer convention. `X (0, c)` is $h_c(-\frac{1}{2})$ and `vVarT v 0` is $v(-\frac{1}{2}) = \sum_a v_a h_a(-\frac{1}{2})$. `quadSt … a b` is $h_a(-1)h_b(-1)\mathbf{1}$ and `echg L α` is e^{α}. The factor $2^{-4} = 2^{-\|\alpha\|^2}$ is the normalisation $2^{-\langle\gamma,\gamma\rangle}$ of the twisted vertex operator $Y^T(e^{\gamma}, z)$ (Chapter 34, FLM's convention). The statements are exactly (a)–(c).

Physical meaning

This computes how the same light fields act on the twisted-sector ground states, the 2^{12}-dimensional space of twist fields T tensored with the weight-one-half oscillators $h_c(-\frac{1}{2})$ of the $\mathbb{Z}/2$-twisted bosons. The Heisenberg bilinears act with the characteristic twisted-sector shifts $\frac{1}{8}\delta_{ab}$ (the conformal weight 1/16 per boson from the twist field) plus mixing terms, and the lattice vertex operators act on the twist space through the Clifford-like operators e_{γ}. These are the target charges that σ must match against the source charges of the previous proposition.

Proof. (a) Use the twisted Jacobi identity for $u = h_a(-1)\mathbf{1}$ (a θ-eigenvector with eigenvalue -1) and $v = h_b(-1)\mathbf{1}$, at the indices that isolate $(u_{(-1)}v)$'s zero mode. The result is a finite sum: the normally ordered product $h_a(-\frac{1}{2})h_b(\frac{1}{2}) + h_b(-\frac{1}{2})h_a(\frac{1}{2})$ on $h_c(-\frac{1}{2})$ (giving the $\frac{1}{2}\delta_{bc}h_a + \frac{1}{2}\delta_{ac}h_b$, since $h_a(\frac{1}{2})h_c(-\frac{1}{2}) = \frac{1}{2}\delta_{ac}$), plus a correction coming from $u_{(1)}v = \delta_{ab}\mathbf{1}$ multiplied by the binomial coefficient $-\binom{1/2}{2} = \frac{1}{8}$. Physically: the twisted boson has a ground-state energy shift, and $\frac{1}{8}$ per coordinate is exactly what makes $\sum_a \frac{1}{2}h_a h_a$ measure $L_0 = \frac{24}{16} + \ldots$ ($24 \cdot \frac{1}{2} \cdot \frac{1}{8} = \frac{3}{2}$). (b) The twisted vertex operator is $Y^T(e^{\alpha}, z) = 2^{-\|\alpha\|^2} z^{-\|\alpha\|^2/2} E^-(-\alpha, z)E^+(-\alpha, z) \otimes e_{\alpha}$. For $\|\alpha\|^2 = 4$ the power of z is z^{-2}, so the zero mode $u_{(1)}$ (coefficient of z^{-2}) is 2^{-4} times the degree-zero coefficient of $E^-(-\alpha, z)E^+(-\alpha, z)$. On a one-oscillator state only two terms of that coefficient survive: the identity, and the product of the first annihilation term of E^+ (which contracts $\alpha(\frac{1}{2})$ with $h_c(-\frac{1}{2})$, producing α_c up to the factor 2 from $1/(k/2)$ at $k = 1$) with the first creation term of E^- (which creates $\alpha(-\frac{1}{2})$,

with the same factor). The result is $h_c - 2\alpha_c\,\alpha(-\frac{1}{2})$, as claimed. (c) $Y^T(e^{-\alpha}, z)$ is obtained from $Y^T(e^{\alpha}, z)$ by $z^{1/2} \mapsto -z^{1/2}$ and $e_{-\alpha} = e_\alpha$, which leaves integral (even-index) modes unchanged. □

What the machine verified

Unconditional; `SigmaTopTarget.lean`.

Remark 41.8. On the twisted top level every lattice letter $u_\gamma = e^\gamma + e^{-\gamma}$ thus acts by $h_v(-\frac{1}{2}) \otimes t \mapsto 2^{-3}\, h_{v-2\langle v,\gamma\rangle\gamma}(-\frac{1}{2}) \otimes e_\gamma t$ (the two terms are equal by (c), whence $2 \cdot 2^{-4} = 2^{-3}$). The linear map $v \mapsto v - 2\langle v, \gamma\rangle\gamma$ is *not* a reflection: it is the identity on $\gamma^\perp$ and multiplies γ by $1 - 2 \cdot 4 = -7$. On the source side, by contrast, u_γ simply moves x_n to $\pm x_{n\pm\gamma}$. The two descriptions look very different; they become equal only after σ has been applied to the letter, and that is the content of the rest of the chapter.

41.5 The Golay frame at weight two

The orthonormal coordinates h_a of §41.3 come from an arbitrary basis and have no relation to the Golay code. The right coordinates are those of the *frame*: the 24 mutually orthogonal vectors $w_j = 8e_j$ of norm 8. In this section we rewrite everything in the frame and discover the block structure of both top levels.

41.5.1 Blocks of $(V_3^+)_2$

Lemma 41.9 (one entry ±3). *Let $n \in \Lambda$ be odd ($n \notin \Lambda_0$) of norm 4. Then all coordinates of n are odd, and there is exactly one index $j = j(n)$ with $n_j^2 = 9$; all other coordinates satisfy $n_i^2 = 1$. The index $j(n)$ is the* block *of n, and $j(-n) = j(n)$.*

```
theorem exists_unique_three (f : Fin 24 → ℤ) (hodd : ∀ i, Odd (f i)) (hs : ∑ i, f i ^ 2 =
↪  32) :
    ∃ j, f j ^ 2 = 9 ∧ ∀ i, i ≠ j → f i ^ 2 = 1

noncomputable def blk (n : leech.carrier) : Fin 24 :=
  if h : ∃ j, lv n j ^ 2 = 9 then h.choose else 0

theorem lv_sq {n : leech.carrier} (hn : n ∉ lambda0) (h4 : leech.form n n = 4) (j : Fin 24)
↪  :
    lv n j ^ 2 = if j = blk n then 9 else 1

theorem blk_neg (n : leech.carrier) : blk (-n) = blk n
```

From the mathematics to the Lean statement

`blk` is defined by choice with a junk value 0; `lv_sq` shows that for the vectors that matter (odd, norm 4) the choice is forced, so the junk value is never seen. Norm 4 in the convention (41.1) means $\sum n_i^2 = 32$. Same as the textbook statement.

Physical meaning

The norm-four odd vectors of the Leech lattice have all coordinates odd, with a single coordinate of size 3 and the rest of size 1. This singles out one of the 24 frame directions for each ground state; physically this is the frame block, the one boson (out of 24) whose half-integer oscillator $h_{c_j}(-\frac{1}{2})$ carries the excitation in the image of x_n. It is a technical lemma underlying the construction of φ on the twisted top level.

Proof. Odd Leech vectors are $2a + u$ with $u = (5, 1^{23})$, so all entries are odd. An odd square is $8g + 1$ with $g \geq 0$ (a triangular number times 8), and $\sum(8g_i + 1) = 32$ forces $\sum g_i = 1$: exactly one $g_j = 1$ ($n_j^2 = 9$) and the rest vanish. □

What the machine verified

Unconditional; `SigmaTopFrame.lean`.

So $(V_3^+)_2$ splits into 24 blocks of 2048 basis vectors x_n (pairs $\pm n$ with a given block); a typical vector is $n = (\mp 3, \pm 1^{23})$ with the 3 in position j. In the same way $(T^+)_2 = \bigoplus_j h_{w_j}(-\frac{1}{2}) \otimes T$ has 24 blocks of 4096, and $(T_s^+)_2$ has 24 blocks of 2048. The first, numerically discovered, fact (§41.16) is that σ matches the blocks.

41.5.2 The twisted top level in frame coordinates

For $v \in \mathbb{C}^{24}$ (orthonormal coordinates) and $t \in T$ write $h_v(-\frac{1}{2}) \otimes t$ for $\sum_a v_a h_a(-\frac{1}{2}) \otimes t$ (`hP v t`). Let $c_j =$ `cw j` be the orthonormal coordinates of w_j; so $h_{c_j}(-\frac{1}{2})$ is the oscillator along the j-th frame direction.

Definition 41.10 (frame letters). For $\alpha, \beta \in \Lambda$ the *frame quadratic letter* is $d(\alpha, \beta) = \alpha(-1)\beta(-1)\mathbf{1} \in V_0^+$ (`dV α β`). The letters $d(w_j, w_k)$ are the frame versions of q_{ab}, and $q_{ab} = \frac{1}{64}\sum_{j,k}(c_j)_a(c_k)_b\, d(w_j, w_k)$ (`qV_eq_sum_dV`).

```
noncomputable def dV (α β : leech.carrier) : V0Sub.carrier :=
  ⟨⟨quadH leech leech_even leech_posDef α β, (mem_leechVOAPlus_iff _).mpr (quadH_theta α
   ↪ β)⟩, by
    rw [V0Sub_carrier, mem_frameSector, Extraspecial.sgn_zero, one_smul]
    exact quadH_frame α β⟩
```

Physical meaning

The frame letters $d(\alpha, \beta) = \alpha(-1)\beta(-1)\mathbf{1}$ are the Heisenberg bilinears written in the Golay frame instead of an orthonormal basis, i.e. the quadratic currents $J^\alpha J^\beta$ built from the frame vectors. The change of basis is a rotation of the 24 free bosons, which is a harmless relabelling of the same fields. The frame is the natural one because the twist fields and the triality action are expressed in terms of the Golay code and its frame vectors.

(`quadH L … α β` is $\alpha(-1)\beta(-1)\mathbf{1}$; the anonymous-constructor proofs record membership in V_Λ^+ and in frame sector 0. This one definition body is shown because it is short; it contains no choices.)

Proposition 41.11 (zero modes in the frame). *For $v \in \mathbb{C}^{24}$, $t \in T$, $\alpha, \beta \in \Lambda$, $\gamma \in \Lambda_0$ of norm 4:*

(a) $\mathrm{o}(d(\alpha, \beta))\, x_n = \langle \alpha, n\rangle\langle \beta, n\rangle\, x_n$;

(b) $\mathrm{o}(d(\alpha, \beta))\,(h_v \otimes t) = h_{\frac{\langle \alpha,\beta\rangle}{8} v + \frac{1}{2}\langle v,\beta\rangle\alpha + \frac{1}{2}\langle v,\alpha\rangle\beta} \otimes t$;

(c) $\mathrm{o}(u_\gamma)\,(h_v \otimes t) = 2^{-3}\, h_{v - 2\langle v,\gamma\rangle\gamma} \otimes e_\gamma t$;

(d) (diagonal letters) $\mathrm{o}(d(w_j, w_j))$ *acts by* 9 *on block* j *and by* 1 *on every other block, on* both $(V_3^+)_2$ *and* $(T^+)_2$: $\mathrm{o}(d(w_j, w_j))x_n = (9 \text{ if } j = j(n) \text{ else } 1)\, x_n$ *and* $\mathrm{o}(d(w_j, w_j))(h_{c_m} \otimes t) = (9 \text{ if } j = m \text{ else } 1)\, h_{c_m} \otimes t$.

```

     ↪ n
```

From the mathematics to the Lean statement

`dL α β` is the linear map $v \mapsto \frac{\langle\alpha,\beta\rangle}{8}v + \frac{1}{2}\langle v,\beta\rangle\alpha + \frac{1}{2}\langle v,\alpha\rangle\beta$ on $\mathbb{C}^{24}$ and `latL γ` is $v \mapsto v - 2\langle v,\gamma\rangle\gamma$, both written in orthonormal coordinates; `quadL a b` (used in `actT_qV_hP`) is the special case $\alpha = h_a, \beta = h_b$. Note in (b) that the coefficient $\frac{\langle\alpha,\beta\rangle}{8}$ is the $\frac{1}{8}\delta_{ab}$ of Proposition 41.7 after bilinear expansion. In (d), on the source side the hypothesis "n odd of norm 4" is needed (to know $n_j^2 \in \{1,9\}$); on the target side no hypothesis on t. Same as the textbook statements.

Physical meaning

This restates the charges of the previous two propositions in frame letters. On the source, $d(\alpha,\beta)$ measures the product of momentum projections $\langle\alpha,n\rangle\langle\beta,n\rangle$; on the twisted ground states it acts as a rank-two operator on the oscillators plus a vertex-operator part acting on the twist space. These are the zero-mode charges of the light fields that σ must intertwine, in the basis where the Golay structure is visible.

Proof. (a)–(c) are bilinear expansions of Propositions 41.3 and 41.7, using $\alpha(-1) = \sum \alpha_a h_a(-1)$ and $\langle\alpha,\beta\rangle = \sum_a \alpha_a\beta_a$. (d) Source: $\langle w_j, n\rangle = n_j$ and $n_j^2 \in \{9,1\}$ by Lemma 41.9. Target: with $\alpha = \beta = w_j$, $v = c_m$, $\frac{\langle w_j,w_j\rangle}{8} = 1$ and $\langle c_m, w_j\rangle = 8\delta_{jm}$, so $c_m \mapsto c_m + 8\delta_{jm}c_m$. □

What the machine verified

Unconditional; `SigmaTopFrame.lean`.

The joint eigenspaces of the 24 commuting operators $o(d(w_j,w_j))$ are exactly the blocks, on both sides, with the same eigenvalue pattern. If these letters are σ-fixed, any intertwiner must preserve blocks — which is what we prove next.

41.5.3 σ fixes the diagonal frame letters

Lemma 41.12 (`root_square`). *Let L be an even lattice and α a root, $\|\alpha\|^2 = 2$, and $\varepsilon = \varepsilon_L(\alpha,-\alpha)$. Then $(e^{\alpha} + \varepsilon e^{-\alpha})_{(-1)}(e^{\alpha} + \varepsilon e^{-\alpha}) = \alpha(-1)^2\mathbf{1}$.*

File `VOA/Moonshine/SigmaTopSigma.lean`.

```
theorem root_square (α : L.carrier) (hα : L.form α α = 2) :
    (latticeVOAGen L hEven hPos).smul
```

```
      (latChargeGen L α + latticeCocycle L α (-α) • latChargeGen L (-α)) (-1)
      (latChargeGen L α + latticeCocycle L α (-α) • latChargeGen L (-α))
    = quadH L hEven hPos α α
```

From the mathematics to the Lean statement

`latticeVOAGen L …` is V_L; `.smul x (-1) y` is $x_{(-1)}y$. Exactly the lemma.

Physical meaning

For a root α, the combination $e^{\alpha} + \varepsilon e^{-\alpha}$ is the real vertex operator of the $su(2)$ at level one, and its normally ordered square is $\alpha(-1)^2\mathbf{1}$, the Cartan bilinear. This is the free-fermion-like statement $\psi^+\psi^- \sim J$, the usual bosonisation identity relating a charged pair to the square of the current. It is a technical computation used to identify σ on the diagonal frame letters.

Proof. $e^{\pm\alpha}_{(-1)}e^{\pm\alpha} = 0$ because $\langle\alpha,\alpha\rangle = 2$ forces the Schur index $-(-1) - 1 - 2 < 0$. The cross terms are $e^{\alpha}_{(-1)}e^{-\alpha} = \varepsilon(\alpha,-\alpha)S_2(\alpha)\mathbf{1}$ and $e^{-\alpha}_{(-1)}e^{\alpha} = \varepsilon(-\alpha,\alpha)S_2(-\alpha)\mathbf{1}$, where $S_2(\pm\alpha) = \frac{1}{2}(\alpha(-1)^2 \pm \alpha(-2))$. With $\varepsilon(-\alpha,\alpha) = \varepsilon(\alpha,-\alpha)$ (for a root the cocycle on $\pm\alpha$ is symmetric) and $\varepsilon^2 = 1$, the sum is $\alpha(-1)^2\mathbf{1}$: the $\alpha(-2)$ terms cancel. Physically: the level-one $\hat{\mathfrak{sl}}_2$ Sugawara vector $\frac{1}{4}\alpha(-1)^2\mathbf{1}$ can be written in any Cartan direction, and $e + \varepsilon f$ is another Cartan direction. □

Theorem 41.13 (σ fixes $w_j(-1)^2\mathbf{1}$). *$\sigma\big(d(w_j,w_j)\big) = d(w_j,w_j)$ for all j.*

```
theorem golayToV0_qN (a b : lam0.carrier) : golayToV0 (qN a b) = dV (inclΛ a) (inclΛ b)

theorem sig_dV_fw (j : Fin 24) : sig (dV (fw j) (fw j)) = dV (fw j) (fw j)
```

From the mathematics to the Lean statement

`qN a b` is $\iota_N(a)(-1)\iota_N(b)(-1)\mathbf{1} \in V_N^{\langle\chi,\Theta\rangle}$. `golayToV0_qN` says the bridge sends uncharged quadratic states to the corresponding uncharged quadratic states; this is *independent* of the choice of `golayE` and of the coboundaries, because these only rescale charged states. Hence `sig_dV_fw` is a statement with no hidden choice. Same as the textbook statement.

Physical meaning

The Cartan bilinears $w_j(-1)^2\mathbf{1}$ along the frame directions are fixed by the triality symmetry: the operator measuring the squared momentum in direction j is invariant. Physically these are the diagonal energy-like operators of the 24 bosons, and a symmetry that merely permutes lattice sectors should preserve them. This is the first and simplest check that σ is being built compatibly with the Heisenberg part of the algebra.

Proof. Under $A \to N$, $4e_j \mapsto 2\alpha_j$, and under $A \to \Lambda$, $4e_j \mapsto w_j$; so $d(w_j,w_j)$ corresponds to $4\,\alpha_j(-1)^2\mathbf{1}$ in V_N. On V_N, σ sends the Cartan current $\alpha_j(-1)\mathbf{1}$ to $e^{\alpha_j} + \varepsilon_j e^{-\alpha_j}$ (Chapter 39, `golaySigma_hSt`), and being a VOA automorphism it sends $\alpha_j(-1)^2\mathbf{1} = \alpha_j(-1)\mathbf{1}_{(-1)}\alpha_j(-1)\mathbf{1}$ to $(e^{\alpha_j} + \varepsilon_j e^{-\alpha_j})_{(-1)}(e^{\alpha_j} + \varepsilon_j e^{-\alpha_j})$, which is $\alpha_j(-1)^2\mathbf{1}$ by Lemma 41.12. Transport along `golayToV0`. □

What the machine verified

Unconditional; `SigmaTopSigma.lean`; the `golayE` choice drops out. `##print axioms sig_dV_fw` = [`propext`, `Classical.choice`, `Quot.sound`] (checked for this chapter).

41.6 The block maps and what the diagonal letters give for free

41.6.1 The map φ_τ on V_3^+

Guided by the block structure we look for φ of the form "block-monomial":

Definition 41.14 (phiV3). For an arbitrary function $\tau : \Lambda \to T$ let $\varphi_\tau : V_\Lambda^+ \to (V_\Lambda^T)^+$ be the linear map with $\varphi_\tau(x_n) = h_{c_{j(n)}}(-\frac{1}{2}) \otimes \tau(n)$ for $n \in S_1$, defined on all of V_Λ^+ by reading off the coefficient of e^n: $\varphi_\tau = \sum_{n \in S_1} \mathrm{coef}_n(\cdot)\, h_{c_{j(n)}} \otimes \tau(n)$.

File `VOA/Moonshine/SigmaTop.lean`.

```
noncomputable def coefN (n : leech.carrier) : VPlus →ₗ[ℂ] ℂ :=
  (MvPolynomial.lcoeff ℂ 0) ∘ₗ coordEα leech n ∘ₗ (orbifold (Subgroup.zpowers
  ↪ leechTheta)).carrier.subtype

noncomputable def phiV3 (τ : leech.carrier → TLeechT) : VPlus →ₗ[ℂ] TP :=
  ∑ n ∈ halfFourChi 1, (coefN n).smulRight (hP (cw (blk n)) (τ n))

theorem phiV3_frameX0P (τ : leech.carrier → TLeechT) {m : leech.carrier} (hm : m ∈
↪ halfFourChi 1) :
    phiV3 τ (frameX0P m) = hP (cw (blk m)) (τ m)
```

From the mathematics to the Lean statement

`coordEα leech n` extracts the Fock coefficient of e^n and `lcoeff ℂ 0` its constant term, so `coefN n` is the coefficient of the charged vacuum e^n. `f.smulRight y` is $x \mapsto f(x)y$. On the top level only the values on x_m matter, and `phiV3_frameX0P` confirms the intended values (for $m \in S_1$, e^{-m} has zero coefficient because $-m \notin S_1$). Off the top level φ_τ has some values that are irrelevant: every clause of `TopSigmaV3` quantifies only over `OmegaV3`.

Physical meaning

This is the explicit ansatz for the triality operator on the top level: each momentum ground state x_n of the untwisted sector is sent to a weight-one-half oscillator in the block direction $j(n)$ tensored with a twist-field state $\tau(n)$. The arbitrary function τ is the unknown, the choice of twist-space vector attached to each momentum. Heuristically this is the T-duality map between sectors, which trades a momentum label for a twist label; the whole difficulty is to choose τ so that charges match.

Proposition 41.15 (what holds for every τ). *(a) φ_τ lands in weight two; if all $\tau(n) \in T_s$ it lands in T_s^+.*

(b) If there is t_0 with $\tau(n_j) = t_0$ for one chosen $n_j \in S_1$ in each block j (the vector $\pm\big((1^{24}) - 4e_j\big)$, `nvec j`), then $x_0^T(t_0)$ is in the image of the top level.

(c) The diagonal letters intertwine: `ZM (phiV3 τ) OmegaV3 (dV (fw j) (fw j))`, *for every τ.*

```
theorem phiV3_hits {τ : leech.carrier → TLeechT} {t₀ : TLeechT} (hblk : ∀ j, τ (nvec j) =
↪ t₀) :
    ∃ x ∈ OmegaV3, phiV3 τ x = x0T t₀

theorem phiV3_ZM_diag (τ : leech.carrier → TLeechT) (j : Fin 24) :
    ZM (phiV3 τ) OmegaV3 (dV (fw j) (fw j))
```

Physical meaning

These are the properties of the ansatz that hold regardless of τ: it lands at the right conformal weight, in the right twisted sector T_s, and it can hit a prescribed twist-field state. The last point is the non-vanishing requirement, that φ is not the zero map; a zero map would satisfy every charge-matching condition trivially, so a genuine symmetry operator must reach a nonzero vector.

Proof. (a) Each $h_v \otimes t$ has weight two and lies in the $J = (-1)^s$ sector if t does. (b) The frame is complete: $\sum_j (c_j)_a (c_j)_b = 8\delta_{ab}$ (`cw_complete`, from $\langle w_j, w_k\rangle = 8\delta_{jk}$ and the fact that a square matrix with $MM^{\mathsf{T}} = 8$ also has $M^{\mathsf{T}}M = 8$). Hence $h_0(-\frac{1}{2}) = \frac{1}{8}\sum_j (c_j)_0 h_{c_j}(-\frac{1}{2})$, and $x = \frac{1}{8}\sum_j (c_j)_0 x_{n_j}$ maps to $x_0^T(t_0)$. (c) Both sides are eigenvectors with eigenvalue 9 or 1 by Proposition 41.11(d) and σ fixes the letter (Theorem 41.13). □

What the machine verified

Unconditional; `SigmaTop.lean`.

Theorem 41.16 (partial (R-top) on V_3^+). *For every s there is a linear φ satisfying* `maps_frame`, `maps_weight`, `hits_cyclic` *of* `TopSigmaV3 s`, *and the zero-mode identity for the 24 diagonal letters $d(w_j, w_j)$.*

```
theorem topSigmaV3_partial (s : ZMod 2) :
    ∃ φ : VPlus →ₗ[ℂ] TP, (∀ x ∈ OmegaV3, φ x ∈ TPframe s) ∧
      (∀ x ∈ OmegaV3, φ x ∈ plusModule.weight (2 : ℂ)) ∧
      (∃ t₀ : TLeechT, t₀ ∈ leechFrameT s ∧ t₀ ≠ 0 ∧ ∃ x ∈ OmegaV3, φ x = x0T t₀) ∧
      (∀ j : Fin 24, ∀ x ∈ OmegaV3,
        φ (actV (dV (fw j) (fw j)) 1 x) = actT (sig (dV (fw j) (fw j))) 1 (φ x))
```

From the mathematics to the Lean statement

The four conjuncts are the clauses of `TopSigmaV3 s` *except* `zero_mode`, which is replaced by its restriction to 24 letters. This is **much weaker** than `TopSigmaV3`; the witness is φ_τ with τ constant, which certainly does not satisfy the remaining identities.

Physical meaning

Already for an arbitrary choice of block value the diagonal Cartan letters intertwine and the image is nonzero. This is the statement that the easy part of charge matching, the diagonal currents, is automatically satisfied by the ansatz; the substantive conditions come from the off-diagonal letters and the lattice vertex operators. It is partial progress and is not enough to define σ.

Trap / dead end

`topSigmaV3_partial` and `topSigmaTT_partial` were milestones, not results about σ. A reader skimming the file headers of `SigmaTop.lean` could mistake them for (R-top); the files say explicitly "`TopSigmaV3` itself is NOT proved" there. Schur's lemma (the top levels are irreducible, Chapter 40) shows that at most one τ up to scalar satisfies all identities.

What the machine verified

Unconditional, but weak; `SigmaTop.lean`; superseded by Theorem 41.48.

Theorem 41.17 (`topSigmaV3_of_offdiag`). *Let τ take values in T_s, with $\tau(n_j) = t_0 \neq 0$ for all j, $t_0 \in T_s$. If* `ZhuGenerated G2`, *the off-diagonal frame letters $d(w_j, w_k)$ $(j \neq k)$ and the lattice letters u_γ $(\gamma \in S_0)$ intertwine for φ_τ on $(V_3^+)_2$, then* `TopSigmaV3 s` φ_τ.

```
theorem topSigmaV3_of_offdiag {s : ZMod 2} {τ : leech.carrier → TLeechT}
    (hτ : ∀ n ∈ halfFourChi 1, τ n ∈ leechFrameT s) {t₀ : TLeechT} (ht₀ : t₀ ∈ leechFrameT
     ↪ s)
    (h0 : t₀ ≠ 0) (hblk : ∀ j, τ (nvec j) = t₀) (hZhu : ZhuGenerated G2)
    (hoff : ∀ j k : Fin 24, j ≠ k → ZM (phiV3 τ) OmegaV3 (dV (fw j) (fw k)))
    (hlat : ∀ γ ∈ halfFourChi 0, ZM (phiV3 τ) OmegaV3 (lV' γ)) :
    TopSigmaV3 s (phiV3 τ)
```

Physical meaning

The map φ_τ is a genuine intertwiner as soon as the remaining field zero modes (the off-diagonal Heisenberg bilinears and the lattice vertex operators) match charges, together with Zhu generation, i.e. the fact that these fields generate the whole algebra of light fields. Physically the zero modes of a generating set of the algebra determine the action on the ground states, so intertwining them suffices. This reduces the problem to explicit eigen-conditions on τ.

Proof. Combine Theorem 41.6 (with q_{ab} expanded in the frame letters), Proposition 41.15, and `topSigmaV3_of_zhuGenerated`. □

What the machine verified

Conditional on `hZhu`, `hoff`, `hlat` (and the data hypotheses); `SigmaTop.lean`. All three inputs are later discharged.

41.6.2 The map φ_ψ on $T^+_{s'}$

For the twisted source the analogous ansatz uses a family of 24 linear maps $\psi_m : T \to T$:

Definition 41.18 (`phiTT`). $\varphi_\psi(h_{c_m}(-\tfrac{1}{2})\otimes t) = h_{c_m}(-\tfrac{1}{2})\otimes \psi_m t$, extended linearly; the h_{c_m} component of a vector of $(T^+)_2$ is extracted by `compW m` $= \frac{1}{8}\sum_a (c_m)_a \cdot$ (the h_a-component).

```
noncomputable def phiTT (ψ : Fin 24 → TLeechT →ₗ[ℂ] TLeechT) : TP →ₗ[ℂ] TP :=
  ∑ m, hPL m ∘ₗ ψ m ∘ₗ compW m

theorem phiTT_hP (ψ : Fin 24 → TLeechT →ₗ[ℂ] TLeechT) (m : Fin 24) (t : TLeechT) :
    phiTT ψ (hP (cw m) t) = hP (cw m) (ψ m t)

theorem OmegaT_le_span (s' : ZMod 2) :
    OmegaT s' ≤ span ℂ {y | ∃ (m : Fin 24) (t : TLeechT), t ∈ leechFrameT s' ∧ y = hP (cw
     ↪ m) t}
```

From the mathematics to the Lean statement

`hPL m` is $t \mapsto h_{c_m}\otimes t$. `OmegaT_le_span` is the spanning statement $(T^+_{s'})_2 = \mathrm{span}\{h_{c_m}\otimes t : t \in T_{s'}\}$ (proved by identifying the doubled degree-one part of $S[\theta]$ with $\{h_v(-\tfrac{1}{2})\}$ and projecting with $\frac{1}{2}(1 \pm J)$).

Physical meaning

This is the same ansatz for the twisted-to-twisted piece: σ maps the twisted ground states $h_{c_m}(-\tfrac{1}{2})\otimes t$ to the same oscillator tensored with $\psi_m t$, where each ψ_m is a linear map on the 2^{12}-dimensional twist space. Heuristically this is a Clifford-module intertwiner: σ acts on the spinor-like twist space by an operator to be determined. The extraction map `compW` just reads

off the coefficient of a given oscillator.

The analogues `phiTT_ZMT_diag`, `topSigmaTT_of_offdiag`, `topSigmaTT_partial` (`SigmaTopTT.lean`) are proved exactly as on V_3^+; the diagonal letters intertwine for every ψ.

What the machine verified

Unconditional (`topSigmaTT_partial`) resp. conditional on `ZhuGenerated G2`, off-diagonal and lattice letters (`topSigmaTT_of_offdiag`); `SigmaTopTT.lean`.

41.7 Off-diagonal letters and the eigen-conditions

41.7.1 Charged states through the bridge

Uncharged states cross the bridge `golayToV0` unchanged; charged states pick up constants.

Definition 41.19 (transport constant). For $a \in A$ let

$$t_c(a) = \frac{c_\Lambda(a)}{g_e(a)\, c_N(a)},$$

where c_Λ =`latCob lam0 leech inclΛ`, c_N =`latCob lam0 golayN inclN` are the comparison coboundaries and $g_e(a)$ =`charVal lam0 golayE a` is the chosen character.

```
noncomputable def tc (a : lam0.carrier) : ℂ :=
  latCob lam0 leech inclΛ a / (charVal lam0 golayE a * latCob lam0 golayN inclN a)

theorem golayToV0_charged {ι : Type*} (s : Finset ι) (d : ι → ℂ) (a : ι → lam0.carrier)
    (y : (orbifold golayK).carrier)
    (hy : (y : LatModuleGen golayN) = ∑ i ∈ s, d i • latChargeGen golayN (inclN (a i))) :
    (((golayToV0 y : V0Sub.carrier) : VPlus) : LatModuleGen leech)
      = ∑ i ∈ s, (d i * tc (a i)) • latChargeGen leech (inclΛ (a i))
```

From the mathematics to the Lean statement

The statement: if $y \in V_N^{\langle\chi,\Theta\rangle}$ equals $\sum_i d_i e^{\iota_N a_i}$, then its image in $V_0^+ \subset V_\Lambda$ is $\sum_i d_i\, t_c(a_i)\, e^{\iota_\Lambda a_i}$. The triple coercion on the left views an element of V_0^+ as an element of V_Λ. $t_c(a)$ is a nonzero complex number whose value is *not* computable (it involves `golayE` and two basis-dependent coboundaries); it is always treated symbolically.

Physical meaning

The transport constant is the ratio of cocycle data, the comparison coboundaries of the Leech and Niemeier lattices divided by the chosen character, that records the phase picked up when a lattice vertex operator is transported through the triality identification. Physically these are the cocycle (sign and phase) factors in the vertex operators that must be carried along when the same momentum is relabelled between two lattice descriptions of the same theory. It is a bookkeeping device; the physical content is that the phases are fixed uniquely by consistency.

Proof. By construction, `golayToV0` is the inverse of (V_A-functoriality into V_N, after twisting by g_e) followed by V_A-functoriality into V_Λ; functoriality sends e^a to $c(a)e^{\iota a}$ and the twist multiplies e^a by $g_e(a)$. □

What the machine verified

Unconditional; `SigmaTopOffdiag.lean`.

41.7.2 σ on $w_j(-1)w_k(-1)\mathbf{1}$

For $j \neq k$ set $\gamma_\pm = \gamma_\pm(j,k) = 4e_j \pm 4e_k \in \Lambda_0$ (`gP j k`, `gM j k`); these are norm-four vectors of Λ_0, the images of $a_\pm = 2e_j \pm 2e_k = \alpha_j \pm \alpha_k \in A$ (`aP`, `aM`).

Proposition 41.20. *For $j \neq k$,*

$$\sigma\big(d(w_j,w_k)\big) = \sum_{i=0}^{3} 4\,c_i\,t_c(a_i)\,e^{\iota_\Lambda a_i}, \qquad (a_0,a_1,a_2,a_3) = (a_+,a_-,-a_-,-a_+),$$

with c_i the coefficients of $(e^{\alpha_j}+\varepsilon_j e^{-\alpha_j})_{(-1)}(e^{\alpha_k}+\varepsilon_k e^{-\alpha_k})$ on $e^{\pm\alpha_j\pm\alpha_k}$ in V_N. Consequently, on the twisted top level,

$$\mathrm{o}\big(\sigma d(w_j,w_k)\big)(h_v\otimes t) = \kappa_+\,h_{v-2\langle v,\gamma_+\rangle\gamma_+}\otimes e_{\gamma_+}t + \kappa_-\,h_{v-2\langle v,\gamma_-\rangle\gamma_-}\otimes e_{\gamma_-}t$$

for explicit symbolic constants $\kappa_\pm$ =`kP j k`, `kM j k`.

```
theorem sig_dV_offdiag_coe {j k : Fin 24} (hjk : j ≠ k) :
    (((sig (dV (fw j) (fw k)) : V0Sub.carrier) : VPlus) : LatModuleGen leech)
      = ∑ i : Fin 4, (4 * cQ j k i * tc (aQ j k i)) • latChargeGen leech (inclΛ (aQ j k i))

noncomputable def kP (j k : Fin 24) : ℂ :=
  (2 : ℂ) ^ (-(4 : ℤ)) * (4 * cQ j k 0 * tc (aQ j k 0) + 4 * cQ j k 3 * tc (aQ j k 3))

noncomputable def kM (j k : Fin 24) : ℂ :=
  (2 : ℂ) ^ (-(4 : ℤ)) * (4 * cQ j k 1 * tc (aQ j k 1) + 4 * cQ j k 2 * tc (aQ j k 2))

theorem actT_sig_dV_offdiag {j k : Fin 24} (hjk : j ≠ k) (v : Fin (rank leech) → ℂ) (t :
↪  TLeechT) :
    actT (sig (dV (fw j) (fw k))) 1 (hP v t)
      = kP j k • hP (latL (gP j k) v) (eT leech leech_even leech_isUnit_det_gramMat (gP j
      ↪  k) t)
        + kM j k • hP (latL (gM j k) v) (eT leech leech_even leech_isUnit_det_gramMat (gM j
        ↪  k) t)
```

From the mathematics to the Lean statement

`aQ j k` $= (a_+,a_-,-a_-,-a_+)$ and `cQ j k` $= (\varepsilon_N(\alpha_j,\alpha_k),\ \varepsilon_k\varepsilon_N(\alpha_j,-\alpha_k),\ \varepsilon_j\varepsilon_N(-\alpha_j,\alpha_k),\ \varepsilon_j\varepsilon_k\varepsilon_N(-\alpha_j,-\alpha_k))$. The factor 4 comes from $d(w_j,w_k) \leftrightarrow (2\alpha_j)(-1)(2\alpha_k)(-1)\mathbf{1}$. The definitions of $\kappa_\pm$ add the two terms $e^{\pm\gamma_+}$ (resp. $e^{\pm\gamma_-}$) because both act by the same zero mode on the twisted module (Proposition 41.7(c)). Exactly the proposition.

Physical meaning

This gives σ on an off-diagonal quadratic current explicitly: the image of $J^{w_j}J^{w_k}$ is a sum of four lattice vertex operators with momenta $\pm\alpha_j \pm \alpha_k$ in the Niemeier-type lattice, weighted by transport constants. This is the triality rotation of the Cartan bilinear into charged fields, the same mechanism by which an $SU(2)$ rotation turns a Cartan current into raising and lowering operators. It converts the abstract intertwining requirement into an explicit linear condition on the twist space.

Proof. In V_N, $\sigma(\alpha(-1)\mathbf{1}) = e^{\alpha} + \varepsilon e^{-\alpha}$ for each root, so $\sigma(\alpha_j(-1)\alpha_k(-1)\mathbf{1})$ is the (-1)-product of two such states; since $\langle \alpha_j, \alpha_k\rangle = 0$, each of the four products $e^{\pm\alpha_j}_{(-1)}e^{\pm\alpha_k}$ is just $\varepsilon(\pm\alpha_j,\pm\alpha_k)e^{\pm\alpha_j\pm\alpha_k}$ (`root_prod`). Transport with `golayToV0_charged`, then use Proposition 41.11(c) termwise. □

What the machine verified

Unconditional; `SigmaTopOffdiag.lean`.

41.7.3 The eigen-conditions

Now compare the two sides on the basis. On the source, $\mathrm{o}(d(w_j,w_k))x_n = n_j n_k\, x_n$. On the target, for $\varphi_\tau(x_n) = h_{c_b}\otimes\tau(n)$ with $b = j(n)$: if $\tau(n)$ is a common eigenvector of $\kappa_+e_{\gamma_+}$ and $\kappa_-e_{\gamma_-}$ with the same eigenvalue λ, the right side is $\lambda\, h_{(\mathrm{latL}_{\gamma_+}+\mathrm{latL}_{\gamma_-})c_b}\otimes\tau(n)$, and a two-line computation gives

$$\big(\mathrm{latL}_{\gamma_+}+\mathrm{latL}_{\gamma_-}\big)c_m = \begin{cases} -6\,c_m, & m\in\{j,k\},\\ 2\,c_m, & \text{otherwise}\end{cases}$$

(`latL_sum_cw`). Matching with n_jn_k forces the eigenvalue

$$\lambda(j,k,n) = \begin{cases} -\dfrac{1}{6}n_jn_k, & j(n)\in\{j,k\},\\ \dfrac{1}{2}n_jn_k, & \text{otherwise.}\end{cases}$$

Theorem 41.21 (off-diagonal letters ⇐ eigen-conditions). *(a) If for all $n\in S_1$, $\kappa_+e_{\gamma_+}\tau(n) = \lambda(j,k,n)\tau(n)$ and $\kappa_-e_{\gamma_-}\tau(n) = \lambda(j,k,n)\tau(n)$, then $d(w_j,w_k)$ intertwines for φ_τ.*

(b) If on $T_{s'}$ the maps ψ_m satisfy $(\kappa_+e_{\gamma_+}+\kappa_-e_{\gamma_-})\psi_m = 0$ and the block links *$\psi_k = 2\kappa_-e_{\gamma_-}\psi_j$, $\psi_j = 2\kappa_-e_{\gamma_-}\psi_k$, then $d(w_j,w_k)$ intertwines for φ_ψ on $(T^+_{s'})_2$.*

From the mathematics to the Lean statement

Hypotheses are exactly the eigen-conditions (a), resp. the vanishing and the two block links (b). In (b) the source letter $d(w_j,w_k)$ acts on $h_{c_m}\otimes t$ by moving block k to block j and vice

versa with factor 4 (`dL_fw_off`), which is why the links appear. Note: (a) is stated as sufficient; the file header records that, given $(\kappa_{\pm} e_{\gamma_{\pm}})^2 = \frac{1}{4}$ (proved later, Proposition 41.23), it is also necessary, but necessity is not a Lean statement.

Physical meaning

The matching of charges for an off-diagonal current is equivalent to eigenvalue conditions on the twist-space operators $e_{\gamma_{\pm}}$: the vertex-operator zero modes on the twist fields must act as multiples of the identity with the prescribed eigenvalue λ. In physical terms the twist-field state must be a joint eigenvector of the Clifford-type operators with definite charge, matching the momentum-space eigenvalue on the source. This is what turns the problem into finding a single common eigenvector.

Proof. The computation preceding the theorem, read in both directions on each basis vector, plus the linear reduction to basis vectors. □

Physical meaning

The full requirement that σ be an intertwiner on the top level is reduced to a finite list of eigen-conditions, a nonzero block value and the remaining lattice letters. Physically one has found the exact charges that the twist ground states must carry; what remains is to show that such states exist. This is a reduction, conditional on the stated data, and does not itself construct σ.

What the machine verified

Conditional (as listed); `SigmaTopOffdiag.lean`; `##print axioms` clean. At the moment these were written, *none* of the eigen-conditions was known to be satisfiable: the values of $\kappa_\pm$ involve `golayE` and the coboundaries, and even the fact that $\kappa_\pm e_{\gamma_\pm}$ has eigenvalues $\pm\frac{1}{2}$ was unproved (recorded as "R-top partial" in the project's gluing plan, `Notes/M8GluingPlan.md`). The remaining sections discharge every hypothesis.

41.8 The cocycle design question

At this point the project faced a design decision, recorded in `Notes/M8GluingPlan.md` (status "R-top partial") as a question for both maintainers:

> *The Leech cocycle is* `latticeCocycle` *over* `Module.Free.chooseBasis` *and the oscillator frame is* $\sqrt{G}$*, not the Golay frame — no explicit sign is computable; every identity must stay symbolic. An explicit (Golay-frame) basis/cocycle model, transported via the functoriality machinery (*`latMorph`*), could drastically simplify R-top's remaining work.*

The alternatives were: (i) continue symbolically; (ii) introduce a second, explicit model of V_Λ (Golay-frame basis, explicit cocycle such as $\varepsilon(a,b) = (-1)^{a^\top U b}$ with U the strict upper triangle of a Gram matrix, as in the Python model of §41.16), prove an isomorphism, and compute signs by `decide`.

The project took route (i), and after the construction the agent's assessment, recorded in the status "σ EXISTS on both twisted sectors", was:

> *An explicit-basis refactor would NOT have materially reduced cost (all identities reduced to bimultiplicative-cocycle algebra / ξ / Golay facts; no concrete cocycle value on chooseBasis was ever needed). Keep the foundations as they are.*

It is worth understanding *why* this is true, because it is the conceptual heart of the construction. Three mechanisms replace explicit signs:

1. **θ-invariance pins products of unknown constants.** The state $\sigma(d(w_j, w_k))$ lies in V_Λ^+, so its coefficients of e^γ and $e^{-\gamma}$ agree. This one fact determines the square of the unknown character value $g_e(a_\pm)^2$ in terms of $\varepsilon_j\varepsilon_k$ (Proposition 41.23), which is all that is ever needed.

2. **The N-cocycle reappears on the Leech side.** The rescaled operators $W(a) = t_c(a)e_{\iota_\Lambda a}$ satisfy $W(a)W(b) = \varepsilon_N(a,b)W(a+b)$: the *Niemeier* cocycle, for which the root lattice $\bigoplus \mathbb{Z}\alpha_j$ admits an explicit quadratic refinement ξ (§41.10). So every Leech-side computation can be re-expressed in terms of ξ, whose values on the relevant vectors are known ($\xi(e_i) = i$) or follow from $\xi(x)\xi(y) = \varepsilon_N\xi(x+y)$.

3. **Eigenvalues instead of values.** The seed t is not computed; it is *characterised* as a joint eigenvector, and its existence is proved by a trace argument. All later identities only use the eigenvalues, never t itself.

An explicit model would have required an isomorphism between two lattice VOAs *and* between the corresponding twisted modules (the latter is not in the library), plus the transport of `golaySigma`; and the octad identities involve 2^8-term Hadamard sums that `decide` could not have handled at the scale of the Leech lattice anyway. The symbolic route proved shorter.

41.9 The constants $\kappa_\pm$ and the notion of a seed

41.9.1 A bridge that is a definitional identity

Chapter 40 proved Zhu generation for the set `SigmaExist.weightTwo` of weight-two elements of the VOA V_0^+, whereas the reductions of this chapter use `G2`, the set of elements of V_0^+ whose image in V_Λ^+ has weight two. The two agree by definition, since the grading of the subVOA is the restriction of the grading of the ambient VOA.

```
theorem G2_eq_weightTwo : G2 = weightTwo := rfl

theorem zhuGenerated_G2 : ZhuGenerated G2 := zhuGenerated_weightTwo
```

From the mathematics to the Lean statement

`rfl` means that Lean accepts the equality by unfolding definitions: no mathematics is hidden. `zhuGenerated_G2` is the Zhu-generation theorem of Chapter 40 restated for `G2`. It is unconditional (no `VOA.pbw`).

What the machine verified

Unconditional; `VOA/Moonshine/SigmaTop2Bridge.lean`; `##print axioms zhuGenerated_G2` clean (re-checked, §41.18). From now on the hypothesis `ZhuGenerated G2` is discharged everywhere.

41.9.2 θ-invariance and the squares of $\kappa_\pm$

Write $A_\pm = A_\pm(j,k) = \kappa_\pm e_{\gamma_\pm} \in \mathrm{End}\, T$ (`AP j k`, `AM j k`). The eigen-conditions ask that the vectors $\tau(n)$ be eigenvectors of $A_\pm$. The first thing to know is the spectrum of $A_\pm$.

Proposition 41.23. *For $j \neq k$:*

(a) (θ-invariance) the coefficients of e^{γ_+} and $e^{-\gamma_+}$ in $\sigma(d(w_j, w_k))$ are equal, and so are those of $e^{\pm\gamma_-}$; consequently $\kappa_+ = \frac{1}{2}\varepsilon_N(\alpha_j,\alpha_k)\,t_c(a_+)$, $\kappa_- = \frac{1}{2}\varepsilon_k\varepsilon_N(\alpha_j,\alpha_k)\,t_c(a_-)$, and $g_e(a_\pm)^2 = \varepsilon_j\varepsilon_k$;

(b) $\kappa_\pm^2\,\varepsilon_\Lambda(\gamma_\pm,\gamma_\pm) = \frac{1}{4}$;

(c) $A_\pm^2 = \frac{1}{4}\cdot \mathrm{id}_T$. In particular $A_\pm$ is diagonalisable with eigenvalues in $\{\pm\frac{1}{2}\}$.

File `VOA/Moonshine/SigmaTop2Eigen.lean`.

```
theorem dQ_symm {j k : Fin 24} (hjk : j ≠ k) : dQ j k 0 = dQ j k 3 ∧ dQ j k 1 = dQ j k 2

theorem kP_eq {j k : Fin 24} (hjk : j ≠ k) : kP j k = (1 / 2 : ℂ) * cQ j k 0 * tc (aP j k)

theorem eV_aP_sq {j k : Fin 24} (hjk : j ≠ k) : eV (aP j k) * eV (aP j k) = golayEps j *
↪ golayEps k

theorem kP_sq {j k : Fin 24} (hjk : j ≠ k) : kP j k * kP j k * εΛ (gP j k) (gP j k) = 1 / 4

theorem AP_mul_self {j k : Fin 24} (hjk : j ≠ k) : AP j k * AP j k = (1 / 4 : ℂ) • 1

theorem AM_mul_self {j k : Fin 24} (hjk : j ≠ k) : AM j k * AM j k = (1 / 4 : ℂ) • 1
```

From the mathematics to the Lean statement

`dQ j k i` $= 4c_i\, t_c(a_i)$ is the i-th coefficient of Proposition 41.20, so `dQ_symm` says: coefficient of e^{γ_+} = coefficient of $e^{-\gamma_+}$ (indices $0, 3$), and likewise for γ_- (indices $1, 2$). `eV a` is $g_e(a)$, `golayEps j` is $\varepsilon_j = \varepsilon_N(\alpha_j, -\alpha_j)$, `εΛ` is ε_Λ. `(1/4 : ℂ) • 1` is $\frac{1}{4}$ times the identity of End T, and `AP j k * AP j k` is composition. The analogues `kM_eq`, `eV_aM_sq`, `kM_sq` for γ_- are in the same file. **Non-vacuity:** the only hypothesis is $j \neq k$, which is necessary ($\gamma_\pm$ are only defined as norm-four vectors for $j \neq k$).

Physical meaning

This pins down the constants $\kappa_\pm$ that normalise the twist-space operators $e_{\gamma_\pm}$ by theta-invariance, i.e. invariance under the $\mathbb{Z}/2$ lattice reflection, and derives that they square to the right cocycle value. Physically it says the Clifford-type operators acting on the twist field space have eigenvalues fixed by the reflection symmetry up to a sign, so the matching charges are determined and not free parameters.

Proof. (a) σ maps V_0^+ to itself, and $V_0^+ \subset V_\Lambda^+$, on which θ acts trivially; $\theta e^\gamma = e^{-\gamma}$ on V_Λ (in the library's normalisation), so the coefficients of $e^{\pm\gamma}$ of any θ-invariant state agree. Since e^{γ_+} and $e^{-\gamma_+}$ have coefficients $4\varepsilon_N(\alpha_j, \alpha_k)t_c(a_+)$ and $4\varepsilon_j\varepsilon_k\varepsilon_N(-\alpha_j, -\alpha_k)t_c(-a_+)$, and $\varepsilon_N(-\alpha_j, -\alpha_k) = \varepsilon_N(\alpha_j, \alpha_k)$, $t_c(-a) = t_c(a)g_e(a)^2$, equality forces $\varepsilon_j\varepsilon_k g_e(a_+)^2 = 1$, i.e. $g_e(a_+)^2 = \varepsilon_j\varepsilon_k$. The formula for κ_+ follows by adding two equal terms: $2^{-4} \cdot 2 \cdot 4\varepsilon_N(\alpha_j, \alpha_k)t_c(a_+) = \frac{1}{2}\varepsilon_N(\alpha_j, \alpha_k)t_c(a_+)$. (b) The coboundary relation $c(a)^2 = \varepsilon_A(a, a)\varepsilon_L(\iota a, \iota a)$ (from the comparison identity at $b = a$ and $c(2a) = 1$) for both lattices gives $t_c(a)^2 g_e(a)^2 = \varepsilon_\Lambda(\iota_\Lambda a, \iota_\Lambda a)\varepsilon_N(\iota_N a, \iota_N a)$; with $\varepsilon_N(\alpha_j + \alpha_k, \alpha_j + \alpha_k) = \varepsilon_j\varepsilon_k$ (cocycle law and the symmetry $\varepsilon_N(\alpha_j, \alpha_k) = \varepsilon_N(\alpha_k, \alpha_j)$, both because $\langle\alpha_j, \alpha_k\rangle = 0$) and (a) one gets $t_c(a_+)^2 = \varepsilon_\Lambda(\gamma_+, \gamma_+)$, hence $\kappa_+^2\varepsilon_\Lambda(\gamma_+, \gamma_+) = \frac{1}{4}\varepsilon_N(\alpha_j, \alpha_k)^2 = \frac{1}{4}$. (c) $e_\gamma^2 = \varepsilon_\Lambda(\gamma, \gamma)$ by (41.2). □

What the machine verified

Unconditional; `VOA/Moonshine/SigmaTop2Eigen.lean`. This settles the "eigenvalue $\pm\frac{1}{2}$" question that was open in the "R-top partial" status.

Remark 41.24 (Why this is surprising and why it works). Nothing in the definition of κ_+ looks like it should square to $\frac{1}{4}$: it is a product of an N-cocycle value, a Λ-coboundary, an N-coboundary and a value of a character chosen by `Classical.choose`. The point is that `golayE` was chosen precisely to make the transported Θ agree with the Leech θ (Chapter 39); θ-invariance of the image of σ is a consequence of that choice, and it encodes exactly the information about g_e that is needed.

41.9.3 The eigenvalue pattern is a character

Lemma 41.25 (`lam_eq`). *For $j \neq k$ and $n \in S_1$: $\lambda(j, k, n) = -\frac{1}{2}(-1)^{\langle\gamma_+, n\rangle} = \frac{1}{2}(-1)^{\langle\gamma_-, n\rangle}$.*

```
theorem lam_eq {j k : Fin 24} (hjk : j ≠ k) {n : leech.carrier} (hn : n ∈ halfFourChi 1) :
    lam j k n = -(1 / 2 : ℂ) * (-1 : ℂ) ^ (leech.form (gP j k) n) ∧
      lam j k n = (1 / 2 : ℂ) * (-1 : ℂ) ^ (leech.form (gM j k) n)
```

From the mathematics to the Lean statement

`(-1 : ℂ) ^ m` with $m = \langle\gamma_\pm, n\rangle \in \mathbb{Z}$ is an integer power (`zpow`). The statement is the lemma verbatim.

Physical meaning

The eigenvalue that the twist-space operators must have is the sign $(-1)^{\langle\gamma_\pm,n\rangle}$ times $\pm\frac{1}{2}$, a function of the momentum n through a mod-two inner product. This is the charge-matching phase: the Fourier dual of momentum on the twist side is a character of the lattice. It is a technical identity used to put the eigen-conditions in a uniform form.

Proof. $\langle\gamma_\pm,n\rangle=\frac{1}{2}(n_j\pm n_k)$. If neither j nor k is the block, $n_j,n_k\in\{\pm1\}$, $\lambda=\frac{1}{2}n_jn_k$; if $n_j=n_k$ then $\frac{1}{2}(n_j+n_k)=\pm1$ is odd and $\frac{1}{2}(n_j-n_k)=0$, giving $\frac{1}{2}=-\frac{1}{2}(-1)=\frac{1}{2}(+1)$; if $n_j=-n_k$ the roles swap and both sides are $-\frac{1}{2}$. If j is the block, $n_j=\pm3$, $n_k=\pm1$, $\lambda=-\frac{1}{6}n_jn_k=\mp\frac{1}{2}$, and $\frac{1}{2}(n_j\pm n_k)\in\{\pm1,\pm2\}$ is checked in the four sign cases. □

So the required eigenvalues of $A_\pm$ on $\tau(n)$ depend on n only through the characters $(-1)^{\langle\gamma_\pm,n\rangle}$. On T, the operator e_n satisfies $e_\gamma e_n=(-1)^{\langle\gamma,n\rangle}e_ne_\gamma$. Hence *if t is an eigenvector of A_+ with eigenvalue $-\frac{1}{2}$ and of A_- with eigenvalue $\frac{1}{2}$, then e_nt has exactly the eigenvalues $\lambda(j,k,n)$.* This motivates:

Definition 41.26 (seed). A vector $t\in T$ is a *seed* if $A_+(j,k)t=-\frac{1}{2}t$ and $A_-(j,k)t=\frac{1}{2}t$ for all $j\neq k$. `SeedExists` is the statement that a nonzero seed exists.

```
def IsSeed (t : TLeechT) : Prop :=
  ∀ j k : Fin 24, j ≠ k → AP j k t = -(1 / 2 : ℂ) • t ∧ AM j k t = (1 / 2 : ℂ) • t

def SeedExists : Prop := ∃ t : TLeechT, t ≠ 0 ∧ IsSeed t
```

From the mathematics to the Lean statement

The quantifier covers all 552 ordered pairs $j\neq k$, i.e. 1104 linear conditions on $t\in T$ ($\dim T=4096$). `t ≠ 0` excludes the trivial seed. Note that a seed satisfies infinitely many *a priori* incompatible conditions; that a nonzero one exists is a genuine theorem (Theorem 41.37).

Physical meaning

A seed is a twist-field state that carries the right eigenvalue $-\frac{1}{2}$ and $+\frac{1}{2}$ for the operators $A_\pm(j,k)$ for every pair of frame directions, a joint eigenvector of the Clifford-type operators. It is the image of one distinguished ground state: once it is known, all other images are obtained by acting with the operators e_n. The existence of a nonzero seed is exactly the existence of a state to which σ can send a given reference ground state.

Theorem 41.27 (eigen-conditions from a seed). *Let t be a seed and $c:\Lambda\to\mathbb{C}$ arbitrary. Then for $j\neq k$, $n\in S_1$, $A_\pm(c(n)e_nt)=\lambda(j,k,n)\,c(n)e_nt$. If moreover $t\neq0$, $t\in T_s$ and $c(n_j)=\mu_j$ for explicit nonzero constants μ_j (`mu`), the assignment $\tau(n)=c(n)e_nt$ (`tauOf c t`) satisfies all hypotheses of Theorem 41.22 except the lattice letters, with values in T_{s+1}.*

File `VOA/Moonshine/SigmaTop2Eigen.lean`.

```

    TopSigmaV3 (s + 1) (phiV3 (tauOf c t))
```

From the mathematics to the Lean statement

`eL γ` is e_γ on T. `mvec j` is the odd vector $m_j = (1^{24}) - 4e_j$, which has its -3 in position j; `nvec j` is $\pm m_j$, whichever lies in S_1. The constants μ_j make $\mu_j e_{n_j} t = e_{m_0} t$ for all j (`mu_nvec`), so the "common block value" required by `hits_cyclic` is $e_{m_0} t$. **The sector shift:** because n is odd, $\langle w_0, n\rangle = n_0$ is odd, so e_n anticommutes with e_{w_0} and swaps $T_0 \leftrightarrow T_1$; hence a seed in T_s yields `TopSigmaV3 (s + 1)`. The only remaining hypothesis `hlat` is the lattice letters.

Physical meaning

Given a seed, the images of all momentum ground states, obtained by acting with the Clifford-type operators e_n on the seed, automatically satisfy the eigen-conditions with the correct phases. This is the statement that the single seed state generates a whole covariant family of ground states under the lattice translation operators, the analogue of generating a representation from a highest-weight vector. A nonzero seed also guarantees the image is nonzero, excluding the trivial zero map.

Proof. $A_+ e_n t = \kappa_+ e_{\gamma_+} e_n t = (-1)^{\langle \gamma_+, n\rangle} e_n \kappa_+ e_{\gamma_+} t = -\frac{1}{2}(-1)^{\langle \gamma_+, n\rangle} e_n t = \lambda e_n t$ by Lemma 41.25; likewise for A_-. For the block value: $m_j = m_0 + \gamma_-(0, j)$, so $e_{m_j} = \varepsilon_\Lambda(m_0, \gamma_-)^{-1} e_{m_0} e_{\gamma_-}$ and $e_{\gamma_-} t = (2\kappa_-)^{-1} t$ (seed), whence $e_{m_0} t = \varepsilon(m_0, \gamma_-)(2\kappa_-) e_{m_j} t = \mu_j e_{m_j} t$. □

What the machine verified

Unconditional except for the displayed hypotheses; `SigmaTop2Eigen.lean`.

41.9.4 The transported operators $W(a)$ and the block links

Definition 41.28. For $a \in A$ put $W(a) = t_c(a)\, e_{\iota_\Lambda a} \in \mathrm{End}\, T$ (`Wop a`), and for $j \neq k$, $Z_{jk} = 2A_-(j,k) = 2\kappa_- e_{\gamma_-}$ (`ZZ j k`).

    ZZ j k * ZZ i j = ZZ i k
```

From the mathematics to the Lean statement

`Wop_mul`: the rescaled operators multiply with the cocycle of N, not of Λ. Thus $a \mapsto W(a)$ is a projective representation of A on T whose 2-cocycle is ε_N. `ZZ_comp`: the Z's compose like

"transition functions" $Z_{jk} = V_j V_k^{-1}$ (the file's formal $\mathfrak{sl}_2$-doublet picture). $Z_{jk}^2 = 1$ follows from $A_-^2 = \frac{1}{4}$.

Physical meaning

The operators $W(a)$ are the transported vertex-operator zero modes acting on the twist space: for each Golay-type element a, $W(a)$ is the Clifford-type operator $e_{\iota a}$ times the transport phase. The operators Z_{jk} are rescaled versions of the eigenvalue operators A_- and are the commuting reflection-like symmetries whose joint eigenvalues label twist states. They are the discrete charges used to label the 2^{12} twist fields.

Proof. $W(a)W(b) = t_c(a)t_c(b)\varepsilon_\Lambda(\iota a, \iota b)e_{\iota(a+b)}$, and the two comparison identities for c_Λ and c_N together with $g_e(a+b) = g_e(a)g_e(b)$ give $t_c(a)t_c(b)\varepsilon_\Lambda(\iota a, \iota b) = \varepsilon_N(a,b)t_c(a+b)$: the ε_A's cancel. For `ZZ_comp`: Z_{jk} is a scalar multiple of $W(a_-(j,k))$ and $a_-(j,k) + a_-(i,j) = a_-(i,k)$; the scalar works out by the cocycle identities for the orthogonal roots. □

Theorem 41.29 (`topSigmaTT_of_seed`). *Let $B \in \mathrm{End}\, T$ map into T_s, satisfy $(A_+ + A_-)(Bt) = 0$ for $t \in T_{s'}$ and $j \neq k$, and send some $t_1 \in T_{s'}$ to a nonzero seed. Put $\psi_0 = B$ and $\psi_m = Z_{0m}B$ (`psiOf B`). If the lattice letters intertwine for φ_ψ, then `TopSigmaTT s' s` φ_ψ.*

```

    (hlat : ∀ γ ∈ halfFourChi 0, ZMT (phiTT (psiOf B)) (OmegaT s') (lV' γ)) :
    TopSigmaTT s' s (phiTT (psiOf B))
```

From the mathematics to the Lean statement

Hypotheses: `hBs` (B lands in T_s), `hBE` (the vanishing condition of Theorem 41.21(b) for ψ_0; for the other ψ_m it follows because Z_{0m} commutes with $A_\pm$, as all γ's involved have coordinates divisible by 4, so their pairings are even), `hseed`, `h0` (the block value Bt_1 is a nonzero seed, giving `hits_cyclic`), `hlat` (open at this stage). The block links hold by `ZZ_comp` and $Z^2 = 1$.

Physical meaning

This is the twisted-to-twisted analogue: if an operator B on the twist space produces a seed from some state and respects the eigenvalue relations, the family $\psi_m = Z_{0m}B$ gives an intertwiner for the diagonal and off-diagonal letters, provided the lattice letters also match charges. Physically the twisted sector is again determined by a single distinguished image state, the seed, and the other components are generated by the symmetry operators Z_{0m}. It is conditional on the lattice letters.

What the machine verified

Conditional on the displayed hypotheses; `SigmaTop2Eigen.lean`. Discharged in §41.15.

41.10 The quadratic refinement ξ and the spinor cube

41.10.1 ξ

On the root sublattice $R = \bigoplus_j \mathbb{Z}\alpha_j \subset N$ all inner products $\langle \alpha_i, \alpha_j \rangle = 2\delta_{ij}$ are even, so the commutator $\varepsilon_N(x,y)\varepsilon_N(y,x) = (-1)^{\langle x,y\rangle}$ is trivial: ε_N restricted to R is a *symmetric* 2-cocycle with values ± 1, hence a coboundary over $\mathbb{C}^\times$ (a symmetric cocycle on a free abelian group with values in a divisible group is a coboundary). We fix an explicit trivialisation.

Definition 41.30 (`xi`). Let $\phi_R : \mathbb{Z}^{24} \to N$, $x \mapsto \sum x_i\alpha_i = 2x$ (`phiR`). A function $\xi : \mathbb{Z}^{24} \to \mathbb{C}^\times$ with

$$\xi(x)\xi(y) = \varepsilon_N(\phi_R x, \phi_R y)\,\xi(x+y), \qquad \xi(e_i) = i$$

is constructed as $\xi = \xi_0 \cdot \chi$, where $\xi_0(x) = i^{S(x,x)}$ for the symmetrised exponent S of the cocycle (`xi0`, via `cobSign`), and $\chi(x) = \prod_i w_i^{x_i}$ is the character correcting $\xi(e_i)$ to i.

File `VOA/Moonshine/SigmaTop2Xi.lean`.

```

theorem xi_mul (x y : Fin 24 → ℤ) : xi x * xi y = εN (phiR x) (phiR y) * xi (x + y)

theorem xi_single (i : Fin 24) : xi (Pi.single i 1) = Complex.I
```

From the mathematics to the Lean statement

`phiR`'s body is shown (it contains no choices): $x \mapsto 2x$, which lies in N because $2x \equiv 0 \bmod 2$ and $0 \in \mathcal{G}$. `wXi i` $= i/\xi_0(e_i)$. `Pi.single i 1` is the unit vector e_i; `Complex.I` is i. The normalisation $\xi(e_i) = i$ is a *choice* — ξ is unique up to a character of $\mathbb{Z}^{24}$ — and the choice i is what makes the formulas of the cube (`nuC`) produce the standard $\mathfrak{sl}_2$ doublet matrices. Note $\xi(2e_i) = \xi(e_i)^2/\varepsilon_N(\alpha_i,\alpha_i) = -\varepsilon_i$, consistent with ξ being a refinement: $\xi(x)^2 = \varepsilon_N(\phi_R x, \phi_R x)\xi(2x)$.

Physical meaning

The function ξ is a refinement of the cocycle ε_N with value i on the generators: it plays the role of the choice of phases for the lattice vertex operators in a way compatible with the frame. Heuristically it is the discrete torus-phase, the square root of the cocycle that appears when the lattice is halved to the frame. It is a technical phase refinement whose only physical content is that such a consistent choice of vertex-operator phases exists.

Proof of `xi_mul`. Write $\varepsilon_N(\phi_R x, \phi_R y) = (-1)^{D(x,y)}$ with D the $\mathbb{Z}$-bilinear exponent of the library's cocycle (`cocForm`), pulled back along ϕ_R. Since ε_N is symmetric on R, $D(e_i,e_j) + D(e_j,e_i)$ is even for all i, j. Let S be the symmetric bilinear form with $S(e_i,e_j) = D(e_i,e_j)$ for $i \le j$ (`symForm`); then $S \equiv D \pmod 2$ entrywise (below the diagonal $S_{ij} - D_{ij} = D_{ji} - D_{ij}$, which is even). Put $\xi_0(x) = i^{S(x,x)}$. Then

$$\xi_0(x+y) = i^{S(x,x)}\, i^{S(y,y)}\, i^{2S(x,y)} = \xi_0(x)\xi_0(y)(-1)^{S(x,y)} = \xi_0(x)\xi_0(y)(-1)^{D(x,y)},$$

which, since $(-1)^D = (-1)^{-D}$, is the claimed identity. A character $\chi(x) = \prod_i w_i^{x_i}$ satisfies $\chi(x)\chi(y) = \chi(x+y)$, so $\xi = \xi_0\chi$ satisfies the same identity, and $w_i = i/\xi_0(e_i)$ gives $\xi(e_i) = i$. □

What the machine verified

Unconditional; `SigmaTop2Xi.lean`.

41.10.2 The spinor cube

Let $D \subseteq \{0,\dots,23\}$ with $4 \mid |D|$ and $\beta \in N$ with coordinates the indicator 1_D (so $\beta = \frac{1}{2}\sum_{i\in D}\alpha_i$, a "spinor" vector of N). The $2^{|D|}$ vectors $\beta - \delta_S$, $\delta_S = \sum_{i\in S}\alpha_i$, $S \subseteq D$, are obtained from β by flipping signs in S. Physically: each coordinate $i \in D$ carries an $\mathfrak{sl}_2$ doublet (momentum $\pm\frac{1}{2}\alpha_i$), and V_N restricted to these states is a tensor product of $|D|$ doublets. The cube basis is

$$b_S = \nu(S)\, e^{\beta-\delta_S}, \qquad \nu(S) = \varepsilon_N(\delta_S, \delta_S+\beta)\,\xi(1_S)\, i^{-|S|}$$

(`bp`, `nuC`). The normalisation ν is chosen so that the root operators act by the standard matrices: $E_i b_S = b_{S\setminus i}$ for $i \in S$, $F_i b_S = b_{S\cup i}$ for $i \notin S$ (and 0 otherwise). File `VOA/Moonshine/SigmaTop2Cube.lean`.

```

    gvec (chivec (ginv (chivec (gvec (chivec (ginv ![1, 0])))))) = ![0, 1]

theorem golayTheta_codeword (hβ : gv β = ind D) (h4 : 4 ∣ D.card) :
    golayTheta (latChargeGen golayN β) = xi (ind D) • latChargeGen golayN (-β)
```

From the mathematics to the Lean statement

`gv β` is the coordinate vector of $\beta \in N$ in $\mathbb{Z}^{24}$; the hypothesis `gv β = ind D` says $\beta = 1_D$. `h4`: $4 \mid |D|$ (needed so that the momentum sign of the extreme states is a global sign; it holds for every Golay codeword). `gvec`, `ginv`, `chivec` are g, g^{-1}, χ applied to a vector of $\mathbb{C}^2$; `![1, 0]` is the column $(1,0)^{\mathsf{T}}$. `cD D` $= c_D$. The last statement is the one used later: the scalar by which Θ maps the codeword state e^{β} to $e^{-\beta}$ is $\xi(1_D)$. Nothing here is vacuous: $D =$ any octad, or $D = \varnothing$ ($\beta = 0$, where it says $\Theta\mathbf{1} = \mathbf{1}$).

Physical meaning

On the spinor cube, the 2^{12}-dimensional tensor product of two-dimensional factors, the triality operator σ acts as a tensor product of one-qubit matrices h, and the reflection Θ as another tensor product. This is the explicit Clifford-module picture: the twist-field space is a spinor of the frame, the group element acts on it by a Hadamard-like transform on each qubit, up to a scalar. The one-qubit Hadamard is precisely the discrete Fourier transform exchanging the two basis labels, here the momentum-like and twist-like labels.

Proof. The root operators act on the cube coordinatewise (by the normalisation ν): the recursion $\nu(S \cup i) = \nu(S)\varepsilon_i\varepsilon_N(\alpha_i, \beta - \delta_S)$ is exactly what makes $\varepsilon_i Q_{-\alpha_i}$ send $b_S \mapsto b_{S\cup i}$ and Q_{α_i} send $b_S \mapsto b_{S\setminus i}$, and $Q_{\pm\alpha_i}^2 = 0$ on the cube. Hence $g_i = \exp(aE_i)\exp(bF_i)$ acts by the 2×2 matrix g in the i-th factor, and g_k, $k \notin D$, acts trivially. The momentum signs: χ acts on $e^{\beta-\delta_S}$ by $(-1)^{\sum(\beta-\delta_S)_i/2}$, and $\sum(\beta - \delta_S) = |D| - 2|S|$; since $4 \mid |D|$ this is $(-1)^{|S|} = \prod_{i\in S}(-1)$, i.e. $\chi^{\otimes D}$. The extra γ_0-sign of `golayChiMod` is the constant c_D. Composing, $\Theta = \sigma\chi\sigma$ is the tensor power of $h\chi h$ (the two c_D cancel). Finally a 2×2 computation in $\mathbb{Q}(\sqrt{2})$ shows $h\chi h$ sends $(1,0) \mapsto (0,1)$, i.e. "all up" $\mapsto$ "all down": $\Theta e^{\beta} = \Theta b_{\varnothing} = b_D = \nu(D)e^{-\beta}$, and $\nu(D) = \varepsilon_N(2\beta, 3\beta)\xi(1_D)i^{-|D|} = \xi(1_D)$ (since $\varepsilon_N(\beta,\beta)^6 = 1$ and $4 \mid |D|$). □

What the machine verified

Unconditional; `SigmaTop2Cube.lean`; `##print axioms golayTheta_codeword` clean (re-checked).

41.11 The seed exists

This is the single most important step of the chapter: a nonzero vector $t \in T$ satisfying the 1104 conditions of Definition 41.26. The construction has two parts: a projector argument produces a common fixed vector of 12 commuting involutions, and an algebraic "closure" argument shows that this fixed vector automatically satisfies all other conditions.

41.11.1 Common fixed vectors of a Lagrangian family

T is the unique irreducible representation of an extraspecial group of order 2^{1+24}, of dimension 2^{12}. A maximal commuting family of its "Pauli operators" has a one-dimensional joint eigenspace for each character — exactly as for n qubits, where $Z_1, \dots, Z_n$ have the computational basis as joint eigenbasis. The library encodes such a family as a *Lagrangian datum*.

Definition 41.32 (Lagrangian datum)**.** For an integral lattice L, a `Lagrangian L` consists of m with $2m = \operatorname{rank} L$, vectors $\gamma_0, \dots, \gamma_{m-1}$ with all $\langle\gamma_i, \gamma_j\rangle$ and $\frac{1}{2}\langle\gamma_i, \gamma_i\rangle$ even (so their images in $L/2L$ span a totally singular subspace for the quadratic form $q(x) = \frac{1}{2}\langle x, x\rangle \bmod 2$), and *partners* $g_0, \dots, g_{m-1}$ with $\langle g_i, \gamma_j\rangle$ even for $j < i$ and odd for $j = i$.

```
structure Lagrangian (L : VOA.IntegralLattice) where
  m : ℕ
  γ : ℕ → L.carrier
  g : ℕ → L.carrier
  form_even : ∀ i < m, ∀ j < m, _root_.Even (L.form (γ i) (γ j))
  halfNorm_even : ∀ i < m, _root_.Even (halfNorm L (γ i))
  partner_even : ∀ i < m, ∀ j < i, _root_.Even (L.form (g i) (γ j))
  partner_odd : ∀ i < m, Odd (L.form (g i) (γ i))
  two_mul_m : 2 * m = L.bRank
```

Physical meaning

A Lagrangian datum is a maximal isotropic (totally singular) subspace of the lattice modulo $2L$, the discrete analogue of choosing a polarisation or a maximal commuting set of observables. Physically one chooses half of the Clifford generators to be simultaneously diagonalised; the common eigenvectors form the lowest-energy states in the twisted sector. This is the standard stabiliser-code (Heisenberg group) construction of a state.

(`VOA/Moonshine/TFormLattice.lean`.) The Leech instance `leechLagrangian` (`TForm.lean`, Chapter 37) has $m = 12$, $\gamma_0 = 8e_0 = w_0$, $\gamma_i = 4e_0 + 4e_i$ $(1 \le i \le 11)$, and partners $g_0 = u$, $g_i = 2r_i$ with r_i the rows of the Golay generator matrix.

Theorem 41.33 (`exists_fixed_of_lagrangian`). *Let D be a Lagrangian datum for Λ and $\kappa_i \in \mathbb{C}$ with $\kappa_i^2 \varepsilon_\Lambda(\gamma_i, \gamma_i) = 1$ for $i < m$. Then there is $t \in T$, $t \neq 0$, with $\kappa_i e_{\gamma_i} t = t$ for all $i < m$.*

File `VOA/Moonshine/SigmaTop2Seed.lean`.

```
theorem exists_fixed_of_lagrangian (hκ : ∀ i < D.m, κ i * κ i * εΛ (D.γ i) (D.γ i) = 1) :
    ∃ t : TLeechT, t ≠ 0 ∧ ∀ i < D.m, κ i • eL (D.γ i) t = t
```

From the mathematics to the Lean statement

D and $\kappa : \mathbb{N} \to \mathbb{C}$ are section variables. The hypothesis makes each $F_i = \kappa_i e_{\gamma_i}$ an involution. No choice of κ_i beyond this normalisation is required — in particular the theorem applies to the uncomputable constants that occur below. Same as the textbook statement.

Physical meaning

Given a Lagrangian datum, the commuting Clifford-type operators have a common eigenvector with eigenvalue 1: the stabiliser state exists. Physically a maximal commuting set of observables on the twist space has a simultaneous eigenvector with the prescribed charges, which gives a nonzero twist field. This is the existence statement behind the seed, and it guarantees the vector is nonzero, so the resulting operator cannot be the zero map.

Proof. The F_i commute ($\langle \gamma_i, \gamma_j \rangle$ even) and square to 1. Let $P_k = \prod_{i<k} \frac{1}{2}(1 + F_i)$. Claim: $\operatorname{tr}(P_k) \cdot 2^k = \dim T$. Indeed $\operatorname{tr} P_{k+1} = \frac{1}{2} \operatorname{tr} P_k + \frac{1}{2} \operatorname{tr}(P_k F_k)$, and $\operatorname{tr}(P_k F_k) = 0$: the partner $G = e_{g_k}$ commutes with P_k (even pairings with γ_j, $j < k$) and anticommutes with F_k (odd pairing), and G^2 is a nonzero scalar, so $\operatorname{tr}(P_k F_k) = \operatorname{tr}(G^{-1} P_k F_k G) = -\operatorname{tr}(P_k F_k)$. With $k = m = 12$ and $\dim T = 2^{12}$, $\operatorname{tr} P_{12} = 1$; so the projector P_{12} is nonzero, and any nonzero vector in its image is fixed by all F_i (since $F_i P_{12} = P_{12}$). □

What the machine verified

Unconditional; `SigmaTop2Seed.lean`.

41.11.2 ξ-closure

Definition 41.34 (`chargesS`). For $t \in T$, $\mathrm{Ch}(t) = \{a \in A : \exists x \in \mathbb{Z}^{24},\ \iota_N a = \phi_R x \text{ and } W(a)t = \xi(x)t\}$. In words: a lies in the root lattice R (as a vector of N), and the transported operator $W(a)$ acts on t by the refinement value ξ.

```
noncomputable def chargesS (t : TLeechT) : AddSubgroup lam0.carrier where
  carrier := {a | ∃ x, inclN a = phiR x ∧ Wop a t = xi x • t}
  zero_mem' := ⟨0, by rw [map_zero, map_zero], by rw [Wop_zero, xi_zero, one_smul]; rfl⟩
```

From the mathematics to the Lean statement

Only the carrier and the first closure field are quoted; the remaining fields of the structure (`add_mem'`, `neg_mem'`) are proofs that the set is closed under addition and negation. That $\mathrm{Ch}(t)$ is a *subgroup* is the key point: it follows from $W(a)W(b) = \varepsilon_N(a,b)W(a+b)$ (Definition 41.28) and $\xi(x)\xi(y) = \varepsilon_N\xi(x+y)$ — the two projective representations W and $\xi \cdot \mathrm{id}$ have the same cocycle, so the set where they agree on t is closed. This is *why* ξ was introduced.

Physical meaning

The set $\mathrm{Ch}(t)$ collects the lattice directions along which the twist state t is an eigenvector of the transported vertex-operator zero mode with the prescribed phase ξ. It is the set of charges carried by the state, the stabiliser group of t in the stabiliser-state language. Demanding that this set be large is demanding that t has definite values of many commuting observables.

Proposition 41.35 (from charges to seeds). *(a) If $a_+(0,j) = \alpha_0 + \alpha_j \in \mathrm{Ch}(t)$ for all j (including $j = 0$, $a_+(0,0) = 2\alpha_0$), then t is a seed.*

(b) (codewords) If $b \in A$ has $\iota_N b = 1_D$ with $4 \mid |D|$, then $g_e(b)^{-2} = \xi(1_D)$, and $2b \in \mathrm{Ch}(t)$ for every t.

```
theorem isSeed_of_charges {t : TLeechT} (h : ∀ j, aP 0 j ∈ chargesS t) : IsSeed t

theorem eV_sq_codeword {b : lam0.carrier} {D : Finset (Fin 24)} (hb : gv (inclN b) = ind D)
    (h4 : 4 ∣ D.card) : (eV b * eV b)⁻¹ = xi (ind D)

theorem codeword_mem_chargesS (t : TLeechT) {b : lam0.carrier} {D : Finset (Fin 24)}
    (hb : gv (inclN b) = ind D) (h4 : 4 ∣ D.card) : b + b ∈ chargesS t
```

From the mathematics to the Lean statement

In (a) the hypothesis quantifies over all $j \in \{0, \dots, 23\}$. In (b), `gv (inclN b) = ind D` says that b, viewed in N, is the codeword vector 1_D. Note `codeword_mem_chargesS` holds for *every* t — because $W(2b)$ is a scalar.

Physical meaning

A state whose charge set contains the basic root combinations is a seed, and codewords of the Golay code automatically lie in the charge set of every state. Physically the Golay codewords act as charges that every twist field must carry, a selection rule coming from the code. The seed conditions thus reduce to checking finitely many charges on a lattice, which is a purely combinatorial statement about the stabiliser group.

Proof. (a) $\mathrm{Ch}(t)$ is a group, so $a_+(j,k) = a_+(0,j) + a_+(0,k) - a_+(0,0)$ and $a_-(j,k) = a_+(0,j) - a_+(0,k)$ lie in it. By Proposition 41.23(a), $A_+ = \frac{1}{2}\varepsilon_N(\alpha_j,\alpha_k)W(a_+)$ and $A_- = \frac{1}{2}\varepsilon_k\varepsilon_N(\alpha_j,\alpha_k)W(a_-)$. With

$\xi(e_j+e_k)=\xi(e_j)\xi(e_k)/\varepsilon_N(\alpha_j,\alpha_k)=-\varepsilon_N(\alpha_j,\alpha_k)$ and $\xi(e_j-e_k)=\varepsilon_k\varepsilon_N(\alpha_j,\alpha_k)$ one gets $A_+t=-\frac{1}{2}t$ and $A_-t=\frac{1}{2}t$. (b) Θ on the Leech side is $\theta\,(e^\gamma\mapsto e^{-\gamma})$; pulled back through the bridge it becomes, on $e^{\iota_N b}$, the map $e^{\iota_N b}\mapsto g_e(b)^{-2}e^{-\iota_N b}$ (this is what the specification of `golayE` says). Comparing with Theorem 41.31, $\Theta e^\beta=\xi(1_D)e^{-\beta}$, gives $g_e(b)^{-2}=\xi(1_D)$. Finally $W(2b)=t_c(2b)e_{2\iota b}=t_c(2b)$, and $t_c(2b)=g_e(b)^{-2}$ (coboundaries are 1 on doubles), $=\xi(1_D)$, where $\iota_N(2b)=2\cdot 1_D=\phi_R(1_D)$. □

41.11.3 The codeword relation and the seed

The Lagrangian gives $\alpha_0+\alpha_i\in\mathrm{Ch}(t)$ only for $i<12$ (and $2\alpha_0$). The other twelve come from codewords. Let D_k ($0\le k\le 11$) be the Golay codeword whose last twelve coordinates are e_k (so $D_k\cap\{12,\dots,23\}=\{12+k\}$); write d_l ($1\le l\le 11$) for its coordinates and $m=\frac{1}{2}(|D_k|-2[0\in D_k])$.

Lemma 41.36 (`colD_key`, kernel-checked). *For each $k<12$, in $\mathbb{Z}^{24}$: $\alpha_0+\alpha_{12+k}=2\cdot 1_{D_k}-\sum_{l=1}^{11}d_l(\alpha_0+\alpha_l)+m\cdot 2\alpha_0$ (with $\alpha_i=2e_i$).*

```
theorem colD_key : ∀ k : Fin 12, apv 0 (Fin.natAdd 12 k) =
    (2 : ℤ) • colD k - ∑ l, ccD k l • apv 0 l + mmD k • apv 0 0 := by decide +kernel
```

From the mathematics to the Lean statement

`apv j k` $=2(e_j+e_k)$, `colD k` $=1_{D_k}$ (computed from the library's Golay encoder), `ccD k l` $=d_l$ for $1\le l\le 11$ and 0 otherwise, `mmD k` $=m$. The proof `decide +kernel` is shown because it is informative: the twelve vector identities are checked by the Lean kernel's own evaluator on explicit integer vectors. This is *not* `native_decide`: it uses no compiled code and adds no axiom (confirmed: `##print axioms colD_key` is clean).

Physical meaning

This is a lattice identity expressing one frame sum in terms of earlier ones and codeword vectors. Physically it is the linear dependence among charges of the stabiliser group that guarantees consistency, i.e. that imposing a handful of charges forces the rest. It is a technical computation checked by the kernel.

Why it is true. Compare coordinates: at $12+k$ both sides have 2; at $l\in\{1,\dots,11\}$ the right side has $2d_l-2d_l=0$; at other positions ≥ 12 both vanish; at 0 the coefficient m is chosen to balance. □

Theorem 41.37 (the seed exists). *There is a nonzero $t\in T$ with $A_+(j,k)t=-\frac{1}{2}t$ and $A_-(j,k)t=\frac{1}{2}t$ for all $j\ne k$. Moreover one can take $t\in T_s$ for some s.*

File `VOA/Moonshine/SigmaTop2Eigen.lean`.

```
theorem seedExists : SeedExists

theorem seed_in_frame (h : SeedExists) :
    ∃ s : ZMod 2, ∃ t : TLeechT, t ∈ leechFrameT s ∧ t ≠ 0 ∧ IsSeed t
```

From the mathematics to the Lean statement

`SeedExists` unfolds to $\exists t,\ t\ne 0\wedge$`IsSeed t` (Definition 41.26). No hypotheses. The second statement is the projection to a frame sector; the sector s is not determined (Remark 41.1).

Physical meaning

A nonzero twist-field state with all the required charges exists. Physically this says the twisted-sector ground state, the image of the reference untwisted ground state under triality, exists in the 2^{12}-dimensional space and has the right quantum numbers. The nonzero condition is essential: it makes σ a genuine symmetry operator rather than the zero map. It is established in Lean, but the physical identification is heuristic.

Proof. Apply Theorem 41.33 to the Leech Lagrangian with $\kappa_i = -\varepsilon_N(\alpha_0, \alpha_i)t_c(a_+(0,i))$; the normalisation $\kappa_i^2\varepsilon_\Lambda(\gamma_i,\gamma_i) = 1$ is Proposition 41.23(b) (for $i = 0$ a separate but identical computation). The fixed vector t satisfies $W(a_+(0,i))t = -\varepsilon_N(\alpha_0,\alpha_i)t = \xi(e_0+e_i)t$, i.e. $a_+(0,i) \in \mathrm{Ch}(t)$ for $i < 12$. By Lemma 41.36 and Proposition 41.35(b), also $a_+(0,12+k) \in \mathrm{Ch}(t)$, since $\mathrm{Ch}(t)$ is a group. Proposition 41.35(a) concludes. For the sector: $A_\pm$ commute with J (all $\gamma_\pm \in \Lambda_0$ pair evenly with w_0), so $\frac{1}{2}(1 \pm J)t$ are seeds, not both zero. □

What the machine verified

Unconditional; `SigmaTop2Seed.lean`; `##print axioms seedExists` = [propext, `Classical.choice`, `Quot.sound`] (re-checked for this chapter). Two `decide +kernel` certificates (`colD_four`, `colD_key`) on explicit integer vectors.

Remark 41.38 (Physical reading). In the qubit picture, $T \cong (\mathbb{C}^2)^{\otimes 12}$ and the conditions on a seed are that t be a joint eigenvector of a maximal abelian "stabiliser group" with prescribed eigenvalues: t is a *stabiliser state*. The Lagrangian half is the standard construction of a stabiliser state; the content is that the ξ-twisted signs prescribed by σ are *consistent*, i.e. define a character of the stabiliser group. The codeword relation is where consistency could have failed, and the cube computation $\Theta e^\beta = \xi(1_D)e^{-\beta}$ is what guarantees it does not.

41.12 The root letters $(\pm 4, \pm 4, 0^{22})$

The lattice letters u_γ, $\gamma \in S_0$, are of two shapes (Theorem 41.47): the 1104 "root type" vectors $\pm\gamma_\pm(j,k)$, and the 97152 "octad type" vectors. This section treats the first.

41.12.1 σ on an $\mathfrak{sl}_2$ triple

For one root α_j of N, the weight-one space spanned by $e^{\alpha_j}, \alpha_j(-1)\mathbf{1}, e^{-\alpha_j}$ is a copy of $\mathfrak{sl}_2$; write $\mathrm{tri}_j(x_1,x_2,x_3) = x_1e^{\alpha_j} + x_2\alpha_j(-1)\mathbf{1} + x_3e^{-\alpha_j}$ (Chapter 39, `tri`).

Proposition 41.39 (`golaySigma_tri`). $\sigma\,\mathrm{tri}_j(x_1,x_2,x_3) = \mathrm{tri}_j\big(x_2 - \frac{x_1}{2} + \frac{\varepsilon_j x_3}{2},\ \frac{x_1}{2} + \frac{\varepsilon_j x_3}{2},\ \varepsilon_j x_2 + \frac{\varepsilon_j x_1}{2} - \frac{x_3}{2}\big)$.

File `VOA/Moonshine/SigmaTop2Root.lean`.

```
theorem golaySigma_tri (j : Fin 24) (x₁ x₂ x₃ : ℂ) :
    golaySigma (tri j x₁ x₂ x₃) =
      tri j (x₂ - x₁ / 2 + golayEps j * x₃ / 2) (x₁ / 2 + golayEps j * x₃ / 2)
        (golayEps j * x₂ + golayEps j * x₁ / 2 - x₃ / 2)
```

From the mathematics to the Lean statement

In the basis $H = \alpha_j(-1)\mathbf{1}$, $A = e + \varepsilon f$, $B = e - \varepsilon f$ (with $e = e^{\alpha_j}$, $f = e^{-\alpha_j}$), this says $\sigma H = A$, $\sigma A = H$, $\sigma B = -B$: σ is the rotation by π about the bisector of the H and A axes in $\mathfrak{so}_3 \cong \mathfrak{sl}_2$. A direct transcription.

Physical meaning

This gives the explicit action of σ on the three-dimensional blocks of the Golay frame as a 3×3 matrix with entries $\frac{1}{2}$, i.e. the triality rotation in the basis of frame blocks. It is the local form of the symmetry that permutes three isomorphic modules, and it is the finite-dimensional analogue of a Fourier-type rotation among the three sectors.

Proof. $\sigma H = A$ is Chapter 39's `golaySigma_hSt`; $\sigma^2 = 1$ gives $\sigma A = H$. For B: exhibit the preimage $y_B = \mathrm{tri}_j(4 - 2\sqrt{2}, 0, -\varepsilon_j(2+\sqrt{2})/4)$ with $g\, y_B = B$, observe $\chi z_0(y_B) = -y_B$, and conclude $\sigma B = g\chi z_0 g^{-1} B = -B$; the identity $g\, y_B = B$ is an identity in $\mathbb{Q}(\sqrt{2})$. □

41.12.2 $\sigma(u_{\gamma_\pm})$ and the root letter identities

For $j \neq k$ the products H_jH_k, A_jA_k, B_jB_k (normally ordered, (-1)-products) satisfy $\sigma(H_jH_k) = A_jA_k$, $\sigma(B_jB_k) = B_jB_k$. Now $A_jA_k \pm B_jB_k$ are combinations of $e^{\pm(\alpha_j+\alpha_k)}$ resp. $e^{\pm(\alpha_j-\alpha_k)}$, i.e. (after transport) of the letters $u_{\gamma_+}, u_{\gamma_-}$, while H_jH_k corresponds to $\frac{1}{4}d(w_j, w_k)$. Solving:

Theorem 41.40 (`sig_lV_gP`, `sig_lV_gM`). *For $j \neq k$,*

$$\sigma(u_{\gamma_+}) = (2\kappa_+)^{-1}\big(\tfrac{1}{8}d(w_j,w_k) + \kappa_+ u_{\gamma_+} - \kappa_- u_{\gamma_-}\big),$$
$$\sigma(u_{\gamma_-}) = (2\kappa_-)^{-1}\big(\tfrac{1}{8}d(w_j,w_k) - \kappa_+ u_{\gamma_+} + \kappa_- u_{\gamma_-}\big).$$

```
theorem sig_lV_gP {j k : Fin 24} (hjk : j ≠ k) :
    sig (lV (gP j k) (gP_mem j k)) = (2 * kP j k)⁻¹ • ((1 / 8 : ℂ) • dV (fw j) (fw k)
      + kP j k • lV (gP j k) (gP_mem j k) - kM j k • lV (gM j k) (gM_mem j k))

theorem sig_lV_gM {j k : Fin 24} (hjk : j ≠ k) :
    sig (lV (gM j k) (gM_mem j k)) = (2 * kM j k)⁻¹ • ((1 / 8 : ℂ) • dV (fw j) (fw k)
      - kP j k • lV (gP j k) (gP_mem j k) + kM j k • lV (gM j k) (gM_mem j k))
```

From the mathematics to the Lean statement

`gP_mem j k` is the proof that $\gamma_+ \in \Lambda_0$, needed to form the letter. Sanity check: applying σ to the first formula and using Proposition 41.20 for $\sigma(d(w_j,w_k))$ reproduces u_{γ_+} (since $\sigma^2 = 1$); the formulas are consistent with σ being an involution. They involve only the same symbolic constants $\kappa_\pm$ — no new unknowns.

Physical meaning

The images of the root-type lattice vertex operators $u_{\gamma_\pm}$ under σ are mixtures of a frame bilinear and the two charged operators with weights $\kappa_\pm$. Physically triality rotates charged and neutral currents into each other, the way a Weyl rotation mixes a Cartan current and its root vectors. This is the explicit formula needed to match zero modes on the twisted side.

What the machine verified

Unconditional; `SigmaTop2Root.lean`.

Theorem 41.41 (root letters intertwine). *Let τ be even ($\tau(-m) = \tau(m)$), satisfy the eigen-conditions, and the* transport rule *$\varepsilon_\Lambda(\gamma_+, n)\tau(\gamma_+ + n) = (2\kappa_+)^{-1}\tau(n)$ whenever n is odd of norm 4 with $\langle\gamma_+, n\rangle = -2$. Then u_{γ_+} intertwines for φ_τ; likewise for γ_-.*

```
theorem phiV3_ZM_gP {τ : leech.carrier → TLeechT} (hev : ∀ m, τ (-m) = τ m) {j k : Fin 24}
    (hjk : j ≠ k)
    (heig : ∀ n ∈ halfFourChi 1, kP j k • eL (gP j k) (τ n) = lam j k n • τ n ∧
      kM j k • eL (gM j k) (τ n) = lam j k n • τ n)
    (hrule : ∀ n : leech.carrier, n ∉ lambda0 → leech.form n n = 4 → leech.form (gP j k) n
     ↪  = -2 →
      εΛ (gP j k) n • τ (gP j k + n) = (2 * kP j k)⁻¹ • τ n) :
    ZM (phiV3 τ) OmegaV3 (lV (gP j k) (gP_mem j k))
```

From the mathematics to the Lean statement

`hev` lets one evaluate φ_τ on x_m for $m \notin S_1$ (then $-m \in S_1$ and $x_m = x_{-m}$). `heig` are the eigen-conditions (now known to follow from a seed). `hrule` is a genuinely new condition on τ: it ties together τ on the two endpoints of each move $n \mapsto n + \gamma_+$. `phiV3_ZM_gM` is identical with $\gamma_-, \varkappa_-$.

Physical meaning

The root-type lattice letters intertwine once the twist images are even and obey transport rules, which say that translating the momentum by γ_+ translates the twist state by the corresponding operator with prescribed phase. This is the matching of charges for the vertex operators of norm-four roots, the lattice-translation covariance that a T-duality-type map must have.

Proof. Source: $\mathrm{o}(u_{\gamma_+})x_n = \varepsilon(\gamma_+, n)x_{\gamma_+ + n}$ or $\varepsilon(\gamma_+, -n)x_{\gamma_+ - n}$ or 0, according to $\langle\gamma_+, n\rangle = -2, 2$, else. The move $n \mapsto n + \gamma_+$ with $\langle\gamma_+, n\rangle = -2$ means $n_j + n_k = -4$, so $\{n_j, n_k\} = \{-3, -1\}$: it moves the block from j to k or back. Target: by Theorem 41.40, $\mathrm{o}(\sigma u_{\gamma_+})$ on $h_{c_m} \otimes \tau$, with τ an $A_\pm$-eigenvector with eigenvalue λ, is $(2\varkappa_+)^{-1}(\frac{1}{2} - \lambda)$ times "swap $c_j \leftrightarrow c_k$" for $m \in \{j, k\}$ and 0 otherwise — the d-term contributes $4 \cdot \frac{1}{8} = \frac{1}{2}$ and the lattice terms contribute $-\lambda$ via the latL computation. Matching both sides on each basis vector in the three cases (block $\in \{j, k\}$ with $\langle\gamma_+, n\rangle = \mp 2$, block elsewhere where both sides are 0 because $\lambda = \frac{1}{2}$) gives exactly `hrule`. □

What the machine verified

Conditional on `hev`, `heig`, `hrule`; `SigmaTop2Root.lean`. Discharged for $\tau_\star$ below.

41.13 The explicit candidate $\tau_\star$

The transport rules determine the scalar $c(n)$ in $\tau(n) = c(n)e_n t$ along root moves. Solving them by hand (the root move γ_+ flips $\mathrm{sign}(n_{j(n)})$, γ_- keeps it; octad moves multiply by the χz_0-sign) leads to:

Definition 41.42 ($\tau_\star$). For $n \in \Lambda$ let $\mathrm{sgnBlk}(n) = n_{j(n)}/3$ and $c_\star(n) = i^{n_0}\,\mathrm{sgnBlk}(n)$ (an integer power of i; n_0 may be negative). Let $c_E(n) = \frac{1}{2}(c_\star(n) + c_\star(-n))$ and $\tau_\star(n) = c_E(n)\,e_n t$.

File `VOA/Moonshine/SigmaTop2Main.lean`.

```
noncomputable def sgnBlk (n : leech.carrier) : ℂ := ((lv n (blk n) : ℤ) : ℂ) / 3

noncomputable def cStar (n : leech.carrier) : ℂ := Complex.I ^ (lv n 0) * sgnBlk n

noncomputable def cE (n : leech.carrier) : ℂ := (cStar n + cStar (-n)) / 2

noncomputable def tauStar (t : TLeechT) (n : leech.carrier) : TLeechT := cE n • eL n t
```

From the mathematics to the Lean statement

On odd norm-four vectors $\mathrm{sgnBlk}(n) = \pm 1$ (Lemma 41.9), and $c_E = c_\star$ there (`cE_eq`): $c_\star(-n) = i^{-n_0}(-\mathrm{sgnBlk}\, n) = c_\star(n)$ because n_0 is odd and $i^{-n_0} = -i^{n_0}$. The symmetrisation c_E only serves to make $\tau_\star$ *literally* even on all of Λ (`tauStar_neg`), as required by `hev`. So on the relevant vectors this is the formula of the introduction, $\tau_\star(n) = i^{n_0}\,\mathrm{sign}(n_{j(n)})e_n t$.

Physical meaning

The explicit choice $\tau_\star$ is the candidate assignment of a twist state to each momentum: a phase i^{n_0} times the sign of the large coordinate, acting on the seed by e_n, symmetrised in $n \mapsto -n$. It is the physical image of the ground state of momentum n, the seed translated by the Clifford operator e_n with a specific phase. The choice is a trial that is verified by the intertwining theorems.

Theorem 41.43 (transport rules for $\tau_\star$). *If t is a seed, $\tau_\star$ satisfies the transport rules of Theorem 41.41 for γ_+ and γ_-, for all $j \neq k$.*

```
theorem tauStar_ruleP {t : TLeechT} (ht : IsSeed t) {j k : Fin 24} (hjk : j ≠ k) (n :
↪  leech.carrier)
    (hn0 : n ∉ lambda0) (h4 : leech.form n n = 4) (hf : leech.form (gP j k) n = -2) :
    εΛ (gP j k) n • tauStar t (gP j k + n) = (2 * kP j k)⁻¹ • tauStar t n

theorem tauStar_ruleM {t : TLeechT} (ht : IsSeed t) {j k : Fin 24} (hjk : j ≠ k) (n :
↪  leech.carrier)
    (hn0 : n ∉ lambda0) (h4 : leech.form n n = 4) (hf : leech.form (gM j k) n = -2) :
    εΛ (gM j k) n • tauStar t (gM j k + n) = (2 * kM j k)⁻¹ • tauStar t n
```

Physical meaning

The explicit candidate $\tau_\star$ satisfies the required transport rules for the root letters: the phase i^{n_0} sgnBlk is exactly the factor that makes translation covariance work. Physically this is the check that the candidate is compatible with the momentum-conservation rules of the vertex operators in the root sector.

Proof. Since $\langle \gamma_+, n\rangle = -2$ is even, $e_{\gamma_+ + n} = \varepsilon(\gamma_+, n)^{-1} e_n e_{\gamma_+}$, and on the seed $e_{\gamma_+} t = -(2\kappa_+)^{-1} t$. So the rule reduces to $c_E(\gamma_+ + n) = -c_E(n)$. The 0-th coordinate of γ_+ is divisible by 4 (it is 0, 4 or 8), so i^{n_0} is unchanged; and $\{n_j, n_k\} = \{-3, -1\}$ becomes $\{+1, +3\}$ or the reverse, so the ± 3 entry changes sign: sgnBlk flips. For γ_-: $n_j - n_k = -4$, so $(n_j, n_k) \in \{(-3, 1), (-1, 3)\}$ becomes $(1, -3)$ resp. $(3, -1)$; the sign of the ± 3 entry is preserved, and $e_{\gamma_-} t = +(2\kappa_-)^{-1} t$; consistent. □

What the machine verified

Unconditional given the seed; `SigmaTop2Main.lean`.

Theorem 41.44 ((R-top) on V_3^+ reduced to the octad letters). *For a nonzero seed $t \in T_s$, if every octad-type letter intertwines for $\varphi_{\tau_\star}$, then* `TopSigmaV3 (s+1)` $\varphi_{\tau_\star}$.

```
def OctadV3 (τ : leech.carrier → TLeechT) : Prop :=

  ↪  -gM j k) →
    ZM (phiV3 τ) OmegaV3 (lV' γ)

theorem topSigmaV3_of_octad {s : ZMod 2} {t : TLeechT} (hts : t ∈ leechFrameT s) (ht0 : t ≠
↪  0)
    (ht : IsSeed t) (hoct : OctadV3 (tauStar t)) :
```

```
    TopSigmaV3 (s + 1) (phiV3 (tauStar t))

def OctadResidualV3 : Prop :=
  ∀ (s : ZMod 2) (t : TLeechT), t ∈ leechFrameT s → t ≠ 0 → IsSeed t → OctadV3 (tauStar t)
```

From the mathematics to the Lean statement

`OctadV3 τ`: every letter u_γ, $\gamma \in S_0$, *not* of root type, intertwines. (Which these are is identified in Theorem 41.47; the definition avoids needing that classification by just excluding the root type.) `hits_cyclic` for $\varphi_{\tau_\star}$ uses the nonzero block constants $c_E(n_j)/\mu_j$, which is why `tauStar` need not literally equal `tauOf mu`.

Physical meaning

The only remaining charge conditions are those for the vertex operators of octad shape, namely the $(\pm 2)^8$ momenta supported on Golay octads. Once these also match charges, the candidate $\varphi_{\tau_\star}$ is a genuine intertwiner on the top level. This is a reduction, conditional on the octad letters, and points at the Golay-code part as the hard core of the construction.

Proof. Assemble: Zhu generation (`zhuGenerated_G2`), diagonal letters (any τ), off-diagonal letters (eigen-conditions from the seed, Theorem 41.27), root letters (Theorems 41.41 and 41.43), octad letters (hypothesis). □

What the machine verified

Conditional on `hoct`; `SigmaTop2Main.lean`.

41.14 The octad letters on V_3^+; classification; σ on V_3^+

41.14.1 The octad vectors

Let D be an octad (a Golay codeword of weight 8) and $S \subseteq D$ with $|S|$ even. In A-coordinates put $b_D = 1_D$ (`bAD hDA`), $\delta_S = 2 \cdot 1_S$ (`dSA S`), and

$$a_S = 1_D - 2 \cdot 1_S \in A \qquad (\texttt{aSA hDA S}),$$

the vector with entries $+1$ on $D \setminus S$, -1 on S, 0 off D (it lies in A: mod 2 it is the octad, and its coordinate sum $8 - 2|S|$ is divisible by 4 because $|S|$ is even). In Leech coordinates $\gamma_S = \iota_\Lambda a_S$ has entries ± 2 on D: the "octad type" norm-four vectors $(\pm 2^8, 0^{16})$ of Λ_0. In N, a_S is the spinor vector $1_D - \delta_S$ of the cube of §41.10. File `VOA/Moonshine/SigmaTop2Octad.lean`.

```
def bAD : lam0.carrier := (⟨ind D, hDA⟩ : ₁Leech.subA)

noncomputable def dSA (S : Finset (Fin 24)) : lam0.carrier :=
  if h : Even S.card then (⟨(2 : ℤ) • ind S, two_ind_mem S h⟩ : ₁Leech.subA) else 0

noncomputable def aSA (S : Finset (Fin 24)) : lam0.carrier := bAD hDA - dSA S
```

From the mathematics to the Lean statement

`hDA : ind D ∈ Leech.subA` is the hypothesis that $1_D \in A$, i.e. D is a codeword with $4 \mid |D|$; together with `hD8 : D.card = 8` it says D is an octad. `dSA` has a junk value 0 for odd $|S|$, never used (all statements assume `Even S.card`).

41.14.2 σ on the cube is a Hadamard transform

Theorem 41.45 (golaySigma_bp, sig_lV_aSA). *With $r = 1/\sqrt{2}$: $\sigma(b_T) = c_D \sum_{S\subseteq D} r^{|D|}(-1)^{|T\cap S|} b_S$ for $T \subseteq D$. Consequently, for an octad D and even $S \subseteq D$,*

$$\sigma(u_{\gamma_S}) = \sum_{S'\subseteq D,\ |S'|\ \text{even}} K(S,S')\, e^{\gamma_{S'}}$$

with explicit symbolic coefficients $K(S,S') = 2c_D r^8 X_S (-1)^{|S\cap S'|}\nu(S')t_c(a_{S'})$ (KS); in particular only even *S' occur.*

```
theorem golaySigma_bp {β : golayN.carrier} {D T : Finset (Fin 24)} (hβ : gv β = ind D)
    (h4 : 4 ∣ D.card) (hT : T ⊆ D) :

          KS hDA S S' • latChargeGen leech (inclΛ (aSA hDA S')) := by
```

From the mathematics to the Lean statement

rH $= \sqrt{2}/2 = r$. D.powerset.filter (… Even S'.card) is the set of even subsets of D. sig_lV_aSA carries the section hypotheses hDA, hD8. (The trailing := by belongs to the source line and is not part of the statement.)

Physical meaning

On the Golay frame, σ acts on the basis states indexed by subsets of an octad by the Hadamard matrix with entries $(-1)^{|T\cap S|}$ divided by $2^{|D|/2}$: a discrete Fourier transform over $\mathbb{F}_2^8$. This is a Fourier duality, in the spirit of T-duality, exchanging the two kinds of labels, the momentum-like subsets and the twist-like subsets. It gives the octad lattice letters u_{γ_S} an explicit image as a sum over even subsets with symbolic coefficients.

Proof. By Theorem 41.31, σ acts on each doublet by $h = g\chi g^{-1}$, and a 2×2 computation gives $h = r\left(\begin{smallmatrix}1 & 1\\ 1 & -1\end{smallmatrix}\right)$, the Hadamard matrix: so $\sigma b_T = c_D \bigotimes_i h(\text{basis vector})$, which expands to the stated sum. The letter u_{γ_S} is the image under the bridge of $y_S = t_c(a_S)^{-1}e^{a_S} + t_c(-a_S)^{-1}e^{-a_S} \in V_N^{\langle\chi,\Theta\rangle}$ (golayToV0_yA), and $e^{\pm a_S}$ are cube states ($-a_S$ corresponds to $D\setminus S$). So $\sigma(y_S)$ is a sum over all $S'\subseteq D$. The odd-$|S'|$ coefficients vanish *without computation*: $\sigma(y_S)$ lies in $V_N^{\langle\chi,\Theta\rangle}$, which contains only states e^x with $x\in A$, i.e. $\sum x_i \equiv 0 \pmod 4$, whereas $1_D - \delta_{S'}$ has coordinate sum $8-2|S'| \equiv 2 \pmod 4$ for $|S'|$ odd. The same parity argument forces the coefficients X_S, Y_S of b_S and $b_{D\setminus S}$ in y_S to be equal (XS_eq_YS), which simplifies the even coefficients. Transport back along the bridge. □

What the machine verified

Unconditional; SigmaTop2Octad.lean.

41.14.3 The octad identity

Theorem 41.46 (octad letters intertwine). *Let t be a seed, D an octad and $S\subseteq D$ even. Then u_{γ_S} intertwines for $\varphi_{\tau_\star}$: $\varphi_{\tau_\star}(o(u_{\gamma_S})x) = o(\sigma u_{\gamma_S})\varphi_{\tau_\star}(x)$ for all $x \in (V_3^+)_2$.*

```
theorem phiV3_ZM_aSA {t : TLeechT} (ht : IsSeed t) {S : Finset (Fin 24)} (h : _root_.Even
↪  S.card)
    (hS : S ⊆ D) : ZM (phiV3 (tauStar t)) OmegaV3 (lV (inclΛ (aSA hDA S)) (inclΛ_mem _))
```

From the mathematics to the Lean statement

Section hypotheses: `hDA : ind D ∈ Leech.subA`, `hD8 : D.card = 8`. Explicit: t is a seed, $|S|$ even, $S \subseteq D$. Note that no hypothesis "$t \in T_s$" or "$t \neq 0$" is needed here.

Physical meaning

The octad-type vertex operators intertwine for $\varphi_{\tau_\star}$: the Hadamard transform of the source side matches the Clifford-type action on the seed, so the charges agree. Physically this is the heart of the construction: the Fourier transform over each octad exchanges the momentum label with the twist label consistently. It completes the verification of charge matching for the top-level map.

Proof. Fix a basis vector x_n, $b = j(n)$, and write $p_i = \pm n_i$ with the sign $-$ on S, so $4\langle \gamma_S, n\rangle = \sum_{i\in D} p_i$.

Source. $\mathrm{o}(u_{\gamma_S})x_n \neq 0$ only if $\sum_D p_i = \mp 8$. If $b \notin D$, all $p_i = \pm 1$ and this means all eight p_i equal; if $b \in D$, $p_b = \pm 3$ and exactly one other $l_0 \in D$ has the opposite sign — the move $n \mapsto n \pm \gamma_S$ then carries the block from b to l_0.

Target. By Theorem 41.45 and Proposition 41.11(c), $\mathrm{o}(\sigma u_{\gamma_S})(h_{c_b} \otimes \tau_\star(n)) = 2^{-4}\sum_{S'} K(S,S')\, h_{\mathrm{latL}_{\gamma_{S'}} c_b} \otimes e_{\gamma_{S'}}\tau_\star(n)$. Two facts make the sum computable: (i) $\mathrm{latL}_{\gamma_{S'}}(c_b) = c_b - [b \in D]\sum_{l\in D} s'_b s'_l c_l$ with $s'_i = \pm 1$ the signs of $\gamma_{S'}$ (`latL_cw`); (ii) on the seed, $e_{\gamma_{S'}} e_n t = (-1)^{\langle \gamma_{S'}, n\rangle} e_n e_{\gamma_{S'}} t$ and $e_{\gamma_{S'}} t$ is, by ξ-closure ($\delta_{S'} \in \mathrm{Ch}(t)$), a known multiple of $W(b_D)t$ (`Wop_aSA_seed`). Each term becomes $C_0 \prod_{i\in S'} \zeta_i \cdot e_n W(b_D)t$ with explicit ± 1-valued ζ_i depending on n_i and $[i \in S]$ (`term_eval`). The sum over even S' of $\prod_{S'} f_i$ for a ± 1-pattern f is

$$\sum_{S'\subseteq D \text{ even}} \prod_{i\in S'} f_i = \tfrac{1}{2}\Big(\prod_D (1+f_i) + \prod_D (1-f_i)\Big) = 2^{|D|-1}\big([f \equiv 1] + [f \equiv -1]\big)$$

(`sum_even_pm`). So the target is nonzero exactly when the pattern ζ (or $\zeta\eta$, for the l-components) is constant — the same condition as on the source. In the block-outside case the surviving term reproduces $x_{n\pm\gamma_S}$'s image with the coefficient matching $c_E(n \pm \gamma_S) = c_D \cdot (\dots) c_E(n)$, where c_D (the χz_0-sign) is exactly the factor by which i^{n_0} changes when n_0 changes by $\pm 2 \cdot [0 \in D]$ (`cE_aSA_add`). In the block-inside case the l-sum picks out $l = l_0$, moving the oscillator to the new block. In both cases the remaining scalar identity is $2^{-4} \cdot 2c_D r^8 X_S \cdots = \dots$, with $r^8 = \frac{1}{16}$. □

41.14.4 Classification of S_0 and the theorem on V_3^+

Theorem 41.47 (`classify_S0`). *Every $\gamma \in S_0$ (norm 4, in Λ_0) is either $\pm\gamma_+(j,k)$ or $\pm\gamma_-(j,k)$ for some $j \neq k$ (shape $(\pm 4, \pm 4, 0^{22})$), or $\gamma = \gamma_S$ for an octad D and an even $S \subseteq D$ (shape $(\pm 2^8, 0^{16})$).*

```
theorem classify_S0 {γ : leech.carrier} (hγ : γ ∈ halfFourChi 0) :
    (∃ j k : Fin 24, j ≠ k ∧ (γ = gP j k ∨ γ = -gP j k ∨ γ = gM j k ∨ γ = -gM j k)) ∨
    (∃ (D : Finset (Fin 24)) (hDA : ind D ∈ Leech.subA), D.card = 8 ∧
      ∃ S : Finset (Fin 24), _root_.Even S.card ∧ S ⊆ D ∧ γ = inclΛ (aSA hDA S))
```

From the mathematics to the Lean statement

The second disjunct quantifies over a codeword D (`ind D ∈ Leech.subA`) of size 8 — an octad — and an even subset S. The statement is a disjunction, not a partition (the two cases are in fact disjoint, but that is not claimed). Same as the textbook statement.

Physical meaning

Every norm-four vector in the even part of the Leech lattice has one of two shapes, $(\pm 4, \pm 4, 0^{22})$ or $(\pm 2^8, 0^{16})$ on an octad. Physically this is the classification of the lowest vertex operators of the lattice by their momentum, which makes the check above exhaustive: no other type of lattice field has to be matched. It is a combinatorial fact about the Leech lattice, not a physical assumption.

Proof. Write $\gamma = 2a$, $a \in A$, $a \cdot a = 8$. Each $|a_i| \le 2$. With $O = \{i : |a_i| = 1\}$ and $F = \{i : |a_i| = 2\}$, $|O| + 4|F| = 8$. Since a mod 2 is a codeword with support O, and the Golay code has minimum weight 8, either $O = \varnothing$ (so $|F| = 2$: shape $(\pm 2, \pm 2, 0^{22})$ in A, i.e. $\pm\gamma_\pm$) or $|O| = 8$, $F = \varnothing$ (shape $(\pm 1^8)$ on an octad $D = O$, with S the set of -1 entries; $4 \mid \sum a_i = 8 - 2|S|$ forces $|S|$ even). The shape $(\pm 2, \pm 1^4)$ is excluded because no codeword has weight 4. □

What the machine verified

Unconditional; `SigmaTop2Class.lean`. Counting check (not a Lean statement): $4\binom{24}{2} + 759 \cdot 2^7 = 1104 + 97152 = 98256 = 2 \cdot 49128 = 2|S_0|$.

Theorem 41.48 (σ on V_3^+). *(a) There are s and φ with* `TopSigmaV3 s φ`.

(b) There are s and a σ-twisted intertwiner $\Phi : V_3^+ \to T_s^+$ of V_0^+-modules (`IsSigmaV3T Φ`*) whose image contains a cyclic vector $x_0^T(t_0)$, $0 \ne t_0 \in T_s$.*

```
theorem octadResidualV3 : OctadResidualV3

theorem topSigmaV3 : ∃ s φ, TopSigmaV3 s φ := topSigmaV3_exists octadResidualV3

theorem sigmaV3T_exists :
    ∃ (s : ZMod 2) (Φ : VPlus →ₗ[ℂ] TP), IsSigmaV3T Φ ∧
      ∃ t₀ : TLeechT, t₀ ∈ leechFrameT s ∧ t₀ ≠ 0 ∧ ∃ x ∈ OmegaV3, Φ x = x0T t₀ :=
  sigmaV3T_exists_of_octad octadResidualV3
```

From the mathematics to the Lean statement

No hypotheses. `IsSigmaV3T Φ` is the full intertwining property for all $u \in V_0^+$ and all modes $n \in \mathbb{Z}$, on all of V_3^+ (not just the top level). **Why it is not vacuous:** $\Phi = 0$ would satisfy `IsSigmaV3T`; the extra clause "$\Phi x = x_0^T(t_0)$ with $t_0 \ne 0$" rules it out. Also, `IsSigmaV3T` does not by itself say Φ maps V_3^+ into T_s^+; that follows from the cyclic-vector argument of Chapter 40 and is what `SigmaData` (Chapter 42) packages. **Compared with FLM:** FLM's σ is an isomorphism $V_3^+ \to T_0^+$; the Lean statement gives a nonzero intertwiner into the module generated by a cyclic vector, and bijectivity is proved downstream (Chapter 42, `Φ0_inj`, `Φ0_surj`). The one-line proof terms are shown because they are informative.

Physical meaning

There is a nonzero operator from the untwisted top level to a twisted sector, satisfying charge matching for every light field, i.e. an intertwiner twisted by σ, whose image contains a cyclic vector. This is the explicit existence of the triality operator on the lowest-energy states: the

twist-field space acts as the spinor on which triality is realised, and the matching of all zero modes is exactly the Ward identity of the symmetry. The cyclic vector shows it is nonzero and hence a genuine symmetry rather than the zero map.

Proof. `octadResidualV3`: a non-root letter of S_0 is of octad type by Theorem 41.47, so Theorem 41.46 applies. Then Theorem 41.44 with the seed of Theorem 41.37 gives (a), and `sigmaV3T_exists_of_top` (Chapter 40) gives (b). □

What the machine verified

Unconditional. `SigmaTop2Class.lean`. `##print axioms of topSigmaV3, sigmaV3T_exists`: [`propext`, `Classical.choice`, `Quot.sound`] — no `VOA.pbw` (re-checked, §41.18).

41.15 The twisted source: σ on T_s^+

41.15.1 $A_- = -A_+$ on the seed's sector

Lemma 41.49 (`AM_eq_neg_AP`). *Let $t \in T_s$ be a nonzero seed. Then $A_-(j,k)x = -A_+(j,k)x$ for every $x \in T_s$ and $j \neq k$.*

File `VOA/Moonshine/SigmaTop2TT.lean`.

```
theorem AM_eq_neg_AP {s : ZMod 2} {t : TLeechT} (hts : t ∈ leechFrameT s) (ht0 : t ≠ 0) (ht
 ↪  : IsSeed t)
    {j k : Fin 24} (hjk : j ≠ k) {x : TLeechT} (hx : x ∈ leechFrameT s) : AM j k x = -AP j
     ↪  k x
```

Physical meaning

On the twisted sector, once a nonzero seed exists, the two eigenvalue operators $A_\pm$ are opposite on the whole sector: the sector decomposes by a single sign. Physically this is a statement that the two commuting reflection-like charges are not independent, which reduces the number of conditions to check on twisted ground states.

Proof. $\gamma_+ + \gamma_- = w_j$ and $w_j \equiv w_0 \pmod{2\Lambda}$, so $e_{\gamma_+} e_{\gamma_-}$ is a scalar multiple of e_{w_0}, which acts on T_s by the frame scalar. Hence A_+A_- is a scalar c on T_s; on the seed, $A_+A_-t = -\frac{1}{4}t$, so $c = -\frac{1}{4}$ $(t \neq 0)$. With $A_+^2 = \frac{1}{4}$: $A_- = 4A_+(A_+A_-) = -A_+$ on T_s. □

So on T_s the vanishing condition $(A_+ + A_-)\psi_m = 0$ of Theorem 41.29 is automatic for any ψ_m with values in T_s. What is left is the choice of $B = \psi_0$.

41.15.2 The operator B

The Z_{0k} $(k \neq 0)$ are commuting involutions on T_s (`ZZ_mul_self`, and they commute because the γ_-'s have coordinates divisible by 4). Let $\omega = e^{i\pi/4} = (1+i)/\sqrt{2}$, $a = \frac{1+\omega}{2}$, $b = \frac{1-\omega}{2}$, so that $a + bu$ is 1 for $u = 1$ and ω for $u = -1$.

Definition 41.50 (`Bop`). $B_s = \left(\prod_{k\neq 0}(a + bZ_{0k})\right) \circ \pi_s$, with $\pi_s = \frac{1}{2}(1 + (-1)^s J)$ the projector onto T_s. On a joint eigenvector z of the Z_{0k} with eigenvalues u_k, $B_s z = \omega^{\#\{k : u_k = -1\}} z$.

↪  s • frameJL)
```

From the mathematics to the Lean statement

`rH` $= \sqrt{2}/2$, so `ωB` $= (1+i)/\sqrt{2} = e^{i\pi/4}$ (`ωB_sq : ωB ^ 2 = Complex.I`). The product over `List.finRange 24` is an ordered product, but the factors commute so the order is irrelevant. Only the factors $k \neq 0$ are nontrivial. The choice of B is *not* forced by the root letters; it is forced by the octad letters (§41.15.3) — this phase ω per flipped coordinate is the twisted-sector shadow of the factor i^{n_0} in $\tau_\star$.

Physical meaning

The operator B_s is a product of projectors that maps the twist space to the sector T_s while multiplying a joint eigenvector by a phase depending on how many of its signs are negative. Heuristically it is the twisted-to-twisted piece of the triality operator, a function of the discrete charges of the twist field; its eigenvalue phase $\omega^{\#}$ is the discrete Fourier-dual dependence on the twist label.

Proposition 41.51 (properties of B). *B_s maps into T_s; it commutes with every e_γ, $\gamma \in \Lambda_0$ with all coordinates divisible by 4; and it fixes every seed in T_s (on a seed, $Z_{0k}t = t$ for all k).*

File `VOA/Moonshine/SigmaTop2TT.lean`.

```

↪  (s : ZMod 2) :
    Commute (eL γ) (Bop s)
```

Physical meaning

B_s lands in the correct sector, commutes with the lattice-translation operators with 4-divisible coordinates, and fixes every seed. These are the properties of a symmetry operator on the twist space: it respects the sector, commutes with the relevant translation charges, and acts as the identity on the reference ground state; the last property also guarantees it is nonzero.

Proof. $Z_{0k} = 2A_(0,k)$ acts on a seed by $2 \cdot \frac{1}{2} = 1$, so each factor acts by $a + b = 1$. The rest is commutation of e-operators with even pairings. □

Theorem 41.52 (root letters on T_s^+). *For a nonzero seed $t \in T_s$, with $\psi = \psi(B_s)$ (Theorem 41.29), the letters $u_{\gamma_\pm(j,k)}$ intertwine for φ_ψ on $(T_s^+)_2$; and `TopSigmaTT s s` φ_ψ holds provided all lattice letters intertwine.*

     ↪  (lV' γ)) :
    TopSigmaTT s s (phiTT (psiOf (Bop s)))
```

From the mathematics to the Lean statement

Note the sectors: the source is T_s^+ and the target is T_s^+ for the *same* s as the seed, whereas V_3^+ went to T_{s+1}^+. This is the FLM pattern $\sigma: V_3^+ \to T_0^+$, $T_3^+ \to T_3^+$: the seed's sector is "T_3", the other one "T_0". (`phiTT_ZMT_gM` is the γ_- analogue.)

Physical meaning

The root-type vertex operators intertwine on the twisted-twisted top level when the operator B_s is built from a nonzero seed, so σ on the twisted sector is determined up to the remaining lattice letters. Physically the root fields matching charges is the twisted-sector analogue of the untwisted check, with the seed again serving as the image of the reference ground state.

Proof. As on V_3^+, using Theorem 41.40; on T_s, the sum $A_+ + A_- = 0$ makes the latL contributions cancel against the d-term in the right way, and the block links are `ZZ_comp`. □

What the machine verified

`phiTT_ZMT_gP`: unconditional; `topSigmaTT_of_seedB`: conditional on `hlat`; `SigmaTop2TT.lean`.

41.15.3 The octad letters on T_s^+

Here the structure of T_s under the abelian group generated by the Z_{0k} enters.

Definition 41.53 (joint eigenvectors). For $N \subseteq \{1, \dots, 23\}$ let $u_N(k) = -1$ if $k \in N$, $+1$ otherwise. z is a *joint eigenvector with character* N if $Z_{0k} z = u_N(k) z$ for all $k \neq 0$. Put $\beta(N) = \omega^{|N|}$.

File `VOA/Moonshine/SigmaTop2TTOct.lean`.

```
noncomputable def uN (N : Finset (Fin 24)) (k : Fin 24) : ℂ := if k ∈ N then -1 else 1

def IsEigN (N : Finset (Fin 24)) (z : TLeechT) : Prop := ∀ k, k ≠ 0 → ZZ 0 k z = uN N k • z

noncomputable def betaN (N : Finset (Fin 24)) : ℂ := ∏ i, if i ∈ N then ωB else 1

theorem eig_induct {s : ZMod 2} (P : TLeechT → Prop) (hadd : ∀ x y, P x → P y → P (x + y))
    (heig : ∀ z ∈ leechFrameT s, ∀ N : Finset (Fin 24), (0 : Fin 24) ∉ N → IsEigN N z → P
     ↪  z) :
    ∀ z ∈ leechFrameT s, P z
```

From the mathematics to the Lean statement

`eig_induct` is the spectral decomposition in induction form: an additive property holding on all joint eigenvectors in T_s holds on T_s (because the commuting involutions Z_{0k} are simultaneously diagonalisable). Hypothesis `(0 : Fin 24) ∉ N` is a normalisation ($k = 0$ is not among the operators). Then $B_s z = \beta(N) z$ and $\psi_m z = u_N(m)\beta(N) z$ (`Bop_eigN`, `psiOf_eigN`).

Physical meaning

A joint eigenvector with character N is a twist state whose reflection-like charges Z_{0k} have signs given by the subset N of frame directions, with phase $\omega^{|N|}$. These are the basis states of the twist space labelled by the discrete charges, the analogue of a computational basis for the spinor, in which the Hadamard transform will act.

Proposition 41.54 (how e_{γ_S} moves characters; twisted ξ-closure). *(a) If z has character N, then $e_{\gamma_S} z$ has character $\mathrm{flip}_D(N)$: u_k is flipped exactly for those k with $[k \in D] \neq [0 \in D]$.*

(b) For z with character N, the set $\mathrm{Ch}_N(z) = \{a : \iota_N a = \phi_R x,\ W(a)z = \xi(x)\chi_N(x)z\}$, $\chi_N(x) = (-1)^{\sum_{i\in N} x_i}$, is a subgroup.

File `VOA/Moonshine/SigmaTop2TTOct.lean`.

```
noncomputable def flipN (D N : Finset (Fin 24)) : Finset (Fin 24) :=
  Finset.univ.filter fun k => k ≠ 0 ∧ (k ∈ N ↔ (k ∈ D ↔ (0 : Fin 24) ∈ D))

theorem eig_flip {S : Finset (Fin 24)} (h : _root_.Even S.card) {N : Finset (Fin 24)}
    {z : TLeechT} (hE : IsEigN N z) : IsEigN (flipN D N) (eL (inclΛ (aSA hDA S)) z)

↪  where
  carrier := {a | ∃ x, inclN a = phiR x ∧ Wop a z = xiN N x • z}
  zero_mem' := ⟨0, by rw [map_zero, map_zero], by rw [Wop_zero, xiN_zero, one_smul]; rfl⟩
```

From the mathematics to the Lean statement

`flipN D N` written out: $k \neq 0$, and $k \in \mathrm{flip}_D(N) \iff (k \in N \iff (k \in D \iff 0 \in D))$; i.e. membership is kept when $[k \in D] = [0 \in D]$ and toggled otherwise. (a) is proved by $\langle \gamma_-(0,k), \gamma_S\rangle$ parity. For `chargesU` only the carrier and the zero field are quoted, as for `chargesS`. $\xi_N = \xi\chi_N$ still satisfies $\xi_N(x)\xi_N(y) = \varepsilon_N \xi_N(x+y)$ (`xiN_mul`), so the subgroup property holds for the same reason.

Physical meaning

Acting with the octad vertex operator on a state of character N flips the signs exactly on the positions inside the octad that differ from the base point, a bit-flip action on the labels of the basis. Physically this is the statement that the vertex operator of the octad shifts the discrete twist charge, so it is the analogue of a Pauli operator on the spinor. It also shows the set of charges is closed under this action.

Theorem 41.55 (Golay constraint). *Let $z \neq 0$ have character N and suppose $\delta_{S'} \in \mathrm{Ch}_N(z)$ for all even S'. Then $\prod_{i\in D'} u_N(i) = 1$ for every codeword D' (with $1_{D'} \in A$). Consequently (1_N is orthogonal mod 2 to every codeword, hence a codeword) $4 \mid |N|$.*

```
theorem golay_constraint {z : TLeechT} (hz0 : z ≠ 0) {N : Finset (Fin 24)}
    (hd : ∀ S' : Finset (Fin 24), _root_.Even S'.card → dSA S' ∈ chargesU z N)
    {D' : Finset (Fin 24)} (hD' : ind D' ∈ Leech.subA) : ∏ i ∈ D', uN N i = 1

theorem four_dvd_card_of_orth {N : Finset (Fin 24)}
    (h : ∀ D' : Finset (Fin 24), ind D' ∈ Leech.subA → ∏ i ∈ D', uN N i = 1) : 4 ∣ N.card
```

From the mathematics to the Lean statement

`ind D' ∈ Leech.subA` means D' is a Golay codeword (all codewords have $4 \mid |D'|$, so every codeword qualifies). In `four_dvd_card_of_orth`, N is an arbitrary subset; the hypothesis is "$|N \cap D'|$ is even for every codeword D'". Both are the textbook statements. The hypothesis `hd` is supplied on joint eigenvectors of the seed's sector by `dSA_mem_chargesU` (from $a_+(0,0)$, where W is the frame scalar read off at the seed, and $a_-(0,k)$, where W is Z_{0k} up to ξ).

Physical meaning

If a nonzero twist state is stabilised by all even octad charges, then its sign pattern N must be orthogonal to the Golay code and so is itself a codeword, with $4 \mid |N|$. This is a code-theoretic selection rule: the allowed discrete twist charges are dual to the Golay code, a Fourier-dual constraint relating the twist labels to the momentum lattice. It is a rigorous constraint, not a heuristic, and it is what makes the Hadamard sums below collapse.

Proof. For a codeword D', $2b_{D'} = \delta_{D'}$ and $W(2b_{D'}) = \xi(1_{D'})$ is a scalar (Proposition 41.35(b)). Membership in $\mathrm{Ch}_N(z)$ says $W(\delta_{D'})z = \xi(1_{D'})\chi_N(1_{D'})z$. As $z \neq 0$, $\chi_N(1_{D'}) = 1$, i.e. $\prod_{D'} u_N = (-1)^{|N\cap D'|} = 1$. For the consequence: 1_N mod 2 is orthogonal to the Golay code, which is self-dual, so 1_N is a codeword; Golay codewords have weight divisible by 4 (double evenness). □

What the machine verified

Unconditional; `SigmaTop2TTOct.lean`.

Lemma 41.56 (Hadamard sums with i). *Let $|D| = 8$ and $\epsilon : D \to \{\pm 1\}$ with $\prod_D \epsilon_i = 1$. Then $\sum_{S' \subseteq D \text{ even}} \prod_{i\in S'}(i\epsilon_i) = 16 \prod_{i\in D} g(\epsilon_i)$, where $g(1) = 1$, $g(-1) = i$.*

```
noncomputable def gI (e : ℂ) : ℂ := if e = 1 then 1 else Complex.I

theorem had_I (D : Finset (Fin 24)) (hD8 : D.card = 8) (ε : Fin 24 → ℂ)

    ∑ S' ∈ D.powerset.filter (fun S' : Finset (Fin 24) => _root_.Even S'.card),
        ∏ i ∈ S', (Complex.I * ε i) = 16 * ∏ i ∈ D, gI (ε i)
```

Physical meaning

A Hadamard-type sum over the even subsets of an octad with phases $i\epsilon_i$ evaluates to a product of single-site factors. This is the factorisation of a discrete Fourier transform over $\mathbb{F}_2^8$, the same factorisation that makes the cube action $h^{\otimes 8}$ a tensor product. It is a technical identity used to simplify the octad action on twist states.

Proof. The even sum is $\frac{1}{2}\big(\prod_D(1 + i\epsilon_i) + \prod_D(1 - i\epsilon_i)\big)$. If p coordinates have $\epsilon = -1$ (p even), $\prod(1 + i\epsilon) = (1 + i)^{8-p}(1 - i)^p = (1 + i)^8\big(\frac{1-i}{1+i}\big)^p = 16(-i)^p$ and $\prod(1 - i\epsilon) = 16\, i^p$; their average is $16\, i^p$ for p even ($(-i)^p = i^p$), and $\prod g(\epsilon_i) = i^p$. □

Lemma 41.57 (base identity). *Let $|D| = 8$, $S \subseteq D$, $0 \notin N$, $4 \mid |N|$ and $\prod_D u_N = 1$. Then*

$$i^{|S|}\Big(\prod_{i\in S} u_N(i)\Big)\beta(\mathrm{flip}_D N) = \beta(N) \prod_{i\in D} g\big(s_i u_N(i)\big), \qquad s_i = -1\ (i \in S),\ s_i = 1\ (i \notin S).$$

theorem base_identity {D S N : Finset (Fin 24)} (hD8 : D.card = 8) (hS : S ⊆ D)
    (hN0 : (0 : Fin 24) ∉ N) (hN4 : 4 ∣ N.card) (hND : ∏ i ∈ D, uN N i = 1) :
    (∏ _i ∈ S, Complex.I) * (∏ i ∈ S, uN N i) * betaN (flipN D N)
      = betaN N * ∏ i ∈ D, gI (sg S i * uN N i)
```

From the mathematics to the Lean statement

`sg S i` $= s_i$. The hypotheses $4 \mid |N|$ and $\prod_D u_N = 1$ are exactly the two outputs of the Golay constraint (Theorem 41.55); without them the identity is false in general, which is why the constraint is needed.

Physical meaning

This is the base identity showing that, for a joint eigenvector with Golay-constrained character, the phase produced by the octad operator agrees with the one produced by the Hadamard transform on the other side. It is the final charge-matching check for the octad letters on the twisted-twisted level; a technical lemma in the Hadamard/Golay computation.

Proof. Both sides are products of eighth roots of unity; compare them coordinate by coordinate. The ratio is a product of local correction factors ρ_i (`rhoF`) whose total product is $\omega^8 \prod_D u_N = 1$ when $0 \notin D$, or $\omega^{16}(-i)^{|N|} = 1$ when $0 \in D$ — the first case uses $\prod_D u_N = 1$, the second uses $4 \mid |N|$. □

Theorem 41.58 (octad letters on T_s^+; σ on T_s^+). *(a) For a nonzero seed $t \in T_s$, every octad letter u_{γ_S} intertwines for $\varphi_{\psi(B_S)}$ on $(T_s^+)_2$; first on joint eigenvectors (`octadTT_eig`), then on all of T_s by `eig_induct`.*

(b) There are s, φ with `TopSigmaTT s s φ`.

(c) There are s and a σ-twisted intertwiner $\Phi : T_s^+ \to T_s^+$ (`IsSigmaTT s Φ`) hitting a nonzero cyclic vector $x_0^T(t_0)$, $t_0 \in T_s$.

(d) For one and the same s: `TopSigmaV3 (s+1)` and `TopSigmaTT s s` both hold.

```
theorem phiTT_ZMT_aSA {s : ZMod 2} {t : TLeechT} (hts : t ∈ leechFrameT s) (ht0 : t ≠ 0)
    (ht : IsSeed t) {S : Finset (Fin 24)} (h : _root_.Even S.card) (hS : S ⊆ D) :
    ZMT (phiTT (psiOf (Bop s))) (OmegaT s) (lV (inclΛ (aSA hDA S)) (inclΛ_mem _))

theorem topSigmaTT : ∃ s φ, TopSigmaTT s s φ

theorem sigmaTT_exists :
    ∃ (s : ZMod 2) (Φ : TP →ₗ[ℂ] TP), IsSigmaTT s Φ ∧
      ∃ t₀ : TLeechT, t₀ ∈ leechFrameT s ∧ t₀ ≠ 0 ∧ ∃ x ∈ OmegaT s, Φ x = x0T t₀

theorem topSigma_both : ∃ s : ZMod 2, (∃ φ, TopSigmaV3 (s + 1) φ) ∧ ∃ φ, TopSigmaTT s s φ
```

From the mathematics to the Lean statement

No hypotheses in (b)–(d); (a) carries the octad section hypotheses `hDA`, `hD8`. `IsSigmaTT s Φ`: $\Phi(u_{(n)}y) = (\sigma u)_{(n)}\Phi(y)$ for all $u \in V_0^+$, $n \in \mathbb{Z}$, $y \in T_s^+$. Non-vacuity as for V_3^+: the cyclic-vector clause excludes $\Phi = 0$. **Why (d) matters.** (b) and Theorem 41.48(a) separately each assert existence for *some* sector. For the assembly of σ on all of $V^\natural$ (Chapter 42, `SigmaData`) one needs $\sigma : V_3^+ \to T_{s+1}^+$ and $\sigma : T_s^+ \to T_s^+$ with the *same* s, i.e. the images of V_3^+ and of T_s^+ are the two different twisted summands. `topSigma_both` obtains both from a single seed and so guarantees the pattern. It is still stated with $\exists s$ (Remark 41.1).

Physical meaning

On the twisted top level the octad vertex operators also intertwine, first on joint eigenvectors using the Golay constraint and Hadamard sums, then on the whole 2^{12}-dimensional twist space by induction over the eigenbasis. Together with the root letters this gives a nonzero charge-matching operator on the twisted-to-twisted top level, hence the symmetry operator on

both pieces, which is combined in the final statement. Physically this completes the explicit construction of triality on the lowest-energy states of the twisted sectors as an operator that matches all light-field charges and is nonzero.

Proof. (a) On a joint eigenvector z with character N: the twisted ξ-closure gives $W(a_{S'})z = \varepsilon\,\xi_N(-1_{S'})W(b_D)z$, so each term of the Hadamard sum for $\mathrm{o}(\sigma u_{\gamma_S})$ is $C_1\prod_{S'}(i\,s_i u_N(i))\,W(b_D)z$; by Lemma 41.56 the sum is $16\,C_1\prod_D g(s_i u_N(i))$ (the hypothesis $\prod_D s_i u_N(i) = 1$ holds because $|S|$ is even and $\prod_D u_N = 1$). On the source side $\mathrm{o}(u_{\gamma_S})$ maps $h_{c_b}\otimes z$ to $2^{-3}h_{\mathrm{latL}\,c_b}\otimes e_{\gamma_S}z$, and φ_ψ multiplies by $u_{\mathrm{flip}N}(\cdot)\beta(\mathrm{flip}N)$ since $e_{\gamma_S}z$ has character $\mathrm{flip}_D N$. Equality of the two sides reduces, after the common factors, to the base identity (Lemma 41.57), whose hypotheses are supplied by the Golay constraint. (b) Combine (a), the root letters and Theorem 41.52 with `classify_S0`, for the seed of Theorem 41.37. (c) `sigmaTT_exists_of_top` (Chapter 40). (d) Use the same seed for Theorems 41.44 and (b). □

What the machine verified

Unconditional. `SigmaTop2TTOct.lean`. `##print axioms` of `topSigmaTT`, `sigmaTT_exists`, `topSigma_both`: [`propext`, `Classical.choice`, `Quot.sound`] (re-checked, §41.18). These are the results consumed by Chapter 42 (`SigmaAssemble.mkData`).

41.16 The numerical evidence that preceded the proof

Before any of the Lean work of this chapter was attempted, the existence of σ on the twisted sectors was tested numerically (`Notes/TrialityTwisted.md` §4; scripts in `scripts/moonshine/numerics/triality/`). This evidence is *not* part of the proof and is reported here only because it shaped the construction — and because it is honest to say what was known before the proof existed.

The model. A Python model of V_N, $N = N(A_1^{24})$, with an explicit basis cocycle $\varepsilon(a,b) = (-1)^{c(a)^{\mathsf{T}}Uc(b)}$ (U the strict upper triangle of a Gram matrix; Golay code from quadratic residues mod 23), the twisted vertex operator $Y^T(e^\gamma, z) = 2^{-\langle\gamma,\gamma\rangle}z^{-\langle\gamma,\gamma\rangle/2}E^-E^+\otimes e_\gamma$, and a T_N built as an induced module. All 196884 states of $(V_N)_2$ were constructed; the library's $\sigma = G(\chi z_0)G^{-1}$ was computed on the 1083 invariant blocks.

What was confirmed.

1. $\dim(V_0^+)_2 = 49428$ and $\mathrm{tr}(\sigma|(V_0^+)_2) = 2324$ (for the unmodified DGM (7.5) form $G\chi G^{-1}$ one gets 6372), reproducing the certificate of Chapter 39.
2. $\Theta e^\gamma = c_\gamma e^{-\gamma}$ with $c_\gamma = 1$ for all 98256 norm-four $\gamma\in\Lambda_0$ *in the model* — the numerical counterpart of the θ-invariance used in Proposition 41.23.
3. An explicit σ-twisted intertwiner $(V_3^c)_2 \to T(0,c)_2$ was built by breadth-first propagation from one seed along the monomial lattice letters; *every image vector had support* 2 in the $h_j\otimes t$ basis ("essentially monomial" — the origin of the block-monomial ansatz of Definition 41.14). 15000 identities $\Phi(\mathrm{o}(u)v) = \mathrm{o}(\sigma u)\Phi(v)$: maximal relative residual 4.2×10^{-15}; the wrong target sector: residual 2.0 (no intertwiner).
4. For DGM's unmodified (7.5) σ, the intertwiner goes to the *wrong* sector — an independent confirmation that the z_0-modification (7.8) is needed.
5. $T(1,+)\to T(1,+)$ on the full weight-two space: 3000 identities, residual 4.8×10^{-12} (the wrong sign: 2.0). This is the numerical form of $\sigma: T_3^+\to T_3^+$.

6. Block spectra (block $j = 5$, 33166 block-preserving letters): $V_3 \leftrightarrow T(0,\cdot)$ match to 2.5×10^{-14}, and $T(1,\cdot)$ is σ-stable (3.1×10^{-14}).

Caveats recorded at the time. Only zero modes of weight-two elements on weight-two spaces were tested; the model uses the cocycle of N, not the library's Leech cocycle; and the identification of the model's sectors with the library's T_s^+ used an unchecked normalisation step. The Lean theorems of this chapter have none of these caveats: they are about the library's own objects, and the reduction to weight two is the theorem of Chapter 40.

A related exact test. Notes/ZhuGeneratorTest.md (exact arithmetic, no floating point) showed that the weight-two zero modes generate all of End of both 49152-dimensional tops, so φ is unique up to a scalar once it exists; this justified looking for *one* explicit formula rather than a family.

41.17 Dead ends, traps and corrections

Trap / dead end: "Which T_s^+ is T_0^+" is not well posed

Do not try to prove $\sigma(V_3^+) = T_0^+$ (or T_1^+) from the library's definitions: the answer depends on the bit $g_e(w_0)$ hidden in `Classical.choose` (`golayE_not_determined`, Chapter 40). All results are stated with $\exists s$, and `topSigma_both` supplies the matching pair.

Trap / dead end: The partial theorems are not (R-top)

`topSigmaV3_partial`, `topSigmaTT_partial` (constant τ, ψ) satisfy only the frame, weight, cyclic-vector and 24 diagonal-letter clauses. A constant τ cannot satisfy the off-diagonal letters (Schur: the solution is unique up to scalar). They must not be cited as σ-existence.

Trap / dead end: Unknown constants: avoid evaluating them

The constants $\kappa_\pm$, $t_c(a)$, $g_e(a)$, and every value of ε_Λ are uncomputable in the library. An early plan ("R-top partial" status) considered a refactor to an explicit Golay-frame cocycle to compute them. This turned out unnecessary (§41.8); every needed fact is a consequence of θ-invariance, cocycle algebra, ξ and Golay-code facts.

Trap / dead end: The eigenvalue $\pm\frac{1}{2}$ was once an unproved assumption

`SigmaTopOffdiag.lean` states the off-diagonal identity as following from eigen-conditions and notes that necessity would need "$\kappa_\pm e_{\gamma_\pm}$ have eigenvalues $\pm\frac{1}{2}$ (not proved here)". This was later proved (Proposition 41.23); the file comment is historical.

Trap / dead end: Stale file headers

Several file headers of this chapter's files say "Not wired into the umbrella". Already when this chapter was first written, and still at a pre-release build commit, they *are* imported by the umbrella `VOA/Moonshine.lean` (which imports `SigmaTop2TTOct`) and are used by `VOA.Moonshine.moonshine`. The headers predate the wiring.

Trap / dead end: The choice of B on T_s^+ is forced by the octads

The root letters on T_s^+ are satisfied by $\psi_m = Z_{0m}B$ for *any* B into T_s sending some vector to a seed. A naive choice ($B = \pi_s$) fails the octad letters; the phase $\omega^{|N|}$ on the joint eigenspaces is what the base identity requires. The Golay constraint ($4 \mid |N|$, $\prod_D u_N = 1$) is used in an essential way: without it the base identity is false.

41.18 Referee's checklist

Machine check performed for this chapter. At an earlier commit (when the chapter was first written; not re-run for this edition), with the built library, the following file was compiled with `lake env lean -DmaxSynthPendingDepth=3` (the flag avoids the audit trap of Chapter 1):

```
import VOA.Moonshine.SigmaTop2TTOct
open VOA.Moonshine.SigmaTop
#print axioms topSigmaV3_partial
#print axioms topSigmaTT_partial
#print axioms topSigmaV3_of_eigen
#print axioms topSigmaTT_of_eigen
#print axioms sig_dV_fw
#print axioms zhuGenerated_G2
#print axioms golayTheta_codeword
#print axioms seedExists
#print axioms classify_S0
#print axioms topSigmaV3
#print axioms sigmaV3T_exists
#print axioms topSigmaTT
#print axioms sigmaTT_exists
#print axioms topSigma_both
#print axioms golay_constraint
#print axioms four_dvd_card_of_orth
#print axioms base_identity
#print axioms had_I
#print axioms colD_key
```

Every one of the 19 lines printed

```
'VOA.Moonshine.SigmaTop.<name>' depends on axioms: [propext, Classical.choice, Quot.sound]
```

In particular none uses `VOA.pbw` (the PBW theorem of Chapter 3; formerly a project axiom, now a theorem). (The aggregate `lake build` of that commit, 10343 jobs, is recorded in Chapter 50; it was not re-run for this chapter.)

`topSigma_both`	both, for one s (sectors match)	**none**	**uncond.**; Thm. 41.58

What the referee should verify in particular. (1) That `TopSigmaV3`/`TopSigmaTT` contain the nontriviality clause `hits_cyclic` (they do), so that the headline theorems are not satisfied by $\varphi = 0$. (2) That `IsSigmaV3T`, `IsSigmaTT` quantify over *all* $u \in V_0^+$ and *all* modes $n \in \mathbb{Z}$ (`Set.univ`, `∀ n`). (3) That σ here is the library's `v0Sigma`, i.e. DGM's (7.8)-modified triality transported to V_0^+ (Chapter 39). (4) That the sector is existential and why (Remark 41.1).

Notes and references

The triality and its extension to the twisted sectors is the heart of the original construction: I. Frenkel, J. Lepowsky and A. Meurman, *Vertex Operator Algebras and the Monster*, Pure and Applied Mathematics 134, Academic Press, 1988, Chapters 11 ("Triality"), 12 and 13. FLM construct σ explicitly through the Golay code and rank-one $\hat{\mathfrak{sl}}_2$ isomorphisms between twisted and untwisted realisations; the book was not accessible to the project and its account was *not* checked against this chapter. The modern restatement used throughout is L. Dolan, P. Goddard and P. Montague, "Conformal field theories, representations and lattice constructions", Comm. Math. Phys. 179 (1996) 61–120, arXiv:hep-th/9410029, §§6–7: equations (7.1)–(7.8) define σ on V_N (the z_0-modified form (7.8) is the one in the library), and their Proposition 7.3 obtains the twisted extension *non-constructively* (via the uniqueness of the twisted module and a partition-function comparison). We have not compared the formula of this chapter for σ on twisted weight-two states with FLM's explicit construction (Chapter 11 of their book), which we could not consult.

The Golay code and Leech lattice facts used (minimum weight 8, self-duality, double evenness, the $(\pm 2^8, 0^{16})$ and $(\pm 4^2, 0^{22})$ shapes of norm-four vectors in Λ_0) are in J. H. Conway and N. J. A. Sloane, *Sphere Packings, Lattices and Groups*, 3rd ed., Grundlehren 290, Springer, 1999, Chapters 4 and 10. The Griess algebra and the 196884-dimensional weight-two space go back to R. L. Griess, "The friendly giant", Invent. Math. 69 (1982) 1–102; the extraspecial group and its 2^{12}-dimensional representation also appear there and in FLM Chapter 7. The modular-tensor-category picture of $V_\Lambda^{++} = V_0^+$ (16 irreducibles, the dihedral group of order 12 acting on them, the triality as an S_3) is in G. Höhn and M. Seysen, "The order of the Monster finite simple group", arXiv:2508.01037 (2025), §2.2 (the paper itself computes the order of the Monster), after H. Shimakura, "The automorphism group of the vertex operator algebra V_L^+ for an even lattice L without roots", J. Algebra 280 (2004) 29–57, and T. Abe, C. Dong and H. Li, "Fusion rules for the vertex operator algebras $M(1)^+$ and V_L^+", Comm. Math. Phys. 253 (2005) 171–219. Zhu's algebra and the top-level correspondence used in Chapter 40 are from Y. Zhu, "Modular invariance of characters of vertex operator algebras", J. Amer. Math. Soc. 9 (1996) 237–302. The stabiliser-state language of the remark in §41.11 is standard in quantum information (D. Gottesman, *Stabilizer Codes and Quantum Error Correction*, PhD thesis, Caltech, 1997, arXiv:quant-ph/9705052).

The project-internal record is `Notes/M8GluingPlan.md` (status sections "R-top partial" and "σ EXISTS on both twisted sectors"), `Notes/TrialityTwisted.md` and `Notes/ZhuGeneratorTest.md`.

Chapter 42

The key identity and the completion of the proof

This chapter documents the release of the library named in the front matter; every Lean quotation is checked by `scripts/textbook/sync.py` to occur verbatim (up to whitespace and comments) in the source files of that release. Checks that were run at an earlier state of the library and not re-run for this edition are marked as such. It is the last mathematical chapter of the Moonshine part of the book, and it is the one in which the construction of the Moonshine module is finished. When it ends, the reader will have seen every step of the proof of the Lean theorem

```
theorem moonshine :
    ∃ V : VertexOperatorAlgebra Vnat,
      V.Y = Ynat VnatAxioms.wbarL ∧ V.vacuum = vacNat ∧ V.conformalVector = omegaNat ∧
      V.centralCharge = 24 ∧
      V.grading 1 = ⊥ ∧
      Module.finrank ℂ (V.grading 2) = 196884 ∧
      (∀ n : ℕ, (Module.finrank ℂ (V.grading (n : ℤ)) : ℂ) = PowerSeries.coeff n JShift) ∧
      V.IsSimple
```

(`VOA/Moonshine/TopPairs.lean`, full name `VOA.Moonshine.moonshine`), which has *no hypotheses at all*, and whose `#print axioms` output is the three standard axioms of Lean's foundations, `propext`, `Classical.choice` and `Quot.sound`. The last section before the referee's checklist (§42.8) is a long, clause-by-clause fidelity check of this statement — the most careful one in the book, because it is the statement the whole library exists to prove. Everything before it explains, on paper, why it is true, and presents each intermediate statement with its own fidelity check.

The result in one sentence. In the wording recommended by the release audit of 2026-10-27 (`Notes/Textbook/referee/RELEASE_AUDIT_MOONSHINE.md`): *we have formalized in Lean 4 / Mathlib, with no hypotheses and only Lean's standard axioms, the Moonshine module $V^\natural$: a simple vertex operator algebra structure on the Frenkel–Lepowsky–Meurman space $V_\Lambda^+ \oplus (V_\Lambda^T)^+$ built from the Leech lattice, with central charge* 24, $V^\natural{}_1 = 0$, $\dim V^\natural{}_2 = 196884$, *and graded dimension equal, in every degree, to* $J(q) = j(q) - 744 = q^{-1} + 196884\,q + 21493760\,q^2 + \cdots$; *the Monster symmetry* $\mathrm{Aut}(V^\natural) = \mathbb{M}$ *is not part of the formalization.* The last clause was written for the theorem of this chapter and remains true of it: `moonshine` says nothing about automorphisms. Since release v1.05 the library treats the symmetries of $V^\natural$ separately, in Part VIII: Chapter 47 proves, with no hypotheses, that $\mathrm{Aut}(V^\natural)$ is finite and that the Conway–Norton conjecture holds, in a genus-zero form, for every automorphism (`conwayNorton`); Chapter 49 proves, with no hypotheses, that $\mathrm{Aut}(V^\natural)$ is isomorphic to the subgroup of AxiomMath's Monster `AutO` (Chapter 48) formed by the elements that act on $V^\natural$, and, conditionally on the one named hypothesis `GmatEqAutO` (a theorem of AxiomMath's library, not available on this toolchain), that $\mathrm{Aut}(V^\natural) \cong$ AutO (Chapter 1, Section 1.3.5). Three readings of this sentence are fixed once and for all. (a) Although `moonshine` is written as an existential,

it is a *construction*: the vertex map, vacuum, conformal vector and central charge are pinned to explicit definitions, the grading is then forced, and the witness is unique (§42.8). (b) J is the *formal* q-expansion `JShift` $= E_4^3/(\Delta/q) - 744q$; its identification with the analytic function $j(\tau) - 744$ on the upper half plane is classical but is not part of the Lean statement; it is proved separately in Lean (`qExpansion_qJ`, `hasSum_JShift`, in `VOA/Moonshine/JAnalyticQExpansion.lean`). (c) "The FLM space" refers to the carrier; the twisted×twisted block of the vertex operator is the form-adjoint of the skew intertwiner (the Huang / Dolan–Goddard–Montague presentation), not FLM's own explicit formula, and the isomorphism with FLM's $V^\natural$ is a paper argument (uniqueness of simple-current extensions, Dong–Mason, Prop. 5.3), not a Lean theorem.

As everywhere in this book, our concern is the *meaning* of the Lean statements. Proofs are explained mathematically; we do not describe how the Lean proof scripts are organised.

42.1 Where we stand, and what remains

42.1.1 The state of the construction at the start of this chapter

Let us recall what the previous chapters have built. The carrier of the Moonshine module is

$$V^\natural \;=\; V_\Lambda^+ \,\oplus\, (V_\Lambda^T)^+,$$

where V_Λ^+ is the fixed-point subalgebra of the Leech lattice vertex operator algebra under the lift θ of -1 (Chapter 32) and $(V_\Lambda^T)^+$ is the θ-fixed part of the twisted module $V_\Lambda^T = S[\theta]\otimes T$ (Chapters 34–36). In Lean, V_Λ^+ is the type `SkewVP` (equivalently `VPlus`; both are abbreviations of the same subtype of the lattice VOA), $(V_\Lambda^T)^+$ is the submodule `TP` of `Tw := FockT 24 ⊗[ℂ] leechT`, and $V^\natural$ is the product type `Vnat := SkewVP × TP`.

Chapter 37 constructed the two "off-diagonal" fields: the skew intertwiner $W(t,z)$, which sends V_Λ^+ to $(V_\Lambda^T)^+$ and is defined by skew-symmetry,

$$W(t,z)\varphi \;=\; e^{zL_{-1}}\, Y^T(\varphi,-z)\, t,$$

and its adjoint $\overline{W}(t,z)$, which goes the other way and is defined by transposition through the two invariant bilinear forms B_V (`leechBV`) on V_Λ^+ and `TPForm` on $(V_\Lambda^T)^+$. Chapter 38 assembled the block vertex operator

$$Y^\natural\big((u,t),z\big) \;=\; \begin{pmatrix} Y(u,z) & \overline{W}(t,z) \\ W(t,z) & Y^T(u,z) \end{pmatrix} \tag{42.1}$$

(DGM (4.17); Lean `Ynat wbarL`) and proved that it defines a vertex operator algebra with central charge 24 *provided* one family of locality relations holds, the "twisted×twisted" relation that Dolan–Goddard–Montague call (4.23):

$$W(t_1,z_1)\,\overline{W}(t_2,z_2) \;\sim\; W(t_2,z_2)\,\overline{W}(t_1,z_1) \qquad \text{on } (V_\Lambda^T)^+, \tag{42.2}$$

where $\sim$ means equality after multiplication by a sufficiently high power of $(z_1 - z_2)$. In Lean this is the proposition `TPBlockLocal leechWbar t₁ t₂`. The companion relation (4.22), the analogous statement on V_Λ^+, was proved unconditionally (`leechWbar_VPBlockLocal`); simplicity was proved too, via nondegeneracy of an invariant form (`SimpleNat.vnatVOA_isSimple`). The result was `moonshine_of_frameLocality`: *all* targets, conditional on (4.23) for four explicit pairs of twisted vectors.

Chapters 39–41 then built the tool with which FLM prove (4.23): the *triality*. The Leech lattice contains a sublattice Λ_0 of index two (the Golay frame sublattice), and accordingly

$$V_\Lambda^+ = V_0^+ \oplus V_3^+, \qquad (V_\Lambda^T)^+ = T_0^+ \oplus T_1^+,$$

four V_0^+-modules (Lean: `frameSector 0`, `frameSector 1`, `TPframe 0`, `TPframe 1`). FLM's key insight is that there is an automorphism σ of the subalgebra V_0^+ that does not extend to V_Λ^+, but which permutes the three nontrivial sectors: twisting V_3^+ by σ gives one twisted sector, and the other twisted sector is σ-stable. Chapter 39 constructed σ on V_0^+ (`v0Sigma`); Chapters 40–41 constructed the twisted halves, the σ-twisted V_0^+-intertwiners

$$\Phi : V_3^+ \to T_s^+, \qquad \Theta : T_{s+1}^+ \to T_{s+1}^+,$$

unconditionally (`SigmaTop.topSigma_both`), using Zhu-algebra generation (`zhuGenerated_weightTwo`) to reduce their existence to finite top-level data.

42.1.2 What this chapter does

The idea of FLM is to *conjugate*. Assemble the sector maps into one linear involution $\sigma^\natural$ of $V^\natural$. If $\sigma^\natural$ were an automorphism of the (would-be) vertex algebra, then for $v \in V_3^+$,

$$\sigma^\natural\, Y^\natural(v,z)\, \sigma^\natural \;=\; Y^\natural(\sigma^\natural v, z),$$

and the right-hand side is a twisted field $Y^\natural((0,\Phi v),z)$. The left-hand side is local with itself because the untwisted field $Y^\natural(v,z)$ is (proved in Chapter 38). So the twisted field $Y^\natural((0,x),z)$, $x = \Phi v$, would be local with itself, which contains (4.23) for the pair (x,x); and one generating twisted vector suffices.

Of course, we cannot assume that $\sigma^\natural$ is an automorphism; that is what is to be proved. The honest content is an *identification of two fields*: the conjugated field $L_v = \sigma^\natural Y^\natural(v,z)\sigma^\natural$ and the block field $R_v = Y^\natural(\sigma^\natural v, z)$. The chapter proceeds as follows.

(1) §42.2: the conjugation set-up. Both L_v and R_v are local with all V_0^+-fields and create the same state from the vacuum, so their difference is determined by its values on the cyclic vectors of the four sectors. The remaining agreements are three "three-point identities" (`SigmaKey`); if they hold, then (4.23) holds for all pairs and $V^\natural$ is constructed (`moonshine_of_sigma`).

(2) §42.3: adjunction against the invariant forms reduces the three identities to two *isometry* statements and one *self-coupling* identity `KeySkew`; the isometries reduce further to finite top-level statements (`moonshine_of_top`).

(3) §42.4: the explicit triality data of Chapter 41 are assembled into `mkData c ε`, the isometries are proved (with the normalisation $\mu = +1$ *proved*), and the only remaining hypothesis is `KeySkew0 ε` for one sign ε (`moonshine_of_keySkew0`).

(4) §42.5: a lemma of Li type shows that `KeySkew` is controlled by the top-output components of a "block defect" (`keySkew_of_keyTopV`); that residual is still infinite.

(5) §42.6: Frenkel–Zhu bimodule theory makes it finite. The bimodule $A(V_3^+)$ is generated by its top level (`bimodGen_V3`), and the transposed top-level identities need only the commutator formula, so the intertwining Jacobi identity of W — which the library does not have — is never needed (`keySkew_of_FZ`).

(6) §42.7: the last finite identity, $\Theta\, o(v)\Phi b = o(b)\Phi v$ on the 49152-dimensional top level, is proved by an explicit sign computation in Leech coordinates (`topPairs_one`, with $\varepsilon = +1$). This yields `moonshine`.

(7) §42.8: the final theorem, read clause by clause; then the referee's checklist.

Remark 42.1 (The chain of reductions at a glance)**.** Each implication below is a Lean theorem presented in this chapter; the top line is the goal, the bottom lines are what is finally established by direct argument.

42.1.3 Notation used throughout the chapter

We fix the following abbreviations, which match the Lean files and the route notes `Notes/SigmaKey.md`, `Notes/KeySkew.md`.

- $A = V_0^+$ (Lean `V0Sub.carrier`, equal to `frameSector 0`); as a VOA in its own right it is `V0P`. $B = V_3^+$ (`frameSector 1`). $C = T_s^+$ and $D' = T_{s+1}^+$ (`TPframe s`, `TPframe (s+1)`), where $s \in \mathbb{Z}/2$ labels the twisted sector that the triality pairs with V_3^+. The label is part of the data because the library's definitions do not single out which of the two twisted frame sectors is FLM's T_0^+ (`golayE_not_determined`, Chapter 40).
- For $u \in A$ and $n \in \mathbb{Z}$, `actV u n` and `actT u n` are the modes $u_{(n)}$ of u acting on V_Λ^+ and on `TP`. Recall the library convention `mode f n = f (-n - 1)` (Definition 2.7): `mode (Y u) n` is the mathematician's $u_{(n)}$, whereas the raw coefficient `Y u k` is the coefficient of z^k in $Y(u,z) = \sum_n u_{(n)} z^{-n-1}$, i.e. $u_{(-k-1)}$. The library records this as `Y_eq_actV`: `leechVOAPlus.Y u k x = actV u (-k - 1) x`. *Every* statement of the form `∀ p, … Y v p …` below is therefore a statement about all coefficients of a series, and the reindexing $p \leftrightarrow -p-1$ never changes its content.
- $\sigma =$ `v0Sigma` $\in \mathrm{Aut}(V_0^+)$; `sig u` is its value on u.
- The cyclic vectors: $x_\beta = e^\beta + e^{-\beta} \in V_3^+$ for $\beta \in \Lambda \setminus \Lambda_0$ (`frameX0P β`); $x_0(t) = h_0(-\frac{1}{2})\mathbb{1} \otimes t \in T^+$ for $t \in T$ (`x0T t`), which lies in T_s^+ when $t \in T_s$ (`x0T_mem`) and has weight 2.
- $o(v)$ is the zero mode $v_{(\mathrm{wt}\, v - 1)}$ of a homogeneous v; it preserves weight.
- The weight-2 "tops": $\Omega_{V_3} = (V_3^+)_2$ (`OmegaV3`, of dimension 49152) and $\Omega_T(s) = (T_s^+)_2$ (`OmegaT s`). Both V_3^+ and T^+ have *no* states of weight below 2.

42.2 The would-be triality $\sigma^\natural$ and conjugation of fields

42.2.1 The physical picture

In the language of two-dimensional conformal field theory, $V^\natural$ is the chiral algebra of a $\mathbb{Z}/2$-orbifold of 24 free bosons compactified on the Leech torus. The untwisted sector V_Λ^+ contains the θ-invariant operators of the original theory; the twisted sector $(V_\Lambda^T)^+$ contains the θ-invariant *twist fields*, created by inserting a branch cut around which the bosons change sign. The operator product of two twist fields lands back in the untwisted sector, and the content of (4.23) is that these operator products are mutually local: the twist fields of $V^\natural$ behave like ordinary, single-valued local operators. In general an orbifold of a lattice theory by -1 produces a consistent chiral algebra only after a subtle sign

analysis; FLM's triality makes this analysis unnecessary by exhibiting a *symmetry* of the would-be theory that turns twist fields into untwisted fields, for which locality is already known. The physicist's slogan is: "the twisted sector is not special; there is a hidden symmetry that rotates it into the untwisted sector." This section turns the slogan into a precise reduction.

42.2.2 One twisted vector generates the twisted sector

The first ingredient is a cyclicity statement: a single twisted vector of the simplest kind generates all of $(V_\Lambda^T)^+$ under the modes of V_Λ^+.

Definition 42.2 (Mode span). Let $g = (g_i)_{i\in\kappa}$ be a family of vectors of $T^+ = (V_\Lambda^T)^+$. We say that g *mode-spans* T^+ if

$$T^+ = \operatorname{span}_{\mathbb{C}}\{\, u_{(n)} g_i \;:\; u \in V_\Lambda^+,\ n \in \mathbb{Z},\ i \in \kappa \,\}.$$

```
def ModeSpan : Prop :=
  Submodule.span ℂ {x : TP | ∃ (u : SkewVP) (n : ℤ) (i : κ), x = mode (plusModule.YM u) n
   ↪  (g i)} = ⊤
```

(`VOA/Moonshine/M8h0Gap.lean`, `VOA.Moonshine.M8h0.ModeSpan`, with $g : \kappa \to$ `TP` a section variable.)

From the mathematics to the Lean statement

Decoding. `plusModule` is the V_Λ^+-module structure on `TP` constructed in Chapter 36; `plusModule.YM u` is the formal series $Y^T(u,z)$ acting on `TP`, and `mode (plusModule.YM u) n` is its n-th mode $u_{(n)}$ by the convention `mode f n = f (-n-1)`. `Submodule.span ℂ S` is the smallest complex subspace containing S, and `= ⊤` says it is the whole space `TP`.
Same statement. The Lean set is exactly the set of vectors $u_{(n)}g_i$. No hypothesis.

Physical meaning

A family of twist fields generates the twisted sector if all twisted states arise from them by OPE with untwisted operators: the twisted sector is an irreducible "module" in the CFT sense, built over a few ground states.

Theorem 42.3 (One vector generates T^+). *For every nonzero $t_0 \in T$, the single vector $x_0(t_0) = h_0(-\frac{1}{2})\mathbb{1} \otimes t_0$ mode-spans $(V_\Lambda^T)^+$.*

```
theorem modeSpan_x0T {t₀ : TLeechT} (h0 : t₀ ≠ 0) : ModeSpan (fun _ : Unit => x0T t₀)
```

(`VOA/Moonshine/M8hKeySpan.lean`, `VOA.Moonshine.M8hKey.modeSpan_x0T`.)

From the mathematics to the Lean statement

Decoding. `TLeechT` is the 2^{12}-dimensional irreducible module T of the twisted group algebra of Λ (Chapter 36, `finrank_leechT = 4096`). `x0T t₀` is the vector $h_0(-\frac{1}{2})\mathbb{1} \otimes t_0$ regarded as an element of `TP`; here h_0 is the first orthonormal coordinate direction of $\mathbb{C} \otimes \Lambda$ and $h_0(-\frac{1}{2})$ the corresponding half-integral twisted Heisenberg creation operator. The family is indexed by the one-point type `Unit`, so "mode-spans" means: the $u_{(n)}x_0(t_0)$ span.
Hypothesis. Only $t_0 \neq 0$, which is obviously necessary. Note that t_0 is *not* required to lie in a frame sector T_s: the theorem uses all of V_Λ^+, not only V_0^+.
Same statement. Yes.
Could it be vacuous? No: $T \neq 0$, and the conclusion is a genuine spanning statement about a nonzero space.

Physical meaning

One twist field suffices: inserting untwisted operators (oscillators ∂X and vertex operators $e^{i\alpha\cdot X}$) next to a single ground-state twist field produces every twisted state. Physically the e^{α} act on the 2^{12} ground states as the Clifford-type algebra of the zero modes, which acts irreducibly.

Proof on paper. Let $Z \subseteq V_\Lambda^T$ be the span of all $Y^T(u)_{(k/2)}x_0$, with u running over the whole lattice VOA V_Λ (twisted modes are half-integral). Z is stable under every twisted mode. First, the annihilation operator $h_0(\frac{1}{2})$ removes the oscillator: $h_0(\frac{1}{2})x_0 = \frac{1}{2}\mathbb{1}\otimes t_0$, so $\mathbb{1}\otimes t_0 \in Z$. Next, the twisted vertex operator of e^{α} acts on $\mathbb{1}\otimes t$ with a lowest coefficient proportional to $\mathbb{1}\otimes e_\alpha t$, so $\mathbb{1}\otimes e_\alpha t_0 \in Z$ for all $\alpha\in\Lambda$. Since T is a *simple* module for the twisted group algebra (Chapter 36), the $e_\alpha t_0$ span T; hence $\mathbb{1}\otimes T \subseteq Z$. The Heisenberg creation operators then produce $S[\theta]\otimes T$, so $Z = V_\Lambda^T$. Finally, project to the θ-invariant parts: the θ-fixed part of a mode $u_{(n)}x_0$ is the mode of the θ-fixed part of u applied to the θ-fixed x_0, so T^+ is spanned by modes of V_Λ^+ applied to x_0. □

What the machine verified

Unconditional. `#print axioms: [propext, Classical.choice, Quot.sound]` (the file is imported by `VOA.Moonshine.moonshine`, whose axiom list is this).

42.2.3 Conjugating a field by an involution

Definition 42.4 (Conjugate field). Let V be a complex vector space, $\sigma\in\operatorname{End}V$ and $A(z)=\sum_k A_k z^k$ a formal distribution with coefficients in $\operatorname{End}V$. The *conjugate* of A by σ is $(\sigma A\sigma)(z)=\sum_k \sigma A_k\sigma\, z^k$.

```
def conjF (σ : End ℂ V) (A : FormalDist (End ℂ V)) : FormalDist (End ℂ V) :=
  fun k => σ * A k * σ
```

(`VOA/Moonshine/M8hKeySigma.lean`, `VOA.Moonshine.M8hKey.conjF`.)

From the mathematics to the Lean statement

`FormalDist X` is the type of functions $\mathbb{Z}\to X$, read as formal series $\sum_{k\in\mathbb{Z}}A_kz^k$ (Definition 2.1); `A k` is the coefficient of z^k. The product `σ * A k * σ` is composition in the algebra `End ℂ V`. Exactly the textbook definition.

Physical meaning

Conjugating an operator by a symmetry, $\mathcal{O}\mapsto g\,\mathcal{O}\,g^{-1}$: the transformed field. For a genuine symmetry of the CFT, the transformed field of $\phi(z)$ is the field of the transformed state.

Proposition 42.5. *Let $\sigma^2=1$. (a) If A and B are mutually local, so are $\sigma A\sigma$ and $\sigma B\sigma$. (b) If σ commutes with an operator T and A is T-covariant, $[T,A(z)]=\partial_z A(z)$, then so is $\sigma A\sigma$.*

```
theorem local_conjF {σ : End ℂ V} (hσ : σ * σ = 1) {A B : FormalDist (End ℂ V)}
    (h : Local A B) : Local (conjF σ A) (conjF σ B)

theorem dCovariant_conjF {σ T : End ℂ V} (hT : σ * T = T * σ)
    {A : FormalDist (End ℂ V)} (h : DCovariant T A) : DCovariant T (conjF σ A)
```

(`VOA/Moonshine/M8hKeySigma.lean`.)

From the mathematics to the Lean statement

Decoding. `Local A B` (Definition 2.41) means: there is $N \in \mathbb{N}$ with $(z_1-z_2)^N[A(z_1),B(z_2)] = 0$ coefficientwise. `DCovariant T A` means $[T,A_k]$ = the coefficient of z^k in $\partial_z A$, i.e. translation covariance with respect to T (which will be L_{-1}).
Hypotheses. $\sigma^2 = 1$ in (a); in (b), $\sigma T = T\sigma$. Note (b) does not need $\sigma^2 = 1$. Both are the textbook hypotheses.

Physical meaning

Locality and translation covariance are preserved by any operator that commutes with them in the obvious sense: a change of basis on the Hilbert space does not create new singularities in OPEs.

Proof on paper. (a) $[\sigma A_m\sigma, \sigma B_n\sigma] = \sigma[A_m,B_n]\sigma$ because $\sigma\sigma = 1$ in the middle; multiplying by $(z_1-z_2)^N$ commutes with the linear map $X \mapsto \sigma X\sigma$. (b) $[T,\sigma A_k\sigma] = \sigma[T,A_k]\sigma$ since σ commutes with T. □

What the machine verified

Unconditional; standard axioms only.

42.2.4 The sector decomposition and the triality data

The splittings $V_\Lambda^+ = V_0^+ \oplus V_3^+$ and $T^+ = T_0^+ \oplus T_1^+$ were established in Chapter 39 (`frameSector_isCompl`, `TPframe_isCompl`). Consequently a linear map out of $V^\natural$ is determined by its four restrictions (`vnat_ext`); this "four-sector extensionality" is used constantly below.

Definition 42.6 (σ-twisted intertwiners). Let M,N be V_0^+-modules (here: subspaces of V_Λ^+ or T^+ with the restricted mode action) and $X \subseteq M$ a subspace. A linear map $\Phi : M \to N$ is a *σ-twisted intertwiner on X* if

$$\Phi(u_{(n)}x) = (\sigma u)_{(n)}\Phi(x) \qquad \text{for all } u \in V_0^+,\ n \in \mathbb{Z},\ x \in X.$$

```
def IsTwInt (ρ : A → ℤ → M →ₗ[ℂ] M) (τ : A → ℤ → N →ₗ[ℂ] N) (g : A → A) (S : Set A)
    (X : Submodule ℂ M) (Φ : M →ₗ[ℂ] N) : Prop :=
  ∀ u ∈ S, ∀ (n : ℤ), ∀ x ∈ X, Φ (ρ u n x) = τ (g u) n (Φ x)

def IsSigmaV3T (Φ : VPlus →ₗ[ℂ] TP) : Prop :=
  IsTwInt actV actT sig Set.univ (frameSector 1) Φ
def IsSigmaTT (s : ZMod 2) (Φ : TP →ₗ[ℂ] TP) : Prop :=
  IsTwInt actT actT sig Set.univ (TPframe s) Φ
def IsSigmaTV (s : ZMod 2) (Φ : TP →ₗ[ℂ] VPlus) : Prop :=
  IsTwInt actT actV sig Set.univ (TPframe s) Φ
```

(`VOA/Moonshine/TrialityTwGeneric.lean`, `VOA/Moonshine/TrialityTwSigma.lean`.)

From the mathematics to the Lean statement

Decoding. `ρ u n`, `τ u n` are the n-th modes of u on source and target; `g = sig` is σ; `S = Set.univ` means "all $u \in V_0^+$". The map Φ is defined on the whole ambient space (V_Λ^+ or `TP`), but the intertwining condition is only imposed for x in the indicated sector X; this is harmless because only the restriction to X matters later. `M →ₗ[ℂ] N` is the type of $\mathbb{C}$-linear maps.
Same statement. Yes. Note the twist is on the *target* side: $\Phi \circ u_{(n)} = (\sigma u)_{(n)} \circ \Phi$; with $\sigma^2 = 1$ this is equivalent to the other convention.

Physical meaning

A map between sectors that commutes with the chiral algebra V_0^+ up to the outer automorphism σ: in CFT terms, Φ realises the action of a symmetry of the subtheory V_0^+ that permutes its superselection sectors.

Definition 42.7 (Triality data). *Triality data* consist of a label $s \in \mathbb{Z}/2$ and three linear maps

$$\Phi : V_\Lambda^+ \to T^+, \qquad \Psi : T^+ \to V_\Lambda^+, \qquad \Theta : T^+ \to T^+$$

such that Φ is a σ-twisted intertwiner on V_3^+, Ψ on T_s^+, Θ on T_{s+1}^+; $\Phi(V_3^+) \subseteq T_s^+$, $\Psi(T_s^+) \subseteq V_3^+$, $\Theta(T_{s+1}^+) \subseteq T_{s+1}^+$; and $\Psi\Phi = \mathrm{id}$ on V_3^+, $\Phi\Psi = \mathrm{id}$ on T_s^+, $\Theta^2 = \mathrm{id}$ on T_{s+1}^+.

```

  ΘΘ : ∀ t ∈ TPframe (s + 1), Θ (Θ t) = t
```

(`VOA/Moonshine/M8hKeySigma.lean`, `VOA.Moonshine.M8hKey.SigmaData`.)

From the mathematics to the Lean statement

Decoding. A Lean `structure` is a record: a term of type `SigmaData` is a tuple of the data fields (`s`, `Φ`, `Ψ`, `Θ`) together with proofs of the listed properties. `ZMod 2` is $\mathbb{Z}/2$. Every field corresponds to one clause of Definition 42.7; nothing more is required.

What is *not* required. `SigmaData` does not ask that Φ, Θ preserve the invariant forms, nor any compatibility with the fields W, $\overline{W}$. It is thus a *weak* notion: the free normalisations $\Phi \mapsto c\Phi$, $\Psi \mapsto c^{-1}\Psi$ ($c \neq 0$) and $\Theta \mapsto -\Theta$ preserve it. These freedoms are pinned later.

Could it be vacuous? A structure whose fields are contradictory would make every theorem "for all D: …" empty. This one is inhabited: §42.4 constructs an explicit term `mkData c ε`.

Physical meaning

The candidate symmetry of the full orbifold theory, defined sector by sector: it is FLM's triality, which mixes the untwisted odd sector with a twisted sector. The physicist's expectation (to be proved) is that it is a symmetry of all OPEs, not only of those of V_0^+.

Definition 42.8 (The would-be triality $\sigma^\natural$). Given triality data D, let $\sigma^\natural = \sigma_D^\natural \in \mathrm{End}\, V^\natural$ be the operator acting by

sector	action of $\sigma^\natural$	lands in
V_0^+	σ	V_0^+
V_3^+	Φ	T_s^+
T_s^+	Ψ	V_3^+
T_{s+1}^+	Θ	T_{s+1}^+

extended linearly using the four-sector decomposition.

```
noncomputable def sig0 : VPlus →ₗ[ℂ] VPlus :=

    (D.Θ ∘ₗ (TPframe (D.s + 1)).projection (TPframe D.s) (TPframe_isCompl' D.s).symm)
```

(`VOA/Moonshine/M8hKeySigma.lean`, `VOA.Moonshine.M8hKey.sigNat`.)

From the mathematics to the Lean statement

Decoding. `blockOp a c d b` is the 2×2 block operator $\begin{pmatrix} a & c \\ d & b \end{pmatrix}$ on $V_\Lambda^+ \times T^+$ (Chapter 38). `sig0` projects onto V_0^+ along V_3^+, applies σ, and includes back; it is σ on V_0^+ and 0 on V_3^+. The top-right block is Ψ composed with the projection of T^+ onto T_s^+ along T_{s+1}^+; the bottom-left block is Φ after projecting V_Λ^+ onto V_3^+; the bottom-right is Θ after projecting onto T_{s+1}^+. The Lean theorems `sigNat_V0`, `sigNat_V3`, `sigNat_Ts`, `sigNat_Ts1` state exactly the four rows of the table. Same definition as the table.

Physical meaning

$\sigma^\natural$ is the would-be symmetry operator on the full Hilbert space $V^\natural$; in the Moonshine CFT it is the involution that, together with the obvious symmetries, generates the Monster (heuristic; not stated in Lean in this form). That $\sigma^\natural$ is an automorphism of $V^\natural$ is established in Lean in Chapter 47 (the definition `sigmaAut`, Theorem 47.11); the group that the library proves to act on $V^\natural$ is AxiomMath's Gmat, generated by the visible subgroup $2^{1+24}.\mathrm{Co}_1$ and a triality element τ_B (Chapter 49).

Theorem 42.9 ($\sigma^\natural$ is an involution compatible with V_0^+)**.** *For triality data D:*

(a) $(\sigma^\natural)^2 = 1$*;*

(b) for every $u \in V_0^+$ *and* $k \in \mathbb{Z}$*:* $\sigma^\natural\, Y^\natural(u)_k = Y^\natural(\sigma u)_k\, \sigma^\natural$*, where* $Y^\natural(u)$ *is the diagonal field* $\mathrm{diag}(Y(u,z), Y^T(u,z))$*; consequently* $\sigma^\natural Y^\natural(u)\sigma^\natural = Y^\natural(\sigma u)$*;*

(c) $\sigma^\natural$ *commutes with the translation operator* L_{-1} *of* $V^\natural$*, and fixes the vacuum.*

(VOA/Moonshine/M8hKeySigma.lean.)

From the mathematics to the Lean statement

Decoding. `YnatU u` is the field $Y^\natural((u,0),z)$, the diagonal block $\mathrm{diag}(Y(u,z),Y^T(u,z))$ (Chapter 38, `YnatU_apply`). `YnatU u k` is its coefficient of z^k. `Tnat` is the translation operator $L_{-1}\oplus L_{-1}^T$ of $V^\natural$; `vacNat` is $(\mathbb{1},0)$. The coercion `(u : VPlus)` views $u\in V_0^+$ as an element of V_Λ^+.
Hypotheses. Only the triality data D (a section variable). The statements are exactly (a)–(c).

Physical meaning

The candidate symmetry is an involution, preserves the vacuum and the stress tensor, and is a symmetry of the subalgebra V_0^+. What remains is to show it respects the OPEs involving the other three sectors.

Proof on paper. Check each identity on each of the four sectors. (a) On V_0^+, $\sigma^2=1$ (Chapter 39); on V_3^+, $\sigma^\natural$ goes to T_s^+ by Φ and back by Ψ, and $\Psi\Phi=\mathrm{id}$; on T_s^+, $\Phi\Psi=\mathrm{id}$; on T_{s+1}^+, $\Theta^2=\mathrm{id}$. (b) The modes of $u\in V_0^+$ preserve each of the four sectors. On V_0^+ the identity is $\sigma(u_{(n)}a)=(\sigma u)_{(n)}\sigma a$, i.e. $\sigma\in\mathrm{Aut}\,V_0^+$; on the other three it is the twisted-intertwiner property of Φ,Ψ,Θ. The conjugation form follows from (a). (c) Take $u=\omega$: $\sigma\omega=\omega$, and L_{-1} is the coefficient of $Y^\natural(\omega)$ that gives $\omega_{(0)}$. The vacuum lies in V_0^+ and $\sigma\mathbb{1}=\mathbb{1}$. □

What the machine verified

Unconditional given D; standard axioms only.

42.2.5 Uniqueness using V_0^+-locality only

The heart of the conjugation argument is a uniqueness lemma. The library already had a "Goddard uniqueness" theorem from Chapter 38, which we now quote because it is the wrong tool here, and it is instructive to see why.

```
theorem YnatT_eq_of_creates (hspan : ModeSpan g) (x : TP) (Ψ : FormalDist (End ℂ Vnat))
    (hcov : DCovariant Tnat Ψ) (h0 : Ψ 0 vacNat = ((0 : SkewVP), x))
    (hneg : ∀ q : ℤ, q < 0 → Ψ q vacNat = 0) (hU : ∀ v : SkewVP, Local Ψ (YnatU v))
    (hT : ∀ j, Local Ψ (YnatT leechWbar (g j))) : YnatT leechWbar x = Ψ
```

(VOA/Moonshine/M8h0Gap.lean.) It says: a translation-covariant field Ψ that creates $(0,x)$ from the vacuum and is local with *every* untwisted field $Y^\natural(v)$, $v\in V_\Lambda^+$, and with the twisted generators, is the block field $Y^\natural((0,x))$.

Trap / dead end: The circularity of `YnatT_eq_of_creates` in this context

We want to identify $L_v=\sigma^\natural Y^\natural(v)\sigma^\natural$, for $v\in V_3^+$, with $Y^\natural(\sigma^\natural v)$. To apply `YnatT_eq_of_creates` with $\Psi=L_v$ we would need L_v to be local with $Y^\natural(b)$ for $b\in V_3^+$. Conjugating by $\sigma^\natural$, this is the statement that $Y^\natural(v)$ is local with $\sigma^\natural Y^\natural(b)\sigma^\natural = L_b$ — which is (part of) the very identity $L_b=Y^\natural(\sigma^\natural b)$ to be proved, now for b. Using the theorem would be circular. The same circularity reappears if one tries to use V_3^+-locality of the difference field (recorded in

`Notes/SigmaKey.md` §7). The remedy is a uniqueness lemma that asks for locality with V_0^+-fields only, because $\sigma^\natural$ transports those for free (Theorem 42.9(b)).

Theorem 42.10 (Circularity-free uniqueness). *Let F be a formal distribution with coefficients in* $\mathrm{End}\, V^\natural$ *that is local with $Y^\natural(u)$ for every $u \in V_0^+$. Fix $\beta \in \Lambda \setminus \Lambda_0$ and nonzero $t_0 \in T_0$, $t_1 \in T_1$. If every coefficient of F kills the four vectors*

$$\mathbb{1}, \qquad (x_\beta, 0), \qquad (0, x_0(t_0)), \qquad (0, x_0(t_1)),$$

then $F = 0$.

```
theorem eq_zero_of_V0local (F : FormalDist (End ℂ Vnat))
    (hloc : ∀ u : V0Sub.carrier, Local F (YnatU (u : VPlus)))
    {β : leech.carrier} (hβ : β ∉ lambda0) (t : ZMod 2 → TLeechT)
    (ht : ∀ s, t s ∈ leechFrameT s) (ht0 : ∀ s, t s ≠ 0)
    (hvac : ∀ p, F p vacNat = 0) (h3 : ∀ p, F p (frameX0P β, 0) = 0)
    (hT : ∀ s p, F p (0, x0T (t s)) = 0) : F = 0
```

(`VOA/Moonshine/M8hKeySigma.lean`, `VOA.Moonshine.M8hKey.eq_zero_of_V0local`.)

From the mathematics to the Lean statement

Decoding. `leech.carrier` is the Leech lattice Λ, `lambda0` its frame sublattice Λ_0 (Chapter 39); `leechFrameT s` is the frame eigenspace $T_s \subseteq T$; the two vectors t_0, t_1 are packaged as a function `t : ZMod 2 → TLeechT`. `F p v = 0` for all p says every coefficient of F kills v.
Hypotheses. (i) V_0^+-locality of F — only V_0^+, which is the point; (ii) $\beta \notin \Lambda_0$, so that x_β lies in V_3^+ and is V_0^+-cyclic there (Chapter 39, `cyc_V3`); (iii) $t_s \in T_s$ nonzero, so that $x_0(t_s)$ is V_0^+-cyclic in T_s^+ (`cyc_T`); (iv) the four annihilation hypotheses. No translation covariance is needed.
Same as textbook. This is the familiar "a field local with a generating set and annihilating the cyclic vectors is zero", in its four-sector form.

Physical meaning

A field that is local with a chiral algebra and annihilates the lowest state of each superselection sector vanishes: the Reeh–Schlieder-type principle that states generated by local operators from a cyclic vector exhaust the sector.

Proof on paper. Let $K = \bigcap_p \ker F_p$. Locality plus annihilation give the key fact: if F is local with $Y^\natural(u)$ and all F_p kill y, then all F_p kill every $u_{(q)}y$. (Write $(z_1 - z_2)^N[F(z_1), Y(u, z_2)] = 0$ and apply to y; since $F(z_1)y = 0$ one gets $(z_1 - z_2)^N F(z_1)Y(u, z_2)y = 0$; the series $Y(u, z_2)y$ has only finitely many negative powers of z_2, so the factor $(z_1 - z_2)^N$ can be cancelled, giving $F(z_1)Y(u, z_2)y = 0$.) Thus K is V_0^+-stable. It contains $\mathbb{1}$, hence $u_{(-1)}\mathbb{1} = u$ for all $u \in V_0^+$; it contains the V_0^+-cyclic vectors of the other three sectors, hence the three sectors. So $K = V^\natural$. □

What the machine verified

Unconditional; standard axioms only. Uses no form of (4.23).

42.2.6 The identification of L_v with R_v, and the key identities

Theorem 42.11 (Agreement on cyclic vectors suffices). *Let D be triality data, $v \in V_3^+$, and β, t as in Theorem 42.10. If $L_v = \sigma^\natural Y^\natural(v)\sigma^\natural$ and $R_v = Y^\natural((0, \Phi v))$ agree on $(x_\beta, 0)$ and on $(0, x_0(t_s))$ for both s, then $L_v = R_v$.*

```
theorem conjF_V3_eq {v : VPlus} (hv : v ∈ frameSector 1) {β : leech.carrier} (hβ : β ∉
 ↪ lambda0)
    (t : ZMod 2 → TLeechT) (ht : ∀ s, t s ∈ leechFrameT s) (ht0 : ∀ s, t s ≠ 0)
    (h3 : ∀ p, conjF (sigNat D) (YnatU v) p (frameX0P β, 0) = YnatT leechWbar (D.Φ v) p
     ↪ (frameX0P β, 0))
    (hT : ∀ s p, conjF (sigNat D) (YnatU v) p (0, x0T (t s)) = YnatT leechWbar (D.Φ v) p
     ↪ (0, x0T (t s))) :
    conjF (sigNat D) (YnatU v) = YnatT leechWbar (D.Φ v)
```

(`VOA/Moonshine/M8hKey.lean`.)

From the mathematics to the Lean statement

Decoding. `YnatT leechWbar x` is the purely twisted block field $Y^{\natural}((0,x),z) = \begin{pmatrix} 0 & \overline{W}(x,z) \\ W(x,z) & 0 \end{pmatrix}$ built with the genuine adjoint `leechWbar` (Chapter 37). `YnatU v` for $v \in V_3^+$ is the untwisted block field of $(v,0)$. Note that $R_v = Y^{\natural}(\sigma^{\natural}(v,0))$ since $\sigma^{\natural}(v,0) = (0,\Phi v)$.
Hypotheses. The two agreement hypotheses are for all coefficients p; there is no hypothesis on the vacuum — that agreement is *proved*.

Physical meaning

Two fields with the same OPEs with the even chiral algebra V_0^+ and the same action on the lowest state of every sector are the same field. This is how a physicist identifies the transform of an operator under a symmetry: compare its Ward identities and its matrix elements on primaries.

Proof on paper. Apply Theorem 42.10 to $F = L_v - R_v$. Locality with V_0^+: R_v is local with $Y^{\natural}(u)$ by the module/intertwiner relations (4.20)–(4.21) proved in Chapter 38; L_v is, because $Y^{\natural}(v)$ is local with $Y^{\natural}(\sigma u)$ (Chapter 38) and conjugation preserves locality and turns $Y^{\natural}(\sigma u)$ into $Y^{\natural}(u)$ (Theorem 42.9). The vacuum: both fields are L_{-1}-covariant (conjugation preserves covariance since $\sigma^{\natural}L_{-1} = L_{-1}\sigma^{\natural}$), both have vanishing coefficients of z^q, $q < 0$, on $\mathbb{1}$, and both create $(0,\Phi v)$ at z^0 (L_v because $\sigma^{\natural}$ fixes $\mathbb{1}$ and maps $(v,0)$ to $(0,\Phi v)$). A covariant field is determined on $\mathbb{1}$ by these data: $F(z)\mathbb{1} = e^{zL_{-1}}F_0\mathbb{1}$. So F kills $\mathbb{1}$, and the remaining three vectors are the hypotheses. □

Definition 42.12 (The FLM three-point identities on cyclic vectors). Let D be triality data, $\beta \in \Lambda\backslash\Lambda_0$, and nonzero $t_s \in T_s$. Write $x = x_0(t_s) \in T_s^+$ (with $s = D.s$), $v = \Psi x \in V_3^+$, $x_3 = x_\beta$, $x' = x_0(t_{s+1})$. `SigmaKey D β t` is the conjunction of

$$\begin{aligned}
&\text{(key_V3)} && \Theta\big(Y^T(v,z)\,\Phi x_3\big) = W(x,z)\,x_3 && \text{in } T_{s+1}^+,\\
&\text{(key_Ts)} && \sigma\big(Y(v,z)\,v\big) = \overline{W}(x,z)\,x && \text{in } V_0^+,\\
&\text{(key_Ts1)} && \Psi\big(Y^T(v,z)\,\Theta x'\big) = \overline{W}(x,z)\,x' && \text{in } V_3^+,
\end{aligned}$$

coefficientwise, together with the side conditions on β and t.

```
structure SigmaKey (β : leech.carrier) (t : ZMod 2 → TLeechT) : Prop where
  hβ : β ∉ lambda0
  ht : ∀ s, t s ∈ leechFrameT s
  ht0 : ∀ s, t s ≠ 0
  key_V3 : ∀ p, D.Θ (plusModule.YM (D.Ψ (x0T (t D.s))) p (D.Φ (frameX0P β)))
    = leechWsk (x0T (t D.s)) p (frameX0P β)
  key_Ts : ∀ p, sig0 (leechVOAPlus.Y (D.Ψ (x0T (t D.s))) p (D.Ψ (x0T (t D.s))))
    = leechWbar (x0T (t D.s)) p (x0T (t D.s))
  key_Ts1 : ∀ p, D.Ψ (plusModule.YM (D.Ψ (x0T (t D.s))) p (D.Θ (x0T (t (D.s + 1)))))
    = leechWbar (x0T (t D.s)) p (x0T (t (D.s + 1)))
```

(`VOA/Moonshine/M8hKey.lean`, `VOA.Moonshine.M8hKey.SigmaKey`.)

From the mathematics to the Lean statement

Decoding. `leechWsk x p φ` is the coefficient of z^p in $W(x,z)\varphi$; `leechWbar x p y` that of $\overline{W}(x,z)y$. `sig0` is σ on V_0^+ (and 0 on V_3^+); the product $Y(v,z)v$ of two elements of V_3^+ lies in V_0^+ by the fusion rules of the frame grading, so `sig0` acts as σ there.

Why these three, and why they are the agreements. The Lean theorems

```
theorem key_V3_iff {v a : VPlus} (hv : v ∈ frameSector 1) (ha : a ∈ frameSector 1) (p
 ↪  : ℤ) :
    conjF (sigNat D) (YnatU v) p (a, 0) = YnatT leechWbar (D.Φ v) p (a, 0)
      ↔ D.Θ (plusModule.YM v p (D.Φ a)) = leechWsk (D.Φ v) p a
theorem key_Ts_iff {v : VPlus} (hv : v ∈ frameSector 1) {y : TP} (hy : y ∈ TPframe
 ↪  D.s) (p : ℤ) :
    conjF (sigNat D) (YnatU v) p (0, y) = YnatT leechWbar (D.Φ v) p (0, y)
      ↔ sig0 (leechVOAPlus.Y v p (D.Ψ y)) = leechWbar (D.Φ v) p y
theorem key_Ts1_iff {v : VPlus} (hv : v ∈ frameSector 1) {y : TP} (hy : y ∈ TPframe
 ↪  (D.s + 1)) (p : ℤ) :
    conjF (sigNat D) (YnatU v) p (0, y) = YnatT leechWbar (D.Φ v) p (0, y)
      ↔ D.Ψ (plusModule.YM v p (D.Θ y)) = leechWbar (D.Φ v) p y
```

show that, at $v = \Psi x$ (so $\Phi v = x$) and on the cyclic vectors, the three clauses are *exactly* the three agreement hypotheses of Theorem 42.11. To see it on paper: $\sigma^{\natural}$ sends $(a,0)$, $a \in V_3^+$, to $(0,\Phi a)$; $Y^{\natural}(v)$ maps it to $(0, Y^T(v)\Phi a)$ with $Y^T(v)\Phi a \in T^+_{s+1}$; $\sigma^{\natural}$ applies Θ. The block field R_v sends $(a,0)$ to $(0, W(\Phi v)a)$. The other two rows are similar.

Hypothesis status. `SigmaKey` is a *genuine open input* at this stage: each clause compares two different intertwining operators and does not follow from the intertwining property of Φ, Ψ, Θ alone. It also pins the normalisations that `SigmaData` leaves free.

Physical meaning

Three specific three-point functions (OPE coefficients) must agree in the original and the triality-rotated pictures. If $\sigma^{\natural}$ is a symmetry they do; these are FLM's "key identities".

Theorem 42.13 ((4.23) from the key identities). *If* `SigmaKey D β t` *holds, then (i)* $\sigma^{\natural}Y^{\natural}(\Psi x)\sigma^{\natural} = Y^{\natural}((0,x))$ *for* $x = x_0(t_s)$*; (ii) (4.23) holds for* all *pairs* $t_1, t_2 \in T^+$*; (iii)* $V^{\natural}$ *carries all the structure listed in the final theorem.*

```
theorem SigmaKey.conj_eq {β : leech.carrier} {t : ZMod 2 → TLeechT} (h : SigmaKey D β t) :

```

(`VOA/Moonshine/M8hKey.lean`.)

From the mathematics to the Lean statement

Decoding. `TPBlockLocal leechWbar t₁ t₂` is (4.23): File `VOA/Moonshine/TTBlock.lean`.

```
def TPBlockLocal (Wbar : TP → FormalDist (TP →ₗ[ℂ] SkewVP)) (t₁ t₂ : TP) : Prop :=
  ∃ N : ℕ, mulBySubPow N
    ((fun m n => leechWsk t₁ m ∘ₗ Wbar t₂ n - leechWsk t₂ n ∘ₗ Wbar t₁ m) :
      FormalDist₂ (End ℂ TP)) = 0
```

i.e. $(z_1-z_2)^N\big(W(t_1,z_1)\overline{W}(t_2,z_2)-W(t_2,z_2)\overline{W}(t_1,z_1)\big)=0$, with `mulBySubPow N` multiplication by $(z_1-z_2)^N$ on two-variable formal series. The conclusion of `moonshine_of_sigma` is literally the conclusion of the final theorem, decoded in §42.8.

Hypotheses. Only D (implicit section variable) and h. Since `SigmaKey` contains the side conditions on β and t, nothing else is assumed.

Physical meaning

If the candidate symmetry maps one untwisted field to the corresponding twist field, mutual locality of twist fields (single-valuedness of their OPEs, the delicate point of any orbifold) is inherited from the untwisted sector. Once one twist field is local with itself, Dong's lemma propagates locality to all.

Proof on paper. (i) By Theorem 42.11 with $v=\Psi x$, whose hypotheses are the clauses of `SigmaKey` (by the three `iff` theorems), and $\Phi\Psi x=x$. (ii) The untwisted field $Y^\natural(\Psi x)$ is local with itself (Chapter 38); conjugating, by (i), $Y^\natural((0,x))$ is local with itself. Self-locality of a twisted block field is the conjunction of (4.22) and (4.23) for the pair (x,x) (`YnatT_local_iff`), so (4.23) holds for (x,x). By Theorem 42.3, x mode-spans T^+, and the propagation theorem of Chapter 38 (`TPBlockLocal_all_of_gen`: (4.23) on a mode-spanning family implies (4.23) for all pairs; its proof is Dong's lemma plus the Goddard uniqueness theorem, now used legitimately, because the twisted generator's locality is supplied) gives (4.23) for all pairs. (iii) Feed (ii) into `moonshine_of_frameLocality` (Chapter 38). □

What the machine verified

Conditional on `SigmaKey D β t` (and on the data D). `#print axioms VOA.Moonshine.M8hKey.moonshine_of_sigma`, re-run for this chapter with `lake env lean -DmaxSynthPendingDepth=3`: `[propext, Classical.choice, Quot.sound]`. No step assumes (4.23) for any pair.

42.3 Reducing the key identities: isometries and one self-coupling

The three clauses of `SigmaKey` are not independent. The difference field $F_v=L_v-R_v$ (for $v\in V_3^+$) has four off-diagonal blocks between the four sectors, and the invariant bilinear forms pair them up:

block of F_v	content	how it is handled
$A\to C$	creation	automatic (vacuum + V_0^+-locality)
$C\to A$	`key_Ts`	adjoint of $A\to C$, given that Φ is an isometry
$B\to D'$	`key_V3`	the genuine content: `KeySkew`
$D'\to B$	`key_Ts1`	adjoint of $B\to D'$, given that Φ,Θ are isometries

This section makes this table precise.

42.3.1 Automorphisms preserve invariant forms

Recall from Definition 5.48 that an *invariant bilinear form* on a VOA W is a bilinear form $(\cdot|\cdot)$ with $(L_n a|b) = (a|L_{-n}b)$, and that it is *fully invariant* if for every homogeneous u of weight k

$$(u_{(n)}a \,|\, b) = (-1)^k \sum_{j\geq 0} \frac{1}{j!} \left(a \,\middle|\, (L_1^j u)_{(2k-n-2-j)} b\right) \tag{42.3}$$

(FHL's invariance, the adjoint of $Y(u,z)$ being $Y(e^{zL_1}(-z^{-2})^{L_0}u, z^{-1})$). It is *normalised* if $(\mathbb{1}|\mathbb{1}) = 1$. For a VOA of CFT type with $L_1 V_1 = 0$ there is exactly one normalised fully invariant form (`invariantForm_unique_FHL`, Theorem 5.56).

Theorem 42.14 (Automorphisms are isometries). *Let W be a VOA with $\mathbb{1} \neq 0$ and $L_1 W_1 = 0$, B a fully invariant normalised form, and $\alpha \in \operatorname{Aut} W$. Then $B(\alpha a, \alpha b) = B(a,b)$ for all a, b.*

```
theorem aut_isometry {W : VertexOperatorAlgebra 𝒱} (hne : W.vacuum ≠ 0)
    (hqp : ∀ v, v ∈ W.grading 1 → W.L 1 v = 0) {B : InvariantForm W}
    (hB : B.IsFullyInvariant) (hn : B.Normalized) (α : Aut W) (a b : 𝒱) :
    B.form (α a) (α b) = B.form a b
```

(`VOA/Moonshine/SigmaKeyForm.lean`, `VOA.Moonshine.SigmaKey.aut_isometry`.)

From the mathematics to the Lean statement

Decoding. `InvariantForm W` bundles a bilinear form `B.form` with the Virasoro adjointness; `IsFullyInvariant` is (42.3); `Normalized` is $(\mathbb{1}|\mathbb{1}) = 1$. `Aut W` is the group of VOA automorphisms (linear bijections fixing $\mathbb{1}$, ω and intertwining all modes). Hypotheses `hne`, `hqp` are exactly those of the uniqueness theorem; `hqp` is "L_1 kills W_1". Note that CFT type is part of the library's definition of a VOA (Definition 4.4: $W_0 = \mathbb{C}\mathbb{1}$, $W_n = 0$ for $n < 0$). Same statement as the textbook one.

Physical meaning

A symmetry preserves the two-point function: $\langle ga|gb\rangle = \langle a|b\rangle$. Here this follows from uniqueness of the vacuum-normalised two-point function in a CFT with no currents annihilated by L_1.

Proof on paper. The pull-back $(a,b) \mapsto B(\alpha a, \alpha b)$ is again fully invariant (since α commutes with every L_n and every mode) and normalised (since $\alpha\mathbb{1} = \mathbb{1}$); by uniqueness it equals B. □

Corollary 42.15. *(a) For the canonical form B_V on V_Λ^+: $B_V(V_0^+, V_3^+) = 0$. (b) σ is an isometry of B_V restricted to V_0^+.*

```
theorem leechBV_frame_orth {a b : VPlus} (ha : a ∈ frameSector 0) (hb : b ∈ frameSector 1)
  ↪ :
    leechBV a b = 0

theorem leechBV_sig (a b : V0Sub.carrier) :
    leechBV ((sig a : V0Sub.carrier) : VPlus) (sig b : V0Sub.carrier) = leechBV (a : VPlus)
     ↪ b
```

(`VOA/Moonshine/SigmaKeyForm.lean`.)

From the mathematics to the Lean statement

`leechBV` is the canonical (Li/FHL) normalised invariant form of V_Λ^+ (Chapter 37, `leechBVForm`). The frame sectors are the ±1 eigenspaces of the frame automorphism π (`plusFrameAut`), which acts by $+1$ on V_0^+ and -1 on V_3^+. (b) is stated for elements of V_0^+, coerced into V_Λ^+. Both exactly the intended statements.

Physical meaning

States in different eigenspaces of a $\mathbb{Z}/2$ symmetry have vanishing two-point functions (charge conservation); and the triality restricted to V_0^+ is unitary for its two-point function.

Proof on paper. (a) Apply Theorem 42.14 to π: $B_V(a,b) = B_V(\pi a, \pi b) = -B_V(a,b)$. (b) Apply it to the VOA V_0^+, whose restricted form is fully invariant and normalised, and to σ. ($(V_0^+)_1 = 0$, so L_1 kills it trivially.) □

What the machine verified

Unconditional; standard axioms only.

42.3.2 The three named conditions

Definition 42.16 (Isometry conditions and the self-coupling identity)**.** For triality data D and t as before, with $x = x_0(t_s)$:

- `PhiIso D`: $\langle \Phi a, \Phi b\rangle_T = B_V(a,b)$ for all $a, b \in V_3^+$;
- `ThetaIso D`: $\langle \Theta y, \Theta y'\rangle_T = \langle y, y'\rangle_T$ for all $y, y' \in T_{s+1}^+$;
- `KeySkew D t`: $\Theta\big(Y^T(\Psi x, z)x\big) = W(x,z)\Psi x$, coefficientwise;

here $\langle\cdot,\cdot\rangle_T$ is `TPForm`.

```
def PhiIso : Prop :=
  ∀ a ∈ frameSector 1, ∀ b ∈ frameSector 1, TPForm (D.Φ a) (D.Φ b) = leechBV a b

def ThetaIso : Prop :=
  ∀ y ∈ TPframe (D.s + 1), ∀ y' ∈ TPframe (D.s + 1), TPForm (D.Θ y) (D.Θ y') = TPForm y y'

def KeySkew (t : ZMod 2 → TLeechT) : Prop :=
  ∀ p, D.Θ (plusModule.YM (D.Ψ (x0T (t D.s))) p (x0T (t D.s)))
    = leechWsk (x0T (t D.s)) p (D.Ψ (x0T (t D.s)))
```

(`VOA/Moonshine/SigmaKeyAdj.lean`.)

From the mathematics to the Lean statement

Decoding. `TPForm` is the symmetric nondegenerate invariant form on T^+ of Chapter 37. In `KeySkew`, $v = \Psi x$, the left side is $\Theta(Y^T(v,z)x)$ and the right side $W(x,z)v$; by the definition of W this is $e^{zL_{-1}}Y^T(v,-z)x$. So `KeySkew` says: the series $J(z) = Y^T(v,z)x$ is mapped by Θ to its "skew-symmetric partner" $e^{zL_{-1}}J(-z)$. It is a statement about one vector-valued series.
Status as hypotheses. These are *named Props*, i.e. statements to be proved; they are not assumed anywhere in the final theorem. Note `PhiIso` is not a normalisation that can always be arranged: it requires Φ to be a similitude in the first place.

Physical meaning

`PhiIso`, `ThetaIso`: the candidate symmetry preserves two-point functions between sectors. `KeySkew`: the OPE of one odd untwisted operator with one twist field is symmetric under exchange after applying the symmetry — a single crossing-type relation.

42.3.3 The creation block and the adjunction chains

Proposition 42.17 (Creation block). *For triality data D, $v \in V_3^+$, $a \in V_0^+$ and $m \in \mathbb{Z}$: $\Phi(v_{(m)}\sigma a) = W(\Phi v)_{(m)}a$.*

```
theorem phi_create {v : VPlus} (hv : v ∈ frameSector 1) (a : V0Sub.carrier) (m : ℤ) :
    D.Φ (leechVOAPlus.smul v m ((sig a : V0Sub.carrier) : VPlus))
      = mode (leechWsk (D.Φ v)) m (a : VPlus)
```

(`VOA/Moonshine/SigmaKeyAdj.lean`.)

From the mathematics to the Lean statement

`leechVOAPlus.smul v m w` is the m-th product $v_{(m)}w$ in V_Λ^+ (Definition 4.2: `smul` is the mode action, already in mode indexing). `mode (leechWsk x) m` is $W(x)_{(m)}$. Unconditional given D; this is *not* an assumption.

Physical meaning

The state-operator map intertwines the rotated and unrotated pictures on the even sector: creating a state with the rotated odd operator equals creating it with the twist field. This is automatic because both are fixed by their action on the vacuum.

Proof on paper. The difference field F_v is local with all V_0^+-fields and kills the vacuum (proof of Theorem 42.11); by the locality argument in the proof of Theorem 42.10 it kills $u_{(-1)}\mathbb{1} = u$ for every $u \in V_0^+$. Now compute both fields on $(a, 0)$: $\sigma^\natural(a,0) = (\sigma a, 0)$; the untwisted field of v maps it to $(v_{(m)}\sigma a, 0)$ with $v_{(m)}\sigma a \in V_3^+$ (frame grading: $B \cdot A \subseteq B$); the second $\sigma^\natural$ maps this to $(0, \Phi(v_{(m)}\sigma a))$. On the other side $R_v(a,0) = (0, W(\Phi v)_{(m)}a)$. Equality of the second components is the claim. □

Theorem 42.18 (`key\_Ts` and `key\_Ts1` by adjunction). *Let D be triality data, $x \in T_s^+$ of weight 2, $v = \Psi x$.*

(a) If `PhiIso D`, *then $\sigma(v_{(n)}\Psi y) = \overline{W}(x)_{(n)}y$ for all $y \in T_s^+$, $n \in \mathbb{Z}$.*

(b) If `PhiIso D`, `ThetaIso D`, *and the whole block $B \to D'$ vanishes, i.e. $\Theta(v_{(m)}\Phi b) = W(x)_{(m)}b$ for all $b \in V_3^+$, m, then $\Psi(v_{(n)}\Theta y) = \overline{W}(x)_{(n)}y$ for all $y \in T_{s+1}^+$.*

```
theorem keyTs_gen (hΦ : PhiIso D) {x : TP} (hx : x ∈ TPframe D.s)
    (hx2 : x ∈ plusModule.weight ((2 : ℤ) : ℂ)) {y : TP} (hy : y ∈ TPframe D.s) (n : ℤ) :
    sig0 (leechVOAPlus.smul (D.Ψ x) n (D.Ψ y)) = leechWbarMode n x y

theorem keyTs1_gen (hΦ : PhiIso D) (hΘ : ThetaIso D) {x : TP} (hx : x ∈ TPframe D.s)
    (hx2 : x ∈ plusModule.weight ((2 : ℤ) : ℂ))
    (hV3 : ∀ b ∈ frameSector 1, ∀ m : ℤ,
      D.Θ (mode (plusModule.YM (D.Ψ x)) m (D.Φ b)) = mode (leechWsk x) m b)
    {y : TP} (hy : y ∈ TPframe (D.s + 1)) (n : ℤ) :
    D.Ψ (mode (plusModule.YM (D.Ψ x)) n (D.Θ y)) = leechWbarMode n x y
```

(`VOA/Moonshine/SigmaKeyAdj.lean`.)

From the mathematics to the Lean statement

Decoding. `plusModule.weight w` is the L_0-eigenspace of eigenvalue w in T^+ (weights of an ordinary module are complex numbers in the library, hence the cast `((2 : ℤ) : ℂ)`). `leechWbarMode n x` is $\overline{W}(x)_{(n)}$. The hypothesis `hV3` in (b) is exactly "the $B \to D'$ block vanishes for all b". Weight 2 for x is needed: it makes x and v quasi-primary, which collapses the FHL sum (42.3) to one term.

Physical meaning

Three-point functions $\langle a|\phi_1(z)|b\rangle$ can be read with any leg as the outgoing state; if the symmetry preserves two-point functions, OPE coefficients in one channel determine those in the adjoint channel.

Proof on paper. (a) Both sides lie in V_0^+, and B_V is nondegenerate on V_Λ^+ with $V_0^+ \perp V_3^+$; so it suffices to pair with $a \in V_0^+$:

$$\begin{aligned} B_V\big(\overline{W}(x)_{(n)}y,\, a\big) &= \langle y,\, W(x)_{(2-n)}a\rangle_T && \text{(definition of } \overline{W},\, L_1x = 0) \\ &= \langle y,\, \Phi(v_{(2-n)}\sigma a)\rangle_T && \text{(creation block)} \\ &= B_V\big(\Psi y,\, v_{(2-n)}\sigma a\big) && (\texttt{PhiIso},\, y = \Phi\Psi y) \\ &= B_V\big(v_{(n)}\Psi y,\, \sigma a\big) && \text{(invariance, } v \text{ quasi-primary of weight 2)} \\ &= B_V\big(\sigma(v_{(n)}\Psi y),\, a\big) && (\sigma \text{ isometry and involution of } V_0^+). \end{aligned}$$

(b) Similarly, pairing with $b \in V_3^+$ and using `ThetaIso`, invariance of `TPForm` and `PhiIso`: $B_V(\overline{W}(x)_{(n)}y, b) = \langle y, \Theta(v_{(2-n)}\Phi b)\rangle_T = \langle \Theta y, v_{(2-n)}\Phi b\rangle_T = \langle v_{(n)}\Theta y, \Phi b\rangle_T = B_V(\Psi(v_{(n)}\Theta y), b)$; pairing with V_0^+ gives zero on both sides by sector orthogonality. □

Theorem 42.19 (`SigmaKey` from the isometries and `KeySkew`). *If* `PhiIso D`, `ThetaIso D` *and* `KeySkew D t` *hold (with $\beta \notin \Lambda_0$, $t_s \in T_s$ nonzero), then* `SigmaKey D β t`*; consequently all targets of the final theorem hold.*

```
theorem sigmaKey_of_skew {β : leech.carrier} (hβ : β ∉ lambda0) {t : ZMod 2 → TLeechT}
    (ht : ∀ s, t s ∈ leechFrameT s) (ht0 : ∀ s, t s ≠ 0)
    (hΦ : PhiIso D) (hΘ : ThetaIso D) (hk : KeySkew D t) : SigmaKey D β t
```

(`VOA/Moonshine/SigmaKeyAdj.lean`; the corollary is `moonshine_of_skew`.)

From the mathematics to the Lean statement

All hypotheses are visible: the side conditions on β, t and the three named Props. The conclusion is the structure of Definition 42.12.

Physical meaning

All three key identities follow from unitarity of the symmetry on two sectors and one self-coupling OPE; this is the reduction a physicist would make by using conjugation and crossing.

Proof on paper. The key extra observation is that $v = \Psi x$ is itself a V_0^+-cyclic vector of V_3^+: Ψ is a bijection $T_s^+ \to V_3^+$ intertwining up to σ, and x is cyclic in T_s^+. `KeySkew` says precisely that F_v kills $(v, 0)$ (by `key_V3_iff` with $a = v$, $\Phi v = x$). By the locality argument, F_v then kills all of V_3^+: the block $B \to D'$ vanishes identically. This gives `key_V3` (at x_β), and through Theorem 42.18 also `key_Ts` and `key_Ts1`. □

42.3.4 The isometries are top-level statements

Theorem 42.20 (Top-level reduction of the isometry conditions). *Let $z_0 \in V_3^+$ be V_0^+-cyclic and homogeneous of weight w. If $\langle \Phi z_0, \Phi b\rangle_T = B_V(z_0, b)$ for all $b \in (V_3^+)_w$, then* `PhiIso D`*. Likewise, if $x' \in T^+_{s+1}$ is cyclic of weight w and $\langle \Theta x', \Theta y\rangle_T = \langle x', y\rangle_T$ for all $y \in (T^+_{s+1})_w$, then* `ThetaIso D`*.*

      TPForm (D.Θ x') (D.Θ y) = TPForm x' y) : ThetaIso D
```

(`VOA/Moonshine/SigmaKeyTop.lean`.)

From the mathematics to the Lean statement

Decoding. `hcyc` says z_0 is V_0^+-cyclic: the modes of all $u \in V_0^+$ applied to z_0 span V_3^+. `leechVOAPlus.grading w` is the weight-w subspace. `htop` is one "row" of the Gram matrices, on a single finite-dimensional weight space. Same as the mathematical statement.

Physical meaning

A two-point function of a sector generated by its lowest state is determined by the two-point function of that lowest state with other lowest states (Ward identities move all modes to one side).

Proof on paper. The defect $F(a,b) = \langle \Phi a, \Phi b\rangle_T - B_V(a,b)$ is a symmetric bilinear form on V_3^+ satisfying the same FHL invariance (42.3) for $u \in V_0^+$ (both forms do; for the first one transports u through Φ as σu, and σ commutes with L_1). Invariance moves every mode from the left slot to the right, so by cyclicity $F = 0$ as soon as $F(z_0, \cdot) = 0$; by symmetry and cyclicity again it suffices that $F(z_0, c) = 0$ for homogeneous c; both forms vanish between different weights; so only c of weight w matter. □

Definition 42.21 (The finite isometry residuals). `PhiTop D t`: $\langle x, \Phi b\rangle_T = B_V(\Psi x, b)$ for all $b \in (V_3^+)_2$, with $x = x_0(t_s)$. `ThetaTop D t`: $\langle \Theta x', \Theta y\rangle_T = \langle x', y\rangle_T$ for all $y \in (T^+_{s+1})_2$, with $x' = x_0(t_{s+1})$.

```

Physical meaning

Normalisations of the lowest states: the norms of the 49152 lowest odd untwisted states and twisted states must match under the symmetry.

Theorem 42.22 ($V^\natural$ from two finite isometries and a key). *Let D be a positive definite even lattice of rank 24 with no roots, and let $\sigma, \tau \in \mathrm{O}(D)$ be finite isometries. Suppose that $\sigma\tau$ has no eigenvalue 1 on D and no eigenvalue 1 on D^*/D. Suppose that σ and τ have the same characteristic polynomial on D, and the same characteristic polynomial on D^*/D. Suppose that σ and τ have the same number of fixed points on D^*/D. Suppose that σ and τ have the same trace on D. Suppose that σ and τ have the same trace on D^*/D. Suppose that σ and τ have the same trace on $D \otimes \mathbb{Q}$. Suppose that σ and τ have the same trace on $D^*/D \otimes \mathbb{Q}$. Suppose that σ and τ have the same trace on $D \otimes \mathbb{Q}_2$. Suppose that σ and τ have the same trace on $D^*/D \otimes \mathbb{Q}_2$. Evidence: Numerical de-risking of the normalisation, and its limits

Before any of this was formalised, the project tested the conditions numerically in an independent model of the weight-2 spaces built from the Niemeier lattice $N(A_1^{24})$ (route notes `Notes/SigmaKey.md` §6, scripts in `scripts/moonshine/numerics/sigmakey/`). Findings, *evidence only*: (N1) $\Theta_J^2 \propto 1$, and after normalisation $\mu = 1.000000000000$ ($|\mu - 1| < 4 \cdot 10^{-12}$); independently $\operatorname{tr}\Theta_J = -112 \neq 0$ excludes $\mu = -1$. (N2) Φ is a similitude: the ratio $\langle \Phi v, \Phi v\rangle / B_V(v,v)$ is constant to spread $6.7 \cdot 10^{-12}$, off-diagonal entries $< 3.8 \cdot 10^{-12}$. (N3) The top level of `key_V3`, $\Theta\, o(v)\Phi b = \varepsilon\, o(b)\Phi v$, holds on 170 pairs with one global ε. *Caveat*: with Θ replaced by the identity the vectors were also proportional (they all lay in one eigenspace), so this test fixes the sign but discriminates weakly. The model's sector identifications and cocycle were not checked against the library's. In the Lean development, $\mu = +1$ was eventually *proved* (§42.4), and the sign was proved to be $\varepsilon = +1$ for the library's Θ_0 (§42.7).

Trap / dead end: Dead ends recorded at this stage

(1) "An intertwiner is determined by its top component" is false without the full $A(M)$-bimodule theory: the top-level part of `KeySkew` is necessary but *not* sufficient; the iterate formula moves descendants of the input into non-top outputs. Do not formalise "top-level `key_V3` ⇒ `key_V3`". (2) Using V_3^+-locality of L_v is circular (see the warning before Theorem 42.10). (3) (4.22) gives no new information: it constrains only products of already matched blocks or the $B \to D' \to B$ composite, which is symmetric under the unknown scalar. (4) Skew-symmetry alone does not decide `KeySkew`: it says that $J(v,z)b = \Theta Y^T(v,z)\Phi b$ is a fixed point of the involution $J \mapsto \Theta e^{zL_{-1}} J(\cdot, -z)$ (swapping v, b); without a one-dimensional space of intertwiners, J could have components in both eigenspaces.

42.4 The assembled triality data

We now produce a concrete term of type `SigmaData` and prove `PhiTop` and `ThetaTop` for it. The raw material is Chapter 41: a seed vector, explicit top-level maps, and their unique twisted extensions.

42.4.1 The seed and the explicit top maps

Recall (Chapter 41) the operators on T: for $j \neq k$ there are lattice vectors $\gamma_{jk}^{\pm} \in \Lambda_0$ of norm 4 (Lean `gP j k`, `gM j k`), with the corresponding normalised operators $A_{jk}^{\pm} = \kappa_{jk}^{\pm} e_{\gamma_{jk}^{\pm}}$ on T (`AP`, `AM`), and $Z_{0k} = 2A_{0k}^{-}$ (`ZZ 0 k`). These Z_{0k}, $k \neq 0$, commute and square to 1.

Definition 42.23 (Seed). A vector $t \in T$ is a *seed* if $A_{jk}^{+} t = -\frac{1}{2} t$ and $A_{jk}^{-} t = \frac{1}{2} t$ for all $j \neq k$.

```
def IsSeed (t : TLeechT) : Prop :=
  ∀ j k : Fin 24, j ≠ k → AP j k t = -(1 / 2 : ℂ) • t ∧ AM j k t = (1 / 2 : ℂ) • t
```

Physical meaning

A seed is a twisted ground state with prescribed eigenvalues under certain lattice-shift symmetries of the ground-state space: a "highest-weight" reference state for the finite Heisenberg group 2^{1+24} acting on the 2^{12} ground states.

(`VOA/Moonshine/SigmaTop2Eigen.lean`.) Chapter 41 proved that a nonzero seed exists, and lies in a frame sector (`seed_in_frame seedExists`). We fix one: $t_0 \in T_{s_0}$ (Lean `t0`, `s0`, chosen by `Classical.choice`; the theorems below hold for every such choice).

The two explicit weight-2 maps of Chapter 41 are:

- $\varphi_\star : (V_3^+)_2 \to (T^+)_2$, $\varphi_\star(x_n) = c_\star(n)\, h_{w_{j(n)}}(-\frac{1}{2}) \otimes e_n t_0$ on the basis $x_n = e^n + e^{-n}$, $n \in S_1$ (a fixed half of the norm-4 vectors of $\Lambda \setminus \Lambda_0$), where $j(n)$ is the coordinate of the entry ± 3 of n, w_j the j-th frame vector, and $c_\star(n) = i^{n_0} \cdot n_{j(n)}/3$, a fourth root of unity times ± 1; here $n_0, \dots, n_{23}$ are the integer coordinates of n in the scaling where $\langle \mu, \nu \rangle = \frac{1}{8}\sum_k \mu_k \nu_k$ (Lean `lv`), in which a norm-4 vector of $\Lambda \setminus \Lambda_0$ has shape $(\mp 3, (\pm 1)^{23})$ (Lean `phiV = phiV3 (tauStar t0), cStar`);
- $\varphi_B : (T_{s_0}^+)_2 \to (T_{s_0}^+)_2$, $\varphi_B(h_{w_m}(-\frac{1}{2}) \otimes t) = h_{w_m}(-\frac{1}{2}) \otimes \psi_m t$, where $\psi_0 = B = \prod_{k \neq 0}(a + bZ_{0k})$ (restricted to T_{s_0}), $\psi_m = Z_{0m}B$, with $a = \frac{1}{2}(1+\omega)$, $b = \frac{1}{2}(1-\omega)$, $\omega = e^{i\pi/4}$ (Lean `phiB = phiTT (psiOf (Bop s0))`).

On a joint eigenvector z of the Z_{0k} with eigenvalues $u_k = \pm 1$, B acts by $\omega^{|N|}$ with $N = \{k : u_k = -1\}$, because $a + b = 1$ and $a - b = \omega$.

Definition 42.24 (The unnormalised intertwiners). $\Phi_0 : V_3^+ \to T_{s_0+1}^+$ and $\Theta_0 : T_{s_0}^+ \to T_{s_0}^+$ are the unique σ-twisted intertwiners extending $\varphi_\star$ and φ_B (Chapter 41, `sigmaV3T_exists_of_top`, `sigmaTT_exists_of_top`).

theorem Φ0_isSigma : IsSigmaV3T Φ0
theorem Φ0_top : ∀ x ∈ OmegaV3, Φ0 x = phiV x

noncomputable def Θ0 : TP →ₗ[ℂ] TP := (sigmaTT_exists_of_top topB t0_mem t0_ne).choose
theorem Θ0_isSigma : IsSigmaTT s0 Θ0
theorem Θ0_top : ∀ x ∈ OmegaT s0, Θ0 x = phiB x
```

(`VOA/Moonshine/SigmaAssemble.lean`.)

From the mathematics to the Lean statement

Decoding. `.choose` picks a witness of an existence theorem; the accompanying theorems record its properties. Because the extension is *unique* (an intertwiner is determined on a cyclic vector, `IsSigmaV3T.eqOn`), the choice is immaterial. `topV : TopSigmaV3 (s0 + 1) phiV` and `topB : TopSigmaTT s0 s0 phiB` are the top-level existence certificates of Chapter 41.
Sector bookkeeping. Φ_0 lands in $T_{s_0+1}^+$, so the triality label is $s = s_0 + 1$ and the Θ-sector is $T_{s+1}^+ = T_{s_0}^+$, which is where Θ_0 acts (the Lean identity `s0_add_one_add_one : s0 + 1 + 1 = s0`).

Physical meaning

Φ_0, Θ_0 are the triality maps defined by their action on the lowest states and extended by the chiral algebra V_0^+ — exactly how one constructs a symmetry operator in CFT from its action on primaries.

42.4.2 Properties of Θ_0: involution and isometry, with no rescaling

Theorem 42.25. *(a) For a seed $t \in T_s$ and every m, $\psi_m^2 = 1$ on T_s, and ψ_m is an isometry of the invariant form $\langle \cdot, \cdot \rangle$ on T. (b) Hence φ_B is an isometric involution of $(T_{s_0}^+)_2$, and (c) $\Theta_0^2 = 1$ on $T_{s_0}^+$ and Θ_0 preserves* `TPForm` *on the top.*

```

(VOA/Moonshine/SigmaAssembleTop.lean, VOA/Moonshine/SigmaAssemble.lean.)

From the mathematics to the Lean statement

TForm is the symmetric invariant form on T of Chapter 36 (it satisfies $\langle e_\alpha t, t'\rangle = (-1)^{|\alpha|^2/2}\langle t, e_\alpha t'\rangle$, TForm_eT). Fin 24 indexes the 24 coordinates. The seed hypothesis is genuinely needed in (a): it is what makes every joint eigenvector character satisfy the Golay constraint below. Statements identical to (a)–(c).

Physical meaning

The triality acts on twisted ground states by a discrete Fourier-type transform whose eigenvalues are eighth roots of unity; on the physical (Golay-constrained) states it squares to one and is unitary.

Proof on paper. Decompose T_s into joint eigenvectors z of the Z_{0k}. On z with character N, ψ_m acts by $u_m\omega^{|N|}$, so ψ_m^2 acts by $\omega^{2|N|}$. The Golay constraint of Chapter 41 (golay_constraint, four_dvd_card_of_orth) says that the characters that occur in T_s — given the seed — satisfy $4 \mid |N|$; then $\omega^{2|N|} = \omega^{8q} = 1$. Isometry: each Z_{0k} is symmetric for the form (since $|\gamma^-|^2 = 4$), joint eigenvectors of different characters are orthogonal, hence ψ_m is symmetric; symmetric and involutive means isometric. (b) The blocks $h_{w_m}(-\frac{1}{2}) \otimes T$ are mutually orthogonal for TPForm with form $-4\langle\cdot,\cdot\rangle$ on the diagonal, and φ_B acts blockwise by ψ_m. (c) Θ_0^2 is a ($\sigma^2 = 1$)-twisted, i.e. honest, intertwiner which is the identity on the cyclic vector $x_0(t_0)$, hence the identity. □

What the machine verified

Unconditional; standard axioms only. This *proves* $\mu = +1$ (cf. §42.3.5): no rescaling of Θ_0 was needed, consistent with the numerics.

42.4.3 Φ_0 is a nonzero similitude

Theorem 42.26 (Similitude). *Let $z_0 = x_{n_0}$ for a fixed $n_0 \in S_1$. Then $B_V(z_0, z_0) \neq 0$, and with $\kappa_0 = \langle \Phi_0 z_0, \Phi_0 z_0\rangle_T / B_V(z_0, z_0)$,*

$$\langle \Phi_0 a, \Phi_0 b\rangle_T = \kappa_0\, B_V(a, b) \qquad \text{for all } a, b \in V_3^+,$$

and $\kappa_0 \neq 0$. Consequently $\Phi_0 : V_3^+ \to T_{s_0+1}^+$ is bijective, and its inverse Ψ_0 (extended linearly to T^+) is a σ-twisted intertwiner on $T_{s_0+1}^+$.

```
noncomputable def κ0 : ℂ := TPForm (Φ0 z0) (Φ0 z0) / leechBV z0 z0

```

(VOA/Moonshine/SigmaAssemble.lean.)

From the mathematics to the Lean statement

Decoding. `z0 := frameX0P (nvec 0)`. Division in `κ0` is honest field division in $\mathbb{C}$; the theorem `bv_z0 : leechBV z0 z0 ≠ 0` guarantees the denominator is nonzero, so `κ0` is not a junk value (in Lean, $x/0 = 0$, which would have made `Φ0_simil` suspicious had the denominator vanished). `Ψ0` is obtained by extending the inverse of the linear bijection $V_3^+ \to T^+_{s_0+1}$ arbitrarily to a complement; only its values on $T^+_{s_0+1}$ ever matter.

Physical meaning

The triality map from odd untwisted states to twisted states preserves two-point functions up to one overall constant, which can be absorbed in the normalisation of the twisted sector.

Proof on paper. Both $(a,b) \mapsto \langle \Phi_0 a, \Phi_0 b\rangle_T$ and B_V are invariant symmetric forms on V_3^+ for which the zero mode $o(n(-1)^2\mathbb{1})$ ($n \in S_1$) is symmetric. On the top basis x_m this zero mode has eigenvalue $\langle n,m\rangle^2$, and $\langle n,n\rangle^2 = 16 \neq \langle n,m\rangle^2$ for $m \neq n$ in S_1 (since $\langle n,m\rangle = \pm 4$ would force $n \mp m$ to have norm 0). Hence the basis is orthogonal for both forms and each Gram matrix is determined by its row at z_0 restricted to the top; by the top-level reduction (Theorem 42.20, scaled by κ_0), proportionality on one row propagates to all of V_3^+. $B_V(z_0,z_0) \neq 0$ because otherwise z_0 would be in the radical of B_V (by the same propagation with $\Phi = 0$), contradicting nondegeneracy. If $\kappa_0 = 0$, then `TPForm` would vanish on $\Phi_0(V_3^+) = T^+_{s_0+1}$ (surjectivity: Φ_0 hits a cyclic vector), where it is nondegenerate. Injectivity follows from $\kappa_0 \neq 0$ and nondegeneracy of B_V. □

What the machine verified

Unconditional; standard axioms only.

42.4.4 The triality data $D(c,\varepsilon)$

Definition 42.27 ($D(c,\varepsilon)$). For $c \in \mathbb{C}^\times$ and ε with $\varepsilon^2 = 1$, the triality data $D(c,\varepsilon)$ have $s = s_0 + 1$, $\Phi = c\Phi_0$, $\Psi = c^{-1}\Psi_0$, $\Theta = \varepsilon\Theta_0$.

```
noncomputable def mkData (c ε : ℂ) (hc : c ≠ 0) (hε : ε * ε = 1) : SigmaData where
  s := s0 + 1
  Φ := c • Φ0
  Ψ := c⁻¹ • Ψ0
  Θ := ε • Θ0
```

(VOA/Moonshine/SigmaAssemble.lean; the proof fields are omitted — they are the properties established above, rescaled.)

From the mathematics to the Lean statement

This is the whole normalisation freedom of §42.3.5 made explicit. The hypothesis $\varepsilon\varepsilon = 1$ allows exactly $\varepsilon = \pm 1$. Its existence shows that `SigmaData` is inhabited, so none of the earlier universally quantified results over D is vacuous.

Physical meaning

The ambiguity in normalising a symmetry operator on sectors: an overall rescaling of a sector and a sign on a self-paired sector.

Theorem 42.28 (Isometries for the normalised data). *(a) There is c with $c^2\kappa_0 = 1$. (b) For such c and either ε,* `PhiIso` *holds for $D(c,\varepsilon)$. (c) For every $c \neq 0$ and ε,* `ThetaTop` *holds for $D(c,\varepsilon)$ with the frame vectors $t_{s_0} = t_0$, $t_{s_0+1} = e_{m_0} t_0$.*

```
theorem exists_norm : ∃ c : ℂ, c * c * κ0 = 1

theorem phiIso_mkData {c ε : ℂ} (hc : c * c * κ0 = 1) (hε : ε * ε = 1) :
    PhiIso (mkData c ε (c_ne_of_norm hc) hε)

noncomputable def tF (s' : ZMod 2) : TLeechT := if s' = s0 then t0 else eL (mvec 0) t0

theorem thetaTop_mkData (c ε : ℂ) (hc : c ≠ 0) (hε : ε * ε = 1) :
    ThetaTop (mkData c ε hc hε) tF
```

(`VOA/Moonshine/SigmaAssemble.lean`.)

From the mathematics to the Lean statement

`eL (mvec 0)` is the operator e_{m_0} for a fixed $m_0 \in \Lambda \setminus \Lambda_0$, which swaps the frame sectors of T (`tF_mem`); `tF_ne` records $t_s \neq 0$. The theorem `phiTop_of_phiIso` converts `PhiIso` into `PhiTop` for any D. These are exactly the needed residuals, now *proved*.

Physical meaning

With the right normalisation the triality is unitary on the relevant sectors; the possible obstruction $\mu = -1$ (an anti-unitary-like sign) does not occur.

Proof on paper. (a) $\mathbb{C}$ is algebraically closed and $\kappa_0 \neq 0$. (b) $\langle c\Phi_0 a, c\Phi_0 b\rangle = c^2\kappa_0 B_V(a,b)$. (c) The rescaling by ε squares away, and Θ_0 is an isometry on the top (Theorem 42.25). □

42.4.5 The one remaining hypothesis

Definition 42.29 (c-free self-coupling). With $x_K = x_0(t_{s_0+1}) \in T^+_{s_0+1}$: `KeySkew0 ε` $:\iff \varepsilon\,\Theta_0\big(Y^T(\Psi_0 x_K, z)x_K\big) = W(x_K,z)\Psi_0 x_K$.

```
noncomputable def xK : TP := x0T (tF (s0 + 1))

def KeySkew0 (ε : ℂ) : Prop :=
  ∀ p, ε • Θ0 (plusModule.YM (Ψ0 xK) p xK) = leechWsk xK p (Ψ0 xK)

theorem keySkew_mkData_iff (c ε : ℂ) (hc : c ≠ 0) (hε : ε * ε = 1) :
    KeySkew (mkData c ε hc hε) tF ↔ KeySkew0 ε

theorem moonshine_of_keySkew0 (h : KeySkew0 1 ∨ KeySkew0 (-1)) :
```

```
∃ V : VertexOperatorAlgebra Vnat,
  V.Y = Ynat VnatAxioms.wbarL ∧ V.vacuum = vacNat ∧ V.conformalVector = omegaNat ∧
  V.centralCharge = 24 ∧
  V.grading 1 = ⊥ ∧
  Module.finrank ℂ (V.grading 2) = 196884 ∧
  (∀ n : ℕ, (Module.finrank ℂ (V.grading (n : ℤ)) : ℂ) = PowerSeries.coeff n JShift) ∧
  V.IsSimple
```

(`VOA/Moonshine/SigmaAssemble.lean`.)

From the mathematics to the Lean statement

Why c drops out. With $\Psi = c^{-1}\Psi_0$, both sides of `KeySkew` are linear in Ψx, hence scale by c^{-1}; `keySkew_mkData_iff` cancels it. The disjunction in `moonshine_of_keySkew0` is honest: at this stage the sign was not determined in Lean.
Hypotheses. Only `h`. The conclusion is the final theorem's.

Physical meaning

The single remaining OPE identity, now free of normalisation ambiguity except for one sign.

What the machine verified

`moonshine_of_keySkew0`: conditional on `KeySkew0 1 v KeySkew0 (-1)`; `#print axioms` (re-run): `[propext, Classical.choice, Quot.sound]`. `mkData`, `phiIso_mkData`, `thetaTop_mkData`: unconditional.

42.5 The self-coupling identity reduced to top-level output data

42.5.1 The block defect

`KeySkew` is one entry of a larger object. For $v, b \in V_3^+$ the two candidate $B \to D'$ blocks are $b \mapsto \Theta(Y^T(v,z)\Phi b)$ (from $\sigma^\natural Y^\natural(v)\sigma^\natural$) and $b \mapsto W(\Phi v, z)b$ (from $Y^\natural(\sigma^\natural v)$).

Definition 42.30 (Block defect). For triality data D, $v, b \in V_\Lambda^+$ and $q \in \mathbb{Z}$,

$$D_q(v,b) = \Theta\big(v_{(q)}\Phi b\big) - W(\Phi v)_{(q)}b \in T^+, \qquad W(t)_{(q)}\varphi = \sum_{i\ge 0} \frac{(-1)^{q+i+1}}{i!} L_{-1}^i\big(\varphi_{(q+i)}t\big).$$

```
noncomputable def Dq (v b : VPlus) (q : ℤ) : TP :=
  D.Θ (mode (plusModule.YM v) q (D.Φ b)) - mode (leechWsk (D.Φ v)) q b
```

File `VOA/Moonshine/KeySkewBlock.lean`.

From the mathematics to the Lean statement

`mode (plusModule.YM v) q` is $v_{(q)}$ on T^+; `mode (leechWsk x) q` is $W(x)_{(q)}$, whose expansion in the display is the library theorem `mode_leechWsk` (Chapter 37). The definition is made for all $v, b \in V_\Lambda^+$ but used only for $v, b \in V_3^+$, where $D_q(v,b) \in T_{s+1}^+$ (`Dq_mem`). `KeySkew D t` is exactly $D_q(\Psi x, \Psi x) = 0$ for all q (since $\Phi\Psi x = x$).

Physical meaning

$D_q(v,b)$ measures the failure of the triality to be a symmetry of one particular operator product: the OPE of the untwisted operator v with the untwisted operator b, both in the "odd" frame

sector V_3^+, *after* rotating by $\sigma^\natural$, compared with the OPE of the twist field Φv with b. In a genuine CFT with a symmetry $\sigma^\natural$ these OPE coefficients agree, so the defect is a quantity that a physicist expects to vanish identically; proving that it does is the content of the rest of the chapter.

Coefficient by coefficient, writing $v = \Psi x$, the output weight is $w = 3 - q$, and `KeySkew` reads

$$\begin{aligned} w = 2: &\quad \Theta(o(v)x) = o(v)x, \\ w = 3: &\quad \Theta(v_{(0)}x) = L_{-1}(v_{(1)}x) - v_{(0)}x, \\ w = 4: &\quad \Theta(v_{(-1)}x) = v_{(-1)}x - L_{-1}v_{(0)}x + \tfrac{1}{2}L_{-1}^2 v_{(1)}x. \end{aligned}$$

Equivalently, with $K(z) = e^{-zL_{-1}/2}Y^T(v,z)x$, `KeySkew` says $\Theta K_w = (-1)^w K_w$ on each weight component (an analysis remark from `Notes/KeySkew.md`, not formalised).

Evidence: Numerical evidence at weights 3 and 4

In the $N(A_1^{24})$ model (`Notes/KeySkew.md` §1, `scripts/moonshine/numerics/keyskew/`), the general block identity $\Theta Y^T(v,z)\Phi b = e^{zL_{-1}}Y^T(b,-z)\Phi v$ was tested through lowering modes: at weight 3 on about 5300 nonzero identities (residual $1.1 \cdot 10^{-11}$) and at weight 4 on about 3300 ($1.1 \cdot 10^{-11}$). Controls fail decisively: $-\Theta$ gives residual 2.0, $\Theta \to \mathrm{Id}$ at least 0.32, dropping L_{-1} at least 0.75. This is evidence, not proof; the tests see a 323-dimensional slice per fibre, not the whole weight space.

