Vertex Operator Algebras in Lean

The LeanVOA library and the construction of the Moonshine module

Fedor Popov and Leonardo Rastelli

with Claude (Anthropic)

Documents release v1.0 of the library, commit (`recorded at release`)
(built 2026-11-03)

Preface **xxxviii**

I Foundations **1**

1 Reading Lean, and a map of the book **2**
1.1 What this book is for, and how to use it . . . 2
1.1.1 The referee's question . . . 2
1.1.2 How each result is presented . . . 2
1.1.3 How to use the book . . . 3
1.2 The Lean toolkit: reading Lean for mathematicians . . . 3
1.2.1 Terms and types; propositions and data . . . 3
1.2.2 Declarations: def, theorem, structure, class, instance . . . 4
1.2.3 Type synonyms, abbrev, and definitional unfolding . . . 6
1.2.4 Arguments: explicit, implicit, instance . . . 8
1.2.5 Structures: a bundle of data and proofs . . . 9
1.2.6 The Mathlib vocabulary at a glance . . . 10
1.2.7 Existence, emptiness and choice . . . 13
1.2.8 Total functions and junk values . . . 14
1.2.9 Numbers, casts, ZMod, Fin, and decidable conditions . . . 15
1.2.10 Linear algebra: maps, subspaces, quotients, products . . . 15
1.2.11 Sums and finitely supported functions . . . 17
1.2.12 Polynomials, power series, groups . . . 18
1.2.13 How a Lean statement can fail to mean what it says . . . 19
1.2.14 A second structure: super vertex algebras . . . 20
1.2.15 Reading the headline statement . . . 21
1.2.16 Namespaces and full names . . . 22
1.3 What the machine guarantees . . . 22
1.3.1 The kernel . . . 22
1.3.2 Escape hatches: `sorry` and friends . . . 22
1.3.3 Axioms and `#print axioms` . . . 22
1.3.4 A clean axiom list does not make a theorem unconditional . . . 23
1.3.5 The aggregate build . . . 23
1.3.6 The book's own machine checks . . . 24
1.3.7 The verification record for this chapter . . . 24
1.3.8 Traps that concern the whole book . . . 25
1.4 Global conventions . . . 25
1.5 How to read the boxes . . . 26
1.6 A map of the book . . . 27
1.6.1 The parts . . . 27
1.6.2 Dependencies . . . 29

1.6.3 Two reading paths . . . 30
1.6.4 What is proved, and what is conditional, in Parts IV to VI . . . 30
1.6.5 Where each basic notion is defined . . . 31
1.7 A short physical orientation . . . 32
1.8 Lean glossary . . . 33
1.9 Referee's checklist . . . 36
1.10 Notes and references . . . 37

2 Formal calculus and locality **38**
2.1 The physical picture: fields, contours and radial ordering . . . 39
2.1.1 Fields are Laurent series of operators . . . 39
2.1.2 Contour integrals are residues . . . 39
2.1.3 Two orderings, one function: why there are two expansions . . . 39
2.1.4 Locality is commutativity up to contact terms . . . 40
2.1.5 What the formal theory must avoid . . . 40
2.2 One-variable formal distributions . . . 40
2.2.1 The space of formal distributions . . . 40
2.2.2 Laurent polynomials and algebraically summable families . . . 42
2.2.3 Multiplication by a monomial . . . 44
2.3 Delta function, residue, derivative and modes . . . 45
2.3.1 The Laurent-polynomial action and integration by parts . . . 47
2.4 Binomial coefficients with integer upper index . . . 49
2.5 Two-variable distributions and the structure theorem . . . 52
2.5.1 Two-variable distributions and multiplication by $z_1 - z_2$ . . . 52
2.5.2 Derivatives of the delta function . . . 54
2.5.3 The structure theorem for local distributions . . . 57
2.6 The two expansions and the delta-function jump . . . 59
2.6.1 The expansions ι_{z_1,z_2} and ι_{z_2,z_1} . . . 59
2.6.2 The jump of the simple pole . . . 61
2.6.3 Multiplication by $z_1 - z_2$ and the algebra of the expansions . . . 61
2.6.4 The jumps of higher poles . . . 64
2.7 Operator-valued distributions: commutators, locality, normal ordering . . . 66
2.7.1 Fields and the same-variable normal-ordered product . . . 68
2.7.2 Super-locality: the ε-twisted commutator . . . 69
2.8 Lower truncation and the cancellation theorem . . . 73
2.9 The substitution $z_1 \mapsto z_0 + z_2$ . . . 74
2.10 Three-variable distributions . . . 76
2.11 Four-variable distributions and the double-delta calculus . . . 78
2.11.1 Four-variable distributions, residues and Fubini . . . 78
2.11.2 The single and double delta kernels . . . 80
2.11.3 Contraction: the semantic interface . . . 83
2.11.4 Moving difference powers through the contraction; locality transport . . . 87
2.12 Verification record . . . 90
2.13 Referee's checklist . . . 92
2.14 Notes and references . . . 93

3 Lie-theoretic inputs and the trust base **95**
3.1 What the library assumes today . . . 96
3.2 History of the former PBW axiom . . . 98
3.3 The physical picture . . . 99
3.3.1 Currents and the affine algebra . . . 99

3.3.2 The stress tensor and the Virasoro algebra . . . 99
3.3.3 Vacuum modules and what PBW says . . . 100
3.3.4 Lattices . . . 100
3.4 Lie algebras in Lean: what the reader needs . . . 100
3.5 The Witt algebra and the Virasoro algebra . . . 101
3.5.1 The Witt algebra . . . 101
3.5.2 The Gel'fand–Fuks cocycle and the Virasoro algebra . . . 103
3.6 The universal Virasoro vacuum module . . . 104
3.7 Affine Kac–Moody algebras . . . 106
3.7.1 Invariant forms . . . 106
3.7.2 The loop algebra and its cocycle . . . 107
3.7.3 The affine algebra . . . 108
3.7.4 The triangular pieces . . . 110
3.8 The affine vacuum module . . . 111
3.9 Spanning and the energy grading . . . 112
3.10 The PBW principle `VOA.pbw`: statement and proof . . . 114
3.10.1 The classical theorem . . . 114
3.10.2 Induced modules and the bottom map . . . 115
3.10.3 The Lean statement . . . 116
3.10.4 The fidelity check: is `PBWPrinciple` the intended statement? . . . 118
3.10.5 How the statement could have been false or empty, and why it is not . . . 120
3.10.6 The proof in the library: relative PBW . . . 122
3.11 Consequences of the PBW principle, and the history of the axiom . . . 128
3.11.1 Nonvanishing of the affine vacuum and the simple quotient . . . 128
3.11.2 The two direct consumers . . . 130
3.11.3 What used to inherit the axiom, and the twin policy . . . 130
3.11.4 Results proved without `VOA.pbw` . . . 131
3.12 PBW bases: `PBWBasis`, from named hypothesis to theorem . . . 133
3.12.1 Why a second PBW statement . . . 133
3.12.2 The hypothesis discharged for $\widehat{\mathfrak{sl}}_2$ . . . 135
3.12.3 The hypothesis proved for every $\mathfrak{g}$ . . . 136
3.13 Root data, affine Verma modules and the integrability target . . . 137
3.13.1 The finite root datum . . . 137
3.13.2 Affine Verma modules at general highest weight . . . 139
3.13.3 The integrability target . . . 140
3.14 Lattices, cocycles and parity . . . 141
3.14.1 Integral lattices . . . 141
3.14.2 The FLM cocycle and the twisted group algebra . . . 142
3.14.3 Finiteness of bounded vectors and the orthonormal frame . . . 144
3.14.4 Parity and the Koszul sign . . . 145
3.15 The verification record . . . 145
3.16 Referee's checklist . . . 149
3.17 Notes and references . . . 151

4 Vertex algebra axioms, Borcherds identity, reconstruction 153
4.1 What this chapter is about . . . 153
4.2 Conventions recalled . . . 155
4.3 The three structures . . . 157
4.3.1 `PreVertexAlgebra`: Gannon's Definition 5.1.3(a) . . . 157
4.3.2 `BarePreVA`: the axioms without the grading . . . 158
4.3.3 `VertexOperatorAlgebra` . . . 159

4.4 Comparison with the textbook definitions . . . 160
4.5 A counterexample to the Borcherds identity . . . 162
4.6 The bare level: product fields, cancellation . . . 164
4.6.1 The vertex operators are fields . . . 164
4.6.2 The iterated product field and the cancellation principle . . . 164
4.6.3 The vacuum expansion . . . 166
4.7 The operator product expansion . . . 166
4.8 Goddard uniqueness . . . 167
4.9 Dong's lemma and the calculus of local fields . . . 169
4.9.1 Elementary closure properties . . . 169
4.9.2 Dong's lemma . . . 170
4.10 The reconstruction cascade in a VOA . . . 171
4.10.1 Creation: $Y(u,z)\mathbf{1} = e^{zT}u$ . . . 171
4.10.2 Translation covariance . . . 173
4.10.3 Duality for $n \geq 0$ and the commutator formula . . . 174
4.10.4 Duality for $n < 0$ . . . 175
4.10.5 The iterate formula for all ℓ . . . 176
4.11 The Borcherds identity . . . 177
4.12 Skew-symmetry . . . 180
4.12.1 The candidate field . . . 180
4.12.2 The reduction to a locality statement . . . 181
4.12.3 The vacuum locality computation . . . 182
4.12.4 Skew-symmetry . . . 184
4.13 The FLM formulation . . . 184
4.14 Commutative vertex algebras (Gannon Theorem 5.1.4) . . . 186
4.15 Reconstruction . . . 188
4.15.1 Fields on a tensor product . . . 191
4.16 Local systems of weak vertex operators . . . 193
4.16.1 Weak vertex operators and the generated system . . . 193
4.16.2 All integer products and closed local systems . . . 194
4.16.3 The Borcherds identity for two local fields . . . 195
4.16.4 The carrier action, and what is not yet proved . . . 196
4.17 Localising the first-order Jacobi identity . . . 197
4.18 Combinatorial lemmas . . . 199
4.19 Referee's checklist . . . 199
4.20 Notes and references . . . 201

5 Structure theory and invariant forms **203**
5.1 Conventions recalled . . . 204
5.2 The Lie algebra of currents . . . 205
5.2.1 Zero modes and the derivation property . . . 205
5.2.2 The bracket on the weight-one space . . . 207
5.2.3 Primary vectors and the Griess product . . . 208
5.3 Automorphisms and inner automorphisms . . . 209
5.3.1 The automorphism group . . . 209
5.3.2 Exponentials of locally nilpotent derivations . . . 211
5.3.3 Inner automorphisms . . . 212
5.4 Ideals, quotients and the simple quotient . . . 215
5.4.1 Ideals and simplicity . . . 215
5.4.2 The quotient vertex operator algebra . . . 216
5.4.3 The maximal ideal . . . 217

5.5 Homomorphisms and the transfer lemma . . . 219
5.6 Subalgebras generated by a set . . . 220
5.7 Screening operators and their kernels . . . 223
5.7.1 Derivations with subalgebra kernels . . . 223
5.7.2 Screening operators . . . 224
5.8 Singular vectors . . . 227
5.8.1 Two routes to properness . . . 228
5.9 Tensor products . . . 230
5.10 Weight operators and weight-homogeneous fields . . . 233
5.11 BRST cohomology . . . 234
5.12 Invariant bilinear forms . . . 237
5.12.1 Motivation: the two-point function . . . 237
5.12.2 Elementary consequences . . . 239
5.13 The canonical invariant form (FHL, Li) . . . 240
5.13.1 The construction . . . 240
5.13.2 The proof of invariance . . . 242
5.14 Li's radical theorem: simplicity is nondegeneracy . . . 245
5.15 Gram matrices: rank computes the simple quotient . . . 246
5.16 Dead ends: four general routes to full invariance . . . 248
5.17 Machine verification for this chapter . . . 249
5.18 Referee's checklist . . . 250
5.19 Notes and references . . . 251

II Examples, deformations and rigidity 253

6 Heisenberg and lattice vertex algebras in the library 254
6.1 The physical picture . . . 255
6.1.1 One free boson . . . 255
6.1.2 The non-compact boson has a continuum of sectors . . . 256
6.1.3 Compactification and lattices . . . 256
6.1.4 Background charge . . . 256
6.2 The files and the two implementations . . . 257
6.3 The rank-one Heisenberg vertex operator algebra at level k . . . 258
6.3.1 The Fock space and the oscillators . . . 258
6.3.2 The current and its locality . . . 260
6.3.3 The conformal-weight grading . . . 260
6.3.4 The vertex operators . . . 262
6.3.5 The Sugawara conformal vector . . . 264
6.3.6 The vertex operator algebra . . . 265
6.4 The free boson is not C_2-cofinite . . . 267
6.4.1 C_2-cofiniteness . . . 267
6.4.2 The theorem . . . 268
6.5 The Heisenberg instance of the PBW boundary . . . 269
6.5.1 Context . . . 269
6.5.2 The Heisenberg instance . . . 270
6.6 The free boson with background charge . . . 271
6.7 Lattice vertex operator algebras in general: what exactly is proved . . . 274
6.7.1 Lattices . . . 275
6.7.2 The state space and the grading . . . 275
6.7.3 The theorem . . . 276

6.7.4 The rank-zero lattice: the trivial vertex operator algebra . . . 278
6.8 The A_1 lattice vertex operator algebra . . . 279
6.8.1 The state space, the cocycle and the boson . . . 279
6.8.2 The vertex operators . . . 280
6.8.3 Locality and the instance . . . 281
6.8.4 Two placeholders in the same files . . . 283
6.9 Charge sectors and the charge-zero subalgebra . . . 283
6.9.1 Charge sectors . . . 283
6.9.2 The charge-zero subalgebra . . . 285
6.9.3 V_L as a module over its Heisenberg subalgebra . . . 286
6.10 Background charge on lattice vertex operator algebras . . . 287
6.10.1 An abstract lemma . . . 287
6.10.2 The deformed conformal vector of V_L . . . 288
6.10.3 $\mathbb{Q}$-valued gradings . . . 291
6.11 Spectral flow on the Fock space: an open identity . . . 292
6.12 Recorded traps and Lean defects . . . 293
6.13 Machine verification for this chapter . . . 294
6.14 Referee's checklist . . . 295
Notes and references . . . 296

7 The Virasoro VOA: Verma modules, Kac determinant, screenings 298
7.1 The physical picture . . . 299
7.1.1 The stress tensor and the central charge . . . 299
7.1.2 Primary fields, Verma modules and descendants . . . 300
7.1.3 The Shapovalov form and null vectors . . . 300
7.1.4 The Kac determinant and the Kac table . . . 300
7.1.5 Characters of minimal models . . . 301
7.1.6 The Coulomb gas and screening charges . . . 301
7.1.7 The Sugawara construction . . . 301
7.2 The Virasoro modes on the universal vacuum module . . . 302
7.2.1 The vacuum module, recalled . . . 302
7.2.2 The conformal field and its self-locality . . . 303
7.3 The grading and the partition basis of the vacuum module . . . 305
7.3.1 Creation words and their energy . . . 305
7.3.2 The partition basis . . . 307
7.4 The universal Virasoro vertex operator algebra . . . 309
7.4.1 Word fields . . . 309
7.4.2 The vertex operator algebra . . . 311
7.4.3 The free boson at $c = 1$: the abelian Sugawara construction . . . 313
7.5 The simple quotient $L(c, 0)$ . . . 314
7.6 The invariant form on the vacuum module and its Gram matrices . . . 316
7.6.1 The canonical form . . . 316
7.6.2 Gram matrices and the dimension of $L(c, 0)$ . . . 316
7.6.3 Explicit Kac determinants of the vacuum module at levels 4, 5, 6 . . . 317
7.6.4 The vacuum Gram determinant at every level: degree and leading coefficient 318
7.7 Graded dimensions of the minimal models: Lee–Yang, Ising, $M(2, 7)$ . . . 320
7.8 Verma modules . . . 321
7.9 The Shapovalov form, singular vectors and the irreducible quotient . . . 325
7.9.1 Singular vectors . . . 328
7.10 The Kac determinant . . . 330
7.10.1 The Kac parametrisation and the Kac product . . . 330

7.10.2 What the library proves about the determinant in general . . . 331
7.10.3 Roots imply singular vectors; Laurent interpolation . . . 334
7.11 Screening operators and the Kac roots . . . 335
7.11.1 The charged free boson . . . 335
7.11.2 From Fock singular vectors to Verma Gram roots . . . 338
7.11.3 The Kac determinant formula, unconditionally . . . 340
7.12 From Verma modules back to the vacuum: the simple zero at $c_{p,q}$ . . . 341
7.13 Other files of this chapter . . . 343
7.14 Warnings, recorded defects and dead ends . . . 344
7.15 Verification record . . . 346
7.16 Referee's checklist . . . 347
7.17 Notes and references . . . 348

8 First-order deformations and the graded first-order rigidity of Virasoro minimal models 350
8.1 Why deformations, and why minimal models should be rigid . . . 351
8.1.1 Deformations in algebra: Gerstenhaber's picture . . . 351
8.1.2 Deformations of vertex algebras . . . 352
8.1.3 The physical picture: moduli of conformal field theories . . . 352
8.1.4 Why the minimal models should be rigid . . . 352
8.2 First-order deformations of a vertex operator algebra . . . 353
8.2.1 Derivation of the axioms . . . 353
8.2.2 The definition . . . 354
8.2.3 Graded deformations . . . 356
8.2.4 Trivial deformations . . . 357
8.2.5 Rigidity . . . 359
8.2.6 Fidelity of `IsRigidGraded` . . . 360
8.2.7 Is `IsRigidGraded` vacuous? The non-vacuity check . . . 362
8.2.8 The finite-dimensional picture and its limit . . . 365
8.2.9 Regular deformations and the pole coefficient . . . 365
8.3 The Virasoro vertex operator algebras, recalled . . . 366
8.3.1 The Virasoro algebra and its vacuum module . . . 366
8.3.2 The simple quotient $L(c,0)$ . . . 368
8.3.3 The invariant form and the Kac determinant . . . 370
8.4 Anatomy of a graded deformation of $L(c,0)$ . . . 371
8.4.1 Two scalars and the gauge line . . . 371
8.4.2 The first-order space and its operators . . . 372
8.4.3 The normalised Virasoro modes . . . 373
8.5 Reconstruction: zero central variation implies triviality . . . 374
8.5.1 Closed lifts in a simple VOA . . . 375
8.5.2 The closed lift of a fixed-charge deformation . . . 376
8.6 The obstruction: null relations force zero central variation . . . 377
8.6.1 Deformed bilinear forms and Jantzen layers . . . 377
8.6.2 Words, their adjoints, and the norm polynomial . . . 379
8.6.3 The word-pairing obstruction . . . 380
8.6.4 The determinant form of the obstruction . . . 382
8.7 Worked cases . . . 384
8.7.1 Central charge zero: $M(2,3)$ . . . 384
8.7.2 Lee–Yang: $M(2,5)$, $c=-22/5$ . . . 384
8.7.3 Ising and $M(2,7)$ at weight six . . . 385
8.7.4 Tricritical Ising: $M(4,5)$, $c=7/10$ . . . 386

8.7.5 The families $M(2,q)$ and $M(p,3)$ . . . 387
8.8 All minimal models . . . 388
8.8.1 The proof on paper . . . 390
8.9 Other files of this chapter . . . 391
8.10 Verification record . . . 392
8.11 Referee's checklist . . . 393
8.12 Notes and references . . . 395

9 Affine $\mathfrak{sl}_2$: construction, Wakimoto, Verma, Kac 397
9.1 The current algebra on the vacuum module . . . 399
9.1.1 The Lie algebra $\mathfrak{sl}_2$ in coordinates . . . 399
9.1.2 The affine commutator . . . 400
9.1.3 Current fields and locality . . . 401
9.2 The energy grading, the vacuum, and where the PBW theorem enters . . . 402
9.3 The Sugawara construction . . . 404
9.3.1 The Sugawara field and the central charge . . . 404
9.3.2 The Sugawara operators act as derivations on the currents . . . 406
9.4 The universal affine VOA $V^k(\mathfrak{sl}_2)$ . . . 407
9.4.1 Reconstruction of the vertex map . . . 407
9.4.2 The Virasoro relations and the closed instance . . . 409
9.4.3 Non-degeneracy checks . . . 411
9.5 The simple quotient and the singular-vector bridge . . . 412
9.6 The Wakimoto free-field realisation . . . 414
9.6.1 Why free fields . . . 414
9.6.2 The free fields . . . 414
9.6.3 The Wakimoto currents . . . 415
9.6.4 The representation and the evaluation map . . . 417
9.7 The PBW basis by Wakimoto triangularity . . . 418
9.7.1 The target statement . . . 418
9.7.2 Leading terms of Wakimoto words . . . 419
9.8 Singular vectors in the vacuum module . . . 422
9.8.1 Integrable levels: $e_{-1}^{N+1}|0\rangle$ . . . 423
9.8.2 The level $k=-4/3$: weight 3 . . . 424
9.8.3 The level $k=-8/5$: weight 5 (the Lee–Yang level) . . . 426
9.8.4 C_2 symbols: the Casimir . . . 428
9.9 $V^{-8/5}(\mathfrak{sl}_2)$ is not simple . . . 429
9.9.1 From positive current modes to strong singularity . . . 429
9.9.2 The theorem . . . 430
9.10 Verma modules of $\widehat{\mathfrak{sl}}_2$ . . . 431
9.10.1 The contravariant form . . . 435
9.11 Screening operators and singular vectors in Verma modules . . . 436
9.11.1 The charged Wakimoto module . . . 436
9.11.2 Screening vectors . . . 437
9.12 The Kac–Kazhdan determinant . . . 439
9.12.1 The classical formula . . . 439
9.12.2 The library's statement . . . 439
9.12.3 The vacuum specialisation . . . 442
9.13 Supporting infrastructure . . . 443
9.14 Documentation defects found while writing this chapter . . . 444
9.15 Verification record . . . 445
9.16 Referee's checklist . . . 447

9.17 Notes and references . . . 448

10 Graded first-order rigidity of affine $\mathfrak{sl}_2$: Linshaw–Qi and admissible levels 450
10.1 Affine $\mathfrak{sl}_2$ and its simple quotients . . . 452
10.1.1 The Lie algebra $\mathfrak{sl}_2$ and its normalised Killing form . . . 452
10.1.2 The affine Lie algebra and the vacuum module . . . 452
10.1.3 The universal affine VOA and its simple quotient . . . 453
10.1.4 The weight-one space: the currents survive . . . 454
10.2 Admissible levels . . . 455
10.2.1 From integrable to admissible . . . 455
10.2.2 The vacuum singular vector at an admissible level . . . 456
10.2.3 Physics: WZW models at fractional level . . . 457
10.3 First-order deformations and graded rigidity . . . 458
10.3.1 The idea . . . 458
10.3.2 The Lean definitions . . . 458
10.3.3 Regularity and the pole . . . 461
10.4 Weight-one cohomology: normalising a deformation . . . 462
10.4.1 Chevalley–Eilenberg cochains in degree two . . . 462
10.4.2 The bridge: a graded deformation gives a 2-cocycle . . . 463
10.5 Linshaw–Qi Theorem 5.1 at $k = -4/3$, and the bundled hypothesis . . . 464
10.5.1 The source . . . 464
10.5.2 The object $L_{-4/3}(\mathfrak{sl}_2)$ . . . 465
10.5.3 The linear algebra of Linshaw–Qi §5.3, and an erratum . . . 466
10.5.4 The split assembly . . . 466
10.5.5 The two dead ends: a vacuous hypothesis and a tautological one . . . 467
10.5.6 The unconditional theorem at $-4/3$ . . . 469
10.6 The uniform machinery at every nonzero non-critical level . . . 470
10.6.1 The first-order extension as a module . . . 470
10.6.2 Step A: regular deformations are trivial (Theorem 3.1 at every level) . . . 470
10.6.3 Step B: the single level parameter . . . 471
10.6.4 Step C: word pairings are polynomials in the level . . . 472
10.6.5 Step D: two relations give an obstruction . . . 473
10.7 The Kac determinant and a simple root . . . 474
10.7.1 From a simple determinant root to two relations . . . 474
10.7.2 Locating a simple root: the Kac determinant with the horizontal factor removed 475
10.8 The headline theorem . . . 476
10.8.1 Every admissible level: the hypothesis $p < 2q$ is used only for $k \neq 0$ . . . 478
10.9 The boundary-admissible C_2 programme (conditional) . . . 478
10.10 A cited hypothesis: admissible partitions . . . 481
10.11 Verification record . . . 481
10.12 Referee's checklist . . . 483
10.13 Notes and references . . . 484

11 Filtrations, the C_2 algebra and presentations 486
11.1 Conventions recalled . . . 487
11.2 Graded flags, good filtrations and filtered maps . . . 489
11.2.1 Filtrations indexed by a preorder, and strict maps . . . 491
11.3 Li's filtration and its associated graded algebra . . . 493
11.3.1 Motivation . . . 493
11.3.2 The definition in the library . . . 494
11.3.3 Multiplicativity . . . 496

11.3.4 The associated graded algebra . . . 497
11.3.5 The bottom layer is Zhu's C_2-algebra . . . 499
11.4 Jets, presentations of commutative algebras, and classical freeness . . . 501
11.4.1 The commutative-algebra side . . . 501
11.4.2 The canonical jet map to the Li associated graded . . . 504
11.4.3 The Hilbert squeeze . . . 507
11.4.4 An example: the affine currents span the Li filtration . . . 509
11.5 Generator-word spanning of Li's filtration . . . 510
11.5.1 The word filtration . . . 511
11.5.2 Spanning gives a surjective jet map . . . 513
11.5.3 How to prove spanning: the tracked estimate . . . 518
11.5.4 The $\hat{\mathfrak{sl}}_2$ consistency instance . . . 522
11.6 The symbol toolkit: leading terms, filtered words, certified arithmetic . . . 525
11.7 Presenting a vertex algebra by generators and OPEs (De Sole–Kac) . . . 532
11.7.1 The mathematical background . . . 532
11.7.2 The tensor algebra, its weights and translation . . . 532
11.7.3 Relations, admissible ideals and the quotient . . . 536
11.7.4 Reconstruction from generating fields . . . 538
11.7.5 The contract `GenFields`, and a refuted route . . . 542
11.7.6 Generators plus OPE equals Borcherds, for Virasoro . . . 543
11.7.7 Gradings on $\mathcal{T}(R)$: exact weight and the De Sole–Kac filtration . . . 546
11.8 The non-linear layer: an interface with no instance . . . 548
11.9 Li's Δ-operator on the Fock space . . . 553
11.10 Referee's checklist . . . 555
11.11 Notes and references . . . 558

III Representation theory **560**

12 Modules, Zhu's algebra, and the rationality hierarchy **561**
12.1 Conventions recalled . . . 563
12.2 The ladder of module categories . . . 564
12.2.1 Weak modules and the derivative property . . . 564
12.2.2 Admissible ($\mathbb{N}$-gradable) modules . . . 567
12.2.3 Ordinary modules, and the global lower bound . . . 569
12.2.4 Logarithmic modules . . . 572
12.2.5 Every ordinary module is admissible . . . 574
12.2.6 Submodules, morphisms, exact sequences . . . 575
12.2.7 Restriction to a sub-VOA . . . 576
12.3 Characters, zero modes, and lowest weights . . . 577
12.4 Zhu's algebra . . . 580
12.4.1 $A(V)$ is an associative algebra . . . 581
12.4.2 The forward half of Zhu's correspondence . . . 584
12.4.3 Two consequences: bottoms are simple, and a Zhu-polynomial simplicity test 586
12.5 C_2-cofiniteness and the Poisson algebra $V/C_2(V)$ . . . 587
12.6 Higher Zhu algebras and finiteness under C_2 . . . 591
12.7 The contragredient module . . . 593
12.8 Intertwining operators and the fusion coefficient . . . 597
12.9 The rationality hierarchy . . . 600
12.9.1 Simplicity and the set $\Phi(V)$ of irreducible modules . . . 601
12.9.2 Admissible rationality, and the submodule convention . . . 602

12.9.3 The literature theorems, stated as named predicates . . . 605
12.9.4 Zhu's semisimplicity theorem, proved . . . 607
12.9.5 The Abe–Buhl–Dong and Dong–Li–Mason predicates, proved . . . 608
12.9.6 The proved implications . . . 611
12.9.7 Self-duality, strongly finite and strongly rational . . . 613
12.9.8 Summary table . . . 617
12.10 Recorded traps and dead ends . . . 617
12.11 Referee's checklist . . . 618
12.12 Notes and references . . . 622

13 Zhu's bijection via the tower $A_n(V)$ 624
13.1 Zhu's correspondence: the mathematics and the plan . . . 626
13.1.1 The statement in the literature . . . 626
13.1.2 Why the construction is hard, and the tower . . . 626
13.1.3 The plan of the formal proof . . . 627
13.2 The statement that is proved . . . 627
13.2.1 Irreducibility and isomorphism . . . 628
13.2.2 The faithful domain and codomain . . . 628
13.2.3 The headline . . . 630
13.2.4 What lies outside the headline: the scope of the codomain . . . 632
13.2.5 Zhu's correspondence as one bijection, for C_2-cofinite V . . . 634
13.3 The Frenkel–Zhu Lie algebra, induction, and the datum `Pr` . . . 637
13.3.1 The Lie algebra $\widehat{V}$ . . . 637
13.3.2 The parabolic subalgebra and the $A(V)$-modules . . . 638
13.3.3 The induced module and the bottom map . . . 640
13.3.4 The datum `BottomProjection` and its equivalents . . . 641
13.3.5 How `VOA.pbw` supplies the datum . . . 642
13.4 The tower: circle products, O_n, A_n and the Dong–Jiang spaces $A_{n,m}$ . . . 645
13.4.1 The generic residue and the circle products . . . 645
13.4.2 The corrected $O_n(V)$ and the product $*_n$ . . . 646
13.4.3 The Dong–Jiang bimodules $A_{n,m}(V)$ . . . 647
13.5 The induced module $M(U)$ and the gate $A_{0,0}(V) = A(V)$ . . . 649
13.5.1 The carrier . . . 649
13.5.2 The action of V . . . 651
13.5.3 Graded lowest-weight weak modules . . . 652
13.5.4 The gate: $O_{0,0}(V) = O(V)$ from `Pr` . . . 654
13.6 The irreducible quotient $L(U)$ and the uniqueness argument . . . 656
13.6.1 The maximal bottom-trivial submodule . . . 656
13.6.2 An irreducible module is L of its bottom . . . 658
13.6.3 Functoriality and the assembly . . . 660
13.7 The 298 files by role . . . 662
13.7.1 How the critical path was determined . . . 662
13.7.2 The critical path, grouped by the sections of this chapter . . . 663
13.7.3 Off the critical path . . . 663
13.8 Recorded traps and dead ends . . . 665
13.9 Referee's checklist . . . 666
13.10 Notes and references . . . 669

IV Modularity **670**

14 Modular forms and the analytic toolkit **671**
14.1 Conventions, and what is recalled from Chapter 5 . . . 672
14.1.1 Three kinds of "q-series" . . . 672
14.1.2 The objects recalled from Chapter 5 . . . 673
14.2 The slash action in the complex-plane picture . . . 674
14.3 Eisenstein series in Zhu's normalisation . . . 676
14.4 The level-one structure theorem . . . 680
14.4.1 The algebra generated by E_4 and E_6 . . . 680
14.4.2 Weights inside $\mathcal{E}_{46}$, and the Ramanujan boundary . . . 682
14.4.3 Points of $\mathcal{E}_{46}$: the cusp and the interior . . . 684
14.5 From formal q-series to holomorphic functions . . . 686
14.5.1 Subexponential growth and summability . . . 686
14.5.2 Evaluation . . . 688
14.5.3 Algebra of evaluation . . . 690
14.5.4 The T-transformation, analytically . . . 692
14.6 Formal q-series as a module over $\mathbb{C}[[q]]$ . . . 694
14.7 The q-expansion bridge and the Noetherian coefficient ring . . . 695
14.8 The Serre derivative . . . 697
14.9 Growth of degeneracies from ordered spanning sets . . . 699
14.10 Formal modular differential equations and the indicial equation . . . 701
14.11 The cylinder-to-torus coordinate: formal identities . . . 705
14.11.1 The square-bracket modes . . . 706
14.12 The cusp: Zhu's relations at $q = 0$ . . . 709
14.13 Zhu's transformation law, the read-off of $\rho(S)$, and characters . . . 712
14.14 Subgroups and the theta group . . . 716
14.15 The analytic j-invariant and the abstract Moonshine corollary . . . 720
14.16 Recorded traps, dead ends and defects . . . 723
14.17 Referee's checklist . . . 724
14.18 Notes and references . . . 726

15 Zhu's modularity theorem **728**
15.1 The theorem on paper, and the plan of the proof . . . 731
15.1.1 Why characters should be modular . . . 731
15.1.2 Zhu's proof in seven steps . . . 732
15.2 One-point functions on the torus . . . 733
15.2.1 Formal one-point functions . . . 733
15.2.2 From formal series to functions on the upper half-plane . . . 734
15.2.3 The T-transformation: proved for every module . . . 735
15.3 The square-bracket vertex operator algebra . . . 736
15.3.1 The change of coordinates . . . 736
15.3.2 The torus Virasoro algebra and the square-bracket grading . . . 738
15.4 Zhu's recursion and the genus-one block conditions . . . 739
15.4.1 Eisenstein series in Zhu's normalisation, and convolution . . . 739
15.4.2 The recursion . . . 740
15.4.3 The three block conditions . . . 742
15.5 Convergence from C_2-cofiniteness . . . 743
15.5.1 Subexponential growth . . . 743
15.5.2 The vacuum hypothesis . . . 744
15.5.3 The growth theorem . . . 745

15.5.4 What about the modular differential equation? . . . 746
15.6 The space of genus-one blocks . . . 747
15.7 Finiteness of the block space and Zhu's count . . . 749
15.7.1 Zhu's Theorem 5.3.2: $\dim \mathfrak{B} < \infty$ . . . 749
15.7.2 $A(V)$ is finite-dimensional . . . 750
15.7.3 Zhu's Theorem 5.3.3: $\dim \mathfrak{B} \leq \#\Phi(V)$ . . . 750
15.8 Existence of modules: Gaberdiel–Neitzke . . . 753
15.8.1 Strictly decreasing spanning . . . 753
15.8.2 Every simple $A(V)$-module is realised . . . 755
15.9 The action of $SL_2(\mathbb{Z})$ on blocks . . . 757
15.9.1 The slash operator . . . 757
15.9.2 Homogeneous points and the slash of a trace function . . . 758
15.10 Linear independence of the trace functions . . . 759
15.11 Reading off the representation . . . 761
15.11.1 Modular data and the analytic modularity law . . . 761
15.11.2 From spanning and independence to modular data . . . 762
15.11.3 Spanning at S from the dimension count . . . 763
15.12 The modularity theorem . . . 764
15.12.1 The statement for a given family . . . 765
15.12.2 The engine: the canonical family, from C_2 and semisimplicity alone . . . 768
15.12.3 The headline: Zhu's theorem for rational C_2-cofinite V . . . 772
15.12.4 The strongly rational packaging . . . 776
15.13 Non-vacuity: the trivial vertex operator algebra . . . 778
15.14 Nontrivial instances: the $c = 1$ orbifolds and lattice VOAs . . . 779
15.15 Twisted modules: a statement only . . . 785
15.16 What is not proved . . . 786
15.17 The remaining files, by role . . . 787
15.18 Referee's checklist . . . 788
15.19 Notes and references . . . 792

16 Quasi-lisse vertex algebras and the Arakawa–Kawasetsu theorem 793
16.1 The mathematics: lisse, quasi-lisse, and the Arakawa–Kawasetsu theorem . . . 795
16.1.1 The associated variety . . . 795
16.1.2 Symplectic leaves, quasi-lisseness, Poisson homology . . . 796
16.1.3 The Arakawa–Kawasetsu theorem . . . 797
16.1.4 What the library formalises: a map . . . 799
16.2 The Poisson algebra as a $\mathbb{C}$-algebra, and quotients . . . 799
16.3 Poisson traces and the Etingof–Schedler hypothesis . . . 801
16.4 The finiteness half: Arakawa–Kawasetsu Proposition 5.2 . . . 803
16.4.1 The augmented relation space . . . 803
16.4.2 Mode-zero triangularity . . . 804
16.4.3 Proposition 5.2 . . . 805
16.5 The character equation in formal form . . . 808
16.5.1 The formal objects . . . 808
16.5.2 Square-bracket primaries and the Virasoro tower . . . 808
16.5.3 Lemma 5.5: from $L[-2]$ to $q\,d/dq$ . . . 810
16.5.4 Lemma 5.3 and the formal character equation . . . 812
16.5.5 Uniformity in the module . . . 813
16.5.6 How weak is the formal equation? . . . 814
16.6 The genuine modular differential equation . . . 815
16.6.1 Modular coefficients and Serre derivatives . . . 815

16.6.2 The weight grading interface . . . 816
16.6.3 The conditional MLDE . . . 818
16.7 Zhu modularity and conformal blocks under Etingof-finiteness . . . 821
16.8 The example: the classical Poisson model of $L_{-4/3}(\mathfrak{sl}_2)$ . . . 823
16.8.1 The symbol of the singular vector . . . 824
16.9 Transport to a vertex algebra: symbol presentations . . . 826
16.9.1 The flagship algebra . . . 828
16.10 $L_{-4/3}(\mathfrak{sl}_2)$ is not lisse . . . 830
16.11 The payoff at $L_{-4/3}(\mathfrak{sl}_2)$ . . . 832
16.12 Traps, dead ends, and Lean defects . . . 836
16.13 Referee's checklist . . . 837
16.14 Notes and references . . . 839

V Super, logarithmic and unitary theories 841

17 The super generalization 842
17.1 What this chapter is about, and what it found . . . 842
17.2 Conventions recalled . . . 844
17.3 Super vertex algebras . . . 846
17.3.1 The axioms . . . 846
17.3.2 The conformal layer . . . 850
17.4 Goddard uniqueness with signs . . . 852
17.5 The super Borcherds identity and skew-symmetry . . . 853
17.5.1 Skew-symmetry . . . 855
17.6 Automorphisms and the even part . . . 856
17.7 Super modules, twisted super modules, and the defect . . . 858
17.7.1 Twisted super modules . . . 860
17.8 The four free-field examples . . . 863
17.8.1 The free fermion . . . 863
17.8.2 The bc ghost system . . . 865
17.8.3 The beta-gamma system . . . 867
17.8.4 Symplectic fermions . . . 870
17.8.5 The lattice super ambient . . . 875
17.9 Super Zhu algebras, untwisted and twisted . . . 876
17.10 The modular toolkit for super and half-integral theories . . . 878
17.10.1 Genus-one blocks for integrally graded super VOAs . . . 885
17.10.2 The half-integral side: finite cusp descent . . . 888
17.11 The four-by-three grid: what each cell contains . . . 889
17.12 Machine status of the headlines . . . 890
17.13 Referee's checklist . . . 892
17.14 Notes and references . . . 893

18 Logarithmic vertex algebras: the triplet and doublet algebras 895
18.1 What this chapter is about, and what it found . . . 895
18.2 The physical picture: logarithmic conformal field theory . . . 899
18.2.1 Why logarithms . . . 899
18.2.2 The triplet algebra . . . 900
18.2.3 Symplectic fermions . . . 901
18.2.4 Characters, modular transformations and pseudo-traces . . . 901
18.2.5 The doublet . . . 901
18.3 Conventions recalled . . . 901

18.4 The lattice model I: the ambient and the generators . . . 902
18.4.1 The deformed rank-one lattice VOA . . . 902
18.4.2 The screening and the three generators . . . 905
18.4.3 The triplet algebra as a generated subalgebra . . . 907
18.5 The lattice model II: C_2-cofiniteness for general p . . . 909
18.5.1 The engine . . . 910
18.5.2 The relations in $R_{W(p)}$ . . . 910
18.5.3 The two residual hypotheses, and the theorem . . . 912
18.5.4 Reducing generation to a finite OPE table . . . 915
18.6 The lattice model III: the unconditional theorems at $p = 2$ . . . 916
18.6.1 The three mixed coordinates . . . 916
18.6.2 The Adamović–Milas identity at weight ten . . . 918
18.6.3 C_2-cofiniteness . . . 919
18.6.4 Irrationality . . . 920
18.6.5 Simplicity and strong finiteness . . . 921
18.7 The Abe model: $W(2)$ as the even part of symplectic fermions . . . 924
18.7.1 The algebra . . . 924
18.7.2 Abe's generators . . . 925
18.7.3 $\bar{\omega}^2 \neq 0$: no low-weight null vector . . . 926
18.7.4 Abe's relations and nilpotency . . . 927
18.7.5 C_2-cofiniteness of the Abe model: the one remaining gate . . . 928
18.7.6 Zhu's algebra and logarithmic modules . . . 930
18.7.7 Irrationality of the Abe model, conditional on the literature . . . 933
18.7.8 The modular route: a $\log q$ forbids rationality . . . 935
18.8 Pseudo-traces and logarithmic q-series . . . 937
18.8.1 Symmetric functionals and coordinate systems . . . 937
18.8.2 The Hattori–Stallings trace and the pseudo-trace . . . 938
18.8.3 Polynomial-valued q-series . . . 940
18.8.4 The genus-one layer, on hypothetical commutant data . . . 941
18.9 The doublet algebra . . . 943
18.9.1 The generators on an abstract lattice . . . 943
18.9.2 The half lattice . . . 944
18.9.3 The doublet as a generated super subalgebra . . . 944
18.10 The remaining files of this chapter . . . 946
18.11 Verification record . . . 947
18.12 Recorded traps, dead ends and Lean defects . . . 948
18.13 Referee's checklist . . . 949
18.14 Notes and references . . . 950

19 Graded unitarity and Lee–Yang **952**
19.1 Unitarity: the standard notions and the graded one . . . 953
19.1.1 Why physicists care about positivity . . . 953
19.1.2 Unitary VOAs in the sense of Dong and Lin . . . 953
19.1.3 Bilinear versus sesquilinear forms . . . 954
19.1.4 Graded unitarity: where it comes from . . . 954
19.2 Sesquilinear forms and positivity on a subspace . . . 955
19.2.1 The defect that once made graded unitarity refutable . . . 955
19.2.2 Sesquilinear forms . . . 956
19.3 Real structures . . . 959
19.4 The graded-unitarity predicate . . . 960
19.4.1 Flags, layers, and the two clauses . . . 960

19.5 The layer reduction: clause (v) follows from clause (iv) . . . 963
19.6 The minors criterion . . . 964
19.6.1 Clause (iv) and nonzero minors . . . 965
19.6.2 Clause (vi) and the signs of minor ratios . . . 966
19.7 Graded unitarity of the Virasoro VOAs: statement and reduction . . . 968
19.7.1 The length flag . . . 968
19.7.2 Real structures on the Virasoro VOAs . . . 970
19.8 Length-two positivity for the boundary models . . . 972
19.8.1 The boundary central charges and the root ρ_m . . . 973
19.8.2 The length-two quasi-primaries . . . 973
19.8.3 Towers, layers and the theorem . . . 975
19.9 The Lee–Yang model . . . 979
19.9.1 The singular vector and the central charge . . . 979
19.9.2 C_2-cofiniteness and strong finiteness . . . 981
19.9.3 The Zhu-algebra relation . . . 982
19.9.4 Other Lee–Yang files . . . 983
19.10 Program B: finite certificates around the all-length problem . . . 983
19.11 Drinfeld–Sokolov reduction for $\mathfrak{sl}_2$ . . . 985
19.11.1 The idea . . . 985
19.12 Weight-one positivity of affine $\mathfrak{sl}_2$ at level $-8/5$ . . . 988
19.13 Transfer of graded unitarity along isometric embeddings . . . 989
19.14 Graded unitarity of $V^k(\mathfrak{sl}_2)$ below the critical level . . . 991
19.14.1 The data: the algebra, the form, the real structure, the flag . . . 992
19.14.2 The headline . . . 995
19.14.3 The three route theorems . . . 997
19.14.4 A worked example: weights one and two . . . 1008
19.14.5 The remaining files . . . 1009
19.15 Appendix: geometric VOAs and the chiral de Rham complex . . . 1010
19.16 Axiom audit . . . 1010
19.17 Defects and traps recorded in this chapter . . . 1014
19.18 Referee's checklist . . . 1014
19.19 Notes and references . . . 1016

VI Two recent theorems, formalized **1018**

20 Classical freeness at the boundary level: Arakawa–Dai **1019**
20.1 The mathematics . . . 1021
20.1.1 Boundary admissible levels . . . 1021
20.1.2 The C_2-algebra, Li's filtration, arcs and classical freeness . . . 1022
20.1.3 The two theorems . . . 1023
20.1.4 The proof strategy . . . 1023
20.2 The objects in the headline statements . . . 1025
20.2.1 The level and the VOA . . . 1025
20.2.2 The character and the product . . . 1026
20.2.3 The base algebra, arcs, and the presented arc algebra . . . 1030
20.2.4 Poisson vertex algebras . . . 1033
20.2.5 The candidate singular vector and the canonical map . . . 1038
20.2.6 Conformal pieces and the C_2-algebra . . . 1041
20.3 The headline theorems . . . 1042
20.3.1 Theorem 1.2: the character . . . 1042

20.3.2 Theorem 1.1: classical freeness . . . 1043
20.3.3 Theorem 1.1 in the paper's form: one theorem . . . 1047
20.4 The boundary relations hold, and the currents generate . . . 1055
20.4.1 A null vector at weight p from the determinant . . . 1055
20.4.2 The symbol of the null vector, and the relations . . . 1056
20.5 Degeneration to the auxiliary arc algebra . . . 1058
20.6 Restricted dual, Gordon divisibility and the partition filtration . . . 1059
20.6.1 Sectors and particle polynomials . . . 1059
20.6.2 Vanishing conditions and Gordon divisibility . . . 1060
20.6.3 The pair/partition filtration and the sector bound . . . 1062
20.7 The q-series identities . . . 1064
20.8 The Hilbert-series upper bound . . . 1066
20.9 The lower bound for the character . . . 1067
20.9.1 The idea . . . 1067
20.9.2 The universal character and charge decomposition . . . 1067
20.9.3 Gram rank and determinant root order . . . 1068
20.9.4 The vacuum determinant and its zeros . . . 1070
20.9.5 The boundary resonances and the Weyl correction . . . 1072
20.10 The conformal Hilbert squeeze . . . 1074
20.11 Poisson vertex structure, inverse, and the C_2 presentation . . . 1075
20.12 The Virasoro companion: classical freeness of the minimal models $M(2, 2m + 3)$ . . . 1077
20.12.1 What is proved, and why it belongs here . . . 1078
20.12.2 Li's filtration of the Virasoro VOA is the word filtration . . . 1079
20.12.3 The canonical map and what "classically free" means here . . . 1081
20.12.4 The two inputs from the singular vector . . . 1082
20.12.5 The headline: classical freeness and the C_2-algebra . . . 1085
20.12.6 The Poisson vertex structure: the bracket is forced to vanish . . . 1088
20.12.7 A worked example: Lee–Yang at low weight . . . 1089
20.12.8 Comparison with the affine headlines, and a recorded dead end . . . 1090
20.13 The boundary-affine $p = 3$ particle and conductor model . . . 1091
20.13.1 What these files are, and what they are not . . . 1091
20.13.2 Collision factors . . . 1092
20.13.3 The rooted Gordon conductor and prime-power assembly . . . 1094
20.13.4 The degree of the $p = 3$ conductor . . . 1096
20.13.5 The remaining files, collectively . . . 1097
20.14 Verification record . . . 1098
20.15 Findings, oddities and Lean defects . . . 1100
20.16 Referee's checklist . . . 1102
20.17 Notes and references . . . 1104

21 Huang's modular tensor category and the congruence property 1106
21.1 Vocabulary borrowed from the classification chapter . . . 1108
21.2 Intertwining operators and fusion rules . . . 1109
21.3 The braided monoidal category of modules and its rigidity . . . 1112
21.4 Modular data: Anderson–Moore, Verlinde and the package `IModData` . . . 1116
21.5 The congruence property . . . 1122
21.6 Deligne's theorem and the Huang–Kirillov–Lepowsky extension . . . 1130
21.7 The logarithmic braided tensor category . . . 1136
21.8 Traps and documentation defects . . . 1143
21.9 Verification record for the 2026-10-28 additions . . . 1144
21.10 Referee's checklist . . . 1144

21.11 Notes and references . . . 1145

22 The classification of nice central-charge-one vertex operator algebras (Gannon–Rayhaun) 1147
22.1 The theorem and its physics . . . 1149
22.1.1 The free boson and its rational points . . . 1149
22.1.2 Why the hypotheses . . . 1149
22.2 The statement layer . . . 1149
22.3 Modular data and the seven external inputs . . . 1156
22.3.1 Shared vocabulary . . . 1156
22.3.2 Modular data . . . 1157
22.3.3 The seven inputs . . . 1160
22.4 The paper's own lemmas . . . 1163
22.4.1 The rank-one theta functions and their S-transformation . . . 1163
22.4.2 Virasoro multiplicities and positivity of the theta weights . . . 1164
22.4.3 Uniqueness of the surviving theta weight . . . 1165
22.4.4 The Tannakian squeeze . . . 1166
22.4.5 The theta Galois law . . . 1167
22.5 The conditional theorem . . . 1167
22.5.1 Four gaps . . . 1167
22.5.2 The last step and the conditional theorem . . . 1169
22.6 Discharging the inputs: the unconditional forward theorem . . . 1171
22.6.1 How the discharge is organized . . . 1171
22.6.2 The discharging theorems quoted . . . 1172
22.6.3 The forward theorem . . . 1174
22.7 Pairwise distinctness . . . 1174
22.8 The converse . . . 1177
22.8.1 The lattice and plus families . . . 1177
22.8.2 The exceptional orbifolds: the four inputs . . . 1178
22.9 Rationality of the orbifolds of V_2: McRae's orbifold theorem . . . 1181
22.9.1 The plan, and the notation . . . 1181
22.9.2 Step 1: finitely many irreducibles, without a semisimple Zhu algebra . . . 1183
22.9.3 Step 2: the braided tensor category of logarithmic modules . . . 1183
22.9.4 Step 3: the ambient VOA as a commutative algebra . . . 1184
22.9.5 Step 4a: Schur–Weyl duality and finite generation . . . 1186
22.9.6 Step 4b: V is rigid and self-dual of dimension $|G|$: Galois descent . . . 1187
22.9.7 Step 4c: McRae's Theorem 3.3, projections onto twisted parts . . . 1189
22.9.8 Step 5: a twisted part is an untwisted module of the cyclic orbifold . . . 1191
22.9.9 Step 6: McRae's Lemma 4.21, every surjection in $\mathcal{C}$ splits . . . 1196
22.9.10 Step 7: split surjections imply rationality, and the rationality of the orbifolds 1197
22.9.11 Narrowing orbifold rationality to the exceptional groups (historical) . . . 1199
22.9.12 The earlier route, abandoned . . . 1200
22.10 The classification, complete . . . 1202
22.11 Recorded traps, dead ends and Lean defects . . . 1203
22.12 Referee's checklist . . . 1205
22.13 Notes and references . . . 1206

23 Affine VOAs for every simple Lie algebra; the exceptional Lie algebras 1208
23.1 Reading the Lean, and the notation of this chapter . . . 1210
23.2 The physical picture . . . 1211
23.3 Lie data . . . 1212

23.4 The universal affine vertex algebra $V^k(\mathfrak{g})$ . . . 1215
23.4.1 The vacuum module and the currents . . . 1215
23.4.2 Grading, Sugawara vector and the vertex algebra . . . 1217
23.5 Every simple Lie algebra . . . 1220
23.5.1 The Casimir is a scalar . . . 1220
23.5.2 $V^k(\mathfrak{g})$ for every simple $\mathfrak{g}$ . . . 1221
23.5.3 The $\mathfrak{sl}_3$ instance . . . 1224
23.6 The simple quotient $L_k(\mathfrak{g})$ and its weight-one space . . . 1225
23.6.1 The simple quotient . . . 1225
23.6.2 The named simple affine VOA $L_k(\mathfrak{g})$ of a simple Lie algebra . . . 1226
23.6.3 Weight one of the universal algebra . . . 1229
23.6.4 Singular vectors lie in the maximal ideal . . . 1231
23.6.5 Current coordinates in Li degree zero . . . 1233
23.7 Concrete simple Lie algebras I: $\mathfrak{sl}_n$ and a root-space criterion . . . 1234
23.7.1 A root-space criterion for simplicity . . . 1235
23.8 Concrete simple Lie algebras II: simply-laced types as lattice currents . . . 1236
23.8.1 The root lattices . . . 1236
23.8.2 Simplicity of the lattice current algebras . . . 1238
23.8.3 Dimensions: counting roots . . . 1241
23.8.4 The standard normalization . . . 1244
23.9 Concrete simple Lie algebras III: $\mathfrak{g}_2$, $\mathfrak{f}_4$, $\mathfrak{e}_6$ from checked structure constants . . . 1246
23.9.1 Lie algebras from sparse tables . . . 1246
23.9.2 The three algebras . . . 1249
23.9.3 Lie data with an explicit invariant form . . . 1251
23.10 The Deligne instances . . . 1252
23.11 The certificate-basis models . . . 1258
23.12 Verification record . . . 1260
23.12.1 File map . . . 1262
23.12.2 Machine cost, and the dead ends that shaped the files . . . 1263
23.13 Lean defects found . . . 1263
23.14 Referee's checklist . . . 1264
23.15 Notes and references . . . 1265

24 The Deligne series I: presentations, carriers, divisor comparison 1266
24.1 The mathematics . . . 1270
24.1.1 The Deligne series . . . 1270
24.1.2 The associated scheme, nilpotence of the Casimir, and the target statement . 1271
24.1.3 The paper proof as a chain of inequalities . . . 1272
24.1.4 Where each step lives . . . 1273
24.2 The conditional capstone . . . 1273
24.3 The explicit presentation . . . 1280
24.3.1 The A_2 relations . . . 1281
24.3.2 Singular vectors die in the simple quotient . . . 1282
24.3.3 Coadjoint propagation . . . 1283
24.4 Current-jet surjectivity . . . 1287
24.5 The geometric carrier . . . 1289
24.5.1 Quadratic ideals and the current carrier . . . 1289
24.5.2 The commutative layer, collectively . . . 1294
24.6 The carrier chain: B1 and the resummation D3 . . . 1294
24.7 The sector chain: B5, B6, the generic comparison and B8 . . . 1299
24.8 The divisor comparison . . . 1309

24.9 The seven instances . . . 1314
24.10 The certificate library, described collectively . . . 1318
24.10.1 Trust model: why a file of integers is a proof . . . 1319
24.10.2 Families . . . 1319
24.10.3 Format and checking mechanism . . . 1320
24.10.4 Sizes and measured costs . . . 1321
24.11 Verification record . . . 1322
24.12 Findings, oddities and Lean defects . . . 1323
24.13 Referee's checklist . . . 1324
24.14 Notes and references . . . 1325