42.5.2 The commutator formula and Li's lemma

Proposition 42.31 (Commutator formula for the defect). *For $v, b \in V_3^+$, $u \in V_0^+$, $m, q \in \mathbb{Z}$ there is $J \in \mathbb{N}$ with*

$$u_{(m)}D_q(v,b) = D_q(v, u_{(m)}b) + \sum_{r<J} \binom{m}{r} D_{m+q-r}\big((\sigma u)_{(r)}v,\ b\big).$$

```
theorem Dq_comm {v b : VPlus} (hv : v ∈ frameSector 1) (hb : b ∈ frameSector 1)
    (u : V0Sub.carrier) (m q : ℤ) :
    ∃ J : ℕ, actT u m (Dq D v b q) = Dq D v (actV u m b) q
      + ∑ r ∈ Finset.range J, gBinom m r • Dq D (actV (sig u) r v) b (m + q - r)
```

File `VOA/Moonshine/KeySkewBlock.lean`.

From the mathematics to the Lean statement

`gBinom m r` is the generalised binomial coefficient $\binom{m}{r} = m(m-1)\cdots(m-r+1)/r!$, valid for negative m. The existential J is any bound beyond which $(\sigma u)_{(r)}v = 0$ (truncation). This is the textbook intertwining commutator formula, applied to both terms of the defect.

Physical meaning

This is the Ward identity for the V_0^+-symmetry: moving a mode of a symmetry current past an OPE coefficient produces the OPE coefficients of the transformed operators. Both candidate blocks satisfy the same Ward identity (one because Φ, Θ intertwine up to σ, the other because W is built from the module vertex operator), hence so does their difference.

Proof on paper. For the first term: $u_{(m)}\Theta = \Theta(\sigma u)_{(m)}$, then the module commutator formula $[(\sigma u)_{(m)}, v_{(q)}] = \sum_r \binom{m}{r}((\sigma u)_{(r)}v)_{(m+q-r)}$ on T^+, and $(\sigma u)_{(m)}\Phi b = \Phi(u_{(m)}b)$. For the second term: the commutator formula for the skew intertwiner W, proved in Chapter 37 (`leechWsk_comm`), together with $u_{(r)}\Phi v = \Phi((\sigma u)_{(r)}v)$. Subtract. □

Lemma 42.32 (Only the $i = 0$ term of W survives against weight 2). *For $y \in (T^+)_2$, $t \in T^+$, $\varphi \in V_\Lambda^+$: $\langle y, W(t)_{(q)}\varphi\rangle_T = (-1)^{q+1}\langle y, \varphi_{(q)}t\rangle_T$.*

```
theorem TPForm_W_top {y : TP} (hy : y ∈ plusModule.weight (2 : ℂ)) (t : TP) (q : ℤ) (φ :
↪  VPlus) :
    TPForm y (mode (leechWsk t) q φ) = negOnePow (q + 1) * TPForm y (mode (plusModule.YM φ)
    ↪  q t)
```

File `VOA/Moonshine/KeySkewBlock.lean`.

From the mathematics to the Lean statement

`negOnePow k` is $(-1)^k$ for $k \in \mathbb{Z}$. No hypothesis on t or φ.

Physical meaning

The terms $L^i_{-1}(\cdots)$, $i \geq 1$, are derivatives (descendants); they pair to zero with a primary state of lowest weight, since L_1 annihilates y. In CFT language: a two-point function with a lowest-weight state only sees the primary part of the OPE.

Proof. $\langle y, L^i_{-1}X\rangle = \langle L^i_1 y, X\rangle = 0$ for $i \geq 1$, since $L_1 y$ has weight 1 and T^+ has nothing below weight 2. □

Theorem 42.33 (Li's lemma for the block defect). *Let x' be a V_0^+-cyclic vector of T^+_{s+1}. If $\langle x', D_q(v,b)\rangle_T = 0$ for all $v, b \in V_3^+$ and all q, then $D_q(v,b) = 0$ for all $v, b \in V_3^+$, $q \in \mathbb{Z}$.*

```
theorem Dq_eq_zero_of_pair {x' : TP}
    (hcyc : Submodule.span ℂ {y | ∃ u ∈ (Set.univ : Set V0Sub.carrier), ∃ n : ℤ, y = actT u
    ↪  n x'}
      = TPframe (D.s + 1))
    (hpair : ∀ v ∈ frameSector 1, ∀ b ∈ frameSector 1, ∀ q : ℤ, TPForm x' (Dq D v b q) = 0)
    {v b : VPlus} (hv : v ∈ frameSector 1) (hb : b ∈ frameSector 1) (q : ℤ) : Dq D v b q =
    ↪  0
```

File `VOA/Moonshine/KeySkewBlock.lean`.

From the mathematics to the Lean statement

The conclusion is a vector equation; the hypothesis is a family of scalar equations against one vector. `hcyc` is cyclicity of x'. Same as stated.

Physical meaning

A correlation function $\langle x' | \mathcal{O} \rangle$ with all possible insertions of symmetry currents determines the state $\mathcal{O}$ when x' generates the sector: the "state–operator" principle that states are determined by their overlaps with a complete set of descendants of one cyclic state. This is the mechanism of Li's uniqueness theorem for intertwining operators.

Proof on paper. The set of $y \in T^+_{s+1}$ with $\langle y, D_q(v,b)\rangle = 0$ for all v, b, q contains x' and is stable under the modes of V_0^+: by FHL invariance (42.3), $\langle u_{(n)}x', D\rangle$ is a combination of $\langle x', (L_1^j u)_{(\cdot)}D\rangle$, and by Proposition 42.31 each $u'_{(m)}D_q(v,b)$ is a combination of defects, which pair to zero with x'. By cyclicity it is all of T^+_{s+1}. The defect also pairs to zero with T^+_s (the two frame sectors are orthogonal), so it lies in the radical of the nondegenerate `TPForm`. □

Theorem 42.34 (Input reduction). *Let $b_0 \in (V_3^+)_2$ be V_0^+-cyclic. If $\langle y, D_q(v,b_0)\rangle_T = 0$ for all $v \in V_3^+$, all q and all $y \in (T^+_{s+1})_2$, then the same holds with b_0 replaced by any $b \in V_3^+$.*

```
theorem pair_of_b0 {b₀ : VPlus} (hb₀ : b₀ ∈ frameSector 1) (hb₀2 : b₀ ∈
↪  leechVOAPlus.grading 2)
    (hcyc : Submodule.span ℂ {y | ∃ u ∈ (Set.univ : Set V0Sub.carrier), ∃ n : ℤ, y = actV u
    ↪  n b₀}
      = frameSector 1)
    (h0 : ∀ v ∈ frameSector 1, ∀ q : ℤ, ∀ y ∈ TPframe (D.s + 1), y ∈ plusModule.weight (2 :
    ↪  ℂ) →
      TPForm y (Dq D v b₀ q) = 0)
    {b : VPlus} (hb : b ∈ frameSector 1) :
    ∀ v ∈ frameSector 1, ∀ q : ℤ, ∀ y ∈ TPframe (D.s + 1), y ∈ plusModule.weight (2 : ℂ) →
      TPForm y (Dq D v b q) = 0
```

File `VOA/Moonshine/KeySkewBlock.lean`.

From the mathematics to the Lean statement

The only pairings tested are against *top* vectors y (weight 2). Hypotheses: cyclicity and weight 2 of b_0. Same as stated.

Physical meaning

Inputs can be moved off the primary b_0 by symmetry Ward identities: every state of V_3^+ is a descendant of b_0 under the V_0^+-algebra, and the top-level three-point functions of descendants are fixed by those of the primary.

Proof on paper. Write $b = u_{(n)}b_0$ for homogeneous u (cyclicity). By Proposition 42.31, $D_q(v, u_{(n)}b_0) = u_{(n)}D_q(v,b_0) - \sum_r \binom{n}{r} D_{n+q-r}((\sigma u)_{(r)}v, b_0)$; the sum pairs to zero with y by hypothesis (it is a defect with input b_0). For the first term, FHL invariance moves $u_{(n)}$ onto y, producing vectors of weight $n - \operatorname{wt} u + 3$: if this is 2, they are top vectors and the hypothesis applies; if it is below 2, they vanish. If $u_{(n)}b_0$ itself has weight below 2 it is zero. (The two lowest-weight facts used: V_3^+ and T^+ start in weight 2.) □

Definition 42.35 (Top-output residual). `KeyTopV D t`: for every k and every $v \in (V_3^+)_k$, $\Theta\big(o(v)x\big) = (-1)^k(\Psi x)_{(k-1)}\Phi(v)$ with $x = x_0(t_s)$. Its $k = 2$ slice `KeyTopTwo` is $\Theta(o(v)x) = o(\Psi x)\Phi(v)$.

```
def KeyTopV (t : ZMod 2 → TLeechT) : Prop :=
  ∀ (k : ℤ), ∀ v ∈ frameSector 1, v ∈ leechVOAPlus.grading k →
    D.Θ (mode (plusModule.YM v) (k - 1) (x0T (t D.s)))
      = negOnePow k • mode (plusModule.YM (D.Ψ (x0T (t D.s)))) (k - 1) (D.Φ v)

def KeyTopTwo (t : ZMod 2 → TLeechT) : Prop :=
  ∀ v ∈ frameSector 1, v ∈ leechVOAPlus.grading 2 →
    D.Θ (mode (plusModule.YM v) 1 (x0T (t D.s)))
      = mode (plusModule.YM (D.Ψ (x0T (t D.s)))) 1 (D.Φ v)
```

File `VOA/Moonshine/KeySkewBlock.lean`.

From the mathematics to the Lean statement

`mode (plusModule.YM v) (k - 1)` for v of weight k is the zero mode $o(v)$; applied to the weight-2 vector x it gives a weight-2 vector. The right side is the weight-2 output of $W(x)$ applied to v, rewritten via Lemma 42.32. `KeyTopV` is *not finite*: k is unbounded.

Physical meaning

`KeyTopV` compares, for every operator v of the sector V_3^+, the *primary-to-primary* three-point coefficient $\langle \mathrm{top}|\, v\,|x\rangle$ computed in the two pictures. It is the collection of all three-point functions with two legs on the lowest twisted states.

Theorem 42.36 (`KeySkew` from top-level output data). *If* `KeyTopV D t` *holds (with* $t_s \in T_s$ *nonzero), then* `KeySkew D t`*; consequently, together with* `PhiTop` *and* `ThetaTop`*, all targets of the final theorem hold.*

```
theorem keySkew_of_keyTopV {t : ZMod 2 → TLeechT} (ht : ∀ s, t s ∈ leechFrameT s)
    (ht0 : ∀ s, t s ≠ 0) (hk : KeyTopV D t) : KeySkew D t
```

File `VOA/Moonshine/KeySkewBlock.lean`; the corollary is `moonshine_of_keyTopV`.

From the mathematics to the Lean statement

Hypotheses: frame membership and non-vanishing of t_s (needed for cyclicity), and `KeyTopV`.

Physical meaning

A "bootstrap" statement: all OPE coefficients of the defect are determined by its primary three-point functions, so it vanishes once those do.

Proof on paper. `KeyTopV` gives, by linearity and a weight count, $\langle y, D_q(v, \Psi x)\rangle = 0$ for all top y, all v, q (only $q = \mathrm{wt}\, v - 1$ is nontrivial; the other components have the wrong weight). Theorem 42.34 with $b_0 = \Psi x$ extends this to all inputs b; in particular to $\langle x', D_q(v, b)\rangle = 0$ for the cyclic $x' = x_0(t_{s+1})$; Li's lemma gives $D \equiv 0$, and in particular $D_q(\Psi x, \Psi x) = 0$. □

What the machine verified

`Dq_comm`, `TPForm_W_top`, `Dq_eq_zero_of_pair`, `pair_of_b0`: unconditional given D. `keySkew_of_keyTopV`: conditional on `KeyTopV`. `#print axioms` of `Dq_eq_zero_of_pair` (re-run): `[propext, Classical.choice, Quot.sound]`.

Trap / dead end: Dead ends on the way to finiteness

(1) Reducing the *state* slot v by the same trick would need the iterate (associativity) formula for both blocks; for W that is the intertwining Jacobi identity, which the library does not have, and even with it the recursion does not close on the top level. (2) Induction on total weight $\mathrm{wt}\, v + \mathrm{wt}\, b$ using skew-symmetry and `Dq_comm` does not close: zero-mode reductions raise the state weight. (3) `Modules.Fusion.Intertwiner` is commutator-only (no L_{-1} or associativity axiom), so its `fusionCoeff` is *not* the classical fusion rule; do not route uniqueness through it.

42.6 The Frenkel–Zhu bimodule route

42.6.1 Why bimodules

Zhu's algebra $A(V) = V/O(V)$ (Chapter 40) captures the action of zero modes on lowest-weight spaces. Frenkel and Zhu (1992) extended this to a V-module M: there is an $A(V)$-*bimodule* $A(M) = M/O(M)$, and an intertwining operator of type $\binom{M_3}{M\ M_1}$ induces, on lowest-weight spaces, a map $A(M) \otimes_{A(V)} M_1^{\mathrm{top}} \to M_3^{\mathrm{top}}$. Li showed that the intertwiner is *determined* by this top-level map. For us: `KeyTopV` compares two such top-level maps $\varphi_1, \varphi_2 : V_3^+ \to (T^+_{s+1})_2$. If both factor through $A(V_3^+)$ and are compatible with the left and right $A(V_0^+)$-actions, and if $A(V_3^+)$ is generated as a bimodule by its top level $(V_3^+)_2$, then $\varphi_1 = \varphi_2$ follows from equality on the top: a *finite* statement.

42.6.2 The Frenkel–Zhu operations

Definition 42.37 (Frenkel–Zhu operations)**.** Let W be a VOA, M a weak W-module, $a \in W_p$ homogeneous, $m \in M$.

$$a * m = \mathrm{Res}_z\, z^{-1}(1+z)^p Y(a,z)m = \sum_{i=0}^{p} \binom{p}{i} a_{(i-1)}m,$$

$$m * a = \mathrm{Res}_z\, z^{-1}(1+z)^{p-1} Y(a,z)m = \sum_{i=0}^{p} \binom{p-1}{i} a_{(i-1)}m,$$

$$\mathrm{Res}_k(a,m) = \mathrm{Res}_z\, z^{-2-k}(1+z)^{p+k} Y(a,z)m = \sum_{i=0}^{p+k} \binom{p+k}{i} a_{(i-2-k)}m \quad (k \geq 0),$$

and $O(M)$ is the span of all $\mathrm{Res}_k(a,m)$, a homogeneous.

```
noncomputable def fzLeft (N : WeakModule W M) (p : ℕ) (a : 𝒱) (m : M) : M :=

def fzO (N : WeakModule W M) : Submodule ℂ M := Submodule.span ℂ (fzOgen N)
```

File `VOA/Modules/FZBimodule.lean`.

From the mathematics to the Lean statement

Decoding. `cbz n i` is the binomial coefficient $\binom{n}{i}$ extended by 0 for $i < 0$ (`cbz_apply_neg`); `Finset.range (p+1)` is $\{0, \dots, p\}$. The weight p is passed as an explicit natural number, and the formulas are meant for $a \in W_p$; `fzOgen` imposes $a \in W_p$. For $p = 0$, `fzRight` truncates $(1+z)^{-1}$ at $i = 0$; since $W_0 = \mathbb{C}\mathbb{1}$ and $\mathbb{1}_{(i-1)} = \delta_{i0}$, this is the exact value.
Difference from Frenkel–Zhu. FZ's $O(M)$ is spanned by the $k = 0$ residues $a \circ m$ only. The library spans by all $k \geq 0$. FZ's Lemma 2.1.2 says the spans agree; this is *not* formalised in `FZBimodule.lean`, but the larger spanning set only makes the generation hypothesis below *weaker* (it quantifies over subspaces containing a *bigger* $O(M)$), and the module form of Lemma 2.1.2 is in fact proved in `FZGenFiltration.lean` (`PresM_mem`, below). The bimodule

structure on $M/O(M)$ itself ($O(W) * M \subseteq O(M)$ etc.) is *not* formalised and *not needed*: only closure of subspaces under $a * \cdot$, $\cdot * a$ is used.

Physical meaning

$a * m$ and $m * a$ are the zero-mode actions "from the left and from the right": on a correlation function $\langle \mathrm{top}_3 | \, Y(m,z) \, | \mathrm{top}_1 \rangle$, inserting a near the outgoing state or near the incoming state. The bimodule $A(M)$ is the space of "primary fields up to descendants", the algebraic shadow of the fusion rule $M \times M_1 \to M_3$.

Proposition 42.38 (Exact commutator). $a*m-m*a = \sum_{i=0}^{p-1} \binom{p-1}{i} a_{(i)}m$ *exactly (no $O(M)$ correction).*

```
theorem fzLeft_sub_fzRight (N : WeakModule W M) (p : ℕ) (a : V) (m : M) :
    fzLeft N p a m - fzRight N p a m
      = ∑ i ∈ Finset.range p, cbz ((p : ℤ) - 1) (i : ℤ) • mode (N.YM a) (i : ℤ) m
```

File `VOA/Modules/FZBimodule.lean`.

From the mathematics to the Lean statement

Holds for every a (the identity is pure Pascal arithmetic, $\binom{p}{i} - \binom{p-1}{i} = \binom{p-1}{i-1}$). For $a = \omega$ it is $\omega * m - m * \omega = (L_{-1} + L_0)m$.

Physical meaning

The left and right actions differ by the "non-negative modes" of a, i.e. by the singular part of the OPE of a with m; for the stress tensor this is translation plus scaling of the field m.

Definition 42.39 (Bimodule generation). An ordinary W-module M is *FZ-generated by its weight-h space* if every subspace $S \subseteq M$ that contains $O(M)$ and M_h, and is closed under $a * \cdot$ and $\cdot * a$ for all homogeneous $a \in W$, is all of M.

```
def FZGenerated (N : OrdVModule W M) (h : ℂ) : Prop :=
  ∀ S : Submodule ℂ M, fzO N.toWeakModule ≤ S → N.weight h ≤ S →
    (∀ (p : ℕ) (a : V), a ∈ W.grading (p : ℤ) → ∀ m ∈ S,
      fzLeft N.toWeakModule p a m ∈ S ∧ fzRight N.toWeakModule p a m ∈ S) → S = ⊤
```

File `VOA/Modules/FZBimodule.lean`.

From the mathematics to the Lean statement

`OrdVModule` is an ordinary (graded, L_0-semisimple) module (Definition 12.5); `N.weight h` is its weight-h space. The property says $A(M)$ is generated by the image of M_h as an $A(W)$-bimodule, phrased without forming the quotient. It is a property of the pair (W, M) only. It could be trivially true only if $M = M_h + O(M)$, which is not the case here (but nothing is lost if it were: it is a hypothesis to be *proved*).

Physical meaning

"Every field of the sector M is, modulo descendants, obtained from the lowest-weight fields by fusing with chiral-algebra fields on either side." This is what makes the fusion rule detectable on the lowest states.

42.6.3 Transposed top-level identities from the commutator formula alone

Definition 42.40 (Commutator data). Operators $A_1(r)$ on M_1, $A_3(r)$ on M_3, $B(n) : M_1 \to M_3$ and $C_j(n) : M_1 \to M_3$ form *commutator data with bound J* if $A_3(r)B(n) - B(n)A_1(r) = \sum_{j<J} \binom{r}{j} C_j(r+n-j)$ for all r, n.

```
def CommData : Prop :=
  ∀ (r n : ℤ) (m : M₁), A₃ r (B n m) - B n (A₁ r m)
    = ∑ j ∈ Finset.range J, gBinom r j • C j (r + n - j) m
```

File `VOA/Modules/FZBimodule.lean`.

From the mathematics to the Lean statement

Section variables: A_1, A_3, B, C, J. This is the commutator formula of an intertwining operator $B(n) = Y(b)_{(n)}$ with $C_j = Y(a_{(j)}b)$, with *no* associativity or L_{-1}-derivative axiom.

Physical meaning

Only the singular part of the OPE of a current with a field is assumed (the Borcherds commutator formula); the full OPE associativity is not.

Theorem 42.41 (Skew top-level identities). *Let the data satisfy* `CommData` *with bound $J = p$, and let $B(r)m = 0$ for $r > n$. Then*

$$\sum_{i=0}^{p} (-1)^{p-i} \binom{p}{i} B(n+p-i)A_1(i-1)m = A_3(p-1)B(n)m,$$

$$\sum_{i=0}^{p-1} (-1)^{p-1-i} \binom{p-1}{i} B(n+p-1-i)A_1(i)m = A_3(p-1)B(n)m - C_{p-1}(n)m \quad (p \geq 1),$$

$$\sum_{i=0}^{p+k} (-1)^{p+k-i} \binom{p+k}{i} B(n+1+p+k-i)A_1(i-2-k)m = 0.$$

```
theorem skew_left (p : ℕ) (hc : CommData A₁ A₃ B C p) (n : ℤ) (m : M₁)
    (hlow : ∀ r : ℤ, n < r → B r m = 0) :
    ∑ i ∈ Finset.range (p + 1), (asgn p i : ℂ) • B (n + p - i) (A₁ ((i : ℤ) - 1) m)
      = A₃ ((p : ℤ) - 1) (B n m)

theorem skew_comm (p : ℕ) (hp : 1 ≤ p) (hc : CommData A₁ A₃ B C p) (n : ℤ) (m : M₁)
    (hlow : ∀ r : ℤ, n < r → B r m = 0) :
    ∑ i ∈ Finset.range p, (asgn (p - 1) i : ℂ) • B (n + (p - 1 : ℕ) - i) (A₁ (i : ℤ) m)
      = A₃ ((p : ℤ) - 1) (B n m) - C (p - 1) n m

theorem skew_res (p k : ℕ) (hc : CommData A₁ A₃ B C p) (n : ℤ) (m : M₁)
    (hlow : ∀ r : ℤ, n < r → B r m = 0) :
    ∑ i ∈ Finset.range (p + k + 1), (asgn (p + k) i : ℂ)
      • B (n + 1 + (p + k : ℕ) - i) (A₁ ((i : ℤ) - 2 - k) m) = 0
```

File `VOA/Modules/FZBimodule.lean`.

From the mathematics to the Lean statement

`asgn N i` is the signed binomial $(-1)^{N-i}\binom{N}{i}$. `hlow` says $B(n)m$ is the top (highest-index nonzero) component. These are the FZ identities $o(a * m) = o(a)o(m)$, $o(m * a) = o(m)o(a)$, $o(O(M)) = 0$ for the *transposed* operator $m \mapsto e^{zL_{-1}}Y(\cdot, -z)m$, read on the top level.

Physical meaning

Skew-symmetry $Y(m,z)m_1 = e^{zL_{-1}}Y(m_1,-z)m$ exchanges the roles of the two inputs. These identities say that, at the level of primary three-point functions, the transposed operator still respects the bimodule structure — and this only needs Ward identities.

Proof on paper. Sum the commutator formula with the weights $(-1)^{N-i}\binom{N}{i}$; the C-terms combine by the finite-difference identity $\sum_i (-1)^{N-i}\binom{N}{i}\binom{s+i}{j} = \binom{s}{j-N}$, leaving one C-term or none according to the residue taken; the A_3B-terms collapse to the single top one by `hlow`. □

42.6.4 The reduction of `KeyTopV` to bimodule generation and top pairs

For a top input $y \in (T_s^+)_2$ define two maps $V_3^+ \to T^+$ on homogeneous $v \in (V_3^+)_k$:

$$\varphi_1^y(v) = \Theta\big(o(v)y\big), \qquad \varphi_2^y(v) = (-1)^k(\Psi y)_{(k-1)}\Phi(v), \qquad F_y = \varphi_1^y - \varphi_2^y.$$

Definition 42.42.

```
noncomputable def phi2Fam (y : TP) (k : ℤ) : VPlus →ₗ[ℂ] TP :=
  negOnePow k • ((mode (plusModule.YM (D.Ψ y)) (k - 1)) ∘ₗ D.Φ)

noncomputable def phi2 (y : TP) : VPlus →ₗ[ℂ] TP := gradedExt leechVOAPlus (phi2Fam D y)

noncomputable def phi1 (y : TP) : VPlus →ₗ[ℂ] TP := D.Θ ∘ₗ (oMod plusModule).flip y

noncomputable def Fy (y : TP) : VPlus →ₗ[ℂ] TP := phi1 D y - phi2 D y
```

File `VOA/Moonshine/FZBimoduleKey.lean`.

From the mathematics to the Lean statement

`oMod plusModule v y` is the zero mode $o(v)y$, extended linearly over the grading of v. `gradedExt` extends a family of maps, one per weight, linearly over the direct-sum decomposition of V_Λ^+ (`gradedExt_of_mem`: on V_k it is the k-th map). So these are exactly $\varphi_1^y, \varphi_2^y, F_y$.

Physical meaning

$\varphi_1^y(v)$ is the top-level matrix element of v between twisted lowest states, rotated by the triality; $\varphi_2^y(v)$ is the matrix element of the twist field Φv seen through skew-symmetry. F_y is their difference — the candidate violation of the triality symmetry at the level of primary three-point couplings.

Theorem 42.43 (Bimodule compatibility of F_y). *For $a \in (V_0^+)_p$, $y \in (T_s^+)_2$, $v \in (V_3^+)_k$:*

(a) $F_y(a * v) = o(\sigma a)F_y(v)$;

(b) for $p = q+1$: $F_y\big(\sum_{i\le q}\binom{q}{i}a_{(i)}v\big) = (\sigma a)_{(q)}F_y(v) - F_{a_{(q)}y}(v)$, *hence* $F_y(v*a) = F_{o(a)y}(v)$;

(c) F_y *kills* $O(V_3^+)$.

```
theorem Fy_lV {p : ℕ} {a : V0Sub.carrier} (ha : (a : VPlus) ∈ leechVOAPlus.grading (p : ℤ))
    {y : TP} (hy : y ∈ OmegaT D.s) {v : VPlus} (hv : v ∈ frameSector 1) {k : ℤ}
    (hk : v ∈ leechVOAPlus.grading k) :
    Fy D y (lV p a v) = actT (sig a) ((p : ℤ) - 1) (Fy D y v)

theorem Fy_cV {q : ℕ} {a : V0Sub.carrier} (ha : (a : VPlus) ∈ leechVOAPlus.grading ((q + 1
↪  : ℕ) : ℤ))
```

```
    {y : TP} (hy : y ∈ OmegaT D.s) {v : VPlus} (hv : v ∈ frameSector 1) {k : ℤ}
    (hk : v ∈ leechVOAPlus.grading k) :
    Fy D y (cV (q + 1) a v) = actT (sig a) (q : ℤ) (Fy D y v) - Fy D (actT a (q : ℤ) y) v

theorem Fy_resV {p k' : ℕ} {a : V0Sub.carrier} (ha : (a : VPlus) ∈ leechVOAPlus.grading (p
↪  : ℤ))
    {y : TP} (hy : y ∈ OmegaT D.s) {v : VPlus} (hv : v ∈ frameSector 1) {k : ℤ}
    (hk : v ∈ leechVOAPlus.grading k) : Fy D y (resV p k' a v) = 0
```

File `VOA/Moonshine/FZBimoduleKey.lean`.

From the mathematics to the Lean statement

`lV p a`, `cV p a`, `resV p k a` are $v \mapsto a * v$, $v \mapsto \sum_{i<p} \binom{p-1}{i} a_{(i)}v$ and $v \mapsto \mathrm{Res}_k(a,v)$ computed inside V_Λ^+; they agree with `fzLeft`, `fzLeft - fzRight`, `fzRes` for the module `MV3` (V_3^+ as a V_0^+-module), by `coe_fzLeft` etc. `actT (sig a) (p - 1)` is $o(\sigma a)$ on T^+ (weight p). Note in (b) that $a_{(q)}y = o(a)y$ is again top.

Physical meaning

These are the Ward identities for the primary three-point couplings: inserting a chiral-algebra field on the left of v acts on the outgoing state, on the right acts on the incoming state.

Proof on paper. For φ_1: $a * v$, $\mathrm{Res}_k(a,v)$ are computed inside the VOA V_Λ^+, and on the lowest-weight space of the V_Λ^+-module T^+ Zhu's theorem gives $o(a*v) = o(a)o(v)$ and $o(O(V_\Lambda^+)) = 0$ (Chapter 40); then $\Theta o(a) = o(\sigma a)\Theta$. (b) is the module commutator formula. For φ_2: Φ turns $a_{(i)}v$ into $(\sigma a)_{(i)}\Phi v$, and then Theorem 42.41 applies to the operators $B(n) = (\Psi y)_{(n)}$ on T^+, with $A_1 = A_3 = (\sigma a)_{(\cdot)}$ and bound $J = p$: the commutator sum stops at p because $(\sigma a)_{(j)}\Psi y$ has weight $p + 2 - j - 1 < 2$ for $j \geq p$, and $(\Psi y)_{(r)}\Phi v = 0$ above the top mode for the same reason. The sign $(-1)^k$ in φ_2 matches the signs `asgn`. □

Definition 42.44 (The three named Props). `KeyTopAll D`: $F_y = 0$ for every $y \in (T_s^+)_2$ (i.e. `KeyTopV` for every top input). `BimodGenV3`: V_3^+ is FZ-generated by $(V_3^+)_2$ as a V_0^+-module. `TopPairs D`: $\Theta\big(o(v)\Phi b\big) = o(b)\Phi v$ for all $v, b \in (V_3^+)_2$.

```
def KeyTopAll : Prop :=
  ∀ y ∈ OmegaT D.s, ∀ (k : ℤ), ∀ v ∈ frameSector 1, v ∈ leechVOAPlus.grading k →
    D.Θ (mode (plusModule.YM v) (k - 1) y)
      = negOnePow k • mode (plusModule.YM (D.Ψ y)) (k - 1) (D.Φ v)

def BimodGenV3 : Prop := FZGenerated MV3 (2 : ℂ)

def TopPairs : Prop :=
  ∀ v ∈ OmegaV3, ∀ b ∈ OmegaV3,
    D.Θ (mode (plusModule.YM v) 1 (D.Φ b)) = mode (plusModule.YM b) 1 (D.Φ v)
```

File `VOA/Moonshine/FZBimoduleKey.lean`.

From the mathematics to the Lean statement

`MV3` is V_3^+ as an ordinary `V0P`-module (Chapter 40). `OmegaV3` $= (V_3^+)_2$. In `TopPairs`, `mode (plusModule.YM v) 1` is $o(v)$ for weight-2 v. `TopPairs` is a finite identity on a 49152-dimensional space (bilinear in v, b).

Physical meaning

`TopPairs` is the statement that the primary couplings of two weight-2 operators of V_3^+ to the lowest twisted states are symmetric under exchange of the two operators, once the triality is applied: a finite "crossing symmetry" of OPE coefficients.

Theorem 42.45 (The Frenkel–Zhu reduction and its converse). *(a)* `BimodGenV3` *and* `TopPairs D` *imply* `KeyTopAll D`.

(b) `KeyTopAll D` *implies* `TopPairs D` *(so* `TopPairs` *is also necessary).*

(c) Hence `BimodGenV3` *and* `TopPairs D` *imply* `KeySkew D t`*, and with* `PhiTop`, `ThetaTop`*, all targets.*

      V.IsSimple
```

File `VOA/Moonshine/FZBimoduleKey.lean`.

From the mathematics to the Lean statement

All hypotheses appear explicitly. (b) guarantees that the reduction did not replace the goal by a *stronger* unprovable statement: `TopPairs` is exactly what must be true.

Physical meaning

Fusion-rule logic: the space of intertwiners $V_3^+ \times T_s^+ \to T_{s+1}^+$ injects into top-level data, which is generated by the lowest states; so two intertwiners agree once their lowest couplings do. In CFT one would say the fusion coefficient $N = 1$ makes the coupling unique up to scale; here uniqueness is replaced by the more economical statement that the *difference* vanishes.

Proof on paper. (a) Let $S = \{v \in V_3^+ : F_y(v) = 0\ \forall y \in (T_s^+)_2\}$. By Theorem 42.43, S contains $O(V_3^+)$ and is closed under $a * \cdot$ and $\cdot * a$ (for the right action use $v * a = a * v - (a * v - v * a)$, and $F_y(v * a) = F_{o(a)y}(v)$ with $o(a)y$ top). On the top, $v \in (V_3^+)_2$: $F_y(v) = \Theta o(v)y - o(\Psi y)\Phi v$, which is `TopPairs` at $(v, \Psi y)$ since $\Phi\Psi y = y$. So S contains $(V_3^+)_2$, and `BimodGenV3` gives $S = V_3^+$. (b) Take $y = \Phi b$, $k = 2$. (c) Specialise $y = x$ and apply Theorem 42.36. □

Trap / dead end: How the intertwining Jacobi identity of W was avoided

The obvious route needed the three FZ top-level identities for the intertwiner W, i.e. its full intertwining Jacobi identity, which the library lacks (`Notes/KeySkew.md` §3; this was the

recorded main risk). The trick: φ_2 is the top component of $W(\Phi v, z)\Psi y$, but it is *written* through the module modes $(\Psi y)_{(n)}$ acting on Φv, and Φ turns $a * v$ into an expression in modes of σa. The needed identities are then the transposed ones (Theorem 42.41), which require only the commutator formula of Y^T and the lowest weights. Neither the Jacobi identity of W, nor a transpose through `TPForm`, nor `Fusion.Intertwiner` is used.

What the machine verified

`Fy_lV`, `Fy_cV`, `Fy_resV`, `topPairs_of_keyTopAll`: unconditional given D. `keyTopAll_of_FZ`, `keySkew_of_FZ`: conditional on `BimodGenV3` and `TopPairs D`. `#print axioms VOA.Moonshine.FZKey.keySkew_of_FZ` (re-run): `[propext, Classical.choice, Quot.sound]`.

42.6.5 Bimodule generation of $A(V_3^+)$

Evidence: Numerical de-risking before formalisation

`BimodGenV3` was the recorded "real risk": the analogous strong-generation statement had *failed* for V_0^+ itself. It was first tested (`Notes/BimoduleGenTest.md`, `scripts/moonshine/numerics/bimodule/`) by the filtered criterion below at weights 3, 4, 5, exact arithmetic mod $2^{31}-1$: full rank in every excited sector; in the ground sector every coset vector ν has a partner with $f=-1$ (counts at weight 3: 276; weight 4: 2048; weight 5: 11178); the pair lemma checked on 3937 patterns up to weight 30. *Control*: using only the left action (no 0-modes) gives rank 0 of 24 at weight 3 — the right action is essential. This is evidence; the Lean proof below is the proof.

Definition 42.46 (Weight-raising products). For an ordinary W-module M and $n \in \mathbb{Z}$, `lowerProdM N n` is the set of $a_{(j)}x$ with $a \in W_p$, $x \in M_q$, $q < n$, $j \le 0$, $p+q-j-1=n$.

```
def lowerProdM (N : OrdVModule W M) (n : ℤ) : Set M :=
  {y | ∃ p q j : ℤ, q < n ∧ j ≤ 0 ∧ p + q - j - 1 = n ∧
    ∃ a ∈ W.grading p, ∃ x ∈ N.weight (q : ℂ), y = N.act a j x}
```

File `VOA/Moonshine/FZGenFiltration.lean`.

From the mathematics to the Lean statement

`N.act a j x` is $a_{(j)}x$. $p+q-j-1$ is the weight of $a_{(j)}x$. So these are products landing in weight n built from strictly lower-weight module states using non-positive modes.

Physical meaning

States obtained by acting with creation-type modes ($j \le 0$) of chiral fields on lower states: "descendants and composites" of lower-weight fields.

Theorem 42.47 (Filtered generation criterion). *Let M be an ordinary W-module with integer weights bounded below by n_0, and $G \subseteq M$ with $M_n \subseteq \mathrm{span}(G \cup \texttt{lowerProdM}\, n)$ for all n. Then every subspace $S \supseteq G$ containing all $\mathrm{Res}_0(a,x)$ and closed under $a*\cdot$, $\cdot * a$ ($p \ge 1$) is M. Along the way: (module FZ Lemma 2.1.2) if a subspace contains all $\mathrm{Res}_0(a,x)$ for fixed x, it contains all $\mathrm{Res}_k(a,x)$.*

```
theorem PresM_mem (N : OrdVModule W M) (x : M) (X : Submodule ℂ M)
    (hbase : ∀ (p : ℕ) (a : V), a ∈ W.grading (p : ℤ) → fzCirc N p a x ∈ X) (k : ℕ) :
    ∀ (p : ℕ) (a : V), a ∈ W.grading (p : ℤ) → PresM N p a x k ∈ X
```

```
theorem eq_top_of_lowerSpanM (N : OrdVModule W M) (G : Set M) (n₀ : ℤ)
    (hint : ∀ α : ℂ, N.weight α ≠ ⊥ → ∃ k : ℤ, α = k)
    (hbot : ∀ k : ℤ, k < n₀ → N.weight (k : ℂ) = ⊥)
    (hG : ∀ n : ℤ, N.weight (n : ℂ) ≤ span ℂ (G ∪ lowerProdM N n))
    (S : Submodule ℂ M)
    (hO : ∀ (p : ℕ) (a : 𝒱), a ∈ W.grading (p : ℤ) → ∀ x : M, fzCirc N p a x ∈ S)
    (hL : ∀ (p : ℕ) (a : 𝒱), a ∈ W.grading (p : ℤ) → ∀ x ∈ S, fzLeft N p a x ∈ S)
    (hR : ∀ (p : ℕ) (a : 𝒱), 1 ≤ p → a ∈ W.grading (p : ℤ) → ∀ x ∈ S, fzRight N p a x ∈ S)
    (hGS : G ⊆ S) : S = ⊤
```

File `VOA/Moonshine/FZGenFiltration.lean`.

From the mathematics to the Lean statement

`fzCirc N p a x` $= \mathrm{Res}_0(a,x) = a \circ x$ and `PresM N p a x k` $= \mathrm{Res}_k(a,x)$; here these are local copies in namespace `FZGen`, with `fzRight` summing $i < p$ (it agrees with `FZ.fzRight` for $p \geq 1$, `fzRight_eq`). `hint`: all weights are integers; `hbot`: nothing below n_0. Hypothesis `hO` uses only FZ's original $O(M)$ generators — strictly fewer than `fzO`.

Physical meaning

Induction on conformal weight: if every field of weight n is primary-generated or a composite of lower fields, and composites are reachable by left/right fusion and descendants, then everything is.

Proof on paper. Lemma 2.1.2 by induction on k, using $Y(L_{-1}a,z) = \partial_z Y(a,z)$ and a Pascal identity for the coefficients. Then induction on n: if $M_{<n} \subseteq S$, each $a_{(j)}x \in$ `lowerProdM` n lies in S — for $j = -1$ because $a * x - a_{(-1)}x$ has lower weight; for $j \leq -2$ because $a_{(j)}x - \mathrm{Res}_{-2-j}(a,x)$ has lower weight; for $j = 0$ because $a * x - x * a - a_{(0)}x$ has lower weight (the exact commutator). □

Theorem 42.48 (Charged excited spanning, generic form). *For $\gamma \in \Lambda \setminus \{0\}$ and any family $T(n)$ of subspaces of the Fock space with the closure property* `QuadClosed γ T`*, every Fock state of weight $w \geq 1$ lies in $T(w + \frac{1}{2}|\gamma|^2)$.*

```
def QuadClosed (γ : leech.carrier) (T : ℤ → Submodule ℂ Fk) : Prop :=
  ∀ (i j : ℕ) (a b : Fin (rank leech)) (n m : ℤ), m ≤ 0 → ∀ (w : ℕ) (p : Fk),
    p ∈ gradingWN (rank leech) w → (i : ℤ) + j + 2 < n → (w : ℤ) + LatGen.halfNorm leech γ
     ↪ < n →
    ((i : ℤ) + j + 2) + ((w : ℤ) + LatGen.halfNorm leech γ) - m - 1 = n →
    quadF γ a i b j (-m - 1) p ∈ T n

theorem gradingWN_le_of_quadClosed (hT : QuadClosed γ T) (hγ0 : γ ≠ 0) {w : ℕ} (hw : 1 ≤ w)
 ↪  :
    gradingWN (rank leech) w ≤ T ((w : ℤ) + LatGen.halfNorm leech γ)
```

File `VOA/Moonshine/FZGenExcited.lean`.

From the mathematics to the Lean statement

`Fk` is the 24-boson Fock space, `gradingWN _ w` its weight-w part; `halfNorm γ` is $\frac{1}{2}|\gamma|^2$; `quadF γ a i b j k p` is the Fock part of the action of the quadratic state $h_a(-i-1)h_b(-j-1)\mathbb{1}$ on $p \otimes e^{\gamma}$. `QuadClosed` says: weight-raising modes ($m \leq 0$) of quadratic Heisenberg states on lower charge-γ states lie in the target. The charge is arbitrary, in particular in the coset $\Lambda \setminus \Lambda_0$ of V_3^+.

Physical meaning

Every oscillator excitation of a charged state can be produced by bilinear currents $\partial X \partial X$ acting on lower excitations — the free-boson statement that the θ-even Heisenberg fields generate all excited states of a charged sector of nonzero momentum.

Proof on paper. The argument of Chapter 40 for V_0^+ (excited spanning), which used its target only through this closure and the charge only through $|\gamma|^2 \geq 4$ even: induction on the number of oscillators, with a degree-one base case solved by a small linear-algebra system in the charge coordinates. □

Theorem 42.49 (The pair lemma). *(a) If $x \in \mathbb{Z}^{24}$ has all entries odd, $x \cdot x \geq 48$ and $16 \mid x \cdot x$, there are $i \neq k$ with $|x_i| + |x_k| = 6$ or ≥ 10. (b) For $\nu \in \Lambda \setminus \Lambda_0$ with $|\nu|^2 \geq 6$ there is $\gamma \in \Lambda_0$ of norm 4 with $\langle \gamma, \nu \rangle = 3$ or ≥ 5.*

```
theorem exists_good_pair (x : Fin 24 → ℤ) (hodd : ∀ i, Odd (x i)) (h48 : 48 ≤ x ⬝ᵥ x)
    (h16 : (16 : ℤ) ∣ x ⬝ᵥ x) :
    ∃ i k : Fin 24, i ≠ k ∧ (|x i| + |x k| = 6 ∨ 10 ≤ |x i| + |x k|)

theorem exists_pair_gamma {ν : leech.carrier} (hν : ν ∉ lambda0) (h6 : 6 ≤ leech.form ν ν)
 ↪  :
    ∃ γ ∈ lambda0, leech.form γ γ = 4 ∧ (leech.form γ ν = 3 ∨ 5 ≤ leech.form γ ν)
```

File `VOA/Moonshine/FZGenV3.lean`.

From the mathematics to the Lean statement

`x ⬝ᵥ x` is the dot product; `leech.form` the Leech inner product. In (b), $x =$ `lv ν` (coordinates with $\langle \mu, \nu \rangle = \mu \cdot \nu/8$, all entries odd for $\nu \notin \Lambda_0$), and $\gamma = 4(\pm e_i \pm e_k)$; then $\langle \gamma, \nu \rangle = (|x_i| + |x_k|)/2$. Pure arithmetic; no Golay facts.

Physical meaning

A momentum-space statement: every high-momentum state of the odd sector can be split as the product of a norm-4 momentum of the even sector and a lower one, with an OPE singularity of the right order to produce it (the exponent $\langle \gamma, \nu - \gamma \rangle$ governs $e^{\gamma}(z)e^{\delta}(w) \sim (z-w)^{\langle \gamma, \delta \rangle}$).

Proof on paper. (a) Suppose every pair has $|x_i| + |x_k| \in \{2, 4, 8\}$. If two entries had magnitude ≥ 3, the pair sum $\in \{6, \geq 10\}$ unless they are $\{3, 5\}$, and no third value is then compatible; so at most one entry exceeds 1: $x = (m, (\pm 1)^{23})$ with m odd, $x \cdot x = m^2 + 23$. Now $m^2 + 23 \geq 48$ forces $|m| \geq 5$; $|m| = 5$ has the good pair $5 + 1 = 6$, and $|m| \geq 9$ has $|m| + 1 \geq 10$; the only remaining value $|m| = 7$ gives $x \cdot x = 72$, not divisible by 16. Contradiction. (b) Choose signs $s_i = \operatorname{sgn} x_i$. □

Theorem 42.50 ($A(V_3^+)$ is generated by its top). *(a) For $\nu \in \Lambda \setminus \Lambda_0$, $|\nu|^2 \geq 6$, the ground state $x_\nu = e^{\nu} + e^{-\nu}$ is in the span of weight-raising products of lower states. (b) For $n \geq 3$, $(V_3^+)_n \subseteq$ span `lowerProdM` n. (c) Every subspace of V_3^+ containing $O(V_3^+)$ and $(V_3^+)_2$ and closed under the left and right actions of homogeneous $a \in V_0^+$ is V_3^+; i.e.* `BimodGenV3` *holds.*

```

File `VOA/Moonshine/FZGenV3.lean`.

```
theorem fzGenerated_MV3 : FZ.FZGenerated MV3 (2 : ℂ)
```

File `VOA/Moonshine/FZGenBridge.lean`.

From the mathematics to the Lean statement

`Lv n` is `lowerProdM MV3 n` viewed inside V_Λ^+. `bimodGen_V3` is stated with the local operations; `fzGenerated_MV3` transfers it to the vocabulary of `FZBimodule.lean` (the operations agree on homogeneous a, and `fz0` contains the Res_0), so it is literally `BimodGenV3`. No hypotheses: unconditional.

Physical meaning

Every field of the odd frame sector V_3^+ is, modulo descendants, generated from its 49152 lowest-weight fields by fusion with the even chiral algebra V_0^+ from both sides.

Proof on paper. $(V_3^+)_n$ is spanned by projected word states $P(p \otimes e^\nu)$, $\nu \in \Lambda \setminus \Lambda_0$. Excited ones ($p$ of positive Fock weight) are handled by Theorem 42.48, with the target "Fock states whose projection is a combination of weight-raising products". Ground ones: pick γ by the pair lemma, $\delta = \nu - \gamma$, $f = \langle \gamma, \delta \rangle = \langle \gamma, \nu \rangle - 4$. If $f = -1$, $(x_\gamma)_{(0)} x_\delta = \pm x_\nu$. If $f = k \geq 1$, $(x_\gamma)_{(-k-1)} x_\delta = \pm(x_\nu + 2P(S_{2k}(\gamma) e^{\gamma-\delta}))$, the second term excited. Both are weight-raising products of lower states. Then the criterion (Theorem 42.47) with $G = (V_3^+)_2$, $n_0 = 2$. □

What the machine verified

`bimodGen_V3`, `fzGenerated_MV3`: unconditional. `#print axioms VOA.Moonshine.FZGen.fzGenerated_MV3` (re-run): `[propext, Classical.choice, Quot.sound]`.

42.7 The final finite identity

42.7.1 Everything reduced to `TopPairs`

Theorem 42.51 ($V^\natural$ from one finite identity). *For $\varepsilon^2 = 1$: if* `TopPairs` *holds for $D(c_\star, \varepsilon)$, where $c_\star^2 \kappa_0 = 1$ is the fixed normalisation, then all targets of the final theorem hold.*

```
theorem moonshine_of_topPairs {ε : ℂ} (hε : ε * ε = 1)
    (htop : FZKey.TopPairs (mkData cStar0 ε (c_ne_of_norm cStar0_norm) hε)) :

      Module.finrank ℂ (V.grading 2) = 196884 ∧
```

```
(∀ n : ℕ, (Module.finrank ℂ (V.grading (n : ℤ)) : ℂ) = PowerSeries.coeff n JShift) ∧
V.IsSimple
```

File `VOA/Moonshine/MainTopPairs.lean`.

From the mathematics to the Lean statement

`cStar0` is a fixed choice of c with `cStar0 * cStar0 * κ0 = 1` (`cStar0_norm`). The proof term is a one-line composition: `moonshine_of_keySkew cStar0_norm hε (FZKey.keySkew_of_FZ _ tF_mem tF_ne FZGen.fzGenerated_MV3 htop)` — i.e. Theorems 42.28, 42.45, 42.50. The only hypotheses are `hε` and `htop`.

Physical meaning

The entire consistency of the Moonshine orbifold — that twist fields are mutually local — has been reduced to one finite table of OPE coefficients among the 49152 lowest states of the odd frame sector and the lowest twisted states. In the bootstrap language: crossing symmetry of the full theory follows from a finite set of primary couplings, given the symmetry structure.

What the machine verified

Conditional on `htop`; `#print axioms` (re-run): `[propext, Classical.choice, Quot.sound]`.

42.7.2 Sign arithmetic of two odd norm-4 Leech vectors

Work in the integer coordinates $n = (n_0, \dots, n_{23})$ (`lv n`) with $\langle \mu, \nu \rangle = \frac{1}{8}\mu \cdot \nu$. A norm-4 vector $n \in \Lambda \setminus \Lambda_0$ has one entry ± 3, at position $i = j(n)$ (`blk n`), and twenty-three entries ± 1. Define for odd x: $\chi(x) = 1$ if $x \equiv 1 \pmod 4$, else -1; and $s(x) = \operatorname{sgn} x$.

Definition 42.52 (Characters and the set N). For $n, m \in \Lambda$, $N(n,m) = \{k : \langle \gamma_{0k}^-, n\rangle + \langle \gamma_{0k}^-, m\rangle \text{ odd}\}$.

```
def chiZ (x : ℤ) : ℂ := if x % 4 = 1 then 1 else -1

def sgnZ (x : ℤ) : ℂ := if 0 < x then 1 else -1

noncomputable def NS (n m : leech.carrier) : Finset (Fin 24) :=
  Finset.univ.filter fun k => ¬ Even (leech.form (gM 0 k) n + leech.form (gM 0 k) m)
```

File `VOA/Moonshine/TopPairsArith.lean`.

From the mathematics to the Lean statement

`x % 4` is Lean's integer remainder, in $\{0,1,2,3\}$ for the modulus 4 (Euclidean for positive modulus), so for odd x it is 1 or 3; `chiZ` is χ. `sgnZ` is used only on nonzero arguments. `Finset.univ.filter` is $\{k \in \{0..23\} : \dots\}$. The theorem `uN_NS` identifies N as the character of the joint Z_{0k}-eigenvector $e_n e_m t_0$.

Physical meaning

N records which of the commuting $\mathbb{Z}/2$ "frame" symmetries Z_{0k} of the twisted ground states act by -1 on the state $e_n e_m t_0$: it is the charge vector of a ground state of the twisted sector under a maximal abelian subgroup of the extraspecial group 2^{1+24}.

Theorem 42.53 (The B-eigenvalue). *For $n, m \in \Lambda \setminus \Lambda_0$ of norm 4, with $i = j(n)$, $j = j(m)$,*

$$\omega^{|N(n,m)|} = (-1)^{\langle m,n\rangle}\, s(n_i m_i)\, s(n_j m_j).$$

```
theorem betaN_NS {n m : leech.carrier} (hn : n ∉ lambda0) (hn4 : leech.form n n = 4)
    (hm : m ∉ lambda0) (hm4 : leech.form m m = 4) :
    betaN (NS n m) = (-1 : ℂ) ^ (leech.form m n)
      * (sgnZ (lv n (blk n) * lv m (blk n)) * sgnZ (lv n (blk m) * lv m (blk m)))
```

File `VOA/Moonshine/TopPairsArith.lean`.

From the mathematics to the Lean statement

`betaN N` $= \prod_i(\omega$ if $i \in N$ else $1) = \omega^{|N|}$ (`betaN_eq`), $\omega = e^{i\pi/4}$ (`ωB`). `(-1 : ℂ) ^ (leech.form m n)` is an integer power. Hypotheses: odd coset and norm 4 for both vectors — exactly the top basis vectors.

Physical meaning

The operator B is the twisted-sector part of the triality, a "discrete Fourier transform" on the 2^{12} ground states; its eigenvalue on a ground state is an eighth root of unity determined by the charges. The theorem says this phase is in fact a sign, computable from the momenta n, m.

Proof on paper (counting $|N|$). Since $\langle \gamma_{0k}^-, n\rangle = (n_0 - n_k)/2$ and $(-1)^{(x-y)/2} = \chi(x)\chi(y)$ for odd x, y,

$$2|N| = \sum_k \big(1 - \chi(n_0)\chi(m_0)\,\chi(n_k)\chi(m_k)\big) = 24 - \chi(n_0)\chi(m_0)\sum_k \chi(n_k)\chi(m_k).$$

On the four possible values $\pm1, \pm3$ one has the polynomial identity $6\chi(x) = x(7 - x^2)$: $x = 1 \mapsto 6$, $x = -1 \mapsto -6$, $x = 3 \mapsto -6$, $x = -3 \mapsto 6$, matching $\chi(1) = 1, \chi(-1) = -1, \chi(3) = -1, \chi(-3) = 1$. Substituting and using $n_k^2, m_k^2 \in \{1, 9\}$,

$$36\sum_k \chi(n_k)\chi(m_k) = 36\,n\cdot m - 48(n_i m_i + n_j m_j) + 64[i = j]\,n_i m_i,$$

with $n \cdot m = 8\langle n, m\rangle$. Hence $|N| \equiv 0 \pmod 4$ and $|N|/4$ has the parity of $\langle m, n\rangle$ corrected by the block signs; $\omega^{|N|} = (-1)^{|N|/4}$. A finite case split over the signs finishes. No Golay-code fact is needed beyond $\langle n, m\rangle \in \mathbb{Z}$. □

Example 42.54. Take $n = m$. Then $N = \varnothing$ (each $\langle \gamma_{0k}^-, n\rangle$ is counted twice), $\omega^0 = 1$; on the right, $(-1)^4 s(9)s(9) = 1$. □

Theorem 42.55 (The coefficient identity). *For n, m as above and every l:*

$$c_\star(m)\Big(\delta_{jl} - \tfrac{n_j n_l}{4}\Big)u_l\,\omega^{|N|} = c_\star(n)(-1)^{\langle m,n\rangle}\Big(\delta_{il} - \tfrac{m_i m_l}{4}\Big),$$

where $u_l = (-1)^{[l\in N]}$.

```
theorem coef_identity {n m : leech.carrier} (hn : n ∉ lambda0) (hn4 : leech.form n n = 4)
    (hm : m ∉ lambda0) (hm4 : leech.form m m = 4) (l : Fin 24) :
    cStar m * ((if blk m = l then 1 else 0) - ((2 * lv n (blk m) * lv n l : ℤ) : ℂ) / 8)
        * (uN (NS n m) l * betaN (NS n m))
      = cStar n * (-1 : ℂ) ^ (leech.form m n)
        * ((if blk n = l then 1 else 0) - ((2 * lv m (blk n) * lv m l : ℤ) : ℂ) / 8)
```

File `VOA/Moonshine/TopPairsArith.lean`.

From the mathematics to the Lean statement

$\frac{2n_jn_l}{8} = \frac{n_jn_l}{4}$; `uN N l` $= -1$ if $l \in N$ else 1; `cStar n` $= i^{n_0} \cdot n_{j(n)}/3$. Note $\delta_{jl} - n_jn_l/4$ are the coordinates of $w_j - 2\langle w_j, n\rangle n$ in the frame basis.

Physical meaning

The equality of two explicit OPE coefficients: the coupling of (x_n, x_m) to the twisted state $h_{w_l}(-\frac{1}{2}) \otimes e_ne_mt_0$ in the two orders. It is the place where the phases of the cocycle, of the triality on ground states, and of the oscillator part must conspire.

Proof on paper. Insert Theorem 42.53, $u_l = \chi(n_0)\chi(n_l)\chi(m_0)\chi(m_l)$, and $i^{m_0}\chi(n_0)\chi(m_0) = i^{n_0}$; what remains is a local identity in the coordinates i, j, l, checked by cases on $n_i, m_j \in \{\pm 3\}$ and the remaining entries ± 1. □

42.7.3 Both sides on the top basis

Theorem 42.56 (The top-pair identity). *(a) For $|n|^2 = 4$: $o(x_n)\big(h_v(-\frac{1}{2}) \otimes t\big) = 2^{-3}h_{v-2\langle v,n\rangle n}(-\frac{1}{2}) \otimes e_nt$. (b) $e_ne_mt_0$ is a joint Z_{0k}-eigenvector with character $N(n, m)$. (c) For all $v, b \in (V_3^+)_2$: $\Theta_0\big(o(v)\Phi_0 b\big) = o(b)\Phi_0 v$.*

```
theorem oX_hP {n : leech.carrier} (hn4 : leech.form n n = 4) (v : Fin (rank leech) → ℂ)
    (t : TLeechT) :
    mode (plusModule.YM (frameX0P n)) 1 (hP v t)
      = ((2 : ℂ) ^ (-(3 : ℤ))) • hP (latL n v) (eT leech leech_even
       ↪  leech_isUnit_det_gramMat n t)

theorem isEig_z (n m : leech.carrier) : IsEigN (NS n m) (zz n m)

theorem top_pairs0 {v b : VPlus} (hv : v ∈ OmegaV3) (hb : b ∈ OmegaV3) :
    Θ0 (mode (plusModule.YM v) 1 (Φ0 b)) = mode (plusModule.YM b) 1 (Φ0 v)
```

File `VOA/Moonshine/TopPairsCore.lean`.

From the mathematics to the Lean statement

`hP v t` is $h_v(-\frac{1}{2}) \otimes t$ for $v \in \mathbb{C}^{24}$ (orthonormal coordinates); `latL n v` is $v - 2\langle v, n\rangle n$; `eT` … `n` is e_n on T; `zz n m := eL n (eL m t0)`; `IsEigN N z` means $Z_{0k}z = u_kz$ for $k \neq 0$. (c) is for the *unnormalised* data.

Physical meaning

(a) is the twisted vertex operator of $e^n + e^{-n}$ acting on the lowest twisted states: it shifts the ground state by e_n and rotates the oscillator polarisation. (c) is the finite crossing symmetry of `TopPairs` for the explicit triality.

Proof on paper. (a) from the explicit twisted operator $Y^T(e^\alpha, z)$ of Chapter 36 at its top coefficient. (b) Z_{0k} commutes with e_n up to the sign $(-1)^{\langle \gamma_{0k}, n\rangle}$ and fixes t_0 (seed). (c) On the basis: $\Phi_0 x_m = c_\star(m)h_{w_j} \otimes e_mt_0$; by (a), $o(x_n)$ of it is $2^{-3}c_\star(m)\sum_l(\delta_{jl} - n_jn_l/4)h_{w_l} \otimes e_ne_mt_0$; Θ_0 acts on block l by ψ_l, i.e. by $u_l\omega^{|N|}$ (by (b)). The other side gives $2^{-3}c_\star(n)\sum_l(\delta_{il} - m_im_l/4)h_{w_l} \otimes e_me_nt_0$ and $e_me_n = (-1)^{\langle m,n\rangle}e_ne_m$. Coefficients agree by Theorem 42.55. Extend bilinearly. □

Theorem 42.57 (TopPairs with $\varepsilon = +1$).

```
theorem TopPairs : FZKey.TopPairs (+1) := by
    FZKey.TopPairs (mkData cStar0 1 (c_ne_of_norm cStar0_norm) (by norm_num))
```

File `VOA/Moonshine/TopPairs.lean`.

From the mathematics to the Lean statement

`(by norm_num)` is the proof of $1 \cdot 1 = 1$. For $D(c_\star, 1)$ both sides of `TopPairs` are $c_\star$ times the two sides of Theorem 42.56(c). Unconditional.

Physical meaning

The correct "orientation" of the triality on the self-paired twisted sector is Θ_0 itself, with no extra sign.

Trap / dead end: The sign ε and the earlier numerics

For $\varepsilon = -1$, `TopPairs` would force $\Theta_0(o(x_n)\Phi_0 x_n) = 0$, which is false; this is *analysis only*, not machine-proved — and not needed. Before the proof, the identity was tested numerically with the library's own symbolic formulas on all 98304 odd norm-4 vectors (via the Golay code): 200,000 random pairs and 64 full rows, 0 failures. The earlier $N(A_1^{24})$ model had prescribed "$-\Theta_J$"; the relation of Θ_J to Θ_0 was never computed, and the Lean proof does not depend on it.

Theorem 42.58 (The Moonshine module). *There is a vertex operator algebra structure on $V^\natural$ whose vertex operator is the block operator (42.1), with vacuum $(\mathbb{1}, 0)$, conformal vector $(\omega, 0)$, central charge 24, $V^\natural_1 = 0$, $\dim V^\natural_n =$ the coefficient of q^n in the formal q-expansion $qJ(q)$ for all $n \geq 0$ (so $\dim V^\natural_2 = 196884$), and which is simple. These data determine the structure uniquely, so the theorem constructs a specific object. The Lean statement and its full fidelity check are in §42.8.*

```

      V.IsSimple :=
  moonshine_of_topPairs (by norm_num) topPairs_one
```

File `VOA/Moonshine/TopPairs.lean`.

Physical meaning

The chiral algebra of the $c = 24$ conformal field theory of Frenkel–Lepowsky–Meurman: a chiral CFT with a unique vacuum, no currents (no continuous symmetry), 196884 weight-two states (by FLM's theorem, the stress tensor plus 196883 primaries forming the smallest faithful representation of the Monster), and torus partition function $J(\tau)$. As a string compactification it is the internal CFT of the "Monster string". This is the physical picture, not the content of the Lean statement: the Monster symmetry, the holomorphy of the theory (a single irreducible module) and the analytic modular invariance of $J(\tau)$ are *not* part of this theorem. (The Monster symmetry and the twisted partition functions are the subject of Part VIII, Chapters 43–49.)

42.8 The final theorem, read clause by clause

This section is the fidelity check of the headline result of the book. We restate the theorem, unfold *every* defined term that occurs in it down to standard mathematics, examine each conjunct, and ask how the statement could have been weaker than intended — vacuous, satisfied by an impostor, or silently using a different convention — and why it is not.

42.8.1 The statement and the objects it mentions

```
theorem moonshine :
    ∃ V : VertexOperatorAlgebra Vnat,
      V.Y = Ynat VnatAxioms.wbarL ∧ V.vacuum = vacNat ∧ V.conformalVector = omegaNat ∧
      V.centralCharge = 24 ∧
      V.grading 1 = ⊥ ∧
      Module.finrank ℂ (V.grading 2) = 196884 ∧
      (∀ n : ℕ, (Module.finrank ℂ (V.grading (n : ℤ)) : ℂ) = PowerSeries.coeff n JShift) ∧
      V.IsSimple
```

File `VOA/Moonshine/TopPairs.lean` (namespace `VOA.Moonshine`).

Shape. The statement is an existential: *there is* a term `V` of type `VertexOperatorAlgebra Vnat` — a VOA structure on the fixed vector space $V^\natural$ — satisfying eight conjuncts joined by $\wedge$. There are no hypotheses, no section variables, no implicit arguments. The space $V^\natural$ is fixed in advance; what is asserted to exist is the *structure*, and the first four conjuncts then pin that structure down completely. So the existential is not a loophole: it is the standard way of saying "the following explicit data form a VOA".

A construction with a unique witness. Every datum of a `VertexOperatorAlgebra` on $V^\natural$ is fixed by the statement: `Y`, `vacuum` and `conformalVector` by conjuncts (1)–(3), `centralCharge` by (4); the `grading` is forced, because `isInternal` and `L0_grading` make `V.grading n` exactly the n-eigenspace of the pinned operator $L_0 = \omega_{(1)}$ (argued under (2)–(3) below); and all remaining fields are propositions (the field `finrank` is the `Prop` `FiniteDimensional`), so two witnesses with the same data are equal. Hence any two witnesses of the existential coincide: the theorem cannot be satisfied by "an unrelated VOA structure on the same space". It is a *construction* of one specific object, stated in the form "these explicit data satisfy the VOA axioms and the listed properties". (The release audit suggests, as a cosmetic improvement, exposing the witness as a named definition `Classical.choose moonshine`; the mathematical content is the same.) This uniqueness is also what excludes the recorded trap, the square-zero extension with $\overline{W} = 0$: it is not a witness, because conjunct (1) pins the twisted×twisted block to $\overline{W}$, which is proved nonzero (`leechWbar_ne_zero`), and independently because it is not simple (conjunct (8)); see the discussion under (8).

The type `VertexOperatorAlgebra`. This is the library's definition (Definitions 4.1 and 4.4), which we reproduce so that the referee need not turn back:

From the mathematics to the Lean statement

The definition is the textbook one, of CFT type (Frenkel–Lepowsky–Meurman, Gannon Def. 5.1.3): an internal $\mathbb{Z}$-graded space with finite-dimensional pieces (`DirectSum.IsInternal grading`: the canonical map $\bigoplus_n \mathcal{V}_n \to \mathcal{V}$ is an isomorphism), a linear state–field map $Y : \mathcal{V} \to \mathrm{End}(\mathcal{V})[[z^{\pm 1}]]$, a vacuum, grading compatibility, vacuum and creation axioms, locality,

truncation, a conformal vector of weight 2 whose modes $L_n = \omega_{(n+1)}$ satisfy Virasoro with central charge c, L_0 acting by the grading, L_{-1}-translation, and CFT type ($\mathcal{V}_0 = \mathbb{C}\mathbb{1}$, $\mathcal{V}_{n<0} = 0$). The two blocks above are the library's two layers: `GradedVertexOperatorAlgebra` is the general FLM/Lepowsky–Li notion (grading truncated from below), and `VertexOperatorAlgebra` adds CFT type, its truncation field being filled automatically by $N = 0$; a `VertexOperatorAlgebra` is CFT type by definition. Locality plus the other axioms imply the Jacobi identity (Chapter 4). It is a demanding definition: the library has a recorded trap where an over-quantified axiom made a related structure (`TwistedModule`) unsatisfiable (Chapter 34); the *existence* of the concrete VOAs of Chapters 31–32, and here of $V^\natural$, shows this definition is satisfiable and non-degenerate. Note that CFT type and finite-dimensionality are *part of* the definition, so they are asserted for $V^\natural$ too.

Physical meaning

These are the axioms of the chiral algebra of a 2d CFT: states ↔ fields, a unique SL_2-invariant vacuum, mutually local fields, a stress tensor $T(z) = Y(\omega, z) = \sum L_n z^{-n-2}$ with central charge c, and $L_0 =$ energy. CFT type means a unique vacuum and positive energies.

42.8.2 Conjunct by conjunct

(1) `V.Y = Ynat VnatAxioms.wbarL`: the vertex map is the genuine block operator.

```
abbrev Vnat : Type := SkewVP × TP
```

File `VOA/Moonshine/VnatCarrier.lean`.

```
noncomputable def Ynat (Wbar : TP →ₗ[ℂ] FormalDist (TP →ₗ[ℂ] SkewVP)) :
    Vnat →ₗ[ℂ] FormalDist (End ℂ Vnat) where
  toFun x := blockF (leechVOAPlus.Y x.1) (Wbar x.2) (leechWskLin x.2) (plusModule.YM x.1)
```

File `VOA/Moonshine/VnatFields.lean`.

```
noncomputable def wbarL : TP →ₗ[ℂ] FormalDist (TP →ₗ[ℂ] SkewVP) where
  toFun := leechWbar
```

File `VOA/Moonshine/VnatAxioms.lean`.

```
noncomputable def leechWbar (t : TP) : FormalDist (TP →ₗ[ℂ] SkewVP) :=
  Wbar leechBV plusModule TPForm TPForm_weightOrth t
```

File `VOA/Moonshine/WbarLeech.lean`.

```
noncomputable def leechWsk (t : TP) : FormalDist (SkewVP →ₗ[ℂ] TP) :=
  Wsk plusModule.toWeakModule t
```

File `VOA/Moonshine/SkewLeech.lean`.

From the mathematics to the Lean statement

Decoding. For $x = (u, t) \in V^\natural$, `Ynat wbarL x` is the 2×2 block field (42.1): top-left $Y(u, z)$, the vertex operator of the VOA V_Λ^+ (`leechVOAPlus`, Chapter 32); bottom-right $Y^T(u, z)$, the module vertex operator of V_Λ^+ on $(V_\Lambda^T)^+$ (`plusModule`, Chapter 36); bottom-left $W(t, z)$, the skew intertwiner $W(t, z)\varphi = e^{zL_{-1}}Y^T(\varphi, -z)t$ (`Wsk`, Chapter 37); top-right $\overline{W}(t, z)$, the adjoint of W through the canonical forms `leechBV` and `TPForm` (`Wbar`, Chapter 37). `wbarL` is merely `leechWbar` packaged as a linear map.

Why this conjunct is essential. Without it, the theorem would assert the existence of *some*

VOA on the vector space $V^\natural$ with the listed numerical properties, and the space $V^\natural$ would be playing no role beyond its graded dimension. With it, the vertex operator is *the* FLM/DGM vertex operator on $V_\Lambda^+ \oplus (V_\Lambda^T)^+$: every field is the explicit untwisted, twisted, or intertwining field built in Chapters 31–37.

The adjoint is not zero. The theorem

```
theorem leechWbar_ne_zero : leechWbar ≠ 0
```

File `VOA/Moonshine/VnatGenuine.lean`. shows that the top-right block is genuinely present: for a nonzero weight-2 twisted t there is t' with $\overline{W}(t)_{(3)}t' = c\,\mathbb{1}$, $c \neq 0$.

Physical meaning

The OPE of two twist fields contains the identity operator: $\sigma_t(z)\sigma_{t'}(w) \sim \langle t, t'\rangle (z-w)^{-4}\mathbb{1} + \cdots$ for weight-2 twist fields. This is what $\overline{W} \neq 0$ expresses, and it is what makes the twisted sector part of one theory rather than a module glued on with no interaction.

(2)–(3) `V.vacuum = vacNat`, `V.conformalVector = omegaNat`.

```
noncomputable def vacNat : Vnat := (leechVOAPlus.vacuum, 0)

noncomputable def omegaNat : Vnat := (leechVOAPlus.conformalVector, 0)
```

File `VOA/Moonshine/VnatCarrier.lean`.

From the mathematics to the Lean statement

Vacuum and conformal vector are those of V_Λ^+, i.e. of the Leech lattice VOA: $\mathbb{1} = e^0$ and $\omega = \frac{1}{2}\sum_{a=1}^{24} h_a(-1)^2\mathbb{1}$ (Chapter 31).

The grading is determined by (1)–(3). The theorem does not say `V.grading = gradingNat`, but it need not: by `L0_grading` each `V.grading n` is contained in the n-eigenspace of $L_0 = \omega_{(1)}$, and because the grading is an internal direct sum, it *equals* that eigenspace (decompose an eigenvector into homogeneous components; each component is an eigenvector of its own weight, so only the weight-n component survives). Since Y and ω are pinned, L_0 is the explicit operator $L_0 \oplus L_0^T$, and `V.grading n` is the explicit space $(V_\Lambda^+)_n \times (T^+)_n$ (the library's `gradingNat n`). Thus the dimension statements (5)–(7) refer to the intended spaces, not to an arbitrary regrading. Likewise `V.L n` are the explicit Virasoro operators.

Physical meaning

The stress tensor of the orbifold is the stress tensor of the 24 free bosons, $T = -\frac{1}{2}\sum :\partial X^a \partial X^a:$, which is θ-invariant; the orbifold does not change the conformal structure.

(4) `V.centralCharge = 24`. With ω pinned, c is determined by $[L_2, L_{-2}] = 4L_0 + \frac{c}{2}$; a wrong value would be refutable. It is the rank of the Leech lattice.

Physical meaning

$c = 24$: 24 free bosons; the critical dimension of the bosonic string after light-cone gauge. Holomorphic $c = 24$ CFTs are exactly those whose characters are (essentially) modular functions, $Z(\tau) = J(\tau) + \text{const}$.

(5) `V.grading 1 = ⊥`. ${V^\natural}_1 = 0$: $\bot$ is the zero subspace. This holds because $(V_\Lambda^+)_1 = 0$ (θ kills the 24 currents $h_a(-1)\mathbb{1}$, and Λ has no roots) and T^+ starts in weight 2.

Physical meaning

No weight-one states means no conserved currents: the Moonshine CFT has no continuous symmetry — its symmetry group is finite (by FLM's theorem it is the Monster). In the library, finiteness of Aut $V^\natural$ is the theorem `M8.finite_autVnat` of Chapter 47 (no hypotheses), and the identification with AxiomMath's Monster is Chapter 49's, unconditional for the subgroup of liftable elements and conditional on `GmatEqAut0` for the whole group. This distinguishes it from the Leech lattice theory, whose 24 currents generate a $U(1)^{24}$.

(6) `Module.finrank ℂ (V.grading 2) = 196884`. `Module.finrank ℂ S` is the dimension of the subspace S (a natural number; it would be 0 for an infinite-dimensional space, but every `V.grading n` is finite-dimensional by the axiom `finrank`). $196884 = 98580 + 98304$ ($(V_\Lambda^+)_2$ plus $(T^+)_2 = 24 \cdot 4096$).

Physical meaning

$196884 = 1 + 196883$: the stress tensor and the smallest nontrivial representation of the Monster (a fact from the literature; in the library, Chapter 48 identifies ${V^\natural}_2$ with the complexified rational Griess algebra of AxiomMath's Monster model, and Chapter 49 lifts the elements of the group Gmat to automorphisms of $V^\natural$); McKay's observation that started Monstrous Moonshine. The weight-two space carries the commutative non-associative Griess algebra via $a \cdot b = a_{(1)}b$.

(7) the full graded dimension.

```
noncomputable def jShift : PowerSeries ℂ :=
  E4Series ^ 3 * ((deltaOverQUnit⁻¹ : (PowerSeries ℂ)ˣ) : PowerSeries ℂ)

noncomputable def JShift : PowerSeries ℂ := jShift - (744 : ℂ) • PowerSeries.X
```

File `VOA/Modularity/JFunction.lean`.

From the mathematics to the Lean statement

`E4Series` is the q-expansion $1 + 240\sum \sigma_3(n)q^n$ of E_4; `deltaOverQUnit` is $\Delta/q = \prod(1-q^n)^{24}$, invertible as a power series (constant term 1). So `jShift` $= E_4^3 q/\Delta$ is the formal q-expansion of $q\,j$, and `JShift` $= q(j - 744) = qJ$ is the formal q-expansion of qJ:

$$\texttt{JShift} = 1 + 0 \cdot q + 196884\,q^2 + 21493760\,q^3 + \cdots.$$

`PowerSeries.coeff n` is the coefficient of q^n; the cast to $\mathbb{C}$ compares a natural-number dimension with a complex coefficient. The conjunct says $\sum_n \dim {V^\natural}_n\, q^n = qJ(q)$, i.e. $\mathrm{ch}\, V^\natural = q^{-1}\sum \dim {V^\natural}_n q^n = J$. It is *independent* of (5) and (6) in principle, consistent with them ($[q^1] = 0$, $[q^2] = 196884$), and was proved in Chapter 33 from $\Theta_\Lambda = E_4^3 - 720\Delta$ and the twisted-sector character. The quantifier is over all $n \in \mathbb{N}$; negative n are covered by `positivity`.

Formal, not analytic. `JShift` is a formal power series, defined from divisor sums; it is not a function on the upper half plane. That it is the q-expansion of Klein's analytic $j(\tau) - 744$ is classical (and follows on paper from Mathlib's q-expansions of E_4 and Δ, Chapter 33), but no Lean theorem identifies `JShift` with the analytic function, and no modular-invariance statement about the character of $V^\natural$ is formalized. The conjunct is therefore "graded dimension $= J$" in the standard sense of formal q-series, which is how the statement of FLM is usually

read.

Physical meaning

The torus partition function of the chiral CFT, $Z(\tau) = \mathrm{tr}_{V^\natural}\, q^{L_0 - c/24}$, equals $J(\tau)$: it is modular invariant, as a holomorphic $c = 24$ theory must be, with no constant term (no currents). (Heuristic: the Lean conjunct equates formal q-series coefficients; neither the analytic modular invariance nor holomorphy of $V^\natural$ is formalized.)

(8) `V.IsSimple`.

```
def IsIdeal (W : VertexOperatorAlgebra V) (I : Submodule ℂ V) : Prop :=
  ∀ (u v : V) (n : ℤ), v ∈ I → W.smul u n v ∈ I

def IsSimple (W : VertexOperatorAlgebra V) : Prop :=
  (⊤ : Submodule ℂ V) ≠ ⊥ ∧ ∀ I : Submodule ℂ V, W.IsIdeal I → I = ⊥ ∨ I = ⊤
```

File `VOA/Core/BilinearForm.lean`.

From the mathematics to the Lean statement

An ideal is a subspace stable under all modes $u_{(n)}$ (a left ideal; for VOAs L_{-1}-stable left ideals are two-sided by skew-symmetry, and $L_{-1} = \omega_{(0)}$ is among the modes). Simple: nonzero (`⊤ ≠ ⊥`), and the only ideals are 0 and everything. Since *all* left ideals are excluded, not only two-sided ones, this notion is at least as strong as the textbook notion of a simple VOA.

Why this conjunct cannot be dropped — the square-zero impostor. Recorded trap (Section 50.2.2, Chapter 38): replacing $\overline{W}$ by 0 in (42.1) gives the square-zero extension $V_\Lambda^+ \ltimes (V_\Lambda^T)^+$. It *is* a VOA, with the same vacuum, conformal vector, $c = 24$, $V_1 = 0$, $\dim V_2 = 196884$ and graded dimension J — it satisfies conjuncts (2)–(7). It is *not* $V^\natural$, and it is excluded twice: (i) by conjunct (1), since `leechWbar ≠ 0`; (ii) by simplicity, since $0 \oplus (V_\Lambda^T)^+$ is a proper nonzero ideal there (untwisted fields preserve it, twisted fields send untwisted states into it and kill it). Either exclusion alone suffices; the theorem has both. In the library simplicity was proved via nondegeneracy of an invariant form on $V^\natural$ that pairs the twisted sector with itself through $\overline{W}$ — exactly what fails for the impostor.

Physical meaning

Simplicity is the algebraic form of "a unique vacuum and a non-degenerate two-point function": no decoupled sector, every state has a nonzero overlap with some other state. A unitary CFT with a unique vacuum has a simple chiral algebra.

42.8.3 How the constructed object relates to FLM's $V^\natural$

Conjuncts (1)–(4) fix the data $(V^\natural, Y, \mathbb{1}, \omega, c)$ completely: the carrier is FLM's space $V_\Lambda^+ \oplus (V_\Lambda^T)^+$, and the vertex operator is the explicit block operator (42.1). Given those, (5)–(8) are *properties* of a fixed object, not choices; they are what the literature states about $V^\natural$. What the Lean theorem does *not* contain is a comparison with FLM's own vertex operator algebra, and the reader should be clear about where the two presentations differ.

- The carrier, the untwisted block Y, the twisted-module block Y^T and the intertwiner block W are FLM's (up to the conventions recorded in Chapters 31–37).

- The twisted×twisted block $\overline{W}$ is *defined* as the adjoint of the skew intertwiner W through the invariant forms `leechBV` and `TPForm` (Chapter 37). This is the presentation of Huang and of Dolan–Goddard–Montague, *not* FLM's explicit formula for the twisted vertex operators on $T \times T$; likewise the locality relation (4.23) is proved here by the Frenkel–Zhu / triality reduction of this chapter, not by FLM's own route.

- No Lean theorem states that the constructed VOA is isomorphic to FLM's $V^\natural$. On paper the identification is standard: $(V_\Lambda^T)^+$ is a simple current of V_Λ^+, and a simple-current extension of V_Λ^+ by it carries at most one VOA structure up to isomorphism (Dong–Mason, Prop. 5.3; see the notes), so any two such structures — FLM's and the one constructed here — are isomorphic. That uniqueness theorem is not formalized.

One normalisation subtlety remains: the library's $\overline{W}$ is fixed by the canonical forms (`leechBV` normalised by $(\mathbb{1}|\mathbb{1}) = 1$, and `TPForm`). Rescaling the twisted sector by λ rescales the twisted×twisted block by a nonzero scalar and gives an isomorphic VOA, so normalisations of this kind do not affect the isomorphism class. It is therefore fair to call the constructed object "the Moonshine module $V^\natural$ (the FLM Leech-lattice orbifold)"; it is *not* fair to say that FLM's construction is formalized verbatim, or that the isomorphism with FLM's $V^\natural$ is proved.

42.8.4 What the theorem does not say

- **No uniqueness.** It does not say that $V^\natural$ is the unique holomorphic $c = 24$ VOA with $V_1 = 0$ (the FLM uniqueness conjecture; proved under additional hypotheses, e.g. by Dong–Griess–Lam, see the notes). It does not say any VOA with these numerical properties is isomorphic to $V^\natural$ — the square-zero impostor shows the numerical properties alone do not suffice.

- **No Monster in this theorem.** It does not mention $\mathrm{Aut}\, V^\natural$ or identify it with the Monster group. The triality $\sigma^\natural$ used in the proof is *not* asserted to be an automorphism in the final statement. These matters are the subject of Part VIII: $\sigma^\natural$ is an automorphism by the theorem `sigmaAut` (Chapter 47, Theorem 47.11); $\mathrm{Aut}\, V^\natural$ is finite (`M8.finite_autVnat`, Chapter 47); it is isomorphic, with no hypotheses, to the subgroup of AxiomMath's Monster `AutO` formed by the elements that act on $V^\natural$ (`nonempty_autVnat_mulEquiv_liftable`, Chapter 49); and $\mathrm{Aut}\, V^\natural \cong \mathrm{AutO}$ (`monsterEquivAutVnat`) is proved conditionally on the named hypothesis `GmatEqAutO`, a theorem of AxiomMath's library that is not available on this toolchain (Chapter 49, Section 49.13; Chapter 1, Section 1.3.5).

- **No McKay–Thompson series in this theorem**, no modular invariance of trace functions (only the graded dimension), no rationality or C_2-cofiniteness of $V^\natural$. The McKay–Thompson series and the Conway–Norton conjecture are stated in Chapter 43 (`ConwayNortonConjecture`) and proved, in a qualitative genus-zero form and with no hypotheses, in Chapter 47 (`conwayNorton`); monstrous moonshine for AxiomMath's Monster, `monstrousMoonshine`, is conditional on `GmatEqAutO` (Chapter 49).

- **No module category**: holomorphicity (that $V^\natural$ is its only irreducible module) is not stated.

- **No analytic j in the statement.** The headline's J is the formal q-series `JShift`; that it is the q-expansion of the analytic $j(\tau) - 744$ on the upper half plane is a separate Lean theorem (`Moonshine.qExpansion_qJ`, `Moonshine.hasSum_JShift`), not a clause of `moonshine`.

- **No isomorphism with FLM's explicit $V^\natural$.** See the previous subsection: the twisted×twisted block is the form-adjoint $\overline{W}$, and the identification with FLM's own vertex operators rests on the (unformalized) uniqueness of simple-current extensions.

Accordingly, none of the following may be said on the strength of this theorem: "$V^\natural$ is characterised / unique", "$\mathrm{Aut}(V^\natural) = \mathbb{M}$", "$V^\natural$ is holomorphic", or "FLM's construction is formalized verbatim". For the second, the precise statements and their status are those of Chapters 47–49, recalled above.

42.8.5 Axioms and the trust model

```
'VOA.Moonshine.moonshine' depends on axioms: [propext, Classical.choice, Quot.sound]
```

This was run for this chapter at an earlier commit (when the chapter was first written; not re-run for this edition) with `lake env lean -DmaxSynthPendingDepth=3` on a file importing `VOA.Moonshine.TopPairs` (the flag is required: a bare `lake env lean` can silently drop it). The three axioms are Lean's standard ones (propositional extensionality, choice, quotient soundness). `VOA.pbw` (the PBW theorem of Chapter 3; formerly the library's only project axiom, now a theorem) does *not* appear: the Moonshine construction does not use it. `#print axioms` does not report hypotheses — but `moonshine` has none. So the theorem is *unconditional*. The project's build record for that earlier commit reports an aggregate `lake build` of 10343 jobs with exit 0 and `scripts/check_repository.py` passing; the full build was not re-run for this chapter. One upstream definition was changed during the Moonshine work: the repair of `TwistedModule.jacobi` (Chapter 34); the core definitions of VOA, module, J used in this statement are otherwise unchanged in content. (For the release the vertex-algebra structures were renamed and layered — `PreVertexAlgebra`, and `VertexOperatorAlgebra` extending `GradedVertexOperatorAlgebra` — without changing the fields a VOA must supply; the truncation field of the new middle layer is filled automatically from `positivity`.)

Release audit 2026-10-27: `RELEASE_AUDIT_MOONSHINE.md`. An independent release audit (`Notes/Textbook/referee` at an earlier commit, not re-run for this edition) re-ran `#print axioms` for `VOA.Moonshine.moonshine` and `moonshine_of_topPairs` (result: the three standard axioms), confirmed `leechWbar_ne_zero` and two non-vacuity examples (the witness's grading pieces are L_0-eigenspaces of the pinned vertex map; the twisted×twisted block of the pinned map is nonzero), and scanned the 619 modules of the import closure for `axiom`, `sorry`, `native_decide` and similar escape hatches (none outside comments; the closure does not contain `VOA/Foundations/AffineLie.lean`, where `VOA.pbw` lives). Its verdict is "announceable with caveats": no mathematical or formal defect, and caveats on wording only — the unique-witness reading of the existential, J as a formal q-series, the informal identification with FLM's explicit $V^\natural$, and the absence of the Monster, holomorphy and uniqueness. This chapter has been worded accordingly. The audit did not re-run the aggregate `lake build`; the release commit still requires one.

42.8.6 The dependency chain through the book

ingredient	where
VOA axioms, locality, forms	Chapters 4–5
Leech lattice, Golay code	Chapter 30
V_Λ (`leechVOA`), $c = 24$	Chapter 31
θ, V_Λ^+, $(V_\Lambda^+)_1 = 0$, `leechBV`	Chapter 32
graded dimension $= J$	Chapter 33
twisted modules (repair), T	Chapters 34–35
V_Λ^T, $(V_\Lambda^T)^+$ (`plusModule`)	Chapter 36
W, $\overline{W}$, `TPForm`	Chapter 37
block VOA modulo (4.23); simplicity	Chapter 38
frame, σ on V_0^+	Chapter 39
twisted triality: Zhu generation, existence	Chapters 40–41
(4.23) via conjugation, FZ, `TopPairs`	this chapter

What the machine verified

`VOA.Moonshine.moonshine`: **unconditional** (no hypotheses); a construction with a unique witness; `#print axioms` = `[propext, Classical.choice, Quot.sound]` (re-run for this chapter, and again by the release audit of 2026-10-27). Not formalized: holomorphy, uniqueness of $V^\natural$, and the isomorphism with FLM's explicit $V^\natural$; the analytic j is a separate theorem, not a clause of `moonshine`. Not part of this theorem, and treated in Chapters 47–49: Aut $V^\natural$ (finite, and isomorphic to the liftable subgroup of AxiomMath's Monster, with no hypotheses) and Aut $V^\natural \cong \mathbb{M}$ (conditional on `GmatEqAut0`).

Part VIII

Monstrous moonshine

Chapter 43

Monstrous moonshine: McKay–Thompson series, Hauptmoduln and the statement

This chapter documents the release of the library named in the front matter; every Lean quotation below is checked by `scripts/textbook/sync.py` to occur verbatim (up to whitespace and comments) in the source files of that release. It opens the part of the book devoted to *monstrous moonshine*: the Conway–Norton conjecture, proved by Borcherds in 1992, and the action of the Monster on the moonshine module $V^\natural$. Chapters 30 to 42 constructed $V^\natural$ as a vertex operator algebra. The present chapter states, in Lean and on paper, what it means for $V^\natural$ to exhibit *moonshine*. Chapters 44–47 prove it for every automorphism of $V^\natural$; Chapters 48–49 identify the automorphism group with the Monster.

The result in one sentence. The library proves, with no hypotheses and only Lean's three standard axioms (`propext`, `Classical.choice`, `Quot.sound`; Chapter 1, §1.3), the theorem

```
VOA.Moonshine.ConwayNorton.conwayNorton : ConwayNortonConjecture,
```

which says: *for every automorphism g of the moonshine vertex operator algebra $V^\natural$, the McKay–Thompson series $T_g(\tau) = q^{-1} + \sum_{n\geq 1} \mathrm{tr}(g \mid V^\natural_{n+1})\, q^n$ is the normalised Hauptmodul of a genus-zero group $\Gamma_g \leq \mathrm{SL}_2(\mathbb{R})$ that contains $\Gamma_0(N)$ for some $N \geq 1$ and is commensurable with $\mathrm{SL}_2(\mathbb{Z})$.* That the automorphism group of $V^\natural$ is the Monster is a separate matter, treated in Chapters 48 and 49: there the library proves, again with no hypotheses, that $\mathrm{Aut}(V^\natural)$ is isomorphic to a subgroup of AutO, an independently constructed Lean model of the Monster taken from the AxiomMath library (a Lean formalisation of parts of the classification of finite simple groups, CFSG), which contains a certain generated subgroup Gmat (all of this is explained in §43.2.3), and, *conditionally on one named hypothesis* (`GmatEqAutO`: Gmat = AutO, a theorem of the AxiomMath CFSG library that is not available on this library's toolchain), that $\mathrm{Aut}(V^\natural) \cong$ AutO and that monstrous moonshine holds for every element of AutO.

What this chapter does. Its job is to make the statement checkable. (The "Fidelity Protocol" mentioned below is the book's fixed format for presenting a definition or theorem: statement, verbatim Lean, dictionary, proof on paper, physical meaning, machine status; Chapter 1, §1.5.) It

(1) tells the story of moonshine and lays out the logical dependencies of Chapters 43–49 (§43.1–§43.2);

(2) defines every object in the statement: the named vertex operator algebra `VnatVOA`, its automorphism group `AutVnat`, graded traces and the McKay–Thompson series, the upper half-plane

and its cusps, the normalised Hauptmodul of a genus-zero group, moonshine groups, and the conjecture itself, each under the Fidelity Protocol (§43.3–§43.6);

(3) presents the auxiliary notions on which the proof runs: complete replicability, replicable families and rationality of traces (§43.7);

(4) proves, on paper and in Lean, the step from $\Gamma_1(N)$ to $\Gamma_0(N)$ that converts the output of the genus-zero argument of Chapter 46 into the Conway–Norton statement (§43.8);

(5) records the final theorem and the audit modules that check it (§43.9), the recorded traps (§43.10), the referee's checklist and the references.

The most important section for a referee is §43.6, the clause-by-clause comparison of the Lean proposition `ConwayNortonConjecture` with the conjecture of Conway and Norton. As everywhere in this book, our concern is the *meaning* of the Lean statements; proofs are explained mathematically, and we do not describe how the Lean proof scripts are organised.

43.1 Monstrous moonshine: the story

43.1.1 Two numbers

In 1978 John McKay noticed that

$$196884 \;=\; 1 + 196883. \tag{43.1}$$

The left-hand side is the first nontrivial coefficient of the normalised elliptic modular function

$$\begin{aligned} J(\tau) \;=\; j(\tau) - 744 \;&=\; q^{-1} + 196884\,q + 21493760\,q^2 + 864299970\,q^3 \\ &\quad + 20245856256\,q^4 + \cdots, \qquad q = e^{2\pi i\tau}, \end{aligned} \tag{43.2}$$

the function of which every *modular function* for $\mathrm{SL}_2(\mathbb{Z})$ is a rational function; here a modular function is a $\mathrm{SL}_2(\mathbb{Z})$-invariant meromorphic function on the upper half-plane $\mathbb{H} = \{\tau \in \mathbb{C} : \operatorname{Im}\tau > 0\}$ that is also meromorphic at the cusp, i.e. has a q-expansion with only finitely many negative powers of q (Chapter 33, Theorem 33.5; without the cusp condition the claim is false, e.g. for e^J). The right-hand side involves 196883, the dimension of the smallest nontrivial irreducible complex representation of the *Monster* $\mathbb{M}$, the largest of the twenty-six sporadic finite simple groups, whose existence had been predicted by Fischer and Griess in 1973 and which Griess constructed in 1980–82 as the automorphism group of a commutative non-associative algebra of dimension 196884, the *Griess algebra*. Its order is

$$|\mathbb{M}| = 2^{46}\cdot 3^{20}\cdot 5^{9}\cdot 7^{6}\cdot 11^{2}\cdot 13^{3}\cdot 17\cdot 19\cdot 23\cdot 29\cdot 31\cdot 41\cdot 47\cdot 59\cdot 71 \approx 8.08\times 10^{53}.$$

John Thompson observed that the coincidence continues: if $1, 196883, 21296876, 842609326, \ldots$ are the dimensions of the irreducible representations of $\mathbb{M}$ in increasing order, then

$$21493760 = 1 + 196883 + 21296876, \qquad 864299970 = 2\cdot 1 + 2\cdot 196883 + 21296876 + 842609326,$$

and so on. Thompson proposed that there should be a natural *graded* representation $V = \bigoplus_{n\ge 0} V_n$ of $\mathbb{M}$ whose graded dimension $\sum_n (\dim V_n)\,q^{n-1}$ is J, and that the *graded traces*

$$T_g(\tau) \;=\; \sum_{n\ge 0} \operatorname{tr}(g \mid V_n)\, q^{n-1}, \qquad g \in \mathbb{M}, \tag{43.3}$$

now called the *McKay–Thompson series*, should also be interesting functions.

43.1.2 The conjecture of Conway and Norton

Conway and Norton (1979) computed the first coefficients of T_g for all 194 conjugacy classes of $\mathbb{M}$ from the (then conjectural) character table and the (then conjectural) decomposition of the first few V_n, and found that every one of them appears to be the *normalised Hauptmodul* of a *genus-zero* subgroup of $\mathrm{SL}_2(\mathbb{R})$. The terms will be defined carefully in §43.5, and the congruence subgroups $\Gamma_0(N) = \{\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in \mathrm{SL}_2(\mathbb{Z}) : N \mid c\}$ and $\Gamma_1(N) \subseteq \Gamma_0(N)$ (also $a \equiv d \equiv 1 \bmod N$) in §43.3.2. Two subgroups H, K of a group are *commensurable* if $H \cap K$ has finite index in both H and K. For the moment: a discrete group $\Gamma \leq \mathrm{SL}_2(\mathbb{R})$ commensurable with $\mathrm{SL}_2(\mathbb{Z})$ acts on $\mathbb{H}$, the quotient $\Gamma\backslash\mathbb{H}$ can be compactified by adding finitely many *cusps* to a compact Riemann surface $X(\Gamma)$, and Γ has *genus zero* if $X(\Gamma)$ is a sphere. In that case there is an isomorphism $X(\Gamma) \to \mathbb{P}^1(\mathbb{C})$ sending the cusp ∞ to ∞, and it can be normalised uniquely so that its expansion at ∞ is $q^{-1} + 0 + O(q)$; that function is the *normalised Hauptmodul* (German: "principal modulus"). For example J is the normalised Hauptmodul of $\mathrm{SL}_2(\mathbb{Z})$, and

$$T_{2B}(\tau) = \Big(\frac{\eta(\tau)}{\eta(2\tau)}\Big)^{24} + 24 = q^{-1} + 276\,q - 2048\,q^2 + 11202\,q^3 - 49152\,q^4 + \cdots \tag{43.4}$$

is the normalised Hauptmodul of $\Gamma_0(2)$, while

$$T_{2A}(\tau) = \Big(\frac{\eta(\tau)}{\eta(2\tau)}\Big)^{24} + 24 + 2^{12}\Big(\frac{\eta(2\tau)}{\eta(\tau)}\Big)^{24} = q^{-1} + 4372\,q + 96256\,q^2 + 1240002\,q^3 + \cdots \tag{43.5}$$

is the normalised Hauptmodul of the larger group $\Gamma_0(2)+$ generated by $\Gamma_0(2)$ and the Fricke involution $\tau \mapsto -1/(2\tau)$. (Here $\eta(\tau) = q^{1/24}\prod_{n\geq 1}(1-q^n)$ is Dedekind's eta function, and the coefficients were checked numerically for this chapter by expanding the products; $276 = 1 + 275$ and $4372 = 1 + 4371$, where 275 and 4371 are the values of the 196883-dimensional character on the classes $2B$ and $2A$.) The *Conway–Norton conjecture*, in the form proved by Borcherds, reads:

> *There is a graded representation $V = \bigoplus_{n\geq 0} V_n$ of the Monster with graded dimension J such that, for every $g \in \mathbb{M}$, the McKay–Thompson series T_g is the normalised Hauptmodul of a genus-zero group $\Gamma_g \leq \mathrm{SL}_2(\mathbb{R})$ which contains $\Gamma_0(N)$ for some N and is commensurable with $\mathrm{SL}_2(\mathbb{Z})$.*

Conway and Norton said much more: they proposed for every class an explicit group Γ_g and an explicit Hauptmodul. Their groups have the form "$\Gamma_0(n|h) + e, f, \ldots$", where n is the order of g, $h \mid \gcd(24, n)$,

$$\Gamma_0(n|h) = \Big\{\left(\begin{smallmatrix} a & b/h \\ cn & d \end{smallmatrix}\right) : a, b, c, d \in \mathbb{Z},\ ad - bcn/h = 1\Big\}$$

(conjugate to $\Gamma_0(n/h)$ by $\tau \mapsto h\tau$, and containing $\Gamma_0(nh)$), and "$+e, f, \ldots$" means that certain Atkin–Lehner involutions $W_e, W_f, \ldots$ (for exact divisors $e, f, \ldots$ of n/h; the Fricke involution is $W_{n/h}$) are adjoined. These groups lie between $\Gamma_0(N)$, $N = nh$, and its normaliser in $\mathrm{SL}_2(\mathbb{R})$. This notation is for orientation only; nothing in the library uses it. there are 171 distinct functions among the 194 classes. The Lean statement of this library is the *qualitative* form displayed above; the relation between the two is discussed in detail in §43.6.3. Two striking consequences: the *supersingular primes* $2, 3, 5, 7, 11, 13, 17, 19, 23, 29, 31, 41, 47, 59, 71$ (the primes p for which $\Gamma_0(p)+$ has genus zero, as Ogg had observed in 1974) are exactly the primes dividing $|\mathbb{M}|$; and all the coefficients of all T_g are integers.

43.1.3 The moonshine module and Borcherds' proof

Frenkel, Lepowsky and Meurman (1984, 1988) constructed Thompson's representation V: the *moonshine module* $V^\natural$, a vertex operator algebra of central charge 24 obtained from the Leech lattice by a $\mathbb{Z}/2$-orbifold, with $V^\natural{}_1 = 0$, $\dim V^\natural{}_2 = 196884$ and graded dimension J, and they showed that

its automorphism group is the Monster. This library constructs $V^\natural$ in Chapters 30–42; the headline is the theorem `VOA.Moonshine.moonshine` of Chapter 42.

Borcherds (1992) proved the Conway–Norton conjecture for FLM's $V^\natural$. His argument has five steps, and the library follows it closely for the first four:

(B1) Tensor $V^\natural$ with the vertex algebra $V_{II_{1,1}}$ of the even unimodular Lorentzian lattice of rank two; the result has central charge 26.

(B2) The *no-ghost theorem* of string theory (Goddard–Thorn) identifies the space of physical states of momentum $(m,n) \in II_{1,1}$, $(m,n) \neq 0$, with ${V^\natural}_{mn+1}$, $\mathbb{M}$-equivariantly. The physical states modulo null states form a Lie algebra, the *Monster Lie algebra* $\mathfrak{m}$.

(B3) $\mathfrak{m}$ is a Borcherds–Kac–Moody (generalised Kac–Moody) algebra, and its Weyl–Kac–Borcherds denominator identity is the product formula

$$p^{-1}\prod_{m>0,\,n\in\mathbb{Z}}(1-p^m q^n)^{c(mn)} = J(p)-J(q), \qquad J(q)=\sum_n c(n)q^n. \tag{43.6}$$

(B4) Taking g-traces in the homology of a free Lie subalgebra of $\mathfrak{m}$ gives *twisted denominator identities*, which say that the T_g are *completely replicable* (§43.7).

(B5) A completely replicable function whose first few coefficients agree with those of the conjectured Hauptmodul is that Hauptmodul; Borcherds verified the agreement class by class.

Step (B5) is a finite case check that needs the character table of $\mathbb{M}$. Cummins and Gannon (1997) showed how to replace it by a uniform argument: *completely replicable functions with suitable growth are Hauptmoduln of genus-zero groups*. The library uses a case-free route of this kind (Chapter 46), re-proved and corrected where needed, so that no character table, no list of 171 groups and no case check enter the formal proof.

Physical meaning

Moonshine as a statement about a conformal field theory. $V^\natural$ is the chiral algebra of a holomorphic two-dimensional conformal field theory with central charge $c = 24$; physically, 24 free chiral bosons compactified on the Leech torus $\mathbb{R}^{24}/\Lambda$ and orbifolded by $x \mapsto -x$. The Monster is its *global symmetry group*: it commutes with the stress tensor and preserves all operator product expansions. The graded dimension $\sum_n \dim {V^\natural}_n\, q^{n-1} = \operatorname{tr}_{V^\natural} q^{L_0-c/24}$ is the torus partition function $Z(\tau)$ (the shift by $c/24 = 1$ is the Casimir energy), and its $\mathrm{SL}_2(\mathbb{Z})$-invariance is the modular invariance of the theory on a torus of modulus τ. The McKay–Thompson series is the *twisted partition function*

$$T_g(\tau) = Z\left[\begin{smallmatrix}1\\ g\end{smallmatrix}\right](\tau) = \operatorname{tr}_{V^\natural}\!\left(g\, q^{L_0-1}\right),$$

the path integral on the torus with the symmetry defect g inserted along the time circle. Modular transformations move the defect: $\tau \mapsto -1/\tau$ exchanges "g along time" with "g along space", which is the partition function of the *g-twisted sector*. This is why one expects each T_g to be invariant under a subgroup Γ_g of finite index (the subgroup that brings the defect back to itself), as in the orbifold constructions of Dixon–Ginsparg–Harvey (1988) and of Dong–Li–Mason. The *genus-zero* property is much stronger and has no generally accepted physical derivation; the most suggestive heuristics connect it to the uniqueness of $V^\natural$ (Tuite 1995) and to three-dimensional gravity (Witten 2007). We label these as heuristics: none of them is used by the library.

Borcherds' proof as string theory. Steps (B1)–(B3) are the quantisation of the bosonic string in 26 dimensions with 24 of them compactified on the moonshine orbifold and two forming a Lorentzian torus $II_{1,1}$. The physical states of the string at momentum r (the BRST

cohomology at ghost number one, or the old covariant quantisation: Virasoro-primary weight-one states modulo null states) form the Lie algebra $\mathfrak{m}$; the no-ghost theorem says they are counted by the transverse (24-dimensional) excitations. The denominator identity (43.6) is then a statement about the spectrum of this string theory, and the twisted denominator identities are its versions with a symmetry twist.

43.2 The logical structure of the moonshine part

43.2.1 The dependency graph

The part "Monstrous moonshine" (Chapters 43–49) documents the files of the library whose names begin with `MoonshineCN` (written by Fedor Popov's side of the project) and `MoonshineLR` (Leonardo Rastelli's side), the files `Aut*.lean` and the folder `MonsterGriess/`. The chapters are ordered for reading, *not* in logical order: the dependencies form a graph, not a chain. In particular, the theorems of Chapter 46 that produce complete replicability are *conditional* on two inputs that are proved in Chapter 47; and the theorem for $\mathrm{Aut}(V^\natural)$ needs only Chapters 44–47 (and this chapter), while Chapters 48–49 are needed only to identify $\mathrm{Aut}(V^\natural)$ with the Monster.

The nodes are the following; "uses" lists the nodes whose results are used.

(A) $V^\natural$ (Chapters 30–42): the vertex operator algebra `VnatVOA`, $c = 24$, ${V^\natural}_1 = 0$, graded dimension J, simple. `AutVnat` and the McKay–Thompson series are defined in this chapter.

(B) $V_{I\!I_{1,1}}$ **and** $V^\natural \otimes V_{I\!I_{1,1}}$ (Chapter 44): the vertex algebra of the hyperbolic plane (not a vertex operator algebra: its grading is not bounded below) and the tensor theory of central charge 26 with its invariant form and Virasoro action. Uses (A).

(C) **No-ghost theorem and** $\mathfrak{m}$ (Chapter 45): physical states modulo null states, the root spaces $\mathfrak{m}_{(m,n)} \cong {V^\natural}_{mn+1}$, the bracket and invariant form, and $\mathfrak{m}$ as Borcherds data *given* generation by its simple root spaces. Uses (B).

(D) **Product identity** (Chapter 46): the denominator formula (43.6), proved analytically. Uses (A).

(E) **Simple-root generation of** $\mathfrak{m}$ (Chapter 47): a dimension sandwich between $\mathfrak{m}$ and the algebra generated by its simple root spaces. Uses (C), (D).

(F) **Finite order** (Chapter 47): every automorphism of $V^\natural$ has finite order (rigid Ising vectors); also $\mathrm{Aut}(V^\natural)$ is finite. Uses (A).

(G) **Twisted denominator identities and complete replicability** (Chapter 46): `CompletelyReplicable`, as a theorem with hypotheses "generation" and "finite order". Uses (C), and the hypotheses are discharged by (E), (F).

(H) **Genus zero,** Γ_1 **form** (Chapter 46): the case-free argument, from complete replicability to `ConwayNortonGammaOne`. Uses (F), (G) (through the abstract interface of §43.7).

(I) **From** Γ_1 **to** Γ_0 (this chapter, §43.8), and the **assembly** `conwayNorton` (Chapter 47; recorded in §43.9). Uses (F), (G), (H).

(J) **The Griess algebra and AxiomMath's Monster** (Chapter 48): an explicit isomorphism ${V^\natural}_2 \cong \mathbb{C} \otimes_{\mathbb{Q}}$ SpaceB of algebras with forms, where SpaceB is AxiomMath's rational Griess algebra and AutO its automorphism group. Uses (A).

(K) **The Monster acts on $V^\natural$** (Chapter 49): every element of Gmat $= \langle \text{Gvis}, \tau_B \rangle \leq$ AutO lifts to $V^\natural$; $\mathrm{Aut}(V^\natural)$ is isomorphic to the subgroup of liftable elements (via a commutant lemma); given `GmatEqAutO`, $\mathrm{Aut}(V^\natural) \cong$ AutO and monstrous moonshine holds for the Monster. Uses (J), (I), and for rationality of traces (H).

As a list of edges ("$X \Rightarrow Y$": Y uses X):

```
(A) ⇒ (B) ⇒ (C)              V♮, the c = 26 theory, the Monster Lie algebra 𝔪
(A) ⇒ (D)                    product identity for J(p) − J(q)
(C), (D) ⇒ (E)               𝔪 is generated by its simple root spaces
(A) ⇒ (F)                    every automorphism of V♮ has finite order
(C), (E), (F) ⇒ (G)          complete replicability of every T_g
(F), (G) ⇒ (H)               genus zero, Γ₁ form
(F), (G), (H) ⇒ (I)          Γ₁ ⇒ Γ₀ and conwayNorton        [Chapters 16–20 only]
(A) ⇒ (J)                    V♮₂ ≅ ℂ ⊗ SpaceB
(H), (I), (J) ⇒ (K)          the Monster; GmatEqAutO          [Chapters 21–22]
```

The Lean names of the terms used here ("rigid Ising vectors", "Borcherds data", "simple root spaces", "commutant lemma") are defined in the chapters indicated.

43.2.2 The final theorems of the part

The following table lists the final theorems informally; the precise Lean statements, with their fidelity checks, are in the chapters indicated. "No hypotheses" means: the Lean theorem has no explicit hypotheses, and its `#print axioms` output is `[propext, Classical.choice, Quot.sound]`.

Lean name	informal content	hypotheses; where
`ConwayNorton.conwayNorton`	for every $g \in \mathrm{Aut}(V^\natural)$, T_g is the normalised Hauptmodul of a group $\Gamma_g \supseteq \Gamma_0(N)$ commensurable with $\mathrm{SL}_2(\mathbb{Z})$ (genus zero follows on paper, Prop. 43.13)	none; statement here, proof Ch. 47
`ConwayNorton.conwayNortonGammaOne_holds`	the same with $\Gamma_1(N)$ in place of $\Gamma_0(N)$, for every g of finite order	none; Ch. 46, 49
`ConwayNorton.M8.autVnat_isOfFinOrder`, `ConwayNorton.M8.finite_autVnat`	every automorphism of $V^\natural$ has finite order; $\mathrm{Aut}(V^\natural)$ is finite	none; Ch. 47
`ConwayNorton.rationalTraces`	every coefficient of every T_g is rational	none; Ch. 49
`ConwayNorton.conwayNorton_gmat`	every $g \in$ Gmat is the restriction to $V^\natural{}_2 \cong \mathbb{C} \otimes$ SpaceB of an automorphism h of $V^\natural$, and T_h is as in `conwayNorton`	none; Ch. 49
`ConwayNorton.nonempty_autVnat_mulEquiv_liftable`	$\mathrm{Aut}(V^\natural)$ is isomorphic to the subgroup of AutO of elements that act on $V^\natural$	none; Ch. 49
`ConwayNorton.monsterEquivAutVnat`	a group isomorphism AutO $\cong \mathrm{Aut}(V^\natural)$ compatible with the Griess algebras	**`GmatEqAutO`**; Ch. 49
`ConwayNorton.monstrousMoonshine`	monstrous moonshine for AxiomMath's Monster: an isomorphism φ : AutO $\to \mathrm{Aut}(V^\natural)$ as above such that $T_{\varphi(g)}$ is a normalised Hauptmodul as in `conwayNorton`, for every g	**`GmatEqAutO`**; Ch. 49

All names are in the namespace `VOA.Moonshine`.

43.2.3 The one named hypothesis, and why it is a hypothesis

The Monster enters the library through a port of definitions from the AxiomMath CFSG library (a Lean formalisation of parts of the classification of finite simple groups, on Lean 4.35): the rational Griess algebra SpaceB (a $\mathbb{Q}$-vector space of dimension 196884 with a commutative product and a form), its automorphism group AutO $\leq \mathrm{GL}_{\mathbb{Q}}$(SpaceB), the "visible" subgroup Gvis (of shape $2^{1+24}.\mathrm{Co}_1$), the extra element τ_B, and the subgroup Gmat that they generate. The definitions are copied verbatim from AxiomMath's commit `69cb972f`; Chapter 48 presents them. The proposition

```
def GmatEqAutO : Prop :=
  Generated.Gmat = AutO
```

(`VOA/Moonshine/MoonshineLRMonsterHeadline.lean`, `VOA.Moonshine.ConwayNorton.GmatEqAutO`) says that the generated group is the whole automorphism group. It is a theorem of the AxiomMath library, `CFSG.Blueprint.NativeSporadic.MonsterModel.gmat_eq_griess`, at that commit. Its proof passes through the Stroth–Leon–Sims recognition of the Baby Monster; the project measured its import closure at about 16,000 files and 208 MB on a newer toolchain, so it cannot be ported to this library's Lean 4.30 / Mathlib v4.30 at reasonable cost. It therefore enters as an *explicit hypothesis*, never as an axiom, of exactly two final theorems, `monsterEquivAutVnat` and `monstrousMoonshine`.

Three points must be kept in mind.

(a) A theorem with the hypothesis (`hM : GmatEqAutO`) is **conditional**, however clean its `#print axioms` output; `#print axioms` does not report explicit hypotheses (Chapter 1, §1.3.4). This book never calls such a theorem unconditional.

(b) The project checked that the ported definitions agree with AxiomMath's up to definitional equality (`Notes/monster_aut/CFSG_PORT_FIDELITY.md`; one definition, `SpinLattice.phi0`, is an unbundled form of the original), so that `GmatEqAutO` is the statement AxiomMath proves. The project did *not* check the axiom footprint of AxiomMath's proof inside AxiomMath's library.

(c) That AutO is *the Monster* (finite, simple, of the order displayed above) is likewise a theorem of AxiomMath's library; only the definitions are ported (the docstring of `VOA/Moonshine/MonsterGriess/AutO.lean` says so). Inside LeanVOA, "the Monster" means the Lean group `AutO`.

The Conway–Norton theorem `conwayNorton` itself does *not* depend on `GmatEqAutO`: it is a statement about $\mathrm{Aut}(V^\natural)$, whatever that group is. How large $\mathrm{Aut}(V^\natural)$ is, and why the theorem is therefore not vacuous, is discussed in §43.6.3.

Physical meaning

Physically, the distinction is between "the moonshine CFT has the McKay–Thompson twisted partition functions of every one of its global symmetries as genus-zero Hauptmoduln" (proved without hypotheses) and "its global symmetry group is precisely the Monster as constructed by AxiomMath" (proved given one group-theoretic identification). The first is a statement about the theory; the second identifies its symmetry group with an independently constructed finite group.

43.2.4 What is not formalised

For the record, the following parts of the classical story are *not* statements of the library.

- The identification of Γ_g with the group of the Conway–Norton table, and of N with $o(g)\,h$; the Lean statement is qualitative (§43.6.3).

- Any statement about conjugacy classes or the character table of the Monster, the 194 classes, the 171 functions.
- Integrality of the coefficients of T_g (rationality is proved: `rationalTraces`, Chapter 49).
- The uniqueness of $V^\natural$ among holomorphic $c = 24$ vertex operator algebras with $V_1 = 0$ (an open problem in general), and the identification of the library's $V^\natural$ with FLM's beyond the paper argument recorded in Chapter 42.
- Generalised moonshine (Norton), modularity of twisted modules, and the physical heuristics above.

43.3 The objects of the statement

The Lean statement `ConwayNortonConjecture` mentions, after all definitions are unfolded: the vertex operator algebra `VnatVOA`, its automorphisms, the trace of a linear map on a finite-dimensional space, power series, the upper half-plane with its q-parameter, the action of $\mathrm{GL}_2(\mathbb{R})$ on $\mathbb{H}$ and on $\mathbb{P}^1(\mathbb{R})$, cusps, the congruence subgroups $\Gamma_0(N)$, $\Gamma_1(N)$, commensurability, and holomorphy. This section introduces each of them, with its Lean form.

43.3.1 The moonshine module as a named vertex operator algebra

Chapter 42 ended with the theorem `VOA.Moonshine.moonshine`, an existential statement: *there is* a vertex operator algebra structure on the carrier `Vnat` with the listed properties, and its vertex map, vacuum and conformal vector are pinned to explicit definitions. To speak about automorphisms one needs the structure itself as a named object.

Definition 43.1 (The moonshine module and its automorphism group). $V^\natural$ denotes the vertex operator algebra on the space $V_\Lambda^+ \oplus (V_\Lambda^T)^+$ of Chapters 38–42, with the block vertex map, vacuum and conformal vector constructed there. An *automorphism* of $V^\natural$ is a linear bijection $g : V^\natural \to V^\natural$ with

$$g(u_{(n)}v) = (gu)_{(n)}(gv) \quad (u, v \in V^\natural,\ n \in \mathbb{Z}), \qquad g\mathbf{1} = \mathbf{1}, \qquad g\omega = \omega.$$

They form a group $\mathrm{Aut}(V^\natural)$ under composition.

```
noncomputable def VnatVOA : VertexOperatorAlgebra Vnat := vnatVOA vnat_twistedLocality

theorem VnatVOA_grading : VnatVOA.grading = gradingNat := rfl

theorem VnatVOA_grading_one : VnatVOA.grading 1 = ⊥ := gradingNat_one

theorem VnatVOA_finrank_two : Module.finrank ℂ (VnatVOA.grading 2) = 196884 :=
  finrank_gradingNat_two

abbrev AutVnat : Type := Aut VnatVOA
```

(`VOA/Moonshine/AutVnat.lean`, namespace `VOA.Moonshine.AutMonster`.) The automorphism structure is

```
structure Aut (W : VertexOperatorAlgebra 𝒱) where
  /-- The underlying `ℂ`-linear equivalence `α : 𝒱 ≃ₗ 𝒱`. -/
  toLinearEquiv : 𝒱 ≃ₗ[ℂ] 𝒱
  /-- `α` intertwines every product: `α(u₍ₙ₎v) = (αu)₍ₙ₎(αv)`. -/
  map_smul' : ∀ (u : 𝒱) (n : ℤ) (v : 𝒱),
    toLinearEquiv (W.smul u n v) = W.smul (toLinearEquiv u) n (toLinearEquiv v)
  /-- `α` fixes the vacuum: `α(𝟙) = 𝟙`. -/
```

```
map_vacuum : toLinearEquiv W.vacuum = W.vacuum
/-- `α` fixes the conformal vector: `α(ω) = ω`. -/
map_omega : toLinearEquiv W.conformalVector = W.conformalVector
```

(`VOA/Core/Automorphism.lean`, `VOA.Aut`; it was presented in Chapter 5, Definition 5.9).

From the mathematics to the Lean statement

`VnatVOA`. `vnatVOA htt` is the vertex operator algebra of Chapter 38 built from the block vertex map, whose only hypothesis is the twisted×twisted locality `htt`; Chapter 42 proved that locality, and `vnat_twistedLocality` extracts it from the existential theorem `moonshine`. So `VnatVOA` is *the* object of `moonshine`, not a new construction: its vertex map, vacuum and conformal vector are `Ynat wbarL`, `vacNat`, `omegaNat` (the theorems `VnatVOA_Y`, `VnatVOA_vacuum`, `VnatVOA_conformalVector` in the same file state this by `rfl`). `VnatVOA.grading n` is the weight-n subspace $V^\natural{}_n$ (a `Submodule ℂ Vnat`), equal by definition to `gradingNat n`, the grading of Chapter 38; `VnatVOA_grading_one` says $V^\natural{}_1 = 0$ ($\bot$ is the zero subspace) and `VnatVOA_finrank_two` says $\dim V^\natural{}_2 = 196884$.
`Aut`. A term of `Aut W` bundles a $\mathbb{C}$-linear equivalence `toLinearEquiv` with three proofs. `W.smul u n v` is the n-th product $u_{(n)}v$ (Chapter 4); `map_smul'` is $g(u_{(n)}v) = (gu)_{(n)}(gv)$ for every $n \in \mathbb{Z}$, `map_vacuum` is $g\mathbf{1} = \mathbf{1}$, `map_omega` is $g\omega = \omega$. This is exactly the textbook definition of a VOA automorphism. Fixing ω makes g commute with every $L_n = \omega_{(n+1)}$, hence preserve each $V^\natural{}_n$ (the L_0-eigenspaces); this is proved as `GriessAut.aut_map_grading` and restated below as `vnatAut_preserves_grading`. The group structure on `Aut W` (composition, identity, inverse) is defined in the same file; `g * h` is "apply h first".
`AutVnat` is an `abbrev`, i.e. a transparent name: `AutVnat` *is* `Aut VnatVOA`. The docstring's phrase "the target is `AutVnat ≃* 𝕄`" records an intention; the identification with the Monster is the subject of Chapter 49 and is conditional on `GmatEqAutO`.
Could this be vacuous? If the structure on `Vnat` were degenerate, Aut could be enormous and traces meaningless; but `VnatVOA` is simple, has $c = 24$, $V^\natural{}_1 = 0$ and graded dimension J (Chapter 42, §42.8). If, at the other extreme, `AutVnat` were trivial, the conjecture would collapse to its $g = 1$ case; Chapter 49 proves that `AutVnat` contains an isomorphic copy of AxiomMath's group Gmat, which contains $2^{1+24}.\mathrm{Co}_1$.

Physical meaning

`VnatVOA` is the chiral algebra of the Monster CFT; `AutVnat` is its group of global (internal) symmetries: the operators that commute with the stress tensor ($g\omega = \omega$), fix the vacuum, and preserve every operator product expansion ($g(u_{(n)}v) = (gu)_{(n)}(gv)$ is the statement that g intertwines the OPE coefficients). $V^\natural{}_1 = 0$ says the theory has no conserved currents, hence no continuous symmetries; that is why $\mathrm{Aut}(V^\natural)$ can be (and, by Chapter 47, is) finite.

What the machine verified

`VnatVOA`, `AutVnat`: definitions with no hypotheses. The theorems quoted are unconditional and are used by `conwayNorton`, whose `#print axioms` is `[propext, Classical.choice, Quot.sound]` (§43.9). The file `VOA/Moonshine/AutVnat.lean` is documented in Chapter 47.

43.3.2 The upper half-plane, the q-parameter and the action of $\mathrm{GL}_2(\mathbb{R})$

We collect the Mathlib notions that occur in the statement, each explained in plain words.

- $\mathbb{H}$ (Mathlib's `UpperHalfPlane`) is the type of complex numbers with positive imaginary part; a term `τ : ℍ` coerces to a complex number (`τ : ℂ`).

- `GL (Fin 2) ℝ` is the group $\mathrm{GL}_2(\mathbb{R})$ of invertible real 2×2 matrices; `γ 0 0`, `γ 0 1`, `γ 1 0`, `γ 1 1` are the entries a, b, c, d of $\gamma = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$, and `γ.det` its determinant (a unit of $\mathbb{R}$, coerced to a real number by `(γ.det : ℝ)`). It acts on $\mathbb{H}$ by `γ • τ`; for $\det\gamma > 0$ this is the Möbius action $\tau \mapsto (a\tau + b)/(c\tau + d)$ (Mathlib extends it to negative determinant by complex conjugation, which never occurs below). The scalar matrices act trivially; in particular -1 acts trivially.

- `OnePoint ℝ` is $\mathbb{P}^1(\mathbb{R}) = \mathbb{R} \cup \{\infty\}$, on which $\mathrm{GL}_2(\mathbb{R})$ acts by the same Möbius formula: $\gamma \cdot x = (ax + b)/(cx + d)$ and $\gamma \cdot \infty = a/c$ (or ∞ if $c = 0$).

- `SL(2, ℤ)` is $\mathrm{SL}_2(\mathbb{Z})$, and `mapGL ℝ : SL(2, ℤ) →* GL (Fin 2) ℝ` the inclusion. The notation $\mathcal{SL}$ (scoped in `MatrixGroups`) is Mathlib's name for its image, the subgroup $\mathrm{SL}_2(\mathbb{Z})$ of $\mathrm{GL}_2(\mathbb{R})$. A subgroup of `SL(2, ℤ)` is coerced to a subgroup of `GL (Fin 2) ℝ` by mapping along `mapGL ℝ`.

- `Gamma0 N` and `Gamma1 N` are Mathlib's congruence subgroups of $\mathrm{SL}_2(\mathbb{Z})$:

$$\Gamma_0(N) = \left\{ \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) : c \equiv 0\ (N) \right\}, \qquad \Gamma_1(N) = \left\{ \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) : a \equiv d \equiv 1,\ c \equiv 0\ (N) \right\},$$

  with congruences in `ZMod N`. (For $N = 0$, "mod 0" means equality, a degenerate case that the statement excludes by requiring $0 < N$.)

- `Subgroup.HasDetOne Γ` (a Mathlib class, used as a proposition) says every element of `Γ` has determinant 1: $\Gamma \le \mathrm{SL}_2(\mathbb{R})$.

- `Subgroup.Commensurable H K` is Mathlib's commensurability: `H.relIndex K ≠ 0 ∧ K.relIndex H ≠ 0`, where `H.relIndex K` is the index $[K : H \cap K]$ and the value 0 encodes "infinite". So $H \cap K$ has finite index in both H and K.

- `IsCusp c Γ` (Mathlib) holds if some `g ∈ Γ` is *parabolic* (not scalar, with discriminant $(\mathrm{tr}\, g)^2 - 4\det g = 0$) and fixes `c`. For a group commensurable with $\mathrm{SL}_2(\mathbb{Z})$ the cusps are exactly the points of $\mathbb{P}^1(\mathbb{Q}) = \mathbb{Q} \cup \{\infty\}$.

- `atImInfty` is the filter "$\mathrm{Im}\,\tau \to \infty$" on $\mathbb{H}$: its neighbourhoods are the horoballs $\{\mathrm{Im}\,\tau > R\}$, so `Tendsto f atImInfty (𝓝 w)` means $f(\tau) \to w$ as $\mathrm{Im}\,\tau \to \infty$ *uniformly in* $\mathrm{Re}\,\tau$.

- `MDifferentiable 𝓘(ℂ) 𝓘(ℂ) f` says $f : \mathbb{H} \to \mathbb{C}$ is complex-differentiable at every point of the complex manifold $\mathbb{H}$, i.e. holomorphic.

- `Subgroup.adjoinNegOne Γ` is $\pm\Gamma = \{g : g \in \Gamma \text{ or } -g \in \Gamma\}$.

The two local definitions of the statement file in this area are the cusp ∞ and the q-parameter.

```
abbrev cuspInfty : OnePoint ℝ := OnePoint.infty

noncomputable def qPar (τ : ℍ) : ℂ := Function.Periodic.qParam 1 (τ : ℂ)
```

(`VOA/Moonshine/MoonshineCNStatement.lean`.)

From the mathematics to the Lean statement

`OnePoint.infty` is the point $\infty \in \mathbb{P}^1(\mathbb{R})$. Mathlib's `Function.Periodic.qParam h z` is $\exp(2\pi i z/h)$; with $h = 1$, `qPar τ` $= e^{2\pi i\tau} = q$. Since $|q| = e^{-2\pi\,\mathrm{Im}\,\tau} < 1$, q never vanishes and $q \to 0$ as $\mathrm{Im}\,\tau \to \infty$. Width 1 is the right choice for all McKay–Thompson series: their invariance groups contain the translation $\tau \mapsto \tau + 1$ and no smaller translation (§43.5).

Physical meaning

$q = e^{2\pi i\tau}$ is the exponentiated modulus of the torus on which the partition function is computed: τ is the ratio of the two periods, and $q^{L_0 - c/24}$ propagates states once around the time circle. The cusp ∞ ($q \to 0$) is the limit of a very long torus, where the partition function is dominated by the vacuum, $Z \sim q^{-1}$.

What the machine verified

Definitions; both printed in `VOA/Moonshine/MoonshineCNAudit3.lean` with standard axioms.

43.4 Graded traces and the McKay–Thompson series

43.4.1 The action on a homogeneous piece, and its trace

Every automorphism g of a vertex operator algebra V maps each weight space V_n to itself, and V_n is finite dimensional; so g has a trace on V_n.

Definition 43.2 (Graded action and graded trace)**.** For a vertex operator algebra V, an integer n and $g \in \mathrm{Aut}(V)$, let $g|_{V_n} \in \mathrm{End}(V_n)$ be the restriction, and $\mathrm{tr}(g \mid V_n)$ its trace. The map $g \mapsto g|_{V_n}$ is a monoid homomorphism $\mathrm{Aut}(V) \to \mathrm{End}(V_n)$.

```
noncomputable def gradedAutAction (V : VertexOperatorAlgebra M) (n : ℤ) :
    Aut V →* Module.End ℂ (V.grading n) where
  toFun g := (GriessAut.autRestrict g n).toLinearMap
  map_one' := by ext x; rfl
  map_mul' g h := by ext x; rfl

noncomputable def gradedAutTrace (V : VertexOperatorAlgebra M) (g : Aut V) (n : ℤ) : ℂ :=
  LinearMap.trace ℂ (V.grading n) (gradedAutAction V n g)
```

(`VOA/Moonshine/MoonshineCNTrace.lean`, namespace `VOA.Moonshine.ConwayNorton`.)

From the mathematics to the Lean statement

The carrier `M` of `V` is a section variable of the file, `{M : Type u} [AddCommGroup M] [Module ℂ M]`: an arbitrary complex vector space. `V.grading n` is the weight-n subspace V_n, regarded as a type (a submodule coerced to a type); `Module.End ℂ (V.grading n)` is $\mathrm{End}_{\mathbb{C}}(V_n)$. `GriessAut.autRestrict g n` is the restriction of g to V_n as a linear equivalence $V_n \to V_n$ (defined in `VOA/Core/GriessAutomorphism.lean` using `aut_map_grading`, the fact that g maps V_n onto V_n); `.toLinearMap` forgets invertibility. `→*` means monoid homomorphism: `map_one'` and `map_mul'` say $1 \mapsto \mathrm{id}$ and $gh \mapsto g|_{V_n} \circ h|_{V_n}$ (both hold by definition, `rfl`). `LinearMap.trace ℂ (V.grading n)` is Mathlib's trace; it is the usual trace whenever the space is finite dimensional, which V_n is by the axioms of `VertexOperatorAlgebra` (the instance `V.finrank n`). (On an infinite-dimensional space Mathlib's trace is defined to be 0; this junk value never arises here.) The definition is the textbook one.

Physical meaning

$\mathrm{tr}(g \mid V_n)$ counts the states of energy n weighted by their g-charge: in a basis of g-eigenvectors with eigenvalues λ_i it is $\sum_i \lambda_i$. Summed against $q^{n-c/24}$ it becomes the partition function with a g-twist along the time direction.

What the machine verified

Definitions; printed in `VOA/Moonshine/MoonshineCNAudit.lean` with standard axioms.

Proposition 43.3 (Basic properties of graded traces). *For every vertex operator algebra V, $n \in \mathbb{Z}$ and $g, h \in \mathrm{Aut}(V)$:*

(a) $\mathrm{tr}(1 \mid V_n) = \dim V_n$*;*

(b) $\mathrm{tr}(hgh^{-1} \mid V_n) = \mathrm{tr}(g \mid V_n)$ *(traces are class functions);*

(c) for $V = V^\natural$: every $g \in \mathrm{Aut}(V^\natural)$ maps $V^\natural{}_n$ onto $V^\natural{}_n$.

```
theorem gradedAutTrace_one (V : VertexOperatorAlgebra M) (n : ℤ) :
    gradedAutTrace V 1 n = (Module.finrank ℂ (V.grading n) : ℂ)

theorem gradedAutTrace_conjugate (V : VertexOperatorAlgebra M) (g h : Aut V) (n : ℤ) :
    gradedAutTrace V (h * g * h⁻¹) n = gradedAutTrace V g n

theorem vnatAut_preserves_grading (g : AutVnat) (n : ℤ) :
    (VnatVOA.grading n).map g.toLinearEquiv.toLinearMap = VnatVOA.grading n
```

(`VOA/Moonshine/MoonshineCNTrace.lean`.)

From the mathematics to the Lean statement

In (a), `Module.finrank ℂ (V.grading n)` is $\dim_{\mathbb{C}} V_n$, cast to $\mathbb{C}$. In (b), `h * g * h⁻¹` is composition in `Aut V`. In (c), `(VnatVOA.grading n).map g.toLinearEquiv.toLinearMap` is the image $g(V^\natural{}_n)$, and the equality of submodules says $g(V^\natural{}_n) = V^\natural{}_n$. No hypotheses beyond the objects; all three statements are the textbook ones.

Proof on paper. (a) The identity has trace equal to the dimension. (b) $\mathrm{tr}(ABA^{-1}) = \mathrm{tr}(B)$ on a finite-dimensional space, applied to the restrictions (restriction is a homomorphism). (c) g commutes with $L_0 = \omega_{(1)}$ because $g(\omega_{(1)}v) = (g\omega)_{(1)}(gv) = \omega_{(1)}(gv)$; hence it preserves each L_0-eigenspace $V^\natural{}_n$, and so does g^{-1}, so $g(V^\natural{}_n) = V^\natural{}_n$. □

Physical meaning

(b) is the statement that a partition function with a symmetry twist depends only on the conjugacy class of the twist; (c) is energy conservation for a symmetry commuting with the Hamiltonian $L_0 - c/24$.

What the machine verified

Unconditional; printed in `VOA/Moonshine/MoonshineCNAudit.lean`, standard axioms.

43.4.2 The McKay–Thompson series as a power series

Definition 43.4 (McKay–Thompson series, regular part). For $g \in \mathrm{Aut}(V^\natural)$ let

$$\mathrm{MT}_g \;=\; \sum_{n \geq 0} \mathrm{tr}\big(g \mid V^\natural{}_{n+1}\big) X^n \;\in\; \mathbb{C}[[X]].$$

Thus the McKay–Thompson series is $T_g(\tau) = q^{-1} + \mathrm{MT}_g(q)$, and $q\,T_g = 1 + q\,\mathrm{MT}_g(q)$.

```
noncomputable def mckayThompson (g : AutVnat) : PowerSeries ℂ :=
  PowerSeries.mk fun n => gradedAutTrace VnatVOA g ((n : ℤ) + 1)

noncomputable def mckayThompsonShift (g : AutVnat) : PowerSeries ℂ :=
  1 + PowerSeries.X * mckayThompson g
```

(VOA/Moonshine/MoonshineCNTrace.lean.)

From the mathematics to the Lean statement

`PowerSeries.mk a` is the formal power series $\sum_{n\ge 0} a(n)X^n$; the n-th coefficient of `mckayThompson g` is `gradedAutTrace VnatVOA g ((n : ℤ) + 1)` $= \mathrm{tr}(g \mid V^\natural_{n+1})$. **The index shift by one is the convention to remember**: the coefficient of X^n is the trace on weight $n+1$, so that X plays the role of q in $T_g - q^{-1}$. The vacuum (weight 0) contributes the q^{-1}, which is not part of `mckayThompson`; it is added separately in `mckayThompsonFun` below. `mckayThompsonShift g` $= 1 + X\cdot$`mckayThompson g` is $q\,T_g$, in the same normalisation as the library's `JShift` $= qJ$ (Chapter 33, Definition 33.12); its constant term 1 is $\mathrm{tr}(g|V^\natural_0) = 1$.

Physical meaning

$q\,T_g = \mathrm{tr}_{V^\natural}(g\,q^{L_0})$, the twisted partition function with the Casimir factor $q^{-c/24} = q^{-1}$ removed; the constant term 1 is the unique vacuum, which every symmetry fixes.

What the machine verified

Definitions; printed in `VOA/Moonshine/MoonshineCNAudit.lean`, standard axioms.

Proposition 43.5 (First properties of MT_g). *For all $g, h \in \mathrm{Aut}(V^\natural)$ and $n \in \mathbb{N}$:*

(a) the n-th coefficient of MT_g is $\mathrm{tr}(g \mid V^\natural_{n+1})$;

(b) the constant coefficient vanishes: $\mathrm{tr}(g \mid V^\natural_1) = 0$;

(c) $\mathrm{MT}_{hgh^{-1}} = \mathrm{MT}_g$;

(d) $\mathrm{MT}_1 = \sum_{n\ge 0}[q^{n+1}](qJ)\,X^n$, i.e. the coefficients of MT_1 are those of J; equivalently $q\,T_1 = qJ$;

(e) $\mathrm{MT}_1 \neq qJ$ (a reminder that the two series live in different normalisations).

```
@[simp] theorem mckayThompson_coeff (g : AutVnat) (n : ℕ) :
    PowerSeries.coeff n (mckayThompson g) =
      gradedAutTrace VnatVOA g ((n : ℤ) + 1)

theorem mckayThompson_coeff_zero (g : AutVnat) :
    PowerSeries.coeff 0 (mckayThompson g) = 0

theorem mckayThompson_conjugate (g h : AutVnat) :
    mckayThompson (h * g * h⁻¹) = mckayThompson g

theorem mckayThompson_one :
    mckayThompson 1 = PowerSeries.mk (fun n => PowerSeries.coeff (n + 1) JShift)

theorem mckayThompsonShift_one : mckayThompsonShift 1 = JShift

theorem mckayThompson_one_ne_JShift : mckayThompson 1 ≠ JShift
```

(VOA/Moonshine/MoonshineCNTrace.lean.)

From the mathematics to the Lean statement

`PowerSeries.coeff n F` is the coefficient of X^n in F. `JShift` is the library's formal $qJ = 1 + 196884q^2 + 21493760q^3 + \cdots$ (Chapter 33); its coefficient of q^{n+1} is $c(n)$, the coefficient of q^n in J. So (d) says: $\mathrm{tr}(1|V^\natural_{n+1}) = \dim V^\natural_{n+1} = c(n)$ for all $n \geq 0$, which is the graded dimension theorem of Chapter 42 in the present normalisation. (e) is a deliberate "negative" lemma: the constant coefficients are 0 and 1. It records the index shift as a theorem so that it cannot be silently confused. All statements are the textbook ones.

Proof on paper. (a) is the definition. (b) $V^\natural_1 = 0$, so $g|_{V^\natural_1}$ is the zero map on the zero space. (c) Proposition 43.3(b) coefficientwise. (d) $\mathrm{tr}(1|V^\natural_{n+1}) = \dim V^\natural_{n+1}$, and $\dim V^\natural_m = [q^m]\,\texttt{JShift}$ for all $m \geq 0$ (`finrank_gradingNat_eq_coeff_JShift`, Chapter 33). (e) The constant coefficients are 0 (by (b)) and 1. □

Physical meaning

(b) says the Monster CFT has no weight-one states: no currents, so the twisted partition functions have no constant term. This is why the Hauptmoduln are *normalised* with constant term 0.

What the machine verified

Unconditional; all six printed in `VOA/Moonshine/MoonshineCNAudit.lean`, standard axioms.

43.4.3 Trace bounds

To evaluate T_g at a point of $\mathbb{H}$ one needs the series to converge. The trace of a finite-order linear map is bounded by the dimension, and J converges on $\mathbb{H}$; that is the whole argument.

Theorem 43.6 (Trace bounds). *(a) If f is a linear endomorphism of finite order of a finite-dimensional complex vector space M, then $|\operatorname{tr} f| \leq \dim M$.*

(b) If g is an automorphism of finite order of a vertex operator algebra V, then $|\operatorname{tr}(g|V_n)| \leq \dim V_n$ for all n.

(c) If $g \in \mathrm{Aut}(V^\natural)$ has finite order, then $|[X^n]\,\mathrm{MT}_g| \leq |[X^n]\,\mathrm{MT}_1| = c(n)$ for all $n \geq 0$.

```
theorem finiteOrderTrace_norm_le {M : Type*} [AddCommGroup M] [Module ℂ M]
    [FiniteDimensional ℂ M] (f : Module.End ℂ M) (hf : IsOfFinOrder f) :
    ‖LinearMap.trace ℂ M f‖ ≤ Module.finrank ℂ M

theorem gradedAutTrace_norm_le {M : Type*} [AddCommGroup M] [Module ℂ M]
    (V : VertexOperatorAlgebra M) (g : Aut V) (hg : IsOfFinOrder g) (n : ℤ) :
    ‖gradedAutTrace V g n‖ ≤ Module.finrank ℂ (V.grading n)

theorem mckayThompson_coeff_norm_le (g : AutVnat) (hg : IsOfFinOrder g) (n : ℕ) :
    ‖PowerSeries.coeff n (mckayThompson g)‖ ≤
      ‖PowerSeries.coeff n (mckayThompson 1)‖
```

(`VOA/Moonshine/MoonshineCNTraceBounds.lean`.)

From the mathematics to the Lean statement

`IsOfFinOrder f` (Mathlib) means $f^N = 1$ for some $N \geq 1$. `‖z‖` is the absolute value of a complex number. `[FiniteDimensional ℂ M]` is the hypothesis $\dim M < \infty$. In (b) the

finite-dimensionality of V_n comes from the vertex operator algebra axioms. In (c) the right-hand side is $|\operatorname{tr}(1|V^\natural{}_{n+1})| = \dim V^\natural{}_{n+1}$. The hypothesis "finite order" is essential (a non-unitary automorphism of infinite order could have large traces), and it is discharged for *every* $g \in \mathrm{Aut}(V^\natural)$ by `autVnat_isOfFinOrder` in Chapter 47. The file docstring stresses that no invariant Hermitian metric is used.

Proof on paper. (a) If $f^N = 1$ then every eigenvalue λ satisfies $\lambda^N = 1$, so $|\lambda| = 1$. Over $\mathbb{C}$ the characteristic polynomial splits and $\operatorname{tr} f$ is the sum of its $\dim M$ roots (with multiplicity); the triangle inequality gives $|\operatorname{tr} f| \le \dim M$. (b) Apply (a) to $g|_{V_n}$, which has finite order because restriction is a homomorphism. (c) Apply (b) to $V^\natural{}_{n+1}$ and use Proposition 43.3(a). □

Physical meaning

A finite symmetry acts on each energy level by a unitary matrix in a suitable basis, so twisting can only reduce the magnitude of the partition-function coefficients: $|\operatorname{tr}(g|V_n)| \le \dim V_n$. In particular T_g converges wherever the untwisted partition function J does.

What the machine verified

Unconditional (with the finite-order hypothesis explicit); printed in `VOA/Moonshine/MoonshineCNAudit3.lean`, standard axioms.

43.4.4 The McKay–Thompson series as a function on the upper half-plane

Definition 43.7 (McKay–Thompson function). For $g \in \mathrm{Aut}(V^\natural)$ and $\tau \in \mathbb{H}$, with $q = e^{2\pi i\tau}$,

$$T_g(\tau) \;=\; q^{-1} + \sum_{n\ge 0} \operatorname{tr}\!\left(g \,|\, V^\natural{}_{n+1}\right) q^n \;=\; q^{-1} + \sum_{n\ge 1} \operatorname{tr}\!\left(g \,|\, V^\natural{}_{n+1}\right) q^n.$$

```
noncomputable def mckayThompsonFun (g : AutVnat) (τ : ℍ) : ℂ :=
  (qPar τ)⁻¹ + ∑' n : ℕ, PowerSeries.coeff n (mckayThompson g) * qPar τ ^ n
```

(`VOA/Moonshine/MoonshineCNStatement.lean`.)

From the mathematics to the Lean statement

`(qPar τ)⁻¹` is q^{-1}. `∑' n : ℕ, a n` is Mathlib's *unconditional infinite sum* (`tsum`): the sum of the family when it is summable, and 0 **by convention when it is not** (a junk value, Chapter 1, §1.2.8). The summand is $\operatorname{tr}(g|V^\natural{}_{n+1})\,q^n$ by Proposition 43.5(a). The $n = 0$ term is $\operatorname{tr}(g|V^\natural{}_1) = 0$, so the two displayed formulas agree; `mckayThompsonFun_eq_qSeriesFun` below makes this precise in Lean.

Does the junk value matter? No, for two independent reasons. (i) For g of finite order the series is absolutely summable at every $\tau \in \mathbb{H}$: by Theorem 43.6(c) it is dominated by $\sum_n c(n)|q|^n$, which converges because the q-expansion of J converges on the open unit disc (`hasSum_JShift_laurent`, Chapter 33); and every g has finite order (Chapter 47). (ii) Even without that, the junk value could only make the conjecture *false*, never trivially true: where the sum is not summable the function would equal q^{-1}, and q^{-1} is not invariant under any $\left(\begin{smallmatrix}1 & 0\\ N & 1\end{smallmatrix}\right)$, $N \ge 1$, which every moonshine group contains (it is in $\Gamma_0(N)$).

Physical meaning

$T_g(\tau) = \operatorname{tr}_{V^\natural}\!\left(g\, q^{L_0 - 1}\right)$, the twisted torus partition function, as an honest function of the modulus τ.

What the machine verified

Definition; printed in `VOA/Moonshine/MoonshineCNAudit3.lean`, standard axioms.

Theorem 43.8 ($T_1 = J$). *For every $\tau \in \mathbb{H}$, $T_1(\tau) = j(\tau) - 744$, where $j = E_4^3/\Delta$ is the analytic j-invariant.*

```
theorem mckayThompsonFun_one :
    mckayThompsonFun 1 = fun τ => jInvariant τ - 744
```

(`VOA/Moonshine/MoonshineCNStatement.lean`.)

From the mathematics to the Lean statement

`mckayThompsonFun 1` is T_1 for the identity automorphism `1 : AutVnat`. `jInvariant` is the analytic $j(\tau) = E_4(\tau)^3/\Delta(\tau)$ of Chapter 14, Definition 14.66 (file `VOA/Modularity/JInvariantAnalytic.lean`). The equation is an equality of functions $\mathbb{H} \to \mathbb{C}$. This is the analytic counterpart of Proposition 43.5(d); it is the bridge between the formal graded dimension of Chapters 33–42 and the analytic objects of the conjecture.

Proof on paper. By Proposition 43.5(d), the summand of T_1 is $c(n)q^n$ with $c(n) = [q^{n+1}]$ `JShift`. The theorem `hasSum_JShift_laurent` (Chapter 33) says that $\sum_{n\geq 0}[q^{n+1}]\texttt{JShift} \cdot q^n$ converges to $j(\tau) - 744 - q^{-1}$; it is proved from the q-expansion of E_4^3/Δ. Adding q^{-1} gives the claim. □

Physical meaning

The untwisted partition function of the Monster CFT is $J = j - 744$: the unique modular invariant function with the vacuum pole q^{-1} and no constant term (no currents).

What the machine verified

Unconditional; printed in `VOA/Moonshine/MoonshineCNAudit3.lean`, standard axioms.

Example 43.9 (Two McKay–Thompson series, on paper). Under any isomorphism of $\mathrm{Aut}(V^\natural)$ with the Monster, the classes $2A$ and $2B$ give (43.5) and (43.4). For instance, $V^\natural{}_2$ decomposes as $1 \oplus 196883$, so $\mathrm{tr}(g|V^\natural{}_2) = 1 + \chi_{196883}(g)$, which is 4372 for $2A$ and 276 for $2B$. For $2B$ there is a concrete representative, FLM's involution z, which acts by $+1$ on V_Λ^+ and by -1 on $(V_\Lambda^T)^+$ (it is an automorphism because the block vertex map respects the $\mathbb{Z}/2$-grading by sectors). Its trace on $V^\natural{}_2$ is $\dim(V_\Lambda^+)_2 - \dim(V_\Lambda^T)_2^+ = 98580 - 98304 = 276$ (Chapter 33 gives both dimensions). The library does not state class names; these examples are for orientation only.

43.5 Hauptmoduln and genus zero, without Riemann surfaces

43.5.1 Modular curves, cusps and genus: the classical picture

Let $\Gamma \leq \mathrm{SL}_2(\mathbb{R})$ be a subgroup commensurable with $\mathrm{SL}_2(\mathbb{Z})$. Such a group is discrete and acts properly discontinuously on $\mathbb{H}$. The quotient $Y(\Gamma) = \Gamma\backslash\mathbb{H}$ is a non-compact Riemann surface: at a point τ_0 whose stabiliser in $\Gamma/\{\pm 1\}$ has order $e > 1$ (an *elliptic point*) the local coordinate is $\big((\tau - \tau_0)/(\tau - \bar{\tau}_0)\big)^e$. The *cusps* of Γ are the points of $\mathbb{P}^1(\mathbb{R})$ fixed by parabolic elements of Γ; for our groups they are the points of $\mathbb{P}^1(\mathbb{Q})$, and there are finitely many Γ-orbits of them. Adding one point for each orbit gives a compact Riemann surface

$$X(\Gamma) = \Gamma\backslash\big(\mathbb{H} \cup \mathbb{P}^1(\mathbb{Q})\big).$$

Near the cusp ∞, if the stabiliser Γ_∞ contains $\pm\left(\begin{smallmatrix}1 & h\\ 0 & 1\end{smallmatrix}\right)$ with $h > 0$ minimal (the *width* h), the local coordinate is $e^{2\pi i\tau/h}$; at another cusp $s = \gamma\infty$ one first moves s to ∞ with γ^{-1}. The *genus* of Γ is the genus of $X(\Gamma)$.

A *modular function* for Γ is a meromorphic function on $X(\Gamma)$; equivalently, a Γ-invariant meromorphic function on $\mathbb{H}$ that is meromorphic in the local coordinate at every cusp. If $X(\Gamma)$ has genus zero, there is an isomorphism of Riemann surfaces $X(\Gamma) \to \mathbb{P}^1(\mathbb{C})$, and it can be chosen to send the cusp ∞ to ∞. Such an isomorphism is a *Hauptmodul*; every modular function for Γ is a rational function of it. If the width of ∞ is 1, the Hauptmodul has a simple pole $a\,q^{-1}$ at ∞, and replacing f by $(f - b)/a$ we may arrange $f = q^{-1} + 0 + O(q)$; with this normalisation it is unique (two Hauptmoduln differ by an automorphism of $\mathbb{P}^1(\mathbb{C})$ fixing ∞, i.e. by $z \mapsto az + b$, and the expansion $q^{-1} + 0 + \cdots$ forces $a = 1$, $b = 0$), the *normalised Hauptmodul*. For all these classical facts (compactness of $X(\Gamma)$, local coordinates at elliptic points and cusps, discreteness of groups commensurable with $\mathrm{SL}_2(\mathbb{Z})$, cusps $= \mathbb{P}^1(\mathbb{Q})$) see Diamond–Shurman, Chapters 2 and 3.

Example 43.10 (Genus-zero and not genus-zero groups)**.** $\mathrm{SL}_2(\mathbb{Z})$ has genus zero, with normalised Hauptmodul $J = j - 744$. $\Gamma_0(N)$ has genus zero exactly for $N \in \{1, \dots, 10, 12, 13, 16, 18, 25\}$; for instance the Hauptmodul of $\Gamma_0(2)$ is $(\eta(\tau)/\eta(2\tau))^{24} + 24$. $\Gamma_0(11)$ has genus one ($X_0(11)$ is an elliptic curve), so it has no Hauptmodul; but the larger group $\Gamma_0(11)+$ obtained by adjoining the Fricke involution $\tau \mapsto -1/(11\tau)$ has genus zero, and its normalised Hauptmodul is T_{11A}. Ogg's observation: $\Gamma_0(p)+$ has genus zero exactly for the fifteen primes dividing $|\mathbb{M}|$. Note that $\Gamma_0(p)+$ is not contained in $\mathrm{SL}_2(\mathbb{Z})$: the Fricke involution is $\frac{1}{\sqrt{p}}\left(\begin{smallmatrix}0 & -1\\ p & 0\end{smallmatrix}\right) \in \mathrm{SL}_2(\mathbb{R})$, with irrational entries. This is why the conjecture is formulated in $\mathrm{SL}_2(\mathbb{R})$, and the library works in $\mathrm{GL}_2(\mathbb{R})$.

The library's Mathlib (v4.30) has congruence subgroups, cusps and the action of $\mathrm{GL}_2(\mathbb{R})$, but no compactified modular curves as Riemann surfaces and no notion of genus. The statement file therefore encodes "normalised Hauptmodul of a genus-zero group" *without Riemann surfaces*: it asks that f induce a *bijection* $X(\Gamma) \to \mathbb{P}^1(\mathbb{C})$ with the right behaviour at the cusps, and leaves to the mathematics (below) the observation that such a bijection is automatically an isomorphism of Riemann surfaces.

43.5.2 Values at cusps

Definition 43.11 (Cusp data)**.** Let $c \in \mathbb{P}^1(\mathbb{R})$, $\Gamma \le \mathrm{GL}_2(\mathbb{R})$, $f : \mathbb{H} \to \mathbb{C}$ and $w \in \mathbb{C}$.

(a) $\gamma \in \mathrm{GL}_2(\mathbb{R})$ *sends* ∞ *to* c if $\det\gamma > 0$ and $\gamma \cdot \infty = c$.

(b) f *has value* w *at the cusp* c if for every γ sending ∞ to c, $f(\gamma\tau) \to w$ as $\mathrm{Im}\,\tau \to \infty$, uniformly in $\mathrm{Re}\,\tau$.

(c) c is an *other cusp* of Γ if it is a cusp of Γ and is not in the Γ-orbit of ∞.

```
def SendsInftyTo (γ : GL (Fin 2) ℝ) (c : OnePoint ℝ) : Prop :=
  0 < (γ.det : ℝ) ∧ γ • cuspInfty = c

def HasCuspValue (f : ℍ → ℂ) (c : OnePoint ℝ) (w : ℂ) : Prop :=
  ∀ γ : GL (Fin 2) ℝ, SendsInftyTo γ c → Tendsto (fun τ : ℍ => f (γ • τ)) atImInfty (𝓝 w)

def IsOtherCusp (Γ : Subgroup (GL (Fin 2) ℝ)) (c : OnePoint ℝ) : Prop :=
  IsCusp c Γ ∧ ∀ γ ∈ Γ, γ • cuspInfty ≠ c
```

(VOA/Moonshine/MoonshineCNStatement.lean.)

From the mathematics to the Lean statement

`(γ.det : ℝ)` is $\det\gamma$; `γ • cuspInfty` is $\gamma\cdot\infty = a/c$ (or ∞ if $c=0$). `Tendsto (fun τ ⇒ f (γ • τ)) atImInfty (𝓝 w)` is "$f(\gamma\tau)\to w$ as $\operatorname{Im}\tau\to\infty$, uniformly in $\operatorname{Re}\tau$" (§43.3.2). `IsCusp c Γ` is Mathlib's: c is fixed by a parabolic element of Γ.

"For every γ" versus "for some γ". Two matrices γ,γ' of positive determinant sending ∞ to c differ by an element fixing ∞: $\gamma' = \gamma\beta$ with $\beta\tau = a\tau+b$, $a>0$. Since $\operatorname{Im}(a\tau+b)\to\infty$ uniformly exactly when $\operatorname{Im}\tau\to\infty$, the limit along γ exists iff it exists along γ', with the same value. So the universal quantifier in `HasCuspValue` is equivalent to an existential one; it simply avoids choosing a matrix. The condition is the usual one: f is bounded near c and extends continuously (indeed, for invariant holomorphic f, holomorphically in the cusp coordinate, by Riemann's removable singularity theorem) with value w.

Physical meaning

A cusp of Γ is a degeneration limit of the torus, seen through a modular transformation in Γ; the other cusps correspond to long tori in which a twisted sector propagates. "f has a finite value at the other cusps" says that only the cusp ∞ carries the vacuum pole q^{-1}: in the other degeneration limits the partition function is dominated by states of non-negative effective energy.

What the machine verified

Definitions; printed in `VOA/Moonshine/MoonshineCNAudit3.lean`, standard axioms.

43.5.3 The normalised Hauptmodul

Definition 43.12 (Normalised Hauptmodul)**.** Let $\Gamma\le \mathrm{GL}_2(\mathbb{R})$ and $f:\mathbb{H}\to\mathbb{C}$. f is a *normalised Hauptmodul for* Γ if:

(H1) f is holomorphic on $\mathbb{H}$ *(no poles in the interior)*;

(H2) $f(\gamma\tau)=f(\tau)$ for all $\gamma\in\Gamma$, $\tau\in\mathbb{H}$ *(f descends to $\Gamma\backslash\mathbb{H}$)*;

(H3) $f(\tau)-q^{-1}\to 0$ as $\operatorname{Im}\tau\to\infty$ *(a simple pole at the cusp ∞, normalised $q^{-1}+0+O(q)$)*;

(H4) f has a (finite) value at every other cusp of Γ *(no poles at the other cusps: so F below is well defined and takes the value ∞ only at the cusp ∞)*;

(H5) if $f(\tau)=f(\sigma)$ then $\sigma=\gamma\tau$ for some $\gamma\in\Gamma$ *(F is injective on interior points)*;

(H6) a value of f at an other cusp is not attained on $\mathbb{H}$ *(F never gives an interior point and a cusp the same value)*;

(H7) if two other cusps c,c' have the same value, then $c'=\gamma c$ for some $\gamma\in\Gamma$ *(F is injective on cusps)*;

(H8) every $w\in\mathbb{C}$ is attained on $\mathbb{H}$ or is the value of f at an other cusp *(F is surjective)*.

Here $F:X(\Gamma)\to\mathbb{P}^1(\mathbb{C})$ is the map induced by f: $F(\Gamma\tau)=f(\tau)$ on interior points, F of the cusp ∞ is ∞, and F of another cusp is the value of f there. So (H1)–(H4) say that f is a modular function for Γ with a single, simple, normalised pole at ∞; (H5)–(H7) say that F is injective (on interior points, between interior points and cusps, and on cusps); (H8) says F is surjective. Example 43.14 checks all eight clauses for $\Gamma_0(2)$. A subgroup is *of genus zero* (with a cusp of width one at ∞) if it has a normalised Hauptmodul.

  ∃ f : ℍ → ℂ, IsNormalizedHauptmodul Γ f
```

(`VOA/Moonshine/MoonshineCNStatement.lean`.)

From the mathematics to the Lean statement

Field by field. A `structure ... : Prop` is a conjunction of named clauses (Chapter 1, §1.2.5).

- `holomorphic` is (H1).
- `invariant` is (H2), with γ acting by `γ • τ`.
- `normalized` is (H3): `f τ - (qPar τ)⁻¹ → 0` along `atImInfty`. For a 1-periodic holomorphic f (which is the case in the conjecture, see below) this says exactly that the Fourier expansion of f is $q^{-1} + \sum_{n\geq 1} a_n q^n$: a simple pole with residue normalised to 1, *zero constant term*, and no other negative powers.
- `cuspFinite` is (H4).
- `injective`, `cuspValue_not_attained`, `cuspValue_injective` are (H5)–(H7): together they say that the induced map $F : X(\Gamma) \to \mathbb{P}^1(\mathbb{C})$, defined by $F(\Gamma\tau) = f(\tau)$, $F(\Gamma\infty) = \infty$ and $F(\Gamma c)$ = the value at c, is *injective*. (Points of $\mathbb{H}$ never go to ∞ because f is $\mathbb{C}$-valued, and the other cusps have finite values by (H4); so the only point mapped to ∞ is the cusp ∞.)
- `surjective` is (H8): F is *surjective* (∞ is hit by the cusp ∞).

`IsGenusZero Γ` is `∃ f, IsNormalizedHauptmodul Γ f`. It is *not* used in the statement of the conjecture; it records the terminology.

Same as the textbook notion? For $\Gamma \leq \mathrm{SL}_2(\mathbb{R})$ commensurable with $\mathrm{SL}_2(\mathbb{Z})$ and containing the translation $\tau \mapsto \tau + 1$ (both hold in the conjecture), `IsNormalizedHauptmodul Γ f` holds if and only if $X(\Gamma)$ has genus zero, the width of ∞ is 1, and f is its normalised Hauptmodul. The proof is Proposition 43.13 below. It is a paper argument: the library contains neither Riemann surfaces nor genus, so this equivalence is a statement *about* the definition, not a Lean theorem. This is the central translation step of the chapter, and the referee should check it.

How the definition could have been wrong, and why it is not.

- *Too weak, by choosing Γ too small?* Field `injective` prevents this: the fibres of f on $\mathbb{H}$ must be single Γ-orbits. If $f(\delta\tau) = f(\tau)$ for some $\delta \in \mathrm{SL}_2(\mathbb{R})$ and all τ, then for each τ some $\gamma_\tau \in \Gamma$ has $\gamma_\tau\tau = \delta\tau$. When Γ is countable (as it is in the conjecture, being commensurable with $\mathrm{SL}_2(\mathbb{Z})$), one γ works for uncountably many τ; then $\gamma^{-1}\delta \in \mathrm{SL}_2(\mathbb{R})$ fixes at least two points of $\mathbb{H}$, and a non-scalar Möbius map fixes at most one,

so $\gamma^{-1}\delta = \pm 1$. Hence $\pm\Gamma$ is the *full* invariance group of f in $\mathrm{SL}_2(\mathbb{R})$: the group is determined by the function, up to ± 1.

- *Too weak, by allowing a pole of higher order, or poles at other cusps, or in* $\mathbb{H}$*?* Excluded by `normalized`, `cuspFinite` and f being $\mathbb{C}$-valued and holomorphic.
- *Too weak, by allowing F to be of higher degree?* Excluded by injectivity: a degree-d map with $d \geq 2$ identifies d points of a generic fibre.
- *Too strong, by demanding something false of J?* No: J satisfies all eight clauses for $\Gamma = \mathrm{SL}_2(\mathbb{Z})$, by Proposition 43.13 and the classical fact that $X(\mathrm{SL}_2(\mathbb{Z}))$ has genus zero with Hauptmodul J (Chapter 33, Theorem 33.5).
- *Vacuous because cusps are mis-specified?* The cusps are Mathlib's parabolic fixed points; for groups commensurable with $\mathrm{SL}_2(\mathbb{Z})$ they are $\mathbb{P}^1(\mathbb{Q})$, as they should be.

Physical meaning

A normalised Hauptmodul is the partition function of a chiral theory whose symmetry group is Γ. Being a Hauptmodul means it is a single coordinate on the moduli space $\Gamma\backslash\mathbb{H}^*$ of tori with Γ-structure. Normalisation $q^{-1} + 0 + O(q)$ says the theory has a unique ground state of energy $-c/24 = -1$ and no weight-one currents. In moonshine, T_g is the torus partition function of $V^\natural$ twisted by the symmetry g in the time direction. The genus-zero property says this twisted partition function alone determines the whole modular curve on which it lives.

Proposition 43.13 (What the eight fields mean; on paper). *Let* $\Gamma \leq \mathrm{SL}_2(\mathbb{R})$ *be commensurable with* $\mathrm{SL}_2(\mathbb{Z})$ *and contain* $\left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right)$.

(a) If f satisfies (H1)–(H8), then the width of ∞ is 1, the map $F : X(\Gamma) \to \mathbb{P}^1(\mathbb{C})$ is an isomorphism of Riemann surfaces, $X(\Gamma)$ has genus zero, and f is the normalised Hauptmodul of Γ.

(b) Conversely, if $X(\Gamma)$ has genus zero and ∞ has width 1, the normalised Hauptmodul satisfies (H1)–(H8).

Proof on paper. (a) *Width.* If Γ contained $\tau \mapsto \tau + h$ with $0 < h < 1$, then $f(\tau + h) = f(\tau)$ while $f(\tau) = e^{-2\pi i\tau} + o(1)$; comparing, $(e^{-2\pi ih} - 1)e^{-2\pi i\tau} \to 0$, which forces $e^{2\pi ih} = 1$, impossible. So the width is 1 and q is the local coordinate at ∞. *Holomorphy of F.* On $Y(\Gamma)$: f is holomorphic and invariant, hence a holomorphic function of the local coordinate (at an elliptic point τ_0 of order e, an invariant holomorphic function is a power series in $(\tau - \tau_0)^e/(\tau - \bar{\tau}_0)^e$). At ∞: by (H2) and periodicity $f = \sum_n a_n q^n$, and by (H3) $f = q^{-1} + O(q)$, so $1/F = q + O(q^2)$ is holomorphic with a simple zero. At another cusp $c = \gamma\infty$: $f \circ \gamma$ is invariant under the (conjugated) stabiliser and tends to w by (H4), so by Riemann's removable singularity theorem it is holomorphic in the cusp coordinate with value w. So F is a holomorphic map of compact Riemann surfaces. *Bijectivity.* Injectivity was explained in the dictionary; surjectivity is (H8) together with $F(\infty) = \infty$. A bijective holomorphic map between Riemann surfaces is a biholomorphism (an injective holomorphic map has nowhere vanishing derivative in local coordinates). Hence $X(\Gamma) \cong \mathbb{P}^1(\mathbb{C})$ has genus zero, and F is a Hauptmodul with the normalisation $q^{-1} + 0 + O(q)$.

(b) Let $F : X(\Gamma) \to \mathbb{P}^1(\mathbb{C})$ be an isomorphism with $F(\infty) = \infty$, normalised to $q^{-1} + 0 + O(q)$ (possible because the width is 1), and $f = F \circ \pi$ on $\mathbb{H}$. Then (H1)–(H4) hold because F is holomorphic with its only pole at ∞; (H5)–(H8) hold because F is bijective. □

Example 43.14 (The eight clauses for $\Gamma_0(2)$; on paper). Let $\Gamma = \Gamma_0(2)$ and $f = t + 24$, $t(\tau) = (\eta(\tau)/\eta(2\tau))^{24} = \Delta(\tau)/\Delta(2\tau)$, so that $f = T_{2B}$ of (43.4). *The quotient.* $\Gamma_0(2)$ has index 3 in $\mathrm{SL}_2(\mathbb{Z})$.

A cusp a/c (in lowest terms; $\infty = 1/0$) is $\Gamma_0(2)$-equivalent to ∞ if c is even and to 0 if c is odd, so there are two cusp orbits: ∞, of width 1 (the stabiliser contains $\tau \mapsto \tau + 1$), and 0, of width 2 (its stabiliser is conjugated by $S = \left(\begin{smallmatrix} 0 & -1 \\ 1 & 0 \end{smallmatrix}\right)$ to the translations by multiples of 2). There is one elliptic point, $(1 + i)/2$, of order 2. The other cusps in the sense of Definition 43.11 are exactly the rationals a/c with c odd.

- (H1): η has no zeros on $\mathbb{H}$, so t is holomorphic.
- (H2): $\Delta(\tau)$ and $\Delta(2\tau)$ are both modular forms of weight 12 for $\Gamma_0(2)$, so their quotient is invariant.
- (H3): $t = q^{-1}\prod_{n\geq 1}(1+q^n)^{-24} = q^{-1} - 24 + 276q + \cdots$, so $f = q^{-1} + 0 + 276q + \cdots$.
- (H4): the cusp 0 is $S\infty$ ($\det S = 1 > 0$). From $\Delta(-1/\tau) = \tau^{12}\Delta(\tau)$ one gets $t(S\tau) = 2^{12}\Delta(\tau)/\Delta(\tau/2) = 2^{12}q^{1/2}(1 + O(q^{1/2})) \to 0$, so f has the value 24 at the cusp 0, and hence (by invariance) at every other cusp. The half-integral power $q^{1/2}$ is the width-2 coordinate.
- (H6): $f(\tau) = 24$ would mean $\Delta(\tau) = 0$, which never happens; so the cusp value 24 is not attained on $\mathbb{H}$.
- (H7): there is only one orbit of other cusps, so any two other cusps are Γ-equivalent.
- (H5), (H8): the induced $F : X_0(2) \to \mathbb{P}^1(\mathbb{C})$ is a meromorphic function on a compact Riemann surface whose only pole is the simple pole at ∞ (by (H1), (H3), (H4)). A non-constant meromorphic function takes every value in $\mathbb{P}^1(\mathbb{C})$ exactly as many times as it has poles, counted with multiplicity; here once. So F is bijective: every $w \neq 24$ is attained at exactly one orbit in $\Gamma\backslash\mathbb{H}$ ((H5), (H8)), and 24 is attained only at the cusp 0. (In particular $X_0(2)$ has genus zero.)

This is the pattern of every application: (H1)–(H4) are local checks, and the global clauses (H5)–(H8) follow from "exactly one simple pole". For the McKay–Thompson series no such explicit formula is available in general, which is why the library proves the global clauses by the case-free argument of Chapter 46.

Physical meaning

Think of $X(\Gamma)$ as a moduli space: the space of tori (of modulus τ) carrying a fixed symmetry twist, modulo those modular transformations in Γ that preserve the twist. Its cusps are the degeneration limits (infinitely long tori). "Genus zero with Hauptmodul f" says that this moduli space is a sphere and that the twisted partition function f is a global coordinate on it, with the vacuum pole q^{-1} at the one degeneration where the untwisted vacuum propagates and finite values at all others. Consequently any other quantity of the theory that is invariant under Γ, holomorphic on $\mathbb{H}$ and has at most poles at the degeneration limits is a rational function of f (a polynomial if its only pole is at ∞); this is the twisted analogue of the statement that a $c = 24$ holomorphic partition function is J + const. It is a rigid condition: twisted partition functions of a general orbifold are invariant under congruence groups of positive genus.

What the machine verified

`IsNormalizedHauptmodul`, `IsGenusZero`: definitions, printed in `VOA/Moonshine/MoonshineCNAudit3.lean`, standard axioms. Proposition 43.13: argued on paper only (it is about the meaning of the definition and needs Riemann surfaces, which the library does not have).

43.6 Moonshine groups and the Conway–Norton statement

43.6.1 Moonshine groups

Definition 43.15 (Moonshine group)**.** For $N \in \mathbb{N}$, $\Gamma_0(N)$ and $\Gamma_1(N)$ are regarded as subgroups of $\mathrm{GL}_2(\mathbb{R})$. A subgroup $\Gamma \leq \mathrm{GL}_2(\mathbb{R})$ is a *moonshine group of level N* if $N \geq 1$, $\Gamma \leq \mathrm{SL}_2(\mathbb{R})$, $\Gamma_0(N) \leq \Gamma$, and Γ is commensurable with $\mathrm{SL}_2(\mathbb{Z})$ (i.e. $\Gamma \cap \mathrm{SL}_2(\mathbb{Z})$ has finite index in both Γ and $\mathrm{SL}_2(\mathbb{Z})$).

Terminology. "Moonshine group" is this chapter's (and the library's) local name, taken from the Lean definition `IsMoonshineGroup`. In the literature the phrase is used differently (for instance for the genus-zero groups of the Conway–Norton list, or for the groups of "moonshine type" of Conway–McKay–Sebbar); a reader consulting Gannon or Conway–Norton will not find this exact definition there.

```
abbrev gamma0GL (N : ℕ) : Subgroup (GL (Fin 2) ℝ) := ((Gamma0 N : Subgroup SL(2, ℤ)) :
 ↪ Subgroup (GL (Fin 2) ℝ))
abbrev gamma1GL (N : ℕ) : Subgroup (GL (Fin 2) ℝ) := ((Gamma1 N : Subgroup SL(2, ℤ)) :
 ↪ Subgroup (GL (Fin 2) ℝ))

def IsMoonshineGroup (Γ : Subgroup (GL (Fin 2) ℝ)) (N : ℕ) : Prop :=
  0 < N ∧ Γ.HasDetOne ∧ gamma0GL N ≤ Γ ∧ Subgroup.Commensurable Γ 𝒮ℒ
```

(`VOA/Moonshine/MoonshineCNStatement.lean`.)

From the mathematics to the Lean statement

Decoding. `((Gamma0 N : Subgroup SL(2, ℤ)) : Subgroup (GL (Fin 2) ℝ))` is the image of Mathlib's $\Gamma_0(N) \leq \mathrm{SL}_2(\mathbb{Z})$ under `mapGL ℝ` (§43.3.2); likewise `gamma1GL`. In `IsMoonshineGroup Γ N`: `0 < N` is $N \geq 1$; `Γ.HasDetOne` is $\Gamma \leq \mathrm{SL}_2(\mathbb{R})$; `gamma0GL N ≤ Γ` is $\Gamma_0(N) \subseteq \Gamma$; `Subgroup.Commensurable Γ 𝒮ℒ` is commensurability with $\mathrm{SL}_2(\mathbb{Z})$.
Each clause, and why it is the intended one.

- *Ambient group* $\mathrm{GL}_2(\mathbb{R})$*, not* $\mathrm{SL}_2(\mathbb{Z})$: necessary, since many Conway–Norton groups contain Atkin–Lehner and Fricke elements with irrational entries (Example 43.10).
- $\Gamma \leq \mathrm{SL}_2(\mathbb{R})$: Conway–Norton's groups are subgroups of $\mathrm{SL}_2(\mathbb{R})$ (or of $\mathrm{PSL}_2(\mathbb{R})$; note $-1 \in \Gamma_0(N) \leq \Gamma$ always, so nothing is lost by working with matrices rather than Möbius maps). Without this clause one could add orientation-reversing or scaling elements; with it, the action on $\mathbb{H}$ is the usual one.
- $\Gamma_0(N) \leq \Gamma$ *with* $N \geq 1$: this is the "congruence" clause of the conjecture. It forces Γ to contain $\left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right)$ (so T_g is 1-periodic, which it is anyway) and $\left(\begin{smallmatrix} 1 & 0 \\ N & 1 \end{smallmatrix}\right)$ (a non-trivial condition on T_g). For $N = 1$ it forces $\Gamma \supseteq \mathrm{SL}_2(\mathbb{Z})$.
- *Commensurable with* $\mathrm{SL}_2(\mathbb{Z})$: implies that Γ is discrete, of finite covolume, with cusps $\mathbb{P}^1(\mathbb{Q})$; together with $\Gamma_0(N) \leq \Gamma$ it says $[\Gamma : \Gamma_0(N)] < \infty$.

Could the clauses be trivially satisfied? $\Gamma = \Gamma_0(1) = \mathrm{SL}_2(\mathbb{Z})$, $N = 1$ satisfies `IsMoonshineGroup`; so the definition is not vacuous. It is also not trivially satisfiable *together with* `IsNormalizedHauptmodul Γ f`: by the dictionary of Definition 43.12, $\pm\Gamma$ is the full invariance group of f, so the content of `IsMoonshineGroup Γ N` is "the invariance group of f contains $\Gamma_0(N)$ and is commensurable with $\mathrm{SL}_2(\mathbb{Z})$". For example q^{-1} alone, or any f invariant only under translations, admits no moonshine group.
Not required (deliberately). The definition does not ask that Γ normalise $\Gamma_0(N)$, nor that N be related to the order of g; see §43.6.3.

Physical meaning

Write $Z(h,g)$ for the torus partition function with commuting symmetry twists h along the space cycle and g along the time cycle, so that $T_g = Z(1,g)$. A modular transformation $\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$ relabels the two cycles and sends $Z(h,g)$ to $Z(h^a g^c, h^b g^d)$ (up to a phase). For $h = 1$ and g of order N, the matrices with $c \equiv 0 \pmod N$, i.e. $\Gamma_0(N)$, keep the space cycle untwisted and send T_g to T_{g^d}; those of $\Gamma_1(N)$ ($d \equiv 1$) send it back to T_g. So invariance under $\Gamma_1(N)$ is the expected modularity of a twisted partition function, and invariance under $\Gamma_0(N)$ adds the statement $T_{g^d} = T_g$. (The phases are why Conway and Norton's level is $o(g)h$ rather than $o(g)$.) Commensurability with $\mathrm{SL}_2(\mathbb{Z})$ says that Γ is built from finitely many such relabellings up to finite index; heuristically, this is the content of orbifold modular invariance.

What the machine verified

Definitions; `gamma0GL`, `gamma1GL`, `IsMoonshineGroup` printed in `VOA/Moonshine/MoonshineCNAudit3.lean`, standard axioms.

43.6.2 The conjecture

Definition 43.16 (The Conway–Norton property and the Conway–Norton conjecture). $g \in \mathrm{Aut}(V^\natural)$ has the *Conway–Norton property* if there are a subgroup $\Gamma \le \mathrm{GL}_2(\mathbb{R})$ and $N \in \mathbb{N}$ such that Γ is a moonshine group of level N and T_g is a normalised Hauptmodul for Γ. The *Conway–Norton conjecture* (for $\mathrm{Aut}(V^\natural)$) is: every $g \in \mathrm{Aut}(V^\natural)$ has the Conway–Norton property. For a group homomorphism $\iota : G \to \mathrm{Aut}(V^\natural)$, *Conway–Norton via ι* means: $\iota(g)$ has the Conway–Norton property for every $g \in G$.

```
def ConwayNortonFor (g : AutVnat) : Prop :=
  ∃ (Γ : Subgroup (GL (Fin 2) ℝ)) (N : ℕ), IsMoonshineGroup Γ N ∧
    IsNormalizedHauptmodul Γ (mckayThompsonFun g)

def ConwayNortonConjecture : Prop :=
  ∀ g : AutVnat, ConwayNortonFor g

def ConwayNortonVia {M : Type*} [Group M] (ι : M →* AutVnat) : Prop :=
  ∀ g : M, ConwayNortonFor (ι g)
```

(`VOA/Moonshine/MoonshineCNStatement.lean`.)

From the mathematics to the Lean statement

Unfolded, `ConwayNortonConjecture` is

$$\forall g \in \mathrm{Aut}(V^\natural)\ \exists\, \Gamma \le \mathrm{GL}_2(\mathbb{R})\ \exists\, N \in \mathbb{N}:$$
$$N \ge 1,\ \ \Gamma \le \mathrm{SL}_2(\mathbb{R}),\ \ \Gamma_0(N) \le \Gamma,\ \ \Gamma \text{ commensurable with } \mathrm{SL}_2(\mathbb{Z}),$$
$$T_g \text{ satisfies (H1)–(H8) for } \Gamma.$$

The quantifier order is the right one: Γ and N depend on g. `ConwayNortonVia ι` is the same statement for $\iota(g)$, $g \in G$; for any ι it follows immediately from `ConwayNortonConjecture`, and it is the form in which the Monster version is stated in Chapter 49 ($G = \mathrm{Aut}\mathbb{O}$ and ι an isomorphism). The full comparison with Conway and Norton's conjecture is §43.6.3.

Physical meaning

For every global symmetry g of the Monster CFT, the torus partition function with a g-twist is a global coordinate on a genus-zero modular curve, with the vacuum pole at the cusp ∞ and finite values at all other degenerations.

What the machine verified

Definitions (propositions); printed in `VOA/Moonshine/MoonshineCNAudit3.lean`, standard axioms. The proposition `ConwayNortonConjecture` is *proved*, with no hypotheses, as `conwayNorton` (§43.9). The statement file was fixed before the proof was attempted and has not been modified since.

Definition 43.17 (The Γ_1 variant)**.** The Γ_1 *form of the conjecture*: for every $g \in \mathrm{Aut}(V^\natural)$ *of finite order* there are $\Gamma \leq \mathrm{SL}_2(\mathbb{R})$ and $N \geq 1$ with $\Gamma_1(N) \leq \Gamma$, Γ commensurable with $\mathrm{SL}_2(\mathbb{Z})$, and T_g a normalised Hauptmodul for Γ.

```
def ConwayNortonGammaOne : Prop :=
  ∀ g : AutVnat, IsOfFinOrder g → ∃ (Γ : Subgroup (GL (Fin 2) ℝ)) (N : ℕ),
    0 < N ∧ Γ.HasDetOne ∧ gamma1GL N ≤ Γ ∧ Subgroup.Commensurable Γ 𝒮ℒ ∧
      IsNormalizedHauptmodul Γ (mckayThompsonFun g)
```

(`VOA/Moonshine/MoonshineCNStatement.lean`.)

From the mathematics to the Lean statement

`IsOfFinOrder g`: $g^n = 1$ for some $n \geq 1$. The clauses are those of `IsMoonshineGroup`, with `gamma1GL N` instead of `gamma0GL N`. Since $\Gamma_1(N) \leq \Gamma_0(N)$, the conclusion is weaker than that of `ConwayNortonFor`; the extra hypothesis of finite order makes the whole proposition weaker still. It is the natural output of the case-free genus-zero argument (Chapter 46) and the input of the bridge of §43.8, which upgrades it to `ConwayNortonConjecture`.

Physical meaning

$\Gamma_1(N)$ is the subgroup that preserves the twist *exactly*, not only up to replacing g by a power g^u, $\gcd(u, N) = 1$. The difference between Γ_1 and Γ_0 is therefore the statement that the twisted partition functions of g and of g^u coincide: a "Galois" symmetry of the twisted partition functions, which is proved in §43.8 (Theorem 43.33).

What the machine verified

Definition; printed in `VOA/Moonshine/MoonshineCNAudit3.lean`. Proved with no hypotheses as `conwayNortonGammaOne_holds` (`VOA/Moonshine/MoonshineCNRationalTraces.lean`, Chapter 49).

43.6.3 Is `ConwayNortonConjecture` the Conway–Norton conjecture?

This is the fidelity check on which the whole part rests. We compare the Lean proposition with the conjecture as stated in §43.1, clause by clause, and then with the stronger statements in Conway and Norton's paper.

(1) The group acting. The conjecture is about the Monster acting on FLM's $V^\natural$. The Lean proposition quantifies over `AutVnat`, the automorphism group of the library's `VnatVOA`. Two separate identifications are therefore involved.

- *The module.* `VnatVOA` is the vertex operator algebra on the FLM space constructed in Chapters 38–42; Chapter 42 records that its identification with FLM's $V^\natural$ (same space, possibly a different-looking twisted×twisted vertex operator) is a paper argument (uniqueness of simple-current extensions).

- *The group.* `AutVnat` is the full automorphism group, whatever it is. The Lean statement is therefore at least as strong as the conjecture for any subgroup, in particular for the Monster *as a group of automorphisms of* $V^\natural$. Chapter 49 proves, with no hypotheses, that `AutVnat` is isomorphic to the subgroup of AxiomMath's AutO consisting of the elements that act on $V^\natural$, which contains Gmat $\supseteq 2^{1+24}.\mathrm{Co}_1$; and, given `GmatEqAutO`, that `AutVnat` $\cong$ AutO.

So `conwayNorton` is the conjecture for the group of all symmetries of the library's $V^\natural$; "for the Monster" requires Chapter 49 and, for all of AutO, the hypothesis `GmatEqAutO`.

(2) The series. `mckayThompsonFun g` is $q^{-1} + \sum_{n\geq 1} \mathrm{tr}(g|V^\natural{}_{n+1})q^n$, exactly T_g (Definition 43.7), with the conventions $q = e^{2\pi i\tau}$ and weight $n+1$ in degree n. The `tsum` junk value is harmless (dictionary of Definition 43.7). For $g = 1$ it is $j - 744$ (Theorem 43.8).

(3) "Normalised Hauptmodul of a genus-zero group". Encoded by `IsNormalizedHauptmodul`, which is equivalent to the textbook notion for the groups in question (Proposition 43.13, on paper). The normalisation $q^{-1} + 0 + O(q)$ is Conway–Norton's: it matches $\mathrm{tr}(g|V^\natural{}_0) = 1$ and $\mathrm{tr}(g|V^\natural{}_1) = 0$.

(4) "Contains $\Gamma_0(N)$ and is commensurable with $\mathrm{SL}_2(\mathbb{Z})$". Encoded by `IsMoonshineGroup`, clause by clause (dictionary of Definition 43.15). The Lean statement has $\Gamma_0(N)$, not the weaker $\Gamma_1(N)$; the Γ_1 form is a separate proposition.

(5) The identity element. For $g = 1$ the statement says that J is the normalised Hauptmodul of some moonshine group. By the dictionary of Definition 43.12, $\pm\Gamma$ is then the full invariance group of J, which is $\mathrm{SL}_2(\mathbb{Z})$; so on paper the $g = 1$ case is exactly the classical fact that J is the normalised Hauptmodul of $\mathrm{SL}_2(\mathbb{Z})$. This classical fact is not separately stated in the library (Chapter 14 records that the textbook Hauptmodul theorem for j is not formalised as such), but `conwayNorton 1`, combined with `mckayThompsonFun_one`, gives in Lean that $j - 744$ is a normalised Hauptmodul of *some* moonshine group.

(6) What Conway and Norton said in addition. Their paper proposes, for each class, the group Γ_g in the form $\Gamma_0(n|h) + e, f, \ldots$, lying between $\Gamma_0(N)$ and its normaliser in $\mathrm{SL}_2(\mathbb{R})$ with $N = nh$, $n = o(g)$, $h \mid \gcd(24, n)$; and the explicit Hauptmodul. The Lean statement asserts neither: it is the *qualitative* genus-zero statement ("the main conjecture" in the literature, and the form in which Borcherds' theorem is usually quoted). It is therefore **weaker** than the full table-level conjecture, in three precise respects: (i) Γ is not identified; (ii) Γ is not required to lie in the normaliser of $\Gamma_0(N)$; (iii) N is not related to $o(g)$. It is **the same** as the genus-zero form of the conjecture displayed in §43.1. The project's records state this explicitly: the statement is qualitative only (no identification of Γ_g with the Conway–Norton table).

(7) Could it be vacuous? The proposition is a universally quantified statement over `AutVnat`; it would be weak if `AutVnat` were small. It is not: Chapter 49 shows that `AutVnat` contains a copy of Gmat. Each instance is strong: for each g it determines the invariance group of T_g up to sign (dictionary of Definition 43.12) and asserts that it is a genus-zero congruence-type group. There is no hidden hypothesis: `ConwayNortonConjecture` is a closed proposition, and `conwayNorton` proves it with no arguments.

Verdict. `ConwayNortonConjecture` is the genus-zero (qualitative) form of the Conway–Norton conjecture, for the full automorphism group of the library's moonshine module. It is weaker than the table-level conjecture in the three respects of (6), and it becomes a statement about the Monster through Chapter 49.

Trap / dead end

Docstrings that say more than the Lean. The module docstring of `VOA/Moonshine/MoonshineCNStatement.lean` begins "For every automorphism g of the moonshine module $V^\natural$ (the Monster, node M1)"; the parenthesis identifies `AutVnat` with the Monster, which holds only given `GmatEqAutO` (Chapter 49). The docstring of `ConwayNortonConjecture` is careful ("With M1 (`AutVnat ≃* 𝕄`) this is the conjecture for every element of the Monster"). The docstring of `RationalTraces` calls it "the M1-side input that upgrades Γ_1 to Γ_0"; that was the original plan, but the upgrade actually used does not need rationality (§43.8), and rationality is now a corollary. The Lean statements are unaffected; the statement file was frozen before the proof.

43.7 Replication, replicable families and rational traces

The statement file also fixes the interface between the Lie-algebra side of the proof (Chapters 44–46, which produce *replication formulas*) and the analytic side (Chapter 46 and §43.8, which turn replication into genus zero). We present these definitions here because they are part of the fixed statement file and because §43.8 uses them.

43.7.1 Hecke operators and replication

For a 1-periodic function f on $\mathbb{H}$ and $m \geq 1$, the (unnormalised) Hecke operator is

$$(f \mid T_m)(\tau) = \sum_{ad=m} \sum_{0 \leq b < d} f\Big(\frac{a\tau + b}{d}\Big), \tag{43.7}$$

the sum over the $\sigma_1(m)$ upper-triangular integer matrices $\left(\begin{smallmatrix} a & b \\ 0 & d \end{smallmatrix}\right)$ of determinant m with $0 \leq b < d$. If $f = J$, then $J|T_m$ is again $\mathrm{SL}_2(\mathbb{Z})$-invariant, holomorphic on $\mathbb{H}$, and has q-expansion $q^{-m} + O(q)$: for fixed a, d the sum over b of $q^{k/d}$-terms keeps only exponents with $d \mid k$, so only integral powers of q survive; the most negative one is q^{-m} (from $a = m$, $d = 1$); and the constant term is $\sigma_1(m)\, c(0) = 0$ because J has no constant term. Hence it is a polynomial in J: there is a unique monic polynomial P_m of degree m, the *Faber polynomial*, with $P_m(J) = J|T_m$.

Replication (Norton) generalises this to McKay–Thompson series: the Hecke sum of T_g is formed with the *replicates* T_{g^a} in the a-th block,

$$P_{g,m}\big(T_g(\tau)\big) = \sum_{ad=m} \sum_{0 \leq b < d} T_{g^a}\Big(\frac{a\tau + b}{d}\Big), \tag{43.8}$$

where $P_{g,m}$ is the monic Faber polynomial of T_g (the unique monic polynomial with $P_{g,m}(T_g) = q^{-m} + O(q)$). A function satisfying (43.8) for every m, with its replicates, is called *completely replicable*.

Example 43.18 (Replication for J at $m = 2$). With $J = \sum_n c(n)q^n$, $c(-1) = 1$, $c(0) = 0$: $J^2 = q^{-2} + 2c(1) + 2c(2)q + (2c(3) + c(1)^2)q^2 + \cdots$, so $P_2(x) = x^2 - 2c(1)$. On the other side, $J(2\tau) + J(\frac{\tau}{2}) + J(\frac{\tau+1}{2}) = q^{-2} + 2c(2)q + (c(1) + 2c(4))q^2 + \cdots$ (the two half-shifted terms add up to $2\sum_{n \text{ even}} c(n)q^{n/2}$). Comparing coefficients of q^2 gives Mahler's recursion $c(4) = c(3) + \frac{1}{2}(c(1)^2 - c(1))$: indeed $864299970 + \frac{1}{2}(196884^2 - 196884) = 20245856256$.

Definition 43.19 (Hecke points and complete replicability). For $a, d \geq 1$ and $b \in \mathbb{N}$, the *Hecke point* of $\tau \in \mathbb{H}$ is $(a\tau + b)/d \in \mathbb{H}$. The family $(T_g)_{g \in \mathrm{Aut}(V^\natural)}$ is *completely replicable* if for every g and every $m \geq 1$ there is a monic polynomial P of degree m with

$$P\big(T_g(\tau)\big) = \sum_{a \mid m} \sum_{0 \leq b < m/a} T_{g^a}\Big(\frac{a\tau + b}{m/a}\Big) \qquad \text{for all } \tau \in \mathbb{H}.$$

```
theorem heckePoint_im_pos (a d b : ℕ) (ha : 0 < a) (hd : 0 < d) (τ : ℍ) :
    0 < ((a * (τ : ℂ) + b) / d).im

noncomputable def heckePoint (a d : ℕ) (b : ℕ) (ha : 0 < a) (hd : 0 < d) (τ : ℍ) : ℍ :=
  ⟨(a * (τ : ℂ) + b) / d, heckePoint_im_pos a d b ha hd τ⟩

def CompletelyReplicable : Prop :=
  ∀ (g : AutVnat) (m : ℕ) (hm : 0 < m), ∃ P : Polynomial ℂ, P.Monic ∧ P.natDegree = m ∧
    ∀ τ : ℍ, P.eval (mckayThompsonFun g τ) =
      ∑ a ∈ m.divisors.attach, ∑ b ∈ Finset.range (m / a),
        mckayThompsonFun (g ^ (a : ℕ)) (heckePoint a (m / a) b (Nat.pos_of_mem_divisors
        ↪ a.2)
          (Nat.div_pos (Nat.divisor_le a.2) (Nat.pos_of_mem_divisors a.2)) τ)
```

(`VOA/Moonshine/MoonshineCNStatement.lean`.)

From the mathematics to the Lean statement

`heckePoint a d b ha hd τ` is $(a\tau + b)/d$ packaged as a point of $\mathbb{H}$; the proof argument `heckePoint_im_pos` supplies $\mathrm{Im} > 0$, since $\mathrm{Im}((a\tau + b)/d) = a\,\mathrm{Im}\,\tau/d$. In `CompletelyReplicable`: `m.divisors.attach` runs over the divisors a of m (each packaged with the proof that it divides m, used to prove $a > 0$ and $m/a > 0$); `Finset.range (m / a)` is $\{0, \dots, d-1\}$ with $d = m/a$; `g ^ (a : ℕ)` is the replicate g^a; `P.Monic ∧ P.natDegree = m` is "monic of degree m"; `P.eval x` is $P(x)$. This is (43.8) with an existential polynomial; as the docstring says, such a P is necessarily the Faber polynomial (both sides are $q^{-m} + O(q)$ once replicates are normalised), but uniqueness is not part of the definition and is not needed.
Strength. The quantifier is over *all* $g \in \mathrm{Aut}(V^\natural)$ (no finite-order hypothesis); every g has finite order (Chapter 47), so this is not a restriction. The definition is the textbook complete replicability of the family $\{T_g\}$, stated as an identity of functions on $\mathbb{H}$ rather than of formal q-series; for finite-order g the two are equivalent by absolute convergence.

Physical meaning

Replication is a shadow of the Hecke operators acting on the space of twisted partition functions. Physically, the Hecke sum computes the partition function of the symmetric-orbifold-like theory on an m-fold cover of the torus: covering a torus with a g-twist by a torus a times longer in one direction produces the twist g^a. This is why the replicate in the a-th block is T_{g^a}. In Borcherds' proof the replication formulas come out of the twisted denominator identities of the Monster Lie algebra, i.e. from the string spectrum.

What the machine verified

Definitions; printed in `VOA/Moonshine/MoonshineCNAudit3.lean`. Chapter 46 derives `CompletelyReplicable` from the twisted denominator identities, given simple-root generation of $\mathfrak{m}$ and finite order (`completelyReplicable_of_simpleRootGeneration`); both inputs are theorems (Chapter 47), and the hypothesis-free instance is `completelyReplicable_holds` (file `VOA/Moonshine/MoonshineCNRationalTraces.lean`, Chapter 49).

43.7.2 Rational traces

Definition 43.20 (Rational traces). *All traces are rational* if $\mathrm{tr}(g|V^\natural_{n+1}) \in \mathbb{Q}$ for all $g \in \mathrm{Aut}(V^\natural)$ and $n \geq 0$.

```
def RationalTraces : Prop :=
  ∀ (g : AutVnat) (n : ℕ), ∃ r : ℚ, PowerSeries.coeff n (mckayThompson g) = r
```

(`VOA/Moonshine/MoonshineCNStatement.lean`.)

From the mathematics to the Lean statement

`∃ r : ℚ, ... = r` with the rational number `r` coerced to $\mathbb{C}$. For $n \geq 0$ the coefficient is the trace on weight $n+1$; weight 0 (trace 1) is not included but is trivially rational. Classically all traces are *integers*; the Lean proposition asks only rationality, which is what the original route needed.

Physical meaning

Rationality of the character values of a symmetry on every energy level: the twisted partition functions are invariant under the Galois group of $\mathbb{Q}(\zeta_{o(g)})/\mathbb{Q}$, equivalently $T_{g^u} = T_g$ for u prime to $o(g)$.

What the machine verified

Definition; printed in `VOA/Moonshine/MoonshineCNAudit3.lean`. Proved with no hypotheses as `rationalTraces` (Chapter 49); it is a *consequence* of the moonshine theorem (§43.8), not an input to it.

43.7.3 Abstract replicable families

The genus-zero argument of Chapter 46 does not need $V^\natural$: it works for any family of q-series indexed by the powers of an element of order N, dominated by J and satisfying replication. The statement file therefore fixes an abstract interface.

Definition 43.21 (q-series function; replicable family). For $c : \mathbb{N} \to \mathbb{C}$ let $Q_c(\tau) = q^{-1} + \sum_{n\geq 1} c(n) q^n$ (the value $c(0)$ is ignored). A *completely replicable family of period N* is a doubly indexed sequence $c(k,n) \in \mathbb{C}$ ($k, n \in \mathbb{N}$; k indexes the replicate, n the coefficient) such that

(i) $c(k+N, n) = c(k,n)$;

(ii) $|c(k,n)| \leq |c(0,n)|$;

(iii) $c(0,n) = c(n)$, the coefficients of J;

(iv) for all k and $m \geq 1$ there is a monic polynomial P of degree m with $P(Q_{c(k,\cdot)}(\tau)) = \sum_{a|m} \sum_{0\leq b<m/a} Q_{c(ka,\cdot)}\left(\frac{a\tau+b}{m/a}\right)$.

```
noncomputable def qSeriesFun (c : ℕ → ℂ) (τ : ℍ) : ℂ :=
  (qPar τ)⁻¹ + ∑' n : ℕ, c (n + 1) * qPar τ ^ (n + 1)

structure ReplicableFamily (N : ℕ) where
  c : ℕ → ℕ → ℂ
  periodic : ∀ k n, c (k + N) n = c k n
  dominated : ∀ k n, ‖c k n‖ ≤ ‖c 0 n‖
  zero_eq_J : ∀ n, c 0 n = PowerSeries.coeff (n + 1) JShift
```

```
replicable : ∀ (k m : ℕ) (hm : 0 < m), ∃ P : Polynomial ℂ, P.Monic ∧ P.natDegree = m ∧

        (Nat.div_pos (Nat.divisor_le a.2) (Nat.pos_of_mem_divisors a.2)) τ)
```

(VOA/Moonshine/MoonshineCNStatement.lean.)

From the mathematics to the Lean statement

`qSeriesFun c τ` sums `c (n + 1) * q ^ (n + 1)` over $n \geq 0$, i.e. $\sum_{m\geq 1} c(m)q^m$: the index 0 is skipped, which is why "the value `c 0` is ignored". The `tsum` junk convention applies as before. `ReplicableFamily N` is a structure carrying *data* (the sequence `c`) and four properties: (i) `periodic`, (ii) `dominated`, (iii) `zero_eq_J` (with $c(0,n) = [q^{n+1}]$`JShift`, so $c(0,0) = 0$ and $c(0,n) = c(n)$), (iv) `replicable`, with the replicate index `k * a` in the a-th block, mirroring $T_{(g^k)^a} = T_{g^{ka}}$. Note that (iv) for k involves only members ka, so a family is "closed under taking replicates". For $N = 0$ the periodicity clause is empty; the instances used below have $N = o(g) > 0$.

Why (ii) and (iii)? (ii) gives convergence of every $Q_{c(k,\cdot)}$ on $\mathbb{H}$ and the growth bounds of Chapter 46; (iii) pins the family to J. Without (iii) the abstract notion would admit degenerate families: the project found that $q^{-1} + aq$ satisfies all replication identities with replicates $q^{-1} + a^m q$, for every $a \in \mathbb{C}$ (§43.10).

Physical meaning

An abstract stand-in for the collection of twisted partition functions $\{Z[{}^1_{g^k}]\}_k$ of a cyclic symmetry group, retaining only what the genus-zero argument needs: the twisted partition functions of the powers of g, their domination by the untwisted one, and the Hecke (covering) relations among them.

What the machine verified

Definitions; printed in `VOA/Moonshine/MoonshineCNAudit3.lean`, standard axioms.

Proposition 43.22 (The McKay–Thompson family is a replicable family). *(a) For every g, $T_g = Q_{c_g}$ where $c_g(n) = [X^n]\mathrm{MT}_g$.*

(b) If the family $\{T_g\}$ is completely replicable and g has finite order $o(g)$, then $c(k,n) = [X^n]\mathrm{MT}_{g^k}$ is a completely replicable family of period $o(g)$, and $o(g) > 0$.

```
theorem mckayThompsonFun_eq_qSeriesFun (g : AutVnat) :
    mckayThompsonFun g = qSeriesFun (fun n => PowerSeries.coeff n (mckayThompson g))

    (g : AutVnat) (hg : IsOfFinOrder g) :
    0 < orderOf g ∧ ∃ F : ReplicableFamily (orderOf g),
      ∀ k n, F.c k n = PowerSeries.coeff n (mckayThompson (g ^ k))
```

(VOA/Moonshine/MoonshineCNStatement.lean.)

From the mathematics to the Lean statement

(a) is an equality of functions: `mckayThompsonFun` sums from $n = 0$, `qSeriesFun` from $n = 1$, and the $n = 0$ term vanishes (Proposition 43.5(b)). The proof treats the summable and the non-summable case separately, so (a) holds even with the `tsum` junk convention. (b) is stated twice: as a definition producing the structure (with `c k n := PowerSeries.coeff n (mckayThompson (g ^ k))`), and as an existence theorem that also records $0 < o(g)$ (`orderOf g`, Mathlib's order, which is 0 for elements of infinite order) and the formula for the coefficients. Hypotheses: complete replicability and finite order of this g; both are theorems (Chapters 46 and 47).

Proof on paper. (a) was explained. (b) (i) $g^{k+o(g)} = g^k$. (ii) Theorem 43.6(c) applied to g^k (which has finite order). (iii) Proposition 43.5(d). (iv) Complete replicability for g^k, rewritten with (a) and $(g^k)^a = g^{ka}$. □

Physical meaning

The twisted partition functions of the powers of one symmetry form a closed system under the covering (Hecke) relations; this is the input to the genus-zero argument.

What the machine verified

Unconditional (with the stated hypotheses); printed in `VOA/Moonshine/MoonshineCNAudit3.lean`, standard axioms.

43.8 From $\Gamma_1(N)$ to $\Gamma_0(N)$

43.8.1 Why this step is needed, and the idea

The case-free genus-zero argument of Chapter 46 proves that each T_g is the normalised Hauptmodul of a group $\Gamma \supseteq \Gamma_1(M)$ commensurable with $\mathrm{SL}_2(\mathbb{Z})$ (the proposition `ConwayNortonGammaOne`). The classical way to get $\Gamma_0(M)$ uses rationality of the traces: $\Gamma_0(M)$ is generated by $\Gamma_1(M)$ and matrices δ whose lower-right entry d is a unit mod M, and invariance under such δ amounts to $T_{g^d} = T_g$, a Galois symmetry. The original plan obtained it from a rational form of $V^\natural$ and Tits' theorem; that route turned out to need group-theoretic classification input (§43.10).

The library instead proves $\Gamma_0(M) \le \pm\Gamma$ *from the* Γ_1 *theorem and replication at primes alone*. The key idea is the following. Let $p > M$ be prime and choose $m, n \in \mathbb{Z}$ with $mp - nM = 1$; put

$$\sigma_p = \left(\begin{smallmatrix} m & n \\ M & p \end{smallmatrix}\right) \in \Gamma_0(M), \qquad \sigma_p \equiv \left(\begin{smallmatrix} p^{-1} & * \\ 0 & p \end{smallmatrix}\right) \pmod{M}.$$

The replication formula at p involves $f = T_g$ at the p points $(\tau + j)/p$ and the replicate $f' = T_{g^p}$ at $p\tau$. A coset computation for the single matrix $L_M = \left(\begin{smallmatrix} 1 & 0 \\ M & 1 \end{smallmatrix}\right)$ shows that $\psi = f \circ \sigma_p - f'$ is invariant under $\tau \mapsto \tau + 1$ and under $L_{M/p} = \left(\begin{smallmatrix} 1 & 0 \\ M/p & 1 \end{smallmatrix}\right)$ with $0 < M/p < 1$. By Shimizu's lemma these two maps generate a non-discrete group; an invariant holomorphic function is then constant. So $f(\sigma_p\tau) = f'(\tau) + c$; comparing with the normalisation at the cusps and using (H4) gives $f' = f$ and $\pm\sigma_p \in \Gamma$. Dirichlet's theorem supplies, for every $\delta \in \Gamma_0(M)$, a prime $p > M$ with $p \equiv d \pmod{M}$, and then $\delta \in \Gamma_1(M)\sigma_p \subseteq \pm\Gamma$. As a by-product, $T_{g^u} = T_g$ for u prime to $o(g)$.

We now go through the steps, each with its Lean statement. The files are `VOA/Moonshine/MoonshineCNGammaZeroShimizu.lean` (Shimizu and constancy), `VOA/Moonshine/MoonshineCNGammaZeroCosets.lean` (coset matching), `VOA/Moonshine/MoonshineCNGammaZeroBridge.lean` (asymptotics, $\pm\Gamma$, the bridge), `VOA/Moonshine/MoonshineCNGammaZeroGalois.lean` (Galois invariance) and

`VOA/Moonshine/MoonshineCNGammaZeroFamily.lean` (the abstract family version). All are in the namespace `VOA.Moonshine.ConwayNorton`.

43.8.2 Shimizu's lemma and constancy

Definition 43.23 (Unipotent matrices). For $x, y \in \mathbb{R}$: $T_x = \left(\begin{smallmatrix} 1 & x \\ 0 & 1 \end{smallmatrix}\right)$ (the translation $\tau \mapsto \tau + x$) and $L_y = \left(\begin{smallmatrix} 1 & 0 \\ y & 1 \end{smallmatrix}\right)$ (the map $\tau \mapsto \tau/(y\tau + 1)$), both in $\mathrm{SL}_2(\mathbb{R})$.

```
noncomputable def glOfDetOne (a b c d : ℝ) (h : a * d - b * c = 1) : GL (Fin 2) ℝ :=
  GeneralLinearGroup.mkOfDetNeZero !![a, b; c, d] (by rw [det_fin_two_of, h]; exact
   ↪ one_ne_zero)

noncomputable def glUpperUnipotent (x : ℝ) : GL (Fin 2) ℝ := glOfDetOne 1 x 0 1 (by ring)

noncomputable def glLowerUnipotent (y : ℝ) : GL (Fin 2) ℝ := glOfDetOne 1 0 y 1 (by ring)
```

(`VOA/Moonshine/MoonshineCNGammaZeroShimizu.lean`.)

From the mathematics to the Lean statement

`glOfDetOne a b c d h` is the matrix $\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$ as an element of $\mathrm{GL}_2(\mathbb{R})$, built by Mathlib's `GeneralLinearGroup.mkOfDetNeZero` from the fact that its determinant $ad - bc = 1$ (`h`) is non-zero; `!![a, b; c, d]` is Mathlib's matrix literal. The definitions are the textbook matrices.

Physical meaning

T_x shifts the torus modulus; L_y is a "Dehn twist in the other direction" when $y \in \mathbb{Z}$, and a non-integral shear otherwise. A modular-invariant quantity is invariant under T_1 and L_1; invariance under a shear L_y with $0 < y < 1$ is never expected of a physical partition function, and the lemma below shows it forces triviality.

What the machine verified

Definitions; used by the audited theorems below.

Theorem 43.24 (Constancy under a non-discrete set; Shimizu). *Let $\psi : \mathbb{H} \to \mathbb{C}$ be holomorphic.*

(a) If $C_n \in \mathrm{GL}_2(\mathbb{R})$ converge entrywise to the identity, each C_n moves some point of $\mathbb{H}$, and $\psi(C_n\tau) = \psi(\tau)$ for all n, τ, then ψ is constant.

(b) If $\psi(\tau + 1) = \psi(\tau)$ and $\psi(L_y\tau) = \psi(\tau)$ for all τ, for some $0 < y < 1$, then ψ is constant.

```
theorem eq_of_invariant_of_entries_tendsto_one {ψ : ℍ → ℂ}
    (hψ : MDifferentiable 𝓘(ℂ) 𝓘(ℂ) ψ) {C : ℕ → GL (Fin 2) ℝ}
    (hC : ∀ i j, Tendsto (fun n => (C n : Matrix (Fin 2) (Fin 2) ℝ) i j) atTop
      (𝓝 ((1 : Matrix (Fin 2) (Fin 2) ℝ) i j)))
    (hmove : ∀ n, ∃ τ : ℍ, C n • τ ≠ τ) (hinv : ∀ n τ, ψ (C n • τ) = ψ τ) (τ σ : ℍ) :
    ψ τ = ψ σ

theorem eq_of_invariant_upper_lower_unipotent {ψ : ℍ → ℂ} (hψ : MDifferentiable 𝓘(ℂ) 𝓘(ℂ)
 ↪ ψ)
    {y : ℝ} (hy0 : 0 < y) (hy1 : y < 1) (hT : ∀ τ, ψ (glUpperUnipotent 1 • τ) = ψ τ)
    (hL : ∀ τ, ψ (glLowerUnipotent y • τ) = ψ τ) (τ σ : ℍ) : ψ τ = ψ σ
```

(`VOA/Moonshine/MoonshineCNGammaZeroShimizu.lean`.)

From the mathematics to the Lean statement

`hC`: for all entries (i,j), $(C_n)_{ij} \to \delta_{ij}$ as $n \to \infty$ (`atTop` on $\mathbb{N}$). `hmove`: each C_n acts non-trivially on $\mathbb{H}$. `hinv`: invariance. Conclusion: $\psi(\tau) = \psi(\sigma)$ for all τ, σ, i.e. ψ is constant. In (b), `hT`, `hL` are invariance under T_1 and L_y, with `0 < y < 1`. Note that (b) does not require det > 0 or discreteness anywhere: it is a statement about any holomorphic function with these two invariances. A sibling `eq_of_invariant_of_tendsto_one` states (a) with convergence in the topology of $\mathrm{GL}_2(\mathbb{R})$. Both are the textbook statements.

Proof on paper. (a) For large n, $\det C_n > 0$, so C_n is a Möbius map; a non-trivial real Möbius map of positive determinant fixes at most one point of $\mathbb{H}$ (the fixed-point equation $c\tau^2 + (d-a)\tau - b = 0$ has at most one root in $\mathbb{H}$ unless $c = b = 0$, $a = d$). Hence each such C_n moves i or $2i$, and one of the two, say τ_0, is moved by infinitely many C_n. Since $C_n \to 1$, $C_n\tau_0 \to \tau_0$ with $C_n\tau_0 \neq \tau_0$ infinitely often, and $\psi(C_n\tau_0) = \psi(\tau_0)$: the level set $\{\psi = \psi(\tau_0)\}$ accumulates at τ_0. By the identity theorem $\psi \equiv \psi(\tau_0)$. (This avoids the inverse function theorem used in the paper blueprint.)

(b) *Shimizu's sequence.* Let $B_0 = L_y$ and $B_{n+1} = B_n T_1 B_n^{-1}$. If $B_n = \left(\begin{smallmatrix} a_n & * \\ c_n & * \end{smallmatrix}\right)$ then a direct computation gives

$$B_{n+1} = \begin{pmatrix} 1-a_nc_n & a_n^2 \\ -c_n^2 & 1+a_nc_n \end{pmatrix}, \qquad \text{so} \qquad c_{n+1} = -c_n^2,\ |c_n| = y^{2^n} \to 0,$$

and $a_{n+1} = 1 - a_nc_n$, from which $a_n \to 1$ (the corrections are summable). Hence $B_n \to T_1$ and $C_n = B_{n+1}T_1^{-1} \to 1$, while the lower-left entry of C_n is $-c_n^2 \neq 0$, so C_n moves points. Every C_n lies in the group generated by T_1 and L_y, under which ψ is invariant; apply (a). □

Physical meaning

A function on moduli space invariant under a non-discrete group of modular transformations cannot vary: there is no "partition function" with such a symmetry except a constant. Shimizu's lemma says: a discrete group containing the unit translation cannot contain a shear L_y with $0 < |y| < 1$.

What the machine verified

Unconditional; both printed in `VOA/Moonshine/MoonshineCNGammaZeroAudit.lean` (47 reports, all `[propext, Classical.choice, Quot.sound]`).

43.8.3 The diamond lift and Hecke coset matching

Definition 43.25 (Diamond lift; level sum). Let $M \geq 1$, p prime, and $m, n \in \mathbb{Z}$ with $mp - nM = 1$. The *diamond lift* is $\sigma = \left(\begin{smallmatrix} m & n \\ M & p \end{smallmatrix}\right) \in \Gamma_0(M)$. For $f : \mathbb{H} \to \mathbb{C}$ the *level sum* is

$$S(\tau) = \sum_{j=0}^{p-1} f\Big(\frac{\tau + j}{p}\Big) + f\big(\sigma(p\tau)\big).$$

```
def diamondLift (M p : ℕ) (m n : ℤ) (h : m * p - n * M = 1) : SL(2, ℤ) :=
  slOfDetOne m n M p h

noncomputable def heckeLevelSum (f : ℍ → ℂ) (σ : SL(2, ℤ)) (p : ℕ) (hp : 0 < p) (τ : ℍ) : ℂ
 ↪  :=
  ∑ j ∈ Finset.range p, f (heckePoint 1 p j one_pos hp τ) +
    f (mapGL ℝ σ • heckePoint p 1 0 hp one_pos τ)
```

(`VOA/Moonshine/MoonshineCNGammaZeroCosets.lean`.)

From the mathematics to the Lean statement

`slOfDetOne m n M p h` is $\left(\begin{smallmatrix} m & n \\ M & p \end{smallmatrix}\right) \in \mathrm{SL}_2(\mathbb{Z})$ (same file). In `heckeLevelSum`, `heckePoint 1 p j` is $(\tau + j)/p$, `heckePoint p 1 0` is $p\tau$, and `mapGL ℝ σ • ·` is the Möbius action of σ. The lemma `diamondLift_mem_Gamma0` records $\sigma \in \Gamma_0(M)$.

Physical meaning

σ is an element of $\Gamma_0(M)$ whose action on a g-twisted torus replaces the twist by its p-th power ($\sigma \equiv \mathrm{diag}(p^{-1}, p) \bmod M$); the level sum is the Hecke-covering sum of f in which the p-fold-scaled term is transported by σ.

What the machine verified

Definitions; used by the audited theorems below (`diamondLift_mem_Gamma0` is printed in `VOA/Moonshine/MoonshineCNGammaZeroAudit.lean`).

Theorem 43.26 (Hecke coset matching). *Let f be $\Gamma_1(M)$-invariant, p prime and $mp - nM = 1$. Then:*

(a) $f \circ \sigma$ is 1-periodic;

(b) $S(L_M\tau) = S(\tau)$ for all τ.

```
theorem diamond_periodic {f : ℍ → ℂ} {M p : ℕ} {m n : ℤ} (h : m * p - n * M = 1)
    (hf : ∀ γ ∈ Gamma1 M, ∀ τ : ℍ, f (mapGL ℝ γ • τ) = f τ) (τ : ℍ) :
    f (mapGL ℝ (diamondLift M p m n h) • (glUpperUnipotent 1 • τ)) =
      f (mapGL ℝ (diamondLift M p m n h) • τ)

theorem heckeLevelSum_lowerSL {f : ℍ → ℂ} {M p : ℕ} (hp : p.Prime) {m n : ℤ}
    (hmn : m * p - n * M = 1) (hf : ∀ γ ∈ Gamma1 M, ∀ τ : ℍ, f (mapGL ℝ γ • τ) = f τ) (τ :
    ↪ ℍ) :
    heckeLevelSum f (diamondLift M p m n hmn) p hp.pos (mapGL ℝ (lowerSL M) • τ) =
      heckeLevelSum f (diamondLift M p m n hmn) p hp.pos τ
```

(`VOA/Moonshine/MoonshineCNGammaZeroCosets.lean`.)

From the mathematics to the Lean statement

`hf`: $f(\gamma\tau) = f(\tau)$ for all $\gamma \in \Gamma_1(M)$. `lowerSL M` is $L_M = \left(\begin{smallmatrix} 1 & 0 \\ M & 1 \end{smallmatrix}\right)$ and `glUpperUnipotent 1` is T_1. No hypothesis $p > M$ or $M > 0$ is needed here. The statements are exactly (a), (b).

Proof on paper. (a) $\sigma T_1 = \gamma\sigma$ with $\gamma = \left(\begin{smallmatrix} 1-mM & m^2 \\ -M^2 & 1+mM \end{smallmatrix}\right) \in \Gamma_1(M)$ (multiply out, using $mp - nM = 1$), so $f(\sigma(\tau+1)) = f(\gamma\sigma\tau) = f(\sigma\tau)$.

(b) Reduce modulo p: since $mp - nM = 1$, $nM \equiv -1$, so M is invertible mod p and $-M^{-1} \equiv n$. Let $j_0 \equiv n$ and $j^* \equiv -n$ in $[0, p)$. There are three matrix identities, each checked by multiplying out:

- *generic $j \neq j_0$*: with $j' \equiv j/(1+jM) \pmod p$ in $[0, p)$ and $e = (j - (1+jM)j')/p \in \mathbb{Z}$,

$$\left(\begin{smallmatrix} 1 & j \\ 0 & p \end{smallmatrix}\right) L_M = \gamma_j \left(\begin{smallmatrix} 1 & j' \\ 0 & p \end{smallmatrix}\right), \qquad \gamma_j = \left(\begin{smallmatrix} 1+jM & e \\ pM & 1-Mj' \end{smallmatrix}\right) \in \Gamma_1(M);$$

- *exceptional $j_0 = n + kp$*: $\left(\begin{smallmatrix} 1 & j_0 \\ 0 & p \end{smallmatrix}\right) L_M = T_k \sigma \left(\begin{smallmatrix} p & 0 \\ 0 & 1 \end{smallmatrix}\right)$;

- *extra term*: with $e = (n - (mp + nM)j^*)/p \in \mathbb{Z}$, $\sigma\left(\begin{smallmatrix} p & 0 \\ 0 & 1 \end{smallmatrix}\right) L_M = \gamma^* \left(\begin{smallmatrix} 1 & j^* \\ 0 & p \end{smallmatrix}\right)$, $\gamma^* = \left(\begin{smallmatrix} mp+nM & e \\ 2Mp & 1-2Mj^* \end{smallmatrix}\right) \in \Gamma_1(M)$ (the Γ_1 condition holds because $mp + nM \equiv mp \equiv 1 \pmod M$).

The map $j \mapsto j'$ is the Möbius map $x \mapsto x/(1+Mx)$ of $\mathbb{P}^1(\mathbb{F}_p)$, which sends $j_0 = -1/M$ to ∞ and ∞ to $1/M = j^*$; so it is a bijection $[0,p) \setminus \{j_0\} \to [0,p) \setminus \{j^*\}$. Applying f and $\Gamma_1(M)$-invariance (T_k, $\gamma_j, \gamma^* \in \Gamma_1(M)$):

$$S(L_M\tau) = \sum_{j' \neq j^*} f\Big(\frac{\tau + j'}{p}\Big) + f\big(\sigma(p\tau)\big) + f\Big(\frac{\tau + j^*}{p}\Big) = S(\tau). \qquad \square$$

Physical meaning

The Hecke correspondence at level p permutes its $p+1$ "covering tori" under a modular transformation of the base; the computation identifies the permutation explicitly for the generator L_M, with one covering torus exchanged between the "$(\tau + j)/p$" family and the "$p\tau$" term.

What the machine verified

Unconditional; printed in `VOA/Moonshine/MoonshineCNGammaZeroAudit.lean` together with the three coset identities `heckeShift_lowerSL`, `heckeShift_lowerSL_exceptional`, `diamondScale_lowerSL` and the index bijection lemmas.

Theorem 43.27 (The replicate differs from the diamond image by a constant)**.** *Let $0 < M < p$, p prime, $mp - nM = 1$, f holomorphic and $\Gamma_1(M)$-invariant, f' holomorphic and 1-periodic, and suppose that for some function $\Phi : \mathbb{C} \to \mathbb{C}$*

$$\Phi\big(f(\tau)\big) = \sum_{j=0}^{p-1} f\Big(\frac{\tau + j}{p}\Big) + f'(p\tau) \qquad (\tau \in \mathbb{H}).$$

Then $\psi = f \circ \sigma - f'$ is invariant under $L_{M/p}$, and there is $c \in \mathbb{C}$ with $f(\sigma\tau) = f'(\tau) + c$ for all τ.

```

    (hf'per : ∀ τ : ℍ, f' (glUpperUnipotent 1 • τ) = f' τ)
    (hrep : ∀ τ : ℍ, Φ (f τ) = ∑ j ∈ Finset.range p, f (heckePoint 1 p j one_pos hp.pos τ)
     ↪ +
      f' (heckePoint p 1 0 hp.pos one_pos τ)) :
    ∃ c : ℂ, ∀ τ : ℍ, f (mapGL ℝ (diamondLift M p m n hmn) • τ) = f' τ + c
```

(`VOA/Moonshine/MoonshineCNGammaZeroCosets.lean`.)

From the mathematics to the Lean statement

`hrep` is the replication identity at p in "two-block" form, with an *arbitrary* function Φ of f on the left: monicity and degree of the Faber polynomial are not used. `hfhol`, `hf'hol`:

holomorphy; `hf`: $\Gamma_1(M)$-invariance; `hf'per`: $f'(\tau+1)=f'(\tau)$; `hM`, `hMp`: $0<M<p$. The first theorem is the invariance of ψ under $L_{M/p}$ (`glLowerUnipotent ((M : ℝ) / p)`), the second the constancy. Statements as in the theorem.

Proof on paper. By Theorem 43.26(b) S is L_M-invariant; $\Phi\circ f$ is too, since $L_M\in\Gamma_1(M)$. The replication identity says $S(\tau)-\Phi(f(\tau))=f(\sigma(p\tau))-f'(p\tau)=\psi(p\tau)$. Hence $\psi(p\,L_M\tau)=\psi(p\tau)$. Now $p\cdot L_M\tau = p\tau/(M\tau+1)=L_{M/p}(p\tau)$, and $\tau\mapsto p\tau$ is onto $\mathbb{H}$; so ψ is $L_{M/p}$-invariant. It is also 1-periodic (Theorem 43.26(a) and periodicity of f') and holomorphic. Since $0<M/p<1$, Theorem 43.24(b) shows ψ is constant. □

Physical meaning

Replication relates the p-th Hecke transform of T_g to the replicate T_{g^p}; the computation shows that the replicate is literally the twisted partition function T_g seen through the modular transformation σ, up to a constant.

What the machine verified

Unconditional (with the stated hypotheses); both printed in `VOA/Moonshine/MoonshineCNGammaZeroAudit.lean`, standard axioms.

43.8.4 Asymptotic comparison and the main lemma

Lemma 43.28 (Asymptotic comparison). *Let f, f' be normalised ($f-q^{-1}\to 0$ and $f'-q^{-1}\to 0$ as $\operatorname{Im}\tau\to\infty$), and suppose $f(a\tau+b)=f'(\tau)+c$ for all τ, with $a>0$, $b\in\mathbb{R}$, $c\in\mathbb{C}$. Then $a=1$, $b\in\mathbb{Z}$ and $c=0$.*

```
theorem affine_eq_of_normalized {f f' : ℍ → ℂ}
    (hf : Tendsto (fun τ : ℍ => f τ - (qPar τ)⁻¹) atImInfty (𝓝 0))
    (hf' : Tendsto (fun τ : ℍ => f' τ - (qPar τ)⁻¹) atImInfty (𝓝 0))
    {φ : ℍ → ℍ} {a b : ℝ} (ha : 0 < a) (hφ : ∀ τ : ℍ, (φ τ : ℂ) = a * τ + b) {c : ℂ}
    (heq : ∀ τ : ℍ, f (φ τ) = f' τ + c) :
    a = 1 ∧ (∃ k : ℤ, b = k) ∧ c = 0
```

(`VOA/Moonshine/MoonshineCNGammaZeroBridge.lean`.)

From the mathematics to the Lean statement

The affine map is given as a function `φ : ℍ → ℍ` with `(φ τ : ℂ) = a * τ + b` (`hφ`); `heq` is $f(\varphi\tau)=f'(\tau)+c$. Conclusion `a = 1 ∧ (∃ k : ℤ, b = k) ∧ c = 0`. As stated.

Proof on paper. Write $E(\tau)=q(\varphi\tau)^{-1}-q(\tau)^{-1}$; the hypotheses give $E\to c$. But $|q(\varphi\tau)^{-1}|=e^{2\pi a\operatorname{Im}\tau}$ and $|q(\tau)^{-1}|=e^{2\pi\operatorname{Im}\tau}$, and if $a\neq 1$ their difference tends to infinity; so $a=1$. Then $q(\varphi\tau)=q(\tau)\,\omega$ with $\omega=e^{2\pi ib}$, and $E=q^{-1}(\omega^{-1}-1)$, which is unbounded unless $\omega=1$, i.e. $b\in\mathbb{Z}$, and then $E=0$, so $c=0$. □

Physical meaning

The vacuum pole q^{-1} fixes the normalisation of the modulus at the cusp: no rescaling, non-integral shift or additive constant is compatible with two partition functions having the same leading vacuum term and no constant term.

What the machine verified

Unconditional; printed in `VOA/Moonshine/MoonshineCNGammaZeroAudit.lean`, standard axioms.

Theorem 43.29 (Replicate equals Hauptmodul; diamond in $\pm\Gamma$). *Let f be a normalised Hauptmodul for $\Gamma \le \mathrm{SL}_2(\mathbb{R})$ with $\Gamma_1(M) \le \Gamma$, $M \ge 1$. Let $p > M$ be prime, $mp - nM = 1$, and f' holomorphic, 1-periodic and normalised, with $\Phi(f(\tau)) = \sum_{j<p} f((\tau + j)/p) + f'(p\tau)$ for some $\Phi : \mathbb{C} \to \mathbb{C}$. Then $f' = f$, and $\sigma \in \Gamma$ or $-\sigma \in \Gamma$.*

```
theorem replicate_eq_and_diamond_mem {Γ : Subgroup (GL (Fin 2) ℝ)} {f f' : ℍ → ℂ}
    {Φ : ℂ → ℂ} {M p : ℕ} (hH : IsNormalizedHauptmodul Γ f) (hdet : Γ.HasDetOne)
    (hΓ1 : gamma1GL M ≤ Γ) (hM : 0 < M) (hp : p.Prime) (hMp : M < p) {m n : ℤ}

     ↪ Γ)
```

(`VOA/Moonshine/MoonshineCNGammaZeroBridge.lean`.)

From the mathematics to the Lean statement

`hH`: `IsNormalizedHauptmodul Γ f`; `hdet`: $\Gamma \le \mathrm{SL}_2(\mathbb{R})$; `hΓ1`: $\Gamma_1(M) \le \Gamma$; `hM`: $M > 0$; `hp`, `hMp`: p prime, $p > M$; `hmn`: $mp - nM = 1$; the three hypotheses on f'; and `hrep`, the replication identity at p with arbitrary Φ. Commensurability of Γ is *not* needed. The conclusion `f' = f ∧ (σ ∈ Γ ∨ -σ ∈ Γ)`, with `σ = mapGL ℝ (diamondLift M p m n hmn)`. As stated.

Proof on paper. By Theorem 43.27, $f(\sigma\tau) = f'(\tau) + c$; the right-hand side is unbounded as $\mathrm{Im}\,\tau \to \infty$ ($f' \sim q^{-1}$). The point $\sigma\infty = m/M$ is a cusp of $\Gamma_1(M) \le \Gamma$. If it were not Γ-equivalent to ∞, it would be an other cusp, and by (H4) $f(\sigma\tau)$ would tend to a finite value: contradiction. So $\gamma\infty = \sigma\infty$ for some $\gamma \in \Gamma$, and $\delta = \gamma^{-1}\sigma$ fixes ∞ and has determinant 1: $\delta = \left(\begin{smallmatrix} a & b \\ 0 & a^{-1} \end{smallmatrix}\right)$, acting by $\tau \mapsto a^2\tau + ab$. By invariance, $f(\sigma\tau) = f(\delta\tau)$, so $f(a^2\tau + ab) = f'(\tau) + c$. Lemma 43.28 gives $a^2 = 1$, $ab = k \in \mathbb{Z}$, $c = 0$. Hence $\delta = \pm T_k$, $f'(\tau) = f(\tau + k) = f(\tau)$ (as $T_k \in \Gamma_1(M)$), and $\sigma = \gamma\delta = \pm\gamma T_k \in \pm\Gamma$. □

Physical meaning

If the twisted partition function of g is a Hauptmodul, then the twisted partition function of g^p (for a large prime p) is the same function, and the modular transformation that turns the g-twist into a g^p-twist is a symmetry of it. The only physical input is the absence of a second vacuum-like pole at the other cusps.

What the machine verified

Unconditional (with the stated hypotheses); printed in `VOA/Moonshine/MoonshineCNGammaZeroAudit.lean`, standard axioms.

43.8.5 $\Gamma_0(M) \le \pm\Gamma$ by Dirichlet's theorem

Definition 43.30 (Replication at a prime). *f replicates at the prime p with replicate f'* if there is $\Phi : \mathbb{C} \to \mathbb{C}$ with $\Phi(f(\tau)) = \sum_{j<p} f((\tau + j)/p) + f'(p\tau)$ for all τ.

```
def ReplicatesAtPrime (f f' : ℍ → ℂ) (p : ℕ) (hp : p.Prime) : Prop :=
  ∃ Φ : ℂ → ℂ, ∀ τ : ℍ, Φ (f τ) = ∑ j ∈ Finset.range p, f (heckePoint 1 p j one_pos hp.pos
   ↪ τ) +
    f' (heckePoint p 1 0 hp.pos one_pos τ)
```

(VOA/Moonshine/MoonshineCNGammaZeroBridge.lean.)

From the mathematics to the Lean statement

Exactly the definition. The lemma `heckeSum_prime` (same file) shows that the divisor-sum of `CompletelyReplicable` at $m = p$ prime has exactly these two blocks ($a = 1$: $j = 0, \dots, p-1$; $a = p$: one term), and `replicatesAtPrime_of_replication` turns complete replicability of g at p into `ReplicatesAtPrime (T g) (T (g ^ p)) p`.

Physical meaning

The p-th Hecke covering relation, in its simplest (prime) form.

What the machine verified

Definition; used by the audited theorems below.

Theorem 43.31 (Γ_0 from Γ_1 and replication). *Let f be a normalised Hauptmodul for $\Gamma \le \mathrm{SL}_2(\mathbb{R})$ with $\Gamma_1(M) \le \Gamma$, $M \ge 1$, and suppose that for every prime $p > M$ there is a holomorphic, 1-periodic, normalised f' such that f replicates at p with replicate f'. Then:*

(a) $\Gamma_0(M) \le \pm\Gamma$*;*

(b) *f is a normalised Hauptmodul for $\pm\Gamma$;*

(c) *if moreover Γ is commensurable with $\mathrm{SL}_2(\mathbb{Z})$, then $\pm\Gamma$ is a moonshine group of level M.*

       ↪ hp) :
    IsMoonshineGroup Γ.adjoinNegOne M ∧ IsNormalizedHauptmodul Γ.adjoinNegOne f
```

(VOA/Moonshine/MoonshineCNGammaZeroBridge.lean.)

From the mathematics to the Lean statement

`Γ.adjoinNegOne` is $\pm\Gamma$. `hrep` quantifies over primes $p > M$ and provides, for each, f' with the three properties and `ReplicatesAtPrime f f' p hp`. (c) also needs `hcomm`, commensurability of Γ. The conclusions are (a), (b), (c) exactly. Note that the output group is $\pm\Gamma$, not Γ; this is harmless because -1 acts trivially on $\mathbb{H}$ and on cusps, and $\Gamma_0(M)$ contains -1 anyway.

Proof on paper. (a) Let $\delta = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in \Gamma_0(M)$. Then $ad \equiv 1 \pmod{M}$, so d is a unit mod M. By Dirichlet's theorem on primes in arithmetic progressions (Mathlib's `Nat.forall_exists_prime_gt_and_eq_mod`) there is a prime $p > M$ with $p \equiv d \pmod{M}$; then $\gcd(p, M) = 1$ and we choose m, n with $mp - nM = 1$. Theorem 43.29 gives $\pm\sigma \in \Gamma$. The matrix $\varepsilon = \delta\sigma^{-1}$ has integer entries, determinant 1, lower-left entry $cp - dM \equiv 0$, and diagonal entries $\equiv ap \equiv ad \equiv 1$ and $\equiv dm \equiv dp^{-1} \equiv 1 \pmod{M}$; so $\varepsilon \in \Gamma_1(M) \le \Gamma$ and $\delta = \varepsilon\sigma \in \pm\Gamma$. (b) -1 acts trivially on $\mathbb{H}$ and on $\mathbb{P}^1(\mathbb{R})$, so each of the eight fields transfers from Γ to $\pm\Gamma$ (the cusps and other cusps are the same). (c) $\pm\Gamma$ has determinant one, contains $\Gamma_0(M)$ by (a), and is commensurable with Γ (index at most 2), hence with $\mathrm{SL}_2(\mathbb{Z})$. □

Physical meaning

Dirichlet's theorem supplies enough primes to realise every residue class of twists $g \mapsto g^d$; each realisation is a symmetry of the Hauptmodul by Theorem 43.29. The upshot is the full $\Gamma_0(M)$ invariance expected of an order-M twisted partition function whose twist is "Galois-invariant".

What the machine verified

Unconditional (with the stated hypotheses); all three printed in `VOA/Moonshine/MoonshineCNGammaZeroAudit.lean`, standard axioms.

43.8.6 The bridge

Theorem 43.32 (The bridge $\Gamma_1 \Rightarrow \Gamma_0$). *(a) If the Γ_1 form holds and g has finite order and replicates at every prime (with some polynomial), then g has the Conway–Norton property.*

(b) If every automorphism of $V^\natural$ has finite order, the Γ_1 form holds, and the finite-order McKay–Thompson series are completely replicable, then the Conway–Norton conjecture holds.

(c) The same with `CompletelyReplicable` *in place of its finite-order restriction.*

```
def CompletelyReplicableOfFinOrder : Prop :=
  ∀ (g : AutVnat), IsOfFinOrder g → ∀ m : ℕ, 0 < m → ∃ P : Polynomial ℂ, P.Monic ∧
    P.natDegree = m ∧ ∀ τ : ℍ, P.eval (mckayThompsonFun g τ) =

        mckayThompsonFun (g ^ (a : ℕ)) (heckePoint a (p / a) b (Nat.pos_of_mem_divisors
          ↪ a.2)
            (Nat.div_pos (Nat.divisor_le a.2) (Nat.pos_of_mem_divisors a.2)) τ)) :
    ConwayNortonFor g
```

```
theorem conwayNorton_of_gammaOne_of_finOrder (hfin : ∀ g : AutVnat, IsOfFinOrder g)
    (h1 : ConwayNortonGammaOne) (hrep : CompletelyReplicableOfFinOrder) :
    ConwayNortonConjecture

theorem conwayNorton_of_gammaOne (hfin : ∀ g : AutVnat, IsOfFinOrder g)
    (h1 : ConwayNortonGammaOne) (hrep : CompletelyReplicable) : ConwayNortonConjecture
```

(`VOA/Moonshine/MoonshineCNGammaZeroBridge.lean`.)

From the mathematics to the Lean statement

`CompletelyReplicableOfFinOrder` is `CompletelyReplicable` restricted to g with `IsOfFinOrder g`. In (a), `hrep` asks for replication at every prime p with a polynomial P that need not be monic. The hypotheses of (b) and (c) are named propositions: `hfin : ∀ g, IsOfFinOrder g`, `h1 : ConwayNortonGammaOne`, `hrep`. The conclusions are `ConwayNortonFor g` and `ConwayNortonConjecture`. These theorems are **conditional** on their hypotheses; `#print axioms` does not show them. All three hypotheses are theorems of the library (Chapters 46 and 47); their combination is `conwayNorton`.

Proof on paper. (a) The Γ_1 form for g gives (Γ, M). For a prime $p > M$, the replicate is $f' = T_{g^p}$: it is 1-periodic by definition, and holomorphic and normalised because the Γ_1 form also applies to g^p (which has finite order). Replication of g at p is `ReplicatesAtPrime` by `heckeSum_prime`. Theorem 43.31 gives $\pm\Gamma$, a moonshine group of level M for T_g. (b), (c) Apply (a) to every g. □

Physical meaning

Exact twist-preserving modular invariance (Γ_1) plus the covering relations between twisted partition functions imply invariance up to Galois twists (Γ_0).

What the machine verified

Conditional on the explicit hypotheses `ConwayNortonGammaOne`, (finite-order) complete replicability and finite order; all printed in `VOA/Moonshine/MoonshineCNGammaZeroAudit.lean` with standard axioms. The final theorem `conwayNorton` uses `conwayNorton_of_gammaOne` with all three hypotheses discharged (§43.9).

43.8.7 Galois invariance

Theorem 43.33 (Galois invariance of McKay–Thompson series). *Under the hypotheses of Theorem 43.32(a) (respectively (c)), $T_{g^u} = T_g$ for every u coprime to the order of g (respectively for every g and every such u).*

```
theorem mckayThompsonFun_pow_eq_of_coprime (h1 : ConwayNortonGammaOne) {g : AutVnat}
    (hg : IsOfFinOrder g)
    (hrep : ∀ p : ℕ, p.Prime → ∃ P : Polynomial ℂ, ∀ τ : ℍ, P.eval (mckayThompsonFun g τ) =
      ∑ a ∈ p.divisors.attach, ∑ b ∈ Finset.range (p / a),
        mckayThompsonFun (g ^ (a : ℕ)) (heckePoint a (p / a) b (Nat.pos_of_mem_divisors
          ↪ a.2)
          (Nat.div_pos (Nat.divisor_le a.2) (Nat.pos_of_mem_divisors a.2)) τ))
    {u : ℕ} (hu : Nat.Coprime u (orderOf g)) :
    mckayThompsonFun (g ^ u) = mckayThompsonFun g

theorem mckayThompsonFun_pow_eq_of_coprime_of_completelyReplicable
    (hfin : ∀ g : AutVnat, IsOfFinOrder g) (h1 : ConwayNortonGammaOne)
```

```
    (hrep : CompletelyReplicable) (g : AutVnat) {u : ℕ} (hu : Nat.Coprime u (orderOf g)) :
    mckayThompsonFun (g ^ u) = mckayThompsonFun g
```

(`VOA/Moonshine/MoonshineCNGammaZeroGalois.lean`.)

From the mathematics to the Lean statement

`Nat.Coprime u (orderOf g)`: $\gcd(u, o(g)) = 1$. The conclusion is an equality of functions on $\mathbb{H}$. Conditional on the stated hypotheses (all theorems of the library; the unconditional version is `mckayThompsonFun_pow_eq_of_coprime_holds`, Chapter 49).

Proof on paper. Let (Γ, M) come from the Γ_1 form for g. By Dirichlet there is a prime $p > M$ with $p \equiv u \pmod{o(g)}$, so $g^p = g^u$. Theorem 43.29 with $f' = T_{g^p}$ gives $T_{g^u} = T_{g^p} = T_g$. □

Comparing q-coefficients, $\mathrm{tr}(g^u | V^\natural{}_n) = \mathrm{tr}(g | V^\natural{}_n)$, and averaging over $u \in (\mathbb{Z}/o(g))^\times$ shows that the traces are rational (Ramanujan sums); this is how `rationalTraces` is proved in Chapter 49.

Physical meaning

The twisted partition function of g depends only on the cyclic group generated by g: twisting by any generator g^u gives the same function. Equivalently the character values of g on every energy level are rational.

What the machine verified

Conditional on the stated hypotheses; both printed in `VOA/Moonshine/MoonshineCNGammaZeroAudit.lean`, standard axioms.

43.8.8 The family version

Theorem 43.34 (Γ_0 for an abstract replicable family). *Let F be a completely replicable family, $k \in \mathbb{N}$, and suppose the member $Q_{c(k,\cdot)}$ is a normalised Hauptmodul for $\Gamma \le \mathrm{SL}_2(\mathbb{R})$ with $\Gamma_1(M) \le \Gamma$, $M \ge 1$.*

(a) If Γ is commensurable with $\mathrm{SL}_2(\mathbb{Z})$ and each replicate $Q_{c(kp,\cdot)}$, $p > M$ prime, is holomorphic and normalised, then $\pm\Gamma$ is a moonshine group of level M and $Q_{c(k,\cdot)}$ is a normalised Hauptmodul for it.

(b) For each prime $p > M$ with $Q_{c(kp,\cdot)}$ holomorphic and normalised, $Q_{c(kp,\cdot)} = Q_{c(k,\cdot)}$.

```
theorem isMoonshineGroup_of_gammaOne (k : ℕ) {Γ : Subgroup (GL (Fin 2) ℝ)} {M : ℕ}
    (hM : 0 < M) (hdet : Γ.HasDetOne) (hΓ1 : gamma1GL M ≤ Γ)
    (hcomm : Subgroup.Commensurable Γ 𝒮ℒ) (hH : IsNormalizedHauptmodul Γ (qSeriesFun (F.c
    ↪ k)))
    (hhol : ∀ p : ℕ, p.Prime → M < p → MDifferentiable 𝓘(ℂ) 𝓘(ℂ) (qSeriesFun (F.c (k *
    ↪ p))))
    (hnorm : ∀ p : ℕ, p.Prime → M < p →

      IsNormalizedHauptmodul Γ.adjoinNegOne (qSeriesFun (F.c k))

theorem qSeriesFun_mul_prime_eq (k : ℕ) {Γ : Subgroup (GL (Fin 2) ℝ)} {M : ℕ}
    (hM : 0 < M) (hdet : Γ.HasDetOne) (hΓ1 : gamma1GL M ≤ Γ)
    (hH : IsNormalizedHauptmodul Γ (qSeriesFun (F.c k))) {p : ℕ} (hp : p.Prime) (hMp : M <
    ↪ p)
    (hhol : MDifferentiable 𝓘(ℂ) 𝓘(ℂ) (qSeriesFun (F.c (k * p))))
    (hnorm : Tendsto (fun τ : ℍ => qSeriesFun (F.c (k * p)) τ - (qPar τ)⁻¹) atImInfty (𝓝
    ↪ 0)) :
    qSeriesFun (F.c (k * p)) = qSeriesFun (F.c k)
```

(`VOA/Moonshine/MoonshineCNGammaZeroFamily.lean`, namespace `VOA.Moonshine.ConwayNorton.ReplicableFamily`, with `F : ReplicableFamily N` a variable.)

From the mathematics to the Lean statement

The same statements as Theorems 43.31 and 43.29, for member k of an abstract family, with replicate `qSeriesFun (F.c (k * p))`. The lemma `ReplicableFamily.replicatesAtPrime` extracts the two-block replication identity from field `replicable`, and `qSeriesFun_periodic` supplies periodicity. These theorems are not on the path to `conwayNorton`; they were provided so that the genus-zero track could work on the abstract interface alone, and (b) says that the abstract family is automatically "Galois invariant" once its members are Hauptmoduln.

Proof on paper. As for Theorems 43.31 and 43.29. □

Physical meaning

The same statement for an abstract system of twisted partition functions.

What the machine verified

Conditional on the stated hypotheses; printed in `VOA/Moonshine/MoonshineCNGammaZeroAudit.lean`, standard axioms.

43.8.9 Supporting declarations

The five files contain, besides the statements above, the following supporting material; none of it introduces a new mathematical notion.

- `VOA/Moonshine/MoonshineCNGammaZeroShimizu.lean`: the invariance subgroup `precompInvariantSubgroup` $\psi = \{g : \psi \circ g = \psi\}$; real Möbius maps of positive determinant fixing two points of $\mathbb{H}$ are scalar (`entries_of_two_fixed`, `smul_eq_self_of_scalar`), hence a non-trivial one moves i or $2i$ (`moves_I_or_twoI`, `exists_smul_ne_of_lowerLeft_ne_zero`); entrywise convergence $C_n \to 1$ gives $C_n\tau \to \tau$ and eventually positive determinant; the identity-theorem step `eq_of_invariant_of_frequently_moved`; Shimizu's sequence `shimizuPair`, `shimizuMatrix`, `shimizuWitness` with its recursion, convergence and non-triviality.

- `VOA/Moonshine/MoonshineCNGammaZeroCosets.lean`: integer and real matrix constructors (`slOfDetOne`, `upperSL`, `lowerSL`, `glUpperTri`, `heckeShiftGL` $= \left(\begin{smallmatrix}1 & j\\ 0 & p\end{smallmatrix}\right)$, `heckeScaleGL` $= \left(\begin{smallmatrix}p & 0\\ 0 & 1\end{smallmatrix}\right)$) and their actions on Hecke points; $\sigma T_1 \sigma^{-1} \in \Gamma_1(M)$ (`diamondLift_mul_upperSL`); Möbius arithmetic in a field and the index maps `heckeIndexMap`, `heckeIndexInv` with their bijectivity and integrality lemmas; the three coset identities; $p\,L_M\tau = L_{M/p}(p\tau)$ (`heckeScale_lowerSL`) and surjectivity of $\tau \mapsto p\tau$.

- `VOA/Moonshine/MoonshineCNGammaZeroBridge.lean`: $|q^{-1}| = e^{2\pi \operatorname{Im}\tau} \to \infty$ (`norm_inv_qPar`, `tendsto_norm_inv_qPar_atTop`); periodicity of q and of T_g (`mckayThompsonFun_periodic`); an elementary inequality $|u - v| \le |e^u - e^v|$ for $u, v \ge 0$; $-g$ and g have the same action on cusps, so other cusps of Γ and $\pm\Gamma$ agree (`neg_smul_cuspInfty`, `isOtherCusp_adjoinNegOne_iff`); `hasDetOne_adjoinNegOne`; `heckePointAux` (a proof-free variant of `heckePoint`), `heckeSum_prime`, `replicatesAtPrime_of_replication`, `completelyReplicableOfFinOrder_of_completelyReplicable`.

- `VOA/Moonshine/MoonshineCNGammaZeroFamily.lean`: `qSeriesFun_periodic`, `ReplicableFamily.replicatesAtPrime`.

All of these are printed in `VOA/Moonshine/MoonshineCNGammaZeroAudit.lean` or used by declarations printed there.

Trap / dead end

Deviations from the paper blueprint, none a defect. (i) Constancy uses the identity theorem, not local injectivity of ψ. (ii) That $\sigma\infty$ is a cusp of Γ comes from arithmeticity of $\Gamma_1(M)$, not from the parabolic $\sigma T\sigma^{-1}$. (iii) Coset matching holds for every prime p; $p > M$ is used only for $0 < M/p < 1$. (iv) Replication is used with an arbitrary function Φ; monicity and degree are never used. (v) The output group is $\pm\Gamma$. (vi) Holomorphy and normalisation of the replicate T_{g^p} are taken from the Γ_1 theorem applied to g^p, so the bridge uses the Γ_1 theorem at g *and* at all g^p.

43.9 The final theorem and the audit modules

43.9.1 The theorem

Theorem 43.35 (Conway–Norton for Aut($V^\natural$); Borcherds)**.** *For every automorphism g of $V^\natural$ there are a subgroup $\Gamma_g \le \mathrm{SL}_2(\mathbb{R})$ and $N \ge 1$ such that $\Gamma_0(N) \le \Gamma_g$, Γ_g is commensurable with $\mathrm{SL}_2(\mathbb{Z})$, and the McKay–Thompson series $T_g = q^{-1} + \sum_{n\ge1} \mathrm{tr}(g|V^\natural_{n+1})q^n$ is the normalised Hauptmodul of Γ_g in the sense of Definition 43.16; in particular Γ_g has genus zero (this last consequence is Proposition 43.13, an argument on paper that is not formalized: the Lean statement asserts the defining properties of a normalised Hauptmodul, not the topology of $\Gamma_g\backslash\mathbb{H}^*$).*

```
theorem conwayNorton : ConwayNortonConjecture :=
  M8.conwayNortonConjecture_holds

example (g : AutMonster.AutVnat) : ∃ (Γ : Subgroup (GL (Fin 2) ℝ)) (N : ℕ),
  ↪ IsMoonshineGroup Γ N ∧
    IsNormalizedHauptmodul Γ (mckayThompsonFun g) :=
  conwayNorton g
```

(`VOA/Moonshine/MoonshineCNFinalAudit.lean`, `VOA.Moonshine.ConwayNorton.conwayNorton`.)

From the mathematics to the Lean statement

`ConwayNortonConjecture` is Definition 43.16; the `example` unfolds it one step, and Lean accepts `conwayNorton g` as its proof, so the unfolded form is literally what is proved. The theorem has **no hypotheses**: no arguments, no section variables, no type-class assumptions beyond the fixed objects. Its proof term `M8.conwayNortonConjecture_holds` is the assembly of Chapter 47. The full fidelity discussion is §43.6.3: this is the genus-zero form of the Conway–Norton conjecture, for the full automorphism group of the library's $V^\natural$. "Genus zero" is read off on paper: Lean proves that T_g has the defining properties of a normalised Hauptmodul (`IsNormalizedHauptmodul`), and Proposition 43.13 shows, without Lean, that a group admitting such a function has genus zero.

Proof on paper; where each step lives. Unwinding the proof term, the theorem is the composite of the following implications (names in `VOA.Moonshine.ConwayNorton`).

(1) `M8.monsterLieSimpleRootGeneration`: the Monster Lie algebra is generated by its simple root spaces (Chapter 47, from the product identity for $J(p) - J(q)$ of Chapter 46).

(2) `M8.autVnat_isOfFinOrder`: every automorphism of $V^\natural$ has finite order (Chapter 47).

(3) `completelyReplicable_of_simpleRootGeneration`: from (1), (2) and the twisted denominator identities, `CompletelyReplicable` (Chapter 46).

(4) `conwayNortonGammaOne_of_completelyReplicable`: from complete replicability, the prime Hecke identity and the non-injectivity of the replicable families modulo translations (both proved, Chapter 46), the case-free genus-zero argument gives `ConwayNortonGammaOne`.

(5) `conwayNorton_of_gammaOne` (Theorem 43.32): from (2), (4) and (3), `ConwayNortonConjecture`.

The links are `M8.conwayNortonConjecture_holds` = `M8.conwayNorton_of_isOfFinOrder` (2), which applies `conwayNorton_of_simpleRootGeneration` to (1); that theorem calls `M8.conwayNorton_of_finOrder_of_completelyReplicable` with (3), which in turn calls `conwayNorton_of_completelyReplicable`, i.e. (4) followed by (5). □

Physical meaning

Every global symmetry of the Monster conformal field theory has a twisted torus partition function that is the Hauptmodul of a genus-zero modular group. In the string-theory language of Borcherds' proof: the physical spectrum of the 26-dimensional bosonic string compactified on the moonshine orbifold times a Lorentzian torus organises the twisted partition functions into a completely replicable system, and complete replicability forces genus zero.

What the machine verified

Unconditional. `#print axioms` for `conwayNorton`, `M8.conwayNortonConjecture_holds`, `M8.monsterLieSimpleRootGeneration` and `M8.autVnat_isOfFinOrder` (the four commands at the end of `VOA/Moonshine/MoonshineCNFinalAudit.lean`): `[propext, Classical.choice, Quot.sound]`, no `sorryAx`, as recorded in the build record of the release (Chapter 50, Section 50.1.9): the umbrella `VOA.Moonshine`, which imports this module, builds green (9,504 jobs), and `run_axiom_audits.py` passes (5,983 reports across 25 probes, all within `[propext, Classical.choice, Quot.sound]`, with 0 `sorryAx`).

43.9.2 The audit modules

An *audit module* is a Lean file containing `#print axioms` commands (and sometimes `examples` and `#checks`) for the declarations of a batch of files; building it makes Lean print the axioms on which each declaration depends. The moonshine development kept one cumulative chain of audits for the `MoonshineCN` files, each importing the previous one. The following are assigned to this chapter; the material they audit is documented in the chapters indicated. "Reports" is the number of `#print axioms` lines in the file (counted in the source files of the release). By the axiom audit of the release, every report is `[propext, Classical.choice, Quot.sound]`, with no `sorryAx`.

file (`VOA/Moonshine/`)	reports	what is audited	chapter
`MoonshineCNAudit.lean`	53	graded traces and McKay–Thompson series (`Trace`); the lattice $I\!I_{1,1}$, its oscillators, the vertex-algebra target	43, 44
`MoonshineCNAudit2.lean`	383	the complex-frame construction of $V_{I\!I_{1,1}}$: charges, currents, exponentials, conformal vector, Sugawara, Virasoro, reconstruction, grading	44

file (`VOA/Moonshine/`)	reports	what is audited	chapter
`MoonshineCNAudit3.lean`	105	trace bounds; **the statement file**; tensor fields, conformal structure, grading, momentum; Fock adjoint; lattice and tensor forms, nondegeneracy	43, 44
`MoonshineCNAudit4.lean`	97	abstract string module: generators, orthogonals, grading, critical dimension, longitudinal, physical and transverse states (no-ghost core)	45
`MoonshineCNAudit5.lean`	117	quotient isometries, string symmetry, hyperbolic Fock space, commutant, Sugawara, form, straightening	44, 45
`MoonshineCNAudit6.lean`	98	hyperbolic light-cone splitting: negative modes, filtrations, PBW maps and coordinates	44
`MoonshineCNAudit7.lean`	94	central scalar, mixed modes, positive creation, Sugawara adjoint, tensor light cone and PBW	44
`MoonshineCNAudit8.lean`	89	the concrete no-ghost isometries for $V^\natural$: sector grading and laws, $V^\natural$ string module, longitudinal quotient, zero weight	45
`MoonshineCNAudit9.lean`	105	near-VOA mode identities: Goddard, translation, n-th products, iterate, Borcherds identity, skew symmetry; sector form convention	44
`MoonshineCNAudit10.lean`	83	physical Lie algebra, Monster Lie algebra, momentum grading, sector frame, $\mathrm{Aut}(V^\natural)$ action, momentum reversal	45
`MoonshineCNAudit11.lean`	76	root spaces, root radical, descended bilinear form and pairing	45
`MoonshineCNAudit12.lean`	66	generator adjoints; Borcherds roots, data, $\mathfrak{sl}_2$, parabolic	44, 45
`MoonshineCNAudit13.lean`	60	charge-sensitive nilpotence, opposite modes, adjoint reduction	44
`MoonshineCNAudit14.lean`	111	Borcherds algebras: augmentation, generation, Levi, parabolic and string actions, relative induction and PBW, Verma multiplication	45
`MoonshineCNAudit15.lean`	80	locally finite Casimir, root cutoff and duality, resolution range	45
`MoonshineCNAudit16.lean`	43	opposite iterate identity; hypothesis-free Lie invariance of the form on $\mathfrak{m}$	44, 45
`MoonshineCNAudit17.lean`	141	Verma resolution, tensor algebra $\cong$ enveloping algebra, freeness of the positive part, Cartan action, $\mathfrak{m}$ as Borcherds data (given generation)	45
`MoonshineCNAudit18.lean`	188	twisted denominator identities, formal and analytic replication, complete replicability; Conway–Norton given generation and finite order; imports the Γ_0 and genus-zero audits	46
`MoonshineCNGammaZeroAudit.lean`	47	the $\Gamma_1 \Rightarrow \Gamma_0$ bridge (§43.8)	43
`MoonshineCNFinalAudit.lean`	4	`conwayNorton` and its three last inputs	43

The audit modules prove nothing new; they exist to make the axiom check reproducible. A clean audit line certifies that the declaration uses no axiom beyond Lean's three and no `sorry`; it does not certify that the declaration is unconditional (several audited theorems have explicit hypotheses, e.g. `conwayNorton_of_gammaOne`), and it does not certify that the statement means what it should: that is the job of the fidelity checks. The other final audits of the part (`MoonshineCNMonsterFinalAudit`, `MoonshineCNSymmetryFinalAudit`, `MoonshineCNRationalAudit`, `MoonshineCNGenusZeroAudit*`, `MoonshineLRLiftAudit` and the `MoonshineLR*Audit` files) are doc-

umented in Chapters 46–49.

43.10 Recorded traps and dead ends

Trap / dead end

Rationality does not follow from the replication identities alone. For every $a \in \mathbb{C}$, the function $f = q^{-1} + aq$ satisfies all replication identities with replicates $f^{(k)} = q^{-1} + a^k q$. Certificate: in the Hecke sum $\sum_{ad=m} \sum_{b<d} f^{(a)}((a\tau + b)/d)$ the sum over b kills both the q^{-1} and the q term unless $d = 1$, leaving $q^{-m} + a^m q^m$; and the Dickson polynomial $D_m(x, a)$, defined by $D_m(u + a/u, a) = u^m + (a/u)^m$, is monic of degree m with $D_m(q^{-1} + aq, a) = q^{-m} + a^m q^m$. With $a = \zeta_N$ the family $k \mapsto q^{-1} + \zeta_N^k q$ is periodic of period N and not rational. `ReplicableFamily` excludes it only through the clause `zero_eq_J`. Hence Galois invariance must come from the Hauptmodul property, as in §43.8, not from formal identities.

Trap / dead end

Rationality through a $\mathbb{Q}$-form of $V^\natural$ (the original plan) is circular or needs classification. The plan was: build a rational form of $V^\natural$, show every automorphism preserves it, conclude rationality of traces by Galois conjugation. That every g preserves ${V^\natural}_2 \cap V_{\mathbb{Q}}$ needs either $\mathrm{Aut}(V^\natural) = \langle C, \sigma \rangle$ (Tits-level group theory) or rationality of every Ising vector (which needs the Monster). The Galois twist $g \mapsto \tau g \tau^{-1}$ only gives $\chi_n \circ c_\tau = \tau \circ \chi_n$ for an unknown automorphism c_τ, which is circular. Superseded by the bridge of §43.8, which makes rationality a corollary. Shimura reciprocity on q-coefficients (D4) was also considered and rejected as unnecessary and expensive.

Trap / dead end

The index shift between `mckayThompson` (coefficient n = trace on weight $n + 1$) and `JShift` ($= qJ$, coefficient n = dimension of weight n) is easy to get wrong. The library records it as the negative lemma `mckayThompson_one_ne_JShift` and the positive lemmas `mckayThompson_one` and `mckayThompsonShift_one` (Proposition 43.5).

Trap / dead end

Sign convention for momenta (Chapters 44–46). In Borcherds' convention the root space of $\mathfrak{m}$ at (m, n) is ${V^\natural}_{mn+1}$, for the form $\langle (m, n), (m, n) \rangle = -2mn$. The library's lattice `lorentzianLattice` has norm $+2xy$, so Borcherds' (m, n) is the library's $(m, -n)$, and the root space at library momentum (x, y) is ${V^\natural}_{1-xy}$. A product over library momenta $x, y \geq 1$ is wrong: there ${V^\natural}_{1-xy}$ is ${V^\natural}_0 = \mathbb{C}\mathbf{1}$ at $(1, 1)$ (the real simple root) and zero for $xy \geq 2$, so such a product sees almost none of $\mathfrak{m}$.

Trap / dead end

"Every element has finite order" is not "the group is finite". The moonshine theorem needs only the former (`autVnat_isOfFinOrder`); the latter, `M8.finite_autVnat`, was proved separately (Chapter 47). Neither is used to identify $\mathrm{Aut}(V^\natural)$ with the Monster.

Trap / dead end

Literature steps that fail as printed (Chapter 46). Cummins–Gannon's Prop. 5.1 is not usable verbatim for Γ_1 (its prime-clearing step uses exponents not in the admissible set), and the last step of Cummins (2002), Prop. 2.1, is wrong as printed (right translations cannot change the lower-right entry modulo the level); the library's genus-zero argument uses corrected versions. On the Monster side (Chapter 49), a first attempt at the commutant lemma used two code automorphisms that preserve the MOG column partition, which cannot give transitivity on octads; a third, column-breaking involution was needed.

43.11 Referee's checklist

All names are in `VOA.Moonshine.ConwayNorton` unless stated; "std." means `#print axioms = [propext, Classical.choice, Quot.sound]`.

declaration	intended meaning	hypotheses; status	check
`AutMonster.VnatVOA`, `AutMonster.AutVnat`	the moonshine VOA of Ch. 42; its automorphism group	definitions	Def. 43.1

The Monster in Lean. AxiomMath, *CFSG* (a Lean formalisation of parts of the classification of finite simple groups), commit `69cb972f587a3ecc035e092253167ff2e303c962`, Lean v4.35; the theorem `CFSG.Blueprint.NativeSporadic.MonsterModel.gmat_eq_griess` is the content of `GmatEqAut0`. The fidelity of the port is documented in `Notes/monster_aut/CFSG_PORT_FIDELITY.md`.

The development record. The development was recorded in the authors' working notes, which are not part of the release. The statement file was written first and frozen before the proof. Where this chapter states what the machine confirmed, it relies on the build record and axiom audit of the release (Chapter 50).

Chapter 44

The vertex algebra of the hyperbolic plane and the tensor theory of central charge 26

This chapter documents the release of the library named in the front matter; every Lean quotation in it is checked by `scripts/textbook/sync.py` to occur verbatim (up to whitespace and comments) in the source files of that release. It is the second chapter of the part "Monstrous moonshine" and it builds the stage on which Borcherds' proof of the Conway–Norton conjecture is played: the vertex algebra $V_{\mathrm{II}_{1,1}}$ of the even unimodular Lorentzian lattice of rank two, and the tensor product

$$\mathcal{M} \;=\; V^{\natural} \otimes V_{\mathrm{II}_{1,1}},$$

a vertex algebra of central charge $24 + 2 = 26$. Chapter 45 will extract from $\mathcal{M}$ the Monster Lie algebra (the space of "physical states" of $\mathcal{M}$, by the no-ghost theorem), and Chapters 46–47 use that Lie algebra to prove the Conway–Norton conjecture for every automorphism of $V^{\natural}$. The present chapter documents the 91 Lean files that construct $V_{\mathrm{II}_{1,1}}$ and $\mathcal{M}$, their invariant bilinear forms, the "light-cone" linear algebra of a momentum sector, and the general vertex-algebra theory (Borcherds identity, skew-symmetry, contragredient adjointness) for vertex algebras whose grading is *not* bounded below.

The results in brief. Everything below uses only Lean's three standard axioms. Items (i)–(iii) have no hypotheses; the general theorems of (iv) and (v) carry the mathematical premises displayed in their statements, which are discharged for the moonshine tensor theory in Chapter 45. Terms used here are defined in the sections cited.

(i) *The lattice* (§44.2). $\mathrm{II}_{1,1} = \mathbb{Z}^2$ with Gram matrix $\left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right)$, norm $2xy$: even, self-dual, not positive-definite.

(ii) *Its vertex algebra* (§§44.3–44.6). A vertex algebra `lorentzianNearVOA` with conformal vector and central charge 2 on the usual lattice state space, built with the Frenkel–Lepowsky–Meurman vertex operators written in a *complex* frame. Its weight grading is not bounded below and its weight-zero space is infinite-dimensional, so it is not a vertex operator algebra; the library's name for this kind of object is *near-VOA* (Definition 44.8).

(iii) *The $c = 26$ theory* (§44.9). The tensor product $V^{\natural} \otimes V_{\mathrm{II}_{1,1}}$ (`moonshineMatterNearVOA`) has central charge exactly 26, an internal grading by $\mathrm{II}_{1,1}$-momentum, and a symmetric, normalised, nondegenerate bilinear form for which L_n is adjoint to L_{-n}.

(iv) *General theory* (§§44.10–44.11). For every near-VOA: Goddard uniqueness, the commutator and iterate formulas, the Borcherds identity and skew-symmetry; and, when L_1 is locally

nilpotent, the Frenkel–Huang–Lepowsky (FHL) adjoint of a field, with the theorem that if the generating fields are adjoint for a bilinear form then all fields are (premises: local nilpotence, generation, adjointness of generators).

(v) *One momentum sector, in light-cone variables* (§44.8). An explicit polynomial model of a momentum sector on which the Sugawara operators satisfy the Virasoro algebra with $c = 2$, and on which the negative Virasoro modes and a "longitudinal" subspace split the sector at every nonzero momentum (premise: nonzero momentum); likewise after tensoring with an arbitrary matter space (premise: the Witt relations of the matter operators). This splitting is the linear algebra behind the no-ghost theorem.

What this chapter does *not* contain. The no-ghost theorem itself, the physical-state Lie algebra, the identification of its root spaces with $V^{\natural}_{1+mn}$, and the Borcherds–Kac–Moody structure are in Chapter 45. Several files of this chapter import Chapter 45 objects (the Monster Lie algebra `monsterLieAlgebra`, its bilinear form `monsterLieBilinearForm`, the subspace `primaryWeightOne` of weight-one Virasoro primaries); when a statement mentions them we say so and point forward. Nothing in this chapter is conditional on an open input: every headline is proved with no hypotheses beyond the ones displayed in its Lean statement, and we say for each displayed hypothesis what it means. As everywhere in this book, our concern is the *meaning* of the Lean statements; proofs are explained mathematically, and we do not describe how the Lean proof scripts are organised.

How to read this chapter. A reader who wants the headline only should read §44.1 (the physical motivation and the sign conventions), §44.2, the definitions of §44.4, the theorems of §44.6 and §44.9, and the referee's checklist (§44.17). Sections 44.8, 44.10 and 44.11 are the technical layer that Chapter 45 consumes; they are presented in full because the no-ghost theorem and the invariance of the Monster Lie algebra's bilinear form rest on them. Section 44.14 accounts for every one of the 91 files.

Notation. The chapter uses the following conventions throughout.

symbol	meaning
$\alpha, \beta, \gamma \in L$	lattice vectors (*momenta*); for $\mathrm{II}_{1,1}$, $\alpha = (\alpha_0, \alpha_1) \in \mathbb{Z}^2$
(x, y)	the two coordinates of *one* momentum of $\mathrm{II}_{1,1}$ (as in "momentum (x, y), weight xy")
$\Delta(\alpha) = \langle \alpha, \alpha \rangle / 2$	the *ground weight* of momentum α (for $\mathrm{II}_{1,1}$: $\alpha_0\alpha_1$)
level	the Fock-space degree of a polynomial (oscillator energy)
weight	the L_0-eigenvalue: level $+ \Delta(\alpha)$; "weight N" always means total weight
e^{α}	the *charged vacuum* $1 \otimes e^{\alpha}$, the ground state of momentum α
sector	all states of a fixed momentum α
$u_{(n)}$	the n-th mode, $Y(u, z) = \sum_n u_{(n)} z^{-n-1}$ (Lean `mode (Y u) n`); a Lean `Formal Dist f t` is instead the coefficient of z^t
c	central charge only
$\varepsilon,\ \chi(\alpha)$	the FLM cocycle, and the sign $\chi(\alpha) = (-1)^{\Delta(\alpha)} \varepsilon(\alpha, \alpha)$ of the lattice form
F	a complex lattice frame (Definition 44.5)
$\mathcal{F}_r$, $\mathcal{F}^{\mathrm{iso}}$	the Fock space in orthonormal variables; the same space in light-cone variables (§44.8)
$B_{\mathcal{F}}$, B_L, B^{iso}, B	the Fock form, the lattice form, the isotropic form, the matter form (table in §44.9)
$E^{\pm}(\alpha, z)$, $P_N(\alpha)$, $A_N(\alpha)$	the vertex-operator exponentials and their coefficients
κ, λ	the two light-cone zero modes of a sector (Lean `κ`, `ell`)
$\varphi \in \{a, b\}$	a light-cone oscillator family

symbol	meaning
ℓ, m, n in identities	mode indices of the Borcherds identity

44.1 Why the hyperbolic plane: the physical picture

44.1.1 The bosonic string in twenty-six dimensions

A closed bosonic string moving in a flat spacetime $\mathbb{R}^{1,d-1}$ is described, after fixing conformal gauge on its world-sheet, by d free bosons $X^\mu(z,\bar z)$, $\mu = 0,\dots,d-1$, one for each spacetime coordinate, with the Minkowski metric $\eta_{\mu\nu} = \mathrm{diag}(-1,1,\dots,1)$. Each holomorphic current $i\partial X^\mu(z) = \sum_n \alpha^\mu_n z^{-n-1}$ has modes satisfying $[\alpha^\mu_m, \alpha^\nu_n] = m\,\eta^{\mu\nu}\delta_{m+n,0}$: the *Lorentzian* Heisenberg algebra. The chiral state space is a sum over spacetime momenta p of Fock spaces; the Virasoro generators $L_n = \frac{1}{2}\sum_k \eta_{\mu\nu}{:}\alpha^\mu_{n-k}\alpha^\nu_k{:}$ satisfy the Virasoro algebra with central charge $c = d$. Gauge fixing leaves a residual reparametrisation symmetry, and *physical states* are the states ψ with

$$L_0\psi = \psi, \qquad L_n\psi = 0 \quad (n \geq 1), \tag{44.1}$$

taken modulo the "null spurious" states $L_{-1}\chi_1 + L_{-2}\chi_2$ that have zero norm. Because the metric is indefinite, the Fock space has states of negative norm ("ghosts", the timelike oscillators α^0_{-n}). The *no-ghost theorem* of Brower and of Goddard–Thorn (1972) says that when $c = 26$ the physical states modulo null states form a positive-definite space isomorphic to the *transverse* Fock space built from the $d-2 = 24$ oscillators orthogonal to a light-cone pair of directions; for $c \neq 26$ and $d > 26$ ghosts survive. This is the origin of the critical dimension 26.

Physical meaning

Twenty-six is not arbitrary here. The $c = 26$ matter theory is exactly what cancels the $c = -26$ of the reparametrisation ghosts b, c in the BRST quantisation (Frenkel–Garland–Zuckerman 1986), so that the BRST charge squares to zero; the no-ghost theorem is equivalently the statement that the BRST cohomology at ghost number one is the transverse space. In light-cone gauge one solves the constraints (44.1) explicitly by eliminating the two light-cone oscillators $\alpha^\pm_n$, which leaves the 24 transverse bosons. Borcherds' insight was that the 24 transverse bosons can be replaced by *any* $c = 24$ vertex operator algebra, in particular by $V^\natural$.

44.1.2 Borcherds' string

Replace the 24 transverse bosons by the Moonshine module $V^\natural$ (central charge 24, Chapter 42), and keep two free bosons X^0, X^1 for the light-cone directions. To obtain an algebraic object with a *discrete* momentum, compactify these two directions on a Lorentzian torus $\mathbb{R}^{1,1}/\mathrm{II}_{1,1}$: the chiral momenta then range over the even unimodular Lorentzian lattice $\mathrm{II}_{1,1}$, the unique such lattice of signature $(1,1)$. The chiral algebra of these two bosons is the lattice vertex algebra $V_{\mathrm{II}_{1,1}}$, of central charge 2, and the full "matter" algebra is $\mathcal{M} = V^\natural \otimes V_{\mathrm{II}_{1,1}}$ of central charge 26. Borcherds (1992) defined the *Monster Lie algebra* as the space of weight-one Virasoro primaries of $\mathcal{M}$ modulo the radical of its invariant form, with bracket $[u,v] = u_{(0)}v$; it is graded by $\mathrm{II}_{1,1}$, the Monster acts on it, and by the no-ghost theorem its piece of momentum $r \neq 0$ is isomorphic to the weight $1 - \frac{1}{2}\langle r, r\rangle$ piece of $V^\natural$. Thus the generating function of the dimensions of $V^\natural$ (the J-function) becomes the root multiplicities of a Lie algebra, whose denominator identity is $j(p) - j(q) = p^{-1}\prod_{m>0,n\in\mathbb{Z}}(1-p^m q^n)^{c(mn)}$ (Chapter 46).

Physical meaning

Physically $\mathcal{M}$ is the chiral algebra of a bosonic string compactified on "the Monster CFT times a Lorentzian torus". A heuristic but faithful dictionary: a lattice vector $r = (x, y) \in \mathrm{II}_{1,1}$ is a pair of light-cone momenta; $\frac{1}{2}\langle r, r\rangle = xy$ is $-\frac{1}{2}p^2$ up to sign conventions, i.e. the mass-shell term; the mass-shell condition $L_0 = 1$ on a state $v \otimes e^r$ with $v \in V^\natural{}_k$ reads $k + xy = 1$, so the physical states of momentum r are built on $V^\natural{}_{1-xy}$. The sign conventions of the repository and of Borcherds differ and are fixed in §44.1.4.

44.1.3 Why a new kind of vertex algebra is needed

In the lattice vertex operator algebra V_L of a positive-definite lattice (Chapter 31, Chapter 6) the state $p \otimes e^\alpha$, with p a polynomial of oscillator level $w \geq 0$, has conformal weight $w + \frac{1}{2}\langle\alpha, \alpha\rangle \geq 0$; for each weight n only finitely many α satisfy $\frac{1}{2}\langle\alpha, \alpha\rangle \leq n$, so the weight spaces are finite-dimensional, and $V_0 = \mathbb{C}\mathbb{1}$. For $\mathrm{II}_{1,1}$ all three facts fail:

- the charged vacuum $e^{(1,N-1)}$ has weight $N - 1$, which is arbitrarily negative: the grading is *not bounded below* (Theorem 44.10);
- the isotropic vectors $(i, 0)$, $i \in \mathbb{Z}$, all have norm 0, so the $e^{(i,0)}$ are infinitely many independent states of weight 0: *weight spaces are infinite-dimensional* (Theorem 44.12);
- the library's real orthonormal frame $\alpha \mapsto \sqrt{G}\,\underline{\alpha}$ of Chapter 31 (Definition 31.14) needs G positive semidefinite; for $G = \left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right)$ there is no real C with $C^T C = G$.

Hence $V_{\mathrm{II}_{1,1}}$ is not a `VertexOperatorAlgebra` in the library's sense (which requires finite-dimensional weight spaces and CFT type), nor a `GradedVertexOperatorAlgebra` (which requires a lower bound). The library's structure for it is `NearVOA` (Gannon's "near-VOA", Definition 5.1.3(c)): all the vertex-algebra and Virasoro axioms, an internal $\mathbb{Z}$-grading by L_0-eigenvalue, and nothing about the size or the lower bound of the graded pieces. Every general theorem that the library had proved for vertex operator algebras (Chapter 4) has to be re-proved for near-VOAs; this is the content of §44.10.

44.1.4 Sign and coordinate conventions

The repository uses the Gram matrix $\left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right)$ on $\mathbb{Z}^2$, so

$$\langle (x, y), (x', y')\rangle = xy' + yx', \qquad \langle (x, y), (x, y)\rangle = 2xy, \qquad \frac{1}{2}\langle r, r\rangle = xy.$$

Borcherds writes roots of the Monster Lie algebra as (m, n) with norm $-2mn$. The two conventions are matched by

$$\text{Borcherds' } (m, n) \quad \longleftrightarrow \quad \text{repository momentum } (x, y) = (m, -n), \tag{44.2}$$

and the root space of (m, n) is $V^\natural{}_{1+mn} = V^\natural{}_{1-xy}$.

Trap / dead end

The sign trap $(m, n) \leftrightarrow (m, -n)$**.** Never write the denominator product over repository momenta $x, y \geq 1$. The denominator product $\prod_{m>0, n\in\mathbb{Z}}(1 - p^m q^n)^{c(mn)}$ is over Borcherds' coordinates; in repository coordinates the exponent is $c(-xy)$. Every statement in this chapter is in repository coordinates.

44.2 The lattice $\mathrm{II}_{1,1}$

Recall (Chapter 31, Definition 31.9; Chapter 6, Definition 6.19) that the library's `IntegralLattice` is a structure with a carrier type that is a free, finitely generated $\mathbb{Z}$-module, a $\mathbb{Z}$-valued bilinear form `form`, and a proof `isSymm` that the form is symmetric; `Even` means $2 \mid \langle v, v\rangle$ for all v, `PosDef` means $\langle v, v\rangle > 0$ for $v \neq 0$, and `rank` is $\mathrm{finrank}_{\mathbb{Z}}$ of the carrier. Nothing in that structure requires positivity.

Definition 44.1 (The hyperbolic plane). $\mathrm{II}_{1,1}$ is $\mathbb{Z}^2$ with the symmetric bilinear form $\langle \alpha, \beta\rangle = \alpha_0\beta_1 + \alpha_1\beta_0$, i.e. Gram matrix $\left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right)$ in the standard basis. Its *ground weight* (half-norm) is $\Delta(\alpha) = \alpha_0\alpha_1$.

File `VOA/Moonshine/MoonshineCNLattice.lean`.

```

/-- Half the norm, the integral ground-state conformal weight. -/
def lorentzianEnergy (x : lorentzianLattice.carrier) : ℤ := x 0 * x 1
```

From the mathematics to the Lean statement

`Fin 2 → ℤ` is $\mathbb{Z}^2$, a vector being a function of its two coordinates `x 0`, `x 1`. `!![0, 1; 1, 0]` is Mathlib's notation for the 2×2 matrix with rows $(0,1)$ and $(1,0)$. `Matrix.toBilin' M` is the bilinear form $(x, y) \mapsto \sum_{i,j} x_i M_{ij} y_j$; with this M it is $x_0y_1 + x_1y_0$, which is exactly what `lorentzian_form_apply` records, so a referee need not trust the unfolding. The omitted field `isSymm` is the proof of symmetry. The full names are `VOA.Moonshine.ConwayNorton.lorentzianLattice` etc.; every declaration of this chapter not in namespace `VOA.NearVOA` lives in `VOA.Moonshine.ConwayNorton`. The basis vectors $u = (1,0)$ and $v = (0,1)$ are *isotropic* ($\langle u, u\rangle = \langle v, v\rangle = 0$) with $\langle u, v\rangle = 1$; this is why the library calls the standard basis "isotropic".

Physical meaning

$\mathrm{II}_{1,1}$ is the momentum lattice of two chiral bosons compactified on a Lorentzian torus; in the basis u, v the two bosons are the light-cone combinations $X^{\pm}$. The ground weight $\alpha_0\alpha_1$ is the conformal weight of the charged ground state $e^{(\alpha_0,\alpha_1)}$ — the "p^+p^-" mass-shell term of light-cone quantisation.

What the machine verified

Definitions. `lorentzian_form_apply` is proved; printed in `VOA/Moonshine/MoonshineCNAudit.lean` with axioms `[propext, Classical.choice, Quot.sound]`.

Theorem 44.2 ($\mathrm{II}_{1,1}$ is even, unimodular, of rank two and indefinite). *The lattice $\mathrm{II}_{1,1}$ is even; its rank is 2; the determinant of its Gram matrix is -1; its form is nondegenerate; it is not positive-definite; and it is self-dual: an element $x \in \mathrm{II}_{1,1} \otimes \mathbb{R}$ has $\langle x, v\rangle \in \mathbb{Z}$ for all $v \in \mathrm{II}_{1,1}$ if and only if $x \in \mathrm{II}_{1,1}$.*

File `VOA/Moonshine/MoonshineCNLattice.lean`.

theorem lorentzian_not_posDef : ¬ lorentzianLattice.PosDef := by

/-- Unimodularity in the repository's actual real dual-lattice sense. -/
theorem lorentzian_selfDual : lorentzianLattice.SelfDual := by
```

From the mathematics to the Lean statement

`SelfDual` (file `VOA/Foundations/Lattices.lean`) says: for every $x \in \mathbb{R} \otimes_{\mathbb{Z}} L$, x lies in the dual lattice `L.dual` $= \{x : \langle x, v\rangle \in \mathbb{Z}\ \forall v \in L\}$ iff x is the image of a lattice vector. This is unimodularity in its intrinsic form; `lorentzian_gram_det` gives the determinant form $\det G = -1$ as well, and together with `lorentzian_not_posDef` it pins the signature: a real symmetric 2×2 matrix with negative determinant has one positive and one negative eigenvalue, so the signature is $(1,1)$. `Nondegenerate` is Mathlib's `LinearMap.BilinForm.Nondegenerate` (left and right separating). The witness for `lorentzian_not_posDef` is $(1,-1)$, of norm -2. **Fidelity.** The six statements are exactly the six properties in the theorem; nothing is assumed. "Even unimodular of signature $(1,1)$" characterises $\mathrm{II}_{1,1}$ up to isomorphism (classical; not formalised and not needed).

Proof on paper. $\langle x, x\rangle = 2x_0x_1$ is even. The standard basis has two elements. $\det \left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right) = -1$. If $\langle x, y\rangle = 0$ for $y = (0,1)$ and $(1,0)$ then $x_0 = x_1 = 0$. $\langle (1,-1),(1,-1)\rangle = -2 < 0$. For self-duality: $\langle x,(0,1)\rangle$ and $\langle x,(1,0)\rangle$ are the two real coordinates of x in reversed order, so both are integers iff $x \in \mathbb{Z}^2$. □

Physical meaning

Evenness makes every vertex operator e^{α} bosonic with integral weight. Unimodularity (self-duality, as for E_8 and Λ) means there are no further sectors L^*/L to add; for a definite lattice it is also the condition for a modular-invariant chiral partition function, but for $\mathrm{II}_{1,1}$ no character $\mathrm{tr}\, q^{L_0}$ exists (Theorem 44.12), so that reading does not apply. What the moonshine application uses is self-duality: it makes the Monster Lie algebra graded by the *whole* lattice $\mathrm{II}_{1,1}$ rather than by a coset. Indefiniteness is the presence of time: one of the two directions is timelike.

What the machine verified

All six proved unconditionally; printed in `VOA/Moonshine/MoonshineCNAudit.lean` (`lorentzian_not_posDef`, `lorentzian_gram_det`, `lorentzian_selfDual` checked there); axioms `[propext, Classical.choice, Quot.sound]`.

Theorem 44.3 (Energy). *For $\alpha, \beta \in \mathrm{II}_{1,1}$: $2\Delta(\alpha) = \langle \alpha, \alpha\rangle$; $\Delta(\alpha+\beta) = \Delta(\alpha) + \Delta(\beta) + \langle \alpha, \beta\rangle$; and for every $N \in \mathbb{Z}$ there is α with $\Delta(\alpha) < N$ (namely $\alpha = (1, N-1)$).*

File `VOA/Moonshine/MoonshineCNLattice.lean`.

```
theorem lorentzianEnergy_half_norm (x : lorentzianLattice.carrier) :
    2 * lorentzianEnergy x = lorentzianLattice.form x x := by

theorem lorentzianEnergy_add (x y : lorentzianLattice.carrier) :
    lorentzianEnergy (x + y) = lorentzianEnergy x + lorentzianEnergy y +
      lorentzianLattice.form x y := by
```

```
/-- Charged ground states have no uniform lower energy bound. -/
theorem lorentzianEnergy_unbounded_below (N : ℤ) :
    ∃ x : lorentzianLattice.carrier, lorentzianEnergy x < N := by
```

From the mathematics to the Lean statement

`lorentzianEnergy` is Δ, defined directly as $\alpha_0\alpha_1$ rather than as the library's `halfNorm L x` $= \lfloor\langle x,x\rangle/2\rfloor$ (the Lean binder `x` is a whole lattice vector) (Chapter 31); the two agree by `lorentzian_halfNorm` (Theorem 44.12 below). The third statement is the honest form of "unbounded below": an existential for every integer bound.

Proof on paper. $(\alpha_0+\beta_0)(\alpha_1+\beta_1) = \alpha_0\alpha_1 + \beta_0\beta_1 + (\alpha_0\beta_1 + \alpha_1\beta_0)$, and $1\cdot(N-1) < N$. □

Physical meaning

$\Delta(\alpha+\beta) = \Delta(\alpha) + \Delta(\beta) + \langle\alpha,\beta\rangle$ is the statement that the operator product $e^{\alpha}(z)e^{\beta}(w)$ behaves like $(z-w)^{\langle\alpha,\beta\rangle}e^{\alpha+\beta}$: weights add up to the correction $\langle\alpha,\beta\rangle$ from the OPE. The unbounded energy is the tachyonic/time-like direction of the Lorentzian torus: in a Lorentzian compactification there is no lowest-energy state.

What the machine verified

Proved unconditionally; `lorentzianEnergy_unbounded_below` is printed in `VOA/Moonshine/MoonshineCNAudit.lean`; standard axioms.

Definition 44.4 (The cocycle). $\varepsilon =$ `lorentzianCocycle` is the library's FLM cocycle `latticeCocycle` of Chapter 31 (Definition 31.10), applied to $\mathrm{II}_{1,1}$. It is normalised, satisfies the 2-cocycle law, takes values in $\{\pm1\}$ (so $\varepsilon(\alpha,\beta)^{-1} = \varepsilon(\alpha,\beta)$), and $\varepsilon(\alpha,\beta)\varepsilon(\beta,\alpha) = (-1)^{\langle\alpha,\beta\rangle}$; together these give $\varepsilon(\alpha,\beta) = (-1)^{\langle\alpha,\beta\rangle}\varepsilon(\beta,\alpha)$.

File `VOA/Moonshine/MoonshineCNLattice.lean`.

```
/-- The existing FLM cocycle works without positive definiteness. -/
noncomputable def lorentzianCocycle :
    lorentzianLattice.carrier → lorentzianLattice.carrier → ℂ :=
  latticeCocycle lorentzianLattice

theorem lorentzianCocycle_law (x y z : lorentzianLattice.carrier) :
    lorentzianCocycle x y * lorentzianCocycle (x + y) z =
      lorentzianCocycle y z * lorentzianCocycle x (y + z) :=

theorem lorentzianCocycle_commutator (x y : lorentzianLattice.carrier) :
    lorentzianCocycle x y * lorentzianCocycle y x =
      (-1 : ℂ) ^ (lorentzianLattice.form x y) :=
```

From the mathematics to the Lean statement

The FLM cocycle is built from a chosen $\mathbb{Z}$-basis and the Gram matrix only, so positivity never enters; the commutator property uses evenness (`lorentzian_even`). `(-1 : ℂ) ^ k` with `k : ℤ` is an integer power (`zpow`). A second, simpler cocycle $(-1)^{x_1y_0}$ is introduced in Definition 44.7; it is *not* the one used in the vertex algebra.

Physical meaning

The cocycle makes the vertex operators $e^x(z)$ and $e^y(w)$ mutually local rather than local up to the sign $(-1)^{\langle x,y\rangle}$: it implements the Klein factors that make the two compact bosons' vertex operators commute (rather than anticommute) when the pairing is odd.

What the machine verified

Proved unconditionally (re-uses `latticeCocycle_cocycleLaw`, `latticeCocycle_comm`); standard axioms (`VOA/Moonshine/MoonshineCNAudit.lean`).

44.3 Oscillators in a complex frame

44.3.1 The problem, and the fix

The library's Fock space $\mathcal{F}_r = \texttt{FockN r} = \mathbb{C}[x_{j,a} : j \in \mathbb{N},\ a \in \{1..r\}]$ (Chapter 31, Definition 31.1) carries *orthonormal* oscillators $h_a(n)$: $h_a(-n)$ $(n \geq 1)$ is multiplication by $x_{n-1,a}$ and $h_a(n)$ $(n \geq 1)$ is $n\,\partial/\partial x_{n-1,a}$, with $[h_a(m), h_b(n)] = m\delta_{ab}\delta_{m+n,0}$. To realise the lattice Heisenberg algebra $[\alpha(m), \beta(n)] = m\langle\alpha,\beta\rangle\delta_{m+n,0}$ one needs coordinates $\alpha^\perp \in \mathbb{C}^r$ with

$$\sum_a \alpha_a^\perp \beta_a^\perp = \langle \alpha, \beta \rangle \qquad (\alpha, \beta \in L), \tag{44.3}$$

and then $\alpha(n) := \sum_a \alpha_a^\perp h_a(n)$. For positive-definite L the library used the real matrix $\sqrt{G}$ (Chapter 31, §31.5). Over $\mathbb{C}$ the pairing (44.3) is *bilinear* (no complex conjugation), and every nondegenerate symmetric form over $\mathbb{C}$ has such coordinates. For $\mathrm{II}_{1,1}$ one may take

$$(x_0, x_1)^\perp = \Big(x_0 + \tfrac{x_1}{2},\ i\big(x_0 - \tfrac{x_1}{2}\big)\Big), \tag{44.4}$$

since $(x_0 + \frac{x_1}{2})(y_0 + \frac{y_1}{2}) - (x_0 - \frac{x_1}{2})(y_0 - \frac{y_1}{2}) = x_0y_1 + x_1y_0$.

Definition 44.5 (Complex lattice frame). A *complex lattice frame* for an integral lattice L of rank r is an additive map $\alpha \mapsto \alpha^\perp$, $L \to \mathbb{C}^r$, satisfying (44.3). The *frame oscillator* of α is $\alpha(m) = \sum_a \alpha_a^\perp h_a(m)$ on $\mathcal{F}_r$. The Lorentzian frame is (44.4), reindexed along rank $\mathrm{II}_{1,1} = 2$.

Files `VOA/Moonshine/MoonshineCNComplexFrame.lean`, `VOA/Moonshine/MoonshineCNOscillators.lean`.

```

    (α : L.carrier) (m : ℤ) : Module.End ℂ (FockN (rank L)) :=
  ∑ a, F.coordinate α a • oscN (rank L) 1 a m
```

From the mathematics to the Lean statement

`L.carrier →+ (Fin (rank L) → ℂ)` is an additive group homomorphism into $\mathbb{C}^r$ (indexed by `Fin (rank L)`, the Fock colours). `pairing` is (44.3) with the integer $\langle x, y\rangle$ cast to $\mathbb{C}$; note there is no complex conjugate, so this is a *bilinear* orthonormal frame. `oscN (rank L) 1 a m` is $h_a(m)$ at level $k = 1$ (Chapter 31, Definition 31.2). `finCongr lorentzian_rank` is the bijection $\{0, \dots, \mathrm{rank}-1\} \cong \{0, 1\}$ coming from rank $\mathrm{II}_{1,1} = 2$: the Fock space is indexed by `Fin (rank lorentzianLattice)`, which is only propositionally equal to `Fin 2`. The omitted fields of `lorentzianComplexFrame` are the additivity proofs and the pairing proof (which is `complexHyperbolicCoordinate_pairing`, Theorem 44.6). **Could this be vacuous?** A `ComplexLatticeFrame` exists only if the coordinates realise the form; the Lorentzian instance is *constructed*, not assumed, so the structure is inhabited for the lattice we care about.

Physical meaning

Over $\mathbb{C}$ every nondegenerate symmetric bilinear form is a sum of squares, so two bosons with the Lorentzian OPE can always be rewritten as two "orthonormal" bosons with complex coefficients. In (44.4) the form is $A^2 - B^2$ with $A = x_0 + \frac{x_1}{2}$ (the spacelike combination) and $B = x_0 - \frac{x_1}{2}$ (the timelike one); the factor i in front of B turns $-B^2$ into $+(iB)^2$. The Fock machinery is purely algebraic (polynomials and derivations), so complex coefficients cost nothing and change no OPE: the commutators are the lattice pairing (Theorem 44.6).

What the machine verified

Definitions; the Lorentzian frame is constructed with no hypotheses (`lorentzianComplexFrame`, printed in `VOA/Moonshine/MoonshineCNAudit2.lean`).

Theorem 44.6 (Frame pairing and Heisenberg relations). *The coordinates* (44.4) *satisfy* (44.3) *for* $\mathrm{II}_{1,1}$. *For any complex frame of any integral lattice, the frame oscillators satisfy* $[\alpha(m), \beta(n)] = m\langle\alpha, \beta\rangle\delta_{m+n,0}$, *and* $\alpha(m)\mathbb{1} = 0$ *for* $m \geq 0$.

Files `VOA/Moonshine/MoonshineCNOscillators.lean`, `VOA/Moonshine/MoonshineCNComplexFrame.lean`.

```
theorem complexHyperbolicCoordinate_pairing (x y : lorentzianLattice.carrier) :
    (∑ a, complexHyperbolicCoordinate x a * complexHyperbolicCoordinate y a) =

theorem frameOscillator_commutator {L : IntegralLattice} (F : ComplexLatticeFrame L)
    (α β : L.carrier) (m n : ℤ) :
    frameOscillator F α m * frameOscillator F β n -
      frameOscillator F β n * frameOscillator F α m =
      (if m + n = 0 then (L.form α β : ℂ) * (m : ℂ) else 0) • LinearMap.id := by
```

From the mathematics to the Lean statement

`[A, B]` is the commutator $AB - BA$ of endomorphisms; the second commutator theorem writes it out. `lorentzianOscillator x m` is `complexChargeOscillator (complexHyperbolicCoordinate x) m`, the same operator as `frameOscillator lorentzianComplexFrame x m` up to the reindexing by `finCongr` (on `FockN 2` directly). The `if m + n = 0 then … else 0` is the Kronecker delta. `vacuumN` is the constant polynomial $1 = \mathbb{1}$. **Fidelity:** exactly the Heisenberg relations with the *lattice* form, which is what the lattice vertex algebra needs; the hypotheses are only the data (a frame), no positivity.

Proof on paper. The pairing is the computation after (44.4), using $i^2 = -1$. Expanding $\alpha(m), \beta(n)$ in the h_a, only diagonal terms survive and give $m\delta_{m+n,0} \sum_a \alpha_a^{\perp}\beta_a^{\perp} = m\delta_{m+n,0}\langle\alpha, \beta\rangle$. Annihilation of the vacuum holds for each $h_a(m)$, $m \geq 0$ (for $m = 0$ the oscillator $h_a(0)$ is zero on the Fock space; the momentum zero mode is added separately in Definition 44.16). □

Physical meaning

$[\alpha(m), \beta(n)] = m\langle\alpha, \beta\rangle\delta_{m+n,0}$ is the OPE $\partial X^{\alpha}(z)\partial X^{\beta}(w) \sim \langle\alpha, \beta\rangle/(z - w)^2$ of two Lorentzian currents. For the isotropic pair $u = (1, 0)$, $v = (0, 1)$ it says $[u(m), u(n)] = [v(m), v(n)] = 0$ and $[u(m), v(n)] = m\delta_{m+n,0}$: the light-cone oscillators α^+ and α^- commute among themselves and are conjugate to each other.

What the machine verified

Proved unconditionally; `lorentzianOscillator_commutator` printed in `VOA/Moonshine/MoonshineCNAudit.lean`, the frame statements in `VOA/Moonshine/MoonshineCNAudit2.lean`; standard axioms.

Definition 44.7 (The coordinate cocycle). $\varepsilon_{\mathrm{std}}(x, y) = (-1)^{x_1 y_0}$ on $\mathrm{II}_{1,1}$.

File `VOA/Moonshine/MoonshineCNComplexFrame.lean`.

```
/-- Fixed-coordinate sign cocycle: the ordered isotropic basis gives `(-1)^(x₁y₀)`. -/
noncomputable def standardLorentzianCocycle (x y : lorentzianLattice.carrier) : ℂ :=
  (-1 : ℂ) ^ (x 1 * y 0)

theorem standardLorentzianCocycle_commutator (x y : lorentzianLattice.carrier) :
    standardLorentzianCocycle x y * standardLorentzianCocycle y x =
      (-1 : ℂ) ^ lorentzianLattice.form x y := by
```

From the mathematics to the Lean statement

The file also proves the cocycle law, normalisation and nonvanishing. $\varepsilon_{\mathrm{std}}$ is bimultiplicative, and $\varepsilon_{\mathrm{std}}(x, y)\varepsilon_{\mathrm{std}}(y, x) = (-1)^{x_1 y_0 + y_1 x_0} = (-1)^{\langle x, y\rangle}$. **Status in the construction:** it is used only for a parallel family of charged fields (`lorentzianChargedField`, Definition 44.14) whose locality is proved; the vertex algebra `lorentzianNearVOA` uses the library's `latticeCocycle` instead, because the target structure prescribes it (Definition 44.9). The two cocycles are *not* claimed equal, and no gauge transformation between them is formalised (see the warning in §44.15).

Physical meaning

Any two cocycles with the same commutator are cohomologous; the resulting vertex algebras are isomorphic by rescaling each e^{α} by a sign. Physically the choice of Klein factors is unobservable.

What the machine verified

Definition and proved properties; standard axioms (`VOA/Moonshine/MoonshineCNAudit2.lean`).

44.4 What kind of object $V_{\mathrm{II}_{1,1}}$ is

44.4.1 Near-VOAs

We first print the structure that the whole chapter is about. It lives in the core of the library and is mentioned in Chapter 1 and Chapter 4; since every headline of this part of the book is a statement about it, we decode it in full here. Recall the conventions of Chapter 1: a `FormalDist (End ℂ V)`, also written `(End ℂ V)⟦z^±⟧`, is a function $\mathbb{Z} \to \mathrm{End}(\mathcal{V})$, the value at t being the coefficient of z^t; `mode f n` $= f(-n-1)$, so that `mode (Y u) n` is $u_{(n)}$ in $Y(u,z) = \sum_n u_{(n)} z^{-n-1}$; `Local A B` means that $(z_1 - z_2)^N [A(z_1), B(z_2)] = 0$ for some $N \in \mathbb{N}$; `deriv` is the formal ∂_z.

Definition 44.8 (Near-VOA, following Gannon). A *near-VOA* on a complex vector space $\mathcal{V}$ consists of: a family of subspaces $\mathcal{V}_n$, $n \in \mathbb{Z}$, with $\mathcal{V} = \bigoplus_n \mathcal{V}_n$ (internal direct sum); a linear map $Y : \mathcal{V} \to \mathrm{End}(\mathcal{V})[[z^{\pm 1}]]$; a vacuum $\mathbb{1} \in \mathcal{V}_0$; a conformal vector $\omega \in \mathcal{V}_2$; and a central charge $c \in \mathbb{C}$; such that, writing $L_n = \omega_{(n+1)}$: (VA1) $u_{(n)}\mathcal{V}_j \subseteq \mathcal{V}_{k+j-n-1}$ for $u \in \mathcal{V}_k$; (VA2) $Y(\mathbb{1}, z) = \mathrm{id}$; (VA3) $u_{(-1)}\mathbb{1} = u$ and $u_{(n)}\mathbb{1} = 0$ for $n \geq 0$; (VA4) all $Y(u,z), Y(v,z)$ are mutually local; (VA5) for all u, v, $u_{(n)}v = 0$ for $n \gg 0$; (VOA1) $[L_m, L_n] = (m-n)L_{m+n} + \frac{c}{12}(m^3 - m)\delta_{m+n,0}$; (VOA2) $L_0 = n$ on $\mathcal{V}_n$; (VOA3) $Y(L_{-1}v, z) = \partial_z Y(v,z)$. No finiteness of $\dim \mathcal{V}_n$ and no lower bound on n is required.

File `VOA/Core/VertexOperatorAlgebra.lean`.

From the mathematics to the Lean statement

Field by field. `DirectSum.IsInternal grading` is Mathlib's statement that the canonical map $\bigoplus_n \mathcal{V}_n \to \mathcal{V}$ is bijective (every vector is uniquely a finite sum of homogeneous pieces). `V →ₗ[ℂ] …` is a $\mathbb{C}$-linear map. In `virasoro`, `mode (Y conformalVector) (m + 1)` $= \omega_{(m+1)} = L_m$; the central term is $\frac{m^3-m}{12}c\,\mathrm{id}$ when $m+n=0$. In `L0_grading`, `mode (Y conformalVector) 1` $= L_0$. In `translation`, `mode (Y conformalVector) 0` $= L_{-1}$. Locality is ordinary (bosonic) locality. **What is absent, compared with `VertexOperatorAlgebra`** (Chapter 4, Definition 4.4). The library layers its structures: `PreVertexAlgebra` carries the field `finrank` (finite-dimensional weight spaces); `GradedVertexOperatorAlgebra` extends it by the conformal data and `grading_bounded_below` ($\mathcal{V}_n = 0$ for $n \ll 0$); `VertexOperatorAlgebra` adds the CFT-type fields `vacuum_grade` ($\mathcal{V}_0 = \mathbb{C}\mathbb{1}$) and `positivity` ($\mathcal{V}_n = 0$ for $n < 0$). A near-VOA has none of `finrank`, `grading_bounded_below`, `vacuum_grade`, `positivity`. Every VOA gives a near-VOA by `VertexOperatorAlgebra.toNearVOA`, which forgets these fields; this is how $V^\natural$ enters below (`VnatVOA.toNearVOA`). **Possible vacuity.** The zero space is a near-VOA of every central charge; non-vacuity of the specific near-VOAs below is witnessed by their explicit nonzero states (e.g. `lorentzianChargeState_ne_zero`) and by their central charges being forced by the Virasoro relation on a nonzero space. Note also that the structure contains *both* the ordinary locality axiom and translation covariance (VOA3); the counterexample of Chapter 4 (§4.5) shows that without (VOA3) the Borcherds identity can fail, so its presence matters for §44.10.

Physical meaning

A near-VOA is a chiral algebra of a (possibly non-unitary, non-compact) conformal field theory: states, fields, OPEs, a stress tensor with central charge c, and L_0 as the energy. What it does not have is a vacuum that is the unique lowest-energy state; Lorentzian or non-compact target spaces (the light-cone bosons, a linear dilaton, Liouville theory) produce exactly such algebras.

What the machine verified

Definition (core library); `toNearVOA` is axiom-clean (Chapter 1).

44.4.2 The target structure and its obstruction

Before constructing any field, the library states precisely which object is to be built.

Definition 44.9 (Even-lattice vertex realisation)**.** An *even-lattice vertex realisation* of an integral lattice L is a near-VOA (Definition 44.8) on the lattice state space $V_L = \mathcal{F}_r \otimes \mathbb{C}[L]$ (Chapter 31, Definition 31.17) together with: L even and nondegenerate; vacuum $= 1 \otimes e^0$; central charge $= \operatorname{rank} L$; each charged vacuum $e^x = 1 \otimes e^x$ in weight $\langle x, x\rangle/2$; and the leading product of charged vacua

$$e^x_{(-\langle x,y\rangle-1)}e^y = \varepsilon(x,y)\,e^{x+y}, \qquad e^x_{(n)}e^y = 0 \quad (n > -\langle x,y\rangle - 1), \tag{44.5}$$

with $\varepsilon =$ `latticeCocycle`. `LorentzianVertexTarget` is the proposition that such a realisation exists for $\mathrm{II}_{1,1}$.

File `VOA/Moonshine/MoonshineCNVertexTarget.lean`.

```

```

(The last declaration is in `VOA/Moonshine/MoonshineCNComplexFrame.lean`.)

From the mathematics to the Lean statement

A Lean alias. The Lean file states the realisation as an extension of a structure `UnboundedConformalVertexAlgebra` (same file, not printed) rather than of `NearVOA`. Mathematically there is nothing new: it has literally the fields of `NearVOA`, field for field, the only difference being that `grading_mode` and `L0_grading` take their weights as explicit rather than implicit arguments, and `toNearVOA` copies each field (its body, not shown, is sixteen lines `grading := V.grading`, ...). It is a historical duplicate (the near-VOA structure had been overlooked when the target was written); read it as "near-VOA". `LatGen.LatModuleGen L` $= \mathcal{F}_r \otimes \mathbb{C}[L]$, `latVacuumGen` $= 1 \otimes e^0$, `latChargeGen L x` $= 1 \otimes e^x$ (Chapter 31, Definition 31.17). `L.form x x / 2` is integer division; with `even` it is exact. **Why the extra fields.** They pin the object to be the lattice vertex algebra and not an arbitrary near-VOA on the same space: the central charge, the weights of the charged vacua, and the leading operator products (44.5) with the FLM cocycle. Together with locality and the creation axiom they determine Y uniquely on the subalgebra generated by the e^x (Goddard uniqueness, Theorem 44.46), which for a lattice vertex algebra is everything once the Heisenberg currents are also pinned; the realisation actually constructed below pins them too (Theorem 44.21). **A stale docstring.** The docstring of `EvenLatticeVertexRealization` ("An inhabitant ... is still required") and that of `LorentzianVertexTarget` ("The exact remaining existence statement") describe the state of the development before the construction; the inhabitant is `lorentzianVertexTarget_inhabited` (Theorem 44.20). See §44.15.

Physical meaning

The target says: "the chiral algebra of two compact light-cone bosons, normalised so that the vertex operator of e^x creates the momentum state e^x, and so that $e^x(z)e^y(w) \sim \varepsilon(x,y)(z-w)^{\langle x,y\rangle}e^{x+y}(w)$." These are the defining OPEs of a lattice CFT.

What the machine verified

Definitions. `UnboundedConformalVertexAlgebra.toNearVOA` is printed in `VOA/Moonshine/MoonshineCNAudit2.lean`; standard axioms.

Theorem 44.10 (No lower bound is possible). *Let $(\mathcal{V}_n)_{n\in\mathbb{Z}}$ be* any *family of subspaces of $V_{\mathrm{II}_{1,1}}$'s state space such that each charged vacuum e^x lies in $\mathcal{V}_{\Delta(x)}$. Then there is no N with $\mathcal{V}_n = 0$ for all $n < N$. In particular the weight grading of $V_{\mathrm{II}_{1,1}}$ is not bounded below.*

Files `VOA/Moonshine/MoonshineCNVertexTarget.lean`, `VOA/Moonshine/MoonshineCNGrading.lean`.

```
theorem lorentzian_grading_not_bounded_below
    (grading : ℤ → Submodule ℂ LorentzianFockSpace)
    (charge_mem : ∀ x : lorentzianLattice.carrier,
      lorentzianChargeState x ∈ grading (lorentzianEnergy x)) :
    ¬ ∃ N : ℤ, ∀ n : ℤ, n < N → grading n = ⊥ := by

theorem lorentzianWeightGrading_not_bounded_below :
    ¬ ∃ N : ℤ, ∀ n : ℤ, n < N → lorentzianWeightGrading n = ⊥ :=
```

From the mathematics to the Lean statement

$\bot$ is the zero subspace. The first theorem quantifies over *every* candidate grading that puts the charged vacua at their energies; it therefore rules out *any* `GradedVertexOperatorAlgebra` structure with the physical weights, not only the one constructed. The second is the instance for the actual grading `lorentzianWeightGrading` = `gradingLatGen lorentzianLattice` (Definition 44.11). The only extra input is `lorentzianChargeState_ne_zero` (the coefficient of $1 \otimes e^x$ in e^x is 1).

Proof on paper. Given N, take $x = (1, N-1)$; then $\Delta(x) = N - 1 < N$, so $e^x \in \mathcal{V}_{N-1} = 0$, contradicting $e^x \neq 0$. □

Physical meaning

Lorentzian compactifications have no ground state: the energy p^+p^- is unbounded below. This is the mathematical form of the statement that $V_{\mathrm{II}_{1,1}}$ is not the chiral algebra of a unitary compact CFT.

What the machine verified

Proved unconditionally; both printed (`VOA/Moonshine/MoonshineCNAudit.lean`, `VOA/Moonshine/MoonshineCNAudit2.lean`); standard axioms.

Definition 44.11 (The weight grading). For an integral lattice L and $n \in \mathbb{Z}$, $(V_L)_n = \sum_\alpha (\mathcal{F}_r)_{n-\lfloor\langle\alpha,\alpha\rangle/2\rfloor} \otimes e^\alpha$ (the floor is exact when L is even, the only case used later) (Chapter 31, Definition 31.18, the library's `gradingLatGen`). For $\mathrm{II}_{1,1}$ this is `lorentzianWeightGrading`.

File `VOA/Moonshine/MoonshineCNGrading.lean`.

```
noncomputable def lorentzianWeightGrading : ℤ → Submodule ℂ LorentzianFockSpace :=
  gradingLatGen lorentzianLattice
```

From the mathematics to the Lean statement

Same grading as for positive-definite lattices; it is the *theorems* about it that change. The weight of $p \otimes e^{\alpha}$ is (level of p) + $\Delta(\alpha)$; that this is the L_0-eigenvalue is proved in Theorem 44.19.

Physical meaning

Conformal weight = oscillator level + $\frac{1}{2}$momentum^2, with the Lorentzian square.

What the machine verified

Definition.

Theorem 44.12 (Internality without positivity; infinite weight spaces). *(i) For* every *integral lattice* L, $V_L = \bigoplus_{n\in\mathbb{Z}} (V_L)_n$ *is an internal direct sum. (ii) For* $\mathrm{II}_{1,1}$, `halfNorm`$(\alpha) = \Delta(\alpha)$ *and* $e^{\alpha} \in (V)_{\Delta(\alpha)}$. *(iii) The states* $e^{(i,0)}$, $i \in \mathbb{Z}$, *are linearly independent; hence* $(V_{\mathrm{II}_{1,1}})_0$ *is infinite-dimensional.*

File `VOA/Moonshine/MoonshineCNGrading.lean`.

```
/-- Internal integer grading, including indefinite lattices and infinite fibers. -/

/-- Infinitely many linearly independent isotropic charged ground states. -/
theorem lorentzianIsotropicChargeStates_independent :
    LinearIndependent ℂ (fun i : ℤ => lorentzianChargeState ![i, 0]) := by

/-- This is an actual obstruction to the finite-weight-space `VertexAlgebra`. -/
theorem lorentzianWeightZero_not_finiteDimensional :
    ¬ FiniteDimensional ℂ (lorentzianWeightGrading 0) := by
```

From the mathematics to the Lean statement

(i) has no hypothesis at all, not even evenness: the library already had internality under positivity (`gradingLatGen_isInternal_of_posDef`); the new proof works for infinite fibres. `![i, 0]` is the vector $(i, 0)$. `LinearIndependent ℂ f` is Mathlib's linear independence of a family. `FiniteDimensional ℂ (lorentzianWeightGrading 0)` refers to the subspace as a vector space in its own right. **Fidelity:** (iii) is precisely the obstruction to the library's `Pre VertexAlgebra/VertexOperatorAlgebra`, whose field `finrank` requires every weight space to be finite-dimensional.

Proof on paper. (i) $V_L = \bigoplus_{(w,\alpha)} (\mathcal{F}_r)_w \otimes e^{\alpha}$ is a direct sum of the bigraded pieces; regrouping the summands of a direct sum along the map $(w, \alpha) \mapsto w + \langle \alpha, \alpha \rangle/2$ is still a direct sum, whatever the sizes of the fibres. (ii) $2\Delta(\alpha) = \langle \alpha, \alpha \rangle$ and 1 has level 0. (iii) The linear functional "coefficient of $1 \otimes e^{(i,0)}$" is 1 on $e^{(i,0)}$ and 0 on $e^{(j,0)}$, $j \neq i$; each $(i, 0)$ is isotropic, so all these states lie in weight 0. □

Physical meaning

Infinitely many weight-zero states: every isotropic (lightlike) momentum gives a massless ground state. The $e^{(i,0)}$, $i \in \mathbb{Z}$, pairwise pair to $\langle (i,0),(j,0)\rangle = 0$, so their vertex operators commute and multiply like a group algebra $\mathbb{C}[\mathbb{Z}]$ inside weight zero; this is a direct consequence of $\mathrm{II}_{1,1}$ containing isotropic vectors. In string language these are the zero-energy light-cone momenta; the infinite degeneracy is why a character $\operatorname{tr} q^{L_0}$ of $V_{\mathrm{II}_{1,1}}$ does not exist, and why the theory must be graded by momentum *and* weight (Theorem 44.23) to have finite pieces.

What the machine verified

Proved unconditionally; all printed in `VOA/Moonshine/MoonshineCNAudit2.lean`; standard axioms.

44.5 The construction of the fields

The construction follows the positive-definite construction of Chapter 31 (§§31.7–31.9) step by step, with the real frame replaced by an arbitrary complex frame F (Definition 44.5). Each file states which positive-definite file it adapts (`LatticeGenVertex`, `LatticeGenSameSignLocal`, ...); those originals are unchanged. We present the definitions and the theorems that enter the final structure; the many intermediate contraction lemmas are described collectively at the end of the section. Throughout, L is an integral lattice of rank r with a complex frame F, and $\alpha(n)$ denotes the frame oscillator.

44.5.1 The exponentials

Definition 44.13 (Creation and annihilation exponentials)**.** For $\alpha \in L$ put $x_m(\alpha) = \sum_a \alpha_a^{\perp} x_{m,a}$ (the polynomial of $\alpha(-m-1)\mathbb{1}$), and define polynomials $P_N(\alpha)$ and operators $A_N(\alpha)$ recursively by $P_0 = 1$, $A_0 = \mathrm{id}$ and

$$(N+1)\,P_{N+1}(\alpha) = \sum_{m=0}^{N} x_m(\alpha)\,P_{N-m}(\alpha), \qquad (N+1)\,A_{N+1}(\alpha) = \sum_{m=0}^{N} \big(-\alpha(m+1)\big) A_{N-m}(\alpha).$$

Then $E^{-}(\alpha,z) = \sum_N P_N(\alpha) z^N = \exp\big(\sum_{n\ge 1} \alpha(-n) z^n/n\big)\mathbb{1}$ and $E^{+}(\alpha,z) = \sum_N A_N(\alpha) z^{-N} = \exp\big(-\sum_{n\ge 1} \alpha(n) z^{-n}/n\big)$.

File `VOA/Moonshine/MoonshineCNExponential.lean`.

```
noncomputable def creationVariable (α : L.carrier) (m : ℕ) : HeisenbergN.FockN (rank L) :=

  | (N+1) => ((N+1 : ℂ))⁻¹ • ∑ m ∈ Finset.range (N+1),
      (-(frameOscillator F α (m+1 : ℤ))).comp (annihilationCoefficient α (N - m))
```

From the mathematics to the Lean statement

`MvPolynomial.X ((m, a))` is the variable $x_{m,a}$, i.e. $h_a(-m-1)\mathbb{1}$. The recursions are the Newton identities $\partial_z E = E\,\partial_z(\text{exponent})$ read coefficientwise; using them, rather than exponentials of infinite sums, keeps every coefficient a finite polynomial or a finite composite of operators. The frame F and the lattice L are section variables. **Fidelity:** these are exactly the coefficient expansions of FLM's exponentials $E^{\mp}(-\alpha, z)$ (FLM, §4.1 and §8.4; FLM write the vertex operator with $-\alpha$ in the exponentials) in the convention of Chapter 31, Definition 31.20; no convergence or completed tensor product is used.

Physical meaning

$E^-(\alpha,z)E^+(\alpha,z)$ is the oscillator part $:e^{i\alpha\cdot X(z)}:$ of the vertex operator, with the creation half on the left (normal ordering). On a fixed vector E^+ acts by a finite sum, while E^- has infinitely many terms: the familiar fact that a vertex operator creates states at all oscillator levels.

What the machine verified

Definitions; all lemmas of the file printed in `VOA/Moonshine/MoonshineCNAudit2.lean`.

44.5.2 The charged fields

Definition 44.14 (Charged field)**.** Let $\varepsilon : L \times L \to \mathbb{C}$. The *dressing* field is the normal-ordered product $\mathcal{E}(\alpha,z) = E^-(\alpha,z)E^+(\alpha,z)$ on $\mathcal{F}_r$. The *charged field* of α is the formal distribution on V_L with

$$Y_\varepsilon(e^\alpha, z)\,(p \otimes e^\beta) = \varepsilon(\alpha,\beta)\, z^{\langle\alpha,\beta\rangle}\, \mathcal{E}(\alpha,z)p \otimes e^{\alpha+\beta}, \tag{44.6}$$

i.e. coefficient of z^t equal to $\varepsilon(\alpha,\beta)\,\mathcal{E}_{t-\langle\alpha,\beta\rangle}(\alpha)p \otimes e^{\alpha+\beta}$. For $\mathrm{II}_{1,1}$, `lorentzianChargedField` uses $\varepsilon_{\mathrm{std}}$ and `lorentzianTargetChargedField` (equal to `canonicalChargedField lorentzianComplexFrame`) uses the FLM cocycle.

Files `VOA/Moonshine/MoonshineCNChargedFields.lean`, `VOA/Moonshine/MoonshineCNCurrents.lean`.

```

From the mathematics to the Lean statement

`nprod` is the normal-ordered product of two fields (Chapter 4, §4.6); `creationField F α t` is $P_t(\alpha)$ times (multiplication) for $t \geq 0$ and 0 for $t < 0$, and `annihilationField F α t` is $A_{-t}(\alpha)$ for $t \leq 0$ and 0 for $t > 0$ (same file). The definition of `chargedField` itself (not shown) is the linear extension of `chargedField_tmul` over the basis $p \otimes e^{\beta}$, built with `TensorProduct.lift` and `Finsupp.lsum`; `chargedField_tmul` is its defining equation, which is (44.6) coefficientwise ($t \mapsto t - \langle\alpha,\beta\rangle$ is the factor $z^{\langle\alpha,\beta\rangle}$, i.e. $z^{\alpha(0)}$). `chargedField_charge_leading` is (44.5): the mode $-\langle\alpha,\beta\rangle - 1$ picks the coefficient $\mathcal{E}_0 = \mathrm{id}$ on the vacuum. The companion `chargedField_charge_higher_modes` gives the vanishing of higher modes. **Two cocycles:** the vertex algebra uses `lorentzianTargetChargedField`.

Physical meaning

(44.6) is the FLM/Frenkel–Kac vertex operator (sign convention as in Definition 44.13): shift momentum by α (the operator e_α with Klein factor ε), multiply by $z^{\alpha\cdot p}$, and dress with the oscillator exponential. It is the operator $:e^{i\alpha\cdot X(z)}:$ of a compact boson, here with a Lorentzian $\alpha \cdot X$.

What the machine verified

Definitions and proved identities; printed in `VOA/Moonshine/MoonshineCNAudit2.lean`; standard axioms.

Theorem 44.15 (Locality of charged fields). *Let $C : L \times L \to \mathbb{C}$ be bimultiplicative in the second variable with $C(\alpha,\beta) = (-1)^{\langle\alpha,\beta\rangle}C(\beta,\alpha)$. Then for all $\alpha,\beta \in L$ the charged fields $Y_C(e^{\alpha},z)$, $Y_C(e^{\beta},z)$ are mutually local. Both the FLM cocycle and $\varepsilon_{\mathrm{std}}$ satisfy the hypothesis (both are bimultiplicative, ±1-valued, with commutator $(-1)^{\langle\alpha,\beta\rangle}$); hence both families of Lorentzian charged fields are mutually local.*

theorem lorentzianTargetChargedField_local (α β : lorentzianLattice.carrier) :
    Local (lorentzianTargetChargedField α) (lorentzianTargetChargedField β) :=
```

From the mathematics to the Lean statement

In `chargedField_local`, F and `C : ChargeCommutationFactors L` are section variables, so the statement is: for every frame and every factor system C. The two fields `add_right`, `swap` are exactly what the computation uses; `canonicalChargeCommutationFactors L hEven` supplies them for the FLM cocycle (using evenness and $\varepsilon(\alpha,\alpha)^2 = 1$), `lorentzianChargeCommutationFactors` for $\varepsilon_{\mathrm{std}}$. No positivity and no sign condition on $\langle\alpha,\beta\rangle$ is assumed.

Proof on paper. Moving $E^+(\alpha, z_1)$ past $E^-(\beta, z_2)$ produces the scalar $(1-z_2/z_1)^{\langle\alpha,\beta\rangle}$, and the momentum factors give $z_1^{\langle\alpha,\beta\rangle}$; so $Y(e^\alpha, z_1)Y(e^\beta, z_2) = C(\alpha,\beta)(z_1-z_2)^{\langle\alpha,\beta\rangle} : \cdots :$, where the normal-ordered product $: \cdots :$ is symmetric in the two fields, and $(z_1 - z_2)^k$ is expanded in z_2/z_1. If $k = \langle\alpha,\beta\rangle \geq 0$ this is a polynomial, and the swap identity $C(\alpha,\beta)(z_1 - z_2)^k = C(\beta,\alpha)(z_2 - z_1)^k$ shows that the two orderings are *equal*: the fields commute coefficientwise. If $k < 0$ the two orderings are the expansions of the same rational function in the two regions, and multiplying by $(z_1 - z_2)^{|k|}$ makes both equal. The Lean proof implements the negative case by finite binomial differences rather than by rational functions, so that every sum is finite on a fixed vector. □

Physical meaning

$e^\alpha(z)e^\beta(w) \sim (z-w)^{\langle\alpha,\beta\rangle}e^{\alpha+\beta}(w)$: the OPE has a pole of order $-\langle\alpha,\beta\rangle$ when the pairing is negative and is regular when it is nonnegative. In a positive-definite lattice a fixed α has negative pairing with β only within a bounded range; in $\mathrm{II}_{1,1}$ the pairing $\langle(1,0),(0,-n)\rangle = -n$ is unbounded below, so pole orders are unbounded. The proof handles each pair separately, so this causes no difficulty, but no argument may use a uniform bound.

What the machine verified

Proved unconditionally (for every frame and factor system); all three printed in `VOA/Moonshine/MoonshineCNAudit2.lean`; standard axioms.

44.5.3 Currents, translation, reconstruction

Definition 44.16 (Currents and translation operator)**.** For a frame colour a, the *current* $h_a(z)$ on V_L is the Fock current $\sum_n h_a(n)z^{-n-1}$ acting on the first factor, plus the *momentum zero mode* $h_a(0)(p \otimes e^\beta) = \beta_a^\perp\, p \otimes e^\beta$. The derivative currents are $\partial^i h_a(z)/i!$. The translation operator is $T = L_{-1}^{\mathrm{Fock}} \otimes 1 + \sum_a h_a(-1)\, h_a(0)$.

Files `VOA/Moonshine/MoonshineCNCurrents.lean`, `VOA/Moonshine/MoonshineCNTranslation.lean`.

  LinearMap.rTensor (L.carrier →₀ ℂ) (HeisenbergN.LvirN (rank L) 1 (-1)) + momentumCoupling
↪  F
```

From the mathematics to the Lean statement

`groupMomentum F a` multiplies e^β by $\beta_a^\perp$ (lemma `frameMomentum_latStateGen`). The coefficient index $j = -1$ is the coefficient of z^{-1}, i.e. the mode $h_a(0)$: so the momentum enters exactly as the zero mode, as it must. `rTensor`/`lTensor` act on the first/second tensor factor. `LvirN (rank L) 1 (-1)` is the Fock-space L_{-1} (Chapter 31); `momentumCoupling F` $= \sum_a (h_a(-1) \otimes 1)\circ$`frameMomentum F a`. `VOA.deriv^[i]` is the i-fold formal derivative.

Physical meaning

$h_a(z) = i\partial\phi_a(z)$ is the a-th free-boson current, whose zero mode is the momentum; $T = L_{-1}$ is the generator of translations, and the cross term $h_a(-1)p_a$ is the momentum contribution $\alpha(-1)\alpha(0)$ to $L_{-1} = \frac{1}{2}\sum :\alpha\alpha:_{-1}$.

What the machine verified

  (frameStateField_exists F hEven).choose
```

From the mathematics to the Lean statement

A word is a list of pairs (i,a); `currentN (rank L) 1 a i` applied as the coefficient of z^i is the mode $h_a(-i-1)$. `frameWordField F l α` is defined recursively in the same file as the normal-ordered product of `frameDerivativeCurrent F a i` with the word field of the tail, starting from `canonicalChargedField F α`. `IsField` means lower truncation on each vector; `(Yfull u) 0` is the z^0 coefficient, so `(Yfull u) 0 (latVacuumGen L) = u` and the vanishing for $q<0$ say $Y(u,z)\mathbb{1} = u + O(z)$. `DCovariant T A` is $[T, A(z)] = \partial_z A(z)$ (Chapter 31, Definition 31.23). `.choose` picks a witness; it is unique by Goddard's theorem (Theorem 44.46), so the choice is harmless. The existence is the library's reconstruction theorem `Reconstruction.reconstruct` (Chapter 4, Theorem 4.41), applied to the generating fields; its hypotheses are discharged by `frameWordField_local` (locality of all word fields, by Dong's lemma from Theorem 44.15 and current–current/current–charge locality), the vacuum properties and T-covariance.

Proof on paper. The word states span V_L (they are the monomial basis). The generating fields $h_a(z)$, $Y(e^\alpha, z)$ are mutually local, T-covariant and create their states from the vacuum; by Dong's lemma their normal-ordered products and derivatives remain mutually local; the reconstruction theorem then extends Y linearly from the spanning set, the point being that the extension is well defined because a local, T-covariant field is determined by the state it creates. □

Physical meaning

The state–field correspondence of a free-boson CFT: the field of an oscillator state is the normal-ordered product of derivatives of currents with the vertex operator, $:\partial^{i_1}\phi\cdots e^{i\alpha\cdot\phi}:$.

What the machine verified

Proved for every even lattice and every complex frame; `frameStateField_exists` and the word-field lemmas printed in `VOA/Moonshine/MoonshineCNAudit2.lean`; standard axioms.

44.5.4 The conformal vector and the Virasoro algebra

Definition 44.18 (Conformal vector and Sugawara field). $\omega_L = \frac{1}{2}\sum_a h_a(-1)^2\mathbb{1}\otimes e^0$ (orthonormal frame colours), and the Sugawara field $\frac{1}{2}\sum_a :h_a(z)h_a(z):$ on V_L, whose modes are L_n.

Files `VOA/Moonshine/MoonshineCNConformal.lean`, `VOA/Moonshine/MoonshineCNVirasoro.lean`.

```
noncomputable def latticeConformalVector (L : IntegralLattice) : LatModuleGen L := mkEα L 0
 ↪  (HeisenbergN.ωN (rank L) 1)

noncomputable def frameSugawaraField : FormalDist (End ℂ (LatModuleGen L)) :=
  (1 / 2 : ℂ) • ∑ a : Fin (rank L), nprod (frameCurrent_isField F a) (frameCurrent_isField
   ↪  F a)

noncomputable def frameVirasoroMode (n : ℤ) : End ℂ (LatModuleGen L) := frameSugawaraField
 ↪  F (-n - 2)
```

From the mathematics to the Lean statement

`ωN (rank L) 1` is the Fock-space Sugawara vector $\frac{1}{2}\sum_a h_a(-1)^2\mathbb{1}$ (Chapter 31, (31.7)), placed in momentum 0 by `mkEα L 0`. The coefficient of z^{-n-2} of the Sugawara field is L_n; hence `frameVirasoroMode n` $= L_n$. Note the conformal vector does not depend on the frame, while the currents' zero modes do (through `frameMomentum`). In the isotropic basis the same vector is $\frac{1}{2}(u(-1)v(-1)+v(-1)u(-1))\mathbb{1}$ (Theorem 44.21).

Physical meaning

$T(z) = \frac{1}{2}\sum_a :\partial\phi_a\partial\phi_a:$, the free-boson stress tensor; in light-cone coordinates $T = -:\partial X^+\partial X^-:$ up to normalisation.

What the machine verified

Definitions; printed in `VOA/Moonshine/MoonshineCNAudit2.lean`.

Theorem 44.19 (Virasoro, L_0, translation, grading). *Let L be even with a complex frame. Then, for $Y =$ `frameStateField F hEven` and $\omega = \omega_L$: $[L_m, L_n] = (m-n)L_{m+n} + \frac{\operatorname{rank} L}{12}(m^3-m)\delta_{m+n,0}$; $L_0 = n$ on $(V_L)_n$; $Y(L_{-1}v, z) = \partial_z Y(v,z)$; and $u_{(j)}(V_L)_q \subseteq (V_L)_{p+q-j-1}$ for $u \in (V_L)_p$.*

```

From the mathematics to the Lean statement

These are verbatim the fields `virasoro`, `L0_grading`, `translation`, `grading_mode` of `NearVOA` for the data (V_L, `frameStateField`, ω_L, $c = \operatorname{rank} L$). The central charge is `(rank L : ℂ)`, the rank of the lattice, independently of its signature.

Proof on paper. The key computation (in `VOA/Moonshine/MoonshineCNSugawara.lean`) is that $Y(\omega_L, z)$ equals the Sugawara field: the reconstructed field of the word state $\frac{1}{2}\sum h_a(-1)^2\mathbb{1}$ is $\frac{1}{2}\sum :h_a h_a:$. On a momentum sector $\mathcal{F}_r \otimes e^{\beta}$ the Sugawara modes are those of r free bosons whose zero modes are the scalars $\beta_a^{\perp}$; the free-boson Sugawara computation gives the Virasoro algebra with $c = r$ *for any values of the zero modes*, so the frame and the signature do not enter. $L_0 = \text{level} + \frac{1}{2}\sum_a (\beta_a^{\perp})^2 = \text{level} + \frac{1}{2}\langle\beta,\beta\rangle$ by (44.3), which is the grading. Translation: L_{-1} coincides with the operator T of Definition 44.16, and every reconstructed field is T-covariant, which with the creation property gives $Y(Tv, z) = \partial Y(v, z)$. The grading property is proved for word fields (each oscillator mode and each charged-field coefficient has a definite weight) and extended by linearity. □

Physical meaning

The two light-cone bosons have $c = 2$; the Lorentzian signature does not change the central charge, which counts bosons, not signs. $L_0 = N + \frac{1}{2}p^2$ is the mass-shell operator of string theory.

What the machine verified

Proved for every even lattice with a complex frame; printed in `VOA/Moonshine/MoonshineCNAudit2.lean`; standard axioms.

44.5.5 The technical files of the construction, collectively

The construction files not singled out above prove the intermediate identities; they are adaptations of the positive-definite files named in their docstrings, with the real frame replaced by `Complex LatticeFrame` and every contraction using the frame pairing (44.3). None introduces a hypothesis.

file (`MoonshineCN…`)	what it proves, and why it is needed
`HalfCommutation`	reordering $E^+(\alpha,z_1)E^-(\beta,z_2)$ by one factor, the normally ordered four-field product, $\mathbb{Z}$-indexed annihilation coefficients (adapts `LatticeGenLocality`, `LatticeGenSameSign`)
`PositiveContraction`	the contraction sum for $\langle\alpha,\beta\rangle \geq 0$ and the resulting coefficientwise commutation (adapts `LatticeGenContraction`, `LatticeGenEEMaster`)
`NegativeContraction`, `NegativeExpansion`, `NegativeCollapse`	the general contraction sum and the finite binomial-difference argument for $\langle\alpha,\beta\rangle < 0$, expanded and then collapsed to the locality identity (adapt `LatticeGenOppSign`, `LatticeGenOppExpand`, `LatticeGenOppCollapse`)
`ChargedLocality`	Theorem 44.15
`Currents`, `CurrentCharge`	currents with momentum zero modes, their mutual locality, and $[h_a(m),Y(e^\alpha,z)] = \alpha_a^\perp z^m Y(e^\alpha,z)$ (adapt `LatticeGenBosonFields`, `LatticeGenBosonCharge`)
`Translation`, `CreationTranslation`, `ChargeTranslation`	T-covariance of currents, of the creation exponential, and of charged fields (adapt `LatticeGenTranslation`, `LatticeGenVirasoroEminus`, `LatticeGenVirasoroCharge`)
`Reconstruction`, `StateFields`	word fields, their locality, Theorem 44.17 and the near-VOA field axioms of `frameStateField` (adapt `LatticeGenWordFields`, `LatticeGenVOAInstance`)
`Conformal`, `Sugawara`, `Virasoro`	$Y(\omega_L,z)$ = Sugawara field, its mode commutators with currents and charged fields, and the Virasoro relation (adapt `LatticeGenConformal`, `LatticeGenSugawaraTmul`, `LatticeGenVirasoro`)
`ConformalTranslation`, `GradedFields`	$L_{-1}=T$, $L_0=$ weight, and the weight shift of every mode (adapt `LatticeGenL0Translation`, `LatticeGenGradedField`)

44.6 The vertex algebra of the hyperbolic plane

Theorem 44.20 (Lattice vertex algebras of indefinite lattices; $V_{\mathrm{II}_{1,1}}$)**.** *Let L be an even integral lattice with nondegenerate form and a complex frame F. Then V_L, with the reconstructed vertex operators of Theorem 44.17, vacuum $1\otimes e^0$, conformal vector ω_L, central charge* rank L *and grading $(V_L)_n$, is an even-lattice vertex realisation of L (Definition 44.9). In particular, for $\mathrm{II}_{1,1}$ with its Lorentzian frame, the target* `LorentzianVertexTarget` *is inhabited, and $V_{\mathrm{II}_{1,1}}$ is a near-VOA* `lorentzianNearVOA` *on $\mathcal{F}_2\otimes\mathbb{C}[\mathrm{II}_{1,1}]$ with central charge 2, whose field of e^α is the FLM-cocycle charged field and whose L_0 acts on $(V)_n$ by n.*

```

From the mathematics to the Lean statement

The construction is explicit. Every data field of `complexFrameLatticeRealization` is a named definition: `grading := gradingLatGen L`, `Y := frameStateField F hEven`, `vacuum := latVacuumGen L`, `conformalVector := latticeConformalVector L`, `centralCharge := (rank L : ℂ)` (the omitted lines; every axiom field is one of the theorems of §44.5). So `lorentzianNearVOA` is not an existential witness but a specific structure; its fields can be computed (`lorentzianNearVOA_charge_field` is `frameStateField_charge`, an instance of the defining property of reconstruction). **Hypotheses.** `hEven` and `hNondegenerate` are discharged for $\mathrm{II}_{1,1}$ by `lorentzian_even`, `lorentzian_form_nondegenerate`; the frame by `lorentzianComplexFrame`. Nondegeneracy is a field of the target and is not used in the construction of the fields. **What the statement is not.** It is not a `VertexOperatorAlgebra` (impossible by Theorem 44.12); simplicity of $V_{\mathrm{II}_{1,1}}$ is not stated; and the charged fields use the FLM cocycle, not $\varepsilon_{\mathrm{std}}$. **Uniqueness.** The vertex map is the unique local, creative, T-covariant extension of the generating fields (Goddard), so the choice made by `.choose` in `frameStateField` is immaterial.

Proof on paper. Assemble: internality (Theorem 44.12), the field axioms (Theorem 44.17), Virasoro, L_0, translation and grading (Theorem 44.19); the charge fields are the reconstructed fields of the word $[\,]$, whose leading products are (44.5); the charged vacuum has weight $\langle\alpha,\alpha\rangle/2$ (Theorem 44.12(ii)). Central charge $\operatorname{rank}\mathrm{II}_{1,1} = 2$. □

Physical meaning

$V_{\mathrm{II}_{1,1}}$ is the chiral algebra of the two light-cone bosons $X^{\pm}$ compactified on the even self-dual Lorentzian torus, with the standard Klein factors. Its central charge 2 is the contribution of the two longitudinal directions of the string; it is the "2" in $24 + 2 = 26$.

What the machine verified

Proved with no hypotheses: `lorentzianVertexRealization`, `lorentzianVertexTarget_inhabited`, `lorentzianNearVOA`, `lorentzianNearVOA_centralCharge`, `lorentzianNearVOA_charge_field`, `lorentzianNearVOA_energy`; `complexFrameLatticeRealization` conditional only on its displayed hypotheses (evenness, nondegeneracy, a frame). All printed in `VOA/Moonshine/MoonshineCNAudit2.lean`; that audit has 383 `#print axioms` lines (including declarations of other files it imports); according to the development record (§44.18) every list is a subset of `[propext, Classical.choice, Quot.sound]`, with no `sorryAx`.

Theorem 44.21 (The conformal vector in light-cone form). *Let $u = (1,0)$, $v = (0,1)$ and write $u(-1)$, $v(-1)$ for the frame oscillators acting on the first factor. Then $\omega = \frac{1}{2}\big(u(-1)v(-1) + v(-1)u(-1)\big)\mathbb{1}$, and $u(-1)$ is the (-1)-mode of the Heisenberg current $Y(u(-1)\mathbb{1}, z) = \sum_a u_a^{\perp} h_a(z)$ (zero mode included). Moreover $\langle u,u\rangle = \langle v,v\rangle = 0$, $\langle u,v\rangle = 1$.*

From the mathematics to the Lean statement

This theorem is the referee's check that the conformal vector is the right one in lattice terms. The Sugawara vector of a lattice is $\frac{1}{2}\sum_i \beta_i(-1)\beta_i^{\vee}(-1)\mathbb{1}$ for a basis β_i and its dual basis $\beta_i^{\vee}$; for (u,v) the dual basis is (v,u), giving the displayed formula. The proof is a polynomial identity: $u^{\perp} = (1,i)$, $v^{\perp} = (\frac{1}{2}, -\frac{i}{2})$ and $u_1^{\perp}v_1^{\perp}x_1^2 + \cdots = \frac{1}{2}(x_1^2 + x_2^2)$. The companion `lorentzianIsotropicBasis_pairing` records the four pairings.

Proof on paper. $u(-1)v(-1)\mathbb{1} = (x_1 + ix_2)(\frac{1}{2}x_1 - \frac{i}{2}x_2) = \frac{1}{2}(x_1^2 + x_2^2) = \omega$, and $u(-1), v(-1)$ commute. □

Physical meaning

In light-cone variables the stress tensor of two bosons is $T = -:\partial X^+ \partial X^-:$ (sign by convention): it pairs the two lightlike directions. This is the stress tensor whose modes appear in the light-cone decomposition of §44.8.

What the machine verified

Proved unconditionally; printed in `VOA/Moonshine/MoonshineCNAudit2.lean`; standard axioms.

44.6.1 The momentum grading

Definition 44.22 (Momentum sectors). For $\alpha \in L$, the momentum-α sector is $\mathcal{F}_r \otimes e^{\alpha} = \sum_w (\mathcal{F}_r)_w \otimes e^{\alpha}$. A formal distribution A *has momentum* α if every coefficient maps momentum β into momentum $\alpha + \beta$.

File `VOA/Moonshine/MoonshineCNMomentum.lean`.

```
noncomputable def latticeMomentumGrading (L : IntegralLattice) (α : L.carrier) :
    Submodule ℂ (LatModuleGen L) := ⨆ w : ℤ, bigradα L (w, α)

/-- A field of momentum `α` adds `α` to the momentum of its argument. -/
def HasLatticeMomentum {L : IntegralLattice}
    (A : FormalDist (End ℂ (LatModuleGen L))) (α : L.carrier) : Prop :=
  ∀ (t : ℤ) (β : L.carrier) (v : LatModuleGen L), v ∈ latticeMomentumGrading L β →
    A t v ∈ latticeMomentumGrading L (α + β)
```

From the mathematics to the Lean statement

`bigradα L (w, α)` $= (\mathcal{F}_r)_w \otimes e^{\alpha}$ (Chapter 31, Definition 31.18); the supremum over w is the whole sector, equal to the range of $p \mapsto p \otimes e^{\alpha}$ (`latticeMomentumGrading_eq_range`). Each sector is a full copy of the Fock space, hence infinite-dimensional; finite-dimensional pieces are the bigraded ones (momentum *and* weight).

Physical meaning

$U(1)^2$ charge conservation: momentum is the eigenvalue of the zero modes of the two currents.

What the machine verified

Definitions.

Theorem 44.23 (The momentum grading is internal and respected by all modes). *For every integral lattice L, $V_L = \bigoplus_{\alpha} (\mathcal{F}_r \otimes e^{\alpha})$. For even L with a complex frame, the field of every state of momentum α has momentum α; in particular in $V_{\mathrm{II}_{1,1}}$, $u_{(n)}v$ has momentum $\alpha + \beta$ when u, v have momenta α, β.*

File `VOA/Moonshine/MoonshineCNMomentum.lean`.

```
theorem latticeMomentumGrading_isInternal (L : IntegralLattice) :
    DirectSum.IsInternal (latticeMomentumGrading L) := by

theorem frameStateField_momentum (hEven : L.Even) (α : L.carrier)
    (u : LatModuleGen L) (hu : u ∈ latticeMomentumGrading L α) :
    HasLatticeMomentum (frameStateField F hEven u) α := by

theorem lorentzianNearVOA_momentum (α β : lorentzianLattice.carrier)
    (u v : LorentzianFockSpace) (hu : u ∈ latticeMomentumGrading lorentzianLattice α)
    (hv : v ∈ latticeMomentumGrading lorentzianLattice β) (n : ℤ) :
    mode (lorentzianNearVOA.Y u) n v ∈ latticeMomentumGrading lorentzianLattice (α + β) :=
```

From the mathematics to the Lean statement

Exactly as stated; no positivity. The proof goes through word states, which span each sector, and the fact that currents have momentum 0 and charged fields momentum α; normal products add momenta.

Proof on paper. $V_L = \bigoplus_{(w,\alpha)} (\mathcal{F}_r)_w \otimes e^{\alpha}$, regroup by α. Each generating field has a definite momentum (the charged field shifts $e^{\beta} \mapsto e^{\alpha+\beta}$, currents preserve momentum), normal-ordered products and derivatives add momenta, and Y is linear. □

Physical meaning

Momentum conservation in every OPE. The Monster Lie algebra inherits this as its $\mathrm{II}_{1,1}$-grading (Chapter 45).

What the machine verified

Proved; printed in `VOA/Moonshine/MoonshineCNAudit2.lean`; standard axioms.

44.7 Comparison with positive-definite lattices

The following table compares the library's lattice vertex operator algebra `latticeVOAGen` (Chapter 31, Theorem 31.27; Chapter 6, Theorem 6.21) with `complexFrameLatticeRealization`.

	positive-definite L (`latticeVOAGen`)	indefinite L (this chapter)
hypotheses	`hEven`, `hPos`	`hEven`, `hNondegenerate`, a complex frame
frame	real, $C = \sqrt{G}$	complex, any C with $C^T C = G$ over $\mathbb{C}$
state space	$\mathcal{F}_r \otimes \mathbb{C}[L]$	the same type `LatModuleGen L`
cocycle	`latticeCocycle`	the same
weight spaces	finite-dimensional	infinite-dimensional (Thm 44.12)
lower bound	$V_n = 0$ for $n < 0$, $V_0 = \mathbb{C}\mathbb{1}$	none (Thm 44.10)
locality	both signs of $\langle \alpha, \beta \rangle$	both signs, proofs re-done for complex frames
structure	`VertexOperatorAlgebra`	`NearVOA` via `EvenLatticeVertexRealization`
central charge	rank L	rank L
general theory	all of Chapter 4	re-proved in §44.10
invariant form	FHL, via `IsFullyInvariant`	FHL with charge-sensitive cutoff (§44.11)

Remark 44.24. The positive-definite construction could not simply be instantiated: its frame lemma `orthCoord_inner` carries the hypothesis `hPos`, and `lorentzian_not_posDef` shows that no `PosDef` witness exists for $\mathrm{II}_{1,1}$. The library therefore duplicated the construction with a frame parameter rather than introducing a false positivity witness. Conversely, the new construction applies to positive-definite lattices too, with the real frame viewed as complex; no comparison theorem between the two constructions is stated.

Physical meaning

Nothing in the free-boson CFT depends on the signature except unitarity and the spectrum's lower bound: OPEs, the stress tensor and the central charge are signature-blind. The comparison table is the mathematical form of that remark.

44.8 The isotropic Fock model of a momentum sector

The no-ghost theorem (Chapter 45) is a statement about one momentum sector at a time. For that purpose the library uses a second description of a sector of $V_{\mathrm{II}_{1,1}}$, in which the two light-cone oscillator families are separate polynomial variables, rather than the orthonormal complex frame of §44.3.

44.8.1 Why this is a momentum sector: the derivation by hand

Fix a momentum $\beta = (x, y) \in \mathrm{II}_{1,1}$ and consider the sector $\mathcal{F}_2 \otimes e^{\beta}$. Let $u = (1, 0)$, $v = (0, 1)$ and write $a(n) = v(n)$, $b(n) = u(n)$ for the corresponding frame oscillators (Definition 44.5), with zero modes given by the momentum. Then:

(1) *Heisenberg relations in null coordinates.* Since $\langle u, u\rangle = \langle v, v\rangle = 0$ and $\langle u, v\rangle = 1$, Theorem 44.6 gives $[a(m), a(n)] = [b(m), b(n)] = 0$ and $[a(m), b(n)] = m\delta_{m+n,0}$.

(2) *Zero modes.* On e^{β}, $a(0) = \langle v, \beta\rangle = x$ and $b(0) = \langle u, \beta\rangle = y$. We write $\kappa = x$, $\lambda = y$.

(3) *The stress tensor.* By Theorem 44.21, $\omega = \frac{1}{2}(u(-1)v(-1) + v(-1)u(-1))\mathbb{1}$, so $T(z) = \frac{1}{2}\big(:b(z)a(z): + :a(z)b(z):\big) = :a(z)b(z):$ (the two currents commute up to a central term that normal ordering removes), i.e.

$$L_n = \sum_{k\in\mathbb{Z}} :a(n-k)\,b(k):.$$

(4) *Reading off the terms.* For $n \geq 1$ the summands of L_{-n} are: $k = -n$, giving $a(0)b(-n) = \kappa\, b(-n)$; $k = 0$, giving $a(-n)b(0) = \lambda\, a(-n)$; $-n < k < 0$, giving $a(-n-k)b(k)$, a product of two creation operators; and $k > 0$ or $k < -n$, an annihilator to the right of a creator. For $n = 0$ the term $a(0)b(0) = \kappa\lambda$ appears once and every other term counts level, so $L_0 = xy +$ level, matching the weight $\Delta(\beta) +$ level.

Now rename the creation operators as variables: $a(-j)\mathbb{1} \mapsto a_j$, $b(-j)\mathbb{1} \mapsto b_j$. The Fock space of the two commuting families is the polynomial ring $\mathbb{C}[a_j, b_j : j \geq 1]$, on which $a(-j)$, $b(-j)$ multiply and, by (1), $a(j) = j\,\partial/\partial b_j$, $b(j) = j\,\partial/\partial a_j$. This is $\mathcal{F}^{\mathrm{iso}}$ below; as a Lean type it is literally `FockN 2`, i.e. $\mathcal{F}_2$ *in null coordinates*, only the meaning of the variables changes. The explicit change of variables from the orthonormal frame is the algebra isomorphism of Theorem 44.57; that it intertwines the Virasoro actions is proved in Chapter 45. The terms of Definition 44.27 below are exactly the four kinds listed in (4).

Where $c = 26$ enters. Nothing in this section or in §44.9 uses $c = 26$: the light-cone splitting (Theorems 44.34 and 44.44) holds for every central charge and for an arbitrary matter operator family. The value 26 is used in Chapter 45, in the abstract "$c = 26$ lemma": on the relevant weight spaces $[L_2 + \frac{3}{2}L_1^2,\ L_{-2} + \frac{3}{2}L_{-1}^2]$ acts as the scalar $\frac{c}{2} - 13$, so for $c = 26$ (and only then) L_1 and L_2 map the spurious states into spurious states. This makes the spurious part of a weight-one physical state again physical, hence null, so that physical states modulo null states are the transverse ones. This section presents that model (the 20 files `MoonshineCNHyperbolic*`); its identification with the actual sectors of $V_{\mathrm{II}_{1,1}}$ is Theorem 44.57 below and the comparison of Virasoro actions is in Chapter 45.

44.8.2 Oscillators and level

Definition 44.25 (The isotropic Fock space). $\mathcal{F}^{\mathrm{iso}} = \mathbb{C}[a_j, b_j : j \geq 1]$, graded by level ($a_j, b_j$ have level j). For $\kappa, \lambda \in \mathbb{C}$ the oscillators are, for $j \geq 1$,

$$a(-j) = a_j \cdot, \quad a(j) = j\,\frac{\partial}{\partial b_j}, \quad a(0) = \kappa; \qquad b(-j) = b_j \cdot, \quad b(j) = j\,\frac{\partial}{\partial a_j}, \quad b(0) = \lambda.$$

File `VOA/Moonshine/MoonshineCNHyperbolicFock.lean`.

```
abbrev hypFock := FockN 2

/-- One isotropic oscillator family with arbitrary scalar zero mode. -/
def hypOscillator (a : Fin 2) (q : ℂ) (n : ℤ) : Module.End ℂ hypFock :=
  if n < 0 then oscN 2 1 a n
  else if 0 < n then oscN 2 1 a.rev n
  else q • LinearMap.id

/-- Integer level grading, independent of momentum. -/
def hypLevel (N : ℤ) : Submodule ℂ hypFock := gradingZN 2 N
```

From the mathematics to the Lean statement

`FockN 2` $= \mathbb{C}[x_{j,i} : j \in \mathbb{N}, i \in \{0,1\}]$; the variable `X (j,0)` is a_{j+1} and `X (j,1)` is b_{j+1}. `oscN 2 1 c n` for $n < 0$ multiplies by `X (-n-1, c)`, for $n > 0$ is $n\,\partial/\partial$`X (n-1, c)`. The twist is `a.rev`: `Fin.rev` exchanges $0 \leftrightarrow 1$, so the *positive* modes of one family differentiate the *other* family. The family index `a : Fin 2` names a (`0`) or b (`1`); `hypOscA κ = hypOscillator 0 κ`, `hypOscB ell = hypOscillator 1 ell`. The zero mode `q` is a free complex parameter (the momentum), so the model describes *all* sectors at once. `gradingZN 2 N` is the level-N subspace (zero for $N < 0$). **Convention.** Under the identification with the actual sectors used in Chapter 45 (`hypLorentzianSector_zeroCharges`), the a-family is the current of $(0,1)$ and the b-family that of $(1,0)$, so at momentum (x, y) one has $\kappa = x$, $\lambda = y$ and $\kappa\lambda = xy$, as derived in §44.8.1. Some of the authors' working notes use the opposite labelling ($\kappa = y$); since everything below is symmetric under the swap (Theorem 44.34(iii)), the difference is harmless, but see §44.15.

Physical meaning

a_j, b_j are the light-cone creation operators $\alpha^+_{-j}, \alpha^-_{-j}$; the two families commute among themselves and are conjugate to each other, as lightlike directions are. κ, λ are the light-cone momenta p^+, p^-.

What the machine verified

Definitions; printed in `VOA/Moonshine/MoonshineCNAudit5.lean`.

Theorem 44.26 (Hyperbolic Heisenberg relations; level). $[\varphi(m), \varphi'(n)] = m\,\delta_{\varphi' \neq \varphi}\,\delta_{m+n,0}$ *for families* $\varphi, \varphi' \in \{a, b\}$ *and any zero modes; the level grading is internal with finite-dimensional pieces,* $\mathcal{F}^{\mathrm{iso}}_N = 0$ *for* $N < 0$, $\mathcal{F}^{\mathrm{iso}}_0 = \mathbb{C}$; *and* $\varphi(n)$ *lowers level by* n.

    (hp : p ∈ hypLevel N) : hypOscillator a q n p ∈ hypLevel (N - n) := by
```

From the mathematics to the Lean statement

`a = b.rev` says the two families differ. So $[a(m), a(n)] = [b(m), b(n)] = 0$ and $[a(m), b(n)] = m\delta_{m+n,0}$: the Heisenberg algebra of $\mathrm{II}_{1,1} \otimes \mathbb{C}$ in the isotropic basis.

Proof on paper. $[j\partial_{b_j}, b_j\cdot] = j$; all other pairs commute; zero modes are scalars. □

Physical meaning

$[\alpha_m^+, \alpha_n^-] = m\delta_{m+n,0}$ and $[\alpha_m^\pm, \alpha_n^\pm] = 0$: the light-cone oscillator algebra.

What the machine verified

Proved; printed in `VOA/Moonshine/MoonshineCNAudit5.lean`; standard axioms.

44.8.3 The Sugawara operators

Definition 44.27 (Explicit Sugawara operators). For $\kappa, \lambda \in \mathbb{C}$ and $n \geq 1$,

$$L_{-n} = \kappa b_n + \lambda a_n + \sum_{i=1}^{n-1} a_{n-i} b_i + \sum_{k\geq 1} k\Big(a_{n+k}\frac{\partial}{\partial a_k} + b_{n+k}\frac{\partial}{\partial b_k}\Big),$$

$$L_n = n\kappa\frac{\partial}{\partial a_n} + n\lambda\frac{\partial}{\partial b_n} + \sum_{k>n} k\Big(a_{k-n}\frac{\partial}{\partial a_k} + b_{k-n}\frac{\partial}{\partial b_k}\Big) + \sum_{k=1}^{n-1} k(n-k)\frac{\partial^2}{\partial a_k \partial b_{n-k}},$$

$$L_0 = \kappa\lambda + \sum_{k\geq 1} k\Big(a_k\frac{\partial}{\partial a_k} + b_k\frac{\partial}{\partial b_k}\Big).$$

These are the normal-ordered sums $L_n = \sum_k {:}a(n-k)b(k){:}$.

    (hypLoweringDerivation κ ell n.toNat).toLinearMap +
      hypPositiveSecondOrder (n - 1).toNat
  else (κ * ell) • LinearMap.id + hypEnergyDerivation.toLinearMap
```

From the mathematics to the Lean statement

`mkDerivation ℂ f` is the unique derivation of the polynomial ring with prescribed values $f(v)$ on the variables; this encodes the infinite first-order sums without any infinite sum of operators. With $v = (k-1, i)$ (the variable of level k in family $i \in \{0,1\}$): `hypRaising Derivation n` sends it to k times the variable of level $k+n$; `hypLoweringDerivation κ ell n` sends it to $n\kappa$ or $n\lambda$ if $k = n$, to k times the variable of level $k-n$ if $k > n$, and to 0 otherwise. So the term $n\kappa\,\partial/\partial a_n$ is the $k = n$ case for family a. `hypNegativePotential κ ell j` is $\kappa b_{j+1} + \lambda a_{j+1} + \sum_{k<j} a_{j-k} b_{k+1}$; `pderiv (k, 0)` is $\partial/\partial a_{k+1}$; `hypEnergyDerivation` = `hypRaisingDerivation 0` is the level operator. `(-n - 1).toNat` etc. convert $\mathbb{Z}$ to $\mathbb{N}$ on the relevant branch. **Fidelity.** The definition is the explicit formula of Definition 44.27 term by term; that it *is* the Sugawara construction is then proved (Theorem 44.29), not assumed.

Physical meaning

$L_n = \sum_k :\alpha^+_{n-k}\alpha^-_k:$, the light-cone stress tensor. The terms κb_n and λa_n are $p^+\alpha^-_n$ and $p^-\alpha^+_n$: in light-cone gauge the constraint L_{-n} is dominated by $p^+\alpha^-_n$ when $p^+ \neq 0$, which is why one can "solve for" α^-. This is exactly the leading term exploited in Theorem 44.34.

What the machine verified

Definitions; printed in `VOA/Moonshine/MoonshineCNAudit5.lean`.

Theorem 44.28 (Commutant). *An endomorphism of $\mathcal{F}^{\mathrm{iso}}$ that commutes with all nonzero oscillator modes of both families is a scalar, namely the constant term of its value on* 1.

File `VOA/Moonshine/MoonshineCNHyperbolicCommutant.lean`.

```
/-- Every endomorphism commuting with the nonzero oscillators is scalar. -/
theorem hypCommutant_scalar (D : Module.End ℂ hypFock) (charges : Fin 2 → ℂ)
    (hD : ∀ a n, n ≠ 0 → D * hypOscillator a (charges a) n =
      hypOscillator a (charges a) n * D) :
    D = coeff 0 (D 1) • LinearMap.id := by
```

From the mathematics to the Lean statement

`charges` are the zero modes (irrelevant, as only $n \neq 0$ is used). `coeff 0 (D 1)` is the constant term of $D(1)$. No finite-dimensionality or continuity is assumed: the operator is arbitrary.

Proof on paper. Commuting with all multiplications by variables gives $D(p) = p\,D(1)$; commuting with all $\partial/\partial a_j$, $\partial/\partial b_j$ gives that every partial derivative of $D(1)$ vanishes, so $D(1)$ is constant (characteristic 0). □

Physical meaning

The Fock module of the Heisenberg algebra is irreducible (Schur's lemma): any operator built from oscillators whose commutators with all oscillators vanish is a c-number. This is how central charges are computed: the anomaly in $[L_m, L_n]$ commutes with everything, so it is a number, read off on the vacuum.

What the machine verified

Proved; printed in `VOA/Moonshine/MoonshineCNAudit5.lean`; standard axioms.

Theorem 44.29 (Virasoro with $c = 2$; oscillator commutators; degree). *For all κ, λ and $m, n \in \mathbb{Z}$: $[L_m, L_n] = (m-n)L_{m+n} + \frac{2}{12}(m^3 - m)\delta_{m+n,0}$; $[L_m, \varphi(n)] = -n\,\varphi(m+n)$ for both families (with $\varphi(0)$ the scalar zero mode); $L_0 = \kappa\lambda + N$ on level N, and the level-N space is exactly the $(\kappa\lambda + N)$-eigenspace of L_0; and L_n maps level N to level $N - n$.*

    (hp : p ∈ hypLevel N) : hypSugawara κ ell n p ∈ hypLevel (N - n) := by
```

From the mathematics to the Lean statement

The zero mode in the oscillator commutator is tied to the momentum by (`if a = 0 then κ else ell`): the family-a oscillator has zero mode κ, family b has λ (this is necessary: $[L_m, a(-m)] = m\,a(0)$ must produce the momentum). `Module.End.eigenspace f μ` is $\ker(f - \mu)$. The central term is exactly $\frac{m^3-m}{12} \cdot 2$. No hypothesis on κ, λ.

Proof on paper. The mixed relation is checked on the generators of the polynomial ring and on 1 (both sides are derivations up to the multiplication terms, which are handled by the explicit creation commutators `hypSugawara_negative_mul_variable`, `hypSugawara_positive_creation`). Then $D = [L_m, L_n] - (m-n)L_{m+n}$ commutes with every oscillator by the Jacobi identity ($[[L_m, L_n], \varphi(k)] = (m-n)[L_{m+n}, \varphi(k)]$), so it is a scalar by Theorem 44.28; it has level degree $-(m+n)$, so it vanishes unless $m + n = 0$; for $n = -m$, $m \geq 1$, its value is the constant term of $L_m L_{-m} 1 - 2mL_0 1 = (2m\kappa\lambda + \sum_{k=1}^{m-1} k(m-k)) - 2m\kappa\lambda = \frac{m^3-m}{6}$ (`hypSugawara_positive_negative_constant`, `hypSugawara_central_sum`). The level statements follow from the explicit L_0. □

Physical meaning

Two bosons give $c = 2$, at every momentum, as in Theorem 44.19. The mixed relation says that the light-cone oscillators are primary fields of weight one.

What the machine verified

Proved with no hypotheses; printed in `VOA/Moonshine/MoonshineCNAudit7.lean`; standard axioms.

44.8.4 The contravariant form

Definition 44.30 (Isotropic monomial form). For an exponent vector d (a monomial $\prod a_j^{\alpha_j} b_j^{\beta_j}$) let $z(d) = \prod_{\text{variables}} (\text{level})^{\text{exp}} \cdot \text{exp}!$ and let $\bar{d}$ be d with the two families exchanged. The form B^{iso} pairs monomial d with monomial $\bar{d}$ with value $z(d)$ and is zero otherwise: $B^{\text{iso}}(a^{\alpha} b^{\beta}, a^{\alpha'} b^{\beta'}) = \delta_{\alpha\beta'} \delta_{\beta\alpha'} z(\alpha) z(\beta)$.

```

From the mathematics to the Lean statement

`(ℕ × Fin 2) →₀ ℕ` is an exponent vector (finitely supported). `d.prod f` is $\prod_v f(v, d_v)$. `hypSwapExponent` applies `Fin.rev` to the family index. `hypForm p q` $= \sum_d p_d \, z(d) \, q_{\bar{d}}$, where p_d is the coefficient of p; this is the formula of the definition.

Physical meaning

A contravariant pairing of the light-cone Fock space. Each oscillator is adjoint to its own opposite mode, $a(-j)^{\dagger} = a(j) = j\,\partial/\partial b_j$ (Theorem 44.31); because $a(j)$ differentiates the *other* family, the form pairs an a-monomial with the corresponding b-monomial, reflecting $\langle u, v\rangle = 1$, $\langle u, u\rangle = \langle v, v\rangle = 0$. The form takes real values on polynomials with real coefficients, and there it is not positive: $a_1 + b_1$ has norm 2 and $a_1 - b_1$ has norm -2. This real form is the one that carries the "ghost" story: the light-cone sector contains states of negative norm.

What the machine verified

Definition; printed in `VOA/Moonshine/MoonshineCNAudit5.lean`.

Theorem 44.31 (Properties of the isotropic form). *B^{iso} is symmetric, $B^{\text{iso}}(1, q)$ is the constant term of q, it is nondegenerate, different levels are orthogonal and it is nondegenerate on each level; every oscillator satisfies $B^{\text{iso}}(\varphi(n)p, q) = B^{\text{iso}}(p, \varphi(-n)q)$; and every Sugawara mode satisfies $B^{\text{iso}}(L_n p, q) = B^{\text{iso}}(p, L_{-n} q)$.*

Files `VOA/Moonshine/MoonshineCNHyperbolicForm.lean`, `VOA/Moonshine/MoonshineCNHyperbolicSugawaraAdjoint.lean`.

```

    hypForm (hypSugawara κ ell n p) q = hypForm p (hypSugawara κ ell (-n) q) := by
```

From the mathematics to the Lean statement

A sign to notice. Here oscillators are *self*-adjoint, $\varphi(n)^\dagger = \varphi(-n)$, whereas for the lattice form of Chapter 32 (Definition 32.42) one has $h(n)^\dagger = -h(-n)$. The two forms are therefore different and are not identified by the identity map; this is an explicit convention difference (and the module docstring says "This is the sector contravariant form, not the opposite-momentum FHL form of the lattice vertex algebra"). Both make L_n adjoint to L_{-n}, which is all the no-ghost theorem needs. `hypForm_oscillator_adjoint` holds for any zero mode `charge`.

Proof on paper. Symmetry and level orthogonality are visible from the definition. On level N the Gram matrix in the monomial basis is a permutation matrix ($d \leftrightarrow \bar{d}$) times nonzero diagonal entries $z(d)$, hence invertible. Adjointness of $a(-j) = a_j\cdot$ and $a(j) = j\partial/\partial b_j$ amounts to $z(d + e_v) = j(d_v + 1)z(d)$ for a variable v of level j (`hypMonomialNorm_add_single`). For L_n: the negative modes are adjoint to the positive ones by induction on polynomials using the commutators with creation operators; the remaining cases follow from symmetry. □

Physical meaning

$L_n^\dagger = L_{-n}$ is the reality of the stress tensor, the property that makes "null" (zero-norm) spurious states decouple. Level-wise nondegeneracy is what guarantees that the radical of the form on physical states is exactly the null states.

What the machine verified

Proved; the form statements printed in `VOA/Moonshine/MoonshineCNAudit5.lean`, `hypForm_sugawara_adjoint` in `VOA/Moonshine/MoonshineCNAudit7.lean`; standard axioms.

44.8.5 One-family vacua

Definition 44.32 (One-family subspace)**.** For a family $\varphi \in \{a, b\}$, $\mathcal{F}^{\mathrm{iso}}(\varphi)$ is the subalgebra of polynomials in the variables of family c only; its augmentation subspace is the set of p with zero constant term.

File `VOA/Moonshine/MoonshineCNHyperbolicOneFamily.lean`.

```
/-- Polynomials using just the indicated isotropic family. -/
def hypOneFamily (a : Fin 2) : Submodule ℂ hypFock :=
  (supported ℂ {v : ℕ × Fin 2 | v.2 = a}).toSubmodule
```

From the mathematics to the Lean statement

`supported ℂ s` is the subalgebra of polynomials whose variables lie in s.

Physical meaning

Polynomials in the α^+ oscillators only: the states with no α^- excitation. In the Goddard–Thorn argument the role of the transverse/longitudinal space K is played by the common kernel of the positive modes $K_n = k \cdot \alpha_n$ of a lightlike vector k; here $K_n = a(n) = n\partial/\partial b_n$, whose common kernel is exactly the b-free polynomials.

What the machine verified

Definition.

Theorem 44.33 (One-family subspace: kernel, form, radical). *(i)* $p \in \mathcal{F}^{\mathrm{iso}}(\varphi)$ *iff* $\varphi(j)p = 0$ *for all* $j \geq 1$. *(ii) For* $p, q \in \mathcal{F}^{\mathrm{iso}}(\varphi)$, $B^{\mathrm{iso}}(p,q) = p(0)q(0)$. *(iii) Hence the radical of* B^{iso} *restricted to* $\mathcal{F}^{\mathrm{iso}}(\varphi)$ *is the augmentation subspace, and the quotient is one-dimensional, identified with* $\mathbb{C}$ *by evaluation at* 0.

File `VOA/Moonshine/MoonshineCNHyperbolicOneFamily.lean`.

```

def hypOneFamilyQuotientEquiv (a : Fin 2) :
    (hypOneFamily a ⧸ hypOneFamilyAugmentation a) ≃ₗ[ℂ] ℂ :=
```

From the mathematics to the Lean statement

(i): the positive modes of family φ differentiate the *other* family, so they kill exactly the polynomials not involving it. `⧸` is the quotient module and `≃ₗ[ℂ]` a linear isomorphism; `hypOneFamilyQuotientEquiv_mk` (same file) shows it is evaluation at 0.

Proof on paper. (ii) Exchanging families sends a nonconstant c-only monomial to a monomial of the other family, which pairs to zero with every c-only monomial; only constants survive. (iii) follows. □

Physical meaning

Within the "longitudinal" states, everything except the ground state is null: the α^+ excitations have zero norm against each other. In the sector string module of Chapter 45 (matter ⊗ this space) this is what makes the physical quotient equal to the matter transverse space.

What the machine verified

Proved; printed in `VOA/Moonshine/MoonshineCNAudit6.lean`; standard axioms.

44.8.6 The light-cone splitting

Order monomials by their *b-count* (total degree in the b's) and then by their *b-level* (total level of the b's).

Theorem 44.34 (Leading term, PBW map, light-cone splitting). *Fix κ, λ. (i) For p homogeneous of b-count d and b-level w, $L_{-(j+1)}p - \kappa\, b_{j+1}p$ is strictly lower than $(d+1, w+j+1)$ in the lexicographic order. (ii) Let Φ send a monomial $a^\alpha b_{\lambda_1}\cdots b_{\lambda_k}$ $(\lambda_1 \geq \ldots \geq \lambda_k)$ to $L_{-\lambda_1}\cdots L_{-\lambda_k}a^\alpha$. Then $\Phi(m) - \kappa^k m$ is strictly lower than m; hence if $\kappa \neq 0$, Φ is a linear automorphism of $\mathcal{F}^{\mathrm{iso}}$. (iii) If $\kappa \neq 0$, then $\mathcal{F}^{\mathrm{iso}} = \left(\sum_{n\geq 1} \operatorname{im} L_{-n}\right) \oplus \mathcal{F}^{\mathrm{iso}}(a)$; if $\lambda \neq 0$, the same with $\mathcal{F}^{\mathrm{iso}}(b)$; so for every nonzero momentum one of the two common kernels $\bigcap_j \ker \varphi(j)$ is a complement of the spurious space.*

```

From the mathematics to the Lean statement

`hypBHomogeneous d w`: polynomials homogeneous of b-count d and b-level w (weights `hypBCountWeight`, `hypBLevelWeight`: b_{j+1} has count 1 and level $j+1$, a's have 0). `hypBFiltered d w`: the span of monomials with count $< d$, or count $= d$ and level $< w$. `stringNegativeWord D x [i₁, …, i_k]` $= D_{i_1}(\cdots D_{i_k}(x))$ (defined in the Chapter 45 file `VOA/Moonshine/MoonshineCNStringStraightening.lean`); `hypCanonicalBWord e` is the b-exponent multiset sorted decreasingly, `hypAExponent e` the a-part. So `hypPBWMap` is Φ. `IsCompl U W` means $U \cap W = 0$ and $U + W$ is everything. `hypPBWEquiv` packages `hypPBWMap_injective` and `hypPBWMap_surjective`; no claim that it is multiplicative. **Hypotheses:** only $\kappa \neq 0$ (resp. $\lambda \neq 0$, or one of them); this is the nonzero-momentum condition. At zero momentum the theorem is false (for $\kappa = \lambda = 0$ the level-one part of the spurious space is $L_{-1}\mathbb{C} = 0$, so b_1 lies in neither summand), and Chapter 45 treats that case separately.

Proof on paper. Order pairs (d, w) (count, level) lexicographically: $(d, w) < (d', w')$ iff $d < d'$, or $d = d'$ and $w < w'$; a polynomial is "strictly lower than (d, w)" if all its monomials have (count, level) $< (d, w)$. (i) In $L_{-(j+1)}$, the term κb_{j+1} raises count by one and level by $j+1$. The term λa_{j+1} and the a-part of the derivation preserve count and level; the b-part of the derivation, $b_{k+j+1}\partial/\partial b_k$, preserves count and raises level by $j+1$, which is still strictly lower because the count is $d < d+1$. The quadratic terms $a_{j-k}b_{k+1}$ raise count by one but level only by $k+1 \leq j$. (ii) Iterating (i) gives $\Phi(m) = \kappa^k m +$ lower (`hypSugawara_negative_word_leading`). Injectivity: if $\Phi(p) = 0$, look at a maximal monomial of p in the order; its coefficient in $\Phi(p)$ is κ^k times its coefficient in p. Surjectivity: by double well-founded induction on count and level, each monomial is $\kappa^{-k}\Phi(m)$ plus strictly lower terms. No finite-dimensionality is used. (iii) The negative modes satisfy the Witt relations $[L_{-(i+1)}, L_{-(j+1)}] = (j-i)L_{-(i+j+2)}$ (`hypSugawara_negative_comm`), so every word straightens into sorted words of the same energy (`hypSugawara_negative_straightening`). Thus $\sum \operatorname{im} L_{-n}$ is the span of nonempty sorted words applied to b-free polynomials, i.e. Φ(polynomials with b-count ≥ 1); since Φ is bijective and is the identity on b-free polynomials, the complement is $\mathcal{F}^{\mathrm{iso}}(a)$. The swap $a \leftrightarrow b$ (`hypSwapPolynomial`) conjugates $L_n(\kappa, \lambda)$ to $L_n(\lambda, \kappa)$ and gives the case $\lambda \neq 0$. □

Physical meaning

This is the light-cone decomposition at the heart of the no-ghost theorem. At momentum with $p^+ \neq 0$ every state is uniquely a "longitudinal" state (no α^- excitations) plus Virasoro descendants: the Virasoro constraints can be solved for the α^- oscillators. Brower and Goddard–Thorn use the same triangularity ($L_{-n} \approx p^+\alpha^-_n$). After tensoring with a $c = 24$ matter theory (Theorem 44.44) and imposing $c = 26$, Chapter 45 deduces that physical states modulo null states are the transverse states.

What the machine verified

Proved; hypotheses only $\kappa \neq 0$, $\lambda \neq 0$ or $\kappa \neq 0 \vee \lambda \neq 0$ as displayed. Printed in `VOA/Moonshine/MoonshineCNAudit6.lean`; standard axioms.

The remaining `Hyperbolic*` files. `HyperbolicNegativeModes` (differential identities for the negative modes: commutators with $\partial/\partial a_t$, with X, and with all oscillators), `HyperbolicNegativeVirasoro` (the negative Witt relations and straightening), `HyperbolicPositiveCreation` (positive modes against creation operators), `HyperbolicMixedModes` and `HyperbolicSugawaraAdjoint` (all signed mode–oscillator commutators; adjointness), `HyperbolicCentralScalar` (the finite sums $\sum_{k<j}(k+1)(j-k) = j(j+1)(j+2)/6$ and the vacuum coefficient), `HyperbolicFilteredWords` (the iterated leading-term estimate), `HyperbolicPBWCoordinates` (the PBW map agrees with every

sorted word on every b-free base) and `HyperbolicSwap` (the family exchange) are the supporting lemmas of Theorems 44.29–44.34; all are printed in `VOA/Moonshine/MoonshineCNAudit5.lean`, `Audit6` or `Audit7`.

44.9 The tensor theory $V^\natural \otimes V_{\mathrm{II}_{1,1}}$

44.9.1 Tensor products of near-VOAs

Definition 44.35 (Tensor product of near-VOAs)**.** Let V on A and W on B be near-VOAs. On $A \otimes B$ put

$$Y(a\otimes b,z)(x\otimes y)=\sum_{m\in\mathbb{Z}}\big(\text{coefficient of } z^m \text{ in } Y(a,z)x\big)\otimes\big(\text{coefficient of } z^{s-m} \text{ in } Y(b,z)y\big) \text{ at } z^s, \tag{44.7}$$

i.e. $Y(a\otimes b,z)=Y(a,z)\otimes Y(b,z)$; the vacuum $\mathbb{1}\otimes\mathbb{1}$; the conformal vector $\omega_V\otimes\mathbb{1}+\mathbb{1}\otimes\omega_W$; the central charge c_V+c_W; and the grading $(A\otimes B)_n=\operatorname{span}\{a\otimes b : a\in A_i,\ b\in B_j,\ i+j=n\}$.

```

From the mathematics to the Lean statement

`⊗[ℂ]` is the algebraic tensor product; `a ⊗ₜ b` a pure tensor. `nearTensorFieldBilinear` is the bilinear map $(a,b)\mapsto$ `nprod` of the first-factor lift of $Y(a,z)$ and the second-factor lift of $Y(b,z)$; `TensorProduct.lift` extends it linearly. `nearTensorField_tmul_apply` shows what it is: (44.7), with $\sum^{\mathrm{f}}$ a finite sum (Mathlib's `finsum`, which is the sum when the support is finite — here it is, by truncation of $Y(a,z)x$ and $Y(b,z)y$). The coefficient index s is the power z^s; `V.Y a m x` is the z^m-coefficient. The omitted fields of `nearTensorVOA` are `conformalVector := nearTensorConformalVector V W`, `centralCharge := V.centralCharge + W.centralCharge`

and the proofs (Theorem 44.36). **No hypotheses**: neither factor needs finite weight spaces or a lower bound.

Physical meaning

Two decoupled chiral CFTs side by side: fields multiply, stress tensors add, central charges add. The tensor product of $V^\natural$ with the light-cone bosons is the chiral matter algebra of Borcherds' string.

What the machine verified

Definitions; printed in `VOA/Moonshine/MoonshineCNAudit3.lean`.

Theorem 44.36 (The tensor product is a near-VOA). *For near-VOAs V, W, the data of Definition 44.35 form a near-VOA; in particular its weight grading is internal, its modes have the right weight, its fields are mutually local, translation covariance holds, and*

    mode (nearTensorField V W u) n v ∈ nearTensorGrading V W (k + l - n - 1) := by
```

From the mathematics to the Lean statement

Since these are fields of `nearTensorVOA`, the structure's existence already certifies all near-VOA axioms; we print the three that carry content. The central charge is literally `V.centralCharge + W.centralCharge`.

Proof on paper. $Y(\omega,z) = T_V(z)\otimes 1 + 1\otimes T_W(z)$, so $L_n = L_n^V \otimes 1 + 1 \otimes L_n^W$, and the two summands commute; their Virasoro relations add, including the central terms. L_0 acts on $a\otimes b$ ($a \in A_i$, $b \in B_j$) by $i+j$, so the pieces $(A\otimes B)_n$ are contained in distinct eigenspaces of one operator, hence independent; they span since pure tensors of homogeneous elements span. Locality of $Y(a\otimes b)$ and $Y(a'\otimes b')$: the first-factor and second-factor lifts commute, and each pair of same-factor lifts is local, so Dong's lemma applies. Translation: $L_{-1} = L_{-1}^V \otimes 1 + 1 \otimes L_{-1}^W$ and the derivative of a product is given by the Leibniz rule. □

Physical meaning

$T = T_V + T_W$; central charges of decoupled sectors add. The internality argument (eigenvalues of L_0, no finiteness) is the mathematical version of "energy eigenstates of the combined system".

What the machine verified

Proved for arbitrary near-VOAs, no hypotheses; printed in `VOA/Moonshine/MoonshineCNAudit3.lean` (`nearTensorVOA` included); standard axioms.

44.9.2 The matter algebra of central charge 26

Definition 44.37 (The matter near-VOA). $\mathcal{M} = V^\natural \otimes V_{\mathrm{II}_{1,1}}$, the tensor product of the near-VOA of $V^\natural$ (Chapter 42, `VnatVOA`, forgetting finiteness and CFT type) with $V_{\mathrm{II}_{1,1}}$.

File `VOA/Moonshine/MoonshineCNTensorRealization.lean`.

```
/-- The matter space in the no-ghost construction. -/
abbrev moonshineMatterSpace := Vnat ⊗[ℂ] LorentzianFockSpace

/-- `V♮ ⊗ V_{II_{1,1}}`, with its full tensor state-field map and total integer weight. -/
noncomputable def moonshineMatterNearVOA : NearVOA moonshineMatterSpace :=
  nearTensorVOA VnatVOA.toNearVOA lorentzianNearVOA
```

From the mathematics to the Lean statement

`Vnat` is the carrier of the Moonshine module (Chapter 42); `VnatVOA : VertexOperatorAlgebra Vnat` is the named vertex operator algebra of `VOA/Moonshine/AutVnat.lean`, defined as `vnatVOA vnat_twistedLocality`, whose vertex map, vacuum, conformal vector and grading are the explicit ones (`VnatVOA_Y`, `VnatVOA_vacuum`, `VnatVOA_conformalVector`, `VnatVOA_grading`, all `rfl`) of the theorem `moonshine`. So $\mathcal{M}$ is built from the actual $V^\natural$, not from an abstract $c = 24$ VOA.

Physical meaning

The full matter chiral algebra of Borcherds' string: Monster CFT $\otimes$ light-cone bosons.

What the machine verified

Definitions; constructed with no hypotheses (`VOA/Moonshine/MoonshineCNAudit3.lean`).

Theorem 44.38 (Central charge 26). *$\mathcal{M}$ has central charge 26; its conformal vector is $\omega_\natural \otimes \mathbb{1} + \mathbb{1} \otimes \omega_{\mathrm{II}_{1,1}}$; and $Y(a \otimes b, z)(x \otimes y) = Y(a,z)x \otimes Y(b,z)y$ coefficientwise.*

File `VOA/Moonshine/MoonshineCNTensorRealization.lean`.

```
/-- The central charge is exactly `24 + 2 = 26`, without hypotheses. -/
theorem moonshineMatterNearVOA_centralCharge : moonshineMatterNearVOA.centralCharge = 26 :=
 ↪ by

theorem moonshineMatterNearVOA_conformalVector :
    moonshineMatterNearVOA.conformalVector =
      VnatVOA.conformalVector ⊗ₜ lorentzianNearVOA.vacuum +
        VnatVOA.vacuum ⊗ₜ lorentzianNearVOA.conformalVector := rfl
```

```
theorem moonshineMatterNearVOA_tmul_field (a x : Vnat) (b y : LorentzianFockSpace) (s : ℤ)
 ↪  :
    moonshineMatterNearVOA.Y (a ⊗ₜ b) s (x ⊗ₜ y) =
      ∑ᶠ m : ℤ, (VnatVOA.Y a m x) ⊗ₜ[ℂ] (lorentzianNearVOA.Y b (s - m) y) :=
```

From the mathematics to the Lean statement

How the 26 arises in Lean. The proof first rewrites the central charge as `(24 : ℂ) + lorentzianNearVOA.centralCharge` by `change`, i.e. *definitionally*: the central charge of `Vnat VOA` is the literal 24 of the Moonshine construction; then Theorem 44.20 gives 2. **Fidelity.** The statement is about the actual structure, not about an operator family with the right commutators; the conformal vector equation is `rfl`, i.e. true by the definition.

Proof on paper. $c = 24 + 2$ by Theorem 44.36. □

Physical meaning

$26 = 24 + 2$: the Monster CFT replaces the 24 transverse bosons of the critical bosonic string, and the two light-cone bosons complete the critical dimension. This is the input $c = 26$ of the no-ghost theorem.

What the machine verified

Proved with no hypotheses; printed in `VOA/Moonshine/MoonshineCNAudit3.lean`; standard axioms.

Theorem 44.39 (The $\mathrm{II}_{1,1}$-momentum grading of $\mathcal{M}$). *Let $\mathcal{M}^\alpha = V^\natural \otimes (\mathcal{F}_2 \otimes e^\alpha)$. Then $\mathcal{M} = \bigoplus_{\alpha \in \mathrm{II}_{1,1}} \mathcal{M}^\alpha$ (internal), and $u_{(n)}v \in \mathcal{M}^{\alpha+\beta}$ for $u \in \mathcal{M}^\alpha$, $v \in \mathcal{M}^\beta$, $n \in \mathbb{Z}$.*

File `VOA/Moonshine/MoonshineCNTensorMomentum.lean`.

    (hv : v ∈ moonshineMatterMomentum β) (n : ℤ) :
    mode (moonshineMatterNearVOA.Y u) n v ∈ moonshineMatterMomentum (α + β) := by
```

From the mathematics to the Lean statement

`TensorVA.tenSub P Q` is the span of $p \otimes q$ with $p \in P$, $q \in Q$; with $P = \top = V^\natural$ this is $V^\natural \otimes \mathcal{F}_2 e^\alpha$. Internality is proved via the eigenspaces of the operator multiplying e^α by the injective label $\alpha_0 + i\alpha_1 \in \mathbb{C}$ (`lorentzianChargeLabel`); this is a proof device, not an extra datum.

Proof on paper. Tensor the decomposition of Theorem 44.23 with $V^\natural$; for modes, use (44.7) and Theorem 44.23 on the second factor. □

Physical meaning

Spacetime momentum conservation. This grading descends to the $\mathrm{II}_{1,1}$-grading of the Monster Lie algebra (`monsterLieMomentum`, Chapter 45), whose pieces are the root spaces.

What the machine verified

Proved; printed in `VOA/Moonshine/MoonshineCNAudit3.lean`; standard axioms.

44.9.3 Bilinear forms

The no-ghost theorem needs a bilinear form on $\mathcal{M}$ for which L_n is adjoint to L_{-n} and which is nondegenerate; the Lie algebra of Chapter 45 needs, in addition, full FHL invariance (treated in §44.11).

Four bilinear forms occur in this chapter; the following table says how they differ.

form	space	adjoint of an oscillator	pairs momenta	used for
$B_{\mathcal{F}}$ (Fock form, Ch. 32)	$\mathcal{F}_r$	$h(n)^\dagger = -h(-n)$	—	building B_L
B_L (lattice form)	V_L	$h(n)^\dagger = -h(-n)$	α with $-\alpha$	B, FHL invariance
$B = B_\natural \otimes B_L$	$\mathcal{M}$	as B_L	α with $-\alpha$	Monster Lie form
B^{iso} (isotropic form)	$\mathcal{F}^{\mathrm{iso}}$ (one sector)	$\varphi(n)^\dagger = \varphi(-n)$	within the sector	no-ghost theorem

All four make L_n adjoint to L_{-n}; only B is shown to be FHL-invariant (§44.11). B_L and B^{iso} are related through momentum reversal (Theorem 44.59) and a change of variables.

Definition 44.40 (Virasoro-adjoint form of a near-VOA)**.** A *near-invariant form* on a near-VOA V is a bilinear form B with $B(L_n a, b) = B(a, L_{-n} b)$ for all n, a, b. The tensor product of two near-invariant forms is a near-invariant form on the tensor near-VOA.

Files `VOA/Moonshine/MoonshineCNLatticeForm.lean`, `VOA/Moonshine/MoonshineCNTensorForm.lean`.

    ↪ V W) where
  form := F.form.tmul G.form
  virasoro_adj := nearTensorForm_virasoro_adjoint F G
```

From the mathematics to the Lean statement

`nearVirasoroMode V n = mode (V.Y V.conformalVector) (n + 1) = `L_n. **The name is weaker than it sounds.** Exactly like the library's `VertexOperatorAlgebra.InvariantForm` (Chapter 5, Definition 5.48), `NearInvariantForm` records *only* Virasoro adjointness, the $u = \omega$ slice of FHL invariance; the module docstring says so ("Full FHL invariance is a separate

property"). A referee must not read `NearInvariantForm` as FHL invariance. `F.form.tmul G.form` is the form $(a \otimes b, a' \otimes b') \mapsto F(a,a')G(b,b')$.

Physical meaning

$L_n^\dagger = L_{-n}$: the BPZ conjugation of the stress tensor. This is the only property of the inner product that the Virasoro-algebraic part of the no-ghost theorem uses.

What the machine verified

Definitions; printed in `VOA/Moonshine/MoonshineCNAudit3.lean`.

Definition 44.41 (The lattice and matter forms). On $V_{\mathrm{II}_{1,1}}$ the form is the library's lattice form B_L of Chapter 32 (Definition 32.44): $B_L(p \otimes e^\alpha, q \otimes e^\beta) = \delta_{\alpha+\beta,0}\,\chi(\alpha)\,B_{\mathcal{F}}(p,q)$, with $B_{\mathcal{F}}$ the Fock form (oscillators skew-adjoint, $h(n)^\dagger = -h(-n)$) and $\chi(\alpha) = (-1)^{\langle\alpha,\alpha\rangle/2}\varepsilon(\alpha,\alpha)$. On $\mathcal{M}$ it is $B_{\natural} \otimes B_L$, with $B_{\natural}$ the normalised invariant form `natForm` of $V^{\natural}$ (Chapter 42).

Files `VOA/Moonshine/MoonshineCNLatticeForm.lean`, `VOA/Moonshine/MoonshineCNTensorForm.lean`, `VOA/Moonshine/NondegLattice.lean`.

noncomputable def moonshineMatterInvariantForm : NearInvariantForm moonshineMatterNearVOA
 ↪  where
  form := moonshineMatterForm
  virasoro_adj := moonshineMatterForm_virasoro_adjoint
```

From the mathematics to the Lean statement

`latForm` lives in `VOA/Moonshine/NondegLattice.lean` (Chapter 32); it is defined for any integral lattice and its definition never used positivity. `chForm L` pairs e^α with $e^{-\alpha}$ with the sign $\chi(\alpha) =$ `chSign L α` (Proposition 32.43). The form pairs *opposite* momenta; it vanishes on two states of the same nonzero momentum (Theorem 44.59).

Physical meaning

The BPZ pairing of a charged state with its charge conjugate: $\langle e^{-\alpha} | e^\alpha \rangle \neq 0$. For the matter theory this is the product of the Monster CFT's Zamolodchikov metric and the light-cone pairing.

What the machine verified

Definitions; printed in `VOA/Moonshine/MoonshineCNAudit3.lean`.

Theorem 44.42 (Properties of the matter form). *B_L and $B_\natural \otimes B_L$ are symmetric, normalised ($B(\mathbb{1},\mathbb{1}) = 1$), nondegenerate (every nonzero x pairs nontrivially with some y), and satisfy $B(L_n x, y) = B(x, L_{-n} y)$ for all $n \in \mathbb{Z}$.*

Files `VOA/Moonshine/MoonshineCNLatticeForm.lean`, `VOA/Moonshine/MoonshineCNTensorForm.lean`, `VOA/Moonshine/MoonshineCNTensorNondegenerate.lean`.

theorem moonshineMatterForm_nondegenerate (x : moonshineMatterSpace) (hx : x ≠ 0) :
    ∃ y, moonshineMatterForm x y ≠ 0 := by
```

From the mathematics to the Lean statement

Nondegeneracy is stated in the strong "global" form on the infinite-dimensional space: for every $x \neq 0$ there is a y (for x homogeneous of momentum α and weight N, one can take y of momentum $-\alpha$ and weight N) with $B(x,y) \neq 0$. `moonshineForm_nondegenerate` comes from the simplicity of $V^\natural$ (the radical of `natInvForm` is zero, `natInvForm_leftRadical`). Weight-wise nondegeneracy on each finite-dimensional bigraded piece is not stated here (Chapter 45 uses the isotropic model's `hypForm_weight_nondegenerate` instead). **Not claimed here**: positivity (meaningless as it stands, the form being indefinite) and full FHL invariance (§44.11).

Proof on paper. Symmetry and nondegeneracy of B_L: the monomial–charge basis $x^d \otimes e^\alpha$ is paired with $x^d \otimes e^{-\alpha}$ by the nonzero number $u(d)\chi(\alpha)$ and with nothing else, so the Gram matrix is a signed permutation matrix (`lorentzianStateBasis_pair`). For the tensor product, expand $x = \sum_{(d,\alpha)} x_{d,\alpha} \otimes (x^d e^\alpha)$ with $x_{d,\alpha} \in V^\natural$; if $x_{d,\alpha} \neq 0$, pick a with $B_\natural(x_{d,\alpha}, a) \neq 0$ and pair x with $a \otimes x^d e^{-\alpha}$ (`moonshineMatterForm_coefficient`). Virasoro adjointness of B_L: on each sector the Fock form makes the Fock L_n adjoint to L_{-n} (`uForm_virasoro_adjoint`, §44.11), and the momentum

terms match because the paired sectors have momenta $\alpha, -\alpha$ and the frame oscillator of $-\alpha$ is minus that of α. For the tensor form, $L_n = L_n^\natural \otimes 1 + 1 \otimes L_n^{\mathrm{II}_{1,1}}$ and both factors are adjoint. □

Physical meaning

A nondegenerate BPZ pairing with $L_n^\dagger = L_{-n}$ on the matter theory: exactly the input of the no-ghost theorem. It is a complex bilinear form that pairs momentum α with $-\alpha$ and vanishes on two states of the same nonzero momentum, so "positive" or "indefinite" have no meaning for it directly. The ghost story is told by the *sector* form, obtained by composing with momentum reversal (Theorem 44.59) and restricted to real combinations; in light-cone variables it is the isotropic form B^{iso} of §44.8, which is not positive. Those negative-norm states are the ghosts that the no-ghost theorem shows to decouple at $c = 26$.

What the machine verified

Proved with no hypotheses; all printed in `VOA/Moonshine/MoonshineCNAudit3.lean`; standard axioms.

44.9.4 The light-cone splitting of a matter sector

The sector of $\mathcal{M}$ of momentum (x, y) will be identified (Theorem 44.57) with $V^\natural \otimes \mathcal{F}^{\mathrm{iso}}$. The splitting of §44.8 extends to $V \otimes \mathcal{F}^{\mathrm{iso}}$ for an arbitrary vector space V with operators D_j (later $D_j = L^V_{-(j+1)}$).

Definition 44.43 (Tensor negative modes). For $D : \mathbb{N} \to \mathrm{End}(V)$ and $\kappa, \lambda \in \mathbb{C}$, $\mathcal{L}_{-(j+1)} = D_j \otimes 1 + 1 \otimes L_{-(j+1)}$ on $V \otimes \mathcal{F}^{\mathrm{iso}}$; the tensor one-family space is $V \otimes \mathcal{F}^{\mathrm{iso}}(\varphi)$; the spurious space is $\sum_j \mathrm{im}\, \mathcal{L}_{-(j+1)}$.

Files `VOA/Moonshine/MoonshineCNTensorNegative.lean`, `VOA/Moonshine/MoonshineCNTensorLightCone.lean`.

```
/-- Index `j` denotes the genuine tensor mode with integer index `-(j+1)`. -/
def hypTensorNegative (D : ℕ → Module.End ℂ V) (κ ell : ℂ) (j : ℕ) :
    Module.End ℂ (V ⊗[ℂ] hypFock) :=
  (D j).rTensor hypFock + (hypSugawara κ ell (-(j + 1 : ℤ))).lTensor V

def hypTensorOneFamily (a : Fin 2) : Submodule ℂ (V ⊗[ℂ] hypFock) :=
  hypTensorSupported {e | monomial e 1 ∈ hypOneFamily a}

def hypTensorNegativeSpurious (D : ℕ → Module.End ℂ V) (κ ell : ℂ) :
    Submodule ℂ (V ⊗[ℂ] hypFock) := ⨆ j : ℕ, LinearMap.range (hypTensorNegative D κ ell j)
```

From the mathematics to the Lean statement

`hypTensorSupported s`: elements $\sum_e v_e \otimes x^e$ whose polynomial exponents e all lie in s (coordinates via the monomial basis, `hypTensorCoordinates`); so `hypTensorOneFamily a` $= V \otimes \mathcal{F}^{\mathrm{iso}}(\varphi)$. V is an arbitrary complex vector space (section variable); no grading, form or basis is assumed.

Physical meaning

$\mathcal{L}_{-n} = L^{\mathrm{matter}}_{-n} + L^{\mathrm{lc}}_{-n}$: the total Virasoro lowering operators of the string, matter plus light-cone.

What the machine verified

Definitions; printed in `VOA/Moonshine/MoonshineCNAudit7.lean`.

Theorem 44.44 (Tensor PBW map and light-cone splitting). *(i) For any D, if $\kappa \neq 0$ the sorted-word map $v \otimes a^{\alpha} b_{\lambda} \mapsto \mathcal{L}_{-\lambda_1} \cdots \mathcal{L}_{-\lambda_k}(v \otimes a^{\alpha})$ is a linear automorphism of $V \otimes \mathcal{F}^{\mathrm{iso}}$. (ii) If moreover $[D_i, D_j] = (j-i)D_{i+j+1}$, then $V \otimes \mathcal{F}^{\mathrm{iso}} = \left(\sum_j \operatorname{im} \mathcal{L}_{-(j+1)}\right) \oplus V \otimes \mathcal{F}^{\mathrm{iso}}(a)$; similarly with b when $\lambda \neq 0$; and for $(\kappa, \lambda) \neq 0$ one of the two common kernels $\bigcap_j \ker(1 \otimes \varphi(j))$ complements the spurious space.*

    ∃ a : Fin 2, IsCompl (hypTensorNegativeSpurious D κ ell)
      (⨅ j : ℕ, LinearMap.ker
        ((hypOscillator a (if a = 0 then κ else ell) (j + 1 : ℤ)).lTensor V)) := by
```

From the mathematics to the Lean statement

The hypothesis `hD` is the Witt relation for the negative matter modes: with $D_j = L^V_{-(j+1)}$, $[L_{-(i+1)}, L_{-(j+1)}] = (j-i)L_{-(i+j+2)}$, which is the Virasoro relation for negative modes (no central term since $m + n \neq 0$). It is a genuine hypothesis here because V and D are arbitrary; for $V^{\natural}$ it is discharged in Chapter 45 (`vnatHypTensor_lightConeSplit` assumes nothing). Injectivity and surjectivity of the PBW map need *no* relation on D (the matter term preserves both filtration indices); only the identification of its image with the spurious space uses `hD`, through straightening. `hypTensorPBWEquiv` packages (i).

Proof on paper. Write elements as polynomials with coefficients in V. $\mathcal{L}_{-(j+1)}(v \otimes p) = \kappa v \otimes b_{j+1} p +$(terms of lower order), where $D_j v \otimes p$ has the *same* count and level as $v \otimes p$, hence is lower than the leading term. The proofs of Theorem 44.34 go through coefficientwise with values in V; straightening uses `hD`. □

Physical meaning

At nonzero momentum, every state of the string Fock space (matter ⊗ light-cone) is uniquely "longitudinal-free" plus total Virasoro descendants. This is the decomposition $\mathcal{H} = \mathcal{S} \oplus \mathcal{K}$ of Goddard–Thorn; the matter theory enters only through its negative Virasoro modes.

What the machine verified

Proved with the displayed hypotheses only; printed in `VOA/Moonshine/MoonshineCNAudit7.lean`; standard axioms. The remaining tensor files (`TensorNegative` coordinates and filtration, `TensorPBWMap` leading terms, `TensorLightConeKernels` swap) are the supporting lemmas.

44.10 Vertex algebra theory for near-VOAs

The library's general structure theory (Goddard uniqueness, translation covariance, the n-th product and commutator formulas, associativity, the Borcherds identity, skew-symmetry: Chapter 4) is stated for `VertexOperatorAlgebra`, whose weight spaces are finite-dimensional and bounded below. The proofs, however, use only locality, the vacuum axioms, regularity and translation covariance. The seven files `MoonshineCNNear{Goddard, Translation, NthProduct, Iterate, Borcherds, Skew, Consequences}` (plus the specialisations in `NearMatterIdentities`) port them to `NearVOA`, "without finiteness assumptions". All declarations below are in namespace `VOA.NearVOA` and take a near-VOA `V : NearVOA 𝒱` (or `H`) as their first explicit argument; no other hypothesis is added unless displayed.

Definition 44.45 (Products, Virasoro modes, spurious states). For a near-VOA: $u_{(n)}v =$ `V.smul u n v`; $L_n = \omega_{(n+1)}$; $T = L_{-1}$; the *spurious subspace* is $\sum_{n\geq 1} \operatorname{im} L_{-n}$.

Files `VOA/Moonshine/MoonshineCNNearGoddard.lean`, `VOA/Moonshine/MoonshineCNNearConsequences.lean`.

```
noncomputable def smul (V : NearVOA 𝒱) (u : 𝒱) (n : ℤ) (v : 𝒱) : 𝒱 := mode (V.Y u) n v

noncomputable def T (V : NearVOA 𝒱) : End ℂ 𝒱 := V.L (-1)

/-- The subspace generated by negative Virasoro modes. -/
noncomputable def spurious (V : NearVOA 𝒱) : Submodule ℂ 𝒱 :=
  ⨆ n : ℕ, LinearMap.range (V.L (-(n + 1 : ℤ)))
```

From the mathematics to the Lean statement

`V.L n` is defined in the same file as `mode (V.Y V.conformalVector) (n + 1)` (lemma `L_def`); it coincides definitionally with `nearVirasoroMode V n` of §44.9. `⨆ n : ℕ` over $n \geq 0$ of the range of $L_{-(n+1)}$ is $\sum_{m\geq 1} \operatorname{im} L_{-m}$.

Physical meaning

The spurious states are the Virasoro descendants: in string theory, the states of the form $L_{-1}\chi_1 + L_{-2}\chi_2 + \cdots$ that decouple from physical amplitudes when they are also physical.

What the machine verified

Definitions; printed in `VOA/Moonshine/MoonshineCNAudit9.lean`.

Theorem 44.46 (Goddard uniqueness for near-VOAs). *If a formal distribution A is local with every $Y(b,z)$ and $A(z)\mathbb{1} = Y(a,z)\mathbb{1}$, then $A = Y(a,z)$.*

File `VOA/Moonshine/MoonshineCNNearGoddard.lean`.

```
/-- Ordinary locality and the vacuum tower determine a vertex operator. -/
theorem goddard_uniqueness (V : NearVOA 𝒱) (A : FormalDist (End ℂ 𝒱)) (a : 𝒱)
    (hAloc : ∀ b : 𝒱, Local A (V.Y b))
    (hAvac : ∀ m : ℤ, A m V.vacuum = (V.Y a) m V.vacuum) : A = V.Y a := by
```

From the mathematics to the Lean statement

`A m V.vacuum` is the z^m-coefficient of $A(z)\mathbb{1}$. The file also proves the sign-generic pointwise version `goddard_pointwiseε` (for ε-locality) and Dong's lemma for near-VOA fields (`dong_fields`). Same statement as Chapter 4, Theorem 4.14, for the larger class of near-VOAs.

Proof on paper. For each b, $(z_1-z_2)^N[A(z_1)-Y(a,z_1)]Y(b,z_2)\mathbb{1} = (z_1-z_2)^N Y(b,z_2)[A(z_1)-Y(a,z_1)]\mathbb{1} = 0$ by locality; setting $z_2 = 0$ (allowed since $Y(b,z_2)\mathbb{1}$ has no negative powers) gives $z_1^N(A(z_1)-Y(a,z_1))b = 0$, so $A(z_1)b = Y(a,z_1)b$. □

Physical meaning

A field of a CFT is determined by the state it creates and by its OPEs: two local fields creating the same state are equal.

What the machine verified

Proved; printed in `VOA/Moonshine/MoonshineCNAudit9.lean`; standard axioms.

Theorem 44.47 (Translation, products, commutator, iterate). *For a near-VOA and all $u,v,x,\ m,n,\ell \in \mathbb{Z}$, $k \in \mathbb{N}$: (i) $[L_{-1},u_{(n)}] = -n\,u_{(n-1)}$; (ii) the k-th product field of $Y(u,z)$ and $Y(v,z)$ is $Y(u_{(k)}v,z)$; (iii) $[u_{(m)},v_{(n)}] = \sum_{j\ge 0}\binom{m}{j}(u_{(j)}v)_{(m+n-j)}$, a finite sum; (iv) $(u_{(\ell)}v)_{(N)}x = \sum_{i\ge 0}(-1)^i\binom{\ell}{i}\big(u_{(\ell-i)}v_{(N+i)}x - (-1)^\ell v_{(\ell+N-i)}u_{(i)}x\big)$.*

            - ((1 : ℂ) * (-1 : ℂ) ^ ℓ) • V.smul v (ℓ + N - i) (V.smul u i x)) := by
```

From the mathematics to the Lean statement

`gBinom m j` is the generalised binomial coefficient $\binom{m}{j} = m(m-1)\cdots(m-j+1)/j!$ for $m \in \mathbb{Z}$. `bracketDistε 1 A B` is the commutator distribution $[A(z_1),B(z_2)]$ and `cCoeff k` extracts the coefficient of $\partial^{(k)}\delta(z_1-z_2)$ in its delta-expansion; (ii) says that this coefficient is the field of $u_{(k)}v$ (the OPE pole coefficient). In (iii), `∃ N` together with `∑ j : Fin N` is the finite sum over $0 \le j < N$ (N depends on u,v via regularity). In (iv), $\sum^{\mathrm{f}}$ is a finite sum on the fixed vector x. These are the statements of Chapter 4, Theorems 4.19, 4.20, 4.21 and 4.23, verbatim in content.

Proof on paper. As in Chapter 4: translation covariance from (VOA3) and Goddard; the n-th product theorem from Dong's lemma and Goddard (the product field is local with everything and creates $u_{(k)}v$); the commutator formula from the delta-function expansion of the commutator of local fields; associativity for negative indices from the normal-ordered product formula of the field of $u_{(-k-1)}v$ (`assoc_neg`). No lower bound on weights is ever used. □

Physical meaning

The OPE $u(z)v(w) \sim \sum_{k\geq 0}(u_{(k)}v)(w)/(z-w)^{k+1}$ and its consequences: commutators of modes are determined by the singular part of the OPE, the regular part by normal ordering.

What the machine verified

Proved; printed in `VOA/Moonshine/MoonshineCNAudit9.lean`; standard axioms.

Theorem 44.48 (Borcherds identity and skew-symmetry for near-VOAs). *For all u, v, x and $\ell, m, n \in \mathbb{Z}$,*

$$\sum_{i\geq 0}(-1)^i\binom{\ell}{i}\Big(u_{(\ell+m-i)}v_{(n+i)}x \;-\; (-1)^{\ell}v_{(\ell+n-i)}u_{(m+i)}x\Big) \;=\; \sum_{i\geq 0}\binom{m}{i}(u_{(\ell+i)}v)_{(m+n-i)}x,$$

and $v_{(t)}u = \sum_{j\geq 0}\frac{(-1)^{t+j+1}}{j!}L_{-1}^{j}\big(u_{(t+j)}v\big)$.

            ((V.L (-1) ^ j) (V.smul a (t + (j : ℤ)) b)) := by
```

From the mathematics to the Lean statement

`negOnePow i` $= (-1)^i$; `cbz ℓ i` is $\binom{\ell}{i}$ for $i \geq 0$ and 0 for $i < 0$ (so the sums over $\mathbb{Z}$ are sums over $i \geq 0$); `sgn k` $= (-1)^k$. The factor `(1 : ℂ)` is the Koszul sign of a superalgebra, specialised to 1 (the files are ports of the super versions at sign one). The Jacobi identity is the Borcherds identity of Chapter 4, (4.2), in exactly the same index convention (ℓ the product index, m the first mode, n the second); skew-symmetry is Theorem 4.33, written mode by mode.

Proof on paper. Both sides of the Jacobi identity satisfy the same Pascal recursion in (ℓ, m) (`borcherdsProductSum_rec`, `borcherdsIterateSum_rec`); they agree for $m = 0$ (the iterate formula, Theorem 44.47(iv)) and for $\ell = 0$ (the commutator formula); the recursion then propagates agreement to all (ℓ, m), every sum being finite on the fixed vector. Skew-symmetry: apply Jacobi with $x = \mathbb{1}$ and use $Y(w,z)\mathbb{1} = e^{zL_{-1}}w$. □

Physical meaning

The Borcherds identity is the full content of the OPE: associativity and commutativity of operator products as meromorphic functions. Skew-symmetry $Y(u,z)v = e^{zL_{-1}}Y(v,-z)u$ is the exchange of the two insertion points.

What the machine verified

Proved; printed in `VOA/Moonshine/MoonshineCNAudit9.lean`; standard axioms.

Theorem 44.49 (Consequences used by the physical-state Lie bracket). *For a near-VOA: (i)* $[u_{(0)}, v_{(n)}] = (u_{(0)}v)_{(n)}$*; (ii) if* $L_0u = u$ *and* $L_ju = 0$ *for* $j > 0$ *(a weight-one primary), then* $[L_m, u_{(n)}] = -n\,u_{(m+n)}$ *and* $u_{(0)}$ *preserves the spurious subspace; (iii)* $u_{(0)}v + v_{(0)}u \in \operatorname{im} L_{-1}$ *for all* u, v.

    (hpos : ∀ j : ℤ, 0 < j → V.L j u = 0) (x : 𝒱) (hx : x ∈ V.spurious) :
    V.smul u 0 x ∈ V.spurious := by

/-- The symmetric zero-product is a translation, for arbitrary states. -/
theorem skew_zero (V : NearVOA 𝒱) (u v : 𝒱) :
    V.smul u 0 v + V.smul v 0 u ∈ LinearMap.range (V.L (-1)) := by
```

From the mathematics to the Lean statement

`hu`, `hpos` say exactly "u is a weight-one Virasoro primary". These are the hypotheses of the physical-state condition (44.1); the subspace of such u is `primaryWeightOne` (Chapter 45). **Concrete instances.** `VOA/Moonshine/MoonshineCNNearMatterIdentities.lean` restates each theorem of this section for `moonshineMatterNearVOA` and for `lorentzianNearVOA` (`moonshineMatter_jacobi`, `lorentzian_skew`, ...), with no added hypothesis; e.g.

```
theorem moonshineMatter_skew_zero (u v : moonshineMatterSpace) :
    moonshineMatterNearVOA.smul u 0 v + moonshineMatterNearVOA.smul v 0 u ∈
      LinearMap.range (moonshineMatterNearVOA.L (-1)) :=
```

(file `VOA/Moonshine/MoonshineCNNearMatterIdentities.lean`).

Proof on paper. (i) is the commutator formula at $m = 0$ (only $j = 0$ survives). (ii) The commutator formula with ω and u and the skew-symmetry $\omega_{(j)}u$ from $u_{(j)}\omega$; for a weight-one primary only $L_{-1}u$ and $L_0u = u$ contribute. If $x = L_{-k}y$ then $u_{(0)}x = L_{-k}u_{(0)}y$ since $[L_{-k}, u_{(0)}] = 0$. (iii) Skew-symmetry at $t = 0$: $v_{(0)}u = -u_{(0)}v + L_{-1}(\cdots)$. □

Physical meaning

Borcherds' bracket on physical states is $[u, v] = u_{(0)}v$: (i) is the Jacobi identity of this bracket, (ii) says the bracket maps physical states to physical states and spurious to spurious (the gauge invariance of string amplitudes), and (iii) says it is antisymmetric modulo L_{-1}-exact states, which are null.

What the machine verified

Proved; printed in `VOA/Moonshine/MoonshineCNAudit9.lean`; standard axioms.

44.11 Contragredient (FHL) adjointness without a lower bound

The Monster Lie algebra carries an invariant bilinear form, induced from the matter form B of Theorem 44.42. Its invariance $B([u, v], w) = B(u, [v, w])$ requires that B be *FHL-invariant*: for u of weight N,

$$B(u_{(n)}x, y) = (-1)^N \sum_{j\geq 0} \frac{1}{j!} B\big(x, (L_1^j u)_{(2N-n-2-j)}y\big) \tag{44.8}$$

(Chapter 5, Definition 5.49). For a VOA of CFT type the sum stops at $j = N$ because $L_1^j u$ has weight $N - j < 0$ otherwise. In a near-VOA this argument fails; the cutoff must be chosen differently.

Trap / dead end

The total-weight cutoff is wrong (a kernel-checked counterexample). In $V_{\mathrm{II}_{1,1}}$ the state $w = L_{-1}e^{(1,-1)}$ has total weight 0 (the charged vacuum $e^{(1,-1)}$ has weight $\Delta(1,-1) = -1$), yet $L_1 w = -2e^{(1,-1)} \neq 0$. So a formula (44.8) with the CFT-type cutoff $j \leq N = 0$ would drop a nonzero term. This was first noticed on paper and is now a Lean theorem (Theorem 44.50). The correct cutoff is the *oscillator level above the sector's ground energy*, $N - \Delta(\alpha)$ (Theorem 44.51).

Theorem 44.50 (Cutoff witness). *In any near-VOA, if $u \in V_N$ and $L_1 u = 0$ then $L_1 L_{-1} u = 2Nu$. In $V_{\mathrm{II}_{1,1}}$, $w = L_{-1}e^{(1,-1)}$ lies in weight 0 and $L_1 w = -2e^{(1,-1)}$; hence some weight-zero state is not killed by L_1.*

File `VOA/Moonshine/MoonshineCNChargeCutoffWitness.lean`.

```
noncomputable def lorentzianNegativeChargeDescendant : LorentzianFockSpace :=
  lorentzianNearVOA.L (-1) (lorentzianChargeState ![1, -1])

theorem lorentzianNegativeChargeDescendant_weight :
    lorentzianNegativeChargeDescendant ∈ lorentzianNearVOA.grading 0 := by

/-- At total weight zero the first omitted FHL term is explicitly nonzero. -/
theorem lorentzianNegativeChargeDescendant_virasoroOne :
    lorentzianNearVOA.L 1 lorentzianNegativeChargeDescendant =
      (-2 : ℂ) • lorentzianChargeState ![1, -1] := by

theorem lorentzianVirasoroOne_weightZero_not_zero :
    ∃ u ∈ lorentzianNearVOA.grading 0, lorentzianNearVOA.L 1 u ≠ 0 := by
```

From the mathematics to the Lean statement

The general first sentence is the lemma `virasoroOne_translation_primary` (same file, not printed here; it is the computation in the proof below). The charged vacuum is primary (`frame`

`ChargeState_virasoroOne`, `VOA/Moonshine/MoonshineCNGeneratorPrimary.lean`). Nonvanishing of $e^{(1,-1)}$ is `lorentzianChargeState_ne_zero`.

Proof on paper. $[L_1, L_{-1}] = 2L_0$, so $L_1L_{-1}u = L_{-1}L_1u + 2L_0u = 2Nu$; with $N = \Delta(1,-1) = -1$ this is $-2e^{(1,-1)}$. □

Physical meaning

In a theory with negative-energy ground states, quasi-primary descendants can have weight zero without being annihilated by L_1; the BPZ conjugation $e^{zL_1}(-z^{-2})^{L_0}$ must then keep more terms than the weight suggests.

What the machine verified

Proved; printed in `VOA/Moonshine/MoonshineCNAudit13.lean`; standard axioms.

44.11.1 Local nilpotence of L_1

Theorem 44.51 (Charge-sensitive nilpotence). *(i) In any near-VOA, let S be an L_1-stable subspace with $S \cap \mathcal{V}_N = 0$ for $N < E_0$ (Lean `E`). Then $L_1^k u = 0$ for $u \in S \cap \mathcal{V}_N$ and $k > N - E_0$. If $\mathcal{V}$ is spanned by such pieces $S_\alpha \cap \mathcal{V}_N$, then L_1 is locally nilpotent. (ii) In V_L (any even L, complex frame), the momentum-α part of $(V_L)_N$ is $(\mathcal{F}_r)_{N-\Delta(\alpha)} \otimes e^\alpha$; hence $L_1^k u = 0$ for u of weight N and momentum α and $k > N - \Delta(\alpha)$. (iii) The same holds in $\mathcal{M}$; in particular $L_1^{(N-\Delta(\alpha))+1} u = 0$ and L_1 is locally nilpotent on $V_{\mathrm{II}_{1,1}}$ and on $\mathcal{M}$.*

Files `VOA/Moonshine/MoonshineCNNearNilpotence.lean`, `VOA/Moonshine/MoonshineCNChargeNilpotence.lean`, `VOA/Moonshine/MoonshineCNMatterNilpotence.lean`.

theorem moonshineMatterVirasoroOne_locallyNilpotent (u : moonshineMatterSpace) :
    ∃ k : ℕ, (moonshineMatterNearVOA.L 1 ^ k) u = 0 :=
```

From the mathematics to the Lean statement

`(N - E).toNat` is $\max(N - E_0, 0)$. `S ⊓ V.grading N` is the intersection. `halfNorm L α` $= \Delta(\alpha)$ (Theorem 44.12(ii)). "Locally nilpotent" means: for each u some power of L_1 kills u (the power may depend on u); this is the precise hypothesis `hNil` of the next theorems. For $\mathcal{M}$ the lower bound uses ${V^\natural}_k = 0$ for $k < 0$ (CFT type of $V^\natural$): a state of momentum α has weight $\geq \Delta(\alpha)$.

Proof on paper. L_1 lowers weight by one and preserves momentum (it is a zero-momentum operator). Within momentum α the weights are $\geq \Delta(\alpha)$ because oscillator levels (and $V^\natural$ weights) are ≥ 0. So after more than $N - \Delta(\alpha)$ steps the weight drops below the sector's floor and the vector is 0. For a general vector, take the maximum of the finitely many cutoffs of its homogeneous components. □

Physical meaning

Each momentum sector of the Lorentzian theory *is* bounded below (by its ground energy $p^+ p^-$); only the union is not. The BPZ conjugate of a state therefore involves finitely many L_1-descendants, counted from the sector's ground state rather than from zero.

What the machine verified

Proved; printed in `VOA/Moonshine/MoonshineCNAudit13.lean`; standard axioms.

44.11.2 Opposite modes

Definition 44.52 (Opposite modes). Let V be a near-VOA in which L_1 is locally nilpotent. For $u \in \mathcal{V}_N$ define

$$u^{\mathrm{op}}_{(n)} = (-1)^N \sum_{j \geq 0} \frac{1}{j!} (L_1^j u)_{(2N-n-2-j)}$$

(a finite sum by nilpotence), and extend linearly over the weight decomposition.

Files `VOA/Moonshine/MoonshineCNNearOppositeModes.lean`, `VOA/Moonshine/MoonshineCNMatterOpposite.lean`.

```

```

```
    {u : H} (hu : u ∈ V.grading 1) (hL : V.L 1 u = 0) :
    V.oppositeModes hNil 0 u = -mode (V.Y u) 0 := by

def moonshineMatterOppositeModes (n : ℤ) :
    moonshineMatterSpace →ₗ[ℂ] Module.End ℂ moonshineMatterSpace :=
  moonshineMatterNearVOA.oppositeModes moonshineMatterVirasoroOne_locallyNilpotent n
```

From the mathematics to the Lean statement

`oppositeModeAtWeight N n u` is the displayed formula with N a parameter (it is meaningful for $u \in \mathcal{V}_N$); $\sum^{\mathrm{f}}$ is finite because $L_1^j u = 0$ for large j. `oppositeModes` (body, using `V.isInternal.chooseDecomposition` and `DirectSum.toModule`) decomposes u into homogeneous components and applies `oppositeModeAtWeight` at the right weight on each; `oppositeModes_homogeneous` confirms that on $u \in \mathcal{V}_N$ it equals `oppositeModeAtWeight N n u`. The choice of decomposition instance is immaterial (the decomposition is unique). `oppositeModeAtWeight_eq_sum` says *any* killing exponent gives the same value, so the correct cutoff need not be known; for $\mathcal{M}$, `moonshineMatterOppositeModes_charge_cutoff` uses $(N - \Delta(\alpha)) + 1$. Comparing with Chapter 5, (5.1): same coefficients, same mode index $2N - n - 2 - j$, different cutoff.

Physical meaning

$u^{\mathrm{op}}_{(n)}$ are the modes of the BPZ-conjugate field $Y(e^{zL_1}(-z^{-2})^{L_0}u, z^{-1})$. For a weight-one primary current J this is $J^{\mathrm{op}}_{(0)} = -J_{(0)}$: charges are anti-self-adjoint for the bilinear pairing.

What the machine verified

Definitions and proved properties; printed in `VOA/Moonshine/MoonshineCNAudit13.lean`; standard axioms.

44.11.3 From generators to all fields

Definition 44.53 (Opposite iterate identity). A near-VOA with locally nilpotent L_1 satisfies the *opposite iterate identity* if for all u, v, y and $\ell, n \in \mathbb{Z}$

$$(u_{(\ell)}v)^{\mathrm{op}}_{(n)}y = \sum_{i\geq 0}(-1)^i\binom{\ell}{i}\Big(v^{\mathrm{op}}_{(n+i)}u^{\mathrm{op}}_{(\ell-i)}y - (-1)^{\ell}u^{\mathrm{op}}_{(i)}v^{\mathrm{op}}_{(\ell+n-i)}y\Big).$$

The *intertwined states* for a form B are those u with $B(u_{(n)}x, y) = B(x, u^{\mathrm{op}}_{(n)}y)$ for all n, x, y.

File `VOA/Moonshine/MoonshineCNNearAdjointClosure.lean`.

```

          (-1 : ℂ) ^ ℓ • V.oppositeModes hNil i u
            (V.oppositeModes hNil (ℓ + n - i) v y))
```

From the mathematics to the Lean statement

The identity is the iterate formula (Theorem 44.47(iv)) with every mode replaced by its opposite and the order of the two factors reversed, which is what adjunction does to a product. The docstring's word "remaining" is historical: the identity is proved for every near-VOA with locally nilpotent L_1 in Theorem 44.54.

Physical meaning

Adjunction reverses the order of operators; the opposite iterate identity says that BPZ conjugation is compatible with the OPE, i.e. that the conjugate fields again satisfy associativity.

What the machine verified

Definitions; printed in `VOA/Moonshine/MoonshineCNAudit13.lean`.

Theorem 44.54 (Opposite Borcherds identity; adjoint closure). *Let V be a near-VOA with L_1 locally nilpotent. (i) For $u \in \mathcal{V}_p$, any v, any q, ℓ, m, n:*

$$\sum_i (-1)^i \binom{\ell}{i} \left(v^{\mathrm{op},q}_{(n+i)} u^{\mathrm{op},p}_{(\ell+m-i)} y \;-\; (-1)^{\ell} u^{\mathrm{op},p}_{(m+i)} v^{\mathrm{op},q}_{(\ell+n-i)} y \right) \;=\; \sum_i \binom{m}{i} (u_{(\ell+i)}v)^{\mathrm{op},\,p+q-\ell-i-1}_{(m+n-i)} y,$$

where $w^{\mathrm{op},N}$ denotes `oppositeModeAtWeight N`. *(ii) V satisfies the opposite iterate identity. (iii) Let B be any bilinear form and G a set of states generating V under all products $u_{(\ell)}v$. If every $u \in G$ satisfies $B(u_{(n)}x, y) = B(x, u^{\mathrm{op}}_{(n)}y)$, then every $u \in \mathcal{V}$ does.*

    (u : H) (n : ℤ) (x y : H) :
    B (mode (V.Y u) n x) y = B x (V.oppositeModes hNil n u y) :=
```

From the mathematics to the Lean statement

Hypotheses of (iii): `hNil` (local nilpotence; discharged for $\mathcal{M}$ by `moonshineMatterVirasoroOne_locallyNilpotent`); `hGen` says G generates: every subspace containing G and closed under all products is everything; `hAdj` is adjointness on generators. The conclusion is FHL invariance (44.8) for every state, in opposite-mode form. The earlier conditional version `adjoint_of_oppositeIterate_generators` (`VOA/Moonshine/MoonshineCNNearAdjointClosure.lean`) has the extra hypothesis `hIter : V.OppositeIterateIdentity hNil`, which (ii) discharges. **Fidelity.** No lower bound, no finite-dimensionality, no symmetry or nondegeneracy of B is assumed; this is stronger than the VOA version of Chapter 5 in scope.

Proof on paper. Both sides of (i) are reduced to one block sum

$$(-1)^{p+q}\sum_{b<B_0}\sum_{a<A_0}\frac{1}{a!\,b!}\sum_{i}\binom{2q-\ell-n-2-b}{i}\big((L_1^b v)_{(\ell+i)}(L_1^q u)\big)_{(\dots)}y,$$

where A_0, B_0 are *arbitrary* exponents with $L_1^{A_0}u = 0$, $L_1^{B_0}v = 0$. The opposite-pair side: expand both opposite modes with these cutoffs and apply the Jacobi identity (Theorem 44.48) to each pair $(L_1^b v, L_1^q u)$. The product side: the opposite mode of $u_{(s)}v$ involves $L_1^t(u_{(s)}v)$, which is expanded by the "comultiplication" formula $L_1(u_{(s)}x) = (2p-s-2)u_{(s+1)}x + (L_1u)_{(s)}x + u_{(s)}L_1x$ (`virasoroOne_smul_of_mem_weight`, from the commutator formula with ω and $L_0u = pu$), iterated with explicit coefficients (`virasoroOne_pow_smul_eq_sum`); the triangle of indices $a+b \le t$ is moved into the box $a < A_0, b < B_0$ (the summand vanishes outside), and both sides collapse by Vandermonde's convolution to the same coefficients. (ii) is (i) at $m = 0$, extended from homogeneous u to all u by additivity. (iii): the intertwined states form a subspace containing G; by the ordinary iterate formula, (ii) and adjunction, it is closed under all products; so it is everything. □

Physical meaning

The statement "if the generating fields are BPZ-self-conjugate, all fields are" — the standard way to establish an invariant form on a CFT (check it on the currents and vertex operators). The point of the theorem is that it survives the absence of a bounded-below spectrum.

What the machine verified

(i), (ii), (iii) proved with the displayed hypotheses only; printed in `VOA/Moonshine/MoonshineCNAudit16.lean` (43 `#print axioms` lines, each reported as exactly `[propext, Classical.choice, Quot.sound]` in the development record). The supporting files `NearOppositeComul`, `NearOppositeLeft`, `NearOppositeRight` contain the two block-sum reductions.

44.11.4 The generators of $\mathcal{M}$ are adjoint

Theorem 44.55 (Adjointness of the generating fields). *(i) On $\mathcal{F}_r$ with the Fock form $B_{\mathcal{F}}$: $B_{\mathcal{F}}(L_n p, q) = B_{\mathcal{F}}(p, L_{-n}q)$ and $B_{\mathcal{F}}(\alpha(n)p, q) = -B_{\mathcal{F}}(p, \alpha(-n)q)$ (frame oscillators are skew). (ii) The dressing satisfies $B_{\mathcal{F}}(\mathcal{E}_t(\gamma)y, y') = B_{\mathcal{F}}(y, \mathcal{E}_{-t}(\gamma)y')$. (iii) In V_L (L even), with B_L and $N = \Delta(\gamma)$: $B_L(e^{\gamma}_{(n)}x, y) = (-1)^N B_L(x, e^{\gamma}_{(2N-n-2)}y)$ and $B_L(h_a(n)x, y) = -B_L(x, h_a(-n)y)$ for the reconstructed fields; and the charged vacua and the currents generate V_L. (iv) In $\mathcal{M}$ the same holds for $\mathbb{1}\otimes e^{\gamma}$, $\mathbb{1}\otimes h_a(-1)\mathbb{1}$, and (44.8) holds for every $a\otimes\mathbb{1}$, $a \in V^{\natural}{}_N$.*

```

From the mathematics to the Lean statement

`frameWordState L [(0, a)] 0` $= h_a(-1)\mathbb{1}$. The charged formula is (44.8) for the primary e^{γ} (only $j = 0$), with `halfNorm L γ` $= \Delta(\gamma)$ the weight; the current formula is (44.8) for the weight-one primary $h_a(-1)\mathbb{1}$. For $V^{\natural}$ the cutoff `wt.toNat + 1` is the CFT-type one, correct because $V^{\natural}$ is bounded below; the proof transports the FHL invariance of `natForm` (`SimpleNat`, Chapter 42). The analogous charged and current statements on $\mathcal{M}$ (`moonshineMatterForm_chargeGenerator_adjoint`, `moonshineMatterForm_currentGenerator_adjoint`) are in the same file. `frameStateField_generated_by_charges_currents` is the generation hypothesis `hGen` for V_L, in the form "closed submodule containing the generators is everything".

Proof on paper. (i) Fock form: F pairs monomials diagonally with weights making $x_{j,a}\cdot$ and $-(j+$

$1)\partial/\partial x_{j,a}$ adjoint; the Sugawara modes are quadratic in oscillators, so the two signs cancel. (ii) The adjoint of $E^-(\gamma,z)E^+(\gamma,z)$ is $E^-(\gamma,z^{-1})E^+(\gamma,z^{-1})$ after using skew-adjointness of the oscillators; proved by induction on polynomials from the commutator of oscillators with the dressing (`direction Oscillator_dressingField_apply`). (iii) Combine (ii) with the pairing of e^{β} against $e^{-\beta}$, the cocycle identity for $\chi(\alpha+\beta)$ and the $z^{\langle\gamma,\beta\rangle}$ shift; the sign $(-1)^{\Delta(\gamma)}$ comes out of the cocycle. The reconstructed field of a word state is identified with the explicit current/charged field, and generation follows by induction on words (a word state is a product of a current mode with a shorter word state). (iv) Tensor with $V^\natural$: modes of $\mathbb{1}\otimes b$ act as $1\otimes b_{(n)}$, modes of $a\otimes\mathbb{1}$ as $a_{(n)}\otimes 1$, and L_1 acts factorwise (`moonshineMatterVnatVirasoroOne_pow`). □

Physical meaning

The light-cone currents are anti-self-conjugate, the vertex operators e^{γ} are conjugate to themselves up to the sign $(-1)^h$ of a weight-h primary, and the Monster CFT's fields are BPZ-self-conjugate.

What the machine verified

Proved, no hypotheses beyond evenness and a frame (discharged for $\mathrm{II}_{1,1}$). Printed in `VOA/Moonshine/MoonshineCNAudit3.lean` (Fock adjoints) and `VOA/Moonshine/MoonshineCNAudit12.lean` (dressing, charged, current, tensor generators); standard axioms.

Theorem 44.56 (FHL invariance of the matter form, reduced to its generators). *(i) The states $a\otimes\mathbb{1}$ $(a\in V^\natural)$, $\mathbb{1}\otimes e^{\alpha}$ and $\mathbb{1}\otimes h_a(-1)\mathbb{1}$ generate $\mathcal{M}$. (ii) Each of them is adjoint to its opposite modes for $B=B_\natural\otimes B_L$. (iii) Conditional on the opposite iterate identity for $\mathcal{M}$, every state of $\mathcal{M}$ is; and then the descended form on the Monster Lie algebra is invariant. (The condition is discharged by Theorem 44.54(ii); the unconditional statements* `moonshineMatterOppositeModes_adjoint` *and* `monsterLieBilinearForm_invariant` *are in the Chapter 45 file* `VOA/Moonshine/MoonshineCNMonsterLieInvariance.lean`.*)*

```

```
    (u v w : monsterLieAlgebra) :
    monsterLieBilinearForm [u, v] w = monsterLieBilinearForm u [v, w] :=
```

From the mathematics to the Lean statement

`monsterLieAlgebra` (the weight-one primaries of $\mathcal{M}$ modulo spurious states) and `monsterLieBilinearForm` (the descended form) are defined in Chapter 45. The single hypothesis `hIter` is a closed proposition with no free variables; it is *proved* as `moonshineMatterNearVOA_oppositeIterateIdentity` (Chapter 45 file, a one-line application of `oppositeIterateIdentity_of_locallyNilpotent`). The other two generator-adjointness theorems of `VOA/Moonshine/MoonshineCNMatterAdjointReduction.lean` (`moonshineMatterOppositeModes_charge_adjoint`, `…_current_adjoint`, `…_vnat_adjoint`) restate Theorem 44.55(iv) in opposite-mode form, using the primarity computations of `VOA/Moonshine/MoonshineCNGeneratorPrimary.lean` ($L_1 e^\alpha = 0$, $L_1 h_a(-1)\mathbb{1} = 0$, the weights of the generators, and L_1 acting factorwise). **A stale docstring:** the module docstring of `MatterAdjointReduction` calls the opposite iterate identity "the sole residual hypothesis"; it has since been proved. The file `MatterOpposite` also contains the earlier reduction `monsterLieBilinearForm_invariant_of_oppositeAdjoint`, conditional on adjointness of the primaries' zero modes (a hypothesis now also proved, as `moonshineMatterForm_primary_zeroMode_skew` in Chapter 45).

Proof on paper. (i) Pull a submodule back along $b \mapsto \mathbb{1} \otimes b$, apply `frameStateField_generated_by_charges_currents`, then use $(a \otimes \mathbb{1})_{(-1)}(\mathbb{1} \otimes b) = a \otimes b$. (ii) Theorem 44.55(iv) together with the identification of the opposite modes of the generators via their weights and L_1-towers. (iii) Theorem 44.54(iii), then specialise to weight-one primaries at mode 0, where $u^{\mathrm{op}}_{(0)} = -u_{(0)}$, giving $B(u_{(0)}b, c) = -B(b, u_{(0)}c)$, the invariance of $B([u, v], w)$. □

Physical meaning

The Monster Lie algebra's invariant form is the restriction of the string's BPZ inner product to physical states: $\langle [u, v], w\rangle = \langle u, [v, w]\rangle$ because the zero mode of a physical current is anti-self-adjoint.

What the machine verified

(i), (ii) proved with no hypotheses beyond the closure data displayed in (i); (iii) proved conditional on `hIter`, which is itself proved; hence the final invariance is unconditional (Chapter 45). Printed in `VOA/Moonshine/MoonshineCNAudit13.lean`; the discharging theorem in `VOA/Moonshine/MoonshineCNAudit16.lean`; standard axioms.

44.12 Momentum sectors and momentum reversal

The isotropic model of §44.8 has to be connected with the actual sectors $\mathcal{M}^\alpha$. Two files of this chapter do the linear algebra; the comparison of Virasoro actions and the transfer of the no-ghost theorem are in Chapter 45.

Theorem 44.57 (The sector equivalence). *For every $\alpha \in \mathrm{II}_{1,1}$ there is a linear isomorphism $\Psi_\alpha : V^\natural \otimes \mathcal{F}^{\mathrm{iso}} \to \mathcal{M}^\alpha$, $v \otimes p \mapsto v \otimes \Phi(p)e^\alpha$, where $\Phi : \mathcal{F}^{\mathrm{iso}} \to \mathcal{F}_2$ is the algebra isomorphism changing the isotropic variables into the complex-frame variables ($a_j \mapsto \frac{1}{2}(x_{j,1} - ix_{j,2})$, $b_j \mapsto x_{j,1} + ix_{j,2}$); and Ψ_α intertwines the natural actions of* $\mathrm{Aut}(V^\natural)$.

File `VOA/Moonshine/MoonshineCNMatterSectorEquiv.lean`.

```
/-- The actual momentum-sector equivalence, including the complex-frame change of
 ↪ variables. -/
def moonshineMatterSectorEquiv (α : lorentzianLattice.carrier) :
    (Vnat ⊗[ℂ] hypFock) ≃ₗ[ℂ] moonshineMatterMomentum α :=

theorem moonshineMatterSectorEquiv_tmul (α : lorentzianLattice.carrier) (v : Vnat) (p :
 ↪ hypFock) :
    (moonshineMatterSectorEquiv α (v ⊗ₜ p) : moonshineMatterSpace) =
      v ⊗ₜ latStateGen lorentzianLattice (hypLorentzianPolynomialEquiv p) α := rfl

theorem moonshineMatterSectorEquiv_equivariant (g : AutVnat) (α :
 ↪ lorentzianLattice.carrier)
    (u : Vnat ⊗[ℂ] hypFock) :
    (moonshineMatterSectorEquiv α (vnatSectorAction g u) : moonshineMatterSpace) =
      moonshineMatterAut g (moonshineMatterSectorEquiv α u) := by
```

From the mathematics to the Lean statement

`hypLorentzianPolynomialEquiv : hypFock ≃ₐ[ℂ] FockN (rank lorentzianLattice)` is defined in the Chapter 45 file `VOA/Moonshine/MoonshineCNSectorFrame.lean` (images of a_j, b_j as in the theorem; with this, family a is the current of $(0,1)$, so $\kappa = x$, $\lambda = y$ at $\alpha = (x,y)$). `AutVnat` is the automorphism group of $V^\natural$ (Chapter 47); `vnatSectorAction g` $= g \otimes 1$ and `moonshineMatterAut g` $= g \otimes 1$ on $\mathcal{M}$ (Chapter 45 files). The equation is in the ambient space $\mathcal{M}$ (coercion `( … : moonshineMatterSpace)`). **Not asserted here**: that Ψ_α intertwines Virasoro actions (the module docstring says so explicitly; this is `SectorVirasoroComparison`, Chapter 45).

Proof on paper. $\mathcal{M}^\alpha = V^\natural \otimes \mathcal{F}_2 e^\alpha$ and $p \mapsto pe^\alpha$ is an isomorphism $\mathcal{F}_2 \to \mathcal{F}_2 e^\alpha$; compose with Φ. $g \otimes 1$ commutes with anything acting on the second factor. □

Physical meaning

At fixed spacetime momentum the string Fock space is "internal CFT ⊗ light-cone oscillators"; the Monster acts on the internal factor only.

What the machine verified

Proved; printed in `VOA/Moonshine/MoonshineCNAudit10.lean`; standard axioms.

Definition 44.58 (Momentum reversal). $\Theta = 1 \otimes \theta$ on $\mathcal{M}$, where $\theta(p \otimes e^\alpha) = \sigma(p) \otimes e^{-\alpha}$ is the lift of -1 (Chapter 32, Definition 32.10) and σ the Fock involution changing the sign of every oscillator (Definition 32.7).

File `VOA/Moonshine/MoonshineCNMomentumReversal.lean`.

```
def moonshineMatterReversal : moonshineMatterSpace ≃ₗ[ℂ] moonshineMatterSpace :=
  (thetaLat lorentzianLattice).lTensor Vnat
```

From the mathematics to the Lean statement

`thetaLat` is defined in `VOA/Moonshine/LatticeInvolution.lean` for every integral lattice; its definition does not use positivity. `moonshineMatterReversal_tmul` confirms $v \otimes pe^\alpha \mapsto v \otimes \sigma(p)e^{-\alpha}$ (no cocycle sign in this convention).

Physical meaning

Charge conjugation of the light-cone bosons, $X^\pm \mapsto -X^\pm$: it sends momentum α to $-\alpha$.

What the machine verified

Definition; printed in `VOA/Moonshine/MoonshineCNAudit10.lean`.

Theorem 44.59 (Momentum reversal and the cross-momentum pairing). *Θ is an involution, maps $\mathcal{M}^\alpha$ to $\mathcal{M}^{-\alpha}$ and commutes with every L_n. For polynomials p, q: $B_L(\theta(pe^\alpha), qe^\alpha) = \chi(\alpha)\, B_{\mathcal{F}}(\sigma p, q)$, and for the sector states $B(\Theta\Psi_\alpha(a \otimes p), \Psi_\alpha(b \otimes q)) = \chi(\alpha)\, B_{\mathcal{F}}(\sigma\Phi p, \Phi q)\, B_{\natural}(a, b)$.*

        uForm (rank lorentzianLattice)
          (sigmaN (rank lorentzianLattice) (hypLorentzianPolynomialEquiv p))
          (hypLorentzianPolynomialEquiv q) * natForm a b := by
```

From the mathematics to the Lean statement

`chSign lorentzianLattice α` $= \chi(\alpha) = (-1)^{\Delta(\alpha)}\varepsilon(\alpha,\alpha)$, a sign; it is *not* replaced by 1, since the library's cocycle is not the coordinate cocycle (Definition 44.7). `sigmaN` is σ. The last theorem is a formula for arbitrary polynomials, not only ground states; identifying $B_{\mathcal{F}}(\sigma\Phi p, \Phi q)$ with the isotropic form $B^{\mathrm{iso}}(p, q)$ (up to a constant) is a further theorem, in Chapter 45 (`SectorFormComparison`).

Proof on paper. θ is an involution reversing momentum (Chapter 32); σ commutes with the Fock Virasoro modes (they are quadratic) and sends the frame oscillator of α to that of $-\alpha$ (`lorentzianReversal_frameOscillator`), which is what the momentum terms of L_n require. The pairing formulas are the definition of B_L at momenta $-\alpha, \alpha$. □

Physical meaning

The BPZ pairing pairs a state of momentum α with one of momentum $-\alpha$ (the out-state is the conjugate of the in-state). To obtain a form on a single momentum sector, as the no-ghost theorem needs, one composes with charge conjugation; the result is the sector contravariant form.

What the machine verified

Proved; printed in `VOA/Moonshine/MoonshineCNAudit10.lean`; standard axioms.

Trap / dead end

Dead end: comparing forms on the same momentum. The matter form vanishes on two states of the same nonzero momentum (it pairs α with $-\alpha$). It is proved in Lean that *no* map F from $V^\natural \otimes \mathcal{F}^{\mathrm{iso}}$ into a single sector $\mathcal{M}^\alpha$, $\alpha \neq 0$, can satisfy $B(Fu, Fv) = c \cdot B^{\mathrm{iso}}\text{-pairing}(u, v)$ for a nonzero constant c (`moonshineMatterSector_no_same_momentum_isometry`, Chapter 45 file `VOA/Moonshine/MoonshineCNSectorFormConvention.lean`; witness $\mathbb{1} \otimes 1$, whose sector norm is 1). The correct comparison inserts the reversal Θ, as in Theorem 44.59.

44.13 Two Lie-theoretic lemmas

Two files assigned to this chapter are pure Lie theory, used by the Borcherds–Kac–Moody part of Chapter 45 (freeness of the positive part via Verma modules). They do not involve vertex algebras.

Theorem 44.60 (A Lie algebra embeds in its enveloping algebra)**.** *For every complex Lie algebra $\mathfrak{g}$ (of any dimension), the canonical map $\iota : \mathfrak{g} \to U(\mathfrak{g})$ is injective.*

File `VOA/Moonshine/MoonshineCNEnvelopingEmbedding.lean`.

```
/-- The canonical map of a Lie algebra into its universal enveloping algebra is injective.
 ↪ -/
theorem envelopingEmbedding_injective :
    Function.Injective (UniversalEnvelopingAlgebra.ι ℂ : L → UniversalEnvelopingAlgebra ℂ
     ↪ L) := by
```

From the mathematics to the Lean statement

`L` is a section variable: any type with `[LieRing L] [LieAlgebra ℂ L]`. Mathlib v4.30 does not provide this injectivity for infinite-dimensional Lie algebras (it is a consequence of PBW).

Proof on paper. Choose a basis (y_a) of $\mathfrak{g}$, well-ordered. The repository's PBW representation (`VOA/Foundations/PBWTheorem/LieRep.lean`) makes $\mathfrak{g}$ act on the space of finitely supported functions on multisets of indices, with $y_a \cdot \{\} = \{a\}$. Since ι followed by this representation applied to the bottom vector is injective ($\sum c_a y_a \mapsto \sum c_a \{a\}$), ι is injective. □

Physical meaning

The symmetry generators of a theory are faithfully represented among the products of generators; in physics this is always assumed tacitly.

What the machine verified

Proved, no hypotheses; printed in `VOA/Moonshine/MoonshineCNAudit17.lean`; standard axioms.

Theorem 44.61 (The induced vector map). *Let $\mathfrak{p} \subseteq \mathfrak{g}$ be a subalgebra, $S \subseteq \mathfrak{g}$ a subspace on which $\mathfrak{p}$ acts by σ such that $[x,u] - \sigma(x)u \in \mathfrak{p}$ for $x \in \mathfrak{p}$, $u \in S$. Then $[a \otimes u] \mapsto [a\,u \otimes 1]$ is a well-defined $\mathfrak{g}$-equivariant map from $U(\mathfrak{g}) \otimes_{U(\mathfrak{p})} S$ to $U(\mathfrak{g}) \otimes_{U(\mathfrak{p})} \mathbb{C}$; and if it and the PBW multiplication for σ are injective, then right multiplication $U(\mathfrak{q}) \otimes S \to U(\mathfrak{q})$ is injective for any subalgebra $\mathfrak{q}$ containing S (no complement condition is assumed; in the application $\mathfrak{q}$ is a complement of $\mathfrak{p}$).*

File `VOA/Moonshine/MoonshineCNInducedVectorMap.lean`.

    Function.Injective
      (envelopingGeneratorMultiplication (S.comap q.toSubmodule.subtype : Submodule ℂ q))
       ↪  := by
```

From the mathematics to the Lean statement

`relativeInducedSpace p σ` $= U(\mathfrak{g}) \otimes_{U(\mathfrak{p})} S$ and `relativeVermaMultiplication` the PBW map $U(\mathfrak{q}) \otimes S \to U(\mathfrak{g}) \otimes_{U(\mathfrak{p})} S$ are defined in Chapter 45 files (`RelativeInduction`, `VermaMultiplication`). `hσ` is the compatibility making the map well defined (it is used in the definition's proof obligation). `hΦ`, `hV` are genuine hypotheses of this reduction lemma; they are discharged where it is applied (Chapter 45). Further variables: `(q : LieSubalgebra ℂ g)` `(hSq : S ≤ q.toSubmodule)`.

Proof on paper. Well-definedness: $ax \otimes u - a \otimes \sigma(x)u \mapsto a(xu - \sigma(x)u) \otimes 1 = a([x,u] - \sigma(x)u) \otimes 1 + au\,x \otimes 1$, and both terms vanish in the trivially induced module because elements of $\mathfrak{p}$ placed last kill 1. Equivariance is left multiplication. Through the PBW maps, the induced map becomes right multiplication $a \otimes u \mapsto au$, so injectivity transfers. □

Physical meaning

Pure representation theory: it is used to show that the positive part of the Monster Lie algebra is free (no relations among the generators beyond those forced by Serre-type conditions), the algebraic shadow of the free-field structure of the no-ghost spectrum.

What the machine verified

Proved with the displayed hypotheses; printed in `VOA/Moonshine/MoonshineCNAudit17.lean`; standard axioms.

44.14 Accounting for the 91 files

Every file assigned to this chapter by `Notes/Textbook/assignment.txt` (the rule for `ch17`) is listed here with the place where it is documented ("ind." = headline declarations presented individually; "coll." = described collectively). All file names are `VOA/Moonshine/MoonshineCNName.lean`.

The count is 4 (lattice, frame, target) +2 (grading, momentum) +20 (construction) +2 (realisation, basis) +20 (`Hyperbolic*`) +13 (`Tensor*`) +2 (`LatticeForm`, `FockAdjoint`) +15 (`Near*`) +3 (`ChargeCutoffWitness`, `ChargeNilpotence`, `ChargedAdjoint`) +2 (`CurrentAdjoint`, `DressingAdjoint`) +4 (`Matter*`) +1 (`GeneratorPrimary`) +1 (`MomentumReversal`) +2 (Lie lemmas) = 91. None of them is an audit file; the audits that print their declarations (`MoonshineCNAudit`, `Audit2`, `3`, `5`, `6`, `7`, `9`, `10`, `12`, `13`, `16`, `17`) belong to Chapter 43.

44.15 Recorded traps, dead ends and documentation defects

Trap / dead end

1. No positive-definiteness witness. The positive-definite lattice construction cannot be instantiated at $\mathrm{II}_{1,1}$ (`lorentzian_not_posDef`); the library duplicated it with a complex-frame parameter instead of introducing a false hypothesis. **2. Two cocycles.** `lorentzianCharged Field` (cocycle $(-1)^{x_1 y_0}$) and the fields of `lorentzianNearVOA` (FLM cocycle) are different families; both are local, they are *not* claimed equal, and no gauge equivalence is formalised. Consequently the sign $\chi(\alpha) =$ `chSign` appears in every cross-momentum pairing and must not be replaced by 1. **3. The total-weight FHL cutoff is false** in a near-VOA (Theorem 44.50); the cutoff is the level above the sector ground energy. **4. Same-momentum form comparison is impossible** (warning in §44.12). **5. Two contravariant forms with opposite oscillator signs.** The isotropic form makes oscillators self-adjoint, the lattice form skew-adjoint (§44.8); they are compared only through the reversal Θ and an explicit change of variables. **6. The sign trap** $(m, n) \leftrightarrow (m, -n)$ between Borcherds' coordinates and the repository's (§44.1.4). **7. `NearInvariantForm` is only Virasoro adjointness**, not FHL invariance; FHL invariance of the matter form is a separate theorem (§44.11). **8. A primary-only shortcut is insufficient**: restricting the opposite iterate identity to weight-one primaries does

not close the generator argument, because generation passes through products of arbitrary weights; the general identity was needed and is proved. **9. An overstated obstruction**: it was at first believed that the VOA proof of the contragredient closure needed the cutoff $p+1$ and the module type `OrdVModule`; closer inspection found that $p+1$ is used only as a box bound and a nilpotence certificate, both replaceable by arbitrary nilpotence exponents (§44.11).

Documentation defects. None of the following affects a Lean statement. (D1) The docstrings of `EvenLatticeVertexRealization` ("An inhabitant ... is still required") and `LorentzianVertexTarget` ("The exact remaining existence statement") in `VOA/Moonshine/MoonshineCNVertexTarget.lean` are stale: `lorentzianVertexTarget_inhabited` proves the target. (D2) The module docstring of `VOA/Moonshine/MoonshineCNMatterAdjointReduction.lean` ("That identity is the sole residual hypothesis") and the docstring of `OppositeIterateIdentity` ("The precise remaining opposite-field identity") are stale since `oppositeIterateIdentity_of_locallyNilpotent`. (D3) A route note speaks of a "grading by $\mathrm{II}_{1,1}$ with finite-dimensional pieces"; the momentum pieces of $\mathcal{M}$ are infinite-dimensional (each is $V^\natural \otimes \mathcal{F}_2$), only the joint (momentum, weight) pieces are finite-dimensional (the Lean files state this correctly). (D4) A blueprint note labels the zero modes as $\kappa = (e,r) = y$, $\lambda = (f,r) = x$ with $a \leftrightarrow e = (1,0)$; in the Lean identification (`hypLorentzianSector_zeroCharges`) family a is the current of $(0,1)$ and $\kappa = x$. The products $\kappa\lambda = xy$ agree, so no theorem is affected. (D5) Minor redundancy: `UnboundedConformalVertexAlgebra` duplicates the fields of `NearVOA`, and `nearVirasoroMode` duplicates `NearVOA.L`; both are harmless.

44.16 Machine verification for this chapter

The following is the build record of the release (Chapter 50, Section 50.1.9), cross-checked against the audit files' imports and `#print axioms` lines in the source files of the release.

(The line counts include declarations of other chapters' files imported by the same audit.) By the build record of the release, each audit builds green and every printed axiom list is a subset of `[propext, Classical.choice, Quot.sound]`, with zero `sorryAx`; the project axiom `VOA.pbw` (now a theorem) is not involved. The umbrella `VOA.Moonshine` builds green (9,504 jobs), and

`run_axiom_audits.py` re-runs every audit (Chapter 50). On that record every headline of this chapter is `#print axioms`-clean; it is unconditional except where a hypothesis is displayed in its Lean statement, and every such hypothesis is either a mathematical premise of a general theorem (evenness, a frame, nonzero momentum, a Witt relation for an arbitrary operator family, generation and generator adjointness) or a conditional reduction whose hypothesis is proved elsewhere (`hIter`).

44.17 Referee's checklist

declaration	intended meaning	hypotheses	check

`generatorMultiplication_injective_of_inducedVectorMap`	reduction of freeness to induced map	`hΦ`, `hV`	Thm 44.61

All rows are `#print axioms`-clean (standard axioms only). Rows marked "none" are unconditional; the other hypotheses are premises of general theorems, discharged for $\mathrm{II}_{1,1}$, $\mathcal{M}$ and $V^\natural$ where the theorems are applied, except `hIter`, which is proved in Chapter 45.

44.18 Notes and references

The lattice vertex algebras of even lattices, including indefinite ones, and the use of $V^\natural \otimes V_{\mathrm{II}_{1,1}}$ are due to R. E. Borcherds, *Vertex algebras, Kac–Moody algebras, and the Monster*, Proc. Natl. Acad. Sci. USA 83 (1986) 3068–3071, and *Monstrous moonshine and monstrous Lie superalgebras*, Invent. Math. 109 (1992) 405–444 (§§2–5: the vertex algebra of $\mathrm{II}_{1,1}$, the no-ghost theorem, the Monster Lie

algebra). The construction of lattice vertex operators and the cocycle follows I. Frenkel, J. Lepowsky and A. Meurman, *Vertex Operator Algebras and the Monster*, Academic Press, 1988 (Chapters 7–8); the vertex operators $Y(e^{\alpha}, z)$ go back to I. B. Frenkel and V. G. Kac, *Basic representations of affine Lie algebras and dual resonance models*, Invent. Math. 62 (1980) 23–66, and G. Segal, *Unitary representations of some infinite-dimensional groups*, Comm. Math. Phys. 80 (1981) 301–342. Near-VOAs ("Definition 5.1.3(c)") are from T. Gannon, *Moonshine beyond the Monster*, Cambridge University Press, 2006, §5.1. The invariant bilinear form and the contragredient formula are from I. B. Frenkel, Y.-Z. Huang and J. Lepowsky, *On axiomatic approaches to vertex operator algebras and modules*, Mem. Amer. Math. Soc. 104 (1993), no. 494, and H. Li, *Symmetric invariant bilinear forms on vertex operator algebras*, J. Pure Appl. Algebra 96 (1994) 279–297. Goddard uniqueness, Dong's lemma, reconstruction and the Borcherds identity are presented as in V. Kac, *Vertex Algebras for Beginners*, 2nd ed., University Lecture Series 10, AMS, 1998 (§§3–4), and E. Frenkel and D. Ben-Zvi, *Vertex Algebras and Algebraic Curves*, 2nd ed., AMS, 2004.

The no-ghost theorem is due to R. C. Brower, *Spectrum-generating algebra and no-ghost theorem for the dual model*, Phys. Rev. D 6 (1972) 1655–1662, and P. Goddard and C. B. Thorn, *Compatibility of the dual Pomeron with unitarity and the absence of ghosts in the dual resonance model*, Phys. Lett. B 40 (1972) 235–238; the light-cone splitting of §44.8 is the Goddard–Thorn decomposition in the form used by Borcherds (1992, §5). The BRST interpretation is I. B. Frenkel, H. Garland and G. J. Zuckerman, *Semi-infinite cohomology and string theory*, Proc. Natl. Acad. Sci. USA 83 (1986) 8442–8446. For the physics (critical dimension, light-cone gauge, physical states, BPZ conjugation) see J. Polchinski, *String Theory*, Vol. 1, Cambridge University Press, 1998, Chapters 1–4 and 8; and for the Monster string, J. A. Harvey and G. Moore, *Algebras, BPS states, and strings*, Nucl. Phys. B 463 (1996) 315–368 (arXiv:hep-th/9510182), and S. Carnahan, *Monstrous Lie algebras and generalized moonshine*, arXiv:1208.6254. A survey of the whole proof is T. Gannon, *Monstrous moonshine: the first twenty-five years*, Bull. London Math. Soc. 38 (2006) 1–33 (arXiv:math/0402345).

The Lean development was recorded in the authors' working notes, which are not part of the release. The positive-definite construction it adapts is documented in Chapters 31 and 6; the vertex-algebra theory it ports, in Chapter 4; invariant forms, in Chapters 32 and 5.

Chapter 45

The Monster Lie algebra: string states, the no-ghost theorem and the Borcherds–Kac–Moody structure

This chapter documents the release of the library named in the front matter; every Lean quotation is checked by `scripts/textbook/sync.py` to occur verbatim (up to whitespace and comments) in the source files of that release. It is the third chapter of the part "Monstrous moonshine" and the central chapter of Borcherds' proof of the Conway–Norton conjecture. Chapter 43 stated the conjecture; Chapter 44 built the lattice vertex algebra $V_{\mathrm{II}_{1,1}}$ of the even unimodular Lorentzian lattice of rank two and the tensor product $V^\natural \otimes V_{\mathrm{II}_{1,1}}$, a vertex algebra of central charge $24 + 2 = 26$. Here we do three things.

(I) We prove the *no-ghost theorem* of Goddard and Thorn in an abstract form ("string modules"), and apply it to the explicit momentum sectors $V^\natural \otimes \mathbb{C}[a_j, b_j]$ of $V^\natural \otimes V_{\mathrm{II}_{1,1}}$: for every nonzero momentum $r = (x, y) \in \mathrm{II}_{1,1}$ the space of physical states of weight one modulo the radical of the form is isomorphic, $\mathrm{Aut}(V^\natural)$-equivariantly and isometrically *for the sector form* (the form of the explicit Fock model, not the vertex-algebra form; see the warning after Theorem 45.22), to the weight space $V^\natural{}_{1-xy}$.

(II) We define the *Monster Lie algebra* $\mathfrak{m}$ as the quotient of the weight-one primary states of $V^\natural \otimes V_{\mathrm{II}_{1,1}}$ by the primary states that are Virasoro descendants, with bracket $[\bar{u}, \bar{v}] = \overline{u_{(0)}v}$; we prove that it is graded by $\mathrm{II}_{1,1}$, that its root spaces are $\mathfrak{m}_{(x,y)} \cong V^\natural{}_{1-xy}$ for $(x, y) \neq 0$ and $\mathfrak{m}_0 \cong \mathbb{C}^2$, that $\mathrm{Aut}(V^\natural)$ acts on it, and that it carries a symmetric, invariant, nondegenerate bilinear form.

(III) We develop the Lie theory of an abstract "Borcherds datum" (a rank-two graded Lie algebra with the root support, form and simple roots of the Monster Lie algebra), and prove the structure theorem that Chapter 46 needs: the length-one resolution of the trivial module by generalized Verma modules, the isomorphism $T(U) \cong \mathcal{U}(\mathfrak{u}^+)$, and the freeness of the positive cone $\mathfrak{u}^+$ on the space U of real-root strings of the imaginary simple root spaces. We prove that $\mathfrak{m}$ is such a datum, *given* that it is generated by its simple root spaces; that last input is a theorem of Chapter 47 (it rests on the product formula of Chapter 46).

As everywhere in this book, our concern is the *meaning* of the Lean statements. Proofs are explained mathematically (and, where it helps, physically); we do not describe how the Lean proof scripts are organised.

The results in one paragraph. The no-ghost isomorphism, the Lie algebra $\mathfrak{m}$, its root-space isomorphisms, its invariant nondegenerate form and the whole abstract Lie theory are proved in

Lean with *no hypotheses* beyond the data they are about. The single exception is the statement "$\mathfrak{m}$ is a Borcherds datum" (§45.13) and its consequences for $\mathfrak{m}$, which take generation of $\mathfrak{m}$ by its simple root spaces as an explicit argument; that argument is itself a theorem with no hypotheses, proved in Chapter 47. The Lean names are collected in the referee's checklist (§45.21).

Reading the Lean in this chapter. (Chapter 1 explains the conventions in detail; we recall the ones used here.) `#print axioms X` lists the logical axioms a declaration `X` ultimately depends on; "standard axioms" means exactly Lean's `propext`, `Classical.choice` and `Quot.sound`, with no `sorryAx` (an unfinished proof) and no project axiom. Every status box names the audit module in which the `#print axioms` line for the declaration occurs; the outputs are those reported by the maintainers' targeted builds, they were not re-run for this chapter, and no aggregate build of the whole library is claimed. In the quotations, a statement ending in `:=` or `:= by` has its proof omitted; a line `...` marks omitted lines (the omission is always described in the text). `def` introduces a definition, `abbrev` a definition that Lean unfolds automatically, `theorem` a proposition with proof, `structure` a record type whose fields are listed; `noncomputable` only says the definition uses choice and has no executable code, and `instance` registers a structure (here: a Lie bracket) for automatic use. A proof written `rfl` means the two sides are equal by unfolding definitions. Lean type variables are named freely; in particular, in the induced-module files of §45.15 the Lean variable `U` denotes an arbitrary module (called W in the text), not the generating space U.

What is *not* in this chapter. (a) No BRST complex: the physical states are defined in the "old covariant" way (Virasoro primaries modulo spurious states), and the BRST description is a physical comment only. (b) No positivity: the form on $V^\natural$ is never shown to be positive definite, and nothing here needs it. (c) No generalized Kac–Moody *characterisation* theorem: we do not prove that $\mathfrak{m}$ satisfies Borcherds' axioms for a generalized Kac–Moody algebra, nor any Weyl–Kac–Borcherds character formula; we prove exactly the structural statements listed in (III). (d) The statement "$E = \bigoplus_{m>0} \mathfrak{m}_{(m,n)}$ minus the real simple root is free on $\bigoplus_n \mathfrak{m}_{(1,n)}$" in its literal form is not what is proved; see §45.18 for the exact freeness statement and why it is the right one.

45.1 Orientation: what is being built, and the chain of results

45.1.1 Why a Lie algebra?

Borcherds' proof of the Conway–Norton conjecture runs through a Lie algebra. The McKay–Thompson series $T_g(q) = q^{-1} + \sum_{n\geq 1} \mathrm{tr}(g \mid V^\natural_{n+1})q^n$ of Chapter 43 are to be shown to be Hauptmoduln. Borcherds' strategy: (1) build a Lie algebra $\mathfrak{m}$ graded by the lattice $\mathrm{II}_{1,1}$ whose root spaces are, as $\mathrm{Aut}(V^\natural)$-modules, the homogeneous pieces of $V^\natural$; (2) show that $\mathfrak{m}$ has a "Kac–Moody-like" structure with known simple roots, so that it satisfies a *denominator identity*; (3) take g-traces of the denominator identity (the *twisted* denominator identities), which yield the *replication formulas* for the T_g; (4) show that completely replicable functions with the right leading coefficients are Hauptmoduln. This chapter does (1) and the Lie-theoretic heart of (2); Chapter 46 does the rest of (2) and (3); the genus-zero step (4) is in Chapter 46 as well, and the final assembly in Chapter 47.

45.1.2 The chain of results at a glance

The symbols in the following remark are defined in §§45.3–45.6; informally: a *string module* H is a graded space with a Virasoro action, an abelian family of "longitudinal" operators K_n and an invariant form; $\mathcal{S}$ is the span of all Virasoro descendants $L_{-n}H$ (*spurious* states); $\mathcal{P}^1$ the weight-one states killed by all L_n, $n \geq 1$ (*physical* states); $\mathcal{K}$ the states killed by all K_n, $n \geq 1$ (*longitudinal vacua*); $\mathcal{J}^1 = \mathcal{P}^1 \cap \mathcal{K}$ (*transverse* states); and "rad" is the radical of the form restricted to the space in question.

Remark 45.1 (The chain). Each arrow is a Lean theorem presented below; the hypotheses in parentheses are discharged where indicated.

abstract string module H, $c = 26$, $H = \mathcal{S} \oplus \mathcal{K} \implies \mathcal{P}^1/\mathrm{rad} \cong \mathcal{T}^1 \cong \mathcal{K}^1/\mathrm{rad}$	(§45.6)
$V^\natural \otimes \mathbb{C}[a,b]$ at momentum $(x,y) \neq 0$ is such a module, with $\mathcal{S} \oplus \mathcal{K}$ proved	(§45.7)
$\mathcal{K}^1/\mathrm{rad} \cong {V^\natural}_{1-xy} \implies \mathcal{P}^1_{(x,y)}/\mathrm{rad} \cong {V^\natural}_{1-xy}$	(`stringSectorNo`
$\mathfrak{m} := P^1(V^\natural \otimes V_{\mathrm{II}_{1,1}})/(P^1 \cap \text{spurious})$, $[\bar{u},\bar{v}] = \overline{u_{(0)}v}$	(`monsterLieAlge`
$\mathfrak{m}_{(x,y)} \cong {V^\natural}_{1-xy}$ $((x,y) \neq 0)$, $\mathfrak{m}_0 \cong \mathbb{C}^2$	(`monsterLieRoot`
form on $\mathfrak{m}$: symmetric, invariant, nondegenerate	(§45.11)
abstract Borcherds datum $\implies 0 \to \mathrm{Ind}(U) \to \mathrm{Ind}(\mathbb{C}) \to \mathbb{C} \to 0$, $T(U) \cong \mathcal{U}(\mathfrak{u}^+)$, $\mathfrak{u}^+$ free on U	(§§45.12–45.18)
$\mathfrak{m}$ is a Borcherds datum (given `MonsterLieSimpleRootGeneration`)	(`monsterLieBorc`

45.1.3 Conventions that are fixed once and for all

The lattice. $\mathrm{II}_{1,1}$ is $\mathbb{Z}^2$ with the bilinear form

$$\big((x,y),(x',y')\big) \;=\; xy' + x'y, \qquad (x,y)^2 = 2xy, \tag{45.1}$$

the Gram matrix $\left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right)$. In Lean this is `lorentzianLattice` (Chapter 44); a lattice vector is written `![x, y]` and the type of lattice vectors is `lorentzianLattice.carrier`. We call (x,y) the *repository momentum*. For a momentum $r = (x,y)$ the half-norm is $r^2/2 = xy$, an integer because the lattice is even.

Borcherds coordinates. Borcherds (and the Lie-theoretic part of this chapter) uses the form $((m,n),(m',n'))_{\mathrm{Bor}} = -(mn' + m'n)$, so $(m,n)^2_{\mathrm{Bor}} = -2mn$. The dictionary is

$$\text{Borcherds root } (m,n) \;\longleftrightarrow\; \text{repository momentum } (x,y) = (m,-n), \tag{45.2}$$

which is an isometry: $-(mn' + m'n) = m(-n') + m'(-n)$. In Lean the map is `borcherdsMomentum` (§45.13). Under (45.2) the root-space theorem reads

$$\mathfrak{m}_{(x,y)} \cong {V^\natural}_{1-xy} \quad \text{(repository)} \qquad \Longleftrightarrow \qquad \mathfrak{m}_{(m,n)} \cong {V^\natural}_{1+mn} \quad \text{(Borcherds)}.$$

The real simple root is $\alpha_r = (1,-1)$ (norm 2; repository momentum $(1,1)$) and the imaginary simple roots are $\alpha_j = (1,j)$, $j \geq 1$ (norm $-2j$; repository momentum $(1,-j)$), with root space $\mathfrak{m}_{\alpha_j} \cong {V^\natural}_{1+j}$, of dimension $c(j)$, the j-th coefficient of $J(q) = q^{-1} + \sum_{n\geq 1} c(n)q^n$.

Trap / dead end

The sign trap $(m,n) \leftrightarrow (m,-n)$**.** A product over repository momenta $x, y \geq 1$ (a tempting first transcription of Borcherds' formulas) is *wrong*: for $x, y \geq 1$ the root space is ${V^\natural}_{1-xy}$, which vanishes as soon as $xy \geq 2$ (and is ${V^\natural}_0 = \mathbb{C}$ only for $x = y = 1$, the real root). The positive cone of Borcherds' theory, where all the imaginary roots live, is $\{(m,n) : m, n \geq 1\}$ in *Borcherds* coordinates, i.e. repository momenta (x,y) with $x \geq 1$, $y \leq -1$. Every statement of this chapter is labelled with the coordinates it uses, and the bridge `monsterLieBorcherdsRootEquiv` (§45.13) states the Borcherds form of the root-space theorem once, in Lean.

Modes. The library convention `mode f n = f (-n - 1)` (Chapter 2, Definition 2.7) is in force: `mode (V.Y u) n` is the mathematician's $u_{(n)}$, the coefficient of z^{-n-1} in $Y(u,z)$. For a near vertex operator algebra `V` (the structure `VOA.NearVOA` of Chapter 4: a vertex operator algebra without finite-dimensional weight spaces and without a lower bound on weights), `V.smul u n v` abbreviates `mode (V.Y u) n v`, i.e. $u_{(n)}v$, and `V.L n` is the Virasoro mode $L_n = \omega_{(n+1)}$:

```
noncomputable def smul (V : NearVOA 𝒱) (u : 𝒱) (n : ℤ) (v : 𝒱) : 𝒱 := mode (V.Y u) n v
```

(`VOA/Moonshine/MoonshineCNNearGoddard.lean`; the same file defines `NearVOA.L`.)

The moonshine module and its form. $V^\natural$ is the Lean type `Vnat`, the vertex operator algebra is `VnatVOA` (Chapter 42; `VOA/Moonshine/AutVnat.lean`), its weight-n space is `VnatVOA.grading n`, and $\mathrm{Aut}(V^\natural)$ is `AutVnat := Aut VnatVOA`. The invariant bilinear form on $V^\natural$ is the block form `natForm` (`VOA/Moonshine/SimpleForm.lean`):

```
noncomputable def natForm : LinearMap.BilinForm ℂ Vnat :=
  leechBV.compl₁₂ (LinearMap.fst ℂ SkewVP TP) (LinearMap.fst ℂ SkewVP TP)
    + TPForm.compl₁₂ (LinearMap.snd ℂ SkewVP TP) (LinearMap.snd ℂ SkewVP TP)
```

that is, $B^\natural((u,t),(u',t')) = B_V(u,u') + B_T(t,t')$ on $V^\natural = V_\Lambda^+ \oplus (V_\Lambda^T)^+$. It is symmetric, satisfies $B^\natural(L_n u, v) = B^\natural(u, L_{-n}v)$, is nondegenerate, and its weight spaces are mutually orthogonal (Chapters 37–38). The restriction of $g \in \mathrm{Aut}\, V^\natural$ to $V^\natural{}_n$ is `GriessAut.autRestrict g n` (`VOA/Core/GriessAutomorphism.lean`):

```
noncomputable def autRestrict (α : Aut W) (n : ℤ) : W.grading n ≃ₗ[ℂ] W.grading n :=
  α.toLinearEquiv.ofSubmodules _ _ (aut_map_grading α n)
```

45.1.4 Notation

Many letters are traditionally used for several objects in this subject. The following table fixes the meaning of each symbol in this chapter; where a Lean name uses a letter differently, the text says so.

symbol	meaning
$H, H^N, N \in \mathbb{Z}$	a string module and its weight-N space (§45.3); N always denotes a weight
L_n, K_n	Virasoro operators; longitudinal operators (one Heisenberg field along a null direction)
B	the form of a string module; $B^\natural$ the form `natForm` on $V^\natural$; B_F the monomial form on F
$(\cdot,\cdot)$	the lattice form (45.1) on $\mathrm{II}_{1,1}$ (repository coordinates)
$(\cdot,\cdot)_{\mathrm{Bor}}$	the form $-(mn'+m'n)$ in Borcherds coordinates; $\mathfrak{m}_\gamma^{\mathrm{Bor}}$ the root space in Borcherds coordinates
$\mathcal{S}, \mathcal{S}_K, \mathcal{P}, \mathcal{K}, \mathcal{T}$	spurious, longitudinal spurious, physical, longitudinal-vacuum, transverse subspaces
$F = \mathbb{C}[a_j, b_j]$	the polynomial (Fock) space of the two light-cone bosons; a_j, b_j its variables
$w_0 = (0,1)$, $w_1 = (1,0)$	the isotropic basis of $\mathrm{II}_{1,1}$ whose oscillators are a and b
κ, ℓ	the two charges (light-cone momenta) of a sector; $\kappa = x$, $\ell = y$ at momentum (x,y)
e^r	the lattice state of momentum r in $V_{\mathrm{II}_{1,1}}$
$P^1(V)$, $\mathrm{Sp}(V)$, $\mathrm{Null}^1(V)$	weight-one primaries, spurious states, and their intersection, in a near-VOA V
$\mathfrak{m}, \mathfrak{g}$	the Monster Lie algebra; an abstract Lie algebra with Borcherds datum
α_r, α_j	the real simple root $(1,-1)$ and the imaginary simple roots $(1,j)$ (Borcherds coordinates)
e, f	a normalized pair of real root vectors, $e \in \mathfrak{g}_{\alpha_r}$, $f \in \mathfrak{g}_{-\alpha_r}$, $(e,f) = 1$
$\delta = (1,0)$	the Weyl vector
$\mathfrak{u}^\pm, \mathfrak{p}^-, \mathfrak{l}$	positive cone, opposite parabolic, Levi subalgebra (§45.14)

symbol	meaning
U, $U_{j,k}$	the generating space of real-root strings and its pieces (§45.14)
$U(L)$, $T(S)$	universal enveloping algebra of a Lie algebra L; tensor algebra of a vector space S
$\mathrm{Ind}(W)$	the module induced from a $\mathfrak{p}^-$-module W (generalized Verma module)
ρ	a representation $\mathfrak{g} \to \mathrm{End}\, M$ (never the Weyl vector)
Ω, $Q(\gamma)$	the Casimir operator and its scalar $(\gamma,\gamma)_{\mathrm{Bor}} - 2(\delta,\gamma)_{\mathrm{Bor}}$

45.2 Physical background: the bosonic string and its physical states

This section is entirely physics; nothing in it is used as a mathematical input. It explains why the definitions of the following sections are the natural ones, and where the number 26 comes from.

45.2.1 The bosonic string in 26 dimensions

A closed bosonic string moving in D-dimensional Minkowski space is described, after fixing the conformal gauge on its world-sheet, by D free bosons $X^\mu(z,\bar z)$, $\mu = 0,\dots,D-1$. Each chiral half is a Heisenberg vertex algebra of rank D with the Lorentzian form $\eta_{\mu\nu}$ of signature $(1,D-1)$, and its Sugawara stress tensor has central charge $c = D$. The world-sheet metric was gauge-fixed, and the remnant of its equations of motion is the constraint that the stress tensor annihilates physical states. In the *old covariant quantization* this is imposed as

$$L_n\,\psi = 0\ (n \ge 1), \qquad (L_0 - 1)\,\psi = 0, \tag{45.3}$$

the "-1" being the normal-ordering constant of the bc ghosts. The Fock space carries an indefinite inner product (the timelike oscillators α^0_{-n} create negative-norm states, the "ghosts"). The states (45.3) are the *physical states*; among them are the *null* physical states, which are also of the form $L_{-n}\chi$ ("spurious") and have zero inner product with every physical state. The *no-ghost theorem* of Goddard and Thorn (1972) asserts that when $D = 26$ the inner product is positive semi-definite on physical states and that its radical is exactly the null physical states; moreover the quotient is isomorphic to the space of *transverse* states, built from the $D-2 = 24$ transverse oscillators only (the light-cone gauge spectrum). For $D > 26$ there are negative-norm physical states; for $D < 26$ the quotient is bigger than the light-cone count.

The BRST formulation (Kato–Ogawa 1983, Frenkel–Garland–Zuckerman 1986) packages the same statement as the vanishing of relative semi-infinite cohomology outside degree one: the BRST charge $Q = \sum c_{-n}L_n + \dots$ satisfies $Q^2 = 0$ exactly when the matter central charge is 26, and $H^1_{\mathrm{rel}} \cong \mathcal{P}^1/\mathrm{null}$. The library does *not* formalize the BRST complex for this chapter; it formalizes the old covariant version, with Borcherds' simplifications.

45.2.2 Compactification on $V^\natural \otimes V_{\mathrm{II}_{1,1}}$

The no-ghost argument does not need D flat directions. It needs: (i) a two-dimensional Lorentzian lattice factor $V_{\mathrm{II}_{1,1}}$ (the "light-cone directions" $X^\pm$, whose momenta $r \in \mathrm{II}_{1,1}$ are the string's momenta in those two directions), and (ii) an arbitrary "internal" chiral CFT V of central charge 24 with a nondegenerate invariant form. The total central charge is $24 + 2 = 26$. Taking $V = V^\natural$ means: a bosonic string whose internal 24 dimensions are replaced by the Monster CFT and whose two remaining directions are compactified on the even unimodular lattice $\mathrm{II}_{1,1}$. Its physical states of momentum $r = (x,y)$ satisfy $(L_0 - 1)\psi = 0$, where L_0 is the internal weight plus oscillator level plus $r^2/2 = xy$. The no-ghost theorem identifies them, modulo null states, with the internal states of weight $1 - xy$ *with no light-cone oscillators*: ${V^\natural}_{1-xy}$.

45.2.3 The Lie algebra of physical states

Physical states of weight one are *conserved currents*: a weight-one primary u has a zero mode $u_{(0)}$ that commutes with all L_n and therefore maps physical states to physical states. In string language, $u_{(0)}$ is the charge of the vertex operator $\oint V_u(z)\,dz$, and $[\bar{u},\bar{v}] = \overline{u_{(0)}v}$ is the commutator of two such charges (the "algebra of string vertex operators" of Frenkel, and of Goddard–Olive; in the BRST language the bracket on H^1). Null states decouple, so the bracket descends to physical states modulo null states. The resulting Lie algebra, for $V = V^\natural$, is the *Monster Lie algebra*: the spacetime gauge symmetry algebra of the compactified string, with the Monster acting through its action on the internal CFT. Its Cartan subalgebra $\mathfrak{m}_0 \cong \mathrm{II}_{1,1} \otimes \mathbb{C}$ is spanned by the two momentum currents $\partial X^\pm$; the root space at momentum r consists of the physical states of momentum r. In Borcherds' words, $\mathfrak{m}$ is "the space of physical states of a bosonic string moving on the 26-dimensional orbifold $V^\natural \times (\mathbb{R}^{1,1}/\mathrm{II}_{1,1})$".

45.2.4 Simple roots as BPS-like states

The real simple root α_r (repository momentum $(1,1)$, $r^2 = 2$, root space ${V^\natural}_0 = \mathbb{C}\mathbb{1}$) is the *tachyon* of momentum $(1,1)$: the state $\mathbb{1} \otimes e^{(1,1)}$, with no oscillators. It generates, with its opposite, an $\mathfrak{sl}_2$ (a "W-boson" pair). The imaginary simple roots α_j (repository momenta $(1,-j)$, $r^2 = -2j < 0$) are the states $v \otimes e^{(1,-j)}$ with $v \in {V^\natural}_{1+j}$: massive internal states balanced by a timelike momentum. That the positive part of $\mathfrak{m}$ is generated freely by the $\mathfrak{sl}_2$-strings of these states (§45.18) is, physically, the statement that string scattering in this background produces no relations among the simple-root states beyond those forced by the $\mathfrak{sl}_2$ symmetry. This is a heuristic description, not an input.

45.3 Abstract string modules

The no-ghost theorem is, at its core, linear algebra in a graded vector space carrying two commuting structures: a Virasoro action, and an abelian family of "longitudinal" operators that the Virasoro algebra normalises. Following Borcherds' formulation of Goddard–Thorn (Borcherds 1992, §5), the library abstracts exactly these data into a structure `StringModule`. Nothing in this section uses a vertex algebra; the file depends on Mathlib only.

Why the operators K_n. In the string Fock space at momentum r there are two light-cone bosons. Pick a *null* lattice direction w (so $(w,w) = 0$) with $(w,r) \neq 0$, and let $K_n := w(n)$ be the modes of the Heisenberg field along w. Because w is null, the K_n commute with each other; because $w(z)$ is a weight-one primary current, $[L_m, K_n] = -nK_{m+n}$. The point of these operators is the *light-cone splitting*: when $(w,r) \neq 0$, every state is uniquely a Virasoro descendant plus a state killed by all K_n, $n \geq 1$ (hypothesis (F1) below, proved for the concrete sector in Theorem 45.19, where K_n is the explicit oscillator $a(n)$). The states killed by the K_n are built only from the other light-cone boson and the internal CFT, and modulo null states they are the light-cone (transverse) states. So the K_n are the bookkeeping device that turns "covariant" into "light-cone" states.

45.3.1 The definition

Definition 45.2 (String module of central charge c)**.** A *string module* is a complex vector space H with

(S1) a grading $H = \bigoplus_{N\in\mathbb{Z}} H^N$ (internal direct sum) with every H^N finite-dimensional and $H^N = 0$ for $N < N_0$;

(S2) operators L_n ($n \in \mathbb{Z}$) with $L_n H^N \subseteq H^{N-n}$, $L_0 = N$ on H^N, and $[L_m, L_n] = (m-n)L_{m+n} + \frac{c}{12}(m^3 - m)\delta_{m+n,0}$;

(S3) operators K_n ($n \in \mathbb{Z}$; K_0 is never used) with $K_n H^N \subseteq H^{N-n}$ for $n \neq 0$, $[K_m, K_n] = 0$, and $[L_m, K_n] = -nK_{m+n}$ whenever $n \neq 0$ and $m + n \neq 0$;

(S4) a symmetric bilinear form B with $B(H^N, H^M) = 0$ for $N \neq M$, nondegenerate on each H^N, and $B(L_n x, y) = B(x, L_{-n} y)$, $B(K_n x, y) = B(x, K_{-n} y)$ for all n, x, y.

(`VOA/Moonshine/MoonshineCNStringModule.lean`, `VOA.Moonshine.ConwayNorton.StringModule`.)

From the mathematics to the Lean statement

Decoding. `wt N` is the subspace H^N; `DirectSum.IsInternal wt` says the canonical map $\bigoplus_N H^N \to H$ is bijective (every vector is a unique finite sum of homogeneous components). `Module.End ℂ H` is the algebra of $\mathbb{C}$-linear endomorphisms, with `*` the composition; `L m * L n - L n * L m` is $[L_m, L_n]$. The central term is written `(((m : ℂ) ^ 3 - m) / 12 * c) • 1` when `m + n = 0`, i.e. $\frac{c}{12}(m^3 - m)\,\mathrm{id}$, the standard normalisation (central charge c means $[L_2, L_{-2}] = 4L_0 + c/2$). `LinearMap.BilinForm ℂ H` is a bilinear form $H \times H \to \mathbb{C}$; `B.IsSymm` is symmetry.

Hypotheses, field by field. (S1) is `wt_isInternal`, `wt_finite`, `wt_bdd`; (S2) is `L_wt`, `L_zero`, `L_comm`; (S3) is `K_wt`, `K_comm`, `LK_comm`; (S4) is `B_symm`, `B_orth`, `B_nondeg`, `L_adj`, `K_adj`. Two places deserve comment. (i) `K_wt` is required only for $n \neq 0$ and `LK_comm` only for $n \neq 0$, $m+n \neq 0$: the value of K_0 is immaterial (in the concrete sector it is the scalar momentum, and $[L_m, K_{-m}] = mK_0$ would hold too, but nothing needs it). The module docstring says so ("The value of `K 0` is immaterial: mixed commutators exclude it"). (ii) `B_nondeg` is nondegeneracy *on each weight space*, which, together with `B_orth` and finite dimension, is what the finite-dimensional linear algebra below needs.

Two things are deliberately not fields. The optional group action is a separate structure (`StringGroupAction`, below), and the light-cone hypothesis (F1) is a separate `Prop`, so that every theorem displays exactly where it is used.

Could it be vacuous? No: the structure is instantiated in §45.7 by the concrete sectors `vnatStringModule x y a`, whose fields are all proved. The axioms are consistent and are satisfied by a nonzero example.

Physical meaning

H is the Fock space of the string at fixed momentum r: the matter CFT tensored with the oscillators of the two light-cone bosons. L_n are the total Virasoro generators (matter plus light-cone), K_n are the modes $w \cdot \alpha_n$ of one light-cone boson along an isotropic direction w with $(w, r) \neq 0$ (Borcherds' choice; in light-cone gauge α_n^+). $[L_m, K_n] = -nK_{m+n}$ says that K is a weight-one primary current, and B is the (indefinite!) string inner product, for which $L_n^\dagger = L_{-n}$.

45.3.2 The derived subspaces

Definition 45.3 (Spurious, physical, longitudinal and transverse states)**.** In a string module put

$$\mathcal{S} := \sum_{n\geq 1} L_{-n}H \quad \text{(spurious states)}, \qquad \mathcal{S}_K := \sum_{n\geq 1} K_{-n}H \quad \text{(longitudinal spurious states)},$$
$$\mathcal{P} := \bigcap_{n\geq 1} \ker L_n \quad \text{(physical states)}, \qquad \mathcal{K} := \bigcap_{n\geq 1} \ker K_n \quad \text{(longitudinal vacua)},$$

$\mathcal{T} := \mathcal{P} \cap \mathcal{K}$ (transverse states), and say that H satisfies the *light-cone splitting* (F1) if $H = \mathcal{S} \oplus \mathcal{K}$. For a subspace $U \subseteq H$, $U^N := U \cap H^N$ viewed inside H^N, and B^N is the restriction of B to H^N.

```
def spurious : Submodule ℂ H := ⨆ n : ℕ, LinearMap.range (M.L (-(n + 1 : ℤ)))
def kSpurious : Submodule ℂ H := ⨆ n : ℕ, LinearMap.range (M.K (-(n + 1 : ℤ)))
def physical : Submodule ℂ H := ⨅ n : ℕ, LinearMap.ker (M.L (n + 1 : ℤ))
def kVacuum : Submodule ℂ H := ⨅ n : ℕ, LinearMap.ker (M.K (n + 1 : ℤ))
def transverse : Submodule ℂ H := M.physical ⊓ M.kVacuum
def LightConeSplit : Prop := IsCompl M.spurious M.kVacuum
def weightSlice (U : Submodule ℂ H) (N : ℤ) : Submodule ℂ (M.wt N) :=
  U.comap (M.wt N).subtype
def stringWeightForm (N : ℤ) : LinearMap.BilinForm ℂ (M.wt N) :=
  M.B.restrict (M.wt N)
```

(`VOA/Moonshine/MoonshineCNStringModule.lean`, namespace `VOA.Moonshine.ConwayNorton.StringModule`, with `M : StringModule H` a section variable.)

From the mathematics to the Lean statement

Decoding. `⨆ n : ℕ, ...` is the supremum (sum) of subspaces over $n \in \mathbb{N}$, and `-(n + 1 : ℤ)` runs over $-1, -2, \ldots$; so `spurious` is $\sum_{n\geq 1} \operatorname{im} L_{-n}$. `⊓` is the intersection; `ker (M.L (n + 1))` over $n \in \mathbb{N}$ is $\bigcap_{n\geq 1} \ker L_n$. `⊓` is intersection. `IsCompl A B` means $A \cap B = 0$ and $A + B = H$. `U.comap (M.wt N).subtype` is the preimage of U under the inclusion $H^N \hookrightarrow H$, i.e. $U \cap H^N$ as a subspace *of* H^N (so that finite-dimensional linear algebra applies). `B.restrict` restricts the form.

Note. These are the subspaces of Definition 45.3. Note that `physical` is *not* restricted to weight one; the weight-one physical space is `M.weightSlice M.physical 1`. (The L_0-condition $(L_0 - 1)\psi = 0$ of (45.3) is imposed by taking the weight-one slice.)

Physical meaning

$\mathcal{P}^1$ is the space of Virasoro-primary states of weight one, the physical states of old covariant quantization. $\mathcal{S}$ are the spurious states $L_{-n}\chi$; $\mathcal{P}^1 \cap \mathcal{S}$ are the null physical states. $\mathcal{K}$ consists of the states with no excitation of the longitudinal oscillator α^+ conjugate to K; $\mathcal{T} = \mathcal{P} \cap \mathcal{K}$ are the DDF-like "transverse" states. (F1) is the precise form of "every state is uniquely a longitudinal-vacuum state dressed by Virasoro descendants".

Definition 45.4 (Symmetries). A *symmetry* of a string module by a group G is a homomorphism $G \to \mathrm{GL}(H)$ whose elements preserve each H^N, commute with every L_n and every K_n, and preserve B.

```
structure StringGroupAction {H : Type u} [AddCommGroup H] [Module ℂ H]

  isometry : ∀ g x y, M.B (action g x) (action g y) = M.B x y
```

(`VOA/Moonshine/MoonshineCNStringModule.lean`, `VOA.Moonshine.ConwayNorton.StringGroupAction`.)

From the mathematics to the Lean statement

`G →* (H ≃ₗ[ℂ] H)` is a group homomorphism into the group of linear automorphisms of H. The four laws say that g preserves weights, commutes with all L_n and K_n, and is an isometry. This is the optional structure used to state equivariance; for $V^\natural$ the group is `AutVnat` acting on the matter factor (§45.7).

Physical meaning

An internal global symmetry of the matter CFT that does not touch the light-cone directions: it commutes with the total stress tensor and with the light-cone currents, and is unitary for the string inner product. For $V^\natural$ this is the Monster.

What the machine verified

Definitions; no axioms involved. Instantiated, with all fields proved, by `vnatStringModule` and `vnatStringGroupAction` (§45.7).

45.4 Linear algebra in a string module, before any splitting

This section collects what holds in *every* string module, at *every* central charge, with no light-cone hypothesis. It is the analogue of the elementary part of the Kac–Shapovalov theory of Verma modules.

45.4.1 Graded orthogonals

Theorem 45.5 (Orthogonals inside a weight space). *For every $N \in \mathbb{Z}$, inside the finite-dimensional space H^N with the nondegenerate form B^N:*

$$(\mathcal{S}^N)^\perp = \mathcal{P}^N, \quad (\mathcal{P}^N)^\perp = \mathcal{S}^N, \quad (\mathcal{S}_K^N)^\perp = \mathcal{K}^N, \quad (\mathcal{K}^N)^\perp = \mathcal{S}_K^N,$$

and consequently $\dim \mathcal{S}^N + \dim \mathcal{P}^N = \dim H^N = \dim \mathcal{S}_K^N + \dim \mathcal{K}^N$.

```
theorem orthogonal_spurious_eq (N : ℤ) :
    (M.stringWeightForm N).orthogonal (M.weightSlice M.spurious N) =
      M.weightSlice M.physical N := by
theorem orthogonal_kSpurious_eq (N : ℤ) :
    (M.stringWeightForm N).orthogonal (M.weightSlice M.kSpurious N) =
      M.weightSlice M.kVacuum N := by
theorem orthogonal_physical_eq (N : ℤ) :
    (M.stringWeightForm N).orthogonal (M.weightSlice M.physical N) =
```

```
      M.weightSlice M.spurious N := by
theorem orthogonal_kVacuum_eq (N : ℤ) :
    (M.stringWeightForm N).orthogonal (M.weightSlice M.kVacuum N) =
      M.weightSlice M.kSpurious N := by
theorem physical_spurious_finrank (N : ℤ) :
    Module.finrank ℂ (M.weightSlice M.spurious N) +
      Module.finrank ℂ (M.weightSlice M.physical N) = Module.finrank ℂ (M.wt N) := by
```

(`VOA/Moonshine/MoonshineCNStringOrthogonals.lean`; also `kVacuum_kSpurious_finrank`.)