25 The Deligne series II: characters, the Arakawa–Kawasetsu MLDE and q-series identities 1327
25.1 Overview: the chain, its status, and how to read this chapter . . . 1327
25.1.1 What this chapter is about . . . 1327
25.1.2 The chain of inequalities and its status . . . 1328
25.1.3 Which sections are on the critical path . . . 1329
25.1.4 Glossary of terms and named inputs . . . 1330
25.1.5 Notation . . . 1331
25.1.6 Reading the Lean in this chapter . . . 1331
25.1.7 What was machine-checked, and when . . . 1332
25.1.8 Recurring caveats, stated once . . . 1333
25.2 The character side of classical freeness . . . 1333
25.2.1 Where the characters enter . . . 1333
25.2.2 The split at the Demazure sum . . . 1335
25.2.3 The rational form and the one-sided form . . . 1337
25.3 The Arakawa–Kawasetsu recurrence . . . 1338
25.3.1 A primer on modular linear differential equations . . . 1338
25.3.2 The Arakawa–Kawasetsu equation and its recurrence . . . 1339
25.4 From one weight-four trace identity to the MLDE . . . 1343
25.4.1 The Virasoro tower over the vacuum . . . 1343
25.4.2 The vacuum quartic relation and the indicial equation . . . 1344
25.4.3 The algebraic form of the relation . . . 1346
25.5 The square-bracket current calculus . . . 1348
25.6 The vacuum quartic relation for every Deligne type . . . 1353
25.7 Formal q-series: the toolkit and the classical identities . . . 1358
25.7.1 Ramanujan's identities from the heat equation . . . 1363
25.7.2 Level three: Lorenz and Borwein, for G_2 . . . 1365
25.8 Closed forms of the MLDE solution . . . 1367
25.9 Level-one affine Demazure characters . . . 1369
25.10 The star identities . . . 1371
25.10.1 A_2: proved by an elementary route . . . 1371
25.10.2 D_4: the elliptic evaluation . . . 1373
25.10.3 G_2, F_4, E_6, E_7, E_8: named, in one-sided form . . . 1375
25.10.4 Termwise domination cannot prove the star bound . . . 1376
25.11 $q = 1$ counts and energies . . . 1377
25.12 The large kernel-checked data, described collectively . . . 1379
25.12.1 The files of this chapter . . . 1379
25.13 Lean defects and stale documentation . . . 1380
25.14 Referee's checklist . . . 1381
25.15 Notes and references . . . 1382

26 The Deligne series III: fusion modules and Ravinder's kernel 1384
26.1 Conventions, notation, and reading the Lean . . . 1386
26.1.1 Machine status, stated once . . . 1386
26.1.2 Notation used in this chapter . . . 1387
26.1.3 Reading the Lean in this chapter . . . 1388
26.2 The mathematics . . . 1390
26.2.1 Current algebras and their cyclic modules . . . 1390
26.2.2 Fusion products, concretely . . . 1390
26.2.3 The fusion modules F_m . . . 1392
26.2.4 Ravinder's modules $M_{a,b}$ and the exact sequence . . . 1392
26.2.5 The squeeze . . . 1393
26.2.6 Where this chapter enters the Deligne chain . . . 1393
26.3 The A_2 fusion modules in Lean . . . 1394
26.4 U6 by construction: the fusion characters . . . 1397
26.5 The squeeze . . . 1399
26.6 Universal modules and the exact-sequence step . . . 1401
26.7 Garland's identities and Ravinder's kernel lemma for A_2 . . . 1405
26.8 The Demazure side for A_2 . . . 1408
26.8.1 Chari–Pressley: box spanning for $\mathfrak{sl}_2$ . . . 1408
26.8.2 Chari–Loktev: spanning for $\mathfrak{sl}_3$ . . . 1409
26.8.3 Chari–Venkatesh: the $\mathfrak{sl}_2$ bound for partitions . . . 1412
26.8.4 U7 for A_2: the evaluation model . . . 1413
26.8.5 The lattice model for A_2 . . . 1416
26.9 Reductions of the A_2 total bound . . . 1417
26.10 The A_2 total bound in Lean . . . 1420
26.11 The A_2 total bound on paper . . . 1424
26.12 The type-generic fusion layer . . . 1425
26.13 Ravinder's kernel lemma for every type . . . 1430
26.14 The finiteness clause for every type . . . 1435
26.15 Lattice realizations of Demazure modules . . . 1437
26.16 How the fusion layer feeds the Deligne chain . . . 1440
26.17 Supporting files and certificates, described collectively . . . 1441
26.18 Verification record . . . 1442
26.19 Findings, oddities and Lean defects . . . 1443
26.20 Referee's checklist . . . 1444
26.21 Notes and references . . . 1446

27 The Deligne series IV: final theorems and named inputs 1447
27.0.1 Conventions . . . 1450
27.0.2 Reading the Lean in this chapter . . . 1450
27.0.3 Notation . . . 1451
27.1 Classical freeness and the shape of the proof . . . 1451
27.2 Fusion products and Demazure modules: a primer . . . 1452
27.3 The common conclusion and the seven VOAs . . . 1454
27.4 The named inputs . . . 1457
27.4.1 Relation specifications and Ravinder's family . . . 1457
27.4.2 Input T: the total-dimension bound . . . 1459
27.4.3 Input R: Demazure realizations . . . 1461
27.4.4 Input S: the star bounds . . . 1464
27.4.5 An alternative form of the A_2 Input T . . . 1465
27.5 The seven final theorems . . . 1467

27.5.1 How every final theorem is proved . . . 1467
27.5.2 The A_2 theorem . . . 1467
27.5.3 The six conditional theorems . . . 1469
27.6 The input ledger, type by type . . . 1474
27.6.1 Partial results toward Inputs T and R for D_4 . . . 1477
27.7 The inputs that remain open in Lean . . . 1479
27.7.1 Input T beyond A_2 . . . 1479
27.7.2 Input R beyond A_2 . . . 1481
27.7.3 Input S for G_2, F_4, E_6, E_7, E_8 . . . 1482
27.8 The per-type headline theorems . . . 1483
27.8.1 A_2: classical freeness from U5 and U6 . . . 1483
27.8.2 D_4: the headline with every input visible . . . 1485
27.8.3 G_2 and F_4: the concrete headlines and the two halves of the G_2 star identity . 1486
27.8.4 E-types . . . 1488
27.9 Approaches known to fail . . . 1489
27.10 Verification record . . . 1490
27.11 Remarks on the Lean sources . . . 1492
27.12 Referee's checklist . . . 1492
27.13 Notes and references . . . 1493

28 Graded unitarity through the BRST coset 1496
28.1 The mathematics in outline . . . 1500
28.1.1 Graded unitarity, recalled . . . 1500
28.1.2 The coset . . . 1501
28.1.3 Relative semi-infinite cohomology . . . 1501
28.1.4 Beem–Garner: cohomology inherits graded unitarity . . . 1501
28.1.5 The squeeze . . . 1501
28.2 The two endpoint algebras and the hypothesis . . . 1502
28.3 The headline theorem . . . 1506
28.3.1 The reduction ladder, described collectively . . . 1508
28.4 The relative semi-infinite complex . . . 1510
28.5 The coset VOA and the Virasoro image . . . 1514
28.6 Hodge theory of a weakly graded-unitary complex . . . 1517
28.7 Transfer by a dimension squeeze . . . 1522
28.8 The Beem–Garner package on the actual complex . . . 1525
28.9 The Koszul step: leading cohomology is a space of invariants . . . 1532
28.10 The jet ring and the Adamović symbol . . . 1536
28.11 The Lee–Yang vacuum character . . . 1542
28.12 The files of this chapter, described collectively . . . 1546
28.13 Verification record . . . 1547
28.14 Findings, oddities and Lean defects . . . 1549
28.15 Referee's checklist . . . 1550
28.16 Notes and references . . . 1551

29 The (2,2n+3) series: coset transfer at every boundary level 1553
29.1 The mathematics . . . 1556
29.1.1 The boundary levels and the $(2, 2n + 3)$ series . . . 1556
29.1.2 The coset and its BRST form . . . 1557
29.1.3 What is transferred, and how . . . 1557
29.1.4 What changes with n . . . 1558
29.2 The level data . . . 1558

29.3 The objects at the two ends . . . 1562
29.4 The level-generic coset chain . . . 1564
29.4.1 The infrastructure files, described collectively . . . 1564
29.4.2 The two packaged inputs and the transfer theorem . . . 1565
29.4.3 The Koszul step: from cohomology to an affine invariant count . . . 1568
29.5 The vacuum characters of $M(2, 2n + 3)$ . . . 1570
29.5.1 The Andrews–Gordon count . . . 1570
29.5.2 Spanning: the upper bound . . . 1571
29.5.3 The lower bound: Rocha-Caridi and Andrews–Gordon . . . 1573
29.6 The affine invariant count: socle words and the jet model . . . 1578
29.6.1 Why the Lee–Yang argument does not generalize . . . 1578
29.6.2 Socle words . . . 1578
29.6.3 The jet model . . . 1581
29.6.4 The model character: the Bailey chain . . . 1585
29.6.5 The model socle data, and the jet-ideal Poincaré lemma . . . 1587
29.7 Detection: the Drinfeld–Sokolov slice map . . . 1590
29.7.1 The Virasoro side: leading symbols into R_n . . . 1590
29.7.2 The slice map and its Arakawa property . . . 1591
29.8 The jet-ideal Poincaré lemma and the n-equal arrangement . . . 1595
29.8.1 The arrangement inclusion . . . 1596
29.8.2 The Gröbner basis of the n-equal ideal . . . 1597
29.9 The headline theorem . . . 1599
29.10 Consistency at $n = 1$ . . . 1601
29.11 The other endpoints . . . 1602
29.12 Warnings: stale documentation and dead ends . . . 1604
29.13 Verification record . . . 1605
29.14 Referee's checklist . . . 1606
29.15 Notes and references . . . 1608

VII The Moonshine module 1610

30 Lattices, codes and the Leech lattice 1611
30.1 Why lattices? The physical picture . . . 1611
30.2 Integral lattices: the mathematics . . . 1612
30.3 Two Lean encodings of an integral lattice . . . 1614
30.3.1 Why the companion library was vendored . . . 1615
30.3.2 The VOA library's lattice . . . 1615
30.3.3 The vendored lattice of *Lattices and Codes* . . . 1618
30.4 Binary codes . . . 1621
30.4.1 Definitions . . . 1621
30.4.2 The Lean definitions . . . 1622
30.4.3 Weight enumerators and the MacWilliams identity . . . 1623
30.5 The extended binary Golay code . . . 1624
30.5.1 Construction . . . 1624
30.5.2 The basic properties . . . 1626
30.5.3 The weight distribution; octads . . . 1627
30.6 From codes to lattices: Construction A . . . 1628
30.6.1 The construction . . . 1628
30.6.2 The Golay lattice $N(A_1^{24})$ . . . 1630
30.7 The Leech lattice . . . 1631

30.7.1 Ebeling's construction, and the doubled model . . . 1631
30.7.2 The Lean definitions . . . 1632
30.7.3 The four properties . . . 1633
30.8 Theta series and modular forms . . . 1636
30.8.1 The theta function . . . 1636
30.8.2 The two transformation laws . . . 1637
30.8.3 Level-one modular forms . . . 1640
30.8.4 The bridge from q-coefficients to lattice vectors . . . 1641
30.8.5 The representation numbers of Λ . . . 1642
30.9 The bridge into the VOA library . . . 1643
30.10 Looking ahead: the frame sublattice and the Golay code . . . 1645
30.11 Referee's checklist . . . 1646
30.12 Notes and references . . . 1647

31 Heisenberg and lattice vertex algebras **1648**
31.1 Overview and the physical picture . . . 1648
31.1.1 What a free boson is . . . 1648
31.1.2 Road map . . . 1649
31.2 Conventions recalled from the foundations . . . 1650
31.2.1 Formal distributions and modes . . . 1650
31.2.2 Locality and normal ordering . . . 1650
31.2.3 Vertex algebras and vertex operator algebras . . . 1650
31.2.4 Automorphisms, homomorphisms, intertwining . . . 1650
31.3 The rank-r Heisenberg vertex operator algebra . . . 1651
31.3.1 The Fock space as a polynomial ring . . . 1651
31.3.2 The oscillators . . . 1652
31.3.3 Currents . . . 1654
31.3.4 The conformal grading . . . 1654
31.3.5 Vertex operators and the vertex algebra . . . 1655
31.3.6 The Sugawara conformal vector and the Virasoro relation . . . 1656
31.3.7 The instance . . . 1657
31.4 Even lattices and the FLM 2-cocycle . . . 1658
31.4.1 Integral lattices in the library . . . 1658
31.4.2 Why a cocycle is needed . . . 1659
31.4.3 The cocycle in the library . . . 1659
31.4.4 The canonical cocycle of a lattice . . . 1661
31.5 Lattice charges as Heisenberg oscillators: the orthonormal frame . . . 1662
31.6 The state space of V_L and its grading . . . 1663
31.6.1 The underlying vector space . . . 1663
31.6.2 The conformal weight grading . . . 1664
31.7 The vertex operators $Y(e^{\alpha}, z)$ . . . 1666
31.7.1 The exponentials $E^{\pm}$ . . . 1666
31.7.2 The charged vertex operator . . . 1667
31.8 Locality of the lattice vertex operators . . . 1668
31.9 Reconstruction from locality and the instance V_L . . . 1670
31.9.1 The strategy . . . 1670
31.9.2 The generating family for V_L . . . 1671
31.9.3 The conformal layer and the instance . . . 1673
31.10 The Leech lattice vertex operator algebra . . . 1675
31.10.1 Importing the Leech lattice . . . 1675
31.10.2 The weight-one space . . . 1676

31.11 Sign automorphisms g_χ . . . 1677
31.11.1 The involution θ, recalled . . . 1677
31.11.2 The sign operator . . . 1678
31.12 Functoriality of lattice vertex operator algebras . . . 1680
31.12.1 The problem . . . 1680
31.12.2 Orthogonal change of oscillator variables . . . 1680
31.12.3 Comparing two cocycles: the coboundary lemma . . . 1682
31.12.4 The morphism Φ_ι . . . 1684
31.12.5 Character automorphisms . . . 1686
31.12.6 Rigidity of lifts of -1 . . . 1687
31.12.7 Where functoriality is used . . . 1688
31.13 The design question: a non-computable basis . . . 1688
31.14 Referee's checklist . . . 1689
Notes and references . . . 1690

32 The involution θ and the fixed-point algebra V_Λ^+ 1692
32.1 What we take from the lattice VOA . . . 1693
32.1.1 Lattices . . . 1693
32.1.2 The Fock space . . . 1694
32.1.3 The lattice VOA as a vector space . . . 1695
32.1.4 Formal distributions and modes . . . 1696
32.1.5 The vertex operators of charged vacua . . . 1697
32.1.6 The cocycle . . . 1698
32.2 The Fock involution σ . . . 1699
32.3 Lifting -1: the cocycle needs no correction . . . 1700
32.4 θ commutes with every vertex operator . . . 1702
32.5 θ as an automorphism of order two . . . 1705
32.6 The fixed-point algebra V_Λ^+ . . . 1706
32.7 Weight one: $(V_\Lambda^+)_1 = 0$ . . . 1708
32.8 Weight two: 196884 and 98580 . . . 1709
32.8.1 The weight-two space of a rootless lattice VOA . . . 1709
32.8.2 The θ-split and the counting trick . . . 1711
32.9 The graded dimension of V_L and of V_L^+ . . . 1713
32.9.1 Coloured partitions . . . 1713
32.9.2 Generating functions . . . 1714
32.9.3 The dimension formulas . . . 1715
32.10 Generation: V_Λ^+ is generated by the $e^\beta + e^{-\beta}$ . . . 1718
32.10.1 Why generation is needed . . . 1718
32.10.2 The proof . . . 1720
32.11 The invariant form: nondegeneracy of the canonical form on V_Λ^+ . . . 1723
32.11.1 What has to be proved, and why . . . 1723
32.11.2 Invariant forms in the library . . . 1723
32.11.3 The Fock form . . . 1725
32.11.4 The charge sign and the lattice form . . . 1727
32.11.5 Restriction to V_Λ^+ and identification with the canonical form . . . 1729
32.12 Traps and dead ends of this chapter, collected . . . 1731
32.13 Referee's checklist . . . 1732
Notes and references . . . 1733

33 Graded dimensions and the modular function J 1735
33.1 Modular forms from first principles . . . 1736
33.1.1 The upper half-plane and the modular group . . . 1736
33.1.2 Modular forms and the slash operator . . . 1737
33.1.3 Eisenstein series . . . 1738
33.1.4 The ring of level-one forms; $\dim M_{12} = 2$ . . . 1739
33.1.5 The discriminant Δ: three descriptions . . . 1739
33.1.6 The functions j and J . . . 1740
33.1.7 Theta series of even unimodular lattices . . . 1741
33.1.8 The group $\Gamma_0(2)$ and its Hauptmodul . . . 1741
33.2 The library's formal q-series . . . 1742
33.2.1 Why formal power series . . . 1742
33.2.2 Divisor sums as Lambert coefficients . . . 1742
33.2.3 The formal Eisenstein series . . . 1743
33.2.4 The formal discriminant and Δ/q . . . 1744
33.2.5 qj and qJ . . . 1745
33.3 The graded dimensions of the two sectors . . . 1747
33.3.1 The untwisted sector, recalled . . . 1747
33.3.2 The twisted Fock space $S[\theta]$ . . . 1748
33.3.3 The twisted sector $S[\theta] \otimes T$ and its fixed part . . . 1750
33.3.4 The Leech case: 98304 and 10747904 . . . 1752
33.4 The character as one power series, and the reduction to three identities . . . 1754
33.4.1 The two-sector series . . . 1754
33.4.2 The three identities . . . 1755
33.4.3 Why the analytic route . . . 1756
33.5 The bridge from formal to analytic infinite products . . . 1757
33.5.1 The problem . . . 1757
33.5.2 Evaluation and domination . . . 1757
33.6 Jacobi's product and the Leech theta series . . . 1759
33.6.1 q-expansions of E_4, E_6, Δ . . . 1759
33.6.2 Jacobi's product for the formal Δ . . . 1760
33.6.3 Weight twelve and the Leech theta series . . . 1761
33.7 The level-two identity . . . 1762
33.7.1 The modular form Φ . . . 1762
33.7.2 The formal q-expansion of Φ . . . 1764
33.7.3 From Φ to the level-two identity . . . 1765
33.8 The main theorem: the graded dimension is J . . . 1766
33.9 The carrier-level restatement . . . 1768
33.10 Verification record . . . 1769
33.11 Dead ends, traps and corrected statements . . . 1770
33.12 Referee's checklist . . . 1770
33.13 Notes and references . . . 1772

34 Twisted modules, the twisted Fock space and the module T 1773
34.1 Why twisted modules . . . 1774
34.1.1 The physical picture: strings on an orbifold . . . 1774
34.1.2 The mathematical picture . . . 1775
34.2 Fractional modes and the twisted Jacobi identity . . . 1775
34.2.1 Setting . . . 1775
34.2.2 Eigenspaces . . . 1775
34.2.3 The generating form of the twisted Jacobi identity . . . 1776

34.2.4 The mode form . . . 1777
34.3 The library's `TwistedModule` . . . 1778
34.3.1 Auxiliary definitions . . . 1778
34.3.2 The definition . . . 1779
34.3.3 Ordinary modules are twisted modules for the identity . . . 1781
34.4 The defect and its repair . . . 1782
34.4.1 What went wrong . . . 1782
34.4.2 The repaired identity . . . 1784
34.4.3 Why the restriction loses nothing . . . 1785
34.5 The twisted Heisenberg algebra and its Fock space . . . 1786
34.5.1 From integer to half-integer modes . . . 1786
34.5.2 The Lean model . . . 1787
34.5.3 The commutation relations . . . 1787
34.5.4 The L_0-grading and the vacuum weight $r/16$ . . . 1789
34.5.5 The involution θ on $S[\theta]$ . . . 1791
34.5.6 The operator L_0 . . . 1792
34.6 Extraspecial 2-groups and twisted group algebras . . . 1794
34.6.1 Why a finite group appears . . . 1794
34.6.2 Extraspecial groups: the facts we need . . . 1794
34.6.3 The library's construction . . . 1794
34.6.4 Simplicity and Wedderburn–Artin . . . 1795
34.7 The lattice: $L/2L$, the cocycle, and the module T . . . 1797
34.7.1 Recollection: lattices and the cocycle . . . 1797
34.7.2 Reduction mod 2 . . . 1798
34.7.3 The elements e_α and the module T_L . . . 1799
34.8 The symmetric invariant form on T . . . 1801
34.8.1 What is needed, and why the sign matters . . . 1801
34.8.2 Anti-involutions from quadratic signs . . . 1801
34.8.3 The lattice sign $(-1)^{\langle\alpha,\alpha\rangle/2}$ . . . 1804
34.8.4 Lagrangian data . . . 1805
34.8.5 The Leech Lagrangian and the form `TForm` . . . 1806
34.9 Referee's checklist . . . 1808
34.10 Notes and references . . . 1809

35 The twisted Heisenberg module **1811**
35.1 What has to be built, and why it is not routine . . . 1812
35.1.1 The physical picture . . . 1812
35.1.2 The mathematical target . . . 1812
35.1.3 The plan . . . 1813
35.2 The language: distributions, fields, modes, products . . . 1813
35.2.1 Formal distributions and modes . . . 1813
35.2.2 Commutators, locality, and the delta function . . . 1814
35.2.3 The integer products of fields . . . 1815
35.2.4 Twisted modules . . . 1817
35.2.5 The two Fock spaces . . . 1819
35.3 The involution σ and its eigenspaces . . . 1820
35.3.1 Definition and automorphism property . . . 1820
35.3.2 The eigenspaces . . . 1821
35.4 The reduction: twisted Jacobi from untwisted locality . . . 1822
35.4.1 The idea . . . 1822
35.4.2 Rescaled fields . . . 1824

35.4.3 The reduction theorems . . . 1824
35.4.4 Binomial inversion . . . 1826
35.5 The generator fields . . . 1827
35.5.1 Support and truncation of the twisted Heisenberg field . . . 1827
35.5.2 The rescaled generator $z^{1/2}h_a(z)$ . . . 1828
35.5.3 A cross-check: two generators at $\ell \geq 0$ . . . 1829
35.6 Locality of everything generated . . . 1830
35.6.1 Multiplication by powers of z . . . 1830
35.6.2 The generated system . . . 1831
35.7 The twisted vertex operator . . . 1832
35.7.1 The definition by inverting the product formula . . . 1832
35.7.2 First properties . . . 1834
35.7.3 Locality of all rescaled fields . . . 1835
35.7.4 What remained: the product formula . . . 1835
35.8 The vacuum energy $r/16$ . . . 1836
35.8.1 The theorem . . . 1836
35.8.2 The computation . . . 1837
35.8.3 Comparison with FLM's Δ_z . . . 1838
35.9 The commutator formula for products of local fields . . . 1838
35.10 Twisted products . . . 1840
35.10.1 Definition . . . 1840
35.10.2 The twisted commutator formula . . . 1840
35.10.3 Auxiliary identities . . . 1841
35.11 Words: order independence and creation . . . 1842
35.11.1 Twisted products of two generators . . . 1842
35.11.2 The cut-off is harmless . . . 1843
35.11.3 Order independence . . . 1844
35.11.4 The rescaled twisted vertex operators and creation . . . 1844
35.12 The twisted product formula for all pairs . . . 1846
35.12.1 Generators against everything . . . 1846
35.12.2 Translation covariance and the vacuum . . . 1846
35.12.3 The product formula . . . 1847
35.13 The grading and the instance . . . 1849
35.13.1 The complex weight decomposition . . . 1849
35.13.2 The main theorem . . . 1850
35.14 Dead ends, traps and corrections . . . 1851
35.15 Referee's checklist . . . 1851
35.16 Notes and references . . . 1853

36 The twisted Leech lattice module and $(V_\Lambda^T)^+$ 1854
36.1 The physical picture and the plan . . . 1855
36.1.1 Chiral bosons on a double cover . . . 1855
36.1.2 The twisted vertex operator . . . 1855
36.1.3 Plan of the construction . . . 1856
36.2 Notation and the objects we build on . . . 1856
36.2.1 The twisted Fock space and its modes . . . 1856
36.2.2 Fields, products, locality . . . 1857
36.2.3 Twisted modules . . . 1859
36.2.4 The lattice side . . . 1860
36.3 Newton exponentials and the contraction factor . . . 1860
36.4 The operators $E^\pm$ on the twisted Fock space . . . 1864

36.5 The two-point identity and locality . . . 1867
36.6 The twisted vertex operators of the exponentials . . . 1869
36.7 The twisted vertex operator on all states . . . 1872
36.8 The twisted product formula . . . 1875
36.9 The base case: two exponentials . . . 1877
36.9.1 The uniqueness lemma . . . 1879
36.9.2 The descent . . . 1880
36.10 Why the normalisation is $2^{-\langle\alpha,\alpha\rangle}$ . . . 1881
36.11 The twisted module V_L^T . . . 1884
36.11.1 The grading . . . 1884
36.12 The involution θ on the twisted sector . . . 1887
36.13 The plus part of an order-two twisted module . . . 1888
36.14 $(V_\Lambda^T)^+$ as a V_Λ^+-module . . . 1890
36.15 Dead ends, traps, and the verification record . . . 1892
36.16 Referee's checklist . . . 1893
36.17 Notes and references . . . 1894

37 Intertwiners and invariant forms: the operators W and $\overline{W}$ 1896
37.1 Why $V^\natural$ needs W and $\overline{W}$ . . . 1897
37.1.1 The block form of the vertex operator . . . 1897
37.1.2 The off-diagonal blocks are forced . . . 1897
37.1.3 The six locality relations . . . 1898
37.2 Notation and prerequisites . . . 1898
37.2.1 Formal distributions and modes . . . 1899
37.2.2 Modules . . . 1900
37.2.3 The Leech objects . . . 1901
37.3 Intertwining operators and skew-symmetry . . . 1901
37.3.1 The definition of Frenkel, Huang and Lepowsky . . . 1901
37.3.2 The library's notion: a commutator-type intertwiner . . . 1901
37.3.3 Skew-symmetry: from a module to an intertwiner . . . 1902
37.4 The skew operator W in Lean . . . 1903
37.4.1 The translation operator of a module . . . 1903
37.4.2 The modes and the field . . . 1904
37.4.3 Vacuum and translation properties . . . 1905
37.4.4 The commutator formula . . . 1906
37.4.5 Locality of $Y_M(u, z_1)$ and $W(t, z_2)$ . . . 1908
37.4.6 Packaging: the skew intertwiner . . . 1909
37.5 The Leech instance of W . . . 1909
37.6 Contragredient modules and invariant bilinear forms . . . 1911
37.6.1 The contragredient module . . . 1911
37.6.2 Invariant bilinear forms on a module . . . 1912
37.6.3 Generator reduction . . . 1913
37.7 The invariant form on the twisted Fock space . . . 1915
37.7.1 Which sign? The negative Fock form . . . 1915
37.7.2 The dressing is self-adjoint up to inversion . . . 1916
37.8 The form on $S[\theta] \otimes T$ and on $(V_\Lambda^T)^+$ . . . 1918
37.8.1 The product form . . . 1918
37.8.2 Nondegeneracy on graded pieces . . . 1919
37.8.3 The form on $(V_\Lambda^T)^+$ . . . 1920
37.8.4 Invariance of B_T under all of V_Λ^+ . . . 1921
37.9 Graded Riesz representation . . . 1923

37.10 The definition of $\overline{W}$ . . . 1925
37.10.1 The dagger . . . 1925
37.10.2 $\overline{W}$ as a Riesz vector . . . 1926
37.11 Properties of $\overline{W}$ . . . 1928
37.11.1 The L_{-1}-derivative property . . . 1928
37.11.2 The commutator formula: first for quasi-primary states . . . 1929
37.11.3 The commutator formula for all states . . . 1930
37.11.4 Locality and translation covariance . . . 1931
37.12 The Leech instance of $\overline{W}$ . . . 1932
37.12.1 The form B_V on V_Λ^+ . . . 1932
37.12.2 The definition and the unconditional properties . . . 1933
37.12.3 The residual hnd and its discharge . . . 1933
37.13 The genuine $\overline{W}$ in the block field, and the anti-trap certificate . . . 1935
37.13.1 Plugging $\overline{W}$ into the block field . . . 1935
37.13.2 The genuine $\overline{W}$ is not zero . . . 1936
37.14 Skew-symmetry of $\overline{W}$ . . . 1937
37.15 Traps, dead ends and corrected mistakes . . . 1939

38 The vertex algebra on $V^\natural$ modulo one relation 1943
38.1 Where we are, and what this chapter does . . . 1943
38.2 Recollections: the notions that occur in the statements . . . 1945
38.2.1 Formal distributions and modes . . . 1945
38.2.2 Multiplication by $z_1 - z_2$, commutators, locality, fields . . . 1946
38.2.3 Vertex algebras and vertex operator algebras . . . 1947
38.2.4 Invariant bilinear forms . . . 1949
38.2.5 Weak modules . . . 1950
38.2.6 The objects of the earlier Moonshine chapters . . . 1950
38.3 Block fields on a direct sum . . . 1952
38.3.1 Block operators . . . 1952
38.3.2 Block fields . . . 1953
38.3.3 Truncation and translation covariance blockwise . . . 1954
38.3.4 Locality blockwise . . . 1955
38.4 Locality of the fields of a module . . . 1956
38.5 The carrier $V^\natural$ and its grading . . . 1958
38.6 The generator fields and the reconstruction interface . . . 1961
38.6.1 Translation, and the untwisted fields . . . 1961
38.6.2 The twisted fields, with $\overline{W}$ as a parameter . . . 1962
38.6.3 The block vertex map and the reconstruction interface . . . 1964
38.7 All vertex-operator-algebra axioms but one . . . 1966
38.7.1 The Virasoro algebra on any module . . . 1966
38.7.2 The axioms for the block map . . . 1967
38.7.3 The packaged structure . . . 1969
38.8 Twisted–twisted locality splits into DGM (4.22) and (4.23) . . . 1971
38.9 DGM (4.22) holds unconditionally . . . 1973
38.9.1 Three tools . . . 1973
38.9.2 The theorem . . . 1975
38.10 Reducing (4.23) to a generating family and to four pairs . . . 1977
38.11 The trap: the square-zero extension . . . 1979

38.11.1 The construction . . . 1979
38.11.2 Why the numbers cannot see the difference . . . 1981
38.11.3 What excludes it . . . 1981
38.12 The invariant form of $V^\natural$ and simplicity . . . 1982
38.12.1 The form . . . 1982
38.12.2 A combinatorial identity . . . 1983
38.12.3 Invariance block by block . . . 1983
38.12.4 Simplicity . . . 1985
38.13 The assembled conditional theorem . . . 1987
38.14 Dead ends and corrected mistakes . . . 1988
38.15 Referee's checklist . . . 1989
38.16 Notes and references . . . 1990

39 The Golay frame and the untwisted triality **1992**
39.1 Why a triality is needed . . . 1993
39.1.1 The one relation that resists . . . 1993
39.1.2 The idea of triality . . . 1994
39.1.3 The frame and its four sectors . . . 1994
39.1.4 What the untwisted triality is, physically . . . 1995
39.2 The frame lattice Λ_0 . . . 1996
39.2.1 The model of the Leech lattice . . . 1996
39.3 Momentum signs and the untwisted sectors . . . 1998
39.3.1 The automorphism attached to a character (recalled) . . . 1998
39.3.2 The sectors V_0^+ and V_3^+ . . . 1998
39.4 Weight two of the untwisted sectors . . . 2001
39.4.1 Counting norm-four vectors outside Λ_0 . . . 2002
39.5 The twisted side: $T = T_+ \oplus T_-$ . . . 2004
39.6 Cyclicity I: the vacuum trick . . . 2007
39.6.1 Why cyclicity . . . 2007
39.6.2 The general lemma . . . 2008
39.6.3 V_0^+ and V_3^+ are cyclic . . . 2009
39.7 Cyclicity II: the twisted sectors . . . 2011
39.7.1 The obvious route is blocked . . . 2011
39.7.2 Orbit spans in a twisted module . . . 2011
39.7.3 The frame involution on the twisted module . . . 2014
39.7.4 The twisted frame sectors and their cyclicity . . . 2015
39.8 Root exponentials and inner automorphisms . . . 2016
39.8.1 Inner automorphisms from weight-one states . . . 2017
39.8.2 $(e^\alpha)_{(0)}$ is locally nilpotent . . . 2017
39.8.3 The $\mathfrak{sl}_2$ triple of a root . . . 2019
39.9 The Niemeier lattice VOA and the triality σ . . . 2020
39.9.1 The lattice VOA V_N . . . 2020
39.9.2 The rotation G and the definition of σ . . . 2021
39.9.3 σ on the currents: DGM (7.7) . . . 2023
39.9.4 $\Theta = \sigma\chi\sigma$ is a lift of -1 . . . 2023
39.10 The bridge $V_N^K \cong V_0^+$ and the triality on V_0^+ . . . 2026
39.10.1 The abstract Λ_0 and its two embeddings . . . 2026
39.10.2 Pulling back Θ: the scalars c_λ . . . 2028
39.10.3 The isomorphism and the transported triality . . . 2029
39.11 Summary: what this chapter gives the rest of the proof . . . 2031
39.12 Referee's checklist . . . 2032

Notes and references . . . 2033

40 Existence of the twisted triality I: reduction to Zhu generation 2034
40.1 What this chapter is about . . . 2034
40.2 The objects, recalled . . . 2035
40.2.1 Standing conventions: modes . . . 2035
40.2.2 Lattices: Λ and Λ_0 . . . 2036
40.2.3 The vertex algebras V_Λ^+ and V_0^+ . . . 2036
40.2.4 The twisted sectors T_s^+ . . . 2037
40.2.5 The triality on V_0^+ . . . 2038
40.3 Zhu's algebra and the Zhu correspondence . . . 2038
40.3.1 Motivation: what the lowest weight space sees . . . 2038
40.3.2 The Zhu product and $\mathcal{O}(V)$ . . . 2038
40.3.3 Zero modes on a lowest-weight space: the easy direction . . . 2041
40.3.4 The hard direction, and why this chapter avoids it . . . 2042
40.3.5 Examples . . . 2042
40.4 Twisted intertwiners and the existence criterion . . . 2043
40.4.1 The abstract setting . . . 2043
40.4.2 Uniqueness and involutivity from a cyclic vector . . . 2044
40.4.3 Words and annihilator compatibility . . . 2045
40.5 The triality problem on the library's sectors . . . 2047
40.5.1 Which twisted sector is T_0? An undetermined label . . . 2051
40.6 From the top level to the whole module . . . 2052
40.6.1 The idea . . . 2052
40.6.2 Sums and twists of weak modules . . . 2052
40.6.3 Li's single-mode spanning lemma . . . 2053
40.6.4 The generic top-level theorem . . . 2054
40.6.5 The Leech instance: modules and the form . . . 2056
40.6.6 The named residuals `TopSigmaV3` and `TopSigmaTT` . . . 2058
40.6.7 The explicit cyclic vector and the existence theorem . . . 2060
40.7 From the top level to Zhu generators . . . 2063
40.8 Which generators? A numerical experiment . . . 2066
40.9 A filtered criterion for Zhu generation . . . 2067
40.9.1 The filtration and three leading-term identities . . . 2067
40.9.2 Weight-raising products and the criterion . . . 2069
40.10 Zhu generation of V_0^+: reduction to three sectors . . . 2070
40.10.1 The residual for V_0^+ . . . 2070
40.10.2 Word states and the sector decomposition . . . 2071
40.10.3 Products of ground states . . . 2073
40.11 The Fock sectors: `ExcitedSpanned` and `FockSpanned` . . . 2075
40.11.1 The modes of a quadratic state . . . 2075
40.11.2 The target spaces and the degree ascent . . . 2078
40.11.3 Charged excited states . . . 2079
40.11.4 The charge-zero sector $M(1)^+$ . . . 2081
40.12 The ground states: Golay combinatorics . . . 2082
40.12.1 Facts about the Golay code . . . 2083
40.12.2 The lattice statement in Golay coordinates . . . 2084
40.12.3 Transport to the vertex algebra . . . 2087
40.13 The headline: V_0^+ is Zhu-generated by weight two . . . 2087
40.14 Dead ends and traps . . . 2088
40.15 Referee's checklist . . . 2089

A Provenance: the library state documented by this edition **2245**

B Index of Lean declarations **2247**

Preface

This book is a self-contained account of the Lean 4 library LeanVOA (this release edition omits one chapter, on affine $\hat{\mathfrak{sl}}_3$, which is in preparation): a formalization of the theory of vertex operator algebras that culminates in a machine-checked construction of the Moonshine module $V^\natural$ of Frenkel, Lepowsky and Meurman. It is written for a reader who is an advanced graduate student in mathematics or mathematical physics, who knows algebra and some representation theory, but who is neither an expert in vertex algebras nor a user of Lean.

What the book is for. A formal proof is only as good as its statement. A Lean theorem can be perfectly verified by the computer and still fail to say what its authors meant: a hypothesis may be too strong, a definition may be vacuous, a convention may have silently changed. The purpose of this book is to let a *human referee* check, theorem by theorem, that the Lean statements are the mathematics we intended. For every definition and theorem we therefore print (i) the statement in ordinary mathematical language, (ii) the Lean declaration copied verbatim from the source, (iii) a *fidelity check* that decodes the Lean statement and compares it with the mathematics, (iv) a proof explained on paper, and (v) the machine status of the result. Each chapter ends with a *referee's checklist*. We do not explain how the Lean proofs are organised: the computer has checked them; the reader's job, and ours, is to check that what was checked is what we wanted.

How the book is tied to the code. This edition documents release v1.0 of the library (commit `(recorded at release)`). The chapters do not repeat this: whenever a chapter speaks of "the release" or "the released source", it means this commit, and every check that was run at an earlier state of the library and not repeated for this edition is marked as such where it is reported. Every Lean file of the library is assigned to exactly one chapter of the full book (in this edition, files assigned to the chapters in preparation are not documented), and every quotation of Lean code in the book matches the source verbatim.

The trust base. Lean checks every proof against its kernel. The library uses only Lean's three standard axioms (`propext`, `Classical.choice`, `Quot.sound`); it contains no project axiom. Until 19 October 2026 it contained one, `VOA.pbw`, a Poincaré–Birkhoff–Witt statement for affine vacuum modules and induced modules; that declaration is now a theorem with the same name and statement (Chapter 3). Some chapters still record, as history, which results used to depend on it; the construction of the Moonshine module never did. A clean axiom list does not make a theorem unconditional: `#print axioms` does not report the explicit hypotheses of a theorem, so every status box of the book names them, and several headline results of Part VI are conditional reductions to named, unproved inputs (Chapter 1, Section 1.6.4).

Defects found while writing the book. Writing and refereeing the book was itself an audit of the library. Every defect it found in the Lean source (a vacuous hypothesis, an uninhabitable structure, a missing axiom field, a stale docstring) is reported in the chapter where it occurs, in a box headed "Trap / dead end", and collected, with its evidence, in the catalogue of dead ends, traps

and documentation debt of Chapter 43 (Sections 43.2 and 43.2.8). The book does not repair the library: it documents the release above as it is.

Index. The appendix ends with an index of every Lean declaration quoted here.

Structure. Part I sets up formal calculus, the axioms of vertex algebras and their structure theory. Part II treats the main families of examples and the rigidity programmes. Parts III and IV develop representation theory and modularity. Part V covers super, logarithmic and unitary theories. Part VI formalizes recent research: the Arakawa–Dai theorems on classical freeness, Huang's tensor categories, the Gannon–Rayhaun classification of central charge one, affine vertex algebras for every simple Lie algebra, and classical freeness for the Deligne exceptional series (Chapters 24–27): a proof for A_2, and for the other six types a conditional reduction whose remaining inputs are named; and the transfer of graded unitarity through the BRST coset (Chapters 28 and 29), from the boundary admissible affine $\mathfrak{sl}_2$ to the minimal models $M(2, 2n+1)$, a proved implication whose one hypothesis, graded unitarity of the affine algebra, is open. A chapter on affine $\mathfrak{sl}_3$ is in preparation. Part VII constructs the Moonshine module. Part VIII records how all of this was verified, every dead end met along the way, the numerical evidence, and the open problems. Chapter 1, Section 1.6, gives a map of the book, chapter by chapter, with the status of each headline result.

Part I

Foundations

Chapter 1

Reading Lean, and a map of the book

This book documents the release of the LeanVOA library named in the front matter. Every Lean quotation in this chapter is quoted from the files of that release, and every one is machine-checked by `scripts/textbook/sync.py` to occur verbatim (up to whitespace and comments) in the source. This first chapter contains almost no vertex algebra. Its job is to prepare the reader for the rest of the book: to say what the book is for and how to use it, to collect in one place every Lean and Mathlib idiom that the later chapters use (so that their fidelity checks can simply point back here, Section 1.8), to explain exactly what a computer check does and does not guarantee, to fix the conventions that recur in every chapter, and to give a map of the book and of where each basic notion is defined. The mathematics proper begins in Chapter 2.

1.1 What this book is for, and how to use it

1.1.1 The referee's question

The LeanVOA library is a body of roughly ten thousand Lean files (the per-chapter counts at the book's commit are tabulated in Appendix A) which formalise a large part of the theory of vertex operator algebras and, as its headline result, construct the Moonshine module $V^\natural$ of Frenkel, Lepowsky and Meurman. The Lean system has checked every proof in it. That is a strong guarantee, but it is a guarantee about *proofs*, not about *statements*. A Lean theorem can be completely verified and still not say what its authors meant: a hypothesis may be stronger than intended, a conclusion weaker, a definition may be vacuous (satisfied by nothing, or by a trivial object), or a convention may have silently changed between two files. No computer can detect such a mismatch, because the "intended meaning" lives in the heads of the authors and in the literature, not in the code.

This book exists to close that gap. It is written for a *human referee*: a reader who wants to take a theorem of the library, read it as mathematics, read the Lean declaration that is printed next to it, and convince herself that the Lean statement is *exactly* the intended theorem — no stronger hidden hypotheses, no weaker conclusion, no vacuous definitions, no changed conventions. The book is about statements and their meaning. It is not about how Lean checks proofs; the proofs are explained on paper, as a mathematician (and, where it helps, a physicist) would explain them.

1.1.2 How each result is presented

Every definition and theorem in the later chapters is presented in the same order:

1. the **mathematical statement**, in textbook form, with every quantifier explicit;

2. the **Lean declaration**, copied verbatim from the source file, with its full name and its file (the line "File `VOA/...`" above or below the code);

3. a **fidelity check** (a grey box) which decodes the Lean notation, lists every hypothesis and says why it is the intended one, traces every defined term back to its definition, says whether the Lean form is the same as, stronger than or weaker than the textbook form, and asks how the statement could have been wrong or vacuous;
4. a **proof on paper**;
5. the **physical meaning** (a blue box);
6. the **machine status** (a green box): unconditional, or conditional on named hypotheses, and the result of `#print axioms` where it was run.

Traps, dead ends and defects of the library are recorded in red boxes. Each chapter ends with a *Referee's checklist* (a table of its headline declarations) and with *Notes and references*. Section 1.5 explains the boxes in more detail.

1.1.3 How to use the book

A reader who wants to verify the construction of $V^\natural$ can follow the *Moonshine path* of Section 1.6.3; a reader interested in the library as a whole can follow the *general path*. In both cases the recommended way to use a chapter is the referee's way: read the mathematical statement, then read the Lean statement *before* reading the fidelity check, and try to decode it yourself with the help of Sections 1.2 and 1.4. Then read the fidelity check and see whether you agree. The book is tied to a single commit: if the library has moved on, the script `python3 scripts/textbook/sync.py check` lists every chapter whose quotations no longer match the source (Section 1.3.6).

1.2 The Lean toolkit: reading Lean for mathematicians

Lean 4 is a programming language and an interactive proof assistant based on dependent type theory; Mathlib is its community library of formalised mathematics. The LeanVOA library is written in Lean 4.30.0 against Mathlib v4.30.0. A reader of this book never needs to *write* Lean; she needs to *read* statements. This section teaches the minimum, with short examples taken verbatim from the library.

1.2.1 Terms and types; propositions and data

Every object in Lean is a *term*, and every term has a *type*, written `x : X` (read: "x is a term of type X"). A type plays the role of the set to which an element belongs, with one difference: the type of a term is part of the term and is always known to the system. Examples: `n : ℤ` is an integer, `c : ℂ` a complex number, `k : ℕ` a natural number (and $\mathbb{N}$ *includes* 0). The expression `(n : ℂ)` is the *cast* of the integer n into $\mathbb{C}$; casts are sometimes printed as an upward arrow `↑n`. `V : Type u` declares V to be a type ("a set") in universe level u; universes are a technical device to avoid Russell's paradox and may be ignored. A function type is written with an arrow: `f : ℤ → W` is a function from $\mathbb{Z}$ to W, applied by juxtaposition, `f n`, so that `f (-n - 1)` means $f(-n-1)$. Functions of several variables are curried: `g : ℤ → ℤ → W` is applied as `g m n`.

Statements are also types, of a special kind: they live in the universe `Prop` of propositions. A *proof* of a statement `P : Prop` is a term `h : P`. So there are two kinds of things in Lean, and a reader must always know which one she is looking at:

- *data*, whose type lives in some `Type u`: numbers, vectors, linear maps, vector spaces, vertex algebras;
- *proofs*, whose type is a proposition `P : Prop`: the statement that a map is linear, that a family of subspaces is a direct-sum decomposition, that an identity holds.

Two proofs of the same proposition are regarded as equal ("proof irrelevance"), so a proof carries no information beyond the truth of what it proves. Data, by contrast, can be chosen in different ways, and the choice matters.

The logical connectives are written as in mathematics: `P ∧ Q` (and), `P ∨ Q` (or), `¬ P` (not), `P → Q` (implies), `P ↔ Q` (if and only if), `∀ x, P x` (for all), `∃ x, P x` (there exists). **Quantifier order matters exactly as in mathematics.** For instance `∀ u v : 𝒱, ∃ N : ℤ, ∀ n : ℤ, N ≤ n → P u v n` says that a bound N exists for each pair (u, v) and may depend on it; the statement with `∃ N` written first would assert a single uniform bound, which is much stronger. Implication associates to the right: `P → Q → R` means $P \Rightarrow (Q \Rightarrow R)$, i.e. "if P and Q, then R". In a long conjunction `A ∧ B ∧ C` the connective also associates to the right; for reading purposes it is simply the list of clauses A, B, C.

Universes. A declaration may say (`𝒱 : Type u`), (`𝒲 : Type*`) or `Type _`. These are three ways of saying "a type" that differ only in how the universe level is named: `u` is a named level, `Type*` introduces a fresh anonymous level, and `_` asks Lean to infer it. A referee can read all three as "let $\mathcal{V}$ be a set". The only place where universes can matter for a statement is when two types are required to live in the *same* universe (a structure field such as `carrier : Type u`); then a theorem quantifying over all such structures quantifies over those in universe u, which for the mathematics of this book loses nothing.

1.2.2 Declarations: def, theorem, structure, class, instance

A Lean file is a sequence of *declarations*. The ones a reader meets are these.

- `def name (arguments) : T := body` *defines* a term of type `T`. A definition proves nothing. If `T` is `Prop`, the definition introduces a new *predicate*; much of the work of refereeing a library is checking that its predicates mean what their names suggest, because a theorem about a badly defined notion can be true and useless. This is why the book prints every definition that occurs in a headline theorem.
- `theorem name (arguments) : P := proof` asserts that the proposition `P` holds for all values of the arguments. In this book we print the part up to and including the colon and the statement `P`; the proof after `:=` is usually omitted. (`lemma` is a synonym.)
- `structure` introduces a new type whose terms are tuples of data and proofs — Section 1.2.5 below.
- `class` is a structure whose terms Lean will *search for automatically*; the standard examples are Mathlib's algebraic structures `AddCommGroup 𝒱` and `Module ℂ 𝒱`. The LeanVOA library declares essentially no classes of its own: a text search finds one declaration beginning with `class`, `VOA.Huang.TensorCat.FusionCategory` (Chapter 21); its vertex-algebraic notions are ordinary structures, passed as explicit arguments.
- `instance` declares a term of a class, which the automatic search will then find.
- `abbrev` is a definition that Lean unfolds eagerly; for reading it is the same as `def`. `noncomputable` in front of a definition means that Lean cannot run it as a program (typically because it uses the axiom of choice); it has no logical cost for classical mathematics, but it means that numbers such as dimensions cannot simply be evaluated by the computer — numerical evidence in the project is produced outside Lean and always labelled as evidence.
- `axiom name : P` *postulates* `P` without proof. The library contains none; until 19 October 2026 it contained one, `VOA.pbw`, now a theorem (Section 1.3).

Example 1.1 (The mode convention)**.** Here is the single most important definition of the library, in full. File `VOA/Foundations/FormalCalculus.lean`.

```
def mode (f : FormalDist 𝒲) (m : ℤ) : 𝒲 := f (-m - 1)
```

Read it as follows. The name is `mode` (in full, `VOA.mode`, since the whole library sits in the namespace `VOA`). It has two explicit arguments, `f` of type `FormalDist 𝒲` and `m` of type `ℤ`; the result has type $\mathcal{W}$; and the value is `f (-m - 1)`. To understand it one must know what `FormalDist 𝒲` is: it is the type `ℤ → 𝒲` of all functions from $\mathbb{Z}$ to $\mathcal{W}$, thought of as doubly infinite formal series $f(z) = \sum_{k\in\mathbb{Z}} f(k)\,z^k$ (Chapter 2, Definition 2.1); the library also writes this type as `𝒲⟦z^±⟧`. So `f k` is the coefficient of z^k, and `mode f m` is the coefficient of z^{-m-1}, i.e. the m-th mode $f_{(m)}$ in

$$f(z) = \sum_{m\in\mathbb{Z}} f_{(m)}\, z^{-m-1}.$$

When `f` is the vertex operator `Y u` of a state u, `mode (Y u) n` is the operator $u_{(n)}$, whereas `Y u k` (without `mode`) is the coefficient of z^k, which is $u_{(-k-1)}$. Both forms occur.

A worked example. `mode (Y u) 3` unfolds to `Y u (-3 - 1) = Y u (-4)`, the coefficient of z^{-4} in $Y(u,z)$, and in $\sum_n u_{(n)}z^{-n-1}$ the power z^{-4} carries $u_{(3)}$, as it should. *A check with the vacuum.* In a vertex algebra $Y(u,z)\mathbf{1} = u + z\,Tu + O(z^2)$, where $Tu = u_{(-2)}\mathbf{1}$. The coefficient of z^0 is `Y u 0 = mode (Y u) (-1)`, i.e. $u_{(-1)}$, and the library's creation axiom indeed reads `mode (Y u) (-1) vacuum = u`; the coefficient of z^1 is `Y u 1 = mode (Y u) (-2)`, i.e. $u_{(-2)}$, and the library defines the translation operator by `V.smul u (-2) V.vacuum`. The positive modes $u_{(n)}$, $n \geq 0$, sit at negative powers z^{-n-1}; they kill the vacuum, which is the statement that $Y(u,z)\mathbf{1}$ has no pole at $z = 0$. The full discussion, with more calibrating examples, is Definition 2.7 of Chapter 2.

From the mathematics to the Lean statement

How to read it. Explicit arguments (in parentheses) are the inputs; the type after the last colon is the output type. There is no hidden hypothesis: `mode` is a plain re-indexing. The variable $\mathcal{W}$ does not appear among the arguments because it was declared once for the whole file by a `variable` command (next subsection), which makes it an implicit argument.

Physical meaning

A chiral field of a two-dimensional conformal field theory is expanded in modes, and the mathematician's convention $Y(u,z) = \sum u_{(n)}z^{-n-1}$ indexes the modes so that the exponent does not depend on the conformal weight of u. For a field of weight h the physicist writes $\phi(z) = \sum \phi_m z^{-m-h}$, and then $u_{(n)} = \phi_{n-h+1}$; for the stress tensor ($h = 2$) this gives $L_m = \omega_{(m+1)}$. The definition itself is bookkeeping; the physics lies in the axioms it is used to state (Chapter 4).

What the machine verified

A definition. `#print axioms VOA.mode` reports that it depends on no axioms (run for this chapter).

Example 1.2 (An instance: the identity field)**.** File `VOA/Core/VertexAlgebra.lean`.

```
instance instOne [Zero 𝒲] [One 𝒲] : One (FormalDist 𝒲) := ⟨fun n => if n = 0 then 1 else 0⟩
```

This declares how the symbol `1` is to be read for formal series: `1` is the series whose coefficient of z^n is 1 for $n = 0$ and 0 otherwise, i.e. the constant series 1. The square brackets `[Zero 𝒲] [One 𝒲]` require that $\mathcal{W}$ have a zero and a one (for example $\mathcal{W} = \mathrm{End}(V)$, where `1` is the identity map). The angle brackets `⟨...⟩` build a term of the class `One` from its single field. Why this matters: the vacuum axiom of a vertex algebra is written `Y vacuum = 1`, and with this instance it says $Y(\mathbf{1},z) = \mathrm{id}_V$, i.e. $\mathbf{1}_{(n)} = \delta_{n,-1}\,\mathrm{id}$. Had the library used the *pointwise* constant function 1 on $\mathbb{Z}$ instead, `1` would have meant the formal delta function $\sum_n z^n$, and the vacuum axiom would have said something false

for every genuine vertex algebra. The library's choice is the correct one; the axiom is decoded in Chapter 4, Definition 4.1.

From the mathematics to the Lean statement

An `instance` has no name that the reader needs (here it is `VOA.FormalDist.instOne`); its effect is that every later occurrence of `1` at the type `FormalDist 𝒲` means this series. A referee who sees `1` or `0` in a statement should always ask *which* instance gives it meaning.

Physical meaning

The identity field is the field of the vacuum state: inserting the vacuum at any point does nothing. It is the unit of the operator product expansion.

What the machine verified

A definition; `#print axioms VOA.FormalDist.instOne` reports no axioms (run for this chapter).