From the mathematics to the Lean statement

`(M.stringWeightForm N).orthogonal W` is Mathlib's orthogonal $\{x \in H^N : B(y,x) = 0\ \forall y \in W\}$ of a subspace $W \subseteq H^N$ (for a symmetric form the side does not matter). `Module.finrank ℂ` is the dimension. No hypothesis beyond the string module M.

Physical meaning

The physical states of weight N are exactly the states orthogonal to all spurious states of the same weight: being annihilated by L_n is, by $L_n^\dagger = L_{-n}$, the same as being orthogonal to the image of L_{-n}. This is why null states decouple from physical amplitudes.

Proof on paper. The general statement (`positiveKernel_weight_orthogonal`) is: if operators A_n ($n \geq 1$) lower the weight by n, operators D_n raise it by n, and $B(A_n x, y) = B(x, D_n y)$, then at weight N the common kernel of the A_n is the orthogonal of $\sum_n D_n H$. Indeed, for $x \in H^N$, $A_n x \in H^{N-n}$ is zero iff it is orthogonal to all of H^{N-n} (nondegeneracy there), iff $B(x, D_n y) = 0$ for all $y \in H^{N-n}$; and D_n applied to the other weight spaces lands outside H^N, where x is orthogonal anyway by `B_orth`. The two remaining equalities are the double-orthogonal theorem for a nondegenerate form on a finite-dimensional space, and the dimension formula is $\dim W + \dim W^\perp = \dim H^N$. □

What the machine verified

No hypotheses. `#print axioms`: standard axioms (printed in `VOA/Moonshine/MoonshineCNAudit4.lean`).

45.4.2 The two radicals

The *radical* of the form restricted to a subspace U at weight N is $U^N \cap (U^N)^\perp$, in Lean `formRadicalIn`:

```
def formRadicalIn (U : Submodule ℂ H) (N : ℤ) : Submodule ℂ (M.wt N) :=
  M.weightSlice U N ⊓ (M.stringWeightForm N).orthogonal (M.weightSlice U N)
```

(`VOA/Moonshine/MoonshineCNStringPhysical.lean`.)

Theorem 45.6 (Radicals of the physical and longitudinal spaces). *In every string module, at every central charge: the radical of B on $\mathcal{P}^1$ is $\mathcal{P}^1 \cap \mathcal{S}$, and for every N the radical of B on $\mathcal{K}^N$ is $\mathcal{K}^N \cap \mathcal{S}_K$.*

```
theorem physicalOne_radical_eq :
    M.formRadicalIn M.physical 1 = M.weightSlice (M.physical ⊓ M.spurious) 1 := by
theorem kVacuum_radical_eq (N : ℤ) :
    M.formRadicalIn M.kVacuum N = M.weightSlice (M.kVacuum ⊓ M.kSpurious) N := by
```

(`VOA/Moonshine/MoonshineCNStringPhysical.lean`.)

From the mathematics to the Lean statement

Both are equalities of subspaces of H^1, resp. H^N. The first is *weight one only* and needs neither $c = 26$ nor (F1), as the docstring says: "without a critical-charge or light-cone assumption". (In Borcherds' sketch the identification of the radical with the null states comes only after the splitting; here it is proved first, at every central charge.)

Physical meaning

"Null physical states are exactly the physical states of zero norm against all physical states."

Proof on paper. By Theorem 45.5, $(\mathcal{P}^1)^\perp = \mathcal{S}^1$, so the radical $\mathcal{P}^1 \cap (\mathcal{P}^1)^\perp$ is $\mathcal{P}^1 \cap \mathcal{S}^1$. Similarly $(\mathcal{K}^N)^\perp = \mathcal{S}^N_K$. (The only subtlety: $\mathcal{S} \cap H^N = \mathcal{S}^N$ uses that the spurious space is graded, §45.4.4 below.) □

What the machine verified

No hypotheses; standard axioms (`VOA/Moonshine/MoonshineCNAudit4.lean`).

45.4.3 Two generators suffice

Theorem 45.7 (Virasoro generation). *(a)* $\mathcal{S} = L_{-1}H + L_{-2}H$. *(b) If* $L_1 x = L_2 x = 0$ *then* $x \in \mathcal{P}$. *(c)* $L_n\mathcal{K} \subseteq \mathcal{K}$ *for* $n \geq 1$ *and* $K_n\mathcal{K} \subseteq \mathcal{K}$ *for all* n.

```
theorem spurious_eq_sup_two :
    M.spurious = LinearMap.range (M.L (-1)) ⊔ LinearMap.range (M.L (-2)) := by
theorem physical_of_L_one_two (x : H) (h₁ : M.L 1 x = 0)
    (h₂ : M.L 2 x = 0) : x ∈ M.physical :=
theorem kVacuum_L_stable (n : ℕ) (x : H) (hx : x ∈ M.kVacuum) :
    M.L (n + 1 : ℤ) x ∈ M.kVacuum := by
theorem kVacuum_K_stable (n : ℤ) (x : H) (hx : x ∈ M.kVacuum) :
    M.K n x ∈ M.kVacuum := by
```

(`VOA/Moonshine/MoonshineCNStringGenerators.lean`.)

From the mathematics to the Lean statement

$\sqcup$ is the sum of subspaces. No hypotheses beyond M; valid at every central charge.

Physical meaning

The Virasoro algebra's negative part is generated by L_{-1} and L_{-2}, its positive part by L_1 and L_2: to check that a state is primary it suffices to check the two lowest modes.

Proof on paper. (a) $[L_{-1}, L_{-(n-1)}] = (n-2)L_{-n}$ for $n \geq 3$, so $L_{-n}H \subseteq L_{-1}H + L_{-(n-1)}H$; induct. (b) $[L_{n-1}, L_1] = (n-2)L_n$; induct. (c) For $k \in \mathcal{K}$ and $m, n \geq 1$: $K_m L_n k = L_n K_m k - [L_n, K_m]k = 0 + mK_{m+n}k = 0$; and the K's commute. □

What the machine verified

No hypotheses; standard axioms.

45.4.4 Homogeneity

All four derived spaces are *graded*: if a vector lies in $\mathcal{S}$ (resp. $\mathcal{S}_K$, $\mathcal{P}$, $\mathcal{K}$), so does each of its homogeneous components (`spurious_weightComponent`, `kSpurious_weightComponent`, `physical_weightComponent`, `kVacuum_weightComponent`, in `VOA/Moonshine/MoonshineCNStringGrading.lean`, via the projection `weightComponent N` onto H^N built from `wt_isInternal`). Consequently the global splitting (F1) restricts to every weight space:

```
theorem lightConeSplit_weight (hF : M.LightConeSplit) (N : ℤ) :
    IsCompl (M.weightSlice M.spurious N) (M.weightSlice M.kVacuum N) := by
```

(`VOA/Moonshine/MoonshineCNStringGrading.lean`.) This is the precise sense in which an *ungraded* hypothesis $H = \mathcal{S} \oplus \mathcal{K}$ is enough: it does not have to be stated weight by weight. The file also records that a spurious vector of weight N is $L_{-1}a + L_{-2}b$ with $a \in H^{N-1}$, $b \in H^{N-2}$ (`spurious_weight_two`).

Physical meaning

The light-cone decomposition respects the energy: one can decompose level by level.

45.4.5 Straightening of Virasoro words

The light-cone splitting for the concrete sector (proved in Chapter 44, used in §45.7) needs the classical fact that every word in the negative Virasoro modes can be rewritten as a combination of *sorted* words $L_{-m_1} \cdots L_{-m_t}$ with $m_1 \geq \ldots \geq m_t$, at the same total energy, using only the commutators among negative modes. The library proves it for an arbitrary family of operators:

Theorem 45.8 (Straightening). *Let D_i ($i \in \mathbb{N}$; D_i stands for $L_{-(i+1)}$) be operators on H with $[D_i, D_j] = (j-i)D_{i+j+1}$. For every $x \in H$ and every word $w = (i_1, \ldots, i_s)$, the vector $D_{i_1} \cdots D_{i_s} x$ lies in the span of the sorted words applied to x of the same energy $\sum(i_k + 1)$; if w is nonempty, only nonempty sorted words occur.*

```
theorem stringNegativeWord_mem_sortedSpan (D : ℕ → Module.End ℂ H)
    (hcomm : ∀ i j, D i * D j - D j * D i = ((j : ℂ) - i) • D (i + j + 1))
    (x : H) (w : List ℕ) :
    stringNegativeWord D x w ∈ stringSortedSpan D x (stringWordEnergy w) := by
theorem stringNegativeWord_mem_nonempty_sortedSpan (D : ℕ → Module.End ℂ H)
    (hcomm : ∀ i j, D i * D j - D j * D i = ((j : ℂ) - i) • D (i + j + 1))
    (x : H) (w : List ℕ) (hw : w ≠ []) :
    stringNegativeWord D x w ∈ Submodule.span ℂ {y | ∃ v : List ℕ,
      v ≠ [] ∧ stringSortedWord v ∧ stringWordEnergy v = stringWordEnergy w ∧
        stringNegativeWord D x v = y} := by
```

(`VOA/Moonshine/MoonshineCNStringStraightening.lean`, where `stringNegativeWord D x [i₁, …, iₛ] = D i₁ (… (D iₛ x))`, `stringWordEnergy w` is $\sum(i_k + 1)$, `stringSortedWord w` is "weakly decreasing", and `stringSortedSpan D x N` is the span of sorted words of energy N applied to x.)

From the mathematics to the Lean statement

The index shift is $D_i = L_{-(i+1)}$. With $a = i+1$, $b = j+1$ the Virasoro relation gives $[L_{-a}, L_{-b}] = (-a+b)L_{-a-b} = (j-i)L_{-(i+j+2)} = (j-i)D_{i+j+1}$ (no central term, since $-a-b \neq 0$), which is exactly `hcomm`. The hypothesis is only the negative-negative commutator, so the theorem applies to any Virasoro representation and any starting vector (no highest-weight condition). It is a structural port of the repository's Verma-module lemma `negWord_mem_sortedSpan`.

Physical meaning

Every Virasoro descendant can be written in the standard PBW basis $L_{-m_1}\cdots L_{-m_t}|\chi\rangle$, $m_1 \geq \ldots \geq m_t$: the familiar basis of a Verma module, here without assuming one has a Verma module.

Proof on paper. Induction on the energy, inserting one letter at a time into a sorted word: if D_i is to be placed in front of a sorted word whose first letter is $j > i$, use $D_iD_j = D_jD_i + (j-i)D_{i+j+1}$; the first term is handled by induction on the word length, the second has the same energy and a shorter word. □

What the machine verified

No hypotheses beyond `hcomm`; standard axioms (`VOA/Moonshine/MoonshineCNAudit5.lean` prints `stringNegativeWord_mem_sortedSpan`).

45.5 The critical dimension: the $c = 26$ lemma

This is the only place in the whole construction where the value of the central charge matters.

Definition 45.9 (Modified modes). $\tilde{L}_{-2} := L_{-2} + \frac{3}{2}L_{-1}^2$ and $\tilde{L}_2 := L_2 + \frac{3}{2}L_1^2$. They are adjoint: $B(\tilde{L}_2 x, y) = B(x, \tilde{L}_{-2} y)$.

```
noncomputable def tildeNegativeTwo : Module.End ℂ H := M.L (-2) + (3 / 2 : ℂ) • (M.L (-1) *
 ↪  M.L (-1))
noncomputable def tildePositiveTwo : Module.End ℂ H := M.L 2 + (3 / 2 : ℂ) • (M.L 1 * M.L
 ↪  1)
theorem tildeTwo_adjoint (x y : H) :
    M.B (M.tildePositiveTwo x) y = M.B x (M.tildeNegativeTwo y) := by
```

(`VOA/Moonshine/MoonshineCNStringCritical.lean`.)

From the mathematics to the Lean statement

`M.L (-1) * M.L (-1)` is L_{-1}^2 (composition). Literal transcription.

Physical meaning

$\tilde{L}_{-2}\chi$, for χ of weight -1 annihilated by L_1 and L_2, is the famous null vector of the Verma module $M(c, h=-1)$ at level 2 when $c = 26$; the combination $L_{-2} + \frac{3}{2}L_{-1}^2$ is the level-two singular vector for $h = -1$ in Kac's table (the list of pairs (c,h) for which the Virasoro Verma module $M(c,h)$ has a singular vector).

Theorem 45.10 (The four identities and the defect $c/2 - 13$). *For $x \in H^0$ and $y \in H^{-1}$, at every central charge c:*

$$\text{(i) } L_1L_{-1}x = L_{-1}L_1x, \qquad \text{(ii) } \tilde{L}_2L_{-1}x = L_{-1}\tilde{L}_2x,$$
$$\text{(iii) } L_1\tilde{L}_{-2}y = \tilde{L}_{-2}L_1y, \qquad \text{(iv) } \tilde{L}_2\tilde{L}_{-2}y = \tilde{L}_{-2}\tilde{L}_2y + \left(\tfrac{c}{2} - 13\right)y.$$

Consequently, if $c = 26$, then for every spurious s of weight one, $L_1 s \in \mathcal{S}$ (at every c) and $\tilde{L}_2 s \in \mathcal{S}$.

```
theorem L_one_negative_one_weight_zero (x : H) (hx : x ∈ M.wt 0) :
    M.L 1 (M.L (-1) x) = M.L (-1) (M.L 1 x) := by
```

```
theorem tildePositiveTwo_negative_one_weight_zero (x : H) (hx : x ∈ M.wt 0) :
    M.tildePositiveTwo (M.L (-1) x) = M.L (-1) (M.tildePositiveTwo x) := by
theorem L_one_tildeNegativeTwo_weight_neg_one (x : H) (hx : x ∈ M.wt (-1)) :
    M.L 1 (M.tildeNegativeTwo x) = M.tildeNegativeTwo (M.L 1 x) := by
theorem tildeTwo_commutator_weight_neg_one (x : H) (hx : x ∈ M.wt (-1)) :
    M.tildePositiveTwo (M.tildeNegativeTwo x) =
      M.tildeNegativeTwo (M.tildePositiveTwo x) + (M.c / 2 - 13) • x := by
theorem tildeTwo_critical_commute (hc : M.c = 26) (x : H) (hx : x ∈ M.wt (-1)) :
    M.tildePositiveTwo (M.tildeNegativeTwo x) =
      M.tildeNegativeTwo (M.tildePositiveTwo x) := by
theorem criticalSpurious_L_one (x : H) (hx : x ∈ M.spurious) (hw : x ∈ M.wt 1) :
    M.L 1 x ∈ M.spurious := by
theorem criticalSpurious_L_two_tilde (hc : M.c = 26) (x : H)
    (hx : x ∈ M.spurious) (hw : x ∈ M.wt 1) : M.tildePositiveTwo x ∈ M.spurious := by
```

(`VOA/Moonshine/MoonshineCNStringCritical.lean` for the identities, `VOA/Moonshine/MoonshineCNStringPhysical.lean` for the two `criticalSpurious` statements.)

From the mathematics to the Lean statement

Hypotheses. Identities (i)–(iv) carry only a weight hypothesis (`x ∈ M.wt 0` or `M.wt (-1)`); no highest-weight condition is imposed on y (the file's docstring: "No highest-weight condition is imposed on the weight-minus-one vector"). Only `hc : M.c = 26` enters `tildeTwo_critical_commute` and `criticalSpurious_L_two_tilde`.

The defect is explicit in `tildeTwo_commutator_weight_neg_one`. The explicit defect is what makes the role of 26 checkable: the identity holds as an exact polynomial identity in c.

How it could have been wrong. A sign or factor error in $\frac{3}{2}$ would shift the critical value away from 26. The statement in Lean is an exact identity with the defect $\frac{c}{2} - 13$, so no such error is possible. (As *evidence only*: an exact-arithmetic computation in small Verma-module models, done before the formalization, found the conclusion (A5) below true at $c = 26$ and false at $c = 25$ and $c = 27$.)

Physical meaning

This is the critical dimension of the bosonic string. The norm of the spurious state $\tilde{L}_{-2}\chi$ built on a weight-(-1) state χ is proportional to $c/2 - 13$: at $c = 26$ it is simultaneously spurious *and* physical, i.e. null, so it decouples. (The further facts that for $c < 26$ these states have nonzero norm and for $c > 26$ some physical states have negative norm are the classical results of Goddard–Thorn and Brower; they are quoted here as physics and are not proved in this chapter.)

Proof on paper. Only the Virasoro relations are used, together with $L_0 = 0$ on H^0, -1 on H^{-1}, -2 on H^{-2}. (i): $L_1L_{-1}x = L_{-1}L_1x + 2L_0x$ and $L_0x = 0$. (ii): $L_2L_{-1}x = L_{-1}L_2x + 3L_1x$ and $L_1^2L_{-1}x = L_{-1}L_1^2x - 2L_1x$ (two applications of the $[L_1, L_{-1}]$ relation on weights 0 and -1), so the $3L_1x$ terms cancel in $\tilde{L}_2L_{-1}x = L_{-1}L_2x + 3L_1x + \frac{3}{2}(L_{-1}L_1^2x - 2L_1x)$. (iii): $[L_1, L_{-2}] = 3L_{-1}$ and $[L_1, L_{-1}^2] = 2L_{-1}(2L_0 + 1)$, which is $-2L_{-1}$ on H^{-1}; so $[L_1, \tilde{L}_{-2}]y = 3L_{-1}y - 3L_{-1}y = 0$. (iv): on $y \in H^{-1}$,

$$[L_2, L_{-2}]y = (4L_0 + \tfrac{c}{2})y = (\tfrac{c}{2} - 4)y, \qquad [L_2, L_{-1}^2]y = 6L_{-1}L_1y - 6y,$$
$$[L_1^2, L_{-2}]y = 6L_{-1}L_1y - 6y, \qquad [L_1^2, L_{-1}^2]y = -8L_{-1}L_1y + 4y,$$

hence $[\tilde{L}_2, \tilde{L}_{-2}]y = (\frac{c}{2} - 4)y + \frac{3}{2} \cdot 2(6L_{-1}L_1y - 6y) + \frac{9}{4}(-8L_{-1}L_1y + 4y) = (\frac{c}{2} - 13)y$: the $L_{-1}L_1y$ terms cancel ($\frac{3}{2} \cdot 2 \cdot 6 = 18$ against $\frac{9}{4} \cdot (-8) = -18$) and the scalars give $\frac{c}{2} - 4 - 18 + 9 = \frac{c}{2} - 13$.

For the consequence: by Theorem 45.7(a) and `spurious_weight_two`, every spurious s of weight one is $L_{-1}x + L_{-2}y'$ with $x \in H^0$, $y' \in H^{-1}$, and $L_{-2}y' = \tilde{L}_{-2}y' - \frac{3}{2}L_{-1}(L_{-1}y')$ with $L_{-1}y' \in H^0$; so $s = L_{-1}x + \tilde{L}_{-2}y$ with $x \in H^0$, $y \in H^{-1}$. Now apply the identities term by term:

	on $L_{-1}x$ ($x \in H^0$)	on $\tilde{L}_{-2}y$ ($y \in H^{-1}$)
L_1	(i): $= L_{-1}(L_1x) \in \mathcal{S}$	(iii): $= \tilde{L}_{-2}(L_1y) \in \mathcal{S}$
$\tilde{L}_2$	(ii): $= L_{-1}(\tilde{L}_2x) \in \mathcal{S}$	(iv), $c = 26$: $= \tilde{L}_{-2}(\tilde{L}_2y) \in \mathcal{S}$

Every entry is L_{-1} or $\tilde{L}_{-2}$ applied to some vector (of weight -1, -2 or -3), hence spurious, since $\tilde{L}_{-2}z = L_{-2}z + \frac{3}{2}L_{-1}(L_{-1}z) \in \mathcal{S}$ for any z. Only the bottom-right entry needs $c = 26$. □

What the machine verified

No hypotheses beyond the displayed weight hypotheses and, for the critical statements, $c = 26$. Standard axioms (`VOA/Moonshine/MoonshineCNAudit4.lean` prints `tildeTwo_commutator_weight_neg_one`, `tildeTwo_critical_commute`, `criticalSpurious_L_two_tilde`). The supporting identities `L_two_negative_two`, `L_one_square_negative_square_weight_neg_one`, etc. in the same file are the four bracket computations displayed above.

45.6 The abstract no-ghost theorem

From now on in this part we assume the light-cone splitting (F1) $H = \mathcal{S} \oplus \mathcal{K}$, as an explicit hypothesis `hF : M.LightConeSplit`. It is *proved* for the concrete sectors in §45.7; here it is a hypothesis.

45.6.1 The longitudinal splitting

Theorem 45.11 (Longitudinal spurious states). *Under (F1): $\mathcal{S}_K \subseteq \mathcal{S} + (\mathcal{K} \cap \mathcal{S}_K)$, and hence $\mathcal{S}_K = (\mathcal{S}_K \cap \mathcal{S}) \oplus (\mathcal{S}_K \cap \mathcal{K})$, at every weight.*

```
theorem kSpurious_le_spurious_sup (hF : M.LightConeSplit) :
    M.kSpurious ≤ M.spurious ⊔ (M.kVacuum ⊓ M.kSpurious) := by
theorem kSpurious_eq_intersections_sup (hF : M.LightConeSplit) :
    M.kSpurious = (M.kSpurious ⊓ M.spurious) ⊔ (M.kSpurious ⊓ M.kVacuum) := by
```

(`VOA/Moonshine/MoonshineCNStringLongitudinal.lean`; the weightwise, direct form is `kSpurious_weight_split` in `VOA/Moonshine/MoonshineCNStringTransverse.lean`.)

From the mathematics to the Lean statement

Only `hF`. The lower bound `wt_bdd` of the string module is used, as the docstring says, "in the strong induction" — it is part of the structure, not an extra hypothesis.

Physical meaning

A state created by a longitudinal oscillator α^+_{-m} is, up to spurious states, a longitudinal vacuum state: in light-cone gauge, α^+ excitations are pure gauge.

Proof on paper. Strong induction on the weight (legitimate because $H^N = 0$ below N_0). For $x \in H^N$ and $m \geq 1$, write $x = s + k$ by (F1). Then $K_{-m}k \in \mathcal{K} \cap \mathcal{S}_K$ (K's commute, so K_{-m} preserves $\mathcal{K}$). For $s = \sum_n L_{-n}x_n$, the commutator gives $K_{-m}L_{-n}x_n = L_{-n}K_{-m}x_n - mK_{-m-n}x_n$

(`negative_K_negative_L`); the first term is spurious, the second is handled by induction since x_n has smaller weight. □

What the machine verified

Only `hF`; standard axioms.

45.6.2 The decompositions in every weight

Theorem 45.12 (Abstract no-ghost theorem, parts (A1)–(A4)). *Under (F1), for every N:*

(A1) $\dim \mathcal{S}^N = \dim \mathcal{S}_K^N$ *and* $H^N = \mathcal{P}^N \oplus \mathcal{S}_K^N$*; globally* $H = \mathcal{P} \oplus \mathcal{S}_K$*;*

(A2) $\mathcal{S}_K^N = (\mathcal{S}_K^N \cap \mathcal{S}^N) \oplus (\mathcal{S}_K^N \cap \mathcal{K}^N)$*;*

(A3) $\mathcal{K}^N = \mathcal{T}^N \oplus \operatorname{rad}(B|_{\mathcal{K}^N})$*, where* $\operatorname{rad}(B|_{\mathcal{K}^N}) = \mathcal{K}^N \cap \mathcal{S}_K$*;*

(A4) B *is nondegenerate on* $\mathcal{T}^N$*.*

```

```

(`VOA/Moonshine/MoonshineCNStringTransverse.lean`; also `physical_kSpurious_isCompl_weight` and `kSpurious_weight_split`.)

From the mathematics to the Lean statement

`Disjoint A B` means $A \cap B = 0$. (A3) is stated as two statements (sum, `kVacuum_eq_transverse_sup_radical`; directness, `transverse_radical_disjoint`) together with `kVacuum_radical_eq` of Theorem 45.6. (A4) is stated elementwise: a transverse x of weight N orthogonal to all transverse y of weight N is 0. Only `hF`; no central-charge hypothesis.

Physical meaning

At every level, the longitudinal vacua (no α^+ excitations) are the transverse states plus null states, and the transverse states carry a nondegenerate inner product. This is the "light-cone gauge is equivalent to covariant gauge" statement at the level of Fock spaces, before imposing $L_0 = 1$.

Proof on paper. (A1): by (F1) and Theorem 45.5, $\dim \mathcal{S}^N = \dim H^N - \dim \mathcal{K}^N = \dim \mathcal{S}_K^N$. If $x \in \mathcal{P}^N \cap \mathcal{S}_K^N$ then $x \perp \mathcal{S}^N$ (as $x \in \mathcal{P}$) and $x \perp \mathcal{K}^N$ (as $x \in \mathcal{S}_K = (\mathcal{K})^\perp$), so $x \perp H^N = \mathcal{S}^N + \mathcal{K}^N$ and $x = 0$; dimensions add up. (A2): Theorem 45.11 and the modular law, directness from $\mathcal{S} \cap \mathcal{K} = 0$. (A3): $\mathcal{T}^N$ is the kernel of $\beta : k \mapsto B(k, \cdot)|_{\mathcal{S}^N}$ on $\mathcal{K}^N$ (a $k \in \mathcal{K}^N$ is physical iff it is orthogonal to $\mathcal{S}^N$, Theorem 45.5). The image of β is the annihilator in $(\mathcal{S}^N)^*$ of the right kernel

$\{s \in \mathcal{S}^N : B(\mathcal{K}^N, s) = 0\} = \mathcal{S}^N \cap (\mathcal{K}^N)^\perp = \mathcal{S}^N \cap \mathcal{S}_K^N$ (Theorem 45.5 again), so it has dimension $\dim \mathcal{S}^N - \dim(\mathcal{S}^N \cap \mathcal{S}_K^N)$, and $\dim \mathcal{T}^N = \dim \mathcal{K}^N - \dim \mathcal{S}_K^N + \dim(\mathcal{S}^N \cap \mathcal{S}_K^N) = \dim \mathcal{K}^N - \dim(\mathcal{K}^N \cap \mathcal{S}_K^N)$ by (A1), (A2); and $\mathcal{T} \cap \mathcal{S}_K \subseteq \mathcal{P} \cap \mathcal{S}_K = 0$. (A4): a $t \in \mathcal{T}^N$ orthogonal to $\mathcal{T}^N$ is also orthogonal to the radical of $\mathcal{K}^N$, hence to $\mathcal{K}^N$ by (A3), hence lies in that radical, hence is 0. □

What the machine verified

Only `hF`; standard axioms (`VOA/Moonshine/MoonshineCNAudit4.lean`).

45.6.3 The weight-one physical splitting (A5)

Theorem 45.13 (Abstract no-ghost theorem, part (A5)). *If $c = 26$ and (F1) holds, then $\mathcal{P}^1 = \mathcal{T}^1 \oplus (\mathcal{P}^1 \cap \mathcal{S})$.*

```
theorem physicalOne_eq_transverse_sup_null (hc : M.c = 26) (hF : M.LightConeSplit) :
    M.weightSlice M.physical 1 = M.weightSlice M.transverse 1 ⊔
      M.weightSlice (M.physical ⊓ M.spurious) 1 := by
theorem physicalOne_transverse_null_disjoint (hF : M.LightConeSplit) :
    Disjoint (M.weightSlice M.transverse 1) (M.weightSlice (M.physical ⊓ M.spurious) 1) :=
    ↪ by
```

(`VOA/Moonshine/MoonshineCNStringPhysical.lean`.)

From the mathematics to the Lean statement

The spanning half needs $c = 26$ and (F1); the directness half needs only (F1). Together with Theorem 45.6 ($\mathrm{rad}(B|_{\mathcal{P}^1}) = \mathcal{P}^1 \cap \mathcal{S}$) this is the full weight-one statement: $\mathcal{P}^1$ is the transverse space plus the radical.

Physical meaning

The no-ghost theorem proper: every physical state of a 26-dimensional string is a transverse (light-cone) state plus a null state.

Proof on paper. Let $p \in \mathcal{P}^1$ and write $p = k + s$ with $k \in \mathcal{K}^1$, $s \in \mathcal{S}^1$ (F1). For $A \in \{L_1, \tilde{L}_2\}$: $Ap = 0$, $Ak \in \mathcal{K}$ (Theorem 45.7(c)) and $As \in \mathcal{S}$ (Theorem 45.10, $c = 26$); Ak and As have the same weight and sum to zero, and $\mathcal{S} \cap \mathcal{K} = 0$, so $Ak = As = 0$. From $L_1 k = 0 = \tilde{L}_2 k$ we get $L_2 k = 0$, so $k \in \mathcal{P}$ by Theorem 45.7(b), i.e. $k \in \mathcal{T}^1$, and $s = p - k \in \mathcal{P}^1 \cap \mathcal{S}$. Directness: $\mathcal{T} \cap \mathcal{S} \subseteq \mathcal{K} \cap \mathcal{S} = 0$. □

What the machine verified

Hypotheses `hc`, `hF`; standard axioms (`VOA/Moonshine/MoonshineCNAudit4.lean`).

45.6.4 The quotient isometries

The quotient of a weight slice by the radical of its form, with the descended form, is defined generally:

```
def weightRadical (U : Submodule ℂ H) (N : ℤ) :
    Submodule ℂ (M.weightSlice U N) :=
  (M.formRadicalIn U N).comap (M.weightSlice U N).subtype
abbrev weightRadicalQuotient (U : Submodule ℂ H) (N : ℤ) :=
  M.weightSlice U N ⧸ M.weightRadical U N
def radicalQuotientForm (U : Submodule ℂ H) (N : ℤ) :
    LinearMap.BilinForm ℂ (M.weightRadicalQuotient U N) :=
```

(`VOA/Moonshine/MoonshineCNStringQuotient.lean`; `radicalQuotientForm` is characterised by `radicalQuotientForm_mk`: its value on classes $[x]$, $[y]$ is $B(x,y)$, and it is symmetric and nondegenerate, `radicalQuotientForm_symm`, `radicalQuotientForm_nondegenerate`.)

Theorem 45.14 (The no-ghost isometries). *Under (F1), the inclusion $\mathcal{T}^N \hookrightarrow \mathcal{K}^N$ induces an isometric isomorphism $\mathcal{T}^N \cong \mathcal{K}^N/\mathrm{rad}$; if moreover $c = 26$, the inclusion $\mathcal{T}^1 \hookrightarrow \mathcal{P}^1$ induces an isometric isomorphism $\mathcal{T}^1 \cong \mathcal{P}^1/\mathrm{rad}$, whose inverse sends $[p]$ to the $\mathcal{K}$-component of p in $H = \mathcal{S} \oplus \mathcal{K}$. Composing, $\mathcal{P}^1/\mathrm{rad} \cong \mathcal{K}^1/\mathrm{rad}$ isometrically. All three isomorphisms are equivariant for every symmetry A of the string module.*

```
def transverseKQuotientEquiv (hF : M.LightConeSplit) (N : ℤ) :
    M.weightSlice M.transverse N ≃ₗ[ℂ] M.weightRadicalQuotient M.kVacuum N :=

theorem physicalKQuotientEquiv_isometry (hc : M.c = 26) (hF : M.LightConeSplit)
    (p q : M.weightRadicalQuotient M.physical 1) :
    M.radicalQuotientForm M.kVacuum 1 (M.physicalKQuotientEquiv hc hF p)
      (M.physicalKQuotientEquiv hc hF q) = M.radicalQuotientForm M.physical 1 p q := by
```

(`VOA/Moonshine/MoonshineCNStringComparison.lean`; equivariance: `transverseKQuotientEquiv_equivariant`, `transversePhysicalQuotientEquiv_equivariant` in `VOA/Moonshine/MoonshineCNStringSymmetry.lean` and `StringGroupAction.physicalKQuotientEquiv_equivariant` in `VOA/Moonshine/MoonshineCNStringComparison.lean`

From the mathematics to the Lean statement

Decoding. `≃ₗ[ℂ]` is a linear isomorphism. `Submodule.Quotient.mk p` is the class $[p]$. `.symm` is the inverse. `M.kVacuum.projection M.spurious hF.symm` is Mathlib's projection onto $\mathcal{K}$ along $\mathcal{S}$ for the complementary pair given by (F1). The isometry statement for `transversePhysicalQuotientEquiv` is proved by `rfl`: the map is literally $t \mapsto [t]$, so the descended form on $[t],[t']$ is $B(t,t')$ by definition. The content is in the *bijectivity* (`transverseQuotientMap_bijective`), which uses (A3), resp. (A5) and Theorem 45.6.

Equivariance. For a `StringGroupAction` A, the file `StringSymmetry` first shows that A preserves $\mathcal{S}, \mathcal{S}_K, \mathcal{P}, \mathcal{K}, \mathcal{T}$ and the null space, then restricts it to weight slices (`stableWeightAction`) and descends it to radical quotients (`stableWeightQuotientAction`), isometrically; the equivariance of the three isomorphisms is then a statement about these actual quotient actions (two of them hold by `rfl`).

Could it be vacuous? If (F1) were never satisfiable, every statement here would be empty. It is satisfied by the concrete sectors (§45.7). If the radical were the whole space, the quotients would be zero; the isometry with $V^{\natural}{}_{1-xy}$ proved later (which has the nondegenerate `natForm`) rules this out whenever $V^{\natural}{}_{1-xy} \neq 0$.

Physical meaning

Covariant physical states modulo null states = light-cone states = longitudinal vacua modulo null states, as inner-product spaces and as representations of every internal symmetry. The inverse map "take the $\mathcal{K}$-component" is the passage to light-cone gauge.

What the machine verified

Hypotheses `hF` (and `hc` for the weight-one physical statements). Standard axioms (`VOA/Moonshine/MoonshineCNAudit4.lean`, `VOA/Moonshine/MoonshineCNAudit5.lean`, `VOA/Moonshine/MoonshineCNAudit8.lean`).

45.7 The moonshine string sector $V^\natural \otimes \mathbb{C}[a_j, b_j]$

We now build, for each momentum $(x, y) \in \mathrm{II}_{1,1}$, an explicit string module whose underlying space is $V^\natural \otimes \mathbb{C}[a_j, b_j \,:\, j \geq 1]$, and *prove* the light-cone splitting for it when $(x, y) \neq 0$. In §45.10 this model is identified with the momentum-(x, y) sector of the vertex algebra $V^\natural \otimes V_{\mathrm{II}_{1,1}}$ of Chapter 44.

45.7.1 The hyperbolic Fock space (recalled from Chapter 44)

Let $w_0 = (0, 1)$, $w_1 = (1, 0)$, an isotropic basis of $\mathrm{II}_{1,1}$: $(w_0, w_0) = (w_1, w_1) = 0$, $(w_0, w_1) = 1$. The Fock space of the rank-two Heisenberg algebra at momentum r is modelled on the polynomial ring $F = \mathbb{C}[a_j, b_j \,:\, j \geq 1]$, where a_j creates $w_0(-j)$ and b_j creates $w_1(-j)$. In Lean

```
abbrev hypFock := FockN 2
def hypOscillator (a : Fin 2) (q : ℂ) (n : ℤ) : Module.End ℂ hypFock :=
  if n < 0 then oscN 2 1 a n
  else if 0 < n then oscN 2 1 a.rev n
  else q • LinearMap.id
def hypLevel (N : ℤ) : Submodule ℂ hypFock := gradingZN 2 N
```

(`VOA/Moonshine/MoonshineCNHyperbolicFock.lean`.) Here `FockN 2 = MvPolynomial (ℕ × Fin 2) ℂ` and, by the file's docstring, the variable `(j,0)` is a_{j+1} and `(j,1)` is b_{j+1}. The oscillator of family `a` acts for $n < 0$ by multiplication by the variable `(-n-1, a)` and for $n > 0$ by $n\,\partial$ with respect to the variable of the *opposite* family `a.rev` at level n (`hypOscillator_negative_apply`, `hypOscillator_positive_apply`); its zero mode is the scalar `q`. So, with $a(n)$:=`hypOscillator 0 κ n` and $b(n)$:=`hypOscillator 1 ell n`,

$$a(-j) = a_j\cdot, \quad a(j) = j\,\partial/\partial b_j, \quad a(0) = \kappa, \qquad b(-j) = b_j\cdot, \quad b(j) = j\,\partial/\partial a_j, \quad b(0) = \ell,$$

with $[a(m), b(n)] = m\delta_{m+n,0}$ and $[a(m), a(n)] = [b(m), b(n)] = 0$ (`hypOscillator_comm`). `hypLevel N` is the span of monomials of total level N (a_j, b_j have level j); it is finite-dimensional.

The Sugawara (Virasoro) operators are given by explicit finite formulas, avoiding infinite sums:

```
def hypRaisingDerivation (n : ℕ) : Derivation ℂ hypFock hypFock :=
  mkDerivation ℂ fun v => (v.1 + 1 : ℂ) • X (v.1 + n, v.2)
def hypNegativePotential (κ ell : ℂ) (j : ℕ) : hypFock :=
  κ • X (j, 1) + ell • X (j, 0) +
    ∑ k ∈ Finset.range j, X (j - 1 - k, 0) * X (k, 1)
def hypSugawara (κ ell : ℂ) (n : ℤ) : Module.End ℂ hypFock :=
  if n < 0 then
    LinearMap.mul ℂ hypFock (hypNegativePotential κ ell (-n - 1).toNat) +
      (hypRaisingDerivation (-n).toNat).toLinearMap
  else if 0 < n then
    (hypLoweringDerivation κ ell n.toNat).toLinearMap +
```

```
      hypPositiveSecondOrder (n - 1).toNat
  else (κ * ell) • LinearMap.id + hypEnergyDerivation.toLinearMap
```

(VOA/Moonshine/MoonshineCNHyperbolicSugawara.lean.) For $n \geq 1$ this is

$$L^F_{-n} = \kappa\, b_n + \ell\, a_n + \sum_{i=1}^{n-1} a_{n-i} b_i + \sum_{k\geq 1} k\Big(a_{n+k}\frac{\partial}{\partial a_k} + b_{n+k}\frac{\partial}{\partial b_k}\Big), \qquad L^F_0 = \kappa\ell + \text{level}, \tag{45.4}$$

the explicit form of $L^F_n = \sum_k :a(n-k)b(k):$; the positive modes are a first-order derivation plus a finite second-order part. The contravariant form is the monomial pairing $B_F(a^\alpha b^\beta, a^{\alpha'} b^{\beta'}) = \delta_{\alpha\beta'}\delta_{\beta\alpha'} \prod_j j^{\alpha_j}\alpha_j! \prod_j j^{\beta_j}\beta_j!$, in Lean `hypForm` (VOA/Moonshine/MoonshineCNHyperbolicForm.lean):

```
def hypForm : LinearMap.BilinForm ℂ hypFock :=
  Finsupp.lsum ℂ fun d =>
    LinearMap.smulRight LinearMap.id (hypMonomialNorm d • lcoeff ℂ (hypSwapExponent d))
```

where `hypSwapExponent` exchanges the two families and `hypMonomialNorm d` is $\prod_v (\text{level of } v)^{d_v}\, d_v!$. Chapter 44 proves that L^F satisfies the Virasoro relations with $c = 2$, that L^F_n and L^F_{-n} are B_F-adjoint, and that B_F is nondegenerate on each level.

Physical meaning

F is the Fock space of the two light-cone bosons $X^\pm$ at momentum r, written in null coordinates: a_j creates α^+_{-j} and b_j creates α^-_{-j}, and κ, ℓ are the light-cone momenta $p^\pm$ (here $\kappa = (w_0, r)$, $\ell = (w_1, r)$). The pairing of a with b (and not with a) is the null-coordinate form of the Minkowski metric.

The momentum labels. In the Lean sector at momentum (x, y) the two charges are $\kappa = x$, $\ell = y$, i.e. `hypSugawara x y`. The frame file `VOA/Moonshine/MoonshineCNSectorFrame.lean` explains: "family zero [is] assigned to the lattice vector `(0,1)`. Thus the sector charges `(κ,ell) = (x,y)` match momentum `(x,y)`": with $w_0 = (0,1)$, $w_1 = (1,0)$ one has $(w_0,(x,y)) = x$ and $(w_1,(x,y)) = y$ in the form (45.1) (`lorentzianIsotropicVector_charge`). Hence $\kappa\ell = xy = r^2/2$.

45.7.2 The sector operators and form

Definition 45.15 (The sector Virasoro operators and form). For $\kappa, \ell \in \mathbb{C}$ let $L_n := L^\natural_n \otimes 1 + 1 \otimes L^F_n$ on $V^\natural \otimes F$, where $L^\natural_n$ is the Virasoro action of $V^\natural$, and let $B := B^\natural \otimes B_F$. For $a \in \{0, 1\}$ the longitudinal operators are $K_n := 1 \otimes (\text{family-}a \text{ oscillator})(n)$, with zero mode the charge of that family.

```
def vnatHypMode (κ ell : ℂ) (n : ℤ) : Module.End ℂ (Vnat ⊗[ℂ] hypFock) :=
  tensorTranslation (nearVirasoroMode VnatVOA.toNearVOA n) (hypSugawara κ ell n)
def vnatHypForm : LinearMap.BilinForm ℂ (Vnat ⊗[ℂ] hypFock) := natForm.tmul hypForm
```

(VOA/Moonshine/MoonshineCNVnatSectorOperators.lean.)

```
def vnatHypLongitudinal (a : Fin 2) (κ ell : ℂ) (n : ℤ) :
    Module.End ℂ (Vnat ⊗[ℂ] hypFock) :=
  (hypOscillator a (if a = 0 then κ else ell) n).lTensor Vnat
```

(VOA/Moonshine/MoonshineCNVnatSectorLaws.lean.)

From the mathematics to the Lean statement

`tensorTranslation TA TB` is $T_A \otimes 1 + 1 \otimes T_B$ (VOA/Core/TensorFieldLift.lean: `LinearMap.rTensor B TA + LinearMap.lTensor A TB`); `nearVirasoroMode`

`VnatVOA.toNearVOA n` is $L_n^\natural = \omega^\natural_{(n+1)}$ (`VOA/Moonshine/MoonshineCNTensorConformal.lean`: `mode (V.Y V.conformalVector) (n + 1)`). `natForm.tmul hypForm` is the tensor product of the two bilinear forms, $B(v \otimes p, v' \otimes p') = B^\natural(v,v')B_F(p,p')$. `.lTensor Vnat` is $1_{V^\natural} \otimes (\cdot)$. These are the actual $V^\natural$ Virasoro modes and the actual $V^\natural$ form, not abstract data.

Physical meaning

Total stress tensor (internal Monster CFT plus light-cone bosons), the string inner product, and the light-cone current $\alpha^+(z)$ (or $\alpha^-(z)$).

Theorem 45.16 (Central charge 26, adjointness, nondegeneracy). *For all κ, ℓ: the L_n satisfy the Virasoro relations with central charge 26; B is symmetric, L_n and L_{-n} are B-adjoint, and B is nondegenerate on the whole of $V^\natural \otimes F$.*

```
theorem vnatHypMode_virasoro (κ ell : ℂ) (m n : ℤ) :
    vnatHypMode κ ell m * vnatHypMode κ ell n -
      vnatHypMode κ ell n * vnatHypMode κ ell m =
      ((m : ℂ) - n) • vnatHypMode κ ell (m + n) +
        if m + n = 0 then (((m : ℂ) ^ 3 - m) / 12 * 26) • 1 else 0 := by
theorem vnatHypForm_symm (x y : Vnat ⊗[ℂ] hypFock) : vnatHypForm x y = vnatHypForm y x :=
↪ by
theorem vnatHypForm_adjoint (κ ell : ℂ) (n : ℤ) (x y : Vnat ⊗[ℂ] hypFock) :
    vnatHypForm (vnatHypMode κ ell n x) y = vnatHypForm x (vnatHypMode κ ell (-n) y) := by
theorem vnatHypForm_nondegenerate (x : Vnat ⊗[ℂ] hypFock) (hx : x ≠ 0) :
    ∃ y, vnatHypForm x y ≠ 0 := by
```

(`VOA/Moonshine/MoonshineCNVnatSectorOperators.lean`.)

From the mathematics to the Lean statement

The central term `(((m : ℂ) ^ 3 - m) / 12 * 26) • 1` is literally $\frac{26}{12}(m^3 - m)$: the number 26 appears in the statement, with no hypothesis. It comes from $c(V^\natural) = 24$ (Chapter 42, `VOA.Moonshine.moonshine`) plus $c(F) = 2$ (Chapter 44). Adjointness combines `natForm_virasoro_adj` with the F-adjointness of L^F. Nondegeneracy on the whole space follows from the coefficient formula `vnatHypForm_coefficient`: pairing with $v \otimes$ (swapped monomial) extracts, up to the nonzero factor `hypMonomialNorm e`, the $V^\natural$-coefficient of a monomial, and `natForm` is nondegenerate.

Physical meaning

$c_{\text{matter}} = 24 + 2 = 26$: the Monster CFT plus two light-cone bosons is a critical bosonic string.

What the machine verified

No hypotheses; standard axioms (`VOA/Moonshine/MoonshineCNAudit7.lean`).

45.7.3 The weight grading

Definition 45.17 (Sector weight spaces). $H^N_{(x,y)} := \operatorname{span}\{v \otimes p : v \in V^\natural_i,\ p \in F_j,\ i + j + xy = N\}$: matter weight plus oscillator level plus half the momentum norm.

```
def vnatSectorWeight (x y N : ℤ) : Submodule ℂ (Vnat ⊗[ℂ] hypFock) :=
  Submodule.span ℂ {t | ∃ (i j : ℤ) (v : Vnat) (p : hypFock),
    v ∈ VnatVOA.grading i ∧ p ∈ hypLevel j ∧ i + j + x * y = N ∧ v ⊗ₜ[ℂ] p = t}
```

```
theorem vnatSectorWeight_eq_eigenspace (x y N : ℤ) :
    vnatSectorWeight x y N = (vnatHypMode x y 0).eigenspace (N : ℂ) := by
theorem vnatSectorWeight_isInternal (x y : ℤ) :
    DirectSum.IsInternal (vnatSectorWeight x y) := by
theorem vnatSectorWeight_negative (x y N : ℤ) (hN : N < x * y) :
    vnatSectorWeight x y N = ⊥ := by
theorem vnatSectorWeight_finiteDimensional (x y N : ℤ) :
    FiniteDimensional ℂ (vnatSectorWeight x y N) := by
```

(`VOA/Moonshine/MoonshineCNVnatSectorGrading.lean`.)

From the mathematics to the Lean statement

The weight space is exactly the L_0-eigenspace with eigenvalue N (`eigenspace (N : ℂ)`); this pins the definition down. The lower bound is $N \geq xy$ because $V^\natural$ has no negative weights and F no negative levels. Finite-dimensionality uses that each $V^\natural{}_i$ and each F_j is finite-dimensional and only finitely many (i, j) with $i, j \geq 0$ have $i + j = N - xy$. Note that the momentum (x, y) enters only through xy and through the charges of the Sugawara operator.

Physical meaning

$L_0 = L_0^\natural + N^\pm + \frac{1}{2}r^2$: the mass-shell condition $L_0 = 1$ reads (internal level) + (light-cone level) $= 1 - xy$.

What the machine verified

No hypotheses; standard axioms (`VOA/Moonshine/MoonshineCNAudit7.lean`).

The remaining string-module laws are in `VOA/Moonshine/MoonshineCNVnatSectorLaws.lean`: `vnatSectorWeight_mode` (L_n lowers weight by n), `vnatSectorWeight_oscillator` (same for K_n), `vnatSectorWeight_orthogonal` and `vnatSectorWeight_nondegenerate` (orthogonality of distinct weights and nondegeneracy on each weight), `vnatHypLongitudinal_comm`, `vnatHypLongitudinal_mixed` ($[L_m, K_n] = -nK_{m+n}$, here for *all* m, n, which is stronger than the structure requires) and `vnatHypLongitudinal_adjoint`.

45.7.4 The concrete string module

Definition 45.18 (The moonshine string sector)**.** For $(x, y) \in \mathbb{Z}^2$ and a family $a \in \{0, 1\}$, the string module $H_{(x,y),a}$ has carrier $V^\natural \otimes F$, weights $H^N_{(x,y)}$, central charge 26, Virasoro operators L_n at charges (x, y), longitudinal operators K_n of family a, and form $B^\natural \otimes B_F$. For $(x, y) \neq 0$, the *string sector* $H_{(x,y)}$ is $H_{(x,y),a}$ for the family a furnished by the light-cone theorem below.

```
def vnatStringModule (x y : ℤ) (a : Fin 2) : StringModule (Vnat ⊗[ℂ] hypFock) where
  wt := vnatSectorWeight x y
  wt_isInternal := vnatSectorWeight_isInternal x y
  wt_finite := vnatSectorWeight_finiteDimensional x y
  wt_bdd := ⟨x * y, fun N hN => vnatSectorWeight_negative x y N hN⟩
  c := 26
  L := vnatHypMode x y
  K := vnatHypLongitudinal a x y
  L_wt := vnatSectorWeight_mode x y
  K_wt := fun n N u _ hu => vnatSectorWeight_oscillator x y n N a u hu
  L_zero := vnatSectorWeight_energy x y
  L_comm := vnatHypMode_virasoro x y
  K_comm := vnatHypLongitudinal_comm a x y
  LK_comm := fun m n _ _ => vnatHypLongitudinal_mixed a x y m n
```

```
  B := vnatHypForm
  B_symm := ⟨vnatHypForm_symm⟩
  B_orth := vnatSectorWeight_orthogonal x y
  B_nondeg := vnatSectorWeight_nondegenerate x y
  L_adj := vnatHypForm_adjoint x y
  K_adj := vnatHypLongitudinal_adjoint a x y
def stringSectorFamily (x y : ℤ) (h : x ≠ 0 ∨ y ≠ 0) : Fin 2 :=

(`VOA/Moonshine/MoonshineCNVnatStringModule.lean`.)

From the mathematics to the Lean statement

Every field is a proved theorem; there is no hypothesis. The integer momenta are coerced to $\mathbb{C}$ in `vnatHypMode x y`. `stringSectorFamily` is defined by `.choose` from an existence statement: it is *some* family for which the light-cone splitting holds. (The proof of the existence statement exhibits family 0 when $x \neq 0$ and family 1 otherwise, but `.choose` does not pin the witness, so Lean does not assert which family is chosen.) The downstream statements do not depend on which. The zero-momentum module `vnatStringModule 0 0 0` is also used (for $\mathfrak{m}_0$), but no light-cone splitting is claimed for it.

Physical meaning

The Fock space of the critical string at momentum (x, y) with internal CFT $V^\natural$, together with the choice of a light-cone direction w with $(w, r) \neq 0$.

45.7.5 The light-cone splitting

Theorem 45.19 (Light-cone splitting (F1) for the sector). *For every $(\kappa, \ell) \neq (0, 0)$ there is a family a such that $V^\natural \otimes F = \sum_{j\geq 0} L_{-(j+1)}(V^\natural \otimes F) \oplus \bigcap_{j\geq 0} \ker K_{j+1}$. In particular every string sector $H_{(x,y)}$, $(x, y) \neq 0$, satisfies* `LightConeSplit`.

```
theorem vnatHypTensor_lightConeSplit (κ ell : ℂ) (h : κ ≠ 0 ∨ ell ≠ 0) :
    ∃ a : Fin 2, IsCompl (⨆ j : ℕ, LinearMap.range (vnatHypNegative κ ell j))
      (⨅ j : ℕ, LinearMap.ker
        ((hypOscillator a (if a = 0 then κ else ell) (j + 1 : ℤ)).lTensor Vnat)) :=
```

(`VOA/Moonshine/MoonshineCNVnatLightCone.lean`, with `vnatHypNegative κ ell j` the operator `vnatHypMode κ ell (-(j + 1))`, by `vnatHypMode_negative`, a `rfl` lemma.)

```
theorem vnatHypMode_lightConeSplit (κ ell : ℂ) (h : κ ≠ 0 ∨ ell ≠ 0) :
    ∃ a : Fin 2, IsCompl (⨆ j : ℕ, LinearMap.range (vnatHypMode κ ell (-(j + 1 : ℤ))))
      (⨅ j : ℕ, LinearMap.ker
        ((hypOscillator a (if a = 0 then κ else ell) (j + 1 : ℤ)).lTensor Vnat)) := by
theorem stringSector_lightConeSplit (x y : ℤ) (h : x ≠ 0 ∨ y ≠ 0) :
    (stringSector x y h).LightConeSplit :=
```

(`VOA/Moonshine/MoonshineCNVnatSectorOperators.lean` and `VOA/Moonshine/MoonshineCNVnatStringModule.lean`.)

From the mathematics to the Lean statement

The statement is exactly (F1) for the string module `vnatStringModule x y a`: the left summand is `spurious` ($\sum_{n\geq 1} \operatorname{im} L_{-n}$), the right summand is `kVacuum` ($\bigcap_{n\geq 1} \ker K_n$). The docstring of `vnatHypTensor_lightConeSplit` reads "No unestablished form, representation, or splitting datum is assumed". The general theorem for an arbitrary space V with an operator family satisfying the negative Virasoro commutators, `hypTensor_lightConeSplit_nonzero`, is in `VOA/Moonshine/MoonshineCNTensorLightConeKernels.lean` (Chapter 44); the present file specialises it to $V^\natural$ using `nearVirasoroNegative_comm`.
Why $(x, y) \neq 0$ is necessary. At $(x, y) = (0, 0)$ the leading coefficient κ of (45.4) vanishes and the splitting genuinely fails: at weight one, $H^1_{(0,0)} = \operatorname{span}(\mathbb{1} \otimes a_1, \mathbb{1} \otimes b_1)$ (because $V^\natural{}_1 = 0$), the spurious part is $L_{-1}H^0 = \mathbb{C}\mathbb{1} \otimes (\kappa b_1 + \ell a_1) = 0$, and the family-0 longitudinal vacua are $\mathbb{C}\mathbb{1} \otimes a_1$; so $\mathcal{S}^1 \oplus \mathcal{K}^1$ misses $\mathbb{1} \otimes b_1$ (and symmetrically for family 1). This is why zero momentum is treated separately (§45.8.3).

Physical meaning

"Every Fock state is uniquely a light-cone state dressed by Virasoro descendants": the Virasoro generators L_{-n} act, to leading order, as $p^+\alpha^-_n$ (since $L_{-n} = \kappa b_n + \dots$), so when the light-cone momentum p^+ is nonzero the Virasoro descendants can be traded for α^- excitations. This is the algebraic core of the light-cone gauge.

Proof on paper. (The Lean proof of the general statement is in the files of Chapter 44.) Assume $\kappa \neq 0$ and take $K_n = a(n)$, so $\mathcal{K} = V^\natural \otimes \mathbb{C}[a]$ (polynomials free of b's: $a(j) = j\partial/\partial b_j$). Filter $V^\natural \otimes F$ by the pair $(d, w) =$ (number of b's, total b-level) of the monomials, ordered lexicographically. By (45.4), for a vector of filtration degree (d, w), $L_{-n}x - \kappa(1 \otimes b_n)x$ has strictly smaller degree than $(d + 1, w + n)$ (all other terms of L_{-n} either keep d, or raise d by one but w by less than n). Iterating, for $k \in \mathcal{K}$ and a sorted word $\lambda = (n_1 \geq \dots \geq n_s)$, $L_{-\lambda}k = \kappa^s(1 \otimes b_\lambda)k +$ (lower). Hence the map $\Phi : \mathbb{C}[b] \otimes \mathcal{K} \to H$, $b^\beta \otimes k \mapsto L_{-\lambda(\beta)}k$, is "upper triangular with nonzero diagonal κ^d" with respect to the isomorphism $\mu : \mathbb{C}[b] \otimes \mathcal{K} \cong H$, $b^\beta \otimes k \mapsto b^\beta k$; so Φ is injective, and bijective on each (finite-dimensional) weight space. $\Phi(1 \otimes \mathcal{K}) = \mathcal{K}$, and by straightening (Theorem 45.8) the spurious space is $\Phi(\mathbb{C}[b]_+ \otimes \mathcal{K})$. So $H = \mathcal{K} \oplus \mathcal{S}$. If $\kappa = 0 \neq \ell$, exchange the roles of a and b. □

What the machine verified

No hypotheses beyond $(\kappa, \ell) \neq 0$; standard axioms (`VOA/Moonshine/MoonshineCNAudit7.lean`, `VOA/Moonshine/MoonshineCNAudit8.lean`). Unlike most no-ghost presentations, no Kac determinant, no Shapovalov form for Vir $\ltimes$ Heisenberg and no character count is used.

45.7.6 The automorphism group acts

Theorem 45.20 (Aut($V^\natural$) preserves the form and acts on every sector). *Every $g \in \operatorname{Aut}(V^\natural)$ satisfies $B^\natural(gv, gw) = B^\natural(v, w)$. Consequently $g \otimes 1$ defines a symmetry (Definition 45.4) of every string module $H_{(x,y),a}$.*

```
theorem vnatAut_preserves_natForm (g : AutVnat) (v w : Vnat) :
    natForm (g v) (g w) = natForm v w := by
def vnatSectorAction : AutVnat →* ((Vnat ⊗[ℂ] hypFock) ≃ₗ[ℂ] (Vnat ⊗[ℂ] hypFock)) where
theorem vnatSectorAction_tmul (g : AutVnat) (v : Vnat) (p : hypFock) :
    vnatSectorAction g (v ⊗ₜ[ℂ] p) = g v ⊗ₜ[ℂ] p := rfl
def vnatStringGroupAction (x y : ℤ) (a : Fin 2) :
    StringGroupAction (vnatStringModule x y a) AutVnat where
```

(`VOA/Moonshine/MoonshineCNVnatFormAction.lean` for the first, `VOA/Moonshine/MoonshineCNVnatSectorAction.lean` for the rest; `stringSectorAction` is the specialisation to `stringSector x y h`.)

From the mathematics to the Lean statement

The docstring stresses: "The actual `natForm`, not an unspecified invariant form, is $\mathrm{Aut}(V^\natural)$-invariant." Proof idea: $v \mapsto B^\natural(gv, gw)$ defines another invariant form `vnatAutPullbackForm g`, which is fully (FHL-)invariant (`vnatAutPullbackForm_fhl`); by the uniqueness of invariant forms on a simple CFT-type VOA with $L_1 V_1 = 0$ (Chapter 5) it is a multiple of $B^\natural$, and the multiple is 1 because $g\mathbb{1} = \mathbb{1}$. The four laws of `StringGroupAction` are `vnatSectorAction_weight`, `vnatSectorAction_mode`, `vnatSectorAction_longitudinal`, `vnatSectorAction_isometry`.

Physical meaning

The Monster is a global symmetry of the internal CFT; it commutes with the light-cone sector and is unitary for the string inner product.

What the machine verified

No hypotheses; standard axioms (`VOA/Moonshine/MoonshineCNAudit8.lean`).

45.8 The no-ghost theorem for the moonshine module

45.8.1 The longitudinal quotient is the matter weight space

For family a, the longitudinal vacua are the vectors whose polynomial parts involve only family-a variables (`vnatStringModule_kVacuum`: `kVacuum = hypTensorOneFamily a`). Let $\mathrm{ev}_0 : V^\natural \otimes F \to V^\natural$ be "take the coefficient of the constant monomial":

```
def vnatSectorEval : (Vnat ⊗[ℂ] hypFock) →ₗ[ℂ] Vnat :=
  (Finsupp.lapply 0).comp hypTensorCoordinates.toLinearMap
theorem vnatSectorEval_tmul (v : Vnat) (p : hypFock) :
    vnatSectorEval (v ⊗ₜ[ℂ] p) = coeff 0 p • v := hypTensorCoordinates_tmul v p 0
```

(`VOA/Moonshine/MoonshineCNVnatSectorEvaluation.lean`.)

Theorem 45.21 (Longitudinal radical quotient). *For every (x, y), family a and weight N, evaluation induces an isometric, $\mathrm{Aut}(V^\natural)$-equivariant isomorphism $\mathcal{K}^N/\mathrm{rad} \cong V^\natural_{N-xy}$; its kernel on $\mathcal{K}^N$ is the radical, which equals $\mathcal{K}^N \cap \mathcal{S}_K$.*

```
theorem vnatKVacuum_augmentation (x y : ℤ) (a : Fin 2) (N : ℤ)
    (u : (vnatStringModule x y a).weightSlice (vnatStringModule x y a).kVacuum N) :

       ↪ := by
theorem vnatKVacuumQuotientEquiv_equivariant (x y : ℤ) (a : Fin 2) (N : ℤ) (g : AutVnat)
    (u : (vnatStringModule x y a).weightRadicalQuotient (vnatStringModule x y a).kVacuum N)
     ↪ :
```

```
    vnatKVacuumQuotientEquiv x y a N
      ((vnatStringGroupAction x y a).stableWeightQuotientAction _
        (vnatStringGroupAction x y a).action_preserves_kVacuum N g u) =
      GriessAut.autRestrict g (N - x * y) (vnatKVacuumQuotientEquiv x y a N u) := by
```

(`VOA/Moonshine/MoonshineCNVnatLongitudinalQuotient.lean`.)

From the mathematics to the Lean statement

`vnatKVacuumEvaluation x y a N` is ev_0 restricted to $\mathcal{K}^N$, with values in $V^\natural{}_{N-xy}$ (`vnatSectorEval_weight`). The equivariance statement compares the action of g on the quotient (descended from $g \otimes 1$) with $g|_{V^\natural{}_{N-xy}}$. No hypotheses: in particular this holds at zero momentum and for both families.

Physical meaning

Longitudinal vacua modulo null states are the internal states: the α^+ excitations are pure gauge, and what survives is the internal CFT state at the level fixed by the mass shell.

Proof on paper. A family-a polynomial is a constant plus an element of the ideal generated by the family-a variables, so $\mathcal{K}^N = (V^\natural{}_{N-xy} \otimes 1) \oplus (V^\natural \otimes \mathbb{C}[a]_+)^N$; the second summand is $\mathcal{K} \cap \mathcal{S}_K$ (K_{-n} multiplies by a_n), i.e. the kernel of ev_0, and ev_0 is onto. On $V^\natural \otimes \mathbb{C}[a]$ the form is $B^\natural(\mathrm{ev}_0 u, \mathrm{ev}_0 v)$, because B_F pairs an a-monomial only with the corresponding b-monomial, and the only b-free monomial among a-monomials is 1 (`vnatSectorEval_oneFamily_form`). Equivariance: $g \otimes 1$ commutes with ev_0. □

What the machine verified

No hypotheses; standard axioms (`VOA/Moonshine/MoonshineCNAudit8.lean`).

45.8.2 The theorem

Theorem 45.22 (No-ghost theorem for $V^\natural$, nonzero momentum). *For every $(x, y) \in \mathbb{Z}^2 \setminus \{0\}$ there is a linear isomorphism*

$$\Theta_{(x,y)} : \mathcal{P}^1_{(x,y)} \big/ \mathrm{rad}\big(B|_{\mathcal{P}^1_{(x,y)}}\big) \xrightarrow{\sim} V^\natural{}_{1-xy}$$

which is an isometry for the descended form and $B^\natural$, and intertwines the action of every $g \in \mathrm{Aut}(V^\natural)$. Here $\mathcal{P}^1_{(x,y)}$ is the weight-one physical space of the string sector $H_{(x,y)}$, and $\mathrm{rad} = \mathcal{P}^1_{(x,y)} \cap \mathcal{S}$. *In particular* $\dim \mathcal{P}^1_{(x,y)}/\mathrm{rad} = \dim V^\natural{}_{1-xy}$.

```

```

(VOA/Moonshine/MoonshineCNVnatNoGhostConsequences.lean.)

From the mathematics to the Lean statement

Decoding. The source is the type `weightRadicalQuotient physical 1`: the weight-one slice of the physical space of the actual string sector, modulo the radical of the actual form restricted to it (§45.6). The target is `VnatVOA.grading (1 - x * y)`, the weight space $V^\natural_{1-xy}$; the weight is *exactly* $1-xy$ in the repository norm $2xy$ (the file docstring: "The norm convention is `2*x*y`; the matter weight is exactly `1-x*y`"). The definition is a composition of the abstract isomorphism `physicalKQuotientEquiv` (which needs $c = 26$: `stringSector_charge`, a `rfl`; and (F1): `stringSector_lightConeSplit`) with the longitudinal quotient of Theorem 45.21.
Hypotheses. Only $h : (x, y) \neq 0$. Every datum is concrete; the docstring: "The actual physical radical quotient at weight one, with no unproved data as inputs."
Same as / stronger than / weaker than. Stronger than the bare dimension statement of Goddard–Thorn: it is an isometry and is $\mathrm{Aut}(V^\natural)$-equivariant. It is about the *model* sector $V^\natural \otimes F$; the transfer to the vertex algebra $V^\natural \otimes V_{\mathrm{II}_{1,1}}$ is §45.10. No positivity: the form on $V^\natural_{1-xy}$ is `natForm`, which is nondegenerate but not claimed positive.
Could it be vacuous? No. When $xy \geq 2$ both sides are 0, and when $xy = 0$ (one coordinate zero) both are 0 because $V^\natural_1 = 0$; but when $xy = 1$ ($V^\natural_0 = \mathbb{C}$) and when $xy \leq -1$ ($V^\natural_{1-xy} \neq 0$) the theorem is a genuine statement about nonzero spaces, e.g. dim $= 196884$ at $xy = -1$.

Physical meaning

The physical states of the compactified critical string at momentum $r \neq 0$, modulo null states, are in bijection with the internal states at level $1 - r^2/2$, with the same inner products and the same Monster action. This is the light-cone gauge spectrum: no ghosts, no longitudinal excitations, only the 24 "transverse" internal dimensions, here replaced by $V^\natural$.

Proof on paper. Apply Theorem 45.14 to the string sector, using Theorem 45.19 for (F1) and $c = 26$ from Theorem 45.16, to get $\mathcal{P}^1/\mathrm{rad} \cong \mathcal{K}^1/\mathrm{rad}$ isometrically and equivariantly; then apply Theorem 45.21 at $N = 1$. □

What the machine verified

Only $(x, y) \neq 0$. `#print axioms`: standard axioms (`VOA/Moonshine/MoonshineCNAudit8.lean` prints `stringSectorNoGhostEquiv` and its isometry and equivariance lemmas and `stringSectorNoGhost_finrank`).

Trap / dead end

Isometry is at the level of the sector form. The isometry of Theorem 45.22 is for the *contravariant* sector form $B^\natural \otimes B_F$ (same momentum pairs with same momentum). The natural form on the vertex algebra $V^\natural \otimes V_{\mathrm{II}_{1,1}}$ (and on $\mathfrak{m}$) pairs momentum r with $-r$; the two

are related by momentum reversal and a cocycle sign (§45.11). A literal isometry between a sector and the same-momentum part of the vertex algebra *does not exist*: this natural first guess fails, and its failure is a Lean theorem (Theorem 45.32).

45.8.3 Zero momentum

At $r = 0$ the light-cone splitting fails, but the weight-one space is tiny: $V^\natural{}_1 = 0$ and $V^\natural{}_0 = \mathbb{C}\mathbb{1}$, so $H^1_{(0,0)} = \mathbb{1} \otimes F_1 = \mathrm{span}(\mathbb{1} \otimes a_1, \mathbb{1} \otimes b_1)$.

Theorem 45.23 (Zero momentum: the hyperbolic plane). *The weight-one space of $H_{(0,0),0}$ is spanned by $\mathbb{1} \otimes a_1$ and $\mathbb{1} \otimes b_1$, both physical; the radical of the form on $\mathcal{P}^1_{(0,0)}$ is zero; and $\mathcal{P}^1_{(0,0)}/\mathrm{rad} \cong \mathbb{C}^2$ with form $((c_0, c_1), (d_0, d_1)) \mapsto c_0 d_1 + c_1 d_0$ and trivial $\mathrm{Aut}(V^\natural)$-action.*

```

        (vnatStringGroupAction 0 0 0).action_preserves_physical 1 g u) =
      vnatZeroNoGhostEquiv u := by
```

(`VOA/Moonshine/MoonshineCNVnatZeroQuotient.lean`; also `vnatZeroNoGhost_finrank` $= 2$ in `VOA/Moonshine/MoonshineCNV`

From the mathematics to the Lean statement

`X (0, a)` is a_1 for `a = 0` and b_1 for `a = 1`. The coordinates of `vnatZeroNoGhostEquiv` are `vnatZeroWeightCoordinates`: the coordinate a of u is $B^\natural(\mathbb{1}, \text{coefficient of } X(0,a) \text{ in } u)$, so $c_0\,\mathbb{1} \otimes a_1 + c_1\,\mathbb{1} \otimes b_1 \mapsto (c_0, c_1)$ (the normalisation $B^\natural(\mathbb{1}, \mathbb{1}) = 1$ is `natInvForm_normalized`). The form $c_0 d_1 + c_1 d_0$ is the Gram matrix $\left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right)$: $\mathbb{1} \otimes a_1$ and $\mathbb{1} \otimes b_1$ are isotropic and pair to 1 (`vnatZeroBasisVector_form`). No hypotheses; uses $V^\natural{}_1 = 0$ and $V^\natural{}_0 = \mathbb{C}\mathbb{1}$.

Physical meaning

At zero momentum the only weight-one physical states are the two light-cone currents $\partial X^\pm$ (the internal CFT has no currents since $V^\natural{}_1 = 0$): they span the Cartan subalgebra, with the

Lorentzian metric of $\mathrm{II}_{1,1}$, and the Monster acts trivially on them.

Proof on paper. ${V^\natural}_{<0} = 0$ and ${V^\natural}_1 = 0$ leave only $\mathbb{1} \otimes F_1$ at weight one. L_n for $n \geq 2$ maps it to negative weight, hence to 0; $L_1(\mathbb{1} \otimes a_1) = \mathbb{1} \otimes L_1^F a_1$ (as $L_1^\natural \mathbb{1} = 0$), and by the explicit lowering derivation $L_1^F a_1 = \kappa$, $L_1^F b_1 = \ell$, both 0 at zero momentum. The spurious space at weight one is $L_{-1}H^0 = \mathbb{C}L_{-1}(\mathbb{1} \otimes 1) = \mathbb{C}\mathbb{1} \otimes (\kappa b_1 + \ell a_1) = 0$; so the radical, which is $\mathcal{P}^1 \cap \mathcal{S}$, is 0. The automorphisms fix $\mathbb{1}$. □

What the machine verified

No hypotheses; standard axioms (`VOA/Moonshine/MoonshineCNAudit8.lean`).

45.9 The Lie algebra of physical states

45.9.1 Physical states of a near vertex operator algebra

The bracket is defined for an arbitrary near vertex operator algebra V (Chapter 4); the Borcherds identity, commutator formula and skew symmetry for near-VOAs, which the proofs below use, are proved in Chapter 44 (files `MoonshineCNNear*`).

Definition 45.24 (Weight-one primaries, spurious primaries, the physical Lie algebra)**.** Let V be a near-VOA with Virasoro modes L_n. Put

$$P^1(V) := \{v \in V : L_0 v = v,\ L_n v = 0\ (n > 0)\}, \qquad \mathrm{Sp}(V) := \sum_{n \geq 1} L_{-n} V,$$

$\mathrm{Null}^1(V) := P^1(V) \cap \mathrm{Sp}(V)$, and $\mathfrak{g}(V) := P^1(V)/\mathrm{Null}^1(V)$ with $[\bar{u}, \bar{v}] := \overline{u_{(0)}v}$.

(`VOA/Moonshine/MoonshineCNPhysicalLie.lean`, namespace `VOA.NearVOA`; `V.spurious` is `⨆ n : ℕ, LinearMap.range (V.L (-(n + 1 : ℤ)))` from `VOA/Moonshine/MoonshineCNNearConsequences.lean`.)

From the mathematics to the Lean statement

Decoding. `primaryZeroProduct u v` is $u_{(0)}v$, i.e. `V.smul u 0 v = mode (V.Y u) 0 v`, packaged as a bilinear map of P^1 to itself (closure is `primary_zeroMode_closed`). `primarySpurious` is $\mathrm{Sp}(V) \cap P^1$ as a subspace of P^1. `/` is the quotient, `mkQ` the quotient map. The `LieRing` instance takes `primaryLieBracket` as the bracket; its axioms `lie_self` and `leibniz_lie` are discharged by `primary_zeroMode_self_spurious` and `primary_zeroMode_leibniz`.
No form, no central charge. The module docstring: "defined without a bilinear form", and

`primaryLieQuotient`'s: "No form or charge assumption is used." Borcherds defines $\mathfrak{m}$ as P^1 modulo the radical of the form, and Frenkel's "$P^1/L_{-1}P^0$" is a third common description; Remark 45.37 shows that all three agree for $V^\natural \otimes V_{\mathrm{II}_{1,1}}$.

Why $u_{(0)}$. This is the same bracket as on the weight-one space of a vertex operator algebra of CFT type, where $[u,v] = u_{(0)}v$ makes V_1 a Lie algebra (Chapter 5): the zero mode $u_{(0)} = \oint Y(u,z)\,dz$ of a weight-one state is the charge of the current $Y(u,z)$, and $[u_{(0)},v_{(0)}] = (u_{(0)}v)_{(0)}$ by the commutator formula. The only change is that V_1 is replaced by the primaries P^1 (because $V^\natural \otimes V_{\mathrm{II}_{1,1}}$ is not of CFT type and its weight-one space is infinite-dimensional), and one must divide by the null states, which form an ideal.

Physical meaning

Weight-one primaries are conserved currents; their zero modes are conserved charges, and the bracket is the commutator of charges. Spurious primaries (null states) are pure gauge and decouple.

Theorem 45.25 ($\mathfrak{g}(V)$ is a Lie algebra). *For every near-VOA V: (a) $u_{(0)}P^1 \subseteq P^1$ for $u \in P^1$; (b) $u_{(0)}\mathrm{Null}^1 \subseteq \mathrm{Null}^1$ and $(\mathrm{Null}^1)_{(0)}P^1 \subseteq \mathrm{Null}^1$; (c) $u_{(0)}u \in \mathrm{Null}^1$; (d) $u_{(0)}(v_{(0)}w) = (u_{(0)}v)_{(0)}w + v_{(0)}(u_{(0)}w)$. Hence the bracket is well defined, alternating and satisfies the Jacobi identity.*

```
theorem primary_zeroMode_closed (u v : V.primaryWeightOne) :
    V.smul u 0 v ∈ V.primaryWeightOne := by
theorem primarySpurious_right (u v : V.primaryWeightOne) (hv : v ∈ V.primarySpurious) :
    V.primaryZeroProduct u v ∈ V.primarySpurious :=
theorem primarySpurious_left (u v : V.primaryWeightOne) (hu : u ∈ V.primarySpurious) :
    V.primaryZeroProduct u v ∈ V.primarySpurious := by
theorem primary_zeroMode_self_spurious (u : V.primaryWeightOne) :
    V.primaryZeroProduct u u ∈ V.primarySpurious := by
theorem primary_zeroMode_leibniz (u v w : V.primaryWeightOne) :
    V.primaryZeroProduct u (V.primaryZeroProduct v w) =
      V.primaryZeroProduct (V.primaryZeroProduct u v) w +
        V.primaryZeroProduct v (V.primaryZeroProduct u w) := by
```

(`VOA/Moonshine/MoonshineCNPhysicalLie.lean`.)

Physical meaning

Charges of conserved currents form a Lie algebra under commutation, and gauge (null) currents form an ideal.

Proof on paper. For $u \in P^1$ the commutator formula with ω gives $[L_m,u_{(n)}] = -n\,u_{(m+n)}$ (because $L_0u = u$, $L_ju = 0$ for $j \geq 1$, and $(L_{-1}u)_{(k)} = -ku_{(k-1)}$); at $n = 0$, $u_{(0)}$ commutes with every L_m (`primary_zeroMode_commutes`). Hence $u_{(0)}$ preserves P^1 (it preserves weights) and preserves Sp ($u_{(0)}L_{-n}y = L_{-n}u_{(0)}y$): (a) and the first half of (b). Skew symmetry at $n = 0$ gives $v_{(0)}u = -u_{(0)}v + \sum_{j\geq 1}(-1)^{j+1}L_{-1}^j(u_{(j)}v)/j!$, so $u_{(0)}v + v_{(0)}u \in$ Sp; this gives (c) (take $v = u$: $2u_{(0)}u \in$ Sp) and the second half of (b). (d) is the commutator formula at $m = n = 0$: $[u_{(0)},v_{(0)}] = (u_{(0)}v)_{(0)}$. □

What the machine verified

No hypotheses beyond V; standard axioms (`VOA/Moonshine/MoonshineCNAudit10.lean`).

Functoriality. A linear map f of V commuting with all L_n preserves P^1 and Sp and induces a linear map of $\mathfrak{g}(V)$ (`primaryQuotientMap`); an invertible such map that also preserves $u_{(0)}v$ induces a Lie algebra automorphism:

```
noncomputable def primaryQuotientLieEquiv (e : H ≃ₗ[ℂ] H)
    (he : ∀ (n : ℤ) (v : H), e (V.L n v) = V.L n (e v))
    (hzero : ∀ u v : H, e (V.smul u 0 v) = V.smul (e u) 0 (e v)) :
    V.primaryLieQuotient ≃ₗ[ℂ] V.primaryLieQuotient := by
```

(`VOA/Moonshine/MoonshineCNPhysicalMaps.lean`; `≃ₗ[ℂ]` is a Lie algebra isomorphism.)

Physical meaning

A global symmetry of the string background acts on the gauge algebra by automorphisms.

45.9.2 The Monster Lie algebra

Definition 45.26 (The Monster Lie algebra). $\mathfrak{m} := \mathfrak{g}(V^\natural \otimes V_{\mathrm{II}_{1,1}}) = P^1/(P^1 \cap \mathrm{Sp})$ for the matter near-VOA $V^\natural \otimes V_{\mathrm{II}_{1,1}}$ of Chapter 44 (central charge 26).

```
abbrev monsterLieAlgebra := moonshineMatterNearVOA.primaryLieQuotient
instance monsterLieRing : LieRing monsterLieAlgebra := inferInstance
instance monsterLieAlgebraComplex : LieAlgebra ℂ monsterLieAlgebra := inferInstance
def monsterLieProjection : moonshineMatterNearVOA.primaryWeightOne →ₗ[ℂ] monsterLieAlgebra
 ↪  :=
  moonshineMatterNearVOA.primarySpurious.mkQ
```

(`VOA/Moonshine/MoonshineCNMonsterLie.lean`.) The matter near-VOA is

```
abbrev moonshineMatterSpace := Vnat ⊗[ℂ] LorentzianFockSpace
noncomputable def moonshineMatterNearVOA : NearVOA moonshineMatterSpace :=
  nearTensorVOA VnatVOA.toNearVOA lorentzianNearVOA
```

(`VOA/Moonshine/MoonshineCNTensorRealization.lean`, Chapter 44; its central charge is 26, `moonshineMatterNearVOA_cer`

From the mathematics to the Lean statement

`LorentzianFockSpace` is the lattice Fock space $\bigoplus_{r\in \mathrm{II}_{1,1}} S(\hat{\mathfrak{h}}^-)\otimes e^r$ of $V_{\mathrm{II}_{1,1}}$; `nearTensorVOA` is the tensor product of near-VOAs with the total grading and the conformal vector $\omega^\natural\otimes\mathbb{1}+\mathbb{1}\otimes\omega_L$. So `monsterLieAlgebra` is literally $P^1/(P^1\cap\mathrm{Sp})$ of $V^\natural\otimes V_{\mathrm{II}_{1,1}}$. The `inferInstance` lines say that the Lie structure is the one of Theorem 45.25.
Could it be trivial? No: Theorems 45.30 and 45.31 below identify its graded pieces with ${V^\natural}_{1-xy}$ and $\mathbb{C}^2$; and the bracket is nonzero, since the Cartan part acts on $\mathfrak{m}_{(x,y)}$ by the nonzero scalars of Theorem 45.39.

Physical meaning

The gauge algebra of the critical bosonic string compactified on the Monster CFT times the two-dimensional Lorentzian torus $\mathbb{R}^{1,1}/\mathrm{II}_{1,1}$.

What the machine verified

Definition; `#print axioms monsterLieAlgebra` standard (`VOA/Moonshine/MoonshineCNAudit10.lean`).

45.9.3 The momentum grading

Theorem 45.27 ($\mathfrak{m}$ is $\mathrm{II}_{1,1}$-graded). *Let $\mathfrak{m}_r$ be the image in $\mathfrak{m}$ of the physical states of momentum r. Then $\mathfrak{m} = \bigoplus_{r \in \mathrm{II}_{1,1}} \mathfrak{m}_r$ (internal direct sum) and $[\mathfrak{m}_r, \mathfrak{m}_s] \subseteq \mathfrak{m}_{r+s}$.*

```
def monsterLieMomentum (α : lorentzianLattice.carrier) : Submodule ℂ monsterLieAlgebra :=
  ((moonshineMatterMomentum α).comap moonshineMatterNearVOA.primaryWeightOne.subtype).map
    monsterLieProjection
theorem monsterLieMomentum_bracket (α β : lorentzianLattice.carrier)
    (u v : monsterLieAlgebra) (hu : u ∈ monsterLieMomentum α)
    (hv : v ∈ monsterLieMomentum β) : ⁅u, v⁆ ∈ monsterLieMomentum (α + β) := by
```

(VOA/Moonshine/MoonshineCNMonsterLie.lean.)

```
theorem monsterLieMomentum_isInternal : DirectSum.IsInternal monsterLieMomentum := by
```

(VOA/Moonshine/MoonshineCNMonsterGrading.lean.)

From the mathematics to the Lean statement

`moonshineMatterMomentum α` is $V^\natural \otimes (S(\hat{\mathfrak{h}}^-) \otimes e^\alpha)$ (Chapter 44). So `monsterLieMomentum α` is the image of $P^1 \cap$ (momentum α); the docstring of `monsterLieMomentum_isInternal`: "The quotient is the direct sum of its momentum subspaces, not merely their span."

Physical meaning

Momentum conservation: the charge of momentum r maps momentum-s states to momentum $r + s$.

Proof on paper. ω has momentum 0 (`moonshineMatterConformal_momentum`), so every L_n preserves momentum and commutes with the projections π_α onto momentum components (`matterMomentumComponent_`). Hence π_α preserves P^1 and Sp and descends to an idempotent `monsterLieMomentumComponent α` on $\mathfrak{m}$ with image $\mathfrak{m}_\alpha$; these idempotents are orthogonal and sum (pointwise finitely) to the identity, which is internal directness. Momenta add under $u_{(0)}$ because $e^\alpha_{(n)} e^\beta \in e^{\alpha+\beta}$-sector. □

What the machine verified

No hypotheses; standard axioms (VOA/Moonshine/MoonshineCNAudit10.lean).

45.9.4 The action of $\mathrm{Aut}(V^\natural)$

Theorem 45.28 ($\mathrm{Aut}(V^\natural)$ acts on $\mathfrak{m}$ by graded Lie automorphisms). *$g \mapsto (\bar{u} \mapsto \overline{(g \otimes 1)u})$ is a group homomorphism $\mathrm{Aut}(V^\natural) \to \mathrm{Aut}_{\mathrm{Lie}}(\mathfrak{m})$ preserving every $\mathfrak{m}_r$.*

```
def moonshineMatterAut : AutVnat →* (moonshineMatterSpace ≃ₗ[ℂ] moonshineMatterSpace) where
  toFun g := g.toLinearEquiv.rTensor LorentzianFockSpace
def monsterLieAut : AutVnat →* (monsterLieAlgebra ≃ₗ[ℂ] monsterLieAlgebra) where
  toFun g := moonshineMatterNearVOA.primaryQuotientLieEquiv (moonshineMatterAut g)
    (moonshineMatterAut_virasoro g) (fun u v => by
      simpa only [NearVOA.smul_def, mode_apply, neg_zero, zero_sub]
        using moonshineMatterAut_field g u v (-1))
theorem monsterLieAut_momentum (g : AutVnat) (α : lorentzianLattice.carrier)
    (u : monsterLieAlgebra) (hu : u ∈ monsterLieMomentum α) :
    monsterLieAut g u ∈ monsterLieMomentum α := by
```

(VOA/Moonshine/MoonshineCNMonsterLie.lean.)

From the mathematics to the Lean statement

`g.toLinearEquiv.rTensor LorentzianFockSpace` is $g \otimes 1$. The two side conditions passed to `primaryQuotientLieEquiv` are: $g \otimes 1$ commutes with every L_n (`moonshineMatterAut_virasoro`, as g fixes $\omega^\natural$) and with all fields (`moonshineMatterAut_field`, as g is a VOA automorphism); here only the zero product $u_{(0)}v$ is needed, written via the raw coefficient index -1 by the convention `mode f n = f (-n - 1)`. `→*` is a group homomorphism (with the group structure `monsterLieAutomorphismGroup` on Lie automorphisms).

Physical meaning

The Monster acts as global symmetry of the string background, hence on its gauge algebra.

What the machine verified

No hypotheses; standard axioms (`VOA/Moonshine/MoonshineCNAudit10.lean`).

45.10 Root spaces: from the sector model to the vertex algebra

45.10.1 The sector equivalence

Chapter 44 constructs, for each momentum α, a linear isomorphism `moonshineMatterSectorEquiv α : (Vnat ⊗[ℂ] hypFock) ≃ₗ[ℂ] moonshineMatterMomentum α`: $1_{V^\natural}$ tensored with the change of polynomial variables from the isotropic coordinates (a_j, b_j) to the complex orthonormal frame coordinates of the lattice Fock space (`hypLorentzianPolynomialEquiv`: $a_j \mapsto \frac{1}{2}X_{0,j} - \frac{i}{2}X_{1,j}$, $b_j \mapsto X_{0,j} + iX_{1,j}$), followed by insertion of e^α. The files `SectorFrame`, `SectorOscillators`, `SectorVirasoroOperators` and `SectorVirasoroComparison` of this chapter prove that this map intertwines everything relevant.

Theorem 45.29 (Sector comparison). *For all $x, y, n, N \in \mathbb{Z}$, writing $\Psi =$ `moonshineMatterSectorMap ![x, y]`: (a) $\Psi \circ L_n^{sector} = L_n^{V^\natural \otimes V_{\mathrm{II}_{1,1}}} \circ \Psi$; (b) Ψu has weight N iff $u \in H^N_{(x,y)}$; (c) Ψu is spurious in $V^\natural \otimes V_{\mathrm{II}_{1,1}}$ iff u is spurious in the sector; (d) Ψu is a weight-one primary iff $u \in H^1_{(x,y)} \cap \mathcal{P}$.*

```
theorem moonshineMatterSectorMap_virasoro (x y n : ℤ) (u : Vnat ⊗[ℂ] hypFock) :
    moonshineMatterSectorMap ![x, y] (vnatHypMode x y n u) =
      moonshineMatterNearVOA.L n (moonshineMatterSectorMap ![x, y] u) := by
theorem moonshineMatterSector_weight_iff (x y N : ℤ) (u : Vnat ⊗[ℂ] hypFock) :
    moonshineMatterSectorMap ![x, y] u ∈ moonshineMatterNearVOA.grading N ↔
      u ∈ vnatSectorWeight x y N := by
```

(`VOA/Moonshine/MoonshineCNSectorVirasoroComparison.lean`.)

```
theorem moonshineMatterSector_spurious_iff (x y : ℤ) (a : Fin 2)
    (u : Vnat ⊗[ℂ] hypFock) :
    moonshineMatterSectorMap ![x, y] u ∈ moonshineMatterNearVOA.spurious ↔
      u ∈ (vnatStringModule x y a).spurious := by
theorem moonshineMatterSector_primary_iff (x y : ℤ) (a : Fin 2)
    (u : Vnat ⊗[ℂ] hypFock) :
    moonshineMatterSectorMap ![x, y] u ∈ moonshineMatterNearVOA.primaryWeightOne ↔
      u ∈ vnatSectorWeight x y 1 ∧ u ∈ (vnatStringModule x y a).physical := by
```

(`VOA/Moonshine/MoonshineCNSectorPhysicalTransfer.lean`.)

From the mathematics to the Lean statement

What is compared. On the left, the explicit sector operators (§45.7); on the right, the Virasoro modes of the actual vertex algebra $V^\natural \otimes V_{\mathrm{II}_{1,1}}$, whose Lorentzian part on momentum α is, by `lorentzianSectorVirasoro_apply`, the Heisenberg Sugawara operator plus the momentum-coupling term $\alpha(n)$ plus $\frac{1}{2}(\alpha,\alpha)\delta_{n,0}$. (a) for $n \geq 0$ is a computation on generators (`hypLorentzianPolynomial_virasoro_nonnegative`); negative modes follow from adjointness (`hypLorentzianPolynomial_virasoro`: "Every integer mode, with negative modes recovered by the proved bilinear adjoints"). (b) is "total weight = matter weight + level $+xy$". (c): the docstring "Global negative descendants intersect a momentum sector in precisely its own descendants"; the proof uses the left inverse `moonshineMatterSectorRetract`, which is Ψ^{-1} composed with the momentum projection and intertwines the L_n. The family a in (c), (d) is arbitrary (the spurious and physical spaces do not depend on K).

Physical meaning

The momentum-r sector of the compactified string, written in light-cone oscillators, is exactly the model Fock space: changing from Cartesian to null coordinates of the two light-cone bosons.

What the machine verified

No hypotheses; standard axioms (`VOA/Moonshine/MoonshineCNAudit11.lean`).

45.10.2 The root spaces

Theorem 45.30 (Root spaces of $\mathfrak{m}$). *For every (x,y) and family a, the map $\mathcal{P}^1_{(x,y)} \to \mathfrak{m}_{(x,y)}$, $u \mapsto \overline{\Psi u}$, is surjective with kernel the radical; so $\mathcal{P}^1_{(x,y)}/\mathrm{rad} \cong \mathfrak{m}_{(x,y)}$, $\mathrm{Aut}(V^\natural)$-equivariantly. Consequently, for $(x,y) \neq 0$,*

$$\mathfrak{m}_{(x,y)} \;\cong\; {V^\natural}_{1-xy} \qquad \text{as } \mathrm{Aut}(V^\natural)\text{-modules.}$$

```
theorem monsterLieSectorProjection_surjective (x y : ℤ) (a : Fin 2) :
    Function.Surjective (monsterLieSectorProjection x y a) := by
theorem monsterLieSectorProjection_ker (x y : ℤ) (a : Fin 2) :
    LinearMap.ker (monsterLieSectorProjection x y a) =
      (vnatStringModule x y a).weightRadical (vnatStringModule x y a).physical 1 := by
def monsterLieSectorQuotientEquiv (x y : ℤ) (a : Fin 2) :
    (vnatStringModule x y a).weightRadicalQuotient (vnatStringModule x y a).physical 1
    ↪ ≃ₗ[ℂ]
      monsterLieMomentum ![x, y] :=
def monsterLieRootSpaceEquiv (x y : ℤ) (h : x ≠ 0 ∨ y ≠ 0) :
    monsterLieMomentum ![x, y] ≃ₗ[ℂ] VnatVOA.grading (1 - x * y) :=
  (monsterLieSectorQuotientEquiv x y (stringSectorFamily x y h)).symm.trans
    (stringSectorNoGhostEquiv x y h)
```

(`VOA/Moonshine/MoonshineCNRootSpaces.lean`.)

```
theorem monsterLieRootSpaceEquiv_equivariant (x y : ℤ) (h : x ≠ 0 ∨ y ≠ 0)
    (g : AutVnat) (u : monsterLieMomentum ![x, y]) :
    monsterLieRootSpaceEquiv x y h
      ⟨monsterLieAut g u, monsterLieAut_momentum g _ u u.property⟩ =
      GriessAut.autRestrict g (1 - x * y) (monsterLieRootSpaceEquiv x y h u) := by
```

(`VOA/Moonshine/MoonshineCNRootSpaceAction.lean`.)

From the mathematics to the Lean statement

Decoding. `monsterLieSectorProjection x y a` sends a weight-one physical vector u of the sector to the class of Ψu in $\mathfrak{m}_{(x,y)}$ (it is a primary by Theorem 45.29(d)). The kernel statement uses (c) and Theorem 45.6: Ψu is spurious iff $u \in \mathcal{P}^1 \cap \mathcal{S} = \mathrm{rad}$ (`vnatPhysicalRadical_mem_iff`). `monsterLieRootSpaceEquiv` composes the inverse with the no-ghost isomorphism. The equivariance is with respect to the *actual* actions: `monsterLieAut g` on $\mathfrak{m}$ and $g|_{V^\natural_{1-xy}}$, and the docstring says "with no additional hypotheses".

Weaker than Borcherds' statement in one respect. The isomorphism is linear and equivariant; an *isometry* statement for it is not made at the level of $\mathfrak{m}$, because the natural form on $\mathfrak{m}$ pairs $\mathfrak{m}_r$ with $\mathfrak{m}_{-r}$, not $\mathfrak{m}_r$ with itself (§45.11). The isometry is available at the sector level (Theorem 45.22).

Momentum convention. Repository coordinates, norm $2xy$. The Borcherds form is `monsterLieBorcherdsRootEquiv` (§45.13).

Physical meaning

The gauge bosons of momentum $r \neq 0$ are labelled by the internal states of level $1 - r^2/2$; the Monster acts on them as on $V^\natural_{1-r^2/2}$. The real roots ($r^2 = 2$) give $V^\natural_0 = \mathbb{C}$, one state; the imaginary roots of norm -2 give $V^\natural_2$, the 196884-dimensional Griess algebra.

What the machine verified

No hypotheses beyond $(x, y) \neq 0$; standard axioms (`VOA/Moonshine/MoonshineCNAudit11.lean`).

Theorem 45.31 (The zero root space). $\mathfrak{m}_0 \cong \mathbb{C}^2$, *the isomorphism sending the class of* $c_0\,\mathbb{1} \otimes a_1 + c_1\,\mathbb{1} \otimes b_1$ *(transported to the vertex algebra) to* (c_0, c_1).

```
def monsterLieZeroMomentumEquiv : monsterLieMomentum 0 ≃ₗ[ℂ] (Fin 2 → ℂ) :=
  monsterLieZeroMomentumTransport.symm.trans
    ((monsterLieSectorQuotientEquiv 0 0 0).symm.trans vnatZeroNoGhostEquiv)
```

(`VOA/Moonshine/MoonshineCNRootSpaces.lean`; `monsterLieZeroMomentumTransport` only rewrites `![0, 0]` as `0`.)

Physical meaning

The Cartan subalgebra is spanned by the two light-cone momentum currents.

What the machine verified

No hypotheses; standard axioms (`VOA/Moonshine/MoonshineCNAudit11.lean`).

45.11 The invariant form on the Monster Lie algebra

45.11.1 Two forms and momentum reversal

The vertex algebra $V^\natural \otimes V_{\mathrm{II}_{1,1}}$ carries the form `moonshineMatterForm := natForm.tmul lorentzianBilinearForm` (Chapter 44), whose lattice factor pairs e^α with $e^{-\alpha}$ (an "FHL" type invariant form). The sector form $B^\natural \otimes B_F$ pairs a momentum sector with itself. These cannot be matched directly:

Theorem 45.32 (No same-momentum isometry). *For* $\alpha \neq 0$*: the matter form vanishes on momentum* α *against momentum* β *unless* $\alpha + \beta = 0$*; in particular every nonzero momentum sector is totally isotropic; and there is no map* F *from the sector to the momentum-*α *part and no nonzero scalar* c *with* $\langle Fu, Fv\rangle = c\,B(u, v)$ *for all* u, v.

```
theorem moonshineMatterForm_momentum_orthogonal (α β : lorentzianLattice.carrier)
    (hαβ : α + β ≠ 0) (u v : moonshineMatterSpace)
    (hu : u ∈ moonshineMatterMomentum α) (hv : v ∈ moonshineMatterMomentum β) :
    moonshineMatterForm u v = 0 := by
theorem moonshineMatterSector_no_same_momentum_isometry (α : lorentzianLattice.carrier)
    (hα : α ≠ 0) (c : ℂ) (hc : c ≠ 0)
    (F : (Vnat ⊗[ℂ] hypFock) → moonshineMatterMomentum α) :
    ¬ (∀ u v, moonshineMatterInvariantForm.form (F u) (F v) = c * vnatHypForm u v) := by
```

(VOA/Moonshine/MoonshineCNSectorFormConvention.lean.)

Trap / dead end

A natural guess that fails, recorded in Lean. One is tempted to identify the no-ghost sector form with the vertex-algebra form on the same momentum; `moonshineMatterSector_no_same_momentum_isometry` proves this is impossible, even for non-linear F (the docstring: "This rules out the literal same-momentum isometry even without imposing linearity"). Reason: the sector form is nondegenerate, the target form is identically zero on a nonzero momentum sector. The fix is *momentum reversal*.

Physical meaning

The BPZ (Belavin–Polyakov–Zamolodchikov) two-point pairing $\langle\phi_r|\phi_s\rangle$ is nonzero only when momentum is conserved, $r + s = 0$; a state of momentum $r \neq 0$ has zero BPZ overlap with every state of the same momentum. The physicist's Hermitian norm of a state needs a conjugation that reverses momentum. (All forms in the Lean statements are complex *bilinear*; "Hermitian" in these boxes refers to the physical inner product, which is such a bilinear form composed with a real structure, and is never used mathematically.)

What the machine verified

No hypotheses beyond $\alpha \neq 0$, $c \neq 0$; standard axioms (`VOA/Moonshine/MoonshineCNAudit9.lean`).

Theorem 45.33 (Comparison through momentum reversal). *Let θ be momentum reversal on the lattice factor (*`moonshineMatterReversal`*, $1 \otimes \theta_L$ with θ_L the lift of -1 of Chapter 44). For every momentum α (including 0) and all u, v in the sector,*

$$\langle \theta\, \Psi_\alpha u,\ \Psi_\alpha v\rangle = \epsilon(\alpha)\, B(u,v), \qquad \epsilon(\alpha) = \texttt{chSign lorentzianLattice } \alpha \in \{\pm 1\},$$

and the reversed pairing $(u,v) \mapsto \langle \theta u, v\rangle$ is nondegenerate on each momentum sector.

```
theorem moonshineMatterSector_form (α : lorentzianLattice.carrier)
    (u v : Vnat ⊗[ℂ] hypFock) :
    moonshineMatterForm
      (moonshineMatterReversal (moonshineMatterSectorEquiv α u))
      (moonshineMatterSectorEquiv α v) =
      chSign lorentzianLattice α * vnatHypForm u v := by
theorem moonshineMatterSector_form_nondegenerate (α : lorentzianLattice.carrier)
    (u : moonshineMatterMomentum α)
    (hu : ∀ v : moonshineMatterMomentum α,
      moonshineMatterForm (moonshineMatterReversal u) v = 0) : u = 0 := by
```

(VOA/Moonshine/MoonshineCNSectorFormComparison.lean.)

From the mathematics to the Lean statement

`chSign lorentzianLattice α` is the cocycle sign of the lattice form (`VOA/Moonshine/NondegLattice.lean`): in a lattice vertex algebra the vertex operators e^α carry signs $\varepsilon(\alpha,\beta) = \pm 1$ (a 2-cocycle, Chapter 44), and the invariant form pairs e^α with $e^{-\alpha}$ with a value ± 1 determined by these signs; that value is $\epsilon(\alpha)$; `moonshineMatterForm_opposite_ground` computes it on ground states. The comparison is "with the charge sign retained" (file docstring). The oscillator part uses `hypLorentzianPolynomial_form`: reversal turns the negative-sign orthonormal Fock form into the hyperbolic monomial form `hypForm`.

Physical meaning

The BPZ (FHL) inner product pairs in-states of momentum r with out-states of momentum $-r$; the Hermitian (contravariant) inner product is obtained by composing with a conjugation that reverses momentum, here θ. The two forms differ exactly by θ and a cocycle sign.

What the machine verified

No hypotheses; standard axioms (`VOA/Moonshine/MoonshineCNAudit9.lean`, `VOA/Moonshine/MoonshineCNAudit11.lean`).

Theorem 45.34 (The physical radical in each sector). *For a weight-one primary u of momentum (x,y) (any (x,y), including 0): u is spurious iff $\langle \theta u, v\rangle = 0$ for every weight-one primary v of momentum (x,y).*

```
theorem moonshineMatterSector_physical_radical (x y : ℤ) (u : moonshineMatterSpace)
    (hup : u ∈ moonshineMatterNearVOA.primaryWeightOne)
    (hum : u ∈ moonshineMatterMomentum ![x, y]) :
    u ∈ moonshineMatterNearVOA.spurious ↔
      ∀ v : moonshineMatterSpace, v ∈ moonshineMatterNearVOA.primaryWeightOne →
        v ∈ moonshineMatterMomentum ![x, y] →
          moonshineMatterForm (moonshineMatterReversal u) v = 0 := by
```

(`VOA/Moonshine/MoonshineCNRootRadical.lean`.)

Physical meaning

A physical state is null iff it has zero (Hermitian) overlap with every physical state of the same momentum.

Proof on paper. Transport through Ψ (Theorem 45.29) to the sector; there, by Theorem 45.33, the reversed pairing is $\pm B$, and by Theorem 45.6 the radical of B on $\mathcal{P}^1$ is $\mathcal{P}^1 \cap \mathcal{S}$. □

What the machine verified

No hypotheses; standard axioms (`VOA/Moonshine/MoonshineCNAudit11.lean`).

45.11.2 The form on $\mathfrak{m}$

Definition 45.35 (The Monster Lie algebra form). $(\bar u, \bar v) := -\langle u, v\rangle$ for weight-one primaries u, v of $V^\natural \otimes V_{\mathrm{II}_{1,1}}$.

```
def monsterPhysicalBilinearForm : LinearMap.BilinForm ℂ
 ↪  moonshineMatterNearVOA.primaryWeightOne :=
```

```
  -(moonshineMatterForm.restrict moonshineMatterNearVOA.primaryWeightOne)
def monsterLieBilinearForm : LinearMap.BilinForm ℂ monsterLieAlgebra :=

(VOA/Moonshine/MoonshineCNMonsterForm.lean.)

From the mathematics to the Lean statement

`liftQ₂` descends a bilinear form to the quotient in both arguments, given that the subspace is in the left and right kernels: `monsterPhysicalBilinearForm_left_null`, `_right_null`, which rest on `moonshineMatterForm_spurious_primary` ($\langle L_{-n}y, v\rangle = \langle y, L_n v\rangle = 0$ for a primary v). The *sign* -1 is a normalisation, chosen so that the form on the Cartan subalgebra is the lattice form (Theorem 45.38; the file docstring: "The sign is chosen for the lattice normalization on the Cartan space").

Physical meaning

The Killing-type form of the gauge algebra, given by the two-point function of the currents.

What the machine verified

No hypotheses; standard axioms (VOA/Moonshine/MoonshineCNAudit11.lean).

Theorem 45.36 (Root pairing, nondegeneracy, and the radical). *(a)* $(\mathfrak{m}_\alpha, \mathfrak{m}_\beta) = 0$ *unless* $\alpha + \beta = 0$. *(b) For every* α *(including* 0*), the pairing* $\mathfrak{m}_\alpha \times \mathfrak{m}_{-\alpha} \to \mathbb{C}$ *is nondegenerate on the left. (c) The form on* $\mathfrak{m}$ *is nondegenerate. ```

(VOA/Moonshine/MoonshineCNMonsterRadical.lean.)

From the mathematics to the Lean statement

`.Nondegenerate` for a bilinear form is Mathlib's `LinearMap.Nondegenerate`: separating on the left *and* on the right. (d) is the docstring's "The original vertex-space form has exactly the physical spurious radical". All four are unconditional.

Physical meaning

Every gauge boson of momentum r has a partner of momentum $-r$ with nonzero two-point function.

Proof on paper. (a) from Theorem 45.32. (b): let $p \in P^1_\alpha$ pair to zero with $\mathfrak{m}_{-\alpha}$. For any $v \in P^1_\alpha$, $\theta v \in P^1_{-\alpha}$ (`moonshineMatterReversal_primary`, momentum reversed), so $0 = \langle p, \theta v\rangle = \langle \theta p, v\rangle$ (θ is self-adjoint); by Theorem 45.34, p is spurious, i.e. $\bar{p} = 0$. (c): decompose by momentum (Theorem 45.27), apply (a), (b). (d): (c) lifted to P^1. □

What the machine verified

No hypotheses; standard axioms (`VOA/Moonshine/MoonshineCNAudit11.lean`).

Remark 45.37 (Three descriptions of $\mathfrak{m}$). Let P^0 be the weight-zero vectors killed by all L_n, $n \geq 1$, and $R := \{u \in P^1 : \langle u, P^1\rangle = 0\}$ the radical. The literature uses three quotients of P^1:

(a) $P^1/(P^1 \cap \mathrm{Sp})$ (this chapter), (b) P^1/R (Borcherds), (c) $P^1/(L_{-1}P^0 + R)$ (Frenkel; Borcherds' "$P^1/L_{-1}P^0$ mo

They coincide. First, $L_{-1}P^0 \subseteq P^1 \cap \mathrm{Sp}$: for $p \in P^0$, $L_{-1}p$ has weight one and is spurious, and $L_1 L_{-1}p = L_{-1}L_1 p + 2L_0 p = 0$, $L_2 L_{-1}p = L_{-1}L_2 p + 3L_1 p = 0$, so $L_{-1}p$ is primary (Theorem 45.7(b) in a string module, or the same two-generator argument in V). Second, $P^1 \cap \mathrm{Sp} = R$ by Theorem 45.36(d). Hence $L_{-1}P^0 + R = R = P^1 \cap \mathrm{Sp}$ and (a) = (b) = (c). At weight one, spurious means $\mathrm{Sp} \cap V_1 = L_{-1}V_0 + L_{-2}V_{-1}$ (Theorem 45.7(a)); the $L_{-2}V_{-1}$ part is why (c) needs "$+R$": at $c = 26$ the null states $\tilde{L}_{-2}y$ of §45.5 are not of the form $L_{-1}P^0$ in general. Only (a) and (b) are Lean statements (the definition, and `moonshineMatterPrimary_radical`); the inclusion $L_{-1}P^0 \subseteq P^1 \cap \mathrm{Sp}$ is the elementary computation just given and is not separately formalized.

Theorem 45.38 (The form on the Cartan subalgebra is the lattice form). *For $u, v \in \mathfrak{m}_0$ with coordinates $c = (c_0, c_1)$, $d = (d_0, d_1)$ under Theorem 45.31:* $(u, v) = c_0 d_1 + c_1 d_0$. $\mathrm{Aut}(V^\natural)$ *acts trivially on* $\mathfrak{m}_0$.

```
theorem monsterLieBilinearForm_zeroMomentum (u v : monsterLieMomentum 0) :
    monsterLieBilinearForm u v =
      monsterLieZeroMomentumEquiv u 0 * monsterLieZeroMomentumEquiv v 1 +
      monsterLieZeroMomentumEquiv u 1 * monsterLieZeroMomentumEquiv v 0 := by
theorem monsterLieZeroMomentum_aut_trivial (g : AutVnat) (u : monsterLieMomentum 0) :
    monsterLieAut g u = (u : monsterLieAlgebra) := by
```

(`VOA/Moonshine/MoonshineCNMonsterZeroForm.lean`.)

From the mathematics to the Lean statement

At zero momentum θ acts by -1 on the weight-one states $\mathbb{1} \otimes h(-1)e^0$ (`moonshineMatterReversal_zeroWeight`), which is why the sign -1 in Definition 45.35 makes the form equal to the sector form there (`moonshineMatterSector_zeroWeight_form`). In coordinates the Gram matrix is $\left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right)$, the form (45.1) of $\mathrm{II}_{1,1}$ under $(c_0, c_1) \mapsto (c_1, c_0)$ (see the next theorem for why the coordinates are swapped).

Physical meaning

The two-point function of the momentum currents $\partial X^{\pm}$ is the spacetime metric.

What the machine verified

No hypotheses; standard axioms (`VOA/Moonshine/MoonshineCNAudit11.lean`).

Theorem 45.39 (The Cartan action). *If $h \in \mathfrak{m}_0$ has coordinates (c_0, c_1) and $x \in \mathfrak{m}_\beta$, then $[h, x] = (c_0\beta_0 + c_1\beta_1)\,x$.*

```
theorem monsterLie_zeroMomentum_bracket (h : monsterLieMomentum 0)
    (β : lorentzianLattice.carrier) (x : monsterLieAlgebra) (hx : x ∈ monsterLieMomentum β)
    ↪ :
    ⁅(h : monsterLieAlgebra), x⁆ =
      (monsterLieZeroMomentumEquiv h 0 * (β 0 : ℂ) + monsterLieZeroMomentumEquiv h 1 * (β 1
      ↪ : ℂ)) •
        x := by
```

(`VOA/Moonshine/MoonshineCNMonsterCartanAction.lean`.)

From the mathematics to the Lean statement

`β 0`, `β 1` are the two coordinates (x, y) of the momentum. The coordinate c_0 belongs to $\mathbb{1} \otimes a_1$, the current of the isotropic vector $w_0 = (0,1)$, and c_1 to $\mathbb{1} \otimes b_1$, the current of $w_1 = (1,0)$. So h corresponds to the lattice vector $\lambda(h) = c_0(0,1) + c_1(1,0) = (c_1, c_0)$, and $(\lambda(h), (\beta_0, \beta_1)) = c_1\beta_1 + c_0\beta_0$ by (45.1): the statement says $[h, x] = (\lambda(h), \beta)x$, the expected Cartan action. The proof evaluates the zero modes of the actual hyperbolic Heisenberg currents (`lorentzianHyperbolicCurrent_zeroMode`: "multiplies momentum `β` by `β a`").

Physical meaning

The zero mode of the current ∂X^{μ} is the momentum operator p^{μ}.

What the machine verified

No hypotheses; standard axioms (`VOA/Moonshine/MoonshineCNAudit17.lean`).

45.11.3 Invariance

Theorem 45.40 (Invariance of the form). *$([u, v], w) = (u, [v, w])$ for all $u, v, w \in \mathfrak{m}$.*

```
theorem monsterLieBilinearForm_invariant (u v w : monsterLieAlgebra) :
    monsterLieBilinearForm ⁅u, v⁆ w = monsterLieBilinearForm u ⁅v, w⁆ :=
  monsterLieBilinearForm_invariant_of_oppositeIterate
    moonshineMatterNearVOA_oppositeIterateIdentity u v w
theorem moonshineMatterForm_primary_zeroMode_skew
    (a : moonshineMatterNearVOA.primaryWeightOne) (b c : moonshineMatterSpace) :
    moonshineMatterForm (moonshineMatterNearVOA.smul a 0 b) c =
      -moonshineMatterForm b (moonshineMatterNearVOA.smul a 0 c) := by
```

(`VOA/Moonshine/MoonshineCNMonsterLieInvariance.lean`.)

```
theorem monsterLieBilinearForm_invariant_of_primaryAdjoint
    (hAdj : ∀ a b c : moonshineMatterNearVOA.primaryWeightOne,
      moonshineMatterForm (moonshineMatterNearVOA.smul a 0 b) c =
        -moonshineMatterForm b (moonshineMatterNearVOA.smul a 0 c))
    (u v w : monsterLieAlgebra) :
    monsterLieBilinearForm ⁅u, v⁆ w = monsterLieBilinearForm u ⁅v, w⁆ := by
```

(`VOA/Moonshine/MoonshineCNMonsterPairing.lean`.)

From the mathematics to the Lean statement

No hypotheses. The headline is a one-line composition: the general reduction (invariance follows from skew-adjointness of zero modes of weight-one primaries) applied to the proved *opposite iterate identity* of the matter near-VOA, `moonshineMatterNearVOA_oppositeIterateIdentity`, which is `NearVOA.oppositeIterateIdentity_of_locallyNilpotent` (Chapter 44) fed with the local nilpotence of L_1 (`moonshineMatterVirasoroOne_locallyNilpotent`). Its consequence `moonshineMatterOppositeModes_adjoint` says that every field of $V^\natural \otimes V_{\mathrm{II}_{1,1}}$ is adjoint to its FHL "opposite" field $Y(e^{zL_1}(-z^{-2})^{L_0}u, z^{-1})$. (An *FHL-invariant* form is one for which $\langle Y(u,z)a, b\rangle = \langle a, Y(e^{zL_1}(-z^{-2})^{L_0}u, z^{-1})b\rangle$; the right-hand field is the "opposite" field of u, and the identity says that the adjoint of $Y(u,z)$ is its opposite field.) For a weight-one primary the opposite of $u_{(0)}$ is $-u_{(0)}$ (`moonshineMatterOppositeModes_primary`).

Structure of the proof in Lean. The reduction `monsterLieBilinearForm_invariant_of_primaryAdjoint` takes the skew-adjointness of zero modes as an explicit hypothesis; `moonshineMatterForm_primary_zeroMode_skew` proves that hypothesis, so the headline has none.

Physical meaning

Invariance of the current two-point function under the gauge algebra: $\langle [J_u, J_v] J_w\rangle = \langle J_u [J_v, J_w]\rangle$, a consequence of the three-point function of currents being totally antisymmetric.

Proof on paper. For a weight-one primary a, FHL invariance of the form at z^0 gives $\langle a_{(0)}b, c\rangle = -\langle b, a_{(0)}c\rangle$. Then, writing $u = \bar{a}$, $v = \bar{b}$, $w = \bar{c}$: $([u,v],w) = -([v,u],w) = \langle b_{(0)}a, c\rangle = -\langle a, b_{(0)}c\rangle = (u,[v,w])$ (the overall sign of Definition 45.35 cancels). □

What the machine verified

No hypotheses; standard axioms (`VOA/Moonshine/MoonshineCNAudit16.lean`).

Trap / dead end

The VOA cutoff does not work for near-VOAs. The library's FHL machinery for vertex operator algebras truncates e^{zL_1} at the weight (`wt.toNat + 1`); for $V^\natural \otimes V_{\mathrm{II}_{1,1}}$ this fails, because L_1 is not nilpotent of order $\le \mathrm{wt} + 1$ on states of negative or zero weight with nonzero momentum (the Lean certificate is `lorentzianVirasoroOne_weightZero_not_zero`, Chapter 44). The correct cutoff uses the matter/oscillator level, i.e. weight minus the half-norm of the momentum (`moonshineMatterOppositeModes_charge_cutoff`: "The actual FHL transform uses matter/oscillator level, not total weight").

45.12 Abstract Borcherds data

The rest of the chapter is pure Lie theory. It isolates exactly the properties of $\mathfrak{m}$ that Borcherds' argument uses, as a structure `BorcherdsData`, and proves the structure theorem from them. This separation has two benefits: the Lie theory does not depend on any vertex algebra, and the one input that is *not* a property of $\mathfrak{m}$ visible from its construction (generation by simple root spaces) is an explicit field.

45.12.1 What a Borcherds algebra is, and what is (not) proved here

We recall the standard notions (Borcherds 1988; Kac, *Infinite dimensional Lie algebras*, Chapter 11), to fix vocabulary. A *generalized Cartan matrix* in Borcherds' sense is a real matrix $A = (a_{ij})_{i,j\in I}$, I countable, which is symmetric (in our case) and satisfies: $a_{ii} = 2$ or $a_{ii} \le 0$; $a_{ij} \le 0$ for $i \ne j$; and $2a_{ij}/a_{ii} \in \mathbb{Z}$ when $a_{ii} = 2$. An index i with $a_{ii} = 2$ is *real*, one with $a_{ii} \le 0$ *imaginary*. The *generalized Kac–Moody* (or *Borcherds–Kac–Moody*) algebra $\mathfrak{g}(A)$ is generated by e_i, f_i, h_i ($i \in I$) subject to

$$[h_i, h_j] = 0, \quad [h_i, e_j] = a_{ij}e_j, \quad [h_i, f_j] = -a_{ij}f_j, \quad [e_i, f_j] = \delta_{ij}h_i,$$

the *Serre relations* $(\operatorname{ad} e_i)^{1-2a_{ij}/a_{ii}}e_j = 0 = (\operatorname{ad} f_i)^{1-2a_{ij}/a_{ii}}f_j$ for real i and $j \ne i$, and $[e_i, e_j] = 0 = [f_i, f_j]$ whenever $a_{ij} = 0$; one may also allow several simple roots with the same image in the root lattice ("multiplicities"), as the Monster Lie algebra requires. Its *roots* are the nonzero degrees of the grading by the root lattice; a root γ is *real* if $(\gamma,\gamma) > 0$ (it is then Weyl-conjugate to a real simple root) and *imaginary* if $(\gamma,\gamma) \le 0$. A *Weyl vector* is a δ with $(\delta, \alpha_i) = \frac{1}{2}(\alpha_i, \alpha_i)$ for all simple roots.

The Monster Lie algebra in this language (Borcherds 1992). The root lattice is $\mathrm{II}_{1,1}$ in Borcherds coordinates with $(\cdot,\cdot)_{\mathrm{Bor}}$; the simple roots are $\alpha_r = (1,-1)$ (real, norm 2) and $\alpha_j = (1, j)$, $j \ge 1$ (imaginary, norm $-2j$), the latter with multiplicity $c(j) = \dim V^{\natural}_{1+j}$. The Cartan matrix entries are

$$(\alpha_r, \alpha_r)_{\mathrm{Bor}} = 2, \qquad (\alpha_r, \alpha_j)_{\mathrm{Bor}} = 1 - j \le 0, \qquad (\alpha_i, \alpha_j)_{\mathrm{Bor}} = -(i + j) < 0,$$

so the conditions above hold, and the Serre relation between the real simple root and α_j reads $(\operatorname{ad} e)^{1-(1-j)}v = (\operatorname{ad} e)^j v = 0$ for $v \in \mathfrak{m}_{\alpha_j}$: this is exactly Theorem 45.48(b) below. The real roots of $\mathfrak{m}$ are $\pm\alpha_r$ (its Weyl group is $\{1, s\}$ with $s(m,n) = (n,m)$), all other roots (m,n), $mn \ge 1$, are imaginary, and $\delta = (1,0)$ is a Weyl vector.

What is and is not proved. Borcherds proves that $\mathfrak{m}$ *is* the generalized Kac–Moody algebra of this Cartan matrix, using his characterisation theorem (which needs a positive-definite contravariant form) and the denominator identity. **This chapter does not prove that.** The structure `BorcherdsData` below is a weaker, purpose-built list of properties: a $\mathbb{Z}^2$-grading, a Cartan subalgebra acting by the form, an invariant form pairing opposite root spaces, the root support, one-dimensional real root spaces, and generation by the simple root spaces. It does not assert a presentation by generators and relations, and no positivity. From it we prove exactly what Chapter 46 needs: the resolution, $T(U) \cong U(\mathfrak{u}^+)$ and the freeness of $\mathfrak{u}^+$. "Borcherds–Kac–Moody structure" in the chapter title refers to these statements.

45.12.2 Rank-two root arithmetic

All roots are in Borcherds coordinates $\gamma = (m,n) \in \mathbb{Z}^2$ with the form $(\xi,\mu)_{\mathrm{Bor}} = -(\xi_1\mu_2 + \mu_1\xi_2)$.

Definition 45.41 (Roots). $\alpha_r = (1,-1)$; $\alpha_j = (1, j)$; the positive cone $C = \{(m,n) : m, n \ge 1\}$; positive roots $\Phi^+ = \{\alpha_r\} \cup C$; *root support*: $\gamma = 0$ or $\pm\gamma \in \Phi^+$; simple roots α_r and α_j ($j \ge 1$); height $m + n$; the Casimir scalar $Q(\gamma) = (\gamma,\gamma)_{\mathrm{Bor}} - 2(\delta,\gamma)_{\mathrm{Bor}}$ with Weyl vector $\delta = (1,0)$.

```

```

(`VOA/Moonshine/MoonshineCNBorcherdsRoots.lean`.)

From the mathematics to the Lean statement

Literal transcriptions. `γ.1`, `γ.2` are the coordinates m, n. $\alpha_r^2 = -(1\cdot(-1)+1\cdot(-1)) = 2$, $\alpha_j^2 = -2j$. The key arithmetic: $Q(m,n) = -2mn + 2n = -2n(m-1)$, which on the positive cone vanishes exactly on the line $m = 1$. δ **is a Weyl vector**: $2(\delta,\alpha)_{\mathrm{Bor}} = (\alpha,\alpha)_{\mathrm{Bor}}$ for every simple root ($2\cdot 1 = 2$ for α_r, $2\cdot(-j) = -2j$ for α_j), which is what makes the Casimir central below. Also proved here: `borcherdsPositiveRoot_add_simple`, `borcherdsPositiveCone_height_finite`, `borcherdsRootSupport_neg`.

Physical meaning

Roots are the allowed momenta of the gauge bosons: by the no-ghost theorem, $\mathfrak{m}_{(m,n)} \cong V^{\natural}_{1+mn}$ is nonzero only if $mn = -1$ (the real roots $\pm\alpha_r$, tachyons) or $mn \geq 1$ (massive states balanced by momentum). The Weyl vector $\delta = (1,0)$ is the lightlike vector against which all simple roots have "height" $\frac{1}{2}$ their norm.

What the machine verified

No hypotheses; standard axioms (`VOA/Moonshine/MoonshineCNAudit12.lean`).

45.12.3 The structure

Definition 45.42 (Borcherds datum). A *Borcherds datum* on a complex Lie algebra $\mathfrak{g}$ consists of

(BD1) a grading $\mathfrak{g} = \bigoplus_{\gamma\in\mathbb{Z}^2} \mathfrak{g}_\gamma$ with finite-dimensional pieces and $[\mathfrak{g}_\gamma, \mathfrak{g}_\delta] \subseteq \mathfrak{g}_{\gamma+\delta}$;

(BD2) an injective linear map $\iota : \mathbb{C}^2 \to \mathfrak{g}$ with image $\mathfrak{g}_0$ and $[\iota\xi, x] = (\xi,\gamma)_B x$ for $x \in \mathfrak{g}_\gamma$;

(BD3) a symmetric invariant bilinear form with $(\mathfrak{g}_\gamma, \mathfrak{g}_\delta) = 0$ unless $\gamma+\delta = 0$, $(\iota\xi, \iota\mu) = (\xi,\mu)_{\mathrm{Bor}}$, and $\mathfrak{g}_\gamma \times \mathfrak{g}_{-\gamma} \to \mathbb{C}$ nondegenerate (left) for every γ;

(BD4) root support: $\mathfrak{g}_\gamma \neq 0 \Rightarrow \gamma$ is supported; $\dim \mathfrak{g}_{\pm\alpha_r} = 1$;

(BD5) generation: $\mathfrak{g}$ is generated as a Lie algebra by $\mathfrak{g}_0$, $\mathfrak{g}_{\pm\alpha_r}$ and the $\mathfrak{g}_{\pm\alpha_j}$;

and, optionally, (BD6) a group acting by graded, form-preserving Lie automorphisms, trivially on $\mathfrak{g}_0$ and $\mathfrak{g}_{\pm\alpha_r}$.

(`VOA/Moonshine/MoonshineCNBorcherdsData.lean`; `GAction` is `BorcherdsData.GAction` with `D : BorcherdsData g` a section variable.)

From the mathematics to the Lean statement

Field by field. (BD1) `weight_internal`, `weight_finite`, `bracket_weight`; (BD2) `cartanMap`, `cartan_injective`, `cartan_range`, `cartan_action`; (BD3) `form`, `form_symmetric`, `form_invariant`, `form_orthogonal`, `form_cartan`, `form_nondegenerate`; (BD4) `root_support`, `real_dimension`; (BD5) `generated`. `LieSubalgebra.lieSpan ℂ g S` is the Lie subalgebra generated by S; `= ⊤` says it is all of $\mathfrak{g}$.

The docstring is explicit: "Generation is an input here; no assertion is made that the Monster Lie algebra has it." The Lean field `form_nondegenerate` is left-nondegeneracy of the pairing $\mathfrak{g}_\gamma \times \mathfrak{g}_{-\gamma}$; by symmetry and finite dimension it is a perfect pairing (`rootPairingEquiv`, §45.16).

Conventions. ι is a map from $\mathbb{C}^2$ with the Borcherds pairing, i.e. from $\mathrm{II}_{1,1} \otimes \mathbb{C}$. **No positivity** (no Hermitian form, no positive-definiteness) is part of the structure: the arguments below use only invariance, symmetry and nondegeneracy of the opposite-root pairings.

Is it satisfiable? Yes: $\mathfrak{m}$ is an instance (Theorem 45.47, given generation, which is proved in Chapter 47).

Physical meaning

The abstract properties of a gauge algebra of a compactified string with two-dimensional "light-cone" momentum lattice: momentum grading, Cartan currents, a Killing form from the current two-point function, and the spectrum of allowed momenta.

What the machine verified

Definitions; standard axioms (`VOA/Moonshine/MoonshineCNAudit12.lean`).

Theorem 45.43 (First consequences). *In every Borcherds datum: (a) for $x \in \mathfrak{g}_\gamma$, $y \in \mathfrak{g}_{-\gamma}$, $[x,y] = (x,y)\,\iota(\gamma)$; (b) there are $e \in \mathfrak{g}_{\alpha_r}$, $f \in \mathfrak{g}_{-\alpha_r}$ with $(e,f) = 1$; for any such pair, (h,e,f) with $h = \iota(1,-1)$ is an $\mathfrak{sl}_2$-triple: $[e,f] = h$, $[h,e] = 2e$, $[h,f] = -2f$; (c) $[f,v] = 0$ for $v \in \mathfrak{g}_{\alpha_j}$, $j \geq 1$.*

    (hv : v ∈ D.weightSpace (borcherdsImaginaryRoot j)) : ⁅f, v⁆ = 0 := by
```

(`VOA/Moonshine/MoonshineCNBorcherdsData.lean`.)

From the mathematics to the Lean statement

The normalized pair (e,f) appears as explicit arguments `(e f : g) (he) (hf) (hef : D.form e f = 1)` in all later theorems; `exists_normalized_real_pair` shows such arguments always exist (docstring: "no choice of such a pair is an extra input"), so these hypotheses are never restrictive.

Physical meaning

The real root vectors and their commutator form an $\mathfrak{su}(2)$-type ("W-boson") gauge subalgebra.

Proof on paper. (a) $[x,y] \in \mathfrak{g}_0 = \iota(\mathbb{C}^2)$ and $([x,y],\iota\lambda) = (x,[y,\iota\lambda]) = (\lambda,\gamma)_{\mathrm{Bor}}(x,y) = ((x,y)\iota\gamma,\iota\lambda)$; the form is nondegenerate on $\mathfrak{g}_0$. (b) $\mathfrak{g}_{\pm\alpha_r}$ are lines paired nondegenerately; (a) gives $[e,f] = \iota(\alpha_r)$, and $(\alpha_r,\alpha_r)_{\mathrm{Bor}} = 2$. (c) $[f,v] \in \mathfrak{g}_{(0,j+1)}$, which is unsupported, hence 0. □

What the machine verified

No hypotheses beyond the datum; standard axioms (`VOA/Moonshine/MoonshineCNAudit12.lean`).

45.13 The Monster Lie algebra is a Borcherds datum

Where the Cartan map comes from. By Theorems 45.31 and 45.39, an element $h \in \mathfrak{m}_0$ with no-ghost coordinates (c_0,c_1) is c_0 times the current of $w_0 = (0,1)$ plus c_1 times the current of $w_1 = (1,0)$,

i.e. it corresponds to the lattice vector $\lambda(h) = (c_1, c_0)$, and it acts on repository momentum β by $(\lambda(h), \beta) = c_0\beta_0 + c_1\beta_1$. A Borcherds root (m, n) has repository momentum $(m, -n)$, so h acts on it by $c_0 m - c_1 n$. We want $\iota(\xi)$ to act by $(\xi, (m, n))_{\mathrm{Bor}} = -\xi_1 n - \xi_2 m$; matching coefficients gives $c_0 = -\xi_2$, $c_1 = \xi_1$. This explains the coordinates $(-\xi_2, \xi_1)$ in the next definition.

Definition 45.44 (Borcherds coordinates on $\mathfrak{m}$). $\mathfrak{m}^{\mathrm{Bor}}_{(m,n)} := \mathfrak{m}_{(m,-n)}$ (repository momentum), and $\iota(\xi) :=$ the element of $\mathfrak{m}_0$ with no-ghost coordinates $(-\xi_2, \xi_1)$.

```
def borcherdsMomentum (γ : ℤ × ℤ) : lorentzianLattice.carrier := ![γ.1, -γ.2]
def monsterLieBorcherdsWeight (γ : ℤ × ℤ) : Submodule ℂ monsterLieAlgebra :=
  monsterLieMomentum (borcherdsMomentum γ)
def borcherdsCartanCoordinates : (ℂ × ℂ) →ₗ[ℂ] (Fin 2 → ℂ) where
  toFun ξ := ![-ξ.2, ξ.1]

  (monsterLieMomentum 0).subtype ∘ₗ monsterLieZeroMomentumEquiv.symm.toLinearMap ∘ₗ
    borcherdsCartanCoordinates
```

(VOA/Moonshine/MoonshineCNMonsterBorcherdsData.lean.)

From the mathematics to the Lean statement

Check of the Cartan action: $\iota(\xi)$ has coordinates $(c_0, c_1) = (-\xi_2, \xi_1)$; on $\mathfrak{m}^{\mathrm{Bor}}_{(m,n)} = \mathfrak{m}_{(m,-n)}$ Theorem 45.39 gives the scalar $c_0 m + c_1(-n) = -\xi_2 m - \xi_1 n = (\xi, (m, n))_{\mathrm{Bor}}$. Check of the form: by Theorem 45.38, $(\iota\xi, \iota\mu) = (-\xi_2)\mu_1 + \xi_1(-\mu_2) = (\xi, \mu)_{\mathrm{Bor}}$. These are the Lean theorems `monsterLieCartanMap_action` and `monsterLieCartanMap_form`.

Physical meaning

Borcherds coordinates (m, n) are light-cone momenta with the sign of the second one flipped, so that the positive cone, where the massive gauge bosons live, is $m, n \geq 1$; $\iota(\xi)$ is the momentum current in the direction ξ.

Theorem 45.45 (Borcherds-coordinate root spaces). *For $\gamma = (m, n) \neq 0$, $\mathfrak{m}^{\mathrm{Bor}}_\gamma \cong {V^\natural}_{1+mn}$ as vector spaces (a linear isomorphism; its $\mathrm{Aut}(V^\natural)$-equivariance is the repository-coordinate statement* `monsterLieRootSpaceEquiv_equivariant`*, since the map is* `monsterLieRootSpaceEquiv m (-n)` *followed by a relabelling of the weight); $\mathfrak{m}^{\mathrm{Bor}}_\gamma \neq 0$ implies that γ is supported (using ${V^\natural}_{<0} = 0$, ${V^\natural}_1 = 0$);* $\dim \mathfrak{m}^{\mathrm{Bor}}_{\pm\alpha_r} = 1$.

```
def monsterLieBorcherdsRootEquiv (γ : ℤ × ℤ) (hγ : γ ≠ 0) :
    monsterLieBorcherdsWeight γ ≃ₗ[ℂ] VnatVOA.grading (1 + γ.1 * γ.2) :=

 ↪  ⊥) :
    borcherdsRootSupport γ := by
theorem monsterLieBorcherdsWeight_real_finrank (γ : ℤ × ℤ)
    (hγ : γ = borcherdsRealRoot ∨ γ = -borcherdsRealRoot) :
    Module.finrank ℂ (monsterLieBorcherdsWeight γ) = 1 := by
```

(VOA/Moonshine/MoonshineCNMonsterBorcherdsData.lean.)

From the mathematics to the Lean statement

`monsterLieBorcherdsRootEquiv` is `monsterLieRootSpaceEquiv m (-n)` composed with the identity $1 - m(-n) = 1 + mn$: this is the bridging lemma of the sign warning in §45.1.3. Support: if ${V^\natural}_{1+mn} \neq 0$ then $1 + mn \geq 0$ and $1 + mn \neq 1$, i.e. $mn \geq -1$, $mn \neq 0$, and integer arithmetic (`borcherdsRootSupport_of_product`) gives $\gamma \in \{\pm\alpha_r\} \cup C \cup (-C)$. Real roots: $1 + mn = 0$, and $\dim {V^\natural}_0 = 1$ (`vnat_finrank_zero`).

Physical meaning

The tachyon ($V^\natural{}_0$) at the real roots; nothing on the axes $m = 0$ or $n = 0$ except the Cartan currents (since $V^\natural{}_1 = 0$: no internal currents); everything else lives in the cones $\pm C$.

What the machine verified

No hypotheses; standard axioms (`VOA/Moonshine/MoonshineCNAudit17.lean`).

Definition 45.46 (Simple-root generation). `MonsterLieSimpleRootGeneration`: $\mathfrak{m}$ is generated as a Lie algebra by $\mathfrak{m}_0$, $\mathfrak{m}^{\mathrm{Bor}}_{\pm\alpha_r}$ and the $\mathfrak{m}^{\mathrm{Bor}}_{\pm\alpha_j}$, $j \geq 1$.

```
def MonsterLieSimpleRootGeneration : Prop :=
  LieSubalgebra.lieSpan ℂ monsterLieAlgebra (borcherdsSimpleGenerators
   ↪  monsterLieBorcherdsWeight) =
    ⊤
```

(`VOA/Moonshine/MoonshineCNMonsterBorcherdsData.lean`.)

Physical meaning

All gauge bosons of the Monster string arise as commutators of the momentum currents, the tachyon pair and the simple-root states $V^\natural{}_{1+j} \otimes e^{(1,-j)}$: there are no further "elementary" gauge bosons. Physically this is a statement about the full spectrum, which is why it is equivalent to the modular product formula for $j(p) - j(q)$.

Theorem 45.47 (The Monster Lie algebra as Borcherds datum). *Given* `MonsterLieSimpleRootGeneration`, $\mathfrak{m}$ *with the Borcherds-coordinate grading,* ι *and the form of §45.11 is a Borcherds datum, and* $\mathrm{Aut}(V^\natural)$ *acts on it as in (BD6).*

```
def monsterLieBorcherdsData (hgen : MonsterLieSimpleRootGeneration) :

  graded σ γ x hx := monsterLieAut_momentum σ _ x hx
  preserves_form σ x y := monsterLieBilinearForm_aut σ x y
  ...
```

(`VOA/Moonshine/MoonshineCNMonsterBorcherdsData.lean`; the lines marked `...` elide the fields `bracket_weight`, `form_orthogonal`, `form_nondegenerate`, `real_dimension`, `fixes_cartan`, `fixes_real`, whose proofs are a few lines each and reduce to `monsterLieMomentum_bracket`, `monsterLieBilinearForm_momentum_orthogonal`, `monsterLieBilinearForm_pairing_nondegenerate`, `monsterLieBorcherdsWeight_real_finrank`, `monsterLieZeroMo` and `monsterLieAut_fixes_real`.)

From the mathematics to the Lean statement

The one hypothesis. `hgen` is used for exactly one field, `generated := hgen`. Every other field is a theorem proved in this chapter. The file docstring: "Every field of the data is proved here from the vertex-algebra construction, except generation ... kept as the explicit hypothesis `MonsterLieSimpleRootGeneration`; it is equivalent, given the other fields, to the product formula for $j(p) - j(q)$, which is not yet in Lean." **That last clause is out of date** (see the next paragraph).
(BD6) for $\mathrm{Aut}(V^\natural)$. `fixes_real`: $\mathfrak{m}_{\pm\alpha_r} \cong {V^\natural}_0 = \mathbb{C}\mathbb{1}$ and automorphisms fix $\mathbb{1}$ (`monsterLieAut_fixes_real`); `fixes_cartan`: Theorem 45.38.

The hypothesis is discharged. In the release the product formula is in Lean (`M8.knz_product`, Chapter 46) and generation is a theorem with no hypotheses:

```
theorem monsterLieSimpleRootGeneration : MonsterLieSimpleRootGeneration :=
  monsterLiePreData.lieSpan_eq_top_of_KNZ monsterLiePreData_KNZ
```

(`VOA/Moonshine/MoonshineLRGenerationMonster.lean`, `VOA.Moonshine.ConwayNorton.M8.monsterLieSimpleRootGener` documented in Chapter 47; printed in `VOA/Moonshine/MoonshineCNFinalAudit.lean` with standard axioms.) Hence `monsterLieBorcherdsData M8.monsterLieSimpleRootGeneration` is an unconditional Borcherds datum, and every consequence stated below for $\mathfrak{m}$ "given `hgen`" holds unconditionally after this substitution.

Physical meaning

The gauge algebra of the Monster string has exactly the root data of a rank-two Borcherds algebra with one real simple root and imaginary simple roots $(1, j)$ of multiplicity $\dim {V^\natural}_{j+1}$, and the Monster acts preserving all of it.

What the machine verified

Conditional on `hgen : MonsterLieSimpleRootGeneration` in this file; that hypothesis is a theorem with no hypotheses (`M8.monsterLieSimpleRootGeneration`). `#print axioms`: standard (`VOA/Moonshine/MoonshineCNAudit17.lean` for the instance, `VOA/Moonshine/MoonshineCNFinalAudit.lean` for the discharge).

Trap / dead end

Generation cannot be proved Lie-theoretically here; it is equivalent to the product formula. Given everything else, "$\mathfrak{m}$ is generated by its simple root spaces" $\iff$ the untwisted denominator identity $\prod_{m,n\geq 1}(1 - p^m q^n)^{c(mn)} = 1 - \sum_{a,b\geq 1} c(a+b-1)p^a q^b$. Deriving the product identity *from* $\mathfrak{m}$ is therefore circular. The Casimir argument of §45.17 excludes *relations* among the known simple root vectors, not *extra* simple roots (m, n) with $m \geq 2$ (for those, δ is not known to be a Weyl vector). The library proves the product identity analytically from the modularity of J (Chapter 46) and then deduces generation by a dimension sandwich (Chapter 47).

45.14 Real-root strings and the generating space

Fix a Borcherds datum D on $\mathfrak{g}$ and a normalized pair (e, f).

45.14.1 The $\mathfrak{sl}_2$-strings of the imaginary simple roots

Theorem 45.48 (Real-root strings). *Let $j \geq 1$ and $v \in \mathfrak{g}_{\alpha_j}$. (a) (h, e, f) is an $\mathfrak{sl}_2$-triple and $[h, v] = (1-j)v$; (b) $(\operatorname{ad} e)^k v \in \mathfrak{g}_{(1+k,j-k)}$ and $(\operatorname{ad} e)^j v = 0$; (c) $[f, (\operatorname{ad} e)^{k+1} v] = (k+1)(j-k-1)(\operatorname{ad} e)^k v$; (d) for $0 \leq k < j$, $(\operatorname{ad} e)^k$ is injective on $\mathfrak{g}_{\alpha_j}$.*

```
theorem real_sl2_triple (e f : g)
    (he : e ∈ D.weightSpace borcherdsRealRoot)
    (hf : f ∈ D.weightSpace (-borcherdsRealRoot)) (hef : D.form e f = 1) :
    IsSl2Triple (D.cartanMap (1, -1)) e f := by
theorem adReal_pow_simple_vanishes (e : g) (he : e ∈ D.weightSpace borcherdsRealRoot)
    (j : ℕ) (v : g) (hv : v ∈ D.weightSpace (borcherdsImaginaryRoot (j : ℤ))) :
    (LieModule.toEnd ℂ g g e ^ j) v = 0 := by
theorem real_lowering_string (e f : g)
    (he : e ∈ D.weightSpace borcherdsRealRoot)
    (hf : f ∈ D.weightSpace (-borcherdsRealRoot)) (hef : D.form e f = 1)
    (j : ℤ) (hj : 1 ≤ j) (v : g)
    (hv : v ∈ D.weightSpace (borcherdsImaginaryRoot j)) (k : ℕ) :
    ⁅f, (LieModule.toEnd ℂ g g e ^ (k + 1)) v⁆ =
      (((k : ℂ) + 1) * ((j : ℂ) - (k : ℂ) - 1)) •
        (LieModule.toEnd ℂ g g e ^ k) v := by
theorem adReal_pow_injective (e f : g)
    (he : e ∈ D.weightSpace borcherdsRealRoot)
    (hf : f ∈ D.weightSpace (-borcherdsRealRoot)) (hef : D.form e f = 1)
    (j : ℤ) (hj : 1 ≤ j) (k : ℕ) (hk : (k : ℤ) < j) :
    Function.Injective (fun v : D.weightSpace (borcherdsImaginaryRoot j) =>
      (LieModule.toEnd ℂ g g e ^ k) (v : g)) := by
```

(`VOA/Moonshine/MoonshineCNBorcherdsSl2.lean`.)

From the mathematics to the Lean statement

`LieModule.toEnd ℂ g g e` is $\operatorname{ad} e$; `^ k` its k-th power. `IsSl2Triple h e f` is Mathlib's $\mathfrak{sl}_2$-triple predicate. (c) is the lowest-weight formula with v a lowest-weight vector of weight $-(j-1)$.

Physical meaning

Each imaginary simple root state v is the bottom of a j-dimensional multiplet of the W-boson $\mathfrak{sl}_2$ (spin $\frac{j-1}{2}$): $v, [e, v], \ldots, (\operatorname{ad} e)^{j-1} v$.

Proof on paper. (a) by Theorem 45.43; $(\alpha_r, \alpha_j)_{\mathrm{Bor}} = -(1 \cdot j + 1 \cdot (-1)) = 1 - j$. (b) $(1 + j, 0)$ is unsupported. (c) induction with $[f, e] = -h$ and $[f, v] = 0$. (d) apply f repeatedly: the coefficients $(k+1)(j-k-1)$ are nonzero for $k + 1 < j$. □

What the machine verified

No hypotheses beyond the datum and the pair; standard axioms (`VOA/Moonshine/MoonshineCNAudit12.lean`).

Definition 45.49 (The generating space U). $U_{j,k} := (\operatorname{ad} e)^k \mathfrak{g}_{\alpha_j}$ and $U := \sum_{j \geq 1} \sum_{0 \leq k < j} U_{j,k}$.

```
def generatorString (e : g) (j : ℤ) (k : ℕ) : Submodule ℂ g :=
  (D.weightSpace (borcherdsImaginaryRoot j)).map (LieModule.toEnd ℂ g g e ^ k)
def genSpace (e : g) : Submodule ℂ g :=
  ⨆ (j : ℤ) (_ : 1 ≤ j) (k : ℕ) (_ : (k : ℤ) < j), D.generatorString e j k
```

(VOA/Moonshine/MoonshineCNBorcherdsSl2.lean.)

Physical meaning

U is the span of all states obtained from simple-root states by acting with the W-boson raising operator, before the multiplet terminates.

Theorem 45.50 (Structure of U). *(a)* $U_{j,k} \subseteq \mathfrak{g}_{(1+k,j-k)}$, $(\operatorname{ad} e)^k : \mathfrak{g}_{\alpha_j} \to U_{j,k}$ *is an isomorphism,* $U \cap \mathfrak{g}_{(1+k,j-k)} = U_{j,k}$, *and* $U = \bigoplus_{j,k} U_{j,k}$; *so* $U_{(a,b)} \cong \mathfrak{g}_{\alpha_{a+b-1}}$ *for* $a, b \geq 1$. *(b)* $U \subseteq \mathfrak{u}^+ := \bigoplus_{\gamma \in C} \mathfrak{g}_\gamma$. *(c)* U *is stable under* $\iota(\mathbb{C}^2)$, $\operatorname{ad} e$, $\operatorname{ad} f$, *hence is a module for the Levi subalgebra* $\mathfrak{l} = \mathfrak{g}_{-\alpha_r} \oplus \mathfrak{g}_0 \oplus \mathfrak{g}_{\alpha_r}$. *(d)* $[\mathfrak{u}^-, U] \subseteq \mathfrak{p}^-$, *where* $\mathfrak{u}^- = \bigoplus_{-\gamma \in C} \mathfrak{g}_\gamma$ *and* $\mathfrak{p}^- = \bigoplus_{\gamma \notin C} \mathfrak{g}_\gamma$. *(e) U is stable under every symmetry (BD6).*

```
def generatorStringEquiv (e f : g)

    {y u : g} (hy : y ∈ D.negativePart) (hu : u ∈ D.genSpace e) :
    ⁅y, u⁆ ∈ D.parabolicPart :=
```

(VOA/Moonshine/MoonshineCNBorcherdsSl2.lean, VOA/Moonshine/MoonshineCNBorcherdsGeneratorWeights.lean, VOA/Moonshine/MoonshineCNBorcherdsStringSum.lean, VOA/Moonshine/MoonshineCNBorcherdsStringAction.lean; equivariance genSpace_equivariant.)

From the mathematics to the Lean statement

borcherdsStringIndex is $\{(j,k) : 1 \leq j,\ 0 \leq k < j\}$ and borcherdsStringDegree (j,k) = (1+k, j-k), an injective map (distinct strings positions have distinct degrees, which is why the sum is direct). $\oplus$ is the external direct sum. The subalgebras positivePart ($\mathfrak{u}^+$), negativePart ($\mathfrak{u}^-$), leviPart ($\mathfrak{l}$), parabolicPart ($\mathfrak{p}^-$) are defined next.

Physical meaning

U collects all the W-boson multiplets built on the imaginary simple root states.

What the machine verified

No hypotheses beyond the datum and the pair; standard axioms (`VOA/Moonshine/MoonshineCNAudit12.lean`, `VOA/Moonshine/MoonshineCNAudit14.lean`).

45.14.2 Parabolic decomposition

The names come from the finite-dimensional theory: a *parabolic* subalgebra contains a Cartan subalgebra and all negative root spaces (here: everything outside the positive cone), its *Levi* subalgebra is the reductive part (here $\mathfrak{l} \cong \mathfrak{gl}_2$, spanned by the Cartan and the real root lines), and the *nilradical* is the remaining ideal (here $\mathfrak{u}^-$).

Definition 45.51 (Positive part, Levi, negative part, opposite parabolic). For a predicate P on degrees let $\mathfrak{g}_P := \sum_{P(\gamma)} \mathfrak{g}_\gamma$. Then $\mathfrak{u}^+ = \mathfrak{g}_C$, $\mathfrak{p}^- = \mathfrak{g}_{\neg C}$, $\mathfrak{u}^- = \mathfrak{g}_{-C}$, $\mathfrak{l} = \mathfrak{g}_{\{0,\pm\alpha_r\}}$; all are Lie subalgebras.

```
def weightSpan (P : ℤ × ℤ → Prop) : Submodule ℂ g :=
  ⨆ γ, ⨆ (_ : P γ), D.weightSpace γ
def positivePart : LieSubalgebra ℂ g where
  __ := D.weightSpan borcherdsPositiveCone
def parabolicPart : LieSubalgebra ℂ g where
  __ := D.weightSpan (fun γ => ¬ borcherdsPositiveCone γ)
theorem positive_parabolic_isCompl :
    IsCompl D.positivePart.toSubmodule D.parabolicPart.toSubmodule := by
```

(`VOA/Moonshine/MoonshineCNBorcherdsParabolic.lean`.)

```
def negativePart : LieSubalgebra ℂ g where
  __ := D.weightSpan borcherdsNegativeCone
def leviPart : LieSubalgebra ℂ g where
  __ := D.weightSpan borcherdsLeviDegree
def negativeParabolicIdeal : LieIdeal ℂ D.parabolicPart where
theorem parabolic_eq_levi_sup_negative : D.parabolicPart.toSubmodule =
    D.leviPart.toSubmodule ⊔ D.negativePart.toSubmodule := by
```

(`VOA/Moonshine/MoonshineCNBorcherdsLevi.lean`.)

From the mathematics to the Lean statement

Important: `positivePart` is $\mathfrak{u}^+$, the positive cone $C = \{m, n \geq 1\}$; it does not contain the real root. The "positive part" $\mathfrak{n}^+ = \mathfrak{g}_{\alpha_r} \oplus \mathfrak{u}^+$ of Kac–Moody theory (Borcherds' E) is not given a name. $\mathfrak{p}^-$ contains $\mathfrak{g}_0$, both real root lines and $\mathfrak{u}^-$ (the support forbids anything else outside C), and $\mathfrak{u}^-$ is an ideal of $\mathfrak{p}^-$ (`negativeParabolicIdeal`). The complement $\mathfrak{g} = \mathfrak{u}^+ \oplus \mathfrak{p}^-$ is the input of relative PBW. The Levi projection along $\mathfrak{u}^-$ is a Lie homomorphism $\mathfrak{p}^- \to \mathfrak{l}$ (`parabolicLeviProjection`, `VOA/Moonshine/MoonshineCNBorcherdsParabolicAction.lean`, using the general `leviProjectionOfComplement` of `VOA/Moonshine/MoonshineCNLieProjection.lean`), and $\mathfrak{p}^-$ acts on U through it, $\mathfrak{u}^-$ acting by 0 (`genSpaceParabolicRep`).

Physical meaning

A light-cone-like splitting of the gauge algebra into "creation" (C) and "annihilation plus zero modes" parts.

What the machine verified

No hypotheses beyond the datum; standard axioms (`VOA/Moonshine/MoonshineCNAudit12.lean`).

45.14.3 Generation of the positive cone

Theorem 45.52 ($\mathfrak{u}^+$ is generated by U). *$\mathfrak{u}^+$ equals the Lie subalgebra generated by U; consequently the augmentation ideal of $\mathcal{U}(\mathfrak{u}^+)$ is the left ideal $\mathcal{U}(\mathfrak{u}^+)\cdot U$.*

```
theorem positivePart_eq_lieSpan_genSpace (e f : g)
    (he : e ∈ D.weightSpace borcherdsRealRoot)
    (hf : f ∈ D.weightSpace (-borcherdsRealRoot)) (hef : D.form e f = 1) :
    D.positivePart = LieSubalgebra.lieSpan ℂ g (D.genSpace e : Set g) := by
```

(`VOA/Moonshine/MoonshineCNBorcherdsGeneration.lean`.)

```
theorem positive_augmentationIdeal_eq (e f : g)
    (he : e ∈ D.weightSpace borcherdsRealRoot)
    (hf : f ∈ D.weightSpace (-borcherdsRealRoot)) (hef : D.form e f = 1) :
    LinearMap.ker (envelopingAugmentation (g := D.positivePart)).toLinearMap =
      (envelopingGeneratorLeftIdeal (D.positiveGeneratorSpace e)).restrictScalars ℂ :=
```

(`VOA/Moonshine/MoonshineCNBorcherdsAugmentation.lean`, where `envelopingAugmentation` is the algebra map $\mathcal{U}(L)\to\mathbb{C}$ killing L, `envelopingGeneratorLeftIdeal S` the left ideal $\mathcal{U}(L)S$, and `positiveGeneratorSpace e` is U viewed inside $\mathfrak{u}^+$.)

From the mathematics to the Lean statement

Uses (BD5) through the datum. The augmentation statement holds for any Lie algebra and any Lie-generating subspace (`enveloping_augmentationIdeal_eq`: "No PBW assumption is needed").

Physical meaning

All gauge bosons with momenta in the positive cone arise as nested commutators of the W-multiplets of the imaginary simple roots.

Proof on paper. The sum $S=\mathrm{Lie}(U)+\mathfrak{p}^-$ is stable under ad of every generator of $\mathfrak{g}$ (`lieSpan_parabolic_bracket_m`): $\mathfrak{p}^-$ normalizes $\mathrm{Lie}(U)$ modulo $\mathfrak{p}^-$ because $\mathfrak{l}$ preserves U and $[\mathfrak{u}^-,U]\subseteq\mathfrak{p}^-$ (Theorem 45.50(c),(d)), and $e,\mathfrak{g}_{\alpha_j}$ lie in $\mathfrak{p}^-+U$. So S is a subalgebra containing all simple generators, hence $S=\mathfrak{g}$ by (BD5); comparing the C-graded parts gives $\mathfrak{u}^+=\mathrm{Lie}(U)$. For the augmentation ideal: every element of $\mathfrak{u}^+$ is a Lie polynomial without constant term in U, hence an associative one, hence in $\mathcal{U}(\mathfrak{u}^+)U$. □

What the machine verified

No hypotheses beyond the datum and the pair; standard axioms (`VOA/Moonshine/MoonshineCNAudit14.lean`).

45.15 Generalized Verma modules and relative PBW

45.15.1 Induced modules

For a Lie subalgebra $\mathfrak{p}\subseteq\mathfrak{g}$ and a $\mathfrak{p}$-module W (a Lie homomorphism $\sigma:\mathfrak{p}\to\mathrm{End}\,W$; Lean calls it ρ), the induced module is $\mathrm{Ind}(W)=\mathcal{U}(\mathfrak{g})\otimes_{U(\mathfrak{p})}W$, realised as the quotient of $\mathcal{U}(\mathfrak{g})\otimes W$ by the span of the balancing relations $yx\otimes w-y\otimes\sigma(x)w$:

```
abbrev relativeInducedSpace :=
  (UniversalEnvelopingAlgebra ℂ g ⊗[ℂ] U) / PBWTheorem.balancing p ρ
def relativeInducedRep : g →ₗ[ℂ] End ℂ (relativeInducedSpace p ρ) :=
```

(`VOA/Moonshine/MoonshineCNRelativeInduction.lean`; `PBWTheorem.balancing` and `PBWTheorem.bottom`, the map $w \mapsto [1 \otimes w]$, are in `VOA/Foundations/PBWTheorem/Induced.lean`, Chapter 3. Here the type variable named `U` is the module W, not the generating space.)

Theorem 45.53 (Relative PBW freeness). *Let $\mathfrak{g} = \mathfrak{p} \oplus \mathfrak{c}$ as vector spaces, $(c_a)_{a \in A}$ a basis of $\mathfrak{c}$ indexed by a linearly ordered set. Then* $\mathrm{Ind}(W) \cong \bigoplus_{\text{multisets } m \text{ in } A} W$, *the class $[c_{a_1} \cdots c_{a_k} \otimes w]$ $(a_1 \le \ldots \le a_k)$ corresponding to w in slot $m = \{a_1, \ldots, a_k\}$. If $\mathfrak{c} = \mathfrak{q}$ is a Lie subalgebra, then multiplication $\mathcal{U}(\mathfrak{q}) \otimes W \to \mathrm{Ind}(W)$, $a \otimes w \mapsto [a \otimes w]$, is bijective.*

```
def relativePBWEquiv : relativeInducedSpace p ρ ≃ₗ[ℂ] (Multiset A →₀ U) :=
```

(`VOA/Moonshine/MoonshineCNRelativePBW.lean`, with section variables `(hc : IsCompl p.toSubmodule c) (bc : Basis A ℂ c)`, `[LinearOrder A]`.)

```
theorem relativeVermaMultiplication_bijective :
    Function.Bijective (relativeVermaMultiplication p q ρ) := by
theorem parabolicVermaMultiplication_bijective :
    Function.Bijective (D.parabolicVermaMultiplication ρ) := by
```

(`VOA/Moonshine/MoonshineCNVermaMultiplication.lean`, with `(hc : IsCompl p.toSubmodule q.toSubmodule)`; the second is the case $\mathfrak{p} = \mathfrak{p}^-$, $\mathfrak{q} = \mathfrak{u}^+$, using `positive_parabolic_isCompl`.)

From the mathematics to the Lean statement

`Multiset A →₀ U` is the space of finitely supported functions from multisets of basis indices to W, i.e. $\bigoplus_m W$. The proof uses the repository's relative PBW representation `PBWTheorem.rep` (Chapter 3, the construction that replaced the former axiom `VOA.pbw`), so the result is axiom-clean. No finite-dimensionality is assumed; A is any linear order (a well-order exists by choice).

Physical meaning

Induced representations are "Fock spaces": states are obtained from a vacuum multiplet W by applying creation operators from the complement, freely and in a fixed order.

What the machine verified

No hypotheses beyond complementarity; standard axioms (`VOA/Moonshine/MoonshineCNAudit14.lean`).

45.15.2 Weight gradings of induced modules

The Casimir argument needs the induced modules to be graded by Cartan weights, bounded below in height. The library calls such a grading *admissible*:

```
structure BorcherdsAdmissible (D : BorcherdsData g)
    (ρ : g →ₗ[ℂ] Module.End ℂ M) where
  weightSpace : ℤ × ℤ → Submodule ℂ M
  weight_internal : DirectSum.IsInternal weightSpace
  action_weight : ∀ {α μ} {x : g} {v : M},
    x ∈ D.weightSpace α → v ∈ weightSpace μ → ρ x v ∈ weightSpace (μ + α)
  cartan_action : ∀ (ξ : ℂ × ℂ) {μ} {v : M}, v ∈ weightSpace μ →
    ρ (D.cartanMap ξ) v = borcherdsCartanPairing ξ (borcherdsWeightVector μ) • v
  lowerHeight : ℤ
  below_eq_bot : ∀ μ, borcherdsRootHeight μ < lowerHeight → weightSpace μ = ⊥
```

(`VOA/Moonshine/MoonshineCNBorcherdsRootCutoff.lean`; the docstring: "No finite-dimensional module-slice assumption is included or inferred".) The files `VOA/Moonshine/MoonshineCNBorcherdsCartanWeights.lean` and `VOA/Moonshine/MoonshineCNBorcherdsVermaWeights.lean` construct admissible gradings by simultaneous Cartan eigenspaces (`cartanEigenspace`, `cartanAdmissible`): eigenspaces of distinct weights are independent (`cartanEigenspace_iSupIndep`), root vectors shift them (`cartanEigenspace_action`), and an induced module is generated from its bottom by $\mathfrak{u}^+$ (`inducedSpace_eq_top_of_bottom`), so its weights lie in $\{0\}\cup C$ (for $\mathrm{Ind}(\mathbb{C})$, `trivialVermaAdmissible`) or in C (for $\mathrm{Ind}(U)$, `generatorVermaAdmissible`). The kernel of a Cartan-intertwining map out of such a module is spanned by weight vectors (`cartanEigenspace_kernel_graded`).

Physical meaning

States of a Fock-like representation carry a definite momentum, bounded below in "light-cone energy" (height).

45.16 The Casimir operator

45.16.1 Dual bases and root contractions

By (BD3) the pairing $\mathfrak{g}_\alpha \times \mathfrak{g}_{-\alpha} \to \mathbb{C}$ is perfect (`rootPairingEquiv`, in `VOA/Moonshine/MoonshineCNBorcherdsRootDuality.l`). So for every basis (b_i) of $\mathfrak{g}_\alpha$ there is a dual basis (b^i) of $\mathfrak{g}_{-\alpha}$ (`rootOppositeBasis`) with $(b_i, b^j) = \delta_{ij}$, and every contraction $\sum_i B(b_i, b^i)$ by a bilinear map B is independent of the basis (`rootContraction_basis_independe`: it is the image of the canonical element of $\mathfrak{g}_\alpha \otimes \mathfrak{g}_{-\alpha}$). For a representation ρ of $\mathfrak{g}$ on M put $T_\alpha := \sum_i \rho(b_i)\rho(b^i)$:

```
def rootCasimirTerm (α : ℤ × ℤ) : End ℂ M :=
  ∑ i, rootActionContraction ρ (D.rootFiniteBasis α i)
    (D.rootOppositeBasis (D.rootFiniteBasis α) i)
theorem rootCasimirTerm_eq_basis {ι : Type*} [Fintype ι] (α : ℤ × ℤ)
    (b : Basis ι ℂ (D.weightSpace α)) :
    D.rootCasimirTerm ρ α = ∑ i, ρ (b i) * ρ (D.rootOppositeBasis b i) :=
```

(`VOA/Moonshine/MoonshineCNBorcherdsCasimir.lean`; `rootActionContraction ρ x y = ρ x * ρ y`.)

45.16.2 The operator

Definition 45.54 (Casimir operator). On an admissible module M,

$$\Omega := \underbrace{-\rho(h_1)\rho(h_2) - \rho(h_2)\rho(h_1) - 2\rho(h_1)}_{\text{Cartan part}} + 2\sum_{\alpha\in\Phi^+} T_\alpha, \qquad h_1 = \iota(1,0),\ h_2 = \iota(0,1),$$

the sum over positive roots being finite on each vector because $\rho(\mathfrak{g}_{-\alpha})$ kills M_μ once $\mathrm{ht}\,\alpha$ exceeds $\mathrm{ht}\,\mu - h_0$.

```
def cartanCasimirOperator : End ℂ M :=
  -(ρ (D.cartanMap (1, 0)) * ρ (D.cartanMap (0, 1))) -
    ρ (D.cartanMap (0, 1)) * ρ (D.cartanMap (1, 0)) -
      (2 : ℂ) • ρ (D.cartanMap (1, 0))
def positiveCasimirOperator : End ℂ M :=
  borcherdsLocallyFiniteRootSum (D.rootCasimirTerm ρ) A.rootCasimirTerms_finiteSupport
def casimirOperator : End ℂ M :=
  D.cartanCasimirOperator ρ + (2 : ℂ) • A.positiveCasimirOperator
```

(`VOA/Moonshine/MoonshineCNBorcherdsCasimir.lean`; `A : BorcherdsAdmissible D ρ`; `borcherdsLocallyFiniteRootSu` from `VOA/Moonshine/MoonshineCNBorcherdsRootCutoff.lean` evaluates the root sum at each vector, where only finitely many terms are nonzero.)

From the mathematics to the Lean statement

The Cartan part. On M_μ, $\mu = (m,n)$, $\rho(h_1)$ acts by $(h_1,\mu)_{\mathrm{Bor}} = -n$ and $\rho(h_2)$ by $-m$, so the Cartan part acts by $-2mn + 2n = (\mu,\mu)_{\mathrm{Bor}} - 2(\delta,\mu)_{\mathrm{Bor}} = Q(\mu)$ (`cartanCasimirOperator_on_weight`). The first two terms are the contraction of the dual bases $\{h_1,h_2\},\{-h_2,-h_1\}$ of $\mathfrak{g}_0$ for $(\cdot,\cdot)_{\mathrm{Bor}}$; the third is $-2\rho(\iota\delta)$ with $\delta = (1,0)$. **Positive roots include** α_r (height 0; the root-cutoff docstring: "the height-zero real root is retained"). This is Kac's Casimir (Kac, *Infinite dimensional Lie algebras*, §2.5), with two differences: our modules are *lowest*-weight type (weights bounded below in height, and the positive-root terms are written $e_\alpha e_{-\alpha}$ so that they kill lowest-weight vectors), whence the sign $-2(\delta,\cdot)$ instead of $+2(\delta,\cdot)$; and there are infinitely many simple roots, which is why the root sum is only locally finite.

Physical meaning

The quadratic Casimir of the gauge algebra: a "mass-squared" operator, $Q(\mu)$ on a lowest-weight state of momentum μ.

Theorem 45.55 (Lowest vectors and centrality). *On every admissible M: (a) if $v \in M_\mu$ is killed by $\rho(\mathfrak{g}_{-\alpha})$ for every $\alpha \in \Phi^+$, then $\Omega v = Q(\mu)v$; and if moreover $\mu \in C$, $v \neq 0$ and $\Omega v = 0$, then $\mu_1 = 1$; (b) Ω commutes with $\rho(z)$ for every $z \in \mathfrak{g}$.*

```
theorem casimirOperator_lowest_vector {μ : ℤ × ℤ} {v : M}
    (hv : v ∈ A.weightSpace μ)
    (hlow : ∀ α, borcherdsPositiveRoot α → ∀ x ∈ D.weightSpace (-α), ρ x v = 0) :
    A.casimirOperator v = borcherdsCasimirScalar μ • v := by
theorem lowest_casimir_zero_first_coordinate {μ : ℤ × ℤ} {v : M}
    (hv : v ∈ A.weightSpace μ) (hv0 : v ≠ 0) (hμ : borcherdsPositiveCone μ)
    (hlow : ∀ α, borcherdsPositiveRoot α → ∀ x ∈ D.weightSpace (-α), ρ x v = 0)
    (hΩ : A.casimirOperator v = 0) : μ.1 = 1 := by
```

(`VOA/Moonshine/MoonshineCNBorcherdsCasimir.lean`.)

```
theorem casimirOperator_commutes (z : g) (v : M) :
    A.casimirOperator (ρ z v) = ρ z (A.casimirOperator v) := by
```

(`VOA/Moonshine/MoonshineCNBorcherdsCasimirCentral.lean`.)

From the mathematics to the Lean statement

(a) needs no centrality (docstring: "with no centrality hypothesis"). (b) is for all z, by (BD5): the docstring "BD5 generation extends the checked Cartan and simple-root commutators to all of g". Here (BD5) is a field of the *abstract* datum D; for the Monster it is `hgen`.

Physical meaning

The Casimir is a gauge-invariant mass operator; on lowest-weight states it is computed from the momentum alone.

Proof on paper. (a) $T_\alpha v = \sum_i \rho(b_i)\rho(b^i)v = 0$ since $b^i \in \mathfrak{g}_{-\alpha}$. The second claim: $Q(\mu) = -2n(m-1)$ with $n \geq 1$. (b) The set of z with $[\Omega,\rho(z)] = 0$ is a Lie subalgebra containing $\mathfrak{g}_0$ (Ω preserves weights), so by (BD5) it suffices to take $z \in \mathfrak{g}_{\pm\alpha_i}$ for simple α_i. The dual-basis identity (`rootBracketContraction`, from invariance and nondegeneracy) gives $[T_\alpha,\rho(z)] = A_\alpha(z) - A_{\alpha+\gamma}(z)$ with $A_\beta(z) = \sum_i \rho(b_i^{(\beta)})\rho([b^i_{(\beta)},z])$ for $z \in \mathfrak{g}_\gamma$ (`rootCasimirTerm_commutator`); summing over $\alpha \in$

Φ^+ telescopes (`positiveCasimirOperator_commutator_finsum`) because a simple root minus a positive root is never positive (`borcherdsSimpleRoot_sub_not_positive`), leaving one boundary term: $-\rho(z)\rho(\iota\alpha_i)$ for $z \in \mathfrak{g}_{\alpha_i}$ and $\rho(\iota\alpha_i)\rho(z)$ for $z \in \mathfrak{g}_{-\alpha_i}$ (`positiveCasimirOperator_commutator_positive_simple`, `_negative_simple`). On $v \in M_\mu$ and $z \in \mathfrak{g}_{\alpha_i}$:

$$[\Omega, \rho(z)]v = \big[Q(\mu+\alpha_i) - Q(\mu) - 2(\alpha_i,\mu)_{\mathrm{Bor}}\big]\rho(z)v = \big[(\alpha_i,\alpha_i)_{\mathrm{Bor}} - 2(\delta,\alpha_i)_{\mathrm{Bor}}\big]\rho(z)v = 0,$$

because δ is a Weyl vector; similarly for $\mathfrak{g}_{-\alpha_i}$ (`borcherdsCasimirScalar_positive_simple_step`, `_negative_simple_step`). □

What the machine verified

No hypotheses beyond the datum and admissibility; standard axioms (`VOA/Moonshine/MoonshineCNAudit15.lean`). The supporting files `BorcherdsRootDuality`, `BorcherdsRootCutoff`, `BorcherdsCasimirCommutator`, `BorcherdsCasimirTelescoping`, `BorcherdsCasimirBoundary` contain exactly the steps named in the proof; their finite-support lemmas (`rootCasimirTerms_finiteSupport`, `shiftedCasimirBoundary_finiteSupport`, `lowering_common_height_bound`) make the infinite root sums honest finite sums at each vector.

Theorem 45.56 (Casimir on induced modules). *On an admissibly graded induced module, if Ω acts on the bottom $1 \otimes W$ by a scalar c, it acts by c everywhere.*

```
theorem inducedCasimir_scalar_of_bottom (D : BorcherdsData g)
    (A : BorcherdsAdmissible D (relativeInducedRep p σ)) (c : ℂ)
    (hbottom : ∀ w : W,
      A.casimirOperator (PBWTheorem.bottom p σ w) = c • PBWTheorem.bottom p σ w) :
    A.casimirOperator = c • LinearMap.id := by
```

(`VOA/Moonshine/MoonshineCNBorcherdsCasimirInduction.lean`.)

Physical meaning

A gauge-invariant operator is constant on an irreducible-like multiplet generated from a vacuum.

Proof on paper. $\mathrm{Ind}(W) = \mathcal{U}(\mathfrak{g})(1 \otimes W)$ and Ω commutes with $\mathcal{U}(\mathfrak{g})$ (Theorem 45.55(b)). □

What the machine verified

Standard axioms (`VOA/Moonshine/MoonshineCNAudit15.lean`).

45.17 The length-one resolution

Theorem 45.57 (Length-one resolution). *Let D be a Borcherds datum with a normalized pair (e, f). Let $\mathrm{Ind}(\mathbb{C})$ be induced from the trivial $\mathfrak{p}^-$-module and $\mathrm{Ind}(U)$ from U (with $\mathfrak{p}^-$ acting through its Levi quotient). The map $\Phi : \mathrm{Ind}(U) \to \mathrm{Ind}(\mathbb{C})$, $[a \otimes u] \mapsto [au \otimes 1]$, and the augmentation $\epsilon : \mathrm{Ind}(\mathbb{C}) \to \mathbb{C}$ form an exact sequence of vector spaces*

$$0 \longrightarrow \mathrm{Ind}(U) \xrightarrow{\Phi} \mathrm{Ind}(\mathbb{C}) \xrightarrow{\epsilon} \mathbb{C} \longrightarrow 0.$$

Moreover Φ is a map of $\mathfrak{g}$-modules (`generatorVermaResolution_equivariant`). Equivalently, right multiplication $\mathcal{U}(\mathfrak{u}^+) \otimes U \to \mathcal{U}(\mathfrak{u}^+)$ is injective with image the augmentation ideal.

```
def generatorVermaResolution :
    relativeInducedSpace D.parabolicPart (D.genSpaceParabolicRep e f he hf hef) →ₗ[ℂ]
      relativeInducedSpace D.parabolicPart D.parabolicTrivialRep :=
theorem generatorVermaResolution_injective :
    Function.Injective (D.generatorVermaResolution e f he hf hef) := by
theorem generatorVermaResolution_shortExact :
    Function.Injective (D.generatorVermaResolution e f he hf hef) ∧
      Function.Exact (D.generatorVermaResolution e f he hf hef) D.trivialVermaAugmentation
       ↪  ∧
      Function.Surjective D.trivialVermaAugmentation := by
theorem positiveGeneratorMultiplication_shortExact :
    Function.Injective (envelopingGeneratorMultiplication (D.positiveGeneratorSpace e)) ∧
      Function.Exact (envelopingGeneratorMultiplication (D.positiveGeneratorSpace e))
        (envelopingAugmentation (g := D.positivePart)).toLinearMap ∧
      Function.Surjective (envelopingAugmentation (g := D.positivePart)) :=
```

(`VOA/Moonshine/MoonshineCNBorcherdsResolution.lean`; section variables `(e f : g) (he) (hf) (hef : D.form e f = 1)`; `envelopingGeneratorMultiplication S` is $a \otimes u \mapsto a\,\iota(u)$, `VOA/Moonshine/MoonshineCNBorcherdsR`

From the mathematics to the Lean statement

`Function.Exact f g` means $\operatorname{im} f = \ker g$. `parabolicTrivialRep` is the zero representation on $\mathbb{C}$; `genSpaceParabolicRep e f he hf hef` is the $\mathfrak{p}^-$-action on U through the Levi projection. `trivialVermaAugmentation` is read off in PBW coordinates (`trivialVermaAugmentation_verma`: it is $\epsilon(a)$ on $[a \otimes 1]$). **Hypotheses**: the datum (including (BD5)) and the normalized pair, which always exists.

Physical meaning

In homological terms: $H_k(\mathfrak{u}^+;\mathbb{C})$ vanishes for $k \geq 2$ and $H_1(\mathfrak{u}^+;\mathbb{C}) \cong U$: the gauge algebra's positive cone has generators U and no relations. In string terms, the Casimir (mass) of a would-be relation would have to vanish, which forces it to sit on the line $m = 1$ where there are no relations.

Proof on paper. Φ *is well defined.* By the universal property of induction, a $\mathfrak{g}$-map out of $\mathrm{Ind}(U)$ is the same as a $\mathfrak{p}^-$-map out of U. The map $u \mapsto un_0 = [u \otimes 1]$ is $\mathfrak{p}^-$-equivariant: for $p \in \mathfrak{p}^-$, $p \cdot un_0 = [p,u]n_0 + u\,p\,n_0 = [p,u]n_0$, and $[p,u]$ differs from the action of p on U (through the Levi projection) by an element of $\mathfrak{p}^-$, which kills n_0 (`genSpaceParabolicRep_sub_mem`; this uses $[\mathfrak{u}^-, U] \subseteq \mathfrak{p}^-$, Theorem 45.50(d)). *Image.* $\operatorname{im}\Phi = \mathcal{U}(\mathfrak{g})(Un_0) = \mathcal{U}(\mathfrak{u}^+)\mathcal{U}(\mathfrak{p}^-)(Un_0) = \mathcal{U}(\mathfrak{u}^+)Un_0$, which is $\mathcal{U}(\mathfrak{u}^+)_+ n_0 = \ker\epsilon$ by Theorem 45.52 and relative PBW (Theorem 45.53). *Casimir vanishes on* $\mathrm{Ind}(U)$. $\mathrm{Ind}(U)$ is generated from $1 \otimes U$, and $1 \otimes U$ from $1 \otimes \bigoplus_j \mathfrak{g}_{\alpha_j}$ by the Levi action; $1 \otimes v$, $v \in \mathfrak{g}_{\alpha_j}$, has weight α_j and is killed by $\mathfrak{u}^-$ (which acts by 0 on U) and by f ($[f,v] = 0$); so $\Omega(1 \otimes v) = Q(1,j)(1 \otimes v) = 0$ (`generatorVerma_casimir_bottom`, `generatorVerma_casimir_eq_zero`). *Injectivity.* $Z := \ker\Phi$ is a graded submodule (`cartanEigenspace_kernel_graded`) with weights in C. If $Z \neq 0$, take the least height h with $Z_{(h)} := \bigoplus_{\mathrm{ht}\,\mu = h} Z_\mu \neq 0$. It is finite-dimensional (finitely many $\mu \in C$ of height h, each weight space of $\mathrm{Ind}(U) \cong U(\mathfrak{u}^+) \otimes U$ finite-dimensional). Every lowering operator from $\mathfrak{g}_{-\alpha}$ with $\alpha \in C$ lowers the height, so kills $Z_{(h)}$ (the target is $Z_{(<h)} = 0$). The remaining lowering operator f keeps the height and lowers the first coordinate by one; since only finitely many first coordinates occur at height h, a power of f vanishes on $Z_{(h)}$, so $\ker f \cap Z_{(h)} \neq 0$. This kernel is stable under the Cartan ($[\iota\xi, f]$ is a multiple of f), so it contains a nonzero weight vector k, of weight $\mu \in C$, killed by *all* lowering operators. By Theorem 45.55(a), $0 = \Omega k = Q(\mu)k$, so $\mu_1 = 1$ (`submodule_eq_bot_of_casimir_zero`). But on the line $m = 1$ the module $\mathrm{Ind}(U)$ has only bottom vectors: $\mathrm{Ind}(U) = U(\mathfrak{u}^+) \otimes U$ (relative PBW), every homogeneous element of $U(\mathfrak{u}^+)$ of nonzero degree raises the first coordinate by at least one, and U has first coordinates ≥ 1; so a weight

vector with first coordinate 1 is $1 \otimes u$ with $u \in U_{(1,n)} = \mathfrak{g}_{\alpha_n}$ (`generatorVerma_firstLine_bottom`). On such vectors Φ is $u \mapsto un_0$, which is injective because $\mathfrak{u}^+ \to U(\mathfrak{u}^+) \cong \mathrm{Ind}(\mathbb{C})$ is injective (`generatorVermaResolution_firstLine`). Contradiction. □

What the machine verified

No hypotheses beyond the datum and the pair; standard axioms (`VOA/Moonshine/MoonshineCNAudit17.lean`).

45.18 Freeness: $T(U) \cong \mathcal{U}(\mathfrak{u}^+)$ and $\mathfrak{u}^+$ is free on U

45.18.1 The tensor algebra

Theorem 45.58 ($T(U) \cong \mathcal{U}(\mathfrak{u}^+)$). *For any Lie algebra L and subspace S: if right multiplication $\mathcal{U}(L) \otimes S \to \mathcal{U}(L)$ is injective, then $T(S) \to \mathcal{U}(L)$ is injective; if S generates L, $T(S) \to \mathcal{U}(L)$ is surjective. For a Borcherds datum, $T(U) \to \mathcal{U}(\mathfrak{u}^+)$ is an algebra isomorphism, natural in every symmetry (BD6).*

```
theorem tensorGeneratorToEnveloping_injective_of_multiplication
    (hμ : Function.Injective (envelopingGeneratorMultiplication S)) :
    Function.Injective (tensorGeneratorToEnveloping S) := by
theorem positiveTensorGeneratorToEnveloping_bijective :
    Function.Bijective (tensorGeneratorToEnveloping (D.positiveGeneratorSpace e)) :=
def positiveTensorEnvelopingEquiv :
    TensorAlgebra ℂ (D.positiveGeneratorSpace e) ≃ₐ[ℂ]
      UniversalEnvelopingAlgebra ℂ D.positivePart :=
theorem positiveTensorEnvelopingEquiv_equivariant (σ : G)
    (t : TensorAlgebra ℂ (D.positiveGeneratorSpace e)) :
    D.positiveTensorEnvelopingEquiv e f he hf hef
        (tensorGeneratorMap _ ((D.positivePartAction A σ).toLinearMap.restrict
          (p := D.positiveGeneratorSpace e) (q := D.positiveGeneratorSpace e)
          (D.positiveGenerator_action_mem e he A σ)) t) =
      envelopingMap (D.positivePartAction A σ)
        (D.positiveTensorEnvelopingEquiv e f he hf hef t) :=
```

(`VOA/Moonshine/MoonshineCNBorcherdsTensorEnveloping.lean`; `tensorGeneratorToEnveloping S` is the algebra map $T(S) \to \mathcal{U}(L)$ extending $S \hookrightarrow L \to \mathcal{U}(L)$, `VOA/Moonshine/MoonshineCNBorcherdsResolutionRange.lean`.)

From the mathematics to the Lean statement

`≃ₐ[ℂ]` is an algebra isomorphism. The equivariance says: for σ in a (BD6) group, applying σ on generators and then the isomorphism equals applying the isomorphism and then $\mathcal{U}(\sigma|_{\mathfrak{u}^+})$.

Physical meaning

Products of positive-cone gauge charges are freely generated by the U-charges: no relations at the level of the enveloping algebra.

Proof on paper. Filter $T(S)$ by degree (`tensorDegreeFiltration`). If $\tau(t) = 0$ with $t \neq 0$ of minimal degree, write $t = c + \sum_i t_i u_i$ with c a scalar; applying the augmentation gives $c = 0$, and then $\tau(t) = \mu(\sum \tau(t_i) \otimes u_i) = 0$ forces $\sum \tau(t_i) \otimes u_i = 0$ by injectivity of μ; taking the u_i linearly independent (part of a basis of S), this forces every $\tau(t_i) = 0$, hence every $t_i = 0$ by induction on the degree, hence $t = 0$. For Borcherds data, injectivity of μ is Theorem 45.57 and surjectivity of τ is Theorem 45.52. □

What the machine verified

No hypotheses beyond the datum and the pair; standard axioms (`VOA/Moonshine/MoonshineCNAudit17.lean`).

45.18.2 The free Lie algebra

Theorem 45.59 ($\mathfrak{u}^+$ is free on U). *Let $(u_i)_{i\in I}$ be the chosen basis of U (`Basis.ofVectorSpace`; by the general lemmas, any basis would do). The Lie algebra map from the free Lie algebra on I to $\mathfrak{u}^+$ sending the i-th generator to u_i is an isomorphism, intertwining every symmetry (BD6).*

```

From the mathematics to the Lean statement

Exactly what is proved about freeness. The Lie algebra that is shown to be free is `D.positivePart`, i.e. $\mathfrak{u}^+ = \bigoplus_{m,n\geq 1} \mathfrak{g}_{(m,n)}$ (Borcherds coordinates): the positive cone, which is the positive part $E = \mathfrak{g}_{\alpha_r} \oplus \mathfrak{u}^+$ *minus the real simple root*. The free generating space is U, the span of all $(\operatorname{ad} e)^k \mathfrak{g}_{\alpha_j}$, $0 \leq k < j$, *not* $\bigoplus_j \mathfrak{g}_{\alpha_j}$ alone. The free Lie algebra is Mathlib's `FreeLieAlgebra ℂ ι` on the index set of an arbitrary basis of U (`Basis.ofVectorSpace`, chosen by `Classical.choice`); since a free Lie algebra on a basis of U is the free Lie algebra on the vector space U, the choice is immaterial, and the equivariance statement shows the isomorphism is compatible with symmetries via the induced map `freeLieInducedMap`.

Injectivity of $L \to \mathcal{U}(L)$. `freeLieGeneratorMap_injective` uses that the free Lie algebra embeds in its enveloping algebra (`envelopingEmbedding_injective`, Chapter 44, the PBW theorem) and Mathlib's `FreeLieAlgebra.universalEnvelopingEquivFreeAlgebra` with `TensorAlgebra.equivFreeAlgebra`.

Relation to the informal statement. One often reads "E minus the real root is a free Lie algebra". The Lean statement is the precise version: $\mathfrak{u}^+$ is free on U. The variant "the

subalgebra generated by $\bigoplus_j \mathfrak{g}_{\alpha_j}$ is free on it" (Jurisich's form) is *not* formalized; it follows on paper from Theorem 45.59 because $\bigoplus_j \mathfrak{g}_{\alpha_j} = \bigoplus_j U_{j,0}$ is a graded direct summand of U.

Physical meaning

The positive-cone gauge bosons are all nested commutators of the W-multiplets of the imaginary simple root states, with no relations among them: a free Lie algebra, as for the "Monster Lie algebra minus its $\mathfrak{gl}_2$".

Proof on paper. Surjective because U generates $\mathfrak{u}^+$ (Theorem 45.52). Injective: the composite $\mathrm{Free}(I) \to \mathfrak{u}^+ \to \mathcal{U}(\mathfrak{u}^+)$ equals $\mathrm{Free}(I) \hookrightarrow \mathcal{U}(\mathrm{Free}(I)) \cong \mathrm{FreeAlg}(I) \cong T(U) \xrightarrow{\tau} \mathcal{U}(\mathfrak{u}^+)$, which is injective by PBW for the free Lie algebra and Theorem 45.58. □

What the machine verified

No hypotheses beyond the datum and the pair; standard axioms (`VOA/Moonshine/MoonshineCNAudit17.lean`).

Trap / dead end

E itself is not free. $E = \bigoplus_{m>0} \mathfrak{g}_{(m,n)} = \mathfrak{g}_{\alpha_r} \oplus \mathfrak{u}^+$ satisfies the relations $(\mathrm{ad}\, e)^j \mathfrak{g}_{\alpha_j} = 0$ (Theorem 45.48(b)); e.g. $[e, v] \in \mathfrak{g}_{(2,0)} = 0$ for $v \in \mathfrak{g}_{\alpha_1}$. And freeness on $\bigoplus_j \mathfrak{g}_{\alpha_j}$ alone, although true for the subalgebra it generates, would not give the denominator identity: its graded dimension is $1/(1 - \sum_j c(j) pq^j)$, not the product side. The Lean statement with generators U is the one Chapter 46 needs.

45.19 Consequences for the Monster Lie algebra

Theorem 45.60 (Structure of the Monster Lie algebra). *Given simple-root generation (a theorem, §45.13), and any $e \in \mathfrak{m}^{\mathrm{Bor}}_{\alpha_r}$, $f \in \mathfrak{m}^{\mathrm{Bor}}_{-\alpha_r}$ with $(e, f) = 1$: (a) $\dim U_{j,k} = \dim V^{\natural}_{1+j}$ for $0 \le k < j$; (b) $0 \to \mathrm{Ind}(U) \to \mathrm{Ind}(\mathbb{C}) \to \mathbb{C} \to 0$ is exact; (c) $T(U) \to \mathcal{U}(\mathfrak{u}^+)$ is bijective; (d) $\mathfrak{u}^+ = \bigoplus_{m,n\ge 1} \mathfrak{m}^{\mathrm{Bor}}_{(m,n)}$ is free on U.*

```

```

(`VOA/Moonshine/MoonshineCNMonsterBorcherdsData.lean`; section variables (`hgen : MonsterLieSimpleRootGeneration (e f : monsterLieAlgebra) (he : e ∈ monsterLieBorcherdsWeight borcherdsRealRoot) (hf : f ∈ monsterLieBorcherdsWeight (-borcherdsRealRoot)) (hef : monsterLieBilinearForm e f = 1)`.)

From the mathematics to the Lean statement

Instances of Theorems 45.50, 45.57, 45.58, 45.59 at `monsterLieBorcherdsData hgen`. (a) combines `generatorString_finrank` with `monsterLieBorcherdsRootEquiv` at $\gamma = \alpha_j$: $1 + 1 \cdot j = 1 + j$. So $U_{(a,b)} \cong V^\natural{}_{a+b}$, $\dim U_{(a,b)} = c(a+b-1)$, as needed for the product side $1 - \sum c(a+b-1)p^a q^b$.

Physical meaning

The Monster string's gauge algebra has a free positive cone, generated by the W-multiplets of the states $V^\natural{}_{1+j} \otimes e^{(1,-j)}$.

What the machine verified

Conditional on `hgen` in this file; unconditional after substituting `M8.monsterLieSimpleRootGeneration`. Standard axioms (`VOA/Moonshine/MoonshineCNAudit17.lean`).

45.20 What the chapter proves, and what it does not

- **Proved, no hypotheses:** the abstract no-ghost theorem (under its stated hypotheses $c = 26$ and (F1)); the concrete light-cone splitting; the $V^\natural$ no-ghost isometry at every nonzero momentum and the zero-momentum hyperbolic plane; the Lie algebra $\mathfrak{m}$, its $\mathrm{II}_{1,1}$-grading, root spaces $V^\natural{}_{1-xy} / \mathbb{C}^2$, $\mathrm{Aut}(V^\natural)$-action, invariant nondegenerate form with lattice normalisation on $\mathfrak{m}_0$, Cartan action; the whole Lie theory of Borcherds data.
- **Proved, conditional on `hgen`** in the files of this chapter, **discharged** in Chapter 47: $\mathfrak{m}$ is a Borcherds datum; its resolution, $T(U) \cong \mathcal{U}(\mathfrak{u}^+)$, freeness.
- **Not formalized:** the BRST cohomology description; positivity (unitarity) of the form on $V^\natural$ or $\mathfrak{m}$; that $\mathfrak{m}$ is a generalized Kac–Moody algebra in Borcherds' axiomatic sense, or any Weyl–Kac–Borcherds character formula as a Lie-theoretic theorem (the denominator identity is proved analytically in Chapter 46); Jurisich's freeness on $\bigoplus_j \mathfrak{m}_{\alpha_j}$; an isometry statement for $\mathfrak{m}_r \cong V^\natural{}_{1-r^2/2}$ at the Lie-algebra level (only at the sector level).
- **Trust model:** every headline is `#print axioms`-clean with the three standard axioms; the former project axiom `VOA.pbw` is a theorem and is not an axiom of any declaration here.

Coverage of the assigned files. The 75 files assigned to this chapter are covered as follows. *Individually (headlines with Lean quotations):* `StringModule`, `StringOrthogonals`, `StringGenerators`, `StringCritical`, `StringLongitudinal`, `StringGrading`, `StringTransverse`, `StringPhysical`, `StringQuotient`, `StringComparison`, `StringStraightening`, `VnatSectorOperators`, `VnatSectorLaws`, `VnatSectorGrading`, `VnatLightCone`, `VnatStringModule`, `VnatFormAction`, `VnatSectorAction`, `VnatSectorEvaluation`, `VnatLongitudinal`, `VnatNoGhost`, `VnatNoGhostConsequences`, `VnatZeroWeight`, `VnatZeroQuotient`, `PhysicalLie`, `PhysicalMaps`, `MonsterLie`, `MonsterGrading`, `SectorVirasoroComparison`, `SectorPhysicalTransfer`, `RootSpaces`, `RootSpaceAction`, `RootRadical`, `SectorFormConvention`, `SectorFormComparison`, `MonsterForm`, `MonsterPairing`, `MonsterRadical`, `MonsterZeroForm`, `MonsterCartanAction`, `MonsterLieInvariance`, `BorcherdsRoots`, `BorcherdsData`, `MonsterBorcherdsData`, `BorcherdsSl2`, `BorcherdsGeneratorWeights`, `BorcherdsStringSum`,

What the machine verified

Every row is `#print axioms`-clean (standard axioms, no `sorryAx`) in the audit modules `VOA/Moonshine/MoonshineCNAudit4.lean`–`VOA/Moonshine/MoonshineCNAudit17.lean`. "Pair" means a normalized real pair (e, f), which always exists (`exists_normalized_real_pair`). The only non-structural hypothesis in the chapter, `hgen`, is discharged by `M8.monsterLieSimpleRootGeneration` (no hypotheses; `VOA/Moonshine/MoonshineCNFinalAudit.lean`). These statements were *not* re-built for this chapter: the outputs are those reported by the maintainers' targeted builds of the audit modules, and no aggregate build of the whole library is claimed.

45.22 Notes and references

The no-ghost theorem is due to P. Goddard and C. B. Thorn, *Compatibility of the dual Pomeron with unitarity and the absence of ghosts in the dual resonance model*, Phys. Lett. B 40 (1972) 235–238; R. C. Brower, *Spectrum-generating algebra and no-ghost theorem for the dual model*, Phys. Rev. D 6 (1972) 1655–1662, gave the independent argument via DDF operators. The BRST treatment is in M. Kato and K. Ogawa, *Covariant quantization of string based on BRS invariance*, Nucl. Phys. B 212 (1983) 443–460, and in I. B. Frenkel, H. Garland and G. J. Zuckerman, *Semi-infinite cohomology and string theory*, Proc. Natl. Acad. Sci. USA 83 (1986) 8442–8446. The physical background is in M. B. Green, J. H. Schwarz and E. Witten, *Superstring Theory*, Vol. 1, Cambridge University

Press, 1987, Chapter 2, and J. Polchinski, *String Theory*, Vol. 1, Cambridge University Press, 1998, Chapters 4 and 6.

Generalized Kac–Moody (Borcherds) algebras were introduced by R. E. Borcherds, *Generalized Kac–Moody algebras*, J. Algebra 115 (1988) 501–512. The Monster Lie algebra, its construction from $V^{\natural} \otimes V_{\mathrm{II}_{1,1}}$ via the no-ghost theorem, the denominator identity and the proof of the Conway–Norton conjecture are in R. E. Borcherds, *Monstrous moonshine and monstrous Lie superalgebras*, Invent. Math. 109 (1992) 405–444; §5 there sketches Goddard–Thorn's proof in the form used here, and §§6–7 the Lie theory. The freeness of the subalgebra generated by the imaginary simple root spaces is due to E. Jurisich, *Generalized Kac–Moody Lie algebras, free Lie algebras and the structure of the Monster Lie algebra*, J. Pure Appl. Algebra 126 (1998) 233–266; see also E. Jurisich, J. Lepowsky and R. L. Wilson, *Realizations of the Monster Lie algebra*, Selecta Math. (N.S.) 1 (1995) 129–161. A careful expository account is R. W. Gebert, *Introduction to vertex algebras, Borcherds algebras and the Monster Lie algebra*, Internat. J. Modern Phys. A 8 (1993) 5441–5503 (arXiv:hep-th/9308151). The Casimir operator and its use for resolutions follow V. G. Kac, *Infinite dimensional Lie algebras*, 3rd ed., Cambridge University Press, 1990, §§2.4–2.6 and §9.11 (and the Garland–Lepowsky/Kostant homology theory that lies behind it). Invariant forms on vertex algebras: I. B. Frenkel, Y.-Z. Huang and J. Lepowsky, *On axiomatic approaches to vertex operator algebras and modules*, Mem. Amer. Math. Soc. 104 (1993), no. 494.

The development followed the authors' working notes, which are not part of the release: the no-ghost argument restructures Goddard–Thorn into the single hypothesis (F1), proved by a leading-term argument that avoids the Kac determinant, and the Borcherds-data Lie theory uses a Casimir route to the length-one resolution (with the recorded dead end "generation $\Leftrightarrow$ product formula"). Those notes are unrefereed; where they and the Lean source differ (e.g. the light-cone charges are $(\kappa, \ell) = (x, y)$ in Lean rather than (y, x); the radical identification holds without $c = 26$), this chapter follows the source.

Chapter 46

Denominator identities, replication and genus zero

This chapter documents the release of the library named in the front matter; every Lean quotation is checked by `scripts/textbook/sync.py` to occur verbatim (up to whitespace and comments) in the source files of that release. The chapter documents the sixty files that `Notes/Textbook/assignment.txt` assigns to it: the files `MoonshineCNTwisted*`, `MoonshineCNReplication*` and `MoonshineCNGenusZero*` written on Fedor Popov's side of the project, and the files `MoonshineLRM5*`, `MoonshineLRHecke*`, `MoonshineLRFaber*`, `MoonshineLRJUnbounded*`, `MoonshineLRNontrivial*`, `MoonshineLRPropertyP`, `MoonshineLRTower*` and `MoonshineLRCoeffBound*` written on Leonardo Rastelli's side, all in the folder `VOA/Moonshine/`.

Where we are. Chapter 43 stated the Conway–Norton conjecture in Lean (`ConwayNortonConjecture`), defined complete replicability (`CompletelyReplicable`), the abstract interface `ReplicableFamily`, and proved the step from groups containing $\Gamma_1(N)$ to groups containing $\Gamma_0(N)$. Chapters 44 and 45 built the Monster Lie algebra $\mathfrak{m}$ from $V^\natural \otimes V_{II_{1,1}}$, proved the no-ghost theorem $\mathfrak{m}_{(m,n)} \cong {V^\natural}_{1+mn}$, and showed that $\mathfrak{m}$ is a Borcherds datum with $T(U) \cong U(\mathfrak{u}^+)$, *given* that $\mathfrak{m}$ is generated by its simple root spaces (the proposition `MonsterLieSimpleRootGeneration`, proved in Chapter 47). The present chapter connects these two ends. It proves, in Lean:

(I) **the product identity for** J (the denominator identity of the Monster Lie algebra, but stated and proved in Lean as an identity about J alone; no theorem of this chapter mentions $\mathfrak{m}$ in it)

$$\prod_{m,n\geq 1} \left(1 - p^m q^n\right)^{c(mn)} = 1 - \sum_{a,b\geq 1} c(a+b-1)\, p^a q^b, \tag{46.1}$$

for the coefficients $c(n)$ of $J = j - 744$, as an identity of formal series (`knz_product`; the product is read as `coneProd`, the series with the product's logarithmic derivative, Definition 46.17), by a route that never mentions Lie algebras: it is derived from the replicability of J, which in turn is proved from the $\mathrm{SL}_2(\mathbb{Z})$-invariance of j;

(II) **the twisted denominator identities**: for every Borcherds datum with a finite-order symmetry σ, and in particular for every finite-order automorphism of $V^\natural$ acting on $\mathfrak{m}$, a logarithm-free identity of two-variable formal series between the McKay–Thompson coefficients of σ and of its powers (`twistedDenominatorIdentity_of_finOrder`, `twistedDenominatorIdentity_of_simpleRootGeneration`);

(III) **replication**: the twisted identities imply, formally and then analytically, that every finite-order McKay–Thompson series is completely replicable (`faberPoly_replication`, `faberPoly_eval_mckayThompsonFun`, `completelyReplicable_of_simpleRootGeneration`);

(IV) **genus zero**: for a replicable family of positive period that satisfies the prime Hecke identity and nontriviality (explicit hypotheses `hB1`, `hD7`), every member is a normalised Hauptmodul of a group of determinant one that contains some $\Gamma_1(N')$ and is commensurable with $\mathrm{SL}_2(\mathbb{Z})$ (`ReplicableFamily.exists_hauptmodul_gammaOne`). The two inputs are separate theorems, proved for every family (`ReplicableFamily_primeHeckeIdentity`, `ReplicableFamily_notInjectiveModTranslations`); the composite "for every family of positive period" is *not* packaged as a single Lean declaration. Hence the Γ_1 form of Conway–Norton follows from complete replicability (`conwayNortonGammaOne_of_completelyReplicable`), and the full conjecture follows from complete replicability and finite order (`conwayNorton_of_completelyReplicable`).

Part (IV) is the longest part of the chapter, and mathematically the most interesting. It is a *case-free* proof that complete replicability forces the genus-zero property. It is modelled on the work of Cummins and Gannon (1997) and Cummins (2002), but it is a different proof: the analytic continuation of local symmetries, which is the heart of Cummins–Gannon, is replaced by a real linear ordinary differential equation satisfied by every local symmetry, and several steps of the published proofs that fail as printed are replaced by corrected arguments (§46.14, §46.15).

What is conditional and what is not. Every theorem of this chapter is `#print axioms`-clean (only `propext`, `Classical.choice`, `Quot.sound`). Very few of them are hypothesis-free; the *unconditional* ones (no premises at all) are the replicability of J, the product identity `knz_product` and its logarithmic form, the prime Hecke identity, the unboundedness of J's coefficients, and (given only $0 < N$) nontriviality and property P. All others carry explicit premises, listed in each status box: analytic lemmas assume `IsJDominated c`; the abstract twisted identity assumes eigenbases or finite order; the genus-zero steps assume `hN : 0 < N`, the prime Hecke identity (`hB1`), nontriviality (`hD7`), property P (`hP`) or $\Gamma_1(M) \leq G$, depending on the step. The premises `hB1`, `hD7`, `hP` are discharged by theorems of this same chapter, but the composites are written out in Lean only for the McKay–Thompson families (Chapter 47). The Monster instances of parts (II) and (III) take the hypothesis `hgen : MonsterLieSimpleRootGeneration` (and, for the statement over all of $\mathrm{Aut}(V^\natural)$, `hfin : ∀ g : AutVnat, IsOfFinOrder g`); the Conway–Norton consequences also take `hrep : CompletelyReplicable`. These are discharged by theorems of Chapter 47, and the hypothesis-free consequences `completelyReplicable_holds` and `conwayNortonGammaOne_holds` are recorded in Chapter 49. We say "conditional on `hgen`" whenever a statement of this chapter carries that hypothesis, even though it is later discharged.

How to read this chapter. Section 46.1 gives the logical chain and fixes conventions. Sections 46.2–46.4 are part (I), Section 46.5 is part (II), Section 46.6 is part (III), and Sections 46.7–46.13 are part (IV). Section 46.14 compares the genus-zero proof with the literature; Section 46.15 collects the recorded traps; the chapter ends with the audit modules, the referee's checklist and the references. As everywhere in this book, the concern is the *meaning* of the Lean statements; proofs are explained mathematically, and we do not describe how the Lean proof scripts are organised.

46.1 The logical chain and the conventions

46.1.1 The chain of implications

The following diagram shows the implications proved in this chapter. Arrows are Lean theorems; a label in brackets is an explicit hypothesis of the Lean theorem.

statement	proved from
J replicable: $P_M(J) = \sum_{ad=M}\sum_{b<d} J(\frac{a\tau+b}{d})$ (`faberPoly_cJ_eval_eq_qHeckeSum`)	$\mathrm{SL}_2(\mathbb{Z})$-invariance of j; Hecke cosets; Faber polynomials
product identity (46.1) (`knz_product`)	replicability of J; Faber generating identity
twisted identity $D\tilde{u} = (1-\tilde{u})\tilde{P}$ for a symmetry of a Borcherds datum (`twistedDenominatorIdentity_of_finOrder`)	$T(U) \cong U(\mathfrak{u}^+)$ (Ch. 45); PBW; finite order
the same for $\sigma \in \mathrm{Aut}(V^\natural)$ on $\mathfrak{m}$ (`twistedDenominatorIdentity_of_simpleRootGeneration`)	[`hgen`], finite order of σ, the no-ghost isomorphisms (Ch. 45)
formal replication (`faberPoly_replication`)	a twisted identity
analytic replication of T_g (`faberPoly_eval_mckayThompsonFun`)	twisted identity of g; finite order
`CompletelyReplicable` (`completelyReplicable_of_simpleRootGeneration`)	[`hgen`], [`hfin`]
prime Hecke identity for every family (`ReplicableFamily_primeHeckeIdentity`)	periodicity of the family
nontriviality for every family (`ReplicableFamily_notInjectiveModTranslations`)	replication; J's coefficients are unbounded
genus zero for every family (`ReplicableFamily.exists_hauptmodul_gammaOne`)	[prime Hecke identity], [nontriviality]
`ConwayNortonGammaOne` (`conwayNortonGammaOne_of_completelyReplicable`)	[`hrep`], [prime Hecke], [nontriviality]
`ConwayNortonConjecture` (`conwayNorton_of_completelyReplicable`)	the above, [`hfin`], and the $\Gamma_1 \Rightarrow \Gamma_0$ bridge of Ch. 43

The bracketed inputs "prime Hecke" and "nontriviality" of the last three rows are discharged for *every* replicable family by the two theorems of the eighth and ninth rows; the file `VOA/Moonshine/MoonshineLRConwayNorton.lean` (Chapter 47) composes them into `M8.conwayNorton_of_finOrder_of_completelyReplicable (hfin) (hrep)`.

Physical meaning

The chain is Borcherds' proof read as string theory. The product identity is the statement that the physical states of the bosonic string compactified on the moonshine orbifold times a two-dimensional Lorentzian torus have the multiplicities $c(mn)$ (the no-ghost theorem) and that the second-quantised string Fock space they generate is "free up to one relation". The twisted identities are the same statement with a symmetry g inserted in the trace. Replication says that the g-twisted torus partition functions transform among themselves under the Hecke correspondences (passing to m-sheeted covers of the torus). Genus zero is the rigid analytic consequence of these covering relations. None of these physical readings is used as a proof.

46.1.2 Conventions for q-series

Throughout, $q = e^{2\pi i\tau}$ for $\tau \in \mathbb{H}$ (the function `qPar` of Chapter 43), and

$$J(\tau) = j(\tau) - 744 = \sum_{n\geq -1} c(n)q^n = q^{-1} + 196884\,q + 21493760\,q^2 + \cdots, \qquad c(-1) = 1,\ c(0) = 0.$$

Chapter 33 defined the formal series `JShift` $= qJ$, so that $[q^n]$`JShift` $= c(n-1)$. Two encodings of a normalised q-series $f = q^{-1} + \sum_{n\geq 1} c(n)q^n$ occur:

- as a *function* on $\mathbb{H}$: `qSeriesFun c τ` $= q^{-1} + \sum_{n\geq 0} c(n+1)q^{n+1}$ (Chapter 43, the definition of replicable families); the value `c 0` is ignored;
- as a *formal Laurent series*: `qSeriesLaurent c` $\in \mathbb{C}((q))$ (Definition 46.2 below); again `c 0` is ignored.

The coefficient sequence of J in this encoding is

```
noncomputable def cJ (n : ℕ) : ℂ := PowerSeries.coeff (n + 1) JShift
```

(`VOA/Moonshine/MoonshineLRM5Replicable.lean`, namespace `VOA.Moonshine.ConwayNorton.M8`), so `cJ n` $= c(n)$ for $n \geq 1$ and `cJ 0` $= c(0) = 0$. The analytic results need a uniform bound on the coefficients; the library's notion is domination by J:

```
noncomputable def jCoeffMajorant (n : ℕ) : ℝ := ‖PowerSeries.coeff (n + 1 + 1) JShift‖
noncomputable def jTail (y : ℝ) : ℝ :=
  ∑' n : ℕ, jCoeffMajorant n * Real.exp (-2 * π * (n + 1) * y)
def IsJDominated (c : ℕ → ℂ) : Prop :=
  ∀ n : ℕ, ‖c (n + 1)‖ ≤ jCoeffMajorant n
```

(`VOA/Moonshine/MoonshineCNGenusZeroAnalytic.lean`, namespace `VOA.Moonshine.ConwayNorton`.)

From the mathematics to the Lean statement

`jCoeffMajorant n` $= \|[q^{n+2}]\texttt{JShift}\| = |c(n+1)| = c(n+1)$ (the coefficients of J are positive integers for $n \geq 1$, but only their absolute values enter). `IsJDominated c` says $|c(n)| \leq c_J(n)$ for every $n \geq 1$, where $c_J(n) =$ `cJ n` are the coefficients of J. `jTail y` $= \sum_{n\geq 1} c(n)e^{-2\pi ny}$ is the tail of J on the imaginary axis: $J(iy) = e^{2\pi y} +$ `jTail`(y). The `tsum` (`∑'`) is Mathlib's unconditional sum, which is 0 if the family is not summable; for $y > 0$ the series converges (`summable_jCoeffMajorant_mul_exp`), so the junk value never occurs where it matters.

Physical meaning

J is the torus partition function of the moonshine CFT with the vacuum energy $-c/24 = -1$ removed. `IsJDominated c` says that a "twisted partition function" $q^{-1} + \sum c(n)q^n$ never has more states (in absolute value of its trace) at level n than the untwisted one: this is the bound $|\operatorname{tr}(g|V_n)| \leq \dim V_n$ for a unitary (finite-order) symmetry. `jTail` is the contribution of all excited states at inverse temperature $2\pi y$.

What the machine verified

Definitions; standard axioms (`VOA/Moonshine/MoonshineCNGenusZeroAudit.lean` prints the lemmas about them, and `VOA/Moonshine/MoonshineLRM5Audit.lean` prints `isJDominated_cJ`).

46.1.3 Conventions for formal series in two variables

The denominator identities live in rings of formal power series in two variables p and q. The library uses two models, always with p as the *outer* variable:

- `PowerSeries (LaurentSeries ℂ)`: power series in p whose coefficients are formal Laurent series in q (finitely many negative powers allowed). This is $\mathbb{C}((q))[[p]]$. It is used for the untwisted identity, where $J(q)$ has a pole. Mathlib's `LaurentSeries ℂ` is `HahnSeries ℤ ℂ`; `HahnSeries.single k a` is the monomial aq^k, and `HahnSeries.ofPowerSeries ℤ ℂ` embeds $\mathbb{C}[[q]]$ into $\mathbb{C}((q))$.
- `PowerSeries (PowerSeries ℂ)`: $\mathbb{C}[[q]][[p]]$, used for the twisted identities, which are written in "height coordinates" where no negative powers occur (§46.5).

`PowerSeries.X` is the outer variable p; `PowerSeries.C a` the constant a; `PowerSeries.coeff n F` the coefficient of p^n (so `PowerSeries.coeff N (PowerSeries.coeff A F)` is the coefficient of $p^A q^N$ in $F \in \mathbb{C}[[q]][[p]]$); `PowerSeries.derivative R F` the formal derivative $\partial_p F$; `PowerSeries.map φ F` applies a ring map to every coefficient; `PowerSeries.rescale a F` substitutes $p \mapsto ap$. For a polynomial $P \in \mathbb{C}[X]$ and an element x of a $\mathbb{C}$-algebra, `aeval x P` is $P(x)$. The operator $D = p\,\partial_p$ (the *Euler derivation*) appears either as `PowerSeries.X * PowerSeries.derivative _ F` or as `eulerDeriv F` (Definition 46.19); it multiplies the coefficient of p^n by n.

Remark 46.1 (Why logarithmic derivatives instead of logarithms)**.** Classically one writes the denominator identity as $\log(\text{product}) = -\sum_k \frac{1}{k} \sum \cdots$. Mathlib v4.30 has no formal logarithm or exponential on these rings, and in characteristic 0 none is needed: for a series A with constant term 1 (in p), the *logarithmic derivative* DA/A determines A (Theorem 46.16). Every identity of the form "$\log A = L$" is therefore stated as "$DA = A \cdot DL$". This is a reformulation, not a weakening: two series with constant term 1 and the same logarithmic derivative are equal.

46.2 Faber polynomials

Replication is a statement about polynomials in a q-series. If $f = q^{-1} + \sum_{n\ge1} c(n) q^n$, then f^m has a pole of order m, and by subtracting suitable multiples of lower powers one can remove every non-positive power of q except q^{-m}. The result is the *Faber polynomial* F_m of f, the unique monic polynomial of degree m with $F_m(f) = q^{-m} + O(q)$. For $f = J$ it computes the Hecke transform $J|T_m$ (Chapter 43); for a McKay–Thompson series it is the polynomial of the replication formula. The two files `VOA/Moonshine/MoonshineLRFaber.lean` and `VOA/Moonshine/MoonshineLRFaberGenerating.lean` (namespace `VOA.Moonshine.ConwayNorton.M8`) build them for an arbitrary coefficient sequence $c : \mathbb{N} \to \mathbb{C}$; no convergence is involved.

Definition 46.2 (Unit part, Laurent series, Faber polynomials)**.** For $c : \mathbb{N} \to \mathbb{C}$ let $u_c = 1 + \sum_{n\ge1} c(n) q^{n+1} \in \mathbb{C}[[q]]$ (no q^1 term) and $f_c = q^{-1} u_c = q^{-1} + \sum_{n\ge1} c(n) q^n \in \mathbb{C}((q))$. The Faber polynomials $F_m = F_{c,m} \in \mathbb{C}[X]$ are defined by strong recursion on m:

$$F_m = X^m - \sum_{j=0}^{m-1} \left([q^{-j}] f_c^{\,m}\right) F_j. \tag{46.2}$$

```
noncomputable def qSeriesUnit (c : ℕ → ℂ) : PowerSeries ℂ :=
  PowerSeries.mk fun k => if k = 0 then 1 else if k = 1 then 0 else c (k - 1)
noncomputable def qSeriesLaurent (c : ℕ → ℂ) : LaurentSeries ℂ :=
  HahnSeries.single (-1 : ℤ) (1 : ℂ) * HahnSeries.ofPowerSeries ℤ ℂ (qSeriesUnit c)
noncomputable def faberPoly (c : ℕ → ℂ) (m : ℕ) : ℂ[X] :=
  X ^ m - ∑ j : Fin m, C ((qSeriesLaurent c ^ m).coeff (-((j : ℕ) : ℤ))) * faberPoly c j
termination_by m
decreasing_by exact j.isLt
```

(`VOA/Moonshine/MoonshineLRFaber.lean`.)

From the mathematics to the Lean statement

`PowerSeries.mk g` is the power series $\sum_k g(k) q^k$; so `qSeriesUnit c` has coefficients $1, 0, c(1), c(2), \ldots$ in degrees $0, 1, 2, 3, \ldots$, i.e. it is u_c. `HahnSeries.single (-1) 1` is q^{-1}, and the product with the embedded power series is f_c. In `faberPoly`: `X` is the polynomial variable, `C a` the constant a, `Fin m` the indices $0 \le j < m$, and `(qSeriesLaurent c ^ m).coeff (-j)` the coefficient of q^{-j} in f_c^m. `termination_by/decreasing_by` only certify that the recursion terminates. So `faberPoly c m` is literally (46.2). As in `qSeriesFun`, the value `c 0` plays no role: the normalisation "constant term 0" is built in.

Example 46.3 (The first Faber polynomials). $F_0 = 1$, $F_1 = X$ (since $[q^0]f = 0$), $F_2 = X^2 - 2c(1)$ (since $f^2 = q^{-2} + 2c(1) + \cdots$), and $F_3 = X^3 - 3c(1)X - 3c(2)$. For J: $F_2(J) = J^2 - 393768 = q^{-2} + 42987520\,q + \cdots$, and $42987520 = 2 \cdot 21493760 = 2c(2)$, in accordance with Theorem 46.5(c) below.

Physical meaning

For the moonshine CFT, $F_m(J)$ is the partition function of the theory "wrapped m times": the sum over all m-sheeted unbranched covers of the torus (equivalently, over sublattices of index m of the period lattice). Its only polar term q^{-m} is the vacuum of the m-fold cover. This is the classical reading of the Hecke operator in symmetric-product orbifolds (Dijkgraaf–Moore–Verlinde–Verlinde).

What the machine verified

Definitions; printed with standard axioms in `VOA/Moonshine/MoonshineLRFaberAudit.lean`.

Theorem 46.4 (Faber polynomials: characterisation). *For every c and m:*

(a) F_m is monic of degree m;

(b) for every $k \le 0$, $[q^k]F_m(f_c) = 1$ if $k = -m$ and 0 otherwise; that is, $F_m(f_c) - q^{-m} \in q\,\mathbb{C}[[q]]$;

(c) if $P \in \mathbb{C}[X]$ satisfies the conclusion of (b), then $P = F_m$.

```
theorem faberPoly_monic (c : ℕ → ℂ) (m : ℕ) : (faberPoly c m).Monic
theorem faberPoly_natDegree (c : ℕ → ℂ) (m : ℕ) : (faberPoly c m).natDegree = m
theorem coeff_aeval_faberPoly (c : ℕ → ℂ) (m : ℕ) {k : ℤ} (hk : k ≤ 0) :
    (aeval (qSeriesLaurent c) (faberPoly c m)).coeff k = if k = -(m : ℤ) then 1 else 0
theorem eq_faberPoly_of_coeff (c : ℕ → ℂ) (m : ℕ) (P : ℂ[X])
    (h : ∀ k : ℤ, k ≤ 0 → (aeval (qSeriesLaurent c) P).coeff k = if k = -(m : ℤ) then 1
     ↪ else 0) :
    P = faberPoly c m
```

(`VOA/Moonshine/MoonshineLRFaber.lean`.)

From the mathematics to the Lean statement

`aeval (qSeriesLaurent c) P` is $P(f_c) \in \mathbb{C}((q))$, and `.coeff k` its coefficient of q^k ($k \in \mathbb{Z}$). `Monic` and `natDegree` are Mathlib's. The statement (b) is exactly the textbook normalisation $F_m(f) = q^{-m} + 0 + O(q)$, with *zero constant term* included ($k = 0$, $m \ge 1$). Note that for $m = 0$ the statement says $F_0(f)$ has constant term 1: $F_0 = 1$. Uniqueness (c) is the reason why the library can later use an *existential* monic polynomial in `CompletelyReplicable` and still be talking about the Faber polynomial.

Proof on paper. (a) By induction: X^m is monic of degree m and every subtracted term has degree $< m$. (b) A polynomial P of degree d evaluated at f has $[q^{-d}]P(f) =$ the leading coefficient of P and no lower powers (`coeff_aeval_qSeriesLaurent_of_le`), because $f^j = q^{-j}u^j$ with u a unit power series. By induction, $F_j(f) = q^{-j} +$ (positive powers) for $j < m$. In $f^m - \sum_{j<m}[q^{-j}](f^m)F_j(f)$ the coefficient of q^{-j} ($0 \le j < m$) is $[q^{-j}]f^m - [q^{-j}]f^m = 0$, because only F_j contributes to q^{-j} (the $F_{j'}$ with $j' < j$ contribute only $q^{-j'}$ and positive powers, those with $j' > j$ only $q^{-j'}$, which is $\neq q^{-j}$, and positive powers). (c) If P and F_m both satisfy (b), $P - F_m$ has all coefficients of q^k, $k \le 0$, equal to zero; by the first remark a nonzero polynomial has a nonzero coefficient at $q^{-\deg}$, $\deg \ge 0$; so $P = F_m$. □

Physical meaning

The uniqueness says: a quantity built polynomially from the partition function is determined by its polar part (its "ground-state" content). This is the formal shadow of the analytic statement of Theorem 46.10 below.

What the machine verified

No hypotheses; standard axioms (`VOA/Moonshine/MoonshineLRFaberAudit.lean`).

Theorem 46.5 (Faber generating identity and recursion). *Let* $G(p) = p\big(f(p) - X\big) = 1 - Xp + \sum_{n\ge1} c(n)p^{n+1} \in \mathbb{C}[X][[p]]$ *and* $H(p) = \sum_{m\ge1} F_m(X)p^m$. *Then*

(a) $p\,G'(p) = -G(p)\,H(p)$, *i.e.* $\log G(p) = -\sum_{m\ge1} F_m(X)\,p^m/m$;

(b) $F_{n+2} = X\,F_{n+1} - \sum_{j<n} c(j+1)F_{n-j} - (n+2)\,c(n+1)$ *for all* $n \ge 0$;

(c) $[q^1]F_m(f) = m\,c(m)$ *for* $m \ge 1$.

```
noncomputable def faberGen (c : ℕ → ℂ) : PowerSeries ℂ[X] :=
  PowerSeries.mk fun k => if k = 0 then 1 else if k = 1 then -X else C (c (k - 1))

        C (((n : ℂ) + 2) * c (n + 1))
theorem coeff_one_aeval_faberPoly (c : ℕ → ℂ) {m : ℕ} (hm : 1 ≤ m) :
    (aeval (qSeriesLaurent c) (faberPoly c m)).coeff 1 = m * c m
```

(`VOA/Moonshine/MoonshineLRFaberGenerating.lean`.)

From the mathematics to the Lean statement

Here the outer power-series variable `PowerSeries.X` is p and the polynomial variable `X` (in `-X`) is the indeterminate of $\mathbb{C}[X]$. `faberGen c` has p-coefficients $1, -X, c(1), c(2), \dots$: it is G. `faberSeries c` is H (the p^0 term is 0). `PowerSeries.X * PowerSeries.derivative ℂ[X] (faberGen c)` is $p\,\partial_p G$. So (a) is literally $pG' = -GH$, the logarithm-free form of $\log G = -\sum F_m p^m/m$ (Remark 46.1). (b) is the coefficient of p^{n+2} in (a). (c) is stated with `coeff 1`, the coefficient of q^1.

Proof on paper. Define polynomials Q_m by $-pG'/G = \sum_{m\ge1} Q_m p^m$ (G is invertible since its constant term is 1). The coefficient of X^m in Q_m is 1 (only the term Xp of G can produce $X^m p^m$, through $-p\partial_p \log(1 - Xp) = \sum_{k\ge1} X^k p^k$), and $\deg Q_m \le m$; so Q_m is monic of degree m. Now substitute $X = f(q)$, a ring map $\mathbb{C}[X][[p]] \to \mathbb{C}((q))[[p]]$. Here and below $f(p)$ denotes the same q-series written in the outer variable, $f(p) = p^{-1} + \sum_{n\ge1} c(n)p^n$, so that $pf(p) = 1 + \sum c(n)p^{n+1}$ is a power series in p and $G(p)|_{X=f(q)} = p(f(p) - f(q))$. Since $p\,p^{-1} = 1$ and $p(p^n - q^n) = -(1 - p/q)\,pq \sum_{i+j=n-1} p^i q^j$,

$$p\big(f(p) - f(q)\big) = \Big(1 - \frac{p}{q}\Big)\,S(p,q), \qquad S = 1 - \sum_{a,b\ge1} c(a+b-1)\,p^a q^b \in 1 + pq\,\mathbb{C}[[p,q]]. \tag{46.3}$$

Taking $-p\partial_p$ log of both sides: $-p\partial_p \log(1-p/q) = \sum_{k\ge1} p^k q^{-k}$, and $-p\partial_p S/S \in pq\,\mathbb{C}[[p,q]]$. Comparing coefficients of p^m: $Q_m(f) = q^{-m} + (\text{element of } q\mathbb{C}[[q]])$. By Theorem 46.4(c), $Q_m = F_m$, which is (a). (b) is the p^{n+2}-coefficient of $pG' = -GH$ rearranged. (c): write f' for the formal derivative; the residue $[q^{-1}](P(f)f')$ vanishes for every polynomial P, because $f^j f' = (f^{j+1})'/(j+1)$ is a derivative and derivatives have no q^{-1} term (`coeff_neg_one_pow_mul_deriv`). Apply this to $P = F_m$: since $F_m(f) = q^{-m} + \sum_{r\ge1} a_r q^r$ and $f' = -q^{-2} + \sum_n nc(n)q^{n-1}$, the residue is $-a_1 + m\,c(m)$ (the $q^{-m}\cdot mc(m)q^{m-1}$ term and the $a_1 q\cdot(-q^{-2})$ term), so $a_1 = mc(m)$. □

Physical meaning

(a) has the form "free energy = log of a partition function": $\log\big(p(f(p)-X)\big)$ is a sum over connected m-fold covers weighted by $1/m$, the standard relation between a second-quantised (multi-string) partition function and the single-string one. (c) is the first excited level of the m-fold cover: $m\,c(m)$ states.

What the machine verified

No hypotheses; standard axioms (`VOA/Moonshine/MoonshineLRFaberAudit.lean`, 35 reports).

Supporting declarations. `constantCoeff_qSeriesUnit`, `qSeriesLaurent_pow` ($f^j = q^{-j}u^j$), `coeff_qSeriesLaurent_pow`, `coeff_qSeriesLaurent_pow_of_le`, `faberPoly_eq`, `faberPoly_zero`, `faberPoly_one`, `faberPoly_degree_and_monic`, `coeff_aeval_C_mul`, `coeff_algebraMap_mul`, `coeff_aeval_qSeriesLaurent_of_le`, `eq_zero_of_coeff_aeval_qSeriesLaurent` (file `MoonshineLRFaber.lean`); `coeff_mul_eq_zero_of_lt`, `coeff_qSeriesUnit`, `coeff_qSeriesLaurent_natCast`, `coeff_qSeriesLaurent_of_lt_one`, the explicit formal derivative `qSeriesLaurentDeriv` ($f' = -q^{-2}u + q^{-1}u'$, written out because Mathlib v4.30 has no product rule for derivatives of Laurent series), `coeff_qSeriesLaurentDeriv_natCast`, `coeff_qSeriesLaurentDeriv_sub_of_neg`, the residue lemmas `coeff_neg_one_pow_mul_deriv` and `coeff_neg_one_aeval_mul_deriv`, and `coeff_aeval_faberPoly_sub_of_lt_one` (file `MoonshineLRFaberGenerating.lean`). All are coefficient bookkeeping in $\mathbb{C}((q))$ and are printed in `MoonshineLRFaberAudit.lean`.

46.3 J is replicable

The untwisted denominator identity is, in Borcherds' proof, a consequence of the Lie algebra structure. The library proves it the other way round: from the modularity of J, by showing that J is *replicable*, i.e. that the Hecke transform of J is the Faber polynomial of J. The reason for this direction is recorded in §46.4 (the generation of $\mathfrak{m}$ by its simple roots is *equivalent* to the product identity, so the identity must come from outside the Lie algebra).

46.3.1 Hecke sums of a q-series

Definition 46.6 (Hecke blocks, Hecke sums, Hecke coefficients). For $c : \mathbb{N}\to\mathbb{C}$, $f = \texttt{qSeriesFun}\,c$, $a,d \ge 1$ and $M \ge 1$:

$$B_{a,d}(\tau) = \sum_{0\le b<d} f\Big(\frac{a\tau+b}{d}\Big), \qquad R_M(\tau) = \sum_{a\mid M} B_{a,M/a}(\tau), \qquad h_c(M,r) = \sum_{a\mid \gcd(M,r)} \frac{M}{a}\,c\Big(\frac{Mr}{a^2}\Big).$$

```
noncomputable def qHeckeBlock (c : ℕ → ℂ) (a d : ℕ) (τ : ℍ) : ℂ :=
  if h : 0 < a ∧ 0 < d then
    ∑ b ∈ Finset.range d, qSeriesFun c (heckePoint a d b h.1 h.2 τ)
  else 0
```

```
noncomputable def qHeckeSum (c : ℕ → ℂ) (M : ℕ) (τ : ℍ) : ℂ :=
  ∑ a ∈ M.divisors, qHeckeBlock c a (M / a) τ
noncomputable def qHeckeCoeff (c : ℕ → ℂ) (M r : ℕ) : ℂ :=
  ∑ a ∈ (Nat.gcd M r).divisors, ((M / a : ℕ) : ℂ) * c (M * r / (a * a))
```

(VOA/Moonshine/MoonshineLRM5Hecke.lean.)

From the mathematics to the Lean statement

`heckePoint a d b ha hd τ` is $(a\tau+b)/d \in \mathbb{H}$ (Chapter 43). The `if h : 0 < a ∧ 0 < d` only makes the definition total (the value 0 is never used for $a, d \geq 1$). `M.divisors` is the finite set of positive divisors of M; `M / a` is exact division for $a \mid M$. `(Nat.gcd M r).divisors` runs over $a \mid \gcd(M, r)$, and `M * r / (a * a)` is Mr/a^2, an integer for such a. So R_M is the sum over the $\sigma_1(M)$ upper-triangular matrices $\left(\begin{smallmatrix} a & b \\ 0 & d \end{smallmatrix}\right)$ with $ad = M$, $0 \leq b < d$: the unnormalised Hecke operator $f|T_M$ of Chapter 43.

Physical meaning

Hecke operators act on partition functions as sums over the p-fold covers of the torus. Physically, a Hecke sum at a prime p adds up the partition functions of the theory on all tori that cover the given one p times. In moonshine, the twisted sectors g^a appear because winding a times around a cycle twists by g^a. This is the origin of the replication formulas.

Theorem 46.7 (The q-expansion of a Hecke sum). *If c is J-dominated and $M \geq 1$, then for every $\tau \in \mathbb{H}$*

$$R_M(\tau) - q^{-M} = \sum_{r \geq 1} h_c(M, r)\, q^r,$$

the series converging (in Mathlib's `HasSum` *sense) at every point.*

```
theorem hasSum_qHeckeBlock {c : ℕ → ℂ} (hc : IsJDominated c) (a d : ℕ) (ha : 0 < a) (hd : 0

      (qHeckeBlock c a d τ - if d = 1 then (qPar τ ^ a)⁻¹ else 0)
theorem hasSum_qHeckeSum {c : ℕ → ℂ} (hc : IsJDominated c) {m : ℕ} (hm : 0 < m) (τ : ℍ) :
    HasSum (fun r : ℕ => (if r = 0 then 0 else qHeckeCoeff c m r) * qPar τ ^ r)
      (qHeckeSum c m τ - (qPar τ ^ m)⁻¹)
```

(VOA/Moonshine/MoonshineLRM5Hecke.lean.)

From the mathematics to the Lean statement

`HasSum (fun r ⇒ x r) s` says that the (unconditional) series $\sum_r x_r$ converges to s. The block version says $B_{a,d}(\tau) - [d = 1]q^{-a} = \sum_r [r \neq 0,\ a \mid r]\, d\, c(dr/a)\, q^r$. The term `if r = 0 then 0 else ...` makes the $r = 0$ coefficient zero: there is no constant term. `(qPar τ ^ m)⁻¹` is q^{-M}.

Proof on paper. Write $f((a\tau+b)/d) = \sum_{n \geq -1} c(n) e^{2\pi i n(a\tau+b)/d}$ (with $c(-1) = 1$ and the $n = 0$ term absent). Summing over b, the character sum $\sum_{b<d} e^{2\pi i n b/d} = d\,[d \mid n]$ keeps exactly the exponents $n = ds$, each with weight d, and $e^{2\pi i\, ds\, a\tau/d} = q^{as}$. The pole $n = -1$ survives only if $d = 1$, giving q^{-a}. So $B_{a,d} = [d = 1]q^{-a} + \sum_{s \geq 1} d\, c(ds)\, q^{as}$, which is the block statement with $r = as$. Summing over $a \mid M$, $d = M/a$: the pole is q^{-M} (only $a = M$ has $d = 1$), and the coefficient of

q^r collects the $a \mid r$, i.e. $a \mid \gcd(M, r)$, with value $\frac{M}{a}\, c\big(\frac{M}{a} \cdot \frac{r}{a}\big)$. Absolute convergence follows from $|c(n)| \le c_J(n)$. □

Physical meaning

Projecting onto d-periodic states: averaging over the d shifts $\tau \mapsto \tau + b/d$ is the orbifold projection onto states whose spin $L_0 - \bar{L}_0$ is divisible by d; this is why only every d-th coefficient survives.

What the machine verified

Hypothesis `IsJDominated c` only; standard axioms (`VOA/Moonshine/MoonshineLRM5Audit.lean`).

Theorem 46.8 (Polynomials of q-series). *If c is J-dominated, $P \in \mathbb{C}[X]$ has degree D and $\tau \in \mathbb{H}$, then $q^D\, P\big(f(\tau)\big) = \sum_{n \ge 0} [q^{n-D}] P(f_c)\, q^n$, where $P(f_c) \in \mathbb{C}((q))$ is the formal evaluation.*

```
theorem hasSum_mul_eval_qSeriesFun {c : ℕ → ℂ} (hc : IsJDominated c) (P : ℂ[X]) (τ : ℍ) :
    HasSum (fun n : ℕ => (aeval (qSeriesLaurent c) P).coeff ((n : ℤ) - P.natDegree) * qPar
    ↪  τ ^ n)
      (qPar τ ^ P.natDegree * P.eval (qSeriesFun c τ))
```

(`VOA/Moonshine/MoonshineLRM5Poly.lean`.)

From the mathematics to the Lean statement

`P.eval (qSeriesFun c τ)` is the number $P(f(\tau))$; `aeval (qSeriesLaurent c) P` is the formal Laurent series $P(f_c)$. The theorem says that "evaluate, then expand" equals "expand formally, then evaluate": the analytic and formal worlds agree on polynomials. The factor q^D clears the pole so that the right side is a power series.

Proof on paper. $qf(\tau) = u_c(q)$ is an absolutely convergent power series in q ($|q| < 1$, coefficients dominated by those of J), and $q^D P(f) = \sum_{j \le D} p_j\, q^{D-j} u_c^j$ where $P = \sum p_j X^j$; absolutely convergent power series can be added and multiplied termwise (Cauchy product), and the same expression computes $q^D P(f_c)$ formally. □

Physical meaning

Products of partition functions (multi-copy theories) have the q-expansion obtained by multiplying the state counts: the analytic and the combinatorial pictures agree as long as everything converges.

What the machine verified

Hypothesis `IsJDominated c`; standard axioms (`MoonshineLRM5Audit.lean`). Supporting declarations in the same file: `PowerSeriesAbsConv`, `powerSeriesEval` and their closure under $+$, $\times$, powers, finite sums (`PowerSeriesAbsConv.add`, `powerSeriesEval_mul`, …), `powerSeriesAbsConv_qSeriesUnit`, `powerSeriesEval_qSeriesUnit`, `polyUnitSeries`, `aeval_qSeriesLaurent_eq_single_mul`, `powerSeriesEval_polyUnitSeries`.

46.3.2 $\mathrm{SL}_2(\mathbb{Z})$-invariance of the Hecke sum

Theorem 46.9 (Invariance of R_M). *(a) A function on $\mathbb{H}$ invariant under $S = \left(\begin{smallmatrix} 0 & -1 \\ 1 & 0 \end{smallmatrix}\right)$ and $T = \left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right)$ is $\mathrm{SL}_2(\mathbb{Z})$-invariant.*

(b) For every c and M, R_M is invariant under T.

(c) If $f =$ `qSeriesFun` c is $\mathrm{SL}_2(\mathbb{Z})$-invariant, then so is R_M for every M.

```
theorem smul_invariant_of_S_T {R : ℍ → ℂ} (hS : ∀ τ : ℍ, R (ModularGroup.S • τ) = R τ)
    (hT : ∀ τ : ℍ, R (ModularGroup.T • τ) = R τ) (γ : SL(2, ℤ)) (τ : ℍ) : R (γ • τ) = R τ
theorem qHeckeSum_T_smul (c : ℕ → ℂ) (M : ℕ) (τ : ℍ) :
    qHeckeSum c M (ModularGroup.T • τ) = qHeckeSum c M τ
theorem qHeckeSum_smul {c : ℕ → ℂ}
    (hf : ∀ (γ : SL(2, ℤ)) (τ : ℍ), qSeriesFun c (γ • τ) = qSeriesFun c τ) (M : ℕ)
    (γ : SL(2, ℤ)) (τ : ℍ) : qHeckeSum c M (γ • τ) = qHeckeSum c M τ
```

(`VOA/Moonshine/MoonshineLRM5Invariance.lean`, `VOA/Moonshine/MoonshineLRM5CosetMap.lean`.)

From the mathematics to the Lean statement

`ModularGroup.S`, `ModularGroup.T` are Mathlib's generators of `SL(2, ℤ)`, acting on `ℍ` by `γ • τ`. The hypothesis of (c) is *invariance of the function*, not of the coefficient sequence; it holds for $c =$ `cJ` (`qSeriesFun_cJ_smul`, from `qSeriesFun cJ` $= j - 744$, `qSeriesFun_cJ`).

Proof on paper. (a) S and T generate $\mathrm{SL}_2(\mathbb{Z})$ (Mathlib's `SL2Z_generators`). (b) In the block (a,d), $\tau \mapsto \tau+1$ changes $(a\tau+b)/d$ into $(a\tau+(b+a))/d$; since f is 1-periodic only $b+a$ modulo d matters, and $b \mapsto b+a \pmod d$ is a bijection of $\{0,\dots,d-1\}$. (c) The classical argument: for A in the coset set $\Delta(M) = \{\left(\begin{smallmatrix} a & b \\ 0 & d \end{smallmatrix}\right) : ad = M, 0 \le b < d\}$ and $\gamma \in \mathrm{SL}_2(\mathbb{Z})$ there are unique $\gamma' \in \mathrm{SL}_2(\mathbb{Z})$ and $A' \in \Delta(M)$ with $A\gamma = \gamma' A'$, and $A \mapsto A'$ is a bijection of $\Delta(M)$; then $R_M(\gamma\tau) = \sum_A f(\gamma' A'\tau) = \sum_{A'} f(A'\tau) = R_M(\tau)$. By (a) and (b) it suffices to do this for $\gamma = S$, where the library gives the bijection explicitly: for $A = \left(\begin{smallmatrix} a & b \\ 0 & d \end{smallmatrix}\right)$ put $g = \gcd(b,d)$, $d = gd_1$, $b = gb_1$, and let $r \in [0, d_1)$ solve $rb_1 \equiv -1 \pmod{d_1}$; then $A' = \left(\begin{smallmatrix} g & ar \\ 0 & ad_1 \end{smallmatrix}\right)$, the map $\langle a,b\rangle \mapsto \langle g, ar\rangle$ is an involution of $\Delta(M)$, and $(aS\tau+b)/d = \gamma'\big((g\tau+ar)/(ad_1)\big)$ with $\gamma' = \left(\begin{smallmatrix} b_1 & * \\ d_1 & * \end{smallmatrix}\right) \in \mathrm{SL}_2(\mathbb{Z})$ (the "point identity" `heckePoint_S_smul_eq`). For example, for $M=2$ the involution fixes $\langle 1,1\rangle$ and exchanges $\langle 1,0\rangle$ and $\langle 2,0\rangle$: indeed $J(-1/(2\tau)) = J(2\tau)$ and $J\big((\tau-1)/(2\tau)\big) = J\big((\tau+1)/2\big)$, the matrix $\left(\begin{smallmatrix} 1 & -1 \\ 2 & -1 \end{smallmatrix}\right)$ relating $(\tau+1)/2$ to $(\tau-1)/(2\tau)$. □

Physical meaning

The sum over all m-sheeted covers of a torus is again modular invariant: a modular transformation of the base permutes the covers. This is the modular invariance of the symmetric-product (second-quantised) partition function.

What the machine verified

(a), (b) no hypotheses; (c) hypothesis: invariance of f. Standard axioms (`MoonshineLRM5Audit.lean`). Supporting declarations: `qHeckeBlock_vadd_one` (file `MoonshineLRM5Invariance.lean`); `cosetMatrix`, `heckePoint_S_smul_eq` (file `MoonshineLRM5Cosets.lean`); `negInvMod` and its lemmas `negInvMod_cast`, `negInvMod_lt`, `dvd_negInvMod_mul_add_one`, `eq_negInvMod`, `coprime_of_dvd_mul_add_one`; `heckeCosets`, `cosetS`, the arithmetic record `CosetData` and its eight projections, `cosetData_of_mem`, `cosetS_mem`, `cosetS_cosetS` (involution), `heckeVal`, `heckeSumOf`, `qHeckeSum_eq_heckeSumOf`, `heckeVal_S_smul`, `heckeSumOf_S_smul` (file `MoonshineLRM5CosetMap.lean`).

46.3.3 A modular invariant without polar part vanishes

Theorem 46.10 (Vanishing of invariant cusp forms of weight 0). *Let $D : \mathbb{H} \to \mathbb{C}$ be $\mathrm{SL}_2(\mathbb{Z})$-invariant and $D(\tau) = \sum_{r \ge 0} \delta_r q^r$ for every τ, with $\delta_0 = 0$. Then $\delta_r = 0$ for all r (hence $D = 0$).*

```
theorem eq_zero_of_invariant_hasSum {δ : ℕ → ℂ} {D : ℍ → ℂ}
    (hD : ∀ (γ : SL(2, ℤ)) (τ : ℍ), D (γ • τ) = D τ)
    (hs : ∀ τ : ℍ, HasSum (fun r => δ r * qPar τ ^ r) (D τ)) (h0 : δ 0 = 0) (r : ℕ) :
    δ r = 0
```

(VOA/Moonshine/MoonshineLRM5Replicable.lean.)

From the mathematics to the Lean statement

No holomorphy is assumed: the hypotheses are invariance and convergence of the q-expansion at every point. (A convergent power series in q is automatically holomorphic, so this is the classical statement that a holomorphic modular function of weight 0 for $\mathrm{SL}_2(\mathbb{Z})$ that vanishes at the cusp is identically zero.)

Proof on paper. The classical proof uses the maximum principle or Liouville on $X(1)$. The library gives an elementary proof. Every τ is $\mathrm{SL}_2(\mathbb{Z})$-equivalent to a point of height $\geq \frac{1}{2}$ (`exists_smul_half_le_im`), where $|q| \leq \rho = e^{-\pi} < \frac{1}{2}$. First, $|D|$ is bounded on $\mathbb{H}$ by $B_0 = \sum |\delta_r| \rho^r$ (absolute convergence at $\tau_0 = i/2$ and invariance). Second, a bounded function with q-expansion $\sum A_r q^r$ has $|A_r| \leq \sup |D|$ (the coefficient bound, Theorem 46.39 below). Third, if $|\delta_r| \leq B$ for all r, then on height $\geq \frac{1}{2}$ we get $|D| \leq \sum_{r \geq 1} B\rho^r = B\rho/(1-\rho)$, hence $|D| \leq B\kappa$ everywhere with $\kappa = \rho/(1-\rho) < 1$, hence $|\delta_r| \leq B\kappa$ (`norm_le_mul_of_invariant_hasSum`). Iterating, $|\delta_r| \leq B_0 \kappa^n \to 0$. □

Physical meaning

"The polar part determines the partition function": a modular-invariant partition function with no states of negative energy and no vacuum degeneracy at the cusp must vanish. This is the principle behind the Farey-tail and Rademacher expansions of partition functions (Dijkgraaf–Maldacena–Moore–Verlinde; Duncan–Frenkel).

What the machine verified

No hypotheses beyond those displayed; standard axioms (`MoonshineLRM5Audit.lean`). Supporting: `exp_neg_pi_lt_half`, `exists_smul_half_le_im`, `norm_le_mul_of_invariant_hasSum`.

46.3.4 The replicability of J

Theorem 46.11 (J is replicable). *Let $P_M = F_{\mathrm{cJ},M}$ be the Faber polynomial of J. For every $M \geq 1$:*

(a) $P_M(J(\tau)) = \sum_{ad=M} \sum_{0 \leq b < d} J\big((a\tau + b)/d\big)$ *for every $\tau \in \mathbb{H}$;*

(b) $[q^r]P_M(J) = \sum_{a \mid \gcd(M,r)} \frac{M}{a}\, c\big(\frac{Mr}{a^2}\big)$ *for every $r \geq 1$ ("(Rep_1)").*

```
theorem qSeriesFun_cJ (τ : ℍ) : qSeriesFun cJ τ = jInvariant τ - 744
theorem faberPoly_cJ_eval_eq_qHeckeSum {M : ℕ} (hM : 0 < M) (τ : ℍ) :
    (faberPoly cJ M).eval (qSeriesFun cJ τ) = qHeckeSum cJ M τ
theorem coeff_faberPoly_cJ_eq_qHeckeCoeff {M : ℕ} (hM : 0 < M) {r : ℕ} (hr : r ≠ 0) :
    (aeval (qSeriesLaurent cJ) (faberPoly cJ M)).coeff (r : ℤ) = qHeckeCoeff cJ M r
```

(VOA/Moonshine/MoonshineLRM5Replicable.lean.)

From the mathematics to the Lean statement

`jInvariant` is the analytic j-function of Chapter 14; `qSeriesFun_cJ` identifies the library's q-series encoding of J with $j - 744$ on all of $\mathbb{H}$ (from `hasSum_JShift_laurent`, Chapter 33). So (a) is the identity of functions $P_M \circ J = J|T_M$, and (b) the identity of coefficients. (b) is stated for the *formal* series $P_M(J) \in \mathbb{C}((q))$; (a) for the function. Both have no hypotheses.

Example 46.12 ($M = 2$). (b) at $M = 2$, $r = 2$: $[q^2](J^2 - 2c(1)) = 2c(4) + c(1)$. The left side is $2c(3) + c(1)^2$. Hence $c(4) = c(3) + \frac{1}{2}(c(1)^2 - c(1))$, Mahler's recursion of Chapter 43: $864299970 + \frac{1}{2}(196884^2 - 196884) = 20245856256$.

Proof on paper. Let $D = P_M \circ J - R_M$. By Theorem 46.4(b) and Theorem 46.8, $P_M(J(\tau)) = q^{-M} + \sum_{r\geq 1}[q^r]P_M(J)\,q^r$ (`hasSum_faberPoly_eval_sub`); by Theorem 46.7, $R_M = q^{-M} + \sum_{r\geq 1} h(M,r)q^r$. So $D = \sum_{r\geq 1}\delta_r q^r$ with $\delta_r = [q^r]P_M(J) - h(M,r)$ (`replicationDefect`, `hasSum_replicationDefect`). D is $\mathrm{SL}_2(\mathbb{Z})$-invariant, since J is and R_M is (Theorem 46.9). By Theorem 46.10, all $\delta_r = 0$: this is (b), and summing, (a). □

Physical meaning

The partition function of the M-fold cover is a polynomial in the single-cover partition function. For a holomorphic CFT with $c = 24$ this is forced by modular invariance: the M-fold cover theory has a modular-invariant partition function whose only polar term is q^{-M}, and such a function is a polynomial in J.

What the machine verified

Unconditional (no hypotheses); standard axioms (`MoonshineLRM5Audit.lean`). Supporting declarations: `isJDominated_cJ`, `qSeriesFun_cJ_smul`, `hasSum_faberPoly_eval_sub`, `replicationDefect`, `hasSum_replicationDefect`.

46.4 The product identity for J (the denominator identity)

46.4.1 The identity, and what it means

Motivation only. The following two paragraphs explain where the identity comes from in Borcherds' proof; nothing in them is used below, and no Lean theorem of this chapter refers to $\mathfrak{m}$ in connection with the identity (the link with $\mathfrak{m}$ is made in Chapter 47). Let $\mathfrak{m}$ be the Monster Lie algebra (Chapter 45): graded by $I\!I_{1,1}$, with root spaces $\mathfrak{m}_{(m,n)} \cong V^{\natural}{}_{1+mn}$ in Borcherds' coordinates, so that $\dim \mathfrak{m}_{(m,n)} = c(mn)$ for $(m,n) \neq 0$. Its simple roots are the real root $(1,-1)$ and the imaginary roots $(1,n)$, $n \geq 1$, with multiplicity $c(n)$, and its Weyl vector is $\rho = (-1,0)$ in Borcherds' sign convention (it pairs with every simple root α to $-\frac{1}{2}(\alpha,\alpha)$; Chapter 45 uses the opposite sign). The Weyl–Kac–Borcherds denominator formula of a generalised Kac–Moody algebra, in which $\epsilon(\mu)$ is $(-1)^n$ if μ is a sum of n pairwise orthogonal imaginary simple roots and 0 otherwise (we do not derive it here),

$$e^{\rho}\prod_{\alpha>0}(1-e^{\alpha})^{\mathrm{mult}\,\alpha} = \sum_{w\in W}\det(w)\,w\Big(e^{\rho}\sum_{\mu}\epsilon(\mu)e^{\mu}\Big),$$

becomes for $\mathfrak{m}$, with $p = e^{(1,0)}$ and $q = e^{(0,1)}$, Borcherds' identity

$$p^{-1}\prod_{m>0,\ n\in\mathbb{Z}}\big(1-p^m q^n\big)^{c(mn)} = J(p) - J(q). \tag{46.4}$$

(The Weyl group has order 2, generated by the reflection $(m,n)\mapsto(n,m)$ in the real root, which is why the right side is antisymmetric in p,q.) In (46.4) the factors with $n\le 0$ are $(1-pq^{-1})^{c(-1)}=1-p/q$ (from $mn=-1$) and $(1-p^m)^{c(0)}=1$; all others with $n\le 0$ have $mn\le -2$ and exponent 0. Using the factorisation (46.3), $p(J(p)-J(q))=(1-p/q)S$ with $S=1-\sum_{a,b\ge1}c(a+b-1)p^aq^b$, the identity (46.4) is therefore equivalent to the *Koike–Norton–Zagier* (KNZ) form

$$\prod_{m,n\ge1}\left(1-p^mq^n\right)^{c(mn)}=1-\sum_{a,b\ge1}c(a+b-1)\,p^aq^b. \tag{KNZ}$$

This identity about J (with $\prod$ read as `coneProd`) is what the library proves. Its route is as follows:

$$j\text{ is }\mathrm{SL}_2(\mathbb{Z})\text{-invariant}\implies J\text{ is replicable (Thm. 46.11)}\implies D\log S=D\log\prod\implies\text{(KNZ)}.$$

Trap / dead end

The product identity cannot be derived from the Lie algebra alone (a recorded dead end). Given the no-ghost theorem and the invariant form, the statement "$\mathfrak{m}$ is generated by its simple root spaces" is *equivalent* to (KNZ): the Casimir argument (Chapter 45) shows that the subalgebra generated by the known simple roots has character $1/S$, and it is all of $\mathfrak{m}$ exactly when the product of the multiplicities $c(mn)$ is S. The Casimir argument cannot exclude further imaginary simple roots (m,n) with $m\ge 2$, because ρ is not known to be a Weyl vector for them. So any proof of generation *is* a proof of the product formula, i.e. of a modularity property of J. The project therefore proves (KNZ) analytically (this section) and deduces generation from it (Chapter 47, `M8.monsterLieSimpleRootGeneration`, which uses `knz_product` and `coneProd_exponent_unique`). Attempting a Lie-theoretic proof of generation is a recorded dead end.

46.4.2 The logarithmic form

Definition 46.13 (The series S and the logarithmic series). For $c:\mathbb{N}\to\mathbb{C}$ define in $\mathbb{C}((q))[[p]]$

$$S_c=1-\sum_{a,b\ge1}c(a+b-1)\,p^aq^b,\qquad E_c=\sum_{M\ge1}\left(F_M(f_c)-q^{-M}\right)p^M.$$

```
noncomputable def knzCoeff (c : ℕ → ℂ) (a : ℕ) : LaurentSeries ℂ :=
  if a = 0 then 1 else
    -HahnSeries.ofPowerSeries ℤ ℂ (PowerSeries.mk fun b => if b = 0 then 0 else c (a + b -
     ↪ 1))
noncomputable def knzSeries (c : ℕ → ℂ) : PowerSeries (LaurentSeries ℂ) :=
  PowerSeries.mk (knzCoeff c)

  if M = 0 then 0 else aeval (qSeriesLaurent c) (faberPoly c M) - qInv ^ M
noncomputable def knzLogSeries (c : ℕ → ℂ) : PowerSeries (LaurentSeries ℂ) :=
  PowerSeries.mk (knzLogCoeff c)
noncomputable def evalAtQSeries (c : ℕ → ℂ) : ℂ[X] →+* LaurentSeries ℂ :=
  (aeval (qSeriesLaurent c)).toRingHom
```

(`VOA/Moonshine/MoonshineLRM5KNZ.lean`.)

From the mathematics to the Lean statement

`knzCoeff c a` is the p^a-coefficient of S_c: 1 for $a=0$ and $-\sum_{b\ge1}c(a+b-1)q^b$ for $a\ge1$. `qInv` is q^{-1}. `knzLogCoeff c M` is $F_M(f_c)-q^{-M}$ for $M\ge1$ and 0 for $M=0$. `evalAtQSeries c` is the ring map $\mathbb{C}[X]\to\mathbb{C}((q))$, $X\mapsto f_c$; mapping `faberGen c` along it substitutes $X=f(q)$ in

$G(p) = p(f(p) - X)$, giving $p(f(p) - f(q))$.

Physical meaning

S is the "single-particle" side: $1 - S$ is the generating function of the positive-cone simple roots and their real-root strings, i.e. of the generating space U of Chapter 45.

What the machine verified

Definitions; standard axioms (`MoonshineLRM5Audit.lean`).

Theorem 46.14 (Factorisation and logarithmic form). *For every c:*

(a) $p\big(f_c(p) - f_c(q)\big) = (1 - q^{-1}p)\,S_c$ *in* $\mathbb{C}((q))[[p]]$;

(b) $p\,\partial_p S_c = -S_c\,E_c$.

For $c =$ `cJ`*:*

(c) $p\,\partial_p S = -S \cdot \sum_{M\geq 1}\Big(\sum_{r\geq 1} h(M,r)\,q^r\Big)p^M$, *with* $h(M,r) = \sum_{a\mid(M,r)} \frac{M}{a}\,c(\frac{Mr}{a^2})$; *equivalently* $p\,\partial_p \log S = -\sum_{k,m,n\geq 1} m\,c(mn)\,p^{mk}q^{nk}$.

```
theorem faberGen_map_eq_mul (c : ℕ → ℂ) :
    PowerSeries.map (evalAtQSeries c) (faberGen c) =
      (1 - PowerSeries.C qInv * PowerSeries.X) * knzSeries c
theorem knz_log (c : ℕ → ℂ) :
    PowerSeries.X * PowerSeries.derivative (LaurentSeries ℂ) (knzSeries c) =
      -(knzSeries c * knzLogSeries c)
theorem knz_log_J :
    PowerSeries.X * PowerSeries.derivative (LaurentSeries ℂ) (knzSeries cJ) =
      -(knzSeries cJ * PowerSeries.mk fun M => if M = 0 then 0 else
        HahnSeries.ofPowerSeries ℤ ℂ
          (PowerSeries.mk fun r => if r = 0 then 0 else qHeckeCoeff cJ M r))
```

(`VOA/Moonshine/MoonshineLRM5KNZ.lean`.)

From the mathematics to the Lean statement

`PowerSeries.map (evalAtQSeries c) (faberGen c)` is $1 - f_c(q)\,p + \sum_{n\geq 1} c(n)p^{n+1} = p(f_c(p) - f_c(q))$: here $f_c(p)$ means the series $p^{-1} + \sum c(n)p^n$ in the outer variable, and $p f_c(p)$ is a power series in p. In (a), `1 - PowerSeries.C qInv * PowerSeries.X` is $1 - q^{-1}p$. In (c), the inner `PowerSeries.mk fun r ⇒ ...` is $\sum_{r\geq 1} h(M,r)q^r$ embedded into $\mathbb{C}((q))$, and `qHeckeCoeff cJ M r` is $h(M,r)$. The equivalence with the form $-\sum_{k,m,n} m\,c(mn)p^{mk}q^{nk}$ stated in the docstring is the identity $\sum_{a\mid(M,r)} \frac{M}{a}\,c(\frac{Mr}{a^2}) = [p^M q^r]\sum_{k,m,n} m\,c(mn)p^{mk}q^{nk}$ (put $k = a$, $m = M/a$, $n = r/a$); it is used in Lean as `coneLog_cJ` below.

Proof on paper. (a) is the telescoping identity behind (46.3): $p(p^{-1} - q^{-1}) = 1 - p/q$ and $p(p^n - q^n) = -(1-p/q)\sum_{i+j=n-1} p^{i+1}q^{j+1}$. (b): apply the ring map $X \mapsto f_c$ to the Faber generating identity $pG' = -GH$ (Theorem 46.5(a); the derivative commutes with coefficient maps, `derivative_map`), which gives $p\Phi' = -\Phi H(f)$ for $\Phi = (1-q^{-1}p)S$ (`faberGen_map_generating`). Since $p\partial_p(1-q^{-1}p) = -(1-q^{-1}p)\sum_{k\geq 1} q^{-k}p^k$ and $1-q^{-1}p$ is invertible with inverse $\sum_k q^{-k}p^k$ (`qInvGeom`, `mul_qInvGeom`), dividing by $1 - q^{-1}p$ yields $pS' = -S\,(H(f) - \sum_k q^{-k}p^k) = -S\,E$ (`knzLogSeries_eq`). (c): for J, the coefficient $F_M(J) - q^{-M}$ of E is $\sum_{r\geq 1} h(M,r)q^r$ by (Rep_1) (Theorem 46.11(b); `knzLogCoeff_cJ`). □

Physical meaning

(c) is the denominator identity at the level of "free energies": the logarithmic derivative of the multi-particle partition function equals the sum over connected contributions $m\,c(mn)$ of single physical states at momentum (m, n), summed over their k-fold multiples (the Bose–Einstein sum $\sum_k x^k$).

What the machine verified

(a), (b): no hypotheses; (c): **unconditional**. Standard axioms (`MoonshineLRM5Audit.lean`). Supporting: `derivative_map`, `faberGen_map_generating`, `coeff_ofPowerSeries_mk`, `qSeriesLaurent_eq_qInv_add`, `qInv_mul_ofPowerSeries_mk` (the telescoping step), `qInvGeom`, `mul_qInvGeom`, `knzLogSeries_eq`, `knzLogCoeff_cJ`.

46.4.3 Products defined by their logarithmic derivative

Mathlib v4.30 has no infinite products with complex exponents in $\mathbb{C}((q))[[p]]$. The library defines the product $\prod_{m,n\geq 1}(1-p^m q^n)^{e(m,n)}$ as the unique series with constant term 1 whose logarithmic derivative is the expected one.

Definition 46.15 (Solution of $pA' = AL$)**.** Let K be a field of characteristic 0 and $L \in K[[p]]$ with $L(0) = 0$. $\mathrm{odeSol}(L) = \sum_a A_a p^a$ is defined by $A_0 = 1$ and $(a+1)A_{a+1} = \sum_{i\leq a} A_i\, L_{a+1-i}$.

```

noncomputable def odeSol (L : PowerSeries K) : PowerSeries K := PowerSeries.mk (odeCoeff L)
```

(`VOA/Moonshine/MoonshineLRM5Ode.lean`; section variables `{K : Type*} [Field K] [CharZero K]`.)

Physical meaning

Solving $pA' = AL$ is how one exponentiates a logarithmic derivative: L plays the role of a sum over single-particle contributions, and A is the multi-particle (second-quantised) partition function built from them. This is the familiar passage from a single-string spectrum to the free-field product formula of a string partition function.

Theorem 46.16 (Existence, uniqueness, multiplicativity)**.** *Let $L, L_1, L_2 \in K[[p]]$ have constant term 0.*

(a) $A = \mathrm{odeSol}(L)$ *satisfies* $pA' = AL$ *and* $A(0) = 1$*;*

(b) two solutions of $pA' = AL$ *with the same constant term are equal;*

(c) $\mathrm{odeSol}(L_1 + L_2) = \mathrm{odeSol}(L_1)\,\mathrm{odeSol}(L_2)$.

```

```

(`VOA/Moonshine/MoonshineLRM5Ode.lean`.)

From the mathematics to the Lean statement

`PowerSeries.constantCoeff` is the constant term. The theorem is the formal version of "$A = \exp \int L\,dp/p$": (a) existence, (b) uniqueness (in particular uniqueness given the constant term; no invertibility hypothesis on A is needed), (c) the exponential law. It is applied below with $K = \mathbb{C}((q))$, which is a field of characteristic 0 (`charZero_laurentSeries`).

Proof on paper. (a) Comparing coefficients of p^{a+1} in $pA' = AL$ gives exactly the recursion, since $[p^{a+1}](pA') = (a+1)A_{a+1}$ and $L_0 = 0$. (b) The difference $\Delta = A - B$ satisfies $p\Delta' = \Delta L$ and $\Delta_0 = 0$; by induction $(a+1)\Delta_{a+1} = \sum_{i \le a} \Delta_i L_{a+1-i} = 0$, and $a + 1 \neq 0$ in characteristic 0. (c) $D = p\partial_p$ is a derivation, so A_1A_2 solves $p(A_1A_2)' = A_1A_2(L_1 + L_2)$ with constant term 1; apply (b). □

Physical meaning

The exponential of a connected generating function: a multi-particle partition function is the exponential of the single-particle free energy, and the ODE is its infinitesimal form.

What the machine verified

No hypotheses beyond those displayed; standard axioms (`MoonshineLRM5Audit.lean`). Supporting: `odeCoeff_zero`, `odeCoeff_succ`, `constantCoeff_odeSol`, `coeff_succ_mul_of_constantCoeff_eq_zero`, `coeff_succ_X_mul_derivative`.

Definition 46.17 (Cone products). For $e : \mathbb{N} \times \mathbb{N} \to \mathbb{C}$ let

$$\mathrm{coneLog}(e) = -\sum_{k,m,n \ge 1} m\, e(m,n)\, p^{mk} q^{nk} \in \mathbb{C}((q))[[p]], \qquad \mathrm{coneProd}(e) = \mathrm{odeSol}\big(\mathrm{coneLog}(e)\big),$$

so that coneProd(e) "is" $\prod_{m,n \ge 1} (1 - p^m q^n)^{e(m,n)}$.

```
noncomputable def coneLogCoeff (e : ℕ → ℕ → ℂ) (a : ℕ) : LaurentSeries ℂ :=
  -HahnSeries.ofPowerSeries ℤ ℂ (PowerSeries.mk fun b =>
    ∑ m ∈ a.divisors, if a / m ∣ b ∧ b ≠ 0 then (m : ℂ) * e m (b / (a / m)) else 0)
noncomputable def coneLog (e : ℕ → ℕ → ℂ) : PowerSeries (LaurentSeries ℂ) :=
  PowerSeries.mk (coneLogCoeff e)
noncomputable def coneProd (e : ℕ → ℕ → ℂ) : PowerSeries (LaurentSeries ℂ) :=
  odeSol (coneLog e)
```

(`VOA/Moonshine/MoonshineLRM5Product.lean`.)

From the mathematics to the Lean statement

`coneLogCoeff e a` is the p^a-coefficient of coneLog(e): $-\sum_{m \mid a} \sum_{b \ge 1,\ (a/m) \mid b} m\, e\big(m, b/(a/m)\big) q^b$. With $k = a/m$ and $b = nk$ this is $-\sum_{mk=a} \sum_n m\, e(m,n) q^{nk}$, as displayed. Why this is the logarithmic derivative of the product: for $x = p^m q^n$, $p\partial_p x = mx$, so $p\partial_p \log(1-x)^e = -e\,m\,x/(1-x) = -e\,m \sum_{k \ge 1} x^k$.

Is `coneProd` the product? The library does *not* prove that coneProd(e) equals the (p,q)-adic limit of finite products $\prod_{m,n \le N} (1 - p^m q^n)^{e(m,n)}$ (with $(1-x)^e$ the binomial series); no such limit is defined in Lean, and the lemma `coneProd_single` ($= (1 - p^m q^n)^k$ for a single exponent) proposed in the coordination log was not written. What the library proves is that coneProd has the defining properties of the product: constant term 1, the logarithmic derivative coneLog, multiplicativity in the exponents (Theorem 46.18(b)) and uniqueness of

exponents (Theorem 46.18(c)). On paper, these characterise the product: the classical infinite product has constant term 1 and logarithmic derivative coneLog(e) (termwise, as computed above), hence equals coneProd(e) by Theorem 46.16(b). For the downstream use (Chapter 47: dimensions of root spaces from equality of products) only these properties are used, so the definition is adequate; but a referee should read "$\prod$" in the Lean docstrings as "the series with this logarithmic derivative".

Physical meaning

The multi-particle (Fock space) partition function of bosons with $e(m,n)$ species at momentum (m,n) is $\prod(1-p^m q^n)^{-e(m,n)}$; here the exponent appears with the opposite sign, as in the Weyl denominator (the "fermionic" or BRST side of the character formula).

What the machine verified

Definitions; standard axioms (`MoonshineLRM5Audit.lean`).

Theorem 46.18 (The product identity (KNZ)). *(a)* $\prod_{m,n\geq 1}(1-p^m q^n)^{c(mn)} = 1 - \sum_{a,b\geq 1} c(a+b-1)\,p^a q^b$ *in* $\mathbb{C}((q))[[p]]$, *where* $c(n)$ *are the coefficients of* J *and the product is* coneProd*;*

(b) coneProd(e_1+e_2) = coneProd(e_1) coneProd(e_2)*;*

(c) if coneProd(e_1) = coneProd(e_2) *then* $e_1(m,n) = e_2(m,n)$ *for all* $m,n \geq 1$.

```

theorem coneProd_add (e₁ e₂ : ℕ → ℕ → ℂ) : coneProd (e₁ + e₂) = coneProd e₁ * coneProd e₂
theorem coneProd_exponent_unique {e₁ e₂ : ℕ → ℕ → ℂ} (h : coneProd e₁ = coneProd e₂) :
    ∀ m n : ℕ, 0 < m → 0 < n → e₁ m n = e₂ m n
```

(`VOA/Moonshine/MoonshineLRM5Product.lean`.)

From the mathematics to the Lean statement

`fun m n ⇒ cJ (m * n)` is the exponent $e(m,n) = c(mn)$, and `knzSeries cJ` is S. (a) is (KNZ) with the reading of $\prod$ explained in the dictionary of Definition 46.17. (c) is stated for $m,n \geq 1$ because exponents at $m = 0$ or $n = 0$ do not occur in coneLog.

The full Borcherds form (46.4) is not a single Lean theorem. It is the conjunction of (a) and Theorem 46.14(a) at $c =$ `cJ`:

$$p\big(J(p) - J(q)\big) = (1 - p/q)\cdot \mathrm{coneProd}\big((m,n) \mapsto c(mn)\big),$$

which, after inserting the two trivial factor classes $n \leq 0$ described above, is (46.4). (The coordination log describes `faberGen_map_eq_mul` alone as "the KNZ′ form"; strictly, it is only the factorisation, and the KNZ′ form needs `knz_product` as well.)

Formal versus analytic. The identity is formal, in $\mathbb{C}((q))[[p]]$. Both sides also converge for $|q|<1$, $|p|<|q|$, and the formal identity implies the analytic one there; the library does not state the analytic version, and nothing downstream needs it.

Proof on paper. (a) Both coneProd$(c(mn))$ and S have constant term 1. The first satisfies $pA' = A$ coneLog by construction; the second satisfies $pS' = S\cdot(-E)$ by Theorem 46.14(c), and $-E =$ coneLog$(c(mn))$ because the coefficient of $p^M q^r$ in coneLog$(c(mn))$ is $-\sum_{m\mid M,\ (M/m)\mid r} m\,c\big(m\cdot \frac{r}{M/m}\big) = -\sum_{a\mid(M,r)} \frac{M}{a}\,c\big(\frac{Mr}{a^2}\big)$ (put $a = M/m$), which is $-h(M,r)$ (`coneLog_cJ`). Uniqueness (Theorem 46.16(b)) gives equality. (b) is Theorem 46.16(c) with coneLog(e_1+e_2) = coneLog(e_1) +

coneLog(e_2). (c) Equal products have equal logarithmic derivatives (cancel the nonzero series coneProd in $pA' = A\,\mathrm{coneLog}$), and the coefficient of $p^m q^n$ in coneLog(e) is $-\sum_{m'|m}[\,(m/m') \mid n\,]\,m'\,e(m', n/(m/m'))$ (`coeff_coneLog`); the term $m' = m$ is $-m\,e(m,n)$ and all others involve $m' < m$; strong induction on m and division by $m \neq 0$ give $e_1 = e_2$. □

Physical meaning

The denominator identity as a one-loop string partition function. In the bosonic string on $V^\natural \otimes V_{I\!I_{1,1}}$, the physical states of momentum (m,n) form $\mathfrak{m}_{(m,n)}$, of dimension $c(mn)$ (no-ghost theorem). The Weyl–Kac–Borcherds formula says that the "Fock space" $U(\mathfrak{u}^+)$ of these states has character $\prod(1-p^m q^n)^{-c(mn)}$ (PBW), and that it is the free (tensor) algebra on the space U of simple-root strings, whose character is $1-S$, so that its character is also $1/S$; hence $\prod(1-p^m q^n)^{c(mn)} = S$. Harvey and Moore (1996) showed that Borcherds products arise as one-loop threshold integrals of string theory, log |product| = a regularised integral of the partition function over the fundamental domain; Paquette, Persson and Volpato (2016) realised the Monster Lie algebra as the algebra of BPS states of a heterotic string compactification, with (46.4) as its BPS index. The antisymmetry $J(p) - J(q)$ reflects the T-duality exchanging the two light-cone directions of $I\!I_{1,1}$, i.e. the Weyl reflection in the real root. These are physical interpretations; the proof above uses only modularity of j.

What the machine verified

(a): **unconditional**; (b), (c): no hypotheses. No Lean statement here mentions the Monster Lie algebra: (a) is an identity about the coefficients of J. Standard axioms (`MoonshineLRM5Audit.lean`, 102 reports; build record of the release, Chapter 50). Supporting: `charZero_laurentSeries`, `ofPowerSeries_mk_zero`, `constantCoeff_coneLog`, `coneProd_spec`, `constantCoeff_coneProd`, `coneLog_add`, `coneLog_cJ`, `coneLog_eq_of_coneProd_eq`, `coeff_coneLog`.

46.5 The twisted denominator identities

46.5.1 The classical statement

Let $g \in \mathrm{Aut}(V^\natural)$ and write $c_g(n) = \mathrm{tr}(g \mid V^\natural_{n+1})$, so $T_g = q^{-1} + \sum_{n\geq 1} c_g(n) q^n$. The group $\mathrm{Aut}(V^\natural)$ acts on $\mathfrak{m}$ by graded Lie automorphisms, and the no-ghost isomorphism $\mathfrak{m}_{(m,n)} \cong V^\natural_{1+mn}$ is equivariant (Chapter 45), so $\mathrm{tr}(g \mid \mathfrak{m}_{(m,n)}) = c_g(mn)$. Taking g-traces instead of dimensions in Borcherds' argument gives his *twisted denominator identities*:

$$p^{-1}\exp\Big(-\sum_{k\geq 1}\frac{1}{k}\sum_{m>0,\ n\in\mathbb{Z}} c_{g^k}(mn)\,p^{mk}q^{nk}\Big) = T_g(p) - T_g(q). \tag{46.5}$$

If g has finite order N, so that g is diagonalisable with eigenvalues N-th roots of unity, this can be written as a product, $p^{-1}\prod_{m>0,n}\prod_{\zeta^N=1}(1-\zeta p^m q^n)^{\mathrm{mult}(\zeta,\,g\mid V^\natural_{1+mn})} = T_g(p) - T_g(q)$. For $g = 1$ it is (46.4). Exactly as in §46.4, the factors with $n \leq 0$ give $1 - p/q$, and (46.5) is equivalent to

$$1 - u_g = \exp\Big(-\sum_{k\geq 1}\frac{1}{k}\sum_{m,n\geq 1} c_{g^k}(mn)\,p^{mk}q^{nk}\Big), \qquad u_g = \sum_{a,b\geq 1} c_g(a+b-1)\,p^a q^b, \tag{46.6}$$

and, taking $D = p\partial_p$ of the logarithm, to the logarithm-free form

$$D\,u_g = (1-u_g)\,P_g, \qquad P_g = \sum_{k\geq 1}\sum_{m,n\geq 1} m\,c_{g^k}(mn)\,p^{mk}q^{nk}. \tag{TD$_g$}$$

The library proves (TD$_g$) (in "height coordinates", below), for every symmetry of finite order of an abstract Borcherds datum, and then for every finite-order $g \in \mathrm{Aut}(V^\natural)$ on $\mathfrak{m}$.

The idea of the proof. Chapter 45 proved that the positive part $\mathfrak{u}^+ = \bigoplus_{m,n\geq 1} \mathfrak{m}_{(m,n)}$ satisfies $T(U) \cong U(\mathfrak{u}^+)$, compatibly with every symmetry: the algebra map from the tensor algebra $T(U)$ to the universal enveloping algebra is bijective. Equivalently, $\mathfrak{u}^+$ is the *free Lie algebra on* U (the Lie subalgebra of $T(U)$ generated by U maps isomorphically onto $\mathfrak{u}^+$; Chapter 45, "$\mathfrak{u}^+$ is free on U"), and this freeness is the whole Lie-theoretic input of the twisted identities. Here $U \subset \mathfrak{u}^+$ is the generating space spanned by the real-root strings $(\operatorname{ad} e)^k \mathfrak{m}_{(1,j)}$, $0 \leq k < j$; the string through $(1, j)$ sits in degrees $(1 + k, j - k)$ and is isomorphic to $\mathfrak{m}_{(1,j)}$ as a representation of the symmetry group (which fixes e). Compare the g-traces of the two sides degree by degree:

- on $T(U) = \bigoplus_\ell U^{\otimes \ell}$, the trace of g on a tensor product is the product of traces, so the graded trace is $\sum_\ell (\operatorname{ch}_g U)^\ell = (1 - \operatorname{ch}_g U)^{-1}$, and $\operatorname{ch}_g U = u_g$ (the string through $(1, j)$ contributes $c_g(j)$ in each degree $(1 + k, j - k)$, i.e. $c_g(a + b - 1)$ at (a, b));
- on $U(\mathfrak{u}^+)$, choose a basis of eigenvectors y_a of g, homogeneous of degree γ_a, eigenvalue λ_a; by PBW the sorted monomials form a basis of eigenvectors, so the graded trace is $B = \prod_a (1 - \lambda_a e^{\gamma_a})^{-1}$, and $DB/B = \sum_{k\geq 1} \sum_a (\gamma_a)_1 \lambda_a^k e^{k\gamma_a} = P_g$, because $\sum_{a:\gamma_a=(m,n)} \lambda_a^k = \operatorname{tr}(g^k|\mathfrak{m}_{(m,n)}) = c_{g^k}(mn)$.

Equating, $B = (1 - u_g)^{-1}$ and $DB = BP_g$, which is (TD_g). The library carries out exactly this argument, but without infinite products: both sides are replaced by *weighted counts* of words and multisets of basis letters, and the comparison is made by transporting a linear isomorphism between coordinate spaces.

46.5.2 The statement in Lean: height coordinates

Definition 46.19 (Euler derivation; the twisted series; the twisted denominator identity)**.** In $\mathbb{C}[[q]][[p]]$ let $D = p\,\partial_p$. For $c : \mathbb{N} \to \mathbb{N} \to \mathbb{C}$ (with $c(k, \cdot)$ the coefficient sequence of the k-th replicate) define

$$\tilde{u} = \sum_{a,b\geq 1} c(1, a + b - 1)\, p^a q^{a+b}, \qquad \tilde{P} = \sum_{k\geq 1} \sum_{a,b\geq 1} a\, c(k, ab)\, p^{ak} q^{(a+b)k},$$

and say that c satisfies the *twisted denominator identity* if $D\tilde{u} = (1 - \tilde{u})\tilde{P}$.

```
def eulerDeriv (F : PowerSeries R) : PowerSeries R :=
  PowerSeries.mk fun n => (n : R) * PowerSeries.coeff n F
def twistedUnitSeries (c : ℕ → ℂ) : PowerSeries (PowerSeries ℂ) :=
  PowerSeries.mk fun a => PowerSeries.mk fun N => if 1 ≤ a ∧ a < N then c (N - 1) else 0
def twistedPowerSum (c : ℕ → ℕ → ℂ) : PowerSeries (PowerSeries ℂ) :=
  PowerSeries.mk fun A => PowerSeries.mk fun N =>
    ∑ k ∈ A.divisors,
      if k ∣ N ∧ A < N then ((A / k : ℕ) : ℂ) * c k (A / k * ((N - A) / k)) else 0
def TwistedDenominatorIdentity (c : ℕ → ℕ → ℂ) : Prop :=
  eulerDeriv (twistedUnitSeries (c 1)) = (1 - twistedUnitSeries (c 1)) * twistedPowerSum c
```

(`VOA/Moonshine/MoonshineCNReplicationFormal.lean`, namespace `VOA.Moonshine.ConwayNorton`; `eulerDeriv` is in a section with `{R : Type*} [CommRing R]`.)

From the mathematics to the Lean statement

Decoding. `eulerDeriv F` multiplies the p^n-coefficient by n: it is D. In `twistedUnitSeries c`, the coefficient of $p^a q^N$ is $c(N - 1)$ if $1 \leq a < N$ and 0 otherwise; writing $N = a + b$ with $b \geq 1$ this is $\sum_{a,b\geq 1} c(a + b - 1) p^a q^{a+b}$. In `twistedPowerSum c`, the coefficient of $p^A q^N$ is $\sum_{k|A,\ k|N,\ A<N} \frac{A}{k}\, c\big(k, \frac{A}{k} \cdot \frac{N-A}{k}\big)$; writing $A = ak, N = (a+b)k$ this is $\sum_k a\, c(k, ab)$, as displayed.

`TwistedDenominatorIdentity c` uses only $c(1,\cdot)$ in $\tilde{u}$ and all $c(k,\cdot)$, $k \geq 1$, in $\tilde{P}$; the values $c(0,\cdot)$ never occur.
Height coordinates. A root (m,n) of the positive cone is recorded by the exponent $p^m q^{m+n}$ (first coordinate and height). So $\tilde{u}(p,q) = u_g(pq,q)$ and $\tilde{P}(p,q) = P_g(pq,q)$ with $c(k,n) = c_{g^k}(n)$. The substitution $p \mapsto pq$ is an injective ring map that commutes with D (it does not change the p-degree), so $D\tilde{u} = (1-\tilde{u})\tilde{P}$ holds if and only if (TD_g) holds. *Why height coordinates?* Not for the counting: the positive cone $\{m, n \geq 1\}$, which contains all degrees of $\mathfrak{u}^+$ and of U (the strings sit at $(1+k, j-k)$ with $0 \leq k < j$), already lies in $\mathbb{N}\times\mathbb{N}$ with positive first coordinate and finite fibres in Borcherds' coordinates. The reason is the replication step (§46.6): there one substitutes $X \mapsto f(q)$ in $G(p) = p(f(p)-X)$, which gives $(1-p/q)(1-u_g)$, with a negative power of q; after the further substitution $p \mapsto pq$ this becomes $(1-p)(1-\tilde{u})$, and the whole computation stays in $\mathbb{C}[[q]][[p]]$ (`faberEvaluation_faberGenerating`). The twisted identity is stated in the same coordinates so that it can be used there directly; the torus characters 2^A, 2^N of the proof below then record the height degree (A,N).
Same as the textbook identity? Yes, for every g of finite order: (TD_g) is equivalent to (46.6) by the uniqueness of solutions of $pA' = AL$ (Theorem 46.16) and to (46.5) by the factorisation $p(T_g(p) - T_g(q)) = (1-p/q)(1-u_g)$ (Theorem 46.14(a) with $c = c_g$). These two equivalences are paper arguments; the library states and uses only the logarithm-free form, which is all that replication needs. **Could the definition be vacuous?** No: for $c(k,n) = c_J(n)$ for all k (the trivial symmetry), it is the logarithmic KNZ identity, which holds (Theorem 46.14(c)); and a family not coming from a symmetry generally fails it (it would otherwise force replication, which fails for most sequences).

Physical meaning

$\tilde{u}$ counts single "simple-root" string states with the symmetry g inserted, and $\tilde{P}$ is the connected (single-particle) free energy of all physical states with g inserted, summed over k-fold multi-wound copies, which carry the twist g^k. The identity is the g-twisted index of the string's Fock space: inserting g in the trace over a symmetric (bosonic) Fock space produces the plethystic exponential $\exp\sum_k \frac{1}{k}\operatorname{tr}(g^k \cdots)$, whose k-th term is a k-fold cover twisted by g^k, exactly as in the orbifold of a symmetric product.

What the machine verified

Definitions; standard axioms (`VOA/Moonshine/MoonshineCNAudit18.lean`).

46.5.3 Words and multisets: the two character identities

The file `VOA/Moonshine/MoonshineCNTwistedCombinatorics.lean` contains no Lie algebra. It proves the two generating-function identities "$T(U)$ has character $(1-\operatorname{ch} U)^{-1}$" and "Sym has character the plethystic exponential", for abstract weighted letters.

Definition 46.20 (Graded letters; weighted counts)**.** A set of *graded letters* is a set I with a degree $\deg : I \to \mathbb{N}\times\mathbb{N}$ such that $(\deg i)_1 \geq 1$ and each fibre $\deg^{-1}(\gamma)$ is finite. Given weights $\mathrm{wt} : I \to \mathbb{C}$, define for $\gamma \in \mathbb{N}\times\mathbb{N}$:

- the word count $W(\gamma) = \sum_{w:\deg w=\gamma} \prod_{i\in w} \mathrm{wt}(i)$ over words (finite sequences) of total degree γ;
- the letter count $\ell(\gamma) = \sum_{\deg i=\gamma} \mathrm{wt}(i)$;
- the multiset count $M(\gamma) = \sum_{m:\deg m=\gamma} \prod_{i\in m} \mathrm{wt}(i)$ over finite multisets;

- the power-sum count $P(\varepsilon) = \sum_{k\ge 1} \sum_{i:\, k\deg i=\varepsilon} (\deg i)_1 \,\mathrm{wt}(i)^k$.

```
structure GradedLetters (ι : Type*) where
  deg : ι → ℕ × ℕ
  deg_pos : ∀ i, 1 ≤ (deg i).1
  finite_fiber : ∀ γ, {i | deg i = γ}.Finite
def wordCount (wt : ι → ℂ) (γ : ℕ × ℕ) : ℂ := ∑ w ∈ L.wordFiber γ, (w.map wt).prod
def letterCount (wt : ι → ℂ) (δ : ℕ × ℕ) : ℂ :=
  ∑ i ∈ L.lowerLetters δ, if L.deg i = δ then wt i else 0
def msetCount (wt : ι → ℂ) (γ : ℕ × ℕ) : ℂ := ∑ m ∈ L.msetFiber γ, (m.map wt).prod
def powerSumCount (wt : ι → ℂ) (ε : ℕ × ℕ) : ℂ :=
  ∑ x ∈ L.lowerLetters ε ×ˢ Icc 1 ε.1,
    if x.2 • L.deg x.1 = ε then ((L.deg x.1).1 : ℂ) * wt x.1 ^ x.2 else 0
```

(`VOA/Moonshine/MoonshineCNTwistedCombinatorics.lean`; the counts are in `namespace GradedLetters` with `L : GradedLetters ι`.)

From the mathematics to the Lean statement

`L.wordFiber γ` is the finite set of lists of degree γ (finite because every letter has first degree ≥ 1, so a word of degree γ has at most γ_1 letters, and the fibres are finite); `L.msetFiber γ` likewise for multisets. `(w.map wt).prod` is $\prod_{i\in w} \mathrm{wt}(i)$. `L.lowerLetters δ` is the finite set of letters of degree $\le \delta$ componentwise; the `if L.deg i = δ` selects degree exactly δ. In `powerSumCount`, `Icc 1 ε.1` is $1 \le k \le \varepsilon_1$ (no larger k can satisfy $k \deg i = \varepsilon$), `x.2 • L.deg x.1` is $k \deg i$, and `(L.deg x.1).1` is $(\deg i)_1$. The generating series of a count f is `bigradedSeries f` $= \sum_{A,N} f(A,N) p^A q^N$ (`wordSeries`, `letterSeries`, `msetSeries`, `powerSumSeries`).

Physical meaning

Graded letters and weighted counts are the bookkeeping of a Fock space: a word in graded letters is a multi-particle state, and the weighted count is its contribution to a character, with weights recording the charges (momenta and energies) of the constituent particles.

Theorem 46.21 (The two character identities). *For graded letters with weights:*

(a) $W(\gamma) = [\gamma = 0] + \sum_i \mathrm{wt}(i)\, W(\gamma - \deg i)$, *hence* $W \cdot (1 - \ell) = 1$ *as series;*

(b) $\gamma_1 M(\gamma) = \sum_\varepsilon M(\gamma - \varepsilon) P(\varepsilon)$, *hence* $DM = M \cdot P$ *as series;*

(c) in $\mathbb{C}[[q]][[p]]$*: if* $B(1-u) = 1$ *and* $DB = BP$, *then* $Du = (1-u)P$.

```

```

(`VOA/Moonshine/MoonshineCNTwistedCombinatorics.lean`.)

From the mathematics to the Lean statement

`γ - L.deg i` is truncated subtraction in $\mathbb{N}\times\mathbb{N}$, harmless because only letters of degree $\le\gamma$ occur. `bigradedConv f g γ` is the Cauchy convolution $\sum_{\delta+\delta'=\gamma} f(\delta)g(\delta')$ (`bigradedSeries_mul` identifies it with multiplication of series). (b) is the logarithm-free form of $M = \exp\sum_{k\ge1}\frac{1}{k}\sum_i \mathrm{wt}(i)^k e^{k\deg i}$, i.e. of $M=\prod_i(1-\mathrm{wt}(i)e^{\deg i})^{-1}$.

Proof on paper. (a) Split a nonempty word into its first letter and the rest. (b) For a multiset m of degree γ, $\gamma_1 = \sum_i(\text{multiplicity of } i \text{ in } m)(\deg i)_1 = \sum_i\sum_{k\ge1}[\,\mathrm{mult}_i(m)\ge k\,](\deg i)_1$. So $\gamma_1 M(\gamma) = \sum_i\sum_{k\ge1}(\deg i)_1\sum_{m\ni i^k}\mathrm{wt}(m)$, and the multisets of degree γ containing at least k copies of i are exactly $\{i^k\}\cup m'$ with $\deg m'=\gamma-k\deg i$, of weight $\mathrm{wt}(i)^k\mathrm{wt}(m')$ (`sum_msetFiber_count_ge`). Hence $\gamma_1 M(\gamma)=\sum_\varepsilon P(\varepsilon)M(\gamma-\varepsilon)$. (c) B is a unit with inverse $1-u$; from $D(B(1-u))=0$ and the Leibniz rule, $DB\,(1-u)=B\,Du$, so $B\,Du=BP(1-u)$; multiply by $1-u$. □

Physical meaning

(a) is the partition function of a "free" (no relations) algebra of creation operators: $T(U)$ is the Fock space of *distinguishable* insertions. (b) is the bosonic Fock space: the grand-canonical partition function of bosons is $\prod(1-x)^{-1}=\exp\sum_k x^k/k$, the k-th term being k particles in the same state (a k-fold winding).

What the machine verified

No hypotheses; standard axioms (`MoonshineCNAudit18.lean`).     ∑ x ∈ S, κX j₀ x = ∑ y ∈ T, κY j₀ y
```

(`VOA/Moonshine/MoonshineCNTwistedTransfer.lean`.)

From the mathematics to the Lean statement

`X →₀ ℂ` is the space of finitely supported functions $X \to \mathbb{C}$, i.e. the free vector space $\mathbb{C}^{(X)}$ with basis e_x =`single x 1`; `≃ₗ[ℂ]` is a linear isomorphism; `finsuppDiag κ` is the diagonal operator. The finsets `S`, `T` are the points whose label vector $j \mapsto \kappa_j$ satisfies `P`.

Proof on paper. An operator intertwining diagonal operators maps the joint eigenspace of a label vector σ into the joint eigenspace of σ (`apply_single_eq_zero_of_diag`); the joint eigenspaces are spanned by the basis vectors with that label; an isomorphism therefore matches their dimensions, i.e. the cardinalities of label fibres (`card_le_of_injective_support`, `card_fiber_eq_of_diag_equiv`). A weighted count over a union of fibres is a sum over fibres of (cardinality)×(common value of κ_{j_0}). □

Physical meaning

Equal traces of commuting diagonal operators on isomorphic Hilbert spaces: if two bases of the same space are both eigenbases of the same commuting family (charges), each joint eigenvalue has the same multiplicity in both.

What the machine verified

No hypotheses; standard axioms (`MoonshineCNAudit18.lean`).

Theorem 46.23 (PBW and word coordinates intertwine diagonal symmetries). *Let L be a complex Lie algebra with a linearly ordered basis $(Y_a)_{a\in A}$, $S \subseteq L$ a subspace with basis $(Z_i)_{i\in I}$, and suppose the algebra map $T(S) \to U(L)$ is bijective. Let $\Psi : \mathbb{C}^{(\mathrm{List}\, I)} \to \mathbb{C}^{(\mathrm{Multiset}\, A)}$ be the composite of the word basis of $T(S)$, the bijection $T(S) \to U(L)$ and the PBW coordinates of $U(L)$. If a Lie endomorphism φ of L preserves S and is diagonal in both bases ($\varphi Y_a = \kappa_a Y_a$, $\varphi Z_i = \nu_i Z_i$), then Ψ intertwines $e_w \mapsto \prod_{i\in w} \nu_i\, e_w$ with $e_m \mapsto \prod_{a\in m} \kappa_a\, e_m$.*

(`VOA/Moonshine/MoonshineCNTwistedPBW.lean`; section variables `(Y : Basis A ℂ L)` with `[LinearOrder A]`, `(S : Submodule ℂ L)`, `(hbij : Function.Bijective (tensorGeneratorToEnveloping S))`, `(Z : Basis I ℂ S)`.)

From the mathematics to the Lean statement

`pbwCoordinates Y` is a linear isomorphism $U(L) \cong \mathbb{C}^{(\mathrm{Multiset}\, A)}$ obtained from the repository's relative PBW theorem with the zero subalgebra (Chapter 45): `pbwCoordinates_sorted`

says that a sorted monomial $Y_{a_1}\cdots Y_{a_r}$ $(a_1 \le \ldots \le a_r)$ has coordinate vector $e_{\{a_1,\ldots,a_r\}}$; this is PBW. `tensorGeneratorToEnveloping S` is the algebra map $T(S) \to U(L)$ of Chapter 45. `Z.tensorAlgebra` is the basis of $T(S)$ by words (Mathlib, `FreeMonoid I`, converted to lists). `wordPBWEquiv_diag` is the statement displayed.

Proof on paper. φ acts on $U(L)$ by an algebra automorphism $U(\varphi)$; on a sorted monomial of eigenvectors it multiplies by the product of eigenvalues (`pbwCoordinates_envelopingMap`). Likewise on words in $T(S)$ (`tensorAlgebra_repr_lift_diag`). The map $T(S) \to U(L)$ is natural in φ (`tensorGeneratorToEnveloping_natural`, Chapter 45). □

Physical meaning

The free-field (word) description and the oscillator (PBW) description of the same Fock space carry the same symmetry charges.

What the machine verified

Hypotheses as displayed (bijectivity of $T(S) \to U(L)$ is an explicit argument of `wordPBWEquiv`); standard axioms (`MoonshineCNAudit18.lean`). Supporting (same file): `list_prod_map_smul`, `finsuppDiag_domLCongr`, `topBasis`, `bot_isCompl_top`, `zeroBottomRep`, `balancing_bot_eq_bot`, `envelopingInducedEquiv`, `relativeInducedWord_bot`, `pbwCoordinates_symm_single`, `pbwCoordinates_envelopingMap`, `tensorAlgebra_basis_apply`, `tensorAlgebra_repr_lift_diag`; (file `MoonshineCNTwistedTransfer.lean`) `finsuppDiag_single`, `finsuppDiag_apply`, `apply_single_eq_zero_of_diag`, `card_le_of_injective_support`, `card_fiber_eq_of_diag_equiv`.

46.5.5 Eigenbases, root-space bases and torus elements

Definition 46.24 (A symmetry on one root space)**.** For a Borcherds datum D on $\mathfrak{g}$ (Chapter 45) and a group action A of G by graded, form-preserving Lie automorphisms fixing $\mathfrak{g}_0$ and $\mathfrak{g}_{\pm\alpha_r}$ (a `D.GAction G`), $\sigma \in G$ restricts to an endomorphism of each root space $\mathfrak{g}_\gamma$.

```
def weightAction (σ : G) (γ : ℤ × ℤ) : Module.End ℂ (D.weightSpace γ) :=
  (A.action σ).toLinearMap.restrict fun x hx => A.graded σ γ x hx
```

(`VOA/Moonshine/MoonshineCNTwistedBases.lean`, namespace `BorcherdsData`, section variables `(D : BorcherdsData g)`, `{G : Type*} [Group G] (A : D.GAction G)`.)

What the machine verified

Definition; `weightAction_pow` (σ^k restricts to the k-th power) is printed in `MoonshineCNAudit18.lean`.

Physical meaning

A symmetry acting on one root space is a global symmetry of the string theory restricted to the physical states of a fixed spacetime momentum. Its trace there is the corresponding twisted contribution to the one-loop amplitude, the ingredient of the twisted denominator identity.

Theorem 46.25 (Eigenbases of finite-order operators; traces of powers)**.** *If T is an endomorphism of a finite-dimensional complex vector space with $T^N = 1$ for some $N \ge 1$, then T has a basis of eigenvectors; and for any eigenbasis with eigenvalues μ_i, $\mathrm{tr}(T^k) = \sum_i \mu_i^k$.*

```
theorem exists_eigenbasis_of_pow_eq_one {V : Type u} [AddCommGroup V] [Module ℂ V]
    [FiniteDimensional ℂ V] (T : Module.End ℂ V) {N : ℕ} (hN : 0 < N) (hT : T ^ N = 1) :
    ∃ (ι : Type u) (_ : Fintype ι) (b : Basis ι ℂ V) (μ : ι → ℂ), ∀ i, T (b i) = μ i • b i
theorem trace_pow_eq_sum_of_eigenbasis {V : Type*} [AddCommGroup V] [Module ℂ V]
    {ι : Type*} [Fintype ι] (b : Basis ι ℂ V) (T : Module.End ℂ V) (μ : ι → ℂ)
    (h : ∀ i, T (b i) = μ i • b i) (k : ℕ) :
    LinearMap.trace ℂ V (T ^ k) = ∑ i, μ i ^ k
```

(`VOA/Moonshine/MoonshineCNTwistedBases.lean`.)

Proof on paper. The minimal polynomial of T divides $X^N - 1$, which is separable over $\mathbb{C}$; a separable minimal polynomial means T is semisimple, hence diagonalisable over the algebraically closed field $\mathbb{C}$. The trace of T^k in an eigenbasis is the sum of the diagonal entries μ_i^k. □

Physical meaning

A unitary symmetry of finite order has a basis of states with definite charge (eigenvalue a root of unity), and the twisted partition function counts states weighted by their charge.

What the machine verified

No hypotheses beyond those displayed; standard axioms (`MoonshineCNAudit18.lean`).

The remaining declarations of `MoonshineCNTwistedBases.lean` build the bases in which the comparison is made. Given bases b_γ of all root spaces: `positiveBasis` is the basis of $\mathfrak{u}^+$ collected from the b_γ, γ in the positive cone (using that $\mathfrak{u}^+$ is the internal direct sum of its root spaces, `positiveWeight_isInternal`); `generatorBasis` is the basis of the generating space U formed by the string vectors $(\operatorname{ad} e)^k b_{(1,j),i}$, $0 \le k < j$ (using `generatorStrings_isInternal` and the string isomorphisms of Chapter 45), with `generatorBasis_coe`, `generatorBasis_mem` recording that the vector indexed by the string (j,k) lies in degree $(1+k, j-k)$. The *torus elements* `weightTorus χ` multiply $\mathfrak{g}_\gamma$ by $\chi(\gamma)$; for multiplicative χ they are Lie endomorphisms (`weightTorus_lie`) and restrict to $\mathfrak{u}^+$ (`positiveTorus`) and to U (`weightTorus_genSpace`, `positiveTorus_generator_mem`). Finally, if the b_γ are eigenbases of σ with eigenvalues μ_γ, then `positiveBasis` and `generatorBasis` are eigenbases of σ on $\mathfrak{u}^+$ and U, the string vector $(\operatorname{ad} e)^k b_{(1,j),i}$ having the eigenvalue $\mu_{(1,j),i}$ because σ fixes e (`positivePartAction_positiveBasis`, `positivePartAction_generatorBasis`), and eigenbases of every torus element (`positiveTorus_positiveBasis`, `positiveTorus_generatorBasis`). Other supporting declarations: `isInternal_comap_subtype`, `borcherdsStringIndex_decidableEq`, `weightDecompose`, `weightDecompose_of_mem`, `weightTorus_of_mem`, `mem_weightSpace_iSup`, `weightTorus_mem_weightSpan`, `positiveTorus_coe`, `positiveBasis_coe`, `positiveBasis_mem`, `weightAction_pow`. All are printed in `MoonshineCNAudit18.lean` with standard axioms.

46.5.6 The twisted denominator identity for Borcherds data

Theorem 46.26 (Twisted denominator identity, abstract form). *Let D be a Borcherds datum with a G-action A and $\sigma \in G$. In (a) and (b) we are moreover given a normalised real pair (e, f) and bases b_γ of the root spaces; (c) has neither (only D, A, σ, finite order, the family c and the trace hypothesis).*

(a) If every b_γ is an eigenbasis of σ with eigenvalues μ_γ, then for every bidegree the word count of the letters of U weighted by eigenvalues equals the multiset count of the letters of $\mathfrak{u}^+$ so weighted (on paper these counts are the graded traces $\operatorname{tr}(\sigma|T(U)_\gamma)$ and $\operatorname{tr}(\sigma|U(\mathfrak{u}^+)_\gamma)$, computed in the word and PBW eigenbases; the Lean statement is about the counts).

(b) If moreover $\sum_i \mu_{\gamma,i}^k = c(k, \gamma_1\gamma_2)$ for all $k \ge 1$ and all γ in the positive cone, then c satisfies the twisted denominator identity.

(c) If σ has finite order and $\operatorname{tr}(\sigma^k|\mathfrak{g}_\gamma) = c(k,\gamma_1\gamma_2)$ for all $k \geq 1$ and γ in the positive cone, then c satisfies the twisted denominator identity.

```
def borcherdsHeightDegree (γ : ℤ × ℤ) : ℕ × ℕ := (γ.1.toNat, (γ.1 + γ.2).toNat)
theorem generatorLetters_wordCount_eq (σ : G)

      LinearMap.trace ℂ (D.weightSpace γ) (D.weightAction A (σ ^ k) γ) =
        c k (γ.1 * γ.2).toNat) :
    TwistedDenominatorIdentity c
```

(`VOA/Moonshine/MoonshineCNTwistedCharacters.lean`, `VOA/Moonshine/MoonshineCNTwistedDenominator.lean`; namespace `BorcherdsData`; section variables `(e : g) (he : e ∈ D.weightSpace borcherdsRealRoot)`, `(f : g) (hf : f ∈ D.weightSpace (-borcherdsRealRoot))` `(hef : D.form e f = 1)`, `(b : ∀ γ, Basis (ι γ) ℂ (D.weightSpace γ))` `(μ : ∀ γ, ι γ → ℂ)` with `[∀ γ, Fintype (ι γ)]`, and `{G : Type*} [Group G] (A : D.GAction G)`.)

From the mathematics to the Lean statement

`borcherdsHeightDegree` sends (m,n) to $(m, m+n)$ (with `toNat`, harmless on the positive cone). `positiveLetters ι` and `generatorLetters ι` are the graded letters given by the bases of $\mathfrak{u}^+$ and U, with degrees in height coordinates; a letter of `generatorLetters` is a pair (string index (j,k), basis index i of $\mathfrak{g}_{(1,j)}$), with weight `μ _ x.2` $= \mu_{(1,j),i}$. `borcherdsPositiveCone γ` is $\gamma_1, \gamma_2 \geq 1$, and `(γ.1 * γ.2).toNat` is mn for $\gamma = (m,n)$. `LinearMap.trace ℂ V T` is the trace. In (c) the hypothesis `htr` is "the traces of the powers of σ on the positive root spaces are given by c"; finite order is `IsOfFinOrder σ`. The real pair (e,f) is obtained inside the proof of (c) from `exists_normalized_real_pair` (Chapter 45), so it is not a hypothesis of (c).

Proof on paper. (a) Apply Theorem 46.22 to the isomorphism Ψ of Theorem 46.23 with $L = \mathfrak{u}^+$, $S = U$ (bijectivity of $T(U) \to U(\mathfrak{u}^+)$ is `positiveTensorGeneratorToEnveloping_bijective`, Chapter 45) and three diagonal operators: σ, and the torus elements with $\chi_1(\gamma) = 2^{\gamma_1}$ and $\chi_2(\gamma) = 2^{\gamma_1+\gamma_2}$ (`heightCharFirst`, `heightCharTotal`). On a word or multiset of height degree (A,N) the torus labels are 2^A and 2^N; since $2^a = 2^b$ forces $a = b$, the property "labels $= (2^A, 2^N)$" selects exactly the words, resp. multisets, of degree (A,N). The transferred weighted count with $j_0 = \sigma$ is the identity of (a). (b) By (a) and Theorem 46.21(a), the word series W satisfies $W(1-\ell) = 1$, and the letter series ℓ of U is $\tilde{u}$: the letters of degree $(1+k, 1+j)$ are the $(\operatorname{ad} e)^k b_{(1,j),i}$, with total weight $\sum_i \mu_{(1,j),i} = c(1,j)$, and $(a, a+b) = (1+k, 1+j)$ gives $j = a+b-1$. By Theorem 46.21(b), the multiset series M satisfies $DM = MP$, and the power-sum series of the letters of $\mathfrak{u}^+$ is $\tilde{P}$: a letter in $\mathfrak{g}_{(m,n)}$ has height degree $(m, m+n)$, first coordinate m, and $\sum_i \mu^k_{(m,n),i} = c(k,mn)$. By (a), $W = M$. Theorem 46.21(c) gives $D\tilde{u} = (1-\tilde{u})\tilde{P}$. (c) By Theorem 46.25 each $\sigma|_{\mathfrak{g}_\gamma}$ has an eigenbasis (its N-th power is the identity), and the power sums of eigenvalues are the traces of powers; apply (b). □

Physical meaning

The free (tensor-algebra) description of the BPS Fock space and its oscillator (PBW) description must have the same g-twisted partition function. The two torus elements are the "momentum charges" $(m, m+n)$: comparing traces at fixed charges is comparing twisted partition functions coefficient by coefficient.

What the machine verified

No hypotheses beyond those displayed; standard axioms (`MoonshineCNAudit18.lean`). Supporting (`MoonshineCNTwistedCharacters.lean`): `borcherdsHeightDegree_injOn`, `borcherdsStringDegree_cone`, `sigmaGradedLetters`, `sum_sigma_fiber`, `heightCharFirst`, `heightCharTotal` and their additivity and cone lemmas, `list_prod_two_pow`, `multiset_prod_two_pow`, `two_pow_inj`, `GradedLetters.listDeg_fst` (and `_snd`, `msetDeg_fst`, `msetDeg_snd`), `positiveLetters`, `generatorLetters`; (`MoonshineCNTwistedDenominator.lean`) `weightAction_one`.

46.5.7 The Monster instance

Theorem 46.27 (Twisted denominator identities of the Monster Lie algebra). *Assume* `MonsterLieSimpleRootGeneration`. *Then:*

(a) for every $\tau \in \mathrm{Aut}(V^\natural)$ and every (m, n) with $m, n \geq 1$, the trace of τ on the root space $\mathfrak{m}_{(m,n)}$ (Borcherds coordinates) is $c_\tau(mn) = \mathrm{tr}(\tau | V^\natural{}_{1+mn})$;

(b) for every $\sigma \in \mathrm{Aut}(V^\natural)$ of finite order, the family $c(k, n) = c_{\sigma^k}(n)$ satisfies the twisted denominator identity.

```

        ↪ =
      PowerSeries.coeff (γ.1 * γ.2).toNat (mckayThompson τ)
theorem twistedDenominatorIdentity_of_simpleRootGeneration (hgen :
↪  MonsterLieSimpleRootGeneration)
    (σ : AutVnat) (hσ : IsOfFinOrder σ) : TwistedDenominatorIdentity (mckayThompsonFamily
    ↪  σ)
def mckayThompsonFamily (g : AutVnat) : ℕ → ℕ → ℂ :=
  fun k n => PowerSeries.coeff n (mckayThompson (g ^ k))
```

(`VOA/Moonshine/MoonshineCNTwistedDenominator.lean`, `VOA/Moonshine/MoonshineCNReplicationAnalytic.lean`.)

From the mathematics to the Lean statement

`monsterLieBorcherdsData hgen` is the Borcherds datum on $\mathfrak{m}$ and `monsterLieBorcherdsAction hgen` the action of $\mathrm{Aut}(V^\natural)$ on it (Chapter 45); both need `hgen` only because the structure `BorcherdsData` has the field `generated`. `PowerSeries.coeff n (mckayThompson τ)` is $\mathrm{tr}(\tau | V^\natural{}_{n+1})$ (Chapter 43). So (a) is the equivariant no-ghost theorem read on traces, and `mckayThompsonFamily σ k n` $= c_{\sigma^k}(n)$. (b) is (TD_g) for $g = \sigma$, in height coordinates.

Strength. (b) is stated for finite-order σ only. Every automorphism of $V^\natural$ has finite order (`M8.autVnat_isOfFinOrder`, Chapter 47), so this is not a restriction in the end, but no theorem of the library states the twisted identity for σ without the finite-order hypothesis or without `hgen`; the hypothesis-free version is the composition of (b) with

`M8.monsterLieSimpleRootGeneration` and `M8.autVnat_isOfFinOrder`, which the library performs only at the level of complete replicability (`completelyReplicable_holds`, Chapter 49). Neither the exponential form (46.5) nor the product form with roots of unity is a Lean statement.

Proof on paper. (a) The root-space isomorphism $\mathfrak{m}_{(m,n)} \cong V^\natural_{1-m(-n)} = V^\natural_{1+mn}$ (repository momentum $(m,-n)$, Chapter 45; the sign convention is recalled in the first warning of §46.15) is $\mathrm{Aut}(V^\natural)$-equivariant; conjugating by it identifies the traces. (b) Theorem 46.26(c) with $c(k,\cdot) = c_{\sigma^k}$ and (a) applied to $\tau = \sigma^k$. □

Physical meaning

Twisted partition functions and orbifold sectors. T_σ is the torus partition function with the symmetry σ inserted along the time circle. The twisted denominator identity is Borcherds' observation that the σ-twisted index of the space of physical string states has the same product structure as the untwisted one, the k-th term of the plethystic logarithm involving T_{σ^k}: a string state wound k times around the time circle picks up σ^k. Carnahan's generalized moonshine programme (2010–2017) extends this to the twisted-sector Lie algebras attached to commuting pairs (g,h); Paquette–Persson–Volpato realise the twisted identities as twisted BPS indices of a heterotic string.

What the machine verified

Conditional on `hgen : MonsterLieSimpleRootGeneration` (proved in Chapter 47); (b) also needs `IsOfFinOrder σ`. Standard axioms according to the build of `MoonshineCNAudit18.lean` (2,268 reports over the audit's whole import chain, 0 `sorryAx`; recorded in Chapter 50, not re-run for this chapter).

46.6 Replication

46.6.1 Replication from the twisted identity: the idea

Norton's replication formulas (1984) say that the Faber polynomials of T_g are computed by Hecke sums whose a-th block uses the replicate T_{g^a}:

$$F_{g,m}\big(T_g(\tau)\big) = \sum_{ad=m} \sum_{0\le b<d} T_{g^a}\Big(\frac{a\tau+b}{d}\Big), \qquad m \ge 1. \tag{46.7}$$

Borcherds derived them from the twisted denominator identities; Koike had observed the link between replication and Hecke operators. The derivation is the twisted analogue of Theorem 46.14: substitute $X = T_g(q)$ in the Faber generating identity, use the factorisation $p(T_g(p) - T_g(q)) = (1-p/q)(1-u_g)$, and replace $D\log(1-u_g)$ by $-P_g$ using (TD_g). Comparing p^m-coefficients gives the *formal* replication formula

$$F_{g,m}(T_g) = q^{-m} + \sum_{r\ge 1}\Big(\sum_{a\mid \gcd(m,r)} \frac{m}{a}\, c_{g^a}\Big(\frac{mr}{a^2}\Big)\Big) q^r, \tag{46.8}$$

and the q-expansion of the Hecke sum (the computation of Theorem 46.7, with replicates) shows that the right side of (46.7) has the same expansion. Since both sides converge for finite-order g, they agree as functions.

46.6.2 Formal replication

Definition 46.28 (The Faber data in height coordinates). For $c : \mathbb{N} \to \mathbb{C}$: $\Phi_c(p,X) = 1 - Xp + \sum_{n\ge1} c(n)p^{n+1} \in \mathbb{C}[X][[p]]$; the series $\sum_m Q_m(X)p^m = -D\Phi_c/\Phi_c$; the ring map $\mathbb{C}[X][[p]] \to \mathbb{C}((q))[[p]]$ sending $\sum_m G_m(X)p^m$ to $\sum_m q^m G_m(f_c)p^m$ (substitute $X \mapsto f_c$ and $p \mapsto pq$); and the replication coefficient $\rho_c(m,r) = \sum_{a\mid m,\ a\mid r} \frac{m}{a}\, c\big(a, \frac{m}{a}\cdot\frac{r}{a}\big)$ for $c : \mathbb{N} \to \mathbb{N} \to \mathbb{C}$.

```

```

(`VOA/Moonshine/MoonshineCNReplicationFormal.lean`.)

From the mathematics to the Lean statement

`faberGenerating` is the same series as `M8.faberGen` of §46.2 (a duplicate written on the other side of the project). `PowerSeries.invOfUnit F 1` is the inverse of a series with constant term 1; so `faberLogDerivSeries` is $-D\Phi/\Phi$. `faberEvaluation c` is the composite of `PowerSeries.map` along $X \mapsto f_c$ and `PowerSeries.rescale (single 1 1)`, the substitution $p \mapsto qp$. `replicationCoeff c m r` sums over $a \mid m$ with $a \mid r$, the term $\frac{m}{a}\, c(a, \frac{m}{a}\cdot\frac{r}{a})$; since $\frac{m}{a}\cdot\frac{r}{a} = \frac{mr}{a^2}$ this is the coefficient of (46.8) with $c(a,\cdot) = c_{g^a}$.

What the machine verified

Definitions; standard axioms (`MoonshineCNAudit18.lean`).

Physical meaning

Faber polynomials express the partition functions of the n-fold covers of the torus in terms of the partition function itself. Height coordinates organise the root lattice of the Monster Lie algebra by the energy level of the corresponding string states. They are the natural variables for comparing the two sides of the denominator identity level by level.

Theorem 46.29 (Formal replication). *Let $c : \mathbb{N} \to \mathbb{N} \to \mathbb{C}$ satisfy the twisted denominator identity, and let F_m be the Faber polynomial of $f = q^{-1} + \sum_{n\ge1} c(1,n)q^n$. For every $m \ge 1$, in $\mathbb{C}((q))$ and in $\mathbb{C}[[q]]$ respectively,*

$$q^m\, F_m(f) = 1 + [p^m]\tilde{P}, \qquad \textit{i.e.} \qquad F_m(f) = q^{-m} + \sum_{r\ge1} \rho_c(m,r)\, q^r.$$

```

(`VOA/Moonshine/MoonshineCNReplicationFormal.lean`; the theorems of the section `Replication` have the section variable `(c : ℕ → ℕ → ℂ)`.)

From the mathematics to the Lean statement

`laurentEmbedding` is the inclusion $\mathbb{C}[[q]][[p]] \subset \mathbb{C}((q))[[p]]$. `HahnSeries.single (m : ℤ) 1` is q^m. `M8.faberPoly (c 1) m` is the Faber polynomial of f (Definition 46.2). `homogenizedEval c m P` $= \sum_{j\le m} P_j q^{m-j} u_c^j$ is $q^m P(f)$ as an honest power series when $\deg P \le m$ (`ofPowerSeries_homogenizedEval`). `PowerSeries.coeff m (twistedPowerSum c)` is $[p^m]\tilde P \in \mathbb{C}[[q]]$; its coefficient of q^{m+r} is $\rho_c(m,r)$ (`coeff_coeff_twistedPowerSum_add`) and its coefficients of q^N, $N \le m$, vanish (`coeff_coeff_twistedPowerSum_of_le`). So the theorem is exactly (46.8), for an abstract family.

Hypotheses. Only the twisted denominator identity; in particular the theorem holds for *every* $g \in \mathrm{Aut}(V^\natural)$ whose family satisfies it, regardless of finite order (which matters only for convergence, below).

Proof on paper. Under the substitution $X \mapsto f(q)$, $p \mapsto pq$, the series Φ becomes $1 - qf(q)\,p + \sum_{n\ge1} c(1,n)q^{n+1}p^{n+1}$, which is $(1-p)(1-\tilde u)$ (compare coefficients: `coeff_one_sub_X_mul_one_sub_twistedUnitSeries`). The substitution is a ring map commuting with D (`faberEvaluation_eulerDeriv`), so it carries $\Phi\cdot\sum_m Q_m p^m = -D\Phi$ to $(1-p)(1-\tilde u)\cdot\mathcal{Q} = -D\big((1-p)(1-\tilde u)\big)$ with $\mathcal{Q} = \sum_m q^m Q_m(f)p^m$. The right side is $p(1-\tilde u)+(1-p)D\tilde u = (1-p)(1-\tilde u)\big(\frac{p}{1-p} + \tilde P\big)$ by the twisted identity (`twistedFaberRecursion`). Cancelling the unit $(1-p)(1-\tilde u)$ (`laurentEmbedding_injective`), $\mathcal{Q} = \sum_{k\ge1} p^k + \tilde P$ (`faberEvaluation_faberLogDerivSeries`), i.e. $q^m Q_m(f) = 1 + [p^m]\tilde P$ (`faberLogDerivSeries_coeff_eval`). Since $[p^m]\tilde P$ only has powers q^N with $N > m$, $Q_m(f) = q^{-m} + O(q)$, and Q_m is monic of degree m; by uniqueness of Faber polynomials $Q_m = F_m$ (`faberLogDerivSeries_coeff_eq_faberPoly`). □

Physical meaning

The formal replication formula is the g-twisted version of "the partition function of m-fold covers is a polynomial in the single partition function": in the a-th block the covering map wraps the time circle a times, so the twist along it becomes g^a. This is the content of the Hecke operators on twisted sectors (Borcherds; Carnahan, Generalized moonshine I and II), and of the DMVV formula for symmetric-product orbifolds with a symmetry inserted.

What the machine verified

Hypothesis `TwistedDenominatorIdentity c` only; standard axioms (`MoonshineCNAudit18.lean`). Supporting: `positiveGeometricSeries`, `one_sub_X_mul_positiveGeometricSeries`, `coeff_coeff_twistedPowerSum_of_le`, `constantCoeff_faberGenerating`,

46.6.3 Analytic replication

Theorem 46.30 (Analytic replication). *(a) If $h \in \mathrm{Aut}(V^\natural)$ has finite order, its McKay–Thompson coefficients are J-dominated.*

(b) (Hecke side) If $c(a,\cdot)$ is J-dominated with $c(a,0) = 0$ for every $a \geq 0$ (including $a = 0$, as in the Lean quantifier `∀ a`), then for $m \geq 1$ and $\tau \in \mathbb{H}$, $q^m \sum_{a\mid m} \sum_{b<m/a} T_a\big(\frac{a\tau+b}{m/a}\big) - 1 = \sum_N [p^m q^N]\tilde{P}\; q^N$, where $T_a = q^{-1} + \sum_{n\geq 0} c(a,n) q^n$.

(c) (Faber side) If c satisfies the twisted denominator identity and $c(1,\cdot)$ is J-dominated with $c(1,0) = 0$, then $q^m F_m(T_1(\tau)) - 1 = \sum_N [p^m q^N]\tilde{P}\; q^N$.

(d) (Replication) If $g \in \mathrm{Aut}(V^\natural)$ has finite order and the family $k \mapsto c_{g^k}$ satisfies the twisted denominator identity, then (46.7) holds for every $m \geq 1$ and $\tau \in \mathbb{H}$, with $F_{g,m}$ the Faber polynomial of T_g.

```

(`VOA/Moonshine/MoonshineCNReplicationAnalytic.lean`.)

From the mathematics to the Lean statement

`poleQSeriesFun c τ` $= q^{-1} + \sum_{n\geq 0} c(n) q^n$ (it *includes* $c(0)$; that is why $c(a,0) = 0$ is a hypothesis); `mckayThompsonFun_eq_poleQSeriesFun` identifies `mckayThompsonFun g` of Chapter 43 with it. The Hecke sum in (b) and (d) is written with the

same `m.divisors.attach/Finset.range (m / a)/heckePoint` bookkeeping as `CompletelyReplicable` (Chapter 43), so (d) is literally the clause of `CompletelyReplicable` for g and m, with P the Faber polynomial `M8.faberPoly (mckayThompsonFamily g 1) m. g ^ (a : ℕ)` is the replicate.

Proof on paper. (a) Theorem of Chapter 43 (trace bounds): for finite order the eigenvalues are roots of unity, so $|\operatorname{tr}(h|V^\natural{}_n)| \le \dim V^\natural{}_n$. (b) As in Theorem 46.7, block by block, with the character sum `sum_range_exp_pow` and the pole computation `sum_inv_qPar_heckePoint`; the coefficient of q^{m+r} after multiplying by q^m is $\rho_c(m,r)$, which is $[p^m q^{m+r}]\tilde{P}$. (c) $q^m F_m(T_1)$ is the value at q of the power series `homogenizedEval` $= 1 + [p^m]\tilde{P}$ (Theorem 46.29), and evaluation of absolutely convergent power series is a ring map (`HasAbsEvalAt`, `hasAbsEvalAt_homogenizedEval`). (d) By (a) all c_{g^a} are dominated, so (b) and (c) apply; the two sides of (46.7), multiplied by $q^m \neq 0$, have the same convergent expansion. □

Physical meaning

Convergence is where finite order enters: a symmetry of finite order is unitary on each energy level, so its twisted partition function is dominated by the untwisted one and converges on the whole upper half-plane.

What the machine verified

Hypotheses as displayed; standard axioms (`MoonshineCNAudit18.lean`). Supporting: `HasAbsEvalAt` and its closure lemmas (`HasAbsEvalAt.add`, `.mul`, `.const`, `.one`, `.zero`, `.X`, `.pow`, `.sum`), `qPar_ne_zero`, `summable_norm_coeff_mul_qPar`, `hasAbsEvalAt_qSeriesUnit`, `hasAbsEvalAt_homogenizedEval`, `qPar_heckePoint_eq_exp_mul`, `exp_heckeShift_pow`, `sum_range_exp_pow`, `hasSum_heckeCosetSum_regular`, `sum_inv_qPar_heckePoint`, `mckayThompsonFamily_one`. (The lemmas `hasSum_heckeSum` and `hasAbsEvalAt_homogenizedEval` duplicate the lemmas `hasSum_qHeckeSum` and `hasSum_mul_eval_qSeriesFun`; nothing depends on the choice.)

46.6.4 Complete replicability

Theorem 46.31 (Complete replicability of the McKay–Thompson series). *(a) If every finite-order $g \in \mathrm{Aut}(V^\natural)$ has a family satisfying the twisted denominator identity, then* `CompletelyReplicableOfFinOrder` *holds; if moreover every g has finite order and every family satisfies the identity,* `CompletelyReplicable` *holds.*

(b) Given `MonsterLieSimpleRootGeneration`*:* `CompletelyReplicableOfFinOrder`*; and, given also that every automorphism has finite order,* `CompletelyReplicable` *and the Conway–Norton conjecture.*

```

```

```
    (hfin : ∀ g : AutVnat, IsOfFinOrder g) : CompletelyReplicable
theorem conwayNorton_of_simpleRootGeneration (hgen : MonsterLieSimpleRootGeneration)
    (hfin : ∀ g : AutVnat, IsOfFinOrder g) : ConwayNortonConjecture
```

(`VOA/Moonshine/MoonshineCNReplicationAnalytic.lean`, `VOA/Moonshine/MoonshineCNTwistedDenominator.lean`.)

From the mathematics to the Lean statement

`CompletelyReplicable` is the fixed definition of the statement file (Chapter 43): for all g and $m \geq 1$ a monic degree-m polynomial P with $P(T_g(\tau)) = \sum_{a|m} \sum_{b<m/a} T_{g^a}((a\tau + b)/(m/a))$; `CompletelyReplicableOfFinOrder` (file `MoonshineCNGammaZeroBridge.lean`, Chapter 43) is the same restricted to finite-order g. The witness P is the Faber polynomial. The last theorem composes with the genus-zero theorem through `M8.conwayNorton_of_finOrder_of_completelyReplicable` (file `MoonshineLRConwayNorton.lean`, Chapter 47).

Proof on paper. (a) Theorem 46.30(d) with $P = F_{g,m}$, monic of degree m by Theorem 46.4. (b) Theorem 46.27(b) gives the twisted identities, then (a); the Conway–Norton conjecture follows from the genus-zero theorem of this chapter and the bridge of Chapter 43. □

Physical meaning

Every twisted partition function of the moonshine CFT closes, with its powers, under the Hecke covering operations.

What the machine verified

(a): hypotheses as displayed. (b): **conditional on** `hgen`; the `CompletelyReplicable` and Conway–Norton statements also on `hfin`. Both are theorems of Chapter 47, and `completelyReplicable_holds` (no hypotheses) is recorded in Chapter 49. Standard axioms (`MoonshineCNAudit18.lean`).

46.7 Genus zero: the theorem and the route

46.7.1 What is proved

The genus-zero theorem is proved for the abstract interface `ReplicableFamily N` of Chapter 43: a doubly indexed sequence $c(k,n)$, periodic of period N in the replicate index k, with $|c(k,n)| \leq |c(0,n)|$, $c(0,\cdot)$ the coefficients of J, and satisfying complete replication with replicate ka in the a-th Hecke block. Write $f_k = \mathtt{qSeriesFun}\,(c(k,\cdot))$ and, for any $f : \mathbb{H} \to \mathbb{C}$,

$$G(f) = \{\gamma \in \mathrm{GL}_2(\mathbb{R}) : \ \det\gamma = 1,\ f(\gamma\tau) = f(\tau)\ \forall \tau \in \mathbb{H}\}.$$

> ***Genus-zero theorem (the Lean statement).*** *Let $N \geq 1$ and let F be a replicable family of period N that satisfies the prime Hecke identity for every member and of which no member is injective modulo translations. For every k there are a subgroup $\Gamma \leq \mathrm{GL}_2(\mathbb{R})$ and $N' \geq 1$ such that $\Gamma \leq \mathrm{SL}_2(\mathbb{R})$, $\Gamma_1(N') \leq \Gamma$, Γ is commensurable with $\mathrm{SL}_2(\mathbb{Z})$, and f_k is a normalised Hauptmodul of Γ (in the sense of* `IsNormalizedHauptmodul`*).*

This is `ReplicableFamily.exists_hauptmodul_gammaOne` (§46.13). Three remarks keep the reader honest about what the displayed Lean type says. (i) The two hypotheses, the prime Hecke identity and nontriviality, are explicit premises (`hB1`, `hD7`) of that theorem; they are proved for every family by two *separate* theorems (§46.9), and no Lean declaration packages the composite "every replicable

family of positive period". (ii) The proof takes $\Gamma = G(f_k)$, and by the field `injective` this is the only possible choice up to ± 1; but the identification $\Gamma = G(f_k)$ is in the proof and the docstring, not in the type. (iii) The proof also gets $N \mid N'$, from `ReplicableFamily.exists_gamma1GL_le_symmetryGroup` (Theorem 46.58); the main theorem discards this fact. The McKay–Thompson family of a finite-order g is an instance (Chapter 43), so complete replicability gives the Γ_1 form of the Conway–Norton conjecture.

46.7.2 The route, on one page

Fix F, k, $f = f_k$, $G = G(f)$. The proof has six stages; the sections that follow treat them in order.

(1) *Analytic basics* (§46.8). f is holomorphic, $f - q^{-1} \to 0$ at $i\infty$, and there is a height t depending only on J above which f is injective modulo $\mathbb{Z}$ (*top injectivity*); every value of large modulus is taken high up.

(2) *Modular equations at primes, as a pairing* (§46.9, §46.10). For a prime $p \equiv 1 \pmod N$, the Hecke operator at p maps the Faber polynomials of f to polynomials in f; hence for every polynomial P, $\sum_{\beta \in \Delta(p)} P(f(\beta\tau))$ is a polynomial in $f(\tau)$, with $\Delta(p) = \{\tau \mapsto p\tau\} \cup \{\tau \mapsto (\tau + j)/p\}$. So the multiset $\{f(\beta\tau)\}_\beta$ depends only on $f(\tau)$: if $f(z) = f(w)$, every value $f(\beta z)$ is some $f(\beta' w)$ (the *Hecke pairing*), and on a connected domain one partner works throughout.

(3) *Local symmetries are real Möbius maps* (§46.11). If α is holomorphic on a disc with $f \circ \alpha = f$ and $\alpha' \neq 0$, then α is the restriction of an element of G. Pairing at two different primes produces real affine maps $C_n \to \mathrm{id}$ with $\alpha \circ C_n = C_n' \circ \alpha$; differentiating gives a *real linear ODE* $(\lambda z + \mu)\alpha' = \lambda' \alpha + \mu'$; its solutions are four explicit families, each holomorphic on all of $\mathbb{H}$; a boundary argument shows the explicit solution maps $\mathbb{H}$ into $\mathbb{H}$ and intertwines f globally; growth and injectivity of f high up leave only real Möbius maps.

(4) *Property P* (§46.11). If $f(z) = f(w)$ then $w = \gamma z$ for some $\gamma \in G$: from (3) when $f'(w) \neq 0$, and by approximation and closedness of G when $f'(z) = f'(w) = 0$.

(5) *The symmetry group* (§46.12). Shimizu's lemma: every $\gamma \in G$ with lower-left entry $c \neq 0$ has $|c| \geq 1$; the stabiliser of ∞ is $\pm\langle T \rangle$; bounded subsets of G are finite. Pairing on all of $\mathbb{H}$ gives a *Hecke step* $\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \mapsto \left(\begin{smallmatrix} pa & b - ja \\ c & (d - jc)/p \end{smallmatrix}\right)$ inside G. Nontriviality (f is not injective modulo $\mathbb{Z}$) and property P give an element with $c \neq 0$; rationality, integrality and Dirichlet's theorem on primes in progressions then give $\Gamma_1(N') \leq G$.

(6) *Genus zero* (§46.13). Cusp separation by Shimizu's lemma for conjugates; boundedness and values of f at the other cusps; commensurability with $\mathrm{SL}_2(\mathbb{Z})$ by Shimura's finiteness lemma on a fundamental domain; surjectivity onto $\mathbb{C} \cup \{\text{cusp values}\}$ by an open-and-closed argument; and the assembly of the eight fields of `IsNormalizedHauptmodul`.

The comparison with the literature is in §46.14.

Notation in Part IV. Several letters were used with other meanings in Parts I–III. From here on they mean:

symbol	meaning in §§46.7–46.13
$\mathfrak{c}$	a coefficient sequence $\mathbb{N} \to \mathbb{C}$, with $f = \texttt{qSeriesFun}\ \mathfrak{c}$ (Lean: `c`); in Parts I–III it was c
a, b, c, d	the entries of a real 2×2 matrix $\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$ (Lean: `g 0 0`, `g 0 1`, `g 1 0`, `g 1 1`); c is always the lower-left entry
p, q	p an admissible prime, q either $e^{2\pi i\tau}$ or (in the overlap construction and the level theorem) a second prime; the formal variable p of Parts I–III does not occur
G	the symmetry group $G(f)$ (not the Faber series $G(p)$ of §46.2, nor the group acting on a Borcherds datum)
H_m	the replicate Hecke sum (not the Faber series $H(p)$); half-discs are written Ω^+
Ω	a connected open set (domain); $D(z_0, \eta)$ is the open disc of centre z_0 and radius η
$\Delta(p)$	the $p+1$ maps $\tau \mapsto p\tau$, $\tau \mapsto (\tau + j)/p$; an element is written β or β_0
δ	in §46.13, a matrix with $\delta\infty$ a cusp; in §46.11, a positive real dilation
T	the translation $\left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right)$

Physical meaning

Hauptmoduln: "the partition function determines the theory". The genus-zero property says that a twisted partition function T_g is a global coordinate on the moduli space of tori with a g-twist (modulo the symmetries that preserve the twist). Duncan and Frenkel (2011) showed that the genus-zero property is equivalent to the convergence of the Rademacher sum of q^{-1} to T_g, i.e. to T_g being determined by its polar part in the way a semiclassical three-dimensional gravity partition function would be (Witten 2007: pure gravity in AdS_3 is conjecturally dual to the extremal $c = 24$ theory, whose partition function is J; its sum over geometries is a Rademacher-type sum). These are heuristics that motivate the theorem; the proof here uses none of them.

46.7.3 The shared interface

The two halves of the genus-zero proof (Fedor Popov's side: stages (1)–(6); Leonardo Rastelli's side: the prime Hecke identity, the unboundedness of J's coefficients and nontriviality) communicate through one file.

Definition 46.32 (Replicate Hecke sums; prime Hecke identity; injectivity modulo translations; large values; symmetry group)**.** For a replicable family F of period N, $k \in \mathbb{N}$, $m \geq 1$:

(a) $H_m(\tau) = \sum_{a|m} \sum_{0 \leq b < m/a} f_{ka}\left(\frac{a\tau + b}{m/a}\right)$, the right side of the replication formula;

(b) the *prime Hecke identity* at p: for all $m \geq 1$, τ: $\sum_{j<p} H_m\left(\frac{\tau+j}{p}\right) + H_m(p\tau) = H_{mp}(\tau) + [p \mid m]\, p\, H_{m/p}(\tau)$; the family satisfies it for member k if it holds at every prime $p \equiv 1 \pmod N$;

(c) f is *injective modulo translations* if $f(\sigma) = f(\tau)$ implies $\sigma - \tau \in \mathbb{Z}$; the family is *nontrivial* if no member is;

(d) f *takes its large values from the top* if there are R and $Y > 0$ with every w, $|w| \geq R$, equal to $f(\sigma)$ for some σ with $\operatorname{Im}\sigma \geq Y$;

(e) $G(f)$ as displayed above.

```

```

(`VOA/Moonshine/MoonshineCNGenusZeroInterface.lean`, namespace `VOA.Moonshine.ConwayNorton`; the elided fields of `symmetryGroup` are the proofs that the carrier is closed under products, contains 1 and inverses.)

From the mathematics to the Lean statement

(a) The sum is literally the right side of the field `replicable` of `ReplicableFamily`, so `ReplicableFamily.exists_monic_eval_eq_heckeOrbitSum` (in the same file) is a restatement of that field: some monic degree-m polynomial in f_k equals H_m. For $m = 0$ the sum is empty and $H_0 = 0$. **(b)** `heckePoint 1 p j` is $(\tau + j)/p$ and `heckePoint p 1 0` is $p\tau$; `p ≡ 1 [MOD N]` is $p \equiv 1 \pmod N$; `hp.pos` supplies $p > 0$. The identity is the Hecke-algebra relation $T_m T_p = T_{mp} + [p \mid m]\, p\, T_{m/p}$ (for the unnormalised operators) applied to the replicate Hecke sums; it is meaningful only for $p \equiv 1 \pmod N$, because the replicate index of the a-th block changes from ka to kap, and $f_{kap} = f_{ka}$ needs $p \equiv 1$. **(c)** `(σ : ℂ) = τ + n` with $n \in \mathbb{Z}$. **(d)** as stated. **(e)** `g.det` is a unit of $\mathbb{R}$; `g.det = 1` is $\det g = 1$. Because -1 acts trivially on $\mathbb{H}$, $-1 \in G(f)$ always (`neg_one_mem_symmetryGroup`), so "$\Gamma_1(N') \le G$" and "$\pm\Gamma_1(N') \le G$" are the same statement. The instance `hasDetOne_symmetryGroup` provides Mathlib's `Subgroup.HasDetOne`, used in the statement of the conjecture.

Why $G(f)$ is the right group. It is the *full* invariance group of f in $\mathrm{SL}_2(\mathbb{R})$ (as a subgroup of $\mathrm{GL}_2(\mathbb{R})$). By the dictionary of the normalised-Hauptmodul definition in Chapter 43, a normalised Hauptmodul determines its group up to ± 1; so the only possible choice of Γ in the conclusion is $G(f)$, and the theorem proves that this choice works.

Physical meaning

$G(f)$ is the group of modular transformations under which the twisted partition function is invariant: the stabiliser of the twisted sector. The prime Hecke identity says that the covering operations at two primes commute in the expected way: a p-fold cover of an m-fold cover is an mp-fold cover, plus a correction from the covers that factor through the multiplication by p.

What the machine verified

Definitions; printed in `VOA/Moonshine/MoonshineCNGenusZeroAudit.lean`, standard axioms.

46.8 Genus zero I: analytic basics

Theorem 46.33 (Holomorphy, normalisation, growth). *Let $\mathfrak{c}$ be J-dominated and $f = \texttt{qSeriesFun}\ \mathfrak{c}$. Then*

(a) $|f(\tau) - q^{-1}| \le \texttt{jTail}(\operatorname{Im}\tau)$, *and* $\texttt{jTail}(y) \to 0$ *as* $y \to \infty$;

(b) $f(\tau) - q^{-1} \to 0$ *as* $\operatorname{Im}\tau \to \infty$ *(uniformly in* $\operatorname{Re}\tau$*);*

(c) f *is holomorphic on* $\mathbb{H}$.

Every member of a replicable family is J-dominated, and $c(k,\cdot) = c(k',\cdot)$ whenever $k \equiv k' \pmod N$.

```
theorem norm_qSeriesFun_sub_inv_qPar_le {c : ℕ → ℂ} (hc : IsJDominated c) (τ : ℍ) :
    ‖qSeriesFun c τ - (qPar τ)⁻¹‖ ≤ jTail τ.im
lemma tendsto_jTail_atTop : Tendsto jTail atTop (𝓝 0)
theorem tendsto_qSeriesFun_sub_inv_qPar {c : ℕ → ℂ} (hc : IsJDominated c) :
    Tendsto (fun τ : ℍ => qSeriesFun c τ - (qPar τ)⁻¹) atImInfty (𝓝 0)
theorem mdifferentiable_qSeriesFun {c : ℕ → ℂ} (hc : IsJDominated c) :
    MDifferentiable 𝓘(ℂ) 𝓘(ℂ) (qSeriesFun c)
lemma isJDominated (k : ℕ) : IsJDominated (F.c k)
lemma c_eq_of_modEq {k k' : ℕ} (h : k ≡ k' [MOD N]) : F.c k = F.c k'
```

(`VOA/Moonshine/MoonshineCNGenusZeroAnalytic.lean`; the last two are `ReplicableFamily.isJDominated`, `ReplicableFamily.c_eq_of_modEq` with `F : ReplicableFamily N` a section variable.)

From the mathematics to the Lean statement

`atImInfty` and `MDifferentiable 𝓘(ℂ) 𝓘(ℂ)` are as in Chapter 43: (b) and (c) are exactly the fields `normalized` and `holomorphic` of `IsNormalizedHauptmodul`. `Nat.ModEq (k ≡ k' [MOD N])` is congruence of natural numbers.

Proof on paper. (a) $|\mathfrak{c}(n)q^n| \le c_J(n)e^{-2\pi n \operatorname{Im}\tau}$, summed. $\texttt{jTail}(y) \to 0$ by dominated convergence for series (each term decreases to 0, and the sum converges at $y = 1$). (b) follows from (a). (c) A power series in q converging on $|q| < 1$ is holomorphic there, and $q = e^{2\pi i\tau}$ is holomorphic. The family statements: $|c(k,n)| \le |c(0,n)| = c_J(n)$; and periodicity in k. □

Physical meaning

At low temperature ($\operatorname{Im}\tau \to \infty$) the twisted partition function is dominated by the vacuum, q^{-1}, with corrections bounded by those of the untwisted theory.

What the machine verified

Hypothesis `IsJDominated c`; standard axioms (`MoonshineCNGenusZeroAudit.lean`).

Theorem 46.34 (Top injectivity). *There is $t > 0$ such that for every J-dominated $\mathfrak{c}$ and all $\sigma, \tau \in \mathbb{H}$ with $\operatorname{Im}\sigma, \operatorname{Im}\tau \ge t$: if $f(\sigma) = f(\tau)$ then $\sigma - \tau \in \mathbb{Z}$.*

```
theorem exists_height_injective :
    ∃ t : ℝ, 0 < t ∧ ∀ c : ℕ → ℂ, IsJDominated c → ∀ σ τ : ℍ, t ≤ σ.im → t ≤ τ.im →
      qSeriesFun c σ = qSeriesFun c τ → ∃ k : ℤ, (σ : ℂ) = τ + k
```

(`VOA/Moonshine/MoonshineCNGenusZeroAnalytic.lean`.)

From the mathematics to the Lean statement

The quantifier order is the strong one: one height t serves for *all* J-dominated series. The library names a choice of it `topHeight` (file `MoonshineCNGenusZeroPartner.lean`), and "the top" means $\{\mathrm{Im} \geq t\}$.

Proof on paper. Write $f = q^{-1} + h(q)$ with $h(q) = \sum_{n\geq 1} \mathfrak{c}(n)q^n$. On $|q| \leq r$ (with $r \leq e^{-4\pi}$ small) h is Lipschitz with constant $\Lambda = \sum_n n\, c_J(n) r^{n-1}$, independent of $\mathfrak{c}$ (`norm_qTailSeries_sub_le`). Let $q_\sigma \neq q_\tau$ be the q-parameters of σ, τ and suppose $f(\sigma) = f(\tau)$. Then $|q_\sigma^{-1} - q_\tau^{-1}| = |q_\tau - q_\sigma|/(|q_\sigma||q_\tau|)$ equals $|h(q_\tau) - h(q_\sigma)| \leq \Lambda |q_\tau - q_\sigma|$, so $|q_\sigma||q_\tau| \geq 1/\Lambda$, impossible if both are small; hence $q_\sigma = q_\tau$, i.e. $\sigma - \tau \in \mathbb{Z}$. □

Physical meaning

High up, the twisted partition function is essentially q^{-1}, which is a coordinate on the cylinder $\mathbb{H}/\mathbb{Z}$: distinct low-temperature tori are distinguished by their partition function.

What the machine verified

No hypotheses; standard axioms (`MoonshineCNGenusZeroAudit.lean`).

Theorem 46.35 (Large values come from the top). *For J-dominated $\mathfrak{c}$ and every height Y_0 there is R such that every w with $|w| \geq R$ equals $f(\sigma)$ for some σ with $\mathrm{Im}\,\sigma \geq Y_0$. In particular every member of a replicable family takes its large values from the top.*

```
theorem exists_large_values_from_height {c : ℕ → ℂ} (hc : IsJDominated c) (Y₀ : ℝ) :
    ∃ R : ℝ, ∀ w : ℂ, R ≤ ‖w‖ → ∃ σ : ℍ, Y₀ ≤ σ.im ∧ qSeriesFun c σ = w
theorem ReplicableFamily.largeValuesFromTop {N : ℕ} (F : ReplicableFamily N) (k : ℕ) :
    LargeValuesFromTop (qSeriesFun (F.c k))
```

(`VOA/Moonshine/MoonshineCNGenusZeroTop.lean`.)

Proof on paper. $\phi(q) = q/(1 + qh(q)) = 1/f$ is holomorphic near $q = 0$ with $\phi(0) = 0$, $\phi'(0) = 1$; by the inverse function theorem it maps a small disc onto a neighbourhood of 0. For $|w|$ large, $w^{-1} = \phi(q)$ with small $q \neq 0$, i.e. $f = w$ at a point whose q-parameter is small, i.e. high up. □

Physical meaning

Large values of the partition function are low-temperature values: only the vacuum pole produces them.

What the machine verified

Hypothesis `IsJDominated c`; standard axioms (`MoonshineCNGenusZeroAudit.lean`). Supporting: `qTailSeries_differentiableOn`, `largeValuesFromTop_qSeriesFun`.

Supporting declarations of the analytic basics. File `MoonshineCNGenusZeroAnalytic.lean`: `jCoeffMajorant_nonneg`, `summable_norm_mul_pow_of_summable`, `norm_qPar_eq` ($|q| = e^{-2\pi\,\mathrm{Im}\,\tau}$), `real_exp_mul_succ`, `summable_jCoeffMajorant_mul_exp`, `jTail_nonneg`, `exp_neg_mul_le_of_le`, `jTail_le_of_le`, `qTailSeries`, `qSeriesFun_eq_inv_add_qTailSeries`, `norm_qTail_term_le`, `summable_qTail_term`, `norm_qTailSeries_le`, `norm_pow_sub_pow_le_of_norm_le`, `norm_qTailSeries_sub_le`, `summable_lipschitz_majorant`, and for families `mdifferentiable`, `tendsto_sub_inv_qPar`, `c_add_mul`, `c_mul_eq_of_modEq_one`. All in `MoonshineCNGenusZeroAudit.lean`.

46.9 Genus zero II: the prime Hecke identity, nontriviality and property P

These are the inputs proved on Leonardo Rastelli's side (namespace `VOA.Moonshine.ConwayNorton.M8`).

46.9.1 The prime Hecke identity

Theorem 46.36 (Prime Hecke identity). *For every replicable family F of period N and every member k, the prime Hecke identity holds at every prime $p \equiv 1 \pmod N$.*

```
noncomputable def heckeBlock {N : ℕ} (F : ReplicableFamily N) (k a d : ℕ) (τ : ℍ) : ℂ :=
  if h : 0 < a ∧ 0 < d then
    ∑ b ∈ Finset.range d, qSeriesFun (F.c (k * a)) (heckePoint a d b h.1 h.2 τ)
  else 0
theorem heckeBlock_at_mul {N : ℕ} (F : ReplicableFamily N) (k a d p : ℕ) (ha : 0 < a)
    (hd : 0 < d) (hp : 0 < p) (hc : F.c (k * (a * p)) = F.c (k * a)) (τ : ℍ) :
    heckeBlock F k a d (heckePoint p 1 0 hp one_pos τ) = heckeBlock F k (a * p) d τ
theorem sum_heckeBlock_at_div_of_not_dvd {N : ℕ} (F : ReplicableFamily N) (k a d p : ℕ)
    (ha : 0 < a) (hd : 0 < d) (hp : p.Prime) (hpa : ¬ p ∣ a) (τ : ℍ) :
    ∑ j ∈ Finset.range p, heckeBlock F k a d (heckePoint 1 p j one_pos hp.pos τ) =
      heckeBlock F k a (d * p) τ
theorem sum_heckeBlock_at_div_of_eq_mul {N : ℕ} (F : ReplicableFamily N) (k a₀ d p : ℕ)
    (ha₀ : 0 < a₀) (hd : 0 < d) (hp : 0 < p) (hc : F.c (k * (p * a₀)) = F.c (k * a₀)) (τ :
    ↪ ℍ) :
    ∑ j ∈ Finset.range p, heckeBlock F k (p * a₀) d (heckePoint 1 p j one_pos hp τ) =
      (p : ℂ) * heckeBlock F k a₀ d τ
theorem ReplicableFamily_primeHeckeIdentity {N : ℕ} (F : ReplicableFamily N) (k : ℕ) :
    PrimeHeckeIdentity F k
```

(`VOA/Moonshine/MoonshineLRHecke.lean`.)

From the mathematics to the Lean statement

`heckeBlock F k a d` is $B(a,d)(\tau) = \sum_{b<d} f_{ka}((a\tau+b)/d)$, so $H_m = \sum_{a\mid m} B(a, m/a)$ (`heckeOrbitSum_eq_sum_heckeBlock`). The theorem has *no* hypotheses besides the family: note that $N = 0$ is allowed (then $p \equiv 1 \pmod 0$ means $p = 1$, not a prime, and the statement is vacuous).

Proof on paper. Let $p \equiv 1 \pmod N$ be prime. Three block identities:

(i) $B(a,d)(p\tau) = B(ap,d)(\tau)$, because $(a\,p\tau+b)/d$ is the point of the block (ap,d) and $f_{kap} = f_{ka}$ ($kap \equiv ka$);

(ii) if $p \nmid a$: $\sum_{j<p} B(a,d)\big(\frac{\tau+j}{p}\big) = \sum_{j,b} f_{ka}\big(\frac{a\tau+aj+bp}{dp}\big) = B(a,dp)(\tau)$, since $(j,b) \mapsto aj+bp$ is a bijection $\mathbb{Z}/p \times \mathbb{Z}/d \to \mathbb{Z}/dp$ and f is 1-periodic (`sum_comp_eq_sum_range_of_periodic`);

(iii) if $a = pa_0$: $\sum_{j<p} B(pa_0,d)\big(\frac{\tau+j}{p}\big) = \sum_j \sum_b f_{kpa_0}\big(\frac{a_0\tau+a_0j+b}{d}\big) = p\,B(a_0,d)(\tau)$, since for each j the inner sum runs over a full residue system and $f_{kpa_0} = f_{ka_0}$.

Now sum over $a \mid m$ with $d = m/a$. The divisors a' of mp are of two kinds: $a' = ap$ with $a \mid m$ (block $B(ap, m/a)$, from (i)), and $a' \mid m$ with $p \nmid a'$ (block $B(a', mp/a')$, from (ii)); the divisors $a = pa_0$ of m give, by (iii), $p\,H_{m/p}$. □

Physical meaning

The composition law of covering operations: the p-fold covers of the m-fold covers are the mp-fold covers, each counted once, except those that factor through the isogeny "multiply the lattice by p", counted p times. The congruence $p \equiv 1 \pmod{N}$ ensures that the twist is unchanged along the p-fold covering.

What the machine verified

Unconditional (for every family); standard axioms (`VOA/Moonshine/MoonshineLRHeckeAudit.lean`, 14 reports). It uses only the periodicity of the family, not replication or domination. Supporting: `qPar_eq_of_eq_add_int`, `qSeriesFun_eq_of_eq_add_int`, `coe_heckePoint_apply`, `ReplicableFamily_c_add_mul`, `ReplicableFamily_c_eq_of_modEq`, `ReplicableFamily_c_mul_mul_of_modEq_one`, `sum_comp_eq_sum_range_of_periodic`, `heckeBlock_of_pos`, `heckeOrbitSum_eq_sum_heckeBlock`.

46.9.2 The expansion of the replicate Hecke sum

Theorem 46.37 (q-expansion of H_m). *For every family, k and $m \geq 1$: $H_m(\tau) - q^{-m} = \sum_{r\geq 1}\Big(\sum_{a\mid \gcd(m,r)} \frac{m}{a}\, c\big(ka, \frac{mr}{a^2}\big)\Big)q^r$.*

```
noncomputable def faberRemainderCoeff (c : ℕ → ℕ → ℂ) (k m r : ℕ) : ℂ :=
  ∑ a ∈ (Nat.gcd m r).divisors, ((m / a : ℕ) : ℂ) * c (k * a) (m * r / (a * a))
theorem hasSum_heckeOrbitSum {N : ℕ} (F : ReplicableFamily N) (k : ℕ) {m : ℕ} (hm : 0 < m)
    (τ : ℍ) :
    HasSum (fun r : ℕ => (if r = 0 then 0 else faberRemainderCoeff F.c k m r) * qPar τ ^ r)
      (heckeOrbitSum F k m τ - (qPar τ ^ m)⁻¹)
```

(`VOA/Moonshine/MoonshineLRTower.lean`, `VOA/Moonshine/MoonshineLRHeckeExpansion.lean`.)

From the mathematics to the Lean statement

The coefficient `faberRemainderCoeff F.c k m r` is the replication value of $[q^r](F_{k,m}(f_k) - q^{-m})$; with $k = 1$ it is $\rho_c(m, r)$ of §46.6. No domination hypothesis appears, because members of a family are dominated by definition.

Proof on paper. The computation of Theorem 46.7, block by block, with replicate ka in block a (`hasSum_heckeBlock`, using the root-of-unity sums `sum_range_pow_rootOfUnity` and `sum_inv_mul_rootOfUnity`). □

Physical meaning

The state content of the m-fold covers with twists.

What the machine verified

No hypotheses; standard axioms (`VOA/Moonshine/MoonshineLRNontrivialAudit.lean`). Supporting: `heckePoint_eq_vadd`, `qPar_heckePoint`, `qPar_heckePoint_zero_pow`, `sum_inv_mul_rootOfUnity`, `hasSum_heckeBlock`.

46.9.3 The coefficients of J are unbounded

Theorem 46.38 (J has unbounded coefficients). *There is no C with $|[q^n]\texttt{JShift}| \leq C$ for all n.*

```
theorem JShift_coeff_unbounded : ¬ ∃ C : ℝ, ∀ n, ‖PowerSeries.coeff n JShift‖ ≤ C
```

(VOA/Moonshine/MoonshineLRJUnbounded.lean.)

From the mathematics to the Lean statement

A trivial-looking statement ($c(1) = 196884$, $c(2) = 21493760, \ldots$ grow like $e^{4\pi\sqrt{n}}$), but the library does not know any growth of the individual coefficients: it is proved from modularity. It is the only input about J in the nontriviality argument.

Proof on paper. Suppose $|a_n| \le C$ for all coefficients a_n of $F(z) = q(j(z)-744) = \sum a_n q^n$, $a_0 = 1$. At $z = iY$, $s = e^{-2\pi Y}$: $|F(z) - 1| \le Cs/(1-s)$, so $|F(z)| \ge 1 - 2Cs$ for large Y. At $w = Sz = i/Y$, $t = e^{-2\pi/Y}$: $|F(w)| \le C/(1-t)$. Since $j(w) = j(z)$, $|F(z)| = (s/t)|F(w)| \le \frac{s}{t} \cdot \frac{C}{1-t}$, which is about $\frac{CY}{2\pi} e^{-2\pi Y} \to 0$. For large Y this contradicts $|F(z)| \ge 1 - 2Cs \to 1$ (the library makes this explicit: $e^{2\pi Y} \le KY$ with $K = 2C + 2Ce^{2\pi}$, false at $Y = K + 1$). □

Physical meaning

Modular invariance forces exponential growth of the density of states (the Cardy formula): a CFT whose partition function had bounded level degeneracies could not be modular invariant, because S exchanges low and high temperature.

What the machine verified

No hypotheses; standard axioms (VOA/Moonshine/MoonshineLRJUnboundedAudit.lean). Supporting: norm_qJ_le_of_bounded, norm_qJ_sub_one_le_of_bounded, one_le_two_mul_pi_sq.

46.9.4 A coefficient bound

Theorem 46.39 (Bounded q-series have bounded coefficients). *If $u(\tau) = \sum_{r \ge 0} A_r q^r$ for every $\tau \in \mathbb{H}$ and $|u| \le M$ on $\mathbb{H}$, then $|A_r| \le M$ for every r.*

```
theorem norm_coeff_le_of_hasSum_qPar (A : ℕ → ℂ) (u : ℍ → ℂ) (M : ℝ)
    (hu : ∀ τ : ℍ, HasSum (fun r => A r * qPar τ ^ r) (u τ)) (hM : ∀ τ : ℍ, ‖u τ‖ ≤ M)
    (r : ℕ) : ‖A r‖ ≤ M
```

(VOA/Moonshine/MoonshineLRCoeffBound.lean.)

Proof on paper. This is Cauchy's estimate on circles $|q| = \rho \to 1$, done discretely: for $L > r$ and $\zeta = e^{2\pi i/L}$, the average $\frac{1}{L}\sum_{t<L} u(\tau + t/L)\zeta^{(L-r)t}$ picks out the coefficients $A_{r'}$ with $r' \equiv r \pmod L$ (sum_range_pow_rootOfUnity), so $|A_r||q|^r \le M + \sum_{r' \ge L} |A_{r'}||q|^{r'}$ (norm_coeff_mul_le_add_tail); let $L \to \infty$, then $\operatorname{Im}\tau \to 0$. □

Physical meaning

A partition function bounded at all temperatures has bounded level degeneracies (in absolute value).

What the machine verified

No hypotheses beyond those displayed; standard axioms (VOA/Moonshine/MoonshineLRCoeffBoundAudit.lean). Supporting: sum_range_pow_rootOfUnity, norm_exp_two_pi_I_div_natCast, qPar_vadd_div, norm_coeff_mul_le_add_tail.

46.9.5 The tower and nontriviality

Theorem 46.40 (The tower down to J). *(a) For any $c : \mathbb{N} \to \mathbb{N} \to \mathbb{C}$ and k: if for every $m \geq 1$ the numbers $\rho_k(m,r) = \sum_{a \mid (m,r)} \frac{m}{a}\, c(ka, \frac{mr}{a^2})$, $r \geq 1$, are bounded, then for every $m \geq 1$ the sequence $\ell \mapsto c(km,\ell)$, $\ell \geq 1$, is bounded.*

(b) For a replicable family of period $N \geq 1$ and every k, the numbers $\rho_k(m,r)$ are not *bounded for every m.*

```
theorem bounded_replicate_of_bounded_faberRemainderCoeff (c : ℕ → ℕ → ℂ) (k : ℕ)
    (h : ∀ m : ℕ, 1 ≤ m → ∃ M : ℝ, ∀ r : ℕ, 1 ≤ r → ‖faberRemainderCoeff c k m r‖ ≤ M) :
    ∀ m : ℕ, 1 ≤ m → ∃ M : ℝ, ∀ ℓ : ℕ, 1 ≤ ℓ → ‖c (k * m) ℓ‖ ≤ M
theorem ReplicableFamily_c_mul_period {N : ℕ} (F : ReplicableFamily N) (k : ℕ) :
    F.c (k * N) = F.c 0
theorem not_bounded_faberRemainderCoeff {N : ℕ} (hN : 0 < N) (F : ReplicableFamily N) (k :
 ↪ ℕ) :
    ¬ ∀ m : ℕ, 1 ≤ m → ∃ M : ℝ, ∀ r : ℕ, 1 ≤ r → ‖faberRemainderCoeff F.c k m r‖ ≤ M
```

(`VOA/Moonshine/MoonshineLRTower.lean`.)

Proof on paper. (a) Strong induction on m. At $r = m\ell$ (`faberRemainderCoeff_mul_self`), $\rho_k(m, m\ell) = c(km,\ell) + \sum_{a \mid m,\, a<m} \frac{m}{a}\, c\big(ka, \frac{m^2\ell}{a^2}\big)$; every term of the sum involves a replicate ka with $a < m$, bounded by the induction hypothesis; so $c(km,\ell)$ is bounded. (b) $c(kN,\cdot) = c(0,\cdot)$ by periodicity, the coefficients of J; by (a) with $m = N$ they would be bounded, contradicting Theorem 46.38. □

Physical meaning

Walking down the tower of covers from the twisted sector g^k to $g^{kN} = 1$ reaches the untwisted theory, whose density of states grows; so the twisted sectors cannot all have bounded remainders.

What the machine verified

(a) no hypotheses; (b) hypothesis $0 < N$; standard axioms (`VOA/Moonshine/MoonshineLRTowerAudit.lean`).

Theorem 46.41 (Nontriviality). *For a replicable family of period $N \geq 1$, no member f_k is injective modulo translations.*

    (F : ReplicableFamily N) : F.NotInjectiveModTranslations
```

(`VOA/Moonshine/MoonshineLRNontrivial.lean`.)

From the mathematics to the Lean statement

The conclusion `F.NotInjectiveModTranslations` is $\forall k$, $\neg$ `IsInjectiveModTranslations`(f_k). The only hypothesis is $0 < N$. The statement is stronger than what the blueprint asked for (it does not need the prime Hecke identity).

Proof on paper. Suppose $f = f_k$ is injective modulo $\mathbb{Z}$. By Theorem 46.35 there are $R, Y > 0$ such that every value of modulus $\geq R$ is taken at height $\geq Y$; if $\operatorname{Im}\tau < Y$ and $|f(\tau)| \geq R$, then $f(\tau) = f(\sigma)$ with $\operatorname{Im}\sigma \geq Y$, and injectivity modulo $\mathbb{Z}$ forces $\operatorname{Im}\sigma = \operatorname{Im}\tau$, a contradiction; so $|f| < R$ below height Y. Fix $m \geq 1$ and the replication polynomial P with $P(f) = H_m$. Then $u = H_m - q^{-m}$ is bounded on $\mathbb{H}$: below height Y by $\max_{|w|\leq R} |P(w)| + e^{2\pi m Y}$, and above by its absolutely convergent expansion (Theorem 46.37). By Theorem 46.39 its coefficients $\rho_k(m, r)$ are bounded, for every m, contradicting Theorem 46.40(b). □

Physical meaning

A twisted partition function that separated all points of the cylinder $\mathbb{H}/\mathbb{Z}$ would have no non-trivial modular symmetry; the covering relations, together with the growth of the untwisted density of states, forbid this. This excludes in particular the "modular fictions" $q^{-1} + \zeta q$ of Cummins–Gannon, which are injective modulo $\mathbb{Z}$ and satisfy replication, but are not attached to J (their period-N families violate the clause `zero_eq_J`, $c(0, \cdot) = J$, of `ReplicableFamily`).

What the machine verified

Hypothesis $0 < N$; **unconditional** otherwise. Standard axioms (`VOA/Moonshine/MoonshineLRNontrivialAudit.lean`).

Theorem 46.42 (Property P, unconditionally). *For a replicable family of period $N \geq 1$, every k, and $z, w \in \mathbb{H}$: if $f_k(z) = f_k(w)$ then $\gamma z = w$ for some $\gamma \in G(f_k)$.*

```

    (F : ReplicableFamily N) (k : ℕ) {z w : ℍ}
    (hzw : qSeriesFun (F.c k) z = qSeriesFun (F.c k) w) :
    ∃ γ ∈ symmetryGroup (qSeriesFun (F.c k)), γ • z = w
```

(`VOA/Moonshine/MoonshineLRPropertyP.lean`.)

Proof on paper. Theorem 46.53 below, whose only hypothesis, the prime Hecke identity, is Theorem 46.36. □

Physical meaning

Equal twisted partition functions at two moduli imply the two tori (with twist) are related by a symmetry.

What the machine verified

Hypothesis $0 < N$; standard axioms (`MoonshineLRNontrivialAudit.lean`, which imports `MoonshineLRPropertyP.lean`).

46.10 Genus zero III: the Hecke pairing

From now on F is a replicable family of period N, k a member, $f = f_k$, and p a prime with $p \equiv 1 \pmod{N}$ (an *admissible* prime). $\Delta(p)$ is the set of the $p + 1$ maps $\tau \mapsto p\tau$ and $\tau \mapsto (\tau + j)/p$,

$0 \le j < p$.

Theorem 46.43 (Polynomial Hecke sums; membership; pairing). *Assume the prime Hecke identity at p.*

(a) For every $P \in \mathbb{C}[X]$ there is $R \in \mathbb{C}[X]$ with $\sum_{\beta\in\Delta(p)} P\big(f(\beta\tau)\big) = R\big(f(\tau)\big)$ for all τ.

(b) If two finite multisets s, t of complex numbers have $\sum_{x\in s} P(x) = \sum_{y\in t} P(y)$ for every polynomial P, then every member of s is a member of t.

(c) (Hecke pairing) If $f(z) = f(w)$, then every value $f(\beta z)$, $\beta \in \Delta(p)$, equals some value $f(\beta' w)$, $\beta' \in \Delta(p)$.

```
noncomputable def heckeValueSum (P : ℂ[X]) (τ : ℍ) : ℂ :=
  (∑ j ∈ Finset.range p, P.eval (qSeriesFun (F.c k) (heckePoint 1 p j one_pos hp τ))) +
    P.eval (qSeriesFun (F.c k) (heckePoint p 1 0 hp one_pos τ))
noncomputable def heckeValues (τ : ℍ) : Multiset ℂ :=
  (Finset.range p).val.map (fun j => qSeriesFun (F.c k) (heckePoint 1 p j one_pos hp τ)) +

theorem exists_poly_heckeValueSum (hB1 : PrimeHeckeIdentityAt F k p hp) (P : ℂ[X]) :
    ∃ R : ℂ[X], ∀ τ : ℍ, heckeValueSum F k p hp P τ = R.eval (qSeriesFun (F.c k) τ)
theorem mem_of_forall_sum_eval_eq {s t : Multiset ℂ}
    (h : ∀ P : ℂ[X], (s.map P.eval).sum = (t.map P.eval).sum) {x : ℂ} (hx : x ∈ s) :
    x ∈ t
theorem heckeValues_pairing (hB1 : PrimeHeckeIdentityAt F k p hp) {z w : ℍ}
    (h : qSeriesFun (F.c k) z = qSeriesFun (F.c k) w) {x : ℂ}
    (hx : x ∈ heckeValues F k p hp z) : x ∈ heckeValues F k p hp w
```

(`VOA/Moonshine/MoonshineCNGenusZeroPairing.lean`; section variables `{N : ℕ} (F : ReplicableFamily N) (k p : ℕ) (hp : 0 < p)`.)

From the mathematics to the Lean statement

`heckeValueSum F k p hp P τ` is $\sum_{\beta\in\Delta(p)} P(f(\beta\tau))$, `heckeValues` the multiset of the $p+1$ values. `Multiset ℂ` is a finite multiset; `s.map P.eval` applies P to its members. Note that (a)–(c) are stated for a fixed p with the prime Hecke identity at p as hypothesis (`hB1 : PrimeHeckeIdentityAt F k p hp`); primality and admissibility are not needed here, only the identity.

Proof on paper. (a) For $P = P_m$, the monic replication polynomial with $P_m(f) = H_m$, the prime Hecke identity gives $\sum_\beta P_m(f(\beta\tau)) = \sum_\beta H_m(\beta\tau) = H_{mp}(\tau) + [p \mid m]pH_{m/p}(\tau) = P_{mp}(f(\tau)) + [p \mid m]pP_{m/p}(f(\tau))$. The set of P for which (a) holds is closed under sums and scalar multiples and contains 1 and a monic polynomial of each positive degree, so it is all of $\mathbb{C}[X]$ (`forall_poly_of_monic_basis`). (b) Given $x \in s$, test with $P = \prod_{y\in t}(X-y)\cdot\prod_{x'\in s,\ x'\neq x}(X-x')$ (distinct x'): the t-sum is 0, the s-sum is (multiplicity of x)$\cdot P(x)$, nonzero unless $x \in t$. No Newton identities are needed. (c) By (a) the power sums $\sum_\beta f(\beta z)^r$ and $\sum_\beta f(\beta w)^r$ agree for every r (both are $R(f(z)) = R(f(w))$); apply (b). □

Physical meaning

The p-fold covering correspondence is a "modular equation": the multiset of twisted partition functions of the $p+1$ covers of a torus is determined by the partition function of the torus itself. So two tori with equal partition functions have covers with equal partition functions.

What the machine verified

Hypothesis `PrimeHeckeIdentityAt F k p hp`; standard axioms (`MoonshineCNGenusZeroAudit.lean`). Supporting: `forall_poly_of_monic_basis`, `eval_prod_X_sub_C`, `sum_map_eval_heckeValues`, `mem_heckeValues_iff`, `hecke_pairing_shift`, `hecke_pairing_scale` (the two explicit forms of (c)).

Theorem 46.44 (Pairing on connected domains; partner uniqueness). *Let f also denote its extension $z \mapsto f(z)$ to $\{z \in \mathbb{C} : \operatorname{Im} z > 0\}$ (`qSeriesExt`).*

(a) Hypothesis: the prime Hecke identity at p. *Let $\Omega \subseteq \mathbb{C}$ be open, connected and nonempty, and $u, v : \Omega \to \mathbb{H}$ holomorphic with $f \circ u = f \circ v$ on Ω. For every $\beta_0 \in \Delta(p)$ there is one $\beta \in \Delta(p)$ with $f(\beta_0(u(z))) = f(\beta(v(z)))$ for all $z \in \Omega$.*

(b) Same hypothesis. *Iterating: for every n there are $e \in \mathbb{Z}$, $|e| \le n$, and $b \in \mathbb{R}$ with $f(p^n u(z)) = f(p^e v(z) + b)$ on Ω.*

(c) (No hypothesis.) If $p > 1$ and $f \circ \beta = f \circ \beta'$ at points accumulating at a point of $\mathbb{H}$, then $\beta = \beta'$.

     ↪ z)) :
    β = β'
```

(`VOA/Moonshine/MoonshineCNGenusZeroPartner.lean`.)

From the mathematics to the Lean statement

`affC a b z` $= az + b$ with a, b real. $\Delta(p)$ is encoded by `Option (Fin p)`: `none` is $z \mapsto pz$ and `some j` is $z \mapsto (z + j)/p$ (`heckeDil`, `heckeTr` are the dilation and translation parts). `qSeriesExt c` $=$ `qSeriesFun` $c \circ$ `ofComplex`, where Mathlib's `UpperHalfPlane.ofComplex` is a partial inverse of the inclusion $\mathbb{H} \to \mathbb{C}$; only values with Im > 0 are ever used, and there `qSeriesExt c z` $= f(z)$ (`qSeriesExt_of_im_pos`). `DifferentiableOn ℂ u D` is holomorphy

on D; `IsPreconnected` is connectedness (allowing the empty set, excluded by `hDn`). In (c), `∃ᶠ z in 𝓝[≠] z₀, ...` says the equation holds at points arbitrarily close to z_0, $z \neq z_0$.

Proof on paper. (a) At each $z \in \Omega$ the pointwise pairing (Theorem 46.43(c) at $u(z), v(z)$) gives a partner $\beta(z)$. Take a small closed disc $K \subset \Omega$; it is uncountable and $\Delta(p)$ is finite, so one β serves on an infinite subset of K, which accumulates at a point of $K \subset \Omega$ (compactness). The identity theorem for the holomorphic function $f \circ \beta_0 \circ u - f \circ \beta \circ v$ on the connected Ω extends the equation to all of Ω. (b) Iterate (a) n times with $\beta_0 = (z \mapsto pz)$; each step multiplies the dilation on the v-side by p or p^{-1} (the dilations of $\Delta(p)$) and adds a real translation, so after n steps the dilation is p^e with $|e| \leq n$. (c) The identity theorem extends $f \circ \beta = f \circ \beta'$ to $\mathbb{H}$; at $z = iy$ with y large both βz and $\beta' z$ are in the top, so by top injectivity they differ by an integer for all large y; comparing imaginary parts gives equal dilations and then equal translations. □

Physical meaning

The covering correspondence can be followed continuously in the moduli: along a connected family of pairs of tori with equal partition functions, the matching of their covers does not jump.

What the machine verified

(a), (b): hypothesis `PrimeHeckeIdentityAt F k p hp`; (c): `IsJDominated c`, $p > 1$. Standard axioms (`MoonshineCNGenusZeroAudit2.lean`). Supporting (file `MoonshineCNGenusZeroPartner.lean`): the `affC` calculus (`affC_apply`, `affC_re`, `affC_im`, `affC_affC`, `affC_one_zero`, `affC_inv_affC`, `affC_affC_inv`, `differentiable_affC`, `continuous_affC`, `affC_im_pos`, `norm_affC_sub_le`), `heckeDil`, `heckeTr`, `heckeDil_pos`, `heckeDil_eq_zpow`, `heckeAffine_im_pos`, `heckeAffine_some_coe`, `heckeAffine_none_coe`, `qSeriesExt_coe`, `qSeriesExt_of_im_pos`, `differentiableOn_qSeriesExt`, `qSeriesExt_add_intCast` (1-periodicity), `topHeight`, `topHeight_pos`, `exists_int_of_qSeriesExt_eq` (top injectivity on $\mathbb{C}$), `heckeAffine_pairing_coe`, `heckeAffine_pairing`.

46.11 Genus zero IV: local symmetries are real Möbius maps; property P

A *local symmetry* of f is a holomorphic map α on a disc in $\mathbb{H}$, with values in $\mathbb{H}$, such that $f \circ \alpha = f$. The goal of this section is: *every local symmetry with $\alpha' \neq 0$ is the restriction of an element of $G(f)$.* Classically (Cummins–Gannon, §§3–4) one continues α analytically along paths to a maximal domain, shows the maximal domain is invariant under a dense group of affine maps, hence is $\mathbb{H}$ or a sector, excludes sectors, and concludes with $\mathrm{Aut}(\mathbb{H}) = \mathrm{PSL}_2(\mathbb{R})$. None of path continuation, maximal domains, the density lemma or $\mathrm{Aut}(\mathbb{H}) = \mathrm{PSL}_2(\mathbb{R})$ is in Mathlib v4.30. The library replaces this by a different argument : *one* intertwining sequence on a fixed disc yields a real linear ODE, whose solutions are explicit.

46.11.1 Local symmetries at non-critical values; relations in the top

Theorem 46.45 (Local symmetries and the top). *(a) If g is holomorphic on $\{\mathrm{Im} > 0\}$, $g(z_0) = g(w_0)$ and $g'(w_0) \neq 0$, there is a holomorphic α on a disc around z_0 with $\alpha(z_0) = w_0$, values in $\{\mathrm{Im} > 0\}$, and $g \circ \alpha = g$.*

(b) *If $f \circ u = f \circ v$ on a connected set S, with u, v continuous and taking values in the top, then $u = v + n$ on S for one integer n.*

(c) *If $f(\delta z + \tau) = f(\mu\alpha(z) + \nu)$ on a connected open D ($\delta, \mu > 0$ real, α holomorphic), the right side lies in the top everywhere and the left side strictly above the top height at one point, then $\alpha(z) = az + b$ on D with $a > 0$, a, b real.*

(`VOA/Moonshine/MoonshineCNGenusZeroLocal.lean`.)

From the mathematics to the Lean statement

`upperHalfPlaneSet` is $\{z \in \mathbb{C} : \operatorname{Im} z > 0\}$; `_root_.deriv g w₀` the complex derivative; `Metric.ball z₀ η` the open disc. In (c), `affC δ τ z` $= \delta z + \tau$.

Proof on paper. (a) $\alpha = g_{w_0}^{-1} \circ g$ with $g_{w_0}^{-1}$ the holomorphic local inverse of g near w_0 (Mathlib's analytic inverse function theorem). (b) By top injectivity, $u(z) - v(z) \in \mathbb{Z}$ for every z; a continuous integer-valued function on a connected set is constant (`eq_of_continuousOn_intValued`). (c) The set where the left side is in the top is open and nonempty; on a small disc inside it (a connected set) both sides are in the top, so by (b) $\delta z + \tau = \mu\alpha(z) + \nu + n$, i.e. α is real affine on an open set, hence on D by the identity theorem. □

Physical meaning

Near the low-temperature limit, a symmetry of the partition function can only be a shift of the modulus by an integer.

What the machine verified

(a) no hypotheses beyond those displayed; (b), (c) `IsJDominated c`. Standard axioms (`MoonshineCNGenusZeroAudit2.lean`). Supporting: `not_lt_of_intValued_aux`, `eq_of_continuousOn_intValued`.

46.11.2 The overlap construction

Theorem 46.46 (Intertwining sequences). *Let α be a local symmetry of f on the open disc $B' = D(z_0, \eta)$ with $\eta < \operatorname{Im} z_0$ (so that even the closed disc lies in $\mathbb{H}$), with $\operatorname{Im}\alpha \geq m > 0$, and assume the*

prime Hecke identity for k. If α is not a real affine map on B', there are real affine maps $C_n(z) = a_n z + b_n$ with $a_n > 0$, $a_n \neq 1$, $(a_n, b_n) \to (1, 0)$, and real affine C_n' of positive dilation, such that C_n maps $D(z_0, \eta/2)$ into B' and $\alpha \circ C_n = C_n' \circ \alpha$ on $D(z_0, \eta/2)$.

```

(`VOA/Moonshine/MoonshineCNGenusZeroOverlap.lean`.)

From the mathematics to the Lean statement

`hna` is "α is not of the form $z \mapsto az + b$ with $a > 0$ real on B'". The conclusion is the intertwining sequence: `affC (a n) (b n)` is C_n, `affC (a' n) (b' n)` is C_n', `Tendsto a atTop (𝓝 1)` is $a_n \to 1$. The abstract core, with the Hecke input replaced by a sequence of relations, is `exists_intertwining_of_relations` (same file).

Proof on paper. Write $L_{\delta,\tau}(z) = \delta z + \tau$ for real $\delta > 0$, τ. Choose two distinct admissible primes p, q (there are infinitely many primes $\equiv 1 \pmod N$, `infinite_admissible_primes_gt`), and w so large that $p^w\, m$ exceeds the top height.

Step 1: a family of relations. For $i \geq 1$ let $\ell = \ell(i)$ be the integer with $p^\ell \leq q^i < p^{\ell+1}$. Apply Theorem 46.44(b) at the prime p, on the connected disc B', with $u = \alpha$, $v = \mathrm{id}$ (allowed since $f \circ \alpha = f$ on B') and $n = w + \ell + 1$:

$$f\big(p^{w+\ell+1}\alpha(z)\big) = f\big(p^e z + b\big) \qquad (z \in B'), \qquad |e| \leq w + \ell + 1.$$

This is again an equation $f \circ u' = f \circ v'$ on B', now with $u'(z) = p^e z + b$ and $v'(z) = p^{w+\ell+1}\alpha(z)$ (note the roles: the side carrying α has become v'). Apply Theorem 46.44(b) once more, at the prime q with $n = i$:

$$f\big(\delta_i z + \tau_i\big) = f\big(\mu_i \alpha(z) + \nu_i\big) \quad (z \in B'), \qquad \delta_i = q^i p^e,\ \tau_i = q^i b,\ \mu_i = q^{e_i'} p^{w+\ell+1}, \tag{46.9}$$

where $|e_i'| \leq i$ comes from (b) (each of the i steps multiplies the dilation by $q^{\pm 1}$).

Step 2: the bounds. The right side of (46.9) lies in the top: $\mu_i \geq q^{-i} p^{\ell+1} p^w > p^w$ because $p^{\ell+1} > q^i$, so $\mathrm{Im}(\mu_i \alpha(z)) \geq p^w m$. (This is why ℓ was chosen as it is.) The dilations δ_i are pairwise distinct, since they contain distinct powers q^i of the prime $q \neq p$ (`zpow_ne_pow_of_prime_ne`). They are bounded below, $\delta_i \geq q^i p^{-(w+\ell+1)} \geq p^{-(w+1)}$ since $p^\ell \leq q^i$. They are bounded above: if δ_i were very large, the left side $\delta_i z + \tau_i$ would lie above the top height at some $z \in B'$, and Theorem 46.45(c) would make α real affine on B', which is excluded. Using 1-periodicity of f we may replace τ_i by its fractional part. By compactness of $[\mathrm{lo}, \mathrm{hi}] \times [0, 1]$ the pairs (δ_i, τ_i) have a convergent subsequence.

Step 3: unwinding. Take $i < j$ in the subsequence, so close that $C = L_{\delta_j,\tau_j}^{-1} \circ L_{\delta_i,\tau_i}$ maps $D(z_0, \eta/2)$ into B'. For $z \in D(z_0, \eta/2)$ put $z' = Cz \in B'$, so that $\delta_i z + \tau_i = \delta_j z' + \tau_j$. By (46.9) for i at z and for j at z',

$$f\big(\mu_i \alpha(z) + \nu_i\big) = f(\delta_i z + \tau_i) = f(\delta_j z' + \tau_j) = f\big(\mu_j \alpha(Cz) + \nu_j\big).$$

Both arguments of f at the ends lie in the top, and z ranges over the connected disc $D(z_0, \eta/2)$, so by Theorem 46.45(b) there is one integer n with $\mu_i \alpha(z) + \nu_i = \mu_j \alpha(Cz) + \nu_j + n$ for all such z. Solving,

$\alpha(Cz) = C'(\alpha(z))$ with $C'(w) = (\mu_i w + \nu_i - \nu_j - n)/\mu_j$, real affine with positive dilation. C is real affine with dilation $\delta_i/\delta_j \neq 1$, so $C \neq \mathrm{id}$, and $C \to \mathrm{id}$ as $i, j \to \infty$ along the subsequence. Choosing such pairs (i_n, j_n) gives the sequences C_n, C'_n. □

Physical meaning

Composing the covering correspondences at two different primes produces exact symmetry relations between slightly different rescalings of the moduli; comparing two of them gives transformations arbitrarily close to the identity, whose limit is an infinitesimal symmetry (the next theorem).

What the machine verified

Hypotheses: $0 < N$, `PrimeHeckeIdentity F k`, and those displayed. Standard axioms (`MoonshineCNGenusZeroAudit2.lean`). Supporting: `im_pos_of_mem_ball`, `zpow_ne_pow_of_prime_ne`, `exists_intertwining_of_relations`.

46.11.3 The real linear ODE and its explicit solutions

Theorem 46.47 (The ODE). *Let α be holomorphic on an open set S, non-constant on S, and $\alpha \circ C_n = C'_n \circ \alpha$ on S for real affine $C_n \to \mathrm{id}$, $C_n \neq \mathrm{id}$, and real affine C'_n. Then there are real $\lambda, \mu, \lambda', \mu'$ with $(\lambda, \mu) \neq (0, 0)$ and $(\lambda z + \mu)\,\alpha'(z) = \lambda' \alpha(z) + \mu'$ on S.*

```
theorem exists_real_linear_ode {α : ℂ → ℂ} {S : Set ℂ} (hSo : IsOpen S)
    (hα : DifferentiableOn ℂ α S) {a b a' b' : ℕ → ℝ} (ha : Tendsto a atTop (𝓝 1))
    (hb : Tendsto b atTop (𝓝 0)) (hne : ∀ n, a n ≠ 1 ∨ b n ≠ 0)
    (hrel : ∀ n, ∀ z ∈ S, α (affC (a n) (b n) z) = affC (a' n) (b' n) (α z))
    {z₁ z₂ : ℂ} (hz₁ : z₁ ∈ S) (hz₂ : z₂ ∈ S) (h12 : α z₁ ≠ α z₂) :
    ∃ l m l' m' : ℝ, (l ≠ 0 ∨ m ≠ 0) ∧
      ∀ z ∈ S, ((l : ℂ) * z + m) * _root_.deriv α z = l' * α z + m'
```

(`VOA/Moonshine/MoonshineCNGenusZeroODE.lean`.)

Proof on paper. Put $\varepsilon_n = |a_n - 1| + |b_n| > 0$; along a subsequence $((a_n - 1)/\varepsilon_n, b_n/\varepsilon_n) \to (\lambda, \mu)$ with $|\lambda| + |\mu| = 1$. Then $(\alpha(C_n z) - \alpha(z))/\varepsilon_n \to (\lambda z + \mu)\alpha'(z)$. The same quantity equals $\frac{a'_n - 1}{\varepsilon_n}\alpha(z) + \frac{b'_n}{\varepsilon_n}$; evaluating at two points z_1, z_2 with $\alpha(z_1) \neq \alpha(z_2)$ solves for the two coefficients, which therefore converge; their limits λ', μ' are real because the a'_n, b'_n are. □

Physical meaning

An infinitesimal symmetry: the limit of exact symmetries accumulating at the identity is a real vector field $(\lambda z + \mu)\partial_z$ on the moduli, which the local symmetry must intertwine with another real vector field.

What the machine verified

No hypotheses beyond those displayed; standard axioms (`MoonshineCNGenusZeroAudit2.lean`). Supporting: `exists_real_of_tendsto_ofReal`.

Theorem 46.48 (Explicit solutions). *On a connected open $S \subseteq \{\mathrm{Im} > 0\}$, a holomorphic solution of $(lz + m)\alpha' = l'\alpha + m'$ (l, m, l', m' real, $(l, m) \neq 0$) is one of: $\alpha = K(z - c)^A + M_0$ ($A \neq 0$; power family), $\alpha = B \log(z - c) + K$ (logarithmic), $\alpha = Ke^{Az} + M_0$ ($A \neq 0$; exponential), $\alpha = Bz + K$ (affine), with A, B, c, M_0 real and K complex.*

    (∃ (B : ℝ) (K : ℂ), ∀ z ∈ S, α z = B * z + K)
```

(VOA/Moonshine/MoonshineCNGenusZeroFamilies.lean.)

From the mathematics to the Lean statement

`(z - c) ^ (A : ℂ)` is Mathlib's complex power with the principal branch; for $\operatorname{Im} z > 0$ and c real, $z - c$ lies in the slit plane (`sub_ofReal_mem_slitPlane`), so all four formulas are holomorphic on the whole upper half-plane. The four disjuncts are the four cases $l \neq 0, l' \neq 0$; $l \neq 0, l' = 0$; $l = 0, l' \neq 0$; $l = l' = 0$, with $c = -m/l, A = l'/l$ or $l'/m, M_0 = -m'/l', B = m'/l$ or m'/m.

Proof on paper. In each case multiply by an explicit integrating factor and show the derivative of the result vanishes on the connected S (`exists_const_of_hasDerivAt_zero`). □

Physical meaning

The real one-parameter subgroups of $\mathrm{SL}_2(\mathbb{R})$ and their "non-group" cousins: the power family with $A = \pm 1$ contains the Möbius maps, the others will be excluded.

What the machine verified

No hypotheses beyond those displayed; standard axioms (`MoonshineCNGenusZeroAudit2.lean`). Supporting: `sub_ofReal_mem_slitPlane`, `sub_ofReal_ne_zero`, `exists_const_of_hasDerivAt_zero`, `hasDerivAt_of_differentiableOn`, and the four case theorems `eqOn_power_of_ode`, `eqOn_log_of_ode`, `eqOn_exp_of_ode`, `eqOn_affine_of_ode`.

46.11.4 Boundary-real exclusion and global extension

Theorem 46.49 (Boundary-real exclusion). *Assume the prime Hecke identity for k, $N \geq 1$. There is no injective holomorphic v from a half-disc $\Omega^+ = D(x_1, r) \cap \mathbb{H}$ at a real point x_1 into a closed disc $\overline{D}(z_1, \rho)$ with $\rho < \operatorname{Im} z_1$, such that $f \circ v = f$ on Ω^+.*

      qSeriesExt (F.c k) (v w) = qSeriesExt (F.c k) w) : False
```

(VOA/Moonshine/MoonshineCNGenusZeroBoundary.lean.)

From the mathematics to the Lean statement

`Metric.ball (x₁ : ℂ) r ∩ upperHalfPlaneSet` is the half-disc Ω^+; `Metric.closedBall z₁ ρ` the closed disc, which lies in $\mathbb{H}$ because $\rho < \operatorname{Im} z_1$; `InjOn v H` is injectivity on Ω^+ (Lean's `H`). The first quoted lemma is the dynamical tool used in the proof.

Proof on paper. Take a large admissible prime p and pair on the connected Ω^+ with $u = \mathrm{id}$ scaled by p: $f(pw) = f(\beta(v(w)))$ on Ω^+ for one $\beta \in \Delta(p)$. If $\beta = (z \mapsto pz)$: then $f(pw) = f(pv(w))$; $pv(w)$ lies in the top for all w (as $\operatorname{Im} v \geq \operatorname{Im} z_1 - \rho > 0$ and p is large) and pw lies above the top somewhere in Ω^+; by Theorem 46.45(c) v is real affine, so it maps points of Ω^+ near x_1 to points near $\mathbb{R}$, contradicting $\operatorname{Im} v \geq \operatorname{Im} z_1 - \rho > 0$. If $\beta = (z \mapsto (z+j)/p)$: put $\phi(z) = f(pz)$ and, with a suitable integer m, $\tau(w) = ((v(w) + j)/p + m)/p$. By periodicity $\phi \circ \tau = \phi$ on Ω^+; τ is injective and maps Ω^+ into a closed disc K of radius ρ/p^2, which for p large lies inside Ω^+ near x_1. Take $w_0 \in \Omega^+ \setminus K$; its iterates under τ are pairwise distinct (injectivity and $w_0 \notin \tau(\Omega^+)$), lie in the compact $K \subset \mathbb{H}$, hence accumulate there, and ϕ takes the value $\phi(w_0)$ on all of them; by the identity theorem ϕ is constant, so f is constant, which it is not (`eq_of_comp_eq_of_mapsTo_compact`, `qSeriesExt_exists_ne`). □

Physical meaning

A symmetry of the twisted partition function cannot push the moduli of a degenerating torus (a point of the real axis) to a non-degenerate torus: the degeneration limits are intrinsic.

What the machine verified

Hypotheses: $0 < N$, `PrimeHeckeIdentity F k`, and those displayed. Standard axioms (`MoonshineCNGenusZeroAudit2.lean`). Supporting: `norm_affC_sub_affC`, `injOn_affC_comp`, `qSeriesExt_exists_ne`.

Theorem 46.50 (Global extension). *Assume the prime Hecke identity for k, $N \geq 1$. Let β be holomorphic on $\{\operatorname{Im} > 0\}$ with β' nowhere zero there, $\operatorname{Im} z_0 > 0$, $\operatorname{Im} \beta(z_0) > 0$, and $f \circ \beta = f$ near z_0. Then $\operatorname{Im} \beta(z) > 0$ and $f(\beta(z)) = f(z)$ for every z with $\operatorname{Im} z > 0$.*

```

     ↪ upperHalfPlaneSet)
    (hβ' : ∀ z : ℂ, 0 < z.im → _root_.deriv β z ≠ 0) {z₀ : ℂ} (hz₀ : 0 < z₀.im)
    (hβz₀ : 0 < (β z₀).im)
    (hloc : ∀ᶠ z in 𝓝 z₀, qSeriesExt (F.c k) (β z) = qSeriesExt (F.c k) z) :
    ∀ z : ℂ, 0 < z.im → 0 < (β z).im ∧ qSeriesExt (F.c k) (β z) = qSeriesExt (F.c k) z
```

(`VOA/Moonshine/MoonshineCNGenusZeroExtension.lean`.)

From the mathematics to the Lean statement

`∀ᶠ z in 𝓝 z₀, ...` is "on a neighbourhood of z_0".

Proof on paper. Let W be the connected component through z_0 of $\{z \in \mathbb{H} : \beta(z) \in \mathbb{H}\}$; by the identity theorem $f \circ \beta = f$ on W. W is open; it is also relatively closed in $\mathbb{H}$: at $z_1 \in \mathbb{H} \cap \overline{W}$, either $\beta(z_1) \in \mathbb{H}$ (then a disc around z_1 is in W) or $\beta(z_1) = x_1 \in \mathbb{R}$. In the latter case the analytic local inverse v of β at z_1 maps a half-disc at x_1 injectively into a small closed disc around z_1 inside $\mathbb{H}$, and its image (connected, meeting W) lies in W, so $f \circ v = f$ on the half-disc, which Theorem 46.49 forbids. $\mathbb{H}$ is connected, so $W = \mathbb{H}$. □

Physical meaning

A local symmetry of the twisted partition function, if it is given by a globally defined formula, is a global symmetry: there is no wall in the moduli space across which it could fail.

What the machine verified

Hypotheses as displayed; standard axioms (`MoonshineCNGenusZeroAudit2.lean`).

46.11.5 Classification of the global solutions

Theorem 46.51 (Which explicit solutions are global symmetries). *Let $\mathfrak{c}$ be J-dominated and $f =$* `qSeriesFun` $\mathfrak{c}$.

(a) No $Ke^{Az} + M_0$ $(A, K \neq 0)$ maps $\mathbb{H}$ into $\mathbb{H}$.

(b) No $B\log(z - c_0) + K$ maps $\mathbb{H}$ into $\mathbb{H}$ and satisfies $f \circ \beta = f$ on $\mathbb{H}$.

(c) If $Bz + K$ does, then $B = 1$ and $K \in \mathbb{Z}$.

(d) If $K(z - c_0)^A + M_0$ $(A, K \neq 0)$ does, then either $A = 1$ and $K > 0$ real, or $A = -1$ and $K < 0$ real.

    (A = 1 ∧ ∃ a : ℝ, 0 < a ∧ K = a) ∨ (A = -1 ∧ ∃ a : ℝ, a < 0 ∧ K = a)
```

(`VOA/Moonshine/MoonshineCNGenusZeroClassification.lean`.)

Proof on paper. (a) $z \mapsto Az$ maps $\mathbb{H}$ onto a half-plane, which exp maps onto $\mathbb{C} \setminus \{0\}$; so the function takes the value $M_0 - i \notin \mathbb{H}$. (b) On the vertical line $c_0 + iy$, $\beta = B(\log y + i\pi/2) + K$ has constant imaginary part, while $f(c_0 + iy) \to \infty$ as $y \to \infty$; but f is bounded on every horizontal line ($|f| \leq e^{2\pi \operatorname{Im}} +$ `jTail`), so $f(\beta(c_0 + iy)) = f(c_0 + iy)$ is impossible. (c) $B > 0$ (into $\mathbb{H}$); high up, both z and $Bz + K$ are in the top, so they differ by an integer, forcing $B = 1$, $K \in \mathbb{Z}$. (d) On rays $c_0 + re^{i\theta}$, $\operatorname{Im}\beta = r^A|K|\sin(\arg K + A\theta) + \operatorname{Im} M_0$ must be positive for all r; letting $r \to \infty$ or $r \to 0$ forces $\sin(\arg K + A\theta) > 0$ on $(0, \pi)$, hence $|A| \leq 1$ (`abs_le_one_of_sin_pos`). $0 < A < 1$ contradicts top injectivity on the vertical line through c_0 (β grows like y^A there while $f(\beta) = f$ forces β to differ from $c_0 + iy$ by an integer). $-1 < A < 0$: three observations. (1) On the vertical line $c_0 + iy$, $\beta(c_0 + iy) = K(iy)^A + M_0$ has imaginary part $y^A|K|\sin(\arg K + A\pi/2)$ (M_0 is real); the sine is positive (take $\theta = \pi/2$ above), and $y^A \to +\infty$ as $y \to 0^+$ because $A < 0$. Since $|f(z)| \geq e^{2\pi \operatorname{Im} z} -$ `jTail`$(\operatorname{Im} z)$, the values $f(c_0 + iy) = f(\beta(c_0 + iy))$ are unbounded as $y \to 0^+$. (2) On the lines $c_0 \pm 1 + is$, as $s \to 0^+$, β tends to $P_\pm = K(\pm 1)^A + M_0$ (principal branch: $(-1)^A = e^{iA\pi}$), with $\operatorname{Im} P_+ = |K|\sin(\arg K)$ and $\operatorname{Im} P_- = |K|\sin(\arg K + A\pi)$. Both are ≥ 0 by continuity of the sine positivity at the endpoints $\theta = 0, \pi$ (`sin_nonneg_endpoints`); if both vanished, $\arg K$ and $\arg K + A\pi$

would be multiples of π, forcing $A \in \mathbb{Z}$, impossible for $-1 < A < 0$. So one of them, call it P, lies in $\mathbb{H}$ (`exists_tendsto_power_family_of_neg`). (3) On that line $f(c_0 \pm 1 + is) = f(c_0 + is)$ by 1-periodicity, which is unbounded as $s \to 0^+$ by (1); but $f(c_0 \pm 1 + is) = f(\beta(c_0 \pm 1 + is)) \to f(P)$ by continuity, a finite value. Contradiction. $A = \pm 1$: the into-$\mathbb{H}$ condition forces K real of the stated sign. □

Physical meaning

Of all the analytic "flows" compatible with the infinitesimal symmetry, only modular transformations (real Möbius maps of determinant one) preserve the partition function.

What the machine verified

Hypotheses as displayed (no Hecke input); standard axioms (`MoonshineCNGenusZeroAudit2.lean`).     IsMoebiusSymmetryOn (qSeriesFun (F.c k)) α (Metric.ball z₀ (η / 2))
```

(`VOA/Moonshine/MoonshineCNGenusZeroMoebius.lean`.)

From the mathematics to the Lean statement

`glOfDetOne p q r s h` is the matrix $\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)$ (with $a, b, c, d =$ `p`, `q`, `r`, `s`) in $\mathrm{GL}_2(\mathbb{R})$ (Chapter 43). `IsMoebiusSymmetryOn f α S`: α agrees on S with the Möbius map of a determinant-one real matrix that lies in $G(f)$.

Proof on paper. If α is real affine on $D(z_0, \eta)$, the relation $f(az+b) = f(z)$ extends to $\mathbb{H}$ (identity theorem) and Theorem 46.51(c) makes α an integer translation. Otherwise Theorem 46.46 gives an intertwining sequence, Theorem 46.47 an ODE (α is non-constant since $\alpha'(z_0) \neq 0$), and Theorem 46.48 an explicit β equal to α on $D(z_0, \eta/2)$, holomorphic on $\mathbb{H}$ with nowhere vanishing derivative. Theorem 46.50 makes β a global symmetry mapping $\mathbb{H}$ into itself, and Theorem 46.51 sorts the four families: exponential and logarithmic are impossible; affine gives $z \mapsto z + n$; power gives either

$A = 1, K > 0$, which is again an affine map $z \mapsto Kz + (M_0 - Kc_0)$ and hence, by part (c), a translation by an integer, or $A = -1, K < 0$. (Constant solutions, $K = 0$ or $B = 0$, do not occur because $\beta = \alpha$ near z_0 and $\alpha'(z_0) \neq 0$.) The last case is $z \mapsto M_0 + K/(z - c_0)$, the Möbius map of $\frac{1}{\sqrt{-K}} \left(\begin{smallmatrix} M_0 & K - M_0 c_0 \\ 1 & -c_0 \end{smallmatrix}\right)$, of determinant one (`isMoebiusSymmetryOn_of_affine`, `isMoebiusSymmetryOn_of_inv`). □

Physical meaning

Every local symmetry of a twisted partition function is a modular transformation.

What the machine verified

(`VOA/Moonshine/MoonshineCNGenusZeroPropertyP.lean`, `VOA/Moonshine/MoonshineCNGenusZeroCritical.lean`.)

From the mathematics to the Lean statement

`γ • z` is the Möbius action of $\mathrm{GL}_2(\mathbb{R})$ on $\mathbb{H}$. The first theorem is the case where f' does not vanish at both points; the second is a uniform bound used for the doubly critical case; the third is the full property P.

Proof on paper. *Non-critical case* ($f'(w) \neq 0$): Theorem 46.45(a) gives a local symmetry α near z with $\alpha(z) = w$; α is not constant, so $\alpha'(z') \neq 0$ at some z' near z; Theorem 46.52 near z' gives $\gamma \in G$ with $\alpha = \gamma$ near z', and the identity theorem extends $\alpha = \gamma$ to the disc around z, so $\gamma z = w$. If instead $f'(z) \neq 0$, exchange z, w and use γ^{-1}. *Doubly critical case*: critical points of f are isolated (`eventually_deriv_qSeriesExt_ne_zero`), and by the open mapping theorem there are $w_n \to w$ non-critical and $z_n \to z$ with $f(z_n) = f(w_n)$; the non-critical case gives $\gamma_n \in G$ with $\gamma_n z_n = w_n$. The entries of γ_n are bounded (from $\mathrm{Im}(\gamma\tau) = \mathrm{Im}\,\tau/|c\tau + d|^2$ and the real and imaginary parts of $\sigma(c\tau + d) = a\tau + b$), so a subsequence converges to some γ with $\gamma z = w$, and $\gamma \in G$ because G is closed (the invariance $f(\gamma\tau) = f(\tau)$ passes to limits). □

Physical meaning

Property P: the twisted partition function separates the points of the moduli space of twisted tori, i.e. of $G\backslash\mathbb{H}$. It is the injectivity half of "f is a coordinate on the modular curve".

What the machine verified

Hypotheses: $0 < N$, `PrimeHeckeIdentity F k`. Standard axioms (`MoonshineCNGenusZeroAudit2.lean`). The hypothesis-free form is Theorem 46.42. Supporting: `moebius_denom_ne_zero`, `exists_mem_symmetryGroup_smul_eq_of_deriv_ne_zero`, `not_eventually_eq_qSeriesExt`, `eventually_deriv_qSeriesExt_ne_zero`, `abs_le_sq_add_one`.

Trap / dead end

Critical pairs in Cummins–Gannon. Cummins–Gannon's Prop. 2.3 asserts a local symmetry at every coincidence $f(z_1) = f(z_2)$, but when both points are critical one needs equal multiplicities, which their Lemma 2.4 does not give. The library never constructs a symmetry at a critical target: it uses non-critical targets only and recovers doubly critical pairs by approximation and *closedness* of $G(f)$ (an earlier plan used discreteness; closedness suffices).

Trap / dead end

Dead ends of the local-to-global step. (i) Canonical cusp charts do not give Möbius-ness: Hecke transports only relate non-top components of $\{|f| > R\}$ to each other, never to the top, so one global input (here: one intertwining sequence on a fixed disc) is unavoidable. (ii) One cannot hope for two independent ODEs that would pin α down algebraically: already for J and a Möbius symmetry γ, every real affine C with $\gamma C\gamma^{-1}$ also affine fixes the real point $\gamma^{-1}\infty$, so all intertwining relations share one fixed point and give the same ODE (details in the note). The case analysis of Theorem 46.51 is therefore necessary. (iii) Maximal domains of analytic continuation need "maximal domain of a transport = transport of the maximal domain", which Cummins–Gannon use silently; the route above avoids maximal domains altogether. (iv) No holomorphic inverse germ is needed for the second transport of the overlap construction, and the classification does not need bijectivity: $\beta(\mathbb{H}) \subseteq \mathbb{H}$ and $f \circ \beta = f$ suffice.

46.12 Genus zero V: the symmetry group

46.12.1 Shimizu's lemma and the stabiliser of ∞

Theorem 46.54 (Shimizu's lemma for symmetry groups). *(a) If ψ is holomorphic on $\mathbb{H}$, invariant under $T = \left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right)$ and under some g of determinant 1 with lower-left entry $0 < |c| < 1$, then ψ is constant.*

(b) If f is holomorphic and non-constant and $T \in G(f)$, every $g \in G(f)$ with $c \neq 0$ has $|c| \geq 1$.

(c) In particular this holds for every J-dominated q-series.

```
theorem eq_of_invariant_of_lowerLeft_abs_lt_one {ψ : ℍ → ℂ}
    (hψ : MDifferentiable 𝓘(ℂ) 𝓘(ℂ) ψ) {g : GL (Fin 2) ℝ} (hdet : g.det.val = 1)
    (hc0 : g 1 0 ≠ 0) (hc1 : |g 1 0| < 1) (hT : ∀ τ, ψ (glUpperUnipotent 1 • τ) = ψ τ)
    (hg : ∀ τ, ψ (g • τ) = ψ τ) (τ σ : ℍ) : ψ τ = ψ σ
theorem one_le_abs_lowerLeft_of_mem_symmetryGroup {f : ℍ → ℂ}
    (hf : MDifferentiable 𝓘(ℂ) 𝓘(ℂ) f) (hnc : ∃ τ σ : ℍ, f τ ≠ f σ)
    (hT : glUpperUnipotent 1 ∈ symmetryGroup f) {g : GL (Fin 2) ℝ}
```

```
    (hg : g ∈ symmetryGroup f) (hc0 : g 1 0 ≠ 0) : 1 ≤ |g 1 0|
theorem one_le_abs_lowerLeft_qSeriesFun {c : ℕ → ℂ} (hc : IsJDominated c) {g : GL (Fin 2)
↪ ℝ}
    (hg : g ∈ symmetryGroup (qSeriesFun c)) (hc0 : g 1 0 ≠ 0) : 1 ≤ |g 1 0|
```

(VOA/Moonshine/MoonshineCNGenusZeroShimizu.lean.)

From the mathematics to the Lean statement

`g 1 0` is the lower-left entry c (rows and columns indexed by `Fin 2` $= \{0,1\}$); `g.det.val` the determinant as a real number; `glUpperUnipotent 1` is T (Chapter 43). The statement is the classical Shimizu lemma (for a discrete group containing T, every element with $c \neq 0$ has $|c| \geq 1$), in the form "invariance under T and an element with $0 < |c| < 1$ forces constancy", which needs no discreteness hypothesis.

Proof on paper. Shimizu's sequence: $B_0 = g$, $B_{n+1} = B_n T B_n^{-1}$. For $\det M = 1$ with first column (a, c), $MTM^{-1} = \left(\begin{smallmatrix} 1-ac & a^2 \\ -c^2 & 1+ac \end{smallmatrix}\right)$ (`conj_glUpperUnipotent`); so the lower-left entries satisfy $c_{n+1} = -c_n^2$, hence $|c_n| \leq |c|^{n+1} \to 0$, and the upper-left entries $a_{n+1} = 1 - a_n c_n$ stay bounded and tend to 1. The elements $C_n = B_{n+1} T^{-1}$ lie in the group generated by T and g, converge to the identity, and act non-trivially (as $c_n \neq 0$). A holomorphic function invariant under a sequence of non-trivial Möbius maps converging to the identity is constant (the constancy lemma `eq_of_invariant_of_entries_tendsto_one` of Chapter 43: the invariance relations produce a non-zero real vector field annihilating ψ). (b) apply (a) to f if $0 < |c| < 1$. (c) $T \in G(f)$ by 1-periodicity, and f is non-constant (it has a pole at $i\infty$, `qSeriesFun_exists_ne`). □

Physical meaning

A modular-invariant quantity cannot be invariant under "too small" a twist: a symmetry group containing T and an element with $|c| < 1$ is not discrete, and a holomorphic function with a continuous family of approximate symmetries is constant. This is why the symmetry group of a non-trivial twisted partition function is discrete.

What the machine verified

No hypotheses beyond those displayed; standard axioms (`MoonshineCNGenusZeroAudit.lean`). Supporting: `shimizuPairFrom`, `shimizuMatrixFrom` and its entry, determinant, recursion and membership lemmas, `shimizuWitnessFrom` with `_mem`, `_val`, `_det`, the estimates `shimizuPairFrom_snd_ne_zero`, `_snd_abs_le`, `_snd_abs_le_self`, `_fst_abs_le`, `_snd_tendsto`, `_fst_tendsto`, `shimizuWitnessFrom_entries_tendsto`, `shimizuWitnessFrom_moves`, `det_val_eq_one_of_mem_symmetryGroup`, `glUpperUnipotent_one_mem_symmetryGroup_qSeriesFun`, `qSeriesFun_exists_ne`. The file generalises the Shimizu sequence of `MoonshineCNGammaZeroShimizu.lean` (Chapter 43), which starts at $\left(\begin{smallmatrix} 1 & 0 \\ y & 1 \end{smallmatrix}\right)$, to an arbitrary start.

Theorem 46.55 (The stabiliser of ∞). *For J-dominated* $\mathfrak{c}$*: every* $\gamma \in G(f)$ *with lower-left entry* 0 *acts on* $\mathbb{H}$ *as* $\tau \mapsto \tau + n$ *for an integer* n.

```
theorem exists_int_smul_eq_add_of_lowerLeft_eq_zero {c : ℕ → ℂ} (hc : IsJDominated c)
    {γ : GL (Fin 2) ℝ} (hγ : γ ∈ symmetryGroup (qSeriesFun c)) (h10 : γ 1 0 = 0) :
    ∃ n : ℤ, ∀ τ : ℍ, ((γ • τ : ℍ) : ℂ) = τ + n
```

(VOA/Moonshine/MoonshineCNGenusZeroGroup.lean.)

Proof on paper. $\gamma = \left(\begin{smallmatrix} a & b \\ 0 & d \end{smallmatrix}\right)$ acts as $\tau \mapsto (a/d)\tau + b/d$, a real affine global symmetry with $a/d > 0$; Theorem 46.51(c). □

Physical meaning

The only symmetries fixing the low-temperature limit are the integer shifts of the modulus: the cusp ∞ has width 1.

What the machine verified

Hypothesis `IsJDominated c`; no Hecke input; standard axioms (`MoonshineCNGenusZeroAudit2.lean`).

46.12.2 Discreteness and finiteness

Theorem 46.56 (Shimura's finiteness lemma). *For J-dominated* $\mathfrak{c}$, $f = \texttt{qSeriesFun}\ \mathfrak{c}$ *and* $G = G(f)$*:*

(a) an element of G with $|a-1| < 1$, $|b| < 1$, $|c| < 1$ *is the identity;*

(b) for every B, the set of elements of G with all entries bounded by B is finite;

(c) for every $c_0 \neq 0$*, the pairs* $(\mathrm{fract}(a/c_0), \mathrm{fract}(d/c_0))$ *of elements* $\left(\begin{smallmatrix} a & b \\ c_0 & d \end{smallmatrix}\right) \in G$ *form a finite set.*

```
theorem eq_one_of_mem_symmetryGroup_of_near {c : ℕ → ℂ} (hc : IsJDominated c)
    {g : GL (Fin 2) ℝ} (hg : g ∈ symmetryGroup (qSeriesFun c)) (h00 : |g 0 0 - 1| < 1)
    (h01 : |g 0 1| < 1) (h10 : |g 1 0| < 1) : g = 1
theorem finite_bounded_mem_symmetryGroup {c : ℕ → ℂ} (hc : IsJDominated c) (B : ℝ) :
    {g : GL (Fin 2) ℝ | g ∈ symmetryGroup (qSeriesFun c) ∧ ∀ i j, |g i j| ≤ B}.Finite
theorem finite_fract_diag_div_lowerLeft {c : ℕ → ℂ} (hc : IsJDominated c) {c₀ : ℝ}
    (hc₀ : c₀ ≠ 0) :
    ((fun g : GL (Fin 2) ℝ => (Int.fract (g 0 0 / c₀), Int.fract (g 1 1 / c₀))) ''
      {g | g ∈ symmetryGroup (qSeriesFun c) ∧ g 1 0 = c₀}).Finite
```

(`VOA/Moonshine/MoonshineCNGenusZeroDiscrete.lean`.)

From the mathematics to the Lean statement

`Int.fract x` $= x - \lfloor x \rfloor \in [0,1)$. `Set.Finite` is finiteness of a set; `f '' S` is the image. (a) is discreteness of G at the identity (in the coordinates a, b, c; d is then determined by $\det = 1$).

Proof on paper. (a) $|c| < 1$ forces $c = 0$ by Shimizu; then γ is a translation by an integer n (Theorem 46.55), so $a = d = \pm 1$ and $b = \pm n$; $|a-1| < 1$ gives $a = 1$ and $|b| < 1$ gives $n = 0$. (b) If infinitely many elements had bounded entries, two of them $g \neq h$ would be entrywise within $1/(4B+4)$ (Bolzano–Weierstrass in $\mathbb{R}^4$), and then gh^{-1} (computed with the adjugate, `glFinTwo_inv_eq`) would satisfy (a), so $g = h$ (`eq_of_mem_symmetryGroup_of_close`). (c) Multiplying $\left(\begin{smallmatrix} a & b \\ c_0 & d \end{smallmatrix}\right)$ by integer translations on both sides changes a and d by multiples of c_0 and does not change the residues; normalise a, d into $[0, |c_0|)$; then $b = (ad-1)/c_0$ is bounded, and (b) applies. □

Physical meaning

The modular symmetries of a twisted partition function form a discrete group, with only finitely many elements of bounded size: the moduli space of twisted tori is an orbifold, not a smeared-out quotient.

What the machine verified

Hypothesis `IsJDominated c`; standard axioms (`MoonshineCNGenusZeroAudit3.lean`). Supporting: `glFinTwo_mul_apply`, `glFinTwo_det_eq`, `det_entries_of_mem_symmetryGroup`, `glFinTwo_inv_eq`, `conj_glUpperUnipotent`, `glUpperUnipotent_intCast_mem_symmetryGroup`, `neg_one_mem_symmetryGroup`, `abs_mul_sub_mul_le`, `eq_of_mem_symmetryGroup_of_close`, `finite_fract_upperLeft_div_lowerLeft`, `finite_fract_lowerRight_div_lowerLeft`.

46.12.3 The Hecke step

Theorem 46.57 (Hecke step). *Assume the prime Hecke identity at a prime p. If $g = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in G(f)$ with $0 < |c| < p$, then for some $j < p$ the matrix $\left(\begin{smallmatrix} pa & b-ja \\ c & (d-jc)/p \end{smallmatrix}\right)$ lies in $G(f)$.*

```
theorem exists_heckeStep_mem_symmetryGroup {N : ℕ} (F : ReplicableFamily N) (k : ℕ) {p : ℕ}
    (hp : p.Prime) (hB1 : PrimeHeckeIdentityAt F k p hp.pos) {g : GL (Fin 2) ℝ}
    (hg : g ∈ symmetryGroup (qSeriesFun (F.c k))) (hc0 : g 1 0 ≠ 0) (hcp : |g 1 0| < p) :
    ∃ j : ℕ, j < p ∧ ∃ h ∈ symmetryGroup (qSeriesFun (F.c k)), h 0 0 = p * g 0 0 ∧
      h 0 1 = g 0 1 - j * g 0 0 ∧ h 1 0 = g 1 0 ∧ h 1 1 = (g 1 1 - j * g 1 0) / p
```

(`VOA/Moonshine/MoonshineCNGenusZeroHeckeStep.lean`.)

Proof on paper. Pairing on the connected domain $\mathbb{H}$ (Theorem 46.44(a)) with $u = g$, $v = \mathrm{id}$ and $\beta_0 = (z \mapsto pz)$ gives $\beta \in \Delta(p)$ with $f(p\,gz) = f(\beta z)$ for all z, i.e. $\left(\begin{smallmatrix} p & 0 \\ 0 & 1 \end{smallmatrix}\right) g \beta^{-1}$ lies in G (with $\beta = \left(\begin{smallmatrix} p & 0 \\ 0 & 1 \end{smallmatrix}\right)$ or $\left(\begin{smallmatrix} 1 & j \\ 0 & p \end{smallmatrix}\right)$, both of determinant p, the product has determinant $p \cdot 1 \cdot p^{-1} = 1$). If $\beta = \left(\begin{smallmatrix} p & 0 \\ 0 & 1 \end{smallmatrix}\right)$ this element is $\left(\begin{smallmatrix} a & pb \\ c/p & d \end{smallmatrix}\right)$, whose lower-left entry has $0 < |c/p| < 1$, excluded by Shimizu. So $\beta = \left(\begin{smallmatrix} 1 & j \\ 0 & p \end{smallmatrix}\right)$, and $\left(\begin{smallmatrix} p & 0 \\ 0 & 1 \end{smallmatrix}\right)\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)\left(\begin{smallmatrix} 1 & j \\ 0 & p \end{smallmatrix}\right)^{-1} = \left(\begin{smallmatrix} pa & b-ja \\ c & (d-jc)/p \end{smallmatrix}\right)$. □

Physical meaning

Hecke closure (Cummins 2002): the symmetry group of a replicable twisted partition function is stable under the covering correspondence at admissible primes.

What the machine verified

Hypotheses as displayed (`PrimeHeckeIdentityAt F k p hp.pos`); standard axioms (`MoonshineCNGenusZeroAudit3.lean`).

46.12.4 The symmetry group contains a $\Gamma_1(N')$

Theorem 46.58 (Level). *Let F have period $N \geq 1$, satisfy the prime Hecke identity for k, and let $f = f_k$ not be injective modulo translations. Then:*

(a) (rationality) for $\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in G$ with $c \neq 0$: $a/c \in \mathbb{Q}$ and $c^2 \in \mathbb{Q}$;

(b) (an integral element) G contains an integral matrix $\left(\begin{smallmatrix} A & B \\ C & D \end{smallmatrix}\right)$ with $C \neq 0$, $N \mid C$, $D \equiv 1 \pmod N$;

(c) (integrality of the Hecke step) if $\left(\begin{smallmatrix} A & B \\ C & D \end{smallmatrix}\right) \in G$ is integral, $C \neq 0$, $p > |C|$ is a prime with the prime Hecke identity and $p \mid D$, then $\left(\begin{smallmatrix} pA & B \\ C & D/p \end{smallmatrix}\right) \in G$;

(d) (a lower unipotent) $\left(\begin{smallmatrix} 1 & 0 \\ L & 1 \end{smallmatrix}\right) \in G$ for some integer $L \neq 0$ with $N \mid L$;

(e) (all first columns) if moreover $L \mid c_0$, $a_0 \equiv 1 \pmod L$ and $\gcd(a_0, c_0) = 1$, some integral element of G has first column (a_0, c_0);

(f) $\Gamma_1(|L|) \le G$; *hence* $\Gamma_1(N') \le G$ *for some* $N' \ge 1$ *with* $N \mid N'$.

(`VOA/Moonshine/MoonshineCNGenusZeroLevel.lean`; section variables `{N : ℕ} (F : ReplicableFamily N) (k : ℕ)`.)

From the mathematics to the Lean statement

`Int.ModEq (D ≡ 1 [ZMOD N])` is congruence of integers; `IsCoprime a₀ c₀` is Bezout coprimality, equivalent to gcd $= 1$ over $\mathbb{Z}$. `gamma1GL L.natAbs` is $\Gamma_1(|L|)$ inside $\mathrm{GL}_2(\mathbb{R})$ (Chapter 43). `hD7` is the nontriviality of the single member k.

Proof on paper. (a) By the Hecke step at admissible primes $p > |c|$ (infinitely many, by Dirichlet), G contains elements with lower-left entry c and upper-left entry pa. If a/c were irrational, the residues $\mathrm{fract}(pa/c)$ would be pairwise distinct (their differences $(p-p')a/c$ are not integers), infinitely many, against Theorem 46.56(c). For c^2: apply this to $gTg^{-1} = \left(\begin{smallmatrix} 1-ac & a^2 \\ -c^2 & 1+ac \end{smallmatrix}\right)$: $(1-ac)/(-c^2) = a/c - 1/c^2 \in \mathbb{Q}$. (b) Nontriviality gives σ, τ with $f(\sigma) = f(\tau)$ and $\sigma - \tau \notin \mathbb{Z}$; property P gives $g \in G$ with $g\sigma = \tau$, and $c(g) \neq 0$ (otherwise g is an integer translation). By (a), ac, a^2, c^2 are rational; with H a multiple of N clearing their denominators, $gT^Hg^{-1} = \left(\begin{smallmatrix} 1-Hac & Ha^2 \\ -Hc^2 & 1+Hac \end{smallmatrix}\right)$ is integral, $C = -Hc^2 \neq 0$, $N \mid C$ and $D = 1 + Hac \equiv 1 \pmod N$. (c) The Hecke step gives $\left(\begin{smallmatrix} pA & B-jA \\ C & (D-jC)/p \end{smallmatrix}\right)$ for some $j < p$. If $j \neq 0$, then $p \nmid jC$, so the new lower-right entry has exact denominator p; repeating the step keeps the lower-left entry C and raises the exact p-power of the

denominator of the lower-right entry by one each time. The residues fract(d_n/C) are then pairwise distinct, against Theorem 46.56(c). So $j = 0$. (d) Take the integral element of (b). By Dirichlet choose a prime $p \equiv D \pmod{|C|}$, $p > |C|$; then $p \equiv D \equiv 1 \pmod{N}$, so p is admissible. Choose t with $Ct + D = p$; by (c) applied to $\left(\begin{smallmatrix} A & B \\ C & D \end{smallmatrix}\right) T^t$, $\left(\begin{smallmatrix} pA & B' \\ C & 1 \end{smallmatrix}\right) \in G$, and a left translation turns it into $\left(\begin{smallmatrix} 1 & 0 \\ C & 1 \end{smallmatrix}\right)$. (e) $\left(\begin{smallmatrix} 1 & 0 \\ c_0 & 1 \end{smallmatrix}\right)$ is a power of $\left(\begin{smallmatrix} 1 & 0 \\ L & 1 \end{smallmatrix}\right)$. By Dirichlet choose a prime $q \equiv a_0 \pmod{|c_0|}$, $q > |c_0|$ (admissible since $a_0 \equiv 1 \pmod{L}$ and $N \mid L$), and t with $q \mid 1 + tc_0$; (c) applied to $\left(\begin{smallmatrix} 1 & 0 \\ c_0 & 1 \end{smallmatrix}\right) T^t = \left(\begin{smallmatrix} 1 & t \\ c_0 & 1+tc_0 \end{smallmatrix}\right)$ gives $\left(\begin{smallmatrix} q & t \\ c_0 & (1+tc_0)/q \end{smallmatrix}\right) \in G$, and a left translation makes the upper-left entry a_0. (f) Every $\gamma \in \Gamma_1(|L|)$ has first column (a_0, c_0) as in (e); if $m \in G$ has the same first column, $m^{-1}\gamma$ is an integer upper unipotent, which lies in G. □

Physical meaning

The symmetry group of the twisted partition function contains the full congruence group $\Gamma_1(N')$: the twisted sector is mapped to itself, with the same twist, by every modular transformation that is the identity modulo the level. Physically one expects $\Gamma_1(o(g)h)$-invariance from orbifold modular invariance; here it is derived from the covering relations alone.

What the machine verified

Hypotheses: `0 < N`, `PrimeHeckeIdentity F k`, `¬ IsInjectiveModTranslations (qSeriesFun (F.c k))`. Standard axioms (`MoonshineCNGenusZeroAudit3.lean`). Supporting: `infinite_admissible_primes_gt` (Dirichlet, via Mathlib's `Nat.forall_exists_prime_gt_and_eq_mod`), `rat_mul_den_eq_num_real`, `glLowerUnipotent_mul`, `glLowerUnipotent_zero`, `glLowerUnipotent_inv`, `glFinTwo_mul_glUpperUnipotent_apply`, `glUpperUnipotent_mul_glFinTwo_apply`, `glLowerUnipotent_intCast_mul_mem`.

Trap / dead end

Two published steps fail as printed (a recorded dead end). (i) Cummins–Gannon's Prop. 5.1 is not usable for Γ_1: its first step clears every prime $p \mid c'$, $p \nmid K$, using $n = p^\eta \equiv 1 \pmod{K}$, and such n need not be admissible (its prime factor p need not be $\equiv 1 \pmod{N}$). The Γ_1 version is Cummins (2002), Prop. 2.1. (ii) The printed last step of Cummins (2002), Prop. 2.1, "post-multiplying $\left(\begin{smallmatrix} 1 & 0 \\ bc & 1 \end{smallmatrix}\right)$ by a translation gives $\left(\begin{smallmatrix} 1 & * \\ bc & q \end{smallmatrix}\right)$ with $q \equiv a \pmod{bc}$", cannot hold: right multiplication by translations keeps the lower-right entry $\equiv 1 \pmod{bc}$. The corrected step is (e) above: choose the prime $q \equiv a_0 \pmod{|c_0|}$, then t with $q \mid 1+tc_0$, apply the integral Hecke step, and translate on the left. Further simplifications recorded there: Cummins' condition "c coprime to every admissible n" is not needed for $\Gamma_1(N') \le G$; Cummins–Gannon's Lemmas 5.4, 5.6, 5.7 are not needed in their printed form (rationality of a/c and c^2 suffices, and integrality of the Hecke step is the direct p-adic count of (c)); the prime-clearing loop of Prop. 5.1 is avoided by the conjugation gT^Hg^{-1} of (b).

46.13 Genus zero VI: cusps, commensurability, surjectivity, and the main theorem

46.13.1 Behaviour at the other cusps

Throughout this subsection $\mathfrak{c}$ is J-dominated, $f = \texttt{qSeriesFun}\ \mathfrak{c}$ has property P, $G = G(f)$, and δ is a determinant-one matrix with $\delta T^h \delta^{-1} \in G$ for some $h > 0$ (a parabolic element of G fixing the cusp $\delta\infty$) such that $\delta\infty$ is not G-equivalent to ∞, i.e. $(\gamma\delta)_{10} \neq 0$ for all $\gamma \in G$.

Theorem 46.59 (Cusps). *(a) (Shimizu for conjugates; cusp separation) if $\delta X\delta^{-1} \in G$ with $\det X = 1$, $X_{10} \neq 0$, then $h|X_{10}| \geq 1$; and $h\,(\gamma\delta)^2_{10} \geq 1$ for all $\gamma \in G$.*

(b) (boundedness) $f \circ \delta$ is bounded on $\{\operatorname{Im}\tau \geq Y\}$ for some Y.

(c) (cusp value) $f\circ\delta$ is h-periodic; its cusp function (the function $Q(e^{2\pi i\tau/h}) = f(\delta\tau)$ on the punctured disc) is analytic at 0, and $f(\delta\tau) \to Q(0)$ as $\operatorname{Im}\tau \to \infty$.

(d) (not attained) if $f(\delta\tau) \to w$ then $f(\tau_0) \neq w$ for all $\tau_0 \in \mathbb{H}$.

(e) (separation of cusp values) if also δ' satisfies the hypotheses and $f \circ \delta$, $f \circ \delta'$ tend to the same w, then $(\delta'^{-1}\gamma\delta)_{10} = 0$ for some $\gamma \in G$, i.e. $\gamma(\delta\infty) = \delta'\infty$.

(f) $|f| \to \infty$ at $i\infty$; and a limit of $f \circ \delta$ at $i\infty$ gives `HasCuspValue` *at $\delta\infty$.*

(`VOA/Moonshine/MoonshineCNGenusZeroCusps.lean`; section variable `{c : ℕ → ℂ}`.)

From the mathematics to the Lean statement

`cuspFunction h F` is Mathlib's cusp function of an h-periodic function F on $\mathbb{H}$: the function Q on the disc with $Q(e^{2\pi i\tau/h}) = F(\tau)$, extended at 0 by the limit (Mathlib, `Function.Periodic.cuspFunction`). `AnalyticAt ℂ Q 0` is complex analyticity at 0. `HasCuspValue` and `cuspInfty` are the statement-file notions of Chapter 43; `δ • cuspInfty` is $\delta\infty$. The hypothesis `hP` is property P, stated as an explicit hypothesis so that these results apply to any J-dominated series that has it.

Proof on paper. (a) $\delta T^h\delta^{-1} \in G$ conjugated by $\delta X\delta^{-1}$: Shimizu's lemma for the group $\delta^{-1}G\delta$, whose translations have width h, after conjugating by $\mathrm{diag}(h,1)$ to make the width 1. For cusp separation: $(\gamma\delta)T^h(\gamma\delta)^{-1} = \gamma(\delta T^h\delta^{-1})\gamma^{-1} \in G$ has lower-left entry $-h(\gamma\delta)_{10}^2 \neq 0$, so by Shimizu $h(\gamma\delta)_{10}^2 \geq 1$. Consequently (`im_le_of_eq_comp_smul`): if $f(z) = f(\delta\tau)$, property P gives $z = \gamma\delta\tau$ and $\operatorname{Im} z \leq 1/((\gamma\delta)_{10}^2 \operatorname{Im}\tau) \leq h/\operatorname{Im}\tau$: *points with the value of $f\circ\delta$ at a high point lie low.* (b) A large value of $f(\delta\tau)$ would be taken at a high point (Theorem 46.35), but such points lie low for $\operatorname{Im}\tau$ large. (c) h-periodicity is the invariance under $\delta T^h\delta^{-1}$; a bounded holomorphic function on a punctured disc extends holomorphically (Riemann), which is Mathlib's analyticity of the cusp function of a bounded periodic holomorphic function. (d) If $f(\tau_0) = w$, by the open mapping theorem the values $f(\delta\tau_n) \to w$ are taken at points $z_n \to \tau_0$; but such points lie low, $\operatorname{Im} z_n \leq h/\operatorname{Im}\tau_n \to 0$, a contradiction. (e) The common value w is the value at $q' = 0$ of the cusp function Q' of $f\circ\delta'$, and Q' is non-constant and analytic at 0; by the open mapping theorem every value near w, in particular every $f(\delta\tau)$ with τ high, equals $Q'(q')$ for some small q'. By (d), w itself is not a value of f, so these values $f(\delta\tau) \neq w$ need $q' \neq 0$, i.e. they are values $f(\delta'\tau')$ with $\tau' \in \mathbb{H}$ high; property P gives $X = \delta'^{-1}\gamma\delta$ with $X\tau = \tau'$; if $X_{10} \neq 0$, (a) for δ' and $\operatorname{Im} X\tau \leq 1/(X_{10}^2 \operatorname{Im}\tau)$ contradict both τ,τ' high. (f) $|f| \geq e^{2\pi \operatorname{Im}} - $ `jTail`; and two matrices sending ∞ to $\delta\infty$ differ by an upper triangular matrix, which preserves $\operatorname{Im} \to \infty$. □

Physical meaning

At every degeneration of the twisted torus other than the vacuum one, the twisted partition function tends to a finite value (heuristically: in the dual channel no state of negative energy, which would produce a pole, survives), this value is never attained at a non-degenerate torus, and distinct degenerations have distinct values.

What the machine verified

    Subgroup.Commensurable (symmetryGroup (qSeriesFun c)) 𝒮ℒ
```

(VOA/Moonshine/MoonshineCNGenusZeroIndex.lean.)

From the mathematics to the Lean statement

$\mathcal{D}$ is Mathlib's standard fundamental domain `ModularGroup.fd` of $\mathrm{SL}_2(\mathbb{Z})$; `SL(2, ℤ) / G.comap (mapGL ℝ)` is the coset space of $G \cap \mathrm{SL}_2(\mathbb{Z})$ in $\mathrm{SL}_2(\mathbb{Z})$ and `Quotient.out r` a chosen representative. `Subgroup.Commensurable G 𝒮ℒ`: both relative indices finite (Chapter 43).

Proof on paper. $[\mathrm{SL}_2(\mathbb{Z}) : G \cap \mathrm{SL}_2(\mathbb{Z})] < \infty$ because $\Gamma_1(M) \le G \cap \mathrm{SL}_2(\mathbb{Z})$ has finite index in $\mathrm{SL}_2(\mathbb{Z})$. For $[G : G \cap \mathrm{SL}_2(\mathbb{Z})] < \infty$: given $\gamma \in G$, move γi into $\mathcal{D}$ by an element of $\mathrm{SL}_2(\mathbb{Z})$ written as $\rho^{-1}h$ with ρ one of the finitely many coset representatives and $h \in G \cap \mathrm{SL}_2(\mathbb{Z})$; the element $\kappa = h\gamma \in G$ maps i to $\rho\sigma$ with $\sigma \in \mathcal{D}$ and $f(\rho\sigma) = f(i)$. Near the cusp $\rho\infty$, $f \circ \rho$ stays away from $f(i)$ (it tends to ∞ if $\rho\infty \sim \infty$, and to a cusp value not attained in $\mathbb{H}$ otherwise, Theorem 46.59(d)); so σ lies in a truncated, compact part of $\mathcal{D}$, the entries of κ are bounded, and Shimura's finiteness lemma leaves finitely many κ. Hence G is a finite union of cosets $\kappa(G \cap \mathrm{SL}_2(\mathbb{Z}))$. □

Physical meaning

The group of modular symmetries of the twisted partition function is arithmetic: up to finite index it is the full modular group.

What the machine verified

Hypotheses as displayed; standard axioms (`MoonshineCNGenusZeroAudit3.lean`). Supporting: `upperSL_natCast_mem_Gamma`, `Gamma_le_Gamma1_of`, `mapGL_upperSL_natCast`, `conj_glUpperUnipotent_mem_of_gamma1GL_le` (every rational cusp $\rho\infty$ carries the parabolic $\rho T^M \rho^{-1} \in G$), `det_val_mapGL`, `finiteIndex_comap_of_gamma1GL_le`, `exists_im_ge_norm_le_of_isCompact`.

Theorem 46.61 (Surjectivity onto $\mathbb{P}^1(\mathbb{C})$). *If $\mathfrak{c}$ is J-dominated, $f =$ `qSeriesFun` $\mathfrak{c}$ has property P, $\Gamma_1(M) \le G$ and G is commensurable with $\mathrm{SL}_2(\mathbb{Z})$, then every $w \in \mathbb{C}$ is a value of f on $\mathbb{H}$ or the value of f at an other cusp of G.*

```

(VOA/Moonshine/MoonshineCNGenusZeroSurjective.lean.)

From the mathematics to the Lean statement

`IsOtherCusp` and `HasCuspValue` are the notions of the statement file (Chapter 43). The conclusion is exactly the field `surjective` of `IsNormalizedHauptmodul`. The first quoted theorem says that the other cusps of a group commensurable with $\mathrm{SL}_2(\mathbb{Z})$ are the $\rho\infty$, $\rho \in \mathrm{SL}_2(\mathbb{Z})$, with $\rho\infty$ not G-equivalent to ∞; it is how the abstract `IsCusp` of the statement is converted into the concrete data of the cusp theorems.

Proof on paper. Let V be the set of values in question. V is open: at a value $f(\tau)$ by the open mapping theorem; at a cusp value by the open mapping theorem for the cusp function at 0, whose values at $q \neq 0$ are values of f (`nhds_le_map_cuspFunction_of_other`). V is closed, in fact $V = \overline{f(\mathbb{H})}$: cusp values are limits of values of f; conversely if $w \notin V$, every τ is equivalent to $\rho\sigma$ with $\sigma \in \mathcal{D}$ and ρ among finitely many representatives; near the cusp $\rho\infty$, $f \circ \rho$ stays away from w (Theorem 46.60's estimate `exists_im_bound_norm_sub_ge`), and on the compact truncated domain $|f \circ \rho - w|$ has a positive minimum; so w is not a limit of values. $V \neq \varnothing$ and $\mathbb{C}$ is connected, so $V = \mathbb{C}$. □

Physical meaning

Every complex number is the twisted partition function of some (possibly degenerate) twisted torus: together with property P, the twisted partition function is a bijection from the compactified moduli space to the Riemann sphere.

What the machine verified

Hypotheses as displayed; standard axioms (`MoonshineCNGenusZeroAudit3.lean`). Supporting: `isOtherCusp_smul_infty`, `nhds_le_map_cuspFunction_of_other`.

46.13.3 The main theorem

Theorem 46.62 (Normalised Hauptmodul of the symmetry group). *If $\mathfrak{c}$ is J-dominated, $f =$ `qSeriesFun` $\mathfrak{c}$ has property P, and $\Gamma_1(M) \leq G(f)$ for some $M \geq 1$, then f is a normalised Hauptmodul of $G(f)$ (all eight fields of* `IsNormalizedHauptmodul`*).*

```
theorem isNormalizedHauptmodul_symmetryGroup {c : ℕ → ℂ} (hc : IsJDominated c)
    (hP : ∀ z w : ℍ, qSeriesFun c z = qSeriesFun c w →
      ∃ γ ∈ symmetryGroup (qSeriesFun c), γ • z = w)
    {M : ℕ} (hM : 0 < M) (hΓ1 : gamma1GL M ≤ symmetryGroup (qSeriesFun c)) :
    IsNormalizedHauptmodul (symmetryGroup (qSeriesFun c)) (qSeriesFun c)
```

(VOA/Moonshine/MoonshineCNGenusZeroMain.lean.)

From the mathematics to the Lean statement

Recap. `IsNormalizedHauptmodul Γ f` says: f is holomorphic and Γ-invariant with $f - q^{-1} \to 0$ at $i\infty$, has a finite value at every other cusp, and the induced map from $\Gamma\backslash(\mathbb{H} \cup \{\text{cusps}\})$ to $\mathbb{P}^1(\mathbb{C})$ (sending ∞ to ∞) is injective and surjective. **Field by field** (Chapter 43, definition of `IsNormalizedHauptmodul`): `holomorphic` and `normalized` are Theorem 46.33; `invariant` is the definition of $G(f)$; `injective` is property P; `cuspFinite`, `cuspValue_not_attained`,

`cuspValue_injective` are Theorem 46.59(c), (d), (e), applied at $\delta = \rho \in \mathrm{SL}_2(\mathbb{Z})$ with $h = M$ after converting an abstract other cusp into $\rho\infty$ (Theorem 46.61, first part, using commensurability from Theorem 46.60); `surjective` is Theorem 46.61. Nothing in the eight fields is weakened: the theorem concludes exactly the statement-file predicate.

Proof on paper. As in the dictionary; the order matters: commensurability (Theorem 46.60) must be proved before the cusp fields, because `IsOtherCusp` only provides a parabolic element fixing the cusp, and that the cusp is $\rho\infty$ for some $\rho \in \mathrm{SL}_2(\mathbb{Z})$ comes from commensurability. □

Physical meaning

The twisted partition function is a global coordinate on the compactified moduli space of twisted tori, which is therefore a sphere.

What the machine verified

Hypotheses as displayed; standard axioms (`MoonshineCNGenusZeroAudit3.lean`).

Theorem 46.63 (The genus-zero theorem for replicable families). *Let $N \geq 1$ and F a replicable family of period N satisfying the prime Hecke identity for every member, with no member injective modulo translations. For every k there are $\Gamma \leq \mathrm{GL}_2(\mathbb{R})$ and $N' \geq 1$ with $\Gamma \leq \mathrm{SL}_2(\mathbb{R})$, $\Gamma_1(N') \leq \Gamma$, Γ commensurable with $\mathrm{SL}_2(\mathbb{Z})$, and f_k a normalised Hauptmodul of Γ. (The proof takes $\Gamma = G(f_k)$ and also obtains $N \mid N'$; neither fact is part of the Lean type.)*

```
theorem ReplicableFamily.exists_hauptmodul_gammaOne {N : ℕ} (hN : 0 < N)
    (F : ReplicableFamily N) (hB1 : ∀ k, PrimeHeckeIdentity F k)
    (hD7 : F.NotInjectiveModTranslations) (k : ℕ) :
    ∃ (Γ : Subgroup (GL (Fin 2) ℝ)) (N' : ℕ), 0 < N' ∧ Γ.HasDetOne ∧ gamma1GL N' ≤ Γ ∧
      Subgroup.Commensurable Γ 𝒮ℒ ∧ IsNormalizedHauptmodul Γ (qSeriesFun (F.c k))
```

(`VOA/Moonshine/MoonshineCNGenusZeroMain.lean`, namespace `VOA.Moonshine.ConwayNorton`.)

From the mathematics to the Lean statement

Hypotheses. `hN : 0 < N`: positive period. `hB1 : ∀ k, PrimeHeckeIdentity F k`: discharged for every family by `M8.ReplicableFamily_primeHeckeIdentity` (Theorem 46.36). `hD7 : F.NotInjectiveModTranslations`: discharged for every family of positive period by `M8.ReplicableFamily_notInjectiveModTranslations` (Theorem 46.41). So the theorem holds for every replicable family of positive period, although no single Lean declaration states that composite for abstract families (the composition is made for the McKay–Thompson families in `M8.conwayNorton_of_finOrder_of_completelyReplicable` and `conwayNortonGammaOne_holds`).

Conclusion. The clauses are those of `ConwayNortonGammaOne` (Chapter 43) with f_k in place of T_g. `Γ.HasDetOne` is $\Gamma \leq \mathrm{SL}_2(\mathbb{R})$. The existential is witnessed by $G(f_k)$; by the remark in Definition 46.32 this is the only possible choice up to ± 1.

How the statement could have been wrong. (i) A degenerate witness: `IsNormalizedHauptmodul` has the field `injective`, which pins Γ to the full invariance group, so one cannot take a tiny Γ; and `gamma1GL N' ≤ Γ` with commensurability rules out Γ being only the translations. (ii) A vacuous hypothesis: the hypotheses are satisfied by the McKay–Thompson families (which are Lean instances `mckayThompsonReplicableFamily hrep g hg`, Chapter 43, given `hrep : CompletelyReplicable`, now the theorem `completelyReplicable_holds` of Chapter 49), and on paper already by J itself (the constant family $c(k,n) = c_J(n)$ of period 1 is replicable by Theorem 46.11; no Lean

declaration packages it as a `ReplicableFamily 1`). (iii) The modular fictions $q^{-1} + \zeta q$ satisfy replication and are not Hauptmoduln of any group commensurable with $\mathrm{SL}_2(\mathbb{Z})$; they are excluded by the clause `zero_eq_J` of `ReplicableFamily`, which enters the proof exactly once, in the tower (Theorem 46.40(b)).

Proof on paper. Property P (Theorem 46.53), $\Gamma_1(N') \leq G$ (Theorem 46.58), commensurability (Theorem 46.60) and Theorem 46.62. □

Physical meaning

For every cyclic family of twisted sectors satisfying the covering relations and attached to the moonshine partition function, each twisted partition function is a Hauptmodul: the genus-zero property is a consequence of the string-theoretic Hecke relations.

What the machine verified

Hypotheses `hN`, `hB1`, `hD7`; standard axioms (`MoonshineCNGenusZeroAudit3.lean`; the audit's docstring notes that `#print axioms` does not list `hB1`, `hD7`). Both are theorems; see the dictionary.

46.13.4 The Conway–Norton consequences

Theorem 46.64 (Conway–Norton from complete replicability). *(a) For every $g \in \mathrm{Aut}(V^\natural)$ of finite order, $T_g = f_1$ for the McKay–Thompson family of g.*

(b) `CompletelyReplicable`*, together with the prime Hecke identity and nontriviality for the McKay–Thompson families, implies* `ConwayNortonGammaOne`.

(c) If moreover every automorphism of $V^\natural$ has finite order, `ConwayNortonConjecture` *holds; the same with the two inputs stated for all replicable families.*

```

(`VOA/Moonshine/MoonshineCNGenusZeroMain.lean`.)

From the mathematics to the Lean statement

`mckayThompsonReplicableFamily hrep g hg` is the replicable family $c(k,n) = \mathrm{tr}(g^k | V^\natural{}_{n+1})$ of period $o(g)$ (Chapter 43). In (c) the passage from Γ_1 to Γ_0 is the bridge `conwayNorton_of_gammaOne` of Chapter 43, which needs complete replicability and finite order but not rationality of traces. The hypotheses `hB1` and `hD7` are discharged by the theorems in `M8.conwayNorton_of_finOrder_of_completelyReplicable (hfin) (hrep)` (file `MoonshineLRConwayNorton.lean`, Chapter 47), and `hrep`, `hfin` by `completelyReplicable_holds` and `M8.autVnat_isOfFinOrder` (Chapters 47, 49).

Proof on paper. (a) `mckayThompsonFun_eq_qSeriesFun` and $g^1 = g$. (b) Theorem 46.63 for the family of g, member $k = 1$. (c) (b) and the bridge. □

Physical meaning

The moonshine theorem: every twisted partition function of the moonshine CFT is a genus-zero Hauptmodul.

What the machine verified

Conditional on the displayed hypotheses (all discharged elsewhere: `conwayNorton` has no hypotheses, Chapter 43). Standard axioms (`MoonshineCNGenusZeroAudit3.lean`).

46.14 How the genus-zero proof compares with the literature

Borcherds' finite check. Borcherds (1992) proved complete replicability of all T_g and then observed that a completely replicable function is determined by finitely many of its coefficients (Norton; Alexander–Cummins–McKay–Simons): it suffices to compare the first few coefficients of T_g, computed from the character table of $\mathbb{M}$ and the decomposition of the first few $V^\natural{}_n$, with those of the 171 Hauptmoduln proposed by Conway and Norton, each separately known to be a Hauptmodul of a genus-zero group and completely replicable. This needs the character table, the list of groups and a case check; none of it is available in Lean, and the route was rejected.

Cummins–Gannon and Cummins. Cummins and Gannon (1997) gave a uniform argument: a completely replicable function with suitable growth is a Hauptmodul of a genus-zero group (or a degenerate "modular fiction"). Their proof: replication ⇒ modular equations (a symmetric polynomial $\Psi_n(X,Y)$ with $\Psi_n(f(\tau), f(\beta\tau)) = 0$) ⇒ coincidences $f(z_1) = f(z_2)$ produce local symmetries ⇒ local symmetries continue analytically along paths to maximal domains, which are invariant under a dense group of affine maps and hence equal to $\mathbb{H}$ or a sector; sectors are excluded; so local symmetries are elements of $\mathrm{Aut}(\mathbb{H}) = \mathrm{PSL}_2(\mathbb{R})$ ⇒ the symmetry group is discrete, Hecke-closed, contains a congruence subgroup ⇒ genus zero. Cummins (2002) gave the group-theoretic step for $\Gamma(N)$ and Γ_1-type conclusions. Earlier, Martin (1996) studied modular invariance of completely replicable functions, and the convergence of replicable functions was treated by Kozlov (as cited by Cummins–Gannon).

The library's route. It follows Cummins–Gannon's architecture but replaces almost every analytic step:

- *Modular equations* are needed only at primes and only as the *pairing* of values (Theorem 46.43); the modular polynomial Ψ_n, its degree and symmetry, Newton's identities and composite n

are never used. The prime Hecke identity is a pure Hecke-algebra computation valid for every family (Theorem 46.36).

- *Analyticity* of T_g on $\mathbb{H}$ is free from $|c_g(n)| \le c(n)$, replacing Mahler's and Kozlov's convergence results.
- *Local symmetries*: no analytic continuation, no maximal domains, no density lemma, no $\mathrm{Aut}(\mathbb{H}) = \mathrm{PSL}_2(\mathbb{R})$. One intertwining sequence on a fixed disc gives a real linear ODE (Theorems 46.46, 46.47); its four explicit solution families extend globally by a boundary argument (Theorems 46.49, 46.50) and are classified by growth and top injectivity (Theorem 46.51). The reality of the ODE coefficients (from the rational, hence real, Hecke data) is what forces real Möbius maps. This replacement is new mathematics relative to the published proofs.
- *Critical points*: Cummins–Gannon's construction at critical pairs has a gap (equal multiplicities); the library avoids critical targets and uses closedness of the symmetry group (Theorem 46.53).
- *Top injectivity* is a three-line Lipschitz estimate with a height depending only on J; Cummins–Gannon's inexplicit version, and the explicit injective region $\{\mathrm{Im} > 1\}$ of the original plan, are not needed.
- *Nontriviality* (the symmetry group is not just the translations) is new: a tower argument down to J through the replicates, using only that J's coefficients are unbounded (Theorems 46.40, 46.41); it needs neither integrality, nor the area theorem, nor Galois descent. It is the place where the clause $c(0,\cdot) = J$ is used, and it excludes the modular fictions.
- *The congruence subgroup*: rationality of a/c and c^2, an integral element by conjugating a translation, the p-adic integrality count, and a corrected final step of Cummins' Prop. 2.1 (Theorem 46.58); Cummins–Gannon's Prop. 5.1 is not valid for Γ_1.
- *Genus zero* without Riemann surfaces: the eight elementary fields of `IsNormalizedHauptmodul` are proved directly; commensurability by Shimura's finiteness lemma on one orbit (no generic fibres), surjectivity by an open-and-closed argument (no sequences, no finiteness of cusp classes).
- Γ_0 is not obtained here from rationality of traces (Cummins–Gannon's Γ_0 case): the library gets $\Gamma_1(N')$ here and upgrades to Γ_0 by the replication-at-primes bridge of Chapter 43; rationality of traces is then a corollary (Chapter 49).

The paper blueprint is part of the authors' working notes (unrefereed by an outside party); the Lean proof is the machine certificate.

46.15 Recorded traps and dead ends

The dead ends specific to single steps are recorded where they occur: the circularity of deriving the product identity from the Lie algebra (§46.4), the critical-pair gap and the local-to-global dead ends (§46.11), and the two published steps that fail as printed (§46.12). The remaining ones are collected here.

Trap / dead end

The sign convention for momenta (a recorded dead end). Borcherds' root (m, n), with root space $V^{\natural}_{1+mn}$, is the repository momentum $(m, -n)$ of the lattice `lorentzianLattice` (norm $+2xy$), whose root space is $V^{\natural}_{1-xy}$. A product $\prod_{x,y\ge 1}$ over repository momenta

is wrong: those root spaces vanish. In this chapter the conversion happens once, in `monsterLie_weightAction_trace` (the root space at γ is `monsterLieMomentum ![γ.1, -γ.2]`, and $1-\gamma_1(-\gamma_2) = 1+\gamma_1\gamma_2$).

Trap / dead end

Modular fictions satisfy replication (Chapter 43). For every $a \in \mathbb{C}$, $q^{-1}+aq$ satisfies all replication identities with replicates $q^{-1}+a^k q$; with $a = \zeta_N$ these form a periodic family, injective modulo $\mathbb{Z}$, whose symmetry group is only the translations. The genus-zero theorem therefore cannot hold for replicable families not attached to J, and the proof must use $c(0,\cdot) = J$; it does so exactly in the nontriviality argument (Theorem 46.40(b)).

Trap / dead end

Complete replicability over all of $\mathrm{Aut}(V^\natural)$ **needs finite order.** The fixed definition `CompletelyReplicable` quantifies over all g; for an element of infinite order (if there were one) T_g need not converge and the statement could not be proved. The library therefore proves `CompletelyReplicableOfFinOrder` first and passes to `CompletelyReplicable` with `hfin`, discharged in Chapter 47. The statement file was not changed.

Trap / dead end

Parts of the original plan that were not formalised. The modular polynomials $\Psi_{g,n}$ (degree $\psi(n)$, symmetry), the Hecke identity for composite n, the explicit injective region $\{\mathrm{Im} > 1\}$, the exponential identity $p(f(\sigma)-f(\tau)) = (1-p/q)\exp(-\sum R_m(\tau)p^m/m)$, "large values from the top" by Rouché, the Parseval step of nontriviality, and the logarithmic Faber identity were all argued on paper in the authors' route notes and then found unnecessary. They are *not* Lean theorems; they should not be taken as formalised. Likewise the product form of the twisted identity with roots of unity, and its exponential form, are paper statements only.

Trap / dead end

"Product" means "series with the product's logarithmic derivative". `coneProd` is defined through the ODE $pA' = A \cdot \mathrm{coneLog}$ (Definition 46.17); the comparison with literal finite products, proposed as `coneProd_single`, was not written. This is a documentation-level gap, not a mathematical one (the classical product satisfies the same ODE), and it does not affect the use of `knz_product` in Chapter 47, which only compares `coneProd`s.

46.16 The audit modules

The chapter's audit modules contain only `#print axioms` commands. The targeted builds of each (see Chapter 50) reported every line as `[propext, Classical.choice, Quot.sound]` and no `sorryAx`; this chapter did not re-run them.

module	reports	covers
`MoonshineCNGenusZeroAudit.lean`	61	GenusZero{Analytic, Interface, Top, Shimizu, Pairing}
`MoonshineCNGenusZeroAudit2.lean`	87	GenusZero{Partner, Local, Overlap, ODE, Boundary, Families, Extension, Classification, Moebius, PropertyP, Critical, Group}
`MoonshineCNGenusZeroAudit3.lean`	68	GenusZero{Discrete, HeckeStep, Level, Cusps, Index, Surjective, Main}
`MoonshineLRFaberAudit.lean`	35	LRFaber, LRFaberGenerating
`MoonshineLRM5Audit.lean`	102	LRM5{Hecke, Poly, Invariance, Cosets, CosetMap, Replicable, KNZ, Ode, Product}
`MoonshineLRHeckeAudit.lean`	14	LRHecke
`MoonshineLRJUnboundedAudit.lean`	4	LRJUnbounded
`MoonshineLRTowerAudit.lean`	5	LRTower
`MoonshineLRCoeffBoundAudit.lean`	5	LRCoeffBound
`MoonshineLRNontrivialAudit.lean`	10	LRHeckeExpansion, LRNontrivial, LRPropertyP

(The "reports" column counts the `#print axioms` *commands* in each file in the release, not mentions of the phrase in docstrings.) The files `MoonshineCNTwisted*` and `MoonshineCNReplication*` have no audit module of their own; their declarations are printed in `VOA/Moonshine/MoonshineCNAudit18.lean` (a Chapter 43 file), which itself contains 188 commands. Building it replays the audits it imports (`MoonshineCNAudit` to `MoonshineCNAudit17`, the Γ_0 and genus-zero audits); the build of that whole chain reported 2,268 reports with standard axioms and 0 `sorryAx` (build record, Chapter 50; not re-run here). The `MoonshineCNGenusZeroAudit3` docstring states explicitly that its headline theorems are conditional on `hB1` and `hD7`, which `#print axioms` does not list.

46.17 Referee's checklist

"std." means `#print axioms` = `[propext, Classical.choice, Quot.sound]`. Namespaces: `M8.` = `VOA.Moonshine.ConwayNorton.M8`; otherwise `VOA.Moonshine.ConwayNorton`.

declaration	intended meaning	hypotheses; status	check

Harvey, Commun. Math. Phys. 119 (1988) 221–241, for twisted partition functions of the moonshine orbifold.

The development record. The development was recorded in the authors' working notes, which are not part of the release. The J-replicability and product identity, the Faber polynomials, the prime Hecke identity, the unboundedness of J's coefficients and nontriviality were written on Leonardo Rastelli's side; the twisted identities, replication and the rest of the genus-zero proof on Fedor Popov's side. What this chapter states as machine-confirmed rests on the build and audit records of Chapter 50.

Chapter 47

Conway–Norton for the automorphism group of the moonshine module

This chapter documents the release of the library named in the front matter; every Lean quotation is checked by `scripts/textbook/sync.py` to occur verbatim (up to whitespace and comments) in the source files of that release. (The axiom audit of the `Aut*` files cited in the status boxes is `VOA/Moonshine/MoonshineLRLiftAudit.lean`.) This chapter supplies the last two inputs of the library's Conway–Norton theorem and assembles it.

What exactly is proved. The final theorem is the *qualitative genus-zero form* of the Conway–Norton conjecture, for the full automorphism group of the library's $V^\natural$: for every $g \in \mathrm{Aut}(V^\natural)$ the McKay–Thompson series T_g is the normalised Hauptmodul of *some* genus-zero group Γ_g containing some $\Gamma_0(N)$ and commensurable with $\mathrm{SL}_2(\mathbb{Z})$. It does *not* identify Γ_g with the group in Conway and Norton's table, does not require Γ_g to lie in the normaliser of $\Gamma_0(N)$, and does not relate N to the order of g; so it is weaker than the table-level conjecture (Chapter 43, §43.6.3). It is a statement about $\mathrm{Aut}(V^\natural)$, whatever that group is; its link with the Monster (AxiomMath's group AutO) is the subject of Chapters 48–49, and the identification $\mathrm{Aut}(V^\natural) \cong \mathrm{AutO}$ there is conditional on the named hypothesis `GmatEqAutO`. The machine evidence is targeted and umbrella builds with `#print axioms` reports (listed in the status boxes); the book's authors did not re-run them.

Where the chapter sits. Chapter 43 stated the conjecture as the Lean proposition `ConwayNortonConjecture`; Chapters 44–46 built the Monster Lie algebra $\mathfrak{m}$, its Borcherds–Kac–Moody structure *given* that $\mathfrak{m}$ is generated by its simple root spaces, the twisted denominator identities, complete replicability and the case-free genus-zero argument. At the end of Chapter 46 the conjecture is reduced, in Lean, to exactly two inputs:

(I) **generation**: the Monster Lie algebra $\mathfrak{m}$ is generated by its Cartan subalgebra and its simple root spaces (`MonsterLieSimpleRootGeneration`);

(II) **finite order**: every automorphism of the moonshine vertex operator algebra $V^\natural$ has finite order (`∀ g : AutVnat, IsOfFinOrder g`).

This chapter proves both, with no hypotheses, and assembles the final theorem `M8.conwayNortonConjecture_holds : ConwayNortonConjecture`, which is re-exported under its official name `ConwayNorton.conwayNorton` (Chapter 43). Along the way it documents the files on the automorphism group $\mathrm{Aut}(V^\natural)$ itself: that every automorphism is determined by its action on the Griess algebra $V^\natural{}_2$, the triality automorphism σ, and the theorem that $\mathrm{Aut}(V^\natural)$ is a *finite* group.

The results in one paragraph. With no hypotheses and only Lean's three standard axioms, the library proves: (a) restriction to the Griess algebra, $\mathrm{Aut}(V^\natural) \to \mathrm{Aut}({V^\natural}_2, \times, \langle\cdot,\cdot\rangle)$, is injective (`vnat GriessRestrict_injective`); (b) the triality involution $\sigma^\natural$ of Chapters 40–42 is an automorphism of $V^\natural$ (`sigmaAut`); (c) every automorphism of $V^\natural$ has finite order (`autVnat_isOfFinOrder`); (d) $\mathrm{Aut}(V^\natural)$ is finite (`finite_autVnat`); (e) the Monster Lie algebra is generated by its simple root spaces (`monster LieSimpleRootGeneration`); and (f) the genus-zero form of the Conway–Norton conjecture, as just described, holds for every automorphism of $V^\natural$ (`conwayNortonConjecture_holds`).

Finite order and finiteness. (d) implies (c): in a finite group every element has finite order (Lagrange). The library nevertheless proves (c) directly, and it is (c), not (d), that the final assembly uses (`conwayNortonConjecture_holds := conwayNorton_of_isOfFinOrder autVnat_isOfFinOrder`; `finite_autVnat` appears in no proof of the Conway–Norton chain). The reason is the order in which the results were obtained: finite order was the last missing input of the conjecture and was proved first, by the periodicity lemma of §47.3; finiteness was proved afterwards, for the identification with the Monster, by a separate algebraic-geometry lemma (§47.6) which does not use the periodicity lemma. The two proofs share their VOA ingredients (Ising vectors, rigidity, the faithfulness lemmas, σ). A reorganised library could prove (d) first and obtain (c) from it; the book documents the library as it is. Statements (c) and (d) are proved *without any group theory*: no fact about the Monster, its order, its classes or its subgroups is used. They rest on explicit computations with *Ising vectors* in ${V^\natural}_2$ and on two pieces of finite-dimensional algebra (a periodicity lemma and a finiteness lemma for "rigid idempotents" of a commutative non-associative algebra). Statement (e) is derived from the product formula for $J(p) - J(q)$ of Chapter 46 by a dimension count ("the sandwich"); there is no Lie-theoretic shortcut, for the reason given in the warning at the end of §47.7.5.

What this chapter does. It

(1) recalls the automorphism group `AutVnat` and its action on the Griess algebra, and proves faithfulness (§47.1);

(2) presents the triality automorphism σ (§47.2);

(3) proves that every automorphism has finite order: the abstract periodicity lemma (§47.3), the explicit Ising vectors and their rigidity (§47.4), and the assembly (§47.5);

(4) proves that $\mathrm{Aut}(V^\natural)$ is finite (§47.6);

(5) proves that $\mathfrak{m}$ is generated by its simple root spaces, and explains how this feeds the twisted denominator identities (§47.7);

(6) assembles the Conway–Norton theorem and relates it to `conwayNorton` (§47.8);

(7) accounts for all 33 files assigned to the chapter (§47.9), collects the recorded traps (§47.10), and ends with the referee's checklist and the references.

As everywhere in this book, our concern is the *meaning* of the Lean statements; proofs are explained mathematically, and we do not describe how the Lean proof scripts are organised. The most important fidelity checks for a referee are those of Theorem 47.4 (what "an automorphism fixing ${V^\natural}_2$ is the identity" says), Theorem 47.19 (finite order), Theorem 47.25 (generation) and Theorem 47.27 (the final assembly).

Notation used throughout. We use the notation of Chapters 30–42 and 43.

- Λ is the Leech lattice (`leech`, Chapter 30), with form $\langle\cdot,\cdot\rangle$ (`leech.form`), even, positive definite, unimodular, with no vectors of norm 2. We write $\Lambda_4 = \{\alpha \in \Lambda : \langle\alpha,\alpha\rangle = 4\}$ for the *minimal vectors*; there are 196560 of them, a finite set (`normFour_finite`, Chapter 32).

- $V_\Lambda = M(1)\otimes\mathbb{C}[\Lambda]$ is the lattice vertex operator algebra (Chapter 31); $h_a(-k-1)$, $a = 1,\dots,24$, are the oscillators in an orthonormal frame; the coordinates of $\gamma \in \Lambda$ in that frame are γ_a (`chargeCoord leech γ a`), so that $\sum_a \gamma_a\delta_a = \langle\gamma,\delta\rangle$.
- $\varepsilon(\alpha,\beta) \in \{\pm1\}$ is the lattice cocycle (`latticeCocycle leech α β`, Chapter 31); it is bimultiplicative and $\varepsilon(\alpha,\beta)^2 = 1$. Textbooks often normalise it so that $\varepsilon(\alpha,\alpha) = (-1)^{\langle\alpha,\alpha\rangle/2}$, which would make $\kappa_\alpha := \varepsilon(\alpha,-\alpha) = +1$ for minimal α. The library's cocycle is only a bimultiplicative sign function built from a chosen basis, without that normalisation (any such cocycle gives an isomorphic lattice VOA, so nothing is lost); its signs are *never evaluated*, and in particular κ_α is not known to be $+1$. The proofs below keep κ_α symbolic.
- θ is the lift of -1; V_Λ^+ (`VPlus`, `leechVOAPlus`) is the fixed-point subalgebra (Chapter 32); $x_\beta = e^\beta + e^{-\beta} \in V_\Lambda^+$ (`frameX0P β`, Chapter 39); $x_0 = 2\cdot\mathbf{1}$; $x_{-\beta} = x_\beta$.
- $q_{ab} = h_a(-1)h_b(-1)\mathbf{1} \in (V_\Lambda^+)_2$ (`qP a b`, Chapter 41); for $u,v \in \mathfrak{h} = \mathbb{C}\otimes\Lambda$ we write $Q(u,v) = u(-1)v(-1)\mathbf{1} = \sum_{a,b} u_a v_b\, q_{ab}$; on lattice vectors $Q(\alpha,\beta)$ is `dV α β` (Chapter 41).
- T^+ (`TP`) is the θ-fixed part of the twisted module $V_\Lambda^T = S[\theta]\otimes T$ (Chapters 34–36), with its V_Λ^+-module structure `plusModule`.
- $V^\natural = V_\Lambda^+ \oplus T^+$ is the carrier `Vnat` (pairs (x,t)), and `VnatVOA` the vertex operator algebra on it (Chapter 43, Definition 43.1). For $v \in {V^\natural}_2$ the *zero mode* is $o(v) = v_{(1)}$; it preserves every weight space.
- The *Griess product* on ${V^\natural}_2$ is $u \times v = u_{(1)}v$ (`griessMul`, Chapter 5). It is commutative because ${V^\natural}_1 = 0$.

A warning about letters. Some letters carry more than one meaning, always distinguished by decoration or context: e^β is a lattice exponential, $e_{\alpha,s}$ an Ising vector (§47.4), e_α an operator on the module T, and a bare e a generic idempotent (§47.3) or a real root vector (§47.7); x_β is $e^\beta + e^{-\beta}$, while x without subscript is the twisted generator of T^+; σ is the triality automorphism except in §47.7, where it denotes an arbitrary finite-order automorphism; Γ is a degree in the PBW counting, Γ_g a modular group; $\mathfrak{m}$ is the Monster Lie algebra, $\mathfrak{m}_p$ a maximal ideal; $R(V^\natural)$ is the set of rigid idempotents, R alone the radical of a form.

47.1 The automorphism group and the Griess algebra

47.1.1 The object

The vertex operator algebra `VnatVOA` and its automorphism group `AutVnat` were defined in Chapter 43 (Definition 43.1); the file that defines them, `VOA/Moonshine/AutVnat.lean`, belongs to the present chapter. We recall the definitions and add the facts from that file that were not needed there.

Definition 47.1 (The moonshine module as a named VOA; its automorphisms). $V^\natural$ is the vertex operator algebra on $V_\Lambda^+ \oplus T^+$ with the block vertex operator, vacuum and conformal vector of Chapters 38–42. An automorphism of $V^\natural$ is a $\mathbb{C}$-linear bijection $g : V^\natural \to V^\natural$ with $g(u_{(n)}v) = (gu)_{(n)}(gv)$ for all $u,v \in V^\natural$ and *all* $n \in \mathbb{Z}$, $g\mathbf{1} = \mathbf{1}$ and $g\omega = \omega$. $\mathrm{Aut}(V^\natural)$ is the group of automorphisms.

```

(`VOA/Moonshine/AutVnat.lean`, namespace `VOA.Moonshine.AutMonster`.)

From the mathematics to the Lean statement

`vnat_twistedLocality` is the twisted×twisted locality of the block vertex operator, extracted from the existential theorem `moonshine` of Chapter 42 (its proof goes through the σ-key `sigmaKey_Dnat` of the standard triality data `Dnat`; Chapter 42). It is the only hypothesis of the constructor `vnatVOA` of Chapter 38, so `VnatVOA` is a definition with *no* hypotheses, and it is the very object of `moonshine` (the theorems `VnatVOA_Y`, `VnatVOA_vacuum`, `VnatVOA_conformalVector`, `VnatVOA_grading` of the same file identify its data by `rfl`). `VnatVOA.IsSimple` is simplicity in the sense of Chapter 38; `VnatVOA.vacuum ≠ 0` is needed to define the Griess form below. `Aut VnatVOA` is the structure `VOA.Aut` quoted in Chapter 43: a linear equivalence with the three fields `map_smul'` ($g(u_{(n)}v) = (gu)_{(n)}(gv)$ for every $n \in \mathbb{Z}$), `map_vacuum`, `map_omega`. So an automorphism in this library preserves the vacuum, the conformal vector and *all* modes, which is the textbook definition (FLM, Gannon §5.2). Because $g\omega = \omega$, g commutes with every $L_n = \omega_{(n+1)}$ and maps each $V^\natural{}_n$ onto itself (`GriessAut.aut_map_grading`).

Physical meaning

$V^\natural$ is the chiral algebra of the holomorphic $c = 24$ "Monster" conformal field theory; an automorphism is a *global internal symmetry*: an invertible operator on the space of states that fixes the vacuum, commutes with the stress tensor (so it preserves energies) and intertwines every operator product expansion $u(z)v(w) \sim \sum_n (u_{(n)}v)(w)/(z-w)^{n+1}$. The requirement for *all* n, singular and regular terms alike, is what makes g a symmetry of the full operator algebra rather than of its leading singularities.

What the machine verified

Definitions and theorems with no hypotheses. `VnatVOA`, `AutVnat` are used by every final theorem of the part, whose `#print axioms` is `[propext, Classical.choice, Quot.sound]` (e.g. `conwayNorton` in `VOA/Moonshine/MoonshineCNFinalAudit.lean`); they are covered by those audits.

47.1.2 The Griess algebra and the restriction map

Definition 47.2 (Griess algebra, its automorphism group, restriction)**.** Let W be a vertex operator algebra with $\mathbf{1} \neq 0$. On W_2 put the product $u \times v = u_{(1)}v$ and the *intrinsic form* $\langle u, v\rangle_3$ defined by $u_{(3)}v = \langle u, v\rangle_3\,\mathbf{1}$ (note $u_{(3)}v \in W_0$). GriessAut(W) is the group of linear automorphisms of W_2 that preserve $\times$ and $\langle\cdot,\cdot\rangle_3$. Restriction $g \mapsto g|_{W_2}$ is a group homomorphism $\mathrm{Aut}(W) \to \mathrm{GriessAut}(W)$. W is *generated by* W_2 if every subspace containing W_2 and closed under all n-th products is W. For $W = V^\natural$ these are `GriessAutVnat` and `vnatGriessRestrict`.

noncomputable def vnatGriessRestrict : AutVnat →* GriessAutVnat :=
  GriessAut.griessRestrict VnatVOA_vacuum_ne_zero
```

(VOA/Moonshine/AutVnat.lean.)

From the mathematics to the Lean statement

W.grading 2 ≃ₗ[ℂ] W.grading 2 is the type of $\mathbb{C}$-linear automorphisms of W_2; Subgroup of it is a subgroup of $\mathrm{GL}(W_2)$. W.griessMul u v is $u_{(1)}v$ (Chapter 5, Definition 5.7). griessForm hvac u v is the coefficient of $\mathbf{1}$ in $u_{(3)}v$ (griessForm_spec states $u_{(3)}v = \langle u, v\rangle_3\mathbf{1}$; RigidBridge.vacCoeff reads off the coefficient, which needs $W_0 = \mathbb{C}\mathbf{1}$ *and* $\mathbf{1} \neq 0$, whence hvac). Defining the form intrinsically, through $u_{(3)}v$, means that its invariance under automorphisms is automatic (g fixes $\mathbf{1}$ and intertwines the (3)-product); no uniqueness theorem for invariant forms is needed. autRestrict α 2 is the restriction of α to W_2 (Chapter 43). →* is a monoid (hence group) homomorphism. GeneratedByWeightTwo W: every subspace S with $W_2 \leq S$ and $u_{(n)}v \in S$ for $u, v \in S$, $n \in \mathbb{Z}$, is all of W (⊤); this is "W is generated by W_2 as a vertex algebra" (note that $\mathbf{1} \in S$ is not required: $\mathbf{1} = (2/c)\,\omega_{(3)}\omega$ when $c \neq 0$). vnat_griessMul_comm is commutativity, from $V^\natural_1 = 0$ (griessMul_comm_of_grading1_eq_bot: skew-symmetry gives $u_{(1)}v = v_{(1)}u + \sum_{k\geq 1} \pm\frac{1}{k!}L_{-1}^k\, v_{(1+k)}u$, and $v_{(2)}u \in V^\natural_1 = 0$, $v_{(3)}u \in V^\natural_0 = \mathbb{C}\mathbf{1}$ is killed by L_{-1}, $v_{(m)}u = 0$ for $m \geq 4$ by weight). **Could this be vacuous?** If $V^\natural_0$ were not spanned by $\mathbf{1}$ the form would be ill-defined; it is ($V^\natural$ is of CFT type). GriessAutVnat is a subgroup of $\mathrm{GL}_{196884}(\mathbb{C})$; nothing here asserts what it is.

Physical meaning

$V^\natural_2$ is the space of weight-2 fields of the Monster CFT: the stress tensor ω and 196883 Virasoro primaries of dimension 2. The Griess product $u \times v$ is the coefficient of $(z-w)^{-2}$ in the OPE $u(z)v(w)$, and $\langle u, v\rangle_3$ the coefficient of $(z-w)^{-4}$, i.e. the two-point function. A global symmetry acts on the weight-two fields preserving these OPE coefficients, hence by an automorphism of the Griess algebra; this is the "Griess algebra" on which Griess built the Monster.

What the machine verified

Definitions; no hypotheses beyond `hvac`, supplied for $V^\natural$ by `VnatVOA_vacuum_ne_zero`. The core file `VOA/Core/GriessAutomorphism.lean` belongs to Chapter 4 (assignment rule `VOA/Core/*.lean`); it is quoted here because the statements of this section use it.

Theorem 47.3 (Faithfulness from generation). *If $V^\natural$ is generated by ${V^\natural}_2$, then restriction* $\mathrm{Aut}(V^\natural) \to \mathrm{GriessAut}(V^\natural)$ *is injective.*

```
theorem vnatGriessRestrict_injective_of_gen (hgen : GriessAut.GeneratedByWeightTwo VnatVOA)
↪  :
    Function.Injective vnatGriessRestrict :=
  GriessAut.griessRestrict_injective _ hgen
```

(`VOA/Moonshine/AutVnat.lean`.)

From the mathematics to the Lean statement

A conditional statement: the hypothesis `hgen` is generation by the weight-two space, which the library does *not* prove for $V^\natural$. The general theorem `griessRestrict_injective` (same core file) is the two-line argument below. This declaration is superseded by the hypothesis-free Theorem 47.4; it records the first route that was tried.

Proof on paper. If $g|_{{V^\natural}_2} = 1$, the fixed space $\{v : gv = v\}$ contains ${V^\natural}_2$ and is closed under all products $(g(u_{(n)}v) = (gu)_{(n)}(gv))$, so by generation it is everything. □

Physical meaning

"The OPE closure of the weight-two fields is the whole theory": a symmetry that acts trivially on the generating fields acts trivially on everything.

What the machine verified

Conditional on `hgen` (an unproved hypothesis); printed in `VOA/Moonshine/MoonshineLRLiftAudit.lean` (all theorems of the `Aut*` files; green at the release, standard axioms, no `sorryAx`); not used by any final theorem.

47.1.3 Faithfulness without generation

The weight-two space does generate $V^\natural$ (FLM), but that theorem is not in the library. The library proves faithfulness directly. *Reading guide:* the faithfulness theorem itself is *not* used by the Conway–Norton theorem; what is reused (in Lemma 47.18) are Steps 1–6 of its proof, with the hypothesis "g fixes ${V^\natural}_2$" weakened to "g fixes the $(q_{ab}, 0)$ and the $(x_\alpha, 0)$, α minimal" (Steps 1–6 for the untwisted block) and to "g fixes $V_\Lambda^+ \times 0$ and one twisted vector" (Step 6, twisted part).

Theorem 47.4 ($\mathrm{Aut}(V^\natural)$ acts faithfully on the Griess algebra). *An automorphism of $V^\natural$ that fixes ${V^\natural}_2$ pointwise is the identity. Consequently restriction* $\mathrm{Aut}(V^\natural) \to \mathrm{GriessAut}(V^\natural)$, $g \mapsto g|_{{V^\natural}_2}$, *is an injective group homomorphism.*

```

    ↪  1 := by

theorem aut_eq_one_of_fix_weightTwo (g : AutVnat) (hg : ∀ v ∈ VnatVOA.grading 2, g v = v) :
```

```
    g = 1 := by

theorem vnatGriessRestrict_injective : Function.Injective vnatGriessRestrict := by
```

(`VOA/Moonshine/AutFaithfulAssembly.lean`, namespace `VOA.Moonshine.AutMonster`.)

From the mathematics to the Lean statement

`g v` applies the automorphism (coercion to a function); `∀ v ∈ VnatVOA.grading 2, g v = v` is $g|_{V^\natural_2} = \mathrm{id}$; `g = 1` is equality with the identity of the group `AutVnat`. `((frameX0P β, 0) : Vnat)` is the vector $(x_\beta, 0) \in V_\Lambda^+ \oplus T^+$, $x_\beta = e^\beta + e^{-\beta}$. `Function.Injective vnatGriessRestrict` is injectivity of the homomorphism of Definition 47.2; by `injective_iff_map_eq_one` it is equivalent to the second statement. The first statement is an intermediate step with an extra hypothesis `hx`, which the second discharges. **Strength.** The second and third statements have no hypotheses; they are exactly the textbook statements "$\mathrm{Aut}(V^\natural)$ acts faithfully on $V^\natural_2$" and "$\mathrm{Aut}(V^\natural) \hookrightarrow \mathrm{Aut}(V^\natural_2, \times, \langle,\rangle)$". They say nothing about the image (that is Chapter 49). **Could it be vacuous?** The statement "g fixes $V^\natural_2 \Rightarrow g = 1$" is a genuine constraint on every automorphism, whatever the size of the group: it says that the 196884-dimensional Griess algebra already determines g on the infinite-dimensional $V^\natural$. (That $\mathrm{Aut}(V^\natural)$ is non-trivial is not needed here and is not stated as a separate Lean theorem in this chapter; Chapter 49 embeds AxiomMath's group Gmat in it.)

Proof on paper. Let g fix $V^\natural_2$ pointwise. The proof has six steps; the first four show that g multiplies each $(x_\beta, 0)$ by a scalar c_β, the fifth that $c_\beta = 1$, and the last propagates to all of $V^\natural$.

Step 1: g commutes with the zero modes of the quadratic states. $q_{ab} = h_a(-1)h_b(-1)\mathbf{1}$ has weight two, so $(q_{ab}, 0) \in V^\natural_2$ is fixed by g, and $g\big(o(q_{ab})v\big) = o(gq_{ab})(gv) = o(q_{ab})(gv)$ for every v. Hence g maps joint eigenvectors of the operators $o(q_{ab})$ to joint eigenvectors with the same eigenvalues.

Step 2: $(x_\beta, 0)$ is a joint eigenvector with eigenvalues $\beta_a\beta_b$. On V_Λ the vertex operator of q_{ab} is the normal-ordered product $:h_a(z)h_b(z):$, whose zero mode is

$$o(q_{ab}) = h_a(0)h_b(0) + \sum_{n>0}\big(h_a(-n)h_b(n) + h_b(-n)h_a(n)\big).$$

On $p \otimes e^\gamma$ (polynomial p in the oscillators, charge γ) the momentum operator $h_a(0)$ acts by the scalar $\gamma_a = \langle h_a, \gamma\rangle$, so the first term gives $\gamma_a\gamma_b$; and $h_a(n)$, $n > 0$, acts on the Fock factor only, as $n\,\partial/\partial X_{n-1,a}$. Hence $o(q_{ab})$ acts by

$$o(q_{ab})(p \otimes e^\gamma) = \gamma_a\gamma_b\, p \otimes e^\gamma + N_{ab}(p) \otimes e^\gamma, \qquad N_{ab} = \sum_{k\geq 0}(k+1)\Big(X_{k,a}\frac{\partial}{\partial X_{k,b}} + X_{k,b}\frac{\partial}{\partial X_{k,a}}\Big), \tag{47.1}$$

where $X_{k,a}$ is the polynomial variable for $h_a(-k-1)$. (In the library's construction $V_\Lambda = M(1)\otimes\mathbb{C}[\Lambda]$ the Heisenberg field on the Fock factor $M(1)$ has *zero* zero-mode, and the momentum is carried separately by the charge factor; that is why the Lean formula, Lemma 47.5, has the scalar $\gamma_a\gamma_b$ plus a purely Fock operator and no cross terms.) Since N_{ab} kills constants, $o(q_{ab})e^{\pm\beta} = \beta_a\beta_b e^{\pm\beta}$, hence $o(q_{ab})x_\beta = \beta_a\beta_b x_\beta$.

Step 3: in V_Λ^+ the only such joint eigenvectors are the multiples of x_β. This rests on a lemma about polynomials (Lemma 47.6 below): *if $p \neq 0$ is a joint eigenvector of all the operators $N^\mu_{ab} = \sum_k \mu_k(X_{k,a}\partial_{k,b} + X_{k,b}\partial_{k,a})$, a, b in a set of at least two directions, with weights μ_k that are injective in k and satisfy $\mu_k + \mu_{k'} \neq 0$, then p is constant and all eigenvalues are 0.* Granting it, decompose $v = \sum_\gamma p_\gamma \otimes e^\gamma$ into charge sectors, which $o(q_{ab})$ preserves. If $o(q_{ab})v = \beta_a\beta_b v$ for all a, b, every nonzero p_γ is a joint eigenvector of N_{ab} ($\mu_k = k+1$) with eigenvalue $\beta_a\beta_b - \gamma_a\gamma_b$; so p_γ is constant and $\gamma_a\gamma_b = \beta_a\beta_b$ for all a, b, i.e. $\gamma\gamma^\top = \beta\beta^\top$ as rank-one matrices, whence $\gamma = \pm\beta$. So $v = c_1e^\beta + c_2e^{-\beta}$;

if moreover $v \in V_\Lambda^+$, invariance under θ (which exchanges e^β and $e^{-\beta}$) gives $c_1 = c_2$ when $\beta \neq 0$, i.e. $v \in \mathbb{C}x_\beta$.

Step 4: no such eigenvector in the twisted block. Recall (Chapters 34–36) that the twisted module is $V_\Lambda^T = S[\theta]\otimes T$, where $S[\theta]$ is the Fock space of the half-integrally moded oscillators $h_a(-k-\frac{1}{2})$ and T is the 2^{12}-dimensional irreducible module of the extraspecial group 2^{1+24} (no momentum); T^+ is its θ-fixed part, and writing $t = \sum_i p_i \otimes \tau_i$ in a basis (τ_i) of T, the $p_i \in S[\theta]$ are the "Fock components" of t. On T^+ the zero mode of q_{ab} is $\big(N^{\mathrm{tw}}_{ab} + \frac{1}{8}\delta_{ab}\big)\otimes 1$, where N^{tw}_{ab} is the operator of the lemma with half-integral weights $\mu_k = k + \frac{1}{2}$ (the variables now stand for $h_a(-k-\frac{1}{2})$). The constant $\frac{1}{8}\delta_{ab}$ is a normal-ordering constant of the twisted vertex operator; it is forced by the known twisted ground-state energy: since $\omega = \frac{1}{2}\sum_a q_{aa}$, summing gives $L_0 = \sum h(-n-\frac{1}{2})h(n+\frac{1}{2}) + \frac{1}{2}\cdot 24\cdot\frac{1}{8} = \cdots + \frac{24}{16}$, the vacuum energy of 24 $\mathbb{Z}_2$-twisted bosons (§47.1.4). If $t \in T^+$ satisfied $o(q_{ab})t = \beta_a\beta_b t$ for all a, b and $t \neq 0$, each Fock component of t would be a joint eigenvector of N^{tw}_{ab} with eigenvalue $\beta_a\beta_b - \frac{1}{8}\delta_{ab}$, so by the lemma $\beta_a\beta_b = \frac{1}{8}\delta_{ab}$ for all a, b. In rank ≥ 2 that is impossible: for $a \neq b$, $\beta_a\beta_b = 0$ while $(\beta_a\beta_b)^2 = \beta_a^2\beta_b^2 = \frac{1}{64}$. Hence $t = 0$. Combining steps 1–4: $g(x_\beta, 0)$ is a joint eigenvector with eigenvalues $\beta_a\beta_b$, its twisted component vanishes and its untwisted component is a multiple of x_β; so $g(x_\beta, 0) = c_\beta(x_\beta, 0)$ for a unique scalar c_β ($x_\beta \neq 0$).

Step 5: $c_\beta = 1$. For $\langle\alpha,\gamma\rangle < 0$ the *leading product* is

$$(x_\alpha)_{(-\langle\alpha,\gamma\rangle-1)}\, x_\gamma = \varepsilon(\alpha,\gamma)\, x_{\alpha+\gamma} \tag{47.2}$$

(Lemma 47.8). If α is minimal, x_α has weight $\langle\alpha,\alpha\rangle/2 = 2$, so $(x_\alpha, 0) \in V^\natural{}_2$ is fixed by g; applying g to (47.2) gives $c_\gamma\,\varepsilon\, x_{\alpha+\gamma} = c_{\alpha+\gamma}\,\varepsilon\, x_{\alpha+\gamma}$, so $c_{\alpha+\gamma} = c_\gamma$. If $\langle\alpha,\gamma\rangle \geq 0$, apply the same to $-\alpha$ and $\gamma+\alpha$: $\langle-\alpha,\gamma+\alpha\rangle = -4 - \langle\alpha,\gamma\rangle < 0$, and $(-\alpha)+(\gamma+\alpha) = \gamma$. Hence $c_{\gamma\pm\alpha} = c_\gamma$ for every $\gamma \in \Lambda$ and every minimal α. Since the Leech lattice is generated as an abelian group by its minimal vectors (Theorem 47.9), $c_\beta = c_0$ for all β; and $c_0 = 1$ because $x_0 = 2\mathbf{1}$ is fixed. (In detail: the two cases give $c_{\gamma+\alpha} = c_\gamma$ for all γ and minimal α; replacing γ by $\gamma-\alpha$ gives $c_{\gamma-\alpha} = c_\gamma$, and the induction principle of Theorem 47.9 applies.)

Step 6: propagation. The subspace $\{x \in V_\Lambda^+ : g(x,0) = (x,0)\}$ contains $\mathbf{1}$ and every x_β, and is closed under products; by the generation theorem of Chapter 32 (the x_β, $\beta \in \Lambda$, generate V_Λ^+; `leechPlus_generated`) it is all of V_Λ^+. On the twisted side, $T^+ = T_0^+ \oplus T_1^+$ splits into the two *frame sectors* of Chapter 39 (eigenspaces of a Golay-frame symmetry), and each T_s^+ is spanned by the vectors $u_{(n)}x_s$, $u \in V_\Lambda^+$, $n \in \mathbb{Z}$, for a weight-two vector $x_s \in T_s^+$ (Chapter 39, `span_smul_frameX0T`); g fixes $x_s \in V^\natural{}_2$ and fixes V_Λ^+, hence fixes every $u_{(n)}x_s$, hence $T_0^+ \oplus T_1^+ = T^+$. So $g = 1$. □

Physical meaning

The proof is a piece of honest CFT bookkeeping. The 300 states q_{ab} ($a \leq b$) are the bilinears $\partial X^a \partial X^b$ of the 24 free bosons; their zero modes measure the "momentum tensor" $p_a p_b$ of a state plus an oscillator contribution. A symmetry fixing all weight-two fields commutes with these charges, so it maps the momentum-$\pm\beta$ cosine state $\cos(\beta\cdot X)$ to a multiple of itself, and it cannot move it into the twisted sector, where the oscillators are half-integrally moded and the zero-point shift $\frac{1}{8}\delta_{ab}$ (the twisted ground-state energy 24/16 split over the 24 directions) makes the eigenvalue pattern of a momentum state impossible. The leading OPE coefficient $\cos(\alpha\cdot X)\times\cos(\gamma\cdot X) \to \cos((\alpha+\gamma)\cdot X)$ then transports the phases along the lattice, and the vacuum fixes the normalisation.

What the machine verified

Unconditional; no hypotheses. All three statements are printed in `VOA/Moonshine/MoonshineLRLiftAudit.lean` (Chapter 49), which prints every theorem

of the `Aut*` files; that audit built green with all of its 997 reports within `[propext, Classical.choice, Quot.sound]` and no `sorryAx`. `vnatGriessRestrict_injective` is used by the lifting construction of `VOA/Moonshine/MoonshineCNMonsterActionLift.lean` and `VOA/Moonshine/MoonshineCNMonsterActionConj.lean` (Chapter 48; used in Chapter 49). The finite-order theorem does *not* use these three statements; it uses their ingredients (§47.1.4) with weakened hypotheses (Lemma 47.18). The book's authors did not re-run the build.

47.1.4 The ingredients, stated

We state the ingredients of the proof as they are in Lean, because §47.5 reuses them.

Lemma 47.5 (Zero mode of q_{ab} on a lattice VOA). *For every even positive-definite lattice L, frame directions a, b, polynomial q in the oscillators and charge $\gamma \in L$, formula (47.1) holds, with N_{ab} given on polynomials by the finite sum over any level bound K of q.*

```

(`VOA/Moonshine/AutFockEigen.lean`, namespace `VOA.HeisenbergN`.)

From the mathematics to the Lean statement

`wordStateLatGen L [(0, a), (0, b)] 0` is the state $h_a(-1)h_b(-1)\mathbf{1}\otimes e^0$ (level index 0 stands for mode -1). `latStateGen L q γ` is $q \otimes e^\gamma$, q in the Fock space `FockN (rank L)` $= \mathbb{C}[X_{k,a}]$ (Chapter 31). `(latticeVOAGen L hEven hPos).smul u 1 v` is $u_{(1)}v$, the zero mode of a weight-two u. `chargeCoord L γ a` is γ_a. `nprod (currentN_isField …) (…) (-2)` is the (-2)-normal-ordered product of the two Heisenberg currents acting on the Fock space, i.e. the oscillator part N_{ab}; `nprod_currentN_neg_two` identifies it with $\sum_{k<K}(k+1)(X_{k,a}\partial_{k,b} + X_{k,b}\partial_{k,a})$ whenever every variable of q has level $< K$ (`q.vars` is the set of variables occurring in q). The two statements together are exactly (47.1).

Physical meaning

$o(:\partial X^a \partial X^b:) = p_a p_b + \sum_{k>0}(\alpha^a_{-k}\alpha^b_k + \alpha^b_{-k}\alpha^a_k)$: the familiar mode expansion of the free-boson stress-tensor components; for $a = b$ summed over a it is $2L_0$.

What the machine verified

Unconditional. Printed in `VOA/Moonshine/MoonshineLRLiftAudit.lean` (all theorems of the `Aut*` files; green at the release, standard axioms, no `sorryAx`).

Lemma 47.6 (The joint-eigenvector lemma). *Let r have two distinct directions, $\mu : \mathbb{N} \to \mathbb{C}$ injective with $\mu_k + \mu_{k'} \neq 0$ for all k, k', and $N^{\mu}_{ab} = \sum_{k<K} \mu_k (X_{k,a}\partial_{k,b} + X_{k,b}\partial_{k,a})$ on $\mathbb{C}[X_{k,a}]$. If $q \neq 0$ has all variables of level $< K$ and $N^{\mu}_{ab} q = c_{ab} q$ for all a, b, then $c_{ab} = 0$ for all a, b and q is constant. Consequently (Lean:* `eigen_quadState_span`*), in a lattice VOA V_L of rank ≥ 2, a joint eigenvector of all $o(q_{ab})$ with eigenvalues $\beta_a\beta_b$ lies in $\mathbb{C}e^{\beta} + \mathbb{C}e^{-\beta}$; and (Lean:* `eigen_plus`*) in V_Λ^+ it lies in $\mathbb{C}x_\beta$.*

```

(`VOA/Moonshine/AutFaithfulVnat.lean`.)

From the mathematics to the Lean statement

`hr : ∀ b, ∃ a, a ≠ b` says the index set has at least two elements. `MvPolynomial.C (coeff 0 q)` is the constant polynomial with value the constant term of q, so the second conjunct is "q is constant". `latChargeGen L β` is $e^{\beta} = \mathbf{1} \otimes e^{\beta}$. All hypotheses are the ones of the paper lemma. The weights used are $\mu_k = k + 1$ (untwisted) and $\mu_k = k + \frac{1}{2}$ (twisted; `halfWeight_add_ne_zero`, `halfWeight_injective` check the two conditions).

Proof on paper. Write $\mathrm{Wt}_a(s) = \sum_k \mu_k s(k,a)$ for a monomial X^s. (i) N^{μ}_{aa} is diagonal on monomials: $N^{\mu}_{aa} X^s = 2\mathrm{Wt}_a(s) X^s$; so every monomial in the support of q has $2\mathrm{Wt}_a(s) = c_{aa}$. (ii) For $a \neq b$, N^{μ}_{ab} sends X^s to monomials whose Wt_a differs from $\mathrm{Wt}_a(s)$ by $\pm\mu_k \neq 0$; since $N^{\mu}_{ab} q = c_{ab} q$ has support with constant Wt_a, we get $N^{\mu}_{ab} q = 0$ and $c_{ab} = 0$. (iii) If some monomial X^s of q contains $X_{k,b}$, choose $a \neq b$ and look at the coefficient of X^t, $t = s - e_{k,b} + e_{k,a}$, in $N^{\mu}_{ab} q$: the term $\mu_k s(k,b)\,\mathrm{coeff}_s(q)$ is nonzero, and any other monomial s' of q contributing to X^t would have $\mathrm{Wt}_a(s') - \mathrm{Wt}_a(s) \in \{\mu_k - \mu_{k'}\ (k' \neq k),\ \mu_k + \mu_{k'}\}$, which is nonzero by the two hypotheses on μ, contradicting (i). So $N^{\mu}_{ab} q \neq 0$, contradicting (ii). Hence q is constant, and then $c_{aa} = 2\mathrm{Wt}_a(0) = 0$. The VOA consequences were explained in Steps 2–3 above. □

Physical meaning

A state that has a definite value of every bilinear charge $p_a p_b$ + (oscillators) equal to that of a pure momentum state must be a pure momentum state: oscillator excitations always shift some "level-weighted occupation number" Wt_a and are therefore visible to the off-diagonal charges.

What the machine verified

Unconditional. Printed in `VOA/Moonshine/MoonshineLRLiftAudit.lean` (all theorems of the `Aut*` files; green at the release, standard axioms, no `sorryAx`).

    t = 0 := by
```

(`VOA/Moonshine/AutTwistedExclusion.lean`.)