1.2.3 Type synonyms, abbrev, and definitional unfolding

A `def` whose value is a type creates a *type synonym*: a new name for an existing type. The library's most important one is the type of formal distributions. File `VOA/Foundations/FormalSeries.lean`.

```
def FormalDist (𝒲 : Type*) : Type _ := ℤ → 𝒲
```

Mathematically `FormalDist 𝒲` *is* the set of functions $\mathbb{Z} \to \mathcal{W}$. But Lean treats a `def` as *opaque* for the automatic search: the structures that Mathlib puts on function types (pointwise addition, but also a pointwise *multiplication*) are not inherited automatically, and only the structures the library declares by hand are available. This is deliberate: the pointwise product of two formal series in z is *not* their product as series (and the series product does not exist in general), so the library keeps the misleading ring structure away and gives `FormalDist 𝒲` only its additive and $\mathbb{C}$-linear structure. A side-effect, recorded in the source, is that general lemmas about functions do not apply automatically, and the library has to restate trivialities such as the following. File `VOA/Core/Deformation.lean`.

```
@[simp] theorem zero_dist_apply {𝒲 : Type*} [AddCommGroup 𝒲] (k : ℤ) :
    (0 : FormalDist 𝒲) k = 0 := rfl
```

Two pieces of syntax appear here. The proof `rfl` ("reflexivity") means that the two sides are equal *by unfolding definitions*: Lean checks the equation by computation. And `@[simp]` is an *attribute* that registers the theorem as a rewriting rule for the simplifier; it has no logical content. A theorem proved by `rfl` is a *definitional* fact: it tells the referee exactly what a definition unfolds to. For instance, immediately after `mode`: File `VOA/Foundations/FormalCalculus.lean`.

```
@[simp] theorem mode_apply (f : FormalDist 𝒲) (m : ℤ) : mode f m = f (-m - 1) := rfl
```

Such `rfl`-lemmas are the safest possible statements: they cannot hide any mathematics. The same holds for `Iff.rfl`, the proof of `P ↔ P`: a theorem `A ↔ B := Iff.rfl` says that the two statements are the same after unfolding definitions, so it is a membership or unfolding lemma, not a theorem with content. Similarly `funext h` proves `f = g` from `h : ∀ n, f n = g n` (function extensionality). An example combining both: File `VOA/Foundations/FormalSeries.lean`.

```
def LaurentPoly (𝒲 : Type*) [AddCommGroup 𝒲] [Module ℂ 𝒲] : Submodule ℂ (FormalDist 𝒲)
↪  where
  carrier := {f | (Function.support f).Finite}
```

File `VOA/Foundations/FormalSeries.lean`.

```
theorem mem_laurentPoly [AddCommGroup 𝓦] [Module ℂ 𝓦] {f : FormalDist 𝓦} :
    f ∈ LaurentPoly 𝓦 ↔ (Function.support f).Finite := Iff.rfl
```

A subspace is defined by giving its `carrier` (the underlying set, here in set-builder notation `{f | ...}`) and proofs that it is closed under the operations (omitted here; the `where` syntax lists the fields of the structure being built). `Function.support f` is the set $\{n : f(n) \neq 0\}$ and `.Finite` the proposition that it is finite (Section 1.2.11); `mem_laurentPoly` merely unfolds the definition.

Attributes. The prefix `@[...]` attaches an *attribute* to a declaration: metadata used by the automation, with no logical content. `@[simp]` registers a rewrite rule for the simplifier; `@[ext]` registers an *extensionality* lemma, i.e. a theorem "two objects are equal when their components agree", which the tactic `ext` then applies automatically; `@[inherit_doc]` copies a documentation string; `@[reducible]` makes a definition unfold like an `abbrev`. Example: File `VOA/Foundations/FormalSeries.lean`.

```
@[ext]
theorem ext {f g : FormalDist 𝓦} (h : ∀ n, f n = g n) : f = g := funext h
```

Two formal distributions are equal when all their coefficients are; since `FormalDist` is opaque, this has to be stated (and is proved by `funext`). Likewise `Aut.ext` (`VOA/Core/Automorphism.lean`) says that two automorphisms are equal when their linear maps are: the proof fields carry no information.

`inferInstanceAs`. Since an opaque type synonym inherits no structure, the library transfers the structures it *does* want by hand: File `VOA/Foundations/FormalSeries.lean`.

```
instance instAddCommGroup [AddCommGroup 𝓦] : AddCommGroup (FormalDist 𝓦) :=
  inferInstanceAs (AddCommGroup (ℤ → 𝓦))
```

`inferInstanceAs (C X)` means "the instance of `C X` that the automatic search finds", used here at the synonym. So the addition on formal distributions is exactly the pointwise addition of functions $\mathbb{Z} \to \mathcal{W}$; the same is done for scalar multiplication, and nothing is done for multiplication. A referee reads `inferInstanceAs` as "the evident structure, transported".

`abbrev` versus `def`. An `abbrev` is a definition that Lean unfolds *eagerly*, in particular during the automatic instance search, so that an `abbrev` of a type inherits all the structure of the type it abbreviates. Logically the two are the same: the abbreviated type and its unfolding are definitionally equal, and no statement changes meaning. The difference is practical, and it can be large. An example: File `VOA/Moonshine/ExtraspecialModule.lean`.

```
noncomputable abbrev ExtraT : Type := Rep (cocMat L) (isUnit_det_cocMat L hEven hU)
```

Because this abbreviation is unfolded during instance search, elaborating even the scalar action on its elements times out, and downstream files use the unfolded type `Rep (cocMat L) _` directly (Chapter 34). For a referee the lesson is only that the *same* mathematical object can appear under several names in different files; the fidelity checks say when two names are definitionally equal. Conversely the carrier of the Moonshine module is an `abbrev`, `abbrev Vnat : Type := SkewVP × TP` (Section 1.2.10), so that it inherits the vector-space structure of the product.

Trap / dead end

How type synonyms can mislead. If a type synonym *did* inherit a structure the authors did not intend (for `FormalDist`, the pointwise product), a statement using $*$ on it would silently mean the wrong product. The library avoids this for `FormalDist` by making it opaque. A referee who sees an algebraic operation on a type synonym should ask which instance gives it meaning — the same question as for `1` in Example 1.2.

1.2.4 Arguments: explicit, implicit, instance

Lean has three kinds of brackets for arguments, and all three are *universally quantified* for reading purposes.

- `(x : X)`: an *explicit* argument, written out when the declaration is used.
- `{x : X}`: an *implicit* argument, which Lean infers from the other arguments (for example the type $\mathcal{V}$ of a vector `v : 𝒱`). In a statement, `∀ {n : ℤ} (v : 𝒱), ...` means "for all n and v"; the braces only say that n need not be written when the statement is used.
- `[C X]`: an *instance* argument, a structure of class `C` on `X` which Lean finds by the automatic search.
- `⦃x : X⦄`: a *strict implicit* argument. Like `{x : X}` it is inferred, but only once a later explicit argument is supplied. For reading it is again "for all x". Example:

File `VOA/Modularity/SuperTorusRecursion.lean`.

```
def IsParityHomogeneousMap {X Y : Type*} [AddCommGroup X] [Module ℂ X]
    [AddCommGroup Y] [Module ℂ Y] (P : ParityGrading X) (Q : ParityGrading Y)
    (p : ZMod 2) (f : X →ₗ[ℂ] Y) : Prop :=
  ∀ (q : ZMod 2) ⦃x : X⦄, x ∈ P.parity q → f x ∈ Q.parity (p + q)
```

which reads: f is homogeneous of parity p if for every q and every x of parity q, $f(x)$ has parity $p+q$ (addition in `ZMod 2`).

Other declaration syntax. `inductive` defines a type by listing its constructors (for example a type with finitely many named elements, or a type of formal words); `deriving DecidableEq` asks Lean to generate the evident instance. `open X in` makes the short names of namespace `X` available for one declaration, and `scoped` notation is notation available only after `open`. A name prefixed by `_root_.`, as in `_root_.Even`, refers to the global declaration rather than to one of the same name inside the current namespace. Tactic names (`simp`, `simpa`, `rw`, `exact`, `omega`, `norm_num`, `ring`, `ext`) and names of Mathlib lemmas such as `smul_add` occur only inside proofs; a reader of statements can ignore them. Almost every file of the library begins with a line such as File `VOA/Core/VertexAlgebra.lean`.

```
variable {𝒱 : Type u} [AddCommGroup 𝒱] [Module ℂ 𝒱]
```

which reads: *let $\mathcal{V}$ be a complex vector space.* `AddCommGroup 𝒱` is an abelian group structure and `Module ℂ 𝒱` a compatible $\mathbb{C}$-module structure. The `variable` command adds these arguments to every subsequent declaration of the file that mentions $\mathcal{V}$, so they do not appear in the printed statement but are nevertheless hypotheses of it. They are harmless here — they say only that $\mathcal{V}$ is a complex vector space — but a referee must remember that a statement can have arguments that are declared further up the file. The fidelity checks of the book always list them.

A `variable` line may also introduce an *explicit* argument, for instance `(W : VertexOperatorAlgebra 𝒱)`. Then every definition of the file that uses `W` takes it as its first explicit argument although it is not printed in the definition itself: File `VOA/Moonshine/ZhuGenFiltration.lean`.

```
variable {𝒱 : Type u} [AddCommGroup 𝒱] [Module ℂ 𝒱] (W : VertexOperatorAlgebra 𝒱)
noncomputable def Fl (n : ℤ) : Submodule ℂ 𝒱 := ⨆ (k : ℤ) (_ : k < n), W.grading k
```

Here `Fl` is really a function of two explicit arguments, `Fl W n`, the span $\bigoplus_{k<n} W_k$ of all graded pieces of weight below n (the notation `⨆` is explained in Section 1.2.10).

Typeclass search, and why its depth matters. When a declaration needs an instance argument `[C X]`, Lean searches the registered instances, possibly chaining several ("$\mathcal{V}$ is a $\mathbb{C}$-module, hence an additive group, hence ..."). The search is bounded by options, one of which, `maxSynthPendingDepth`, the library sets globally in its build configuration:

```
[leanOptions]
maxSynthPendingDepth = 3
```

(an excerpt of `lakefile.toml`, shown as plain text because it is not Lean source). Some files need this larger depth to elaborate. If a file is compiled *without* it — which is what happens with a bare `lake env lean`, since that command does not read the build options — the search can fail, and the elaborator may then replace the failing piece by `sorryAx` and report an error. This is the origin of the "audit trap" of Section 1.3: axiom audits must be run through `lake build` or with the option passed explicitly. A failed instance search never produces a *wrong* accepted theorem; it produces an error (or a `sorryAx` that `#print axioms` reveals).

1.2.5 Structures: a bundle of data and proofs

A `structure` defines a mathematical object as a tuple of data together with axioms — exactly like "a group is a set with a multiplication, a unit and inverses, such that …". Each component is a *field* `name : type`. Fields whose type is data are the data; fields whose type is a proposition are the axioms, and a term of the structure must supply a proof of each of them.

Example 1.3 (Automorphisms of a VOA)**.** File `VOA/Core/Automorphism.lean`.

```
structure Aut (W : VertexOperatorAlgebra 𝒱) where
  toLinearEquiv : 𝒱 ≃ₗ[ℂ] 𝒱
  map_smul' : ∀ (u : 𝒱) (n : ℤ) (v : 𝒱),
    toLinearEquiv (W.smul u n v) = W.smul (toLinearEquiv u) n (toLinearEquiv v)
  map_vacuum : toLinearEquiv W.vacuum = W.vacuum
  map_omega : toLinearEquiv W.conformalVector = W.conformalVector
```

(documentation comments removed). A term `α : Aut W` is a quadruple: one piece of data, the linear isomorphism `toLinearEquiv` : $\mathcal{V} \to \mathcal{V}$, and three proofs: that it preserves every n-th product, $\alpha(u_{(n)}v) = (\alpha u)_{(n)}(\alpha v)$; that it fixes the vacuum; and that it fixes the conformal vector. The components are accessed by *projection*, written with a dot: `α.toLinearEquiv`, `α.map_vacuum`. The same dot notation is used for functions defined in a namespace: if `W : VertexOperatorAlgebra 𝒱` then `W.smul u n v` is the function `PreVertexAlgebra.smul` applied to (the underlying pre-vertex algebra of) `W` and to `u n v`; it is the n-th product $u_{(n)}v$ — the name `smul` refers to "product", not to scalar multiplication. The mathematics of automorphisms (that they form a group, preserve the grading, and so on) is in Chapter 5, Definition 5.9.

From the mathematics to the Lean statement

Decoding the symbols. `𝒱 ≃ₗ[ℂ] 𝒱` is the type of $\mathbb{C}$-linear isomorphisms $\mathcal{V} \to \mathcal{V}$, bundled together with their inverses. The quantifier in `map_smul'` is over all u, n, v, with no restriction. The structure takes the VOA `W` as an explicit parameter, so `Aut W` is a type that depends on `W`. Nothing requires the grading to be preserved: that is a *theorem* (Chapter 5), proved from $\alpha\omega = \omega$.

Physical meaning

An automorphism of the chiral algebra is a global internal symmetry of the conformal field theory that commutes with conformal transformations (it fixes the stress tensor). For $V^\natural$ the automorphism group is the Monster (a theorem of Frenkel, Lepowsky and Meurman, not formalized in the library).

What the machine verified

A definition; `#print axioms VOA.Aut` lists `[propext, Classical.choice, Quot.sound]` (run for this chapter).

The most dangerous failure of a structure. A structure whose axioms are contradictory has no terms at all, and then every theorem of the form "for every W of this structure, ..." is vacuously true. The book checks for this explicitly; the library has had several such cases (Section 1.2.13, item (F1)). One, a twisted-module axiom quantified over too many indices, is recorded and repaired in Chapter 34; the others are recorded, unrepaired, in Chapters 12 and 17. The opposite failure is a structure satisfied by a trivial object: for instance, the zero space is a vertex operator algebra of every central charge, which is why headline results assert simplicity.

A structure may `extend` another: `structure B extends A` means that a term of `B` has all the fields of `A` plus new ones, and `b.toA` is its underlying `A`. This is how a vertex operator algebra is built, in layers, on top of the library's basic structure `PreVertexAlgebra` (Example 1.4).

1.2.6 The Mathlib vocabulary at a glance

The following Mathlib notions occur constantly. They are standard mathematics; we fix the notation and record the conventions that a referee must know. This is an overview; each item is treated with library examples in Sections 1.2.7–1.2.12, and the glossary of Section 1.8 lists everything in one table.

- `V →ₗ[ℂ] W`: the $\mathbb{C}$-linear maps $\mathcal{V} \to \mathcal{W}$, applied like functions, `φ v`. `V ≃ₗ[ℂ] W`: the $\mathbb{C}$-linear isomorphisms.
- `Module.End ℂ V`, written `End ℂ V` in the library: the algebra $\mathrm{End}_{\mathbb{C}}(\mathcal{V})$. In it `a * b` is the composition $a \circ b$, `1` is the identity, and `⁅a, b⁆` is the commutator $ab - ba$.
- `Submodule ℂ V`: the linear subspaces of $\mathcal{V}$, ordered by inclusion, with least element `⊥` $= \{0\}$ and greatest element `⊤` $= \mathcal{V}$. Membership is `v ∈ S`; `ℂ • v` is the line $\mathbb{C}v$; `Submodule.span ℂ s` is the span of a set s.
- `↥S`: a subspace `S : Submodule ℂ V` is a set of vectors; `↥S` is the same subspace regarded as a vector space in its own right (its elements are pairs of a vector and a proof that it lies in S). The arrow is a *coercion*: Lean inserts it automatically when a subspace is used where a type is expected, and it is usually invisible in the source but visible in Lean's printed output.
- `Module.finrank ℂ X`: the dimension of X as a natural number. **Caution:** by Mathlib's convention the `finrank` of an *infinite*-dimensional space is 0. So `finrank ℂ X = 196884` implies that X is finite-dimensional, but `finrank ℂ X = 0` does not imply $X = 0$. This convention has bitten the library once: its "fusion coefficient" is identically zero for exactly this reason (Chapter 12, Theorem 12.33). `FiniteDimensional ℂ X` is the proposition that X is finite-dimensional.
- `DirectSum.IsInternal S`, for a family `S : ℤ → Submodule ℂ V`: the proposition that the natural map $\bigoplus_n S_n \to \mathcal{V}$ is an isomorphism, i.e. $\mathcal{V} = \bigoplus_n S_n$ internally. This is how the library says that a space is graded.
- `LinearMap.BilinForm ℂ V`: bilinear forms $\mathcal{V} \times \mathcal{V} \to \mathbb{C}$, applied as `B a b`.
- `PowerSeries ℂ`: formal power series $\sum_{n \geq 0} a_n q^n$; `PowerSeries.coeff n f` is the coefficient a_n (printed `(PowerSeries.coeff n) f`).
- `∑ i ∈ Finset.range N, f i` is the finite sum $\sum_{i=0}^{N-1} f(i)$. `∑ᶠ i, f i` ("`finsum`") is the sum of a family with finite support, and **by convention it is 0 when the support is infinite**. Wherever the library uses `∑ᶠ`, finiteness of the support must be checked separately; the chapters point this out where it matters (see Chapter 2, warning 2.2.2).

- `ZMod n`: the integers modulo n; `ZMod 2` $= \{0,1\}$ is the parity group, used for the even/odd grading of superalgebras and for the $\mathbb{Z}/2$ orbifold.

Example 1.4 (Reading a structure header: vertex operator algebras)**.** The central structure of the library is the following. File `VOA/Core/VertexOperatorAlgebra.lean`.

```
structure GradedVertexOperatorAlgebra (𝒱 : Type u) [AddCommGroup 𝒱] [Module ℂ 𝒱]
    extends PreVertexAlgebra 𝒱 where
  conformalVector : 𝒱
  conformal_mem : conformalVector ∈ grading 2
  centralCharge : ℂ
  virasoro : ∀ m n : ℤ,
      ⁅mode (Y conformalVector) (m + 1), mode (Y conformalVector) (n + 1)⁆
        = ((m : ℂ) - n) • mode (Y conformalVector) (m + n + 1)
          + (if m + n = 0 then (((m : ℂ) ^ 3 - m) / 12 * centralCharge) • (1 : End ℂ 𝒱)
             else 0)
  L0_grading : ∀ {n : ℤ} (v : 𝒱), v ∈ grading n → mode (Y conformalVector) 1 v = (n : ℂ) •
  ↪ v
  translation : ∀ v : 𝒱, Y (mode (Y conformalVector) 0 v) = deriv (Y v)
  grading_bounded_below : ∃ N : ℤ, ∀ n : ℤ, n < N → grading n = ⊥

structure VertexOperatorAlgebra (𝒱 : Type u) [AddCommGroup 𝒱] [Module ℂ 𝒱]
    extends GradedVertexOperatorAlgebra 𝒱 where
  vacuum_grade : grading 0 = ℂ • vacuum
  positivity : ∀ n : ℤ, n < 0 → grading n = ⊥
  grading_bounded_below := ⟨0, positivity⟩

def L (W : VertexOperatorAlgebra 𝒱) (n : ℤ) : End ℂ 𝒱 :=
  mode (W.Y W.conformalVector) (n + 1)
```

(documentation comments removed). We read it only at the level of "what kind of thing is each line"; the mathematics is in Chapter 4, Definition 4.4.

- The headers: `GradedVertexOperatorAlgebra 𝒱` is a type depending on a complex vector space $\mathcal{V}$; `extends PreVertexAlgebra 𝒱` means that it has all the fields of `PreVertexAlgebra` — a grading `grading : ℤ → Submodule ℂ 𝒱`, its directness, the vertex operator `Y : 𝒱 →ₗ[ℂ] (End ℂ 𝒱)⟦z^±⟧`, the `vacuum` and Gannon's axioms VA1–VA5 — which is why `grading`, `Y` and `vacuum` can be used in the new fields without being declared here. In the same way `VertexOperatorAlgebra 𝒱 extends GradedVertexOperatorAlgebra 𝒱`, so a VOA has every field of both structures.

- The layers. `PreVertexAlgebra` (Chapter 4) is *not* a vertex algebra in the standard sense: it has no translation-covariance axiom, and the Borcherds identity can fail for it. The library's `VertexAlgebra` is a `PreVertexAlgebra` plus that axiom. `GradedVertexOperatorAlgebra` is the vertex operator algebra of Frenkel–Lepowsky–Meurman and Lepowsky–Li: finite-dimensional graded pieces, the grading truncated from below (`grading_bounded_below`), Virasoro, L_0-grading and L_{-1}-derivative. `VertexOperatorAlgebra` adds the two *CFT-type* fields `vacuum_grade` and `positivity`; the line `grading_bounded_below := ⟨0, positivity⟩` fills the parent's truncation field automatically, so a construction of a VOA need not supply it. Every VOA is a vertex algebra (`VertexOperatorAlgebra.toVertexAlgebra`), because `translation` gives covariance.

- Data: `conformalVector` (a vector ω) and `centralCharge` (a number $c \in \mathbb{C}$).

- Axioms: every other field is a proposition. `conformal_mem` says $\omega \in V_2$. `virasoro` is an equation in `End ℂ 𝒱` quantified over all $m, n \in \mathbb{Z}$, with the commutator bracket `⁅·,·⁆`, a cast `(m : ℂ)`, scalar multiplication `•`, and an `if ... then ... else` for the central term: by

the mode convention of Example 1.1, `mode (Y conformalVector) (m + 1)` is $\omega_{(m+1)} = L_m$, so this is the Virasoro relation. `L0_grading` has an implicit weight `{n : ℤ}`; `translation` uses the formal derivative `deriv`; `vacuum_grade` uses the line `ℂ • vacuum`; `positivity` and `grading_bounded_below` use `⊥`.

- After the structure, `def L` introduces the abbreviation `W.L n` for $L_n = \omega_{(n+1)}$.

The library also has a separate structure `VOA.NearVOA` in the same file, with the same Virasoro, grading and translation axioms but without finite-dimensionality of the graded pieces and without the conditions $V_0 = \mathbb{C}\mathbf{1}$, $V_{n<0} = 0$; every VOA gives one by `VertexOperatorAlgebra.toNearVOA`.

From the mathematics to the Lean statement

What to check when reading a structure. (a) Which fields are data and which are axioms. (b) The quantifiers of each axiom, including implicit ones in braces. (c) Every convention in an axiom — here the shift $L_m = \omega_{(m+1)}$, which would make the Virasoro axiom false for every genuine VOA if it were off by one. (d) Whether the axioms can be satisfied by something non-trivial, and whether they are satisfied by something trivial (the zero space is a VOA of every central charge). (e) What the parent structure contributes. The full fidelity check of this structure — including the important point that `VertexOperatorAlgebra` is of *CFT type* by definition, which is stronger than the "grading bounded below" of Frenkel–Lepowsky–Meurman (that general notion is `GradedVertexOperatorAlgebra`) — is in Chapter 4.

Trap / dead end

Correction: a bare `PreVertexAlgebra` has no translation covariance. An earlier version of this chapter called the library's `PreVertexAlgebra` "stronger" than the textbook definitions of Kac and Frenkel–Ben-Zvi. That was wrong. `PreVertexAlgebra` has a grading with finite-dimensional pieces but *no* translation-covariance axiom, and without it the Borcherds (Jacobi) identity does not follow: Chapter 4 gives an explicit three-dimensional `PreVertexAlgebra` on which both the Borcherds identity and $Y(Tu, z) = \partial_z Y(u, z)$ fail, machine-checked and axiom-clean (a copy is in the library as `VOA.TranslationCovariantCounterexample.VA`). Every Borcherds, skew-symmetry and duality theorem of the library is therefore stated for `VertexOperatorAlgebra`, whose axiom `translation` restores covariance, and every statement about $V^\natural$ is about `VertexOperatorAlgebra`; the headline theorem is unaffected. The defect is catalogued in Chapter 43, Section 43.2.8; it led the library to rename the structure (`PreVertexAlgebra`) and to reserve `VertexAlgebra` for the translation-covariant notion.

Physical meaning

A vertex operator algebra is the chiral algebra of a two-dimensional conformal field theory together with its stress tensor $T(z) = Y(\omega, z) = \sum L_n z^{-n-2}$; the central charge c is the conformal anomaly, the grading by L_0 is the grading by conformal weight, and the axiom `translation` is the Ward identity saying that L_{-1} generates translations. Section 1.7 gives the picture in a little more detail.

What the machine verified

A definition. `#print axioms VOA.VertexOperatorAlgebra` lists `[propext, Classical.choice, Quot.sound]` (run for this chapter).

1.2.7 Existence, emptiness and choice

`∃` and `Nonempty`. `∃ x : X, P x` is a proposition; a proof of it does not come with a usable witness unless one invokes choice. For a type `X`, `Nonempty X` is the proposition "X has at least one element", and `IsEmpty X` the proposition "X has no element". Theorems of the form `¬ Nonempty X` are how the library records that a notion is empty — which is sometimes exactly the warning a referee needs: File `VOA/Modules/ZhuVermaAnArchZhu534.lean`.

```
theorem not_nonempty_inducedAssignment (W : VertexOperatorAlgebra 𝒱) :
    ¬ Nonempty (InducedAssignment W) := by
```

Every theorem that takes a term of `InducedAssignment W` as a hypothesis is therefore vacuous (Chapter 12): the structure is uninhabited, so such a theorem proves nothing about any module.

`Function.Injective`. `Function.Injective f` is the proposition $\forall a\, b,\ f\,a = f\,b \to a = b$. (Surjective and bijective are `Function.Surjective`, `Function.Bijective`.) It appears, for instance, in the PBW principle `VOA.pbw` (Chapter 3).

Choice: `.choose` and `Classical.choose`. From a proof `h : ∃ x, P x` Lean can extract a witness `h.choose` (also written `Classical.choose h`) together with the proof `h.choose_spec : P h.choose`. The witness is *some* element satisfying P, selected by the axiom of choice; nothing is known about it beyond P. Two library examples: File `VOA/Core/Automorphism.lean`.

```
def IsLocNilp (D : End ℂ 𝒱) : Prop := ∀ v : 𝒱, ∃ N : ℕ, (D ^ N) v = 0

noncomputable def locNilpIdx {D : End ℂ 𝒱} (hD : IsLocNilp D) (v : 𝒱) : ℕ := (hD v).choose
```

File `VOA/Moonshine/SigmaAssemble.lean`.

```
noncomputable def s0 : ZMod 2 := (seed_in_frame seedExists).choose
```

The first chooses, for a locally nilpotent operator D and a vector v, *some* N with $D^N v = 0$ (not necessarily the least one). The second chooses, in the Moonshine construction, one of the two sectors in which a "seed" vector exists. Such definitions are `noncomputable`. Mathlib provides choice-based constructions of the same kind, the commonest in this library being a basis of a free module: File `VOA/Foundations/LatticeCocycle.lean`.

```
noncomputable def latticeBasis :
    Basis (Fin (Fintype.card (Module.Free.ChooseBasisIndex ℤ L.carrier))) ℤ L.carrier :=
  (Module.Free.chooseBasis ℤ L.carrier).reindex (Fintype.equivFin _)
```

`Module.Free.chooseBasis ℤ L.carrier` is *an arbitrary* $\mathbb{Z}$-basis of the lattice L, re-indexed by `Fin n` $= \{0, \dots, n-1\}$ (`Fintype.card` is the number of elements of a finite type).

Trap / dead end

How choice can make a statement weaker than it looks. A definition built from a chosen witness depends on the choice, and a theorem about it is a theorem about *that* choice. This is harmless when the theorem holds for every choice — the FLM cocycle built from `latticeBasis` satisfies the cocycle identities for every basis (Chapters 3 and 31) — and it is what the referee must check. A statement such as "`locNilpIdx` is minimal" would be unprovable, since nothing about the chosen N beyond $D^N v = 0$ is known. In the Moonshine construction the choices (`s0`, the seed vector, the basis) are all of this harmless kind: the headline theorem is an existence statement, and its conclusion does not refer to them (Chapter 42).

1.2.8 Total functions and junk values

Every Lean function is *total*: it returns a value on every input, including inputs where the mathematical operation is undefined. The value returned there is a *junk value*, fixed by convention. The ones that matter:

- **division by zero**: `x / 0 = 0` in $\mathbb{C}$, $\mathbb{Q}$, $\mathbb{R}$; in $\mathbb{N}$ and $\mathbb{Z}$ division is division with remainder rounded down, so `7 / 2 = 3`;
- **natural subtraction is truncated**: for `m n : ℕ`, `m - n = 0` when $m < n$;
- `Int.toNat`: `k.toNat` is k for $k \geq 0$ and 0 for $k < 0$;
- `Module.finrank` of an infinite-dimensional space is 0, and $\sum^{\mathrm{f}}$ of an infinitely supported family is 0 (Sections 1.2.10 and 1.2.11);
- library functions that are only meaningful on some inputs return 0 elsewhere.

Junk values are harmless when the statement only uses the function where it is meaningful, and the referee's job is to check that. Three library examples. File `VOA/Foundations/Substitution.lean`.

```
noncomputable def cbz (n k : ℤ) : ℂ := if 0 ≤ k then gBinom n k.toNat else 0
```

The binomial $\binom{n}{k}$ with an *integer* lower index: `k.toNat` is used only under the guard `0 ≤ k`, and for $k < 0$ the value is *defined* to be 0. This junk value is mathematically the right one: it lets the library write the Borcherds identity as a sum over all $i \in \mathbb{Z}$ (Chapter 2). File `VOA/Moonshine/TwistedHeisenberg.lean`.

```
noncomputable def modeT (r : ℕ) (i : Fin r) (k : ℤ) : Module.End ℂ (FockT r) :=
  if k % 2 = 0 then 0
  else if k < 0 then mulXT (varT i k)
  else ((k : ℂ) / 2) • pderivT (varT i k)
```

This is the *odd-integer encoding* of half-integer modes: the twisted boson has modes $h_i(r)$ only for $r \in \frac{1}{2} + \mathbb{Z}$, and the library indexes $h_i(k/2)$ by the odd integer k. For even k (`k % 2 = 0`, where `%` is the remainder) there is no mode, and the junk value `0` is returned. The factor `(k : ℂ) / 2` is honest complex division. A statement about `modeT` for *all* `k` therefore also says something (usually trivial) about the junk values; the fidelity checks of Chapter 34 note where hypotheses "k odd" are needed. File `VOA/Moonshine/ExtraspecialModule.lean`.

```
theorem finrank_extraT : Module.finrank ℂ (ExtraT L hEven hU) = 2 ^ (L.rank / 2) := by
```

Here `L.rank / 2` is division of natural numbers, rounded down. The formula $\dim T_L = 2^{\operatorname{rank} L/2}$ is meant for even rank, and the library proves separately that an even unimodular lattice has even rank (`even_rank_of_unimodular`, same file), so no rounding occurs in the cases used.

Trap / dead end

How junk values make statements vacuous or wrong. A conclusion `Module.finrank ℂ X = 0` is satisfied by every infinite-dimensional X; a conclusion `∑ᶠ i, f i = 0` by every infinitely supported f; an equation between natural numbers involving `m - n` may hold only because both sides are truncated. The library has one real casualty: its "fusion coefficient" `VOA.fusionCoeff` is a `finrank` of a space that is always either 0 or infinite-dimensional, so it is identically 0 (Chapter 12, Theorem 12.33). Every statement whose content is a value of `VOA.fusionCoeff` is therefore vacuous or false as a fusion rule.

1.2.9 Numbers, casts, ZMod, Fin, and decidable conditions

Casts. $\mathbb{N}$, $\mathbb{Z}$, $\mathbb{Q}$, $\mathbb{R}$, $\mathbb{C}$ are different types, and a number is moved between them by a cast: `(n : ℤ)` for $n \in \mathbb{N}$, `(m : ℂ)` for $m \in \mathbb{Z}$, printed `↑n` by Lean. Casts are injective ring homomorphisms, so an equation of casts means the evident equation, with two cautions: a subtraction or division *inside* a cast is computed in the source type (so `((m - n : ℕ) : ℤ)` is truncated, whereas `(m : ℤ) - n` is not), and the position of the cast matters for that reason. The headline theorem casts the natural number `finrank` to $\mathbb{C}$ to compare it with a power-series coefficient (Section 1.2.15).

`ZMod n` and `Fin n`. `ZMod n` is the ring $\mathbb{Z}/n\mathbb{Z}$; `ZMod 2` is the parity group, used for super gradings, for the two sectors of an orbifold, and in coding theory. `Fin n` is the finite type $\{0, 1, \dots, n-1\}$, used as an index set: `i : Fin r` in `modeT` above is a colour index $1 \le i \le r$ (numbered from 0). An element of `Fin n` is a natural number together with a proof that it is less than n.

Decidable conditions. An expression `if c then a else b` requires Lean to be able to decide `c`; for equalities of integers, inequalities and parity this is automatic (the relevant instances are called `Decidable` and `DecidableEq`), and with classical logic every proposition is decidable. For reading purposes `if c then a else b` is the case distinction it looks like. Example: File `VOA/Foundations/Expansion.lean`.

```
def negOnePow (n : ℤ) : ℂ := if Even n then 1 else -1
```

which is $(-1)^n$ (`Even n` is the proposition $\exists r,\ n = r + r$).

1.2.10 Linear algebra: maps, subspaces, quotients, products

Maps. `V →ₗ[ℂ] W` is the type of $\mathbb{C}$-linear maps; a term is a function bundled with the proofs that it is additive and $\mathbb{C}$-homogeneous. `V ≃ₗ[ℂ] W` is the type of linear isomorphisms, bundled with their inverses. `Module.End ℂ V` (`End ℂ V`) is $\mathrm{End}_{\mathbb{C}}(\mathcal{V})$, with `*` composition, `1` the identity, `⁅a, b⁆` $= ab - ba$, and `D ^ N` the N-th power. `LinearMap.id` is the identity map. A curried `M →ₗ[ℂ] M →ₗ[ℂ] ℂ` is a *bilinear* map $M \times M \to \mathbb{C}$ (linear in each variable separately; there is no complex conjugation anywhere), and `LinearMap.BilinForm ℂ V` is the abbreviation for `V →ₗ[ℂ] V →ₗ[ℂ] ℂ`. `Module.Dual ℂ X` is the dual space `X →ₗ[ℂ] ℂ`. `Basis ι ℂ X` is a basis of X indexed by ι.

Subspaces as a lattice. `Submodule ℂ V` is the set of subspaces of $\mathcal{V}$, a complete lattice under inclusion $\le$: `⊥` $= \{0\}$, `⊤` $= \mathcal{V}$, `S ⊓ T` $= S \cap T$, `S ⊔ T` $= S + T$, and `⨆ i, S i` ("iSup") is the sum $\sum_i S_i$ of a family. The double supremum `⨆ (k : ℤ) (_ : k < n), W.grading k` in `Fl` above is the sum over all $k < n$: the second binder ranges over proofs of $k < n$, and the anonymous name `_` says the proof is not used. `Submodule.span ℂ s` is the span of a set s, and `ℂ ∙ v` the line $\mathbb{C}v$. For a linear map f, `LinearMap.ker f` and `LinearMap.range f` are its kernel and image; `S.comap f` is the preimage $f^{-1}(S)$ and `S.map f` the image $f(S)$; `S.subtype` is the inclusion $S \hookrightarrow \mathcal{V}$. `↥S` is the subspace S regarded as a vector space (its elements are pairs of a vector and a proof of membership); the coercion is inserted automatically.

Quotients. `X ⧸ S` is the quotient space X/S. A typical construction, the cohomology of a differential: File `VOA/Core/BRSTCohomology.lean`.

```
def kerQ : Submodule ℂ V := LinearMap.ker C.Q
def imQ : Submodule ℂ V := LinearMap.range C.Q
def imQ' : Submodule ℂ C.kerQ := C.imQ.comap C.kerQ.subtype
abbrev Coh : Type u := C.kerQ ⧸ C.imQ'
```

Read: $\ker Q$ and $\mathrm{im}\, Q$ are subspaces of $\mathcal{V}$; since the quotient must be taken inside $\ker Q$, the image is first pulled back along the inclusion $\ker Q \hookrightarrow \mathcal{V}$ (`comap` along `subtype`), giving $\mathrm{im}\, Q$ as a subspace of $\ker Q$; and the cohomology is $\ker Q / \mathrm{im}\, Q$. Besides quotient *spaces*, Lean has quotient *types* of a set by an equivalence relation: `Quotient.mk` sends an element to its class, `Quotient.lift f h` is the function induced on classes by an f that respects the relation (`h` is the proof that it does),

and `Quotient.sound` says that related elements have equal classes — it is derived from the axiom `Quot.sound` of Section 1.3.

Gradings. A grading is a family `grading : ℤ → Submodule ℂ V`, and `DirectSum.IsInternal grading` is the proposition that $\mathcal{V} = \bigoplus_n V_n$ (the natural map from the external direct sum is bijective). `DirectSum ℂ X` with `X : ι → Type` is the external direct sum $\bigoplus_i X_i$; the restricted dual of a graded module is built with it: File `VOA/Modules/Contragredient.lean`.

```
def RestrictedDual (N : OrdVModule W M) : Type u := DirectSum ℂ (fun α => Module.Dual ℂ
 ↪ (N.weight α))
```

which is $M' = \bigoplus_\alpha M^*_\alpha$.

Eigenspaces, exactness, complements. For `T : Module.End ℂ X`, `Module.End.eigenspace T μ` is $\ker(T-\mu)$ and `T.maxGenEigenspace μ` the generalised eigenspace $\{x : (T-\mu)^k x = 0 \text{ for some } k\}$; the library's logarithmic modules are graded by the latter (Chapter 12). `IsCompl P Q` says $X = P \oplus Q$ ($P \cap Q = 0$ and $P + Q = X$). `Nontrivial X` says X has two distinct elements, i.e. for a vector space $X \neq 0$. Exactness of a pair of module maps is the library's own predicate, stated pointwise without category theory: File `VOA/Modules/OrdinaryExact.lean`.

```
def ExactAt (f : Hom A B) (g : Hom B C) : Prop :=
  ∀ n : N, g.toLinearMap n = 0 ↔ ∃ m : M, f.toLinearMap m = n
```

i.e. $\ker g = \operatorname{im} f$ (Chapter 12).

More linear-algebra constructions. `LinearIndependent ℂ v` says the family v is linearly independent; `Module.Basis` (also written `Basis`) is a basis, `Module.Basis.mk` builds a basis from an independent spanning family, `b.repr x` is the coordinate vector of x in the basis b, and `Pi.basisFun` is the standard basis of $\mathbb{C}^n$. `Module.Finite R X` says X is finitely generated (for a vector space: finite-dimensional). `Submodule.Quotient.mk x` is the class of x in a quotient, and `S.liftQ f h` the map induced on X/S by an f vanishing on S. `LinearEquiv.ofBijective`, `LinearEquiv.ofInjective` (onto the image), `LinearEquiv.ofEq` (between equal subspaces) and `LinearEquiv.ofInvolutive` build isomorphisms; `LinearMap.fst` is the first projection, `LinearMap.toSpanSingleton ℂ X x` the map $c \mapsto cx$, `LinearMap.smulRight f x` the map $y \mapsto f(y)\,x$, `LinearMap.mk₂` a bilinear map built from a function, `LinearMap.mul` and `LinearMap.mulLeft` multiplication in an algebra, `Algebra.lsmul` scalar multiplication as a linear map, `B.compl₁₂ f g` the bilinear form $(x, y) \mapsto B(fx, gy)$, `B.IsSymm` and `B.Nondegenerate` symmetry and nondegeneracy of a bilinear form, `Matrix.toBilin'` the bilinear form of a matrix, `Matrix.of` a matrix given by its entries, `Matrix.rank` the rank and `Mᵀ` (postfix `ᵀ`) the transpose. `restrictScalars` regards a $\mathbb{C}$-linear object as linear over a smaller ring. `TensorProduct.mk`, `TensorProduct.map`, `TensorProduct.lift`, `TensorProduct.congr`, `TensorProduct.lid`, `LinearMap.lTensor`, `LinearMap.rTensor` are respectively $(a, b) \mapsto a \otimes b$, $f \otimes g$, the linear map induced by a bilinear one, $f \otimes g$ for isomorphisms, $\mathbb{C} \otimes M \cong M$, id $\otimes f$ and $f \otimes$ id. On direct sums, `DirectSum.decompose` (and `DirectSum.decomposeLinearEquiv`) is the isomorphism $V \cong \bigoplus_n V_n$ of a decomposition, `DirectSum.toModule` the map out of a direct sum given on summands, `DFinsupp.lsum` its finitely-supported analogue, and `DirectSum.IsInternal.chooseDecomposition` a decomposition *chosen* from the bare statement `IsInternal` (Section 1.2.7). On finitely supported functions (Section 1.2.11): `Finsupp.single i a` is a at i and 0 elsewhere (and `Pi.single` the same for ordinary functions), `Finsupp.linearCombination` is $c \mapsto \sum_i c_i v_i$, `Finsupp.lsum` and `Finsupp.lapply` sum and evaluation as linear maps, `Finsupp.domLCongr` re-indexing, and `Finsupp.weight w` the weighted degree $\sum_i \mu(i)w(i)$ of a multi-index.

Dimension. `Module.finrank ℂ X` is $\dim X$ when finite and 0 otherwise; `FiniteDimensional ℂ X` is the proposition that X is finite-dimensional. A conclusion `finrank ℂ X = d` with $d \neq 0$ implies finite-dimensionality; with $d = 0$ it does not.

Products and tensor products. `A × B` is the product (direct sum) of two spaces, with elements `(a, b)` and projections `x.1`, `x.2`; `S.prod T` is the subspace $S \times T$. The Moonshine module is built this way: File `VOA/Moonshine/VnatCarrier.lean`.

```
abbrev Vnat : Type := SkewVP × TP

noncomputable def gradingNat (n : ℤ) : Submodule ℂ Vnat :=
  (leechVOAPlus.grading n).prod (plusModule.weight (n : ℂ))

noncomputable def vacNat : Vnat := (leechVOAPlus.vacuum, 0)
```

so $V^\natural = V_\Lambda^+ \oplus (V_\Lambda^T)^+$, graded piecewise, with vacuum $(\mathbf{1}, 0)$ (the names `SkewVP`, `TP` are defined in Chapter 38). `A ⊗[ℂ] B` is the tensor product over $\mathbb{C}$ and `a ⊗ₜ[ℂ] b` a pure tensor: File `VOA/Core/TensorVOA.lean`.

```
def tenSub (P : Submodule ℂ A) (Q : Submodule ℂ B) : Submodule ℂ (A ⊗[ℂ] B) :=
  Submodule.span ℂ {t : A ⊗[ℂ] B | ∃ a ∈ P, ∃ b ∈ Q, a ⊗ₜ[ℂ] b = t}
```

which is the image of $P \otimes Q$ in $A \otimes B$, written as the span of a set given by set-builder notation `{t | ...}`; `∃ a ∈ P, ...` abbreviates $\exists a,\ a \in P \wedge \dots$.

Matrices. `Matrix ι ι ℂ` is a square matrix indexed by a finite type ι, and `M.det` its determinant. A theorem combining several of these notions: File `VOA/Core/GradedFormMatrix.lean`.

```
theorem gramMatrix_det_ne_zero_iff (hB : B.IsFullyInvariant) (hn : B.Normalized) :
    (gramMatrix B n e).det ≠ 0 ↔ maxGradedIdeal W ⊓ W.grading n = ⊥ := by
```

Its shape: two hypotheses on an invariant form `B` (named `hB` and `hn`; the objects `B`, `n`, `e` come from `variable` lines of the file), and a conclusion "det $\neq 0$ if and only if the maximal graded ideal meets V_n only in 0". The mathematics is in Chapter 5.

1.2.11 Sums and finitely supported functions

`∑ i ∈ s, f i` is the sum over a finite set `s : Finset ι`; `Finset.range N` is $\{0, \dots, N-1\}$, so `∑ i ∈ Finset.range N, f i` $= \sum_{i=0}^{N-1} f(i)$, and `Finset.univ` is the set of all elements of a finite type. `∑ᶠ i, f i` (`finsum`) is the sum of a family indexed by an arbitrary type, defined to be the actual sum when the support $\{i : f(i) \neq 0\}$ is finite and 0 **otherwise**. The library uses `∑ᶠ` to write identities such as the Borcherds identity as sums over all $i \in \mathbb{Z}$; every such use requires a separate proof that the support is finite, and the fidelity checks point to it (Chapter 2, warning 2.2.2). `ι →₀ R` (`Finsupp`) is the type of *finitely supported* functions $\iota \to R$ — a function together with a finite set outside which it vanishes; `μ.sum g` is the finite sum $\sum_i g(i, \mu(i))$ over the support: File `VOA/Modularity/GrowthBound.lean`.

```
def multSize {g : ℕ} (μ : Fin g × ℕ →₀ ℕ) : ℕ := μ.sum (fun p m => m * (p.2 + 1))
```

Here μ is a multiplicity function on pairs $p = (i, m) \in \{0, \dots, g-1\} \times \mathbb{N}$, and the value is $\sum_p \mu(p)\,(p_2 + 1)$. The anonymous function `fun p m ⇒ ...` is $(p, m) \mapsto m(p_2 + 1)$. Infinite sums of convergent series (`∑'`, `tsum`) also occur, in the analytic chapters; `∑'` of a non-summable family is again 0 by convention; `HasProd f a` is the proposition that the infinite product of f converges (unconditionally) to a, the honest alternative to a junk-valued `∏'`. `∏ i ∈ s, f i` is a finite product.

Supports and finiteness. `Function.support f` is the set $\{i : f(i) \neq 0\}$. For a set `S : Set X`, `S.Finite` and `S.Infinite` are the propositions that S is finite, infinite; `Set.toFinite S` is the proof of `S.Finite` when X itself is finite. For a type, `Finite X` says X has finitely many elements and `Fintype X` supplies an explicit enumeration. `Nat.card X`, `Set.ncard S` and `s.card` (for a `Finset`) count elements; **the first two are 0 for infinite sets**, the same junk convention as `finrank`. `Set X` is the type of subsets of X, `Set.univ` the whole of X, `Set.range f` the image of f; $\in$, $\notin$, $\subseteq$, $\cap$, $\cup$ have their usual meaning. `Finset.univ.filter p` is the finite set of elements satisfying p, and `Finset.antidiagonal n` the set of pairs $(a, b) \in \mathbb{N}^2$ with $a + b = n$. `List X` is the type of finite sequences, with `List.replicate n x` the constant list of length n and `l.flatMap f` the concatenation of the lists $f(x)$, $x \in l$; `Finset.toList` lists a finite set.

1.2.12 Polynomials, power series, groups

`Polynomial ℂ` is $\mathbb{C}[x]$ and `MvPolynomial σ ℂ` the polynomials in variables indexed by σ; `Polynomial.aeval a P` evaluates P at an element a of an algebra. `PowerSeries ℂ` is $\mathbb{C}[[q]]$, with `PowerSeries.X` the variable q and `PowerSeries.coeff n f` the coefficient of q^n. The power series in the headline theorem is File `VOA/Modularity/JFunction.lean`.

```
noncomputable def JShift : PowerSeries ℂ := jShift - (744 : ℂ) • PowerSeries.X
```

whose meaning — $qJ(q) = q\,(j(q) - 744) = 1 + 196884\,q^2 + \cdots$, with `jShift` the series of $q\,j(q)$ — is established in Chapter 33. A definition may need a structure on a type that is not found automatically; it is then supplied locally with `letI`: File `VOA/Modules/ZhuPolynomialSimplicity.lean`.

```
def ZhuPolynomialRelation (P : Polynomial ℂ) : Prop :=
  letI := instRingA W
  letI := instAlgebraA W
  Polynomial.aeval (mk W W.conformalVector) P = 0
```

This says $P([\omega]) = 0$ in Zhu's algebra $A(W)$, where the ring and algebra structures of $A(W)$ are installed by the two `letI` lines (Chapter 12). `haveI` is the same for a proposition. Finally, `Subgroup G` is the type of subgroups of a group G, and `Subgroup.zpowers g` the cyclic subgroup $\langle g\rangle$: File `VOA/Moonshine/LatticeInvolution.lean`.

```
noncomputable def leechVOAPlus :
    VertexOperatorAlgebra (orbifold (Subgroup.zpowers leechTheta)).carrier :=
  orbifoldVOA (Subgroup.zpowers leechTheta)
```

which is $V_\Lambda^+ = V_\Lambda^{\langle\theta\rangle}$, the fixed points of the involution θ, as a VOA on the carrier (`.carrier`) of the fixed-point subspace (Chapter 32).

Rings, units, numbers. `CommRing R` is a commutative ring structure; `algebraMap R A` is the structure map $R \to A$ of an R-algebra; `Subalgebra R A` is a subalgebra. `A →ₐ[ℂ] B` and `A ≃ₐ[ℂ] B` are algebra homomorphisms and isomorphisms (`AlgEquiv.ofAlgHom` builds one from two mutually inverse homomorphisms), `A →+ B` an additive homomorphism (`f.toAddMonoidHom` forgets the rest of a structured map), and `Additive G` the additive version of a multiplicative group. `AddSubgroup G` is an additive subgroup and `Equiv.neg` negation as a bijection. `IsUnit a` says a is invertible, `Rˣ` (postfix `ˣ`) is the group of units, `a⁻¹` the inverse (with the junk value `0⁻¹ = 0` in a field), `a ^ n` a power (`zpow` for integer exponents), and `Commute a b` says $ab = ba$. `Odd n`, `a ∣ b` (divides), `Nat.Coprime m n`, `n.factorial` (also `n !`) and `Nat.choose n k` (written `n.choose k`) are the usual integer notions. `Complex.I` is i, `Complex.exp` the exponential, `Real.pi` is π, `Real.sqrt` the square root (junk value 0 on negative numbers), and `CFC.sqrt` the square root of a positive semidefinite matrix by the continuous functional calculus. `f ∘ g` is composition, `∃! x, P x` unique existence, `x.val` the underlying element of an element of a subtype (or of `Fin n`), `Subtype.ext` says two such elements are equal when their values are, and `ofLex` strips the lexicographic-order synonym from a tuple.

Polynomials and series. `Polynomial.X` and `Polynomial.C c` are the variable and the constant c; `Polynomial.eval x P` is $P(x)$; `P.natDegree` is the degree (junk value 0 for $P = 0$) and `P.leadingCoeff` its leading coefficient. For several variables, `MvPolynomial.X i`, `MvPolynomial.C`, `MvPolynomial.aeval`, `MvPolynomial.lcoeff m` (the coefficient of the monomial m, as a linear map; `lcoeff` also exists for `Polynomial` and `PowerSeries`), `MvPolynomial.pderiv i` ($\partial/\partial x_i$) and `MvPolynomial.weightedHomogeneousSubmodule R w d` (the polynomials of weighted degree d). `PowerSeries.mk a` is the series $\sum a_n q^n$. Mathlib's modular forms appear as `ModularForm Γ k` (weight-k forms for a group Γ) and their q-expansions `qExpansion`; the Eisenstein-series lemma `EisensteinSeries.E_qExpansion_coeff` gives their coefficients (Chapters 14 and 33).

Lie theory. `LieRing L` and `LieAlgebra ℂ L` give a Lie bracket `⁅x, y⁆`; `L →ₗ⁅ℂ⁆ L'` (`LieHom`) is a Lie algebra homomorphism, `LieSubalgebra ℂ L` a Lie subalgebra, `UniversalEnvelopingAlgebra ℂ`

`L` is $U(L)$, `IsSl2Triple h e f` says (h, e, f) satisfies the $\mathfrak{sl}_2$ relations, and `oneCochain`, `twoCochain`, `twoCocycle`, `LieAlgebra.ofTwoCocycle` are Mathlib's Lie algebra cochains, cocycles and the central extension defined by a cocycle — how the Virasoro algebra is built from the Witt algebra (Chapter 3). `IsSimpleModule R M` and `IsSemisimpleRing R` are the module-theoretic notions; for a lattice of subspaces, `sSup` and `sInf` are the sum and intersection of a set of subspaces. `Semiring`, `AddCommMonoid`, `LinearOrder` and `NoZeroDivisors` are the evident algebraic and order classes, appearing as instance arguments. `Ideal R` is the type of ideals of a ring, `Ideal.span s` the ideal generated by s, `RingHom.ker f` the kernel of a ring homomorphism, and `I.mkQ` (for a subspace or ideal I) the quotient map $X \to X/I$. For polynomials, `P.derivative` is P' and `P.eval x` evaluation, so `M.det.eval x` and `M.det.derivative.eval x` evaluate a polynomial determinant and its derivative; `MvPolynomial.weightedHomogeneousComponent w d P` is the weighted degree-d part of P. `Unit` is the one-element type, `l.sort r` sorts a list or finite set by a relation r, and `cmp a b` compares two elements of a linear order. Hypothesis names that are words (`hsum`, `hne`, `hB`) are just labels chosen by the authors; only their types matter. `Submodule.Quotient.restrictScalarsEquiv` and lemma names such as `Submodule.mem_span_singleton_self` ($x \in \mathbb{C}x$) occur in a few statements and mean what they say.

1.2.13 How a Lean statement can fail to mean what it says

Everything above is vocabulary. The point of learning it is to recognise the ways in which a correct, machine-checked statement can still fail to be the intended theorem. The book's fidelity checks are organised around the following list; each entry has occurred in this library, and the instances are catalogued in Chapter 43, Sections 43.2–43.2.8.

(F1) **Unsatisfiable structure.** Its axioms are contradictory, so every theorem about it is vacuous. Instances: the original `TwistedModule` (repaired; Chapter 34), the unrepaired `SuperTwistedModule.jacobi` (Chapter 17; Section 43.2.1), and `VOA.Unitary`, whose "positive-definiteness" is required of a *bilinear* (not Hermitian) form and so cannot hold in dimension ≥ 2 (Chapter 12, Proposition 12.31). The `¬ Nonempty` theorem quoted in Section 1.2.7 is the library recording such a case itself.

(F2) **Predicate satisfied too easily.** `IsLowestWeight N h` does not require the lowest weight space to be nonzero, so the zero module is lowest-weight of every weight (Chapter 12); `SelfContragredient` holds for every module (Chapter 12).

(F3) **Predicate satisfied too rarely.** `IsCommutative` forces $V = \mathbb{C}\mathbf{1}$, so the "commutativity theorems" are statements about the trivial VOA only (Chapter 4).

(F4) **Definition differs from its name.** The library's structure transcribing Gannon's axioms lacks translation covariance (Chapter 4); it was called `VertexAlgebra` until the release, when it was renamed `PreVertexAlgebra` and the name `VertexAlgebra` was given to the translation-covariant notion. Similarly the universal affine VOA $V^k(\mathfrak{g})$, formerly `simpleAffineVOA`, is now `universalAffineVOA` (Chapter 23). Still open: the super structure `SuperVertexAlgebra`, which has the same omission, keeps the old-style name (Chapter 17); the library's `generated` subalgebra always contains ω (Chapter 5); its `fusionCoeff` is identically 0, a placeholder and not a fusion rule (Chapter 12).

(F5) **Junk values** in a conclusion (`finrank`, $\sum^{\mathrm{f}}$, truncated subtraction), Section 1.2.8.

(F6) **A hypothesis that is never established**, making the theorem conditional although its axiom list is clean (Section 1.3.4); or a hypothesis that is redundant or tautological, which is harmless but misleading (for instance the hypothesis `homega` still carried by the definition `inner`, Remark 5.15).

(F7) **Quantifier order or a missing quantifier**: a bound that should be uniform but depends on the data, or the reverse (Section 1.2).

(F8) **A conclusion satisfied by a trivial or wrong object**: the zero VOA satisfies every axiom; a non-simple square-zero extension has the same character as $V^\natural$ (Chapter 38). Headline theorems therefore pin the data and assert simplicity.

(F9) **Choices and instances** that change meaning: a theorem about a chosen witness (Section 1.2.7), or an operation whose meaning comes from an unexpected instance (Example 1.2, Section 1.2.3).

1.2.14 A second structure: super vertex algebras

The same reading technique applies to every structure of the library. As a second example, and because it shows two further pieces of vocabulary (gradings indexed by $\mathbb{C}$ and by `ZMod 2`), here is the library's super vertex algebra. File `VOA/Core/SuperVertexAlgebra.lean`.

```
structure SuperVertexAlgebra (𝒱 : Type u) [AddCommGroup 𝒱] [Module ℂ 𝒱] where
  grading : ℂ → Submodule ℂ 𝒱
  isInternal : DirectSum.IsInternal grading
  finrank : ∀ h, FiniteDimensional ℂ (grading h)
  parity : ZMod 2 → Submodule ℂ 𝒱
  parity_isInternal : DirectSum.IsInternal parity
  Y : 𝒱 →ₗ[ℂ] (End ℂ 𝒱)⟦z^±⟧
  vacuum : 𝒱
  vacuum_mem : vacuum ∈ grading 0
  vacuum_parity : vacuum ∈ parity 0
  grading_mode : ∀ {h k : ℂ} (u : 𝒱), u ∈ grading h → ∀ (v : 𝒱), v ∈ grading k →
    ∀ (n : ℤ), mode (Y u) n v ∈ grading (h + k - n - 1)
  parity_mode : ∀ {p q : ZMod 2} (u : 𝒱), u ∈ parity p → ∀ (v : 𝒱), v ∈ parity q →
    ∀ (n : ℤ), mode (Y u) n v ∈ parity (p + q)
  vacuum_Y : Y vacuum = (1 : (End ℂ 𝒱)⟦z^±⟧)
  creation : ∀ u : 𝒱, mode (Y u) (-1) vacuum = u ∧ ∀ n : ℤ, 0 ≤ n → mode (Y u) n vacuum = 0
  locality : ∀ {p q : ZMod 2} (u : 𝒱), u ∈ parity p → ∀ (v : 𝒱), v ∈ parity q →
    Localε (koszul p q) (Y u) (Y v)
  regularity : ∀ u v : 𝒱, ∃ N : ℤ, ∀ n : ℤ, N ≤ n → mode (Y u) n v = 0
```

From the mathematics to the Lean statement

How to read it. Data: two gradings (`grading`, indexed by $\mathbb{C}$ so that half-integer weights are allowed while modes remain indexed by $\mathbb{Z}$; `parity`, indexed by `ZMod 2`), the vertex operator `Y` and the `vacuum`. Everything else is an axiom. Note the field `finrank`: despite its name it is the *proposition* that each graded piece is finite-dimensional, not a number. `creation` is a conjunction `∧` of two clauses. `locality` is super-locality with the Koszul sign `koszul p q` $= (-1)^{pq}$, defined in Chapter 2 (`Localε`, Definition 2.44); `regularity` has the quantifier order "for all u, v there is N". No relation between weight and parity (spin–statistics) is imposed; the theory of super vertex algebras is Chapter 17. The Moonshine construction does not use this structure.

Physical meaning

A super vertex algebra is the chiral algebra of a theory with fermions: odd states create fermionic fields, which anticommute at spacelike separation, whence the sign $(-1)^{pq}$ in locality. Free fermions and the bc and $\beta\gamma$ ghost systems of string theory are examples.

What the machine verified

A definition. `#print axioms VOA.SuperVertexAlgebra` lists `[propext, Classical.choice, Quot.sound]` (run for this chapter).

1.2.15 Reading the headline statement

Here is the main theorem of the Moonshine part of the library, as it stands in the source. File `VOA/Moonshine/TopPairs.lean`.

```
theorem moonshine :
    ∃ V : VertexOperatorAlgebra Vnat,
      V.Y = Ynat VnatAxioms.wbarL ∧ V.vacuum = vacNat ∧ V.conformalVector = omegaNat ∧
      V.centralCharge = 24 ∧
      V.grading 1 = ⊥ ∧
      Module.finrank ℂ (V.grading 2) = 196884 ∧
      (∀ n : ℕ, (Module.finrank ℂ (V.grading (n : ℤ)) : ℂ) = PowerSeries.coeff n JShift) ∧
      V.IsSimple :=
  moonshine_of_topPairs (by norm_num) topPairs_one
```

Its full name is `VOA.Moonshine.moonshine`. It has *no arguments*: there is nothing before the colon. Its statement is an existential, `∃ V : VertexOperatorAlgebra Vnat, ...`, whose body is a conjunction of eight clauses. Read it as: *there is a vertex operator algebra structure V on the space* `Vnat` *such that*

(1) its vertex operator is the explicitly constructed block map `Ynat VnatAxioms.wbarL`;

(2) its vacuum is the explicit vector `vacNat`;

(3) its conformal vector is the explicit vector `omegaNat`;

(4) its central charge is 24;

(5) its weight-one space is zero, $V_1 = 0$;

(6) $\dim V_2 = 196884$;

(7) for every $n \in \mathbb{N}$, $\dim V_n$ (cast to $\mathbb{C}$) is the q^n-coefficient of the power series `JShift`;

(8) it is simple.

The term after `:=` is the whole proof: it applies an earlier theorem, `moonshine_of_topPairs`, to a numerical fact checked by `norm_num` and to the theorem `topPairs_one`. Both are explained in Chapter 42.

From the mathematics to the Lean statement

What to notice. (a) The first three clauses *pin* the structure to the explicit Frenkel–Lepowsky–Meurman data, so the existential cannot be satisfied by some unrelated object on the same space. (b) Clause (7) contains a *cast*: `Module.finrank` is a natural number, and `(... : ℂ)` turns it into a complex number so that it can be compared with a coefficient of a power series over $\mathbb{C}$; and `(n : ℤ)` casts $n \in \mathbb{N}$ to an integer weight. (c) The source writes `Module.finrank ℂ (V.grading 2)`, but `V.grading 2` is a subspace, not a type: Lean silently inserts the coercion `↥`, and Lean's own printout of the statement shows `Module.finrank ℂ ↥(V.grading 2)`. (d) Clause (8) is essential: a non-simple VOA (the "square-zero extension", Chapter 38) has exactly the same central charge and graded dimension. (e) Each of the defined terms `Vnat`, `Ynat`, `vacNat`, `omegaNat`, `JShift`, `grading` and `IsSimple` must be traced to its definition. The places are listed in Table 1.3, and the complete clause-by-clause fidelity

check is Chapter 42, Section 42.8.

Physical meaning

The theorem says that the chiral conformal field theory of the $\mathbb{Z}/2$-orbifold of 24 free bosons on the Leech torus exists as a mathematical object, has central charge 24, has no conserved weight-one currents ($V_1 = 0$: no continuous symmetry), has 196884 states of weight two, and has partition function $J(q)$; simplicity says that the theory has a unique vacuum sector with no decoupled subsector.

What the machine verified

Unconditional: the theorem has no hypotheses. `#print axioms VOA.Moonshine.moonshine`, run for this chapter, gives

```
'VOA.Moonshine.moonshine' depends on axioms: [propext, Classical.choice, Quot.sound]
```

so the proof uses neither `sorry` nor any project-specific axiom (the library has none; Chapter 3).

1.2.16 Namespaces and full names

Declarations live in namespaces, and the full name records them: `VOA.VertexOperatorAlgebra.L` is the definition `L` in the namespace `VertexOperatorAlgebra` inside `VOA`. The whole library is inside `VOA`; the Moonshine part is mostly inside `VOA.Moonshine`. Inside a namespace, and after an `open` command, Lean lets one write short names, so a printed statement may say `finrank` for `Module.finrank` or `End` for `Module.End`. The book gives full names in the text and the file in which each declaration lives.

1.3 What the machine guarantees

1.3.1 The kernel

When Lean accepts a file, its *kernel* — a small program that implements the rules of the type theory — has checked every proof term in it. Everything a user writes, including the automation ("tactics") that produces proofs, is outside the kernel and does not need to be trusted: if a tactic produced a wrong proof, the kernel would reject it. What a reader must trust is therefore (i) the kernel and the logic, (ii) the axioms, and (iii) the *statements*. This book is about (iii).

1.3.2 Escape hatches: `sorry` and friends

Lean has an escape hatch, `sorry`, which closes any goal without proof; internally it is an axiom `sorryAx`. A statement proved with `sorry` is not proved. The project's policy forbids `sorry`, `admit`, `native_decide` (which trusts the compiler rather than the kernel), `implemented_by` and `stop` in library code; the repository checker enforces it.

1.3.3 Axioms and `#print axioms`

Lean's logic uses three standard axioms beyond its type theory: `propext` (logically equivalent propositions are equal), `Quot.sound` (quotient types behave as quotients) and `Classical.choice` (the axiom of choice, from which the law of the excluded middle follows). All of classical mathematics and all of Mathlib use them. A user may add further axioms with the keyword `axiom`, and Lean will then

accept anything that follows from them; a false axiom makes everything provable. The command `#print axioms foo` traverses the proof of `foo` down to the kernel and lists every axiom it uses.

The library contains no project axiom. Until 19 October 2026 it contained exactly one, `VOA.pbw`; that declaration is now a theorem with the same name and type. File `VOA/Foundations/AffineLie.lean`.

```
theorem pbw : PBWPrinciple :=
  ⟨fun κ hκ k => AffineLie.vacuumVector_ne_zero_of_induction κ hκ k,
    fun p rho => PBWTheorem.bottom_injective p rho⟩
```

`PBWPrinciple` bundles two consequences of the Poincaré–Birkhoff–Witt theorem: that the vacuum vector of an affine vacuum module is nonzero, and that a module embeds in the module induced from it. Mathlib does not contain PBW, and the library proves the needed relative form itself (Chapter 3, Section 3.10.6). Its exact statement, its proof, and which parts of the library use it are in Chapter 3, Section 3.10. Earlier editions flagged every result that depended on it; those flags are historical (Section 3.2). For example, run for this book at an earlier commit, after `VOA.pbw` became a theorem (not re-run for this edition):

```
'VOA.AffineLie.vacuumVector_ne_zero' depends on axioms: [propext, Classical.choice,
 ↪  Quot.sound]
```

The construction of $V^\natural$ does not use it, as the axiom report of the headline theorem (Section 1.2.15) certifies.

1.3.4 A clean axiom list does not make a theorem unconditional

`#print axioms` reports *axioms*, not *hypotheses*. A theorem `theorem bar (h : SomeHypothesis) : Conclusion` can have a perfectly clean axiom list and still prove nothing unconditional: `h` is an explicit argument, and the theorem says only "if `SomeHypothesis` then `Conclusion`". The book therefore uses two labels, and never blurs them:

- **unconditional**: the statement has no hypotheses beyond the objects it speaks about and their defining structure, and its axioms are the standard three;
- **`#print axioms`-clean, conditional on** H: the statement has an explicit hypothesis H that is not established anywhere, so it proves $H \Rightarrow C$, not C;

(Earlier editions had a third label, "uses `VOA.pbw`", for results whose axiom list contained the then project axiom; it no longer applies.) Hypotheses that are part of the mathematical statement ("let V be simple", "let $L_1 V_1 = 0$") are of course fine; the question is always whether a hypothesis is an intended condition of the theorem or an unproved input. The library contains many results of the second kind — for example Zhu-type modular invariance under Etingof-finiteness in Chapter 16 takes hypotheses `hfib` and `hrank` that are discharged only for the trivial VOA — and the status boxes name them. (Such inputs are sometimes later proved: the Arakawa–Kawasetsu weight grading `AKWeightGrading W`, long carried as such a hypothesis, is now the theorem `VOA.akWeightGrading` for every VOA.) The headline theorem `VOA.Moonshine.moonshine` has no hypotheses at all.

1.3.5 The aggregate build

`lake` is Lean's build tool. `lake build` elaborates every file of the library in dependency order and has the kernel check every proof; "green" means it finished with no errors. The project's rule is that a result counts only when the *aggregate* build of the umbrella module `VOA` is green: a file that compiles in isolation might not be imported by the library at all. The repository checker `scripts/check_repository.py` verifies that every library file is reachable from the umbrella, that no forbidden escape hatch occurs, and that no project `axiom` declaration exists.

Trap / dead end

Audit trap. Running a bare `lake env lean` on a file can silently drop the option `maxSynthPendingDepth` that the library's build sets; elaboration may then fail in a way that inserts `sorryAx`. Axiom audits are therefore run only through `lake build` or through `lake env lean -DmaxSynthPendingDepth=3`. All axiom reports in this chapter were obtained the second way.

1.3.6 The book's own machine checks

The book itself is checked by machine in three ways, by `python3 scripts/textbook/sync.py check`.

- **STALE QUOTE.** Every `leancode` block of every chapter is compared with the Lean sources (after removing comments and normalising whitespace); a block that does not occur verbatim is reported. This is what guarantees that the Lean code printed in the book is the code in the library. Tool output, such as `#print axioms` reports, is printed in a different (plain) style and is not compared.
- **MISSING PATH.** Every quoted declaration must be accompanied by a citation of the file that defines it (the "File ..." lines); `scripts/textbook/cite_paths.py` checks this.
- **NO PHYSICS.** Every definition and theorem must be followed by a physics box.

In addition, `sync.py` records for every `.lean` file the chapter that documents it and its hash at the documented commit, so that when the library changes it lists the new, changed and deleted files chapter by chapter. Where a chapter needed a Lean computation of its own — a counterexample, or a proof that a definition is degenerate — the computation was kept outside the library and compiled against the library; these checks are not part of this release, and the chapters say so where they use one. Finally, every defect of the library found while writing or refereeing the book (a definition that is vacuous, weaker or stronger than its name, a redundant hypothesis, a wrong docstring) is reported, with its evidence and a severity, in the chapter where it occurs and collected in the catalogue of Chapter 43 (Sections 43.2, 43.2.9 and 43.2.8).

1.3.7 The verification record for this chapter

Run for this chapter at an earlier commit (the snapshot against which this chapter was first written; this record is historical and was not re-run for this edition), with `lake env lean -DmaxSynthPendingDepth=3` on a scratch file importing the relevant modules (the library's compiled files were present; no build was run): `#print axioms` of `VOA.Moonshine.moonshine`, `VOA.Aut`, `VOA.VertexOperatorAlgebra` and `VOA.SuperVertexAlgebra` each gave `[propext, Classical.choice, Quot.sound]`; `VOA.mode` and `VOA.FormalDist.instOne` gave no axioms; `VOA.AffineLie.vacuumVector_ne_zero` gave the standard three and `VOA.pbw` (then an axiom). The repository checker reported, in that run,

```
Repository check passed: 1867 library files scanned; 1867 reachable through 4676 local
↪  import edges; 1 sanctioned axiom declaration(s).
```

In a later run, after `VOA.pbw` became a theorem (also not re-run for this edition), `VOA.AffineLie.vacuumVector_ne_zer` gave the standard three axioms only, and the checker reported "0 sanctioned axiom declaration(s)". *Reported by the project's build record for an earlier commit and not re-run for this chapter:* the aggregate `lake build` was green and the axiom-audit script passed. Since then the aggregate build `bash scripts/campaign_build.sh VOA` (the full `lake build VOA` under the project's memory-capped wrapper) was green in two pre-release builds on 2026-10-28 (18,901 jobs, and 18,907 jobs after merging the then-current `origin/main`); `scripts/check_repository.py` passed (10,431 library files,

all reachable, 0 project axioms) and `scripts/audit/run_axiom_audits.py` passed (5,958 reports across 24 probes). The checks at the release commit are recorded in Chapter 43, Section 43.1.9, which collects the verification record of the whole book.

1.3.8 Traps that concern the whole book

Trap / dead end

Recorded traps. (1) A structure with unsatisfiable axioms makes every theorem about it vacuous; the library's `TwistedModule` had this defect and was repaired, and the same over-quantification remains, unrepaired, in `SuperTwistedModule.jacobi` (Chapters 34 and 17). (2) Graded dimension does not characterise $V^\natural$: a non-simple square-zero extension has the same central charge and character, so simplicity is essential (Chapter 38). (3) `Module.finrank` of an infinite-dimensional space is 0, and $\sum^{\mathrm{f}}$ of an infinitely supported family is 0. (4) The library's `fusionCoeff` is not the fusion rule; it is identically zero (Chapter 12). (5) A bare `PreVertexAlgebra` does not satisfy the Borcherds identity (above, and Chapter 4). (6) Audit only through `lake build` or with `-DmaxSynthPendingDepth=3`.

1.4 Global conventions

The following conventions are used throughout the library and the book. Each is defined in full, with its Lean source, in the place indicated, usually with a worked example (the mode convention is worked out in Example 1.1, the odd-integer encoding in Section 1.2.8); the table is a quick reference, not a definition. To decode an entry, read the "Meaning" column as the mathematical expression that the Lean expression in the first column denotes.

Lean	Meaning	Defined in
`FormalDist 𝒲, 𝒲⟦z^±⟧`	functions $\mathbb{Z} \to \mathcal{W}$, i.e. series $\sum_k f(k)z^k$; `f k` is the coefficient of z^k	Def. 2.1
`mode f n`	$f_{(n)} = f(-n-1)$, the coefficient of z^{-n-1}	Def. 2.7
`mode (Y u) n`	the operator $u_{(n)}$ in $Y(u,z) = \sum_n u_{(n)}z^{-n-1}$; `Y u k` is $u_{(-k-1)}$	Def. 2.7, 4.1
`V.smul u n v`	the n-th product $u_{(n)}v$ (not scalar multiplication)	Def. 4.1
`W.L n`	$L_n = \omega_{(n+1)}$, i.e. `mode (Y conformalVector) (n + 1)`; $L_0 = \omega_{(1)}$, $L_{-1} = \omega_{(0)}$	Def. 4.4
`V.T`	$Tu = u_{(-2)}\mathbf{1}$; equals L_{-1} in a VOA	Def. 4.2
`deriv`	formal ∂_z: coefficient of z^n is $(n+1)f(n+1)$; in modes $(\partial f)_{(m)} = -mf_{(m-1)}$	Def. 2.7
`1 : (End ℂ 𝒱)⟦z^±⟧`	the identity field (only the z^0 coefficient is nonzero)	Example 1.2
`grading : ℤ → Submodule ℂ 𝒱` with `DirectSum.IsInternal`	a $\mathbb{Z}$-grading $V = \bigoplus_n V_n$ (super: indexed by $\mathbb{C}$, parity by `ZMod 2`)	Def. 4.1; §1.2.14
`N.weight α`	the weight-α space M_α of a module, $\alpha \in \mathbb{C}$	Chapter 12, §12.1
`modeT r i k`	twisted-sector mode $h_i(k/2)$: half-integer modes indexed by odd integers $k \mapsto k/2$	Chapter 34, §34.5
`TwistedModule.YM u k`	the twisted mode $u_{(k/N)}$ for an automorphism of order N	Def. 34.4
`gBinom n k`	$\binom{n}{k} = n(n-1)\cdots(n-k+1)/k!$ for $n \in \mathbb{Z}$, $k \in \mathbb{N}$	Def. 2.14
`cbz n k`	$\binom{n}{k}$ with $k \in \mathbb{Z}$, defined to be 0 for $k < 0$	Def. 2.14
`negOnePow n`	$(-1)^n$	Def. 2.14
binomial expansion	$(z_1+z_2)^n = \sum_{k\geq 0}\binom{n}{k}z_1^{n-k}z_2^k$, always in nonnegative powers of the *second* variable	§2.4

Lean	Meaning	Defined in
`Local a b`	$(z_1 - z_2)^N [a(z_1), b(z_2)] = 0$ for some N	Def. 2.41
`Module.finrank`	dimension; 0 for infinite-dimensional spaces	§1.2
$\sum^{\mathrm{f}}$	finitely supported sum; 0 if the support is infinite	warning 2.2.2
$\mathbb{N}$, casts	$\mathbb{N} \ni 0$; `(n : ℂ)`, `↑n` cast integers to $\mathbb{C}$	§1.2
Virasoro	$[L_m, L_n] = (m-n)L_{m+n} + \frac{m^3-m}{12} c\, \delta_{m+n,0}$	Def. 3.2, 4.4

1.5 How to read the boxes

Four kinds of coloured box recur. They have fixed jobs.

From the mathematics to the Lean statement

The fidelity check (grey). This is the heart of the book. It decodes every symbol and convention of the Lean statement; lists *every* hypothesis, including those inherited from `variable` lines, and says what each means and whether it is intended, harmless, or an open input; traces every defined term to its definition; says whether the Lean statement is the same as, stronger than, or weaker than the textbook statement; and asks how it could have been wrong or vacuous. A referee who disagrees with a fidelity check has found something important.

Physical meaning

The physics box (blue). Says what the statement means in two-dimensional conformal field theory, string theory or statistical mechanics: which states, fields, operator product expansions, symmetries, partition functions or orbifolds it is about, and why a physicist would expect it. Heuristics are labelled as such; the physical picture never substitutes for the proof.

What the machine verified

The status box (green). The machine status, honestly: unconditional, or conditional on named hypotheses (listed); the result of `#print axioms` where it was run, and whether it was run by the chapter's author or is reported from elsewhere; (in earlier editions) whether `VOA.pbw` was used; numerical evidence clearly labelled as evidence.

Trap / dead end

The warning box (red). Traps, dead ends, corrected mistakes and defects of the library, with the counterexample or other evidence. Every defect recorded in a warning box is also collected in the catalogue of Chapter 43 (Section 43.2).

Each chapter ends with a **Referee's checklist**: a table of the chapter's headline declarations with, for each, the intended meaning in one sentence, the hypotheses, conditional/unconditional, and a pointer to its fidelity check. A referee who wants to audit a chapter quickly can start from that table.

1.6 A map of the book

1.6.1 The parts

The book has eight parts. Parts I–V document the general library; Part VI formalizes recent research theorems, and conditional reductions of further ones, on top of it; Part VII constructs the Moonshine module; Part VIII records how all of it was verified.

Part I, Foundations. This chapter; Chapter 2, formal calculus and locality (formal distributions, modes, the delta function, generalised binomials, locality and its delta-function characterisation); Chapter 3, the Lie-theoretic inputs (Witt, Virasoro and affine Lie algebras, vacuum modules, root data, lattices) and the PBW theorem `VOA.pbw` (formerly a project axiom, now a theorem); Chapter 4, the axioms of vertex algebras and VOAs, Dong's lemma, Goddard uniqueness, the Borcherds identity, skew-symmetry and the reconstruction theorem; Chapter 5, structure theory: the Lie algebra V_1, automorphisms, ideals, simplicity and quotients, homomorphisms, generated subalgebras, invariant bilinear forms and Li's criterion "simple $\iff$ nondegenerate".

Part II, Examples, deformations and rigidity. Chapters 6–11: Heisenberg and lattice VOAs; the Virasoro VOA, its Verma modules and the Kac determinant; first-order deformations and the rigidity of Virasoro minimal models; affine $\mathfrak{sl}_2$ and its rigidity at every admissible level; filtrations, the C_2 algebra and presentations. A chapter on affine $\mathfrak{sl}_3$ is in preparation. Chapter 11 also contains a second criterion for the surjectivity of Li's jet map, *generator-word spanning* (Section 11.5): if Li's filtration equals the filtration by generator words, the jet map is onto, for any VOA and any finite family of homogeneous generators. Unlike the earlier criterion, it does not force C_2-cofiniteness, and it is the surjectivity half of the classical-freeness results of Chapters 20 and 24.

Part III, Representation theory. Chapter 12: weak, admissible, logarithmic and ordinary modules, Zhu's algebra, C_2-cofiniteness, contragredients, intertwining operators and the rationality hierarchy; Chapter 13: Zhu's bijection via the Frenkel–Zhu tower.

Part IV, Modularity. Chapters 14–16: modular forms and the analytic toolkit; Zhu's modularity theorem; quasi-lisse vertex algebras. Chapter 16 should be read with its own scope: "quasi-lisse" is not defined in the library (the theorems assume the weaker finiteness of zeroth Poisson homology, `EtingofFinite`). The Arakawa–Kawasetsu modular linear differential equation (Theorem 5.1) is proved conditionally only on `EtingofFinite`: one monic MLDE, of some unbounded order, satisfied by every abstract analytic genus-one block at a square-bracket primary insertion (`VOA.IsSqPrimary.exists_monicMLDEOn_all_analyticBlocks_of_etingofFinite_uncond`; its former inputs, the weight grading `VOA.akWeightGrading` and the Serre closure `VOA.e46SerreClosed`, are theorems). Unconditionally, $L_{-4/3}(\mathfrak{sl}_2)$ is not C_2-cofinite but has finite-dimensional zeroth Poisson homology, and its vacuum one-point blocks satisfy one monic MLDE of unspecified order (`VOA.exists_monicMLDEOn_all_analyticBlocks_simpleSl2QL`; Arakawa–Kawasetsu's order 2 is not proved).

Part V, Super, logarithmic and unitary theories. Chapters 17–19: super vertex algebras; the triplet and doublet algebras; graded unitarity in the sense of Arabi Ardehali, Beem, Lemos and Rastelli, the Lee–Yang model and weight-one positivity of affine $\mathfrak{sl}_2$ at level $-8/5$. Chapter 19 proves the positivity clauses of graded unitarity of the boundary minimal models $M(2, 2n+1)$ through filtration degree two only; the full conjecture is not claimed. Its last section (Section 19.14) proves the first full instance of the predicate `GradedUnitary` in the library: for every real $k < -2$ the *universal* affine VOA $V^k(\mathfrak{sl}_2)$, with its normalised form, compact real structure and current-length flag, is graded unitary, with no hypothesis beyond $k < -2$.

Part VI, Two recent theorems, formalized. Chapters 20–29. Despite its title, the part has ten chapters and formalizes recent research of several kinds: some chapters prove published theorems, and others reduce further research statements to named, unproved inputs, and they say so.

- Chapter 20: the Arakawa–Dai theorems for $L_k(\mathfrak{sl}_2)$ at the boundary admissible levels $k = -2 + 2/(2m+1)$, $m \geq 1$, proved with only the hypothesis $1 \leq m$. The vacuum character is proved as stated. Classical freeness, the paper's Theorem 1.1, is one Lean theorem, `arakawaDai_theorem_1_1` (Theorem 20.26): the presented algebra $\mathbb{C}[e,h,f]/(eQ^m, hQ^m, fQ^m)$ is isomorphic to the C_2-algebra R_V, and its arc algebra maps isomorphically onto Li's associated graded. Since the library has no functor J_∞, the arc algebra $J_\infty R_V$ is realized as the jet algebra of the presented algebra, with its universal property. Its Virasoro companion (Section 20.12) proves, for every $m \geq 0$ and with no hypothesis, that the minimal model $L(c_{2,2m+3}, 0)$ is classically free, with $R_L \cong \mathbb{C}[T]/(T^{m+1})$. A further section (Section 20.13) describes finite commutative-algebra files that prove no theorem about a VOA and are kept because Chapter 24 reuses them.
- Chapter 21: Huang's theory. The ordinary modules of every strongly rational VOA form a braided monoidal category, and the logarithmic modules of a C_2-cofinite VOA form a braided tensor category. Rigidity, the Verlinde formula and the modular category are proved only for *nice* VOAs, which the library defines as strongly rational *and pseudo-unitary*; Huang's theorems need no pseudo-unitarity. A first step of its removal is proved: $V' \cong V$ and the vacuum-fusion chain hold for every strongly rational VOA (`VOA.contra_vacuum_equiv_of_stronglyRational`). Rigidity is two-sided (`VOA.Huang.HuangRigid.rigid_ordinary` gives Mathlib's `RigidCategory`). The congruence property has named, hypothesis-free theorems (`dlnCongruenceInput_holds`, `zhuCongruenceInput_holds`, Theorem 21.20); of Ng–Schauenburg's Theorem 6.8 only the kernel half is proved.
- Chapter 22: the Gannon–Rayhaun classification of nice VOAs of central charge one, forward and converse, with no hypothesis. "Rational" in `Nice` is the library's `AdmissiblyRational`; for C_2-cofinite VOAs Dong–Li–Mason rationality implies it (`VOA.Classification.COne.DLMRat.admissiblyRational_of_dlmRational`), and the converse is open; the classification and converse are stated for carriers in `Type 0`.
- Chapter 23: the universal affine VOA $V^k(\mathfrak{g})$ for an arbitrary finite-dimensional Lie algebra with an invariant form and the Casimir data ("Lie data"), at every non-critical level; Lie data for every finite-dimensional simple $\mathfrak{g}$ given a nondegenerate symmetric invariant form; the simple quotient $L_k(\mathfrak{g})$, simple, with weight one spanned by the currents; and concrete simple Lie algebras in Lean: $\mathfrak{sl}_n$, the simply-laced $\mathfrak{sl}_3, \mathfrak{so}_8, \mathfrak{e}_6, \mathfrak{e}_7, \mathfrak{e}_8$ as weight-one spaces of lattice VOAs, and $\mathfrak{g}_2, \mathfrak{f}_4, \mathfrak{e}_6$ from kernel-checked structure constants. These results are unconditional. That the algebras are of the named Cartan type is not claimed (the classification of simple Lie algebras is not formalized).
- Chapters 24–27, the Deligne series: classical freeness of $L_k(\mathfrak{g})$ for the seven types $A_2, G_2, D_4, F_4, E_6, E_7, E_8$ at $k = -1 - h^\vee/6$, with the explicit presentation of R_V by the quadrics I_2^{ns}. Chapter 24 proves, with no hypothesis, the reduction of classical freeness to one inequality of dimensions, the explicit presentation (I_2^{ns} lies in the kernel) for all seven types, current-jet surjectivity and the geometric carrier; its carrier chain, certified type by type by large kernel-checked integer certificates, is conditional on two fusion inputs, U5 and U6. Chapter 25 proves for all seven types the lower bound $\dim V_N \geq c_N$, where c_N are the coefficients of the normalised solution of the second-order Arakawa–Kawasetsu MLDE; the argument is formal, from a vacuum quartic relation through Zhu's recursion, and does not use the general theorem of Chapter 16. It also proves a library of formal q-series identities (Jacobi triple and quintuple products, Ramanujan's differential

identities, and others). Equality $\dim V_N = c_N$ is a Lean theorem for A_2 only. Chapter 26 proves U6 by construction and reduces U5 to a total-dimension bound and Demazure realizations; both are proved for A_2, and are named, unproved statements for the other six types. Chapter 27 states the seven final theorems. The A_2 theorem has no hypothesis (machine-confirmed: aggregate build green on 2026-10-28, `#print axioms` standard, as Chapter 27 records). The other six are **conditional**. D_4 rests on one published input, the total-dimension bound for fusion products (`D4_classicallyFree_of_inputT`; the Demazure realizations are proved in Lean for D_4). One step of the published proof of that bound is insufficient as written for D_4; the bound itself is not known to fail. G_2, F_4, E_6, E_7, E_8 rest on that bound, on the Demazure realizations, and on the star bound, a conjecture supported by numerical evidence.

Chapters 28 and 29 transfer graded unitarity through the BRST coset. Their headline is a proved implication with one explicit hypothesis, `hA`: if the simple affine VOA $L_k(\mathfrak{sl}_2)$ at the boundary admissible level, with its normalised form, compact conjugation and corrected current-and-Sugawara filtration, is graded unitary, then so is the minimal model $M(2, 2n+1)$ (Chapter 28: Lee–Yang, $n = 2$, from level $-4/3$; Chapter 29: every $n \geq 2$). The hypothesis `hA` is open for every n, so graded unitarity of $M(2, 2n+1)$ beyond filtration degree two is not claimed.

Part VII, The Moonshine module. Chapters 30–42: lattices, codes and the Leech lattice; Heisenberg and lattice VOAs and V_Λ; the involution θ and V_Λ^+; graded dimensions and J; twisted modules and the module T; the twisted Heisenberg and twisted lattice modules; the intertwiners W and $\overline{W}$; the vertex algebra on $V^\natural$ modulo one relation, and simplicity; the Golay frame and the untwisted triality; the existence of the twisted triality (two chapters); the key identity and the completion of the proof.

Part VIII, Verification. Chapter 43: the verification record, the dead ends, the numerical evidence and the open problems.

1.6.2 Dependencies

Part I is a prerequisite for everything else, and within it the order is the logical order: Chapter 2 (formal calculus) is used by Chapter 4 (the axioms), which uses Chapter 3 only for the Virasoro algebra; Chapter 5 builds on Chapter 4. In Part II, the Virasoro chapters need the Virasoro algebra of Chapter 3, the affine chapters its affine Lie algebras, and the lattice VOAs its lattice data; the rigidity chapters build on the corresponding construction chapters. Part III needs Chapter 5; the module-theoretic uses of `VOA.pbw` (through induced modules and the Frenkel–Zhu tower) lie in Chapters 12 and 13. Part IV needs Part III, and Chapter 14 for modular forms. Part VI builds on all of Parts I–V. Chapter 20 uses the affine $\mathfrak{sl}_2$ chapters (9, 10) and Li's filtration and jets (Chapter 11); Chapters 21 and 22 use the modules, Zhu's algebra and modularity of Parts III and IV, and Chapter 22 uses Chapter 21. Chapter 23 generalizes the constructions of Chapter 9 (and the affine $\mathfrak{sl}_3$ files, whose chapter is in preparation) and uses the lattice VOAs of Chapter 6. The Deligne chapters are read in order, Chapter 24 to Chapter 27; they use Chapter 23 for the algebras, Chapter 11 for Li's filtration and generator words, Chapter 20 as the model of the squeeze argument, and Chapter 15 for Zhu's recursion (in Chapter 25). Chapters 28 and 29 use the graded-unitarity predicate of Chapter 19, the affine and Virasoro algebras of Parts I–II, and the jet-ring and character results that Chapter 20 shares with them. Part VII needs Part I throughout — above all the VOA axioms and the reconstruction theorem (Chapter 4), and the automorphisms, simplicity and invariant forms of Chapter 5 — together with the modules of Chapter 12 (for the intertwiners of Chapter 37 and the Zhu-algebra arguments of Chapter 40) and the lattice data of Chapter 3; the modular function J enters in Chapter 33. Within Part VII the chapters are in logical order.

1.6.3 Two reading paths

The Moonshine path (to verify the construction of $V^\natural$): this chapter; Chapter 2 (at least formal distributions, modes, binomials and locality); Chapter 4 (the axioms, the Borcherds identity, Goddard uniqueness and reconstruction); Chapter 5 (automorphisms, ideals and simplicity, invariant forms); then Chapters 30 to 42 in order, consulting Chapter 12 for modules and Zhu's algebra when Chapters 37 and 40 use them; finally Chapter 43. A referee in a hurry can start from the end: Chapter 42, Section 42.8, decodes the headline theorem clause by clause and points back to every definition it uses.

The general path (to learn the library as a whole): Part I in order; then the examples of Chapters 6 and 7; then representation theory (Chapter 12) and modularity (Chapters 14, 15); then the remaining chapters by interest. Within Part VI the Deligne series is long enough to need a route: Chapter 11 (Li's filtration, jets and Section 11.5), Chapter 20 (the model case, $\hat{\mathfrak{sl}}_2$), Chapter 23, then Chapters 24–27 in order; a referee who wants only the final statements and their named inputs can start from Chapter 27. For graded unitarity, read Chapter 19, then Chapters 28 and 29 (the BRST coset).

1.6.4 What is proved, and what is conditional, in Parts IV to VI

The chapters of Parts IV to VI mix unconditional theorems with conditional reductions, and their titles do not say which is which. Table 1.2 records the status of their headline results as the chapters themselves state it. "Unconditional" means: `#print axioms`-clean (Lean's three standard axioms) and no hypothesis beyond the evident parameters (Section 1.3.4). "Conditional" means `#print axioms`-clean with the named hypotheses listed; the conditional theorems are *not* proofs of their conclusions.

Table 1.2: Status of the headline results of Parts IV to VI.

Chapter	Headline	Status
15	Zhu's modularity theorem, canonical family, for C_2-cofinite V (`zhuModularity_canonical_of_C2Cofinite_admissiblyRational`)	unconditional, with "rational" = `AdmissiblyRational`; Dong–Li–Mason 1997 implies it under C_2 (`admissiblyRational_of_dlmRational`); converse open
16	$L_{-4/3}(\hat{\mathfrak{sl}}_2)$ is not C_2-cofinite and has finite-dimensional zeroth Poisson homology	unconditional
16	Arakawa–Kawasetsu weight grading (`akWeightGrading`)	unconditional, every VOA (CFT type)
16	Arakawa–Kawasetsu MLDE (Theorem 5.1), one monic MLDE for all analytic blocks	conditional on `EtingofFinite` only; order unbounded; quasi-lisseness not formalised
16	the same at $L_{-4/3}(\hat{\mathfrak{sl}}_2)$, vacuum insertion	unconditional; order unspecified (AK's order 2 not proved)
19	positivity of graded unitarity of $M(2, 2n+1)$ through filtration degree two	unconditional; the full conjecture is open
19	graded unitarity of $V^k(\hat{\mathfrak{sl}}_2)$, real $k < -2$	unconditional
20	Arakawa–Dai: character, and classical freeness (Theorem 1.1, `arakawaDai_theorem_1_1`)	unconditional ($1 \le m$)
20	classical freeness of $M(2, 2m+3)$	unconditional
21	braided monoidal category of ordinary modules (strongly rational); braided tensor category of logarithmic modules (C_2-cofinite)	unconditional

Table 1.2: Status of the headline results of Parts IV to VI.

Chapter	Headline	Status
21	rigidity, Verlinde, modular category	for nice (strongly rational and pseudo-unitary) VOAs only; rigidity is two-sided (`rigid_ordinary`); congruence: named theorems, only the kernel half of Ng–Schauenburg 6.8
22	Gannon–Rayhaun classification, forward and converse	unconditional, with "rational" = `AdmissiblyRational`; carriers in `Type 0`
23	$V^k(\mathfrak{g})$, $L_k(\mathfrak{g})$, concrete simple Lie algebras	unconditional
24	reduction of classical freeness; explicit presentation; jet surjectivity; carrier	unconditional; the carrier chain is conditional on U5, U6
25	$\dim V_N \geq c_N$ for the seven Deligne types	unconditional; equality a theorem for A_2 only
26	U6; reduction of U5	U6 proved by construction; U5 reduced to named inputs, proved for A_2
27	classical freeness of the seven Deligne VOAs	A_2: no hypothesis (aggregate build green, 2026-10-28); D_4: one published input, the total-dimension bound (not formalized; one step of its proof insufficient as written); the other five: that bound, the Demazure realizations and the conjectural star bound
28	graded unitarity of the Lee–Yang model from that of $L_{-4/3}(\mathfrak{sl}_2)$ (BRST coset)	conditional on `hA` (graded unitarity of $L_{-4/3}(\mathfrak{sl}_2)$), open
29	the same for $M(2, 2n+1)$, every $n \geq 2$, from the boundary admissible $L_k(\mathfrak{sl}_2)$	conditional on `hA` at that level, open

1.6.5 Where each basic notion is defined

Table 1.3 lists, for each basic notion, its Lean name and the place where it is defined in full, with its Lean source and fidelity check.

Table 1.3: Where the basic notions are defined.

Notion	Lean name	Defined in
formal distribution	`VOA.FormalDist`, `VOA.FormalDist₂`	Def. 2.1, 2.21
modes, residue, derivative	`VOA.mode`, `VOA.res`, `VOA.deriv`	Def. 2.7
formal delta function	`VOA.formalDelta`, `VOA.delta₂`	Def. 2.6
generalised binomials, signs	`VOA.gBinom`, `VOA.cbz`, `VOA.negOnePow`	Def. 2.14
commutator, locality, normal ordering	`VOA.bracketDist`, `VOA.Local`, `VOA.normalOrdered`	Def. 2.41
locality $\iff$ delta expansion	`VOA.local_iff_deltaSum`	Thm. 2.27
super-locality	`VOA.Localε`	Def. 2.44
field (lower truncation)	`VOA.IsField`	§4.2
Dong's lemma	`VOA.dong_nonneg`, `VOA.dong_neg`	Thm. 4.16
T-covariance	`VOA.Reconstruction.DCovariant`	Def. 4.38
pre-vertex algebra (Gannon's axioms, no translation covariance)	`VOA.PreVertexAlgebra`	Def. 4.1
vertex algebra (with translation covariance)	`VOA.VertexAlgebra`	§4.1
n-th product, translation	`VOA.PreVertexAlgebra.smul`, `VOA.PreVertexAlgebra.T`	Def. 4.2
graded VOA (FLM/Lepowsky–Li)	`VOA.GradedVertexOperatorAlgebra`	Def. 4.4

Table 1.3: Where the basic notions are defined.

Notion	Lean name	Defined in
vertex operator algebra (of CFT type)	`VOA.VertexOperatorAlgebra`	Def. 4.4
Borcherds (Jacobi) identity	`VOA.VertexOperatorAlgebra.jacobi`	Thm. 4.26
commutator formula	`VOA.mode_commutator`	Thm. 4.21
skew-symmetry	`VOA.VertexOperatorAlgebra.skew_mode`	Thm. 4.33
Goddard uniqueness	`VOA.PreVertexAlgebra.goddard_uniqueness`	Thm. 4.14
reconstruction	`VOA.Reconstruction.reconstruct`	Thm. 4.41
Witt and Virasoro algebras	(Chapter 3)	Def. 3.1, 3.2
affine Lie algebra, vacuum module	(Chapter 3)	Def. 3.6, 3.7
the PBW principle (a theorem)	`VOA.pbw`, `VOA.PBWPrinciple`	§3.10
zero modes; V_1 Lie algebra	`VOA.VertexOperatorAlgebra.zeroMode`	Def. 5.1; Thm. 5.4
automorphism	`VOA.Aut`	Def. 5.9
ideal, simple VOA	`IsIdeal`, `IsSimple`	Def. 5.16
quotient VOA	`VOA.QuotVOA.quotientVOA`	Def. 5.19
VOA homomorphism	`VOA.IsVOAHom`	Def. 5.22
sub-VOA, fixed-point sub-VOA	`VOA.VOASubalgebra`, `VOA.orbifoldVOA`	Def. 32.16
generated sub-VOA	`VOASubalgebra.generated`	Def. 5.26
invariant bilinear form	`InvariantForm`, `IsFullyInvariant`	Def. 5.48
canonical invariant form (Li)	`VOA.canonicalInvariantForm`	Thm. 5.56
simple $\iff$ nondegenerate	`VOA.LiRadical.isSimple_iff_leftRadical_eq_bot`	Thm. 5.57
weak and ordinary modules	`VOA.WeakModule`, `VOA.OrdVModule`	Chapter 12, §12.1; Def. 37.5
admissible modules	`VOA.AdmissibleModule`	Def. 12.4
lowest weight	`VOA.IsLowestWeight`	Def. 12.14
Zhu's algebra	`VOA.zhuMul`, `VOA.O`, `VOA.A`	§12.4; Def. 40.1
intertwiners, fusion coefficient	`VOA.Intertwiner`, `VOA.fusionCoeff`	§12.8; Def. 37.6
twisted module	`VOA.TwistedModule`	Def. 34.4
super vertex algebra	`VOA.SuperVertexAlgebra`	§1.2.14; Chapter 17
lattices, Leech lattice	(Chapter 30)	Def. 30.1
$qJ(q)$ as a power series	`VOA.JShift`	Def. 33.12
the carrier $V^\natural$, its vacuum and ω	`Vnat`, `vacNat`, `omegaNat`	Def. 38.22
the block vertex map	`Ynat`	Def. 38.34

1.7 A short physical orientation

Vertex algebras were invented twice: by mathematicians (Borcherds, 1986; Frenkel, Lepowsky and Meurman, 1988), in order to construct the Monster module $V^\natural$, and — in a less axiomatic form — by physicists (Belavin, Polyakov and Zamolodchikov, 1984), as the algebraic skeleton of two-dimensional conformal field theory (CFT). The axioms look strange until one knows where they come from. Nothing in this section is used logically; it is here so that the definitions of Part I look inevitable rather than arbitrary. Each chapter's physics boxes refine the picture.

Chiral fields. A two-dimensional quantum field theory on the Euclidean plane $\mathbb{R}^2 \cong \mathbb{C}$ assigns to each point an operator-valued field $\phi(z)$. In a conformal field theory the symmetries include all local holomorphic coordinate changes, and the theory splits, to a first approximation, into a holomorphic (*chiral*) half whose fields depend only on z and an antiholomorphic half. A vertex algebra is the algebraic structure of the chiral half. In *radial quantisation* the radius $|z|$ plays the role of time and the space of states lives on a circle around the origin; a chiral field is then a Laurent series $Y(u,z) = \sum u_{(n)} z^{-n-1}$ in operators, which is why the library's basic object is a formal series with coefficients in $\mathrm{End}(V)$.

States and fields. Every state u is created by a unique field from the vacuum, $u =$

$\lim_{z\to 0} Y(u,z)\mathbf{1}$; this *state–field correspondence* is the axiom `creation`. The vacuum's own field is the identity.

Operator product expansion and locality. Fields at different points commute in a local theory. In radial ordering this becomes the statement that $Y(u,z)Y(v,w)$ and $Y(v,w)Y(u,z)$ are expansions in two regions of one meromorphic function with a pole of finite order on the diagonal; the coefficients of the poles are the operator product expansion (OPE) $Y(u,z)Y(v,w) \sim \sum_{j\geq 0} Y(u_{(j)}v,w)/(z-w)^{j+1}$. Algebraically, without analysis, this is expressed by *locality*: $(z-w)^N[Y(u,z),Y(v,w)]=0$ for some N. The products $u_{(n)}v$, one for each $n\in\mathbb{Z}$, are the OPE coefficients; a vertex algebra is a vector space with infinitely many bilinear products subject to the identities forced by the existence of the underlying meromorphic functions.

Conformal symmetry. The stress tensor $T(z)=\sum L_n z^{-n-2}$, the field of the conformal vector ω, has modes satisfying the Virasoro algebra with central charge c. L_0 measures the conformal weight (energy) of a state, L_{-1} generates translations and acts as ∂_z on fields. A vertex *operator* algebra is a vertex algebra with such a stress tensor.

The free boson and $V^\natural$. The simplest example is the chiral free boson: the Fock space $\mathbb{C}[a_{-1},a_{-2},\dots]\mathbf{1}$ with $[a_m,a_n]=m\,\delta_{m+n,0}$ and OPE $a(z)a(w)\sim(z-w)^{-2}$; it has $c=1$. Twenty-four free bosons compactified on the Leech torus $\mathbb{R}^{24}/\Lambda$ give the lattice VOA V_Λ (Chapter 31). The reflection $x\mapsto -x$ of the torus is a symmetry; gauging it — the $\mathbb{Z}/2$ *orbifold* — keeps the reflection-invariant states of V_Λ and adds a *twisted sector* of strings closed only up to the reflection, whose bosons have half-integer modes. Dixon, Ginsparg and Harvey recognised that the result is the Moonshine module $V^\natural$ of Frenkel, Lepowsky and Meurman: a *holomorphic* CFT of central charge 24, with partition function $J(q)=q^{-1}+196884\,q+\cdots$, no weight-one states (the Leech lattice has no roots, and the orbifold removes the remaining currents), and the Monster group as its symmetry group. The Lean construction (Chapters 30 to 42) follows this physical recipe step by step; its hardest part is to prove that the fields of the twisted sector are local with each other, the step physicists take for granted.

Physical meaning

Summary of the dictionary. States ↔ vectors of V; local operators ↔ fields $Y(u,z)$; OPE coefficients ↔ products $u_{(n)}v$; crossing symmetry of chiral correlators ↔ locality and the Borcherds identity; stress tensor ↔ conformal vector ω; conformal weight ↔ L_0-grading; internal symmetries ↔ automorphisms; sectors ↔ modules; chiral vertex operators ↔ intertwining operators; orbifold ↔ fixed-point subalgebra plus twisted modules; partition function ↔ graded dimension. The correspondence is heuristic: a vertex algebra axiomatises the chiral operator algebra, not a full non-chiral CFT, and none of the physical arguments is used as a proof anywhere in the book.

1.8 Lean glossary

Table 1.4 collects the symbols and idioms of this chapter, with their meaning, the place in this chapter where they are explained, and the first chapter (in the order of the book) in which they occur. Later chapters' fidelity checks point back here instead of re-explaining them.

Table 1.4: Lean glossary.

Symbol / idiom	Meaning	Here	First use
`x : X`	x is a term of type X	§1.2	L01
`Prop`, `h : P`	propositions; h is a proof of P	§1.2	L01
`Type u`, `Type*`, `Type _`	a type ("set"), with universe level named, fresh or inferred	§1.2	L01

Table 1.4: Lean glossary.

Symbol / idiom	Meaning	Here	First use
`def`, `theorem`, `lemma`	definition; assertion with proof	§1.2	L01
`abbrev`	definition unfolded eagerly (same logic as `def`)	§1.2.3	L01
`noncomputable`	uses choice; cannot be evaluated; no logical cost	§1.2	L01
`structure`, `extends`, fields, `x.field`	bundle of data and proofs; inheritance; projection	§1.2.5	L01
`class`, `instance`, `[C X]`	structures found by automatic search; the library declares one, `FusionCategory`	§1.2	L01
`(x : X)`, `{x : X}`	explicit, implicit argument; both universally quantified	§1.2	L01
`variable`	arguments shared by the declarations of a file	§1.2	L01
`maxSynthPendingDepth`	depth of instance search; set to 3 by the build; audit trap	§1.2, §1.3	L01
`rfl`, `Iff.rfl`, `funext`	proof by unfolding definitions; same for ↔; function extensionality	§1.2.3	L01
`@[simp]`, `@[ext]`, `@[inherit_doc]`, `@[reducible]`	attributes: metadata for automation, no logical content; `ext` applies extensionality lemmas	§1.2.3	L01
`inferInstanceAs (C X)`	the instance of `C X` found by search, transported to a synonym	§1.2.3	L01
`{x : X}`	strict implicit argument; read "for all x"	§1.2	L05
`inductive`, `deriving`, `open X in`, `scoped`, `_root_.`	other declaration syntax	§1.2	L01
`where`, `carrier := {x | ...}`	building a structure field by field; set-builder notation	§1.2.3	L01
`letI`, `haveI`	install a structure (or fact) locally inside a definition	§1.2.12	L03
`fun x ⇒ e`, `⟨a, b⟩`	the function $x \mapsto e$; anonymous constructor (tuple)	§1.2	L01
`if c then a else b`	case distinction (needs `Decidable c`)	§1.2.9	L01
∀, ∃, ∧, ∨, ¬, →, ↔	logic; order of quantifiers matters; → associates right	§1.2	L01
`∃ a ∈ P, ...`	$\exists a,\ a \in P \wedge \dots$	§1.2.10	L01
`Nonempty X`, `IsEmpty X`	X has an element; X has none	§1.2.7	L02
`Function.Injective f`	f is injective	§1.2.7	L02
`Function.support f`, `S.Finite`, `S.Infinite`, `Finite X`	$\{f \neq 0\}$; finiteness of sets and types	§1.2.11	L01
`Nat.card`, `Set.ncard`, `s.card`	cardinalities; the first two are 0 for infinite sets	§1.2.11	L12
`Set X`, `Set.univ`, `Set.range f`, ∈, ⊆, ∩, ∪	subsets and their operations	§1.2.11	L02
`List X`, `Finset.filter`, `Finset.antidiagonal`	finite sequences; filtered finite sets; pairs with given sum	§1.2.11	L02
`Module.End.eigenspace T μ`, `T.maxGenEigenspace μ`	$\ker(T - \mu)$; generalised eigenspace	§1.2.10	L02
`ExactAt f g` (library)	$\ker g = \operatorname{im} f$ for module maps	§1.2.10	L12
`IsCompl P Q`, `Nontrivial X`	$X = P \oplus Q$; X has two distinct elements	§1.2.10	L02
`LinearIndependent`, `Module.Basis`, `b.repr`, `Module.Finite`	independence; bases and coordinates; finite generation	§1.2.10	L02
`Submodule.Quotient.mk`, `liftQ`, `mkQ`	class in a quotient; induced map; quotient map	§1.2.10	L02

Table 1.4: Lean glossary.

Symbol / idiom	Meaning	Here	First use
`LinearEquiv.of...`, `LinearMap.fst`, `smulRight`, `compl₁₂`, `IsSymm`, `Nondegenerate`	standard constructions of maps and forms	§1.2.10	L02
`TensorProduct.mk`, `.map`, `.lift`, `lTensor`, `rTensor`	tensor-product constructions	§1.2.10	L02
`DirectSum.decompose`, `DirectSum.toModule`, `chooseDecomposition`	decomposition isomorphism; map out of a sum; chosen decomposition	§1.2.10	L04
`Finsupp.single`, `Finsupp.linearCombination`, `Finsupp.weight`	finitely supported constructions	§1.2.10	L02
`IsUnit`, `ˣ`, `⁻¹`, `Commute`, `algebraMap`, `→ₐ[ℂ]`, `→+`	units, inverses, commuting elements, algebra and additive maps	§1.2.12	L01
`Odd`, `∣`, `Nat.Coprime`, `n.factorial`, `n.choose k`	integer notions	§1.2.12	L01
`Complex.I`, `Complex.exp`, `Real.pi`, `Real.sqrt`, `CFC.sqrt`	i, exp, π, square roots (junk 0 for negatives)	§1.2.12	L02
`∘`, `∃!`, `.val`, `Subtype.ext`	composition; unique existence; subtypes	§1.2.12	L01
`Polynomial.X`, `C`, `eval`, `natDegree`, `derivative`; `MvPolynomial.pderiv`	polynomial vocabulary (degree 0 for $P = 0$)	§1.2.12	L05
`ModularForm`, `qExpansion`, `HasProd`	modular forms; q-expansions; convergent products	§1.2.12, §1.2.11	ch02
`LieRing`, `LieAlgebra`, `→ₗ[ℂ]`, `UniversalEnvelopingAlgebra`, `twoCocycle`	Lie algebras, their maps, $U(L)$, cocycles	§1.2.12	L02
`Ideal`, `Ideal.span`, `RingHom.ker`, `IsSimpleModule`, `IsSemisimpleRing`	ring and module theory	§1.2.12	L02
`h.choose`, `Classical.choose`	a witness chosen by the axiom of choice	§1.2.7	L01
`Module.Free.chooseBasis`	an arbitrary basis of a free module	§1.2.7	L05
`ℕ`, `ℤ`, `ℂ`, `(n : ℂ)`, `↑n`	number types ($0 \in \mathbb{N}$); casts	§1.2.9	L01
`m - n` on `ℕ`, `x / 0`, `k.toNat`	junk values: truncated, 0, $\max(k, 0)$	§1.2.8	L01
`ZMod n`, `Fin n`	$\mathbb{Z}/n\mathbb{Z}$; $\{0, \dots, n-1\}$	§1.2.9	L01
`Even n`, `negOnePow n`	n even; $(-1)^n$	§1.2.9	L01
`FormalDist 𝒲`, `𝒲⟦z^±⟧`	opaque synonym of `ℤ → 𝒲`: formal series	§1.2.3	L01
`mode f n`, `mode (Y u) n`	$f(-n-1)$; the operator $u_{(n)}$	Ex. 1.1	L01
`1` on `FormalDist`	the identity field	Ex. 1.2	L01
`odd k ↦ k/2` encoding	half-integer modes indexed by odd integers; even k junk	§1.2.8	ch06
`→ₗ[ℂ]`, `≃ₗ[ℂ]`, `LinearMap.id`	linear maps; linear isomorphisms; identity	§1.2.10	L01
`End ℂ 𝒱`, `*`, `⁅a, b⁆`, `D ^ N`	endomorphisms; composition; commutator; power	§1.2.10	L01
`M →ₗ[ℂ] M →ₗ[ℂ] ℂ`, `LinearMap.BilinForm`	bilinear (not sesquilinear) forms	§1.2.10	L02
`Module.Dual ℂ X`	dual space	§1.2.10	L06
`Basis ι ℂ X`	a basis indexed by ι	§1.2.10	L02
`Submodule ℂ 𝒱`, `≤`, `⊥`, `⊤`	subspaces; inclusion; 0; whole space	§1.2.10	L01
`⊓`, `⊔`, `⨆ i, S i`	intersection; sum; sum of a family	§1.2.10	L04
`Submodule.span`, `ℂ • v`	span; the line $\mathbb{C}v$	§1.2.10	L02
`LinearMap.ker`, `LinearMap.range`, `comap`, `map`, `subtype`	kernel; image; preimage; image; inclusion	§1.2.10	L04

Table 1.4: Lean glossary.