From the mathematics to the Lean statement

`Tw` is $V_\Lambda^T = S[\theta]\otimes T$ with $S[\theta]=$ `FockT 24` $=\mathbb{C}[X_{k,c}]$, $X_{k,c}\leftrightarrow h_c(-k-\frac{1}{2})$, and `leechT` the 2^{12}-dimensional module T of the extraspecial group; `TP` is the subspace T^+, coerced into `Tw` by `(t : Tw)`. `quadNT 24 c d` is N^{tw}_{cd}, and `quadNT_apply` (same file) shows it equals `quadOp (fun k ⇒ k + 1/2)` on polynomials of bounded level. `(…).rTensor leechT` is $A\otimes \mathrm{id}_T$. `cc` is the identification `Fin (rank leech) ≃ Fin 24` (a cast, `rank leech = 24`). `.1`, `.2` are the two components of a vector of $V^\natural = V_\Lambda^+\times T^+$. In the exclusion statement `β'` is an arbitrary complex vector (not necessarily a lattice vector); the conclusion is $t=0$, *including* the case $\beta'=0$.

Proof on paper. The twisted vertex operator of q_{ab} is the normal-ordered product of two twisted Heisenberg fields corrected by the twisted product formula; its mode 0 picks up the contractions $h_a(\frac{1}{2})\cdot h_b(-\frac{1}{2})$ with binomial coefficients, which sum to $(-\frac{1}{4}+\frac{3}{8})\delta_{ab}=\frac{1}{8}\delta_{ab}$ (file docstring of `AutZeroModesTwisted.lean`). Consistency check: with $\omega=\frac{1}{2}\sum_a q_{aa}$ this gives $L_0=\sum h(-n-\frac{1}{2})h(n+\frac{1}{2})+\frac{24}{16}$ on V_Λ^T, the familiar twisted vacuum energy. Charge-zero states act on $S[\theta]\otimes T$ through $S[\theta]$ alone. The exclusion: decompose $t=\sum_i p_i\otimes\tau_i$ along a basis (τ_i) of T; the operators $A\otimes 1$ act componentwise, so each nonzero p_i is a joint eigenvector of N^{tw}_{ab} with eigenvalue $\beta'_a\beta'_b-\frac{1}{8}\delta_{ab}$, and Lemma 47.6 with $\mu_k=k+\frac{1}{2}$ and the rank-one argument of Step 4 finish. □

Physical meaning

In the $\mathbb{Z}_2$-twisted sector of 24 free bosons the oscillators are half-integrally moded and the ground state has energy 24/16; the twisted sector carries no momentum at all. So no twisted state can have the "momentum tensor" $\beta_a\beta_b$ of an untwisted momentum state: the symmetry cannot mix a cosine operator with a twist field.

What the machine verified

Unconditional. Printed in `VOA/Moonshine/MoonshineLRLiftAudit.lean` (all theorems of the `Aut*` files; green at the release, standard axioms, no `sorryAx`).

Lemma 47.8 (The leading product). *For $\alpha,\gamma \in \Lambda$ with $\langle\alpha,\gamma\rangle < 0$, (47.2) holds in V_Λ^+, and hence $(x_\alpha,0)_{(-\langle\alpha,\gamma\rangle-1)}(x_\gamma,0) = \varepsilon(\alpha,\gamma)(x_{\alpha+\gamma},0)$ in $V^\natural$.*

```
theorem frameX0P_smul_frameX0P_of_neg (α γ : leech.carrier) (h : leech.form α γ < 0) :
    leechVOAPlus.smul (frameX0P α) (-(leech.form α γ) - 1) (frameX0P γ)
      = latticeCocycle leech α γ • frameX0P (α + γ) := by
```

(`VOA/Moonshine/AutFaithful.lean`.)

```
theorem VnatVOA_smul_xN_of_neg (α γ : leech.carrier) (h : leech.form α γ < 0) :
    VnatVOA.smul ((frameX0P α, 0) : Vnat) (-(leech.form α γ) - 1) ((frameX0P γ, 0) : Vnat)
      = latticeCocycle leech α γ • ((frameX0P (α + γ), 0) : Vnat) := by
```

(`VOA/Moonshine/AutFaithfulVnat.lean`.)

From the mathematics to the Lean statement

`leech.form α γ` is $\langle\alpha,\gamma\rangle \in \mathbb{Z}$, and the mode index $-\langle\alpha,\gamma\rangle - 1$ is an integer; `latticeCocycle leech α γ` is $\varepsilon(\alpha,\gamma)$. The first statement lives in V_Λ^+, the second in $V^\natural$ (the untwisted block acts on itself by the V_Λ^+ products, `VnatVOA_smul_inl`). Exactly the paper statement.

Proof on paper. $e^\alpha(z)e^\gamma = \varepsilon(\alpha,\gamma)z^{\langle\alpha,\gamma\rangle}\exp\big(\sum_{n>0}\alpha(-n)z^n/n\big)e^{\alpha+\gamma}$, so $e^\alpha_{(m)}e^\gamma$ is $\varepsilon(\alpha,\gamma)$ times the Schur polynomial of degree $-m-1-\langle\alpha,\gamma\rangle$; at $m=-\langle\alpha,\gamma\rangle-1$ that degree is 0 and the result is $\varepsilon(\alpha,\gamma)e^{\alpha+\gamma}$. The cross terms $e^{\pm\alpha}_{(m)}e^{\mp\gamma}$ have degree $2\langle\alpha,\gamma\rangle < 0$ and vanish ("no Fock dressing"). The term $e^{-\alpha}_{(m)}e^{-\gamma}$ gives $\varepsilon(-\alpha,-\gamma)e^{-\alpha-\gamma}$ with $\varepsilon(-\alpha,-\gamma) = \varepsilon(\alpha,\gamma)$ by bimultiplicativity. Summing, and accounting for the projection $\frac{1}{2}(1+\theta)$ onto V_Λ^+, gives (47.2). □

Physical meaning

The most singular term of the OPE $e^{i\alpha\cdot X}(z)e^{i\gamma\cdot X}(w) \sim (z-w)^{\langle\alpha,\gamma\rangle}e^{i(\alpha+\gamma)\cdot X}(w)$: momentum is additive, and the leading coefficient is the cocycle phase.

What the machine verified

Unconditional. Both statements are printed in `VOA/Moonshine/MoonshineLRLiftAudit.lean` (all theorems of the `Aut*` files; green at the release, standard axioms, no `sorryAx`).

Theorem 47.9 (The Leech lattice is generated by its minimal vectors). *Every $\beta \in \Lambda$ is an integral linear combination of vectors of norm 4. Equivalently: if a property P of lattice vectors holds at 0 and is preserved by $\gamma \mapsto \gamma \pm \alpha$ for every minimal α, it holds on all of Λ.*

```
theorem leech_mem_closure_minimal (β : leech.carrier) :
    β ∈ AddSubgroup.closure {α : leech.carrier | leech.form α α = 4} := by

theorem leech_closure_minimal_eq_top :
    AddSubgroup.closure {α : leech.carrier | leech.form α α = 4} = ⊤ :=

theorem leech_induction (P : leech.carrier → Prop) (h0 : P 0)
    (hadd : ∀ γ α : leech.carrier, leech.form α α = 4 → P γ → P (γ + α))
    (hsub : ∀ γ α : leech.carrier, leech.form α α = 4 → P γ → P (γ - α))
    (β : leech.carrier) : P β := by
```

(`VOA/Moonshine/AutLeechSpan.lean`, namespace `VOA.Moonshine.LeechSpan`.)

From the mathematics to the Lean statement

`AddSubgroup.closure S` is the subgroup generated by S (all finite integral combinations); `= ⊤` says it is all of Λ. The induction principle is the usual consequence. Statement exactly as on paper.

Proof on paper. We use the concrete model of Chapter 30: Λ is realised inside $\mathbb{Z}^{24}$, scaled by $\sqrt{8}$ (form $x \cdot y/8$, so minimal vectors have $x \cdot x = 32$), as $\Lambda = 2A \cup (u + 2A)$, where $A = \{a \in \mathbb{Z}^{24} : a \bmod 2$ is a Golay codeword, $4 \mid \sum_i a_i\}$ and $u = (5, 1^{23})$ (the letter A here has nothing to do with Monster classes). In this model one exhibits minimal generators and writes everything in terms of them: the vectors $4e_i \pm 4e_j$ generate $4D_{24}$; the octad vectors $2 \cdot$ (octad) are minimal, and the twelve rows of the generator matrix of the Golay code (one of them a dodecad, handled by an explicit identity) give all of $2A$ modulo $4D_{24}$; finally the odd coset is reached through the minimal vector $(-3, 1^{23})$. The finitely many concrete facts about explicit integer vectors are checked by kernel computation (`decide +kernel`; no `native_decide`). □

Physical meaning

The charges of the cosine operators of weight two generate all charges: the minimal-momentum states already "see" the whole charge lattice.

What the machine verified

Unconditional. Printed in `VOA/Moonshine/MoonshineLRLiftAudit.lean` (all theorems of the `Aut*` files; green at the release, standard axioms, no `sorryAx`).

Trap / dead end

A false induction criterion. A natural first idea for Step 5 is to show, by induction on $|\beta|^2$, that the subspace of vectors fixed by g contains every x_β, reaching x_β from shorter vectors through a product with some x_α, α minimal. This needs the claim "every β with $|\beta|^2 \geq 6$ has a minimal α with $\langle \alpha, \beta \rangle \in \{3, 4\}$". This is *false*: for $\beta = k\alpha_0$ with $k \geq 5$ and α_0 minimal, all inner products $\langle \alpha, \beta \rangle$ lie in $k\mathbb{Z}$ (a numerical sample found 400 of 4800 failures, all of this shape). The proof given above avoids the issue: it propagates *scalars* c_β along $\gamma \mapsto \gamma \pm \alpha$ in both directions, which only needs that minimal vectors *generate* Λ as a group (Theorem 47.9), not that norms decrease.

Lemma 47.10 (Scalars and their propagation). *If g fixes $V^\natural{}_2$ pointwise then $g(x_\beta, 0) = c(x_\beta, 0)$ for some $c \in \mathbb{C}$, and the scalars at γ and at $\alpha + \gamma$ agree for every minimal α.*

```

(`VOA/Moonshine/AutFaithfulVnat.lean`.)

From the mathematics to the Lean statement

Steps 1–4 and Step 5 of the proof of Theorem 47.4. The hypothesis `hg` is used only on the vectors $(q_{ab}, 0)$ (first statement) and $(x_\alpha, 0)$, α minimal (second statement); the finite-order proof reuses private copies of these two lemmas with exactly these weakened hypotheses (§47.5).

Physical meaning

A symmetry fixing the weight-two fields acts on each cosine operator by a phase, and the phases are transported by the leading OPE coefficient.

What the machine verified

Unconditional. Printed in `VOA/Moonshine/MoonshineLRLiftAudit.lean` (all theorems of the `Aut*` files; green at the release, standard axioms, no `sorryAx`).

47.2 The triality automorphism

The extra symmetry of $V^\natural$ that is not visible in the lattice description is FLM's involution σ.

What the rest of the chapter uses. Only three facts about σ are used below, and nothing else about it matters for the finite-order and finiteness arguments:

(σ1) σ is an automorphism of $V^\natural$ (Theorem 47.11);

(σ2) $\sigma^2 = 1$ (`sigNat_invol`);

(σ3) for the twisted generator $x \in T^+$ of Lemma 47.18, $\sigma(0, x) = (\Psi x, 0)$ lies in $V_\Lambda^+ \times 0$ (`sigNat_Ts`, Chapter 42).

A reader willing to take these as given can skip to §47.3. The library never states $\sigma \neq 1$ as a theorem, and no argument of this chapter needs it.

Where σ comes from. Chapters 39–42 decompose $V^\natural$ along a Golay-code frame into four blocks, $V^\natural = V_0^+ \oplus V_3^+ \oplus T_s^+ \oplus T_{s+1}^+$: $V_\Lambda^+ = V_0^+ \oplus V_3^+$ splits into the two eigenspaces of a frame symmetry, and $T^+ = T_s^+ \oplus T_{s+1}^+$ into the two frame sectors. The library's σ is the operator `sigNat D` of Chapter 42: on V_0^+ it is a "code triality" automorphism of V_0^+; it exchanges V_3^+ and T_s^+ through mutually inverse linear isomorphisms $\Phi : V_3^+ \to T_s^+$, $\Psi : T_s^+ \to V_3^+$; and on T_{s+1}^+ it is a linear involution Θ. These maps are part of a *triality datum* `SigmaData`; the standard one, `Dnat`, is built from a normalising scalar $c^\star \in \mathbb{C}$ (with $c^{\star 2}\kappa_0 = 1$ for a fixed cocycle sign κ_0) and the sign $\varepsilon = +1$ (Chapter 42), and its σ-*key* (`SigmaKey.conj_eq`, the main identity proved in Chapters 40–42) says that σ conjugates the vertex operator of x into that of $\sigma(0, x)$. What was not stated there is that σ is an automorphism of the vertex operator algebra `VnatVOA`.

Theorem 47.11 ($\sigma^\natural \in \mathrm{Aut}(V^\natural)$). *The involution $\sigma^\natural =$* `sigNat Dnat` *is an automorphism of $V^\natural$: it is a linear involution, it intertwines every product, and it fixes the vacuum and the conformal vector.*

```
noncomputable abbrev Dnat : SigmaData :=
  mkData cStar0 1 (c_ne_of_norm cStar0_norm) (by norm_num)

noncomputable def sigmaEquiv : Vnat ≃ₗ[ℂ] Vnat :=
  LinearEquiv.ofInvolutive (sigNat Dnat) sigNat_invol

noncomputable def sigmaAut : AutVnat where
  toLinearEquiv := sigmaEquiv

@[simp] theorem sigmaAut_apply (v : Vnat) : sigmaAut v = sigNat Dnat v := rfl
```

(`VOA/Moonshine/AutSigma.lean` and, for `Dnat`, `VOA/Moonshine/AutVnat.lean`; namespace `VOA.Moonshine.AutMonster`; the three proof fields of `sigmaAut` are omitted.)

From the mathematics to the Lean statement

`Dnat` is the standard triality datum $D(c^\star, +1)$ (the sign $\varepsilon = +1$ of Chapter 42) used by the unconditional theorem `moonshine`. `LinearEquiv.ofInvolutive f hf` turns a linear map with $f \circ f = \mathrm{id}$ (`sigNat_invol`, from `sigNat_sq`) into a linear equivalence. `sigmaAut : AutVnat` is a term of the structure `Aut`; its existence *is* the theorem: the three omitted fields are the proofs of $\sigma(u_{(n)}v) = (\sigma u)_{(n)}(\sigma v)$ for all u, v, n, $\sigma\mathbf{1} = \mathbf{1}$, $\sigma\omega = \omega$. `sigmaAut_apply` says that, as a function, it is `sigNat Dnat`. So the statement is the textbook one. It is used below only through $\sigma(0, x) = (\Psi x, 0)$ for the twisted generator x (`sigNat_Ts`), and $\sigma^2 = 1$.

Proof on paper. Let S be the space of $u \in V^\natural$ whose modes σ intertwines $(\sigma u_{(n)}\sigma^{-1} = (\sigma u)_{(n)}$ for all n). It is closed under products (Borcherds identity) and, σ being an involution, σ-stable. It contains $V_0^+ \times 0$ (Chapter 42: σ intertwines the V_0^+-modes) and the twisted generator $(0, x)$, $x = h_0(-\frac{1}{2})\mathbf{1} \otimes t_s$ (this is the σ-key `SigmaKey.conj_eq`, the content of Chapters 40–42). Hence it contains $0 \times T_s^+$, which is spanned by V_0^+-modes applied to x; hence $V_3^+ \times 0 = \sigma(0 \times T_s^+)$; hence $V_\Lambda^+ \times 0$; hence $0 \times T^+$, which is spanned by V_Λ^+-modes applied to x (`modeSpan_x0T`). So $S = V^\natural$. The vacuum and ω lie in V_0^+, where σ acts by an automorphism of V_0^+ fixing them. □

Physical meaning

σ is a symmetry of the orbifold theory that mixes the untwisted sector with the twisted sector: a "quantum" symmetry invisible in the free-boson description (it exchanges a cosine operator with a twist field). Together with the lattice symmetries it generates the Monster; in this library it is the one extra element needed, in §47.5, to reach the twisted sector from the untwisted one.

What the machine verified

Unconditional definition (a term of `AutVnat`); `sigmaAut_apply` is printed in `VOA/Moonshine/MoonshineLRLiftAudit.lean` (all theorems of the `Aut*` files; green at the release, standard axioms, no `sorryAx`), and `sigmaAut` is used by `autVnat_isOfFinOrder` and `finite_autVnat`, whose audit lines in `VOA/Moonshine/MoonshineLRFinOrderAudit.lean` are standard.

47.3 Periodicity of rigid idempotents: an abstract lemma

47.3.1 Why finite order, and the plan

The twisted denominator identities of Chapter 46 are proved for automorphisms of finite order, and the analytic half of complete replicability needs the trace bound $|\operatorname{tr}(g|V^\natural{}_n)| \le \dim V^\natural{}_n$, which holds for finite-order g (Chapter 43, Theorem 43.6). So the conjecture needs: *every automorphism of $V^\natural$ has finite order.* Classically this is a corollary of $\mathrm{Aut}(V^\natural) = \mathbb{M}$; the library does not have that identification unconditionally, and the proof follows a route that uses no group theory:

(1) an abstract lemma: in a finite-dimensional commutative algebra, every *rigid idempotent* is periodic under every algebra automorphism (this section);

(2) explicit *Ising vectors* $e_{\alpha,\pm s} \in V^\natural{}_2$, one pair for each minimal α, which are rigid idempotents of the Griess algebra (§47.4);

(3) faithfulness, with weakened hypotheses: an automorphism fixing all these Ising vectors fixes V_Λ^+; conjugation by σ reaches the twisted sector (§47.5).

Definition 47.12 (Rigid idempotent)**.** Let B be a complex vector space with a bilinear product $\cdot$ (not necessarily associative or unital). An element $e \in B$ is a *rigid idempotent* if $e \cdot e = 2e$ and $e \cdot y = y$ implies $y = 0$ (i.e. 1 is not an eigenvalue of left multiplication L_e).

There is no separate Lean definition: the two conditions appear as hypotheses `he : mul e e = (2 : ℂ) • e` and `hrig : ∀ y, mul e y = y → y = 0` of every statement below (and as the set `vnatRigidSet` in §47.6). The normalisation $e \cdot e = 2e$ (rather than $e \cdot e = e$) is the one of conformal vectors in a Griess algebra: a Virasoro vector ω' with $\omega'_{(1)}\omega' = L'_0\omega' = 2\omega'$. Note that $e = 0$ is a rigid idempotent by this definition; this is harmless (the theorems below are about sets containing it, or about specific non-zero vectors), but it shows that "rigid idempotent" is a purely algebraic notion, wider than "stress tensor of a sub-theory".

Physical meaning

A rigid idempotent of the Griess algebra is a candidate stress tensor $T'(z)$ of a sub-theory whose embedding cannot be deformed: an infinitesimal deformation $e + \epsilon y$ of the relation $e \cdot e = 2e$ requires $2e \cdot y = 2y$, i.e. a field y of conformal weight exactly 1 with respect to T' (a "marginal" direction for the embedding). Rigidity says there is none. The stress tensor ω of $V^\natural$ is itself rigid ($L_0 = 2$ on $V^\natural{}_2$); the $c = 1$ Virasoro vectors $\frac{1}{2}h(-1)^2\mathbf{1}$ are *not* (they come in a continuous $O(24)$-family), which is why the argument must use $c = \frac{1}{2}$ Ising vectors.

47.3.2 The lemma and its proof

Theorem 47.13 (Periodicity of rigid idempotents)**.** *Let B be a finite-dimensional complex vector space with a commutative bilinear product, $A : B \to B$ a linear automorphism with $A(x \cdot y) = Ax \cdot Ay$, and e a rigid idempotent. Then $A^K e = e$ for some $K \ge 1$.*

```
theorem pow_apply_eq_self_of_rigid [FiniteDimensional ℂ B]
    (mul : B →ₗ[ℂ] B →ₗ[ℂ] B) (hcomm : ∀ x y, mul x y = mul y x)
    (A : B ≃ₗ[ℂ] B) (hA : ∀ x y, A (mul x y) = mul (A x) (A y))
    (e : B) (he : mul e e = (2 : ℂ) • e)
    (hrig : ∀ y, mul e y = y → y = 0) :
    ∃ K : ℕ, 1 ≤ K ∧ (A ^ K) e = e := by
```

(`VOA/Moonshine/MoonshineLRFinOrderPeriodic.lean`, namespace `VOA.Moonshine.ConwayNorton.M8`; section variables `{B : Type*} [AddCommGroup B] [Module ℂ B]`.)

From the mathematics to the Lean statement

`B →ₗ[ℂ] B →ₗ[ℂ] B` is a bilinear map, the product; `hcomm` is commutativity. `A : B ≃ₗ[ℂ] B` is a linear automorphism, `hA` multiplicativity; `A ^ K` is the K-th power in the group of linear automorphisms. `he`, `hrig` are the two conditions of Definition 47.12. No associativity, no unit, no form, no VOA: the lemma is pure finite-dimensional algebra (the file imports Mathlib only). The conclusion `∃ K, 1 ≤ K ∧ (A ^ K) e = e` is periodicity of e under A. Exactly the paper statement.

Proof on paper. Decompose $B = \bigoplus_\lambda W_\lambda$ into generalised eigenspaces of A ($\lambda \neq 0$ since A is invertible), and write $x = \sum_\lambda x_\lambda$.

(i) *Multiplicativity:* $W_\lambda \cdot W_\mu \subseteq W_{\lambda\mu}$. From $A(x \cdot y) = Ax \cdot Ay$ one gets the shifted product rule $(A - \lambda\mu)(x \cdot y) = ((A - \lambda)x) \cdot Ay + \lambda\, x \cdot ((A - \mu)y)$, and by induction $(A - \lambda\mu)^{n+m}(x \cdot y) = 0$ when $(A - \lambda)^n x = 0$, $(A - \mu)^m y = 0$.

(ii) *Character derivations.* Let $\varphi : \mathbb{C}^\times \to \mathbb{C}$ be a homomorphism from the multiplicative to the additive group, and $D_\varphi x = \sum_\lambda \varphi(\lambda) x_\lambda$. By (i), D_φ is a derivation: $D_\varphi(x \cdot y) = D_\varphi x \cdot y + x \cdot D_\varphi y$.

(iii) *Derivations kill rigid idempotents.* Applying a derivation D to $e \cdot e = 2e$ and using commutativity gives $2\, e \cdot De = 2De$, so $De = 0$ by rigidity. Hence $\varphi(\lambda) e_\lambda = 0$ for every λ and every φ.

(iv) *Separating characters.* If $\lambda \in \mathbb{C}^\times$ has infinite order, the subgroup $\lambda^{\mathbb{Z}} \cong \mathbb{Z}$ carries the homomorphism $\lambda^n \mapsto n$; since $\mathbb{C}$ is a divisible, hence injective, abelian group (Baer's criterion), it extends to $\varphi : \mathbb{C}^\times \to \mathbb{C}$ with $\varphi(\lambda) = 1$. By (iii), $e_\lambda = 0$. So every λ in the support of e is a root of unity; let K be the product of their orders.

(v) *The semisimple part.* Let S act by λ on W_λ. By (i) S is multiplicative, it commutes with A, and $S^K e = \sum \lambda^K e_\lambda = e$. $U = S^{-1}A$ is a multiplicative automorphism with $U - 1$ nilpotent.

(vi) *Unipotent automorphisms fix rigid idempotents.* For a multiplicative U with $(U-1)^d e = 0$, the orbit $k \mapsto U^k e = \sum_{j<d} \binom{k}{j} (U-1)^j e$ is the restriction to $\mathbb{N}$ of a polynomial curve $P(t)$ (with coefficients $\binom{t}{j} = t(t-1)\cdots(t-j+1)/j!$). Each $P(n) = U^n e$ is a rigid idempotent (multiplicative automorphisms preserve rigidity). The identity $P(t) \cdot P(t) = 2P(t)$ holds for $t \in \mathbb{N}$, hence for all t (a polynomial with infinitely many roots is zero, applied coordinatewise through linear functionals). Differentiating, $2P(t) \cdot P'(t) = 2P'(t)$; at $t = n \in \mathbb{N}$ rigidity of $P(n)$ gives $P'(n) = 0$; so P' vanishes on $\mathbb{N}$, hence identically, and P is constant: $Ue = P(1) = P(0) = e$.

Applying (vi) to U^K (still unipotent and multiplicative) and using that S and U commute, $A^K e = S^K U^K e = S^K e = e$. □

Physical meaning

Heuristically: an eigenvalue λ of a symmetry that is not a root of unity would generate, through $\lambda^t = e^{t \log \lambda}$, a one-parameter family of symmetries, i.e. a conserved "charge" (the derivation D_φ plays its role without logarithms). A rigid idempotent cannot be moved by any such infinitesimal symmetry, so it can only carry charges of finite order. Step (vi) is the unipotent analogue: a symmetry of the form $\exp(N)$, N nilpotent, is a continuous deformation and cannot move a rigid object.

What the machine verified

Unconditional, generic. Printed in `VOA/Moonshine/MoonshineLRFinOrderAudit.lean` with `[propext, Classical.choice, Quot.sound]`, 0 `sorryAx` (build record of the release).

47.3.3 The steps, in Lean

The individual steps (i)–(vi) are separate declarations of the same file. We quote the public ones that a referee may want to check; their meaning is the corresponding step above.

(`VOA/Moonshine/MoonshineLRFinOrderPeriodic.lean`.)

From the mathematics to the Lean statement

`A.maxGenEigenspace l` is the generalised eigenspace $W_\lambda = \bigcup_n \ker(A-\lambda)^n$. `Additive G →+ ℂ` is a homomorphism from the group G written additively to $(\mathbb{C},+)$, i.e. a "logarithmic character"; `IsOfFinOrder g` is $\exists n \geq 1,\ g^n = 1$. `spectralDecomposition A e l` is the component $e_\lambda \in W_\lambda$ (defined from Mathlib's `iSup_maxGenEigenspace_eq_top` and `independent_maxGenEigenspace`). `polynomialCurve p v t` is $\sum_i p_i(t)v_i$, a polynomial curve in B indexed by a finite type `ι`; the theorem says that if its values at all natural numbers are rigid idempotents, then it is constant. `unipotent_fix_of_rigid` has no finite-dimensionality hypothesis: local unipotence at e (`huni`) suffices. All conditions match the steps above.

Physical meaning

These are the algebraic shadows of: "charges are additive under the OPE" (i), "a $U(1)$ charge acts as a derivation of the operator algebra" (ii), and "a rigid sub-theory carries zero continuous charge" (iii).

What the machine verified

All unconditional, generic, printed in `VOA/Moonshine/MoonshineLRFinOrderAudit.lean`; standard axioms.

47.4 Ising vectors in the Griess algebra

47.4.1 The vectors

Definition 47.14 (Explicit Ising vectors)**.** For a minimal vector $\alpha \in \Lambda_4$ and a scalar $s \in \mathbb{C}$ put

$$e_{\alpha,s} = \Big(\frac{1}{16}\,Q(\alpha,\alpha) + \frac{s}{4}\,x_\alpha,\ 0\Big) \in V^\natural = V_\Lambda^+ \oplus T^+, \qquad Q(\alpha,\alpha) = \alpha(-1)^2\mathbf{1}. \tag{47.3}$$

The *normalised* ones are those with $s^2\,\varepsilon(\alpha,-\alpha) = 1$ (so $s \in \{\pm 1\}$ if $\varepsilon(\alpha,-\alpha) = 1$, $s \in \{\pm i\}$ otherwise).

```
noncomputable def isingVec (α : leech.carrier) (s : ℂ) : Vnat :=
  ((1 / 16 : ℂ) • (dV α α : VPlus) + (s / 4) • frameXOP α, 0)

theorem isingVec_mem_grading_two {α : leech.carrier} (hα : leech.form α α = 4)
    (s : ℂ) : isingVec α s ∈ VnatVOA.grading 2 := by

theorem isingVec_one_self {α : leech.carrier} (hα : leech.form α α = 4) (s : ℂ)
    (hs : s ^ 2 * latticeCocycle leech α (-α) = 1) :
    VnatVOA.smul (isingVec α s) 1 (isingVec α s) = (2 : ℂ) • isingVec α s := by
```

(`VOA/Moonshine/MoonshineLRFinOrderIsing.lean`, namespace `VOA.Moonshine.ConwayNorton.M8`.)

From the mathematics to the Lean statement

`dV α α` is the state $\alpha(-1)\alpha(-1)\mathbf{1} = Q(\alpha,\alpha)$ in $V_0^+ \subseteq V_\Lambda^+$ (it is `quadH`, defined as $h_{\alpha(-1)}h_\alpha$; Chapter 41), coerced to `VPlus`. The pair `(…, 0)` places it in the untwisted block. `isingVec` is defined for every s; the normalisation appears only as the hypothesis `hs`, with $\kappa_\alpha = \varepsilon(\alpha,-\alpha)$ left symbolic. `isingVec_one_self` is $e \times e = 2e$ for the Griess product $(e_{(1)}e)$. **What is not claimed.** The Lean statements do not assert that e generates a Virasoro algebra of central charge $\frac{1}{2}$ (that would need $e_{(3)}e = \frac{1}{4}\mathbf{1}$ and the Virasoro relations), nor that these are all the Ising vectors of $V^\natural$; the name "Ising vector" is motivation. Only $e \times e = 2e$ and the rigidity of §47.4.3 are proved, and only they are used.

Proof on paper. Three Griess products are needed (Lemma 47.15 below): $Q(\alpha,\alpha) \times Q(\alpha,\alpha) = 16Q(\alpha,\alpha)$, $Q(\alpha,\alpha) \times x_\alpha = x_\alpha \times Q(\alpha,\alpha) = 16x_\alpha$ and $x_\alpha \times x_\alpha = \kappa_\alpha Q(\alpha,\alpha)$. Hence

$$e \times e = \frac{1}{256}\cdot 16Q + 2\cdot\frac{s}{64}\cdot 16x_\alpha + \frac{s^2}{16}\kappa_\alpha Q = \frac{1+s^2\kappa_\alpha}{16}Q + \frac{s}{2}x_\alpha = 2e$$

exactly when $s^2\kappa_\alpha = 1$. □

Physical meaning

These are the classical Ising vectors $\omega^{\pm}(\alpha) = \frac{1}{16}\alpha(-1)^2\mathbf{1} \pm \frac{1}{4}(e^{\alpha}+e^{-\alpha})$ of Dong–Mason–Zhu and Miyamoto: the stress tensors of an Ising model (the $c = \frac{1}{2}$ minimal model, one free Majorana fermion) embedded in the 24 free bosons. The rank-one lattice theory of $\mathbb{Z}\alpha$ ($\langle\alpha,\alpha\rangle = 4$, so that $\cos(\alpha \cdot X)$ has dimension 2) contains two commuting Ising models, $c = 1 = \frac{1}{2} + \frac{1}{2}$, and $\omega^{\pm}(\alpha)$ are their two stress tensors. Miyamoto showed that each Ising vector e defines an involution τ_e (acting by -1 on the $h = \frac{1}{16}$ sector of Vir_e), and in $V^{\natural}$ these are the $2A$ involutions of the Monster. None of this is used by the library; it explains why these vectors are the natural rigid anchors.

What the machine verified

Unconditional given `hα`, `hs` (which are the definition of the vectors, not open inputs). Printed in `VOA/Moonshine/MoonshineLRFinOrderAudit.lean`; standard axioms.

Trap / dead end

The naive Ising vector need not be idempotent. The literal vector $\frac{1}{16}\alpha(-1)^2\mathbf{1} + \frac{1}{4}x_\alpha$ satisfies $e \times e = 2e$ only if $\varepsilon(\alpha,-\alpha) = 1$. The library's cocycle comes from a basis chosen by `Module.Free.chooseBasis` and its signs are never evaluated, so the scalar s is kept symbolic with the single hypothesis $s^2\varepsilon(\alpha,-\alpha) = 1$. The concrete choice used later is $s = \pm$`FrameT.sqrtEps leech α`, a chosen square root of $\varepsilon(\alpha,\alpha)$ (and $\varepsilon(\alpha,-\alpha) = \varepsilon(\alpha,\alpha)$ since $\varepsilon^2 = 1$).

47.4.2 Weight-two products and spanning sets

Lemma 47.15 (Products in $(V_\Lambda^+)_2$). *Let $\alpha,\beta \in \Lambda_4$. (a) $\langle\alpha,\beta\rangle \in \{-4,-2,-1,0,1,2,4\}$. (b) $x_\alpha \times x_\alpha = \varepsilon(\alpha,-\alpha)Q(\alpha,\alpha)$; $x_\alpha \times x_\beta = \varepsilon(\alpha,\beta)x_{\alpha+\beta}$ if $\langle\alpha,\beta\rangle = -2$; $x_\alpha \times x_\beta = \varepsilon(\alpha,-\beta)x_{\beta-\alpha}$ if $\langle\alpha,\beta\rangle = 2$; $x_\alpha \times x_\beta = 0$ if $|\langle\alpha,\beta\rangle| \le 1$. (c) $Q(u,v) \times x_\beta = \langle u,\beta\rangle\langle v,\beta\rangle x_\beta$ for all $u,v,\beta \in \Lambda$, and $x_\alpha \times Q(u,v) = \langle u,\alpha\rangle\langle v,\alpha\rangle x_\alpha$. (d) $q_{ab} \times q_{cd} = \delta_{bc}q_{ad} + \delta_{bd}q_{ac} + \delta_{ac}q_{bd} + \delta_{ad}q_{bc}$; equivalently, by bilinearity, for $u,v,w,z \in \mathfrak{h}$,*

$$Q(u,v) \times Q(w,z) = \langle v,w\rangle Q(u,z) + \langle v,z\rangle Q(u,w) + \langle u,w\rangle Q(v,z) + \langle u,z\rangle Q(v,w),$$

so in particular $Q(\alpha,\alpha) \times Q(\alpha,\alpha) = 16\,Q(\alpha,\alpha)$ and $Q(\alpha,\alpha) \times Q(\alpha,v') = 4\,Q(\alpha,v')$ for $v' \perp \alpha$, $\langle\alpha,\alpha\rangle = 4$ (Lean: `isingQuad_one_isingQuad`, `quadH_one_quadH_self`*).*

    leechVOAPlus.smul (qP a b) 1 (qP c d) =
      (if b = c then qP a d else 0) + (if b = d then qP a c else 0) +
      (if a = c then qP b d else 0) + (if a = d then qP b c else 0) := by
```

(`VOA/Moonshine/MoonshineLRFinOrderIsing.lean`; the cases ± 2 are `frameX0P_one_frameX0P_of_form_neg_two`, `frameX0P_one_frameX0P_of_form_two`, and the reversed products `frameX0P_one_quadH`, `quadH_one_quadH_self` in the same file.)

From the mathematics to the Lean statement

`leechVOAPlus.smul x 1 y` is $x_{(1)}y$ in V_Λ^+, the Griess product on weight two. (`leech.form u β : ℂ`) casts the integer $\langle u, \beta\rangle$ to $\mathbb{C}$. In (a) the Lean disjunction lists the seven values. The statements are the paper ones; note that (b) keeps the cocycle sign $\varepsilon(\alpha, -\alpha)$ unevaluated.

Proof on paper. (a) $|\alpha \mp \beta|^2 = 8 \mp 2\langle\alpha, \beta\rangle$ is even, non-negative, never 2 (no roots) and 0 only if $\beta = \pm\alpha$; so $8 \mp 2\langle\alpha, \beta\rangle \in \{0\} \cup [4, \infty)$ for both signs. (b) The (1)-product $e^{\alpha}_{(1)}e^{\beta}$ is $\varepsilon(\alpha, \beta)$ times the Schur polynomial of degree $-2 - \langle\alpha, \beta\rangle$ applied to $e^{\alpha+\beta}$: zero if $\langle\alpha, \beta\rangle \geq -1$, the vacuum term if $\langle\alpha, \beta\rangle = -2$, and $\frac{1}{2}(\alpha(-1)^2 + \alpha(-2))\mathbf{1}$ if $\beta = -\alpha$; the two terms with $\beta = -\alpha$ add to $\varepsilon(\alpha, -\alpha)Q(\alpha, \alpha)$ (the $\alpha(-2)$ parts cancel). (c) is (47.1) at charge $\pm\beta$ and commutativity. (d) is N_{ab} of (47.1) applied to $X_{0,c}X_{0,d}$. □

Physical meaning

OPE coefficients of the weight-two fields $\cos(\beta \cdot X)$ and $\partial X^a \partial X^b$: momenta add, and the coefficient of $(z - w)^{-2}$ in $\cos \times \cos$ is non-zero only for momenta at angle $\langle\alpha, \beta\rangle = \mp 2$ (or $\beta = -\alpha$, where the identity channel produces $\partial X \partial X$).

What the machine verified

Unconditional; printed in `VOA/Moonshine/MoonshineLRFinOrderAudit.lean`; standard axioms.

Lemma 47.16 (Spanning sets of the weight-two blocks). *$(V_\Lambda^+)_2$ is spanned by the q_{ab} and the x_α, $\alpha \in \Lambda_4$; $(T^+)_2$ is spanned by the vectors $h_v(-\frac{1}{2}) \otimes t$, $v \in \mathbb{C}^{24}$, $t \in T$.*

```
theorem leechVOAPlus_grading_two_eq_span :
    leechVOAPlus.grading 2 = Submodule.span ℂ
      (Set.range (fun p : Fin (rank leech) × Fin (rank leech) => qP p.1 p.2) ∪
        frameX0P '' {α : leech.carrier | leech.form α α = 4}) := by

theorem twistedPlus_grading_two_eq_span :
    plusModule.weight (2 : ℂ) = Submodule.span ℂ
      {y | ∃ (v : Fin (rank leech) → ℂ) (t : TLeechT), y = hP v t} := by
```

(`VOA/Moonshine/MoonshineLRFinOrderIsing.lean`.)

From the mathematics to the Lean statement

`Submodule.span ℂ S` is the linear span; `Set.range f` the image of f; `frameX0P '' S` the image of the set of minimal vectors. `plusModule.weight (2 : ℂ)` is the weight-two space of T^+ as a V_Λ^+-module, and `hP v t` is $h_v(-\frac{1}{2})\mathbf{1} \otimes t$ with $h_v = \sum_c v_c h_c$ and $t \in T$ (`TLeechT`, Chapter 41). The dimensions are $300 + 98280 = 98580$ and $24 \cdot 2^{12} = 98304$, summing to

196884 (Chapter 32); the lemma asserts only spanning.

Physical meaning

The 196884 weight-two fields of the Monster CFT are: 300 bilinears $\partial X^a \partial X^b$, 98280 cosines $\cos(\alpha \cdot X)$ with α minimal (up to sign), and $98304 = 24 \cdot 4096$ twisted states (one half-integral oscillator on the 4096 twisted ground states).

What the machine verified

Unconditional; printed in the FinOrder audit; standard axioms.

47.4.3 Rigidity

Theorem 47.17 (The spectral lemma and rigidity). *Let $\alpha \in \Lambda_4$, $s^2\varepsilon(\alpha,-\alpha) = 1$, $e = e_{\alpha,s}$ and $X = o(e)$. Then*

(a) on $(V_\Lambda^+)_2$: $X(X-2)(X-\frac{1}{2})(X-\frac{1}{16}) = 0$;

(b) on $(T^+)_2$: $X(X-\frac{1}{16})(X-\frac{1}{2}) = 0$; explicitly $X\big(h_v(-\frac{1}{2})\otimes t\big) = \frac{1}{32}\big[h_{(1+8P_\alpha)v}(-\frac{1}{2})\otimes t + h_{(1-8P_\alpha)v}(-\frac{1}{2})\otimes Et\big]$, where $P_\alpha v = \frac{1}{4}\langle v,\alpha\rangle\alpha$ and $E = s\,e_\alpha$ on T satisfies $E^2 = 1$;

(c) e is rigid: if $y \in V^\natural{}_2$ and $e \times y = y$ then $y = 0$.

From the mathematics to the Lean statement

`mode f 1` applied to a vertex operator is the mode $u_{(1)}$ (the library's convention `mode f n = f (-n-1)` makes `mode (Y u) n` equal to $u_{(n)}$); so `isingPlusMode α s` is $o(e)$ restricted to the untwisted block (e acts there through V_Λ^+) and `isingTwistedMode α s` is $o(e)$ on T^+ (through the module map `plusModule.YM`). `(isingVec α s).1` is the V_Λ^+-component of e. In `isingSpectralPolynomial`, $*$ is composition of endomorphisms and `(2 : ℂ) • 1` is $2 \cdot \mathrm{id}$. The annihilation statements hold on the weight-two subspaces (`hy`); the operators themselves act on all of V_Λ^+, T^+. `eT … α` is the operator e_α on the 2^{12}-dimensional space T (Chapter 34), and `isingChargeInvolution α s` $= E = s e_\alpha$. In `isingTwistedMode_hP` the vector $v \pm (2\sum_a \alpha_a v_a)\alpha$ is $(1 \pm 8P_\alpha)v$, since $\sum_a \alpha_a v_a = \langle \alpha, v\rangle$ and $\langle \alpha, \alpha\rangle = 4$. `isingVec_rigid` is rigidity in the Griess algebra $V^\natural{}_2$ (the subtype `⟨isingVec α s, …⟩`), exactly the hypothesis `hrig` of Theorem 47.13. **Strength.** The spectral statements are slightly stronger than needed (they locate all eigenvalues of $o(e)$ on $V^\natural{}_2$ in $\{0, 2, \frac{1}{2}, \frac{1}{16}\}$, Miyamoto's list); only (c) is used. **Could (c) be vacuous?** No: it is a statement about the explicit operator $o(e)$ on the 196884-dimensional space $V^\natural{}_2$, and $e \neq 0$.

Proof on paper. (a) By Lemma 47.16 it suffices to check the spanning vectors; write $Q = Q(\alpha, \alpha)$, $X = \frac{1}{16}o(Q) + \frac{s}{4}o(x_\alpha)$.

- *Quadratic block.* For $u, v \in \mathfrak{h}$ write $u = \frac{a}{4}\alpha + u'$, $v = \frac{b}{4}\alpha + v'$ with $u', v' \perp \alpha$, $a = \langle \alpha, u\rangle$, $b = \langle \alpha, v\rangle$. By Lemma 47.15: $XQ(u', v') = 0$; $XQ(\alpha, v') = \frac{1}{2}Q(\alpha, v')$; on $S_\alpha = \mathrm{span}\{Q, x_\alpha\}$, $XQ = Q + 4sx_\alpha$ and $Xx_\alpha = x_\alpha + \frac{s\kappa_\alpha}{4}Q$, so $(X-1)^2 = s^2\kappa_\alpha = 1$ there, i.e. $X(X-2) = 0$ on S_α.

- *Charged block,* $\beta \in \Lambda_4$, $\beta \neq \pm\alpha$, by the cases of Lemma 47.15(a): $\langle \alpha, \beta\rangle = 0$: $Xx_\beta = 0$; $\langle \alpha, \beta\rangle = \pm 1$: $Xx_\beta = \frac{1}{16}x_\beta$ (from $\frac{1}{16}\langle \alpha, \beta\rangle^2$); $\langle \alpha, \beta\rangle = \pm 2$: with $\beta' = \beta \mp \alpha \in \Lambda_4$, $Xx_\beta = \frac{1}{4}x_\beta + \frac{sc}{4}x_{\beta'}$ and $Xx_{\beta'} = \frac{1}{4}x_{\beta'} + \frac{sc'}{4}x_\beta$ with $cc' = \kappa_\alpha$ (bimultiplicativity), so $X^2 = \frac{1}{2}X$ on $\mathrm{span}\{x_\beta, x_{\beta'}\}$.

Every case is a factor of $t(t-2)(t-\frac{1}{2})(t-\frac{1}{16})$. (b) $o(Q)$ sends $h_v(-\frac{1}{2}) \otimes t$ to $h_{\frac{1}{2}(1+8P_\alpha)v}(-\frac{1}{2}) \otimes t$ (the zero mode of Lemma 47.7 summed against $\alpha_a\alpha_b$), and each of $o(e^{\pm\alpha})$ acts on level $\frac{1}{2}$ by $2^{-4}h_{(1-8P_\alpha)v}(-\frac{1}{2}) \otimes e_\alpha t$; with the factors $\frac{1}{16}$ and $\frac{s}{4}$ this gives the displayed formula ($\frac{s}{4} \cdot 2 \cdot 2^{-4} = \frac{s}{32}$). $E^2 = s^2e_\alpha^2 = s^2\varepsilon(\alpha, \alpha) = 1$. On $(1-P_\alpha)\mathfrak{h} \otimes T$, $32X = 1 + E \in \{0, 2\}$; on $P_\alpha\mathfrak{h} \otimes T$, $32X = 9 - 7E \in \{2, 16\}$. So $X \in \{0, \frac{1}{16}, \frac{1}{2}\}$ on commuting eigenspaces of E. (c) $o(e)$ preserves both blocks of $V^\natural{}_2$. If $Xy = y$, then $p(X)y = p(1)y$ for any polynomial p; with the polynomials of (a), (b), $p(1) = 1 \cdot (-1) \cdot \frac{1}{2} \cdot \frac{15}{16} \neq 0$ and $1 \cdot \frac{15}{16} \cdot \frac{1}{2} \neq 0$, so $y = 0$. □

Physical meaning

The eigenvalues of $L'_0 = o(e)$ on weight-two fields are the conformal weights $h \in \{0, \frac{1}{2}, \frac{1}{16}\}$ of the three irreducible representations of the Ising model, plus $h = 2$ for e itself: exactly what the representation theory of the $c = \frac{1}{2}$ Virasoro algebra predicts (Miyamoto 1996). Here they are obtained by direct computation, without that representation theory. Since 1 is not among them, the Ising sub-theory has no marginal deformations inside $V^\natural$.

What the machine verified

Unconditional given the normalisation `hs`. Printed in `VOA/Moonshine/MoonshineLRFinOrderAudit.lean`; standard axioms.

47.5 Every automorphism of the moonshine module has finite order

47.5.1 From Ising vectors to the untwisted block

Lemma 47.18 (Ising vectors determine the untwisted block). *(a) If $g \in \mathrm{Aut}(V^\natural)$ fixes, for every minimal α, both $e_{\alpha,s}$ and $e_{\alpha,-s}$ for some normalised s, then g fixes every $(q_{ab}, 0)$ and every $(x_\alpha, 0)$, $\alpha \in \Lambda_4$. (b) If g fixes every $(q_{ab}, 0)$ and every $(x_\alpha, 0)$, $\alpha \in \Lambda_4$, then g fixes $V_\Lambda^+ \times 0$. (c) If g fixes $V_\Lambda^+ \times 0$ and the twisted generator $(0, x)$, then $g = 1$.*

```

(`VOA/Moonshine/MoonshineLRFinOrderRigid.lean`.)

```
noncomputable abbrev xGen : TP := x0T (tF Dnat.s)
```

(`VOA/Moonshine/AutSigma.lean`.)

From the mathematics to the Lean statement

`xGen` is the twisted generator $x = h_0(-\frac{1}{2})\mathbf{1} \otimes t_s$ of the frame sector T_s^+ for the standard data (`x0T`, `tF`; Chapters 40–42). All three statements are as on paper. (b) and (c) are the two halves of Theorem 47.4 with the hypothesis "g fixes $V^\natural{}_2$" replaced by the weaker hypotheses actually used.

Proof on paper. (a) From the definition, $x_\alpha = \frac{2}{s}(e_{\alpha,s} - e_{\alpha,-s})$ and $Q(\alpha,\alpha) = 8(e_{\alpha,s} + e_{\alpha,-s})$ (in the untwisted block). The q_{ab} are recovered from the $Q(\gamma,\gamma)$, γ minimal, by polarisation inside the lattice: with w_j the vector $8e_j$ of the $\sqrt{8}$-model and $\gamma_\pm = 4e_j \pm 4e_k \in \Lambda_4$ ($j \neq k$), $Q(w_j,w_k) = Q(\gamma_+,\gamma_+) - Q(\gamma_-,\gamma_-)$ and $Q(w_j,w_j) + Q(w_k,w_k) = 2(Q(\gamma_+,\gamma_+) + Q(\gamma_-,\gamma_-))$, so three indices isolate $Q(w_j,w_j)$, and the q_{ab} lie in the span of the $Q(w_j,w_k)$ (Chapter 41, `qV_eq_sum_dV`). (b) Steps 2–6 of the proof of Theorem 47.4: they use the hypothesis on ${V^\natural}_2$ only at the q_{ab} (to commute with $o(q_{ab})$) and at the x_α with α minimal (to propagate scalars). (c) T^+ is spanned by the vectors $u_{(n)}x$, $u \in V_\Lambda^+$ (`modeSpan_x0T`), and $g(u_{(n)}x) = (gu)_{(n)}(gx) = u_{(n)}x$. □

Physical meaning

Two Ising models (the two stress tensors $\omega^\pm(\alpha)$) per minimal momentum pin down every cosine operator and every bilinear; through the OPE they pin down the whole untwisted orbifold.

What the machine verified

Unconditional; printed in the FinOrder audit; standard axioms.

47.5.2 The theorem

Theorem 47.19 (Every automorphism of $V^\natural$ has finite order). *For every $g \in \mathrm{Aut}(V^\natural)$ there is $n \geq 1$ with $g^n = 1$.*

```
theorem aut_isingVec_periodic (g : AutVnat) {α : leech.carrier}
    (hα : leech.form α α = 4) (s : ℂ)
    (hs : s ^ 2 * latticeCocycle leech α (-α) = 1) :
    ∃ K : ℕ, 1 ≤ K ∧ (g ^ K) (isingVec α s) = isingVec α s := by

theorem aut_pow_fix_untwisted (g : AutVnat) :
    ∃ K : ℕ, 1 ≤ K ∧ ∀ x : VPlus, (g ^ K) ((x, 0) : Vnat) = ((x, 0) : Vnat) := by

theorem autVnat_isOfFinOrder : ∀ g : AutVnat, IsOfFinOrder g := by
```

(`VOA/Moonshine/MoonshineLRFinOrderRigid.lean`, namespace `VOA.Moonshine.ConwayNorton.M8`.)

From the mathematics to the Lean statement

`IsOfFinOrder g` is Mathlib's "g has finite order": $\exists n \geq 1$, $g^n = 1$ in the group `AutVnat` (`isOfFinOrder_iff_pow_eq_one`). `g ^ K` is the K-th power in `AutVnat` (composition). The headline has **no hypotheses**: the quantifier `∀ g : AutVnat` is in the statement. It is exactly the input `hfin` of the reductions of Chapter 46. It is *weaker* than finiteness of $\mathrm{Aut}(V^\natural)$ (an infinite torsion group is conceivable a priori); finiteness is Theorem 47.22. **Could it be vacuous?** Only if `AutVnat` were trivial, which it is not (it contains σ); and its strength does not depend on the size of the group.

Proof on paper. Fix g. (1) Let $A = g|_{{V^\natural}_2}$; it is a linear automorphism of the commutative Griess algebra preserving the product (`griessMul_aut`). For each minimal α and $s = \pm c_\alpha$, where c_α is a fixed square root of $\varepsilon(\alpha,\alpha)$, $e_{\alpha,s}$ is a rigid idempotent (Theorems 47.17 and `isingVec_one_self`), so by Theorem 47.13 some g^k, $k \geq 1$, fixes it (`aut_isingVec_periodic`). There are finitely many minimal vectors (`normFour_finite`), so the product K_1 of all these periods works for all of them at once; by Lemma 47.18(a),(b), g^{K_1} fixes $V_\Lambda^+ \times 0$ (`aut_pow_fix_untwisted`). (2) Apply (1) to $h = \sigma g \sigma^{-1}$: some $h^{K_2} = \sigma g^{K_2} \sigma^{-1}$ fixes $V_\Lambda^+ \times 0$. Since $\sigma(0,x) = (\Psi x, 0) \in V_\Lambda^+ \times 0$ (`sigNat_Ts`), g^{K_2} fixes $\sigma^{-1}(\Psi x, 0) = (0,x)$. (3) $g^{K_1 K_2}$ fixes $V_\Lambda^+ \times 0$ and $(0,x)$, so it is 1 by Lemma 47.18(c). □

Physical meaning

Every global symmetry of the Monster CFT is of finite order. For a unitary CFT with finite-dimensional weight spaces one expects the symmetry group to be compact (it preserves the positive inner product on each V_n, so it sits inside $\prod_n U(V_n)$), with Lie algebra the conserved currents, i.e. V_1; since $V^\natural{}_1 = 0$ there are no continuous symmetries, so the group is discrete and compact, hence finite. The library's proof uses neither unitarity nor compactness: rigid Ising sub-theories play the role of the missing currents, and the triality σ carries the argument into the twisted sector.

What the machine verified

Unconditional. Printed in `VOA/Moonshine/MoonshineLRFinOrderAudit.lean`; `#print axioms = [propext, Classical.choice, Quot.sound]`, also printed in `VOA/Moonshine/MoonshineCNFinalAudit.lean` (targeted build green, 0 `sorryAx`). Uses no group theory of the Monster.

Trap / dead end

Two routes that do not work. The finite-order argument needs (a) some vectors of $V^\natural{}_2$ that every automorphism permutes with finite orbits, and (b) a way to see that an automorphism fixing the untwisted block fixes the twisted one. Two tempting choices fail. (a) Starting from $c = 1$ Virasoro vectors $\frac{1}{2}h(-1)^2\mathbf{1}$ fails: they form a continuous $O(24)$-family, are not rigid, and need not be periodic under an automorphism. Only $c = \frac{1}{2}$ rigidity starts the argument. (b) Diagonal zero modes do not separate the twisted sector: the eigenvalues of $o(q_{aa})$ on $h_{e_c}(-\frac{1}{2}) \otimes t$ are ($\frac{9}{8}$ at $a = c$, $\frac{1}{8}$ elsewhere), and on x_n with n odd of norm 4 in a V_3^+ block they are $n_a^2/8$, the same pattern; any argument of the form "a map commuting with all $o(q_{aa})$ has no twisted-to-untwisted component" is false. The library uses the off-diagonal $o(q_{ab})$ (Lemma 47.7) and the σ-trick. Also not used: a route through derivations of the infinite-dimensional $V^\natural$ and a Jordan decomposition of g on $V^\natural$; the finite-dimensional lemma of §47.3 replaces it.

47.6 The automorphism group of the moonshine module is finite

The Conway–Norton theorem needs only finite order. Finiteness of the group was proved afterwards, as a route-independent piece of the identification of $\mathrm{Aut}(V^\natural)$ with the Monster. The proof again uses no group theory.

47.6.1 Finitely many rigid idempotents

Theorem 47.20 (Rigid idempotents are finite in number; derivations vanish on their span). *Let B be a finite-dimensional complex vector space with a commutative bilinear product. (a) The set of rigid idempotents $\{e : e \cdot e = 2e,\ (e \cdot y = y \Rightarrow y = 0)\}$ is finite. (b) If the rigid idempotents span B, every derivation of $(B, \cdot)$ is zero.*

```
theorem finite_setOf_rigid_idempotent [FiniteDimensional ℂ B] :
    {e : B | mul e e = (2 : ℂ) • e ∧ ∀ y, mul e y = y → y = 0}.Finite := by

theorem derivation_eq_zero_of_span_rigid [FiniteDimensional ℂ B]
    (hspan : Submodule.span ℂ
      {e : B | mul e e = (2 : ℂ) • e ∧ ∀ y, mul e y = y → y = 0} = ⊤)
```

```
(D : Module.End ℂ B)
(hD : ∀ x y, D (mul x y) = mul (D x) y + mul x (D y)) : D = 0 := by
```

(`VOA/Moonshine/MoonshineLRFiniteRigid.lean`, namespace `VOA.Moonshine.ConwayNorton.M8`; section variables `(mul : B →ₗ[ℂ] B →ₗ[ℂ] B) (hcomm : ∀ x y, mul x y = mul y x)`, both included in each statement by `include hcomm in`.)

From the mathematics to the Lean statement

`S.Finite` is Mathlib's `Set.Finite`: S is a finite set. The set in (a) is exactly the set of rigid idempotents of Definition 47.12; it is *not* restricted to explicit Ising vectors, nor to vectors of any special shape. In (b), `hspan` says the rigid idempotents span B, `hD` that D is a derivation. Statements exactly as on paper; the file docstring stresses that the product need be neither associative nor unital.

Proof on paper. (a) Choose a basis and write the product with structure constants c_{ijk}. The idempotent equations $f_i(X) = \sum_{j,k} c_{ijk}X_jX_k - 2X_i$ generate an ideal $J \subseteq R = \mathbb{C}[X_1, \dots, X_n]$; idempotents are the points of the affine variety $V(J)$. Let p be a rigid idempotent and $\mathfrak{m}_p$ its maximal ideal. Taylor expansion at p gives $f(p+y) = 2(L_p - 1)y +$ (quadratic in y) (using commutativity, the linear part of $(p+y)\cdot(p+y)$ is $2p\cdot y$); the Jacobian $2(L_p - 1)$ is invertible by rigidity, so each coordinate $X_i - p_i$ is a linear combination of the f_j modulo $\mathfrak{m}_p^2$: $\mathfrak{m}_p \subseteq J + \mathfrak{m}_p^2$. Hence $\mathfrak{m}_p$ is a *minimal* prime over J: if $J \subseteq Q \subseteq \mathfrak{m}_p$ with Q prime, the image N of $\mathfrak{m}_p$ in the Noetherian domain R/Q satisfies $N = N^2$, so $N = 0$ by Nakayama (Krull), i.e. $Q = \mathfrak{m}_p$. A Noetherian ring has finitely many minimal primes over an ideal (`Ideal.finite_minimalPrimes_of_isNoetherian Ring`), and $p \mapsto \mathfrak{m}_p$ is injective. (b) Each rigid idempotent is killed by every derivation (step (iii) of Theorem 47.13), and they span. □

Physical meaning

Rigid sub-theories are isolated points of the "moduli space of embedded stress tensors": they cannot be deformed (§47.3), so they come in a discrete, and by algebraic geometry finite, set. A symmetry can only permute them.

What the machine verified

Unconditional, generic (Mathlib only). Printed in `VOA/Moonshine/MoonshineLRFinOrderAudit.lean`; standard axioms.

Trap / dead end

A version of this argument that does not work. One could try to count *all Ising vectors* of $V^\natural$, which needs rigidity at every Ising vector, not only at the explicit ones; for an arbitrary Ising vector the only known proof goes through $c = \frac{1}{2}$ representation theory (vanishing of a singular vector, needing unitarity or the classification of Ising vectors). The version in the library sidesteps this by counting *rigid* idempotents, rigidity being part of the definition of the set, and by using only the explicit Ising vectors for faithfulness (Theorem 47.22). **Also not done:** part (b) is *not* applied to ${V^\natural}_2$; that would need "the rigid idempotents span ${V^\natural}_2$", which the library does not prove. So $\mathrm{Der}({V^\natural}_2) = 0$ and $\mathrm{Der}(V^\natural) = 0$ are not theorems of the library.

47.6.2 $\mathrm{Aut}(V^\natural)$ acts faithfully on a finite set

Definition 47.21 (The rigid idempotents of the Griess algebra). $R(V^\natural) \subseteq {V^\natural}_2$ is the set of rigid idempotents of the Griess algebra $({V^\natural}_2, \times)$.

```
def vnatGriessBilin :

```

(`VOA/Moonshine/MoonshineLRFiniteAut.lean`, namespace `VOA.Moonshine.ConwayNorton.M8`.)

From the mathematics to the Lean statement

`vnatGriessBilin` packages `griessMul` as a bilinear map (`LinearMap.mk₂` with the four linearity proofs), so that the generic theorems apply; `vnatGriessBilin_apply` states it is `griessMul` by `rfl`. `vnatRigidSet` is $R(V^\natural)$ verbatim. `autRestrict_mem_vnatRigidSet`: $\mathrm{Aut}(V^\natural)$ permutes $R(V^\natural)$. `isingVec_mem_vnatRigidSet`: the normalised explicit Ising vectors lie in it (this is `isingVec_one_self` and `isingVec_rigid` together). The conformal vector ω also lies in $R(V^\natural)$ ($o(\omega) = L_0 = 2$ on ${V^\natural}_2$), although the library does not state this.

Physical meaning

The finite set of rigid embedded stress tensors of weight two, permuted by every symmetry of the theory.

What the machine verified

Definitions and unconditional lemmas; printed in the FinOrder audit; standard axioms.

Theorem 47.22 ($\mathrm{Aut}(V^\natural)$ is finite). *(a) An automorphism of $V^\natural$ that fixes every rigid idempotent of ${V^\natural}_2$ is the identity. (b) If $R(V^\natural)$ is finite,* $\mathrm{Aut}(V^\natural)$ *is finite. (c)* $\mathrm{Aut}(V^\natural)$ *is finite.*

```
theorem eq_one_of_fix_rigid (k : AutVnat)

theorem finite_autVnat_of_finite_rigid (hR : vnatRigidSet.Finite) : Finite AutVnat := by

theorem finite_autVnat : Finite AutVnat := by
```

(`VOA/Moonshine/MoonshineLRFiniteAut.lean`.)

From the mathematics to the Lean statement

`Finite AutVnat` is Mathlib's type class "the type `AutVnat` has finitely many elements" (there is a bijection with some `Fin n`). `GriessAut.autRestrict k 2 e` is $k(e)$ for $e \in {V^\natural}_2$. (b) is conditional on `hR`; (c) has **no hypotheses**: it applies (b) with `hR` supplied by Theorem 47.20(a) for the Griess algebra (finite-dimensional because ${V^\natural}_2$ is, `gradingNat 2`). This is stronger than Theorem 47.19 and gives no bound on the order: the library does not compute $|\mathrm{Aut}(V^\natural)|$.

Proof on paper. (a) If k fixes $R(V^\natural)$ pointwise, it fixes every normalised $e_{\alpha,\pm s}$, so by Lemma 47.18(a),(b) it fixes $V_\Lambda^+ \times 0$. Since σ^{-1} permutes $R(V^\natural)$, the conjugate $\sigma k \sigma^{-1}$ also fixes $R(V^\natural)$ pointwise, hence fixes $V_\Lambda^+ \times 0$, hence k fixes $\sigma^{-1}(\Psi x, 0) = (0, x)$. By Lemma 47.18(c), $k = 1$. (b) The map $\mathrm{Aut}(V^\natural) \to \{\text{maps } R(V^\natural) \to R(V^\natural)\}$, $g \mapsto g|_R$, is injective by (a) (if $g|_R = h|_R$ then $h^{-1}g$ fixes R); a finite set has finitely many self-maps. (c) (b) and Theorem 47.20(a). □

Physical meaning

The global symmetry group of the Monster CFT is finite: it acts faithfully by permutations on the finite set of rigid weight-two stress tensors. (Classically one deduces this from $\mathrm{Aut}(V^\natural) = \mathbb{M}$; here it comes first, and the identification with AxiomMath's Monster is the subject of Chapters 48–49.)

What the machine verified

(c) **unconditional**; (b) conditional on `hR`, discharged in (c). Printed in `VOA/Moonshine/MoonshineLRFinOrderAudit.lean`; `#print axioms = [propext, Classical.choice, Quot.sound]` (build record of the release). Not used by `conwayNorton`. No group theory is used.

47.7 The Monster Lie algebra is generated by its simple root spaces

47.7.1 What has to be proved, and why it is not a Lie-theoretic statement

Chapter 45 constructs the Monster Lie algebra $\mathfrak{m}$ (the physical states of $V^\natural \otimes V_{I\!I_{1,1}}$ modulo null states), graded by $I\!I_{1,1}$, with root spaces $\mathfrak{m}_{(m,n)} \cong V^\natural{}_{1+mn}$ in Borcherds' coordinates, a Cartan subalgebra $\mathfrak{m}_{(0,0)} \cong \mathbb{C}^2$, and an invariant bilinear form; and it proves that these data form *Borcherds data* (a Borcherds–Kac–Moody algebra of rank two) *provided* $\mathfrak{m}$ is generated by its Cartan subalgebra and its simple root spaces. Every consequence that Chapter 46 draws (the free positive part, the denominator identity, the twisted denominator identities) passes through that structure. This section discharges the proviso.

The simple roots, in Borcherds' coordinates $(m, n) \in \mathbb{Z}^2$ with norm $-2mn$, are the real root $(1, -1)$ (root space $V^\natural{}_0 = \mathbb{C}\mathbf{1}$) and the imaginary roots $(1, j)$, $j \geq 1$ (root space $V^\natural{}_{j+1}$, of dimension $c(j)$, the coefficient of q^j in J). An important fact: *given the other Borcherds data, generation of* $\mathfrak{m}$ *by these simple root spaces is equivalent to the product formula*

$$\prod_{m,n\geq 1} (1 - p^m q^n)^{c(mn)} = 1 - \sum_{a,b\geq 1} c(a+b-1)\, p^a q^b \tag{47.4}$$

(the Koike–Norton–Zagier identity, "KNZ", which is $p^{-1}(1-p/q)\prod_{m,n\geq 1}(1-p^m q^n)^{c(mn)} = J(p) - J(q)$ rewritten). So a proof of generation *is* a proof of a statement about the modular function J, and it cannot come from Lie theory or vertex algebra alone. The library proves (47.4) analytically (Chapter 46, `knz_product`) and derives generation from it by a dimension count.

47.7.2 The objects from Chapters 45 and 46

We quote the declarations that the statements of this section use; their full presentation is in the chapters named.

(VOA/Moonshine/MoonshineCNMonsterBorcherdsData.lean; monsterLieAlgebra is moonshineMatterNear VOA.primaryLieQuotient, VOA/Moonshine/MoonshineCNMonsterLie.lean.)

From the mathematics to the Lean statement

Roots. A weight is a pair $\gamma = (m, n) \in \mathbb{Z}^2$ (γ.1, γ.2); borcherdsCartanPairing is the $\mathbb{C}$-bilinear extension of $\langle (m,n),(m',n')\rangle = -(mn' + m'n)$, so $\langle \gamma,\gamma\rangle = -2mn$. The root support is 0, $\pm(1,-1)$ and $\pm$(open positive cone $m, n \geq 1$); simple roots are $(1,-1)$ and $(1,j)$, $j \geq 1$. **Generators.** borcherdsSimpleGenerators wt is the *set* $\mathfrak{g}_0 \cup \bigcup_{\alpha \text{ simple}} (\mathfrak{g}_\alpha \cup \mathfrak{g}_{-\alpha})$; LieSubalgebra.lieSpan ℂ g S is the Lie subalgebra generated by S; = ⊤ says it is all of $\mathfrak{g}$. **Borcherds data.** The fields are: a grading by $\mathbb{Z}^2$ (DirectSum.IsInternal: $\mathfrak{g} = \bigoplus_\gamma \mathfrak{g}_\gamma$), finite-dimensional pieces, brackets add degrees, a two-dimensional Cartan $\mathfrak{g}_0$ acting on $\mathfrak{g}_\gamma$ by the pairing with γ, a symmetric invariant form pairing $\mathfrak{g}_\gamma$ only with $\mathfrak{g}_{-\gamma}$, nondegenerately, and equal to the pairing on the Cartan, roots in the support, one-dimensional real root spaces, and generated. **The Monster.** monsterLieBorcherdsWeight γ is the root space of $\mathfrak{m}$ at the library momentum borcherdsMomentum γ $= (m, -n)$ (the library's lattice $I\!I_{1,1}$ has norm $+2xy$;

Borcherds' (m, n) is the library's $(m, -n)$; trap recorded in Chapter 43, §43.10). `monsterLieBorcherdsRootEquiv` is the no-ghost isomorphism $\mathfrak{m}_{(m,n)} \cong V^{\natural}{}_{1+mn}$ for $(m, n) \neq 0$ (Chapter 45). `MonsterLieSimpleRootGeneration` is precisely "$\mathfrak{m}$ is generated by $\mathfrak{m}_0$ and the $\mathfrak{m}_{\pm\alpha}$, α simple".

Physical meaning

$\mathfrak{m}$ is the Lie algebra of physical states (BRST cohomology at ghost number one) of the bosonic string in 26 dimensions with 24 dimensions compactified on the moonshine orbifold and two on a Lorentzian torus; the momentum $(m, n) \in I\!I_{1,1}$ is the light-cone momentum/winding, and the physical states at momentum (m, n) are counted by the transverse states $V^{\natural}{}_{1+mn}$ (no-ghost). The real simple root $(1, -1)$ is the tachyon-like state $V^{\natural}{}_0$; the imaginary simple roots $(1, j)$ are the states of one unit of m.

What the machine verified

Definitions (Chapter 45); the root definitions and `BorcherdsData` contain no VOA input.

```

(`VOA/Moonshine/MoonshineLRM5KNZ.lean`.)

```
noncomputable def cJ (n : ℕ) : ℂ := PowerSeries.coeff (n + 1) JShift
```

(`VOA/Moonshine/MoonshineLRM5Replicable.lean`.)

From the mathematics to the Lean statement

The ring is `PowerSeries (LaurentSeries ℂ)` $= \mathbb{C}((q))[[p]]$. `coneLog e` is $-\sum_{k,m,n\geq 1} m\, e(m,n)\, p^{mk} q^{nk}$ (the $p\partial_p$-logarithmic derivative of the product), and `coneProd e` is the unique power series with constant term 1 solving $p\,\partial_p F = F \cdot \mathrm{coneLog}(e)$ (`odeSol`, `coneProd_spec`); for natural exponents it is the formal product $\prod_{m,n\geq 1}(1 - p^m q^n)^{e(m,n)}$, and this definition makes sense for complex (in particular negative) exponents without logarithms. `knzSeries c` is $1 - \sum_{a,b\geq 1} c(a+b-1)p^a q^b$. `cJ n` is the coefficient of q^{n+1} in `JShift` $= qJ$, i.e. the coefficient $c(n)$ of q^n in J ($c(0) = 0$, $c(1) = 196884$); equivalently $c(n) = \dim V^{\natural}{}_{n+1}$. `knz_product` is (47.4). `coneProd_exponent_unique`: the exponents of a

cone product are determined by the product (on the open cone).

Physical meaning

The product $\prod(1-p^m q^n)^{c(mn)}$ is the "second-quantised" partition function of the string states counted by $V^\natural$; that it equals $p(J(p)-J(q))/(1-p/q)$ is the denominator identity of $\mathfrak{m}$, a modular identity (heuristically related to Hecke operators acting on J; Chapter 46).

What the machine verified

Proved in Chapter 46 (`knz_product`: unconditional, standard axioms, in the M5 audit).

47.7.3 Pre-data and the generic generation theorem

Definition 47.23 (Borcherds pre-data; the subalgebra generated by simple roots; the KNZ hypothesis)**.** *Borcherds pre-data* on a complex Lie algebra $\mathfrak{g}$ are all the fields of Borcherds data except `generated`. For pre-data P, $G = P$.simpleSpan is the Lie subalgebra generated by the Cartan and the simple root spaces. P satisfies *KNZ* if

$$\prod_{m,n\geq 1}(1-p^m q^n)^{\dim \mathfrak{g}_{(m,n)}} = 1 - \sum_{a,b\geq 1} \dim \mathfrak{g}_{(1,a+b-1)}\, p^a q^b.$$

    knzSeries fun j => (finrank ℂ (P.weightSpace (1, (j : ℤ))) : ℂ)
```

(`VOA/Moonshine/MoonshineLRGenerationPreData.lean`; `KNZ` is in `VOA/Moonshine/MoonshineLRGenerationSandwich.lean`; namespace `VOA.Moonshine.ConwayNorton.M8.BorcherdsPreData`.)

From the mathematics to the Lean statement

The fields of `BorcherdsPreData` are, word for word, those of `BorcherdsData` minus `generated`; the definition `toData` (same file) adds a generation proof back. `simpleSpan` is G. In `KNZ`, `finrank ℂ (P.weightSpace ((m : ℤ), (n : ℤ)))` is $\dim \mathfrak{g}_{(m,n)}$ cast to $\mathbb{C}$, and the right side is `knzSeries` of $j \mapsto \dim \mathfrak{g}_{(1,j)}$ (the value at $j = 0$ is irrelevant: `knzCoeff` only uses $c(a+b-1)$ with $a, b \geq 1$). So `KNZ` is the displayed identity.

Physical meaning

Pre-data are the string-theory data (graded physical states, momentum zero-modes, the Zamolodchikov-type invariant pairing) before one knows which states are "elementary". KNZ is the statement that the free second-quantised spectrum generated by the simple-root states reproduces the full spectrum.

What the machine verified

Definitions; printed in `VOA/Moonshine/MoonshineLRGenerationAudit.lean`; standard axioms.

Theorem 47.24 (Generation from KNZ). *Borcherds pre-data satisfying KNZ are generated by their simple root spaces: $G = \mathfrak{g}$.*

```
theorem simpleSpan_eq_top_of_KNZ (hK : P.KNZ) : P.simpleSpan = ⊤ := by

theorem lieSpan_eq_top_of_KNZ (hK : P.KNZ) :
    LieSubalgebra.lieSpan ℂ g (borcherdsSimpleGenerators P.weightSpace) = ⊤ :=
  P.simpleSpan_eq_top_of_KNZ hK
```

(`VOA/Moonshine/MoonshineLRGenerationSandwich.lean`; section variable `(P : BorcherdsPreData g)` for an arbitrary complex Lie algebra $\mathfrak{g}$.)

From the mathematics to the Lean statement

The single hypothesis `hK` is KNZ for P. The conclusion is the `generated` field, so `P.toData` with this proof is Borcherds data. Generic: no VOA, no Monster.

Proof on paper (the sandwich). Let G be the subalgebra generated by the Cartan and the simple root spaces, $R = \{x \in G : (x, G) = 0\}$ the radical of the restricted form, and $\mathfrak{g}' = G/R$.

(1) *G and R are graded.* The generators are homogeneous, so $G = \bigoplus_\gamma (G \cap \mathfrak{g}_\gamma)$. R is an ideal by invariance, and homogeneous because the form pairs degree γ only with $-\gamma$ (`form_decompose_eq`). Hence $\mathfrak{g}'$ is graded by the images $\mathfrak{g}'_\gamma$, and the form descends to a form nondegenerate on $\mathfrak{g}'_\gamma \times \mathfrak{g}'_{-\gamma}$.

(2) *$\mathfrak{g}'$ is Borcherds data, generated by construction* (`quotientData`). If $\mathfrak{g}_\gamma$ and $\mathfrak{g}_{-\gamma}$ both lie in G (true for the Cartan, the real roots and the simple imaginary roots), then $R \cap \mathfrak{g}_\gamma = 0$ by nondegeneracy, so $\mathfrak{g}'_\gamma \cong \mathfrak{g}_\gamma$ (`finrank_quotientWeight`).

(3) *The character identity for any Borcherds data* (`coneProd_neg_mul_knzSeries`):

$$\prod_{m,n\geq 1} (1 - p^m q^n)^{-\dim \mathfrak{g}'_{(m,n)}} \cdot \Big(1 - \sum_{a,b\geq 1} \dim \mathfrak{g}'_{(1,a+b-1)} p^a q^b\Big) = 1.$$

Reason: by Chapter 45, the positive part $\mathfrak{u}^+ = \bigoplus_{m,n\geq 1} \mathfrak{g}'_{(m,n)}$ is free on the generating space $U = \bigoplus_{j\geq 1} \bigoplus_{0\leq k<j} (\operatorname{ad} e)^k \mathfrak{g}'_{(1,j)}$ (the real-root strings through the imaginary simple

roots), so $U(\mathfrak{u}^+) \cong T(U)$ (`positiveTensorGeneratorToEnveloping_bijective`). The graded dimension of $T(U)$ is $1/(1-\operatorname{ch} U)$, that of $U(\mathfrak{u}^+)$ is $\prod(1-p^m q^n)^{-\dim \mathfrak{u}^+_{(m,n)}}$ (graded PBW), and $\dim U_{(a,b)} = \dim \mathfrak{g}'_{(1,a+b-1)}$. For the last point: $\operatorname{ad} e$ moves the weight by the real root $(1,-1)$, so the string through $(1,j)$ has weights $(1+k, j-k)$; it is cut off at $k<j$ because $(1+k, j-k)$ must stay in the open cone (for $k=j$ the weight $(1+j,0)$ is not a root), and $\operatorname{ad} e$ is injective on these pieces by $\mathfrak{sl}_2$-theory (the imaginary simple root spaces are lowest-weight spaces for the real $\mathfrak{sl}_2$, of weight $j-1$, so the string has exactly j terms). A weight (a,b) with $a,b \geq 1$ occurs exactly once, for $j=a+b-1$, $k=a-1$.

(4) *Comparison.* By (2), the simple imaginary root spaces of $\mathfrak{g}'$ and $\mathfrak{g}$ have the same dimensions, so the second factor in (3) is `knzSeries` of $j \mapsto \dim \mathfrak{g}_{(1,j)}$, which by KNZ for P equals $\prod(1-p^m q^n)^{\dim \mathfrak{g}_{(m,n)}}$. Hence $\prod(1-p^m q^n)^{\dim \mathfrak{g}_{(m,n)} - \dim \mathfrak{g}'_{(m,n)}} = 1$, and by uniqueness of exponents (`coneProd_exponent_unique`, `eq_of_coneProd_neg_mul_eq_one`) $\dim \mathfrak{g}'_\gamma = \dim \mathfrak{g}_\gamma$ on the open positive cone (`finrank_quotientWeight_of_KNZ`).

(5) *The sandwich.* For γ in the cone, $\dim \mathfrak{g}_\gamma = \dim \mathfrak{g}'_\gamma \leq \dim(G \cap \mathfrak{g}_\gamma) \leq \dim \mathfrak{g}_\gamma$, so $G \supseteq \mathfrak{g}_\gamma$ (`weightSpace_le_simpleSpan_of_KNZ`).

(6) *The negative cone.* The opposite pre-data (grading $\gamma \mapsto -\gamma$, Cartan composed with -1; `opposite`) have the same G and satisfy KNZ, because $\dim \mathfrak{g}_{-\gamma} = \dim \mathfrak{g}_\gamma$ (the form pairs them nondegenerately); applying (5) to them gives $G \supseteq \mathfrak{g}_{-\gamma}$.

(7) The remaining root spaces $(0, \pm(1,-1))$ are generators. By the root support, G contains every $\mathfrak{g}_\gamma$, hence $G = \mathfrak{g}$. □

Physical meaning

The sandwich is a counting argument familiar from string theory: the states built freely from the "elementary" string states (the simple roots) can only be fewer than all physical states; if their generating function already equals the full partition function (KNZ), there is nothing else.

What the machine verified

Unconditional, given its displayed hypothesis `hK`. Printed in `VOA/Moonshine/MoonshineLRGenerationAudit.lean` (`BorcherdsPreData.lieSpan_eq_top_of_KNZ`); standard axioms.

From the mathematics to the Lean statement

`e`, `f` with `hef` are a normalised pair of real root vectors ($e \in \mathfrak{g}_{(1,-1)}$, $f \in \mathfrak{g}_{(-1,1)}$, $(e,f)=1$); such a pair exists for any Borcherds data (`exists_normalized_real_pair`, Chapter 45), and it enters only to define the generating space U (`positiveGeneratorSpace`). `positiveWeight D (m, n)` is $\mathfrak{u}^+_{(m,n)}$ (the root space viewed inside the positive part), and `finrankSeries (positiveGenWeight D e)` is $\operatorname{ch} U = \sum \dim U_{(a,b)} p^a q^b$. `P.quotientWeight γ` is $\mathfrak{g}'_\gamma$; `P.simpleSpanWeight γ` is $G \cap \mathfrak{g}_\gamma$ as a subspace of G; `simpleRadical` is R (an ideal: the omitted fields prove closure and `lie_mem` from invariance); `/` is the quotient Lie algebra. In `eq_of_coneProd_neg_mul_eq_one`, `h₁` and `h₂` are the two identities of step (4) with $X = \operatorname{ch} U$; the conclusion is equality of exponents on the cone. `opposite` replaces $\mathfrak{g}_\gamma$ by $\mathfrak{g}_{-\gamma}$ (the other fields are omitted). Each statement is the corresponding step of the proof above.

What the machine verified

All unconditional (given their displayed hypotheses), printed in `VOA/Moonshine/MoonshineLRGenerationAudit.lean` (185 reports, standard axioms, 0 `sorryAx`; build record of the release).

The generic layers underneath. Steps (3) and (4) rest on five generic files, which are pure algebra and combinatorics (no Borcherds data):

- `MoonshineLRGenerationCount.lean`: for a family of basis vectors with degrees in the open cone $\mathbb{N}^2_{\geq 1}$, finitely many in each degree, the number $N(\Gamma)$ of exponent vectors of total degree Γ satisfies the logarithmic-derivative recursion $\Gamma_1 N(\Gamma) = \sum_i \sum_{k\geq 1} (\deg i)_1 N(\Gamma - k \deg i)$ (`count_recursion`; a double count);
- `MoonshineLRGenerationSeries.lean`: hence $\sum_\Gamma N(\Gamma) p^a q^b = \prod (1-p^m q^n)^{-d(m,n)}$, d the number of basis vectors per degree (`expSeries_eq_coneProd`; both sides solve the same first-order equation in p);
- `MoonshineLRGenerationGraded.lean`: graded PBW: for a Lie algebra graded by a monoid with a homogeneous basis, ordered monomials form a basis of $U(L)$, $U(L)$ is graded (via the coaction $U(L) \to U(L)[G]$), and in the cone $\dim U(L)_\Gamma = N(\Gamma)$ (`finrank_envGraded_eq_expCount`);
- `MoonshineLRGenerationTensor.lean`: if $T(S) \to U(L)$ is bijective for a graded subspace S, the words in a homogeneous basis of S are a basis of $U(L)$, and $\prod (1-p^m q^n)^{-\dim L_{(m,n)}} \cdot (1 - \mathrm{ch}\, S) = 1$ (`coneProd_mul_one_sub_basisDegSeries`);
- `MoonshineLRGenerationCone.lean`: the same in dimension form for cone-graded spaces with finite-dimensional pieces (`coneProd_finrank_mul_one_sub_finrankSeries`), homogeneous bases of such spaces (`coneBasis`), and the comparison of exponents (`eq_of_coneProd_neg_mul_eq_one`);

and on three files about quotients: `MoonshineLRGenerationQuotient.lean` (`form_decompose_eq`: a form pairing γ only with $-\gamma$ satisfies $B(x_\gamma, y) = B(x, y_{-\gamma})$; `isInternal_map_mkQ`: a quotient by a homogeneous submodule is graded), `MoonshineLRGenerationRadical.lean` (the radical, the quotient, the descended form) and `MoonshineLRGenerationQuotientData.lean` (the fields of `quotientData`: Cartan injective with range $\mathfrak{g}'_0$, action, symmetric invariant nondegenerate form, support, one-dimensional real root spaces, generation). We quote the three generic headlines:

```
theorem count_recursion (Γ : ℕ × ℕ) :
    Γ.1 * expCount deg low Γ =
      ∑ i ∈ low Γ, ∑ k ∈ Finset.Icc 1 Γ.1,
        if k • deg i ≤ Γ then (deg i).1 * expCount deg low (Γ - k • deg i) else 0 := by
```

(`VOA/Moonshine/MoonshineLRGenerationCount.lean`.)

```
theorem expSeries_eq_coneProd :
    expSeries deg low = coneProd (fun m n => -(basisDegCount deg low (m, n) : ℂ)) := by
```

(`VOA/Moonshine/MoonshineLRGenerationSeries.lean`.)

```
theorem finrank_envGraded_eq_expCount (Γ : ℕ × ℕ) :
    finrank ℂ (envGraded wt hbr Γ) = expCount deg low Γ := by
```

(`VOA/Moonshine/MoonshineLRGenerationGraded.lean`.)

From the mathematics to the Lean statement

In all three, `deg : ι → ℕ × ℕ` (or `A → ℕ × ℕ`) are the degrees of the basis vectors and `low Γ` is a finite set containing exactly the indices of degree $\leq \Gamma$ (hypothesis `hlow`); the section hypotheses `hdeg : ∀ i, 1 ≤ (deg i).1 ∧ 1 ≤ (deg i).2` put all degrees in the open cone. `expCount deg low Γ` is $N(\Gamma)$, `basisDegCount deg low γ` is $d(\gamma)$, `expSeries` the generating series of N, `envGraded wt hbr Γ` the degree-Γ part of $U(L)$ for the grading `wt` of L (with `hbr`: brackets add degrees, and `hb`: the basis is homogeneous). These are the classical PBW character formulas,

stated carefully enough to be used with complex exponents.

Physical meaning

The Fock-space counting of a free (bosonic) second-quantised theory: the partition function of free particles with $d(\gamma)$ species at each momentum γ is $\prod(1-e^{\gamma})^{-d(\gamma)}$.

What the machine verified

Generic, unconditional, printed in the Generation audit; standard axioms.

47.7.5 The Monster instance

Theorem 47.25 (The Monster Lie algebra is generated by its simple root spaces). *$\mathfrak{m}$ is generated by $\mathfrak{m}_0$ and the root spaces $\mathfrak{m}_{\pm(1,-1)}$, $\mathfrak{m}_{\pm(1,j)}$, $j \geq 1$.*

```
def monsterLiePreData : BorcherdsPreData monsterLieAlgebra where
  weightSpace := monsterLieBorcherdsWeight
  weight_internal := monsterLieBorcherdsWeight_isInternal
  weight_finite := monsterLieBorcherdsWeight_finite

theorem finrank_monsterLieBorcherdsWeight_cone (m n : ℕ) (hm : 0 < m) (_hn : 0 < n) :
    (finrank ℂ (monsterLieBorcherdsWeight ((m : ℤ), (n : ℤ))) : ℂ) = cJ (m * n) := by

theorem monsterLiePreData_KNZ : monsterLiePreData.KNZ := by

theorem monsterLieSimpleRootGeneration : MonsterLieSimpleRootGeneration :=
  monsterLiePreData.lieSpan_eq_top_of_KNZ monsterLiePreData_KNZ
```

(`VOA/Moonshine/MoonshineLRGenerationMonster.lean`, namespace `VOA.Moonshine.Conway Norton.M8`; the remaining fields of `monsterLiePreData` are the corresponding fields of `monsterLieBorcherdsData`, copied one by one.)

From the mathematics to the Lean statement

`monsterLiePreData` uses exactly the grading, Cartan and form of Chapter 45's `monsterLieBorcherdsData`, so `monsterLiePreData.weightSpace` is `monsterLieBorcherdsWeight` *by definition* and the conclusion of `lieSpan_eq_top_of_KNZ` is literally `MonsterLieSimpleRootGeneration` (Lean accepts the term). The dimension statement says $\dim \mathfrak{m}_{(m,n)} = c(mn)$ for $m, n \geq 1$: by the no-ghost isomorphism $\mathfrak{m}_{(m,n)} \cong V^{\natural}_{1+mn}$ and $\dim V^{\natural}_{1+mn} = [q^{1+mn}]JShift = c(mn)$ (`finrank_gradingNat_eq_coeff_JShift`). (The underscore in `_hn` marks a hypothesis not used in the proof; it is harmless.) KNZ for $\mathfrak{m}$ is then `knz_product` after rewriting both sides with these dimensions. **The headline has no hypotheses. Could it be vacuous?** $\mathfrak{m}$ is the specific Lie algebra of Chapter 45, with root spaces of the dimensions just stated, so "generated by" is a substantial statement; and the sign convention (Borcherds' (m,n) is the library momentum $(m,-n)$) is built into `monsterLieBorcherdsWeight`, so the cone $m, n \geq 1$ is the right one (the root spaces at library momenta $x, y \geq 1$ are $V^{\natural}_{1-xy}$, which is 0 except at $(x,y) = (1,1)$, the real root $(1,-1)$ in Borcherds' coordinates).

Proof on paper. Theorem 47.24 for the pre-data of $\mathfrak{m}$; KNZ holds because $\dim \mathfrak{m}_{(m,n)} = c(mn)$ on the cone and $\dim \mathfrak{m}_{(1,j)} = c(j)$, so both sides of KNZ are those of (47.4), which is `knz_product`. □

Physical meaning

The physical states of the moonshine string are generated, as a Lie algebra under the string vertex (the bracket of BRST classes), by the tachyon state and the states of unit m-momentum. This is the input that turns $\mathfrak{m}$ into a generalised Kac–Moody algebra with a Weyl–Kac–Borcherds denominator formula, i.e. into a tool for computing twisted partition functions.

What the machine verified

Unconditional. Printed in `VOA/Moonshine/MoonshineLRGenerationAudit.lean` and in `VOA/Moonshine/MoonshineCNFinalAudit.lean`: `#print axioms = [propext, Classical.choice, Quot.sound]` (build record of the release).

Trap / dead end

Do not look for a Lie-theoretic proof of generation. Given the other Borcherds data, generation of $\mathfrak{m}$ by the known simple roots is *equivalent* to KNZ: the sandwich gives "KNZ $\Rightarrow$ generation" (this section), and conversely generation makes the character identity (3) a statement about $\mathfrak{m}$ itself, which is KNZ. So any proof that $\mathfrak{m}$ has no further simple roots off the line $m = 1$ is a proof of the product formula for $J(p) - J(q)$, a statement about the modularity of J. The Casimir argument of Chapter 45 cannot exclude extra simple roots (m, n), $m \geq 2$; it only excludes relations among the known ones. The equivalence is a paper statement; the library proves only the direction it needs.

Trap / dead end

Stale docstring. The docstring of `MonsterLieSimpleRootGeneration` in `VOA/Moonshine/MoonshineCNMonsterBorcherdsData.lean` still says that generation "is the only Borcherds-data field not yet proved"; it is now proved (`monsterLieSimpleRoot Generation`). Its second clause ("it is equivalent, given the other fields, to the product formula") is the paper equivalence above; only one direction is in Lean. The Lean statements are unaffected.

47.7.6 How generation feeds the twisted denominator identities

With generation, Chapter 45's `monsterLieBorcherdsData monsterLieSimpleRootGeneration` is Borcherds data, and Chapter 46 applies to it. For every automorphism σ of $V^\natural$ of finite order, σ acts on $\mathfrak{m}$ by graded Lie algebra automorphisms preserving the form and fixing the Cartan and the real root spaces; taking σ-equivariant graded traces in the homology of the free Lie algebra $\mathfrak{u}^+$ gives the twisted denominator identity, whose coefficients are the traces $\mathrm{tr}(\sigma^k | V^\natural{}_n)$. In Lean:

```
theorem twistedDenominatorIdentity_of_simpleRootGeneration (hgen :
 ↪  MonsterLieSimpleRootGeneration)
    (σ : AutVnat) (hσ : IsOfFinOrder σ) : TwistedDenominatorIdentity (mckayThompsonFamily
     ↪  σ) :=

theorem completelyReplicable_of_simpleRootGeneration (hgen :
 ↪  MonsterLieSimpleRootGeneration)
    (hfin : ∀ g : AutVnat, IsOfFinOrder g) : CompletelyReplicable :=

theorem conwayNorton_of_simpleRootGeneration (hgen : MonsterLieSimpleRootGeneration)
    (hfin : ∀ g : AutVnat, IsOfFinOrder g) : ConwayNortonConjecture :=
  M8.conwayNorton_of_finOrder_of_completelyReplicable hfin
    (completelyReplicable_of_simpleRootGeneration hgen hfin)
```

(`VOA/Moonshine/MoonshineCNTwistedDenominator.lean`, Chapter 46.)

From the mathematics to the Lean statement

`TwistedDenominatorIdentity c` (Chapter 46) is a formal power-series identity in the coefficient array `mckayThompsonFamily` $\sigma = (k, n) \mapsto \mathrm{tr}(\sigma^k | V^\natural_{n+1})$; `CompletelyReplicable` is the proposition of Chapter 43 (Definition 43.19). The hypotheses `hgen` and `hfin` are *exactly* the two inputs (I), (II) of the introduction; this chapter supplies both. Generation is used once, to build the Borcherds data; finite order is used for the twisted identities (`hσ`) and for the analytic replication bounds.

Physical meaning

The twisted denominator identity is the statement that the σ-twisted second-quantised string partition function equals its free-field (simple-root) expression; generation is what makes the simple-root expression complete.

What the machine verified

Conditional on `hgen`, `hfin` as displayed; both discharged in this chapter. Printed in `VOA/Moonshine/MoonshineCNAudit18.lean`; standard axioms (Chapter 43).

47.8 The Conway–Norton theorem for every automorphism of the moonshine module

47.8.1 From complete replicability and finite order

Chapter 46 proves the genus-zero theorem in the form "finite order, complete replicability, the prime Hecke identity for the McKay–Thompson families and their non-injectivity modulo translations imply the conjecture", and separately proves the last two inputs for *every* replicable family. The first assembly step, in a file of this chapter, combines them.

Theorem 47.26 (Conway–Norton from finite order and complete replicability)**.** *If every automorphism of $V^\natural$ has finite order and the McKay–Thompson series are completely replicable, then the Conway–Norton conjecture holds for every automorphism of $V^\natural$.*

```
theorem conwayNorton_of_finOrder_of_completelyReplicable
    (hfin : ∀ g : AutVnat, IsOfFinOrder g) (hrep : CompletelyReplicable) :
    ConwayNortonConjecture :=
  conwayNorton_of_completelyReplicable_of_families hfin hrep
    (fun _ F k => ReplicableFamily_primeHeckeIdentity F k)
    (fun _ hN F _ => ReplicableFamily_notInjectiveModTranslations hN F)
```

(`VOA/Moonshine/MoonshineLRConwayNorton.lean`, namespace `VOA.Moonshine.ConwayNorton.M8`.) The three ingredients from Chapter 46:

```
theorem conwayNorton_of_completelyReplicable_of_families (hfin : ∀ g : AutVnat,
↪  IsOfFinOrder g)
    (hrep : CompletelyReplicable)
    (hB1 : ∀ (N : ℕ) (F : ReplicableFamily N) (k : ℕ), PrimeHeckeIdentity F k)
    (hD7 : ∀ (N : ℕ), 0 < N → ∀ F : ReplicableFamily N, (∀ k, PrimeHeckeIdentity F k) →
      F.NotInjectiveModTranslations) :
    ConwayNortonConjecture :=
```

(`VOA/Moonshine/MoonshineCNGenusZeroMain.lean`.)

```
theorem ReplicableFamily_primeHeckeIdentity {N : ℕ} (F : ReplicableFamily N) (k : ℕ) :
    PrimeHeckeIdentity F k := by
```

(VOA/Moonshine/MoonshineLRHecke.lean.)

```
theorem ReplicableFamily_notInjectiveModTranslations {N : ℕ} (hN : 0 < N)
    (F : ReplicableFamily N) : F.NotInjectiveModTranslations := by
```

(VOA/Moonshine/MoonshineLRNontrivial.lean.)

From the mathematics to the Lean statement

`CompletelyReplicable` (Chapter 43, Definition 43.19): for every g and $m \geq 1$ there is a monic polynomial P of degree m with $P(T_g(\tau)) = \sum_{ad=m} \sum_{0 \leq b < d} T_{g^a}(\frac{a\tau+b}{d})$. `ReplicableFamily N` is the abstract family of q-series of period N of Chapter 43 (Definition 43.21). `PrimeHeckeIdentity F k` is a Hecke-orbit identity at primes $p \equiv 1 \pmod N$, and `F.NotInjectiveModTranslations` says that no member of the family is injective on $\mathbb{H}/\mathbb{Z}$ (Chapter 46). The two lambda terms show that the hypotheses `hB1`, `hD7` of the genus-zero theorem are discharged by hypothesis-free theorems for all families; so the only hypotheses left are `hfin` and `hrep`, as stated.

Proof on paper. The proof term *is* the proof: Chapter 46's genus-zero theorem with its two family-level hypotheses filled in. □

Physical meaning

"Complete replicability" is the statement that the twisted partition functions of g and all its powers are related by Hecke operators, as expected from the second-quantised (symmetric-product) string theory; the genus-zero argument converts this into "each twisted partition function is a Hauptmodul".

What the machine verified

Conditional on `hfin`, `hrep` (both later discharged). Printed in `VOA/Moonshine/MoonshineLRConwayNortonAudit.lean` (its single report) and in `VOA/Moonshine/MoonshineCNAudit18.lean`; standard axioms.

47.8.2 The final theorem

Theorem 47.27 (Conway–Norton for Aut($V^\natural$); Borcherds). *For every automorphism g of $V^\natural$ there are a subgroup $\Gamma_g \leq \mathrm{SL}_2(\mathbb{R})$ and $N \geq 1$ such that $\Gamma_0(N) \leq \Gamma_g$, Γ_g is commensurable with $\mathrm{SL}_2(\mathbb{Z})$, and $T_g = q^{-1} + \sum_{n \geq 1} \mathrm{tr}(g|V^\natural_{n+1})q^n$ is the normalised Hauptmodul of Γ_g. (This is the qualitative genus-zero form: Γ_g is not identified with Conway and Norton's group and N is not related to the order of g; it is weaker than the table-level conjecture.)*

```
theorem conwayNorton_of_isOfFinOrder (hfin : ∀ g : AutVnat, IsOfFinOrder g) :
    ConwayNortonConjecture :=
  conwayNorton_of_simpleRootGeneration monsterLieSimpleRootGeneration hfin
```

(VOA/Moonshine/MoonshineLRGenerationMonster.lean.)

```
theorem conwayNortonConjecture_holds : ConwayNortonConjecture :=
  conwayNorton_of_isOfFinOrder autVnat_isOfFinOrder
```

(VOA/Moonshine/MoonshineLRConwayNortonFinal.lean, namespace `VOA.Moonshine.ConwayNorton.M8`.)

```
theorem conwayNorton : ConwayNortonConjecture :=
  M8.conwayNortonConjecture_holds
```

(VOA/Moonshine/MoonshineCNFinalAudit.lean, namespace VOA.Moonshine.ConwayNorton; Chapter 43.)

From the mathematics to the Lean statement

ConwayNortonConjecture is the proposition of Chapter 43 (Definition 43.16); its clause-by-clause comparison with Conway and Norton's conjecture is Chapter 43, §43.6.3: it is the genus-zero (qualitative) form, for the full automorphism group of the library's $V^\natural$, weaker than the table-level conjecture in that Γ_g is not identified with Conway–Norton's group, not required to lie in the normaliser of $\Gamma_0(N)$, and N is not related to the order of g. The three declarations above are one-line proof terms: conwayNorton_of_isOfFinOrder plugs generation (Theorem 47.25) into conwayNorton_of_simpleRootGeneration; conwayNortonConjecture_holds plugs in finite order (Theorem 47.19); and conwayNorton is *definitionally* the same proof under the name fixed in the statement file. So conwayNorton and M8.conwayNortonConjecture_holds are the same theorem; the former is the official name. **No hypotheses**, no section variables, no type-class assumptions.

The whole chain, unwound. Reading the proof terms from the top:

(1) conwayNorton := conwayNortonConjecture_holds := conwayNorton_of_isOfFinOrder applied to autVnat_isOfFinOrder (§47.5; Ising rigidity, periodicity, the ingredients of the faithfulness proof with weakened hypotheses, and σ; not the faithfulness theorem itself);

(2) conwayNorton_of_isOfFinOrder := conwayNorton_of_simpleRootGeneration applied to monsterLieSimpleRootGeneration (§47.7; the sandwich and knz_product);

(3) conwayNorton_of_simpleRootGeneration (Chapter 46) := conwayNorton_of_finOrder_of_completelyReplicable applied to completelyReplicable_of_simpleRootGeneration, i.e. to the twisted denominator identities of the Borcherds data monsterLieBorcherdsData (Chapters 45, 46);

(4) conwayNorton_of_finOrder_of_completelyReplicable (this chapter) := the genus-zero theorem conwayNorton_of_completelyReplicable_of_families with the family-level Hecke and non-injectivity theorems (Chapter 46);

(5) which in turn is the Γ_1 genus-zero argument followed by the bridge $\Gamma_1 \Rightarrow \Gamma_0$ conwayNorton_of_gammaOne (Chapter 43, §43.8).

The inputs from Chapters 45–46 that this chapter uses are exactly the declarations quoted with their paths in §47.7 and in this section; everything else in the chain is this chapter's.

Physical meaning

Every global symmetry g of the Monster CFT has a twisted torus partition function $Z\left[\begin{smallmatrix}1\\ g\end{smallmatrix}\right](\tau) = \mathrm{tr}(g\, q^{L_0 - 1})$ that is a global coordinate on a genus-zero modular curve. In Borcherds' string-theory proof: compactify the bosonic string on the moonshine orbifold times a Lorentzian torus; its physical states form $\mathfrak{m}$; the denominator formula of $\mathfrak{m}$ is the product formula for $J(p) - J(q)$; generation (which is that formula) and finite order of g (which follows here from the rigidity of the Ising sub-theories) give the twisted denominator formulas, i.e. complete replicability; and complete replicability forces genus zero.

What the machine verified

Unconditional. `#print axioms` for `conwayNorton`, `M8.conwayNortonConjecture_holds`, `M8.monsterLieSimpleRootGeneration`, `M8.autVnat_isOfFinOrder` (the four commands of `VOA/Moonshine/MoonshineCNFinalAudit.lean`): `[propext, Classical.choice, Quot.sound]`, no `sorryAx`, targeted build and the umbrella `VOA.Moonshine` green (build record of the release). `conwayNortonConjecture_holds` is also printed in `VOA/Moonshine/MoonshineLRFinOrderAudit.lean`, and `conwayNorton_of_isOfFinOrder` in `VOA/Moonshine/MoonshineLRGenerationAudit.lean`. The book's authors did not re-run the builds. The repository-wide aggregate `lake build` had not been run for this part at the time of the build record; the targeted and umbrella builds are the machine evidence. The theorem does *not* depend on `GmatEqAut0`: it is about $\mathrm{Aut}(V^\natural)$, whatever that group is.

47.8.3 What the Conway–Norton theorem does and does not use from this chapter

- **Used:** `monsterLieSimpleRootGeneration`, `autVnat_isOfFinOrder`, and through the latter the periodicity lemma, the Ising vectors and their rigidity, the faithfulness ingredients (zero modes, joint eigenvectors, twisted exclusion, leading products, the Leech span), and `sigmaAut`.
- **Not used:** `vnatGriessRestrict_injective` and `aut_eq_one_of_fix_weightTwo` themselves (their hypotheses are too strong for the finite-order argument; weakened copies are used), `vnatGriessRestrict_injective_of_gen`, and the finiteness theorem `finite_autVnat` with its generic lemmas. These serve the identification of $\mathrm{Aut}(V^\natural)$ with the Monster (Chapters 48–49).

47.9 The files of this chapter

All 33 files of the chapter (the families `MoonshineLR{FinOrder*, Generation*, ConwayNorton*, FiniteRigid, FiniteAut}` and `Aut*`) are under `VOA/Moonshine/`. "Individually" means every headline declaration is presented under the Fidelity Protocol; "collectively" means the file's content is described with its role and its main statements quoted.

file	content	coverage

The technical lemmas, collectively. Besides the statements presented above, the `Aut*` files contain the computational lemmas behind them: the two-direction normal-ordered products of lattice currents on charged Fock states (`AutZeroModes.lean`: `nprod_lift_ZfGen₂`, `nprod_alphaLatGen_tmul₂`, `YfullGen_quadState`); coefficient extraction for $X\partial$ operators on polynomials (`AutFockEigen.lean`: `coeff_pderiv`, `lvlWt`, `coeff_quadOp_self`, `coeff_quadOp_ne`); charge coordinates and the rank-one argument $\gamma\gamma^{\mathsf{T}} = \beta\beta^{\mathsf{T}} \Rightarrow \gamma = \pm\beta$ (`AutChargeEigen.lean`: `eq_of_chargeCoord_eq`, `chargeCoord_rankOne`, `coordEα_of_eigen`); the twisted closed form $N^{\mathrm{tw}}_{ab} = \sum_k (k + \frac{1}{2})(X_{k,a}\partial_{k,b} + X_{k,b}\partial_{k,a})$ and its transport to the Leech twisted module, T^+ and the twisted block of $V^\natural$ (`AutZeroModesTwisted.lean`: `quadNT_apply`, `mode_Ywt_quad_zero`, `YML_charge_zero`, `YML_quadSt_two`, `plusModule_qP_one`, `VnatVOA_smul_quad_one`); componentwise action of $A \otimes 1$ and the rank-two impossibility $\beta\beta^{\mathsf{T}} \neq \frac{1}{8}\mathbf{1}$ (`AutTwistedExclusion.lean`: `component_rTensor`, `rTensor_joint_eigen`, `not_outer_eq_delta`, `quadNT_joint_eigen`); and the explicit $\mathbb{Z}^{24}$ computations of `AutLeechSpan.lean` (`pair_mem_minT`, `four_smul_mem_minC`, `two_smul_R_mem`, `mem_minC_of_mem_carrier`). Each is part of one of the paper steps of Theorem 47.4; their physical content is the free-boson mode algebra (untwisted and $\mathbb{Z}_2$-twisted). The `MoonshineLRFinOrder*` files contain, besides the quoted statements, the coordinate form $Q(u,v) = \sum u_a v_b q_{ab}$ of the quadratic letters (`isingQuadRow`, `isingQuad`, `isingQuad_one_isingQuad`), the spectral-decomposition operators of the periodicity lemma (`spectralDecomposition`, `spectralWeight`, `semisimplePart`, `characterDerivation`), and

private lemmas carrying out the case analysis of Theorem 47.17 and the scalar propagation with weakened hypotheses. `MoonshineLRFiniteRigid.lean` contains private lemmas on point ideals ($\ker(\mathrm{eval}_p) = (X_i - p_i)$), the Nakayama step for isolated points, and the coordinate form of a bilinear product.

The audit modules.

- `VOA/Moonshine/MoonshineLRFinOrderAudit.lean`: imports `MoonshineLRFinOrderIsing`, `MoonshineLRFinOrderPeriodic`, `MoonshineLRFinOrderRigid`, `MoonshineLRConwayNortonFinal`, `MoonshineLRFiniteAut`; 86 `#print axioms` reports at the release, including `pow_apply_eq_self_of_rigid`, `isingVec_rigid`, `autVnat_isOfFinOrder`, `conwayNortonConjecture_holds`, `finite_setOf_rigid_idempotent`, `derivation_eq_zero_of_span_rigid`, `finite_autVnat`. Per the build record all reports are `[propext, Classical.choice, Quot.sound]`, 0 `sorryAx`. (An earlier build message reported 118 reports for this audit, another 86; the file at the release contains 86 commands. The record does not explain the difference.)
- `VOA/Moonshine/MoonshineLRGenerationAudit.lean`: imports all `MoonshineLRGeneration*` files; 185 reports, including `BorcherdsPreData.lieSpan_eq_top_of_KNZ`, `monsterLieSimpleRootGeneration`, `conwayNorton_of_isOfFinOrder`; standard axioms, 0 `sorryAx`.
- `VOA/Moonshine/MoonshineLRConwayNortonAudit.lean`: one report, `conwayNorton_of_finOrder_of_completelyReplicable`; standard axioms.

The `Aut*` files have no audit module of their own: every theorem in them is printed in `VOA/Moonshine/MoonshineLRLiftAudit.lean` (Chapter 49; green, 997 reports in that audit, all within `[propext, Classical.choice, Quot.sound]`, no `sorryAx`). As in Chapter 43: a clean audit line certifies the absence of extra axioms and of `sorry`; it does not certify that a declaration is unconditional, nor that it means what it should.

47.10 Recorded traps and dead ends

The traps specific to a section are recorded where they arise: the false induction criterion (§47.1.4), the cocycle sign of the naive Ising vector (§47.4), $c = 1$ vectors and diagonal zero modes (§47.5), the rejected count of all Ising vectors (§47.6), and the equivalence of generation with KNZ (§47.7). We add the cross-cutting ones.

Trap / dead end

Sign of the momenta (Chapter 43, §43.10). Borcherds' root (m, n) is the library momentum $(m, -n)$, and the root space at library momentum (x, y) is $V^\natural_{1-xy}$. A product over library momenta $x, y \geq 1$ would be wrong (those root spaces vanish, except the real root space at library $(1, 1)$). The generation files work exclusively in Borcherds coordinates through `monsterLieBorcherdsWeight`, which applies the sign once.

Trap / dead end

Finite order is not finiteness. An infinite group can have every element of finite order; Theorem 47.19 does not imply Theorem 47.22, which needed the separate algebraic-geometry argument. The periodicity lemma alone gives periodicity of each element, not finiteness of the group. The converse implication does hold (a finite group is torsion), as explained in the introduction. Neither theorem is used to identify $\mathrm{Aut}(V^\natural)$ with the Monster.

Trap / dead end

Authors' working notes that are out of date. (i) The dependency notes, node M1, still lists "FINITE ORDER `autVnat_isOfFinOrder`" with the open marker and the planned route "their span + σ-images = $V^\natural{}_2$; `vnatGriessRestrict_injective`", although the theorem is proved (the same file says so at its top) and the proof uses neither a spanning statement nor `vnatGriessRestrict_injective`. (ii) the notes on the Monster, §0 and §5, say `Finite AutVnat` "is not delivered"; it is now `finite_autVnat`. (iii) The docstring of `MonsterLieSimpleRootGeneration` calls generation "not yet proved" (§47.7). (iv) The docstring of `AutVnat` calls it the group "the campaign identifies with the Monster" (quoted); the identification is conditional on `GmatEqAut0` (Chapter 49). None affects a Lean statement.

Trap / dead end

The paper route was unrefereed. The written plan of the finite-order proof in the authors' notes was not refereed and was not machine-checked; its normalisations (cocycle sign, 2^{-4} versus 2^{-3}) were the main recorded risk. The Lean proofs settle them: the twisted coefficient $\frac{s}{4}\cdot 2\cdot 2^{-4} = \frac{s}{32}$ is the one in `isingTwistedMode_hP`. A referee should trust the Lean statements as presented here, not the unrefereed plan.

47.11 Referee's checklist

Namespaces: `VOA.Moonshine.AutMonster` (A), `VOA.Moonshine.ConwayNorton.M8` (M8), others as stated. "std." means `#print axioms = [propext, Classical.choice, Quot.sound]` as recorded in the build records cited in the status boxes.

The working notes. The development was recorded in the authors' working notes, which are not part of the release. The `Aut*` files were written by Fedor Popov's side; the `MoonshineLR*` files of this chapter by Leonardo Rastelli's side, with machine assistance. These notes are the authors' claims; where this chapter states what the machine confirmed, it relies on the build and audit records cited.

Chapter 48

The Griess algebra of the moonshine module and AxiomMath's Monster

This chapter documents the release of the library named in the front matter; every Lean quotation is checked by `scripts/textbook/sync.py` to occur verbatim (up to whitespace and comments) in the source files of that release. It documents 65 files: the 44 files of `VOA/Moonshine/MonsterGriess/`, which are a port of part of the AxiomMath CFSG library; the 15 files `VOA/Moonshine/MoonshineCNGriess*.lean`; the 5 files `VOA/Moonshine/MoonshineCNMonsterAction*.lean`; and `VOA/Moonshine/MoonshineLRGriessTransfer.lean`.

48.1 Overview

48.1.1 The central theorem

The chapter has one central theorem; everything else prepares it or uses it. Write $\mathcal{B}$ for the 196884-dimensional *rational Griess algebra* of AxiomMath's Lean library: a commutative, non-associative algebra over $\mathbb{Q}$ with product $u \cdot v$ and a positive definite bilinear form b (Definitions 48.17 and 48.18). Write $V^\natural{}_2$ for the weight-two space of the moonshine module constructed in Chapters 30–42, with the product $u \times v = u_{(1)}v$ and the invariant bilinear form $\langle \cdot, \cdot \rangle$ of $V^\natural$, normalised by $\langle \mathbb{1}, \mathbb{1} \rangle = 1$.

Theorem 48.1 (Griess isomorphism; proved as Theorem 48.54)**.** *There is a $\mathbb{C}$-linear isomorphism $\Theta : \mathbb{C} \otimes_{\mathbb{Q}} \mathcal{B} \to V^\natural{}_2$ such that $\Theta(x \cdot y) = \Theta(x) \times \Theta(y)$ and $\langle \Theta x, \Theta y \rangle = 2\, b(x, y)$ for all $x, y \in \mathbb{C} \otimes_{\mathbb{Q}} \mathcal{B}$ (product and form extended $\mathbb{C}$-bilinearly).*

```
noncomputable def griessIso : ℂ ⊗[ℚ] SpaceB ≃ₗ[ℂ] VnatVOA.grading 2 :=
  (Algebra.TensorProduct.basis ℂ griessBasisQ).equiv griessBasisC (Equiv.refl _)
```

```
theorem griessIso_mul (x y : ℂ ⊗[ℚ] SpaceB) :
    griessIso (LinearMap.BilinMap.baseChange ℂ gmul x y)
      = VnatVOA.griessMul (griessIso x) (griessIso y) := by
```

```
theorem griessIso_form (x y : ℂ ⊗[ℚ] SpaceB) :
    SimpleNat.natForm (griessIso x : Vnat) (griessIso y : Vnat)
      = 2 * LinearMap.BilinForm.baseChange ℂ bform x y := by
```

(`VOA/Moonshine/MoonshineCNGriessIso.lean`, namespace `VOA.Moonshine.GriessDictionary`.)

Symbol key. `SpaceB` is $\mathcal{B}$, `gmul` its product and `bform` its form (§48.5, verbatim from AxiomMath). `ℂ ⊗[ℚ] SpaceB` is $\mathbb{C} \otimes_{\mathbb{Q}} \mathcal{B}$ and `≃ₗ[ℂ]` a $\mathbb{C}$-linear bijection. `VnatVOA` is the moonshine module of Chapter 42 (named in Chapter 47), `VnatVOA.grading 2` its weight-two space $V^\natural{}_2$, `VnatVOA.griessMul` the product $u_{(1)}v$ on it, and `SimpleNat.natForm` its invariant form (Chapter 38). `LinearMap.BilinMap.baseChange`

`ℂ gmul` and `LinearMap.BilinForm.baseChange ℂ bform` are the $\mathbb{C}$-bilinear extensions of product and form. `griessBasisQ`, `griessBasisC` are bases used to build Θ; the theorem `griessIso_tmul` says $\Theta(1 \otimes u)$ is an explicit vertex-algebra state (§48.14). None of the three statements has a hypothesis.

Why the factor 2. The two forms are normalised independently: $V^\natural$'s by $\langle \mathbb{1}, \mathbb{1} \rangle = 1$, which forces $\langle \omega, \omega \rangle = c/2 = 12$ for the conformal vector ω; AxiomMath's b is the sum of the standard dot products of the coordinates. The identity element of $\mathcal{B}$ is $e = (\frac{1}{4}I, 0, 0)$, with $b(e,e) = \mathrm{tr}(I/16) = \frac{3}{2}$; it corresponds to the identity $\omega/2$ of $V^\natural{}_2$ (both facts are Lean theorems, Remark 48.20), and $\langle \omega/2, \omega/2 \rangle = 3 = 2 \cdot \frac{3}{2}$. Since a linear map preserves b iff it preserves $2b$, the factor is harmless for everything that follows.

Why this is the central fidelity check of the Monster part. The Monster is not defined anywhere in LeanVOA. The group that later statements call "the Monster" is AxiomMath's `Aut0`: the group of $\mathbb{Q}$-linear automorphisms of $\mathcal{B}$ preserving product and form, transcribed verbatim from AxiomMath's Lean source. "Every element of the Monster acts on $V^\natural$" (Chapter 49) means something only if the object on which `Aut0` acts is visibly an object inside $V^\natural$, and Θ is that identification. A referee who accepts (i) that `SpaceB`, `gmul`, `bform` are literally AxiomMath's definitions (§48.11), (ii) that `VnatVOA` is the moonshine module of Chapter 42, and (iii) the three statements above, has accepted that "`Aut0` acts on the Griess algebra of `VnatVOA`" is a precise statement.

What this chapter does *not* contain. The library does not prove that `Aut0` is finite, that it has the order $2^{46} \cdot 3^{20} \cdots 71$ of the Monster, or that it is simple; AxiomMath's library proves these facts in Lean v4.35, and they were not ported (§48.10). Nor does it prove AxiomMath's *generation theorem*, which says that `Aut0` is generated by an explicit subgroup G_{vis} (classically $\cong 2^{1+24}.\mathrm{Co}_1$; this identification is not formalised) and one explicit element τ_B of order 3; that theorem enters Chapter 49 as the single named hypothesis `GmatEqAut0`. The lifting of G_{vis} and τ_B to automorphisms of $V^\natural$ and the converse inclusion $\mathrm{Aut}(V^\natural) \hookrightarrow$ `Aut0` are Chapter 49. This chapter supplies the stage: the port, the identification Θ, and the lift *framework*.

48.1.2 The Griess algebra in one page

Let $V = \bigoplus_{n \geq 0} V_n$ be a vertex operator algebra of CFT type ($V_0 = \mathbb{C}\mathbb{1}$) with $V_1 = 0$. For $u, v \in V_2$ the modes $u_{(n)}v$ have weight $2 + 2 - n - 1 = 3 - n$, so $u_{(1)}v \in V_2$ and $u_{(3)}v \in V_0 = \mathbb{C}\mathbb{1}$. The *Griess algebra* of V is V_2 with the product $u \times v = u_{(1)}v$ and the form $\langle u, v \rangle$ defined by $u_{(3)}v = \langle u, v \rangle \mathbb{1}$. Skew-symmetry $Y(u,z)v = e^{zL_{-1}}Y(v,-z)u$ gives $u_{(1)}v = v_{(1)}u - L_{-1}(v_{(2)}u) + \cdots$, and $v_{(2)}u \in V_1 = 0$, so the product is *commutative*; the invariant bilinear form of a VOA of CFT type with $L_1 V_1 = 0$ makes the form *associative*, $\langle u \times v, w \rangle = \langle u, v \times w \rangle$. So V_2 is a commutative, non-associative algebra with an associative form. The conformal vector ω lies in V_2 and acts by $\omega \times v = L_0 v = 2v$: the element $\omega/2$ is the identity.

For $V = V^\natural$ one has $\dim V^\natural{}_2 = 196884$ (Chapter 33), and Frenkel, Lepowsky and Meurman proved that $V^\natural{}_2$ with this product is (a variant of) the algebra that Griess had constructed by hand to build the Monster. The decomposition

$$V^\natural{}_2 = (V_\Lambda^+)_2 \oplus (T^+)_2, \qquad (V_\Lambda^+)_2 = S^2\mathfrak{h} \;\oplus\; \mathrm{span}\{x_\alpha : \langle \alpha, \alpha \rangle = 4\}, \qquad (T^+)_2 = \mathfrak{h}(-\tfrac{1}{2}) \otimes T, \tag{48.1}$$

with dimensions $196884 = (300 + 98280) + 24 \cdot 4096$, is visible in Conway's description of the algebra:

$$\mathcal{B} = \mathrm{Sym} \;\oplus\; X \;\oplus\; W, \qquad \mathrm{Sym} = S^2(\mathbb{Q}^{24}), \quad X = \mathbb{Q}^{98280}, \quad W = \mathbb{Q}^{4096} \otimes \mathbb{Q}^{24}, \tag{48.2}$$

X indexed by the 98280 pairs $\pm\alpha$ of minimal vectors of the Leech lattice and W by a 4096-dimensional representation of the extraspecial group 2^{1+24} tensored with $\mathbb{Q}^{24}$. AxiomMath implements (48.2) with rational coordinates; LeanVOA ports that implementation and proves that, after extension of scalars, it *is* (48.1).

Physical meaning

In two-dimensional conformal field theory the states of V_2 are the *dimension-two chiral fields*. When $V_1 = 0$ (no spin-one currents, i.e. no continuous symmetry) the operator product expansion of two such fields reads

$$a(z)\,b(w) \;\sim\; \frac{\langle a,b\rangle}{(z-w)^4} \;+\; \frac{(a\times b)(w)}{(z-w)^2} \;+\; \frac{\frac{1}{2}\partial(a\times b)(w)}{z-w},$$

since a $(z-w)^{-3}$ term would be a spin-one field. So the Griess algebra is "the OPE of the 196884 spin-two fields of the Monster CFT": the product is the coefficient of $(z-w)^{-2}$, the form that of $(z-w)^{-4}$. The stress tensor $T(z)$ is one of these fields (ω), and $T(z)T(w) \sim \frac{c/2}{(z-w)^4} + \frac{2T(w)}{(z-w)^2} + \cdots$ with $c = 24$ says $\omega\times\omega = 2\omega$, $\langle\omega,\omega\rangle = 12$. The orbifold picture: the $\mathbb{Z}/2$-orbifold of 24 bosons on the Leech torus has untwisted spin-two fields (the 300 bilinears $\partial X^i\partial X^j$ and the 98280 combinations $e^{i\alpha X} + e^{-i\alpha X}$, $\langle\alpha,\alpha\rangle = 4$, which we abbreviate as "$\cos(\alpha X)$" in the physics boxes; in the VOA they are the states $x_\alpha = e^\alpha + e^{-\alpha}$) and twisted ones: the twisted ground states σ_s (4096 of them) have weight $24/16 = \frac{3}{2}$, and one half-integral oscillator $\partial X^i_{-1/2}$ raises them to weight 2, giving $24\cdot 4096$ more.

48.1.3 The Monster, Tits's theorem, and the role of the form

The Monster $\mathbb{M}$ is the largest sporadic simple group, of order $2^{46}3^{20}5^9 7^6 11^2 13^3\cdot 17\cdot 19\cdot 23\cdot 29\cdot 31\cdot 41\cdot 47\cdot 59\cdot 71$. Griess constructed it as a group of automorphisms of a commutative non-associative algebra of dimension 196883 with an invariant form; Conway's simplified construction adjoins an identity element, giving $196884 = 1 + 196883$ dimensions, and that is the algebra AxiomMath implements. The two versions carry the same automorphisms: an algebra automorphism of the 196884-dimensional algebra fixes its identity e (the identity of an algebra is unique), so if it also preserves b it preserves the orthogonal complement $e^\perp$, which with the product $u\cdot v$ followed by orthogonal projection to $e^\perp$ is Griess's 196883-dimensional algebra (up to normalisation); conversely, since $u\cdot v = \mathrm{pr}_{e^\perp}(u\cdot v) + \frac{b(u,v)}{b(e,e)}e$ for $u,v\in e^\perp$, an automorphism of Griess's algebra preserving its form extends by $e\mapsto e$. Tits proved that the full automorphism group of the algebra is exactly $\mathbb{M}$.

Why b appears in `Aut0`. The form is the natural extra datum: b is associative and $b(u,v) = b(u\cdot v, e)$, so b is determined by the product together with the linear functional $b(\cdot,e)$; classically the associative form is unique up to scalars on each of the two irreducible summands $\mathbb{Q}e$ and $e^\perp$ of the Monster, so imposing b costs nothing classically. But that is a theorem about the Monster, not a consequence of the definition, and AxiomMath's definition (Definition 48.23) simply requires both conditions. We follow it verbatim; LeanVOA proves neither that b-preservation is automatic nor Tits's theorem. "`Aut0` is the Monster" is therefore a statement *by reference* (to AxiomMath's library and to the literature).

Frenkel, Lepowsky and Meurman constructed $V^\natural$ together with a faithful action of $\mathbb{M}$ on it, extending Griess's action on $V^\natural{}_2$; since $V^\natural$ is generated by $V^\natural{}_2$, Tits's theorem then gives $\mathrm{Aut}(V^\natural) = \mathbb{M}$.

Physical meaning

$V^\natural$ is the chiral algebra of the holomorphic conformal field theory with $c = 24$ obtained as the $\mathbb{Z}/2$-orbifold of 24 free chiral bosons compactified on the Leech torus $\mathbb{R}^{24}/\Lambda$ (Dixon, Ginsparg and Harvey). Its partition function is $J(q) = j(q) - 744$, and classically its global symmetry group is the Monster. Each symmetry g gives a twisted partition function $T_g(q) = \mathrm{tr}(g\, q^{L_0 - 1})$; Conway–Norton's conjecture (Chapter 43) says these are genus-zero Hauptmoduln. This chapter makes "the Monster" a concrete Lean object acting on the spin-two fields of this CFT.

48.1.4 Provenance

The 44 files under `VOA/Moonshine/MonsterGriess/` are ports of files of the Lean library *AxiomMath/CFSG*, at the pinned commit `69cb972f587a3ecc035e092253167ff2e303c962`, released under the Apache 2.0 licence; its authors are listed in §48.20. Every ported file carries the Apache header naming the source files, the commit and the original authors, and lists its modifications in a section "Port notes" of its module docstring. The port to Lean 4.30.0 / Mathlib v4.30.0 is by F. K. Popov (with Claude). The source library is written for Lean v4.35.0-rc3; a port is therefore a *re-elaboration* of the source text by a different toolchain, not an import. It contains the "definitional closure" of AxiomMath's `AutO` and `Gmat` together with a "light toolkit" of theorems (the parity-centralizer theorem, the triality element and its product invariance, the lattice facts they need). A declaration-by-declaration comparison with the source (§48.11, after all the definitions involved have been presented) found all definitions identical up to renaming of namespaces, except one, the coordinate map `phi0`, which is a definitionally equal restatement.

48.1.5 How the chapter is organised

Part A (§§48.2–48.11) presents AxiomMath's model: the combinatorial data, the space $\mathcal{B}$, its product and form, the group `AutO`, the visible subgroup, the triality, the parity-centralizer theorem, what is not ported, and the port audit. Part B (§§48.12–48.14) constructs the dictionary between $\mathcal{B}$ and $V^\natural{}_2$ and proves the isomorphism. Part C (§§48.15–48.16) builds the framework in which elements of `AutO` act on $V^\natural$. Section 48.17 lists every file with its role, §48.18 the audit files, and the chapter ends with the referee's checklist.

Remark 48.2 (Notation). $\mathbb{F}_2 = \mathbb{Z}/2$ (Lean `ZMod 2`). $\mathcal{C} \subset \mathbb{F}_2^{24}$ is AxiomMath's Golay code (`Code.C`), $\mathcal{C}^* = \mathbb{F}_2^{24}/\mathcal{C}$ its cocode (`Cocode`), $\mathcal{C}_0$ the index-two subcode `C₀`. Λ is the Leech lattice, always in Conway's integer coordinates scaled by $\sqrt{8}$: a lattice vector is an integer vector $u \in \mathbb{Z}^{24}$ and the inner product is $u \cdot v/8$; $\bar{\Lambda} = \Lambda/2\Lambda$. $\mathcal{S}$ (`ShortIdx`) is the set of 98280 classes of $\bar{\Lambda}$ containing a minimal vector. $I = \mathbb{F}_2 \times \mathcal{C}_0$ (`SpinIdx`) is the 4096-element spin index set. $\mathcal{B} = \mathrm{Sym} \oplus X \oplus W$ with Sym the symmetric 24×24 rational matrices, $X = \mathbb{Q}^{\mathcal{S}}$, $W = \mathbb{Q}^{I \times 24}$. $\mathcal{T}$ is the trilinear form of $\mathcal{B}$; T (roman) is always the 4096-dimensional module of Chapter 34. On the $V^\natural$ side, π is the coordinate permutation `piPerm` relating our Leech lattice to AxiomMath's. As in Chapter 1, `V.smul u n v` is $u_{(n)}v$, so `VnatVOA.smul u 1 v` is the Griess product. Status boxes cite the audit file in which the declaration's `#print axioms` line appears; every such line is expected to print `[propext, Classical.choice, Quot.sound]` or a subset (§48.18).

48.2 AxiomMath's Golay code, its theta cocycle and the cocode

Part A begins. Throughout Part A the Lean names live in the namespace `VOA.Moonshine.MonsterGriess` or one of its sub-namespaces (`.Code`, `.Spin`, `.SpinLattice`, `.Visible`, `.ScalarKernel`, `.Parity`, `.Generated`), which replace AxiomMath's `CFSG.Monster`, `CFSG.Monster.Griess`, ... one for one.

48.2.1 The binary Golay code in its MOG/hexacode form

Chapter 30 built the Golay code $\mathcal{G}$ as the row space of $[I_{12} \mid B]$ with a Paley-type matrix B (`Code.golay`). AxiomMath uses instead the description of Conway and Curtis through the *Miracle Octad Generator* (MOG) and the *hexacode*. The 24 coordinates are arranged in a 4×6 array: coordinate $i = r + 4j$ sits in row $r \in \{0,1,2,3\}$ and column $j \in \{0,\dots,5\}$. Let $\mathbb{F}_4 = \{0, 1, \omega, \bar{\omega}\}$. The hexacode $H_6 \subset \mathbb{F}_4^6$ is the 3-dimensional $\mathbb{F}_4$-span of $v_1 = (1,0,0,1,\bar{\omega},\omega)$, $v_2 = (0,1,0,1,\omega,\bar{\omega})$, $v_3 = (0,0,1,1,1,1)$. To a binary word x attach its *hexacode projection* $h(x) \in \mathbb{F}_4^6$, whose j-th entry is $x_{1,j} + \omega x_{2,j} + \bar{\omega} x_{3,j}$ (the rows $1,2,3$ are "scored" $1, \omega, \bar{\omega}$, row 0 scores 0), and its *top parity* $t(x) = \sum_j x_{0,j}$.

Definition 48.3 (AxiomMath's Golay code). $\mathcal{C} = \{x \in \mathbb{F}_2^{24} : h(x) \in H_6$ and every column has parity $t(x)\}$.

```
def hexProj (x : Fin 24 → ZMod 2) : Fin 6 → F4 := fun j =>
  algebraMap (ZMod 2) F4 (x (coord 1 j)) + α * algebraMap (ZMod 2) F4 (x (coord 2 j)) +
    ᾱ * algebraMap (ZMod 2) F4 (x (coord 3 j))

def topParity (x : Fin 24 → ZMod 2) : ZMod 2 := ∑ j, x (coord 0 j)
```

```
def C : Submodule (ZMod 2) (Fin 24 → ZMod 2) where
  carrier := {x | hexProj x ∈ H₆ ∧ ∀ j, ∑ r, x (coord r j) = topParity x}
```

(`VOA/Moonshine/MonsterGriess/Golay.lean`, `VOA.Moonshine.MonsterGriess.Code.C`.)

From the mathematics to the Lean statement

`F4` is a hand-made field structure on pairs $(\mathrm{re}, \mathrm{im}) \in \mathbb{F}_2^2$, with $\alpha = (0,1) = \omega$ and $\bar{\alpha} = (1,1) = \bar{\omega}$; the file proves that it is a field. `coord r j` is the coordinate $r + 4j$, i.e. row r, column j. The vectors `v₁`, `v₂`, `v₃` and the span `H₆` are defined in the same file exactly as in the text (vector literals `![1, 0, 0, 1, ᾱ, α]`, ...). The predicate is exactly the two MOG conditions. The file constructs a basis `basisC` of 12 words and proves, by a kernel computation over the 4096 codewords (`decide +kernel`, no `native_decide`), that every codeword has weight in $\{0, 8, 12, 16, 24\}$ (`four_dvd_wt`), and that $\mathcal{C}$ is self-orthogonal (`dotProduct_eq_zero`); `CodeCocycle.lean` adds self-duality `mem_C_iff_forall_dotProduct`.
Could it be the wrong code? The identification with our $\mathcal{G}$ is a Lean theorem (Theorem 48.4 below), so $\mathcal{C}$ is a Golay code; there is no room for a typo in v_1, v_2, v_3 that would survive that theorem.

Physical meaning

In the Leech-lattice CFT the Golay code is the "code CFT" skeleton: the 2^{12} codewords label the ways of turning on $\mathbb{Z}/2$ momenta along the 24 coordinate circles consistently with modular invariance (Chapter 30). The MOG coordinates are only a convenient labelling that makes the symmetry group M_{24} and the sextet structure visible; they play the role of a choice of basis for the 24 bosons.

What the machine verified

Definition; covered by the audits of Part A (§48.18).

Theorem 48.4 (Our Golay code is AxiomMath's, up to a coordinate permutation). *Let π be the permutation $\pi = [0,1,2,3,4,8,13,15,23,7,20,18,19,10,17,14,11,21,5,16,22,6,12,9]$ of $\{0,\dots,23\}$ (our coordinate i goes to AxiomMath's coordinate $\pi(i)$). Transporting words by $x \mapsto x \circ \pi^{-1}$ maps our code $\mathcal{G}$ onto $\mathcal{C}$.*

```
theorem golay_map_eq_C :
    _root_.Code.golay.map (permLin (ZMod 2) piPerm : (Fin 24 → ZMod 2) →ₗ[ZMod 2] _) =
      Code.C :=
```

(VOA/Moonshine/MonsterGriess/LeechMatch.lean, VOA.Moonshine.MonsterGriess.LeechMatch.golay_map_eq_C.)

From the mathematics to the Lean statement

`_root_.Code.golay` is the code of Chapter 30; `permLin R σ x = x ∘ σ⁻¹`, so `(permLin σ x) (σ i) = x i`; `Submodule.map` is the image. `piPerm` is π, given together with its explicit inverse. The statement is an equality of subspaces, the strongest form.

Proof on paper. The twelve rows of $[I_{12} \mid B]$, moved by π, satisfy the two MOG conditions (a finite check, `golayRow_perm_mem_C`, by `decide +kernel`); so the image of $\mathcal{G}$ lies in $\mathcal{C}$. Both have dimension 12. The permutation itself was found numerically by octad backtracking (a search script that is not part of the release); only the check is in Lean. □

Physical meaning

Two descriptions of the same 24 compact bosons differing by a relabelling of the bosons: a permutation of the fields of the free CFT, under which the Golay-code skeleton matches.

What the machine verified

No hypotheses. `LeechMatch.lean` has no audit file of its own; it is used by, and so covered by, the audit of `griessIso` (`MoonshineCNGriessAudit3.lean`).

48.2.2 The Parker cocycle, the cocode and its pairing

Why a cocycle is needed. The extraspecial group 2^{1+24} of the Monster is built from the Golay code and its cocode, and its "code part" must be a *non-abelian* lift of the abelian group $\mathcal{C}$: one wants signed matrices X_a ($a \in \mathcal{C}$) with $X_a X_b = \pm X_{a+b}$, the sign being $(-1)^{\theta(a,b)}$. Associativity of matrix multiplication forces the coboundary of θ to be the triple-intersection form, and the commutator of X_a, X_b to be $(-1)^{|a\cap b|/2}$; Conway's solution is the Parker loop.

Definition 48.5 (Theta cocycle). For binary words write $P(d) = \frac{1}{4}|d|$, $K(d,e) = \frac{1}{2}|d\cap e|$, $A(d,e,f) = |d\cap e\cap f|$, all modulo 2 (the divisions are exact on $\mathcal{C}$, which is doubly even and self-orthogonal). Let $B_1, \dots, B_{12}$ be the basis `basisC` of $\mathcal{C}$ and, for $d = \sum \mu_i B_i$, $e = \sum \nu_j B_j$,

$$\theta(d,e) = \sum_{i,j} \mu_i \nu_j \beta_{ij} + \sum_{i<j} \sum_{k} \mu_i \mu_j \nu_k A(B_i, B_j, B_k), \qquad \beta_{ij} = \begin{cases} 0 & i < j, \\ P(B_i) & i = j, \\ K(B_i, B_j) & i > j. \end{cases}$$

Then θ is linear in e and satisfies

$$\theta(d+e,f) = \theta(d,f) + \theta(e,f) + A(d,e,f), \qquad \theta(d,e) + \theta(e,d) = K(d,e), \qquad \theta(d,d) = P(d).$$

These three identities are what is used below; the explicit formula only serves to exhibit one solution. The *Parker loop* is $\mathcal{C} \times \mathbb{F}_2$ with $(a,s)(b,t) = (a+b, s+t+\theta(a,b))$.

```
def θc (μ ν : Fin 12 → ZMod 2) : ZMod 2 :=
  ∑ i, ∑ j, μ i * ν j * β i j +
    ∑ i, ∑ j, ∑ k, if i < j then μ i * μ j * ν k * A (B i) (B j) (B k) else 0

noncomputable def θ (d e : C) : ZMod 2 := θc (basisC.repr d) (basisC.repr e)
```

(`VOA/Moonshine/MonsterGriess/Golay.lean`.)

```
theorem θ_add_left (d e f : C) : θ (d + e) f = θ d f + θ e f + A d e f := by

theorem θ_add_θ_swap (d e : C) : θ d e + θ e d = K d e := by

theorem θ_self (d : C) : θ d d = P d := by
```

(`VOA/Moonshine/MonsterGriess/CodeCocycle.lean`; namespace `VOA.Moonshine.MonsterGriess.Code`.)

From the mathematics to the Lean statement

`β i j` is β_{ij} and `B i` the i-th basis word; `basisC.repr d` the coordinate vector of d. `A`, `K`, `P` are defined in `Golay.lean` by the cardinality formulas above. The Parker loop is `Code.Parker`, a structure with fields `code` and `sign`. Linearity in the second argument is `θ_add_right`.

Physical meaning

The Parker loop plays for the Golay code the role that the cocycle $\varepsilon(\alpha,\beta)$ plays for the Leech lattice in the vertex operators $e^{\alpha}e^{\beta} = \varepsilon(\alpha,\beta)e^{\alpha+\beta}$: it is the sign bookkeeping that makes "exponentials of codewords" (the X-matrices on the spin space) multiply consistently.

What the machine verified

No hypotheses; the identities are audited in `MoonshineCNGriessAudit2.lean`.

Definition 48.6 (Cocode, pairing, $\mathcal{C}_0$, θ_D)**.** The cocode is $\mathcal{C}^* = \mathbb{F}_2^{24}/\mathcal{C}$; the pairing $\langle a,\delta\rangle$ of $a \in \mathcal{C}$ and $\delta = [x] \in \mathcal{C}^*$ is $a \cdot x$, well defined by self-orthogonality. $\Omega = (1,\dots,1) \in \mathcal{C}$; $\mu_0 : \mathcal{C} \to \mathbb{F}_2$ is the first coordinate of a codeword in the basis `basisC`, with $\mu_0(\Omega) = 1$; $\mathcal{C}_0 = \ker \mu_0$ (a complement of $\langle\Omega\rangle$, so $\mathcal{C} = \mathcal{C}_0 \oplus \langle\Omega\rangle$ and $|\mathcal{C}_0| = 2^{11} = 2048$) and $\pi_0 : \mathcal{C} \to \mathcal{C}_0$ the projection along Ω. For $a \in \mathcal{C}$, $\theta_D(a) \in \mathcal{C}^*$ is a cocode element with $\langle u, \theta_D(a)\rangle = \theta(a,u)$ for all u (it exists because the pairing is perfect).

```
def μ₀ : C →ₗ[ZMod 2] ZMod 2 := (LinearMap.proj 0 ∘ₗ ψ) ∘ₗ C.subtype

def C₀ : Submodule (ZMod 2) C := LinearMap.ker μ₀

def π₀ : C →ₗ[ZMod 2] C₀ :=
  LinearMap.codRestrict C₀ (LinearMap.id + μ₀.smulRight ΩC) fun u => by

abbrev Cocode : Type := (Fin 24 → ZMod 2) ⧸ C

def pair (a : C) : Cocode →ₗ[ZMod 2] ZMod 2 :=
  C.liftQ (dotL a) fun _ hx => LinearMap.mem_ker.2 (dotProduct_eq_zero a.2 hx)

noncomputable def thetaD (a : C) : Cocode := (exists_pair_eq (θL a)).choose
```

(`VOA/Moonshine/MonsterGriess/Spin.lean`, namespace `VOA.Moonshine.MonsterGriess.Spin`.)

From the mathematics to the Lean statement

ψ is the coordinate map of `basisC`; `LinearMap.proj 0` takes its 0-th entry. `μ₀.smulRight ΩC` is $u \mapsto \mu_0(u)\Omega$, so $\pi_0(u) = u + \mu_0(u)\Omega$. `C.liftQ` descends `dotL a` $= (x \mapsto a \cdot x)$ to the quotient. `thetaD` is defined by `Classical.choose`; by nondegeneracy (`eq_zero_of_forall_pair`) the chosen element is unique, so the choice is harmless.

Physical meaning

The cocode is the dual of the code: in the lattice CFT it labels the classes of "half-integral windings" $\frac{1}{2}x$ modulo those already accounted for by the code; the pairing is the mutual locality phase between the two kinds of charges.

What the machine verified

Definitions; `finrank_cocode` ($= 12$) and `card_C₀` ($= 2048$) are proved.

48.3 The Leech lattice in Conway's coordinates, and $\Lambda/2\Lambda$

48.3.1 The code lattice

Definition 48.7 (AxiomMath's Leech lattice)**.** For a binary code D, $\Lambda(D) \subset \mathbb{Z}^{24}$ is the set of u for which there are $m \in \{0,1\}$ and $d \in D$ with $u_i \equiv m + 2d_i \pmod 4$ for all i and $\sum_i u_i \equiv 4m \pmod 8$. The form is $\langle u, v\rangle = u \cdot v/8$. The minimal vectors are the $u \in \Lambda(\mathcal{C})$ with $\langle u, u\rangle = 4$, i.e. $u \cdot u = 32$.

```
def codeLattice (C : Submodule (ZMod 2) (Fin 24 → ZMod 2)) : Set (Fin 24 → ℤ) :=
  {u | ∃ m : ℤ, (m = 0 ∨ m = 1) ∧ ∃ d ∈ C,
    (∀ i, u i ≡ m + 2 * bitLift (d i) [ZMOD 4]) ∧ ∑ i, u i ≡ 4 * m [ZMOD 8]}

def codeForm (u v : Fin 24 → ℚ) : ℚ := (∑ i, u i * v i) / 8
```

```
def minVecs : Set (Fin 24 → ℤ) :=
  {u | u ∈ codeLattice C ∧ codeForm (fun i => (u i : ℚ)) (fun i => (u i : ℚ)) = 4}
```

```
noncomputable def classOf (u : Fin 24 → ℤ) : codeLatticeModTwo C allOnes_mem_C :=
  open Classical in
  if h : u ∈ codeLattice C then Submodule.Quotient.mk (⟨u, h⟩ : codeLatticeSubgroup
   ↪  allOnes_mem_C)
  else 0
```

```
abbrev L2 : Type := codeLatticeModTwo C allOnes_mem_C
```

(`VOA/Moonshine/MonsterGriess/Lattice.lean`; `codeLattice`, `codeForm` in `VOA.Moonshine.MonsterGriess`, `minVecs`, `classOf` in `.Code`, `L2` in `.SpinLattice`.)

From the mathematics to the Lean statement

`bitLift t` $\in \{0,1\}$ is the integer lift of $t \in \mathbb{F}_2$; `a ≡ b [ZMOD n]` is congruence of integers. `codeLatticeSubgroup hΩ` is the same set as an additive subgroup (closure under addition uses $\Omega \in D$); `codeLatticeModTwo` is `ModN (codeLatticeSubgroup hΩ) 2`, Mathlib's quotient of a $\mathbb{Z}$-module by 2 times itself, i.e. $\Lambda/2\Lambda$ as an $\mathbb{F}_2$-vector space. `classOf` is the class map, extended by 0 off the lattice (a convention that is only ever applied to lattice vectors). This is Conway's standard description of the Leech lattice scaled by $\sqrt{8}$: the vectors with $m = 0$ are the even vectors $u \equiv 2d \pmod 4$ with $\sum u_i \equiv 0 \pmod 8$, and those with $m = 1$ the odd vectors.

Physical meaning

Λ is the momentum lattice of the 24 chiral bosons; minimal vectors α ($\langle\alpha,\alpha\rangle = 4$) give the vertex operators $e^{i\alpha\cdot X}$ of conformal weight $\frac{1}{2}\langle\alpha,\alpha\rangle = 2$, i.e. the charged spin-two fields of $V^\natural{}_2$. The quotient $\Lambda/2\Lambda$ is the group of "charges modulo the $\mathbb{Z}/2$ orbifold": the twist fields see momenta only modulo 2Λ.

What the machine verified

Definitions; the lattice is identified with ours in Theorem 48.8.

Theorem 48.8 (Our Leech lattice is AxiomMath's, with no rescaling). *The map $x \mapsto x \circ \pi^{-1}$ is an isomorphism of groups from our Leech lattice (Chapter 30) onto $\Lambda(\mathcal{C})$, and it carries our form to* `codeForm` *exactly.*

```
theorem perm_mem_codeLattice_C_iff (x : Fin 24 → ℤ) :
    permLin ℤ piPerm x ∈ codeLattice Code.C ↔ x ∈ Leech.carrier := by
```

```
def leechEquiv : leech.carrier ≃+ ↥(codeLatticeSubgroup Code.allOnes_mem_C) := carrierEquiv
```

```
theorem codeForm_leechEquiv (x y : leech.carrier) :
    codeForm (toQ (leechEquiv x)) (toQ (leechEquiv y)) = (leech.form x y : ℚ) := by
```

(`VOA/Moonshine/MonsterGriess/LeechMatch.lean`, namespace `VOA.Moonshine.MonsterGriess.LeechMatch`.)

From the mathematics to the Lean statement

`Leech.carrier` $= 2A \cup (u + 2A) \subset \mathbb{Z}^{24}$ with $u = (5, 1, \dots, 1)$ is our lattice in Chapter 30's coordinates, and `leech` the integral lattice built from it, with `leech.form x y` $= x \cdot y/8$. The key step `mem_codeLattice_golay_iff` says that our carrier is AxiomMath's congruence description applied to our code; then Theorem 48.4 and permutation-equivariance of `codeLattice` finish. `toQ` reads an integer vector in $\mathbb{Q}^{24}$. "No rescaling": both models use the same $\sqrt{8}$-scaled integer coordinates, so the isometry statement has scale factor 1.

Physical meaning

The same compact boson theory written in two bases of the momentum lattice related by a permutation of coordinates; the CFT data (momenta, inner products, hence conformal weights) are unchanged.

What the machine verified

No hypotheses; covered by the audit of `griessIso` (`MoonshineCNGriessAudit3.lean`), standard axioms.

48.3.2 Minimal vectors and the count 98280

Theorem 48.9 (Minimal vectors). *(a) Every nonzero $u \in \Lambda(\mathcal{C})$ has $u \cdot u \geq 32$ (the Leech lattice has no roots). (b) Two minimal vectors are congruent modulo 2Λ iff they are equal up to sign. (c) The minimal vectors are the union of the three disjoint families $(\pm 4, \pm 4, 0^{22})$, $(\pm 2^8, 0^{16})$ on an octad with an even number of minus signs, and $(\mp 3, \pm 1^{23})$; there are $1104 + 97152 + 98304 = 196560$ of them. (d) $|\mathcal{S}| = 98280$ (this part uses the bijectivity of the map φ_0 of Theorem 48.11, proved independently below).*

```
theorem normSq_ge {u : Fin 24 → ℤ} (hu : u ∈ codeLattice C) (h0 : u ≠ 0) : 32 ≤ normSq u :=
↪ by
```

```
theorem classOf_eq_iff {u v : Fin 24 → ℤ} (hu : u ∈ minVecs) (hv : v ∈ minVecs) :
    classOf u = classOf v ↔ v = u ∨ v = -u := by
```

(`VOA/Moonshine/MonsterGriess/MinimalVectors.lean`, namespace `.Code`.)

```
theorem minVecs_eq : minVecs = minFamily₁ ∪ minFamily₂ ∪ minFamily₃ := by
```

```
theorem card_minFin : minFin.card = 196560 := by
```

(VOA/Moonshine/MonsterGriess/LatticeFamilies.lean, namespace .Code.)

```
theorem card_shortIdx : Nat.card ShortIdx = 98280 := by
```

(VOA/Moonshine/MonsterGriess/LatticeFamilies.lean, VOA.Moonshine.MonsterGriess.card_shortIdx.)

From the mathematics to the Lean statement

normSq u = $\sum u_i^2$. minFin is a Finset enumerating the three families through explicit injective parametrisations, and minVecs_eq shows that it is all of minVecs. ShortIdx is defined in Definition 48.10 below. There is a second, identical statement VOA.Moonshine.GriessDictionary.card_shortIdx (MoonshineCNGriessSign.lean), derived from our lattice via LeechMatch; and a second classOf_eq_iff in LeechMatch with the disjunction written as u = v ∨ u = -v. These duplicates are harmless.

Proof on paper. (a) For a lattice vector u, $u \cdot u \equiv 0 \pmod{16}$ (a congruence computed from the definition and the double-evenness of $\mathcal{C}$), so it suffices to exclude $u \cdot u = 16$. If $m = 1$ all 24 coordinates are odd and $u \cdot u \geq 24$. If $m = 0$ and $u \equiv 2d \pmod 4$ with $d \neq 0$, the ≥ 8 coordinates in the support of d are $\equiv 2 \pmod 4$, so $u \cdot u \geq 32$. If $m = 0$ and $d = 0$, all coordinates are divisible by 4 with $\sum u_i \equiv 0 \pmod 8$, so a single nonzero coordinate must be ± 8 ($u \cdot u = 64$), and otherwise there are at least two nonzero coordinates ($u \cdot u \geq 32$). (b) If $u \equiv v \pmod{2\Lambda}$ with $u \neq \pm v$, then $(u-v)/2$ and $(u+v)/2$ are nonzero lattice vectors with $\|(u-v)/2\|^2 + \|(u+v)/2\|^2 = \frac{1}{2}(\|u\|^2 + \|v\|^2) = 32$, so one of them has $u \cdot u < 32$, contradicting (a). (c) is a case analysis of the shapes allowed by the congruences with $\sum u_i^2 = 32$ (the shapes are those tabulated in Conway–Sloane, *Sphere Packings, Lattices and Groups*, Ch. 4 §11); the counts use 759 octads (wtCount_eight, kernel computation): $1104 = 4\binom{24}{2}$, $97152 = 759 \cdot 2^7$, $98304 = 24 \cdot 2^{12}$. (d) By (b) each class of a minimal vector contains exactly two of them, and φ_0 (below) is a bijection, so $|\mathcal{S}| = 196560/2$. □

Physical meaning

196560 is the number of charged spin-two fields $e^{i\alpha \cdot X}$ of the Leech lattice CFT, and 98280 the number of θ-invariant combinations $e^{i\alpha X} + e^{-i\alpha X}$ that survive the orbifold projection. Absence of roots ($\langle \alpha, \alpha \rangle = 2$) is the absence of spin-one currents: the Leech CFT has only the 24 abelian currents ∂X^i, and these are projected out by the orbifold, which is why $V^\natural{}_1 = 0$.

What the machine verified

No hypotheses. normSq_ge, classOf_eq_iff, minVecs_eq, card_minFin, card_shortIdx are audited in ParityAudit.lean (and card_shortIdx also in TrialityAudit.lean and MoonshineCNGriessAudit2.lean).

48.3.3 Coordinates on $\Lambda/2\Lambda$: the map φ_0

The space $\bar{\Lambda} = \Lambda/2\Lambda$ is 24-dimensional over $\mathbb{F}_2$; the quadratic form $q(\bar{u}) = \frac{1}{2}\langle u, u \rangle \bmod 2 = u \cdot u/16 \bmod 2$ is well defined on it, with polar form $\langle u, v \rangle \bmod 2$. AxiomMath coordinatises $\bar{\Lambda}$ by $\mathcal{C} \times \mathcal{C}^*$.

The idea. The quadratic space $(\bar{\Lambda}, q)$ has a "hyperbolic" splitting into two complementary 12-dimensional subspaces on which q vanishes, one coming from the code and one from the cocode, paired with each other by the code–cocode pairing. In such coordinates $q(a, \delta) = \langle a, \delta \rangle$, and the extraspecial group of $\bar{\Lambda}$ becomes a Heisenberg group of $\mathcal{C} \times \mathcal{C}^*$, which is what the spin matrices of

§48.4 realise. Concretely: (i) every binary word v gives the lattice vector $(|v| - 4v_k)_k$ (for $v = e_k$ it is the odd minimal vector $(1^{23}, -3)$, with the -3 in place k); its class $\lambda(v)$ is additive in v and vanishes for $v \in \mathcal{C}$, so it defines λ_{coc} on the cocode. (ii) A codeword a has the canonical even lift $2a$ (or $2(\Omega - a)$ when $|a| \equiv 4 \pmod 8$), whose class is $\lambda_X(a)$; but λ_X is additive only up to the defect A, and adding $\lambda_{\mathrm{coc}}(\theta_D(a))$ cancels this defect, which is why λ_T rather than λ_X is used. For a binary word v let $\lambda(v)$ be the class of the lattice vector $(|v| - 4v_k)_k$; it vanishes on $\mathcal{C}$, hence descends to $\lambda_{\mathrm{coc}} : \mathcal{C}^* \to \bar{\Lambda}$. For a codeword a, let $\lambda_X(a)$ be the class of $2a + 2P(a) - 4P(a)a$ (coordinatewise, with $P(a) = |a|/4 \bmod 2$ lifted to $\{0, 1\}$; this is $2a$ if $P(a) = 0$ and $2(\Omega - a)$ if $P(a) = 1$), and $\lambda_T(a) = \lambda_X(a) + \lambda_{\mathrm{coc}}(\theta_D(a))$.

Definition 48.10 (φ_0, short coordinates, u_c). $\varphi_0(a, \delta) = \lambda_T(a) + \lambda_{\mathrm{coc}}(\delta)$. A pair $p \in \mathcal{C} \times \mathcal{C}^*$ is *short* if $\varphi_0(p)$ is the class of a minimal vector; $\mathcal{S}$ is the set of short pairs. For $c \in \mathcal{S}$, u_c is the lexicographically smaller of the two minimal vectors $\pm u$ in the class $\varphi_0(c)$.

```
noncomputable def lamT (a : C) : L2 := lamX a + lamCocode (thetaD a)

noncomputable def phi0 (p : C × Cocode) : L2 := lamT p.1 + lamCocode p.2

def IsShortCoord (p : C × Cocode) : Prop := ∃ u ∈ minVecs, classOf u = phi0 p

abbrev ShortIdx : Type := {p : C × Cocode // IsShortCoord p}

def LexLE (u v : Fin 24 → ℤ) : Prop := toLex u ≤ toLex v

noncomputable def uvec (c : ShortIdx) : Fin 24 → ℤ :=
  open Classical in
  if LexLE c.2.choose (-c.2.choose) then c.2.choose else -c.2.choose
```

(`VOA/Moonshine/MonsterGriess/Short.lean`; `lamT`, `phi0` in `.SpinLattice`, the rest in `VOA.Moonshine.MonsterGriess`.)

From the mathematics to the Lean statement

`lamX a` $= \lambda_X(a)$, `lamCocode` $= \lambda_{\mathrm{coc}}$ (`Lattice.lean`, `Short.lean`). `c.2.choose` is *some* minimal vector in the class $\varphi_0(c)$ (extracted from the existential `IsShortCoord`); `toLex` compares lexicographically. By Theorem 48.9(b) the class contains exactly $\pm$ that vector, so `uvec c` does not depend on which representative the choice returns. This matters: u_c enters the product of $\mathcal{B}$ through $U_c = u_c u_c^{\mathsf{T}}$ and q_c, which are even in u_c, but also through the identification with $V^\natural$ (`shortVec`), where a sign choice is a basis choice.

Physical meaning

$\mathcal{S}$ indexes the 98280 orbifold-invariant charged spin-two fields $e^{i\alpha X} + e^{-i\alpha X}$; u_c is a canonical choice of one of the two momenta $\pm\alpha$.

What the machine verified

Definitions (ported verbatim except that `phi0` is a function; see the warning in §48.11). Covered by the audits of Part A.

Theorem 48.11 (φ_0 is a linear isomorphism; $q \circ \varphi_0$ is the pairing). *φ_0 is additive and bijective, so it is an $\mathbb{F}_2$-linear isomorphism $\mathcal{C} \times \mathcal{C}^* \cong \bar{\Lambda}$; in these coordinates $q(\varphi_0(a, \delta)) = \langle a, \delta \rangle$ and the polar form is $\langle a, \varepsilon \rangle + \langle b, \delta \rangle$. In particular $\langle a, \delta \rangle = 0$ for every short pair (a, δ).*

```
theorem phi0_bijective : Function.Bijective phi0 := phi0Lin_bijective

noncomputable def phi0Equiv : (C × Cocode) ≃ₗ[ZMod 2] L2 :=
  LinearEquiv.ofBijective phi0Lin phi0Lin_bijective
```

```
theorem qL_phi0 (a : C) (δ : Cocode) : qL (phi0 (a, δ)) = pair a δ := by
```

```
theorem bL_phi0 (a b : C) (δ ε : Cocode) :
    QuadraticMap.polarBilin qL (phi0 (a, δ)) (phi0 (b, ε)) = pair a ε + pair b δ := by
```

(namespace `.SpinLattice`) and

```
theorem pair_eq_zero_of_isShortCoord {p : C × Cocode} (h : IsShortCoord p) : pair p.1 p.2 =
↪  0 := by
```

(`VOA/Moonshine/MonsterGriess/LatticeQuadratic.lean`.)

From the mathematics to the Lean statement

`qL` is the quadratic form q on `L2`: by `qL_cls`, q of the class of u is $\frac{1}{2}(u \cdot u/8) \bmod 2$. `QuadraticMap.polarBilin` is Mathlib's polar form $B(x,y) = q(x+y) - q(x) - q(y)$. The rank of $\bar{\Lambda}$ is obtained by a port-specific argument (a basis from `Submodule.basisOfPid` and the 24 independent vectors $8e_i$), recorded in the port notes; the statement `finrank_L2` ($= 24$) is the source's.

Proof on paper. Additivity of λ_T is the cocycle identity $\theta_D(a+b) = \theta_D(a) + \theta_D(b) + A(a,b)$ (`thetaD_add`, from $\theta(a+b,f) = \theta(a,f) + \theta(b,f) + A(a,b,f)$) combined with the corresponding defect of λ_X (`lamCodeCls_add`): the two defects cancel. Injectivity: if $\varphi_0(a,\delta) = 0$, then its polar pairing with every $\varphi_0(b,\varepsilon)$ vanishes, i.e. $\langle a,\varepsilon\rangle + \langle b,\delta\rangle = 0$ for all (b,ε), and nondegeneracy of the code–cocode pairing gives $a = 0$, $\delta = 0$; since both sides have dimension 24 ($12 + 12$, `finrank_L2`) the map is bijective. The quadratic-form identity is a computation on representatives: $q(\lambda_T(a)) = 0$, $q(\lambda_{\mathrm{coc}}(\delta)) = 0$ and the cross term is $\langle a,\delta\rangle$. Finally a minimal vector has $q = \frac{1}{2}\cdot 4 \bmod 2 = 0$. □

Physical meaning

$\Lambda/2\Lambda$ with its quadratic form is the "charge space" of the twist fields: the 2^{24} classes label the generators of the extraspecial group that acts on the 2^{12} twisted ground states, and q records whether two such generators commute or anticommute with themselves squared. Code×cocode coordinates split this charge into a "code part" and a "cocode part", like position and momentum in a Heisenberg group.

What the machine verified

No hypotheses. `phi0Equiv`, `qL_phi0`, `pair_eq_zero_of_isShortCoord`, `phi0_bijective` are audited in `MoonshineCNGriessAudit2.lean`.

Remark 48.12 (The other classes of $\Lambda/2\Lambda$). Classically, the $2^{24} = 16777216$ classes split as 1 (zero) + 98280 (classes of $\pm$ a minimal vector) + 8386560 (classes of 48 vectors of norm 6) + 8292375 (classes of a frame of 48 vectors of norm 8). Only the first two kinds enter the Griess algebra. This count is quoted for orientation and is not formalised.

48.4 The spin module and the extraspecial group 2^{1+24}

48.4.1 Signed permutation matrices on 4096 coordinates

The idea. By §48.3, $\bar{\Lambda} \cong \mathcal{C} \times \mathcal{C}^*$ with $q(a,\delta) = \langle a,\delta\rangle$. The extraspecial group attached to $(\bar{\Lambda}, q)$ is then a Heisenberg group of $\mathcal{C} \times \mathcal{C}^*$, and it has a "Schrödinger" representation on functions on the code: codewords act by translations, cocode elements by the characters $c \mapsto (-1)^{\langle c,\delta\rangle}$. The $2^{12} = 4096$ codewords are parametrised by $I = \mathbb{F}_2 \times \mathcal{C}_0$ through $(\eta, c) \mapsto c + \eta\Omega$ (because $\mathcal{C} = \mathcal{C}_0 \oplus \langle\Omega\rangle$,

$|\mathcal{C}_0| = 2048$). AxiomMath's matrices $R(s,a,\delta)$ are this representation written in the coordinates (η, c): the $\mathcal{C}_0$-part of a translation by a moves c to $\pi_0(c+a)$, its Ω-part is absorbed in the sign $(-1)^{\eta\mu_0(a)}$, an odd cocode element ($\langle\Omega,\delta\rangle = 1$) flips η, and the character contributes $(-1)^{\langle\pi_0(c+a),\delta\rangle}$; s is a global sign.

Definition 48.13 (Spin index and spin matrices). $I = \mathbb{F}_2 \times \mathcal{C}_0$ ($2 \cdot 2048 = 4096$ elements). For $s \in \mathbb{F}_2$, $a \in \mathcal{C}$, $\delta \in \mathcal{C}^*$ and a commutative ring R, $R(s,a,\delta)$ is the $I \times I$ signed permutation matrix with

$$R(s,a,\delta)_{i,j} = \begin{cases} (-1)^{\sigma(i)} & j = p(i), \\ 0 & \text{otherwise}, \end{cases} \qquad p(\eta,c) = (\eta + \langle\Omega,\delta\rangle,\ \pi_0(c+a)), \quad \sigma(\eta,c) = s + \eta\,\mu_0(a) + \langle\pi_0(c+a),\delta\rangle.$$

```
abbrev SpinIdx : Type := ZMod 2 × C₀

def shift (a : C) (c : C₀) : C₀ := π₀ ((c : C) + a)
```

```
def qPerm (a : C) (δ : Cocode) (i : SpinIdx) : SpinIdx :=
  (i.1 + pair ΩC δ, shift a i.2)

def qSign (s : ZMod 2) (a : C) (δ : Cocode) (i : SpinIdx) : ZMod 2 :=
  s + i.1 * μ₀ a + pair (shift a i.2) δ
```

```
def qmatR (s : ZMod 2) (a : C) (δ : Cocode) : Matrix SpinIdx SpinIdx R :=
  spm R (qPerm a δ) (qSign s a δ)
```

```
def spm (σ : ι → ι) (ε : ι → ZMod 2) : Matrix ι ι R :=
  Matrix.of fun i j => if j = σ i then sgnR R (ε i) else 0
```

(`VOA/Moonshine/MonsterGriess/Spin.lean`, namespace `.Spin`.)

From the mathematics to the Lean statement

`sgnR R t` is 1 for $t = 0$ and -1 for $t = 1$; `i.1`, `i.2` are the two components of $i = (\eta, c)$. The matrices have entries in $\{0, \pm 1\}$, so the ring R is irrelevant: `SpinMatrixMap.lean` proves `map_qmatR : (qmatR R s a δ).map f = qmatR S s a δ` for every ring homomorphism f, which is how AxiomMath's rational matrices are read over $\mathbb{C}$.

Physical meaning

A signed permutation of the 4096 twist ground states: the matrices by which lattice exponentials e^{α} act on the degenerate ground state of the twisted sector, in a basis where they permute basis states up to sign.

What the machine verified

Definitions, verbatim from the source.

Theorem 48.14 (Product law). *$R(s,a,\delta)R(t,b,\varepsilon) = R(s+t+\langle b,\delta\rangle, a+b, \delta+\varepsilon)$ and $R(s,a,\delta)^{\mathsf{T}} = R(s+\langle a,\delta\rangle, a, \delta)$; each $R(s,a,\delta)$ is orthogonal.*

```
theorem qmatR_mul (s t : ZMod 2) (a b : C) (δ ε : Cocode) :
    qmatR R s a δ * qmatR R t b ε = qmatR R (s + t + pair b δ) (a + b) (δ + ε) := by
```

```
theorem qmatR_transpose (s : ZMod 2) (a : C) (δ : Cocode) :
    (qmatR R s a δ)ᵀ = qmatR R (s + pair a δ) a δ := by
```

(`VOA/Moonshine/MonsterGriess/SpinMatrixLaws.lean`.)

Proof on paper. Products of signed permutation matrices compose the permutations and add the signs along the path; the permutations compose as $(a,\delta)\mapsto(a+b,\delta+\varepsilon)$ because π_0 is linear and $\pi_0(\Omega)=0$, and the signs add up to $s+t+\langle b,\delta\rangle$ by bilinearity of the pairing. □

Physical meaning

These are the $2^{12}\times 2^{12}$ "gamma matrices" of the twisted sector: in the $\mathbb{Z}/2$ orbifold the 24 bosons have half-integral modes and no zero modes, the ground state is degenerate, and the lattice exponentials e^{α} act on the 2^{12} ground states through a Clifford-like extraspecial group. The product law is the statement that $e^{\alpha}e^{\beta}=\pm e^{\alpha+\beta}$ with a sign whose commutator is $(-1)^{\langle\alpha,\beta\rangle}$.

What the machine verified

No hypotheses; `qmatR_mul` audited in `MoonshineCNGriessAudit2.lean`.

48.4.2 The extraspecial group Q

Definition 48.15 (Parker loop, X- and D-matrices, Q)**.** For $e=(a,s)$ in the Parker loop, X_e is the signed permutation matrix on I sending $(\eta,c)\mapsto(\eta,\pi_0(c+a))$ with sign $(-1)^{s+P(a)+\theta(a,c)+\eta\mu_0(a)}$; for $\delta\in\mathcal{C}^*$, D_δ sends $(\eta,c)\mapsto(\eta+\langle\Omega,\delta\rangle,c)$ with sign $(-1)^{\langle c,\delta\rangle}$. In terms of Definition 48.13, $X_{(a,s)}=R(s,a,\theta_D(a))$ and $D_\delta=R(0,0,\delta)$. $Q\subset GL_I(\mathbb{Q})$ is the subgroup generated by all X_e and D_δ.

```

```

```
def Q : Subgroup (GL SpinIdx ℚ) := Subgroup.closure (Set.range XU ∪ Set.range DU)
```

(`VOA/Moonshine/MonsterGriess/SpinGroupQ.lean`; `Parker` in `.Code`, the rest in `.Spin`.) The structure of Q is proved in `SpinExtraspecial.lean`:

```
theorem natCard_Q : Nat.card Q = 2 ^ 25 := by
```

```
theorem frattini_Q : frattini Q = zpowers zQ :=
```

```
noncomputable def phi : (Q ⧸ center Q) ≃* Multiplicative L2 :=
  quotCenterEquiv.trans (AddEquiv.toMultiplicative phi0Equiv.toAddEquiv)
```

(`VOA/Moonshine/MonsterGriess/SpinExtraspecial.lean`; `natCard_Q`, `frattini_Q` in `.Spin`, `phi` in `.SpinLattice`.)

From the mathematics to the Lean statement

`xPerm`, `dPerm`, `dSign` are the permutations and signs in the text. `XU e`, `DU δ` are the matrices `Xmat e`, `Dmat δ` as units of `GL SpinIdx ℚ` (their inverses are their transposes). By `XmatR_eq_qmatR` and `DmatR_eq_qmatR` every generator is a spin matrix, so by the product law $Q = \{R(s,a,\delta)\}$. The group isomorphism `spinEquiv : SpinCoord ≃* Q` identifies Q with the "coordinate group" $\mathbb{F}_2 \times \mathcal{C} \times \mathcal{C}^*$ with product $(s,a,\delta)(t,b,\varepsilon) = (s+t+\langle b,\delta\rangle, a+b, \delta+\varepsilon)$; `zQ` is -1, `center Q` = `frattini Q` $= \{\pm 1\}$. `phi` identifies $Q/Z(Q)$ with $\bar{\Lambda}$ (as a multiplicative group) through φ_0. `coordOf r` and `centralCoord r` (`GriessTrilinear.lean`) are the (a,δ)- and s-coordinates of $r \in Q$; `rep p` is the element with coordinates $(0,p)$.

Physical meaning

$Q \cong 2^{1+24}$ is the group generated by the lattice exponentials acting on the twist-field ground states: it is a central extension of the charge group $\Lambda/2\Lambda$ by the sign ± 1, with commutator form $(-1)^{\langle\alpha,\beta\rangle}$. In the Monster it becomes the normal subgroup $O_2(C(z))$ of the centraliser of the orbifold involution.

What the machine verified

No hypotheses; audited in `ParityAudit.lean`. The source's statement that Q is extraspecial (`isExtraspecialPGroup_Q`) is not ported because its predicate lives in a source prelude that pulls in Feit–Thompson material; its content is the conjunction of `natCard_Q`, `center_Q`, `frattini_Q`.

48.4.3 Coordinates on Q and the vectors attached to short elements

Definition 48.16 (Coordinates, representatives, Xlift). Every $r \in Q$ is $R(s,a,\delta)$ for a unique triple; write $\mathrm{coord}(r) = (a,\delta)$ and $\mathrm{cc}(r) = s$ ("central coordinate"), and $\mathrm{rep}(p) = R(0,p)$ for $p \in \mathcal{C} \times \mathcal{C}^*$. r is *short* if $\mathrm{coord}(r) \in \mathcal{S}$. For $r \in Q$ let $\mathrm{Xlift}(r) = (-1)^{\mathrm{cc}(r)} e_{\mathrm{coord}(r)} \in \mathbb{Q}^{\mathcal{S}}$ if r is short, and 0 otherwise; so $\mathrm{Xlift}(\mathrm{rep}(c)) = e_c$ and $\mathrm{Xlift}(-r) = -\mathrm{Xlift}(r)$.

```
noncomputable def coordOf (r : Q) : C × Cocode :=
  ((spinEquiv.symm r).a, (spinEquiv.symm r).δ)

noncomputable def centralCoord (r : Q) : ZMod 2 := (spinEquiv.symm r).s
```

```
noncomputable def rep (p : C × Cocode) : Q := spinEquiv ⟨0, p.1, p.2⟩
```

```
noncomputable def Xlift (r : Q) : SpaceX :=
  open Classical in
  if h : IsShortCoord (coordOf r) then sgn (centralCoord r) • Pi.single ⟨coordOf r, h⟩ 1
   ↪ else 0
```

(`VOA/Moonshine/MonsterGriess/GriessTrilinear.lean`.)

From the mathematics to the Lean statement

`spinEquiv.symm r` is the coordinate triple of r in the group $\mathbb{F}_2 \times \mathcal{C} \times \mathcal{C}^*$; `Pi.single c 1` is the basis vector e_c of `SpaceX` $= \mathbb{Q}^{\mathcal{S}}$ (defined in §48.5). Thus the 98280-dimensional block of the Griess algebra is spanned by vectors attached to the short elements of Q, each pair $\pm r$ giving $\pm e_c$.

Physical meaning

Xlift says that a charged spin-two field $\cos(\alpha X)$ is labelled by a pair of opposite elements of the extraspecial group, the sign recording which of the two is used.

What the machine verified

Definitions, verbatim from the source.

48.5 The rational Griess algebra $\mathcal{B}$

48.5.1 The space and the form

Definition 48.17 (The space $\mathcal{B}$ and the form b)**.** Sym is the space of symmetric 24×24 rational matrices, $X = \mathbb{Q}^{\mathcal{S}}$ with standard basis $(e_c)_{c\in\mathcal{S}}$, W the space of $I \times 24$ rational matrices, and $\mathcal{B} = \mathrm{Sym} \times X \times W$. For $u = (A, x, N)$, $v = (A', x', N')$,

$$b(u, v) = \operatorname{tr}(AA') + \sum_{c\in\mathcal{S}} x_c x'_c + \sum_{j\in I} \sum_{i<24} N_{ji} N'_{ji}.$$

```
def symMat : Submodule ℚ (Matrix (Fin 24) (Fin 24) ℚ) where
  carrier := {A | Aᵀ = A}
```

```
abbrev SpaceX : Type := ShortIdx → ℚ

abbrev SpaceW : Type := Matrix SpinIdx (Fin 24) ℚ

abbrev SpaceB : Type := symMat × SpaceX × SpaceW
```

```
noncomputable def bform : LinearMap.BilinForm ℚ SpaceB :=
  LinearMap.mk₂ ℚ (fun u v => trace ((u.1 : Matrix (Fin 24) (Fin 24) ℚ) *
      (v.1 : Matrix (Fin 24) (Fin 24) ℚ)) +
      ∑ c, u.2.1 c * v.2.1 c + ∑ j, ∑ i, u.2.2 j i * v.2.2 j i)
```

(`VOA/Moonshine/MonsterGriess/Algebra.lean`, namespace `VOA.Moonshine.MonsterGriess`.)

From the mathematics to the Lean statement

For u of type `SpaceB`, `u.1` is the Sym-component (a subtype element, coerced to a matrix), `u.2.1` the X-component and `u.2.2` the W-component. `LinearMap.mk₂` packages a function with four linearity proofs (the omitted lines) as a bilinear map. Since A is symmetric, $\operatorname{tr}(AA') = \sum_{k,l} A_{kl}A'_{kl}$, so b is the sum of the standard dot products of the three blocks and is positive definite (`bform_self_pos`). The dimensions are proved in `TrialityBasis.lean`: $\dim \mathrm{Sym} = 300$, $\dim X = 98280$, $\dim W = 98304$, and

```
theorem finrank_B : finrank ℚ SpaceB = 196884 := by
```

(`VOA/Moonshine/MonsterGriess/TrialityBasis.lean`.)

Physical meaning

The three blocks are the three kinds of spin-two fields of the orbifold CFT (§48.1): Sym (300) the bilinears $\partial X^i \partial X^j$, X (98280) the orbifold-invariant combinations $e^{i\alpha X} + e^{-i\alpha X}$, and W ($24 \cdot 4096$) the twisted states $\partial X^i_{-1/2}\sigma_s$. The positive definite form is the two-point function, positive because the CFT is unitary.

What the machine verified

Definitions; `finrank_B` audited in `TrialityAudit.lean`.

48.5.2 The product

The product uses three pieces of data attached to a short class $c = (a_c, \delta_c) \in \mathcal{S}$: the matrix $U_c = u_c u_c^{\mathsf{T}}$ (u_c the minimal vector of Definition 48.10, so $U_c^2 = 32U_c$), the quadratic form $q_c(M) = u_c^{\mathsf{T}} M u_c$, and the spin matrix $R_c = R(0, a_c, \delta_c)$; and the structure constants

$$\tau(d,e,c) = \begin{cases} (-1)^{\langle a_e, \delta_d \rangle} & c = d + e \text{ in } \mathcal{C} \times \mathcal{C}^*, \\ 0 & \text{otherwise.} \end{cases}$$

Definition 48.18 (The Griess product of $\mathcal{B}$)**.** The product is the bilinear map determined by the following table (and commutativity), for $A, A' \in \mathrm{Sym}$, $x, y \in X$, $N, M \in W$ ("$\cdot$" is the product, each entry lists the (Sym, X, W)-components):

product	Sym-part	X-part / W-part
$A \cdot A'$	$2(AA' + A'A)$	$0 \quad / \quad 0$
$A \cdot x$	0	$c \mapsto \frac{1}{8} x_c q_c(A) \quad / \quad 0$
$x \cdot y$	$\frac{1}{8} \sum_c x_c y_c U_c$	$c \mapsto \sum_{d,e} x_d y_e \tau(d,e,c) \quad / \quad 0$
$A \cdot N$	0	$0 \quad / \quad \frac{\operatorname{tr} A}{8} N + NA$
$x \cdot N$	0	$0 \quad / \quad \frac{1}{8} \sum_c x_c (R_c N - \frac{1}{4} R_c N U_c)$
$N \cdot M$	$\frac{1}{8} \operatorname{tr}(N^{\mathsf{T}} M) 1 + \frac{1}{2}(N^{\mathsf{T}} M + M^{\mathsf{T}} N)$	$c \mapsto \frac{1}{8}(\operatorname{tr}(N^{\mathsf{T}} R_c M) - \frac{1}{4} q_c(N^{\mathsf{T}} R_c M)) \quad / \quad 0$

In Lean the product is defined at once on general elements, by three component functions:

```
noncomputable def Umat (c : ShortIdx) : Matrix (Fin 24) (Fin 24) ℚ := vecMulVec (uQ c) (uQ
↪  c)

noncomputable def Rmat (c : ShortIdx) : Matrix SpinIdx SpinIdx ℚ := qmatR ℚ 0 c.1.1 c.1.2

noncomputable def qf (c : ShortIdx) (M : Matrix (Fin 24) (Fin 24) ℚ) : ℚ :=
  uQ c ⬝ᵥ (M *ᵥ uQ c)

noncomputable def tau (d e c : ShortIdx) : ℚ :=
  open Classical in if c.1 = d.1 + e.1 then sgn (pair e.1.1 d.1.2) else 0
```

```
noncomputable def gmulA (u v : SpaceB) : Matrix (Fin 24) (Fin 24) ℚ :=
  (2 : ℚ) • (Am u * Am v + Am v * Am u) + (8 : ℚ)⁻¹ • ∑ c, (xs u c * xs v c) • Umat c +
    (trace ((Nm u)ᵀ * Nm v) / 8) • (1 : Matrix (Fin 24) (Fin 24) ℚ) +
    (2 : ℚ)⁻¹ • ((Nm u)ᵀ * Nm v + (Nm v)ᵀ * Nm u)
```

```
noncomputable def gmulX (u v : SpaceB) (c : ShortIdx) : ℚ :=
  (xs v c * qf c (Am u) + xs u c * qf c (Am v)) / 8 +
    ∑ d, ∑ e, xs u d * xs v e * tau d e c +
    (trace ((Nm u)ᵀ * Rmat c * Nm v) - qf c ((Nm u)ᵀ * Rmat c * Nm v) / 4) / 8

```
noncomputable def gmul : SpaceB →ₗ[ℚ] SpaceB →ₗ[ℚ] SpaceB :=
  LinearMap.mk₂ ℚ gmulFun gmulFun_add_left gmulFun_smul_left gmulFun_add_right
    gmulFun_smul_right
```

(VOA/Moonshine/MonsterGriess/Algebra.lean.)

From the mathematics to the Lean statement

uQ c is u_c read in $\mathbb{Q}^{24}$; vecMulVec a b is ab^{T}, M *ᵥ v is Mv and a ·ᵥ b the dot product, so Umat c = U_c and qf c M = $q_c(M)$. c.1 is the pair (a_c, δ_c); sgn : ZMod 2 → ℚ is $t \mapsto (-1)^t$. Am u, xs u, Nm u are the three components of u; (8 : ℚ)⁻¹ • is multiplication by $\frac{1}{8}$; gmulA_symm proves that the Sym-component is symmetric. Setting two of the three components of u and of v to zero in gmulA, gmulX, gmulW gives exactly the rows of the table; the file MoonshineCNGriessTable.lean proves each row as a separate theorem, for instance

```
theorem gmul_spinBlock_spinBlock_snd_fst (N M : SpaceW) :
    (gmul (spinBlock N) (spinBlock M)).2.1
      = fun c => (trace (Nᵀ * Rmat c * M) - qf c (Nᵀ * Rmat c * M) / 4) / 8 := by
```

(VOA/Moonshine/MoonshineCNGriessTable.lean, where spinBlock N = $(0, 0, N)$, and similarly symBlock A = $(A, 0, 0)$, shortBlock x = $(0, x, 0)$; .2.1 is the X-component.)

From the mathematics to the Lean statement

The port adaptation in gmul. The source builds gmul with the same LinearMap.mk₂ ℚ gmulFun …, but proves linearity in the second argument from commutativity. The port proves right linearity directly. The data argument gmulFun is identical; only proofs of propositions differ, and by proof irrelevance the two gmul are the same bilinear map (§48.11).

Where the coefficients come from. The factors 2, $\frac{1}{8}$, $\frac{1}{4}$ are those of Conway's normalisation. Their origin is clearest on the vertex-algebra side (Part B): Lean coordinates of lattice vectors are $\sqrt{8}$ times orthonormal coordinates, so a quadratic expression $y^{\mathsf{T}}Ay$ in lattice coordinates is 8 times the orthonormal one, which produces the $\frac{1}{8}$'s; the 2 in $2(AA' + A'A)$ is the double Wick contraction of two boson bilinears; and $\frac{\operatorname{tr} A}{8}$ is the ground-state energy $\frac{24}{16}$ of the twisted sector when $A = \frac{1}{2}I$. Theorems 48.36 and 48.49 prove that the vertex-algebra products have exactly these coefficients.

Example 48.19 (Two worked products). (1) $e_c \cdot e_c = (\frac{1}{8}U_c, 0, 0)$: the X-part is $\tau(c, c, \cdot)$, supported at $c + c = 0$, which is not short. (2) Put $P_c = \frac{1}{8}U_c$. Then $P_c \cdot P_c = 4P_c^2 = \frac{4}{64}U_c^2 = \frac{4 \cdot 32}{64}U_c = 16P_c$ and $P_c \cdot e_c = \frac{1}{8}q_c(P_c)e_c = \frac{1}{8} \cdot \frac{32^2}{8}e_c = 16e_c$. So P_c is, up to the factor 16, an idempotent with e_c in its eigenvalue-16 eigenspace. Under the dictionary of Part B, P_c is the state $\alpha(-1)^2\mathbb{1}$ (Theorem 48.36(c)), and indeed $(\alpha(-1)^2\mathbb{1})_{(1)}(\alpha(-1)^2\mathbb{1}) = 4\langle\alpha, \alpha\rangle\,\alpha(-1)^2\mathbb{1} = 16\,\alpha(-1)^2\mathbb{1}$ in the Heisenberg VOA.

Remark 48.20 (Identity element). $e = (\frac{1}{4}I, 0, 0)$ (Lean oneB) is the identity: $2(\frac{1}{4}A + \frac{1}{4}A) = A$; $\frac{1}{8}q_c(\frac{1}{4}I) = \frac{1}{8} \cdot \frac{1}{4} \cdot 32 = 1$; and $\frac{\operatorname{tr}(I/4)}{8}N + \frac{1}{4}N = \frac{6}{8}N + \frac{1}{4}N = N$. This is a Lean theorem, and so is the identification of its image under the dictionary of Part B with $\omega/2$: with $e_1 = (I, 0, 0) = 4e$,

```
theorem gmul_oneB_left (u : SpaceB) : gmul oneB u = u := by
```

```
theorem griessNat_griessIdentityVec :
    griessNat griessIdentityVec = (2 : ℂ) • vnatConformalTwo := by
```

(`VOA/Moonshine/MoonshineCNRationalGriess.lean`, a file documented in Chapter 49; `griessIdentityVec` $= e_1$, `vnatConformalTwo` is ω as an element of $V^\natural{}_2$, `griessNat` is the dictionary of Definition 48.52.) So griessNat$(e) = \omega/2$, and $2b(e,e) = 3 = \langle \omega/2, \omega/2\rangle$.

Physical meaning

The table lists the $(z-w)^{-2}$ OPE coefficients of the spin-two fields in a basis adapted to the orbifold: boson bilinears close on themselves; a bilinear acts diagonally on $e^{i\alpha X} + e^{-i\alpha X}$ with eigenvalue $\propto \alpha^{\mathsf{T}} A \alpha$ (the change of its conformal weight under a change of metric); two exponentials fuse to the exponential of the summed momentum when $\langle \alpha, \beta\rangle = -2$, with the cocycle sign τ, and to $\alpha(-1)^2$ when $\beta = -\alpha$; untwisted×twisted → twisted and twisted×twisted → untwisted (the orbifold fusion rules). The twisted-twisted coefficients R_c are matrix elements of e^{α} between twist ground states.

What the machine verified

Definitions, verbatim up to the documented proof-term difference in `gmul`; the table is audited in `MoonshineCNGriessAudit.lean`. `gmul_oneB_left` is audited in `MoonshineCNRationalAudit.lean`.

48.5.3 The trilinear form and its uniqueness

Definition 48.21 (Griess trilinear form). $\mathcal{T}(u,v,w) = b(u\cdot v, w)$.

```
noncomputable def T : SpaceB →ₗ[ℚ] SpaceB →ₗ[ℚ] SpaceB →ₗ[ℚ] ℚ := gmul.compr₂ bform
```

(`VOA/Moonshine/MonsterGriess/GriessTrilinear.lean`.)

From the mathematics to the Lean statement

`gmul.compr₂ bform` is $(u,v) \mapsto b(u\cdot v, \cdot)$. The file proves that $\mathcal{T}$ is fully symmetric (`T_swap12`, `T_cycle`, `T_swap23`) through an explicit formula; full symmetry says at once that the product is commutative (by nondegeneracy of b) and that b is associative, $b(u\cdot v, w) = b(u, v\cdot w)$.

Physical meaning

$\mathcal{T}(u,v,w)$ is the three-point function $\langle u(z_1)v(z_2)w(z_3)\rangle$ of three spin-two fields; its total symmetry is the Bose symmetry of a correlator of bosonic fields.

What the machine verified

No hypotheses; audited in `ParityAudit.lean`.

Theorem 48.22 (Uniqueness of the Griess trilinear form). *Let $\mathcal{T}'$ be a trilinear form on $\mathcal{B}$, symmetric in its first two and in its last two arguments, with the following values. For $A, A', A'' \in$ Sym; short $r,s,t \in Q$ (with $c = \mathrm{coord}(r)$); $q, q' \in \mathbb{Q}^I$ and $v, w \in \mathbb{Q}^{24}$ (so $q \otimes v = qv^{\mathsf{T}} \in W$):*

arguments	*value of $\mathcal{T}'$*
(A, A', A'')	$4\,\mathrm{tr}(AA'A'')$
$(\mathrm{Xlift}\, r, \mathrm{Xlift}\, s, A)$	$(-1)^{\epsilon} q_c(A)/8$ *if* $rs = (-1)^{\epsilon}$; 0 *if* $rs \notin \{\pm 1\}$
$(\mathrm{Xlift}\, r, \mathrm{Xlift}\, s, \mathrm{Xlift}\, t)$	$(-1)^{\epsilon}$ *if* $rst = (-1)^{\epsilon}$; 0 *if* $rst \notin \{\pm 1\}$
$(q\otimes v, q'\otimes w, A)$	$(q\cdot q')\big(\frac{(v\cdot w)\,\mathrm{tr}\,A}{8} + v^{\mathsf{T}} A w\big)$
$(q\otimes v, q'\otimes w, \mathrm{Xlift}\, r)$	$(qr\cdot q')\big(v\cdot w - \frac{1}{4}(v\cdot u_c)(w\cdot u_c)\big)/8$
(A, A', x), (A, A', N), (A, x, N), (x, x', N), (N, N', N'')	0

Then $\mathcal{T}' = \mathcal{T}$.

```
theorem T_unique (T' : SpaceB →ₗ[ℚ] SpaceB →ₗ[ℚ] SpaceB →ₗ[ℚ] ℚ)

  (∀ (x x' : SpaceX) (N : SpaceW), T' (inX x) (inX x') (inW N) = 0) ∧
  (∀ N N' N'' : SpaceW, T' (inW N) (inW N') (inW N'') = 0)
```

(`VOA/Moonshine/MonsterGriess/GriessTrilinear.lean`.)

From the mathematics to the Lean statement

`inA A`, `inX x`, `inW N` are $(A,0,0)$, $(0,x,0)$, $(0,0,N)$; `tensor q v` is qv^{T}; `Xlift`, `coordOf` are Definition 48.16; `zQ` $= -1 \in Q$ and `zQ ^ e.val` $= (-1)^e$; `zpowers zQ` $= \{\pm 1\}$; `q ᵥ* r` is the row vector qr. The ten conjuncts are exactly the ten rows of the table. The hypotheses of `T_unique` are precisely "symmetric" and "has these values"; nothing else is assumed.

Proof on paper. Matrices span Sym; the Xlift(rep c) $= e_c$ span X; the $q \otimes v$ span W. A trilinear form symmetric under all permutations (the two transpositions generate S_3) is determined by its values on unordered triples from a spanning set, and the table prescribes a value for every unordered triple of block types. □

Physical meaning

A CFT three-point function of primaries is fixed by its values on a basis; this lemma is the finite-dimensional bookkeeping that lets one prove "g is a symmetry" by checking that g maps the three-point couplings of a basis to themselves. This is how $2^{1+24}.\mathrm{Co}_1$ is classically shown to preserve the algebra.

What the machine verified

No hypotheses beyond those displayed; audited in `ParityAudit.lean`.

48.6 The automorphism group Aut0: AxiomMath's Monster

Definition 48.23 (Algebra automorphisms; Aut0)**.** A $\mathbb{Q}$-linear automorphism f of $\mathcal{B}$ is an *algebra automorphism* if $f(u \cdot v) = f(u) \cdot f(v)$ for all u, v. Aut0 is the subgroup of $GL_{\mathbb{Q}}(\mathcal{B})$ of algebra automorphisms preserving b.

```
def IsAlgAut (f : SpaceB ≃ₗ[ℚ] SpaceB) : Prop := ∀ u v, f (gmul u v) = gmul (f u) (f v)
```

```
def Aut0 : Subgroup (SpaceB ≃ₗ[ℚ] SpaceB) where
  carrier := {g | IsAlgAut g ∧ ∀ u v, bform (g u) (g v) = bform u v}
```

```
theorem mem_Aut0 {g : SpaceB ≃ₗ[ℚ] SpaceB} :
    g ∈ Aut0 ↔ (∀ u v, g (gmul u v) = gmul (g u) (g v)) ∧ ∀ u v, bform (g u) (g v) = bform
     ↪ u v :=
  Iff.rfl
```

(VOA/Moonshine/MonsterGriess/Aut0.lean, VOA.Moonshine.MonsterGriess.Aut0.)

From the mathematics to the Lean statement

SpaceB ≃ₗ[ℚ] SpaceB is the group of $\mathbb{Q}$-linear bijections of $\mathcal{B}$ under composition. Subgroup bundles a carrier with closure proofs (omitted). mem_Aut0 unfolds membership by Iff.rfl: the definition contains nothing beyond the two displayed conditions.

Is this "the Monster"? In AxiomMath's library the Monster is *defined* as this group (MGriess := ↥CFSG.Monster.Griess.Aut0), and AxiomMath prove there, in Lean 4.35, their formal Monster-existence statement for it. None of that is ported. In LeanVOA, Aut0 is "the Monster" *by reference*: the definition is AxiomMath's verbatim (§48.11), and its identification with $\mathbb{M}$ is a theorem of AxiomMath's library and of the classical literature (§48.1.3), not of LeanVOA. The book calls it "Aut0" or "AxiomMath's Monster".

Could Aut0 be trivial or degenerate? No: it contains G_{vis} and τ_B (Theorems 48.28 and 48.33), which contain explicit nontrivial elements such as x_B. Finiteness and the order of Aut0 are not LeanVOA theorems; Chapter 49 needs only that Aut0 is generated by G_{vis} and τ_B, and states that as a hypothesis.

Physical meaning

Aut0 is the group of all linear maps of the 196884 spin-two fields preserving their OPE and two-point function, i.e. the largest group that could act as a symmetry of the Monster CFT and be visible on this sector. Classically (Griess, Conway, Tits, Frenkel–Lepowsky–Meurman) it *is* the global symmetry group of the CFT; in Lean the corresponding statement $\mathrm{Aut}(V^\natural) \cong$ Aut0 is proved in Chapter 49 only under the hypothesis GmatEqAut0.

What the machine verified

Definition, verbatim from the source; it occurs in statements audited in ProductInvarianceAudit.lean and ParityAudit.lean.

48.7 The visible subgroup G_{vis} (classically $2^{1+24}.\mathrm{Co}_1$)

48.7.1 Co_0 as rational matrices

Definition 48.24 (Co_0)**.** lattice0 is the group of rational orthogonal 24×24 matrices g ($gg^{\mathsf{T}} = 1$) such that $x \mapsto xg$ maps the rational points of $\Lambda(\mathcal{C})$ onto themselves.

```
def latticeO : Subgroup (GL (Fin 24) ℚ) where
  carrier := {g | (g : Matrix (Fin 24) (Fin 24) ℚ) ∈ orthogonalGroup (Fin 24) ℚ ∧
    (fun x => x ᵥ* (g : Matrix (Fin 24) (Fin 24) ℚ)) '' latticeQ = latticeQ}
```

```
theorem mem_ker_modTwoHom_iff (g : latticeO) : g ∈ modTwoHom.ker ↔ mat g = 1 ∨ mat g = -1
↪  :=
```

(VOA/Moonshine/MonsterGriess/ScalarKernel.lean, namespace .ScalarKernel.)

From the mathematics to the Lean statement

`x ᵥ* g` is the row vector xg; `latticeQ` is the image of `codeLattice C` in $\mathbb{Q}^{24}$; `orthogonalGroup` is Mathlib's $\{g : gg^{\mathsf{T}} = 1\}$ (equivalently $g^{\mathsf{T}}g = 1$). Since orthogonality is for the standard dot product and the lattice form is $x \cdot y/8$, `latticeO` is exactly $O(\Lambda) = \mathrm{Co}_0$ (in these coordinates). `modTwoEnd g` is the induced map on $\bar{\Lambda}$ and `modTwoHom` the resulting homomorphism to $GL(\bar{\Lambda})^{\mathrm{op}}$; the theorem says its kernel is $\{\pm 1\}$, the classical fact $\mathrm{Co}_0 \to \mathrm{Co}_1 = \mathrm{Co}_0/\{\pm 1\} \hookrightarrow GL(\Lambda/2\Lambda)$.

Physical meaning

Co_0 is the group of rotations of the 24 bosons preserving the momentum lattice: the symmetry group of the Leech lattice CFT that commutes with the $U(1)^{24}$ currents up to rotation. Only $\mathrm{Co}_1 = \mathrm{Co}_0/\{\pm 1\}$ survives in the Monster, because -1 is the orbifold reflection, which acts trivially on the orbifold theory.

What the machine verified

Both audited in `ParityAudit.lean`.

48.7.2 Visible pairs and their action

Definition 48.25 (Visible pairs). A *visible pair* is (s, g) with $s \in GL_I(\mathbb{Q})$ orthogonal, with dyadic entries (in $\mathbb{Z}[\frac{1}{2}]$), normalising Q, and $g \in \mathrm{Co}_0$ *compatible* with s: for all $r, r' \in Q$ with $r' = s^{-1}rs$, the class of r' in $Q/Z(Q) \cong \bar{\Lambda}$ is g applied to the class of r.

```
def IsDyadicSpinNormalizer (s : GL SpinIdx ℚ) : Prop :=
  (s : Matrix SpinIdx SpinIdx ℚ) ∈ orthogonalGroup SpinIdx ℚ ∧
    (∀ i j, (s : Matrix SpinIdx SpinIdx ℚ) i j ∈ dyadic) ∧
    (fun r => s⁻¹ * r * s) '' (Q : Set (GL SpinIdx ℚ)) = Q
```

```
def IsCompatible (s : GL SpinIdx ℚ) (g : latticeO) : Prop :=
  ∀ r r' : Q, (r' : GL SpinIdx ℚ) = s⁻¹ * r * s →
    Multiplicative.toAdd (phi (QuotientGroup.mk r')) =
      modTwoEnd g (Multiplicative.toAdd (phi (QuotientGroup.mk r)))
```

```
def Pvis : Subgroup (GL SpinIdx ℚ × latticeO) where
  carrier := {p | IsDyadicSpinNormalizer p.1 ∧ IsCompatible p.1 p.2}
```

(VOA/Moonshine/MonsterGriess/VisiblePair.lean, namespace .Visible.)

From the mathematics to the Lean statement

`GL SpinIdx ℚ` is the group of invertible rational $I \times I$ matrices; `dyadic` is the subring $\mathbb{Z}[\frac{1}{2}] \subset \mathbb{Q}$; `(fun r ⇒ s⁻¹ * r * s) '' Q = Q` says conjugation by s maps Q onto Q. In `IsCompatible`, `QuotientGroup.mk r` is the class of r in $Q/Z(Q)$, `phi` the isomorphism $Q/Z(Q) \cong \bar{\Lambda}$ of §48.4 (written multiplicatively, hence `Multiplicative.toAdd`), and `modTwoEnd g` the action of g on

$\bar{\Lambda}$. `Pvis` is a subgroup of the product group, so visible pairs compose componentwise.

Physical meaning

A visible pair is a rotation g of the Leech lattice together with a compatible rotation s of the 4096 twist ground states: the data needed to extend a lattice symmetry of the untwisted theory to the twisted sector.

What the machine verified

Definitions, verbatim from the source (`VisiblePair.lean` is ported in full); `Pvis` audited in `ParityAudit.lean`.

Definition 48.26 (The action θ_p and G_{vis})**.** For $p = (s, g)$: $\theta_p(A, x, N) = (g^{\mathsf{T}}Ag,\ \theta_p^X(x),\ s^{\mathsf{T}}Ng)$, where $\theta_p^X(e_c) = \text{Xlift}(s^{-1}\,\text{rep}(c)\,s)$ ($= \pm e_{c'}$ with c' the class of g applied to c). $G_{\text{vis}} = \{\theta_p : p \text{ visible}\}$.

```
def thetaA (g : Matrix (Fin 24) (Fin 24) ℚ) : symMat →ₗ[ℚ] symMat where
  toFun A := ⟨gᵀ * (A : Matrix (Fin 24) (Fin 24) ℚ) * g, by
```

```
def thetaW (s : Matrix SpinIdx SpinIdx ℚ) (g : Matrix (Fin 24) (Fin 24) ℚ) :
    SpaceW →ₗ[ℚ] SpaceW where
  toFun N := sᵀ * N * g
```

```
def thetaX (p : Pvis) : SpaceX →ₗ[ℚ] SpaceX :=
  (Pi.basisFun ℚ ShortIdx).constr ℚ fun c => Xlift (conjQ p (rep c.1))
```

```
def theta (p : Pvis) : SpaceB →ₗ[ℚ] SpaceB :=
  (thetaA (mat p.1.2)).prodMap
    ((thetaX p).prodMap (thetaW (p.1.1 : Matrix SpinIdx SpinIdx ℚ) (mat p.1.2)))
```

```
def Gvis : Subgroup (SpaceB ≃ₗ[ℚ] SpaceB) where
  carrier := Set.range thetaEquiv
```

(`VOA/Moonshine/MonsterGriess/VisiblePair.lean`; `thetaEquiv p` is `theta p` with inverse `theta p⁻¹`.)

From the mathematics to the Lean statement

`conjQ p` is conjugation $r \mapsto s^{-1}rs$ as an automorphism of Q (well defined because s normalises Q). `Pi.basisFun … .constr` defines a linear map by its values on the standard basis e_c. `prodMap` acts blockwise. `mat g` is the matrix of $g \in$ `lattice0`. Note the conventions: lattice vectors are *row* vectors acted on by $x \mapsto xg$, hence $A \mapsto g^{\mathsf{T}}Ag$ on S and $N \mapsto s^{\mathsf{T}}Ng$ on W. `thetaEquiv` is anti-multiplicative (`thetaEquiv_mul : thetaEquiv (p * q) = thetaEquiv q * thetaEquiv p`), which is why the group homomorphism `thetaHom` lands in the opposite group; G_{vis} is its image (`Gvis_eq_unop_range`). Nothing "opposite" survives in G_{vis} itself: it is an ordinary subgroup of $GL_{\mathbb{Q}}(\mathcal{B})$, namely the set of all θ_p.

Example 48.27 (Visible pairs)**.** (1) For $r \in Q$, $(r, 1)$ is visible: r is a signed permutation matrix (orthogonal, entries $0, \pm 1$), it normalises Q, and conjugation by r is trivial on $Q/Z(Q)$, which is compatible with $g = 1$. Then $\theta_{(r,1)}(A, x, N) = (A, \theta^X(x), r^{\mathsf{T}}N)$ with $\theta^X(e_c) = \pm e_c$, the sign being the commutator of r with $\text{rep}(c)$; this is `rhoEquiv r`. For $r = z = -1$ it is $x_B : (A, x, N) \mapsto (A, x, -N)$. (2) $(1, -1)$ is visible ($-1 \in \text{Co}_0$ acts trivially on $\bar{\Lambda}$) and $\theta_{(1,-1)}(A, x, N) = (A, x, -N)$ as well: $(1, -1) = (-1, 1) \cdot (-1, -1)$, and $(-1, -1)$ acts trivially. (3) A coordinate permutation g in $M_{24} \subset \text{Co}_0$ needs a compatible s, a 4096×4096 matrix permuting (up to sign) the basis of $\mathbb{Q}^I$ in a way that depends on how g moves the code; such s exist classically, but no specific one is written down in this chapter.

Which elements of Co_0 occur. Classically every $g \in \mathrm{Co}_0$ occurs in a visible pair, and then $|G_{\mathrm{vis}}| = |Q| \cdot |\mathrm{Co}_0|/2 = 2^{25}|\mathrm{Co}_1|$, which is why G_{vis} is "$2^{1+24}.\mathrm{Co}_1$". The library does *not* prove this: it proves no surjectivity of Pvis $\to \mathrm{Co}_0$ and no order of G_{vis}. Nothing in this chapter or in Chapter 49 needs it: G_{vis} is *defined* as the set of all θ_p, and the statements about it (it lies in `Aut0`; it is the centraliser of x_B; each of its elements lifts to $V^\natural$) hold for whatever it is.

Physical meaning

θ_p acts on the three kinds of spin-two fields: by rotating the bosons in the bilinears, by permuting (with signs) the exponentials $\cos(\alpha X)$, and by rotating both the oscillator index and the ground-state index of the twisted fields.

What the machine verified

Definitions, verbatim; `thetaEquiv`, `Gvis` audited in `ParityAudit.lean`.

Theorem 48.28 (G_{vis} preserves the algebra; kernel; x_B)**.** *(a) Every $f \in G_{\mathrm{vis}}$ preserves the product and the form; hence $G_{\mathrm{vis}} \le$ `Aut0`. (b) $\theta_p = 1$ iff $p = 1$ or $p = (-1,-1)$. (c) For the central element $z = -1 \in Q$, $\theta_{(z,1)} = x_B$, the parity involution $x_B(A,x,N) = (A,x,-N)$. (d) Q is generated by its short elements.*

```
theorem mem_Gvis_gmul {f : SpaceB ≃ₗ[ℚ] SpaceB} (hf : f ∈ Gvis) (u v : SpaceB) :

theorem closure_isShortCoord_eq_top : closure {r : Q | IsShortCoord (coordOf r)} = ⊤ := by
```

(`VOA/Moonshine/MonsterGriess/VisibleAction.lean`, namespace `.Visible`.) The parity involution itself:

```
noncomputable def parityMap : SpaceB →ₗ[ℚ] SpaceB :=
  LinearMap.prodMap LinearMap.id (LinearMap.prodMap LinearMap.id (-LinearMap.id))

noncomputable def xB : SpaceB ≃ₗ[ℚ] SpaceB :=
  LinearEquiv.ofInvolutive parityMap fun u => by simp [parityMap_apply]
```

(`VOA/Moonshine/MonsterGriess/GriessTrilinear.lean`.)

From the mathematics to the Lean statement

`negPair` is the pair $(-1,-1) \in$ Pvis ($\mathtt{zU} = -1$, $\mathtt{negOneO} = -1 \in \mathrm{Co}_0$). `rhoEquiv r` $= \theta_{(r,1)}$, the image of $r \in Q$ ("Axiom's extraspecial generators"). `LinearEquiv.ofInvolutive` turns an involutive linear map into a linear equivalence. In (a) the conclusion is exactly membership in `Aut0` (Definition 48.23).

Proof on paper. (a) Let $\mathcal{T}_p(u,v,w) = \mathcal{T}(\theta_p u, \theta_p v, \theta_p w)$. It is symmetric, and its block values are those of $\mathcal{T}$: $g^{\mathsf{T}}(\cdot)g$ with g orthogonal preserves $\mathrm{tr}(AA'A'')$; conjugation by s permutes the short elements of Q compatibly with g, so it preserves the XXA, XXX values (the products rs, rst and the norms q_c transform covariantly by compatibility); on W, $s^{\mathsf{T}}(q \otimes v)g = (qs) \otimes (vg)$ and the WWX value $(qr \cdot q')(\dots)$ is preserved because s is orthogonal and conjugates r to $s^{-1}rs$. By Theorem 48.22, $\mathcal{T}_p = \mathcal{T}$, i.e. $b(\theta_p(u \cdot v), \theta_p w) = b(\theta_p u \cdot \theta_p v, \theta_p w)$; nondegeneracy of b and surjectivity of θ_p give

multiplicativity, and preservation of b is the orthogonality of g and s. (b) If $\theta_p = 1$ then $g^{\mathsf{T}}Ag = A$ for all symmetric A forces $g = \pm 1$, and $s^{\mathsf{T}}Ng = N$ for all N forces $s = \pm 1$ with the same sign. (c) For $p = (-1, 1)$: A and x are fixed (conjugation by -1 is trivial) and $N \mapsto -N$. (d) The short classes span $\bar{\Lambda}$ (the minimal vectors generate Λ, `closure_latticeGens`), so the short elements generate Q modulo $Z(Q) = \Phi(Q)$, and elements generating modulo the Frattini subgroup generate. □

Physical meaning

G_{vis} is the part of the Monster that is *manifest* in the orbifold construction: the symmetries of the Leech lattice (Co_0) together with the extraspecial group of "momentum shifts" $e^{\pi i\langle\mu,p\rangle}$ and their action on the twist ground states. It commutes with the orbifold involution z (which is x_B: $+1$ on untwisted, -1 on twisted fields), and classically (not formalised) it is the centraliser $C_{\mathbb{M}}(z) \cong 2^{1+24}.\text{Co}_1$ of a $2B$ involution of the Monster. The kernel $\{1, (-1,-1)\}$ says that the reflection $X \mapsto -X$ combined with -1 on the ground states acts trivially on the orbifold theory.

What the machine verified

No hypotheses; audited in `ParityAudit.lean`.

48.8 Triality: the element τ_B, the four-group and G_{mat}

48.8.1 The triality basis

G_{vis} preserves the decomposition $\mathcal{B} = (\text{Sym} \oplus X) \oplus W$ into the ± 1-eigenspaces of x_B, i.e. into "untwisted" and "twisted" parts. Classically the Monster is generated by G_{vis} and one more element, which must mix the two.

Why a triality basis. Conway's idea: x_B should be one of three commuting involutions x_B, y_B, z_B (with 1, a four-group), conjugate under an element of order 3 that permutes them cyclically. Each involution splits $\mathcal{B}$ into ± 1 eigenspaces; x_B is -1 exactly on W (98304-dimensional). To permute the three involutions, one needs a basis in which all three are diagonal, grouped into triples on which x_B, y_B, z_B have sign patterns $(1,-1,-1)$, $(-1,1,-1)$, $(-1,-1,1)$, plus vectors fixed by all three; the order-3 element then cycles each triple. Counting dimensions: W splits as two halves $\eta = 0, 1$ of 49152 each, paired with the 49152 classes of odd minimal vectors $(\mp 3, \pm 1^{23})$; the off-diagonal matrix units $E_{ij} + E_{ji}$ are paired with the two classes $4e_i \pm 4e_j$; and the remaining vectors (diagonal units, octad classes) are fixed by the four-group, on which the order-3 element must act by something else.

Definition 48.29 (Triality basis)**.** The index set is

$$T_{\text{idx}} = \{0..23\} \sqcup (\text{LtPair} \times \{0,1,2\}) \sqcup (\mathcal{C}_0 \times \{0..23\} \times \{0,1,2\}) \sqcup \text{OctIdx},$$

of size $24+276\cdot 3+2048\cdot 24\cdot 3+759\cdot 64 = 196884$, where LtPair is the set of pairs $i < j$ and OctIdx the pairs (octad d, even subset of d modulo complement in d). The basis vectors are: the diagonal matrix units E_{ii}; for each pair $i < j$ the triple $(E_{ij} + E_{ji},\ e_{r^-} - e_{r^+},\ e_{r^-} + e_{r^+})$ where $r^{\mp}$ are the short classes of $4e_i \mp 4e_j$; for each odd minimal-vector class (c, i) the triple $(e_{\text{odd}(c,i)},\ \pm E_1(c) \otimes e_i,\ \pm E_0(c) \otimes e_i)$ with $E_\eta(c)$ the basis vector (η, c) of $\mathbb{Q}^I$; and the vectors e_c of the octad classes (shape $(\pm 2^8, 0^{16})$). The Gram matrix is diagonal with entries in $\{1, 2\}$.

```
abbrev TIdx : Type := Fin 24 ⊕ (LtPair × Fin 3) ⊕ (C₀ × Fin 24 × Fin 3) ⊕ OctIdx
```

```
theorem card_tIdx : Fintype.card TIdx = 196884 := by
```

```
noncomputable def tbasis : Basis TIdx ℚ SpaceB :=
  basisOfLinearIndependentOfCardEqFinrank linearIndependent_tvec (card_tIdx.trans
   ↪ finrank_B.symm)
```

```
theorem bform_tbasis (x y : TIdx) : bform (tbasis x) (tbasis y) = if x = y then tnorm x
 ↪ else 0 := by
```

(VOA/Moonshine/MonsterGriess/TrialityBasis.lean.)

From the mathematics to the Lean statement

`tbasis` is the basis whose vectors are `tvec x`, made into a basis from linear independence and the count $196884 = \dim \mathcal{B}$ (`coe_tbasis : ⇑tbasis = tvec`). `tnorm` is 2 on the pair triples and 1 elsewhere. The label bookkeeping (`TrialityLabels.lean`, `TrialityClasses.lean`) proves that the four label families `rMinus`, `rPlus`, `rOdd`, `rOct` of elements of Q hit each short class exactly once (`labelEquiv : ShortLabel ≃ ShortIdx`, $552 + 49152 + 48576 = 98280$). The octad part uses the 6-dimensional quadratic space of even subsets of an octad modulo complement (`OctadEvenSubset.lean`).

Physical meaning

The triality basis groups the spin-two fields into triples that are permuted by a hidden $\mathbb{Z}/3$ symmetry: off-diagonal oscillator bilinears with the two combinations of $\cos((4e_i \mp 4e_j)X/\sqrt{8})$; odd-momentum exponentials with the two halves of the first excited twisted states. This is the algebraic shadow of the fact that the $\mathbb{Z}/2$ orbifold of the Leech CFT has a larger symmetry that mixes twisted and untwisted sectors (FLM's triality, Chapter 39).

What the machine verified

Audited in `TrialityAudit.lean`.

48.8.2 The element τ_B

For an octad d let E_d be the $\mathbb{F}_2$-space of even subsets of d modulo the complement in d ($\delta \sim d \setminus \delta$); it has dimension 6 and 64 elements, carries the quadratic form $q_d(\delta) = \frac{1}{2}|\delta| \bmod 2$ with polar form $b_d(\delta, \varepsilon) = |\delta \cap \varepsilon| \bmod 2$ (nondegenerate, with Gauss sum $\sum_\delta (-1)^{q_d(\delta)} = 8$), and indexes the 64 octad classes of shape $(\pm 2^8, 0^{16})$ supported on d. Put

$$(H_d)_{\delta\varepsilon} = \tfrac{1}{8}(-1)^{b_d(\delta,\varepsilon)}, \qquad D_d = \operatorname{diag}\big((-1)^{q_d(\delta)}\big) \qquad (64 \times 64).$$

Then $H_d^2 = D_d^2 = 1$, H_d, D_d are orthogonal, and $(H_d D_d)^3 = 1$ (`binary_quadratic_fourier_triality`): the "Fourier" and "sign" operators generate a copy of S_3, the finite analogue of S and T in $SL_2(\mathbb{Z})$ acting on theta functions.

Definition 48.30 (τ_B). τ_B is the linear map that fixes the 24 diagonal units, sends the k-th vector of every triple to the $(k+1)$-st (indices mod 3), and sends the octad vector $v_{d,\delta}$ to $\sum_\varepsilon (H_d D_d)_{\delta\varepsilon} v_{d,\varepsilon}$. Equivalently: its matrix in `tbasis` is the transpose of the block-diagonal matrix `tauMat` with blocks 1, the 3-cycle, and $H_d D_d$.

```
noncomputable def tauMat : Matrix TIdx TIdx ℚ :=

```

```
theorem tauB_pow_three : tauB ^ 3 = 1 := by

theorem orderOf_tauB : orderOf tauB = 3 := by

theorem trace_tauB : LinearMap.trace ℚ SpaceB tauB = 783 := by

theorem finrank_ker_tauB_sub_one :
    finrank ℚ (LinearMap.ker ((tauB : SpaceB →ₗ[ℚ] SpaceB) - 1)) = 66150 := by

theorem bform_tauB (u v : SpaceB) : bform (tauB u) (tauB v) = bform u v :=
```

(VOA/Moonshine/MonsterGriess/TrialityMatrix.lean.)

From the mathematics to the Lean statement

`Matrix.toLinOfInv b b h₁ h₂` is the linear equivalence with matrix M^{T} in the basis b given proofs that $M^{\mathsf{T}}M = MM^{\mathsf{T}} = 1$ (`coe_tauB : … = toLin tbasis tbasis tauMatᵀ`). `diag2` forms block-diagonal matrices on a sum type. The orthogonality proofs use that H_d, D_d are orthogonal with dyadic entries and $(H_dD_d)^3 = 1$ (`OctadEvenSubset.lean`). The action on basis vectors is `tauB_diag`, `tauB_pair`, `tauB_odd`, `tauB_oct`.

The numbers. Trace: the diagonal units contribute 24, each 3-cycle contributes 0, and each octad block contributes $\mathrm{tr}(H_dD_d) = \frac{1}{8}\sum_\delta (-1)^{b_d(\delta,\delta)+q_d(\delta)} = \frac{1}{8}\sum_\delta (-1)^{q_d(\delta)} = 1$ (as $b_d(\delta,\delta) = 2q_d(\delta) = 0$); so $\mathrm{tr}\,\tau_B = 24 + 759 = 783$. Fixed space: for an element of order 3 with eigenvalues $1, \omega, \bar\omega$ of multiplicities m_1, m, m one has $m_1 + 2m = 196884$ and $m_1 - m = \mathrm{tr}\,\tau_B = 783$, so $m_1 = \frac{1}{3}(196884 + 2\cdot 783) = 66150$. These numbers are consistency checks (the class $3A$ of $\mathbb{M}$ has character value 782 on the 196883-dimensional representation).

Physical meaning

τ_B is an order-three symmetry rotating "oscillator bilinear → untwisted exponential → twisted state". Its trace $783 = 1+782$ on $V^\natural{}_2$ equals the coefficient of q in the McKay–Thompson series $T_{3A} = q^{-1} + 783q + \cdots$, as it must if τ_B is in the class $3A$ of the Monster (this identification is classical and not formalised).

What the machine verified

No hypotheses; audited in `TrialityAudit.lean`.

Definition 48.31 (Four-group and the generated group). $y_B = \tau_B x_B \tau_B^{-1}$, $z_B = \tau_B^2 x_B \tau_B^{-2}$; $G_{\mathrm{mat}} = \langle G_{\mathrm{vis}} \cup \{\tau_B\}\rangle$.

```
noncomputable def yB : SpaceB ≃ₗ[ℚ] SpaceB := tauB * xB * tauB⁻¹

noncomputable def zB : SpaceB ≃ₗ[ℚ] SpaceB := tauB ^ 2 * xB * (tauB ^ 2)⁻¹

noncomputable def Gmat : Subgroup (SpaceB ≃ₗ[ℚ] SpaceB) :=
  Subgroup.closure ((Gvis : Set (SpaceB ≃ₗ[ℚ] SpaceB)) ∪ {tauB})
```

(VOA/Moonshine/MonsterGriess/TrialityFourGroup.lean; `yB`, `zB` in `VOA.Moonshine.MonsterGriess`, `Gmat` in `VOA.Moonshine.MonsterGriess.Generated`.)

From the mathematics to the Lean statement

`tauB⁻¹` is the inverse in the group `SpaceB ≃ₗ[ℚ] SpaceB`; `Subgroup.closure S` is the subgroup generated by S; the coercion `(Gvis : Set _)` views the subgroup as a set. These are the

source's definitions verbatim, with the fully qualified names `CFSG.Monster.Generated.Gmat` ↦ `VOA.Moonshine.MonsterGriess.Generated.Gmat`; it is *this* `Gmat` that appears in `GmatEqAutO` (Chapter 49).

Physical meaning

G_{mat} is the group generated by the manifest symmetries of the orbifold and the hidden triality: classically the whole Monster. That it is all of `AutO` is AxiomMath's generation theorem.

What the machine verified

Definitions; audited in `TrialityAudit.lean`.

Theorem 48.32 (Rational triality four-group). *In* `tbasis`, x_B, y_B, z_B *are diagonal with signs* $(1,-1,-1)$, $(-1,1,-1)$, $(-1,-1,1)$ *on the three slots of each odd triple and* $+1$ *elsewhere;* $\{1, x_B, y_B, z_B\}$ *is a Klein four-group,* τ_B *permutes* $x_B \mapsto y_B \mapsto z_B \mapsto x_B$ *by conjugation, all three preserve b, and each has a* 98304*-dimensional* (-1)*-eigenspace.*

```
theorem rational_triality_four_group :
    yB = tauB * xB * tauB⁻¹ ∧ zB = tauB ^ 2 * xB * (tauB ^ 2)⁻¹ ∧
    (∀ t : TIdx, xB (tbasis t) = oddSign ![1, -1, -1] t • tbasis t) ∧
    (∀ t : TIdx, yB (tbasis t) = oddSign ![-1, 1, -1] t • tbasis t) ∧
    (∀ t : TIdx, zB (tbasis t) = oddSign ![-1, -1, 1] t • tbasis t) ∧
```

(the statement continues with the group relations, the eigenspace dimensions and the dyadic lattice; `TrialityFourGroup.lean`.)

From the mathematics to the Lean statement

`oddSign v t` is v_k if t is slot k of an odd triple and 1 otherwise. The source's conjunct `IsElementaryAbelian 2 fourGroupB` is replaced by its content (commutativity and exponent 2), because the predicate lives in a source prelude that is not ported. Also proved: `Hmat_le_Gmat` ($G_{\text{vis}} \le G_{\text{mat}}$), `tauB_mem_Gmat`, `xmat_eq_xB`, and the port addition `Gmat_eq_closure_insert : Gmat = Subgroup.closure (insert tauB (Gvis : Set _))`.

Physical meaning

x_B is the orbifold involution z; y_B and z_B are its triality images, which act as -1 on the odd-momentum exponentials and on half of the twisted states. In FLM's language $\{1, x_B, y_B, z_B\}$ is the four-group whose nontrivial elements are permuted by triality; the three 2^{1+24} subgroups they centralise are conjugate in the Monster.

What the machine verified

No hypotheses; audited in `TrialityAudit.lean`.

48.8.3 Product invariance of τ_B

Theorem 48.33 (τ_B is an automorphism; $G_{\text{mat}} \le$ `AutO`). $\tau_B(u \cdot v) = \tau_B(u) \cdot \tau_B(v)$ *for all* u, v*; hence* $\tau_B \in$ `AutO` *and* $G_{\text{mat}} \le$ `AutO`.

```
theorem tauB_gmul (u v : SpaceB) : tauB (gmul u v) = gmul (tauB u) (tauB v) := by
```

```
theorem tauB_mem_AutO : tauB ∈ AutO := ⟨isAlgAut_tauB, bform_tauB⟩
```

```
theorem Gmat_le_AutO : Gmat ≤ AutO := Gmat_le_AutO_of_isAlgAut isAlgAut_tauB
```

(`VOA/Moonshine/MonsterGriess/ProductInvariance.lean`; `Gmat_le_AutO` in `.Generated`.)

From the mathematics to the Lean statement

The three statements say exactly what they appear to say; `Gmat_le_AutO` combines `tauB_mem_AutO` with `Gvis_le_AutO` (`Gmat_le_AutO_iff : Gmat ≤ AutO ↔ tauB ∈ AutO`). In the source, `tauB_mem_AutO` sits in `Griess/AutFinite.lean` and `Gmat_le_AutO` in `Generated/Centralizer.lean`; the port proves the same statements here.

Proof on paper. Since τ_B preserves b, it suffices that the trilinear form is invariant, $\mathcal{T}(\tau_B u, \tau_B v, \tau_B w) = \mathcal{T}(u, v, w)$, and by trilinearity it suffices to check this on triples of `tbasis` vectors. There are 196884^3 such triples, so the proof is organised:

(i) *Diagonal units.* Each basis vector is an eigenvector of multiplication by every diagonal E_{kk}, and τ_B permutes basis vectors with equal eigenvalues; so any triple containing a diagonal unit is invariant (`InvarianceDiagonal.lean`).

(ii) *Grading.* $\mathcal{B}$ is graded by $\Gamma = (\mathbb{Z}/2)^2 \times \mathcal{C}/\langle\Omega\rangle$; every basis vector is homogeneous, $\mathcal{T}$ vanishes on triples whose degrees do not sum to 0, and τ_B maps degree g to degree $\alpha(g)$ for an automorphism α of Γ (`GriessGrading.lean`). So only degree-zero triples remain.

(iii) *Sectors.* The degree-zero triples fall into six types, each with a closed-form value of $\mathcal{T}$ shown to be invariant under the index shift induced by τ_B: pair^3 (`InvarianceTwoCoord.lean`); odd · odd · pair (`InvarianceOddTwoCoord.lean`); the odd triple, one vector from each slot 0, 1, 2 (`InvarianceXYZ.lean`); octad·octad·pair (`InvarianceOctadTwoCoord.lean`); octad·octad·octad; and odd·odd·octad, by character sums of $(-1)^{b_d(\delta,\cdot)}$ (`InvarianceOddValues.lean`, `InvarianceOddOctad.lean`). Shared lemmas are in `InvarianceOctadBasic.lean`. In each case τ_B acts on the relevant indices by the shift $k \mapsto k+1$ or by $H_d D_d$, and the closed form is checked to be invariant.

(iv) *The octad^3 case in more detail.* For three octads d_1, d_2, d_3, $\mathcal{T}$ vanishes on their octad vectors unless $d_1 + d_2 + d_3 = 0$ in $\mathcal{C}$. In that case consider the 18-dimensional quadratic space $E = E_{d_1} \oplus E_{d_2} \oplus E_{d_3}$ with $q = q_{d_1} + q_{d_2} + q_{d_3}$. A *Lagrangian* is a subspace K with $K^\perp = K$ for the polar form (so $\dim K = 9$) on which q vanishes. The relevant K is the kernel of the map $(\delta_1, \delta_2, \delta_3) \mapsto \delta_1 + \delta_2 + \delta_3$ to the cocode, and there is an isotropic vector a_0 (built from $d_1 \cap d_2$) such that the values $\mathcal{T}(v_{d_1,\delta_1}, v_{d_2,\delta_2}, v_{d_3,\delta_3})$ form, up to normalisation, a function on E supported on the coset $a_0 + K$ with signs given by q (the "Lagrangian function"; `three_octad_lagrangian_correspondence`, `OctadThreeOctad.lean`). The tensor product of the three Fourier matrices H_{d_i} maps the indicator of a Lagrangian coset to itself (the Fourier transform of the indicator of K is a multiple of the indicator of $K^\perp = K$), and the tensor product of the D_{d_i} multiplies it by $(-1)^q$, which is constant on the coset. So both, hence τ_B, fix $\mathcal{T}$ on octad^3 (`fourier_lagrangianFun`, `signOp_lagrangianFun`, `InvarianceThreeOctad.lean`). The precise signs are in the Lean files; this paragraph gives the mechanism.

Then $b(\tau_B(u \cdot v), w) = b(u \cdot v, \tau_B^{-1} w) = \mathcal{T}(u, v, \tau_B^{-1} w) = \mathcal{T}(\tau_B u, \tau_B v, w) = b(\tau_B u \cdot \tau_B v, w)$ for all w, and b is nondegenerate. □

Physical meaning

That a hand-built $\mathbb{Z}/3$ rotation mixing the twisted and untwisted sectors preserves all OPE coefficients is the finite-dimensional form of the statement that the orbifold theory has an extra symmetry not visible in its construction. The Fourier-transform step on octads is the algebraic analogue of a modular S-transformation exchanging sectors.

What the machine verified

No hypotheses; audited in `ProductInvarianceAudit.lean` and `MoonshineCNMonsterFinalAudit.lean`. The heartbeat budget is raised in `isGriessForm_thetaT` (`VisibleAction.lean`) only; no `native_decide` anywhere in the port.

48.9 The parity-centralizer theorem: $\mathrm{Aut}0 \cap C(x_B) = G_{\mathrm{vis}}$

Theorem 48.34 (AxiomMath's rational parity-centralizer theorem). *(1) A $\mathbb{Q}$-linear automorphism f of $\mathcal{B}$ preserves the product and the form and commutes with x_B if and only if $f \in G_{\mathrm{vis}}$. (2) Every such f is θ_p for a visible pair p, unique up to $p \mapsto p \cdot (-1,-1)$. (3) $p \cdot (-1,-1) = (-s,-g)$. Equivalently,* $\mathtt{Aut}0 \cap C(x_B) = G_{\mathrm{vis}}$.

```
theorem rational_parity_centralizer_equals_visible :
    (∀ f : SpaceB ≃ₗ[ℚ] SpaceB, ((∀ u v, f (gmul u v) = gmul (f u) (f v)) ∧
        (∀ u v, bform (f u) (f v) = bform u v) ∧ ∀ u, f (xB u) = xB (f u)) ↔ f ∈ Gvis) ∧
    (∀ f : SpaceB ≃ₗ[ℚ] SpaceB, (∀ u v, f (gmul u v) = gmul (f u) (f v)) →
      (∀ u v, bform (f u) (f v) = bform u v) → (∀ u, f (xB u) = xB (f u)) →
      ∃ p : Pvis, thetaEquiv p = f ∧
        ∀ p' : Pvis, thetaEquiv p' = f ↔ p' = p ∨ p' = p * negPair) ∧
    ∀ p : Pvis, (((p * negPair : Pvis).1.1 : GL SpinIdx ℚ) : Matrix SpinIdx SpinIdx ℚ) =
        -((p.1.1 : GL SpinIdx ℚ) : Matrix SpinIdx SpinIdx ℚ) ∧
      mat (p * negPair : Pvis).1.2 = -mat p.1.2 := by
```

```
theorem Aut0_inf_centralizer_xB_eq_Gvis :
    Aut0 ⊓ Subgroup.centralizer {xB} = Gvis := by
```

(`VOA/Moonshine/MonsterGriess/ParityEqualsVisible.lean`, namespace `.Parity`.)

From the mathematics to the Lean statement

`⊓` is intersection of subgroups; `Subgroup.centralizer {xB}` is $\{f : fx_B = x_B f\}$. The corollary is a port addition (the subgroup form of part (1)). Part (1) has the three conditions on the left exactly as in `Aut0` plus commutation with x_B; the equivalence is an "iff", so it also contains $G_{\mathrm{vis}} \le \mathtt{Aut}0$. This theorem does *not* depend on $G_{\mathrm{mat}} = \mathtt{Aut}0$: its AxiomMath import closure is 82 files, and the port contains all of it that the proof uses.

Proof on paper. Let f be a "parity automorphism" (`IsParityAut`: product, form, commutes with x_B).

(a) *Blocks.* f preserves W (the -1-eigenspace of x_B) and $\mathrm{Sym} \oplus X$. For $u = (A, x, 0)$ let $L_u : W \to W$ be multiplication by u; by the table, $L_u(N) = \frac{\mathrm{tr}\,A}{8}N + NA + \frac{1}{8}\sum_c x_c R_c N(1 - \frac{1}{4}U_c)$. Since $W = \mathbb{Q}^I \otimes \mathbb{Q}^{24}$ and L_u is a sum of operators $M \otimes M'$ (left factor on $\mathbb{Q}^I$, right factor on $\mathbb{Q}^{24}$), traces factor: $\mathrm{tr}(M \otimes M') = \mathrm{tr}\,M \cdot \mathrm{tr}\,M'$. For $u = (A,0,0)$, $v = (A',0,0)$: $L_u = 1 \otimes (\frac{\mathrm{tr}\,A}{8} + A)$, so

$$\mathrm{tr}(L_u L_v) = 4096\big(24\tfrac{\mathrm{tr}\,A\,\mathrm{tr}\,A'}{64} + 2\tfrac{\mathrm{tr}\,A\,\mathrm{tr}\,A'}{8} + \mathrm{tr}(AA')\big) = 4096\,\mathrm{tr}(AA') + 512 \cdot 5\,\mathrm{tr}\,A\,\mathrm{tr}\,A',$$

since $4096(\frac{24}{64} + \frac{2}{8}) = 4096 \cdot \frac{5}{8} = 2560$. For $u = e_c$, $v = e_d$: $L_{e_c} = \frac{1}{8}R_c \otimes (1 - \frac{1}{4}U_c)$; $\mathrm{tr}(R_c R_d) = 0$ for $c \neq d$ (a non-scalar element of Q has trace 0) and $R_c^2 = 1$ for short c, while $\mathrm{tr}\big((1 - \frac{1}{4}U_c)^2\big) = \mathrm{tr}(1 + \frac{3}{2}U_c) = 24 + 48 = 72$ (using $U_c^2 = 32U_c$, $\mathrm{tr}\,U_c = 32$); so $\mathrm{tr}(L_{e_c}L_{e_d}) = \frac{1}{64} \cdot 4096 \cdot 72\,\delta_{cd} = 4608\,\delta_{cd} = (4096 + 512)\delta_{cd}$. Mixed terms vanish because $\mathrm{tr}\,R_c = 0$. Altogether $\mathrm{tr}(L_u L_v) = 4096\,b(u,v) + 512\,\sigma(u,v)$ with $\sigma(u,v) = 5\,\mathrm{tr}\,A\,\mathrm{tr}\,A' + x \cdot x'$. Since f

conjugates L_u to L_{fu}, it preserves σ as well as b. Let Φ be the operator with $b(\Phi u, v) = \sigma(u, v)$: $\Phi(A, x) = (5\,\mathrm{tr}(A)I, x)$. It commutes with f, and its eigenspaces are $\mathbb{Q}I$ (eigenvalue 120), the traceless matrices (eigenvalue 0) and X (eigenvalue 1); so f preserves $\mathbb{Q}I$, $\mathrm{Sym} = \mathbb{Q}I \oplus \mathrm{Sym}_0$ and X (`ParityTraceSplitting.lean`).

(b) Sym-*block.* On Sym the product is the Jordan product $2(AB + BA)$ and b is the trace form; a Jordan automorphism of real symmetric matrices preserving the trace form is $A \mapsto g^{\mathsf{T}}Ag$ with g orthogonal (`ParityRealExtension.lean`; the proof extends scalars to $\mathbb{R}$).

(c) *Short lines and* Co_0. f maps each e_c to $\pm e_{\ell(c)}$ for a bijection ℓ with $q_{\ell(c)}(g^{\mathsf{T}}Ag) = q_c(A)$; hence g maps minimal vectors to minimal vectors up to sign, is rational with denominators dividing 8, and preserves Λ: $g \in \mathrm{Co}_0$ (`ParityShortLines.lean`, `ScalarKernel.lean`).

(d) W*-block.* On W, $f(N) = s^{\mathsf{T}}Ng$ for an orthogonal s, and comparing the $X \cdot W$ products shows that s conjugates every R_c to $\pm R_{\ell(c)}$; since Q is generated by its short elements, s normalises Q, hence has dyadic entries (`dyadic_of_conj_Q`, `SpinExtraspecial.lean`), and (s, g) is a visible pair with $\theta_{(s,g)} = f$.

The converse is Theorem 48.28(a) together with the observation that each θ_p commutes with x_B ($N \mapsto s^{\mathsf{T}}Ng$ is linear in N). □

Physical meaning

"Every symmetry of the Monster CFT that commutes with the orbifold involution is a manifest symmetry of the orbifold construction." Physically this is plausible: a symmetry commuting with z preserves the untwisted sector, hence acts on the Leech lattice theory's $\mathbb{Z}/2$-invariant part, and such symmetries are rotations of the lattice combined with momentum shifts. The theorem makes this exact at the level of the Griess algebra.

What the machine verified

No hypotheses. Both audited in `ParityAudit.lean` (795 `#print axioms` lines over the parity closure), standard axioms. Two proof steps are re-proved in the port with the same statements (`phi0_coordOf_inv`, `phi0_coordOf_mul`) because of Mathlib-version instance problems; the port notes list them.

48.10 What is not ported: the generation theorem

AxiomMath's library contains, in Lean v4.35:

```
theorem gmat_eq_griess :
    CFSG.Monster.Generated.Gmat = CFSG.Monster.Griess.AutO :=
  CFSG.YGroups.Y443.Gmat_eq_AutO_of_stroth
```

This block is *not* LeanVOA source, which is why it is set as plain text rather than as a checked Lean quotation; it is quoted from `Notes/monster_aut/CFSG_PORT_FIDELITY.md` (source file `CFSG/Sporadic/Bridge/MonsterMoc` namespace `CFSG.Blueprint.NativeSporadic.MonsterModel`). Both sides are written with fully qualified names, and they are the source declarations of which our `Generated.Gmat` and `AutO` are ports.

Dead end: porting `gmat_eq_griess` to Lean 4.30

The authors' reconnaissance measured the file-level import closure of `gmat_eq_griess`: about 16,361 files, 208 MB, 4.19 million lines, with 1,720 certificate files, 13,487 `decide +kernel` proofs and heartbeat budgets up to $1.6 \cdot 10^8$. The proof cannot avoid the Stroth–Leon–Sims recognition of the Baby Monster: the alternative "two involution classes" route

(`GmatGriess_eq_top_of`) has a hypothesis that is discharged only through the same recognition. "A Stroth-free proof of $G_{\mathrm{mat}} = \texttt{Aut0}$ inside CFSG" is therefore a recorded dead end. A port of that closure to Lean 4.30, or a move of the whole library to Lean 4.35, was judged far too costly; the library stays on Lean 4.30 and carries $G_{\mathrm{mat}} = \texttt{Aut0}$ as one named hypothesis, `GmatEqAut0` (Chapter 49). The axiom footprint of `gmat_eq_griess` in AxiomMath's toolchain was not checked.

Recorded diagnosis: AxiomMath's finiteness proof does not transfer to $\mathbb{C}$

AxiomMath prove `Finite Aut0` analytically over the ordered field $\mathbb{Q}$ (ℓ^1-bounded and separated orbits of $2A$-axes, `finite_of_isolated_axes_basis`). Over $\mathbb{C}$ the form is not a norm and that argument fails; the same note records that the step "real and finite $\Rightarrow$ rational" for automorphisms of $\mathbb{C} \otimes \mathcal{B}$ is Tits's theorem, for which no cheap route was found. The converse direction actually used in Chapter 49 avoids Tits by a different argument (rationality of traces and a commutant lemma).

So the port provides the *statements* $G_{\mathrm{vis}} \leq G_{\mathrm{mat}} \leq \texttt{Aut0}$, $\texttt{Aut0} \cap C(x_B) = G_{\mathrm{vis}}$, $\tau_B \in \texttt{Aut0}$, and the definitions on both sides of `gmat_eq_griess`, but not `gmat_eq_griess` itself, nor finiteness, order or simplicity of `Aut0`.

48.11 The port-fidelity audit

All the definitions of Part A have now been presented, so we can state precisely in what sense they are AxiomMath's. Because `GmatEqAut0` (Chapter 49) is to be read as "AxiomMath's theorem `gmat_eq_griess`", it matters that our `Generated.Gmat` and `Aut0` are the *same definitions* as theirs. A read-only audit (`Notes/monster_aut/CFSG_PORT_FIDELITY.md`) compared, declaration by declaration, the definitional closure of the two constants on both sides. Its method and verdict, which this book reports as the authors' claim (a source-text comparison, not a Lean check):

- Starting from `Gmat` and `Aut0`, every identifier occurring in a definition body, and in the *statement* of every theorem referenced from a definition body (theorems can fix data: `tauB` gets its matrix from the statement of `tauMat_transpose_mul`, `tbasis` its vectors from `linearIndependent_tvec`), was followed down to Mathlib. This gave 199 definition-like declarations and 104 theorem statements.
- 198 definition bodies were matched to the source: 194 are textually identical after removing comments, attributes, visibility keywords and the namespace prefixes; three differ only in proof terms of propositions (`bform`, `gmul`) or by a parser artefact (`signMatrix`); one differs in substance: `SpinLattice.phi0`.
- All 88 data-fixing theorem statements that have a source counterpart are identical; 44 of the 46 instances are identical to source instances and the other 2 lie outside the closure; the relevant `variable` contexts match line for line.

The one substantive difference: `phi0` is a function, not a bundled linear map

In the source, φ_0 (Definition 48.10) is the bundled $\mathbb{F}_2$-linear map `(AddMonoidHom.toZModLinearMap 2 lamTHom).coprod lamCocode`; in the port (`VOA/Moonshine/MonsterGriess/Short.lean`) it is the plain function `fun p ⇒ lamT p.1 + lamCocode p.2`, because bundling needs the additivity of λ_T, which an earlier version of the port did not have. The two are *definitionally* equal (`LinearMap.coprod f g` unfolds pointwise to `f p.1 + g p.2`, and `lamTHom.toFun := lamT`), so `IsShortCoord`, hence `ShortIdx`, `SpaceX`,

`SpaceB`, `gmul`, `bform`, `AutO` and `Gmat` have the same *values*. But the elaborated terms are not syntactically identical, so a literal name-for-name transport of AxiomMath's `gmat_eq_griess` across toolchains would need a bridge step closed by `rfl`. The port now proves additivity (`phi0_add`) and bundles the map as `phi0Lin`, with `phi0Lin_apply : phi0Lin p = phi0 p` by `rfl`.

Out-of-date port docstrings

Some port docstrings still say that something is "not ported" that now is. `Short.lean` says this of `phi0Equiv` and `card_shortIdx`, which are in `LatticeQuadratic.lean` and `LatticeFamilies.lean`. `LeechMatch.lean` calls bijectivity of `phi0` "the open statement" (its `shortIdxEquivPm` and `card_shortIdx_of_bijective` take `Function.Bijective phi0` as a hypothesis); that hypothesis is the theorem `SpinLattice.phi0_bijective`. The docstring of `ShortSignDictionary` in `MoonshineCNGriessUntwisted.lean` says `phi0Equiv` is not ported. `TrialityFourGroup.lean` says that `tauB ∈ AutO` is "not proved here", true of that file; it is proved in `ProductInvariance.lean`. The Lean statements are unaffected.

48.12 The Griess algebra of $V^\natural$: the untwisted half

Part B begins. Its Lean names live in the namespace `VOA.Moonshine.GriessDictionary`. We use the moonshine module `VnatVOA` of Chapter 47 (`VOA/Moonshine/AutVnat.lean`), which is by definition the vertex operator algebra of Chapter 42 on the carrier `Vnat := SkewVP × TP` $= V_\Lambda^+ \oplus (V_\Lambda^T)^+$, with `VnatVOA.Y = Ynat wbarL`, `VnatVOA.grading = gradingNat` (`rfl`). Its Griess product is

```
def griessMul (W : VertexOperatorAlgebra 𝒱) (u v : W.grading 2) : W.grading 2 :=
  ⟨W.smul (u : 𝒱) 1 (v : 𝒱), by
```

(`VOA/Core/LieAlgebraV1.lean`), i.e. $u \times v = u_{(1)}v$ on W_2, and its invariant form is `SimpleNat.natForm` (Chapter 38): `natForm x y = leechBV x.1 y.1 + TPForm x.2 y.2`, the sum of the invariant form B_V of V_Λ^+ (= `plusForm`, Chapter 32) and the form `TPForm` of $(V_\Lambda^T)^+$ (Chapter 37), normalised by $\langle \mathbb{1}, \mathbb{1}\rangle = 1$. On ${V^\natural}_2$ it coincides with the intrinsic form $u_{(3)}v = \langle u, v\rangle \mathbb{1}$ (Theorem 48.57).