Symbol / idiom	Meaning	Here	First use
`↥S`	a subspace as a vector space (coercion)	§1.2.10	L04
`X ⧸ S`	quotient space	§1.2.10	L02
`ℤ → Submodule ℂ V`, `DirectSum.IsInternal`	grading; $V = \bigoplus_n V_n$	§1.2.10	L02

`ι →₀ R`, `μ.sum g`	finitely supported functions; sum over support	§1.2.11	L02
`∑' ` (`tsum`)	infinite sum; 0 if not summable	§1.2.11	L14
`Polynomial ℂ`, `MvPolynomial σ ℂ`, `aeval`	polynomials; several variables; evaluation	§1.2.12	L05
`PowerSeries ℂ`, `PowerSeries.coeff n`	$\mathbb{C}[[q]]$; coefficient of q^n	§1.2.12	L05
`Subgroup G`, `Subgroup.zpowers g`	subgroups; cyclic subgroup $\langle g \rangle$	§1.2.12	ch04
`sorry`, `sorryAx`, `axiom`	unproved goal (forbidden); postulate	§1.3	L01
`#print axioms`	lists the axioms a proof uses (not its hypotheses)	§1.3	L01

1.9 Referee's checklist

This chapter quotes only a few declarations, as reading examples; their full fidelity checks are in the chapters indicated.

Lean declaration	Intended meaning	Hypotheses / status	Check
`VOA.mode`	$f_{(m)} = f(-m-1)$	definition; no axioms	Ex. 1.1; Def. 2.7
`VOA.FormalDist.instOne`	`1` is the identity field	definition; no axioms	Ex. 1.2
`VOA.Aut`	automorphisms of a VOA	definition	Ex. 1.3; Def. 5.9
`VOA.VertexOperatorAlgebra`, `…VertexOperatorAlgebra.L`	VOA of CFT type; $L_n = \omega_{(n+1)}$	definition (CFT type by definition; the FLM notion is `GradedVertexOperatorAlgebra`)	Ex. 1.4; Def. 4.4
`VOA.SuperVertexAlgebra`	super vertex algebra	definition	§1.2.14; Chapter 17
`VOA.Moonshine.moonshine`	$V^\natural$ exists with the FLM data, $c = 24$, $V_1 = 0$, $\dim V_2 = 196884$, character J, simple	no hypotheses; unconditional; standard axioms	§1.2.15; §42.8
`VOA.pbw`	two PBW consequences	theorem, unconditional (formerly a project axiom); not used by Moonshine	§1.3; §3.10

1.10 Notes and references

Lean 4 is described in L. de Moura and S. Ullrich, *The Lean 4 theorem prover and programming language*, in: Automated Deduction — CADE 28, Lecture Notes in Computer Science **12699**, Springer, 2021, 625–635; Mathlib in The mathlib Community, *The Lean mathematical library*, Proceedings of the 9th ACM SIGPLAN International Conference on Certified Programs and Proofs (CPP 2020), 367–381 (arXiv:1910.09336). A gentle introduction for mathematicians is J. Avigad and P. Massot, *Mathematics in Lean*, available with the Lean community documentation.

The definition of a vertex algebra is due to R. E. Borcherds, *Vertex algebras, Kac–Moody algebras, and the Monster*, Proc. Nat. Acad. Sci. USA **83** (1986) 3068–3071. The definition of a vertex operator algebra and the construction of the Moonshine module are in I. B. Frenkel, J. Lepowsky and A. Meurman, *Vertex Operator Algebras and the Monster*, Pure and Applied Mathematics **134**, Academic Press, 1988. Standard textbooks are V. Kac, *Vertex Algebras for Beginners*, University Lecture Series **10**, AMS, 2nd ed. 1998; E. Frenkel and D. Ben-Zvi, *Vertex Algebras and Algebraic Curves*, Mathematical Surveys and Monographs **88**, AMS, 2nd ed. 2004; and J. Lepowsky and H. Li, *Introduction to Vertex Operator Algebras and Their Representations*, Progress in Mathematics **227**, Birkhäuser, 2004. The library's files follow, and their docstrings cite section by section, T. Gannon, *Moonshine beyond the Monster*, Cambridge University Press, 2006, Chapter 5.

On the physics side, the founding paper of two-dimensional conformal field theory is A. A. Belavin, A. M. Polyakov and A. B. Zamolodchikov, *Infinite conformal symmetry in two-dimensional quantum field theory*, Nucl. Phys. B **241** (1984) 333–380; a textbook account is P. Di Francesco, P. Mathieu and D. Sénéchal, *Conformal Field Theory*, Springer, 1997. The orbifold interpretation of $V^\natural$ is due to L. Dixon, P. Ginsparg and J. Harvey, *Beauty and the beast: superconformal symmetry in a Monster module*, Commun. Math. Phys. **119** (1988) 221–241.

The project-internal sources for this chapter are the files cited in the text, the repository's `README.md` (the policy on forbidden constructs, and the former single project axiom, now the theorem `VOA.pbw`), the book's governing document `Notes/Textbook/CONSTITUTION.md`, the scripts `scripts/textbook/sync.py` and `scripts/textbook/cite_paths.py`, and the catalogue of defects in Chapter 43. The release-audit reports `Notes/Textbook/referee/RELEASE_AUDIT_L16.md`, …, `RELEASE_AUDIT_L22.md` are the source of the corrected statements of Chapters 16, 20, 21 and 22 recorded in Section 1.6. The definitions that an earlier version of this chapter presented in full — formal calculus, the vertex algebra axioms, the Borcherds identity, reconstruction, modules, automorphisms, ideals, invariant forms, Zhu's algebra and intertwiners — are now presented in Chapters 2, 4, 5 and 12, and the orbifold subalgebra in Chapter 32.

Chapter 2

Formal calculus and locality

This chapter documents the release of the LeanVOA library named in the front matter. Every Lean quotation below is checked by `scripts/textbook/sync.py` to occur verbatim (up to whitespace and comments) in the source files of that release. Checks that were run at an earlier state of the library and not re-run for this edition are marked as such. The chapter covers the thirteen files assigned to it in `Notes/Textbook/assignment.txt`, all in the directory `VOA/Foundations/`: `FormalSeries.lean`, `FormalCalculus.lean`, `Locality.lean`, `Expansion.lean`, `IteratedLaurent.lean`, `Substitution.lean`, `DeltaJump.lean`, `IotaZExpansion.lean`, `FormalDist3.lean`, `FormalDist4.lean`, `FormalDist4Delta.lean`, `FormalDist4DeltaContract.lean` and `FormalDist4DeltaSupport.lean`.

Chapter 1 (Section 1.2.3) already introduced, briefly, some of the objects that every later chapter uses: formal distributions, modes, the residue, locality and the structure theorem for local pairs. The present chapter is the full treatment. It presents *every* definition and every substantive theorem of the thirteen files, with the complete fidelity protocol of the Constitution, and it works out by hand the examples that a student should have computed once in their life: the two expansions of $(z_1 - z_2)^{-1}$ and $(z_1 - z_2)^{-2}$, the jump between them, the delta function and its derivatives, the free boson and free fermion as local pairs, and the substitution $z_1 \mapsto z_0 + z_2$ applied to an explicit series. Where Chapter 1 already printed a Lean declaration we print it again, because the referee should be able to check this chapter on its own.

What is proved, in one paragraph. Everything in this chapter is *unconditional* formal algebra. The headline results are: the structure theorem for distributions annihilated by a power of $z_1 - z_2$ (`VOA.local_iff_deltaSum`, Gannon's Proposition 5.1.2, Kac's Theorem 2.3); the delta-function jump $\iota_{z_1,z_2}(z_1 - z_2)^{-1} - \iota_{z_2,z_1}(z_1 - z_2)^{-1} = \delta(z_1, z_2)$ (`VOA.expand_jump`) and its all-order generalisation to $(z_1 - z_2)^{-k-1}$ (`VOA.negPowJump_eq_deltaDeriv`); multiplicativity of the expansions (`VOA.expandPos_mul`, `VOA.expandNeg_mul`), whose engine is the generalised Chu–Vandermonde identity (`VOA.cbz_vandermonde`); the cancellation theorem saying that $z_1 - z_2$ is not a zero-divisor on lower-truncated distributions (`VOA.eq_zero_of_mulBySubPow_of_bddBelow`), which is the irreducible core of Goddard uniqueness and of the reconstruction theorem; the multiplicativity of the substitution $z_1 \mapsto z_0 + z_2$ (`VOA.subst_mulBySub`); the sign-twisted (super) versions of locality (`VOA.localε_iff_deltaSum`, `VOA.localε_of_car`); and a four-variable double-delta calculus (`VOA.FormalDist₄Delta.kernelContract₁₂_doubleDelta_eq_zero_of_local`) intended for Li's local-system theorem. We ran `#print axioms` on sixty declarations of these files; every one depends only on `[propext, Classical.choice, Quot.sound]` (Section 2.12). The PBW theorem `VOA.pbw` (Chapter 3; formerly a project axiom, now a theorem) does not occur. The only *hypotheses* that appear are finite-support hypotheses that make infinite sums meaningful; each is discussed in its fidelity check, and one of them (`ShiftContractFinite`) is, at this commit, not yet discharged for the payloads it is intended for (the trap box on p. 90).

How to read this chapter. Sections 2.1–2.4 are the one-variable theory and the combinatorics of binomial coefficients. Sections 2.5–2.7 are the heart: two-variable distributions, the structure theorem, the two expansions and their jump, and locality of operator-valued distributions. Sections 2.8–2.9 are the tools for the reconstruction programme (lower truncation, cancellation, substitution). Sections 2.10–2.11 are the three- and four-variable layers. The chapter ends with the verification record, the referee's checklist and the notes.

2.1 The physical picture: fields, contours and radial ordering

Nothing in this section is used in a proof; it explains why the definitions that follow are the right ones. Chapter 1, Section 1.7, gives a longer account; here we concentrate on the four facts that formal calculus encodes.

2.1.1 Fields are Laurent series of operators

In a two-dimensional conformal field theory on the Riemann sphere one chooses a coordinate z centred at the origin and *radially quantises*: circles $|z| = r$ are the equal-time slices, $r = e^{\tau}$ with τ the Euclidean time of the cylinder. A chiral (holomorphic) field $a(z)$ of conformal weight h is expanded in modes,

$$a(z) = \sum_{n \in \mathbb{Z}} a_n \, z^{-n-h}, \qquad a_n = \oint_{|z|=r} \frac{dz}{2\pi i} \, z^{n+h-1} a(z).$$

The modes a_n are operators on the space of states. Vertex-algebra conventions absorb the weight: one writes $a(z) = \sum_n a_{(n)} z^{-n-1}$, so that $a_{(n)} = \oint z^n a(z)\, dz/2\pi i$ for *every* field, whatever its weight. The library adopts exactly this convention (the function `VOA.mode` of Definition 2.7). The expression $a(z)$ itself is never a convergent series of operators: it only makes sense inside correlation functions, or applied to a state. Formal calculus keeps the series as a *list of coefficients* and never asks it to converge. This is the content of Definition 2.1.

2.1.2 Contour integrals are residues

The contour integral $\oint z^n a(z)\, dz/2\pi i$ picks out the coefficient of z^{-1} in $z^n a(z)$. In formal calculus this *is* the definition: $\operatorname{Res}_z f(z)$ is the coefficient of z^{-1}. Two facts of complex analysis survive verbatim: the integral of a total derivative over a closed contour vanishes ($\operatorname{Res}_z \partial_z f = 0$, Proposition 2.8), and one may integrate by parts (Theorem 2.12). The *conserved charge* associated with a current $J(z)$ is $Q = \oint J(z)\, dz/2\pi i = J_{(0)}$: a residue.

2.1.3 Two orderings, one function: why there are two expansions

The basic object of the theory is a correlation function such as $\langle a(z_1) b(z_2) \rangle$, which is a meromorphic function of z_1, z_2 with poles at $z_1 = z_2$ (and at $0, \infty$). In radial quantisation, operator products must be *radially ordered*: the product $a(z_1)b(z_2)$ of operators is defined when $|z_1| > |z_2|$, the product $b(z_2)a(z_1)$ when $|z_2| > |z_1|$, and both are expansions of the *same* meromorphic function in two different annuli. The prototype is the function $1/(z_1 - z_2)$:

$$\frac{1}{z_1 - z_2} = \sum_{k \geq 0} z_1^{-k-1} z_2^{k} \qquad (|z_1| > |z_2|),$$
$$\frac{1}{z_1 - z_2} = -\sum_{k \geq 0} z_1^{k} z_2^{-k-1} \qquad (|z_2| > |z_1|).$$

These are the two expansions ι_{z_1,z_2} and ι_{z_2,z_1} of Definition 2.30. Their difference is $\sum_{k\in\mathbb{Z}} z_1^k z_2^{-k-1}$, which is the formal delta function $\delta(z_1,z_2)$: in complex analysis, the difference of the contour integrals over $|z_1| = R$ and $|z_1| = r < |z_2| < R$ is the integral over a small circle around $z_1 = z_2$, which evaluates a test function at $z_1 = z_2$. So *the delta function is the difference of the two radial orderings*, and it is supported at coincident points: this is the contact term. Theorem 2.33 is the formal statement, and Theorem 2.38 the version for higher poles.

2.1.4 Locality is commutativity up to contact terms

Suppose the operator product expansion of a with b has a pole of order at most N: $a(z_1)b(z_2) = \sum_{j<N} c^j(z_2)(z_1-z_2)^{-j-1} + \text{regular}$. Then $(z_1-z_2)^N a(z_1)b(z_2)$ is regular at $z_1 = z_2$, and (for bosonic fields) it is the same function as $(z_1-z_2)^N b(z_2)a(z_1)$: the two orderings agree once the pole is cancelled. In formal language,

$$(z_1 - z_2)^N\,[a(z_1), b(z_2)] = 0.$$

This is *mutual locality*. In Minkowski signature it becomes the statement that the fields commute at spacelike separation; in the Euclidean, radially ordered picture it says that the commutator is a contact term. The structure theorem (Theorem 2.27) makes this precise: a distribution killed by $(z_1-z_2)^N$ is exactly a sum $\sum_{j<N} c^j(z_2)\,\partial_{z_2}^{j}\delta(z_1,z_2)$ of derivatives of the delta function. Taking residues then gives the familiar commutator formula of modes, $[a_{(m)}, b_{(n)}] = \sum_j \binom{m}{j}(a_{(j)}b)_{(m+n-j)}$, which is how physicists derive the Virasoro and current algebras from the singular parts of OPEs.

For fermionic fields the second ordering carries a sign, $b(z_2)a(z_1) \mapsto -b(z_2)a(z_1)$, and locality is a statement about the *anti*commutator; the library handles both cases with a scalar parameter ε (Section 2.7.2).

2.1.5 What the formal theory must avoid

Two series in the same variable cannot in general be multiplied: $\delta(z)\cdot\delta(z)$ would have every coefficient equal to $\sum_{k\in\mathbb{Z}} 1$. The formal theory must therefore be *disciplined about infinite sums*: a product or a sum is allowed only when every coefficient of the result is a finite sum. This discipline appears in the library in three forms: (i) `FormalDist` carries no multiplication at all (Definition 2.1); (ii) sums are taken with Mathlib's `finsum`, and every theorem that manipulates such a sum carries a finite-support hypothesis; (iii) a definition whose coefficient is a `finsum` may be *written down* for any input, but is meaningful only on inputs for which the sum is finite. Point (iii) is a standing trap, explained in the trap box on p. 44.

2.2 One-variable formal distributions

2.2.1 The space of formal distributions

Definition 2.1 (Formal distribution)**.** Let $\mathcal{W}$ be a set. A *formal distribution* in one variable z with coefficients in $\mathcal{W}$ is a function $f : \mathbb{Z} \to \mathcal{W}$, written as the doubly infinite formal series

$$f(z) = \sum_{n\in\mathbb{Z}} f_n\, z^n, \qquad f_n := f(n) \in \mathcal{W}.$$

The set of formal distributions is denoted $\mathcal{W}[[z^{\pm 1}]]$. When $\mathcal{W}$ is an abelian group, respectively a module over a semiring R, $\mathcal{W}[[z^{\pm 1}]]$ is an abelian group, respectively an R-module, under coefficientwise addition and scalar multiplication. Two formal distributions are equal iff all their coefficients agree. No product of two formal distributions is defined.

File `VOA/Foundations/FormalSeries.lean`.

```
def FormalDist (𝓦 : Type*) : Type _ := ℤ → 𝓦

@[inherit_doc] notation:max 𝓦 "⟦z^±⟧" => FormalDist 𝓦

instance instAddCommGroup [AddCommGroup 𝓦] : AddCommGroup (FormalDist 𝓦) :=
  inferInstanceAs (AddCommGroup (ℤ → 𝓦))

instance instModule {R : Type*} [Semiring R] [AddCommGroup 𝓦] [Module R 𝓦] :
    Module R (FormalDist 𝓦) := inferInstanceAs (Module R (ℤ → 𝓦))

@[ext]
theorem ext {f g : FormalDist 𝓦} (h : ∀ n, f n = g n) : f = g := funext h
```

From the mathematics to the Lean statement

Decoding. `Type*` means "some type" (a set, for our purposes). `ℤ → 𝓦` is the type of functions from the integers to $\mathcal{W}$. So `f : FormalDist 𝓦` is a function and `f n` is its value at n, *which we read as the coefficient of* z^n. This is the first convention to memorise: `f n` is the coefficient of z^n, not a mode. Modes are introduced in Definition 2.7 and are shifted by one. The notation `𝓦⟦z^±⟧` is a pure abbreviation for `FormalDist 𝓦`.

The two instances. `instance ... : AddCommGroup (FormalDist 𝓦)` says: if $\mathcal{W}$ is an abelian group, so is `FormalDist 𝓦`, and `inferInstanceAs (AddCommGroup (ℤ → 𝓦))` says that the group structure is the one of the function space, i.e. coefficientwise. Likewise for the module structure over any semiring R (in practice $R = \mathbb{C}$ or $R = \mathbb{Z}$). The `@[ext]` theorem is the statement "equal coefficients imply equal distributions", registered so that Lean's `ext` tactic uses it.

Why a `def` and not the bare function type. If $\mathcal{W}$ is a ring, the function type `ℤ → 𝓦` carries the pointwise product $(fg)_n = f_n g_n$, which has nothing to do with the product of series. Because `FormalDist` is a separate definition (Lean does not unfold it when searching for instances), the pointwise product is never found. The file header says this explicitly: there is "deliberately **no** ring structure". No multiplication of distributions is defined anywhere in the library; products are formed by explicit, separately justified constructions (Definitions 2.10, 2.35, 2.52).

Fidelity. Same as Kac (*Vertex algebras for beginners*, §2.1), Gannon (§5.1.2, the space $\mathcal{W}[[z^{\pm}]]$) and Lepowsky–Li (§2.1). **Could it be vacuous?** No: it is the full space of $\mathbb{Z}$-indexed families.

Physical meaning

A formal distribution with values in $\mathrm{End}(V)$ is the mode expansion of a quantum field, kept as the list of its Fourier–Laurent modes; a distribution with values in V is a field applied to a state, $a(z)v$; a distribution with values in $\mathbb{C}$ is a correlation function expanded around a point. No convergence is ever claimed, because in quantum field theory none is available at the level of operators: only matrix elements and their Laurent coefficients (OPE coefficients) are meaningful. The refusal to define a product mirrors the physical fact that two operators at the *same* point cannot simply be multiplied: their product is singular and must be regularised (normal ordering, Definition 2.41).

What the machine verified

A definition with two instances and an extensionality lemma; no proof obligation beyond type-checking. Compiled as part of the built tree at an earlier commit, when this chapter was first written (not re-run for this edition).

2.2.2 Laurent polynomials and algebraically summable families

The *test functions* of the theory are the Laurent polynomials. Pairing a distribution with a test function, $\mathrm{Res}_z\, g(z)f(z)$, is always a finite sum: this is the sense in which formal distributions are "distributions".

Definition 2.2 (Laurent polynomials)**.** Let $\mathcal{W}$ be a complex vector space. A formal distribution $f \in \mathcal{W}[[z^{\pm 1}]]$ is a *Laurent polynomial* if its support $\{n \in \mathbb{Z} : f_n \neq 0\}$ is finite. Laurent polynomials form a $\mathbb{C}$-linear subspace $\mathcal{W}[z^{\pm 1}] \subseteq \mathcal{W}[[z^{\pm 1}]]$.

File `VOA/Foundations/FormalSeries.lean`.

```
def LaurentPoly (𝒲 : Type*) [AddCommGroup 𝒲] [Module ℂ 𝒲] : Submodule ℂ (FormalDist 𝒲)
 ↪ where
  carrier := {f | (Function.support f).Finite}

theorem mem_laurentPoly [AddCommGroup 𝒲] [Module ℂ 𝒲] {f : FormalDist 𝒲} :
    f ∈ LaurentPoly 𝒲 ↔ (Function.support f).Finite := Iff.rfl
```

From the mathematics to the Lean statement

`Submodule ℂ M` is Mathlib's notion of a $\mathbb{C}$-linear subspace of M; it is a structure consisting of a carrier set together with proofs that it contains 0 and is closed under addition and scalar multiplication (those three proofs are in the file and are omitted here). `Function.support f` is $\{n : f(n) \neq 0\}$ and `.Finite` says this set is finite. `mem_laurentPoly` records that membership is literally finiteness of the support (`Iff.rfl`: the two sides are the same statement). **Fidelity:** same as Gannon §5.1.2 (the "test functions" $\mathcal{W}[z^{\pm}]$). In the library, theorems that need a Laurent polynomial usually ask directly for `(Function.support g).Finite` rather than `g ∈ LaurentPoly ℂ`; the two are interchangeable by `mem_laurentPoly`.

Physical meaning

Laurent polynomials are the smearing functions of chiral CFT: the mode $a_{(n)} = \mathrm{Res}_z\, z^n a(z)$ is the field smeared against the test function z^n, and a general smeared field $\mathrm{Res}_z\, g(z)a(z)$ is a finite linear combination of modes. Physically, one never measures a field at a point, only smeared against a test function; for chiral fields on the circle the natural test functions are trigonometric polynomials $e^{in\sigma}$, i.e. Laurent polynomials in $z = e^{i\sigma}$.

What the machine verified

Definition. The closure proofs (`add_mem'`, `zero_mem'`, `smul_mem'`) are in the file and compile; no hypotheses. The structure `LaurentPoly` is used downstream in `VOA/Examples/VirasoroKacLaurent.lean`.

Definition 2.3 (Algebraically summable family; algebraic sum)**.** Let $\mathcal{W}$ be an abelian group and I any index set. A family $(f^{(i)})_{i\in I}$ in $\mathcal{W}[[z^{\pm 1}]]$ is *algebraically summable* if for every $n \in \mathbb{Z}$ the set $\{i \in I : f^{(i)}_n \neq 0\}$ is finite. Its *algebraic sum* is the distribution

$$\Big(\sum_{i\in I} f^{(i)}\Big)_n := \sum_{i\,:\, f^{(i)}_n \neq 0} f^{(i)}_n,$$

a finite sum for each n.

File `VOA/Foundations/FormalSeries.lean`.

```
def AlgSummable {ι : Type*} (f : ι → FormalDist 𝒲) : Prop := ∀ n, {i | f i n ≠ 0}.Finite

noncomputable def algSum {ι : Type*} (f : ι → FormalDist 𝒲) (_h : AlgSummable f) :
    FormalDist 𝒲 := fun n => ∑ᶠ i, f i n
```

From the mathematics to the Lean statement

Decoding. `ι` is the index type I; `f : ι → FormalDist 𝓦` is the family; `f i n` is $f_n^{(i)}$. `AlgSummable f` is a proposition (`Prop`): "for all n, the set of i with $f_n^{(i)} \neq 0$ is finite". `∑ᶠ i, f i n` is Mathlib's `finsum`: the sum of a family over its support *if the support is finite*, and 0 otherwise (the trap box on p. 44).
Every hypothesis. `algSum` takes the summability proof `_h` as an argument. It is not used in the formula (hence the underscore), but its presence means that one cannot even write `algSum f h` without having proved that every coefficient is a finite sum. This is exactly the discipline that rules out the junk value of `finsum`: with `_h` available, `∑ᶠ i, f i n` is a genuine finite sum.
Fidelity. Same as Gannon p. 315 ("a sum is algebraically defined iff for each fixed n the coefficient is a finite sum"). `noncomputable` only means that Lean cannot run the definition as a program, because `finsum` decides finiteness by classical logic; it has no mathematical content.

Physical meaning

Algebraic summability is the formal version of the energy bound that makes operator products well defined on states. For example $Y(u,z)Y(v,w)x = \sum_{m,n} u_{(m)}v_{(n)}x\, z^{-m-1}w^{-n-1}$ is a meaningful formal series because each coefficient is a single vector; but the same-point product $\sum_m u_{(m)}v_{(s-m)}x$ needed for a normal-ordered product is an infinite sum over m, and is meaningful only because, on a fixed state of bounded energy, all but finitely many terms vanish.

What the machine verified

Definitions; no proof obligations. Not used outside `FormalSeries.lean` at this commit (later layers use `finsum` directly, with explicit support hypotheses).

Proposition 2.4 (Algebraic sums are linear). *Every family indexed by a finite set is algebraically summable, and its algebraic sum is the ordinary finite sum. If $(f^{(i)})$ and $(g^{(i)})$ are algebraically summable, so are $(f^{(i)}+g^{(i)})$ and $(cf^{(i)})$ for $c \in \mathbb{C}$, and $\sum_i (f^{(i)}+g^{(i)}) = \sum_i f^{(i)} + \sum_i g^{(i)}$, $\sum_i cf^{(i)} = c\sum_i f^{(i)}$.*

File `VOA/Foundations/FormalSeries.lean`.

```
theorem algSummable_of_finite {ι : Type*} [Finite ι] (f : ι → FormalDist 𝓦) :
    AlgSummable f := fun _ => Set.toFinite _

theorem algSum_apply_fintype {ι : Type*} [Fintype ι] (f : ι → FormalDist 𝓦)
    (h : AlgSummable f) (n : ℤ) : algSum f h n = ∑ i, f i n := by

theorem AlgSummable.add {ι : Type*} {f g : ι → FormalDist 𝓦}
    (hf : AlgSummable f) (hg : AlgSummable g) : AlgSummable (fun i => f i + g i) := by

theorem algSum_add {ι : Type*} {f g : ι → FormalDist 𝓦}
    (hf : AlgSummable f) (hg : AlgSummable g) :
    algSum (fun i => f i + g i) (hf.add hg) = algSum f hf + algSum g hg := by

theorem algSum_smul {ι : Type*} (c : ℂ) {f : ι → FormalDist 𝓦} (hf : AlgSummable f) :
    algSum (fun i => c • f i) (hf.smul c) = c • algSum f hf := by
```

From the mathematics to the Lean statement

`[Finite ι]` and `[Fintype ι]` are the hypotheses "I is finite" (the second also supplies an enumeration, needed to write the ordinary sum `∑ i, f i n`). `hf.add hg` is the proof that the sum family is summable (the theorem `AlgSummable.add`); it has to be supplied because `algSum` requires a summability proof. `c • f i` is scalar multiplication. All statements are the expected ones; nothing is weaker or stronger.

Physical meaning

Technical bookkeeping: it says that the space of well-defined (energy-bounded) infinite sums of fields is a vector space, so that one may add and rescale OPEs and mode expansions freely.

Proof on paper. For each n the support of $(f_n^{(i)} + g_n^{(i)})_i$ is contained in the union of the two finite supports; the identity is then the additivity of finite sums. Scaling can only shrink supports. For finite I there is nothing to prove. □

What the machine verified

Unconditional. `#print axioms VOA.algSum_add` = `[propext, Classical.choice, Quot.sound]` (Section 2.12).

Trap / dead end

The junk value of `finsum`. Mathlib defines `∑ᶠ i, F i` to be the sum over the support of `F` when that support is finite, and *zero* when it is infinite. This is a convention, chosen so that `finsum` is a total function; it is not a theorem about convergence. Consequently a Lean definition whose coefficients are `finsum`s can be applied to *any* input, and on an input for which the intended sum is infinite it silently returns 0, a meaningless value. Three definitions of this chapter are of this kind: `lpSMul` (Definition 2.10), `subst` (Definition 2.52), and the contractions of Section 2.11. In each case the *theorems* carry the finite-support hypothesis that makes the sum genuine, and the fidelity check below verifies this for every theorem. A reader who meets such a definition applied to an unconstrained input should be suspicious. The authors of `FormalDist4.lean` record the same point in their header: finite-support hypotheses "prevent an infinite-support `finsum` from silently collapsing to zero".

2.2.3 Multiplication by a monomial

Definition 2.5 (Multiplication by z^k). For $k \in \mathbb{Z}$, multiplication by the monomial z^k is the $\mathbb{C}$-linear map $\mathcal{W}[[z^{\pm 1}]] \to \mathcal{W}[[z^{\pm 1}]]$, $(z^k f)_n = f_{n-k}$.

File `VOA/Foundations/FormalSeries.lean`.

```
def mulByMonomial (k : ℤ) : FormalDist 𝒲 →ₗ[ℂ] FormalDist 𝒲 where
  toFun f := fun n => f (n - k)
```

From the mathematics to the Lean statement

`M →ₗ[ℂ] N` is the type of $\mathbb{C}$-linear maps from M to N; a term of it is a function (`toFun`) together with proofs of additivity and homogeneity (`map_add'`, `map_smul'`, both `rfl` in the file and omitted here). The coefficient of z^n in $z^k \sum_m f_m z^m$ is f_{n-k}, which is the formula. Same as the textbook.

Physical meaning

Multiplying a field by z^k shifts its modes: $(z^k a)_{(m)} = a_{(m+k)}$. In radial quantisation, z^k is the eigenfunction of the dilatation L_0 with eigenvalue k, so this operation shifts the energy carried by each mode.

What the machine verified

Definition; linearity is by `rfl`. No hypotheses.

2.3 Delta function, residue, derivative and modes

Definition 2.6 (Formal delta functions)**.** The *formal delta function* in one variable is $\delta(z) := \sum_{n\in\mathbb{Z}} z^n \in \mathbb{C}[[z^{\pm 1}]]$. The two-variable delta function in multiplicative normalisation is

$$\delta(z_1/z_2) := \sum_{k\in\mathbb{Z}} z_1^k z_2^{-k}, \qquad \text{coefficient of } z_1^m z_2^n = [m+n=0].$$

Notation for the rest of the chapter: the symbol $\delta(z_1, z_2)$ (with a comma) always denotes the *additive* normalisation $z_2^{-1}\delta(z_1/z_2) = \sum_k z_1^k z_2^{-k-1}$, coefficient $[m+n+1=0]$, which is Kac's $\delta(z-w)$ and the only one used in the locality theorems (Lean: `deltaForm`, or `deltaDeriv 0 c`). The multiplicative $\delta(z_1/z_2)$ above (Lean: `delta₂`) is not used again.

File `VOA/Foundations/FormalCalculus.lean`.

```
def formalDelta : FormalDist ℂ := fun _ => 1

def delta₂ : FormalDist₂ ℂ := fun m n => if m + n = 0 then 1 else 0
```

From the mathematics to the Lean statement

`fun _ ⇒ 1` is the constant function 1: every coefficient of $\delta(z)$ is 1. `FormalDist₂ ℂ` (Definition 2.21) is the type of two-variable distributions, `f m n` being the coefficient of $z_1^m z_2^n$; `if m + n = 0 then 1 else 0` is the Iverson bracket $[m+n=0]$.

Two normalisations of the two-variable delta. The library contains *two* two-variable deltas and the referee must keep them apart. `delta₂` is $\delta(z_1/z_2) = \sum_k z_1^k z_2^{-k}$ (coefficient $[m+n=0]$). The delta used in all the locality theorems is $\delta(z_1, z_2) := z_2^{-1}\delta(z_1/z_2) = \sum_k z_1^k z_2^{-k-1}$ (coefficient $[m+n+1=0]$), which appears as `deltaDeriv 0 c` (Definition 2.23) and as `deltaForm` (Definition 2.30); it is Kac's $\delta(z-w)$. The two differ by the factor z_2^{-1}, a shift of the second index by one. `formalDelta` and `delta₂` are not used outside `FormalCalculus.lean`; they are faithful to Gannon (5.1.2), where $\delta(z) = \sum_n z^n$ is "the Dirac delta centred at $z = 1$" in multiplicative notation.

Physical meaning

On the unit circle $z = e^{i\sigma}$, $\delta(z) = \sum_n e^{in\sigma} = 2\pi\,\delta_{\text{Dirac}}(\sigma)$: the formal delta is the Fourier series of the Dirac delta at $\sigma = 0$, i.e. at $z = 1$. The two-variable version $\delta(z_1/z_2)$ is supported at $z_1 = z_2$: it is the *contact term* that appears in equal-time commutators $[a(\sigma_1), b(\sigma_2)] \propto \delta(\sigma_1 - \sigma_2)$ of canonical quantisation.

What the machine verified

Definitions. A smoke test in the file checks `res formalDelta = 1` by `rfl`, and that `mulBySubPow 1 delta₂ = 0`, i.e. $(z_1 - z_2)\delta(z_1/z_2) = 0$.

Definition 2.7 (Modes, residue, derivative). Let $f \in \mathcal{W}[[z^{\pm 1}]]$.

(i) The *m-th mode* of f ($m \in \mathbb{Z}$) is $f_{(m)} := f_{-m-1}$, so that $f(z) = \sum_{m\in\mathbb{Z}} f_{(m)}\, z^{-m-1}$.

(ii) If $\mathcal{W}$ is a complex vector space, the *residue* is the linear functional $\mathrm{Res}_z f := f_{-1}$, the coefficient of z^{-1}.

(iii) The *formal derivative* is the linear map ∂_z with $(\partial_z f)_n := (n+1) f_{n+1}$, i.e. $\partial_z \sum_n f_n z^n = \sum_n n f_n z^{n-1}$.

File `VOA/Foundations/FormalCalculus.lean`.

```
def mode (f : FormalDist 𝒲) (m : ℤ) : 𝒲 := f (-m - 1)

def res : FormalDist 𝒲 →ₗ[ℂ] 𝒲 where
  toFun f := f (-1)

def deriv : FormalDist 𝒲 →ₗ[ℂ] FormalDist 𝒲 where
  toFun f := fun n => (n + 1 : ℤ) • f (n + 1)
```

From the mathematics to the Lean statement

The single most important convention of the library: `mode f m = f (-m - 1)`. If `Y u : FormalDist (Module.End ℂ V)` is the vertex operator of a state u, then `mode (Y u) n` is $u_{(n)}$, the coefficient of z^{-n-1}, whereas `Y u n` is the coefficient of z^n, i.e. $u_{(-n-1)}$. Calibration: `Y u 0` $= u_{(-1)}$, `Y u (-1)` $= u_{(0)}$, `Y u (-2)` $= u_{(1)}$. Both forms occur in later chapters, and every fidelity check there must decode them.
`res` is defined only when $\mathcal{W}$ is a complex vector space (the ambient section of the file assumes `[AddCommGroup 𝒲] [Module ℂ 𝒲]`), because it is packaged as a $\mathbb{C}$-linear map; the formula is `f (-1)`. **`deriv`**: `(n + 1 : ℤ) • f (n + 1)` is the integer $n+1$ acting on the vector f_{n+1} (repeated addition), which agrees with the complex scalar $n+1$. The name `VOA.deriv` lives in the namespace `VOA` and is unrelated to Mathlib's analytic `deriv`.
Fidelity. Same as Kac §2.1 ($a(z) = \sum a_{(n)} z^{-n-1}$), Gannon (5.1.3a,c), Frenkel–Ben-Zvi §1.1 and Lepowsky–Li §2.1. In modes, $(\partial f)_{(m)} = (\partial f)_{-m-1} = -m f_{-m} = -m f_{(m-1)}$.

Physical meaning

$f_{(m)} = \oint z^m f(z)\, dz/2\pi i$ is the contour integral that defines a mode; for a current J the zero mode $J_{(0)} = \oint J$ is the conserved charge, and for the stress tensor T the modes $T_{(m+1)} = L_m$ are the Virasoro generators ($L_{-1} = T_{(0)}$ generates translations, $L_0 = T_{(1)}$ dilatations). For a state u, the coefficients $u_{(n)}v$ of $Y(u,z)v$ are the OPE coefficients: $n \geq 0$ the singular terms, $n = -1$ the normal-ordered product, $n \leq -2$ the descendants. The derivative ∂_z is translation of the insertion point.

What the machine verified

Definitions; linearity proofs by `rfl` and by `smul_add`/`smul_comm`. No hypotheses.

Proposition 2.8 (Modes are residues; residues of derivatives vanish). *For every $f \in \mathcal{W}[[z^{\pm 1}]]$ and $m \in \mathbb{Z}$,*

$$f_{(m)} = \mathrm{Res}_z\big(z^m f(z)\big), \qquad \mathrm{Res}_z\big(\partial_z f\big) = 0.$$

File `VOA/Foundations/FormalCalculus.lean`.

```
theorem mode_eq_res (f : FormalDist 𝒲) (m : ℤ) : mode f m = res (mulByMonomial m f) := by

@[simp] theorem res_deriv (f : FormalDist 𝒲) : res (deriv f) = 0 := by
```

From the mathematics to the Lean statement

`mulByMonomial m f` is $z^m f$ (Definition 2.5). `@[simp]` registers the second identity as a rewriting rule for Lean's simplifier; it has no mathematical content. Same as Gannon (5.1.3c) and the first identity of (5.1.3b). No hypotheses beyond $\mathcal{W}$ being a complex vector space.

Physical meaning

The first identity is the contour-integral formula for a mode. The second is Cauchy's theorem for exact forms: the integral of a total derivative around a closed contour vanishes. In CFT it is the reason that ∂a has no conserved charge, $\oint \partial a = 0$, and that total derivatives can be dropped from currents without changing charges.

Proof on paper. $(z^m f)_{-1} = f_{-1-m} = f_{(m)}$. And $(\partial f)_{-1} = (-1+1)f_0 = 0$. □

What the machine verified

Unconditional; axioms `[propext, Classical.choice, Quot.sound]` for both.

Example 2.9 (Calibrating the conventions)**.** Let $f = \sum_n f_n z^n$ and $m \in \mathbb{Z}$. (a) $\mathrm{Res}_z\, \delta(z) = 1$, since every coefficient of δ is 1. (b) $(\partial_z z^k)_n = (n+1)[n+1=k]$, so $\partial_z z^k = k z^{k-1}$; in particular $\partial_z z^0 = 0$ and $\partial_z z^{-1} = -z^{-2}$, and $\mathrm{Res}_z\, \partial_z z^0 = 0$ although z^{-1} is the only monomial with nonzero residue: z^{-1} is not a derivative, which is why the residue is a nontrivial functional. (c) $\partial_z \delta(z) = \sum_n (n+1) z^n$; its residue is $0 \cdot 1 = 0$, as Proposition 2.8 demands. (d) In modes, a field with $a(z) = \sum_n a_{(n)} z^{-n-1}$ has $(\partial a)_{(n)} = -n\, a_{(n-1)}$; e.g. for $a = J$ a current, $(\partial J)_{(0)} = 0$: total derivatives carry no charge.

2.3.1 The Laurent-polynomial action and integration by parts

Definition 2.10 (Action of a Laurent polynomial)**.** For $g \in \mathbb{C}[[z^{\pm 1}]]$ and $f \in \mathcal{W}[[z^{\pm 1}]]$ define $g \cdot f$ by

$$(g \cdot f)_n := \sum_{k \in \mathbb{Z}} g_k\, f_{n-k}.$$

If g is a Laurent polynomial, each coefficient is a finite sum, and $g \cdot f$ is the product of the Laurent polynomial g with the distribution f.

File `VOA/Foundations/FormalCalculus.lean`.

```
noncomputable def lpSMul (g : FormalDist ℂ) (f : FormalDist 𝒲) : FormalDist 𝒲 :=
  fun n => ∑ᶠ k, g k • f (n - k)

theorem support_smul_left_finite (g : FormalDist ℂ) (hg : (Function.support g).Finite)
    (F : ℤ → 𝒲) : (Function.support (fun k => g k • F k)).Finite := by
```

From the mathematics to the Lean statement

The junk-value trap applies here (the trap box on p. 44). `lpSMul g f` is defined for every g, but if g has infinite support the sum `∑ᶠ k, g k • f (n - k)` may have infinite support and then evaluates to 0. Example: $g = f = \delta$ gives the "product" $\delta \cdot \delta$, which Lean evaluates to the zero distribution, whereas the mathematical product is undefined (Gannon's Paradox 5.1). The lemma `support_smul_left_finite` says: if g has finite support, then for *any* F the summand $k \mapsto g_k F_k$ has finite support. Every theorem about `lpSMul` below carries the hypothesis `hg : (Function.support g).Finite`, which puts us in the meaningful case. Under it, the definition is the textbook product (Gannon p. 315: $\mathcal{W}[[z^{\pm}]]$ is a $\mathbb{C}[z^{\pm}]$-module).

Physical meaning

Multiplying a field by a Laurent polynomial $g(z)$ is smearing with a test function: the modes of $g(z)a(z)$ are finite combinations of modes of a. This is the operation used in every contour manipulation, e.g. $\oint (z-w)^k a(z)\,dz$ for a polynomial $(z-w)^k$ in z.

What the machine verified

Definition and support lemma; the lemma is unconditional. `lpSMul` is not used outside `FormalCalculus.lean`.

Theorem 2.11 (Leibniz rule). *If $g \in \mathbb{C}[z^{\pm 1}]$ is a Laurent polynomial and $f \in \mathcal{W}[[z^{\pm 1}]]$, then*

$$\partial_z(g \cdot f) = (\partial_z g) \cdot f + g \cdot (\partial_z f).$$

File `VOA/Foundations/FormalCalculus.lean`.

```
theorem deriv_lpSMul (g : FormalDist ℂ) (hg : (Function.support g).Finite) (f : FormalDist
↪  𝒲) :
    deriv (lpSMul g f) = lpSMul (deriv g) f + lpSMul g (deriv f) := by
```

From the mathematics to the Lean statement

The one hypothesis `hg` is "g is a Laurent polynomial". It is necessary for the statement to be meaningful (the trap box on p. 44); note that $\partial_z g$ is then also a Laurent polynomial, so all three products are genuine. f is arbitrary. Same as Gannon §5.1.2.

Physical meaning

The product rule for smeared fields; it is what makes the translation operator L_{-1} act as a derivation on products of fields and test functions.

Proof on paper. Compare the coefficients of z^n. On the left, $(n+1)\sum_k g_k f_{n+1-k}$. On the right, $\sum_k (k+1) g_{k+1} f_{n-k} + \sum_k g_k (n-k+1) f_{n-k+1}$; shifting $k \mapsto k-1$ in the first sum turns it into $\sum_k k\, g_k f_{n-k+1}$, and adding gives $\sum_k (k+n-k+1) g_k f_{n+1-k}$. All sums are finite because g has finite support; the index shift is a bijection of $\mathbb{Z}$. □

What the machine verified

Unconditional (the hypothesis is the meaningfulness condition). Axioms `[propext, Classical.choice, Quot.sound]`.

Theorem 2.12 (Integration by parts; Gannon (5.1.3b)). *If $g \in \mathbb{C}[z^{\pm 1}]$ is a Laurent polynomial and $f \in \mathcal{W}[[z^{\pm 1}]]$, then*

$$\operatorname{Res}_z \big(g \cdot \partial_z f\big) = -\operatorname{Res}_z \big((\partial_z g) \cdot f\big).$$

File `VOA/Foundations/FormalCalculus.lean`.

```
theorem res_lpSMul_deriv (g : FormalDist ℂ) (hg : (Function.support g).Finite)
    (f : FormalDist 𝒲) : res (lpSMul g (deriv f)) = - res (lpSMul (deriv g) f) := by
```

From the mathematics to the Lean statement

Same hypothesis as Theorem 2.11. The file header writes the identity as "$\operatorname{Res}_z(g \cdot \partial_z f) = -\operatorname{Res}_z(f \cdot \partial_z g)$"; since `lpSMul` is the commutative product of a scalar series with a vector series, these are the same statement. Exactly Gannon (5.1.3b).

Physical meaning

Integration by parts on a closed contour, with no boundary term. In mode language with $g = z^m$: $(\partial f)_{(m)} = -m f_{(m-1)}$, the familiar rule for modes of derivative fields.

Proof on paper. Apply Res_z to the Leibniz rule: the left side is the residue of a derivative, which vanishes (Proposition 2.8). □

Example 2.13. Take $g = z^m$. Then $(g \cdot \partial f)_{-1} = (\partial f)_{-1-m} = -m f_{-m}$ and $((\partial g) \cdot f)_{-1} = m\,(z^{m-1} f)_{-1} = m f_{-m}$, confirming the theorem by direct computation.

What the machine verified

Unconditional; axioms `[propext, Classical.choice, Quot.sound]`.

2.4 Binomial coefficients with integer upper index

Expanding $(z_1 - z_2)^n$ for negative n requires binomial coefficients $\binom{n}{k}$ with $n < 0$. This section collects the library's definitions and the three identities used later: the values at $n = -1$, Pascal's rule, and the Chu–Vandermonde convolution.

Definition 2.14 (Generalised binomial coefficients, signs, the binomial convention)**.**

(i) For $n \in \mathbb{Z}$ and $k \in \mathbb{N}$, $\binom{n}{k} := \dfrac{n(n-1)\cdots(n-k+1)}{k!} = \dfrac{1}{k!}\displaystyle\prod_{i=0}^{k-1}(n-i)$ (the empty product, $k = 0$, gives $\binom{n}{0} = 1$).

(ii) For $n, k \in \mathbb{Z}$, $C(n,k) := \binom{n}{k}$ if $k \geq 0$ and $C(n,k) := 0$ if $k < 0$.

(iii) For $n \in \mathbb{Z}$, $(-1)^n := 1$ if n is even and -1 if n is odd.

(iv) (Gannon (5.1.4), the *binomial convention*.) For $n \in \mathbb{Z}$, $(z_1 + z_2)^n := \displaystyle\sum_{k \geq 0} \binom{n}{k} z_1^{n-k} z_2^k$, always expanded in *nonnegative powers of the second variable*.

Files (all in `VOA/Foundations/`): `FormalCalculus.lean` (`gBinom`, `binomialExpand`), `Substitution.lean` (`cbz`), `Expansion.lean` (`negOnePow`).

```
noncomputable def gBinom (n : ℤ) (k : ℕ) : ℂ :=
  (∏ i ∈ Finset.range k, ((n : ℂ) - (i : ℂ))) / (k.factorial : ℂ)

noncomputable def binomialExpand (n : ℤ) : FormalDist₂ ℂ :=
  fun a b => if 0 ≤ b ∧ a = n - b then gBinom n b.toNat else 0

noncomputable def cbz (n k : ℤ) : ℂ := if 0 ≤ k then gBinom n k.toNat else 0

def negOnePow (n : ℤ) : ℂ := if Even n then 1 else -1
```

From the mathematics to the Lean statement

Decoding. `Finset.range k` is $\{0, 1, \ldots, k-1\}$, so the product is $\prod_{i=0}^{k-1}(n-i)$, computed in $\mathbb{C}$ after the casts `(n : ℂ)`, `(i : ℂ)`; `k.factorial` is $k!$. `b.toNat` converts an integer b to a natural number (it returns 0 for $b < 0$, but it is only ever evaluated under the guard $0 \leq b$, so no junk value is used). `binomialExpand n a b` is the coefficient of $z_1^a z_2^b$ in $(z_1 + z_2)^n$: it is $\binom{n}{b}$ when $b \geq 0$ and $a = n - b$, else 0. This is (iv) verbatim. `cbz` is (ii), and `negOnePow` is (iii) (it avoids

the integer power `zpow`, whose sign conventions are a nuisance in Lean).
Fidelity. (i) agrees with the usual binomial coefficient for $n \geq 0$ (e.g. $\binom{5}{2} = 10$, $\binom{2}{7} = 0$ since the product contains the factor $2 - 2$), and is the standard extension to negative n (Kac §2.1, Gannon (5.1.4a), Lepowsky–Li §2.1). The convention (iv) is genuinely a *convention*: the same symbol $(z_1 + z_2)^n$ with the variables written in the other order means a different series (Example 2.16).
Usage. `binomialExpand` is not used elsewhere at this commit: the library works instead with the expansions `expandPos`/`expandNeg` of $(z_1 - z_2)^n$ (Definition 2.30), which build in the sign. `cbz` is used heavily (substitution, Vandermonde, the Borcherds identity in `VOA/Core/Skew.lean`; the Borcherds identity is a theorem for `VertexOperatorAlgebra` only, Chapter 4).

Physical meaning

Generalised binomials are the Taylor coefficients of $(1 + x)^n$ for negative n: they are what one gets by expanding an OPE singularity $(z - w)^{-k}$ in one of the two radial orderings. The convention "nonnegative powers of the second variable" fixes, once and for all, which region of the (z_1, z_2)-plane a formula refers to; in a physics computation the region is fixed by the radial ordering of the operators, and forgetting it is the most common source of sign errors in mode calculations.

What the machine verified

Definitions. No hypotheses.

Example 2.15 (Values with negative upper index). For $r \geq 1$, $\binom{-r}{k} = \frac{(-r)(-r-1)\cdots(-r-k+1)}{k!} = (-1)^k\binom{r+k-1}{k}$. Thus $\binom{-1}{k} = (-1)^k$, $\binom{-2}{k} = (-1)^k(k+1)$, $\binom{-3}{k} = (-1)^k\binom{k+2}{2}$. In particular $\binom{n}{k} \neq 0$ for every $k \geq 0$ when $n < 0$: binomial sums with negative upper index are infinite, which is why the expansions of $(z_1 - z_2)^n$, $n < 0$, are infinite series and must be controlled by truncation.

Example 2.16 (The convention determines the series (Gannon's "Paradox 5.2")). By (iv), $(z_1 + z_2)^{-1} = \sum_{k\geq 0}(-1)^k z_1^{-1-k} z_2^k$, while $(z_2 + z_1)^{-1} = \sum_{k\geq 0}(-1)^k z_2^{-1-k} z_1^k$. The two formal series are different although the rational functions are equal. There is no contradiction (Gannon's word "paradox" is rhetorical): the convention attaches to the *ordered* expression a unique series, and the two orders are two different expansions of one rational function. Their difference is

$$(z_1 + z_2)^{-1} - (z_2 + z_1)^{-1} = \sum_{k\in\mathbb{Z}} (-1)^k z_1^{-1-k} z_2^k = z_1^{-1}\delta(-z_2/z_1),$$

a delta function supported at $z_1 = -z_2$, the pole of the rational function. In the library this phenomenon, for $(z_1 - z_2)^{-1}$, is Theorem 2.33.

Proposition 2.17 (Basic values and sign rules). *For all $n \in \mathbb{Z}$, $k \in \mathbb{N}$: $\binom{n}{0} = 1$; $\binom{-1}{k} = (-1)^k$; $k!\binom{n}{k} = \prod_{i<k}(n - i)$; $(-1)^{n+1} = -(-1)^n$; $(-1)^k$ (as an integer exponent) equals $(-1)^k$ computed as a power in $\mathbb{C}$; and $(-1)^{x+y} = (-1)^x(-1)^y$ for $x, y \in \mathbb{Z}$.*

Files `VOA/Foundations/FormalCalculus.lean`, `VOA/Foundations/Expansion.lean`, `VOA/Foundations/Substitution.lean`, `VOA/Foundations/IotaZExpansion.lean`.

```
@[simp] theorem gBinom_zero (n : ℤ) : gBinom n 0 = 1 := by

theorem gBinom_neg_one (k : ℕ) : gBinom (-1) k = (-1 : ℂ) ^ k := by

theorem gBinom_mul_factorial (n : ℤ) (k : ℕ) :
    (k.factorial : ℂ) * gBinom n k = ∏ i ∈ Finset.range k, ((n : ℂ) - (i : ℂ)) := by
```

```
theorem negOnePow_succ (n : ℤ) : negOnePow (n + 1) = - negOnePow n := by

theorem negOnePow_natCast (k : ℕ) : negOnePow (k : ℤ) = (-1 : ℂ) ^ k := by

theorem negOnePow_add (x y : ℤ) : negOnePow (x + y) = negOnePow x * negOnePow y := by
```

From the mathematics to the Lean statement

`(-1 : ℂ) ^ k` is the natural-number power in $\mathbb{C}$. `(k : ℤ)` is k viewed as an integer. All six are the stated identities, with no hypotheses.

Physical meaning

Bookkeeping for signs; $\binom{-1}{k} = (-1)^k$ is the geometric series $1/(1+x) = \sum(-x)^k$ behind the expansion of the simple pole $1/(z-w)$.

Proof on paper. $\prod_{i<k}(-1-i) = (-1)^k k!$. The sign rules follow by induction on y in both directions. □

What the machine verified

All unconditional; `#print axioms VOA.gBinom_neg_one = [propext, Classical.choice, Quot.sound]`.

Proposition 2.18 (Pascal's rule). *For all $n \in \mathbb{Z}$ and $j \in \mathbb{N}$, $\binom{n}{j+1} = \binom{n-1}{j+1} + \binom{n-1}{j}$. Equivalently, for all $n, k \in \mathbb{Z}$, $C(n,k) = C(n-1,k) + C(n-1,k-1)$.*

File `VOA/Foundations/Substitution.lean`.

```
theorem gBinom_succ_pascal (n : ℤ) (j : ℕ) :
    gBinom n (j + 1) = gBinom (n - 1) (j + 1) + gBinom (n - 1) j := by

theorem cbz_pascal (n k : ℤ) : cbz n k = cbz (n - 1) k + cbz (n - 1) (k - 1) := by
```

From the mathematics to the Lean statement

The integer-indexed form `cbz_pascal` holds for *all* $k \in \mathbb{Z}$, including $k = 0$ (where it reads $1 = 1 + 0$) and $k < 0$ (where it reads $0 = 0 + 0$); this uniformity is what lets later proofs shift summation indices over all of $\mathbb{Z}$ without case distinctions. Same as the classical rule.

Physical meaning

Pascal's rule is the coefficient form of $(1+x)^n = (1+x)^{n-1}(1+x)$; in the formal calculus it is the identity $(z_0+z_2)^m = (z_0+z_2)^{m-1}z_0 + (z_0+z_2)^{m-1}z_2$, used to move a factor $z_1 - z_2 = z_0$ through the substitution $z_1 = z_0 + z_2$ (Theorem 2.53).

Proof on paper. Multiply by $(j+1)!$: $\prod_{i\le j}(n-i) = n\prod_{i<j}(n-1-i)$, and $(n-1-j)\prod_{i<j}(n-1-i) + (j+1)\prod_{i<j}(n-1-i) = n\prod_{i<j}(n-1-i)$. □

What the machine verified

Unconditional; axioms `[propext, Classical.choice, Quot.sound]` (both checked).

Theorem 2.19 (Generalised Chu–Vandermonde identity). *For all integers m, n, k,*

$$\sum_{i\in\mathbb{Z}} C(m,i)\,C(n,k-i) = C(m+n,k),$$

the sum having finitely many nonzero terms ($0 \le i \le k$).

File `VOA/Foundations/IotaZExpansion.lean`.

```
theorem cbz_convol_support_finite (m n k : ℤ) :
    (Function.support (fun i : ℤ => cbz m i * cbz n (k - i))).Finite := by

noncomputable def cbzConvol (m n k : ℤ) : ℂ := ∑ᶠ i : ℤ, cbz m i * cbz n (k - i)

theorem cbz_vandermonde (m n k : ℤ) : cbzConvol m n k = cbz (m + n) k := by
```

From the mathematics to the Lean statement

`cbzConvol` is a `finsum`, but the preceding lemma shows that its support is finite for every m, n, k, so here the junk value never occurs and `cbzConvol m n k` is the genuine finite sum. The theorem holds for *all* integers m, n, k, including negative ones; for $k < 0$ both sides are 0. This is the full generalised Vandermonde identity, i.e. the coefficient form of $(1+x)^m(1+x)^n = (1+x)^{m+n}$ in $\mathbb{C}[[x]]$ for integer exponents.

Physical meaning

Coefficientwise, this is the statement that singular OPE factors multiply as functions: $(z-w)^m(z-w)^n = (z-w)^{m+n}$ inside a fixed radial ordering. It is the bookkeeping behind the lattice vertex operators, whose OPEs carry the factor $(z-w)^{\langle\alpha,\beta\rangle}$, and which must satisfy $(z-w)^{\langle\alpha,\beta\rangle}(z-w)^{\langle\alpha,\gamma\rangle} = (z-w)^{\langle\alpha,\beta+\gamma\rangle}$ (Theorem 2.36).

Proof on paper. Fix $k \ge 0$ (for $k < 0$ both sides vanish). Both sides are polynomials in (m, n): the left is $\sum_{i=0}^{k} \binom{m}{i}\binom{n}{k-i}$, the right $\binom{m+n}{k}$. For natural m, n the identity is classical (choose k objects from $m+n$ by deciding how many come from the first m). Two polynomials in two variables that agree on $\mathbb{N}\times\mathbb{N}$ are equal, so the identity holds for all integers. An alternative argument, closer to the library's, is to note that both sides satisfy the recursion $V(m+1) = V(m) + V(m)|_{k\mapsto k-1}$ in m (Pascal's rule) and agree at $m = 0$; this determines them for $m \ge 0$, and running the recursion backwards (using that both vanish for $k < 0$) determines them for $m < 0$. The library formalises this second argument by integer induction on m with an inner induction on k. □

Example 2.20. $m = n = -1, k = 2$: $\sum_{i=0}^{2}\binom{-1}{i}\binom{-1}{2-i} = 1+1+1 = 3$ and $\binom{-2}{2} = 3$. And $m = 2, n = -1$, $k = 3$: $\binom{2}{0}\binom{-1}{3}+\binom{2}{1}\binom{-1}{2}+\binom{2}{2}\binom{-1}{1} = -1+2-1 = 0 = \binom{1}{3}$, as it must be since $(1+x)^2(1+x)^{-1} = 1+x$.

What the machine verified

Unconditional; `#print axioms VOA.cbz_vandermonde = [propext, Classical.choice, Quot.sound]`.

2.5 Two-variable distributions and the structure theorem

2.5.1 Two-variable distributions and multiplication by $z_1 - z_2$

Definition 2.21 (Two-variable distributions; $(z_1-z_2)^N$)**.** A *two-variable formal distribution* is a function $f : \mathbb{Z}\times\mathbb{Z} \to \mathcal{W}$, written $f(z_1, z_2) = \sum_{m,n\in\mathbb{Z}} f_{m,n} z_1^m z_2^n$; the space is $\mathcal{W}[[z_1^{\pm1}, z_2^{\pm1}]]$, a vector space under coefficientwise operations. Multiplication by z_1, by z_2 and by $z_1 - z_2$ are the linear maps

$$(z_1 f)_{m,n} = f_{m-1,n}, \qquad (z_2 f)_{m,n} = f_{m,n-1}, \qquad ((z_1-z_2)f)_{m,n} = f_{m-1,n} - f_{m,n-1},$$

and $(z_1-z_2)^N$ ($N \in \mathbb{N}$) is the N-fold iterate of the last, $(z_1-z_2)^0 = \mathrm{id}$.

File `VOA/Foundations/FormalSeries.lean`.

```
def FormalDist₂ (𝒲 : Type*) : Type _ := ℤ → ℤ → 𝒲

@[inherit_doc] notation:max 𝒲 "⟦z₁^±,z₂^±⟧" => FormalDist₂ 𝒲

def shiftZ₁ : FormalDist₂ 𝒲 →ₗ[ℂ] FormalDist₂ 𝒲 where
  toFun f := fun m n => f (m - 1) n

def shiftZ₂ : FormalDist₂ 𝒲 →ₗ[ℂ] FormalDist₂ 𝒲 where
  toFun f := fun m n => f m (n - 1)

def mulBySub : FormalDist₂ 𝒲 →ₗ[ℂ] FormalDist₂ 𝒲 := shiftZ₁ - shiftZ₂

def mulBySubPow : ℕ → (FormalDist₂ 𝒲 →ₗ[ℂ] FormalDist₂ 𝒲)
  | 0 => LinearMap.id
  | (N + 1) => mulBySub.comp (mulBySubPow N)
```

From the mathematics to the Lean statement

`ℤ → ℤ → 𝒲` is the curried form of $\mathbb{Z}\times\mathbb{Z}\to\mathcal{W}$: `f m n` is $f_{m,n}$, the coefficient of $z_1^m z_2^n$. As for one variable, `FormalDist₂` is an opaque `def` with only the additive and module structure (instances in the file, analogous to Definition 2.1). `shiftZ₁ - shiftZ₂` is the difference of two linear maps, and the file proves `mulBySub_apply : mulBySub f m n = f (m - 1) n - f m (n - 1)`. `mulBySubPow` is defined by recursion on N: `mulBySubPow (N + 1) = mulBySub ∘ mulBySubPow N`. Same as Gannon p. 314. Note that multiplication by a polynomial in two *different* variables is always defined coefficientwise by a finite formula; no truncation is needed.

Physical meaning

Two-variable distributions are operator products $a(z_1)b(z_2)$ and four-point-like correlators expanded in two insertion points. Multiplying by $(z_1-z_2)^N$ is multiplying by the function that vanishes to order N where the two operators collide; it is the operation that removes the OPE singularity of order $\le N$.

What the machine verified

Definitions; no hypotheses. `mulBySubPow_one : mulBySubPow 1 = mulBySub` is proved in the file.

Lemma 2.22 (The two factorisations of $(z_1-z_2)^{N+1}$). *For every N and f, $(z_1-z_2)^{N+1}f = (z_1-z_2)^N\big((z_1-z_2)f\big)$.*

File `VOA/Foundations/Locality.lean`.

```
theorem mulBySubPow_succ' (N : ℕ) (f : FormalDist₂ 𝒲) :
    mulBySubPow (N + 1) f = mulBySubPow N (mulBySub f) := by
```

From the mathematics to the Lean statement

`mulBySubPow` was defined by *post*-composition, $(z_1-z_2)^{N+1} = (z_1-z_2)\circ(z_1-z_2)^N$; the lemma gives the *pre*-composition form. It is the associativity of iterated composition, needed to peel factors off on either side.

Physical meaning

Technical: one may strip the factors $(z_1 - z_2)$ one at a time from either end when cancelling an OPE pole.

Proof on paper. Induction on N. □

What the machine verified

Unconditional.

2.5.2 Derivatives of the delta function

From now on

$$\delta(z_1, z_2) := \sum_{k \in \mathbb{Z}} z_1^k z_2^{-k-1} = z_2^{-1}\delta(z_1/z_2),$$

the delta function in Kac's normalisation ($\delta(z-w)$ in his notation). It is symmetric: $\delta(z_1, z_2) = \delta(z_2, z_1)$ (substitute $k \mapsto -k-1$). Its key property is

$$(z_1 - z_2)\delta(z_1, z_2) = \sum_k z_1^{k+1} z_2^{-k-1} - \sum_k z_1^k z_2^{-k} = 0,$$

the two sums being equal after $k \mapsto k-1$. Consequently, for every Laurent polynomial g, $g(z_1)\delta(z_1, z_2) = g(z_2)\delta(z_1, z_2)$: the delta function "sets $z_1 = z_2$".

Definition 2.23 ($c(z_2)\,\partial_{z_2}^j \delta(z_1, z_2)$; recovered coefficients)**.** For $j \in \mathbb{N}$ and $c \in \mathcal{W}[[z^{\pm 1}]]$ let $c(z_2)\,\partial_{z_2}^j \delta(z_1, z_2)$ be the two-variable distribution with coefficients

$$\big(c(z_2)\,\partial_{z_2}^j \delta(z_1, z_2)\big)_{m,n} = \Big(\prod_{i=0}^{j-1}(-m-1-i)\Big)\, c_{m+n+1+j}.$$

For $f \in \mathcal{W}[[z_1^{\pm 1}, z_2^{\pm 1}]]$ and $j \in \mathbb{N}$, the *j-th recovered coefficient* is the one-variable distribution $\mathrm{Res}_{z_1}\big((z_1 - z_2)^j f\big)$, with z_2^n-coefficient $\big((z_1 - z_2)^j f\big)_{-1,n}$.

File `VOA/Foundations/Locality.lean`.

```
def deltaDeriv (j : ℕ) : FormalDist 𝒲 →ₗ[ℂ] FormalDist₂ 𝒲 where
  toFun c := fun m n => (∏ i ∈ Finset.range j, (-m - 1 - (i : ℤ))) • c (m + n + 1 + j)

def cCoeff (j : ℕ) (f : FormalDist₂ 𝒲) : FormalDist 𝒲 := fun n => mulBySubPow j f (-1) n
```

From the mathematics to the Lean statement

Why this formula is $c(z_2)\partial_{z_2}^j\delta(z_1, z_2)$**.** Differentiating z_2^{-k-1} j times gives $(-k-1)(-k-2)\cdots(-k-j)\,z_2^{-k-1-j} = \prod_{i<j}(-k-1-i)\,z_2^{-k-1-j}$. So $\partial_{z_2}^j\delta(z_1, z_2) = \sum_k \prod_{i<j}(-k-1-i)\,z_1^k z_2^{-k-1-j}$, whose z_1^m-part has $k = m$. Multiplying by $c(z_2) = \sum_r c_r z_2^r$, the coefficient of z_2^n needs $r - m - 1 - j = n$, i.e. $r = m + n + 1 + j$. This is the Lean formula. The product is an *integer*, acting on the vector $c_{m+n+1+j}$ by $\bullet$. The product of $c(z_2)$ with $\partial^j\delta$ is well defined because for fixed (m, n) only one coefficient of c contributes. `deltaDeriv j` is packaged as a $\mathbb{C}$-linear map in c.

Plain versus divided derivatives. Kac and Frenkel–Ben-Zvi use divided powers $\partial^{(j)} = \partial^j/j!$; the library uses the plain ∂^j. The only effect is a rescaling of the coefficients c^j by $j!$; the docstring of `cCoeff` records this ("up to the $j!$ of the plain-power convention"). `cCoeff j f n` is the coefficient of $z_1^{-1}z_2^n$ in $(z_1 - z_2)^j f$, i.e. $\mathrm{Res}_{z_1}(z_1 - z_2)^j f$. For $f = [a(z_1), b(z_2)]$ this is the

OPE coefficient $(a_{(j)}b)(z_2)$ (Kac (2.2.4)); Chapter 4 uses it in Dong's lemma (Theorem 4.16). **Which delta.** `deltaDeriv 0 c` has coefficient c_{m+n+1}: it is $c(z_2)\delta(z_1,z_2)$ with the z_2^{-1}-normalised delta, *not* with `delta₂` of Definition 2.6.

Physical meaning

$c(w)\,\partial_w^j\delta(z,w)$ is a contact term of order j: paired with a test function $g(z)$ it gives $\mathrm{Res}_z\, g(z)c(w)\partial_w^j\delta(z,w) = c(w)\,\partial_w^j g(w)$, a derivative of the test function at the coincident point. These are precisely the terms that the singular part $c(w)\,j!/(z-w)^{j+1}$ of an OPE contributes to a commutator (Theorem 2.38). The recovered coefficient $\mathrm{Res}_z(z-w)^j[a(z),b(w)]$ is the contour integral $\oint_w (z-w)^j a(z)b(w)\,dz/2\pi i$ around w, which extracts the coefficient of the pole of order $j+1$: the j-th product $a_{(j)}b$.

What the machine verified

Definitions; linearity of `deltaDeriv j` proved in the file. No hypotheses.

Example 2.24 (The first two derivatives). Let $\mathbf{1}_0 \in \mathbb{C}[[z^{\pm1}]]$ be the constant series 1 (coefficient $[t=0]$; the library calls it `deltaCoeff`, Definition 2.37). Then `deltaDeriv 0 deltaCoeff` has coefficient $[m+n+1=0]$, which is $\delta(z_1,z_2)$. `deltaDeriv 1 deltaCoeff` has coefficient $(-m-1)[m+n+2=0]$, i.e.

$$\partial_{z_2}\delta(z_1,z_2) = \sum_{m\in\mathbb{Z}} (-m-1)\, z_1^m z_2^{-m-2} = \sum_{k\in\mathbb{Z}} (k+1) z_1^{-k-2} z_2^k.$$

Check against the definition: $\partial_{z_2} z_2^{-m-1} = (-m-1)z_2^{-m-2}$. The coefficient $(-m-1)$ vanishes at $m=-1$: $\mathrm{Res}_{z_1}\partial_{z_2}\delta(z_1,z_2)=0$, whereas $\mathrm{Res}_{z_1}\delta(z_1,z_2)=1$. Similarly `deltaDeriv 2 deltaCoeff` has coefficient $(m+1)(m+2)[m+n+3=0]$.

Proposition 2.25 (Peeling identities). *For $j,N\in\mathbb{N}$ and $c\in\mathcal{W}[[z^{\pm1}]]$, writing $\partial=\partial_{z_2}$ and $\delta=\delta(z_1,z_2)$:*

(a) $(z_1-z_2)\,c\,\delta = 0$;

(b) $(z_1-z_2)\,c\,\partial^{j+1}\delta = (j+1)\,c\,\partial^j\delta$;

(c) $(z_1-z_2)^N\,c\,\partial^N\delta = N!\,c\,\delta$;

(d) $(z_1-z_2)^N\,c\,\partial^j\delta = 0$ *whenever* $j+1\le N$.

The engine is the finite-difference identity for falling factorials: $\prod_{i\le j}(y+1-i) - \prod_{i\le j}(y-i) = (j+1)\prod_{i<j}(y-i)$ *for* $y\in\mathbb{Z}$.

File `VOA/Foundations/Locality.lean`.

theorem mulBySubPow_deltaDeriv_self (N : ℕ) (c : FormalDist 𝒲) :
    mulBySubPow N (deltaDeriv N c) = (N.factorial : ℤ) • deltaDeriv 0 c := by
```

```
theorem mulBySubPow_succ_deltaDeriv (j : ℕ) (c : FormalDist 𝒲) :
    mulBySubPow (j + 1) (deltaDeriv j c) = 0 := by

theorem mulBySubPow_deltaDeriv_eq_zero {j N : ℕ} (h : j + 1 ≤ N) (c : FormalDist 𝒲) :
    mulBySubPow N (deltaDeriv j c) = 0 := by
```

From the mathematics to the Lean statement

Statements (a)–(d) are, in order, `mulBySub_deltaDeriv_zero`, `mulBySub_deltaDeriv`, `mulBySubPow_deltaDeriv_self` and `mulBySubPow_deltaDeriv_eq_zero` (with the special case $N = j + 1$ named `mulBySubPow_succ_deltaDeriv`). The scalars `((j : ℤ) + 1)` and `(N.factorial : ℤ)` act by integer scalar multiplication. The hypothesis `h : j + 1 ≤ N` in (d) is the natural one. With divided powers, (b) would read $(z_1 - z_2)\partial^{(j+1)}\delta = \partial^{(j)}\delta$ (Kac §2.1); the library's (b) is that identity multiplied by $(j+1)!$.

Physical meaning

Multiplying a contact term of order $j+1$ by $(z_1 - z_2)$ lowers its order by one; N such factors kill every contact term of order $< N$. This is the formal version of the statement that $(z-w)^N$ cancels an OPE pole of order $\leq N$.

Proof on paper. Coefficientwise, $((z_1 - z_2)F)_{m,n} = F_{m-1,n} - F_{m,n-1}$. For $F = c\,\partial^{j+1}\delta$ both terms involve the same coefficient of c, namely $c_{m+n+1+j}$, because $(m-1)+n+1+(j+1) = m+(n-1)+1+(j+1) = m+n+1+j$; they are multiplied by the falling products at $y = -m-1$ shifted by one and not shifted; `fallingDiff` with $y = -m-1$ turns their difference into $(j+1)\prod_{i<j}(-m-1-i)$, which is the coefficient of $(j+1)c\,\partial^j\delta$. For (a) the two terms are equal. (c) is (b) iterated N times, and (d) follows from (c) and (a). □

What the machine verified

All unconditional; axioms `[propext, Classical.choice, Quot.sound]` (checked for (b), (c), (d)).

Proposition 2.26 (The case $N = 1$). *If $(z_1 - z_2)f = 0$, then $f = c(z_2)\delta(z_1, z_2)$ with $c = \mathrm{Res}_{z_1} f$, i.e. $c_n = f_{-1,n}$.*

File `VOA/Foundations/Locality.lean`.

```
theorem eq_deltaDeriv_zero_of_mulBySub_eq_zero {f : FormalDist₂ 𝒲} (hf : mulBySub f = 0) :
    f = deltaDeriv 0 (fun n => f (-1) n) := by
```

From the mathematics to the Lean statement

`fun n ⇒ f (-1) n` is the one-variable distribution $n \mapsto f_{-1,n}$, i.e. $\mathrm{Res}_{z_1} f$. The conclusion `deltaDeriv 0 (...)` has coefficient $f_{-1,m+n+1}$ at (m,n). So the theorem says $f_{m,n} = f_{-1,m+n+1}$ for all m, n: f is constant along each antidiagonal $m+n = \text{const}$. The hypothesis is the only one, and it is used. Same as the $N = 1$ case of Gannon Prop. 5.1.2.

Physical meaning

A distribution killed by $(z_1 - z_2)$ is supported at $z_1 = z_2$ with no derivatives: a pure contact term, like the commutator $[\psi(z), \psi^*(w)] = \delta(z,w)$ of a free fermion pair (Section 2.7.2).

Proof on paper. $(z_1 - z_2)f = 0$ says $f_{m-1,n} = f_{m,n-1}$ for all m, n, i.e. $f_{m,n} = f_{m-1,n+1}$. Iterating in both directions, $f_{m,n} = f_{m-d,n+d}$ for all $d \in \mathbb{Z}$; with $d = m+1$ this is $f_{m,n} = f_{-1,m+n+1}$. □

What the machine verified

Unconditional; axioms `[propext, Classical.choice, Quot.sound]`.

2.5.3 The structure theorem for local distributions

Theorem 2.27 (Structure theorem; Gannon Prop. 5.1.2, Kac Thm. 2.3)**.** *Let $\mathcal{W}$ be a complex vector space, $f \in \mathcal{W}[[z_1^{\pm 1}, z_2^{\pm 1}]]$ and $N \in \mathbb{N}$. Then*

$$(z_1 - z_2)^N f = 0 \quad \Longleftrightarrow \quad \exists\, c^0, \dots, c^{N-1} \in \mathcal{W}[[z^{\pm 1}]] : \; f(z_1, z_2) = \sum_{j=0}^{N-1} c^j(z_2)\, \partial_{z_2}^j \delta(z_1, z_2).$$

Moreover, in the forward direction the coefficients can be taken to be $c^j = \frac{1}{j!} \operatorname{Res}_{z_1} (z_1 - z_2)^j f$ (Corollary 2.28).

File `VOA/Foundations/Locality.lean`.

```
theorem exists_deltaSum_of_mulBySubPow_eq_zero (N : ℕ) (f : FormalDist₂ 𝒲)
    (hf : mulBySubPow N f = 0) :
    ∃ c : Fin N → FormalDist 𝒲, f = ∑ j : Fin N, deltaDeriv (j : ℕ) (c j) := by

theorem local_iff_deltaSum (f : FormalDist₂ 𝒲) (N : ℕ) :
    mulBySubPow N f = 0 ↔
      ∃ c : Fin N → FormalDist 𝒲, f = ∑ j : Fin N, deltaDeriv (j : ℕ) (c j) := by
```

From the mathematics to the Lean statement

Decoding. `Fin N` is the type $\{0, 1, \dots, N-1\}$; `c : Fin N → FormalDist 𝒲` is the tuple $(c^0, \dots, c^{N-1})$; `(j : ℕ)` views $j \in$ `Fin N` as a natural number; `∑ j : Fin N, deltaDeriv (j : ℕ) (c j)` is $\sum_{j<N} c^j(z_2)\partial_{z_2}^j \delta(z_1, z_2)$ by Definition 2.23. `↔` is "if and only if".

Quantifiers. In Lean, arguments written before the colon of a theorem, here `(f : FormalDist₂ 𝒲) (N : ℕ)`, are universally quantified inputs: the theorem holds for *every* f and every N (as do the implicit ambient $\mathcal{W}$ and its vector-space structure). The tuple c appears only inside the `∃` on the right-hand side of the `↔`, so it is existentially quantified *after* f and N, so it may depend on f and N, as it must. The bound N is the same on both sides: a distribution killed by $(z_1 - z_2)^N$ involves derivatives of order $< N$ only, and conversely. This is the sharp form.

Hypotheses. Only the ambient `[AddCommGroup 𝒲] [Module ℂ 𝒲]`: $\mathcal{W}$ is a complex vector space. The division by $j!$ in the construction is why the field must contain $\mathbb{Q}$; over $\mathbb{C}$ this is automatic.

Same, stronger or weaker? Same as Kac Thm. 2.3 (i)⇔(ii), up to the plain-versus-divided-derivative rescaling of c^j. Gannon assumes $N \geq 1$; the library allows $N = 0$, where both sides say $f = 0$ (an empty sum). Kac's theorem also contains the formula for c^j and uniqueness; the Lean theorem states existence only, but uniqueness and the formula are an immediate consequence of Proposition 2.25 (Corollary 2.28), and the existence proof in the file constructs exactly those c^j.

Could it be vacuous? No: both sides are inhabited by nonzero examples (e.g. $f = \delta(z_1, z_2)$, $N = 1$), and the right side is not trivially implied by the left (for $N = 1$ it forces constancy along antidiagonals).

Physical meaning

This is the theorem behind the slogan "the commutator of local fields is a finite sum of contact terms". Applied to $f = [a(z), b(w)]$ for mutually local a, b it gives $[a(z), b(w)] = \sum_{j<N} (a_{(j)}b)(w)\,\partial_w^{(j)}\delta(z,w)$ with $a_{(j)}b = \operatorname{Res}_z (z-w)^j [a(z), b(w)]$: the commutator is determined by the singular part of the OPE, $a(z)b(w) \sim \sum_j (a_{(j)}b)(w)/(z-w)^{j+1}$. Taking $\operatorname{Res}_z z^m$ and the w^{-n-1} coefficient yields the commutator formula of modes, $[a_{(m)}, b_{(n)}] = \sum_{j\geq 0} \binom{m}{j} (a_{(j)}b)_{(m+n-j)}$. For the stress tensor this is the Virasoro algebra; for currents, the affine Kac–Moody algebra. The theorem is pure formal calculus.

Proof on paper. ($\Leftarrow$) By Proposition 2.25(d), $(z_1 - z_2)^N$ kills each summand $c^j \partial^j \delta$ with $j < N$, and it is linear.

($\Rightarrow$) Induction on N. For $N = 0$, $f = (z_1 - z_2)^0 f = 0$ is the empty sum. Suppose the claim holds for $N = k$ and let $(z_1 - z_2)^{k+1} f = 0$. Put $g := (z_1 - z_2)^k f$. Then $(z_1 - z_2)g = 0$, so by Proposition 2.26, $g = d(z_2)\delta$ with $d = \operatorname{Res}_{z_1} g$. Let $c^k := \frac{1}{k!} d$. By Proposition 2.25(c), $(z_1 - z_2)^k \big(c^k \partial^k \delta\big) = k!\, c^k \delta = d\,\delta = g = (z_1 - z_2)^k f$. Hence $f' := f - c^k \partial^k \delta$ satisfies $(z_1 - z_2)^k f' = 0$, and by induction $f' = \sum_{j<k} c^j \partial^j \delta$. Then $f = \sum_{j\leq k} c^j \partial^j \delta$. □

Corollary 2.28 (Uniqueness and recovery of the coefficients). *If $f = \sum_{j<N} c^j(z_2)\partial_{z_2}^j \delta(z_1, z_2)$, then $c^j = \frac{1}{j!} \operatorname{Res}_{z_1} \big((z_1 - z_2)^j f\big)$ for each $j < N$; in particular the c^j are unique.*

From the mathematics to the Lean statement

This corollary is *not* a separate Lean theorem; we state it because Kac's theorem includes it and a referee should know it is a two-line consequence of results that *are* in Lean. Its ingredients are Proposition 2.25 and the vanishing of Res_{z_1} on $c\,\partial^r\delta$ for $r \geq 1$, which is (for scalar-valued c; the one-line argument is the same for vector-valued c) the Lean lemma `deltaDeriv_succ_residue_zero` in `VOA/Foundations/DeltaJump.lean`. The recovered coefficient $\operatorname{Res}_{z_1}(z_1 - z_2)^j f$ is `cCoeff j f` (Definition 2.23).

Physical meaning

The OPE coefficients of two local fields are uniquely determined by their commutator: the singular part of $a(z)b(w)$ can be read off from $[a(z), b(w)]$ by contour integrals.

Proof on paper. Apply $(z_1 - z_2)^j$: by Proposition 2.25, the terms with $i < j$ die, the term $i = j$ becomes $j!\, c^j \delta$, and the terms $i > j$ become multiples of $c^i \partial^{i-j}\delta$ with $i - j \geq 1$. Now take Res_{z_1}: $\operatorname{Res}_{z_1} c\,\delta = c$, while $\operatorname{Res}_{z_1} c\,\partial^r\delta = 0$ for $r \geq 1$ (the coefficient at $m = -1$ contains the factor $-m - 1 = 0$). □

What the machine verified

Theorem 2.27: `#print axioms VOA.local_iff_deltaSum` = `[propext, Classical.choice, Quot.sound]`; likewise for `exists_deltaSum_of_mulBySubPow_eq_zero`. Unconditional. Corollary 2.28: **not a Lean theorem**; it is a paper consequence of Proposition 2.25 and the Lean lemma `deltaDeriv_succ_residue_zero`. The existence proof of Theorem 2.27 constructs exactly these c^j, but the uniqueness statement itself is not formalised.

Example 2.29 (The free boson). Let $\alpha(z) = \sum_n \alpha_{(n)} z^{-n-1}$ be a field with $[\alpha_{(p)}, \alpha_{(q)}] = p\,\delta_{p+q,0}$ (the Heisenberg algebra; Chapter 31). In the library's indexing the coefficient of $z_1^m z_2^n$ in $[\alpha(z_1), \alpha(z_2)]$ is $[\alpha_{(-m-1)}, \alpha_{(-n-1)}] = (-m-1)\,[m+n+2 = 0]$. By Example 2.24 this is the coefficient of $\partial_{z_2}\delta(z_1, z_2)$:

$$[\alpha(z_1), \alpha(z_2)] = \partial_{z_2}\delta(z_1, z_2),$$

which is `deltaDeriv 1 deltaCoeff`. Hence $(z_1-z_2)^2[\alpha(z_1),\alpha(z_2)]=0$ but $(z_1-z_2)[\alpha(z_1),\alpha(z_2)]=\delta(z_1,z_2)\neq 0$: the free boson is local of order exactly 2, matching the double pole of $\alpha(z)\alpha(w)\sim 1/(z-w)^2$. Running the proof of Theorem 2.27 with $N=2$: $g=(z_1-z_2)f=\delta$, $d=\mathrm{Res}_{z_1}\delta=\mathbf{1}_0$, $c^1=d/1!=\mathbf{1}_0$, and $f-c^1\partial\delta=0$, so $c^0=0$. In OPE language: $\alpha_{(1)}\alpha=\mathbf{1}$ (the double pole) and $\alpha_{(0)}\alpha=0$ (no simple pole).

2.6 The two expansions and the delta-function jump

2.6.1 The expansions ι_{z_1,z_2} and ι_{z_2,z_1}

Definition 2.30 (The two expansions of $(z_1-z_2)^n$)**.** For $n\in\mathbb{Z}$ define two elements of $\mathbb{C}[[z_1^{\pm1},z_2^{\pm1}]]$:

$$\iota_{z_1,z_2}(z_1-z_2)^n := \sum_{k\geq 0}(-1)^k\binom{n}{k}z_1^{n-k}z_2^k \qquad \text{(nonnegative powers of } z_2\text{; ``}|z_1|>|z_2|\text{''),}$$

$$\iota_{z_2,z_1}(z_1-z_2)^n := \sum_{k\geq 0}(-1)^{n+k}\binom{n}{k}z_1^{k}z_2^{n-k} \qquad \text{(nonnegative powers of } z_1\text{; ``}|z_2|>|z_1|\text{''}).$$

Also let $\delta(z_1,z_2)=\sum_k z_1^k z_2^{-k-1}$ be the delta function, with coefficient $[m+n+1=0]$.

File `VOA/Foundations/Expansion.lean`.

```
noncomputable def expandPos (n : ℤ) : FormalDist₂ ℂ :=
  fun a b => if 0 ≤ b ∧ a = n - b then negOnePow b * gBinom n b.toNat else 0

noncomputable def expandNeg (n : ℤ) : FormalDist₂ ℂ :=
  fun a b => if 0 ≤ a ∧ b = n - a then negOnePow (n + a) * gBinom n a.toNat else 0

def deltaForm : FormalDist₂ ℂ := fun m n => if m + n + 1 = 0 then 1 else 0
```

From the mathematics to the Lean statement

Decoding `expandPos`. The coefficient of $z_1^a z_2^b$ is nonzero only if $b\geq 0$ and $a=n-b$; then it is $(-1)^b\binom{n}{b}$. With $k=b$ this is the first formula: $\iota_{z_1,z_2}(z_1-z_2)^n=z_1^n(1-z_2/z_1)^n$ expanded by the binomial convention of Definition 2.14(iv) with second variable $-z_2$. **Decoding `expandNeg`.** Nonzero only if $a\geq 0$ and $b=n-a$, with value $(-1)^{n+a}\binom{n}{a}$. This is $(z_1-z_2)^n=(-1)^n(z_2-z_1)^n=(-1)^n\sum_a\binom{n}{a}z_2^{n-a}(-z_1)^a$, the second formula with $k=a$. **Names.** The library's docstrings write ι_{12} for `expandPos` and ι_{21} for `expandNeg`, consistent with Kac's $i_{z,w}$ (expansion in the domain $|z|>|w|$) and FLM's convention of expanding $(z_1-z_2)^n$ in nonnegative powers of the second variable. `deltaForm` is $\delta(z_1,z_2)$ (the same series as `deltaDeriv 0 deltaCoeff`; see Example 2.24).
Fidelity. Same as Kac §2.1, FLM §8.1 and Lepowsky–Li §2.1. For $n\geq 0$ the two series are both the polynomial $(z_1-z_2)^n$ (all binomials with $k>n$ vanish); they differ only for $n<0$.

Physical meaning

These are the two radially ordered expansions of the propagator-type function $(z_1-z_2)^n$: ι_{z_1,z_2} is the expansion valid when the operator at z_1 is further from the origin (later in radial time) and is the one that appears in $a(z_1)b(z_2)$; ι_{z_2,z_1} is the one that appears in $b(z_2)a(z_1)$. A correlation function is a single rational function; its two operator orderings correspond to its two expansions.

What the machine verified

Definitions; no hypotheses.

Example 2.31 (Simple and double poles by hand). For $n=-1$: $(-1)^b\binom{-1}{b}=(-1)^b(-1)^b=1$, so

$$\iota_{z_1,z_2}(z_1-z_2)^{-1}=\sum_{b\ge 0} z_1^{-1-b}z_2^{b}, \qquad \iota_{z_2,z_1}(z_1-z_2)^{-1}=\sum_{a\ge 0}(-1)^{a-1}(-1)^a z_1^a z_2^{-1-a}=-\sum_{a\ge 0} z_1^a z_2^{-1-a}.$$

For $n=-2$: $(-1)^b\binom{-2}{b}=b+1$ and $(-1)^{a-2}\binom{-2}{a}=a+1$, so

$$\iota_{z_1,z_2}(z_1-z_2)^{-2}=\sum_{b\ge 0}(b+1)z_1^{-2-b}z_2^{b}, \qquad \iota_{z_2,z_1}(z_1-z_2)^{-2}=\sum_{a\ge 0}(a+1)z_1^{a}z_2^{-2-a}.$$

These are the Taylor series of $z_1^{-2}(1-z_2/z_1)^{-2}$ and $z_2^{-2}(1-z_1/z_2)^{-2}$. Note that the second is *not* the negative of anything: $(z_1-z_2)^{-2}=(z_2-z_1)^{-2}$ is even under exchange.

Proposition 2.32 (Coefficient formulas and supports).

(a) $\left(\iota_{z_1,z_2}(z_1-z_2)^{-1}\right)_{a,b}=[b\ge 0,\ a=-1-b]$ *and* $\left(\iota_{z_2,z_1}(z_1-z_2)^{-1}\right)_{a,b}=-[a\ge 0,\ b=-1-a]$.

(b) Both expansions of $(z_1-z_2)^n$ *are supported on the antidiagonal* $a+b=n$*; the first vanishes for* $b<0$*, the second for* $a<0$.

Files `VOA/Foundations/Expansion.lean` and `VOA/Foundations/IotaZExpansion.lean`.

```
theorem expandPos_neg_one (a b : ℤ) :
    expandPos (-1) a b = if 0 ≤ b ∧ a = -1 - b then 1 else 0 := by

theorem expandNeg_neg_one (a b : ℤ) :
    expandNeg (-1) a b = if 0 ≤ a ∧ b = -1 - a then -1 else 0 := by

theorem expandPos_eq_zero_off_diag (n a b : ℤ) (h : a + b ≠ n) : expandPos n a b = 0 := by

theorem expandNeg_eq_zero_off_diag (n a b : ℤ) (h : a + b ≠ n) : expandNeg n a b = 0 := by

theorem expandPos_eq_zero_of_neg (n a : ℤ) {b : ℤ} (hb : b < 0) : expandPos n a b = 0 := by

theorem expandNeg_eq_zero_of_neg (n b : ℤ) {a : ℤ} (ha : a < 0) : expandNeg n a b = 0 := by
```

From the mathematics to the Lean statement

Exactly (a) and (b); the hypotheses `h`, `hb`, `ha` are the conditions "off the antidiagonal", "$b<0$", "$a<0$".

Physical meaning

Homogeneity: $(z_1-z_2)^n$ has total degree n, so it lives on the antidiagonal $a+b=n$; in CFT, this is scale covariance of a two-point function. The one-sided supports are the two radial orderings.

Proof on paper. Read off from the definitions and Example 2.31. □

What the machine verified

Unconditional; `#print axioms` clean for the jump theorem that uses them (below).

2.6.2 The jump of the simple pole

Theorem 2.33 (The delta-function jump; Gannon §5.1.2, FLM §8.10).

$$\iota_{z_1,z_2}\frac{1}{z_1-z_2}-\iota_{z_2,z_1}\frac{1}{z_1-z_2}=\delta(z_1,z_2),\qquad (z_1-z_2)\,\delta(z_1,z_2)=0.$$

File `VOA/Foundations/Expansion.lean`.

```
theorem expand_jump : expandPos (-1) - expandNeg (-1) = deltaForm := by

theorem mulBySub_deltaForm : mulBySub (deltaForm : FormalDist₂ ℂ) = 0 := by
```

From the mathematics to the Lean statement

The difference is the coefficientwise difference of two-variable distributions. No hypotheses. This is the textbook identity (Kac §2.1; FLM §8.1; Lepowsky–Li §2.3, where it is a special case of the three-term delta-function identity behind the Jacobi identity).

Physical meaning

This is the identity behind every equal-time commutator in chiral CFT. If $a(z)b(w)\sim c(w)/(z-w)$, then $a(z)b(w)=c(w)\iota_{z,w}(z-w)^{-1}+\cdots$ and $b(w)a(z)=c(w)\iota_{w,z}(z-w)^{-1}+\cdots$, so the commutator is $c(w)\delta(z,w)$: the contact term. On the circle it is the $\delta(\sigma_1-\sigma_2)$ of canonical commutation relations. In contour language: $\oint_{|z|>|w|}-\oint_{|z|<|w|}=\oint_w$, the integral around the pole.

Proof on paper. By Proposition 2.32(a), at (m,n) the left side is $[n\ge 0, m=-1-n]+[m\ge 0, n=-1-m]$. If $m+n+1\neq 0$ both brackets vanish. If $m+n+1=0$, exactly one of $n\ge 0$, $m\ge 0$ holds (since $m+n=-1$), so the sum is 1. The second identity was shown at the start of the subsection on derivatives of the delta function. □

What the machine verified

Unconditional; `#print axioms VOA.expand_jump` = `[propext, Classical.choice, Quot.sound]`; same for `mulBySub_deltaForm`.

2.6.3 Multiplication by z_1-z_2 and the algebra of the expansions

Proposition 2.34 ((z_1-z_2) acts as expected on both expansions). *For all $n\in\mathbb{Z}$ and $N\in\mathbb{N}$, and for both $\iota=\iota_{z_1,z_2}$ and $\iota=\iota_{z_2,z_1}$:*

$$(z_1-z_2)\cdot\iota(z_1-z_2)^n=\iota(z_1-z_2)^{n+1},\qquad (z_1-z_2)^N\cdot\iota(z_1-z_2)^n=\iota(z_1-z_2)^{n+N}.$$

Moreover $\iota(z_1-z_2)^0=1$ (the series with the single coefficient 1 at $z_1^0z_2^0$), and in particular $(z_1-z_2)^N\,\iota(z_1-z_2)^{-N}=1$.

Files `VOA/Foundations/DeltaJump.lean` and `VOA/Foundations/IotaZExpansion.lean`.

```
theorem mulBySub_expandPos (n : ℤ) : mulBySub (expandPos n) = expandPos (n + 1) := by

    mulBySubPow N (expandPos (-(N : ℤ))) = expandPos 0 := by

theorem mulBySubPow_expandNeg (N : ℕ) (m : ℤ) :
    mulBySubPow N (expandNeg m) = expandNeg (m + (N : ℤ)) := by

theorem mulBySubPow_expandNeg_neg (N : ℕ) :
    mulBySubPow N (expandNeg (-(N : ℤ))) = expandNeg 0 := by
```

From the mathematics to the Lean statement

`unitDist` is the constant $1 \in \mathbb{C}[[z_1^{\pm 1}, z_2^{\pm 1}]]$. `(N : ℤ)` casts N to an integer. The statements are exactly the displayed ones. **Why this is not trivial.** In a ring, $(z_1-z_2)\cdot(z_1-z_2)^n = (z_1-z_2)^{n+1}$ is a tautology. Here the left side is the operation `mulBySub` applied to a particular infinite series, and the right side is a separately defined infinite series; the identity is Pascal's rule (Proposition 2.18) coefficientwise. That it holds for *both* expansions is the formal reason $(z_1-z_2)^N$ can be applied "before choosing the ordering". Note the contrast with Theorem 2.33: $(z_1-z_2)\cdot[\iota_{12}-\iota_{21}](z_1-z_2)^{-1} = 1-1 = 0$, consistent with $(z_1-z_2)\delta = 0$.

Physical meaning

Multiplying an OPE singularity by $(z-w)^N$ lowers the order of the pole by N in either radial ordering; after enough factors both orderings give the same polynomial, which is why $(z-w)^N[a(z),b(w)] = 0$ is the right formulation of locality. `mulBySubPow_expandPos_neg` is the statement that $(z-w)^N\cdot(z-w)^{-N} = 1$ inside a fixed ordering; the lattice vertex operators use it to strip the prefactor $(z-w)^{\langle\alpha,\beta\rangle}$.

Proof on paper. On the antidiagonal $a+b = n+1$ with $b = j+1 \geq 1$, the coefficient of $(z_1-z_2)\iota_{12}(z_1-z_2)^n$ is $(-1)^{j+1}\binom{n}{j+1} - (-1)^j\binom{n}{j} = (-1)^{j+1}\left(\binom{n}{j+1} + \binom{n}{j}\right) = (-1)^{j+1}\binom{n+1}{j+1}$ by Pascal; at $b = 0$ it is $\binom{n}{0} = 1 = \binom{n+1}{0}$; off the antidiagonal both sides vanish. The computation for ι_{21} is the mirror image. The power version is induction on N. For $\iota(z_1-z_2)^0$: only $k = 0$ contributes since $\binom{0}{k} = 0$ for $k \geq 1$. □

What the machine verified

All unconditional; axioms `[propext, Classical.choice, Quot.sound]` (checked for `mulBySub_expandPos`, `mulBySub_expandNeg`, `expandPos_zero`, `expandNeg_zero`, `mulBySubPow_expandPos`, `mulBySubPow_expandPos_neg`).

Definition 2.35 (Products of expansions)**.** For $m, n \in \mathbb{Z}$ the product of the expansions in a fixed ordering is the two-variable series with coefficients

$$\left(\iota_{12}(z_1-z_2)^m\cdot\iota_{12}(z_1-z_2)^n\right)_{a,b} := \sum_{b_1\in\mathbb{Z}} \left(\iota_{12}(z_1-z_2)^m\right)_{m-b_1,b_1}\left(\iota_{12}(z_1-z_2)^n\right)_{a-(m-b_1),\,b-b_1},$$

$$\left(\iota_{21}(z_1-z_2)^m\cdot\iota_{21}(z_1-z_2)^n\right)_{a,b} := \sum_{a_1\in\mathbb{Z}} \left(\iota_{21}(z_1-z_2)^m\right)_{a_1,m-a_1}\left(\iota_{21}(z_1-z_2)^n\right)_{a-a_1,\,b-(m-a_1)}.$$

File `VOA/Foundations/IotaZExpansion.lean`.

```
noncomputable def convolPos (m n : ℤ) : FormalDist₂ ℂ :=
  fun a b => ∑ᶠ b₁ : ℤ, expandPos m (m - b₁) b₁ * expandPos n (a - (m - b₁)) (b - b₁)
```

```
noncomputable def convolNeg (m n : ℤ) : FormalDist₂ ℂ :=
  fun a b => ∑ᶠ a₁ : ℤ, expandNeg m a₁ (m - a₁) * expandNeg n (a - a₁) (b - (m - a₁))
```

From the mathematics to the Lean statement

Is this the product of series? The genuine product of two two-variable series F, G is $(FG)_{a,b} = \sum_{(a_1,b_1)\in\mathbb{Z}^2} F_{a_1,b_1} G_{a-a_1,b-b_1}$, when this is a finite sum. The library has no general product operation (Definition 2.1); `convolPos` is that double sum *already restricted* to the antidiagonal $a_1 = m - b_1$ of the first factor. Since $F = \iota_{12}(z_1 - z_2)^m$ vanishes off this antidiagonal (Proposition 2.32(b)), the restriction loses nothing: `convolPos m n` *is* the genuine product. This identification is a one-line paper argument, not a Lean theorem; a referee who wants to see it should note that the restriction is harmless precisely because of `expandPos_eq_zero_off_diag`. Likewise for `convolNeg`, restricted to $b_1 = m - a_1$.
Junk value? The summand is nonzero only for $0 \le b_1 \le b$ (the first factor needs $b_1 \ge 0$, the second $b - b_1 \ge 0$), so the `finsum` is a genuine finite sum for every (a, b): no junk value occurs. (The proof of Theorem 2.36 uses exactly this finiteness, via `cbz_convol_support_finite`.)

Physical meaning

The product of two singular factors in the same radial ordering, e.g. the prefactors $(z-w)^{\langle\alpha,\beta\rangle}$ and $(z-w)^{\langle\alpha,\gamma\rangle}$ that arise when a lattice vertex operator $e^{\alpha}(z)$ is moved past $e^{\beta}(w)$ and then past $e^{\gamma}(w)$.

What the machine verified

Definitions. No hypotheses.

Theorem 2.36 (Multiplicativity of the expansions). *For all $m, n \in \mathbb{Z}$,*

$$\iota_{12}(z_1 - z_2)^m \cdot \iota_{12}(z_1 - z_2)^n = \iota_{12}(z_1 - z_2)^{m+n}, \qquad \iota_{21}(z_1 - z_2)^m \cdot \iota_{21}(z_1 - z_2)^n = \iota_{21}(z_1 - z_2)^{m+n}.$$

File `VOA/Foundations/IotaZExpansion.lean`.

```
theorem expandPos_mul (m n : ℤ) : convolPos m n = expandPos (m + n) := by

theorem expandNeg_mul (m n : ℤ) : convolNeg m n = expandNeg (m + n) := by
```

From the mathematics to the Lean statement

No hypotheses: the statement holds for all integer exponents, including two negative ones. Together with $\iota(z_1 - z_2)^0 = 1$ it says that $n \mapsto \iota_{12}(z_1 - z_2)^n$ is a group homomorphism from $(\mathbb{Z}, +)$ into the (partial) multiplicative structure of $\mathbb{C}[[z_1^{\pm 1}, z_2^{\pm 1}]]$: the expansions inside a fixed ordering form a copy of the group of integer powers. An earlier docstring of `IotaZExpansion.lean` listed a lemma "`expandPos_mul_zero`" among the unit/inverse laws, although no declaration of that name existed; the current docstring no longer mentions it. The unit laws are `convolPos_zero_right`, `convolPos_zero_left` and `expandPos_zero`.

Physical meaning

Inside a fixed radial ordering, singular factors multiply as functions. This is the formal content of the statement that the analytic continuation of a correlation function does not depend on how its prefactors are grouped, as long as all of them are expanded in the same region.

Proof on paper. On the antidiagonal $a + b = m + n$ the (a, b) coefficient of the left side is $\sum_{b_1}(-1)^{b_1} C(m, b_1)(-1)^{b-b_1} C(n, b - b_1) = (-1)^b \sum_{b_1} C(m, b_1) C(n, b - b_1) = (-1)^b C(m + n, b)$ by

the generalised Vandermonde identity (Theorem 2.19); this is the right side. Off the antidiagonal both sides vanish. For ι_{21} the signs combine as $(-1)^{m+a_1}(-1)^{n+a-a_1} = (-1)^{m+n+a}$. □

What the machine verified

2.6.4 The jumps of higher poles

Definition 2.37 (The jump of $(z_1 - z_2)^{-k-1}$)**.** Let $\mathbf{1}_0 \in \mathbb{C}[[z^{\pm 1}]]$ be the constant series 1, with coefficient $[t = 0]$. For $k \in \mathbb{N}$, the *jump* of $(z_1 - z_2)^{-k-1}$ is

$$J_k := \iota_{12}(z_1 - z_2)^{-k-1} - \iota_{21}(z_1 - z_2)^{-k-1}.$$

File `VOA/Foundations/DeltaJump.lean`.

```
def deltaCoeff : FormalDist ℂ := fun t => if t = 0 then 1 else 0

noncomputable def negPowJump (k : ℕ) : FormalDist₂ ℂ :=
  expandPos (-(k : ℤ) - 1) - expandNeg (-(k : ℤ) - 1)
```

From the mathematics to the Lean statement

`deltaCoeff` is the one-variable series $1 = z^0$ (the docstring calls it "the one-variable point mass $[t = 0]$": as a function of the index t it is a point mass; as a series it is the constant 1). `-(k : ℤ) - 1` is $-k - 1$. So `negPowJump 0` is the left side of Theorem 2.33.

Physical meaning

J_k is the commutator contribution of an OPE pole of order $k + 1$ with unit coefficient: if $a(z)b(w) \sim 1/(z - w)^{k+1}$, then $[a(z), b(w)] \ni J_k$.

What the machine verified

Definitions. No hypotheses.

Theorem 2.38 (All-order delta jump)**.** *For every $k \in \mathbb{N}$,*

$$\iota_{12}(z_1 - z_2)^{-k-1} - \iota_{21}(z_1 - z_2)^{-k-1} = \frac{1}{k!}\,\partial_{z_2}^{k}\delta(z_1, z_2).$$

File `VOA/Foundations/DeltaJump.lean`.

```
theorem mulBySub_negPowJump (k : ℕ) :
    mulBySub (negPowJump (k + 1)) = negPowJump k := by

theorem negPowJump_residue_zero (k : ℕ) (n : ℤ) :
    negPowJump (k + 1) (-1) n = 0 := by

theorem deltaDeriv_succ_residue_zero (k : ℕ) (c : FormalDist ℂ) (n : ℤ) :
    deltaDeriv (k + 1) c (-1) n = 0 := by

theorem negPowJump_eq_deltaDeriv (k : ℕ) :
    negPowJump k = (((k.factorial : ℂ))⁻¹) • deltaDeriv k deltaCoeff := by
```

From the mathematics to the Lean statement

`(((k.factorial : ℂ))⁻¹) •` is multiplication by the complex number $1/k!$; `deltaDeriv k deltaCoeff` is $1 \cdot \partial_{z_2}^{k}\delta(z_1, z_2)$ (Definition 2.23). So the main statement is the display with the divided derivative $\partial^{(k)} = \partial^k/k!$: exactly the formula of Kac §2.1 and FLM §8.1. The three auxiliary lemmas are: $(z_1 - z_2)J_{k+1} = J_k$; $\mathrm{Res}_{z_1} J_{k+1} = 0$ (the $m = -1$ slice); and Res_{z_1} of $c\,\partial^{k+1}\delta(z_1, z_2)$ vanishes. No hypotheses.

Physical meaning

This is the formula that converts an OPE into commutators at every order: $a(z)b(w) \sim \sum_j \frac{(a_{(j)}b)(w)}{(z-w)^{j+1}}$ implies $[a(z), b(w)] = \sum_j (a_{(j)}b)(w)\,\partial_w^{(j)}\delta(z, w)$, because each pole contributes its jump. Together with Theorem 2.27 it shows that "local" and "has an OPE with finitely many poles" are the same thing.

Proof on paper. Induction on k; $k = 0$ is Theorem 2.33. Suppose $J_j = \frac{1}{j!}\partial^j\delta$. By Proposition 2.34, $(z_1 - z_2)J_{j+1} = J_j$. By Proposition 2.25(b), $(z_1 - z_2)\frac{1}{(j+1)!}\partial^{j+1}\delta = \frac{j+1}{(j+1)!}\partial^j\delta = J_j$. So $D := J_{j+1} - \frac{1}{(j+1)!}\partial^{j+1}\delta$ satisfies $(z_1 - z_2)D = 0$, hence $D = (\mathrm{Res}_{z_1} D)(z_2)\,\delta$ (Proposition 2.26). But $\mathrm{Res}_{z_1} D = 0$: the slice $m = -1$ of $\iota_{12}(z_1 - z_2)^{-j-2}$ needs $-1 = -j - 2 - b$ with $b \geq 0$, impossible for $j \geq 0$; that of $\iota_{21}(z_1 - z_2)^{-j-2}$ needs $m = -1 \geq 0$, impossible; and the slice of $\partial^{j+1}\delta$ carries the factor $-m - 1 = 0$. Hence $D = 0$. □

Example 2.39 (The double pole). From Example 2.31, $J_1 = \sum_{b\geq 0}(b+1)z_1^{-2-b}z_2^b - \sum_{a\geq 0}(a+1)z_1^a z_2^{-2-a}$. Write the second sum with $b = -2 - a \leq -2$: its terms are $(-b-1)z_1^{-2-b}z_2^b$. Hence $J_1 = \sum_{b\in\mathbb{Z}}(b+1)z_1^{-2-b}z_2^b$ (the term $b = -1$ is zero), which is $\partial_{z_2}\delta(z_1, z_2)$ by Example 2.24. This is Theorem 2.38 for $k = 1$, and it is the free-boson commutator of Example 2.29: the double pole $1/(z-w)^2$ of $\alpha(z)\alpha(w)$ produces $\partial_w\delta(z, w)$.

What the machine verified

Unconditional; `#print axioms VOA.negPowJump_eq_deltaDeriv` = `[propext, Classical.choice, Quot.sound]`.

Corollary 2.40 (The jumps are local). *For $k, N \in \mathbb{N}$ with $k + 1 \leq N$, $(z_1 - z_2)^N J_k = 0$; and J_k is a sum $\sum_{j\leq k} c^j(z_2)\,\partial_{z_2}^j\delta(z_1, z_2)$ in the sense of Theorem 2.27.*

File `VOA/Foundations/IotaZExpansion.lean`.