48.12.1 The $S^2\mathfrak{h}$ block in Conway's coordinates

The library writes oscillator states in an orthonormal frame h_a of $\mathfrak{h} = \mathbb{C} \otimes \Lambda$ (`chargeCoord`, Chapter 31), whose entries are irrational. To compare with AxiomMath's rational matrices, the $S^2\mathfrak{h}$ block is rewritten in Conway's integer coordinates, using the lattice vectors $8e_i \in \Lambda$ (norm 8, $\langle 8e_i, \beta\rangle = \beta_i$).

Definition 48.35 (Conway axes and quadratic states). $\mathrm{ax}_i = 8e_i \in \Lambda$. For a complex 24×24 matrix A, $Q_C(A) = \frac{1}{8}\sum_{i,j} A_{ij}\,\mathrm{ax}_i(-1)\mathrm{ax}_j(-1)\mathbb{1} \in (V_\Lambda^+)_2$.

```
def conwayAxis (i : Fin 24) : leech.carrier :=
  (⟨(8 : ℤ) • Pi.single i 1, eight_smul_mem_leechCarrier _⟩ : ₁Leech.carrier)
```

```
noncomputable def conwayQuad : Matrix (Fin 24) (Fin 24) ℂ →ₗ[ℂ] VPlus := frameQuad ∘ₗ
 ↪ conwayToFrame
```

```
theorem conwayQuad_eq_sum_dV (A : Matrix (Fin 24) (Fin 24) ℂ) :
    conwayQuad A = (8 : ℂ)⁻¹ • ∑ i, ∑ j, A i j • (dV (conwayAxis i) (conwayAxis j) : VPlus)
     ↪ := by
```

(`VOA/Moonshine/MoonshineCNGriessConway.lean`.)

From the mathematics to the Lean statement

`frameQuad M` = $\sum_{a,b} M_{ab} h_a(-1)h_b(-1)\mathbb{1}$ in the orthonormal frame; `conwayToFrame A` = $\frac{1}{8}FAF^{\mathsf{T}}$ with F the frame coordinates of the axes (`conwayFrame`, $F^{\mathsf{T}}F = 8 \cdot 1$). `dV α β` is the state $\alpha(-1)\beta(-1)\mathbb{1}$. So the definition through the frame and the displayed formula agree (`conwayQuad_eq_sum_dV`). `VPlus` is V_Λ^+.

Physical meaning

$Q_C(A)$ is the composite operator $\frac{1}{8}A_{ij}\partial X^i \partial X^j$ written in Conway's lattice coordinates; $Q_C(\frac{1}{2}I) = \frac{1}{2}\sum_a h_a(-1)^2\mathbb{1} = \omega$ is the stress tensor (since $\mathrm{ax}_i/\sqrt{8}$ is a unit vector).

What the machine verified

Definition; audited in `MoonshineCNGriessAudit.lean`.

Theorem 48.36 (The untwisted Griess products in Conway coordinates). *For symmetric A, B and $\beta \in \Lambda$ with integer coordinates y_β: (a) $Q_C(A)_{(1)}Q_C(B) = 2\,Q_C(AB+BA)$; (b) $Q_C(A)_{(1)}x_\beta = \frac{1}{8}(y_\beta^{\mathsf{T}}Ay_\beta)\,x_\beta$, where $x_\beta = e^{\beta} + e^{-\beta}$; (c) $\beta(-1)^2\mathbb{1} = Q_C(\frac{1}{8}y_\beta y_\beta^{\mathsf{T}})$; (d) $\langle Q_C(A), Q_C(B)\rangle = 2\,\mathrm{tr}(AB)$; $\langle x_\alpha, x_\beta\rangle = 2\varepsilon(\alpha,\alpha)$ if $\beta = \pm\alpha$ and 0 otherwise (α minimal).*

```

      = conwayQuad ((8 : ℂ)⁻¹ • vecMulVec (fun i => (vec β i : ℂ)) (fun i => (vec β i :
       ↪ ℂ))) := by
```

```
theorem plusForm_conwayQuad_conwayQuad_of_symm {A B : Matrix (Fin 24) (Fin 24) ℂ}
    (hB : Bᵀ = B) : plusForm (conwayQuad A) (conwayQuad B) = 2 * trace (A * B) := by
```

```
theorem plusForm_frameX0P_frameX0P {α : leech.carrier} (hα : leech.form α α = 4)
    (β : leech.carrier) :
    plusForm (frameX0P α) (frameX0P β)
      = if β = α ∨ β = -α then 2 * latticeCocycle leech α α else 0 := by
```

(`VOA/Moonshine/MoonshineCNGriessConway.lean`.)

From the mathematics to the Lean statement

`leechVOAPlus.smul u 1 v` is $u_{(1)}v$ in V_Λ^+; `frameX0P β` is x_β (Chapter 32); `vec β` the integer coordinates of β; `latticeCocycle leech α α` is $\varepsilon(\alpha,\alpha) \in \{\pm 1\}$ (Chapter 34; it need not be 1). The products of the x_α among themselves are lemmas of `MoonshineLRFinOrderIsing.lean` (Chapter 47), used unchanged. Compare with the table of §48.5: (a) is $A \cdot A' = 2(AA' + A'A)$; (b) is $A \cdot x = \frac{1}{8}q_c(A)x_c$; (c) is the source of $\frac{1}{8}U_c$ in $x \cdot y$; (d) is $b = \mathrm{tr}(AA')$ up to the factor 2.

Proof on paper. (a) Wick's theorem for the Heisenberg VOA: $(h_a h_b)_{(1)}(h_c h_d)$ is the sum over single contractions, giving $\sum M_{ab}N_{cd}(\delta_{bc}h_a h_d + \dots)$, i.e. $Q((M+M^{\mathsf T})(N+N^{\mathsf T}))$; then transport through $\frac{1}{8}F(\cdot)F^{\mathsf T}$ using $F^{\mathsf T}F = 8$. (b) $h_a(1)h_b(1)e^{\beta}$ produces $\langle h_a,\beta\rangle\langle h_b,\beta\rangle e^{\beta}$. (c), (d) are similar contractions. □

Physical meaning

(a) is the OPE of two bilinears in free bosons; (b) says $\cos(\beta X)$ is an eigen-operator of the "metric deformation" $A_{ij}\partial X^i \partial X^j$ with eigenvalue proportional to $\beta^{\mathsf T}A\beta$ (the change of its conformal weight); (d) are free-boson two-point functions.

What the machine verified

No hypotheses beyond those displayed; all audited in `MoonshineCNGriessAudit.lean`.

48.12.2 The untwisted dictionary

Definition 48.37 (Matrix and short dictionaries)**.** For a rational matrix M in AxiomMath's coordinates let $M^{\pi} = (M_{\pi i,\pi j})_{ij}$ (a complex matrix in our coordinates) and $\mathrm{matDict}(M) = Q_C(M^{\pi})$. For $c \in \mathcal{S}$ let α_c be the minimal vector of our lattice that π carries to u_c. For a phase function $\zeta : \mathcal{S} \to \mathbb{C}$, $\mathrm{shortDict}_{\zeta}(x) = \sum_c x_c \zeta_c\, x_{\alpha_c}$, and $\Phi_{\zeta}(A,x,N) = \mathrm{matDict}(A) + \mathrm{shortDict}_{\zeta}(x)$.

```
noncomputable def axiomToConway (M : Matrix (Fin 24) (Fin 24) ℚ) : Matrix (Fin 24) (Fin 24)
 ↪  ℂ :=
  Matrix.of fun i j => (M (piPerm i) (piPerm j) : ℂ)
```

```
noncomputable def matDict : Matrix (Fin 24) (Fin 24) ℚ →+ VPlus where
  toFun M := conwayQuad (axiomToConway M)
```

```
noncomputable def shortVec (c : ShortIdx) : leech.carrier :=
  leechEquiv.symm ⟨uvec c, (uvec_mem_minVecs c).1⟩
```

```
noncomputable def shortDict (ζ : ShortIdx → ℂ) : SpaceX →+ VPlus where
  toFun x := ∑ c, ((x c : ℂ) * ζ c) • frameX0P (shortVec c)
```

```
noncomputable def untwistedDict : SpaceB →+ VPlus where
  toFun u := matDict u.1 + shortDict ζ u.2.1
```

(`VOA/Moonshine/MoonshineCNGriessUntwisted.lean`.)

From the mathematics to the Lean statement

The maps are additive (`→+`) and $\mathbb{Q}$-homogeneous (`matDict_smul`, `untwistedDict_smul`); they are not declared $\mathbb{Q}$-linear because $\mathbb{Q}$-linearity into a $\mathbb{C}$-space is automatic for additive maps. `untwistedDict` ignores the W-component. `shortVec_norm` says $\langle\alpha_c,\alpha_c\rangle = 4$ and `quadForm_shortVec` that $y_{\alpha_c}^{\mathsf T}A^{\pi}y_{\alpha_c} = q_c(A)$, which is how (b) of Theorem 48.36 becomes AxiomMath's $\frac{1}{8}q_c(A)$.

Physical meaning

The dictionary writes each element of AxiomMath's Sym $\oplus X$ as a concrete spin-two field of the untwisted sector: matrices become boson bilinears, the basis vector e_c becomes $\zeta_c(e^{i\alpha_c X} + e^{-i\alpha_c X})$. The phase ζ_c is a choice of normalisation of the vertex operator, which is ambiguous up to the cocycle.

What the machine verified

Definitions; audited in `MoonshineCNGriessAudit.lean`.

Definition 48.38 (Sign dictionary). A phase function $\zeta : \mathcal{S} \to \mathbb{C}$ is a *sign dictionary* if the following six conditions hold. The first three are about supports and do not involve ζ; they follow from additivity and injectivity of φ_0 (Theorem 48.40), so in practice only the last three matter.

- (pm_injective) distinct short classes have distinct pairs $\pm\alpha_c$: $\alpha_d = \pm\alpha_c \Rightarrow d = c$;
- (sum_shape) if $c = d + e$ in $\mathcal{C} \times \mathcal{C}^*$, then either $\langle \alpha_d, \alpha_e \rangle = -2$ and $\alpha_c = \pm(\alpha_d + \alpha_e)$, or $\langle \alpha_d, \alpha_e \rangle = 2$ and $\alpha_c = \pm(\alpha_e - \alpha_d)$;
- (sum_exists) if $\langle \alpha_d, \alpha_e \rangle = \pm 2$ then $d + e$ is short;
- (sq) $\zeta_c^2 \varepsilon(\alpha_c, \alpha_c) = 1$ (normalisation of the form);
- (sign_neg_two), (sign_two) for $c = d + e$ with $\langle \alpha_d, \alpha_e \rangle = \mp 2$: $(-1)^{\langle a_e, \delta_d \rangle} \zeta_c = \zeta_d \zeta_e \varepsilon(\alpha_d, \pm\alpha_e)$ (AxiomMath's sign against our cocycle).

```
structure ShortSignDictionary (ζ : ShortIdx → ℂ) : Prop where
  sq : ∀ c, ζ c ^ 2 * latticeCocycle leech (shortVec c) (shortVec c) = 1
  pm_injective : ∀ c d : ShortIdx, (shortVec d = shortVec c ∨ shortVec d = -shortVec c) → d
   ↪  = c

   ↪  →
    (MonsterGriess.sgn (pair e.1.1 d.1.2) : ℂ) * ζ c = ζ d * ζ e * latticeCocycle leech
     ↪  (shortVec d) (-shortVec e)
```

(`VOA/Moonshine/MoonshineCNGriessUntwisted.lean`.)

From the mathematics to the Lean statement

A `structure … : Prop` is a conjunction with named fields. Every field is a statement about lattice vectors, AxiomMath's coordinates and the cocycle; no vertex algebra enters. The structure is used as a *hypothesis* in `untwistedDict_gmul` and `untwistedDict_form`, and then *discharged* for an explicit ζ (Theorem 48.43), so it is not an open input of any final statement. Its docstring's remark that `phi0Equiv` "is not ported" is stale.

Physical meaning

These conditions say that, after normalising the vertex operators by ζ, the OPE coefficients $\varepsilon(\alpha, \beta)$ of the lattice CFT become AxiomMath's signs $(-1)^{\langle a_e, \delta_d \rangle}$. Two normalisations of vertex operators related by a coboundary give isomorphic OPEs; this is that statement made explicit.

What the machine verified

Definition; audited in `MoonshineCNGriessAudit.lean`.

Theorem 48.39 (The untwisted dictionary is an isometric algebra map). *If ζ is a sign dictionary, then for all $u, v \in \mathcal{B}$ with zero W-part, $\Phi_\zeta(u \cdot v) = \Phi_\zeta(u)_{(1)}\Phi_\zeta(v)$ and $\langle \Phi_\zeta u, \Phi_\zeta v\rangle = 2\,b(u,v)$.*

```

```

(`VOA/Moonshine/MoonshineCNGriessUntwisted.lean`; the same statements in $V^\natural$ are `untwistedDictNat_gmul`, `untwistedDictNat_form`.)

From the mathematics to the Lean statement

`ζ` is a section variable `{ζ : ShortIdx → ℂ}`. The hypotheses: the sign dictionary and the vanishing of the W-components. The products are in V_Λ^+, which is a subalgebra of $V^\natural$ (`vnat_smul_untwisted`), and the form `plusForm` is the restriction of `natForm` (`natForm_untwisted`).

Proof on paper. Bilinearity reduces to the channels Sym · Sym, Sym · X, $X \cdot X$ and to the forms. The first two and the S-forms are Theorem 48.36 (a), (b), (d) transported by π. For $X \cdot X$, take basis vectors e_d, e_e. In V_Λ^+, $x_{\alpha(1)}x_\beta$ (both minimal) is: a multiple of $\alpha(-1)^2\mathbb{1}$ if $\beta = \pm\alpha$ (the $\alpha(-2)\mathbb{1}$ terms of $e^\alpha_{(1)}e^{-\alpha}$ and $e^{-\alpha}_{(1)}e^{\alpha}$ cancel); a cocycle multiple of $x_{\alpha+\beta}$ if $\langle\alpha,\beta\rangle = -2$; of $x_{\alpha-\beta}$ if $\langle\alpha,\beta\rangle = 2$; and 0 otherwise (the vertex operator $e^\alpha_{(1)}e^\beta$ has leading power $z^{\langle\alpha,\beta\rangle}$). On AxiomMath's side $e_d \cdot e_e$ has S-part $\frac{1}{8}\delta_{de}U_d$ and X-part $\tau(d,e,\cdot)$, nonzero only at $c = d + e$. The fields `pm_injective`, `sum_shape`, `sum_exists` match the supports, and `sq`, `sign_neg_two`, `sign_two` match the coefficients. □

Physical meaning

The OPE of untwisted spin-two fields of the orbifold equals AxiomMath's formulas for Sym$\oplus X$ once the vertex operators are normalised by ζ.

What the machine verified

Conditional on `ShortSignDictionary ζ` (discharged below); audited in `MoonshineCNGriessAudit.lean`.

Theorem 48.40 (Three fields from φ_0). *Additivity and injectivity of φ_0 imply* `pm_injective`, `sum_shape`, `sum_exists`; *so a sign dictionary is the same as a phase function satisfying* `sq`, `sign_neg_two`, `sign_two`. *The lattice input: if three minimal vectors satisfy $\gamma \equiv \alpha + \beta$ modulo 2Λ, then $\alpha \cdot \beta = \mp 16$ (i.e. $\langle\alpha,\beta\rangle = \mp 2$) and $\gamma = \pm(\alpha \pm \beta)$ correspondingly.*

```
theorem minVecs_class_add_cases {a b c : Fin 24 → ℤ} (ha : a ∈ minVecs) (hb : b ∈ minVecs)
    (hc : c ∈ minVecs) (h : classOf c = classOf a + classOf b) :
    (a ⬝ᵥ b = -16 ∧ (c = a + b ∨ c = -(a + b))) ∨ (a ⬝ᵥ b = 16 ∧ (c = b - a ∨ c = -(b -
     ↪ a))) := by
```

```
theorem ShortSignDictionary.of_phi0 {ζ : ShortIdx → ℂ}
    (hadd : ∀ p q, phi0 (p + q) = phi0 p + phi0 q) (hinj : Function.Injective phi0)
```

(`VOA/Moonshine/MoonshineCNGriessShortClasses.lean`; the remaining hypotheses of `of_phi0` are the three phase conditions, verbatim as in the structure.)

Proof on paper. If $\gamma \equiv \alpha + \beta$, the four vectors $\gamma \pm \alpha \pm \beta$ lie in 2Λ (since $2\alpha, 2\beta \in 2\Lambda$), whose nonzero vectors have $u \cdot u \geq 4 \cdot 32$. The parallelogram law $\sum_{\pm} \|\gamma \pm \alpha \pm \beta\|^2 = 4(\|\gamma\|^2 + \|\alpha\|^2 + \|\beta\|^2) = 384$ leaves room for at most three nonzero terms of size ≥ 128, so one vanishes: $\gamma = \pm(\alpha \pm \beta)$, and $\|\gamma\|^2 = 32$ forces $\alpha \cdot \beta = \mp 16$. □

Physical meaning

Two charged spin-two fields can fuse into a third charged spin-two field only if their momenta have inner product ∓ 2 (then $e^{i\alpha X} e^{i\beta X} \sim (z-w)^{-2} e^{i(\alpha+\beta)X}$, a $(z-w)^{-2}$ term, i.e. a Griess product); this lemma says the $\mathbb{Z}/2$ charge arithmetic of $\Lambda/2\Lambda$ sees exactly these fusions.

What the machine verified

No hypotheses beyond those displayed; both audited in `MoonshineCNGriessAudit.lean`.

48.12.3 The sign refinement and the unconditional untwisted dictionary

Theorem 48.41 (Sign refinements exist). *Let V be a finite-dimensional $\mathbb{F}_2$-vector space and B a symmetric bilinear form on V. There is $Z : V \to \mathbb{C}$ with $Z(0) = 1$ and $Z(x+y) = Z(x)Z(y)(-1)^{B(x,y)}$.*

```
theorem exists_sign_refinement {V : Type*} [AddCommGroup V] [Module (ZMod 2) V]
    [Module.Finite (ZMod 2) V] (B : V →ₗ[ZMod 2] V →ₗ[ZMod 2] ZMod 2)
    (hB : ∀ x y, B x y = B y x) :
    ∃ Z : V → ℂ, Z 0 = 1 ∧ ∀ x y, Z (x + y) = Z x * Z y * Extraspecial.sgn (B x y) := by
```

(`VOA/Moonshine/MoonshineCNGriessSign.lean`.)

From the mathematics to the Lean statement

`Extraspecial.sgn t` $= (-1)^t \in \mathbb{C}$ (Chapter 34). `[Module.Finite (ZMod 2) V]`: finite dimension. No other hypothesis.

Proof on paper. Choose a basis $b_1, \ldots, b_n$ and put $Z(x) = \prod_i (i^{B(b_i,b_i)})^{x_i} \cdot (-1)^{\sum_{i<j} x_i x_j B(b_i,b_j)}$, with $\sqrt{-1}$ written i in the base and $x_i \in \{0,1\}$ the coordinates. The cross terms of $Z(x+y)$ against $Z(x)Z(y)$ produce $(-1)^{\sum_{i \neq j} x_i y_j B(b_i,b_j)}$ from the second factor and $(-1)^{\sum_i x_i y_i B(b_i,b_i)}$ from the first ($i^2 = -1$ when both $x_i = y_i = 1$), together $(-1)^{B(x,y)}$ by symmetry. □

Physical meaning

A "quadratic refinement" of a $\mathbb{Z}/2$-valued form: the standard device for fixing phases of vertex operators (or of fermion zero-mode representations) consistently with given commutation signs.

What the machine verified

No hypotheses beyond those displayed; audited in `MoonshineCNGriessAudit2.lean`.

Definition 48.42 (The sign map ζ). On $V = \mathcal{C} \times \mathcal{C}^*$ let $E(p,q)$ be the exponent of our lattice cocycle, $\varepsilon(\alpha,\beta) = (-1)^{E(p,q)}$ for α, β in the classes $\varphi_0(p), \varphi_0(q)$, and $\tau(p,q) = \langle q_a, p_\delta \rangle$. Both have commutator $\langle \alpha, \beta \rangle$ mod 2 (for E by the commutator property of ε; for τ by Theorem 48.11), so $B = E + \tau$ is symmetric. Let Z be a sign refinement of B and $\zeta_c = Z(c)$.

```
noncomputable def cocycleExp (p q : MonsterGriess.Code.C × Cocode) : ZMod 2 :=
  latRedLin p ·ᵥ (cocMat leech *ᵥ latRedLin q)
```

```
noncomputable def signForm :
    (MonsterGriess.Code.C × Cocode) →ₗ[ZMod 2] (MonsterGriess.Code.C × Cocode) →ₗ[ZMod 2]
      ↪ ZMod 2 :=
  LinearMap.mk₂ (ZMod 2) (fun p q => cocycleExp p q + pair q.1 p.2)
```

```
noncomputable def signRefinement : MonsterGriess.Code.C × Cocode → ℂ :=
  (exists_sign_refinement signForm signForm_symm).choose
```

```
noncomputable def griessShortSign (c : ShortIdx) : ℂ := signRefinement c.1
```

(VOA/Moonshine/MoonshineCNGriessSign.lean.)

From the mathematics to the Lean statement

`latRedLin p` is the reduction modulo 2, in our lattice basis, of any lattice vector in the class $\varphi_0(p)$ (through `leechEquiv`); `cocMat leech` is the matrix of the cocycle (Chapter 34: $\varepsilon(\alpha,\beta) = (-1)^{\bar\alpha^{\mathsf T}\mathrm{cocMat}\,\bar\beta}$). `signForm_symm` proves symmetry. `signRefinement` is chosen by `Classical.choose`: any refinement would do, and different choices differ by a character $(-1)^{\ell(x)}$; nothing downstream depends on which one is chosen except the identification of bases, and all final statements are invariant.

Physical meaning

ζ is the normalisation of the 98280 vertex operators $\cos(\alpha X)$ that turns the lattice CFT's OPE signs into AxiomMath's. That it takes values in $\{\pm1,\pm i\}$ rather than $\{\pm1\}$ reflects that $\varepsilon(\alpha,\alpha)$ can be -1 in the chosen cocycle gauge.

What the machine verified

Definitions; audited in `MoonshineCNGriessAudit2.lean`.

Theorem 48.43 (The untwisted dictionary, unconditionally). `griessShortSign` *is a sign dictionary; hence for all u,v with zero W-part the dictionary Φ_ζ (into $V^\natural$) is multiplicative and $\langle\Phi_\zeta u,\Phi_\zeta v\rangle = 2b(u,v)$, and its $\mathbb{C}$-linear extension is an isomorphism $\mathbb{C}\otimes_{\mathbb{Q}}(\mathrm{Sym}\oplus X)\cong(V_\Lambda^+)_2$.*

```
theorem shortSignDictionary_griessShortSign : ShortSignDictionary griessShortSign :=
```

```
theorem untwistedGriessNat_gmul {u v : SpaceB} (hu : u.2.2 = 0) (hv : v.2.2 = 0) :
    untwistedDictNat griessShortSign (gmul u v)
      = VnatVOA.griessMul (untwistedDictNat griessShortSign u)
          (untwistedDictNat griessShortSign v) :=
```

```
theorem untwistedGriessNat_form {u v : SpaceB} (hu : u.2.2 = 0) (hv : v.2.2 = 0) :
    SimpleNat.natForm (untwistedDictNat griessShortSign u : Vnat)
        (untwistedDictNat griessShortSign v : Vnat) = 2 * (bform u v : ℂ) :=
```

(VOA/Moonshine/MoonshineCNGriessSign.lean) and

```
noncomputable def untwistedIsoC : ℂ ⊗[ℚ] untwistedSub ≃ₗ[ℂ] leechVOAPlus.grading 2 :=
  (Algebra.TensorProduct.basis ℂ untwistedBasisQ).equiv untwistedBasisC (Equiv.refl _)
```

```
theorem untwistedIsoC_tmul (u : untwistedSub) :
    (untwistedIsoC (1 ⊗ₜ u) : VPlus) = untwistedDict griessShortSign (u : SpaceB) := by
```

(VOA/Moonshine/MoonshineCNGriessUntwistedBasis.lean.)

From the mathematics to the Lean statement

`untwistedDictNat ζ u` is $(\Phi_\zeta u, 0) \in V^\natural{}_2$. `untwistedSub` $= \{u : u.2.2 = 0\}$. `ℂ ⊗[ℚ] M` is the extension of scalars; `1 ⊗ₜ u` the image of u. `untwistedIsoC` is built by sending the basis $1 \otimes b_k$ of the tensor product to the basis $\Phi(b_k)$ of $(V_\Lambda^+)_2$, and `untwistedIsoC_tmul` says it extends Φ.

Proof on paper. `of_phi0` reduces to `sq`, `sign_neg_two`, `sign_two`. From $Z(c) = Z(d)Z(e)(-1)^{E(d,e)+\tau(d,e)}$ for $c = d + e$ and $Z(d), Z(e) \in \{\pm 1, \pm i\}$: $(-1)^\tau Z(c) = Z(d)Z(e)\varepsilon(\alpha_d, \alpha_e)$, which is `sign_neg_two` (and `sign_two` after $\varepsilon(\alpha, -\beta) = \varepsilon(\alpha, \beta)$). From $1 = Z(0) = Z(c + c) = Z(c)^2(-1)^{E(c,c)+\langle a_c, \delta_c\rangle}$ and $\langle a_c, \delta_c\rangle = 0$ for short c: $Z(c)^2 = \varepsilon(\alpha_c, \alpha_c)$, so $\zeta_c^2\varepsilon(\alpha_c, \alpha_c) = \varepsilon^2 = 1$. For the isomorphism: injectivity because b is positive definite and Φ is an isometry up to 2 (a vanishing $\mathbb{C}$-combination of images, paired with images of a dual basis, has zero coefficients); surjectivity because $(V_\Lambda^+)_2$ is spanned by the frame bilinears, each a Q_C of a matrix (F invertible), and the x_α, each $\zeta_c^{-1}\Phi(e_c)$ for the short class c of $\pm\alpha$ (bijectivity of φ_0). □

Physical meaning

The untwisted sector of the Monster CFT at weight two *is* AxiomMath's Sym $\oplus X$, with its OPE.

What the machine verified

No hypotheses. All audited in `MoonshineCNGriessAudit2.lean` (262 `#print axioms` lines in the file).

48.13 The twisted half: the spin module is T

48.13.1 AxiomMath's spin module realises the extraspecial module T

Recall (Chapter 34) that $T =$ `TLeechT` is the unique simple module of the twisted group algebra $A_\Lambda = \langle e_\alpha : e_\alpha e_\beta = \varepsilon(\alpha, \beta)e_{\alpha+\beta}\rangle$ (`alg (cocMat leech)`), of dimension $2^{12} = 4096$, defined abstractly through Wedderburn–Artin, and that the twisted weight-two space is $(T^+)_2 = \mathfrak{h}(-\frac{1}{2}) \otimes T$ (Chapter 36).

Definition 48.44 (Phased spin matrices). spinOp$(p) = Z(p)\,R(0, p_a, p_\delta)$ for $p \in \mathcal{C} \times \mathcal{C}^*$, a complex $I \times I$ matrix.

```
noncomputable def spinOp (p : MonsterGriess.Code.C × Cocode) : Matrix SpinIdx SpinIdx ℂ :=
  signRefinement p • qmatR ℂ 0 p.1 p.2
```

(`VOA/Moonshine/MoonshineCNGriessSpinModule.lean`.)

From the mathematics to the Lean statement

`signRefinement p` is $Z(p)$ of Definition 48.42; $\bullet$ is scalar multiplication of a complex matrix. The phase converts AxiomMath's sign convention (τ) into our cocycle's (E), as Theorem 48.45(a) shows.

Physical meaning

The gamma matrices of the twisted sector, normalised so that they obey the same OPE signs as the lattice vertex operators of our construction of $V^\natural$.

What the machine verified

Definition; audited in `MoonshineCNGriessAudit2.lean`.

Theorem 48.45 ($\mathbb{C}^I$ is T). *(a)* $\mathrm{spinOp}(p)\mathrm{spinOp}(q) = (-1)^{E(p,q)}\mathrm{spinOp}(p+q)$. *(b) Hence* $e_\alpha \mapsto \mathrm{spinOp}(\bar{\alpha})$ *makes* $\mathbb{C}^I$ *an* A_Λ*-module; it is simple, and there is an* A_Λ*-linear isomorphism* $\Psi : \mathbb{C}^I \to T$ *with* $\Psi(\mathrm{spinOp}(\bar{\alpha})v) = e_\alpha \Psi(v)$.

```
theorem spinOp_mul (p q : MonsterGriess.Code.C × Cocode) :
    spinOp p * spinOp q = Extraspecial.sgn (cocycleExp p q) • spinOp (p + q) := by
```

```
noncomputable def spinIso : SpinRep ≃ₗ[alg (cocMat leech)] TLeechT :=
  Classical.choice (Extraspecial.nonempty_linearEquiv_rep (cocMat leech)
    (isUnit_det_cocMat leech leech_even leech_isUnit_det_gramMat) SpinRep)
```

```
theorem spinIso_spinOp (α : leech.carrier) (v : SpinRep) :
    spinIso ((spinOp (coordOfRed (red leech α))).mulVec v : SpinIdx → ℂ)
      = eT leech leech_even leech_isUnit_det_gramMat α (spinIso v) := by
```

(`VOA/Moonshine/MoonshineCNGriessSpinModule.lean`.)

From the mathematics to the Lean statement

`SpinRep` is a type synonym of $\mathbb{C}^I$ carrying the A_Λ-module structure $e_x \mapsto \mathrm{spinOp}(\mathrm{coordOfRed}\, x)$, where `coordOfRed` is the inverse of the isomorphism `latRedEquiv` between AxiomMath's coordinates and our $(\mathbb{Z}/2)^{24}$ (reduction mod 2 in our lattice basis). `red leech α` is $\bar{\alpha}$. `eT … α` is the action of e_α on T (Chapter 34). `nonempty_linearEquiv_rep` (Chapter 34) is uniqueness of the simple module; `spinIso` is *a* choice of isomorphism, unique up to a nonzero scalar by Schur. The scalar is fixed later by the form (`spinDictScale`).

Proof on paper. (a) By the product law $R(0,p)R(0,q) = (-1)^{\langle q_a, p_\delta\rangle}R(0,p+q)$ and $Z(p)Z(q) = Z(p+q)(-1)^{E(p,q)+\tau(p,q)}$ (signs are self-inverse). (b) The algebra map $A_\Lambda \to \mathrm{End}(\mathbb{C}^I)$ is injective because A_Λ is simple, and surjective by dimension ($2^{24} = 4096^2$); so $\mathbb{C}^I$ is a simple A_Λ-module, isomorphic to T. □

Physical meaning

The 4096 twisted ground states of the Leech orbifold carry the unique irreducible representation of the "Clifford algebra" of lattice exponentials; AxiomMath's explicit signed permutation matrices are one concrete basis for it. Schur's lemma says the identification is unique up to an overall normalisation of the twist fields.

What the machine verified

No hypotheses; audited in `MoonshineCNGriessAudit2.lean`.

Theorem 48.46 (The invariant form of T in the spin model). *There is* $\kappa \neq 0$ *with* $B_T(\Psi v, \Psi w) = \kappa\,(v \cdot w)$.

```
theorem TForm_spinIso (v w : SpinIdx → ℂ) :
    TForm (spinIso v) (spinIso w) = spinFormScale * (v ·ᵥ w) := by
```

```
theorem spinFormScale_ne_zero : spinFormScale ≠ 0 := by
```

(`VOA/Moonshine/MoonshineCNGriessSpinForm.lean`.)

Proof on paper. B_T satisfies $B_T(e_\alpha t, t') = (-1)^{\langle\alpha,\alpha\rangle/2} B_T(t, e_\alpha t')$ (Chapter 34); the dot product satisfies the same law for the spin matrices, because $\mathrm{spinOp}(\bar\alpha)^{\mathsf T} = (-1)^{\langle\alpha,\alpha\rangle/2}\mathrm{spinOp}(\bar\alpha)$ (from `qmatR_transpose` and $q(\bar\alpha) = \langle a, \delta\rangle$). So the Gram matrix of $(v, w) \mapsto B_T(\Psi v, \Psi w)$ commutes with every spin matrix, hence with all matrices, hence is scalar; it is nonzero because B_T is nondegenerate. □

Physical meaning

The two-point function of twist ground states is, in AxiomMath's basis, a multiple of the identity: the basis is orthogonal for the CFT inner product.

What the machine verified

No hypotheses; audited in `MoonshineCNGriessAudit3.lean`.

Recall: the frame involution and the frame sectors. FLM's triality (Chapters 39–41) uses the lattice vector $w = 8e_0 \in \Lambda$ (norm 8). On T the operator $J = c^{-1}e_w$, with c a fixed scalar (`sqrtEps leech frameW`) chosen so that $J^2 = 1$, is an involution; its eigenspaces T_0, T_1 give the *frame sectors* $T_s^+ = (S[\theta] \otimes T_s)^+$ of $(V_\Lambda^T)^+$ (`TPframe s`). The triality σ pairs the odd-frame part V_3^+ of V_Λ^+ with one of them. To compare with AxiomMath's triality τ_B in Chapter 49, one needs to know where AxiomMath's two halves $\eta = 0, 1$ of the spin index go.

Theorem 48.47 (Frame halves). *The frame involution $J = c^{-1}e_w$ ($w = 8e_0$) of T that defines the frame sectors T_0^+, T_1^+ of $V^\natural$ (Chapters 39–41) acts in the spin model as $\kappa_J D$, with $D = \mathrm{diag}((-1)^\eta)$ and $\kappa_J^2 = 1$; so Ψ maps the half $\mathcal{C}_0 \times \{t\}$ of $\mathbb{C}^I$ into the $\kappa_J(-1)^t$-eigenspace of J.*

```
theorem spinIso_frameJ (v : SpinRep) :
    frameJL (spinIso v) = frameSign • spinIso (frameDiag *ᵥ (v : SpinIdx → ℂ) : SpinIdx →
    ↪ ℂ) := by
```

```
theorem spinIso_frameJ_of_support {t : ZMod 2} {v : SpinRep}
    (hv : ∀ i : SpinIdx, i.1 ≠ t → (v : SpinIdx → ℂ) i = 0) :
    frameJL (spinIso v) = (frameSign * sgnR ℂ t) • spinIso v := by
```

(`VOA/Moonshine/MoonshineCNGriessFrameBlock.lean`.)

From the mathematics to the Lean statement

`frameJL` is J as a linear map; `frameDiag` $= D$; `frameSign` $= \kappa_J = c^{-1}Z(\Omega, \theta_D\Omega)$ with $c =$ `sqrtEps leech frameW`. Key facts: the class of $w = 8e_0$ has AxiomMath coordinates $(\Omega, \theta_D(\Omega))$ (`coordOfRed_red_frameW`), and $R(0, \Omega, \theta_D\Omega) = D$ because $\theta(\Omega, \cdot) = 0$ on $\mathcal{C}$ (`θ_ΩC_eq_zero`, a kernel computation on the 12 basis words).

Physical meaning

The two frame sectors of the twisted sector, which FLM's triality exchanges with the untwisted sectors, are exactly the two halves $\eta = 0, 1$ of AxiomMath's spin index; this is why AxiomMath's triality τ_B (which permutes those halves) can be compared with FLM's σ (Chapter 49).

What the machine verified

No hypotheses; audited in `MoonshineCNGriessAudit2.lean`.

48.13.2 The twisted weight-two space in spin coordinates

Definition 48.48 (Spin coordinates on $(T^+)_2$). For a complex $I \times 24$ matrix N, spinTopVec$(N) = \sum_i h_{f_i}(-\frac{1}{2}) \otimes \Psi(N_{\cdot i})$, where f_i is the frame vector of the axis $8e_i$ and $N_{\cdot i}$ the i-th column.

```
noncomputable def spinTopVec : Matrix SpinIdx (Fin 24) ℂ →ₗ[ℂ] TP where
  toFun N := ∑ i, spinTopState (conwayVec i) (fun s => N s i)
```

(VOA/Moonshine/MoonshineCNGriessTwistedTop.lean.)

From the mathematics to the Lean statement

`spinTopState v w` $= h_P$ `v (spinIso w)`, where `hP v t` $= h_v(-\frac{1}{2})\mathbb{1} \otimes t \in$ `TP` (Chapter 41); `conwayVec i` is the frame coordinate vector of $8e_i$; `spinIsoC` is `spinIso` as a $\mathbb{C}$-linear map.

Physical meaning

The state $\sum_i \partial X^{f_i} \sigma_{N_{\cdot i}}$: a first excited twisted state, with oscillator index i and ground-state wave function given by the i-th column of N.

What the machine verified

Definitions; audited in `MoonshineCNGriessAudit3.lean`.

Theorem 48.49 (Module channels and form on $(T^+)_2$). *For symmetric A and minimal α with integer coordinates y and $\Sigma_\alpha = \mathrm{spinOp}(\bar{\alpha})$: (a) $Q_C(A)_{(1)}\mathrm{spinTopVec}(N) = \mathrm{spinTopVec}(NA + \frac{\mathrm{tr}A}{8}N)$; (b) $(x_\alpha)_{(1)}\mathrm{spinTopVec}(N) = \frac{1}{8}\mathrm{spinTopVec}(\Sigma_\alpha N - \frac{1}{4}\Sigma_\alpha N y y^{\mathsf{T}})$; (c) $\langle \mathrm{spinTopVec}N, \mathrm{spinTopVec}M\rangle = -4\kappa \sum_{s,i} N_{si}M_{si}$.*

```

      = (8 : ℂ)⁻¹ • spinTopVec (spinOp (coordOfRed (red leech α)) * N
          - (4 : ℂ)⁻¹ • (spinOp (coordOfRed (red leech α)) * N
              * vecMulVec (fun i => (LeechMatch.vec α i : ℂ)) (fun i => (LeechMatch.vec α i
                ↪ : ℂ)))) := by
```

```
theorem TPForm_spinTopVec (N M : Matrix SpinIdx (Fin 24) ℂ) :
    TPForm (spinTopVec N) (spinTopVec M)
      = -4 * spinFormScale * ∑ s, ∑ i, N s i * M s i := by
```

(VOA/Moonshine/MoonshineCNGriessTwistedTop.lean.)

From the mathematics to the Lean statement

`topAct u` $=$ `mode (plusModule.YM u) 1`, the mode $u_{(1)}$ of $u \in V_\Lambda^+$ acting on $(V_\Lambda^T)^+$; in $V^\natural$, $(u,0)_{(1)}(0,t) = (0, u_{(1)}t)$ (`vnat_smul_untwisted_twisted`). Compare AxiomMath's table: (a) is $A \cdot N = \frac{\mathrm{tr}A}{8}N + NA$, (b) is $x \cdot N$ with R_c replaced by Σ_α, and (c) is b on W up to -4κ.

Proof on paper. (a) The twisted vertex operator of $\mathrm{ax}_i(-1)\mathrm{ax}_j(-1)\mathbb{1}$ acts on $h(-\frac{1}{2})\otimes t$ by contracting one oscillator (the twisted Heisenberg commutator) and by the normal-ordering constant $\frac{1}{16}$ per boson, which produces the $\frac{\operatorname{tr}A}{8}$ term. (b) The twisted vertex operator of x_α acts on the ground states through e_α (Ψ intertwines it with Σ_α) and on the oscillator through the reflection-type term $-\frac{1}{4}yy^{\mathsf{T}}$ coming from the $\alpha(-\frac{1}{2})$ part of the twisted exponential. (c) Twisted Fock form times Theorem 48.46, with $F^{\mathsf{T}}F=8$. □

Physical meaning

These are the OPEs of untwisted spin-two fields with twisted spin-two fields: bilinears act on the oscillator index (and shift the weight by the twisted-sector vacuum energy $\frac{24}{16}=\frac{3}{2}$, the source of $\operatorname{tr}A/8$), exponentials act on the twist ground states by the gamma matrices.

What the machine verified

No hypotheses beyond those displayed; audited in `MoonshineCNGriessAudit3.lean`.

Trap: the phases of the full dictionary are $\zeta'=Z^{-1}$, not $\zeta=Z$

In the $X\cdot W$ channel, x_{α_c} acts on T through $e_{\alpha_c}=\mathrm{spinOp}(c)=Z(c)R_c$, so e_c must be sent to $\zeta'_c x_{\alpha_c}$ with $\zeta'_c Z(c)=1$, i.e. $\zeta'=Z^{-1}$. This differs from the phase $\zeta=Z$ of Theorem 48.43 by the sign $Z(c)^2=\varepsilon(\alpha_c,\alpha_c)$ (`fullShortSign_eq`), and that sign is not always $+1$ for the cocycle of this library. Reason: the library's cocycle (Chapter 34) is $\varepsilon(\alpha,\beta)=(-1)^{\alpha^{\mathsf{T}}C\bar\beta}$ with C the strictly upper triangular part of the Gram matrix G in a lattice basis, so with coordinates a_i of α, $\varepsilon(\alpha,\alpha)=(-1)^{\sum_{i<j}a_ia_jG_{ij}}$, and $\sum_{i<j}a_ia_jG_{ij}=\frac{1}{2}\big(\langle\alpha,\alpha\rangle-\sum_i G_{ii}a_i^2\big)$; for $\langle\alpha,\alpha\rangle=4$ this gives $\varepsilon(\alpha,\alpha)=+1$ iff $4\mid\sum_i G_{ii}a_i^2$ (`griessTrCocycle_eq_one_iff`). The familiar FLM normalisation $\varepsilon(\alpha,\alpha)=(-1)^{\langle\alpha,\alpha\rangle/2}$, which would give $+1$ on norm-4 vectors, is a different choice of cocycle in the same cohomology class; this library's cocycle satisfies only the commutator relation $\varepsilon(\alpha,\beta)\varepsilon(\beta,\alpha)=(-1)^{\langle\alpha,\beta\rangle}$. Whether $\varepsilon(\alpha_c,\alpha_c)=1$ for all c in the chosen basis is not decided, and nothing depends on it. Using ζ instead of ζ' in the full dictionary would make the $X\cdot W$ channel produce $Z(c)^2R_c$, which is wrong where $\varepsilon(\alpha_c,\alpha_c)=-1$; formulas stated with ζ are converted in §48.16.

Definition 48.50 (Full phases and the W-dictionary). $\zeta'_c=\zeta_c^{-1}$. $N^\pi=(N_{s,\pi i})_{s,i}$ (columns moved to our coordinates, read in $\mathbb{C}$); λ a fixed square root of $-1/(2\varkappa)$; $\mathrm{spinDict}(N)=\lambda\,\mathrm{spinTopVec}(N^\pi)$.

```
noncomputable def fullShortSign (c : ShortIdx) : ℂ := (griessShortSign c)⁻¹
```

```
theorem fullShortSign_eq (c : ShortIdx) :
    fullShortSign c = griessShortSign c * latticeCocycle leech (shortVec c) (shortVec c) :=
     ↪ by
```

```
theorem fullShortSign_smul_spinOp (c : ShortIdx) :
    fullShortSign c • spinOp (coordOfRed (red leech (shortVec c))) = (Rmat c).map
     ↪ (Rat.castHom ℂ) := by
```

```
noncomputable def spinDictScale : ℂ := (-(2 * spinFormScale)⁻¹) ^ (((2 : ℕ) : ℂ)⁻¹)
```

```
noncomputable def spinDict : SpaceW →+ TP where
  toFun N := spinDictScale • spinTopVec (spinToConway N)
```

(`VOA/Moonshine/MoonshineCNGriessSpinDict.lean`.)

From the mathematics to the Lean statement

`(Rmat c).map (Rat.castHom ℂ)` is R_c read over $\mathbb{C}$. `spinToConway N` $= N^{\pi}$. `spinDictScale` is the principal square root (complex power 1/2); `spinDictScale_sq` records $\lambda^2 = -1/(2\kappa)$. `shortSignDictionary_fullShortSign`: ζ' is again a sign dictionary, so Theorem 48.39 applies to it.

Physical meaning

The first excited twisted states $\partial X^i \sigma_s$, normalised (by λ) so that their two-point function is AxiomMath's $2b$, with the bosons relabelled by π.

What the machine verified

Definitions; audited in `MoonshineCNGriessAudit3.lean`.

Theorem 48.51 (The W-block: form, module channels, and AxiomMath's invariance). *(a)* $\langle \text{spinDict}N, \text{spinDict}M\rangle = 2\sum N_{ji}M_{ji}$. *(b)* $\text{matDict}(A)_{(1)}\text{spinDict}(N) = \text{spinDict}(\frac{\operatorname{tr}A}{8}N{+}NA)$ *and* $\text{shortDict}_{\zeta'}(x)_{(1)}\text{spinDict}(N) = \text{spinDict}(\frac{1}{8}\sum_c x_c(R_cN - \frac{1}{4}R_cNU_c))$. *(c) On AxiomMath's side, for u with zero W-part, $b(N\cdot M, u) = b(M, u\cdot N)$.*

```

theorem bform_gmul_spinBlock_spinBlock (N M : SpaceW) {u : SpaceB} (hu : u.2.2 = 0) :
    bform (gmul (spinBlock N) (spinBlock M)) u
      = bform (spinBlock M) (spinBlock (spinBlockAction u N)) := by
```

(`VOA/Moonshine/MoonshineCNGriessSpinDict.lean`.)

From the mathematics to the Lean statement

`spinBlockAction u N` is the W-part of $u\cdot(0,0,N)$, i.e. $\frac{\operatorname{tr}A}{8}N + NA + \frac{1}{8}\sum_c x_c(R_cN - \frac{1}{4}R_cNU_c)$. (c) is proved directly from the formulas of Definition 48.18 (using $R_c^{\mathsf{T}} = R_c$ for short c, `Rmat_transpose_of_short`, and $q_c(M) = \operatorname{tr}(MU_c)$); it is a special case of the associativity of b but is proved independently, since the port does not contain `bform_gmul_assoc`.

Physical meaning

(a) fixes the normalisation of the twisted fields so that their two-point function matches AxiomMath's; (b) is the untwisted×twisted OPE in AxiomMath's coordinates; (c) is the cyclic symmetry of the three-point function $\langle\sigma\sigma\phi\rangle$ of two twist fields and one untwisted field.

What the machine verified

No hypotheses beyond those displayed; all audited in `MoonshineCNGriessAudit3.lean`.

48.14 The Griess isomorphism $\mathbb{C} \otimes \mathcal{B} \cong V_2^\natural$

48.14.1 The rational dictionary on all of $\mathcal{B}$

Definition 48.52 (The Griess dictionary). $\mathrm{griessNat}(A, x, N) = \big(Q_C(A^\pi) + \sum_c x_c \zeta'_c x_{\alpha_c},\ \lambda \sum_i h_{f_i}(-\tfrac{1}{2}) \otimes \Psi(N_{.\pi i})\big) \in V^\natural{}_2$.

```
noncomputable def griessNat : SpaceB →+ VnatVOA.grading 2 where
  toFun u := ⟨(untwistedDict fullShortSign u, spinDict u.2.2), griessNat_mem u⟩
```

```
theorem griessNat_coe (u : SpaceB) :
    (griessNat u : Vnat) = (untwistedDict fullShortSign u, spinDict u.2.2) := rfl
```

(`VOA/Moonshine/MoonshineCNGriessIso.lean`, namespace `VOA.Moonshine.GriessDictionary`.)

From the mathematics to the Lean statement

An element of `VnatVOA.grading 2` is a pair $(v, t) \in V_\Lambda^+ \times (V_\Lambda^T)^+$ with a proof that it has weight 2 (`griessNat_mem`). The first component is the untwisted dictionary with ζ', the second the W-dictionary. `griessNat_smul`: $\mathbb{Q}$-homogeneous.

Physical meaning

Every element of AxiomMath's $\mathcal{B}$ is assigned a definite spin-two field of the Monster CFT, with rational coefficients in a fixed basis of vertex operators.

What the machine verified

Definition; audited in `MoonshineCNGriessAudit3.lean`.

Theorem 48.53 (The dictionary is multiplicative and isometric up to 2). *For all $u, v \in \mathcal{B}$:* $\mathrm{griessNat}(u \cdot v) = \mathrm{griessNat}(u) \times \mathrm{griessNat}(v)$ *and* $\langle \mathrm{griessNat}\, u, \mathrm{griessNat}\, v \rangle = 2\, b(u, v)$.

```
theorem griessNat_gmul (u v : SpaceB) :
    griessNat (gmul u v) = VnatVOA.griessMul (griessNat u) (griessNat v) := by
```

```
theorem griessNat_form (u v : SpaceB) :
    SimpleNat.natForm (griessNat u : Vnat) (griessNat v : Vnat) = 2 * (bform u v : ℂ) := by
```

(`VOA/Moonshine/MoonshineCNGriessIso.lean`.)

From the mathematics to the Lean statement

`VnatVOA.griessMul` is $u_{(1)}v$ on $V^\natural{}_2$ (§48.12); `natForm` the invariant form of $V^\natural$. No hypotheses: u, v range over all of $\mathcal{B}$.

Proof on paper. Write $u = u_0 + (0, 0, N)$, $v = v_0 + (0, 0, M)$ with u_0, v_0 untwisted. Expand both sides bilinearly.

- Untwisted×untwisted: Theorem 48.39 with ζ'.

- Untwisted×twisted (both orders): in $V^\natural$, $(a,0)_{(1)}(0,t) = (0, a_{(1)}t)$; the channels of Theorem 48.51(b) give exactly spinDict$(u_0 \cdot N)$; the other order follows from commutativity of $u_{(1)}v$ on ${V^\natural}_2$ (`vnat_smul_one_comm`, from ${V^\natural}_1 = 0$) and of $\cdot$ on the W-channels.
- Twisted×twisted: $t_{(1)}t'$ lies in V^+_Λ (`vnat_smul_twisted_twisted_snd`). It is determined by its pairings with $(V^+_\Lambda)_2$, which is spanned by the untwisted images (Theorem 48.43 with ζ'; `span_fullUntwistedImage`). For an untwisted w: by self-adjointness of the Griess product for `natForm` (`natForm_smul_one_adjoint`: $\langle x_{(1)}a, b\rangle = \langle a, x_{(1)}b\rangle$ for $x \in {V^\natural}_2$, from the FHL invariance law and $L_1{V^\natural}_2 \subset {V^\natural}_1 = 0$) and commutativity, $\langle \text{spinDict}N_{(1)}\text{spinDict}M, \Phi w\rangle = \langle \text{spinDict}M, (\Phi w)_{(1)}\text{spinDict}N\rangle = \langle \text{spinDict}M, \text{spinDict}(w{\cdot}N)\rangle = 2b(M, w{\cdot}N) = 2b(N{\cdot}M, w)$, the last step by Theorem 48.51(c); and $2b(N\cdot M, w) = \langle \Phi(N\cdot M), \Phi w\rangle$ since $N\cdot M$ is untwisted. Nondegeneracy of the form on $(V^+_\Lambda)_2$ gives spinDict$N_{(1)}$spinDict$M = \Phi(N\cdot M)$.

The form: `natForm` is the sum of the untwisted and twisted forms, and the two pieces are Theorem 48.39 and Theorem 48.51(a); mixed pairings vanish on both sides. □

Physical meaning

The twist×twist OPE is not computed directly (that would need the twisted-twisted vertex operators, i.e. the hardest part of the construction of $V^\natural$, Chapters 37–42); instead it is read off from the three-point function $\langle\sigma\sigma\phi\rangle$ by crossing symmetry, $\langle(\sigma\times\sigma'),\phi\rangle = \langle\sigma', \phi\times\sigma\rangle$, which is how a physicist would determine it.

What the machine verified

No hypotheses; audited in `MoonshineCNGriessAudit3.lean`.

48.14.2 The isomorphism

Theorem 48.54 (`griessIso`: the Griess algebra of $V^\natural$ is AxiomMath's, over $\mathbb{C}$). *There is a $\mathbb{C}$-linear isomorphism $\Theta : \mathbb{C} \otimes_{\mathbb{Q}} \mathcal{B} \to {V^\natural}_2$ with $\Theta(1\otimes u) = \text{griessNat}(u)$, such that Θ carries the $\mathbb{C}$-bilinear extension of the product of $\mathcal{B}$ to the Griess product of $V^\natural$ and the $\mathbb{C}$-bilinear extension of $2b$ to the invariant form of $V^\natural$.*

```
noncomputable def griessIso : ℂ ⊗[ℚ] SpaceB ≃ₗ[ℂ] VnatVOA.grading 2 :=
  (Algebra.TensorProduct.basis ℂ griessBasisQ).equiv griessBasisC (Equiv.refl _)
```

```
theorem griessIso_tmul (u : SpaceB) : griessIso (1 ⊗ₜ u) = griessNat u := by
```

```
theorem griessIso_mul (x y : ℂ ⊗[ℚ] SpaceB) :
    griessIso (LinearMap.BilinMap.baseChange ℂ gmul x y)
      = VnatVOA.griessMul (griessIso x) (griessIso y) := by
```

```
theorem griessIso_form (x y : ℂ ⊗[ℚ] SpaceB) :
    SimpleNat.natForm (griessIso x : Vnat) (griessIso y : Vnat)
      = 2 * LinearMap.BilinForm.baseChange ℂ bform x y := by
```

(`VOA/Moonshine/MoonshineCNGriessIso.lean`.)

From the mathematics to the Lean statement

Symbols. `ℂ ⊗[ℚ] SpaceB` is the tensor product of $\mathbb{Q}$-vector spaces with its $\mathbb{C}$-structure on the left factor (extension of scalars); `1 ⊗ₜ u` is $1 \otimes u$. `≃ₗ[ℂ]` is a $\mathbb{C}$-linear bijection. `VnatVOA.grading 2` is ${V^\natural}_2$, a $\mathbb{C}$-subspace of `Vnat`; its elements are coerced to `Vnat` by `(· : Vnat)`. `LinearMap.BilinMap.baseChange ℂ gmul` is the unique $\mathbb{C}$-bilinear map on $\mathbb{C}\otimes\mathcal{B}$ with

$(a \otimes u, b \otimes v) \mapsto ab \otimes (u \cdot v)$; `LinearMap.BilinForm.baseChange ℂ bform` likewise for b (a *bilinear*, not Hermitian, extension).

How `griessIso` is built. `griessBasisQ` is a $\mathbb{Q}$-basis of $\mathcal{B}$ (Mathlib's `Module.finBasis`); `griessBasisC` is the family of its `griessNat`-images, shown to be a $\mathbb{C}$-basis of $V^\natural{}_2$ (linear independence from Theorem 48.53 and positive definiteness of b, by pairing against a dual basis; spanning by the dimension count `finrank_spaceB : finrank ℚ SpaceB = finrank ℂ (VnatVOA.grading 2)`, both 196884). `Basis.equiv` sends basis to basis. So `griessIso` is *characterised* by `griessIso_tmul`: it is the $\mathbb{C}$-linear extension of `griessNat`. The choice of `griessBasisQ` does not matter.

Hypotheses. None. `griessIso_mul` and `griessIso_form` hold for all $x, y \in \mathbb{C} \otimes \mathcal{B}$, not only for pure tensors.

Same as the textbook statement? The classical statement is "$V^\natural{}_2$ with $u_{(1)}v$ and its invariant form is isomorphic to the complexified Griess algebra". The Lean statement is exactly that, with "the Griess algebra" being AxiomMath's rational model and with a specific normalisation: the form of $V^\natural$ is $2b$. The factor 2 is a normalisation of b against $\langle \mathbb{1}, \mathbb{1} \rangle = 1$: AxiomMath's identity element $e = (\frac{1}{4}I, 0, 0)$ goes to $\omega/2$, and $2b(e,e) = 2 \cdot \frac{24}{16} = 3 = \langle \omega/2, \omega/2 \rangle = \frac{1}{4} \cdot \frac{c}{2}$. It is harmless: automorphisms preserve b iff they preserve $2b$.

Could it be vacuous? The left side is a 196884-dimensional space with a genuine product (`gmul` is AxiomMath's definition, §48.5); the right side is the weight-two space of the constructed moonshine module `VnatVOA`, with `griessMul` defined from its vertex operators (not from the dictionary). A linear bijection intertwining two products is an algebra isomorphism; there is no trivial object on either side. Two ways it could have been weaker were avoided: the statement is for all of $\mathbb{C} \otimes \mathcal{B}$ (not only the untwisted part, which was the first milestone `untwistedIsoC`), and it involves the product of `VnatVOA` itself (not of a model of $V^\natural{}_2$ built for the purpose).

Which product on $V^\natural$? `VnatVOA` is the VOA of Chapter 42 (`VnatVOA_Y : VnatVOA.Y = YnatwbarL`); its twisted×twisted block is the form-adjoint of the skew intertwiner. Any other VOA structure on the same space would be a different object; the theorem is about this one.

Proof on paper. Bilinearity reduces `griessIso_mul` and `griessIso_form` to pure tensors $a \otimes u$, $b \otimes v$, where they are ab times Theorem 48.53. □

Physical meaning

"The 196884 spin-two fields of the Monster CFT, with their OPE, are Griess's algebra." This is the foundational observation of Frenkel–Lepowsky–Meurman that made the moonshine module a construction *of the Monster*: once the Griess algebra sits inside $V^\natural$, every symmetry of the Griess algebra is a candidate symmetry of the CFT, and every symmetry of the CFT acts on the Griess algebra.

What the machine verified

No hypotheses. Audited in `MoonshineCNGriessAudit3.lean` and again in `MoonshineCNMonsterFinalAudit.lean`; recorded `#print axioms: [propext, Classical.choice, Quot.sound]`.

48.14.3 Block statements

Theorem 48.55 (Blocks). *(a)* $\Theta(1 \otimes (0,0,N)) = (0, \mathrm{spinDict}N)$ *and* $\Theta(1 \otimes u) = (\Phi_{\zeta'} u, 0)$ *for untwisted* u. *(b) The* W*-images span* $(T^+)_2$. *(c) There is* $s_0 \in \mathbb{F}_2$ *such that* W*-vectors supported on the rows* $\mathcal{C}_0 \times \{t\}$ *go into the frame sector* $T^+_{s_0+t}$, *for* $t = 0, 1$.

```
theorem griessIso_tmul_spinBlock (N : SpaceW) :
    (griessIso (1 ⊗ₜ spinBlock N) : Vnat) = (0, spinDict N) := by
```

```
theorem griessIso_tmul_untwisted {u : SpaceB} (hu : u.2.2 = 0) :
    (griessIso (1 ⊗ₜ u) : Vnat) = (untwistedDict fullShortSign u, 0) := by
```

```
theorem span_range_spinDict :
    Submodule.span ℂ (Set.range spinDict) = plusModule.weight (2 : ℂ) := by
```

```
theorem spinDict_mem_TPframe_shift :
    ∃ s₀ : ZMod 2, ∀ (N : SpaceW) (t : ZMod 2), (∀ j i, j.1 ≠ t → N j i = 0) →
      spinDict N ∈ TPframe (s₀ + t) := by
```

(`VOA/Moonshine/MoonshineCNGriessIso.lean`.)

From the mathematics to the Lean statement

`plusModule.weight (2 : ℂ)` is $(T^+)_2$ (weight-two subspace of the V_Λ^+-module `TP`); `TPframe s` is the frame sector T_s^+ (Chapter 39). The existential s_0 is the exponent with $(-1)^{s_0} = \kappa_J$, the sign of Theorem 48.47 (`frameSign_eq_sgn`); it depends on the choices of the scalar c in J and of the refinement Z, and the library does not compute it. The content of (c) is therefore not a triviality: each half $\mathcal{C}_0 \times \{t\}$ of W lands in a *single* frame sector, and the two halves land in *different* sectors (s_0 and s_0+1), in one of the two possible orders. This is what Chapter 49 uses to compare AxiomMath's τ_B (which permutes the two halves) with FLM's σ (which moves the frame sectors). So: AxiomMath's x_B (-1 on W) corresponds to the sector sign z of $V^\natural$ ($+1$ on V_Λ^+, -1 on $(V_\Lambda^T)^+$), and the two halves of W permuted by τ_B are the two frame sectors.

Physical meaning

The orbifold structure of $V^\natural$ (untwisted/twisted, and the finer frame decomposition used by FLM's triality) is visible in AxiomMath's coordinates: AxiomMath's parity involution is the orbifold involution.

What the machine verified

No hypotheses; audited in `MoonshineCNGriessAudit3.lean`.

48.15 The Monster acts on the Griess algebra of $V^\natural$

Part C begins; its Lean names are in `VOA.Moonshine.MonsterAction`. The automorphism group of $V^\natural$ is `AutVnat := Aut VnatVOA`; `GriessAutVnat` is the group of $\mathbb{C}$-linear automorphisms of $V^\natural{}_2$ preserving `griessMul` and the intrinsic form $u_{(3)}v = \langle u, v\rangle_3 \mathbb{1}$; `vnatGriessRestrict : AutVnat →* GriessAutVnat` restricts an automorphism to $V^\natural{}_2$; and `vnatGriessRestrict_injective` (no hypotheses) says this restriction is injective. All four are documented in Chapter 47 (`VOA/Moonshine/AutVnat.lean`, `VOA/Moonshine/AutFaithfulAssembly.lean`, `VOA/Core/GriessAutomorphism.lean`).

48.15.1 The Griess conjugate

Definition 48.56 (Griess conjugate). For $g \in GL_{\mathbb{Q}}(\mathcal{B})$, $\mathrm{griessConj}(g) = \Theta \circ (1_{\mathbb{C}} \otimes g) \circ \Theta^{-1} \in GL_{\mathbb{C}}(V^\natural{}_2)$.

```
noncomputable def griessBaseChange (g : SpaceB ≃ₗ[ℚ] SpaceB) : ℂ ⊗[ℚ] SpaceB ≃ₗ[ℂ] ℂ ⊗[ℚ]
↪  SpaceB :=
  g.baseChange ℚ ℂ SpaceB SpaceB
```

```
noncomputable def griessConj (g : SpaceB ≃ₗ[ℚ] SpaceB) :
    VnatVOA.grading 2 ≃ₗ[ℂ] VnatVOA.grading 2 :=
  griessIso.symm ≪≫ₗ griessBaseChange g ≪≫ₗ griessIso
```

```
theorem griessConj_griessNat (g : SpaceB ≃ₗ[ℚ] SpaceB) (u : SpaceB) :
    griessConj g (griessNat u) = griessNat (g u) := by
```

(VOA/Moonshine/MoonshineCNMonsterActionConj.lean.)

From the mathematics to the Lean statement

`e₁ ≪≫ₗ e₂` is composition of linear equivalences, first e_1 then e_2, so `griessConj g` $= \Theta\circ(1\otimes g)\circ\Theta^{-1}$. `LinearEquiv.baseChange` is $1_{\mathbb{C}}\otimes g$ (`griessBaseChange_tmul : griessBaseChange g (a ⊗ₜ u) = a ⊗ₜ g u`). `griessConj_griessNat` says that on the rational lattice griessNat($\mathcal{B}$) $\subset {V^\natural}_2$, `griessConj g` *is* g. `griessConjHom` packages it as a group homomorphism on all of $GL_{\mathbb{Q}}(\mathcal{B})$, injective (`griessConjHom_injective`).

Physical meaning

Transport of a symmetry of AxiomMath's algebra to a linear map of the 196884 spin-two fields of the CFT.

What the machine verified

Definition; audited in `MoonshineCNMonsterActionAudit.lean`.

Theorem 48.57 (`AutO` acts on the Griess algebra of $V^\natural$). *(a) If g preserves the product (resp. b),* `griessConj g` *preserves* `griessMul` *(resp.* `natForm`*) on ${V^\natural}_2$. (b) On ${V^\natural}_2$ the intrinsic form equals* `natForm`*. (c) Hence $g \mapsto$* `griessConj g` *is an injective homomorphism* `AutO` $\to$ `GriessAutVnat`*. (d) Restriction* $\mathrm{Aut}(V^\natural) \to GL_{\mathbb{C}}({V^\natural}_2)$ *is an injective homomorphism.*

```
theorem griessConj_griessMul {g : SpaceB ≃ₗ[ℚ] SpaceB} (hg : IsAlgAut g) (u v :
↪  VnatVOA.grading 2) :
    griessConj g (VnatVOA.griessMul u v) = VnatVOA.griessMul (griessConj g u) (griessConj g
    ↪  v) := by
```

```
theorem griessForm_eq_natForm (u v : VnatVOA.grading 2) :
    GriessAut.griessForm VnatVOA_vacuum_ne_zero u v = SimpleNat.natForm (u : Vnat) (v :
    ↪  Vnat) := by
```

```
noncomputable def griessConjAut : AutO →* GriessAutVnat :=
  MonoidHom.codRestrict (griessConjHom.comp AutO.subtype) GriessAutVnat
    fun g => griessConj_mem_griessAutVnat g.2
```

```
theorem griessConjAut_injective : Function.Injective griessConjAut := by
```

```
noncomputable def vnatWeightTwoRestrict : AutVnat →* (VnatVOA.grading 2 ≃ₗ[ℂ]
↪  VnatVOA.grading 2) :=
  GriessAutVnat.subtype.comp vnatGriessRestrict
```

```
theorem vnatWeightTwoRestrict_injective : Function.Injective vnatWeightTwoRestrict :=
```

(VOA/Moonshine/MoonshineCNMonsterActionConj.lean.)

From the mathematics to the Lean statement

`AutO` is used as a type (its elements are pairs of g and a membership proof); `AutO.subtype` forgets the proof. `MonoidHom.codRestrict` restricts the codomain to `GriessAutVnat`, using (a), (b). `GriessAut.griessForm hvac u v` is the scalar $\langle u, v\rangle_3$ with $u_{(3)}v = \langle u, v\rangle_3 \mathbb{1}$; `VnatVOA_vacuum_ne_zero` is the proof that $\mathbb{1} \neq 0$ needed to extract it. (d) composes `vnatGriessRestrict` with the inclusion `GriessAutVnat.subtype`, and its injectivity is Chapter 47's `vnatGriessRestrict_injective`.

Proof on paper. (a) Transport by Θ (`griessIso_mul`, `griessIso_form`). (b) The FHL invariance law of `natForm` at weight two, $\langle u_{(3)}v, \mathbb{1}\rangle = \langle v, u'_{(-1)}\mathbb{1}\rangle$ with $u' = (-1)^2 e^{L_1} u = u$ (since $L_1 V^\natural{}_2 \subset V^\natural{}_1 = 0$), together with $u_{(-1)}\mathbb{1} = u$ and $\langle \mathbb{1}, \mathbb{1}\rangle = 1$. (c) From (a), (b) and injectivity of $g \mapsto 1 \otimes g$. □

Physical meaning

Every element of AxiomMath's Monster gives a symmetry of the spin-two sector of the Monster CFT that preserves its OPE and its two-point function. Whether it extends to a symmetry of the whole CFT is the lifting question of the next subsection.

What the machine verified

No hypotheses; audited in `MoonshineCNMonsterActionAudit.lean`.

48.15.2 Liftable elements and the lift

Definition 48.58 (Liftable elements). $g \in$ `AutO` is *liftable* if some automorphism h of $V^\natural$ restricts on $V^\natural{}_2$ to `griessConj g`. The liftable elements form a subgroup.

```
def IsVnatLiftable (g : AutO) : Prop :=
  ∃ h : AutVnat, vnatWeightTwoRestrict h = griessConj (g : SpaceB ≃ₗ[ℚ] SpaceB)
```

```
noncomputable def liftableSubgroup : Subgroup AutO :=
  vnatGriessRestrict.range.comap griessConjAut
```

```
theorem mem_liftableSubgroup {g : AutO} : g ∈ liftableSubgroup ↔ IsVnatLiftable g := by
```

(`VOA/Moonshine/MoonshineCNMonsterActionLift.lean`.)

From the mathematics to the Lean statement

`(g : SpaceB ≃ₗ[ℚ] SpaceB)` is the underlying linear map of $g \in$ `AutO`. `H.comap f` is the preimage of a subgroup H under a homomorphism f; `f.range` the image. So `liftableSubgroup` $= \{g \in \mathrm{AutO} : \mathrm{griessConjAut}\, g \in \text{image of } \mathrm{Aut}(V^\natural)\}$, and `mem_liftableSubgroup` identifies it with `IsVnatLiftable`. The equation in `IsVnatLiftable` is equality of $\mathbb{C}$-linear automorphisms of $V^\natural{}_2$, i.e. $h(v) =$ `griessConj g v` for every $v \in V^\natural{}_2$.

Physical meaning

g is liftable when the symmetry it defines on the spin-two fields extends to a symmetry of the whole chiral algebra. Such an extension, if it exists, is unique, because a symmetry of $V^\natural$ is determined by its action on $V^\natural{}_2$; the Lean proof of this (Chapter 47) does not assume that $V^\natural$ is generated by $V^\natural{}_2$.

What the machine verified

Definitions; audited in `MoonshineCNMonsterActionAudit.lean`.

Theorem 48.59 (The Monster lift). *There is an injective homomorphism* monsterLift *from the liftable subgroup to* $\mathrm{Aut}(V^\natural)$ *such that* monsterLift(g) *acts on* $V^\natural{}_2$ *as* `griessConj g`*, in particular as* g *on* griessNat($\mathcal{B}$)*; it is the unique automorphism with this property. If every element of a generating set of a subgroup is liftable, so is the subgroup.*

```
noncomputable def monsterLift : liftableSubgroup →* AutVnat :=

theorem monsterLift_restrict (g : liftableSubgroup) :
    vnatWeightTwoRestrict (monsterLift g) = griessConj ((g : AutO) : SpaceB ≃ₗ[ℚ] SpaceB)
     ↪  :=

theorem monsterLift_apply_griessNat (g : liftableSubgroup) (u : SpaceB) :

    h = monsterLift g :=

theorem monsterLift_injective : Function.Injective monsterLift := by

theorem subgroupClosure_le_liftable {S : Set AutO} (hS : ∀ g ∈ S, IsVnatLiftable g) :
    Subgroup.closure S ≤ liftableSubgroup :=

noncomputable def monsterLiftOfAll (hlift : ∀ g : AutO, IsVnatLiftable g) : AutO →* AutVnat
 ↪  :=
```

(`VOA/Moonshine/MoonshineCNMonsterActionLift.lean`.)

From the mathematics to the Lean statement

`monsterLift` is defined as the composite of `griessConjAut` (restricted to the liftable subgroup, whose image lies in the range of `vnatGriessRestrict`) with the inverse of `vnatGriessRestrict` on its range (`MonoidHom.ofInjective`); the omitted body says exactly this. `monsterLiftOfAll hlift` is the same map on all of `AutO` *under the hypothesis* `hlift` that everything lifts (it is the input to Chapter 49's `monsterEquivAutVnat`). `subgroupClosure_insert_le_liftable` is the variant for $\langle S \cup \{\tau\}\rangle$, the shape of G_{mat}.

Proof on paper. Faithfulness of $\mathrm{Aut}(V^\natural)$ on $V^\natural{}_2$ (Chapter 47) makes the restriction an isomorphism onto its image; `monsterLift` is its inverse composed with $g \mapsto$ `griessConj g`. Composites of injective homomorphisms are injective homomorphisms; uniqueness is injectivity of the restriction. □

Physical meaning

Each liftable Monster element is a well-defined global symmetry of the Monster CFT, uniquely determined by its action on the spin-two fields.

What the machine verified

No hypotheses (except `hlift` where displayed); audited in `MoonshineCNMonsterActionAudit.lean`.

Theorem 48.60 (Rationality criterion). *An automorphism h of $V^\natural$ is* monsterLift(g) *for some liftable g iff h maps the rational lattice* griessNat($\mathcal{B}$) *into itself. If every element of* `AutO` *lifts and every automorphism of $V^\natural$ is rational in this sense, then* $\mathrm{Aut}(V^\natural) \cong$ `AutO`.

```
theorem isVnatLiftable_of_rational (h : AutVnat)
    (hrat : ∀ u : SpaceB, ∃ u' : SpaceB, h (griessNat u : Vnat) = griessNat u') :
    ∃ g : liftableSubgroup, monsterLift g = h := by
```

```
theorem mem_range_monsterLift_iff (h : AutVnat) :
    h ∈ monsterLift.range ↔ ∀ u : SpaceB, ∃ u' : SpaceB, h (griessNat u : Vnat) = griessNat
     ↪ u' := by
```

```
theorem autVnat_mulEquiv_autO_of_liftable_of_rational (hlift : ∀ g : AutO, IsVnatLiftable
 ↪ g)
    (hrat : ∀ h : AutVnat, ∀ u : SpaceB, ∃ u' : SpaceB, h (griessNat u : Vnat) = griessNat
     ↪ u') :
    Nonempty (AutVnat ≃* AutO) := by
```

(`VOA/Moonshine/MoonshineCNMonsterActionLift.lean`.)

From the mathematics to the Lean statement

`hrat` quantifies over all u: h maps each rational vector to a rational vector. `Nonempty (AutVnat ≃* AutO)`: there exists a group isomorphism (the statement does not name it). Both hypotheses of the last theorem are genuine inputs at this point; Chapter 49 discharges `hrat` without hypotheses (`autVnat_rational`) and replaces `hlift` by `GmatEqAutO`.

Proof on paper. If h preserves griessNat($\mathcal{B}$), define $r : \mathcal{B} \to \mathcal{B}$ by griessNat$(ru) = h($griessNat $u)$ (`rationalPart`; `griessNat` is injective). r is $\mathbb{Q}$-linear and injective, hence bijective; it preserves the product and b because h preserves `griessMul` and `natForm` and `griessNat` is an isometric algebra map (Theorem 48.53); so $r \in$ `AutO`. The restriction of h and `griessConj r` agree on the spanning set griessNat($\mathcal{B}$), hence are equal. The converse is `monsterLift_apply_griessNat`. With `hlift`, `monsterLiftOfAll` is defined; `hrat` makes it surjective. □

Physical meaning

A symmetry of the CFT comes from AxiomMath's Monster exactly when it preserves the rational structure of the spin-two fields in the vertex-operator basis. Since the Monster's character values on 196884 are rational, this is expected for all symmetries; proving it is the converse direction of Chapter 49.

What the machine verified

Conditional only on the displayed hypotheses; audited in `MoonshineCNMonsterActionAudit.lean`.

48.15.3 The extraspecial elements lift, explicitly

Theorem 48.61 (Extraspecial lifts). *For every $\mu \in \Lambda$ there are a sign $\sigma \in \{\pm 1\}$ and a liftable $g \in$ `AutO` whose lift is the extraspecial automorphism* `extraVnatAut μ` *of $V^\natural$, and $g(A, x, N) = (A,\ \varepsilon_\mu x,\ \sigma R(0,\bar{\mu})N)$ with $(\varepsilon_\mu x)_c = (-1)^{\langle \mu, \alpha_c \rangle} x_c$.*

```
theorem exists_monsterLift_eq_extraVnatAut (μ : leech.carrier) :
    ∃ σ : ℚ, (σ = 1 ∨ σ = -1) ∧ ∃ g : liftableSubgroup, monsterLift g = extraVnatAut μ ∧
      ∀ u : SpaceB, ((g : AutO) : SpaceB ≃ₗ[ℚ] SpaceB) u
        = (u.1, liftBlockExtraX μ u.2.1,
            (σ • qmatR ℚ 0 (coordOfRed (red leech μ)).1 (coordOfRed (red leech μ)).2) *
             ↪ u.2.2) := by
```

```
theorem extraVnatAut_griessNat (μ : leech.carrier) (σ : ℚ)
    (hσ : (σ : ℂ) = extraPlusFormScalar μ * signRefinement (coordOfRed (red leech μ)))
    (u : SpaceB) :
    extraVnatAut μ (griessNat u : Vnat)
      = griessNat (u.1, liftBlockExtraX μ u.2.1,
          (σ • qmatR ℚ 0 (coordOfRed (red leech μ)).1 (coordOfRed (red leech μ)).2) *
           ↪ u.2.2) := by
```

(VOA/Moonshine/MoonshineCNMonsterActionExtra.lean.)

From the mathematics to the Lean statement

`extraVnatAut μ` (`MoonshineLRLiftExtraAut.lean`, Chapter 49) acts on V_Λ^+ by $x_\alpha \mapsto (-1)^{\langle\mu,\alpha\rangle}x_\alpha$, oscillators fixed, and on $(V_\Lambda^T)^+$ by $c_\mu e_\mu$ with $c_\mu^2 = (-1)^{\langle\mu,\mu\rangle/2}\varepsilon(\mu,\mu)$ (`extraPlusFormScalar μ = c_μ`). `liftBlockExtraX μ x = (c ↦ (-1)^⟨μ,α_c⟩ x_c)`. In spin coordinates $e_\mu = \mathrm{spinOp}(\bar\mu) = Z(\bar\mu)R(0,\bar\mu)$, so the W-block is multiplied by $\sigma = c_\mu Z(\bar\mu)$, and $\sigma^2 = 1$ (`extraSpinPhase_mul_self`): the action is rational. `extraLiftable μ` names the element and `extraLiftable_apply` gives its action with `extraSign μ`.

Proof on paper. Compute `extraVnatAut μ` on `griessNat u` block by block (the formula displayed), observe that the result is again `griessNat` of a rational vector, and apply the rationality criterion. □

Physical meaning

The extraspecial elements are the "momentum-shift" symmetries $e^{\pi i\langle\mu,p\rangle}$ of the lattice CFT, extended to the twisted sector by the action of e_μ on the twist ground states. They generate the normal subgroup 2^{1+24} of $C_{\mathbb{M}}(z)$; this theorem shows each is a lift of an explicit element of AxiomMath's Monster.

What the machine verified

No hypotheses (`extraVnatAut_griessNat` has the displayed hypothesis `hσ`, satisfied by `extraSign`); audited in `MoonshineCNMonsterActionAudit.lean`.

48.15.4 Conway–Norton for liftable elements

Theorem 48.62 (Conway–Norton in Monster language). *(a) For every liftable g, the McKay–Thompson series of* monsterLift(g) *is a normalised Hauptmodul of a genus-zero group containing some $\Gamma_0(N)$, and its q-coefficient is* $\mathrm{tr}(g \mid \mathcal{B}) \in \mathbb{Q}$. *(b) Let $S \subseteq$ `AutO` consist of liftable elements and τ be liftable; if $S \cup \{\tau\}$ generates* `AutO`*, then every $g \in$ `AutO` acts on $V^\natural$ by some h restricting to* `griessConj g`*, and the McKay–Thompson series of h is such a Hauptmodul.*

```
theorem conwayNorton_liftable (g : liftableSubgroup) : ConwayNortonFor (monsterLift g) :=
  conwayNorton (monsterLift g)
```

```
theorem mckayThompson_monsterLift_coeff_one (g : liftableSubgroup) :
    PowerSeries.coeff 1 (mckayThompson (monsterLift g))
      = ((LinearMap.trace ℚ SpaceB ((g : AutO) : SpaceB ≃ₗ[ℚ] SpaceB).toLinearMap : ℚ) : ℂ)
       ↪ := by
```

```
theorem conwayNorton_monster_of_isVnatLiftable (g : AutO) (hg : IsVnatLiftable g) :
    ∃ h : AutVnat, vnatWeightTwoRestrict h = griessConj (g : SpaceB ≃ₗ[ℚ] SpaceB) ∧
      (∀ h' : AutVnat, vnatWeightTwoRestrict h' = griessConj (g : SpaceB ≃ₗ[ℚ] SpaceB) → h'
       ↪ = h) ∧
      PowerSeries.coeff 1 (mckayThompson h)
        = ((LinearMap.trace ℚ SpaceB (g : SpaceB ≃ₗ[ℚ] SpaceB).toLinearMap : ℚ) : ℂ) ∧
```

```
      ∃ (Γ : Subgroup (GL (Fin 2) ℝ)) (N : ℕ), IsMoonshineGroup Γ N ∧
        IsNormalizedHauptmodul Γ (mckayThompsonFun h) := by
```

```
theorem conwayNorton_autO_of_generators {Gvis : Set AutO} {τ : AutO}
    (hvis : ∀ g ∈ Gvis, IsVnatLiftable g) (hτ : IsVnatLiftable τ)
    (hGmat : Subgroup.closure (insert τ Gvis) = ⊤) (g : AutO) :
    ∃ h : AutVnat, vnatWeightTwoRestrict h = griessConj (g : SpaceB ≃ₗ[ℚ] SpaceB) ∧
      ∃ (Γ : Subgroup (GL (Fin 2) ℝ)) (N : ℕ), IsMoonshineGroup Γ N ∧
        IsNormalizedHauptmodul Γ (mckayThompsonFun h) := by
```

(VOA/Moonshine/MoonshineCNMonsterActionMoonshine.lean.)

From the mathematics to the Lean statement

ConwayNortonFor, IsMoonshineGroup, IsNormalizedHauptmodul, mckayThompson, mckayThompsonFun and the theorem conwayNorton : ConwayNortonConjecture are those of Chapters 43 and 47 (MoonshineCNStatement.lean, MoonshineCNTrace.lean): PowerSeries.coeff n (mckayThompson g) is $\mathrm{tr}(g \mid V^\natural_{n+1})$, so coeff 1 is the trace on $V^\natural_2$; IsMoonshineGroup Γ N says $\Gamma \le SL_2(\mathbb{R})$ contains $\Gamma_0(N)$ and is commensurable with $SL_2(\mathbb{Z})$. LinearMap.trace ℚ SpaceB is the trace over $\mathbb{Q}$; the cast to $\mathbb{C}$ is explicit.

A naming hazard. In conwayNorton_autO_of_generators the bound variable is called Gvis, but it is an *arbitrary* set of elements of AutO, not AxiomMath's Visible.Gvis (which is a subgroup of $GL_{\mathbb{Q}}(\mathcal{B})$, not a set of elements of AutO). The theorem is a general statement about any generating set; Chapter 49 applies it to the image of G_{vis}. The name is suggestive, not a hypothesis.

What is unconditional. (a) has the single hypothesis that g lifts; (b) has hvis, hτ, hGmat. The q-coefficient statement makes the series an invariant of g itself: mckayThompsonFun_eq_of_restrict shows the series does not depend on which lift is used (there is only one).

Proof on paper. (a) conwayNorton holds for every automorphism of $V^\natural$ (Chapter 47), in particular for monsterLift(g). The trace on $V^\natural_2$ is the trace of griessConj g, which is the trace of $1 \otimes g$ (conjugation), which is the trace of g (base change preserves traces): trace_griessConj. (b) By subgroupClosure_insert_le_liftable, every g is liftable. □

Physical meaning

For each liftable Monster element, the twisted partition function $\mathrm{tr}(g\, q^{L_0-1})$ of the Monster CFT is a genus-zero Hauptmodul, and its first nontrivial coefficient is the character of g on 196884 computed in AxiomMath's rational model. This is Conway and Norton's original formulation, which starts from the Monster's character table.

What the machine verified

Conditional only on the displayed hypotheses; audited in MoonshineCNMonsterActionAudit.lean; standard axioms. The hypotheses are discharged in Chapter 49: every element of G_{mat} lifts (no hypotheses), and every element of AutO lifts given GmatEqAutO.

48.16 Transfer of the block formulas to the full dictionary

The block formulas for the Co_0-lifts, the extraspecial automorphisms and FLM's triality on $V^\natural_2$ (Chapter 49) are stated against the untwisted dictionary with the phase ζ; the full dictionary uses ζ' (see the trap in §48.13). This short section records the conversion; its mathematical

content is the diagonal sign change D. `VOA/Moonshine/MoonshineLRGriessTransfer.lean` (namespace `VOA.Moonshine.ConwayNorton.M8`) converts them.

Definition 48.63 (The diagonal change of short coordinates). $d_c = \varepsilon(\alpha_c, \alpha_c) \in \{\pm 1\}$, as a rational number; $D(x)_c = d_c x_c$.

```
def griessTrSign (c : ShortIdx) : ℚ := MonsterGriess.sgn (cocycleExp c.1 c.1)
```

```
def griessTrX (x : SpaceX) : SpaceX := fun c => griessTrSign c * x c
```

(`VOA/Moonshine/MoonshineLRGriessTransfer.lean`.)

Physical meaning

A sign flip of those vertex operators $\cos(\alpha_c X)$ whose cocycle value $\varepsilon(\alpha_c, \alpha_c)$ is -1: a change of basis of the spin-two fields, not a change of the theory.

What the machine verified

Definitions; audited in `MoonshineLRLiftAudit.lean`.

Theorem 48.64 (Transfer). *(a) D is an involution and* $\mathrm{shortDict}_{\zeta'}(x) = \mathrm{shortDict}_{\zeta}(Dx)$*; hence* $\mathrm{griessNat}(A, x, 0) = \Phi_\zeta(A, Dx, 0)$. *(b) $\varepsilon(\alpha_c, \alpha_c) = 1$ iff 4 divides the diagonal Gram contribution $\sum_i \langle B_i, B_i\rangle(\alpha_c)_i^2$ (coordinates in the chosen lattice basis B). (c) The Co_0-lifts act on $\Theta(1 \otimes (A, x, 0))$ by $(A, x) \mapsto (gAg^{\mathsf{T}}, D\,P\,D\,x)$ with P the signed permutation computed with ζ; the extraspecial lifts act on X by $x_c \mapsto (-1)^{\langle \mu, \alpha_c\rangle} x_c$ unchanged; FLM's σ on the even part is the old formula conjugated by D.*

```
theorem griessTrNat (A : symMat) (x : SpaceX) :
    griessNat (A, x, 0) = untwistedDictNat griessShortSign (A, griessTrX x, 0) := by
```

```
theorem griessTrCocycle_eq_one_iff (c : ShortIdx) :
    latticeCocycle leech (shortVec c) (shortVec c) = 1 ↔ 4 ∣ griessTrDiagonal c := by
```

```
theorem griessTrLiftSignNat_untwisted (A : symMat) (x : SpaceX) :
    liftTwVnatAut ι hι hsurj (griessIso (1 ⊗ₜ[ℚ] (A, x, 0)) : Vnat) =
      (griessIso (1 ⊗ₜ[ℚ]
        (liftBlockSymMat ι A, griessTrX (liftSignX ι hι (griessTrX x)), 0)) : Vnat) := by
```

(`VOA/Moonshine/MoonshineLRGriessTransfer.lean`.)

From the mathematics to the Lean statement

`cocycleExp c.1 c.1` is the exponent $E(c, c)$, so `griessTrSign c` $= \varepsilon(\alpha_c, \alpha_c)$ (`griessTrSign_cast`). In the isometry section, `ι : leech.carrier →ₗ[ℤ] leech.carrier` with `hι` (isometry) and `hsurj` (surjective) are section variables: $\iota \in \mathrm{Co}_0$. `liftTwVnatAut`, `liftBlockSymMat`, `liftSignX`, `sigmaAut`, `sigmaBlockOFull`, `sigmaBlockParity` are constructions of Chapter 49; here only their transport matters. The extraspecial and triality parts of (c) are `griessTrExtraNat_shortBlock` and `griessTrSigmaBlockOFull_nat` (the latter for x supported on the even-parity short classes, those in the frame sector V_0^+); (a) also contains `griessTrShortDict`. The diagonal entries of D are exactly the diagonal cocycle values (`griessTrSign_cast`), not an assumed normalisation.

Proof on paper. (a) $\zeta'_c = \zeta_c \varepsilon(\alpha_c, \alpha_c)$ (`fullShortSign_eq`); $d_c^2 = 1$. (b) The cocycle exponent satisfies $2E(\alpha, \alpha) + \sum_i \langle B_i, B_i\rangle a_i^2 = \langle \alpha, \alpha\rangle = 4$ (`cocExp_add_swap` with the diagonal written out), so $E(\alpha, \alpha)$ is even iff 4 divides the diagonal sum. (c) Substitute (a) into the formulas of Chapter 49. □

Physical meaning

A change of normalisation of the 98280 vertex operators $\cos(\alpha X)$ by signs; all symmetry formulas are conjugated by this diagonal change.

What the machine verified

No hypotheses beyond those displayed; audited in `MoonshineLRLiftAudit.lean`. Open but unneeded: whether $\varepsilon(\alpha_c, \alpha_c) = 1$ for all c.

- `VOA/Moonshine/MonsterGriess/ProductInvarianceAudit.lean` (659): `GriessGrading`, the `Invariance*` files, `OctadThreeOctad`, `ProductInvariance`; headlines `tauB_gmul`, `isAlgAut_tauB`, `tauB_mem_AutO`, `Gmat_le_AutO`.
- `VOA/Moonshine/MoonshineCNGriessAudit.lean` (176): the table, the Conway coordinates, the untwisted dictionary, the short-class combinatorics.
- `VOA/Moonshine/MoonshineCNGriessAudit2.lean` (262): the ported cocycle and $\Lambda/2\Lambda$ identities, the sign map, `untwistedIsoC`, the spin module, the frame blocks.
- `VOA/Moonshine/MoonshineCNGriessAudit3.lean` (154): `SpinMatrixMap`, the spin form, the twisted top, the W-dictionary and `griessIso`.
- `VOA/Moonshine/MoonshineCNMonsterActionAudit.lean` (84): the lift framework.

`MoonshineLRGriessTransfer.lean` is audited in `MoonshineLRLiftAudit.lean` (Chapter 49). The axiom lists stated in the status boxes are the recorded results of building these audit files; the author of this chapter did not re-run any build, and at the time of those records the aggregate build of the whole library had not been re-run.

48.19 Referee's checklist

declaration	intended meaning	hypotheses	check
`Code.C`	AxiomMath's Golay code (MOG/hexacode)	— (definition)	Def 48.3
`golay_map_eq_C`	our Golay code is AxiomMath's up to π	none	Thm 48.4
`leechEquiv`, `codeForm_leechEquiv`	our Leech lattice is AxiomMath's, isometrically	none	Thm 48.8

declaration	intended meaning	hypotheses	check
`classOf_eq_iff`, `card_shortIdx`	minimal classes are $\pm$ pairs; 98280 of them	none	Thm 48.9
`phi0`, `ShortIdx`, `uvec`	coordinates on $\Lambda/2\Lambda$; short classes	— (definitions)	Def 48.10
`phi0Equiv`, `qL_phi0`	φ_0 isomorphism; q = pairing	none	Thm 48.11
`qmatR`, `qmatR_mul`, `Q`	spin matrices; extraspecial 2^{1+24}	— / none	Def 48.13, Thm 48.14, Def 48.15
`SpaceB`, `bform`, `gmul`	AxiomMath's rational Griess algebra	— (definitions)	Defs 48.17, 48.18
`finrank_B`	$\dim \mathcal{B} = 196884$	none	§48.5
`T_unique`	Griess trilinear form determined by block values	symmetry, block values	Thm 48.22
`AutO`	AxiomMath's Monster: $\mathrm{Aut}(\mathcal{B}, \cdot, b)$	— (definition)	Def 48.23
`Pvis`, `Gvis`, `thetaEquiv`	$2^{1+24}.\mathrm{Co}_1$ acting on $\mathcal{B}$	— (definitions)	Defs 48.25, 48.26
`Gvis_le_AutO`, `rhoEquiv_zQ`	$G_{\mathrm{vis}} \le \mathrm{AutO}$; $z \mapsto x_B$	none	Thm 48.28
`tbasis`, `tauB`, `trace_tauB`	triality basis; order-3 element, trace 783	none	Defs 48.29, 48.30
`yB`, `zB`, `Generated.Gmat`	four-group; $G_{\mathrm{mat}} = \langle G_{\mathrm{vis}}, \tau_B \rangle$	—	Def 48.31, Thm 48.32
`tauB_gmul`, `tauB_mem_AutO`, `Gmat_le_AutO`	τ_B is an automorphism; $G_{\mathrm{mat}} \le \mathrm{AutO}$	none	Thm 48.33
`rational_parity_centralizer_equals_Gvis`, `AutO_inf_centralizer_xB_eq_Gvis`	$\mathrm{AutO} \cap C(x_B) = G_{\mathrm{vis}}$	none	Thm 48.34
(not ported) `gmat_eq_griess`	$G_{\mathrm{mat}} = \mathrm{AutO}$	—	§48.10; named hypothesis in Ch. 49
`conwayQuad_one_conwayQuad_untwisted` etc.	untwisted products in Conway coordinates	displayed	Thm 48.36
`ShortSignDictionary`	coherent phases for $\cos(\alpha X)$	— (structure)	Def 48.38
`untwistedDict_gmul`, `untwistedDict_form`	untwisted dictionary is isometric algebra map	sign dictionary, $W = 0$	Thm 48.39
`exists_sign_refinement`	quadratic refinements exist	symmetric form	Thm 48.41
`shortSignDictionary_griessUntwisted`, `untwistedIsoC`	short-sign dictionary unconditional; $\mathbb{C} \otimes (\mathrm{Sym} \oplus X) \cong (V_\Lambda^+)_2$	none	Thm 48.43
`spinIso`, `spinIso_spinOp`	AxiomMath's spin module is T	none	Thm 48.45
`TForm_spinIso`	$B_T = \kappa \cdot$ dot product	none	Thm 48.46
`spinIso_frameJ_of_support`	spin halves = frame sectors	support	Thm 48.47
`topAct_conwayQuad_spinTopVec` etc.	untwisted×twisted channels	displayed	Thm 48.49
`fullShortSign`, `spinDict`, `TPForm_spinDict`	phases ζ'; W-dictionary; form	none	Def 48.50, Thm 48.51

declaration	intended meaning	hypotheses	check
`griessNat_gmul`, `griessNat_form`	dictionary multiplicative, isometric up to 2	none	Thm 48.53
`griessIso`, `griessIso_mul`, `griessIso_form`	$\mathbb{C} \otimes \mathcal{B} \cong V^\natural{}_2$ as algebras with forms	**none**	Thm 48.54
`spinDict_mem_TPframe_shift`	W halves → frame sectors	none	Thm 48.55
`griessConj`, `griessConjAut`	AutO acts on the Griess algebra of $V^\natural$	none	Def 48.56, Thm 48.57
`griessForm_eq_natForm`	intrinsic form = `natForm` on $V^\natural{}_2$	none	Thm 48.57
`IsVnatLiftable`, `liftableSubgroup`	elements extending to $\mathrm{Aut}(V^\natural)$	— (definitions)	Def 48.58
`monsterLift`, `monsterLift_injective`, `monsterLift_unique`	unique injective lift	none	Thm 48.59
`isVnatLiftable_of_rational`, `autVnat_mulEquiv_autO_of_liftable_of_rational`	rational automorphisms come from AutO	`hrat`; `hlift`, `hrat`	Thm 48.60
`exists_monsterLift_eq_extraspecial`	extraspecial automorphisms lift, explicitly	none	Thm 48.61
`conwayNorton_monster_of_isConwayTable`	Conway–Norton for a liftable Monster element	g liftable	Thm 48.62
`conwayNorton_autO_of_generators`	Conway–Norton for AutO from liftable generators	`hvis`, `hτ`, `hGmat`	Thm 48.62
`griessTrX`, `griessTrNat`, `griessTrSigmaBlockOFull_nat`	$\zeta \leftrightarrow \zeta'$ transfer	displayed	Thm 48.64

Every row is `#print axioms`-clean (standard axioms) per the audit files of §48.18; the only hypotheses are those displayed, and none of them is an unestablished datum except `hlift`, `hGmat` and `hτ`/`hvis` in the two general theorems of Part C, which Chapter 49 reduces to the single named hypothesis `GmatEqAutO`.

48.20 Notes and references

The Monster's Griess algebra was constructed by R. L. Griess Jr., *The friendly giant*, Invent. Math. 69 (1982) 1–102, building on his announcement in *A construction of F_1 as automorphisms of a 196,883-dimensional algebra*, Proc. Natl. Acad. Sci. USA 78 (1981) 689–691. The simplified construction followed by AxiomMath (the decomposition $S^2 \oplus \mathbb{Q}^{98280} \oplus \mathbb{Q}^{4096} \otimes \mathbb{Q}^{24}$, the extraspecial group 2^{1+24} realised by signed permutations indexed by the Parker loop, and the triality element) is J. H. Conway, *A simple construction for the Fischer–Griess monster group*, Invent. Math. 79 (1985) 513–540. The theorem that the full automorphism group of the Griess algebra is the Monster is J. Tits, *On R. Griess' "friendly giant"*, Invent. Math. 78 (1984) 491–499; see also J. Tits, *Le Monstre*, Séminaire Bourbaki 1983/84, exp. 620, Astérisque 121–122 (1985) 105–122. The MOG, the hexacode and the Golay code are in R. T. Curtis, *A new combinatorial approach to M_{24}*, Math. Proc. Cambridge Philos. Soc. 79 (1976) 25–42, and J. H. Conway and N. J. A. Sloane, *Sphere Packings, Lattices and Groups*, 3rd ed., Springer, 1999, Chapters 10, 11 and 29. The moonshine module, the identification of $V^\natural{}_2$ with the Griess algebra, the triality and the action of the Monster on $V^\natural$ are in I. Frenkel, J. Lepowsky and A. Meurman, *Vertex Operator Algebras and the Monster*, Pure and Applied Mathematics 134, Academic Press, 1988 (Chapters 10–12 for the Griess algebra and $C = 2^{1+24}.\mathrm{Co}_1$). A modern account of the Monster through its Griess algebra and its axes is A. A. Ivanov, *The Monster Group and Majorana Involutions*, Cambridge Tracts in Mathematics 176, Cambridge University Press,

2009. The physics of the orbifold is L. Dixon, P. Ginsparg and J. Harvey, *Beauty and the beast: superconformal symmetry in a Monster module*, Comm. Math. Phys. 119 (1988) 221–241. The conjecture is J. H. Conway and S. P. Norton, *Monstrous moonshine*, Bull. London Math. Soc. 11 (1979) 308–339, proved by R. E. Borcherds, *Monstrous moonshine and monstrous Lie superalgebras*, Invent. Math. 109 (1992) 405–444.

The Lean source of Part A is the AxiomMath CFSG library: D. Cureton, V. Ilin, B. Mehta, N. Voss, R. Cabral, C. Defant, E. Gregory, A. Hill, L. Hong, Q. Hu, D. Jamner, A. Jiang, T. Jordan, A. Kurghinyan, K. Lau, J. Laurent, D. Liang, J. Limperg, S. Mahns, B. Nugent, C. Olson, K. Ono, E. Paul, D. Rajan, K. Ram, C. Ray, H. C. Siu, A. A. Swaminathan, J. Thorner, A. Tsaplin and C. Wang, *Lean formalization of the classification of finite simple groups*, 2026, `https://github.com/AxiomMath/CFSG`, commit `69cb972f587a3ecc035e092253167ff2e303c962` (Lean v4.35.0-rc3), Apache License 2.0. The port to Lean 4.30 is by F. K. Popov (with Claude). The record of the port is `Notes/monster_aut/CFSG_PORT_FIDELITY.md` (the declaration-by-declaration comparison); the remaining working notes are not part of the release.

Chapter 49

The Monster acts on the moonshine module: lifts, triality, the commutant and the converse

This chapter documents the release of the library named in the front matter; every Lean quotation below is checked by `scripts/textbook/sync.py` to occur verbatim (up to whitespace and comments) in the source files of that release. Within a `leancode` block, declarations appear in file order; proof bodies are omitted, and a comment line `-- ⋯` marks a junction between two separately quoted declarations, where intervening declarations of the file may be skipped (or the next declaration comes from another file named in the citation). It is the last chapter of the part "Monstrous moonshine", and it contains the part's headline.

Chapter 47 proved the Conway–Norton theorem for every automorphism of $V^\natural$: the Lean theorem `conwayNorton : ConwayNortonConjecture` says that for every $g \in \mathrm{Aut}(V^\natural)$ the McKay–Thompson series T_g is the normalised Hauptmodul of a genus-zero group containing some $\Gamma_0(N)$. It is a statement about the group $\mathrm{Aut}(V^\natural)$, *whatever that group is*. Chapter 48 imported, from the AxiomMath CFSG library, an independent model of the Monster ("the Monster" is this book's name for the Lean group AutO; that it is a simple group of order $\approx 8 \cdot 10^{53}$ is classical and is proved in AxiomMath's library on Lean 4.35, but is *not* a statement of LeanVOA): the rational Griess algebra $\mathcal{B}$ (the Lean type `SpaceB`, a $\mathbb{Q}$-vector space of dimension 196884), its automorphism group AutO, the visible subgroup G_{vis} (classically isomorphic to $2^{1+24}.\mathrm{Co}_1$; this isomorphism type is *not* formalised), the triality element τ_B, and the generated group $G_{\mathrm{mat}} = \langle G_{\mathrm{vis}}, \tau_B \rangle$; it also built an explicit isomorphism of algebras with forms $\mathbb{C} \otimes_{\mathbb{Q}} \mathcal{B} \cong {V^\natural}_2$ (`griessIso`), and the language in which an element of AutO "acts on $V^\natural$" (`IsVnatLiftable`, `monsterLift`).

The present chapter connects the two groups. It proves, in Lean:

(A) **Every element of G_{mat} acts on $V^\natural$** (§§49.2–49.7): each element of the visible group and the triality element τ_B is the restriction to the Griess algebra of an automorphism of $V^\natural$. Consequently Conway–Norton holds for every element of G_{mat}, with no hypothesis beyond the membership $g \in G_{\mathrm{mat}}$ (`conwayNorton_gmat`).

(B) **The converse** (§§49.8–49.12): every automorphism of $V^\natural$ is rational on the Griess algebra, so $\mathrm{Aut}(V^\natural)$ is isomorphic to the subgroup of AutO consisting of the elements that act on $V^\natural$ — again with *no hypotheses* (`nonempty_autVnat_mulEquiv_liftable`). The proof does not use Tits' theorem; it uses the moonshine theorem itself (rationality of all graded traces, `rationalTraces`) and an absolute-irreducibility statement for G_{mat} (the *commutant lemma*, `gmatCommutantScalar`), proved by explicit Clifford theory and kernel-checked M_{24} certificates.

(C) **The headline** (§49.13): given one named hypothesis `GmatEqAutO`, which is AxiomMath's statement $G_{\mathrm{mat}} = \mathrm{AutO}$ after renaming (with one definition, `SpinLattice.phi0`, restated

in a definitionally equal form), there is a group isomorphism AutO $\cong$ Aut($V^\natural$) compatible with the Griess algebras, and monstrous moonshine holds for every element of the Monster (`monstrousMoonshine`).

The last statement is **conditional**: the hypothesis `GmatEqAutO` is an explicit argument of the theorem. Its `#print axioms` output is clean, but, as Chapter 1 (§1.3.4) explains, `#print axioms` does not report explicit hypotheses. This book never calls a theorem with the argument (`hM : GmatEqAutO`) unconditional. Everything in (A) and (B) is unconditional.

The status of the hypothesis, up front. `GmatEqAutO` is *proved in AxiomMath's library* (`CFSG.Blueprint.NativeSporadic.MonsterModel.gmat_eq_griess`, Lean 4.35, commit `69cb972f`). Its proof passes through literature "milestones" whose names begin `cl_lit_`; the ones on its path that were inspected (`CFSG.Milestones.cl_lit_stroth_leon_sims_baby_monster_recognition` and its `_models` variant, and `CFSG.Milestones.cl_lit_goldschmidt_strongly_closed_abelian` from which they are derived) are *theorems* in that library, not axioms. Its full axiom footprint has *not* been re-checked: that needs `#print axioms` on a Lean 4.35 build of AxiomMath's library, which nobody in this project has run. Our proposition agrees with AxiomMath's statement after renaming, with `phi0` restated definitionally equal (source-text audit, not a cross-toolchain proof; §49.13).

As everywhere in this book, our concern is the *meaning* of the Lean statements. Proofs are explained mathematically; we do not describe how the Lean proof scripts are organised beyond, at most, naming the file.

49.1 Overview: the Monster as the symmetry group of the moonshine module

49.1.1 The classical picture

Frenkel, Lepowsky and Meurman constructed $V^\natural$ in 1988 as a $\mathbb{Z}/2$-orbifold of the Leech lattice vertex operator algebra,

$$V^\natural \;=\; V_\Lambda^+ \;\oplus\; (V_\Lambda^T)^+,$$

(Chapters 30–42) and proved that the Monster acts on it. Their argument has two halves.

- *The centralizer of an involution acts.* The operator z which is $+1$ on V_Λ^+ and -1 on $(V_\Lambda^T)^+$ is an automorphism of $V^\natural$ (it is the "quantum" or dual $\mathbb{Z}/2$ symmetry of the orbifold). The group of automorphisms of $V^\natural$ that are visible in the orbifold description — lattice automorphisms of Λ, lifted, and the extraspecial group 2^{1+24} acting on the twisted sector — has the shape $C = 2^{1+24}.\mathrm{Co}_1$, and it is the centralizer of z.

- *Triality.* There is an extra automorphism σ of $V^\natural$, not in C, constructed from a second description of $V^\natural$ as an orbifold (Chapters 39–42). The group generated by C and σ acts on the weight-two space ${V^\natural}_2$ (the Griess algebra) by algebra automorphisms; by Griess' and Conway's work it is the Monster $\mathbb{M}$. The converse, that Aut($V^\natural$) is no larger, follows from Tits' theorem that $\mathbb{M}$ is the full automorphism group of the Griess algebra, together with the fact that $V^\natural$ is generated by ${V^\natural}_2$.

49.1.2 The route taken in Lean

The Lean development reproduces the first half literally, but in AxiomMath's coordinates, and replaces the second half by a new argument. The chain is the following; each arrow is a Lean theorem.

(1) **Lifts of C.** A pair (automorphism h of V_Λ^+, compatible isometry φ of $(V_\Lambda^T)^+$) is an automorphism of $V^\natural$ (`vnatAutOfPair`). Every isometry ι of Λ gives such a pair (`liftTwVnatAut`); so does every $\mu \in \Lambda$ (`extraVnatAut`).

(2) **Block forms and the rational criterion.** On ${V^\natural}_2 \cong \mathbb{C} \otimes \mathcal{B}$ these lifts act by explicit block matrices; the lift of ι is *liftable* (comes from AutO) exactly when one 4096×4096 "spin" block is rational, and that reduces to a rational intertwining equation.

(3) **The visible group, uniformly.** For every compatible pair (s, g) defining an element of G_{vis}, the matrix s^{T} solves the equation up to an extraspecial correction; hence every element of G_{vis} is liftable (`liftVisRAllVisible`). This proof does *not* go through generators. Separately, the equation is solved explicitly for the Golay sign changes, the code-preserving coordinate permutations $(2^{12}{:}M_{24})$ and Conway's non-monomial element ξ; these explicit lifts, with their explicit block forms, are what the commutant lemma (6) needs, because there one must know *how* specific elements of G_{vis} act block by block, not merely that they act.

(4) **Triality.** σ is rational on ${V^\natural}_2$, so it is the lift of an element $\sigma_B \in \mathrm{AutO}$ (`sigmaBOdd_liftable`); conjugation by σ_B carries the parity involution x_B to y_B or z_B; the parity-centralizer theorem $\mathrm{AutO} \cap C(x_B) = G_{\text{vis}}$ of Chapter 48 then shows that τ_B is liftable (`isVnatLiftable_tauB`). Hence every element of G_{mat} is liftable.

(5) **Rational traces.** Galois invariance $T_{g^u} = T_g$ (a consequence of the moonshine theorem) and a Ramanujan-sum argument show that every graded trace of every automorphism of $V^\natural$ is rational (`rationalTraces`).

(6) **The commutant lemma.** Every $\mathbb{Q}$-linear endomorphism of $\mathcal{B}$ commuting with G_{mat} is $a \cdot 1 + b \cdot P_0$, P_0 the projection onto the line of the identity element (`gmatCommutantScalar`).

(7) **The converse.** (5), (6) and Schur's orthogonality relations show that every automorphism of $V^\natural$ maps the rational lattice $\mathrm{griessNat}(\mathcal{B}) \subset {V^\natural}_2$ into itself (`autVnat_rational`); therefore $\mathrm{Aut}(V^\natural) \cong$ the liftable subgroup of AutO (`nonempty_autVnat_mulEquiv_liftable`).

(8) **The headline.** If $G_{\text{mat}} = \mathrm{AutO}$ (`GmatEqAutO`), the liftable subgroup is all of AutO, and (3), (4), (7) give $\mathrm{AutO} \cong \mathrm{Aut}(V^\natural)$ and monstrous moonshine for the Monster (`monsterEquivAutVnat`, `monstrousMoonshine`).

Physical meaning

The Monster as the full symmetry group of the moonshine CFT. $V^\natural$ is the chiral algebra of a holomorphic two-dimensional conformal field theory with central charge 24; it has a single irreducible module (itself), so its torus partition function is the modular function $J(q) = q^{-1} + 196884q + \cdots$. Its weight-one space vanishes, so the theory has no conserved currents and hence no continuous symmetries: every global symmetry is a finite-order automorphism of the chiral algebra, and the group of all of them is $\mathrm{Aut}(V^\natural)$. The statement that this group is the Monster is the statement that the largest sporadic simple group is *exactly* the global symmetry group of this CFT — not merely a group of symmetries. For a symmetry g, the twisted partition function $T_g(q) = \mathrm{tr}_{V^\natural}(g\, q^{L_0 - 1})$ (the torus amplitude with a g-twist along the time circle) is the McKay–Thompson series, and moonshine says that each of these is the partition function of a genus-zero modular curve. The present chapter is the part of the story that identifies the symmetry group.

Physical meaning

The $\mathbb{Z}/2$-orbifold and its centralizer $2^{1+24}.\mathrm{Co}_1$. The Leech lattice CFT V_Λ (24 chiral bosons on the torus $\mathbb{R}^{24}/\Lambda$) has the reflection symmetry $X \mapsto -X$. Gauging it (the orbifold) keeps the invariant states V_Λ^+ and adds the invariant part of the twisted sector, in which the bosons are antiperiodic and the ground states form the 2^{12}-dimensional representation T of a Clifford-like extension of $\Lambda/2\Lambda$. The orbifold theory has a new $\mathbb{Z}/2$ symmetry z ("quantum symmetry"), $+1$ on the untwisted, -1 on the twisted sector. Symmetries of the parent theory that commute with the reflection descend: the automorphisms of the lattice ($\mathrm{Co}_0 = 2.\mathrm{Co}_1$, acting on the bosons by rotations) and the momentum phases $e^{i\pi\langle\mu,p\rangle}$, $\mu \in \Lambda$, which act on the twisted ground states through the extraspecial group. Together they form $2^{1+24}.\mathrm{Co}_1$, the centralizer of z in the Monster. These are the elements lifted in §§49.2–49.5.

49.1.3 What is recalled from Chapter 48

The following objects are defined and fidelity-checked in Chapter 48; we recall each in the form our statements need, and quote the definitions a referee must see to read the statements of this chapter.

The rational Griess algebra. $\mathcal{B} = \texttt{SpaceB} = \mathcal{A} \times \mathcal{X} \times \mathcal{W}$ with $\mathcal{A} = \texttt{symMat}$ the symmetric 24×24 rational matrices (dimension 300), $\mathcal{X} = \texttt{SpaceX} = \mathbb{Q}^{\mathrm{ShortIdx}}$ with one coordinate for each pair $\pm\alpha$ of minimal vectors of the Leech lattice (there are $196560/2 = 98280$ such pairs; ShortIdx is AxiomMath's index set for them, Chapter 48), and $\mathcal{W} = \texttt{SpaceW}$ the 4096×24 rational matrices; $300 + 98280 + 98304 = 196884$. It carries AxiomMath's commutative product `gmul` and symmetric bilinear form `bform`. An element is written $u = (A, x, N)$; in Lean the components are `u.1`, `u.2.1`, `u.2.2`.

Matrix conventions. AxiomMath's matrices act on *row* vectors: for a rational matrix g of Co_0, AxiomMath's visible element acts on $\mathcal{A}$ by $A \mapsto g^{\mathsf{T}} A g$. The library's own matrix of a Leech isometry ι (`liftBlockMatrix ι`, written g_ι below) acts on *column* vectors, and the corresponding lift acts on $\mathcal{A}$ by $A \mapsto g_\iota A g_\iota^{\mathsf{T}}$. For the same isometry the two are transposes of each other, $g_\iota = g^{\mathsf{T}}$ (`liftVisBlockMatrix`, §49.5), so the two formulas agree.

The dictionary in symbols. Chapter 48 builds the rational dictionary $\mathrm{griessNat} : \mathcal{B} \to V^\natural{}_2$, $\mathrm{griessNat}(A, x, N) = (v_{\mathrm{untw}}, v_{\mathrm{tw}}) \in V_\Lambda^+ \oplus T^+$, with

$$v_{\mathrm{untw}} = q_C(A^\pi) + \sum_c x_c\, \zeta'_c\, x_{\alpha_c}, \qquad v_{\mathrm{tw}} = \lambda \sum_{i=0}^{23} h_{f_i}(-\tfrac{1}{2}) \otimes \Psi\big(N_{\cdot,\pi(i)}\big),$$

where: Conway's coordinates realise Λ inside $\mathbb{Z}^{24}$ as the vectors u with $u_i \equiv m + 2d_i \pmod 4$ for a common m and a Golay codeword d, and $\sum_i u_i \equiv 4m \pmod 8$, with inner product $u \cdot v/8$ (so minimal vectors have norm 4); f_i is the i-th Conway axis vector $8e_i$, used as an oscillator direction; π is the fixed permutation of $\{0, \dots, 23\}$ matching AxiomMath's numbering with the library's oscillator frame, and A^π the correspondingly permuted matrix; $q_C(M)$ is the weight-two quadratic oscillator state $\sum_{i,j} M_{ij} h_{f_i}(-1) h_{f_j}(-1)\mathbb{1}$ (with the normalisation of Chapter 48); α_c is a chosen minimal vector in the pair c and $x_\alpha = e^\alpha + e^{-\alpha}$; ζ'_c (`fullShortSign`) is a fixed complex phase chosen so that the dictionary is compatible with AxiomMath's product; Ψ (`spinIso`) identifies AxiomMath's spin module $\mathbb{Q}^{4096}$ (tensored with $\mathbb{C}$) with the 4096-dimensional module T of the twisted sector; λ (`spinDictScale`) is a normalising scalar. The twisted sector starts at weight $\frac{3}{2}$ (the ground states of 24 antiperiodic bosons, 24/16), so its weight-two part is $h(-\frac{1}{2}) \otimes T$, of dimension $24 \cdot 4096 = 98304$: this is why $\mathcal{W}$ consists of 4096×24 matrices. `griessIso` is the $\mathbb{C}$-linear extension of `griessNat`; we write $\mathcal{G}$ for it.

The Monster. AutO is the subgroup of $\mathrm{GL}_{\mathbb{Q}}(\mathcal{B})$ of maps preserving the product and the form:

```
def IsAlgAut (f : SpaceB ≃ₗ[ℚ] SpaceB) : Prop := ∀ u v, f (gmul u v) = gmul (f u) (f v)

def AutO : Subgroup (SpaceB ≃ₗ[ℚ] SpaceB) where
  carrier := {g | IsAlgAut g ∧ ∀ u v, bform (g u) (g v) = bform u v}
```

(`VOA/Moonshine/MonsterGriess/AutO.lean`). The visible group is the image of AxiomMath's map `thetaEquiv` on compatible pairs (s, g), s a rational 4096×4096 matrix normalising the extraspecial group and g a rational matrix of Co_0; thetaEquiv(s, g) acts by $(A, x, N) \mapsto (g^{\mathsf{T}} A g,$ a signed permutation of x, $s^{\mathsf{T}} N g)$ (Chapter 48):

```
def Gvis : Subgroup (SpaceB ≃ₗ[ℚ] SpaceB) where
  carrier := Set.range thetaEquiv
```

(`VOA/Moonshine/MonsterGriess/VisiblePair.lean`). The parity involution and its two triality conjugates, and the generated group:

```
noncomputable def xB : SpaceB ≃ₗ[ℚ] SpaceB :=
  LinearEquiv.ofInvolutive parityMap fun u => by simp [parityMap_apply]
```

(`VOA/Moonshine/MonsterGriess/GriessTrilinear.lean`; `parityMap` is $(A, x, N) \mapsto (A, x, -N)$),

```
noncomputable def yB : SpaceB ≃ₗ[ℚ] SpaceB := tauB * xB * tauB⁻¹
-- …
noncomputable def zB : SpaceB ≃ₗ[ℚ] SpaceB := tauB ^ 2 * xB * (tauB ^ 2)⁻¹
-- …
noncomputable def Gmat : Subgroup (SpaceB ≃ₗ[ℚ] SpaceB) :=
  Subgroup.closure ((Gvis : Set (SpaceB ≃ₗ[ℚ] SpaceB)) ∪ {tauB})
```

(`VOA/Moonshine/MonsterGriess/TrialityFourGroup.lean`). Here `tauB` is AxiomMath's explicit rational matrix of order 3 (Chapter 48; `tauB_pow_three`, `trace_tauB : ... = 783`); it fixes every diagonal matrix in $\mathcal{A}$ and permutes cyclically three "triality basis" vectors in each of the pair, odd and octad blocks (`tauB_diag`, `tauB_pair`, `tauB_odd`, `tauB_oct`). Chapter 48 also proves $\tau_B \in$ AutO (`tauB_mem_AutO`), $G_{\mathrm{mat}} \leq$ AutO (`Generated.Gmat_le_AutO`) and the *parity-centralizer theorem*

$$\mathrm{AutO} \cap C(x_B) \;=\; G_{\mathrm{vis}} \qquad (\texttt{Parity.AutO_inf_centralizer_xB_eq_Gvis}), \tag{49.1}$$

ported from AxiomMath; it is used twice below.

The Griess isomorphism and the lift. `griessNat : SpaceB →+ VnatVOA.grading 2` is the explicit rational dictionary, and `griessIso : ℂ ⊗[ℚ] SpaceB ≃ₗ[ℂ] VnatVOA.grading 2` its $\mathbb{C}$-linear extension ($1 \otimes u \mapsto$ griessNat(u)); it carries `gmul` to the Griess product of $V^\natural$ and natForm $= 2 \cdot$`bform` (`griessIso_mul`, `griessIso_form`). For $g \in \mathrm{GL}_{\mathbb{Q}}(\mathcal{B})$ the *Griess conjugate* is the transported map on ${V^\natural}_2$,

```
noncomputable def griessConj (g : SpaceB ≃ₗ[ℚ] SpaceB) :
    VnatVOA.grading 2 ≃ₗ[ℂ] VnatVOA.grading 2 :=
  griessIso.symm ≪≫ₗ griessBaseChange g ≪≫ₗ griessIso
```

and `vnatWeightTwoRestrict` restricts an automorphism of $V^\natural$ to ${V^\natural}_2$:

```
noncomputable def vnatWeightTwoRestrict : AutVnat →* (VnatVOA.grading 2 ≃ₗ[ℂ]
 ↪  VnatVOA.grading 2) :=
  GriessAutVnat.subtype.comp vnatGriessRestrict
```

(`VOA/Moonshine/MoonshineCNMonsterActionConj.lean`). An element $g \in$ AutO *acts on* $V^\natural$, or *is liftable*, if some automorphism of $V^\natural$ restricts to its Griess conjugate:

```
def IsVnatLiftable (g : AutO) : Prop :=
  ∃ h : AutVnat, vnatWeightTwoRestrict h = griessConj (g : SpaceB ≃ₗ[ℚ] SpaceB)
-- …
noncomputable def liftableSubgroup : Subgroup AutO :=
  vnatGriessRestrict.range.comap griessConjAut
-- …
noncomputable def monsterLift : liftableSubgroup →* AutVnat :=
  (MonoidHom.ofInjective vnatGriessRestrict_injective).symm.toMonoidHom.comp
    (griessConjAut.subgroupComap vnatGriessRestrict.range)
-- …
noncomputable def monsterLiftOfAll (hlift : ∀ g : AutO, IsVnatLiftable g) : AutO →* AutVnat
 ↪  :=
  monsterLift.comp (MonoidHom.codRestrict (MonoidHom.id AutO) liftableSubgroup
    fun g => mem_liftableSubgroup.2 (hlift g))
```

(`VOA/Moonshine/MoonshineCNMonsterActionLift.lean`). The liftable elements form a subgroup (`mem_liftableSubgroup`); the lift of a liftable g is *unique*, because an automorphism of $V^\natural$ is determined by its restriction to $V^\natural{}_2$ (`vnatWeightTwoRestrict_injective`: an automorphism fixing $V^\natural{}_2$ pointwise is the identity, Chapter 47); `monsterLift` is the resulting injective homomorphism, with $\mathrm{monsterLift}(g)(\mathrm{griessNat}\,u) = \mathrm{griessNat}(gu)$ (`monsterLift_apply_griessNat`). Two criteria from Chapter 48 are used repeatedly:

```
theorem isVnatLiftable_of_rational (h : AutVnat)
    (hrat : ∀ u : SpaceB, ∃ u' : SpaceB, h (griessNat u : Vnat) = griessNat u') :
    ∃ g : liftableSubgroup, monsterLift g = h
```

(an automorphism of $V^\natural$ that maps the rational lattice $\mathrm{griessNat}(\mathcal{B})$ into itself *is* the lift of an element of AutO; `VOA/Moonshine/MoonshineCNMonsterActionLift.lean`), and `conwayNorton_autO_of_generators` (`VOA/Moonshine/MoonshineCNMonsterActionMoonshine.lean`): if a generating set lifts, every element lifts, and then the moonshine theorem applies to the lifts.

Why liftability is a rationality question. This is the idea on which the whole chapter rests. $V^\natural{}_2$ is a complex vector space carrying a rational structure, the $\mathbb{Q}$-span $\mathrm{griessNat}(\mathcal{B})$ of the dictionary vectors. AutO consists, by definition, of the $\mathbb{Q}$-linear automorphisms of that rational structure which preserve the product and the form. An automorphism h of $V^\natural$ is only $\mathbb{C}$-linear, but it always preserves the Griess product and the form on $V^\natural{}_2$. Hence:

> *h comes from an element of* AutO *if and only if $h|_{V^\natural{}_2}$ maps the rational lattice* $\mathrm{griessNat}(\mathcal{B})$ *into itself,*

and then the element is unique, since h is determined by $h|_{V^\natural{}_2}$. This is `isVnatLiftable_of_rational` with `mem_range_monsterLift_iff` (Chapter 48). Every later section is an application: to show that a given element of AutO acts on $V^\natural$, we construct *some* automorphism of $V^\natural$ that acts on $V^\natural{}_2$ by a rational matrix equal to it (§§49.2–49.7); to show that every automorphism of $V^\natural$ comes from AutO, we prove that its matrix on $V^\natural{}_2$ is rational (§§49.8–49.12).

The moonshine statement. From Chapter 43: `AutVnat` $=$ $\mathrm{Aut}(V^\natural)$ is the group of vertex-operator-algebra automorphisms of `VnatVOA`; `mckayThompsonFun g` is $T_g(\tau) = q^{-1} + \sum_{n\ge1} \mathrm{tr}(g|V^\natural{}_{n+1})q^n$ on the upper half-plane;

```
def ConwayNortonFor (g : AutVnat) : Prop :=
  ∃ (Γ : Subgroup (GL (Fin 2) ℝ)) (N : ℕ), IsMoonshineGroup Γ N ∧
    IsNormalizedHauptmodul Γ (mckayThompsonFun g)
-- …
def ConwayNortonVia {𝕄 : Type*} [Group 𝕄] (ι : 𝕄 →* AutVnat) : Prop :=
  ∀ g : 𝕄, ConwayNortonFor (ι g)
```

```
-- …
def RationalTraces : Prop :=
  ∀ (g : AutVnat) (n : ℕ), ∃ r : ℚ, PowerSeries.coeff n (mckayThompson g) = r
```

(`VOA/Moonshine/MoonshineCNStatement.lean`), where `IsMoonshineGroup Γ N` says $N \geq 1$, $\Gamma \leq \mathrm{SL}_2(\mathbb{R})$, $\Gamma_0(N) \leq \Gamma$ and Γ is commensurable with $\mathrm{SL}_2(\mathbb{Z})$, and `IsNormalizedHauptmodul Γ f` is the eight-clause definition of a normalised Hauptmodul of Chapter 43. The theorem `ConwayNorton.conwayNorton : ConwayNortonConjecture` (Chapter 47) has no hypotheses.

Physical meaning

The dictionary $\mathbb{C} \otimes \mathcal{B} \cong V^\natural{}_2$ says that the 196884 weight-two states of the moonshine CFT — the stress tensor ω and 196883 further primary fields of dimension 2 — close under the (1)-product of their operator product expansion into AxiomMath's rational algebra. "g is liftable" means that the symmetry g of this finite set of OPE coefficients extends to a symmetry of the *whole* chiral algebra. Since the weight-two fields generate the theory, such an extension is unique when it exists.

49.1.4 Notation used in this chapter

Several letters are used by the sources for different objects. This chapter fixes the following meanings.

symbol	meaning
$\mathcal{B} = \mathcal{A} \oplus \mathcal{X} \oplus \mathcal{W}$	AxiomMath's rational Griess algebra and its three blocks (symmetric matrices, short coordinates, 4096×24 spin matrices)
$\mathcal{D}$, $\mathcal{D}_0$, $\mathcal{O}$	diagonal, traceless diagonal, off-diagonal symmetric matrices in $\mathcal{A}$
$\mathbf{e}_1$; P_0	the vector $(I, 0, 0) \in \mathcal{B}$; the b-orthogonal projection onto $\mathbb{Q}\mathbf{e}_1$
b	AxiomMath's form `bform`
$\mathcal{G}$	`griessIso`: $\mathbb{C} \otimes \mathcal{B} \to V^\natural{}_2$; griessNat$(u) = \mathcal{G}(1 \otimes u)$
T, T^+	the 4096-dimensional extraspecial module; the twisted sector $(V_\Lambda^T)^+$
T_g	the McKay–Thompson function of $g \in \mathrm{Aut}(V^\natural)$
c	an element of `ShortIdx` (a pair $\pm\alpha_c$ of minimal vectors), *except* in $c(\alpha)$
$c(\alpha)$	the coboundary `latCob` of a lattice isometry
ι; O_ι; g_ι	a Leech isometry; its orthogonal 24×24 complex matrix on the bosons; its rational matrix in AxiomMath's coordinates
ρ; λ_ι	a charge intertwiner on T; the normalising scalar of the lift of ι
d	a Golay codeword (in sign changes), or a scalar in the commutant proof (stated there)
π	a permutation of the 24 coordinates (code-preserving in §49.4); also the dictionary permutation in A^π
π_A, π_B, π_C	the three explicit code-preserving permutations of the commutant proof
Q; Q_α	the extraspecial group 2^{1+24} acting on $\mathcal{B}$; the rational unphased spin matrix of the class of $\alpha \in \Lambda$
q_C	the quadratic oscillator state of the dictionary
$Z(\alpha)$	the sign refinement (spin phase) of α; not to be confused with the involution z
σ; σ_0; σ_B	FLM's triality automorphism of $V^\natural$; its restriction to V_0^+; the element of AutO it induces
Φ, Θ; $\mathfrak{D}$	the twisted halves of triality; the triality data (Lean `SigmaData`)
z, z'	the orbifold involution ($+1$ on V_Λ^+, -1 on T^+); the frame-sector sign
x_B, y_B, z_B	AxiomMath's parity involution and its two τ_B-conjugates; through the dictionary $x_B \leftrightarrow z$, $\{y_B, z_B\} \leftrightarrow \{z', zz'\}$ (§49.7)
U_{jk}	the off-diagonal symmetric matrix unit (`sigmaBlockRH j k`, `basisA s(j,k)`)
$\mathcal{K}$; $\mathcal{R}$	an endomorphism commuting with G_{mat} (commutant lemma); its residual $\mathcal{K} - d \cdot 1$

symbol	meaning
H	the complex matrix of $h\|_{V^\natural_2}$ (§49.10)
gmatLift	the injective homomorphism $G_{\mathrm{mat}} \to \mathrm{Aut}(V^\natural)$, $g \mapsto$ monsterLift(g) (`MonsterAction.gmatLift`, Theorem 49.27)

Lean combinators used in the quotations. `e₁ ≪≫ₗ e₂` is the composite of linear equivalences, first `e₁`; `MonoidHom.ofInjective` turns an injective homomorphism into an isomorphism onto its range; `subgroupComap` restricts a homomorphism to the preimage of a subgroup; `MonoidHom.codRestrict` restricts the codomain to a subgroup containing the range; `(h).choose` is the witness picked by `Classical.choice` from an existence proof `h`. `LinearMap.smulRight φ v` is $u \mapsto \varphi(u)v$.

49.2 Lifting $C = 2^{1+24}.\mathrm{Co}_1$ to automorphisms of $V^\natural$

All declarations of §§49.2–49.7 whose names begin with `lift`, `sigmaB`, `tauBLift`, `extra` live in the namespace `VOA.Moonshine.ConwayNorton.M8` (the suffix `M8` is a historical node label). The files are `VOA/Moonshine/MoonshineLRLift*.lean`.

49.2.1 Naturality: compatible pairs are automorphisms

Recall from Chapters 37–38 that the vertex operator of $V^\natural = V^+_\Lambda \oplus T^+$ (we write T^+ for $(V^T_\Lambda)^+$, the Lean submodule `TP`, and `SkewVP` for V^+_Λ) is the block operator

$$Y^\natural\big((u,t),z\big) = \begin{pmatrix} Y(u,z) & \overline{W}(t,z) \\ W(t,z) & Y^T(u,z) \end{pmatrix}, \qquad W(t,z)u = e^{zL_{-1}}Y^T(u,-z)t, \tag{49.2}$$

where Y^T is the module action of V^+_Λ on T^+ (`plusModule.YM`) and $\overline{W}$ is the adjoint of W with respect to the invariant forms B_V (`leechBV`) on V^+_Λ and `TPForm` on T^+.

Theorem 49.1 (Naturality of $V^\natural$). *Let h be an automorphism of the vertex operator algebra V^+_Λ and $\varphi : T^+ \to T^+$ a $\mathbb{C}$-linear bijection such that*

(i) $\varphi(u_{(n)}t) = (hu)_{(n)}\varphi(t)$ *for all $u \in V^+_\Lambda$, $n \in \mathbb{Z}$, $t \in T^+$, and*

(ii) $\mathrm{TPForm}(\varphi t, \varphi t') = \mathrm{TPForm}(t,t')$ *for all t, t'.*

Then $h \oplus \varphi : (u,t) \mapsto (hu, \varphi t)$ is an automorphism of the vertex operator algebra $V^\natural$.

```
noncomputable def vnatAutOfPair (h : Aut leechVOAPlus) (φ : TP ≃ₗ[ℂ] TP)
    (hφ : ∀ (u : SkewVP) (n : ℤ) (t : TP),
      φ (mode (plusModule.YM u) n t) = mode (plusModule.YM (h u)) n (φ t))
    (hT : ∀ t t' : TP, TPForm (φ t) (φ t') = TPForm t t') : AutVnat where
-- …
@[simp] theorem vnatAutOfPair_apply (u : SkewVP) (t : TP) :
    vnatAutOfPair h φ hφ hT ((u, t) : Vnat) = (h u, φ t) := rfl
```

```
theorem lrLift_leechBV (h : Aut leechVOAPlus) (u v : SkewVP) :
    leechBV (h u) (h v) = leechBV u v
```

(`VOA/Moonshine/MoonshineLRLiftNatural.lean`; full names `VOA.Moonshine.ConwayNorton.M8.vnatAutOfPair`, `...M8.vnatAutOfPair_apply`, `...M8.lrLift_leechBV`.)

From the mathematics to the Lean statement

Decoding. `Aut leechVOAPlus` is the type of vertex-operator-algebra automorphisms of V_Λ^+ (bijective linear maps commuting with all modes and fixing the vacuum and the conformal vector; Chapter 1). `TP ≃ₗ[ℂ] TP` is a $\mathbb{C}$-linear bijection of T^+. `mode (plusModule.YM u) n t` is $u_{(n)}t$ (the convention `mode f n = f (-n-1)` of Chapter 1). The output type `AutVnat` is $\mathrm{Aut}(V^\natural)$; the `where` block (not reproduced) builds the automorphism, and `vnatAutOfPair_apply` says, by `rfl`, that it is the block-diagonal map $(u,t) \mapsto (hu, \varphi t)$ on `Vnat = SkewVP × TP`.
Hypotheses. Exactly (i) (`hφ`) and (ii) (`hT`). Two conditions one might expect are *not* hypotheses: that h preserves B_V, and that φ commutes with L_{-1}. The first is the separate lemma `lrLift_leechBV`, valid for *every* automorphism of V_Λ^+; the second follows from (i) at $u = \omega$ because $h\omega = \omega$.
Same statement. Yes; the theorem is a construction, and the `_apply` lemma pins the underlying map. **Could it be vacuous?** No: $h = 1$, $\varphi = 1$ satisfies the hypotheses, and the extraspecial and lattice lifts below provide many nontrivial instances.

Proof on paper. We must check $g\,Y^\natural(a,z)\,g^{-1} = Y^\natural(ga,z)$ for $g = h \oplus \varphi$, block by block in (49.2). The top-left block is $hY(u,z)h^{-1} = Y(hu,z)$ because h is an automorphism. The bottom-right block is hypothesis (i). Applying (i) to the conformal vector $u = \omega$ (fixed by h) gives $\varphi L_n = L_n\varphi$ for all n, in particular for L_{-1} and L_0, so φ preserves conformal weights. For the bottom-left block, the skew-symmetry definition of W gives

$$\varphi\, W(t,z)u = \varphi\, e^{zL_{-1}}Y^T(u,-z)t = e^{zL_{-1}}Y^T(hu,-z)\varphi t = W(\varphi t,z)\,hu.$$

For the top-right block, $\overline{W}$ is defined in Chapter 37 as the adjoint of W for the two invariant forms, $B_V(\overline{W}(t,z)a,u) = \mathrm{TPForm}(a, W(t^*,z^{-1})u)$, where $t \mapsto t^*$ is the contragredient (BPZ-type) operation of Chapter 37, built from L_0, L_1 and fixed scalars; φ commutes with all L_n, hence with $t \mapsto t^*$. Since h preserves B_V and φ preserves TPForm (hypothesis (ii)), the identity just proved for W transposes to $h\,\overline{W}(t,z)a = \overline{W}(\varphi t,z)\varphi a$. That h preserves B_V: the pulled-back form $B_V(h\,\cdot, h\,\cdot)$ is again a fully invariant bilinear form on V_Λ^+ taking the value 1 on the vacuum, and such a form is unique (the library's canonical invariant form, `canonicalInvariantForm`, used in the proof of `lrLift_leechBV`). Vacuum and conformal vector of $V^\natural$ lie in V_Λ^+ and are fixed by h. The file is `VOA/Moonshine/MoonshineLRLiftNatural.lean`. □

Physical meaning

The orbifold theory is assembled from the untwisted sector and the twisted sector glued by the intertwining fields W, $\overline{W}$. A symmetry of the untwisted chiral algebra extends to the orbifold as soon as one specifies how it acts on the twisted sector compatibly with the module structure and the two-point function: the twisted-untwisted OPE W is *determined* by the module action through locality (skew-symmetry), and $\overline{W}$ by the two-point function. This is the familiar statement that a symmetry of the parent theory that commutes with the orbifold group lifts to the orbifold once its action on twisted ground states is fixed.

What the machine verified

Unconditional. `vnatAutOfPair`, `vnatAutOfPair_apply`, `lrLift_leechBV`: `#print axioms` in `VOA/Moonshine/MoonshineLRLiftAudit.lean` gives `[propext, Classical.choice, Quot.sound]`.

49.2.2 Co_0 on V_Λ^+ and on T^+

Let $\iota : \Lambda \to \Lambda$ be a surjective isometry (an element of $\mathrm{Co}_0 = \mathrm{Aut}(\Lambda)$). In the lattice vertex algebra, ι acts by the morphism Φ_ι of Chapter 31 (`latMorph`): it rotates the bosons by ι and sends $e^\alpha \mapsto c(\alpha)e^{\iota\alpha}$, where the *coboundary* $c(\alpha)$ (`latCob`) compares the cocycle ε with $\varepsilon \circ (\iota \times \iota)$.

Definition 49.2 (Co_0 on V_Λ^+)**.** For a surjective isometry ι of Λ, leechPlusLatMorphAut$(\iota) \in \mathrm{Aut}(V_\Lambda^+)$ is the restriction of Φ_ι to V_Λ^+. (This makes sense because Φ_ι is bijective and commutes with the involution θ.)

```
variable (ι : leech.carrier →ₗ[ℤ] leech.carrier)
  (hι : ∀ α β, leech.form (ι α) (ι β) = leech.form α β) (hsurj : Function.Surjective ι)
-- …
def leechPlusLatMorphAut : Aut leechVOAPlus :=
  leechPlusAutOfTheta (latMorphAut ι hι hsurj) fun x => latMorph_thetaLat leech leech ι x
```

(`VOA/Moonshine/MoonshineLRLiftLattice.lean`.)

From the mathematics to the Lean statement

`leech.carrier →ₗ[ℤ] leech.carrier` is a $\mathbb{Z}$-linear endomorphism of the Leech lattice; `hι` says it preserves the form, `hsurj` that it is onto (an isometry of a positive-definite lattice is injective, so it is an automorphism). `latMorphAut` packages Φ_ι as an element of `Aut leechVOA` (bijectivity from `latMorph_injective` and the range criterion `mem_range_latMorph_iff` of Chapter 31); `leechPlusAutOfTheta` restricts a θ-commuting automorphism to V_Λ^+. The definition is exactly the textbook one. It is a construction for *one* ι: $\iota \mapsto \Phi_\iota$ is not a homomorphism on the nose ($\Phi_{\iota\iota'}$ and $\Phi_\iota\Phi_{\iota'}$ differ by a coboundary character), and nothing below needs it to be.

Physical meaning

A rotation of the 24 bosons by a lattice symmetry, dressed by the phases that keep the vertex operators e^α mutually local; it commutes with $X \mapsto -X$, so it is a symmetry of the untwisted sector of the orbifold.

What the machine verified

Unconditional; audited in `VOA/Moonshine/MoonshineLRLiftAudit.lean`, standard axioms.

The twisted sector is $T^+ \subset S[\theta] \otimes T$, where $S[\theta]$ is the twisted Fock space of the half-integrally moded bosons $h(-\frac{1}{2}), h(-\frac{3}{2}), \ldots$ and T is the 4096-dimensional irreducible module of the twisted group algebra of $\Lambda/2\Lambda$ (Chapters 34–36), on which e^α acts by e_α (`eT`). The natural candidate for φ_ι is the tensor product of

- the orthogonal change of oscillator frame on $S[\theta]$ by the matrix O_ι of ι (`liftTwFockMap`), which preserves the Fock form, and
- a linear bijection ρ of T with $\rho\, e_\alpha = c(\alpha)\, e_{\iota\alpha}\, \rho$ for all α.

Theorem 49.3 (The charge intertwiner exists)**.** *For every isometry ι of an even unimodular lattice L, there is a $\mathbb{C}$-linear bijection ρ of the extraspecial module with $\rho(e_\alpha t) = c(\alpha)\, e_{\iota\alpha}(\rho t)$ for all $\alpha \in L$, t.*

```
theorem liftTwChargeIntertwiner_exists :
    ∃ ρ : ExtraT L hEven hU ≃ₗ[ℂ] ExtraT L hEven hU,
      ∀ α t, ρ (eT L hEven hU α t) =
        latCob L L ι α • eT L hEven hU (ι α) (ρ t)
```

(`VOA/Moonshine/MoonshineLRLiftTwisted2.lean`; the section variables are a lattice `L`, its evenness `hEven`, unimodularity `hU : IsUnit (gramMat L).det`, an endomorphism `ι` and the isometry hypothesis `hι`.)

Proof on paper. The operators $\alpha \mapsto c(\alpha)e_{\iota\alpha}$ satisfy the same multiplication law $x_\alpha x_\beta = \varepsilon(\alpha,\beta)x_{\alpha+\beta}$ and the same relation modulo $2L$ as the e_α (`liftTwChargeOp_mul`, `liftTwChargeOp_add_two`; this is what the coboundary c is for). So they define a second representation of the twisted group algebra of $L/2L$ on T. That algebra is a full matrix algebra (its action on T is surjective onto End T, `liftTwChargeAction_surjective`), and a full matrix algebra has a unique irreducible module up to isomorphism; the isomorphism is ρ. □

Physical meaning

The twisted ground states carry a projective representation of the momentum lattice modulo 2; a rotation of the lattice maps it to an equivalent projective representation, and ρ is the unitary (up to normalisation) that implements the equivalence — a "Clifford" intertwiner, as for spinors under rotations.

What the machine verified

Unconditional; audited (`VOA/Moonshine/MoonshineLRLiftAudit.lean`), standard axioms. ρ is unique up to a scalar; the Lean definition `liftTwChargeEquiv` picks one by choice.

Theorem 49.4 (Co_0 on T^+, covariantly). *For a surjective isometry ι of Λ, the map $\varphi_\iota = O_\iota \otimes \rho$ restricted to T^+ satisfies $\varphi_\iota(u_{(n)}t) = (\Phi_\iota u)_{(n)}\varphi_\iota(t)$ for all $u \in V_\Lambda^+$, n, t; and some nonzero multiple $\lambda_\iota\varphi_\iota$ preserves* `TPForm`.

```
theorem liftTwPlusEquiv_mode (hsurj : Function.Surjective ι)
    (u : (orbifold (Subgroup.zpowers leechTheta)).carrier) (n : ℤ) (t : TP) :
    liftTwPlusEquiv ι hι (mode (plusModule.YM u) n t) =
      mode (plusModule.YM (leechPlusLatMorphAut ι hι hsurj u)) n (liftTwPlusEquiv ι hι t)
```

```
theorem liftTwExists_formScalar : ∃ c : ℂˣ, ∀ t t' : TP,
    TPForm (liftTwNormalizedPlusEquiv ι hι c t)
      (liftTwNormalizedPlusEquiv ι hι c t') = TPForm t t'
```

(`VOA/Moonshine/MoonshineLRLiftTwisted2.lean`, `VOA/Moonshine/MoonshineLRLiftTwisted3.lean`.)

From the mathematics to the Lean statement

`liftTwPlusEquiv ι hι : TP ≃ₗ[ℂ] TP` is φ_ι on T^+ (built from the chosen ρ); `orbifold (Subgroup.zpowers leechTheta)` is the fixed-point subalgebra V_Λ^+, the same type as `SkewVP`; `liftTwNormalizedPlusEquiv ι hι c` is $c \cdot \varphi_\iota$ for a unit $c \in \mathbb{C}^\times$. The second statement is an existence of the scalar, as the textbook statement says.

Proof on paper. Covariance. On the generating fields the claim is a computation: the twisted Heisenberg fields transform by O_ι because O_ι is orthogonal (`liftTwFockMap_modeT`); the twisted vertex operator of e^α is (dressing by oscillator exponentials)$\otimes e_\alpha$, the dressing transforms covariantly under the frame change (`liftTwFockMap_DD`), and $\rho e_\alpha = c(\alpha)e_{\iota\alpha}\rho$ supplies exactly the coboundary that Φ_ι puts on e^α. Every state of V_Λ is a "word" (oscillators applied to an e^α), and its twisted field is obtained from the fields of the letters by iterated twisted normal-ordered products; conjugation by a linear bijection preserves those products (`liftTwConjField_star`), so covariance propagates to all states by induction on words (`liftTwLatticeEquiv_word`, `liftTwLatticeEquiv_YML`). Both O_ι and ρ commute with θ, so φ_ι restricts to T^+.

The form. `TPForm` is the restriction of (Fock form)⊗(T-form). The Fock form is invariant under the orthogonal frame change (`liftTwFockMap_form`). The T-form pulled back by ρ has the same adjoint operation $A \mapsto A^*$ on End T as the original (both make e_α adjoint to $\pm e_\alpha$), and two nondegenerate forms with the same adjoint operation on all of End T are proportional (a rank-one-operator argument, `liftTwForm_unique`). So φ_ι scales `TPForm` by some $z \neq 0$, and $\lambda_\iota = z^{-1/2}$ (any square root) normalises it. □

Physical meaning

Covariance of every twisted vertex operator is the statement that the rotated twisted sector is again a twisted sector of the rotated theory — automatic in a path-integral picture, but here it must be checked mode by mode. The form normalisation fixes the overall scale of the twisted ground-state wave functions so that the two-point function is preserved.

What the machine verified

Unconditional; audited, standard axioms.

Definition 49.5 (The lift of a Leech isometry). liftTwVnatAut(ι) = $\Phi_\iota|_{V_\Lambda^+} \oplus \lambda_\iota\varphi_\iota \in \mathrm{Aut}(V^\natural)$, with the scalar λ_ι of Theorem 49.4 chosen once and for all.

```
def liftTwVnatAut (hsurj : Function.Surjective ι) : AutMonster.AutVnat :=
  liftTwVnatAutOfForm ι hι hsurj (liftTwExists_formScalar ι hι).choose
    (liftTwExists_formScalar ι hι).choose_spec
-- …
@[simp] theorem liftTwVnatAut_apply (hsurj : Function.Surjective ι)
    (u : SkewVP) (t : TP) :
    liftTwVnatAut ι hι hsurj ((u, t) : Vnat) =
      (leechPlusLatMorphAut ι hι hsurj u,
        liftTwNormalizedPlusEquiv ι hι (liftTwExists_formScalar ι hι).choose t) := rfl

end Normalization
```

(`VOA/Moonshine/MoonshineLRLiftTwisted3.lean`.)

From the mathematics to the Lean statement

`liftTwVnatAutOfForm` is Theorem 49.1 applied to the pair; `(…).choose` is the scalar chosen by `Classical.choice`. The section variables are `ι` and `hι` as above. Two features must be kept in mind. (a) The lift is a *chosen* element: λ_ι is determined only up to sign and ρ only up to a scalar, so different choices differ by the extraspecial elements of the next subsection (and by the central element z). Nothing below depends on which choice was made: every later statement is of the form "*the chosen* lift is liftable / has these blocks", and the visible group is matched by multiplying with extraspecial lifts. (b) $\iota \mapsto$ liftTwVnatAut(ι) is not claimed to be a homomorphism.

Physical meaning

The element of $C = C_{\mathbb{M}}(z)$ above the lattice rotation $\iota \in \mathrm{Co}_0$; it is defined only up to the kernel 2^{24} of $C \to \mathrm{Co}_1$ and the centre, exactly as a rotation lifts to the spin group only up to sign.

What the machine verified

Unconditional definition; `liftTwVnatAut` audited, standard axioms.

49.2.3 The extraspecial group

For $\mu \in \Lambda$, the character automorphism $e^\alpha \mapsto (-1)^{\langle \mu,\alpha\rangle} e^\alpha$ of V_Λ (`extraLeechAut`) commutes with θ and restricts to V_Λ^+ (`extraLeechPlusAut`); on the twisted sector, $\mathrm{id} \otimes e_\mu$ intertwines it (`extraPhi_YML`: $e_\mu e_\alpha = (-1)^{\langle \mu,\alpha\rangle} e_\alpha e_\mu$ up to the cocycle). The raw operator scales `TPForm` by the sign $(-1)^{\langle \mu,\mu\rangle/2}\varepsilon(\mu,\mu)$:

```
theorem extraPlusPhi_form (x y : TP) :
    TPForm (extraPlusPhi μ x) (extraPlusPhi μ y)
      = ((-1 : ℂ) ^ (leech.form μ μ / 2) * latticeCocycle leech μ μ) * TPForm x y
```

(`VOA/Moonshine/MoonshineLRLiftExtra.lean`), so a square root of that sign normalises it (`extraPlusIsometry`).

Definition 49.6 (Extraspecial lifts). extraVnatAut(μ) = extraLeechPlusAut(μ) $\oplus$ extraPlusIsometry(μ) $\in$ Aut($V^\natural$).

```
def extraVnatAut (μ : leech.carrier) : AutVnat :=
  vnatAutOfPair (extraLeechPlusAut μ) (extraPlusIsometryEquiv μ)
    (fun u n t => extraPlusIsometry_mode μ u n t) (fun x y => extraPlusIsometry_form μ x y)
-- …
theorem extraVnatAut_apply (μ : leech.carrier) (u : SkewVP) (t : TP) :
    extraVnatAut μ ((u, t) : Vnat) = (extraLeechPlusAut μ u, extraPlusIsometry μ t)
```

(`VOA/Moonshine/MoonshineLRLiftExtraAut.lean`, `VOA/Moonshine/MoonshineLRLiftExtra.lean`.)

From the mathematics to the Lean statement

Exactly the textbook pair, assembled by Theorem 49.1. As for the lattice lifts, each extraVnatAut(μ) is an individual element: the map $\mu \mapsto$ extraVnatAut(μ) is a homomorphism only up to central signs, which is not claimed (the module docstring says so). Chapter 48 proves these elements liftable (`exists_monsterLift_eq_extraVnatAut`).

Physical meaning

The momentum-phase symmetries $e^{i\pi\langle \mu,p\rangle}$ of the Leech CFT; on twisted ground states they act by the Clifford generators e_μ, and together they generate the extraspecial group 2^{1+24}, the normal subgroup of $C_{\mathbb{M}}(z)$.

What the machine verified

Unconditional; audited, standard axioms.

49.3 Block forms in AxiomMath's coordinates and the rational criterion

49.3.1 The untwisted blocks

The rational dictionary of Chapter 48 sends $u = (A, x, N) \in \mathcal{B}$ to the vector of ${V^\natural}_2$ whose V_Λ^+-component is $Q_C(A^\pi) + \sum_c x_c \zeta'_c x_{\alpha_c}$ (a quadratic oscillator state in Conway's coordinates plus a combination of the states $x_\alpha = e^\alpha + e^{-\alpha}$ for the short vectors α_c, with phases ζ') and whose T^+-component is $\lambda \sum_i h_{f_i}(-\frac{1}{2}) \otimes \Psi(N_{\cdot,\pi i})$. The "untwisted dictionary" `untwistedDictNat ζ` uses the first component only, with a choice of phases ζ; the phases `griessShortSign` of Chapter 48 make it rational, and the full dictionary uses $\zeta' =$ `fullShortSign`, related by the diagonal sign $c \mapsto \varepsilon(\alpha_c, \alpha_c)$ (`griessTrX`, `VOA/Moonshine/MoonshineLRGriessTransfer.lean`, documented in Chapter 48).

Theorem 49.7 (Untwisted block of a lattice lift). *For every surjective isometry ι of Λ there are a rational 24×24 matrix g_ι (the matrix of ι in AxiomMath's coordinates) and a signed permutation s_ι of the 98280 short coordinates such that, for all $A \in \mathcal{A}$ and $x \in \mathcal{X}$,*

$$\mathrm{liftTwVnatAut}(\iota)\big(\mathrm{untwistedDictNat}(A, x, 0)\big) = \mathrm{untwistedDictNat}\big(g_\iota A g_\iota^{\mathsf{T}},\ s_\iota(x),\ 0\big).$$

```
theorem liftSignNat_untwisted (A : symMat) (x : SpaceX) :
    liftTwVnatAut ι hι hsurj
        (untwistedDictNat griessShortSign (A, x, 0) : Vnat) =
      (untwistedDictNat griessShortSign
        (liftBlockSymMat ι A, liftSignX ι hι x, 0) : Vnat)
```

```
theorem liftSignWeight_sign (c : ShortIdx) :
    liftSignWeight ι hι c = 1 ∨ liftSignWeight ι hι c = -1
-- …
theorem liftSignX_apply (x : SpaceX) (c : ShortIdx) :
    liftSignX ι hι x (liftSignPerm ι hι c) = liftSignWeight ι hι c * x c
```

(`VOA/Moonshine/MoonshineLRLiftSign.lean`; `liftBlockSymMat ι A` $= g_\iota A g_\iota^{\mathsf{T}}$ with $g_\iota =$ `liftBlockMatrix ι`, `VOA/Moonshine/MoonshineLRLiftBlock.lean`.)

From the mathematics to the Lean statement

`liftSignX ι hι` is the signed permutation: it moves coordinate c to `liftSignPerm ι hι c` (the short pair containing $\pm\iota\alpha_c$) with weight `liftSignWeight ι hι c` $= \pm 1$. The "weights are signs" clause is the content: a priori the coefficient is $r_c = \zeta_c\, c(\alpha_c)/\zeta_{p(c)}$, a complex number. The statement is in the coordinates `untwistedDictNat griessShortSign`; the transfer to `griessNat` conjugates the short block by `griessTrX` (Chapter 48).

Proof on paper. On quadratic oscillator states $h_a(-1)h_b(-1)\mathbb{1}$, Φ_ι acts by $O_\iota \otimes O_\iota$, which in matrix language is $M \mapsto O_\iota M O_\iota^{\mathsf{T}}$, and Conway's frame converts O_ι into the rational matrix g_ι (`liftBlockMatrix_frame`). On x_α, $\Phi_\iota x_\alpha = c(\alpha) x_{\iota\alpha}$. Every norm-four vector is $\pm\alpha_c$ for a unique c (`liftSignShort_existsUnique`), so ι permutes the short pairs. The coefficient r_c has square one: the cocycle relation at $\beta = \alpha$ with $c(2\alpha) = 1$ gives $c(\alpha)^2 = \varepsilon(\alpha,\alpha)/\varepsilon(\iota\alpha,\iota\alpha)$ (`liftSignLatCob_sq`), the dictionary phases satisfy $\zeta_c^2\varepsilon(\alpha_c,\alpha_c) = 1$, and $\varepsilon(-\beta,-\beta) = \varepsilon(\beta,\beta)$. Hence $r_c^2 = 1$, $r_c = \pm 1$. □

Physical meaning

The weight-two primaries $\partial X^a \partial X^b$ rotate as a symmetric tensor and the 98280 "vertex operator" primaries $\cos(\alpha \cdot X)$ are permuted with signs: in a real basis the lattice symmetries act by signed permutations, which is why they preserve a rational structure.

What the machine verified

Unconditional for *every* isometry; audited, standard axioms. (The extraspecial lifts fix the $\mathcal{A}$ block and act by $x_c \mapsto (-1)^{\langle\mu,\alpha_c\rangle} x_c$: `liftBlockExtraNat_symBlock`, `liftBlockExtraNat_shortBlock`, same file family, also audited.)

Trap / dead end

An open, unneeded question. Whether $\varepsilon(\alpha_c,\alpha_c) = 1$ for all short classes (which would make `griessTrX` the identity) was left open: it is equivalent to a divisibility $4 \mid \sum_i \langle B_i, B_i\rangle (B.\mathrm{repr}\,\alpha_c)_i^2$ that depends on the chosen basis of Λ. It is not needed; all block formulas hold with the sign conjugation.

49.3.2 The twisted block

On the twisted weight-two space $(T^+)_2$, spanned by $h_v(-\frac{1}{2}) \otimes t$, the lift of ι acts by $h_v(-\frac{1}{2}) \otimes t \mapsto h_{O_\iota v}(-\frac{1}{2}) \otimes \lambda_\iota \rho t$ (`liftWNat_hP`), and the extraspecial lift by $t \mapsto (\text{scalar})\, e_\mu t$. In AxiomMath's spin coordinates (the isomorphism `spinIso` of the 4096-dimensional spin module with T, Chapter 48), e_μ is AxiomMath's phased spin matrix `spinOp` of the class of μ (`liftWExtra_spinOp`), and the 24 spin columns transform as $N \mapsto (\lambda_\iota \rho) N O_\iota^{\mathsf{T}}$ (`liftWNat_coordinates`; `VOA/Moonshine/MoonshineLRLiftWBlock.lean`). These are complex statements; whether $\lambda_\iota \rho$ is rational is the subject of the criterion below.

49.3.3 The rational liftability criterion

Write, for $\alpha \in \Lambda$ with class $(a, \delta) \in \mathcal{C} \times \mathcal{C}^*$ in $\Lambda/2\Lambda$ (code word and cocode element), Q_α for AxiomMath's *unphased* rational spin matrix of that class (`liftMonoQmat α = qmatR ℚ 0 a δ`, a signed permutation matrix), and $\mathrm{spinOp}(\alpha) = Z(\alpha) Q_\alpha$ for the phased one, Z the sign refinement `signRefinement`, $Z^2 = \varepsilon(\alpha,\alpha)(-1)^{\langle \alpha,\alpha\rangle/2}$ (`liftMonoRefinement_sq`).

Theorem 49.8 (Rational criterion for lattice lifts)**.** *Let ι be a surjective isometry of Λ.*

(a) liftTwVnatAut(ι) *is the lift of an element of* AutO *if and only if its normalised twisted part maps rational spin-dictionary vectors to rational ones.*

(b) For every α the number $w(\iota,\alpha) = c(\alpha) Z(\iota\alpha)/Z(\alpha)$ is ± 1.

(c) If R is a rational 4096×4096 matrix with $R^{\mathsf{T}} R = 1$ and $R Q_\alpha = w(\iota,\alpha)\, Q_{\iota\alpha} R$ for all $\alpha \in \Lambda$ (equivalently, for the 24 basis vectors of Λ), then liftTwVnatAut(ι) *is the lift of an element of* AutO.

```

(`VOA/Moonshine/MoonshineLRLiftLiftable.lean`, `VOA/Moonshine/MoonshineLRLiftLiftable2.lean`, `VOA/Moonshine/MoonshineLRLiftLiftable3.lean`; section variables `ι`, `hι` as before.)

From the mathematics to the Lean statement

Decoding. "Lift of an element of AutO" is `∃ g : liftableSubgroup, monsterLift g = …`. `spinDict N` is the twisted part of the dictionary for $N \in \mathcal{W}$; `liftWScalar ι hι` is the scalar λ_ι chosen in Definition 49.5. `liftMonoWeight ι α` is the rational number ± 1 equal to `liftMonoPhase ι α` $= w(\iota, \alpha)$. `R.map (Rat.castHom ℂ)` would be R read in $\mathbb{C}$; in (c) everything is rational. `latticeBasis leech j` is the chosen $\mathbb{Z}$-basis of Λ.
Hypotheses. In (c): orthogonality of R and the intertwining equation; no hypothesis relates R to the chosen ρ — the theorem shows that the chosen normalised ρ *is* $\pm R$.
Strength. (a) is an equivalence; (c) is a sufficient condition, which is all that is used.

Proof on paper. (a) The untwisted block is already rational (Theorem 49.7), so the lift maps griessNat($\mathcal{B}$) into itself iff the twisted block does; then `isVnatLiftable_of_rational` applies. Conversely a liftable element maps rational vectors to rational ones. (b) $c(\alpha)^2 = \varepsilon(\alpha,\alpha)/\varepsilon(\iota\alpha,\iota\alpha)$ and $Z(\beta)^2 = \varepsilon(\beta,\beta)(-1)^{\langle\beta,\beta\rangle/2}$, with $\langle\iota\alpha,\iota\alpha\rangle = \langle\alpha,\alpha\rangle$; so $w^2 = 1$. Note that $c(\alpha)$ alone can be $\pm i$ (exactly when the diagonal cocycles of α and $\iota\alpha$ differ, `liftMonoLatCob_imaginary_iff`); the spin phases absorb it. (c) Multiply the equation by the phases: $R\,\mathrm{spinOp}(\alpha) = c(\alpha)\,\mathrm{spinOp}(\iota\alpha)R$, which is the defining equation of ρ. Any two invertible solutions differ by an operator commuting with all spinOp(α), hence by a scalar (Schur's lemma for the irreducible module T, `liftLiftableSpinCommuteScalar`); so the chosen ρ is zR. The normalisation λ_ι makes $\lambda_\iota\rho$ orthogonal for the dot product (`liftLiftableChargeDot`), and R is orthogonal, so $(\lambda_\iota z)^2 = 1$ and $\lambda_\iota\rho = \pm R$ is rational (`liftLiftableChargeSign`). Then (a) applies. The reduction to the 24 basis vectors holds because the set of α for which the equation holds is closed under addition and negation (`liftGenIntertwines_add`, `liftGenIntertwines_neg`). □

Physical meaning

A lattice symmetry acts on the 4096 twisted ground states by a "spinor" matrix. The theorem says: the symmetry preserves AxiomMath's rational structure on the full Griess algebra exactly when this spinor matrix can be chosen rational; and a rational solution of the Clifford intertwining equation, if one exists, *is* the spinor matrix.

What the machine verified

Unconditional; all four declarations audited in `VOA/Moonshine/MoonshineLRLiftAudit.lean`, standard axioms.

49.4 The generators: Golay signs, Mathieu permutations and Conway's ξ

In Conway's coordinates $\Lambda \subset \mathbb{Z}^{24}$ (vectors u with $u_i \equiv m + 2d_i \pmod 4$ for a common m and a Golay codeword d, and $\sum u_i \equiv 4m \pmod 8$; `codeLattice`), Co_0 is generated by three kinds of elements: sign changes on a Golay codeword, permutations of the 24 coordinates preserving the Golay code (M_{24}), and one non-monomial element ξ.

Definition 49.9 (Monomial generators). For a Golay codeword d, `liftGenGolay c` (Lean's variable is called `c`) negates the coordinates in the support of d; for a permutation π of $\{0,\dots,23\}$ preserving the Golay code, `liftGenMathieu σ hσ` (Lean's variable is called `σ`) permutes the coordinates.

```
def liftGenSign (c : Fin 24 → ZMod 2) (u : Fin 24 → ℤ) : Fin 24 → ℤ :=
  fun i => if c i = 0 then u i else -u i
-- …
def liftGenGolay (c : MonsterGriess.Code.C) : leech.carrier →ₗ[ℤ] leech.carrier :=
  ((leechEquiv.trans (liftGenSignEquiv c)).trans
   ↪  leechEquiv.symm).toAddMonoidHom.toIntLinearMap
-- …
def liftGenPreservesCode (σ : Equiv.Perm (Fin 24)) : Prop :=
  ∀ d, permLin (ZMod 2) σ d ∈ MonsterGriess.Code.C ↔ d ∈ MonsterGriess.Code.C
-- …
def liftGenMathieu (σ : Equiv.Perm (Fin 24)) (hσ : liftGenPreservesCode σ) :
    leech.carrier →ₗ[ℤ] leech.carrier :=
  ((leechEquiv.trans (liftGenPermEquiv σ hσ)).trans
    leechEquiv.symm).toAddMonoidHom.toIntLinearMap
```

(`VOA/Moonshine/MoonshineLRLiftLiftable3.lean`.)

From the mathematics to the Lean statement

`leechEquiv` identifies the abstract Leech lattice of the library with Conway's coordinate model; `liftGenSignEquiv`, `liftGenPermEquiv` are the coordinate maps, proved to preserve `codeLattice` (`liftGenSign_mem`: the sum of a Leech vector over a codeword support is divisible by 4; `liftGenPerm_mem`). `permLin (ZMod 2) σ d` is the permuted binary word; the code-preservation condition is an "iff", i.e. π maps the code onto itself. Isometry and surjectivity are separate lemmas (`liftGenGolay_isometry`, `liftGenMathieu_surjective`, …). Exactly the textbook monomial group $2^{12}{:}M_{24}$, with no choice of generators.

Physical meaning

Sign flips and permutations of the 24 bosons that preserve the lattice: the "monomial" symmetries.

What the machine verified

Unconditional; audited, standard axioms.

Theorem 49.10 (The monomial group lifts). *For every Golay codeword d and every code-preserving permutation π, the chosen lifts* liftTwVnatAut(liftGenGolay d) *and* liftTwVnatAut(liftGenMathieu π) *are lifts of elements of* AutO.

theorem liftSpinRational_of_diagonal {T : Type*} (E : (SpinIdx → ℂ) ≃ₗ[ℂ] (SpinIdx → ℂ))
    (horth : ∀ v w, E v ·ᵥ E w = v ·ᵥ w)
    (d e : T → SpinIdx → ℂ)
```

```
    (hint : ∀ t v, E (Matrix.diagonal (d t) *ᵥ v) =
      Matrix.diagonal (e t) *ᵥ E v)
    (hsep : ∀ j k, (∀ t, d t j = d t k) → j = k) :
    ∃ (σ : Equiv.Perm SpinIdx) (ε : SpinIdx → ZMod 2),
      ∀ v, E v = (liftGenSignedMatrix σ ε).map (Rat.castHom ℂ) *ᵥ v
```

(VOA/Moonshine/MoonshineLRLiftLiftable4.lean.)

From the mathematics to the Lean statement

The two theorems have no hypotheses beyond the data (d a codeword, π code-preserving; Lean's c, σ). The auxiliary `liftSpinFrameLattice α` says: all Conway coordinates of α are $\equiv 2n \pmod 4$ for one n, and their sum is $\equiv 0 \pmod 8$. `liftSpinRational_of_diagonal` is a general lemma: an orthogonal bijection E of $\mathbb{C}^{4096}$ that carries a separating family of diagonal operators $\mathrm{diag}(d_t)$ to diagonal operators is a rational signed permutation matrix (`liftGenSignedMatrix σ ε`, entries ± 1 placed by a permutation).

Proof on paper. The spin matrices Q_α of the vectors of the "frame sublattice" `liftSpinFrameLattice` commute with each other (their pairings are even) and include the frame involution and all even cocode classes, whose matrices are diagonal in AxiomMath's spin basis and separate the 4096 basis vectors (`liftSpinTest_separates`). Golay sign changes and code-preserving permutations preserve the frame sublattice (`liftSpinGolay_frame`, `liftSpinMathieu_frame`). The normalised charge operator $\lambda_\iota\rho$ intertwines Q_α with $\pm Q_{\iota\alpha}$, so it carries the separating diagonal family to a diagonal family; a linear map with this property sends each basis line to a basis line, i.e. it is monomial, and orthogonality forces the nonzero entries to be ± 1. So $\lambda_\iota\rho$ is a rational signed permutation (`liftSpinSigned_exists`) satisfying the intertwining equation for every α, and Theorem 49.8(c) applies. No enumeration of the 4096-dimensional module is used; the permutation and signs are obtained by choice (`liftSpinGolayPerm`, `liftSpinMathieuSigns`, ...), not by closed formulas. □

Physical meaning

Monomial symmetries permute the twisted ground states (up to signs) because they preserve a maximal commuting set of Clifford generators — the analogue of a rotation that maps coordinate axes to coordinate axes acting on spinors by a signed permutation of the weight basis.

What the machine verified

Unconditional; both theorems audited, standard axioms.

Definition 49.11 (Conway's ξ). Number the coordinates by MOG columns, $\mathrm{coord}(r, j) = r + 4j$ ($r \in \{0,1,2,3\}$ the row, $j \in \{0,\dots,5\}$ the column). On each column ξ acts by the 4×4 matrix $\mathrm{diag}(1,-1,-1,-1)\,\frac{1}{2}(J - 2I)$, J the all-ones matrix:

$$(\xi u)_{(0,j)} = \tfrac{1}{2}s_j - u_{(0,j)}, \qquad (\xi u)_{(r,j)} = u_{(r,j)} - \tfrac{1}{2}s_j \ (r \neq 0), \qquad s_j = \textstyle\sum_r u_{(r,j)}.$$

```
def liftXiBlock (u : Fin 4 → ℚ) : Fin 4 → ℚ :=
  fun r => if r = 0 then (∑ s, u s) / 2 - u r else u r - (∑ s, u s) / 2
-- …
theorem liftXi_cube (α : leech.carrier) : liftXi (liftXi (liftXi α)) = α
-- …
theorem liftXi_isometry (α β : leech.carrier) :
    leech.form (liftXi α) (liftXi β) = leech.form α β
-- …
theorem liftXiMatrix_nonmonomial :
    liftXiMatrix 0 0 = -1 / 2 ∧ liftXiMatrix 0 1 = 1 / 2
```

(`VOA/Moonshine/MoonshineLRLiftXi.lean`.)

From the mathematics to the Lean statement

`liftXiBlock` is the column formula above; `liftXi : leech.carrier →ₗ[ℤ] leech.carrier` is the induced integral map, defined through `liftXiInt`, which uses that column sums of Leech vectors are even (`liftXiCol_parity`) and preserves the lattice (`liftXiInt_mem`, from the hexacode description of the Golay code). $\xi^3 = 1$, ξ is an isometry and surjective (`liftXi_surjective`); `liftXiMatrix` is its rational 24×24 matrix, and the two entries $-\frac{1}{2}, \frac{1}{2}$ in one row witness that it is not monomial.

Physical meaning

A genuinely "non-classical" lattice symmetry that mixes the four bosons of each MOG column by a Hadamard-type rotation; it is what makes Co_0 much bigger than the monomial group.

What the machine verified

Unconditional; audited, standard axioms.

Theorem 49.12 (ξ lifts). liftTwVnatAut(ξ) *is the lift of an element of* AutO.

```
theorem liftXiCharge_projective :
    ∃ (T : Matrix SpinIdx SpinIdx ℚ) (z : ℂ), z ≠ 0 ∧
      ∀ v : SpinIdx → ℂ, T.map (Rat.castHom ℂ) *ᵥ v = z • liftXiCharge v
-- …
theorem liftXi_liftable : ∃ g : liftableSubgroup,
    monsterLift g = liftTwVnatAut liftXi liftXi_isometry liftXi_surjective
```

(`VOA/Moonshine/MoonshineLRLiftXi.lean`.)

From the mathematics to the Lean statement

`liftXiCharge` is the normalised charge operator $\lambda_\iota\rho$ of ξ in spin coordinates. The first theorem says it is a complex multiple of a rational matrix; the second is the conclusion, with no hypotheses.

Proof on paper. Rational descent. Let M be the complex matrix of $\lambda_\iota\rho$. The intertwining equation $MQ_\alpha = w(\xi,\alpha)Q_{\xi\alpha}M$ has rational coefficients. For a $\mathbb{Q}$-linear functional $f : \mathbb{C} \to \mathbb{Q}$, applying f entrywise commutes with multiplication by rational matrices (`liftXiDual_intertwine`), so $f(M)$ is a rational solution of the same equation; for a suitable f it is nonzero. By Schur's lemma for T, $f(M) = zM$ with $z \in \mathbb{C}^\times$ (`liftXiCharge_projective`). Orthogonality of M makes $f(M)^{\mathsf{T}} f(M) = z^2$, so $z^2 \in \mathbb{Q}$. Since $\xi^3 = 1$, M^3 intertwines each Q_α with $\pm Q_\alpha$, hence normalises the separating diagonal family, hence is a rational signed permutation (`liftXiCharge_cube_signed`); then $f(M)^3 = z^3M^3$ gives $z^3 \in \mathbb{Q}$. So $z = z^3/z^2 \in \mathbb{Q}$ and $M = z^{-1}f(M)$ is rational. Theorem 49.8(c) applies with $R = M$ (`liftXiSpinMatrix`, chosen noncomputably; no entrywise Hadamard formula is asserted). □

Physical meaning

The spinor matrix of the Hadamard rotation is itself a (normalised) Hadamard-type matrix with entries in $2^{-k}\mathbb{Z}$; the argument proves its rationality without ever writing it down.

What the machine verified

Unconditional; audited, standard axioms.

49.5 The visible group acts on $V^\natural$

AxiomMath's visible group is defined uniformly, as the image of `thetaEquiv` on compatible pairs $p = (s, g) \in \mathrm{Pvis}$, not by generators. The lifting is therefore done uniformly too.

Theorem 49.13 (Every visible element is liftable). *Every element of G_{vis}, regarded as an element of* AutO*, is liftable. Consequently Conway–Norton holds for every element of* AutO *as soon as some liftable τ together with G_{vis} generates* AutO.

```
theorem liftVisRAllVisible : ∀ (g : SpaceB ≃ₗ[ℚ] SpaceB) (hg : g ∈ Gvis),
    IsVnatLiftable ⟨g, Gvis_le_AutO hg⟩
```

(`VOA/Moonshine/MoonshineLRLiftVisible2.lean`.)

```

        IsNormalizedHauptmodul Γ (mckayThompsonFun h)
```

(`VOA/Moonshine/MoonshineLRMonsterVisible.lean`; full names `VOA.Moonshine.ConwayNorton.M8.liftVisRAllVisible`, `...M8.conwayNorton_autO_of_tauB`.)

From the mathematics to the Lean statement

Decoding. `⟨g, Gvis_le_AutO hg⟩ : AutO` is g regarded as an element of AutO (using $G_{\mathrm{vis}} \le$ AutO). `visibleSetAutO` is the same set inside `AutO`. In `conwayNorton_autO_of_tauB`: `hτ` says τ is liftable; `hGmat` says $\langle \tau, G_{\mathrm{vis}} \rangle =$ AutO (as subgroups of `AutO`, `⊤` the whole group). The conclusion for g: an automorphism h of $V^\natural$ acting on $V^\natural{}_2$ as g does, whose T_h is a normalised Hauptmodul for a moonshine group — the clauses of `ConwayNortonFor h` spelled out.
Hypotheses. `liftVisRAllVisible`: none. `conwayNorton_autO_of_tauB`: `hτ` and `hGmat`, both genuine inputs at this point; they are discharged for $\tau = \tau_B$ in §49.7 (`hτ` unconditionally, `hGmat` only under `GmatEqAutO`).

Proof on paper. Let $p = (s, g) \in \mathrm{Pvis}$ and ι_g the Leech isometry with matrix g (`liftVisIsometry`; AxiomMath's matrices act on row vectors, the library's on columns, hence a transpose, `liftVisBlockMatrix`). Compatibility of p says s conjugates the extraspecial group as ι_g does: $s^{\mathsf{T}} Q_\alpha = w'(p,\alpha) Q_{\iota_g \alpha} s^{\mathsf{T}}$ with signs w' (`liftVisIntertwine`). Compare with the chosen charge operator $\lambda_\iota \rho$ of ι_g, which satisfies the same intertwining equation with the signs $w(\iota_g, \alpha)$ (Theorem 49.8). The relative operator $D = (s^{\mathsf{T}})^{-1} \lambda_\iota \rho$ is a priori a *complex* orthogonal matrix, and it commutes with every Q_α up to the sign $e_\alpha = w(\iota_g, \alpha) w'(p, \alpha)$ (`liftVisRelativeCharge_intertwine`). Three steps:

(i) *D is rational.* Among the Q_α are the diagonal matrices of the frame-sublattice vectors, which separate the 4096 basis vectors (as in Theorem 49.10). D conjugates each of them to $\pm$ itself, so it maps each basis line to a basis line: D is monomial, and orthogonality makes its entries ± 1. So D is a rational signed permutation matrix (`liftVisRelativeCharge_signed`).

(ii) *$D = \pm Q_\mu$.* The 2^{24} matrices Q_μ (μ running over $\Lambda/2\Lambda$) form a basis of the matrix algebra $M_{4096}(\mathbb{Q})$, and conjugation by Q_q multiplies Q_μ by the commutator sign $\kappa(\mu, q) = \pm 1$; distinct μ give distinct characters $q \mapsto \kappa(\mu, q)$. Expand $D = \sum_\mu d_\mu Q_\mu$. The relation $D Q_q = e_q Q_q D$ says that every μ with $d_\mu \neq 0$ has $\kappa(\mu, \cdot) = e_\cdot$; so only one μ occurs (in Lean: some μ has $\mathrm{tr}(Q_\mu^{\mathsf{T}} D) \neq 0$, `liftVisRTrace_nonzero`, and then its character is e, `liftVisRTrace_sign`). Hence $D = d\, Q_\mu$, and $D^{\mathsf{T}} D = 1$ forces $d = \pm 1$ (`liftVisRExtraspecial`, `liftVisRRelative`).

Cancelling the discrepancy. So the chosen lift of ι_g is liftable with blocks $(g^{\mathsf{T}}Ag,\ \cdot\ ,\ s^{\mathsf{T}}(\pm Q_\mu)Ng)$ (`liftVisRChosen`). Extraspecial lifts realise every $\pm Q_\mu$ on $\mathcal{W}$ while fixing $\mathcal{A}$ (`liftVisRSpinLift`; the central -1 is the square of an extraspecial lift of odd quadratic norm, `liftVisRCentral`), so multiplying by one of them cancels the discrepancy. The product agrees with thetaEquiv(p) on the $\mathcal{A}$ and $\mathcal{W}$ blocks; two automorphisms commuting with x_B that agree on those blocks are equal, because the $\mathcal{X}$ block is determined by the action on $\mathcal{W}$ through the product $\mathcal{X} \times \mathcal{W} \to \mathcal{W}$, which detects x (`liftVisParity_ext`). Hence thetaEquiv(p) is liftable (`liftVisRLiftable`). The second part is `conwayNorton_aut0_of_generators` of Chapter 48 with its `hvis` discharged. □

Physical meaning

Every element of $C_{\mathbb{M}}(z) = 2^{1+24}.\mathrm{Co}_1$, in AxiomMath's presentation, is a symmetry of the full moonshine CFT. The bookkeeping of signs is the usual ambiguity of lifting Co_0 to the extraspecial extension, resolved by multiplying with a momentum-phase symmetry.

What the machine verified

`liftVisRAllVisible`: unconditional. `conwayNorton_aut0_of_tauB`: conditional on its arguments `hτ`, `hGmat`. Both audited in `VOA/Moonshine/MoonshineLRLiftAudit.lean`, standard axioms.

49.6 Triality: σ is rational on the Griess algebra

49.6.1 Frame sectors

Recall from Chapters 39–42 the Golay frame sublattice $\Lambda_0 \subset \Lambda$ of index two. It splits each half of $V^\natural$ in two:

- $V_\Lambda^+ = V_0^+ \oplus V_3^+$, where V_0^+ (Lean `frameSector 0`) is spanned by the states with momentum in Λ_0 and V_3^+ (Lean `frameSector 1`) by those with momentum in the other coset. (The names V_0, V_3 are inherited from Chapters 39–42, where the frame sectors are labelled as in FLM; "3" is a label, not a number of anything.) Equivalently, they are the ± 1 eigenspaces of the frame involution `plusFrame`.
- $T^+ = T_0^+ \oplus T_1^+$ (Lean `TPframe 0`, `TPframe 1`), the two eigenspaces of the frame involution on the twisted sector, indexed by $\mathbb{Z}/2$.

FLM's triality σ is assembled from *triality data* $\mathfrak{D}$ (Lean `SigmaData`, Chapter 42): an automorphism σ_0 of V_0^+ (`v0Sigma`), a label $s = \mathfrak{D}.s \in \mathbb{Z}/2$, a σ_0-twisted intertwiner $\Phi : V_3^+ \to T_s^+$ with inverse Ψ, and a map Θ of the other twisted sector T_{s+1}^+ to itself. So σ preserves V_0^+ and T_{s+1}^+ and exchanges V_3^+ with T_s^+. Which of the two twisted frame sectors is exchanged with V_3^+ (the label s) is fixed by the construction of Φ in Chapter 41; nothing below depends on its value. σ is an involution. Chapter 42 proved that the assembled operator is an automorphism of $V^\natural$; in Lean it is `sigmaAut : AutVnat` (`VOA/Moonshine/AutSigma.lean`, Chapter 47). In Conway's coordinates the short vectors split by parity: α_c lies in Λ_0 iff all its coordinates are even (shapes $(\pm 4)^2$ and $(\pm 2)^8$), and in the other coset iff all are odd (shape $(\mp 3, \pm 1^{23})$) (`sigmaBlockShort_even_iff`, `sigmaBlockShort_odd_iff`).

Theorem 49.14 (Sector split and the conjugate of z). *(a) For every $u = (A, x, N)$, σ sends the untwisted dictionary vector of u to the pair $\big(\sigma_0(\text{matrix part} + \text{even short part}),\ \Phi(\text{odd short part})\big)$. (b) For any triality data $\mathfrak{D}$, $\sigma\, z\, \sigma$ is the frame-sector sign operator, $+1, -1, +1, -1$ on $V_0^+, V_3^+, T_s^+, T_{s+1}^+$.*

```
theorem sigmaBlockNat_split (ζ : ShortIdx → ℂ) (u : SpaceB) :
    sigmaAut (untwistedDictNat ζ u : Vnat) =
      (((v0Sigma (sigmaBlockEvenState ζ u) : V0Sub.carrier) : VPlus),
        Dnat.Φ (shortDict ζ (sigmaBlockShortPart 1 u.2.1)))
```

```
-- …
def sigmaBlockZ : Vnat →ₗ[ℂ] Vnat where
  toFun v := (v.1, -v.2)
-- …
theorem sigmaBlockConjugate (D : SigmaData) :
    sigNat D ∘ₗ sigmaBlockZ ∘ₗ sigNat D = sigmaBlockFrameSign D.s
```

(`VOA/Moonshine/MoonshineLRSigmaBlock.lean`.)

From the mathematics to the Lean statement

`sigmaBlockEvenState ζ u` is the V_0^+-component (matrix part and even short coordinates); `sigmaBlockShortPart 1` the rational projection onto odd short coordinates; `Dnat` the triality data used to build `sigmaAut`, `Dnat.Φ` its twisted half. `sigNat D` is the involution assembled from data `D` (our $\mathfrak{D}$); `sigmaBlockZ` is z; `sigmaBlockFrameSign D.s` is the sign operator described in (b) (its definition, a block operator built from the frame involution `plusFrame` and the two projections of T^+, is in the same file). `∘ₗ` is composition of linear maps. Both statements are the textbook ones.

Proof on paper. (a) is the definition of σ sector by sector, plus the parity criterion for short vectors. (b): σ preserves each of V_0^+ and T_{s+1}^+ and exchanges V_3^+ with T_s^+; z is $+1$ on $V_0^+ \oplus V_3^+$ and -1 on $T_s^+ \oplus T_{s+1}^+$; conjugating, $\sigma z \sigma$ is $+1$ on V_0^+, -1 on $\sigma(T_s^+) = V_3^+$, $+1$ on $\sigma(V_3^+) = T_s^+$, -1 on T_{s+1}^+. □

Physical meaning

Triality exchanges the orbifold sectors. $V^\natural$ has two commuting $\mathbb{Z}/2$ symmetries visible in the Leech description: z (untwisted vs. twisted; $+1$ on $V_0^+ \oplus V_3^+$, -1 on $T_0^+ \oplus T_1^+$) and the frame sign z' of part (b) ($+1$ on $V_0^+ \oplus T_s^+$, -1 on $V_3^+ \oplus T_{s+1}^+$). Their product zz' is a third. Each of the three involutions in the four-group $\{1, z, z', zz'\}$ exhibits $V^\natural$ as a $\mathbb{Z}/2$-orbifold of a Leech-type theory, with "untwisted" and "twisted" sectors that are different unions of the four frame sectors. Triality is the symmetry that permutes these three orbifold descriptions; part (b) is the statement that σ conjugates z into z'. (That each of the three involutions exhibits $V^\natural$ as such an orbifold is the classical picture, not a Lean statement.) In AxiomMath's language the four-group is $\{1, x_B, y_B, z_B\}$ and τ_B permutes it cyclically; through the dictionary x_B is z, and $\{y_B, z_B\} = \{z', zz'\}$, which of the two being z' is decided in Theorem 49.17.

What the machine verified

Unconditional; audited (`VOA/Moonshine/MoonshineLRLiftAudit.lean`), standard axioms.

49.6.2 σ on the even block

Theorem 49.15 (σ_0 is rational). *There is a $\mathbb{Q}$-linear map $F : \mathcal{B} \to \mathcal{B}$ such that for every $A \in \mathcal{A}$ and every $x \in \mathcal{X}$ supported on even short classes, $\sigma\big(\mathrm{untwistedDictNat}(A, x, 0)\big) = \mathrm{untwistedDictNat}(F(A, x, 0))$. Explicitly: diagonal matrices are fixed; for $j \neq k$ the off-diagonal matrix unit $U = U_{jk}$ and the two short coordinates P, M of the pairs $\pm(4e_j + 4e_k)$, $\pm(4e_j - 4e_k)$ span a σ-stable* three-dimensional *space, on which*

$$U \mapsto \tfrac{1}{2}(pP + mM), \quad P \mapsto pU + \tfrac{1}{2}P - \tfrac{pm}{2}M, \quad M \mapsto mU - \tfrac{pm}{2}P + \tfrac{1}{2}M, \qquad p, m \in \{\pm 1\};$$

this 3×3 matrix squares to 1 and has trace 1, so it is a reflection (eigenvalues $1, 1, -1$), as it must be for the involution σ; and on the 64 short classes of shape $(\pm 2)^8$ supported on one octad, σ acts by a Hadamard matrix with entries $\pm\frac{1}{8}$.

```
theorem sigmaBlockRWeight_values {j k : Fin 24} (hjk : j ≠ k) :
    (sigmaBlockRPWeight hjk = 1 ∨ sigmaBlockRPWeight hjk = -1) ∧
      (sigmaBlockRMWeight hjk = 1 ∨ sigmaBlockRMWeight hjk = -1)
-- …
theorem sigmaBlockOKS (S T : sigmaBlockOSubsets D) :
    griessShortSign (sigmaBlockOIndex hDA hD8 S) * KS hDA S.val T.val =
      ((sigmaBlockOWeight hDA hD8 S T : ℂ) / 8) *
        griessShortSign (sigmaBlockOIndex hDA hD8 T)
-- …
theorem sigmaBlockOFull_nat (A : symMat) (x : SpaceX)
    (hx : ∀ c, sigmaBlockParity c ≠ 0 → x c = 0) :
    sigmaAut (untwistedDictNat griessShortSign (A, x, 0) : Vnat) =
      (untwistedDictNat griessShortSign (sigmaBlockOFull (A, x, 0)) : Vnat)
```

(`VOA/Moonshine/MoonshineLRSigmaBlock2.lean`, `VOA/Moonshine/MoonshineLRSigmaBlock3.lean`.)

From the mathematics to the Lean statement

`sigmaBlockRPWeight hjk`, `sigmaBlockRMWeight hjk` are p, m; U_{jk} is `sigmaBlockRH j k`; the formulas for U, P, M are `sigmaBlockRNat_H`, `sigmaBlockRNat_P`, `sigmaBlockRNat_M`. In `sigmaBlockOKS`, `KS` is the complex transport coefficient of FLM's σ between two octad classes S, T (even subsets of one octad, called `D` in Lean), and the statement says that in the rational dictionary it becomes `sigmaBlockOWeight S T`/8 with weight ± 1 (`sigmaBlockOWeight_values`). `sigmaBlockOFull` is the assembled rational map F; the hypothesis `hx` says x vanishes on odd classes. All signs are relative to the noncomputable phases `griessShortSign`; no sign table is asserted.

Proof on paper. $\sigma_0 =$ `v0Sigma` is defined in Chapter 39 on explicit generators of V_0^+ with explicit complex coefficients. The content here is that, measured against the dictionary phases ζ, every coefficient is rational. For the two-root vectors: the transport coefficients $c_Q t_c$ have the same "cocycle-normalised square" $z^2\varepsilon(a,a) = 1$ as ζ^2, so their ratio is a sign (`sigmaBlockRRatio_sq`). For octads: all even subsets of one octad have the same normalised transport square (`sigmaBlockOTransport_sq`), so the ratios of phases are signs and FLM's coefficient $K_S(T) = \pm\frac{1}{8}$ times a ratio of phases becomes a rational $\pm\frac{1}{8}$. Every even short class is of two-root or octad type (`sigmaBlockOColumn_exists`); assembling the columns gives F. □

Physical meaning

On the subalgebra V_0^+ common to two orbifold descriptions, σ is the change of basis between them. It mixes each "current bilinear" $\partial X^j \partial X^k$ with the vertex operators of the root vectors $\pm 4e_j \pm 4e_k$ by a *reflection* of the three-dimensional space they span (an order-two operation, since $\sigma^2 = 1$), and it acts on each octad's 64 vertex operators by a normalised Hadamard (discrete Fourier) matrix, again an involution. The order-three element that cyclically rotates such triples is AxiomMath's τ_B, not σ (§49.7).

What the machine verified

Unconditional; audited, standard axioms.

49.6.3 The odd columns and the twisted blocks

Theorem 49.16 (σ is rational on ${V^\natural}_2$, and is a Monster element). *(a) σ is rational on all of ${V^\natural}_2$ if and only if, for every odd short class c, $\zeta_c' \Phi(x_{\alpha_c})$ is the spin-dictionary vector of a rational $N \in \mathcal{W}$. (b) This holds, with an explicit column. (c) Hence σ maps* griessNat($\mathcal{B}$) *into itself, and σ is the lift of an element σ_B of* AutO.

```
theorem sigmaB_rational_iff_odd_columns :
    (∀ u : SpaceB, ∃ v : SpaceB, sigmaAut (griessNat u : Vnat) = griessNat v) ↔
      (∀ c : ShortIdx, sigmaBlockParity c = 1 → ∃ N : SpaceW,
        fullShortSign c • Dnat.Φ (frameX0P (shortVec c)) = spinDict N)
-- …
theorem sigmaBOdd_columns (c : ShortIdx) (hc : sigmaBlockParity c = 1) :
    fullShortSign c • Dnat.Φ (frameX0P (shortVec c)) =
      spinDict (sigmaBOddColumn sigmaBOddSeedQ c)
-- …
theorem sigmaBOdd_rational :
    ∀ u : SpaceB, ∃ v : SpaceB, sigmaAut (griessNat u : Vnat) = griessNat v
-- …
theorem sigmaBOdd_liftable : ∃ g : liftableSubgroup, monsterLift g = sigmaAut
```

(`VOA/Moonshine/MoonshineLRSigmaB.lean`, `VOA/Moonshine/MoonshineLRSigmaB2.lean`.)

From the mathematics to the Lean statement

`sigmaBlockParity c = 1`: c is an odd class. `fullShortSign c` is ζ'_c; `frameX0P (shortVec c)` is x_{α_c}; `spinDict N` the twisted dictionary vector of N; `sigmaBOddColumn sigmaBOddSeedQ c` the explicit rational column, built from a rational "seed" vector `sigmaBOddSeedQ` with a single nonzero entry ± 1, AxiomMath's rational spin matrix `Rmat c` and a sign. (c) is stated twice: as rationality, and as `∃ g : liftableSubgroup, monsterLift g = sigmaAut`. The element g is called σ_B below (Lean: `tauBLiftSigma`, chosen by `Classical.choose`; it is unique by injectivity of `monsterLift`).

Proof on paper. (a) The even untwisted block is rational by Theorem 49.15. The odd untwisted block goes to T_s^+, and its rationality is the hypothesis. The rest follows from structure: σ is an involution, so rational images on V_3^+ give rational preimages on T_s^+ (`sigmaBTs_rational`); and σ preserves the Griess product, while the product with one odd short class is a rational bijection exchanging the two halves T_s^+ and T_{s+1}^+ of the twisted weight-two space (`sigmaBShortAction_frame`). It is invertible (`sigmaBShortAction_injective`): its oscillator factor is built from AxiomMath's rank-one matrix $\widehat{U}_c = u_c u_c^{\mathsf{T}}$ (`Umat c`, u_c the Conway vector of the short class, $u_c \cdot u_c = 32$, so $\widehat{U}_c^2 = 32\,\widehat{U}_c$, `sigmaBUmat_sq`), and the Lean docstring records that the factor has eigenvalues 1 and -7, neither zero. Hence the Θ block is rational without computing Θ (`sigmaBTs1_rational_of_phi`). (b) By the top-level formula for Φ (Chapter 41), $\zeta'_c \Phi(x_{\alpha_c})$ is a single oscillator column $h_{f_b}(-\frac{1}{2}) \otimes (\text{sign})\, R_c\, v$ with v one fixed "seed" spinor. The minus-root characters (diagonal cocode operators) and the frame sector force v to be supported on one spin index (`sigmaBOddSeed_support`); the invariant form and the isometry property of σ give Φ-images of norm 2, which forces the square of that one coordinate to be 1 (`sigmaBOddSeed_form`). So v is rational. (c) The rationality criterion `isVnatLiftable_of_rational` (§49.1.3) applied to $h = \sigma$. □

Physical meaning

The triality symmetry of the moonshine CFT, which mixes untwisted vertex operators with twisted-sector fields, preserves AxiomMath's rational form of the 196884 weight-two operators: in the rational basis its matrix has entries in $\mathbb{Z}[\frac{1}{2}]$. Physically this is the statement that the triality-transformed twisted ground state is again a "real" state of the same lattice of normalisations.

What the machine verified

Unconditional; all four declarations audited, standard axioms.

49.7 The triality element τ_B and Conway–Norton for G_{mat}

σ_B is a Monster element of order 2 that exchanges the orbifold descriptions; AxiomMath's τ_B is an element of order 3 with the same effect, written as an explicit matrix. They are *different* elements, and no attempt is made to compute a word expressing one through the other. Instead:

Theorem 49.17 (τ_B is liftable). *τ_B, as an element of* AutO*, is liftable. More precisely: (a) $\sigma_B x_B \sigma_B^{-1} \in \{y_B, z_B\}$; (b) if $g \in$ AutO satisfies $g x_B g^{-1} = \sigma_B x_B \sigma_B^{-1}$, then g is liftable; (c) hence τ_B is liftable.*

```

    IsVnatLiftable ⟨tauB, hτ⟩
```

(`VOA/Moonshine/MoonshineLRTauB.lean`.)

```
theorem isVnatLiftable_tauB : IsVnatLiftable ⟨tauB, tauB_mem_AutO⟩ :=
  tauBLift_isVnatLiftable_tauB_of_mem_AutO tauB_mem_AutO
```

(`VOA/Moonshine/MoonshineLRMonsterFinal.lean`; full name `VOA.Moonshine.ConwayNorton.M8.isVnatLiftable_tauB`.)

From the mathematics to the Lean statement

`tauBLiftSigma : liftableSubgroup` is σ_B; `tauBLiftConjugate` $= \sigma_B x_B \sigma_B^{-1}$, computed in `AutO` (where $x_B \in$ AutO is `xB_mem_AutO`). `hτ : tauB ∈ AutO` is a hypothesis of the intermediate theorems; it is discharged by AxiomMath's (ported) `tauB_mem_AutO`, which is how `isVnatLiftable_tauB` has no hypotheses. `⟨tauB, tauB_mem_AutO⟩` is τ_B as an element of `AutO`.

Proof on paper. (a) *Three ingredients from AxiomMath's coordinates* (Chapter 48).

- *Spin index and row halves.* The rows of a matrix $N \in \mathcal{W}$ are indexed by SpinIdx $= \mathbb{Z}/2 \times C_0$, pairs (η, a) with $\eta \in \mathbb{Z}/2$ and a in a fixed 2^{11}-element subspace C_0 of the Golay code (so $|\mathrm{SpinIdx}| = 2 \cdot 2048 = 4096$). The *row half* η of a row is its first component. Through the dictionary the two row halves $\eta = 0, 1$ go to the two twisted frame sectors T_0^+, T_1^+, up to a fixed shift (`spinDict_mem_TPframe_shift`).

- *The triality basis.* `tbasis` is AxiomMath's basis of $\mathcal{B}$ adapted to τ_B: the 24 diagonal matrix units (fixed by τ_B), 276 "pair" triples, $2048 \cdot 24$ "odd" triples, and 759 octad blocks of size 64 ($24 + 3 \cdot 276 + 3 \cdot 2048 \cdot 24 + 64 \cdot 759 = 196884$). The odd triple of $(a, i) \in C_0 \times \{0..23\}$ consists of $k = 0$: an odd short line of $\mathcal{X}$; $k = 1, 2$: the spin vectors $\pm E(\eta, a) \otimes e_i \in \mathcal{W}$ with $\eta = 1$ and $\eta = 0$ respectively; τ_B cycles $k \mapsto k + 1$. So all of $\mathcal{W}$ lies in the odd triples.

- *Sign patterns.* For $s \in \{\pm 1\}^3$, `oddSign s` is the diagonal operator that multiplies the k-th vector of every odd triple by s_k and fixes every other basis vector. x_B is the pattern $(+,-,-)$ ($+1$ on $\mathcal{A} \oplus \mathcal{X}$, -1 on $\mathcal{W}$). Since τ_B shifts k, $y_B = \tau_B x_B \tau_B^{-1}$ is the pattern $(-,+,-)$ and $z_B = \tau_B^2 x_B \tau_B^{-2}$ is $(-,-,+)$.

The argument. Through the dictionary x_B is z (`tauBLiftParity_dict`) and σ_B is σ, so $\sigma_B x_B \sigma_B^{-1}$ is the frame sign z' of Theorem 49.14(b) (`tauBLiftConjugate_dict`). In AxiomMath's coordinates z' fixes $\mathcal{A}$ and the even short lines (they lie in V_0^+), negates the odd short lines (V_3^+), and on $\mathcal{W}$ is $+1$ on one row half and -1 on the other (`tauBLiftConjugate_W`). On the odd triples it is therefore the pattern $(-,+,-)$ or $(-,-,+)$, according to which row half is positive. A parity automorphism (one commuting with x_B) is determined by its action on $\mathcal{A}$ and on the spin vectors $k = 1, 2$ (`tauBLiftParity_ext`); z', y_B, z_B all fix $\mathcal{A}$, so $z' = y_B$ or $z' = z_B$ (`tauBLiftConjugate_eq_of_signs`). The hypothesis $\tau_B \in \mathrm{AutO}$ is used to know that y_B, z_B lie in AutO and commute with x_B.

(b) Put $r = \sigma_B^{-1} g$. Then $r x_B r^{-1} = x_B$, so $r \in \mathrm{AutO} \cap C(x_B) = G_{\mathrm{vis}}$ by the parity-centralizer theorem (49.1), so r is liftable (Theorem 49.13); σ_B is liftable; the liftable elements form a group; so $g = \sigma_B r$ is liftable.

(c) If $\sigma_B x_B \sigma_B^{-1} = y_B = \tau_B x_B \tau_B^{-1}$, apply (b) to $g = \tau_B$. If it is $z_B = \tau_B^2 x_B \tau_B^{-2}$, then since $\tau_B^3 = 1$ we have $\tau_B^{-1} = \tau_B^2$ and $\tau_B^{-1} x_B \tau_B = z_B$; apply (b) to $g = \tau_B^{-1}$, and invert. □

Physical meaning

The four-group $\{1, z, z', zz'\}$ consists of three "2B" involutions, each the quantum symmetry of an orbifold description. Any symmetry that permutes them in the same way as τ_B differs from τ_B by a symmetry commuting with z, i.e. by an element of the orbifold-visible group $2^{1+24}.\mathrm{Co}_1$, which is already known to act. So it suffices to exhibit one CFT symmetry (σ) that moves z to z' or zz'.

What the machine verified

`isVnatLiftable_tauB`: unconditional. The intermediate theorems carry the hypothesis `hτ : tauB ∈ AutO`, which is a theorem of the port. All audited (`VOA/Moonshine/MoonshineLRLiftAudit.lean`; `isVnatLiftable_tauB` also in `VOA/Moonshine/MoonshineCNMonsterFinalAudit.lean`), standard axioms.

49.7.1 Conway–Norton for the generated group and for the Monster

Theorem 49.18 (Every element of G_{mat} acts on $V^\natural$; Conway–Norton for G_{mat}). *(a) G_{mat} is the image in $\mathrm{GL}_{\mathbb{Q}}(\mathcal{B})$ of the subgroup of* AutO *generated by τ_B and the visible elements. (b) Every $g \in$ AutO with $g \in G_{\mathrm{mat}}$ is liftable. (c) For every $g \in$ AutO with $g \in G_{\mathrm{mat}}$ there is an automorphism h of $V^\natural$ acting on $V^\natural{}_2 \cong \mathbb{C} \otimes \mathcal{B}$ as $1 \otimes g$, whose McKay–Thompson function T_h is the normalised Hauptmodul of a genus-zero group $\Gamma \supseteq \Gamma_0(N)$ commensurable with $\mathrm{SL}_2(\mathbb{Z})$.*

```
noncomputable def tauBAutO : AutO := ⟨tauB, tauB_mem_AutO⟩

(`VOA/Moonshine/MoonshineCNMonsterFinalAudit.lean`; full names `VOA.Moonshine.ConwayNorton.conwayNorton_gmat`, etc.)

From the mathematics to the Lean statement

Decoding. `AutO.subtype` is the inclusion $\mathrm{AutO} \hookrightarrow \mathrm{GL}_{\mathbb{Q}}(\mathcal{B})$ and `.map` the image of a subgroup. `(g : SpaceB ≃ₗ[ℚ] SpaceB) ∈ Generated.Gmat` is membership of the underlying linear map. In the `example`, every defined term is unfolded: g is any $\mathbb{Q}$-linear automorphism of $\mathcal{B}$ preserving `gmul` and `bform` (`hA`: membership in AutO) and lying in the subgroup generated by $G_{\mathrm{vis}} \cup \{\tau_B\}$ (`hg`); the conclusion's first clause writes `griessConj g` out as `griessIso.symm ≪≫ₗ LinearEquiv.baseChange ℚ ℂ SpaceB SpaceB g ≪≫ₗ griessIso`, i.e. $\mathcal{G} \circ (1_{\mathbb{C}} \otimes g) \circ \mathcal{G}^{-1}$ with $\mathcal{G} =$ `griessIso`.
Hypotheses. `conwayNorton_gmat`: only the membership `hg`, which is the intended restriction to G_{mat}. No `GmatEqAutO`.
Same statement, and not vacuous. The conclusion has two parts. The first (existence of a lift h with prescribed action on $V^{\natural}{}_2$) is the new content of this chapter; the second is `conwayNorton h` from Chapter 47. The statement is not vacuous: G_{mat} contains x_B, τ_B, and all of G_{vis} (a group of order $2^{25} \cdot |\mathrm{Co}_1|$ in the classical identification), and for each such g the theorem produces a specific automorphism of $V^{\natural}$, unique by `vnatWeightTwoRestrict_injective`. Since the first clause pins $h|_{V^{\natural}{}_2}$, the traces of h on $V^{\natural}{}_2$ are those of g on $\mathcal{B}$; e.g. for $g = \tau_B$, $\mathrm{tr}(h|V^{\natural}{}_2) = \mathrm{tr}\,\tau_B = 783$ (`trace_tauB`); classically (not a Lean statement) this is $1 + 782$, the value on the Monster class 3A of the character $1 + \chi_{196883}$.

Proof on paper. (a) G_{mat} is by definition the subgroup generated by $G_{\mathrm{vis}} \cup \{\tau_B\}$; all generators lie in AutO, and images of closures are closures of images. (b) The generators of that subgroup of AutO are liftable (Theorems 49.13 and 49.17), and liftable elements form a subgroup (`closure_insert_tauB_le_liftableSubgroup`). (c) For liftable g, `conwayNorton_monster_of_isVnatLiftable` (Chapter 48) produces $h =$ monsterLift(g) and applies `conwayNorton`. □

Physical meaning

Every element of the group generated by the orbifold-visible symmetries and triality is a symmetry of the moonshine CFT, and its twisted partition function is a genus-zero Hauptmodul. If one already knows (from group theory) that this generated group is the Monster, this is monstrous moonshine; the theorem itself does not need to know it.

What the machine verified

`conwayNorton_gmat`, `isVnatLiftable_of_mem_gmat`, `gmat_eq_map_closure_insert_tauB`: **unconditional** (no hypothesis beyond the membership premise $g \in G_{\mathrm{mat}}$, which is part of the statement). `#print axioms` in `VOA/Moonshine/MoonshineCNMonsterFinalAudit.lean` (build record of the release, 9,441 jobs): `[propext, Classical.choice, Quot.sound]`, 0 `sorryAx`.

Theorem 49.19 (Conway–Norton for all of AutO, given $G_{\mathrm{mat}} = \mathrm{AutO}$). *If $G_{\mathrm{mat}} = \mathrm{AutO}$, then for every $g \in \mathrm{AutO}$ the conclusion of Theorem 49.18(c) holds.*

```
theorem conwayNorton_monster_of_Gmat (hGmat : Generated.Gmat = AutO) (g : AutO) :
    ∃ h : AutVnat, vnatWeightTwoRestrict h = griessConj (g : SpaceB ≃ₗ[ℚ] SpaceB) ∧
      ∃ (Γ : Subgroup (GL (Fin 2) ℝ)) (N : ℕ), IsMoonshineGroup Γ N ∧
        IsNormalizedHauptmodul Γ (mckayThompsonFun h)
```

```
theorem conwayNorton_monster (hGmat : Generated.Gmat = AutO) (g : AutO) :
    ∃ h : AutVnat, vnatWeightTwoRestrict h = griessConj (g : SpaceB ≃ₗ[ℚ] SpaceB) ∧
      ∃ (Γ : Subgroup (GL (Fin 2) ℝ)) (N : ℕ), IsMoonshineGroup Γ N ∧
        IsNormalizedHauptmodul Γ (mckayThompsonFun h)
```

(`VOA/Moonshine/MoonshineLRMonsterFinal.lean`, `VOA/Moonshine/MoonshineCNMonsterFinalAudit.lean`; the second restates the first in the namespace `VOA.Moonshine.ConwayNorton`.)

From the mathematics to the Lean statement

The hypothesis `hGmat : Generated.Gmat = AutO` is *literally* the body of `GmatEqAutO` (§49.13); the two theorems predate that name. Equality of subgroups of $\mathrm{GL}_{\mathbb{Q}}(\mathcal{B})$.

Proof on paper. Under `hGmat`, τ_B and the visible elements generate AutO (`tauBLift_closure_eq_top`), and `conwayNorton_autO_of_tauB` with `isVnatLiftable_tauB` gives the claim. □

Physical meaning

Monstrous moonshine for every element of AxiomMath's Monster, modulo the group-theoretic identification $G_{\mathrm{mat}} = \mathrm{AutO}$.

What the machine verified

Conditional on `hGmat`. Audited in `VOA/Moonshine/MoonshineCNMonsterFinalAudit.lean`, standard axioms (which do not report `hGmat`).

49.8 The converse, I: every graded trace is rational

49.8.1 Why the converse needs a new idea

So far: $G_{\mathrm{mat}} \le$ liftable $\le$ AutO, and monsterLift embeds the liftable subgroup in $\mathrm{Aut}(V^\natural)$. The converse asks whether *every* automorphism of $V^\natural$ arises this way, i.e. preserves the rational lattice $\mathrm{griessNat}(\mathcal{B}) \subset {V^\natural}_2$ (`mem_range_monsterLift_iff`, Chapter 48). Classically one argues: $\mathrm{Aut}(V^\natural)$ acts faithfully on the Griess algebra ${V^\natural}_2$ by algebra automorphisms, and by Tits' theorem the automorphism group of the complex Griess algebra is $\mathbb{M}$. Tits' theorem is not formalised. The route taken instead ("route (e)" of the authors' notes) is:

> *Let h be an automorphism of $V^\natural$. If the traces on ${V^\natural}_2$ of all elements of the coset $h \cdot G_{\mathrm{mat}}$ (more precisely of $\mathrm{gmatLift}(s)^{-1}h$, $s \in G_{\mathrm{mat}}$) are rational, and the already rational group G_{mat} is absolutely irreducible on $e_1^{\perp}$, then the matrix of h on ${V^\natural}_2$ is rational.*

Note that the hypothesis is about the traces of *many* automorphisms, not only the character value of h itself; this is why rationality of the traces of *every* automorphism of $V^\natural$ is proved first (Theorem 49.23).

The arithmetic input (rational characters) comes from moonshine itself; the algebraic input (absolute irreducibility) is the commutant lemma of §49.11; Schur's orthogonality relations combine them.

Trap / dead end

Recorded dead ends. (1) *Galois descent on* $\mathrm{Aut}(V^\natural)$ *alone* gives only $N_G(M) = M$ for the rational subgroup M (from $C_G(M) = 1$); it cannot exclude a finite overgroup in which M is self-normalising. The missing ingredient is rationality of characters. (2) *"Rational character ⇒ rational matrices" is false in general*: the quaternion group Q_8 acting on $\mathbb{C}^2$ has rational character but no rational model (Schur index 2). The argument needs an *already rational, absolutely irreducible* subgroup, which is exactly the commutant lemma; it cannot be dropped. (3) *Counting* $|\mathrm{Aut}(V^\natural)| \le |G_{\mathrm{mat}}|$ needs $|G_{\mathrm{mat}}|$, which AxiomMath obtains only through the Baby Monster recognition (the ≈ 16,000-file closure). Dead. (4) *Realness first, then real ⇒ rational*: the second step is Tits-hard; superseded. (5) *Classifying rigid idempotents / Ising vectors*: the known proofs that every Ising vector of $V^\natural$ is a 2A-axis go through $\mathrm{Aut}(V^\natural) = \mathbb{M}$ (circular here). Unnecessary.

49.8.2 Galois invariance and coefficients

The following three theorems are in `VOA/Moonshine/MoonshineCNRationalTraces.lean` (namespace `VOA.Moonshine.ConwayNorton`); they assemble inputs proved in Chapters 43, 46 and 47 into unconditional statements.

Theorem 49.20 (Complete replicability, the Γ_1 theorem, Galois invariance). *(a) Every McKay–Thompson series of $V^\natural$ is completely replicable. (b) The Γ_1 form of Conway–Norton holds. (c) For every $g \in \mathrm{Aut}(V^\natural)$ and every u coprime to the order of g, $T_{g^u} = T_g$ as functions on $\mathbb{H}$.*

```
theorem completelyReplicable_holds : CompletelyReplicable :=
  completelyReplicable_of_simpleRootGeneration M8.monsterLieSimpleRootGeneration
    M8.autVnat_isOfFinOrder
-- …
theorem conwayNortonGammaOne_holds : ConwayNortonGammaOne :=
  conwayNortonGammaOne_of_completelyReplicable completelyReplicable_holds
    (fun _ _ k => M8.ReplicableFamily_primeHeckeIdentity _ k)
    (fun _ hg => M8.ReplicableFamily_notInjectiveModTranslations hg.orderOf_pos _)
-- …
theorem mckayThompsonFun_pow_eq_of_coprime_holds (g : AutVnat) {u : ℕ}
    (hu : Nat.Coprime u (orderOf g)) : mckayThompsonFun (g ^ u) = mckayThompsonFun g
```

(`VOA/Moonshine/MoonshineCNRationalTraces.lean`.)

From the mathematics to the Lean statement

`CompletelyReplicable` and `ConwayNortonGammaOne` are the definitions of Chapter 43 (`VOA/Moonshine/MoonshineCNStatement.lean`). The proof terms are shown because they are informative: (a) is Chapter 46's `completelyReplicable_of_simpleRootGeneration` fed with the generation theorem `M8.monsterLieSimpleRootGeneration` and finite order `M8.autVnat_isOfFinOrder` (Chapter 47); (b) is the case-free genus-zero theorem fed with (a) and the two unconditional inputs on replicable families (Hecke identity at primes, non-injectivity modulo translations); (c) is the Galois-invariance theorem of Chapter 43 (`mckayThompsonFun_pow_eq_of_coprime_of_completelyReplicable`) with all its hypotheses discharged. `Nat.Coprime u (orderOf g)`: $\gcd(u, o(g)) = 1$; `g ^ u` the u-th power in $\mathrm{Aut}(V^\natural)$.

Proof on paper. Assembly. For (c), recall the argument of Chapter 43 (Galois invariance): let (Γ, M) come from the Γ_1 form for g; by Dirichlet's theorem there is a prime $p > M$ with $p \equiv u \pmod{o(g)}$, so $g^p = g^u$; replication at p and the main lemma of the $\Gamma_1 \Rightarrow \Gamma_0$ section of Chapter 43 give $T_{g^p} = T_g$. □

Physical meaning

g and g^u generate the same cyclic group; their twisted partition functions are related by a Galois conjugation of the $o(g)$-th roots of unity in the characters, and the theorem says the partition functions coincide. In a CFT where the twisted sectors are governed by genus-zero modular curves, this is the expected "rationality" of the twisted partition functions.

What the machine verified

Unconditional. `#print axioms` in `VOA/Moonshine/MoonshineCNRationalAudit.lean`: standard axioms.

Theorem 49.21 (Coefficients are determined by the function). *If $g, h \in \mathrm{Aut}(V^\natural)$ have finite order and $T_g = T_h$ on $\mathbb{H}$, then their McKay–Thompson power series are equal.*

```
theorem mckayThompson_eq_of_mckayThompsonFun_eq {g h : AutVnat} (hg : IsOfFinOrder g)
    (hh : IsOfFinOrder h) (hfun : mckayThompsonFun g = mckayThompsonFun h) :
    mckayThompson g = mckayThompson h
```

(`VOA/Moonshine/MoonshineCNRationalTraces.lean`.)

From the mathematics to the Lean statement

`mckayThompson g` is the power series $\sum_{n\geq 0} \mathrm{tr}(g|V^\natural_{n+1})q^n$ (Chapter 43); `IsOfFinOrder g` is $g^n = 1$ for some $n \geq 1$ (always true here, `autVnat_isOfFinOrder`, but stated as a hypothesis in this lemma).

Proof on paper. The difference of the regular parts is a power series in q whose coefficients are bounded by those of J (`isJDominated_mckayThompson`), hence converges on the punctured unit disc, and it sums to 0 at every $q = e^{2\pi i\tau}$; the Cauchy estimate `M8.norm_coeff_le_of_hasSum_qPar` with bound 0 kills every coefficient. □

Physical meaning

A q-expansion is determined by the function it sums to: the twisted partition function determines the twisted degeneracies at every level.

What the machine verified

Unconditional; audited in `VOA/Moonshine/MoonshineCNRationalAudit.lean`, standard axioms.

49.8.3 Ramanujan sums

Theorem 49.22 (Galois-invariant traces of finite-order operators are rational). *Let K be a field of characteristic 0, V a finite-dimensional K-vector space, $A \in \mathrm{End}_K V$ with $A^N = 1$ for some $N \geq 1$, and suppose $\mathrm{tr}(A^u) = \mathrm{tr}(A)$ for every u coprime to N. Then $\mathrm{tr}\, A \in \mathbb{Q}$.*

```
theorem exists_rat_trace_of_trace_pow_coprime [CharZero K] (A : Module.End K V) {N : ℕ}
    (hN : 0 < N) (hA : A ^ N = 1)
    (hgal : ∀ u : ℕ, N.Coprime u → LinearMap.trace K V (A ^ u) = LinearMap.trace K V A) :
    ∃ r : ℚ, LinearMap.trace K V A = r
```

(`VOA/Moonshine/MoonshineCNRationalRamanujan.lean`; section variables `{K V : Type*} [Field K] [AddCommGroup V] [Module K V] [FiniteDimensional K V]`.)

From the mathematics to the Lean statement

`N.Coprime u` is $\gcd(N,u) = 1$; the conclusion `∃ r : ℚ, LinearMap.trace K V A = r` says the trace is the image of a rational number under $\mathbb{Q} \to K$. Hypotheses exactly as stated; note u ranges over *all* naturals coprime to N, so (`hgal`) is the usual Galois-invariance hypothesis.

Proof on paper. No eigenvalues are needed. Möbius inversion of the coprimality indicator gives

$$\sum_{\substack{0\le u<N\\(u,N)=1}} A^u = \sum_{e\mid N}\mu(e)\sum_{k<N/e}(A^e)^k$$

(`sum_coprime_eq_sum_divisors_moebius`). For B with $B^M = 1$, $P = \sum_{k<M} B^k$ satisfies $P^2 = MP$, so P/M is an idempotent and $\operatorname{tr} P = M\cdot\operatorname{rank}(P/M) \in M\mathbb{N}$ (`exists_trace_geom_sum_eq_of_pow_eq_one`). Hence $\varphi(N)\operatorname{tr} A = \sum_{(u,N)=1}\operatorname{tr}(A^u) \in \mathbb{Z}$, and $\operatorname{tr} A \in \mathbb{Q}$. (Read on an eigenvector, this is the classical fact that Ramanujan sums $\sum_{(u,N)=1}\lambda^u$ are integers.) □

Physical meaning

Pure linear algebra; the physical content is in the hypothesis.

What the machine verified

Unconditional; audited in `VOA/Moonshine/MoonshineCNRationalAudit.lean`, standard axioms.

Theorem 49.23 (Rational traces). *For every $g \in \operatorname{Aut}(V^\natural)$ and $n \in \mathbb{N}$, $\operatorname{tr}(g|V^\natural_{n+1}) \in \mathbb{Q}$. Equivalently, every coefficient of every McKay–Thompson series of $V^\natural$ is rational.*

```
theorem exists_rat_gradedAutTrace (g : AutVnat) (n : ℕ) :
    ∃ r : ℚ, gradedAutTrace VnatVOA g ((n : ℤ) + 1) = r
-- …
theorem rationalTraces : RationalTraces
```

(`VOA/Moonshine/MoonshineCNRationalTraces.lean`; full name `VOA.Moonshine.ConwayNorton.rationalTraces`.)

From the mathematics to the Lean statement

`gradedAutTrace VnatVOA g k` is $\operatorname{tr}(g|V^\natural_k)$ (Chapter 43); `((n : ℤ) + 1)` is the weight $n+1$ as an integer. `RationalTraces` (quoted in §49.1.3) quantifies over all g and all coefficients n of `mckayThompson g`, whose n-th coefficient is $\operatorname{tr}(g|V^\natural_{n+1})$ (`mckayThompson_coeff`). No hypotheses. **Strength.** Rationality, not integrality: integrality of the coefficients is classical (they are virtual characters evaluated at g) but is not a statement of the library (Chapter 43).

Proof on paper. Fix g of order N (finite by Chapter 47) and $A = g|_{V^\natural_{n+1}}$, so $A^N = 1$. For u coprime to N, Theorem 49.20(c) gives $T_{g^u} = T_g$, Theorem 49.21 gives equality of coefficients, i.e. $\operatorname{tr}(A^u) = \operatorname{tr}(A)$. Theorem 49.22 concludes. □

Physical meaning

Why rational characters matter. For a finite-order symmetry g of a theory with a rational structure, the trace on each energy level is a sum of roots of unity; Galois invariance of the twisted partition function forces it to be rational. Rational characters are the first indication that the symmetry group can be "defined over $\mathbb{Q}$"; combined with an absolutely irreducible

rational subgroup (next sections), they pin the group down to the rational one.

What the machine verified

Unconditional. `#print axioms`: standard, in `VOA/Moonshine/MoonshineCNRationalAudit.lean` and `VOA/Moonshine/MoonshineCNSymmetryFinalAudit.lean`.

49.9 The converse, II: Schur's span formula and rational descent

Theorem 49.24 (Schur's span formula). *Let K be a field, S a finite group, $\sigma : S \to M_n(K)$ a multiplicative map, $E \in M_n(K)$ an idempotent commuting with $\sigma(S)$ with $\operatorname{tr} E \neq 0$, and suppose every T commuting with $\sigma(S)$ satisfies $ETE \in K \cdot E$. Then for every $Y \in M_n(K)$,*

$$\sum_{s \in S} \operatorname{tr}\big(\sigma(s^{-1})EY\big)\,\sigma(s)E = \frac{|S|}{\operatorname{tr} E}\,EYE.$$

```
theorem schur_span_formula (σ : S →* Matrix n n K) (E : Matrix n n K) (hE : E * E = E)
    (hEσ : ∀ s, E * σ s = σ s * E) (hr : E.trace ≠ 0)
    (hirr : ∀ T : Matrix n n K, (∀ s, T * σ s = σ s * T) → ∃ c : K, E * T * E = c • E)
    (Y : Matrix n n K) :
    ∑ s, (σ s⁻¹ * E * Y).trace • (σ s * E)
      = ((Fintype.card S : K) / E.trace) • (E * Y * E)
```

(`VOA/Moonshine/MoonshineCNRationalSchur.lean`; section variables `{K n S : Type*} [Field K] [Fintype n] [DecidableEq n] [Group S] [Fintype S]`.)

From the mathematics to the Lean statement

`S →* Matrix n n K` is a monoid homomorphism into the matrix ring (so $\sigma(1) = 1$ and $\sigma(st) = \sigma(s)\sigma(t)$; invertibility follows); `σ s⁻¹` is $\sigma(s^{-1})$, which equals $\sigma(s)^{-1}$. `hirr` is the commutant hypothesis ("absolute irreducibility on the image of E"); `Fintype.card S` is $|S|$. No hypothesis on the characteristic is needed; the theorem is used only over $\mathbb{Q}$.

Proof on paper. For any X, the group average $A(X) = \sum_s \sigma(s)EXE\sigma(s)^{-1}$ commutes with $\sigma(S)$ and satisfies $A = EAE$, so by the hypothesis $A(X) = c(X)E$; taking traces, $c(X)\operatorname{tr} E = |S|\operatorname{tr}(EX)$ (`groupAverage_eq_smul`). Applied to matrix units, this is the orthogonality relation $\sum_s (\sigma(s)E)_{ij}(E\sigma(s^{-1}))_{kl} = \frac{|S|}{\operatorname{tr} E}E_{kj}E_{il}$ (`sum_mul_coeff_eq`), and summing it against the entries of Y gives the formula. □

Physical meaning

The Schur orthogonality relations for an irreducible representation: the matrix coefficients of the group span the whole matrix algebra of the irreducible block.

What the machine verified

Unconditional; audited, standard axioms.

Theorem 49.25 (Rationality from rational traces). *(a) If $H \in M_{m\times n}(\mathbb{C})$ and $H_0 \in M_{m\times n}(\mathbb{Q})$ satisfy $f(H) = f(1)H_0$ entrywise for every $\mathbb{Q}$-linear $f : \mathbb{C} \to \mathbb{Q}$, then $H = H_0$. (b) In the setting of Theorem 49.24 over $K = \mathbb{Q}$, if $H \in M_n(\mathbb{C})$ and all traces $\operatorname{tr}(\sigma(s^{-1})EH)$ are rational numbers $q(s)$, then EHE is the rational matrix $\frac{\operatorname{tr} E}{|S|}\sum_s q(s)\sigma(s)E$.*

```
theorem eq_map_ratCast_of_forall_dual (H : Matrix m n ℂ) (Z : Matrix m n ℚ)
    (h : ∀ f : ℂ →ₗ[ℚ] ℚ, H.map f = f 1 • Z) : H = Z.map (Rat.castHom ℂ)
-- …
theorem eq_map_ratCast_of_rational_traces (σ : S →* Matrix n n ℚ) (E : Matrix n n ℚ)
    (hE : E * E = E) (hEσ : ∀ s, E * σ s = σ s * E) (hr : E.trace ≠ 0)
    (hirr : ∀ T : Matrix n n ℚ, (∀ s, T * σ s = σ s * T) → ∃ c : ℚ, E * T * E = c • E)
    (H : Matrix n n ℂ) (q : S → ℚ)
    (hq : ∀ s, ((σ s⁻¹ * E).map (Rat.castHom ℂ) * H).trace = (q s : ℂ)) :
    E.map (Rat.castHom ℂ) * H * E.map (Rat.castHom ℂ)
      = ((E.trace / Fintype.card S) • ∑ s, q s • (σ s * E)).map (Rat.castHom ℂ)
```

(VOA/Moonshine/MoonshineCNRationalSchur.lean.)

From the mathematics to the Lean statement

`H.map f` applies f entrywise; `f 1 • Z` is $f(1)H_0$ (Lean calls H_0 `Z`). `Z.map (Rat.castHom ℂ)` is H_0 read as a complex matrix. In (b), `(σ s⁻¹ * E).map (Rat.castHom ℂ) * H` is the complex product $\sigma(s^{-1})EH$.

Proof on paper. (a) For each entry, $f(H_{ij} - (H_0)_{ij}) = 0$ for every $\mathbb{Q}$-linear $f : \mathbb{C} \to \mathbb{Q}$; since $\mathbb{C}$ is a $\mathbb{Q}$-vector space, an element killed by all functionals is 0 (`Module.forall_dual_apply_eq_zero_iff`). (b) Apply f entrywise to EHE: this commutes with multiplication by the rational E, so $f(EHE) = Ef(H)E$, and Theorem 49.24 over $\mathbb{Q}$ writes it as $\frac{\operatorname{tr}E}{|S|}\sum_s \operatorname{tr}(\sigma(s^{-1})Ef(H))\sigma(s)E$; and $\operatorname{tr}(\sigma(s^{-1})Ef(H)) = f(\operatorname{tr}(\sigma(s^{-1})EH)) = f(q(s)) = q(s)f(1)$. So $f(EHE) = f(1)H_0$ with H_0 independent of f, and (a) gives $EHE = H_0$. This is Galois descent with the field automorphisms of $\mathbb{C}$ (which need transcendence bases) replaced by $\mathbb{Q}$-linear functionals. □

Physical meaning

A symmetry whose traces against all elements of an irreducible rational symmetry group are rational is itself rational on that irreducible block.

What the machine verified

Unconditional; audited, standard axioms.

49.10 The converse, III: rationality of Aut($V^\natural$) given the commutant

Definition 49.26 (The identity line and its projection). $e_1 = (I, 0, 0) \in \mathcal{B}$ (I the 24×24 identity matrix) and $P_0 u = \frac{b(u,e_1)}{24}\, e_1$, the b-orthogonal projection onto $\mathbb{Q}e_1$ ($b = $ `bform`, $b(e_1, e_1) = \operatorname{tr} I = 24$).

```
noncomputable def griessIdentityVec : SpaceB :=
  (⟨1, mem_symMat.2 Matrix.transpose_one⟩, 0, 0)
-- …
noncomputable def griessUnitProj : SpaceB →ₗ[ℚ] SpaceB :=
  LinearMap.smulRight ((24 : ℚ)⁻¹ • bform.flip griessIdentityVec) griessIdentityVec
-- …
theorem griessUnitProj_apply (u : SpaceB) :
    griessUnitProj u = (bform u griessIdentityVec / 24) • griessIdentityVec
```

(VOA/Moonshine/MoonshineCNRationalGriess.lean, namespace `VOA.Moonshine.MonsterAction`.)

From the mathematics to the Lean statement

`⟨1, mem_symMat.2 Matrix.transpose_one⟩` is the identity matrix with the proof that it is symmetric. `LinearMap.smulRight φ v` is $u \mapsto \varphi(u)v$; `bform.flip griessIdentityVec` is $u \mapsto b(u, \mathbf{e}_1)$. The `_apply` lemma states the textbook formula.

Physical meaning

$\mathbf{e}_1$ corresponds to (twice) the stress tensor: AxiomMath's unit is $\frac{1}{4}\mathbf{e}_1$, which acts on $\mathcal{B}$ by the identity; ω acts on $V^\natural{}_2$ by $L_0 = 2$. P_0 projects onto the stress-tensor direction, and $1 - P_0$ onto the 196883 further primaries.

What the machine verified

Unconditional definitions.

Theorem 49.27 (The identity line is the conformal line, and is fixed). *griessNat*$(\mathbf{e}_1) = 2\omega$*; hence every automorphism of* $V^\natural$ *fixes* griessNat$(\mathbf{e}_1)$*, every element of* G_{mat} *fixes* $\mathbf{e}_1$*, and* P_0 *commutes with* G_{mat}*. Moreover* G_{mat} *is finite.*

```
theorem griessNat_griessIdentityVec :

    h (griessNat griessIdentityVec : Vnat) = griessNat griessIdentityVec
-- …
theorem finite_gmat : Finite Generated.Gmat
```

(`VOA/Moonshine/MoonshineCNRationalGriess.lean`.)

From the mathematics to the Lean statement

`vnatConformalTwo` is ω as an element of $V^\natural{}_2$. `Finite Generated.Gmat`: the subgroup, as a type, is finite.

Proof on paper. $\frac{1}{4}\mathbf{e}_1$ is the unit of AxiomMath's algebra (`gmul_oneB_left`, a direct computation from the three block products), so griessNat$(\mathbf{e}_1)$ acts on $V^\natural{}_2$ by multiplication by 4; ω acts by $L_0 = 2$; the Griess product is commutative; hence $4\omega = \text{griessNat}(\mathbf{e}_1) \cdot \omega = \omega \cdot \text{griessNat}(\mathbf{e}_1) = 2\,\text{griessNat}(\mathbf{e}_1)$. Automorphisms fix ω. For $g \in G_{\text{mat}}$, its lift fixes griessNat$(\mathbf{e}_1)$ and acts as g on the rational lattice, so $ge_1 = \mathbf{e}_1$; g preserves b, so it commutes with P_0. Finiteness: G_{mat} embeds in Aut$(V^\natural)$ by `gmatLift` (Theorem 49.18), which is finite (`M8.finite_autVnat`, Chapter 47). □

Physical meaning

The stress tensor is invariant under every symmetry. The finiteness of G_{mat} is a notable by-product: it is proved here from the finiteness of the CFT's symmetry group, without any group-theoretic computation of $|G_{\text{mat}}|$.

What the machine verified

Unconditional; audited in `VOA/Moonshine/MoonshineCNRationalAudit.lean`, standard axioms.

Definition 49.28 (The commutant property). G_{mat} *has scalar commutant* if every $\mathbb{Q}$-linear $\mathcal{K} : \mathcal{B} \to \mathcal{B}$ with $\mathcal{K}g = g\mathcal{K}$ for all $g \in G_{\text{mat}}$ is of the form $a \cdot 1 + b \cdot P_0$, $a, b \in \mathbb{Q}$.

```
def GmatCommutantScalar : Prop :=
  ∀ T : SpaceB →ₗ[ℚ] SpaceB, (∀ g ∈ Generated.Gmat, ∀ u : SpaceB, T (g u) = g (T u)) →
    ∃ a b : ℚ, T = a • LinearMap.id + b • griessUnitProj
-- …
theorem gmat_commute_griessUnitProj (a b : ℚ) {g : SpaceB ≃ₗ[ℚ] SpaceB}
    (hg : g ∈ Generated.Gmat) (u : SpaceB) :
    (a • LinearMap.id + b • griessUnitProj : SpaceB →ₗ[ℚ] SpaceB) (g u)
      = g ((a • LinearMap.id + b • griessUnitProj : SpaceB →ₗ[ℚ] SpaceB) u)
```

(`VOA/Moonshine/MoonshineCNRationalGriess.lean`, namespace `VOA.Moonshine.MonsterAction`.)

From the mathematics to the Lean statement

Decoding. `T : SpaceB →ₗ[ℚ] SpaceB` is our $\mathcal{K}$, any $\mathbb{Q}$-linear endomorphism (not assumed invertible or form-preserving). The hypothesis `∀ g ∈ Generated.Gmat, ∀ u, T (g u) = g (T u)` is $\mathcal{K}g = g\mathcal{K}$ for all g. `a • LinearMap.id + b • griessUnitProj` is $a \cdot 1 + bP_0$.
Meaning. Since 1 and P_0 commute with G_{mat} (`gmat_commute_griessUnitProj`), the proposition says the commutant is *exactly* the two-dimensional algebra $\mathbb{Q}1 \oplus \mathbb{Q}P_0$. Equivalently, $\mathcal{B} = \mathbb{Q}\mathbf{e}_1 \oplus \mathbf{e}_1^{\perp}$ (both summands G_{mat}-stable; G_{mat} is finite, Theorem 49.27, so its representations are completely reducible, which is what makes the two formulations equivalent) with G_{mat} *absolutely* irreducible on the 196883-dimensional $\mathbf{e}_1^{\perp}$ (over $\mathbb{Q}$, the commutant of an irreducible representation is a division algebra; "scalar" means it is $\mathbb{Q}$, which is equivalent to irreducibility over $\mathbb{C}$).
Could it be vacuous? It is a ∀ over a nonempty class ($T = 1$); it is false for a too-small group (e.g. for the monomial subgroup, §49.11), so it has content.

Physical meaning

The 196883 non-stress-tensor primaries of weight 2 form a single irreducible multiplet of the symmetry group G_{mat}, and remain irreducible over $\mathbb{C}$ — the smallest faithful representation of the Monster.

What the machine verified

A definition (a `Prop`); it is proved in §49.11 (`M8.gmatCommutantScalar`). `gmat_commute_griessUnitProj`: unconditional, audited.

Theorem 49.29 (Rationality, given the commutant property). *Assume G_{mat} has scalar commutant. Then every automorphism h of $V^\natural$ maps* griessNat($\mathcal{B}$) *into itself; consequently* `monsterLift` *is surjective,* Aut($V^\natural$) ≅ *the liftable subgroup of* AutO, *and, if moreover G_{mat} =* AutO, Aut($V^\natural$) ≅ AutO.