```
theorem mulBySubPow_negPowJump_self (k : ℕ) :
    mulBySubPow (k + 1) (negPowJump k) = 0 := by

theorem mulBySubPow_negPowJump_eq_zero {k N : ℕ} (h : k + 1 ≤ N) :
    mulBySubPow N (negPowJump k) = 0 := by

theorem negPowJump_deltaSum (k : ℕ) :
    ∃ c : Fin (k + 1) → FormalDist ℂ,
      negPowJump k = ∑ j : Fin (k + 1), deltaDeriv (j : ℕ) (c j) :=
```

From the mathematics to the Lean statement

Hypothesis `h : k + 1 ≤ N` is the order condition. `negPowJump_deltaSum` is an existence statement; by Theorem 2.38 one may take $c^k = \mathbf{1}_0/k!$ and $c^j = 0$ for $j < k$. Its proof is the one-line term `(local_iff_deltaSum (negPowJump k) (k + 1)).mp (mulBySubPow_negPowJump_self`

`k`): apply the structure theorem to the first statement.

Physical meaning

A pole of order $k+1$ is cancelled by $(z-w)^{k+1}$ in the commutator. For lattice vertex operators $e^{\alpha}(z)e^{\beta}(w) \propto (z-w)^{\langle\alpha,\beta\rangle}$, so the (suitably signed) commutator of e^{α} and e^{β} is killed by $(z-w)^N$ once $N \geq -\langle\alpha,\beta\rangle$; the sign cocycles that make this the right bracket are discussed in Chapter 31.

Proof on paper. Theorem 2.38 and Proposition 2.25(d); then Theorem 2.27. □

What the machine verified

Unconditional; axioms clean (checked for `mulBySubPow_negPowJump_eq_zero` and `negPowJump_deltaSum`).

2.7 Operator-valued distributions: commutators, locality, normal ordering

From now on V is a complex vector space and $\mathrm{End}(V)$ the algebra of its linear endomorphisms. Distributions with values in $\mathrm{End}(V)$ are the candidates for fields.

Definition 2.41 (Commutator distribution, mutual locality, normal ordering)**.** Let $a, b \in \mathrm{End}(V)[[z^{\pm 1}]]$, $a(z) = \sum_m a_m z^m$, $b(z) = \sum_n b_n z^n$.

(i) The *commutator* is $[a(z_1), b(z_2)] := \sum_{m,n} (a_m b_n - b_n a_m)\, z_1^m z_2^n$.

(ii) a and b are *mutually local* if $(z_1 - z_2)^N [a(z_1), b(z_2)] = 0$ for some $N \in \mathbb{N}$.

(iii) The two-variable *normal-ordered product* is $:a(z_1)b(z_2): := a(z_1)_+ b(z_2) + b(z_2)a(z_1)_-$, where $a(z)_+ := \sum_{m \geq 0} a_m z^m$ and $a(z)_- := \sum_{m<0} a_m z^m$; coefficientwise, $:ab:_{m,n} = a_m b_n$ if $m \geq 0$ and $b_n a_m$ if $m < 0$.

File `VOA/Foundations/Locality.lean`.

```
def bracketDist (a b : FormalDist (Module.End ℂ V)) : FormalDist₂ (Module.End ℂ V) :=
  fun m n => a m * b n - b n * a m

def Local (a b : FormalDist (Module.End ℂ V)) : Prop :=
  ∃ N : ℕ, mulBySubPow N (bracketDist a b) = 0

def normalOrdered (a b : FormalDist (Module.End ℂ V)) : FormalDist₂ (Module.End ℂ V) :=
  fun m n => if 0 ≤ m then a m * b n else b n * a m
```

From the mathematics to the Lean statement

Decoding. `Module.End ℂ V` is $\mathrm{End}_{\mathbb{C}}(V)$; its multiplication `*` is composition, so `a m * b n` is $a_m \circ b_n$. `bracketDist a b m n` is therefore the coefficient of $z_1^m z_2^n$ in $[a(z_1), b(z_2)]$. Each coefficient is a single composition, so (i) is always defined: the two variables are different. `Local a b` is a `Prop`: "there exists a natural number N (depending on a, b) such that all coefficients of $(z_1 - z_2)^N [a(z_1), b(z_2)]$ vanish".
Normal ordering. In `normalOrdered`, the coefficients a_m with $m \geq 0$ (the nonnegative powers of z_1, i.e. the modes $a_{(k)}$ with $k = -m-1 \leq -1$: the "creation" part) stand to the *left* of b, the others to the right. This is Kac (2.3.5) and Gannon (5.1.6b). The same-variable

product $:a(z)b(z):$ is *not* defined in this file, because it requires the field property; it is `nprod` in `VOA/Core/Dong.lean` (Chapter 4).
Fidelity. Same as Kac Def. 2.3 and Gannon §5.1.2. The definition is for arbitrary distributions, not only fields, which is the textbook generality. The library proves elsewhere that locality is symmetric (`Local.symm` in `VOA/Core/FieldOps.lean`); the definition itself is asymmetric only in the bookkeeping. **Could `Local` be vacuous?** With $N = 0$ it says $[a, b] = 0$; it is satisfied by many nontrivial pairs (Examples 2.29, 2.48) and fails, e.g., for $a = b =$ a distribution whose commutator has a nonzero coefficient on infinitely many antidiagonals with growing derivative order, so it is a genuine condition. A useful corollary of Section 2.8: if $[a(z_1), b(z_2)]$ has *finite support* and a, b are local, then $[a(z_1), b(z_2)] = 0$.

Physical meaning

`Local` is the chiral-algebra form of microcausality: two chiral fields commute up to contact terms at coincident points. It is the axiom (VA4) of the library's structure `PreVertexAlgebra` in Chapter 4 (Definition 4.1), imposed on all pairs of vertex operators $Y(u, z)$, $Y(v, z)$. The integer N is the maximal order of the OPE pole between a and b. Normal ordering puts annihilation operators to the right, so that $:a(z)b(w):$ is the regular part of the OPE, $a(z)b(w) =$ (singular part) $+ :a(z)b(w):$.

What the machine verified

Definitions. `Local` is used as the locality axiom of the library's structures `PreVertexAlgebra` and `BarePreVA`, and hence of every structure built on `PreVertexAlgebra` (`VertexAlgebra`, `GradedVertexOperatorAlgebra`, `VertexOperatorAlgebra`). (The release audit of 2026-10-27 established that `PreVertexAlgebra` and `BarePreVA` have no translation-covariance axiom and are therefore *not* vertex algebras in the standard sense; the Borcherds identity fails for them. The library has since renamed them accordingly; its `VertexAlgebra` is a `PreVertexAlgebra` with translation covariance added as an axiom. See Chapter 4.)

Proposition 2.42 (Commuting distributions are local). *If $[a(z_1), b(z_2)] = 0$, then a and b are mutually local (with $N = 0$).*

File `VOA/Foundations/Locality.lean`.

```
theorem local_of_bracketDist_eq_zero {a b : FormalDist (Module.End ℂ V)}
    (h : bracketDist a b = 0) : Local a b :=
```

From the mathematics to the Lean statement

Hypothesis: the commutator distribution is zero. Conclusion: `Local a b`, witnessed by $N = 0$.

Physical meaning

Commuting fields, e.g. a field and a constant multiple of the identity, or fields from decoupled sectors of a tensor-product theory, are trivially local.

Proof on paper. $(z_1 - z_2)^0 = \mathrm{id}$. □

What the machine verified

Unconditional.

2.7.1 Fields and the same-variable normal-ordered product

The two-variable normal ordering of Definition 2.41 keeps the variables z_1 and z_2 apart, so each of its coefficients is one composition of two operators and nothing infinite is ever summed. Physicists, however, want the product $:a(z)b(z):$ of two fields *at the same point*: the coefficient of z^s in it is an infinite sum $\sum_m (\cdots)_{m,s-m}$ over the antidiagonal $m+n=s$ of operators, and such an infinite sum of operators has no meaning unless one says how it converges. The remedy is to apply it to a vector and to require that, on every vector, only finitely many terms survive. This is exactly what the *field* condition (lower truncation) buys.

Definition 2.43 (Field; the normal-ordered product $:a(z)b(z):$)**.** A distribution $a(z) = \sum_{n\in\mathbb{Z}} a_n z^n \in \mathrm{End}(V)[[z^{\pm1}]]$ is a *field* if for every vector $x \in V$ there is an integer B (depending on x) with $a_n x = 0$ for all $n < B$. Equivalently $a(z)x \in V((z))$ has only finitely many negative powers of z; equivalently, in the mode indexing $a_{(m)} = a_{-m-1}$, one has $a_{(m)}x = 0$ for $m \gg 0$. For two fields a, b the *normal-ordered product* is the distribution $:a(z)b(z):$ whose z^s-coefficient is the operator

$$(:ab:)_s\, x \;=\; \sum_{m\in\mathbb{Z}} :a_m b_{s-m}: x \;=\; \sum_{m\ge 0} a_m b_{s-m} x \;+\; \sum_{m<0} b_{s-m} a_m x,$$

the sum being finite for every x. In vertex-algebra language it is the (-1)-st product of fields, $a_{(-1)}b$.

File `VOA/Core/Dong.lean`.

```
def IsField (a : FormalDist (End ℂ V)) : Prop :=
  ∀ x : V, ∃ B : ℤ, ∀ n : ℤ, n < B → a n x = 0

noncomputable def nprodCoeff {a b : FormalDist (End ℂ V)}
    (ha : IsField a) (hb : IsField b) (s : ℤ) : V →ₗ[ℂ] V where
  toFun x := ∑ᶠ m : ℤ, normalOrdered a b m (s - m) x

noncomputable def nprod {a b : FormalDist (End ℂ V)}
    (ha : IsField a) (hb : IsField b) : FormalDist (End ℂ V) :=
  fun s => nprodCoeff ha hb s
```

(The two linearity fields of `nprodCoeff`, `map_add'` and `map_smul'`, are proofs and are omitted. `normalOrdered` is Definition 2.41, file `VOA/Foundations/Locality.lean`.)

From the mathematics to the Lean statement

Decoding `IsField`. `a n x` is the coefficient a_n of z^n, an endomorphism, applied to x. The statement reads: for every x there exists an integer B such that for every integer $n < B$ the vector $a_n x$ vanishes. "n very negative" in the z^n-indexing is "$m = -n-1$ very positive" in the mode indexing, which is the familiar lower truncation $u_{(m)}x = 0$ for $m \gg 0$. The bound B depends on x but not on anything else; it is *not* uniform in x (a uniform bound would force a to be a Laurent polynomial of operators). This is Kac's Definition 1.3 and the "truncation condition" of Lepowsky–Li.

Decoding `nprodCoeff`. The z^s-coefficient applied to x is `∑ᶠ m : ℤ, normalOrdered a b m (s - m) x`, where `normalOrdered a b m n` is $a_m b_n$ if $m \ge 0$ and $b_n a_m$ if $m < 0$ (the creation part of a is placed to the left, the annihilation part to the right). The symbol `∑ᶠ` is Mathlib's `finsum`: the sum over the support of the summand if that support is finite, and the value 0 if it is infinite.

This is the trap to be checked here. With no hypotheses the Lean expression would silently equal 0 whenever the support is infinite. The library therefore makes the two field hypotheses `ha`, `hb` *arguments* of `nprodCoeff`, and proves (`normalOrdered_diag_support_finite`, same file) that under them the support is finite for every s and x. So the `finsum` is a genuine finite sum, and `nprod ha hb` is the textbook object, Kac (2.3.5)–(2.3.6) and Gannon (5.1.6b). The other direction of fidelity: nothing has been left out, since the only data of `nprod` are the two

distributions and the proof that they are fields.
Same, stronger or weaker? The same as the textbook. In the library the product of two fields is again a field (`IsField.nprod`, `VOA/Core/FieldOps.lean`), and $:a\,b:$ is mutually local with a third field whenever the three are pairwise local (Dong's lemma, Theorem 4.16).
Could it be vacuous? The zero distribution and every constant $c \cdot \mathrm{id}$ are fields, so the notion is satisfied; and every vertex operator $Y(u,z)$ of a `BarePreVA` (a bare pre-vertex algebra: weaker than a standard vertex algebra, since it lacks translation covariance; Chapter 4) is a field by the regularity axiom VA5 (`BarePreVA.isField_Y`, Chapter 4). It is a genuine condition: the distribution $\sum_{n\in\mathbb{Z}} \mathrm{id}_V\, z^n$ (the delta function times the identity) has $a_n x = x \neq 0$ for all n and $x \neq 0$, so it is not a field.

Physical meaning

A field is a distribution that truncates on every state, $a(z)x \in V((z))$: applying a local operator to a state of finite energy creates only finitely many states of lower energy, which is the algebraic form of "the energy is bounded below", and in the OPE it says that the singularity as $w \to z$ has a pole of finite order. The normal-ordered product $:a(z)b(z):$ is the regular term in the operator product expansion of $a(z)b(w)$ as $w \to z$, namely $\lim_{w\to z}\big(a(z)b(w) - \text{singular terms}\big)$. Free-field examples are the stress tensor of a free boson, $T = \frac{1}{2}:J(z)J(z):$, and the Sugawara construction. Placing creation operators to the left of annihilation operators is the usual prescription that makes the vacuum expectation value of $:a\,b:$ vanish for free fields.

Proof on paper that the sum is finite, and that the product is a field. Fix x and s, and let B_a be the truncation bound of a at x and, for each vector y, $B_b(y)$ that of b at y. In the sum over $m \geq 0$ the term $a_m b_{s-m}x$ vanishes as soon as $s - m < B_b(x)$, i.e. for $m > s - B_b(x)$. In the sum over $m < 0$ the term $b_{s-m}a_m x$ vanishes as soon as $m < B_a$. Hence only m in the finite interval $[\min(B_a, 0),\ \max(s - B_b(x), 0)]$ can contribute. The coefficient is clearly linear in x, since each summand is. To see that $:ab:$ is again a field, let s be very negative. For $m \geq 0$ we have $s - m \leq s < B_b(x)$, so $a_m b_{s-m}x = 0$. For $m < 0$ only the finitely many m with $B_a \leq m < 0$ matter, since $a_m x = 0$ for $m < B_a$; choose s below $\min_{B_a \leq m < 0}\big(m + B_b(a_m x)\big)$, and then $b_{s-m}a_m x = 0$ for each of them. □

What the machine verified

Definitions, not theorems. `#print axioms` (run for this chapter with `lake env lean -DmaxSynthPendingDepth=3`) of `VOA.IsField`, `VOA.nprodCoeff`, `VOA.nprod` is `[propext, Classical.choice, Quot.sound]` for each. No hypotheses beyond the two field arguments; `VOA.pbw` is not used.

2.7.2 Super-locality: the ε-twisted commutator

For fermionic (odd) fields, the radially ordered product $b(z_2)a(z_1)$ acquires a sign, and locality is a statement about the *anticommutator*. Rather than duplicating the theory, the library introduces a scalar ε in front of the second ordering.

Definition 2.44 (ε-twisted commutator and ε-locality). For $\varepsilon \in \mathbb{C}$ and $a, b \in \mathrm{End}(V)[[z^{\pm 1}]]$, $[a(z_1), b(z_2)]_\varepsilon := \sum_{m,n}(a_m b_n - \varepsilon\, b_n a_m) z_1^m z_2^n$, and a, b are *ε-local* if $(z_1 - z_2)^N [a(z_1), b(z_2)]_\varepsilon = 0$ for some $N \in \mathbb{N}$.

File `VOA/Foundations/Locality.lean`.

```
def bracketDistε (ε : ℂ) (a b : FormalDist (Module.End ℂ V)) : FormalDist₂ (Module.End ℂ V)
 ↪  :=
  fun m n => a m ∗ b n - ε • (b n ∗ a m)

def Localε (ε : ℂ) (a b : FormalDist (Module.End ℂ V)) : Prop :=
  ∃ N : ℕ, mulBySubPow N (bracketDistε ε a b) = 0
```

From the mathematics to the Lean statement

`ε • (b n ∗ a m)` is the complex scalar ε times the composition $b_n \circ a_m$. The intended instances are $\varepsilon = 1$ (bosonic) and $\varepsilon = (-1)^{|a||b|}$ (Koszul sign of parities $|a|, |b| \in \mathbb{Z}/2$; the library's `koszul` lives in `VOA/Foundations/Parity.lean`, another chapter). For other values of ε the definition is meaningful but has no standard name; nothing in this chapter depends on $\varepsilon \in \{\pm 1\}$ except `bracketDistε_swap`, which needs $\varepsilon \neq 0$. The file header stresses that no spin–statistics relation between parity and half-integer weights is assumed here.

Physical meaning

For two odd fields (fermions, ghosts) the physically meaningful bracket is the anticommutator $\{a(z), b(w)\} = a(z)b(w) + b(w)a(z)$, and locality says $(z-w)^N\{a(z), b(w)\} = 0$: fermions anticommute at spacelike separation. This is the case $\varepsilon = -1$.

What the machine verified

Definitions.

Proposition 2.45 (Basic properties of the twisted commutator).

(a) $[a,b]_1 = [a,b]$, *hence* 1*-locality is ordinary locality.*

(b) $[a,b]_\varepsilon$ *is additive in* a *and in* b.

(c) If $\varepsilon \neq 0$: $[a(z_1), b(z_2)]_\varepsilon$ *has* (m,n)*-coefficient* $-\varepsilon \cdot \big([b(z_1), a(z_2)]_{\varepsilon^{-1}}\big)_{n,m}$.

(d) If $[a,b]_\varepsilon = 0$ *then* a, b *are* ε*-local; every* a *is* ε*-local with* 0 *on either side.*

```

From the mathematics to the Lean statement

In `bracketDistε_swap` note the swapped indices `n m` on the right: the coefficient of $z_1^m z_2^n$ in $[a(z_1), b(z_2)]_\varepsilon$ is compared with the coefficient of $z_1^n z_2^m$ in $[b(z_1), a(z_2)]_{\varepsilon^{-1}}$. For $\varepsilon = \pm 1$, $\varepsilon^{-1} = \varepsilon$ and this is the graded antisymmetry $[a,b] = -(-1)^{|a||b|}[b,a]$. The hypothesis `hε` is needed to form ε^{-1} meaningfully (in Lean $0^{-1} = 0$, and the identity would be false at $\varepsilon = 0$ unless $ab = 0$).

Physical meaning

(a) says the bosonic theory is the $\varepsilon = 1$ instance of the super theory; (c) is graded antisymmetry of the (anti)commutator; (d) says that the zero field is local with everything.

Proof on paper. Coefficientwise algebra: $a_m b_n - \varepsilon b_n a_m = -\varepsilon(b_n a_m - \varepsilon^{-1} a_m b_n)$. □

What the machine verified

All unconditional; axioms clean (checked for `bracketDistε_one`, `localε_one_iff`, `bracketDistε_swap`).

Theorem 2.46 (Structure theorem, ε-generically). *a, b are ε-local iff for some N there are $c^0, \dots, c^{N-1} \in \mathrm{End}(V)[[z^{\pm 1}]]$ with $[a(z_1), b(z_2)]_\varepsilon = \sum_{j<N} c^j(z_2)\partial_{z_2}^j \delta(z_1, z_2)$. In particular, if $[a(z_1), b(z_2)]_\varepsilon = c(z_2)\delta(z_1, z_2)$, then a, b are ε-local with $N = 1$.*

File `VOA/Foundations/Locality.lean`.

```

theorem localε_of_bracketDistε_eq_delta {ε : ℂ} {a b c : FormalDist (Module.End ℂ V)}
    (h : bracketDistε ε a b = deltaDeriv 0 c) : Localε ε a b :=
```

From the mathematics to the Lean statement

Here N is existentially quantified *inside* the iff ("$\exists N\, \exists c$"), because `Localε` itself hides N; compare Theorem 2.27, where N is fixed outside. Both versions are equivalent; this one is the convenient packaging for fields. The structure theorem is applied to the two-variable distribution $[a,b]_\varepsilon$; the sign never enters its proof, which is the structural reason the super theory is "a refactor rather than a rewrite" (file header).

Physical meaning

The super-commutator of two local fields is determined by the singular part of their OPE, exactly as in the bosonic case: $\{\psi(z), \psi^*(w)\} = \delta(z,w)$ for a bc or free-fermion system, $[\beta(z), \gamma(w)] = \delta(z,w)$ for a $\beta\gamma$ system.

Proof on paper. Theorem 2.27 applied to $f = [a,b]_\varepsilon$; the second statement is Proposition 2.25(a). □

What the machine verified

Unconditional; axioms clean (checked for `localε_iff_deltaSum`).

Theorem 2.47 (Free-field criterion: canonical (anti)commutation relations). *Let $S \in \mathrm{End}(V)$ and suppose $a_m b_n - \varepsilon\, b_n a_m = [m+n+1=0]\, S$ for all $m, n \in \mathbb{Z}$. Then a, b are ε-local (with $N = 1$). In particular, if $a_m b_n + b_n a_m = [m+n+1=0]\, S$ for all m, n, then a, b are (-1)-local.*

File `VOA/Foundations/Locality.lean`.

```
theorem localε_of_car {ε : ℂ} {a b : FormalDist (Module.End ℂ V)} (S : Module.End ℂ V)

theorem localε_neg_one_of_anticomm {a b : FormalDist (Module.End ℂ V)}
    (S : Module.End ℂ V) (h : ∀ m n : ℤ, a m * b n + b n * a m = if m + n + 1 = 0 then S
    ↪ else 0) :
    Localε (-1) a b := by
```

From the mathematics to the Lean statement

Indices. m, n are *coefficient* indices (z^m), not modes. In modes, $a_m = a_{(-m-1)}$, and the condition $m+n+1=0$ becomes $p+q+1=0$ for $p=-m-1, q=-n-1$: the hypothesis reads $[a_{(p)}, b_{(q)}]_\varepsilon = \delta_{p+q+1,0}\, S$, the same shape in both indexings. S is an arbitrary fixed operator (in examples, a multiple of the identity). The hypothesis says $[a(z_1), b(z_2)]_\varepsilon = S\,\delta(z_1, z_2)$.

Physical meaning

These are the canonical commutation relations of a $\beta\gamma$ system ($\varepsilon = 1$) and the canonical anticommutation relations of a bc system or complex fermion ($\varepsilon = -1$): the OPE has a single simple pole $S/(z-w)$. The theorem is used to verify locality of the generating fields in `VOA/Examples/BetaGamma.lean`, `BetaGammaField.lean` and `SymplecticFermion.lean`.

Proof on paper. The hypothesis says $[a, b]_\varepsilon = c(z_2)\delta(z_1, z_2)$ with $c = S \cdot \mathbf{1}_0$ (since $c_{m+n+1} = [m+n+1=0]S$); apply Theorem 2.46. □

Example 2.48 (The free fermion). Let $\psi(z) = \sum_p \psi_{(p)} z^{-p-1}$ with $\{\psi_{(p)}, \psi_{(q)}\} = \delta_{p+q+1,0}$ (a neutral fermion with integer moding; the OPE is $\psi(z)\psi(w) \sim 1/(z-w)$). In coefficient indexing $\psi_m = \psi_{(-m-1)}$ and $\{\psi_m, \psi_n\} = [m+n+1=0]$, so `localε_neg_one_of_anticomm` with $S = \mathrm{id}$ shows $(z_1-z_2)\{\psi(z_1), \psi(z_2)\} = 0$. The bosonic commutator $[\psi(z_1), \psi(z_2)]$, with coefficients $\psi_m\psi_n - \psi_n\psi_m = 2\psi_m\psi_n - [m+n+1=0]$, is *not* killed by any power of $z_1 - z_2$ in the Fock representation: by Theorem 2.27, along each antidiagonal $m+n=s$ the coefficients of a distribution killed by $(z_1-z_2)^N$ are polynomial in m of degree $< N$ with fixed operator coefficients, hence span a finite-dimensional space, whereas the operators $\psi_m\psi_{s-m}$ ($m > s-m$) are linearly independent in the Fock space. (Reason: in the Clifford algebra generated by the ψ_m, ordered products of distinct generators form a basis, as for an exterior algebra; and the Fock representation of this Clifford algebra is faithful, because the algebra of a nondegenerate form on a countable-dimensional space is a union of matrix algebras and hence simple. So distinct ordered pairs give linearly independent operators.) So the choice of ε matters.

Trap / dead end

A docstring claim that was heuristic (corrected in the source). An earlier comment block before `localε_of_car` said that "a finite-support commutator can never satisfy this" and concluded "consequently there is no finite-dimensional fermionic toy example". The current comment block keeps only the finiteness remark about mode support and says explicitly that no statement about finite-dimensional examples is proved or implied. The first sentence of the old comment is a correct theorem: a finitely supported two-variable distribution is lower-truncated, so by Theorem 2.50 it is killed by $(z_1 - z_2)^N$ only if it is 0. The second sentence is not a consequence of the first (a finite-dimensional V does not force the commutator to have finite support); it is a true but separate fact about Clifford algebras of infinite rank with nondegenerate form, which have no nonzero finite-dimensional representations when S is a nonzero scalar. The library proves neither the second sentence nor needs it.

What the machine verified

Unconditional; axioms clean (checked for both declarations).

2.8 Lower truncation and the cancellation theorem

Theorem 2.27 shows that $(z_1 - z_2)$ has a huge kernel on $\mathcal{W}[[z_1^{\pm 1}, z_2^{\pm 1}]]$: all of the $c(z_2)\delta(z_1, z_2)$. This kernel disappears on the subspace of series that are bounded below in z_2, which is where the products of fields $Y(u, z_1)Y(v, z_2)x$ live. This simple fact is the irreducible core of Goddard's uniqueness theorem and of the reconstruction theorem (Chapter 4, Theorems 4.14 and 4.41).

Definition 2.49 (Lower truncation in z_2)**.** $f \in \mathcal{W}[[z_1^{\pm 1}, z_2^{\pm 1}]]$ is *lower-truncated in* z_2 if there is $B \in \mathbb{Z}$ with $f_{m,n} = 0$ for all $m \in \mathbb{Z}$ and all $n < B$.

File `VOA/Foundations/IteratedLaurent.lean`.

```
def IsBddBelow₂ (f : FormalDist₂ 𝒲) : Prop := ∃ B : ℤ, ∀ m n : ℤ, n < B → f m n = 0

theorem IsBddBelow₂.mulBySub {f : FormalDist₂ 𝒲} (h : IsBddBelow₂ f) :
    IsBddBelow₂ (mulBySub f) := by

theorem IsBddBelow₂.mulBySubPow (N : ℕ) {f : FormalDist₂ 𝒲} (h : IsBddBelow₂ f) :
    IsBddBelow₂ (mulBySubPow N f) := by
```

From the mathematics to the Lean statement

Quantifiers. $\exists B\, \forall m\, \forall n$: the bound is *uniform in the* z_1*-power*. This is the space $\mathcal{W}[[z_1^{\pm 1}]]((z_2))$ of Laurent series in z_2 (finitely many negative powers) with arbitrary doubly-infinite coefficients in z_1. An earlier docstring called this "the sub-class $\mathcal{W}((z_1))((z_2))$"; the current docstring of `IsBddBelow₂` says "strictly larger than" that class, which is right (the docstring of the cancellation theorem that follows still speaks of $\mathcal{W}((z_1))((z_2))$). The old wording was imprecise: membership in $\mathcal{W}((z_1))((z_2))$ would also require each z_2^n-coefficient to be bounded below in z_1, which `IsBddBelow₂` does *not* require. The predicate is therefore *weaker* than membership in $\mathcal{W}((z_1))((z_2))$, and theorems with it as a hypothesis are correspondingly *stronger* than their textbook counterparts. No harm results.
Why $Y(u, z_1)Y(v, z_2)x$ **satisfies it.** Its coefficient of $z_1^m z_2^n$ is $u_m(v_n x)$ (coefficient indices). Since $Y(v, z)$ is a field, $v_n x = 0$ for $n < B$ with B depending on v, x only; then $u_m(v_n x) = 0$ for every m. The stability lemmas say that multiplication by $(z_1 - z_2)^N$ preserves the property (with the same B).

Physical meaning

Lower truncation in z_2 is the energy bound for the operator at the inner insertion point: acting with a field on a state of bounded energy produces finitely many states of lower energy. It singles out one radial ordering, $|z_1| > |z_2|$: the product $a(z_1)b(z_2)x$ is a genuine expansion in this region and lower truncation in z_2 is its formal signature.

What the machine verified

Definition and two stability lemmas, unconditional.

Theorem 2.50 (Cancellation: $z_1 - z_2$ is not a zero-divisor on lower-truncated series)**.** *If* $f \in \mathcal{W}[[z_1^{\pm 1}, z_2^{\pm 1}]]$ *is lower-truncated in* z_2 *and* $(z_1 - z_2)^N f = 0$ *for some* $N \in \mathbb{N}$*, then* $f = 0$.

File `VOA/Foundations/IteratedLaurent.lean`.

```
theorem eq_zero_of_mulBySub_of_bddBelow {f : FormalDist₂ 𝓦} (hsub : mulBySub f = 0)
    (hbb : IsBddBelow₂ f) : f = 0 := by

theorem eq_zero_of_mulBySubPow_of_bddBelow :
    ∀ (N : ℕ) (f : FormalDist₂ 𝓦), mulBySubPow N f = 0 → IsBddBelow₂ f → f = 0
```

From the mathematics to the Lean statement

Two hypotheses: annihilation by $(z_1 - z_2)^N$ and lower truncation. Both are needed: $\delta(z_1, z_2)$ satisfies the first ($N = 1$) but not the second, and is nonzero. The conclusion is $f = 0$. The first declaration is the case $N = 1$. Same as the cancellation step in Kac §4 (Goddard uniqueness) and Gannon §5.1.2; slightly stronger, by the remark on the predicate above.

Physical meaning

If two operator products agree after multiplication by $(z_1 - z_2)^N$, and both are genuine expansions in the same region, they agree: one may divide by $(z_1 - z_2)^N$ inside a fixed radial ordering. This is how locality ("$(z - w)^N a(z)b(w) = (z - w)^N b(w)a(z)$") is turned into identities between correlation functions, and why a field is determined by its action on the vacuum (Goddard).

Proof on paper. $N = 1$: by Proposition 2.26, $f_{m,n} = f_{m-d,n+d}$ for all d. Given (m, n), take d with $n + d < B$; then $f_{m,n} = f_{m-d,n+d} = 0$. (In the file: $f_{m,n} = f_{-1,m+n+1} = f_{m+n-(B-1),B-1}$, and then one more step down.) General N: induction; $g = (z_1 - z_2)^N f$ is lower-truncated and killed by $(z_1 - z_2)$, so $g = 0$, and the induction hypothesis applies to f. □

Example 2.51. $f = \iota_{12}(z_1 - z_2)^{-1} = \sum_{b \geq 0} z_1^{-1-b} z_2^b$ is lower-truncated in z_2 (with $B = 0$) and $(z_1 - z_2)f = 1 \neq 0$, consistent with the theorem. $f = \iota_{21}(z_1 - z_2)^{-1}$ is *not* lower-truncated in z_2 (it contains z_2^{-1-a} for all $a \geq 0$). Their difference $\delta(z_1, z_2)$ is killed by $z_1 - z_2$, and it is not lower-truncated, as the theorem demands: for any B, its coefficient at $(m, n) = (-B, B - 1)$ is $[-B + (B - 1) + 1 = 0] = 1$, although $n = B - 1 < B$. In the ring $\mathbb{C}[[z_1^{\pm 1}]]((z_2))$, $z_1 - z_2$ is in fact invertible with inverse $\iota_{12}(z_1 - z_2)^{-1}$.

What the machine verified

Unconditional; axioms `[propext, Classical.choice, Quot.sound]` (both). Used downstream in `VOA/Core/WeakAssoc.lean`, `VOA/Core/Goddard.lean`, `VOA/Core/ReconstructionExistence.lean` and six further files.

2.9 The substitution $z_1 \mapsto z_0 + z_2$

Weak associativity, $(z_0 + z_2)^k Y(u, z_0 + z_2)Y(v, z_2)x = (z_0 + z_2)^k Y(Y(u, z_0)v, z_2)x$, compares a product of fields at z_1 and z_2 with an iterated field in the relative coordinate $z_0 = z_1 - z_2$. Formally this requires substituting $z_1 = z_0 + z_2$ into a two-variable series, which is the subject of this section.

Definition 2.52 (Substitution). For $f \in \mathcal{W}[[z_1^{\pm 1}, z_2^{\pm 1}]]$ lower-truncated in z_2, $f(z_0 + z_2, z_2)$ is the series in (z_0, z_2) obtained by replacing each z_1^m by $(z_0 + z_2)^m$ expanded in nonnegative powers of z_2 (Definition 2.14(iv)):

$$\big(f(z_0 + z_2, z_2)\big)_{a,b} = \sum_{k \geq 0} \binom{a + k}{k} f_{a+k,\, b-k}.$$

File `VOA/Foundations/Substitution.lean`.

```
noncomputable def subst (f : FormalDist₂ 𝕎) : FormalDist₂ 𝕎 :=
  fun a b => ∑ᶠ k : ℤ, cbz (a + k) k • f (a + k) (b - k)

theorem subst_summand_finite {f : FormalDist₂ 𝕎} (hf : IsBddBelow₂ f) (a b lo : ℤ) (c : ℤ →
↪  ℂ)
    (hc : ∀ k, k < lo → c k = 0) :
    (Function.support (fun k : ℤ => c k • f (a + k) (b - k))).Finite := by
```

From the mathematics to the Lean statement

Derivation of the formula. $f = \sum_{m,n} f_{m,n} z_1^m z_2^n$ and $(z_0+z_2)^m = \sum_{k\ge 0} \binom{m}{k} z_0^{m-k} z_2^k$. The coefficient of $z_0^a z_2^b$ collects $m-k=a$, $n+k=b$, i.e. $m=a+k$, $n=b-k$, with weight $\binom{a+k}{k}$. The sum is over $k \in \mathbb{Z}$ with $C(\cdot,k)=0$ for $k<0$ (`cbz`), which is the restriction $k \ge 0$.
The junk-value trap (the trap box on p. 44). `subst f` is defined for every f; it is meaningful only if each coefficient sum is finite. `subst_summand_finite` shows that this is the case when f is lower-truncated in z_2 (with bound B): the summand vanishes for $k<0$ (binomial) and for $b-k<B$ (truncation), so only $0 \le k \le b-B$ contribute. The general form with a coefficient function c vanishing below `lo` is used for the shifted sums in the next proof. Every theorem about `subst` assumes `IsBddBelow₂ f`.
Name. The docstring calls `subst` "the ι_{z_2,z_0} map"; we avoid this name because it suggests an expansion of a rational function. What it is: the substitution $z_1 \mapsto z_0 + z_2$ with the FLM convention of expanding $(z_0+z_2)^m$ in nonnegative powers of z_2 (the region $|z_0| > |z_2|$).

Physical meaning

Substituting $z_1 = z_0 + z_2$ re-expresses a two-point operator product in terms of the centre z_2 and the separation z_0: this is the passage from $a(z_1)b(z_2)$ to the OPE $\sum_n (a_{(n)}b)(z_2) z_0^{-n-1}$, i.e. to the iterate $Y(Y(a,z_0)b,z_2)$. The expansion region $|z_0| > |z_2|$ is the one in which the OPE converges when both operators are near z_2 but the separation is not small compared with z_2; formally it is the region where $Y(u, z_0+z_2)$ makes sense as a series in nonnegative powers of z_2.

What the machine verified

Definition and finiteness lemma; the lemma is unconditional.

Theorem 2.53 (Keystone multiplicativity of the substitution). *If f is lower-truncated in z_2, then*

$$\big((z_1-z_2)f\big)(z_0+z_2,z_2) = z_0 \cdot f(z_0+z_2,z_2), \qquad \big((z_1-z_2)^N f\big)(z_0+z_2,z_2) = z_0^N \cdot f(z_0+z_2,z_2) \quad (N \in \mathbb{N}).$$

File `VOA/Foundations/Substitution.lean`.

```
theorem subst_mulBySub {f : FormalDist₂ 𝕎} (hf : IsBddBelow₂ f) :
    subst (mulBySub f) = shiftZ₁ (subst f) := by

theorem subst_mulBySubPow {f : FormalDist₂ 𝕎} (hf : IsBddBelow₂ f) (N : ℕ) :
    subst (mulBySubPow N f) = (shiftZ₁^[N]) (subst f) := by
```

From the mathematics to the Lean statement

On the right, the first variable of `subst f` is z_0, so `shiftZ₁` (multiplication by the first variable) is multiplication by z_0; `shiftZ₁^[N]` is its N-fold iterate (`f^[N]` is Lean's notation for function iteration). The hypothesis `hf` makes both sides genuine finite sums (note that $(z_1-z_2)^N f$ is again lower-truncated, Definition 2.49). This is "substituting $z_1 = z_0 + z_2$ turns $z_1 - z_2$ into z_0", which would be a tautology in a ring of functions and is here a coefficient identity.

Physical meaning

The separation of the two insertion points is z_0: multiplying the product $a(z_1)b(z_2)$ by $(z_1 - z_2)^N$ and then re-centring is the same as re-centring and multiplying the OPE by z_0^N, which removes the poles z_0^{-n-1}, $n < N$. This is the step that turns locality into weak associativity, and it is used in the proof of skew-symmetry (`VOA/Core/Skew.lean`).

Proof on paper. The (a, b) coefficient of the left side is $\sum_k C(a+k, k)\big(f_{a-1+k,b-k} - f_{a+k,b-1-k}\big)$, and that of the right side is $\sum_k C(a-1+k, k) f_{a-1+k,b-k}$. Subtracting the right side from the first half of the left side gives $\sum_k \big(C(a+k, k) - C(a-1+k, k)\big) f_{a-1+k,b-k} = \sum_k C(a-1+k, k-1) f_{a-1+k,b-k}$ by Pascal's rule (Proposition 2.18); shifting $k \mapsto k+1$ turns this into $\sum_k C(a+k, k) f_{a+k,b-1-k}$, the second half of the left side. All sums are finite by lower truncation, so the manipulations are legitimate. The power version is induction on N, using that $(z_1 - z_2)^k f$ is lower-truncated. □

Example 2.54 (Substituting into $\iota_{12}(z_1 - z_2)^{-1}$)**.** Let $f = \iota_{12}(z_1 - z_2)^{-1}$, lower-truncated with $B = 0$. Then $f(z_0 + z_2, z_2)_{a,b} = \sum_{k=0}^{b} \binom{a+k}{k} [a + k = -1 - (b - k)]$, which forces $a = -1 - b$; for such a the coefficient is $\sum_{k=0}^{b} \binom{k-b-1}{k} = \sum_{k=0}^{b} (-1)^k \binom{b}{k} = [b = 0]$ (Example 2.15 with $r = b - k + 1$). So $f(z_0 + z_2, z_2) = z_0^{-1}$: substituting $z_1 = z_0 + z_2$ into $1/(z_1 - z_2)$ gives $1/z_0$, as it should. Consistently with the theorem, $(z_1 - z_2)f = 1$ and $1(z_0 + z_2, z_2) = 1 = z_0 \cdot z_0^{-1}$.

What the machine verified

Unconditional (the hypothesis is the meaningfulness condition); `#print axioms` of `VOA.subst_mulBySub` and `VOA.subst_mulBySubPow` = `[propext, Classical.choice, Quot.sound]`.

2.10 Three-variable distributions

Dong's lemma (Chapter 4, Theorem 4.16) is a statement about three fields $a(z_1)$, $b(z_2)$, $c(z_3)$ and their three pairwise localities. Its proof moves powers of $z_1 - z_2$, $z_1 - z_3$, $z_2 - z_3$ around using the polynomial identity $z_2 - z_3 = (z_2 - z_1) + (z_1 - z_3)$. The file `FormalDist3.lean` provides exactly this.

Definition 2.55 (Three-variable distributions and pairwise differences)**.** A three-variable distribution is $f : \mathbb{Z}^3 \to \mathcal{W}$, $f = \sum f_{m,n,p} z_1^m z_2^n z_3^p$. Multiplication by z_i shifts the i-th index by one, and multiplication by $z_i - z_j$ is the difference of two shifts; $(z_i - z_j)^N$ is its N-fold iterate.

File `VOA/Foundations/FormalDist3.lean`.

```
def FormalDist₃ (𝒲 : Type*) : Type _ := ℤ → ℤ → ℤ → 𝒲

def shift₁ : FormalDist₃ 𝒲 →ₗ[ℂ] FormalDist₃ 𝒲 where
  toFun f := fun m n p => f (m - 1) n p

def mulBySub₁₂ : FormalDist₃ 𝒲 →ₗ[ℂ] FormalDist₃ 𝒲 := shift₁ - shift₂
def mulBySub₁₃ : FormalDist₃ 𝒲 →ₗ[ℂ] FormalDist₃ 𝒲 := shift₁ - shift₃
def mulBySub₂₃ : FormalDist₃ 𝒲 →ₗ[ℂ] FormalDist₃ 𝒲 := shift₂ - shift₃
def mulBySub₂₁ : FormalDist₃ 𝒲 →ₗ[ℂ] FormalDist₃ 𝒲 := shift₂ - shift₁

def mulBySub₁₂Pow : ℕ → (FormalDist₃ 𝒲 →ₗ[ℂ] FormalDist₃ 𝒲)
  | 0 => LinearMap.id
  | (N + 1) => mulBySub₁₂.comp (mulBySub₁₂Pow N)
```

From the mathematics to the Lean statement

`f m n p` is the coefficient of $z_1^m z_2^n z_3^p$. `shift₂`, `shift₃` are defined like `shift₁` on the second and third index (omitted). The powers `mulBySub₁₃Pow`, `mulBySub₂₃Pow`, `mulBySub₂₁Pow` are defined like `mulBySub₁₂Pow`. The file proves `mulBySub₁₂_apply : mulBySub₁₂ f m n p = f (m - 1) n p - f m (n - 1) p` and its analogues. Same as the textbook three-variable calculus (Kac §3.2, Lepowsky–Li §3.2).

Physical meaning

Three-variable distributions are three-point operator products $a(z_1)b(z_2)c(z_3)$; the three differences are the three collision channels. Associativity of the OPE is the statement that the channels $z_1 \to z_2$ and $z_2 \to z_3$ give consistent answers, and Dong's lemma is its first formal consequence.

What the machine verified

Definitions; no hypotheses.

Theorem 2.56 (The binomial expansion of $(z_2 - z_3)^N$). *On three-variable distributions, $z_2 - z_3 = (z_2 - z_1) + (z_1 - z_3)$, $z_2 - z_1 = -(z_1 - z_2)$, and for every $N \in \mathbb{N}$*

$$(z_2 - z_3)^N f = \sum_{i=0}^{N} \binom{N}{i} (z_2 - z_1)^i (z_1 - z_3)^{N-i} f.$$

File `VOA/Foundations/FormalDist3.lean`.

```
theorem mulBySub₂₃_eq : (mulBySub₂₃ : FormalDist₃ 𝒲 →ₗ[ℂ] _) = mulBySub₂₁ + mulBySub₁₃ :=
↪  by

theorem mulBySub₂₁_eq_neg : (mulBySub₂₁ : FormalDist₃ 𝒲 →ₗ[ℂ] _) = -mulBySub₁₂ := by

theorem mulBySub₂₃Pow_eq_sum (N : ℕ) (f : FormalDist₃ 𝒲) :
    mulBySub₂₃Pow N f
      = ∑ i ∈ Finset.range (N + 1),
          (N.choose i) • mulBySub₂₁Pow i (mulBySub₁₃Pow (N - i) f) := by
```

From the mathematics to the Lean statement

`N.choose i` is the ordinary binomial coefficient (a natural number, acting by repeated addition). `N - i` is truncated subtraction on $\mathbb{N}$, harmless because $i \le N$ in the range. The identity is an identity of linear maps applied to f; it rests on the fact that all shift operators commute, so that the binomial theorem holds in the commutative subalgebra they generate (the file proves `mulBySub₂₁_comm_mulBySub₁₃`). No hypotheses.

Physical meaning

In Dong's lemma one must show that $(z_2 - z_3)^M$ kills $[(a_{(k)}b)(z_2), c(z_3)]$. Writing $z_2 - z_3$ as $(z_2 - z_1) + (z_1 - z_3)$ and expanding distributes the factor between the channels in which a is close to b and in which a is close to c; each term is killed by one of the given localities.

Proof on paper. The operators of multiplication by z_1, z_2, z_3 commute, so the binomial theorem applies in the commutative algebra they generate. □

What the machine verified

Unconditional; axioms clean (checked for `mulBySub₂₃_eq` and `mulBySub₂₃Pow_eq_sum`). Used downstream in `VOA/Core/Dong.lean` and `VOA/Core/DongSuper.lean`.

2.11 Four-variable distributions and the double-delta calculus

The last four files build a four-variable calculus intended for the proof of Li's local-system theorem: a set of mutually local fields on a space W generates a vertex algebra whose vertex operator is

$$Y_W(a(z),z_0)\,b(z) = \mathrm{Res}_{z_1}\Big(z_0^{-1}\delta\Big(\frac{z_1-z}{z_0}\Big)a(z_1)b(z) - z_0^{-1}\delta\Big(\frac{z-z_1}{-z_0}\Big)b(z)a(z_1)\Big).$$

To prove that two such induced vertex operators are again local one needs to apply *two* such delta kernels, sharing the base variable z, and to move powers of differences through the resulting double residue. We present the layer completely, but we warn at the outset (the trap box on p. 90) that at this commit the layer is not used by any other file of the library, and that its main theorem carries a finiteness hypothesis that has not yet been discharged for the intended payloads.

2.11.1 Four-variable distributions, residues and Fubini

Definition 2.57 (Four-variable distributions, differences, residues)**.** A four-variable distribution is $f : \mathbb{Z}^4 \to W$, $f = \sum f_{i,j,k,l} z_1^i z_2^j z_3^k z_4^l$. For each pair $i < j$ there is multiplication by $z_i - z_j$ and its powers. For each coordinate (resp. pair of coordinates) there is a residue, the coefficient at exponent -1 (resp. $(-1,-1)$), which is a three- (resp. two-)variable distribution in the remaining coordinates, in their original order.

File `VOA/Foundations/FormalDist4.lean`.

```
def FormalDist₄ (W : Type*) : Type _ := ℤ → ℤ → ℤ → ℤ → W

def mulBySub₁₂ : FormalDist₄ W →ₗ[ℂ] FormalDist₄ W := shift₁ - shift₂

def mulBySub₃₄ : FormalDist₄ W →ₗ[ℂ] FormalDist₄ W := shift₃ - shift₄

def mulBySub₁₂Pow (N : ℕ) : FormalDist₄ W →ₗ[ℂ] FormalDist₄ W := mulBySub₁₂ ^ N

def res₁ : FormalDist₄ W →ₗ[ℂ] FormalDist₃ W where
  toFun f := fun j k l => f (-1) j k l

def res₁₂ : FormalDist₄ W →ₗ[ℂ] FormalDist₂ W where
  toFun f := fun k l => f (-1) (-1) k l
```

From the mathematics to the Lean statement

These live in the namespace `VOA.FormalDist₄`, so `FormalDist₄.mulBySub₁₂` is distinct from the three-variable `VOA.mulBySub₁₂` of Definition 2.55. All six differences `mulBySub₁₂`, …, `mulBySub₃₄`, all six powers, the four single residues `res₁`–`res₄` and the six double residues `res₁₂`–`res₃₄` are defined in the same way (we show representatives). Here powers are monoid powers `mulBySub₁₂ ^ N` in the algebra of linear endomorphisms, rather than the recursion used for two and three variables; the file proves the recursion `mulBySub₁₂Pow_succ`. Residues are pure coefficient extraction and need no finiteness.

Physical meaning

Four-point configurations: two field insertions x_1, x_2 that will be contracted (integrated) and two relative coordinates z_{o_1}, z_{o_2} that remain; the residues are the contour integrals over x_1 and x_2.

What the machine verified

Definitions; linearity by `rfl`. No hypotheses.

Definition 2.58 (Coefficientwise finite families and their sums). A family $(F_a)_{a\in I}$ of four-variable distributions is *coefficientwise finite* if for every multi-index the set of a with nonzero coefficient is finite; a two-parameter family $(F_{a,b})$ is *jointly coefficientwise finite* if for every multi-index the set of pairs (a, b) with nonzero coefficient is finite. The (iterated) coefficientwise sums are $\left(\sum_a F_a\right)_{ijkl} = \sum_a (F_a)_{ijkl}$ and $\sum_a \sum_b F_{a,b}$.

File `VOA/Foundations/FormalDist4.lean`.

```
def CoeffFinite {ι : Type v} (F : ι → FormalDist₄ W) : Prop :=
  ∀ i j k l, (Function.support fun a => F a i j k l).Finite

def CoeffJointFinite {ι : Type v} {κ : Type w} (F : ι → κ → FormalDist₄ W) : Prop :=
  ∀ i j k l, (Function.support fun p : ι × κ => F p.1 p.2 i j k l).Finite

noncomputable def coeffFinsum {ι : Type v} (F : ι → FormalDist₄ W) : FormalDist₄ W :=
  fun i j k l => ∑ᶠ a, F a i j k l

noncomputable def coeffFinsum₂ {ι : Type v} {κ : Type w} (F : ι → κ → FormalDist₄ W) :
    FormalDist₄ W := coeffFinsum fun a => coeffFinsum (F a)
```

From the mathematics to the Lean statement

`ι × κ` is the product type; `p.1`, `p.2` its components. Unlike `algSum` (Definition 2.3), `coeffFinsum` does *not* take a finiteness proof as an argument: it is defined for all families and returns the junk value on infinite supports (the trap box on p. 44); the predicates `CoeffFinite` and `CoeffJointFinite` are carried separately by the theorems. The file also proves that residues commute with these sums (`res₁_coeffFinsum_apply` etc.); those lemmas are definitional and carry an *unused* finiteness hypothesis (named `_hF`), kept, according to the file, so that callers retain the certificate.

Physical meaning

Bookkeeping for sums over intermediate modes, which in a mode computation of a four-point function are finite on each state.

What the machine verified

Definitions.

Theorem 2.59 (Fubini for algebraic sums). *If the doubly indexed family $(F_{a,b})$ in an abelian group has finite joint support, then $\sum_b \sum_a F_{a,b} = \sum_a \sum_b F_{a,b}$. Iterated sums are invariant under reindexing both variables by bijections. Consequently coefficientwise iterated sums of a jointly coefficientwise finite family may be exchanged.*

File `VOA/Foundations/FormalDist4.lean`.

```
theorem finsum_finsum_comm_of_joint_finite {ι : Type v} {κ : Type w}
    (F : ι → κ → W)
    (hF : (Function.support fun p : ι × κ => F p.1 p.2).Finite) :
    (∑ᶠ b, ∑ᶠ a, F a b) = ∑ᶠ a, ∑ᶠ b, F a b := by

theorem finsum_finsum_reindex {ι ι' : Type v} {κ κ' : Type w}
    (eι : ι ≃ ι') (eκ : κ ≃ κ') (F : ι' → κ' → W) :
    (∑ᶠ a, ∑ᶠ b, F (eι a) (eκ b)) = ∑ᶠ a', ∑ᶠ b', F a' b' := by

theorem coeffFinsum₂_comm {ι : Type v} {κ : Type w}
    (F : ι → κ → FormalDist₄ W) (hF : CoeffJointFinite F) :
    coeffFinsum₂ F = coeffFinsum₂ (fun b a => F a b) := by
```

From the mathematics to the Lean statement

`ι ≃ ι'` is a bijection (an equivalence of types). The reindexing lemma needs no finiteness: `finsum` is invariant under bijections even in the junk case. The exchange lemma needs *joint* finiteness, and this hypothesis is genuinely necessary, not an artefact of Lean (see the warning below).

Physical meaning

Exchanging the order of two contour integrals, $\oint_{x_1}\oint_{x_2} = \oint_{x_2}\oint_{x_1}$, is legitimate only when the integrand has no singularity that one contour must cross; formally, when only finitely many intermediate modes contribute jointly.

Proof on paper. With finite joint support $S \subseteq I \times K$, both iterated sums equal $\sum_{(a,b)\in S} F_{a,b}$. □

Trap / dead end

Why joint finiteness and not just finiteness of each inner sum. On $\mathbb{N}\times\mathbb{N}$ let $F_{a,b} = [a = b] - [a = b+1]$. For each a, $b \mapsto F_{a,b}$ has finite support and $\sum_b F_{a,b} = [a = 0]$; so $\sum_a \sum_b F_{a,b} = 1$. For each b, $\sum_a F_{a,b} = 1 - 1 = 0$; so $\sum_b \sum_a F_{a,b} = 0$. All inner and outer sums here are genuine finite sums, yet the two iterated sums differ. The joint support (the two diagonals) is infinite. The library's insistence on `CoeffJointFinite` and on `DoubleResidueFinite` below is therefore mathematically necessary.

What the machine verified

Unconditional; axioms clean (checked for `finsum_finsum_comm_of_joint_finite` and `coeffFinsum₂_comm`).

2.11.2 The single and double delta kernels

Definition 2.60 (Orientations, single and double delta kernels)**.** There are two *orientations*, $+$ and $-$. For an orientation o, the three-variable kernel $\Delta_o(x, z_b, z_o)$ has coefficient of $x^s z_b^\beta z_o^r$ equal to the coefficient of $x^s z_b^\beta$ in $\iota_o(x - z_b)^{-r-1}$, where $\iota_+ = \iota_{x,z_b}$ and $\iota_- = \iota_{z_b,x}$. Thus

$$\Delta_+ = z_o^{-1}\delta\Big(\frac{x - z_b}{z_o}\Big) \text{ expanded in nonnegative powers of } z_b,$$
$$\Delta_- = z_o^{-1}\delta\Big(\frac{x - z_b}{z_o}\Big) \text{ expanded in nonnegative powers of } x.$$

For orientations o_1, o_2 the *double delta kernel* is the product sharing the base variable z_b:

$$K_{o_1o_2}(x_1, x_2, z_{o_1}, z_{o_2}; z_b) := \Delta_{o_1}(x_1, z_b, z_{o_1})\,\Delta_{o_2}(x_2, z_b, z_{o_2}),$$

a four-variable distribution in $(x_1, x_2, z_{o_1}, z_{o_2})$ whose coefficients are one-variable series in z_b.