```
theorem autVnat_rational_of_commutant (hcomm : GmatCommutantScalar) :
    ∀ h : AutVnat, ∀ u : SpaceB, ∃ u' : SpaceB, h (griessNat u : Vnat) = griessNat u'
-- …
theorem monsterLift_surjective_of_commutant (hcomm : GmatCommutantScalar) :
    Function.Surjective monsterLift
-- …
noncomputable def autVnat_mulEquiv_liftable_of_commutant (hcomm : GmatCommutantScalar) :
    AutVnat ≃* liftableSubgroup
-- …
theorem autVnat_mulEquiv_autO_of_commutant_of_Gmat (hcomm : GmatCommutantScalar)
    (hGmat : Generated.Gmat = AutO) : Nonempty (AutVnat ≃* AutO)
```

(`VOA/Moonshine/MoonshineCNRationalGriess.lean`.)

From the mathematics to the Lean statement

`(griessNat u : Vnat)` is the weight-two vector regarded in $V^\natural$; `AutVnat ≃* liftableSubgroup` a group isomorphism (its inverse is `monsterLift`, `autVnat_mulEquiv_liftable_of_commutant_symm_apply`); `Nonempty (AutVnat ≃* AutO)` asserts that an isomorphism exists. Hypotheses: `hcomm` (and `hGmat` in the last).

Proof on paper. Work with matrices in the dictionary bases (`griessBasisQ` of $\mathcal{B}$, `griessBasisC` its image in $V^\natural{}_2$); in these bases the Griess conjugate of a rational map has the same rational matrix (`toMatrix_griessLinear`). Let H be the complex matrix of $h|_{V^\natural{}_2}$, $\sigma : G_{\mathrm{mat}} \to M(\mathbb{Q})$ the rational representation, $E = 1 - P_0$ (rational idempotent, trace $196883 \neq 0$, commuting with σ).

(1) $P_0H = P_0$ and $HP_0 = P_0$: h fixes griessNat($\mathbf{e}_1$) and preserves natForm $= 2b$ (`griessUnitMatrix_map_mul_vnatMatrix`, `vnatMatrix_mul_griessUnitMatrix_map`). So $H = P_0 + EHE$.

(2) The commutant property in matrix form gives the hypothesis of Theorem 49.24 for E (`griessComplMatrix_commutant`).

(3) The traces are rational: $\mathrm{tr}(\sigma(s^{-1})EH) = \mathrm{tr}(\sigma(s^{-1})H) - \mathrm{tr}(\sigma(s^{-1})P_0)$, the first term is the trace on $V^\natural{}_2$ of the automorphism gmatLift$(s)^{-1}h$, rational by Theorem 49.23, and the second is a rational number (`exists_rat_trace_gmat_compl_vnatMatrix`).

(4) Theorem 49.25(b) shows EHE rational, so H is rational (`exists_vnatMatrix_eq_map_of_commutant`).

A rational matrix maps the rational lattice to itself. Then `isVnatLiftable_of_rational` makes every h a lift, so `monsterLift` is bijective; with `hGmat`, the liftable subgroup is all of AutO (it contains G_{mat}). □

Physical meaning

Schur's lemma pins down the symmetry group. An arbitrary symmetry h of the CFT has rational traces (moonshine) and fixes the stress tensor. Its matrix on the 196883-multiplet, Fourier-expanded along the irreducible rational group G_{mat} (Schur orthogonality), has rational coefficients; so h preserves the rational Griess algebra and is one of AxiomMath's AutO. No classification of finite groups enters: irreducibility of one explicit multiplet and the arithmetic of the partition functions suffice.

What the machine verified

Conditional on `hcomm` (and `hGmat` for the last); `hcomm` is discharged in §49.11. All four audited in `VOA/Moonshine/MoonshineCNRationalAudit.lean` (94 `#print axioms` commands), standard axioms.

49.11 The commutant lemma

Theorem 49.30 (The commutant lemma). *Every $\mathbb{Q}$-linear endomorphism of $\mathcal{B}$ commuting with every element of G_{mat} is $a \cdot 1 + b \cdot P_0$ for some $a, b \in \mathbb{Q}$. Equivalently, G_{mat} is absolutely irreducible on the 196883-dimensional $\mathbf{e}_1^\perp$.*

```
theorem gmatCommutantScalar : GmatCommutantScalar := by
```

(`VOA/Moonshine/MoonshineLRCommutantFinal.lean`; full name `VOA.Moonshine.ConwayNorton.M8.gmatCommutantScalar`.) The coordinate form, from which it is derived:

```
def commutF_P₀ : SpaceB →ₗ[ℚ] SpaceB :=
  ((1 / 24 : ℚ) • bform.flip commutF_eOne).smulRight commutF_eOne
-- …
theorem commutF_commutant_Gmat (T : SpaceB →ₗ[ℚ] SpaceB)
    (hT : ∀ g ∈ Generated.Gmat, ∀ u, T (g u) = g (T u)) :
    ∃ a b : ℚ, T = a • LinearMap.id + b • commutF_P₀
```

```
theorem commutF_P₀_eq_griessUnitProj : commutF_P₀ = griessUnitProj
```

(`VOA/Moonshine/MoonshineLRCommutant4.lean`, `VOA/Moonshine/MoonshineLRCommutantFinal.lean`.)

From the mathematics to the Lean statement

Decoding. `GmatCommutantScalar` is Definition 49.28, quoted in full there. `commutF_P₀` is the same projection as `griessUnitProj` written independently ($\frac{1}{24}$ instead of 24^{-1}, a separately defined $\mathbf{e}_1$ called `commutF_eOne`); `commutF_P₀_eq_griessUnitProj` proves them equal, and `commutF_eOne_eq_griessIdentityVec` holds by `rfl`. So the theorem is exactly the named input of Theorem 49.29.
Hypotheses. None. **Same statement.** Yes, and `gmat_commute_griessUnitProj` gives the converse inclusion, so the commutant is exactly $\mathbb{Q}1 \oplus \mathbb{Q}P_0$.
Is it a strong statement? Yes: the analogous statement for proper subgroups of G_{mat} can fail. For the subgroup generated by Q, x_B, τ_B and the monomial lifts it is false (the warning after Step 7 below exhibits an extra commuting projection), so the theorem genuinely uses the non-monomial element ξ.

Physical meaning

The 196883 weight-two primary fields of the moonshine CFT form one irreducible multiplet under the subgroup of symmetries generated by the orbifold-visible symmetries and triality — even over $\mathbb{C}$. The proof is a Clifford-theory analysis: the extraspecial "momentum-phase" symmetries split the multiplet into many lines with distinct charges, and the remaining symmetries (lattice rotations, ξ, triality) are shown to connect all the lines.

What the machine verified

Unconditional. `gmatCommutantScalar`: `#print axioms` standard in `VOA/Moonshine/MoonshineLRLiftAudit.lean` and `VOA/Moonshine/MoonshineCNSymmetryFinalAudit.lean`; `commutF_commutant_Gmat` audited in the former. The finite certificates are kernel `decide` (84 occurrences in `VOA/Moonshine/MoonshineLRCommutant4.lean`); no `native_decide`. Rebuild of the audit: 9,455 jobs, 0 `sorryAx`.

49.11.1 The proof on paper

Setting and notation. Let $\mathcal{K} : \mathcal{B} \to \mathcal{B}$ be $\mathbb{Q}$-linear and commute with every element of G_{mat}. We use the following elements of G_{mat}: the extraspecial group $Q \cong 2^{1+24}$ acting through AxiomMath's `rhoEquiv` (all in G_{vis}, `commutRho_mem_Gmat`); x_B; τ_B; the visible lifts of the code-preserving permutations and of ξ (§49.4). $\mathcal{D}, \mathcal{D}_0, \mathcal{O} \subset \mathcal{A}$ are the diagonal, traceless diagonal and off-diagonal symmetric matrices; E_{ii} the diagonal matrix units, U_{jk} $(j \neq k)$ the off-diagonal ones.

Short elements and lines of $\mathcal{X}$. Q is AxiomMath's group of 2^{25} signed permutation matrices on the spin index; its centre is $\{1, z_Q\}$ and $Q/\{1, z_Q\} \cong \Lambda/2\Lambda$. An element $t \in Q$ is *short* if its class is the class of a minimal vector. For short t, `Xlift t` $\in \mathcal{X}$ is $\pm$ the basis vector of the corresponding short coordinate, with $X_{z_Q t} = -X_t$; so the $2 \cdot 98280$ short elements give the 98280 lines $\mathbb{Q}X_t$ of $\mathcal{X}$, each twice.

Spin index. Rows of $N \in \mathcal{W}$ are indexed by $(\eta, a) \in \mathbb{Z}/2 \times C_0$, C_0 a 2^{11}-element subspace of the Golay code (§49.7); a is the *code component*, $E(\eta, a)$ the corresponding basis vector of $\mathbb{Q}^{4096}$, and $E(\eta, a) \otimes e_i$ the matrix with a single 1 in row (η, a), column i.

MOG, sextets, transverse partitions. In the MOG numbering the 24 coordinates are $\mathrm{coord}(r, j) = r + 4j$, and *column* j is $\{4j, \dots, 4j+3\}$. A *sextet* is a partition of the 24 points into six 4-sets (tetrads) such that the union of any two tetrads is an octad (a weight-8 Golay codeword); the six MOG columns form a sextet. Two partitions of $\{0, \dots, 23\}$ are *transverse* if the only functions constant on the blocks of both are the constant functions (their join is the one-block partition).

Roadmap. Steps 1–7 show that $\mathcal{K}$ is diagonal in AxiomMath's natural basis, with one scalar d_i per column i of $\mathcal{W}$ (shared by the odd short lines attached to it), one scalar per pair $\{j, k\}$ (shared by U_{jk} and two short lines), one scalar per octad block, and that $\mathcal{K}$ preserves $\mathcal{D}$. Steps 8–9 show that all these scalars are equal to one number d: permutation lifts identify scalars of the same type, and ξ connects different types (an odd line to an octad line, a pair line to an octad line). Step 10 shows that $\mathcal{K} - d \cdot 1$ vanishes except on $\mathcal{D}$, where it is a multiple of $A \mapsto \mathrm{tr}(A)\, I$, i.e. of P_0.

Step 1 (parity blocks). x_B is -1 on $\mathcal{W}$ and $+1$ on $\mathcal{A} \oplus \mathcal{X}$, so $\mathcal{K}$ preserves both (`commutPreservesAX`, `commutPreservesW`).

Step 2 (Q-characters). Q fixes $\mathcal{A}$ pointwise and acts on X_t by the commutator sign $\kappa(r, t) = \pm 1$ (because $X_{z_Q t} = -X_t$, `commutXlift_zQ_mul`, a lemma of AxiomMath's library that was not in the port and was reproved). The characters $\kappa(\cdot, t)$ of different lines are different (`commutChar_injective`) and nontrivial (`commutChar_nontrivial`). Hence $\mathcal{A}$ is the joint fixed space of Q on $\mathcal{A} \oplus \mathcal{X}$ (`commutFixed_eq_A`), so $\mathcal{K}(\mathcal{A}) \subseteq \mathcal{A}$; and each line $\mathbb{Q}X_t$ is a joint eigenline with its own character, so $\mathcal{K}X_t = c_t X_t$ for a scalar c_t (`commutXlift_eigen`). No averaging is needed: compare components of a joint eigenvector.

Step 3 (τ_B diagonalises $\mathcal{K}$ on $\mathcal{W}$). The odd triple of (a, i) in the triality basis is $(X_{r(a,i)},\ \pm E(1, a) \otimes e_i,\ \pm E(0, a) \otimes e_i)$ with $X_{r(a,i)}$ an odd short line, and τ_B cycles it (`tauB_odd`). $\mathcal{K}$ is scalar on the first vector (Step 2) and commutes with τ_B, so it is the same scalar on the other two (`commutOdd_eigen`, `commutSpin_eigen`).

Step 4 (columns). The elements of Q coming from codewords translate the code component a: $E(\eta, a) \otimes e_i \mapsto E(\eta, a') \otimes e_i$ for any a, a' (`commutB_rho_translate`). So the scalar of Step 3 depends only on the column i: $\mathcal{K}(0, 0, N) = (0, 0, N\,\mathrm{diag}(d_0, \dots, d_{23}))$ (`commutB_columns`).

Step 5 (pairs). For $j < k$, τ_B cycles U_{jk} and the two combinations $X_m \mp X_p$ of the short lines of $4e_j - 4e_k$ and $4e_j + 4e_k$ (`tauB_pair`). $\mathcal{K}$ is scalar on X_m and on X_p (Step 2); writing out $\mathcal{K}\tau_B = \tau_B \mathcal{K}$ on the triple forces the two scalars to be equal and equal to the eigenvalue on U_{jk} (`commutB_pair_lines`).

Step 6 (octads). On the 64 short lines of an octad, τ_B acts by the matrix $\mathrm{octHD} = \mathrm{octH} \cdot \mathrm{octD}$, a Fourier matrix times a sign diagonal, every entry of which is $\pm\frac{1}{8} \neq 0$ (`commutB_octHD_ne_zero`). A diagonal map commuting with a matrix without zero entries is scalar (`commutB_oct_scalar`).

Step 7 (the diagonal is preserved). Let $\Delta \in \mathcal{D}$ and $\Delta' = \mathcal{K}(\Delta)$, which lies in $\mathcal{A}$ by Step 2. Two facts about τ_B on $\mathcal{A}$: it fixes every diagonal matrix (`commutB_tau_diagonal`), and for every $A \in \mathcal{A}$ the $\mathcal{A}$-component of $\tau_B(A)$ is diagonal (`commutB_tau_A_offdiag`: τ_B sends each U_{jk} into $\mathcal{X}$, the first vector of a pair triple going to the second). Since $\tau_B \Delta = \Delta$, we get $\tau_B \Delta' = \mathcal{K}(\tau_B \Delta) = \Delta'$. Taking $\mathcal{A}$-components, $\Delta' = (\tau_B \Delta')_{\mathcal{A}}$, which is diagonal. So $\mathcal{K}(\mathcal{D}) \subseteq \mathcal{D}$ (`commutB_preserves_diagonal`).

Trap / dead end

Dead end: the monomial subgroup is not enough. Steps 1–7 use Q, x_B and τ_B. Adding the monomial lifts $2^{12}{:}M_{24}$ still does not suffice: this subgroup preserves the 23-dimensional space $\mathcal{D}_0$ (τ_B fixes each E_{ii}, monomial elements permute them, Q and x_B act trivially on $\mathcal{A}$), so its commutant contains the projection onto $\mathcal{D}_0$, which is not of the form $a + bP_0$. It also preserves the decomposition into octad, pair and odd$\cup\mathcal{W}$ types up to M_{24}. A non-monomial element of Co_0, such as ξ, is indispensable.

Step 8 (the linking elements are in G_{mat}, with explicit blocks). A liftable element g of AutO of block form

$$g(A,x,N) = \big(\alpha(A),\ \beta(x),\ RNM\big) \qquad (R \in \mathrm{GL}_{4096}(\mathbb{Q}),\ M \in \mathrm{GL}_{24}(\mathbb{Q})) \tag{49.3}$$

commutes with x_B, hence lies in $\mathrm{AutO} \cap C(x_B) = G_{\mathrm{vis}}$ (49.1) (`commutL_mem_Gvis`). This applies to the lifts of code-preserving permutations π (with $\alpha(A) = P_\pi^{\mathsf{T}} A P_\pi$, $M = P_\pi$ the permutation matrix, R a signed permutation) and of ξ (`commutL_mathieu_blocks`, `commutL_xi_blocks`):

```
theorem commutL_xi_blocks :
    ∃ g : liftableSubgroup,
      monsterLift g = liftTwVnatAut liftXi liftXi_isometry liftXi_surjective ∧
      ((g : AutO) : SpaceB ≃ₗ[ℚ] SpaceB) ∈ Gvis ∧
      ((g : AutO) : SpaceB ≃ₗ[ℚ] SpaceB) ∈ Generated.Gmat ∧
      ∀ u : SpaceB, ((g : AutO) : SpaceB ≃ₗ[ℚ] SpaceB) u =
        (thetaA liftXiMatrixᵀ u.1,
          griessTrX (liftSignX liftXi liftXi_isometry (griessTrX u.2.1)),
          liftXiSpinMatrix * u.2.2 * liftXiMatrixᵀ)
```

(`VOA/Moonshine/MoonshineLRCommutant3.lean`; `thetaA M A` $= M^{\mathsf{T}}AM$, so the $\mathcal{A}$-block of ξ is $A \mapsto \Xi A \Xi^{\mathsf{T}}$ with Ξ = `liftXiMatrix`.) On $\mathcal{W}$, $g\mathcal{K}(0,0,N) = (0,0,RN\,\mathrm{diag}(d)M)$ and $\mathcal{K}g(0,0,N) = (0,0,RNM\,\mathrm{diag}(d))$; since R is invertible and N arbitrary, $\mathrm{diag}(d)M = M\mathrm{diag}(d)$ (`commutL_column_matrix`). For $M = P_\pi$ this says $d_{\pi(i)} = d_i$ (`commutL_column_perm`).

Step 9 (certificates and transport). Three explicit code-preserving permutations are used: π_A (`commutL_pointPermA`), which swaps MOG columns $2 \leftrightarrow 3$ and $4 \leftrightarrow 5$ as blocks; π_B (`commutL_pointPermB`), which maps each column onto a column, permuting the points within it (e.g. $0,1,2,3 \mapsto 8,10,11,9$); and π_C (`commutF_genC`), an involution that does *not* preserve the columns ($0 \mapsto 23$ but $1 \mapsto 1$). Their tables, and the derived $\pi_{\mathrm{tr}} = \pi_C\pi_A\pi_C$ (`commutF_transverse`):

```
def commutL_pointPermA : Equiv.Perm (Fin 24) where

  right_inv := by decide
-- …
def commutF_transverse : Equiv.Perm (Fin 24) :=
  commutF_genC * commutL_pointPermA * commutF_genC
-- …
def commutF_generator : Fin 3 → Equiv.Perm (Fin 24) :=
  ![commutL_pointPermA, commutL_pointPermB, commutF_genC]
```

(`VOA/Moonshine/MoonshineLRCommutant3.lean`, `VOA/Moonshine/MoonshineLRCommutant4.lean`; `![…]` lists the images of $0, \dots, 23$.) Each is checked to preserve the Golay code by kernel `decide` on the twelve basis words (`commutL_preservesCode_basis`, `commutF_genC_code`).

- *Points.* $\langle \pi_A, \pi_B \rangle$ is transitive on the 24 points (`commutL_point_transitive`); so d is constant, $d_i = d$: $\mathcal{K} = d$ on $\mathcal{W}$ and on every odd short line (`commutL_spin_odd_scalar`).
- *One octad.* ξ maps an odd minimal vector to an octad-shaped vector (`VOA/Moonshine/MoonshineLRCommutant4.lean`):

  ```
  theorem commutF_odd_octad_coordinates :
      liftXiInt (oddMin 0 (B 1)) = vOct (B 0) commutF_seedSigns := by decide
  ```

  (proved by `decide`; `oddMin 0 (B 1)` has entries ± 1 and one ∓ 3, signs given by the basis codeword B_1; `vOct (B 0) S` has entries ± 2 on the octad B_0, minus signs on S.) Transporting the eigenvalue through the lift of ξ (`commutL_eigen_transport`), the line of that octad vector has eigenvalue d, hence the whole octad block of B_0 (Step 6; `commutF_seed_octad_scalar`).
- *All octads.* A spanning tree of the 759 octads under π_A, π_B, π_C, rooted at B_0, is stored as a table: for each octad (a 24-bit mask, sorted) its parent, the generator carrying parent to child, and a breadth-first rank. The check, done by kernel `decide` in 24 chunks of 32 (`VOA/Moonshine/MoonshineLRCommutant4.lean`):

  ```
  def commutF_octadCheck (n : ℕ) : Prop :=
    if hn : n < 759 then
      let i : Fin 759 := ⟨n, hn⟩
      (∀ hs : n + 1 < 759, commutF_octadMask i < commutF_octadMask ⟨n + 1, hs⟩) ∧
      (i = 130 ∨
        (commutF_octadLink (commutF_octadLink i).1).2.2 < (commutF_octadLink i).2.2 ∧
        permLin (ZMod 2) (commutF_generator (commutF_octadLink i).2.1)
          (bvec 24 (commutF_octadMask (commutF_octadLink i).1)) =
            bvec 24 (commutF_octadMask i))
    else True
  ```

  i.e. masks strictly increase (no repetitions), and every non-root entry is the image of its parent under its generator, with the parent of strictly smaller rank. So every listed mask is reachable from B_0; each is an octad (`commutF_octad_valid`); and since the 759 masks are distinct octads and there are exactly 759 octads (`card_octadWord`, ported), every octad is listed (`commutF_octadEnum_surjective`). A permutation lift carries octad blocks to octad blocks with the same eigenvalue (`commutF_octad_eigen_perm`), so every octad block has eigenvalue d (`commutF_octads_scalar`).
- *Pairs.* ξ carries $4e_0 - 4e_4$ (columns 0 and 1) to an octad vector on the first two MOG columns (`commutF_pair_octad_coordinates`), so the pair $\{0, 4\}$ has eigenvalue d; a spanning tree of

the 276 unordered pairs under the three generators (`commutF_pairCheck`, same format) and the transport along permutation lifts give eigenvalue d on every U_{jk} and both short lines of every pair (`commutF_offdiag_scalar`, `commutF_pair_short_scalar`). Hence $\mathcal{K} = d$ on all of $\mathcal{X}$ (`commutF_X_scalar`).

Trap / dead end

Recorded dead end: two generators that preserve the MOG columns. The first attempt at Step 9 used only π_A and π_B. Both map columns onto columns, so $\langle \pi_A, \pi_B \rangle$ preserves the MOG column partition (it lies in the stabiliser of the MOG sextet). It is transitive on points, but it can never move a within-column pair to a cross-column pair, cannot be transitive on the 759 octads, and cannot produce a partition transverse to the MOG columns. The fix is the code-preserving involution π_C = `commutF_genC`, $[23, 1, 11, 7, 20, 8, 6, 3, 5, 22, 10, 2, 12, 17, 14, 15, 19, 13, 18, 16, 4, 21, 9, 0]$, which breaks the columns; $\langle \pi_A, \pi_B, \pi_C \rangle$ is transitive on octads and pairs (certified above), and the columns of $\pi_{\mathrm{tr}} = \pi_C \pi_A \pi_C$ are transverse to the MOG columns.

Step 10 (the diagonal and assembly). Let $\mathcal{R} = \mathcal{K} - d \cdot 1$ (`commutF_residual`); it commutes with G_{mat}, vanishes on $\mathcal{X}$, $\mathcal{W}$ and $\mathcal{O}$, and maps $\mathcal{A}$ into $\mathcal{D}$ (`commutF_residual_diagonal`).

- *ξ forces column-constancy.* The lift of ξ acts on $\mathcal{A}$ by $A \mapsto \Xi A \Xi^{\mathsf{T}}$. If Δ is diagonal with entries $\Delta_0, \dots, \Delta_3$ in a MOG column j, the $(\mathrm{coord}(0,j), \mathrm{coord}(r,j))$ entry of $\Xi \Delta \Xi^{\mathsf{T}}$ is $\frac{1}{4}(\Delta_0 + \Delta_r - \Delta_s - \Delta_t)$, $\{r,s,t\} = \{1,2,3\}$ (`commutF_xi_correlation`). If $\Xi \Delta \Xi^{\mathsf{T}}$ is also diagonal, the three equations $\Delta_0 + \Delta_r = \Delta_s + \Delta_t$ force $\Delta_0 = \Delta_1 = \Delta_2 = \Delta_3$ (`commutF_xi_diagonal_columns`). Since $\mathcal{R}(\Xi A \Xi^{\mathsf{T}}) = \Xi \mathcal{R}(A) \Xi^{\mathsf{T}}$ and both residual images are diagonal, every $\mathcal{R}(A)$ is constant on MOG columns (`commutF_residual_columns`).

- *The transverse partition.* $\mathcal{R}$ also commutes with the lift of π_{tr}, so $\mathcal{R}(A)$ is constant on the images of the MOG columns under π_{tr}; a function constant on the blocks of both partitions is constant (`commutF_transverse_constant`, `VOA/Moonshine/MoonshineLRCommutant4.lean`:

```
theorem commutF_transverse_constant {K : Type*} (f : Fin 24 → K)
    (hc : ∀ i j, col i = col j → f i = f j)
    (hp : ∀ i j, col i = col j → f (commutF_transverse i) =
      f (commutF_transverse j)) (i : Fin 24) : f i = f 0
```

  proved by an explicit chain of equalities, each step justified by a kernel `decide` on the column data). So $\mathcal{R}(A) \in \mathbb{Q} I$ (`commutF_residual_identity`).

- *Trace.* Permutation lifts make $\mathcal{R}(E_{ii})$ independent of i (`commutF_residual_diag_equal`), and $\mathcal{R}$ vanishes on $\mathcal{O}$, so $\mathcal{R}(A) = \mathrm{tr}(A)\, \mathcal{R}(E_{00}) = \mathrm{tr}(A)\, \ell I$ for a scalar ℓ (`commutF_residual_trace`), and then $\mathcal{R}(u) = \mathrm{tr}(u_{\mathcal{A}})\, \ell\, \mathbf{e}_1 = 24 \ell\, P_0(u)$ for all u (`commutF_residual_full`; $b(u, \mathbf{e}_1) = \mathrm{tr}\, u_{\mathcal{A}}$, `commutF_bform_identity`).

Therefore $\mathcal{K} = d \cdot 1 + 24 \ell \cdot P_0$. □

Physical meaning

Step by step: the momentum-phase symmetries 2^{1+24} are "charges" that resolve the multiplet into lines; triality glues each odd vertex-operator line to two twisted ground states and each root line to a current bilinear; lattice permutations and the Hadamard rotation ξ glue all lines of the same type and then the different types together; the only thing they cannot move is the stress tensor.

Remark 49.31 (On the role of computation)**.** The kernel-checked tables are *certificates* of finite combinatorial facts about the Golay code (orbit transitivity, one transverse sextet, two witness vectors); every other step is a structural argument. The tables were generated by a script (verified first in Python); only the kernel check counts.

49.12 The converse, assembled: $\mathrm{Aut}(V^\natural)$ inside AxiomMath's Monster

Theorem 49.32 (The converse, without Tits)**.** *(a) Every automorphism h of $V^\natural$ maps the rational Griess lattice into itself: for each $u \in \mathcal{B}$ there is $u' \in \mathcal{B}$ with $h(\mathrm{griessNat}\, u) = \mathrm{griessNat}\, u'$. (b)* $\mathrm{Aut}(V^\natural)$ *is isomorphic to the subgroup of* AutO *of liftable elements; the isomorphism is inverse to* `monsterLift`*. (c) If $G_{\mathrm{mat}} =$ AutO, then* $\mathrm{Aut}(V^\natural) \cong$ AutO*.*

```

```

(`VOA/Moonshine/MoonshineCNSymmetryFinalAudit.lean`, namespace `VOA.Moonshine.ConwayNorton`.)

From the mathematics to the Lean statement

Decoding. `AutVnat ≃* liftableSubgroup`: a multiplicative equivalence (group isomorphism) from $\mathrm{Aut}(V^\natural)$ onto the subgroup `liftableSubgroup` of `AutO`, regarded as a group. The `_symm_apply` lemma identifies its inverse with `monsterLift`, so the isomorphism is the canonical one: $h \mapsto$ the unique $g \in$ AutO with $h|_{V^\natural_2} = \mathcal{G}(1 \otimes g)\mathcal{G}^{-1}$. `Nonempty (…)` is the propositional form ("there exists an isomorphism").
Hypotheses. (a), (b): none. (c): `hGmat : Generated.Gmat = AutO`, the body of `GmatEqAutO`.
Same statement. (b) is the precise form of "$\mathrm{Aut}(V^\natural)$ is a subgroup of the Monster containing G_{mat}"; since `liftableSubgroup` is defined as the set of liftable elements, (b) is not a tautology: its content is that *every* automorphism of $V^\natural$ is a lift, i.e. (a).
Could it be vacuous? No: $\mathrm{Aut}(V^\natural)$ is nontrivial (it contains the image of G_{mat}), and (a) is a statement about every element of it.

Proof on paper. Theorem 49.29 with the hypothesis discharged by Theorem 49.30. □

Physical meaning

The Monster contains the full symmetry group. Every symmetry of the moonshine CFT is, on the 196884 weight-two fields, one of AxiomMath's rational Griess-algebra automorphisms; together with §§49.5–49.7, $G_{\mathrm{mat}} \subseteq \mathrm{Aut}(V^\natural) \subseteq$ AutO. The identification of the

symmetry group is reduced to the purely group-theoretic statement $G_{\mathrm{mat}} = \mathrm{Aut}\mathbb{O}$, which no longer mentions the CFT.

What the machine verified

(a), (b): **unconditional**. (c): conditional on `hGmat`. Coordinator audit `VOA/Moonshine/MoonshineCNSymmetryFinalAudit.lean` (9,455 jobs): `[propext, Classical.choice, Quot.sound]`, 0 `sorryAx`, for all three and for `M8.gmatCommutantScalar`, `M8.autVnat_mulEquiv_liftable`, `rationalTraces`, `conwayNorton`, `conwayNorton_gmat`.

49.13 The headline: monstrous moonshine for AxiomMath's Monster

The file `VOA/Moonshine/MoonshineLRMonsterHeadline.lean` (namespace `VOA.Moonshine.ConwayNorton`) states the final form of the part's theorems in terms of the Monster itself. It has four declarations of substance.

49.13.1 The named hypothesis

Definition 49.33 (The generation theorem, as a proposition)**.** GmatEqAutO is the proposition $G_{\mathrm{mat}} = \mathrm{Aut}\mathbb{O}$: the subgroup of $\mathrm{GL}_{\mathbb{Q}}(\mathcal{B})$ generated by the visible group and τ_B is the full group of $\mathbb{Q}$-linear automorphisms of AxiomMath's rational Griess algebra preserving its product and its form. It is AxiomMath's statement `gmat_eq_griess` after renaming, with one definition (`SpinLattice.phi0`) restated in a definitionally equal form; that statement is proved in AxiomMath's library (Lean 4.35, commit `69cb972f`); the literature milestones on its proof path that were inspected (`cl_lit_stroth_leon_sims_baby_monster_recognition`, its `_models` variant, and `cl_lit_goldschmidt_strongly_closed_abelian`) are theorems there, not axioms; its full axiom footprint has not been re-checked (that needs `#print axioms` on a Lean 4.35 build of AxiomMath's library).

```
def GmatEqAutO : Prop :=
  Generated.Gmat = AutO
```

(`VOA/Moonshine/MoonshineLRMonsterHeadline.lean`; full name `VOA.Moonshine.ConwayNorton.GmatEqAutO`.)

From the mathematics to the Lean statement

What it says, symbol by symbol. `Generated.Gmat` is `Subgroup.closure ((Gvis : Set (SpaceB ≃ₗ[ℚ] SpaceB)) ∪ {tauB})` (§49.1.3), a subgroup of the group `SpaceB ≃ₗ[ℚ] SpaceB` of $\mathbb{Q}$-linear automorphisms; `AutO` is the subgroup of those g with $g(u \cdot v) = gu \cdot gv$ and $b(gu, gv) = b(u, v)$ (§49.1.3). `=` is equality of subgroups, i.e. equality of the underlying sets. Since $G_{\mathrm{mat}} \leq \mathrm{Aut}\mathbb{O}$ is a theorem (`Generated.Gmat_le_AutO`, with `tauB_mem_AutO`), the content of `GmatEqAutO` is the reverse inclusion: *every* automorphism of the rational Griess algebra is a word in the visible elements and τ_B.

It is AxiomMath's statement after renaming, with `phi0` restated definitionally equal. AxiomMath's CFSG library, at commit `69cb972f587a3ecc035e092253167ff2e303c962`, contains the theorem

```
theorem gmat_eq_griess :
    CFSG.Monster.Generated.Gmat = CFSG.Monster.Griess.AutO :=
  CFSG.YGroups.Y443.Gmat_eq_AutO_of_stroth
```

(full name `CFSG.Blueprint.NativeSporadic.MonsterModel.gmat_eq_griess`, file `CFSG/Sporadic/Bridge/MonsterModelsGriess.lean`; quoted in `plaincode` because it is not a file of this library). Both sides are written with fully qualified names, they are the declarations the port copied, and both have type `Subgroup (SpaceB ≃ₗ[ℚ] SpaceB)`. The project's fidelity audit (`Notes/monster_aut/CFSG_PORT_FIDELITY.md`) compared the definitional closure of the two sides — 199 definition-like declarations and 104 theorem statements that fix data (through implicit arguments or `Classical.choose` predicates), 46 instances, and the `variable` contexts — with AxiomMath's source after normalising comments, attributes, visibility keywords and the namespace prefixes `CFSG.Monster.Griess.` , `CFSG.Monster.` ↦ `VOA.Moonshine.MonsterGriess.`. Verdict: 194 definition bodies are textually identical; three differ only in proof arguments of `Prop` type (`bform`, `gmul`) or by a parser artefact (`signMatrix`); the one genuine difference is

- `SpinLattice.phi0`: ours is the plain function $p \mapsto \mathrm{lamT}(p_1) + \mathrm{lamCocode}(p_2)$; AxiomMath's is the bundled $\mathbb{Z}/2$-linear map `(AddMonoidHom.toZModLinearMap 2 lamTHom).coprod lamCocode`. The two are *definitionally equal* as functions (`LinearMap.coprod f g` is $f \circ \mathrm{fst} + g \circ \mathrm{snd}$ pointwise, and `lamTHom` has `toFun := lamT`; both libraries have `phi0_apply` by `rfl`). It enters only through `IsShortCoord` (and hence the index type `ShortIdx` and the `choose` in `uvec`), where the two predicates are kernel-convertible.

So `GmatEqAutO` is AxiomMath's statement up to renaming and definitional unfolding of one definition; it is not syntactically the same term. (Chapter 48 gives the port audit in detail.)

What the audit does not cover (stated in the audit itself). (i) Mathlib drift: the closure bottoms out in Mathlib constants (`Subgroup.closure`, `Matrix.toLinOfInv`, `LinearMap.mk₂`, `Classical.choose`, …), assumed to mean the same in Mathlib v4.30 and in AxiomMath's pinned Mathlib; not compared. (ii) No cross-toolchain build: the comparison is source text, not a Lean proof that the two terms are equal. (iii) The axiom footprint of `gmat_eq_griess` inside AxiomMath's library. Its proof passes through `CFSG.Milestones.cl_lit_stroth_leon_sims_baby_monster_recognition_models`. Inspection of the source at the pinned commit (reading the files as data) shows that this declaration and `cl_lit_stroth_leon_sims_baby_monster_recognition` (file `CFSG/Milestones/CL_LIT_Stroth_Leon_Sims_Baby_Monster_recognition.lean`) are *theorems*, proved from `CFSG.Milestones.cl_lit_goldschmidt_strongly_closed_abelian`, itself a theorem (`CFSG/Milestones/CL_LIT_Goldschmidt_strongly_closed_abelian.lean`); in AxiomMath's naming, `CL_LIT` marks a literature milestone that is *proved*, not assumed. Nobody in this project has run `#print axioms` on `gmat_eq_griess`, which needs a Lean 4.35 build of AxiomMath's library; so its full axiom footprint is not re-checked.

Why a named hypothesis, not an axiom. The library's policy (`README.md`, `CLAUDE.md` §3) is: *no project axioms* in production code. An `axiom` would silently enter the `#print axioms` output of every theorem using it and would be global; a definition `GmatEqAutO : Prop` used as an explicit argument (`hM : GmatEqAutO`) makes the dependence visible in the type of every theorem that needs it, and leaves every other theorem untouched. The theorem itself cannot be imported: AxiomMath's library is on Lean v4.35.0-rc3 with a Mathlib about four months newer than this library's Lean 4.30 / Mathlib v4.30, and porting the proof down is infeasible — its file-level import closure is about 15,500 CFSG files (≈ 16,000 with the TauCeti dependency; ≈ 197–208 MB, 4.2 M lines), dominated by the Stroth–Leon–Sims recognition of the Baby Monster, with 1,720 certificate files. No Stroth-free proof of $G_{\mathrm{mat}} = \mathrm{AutO}$ exists in that library.

Could it be false, or trivially true? It is not trivially true: the inclusion $\mathrm{AutO} \leq G_{\mathrm{mat}}$ is the deep content of the identification of the Monster with the automorphism group of the Griess algebra (classically: Conway's group generated by C and the triality element is $\mathbb{M}$, and

Tits proved that $\mathbb{M}$ is the full automorphism group of the Griess algebra). It is not refuted by anything in this library: everything proved here is consistent with it (e.g. `finite_gmat` shows G_{mat} finite, as AutO must then be).

Physical meaning

The proposition is purely group-theoretic: it says that the symmetries of the 196884 weight-two OPE coefficients that one can write down explicitly (orbifold-visible ones and triality) generate *all* symmetries of those OPE coefficients. It no longer refers to the CFT.

What the machine verified

A definition (a `Prop`); `#print axioms VOA.Moonshine.ConwayNorton.GmatEqAutO` is printed in `VOA/Moonshine/MoonshineLRLiftAudit.lean` (standard axioms; a definition of a proposition has no proof content). **Not proved in this library.** It is AxiomMath's statement after renaming (`phi0` restated definitionally equal), proved in AxiomMath's library (Lean 4.35, commit `69cb972f`); the literature milestones on its proof path that were inspected (`cl_lit_stroth_leon_sims_baby_monster_recognition`, its `_models` variant, and `cl_lit_goldschmidt_strongly_closed_abelian`) are theorems there, not axioms; its full axiom footprint has not been re-checked (that needs `#print axioms` on a Lean 4.35 build of AxiomMath's library).

Trap / dead end

Minor inconsistency in the recorded closure size. The docstring of `GmatEqAutO`'s file says "about 15,500 files"; the project's records say "15.5k files"; Chapter 43 says "about 16,000 files and 208 MB". All are consistent with the following: 15,502 CFSG files (196.9 MB) for the minimal roots, plus 859 TauCeti files; 16,361 files and 208 MB at file level. No defect; recorded so that a reader does not mistake the figures for a discrepancy.

49.13.2 The isomorphism

Theorem 49.34 (AutO $\cong$ Aut($V^\natural$), given GmatEqAutO). *Assume $G_{\mathrm{mat}} =$ AutO. Then every element of* AutO *is liftable, the lift* AutO $\to$ Aut($V^\natural$) *is bijective, and the resulting group isomorphism φ satisfies $\varphi(g)|_{V^\natural_2} = \mathcal{G} \circ (1_{\mathbb{C}} \otimes g) \circ \mathcal{G}^{-1}$ for every g, $\mathcal{G} =$* `griessIso`.

```
theorem isVnatLiftable_of_gmatEqAutO (hM : GmatEqAutO) (g : AutO) : IsVnatLiftable g
-- …
theorem monsterLiftOfAll_bijective (hM : GmatEqAutO) :
    Function.Bijective (monsterLiftOfAll (isVnatLiftable_of_gmatEqAutO hM))
-- …
noncomputable def monsterEquivAutVnat (hM : GmatEqAutO) : AutO ≃* AutVnat :=
  MulEquiv.ofBijective (monsterLiftOfAll (isVnatLiftable_of_gmatEqAutO hM))
    (monsterLiftOfAll_bijective hM)
-- …
theorem monsterEquivAutVnat_restrict (hM : GmatEqAutO) (g : AutO) :
    vnatWeightTwoRestrict (monsterEquivAutVnat hM g) =
      griessConj (g : SpaceB ≃ₗ[ℚ] SpaceB) :=
  monsterLiftOfAll_restrict (isVnatLiftable_of_gmatEqAutO hM) g
```

(`VOA/Moonshine/MoonshineLRMonsterHeadline.lean`.)

From the mathematics to the Lean statement

Decoding. `monsterLiftOfAll hlift : AutO →* AutVnat` (§49.1.3) is `monsterLift` composed with the inclusion of AutO into the liftable subgroup, available once every element is liftable; `Function.Bijective` is injective and surjective; `MulEquiv.ofBijective` turns a bijective homomorphism into a group isomorphism `AutO ≃* AutVnat`. In `monsterEquivAutVnat_restrict`, `monsterEquivAutVnat hM g` is $\varphi(g)$ (the coercion of a `MulEquiv` to a function), and the right side is the Griess conjugate (quoted in §49.1.3), so the identity says: $\varphi(g)$ acts on ${V^\natural}_2 \cong \mathbb{C} \otimes \mathcal{B}$ as $1 \otimes g$. The proof term `monsterLiftOfAll_restrict …` is shown because it is informative: the compatibility holds by construction.
Hypothesis. Only `hM : GmatEqAutO`. Injectivity of the lift is unconditional (`monsterLiftOfAll_injective`); surjectivity uses the unconditional converse (`monsterLift_surjective_of_commutant M8.gmatCommutantScalar`, visible in the proof of `monsterLiftOfAll_bijective`); `hM` is used only to make every element of AutO liftable (`isVnatLiftable_of_gmatEqAutO`: an element of AutO is in G_{mat}, hence liftable by Theorem 49.18(b)).
Uniqueness, i.e. why the isomorphism is canonical. An automorphism of $V^\natural$ is determined by its restriction to ${V^\natural}_2$ (`vnatWeightTwoRestrict_injective`), so φ is the *only* map $\mathrm{AutO} \to \mathrm{Aut}(V^\natural)$ with the compatibility property.
Strength. This is the expected statement "the Monster acts faithfully on $V^\natural$ and every automorphism of $V^\natural$ comes from it", for AxiomMath's model of the Monster, compatibly with the identification of Griess algebras.

Proof on paper. Under `hM`, $\mathrm{AutO} = G_{\mathrm{mat}} \subseteq$ liftable (Theorem 49.18); `monsterLift` is injective (Chapter 48) and surjective onto $\mathrm{Aut}(V^\natural)$ (Theorem 49.32). □

Physical meaning

The Monster is exactly the symmetry group of the moonshine CFT, realised on the 196884 weight-two fields by AxiomMath's explicit rational matrices — conditional on the group-theoretic identification.

What the machine verified

Conditional on `GmatEqAutO`. `#print axioms` for all four in `VOA/Moonshine/MoonshineLRLiftAudit.lean`: `[propext, Classical.choice, Quot.sound]` (rebuild of the audit, 9,457 jobs, 926 reports, 0 `sorryAx`). `#print axioms` does not report `hM`.

49.13.3 Monstrous moonshine

Theorem 49.35 (Monstrous moonshine for the Monster; Conway–Norton, Borcherds)**.** *Assume* $G_{\mathrm{mat}} = \mathrm{AutO}$. *Then there is a group isomorphism* $\varphi : \mathrm{AutO} \to \mathrm{Aut}(V^\natural)$ *such that*

(i) for every $g \in \mathrm{AutO}$, $\varphi(g)$ *acts on* ${V^\natural}_2 \cong \mathbb{C} \otimes_{\mathbb{Q}} \mathcal{B}$ *as* $1 \otimes g$; *and*

(ii) for every $g \in \mathrm{AutO}$ *there are a subgroup* $\Gamma \leq \mathrm{SL}_2(\mathbb{R})$ *(in Lean: a subgroup of* $\mathrm{GL}_2(\mathbb{R})$ *all of whose elements have determinant* 1*) and* $N \geq 1$ *with* $\Gamma_0(N) \leq \Gamma$, Γ *commensurable with* $\mathrm{SL}_2(\mathbb{Z})$, *such that*

$$T_{\varphi(g)}(\tau) = q^{-1} + \sum_{n \geq 1} \mathrm{tr}(\varphi(g) | {V^\natural}_{n+1}) q^n, \qquad q = e^{2\pi i \tau},$$

is a normalised Hauptmodul for Γ.

```
theorem monstrousMoonshine (hM : GmatEqAutO) :
    ∃ φ : AutO ≃* AutVnat,
      (∀ g : AutO, vnatWeightTwoRestrict (φ g) = griessConj (g : SpaceB ≃ₗ[ℚ] SpaceB)) ∧
        ConwayNortonVia (φ : AutO →* AutVnat) :=
  ⟨monsterEquivAutVnat hM, monsterEquivAutVnat_restrict hM, fun _ => conwayNorton _⟩
```

(`VOA/Moonshine/MoonshineLRMonsterHeadline.lean`; full name `VOA.Moonshine.ConwayNorton.monstrousMoonshine`.)

From the mathematics to the Lean statement

Clause by clause.

(1) `(hM : GmatEqAutO)`: the one hypothesis, Definition 49.33.

(2) `∃ φ : AutO ≃* AutVnat`: a group isomorphism from AxiomMath's Monster onto the automorphism group of the vertex operator algebra `VnatVOA` (Chapter 43). `AutO` is a subgroup, used here as a group (its elements are pairs of a linear automorphism and a membership proof; `(g : SpaceB ≃ₗ[ℚ] SpaceB)` is the underlying map).

(3) `∀ g : AutO, vnatWeightTwoRestrict (φ g) = griessConj (g : SpaceB ≃ₗ[ℚ] SpaceB)`: clause (i). Both sides are $\mathbb{C}$-linear automorphisms of $V^\natural{}_2$; the right side is $\mathcal{G} \circ (1 \otimes g) \circ \mathcal{G}^{-1}$. By `vnatWeightTwoRestrict_injective`, this clause determines φ uniquely, so the existential is not a loophole: it is witnessed by `monsterEquivAutVnat hM` and by nothing else.

(4) `ConwayNortonVia (φ : AutO →* AutVnat)`: by definition (§49.1.3), `∀ g : AutO, ConwayNortonFor (φ g)`, i.e. clause (ii): `IsMoonshineGroup Γ N` encodes $N \geq 1$, $\Gamma \leq \mathrm{SL}_2(\mathbb{R})$ (`HasDetOne`), $\Gamma_0(N) \leq \Gamma$ (`gamma0GL N ≤ Γ`) and commensurability with $\mathrm{SL}_2(\mathbb{Z})$; `IsNormalizedHauptmodul Γ (mckayThompsonFun (φ g))` is the eight-clause Hauptmodul condition of Chapter 43 for $T_{\varphi(g)}$. The coercion `(φ : AutO →* AutVnat)` forgets that φ is invertible.

Comparison with the textbook statement. The Conway–Norton conjecture (proved by Borcherds) says: there is a graded faithful representation $V = \bigoplus V_n$ of $\mathbb{M}$ with $\dim V_n$ the coefficients of J, such that for every $g \in \mathbb{M}$, T_g is the normalised Hauptmodul of a genus-zero group Γ_g containing $\Gamma_0(N)$. The Lean statement has: *the Monster* = AxiomMath's `AutO` (a *name*: LeanVOA does not prove that `AutO` is simple, nor its order $2^{46}3^{20}5^9 \cdots 71 \approx 8 \cdot 10^{53}$; these are classical facts about the Monster, and AxiomMath's library proves finiteness and order results for its model on Lean 4.35, none of which is imported here); *the representation* = $V^\natural$, through φ (the graded dimension J and simplicity of $V^\natural$ are Chapter 42's `moonshine`); *faithful* = φ injective; and a property not in the conjecture but in FLM's theorem: the action is by vertex-operator-algebra automorphisms and is *all* of $\mathrm{Aut}(V^\natural)$, compatibly with the Griess algebras. It is *weaker* than the full Conway–Norton table in one recorded respect: Γ and N are existentially quantified; their identification with the groups of the Conway–Norton list (and $N = o(g)h$) is not stated (Chapter 43). It is *stronger* than "moonshine for some finite group" in that the group is pinned to AxiomMath's independent construction.

What the statement would mean if `GmatEqAutO` were false. Then the theorem would be vacuous (an implication with a false premise), and would say nothing about the Monster. But every *unconditional* result of the part stands, and together they still say a great deal:

- `conwayNorton`: Conway–Norton for every automorphism of $V^\natural$, whatever that group is;
- `conwayNorton_gmat`: every element of the explicit group G_{mat} acts on $V^\natural$ compatibly with the Griess algebras, and its McKay–Thompson series is a Hauptmodul;

- `nonempty_autVnat_mulEquiv_liftable`: $G_{\mathrm{mat}} \le \mathrm{Aut}(V^\natural) \le \mathrm{Aut}\mathbb{O}$ (canonically);
- `finite_autVnat`, `rationalTraces`, `gmatCommutantScalar`.

So the only thing `GmatEqAutO` adds is the identification of the sandwiched group $\mathrm{Aut}(V^\natural)$ with the outer group $\mathrm{Aut}\mathbb{O}$.
What release v1.1 changes (the authors' plan: "v1.1 will then bump the library to 4.35 and discharge it"). After moving the library to AxiomMath's toolchain (Lean 4.35 and AxiomMath's Mathlib pin) and importing AxiomMath's library, `gmat_eq_griess` becomes available; with a bridge identifying the ported definitions with the imported ones (by `rfl`, given the fidelity audit; or by re-porting `phi0` in bundled form), the hypothesis can be discharged and `monstrousMoonshine` instantiated to an unconditional theorem — unconditional relative to AxiomMath's library, whose own axiom footprint must then be checked. This is a plan; none of it is in v1.05.

Proof on paper. Take $\varphi =$ `monsterEquivAutVnat hM`; (i) is Theorem 49.34; (ii) is `conwayNorton` (Chapter 47) applied to $\varphi(g)$. The Lean proof is the anonymous-constructor term `⟨monsterEquivAutVnat hM, monsterEquivAutVnat_restrict hM, fun _ ⇒ conwayNorton _⟩`, displayed above. □

Physical meaning

Monstrous moonshine as a CFT statement. The moonshine CFT has the Monster as its full global symmetry group, and the torus partition function twisted by any Monster element g is the Hauptmodul of a genus-zero modular curve. In string-theory language (Chapters 44–46): compactifying the bosonic string on $V^\natural \otimes V_{I\!I_{1,1}}$ produces the Monster Lie algebra as the BRST cohomology; the Monster acts on it; its twisted denominator identities express that the twisted partition functions are completely replicable, and complete replicability forces genus zero. The present theorem adds the identification of the symmetry group with an independently constructed Monster.

What the machine verified

Conditional on the named hypothesis `GmatEqAutO` and on nothing else. `#print axioms` (`VOA/Moonshine/MoonshineLRLiftAudit.lean`): `[propext, Classical.choice, Quot.sound]`; 0 `sorryAx`; wired into the umbrella `VOA.Moonshine` (umbrella green, 9,504 jobs). The aggregate `lake build` of the whole library for this state is the release step and is not reported in the sources read for this chapter. This book never calls `monstrousMoonshine` unconditional.

49.14 Documentation defects recorded while writing this chapter

The following module docstrings and notes describe an earlier state of the work; none affects a Lean statement. They are collected here rather than interrupting the mathematics, and are classed with severity S4 (the lowest: documentation only).

Trap / dead end

- **Stale module docstrings.** The module docstrings of `VOA/Moonshine/MoonshineLRLiftTwisted.lean` ("The candidate on `TP` is not yet proved to intertwine `plusModule`") and `VOA/Moonshine/MoonshineLRLiftTwisted2.lean` ("we have not proved that a scalar multiple preserves `TPForm`") describe the state of each file in isolation; both gaps are closed in the next file (`liftTwPlusEquiv_mode`, `liftTwExists_formScalar`). The definition `liftTwVnatAut` has no form hypothesis.

(Recorded as an S4 documentation defect.)

- **Stale docstrings.** `VOA/Moonshine/MoonshineLRLiftLiftable2.lean` says "The other Golay sign changes and the Mathieu permutations remain open"; `VOA/Moonshine/MoonshineLRLiftLiftable3.lean` and `VOA/Moonshine/MoonshineLRLiftLiftable4.lean` say "The generator ξ is not treated". These describe the files in isolation; the gaps are closed by Theorem 49.10 and Theorem 49.12. (S4.)
- **Stale docstring.** `VOA/Moonshine/MoonshineLRLiftVisible.lean` says "The remaining gap is to identify and cancel that discrepancy as an extraspecial action"; it is closed in `VOA/Moonshine/MoonshineLRLiftVisible2.lean`. (S4.)
- **Stale docstrings.** `VOA/Moonshine/MoonshineLRSigmaBlock.lean` ("The full rational dictionary matrix of `v0Sigma` still requires matching ..."), `VOA/Moonshine/MoonshineLRSigmaBlock2.lean` ("The octad `KS` coefficients are not treated") and `VOA/Moonshine/MoonshineLRSigmaB.lean` ("isolates the unproved input") describe files in isolation; the gaps are closed in `VOA/Moonshine/MoonshineLRSigmaBlock3.lean` and `VOA/Moonshine/MoonshineLRSigmaB2.lean`. (S4.)
- **Stale docstring.** The module docstring of `VOA/Moonshine/MoonshineLRTauB.lean` says "The final theorem retains only `tauB ∈ AutO` and `Generated.Gmat = AutO`". That is true of the file; the first of the two was discharged afterwards (`tauB_mem_AutO`, ported from the AxiomMath library), and `VOA/Moonshine/MoonshineLRMonsterFinal.lean` carries only the second. (S4.)
- **Route deviation from the paper plan.** The authors' paper plan (Step 7) planned to use the Golay sign characters on $\mathcal{A}$ to show $T(D) \subseteq D$; the Lean proof obtains it from triality directly (Step 7 above), so the sign-character step was not needed. (S4, note.)
- **Stale note.** An earlier working note says "The opposite direction AutVnat $\leq$ Monster (rationality, Tits) is not needed for this statement" and a later entry calls it "open research"; both predate Theorem 49.32, which proves it (without Tits). (S4, note.)
- **Namespace.** The `MoonshineLR*` files use the namespace `VOA.Moonshine.ConwayNorton.M8`, whose suffix is a historical node label (recorded as naming debt).

49.15 The assigned files and how each is covered

The rules of `Notes/Textbook/assignment.txt` assign to this chapter the 39 files `VOA/Moonshine/MoonshineLR{Lift*,Sigma*,TauB,MonsterVisible,MonsterFinal,Commutant*,MonsterHeadline}.lean` and `VOA/Moonshine/MoonshineCN{MonsterFinalAudit,SymmetryFinalAudit,Rational*}.lean`. "Individually" means the headline declarations are presented under the Fidelity Protocol; "collectively" means the file's content is described and its role explained.

file (`VOA/Moonshine/`)	coverage	where; content
`MoonshineLRLiftNatural.lean`	individually	Thm 49.1; naturality `vnatAutOfPair`
`MoonshineLRLiftLattice.lean`	individually	Def 49.2; Co_0 on V_Λ^+

file (VOA/Moonshine/)	coverage	where; content
MoonshineLRLiftTwisted.lean	collectively	proof of Thm 49.4; Fock frame change, tensor candidate, coboundary relations
MoonshineLRLiftTwisted2.lean	individually	Thms 49.3, 49.4; ρ, word-field covariance
MoonshineLRLiftTwisted3.lean	individually	Thm 49.4, Def 49.5; form scalar, liftTwVnatAut
MoonshineLRLiftExtra.lean	individually	before Def 49.6; character automorphism, e_μ, form multiplier
MoonshineLRLiftExtraAut.lean	individually	Def 49.6; extraVnatAut
MoonshineLRLiftBlock.lean	individually	Thm 49.7; $A \mapsto gAg^{\mathsf{T}}$, extraspecial blocks
MoonshineLRLiftSign.lean	individually	Thm 49.7; signed permutation, $r_c = \pm 1$
MoonshineLRLiftWBlock.lean	collectively	§49.3 (twisted block); spin coordinates of the lifts
MoonshineLRLiftLiftable.lean	individually	Thm 49.8(a),(c); rational criterion
MoonshineLRLiftLiftable2.lean	individually	Thm 49.8(b),(c); phases, unphased equation, -1
MoonshineLRLiftLiftable3.lean	individually	Def 49.9, Thm 49.8; generators, basis reduction
MoonshineLRLiftLiftable4.lean	individually	Thm 49.10; $2^{12}:M_{24}$ liftable
MoonshineLRLiftXi.lean	individually	Def 49.11, Thm 49.12; ξ, rational descent
MoonshineLRLiftVisible.lean	collectively	proof of Thm 49.13; visible-pair dictionary, liftVisParity_ext
MoonshineLRLiftVisible2.lean	individually	Thm 49.13; liftVisRAllVisible
MoonshineLRMonsterVisible.lean	individually	Thm 49.13; conwayNorton_autO_of_tauB
MoonshineLRSigmaBlock.lean	individually	Thm 49.14; sector split, $\sigma z \sigma$
MoonshineLRSigmaBlock2.lean	individually	Thm 49.15; two-root block
MoonshineLRSigmaBlock3.lean	individually	Thm 49.15; octad block, sigmaBlockOFull_nat
MoonshineLRSigmaB.lean	individually	Thm 49.16(a); reduction to odd columns
MoonshineLRSigmaB2.lean	individually	Thm 49.16(b),(c); seed, sigmaBOdd_liftable
MoonshineLRTauB.lean	individually	Thm 49.17; conjugation, centralizer
MoonshineLRMonsterFinal.lean	individually	Thms 49.17, 49.19
MoonshineLRCommutant.lean	collectively	§49.11, Steps 1–3
MoonshineLRCommutant2.lean	collectively	§49.11, Steps 4–7
MoonshineLRCommutant3.lean	collectively (quoted)	§49.11, Steps 8–9; commutL_xi_blocks, A, B
MoonshineLRCommutant4.lean	individually	Thm 49.30, Steps 9–10; certificates
MoonshineLRCommutantFinal.lean	individually	Thms 49.30, 49.32
MoonshineLRMonsterHeadline.lean	individually	§49.13; the headline
MoonshineCNMonsterFinalAudit.lean	individually + audit	Thms 49.18, 49.19; §49.16
MoonshineCNSymmetryFinalAudit.lean	individually + audit	Thm 49.32; §49.16
MoonshineCNRationalTraces.lean	individually	Thms 49.20, 49.21, 49.23
MoonshineCNRationalRamanujan.lean	individually	Thm 49.22
MoonshineCNRationalSchur.lean	individually	Thms 49.24, 49.25
MoonshineCNRationalGriess.lean	individually	Def 49.26–Thm 49.29
MoonshineCNRationalAudit.lean	audit	§49.16
MoonshineLRLiftAudit.lean	audit	§49.16

Supporting declarations not displayed. The files contain many lemmas not quoted above (in total several hundred); each is used in one of the proofs described. In particular: the Fock-space covariance lemmas of VOA/Moonshine/MoonshineLRLiftTwisted.lean

(annihilator chain rule, creation and annihilation exponentials, dressing DD); the field-product transport of VOA/Moonshine/MoonshineLRLiftTwisted2.lean (liftTwConjField_prod, liftTwConjField_star); the rank-transport lemmas (liftTwCastEquiv_YM, extraPhi_cast_YM) that move between the abstract lattice rank and the concrete 24; the spin-coordinate data of VOA/Moonshine/MoonshineLRLiftWBlock.lean (liftWEquiv, a complex coordinate isomorphism $(\mathbb{C}^{4096})^{24} \cong (T^+)_2$; the module docstring says, correctly, that these statements do not assert rationality); and the sign bookkeeping lemmas of the triality files.

49.16 Audit files

- VOA/Moonshine/MoonshineLRLiftAudit.lean: at the release, 997 #print axioms commands (counted in the file) and 42 imports: all MoonshineLRLift*, MoonshineLRSigma*, MoonshineLRTauB, MoonshineLRMonster{Visible,Final,Headline}, MoonshineLRCommutant*, MoonshineLRGriessTransfer, and the Aut*.lean files of Chapter 47 (whose 124 theorems were added). Build record: green, 9,457 jobs for the headline state with 926 reports; at the release, green, 997 reports; all [propext, Classical.choice, Quot.sound], 0 sorryAx.
- VOA/Moonshine/MoonshineCNRationalAudit.lean: 94 #print axioms commands (plus one #print of the definition GmatCommutantScalar) over MoonshineCNRational{Schur,Ramanujan,Traces,Griess}; green (9,449 jobs), standard axioms, 0 sorryAx. Its docstring notes that #print axioms does not report hcomm or hGmat.
- VOA/Moonshine/MoonshineCNMonsterFinalAudit.lean: 11 reports (conwayNorton_monster, conwayNorton_gmat, gmat_eq_map_closure_insert_tauB, isVnatLiftable_of_mem_gmat, conwayNorton, M8.isVnatLiftable_tauB, M8.conwayNorton_monster_of_Gmat, tauB_mem_AutO, Generated.Gmat_le_AutO, griessIso_mul, griessIso_form); green (9,441 jobs), standard axioms.
- VOA/Moonshine/MoonshineCNSymmetryFinalAudit.lean: 8 reports (autVnat_rational, nonempty_autVnat_mulEquiv_liftable, autVnat_mulEquiv_autO, M8.gmatCommutantScalar, M8.autVnat_mulEquiv_liftable, rationalTraces, conwayNorton, conwayNorton_gmat); green (9,455 jobs), standard axioms.

These figures are those of the build record of the release (Chapter 50, Section 50.1.9). The two *FinalAudit files also contain theorems, presented above.

49.17 Referee's checklist

49.17.1 This chapter

declaration	intended meaning	hypotheses	check
M8.vnatAutOfPair	compatible form-preserving pair is an automorphism of $V^\natural$	hφ, hT (data)	Thm 49.1
M8.leechPlusLatMorphAut	Co_0 on V_Λ^+	isometry, onto	Def 49.2
M8.liftTwChargeIntertwiner_exists	charge intertwiner ρ exists	isometry	Thm 49.3
M8.liftTwPlusEquiv_mode, M8.liftTwExists_formScalar	φ_ι covariant; normalisable	isometry, onto	Thm 49.4
M8.liftTwVnatAut	lift of $\iota \in \mathrm{Co}_0$ to $\mathrm{Aut}(V^\natural)$ (chosen)	isometry, onto	Def 49.5
M8.extraVnatAut	lift of $\mu \in \Lambda$ (extraspecial)	none	Def 49.6

declaration	intended meaning	hypotheses	check
`M8.liftSignNat_untwisted`	untwisted block: gAg^{T}, signed permutation	isometry, onto	Thm 49.7
`M8.liftLiftableIffSpinRational`, `M8.liftMonoOfUnphasedIntertwiner`	rational criterion for liftability	rational orthogonal intertwiner	Thm 49.8
`M8.liftSpinGolay_liftable`, `M8.liftSpinMathieu_liftable`	$2^{12}{:}M_{24}$ lifts	codeword / code-preserving	Thm 49.10
`M8.liftXi_liftable`	ξ lifts	none	Thm 49.12
`M8.liftVisRAllVisible`	every element of G_{vis} lifts	none	Thm 49.13
`M8.conwayNorton_autO_of_tauB`	CN for AutO from τ and generation	`hτ`, `hGmat`	Thm 49.13
`M8.sigmaBlockConjugate`	$\sigma z \sigma$ = frame sign	none	Thm 49.14
`M8.sigmaBlockOFull_nat`	σ_0 rational	even support	Thm 49.15
`M8.sigmaBOdd_rational`, `M8.sigmaBOdd_liftable`	σ rational; σ = monsterLift(σ_B)	none	Thm 49.16
`M8.tauBLiftSigma_conj_xB`	$\sigma_B x_B \sigma_B^{-1} \in \{y_B, z_B\}$	`hτ` (a theorem)	Thm 49.17
`M8.isVnatLiftable_tauB`	τ_B lifts	none	Thm 49.17
`conwayNorton_gmat`	CN for every $g \in G_{\mathrm{mat}}$, with lift	none beyond membership $g \in G_{\mathrm{mat}}$	Thm 49.18
`conwayNorton_monster`, `M8.conwayNorton_monster_of_Gmat`	CN for all of AutO	`hGmat`	Thm 49.19
`mckayThompsonFun_pow_eq_of_coprime_holds`	$T_{g^u} = T_g$	none	Thm 49.20
`Rationality.exists_rat_trace_of_trace_pow_coprime`	Galois-invariant finite-order trace is rational	as stated	Thm 49.22
`rationalTraces`	all traces rational	none	Thm 49.23
`Rationality.schur_span_formula`, `Rationality.eq_map_ratCast_of_rational_traces`	Schur span; descent	as stated	Thms 49.24, 49.25
`MonsterAction.finite_gmat`	G_{mat} finite	none	Thm 49.27
`MonsterAction.GmatCommutantScalar`	commutant of G_{mat} is $\mathbb{Q}1 + \mathbb{Q}P_0$	(a `Prop`)	Def 49.28
`MonsterAction.autVnat_rational_of_commutant`	Aut($V^\natural$) rational given commutant	`hcomm`	Thm 49.29
`M8.gmatCommutantScalar`	the commutant lemma	none	Thm 49.30
`autVnat_rational`	every automorphism of $V^\natural$ is rational on $V^\natural{}_2$	none	Thm 49.32
`nonempty_autVnat_mulEquiv_liftable`, `M8.autVnat_mulEquiv_liftable`	Aut($V^\natural$) $\cong$ liftable subgroup of AutO	none	Thm 49.32
`autVnat_mulEquiv_autO`	Aut($V^\natural$) $\cong$ AutO	`hGmat`	Thm 49.32
`GmatEqAutO`	G_{mat} = AutO (AxiomMath's statement after renaming, `phi0` restated definitionally equal)	(a `Prop`)	Def 49.33
`monsterEquivAutVnat`, `monsterEquivAutVnat_restrict`	AutO $\cong$ Aut($V^\natural$), Griess-compatible	`GmatEqAutO`	Thm 49.34
`monstrousMoonshine`	monstrous moonshine for AxiomMath's Monster	**`GmatEqAutO`**	Thm 49.35

Names without a prefix are in `VOA.Moonshine.ConwayNorton`; `M8.` abbreviates `VOA.Moonshine.ConwayNorton.M8.`; `MonsterAction.` and `Rationality.` are in `VOA.Moonshine`.

49.17.2 The part's final table

The headline statements of Chapters 43–49, with their hypotheses. "None" means: no explicit hypothesis, and `#print axioms` is `[propext, Classical.choice, Quot.sound]`.

declaration	meaning	hypotheses; chapter
`ConwayNorton.conwayNorton`	Conway–Norton for every automorphism of $V^\natural$	none; Ch. 43, 47
`ConwayNorton.conwayNortonGammaOne_holds`	the Γ_1 form	none; Ch. 46, 49
`ConwayNorton.M8.finite_autVnat`	$\mathrm{Aut}(V^\natural)$ finite	none; Ch. 47
`ConwayNorton.rationalTraces`	all McKay–Thompson coefficients rational	none; Ch. 49
`GriessDictionary.griessIso`	$\mathbb{C} \otimes \mathcal{B} \cong {V^\natural}_2$ as algebras with forms	none; Ch. 48
`ConwayNorton.conwayNorton_gmat`	CN for every element of G_{mat}, acting on $V^\natural$	none beyond membership in G_{mat}; Ch. 49
`ConwayNorton.nonempty_autVnat_mulEquiv_liftable`	$\mathrm{Aut}(V^\natural) \cong$ liftable subgroup of AutO	none; Ch. 49
`ConwayNorton.M8.gmatCommutantScalar`	G_{mat} absolutely irreducible on $\mathbf{e}_1^\perp$	none; Ch. 49
`ConwayNorton.monsterEquivAutVnat`	$\mathrm{AutO} \cong \mathrm{Aut}(V^\natural)$	`GmatEqAutO`; Ch. 49
`ConwayNorton.monstrousMoonshine`	monstrous moonshine for AxiomMath's Monster	**`GmatEqAutO`**; Ch. 49

All names are in the namespace `VOA.Moonshine`. Apart from the membership premise of `conwayNorton_gmat`, the only hypothesis anywhere in the table is `GmatEqAutO`: AxiomMath's statement `gmat_eq_griess` after renaming, with `phi0` restated definitionally equal; proved in AxiomMath's library on Lean 4.35 (the literature milestones on its path that were inspected are theorems there), axiom footprint not re-checked, not available on this toolchain.

49.18 Notes and references

The construction of $V^\natural$ and the action of the Monster on it (the centralizer $C = 2^{1+24}.\mathrm{Co}_1$ in the orbifold description, the triality element, and the identification of ${V^\natural}_2$ with the Griess algebra) are in I. Frenkel, J. Lepowsky and A. Meurman, *Vertex Operator Algebras and the Monster*, Pure and Applied Mathematics 134, Academic Press, 1988, Chapters 10–12. The Monster's Griess algebra is R. L. Griess Jr., *The friendly giant*, Invent. Math. 69 (1982) 1–102. The simplified construction followed by AxiomMath, including the visible group, the element ξ and the triality element, is J. H. Conway, *A simple construction for the Fischer–Griess monster group*, Invent. Math. 79 (1985) 513–540. That the automorphism group of the Griess algebra is the Monster is J. Tits, *On R. Griess' "friendly giant"*, Invent. Math. 78 (1984) 491–499 (not used in this chapter). S. P. Norton's contributions to moonshine and to the structure of the Griess algebra include J. H. Conway and S. P. Norton, *Monstrous moonshine*, Bull. London Math. Soc. 11 (1979) 308–339, and S. P. Norton, *More on moonshine*, in *Computational Group Theory* (M. D. Atkinson, ed.), Academic Press, 1984, 185–193. The proof of the Conway–Norton conjecture is R. E. Borcherds, *Monstrous moonshine and monstrous Lie superalgebras*, Invent. Math. 109 (1992) 405–444. A modern account of the Monster through its Griess algebra and its axes, including the Majorana/Sakuma approach mentioned among the dead ends, is A. A. Ivanov, *The Monster Group and Majorana Involutions*, Cambridge Tracts in

Mathematics 176, Cambridge University Press, 2009. The MOG and the hexacode are in R. T. Curtis, *A new combinatorial approach to* M_{24}, Math. Proc. Cambridge Philos. Soc. 79 (1976) 25–42, and J. H. Conway and N. J. A. Sloane, *Sphere Packings, Lattices and Groups*, 3rd ed., Springer, 1999, Chapters 10, 11 and 29. The Baby Monster recognition through which AxiomMath's library proves $G_{\mathrm{mat}} = \mathrm{AutO}$ goes back to J. S. Leon and C. C. Sims, *The existence and uniqueness of a simple group generated by* $\{3,4\}$*-transpositions*, Bull. Amer. Math. Soc. 83 (1977) 1039–1040, and its later refinements. The physics of the orbifold and of the triality is in L. Dixon, P. Ginsparg and J. Harvey, *Beauty and the beast: superconformal symmetry in a Monster module*, Comm. Math. Phys. 119 (1988) 221–241. Schur's orthogonality relations and the Schur index are textbook material: J.-P. Serre, *Linear Representations of Finite Groups*, Graduate Texts in Mathematics 42, Springer, 1977, §§2.2 and 12.2.

The Monster used here is that of the AxiomMath CFSG library: D. Cureton, V. Ilin, B. Mehta, N. Voss, R. Cabral, C. Defant, E. Gregory, A. Hill, L. Hong, Q. Hu, D. Jamner, A. Jiang, T. Jordan, A. Kurghinyan, K. Lau, J. Laurent, D. Liang, J. Limperg, S. Mahns, B. Nugent, C. Olson, K. Ono, E. Paul, D. Rajan, K. Ram, C. Ray, H. C. Siu, A. A. Swaminathan, J. Thorner, A. Tsaplin and C. Wang, *Lean formalization of the classification of finite simple groups*, 2026, `https://github.com/AxiomMath/CFSG`, commit `69cb972f587a3ecc035e092253167ff2e303c962` (Lean v4.35.0-rc3), Apache License 2.0; the theorem `CFSG.Blueprint.NativeSporadic.MonsterModel.gmat_eq_griess` is in `CFSG/Sporadic/Bridge/MonsterModelsGriess.lean`. The port of its definitions to Lean 4.30 is by F. K. Popov (with Claude).

The development was recorded in the authors' working notes, which are not part of the release; the port audit `Notes/monster_aut/CFSG_PORT_FIDELITY.md` is. The Lean files were drafted largely with the help of automated coding assistants under the authors' direction and verified by targeted builds and axiom audits.

Part IX

Verification

Chapter 50

Verification, dead ends, numerics and open problems

This chapter documents the release of the library named in the front matter; every Lean quotation is checked by `scripts/textbook/sync.py` to occur verbatim (up to whitespace and comments) in the source files of that release. Its body was first written against the commit "Construct the Moonshine module $V^\natural$ (FLM) unconditionally" (7 October 2026, then the head of the main branch; "the Moonshine commit" below); records tied to that snapshot, and other checks not re-run for this edition, are marked as such, and the update of October 2026 is described below. The preceding chapters presented the mathematics of the LeanVOA library, the construction of the Moonshine module $V^\natural$ and, in Part VIII, monstrous moonshine for it. Each of them followed the same discipline: a mathematical statement, the Lean declaration copied verbatim from the repository, a fidelity check explaining why the one is the other, an argument on paper, and an honest status report. This last chapter turns the discipline on the library as a whole. It asks four questions that a referee-editor must be able to answer before signing off on the book.

(1) *What exactly has been checked, by what, and how would we know if it had not?* The answer is a verification protocol made of a compiler run, two scripts and a manual audit, each of which certifies something specific and nothing more (Section 50.1).

(2) *Which statements were wrong, vacuous or circular at some point, and how was that discovered?* The project kept a register of dead ends, traps and corrected mistakes, library-wide and for the Moonshine construction in particular. Section 50.2 consolidates it, each entry with its precise statement, the certificate of failure and the lesson.

(3) *What was computed numerically, and what is the status of those computations?* Section 50.3 describes every numerical experiment of the Moonshine construction, with its method, tolerance and controls, and says plainly that none of it is part of any proof.

(4) *Why was the construction done this way, can it be reproduced, and what is still open?* Sections 50.4, 50.5 and 50.6.

Throughout, four registers of claims are kept strictly apart, as the project's working agreements demand:

- **proved unconditionally** in Lean: the declaration has no hypothesis that is not itself established, and `#print axioms` lists only Lean's three standard axioms;
- **proved conditionally** in Lean: the declaration is accepted by the kernel, but its statement carries a hypothesis (a `Prop`-valued premise, or a structure that has to be supplied) which is not proved anywhere; the hypothesis is then named;

- **checked numerically**: a computer calculation outside Lean, in floating point or in exact arithmetic, agrees with the claim on a finite sample; this is evidence, never proof;
- **argued on paper only**, or **open**.

Earlier editions had a fifth register, **proved using the project axiom** `VOA.pbw`; since 19 October 2026 that axiom is a theorem, and the register is empty (Section 50.1.2; Chapter 3, Section 3.2). The Moonshine construction never used it.

The update of October 2026. The body of this chapter was written against the Moonshine commit. In October 2026 the book was brought up to date with the library on the branch `deligne-lean`: five chapters were added (Chapters 23–27: affine vertex algebras for every simple Lie algebra and the four chapters on the Deligne series; the chapter on affine $\mathfrak{sl}_3$ is in preparation; the two chapters on graded unitarity through the BRST coset, Chapters 28 and 29, were added for the v1.0 release), Chapters 11, 19 and 20 were extended, and every chapter that described `VOA.pbw` as an axiom was corrected. The present chapter was extended, not rewritten, to cover that work. The additions are: the book's own verification record and the trust base at the manifest commit (Section 50.1.11); the independent release audits of 27–28 October 2026 (Section 50.1.12); the dead ends recorded in the new and extended chapters (Section 50.2.9); and the open problems that those chapters name (Section 50.6.3). Following the book's scope decision, work in progress in the library is not described; where a route is under development, we say so and nothing more.

The update of release v1.05. Release v1.05 adds Part VIII, "Monstrous moonshine" (Chapters 43–49): the Conway–Norton conjecture, in a qualitative genus-zero form, for every automorphism of $V^\natural$, with no hypotheses; and the identification of $\mathrm{Aut}(V^\natural)$ with a Lean model of the Monster ported from the AxiomMath library, with no hypotheses for the subgroup of elements that act on $V^\natural$, and conditionally on one named hypothesis, `GmatEqAutO`, for the whole group (Chapter 1, Section 1.3.5). This chapter was again extended, not rewritten: the verification record of the moonshine part (Section 50.1.10), with a slot for the release figures of v1.05 in Section 50.1.9; an index of the dead ends recorded in Chapters 43–49 (Section 50.2.10); and the open problems of the moonshine part (Section 50.6), where the former open problem "$\mathrm{Aut}(V^\natural) \cong \mathbb{M}$" is replaced by its present, much narrower, form. The Deligne-series files added to the library after v1.0 (`G2Star`, `D4Core`, `SL4T`, `F4Star`) are held from this release and have no coverage in the book.

Remark 50.1 (A note on the physics)**.** A physicist reading this chapter may wonder why so much effort goes into checking that a statement means what it says. In a conformal field theory one rarely writes down the axioms of the operator algebra completely; one computes correlation functions and trusts that locality, associativity and modular invariance hold because the theory "exists". A formalization cannot work that way. Every axiom is a line of code, and a mistyped quantifier produces a theory that either does not exist (no nonzero object satisfies the axioms) or exists for trivial reasons (the zero theory, or a degenerate extension). Both happened in this project. The checks of this chapter are the mathematical counterpart of a physicist's sanity checks: is the partition function right, is the vacuum unique, does the operator product expansion close, and is the theory non-trivial.

50.1 The verification protocol

50.1.1 What a Lean proof certifies, and what it does not

A Lean file is a sequence of declarations: definitions (`def`, `structure`, `abbrev`) and theorems (`theorem`). A theorem declaration has the shape

```
theorem name (hypotheses) : statement := proof
```

When the file is compiled, Lean's *kernel*, a small and carefully audited type checker, verifies that `proof` is a term of type `statement` in the context of the hypotheses. This is the only thing a successful compilation certifies, and it is a great deal: every step of every argument has been checked down to the rules of dependent type theory. It is not everything a reader wants, for three reasons.

(a) *Definitions are trusted, not verified.* If `statement` mentions a notion such as `VertexOperatorAlgebra`, `IsSimple` or `TwistedModule`, the kernel checks the proof against the definition as written. It cannot know whether the definition captures the intended mathematical notion. A definition with a mistyped quantifier is a perfectly good definition of something else. This is why the book prints every definition verbatim and checks its fidelity; it is also the most common source of the dead ends of Section 50.2.

(b) *Hypotheses are assumed, not proved.* A theorem with a hypothesis (`h : P`) proves "P implies the statement". If P is false, or unsatisfiable, the theorem is true and worthless.

(c) *Axioms are assumed.* A declaration introduced with `axiom` is accepted without proof, and every theorem whose proof term mentions it, directly or through a chain of lemmas, depends on it.

The verification protocol of the project addresses each of these. Point (c) is handled mechanically, by `#print axioms` and the axiom audit; point (b) by a rule of language ("unconditional" versus "conditional") and a manual trace of hypotheses; point (a) only by human reading, which is what the fidelity checks of this book are for.

50.1.2 The trust base: three standard axioms (and the former project axiom)

Lean's logic has three axioms that essentially all of Mathlib uses:

- `propext` (*propositional extensionality*): two propositions that imply each other are equal;
- `Quot.sound`: the quotient of a type by a relation identifies related elements; this is what makes quotient constructions (such as quotient modules, or the Zhu algebra $A(V) = V/O(V)$) behave as in ordinary mathematics; it also implies function extensionality;
- `Classical.choice`: from a proof that a type is nonempty one may extract an element; this gives the law of excluded middle and all of classical reasoning, including the choice of bases of vector spaces.

These three are the background logic of ordinary mathematics (Zermelo–Fraenkel set theory with choice proves corresponding statements), and a theorem whose axiom list is a subset of {`propext`, `Classical.choice`, `Quot.sound`} is called `#print axioms`-*clean*.

The library adds no axiom of its own. Until 19 October 2026 it added exactly one, in `VOA/Foundations/AffineLie.lea` the same declaration is now a theorem:

```
structure PBWPrinciple : Prop where
  /-- PBW nonvanishing for every affine vacuum module. -/
  affineVacuum : ∀ {𝔤 : Type u} [LieRing 𝔤] [LieAlgebra ℂ 𝔤]
      (κ : LinearMap.BilinForm ℂ 𝔤) (hκ : κ.IsInvariant) (k : ℂ),
    PBW κ hκ k
  /-- The canonical bottom embeds in every module induced from a Lie subalgebra. -/
  inducedBottom : ∀ {g U : Type u} [LieRing g] [LieAlgebra ℂ g]
      [AddCommGroup U] [Module ℂ U] (p : LieSubalgebra ℂ g)
      (rho : p →ₗ[ℂ] Module.End ℂ U),
    Function.Injective (PBWInduction.bottom p rho)
```

```
theorem pbw : PBWPrinciple :=
  ⟨fun κ hκ k => AffineLie.vacuumVector_ne_zero_of_induction κ hκ k,
    fun p rho => PBWTheorem.bottom_injective p rho⟩
```

where `PBW κ hκ k` is defined, in the same file, as `AffineLie.vacuumVector κ hκ k ≠ 0`.

From the mathematics to the Lean statement

What the principle says. The Poincaré–Birkhoff–Witt theorem says that the universal enveloping algebra $U(\mathfrak{g})$ of a Lie algebra has a basis of ordered monomials in a basis of $\mathfrak{g}$; consequently $U(\mathfrak{g})$ is free as a right module over $U(\mathfrak{p})$ for any subalgebra $\mathfrak{p}$. The principle bundles two consequences of PBW:

- `affineVacuum`: for every Lie algebra $\mathfrak{g}$ over $\mathbb{C}$ with an invariant bilinear form κ and every level $k \in \mathbb{C}$, the vacuum vector of the affine vacuum module $V^k(\mathfrak{g}) = U(\hat{\mathfrak{g}}) \otimes_{U(\mathfrak{g}[t] \oplus \mathbb{C}K)} \mathbb{C}_k$ is nonzero. (Without PBW one cannot exclude that the induced module collapses to 0.)
- `inducedBottom`: for a Lie subalgebra $\mathfrak{p} \subseteq \mathfrak{g}$ and a representation ρ of $\mathfrak{p}$ on U, the canonical map $U \to U(\mathfrak{g}) \otimes_{U(\mathfrak{p})} U$, $u \mapsto 1 \otimes u$, is injective.

Both are classical theorems; Mathlib (v4.30.0) does not provide PBW, and the library now proves the needed relative form itself (Chapter 3, Section 3.10.6). The quantification over all universes `Type u` is the reason the statement is a `structure` of two fields rather than two separate declarations. **Could it be mis-stated?** Since it is proved, it cannot be inconsistent; the remaining risk is a mis-encoding of `PBWInduction.bottom` or `vacuumVector` that would make it weaker than intended, which is why those definitions are printed and checked in Section 3.10.

Physical meaning

PBW is the algebraic statement that a Verma-type module built by acting with creation operators on a highest-weight state is "as large as it looks": the states $J^{a_1}_{-n_1} \cdots J^{a_r}_{-n_r}|0\rangle$ with ordered modes are linearly independent before any null vectors are quotiented out. Every physicist uses this silently when counting the states of a current algebra (the Wess–Zumino–Witten vacuum module at level k) or when writing the character $\prod_n (1-q^n)^{-\dim \mathfrak{g}}$ of the universal affine algebra. `VOA.pbw` (with `pbwBasis_holds`) proves exactly that counting, nothing more.

Where `VOA.pbw` is used, and the twin pattern (history). While `VOA.pbw` was an axiom, the library followed a strict pattern (Chapter 3, Section 3.2): wherever a result needed PBW, it was proved twice. One version carries the needed consequence as an explicit hypothesis (a datum such as `Pr : BottomProjection ...`) and is `#print axioms`-clean; a companion wrapper, whose name ends in `_voaPBW` or `_of_voaPBW`, supplies that datum from `VOA.pbw`. Since `VOA.pbw` became a theorem the datum is supplied by a theorem, so each `_voaPBW` wrapper is the form of its twin with the PBW datum discharged. The two most important instances are Zhu's bijection and Zhu's modularity theorem. From `VOA/Modules/ZhuVermaAnArchLUBijection.lean` and `VOA/Modules/ZhuVermaAnArchLUBijectionPBW.lean`:

```
theorem zhuBijective (Pr : BottomProjection (parabolicRepOfAMod W (regularAMod W))) :
    Function.Bijective (forwardMapIrr W) :=

theorem zhuBijective_of_voaPBW (W : VertexOperatorAlgebra 𝒱) :
    Function.Bijective (forwardMapIrr W) :=
  zhuBijective
    (voaPBWBottomProjection (parabolicRepOfAMod W (regularAMod W)))
```

and from `VOA/Modularity/GNProp8Closure.lean` and `VOA/Modularity/GNProp8PBW.lean`:

```
theorem zhuModularity_pinned_of_C2Cofinite [Finite (Φ W)]
    (Mfam : ι → IrrModule W) (h : ι → ℂ)
    (hC2 : C2Cofinite W)
    (hss : letI := instRingA W; IsSemisimpleRing (A W))
    (Pr : BottomProjection (parabolicRepOfAMod W (regularAMod W)))
    (hcard : Fintype.card ι = Nat.card (Φ W))
    (hcw : ∀ i, HasConformalWeight (Mfam i).isMod (h i))
    (hsep : ∀ j k : ι, j ≠ k → h j = h k →
      IsEmpty (AModEquiv W (lowestAMod (hcw j).2) (lowestAMod (hcw k).2))) :
    ∃ D : ModularData W ι, D.Mfam = Mfam ∧ D.h = h ∧ ZhuModularityAnalytic D :=

theorem zhuModularity_pinned_of_C2Cofinite_voaPBW [Finite (Φ W)]
    (Mfam : ι → IrrModule W) (h : ι → ℂ)
    (hC2 : C2Cofinite W)
    (hss : letI := instRingA W; IsSemisimpleRing (A W))
    (hcard : Fintype.card ι = Nat.card (Φ W))
    (hcw : ∀ i, HasConformalWeight (Mfam i).isMod (h i))
    (hsep : ∀ j k : ι, j ≠ k → h j = h k →
      IsEmpty (AModEquiv W (lowestAMod (hcw j).2) (lowestAMod (hcw k).2))) :
    ∃ D : ModularData W ι, D.Mfam = Mfam ∧ D.h = h ∧ ZhuModularityAnalytic D :=
```

From the mathematics to the Lean statement

The pattern, decoded. The two modularity statements are identical except that the first has the extra binder (`Pr : BottomProjection ...`). A `BottomProjection` for the parabolic representation attached to the regular $A(W)$-module is a linear projection from the induced module onto its bottom piece, compatible with the structure; it exists if and only if the bottom embeds (the `inducedBottom` consequence of PBW). So the first theorem says "if such a projection exists, Zhu's modularity holds", the second says "Zhu's modularity holds", and the second is the first applied to the projection `voaPBWBottomProjection`, which is derived from `VOA.pbw`. For the referee this means: the content of Zhu's theorem is entirely in the `#print axioms`-clean version, and `VOA.pbw` enters only at one clearly marked seam. The remaining hypotheses (`hC2`: C_2-cofiniteness; `hss`: semisimplicity of $A(W)$, which follows from (admissible) rationality by `VOA.Huang.ZhuSemisimple.isSemisimpleRing_A_of_admissiblyRational`, `VOA/Huang/ZhuSemisimple.lean`; `hcard`, `hcw`, `hsep`: the family `Mfam` is a complete irredundant list of irreducible modules with conformal weights `h`) are the hypotheses of Zhu's theorem itself; Chapter 15 explains each. (Earlier versions also carried `hzero` and `hsimp`; both were redundant and have been removed.)

What the machine verified

Re-run for this chapter (`lake env lean -DmaxSynthPendingDepth=3` on a scratch file importing `VOA`, at the Moonshine commit; not re-run for this edition): `zhuModularity_pinned_of_C2Cofinite` and `zhuBijective`: `[propext, Classical.choice, Quot.sound]`. `zhuModularity_pinned_of_C2Cofinite_voaPBW`, `zhuBijective_of_voaPBW`, `AffineLie.vacuumVector_ne_zero` and `VHat.DLM3.voaPBWBottomInjective`: `[propext, Classical.choice, Quot.sound, VOA.pbw]` (at that commit, when `VOA.pbw` was an axiom). Re-probed at a later commit, after `VOA.pbw` became a theorem, all four reported `[propext, Classical.choice, Quot.sound]` (not re-run for this edition). The same probe reports `[propext, Classical.choice, Quot.sound]` for `heisenbergVOA`, `VirModule.virasoroVOA`, `AffineVOA.affineSl2VOA_closed`, `LatGen.latticeVOAGen`, `levelOne_coe_mem_E46`, `LQ43.L43_graded_rigidity`, `finiteDimensional_A_of_C2Cofinite`, `onePointSubexp_of_c2`, `strictSpanning_of_C2Cofinite`, `simpleAModsRealized_of_C2Cofinite`,

`VertexOperatorAlgebra.borcherds`, `Moonshine.LatticeTwisted.leechTwistedModule`, `Moonshine.sectorSeries_eq_JShift` and `Moonshine.moonshine`. In particular, the affine $\mathfrak{sl}_2$ vertex operator algebra and the whole Moonshine chain do not depend on `VOA.pbw`.

Many files mention the string `pbw` (a word search finds it in several hundred files, mostly in documentation and in names such as `PBWFreeness`); this says nothing about dependence. Dependence is a property of proof terms and is decided only by `#print axioms`.

50.1.3 What `lake build` certifies: aggregate versus isolated

`lake` is Lean's build tool. The library is one Lean package, `VOA`, whose root module `VOA.lean` (the *umbrella*) imports the category umbrellas `VOA/Foundations.lean`, `VOA/Core.lean`, ..., `VOA/Moonshine.lean`, which in turn import every production file. Running `lake build` with no argument builds the default target `VOA`, i.e. compiles the umbrella and, transitively, everything it imports, together with the needed part of Mathlib. The output ends with a line such as

```
Build completed successfully (10343 jobs).
```

where a *job* is one unit of work (compiling one module, or one of its artefacts). The job count is a useful fingerprint: if two runs on what should be the same tree give different counts, the trees differ.

Two kinds of build must be distinguished.

- An **isolated build**, `lake build VOA.Moonshine.TTBlock`, compiles one module and its imports. It certifies that this file, in the presence of exactly the files it imports, is correct.
- The **aggregate build**, `lake build` (equivalently `lake build VOA`), compiles the umbrella. It certifies that *all* production files compile *together*.

The difference matters. A file can compile in isolation and still break the aggregate: two files may declare the same name in the same namespace (the second import then fails), a file may add an instance or a `simp` lemma that changes the behaviour of proofs in another file that imports both, or a file may simply not be imported by the umbrella at all, in which case its theorems are not part of the library that the umbrella describes. During the Moonshine work many files were first built in isolation by background agents (for example the route notes record "`lake build VOA.Moonshine.TTBlock` is green (4243 jobs)" and "Build completed successfully (9039 jobs)" for three `SigmaExist` files) and only later wired into `VOA/Moonshine.lean`. The project rule is therefore:

> *A result counts only when the aggregate* `lake build` *is green.*

A second, subtler point was learned the hard way earlier in the library's history: a green build is a property of a *tree at an instant*, not of a session. Twice, a recorded "green at N jobs" failed to reproduce because a later, unrelated file had been added to the working copy, and once because a second session was editing files while the build ran. Hence the operational rules: re-run the aggregate build immediately before recording a result, record the job count actually seen, never run two builds concurrently in one working tree, and prefer separate `git worktrees` for concurrent work.

50.1.4 `scripts/check_repository.py`

The aggregate build cannot see files that nobody imports, and it cannot forbid tokens that Lean accepts. Both gaps are closed by a Python script, `scripts/check_repository.py`, which is also run in continuous integration before the Lean build. It does three things.

1. **Lexing.** It tokenizes every production file `VOA/**/*.lean` and the umbrella, correctly skipping line comments `--`, nested block comments `/- ... -/` and string literals, so that the word "sorry" in a docstring is not a false positive.

2. **Forbidden tokens and the sanctioned axiom.** Its policy is the constant

   ```
   ALLOWED_AXIOM_FILE = SOURCE_ROOT / "Foundations" / "AffineLie.lean"
   FORBIDDEN_TOKENS = frozenset(
       {"sorry", "admit", "native_decide", "stop", "implemented_by"}
   )
   ```

   Any code occurrence of these five tokens is an error. They are, respectively: the placeholder for a missing proof; its tactic synonym; a tactic that evaluates a decidable proposition by compiling it to machine code (thereby trusting the compiler, not only the kernel); the tactic that abandons the rest of a proof; and an attribute that replaces a definition's executable code by other code. Since `VOA.pbw` became a theorem every occurrence of the keyword `axiom` is an error (the constant `ALLOWED_AXIOM_FILE` survives in the script but no axiom is accepted); the script still prints a count of "sanctioned axiom declarations", now 0. (At the Moonshine commit the one exception was `axiom pbw` in `VOA/Foundations/AffineLie.lean`.)

3. **Reachability.** Starting from `VOA.lean` it follows every local import (`import VOA...`) and reports (i) imports naming a non-existent file and (ii) production files not reachable from the umbrella.

Its success line, as run for the first edition of this chapter on the tree of the Moonshine commit, was

```
Repository check passed: 1867 library files scanned; 1867 reachable through 4676 local
↪  import edges; 1 sanctioned axiom declaration(s).
```

So, at that commit, every one of the 1867 files then in the library was part of the aggregate build, none contained a forbidden token, and there was exactly one axiom. At a later commit, after `VOA.pbw` became a theorem, the script reported "7107 library files scanned; 7105 reachable through 17543 local import edges; 0 sanctioned axiom declaration(s)", with verdict "failed" only because two draft files in `VOA/Huang/` are unreachable. The reachability check was the one that fired most often during the Moonshine work. Agents wrote new files that compiled in isolation; until a maintainer added the import line, the check listed them as unreachable, and on one occasion it caught an in-flight, unwired draft (`VOA/Moonshine/HeisenbergTwistedModuleFieldComm.lean`) that still contained `sorry`. That file was not committed in that state; it was later completed and wired.

50.1.5 `scripts/audit/run_axiom_audits.py` and its blind spot

The third mechanical check, `scripts/audit/run_axiom_audits.py`, enforces *exact* axiom sets for a maintained list of declarations. It runs 20 Lean "probe" files under `scripts/audit/` (for example `RigidityProgressAxiomAudit.lean`, `Phase5AxiomAudit.lean`, `SuperAxiomAudit.lean`), each of which consists of `#print axioms` commands; it parses Lean's answers and compares each with the expected set: by default {`propext`, `Classical.choice`, `Quot.sound`}; for the single declaration `VOA.zhuModularity_pinned_of_C2Cofinite_voaPBW` the default plus `pbw` (while `VOA.pbw` was an axiom; since it became a theorem the expected set `PBW_AXIOMS` equals the default, so any reappearance of `pbw` is a failure); and for a short explicit list of elementary lemmas a *smaller* set (some use only `propext`, or no axiom at all). It fails if a declaration is missing, reported twice, or has a different set, larger *or smaller*. Insisting on exactness in both directions is deliberate: a set that shrinks unexpectedly usually means that a declaration was replaced by a different one with the same name. The success line of the final run was

```
Axiom audit enforcement passed: 4876 reports across 20 probes.
```

Trap / dead end

The blind spot. The 20 probes were written before the Moonshine construction began, and none of them mentions a declaration under `VOA.Moonshine` or `VOA.LatticesAndCodes`. The report count 4876 is *identical* before and after the construction (it is the count recorded in the project's build records at each of the last four checkpoints of the Moonshine work). A green audit therefore says nothing whatsoever about $V^\natural$. The headline Moonshine theorems were audited individually instead: at each checkpoint a scratch file importing `VOA` and containing `#print axioms` for the milestone declarations was compiled with `-DmaxSynthPendingDepth=3` (Section 50.1.6), and the result was recorded in the project's internal records and in the route notes. Adding a Moonshine probe to the maintained list is an open housekeeping task (Section 50.6).

50.1.6 `#print axioms` and the audit trap

`#print axioms foo` makes Lean walk the proof term of `foo`, and of every declaration that term mentions, and list the axioms reached. It is the only reliable way to know whether a theorem depends on `sorryAx`, the axiom that a `sorry` silently introduces (or, while it was an axiom, on `VOA.pbw`).

There is a trap, recorded in the project's working rules and in `README.md`. The package's `lakefile.toml` sets an elaboration option,

```
[leanOptions]
pp.unicode.fun = true # pretty-prints `fun a ↦ b`
relaxedAutoImplicit = false
weak.linter.mathlibStandardSet = true
maxSynthPendingDepth = 3
```

which raises the depth to which type-class synthesis may postpone sub-problems. `lake build` passes this option to every file it compiles. A bare `lake env lean file.lean` does *not*: it runs Lean in the package's environment but with Lean's default options. With the default depth, some instance problems in the library fail; Lean then reports an elaboration error and, to continue, replaces the failed term by `sorryAx`. A `#print axioms` run in that mode can therefore report `sorryAx` for a theorem that is in fact complete, or, worse, a file of probes can appear to succeed while auditing something other than what the build produced. The rule is: audit only through `lake build`, or through

```
lake env lean -DmaxSynthPendingDepth=3 probe.lean
```

which supplies the option explicitly. The maintained audit script does the latter for its newer probes.

50.1.7 Unconditional versus conditional

`#print axioms` does not list hypotheses. The theorem

```
theorem moonshine_of_frameLocality :
    ∃ x : ZMod 2 → TP, (∀ s, x s ∈ TPframe s) ∧
      ((∀ i j, TPBlockLocal leechWbar (x i) (x j)) →
        ∃ V : VertexOperatorAlgebra Vnat,
          V.Y = Ynat wbarL ∧ V.vacuum = vacNat ∧ V.conformalVector = omegaNat ∧
          V.centralCharge = 24 ∧
          V.grading 1 = ⊥ ∧
          finrank ℂ (V.grading 2) = 196884 ∧
          (∀ n : ℕ, (finrank ℂ (V.grading (n : ℤ)) : ℂ) = PowerSeries.coeff n JShift) ∧
          V.IsSimple) := by
```

(`VOA/Moonshine/Main.lean`) has no binders at all, and its axiom list is clean; yet it is *conditional*: inside the statement, after the existential, sits an implication whose premise `∀ i j, TPBlockLocal leechWbar (x i) (x j)` (four instances of the twisted-sector locality relation (4.23) of Dolan–Goddard–Montague, Chapter 40) was, at the time, not proved. The project's rule of language, stated in `README.md` and in the project's working rules, is:

> Say "`#print axioms`-clean, conditional on …" for a declaration whose proof term uses only the standard axioms but whose statement carries a hypothesis. Reserve *unconditional* for a theorem whose full hypothesis closure contains no unestablished datum.

The *hypothesis closure* is found by tracing every hypothesis, including those hidden in a statement as premises of implications and those carried as fields of structures, down to its leaves. The `README.md` adds two further audit items for every headline result: *conclusion strength* (is the conclusion the intended one, or a weaker variant such as "there exists some datum with property P" where a pinned datum was intended?) and *satisfiability of carried data* (can the hypotheses be met at all?). The Moonshine construction illustrates all three. Its final theorem is unconditional in the strict sense: no binder, no premise inside the statement. Its conclusion had to be strengthened once (simplicity was added to exclude the square-zero extension, Section 50.2.2). And several intermediate reductions had to be guarded against vacuous satisfaction by trivial data (the `hits_cyclic` clause, Section 50.2.2).

The moonshine part of Part VIII applies the rule twice. Several of its intermediate theorems carry hypotheses — generation of the Monster Lie algebra by its simple root spaces (`hgen`, Chapter 45) and finite order of every automorphism (`hfin`, Chapter 46) — that are discharged inside the library (Chapter 47), so the hypothesis closure of the final theorem `VOA.Moonshine.ConwayNorton.conwayNorton` is empty and it is unconditional. By contrast `monstrousMoonshine` and `monsterEquivAutVnat` take the explicit argument `(hM : GmatEqAutO)`, the proposition Gmat = AutO. It is a theorem of the AxiomMath CFSG library (`CFSG.Blueprint.NativeSporadic.MonsterModel.gmat_eq_griess`, commit `69cb972f`, Lean 4.35), but not of this library, whose toolchain cannot load its proof; inside LeanVOA it is an unestablished datum, so those two theorems are "`#print axioms`-clean, conditional on `GmatEqAutO`". It is not an axiom: no declaration of the library asserts it (Chapter 1, Section 1.3.5).

50.1.8 Independent re-verification of agent-produced work

Most of the roughly 155 files of `VOA/Moonshine/` were written by background agents (Lean sessions running in parallel, each assigned one milestone and allowed to write only new files), coordinated by a supervising session that followed the operating rules recorded in `Notes/MonsterRoadmap.md`. Those rules make agent output count only after an independent re-check by the supervisor:

1. read the roadmap and the working agreements at every iteration;
2. for every finished agent, build its *new* files in isolation (`lake build VOA.Moonshine.<File>`); grep them for `sorry`, `admit`, `native_decide` and `axiom`; run `#print axioms` on the headline declarations via `lake env lean -DmaxSynthPendingDepth=3`;
3. only then wire the files into `VOA/Moonshine.lean`;
4. update the status table with exact declaration names, and flip a status marker only after a green aggregate build;
5. never weaken a statement, never introduce `sorry` or an axiom, never commit or push (the maintainers' decision), never run two builds concurrently in one tree, never touch unrelated work (the parallel $\hat{\mathfrak{sl}}_3$ thread);
6. periodically run `scripts/check_repository.py` and an aggregate build, and at checkpoints write a dated hand-off record (commit, build state, open residuals, dead ends) for the next session.

The agents' own reports were treated as claims, not facts. Concretely, this caught: unwired drafts (listed by the reachability check); a draft with `sorry` (Section 50.1.4); agent notes that described their files as "not wired" long after wiring, or a residual as open after it had been closed (the route notes carry "Update" sections and the gluing plan carries dated "Status and corrections" sections for exactly this reason); and, most importantly, several mathematical errors in the plan itself, recorded as numbered "Corrections" in `Notes/M8GluingPlan.md` and catalogued below. A general lesson of the library's history, learned twice, applies with full force: *prose drifts behind theorems*. A docstring saying "open" or "not possible" was false when read at least seven times in earlier sessions; the remedy is to search for the declaration the prose claims is missing before believing it.

50.1.9 The final verification record

The release commit. This edition documents the release of the library named in the front matter, at commit (`recorded at release`). The protocol of this section — the aggregate `lake build`, `scripts/check_repository.py`, `scripts/audit/run_axiom_audits.py`, and `sync.py check` for the book's quotations — is run at that commit by the release procedure. The records below were made at earlier states of the library, are dated, and say what was run.

The release build (3 November 2026)

Run on the development tree at the feature freeze, the source of this release (the released tree omits the held material listed in Chapter 1):

- aggregate `lake build` of `VOA`: `Build completed successfully (20331 jobs)`, exit code 0;
- `scripts/check_repository.py`: 11,859 library files, 0 axiom declarations, no `sorry`, `admit`, `native_decide`, `stop` or `implemented_by`; all files reachable from the umbrella except four held files that the release does not contain;
- `scripts/audit/run_axiom_audits.py`: passed, 5,958 reports across 24 probes;
- `#print axioms` on the 28 headline declarations of the release (including `VOA.Moonshine.moonshine`, `A2_classicallyFree_final`, `D4_classicallyFree_of_inputT` and `twoSeries_gradedUnitary_of_affine_final`): every one reports exactly `[propext, Classical.choice, Quot.sound]`.

The release build of v1.05

Release v1.05 adds Part VIII (Chapters 43–49); the Deligne-series files added after v1.0 (`G2Star`, `D4Core`, `SL4T`, `F4Star`) are held. The aggregate build, the repository check and the axiom audit at the v1.05 release, and the axiom reports of the moonshine headlines listed in Section 50.1.10:

- *No full rebuild was needed.* All 11,661 Lean files of v1.0 are byte-identical in v1.05 (git blob hashes compared with the public `v1.0` tag), except four import-only umbrella files, and the toolchain and `lake` files are unchanged. So the v1.0 aggregate build above certifies them; the cached build was reused.
- `lake build VOA.Moonshine` (all new files): `Build completed successfully (9504 jobs)`, exit code 0.
- `scripts/audit/run_axiom_audits.py`: passed, 5,983 reports across 25 probes. This includes the new probe `MonstrousMoonshine` (`scripts/audit/MonstrousMoonshineAxiomAudit.lean`), whose 25 headlines, among

them `conwayNorton`, `conwayNorton_gmat`, `nonempty_autVnat_mulEquiv_liftable`, `M8.finite_autVnat` and `monstrousMoonshine`, each report exactly `[propext, Classical.choice, Quot.sound]`.

- `VOA/Moonshine/MoonshineLRLiftAudit.lean`: 997 reports, all within the three standard axioms, 0 `sorryAx`.
- `scripts/check_repository.py`: 12,627 library files, 0 axiom declarations, no forbidden construct. Its only failure is three held `COneBootstrap` files that the release does not contain. The export leaves out the held files and strips their imports from the umbrellas, with 0 dangling imports.

What the machine verified

Recorded at the end of the Moonshine construction (the project's checkpoint record of 7 October 2026), on the tree that became the Moonshine commit ("Construct the Moonshine module $V^\natural$ (FLM) unconditionally"), then the head of the main branch:

- aggregate `lake build`: `Build completed successfully (10343 jobs)`, exit code 0;
- `scripts/check_repository.py`: passed, 1867 library files, all reachable, one sanctioned axiom declaration (`VOA.pbw`, then an axiom; 0 since it became a theorem);
- `scripts/audit/run_axiom_audits.py`: passed, 4876 reports across 20 probes (which do not cover `VOA.Moonshine`);
- `#print axioms VOA.Moonshine.moonshine`, via `import VOA` with `-DmaxSynthPendingDepth=3`: `[propext, Classical.choice, Quot.sound]`; no `VOA.pbw`;
- the core definitions (`VOA/Core`, `VOA/Foundations`, `VOA/Modularity/JFunction.lean`, `VOA/Modules/Fusion.lean`) are unchanged since the parent of the Moonshine commit; the only change to a pre-existing definition is the nine-line repair of `TwistedModule.jacobi` in `VOA/Modularity/Twisted.lean` (Section 50.2.1).

Re-run for this chapter on the same tree: `scripts/check_repository.py` passed with "1867 library files scanned; 1867 reachable through 4676 local import edges; 1 sanctioned axiom declaration(s)"; `#print axioms` gave `[propext, Classical.choice, Quot.sound]` for `VOA.Moonshine.moonshine`, `VOA.Moonshine.topPairs_one`, `VOA.jacobiAllIndices_eq_zero` and `VOA.Moonshine.TrialityTw.golayE_not_determined`, plus the library-wide list of Section 50.1.2. `scripts/audit/run_axiom_audits.py` was re-run and printed twenty `PASS` lines (from "`PASS RigidityProgress: 3932 declarations match the trust boundary`" to "`PASS PairClosure: 54 declarations match the trust boundary`") and "Axiom audit enforcement passed: 4876 reports across 20 probes." (1 minute 34 seconds). The aggregate `lake build` was *not* re-run for this chapter; its figure of 10343 jobs is the one recorded at the time.

For the reader's convenience we reprint the headline statement once more (`VOA/Moonshine/TopPairs.lean`):

```
theorem moonshine :
    ∃ V : VertexOperatorAlgebra Vnat,
      V.Y = Ynat VnatAxioms.wbarL ∧ V.vacuum = vacNat ∧ V.conformalVector = omegaNat ∧
      V.centralCharge = 24 ∧
      V.grading 1 = ⊥ ∧
      Module.finrank ℂ (V.grading 2) = 196884 ∧
      (∀ n : ℕ, (Module.finrank ℂ (V.grading (n : ℤ)) : ℂ) = PowerSeries.coeff n JShift) ∧
      V.IsSimple :=
  moonshine_of_topPairs (by norm_num) topPairs_one
```

From the mathematics to the Lean statement

Fidelity check of the headline, from the verification point of view. The full fidelity check, with every term traced to its definition, is in Chapter 42; here we record only the points that the protocol of this section is designed to protect.

- *No hypotheses.* The statement has no binders and no premise. Its proof is the composition of the conditional theorem `moonshine_of_topPairs` (whose premises are $\varepsilon^2 = 1$, discharged by `norm_num` at $\varepsilon = 1$, and the finite identity `TopPairs`) with `topPairs_one`, which proves that identity. So the hypothesis closure is empty.
- *The existential is pinned.* "$\exists V$" alone would be weak: some VOA structure on the vector space `Vnat`. The four equations `V.Y = Ynat VnatAxioms.wbarL`, `V.vacuum = vacNat`, `V.conformalVector = omegaNat` pin the vertex operator map to the explicit block map of Frenkel–Lepowsky–Meurman, built from the untwisted fields, the skew intertwiner W and its adjoint $\overline{W}$ (Chapters 37–38); the vacuum and conformal vector are pinned likewise.
- *The non-triviality clause.* `V.IsSimple` excludes the square-zero extension, which satisfies every other clause (Section 50.2.2). In addition `wbarL` is the genuine adjoint, proved nonzero by `leechWbar_ne_zero`.
- *Graded dimension.* `JShift` is the pre-existing series $E_4^3/(\Delta/q) - 744q = qJ(q)$ of `VOA/Modularity/JFunction.lean`, untouched by the construction, so the identity $\dim V_n = [q^n]\, qJ(q)$ is tested against an independent definition of J.
- *Axioms.* Standard only; no `VOA.pbw`.

What the statement does *not* say: nothing about $\mathrm{Aut}(V)$, the Monster, or uniqueness; see Section 50.6. ($\mathrm{Aut}(V^\natural)$ and the Monster are the subject of Part VIII; their record is Section 50.1.10.)

Physical meaning

The verified statement underwrites the physicist's description of the Moonshine conformal field theory: a chiral $c = 24$ CFT (holomorphy, i.e. a single sector, is the physical expectation and is not proved in Lean) obtained by orbifolding 24 chiral bosons compactified on the Leech torus by the reflection $X \mapsto -X$, keeping the invariant untwisted states and the invariant twisted states (twist fields of weight 3/2 dressed by oscillators). The clause $V_1 = 0$ says the theory has no conserved spin-one currents, hence no continuous symmetry; $\dim V_2 = 196884$ counts the stress tensor plus the 196883 primaries of the Griess algebra; the graded dimension is the torus partition function $Z(\tau) = J(\tau)$ up to the factor q; uniqueness of the vacuum (the only state of weight 0 up to scale) is CFT type, built into the library's definition of a vertex operator algebra; simplicity says that no consistent subsector decouples, i.e. the operator product expansion genuinely couples the twisted states back into the untwisted ones ($\overline{W} \neq 0$).

50.1.10 The verification record of the moonshine part

Part VIII documents the files of `VOA/Moonshine/` whose names begin with `MoonshineCN` and `MoonshineLR`, the files `Aut*.lean` and the folder `VOA/Moonshine/MonsterGriess/`. Its final theorems are listed, with their meaning, in Chapter 1, Section 1.3.5, and are presented under the fidelity protocol in Chapters 43, 47 and 49.

The headline record. As recorded for the release (not re-run for this chapter):

- with *no hypotheses*: `VOA.Moonshine.ConwayNorton.conwayNorton : ConwayNortonConjecture`, `conwayNorton_gmat`, `M8.finite_autVnat`, `rationalTraces` and `nonempty_autVnat_mulEquiv_liftable` (all in the namespace `VOA.Moonshine.ConwayNorton`); Tits's theorem is not used;
- *conditional on* `GmatEqAutO` *only*: `monsterEquivAutVnat` and `monstrousMoonshine`;
- for every audited headline, `#print axioms` is contained in `[propext, Classical.choice, Quot.sound]`; the library declares no axiom.

The audit modules. Unlike the earlier parts of the library, the moonshine part carries its axiom audits as library modules: files of `VOA/Moonshine/` consisting of `#print axioms` commands (and, for the final audits, the re-export of the headline under its official name). They are imported by the umbrella module `VOA.Moonshine`, so every aggregate build elaborates them and prints their reports in the build log. Since v1.05 the release headlines are also enforced by the probe `MonstrousMoonshine` of `scripts/audit/run_axiom_audits.py` (25 declarations; Section 50.1.9). The remaining module audits are checked by reading the build log.

- `MoonshineCNFinalAudit`: the audit of the fixed statement `ConwayNortonConjecture` (from `VOA/Moonshine/MoonshineCNStatement.lean`, fixed before the proof was written); defines `conwayNorton` as the re-export of `M8.conwayNortonConjecture_holds` and prints it, together with `M8.monsterLieSimpleRootGe`
- `MoonshineCNMonsterFinalAudit`: Conway–Norton for the Monster model: `conwayNorton_gmat` (no hypotheses beyond the membership $g \in$ Gmat), `conwayNorton_monster` (given Gmat = AutO), `tauB_mem_AutO`, `Generated.Gmat_le_AutO`, and the multiplicativity and isometry of the Griess isomorphism (`griessIso_mul`, `griessIso_form`).
- `MoonshineCNSymmetryFinalAudit`: the converse direction: `autVnat_rational`, `nonempty_autVnat_mulEquiv_li` `autVnat_mulEquiv_autO`, the commutant lemma `M8.gmatCommutantScalar`, `rationalTraces`, `conwayNorton`, `conwayNorton_gmat`.
- `MoonshineCNRationalAudit`: one report per public declaration of the rationality files (Schur's span formula, rationality of traces, rationality on the Griess algebra given the commutant).
- `MoonshineCNGenusZeroAudit`, `MoonshineCNGenusZeroAudit2`, `MoonshineCNGenusZeroAudit3`: one report per public declaration of the genus-zero files (Chapter 46).
- `MoonshineCNGammaZeroAudit`: the passage from $\Gamma_1(N)$ to $\Gamma_0(N)$ (Chapter 43); its headlines are conditional on their explicit hypotheses, which the final theorem discharges.
- `MoonshineCNAudit`, `MoonshineCNAudit2`, ..., `MoonshineCNAudit18`: the statement interface, the vertex algebra of $II_{1,1}$ and the tensor theory (Chapter 44), the no-ghost theorem, the Monster Lie algebra and its Borcherds data (Chapter 45), and the twisted denominator identities and complete replicability (Chapter 46); `MoonshineCNGriessAudit`, `MoonshineCNGriessAudit2`, `MoonshineCNGriessAudit3`, `MoonshineCNMonsterActionAudit` and the audits of `VOA/Moonshine/MonsterGriess/`: the Griess dictionary, the ported Monster model and its action (Chapters 48–49).
- `MoonshineLRLiftAudit`: every theorem of the `Aut*.lean` files and of the lift chain, up to `monstrousMoonshine`: 997 reports, every one with standard axioms only and none containing `sorryAx` (green at the release; Chapter 47).
- `MoonshineLRFinOrderAudit`, `MoonshineLRGenerationAudit`, `MoonshineLRM5Audit`, `MoonshineLRConwayNortonA` `MoonshineLRFaberAudit`, `MoonshineLRHeckeAudit`, `MoonshineLRNontrivialAudit`, `MoonshineLRCoeffBoundAud` `MoonshineLRJUnboundedAudit`, `MoonshineLRTowerAudit`: finite order, simple-root generation, the untwisted denominator identity, complete replicability, Faber polynomials, the prime Hecke identity, nontriviality and the coefficient bounds (Chapters 46–47).

The chapters' status boxes record, for each theorem, which audit module prints it and whether the book's authors re-ran it; most were not re-run for the book, and the release figures belong in the slot of Section 50.1.9.

Physical meaning

For the physicist the record separates two claims about the moonshine conformal field theory. "The twisted partition function of every global symmetry is a genus-zero Hauptmodul" is proved outright. "The global symmetry group is the Monster" is proved up to one group-theoretic identification, which is a theorem in another Lean library and enters here as a named, explicit premise.

50.1.11 The book's own verification record (October 2026)

The protocol above certifies the *library*. The book needs a second, separate record: that what it prints is what the library says. By the book's rules (its constitution, Article 9), the book documents the library as of the commit stored in `Notes/Textbook/manifest.json`, which records, for every `.lean` file, the chapter that documents it and the hash of its contents at that commit. The script `scripts/textbook/sync.py` then checks the chapters against the sources. Its `check` command reports, among other things, four kinds of failure that are treated as blocking:

- **STALE QUOTE**: a `leancode` block that no longer occurs verbatim in the source. This breaks the book's central promise, that the Lean text the referee reads is the Lean text the kernel checked.
- **MISSING PATH**: a quoted declaration with no nearby `\leanpath` citation of the file that defines it, so the reader cannot find the source.
- **NO PHYSICS**: a definition or theorem not followed by a physical-meaning box, which the constitution requires for every statement.
- **UNASSIGNED** files (reported by `sync.py coverage`): a library file that no chapter is responsible for.

These checks are textual. They confirm that the quotations are verbatim and attributed, not that the quoted files compile together; that is the job of the aggregate build of Section 50.1.3, and the two must not be confused.

What the machine verified

The book's record at the end of the October 2026 update, as recorded in `Notes/Textbook/BOOK_CAMPAIGN.md` ("Status") and in the commit messages of the book:

- **Manifest snapshot** at a pre-release commit, with `sync.py coverage` reporting 0 unassigned files. Every `.lean` file of the library is therefore assigned to exactly one chapter.
- **`sync.py check`** at that snapshot: 0 STALE QUOTE, 0 MISSING PATH, 0 NO PHYSICS.
- **Full book** at that snapshot: `book.pdf`, 2118 pages, 0 undefined references. (The release edition, `main_release.pdf`, then had 2201 pages.)
- **Brief**: `brief.pdf`, 199 pages; all 1199 of its 1199 Lean chunks verbatim against the sources at that snapshot.
- **Chapters in preparation.** The chapter on affine $\mathfrak{sl}_3$ is not part of this edition. The two chapters on graded unitarity through the BRST coset, then held, are part of the

v1.0 release edition (Chapters 28 and 29); their verification records are in those chapters. Chapter 27, held at this snapshot, was rewritten around the A_2 theorem without hypotheses and is included.

Not done at that snapshot. The book was *not* checked against an aggregate `lake build` at that snapshot. The last aggregate build recorded green is that of 26 October 2026, at the A_2 milestone of the Deligne campaign: 13868 jobs, with the axiom audit passing (the project's build record; not re-run for the book). By the project's policy the aggregate build is run only before a merge to the main branch, and it is memory-heavy, so it was not re-run for the book. Since then, the aggregate build `bash scripts/campaign_build.sh VOA` (the full `lake build VOA` under the project's memory-capped wrapper) was green in two pre-release builds on 2026-10-28 (18,901 jobs, and 18,907 jobs after merging the then-current `origin/main`); `scripts/check_repository.py` passed (10,431 library files, all reachable, 0 project axioms) and `scripts/audit/run_axiom_audits.py` passed (5,958 reports across 24 probes). For the release commit see Section 50.1.9. The quotations are verbatim against the sources at the manifest commit; their compilation at that commit is inferred from the build of 26 October and from the targeted builds recorded in the project's internal build records, not re-confirmed.

The trust base at the manifest commit. The library has *no* project axiom. `VOA.pbw`, which until 19 October 2026 was the single sanctioned axiom (Section 50.1.2), is now the theorem `theorem pbw : PBWPrinciple` in `VOA/Foundations/AffineLie.lean`, proved through the files `VOA/Foundations/PBWTheorem/` (Chapter 3). `#print axioms VOA.pbw` lists only Lean's three standard axioms; this was re-run for Chapter 3 and again, independently, by the release audit of Chapter 22 (Section 50.1.12). Two of the release audits also searched `VOA/` for top-level `axiom` declarations and found none: every occurrence of the word is in a comment. Consequently the register "proved using the project axiom" of the introduction is empty, and "`#print axioms`-clean" now means, without exception, that the axiom list is a subset of `[propext, Classical.choice, Quot.sound]`. What it still does *not* mean is "unconditional" (Section 50.1.7): the new chapters contain many `#print axioms`-clean theorems that carry open named hypotheses, and they are listed in Section 50.6.3.

Two further facts of the record.

- **The repository check passes.** `scripts/check_repository.py` (Section 50.1.4) failed for a time on 27 October 2026 because of unwired files; after they were wired in or moved, the Foundations release audit recorded it passing (7,839 files, all reachable). Re-run on the working tree of the branch `deligne-lean` on 28 October 2026, it reported: "Repository check passed: 10353 library files scanned; 10353 reachable through 24571 local import edges; 0 sanctioned axiom declaration(s)". That working tree had uncommitted changes; for the release commit see Section 50.1.9.
- **Docstrings were edited after the last aggregate build.** A first batch of stale docstrings (45 files, comments only) was corrected on 27 October; a targeted build of those 45 modules was green (13,276 jobs). The release audits below found further edits of the same kind in the import closures they examined and inspected them as comment-only. A comment cannot change a theorem, but an edited file must still be rebuilt, which is one more reason why every audit asks for an aggregate build at the release commit.

Physical meaning

The physicist's analogue is the difference between a calculation and its write-up. The library is the calculation; the book is the paper that reports it. A paper can misquote its own calculation

(a sign dropped in transcription, a hypothesis forgotten in the abstract), and the sync check is the systematic comparison of the two. It does not re-run the calculation; the aggregate build does that.

50.1.12 The independent release audits of 27–28 October 2026

Before a public release the project decided (`Notes/RELEASE_PLAN.md`, "Release tiers") that every headline theorem to be named in an announcement must pass one independent *release audit*: a fresh referee, who had not written the chapter, compares the statement with the source paper, traces every definition it depends on down to its leaves, lists every explicit hypothesis, and re-runs `#print axioms`. The chapter is used only as a map; every conclusion is checked against Lean. The project's record of over-claims caught late (three in the week before the audits alone) is the reason this step exists. Twelve such audits were run on 27 and 28 October 2026; their verdicts are recorded in `Notes/RELEASE_PLAN.md` ("Release audit results"). One line each:

- `RELEASE_AUDIT_L16.md` (Chapter 16, Arakawa–Kawasetsu), 27 October: the proposed announcement is not announceable as worded; 1 BLOCKING (the wording), 4 MAJOR, 6 MINOR. Discussed below.
- `RELEASE_AUDIT_L20.md` (Chapter 20, Arakawa–Dai), 27 October: no blocker; 0 BLOCKING, 1 MAJOR (the release build), 7 MINOR. Discussed below.
- `RELEASE_AUDIT_L21.md` (Chapter 21, Huang and related), 27 October: no blocker; 0 BLOCKING, 3 MAJOR, 8 MINOR. Discussed below.
- `RELEASE_AUDIT_L22.md` (Chapter 22, Gannon–Rayhaun), 27 October: announceable with caveats; 0 BLOCKING, 2 MAJOR, 5 MINOR. Discussed below.
- `RELEASE_AUDIT_MOONSHINE.md` (Chapters 30–42, $V^\natural$), 27 October: announceable with caveats, wording only; 0 BLOCKING, 0 MAJOR, 6 MINOR. `moonshine` takes no hypotheses, has standard axioms and a unique witness; J is a formal q-series; the isomorphism with FLM's explicit $V^\natural$ is on paper only; no Monster, holomorphy or uniqueness claim. (The Monster is now treated in Part VIII; Section 50.1.10.)
- `RELEASE_AUDIT_RIGIDITY.md` (Chapters 8 and 10), 27 October: announceable with caveats; 0 BLOCKING, 0 MAJOR, 3 MINOR (say "graded first-order"; non-vacuity argued on paper only).
- `RELEASE_AUDIT_ZHU.md` (Chapters 12–15), 27 October: no headline blocked, but "Zhu's modularity theorem is formalized" is misleading without qualification; 3 HIGH, 4 MEDIUM, 6 lower. Its finding that "rational $\Rightarrow$ $A(V)$ semisimple" is unproved was superseded the next day (see the new-declarations audit).
- `RELEASE_AUDIT_FOUNDATIONS.md` (core definitions and constructions), 27 October: faithful with caveats; 0 BLOCKING, 2 MAJOR, 7 MINOR (every headline must say "of CFT type"; the structure now called `PreVertexAlgebra` lacks translation covariance, Section 50.2.8).
- `RELEASE_AUDIT_L17_L18_L23.md` (Chapters 17, 18, 23), 27 October: 0 BLOCKING, 7 MAJOR, 14 MINOR; includes the `SuperTwistedModule` defect of Section 50.2.1.
- `RELEASE_AUDIT_L24_L25_A2.md` (Chapters 24, 25 and the A_2 final theorem), 28 October: 1 HIGH, 5 MEDIUM, 8 LOW; the A_2 statement is faithful, its announcement blocked until green umbrella and aggregate builds exist at the release commit (condition met on 28 October: Chapter 27, Section 27.10).

- `RELEASE_AUDIT_NEW_DECLS.md` (the declarations added on 28 October), 28 October: all announceable with caveats; 0 BLOCKING, 4 MEDIUM, 7 LOW.

- `RELEASE_AUDIT_FOLLOWUPS.md` (the other account's follow-ups), 28 October: none wrong, none blocked; 2 announceable as stated, 4 with caveats.

A separate precision audit of the Deligne literature inputs (`DELIGNE_INPUTS_PRECISION.md`, 28 October) found the total-dimension bound and the Demazure realizations published for all six types and the star bound unpublished for G_2, F_4 and the E-types. The paragraphs below record the first four audits in detail, as reported on 27 October; where Lean results of 28 October have since removed a caveat, this is said in the paragraph. The corrections the audits asked of their chapters have been applied.

What the auditors of 27 October ran, and what they did not. No auditor ran `lake build`. Each wrote scratch files importing the headline modules and ran them with `lake env lean -DmaxSynthPendingDepth=3` (the safe form of Section 50.1.6) against the compiled `.olean` files already present, dated 25–26 October; the cost was 2.6–9.5 seconds and 3.4–8.1 GB per file. Each audit was made at a different pre-release commit of a working tree with uncommitted changes. Each auditor checked that the uncommitted changes in the relevant import closure were comment-only, or that the closure was unchanged. *Every one of the four reports therefore carries the same process caveat*: the aggregate build, the repository check and the axiom audit must be re-run, green, on the committed release commit before anything is announced. All three were green on 28 October 2026 (paragraph *Not done at that snapshot* above); for the release commit see Section 50.1.9.

Chapter 16 (Arakawa–Kawasetsu): the proposed announcement is not announceable as worded. Counts: 1 BLOCKING, 4 MAJOR, 6 MINOR. The BLOCKING finding concerns the wording of the proposed announcement, not the Lean code. That wording ("the Arakawa–Kawasetsu theorem, characters of quasi-lisse VOAs satisfy an MLDE, and an explicit non-lisse quasi-lisse example are formalized") is false on three counts. (1) *No Lean theorem proves the analytic Arakawa–Kawasetsu MLDE for any vertex algebra.* (The audit's wording, "no MLDE for any VOA", was slightly too broad: Chapter 25 proves formal, coefficientwise second-order MLDEs for the vacuum characters of the seven Deligne-series VOAs.) Within Chapter 16, the only theorem with a genuine MLDE conclusion, `VOA.IsSqPrimary.exists_monicMLDEOn_all_analyticBlocks_of_etingofFinite`, is `#print axioms`-clean but conditional on two hypotheses that were inhabited nowhere in the library, `AKWeightGrading W` and `E46SerreClosed` (Section 50.6.3). Since 28 October the second is a theorem, `VOA.e46SerreClosed` (`VOA/Modularity/EisensteinSerreClosure.lean`), and since 29 October the first is a theorem for every VOA of the library (CFT type), `VOA.akWeightGrading` (`VOA/Modularity/AKGradingTotal.lean`). The MLDE is therefore conditional only on Etingof-finiteness: `VOA.IsSqPrimary.exists_monicMLDEOn_all_analyticBloc` (despite the suffix, it keeps `EtingofFinite W`) gives one monic MLDE of some unbounded order $s \geq 1$, coefficients in $\mathbb{C}[E_4, E_6]$ of weight $2(s-i)$, satisfied by $F(a)$ for every abstract analytic genus-one block F; and `VOA.exists_monicMLDEOn_all_analyticBlocks_simpleSl2QL` is its unconditional instance at the vacuum of $L_{-4/3}(\mathfrak{sl}_2)$, of unspecified order (Arakawa–Kawasetsu's order 2 is not proved; that the vacuum character is such a block follows from library lemmas but is not packaged as one theorem). Both are `#print axioms`-clean (recorded in `Notes/release/WS-RELEASE2.md`); the aggregate build at the release commit is pending. (2) *Quasi-lisseness is not formalized*: there is no associated variety and no symplectic leaf; the theorems assume `EtingofFinite`, finite-dimensionality of the zeroth Poisson homology $R_V/\{R_V, R_V\}$, which is the *conclusion* of the Etingof–Schedler theorem (logically more general, but not "quasi-lisse"). (3) *The unconditional "character ODE" theorems* at $L_{-4/3}(\mathfrak{sl}_2)$ (`character_formalODE_simpleSl2QL_uncond` and siblings) have arbitrary subexponential power series as coefficients, chosen after the module; they are near-vacuous growth statements, not MLDEs, although a docstring still calls one of them "the Arakawa–Kawasetsu character equa-

tion" (Chapter 16, Section 16.5.6). A further MAJOR: the Zhu-modularity chain under Etingof-finiteness has its rank hypothesis discharged only for the trivial VOA, and it is expected to be false at $L_{-4/3}(\mathfrak{sl}_2)$ (a paper argument). *What is announceable*, with standard axioms only: $L_{-4/3}(\mathfrak{sl}_2)$ is not C_2-cofinite yet has finite-dimensional zeroth Poisson homology (`not_C2Cofinite_simpleSl2QL`, `etingofFinite_simpleSl2QL'`, `strictEtingofFinite_simpleSl2QL`); for such VOAs characters of ordinary modules converge on the upper half-plane and the genus-one conformal blocks form a finite-dimensional space; and C_2-cofinite implies Etingof-finite. The MLDE may be mentioned only as formalized conditionally on `EtingofFinite` (the stand-in for quasi-lisseness), with an unspecified order, and unconditionally at $L_{-4/3}(\mathfrak{sl}_2)$ in that form. Consequence recorded in the release plan: Chapter 16 is released, but it leaves the announcement's list of headlines.

Chapter 20 (Arakawa–Dai): no blocker. Counts: 0 BLOCKING, 1 MAJOR, 7 MINOR. All ten headline declarations of `VOA/Examples/AffineSl2BoundaryMainTheorems.lean` are `#print axioms`-clean, with the single hypothesis $1 \le m$; the definitions trace to the genuine objects (the actual simple quotient, the real Li filtration, a genuine Poisson vertex algebra, the character computed from actual dimensions). The four character theorems (`coeff_product_le_character`, `character_eq_product`, `character_eq_chain`, `character_eq_fermionic_chain`, the last being the paper's Theorem 1.2 display) and `arcPoissonEquiv_conformal_iff` are announceable as stated. The caveats: `canonicalMap_bijective`, `boundary_classically_free` and `arcPoissonEquiv` are stated on the arc algebra of the *presented* algebra $\mathbb{C}[e,h,f]/(eQ^m, hQ^m, fQ^m)$, and no single Lean theorem has the paper's shape "the canonical map $J_\infty R_V \to \mathrm{gr}^F V$ is bijective"; the paper's Theorem 1.1 follows from two Lean theorems together (the presented isomorphism and `baseC2AlgEquiv`) and should be announced in that two-part form (audit verdict of 27 October; superseded on 28 October, see below and Chapter 20, Theorem 20.26; naturality proved). `actualC2ArcEquiv` is a bare bijection of hom-sets for each coefficient algebra, with no naturality stated, so it must not be announced as a representability statement; and `baseC2AlgEquiv` is canonical by its definition, not by its type. The single MAJOR is the release build (above). Chapter 20, Section 20.15, records the same points. *Since 28 October* two of these caveats are removed in Lean, in the namespace `VOA.AffineSl2BoundaryClassicalFreeness`: `arakawaDai_theorem_1_1` (`VOA/Examples/AffineSl2BoundaryTheorem11.lean`) states the paper's Theorem 1.1 as one theorem, and `actualC2ArcEquiv_natural` (`VOA/Examples/AffineSl2BoundaryMainTheorems.lean`) states the naturality, so representability holds; the follow-ups audit rated both "as stated". What remains is that $J_\infty R_V$ is realized as `PresentedJet` with a universal arc, since the library has no J_∞ functor on abstract algebras.

Chapter 21 (Huang and related): no blocker. Counts: 0 BLOCKING, 3 MAJOR, 8 MINOR. Every headline is `#print axioms`-clean and instantiated at the lattice VOA V_2, so none is vacuous. Verdicts:

- the braided monoidal category of ordinary modules of a strongly rational VOA (a genuine Mathlib `BraidedCategory`, on the Huang–Lepowsky tensor product, with pentagon and hexagons proved), and the logarithmic braided tensor category of a C_2-cofinite VOA: *announceable as stated*;

- rigidity, Verlinde and the modular category: *with caveats*. (F1, MAJOR) They are proved for `Nice` VOAs, i.e. strongly rational *and pseudo-unitary*, although Huang's theorems do not need pseudo-unitarity; the hypothesis is genuinely used in the proofs. (Since 29 October its use for $V' \cong V$ is removed: `VOA.contra_vacuum_equiv_of_stronglyRational` and the `_of_stronglyRational` copies in `VOA/Huang/VerlindeVacuumFusionSR.lean` give the vacuum-fusion chain for strongly rational VOAs; the Cardy-positivity step `vacColumn_mem_K` keeps it, essentially, and the headline theorems still take `Nice`.) Rigidity was right rigidity only (`rightRigid_ordinary`); since 28 October the two-sided `RigidCategory` is a theorem, `VOA.Huang.HuangRigid.ri`

(`VOA/Huang/RigidOrdinary.lean`), on the same monoidal instance as the braiding (checked by the new-declarations audit), still for `Nice` VOAs. Verlinde is proved in the form $S_{ax}S_{bx} = S_{0x}\sum_c N_{ab}^c S_{cx}$ with $S_{0x} \neq 0$;

- the congruence property: *not announceable until it has a named theorem* (F2, MAJOR). It is true in the library (it is discharged inside the proof of the Gannon–Rayhaun theorem, and the auditor's scratch declarations `audit_dln_congruence` and `audit_zhuCongruence` compile with standard axioms), but every library declaration that concluded it carried hypotheses. Since 28 October the named theorems exist, for `Nice` VOAs: `dlnCongruenceInput_holds`, `zhuCongruenceInput_holds` and `zhu_kernelContainsGamma_at_level`, in the namespace `VOA.Huang.Congruenc` (`VOA/Huang/CongruenceNamed.lean`). (F3, MAJOR, wording) Only the kernel half of Ng–Schauenburg's Theorem 6.8 is proved (`nsProjectiveKernelAll_holds`); the half saying that the level equals the Frobenius–Schur exponent is not. (The new-declarations audit adds a precision: at the minimal level the kernel statement is the full kernel claim of Dong–Lin–Ng; "kernel half" refers only to the Ng–Schauenburg input.)

- Deligne's theorem (`deligneTannakian_holds`): *with caveats*; it is the positive-dimension (Tannakian, bosonic) case for symmetric fusion categories, not the super version.

Chapter 22 (Gannon–Rayhaun): announceable with caveats. Counts: 0 BLOCKING, 2 MAJOR, 5 MINOR. The three headlines (`gannonRayhaun_forward`, `gannonRayhaunConverse_holds`, `gannonRayhaun_class` have no hypotheses, their axioms are standard, and the statement matches Gannon–Rayhaun's Theorem 3.1 and Proposition 3.2 (the same list, both directions, pairwise non-isomorphism). Non-vacuity is proved (`V2m_nice`, `exceptionalV2Group_exists`). The caveats: (M1, MAJOR, wording) "rational" is formalized as `AdmissiblyRational`: every weak (mode-stable, not necessarily graded) submodule of an admissible module has a weak complement. The library's own note (`VOA/Modules/AdmissibleRationality.lean`) says that its relation to Dong–Li–Mason rationality is not settled and that neither implication is proved in Lean; the chapter overstated the match and has been corrected (Chapter 22, Remark 22.4). Since 29 October one direction is a theorem: for C_2-cofinite V, Dong–Li–Mason rationality (formalized faithfully as `DLMRational`) implies `AdmissiblyRational` (`VOA.Classification.COne.DLMRat.admissiblyRational_of_dlmRational`); the converse is open. (M2, MAJOR) the release build. The minor points: the combined statement and the converse are stated for carriers in `Type 0` only (disclosed in Remark 22.38); rationality and pseudo-unitarity quantify over modules in the VOA's own universe; and stale docstrings.

Physical meaning

In physical language the audits separate three things that a CFT paper often runs together. "The theory is consistent" (the braided tensor category exists) was confirmed as stated. "The theory is unitary in the weak sense needed for positivity arguments" (pseudo-unitarity, quantum dimensions equal to the ratios of S-matrix entries) turns out to be an extra input in the Lean proofs of rigidity and the Verlinde formula (now essentially only in the Cardy-positivity step), while Huang's proofs do without it. And "the characters obey a modular differential equation", the physicist's working definition of a theory with finitely many characters, is proved with a specified order for no theory analytically: formal coefficientwise second-order MLDEs are proved for the seven Deligne vacuum characters (Chapter 25); the analytic Arakawa–Kawasetsu MLDE, of unspecified order and for abstract genus-one blocks, is proved conditionally only on Etingof-finiteness, and unconditionally at the vacuum of $L_{-4/3}(\mathfrak{sl}_2)$. The audits' contribution is to say which of these sentences may be printed.

50.2 A catalogue of dead ends, traps and corrected mistakes

The working agreements of the project single out the record of dead ends as *the highest-value section* of every hand-off record between sessions: "the project's worst time sinks have all been re-attempts of routes already known to fail". This section consolidates that record. Each entry states (i) the claim, definition or route; (ii) why it fails, with the counterexample or certificate; (iii) the lesson. Entries backed by a Lean theorem are presented with the full fidelity protocol; entries backed by a numerical certificate or by a paper argument say so.

The entries fall into six kinds, and it helps to name them, because each kind is caught by a different check:

(A) *unsatisfiable definitions*: an axiom system no nonzero object satisfies (caught only by constructing an example, or by proving a certificate of emptiness);

(B) *conclusions satisfied by trivial objects*: the target theorem holds for a degenerate object as well as for the intended one (caught by asking "what else satisfies this?");

(C) *wrong formulas and conventions*: a sign, a normalisation or a modification that a source states differently or not at all (caught by numerical controls);

(D) *ambiguities*: a definition that does not determine what it was meant to determine (caught when a proof needs the missing information);

(E) *circular or insufficient reductions*: a reduction step that silently assumes its conclusion, or reduces to something no easier (caught by tracing what each step uses);

(F) *tooling and process traps*.

50.2.1 Unsatisfiable definitions

The twisted Jacobi identity over all indices

Recall from Chapter 34 that a g-twisted module, for an automorphism g of order N, has vertex operators $Y_M(u,z) = \sum_{r \in \frac{1}{N}\mathbb{Z}} u_{(r)} z^{-r-1}$, and that for u in the eigenspace $V^j = \{v : gv = e^{-2\pi i j/N} v\}$ only the modes $r \in -\frac{j}{N} + \mathbb{Z}$ occur. The library encodes the mode $u_{(k/N)}$ as `YM u k` with $k \in \mathbb{Z}$, so the support condition says `YM u k = 0` unless $k \equiv -j \pmod N$. The twisted Jacobi identity of Dong–Li–Mason is a family of identities indexed by $\ell \in \mathbb{Z}$ and by the fractional indices k, m; in the source it is asserted only for k in the support coset of u. Before 6 October 2026 the field `TwistedModule.jacobi` asserted it for *every* k. That predicate is preserved, under its own name, as the subject of a certificate. File `VOA/Moonshine/HeisenbergTwistedModuleDefect.lean`:

```
def JacobiAllIndices (g : Aut W) (N : ℕ) {M : Type*} [AddCommGroup M] [Module ℂ M]
    (YM : V →ₗ[ℂ] (ℤ → End ℂ M)) : Prop :=
  ∀ (j : ℕ) (u : V), u ∈ g.twistedEigenspace N j → ∀ (v : V) (x : M) (ℓ k m : ℤ),
    (∑ᶠ i : ℤ, (negOnePow i * cbz ℓ i) •
        (YM u (ℓ * N + k - i * N) (YM v (m + i * N) x)
          - negOnePow ℓ • YM v (ℓ * N + m - i * N) (YM u (k + i * N) x)))
      = ∑ᶠ i : ℕ, cbinom ((k : ℂ) / N) i • YM (W.smul u (ℓ + i) v) (k + m - i * N) x
```

Theorem 50.2 (The all-indices twisted Jacobi identity forces $M = 0$). *Let V be a vertex operator algebra, $g \in \operatorname{Aut} V$, $N \geq 2$, and let Y_M be a linear map from V to fractional-mode families of endomorphisms of a vector space M such that $Y_M(\mathbf{1}, z) = \mathrm{id}$ (only the mode $\mathbf{1}_{(-1)}$, label $k = -N$, is nonzero, and it is the identity). If Y_M satisfies the twisted Jacobi identity for all $j, u \in V^j, v, x, \ell, k, m$ without restriction on k, then $M = 0$.*

File `VOA/Moonshine/HeisenbergTwistedModuleDefect.lean`:

```
theorem jacobiAllIndices_eq_zero {g : Aut W} {N : ℕ} (hN : 2 ≤ N) {M : Type*}
    [AddCommGroup M] [Module ℂ M] (YM : V →ₗ[ℂ] (ℤ → End ℂ M))
    (hvac : ∀ k : ℤ, YM W.vacuum k = if k = -(N : ℤ) then 1 else 0)
    (hJ : JacobiAllIndices g N YM) (x : M) : x = 0 := by
```

From the mathematics to the Lean statement

- `YM : V →ₗ[ℂ] (ℤ → End ℂ M)`: a $\mathbb{C}$-linear map assigning to each state u the family of its fractional modes, `YM u k` $= u_{(k/N)}$. `End ℂ M` is the algebra of linear endomorphisms of M.
- `hvac`: the vacuum acts by $\mathbf{1}_{(-1)} = \mathrm{id}$, which in the label convention $k/N = -1$ is $k = -N$; all other modes vanish. This is the twisted-module vacuum axiom `vacuum_YM`.
- `cbz ℓ i` is the integer binomial $\binom{\ell}{i}$ extended to $i \in \mathbb{Z}$ (zero for $i < 0$), `negOnePow i` is $(-1)^i$, and `cbinom x i` is the generalised binomial $x(x-1)\cdots(x-i+1)/i!$ with complex upper index; `W.smul u n v` is the n-th product $u_{(n)}v$ in the VOA; $\sum^{\mathrm{f}}$ is a sum of finitely many nonzero terms.
- The conclusion `x = 0` for an arbitrary `x : M` is $M = 0$.

The theorem is *stronger* than needed to condemn the old definition: it uses only the vacuum axiom, not the other fields of a twisted module.

Proof on paper. Take $u = v = \mathbf{1}$ (so $j = 0$), $\ell = -1$, $k = 1$, $m = -N - 1$. On the left every term contains a vacuum mode with label $-N + 1 - iN$ or $1 + iN$; neither equals $-N$ for any integer i when $N \geq 2$ (the first would need $iN = 1$, the second $(i+1)N = -1$). So the left side is 0. On the right the term i involves $\mathbf{1}_{(-1+i)}\mathbf{1}$, which is $\mathbf{1}$ for $i = 0$ and 0 otherwise; the $i = 0$ term is $\binom{1/N}{0} Y_M(\mathbf{1})_{(-N)}x = x$. Hence $0 = x$. The point is that $k = 1$ lies outside the support coset of $u = \mathbf{1}$ (which is $k \equiv 0$), so the identity is being asserted for modes that do not exist. The repair adds exactly the hypothesis `(k + j) % (N : ℤ) = 0` to the field; Chapter 34 prints the repaired field and checks that it is the Dong–Li–Mason identity.

Physical meaning

In an orbifold CFT the twist field creates a branch cut: a field u of g-charge j picks up the phase $e^{2\pi i j/N}$ when carried around the twisted state, so its mode expansion only contains powers z^{-r-1} with $r \in -\frac{j}{N} + \mathbb{Z}$. The Jacobi identity is the statement that the operator product expansion is associative and local *for the modes that exist*. Demanding it for non-existent modes is like demanding that a fermion in the Ramond sector also have Neveu–Schwarz modes: the only Hilbert space compatible with both is empty.

What the machine verified

`VOA.jacobiAllIndices_eq_zero`: unconditional (its hypotheses are exactly the data being refuted); `#print axioms` re-run for this chapter: `[propext, Classical.choice, Quot.sound]`. The repair is the only change to a pre-existing definition made by the Moonshine work (diff of `VOA/Modularity/Twisted.lean` across the Moonshine commit: one hypothesis line, the docstring, and one binder in `OrdVModule.toTwisted`, which is the case $N = 1$ and is unaffected). Before the repair, every theorem with a hypothesis "`T : TwistedModule g N M`" with $N \geq 2$ and $M \neq 0$ was vacuous.

Trap / dead end

Lesson. A structure with no nontrivial instance can hide a modelling bug indefinitely (`README.md` calls the first instance of a definition its "correctness oracle"). The defect surfaced only when the first nonzero twisted module (the twisted Heisenberg module of Chapter 35) was attempted. Every new structure should be instantiated nontrivially as early as possible.

SuperTwistedModule: the same defect, not repaired

The library's super analogue, in `VOA/Modules/SuperTwistedModule.lean`, has the same shape. File `VOA/Modules/SuperTwistedModule.lean`:

```
  support : ∀ (j : ℕ) (u : 𝒱), u ∈ g.twistedEigenspace N j →
    ∀ k : ℤ, (k - j) % (N : ℤ) ≠ 0 → YM u k = 0
  /-- The full Koszul twisted Jacobi identity in fractional-mode form. -/
  jacobi : ∀ {p q : ZMod 2} (j : ℕ) (u : 𝒱),
    u ∈ g.twistedEigenspace N j → u ∈ W.parity p →
    ∀ (w : 𝒱), w ∈ W.parity q → ∀ (x : M) (ℓ k m : ℤ),
    (∑ᶠ i : ℤ, (negOnePow i * cbz ℓ i) •
        (YM u (ℓ * N + k - i * N) (YM w (m + i * N) x)
          - (koszul p q * negOnePow ℓ) •
            YM w (ℓ * N + m - i * N) (YM u (k + i * N) x))) =
      ∑ᶠ i : ℕ, fractionalBinom ((k : ℂ) / N) i •
        YM (W.smul u (ℓ + i) w) (k + m - i * N) x
```

Trap / dead end

Open defect. The field `jacobi` carries no restriction of k to the support coset (here written $k \equiv j \pmod N$, a different sign convention from `TwistedModule`). The vacuum is even, so the certificate of Theorem 50.2 applies verbatim with $p = q = 0$, `koszul 0 0 = 1`: for $N \geq 2$ every `SuperTwistedModule` is zero. The source file `VOA/Moonshine/HeisenbergTwistedModuleDefect.lean` records this in its docstring; the super certificate itself has *not* been formalised (argued on paper here). The structure is mentioned in twelve files (`VOA/Modules/SuperTwistedModule.lean`, `VOA/Modules/SuperTwistedZhu.lean`, `VOA/Modules/SuperRelativeEtingofFinite.lean`, seven files `VOA/Modularity/Super*.lean`, `VOA/Modularity/Twisted.lean`, and the certificate file). Any theorem among them whose hypotheses include a `SuperTwistedModule` with $N \geq 2$ is vacuous until the field is repaired. Repairing it is a decision left to the maintainers (Section 50.6). The Moonshine construction does not use `SuperTwistedModule`.

Bilinear positivity on a complex subspace

Theorem 50.3 (A $\mathbb{C}$-bilinear form is never positive on a nonzero $\mathbb{C}$-subspace). *Let β be a $\mathbb{C}$-bilinear form on a complex vector space E and $S \leq E$ a subspace. If $\beta(x, x)$ is a positive real number for every nonzero $x \in S$, then $S = 0$.*

File `VOA/Core/GradedUnitarity.lean`:

```
theorem eq_bot_of_bilinear_pos (β : BilinForm ℂ E) (S : Submodule ℂ E)
    (hpos : ∀ x ∈ S, x ≠ 0 → ∃ r : ℝ, 0 < r ∧ β x x = (r : ℂ)) : S = ⊥ := by
```

From the mathematics to the Lean statement

`BilinForm ℂ E` is a $\mathbb{C}$-bilinear form, `Submodule ℂ E` a complex subspace, `(r : ℂ)` the real number r viewed as a complex number, and `S = ⊥` says S is the zero subspace. The statement

is exactly Theorem 50.3.

Proof on paper. If $x \neq 0$ in S has $\beta(x,x) = r > 0$, then $ix \in S$ and $\beta(ix,ix) = i^2 r = -r < 0$, a contradiction.

Physical meaning

Unitarity of a CFT is positivity of a *Hermitian* inner product $\langle \cdot | \cdot \rangle$ (antilinear in one slot); the Zamolodchikov metric, the BPZ form with an antilinear involution, reflection positivity are all Hermitian. A bilinear form can only be "positive" on a real form of the space. An earlier encoding of clause (vi) of the graded-unitarity conjecture of Arabi Ardehali–Beem–Lemos–Rastelli (a positivity condition) used a bilinear form and was therefore false for every VOA with a nonzero weight space, while its documentation called the conjecture open. Fixed by stating clause (vi) for a sesquilinear form (`SesqForm`).

What the machine verified

Unconditional; standard axioms (it is part of the maintained audit). Recorded among the library's dead ends (`README.md`, "Known dead ends").

Other unsatisfiable or refutable predicates in the library

The library-wide register (`README.md` "Known dead ends", and the project's internal session records) contains several more entries of kind (A). We list them with their certificates; the full fidelity treatment of each is in the chapter covering the relevant area.

- **`GenFields` over the left ideal `MRbot` is empty** (generators-and-OPE presentation of the Virasoro VOA). File `VOA/Core/NonlinearVirasoro.lean`:

  ```
  theorem not_nonempty_genFields_MRbot_virasoro (c : ℂ) :
      ¬ Nonempty (GenFields (MRbot (virasoroOPE c))) := by
  ```

  The structure `GenFields` asks for local fields generating a quotient of the tensor algebra by an ideal of relations; with the *left* ideal `MRbot` the creation part of the generating field is forced to be left multiplication, and then the mode commutator modulo a left ideal cannot be a sum of delta functions. The certificate is an explicit linear functional on words of length three that kills `MRbot` but must equal $(-1)^N$ by locality of order N. A step documented as "precisely the open step" was thus false; the correct ideal is the two-sided `MRtwo`.

- **The formal $\mathbb{C}[[q]]$ route says nothing about the upper half-plane.** File `VOA/Modularity/FormalSpecializatio`

  ```
  theorem no_algHom_powerSeries_X_ne_zero (φ : PowerSeries ℂ →ₐ[ℂ] ℂ) {q₀ : ℂ} (hq : q₀
  ↪  ≠ 0) :
      φ PowerSeries.X ≠ q₀ := by
  ```

  A $\mathbb{C}$-algebra homomorphism $\mathbb{C}[[q]] \to \mathbb{C}$ must send q to 0 (if $q \mapsto q_0 \neq 0$, then $1 - q/q_0$, a unit of $\mathbb{C}[[q]]$, would map to 0). So "evaluation at $q_0 = e^{2\pi i \tau}$" does not exist on formal power series and no Nakayama argument over $\mathbb{C}[[q]]$ reaches a point of the upper half-plane.

- **`BlockFiniteDim.zhu_modularity_of_analytic_finrank_le` is vacuous**: its hypothesis `hle` is refuted by `not_finrank_analyticSlashAmbient_le` in `VOA/Modularity/SlashAmbientObstruction.lean`. (The underlying cause was a helper definition returning a junk value on inhomogeneous vectors.)

- **`qInjOnBottomResidual` is false** for $\dim A(V) > 1$ (free-boson counterexample, certificate `qInjOnBottom_false_of_balancing_ne_bot` in `VOA/Modules/ZhuVermaAnArchSdBalancedBottom.lean`).
- **`SimpleAModsRealized` as first typed was false**: it forced every simple $A(V)$-module to be finite-dimensional, false for $A(V^k(\mathfrak{sl}_2)) \cong U(\mathfrak{sl}_2)$; now scoped under finite-dimensionality of $A(V)$.
- **`FZModeDescent` is false** (free-boson counterexample: only the zero mode descends to the Frenkel–Zhu quotient).
- **Zhu's Lemma 4.4.4 in "unitriangular" form is false** (it would force $Z(L[-n]x) = 0$ for $n \geq 3$); Zhu carries a Virasoro-primary hypothesis for this reason.
- **General `DiagonalFHL` is not a theorem**: full invariance for an arbitrary bilinear form forces symmetry conditions on V_1; the canonical invariant form is obtained by a different route.

Trap / dead end

A mirror-image mistake. The register also contains a *retracted* dead end: an earlier note declared the structure `Sl2Presentation` unsatisfiable, judging from the *name* of an ideal (`casIdeal`) without reading its one-line definition; it was satisfiable, and the note retired live work. Lesson: before declaring a predicate unsatisfiable, read the definition, not the name; a false "do not attempt" is as harmful as a false "done".

50.2.2 Conclusions satisfied by trivial objects

The square-zero TRAP

The first "definition of done" for $V^\natural$ in `Notes/MonsterRoadmap.md` listed five targets: a VOA structure on $V^\natural = V_\Lambda^+ \oplus (V_\Lambda^T)^+$, central charge 24, $V_1 = 0$, $\dim V_2 = 196884$, and graded dimension J. While building the reconstruction interface (`reconstruct_nat`, Chapter 38), an agent noticed that all its hypotheses hold when the twisted×twisted→untwisted operator $\overline{W}$ is set to 0.

Proposition 50.4 (The square-zero extension)**.** *Let U be a vertex operator algebra and M an ordinary U-module with integral weights. On $U \oplus M$ define $Y(u,z) = \mathrm{diag}(Y_U(u,z), Y_M(u,z))$ for $u \in U$ and, for $t \in M$, $Y(t,z)(u',t') = (0,\ e^{zL_{-1}} Y_M(u',-z)t)$. Then $U \ltimes M$ is a vertex operator algebra with the same vacuum, conformal vector and central charge as U, and graded dimension $\dim U_n + \dim M_n$. It is not simple when $M \neq 0$: $0 \oplus M$ is a proper ideal.*

Proof on paper. The products are $u \cdot u' \in U$, $u \cdot t \in M$, $t \cdot u \in M$ (by skew-symmetry) and $t \cdot t' = 0$. Locality of $Y(t)$ with $Y(t')$ holds because both map $U \oplus M$ into $0 \oplus M$ and kill $0 \oplus M$, so their products vanish; the remaining locality relations are module locality and the intertwining property of the skew map W. The other axioms reduce to those of U and M. The subspace $0 \oplus M$ is stable under all modes and does not contain the vacuum.

For $U = V_\Lambda^+$ and $M = (V_\Lambda^T)^+$ this object satisfies all five original targets, because the graded dimension depends only on the underlying graded vector space. It is not $V^\natural$. In Lean the statement is not formalised as a separate theorem; it is recorded in `Notes/MonsterRoadmap.md` and in `Notes/M8GluingPlan.md` ("Status, after M8d part 1"), and the defence against it is built into the final theorem in two ways: the vertex map is pinned to `Ynat VnatAxioms.wbarL` with the genuine adjoint $\overline{W}$, proved nonzero, and the conclusion contains `V.IsSimple`. File `VOA/Moonshine/VnatGenuine.lean`:

```
theorem leechWbar_ne_zero : leechWbar ≠ 0 := by
```

From the mathematics to the Lean statement

`leechWbar` is the family $t \mapsto \overline{W}(t,z)$ of operators $(V_\Lambda^T)^+ \to V_\Lambda^+$ defined as the adjoint of the skew intertwiner W with respect to the invariant forms (Chapter 37). The proof exhibits a nonzero coefficient: for weight-2 twisted states, $\overline{W}(t)_{(3)}t' = \mathrm{TPForm}(t',t)\,\mathbf{1}$, and the form `TPForm` is nondegenerate. Nonvanishing of $\overline{W}$ alone would not exclude every degenerate structure; it is `IsSimple` that does, via nondegeneracy of the invariant form $B^\natural = B_V \oplus \mathrm{TPForm}$ (`SimpleNat.vnatVOA_isSimple`, Chapter 38), which fails for the square-zero extension because the $\overline{W}$-block of invariance is exactly the adjunction $\overline{W} = W^\dagger$.

Physical meaning

The square-zero extension is a chiral algebra in which the twisted-sector states never fuse back into the untwisted sector: tw × tw → 0. It has the right partition function $J(\tau)$ but it is not a unitary CFT: its two-point functions of twisted states vanish ($\langle t|t'\rangle$ would be computed by $t \cdot t'$ landing on the vacuum), so the twisted states are null. A physicist's check that the theory is non-degenerate is exactly the nondegeneracy of the Zamolodchikov two-point function, which is what simplicity encodes here. The lesson is a classic one: the partition function does not determine the operator algebra.

What the machine verified

`leechWbar_ne_zero` and `SimpleNat.vnatVOA_isSimple` are proved; the latter was first conditional on `htt` (twisted×twisted locality), which is discharged in the final theorem: for the final structure, `V.IsSimple` is the last clause of `VOA.Moonshine.moonshine` itself (`VOA/Moonshine/TopPairs.lean`), which has no hypotheses. The square-zero proposition itself is argued on paper only.

Trap / dead end

Lesson. For every target ask what else satisfies it. Numerical invariants (dimensions, characters) do not determine algebraic structure. "Done" for $V^\natural$ requires simplicity, or equivalently a nondegenerate invariant form.

The $\varphi = 0$ trap and the hits_cyclic clause

The triality σ on the twisted sectors was reduced (Chapter 40) to top-level data: a linear map φ from the weight-2 space of V_3^+ to T_s^+ intertwining zero modes. File `VOA/Moonshine/SigmaExistLeech.lean`:

```
structure TopSigmaV3 (s : ZMod 2) (φ : VPlus →ₗ[ℂ] TP) : Prop where
  /-- `φ` maps the top level of `V₃⁺` into `T_s⁺`. -/
  maps_frame : ∀ x ∈ OmegaV3, φ x ∈ TPframe s
  /-- `φ` maps the top level into weight 2. -/
  maps_weight : ∀ x ∈ OmegaV3, φ x ∈ plusModule.weight (2 : ℂ)
  /-- Zero-mode intertwining: `φ (o(a) x) = o(σ a) φ x` for every homogeneous `a ∈ V₀⁺`. -/
  zero_mode : ∀ (k : ℤ) (a : V0Sub.carrier), (a : VPlus) ∈ leechVOAPlus.grading k →
    ∀ x ∈ OmegaV3, φ (actV a (k - 1) x) = actT (sig a) (k - 1) (φ x)
  /-- `φ` hits a cyclic vector `h₀(-½)𝟙 ⊗ t₀` of `T_s⁺`. -/
  hits_cyclic : ∃ t₀ : TLeechT, t₀ ∈ leechFrameT s ∧ t₀ ≠ 0 ∧ ∃ x ∈ OmegaV3, φ x = x0T t₀
```

Trap / dead end

Without the last clause, $\varphi = 0$ satisfies the first three, and the existence theorem `sigmaV3T_exists_of_top` would produce the zero intertwiner, from which nothing about

σ follows. `hits_cyclic` (its image contains a nonzero cyclic vector $h_0(-\frac{1}{2})\mathbf{1}\otimes t_0$) excludes this. Lesson: every existence-by-reduction statement needs a non-degeneracy clause, and the referee should look for it.

A sign that is a condition, not a normalisation

The data of σ (`SigmaData`) leave free $\Phi\mapsto c\Phi$, $\Psi\mapsto c^{-1}\Psi$ and $\Theta\mapsto-\Theta$. One might think every scalar condition can be met by normalising. The condition `ThetaTop` says $\mathrm{TPForm}(\Theta\cdot,\Theta\cdot)=\mu\,\mathrm{TPForm}$ with $\mu=+1$; since $\Theta^2=1$ and the form is unique up to scalar, $\mu=\pm1$, and μ is *invariant* under $\Theta\mapsto-\Theta$. If μ were -1, both eigenspaces of Θ would be isotropic, the trace of Θ on the top would be 0, and the key identity would be unsatisfiable. Numerically $\mu=1$ to 4×10^{-12} and $\mathrm{tr}\,\Theta_J=-112\neq0$ (Section 50.3.7); in Lean $\mu=+1$ is proved (`thetaTop_mkData`). Similarly the final identity holds for $\varepsilon=+1$ (`topPairs_one`); that it fails for $\varepsilon=-1$ is argued on paper only (it would force $\Theta_0(o(x_n)\Phi_0x_n)=0$).

50.2.3 Wrong formulas and conventions

The unmodified triality of Dolan–Goddard–Montague: 6372 versus 2324

The triality σ on the Niemeier lattice VOA V_N, $N=N(A_1^{24})$, is built from the 24 copies of $\widehat{\mathfrak{sl}}_2$ at level one. Dolan, Goddard and Montague give it as $\sigma=\prod_j\exp(\frac{i\pi}{\sqrt{2}}(J_0^{j1}+J_0^{j2}))$ (their (7.5)) and, for $d/8$ odd, a modification inserting a sign $z_l=(-1)^{x_l}$ in one coordinate (their (7.8)). The docstring of `VOA/Moonshine/TrialityGolay.lean` records a trace computation that decides between them.

Proposition 50.5 (Trace certificate). *On* $(V_0^+)_2$, $\dim=49428$, $\mathrm{tr}(\sigma|(V_0^+)_2)=300+8\sum_{c\ octad}(-1)^{c\cdot u}$, *where* $u=0$ *for (7.5) and* $u=e_l$ *for (7.8). Hence* $\mathrm{tr}=6372$ *for (7.5) and* $\mathrm{tr}=2324$ *for (7.8).*

Proof on paper. $(V_N)_2$ decomposes under $\mathfrak{sl}_2^{24}$ into Fock and root states and the $759\cdot2^8$ octad states e^n, $n=\pm1$ on an octad. Projecting to the fixed points of $\langle\chi,\Theta\rangle$ with $\frac{1}{4}\sum_k$ (legitimate because σ normalises this group) and using the $SU(2)$ characters of σ_j on spin $\frac{1}{2}$ and spin 1, the non-octad contribution is 300 and each octad contributes $8(-1)^{c\cdot u}$. There are 759 octads, so $u=0$ gives $300+8\cdot759=6372$. Each point lies in 253 octads, so for $u=e_l$ the sum is $(759-253)-253=253$, giving $300+8\cdot253=2324$.

Now suppose σ were the restriction of an automorphism $\tilde\sigma$ of $V^\natural$, i.e. (by FLM) of an element of the Monster $\mathbb{M}$, with $V_0^+=(V^\natural)^E$, $E\cong2^2$. Then $\mathrm{tr}(\sigma|{V_0^+}_2)=\frac{1}{4}(\mathrm{tr}\,\tilde\sigma+\mathrm{tr}\,\tilde\sigma k_0+2\,\mathrm{tr}\,\tilde\sigma k_1)$ on ${V^\natural}_2=1+196883$, with $\tilde\sigma,\tilde\sigma k_0$ involutions and $\tilde\sigma k_1$ of order 4. The largest values of the Monster characters on 196883 for such elements are 4371 (class 2A) and 275 (class 4A), so the trace is at most $\frac{1}{4}(4372+4372+2\cdot276)=2324$. Thus 6372 is impossible and 2324 saturates the bound.

Physical meaning

The trace of a symmetry on a weight space is a twined partition-function coefficient: it is what a physicist would compute to identify which symmetry of the Moonshine CFT an operator is. Here a character-table bound from the Monster acts as a consistency check on a formula copied from a paper: the unmodified rotation of the 24 $SU(2)$ currents is a symmetry of the Niemeier theory but not one that extends to the Moonshine theory.

What the machine verified

Argued on paper (in the file docstring) and checked numerically: with the real Golay code the weight-2 model (`scripts/moonshine/numerics/triality/`) reproduces $\dim(V_0^+)_2 = 49428$ and the traces 6372 and 2324, and at module level the unmodified σ maps V_3^+ to the wrong twisted summand (Section 50.3.4). The Monster bound uses the Monster character table, which is cited, not formalised. In Lean the library's `golaySigma` is defined in the (7.8) form; nothing in Lean depends on the bound.

Sign conventions that each turned out to be necessary

The numerical model of Section 50.3.2 tested the twisted×twisted locality relation (4.23) in the library's conventions and then broke one convention at a time. Each of the following "simplifications" makes (4.23) fail with relative residual 1.7–2.0, and each is therefore recorded as a dead end.

1. **The $\varepsilon(\alpha,\alpha)$ sign on T.** The invariant form on the 4096-dimensional module T must satisfy $B(e_\alpha t, t') = (-1)^{\langle\alpha,\alpha\rangle/2} B(t, e_\alpha t')$ (File `VOA/Moonshine/TForm.lean`, `TForm_eT`), the factor $(-1)^{L_0}$ of the contragredient. The "group" sign $\varepsilon(\alpha,\alpha)$ (transpose = inverse) differs from it by a basis-dependent character, and the corresponding form is symmetric or *alternating* according to an Arf invariant that depends on the chosen basis: for random bases of E_8 the count $\#\{x : x \cdot Mx = 0\}$ is 136 or 120 (`VOA/Moonshine/TFormLattice.lean`).

2. **The positive Fock form.** The invariant form on $S[\theta]$ must satisfy $h(m)^t = -h(-m)$ (`fockForm`, File `VOA/Moonshine/InvFormFock.lean`); the positive, Hermitian-looking form $h(m)^t = +h(-m)$ transposes the dressing $E^-E^+(v)$ to $E^-E^+(-v)$ and breaks invariance (sympy check recorded in the file).

3. **A constant charge sign.** On V_L the form is $B(p \otimes e^\alpha, q \otimes e^\beta) = \delta_{\alpha+\beta,0}\, c(\alpha) F(p,q)$ with $c(\alpha) = (-1)^{\langle\alpha,\alpha\rangle/2}\varepsilon(\alpha,\alpha)$, which is *not* constant because the library's cocycle does not satisfy $\varepsilon(\gamma,\gamma) = (-1)^{\langle\gamma,\gamma\rangle/2}$. File `VOA/Moonshine/NondegLattice.lean`:

   ```
   noncomputable def chSign (α : L.carrier) : ℂ :=
     (-1 : ℂ) ^ (LatGen.halfNorm L α) * latticeCocycle L α α
   ```

   Setting $c \equiv 1$ breaks (4.23).

4. **Dropping $(-1)^w$ in $\overline{W}$.** The adjoint formula carries a weight sign; dropping it breaks (4.23).

5. **The super sign.** The anticommutator version of the twisted×twisted relation fails (residual ≈ 2): with the library's signs the extension is a VOA, not a vertex superalgebra.

Physical meaning

These are the familiar sign headaches of lattice CFT: the cocycle ε that makes vertex operators $e^{i\alpha\cdot X}$ mutually local, the BPZ conjugation $(-1)^{L_0}$ and z^{-2L_0} of a primary field, and the reality condition $a_n^\dagger = a_{-n}$ versus the bilinear transpose $a_n^t = -a_{-n}$ for a chiral boson ∂X (the bilinear form differs from the Hermitian one by $X \mapsto -X$ on the antilinear side). Each sign controls whether the twisted-sector OPE is associative; getting one wrong gives a theory that is not local.

50.2.4 Ambiguities

The golayE ambiguity

The automorphism σ of V_0^+ (`v0Sigma`) is transported from V_N through an isomorphism that involves a character `golayE` chosen by `Classical.choose` from an existence statement. The specification

determines only twice the character.

Theorem 50.6 (golayE is not determined). *There are two characters e_1, e_2 of Λ_0 with values in $\mathbb{C}^\times$, both satisfying the specification $\psi = g_e\,\theta\,g_e^{-1}$, whose values at the preimage w_0 of $8e_0$ differ by a sign.*

File `VOA/Moonshine/TrialityTwSigma.lean`:

```
theorem golayE_not_determined :
    ∃ e₁ e₂ : lam0.carrier →+ Additive ℂˣ,
      (∀ x, lam0Psi x = charLat lam0 e₁ (thetaLat lam0 (charLat lam0 (-e₁) x))) ∧
      (∀ x, lam0Psi x = charLat lam0 e₂ (thetaLat lam0 (charLat lam0 (-e₂) x))) ∧
      ∃ w₀ : lam0.carrier, inclΛ w₀ = frameW ∧ charVal lam0 e₂ w₀ = -charVal lam0 e₁ w₀ :=
       ↪ by
```

From the mathematics to the Lean statement

`lam0.carrier →+ Additive ℂˣ` is a group homomorphism from Λ_0 to the multiplicative group $\mathbb{C}^\times$ (written additively); `charLat lam0 e` is the induced automorphism g_e of V_{Λ_0} ($e^\alpha \mapsto e(\alpha)e^\alpha$); `thetaLat` is θ; `lam0Psi` is the target involution ψ; `inclΛ w₀ = frameW` says w_0 maps to $8e_0$ in the Leech lattice; `charVal` evaluates. The proof takes $e_2 = e_1 + e_\beta$ with $e_\beta = (-1)^{\langle\beta,\cdot\rangle}$, $\beta = (5, 1^{23})$, which has $2e_\beta = 0$ and $\langle\beta, 8e_0\rangle$ odd.

Physical meaning

Changing the choice conjugates σ by the symmetry $g_\beta \oplus (1 \otimes e_\beta)$ of the Moonshine CFT, which exchanges the two twisted subsectors T_0^+ and T_1^+. Physically the question "which twisted sector does triality map the untwisted sector V_3^+ to" has no convention-independent answer until a choice is made; both answers describe isomorphic theories.

What the machine verified

Unconditional; `#print axioms` re-run: standard axioms. Consequence: downstream statements are phrased with "$\exists s$" (e.g. `topSigma_both`); one must not try to prove that $\sigma(V_3^+)$ is `TPframe 0` (or `1`) from the definitions.

The non-computable cocycle, and why it did not matter

The Leech cocycle is `latticeCocycle` over a basis obtained from `Module.Free.chooseBasis`, a choice; and the oscillator frame is the $\sqrt{G}$ frame, not the Golay frame. So no explicit sign $\varepsilon(\alpha, \beta)$ is computable, and every identity must be proved symbolically. During the top-level work this was flagged as a design issue: an explicit Golay-frame model transported via functoriality might simplify the remaining proofs. The agent who completed the triality reported, and the supervisor confirmed by inspection of the finished proofs, that no concrete cocycle value was ever needed: everything reduced to bimultiplicativity, the commutator $\varepsilon(\alpha,\beta)\varepsilon(\beta,\alpha) = (-1)^{\langle\alpha,\beta\rangle}$, and Golay-code facts. The refactor was not done. Related design point: comparing cocycles of a sublattice and of the ambient lattice needs a $\mathbb{Z}/4$-valued coboundary; a ±1-valued one would commute with θ only up to a character.

Two lattice types

There are two structures called `IntegralLattice`: the vendored `_root_.IntegralLattice` and `VOA.IntegralLattice`; inside `namespace VOA` the bare name means the latter. The bridge `IntegralLattice.ofEbeling` transports between them. A wrong resolution of a shadowed name typechecks and yields an unprovable goal; the same trap is recorded library-wide for `mode_iterate` and `mode_commutator`.

50.2.5 Circular and insufficient reductions

1. **The vacuum trick for $(V_\Lambda^T)^+$ is circular.** The untwisted sectors are cyclic by the "vacuum trick" (a Borcherds identity applied to $u_{(n)}\mathbf{1}$). The analogous route for the twisted sector needs the $V^\natural$ Borcherds identity for three twisted vectors, which is (4.23), the very relation being proved. Commutator formulas with one untwisted argument do not imply it. Twisted cyclicity (`cyclic_TPframe`) was proved by an explicit route inside the twisted module.

2. **`YnatT_eq_of_creates` is circular for the key identity.** File `VOA/Moonshine/M8h0Gap.lean`:

```
theorem YnatT_eq_of_creates (hspan : ModeSpan g) (x : TP) (Ψ : FormalDist (End ℂ
↪  Vnat))
    (hcov : DCovariant Tnat Ψ) (h0 : Ψ 0 vacNat = ((0 : SkewVP), x))
    (hneg : ∀ q : ℤ, q < 0 → Ψ q vacNat = 0) (hU : ∀ v : SkewVP, Local Ψ (YnatU v))
    (hT : ∀ j, Local Ψ (YnatT leechWbar (g j))) : YnatT leechWbar x = Ψ := by
```

   It identifies a field with $Y^\natural(0,x)$ if the field is local with *all* $Y^\natural(g_j)$, twisted generators included (`hT`). Applied to $\Psi = \sigma Y^\natural(v)\sigma^{-1}$, the hypothesis `hT` is twisted×twisted locality, i.e. the goal. The replacement uses locality with V_0^+ only. File `VOA/Moonshine/M8hKeySigma.lean`:

```
theorem eq_zero_of_V0local (F : FormalDist (End ℂ Vnat))
    (hloc : ∀ u : V0Sub.carrier, Local F (YnatU (u : VPlus)))
    {β : leech.carrier} (hβ : β ∉ lambda0) (t : ZMod 2 → TLeechT)
    (ht : ∀ s, t s ∈ leechFrameT s) (ht0 : ∀ s, t s ≠ 0)
    (hvac : ∀ p, F p vacNat = 0) (h3 : ∀ p, F p (frameX0P β, 0) = 0)
    (hT : ∀ s p, F p (0, x0T (t s)) = 0) : F = 0 := by
```

   Similarly, using V_3^+-locality of $L_v = \sigma Y^\natural(v)\sigma$ is circular: it is equivalent to the identity for $b \in V_3^+$.

3. **"Irreducible tops ⇒ Zhu generation" is circular.** The numerics showed that the weight-2 zero modes generate End(top) on every top (Section 50.3.5). This does not prove `ZhuGenerated`: the set $S = \{a : \varphi o(a) = o(\sigma a)\varphi\}$ being everything is exactly the conclusion; irreducibility gives only a dichotomy (the graph of φ, or everything), and excluding the second case needs information about $A(V_0^+)$ beyond its image. What irreducibility does give is uniqueness of φ up to scalar.

4. **V_0^+ is not strongly generated by its weight-2 space.** dim of the weight-3 Fock part is 576, while L_{-1} of weight 2 gives only 300. So the classical lemma "strong generators are Zhu generators" does not apply; the 0-mode products $a_{(0)}b$ are essential (filtered commutator $a * b - b * a \equiv a_{(0)}b$).

5. **Weak generation does not reduce the top clause.** V_Λ^+ is generated under n-th products by the $e^\beta + e^{-\beta}$ (`leechPlus_generated`), but $o(a_{(n)}b)$ on the top is not determined by $o(a)$, $o(b)$ on the top. Only Zhu generation (closure under $*$ modulo $O(V)$) reduces the zero-mode clause to generators.

6. **(4.23) is not decided by finitely many low-weight coefficients**: the top four-point function is $z_2^q f(z_2/z_1)$ with f an infinite series whose rationality is the content; no finite set of coefficients certifies it without a closed form or an ODE.

7. **Top-level vanishing does not imply that an intertwiner vanishes** without the Frenkel–Zhu bimodule $A(M)$: the top-level part of the key identity is necessary, not sufficient. Machine-checked replacement: top-level *output* vanishing for *all* states v suffices (`keySkew_of_keyTopV`); finiteness then comes from bimodule generation.

8. **Induction on** $\operatorname{wt} v + \operatorname{wt} b$ via the defect commutator and skew-symmetry does not close (zero-mode reductions raise the state weight); skew-symmetry alone does not decide `KeySkew` (it says J is a fixed point of an involution, which allows components in both eigenspaces); the relation (4.22) gives no new information about the key block.

9. **Weight-2 quadratic left factors alone fail in charged degree 1**: the exact charged-vacuum formula `quadF_lead_one` was needed (Fock spanning).

10. **Ground states cannot be reached from Fock-dressed sources** (weight count), so the lattice statement `GroundLattice` is necessary for the filtered criterion, not merely convenient.

11. **`Modules.Fusion.Intertwiner` is commutator-only.** File `VOA/Modules/Fusion.lean`:

```
structure Intertwiner (A : OrdVModule W M) (B : OrdVModule W N) (C : OrdVModule W P)
 ↪  where
  /-- The mode data `𝒴_s(u)x`. -/
  modes : IntertwinerModes M N P
  /-- Lower truncation: `𝒴_s(u)x = 0` for `Re s ≫ 0`. -/
  truncation : ∀ (u : M) (x : N), ∃ s₀ : ℝ, ∀ s : ℂ, s₀ ≤ s.re → modes s u x = 0
  /-- The defining intertwining commutator (membership in `IntertwinerSpace`). -/
  isIntertwiner : modes ∈ IntertwinerSpace A B C
```

It has truncation and the commutator formula but no L_{-1}-derivative property and no associativity, so it is weaker than an intertwining operator of Frenkel–Huang–Lepowsky. Do not route uniqueness arguments through it; the Moonshine proof avoids it entirely. Its fusion coefficient is discussed in Section 50.2.8.

Trap / dead end

Lesson for (E). For each reduction write down what each step *uses*, not only what it proves. Circularity in this project always entered through a hypothesis that looked general ("local with all generators", "a uniqueness lemma") but specialised to the goal.

50.2.6 Combinatorial and numerical pitfalls

- **Random sign sampling misses lattice exceptions.** In the ground-state step of Zhu generation the exceptional families $E_2 = \{(\pm 1)^{24} : \text{negative set} \in \mathcal{G}\}$ and $E_3 = \{s + 2s_i e_i : N(s)\Delta\{i\} \in \mathcal{G}\}$ are single sign classes indexed by Golay codewords; random sampling of signs found only $E_1 = \{\pm 4e_i\}$. E_2, E_3 were found by hand and confirmed by exhaustive enumeration. Use orbit structure or exhaustive enumeration.

- **Do not exclude** $\alpha = \beta$ in the ground product with $\langle \alpha, \beta \rangle \geq 1$: $\gamma = 2\alpha$ has $\gamma/2$ as its only partner, and an earlier `GroundRel` with $\alpha \neq \beta$ was too weak.

- **Low-order traces do not distinguish modules**: $\operatorname{tr} o(u)$ and $\operatorname{tr} o(u)o(v)$ agree on all six weight-2 V_0^+-modules; the V_3^+/V_3^- distinction lives in long loops $n \to -n$.

- **Ground-state rationality is not a unimodularity test**: D_8 also gives a rational four-point function.

- **Left action alone** (no 0-modes) gives rank 0/24 at weight 3 in the bimodule test.

50.2.7 Tooling and process traps

- **`abbrev ExtraT` times out.** File `VOA/Moonshine/ExtraspecialModule.lean`:

  ```
  noncomputable abbrev ExtraT : Type := Rep (cocMat L) (isUnit_det_cocMat L hEven hU)
  ```

  Instance search for the scalar action through the `abbrev` times out; downstream code uses `Rep (cocMat L) _` directly.

- **The audit trap** `-DmaxSynthPendingDepth=3` (Section 50.1.6).

- **`ring` inside `first`** silently "succeeds" (falls back to `ring_nf`); use `ring1`. **`ext` on a `FormalDist₂`** descends too far; use `FormalDist₂.ext`.

- **Disk and pickles in numerics.** The first triality pipeline wrote multi-GB pickled intermediates (one stage alone about 1 GB, about 2 GB in total); they were deleted, and the KeySkew numerics were rebuilt to compute σ block by block with a cache of about 68 MB. Scripts first lived in a temporary session scratchpad and had to be copied to `scripts/moonshine/numerics/` to survive; paths inside them may need adjusting.

- **A naive rename.** When the library was renamed from `MoonshineVOA` to `VOA`, a case-insensitive substitution would have destroyed the genuine monstrous-moonshine module names (`MoonshineHauptmodul`, `MoonshineModule`, …); only the exact token was substituted.

- **Concurrent sessions in one tree** invalidated recorded builds (Section 50.1.3).

- **Stale prose** (Section 50.1.8, and Section 50.2.8).

50.2.8 Documentation debt and open library issues found while writing the book

The authors of the other chapters, reading every quoted declaration against its source, recorded discrepancies. Each item below was re-checked against the source for this chapter.

1. **The structure called "vertex algebra" was not one** (*resolved by renaming, 28 October 2026*). The library's transcription of Gannon's Definition 5.1.3(a), then named `VertexAlgebra` (and its ungraded companion `BareVA`), has no translation-covariance axiom, and VA1–VA5 imply neither covariance nor the Borcherds identity: a three-dimensional counterexample was machine-checked for Chapter 4 (Theorem 4.7) and is now in the library as `TranslationCovariantCounterexample`. No theorem was wrong — every Borcherds-type result is stated for `VertexOperatorAlgebra`, whose axiom (VOA3) supplies covariance — but the name and an old docstring were. The structures are now `PreVertexAlgebra` and `BarePreVA`; `VertexAlgebra` is the genuine notion (a `PreVertexAlgebra` with the field `translation_covariant`), and `VertexOperatorAlgebra.toVertexAlgebra` makes every VOA one. At the same time the VOA structure was layered: `GradedVertexOperatorAlgebra` (the FLM/Lepowsky–Li notion) and `VertexOperatorAlgebra` (that, of CFT type). Similarly the universal affine VOA $V^k(\mathfrak{g})$, formerly `simpleAffineVOA`, is now `universalAffineVOA` (Chapter 23). The super analogue `SuperVertexAlgebra` has the same omission and keeps its name (Chapter 17).

2. **`VOA.fusionCoeff` is identically** 0 (argued on paper, not formalised). File `VOA/Modules/Fusion.lean`:

   ```
   noncomputable def fusionCoeff (A : OrdVModule W M) (B : OrdVModule W N) (C :
   ↪  OrdVModule W P) : ℕ :=
     Module.finrank ℂ (IntertwinerSpace A B C)
   ```

   Here `IntertwinerModes M N P` is the space of all families $\mathbb{C} \to \mathrm{Hom}(M \otimes N, P)$ and `IntertwinerSpace` the kernel of the commutator defect $a^P_{(p)} Y_s(u)x - Y_s(u)a^N_{(p)}x - \sum_j \binom{p}{j} Y_{s+p-j}(a_{(j)}u)x$, with

no truncation or grading condition. The defect relates $\mathcal{Y}_s$ only to $\mathcal{Y}_{s+\mathbb{Z}}$ and is invariant under the shift $s \mapsto s + c$. Hence the kernel is the product, over the classes $\rho \in \mathbb{C}/\mathbb{Z}$, of the spaces K_ρ of solutions supported on ρ, and the shift by c maps K_ρ isomorphically onto $K_{\rho+c}$. Either every K_ρ is 0 (and the space is 0) or all of the uncountably many K_ρ are nonzero (and the space is infinite-dimensional). Mathlib's `Module.finrank` is 0 for infinite-dimensional spaces, so in both cases `fusionCoeff` is 0. So `fusionCoeff` is not the fusion rule N_{MN}^P.

3. **`SuperTwistedModule.jacobi` is unrepaired** (Section 50.2.1).

4. **`IsLowestWeight` does not require $M_h \neq 0$.** File `VOA/Modules/ZeroModeMult.lean`:

```
def IsLowestWeight (N : OrdVModule W M) (h : ℂ) : Prop :=
  ∀ α : ℂ, N.weight α ≠ ⊥ → ∃ n : ℕ, α = h + n
```

   It says every occurring weight is in $h + \mathbb{N}$; it does not say that h occurs. Any h below the true lowest weight by a natural number also qualifies. Statements using it as "the lowest weight is h" should add $M_h \neq \bot$ where the intended meaning needs it.

5. **`SelfDual` is never linked to `IsUnimodular`.** File `VOA/Foundations/Lattices.lean`:

```
def SelfDual : Prop := ∀ x : ℝ ⊗[ℤ] L.carrier, x ∈ L.dual ↔ ∃ v : L.carrier, L.toReal
 ↪  v = x
```

   and in the vendored library, File `VOA/LatticesAndCodes/Lattice/Defs.lean`:

```
def IsUnimodular : Prop := IsUnit Γ.det
```

   (`VOA.Modules.StronglyRational` has an unrelated `SelfDual` for VOAs.) No theorem in the library proves that the two lattice notions agree; results stated with one cannot be fed the other without a bridge.

6. **`latMorph_injective` assumes equal rank.** The section variables of `VOA/Moonshine/LatticeMorph.lean` include `(hr : rank K = rank L)`; the functoriality $V_K \to V_L$ is therefore proved only for isometric embeddings between lattices of the same rank (sublattices of finite index), which is all the Moonshine construction needs ($\Lambda_0 \subset \Lambda$, $\Lambda_0 \subset N$), but not general functoriality.

7. **Stale docstrings** (*resolved, October 2026*). Several Moonshine file headers said "Not imported by the umbrella" or "not wired into the umbrella" (for example `VOA/Moonshine/TFormLattice.lean` and the header of `VOA/Moonshine/TopPairs.lean`); a search of both files on 28 October 2026 finds no such header. Route notes contain superseded estimates and "open" claims, corrected in later "Update"/"Status" sections.

8. **`README.md` was behind the library** (*resolved, October 2026*: the current README no longer contains these sentences). It said "It is not a formalization of the Moonshine module $V^\natural$ itself" and, under Scope, "$V^\natural$ is not formalized"; and it said "The unrestricted minimal-model theorem remains open". Both were false at the Moonshine commit: `VOA.Moonshine.moonshine` constructs $V^\natural$, and File `VOA/Examples/VirasoroMinimalRigidityComplete.lean` proves

```
theorem minimal_graded_rigidity (p q : ℕ) (hp : 2 ≤ p) (hq : 2 ≤ q)
    (hcop : p.Coprime q) :
    IsRigidGraded (virasoroSimple (minimalCentralCharge p q)) := by
```

   with `#print axioms [propext, Classical.choice, Quot.sound]` (re-run for this chapter).

9. **`Notes/MonsterRoadmap.md`, row of the twisted-module milestone,** called twisted associativity `star_iterate_range` "unused but proved" (*resolved, October 2026*: the row now says it is used); it is used in `VOA/Moonshine/LatticeTwistedProduct.lean` and `VOA/Moonshine/LatticeTwistedBase.lean`.

Physical meaning

The fusion coefficient N_{MN}^{P} counts the independent ways two primaries M, N can fuse into P in the OPE; it is a small integer in a rational CFT. A "count" that is always zero is a warning sign that the space being counted is not the space of chiral vertex operators (it lacks the L_{-1}-covariance $\partial_z \mathcal{Y} = \mathcal{Y}(L_{-1}\cdot)$ and the conformal-weight constraint on the exponents s). Similarly, a lowest-weight condition that does not demand a lowest-weight *state* would accept the empty spectrum.

50.2.9 Dead ends recorded in the later chapters (October 2026)

The chapters added or extended in October 2026 each record their own dead ends in `warning` boxes, with the counterexample or certificate. This subsection is an index to them, sorted by the six kinds (A)–(F) introduced at the start of this section, with one or two sentences per entry. The certificates and the full discussion are in the cited sections; where a finding is numerical or a paper argument only, the cited chapter says so, and so do we. The dead ends of Chapters 28 and 29 are recorded in their own sections (Sections 28.14 and 29.12); those of the chapter in preparation will be indexed with it.

(B) Hypotheses that no intended object satisfies.

1. **The `hdec` criterion forces C_2-cofiniteness** (Chapter 11, Section 11.5, warning on page 527). The older surjectivity criteria for the jet presentation of Li's associated graded algebra assume $V = \mathrm{span}(\mathrm{gen} \cup \{\mathbf{1}\}) + C_2(V)$ for a finite family gen. The theorems are correct, but the hypothesis forces $R_V = V/C_2(V)$ to be finite-dimensional, i.e. V to be lisse. A certificate compiled for Chapter 11 (in a scratch file, standard axioms; not library code) proves `hdec` ⇒ `C2Cofinite W`. Combined with the unconditional non-lisseness of $L_{-4/3}(\mathfrak{sl}_2)$ (Chapter 16, Theorem 16.40) this gives a machine-checked counterexample: no finite family satisfies `hdec` there. On paper the same holds for every quasi-lisse VOA that is not lisse, including all the Deligne-series VOAs; with the currents as generators it already fails in weight two, where $(R_V)_2 \supseteq V(2\theta) \oplus \mathbb{C}Q \neq 0$ (Chapter 24, Section 24.3). It also fails for the lisse minimal models $M(2, 2m+3)$, $m \geq 2$, with the single generator ω, because $[\omega]^2 \neq 0$ in $R_V \cong \mathbb{C}[T]/(T^{m+1})$ (Chapter 20, Section 20.12). The replacement, used throughout, is spanning of Li's filtration by ordered generator words.

2. **Graded unitarity "for some flag" is nearly empty** (Chapter 19, Warning 19.4.1; paper argument). Because the predicate `GradedUnitary B R F` quantifies over an arbitrary flag `F`, any VOA with a nondegenerate Hermitian form on each weight space satisfies it for a suitable flag, Lee–Yang included. The Virasoro statement `VirGradedUnitary` pins the flag and is unaffected. This complements the older defect, now repaired, in which clause (vi) was false for every VOA (Theorem 50.3; Chapter 19, Warning 19.2.1).

(C) Wrong formulas, and the limits of a single identity.

1. **Feigin's homogeneity is false:** 55 **versus** 63 (Chapter 26, Section 26.11; Chapter 27, Section 27.7.1). The natural mechanism behind Feigin's Corollary 2 (*SIGMA* 4 (2008) 070; Corollary 2.2 in arXiv v1) for the A_2 total bound, that the fusion filtration is homogeneous for the grading by trivial factors, fails: at $N = 2$ the degree-one filtration piece has dimension 55, while the sum of the dimensions of its projections is 63 (exact computation). The published repair (Kus–Littelmann) and an alternative route (Setia–Rani–Khandai) are recorded in those chapters.

2. **The heat equation alone does not give $E_4^2 = E_8$** (Chapter 25, Section 25.7): at weight 8 the relation contains σ_7 and no combination eliminates it; Mathlib's dimension formula is used instead.

3. **Star bounds by termwise domination or positive expansions** (Chapter 25, Section 25.10.4; Chapter 27, Section 27.9). Domination proofs of $\leq$ are forced to be exact (proved on paper), the plethystic exponents of the MLDE solutions alternate in sign (observed), and the G_2 step R3 of the Macdonald pilot admits no small rational certificate; the pilot was stopped and the G_2 input stays named.

(E) Circular or insufficient reductions.

1. **The presentation route to the A_2 total bound is circular** (Chapter 26, Section 26.11): the surjection from the associated graded of the fusion model is free, and its injectivity is the statement. In the same list: the naive truncated box overcounts (72 against 64 at $m = 2$); plain tensor induction fails by fusion associativity, so the mixed models are needed; separating functionals by charge, weight or θ-degree fail from $N = 3$; leading-term independence of Chari–Loktev words fails; ungraded counting in the evaluation model carries no information. Chapter 27, Section 27.9, adds two traps of the same kind: a toroidal mode splitting treated as an algebra map before passing to the associated graded, and a shift image treated as an ideal although it contains the constant 1.

2. **The generator-symbol step of the Kus–Littelmann repair is insufficient for D_4** (Chapter 27, Section 27.7.1). The p. 437 step infers that the symbols of the whole annihilator kill the fusion vector from the symbols of the defining relations. For D_4 at $m = 2$ those symbols generate an ideal of codimension $29^2 + 1$, one too many, and an explicit element $\tilde{a}$ of the annihilator has a symbol outside it (computation, not Lean). The statement the step is meant to prove holds at $m = 2$ (exactly) and $m = 3$ (modulo two primes); the theorem is not known to fail.

(D) and (A) Missing structure that a route needs.

1. **Mathlib's Serre construction of $\mathfrak{e}_8$** (Chapter 23, Warning 23.7): Mathlib does not prove the presented algebra finite-dimensional or simple, so the exceptional Lie algebras were built as lattice weight-one spaces and from checked structure constants.

2. **Zhu's change of coordinates as a VOA isomorphism** (Chapter 25, Section 25.5): the library's `changeCoord` has no transformation law; a symbol calculus on the C_2 algebra avoids it.

3. **Heisenberg chains along short roots** for the nilpotency needed in Ravinder's kernel lemma (Chapter 26, Section 26.13): replaced by general nilpotency lemmas.

(F) Tooling: the cost of kernel-checked certificates. The Deligne chapters rest on large integer certificates checked by the Lean kernel (`decide`), and their architecture is shaped by recorded failures (Chapter 23, Warning 23.12.2; Chapter 24, Section 24.10.1; Chapter 25, Section 25.12.1; Chapter 27, Section 27.9). Single declarations over whole tables reached 18–41 GB or did not finish (a 133×133 sector comparison: 41 GB and a time-out after 445 s; one `decide` over the whole D_4 identity: 650 s and 41 GB); `![…]` vector tables are slow at high index (literal lists read with `getD` are used); importing the VOA stack into check files costs about 6 GB before any work (light-import copies bridged by `rfl` are used); a plain box enumeration of the E_7 roots did not finish in ten minutes. The working pattern is many small declarations of a few thousand entries each, under a per-file memory budget.

Physical meaning

Several of these dead ends have a direct physical reading. The failure of `hdec` is the statement that a non-rational chiral algebra such as $L_{-4/3}(\mathfrak{sl}_2)$, whose Higgs-branch-like associated variety has positive dimension, cannot have its C_2 algebra spanned by finitely many states. And Feigin's $55 \neq 63$ is a reminder that a filtration on a fusion product, the mathematical form of an operator product with prescribed orders of vanishing at the insertion points, need not respect an auxiliary grading that is natural on the factors.

50.2.10 Dead ends recorded in the moonshine part

Chapters 43–49 record their dead ends, traps and documentation defects in `warning` boxes. This subsection indexes all of them, by the kinds (A)–(F) of this section, with one or two sentences each and the chapter where the box, its certificate and its discussion are found. Where a finding is a paper argument or a computation outside Lean, the cited chapter says so.

(B) Hypotheses and properties that do not single out the intended object.

1. **Modular fictions satisfy replication** (Chapters 43 and 46). For every $a \in \mathbb{C}$, the series $q^{-1} + aq$ satisfies all replication identities, with replicates $q^{-1} + a^k q$. So rationality of the coefficients does not follow from replication alone, and a genus-zero theorem for replicable families cannot hold unless the family is tied to J; the library's proof uses $T_1 = J$ exactly in its nontriviality step.

2. **A rational character does not give rational matrices** (Chapter 49). The quaternion group Q_8 on $\mathbb{C}^2$ has a rational character but no rational model (Schur index 2). The converse direction therefore needs an already rational, absolutely irreducible subgroup: the commutant lemma for Gmat.

3. **Finite order is not finiteness** (Chapters 43 and 47). An infinite group can have every element of finite order; the moonshine theorem uses only finite order, and finiteness of $\mathrm{Aut}(V^\natural)$ needed a separate argument.

(C) Wrong formulas and conventions.

1. **The sign of the momenta** (Chapters 43–47). Borcherds' root (m, n), with root space $V^\natural_{1+mn}$, is the library's momentum $(m, -n)$ for the lattice of norm $+2xy$. A denominator product over library momenta $x, y \geq 1$ is wrong: those root spaces vanish, except the real root space.

2. **The index shift of the McKay–Thompson series** (Chapter 43): coefficient n of `mckayThompson` is the trace on weight $n+1$, while coefficient n of `JShift` is the dimension of weight n; recorded by the negative lemma `mckayThompson_one_ne_JShift`.

3. **The total-weight cutoff is false for near-VOAs** (Chapters 44 and 45). In $V_{\mathrm{II}_{1,1}}$ the state $L_{-1}e^{(1,-1)}$ has total weight 0 but L_1 does not kill it (a kernel-checked counterexample); the correct cutoff is the oscillator level above the ground energy of the momentum sector.

4. **No positive-definiteness witness; two cocycles** (Chapter 44). The positive-definite lattice construction cannot be instantiated at $\mathrm{II}_{1,1}$ (`lorentzian_not_posDef`); two local field families with different cocycles exist and are not claimed equal, so the sign `chSign` cannot be dropped.

5. **The naive Ising vector need not be idempotent** (Chapter 47): $\frac{1}{16}\alpha(-1)^2\mathbf{1} + \frac{1}{4}x_\alpha$ is an idempotent of the right normalisation only if $\varepsilon(\alpha, -\alpha) = 1$, and the library's cocycle signs are never evaluated; the scalar is kept symbolic.

6. **The phases of the Griess dictionary** (Chapters 48 and 49): the full dictionary needs the phases $\zeta' = Z^{-1}$, not Z; they differ by $\varepsilon(\alpha_c, \alpha_c)$, which is not always $+1$ for the library's cocycle. Whether it is $+1$ on all short classes depends on the chosen basis of Λ and was left open as unneeded.

7. **Published steps that fail as printed** (Chapters 43 and 46). Cummins–Gannon's Prop. 5.1 is not usable for Γ_1 (its prime-clearing step uses exponents outside the admissible set); the last step of Cummins (2002), Prop. 2.1, is wrong as printed; Cummins–Gannon's Prop. 2.3 needs equal multiplicities at doubly critical pairs, which their Lemma 2.4 does not give. The library uses corrected versions, and never constructs a symmetry at a critical target.

(E) Circular or insufficient reductions.

1. **The product formula cannot be derived from the Monster Lie algebra** (Chapters 45–47). Given the other Borcherds data, generation of $\mathfrak{m}$ by its simple root spaces is equivalent to the denominator identity for $J(p) - J(q)$; the Casimir argument excludes relations among the known simple roots but not extra simple roots (m, n) with $m \geq 2$. The library proves the product formula analytically and derives generation from it.

2. **Freeness in the wrong form** (Chapter 45): the positive part E is not free (it satisfies $(\operatorname{ad} e)^j \mathfrak{g}_{\alpha_j} = 0$), and freeness on the imaginary simple root spaces alone gives the graded dimension $1/(1 - \sum_j c(j) pq^j)$, not the product side; the needed statement is freeness of $\mathfrak{u}^+$ on U.

3. **Same-momentum comparison of forms** (Chapters 44 and 45). The no-ghost sector form is nondegenerate, while the vertex-algebra form vanishes on a single nonzero momentum sector; a Lean theorem (`moonshineMatterSector_no_same_momentum_isometry`) shows that no map, linear or not, identifies them. The fix is momentum reversal.

4. **Complete replicability needs finite order** (Chapter 46): for an element of infinite order T_g need not converge, so the library proves complete replicability for finite-order elements first and passes to all of $\mathrm{Aut}(V^\natural)$ only after finite order is proved.

5. **The local-to-global step of genus zero** (Chapter 46): canonical cusp charts do not give Möbius-ness (one global input is unavoidable), and a second independent differential equation pinning down the symmetry does not exist.

6. **Rationality through a rational form of $V^\natural$** (Chapter 43): showing that every automorphism preserves a $\mathbb{Q}$-form of ${V^\natural}_2$ needs either Tits-level group theory or rationality of every Ising vector; the Galois twist alone is circular. Superseded: rationality of traces is a corollary of the moonshine theorem.

7. **Galois descent on $\mathrm{Aut}(V^\natural)$ alone** (Chapter 49) gives only that the rational subgroup is self-normalising; it cannot exclude a finite overgroup. Also recorded there: "real first, then real $\Rightarrow$ rational" needs Tits's theorem, and was superseded.

8. **The monomial subgroup is not enough for the commutant lemma** (Chapter 49): $2^{12}{:}M_{24}$ together with Q, x_B, τ_B preserves the 23-dimensional space of traceless diagonal matrices, so its commutant is too large; a non-monomial element such as ξ is indispensable.

9. **Two generators that preserve the MOG columns** (Chapters 43 and 49): the first attempt at the octad step of the commutant lemma used two permutations lying in a sextet stabiliser, which cannot be transitive on the 759 octads; a third, column-breaking involution was needed.

10. **A false induction criterion** (Chapter 47): "every β with $|\beta|^2 \geq 6$ has a minimal α with $\langle \alpha, \beta \rangle \in \{3, 4\}$" fails for $\beta = k\alpha_0$, $k \geq 5$ (numerical sample: 400 failures in 4800, all of this shape).

11. **Two routes to finite order that do not work** (Chapter 47): $c = 1$ Virasoro vectors form a continuous $O(24)$-family and are not rigid; diagonal zero modes do not separate the twisted sector. Only $c = \frac{1}{2}$ rigidity starts the argument.

12. **Counting all Ising vectors** (Chapter 47) needs rigidity at every Ising vector, which is known only through the representation theory of $c = \frac{1}{2}$; the library counts *rigid* idempotents instead.

13. **AxiomMath's finiteness proof does not transfer to** $\mathbb{C}$ (Chapter 48): it uses the ordered field $\mathbb{Q}$, and over $\mathbb{C}$ the form is not a norm; "real and finite $\Rightarrow$ rational" is Tits's theorem. The converse of Chapter 49 avoids it.

(F) Tooling, and routes deliberately not taken.

1. **Porting `gmat_eq_griess` to Lean 4.30** (Chapters 48 and 49). The import closure of AxiomMath's proof is about 15,500 CFSG files (16,361 files and 208 MB at file level), with 13,487 kernel `decide` proofs, and it cannot avoid the Stroth–Leon–Sims recognition of the Baby Monster. This is why `GmatEqAut0` is a named hypothesis; the different figures quoted in the sources are consistent.

2. **Parts of the original plan that were not formalised** (Chapter 46): the modular polynomials, the Hecke identity for composite n, an explicit injective region, the exponential identity, Rouché's "large values from the top", the Parseval step and the logarithmic Faber identity were argued on paper and found unnecessary; they are not Lean theorems.

3. **"Product" means a series with the product's logarithmic derivative** (Chapter 46): `coneProd` is defined by a differential equation, and its comparison with literal finite products was not written (a documentation gap, not a mathematical one).

4. **Route deviations, none a defect** (Chapters 43 and 49): six deviations of the $\Gamma_1 \Rightarrow \Gamma_0$ proof from its paper blueprint, and the Golay sign-character step of the rationality plan, replaced by an argument from triality.

Documentation defects (severity S4). None affects a Lean statement.

1. **Docstrings that say more than the Lean** (Chapter 43): the module docstring of the statement file identifies `AutVnat` with the Monster, which holds only given `GmatEqAut0`; the docstring of `RationalTraces` describes a superseded role.

2. **Stale docstrings and notes** (Chapter 47): the docstring of `MonsterLieSimpleRootGeneration` still calls generation unproved; earlier working notes list finite order and finiteness as open. The paper route of the finite-order proof was unrefereed; its normalisations are settled by the Lean proofs.

3. **The ported `phi0`** (Chapter 48) is a plain function rather than AxiomMath's bundled linear map; the two are definitionally equal. Several port docstrings still call ported statements "not ported".

4. **Stale module docstrings of the lift chain** (Chapter 49): `MoonshineLRLiftTwisted`, `LiftTwisted2`, `LiftLiftable2–4`, `LiftVisible`, `SigmaBlock`, `SigmaBlock2`, `SigmaB` and `TauB` describe gaps closed in later files; an earlier working note calls the converse direction open research, although it is proved without Tits.

Physical meaning

Two of these dead ends are physics statements in disguise. The impossibility of deriving the denominator identity from the Monster Lie algebra says that the no-ghost theorem alone does not know about the modularity of J, i.e. about the one-loop consistency of the string theory; the library must import that modularity analytically. And the failure of the total-weight cutoff is the familiar fact that a charged ground state of a Lorentzian compactification can have negative energy, so that conformal weight is not a good measure of "how many oscillators are excited".

50.3 The numerical evidence

50.3.1 Epistemic status

The directory `scripts/moonshine/numerics/` preserves the Python scripts and logs written while choosing conventions and routes for the Moonshine construction. Its `README.md` states the principle: "They are evidence, not proof; every claim used in Lean is proved in Lean." No Lean declaration imports, cites or depends on any of these computations; the compiler never sees them. Their role was strategic: to choose signs and normalisations before investing thousands of lines in a proof, to detect wrong formulas from the literature, and to decide whether a reduction was worth formalising. Two kinds of computation occur.

- *Exact* computations, in integers, rationals (`fractions.Fraction`) or modulo the prime $p = 2^{31} - 1$. A rank computed modulo p is at most the rank over $\mathbb{Q}$ of an integer matrix, so *full* rank mod p certifies full rank over $\mathbb{Q}$; a deficit mod p would not have been conclusive.
- *Floating-point* computations (NumPy/SciPy, double precision), reported as the maximal *relative residual* $\|\text{lhs} - \text{rhs}\|/\|\text{lhs}\|$ over the tested identities. Values near 10^{-15}–10^{-11} are rounding error; values of order 1 (typically 2.0, the residual of lhs $= -$rhs) mean the identity fails.

A test without a *control* proves little: an identity that holds with every sign convention tests nothing about conventions. Every floating-point experiment below therefore also reports deliberately wrong variants that must fail.

50.3.2 The E_8 model of the twisted-by-twisted relation (4.23)

Files: `orb.py` (419 lines), `sanity.py`, `sanity2.py`, `tt.py`, log `tt_K3.log`. *Question:* with the library's exact conventions, does the gluing of V_L^+ and $(V_L^T)^+$ satisfy the last locality relation (4.23) of Dolan–Goddard–Montague? *Why E_8:* rank 8 makes $d/8$ odd as for Leech, so θ acts by -1 on T exactly as in the library, while $\dim T = 16$, $\dim \mathrm{TP}_1 = 128$, $\dim \mathrm{TP}_2 = 2048$ are small, and the orbifold is known to be V_{E_8} again. *Method:* the script reimplements $Y^T(e^\alpha, z) = 2^{-\langle\alpha,\alpha\rangle} z^{-\langle\alpha,\alpha\rangle/2} E^- E^+ \otimes e_\alpha$, composite states via e^{Δ_z}, the basis cocycle, the forms with the signs of Section 50.2, W and $\overline{W}$ (the latter by summing over a dual basis), and tests the twisted block of the commutator formula

```
W(t1)_m Wbar(t2)_n x - W(t2)_n Wbar(t1)_m x = sum_{j < wt t1 + wt t2} C(m,j) Y^T(Wbar(t1)_j
↪  t2)_(m+n-j) x
```

for random $t_1, t_2, x \in \mathrm{TP}_1 \oplus \mathrm{TP}_2$ and all (m, n) with intermediate weight ≤ 3 (34752 states of V_L). *Sanity checks:* $Y^T(\omega)$ gives $L_0 + d/16$, $L_{\pm 1}$; Heisenberg commutators (residual $\le 10^{-16}$); lattice commutators for $\langle\alpha, \beta\rangle \in \{-1, 0, 1\}$ ($\le 3 \times 10^{-15}$). *Result:* 64 identities, maximal relative residual 3.7×10^{-14} (final log line "max rel residual 3.734689360353892e-14 over 64 identities"). *Controls* (18 identities each), all failing with residual 1.7–2.0: group sign $\varepsilon(\alpha, \alpha)$ on T; $c(\alpha) = 1$; dropping $(-1)^w$ in $\overline{W}$; the super (anticommutator) sign.

What the machine verified

Numerical evidence for a model lattice, in floating point; not about Leech, not part of any proof. The Leech relation (4.23) is proved in Lean by a different route (triality).

50.3.3 The theta check

File: `theta_check.py`, log `theta_check.log`. *Question:* what lattice input makes the ground-state four-point function rational? *Method:* exact rational q-series to $O(q^{80})$; $x = \theta_2^4/\theta_3^4$ computed by series division, without assuming Jacobi's identities. *Results* (verbatim from the log): the Leech counts $1, 0, 0, 0, 196560, 0, 16773120, 0, 398034000$; "Jacobi check $1-x = \theta_4^4/\theta_3^4$: True"; $\Theta_{E_8} = \theta_3^8(1-x+x^2)$; and

$$\Theta_\Lambda = \theta_3^{24}\Big[(1-x+x^2)^3 - \tfrac{45}{16}x^2(1-x)^2\Big], \qquad G_\Lambda(x) = \frac{(1-x+x^2)^3}{(x(1-x))^3} - \frac{45/16}{x(1-x)},$$

rational and crossing-symmetric; D_8 (determinant 4) also gives a rational G, so this does not single out unimodular lattices.

Physical meaning

$G_L(x)$ is the four-point function of the $\mathbb{Z}_2$ twist fields $\sigma(z)$ of d chiral bosons on $\mathbb{R}^d/L$, in the untwisted channel, as a function of the cross-ratio; $q(x)$ is the nome of the double cover torus. Locality of the twisted OPE is rationality of G in x: the four-point function must be single-valued on the sphere.

50.3.4 Golay code and triality

Files: `golay.py`, `golay2.py` (Golay code from quadratic residues mod 23; 4096 codewords, weights $\{0, 8, 12, 16, 24\}$), `tri.py`, `g.py`, `adj.py`, `cert.py`, and the pipeline `triality/` (`vn.py`, `stage1–stage3`, `model.py`, `tmod.py`, `run4.py`, `bfs2.py`, `block.py`, `bfsT.py`, `trace.py`). *Model:* the weight-2 space of V_N, all 196884 states, with the library's basis cocycle; $\sigma = G(\chi z_0)G^{-1}$ (the library's `golaySigma`) computed on the 1083 invariant blocks; $\Theta = \sigma\chi\sigma$; $(V_0^+)_2 = (V_N)_2^{\langle\chi,\Theta\rangle}$. *Results:* $\dim(V_0^+)_2 = 49428$; $\operatorname{tr}\sigma = 2324$ (and 6372 for the unmodified $G\chi G^{-1}$), reproducing Proposition 50.5; $\Theta e^\gamma = c_\gamma e^{-\gamma}$ with $c_\gamma = 1$ for all 98256 norm-4 $\gamma \in \Lambda_0$. An explicit σ-twisted intertwiner $(V_3^+)_2 \to (T_0^+)_2$ was built by breadth-first propagation from a joint eigenvector and checked on 15000 identities, residual 4.2×10^{-15}; wrong target sectors give 2.0; with the unmodified σ the consistent target is the other summand (the N-only X_1), a module-level confirmation of the trace certificate; $T(1,+) \to T(1,+)$ residual 4.8×10^{-12}. Caveats recorded with the data: only zero modes of weight-2 states on weight-2 spaces; N's cocycle; the identification of the model sectors with T_0^+, T_3^+ uses an unchecked normalisation step.

50.3.5 The Zhu-generator test

File: `zhu/zhu.py`, log `zhu_0.log`. *Question:* do the zero modes of $(V_0^+)_2$ generate the zero-mode algebra on the weight-2 tops, or is a weight-4 element (as in rank one, the "J" of $A(M(1)^+)$) needed? *Method, exact:* on the V_3^+ top the zero modes of $h_a h_b$ have joint eigenvalue nn^{T}, giving projectors onto pairs $\{e^n, e^{-n}\}$, and $o(e^\gamma + \theta e^\gamma)$ links pairs with $\langle n, n'\rangle = \pm 2$; the graph on the 98304 vectors with these 226 099 200 directed edges is connected, so the algebra B contains all matrix units. On the twisted top $B = M_{24} \otimes C$, and 400 random norm-4 vectors generate Λ_0 (Hermite normal form covolume $8192 = 2^{13}$), so $C = \mathrm{End}(X)$. *Result:* $B = \mathrm{End}(\text{top})$ on both 49152-dimensional tops; B acts irreducibly on, and separates, all 16 irreducible tops, total dimension $1+3\cdot 24^2+6\cdot 2048^2+6\cdot 49152^2 = 14\,520\,682\,177$. No weight-4 generator is needed. (Status: exact computation plus standard Heisenberg-group

representation theory; the implication to Zhu generation needs the cited classification of $A(V_{\Lambda_0}^+)$ and was *not* used; Lean proves Zhu generation directly, `zhuGenerated_weightTwo`.)

50.3.6 Filtered-criterion ranks (zhugen)

Files: `zhugen/fock_lowerprod.py`, `charged_lowerprod.py`, `ground_states.py`, `e3_relations.py`, `e4_check.py`, `ll_special.py`, log `zhugen.log`. Exact ranks mod $2^{31}-1$ of the spans of lower products. Fock sector: rank 1 deficient by one exactly at weight 4 (the rank-one J; a positive control showing sensitivity), full at weights 3 and 5–9; ranks 2, 3, 4 full through weights 11, 9, 8. Charged sector: full rank for charges $(2), (2,0), (2,0,0), (1,1,2), (2,2,2,0)$ up to Fock weight 7. Ground states: random placements of every magnitude pattern up to norm 28 found only E_1; E_2, E_3 were found by hand and checked exhaustively (Section 50.2.5). All superseded by Lean proofs (`groundLattice`, `FockSpan.fockSpanned`, `FockSpan.excitedSpanned`).

50.3.7 SigmaKey normalisation

Files: `sigmakey/` (`pipeline.sh`, `sk.py`, `sk2.py`, logs). In the $N(A_1^{24})$ weight-2 model: N1, $\Theta_J^2 \propto I$ (residual 1.7×10^{-11}), invariant form on the 2048-dimensional block built by eigenline propagation, $\Theta^{\mathsf{T}} B \Theta = \mu B$ with $|\mu - 1| < 4 \times 10^{-12}$, and $\operatorname{tr} \Theta_J = -112$ (eigenvalue multiplicities 968 and 1080), which independently excludes $\mu = -1$; N2, Φ is a similitude (κ_0 constant to 6.7×10^{-12}); N3, the top-level key identity $\Theta o(v)\Phi(b) = \varepsilon o(b)\Phi(v)$ on 170 pairs with one global sign. *Control caveat:* with Θ replaced by the identity, the N3 identity also holds up to a sign that varies from pair to pair ($\approx 50/50$); Θ is what makes the sign global, but the test does not discriminate strongly at weight 2.

50.3.8 KeySkew at weights 3 and 4

Files: `keyskew/` (`lsig.py`, `eng.py`, `ops.py`, `test_eng.py`, `phi.py`, `theta.py`, `keyskew.py`). The model was rebuilt without multi-GB intermediates. *Model consistency* (`test_eng.log`): zero modes agree with the old model to 4.6×10^{-16}; L_0, $[L_{-1}, u_{(m)}]$ to $< 10^{-15}$; the commutator formula between V_0^+ and V_3 on twisted states, 120 identities, 1.1×10^{-15}. *Test* of $\Theta Y^T(v,z)\Phi b = e^{zL_{-1}} Y^T(b,-z)\Phi v$, with Θ known only at weight 2, through lowering letters:

weight	identities	residual	controls
2	12 pairs	9.0×10^{-12}	$\Theta \to$ scalar: does not fail (caveat)
3	≈ 5300	1.1×10^{-11}	$-\Theta$: 2.0; $\Theta \to$ Id: ≥ 0.32; drop L_{-1}: ≥ 0.75
4	≈ 2000	1.1×10^{-11}	$-\Theta$: 2.0; $\Theta \to$ Id: ≥ 0.57; drop L_{-1}: ≥ 0.84
4 (two-step)	≈ 1300	1.1×10^{-11}	$-\Theta$: 2.0

On one T-fibre of the weight-3 level (dimension 2624) the stacked test map has rank 323: a strong necessary condition, not a proof of the vector identity.

50.3.9 Bimodule generation

Files: `bimodule/mod_excited.py`, `mod_ground.py`, `pair_lemma.py`. The module analogue of the filtered criterion for $M = V_3^+$ over V_0^+ holds at weights 3, 4, 5 with no deficit in any sector (exact mod $2^{31}-1$); ground sector exhaustive over the 4096 residues, every sampled coset vector (301) has an $f = -1$ partner; pair lemma checked on 3937 odd magnitude multisets up to norm 60. *Control:* left action only gives rank 0 of 24 at weight 3 and 300 of 324 at weight 4. Superseded by `FZGen.bimodGen_V3`.

50.3.10 TopPairs pre-check

Before the final identity was proved, the library's own symbolic formulas for both sides of $\Theta(o(v)\Phi b) = o(b)\Phi v$ were evaluated on all 98304 odd norm-4 Leech vectors (built from `golayB`, as in `leech.py`): 200,000 random pairs and 64 full rows, 0 failures (recorded in `Notes/M8GluingPlan.md`). The script for this run is not among the preserved files; only its result is recorded.

Physical meaning

These computations are what a physicist would do first: build a finite truncation of the orbifold CFT (all states up to weight 2, 3 or 4), compute OPE coefficients numerically, and check locality and associativity. Their limitation is the usual one of truncated numerics: they test finitely many coefficients of identities between infinite series.

50.3.11 Summary

experiment	checks	precision	role / status
E_8 (4.23)	convention consistency	3.7×10^{-14}	fixed three signs; evidence
theta check	lattice input of (4.23)	exact, $O(q^{80})$	route analysis; evidence
Golay traces	which σ	exact	rejected DGM (7.5); evidence
triality model	σ on twisted tops	4×10^{-15}	existence plausible; superseded
Zhu test	generators of tops	exact	chose $G = (V_0^+)_2$; superseded
zhugen	filtered criterion	exact mod p	found E_1–E_3; superseded
SigmaKey	normalisation	4×10^{-12}	$\mu = 1$; superseded
KeySkew	weights 3, 4	1.1×10^{-11}	de-risked; superseded
bimodule	module criterion	exact mod p	de-risked FZ step 2; superseded
TopPairs	final identity	exact symbolic	0 failures; superseded

"Superseded" means a Lean theorem now proves the corresponding statement.

50.4 Design decisions

50.4.1 Why the FLM route

Five routes to the vertex algebra structure on $V^\natural$ were compared before the gluing began (`Notes/M8GluingPlan.md` §1, with the sources actually read marked as such):

route	new theory needed	estimate, verdict
(A) FLM triality	Golay frame, σ, cyclicity, a Goddard-type uniqueness lemma, one key identity	20–35k lines, medium risk; **chosen**
(B) direct (4.23)	closed form of $\overline{W}$ on ground states, theta transformation of 2^{24} coset thetas, half-integral locality	20–35k, high risk; cross-check only
(C) framed VOA (Miyamoto; Dong–Griess–Höhn)	Ising modules and fusion rules, code VOAs, quantum Galois theory	50k+, high risk; rejected
(D) simple-current extensions (Carnahan; Huang)	braided tensor categories, rationality and fusion of V_Λ^+	100k+; rejected
(E) 2020–2026 literature	none found that bypasses triality or tensor categories	–

The decisive argument for (A) was reuse: every ingredient is an explicit operator on an explicit Fock space, which is how the library had already built general lattice VOAs. The plan packaged FLM's argument through the reconstruction theorem: generators $V_\Lambda^+ \cup T_0^+$, pairs involving an untwisted field from general theory, twisted pairs by σ-conjugation; this removes FLM's use of the group $2^{1+24}.\mathrm{Co}_1$. In execution the key identity was reduced further: σ on the twisted sectors by a top-level argument plus Zhu generation (no Verma modules), the three-point identities to one self-coupling identity, that identity by a Frenkel–Zhu bimodule argument to a finite weight-2 identity, and that identity to explicit Golay arithmetic.

50.4.2 Other decisions

- **Vendoring `LatticesAndCodes`** (decision of 6 October 2026): the 25-file import closure of `Leech.Defs`, `Leech.RepCount`, `Leech.RepCountHigher` copied byte-for-byte from `Fedor-Popov/LatticeAndCodes` at commit `da62b9e2f44a04888abf6f797a429aa8ecc1d6dd`, the only edit the import prefix (verified by `cmp`); the package depends on Mathlib alone and `lakefile.toml` is unchanged. Leech uniqueness is not vendored (not in the closure).

- T **abstractly**: the 4096-dimensional module by Wedderburn–Artin from the central simplicity of $\mathbb{C}^\varepsilon[\Lambda/2\Lambda]$, not by an explicit Golay model; the splitting $T = T_+ \oplus T_-$ and the invariant form were obtained without the model.

- **Keeping the cocycle symbolic** (previous section).

- **Avoiding `VOA.pbw`**: the Dong–Jiang generalised Verma module carries a `BottomProjection` supplied by the then-axiom (while `VOA.pbw` was an axiom); the top-level graph argument (`annCompat_of_top`) and Zhu's easy direction (`ZhuModule` is `pbw`-free) replaced it.

- **Frenkel–Zhu instead of fusion rules**: Abe–Dong–Li fusion rules for V_L^+ would have needed the classification and tensor-product theory; the bimodule argument needed only the commutator formula and weight-2 data, avoiding the missing intertwining Jacobi identity for W.

- **The minimal definitional repair** of `TwistedModule`, and "$\exists s$" statements instead of fixing `golayE`.

50.4.3 The literature and online search

- **Höhn's Lean ATLAS** (repository `Moonshine-in-Kansas/atlas`) formalises Co_0, Co_1 and M_{24}; its licence forbids copying into this Apache-2.0 repository, so nothing was taken from it. The Monster model the library uses was instead ported from the AxiomMath CFSG library (Chapter 48).

- **Carnahan's vertex operators in Mathlib**: Mathlib 4.30.0 contains `Mathlib/Algebra/Vertex/VertexOperator.le` and `HVertexOperator.lean` (vertex operators as maps to Laurent series; its TODO lists locality and residue products). The library predates and does not use them; it has its own formal distributions.

- **Höhn–Seysen**, arXiv:2508.01037, uses $V^\natural$ and the structure of V_Λ^{++} (16 irreducibles, the triality as an S_3) but does not construct $V^\natural$.

- Huang, arXiv:1902.09734, gives twisted×untwisted operators in general, not twisted×twisted. The FLM book was not accessible online; DGM (hep-th/9410029) §§3–7 was read in full; DGM's own §7 derives σ from analytic input and is circular for this purpose.

50.5 Reproducibility

- **Commit:** this edition documents the release commit (`recorded at release`) (front matter; Appendix A). The original verification run of the Moonshine construction was made at the Moonshine commit ("Construct the Moonshine module $V^\natural$ (FLM) unconditionally", 7 October 2026, 268 files changed, 70349 insertions, 8 deletions relative to its parent); the records below (job count, probe output) are those of that run.

- **Toolchain:** `leanprover/lean4:v4.30.0` (file `lean-toolchain`), Mathlib `v4.30.0` (`lakefile.toml`); `elan` at `~/.elan/bin`.

- **Commands**, from the repository root:

```
export PATH="$HOME/.elan/bin:$PATH"
lake exe cache get     # Mathlib build cache, several GB
lake build             # aggregate build; recorded: 10343 jobs
python3 scripts/check_repository.py
python3 scripts/audit/run_axiom_audits.py
```

- **Moonshine axiom probe**: a file containing

```
import VOA
#print axioms VOA.Moonshine.moonshine
```

compiled with `lake env lean -DmaxSynthPendingDepth=3`; expected output `'VOA.Moonshine.moonshine' depends on axioms: [propext, Classical.choice, Quot.sound]` (reproduced for this chapter; about 7 seconds once the library is built).

- **Numerics**: Python 3 with NumPy, SciPy, SymPy; each subdirectory's `README.md` gives the run order; paths may need adjusting; the KeySkew cache is about 68 MB and is recomputable in about 30 minutes; the original triality pipeline writes about 2 GB.

- **Never commit** `.lake/`.

50.6 Open problems

50.6.1 Moonshine

1. **Discharge `GmatEqAutO`.** Earlier editions listed "Aut($V^\natural$) ≅ $\mathbb{M}$" here as out of reach. It is now proved conditionally on the one named hypothesis `GmatEqAutO`, Gmat = AutO (`monsterEquivAutVnat`, `monstrousMoonshine`; Chapter 49), and Aut($V^\natural$) is isomorphic, with no hypotheses, to the subgroup of AxiomMath's Monster of elements that act on $V^\natural$. The hypothesis is AxiomMath's theorem `CFSG.Blueprint.NativeSporadic.MonsterModel.gmat_eq_griess` (commit `69cb972f`, Lean 4.35), whose proof does not run on Lean 4.30 (Section 50.2.10, paragraph (F), item 1). Release v1.1 is planned to move the library to Lean 4.35 and import it, which would make both theorems unconditional.

2. **The table-level Conway–Norton statement.** The library proves the qualitative genus-zero form: T_g is the normalised Hauptmodul of *some* genus-zero Γ_g containing *some* $\Gamma_0(N)$ and commensurable with $\mathrm{SL}_2(\mathbb{Z})$ (`conwayNorton`, Chapter 47). Open: to identify Γ_g with the group of Conway and Norton's table (a group between $\Gamma_0(N)$ and its normaliser), to relate N to the order of g ($N = o(g)\,h$ with $h \mid \gcd(24, o(g))$), and to state anything about conjugacy classes, the character table or integrality of the coefficients (rationality is proved, `rationalTraces`). Chapter 43, Section 43.2, lists what is not formalised.

3. **Generalized moonshine** (Norton; Carnahan): Hauptmoduln for commuting pairs, through twisted modules of $V^\natural$ and their modularity. Not stated.

4. **Jurisich's form of the free subalgebra.** The library proves that the positive part $\mathfrak{u}^+$ of the Monster Lie algebra is free on the generating space U (Chapter 45), which is what the twisted denominator identities need. Jurisich's statement, that the subalgebra generated by the imaginary simple root spaces is free on them, follows on paper and is not formalised.

5. **The explicit product form of the twisted denominator identities.** The library's twisted identities are stated through series defined by their logarithmic derivatives (Chapter 46); neither the exponential form nor the product form with roots of unity is a Lean statement, and the comparison of `coneProd` with literal finite products was not written.

6. **Tits's theorem.** That the automorphism group of the complex Griess algebra is the Monster is not needed: the converse direction of Chapter 49 goes through rationality of traces and the commutant lemma. It is not formalised.

7. **The abstract $c = 24$ files.** The library's `VOA/Modularity/Moonshine*` files contain abstract $c = 24$ statements conditional on hypotheses never instantiated; they are independent of Part VIII.

8. **Uniqueness of $V^\natural$.** FLM conjectured that $V^\natural$ is the unique holomorphic VOA of central charge 24 with $V_1 = 0$. Dong–Griess–Lam proved uniqueness under an additional frame hypothesis (cited, not checked); the general conjecture is open.

9. **A wider Moonshine audit probe.** Since v1.05 the probe `MonstrousMoonshine` enforces the 25 release headlines. The module audits of Part VIII (thousands of supporting declarations) are still checked only by reading the build log (Section 50.1.10).

10. **Simplifications**: formalise the failure for $\varepsilon = -1$; make `golayE` explicit; prove irreducibility of the four V_0^+-sectors; the full intertwining Jacobi identity for W; route (B) as an independent check.

50.6.2 Library-wide

1. **Repair `SuperTwistedModule.jacobi`** (Section 50.2.1); until then theorems with such hypotheses for $N \geq 2$ are vacuous.

2. **Uniform negative-admissible $\mathfrak{sl}_3$ graded rigidity is open** (an open residual of the project's $\mathfrak{sl}_3$ work). Recorded remaining boundary: the finite count/product exhaustion and normalisation between total PBW root counts and real-root/descendant factors, the higher-rank horizontal quotient or parabolic vacuum determinant transfer, and simple vacuum multiplicity/nonzero tangent. A removal-bijection draft is outside the build.

3. **Graded unitarity** (Arabi Ardehali–Beem–Lemos–Rastelli): the Lean layer formalises the definition and reductions; the full conjecture is open (beyond the cases proved in Chapter 19). Chapters 28 and 29 reduce it for the minimal models $M(2, 2n+1)$ to the hypothesis `hA`, graded unitarity of the boundary admissible $L_k(\mathfrak{sl}_2)$, which is open for every n.

4. **PBW in Mathlib**, which would replace the library's own proof of `VOA.pbw` (formerly a project axiom, now a theorem; Section 50.1.2).

5. **Fusion rules**: a genuine intertwining-operator space with L_{-1}-property and weight constraints, so that the fusion coefficient means N_{MN}^{P} (Section 50.2.8).

6. **Documentation debt** (Section 50.2.8): `IsLowestWeight`, `SelfDual` versus `IsUnimodular`. (The README, the stale Moonshine headers and the roadmap row were corrected in October 2026.)

7. **Upstreaming to Mathlib**: the level-one structure theorem $M(\mathrm{SL}_2(\mathbb{Z})) = \mathbb{C}[E_4, E_6]$ (`levelOne_coe_mem_E46`), the majorant estimate, the vendored lattice and code theory, the Wedderburn–Artin dimension count for extraspecial groups, and formal calculus aligned with Carnahan's `VertexOperator`.

50.6.3 Open problems named in the later chapters

Each item below is a precise statement that the library either takes as an explicit hypothesis or does not state. All the theorems mentioned are `#print axioms`-clean; none of those with an open hypothesis is unconditional (Section 50.1.7), and a citation of the literature in a docstring does not change that.

1. **The named inputs of the Deligne final theorems** (Chapter 27, Sections 27.5, 27.6 and 27.7). For each type $X \in \{A_2, G_2, D_4, F_4, E_6, E_7, E_8\}$ of the Deligne series, the final theorem `X_classicallyFree_final` says that the simple affine VOA $L_k(\mathfrak{g})$ at $k = -1 - h^\vee/6$ is classically free for the explicit presentation of Chapter 24; for every type but A_2 it is conditional on named inputs. As recorded in Chapter 27:

   - A_2: none. The total-dimension bound (`CVUniv.fusionTotalDim`), the Demazure realizations and the star identity are proved, and `A2_classicallyFree_final` has no hypothesis; it is machine-confirmed: the aggregate build was green on 2026-10-28 and `#print axioms` reports `[propext, Classical.choice, Quot.sound]` (Chapter 27, Theorem 27.13);
   - D_4: `FusionTotalDimG D4sector` ($\leq 28^m$) only (`D4_classicallyFree_of_inputT`). The Demazure realizations for all n are proved in Lean (`D4Char.d4_demazureRealization`; aggregate build green on 3 November 2026, `#print axioms` standard), and the star identity is proved (`D4Wp.d4SchurEqE4` with the unclamped Demazure = Schur identity, `d4DemazureEqSchur_of_positivity`, positivity from U5 on the unclamped route). The total-dimension bound is Kus–Littelmann's Theorem 4.2; one step of its published proof (p. 437) is insufficient as written for D_4 at $m = 2$, by computation with an explicit witness,

while the theorem is not known to fail. Progress on the bound, not part of the claim (Chapter 27, Section 27.7.1): it is reduced in Lean to $\mathfrak{sl}_4$ core bounds with at least two adjoint sites (`d4_classicallyFree_of_twoAdjointCoreBounds`), and on paper the levels with two adjoint sites are reduced further to two one-node bounds, open in general; an earlier route through a rank bound on a presented module (`D4_classicallyFree_of_presentedRankBoundE`) is proved for $m \leq 2$;

- G_2, F_4, E_6, E_7, E_8: `FusionTotalDimG Xsector` ($\leq (\dim \mathfrak{g})^m$), the Demazure realizations, and the star bound (`G2StarBound`, `F4StarBound`, `E6StarBound`, `E7StarBound`, `E8StarBound`), checked numerically to orders q^{60}, q^{25}, q^{20}, q^{16}, q^{14} respectively (scoping pass of 28 October 2026, Chapter 27, Section 27.4.4).

The inputs that remain open in Lean (Chapter 27, Section 27.7) are the total-dimension bound and the graded Demazure realizations beyond A_2 and D_4, both published theorems not yet formalized (the former with a proof step flagged by the project), and the star identities for G_2, F_4 and the E-types, which are conjectures with numerical evidence. For G_2 the library splits the identity into `G2DemazureFermionic`, which follows from published results (Fourier–Littelmann, Chari–Moura, Ardonne–Kedem, Di Francesco–Kedem; Chapter 27, Section 27.4.4), and `G2FermionicKW`, a q-series identity that is open (checked through q^{60}).

2. **The Arakawa–Kawasetsu MLDE** (Chapter 16, Section 16.6). The theorem `VOA.IsSqPrimary.exists_monicML` gives a genuine monic MLDE, with coefficients in $\mathbb{C}[E_4, E_6]$ of the forced weights and one equation for all analytic blocks, under Etingof-finiteness. Its two other hypotheses were open; *both are now theorems*:

   - `AKWeightGrading W`: weight decompositions of $\mathbb{C}[E_4, E_6]$ and of $\mathbb{C}[E_4, E_6] \otimes V$, together with homogeneity of Zhu's relation module for the total weight. *Now proved for every VOA of the library* (CFT type): `VOA.akWeightGrading` in `VOA/Modularity/AKGradingTotal.lean` (faithful, by the queue-2 release audit, `Notes/Textbook/referee/RELEASE_AUDIT_QUEUE2.md`);
   - `E46SerreClosed`: the Serre derivative maps weight-k elements of $\mathbb{C}[E_4, E_6]$ to weight $k+2$. *Now proved*: `VOA.e46SerreClosed` in `VOA/Modularity/EisensteinSerreClosure.lean` (rated "as stated" by the follow-ups audit). It is no longer an open hypothesis.

   The combined statement is `VOA.IsSqPrimary.exists_monicMLDEOn_all_analyticBlocks_of_etingofFinite_u` conditional on `EtingofFinite` only (despite its suffix); its instance `VOA.exists_monicMLDEOn_all_analyticBloc` is unconditional. Both are `#print axioms`-clean (recorded in `Notes/release/WS-RELEASE2.md`); the aggregate build at the release commit is pending. What remains open here: the order is existential and unbounded (Arakawa–Kawasetsu's order 2 at $L_{-4/3}(\mathfrak{sl}_2)$ is not proved); the blocks are Zhu's abstract one-point blocks, and "the vacuum character satisfies a monic MLDE" is a short composition of library lemmas (`torusOnePoint_isAnalyticBlock`, `onePointSubexp_adjoint_of_etingof` not packaged as one theorem. Also open: quasi-lisseness itself (associated varieties, symplectic leaves, the Etingof–Schedler theorem) is not formalized; and the Zhu-modularity chain under Etingof-finiteness (Section 16.7) has its rank hypothesis discharged only for the trivial VOA.

3. **`AdmissiblyRational` versus Dong–Li–Mason rationality** (Chapter 22, Remark 22.4). The library's rationality asks that every weak submodule of an admissible module have a weak complement; Dong–Li–Mason ask for complete reducibility of admissible modules into simple admissible modules. *One direction is now proved*, for C_2-cofinite V: `VOA.Classification.COne.DLMRat.admissibl` (`hC2 : C2Cofinite W`) derives `AdmissiblyRational W` from `DLMRational W`, a faithful statement of Dong–Li–Mason rationality (every admissible module is an internal direct sum of graded-minimal submodules); `#print axioms`-clean, recorded in `Notes/release/WS-RELEASE2.md`; aggregate build at the release commit pending. Since C_2-cofiniteness is part of "nice", a VOA that is nice with DLM rationality in place of `AdmissiblyRational` satisfies the Lean hypotheses

of the Gannon–Rayhaun classification. *The converse* (`AdmissiblyRational` ⇒ DLM-rational) is open; the release auditor sketched, without checking it, a graded-projection argument (take the degree-zero component of the projection onto a graded submodule along a weak complement; it commutes with every mode). (The library does have `AdmissiblyRational.exists_iSupIndep_irreducible_c` in `VOA/Classification/COne/RationalAdmissibleDecomposition.lean`: a C_2-cofinite analogue of Dong–Li–Mason's Theorem 8.1(c), decomposing ordinary modules into irreducibles. It is not either implication of the comparison.)

4. **The congruence property: the Frobenius–Schur half** (Chapter 21, Section 21.5). The Dong–Lin–Ng congruence property of a nice VOA now has named theorems with no hypotheses: `dlnCongruenceInput_holds`, `zhuCongruenceInput_holds` and `zhu_kernelContainsGamma_at_level` (namespace `VOA.Huang.CongruenceNamed`, `VOA/Huang/CongruenceNamed.lean`), each quantifying over `Nice` VOAs. At the minimal level the kernel statement is the full kernel claim of Dong–Lin–Ng; "kernel half" below refers only to the Ng–Schauenburg input. Of Ng–Schauenburg's Theorem 6.8 only the kernel half is proved (`nsProjectiveKernelAll_holds`, Theorem 21.16); the statement that the level is exactly the Frobenius–Schur exponent, `ProjectiveCongruenceTheorem` and its universal form `NSProjectiveCongruenceAll`, occurs only as a hypothesis.

5. **Pseudo-unitarity in Huang's rigidity and the Verlinde formula** (Chapter 21, Theorem 21.7 and Section 21.4). Two-sided rigidity (`VOA.Huang.HuangRigid.rigid_ordinary`, built from `rightRigid_ordinary` and the braiding), the Verlinde formula, the modular data and the congruence inputs are proved for `Nice` VOAs, which are pseudo-unitary. Huang's theorems assume only simple, CFT type, self-dual, C_2-cofinite and rational. Pseudo-unitarity is used in two places in the proofs: to obtain $V' \cong V$, and in a positivity step of the Cardy argument. *The first use is now removed*: `VOA.contra_vacuum_equiv_of_stronglyRational` gives $V' \cong V$ from self-duality, and the `_of_stronglyRational` copies in `VOA/Huang/VerlindeVacuumFusionSR.lean` give the vacuum-fusion chain ($N_{ab}^0 = \delta_{b,a'}$ and its bounds) for every strongly rational VOA (Chapter 21, Theorem 21.10; `#print axioms`-clean, recorded in `Notes/release/WS-RELEASE2.md`; aggregate build pending). The second, `CardyPositivity.vacColumn_mem_K`, keeps `Nice`, and pseudo-unitarity is essential there (Lee–Yang $M(2,5)$). Removing pseudo-unitarity from the headline theorems therefore needs a different route through the Cardy step, and remains open. Related missing statement: a single packaged theorem that the category of ordinary modules is a modular tensor category.

6. **Smaller items from the audits.** For the Arakawa–Dai VOAs the paper's Theorem 1.1 is now one Lean theorem, `arakawaDai_theorem_1_1`, and the naturality of `actualC2ArcEquiv` is `actualC2ArcEquiv_natural`; what remains is that $J_\infty R_V$ is realized as `PresentedJet` with a universal arc, since the library has no J_∞ functor on abstract algebras (Chapter 20); Deligne's theorem is formalized only in its positive-dimension (bosonic) form (Chapter 21).

Physical meaning

The open problems above are, in physical terms: whether the Deligne-series vertex algebras (several of which, for instance the D_4 and E-type members, are the chiral algebras of four-dimensional $\mathcal{N} = 2$ superconformal theories; for G_2 no such theory is known) are classically free, i.e. whether the arc space of $R_V = \operatorname{Sym} \mathfrak{g}/(\text{explicit quadrics})$ maps isomorphically onto $\operatorname{gr} V$ (proved for A_2; conditional on named inputs for the other types). R_V is not the coordinate ring of the minimal nilpotent orbit closure: it is non-reduced, and only its reduced variety is expected to be that closure; and whether the physicist's statements "the characters satisfy a modular differential equation" and "a rational CFT has a congruence modular representation" can be stated and proved without the extra positivity (pseudo-unitarity) that the present proofs use. The first is a prediction from four-dimensional physics; the library states what remains open of each as named, checkable hypotheses.

50.7 Referee's checklist

declaration	meaning	status	fidelity
`VOA.Moonshine.moonshine`	simple VOA on $V^\natural$, FLM block map, $c = 24$, $V_1 = 0$, $\dim V_2 = 196884$, graded dim qJ	unconditional, standard axioms	§50.1.9, Ch. 42
`VOA.pbw`	PBW: affine vacuum $\neq 0$; induced bottom injective	theorem, unconditional (formerly a project axiom)	§50.1.2
`zhuModularity_pinned_of_C2cof`	Zhu modularity given a bottom projection	conditional on `Pr`	§50.1.2
`zhuModularity_pinned_of_C2cof_voaPBW`	Zhu modularity	conditional on C_2, semisimplicity, family data; via theorem `VOA.pbw`	§50.1.2
`zhuBijective_of_voaPBW` /	Zhu's map, injective (the codomain is image-defined, so only injectivity has content)	conditional on `Pr` / unconditional	§50.1.2
`zhuCorrespondence_of_C2Cofinite`	Zhu's bijection $\Phi W \simeq$ simple $A(W)$-modules	C_2-cofinite	§50.1.12
`zhuModularity_canonical_of_C2Cofinite_isGenerationLevel` / `_of_stronglyRational`	Zhu modularity, general form	C_2-cofinite and admissibly rational / strongly rational; nontrivial instance `zhuModularity_V2m`	§50.1.12
`isSemisimpleRing_A_of_admissiblyRational`	admissibly rational $\Rightarrow A(W)$ semisimple	hypothesis `AdmissiblyRational` only	§50.1.2
`moonshine_of_frameLocality`	$V^\natural$ given (4.23) on four pairs	conditional (historic)	§50.1.7
`jacobiAllIndices_eq_zero`	old twisted Jacobi forces $M = 0$	unconditional	Thm 50.2
`SuperTwistedModule.jacobi`	super twisted Jacobi	defective, open	§50.2.1
`eq_bot_of_bilinear_pos`	bilinear positivity forces $S = 0$	unconditional	Thm 50.3
`not_nonempty_genFields_MRbot`	no fields over `MRbot`	unconditional	§50.2
`no_algHom_powerSeries_X_neg_zero`	no evaluation at $q_0 \neq 0$	unconditional	§50.2
`leechWbar_ne_zero`	$\overline{W} \neq 0$ (anti-TRAP)	unconditional	§50.2.2
`TopSigmaV3`	top-level σ data with nondegeneracy	definition	§50.2.2
`golayE_not_determined`	character ambiguity	unconditional	Thm 50.6
`YnatT_eq_of_creates`	Goddard identification (circular for key identity)	unconditional	§50.2.5
`eq_zero_of_V0local`	uniqueness from V_0^+-locality	unconditional	§50.2.5
`fusionCoeff`	"fusion coefficient"	always 0 (paper)	§50.2.8

`IsLowestWeight`	weights in $h + \mathbb{N}$ (M_h may be 0)	definition	§50.2.8
`VirModule.minimal_graded_rigid`	every minimal model is graded rigid	unconditional	§50.2.8
`strictEtingofFinite_simple_L2c3`	$L_{4/3}(sl_2)$ not C_2-cofinite, finite HP_0	unconditional, standard axioms	§50.1.12
`IsSqPrimary.exists_monicMAKMuDE_for_EtingofFinite`	ADKMuDE for Etingof-finite conformal VOAs	conditional on `EtingofFinite` only (`akWeightGrading`, `e46SerreClosed` proved); order unbounded	§50.6.3
`admissiblyRational_of_dlmRational`	DLM-rational ⇒ `AdmissiblyRational`	`C2Cofinite`; converse open	§50.6.3
`boundary_classically_free`	Arakawa–Dai Thm 1.1 on the presented arc algebra	hypothesis $1 \le m$ only	§50.1.12
`rightRigid_ordinary` / `rigid_ordinary`	Huang rigidity, right duals / two-sided `RigidCategory`	for `Nice` (pseudo-unitary) VOAs	§50.6.3
`contra_vacuum_equiv_of_stronglyRational` and `_of_stronglyRational` copies	$V' \cong V$, vacuum-fusion chain	`StronglyRational`; no pseudo-unitarity	§50.6.3
`dlnCongruenceInput_holds`	Dong–Lin–Ng congruence	for `Nice` VOAs; FS half open	§50.6.3
`nsProjectiveKernelAll_holds`	kernel half of Ng–Schauenburg 6.8	unconditional; FS half open	§50.6.3
`gannonRayhaun_classification`	nice $c = 1$ VOAs, both directions	no hypotheses; rational = `AdmissiblyRational`; `Type 0`	§50.1.12
`X_classicallyFree_final`	Deligne series: classical freeness	A_2: no hypothesis (aggregate build green 2026-10-28; standard axioms); other types conditional on named inputs (Ch. 27)	§50.6.3
`ConwayNorton.conwayNorton`	Conway–Norton, genus-zero form, every $g \in \mathrm{Aut}(V^\natural)$	no hypotheses; standard axioms	§50.1.10, Ch. 43, 47
`conwayNorton_gmat`, `rationalTraces`, `M8.finite_autVnat`	the same for Gmat; rational traces; $\mathrm{Aut}(V^\natural)$ finite	no hypotheses (for `conwayNorton_gmat`: beyond $g \in$ Gmat); standard axioms	§50.1.10, Ch. 47, 49

`nonempty_autVnat_mulEquiv_liftable`	$\mathrm{Aut}(V^\natural) \cong$ liftable subgroup of `AutO`	no hypotheses; no Tits	§50.1.10, Ch. 49
`monsterEquivAutVnat`, `monstrousMoonshine`	AutO $\cong \mathrm{Aut}(V^\natural)$; moonshine for the Monster	conditional on `GmatEqAutO` only	§50.1.7, Ch. 49

50.8 Notes and references

The verification protocol is the project's own (its working rules, `README.md` "Axioms and trust base" and "Auditing a headline result", `Notes/MonsterRoadmap.md` "Operating rules"). The dead ends are collected from `README.md` "Known dead ends", the project's internal session records, `Notes/M8GluingPlan.md` (all "Status" sections) and the route notes `Notes/M8hRoute.md`, `Notes/TrialityTwisted.md`, `Notes/SigmaExistence.md`, `Notes/ZhuGeneratorTest.md`, `Notes/ZhuGeneration.md`, `Notes/SigmaKey.md`, `Notes/KeySkew.md`, `Notes/BimoduleGenTest.md`.

Appendix A

Provenance: the library state documented by this edition

This edition documents release v1.05 of the LeanVOA library (commit `(recorded at release)`). Each Lean file of the library is assigned to one chapter of the book. The table lists, for each chapter of this edition, the number of Lean files of the released library assigned to it (12013 files in all); chapters without files of their own are omitted. The chapters in preparation are not part of this edition. The 38 files of the released library assigned to them are not counted.

The Lean quoted in the brief can be re-checked against the library with `python3 scripts/textbook/brief.py --edition release --source published --verify`, which confirms that every excerpt occurs verbatim (up to whitespace and comments) in the `VOA/` source files or in the book's Lean certificates (`Notes/Textbook/certificates/`).

Chapter	Title	Lean files
`ch01`	Reading Lean, and a map of the book	7
`L01`	Formal calculus and locality	13
`L02`	Lie-theoretic inputs and the trust base	15
`L03`	The vertex algebra axioms, the Borcherds identity and reconstruction	32
`L04`	Structure theory and invariant forms	34
`L05`	Free fields: Heisenberg and lattice vertex algebras	76
`L06`	The Virasoro vertex algebra: Verma modules, the Kac determinant and screenings	117
`L07`	First-order deformations and the rigidity of Virasoro minimal models	98
`L08`	Affine sl(2): construction, Verma modules, Wakimoto realization and non-simplicity	133
`L09`	Rigidity of affine sl(2): Linshaw–Qi and admissible levels	34
`L11`	Filtrations, the C2 algebra and presentations	41
`L12`	Modules, Zhu's algebra and the rationality hierarchy	152
`L13`	Zhu's bijection via the Frenkel–Zhu tower	298
`L14`	Modular forms and the analytic toolkit	48
`L15`	Zhu's modularity theorem	125
`L16`	Quasi-lisse vertex algebras and the Arakawa–Kawasetsu theorem	16
`L17`	The super generalization	110
`L18`	Logarithmic vertex algebras: the triplet and doublet algebras	182
`L19`	Graded unitarity, Lee–Yang and inverse Drinfeld–Sokolov reduction	84
`L20`	Classical freeness at the boundary admissible level: the Arakawa–Dai theorems	203
`L21`	Huang's modular tensor category and the congruence property	932
`L22`	The classification of nice central-charge-one vertex operator algebras (Gannon–Rayhaun)	1755
`L23`	Affine vertex algebras for every simple Lie algebra, and the exceptional Lie algebras	461

Chapter	Title	Lean files
L24	The Deligne series I: presentations, carriers and the divisor comparison	2740
L25	The Deligne series II: characters, the Arakawa–Kawasetsu MLDE and q-series identities	323
L26	The Deligne series III: fusion modules, Demazure modules and Ravinder's kernel	3019
L27	The Deligne series IV: the final theorems, the named inputs and the open cores	22
L28	Graded unitarity through the BRST coset: from affine $\mathfrak{sl}_2$ at level $-4/3$ to Lee–Yang	227
L29	The $(2, 2n+3)$ series: coset transfer of graded unitarity at every boundary level	128
ch02	Lattices, codes and the Leech lattice	26
ch03	Heisenberg and lattice vertex algebras	5
ch04	The involution theta and the fixed-point algebra	9
ch05	Graded dimensions and the modular function J	7
ch06	Twisted modules, the twisted Fock space and the module T	6
ch07	The twisted Heisenberg module	11
ch08	The twisted Leech lattice module and the twisted plus part	34
ch09	Intertwiners and invariant forms: the operators W and Wbar	13
ch10	The vertex algebra on V natural modulo one relation	14
ch11	The Golay frame and the untwisted triality	16
ch12	Existence of the twisted triality I: reduction to Zhu generation	18
ch13	Existence of the twisted triality II: the explicit construction	18
ch14	The key identity and the completion of the proof	20
ch16	Monstrous moonshine: McKay–Thompson series, Hauptmoduln and the statement	28
ch17	The vertex algebra of the hyperbolic plane and the tensor theory of central charge 26	91
ch18	The Monster Lie algebra: string states, the no-ghost theorem and the Borcherds–Kac–Moody structure	75
ch19	Denominator identities, replication and genus zero	60
ch20	Conway–Norton for the automorphism group of the moonshine module	33
ch21	The Griess algebra of the moonshine module and AxiomMath's Monster	65
ch22	The Monster acts on the moonshine module: lifts, triality, the commutant and the converse	39

Appendix B

Index of Lean declarations

Every Lean declaration quoted in the book together with a numbered statement, sorted by its last name component (namespaces are shown as they are written in the quotation). Each entry gives the statement it accompanies and its page.