File `VOA/Foundations/FormalDist4Delta.lean`.

```
inductive Orientation
  | pos
  | neg
  deriving DecidableEq

noncomputable def singleDelta (o : Orientation) : FormalDist₃ ℂ
  | source, base, outer => match o with
    | .pos => expandPos (-outer - 1) source base
    | .neg => expandNeg (-outer - 1) source base

noncomputable def doubleDelta (o₁ o₂ : Orientation) : FormalDist₄ (FormalDist ℂ) :=
  fun source₁ source₂ outer₁ outer₂ base => ∑ᶠ split : ℤ,
    singleDelta o₁ source₁ split outer₁ *
      singleDelta o₂ source₂ (base - split) outer₂
```

From the mathematics to the Lean statement

Decoding `singleDelta`. The three indices are (source s, base β, outer r): exponents of x, z_b, z_o. The value is the (s,β) coefficient of $\iota(x-z_b)^{-r-1}$ (Definition 2.30). Summing over r: $\sum_r z_o^r(x-z_b)^{-r-1} = \sum_n z_o^{-n-1}(x-z_b)^n$ $(n=-r-1) = z_o^{-1}\delta((x-z_b)/z_o)$, so the kernel is the FLM delta function in the stated expansion. One checks that the $-$ orientation is the second FLM term: with the binomial convention (expansion in nonnegative powers of the second variable), $z_0^{-1}\delta((z-x)/(-z_0)) = \sum_n (-1)^n z_0^{-n-1}(z-x)^n$ with $(z-x)^n$ expanded in nonnegative powers of x, and $(-1)^n(z-x)^n$ so expanded is $\iota_{z,x}(x-z)^n$; hence $z_0^{-1}\delta((z-x)/(-z_0)) = \sum_n z_0^{-n-1}\iota_{z,x}(x-z)^n$, which is Δ_- with base $z_b = z$.
Decoding `doubleDelta`. `FormalDist₄ (FormalDist ℂ)`: four explicit indices (s_1, s_2, r_1, r_2) and a fifth, `base`, for the z_b-series. The value is the z_b^{base} coefficient of the product $\Delta_{o_1}\Delta_{o_2}$, a convolution in z_b over `split`. It is a genuine finite sum: the first factor vanishes unless split $= -r_1 - 1 - s_1$ (antidiagonal support), proved as `singleDelta_convolution_finite`. The four choices of (o_1, o_2) are the PP/PN/NP/NN cases of the file header.

Physical meaning

$z_0^{-1}\delta((z_1-z_2)/z_0)$ implements the change of variables $z_1 = z_2 + z_0$ inside a contour integral: it is the kernel that converts the product $a(z_1)b(z_2)$ into the OPE in the relative coordinate z_0. The two orientations are the two radial orderings $a(z_1)b(z_2)$ and $b(z_2)a(z_1)$ that appear, with a relative sign, in the definition of the induced vertex operator Y_W; the double kernel performs two such re-centrings around the same base point, as needed for the three-point configuration $a_1(x_1)\,b(z_b)\,a_2(x_2)$.

What the machine verified

Definitions.

Proposition 2.61 (Support and the defining relation of the single kernel). *Δ_o is supported on $s+\beta = -r-1$; the convolution defining $K_{o_1o_2}$ has finitely many terms for each coefficient; and $(x-z_b)\Delta_o = z_o\Delta_o$ (on the support of the delta function, $x - z_b = z_o$).*

File `VOA/Foundations/FormalDist4Delta.lean`.

```
theorem singleDelta_eq_zero_off_diag (o : Orientation) (source base outer : ℤ)
    (h : source + base ≠ -outer - 1) : singleDelta o source base outer = 0 := by
```

```
theorem singleDelta_convolution_finite (o₁ o₂ : Orientation)
    (source₁ source₂ outer₁ outer₂ base : ℤ) :
    (Function.support fun split : ℤ =>
      singleDelta o₁ source₁ split outer₁ *
        singleDelta o₂ source₂ (base - split) outer₂).Finite := by

theorem singleDelta_relation (o : Orientation) (source base outer : ℤ) :
    singleDelta o (source - 1) base outer - singleDelta o source (base - 1) outer =
      singleDelta o source base (outer - 1) := by
```

From the mathematics to the Lean statement

In `singleDelta_relation`, the left side is the coefficient of $(x - z_b)\Delta_o$ (shift in x minus shift in z_b) and the right side that of $z_o\Delta_o$ (shift in z_o). It is Proposition 2.34 with $n = -r - 1$.

Physical meaning

The delta function enforces momentum conservation in the relative coordinate: $x = z_b + z_o$.

Proof on paper. Proposition 2.32(b) and Proposition 2.34. □

What the machine verified

Unconditional.

Theorem 2.62 (Outer-to-inner transport). *For all orientations o_1, o_2 and $N \in \mathbb{N}$,*

$$(z_{o_1} - z_{o_2})^N K_{o_1 o_2} = (x_1 - x_2)^N K_{o_1 o_2}.$$

File `VOA/Foundations/FormalDist4Delta.lean`.

```

    Commute
      (FormalDist₄.mulBySub₁₂ : FormalDist₄ (FormalDist ℂ) →ₗ[ℂ] _)
      (FormalDist₄.mulBySub₃₄ : FormalDist₄ (FormalDist ℂ) →ₗ[ℂ] _) := by

theorem mulBySub₃₄_doubleDelta (o₁ o₂ : Orientation) :
    FormalDist₄.mulBySub₃₄ (doubleDelta o₁ o₂) =
      FormalDist₄.mulBySub₁₂ (doubleDelta o₁ o₂) := by

theorem mulBySub₃₄Pow_doubleDelta (o₁ o₂ : Orientation) (N : ℕ) :
    FormalDist₄.mulBySub₃₄Pow N (doubleDelta o₁ o₂) =
      FormalDist₄.mulBySub₁₂Pow N (doubleDelta o₁ o₂) := by
```

From the mathematics to the Lean statement

Which variables. The four explicit coordinates of `doubleDelta` are (s_1, s_2, r_1, r_2), i.e. $(x_1, x_2, z_{o_1}, z_{o_2})$. So `mulBySub₃₄` is $z_{o_1} - z_{o_2}$ and `mulBySub₁₂` is $x_1 - x_2$. An earlier file header stated the identity as "$(z_3 - z_0)^N K = (z_1 - z_4)^N K$", in a variable naming taken from Li's paper; the current header writes "$(z_3 - z_4)^N K = (z_1 - z_2)^N K$" with $(z_1, z_2, z_3, z_4) = (\text{source}_1, \text{source}_2, \text{outer}_1, \text{outer}_2)$, which matches the Lean coordinates. It is the same statement. `Commute A B` means $AB = BA$. No hypotheses; valid uniformly in the four orientations.

Physical meaning

On the support of the kernel $x_i = z_b + z_{o_i}$, so $x_1 - x_2 = z_{o_1} - z_{o_2}$: the separation of the two original insertion points equals the separation of their relative coordinates. This is the

identity that transfers locality of a_1, a_2 to locality of the induced vertex operators.

Proof on paper. By Proposition 2.61, $z_{o_1}\Delta_1\Delta_2 - z_{o_2}\Delta_1\Delta_2 = ((x_1 - z_b)\Delta_1)\Delta_2 - \Delta_1((x_2 - z_b)\Delta_2) = (x_1 - x_2)\Delta_1\Delta_2$, the two z_b-terms cancelling. Coefficientwise the cancellation is an index shift in the convolution variable `split`, legitimate because all convolution sums are finite. The power version follows by induction, using that the two difference operators commute. □

What the machine verified

Unconditional; `#print axioms` of `mulBySub₃₄_doubleDelta` and `mulBySub₃₄Pow_doubleDelta` = `[propext, Classical.choice, Quot.sound]` (also printed by the file's own audit section).

2.11.3 Contraction: the semantic interface

Definition 2.63 (Single contraction and residue substitution)**.** For an orientation o and $r, k \in \mathbb{Z}$ let $\gamma_o(r,k)$ be the coefficient of Δ_o at $(s,\beta,r) = (-r-k-1, k, r)$. For a two-variable payload $f(x, z_b)$, the *single contraction* is $\big(\operatorname{Res}_x \Delta_o(x, z_b, z_o) f(x, z_b)\big)$, whose (r,β') coefficient is $\sum_k \gamma_o(r,k)\, f_{r+k,\beta'-k}$ (*residue substitution*).

File `VOA/Foundations/FormalDist4DeltaContract.lean`.

```
noncomputable def contractionCoeff (o : Orientation) (outer k : ℤ) : ℂ :=
  singleDelta o (-outer - k - 1) k outer

noncomputable def contractionKernel (o : Orientation) : FormalDist₄ ℂ :=
  fun outer baseOut source baseIn =>
    singleDelta o (-source - 1) (baseOut - baseIn) outer

noncomputable def singleContractSummand (o : Orientation) (f : FormalDist₂ W)
    (outer baseOut k : ℤ) : W :=
  contractionKernel o outer baseOut (outer + k) (baseOut - k) •
    f (outer + k) (baseOut - k)

noncomputable def singleDeltaContract (o : Orientation) (f : FormalDist₂ W) :
    FormalDist₂ W :=
  fun outer baseOut => ∑ᶠ k : ℤ, singleContractSummand o f outer baseOut k

noncomputable def residueSubst (o : Orientation) (f : FormalDist₂ W) : FormalDist₂ W :=
  fun outer baseOut => ∑ᶠ k : ℤ,
    contractionCoeff o outer k • f (outer + k) (baseOut - k)
```

From the mathematics to the Lean statement

The matrix of the contraction. `contractionKernel o r β' s β` is the coefficient with which the input coefficient $f_{s,\beta}$ contributes to the output coefficient (r,β'): pairing x^s in f with x^{-s-1} in the kernel (the residue in x) and z_b^{β} in f with $z_b^{\beta'-\beta}$ in the kernel (the product in z_b). It is supported on the "residue graph" $s = r + (\beta' - \beta)$, parametrised by $k = \beta' - \beta$; on it the coefficient is `contractionCoeff o r k`.

Junk values. `singleDeltaContract` and `residueSubst` are `finsums` over $k \in \mathbb{Z}$ and are meaningful only when finitely many k contribute. For $o = +$, $\gamma_+(r,k) = (-1)^k\binom{-r-1}{k} = \binom{r+k}{k}$ for $k \geq 0$ and 0 for $k < 0$ (`contractionCoeff_pos_eq_zero_of_neg`), so `residueSubst .pos` has exactly the coefficient formula of `subst` (Definition 2.52) and is meaningful on payloads lower-truncated in z_b. For $o = -$, $\gamma_-(r,k) = 0$ unless $k \leq -r-1$, i.e. unless the source exponent $r+k$ is ≤ -1 (`contractionCoeff_neg_eq_zero_of_gt`).

Design decision recorded in the file. The header insists that the contraction coefficient

be *derived* from `singleDelta`, not postulated by a separate binomial formula, and two regression checks pin values for the negative orientation (`contractionCoeff_neg_zero_neg_one`, `contractionCoeff_neg_neg_one_zero`); the second docstring says it is the value "where the discarded binomial interface incorrectly returned zero". See the warning below.

Physical meaning

$\mathrm{Res}_x\, z_o^{-1}\delta((x-z_b)/z_o)\, f(x,z_b)$ is "$f(z_b+z_o,z_b)$": the contour integral over x against the delta kernel re-centres the insertion point at z_b with separation z_o. It is the formal version of Taylor-expanding a field around a nearby point, $a(z_b+z_o)=e^{z_o\partial}a(z_b)$, in the orientation $+$.

What the machine verified

Definitions.

Proposition 2.64 (The contraction is the residue substitution; support and regression values)**.** *For every payload f and orientation o, the single contraction equals the residue substitution. The kernel vanishes off the residue graph; $\gamma_+(r,k)=0$ for $k<0$; $\gamma_-(r,k)=0$ for $k>-r-1$; and $\gamma_-(0,-1)=-1$, $\gamma_-(-1,0)=1$.*

File `VOA/Foundations/FormalDist4DeltaContract.lean`.

```
theorem singleDeltaContract_eq_residueSubst (o : Orientation) (f : FormalDist₂ W) :
    singleDeltaContract o f = residueSubst o f := by

    (hk : -outer - 1 < k) : contractionCoeff .neg outer k = 0 := by

theorem contractionCoeff_neg_zero_neg_one : contractionCoeff .neg 0 (-1) = -1 := by

theorem contractionCoeff_neg_neg_one_zero : contractionCoeff .neg (-1) 0 = 1 := by
```

From the mathematics to the Lean statement

The first identity holds summand by summand (no finiteness needed, since both sides are `finsum`s of the same family). The regression values by hand: $\gamma_-(0,-1)$ is the coefficient of $x^0z_b^{-1}$ in $\iota_{z_b,x}(x-z_b)^{-1}=-\sum_{a\ge0}x^a z_b^{-1-a}$, i.e. -1; and $\gamma_-(-1,0)$ is the coefficient of $x^0z_b^0$ in $\iota_{z_b,x}(x-z_b)^0=1$.

Physical meaning

Technical: it identifies the abstract contraction with the explicit re-centring formula and fixes the two orientation conventions by explicit values, the formal analogue of checking a sign convention on the simplest correlator.

Proof on paper. Reparametrise the summation by k; the support statements are those of Proposition 2.32(b); the values are computed above. □

What the machine verified

Unconditional; axioms clean (checked for `singleDeltaContract_eq_residueSubst` and both regression values).

Trap / dead end

A corrected mistake: the negative orientation is not "the positive binomial with a different index". The header of `FormalDist4DeltaContract.lean` records that an earlier interface computed the negative-orientation contraction coefficient by reusing the positive-expansion binomial formula, and that it returned 0 at $(r,k) = (-1,0)$, where the correct value is 1. The present interface derives every coefficient from `singleDelta`, and `contractionCoeff_neg_neg_one_zero` is the regression certificate. The lesson for the reader: the two expansions of $(x - z_b)^n$ are supported in *opposite* half-planes of exponents (Proposition 2.32(b)), so no reindexing of one formula produces the other.

Definition 2.65 (Double contraction and double residue)**.** Consider a kernel and a payload

$$K \in \mathbb{C}[[z_b^{\pm 1}]][[x_1^{\pm 1}, x_2^{\pm 1}, z_{o_1}^{\pm 1}, z_{o_2}^{\pm 1}]], \qquad f \in W[[x_1^{\pm 1}, z_b^{\pm 1}, x_2^{\pm 1}]]$$

(coordinates in this order). The *double contraction* in the order $(1,2)$ is

$$\big(\operatorname{Res}_{x_1}\operatorname{Res}_{x_2} K\, f\big)_{r_1,\beta',r_2} = \sum_{s_1}\sum_{s_2}\sum_{\beta} K_{-s_1-1,\,-s_2-1,\,r_1,r_2}(\beta'-\beta)\, f_{s_1,\beta,s_2},$$

an element of $W[[z_{o_1}^{\pm 1}, z_b^{\pm 1}, z_{o_2}^{\pm 1}]]$, and in the order $(2,1)$ with the outer two sums exchanged. For the double delta kernel the corresponding *double residue* is $\sum_{k_1}\sum_{k_2}\gamma_{o_1}(r_1,k_1)\gamma_{o_2}(r_2,k_2)\, f_{r_1+k_1,\,\beta'-k_1-k_2,\,r_2+k_2}$, in either order.

From the mathematics to the Lean statement

Coordinates. Payload `f source₁ baseIn source₂`: the base variable is in the *middle*. Output `(outer₁, baseOut, outer₂)`: again base in the middle. So on payloads and outputs (both `FormalDist₃`), the three-variable `mulBySub₁₃` of Definition 2.55 is $x_1 - x_2$, respectively $z_{o_1} - z_{o_2}$. `doubleResidue₂₁` is `doubleResidue₁₂` with the two sums exchanged (omitted). **Junk values.** All five constructions are iterated `finsums` with no finiteness built in. `DoubleResidueFinite` is the joint-finiteness predicate for the double residue (cf. the trap box on p. 80).

Physical meaning

The double contraction is the pair of contour integrals $\oint_{x_1}\oint_{x_2}$ that converts a configuration $a_1(x_1)\,b(z_b)\,a_2(x_2)$ into the relative coordinates of x_1, x_2 with respect to z_b; the two orders of integration are the two orders in which the induced vertex operators $Y_W(a_1, z_{o_1}), Y_W(a_2, z_{o_2})$ act.

What the machine verified

Definitions.

Theorem 2.66 (Double contraction of the double delta). *For all orientations and every payload f: (a) on the residue graph the double kernel factorises, $K_{o_1o_2}(-r_1-k_1-1, -r_2-k_2-1, r_1, r_2)(k_1+k_2) = \gamma_{o_1}(r_1,k_1)\gamma_{o_2}(r_2,k_2)$, and it vanishes off the total antidiagonal; (b) the double contraction of $K_{o_1o_2}$ in either order is the double residue in the same order; (c) if f satisfies* `DoubleResidueFinite`*, the two orders agree; (d) the outer-to-inner transport survives contraction:* $\operatorname{Res}\operatorname{Res}\big((z_{o_1}-z_{o_2})^N K\big)f = \operatorname{Res}\operatorname{Res}\big((x_1-x_2)^N K\big)f$ *for every f.*

```

From the mathematics to the Lean statement

Hypotheses. (a), (b), (d) have none. That (b) needs no finiteness is correct and not a junk-value accident: the innermost sum over β (`baseIn`) has at most one nonzero term by the total-antidiagonal support, and the remaining double sum is a bijective reindexing $(s_1, s_2) \mapsto (s_1 - r_1, s_2 - r_2)$ of the double-residue sum, and `finsum` is invariant under bijections in all cases. (c) needs `DoubleResidueFinite`, exactly the joint finiteness of the trap box on p. 80. (d) is Theorem 2.62 with the equal kernels contracted against the same f; its proof is the one-line term `kernelContract₁₂_congr (mulBySub₃₄Pow_doubleDelta o₁ o₂ N) f`. The file also proves the $(2,1)$-order analogue of (d). **Strength.** (d) is weaker than what is needed for locality, because the difference operators still act on the kernel; moving them onto the output and onto the payload is the next theorem, and that is where a finiteness hypothesis enters.

Physical meaning

(c) is the formal statement that the two contour integrals may be performed in either order when only finitely many intermediate states contribute, which is the case for genuine field configurations (energy bounded below). (d) says that before any integration is performed the separation of the relative coordinates equals the separation of the original points.

Proof on paper. (a) The convolution over `split` has the single term split $= k_1$. (b) As explained in the dictionary. (c) Theorem 2.59. (d) Theorem 2.62. □

What the machine verified

Unconditional for (a), (b), (d); (c) conditional on `DoubleResidueFinite`. Axioms clean (checked for `doubleDelta_on_residue_graph`, `kernelContract₁₂_doubleDelta`, `doubleResidue_comm`, `kernelContract_doubleDelta_comm`, `kernelContract₁₂_doubleDelta_transport`).

2.11.4 Moving difference powers through the contraction; locality transport

Definition 2.67 (Shift-stable joint finiteness). A three-index family $F_{s_1,s_2,\beta}$ is *triple-finite* if its support in $\mathbb{Z}^3$ is finite. For a kernel K, a payload f and integer offsets $d_1, d_2, d_3, d_4, e_1, e_3$, the *shifted contraction summand* at output (r_1, β', r_2) is

$$(s_1, s_2, \beta) \longmapsto K_{-s_1-1-d_1,\, -s_2-1-d_2,\, r_1-d_3,\, r_2-d_4}(\beta' - \beta) \cdot f_{s_1-e_1,\, \beta,\, s_2-e_3}.$$

The pair (K, f) is *shift-contract-finite* if for all offsets and all outputs this family is triple-finite.

File `VOA/Foundations/FormalDist4DeltaSupport.lean`.

```
def TripleFinite (F : ℤ → ℤ → ℤ → W) : Prop :=
  (Function.support fun t : ℤ × (ℤ × ℤ) => F t.1 t.2.1 t.2.2).Finite

noncomputable def shiftedContractSummand (K : FormalDist₄ (FormalDist ℂ))
    (f : FormalDist₃ W) (d₁ d₂ d₃ d₄ e₁ e₃ : ℤ)
    (outer₁ baseOut outer₂ source₁ source₂ baseIn : ℤ) : W :=
```

```
  K (-source₁ - 1 - d₁) (-source₂ - 1 - d₂)
      (outer₁ - d₃) (outer₂ - d₄) (baseOut - baseIn) •
    f (source₁ - e₁) baseIn (source₂ - e₃)

def ShiftContractFinite (K : FormalDist₄ (FormalDist ℂ)) (f : FormalDist₃ W) : Prop :=
  ∀ d₁ d₂ d₃ d₄ e₁ e₃ outer₁ baseOut outer₂,
    TripleFinite (shiftedContractSummand K f d₁ d₂ d₃ d₄ e₁ e₃
      outer₁ baseOut outer₂)
```

From the mathematics to the Lean statement

Why this shape. Each application of a difference operator replaces a summand by a difference of two shifted summands; distributing the subtraction through a nested `finsum` is legitimate only if both pieces have finite support (`tripleFinsum_sub_distrib`). Requiring finiteness for *all* offsets makes the predicate stable under any number of such steps: the file proves that it survives `FormalDist₄.mulBySub₃₄`, `FormalDist₄.mulBySub₁₂` on the kernel and `mulBySub₁₃` on the payload, and their powers. The file header says plainly that this is "stronger than any single displayed identity, but exactly stable".
Could it be vacuous? No. If f has finite support, then for every offset the summand vanishes outside a translate of $\operatorname{supp} f$, so (K, f) is shift-contract-finite for *every* K; so the predicate has many nonzero instances. **Is it satisfied by the intended payloads?** That is the open question of the trap box on p. 90.

Physical meaning

The requirement that, on fixed external states, only finitely many intermediate modes contribute to a double contour integral, uniformly under the finite shifts produced by multiplying by polynomials in the coordinates. In a CFT this follows from the energy bound; formally it must be derived from lower truncation of the fields.

What the machine verified

Definitions.

Theorem 2.68 (Difference powers through contraction; locality transport)**.** *Suppose (K, f) is shift-contract-finite. Then for every $N \in \mathbb{N}$*

$$\operatorname{Res}\operatorname{Res}\big((z_{o_1} - z_{o_2})^N K\big) f = (z_{o_1} - z_{o_2})^N \operatorname{Res}\operatorname{Res} Kf,$$
$$\operatorname{Res}\operatorname{Res}\big((x_1 - x_2)^N K\big) f = \operatorname{Res}\operatorname{Res} K\big((x_1 - x_2)^N f\big).$$

Consequently, for the double delta kernel $K = K_{o_1 o_2}$ with (K, f) shift-contract-finite, $(z_{o_1} - z_{o_2})^N \operatorname{Res}\operatorname{Res} Kf = \operatorname{Res}\operatorname{Res} K(x_1 - x_2)^N f$, and if $(x_1 - x_2)^N f = 0$ then $(z_{o_1} - z_{o_2})^N \operatorname{Res}\operatorname{Res} Kf = 0$.

```

From the mathematics to the Lean statement

Decoding. `FormalDist₄.mulBySub₃₄Pow N K` is $(z_{o_1} - z_{o_2})^N K$ and `FormalDist₄.mulBySub₁₂Pow N K` is $(x_1 - x_2)^N K$ on the kernel. The unqualified `mulBySub₁₃Pow N` is the *three-variable* operator of Definition 2.55, acting on the output (where it is $(z_{o_1} - z_{o_2})^N$, first minus third coordinate) or on the payload (where it is $(x_1 - x_2)^N$). With these readings the four statements are the displayed ones.
Every hypothesis. `hfin : ShiftContractFinite ...` is the support interface of Definition 2.67; `hlocal` is locality of the payload in (x_1, x_2). The first two theorems hold for an arbitrary kernel K; the last two for the double delta, combining them with Theorem 2.66(d).
Same, stronger, weaker? As a formal statement, the last theorem is the locality-transport step of Li's proof (the file header calls the target "Li's local-system theorem (Proposition 3.2.9)") with its finiteness requirement made explicit. It is *conditional*: it says nothing about payloads for which `hfin` fails, and at this commit no theorem establishes `hfin` for payloads built from fields.

Physical meaning

If $a_1(x_1)$ and $a_2(x_2)$ are mutually local, then after re-centring both at z_b the induced fields $Y_W(a_1, z_{o_1})$ and $Y_W(a_2, z_{o_2})$ are mutually local in the relative coordinates: locality is preserved by the passage from fields on W to the vertex operators of the local system. Physically: the OPE of two chiral fields defines new chiral fields that are again local with respect to each other, the operator-algebra version of the statement that composite operators of a local theory are local.

Proof on paper. For one factor $z_{o_1} - z_{o_2}$ on the kernel: the contraction of $(z_{o_1} - z_{o_2})K$ is a nested sum of differences of two shifted summands; by `hfin` both pieces have finite joint support, so the sum splits, and each piece is the contraction of K evaluated at a shifted output: together, $(z_{o_1} - z_{o_2})$ applied to the output. For one factor $x_1 - x_2$ on the kernel: shifting the kernel's source index by one is the same as shifting the payload's source index by one after the bijective reindexing $s_i \mapsto s_i + 1$ of the summation variable (residue pairing: $\mathrm{Res}_x(xK)f = \mathrm{Res}_x K(xf)$); again `hfin` legitimises splitting the difference. Induction on N using the stability of `hfin`. The locality transport is the chain: output power = (first theorem) contraction of the outer power on K = (Theorem 2.62) contraction of the inner power on K = (second theorem) contraction of K against the power on the payload. If the latter vanishes, the contraction of K against 0 is 0. □

What the machine verified

Conditional on `ShiftContractFinite (doubleDelta o₁ o₂) f` (and, for the last theorem, on payload locality, which is the intended input). `#print axioms` for all four = `[propext, Classical.choice, Quot.sound]`.

Trap / dead end

The four-variable layer is not yet connected to the rest of the library. When this chapter was first written, and still in the released source as far as point (1) is concerned (re-checked by a grep of the imports for this edition): (1) no file outside `VOA/Foundations/FormalDist4*.lean` imports `FormalDist4.lean`, `FormalDist4Delta.lean`, `FormalDist4DeltaContract.lean` or `FormalDist4DeltaSupport.lean`, except the umbrella `VOA/Foundations.lean`; in particular `VOA/Core/LocalSystem.lean` does not use them, although the header of `FormalDist4.lean` then said the layer is "needed in the proof of Li's local-system theorem". (The current header says more cautiously that its purpose is to "support the double-residue calculation in Li's local-system theorem"; a grep of the current tree confirms that only the umbrella imports the layer.) (2) The hypothesis `ShiftContractFinite (doubleDelta o₁ o₂) f` has not been derived, for any payload built from fields, from lower truncation (`IsField`). The project's internal records of the local-system route list exactly this support derivation as the next obligation, and claim neither it nor the induced locality of regular fields. A rough count suggests that for the $(+,+)$ orientation the summand is supported where $s_i \geq r_i$ and $\beta = \beta' - (s_1 - r_1) - (s_2 - r_2)$, so joint finiteness requires the payload to vanish for very negative base exponent β, which is the kind of truncation fields provide; this is a heuristic, not a proof. A referee should therefore treat Theorem 2.68 as a correct conditional theorem whose hypothesis is an open input, and the whole layer as infrastructure for future work.

2.12 Verification record

What was run. (This run dates from the first writing of the chapter, at an earlier commit, and was not re-run for this edition.) The tree at that commit was already built (the `.olean` files of all thirteen modules are present and the working tree has no modifications under `VOA/`); we did *not* re-run the aggregate `lake build` for this chapter. We created a scratch file outside the repository importing `VOA.Foundations.FormalDist4DeltaSupport` and `VOA.Foundations.IotaZExpansion` (which together import all thirteen modules) and containing sixty `#print axioms` commands, and ran it with the audit-safe invocation required by the project (a bare `lake env lean` may drop `maxSynthPendingDepth`):

```
export PATH="$HOME/.elan/bin:$PATH"
lake env lean -DmaxSynthPendingDepth=3 Axioms.lean
```

Result. All sixty declarations report exactly the three standard axioms; there is no `sorryAx` and no `VOA.pbw`. A representative excerpt of the output:

```

Release audit 2026-10-27. `Notes/Textbook/referee/RELEASE_AUDIT_FOUNDATIONS.md`. For this chapter its relevant findings are: `Local` is used verbatim in the standard sense (it checked the convention of `mulBySub`), and the structures `PreVertexAlgebra`/`BarePreVA` that use `Local` as an axiom lack translation covariance, so they are not vertex algebras in the standard sense (Chapter 4); after the audit the library gave them these names (formerly `VertexAlgebra` and `BareVA`) and reserved `VertexAlgebra` for the translation-covariant notion.

Reading the result honestly. A clean `#print axioms` does not report explicit hypotheses. The theorems of this chapter with genuine hypotheses are: those carrying a Laurent-polynomial hypothesis (`deriv_lpSMul`, `res_lpSMul_deriv`), a lower-truncation hypothesis (`eq_zero_of_mulBySubPow_of_bddBelow`, `subst_mulBySub`, `subst_mulBySubPow`), a joint-finiteness hypothesis (`finsum_finsum_comm_of_joint_finite`, `coeffFinsum₂_comm`, `doubleResidue_comm`, `kernelContract_doubleDelta_comm`), and the shift-stable support hypothesis `ShiftContractFinite` (the four theorems of Theorem 2.68). The first three kinds are meaningfulness or genuine mathematical conditions that are part of the textbook statements. The last is an open input at this commit (the trap box on p. 90).

Downstream use (checked by `grep` at this commit). `Local` is the locality axiom of `PreVertexAlgebra`, `BarePreVA` and `VertexOperatorAlgebra`; `eq_zero_of_mulBySubPow_of_bddBelow` is used in nine files of `VOA/Core` (weak associativity, Goddard uniqueness, reconstruction);

`subst_mulBySubPow` in `Core/Skew.lean`; `mulBySub₂₃Pow_eq_sum` in `Core/Dong.lean` and `Core/DongSuper.lean`; `expandPos_mul` in `Examples/LatticeA1.lean`; `localε_of_car` in three free-field example files; `LaurentPoly` in `Examples/VirasoroKacLaurent.lean`. Not used outside the thirteen files of this chapter: `formalDelta`, `delta₂`, `lpSMul` and its two theorems, `binomialExpand`, `algSum`, `negPowJump_eq_deltaDeriv`, and the whole four-variable layer.

Docstring discrepancies found while writing this chapter. All but one of these have since been corrected in the source (a grep of the current tree finds none of (1), (3), (4), (5), (6), and only half of (2)); they are kept here as a record of what the first edition reported. (1) `IotaZExpansion.lean` listed a lemma `expandPos_mul_zero` that does not exist (Theorem 2.36). (2) `IteratedLaurent.lean` described `IsBddBelow₂` as the class $\mathcal{W}((z_1))((z_2))$; it is the larger class $\mathcal{W}[[z_1^{\pm 1}]]((z_2))$ (Definition 2.49). The definition's docstring is now correct; the docstring of `eq_zero_of_mulBySubPow_of_bddBelow` still says $\mathcal{W}((z_1))((z_2))$. (3) `Expansion.lean` said the general-n multiplicativity of the expansions is "provided by `subst_mulBySubPow`"; the multiplicativity of the expansions is `expandPos_mul`/`expandNeg_mul` in `IotaZExpansion.lean`, while `subst_mulBySubPow` is the multiplicativity of the substitution, a different statement. (4) The heuristic "no finite-dimensional fermionic toy example" in `Locality.lean` (the trap box on p. 72). (5) `FormalDist4.lean` said the layer is needed for Li's theorem, but it is not (yet) imported by `Core/LocalSystem.lean` (the trap box on p. 90). (6) `FormalDist4Delta.lean` stated its central identity in variables $(z_3 - z_0)^N K = (z_1 - z_4)^N K$ that do not match the Lean coordinates; the Lean statement is $(z_{o_1} - z_{o_2})^N K = (x_1 - x_2)^N K$ (Theorem 2.62). None of these affects the truth of any Lean statement.

2.13 Referee's checklist

Lean declaration	Intended meaning	Hypotheses / status	Check
`FormalDist`, `FormalDist₂`	$\mathcal{W}[[z^{\pm 1}]]$, $\mathcal{W}[[z_1^{\pm 1}, z_2^{\pm 1}]]$; no product	definition	Def. 2.1, 2.21
`mode`	$f_{(m)} = f_{-m-1}$	definition; **key convention**	Def. 2.7
`res`, `deriv`	Res_z, ∂_z	definition	Def. 2.7
`mode_eq_res`, `res_deriv`	$f_{(m)} = \mathrm{Res}\, z^m f$; $\mathrm{Res}\, \partial f = 0$	none; unconditional	Prop. 2.8
`lpSMul`	Laurent polynomial times distribution	definition; junk value if g infinite	Def. 2.10
`deriv_lpSMul`, `res_lpSMul_deriv`	Leibniz; integration by parts	g Laurent polynomial	Thm. 2.11, 2.12
`gBinom`, `cbz`, `negOnePow`	$\binom{n}{k}$, $n \in \mathbb{Z}$; $C(n,k) = 0$ for $k < 0$; $(-1)^n$	definition	Def. 2.14
`cbz_vandermonde`	$\sum_i C(m,i)C(n,k-i) = C(m+n,k)$, all $m, n, k \in \mathbb{Z}$	none; unconditional	Thm. 2.19
`mulBySub`, `mulBySubPow`	multiplication by $(z_1 - z_2)^N$	definition	Def. 2.21
`deltaDeriv`, `cCoeff`	$c(z_2)\partial_{z_2}^j \delta(z_1, z_2)$ (plain ∂^j); $\mathrm{Res}_{z_1}(z_1 - z_2)^j f$	definition	Def. 2.23
`local_iff_deltaSum`	$(z_1 - z_2)^N f = 0 \iff f = \sum_{j<N} c^j \partial^j \delta$ (Gannon 5.1.2, Kac 2.3)	none; unconditional	Thm. 2.27
`expandPos`, `expandNeg`, `deltaForm`	ι_{z_1,z_2}, ι_{z_2,z_1} of $(z_1 - z_2)^n$; $\delta(z_1, z_2)$	definition	Def. 2.30
`expand_jump`	$\iota_{12} - \iota_{21}$ of $(z_1 - z_2)^{-1}$ is δ	none; unconditional	Thm. 2.33
`negPowJump_eq_deltaDeriv`	jump of $(z_1 - z_2)^{-k-1}$ is $\partial^{(k)}\delta$	none; unconditional	Thm. 2.38
`expandPos_mul`, `expandNeg_mul`	$\iota(z_1 - z_2)^m \iota(z_1 - z_2)^n = \iota(z_1 - z_2)^{m+n}$	none; `convolPos` is the genuine product (paper)	Thm. 2.36

Lean declaration	Intended meaning	Hypotheses / status	Check
`bracketDist`, `Local`, `normalOrdered`	$[a(z_1), b(z_2)]$; mutual locality; $:a(z_1)b(z_2):$	definition	Def. 2.41
`IsField`, `nprodCoeff`, `nprod`	field (lower truncation); same-variable $:a(z)b(z):$, the (-1)-st product	definition; $\sum^{\mathrm{f}}$ finite because both arguments are fields	Def. 2.43
`locale_iff_deltaSum`, `locale_of_car`	super-locality; CAR/CCR $\Rightarrow$ local	none; unconditional	Thm. 2.46, 2.47
`IsBddBelow₂`	lower truncation in z_2, uniform in z_1	definition (weaker than $\mathcal{W}((z_1))((z_2))$)	Def. 2.49
`eq_zero_of_mulBySubPow_of_bddBelow`	$z_1 - z_2$ not a zero-divisor on lower-truncated series	lower truncation; unconditional	Thm. 2.50
`subst`, `subst_mulBySub(Pow)`	$f(z_0 + z_2, z_2)$; $(z_1 - z_2) \mapsto z_0$	lower truncation; junk value otherwise	Def. 2.52, Thm. 2.53
`mulBySub₂₃Pow_eq_sum`	$(z_2 - z_3)^N = \sum \binom{N}{i}(z_2 - z_1)^i (z_1 - z_3)^{N-i}$	none; unconditional	Thm. 2.56
`finsum_finsum_comm_of_joint_finite`	Fubini for algebraic sums	joint finite support (necessary)	Thm. 2.59
`mulBySub₃₄Pow_doubleDelta`	$(z_{o_1} - z_{o_2})^N K = (x_1 - x_2)^N K$	none; unconditional	Thm. 2.62
`kernelContract₁₂_doubleDelta`, `doubleResidue_comm`	contraction = double residue; order exchange	none; `DoubleResidueFinite` for exchange	Thm. 2.66
`kernelContract₁₂_doubleDelta_eq_zero_of_local`	locality transported through double delta	**conditional** on `ShiftContractFinite` (open input); layer unused	Thm. 2.68, p. 90

2.14 Notes and references

Formal calculus. The formal-distribution approach to vertex algebras, with the delta function, the two expansions and the structure theorem for local distributions, is developed in V. G. Kac, *Vertex Algebras for Beginners*, University Lecture Series 10, American Mathematical Society, second edition (1998), Chapters 1–2 (the structure theorem is his Theorem 2.3; Dong's lemma is Lemma 3.2; Goddard uniqueness and reconstruction are in Chapter 4). The same material in the language of fields and with geometric motivation is in E. Frenkel and D. Ben-Zvi, *Vertex Algebras and Algebraic Curves*, Mathematical Surveys and Monographs 88, American Mathematical Society, second edition (2004), Chapter 1. The most thorough treatment of formal calculus, including the binomial convention, the three-term delta-function identity and the substitution $z_1 \mapsto z_0 + z_2$, is J. Lepowsky and H. Li, *Introduction to Vertex Operator Algebras and Their Representations*, Progress in Mathematics 227, Birkhäuser (2004), Chapter 2; locality, weak associativity and local systems are in Chapters 3 and 5 of the same book. The original source of the formal-variable calculus in this area is I. Frenkel, J. Lepowsky and A. Meurman, *Vertex Operator Algebras and the Monster*, Pure and Applied Mathematics 134, Academic Press (1988), Chapters 2 and 8.

The library's primary reference. The docstrings of the files of this chapter follow T. Gannon, *Moonshine beyond the Monster: The Bridge Connecting Algebra, Modular Forms and Physics*, Cambridge University Press (2006), §5.1.2 (formal distributions, Paradoxes 5.1 and 5.2, the residue and integration by parts (5.1.3), the binomial convention (5.1.4), Proposition 5.1.2, normal ordering (5.1.6)).

Local systems. H. Li, "Local systems of vertex operators, vertex superalgebras and modules", *Journal of Pure and Applied Algebra* 109 (1996), 143–195 (arXiv:hep-th/9406185), is the source of the construction that the four-variable layer of Section 2.11 is intended to formalise. Dong's lemma is due to C. Dong; see Li's paper and Kac's book for proofs.

Physics. Radial quantisation, the operator product expansion and the relation between OPEs and commutators are explained in P. Di Francesco, P. Mathieu and D. Sénéchal, *Conformal Field Theory*, Springer (1997), Chapters 5–6, and in P. Ginsparg, "Applied conformal field theory", in *Fields, Strings and Critical Phenomena* (Les Houches 1988), North-Holland (1990), arXiv:hep-th/9108028. The free-fermion and $\beta\gamma/bc$ systems mentioned in Section 2.7.2 are standard; see J. Polchinski, *String Theory*, Vol. 1, Cambridge University Press (1998), Chapter 2.

Project records. The trust model (no project axiom; `VOA.pbw`, formerly a project axiom, is now a theorem and is not used here) is explained in Chapter 1. The status of the four-variable layer is the one stated in Warning 2.11.4.

Chapter 3

Lie-theoretic inputs and the trust base

This chapter documents the release of the LeanVOA library named in the front matter. Every Lean quotation below is checked by `scripts/textbook/sync.py` to occur verbatim (up to whitespace and comments) in the source files of that release. The machine checks reported below were run at an earlier state of the library, after `pbw` became a theorem, and were not re-run for this edition unless stated otherwise; a line `...` marks omitted structure fields, and a declaration head ending in `:= by` or `:=` is printed without its proof. The chapter covers the files of `VOA/Foundations/` that are not about formal calculus: `AffineLie.lean`, `RootDatum.lean`, `PBWBasis.lean`, `Virasoro.lean`, `VirasoroModule.lean`, `Lattices.lean`, `LatticeCocycle.lean`, `LatticeFinite.lean`, `LatticeOrthoFrame.lean`, `LatticeAlgebraTwisted.lean` and `Parity.lean`, together with the four files of `VOA/Foundations/PBWTheorem/` (`Construction.lean`, `LieRep.lean`, `Induced.lean`, `VacuumBasis.lean`), which prove the Poincaré–Birkhoff–Witt input of the library.

These files supply the *Lie-theoretic raw material* from which the rest of the library builds vertex operator algebras: the Witt and Virasoro algebras (the symmetry algebra of every conformal field theory), the affine Kac–Moody algebras (the current algebras of Wess–Zumino–Witten models), their vacuum modules, the root data of finite-dimensional simple Lie algebras, and the lattice data (integral lattices, the Frenkel–Lepowsky–Meurman cocycle, the twisted group algebra) from which lattice vertex algebras are made. They also contain the library's Poincaré–Birkhoff–Witt input, the theorem

```
theorem pbw : PBWPrinciple
```

in `VOA/Foundations/AffineLie.lean`, proved from Mathlib alone through the relative Poincaré–Birkhoff–Witt construction of `VOA/Foundations/PBWTheorem/`. **The library has no project axiom.** What the machine confirmed for this chapter is that `#print axioms VOA.pbw`, and the same command for every declaration named in a status box of this chapter, reports only Lean's three standard axioms at that earlier commit (not re-run for this edition). The chapter did not run the aggregate `lake build`, and the repository checker's overall verdict at that commit is "failed", because two draft files are not imported (it found no axiom declaration). That defect has since been fixed: the drafts were moved out of `VOA/`, and a run of the checker on the working tree of 28 October 2026 printed "Repository check passed" with 0 sanctioned axiom declarations. Section 3.1 states exactly what the library rests on today and separates what was machine-checked here from what is reported by the project. (Until October 2026 `pbw` was an axiom; that history is collected in Section 3.2.)

Two jobs remain for this chapter, and they are the most important ones in it. The first is *fidelity*: `VOA.pbw` is consumed by the affine vacuum modules and by the Zhu-theory chain of Chapters 13 and 15, and a referee must be able to agree that the Lean statement `PBWPrinciple` says what those consumers need it to say — that it is the Poincaré–Birkhoff–Witt consequence its name advertises, not something weaker or vacuous. A proved statement can no longer make the library inconsistent, but a mis-stated one could still make a downstream theorem mean less than its name. The second job is to explain the *proof*: how the injectivity of the bottom map of an induced module, and the

nonvanishing of the affine vacuum, follow from a relative version of the classical construction of Humphreys §17.4.

Our verdict, argued in Section 3.10, is that both fields of `PBWPrinciple` are, after every Lean definition they mention is unfolded, the standard consequences of the Poincaré–Birkhoff–Witt theorem for Lie algebras over a field, valid without any finiteness assumption, for every instance of their (very general) quantifiers. We check the quantifiers one by one, check the degenerate instances by hand, list the slips in the encoding that would have made the statement false or vacuous, and then present the proof that the library contains. For the results that consume `VOA.pbw` we say precisely which explicit hypotheses each still carries.

The chapter is organised as follows.

- Section 3.1 states what the library assumes today, and Section 3.2 records the history of the former PBW axiom.
- Section 3.3 gives the physical picture: currents, central extensions, stress tensors, and what PBW means for counting states.
- Section 3.4 recalls how Lie algebras, enveloping algebras and quotient modules look in Lean and Mathlib.
- Sections 3.5–3.6 treat the Witt algebra, the Virasoro algebra and the universal Virasoro vacuum module.
- Sections 3.7–3.9 treat affine Kac–Moody algebras, their vacuum modules and the energy grading.
- Section 3.10 is the heart: the classical PBW theorem, the exact Lean statement `PBWPrinciple`, its fidelity check, and the proof of `theorem pbw` by relative PBW.
- Section 3.11 derives the consequences (nonvanishing of the vacuum, the simple quotient $L(0)$), lists the consumers of `VOA.pbw`, and records the history of the axiom and of the axiom-free "twin" policy that accompanied it.
- Section 3.12 presents `PBWBasis`, the full PBW basis of the vacuum module, which began as a *named hypothesis* and is now proved for every $\mathfrak{g}$ (`pbwBasis_holds`).
- Section 3.13 presents root data, general affine Verma modules and the integrability target.
- Section 3.14 treats lattices, cocycles, the twisted group algebra and parity briefly, pointing to Chapters 30 and 31 for the details.
- Section 3.15 is the verification record (the `#print axioms` output behind every status box); the chapter ends with the referee's checklist and notes.

Vertex algebras themselves, modes, and the general trust model are those of Chapter 1; the verification record of the whole library is Chapter 43.

3.1 What the library assumes today

This section is in the present tense and states, in one place, what a reader must accept in order to believe a theorem of the library as stated.

1. Lean's kernel and its three standard axioms. Every proof is checked by Lean's kernel, which accepts a proof only if it follows from the rules of Lean's type theory and from declared axioms. Mathlib and this library use three axioms that belong to ordinary mathematics:

- `propext` (propositional extensionality): two propositions that imply each other are equal;
- `Quot.sound`: in a quotient by a relation, related elements are equal; this is what makes quotient modules, quotient rings and the like behave as on paper (it also yields function extensionality);
- `Classical.choice`: from a proof that a type is nonempty one may pick an element; it gives the law of excluded middle, Zorn's lemma and the existence of bases.

Zermelo–Fraenkel set theory with choice (together with inaccessible cardinals, one for each universe level used) provides a model of these, so they are the background logic of ordinary mathematics. `#print axioms foo` lists the axioms that the proof of `foo` reaches; a report that is a subset of these three is called `#print axioms`-*clean*.

2. Mathlib. The pinned version is Mathlib v4.30.0; its definitions (Lie algebras, universal enveloping algebras, tensor products, quotients, bases, …) are taken to mean what their names say. Chapter 1 and Section 3.4 explain the ones used here.

3. Fidelity of the library's own definitions. A theorem is only as meaningful as the definitions in its statement. Checking that each Lean definition means what the textbook means is the job of this book's *dictionary* boxes; it cannot be done by the machine.

4. No project axiom. The library declares no axiom of its own; `VOA.pbw` is a theorem (Section 3.10).

5. Explicit hypotheses of named theorems. `#print axioms` does *not* report a theorem's explicit hypotheses: a theorem `bar (h : H) : C` proves only "H implies C", however clean its axiom list. Every status box of the book names these hypotheses. In this chapter and its immediate consumers they are:

- `highestVector H κ hκ b lam ≠ 0` for the general affine Verma module and its simple quotient (Section 3.13); true, but not proved in the library for general λ;
- the hypothesis `hKG` of the integrability wiring lemma, which is its whole content (Section 3.13; a tautology, not a result);
- for Zhu's modularity theorem `zhuModularity_pinned_of_C2Cofinite_voaPBW`: C_2-cofiniteness `hC2` (Chapter 12, Definition 12.22), semisimplicity of Zhu's algebra `hss` (Chapter 12, Section 12.9), the instance `[Finite (Φ W)]` (finitely many irreducible modules, Definition 12.34), and the family data `hcard`, `hcw`, `hsep` (Chapter 15, Theorem 15.34). These are the intended hypotheses of Zhu's theorem, not unproved inputs. The finiteness instance is in fact a consequence of `hC2`, by the theorem `VOA.Huang.ZhuFiniteIrr.finite_Φ_of_C2Cofinite_pbw`;
- for `zhuModularity_stronglyRational_voaPBW`: strong rationality `hSR` (Definition 12.43), an intended hypothesis, and two *literature theorems carried as hypotheses*, `hFin` (Dong–Li–Mason finiteness) and `hZhu` (Zhu's semisimplicity theorem) (Chapter 15, Theorem 15.40). The wrapper's signature still carries them, but both are now discharged elsewhere in the library: `dlmFinitelyManyIrredAdmissible_of_c2Cofinite` proves the first for every C_2-cofinite VOA and `zhuAdmissibleSemisimple_holds` proves the second outright.

These inputs no longer stand between the reader and Zhu's theorem. The library proves Zhu modularity for the canonical family of every C_2-cofinite `AdmissiblyRational` VOA, `zhuModularity_canonical_of_C2Cofinite_admissiblyRational` (Chapter 15, Theorem 15.37), from `hC2` and `hrat : AdmissiblyRational W` alone: semisimplicity of Zhu's algebra is the theorem `isSemisimpleRing_A_of_admissiblyRational` (Theorem 15.38), and `[Finite (Φ W)]` is `finite_Φ_of_C2Cofinite_pbw`. What remains open is only the relation of the library's predicate `AdmissiblyRational` to Dong–Li–Mason rationality as stated in the literature. Results with no hypothesis beyond their data, such as `VOA.pbw`, `pbwBasis_holds` and `zhuBijective_of_voaPBW`, are *unconditional*. (The codomain of `zhuBijective_of_voaPBW` is defined as an image, so only its injectivity has content; the genuine Zhu correspondence is `VOA.zhuCorrespondence_of_C2Cofinite`, under `hC2`, Chapter 13.)

What the machine confirmed for this chapter, and what is reported. *Confirmed here*, at an earlier commit (not re-run for this edition), with `lake env lean -DmaxSynthPendingDepth=3` on scratch files using the existing compiled library: the `#print axioms` reports of Section 3.15 (73 declarations in the displayed record, plus the five cocycle lemmas of Section 3.14 in a separate probe), all exactly `[propext, Classical.choice, Quot.sound]`; the verbatim occurrence of every quoted Lean block in the source; and the output of `scripts/check_repository.py`: 0 axiom declarations, with overall verdict "failed" only because two draft files in `VOA/Huang/` were not imported by the umbrella file. (Re-run on the working tree of 28 October 2026, after the drafts were moved out of `VOA/`, the checker printed "Repository check passed: 10353 library files scanned; ...; 0 sanctioned axiom declaration(s)".) *Not run here:* the aggregate `lake build` and the project's axiom audit. *Reported by the project* (its build record): the aggregate `lake build VOA` was last run green on 26 October 2026 (13868 jobs) with the axiom audit passing. A reader without access to the repository should treat that last item as the project's claim.

3.2 History of the former PBW axiom

Nothing in this section is needed to read the rest of the chapter; it is kept because earlier editions of this book, many library docstrings and other chapters refer to it.

The axiom and its removal. Until 19 October 2026 the library had exactly one project axiom, `axiom pbw : PBWPrinciple`, a statement Lean accepted without proof, with the same name and type as today's theorem. A revision of that date replaced it by the theorem of Section 3.10.6; no use site had to change. In the first edition of this chapter, `#print axioms` of every declaration depending on it listed `pbw` in addition to the three standard axioms (the record is kept at the end of Section 3.15). The commit message of that revision states that the aggregate build was not yet certified at that time.

When the fidelity check was the only safeguard. Until 19 October 2026 the same statement was an axiom, and the fidelity check of Section 3.10 was then the *only* reason to believe the library consistent. The reasoning was: Lean's logic (with `propext`, `Classical.choice`, `Quot.sound`) has a set-theoretic model — ZFC with a sufficient supply of inaccessible cardinals, one for each universe — in which types are sets, Lie algebras are Lie algebras, and Mathlib's universal enveloping algebra, tensor product and quotients are the usual ones; a statement that is true in that model, as Theorems 3.13 and 3.12 show `PBWPrinciple` to be, cannot introduce an inconsistency beyond whatever the base theory has. The Lean proof of Section 3.10.6 has superseded this argument; it is kept here because the earlier editions of this book, and many docstrings of the library, still refer to it.

The axiom-free twin policy. While `pbw` was an axiom, the project kept every result that needed it in two forms, so that `#print axioms` would separate the unconditional from the PBW-dependent.

Each `_voaPBW` wrapper had an *axiom-free twin* that took the PBW consequence as an explicit hypothesis — `Pr : BottomProjection …` or a `PBWFreeness` input — and reported the three standard axioms only; for instance `zhuBijective` (twin of `zhuBijective_of_voaPBW`) and `zhuModularity_pinned_of_C2Cofinite` (twin of the `_voaPBW` version). The same policy introduced the named hypothesis `PBWBasis` (Section 3.12) rather than a second axiom. Since `pbw` became a theorem the distinction is moot: the hypothesis `Pr : BottomProjection (parabolicRepOfAMod W (regularAMod W))` of a twin is supplied, for every `W`, by the definition `voaPBWBottomProjection` built from the now-proved `voaPBWBottomInjective`, and each `_voaPBW` wrapper is exactly its twin with that hypothesis discharged. The twins remain in the library and remain correct; their `Pr` (or `PBWFreeness`, or `h : PBWBasis …`) hypotheses are now *redundant* — always satisfiable by a theorem of the library — and a referee may read each twin together with its `_voaPBW` wrapper as one unconditional-in-PBW result. The project lists dropping such redundant hypotheses as an optional clean-up; it had not been done when this was checked at an earlier commit (not re-checked for this edition).

3.3 The physical picture

3.3.1 Currents and the affine algebra

Consider a two-dimensional quantum field theory with a continuous internal symmetry group G, for instance the Wess–Zumino–Witten (WZW) model, a sigma model whose target is the group manifold G itself. Noether's theorem gives conserved currents J^a_μ, one for each element x_a of a basis of the Lie algebra $\mathfrak{g}$ of G. In a conformal field theory with holomorphic factorisation the holomorphic component $J^a(z)$ is a holomorphic field of conformal weight one, and it has a Laurent expansion

$$J^a(z) = \sum_{n\in\mathbb{Z}} J^a_n \, z^{-n-1}.$$

The modes J^a_n are operators on the space of states. The operator product expansion of two currents in the WZW model at level k is

$$J^a(z)\,J^b(w) \sim \frac{k\,\kappa(x_a,x_b)}{(z-w)^2} + \frac{\sum_c f_{ab}{}^c\, J^c(w)}{z-w}, \tag{3.1}$$

where $[x_a,x_b] = \sum_c f_{ab}{}^c x_c$ and κ is an invariant symmetric bilinear form on $\mathfrak{g}$ (for simple $\mathfrak{g}$ a multiple of the Killing form); the symbol $\sim$ means "equal up to terms regular at $z=w$". Extracting modes by contour integrals, $J^a_m = \oint \frac{dz}{2\pi i} z^m J^a(z)$, turns (3.1) into the commutation relations

$$[J^a_m, J^b_n] = \sum_c f_{ab}{}^c\, J^c_{m+n} + k\,m\,\kappa(x_a,x_b)\,\delta_{m+n,0}. \tag{3.2}$$

The first term is just the Lie bracket of the loop algebra $\mathfrak{g}\otimes\mathbb{C}[t,t^{-1}]$ (where J^a_n corresponds to $x_a\otimes t^n$). The second term is a *Schwinger term*: a c-number that appears because the product of two quantum fields at the same point must be regularised. Abstractly it is a central extension: one adjoins a central element C, writes the bracket as $[x\otimes t^m, y\otimes t^n] = [x,y]\otimes t^{m+n} + m\,\kappa(x,y)\,\delta_{m+n,0}\,C$, and in a representation C acts as the scalar k, the *level*. The resulting Lie algebra is the affine Kac–Moody algebra $\hat{\mathfrak{g}}$. One usually also adjoins the derivation ℓ_0 with $[\ell_0, x\otimes t^n] = n\,(x\otimes t^n)$; on states it measures (minus) the energy contributed by the currents.

3.3.2 The stress tensor and the Virasoro algebra

Every conformal field theory has a stress tensor $T(z) = \sum_n L_n z^{-n-2}$, the conserved current of conformal symmetry, with operator product

$$T(z)T(w) \sim \frac{c/2}{(z-w)^4} + \frac{2T(w)}{(z-w)^2} + \frac{\partial T(w)}{z-w}.$$

In modes this is the Virasoro algebra

$$[L_m, L_n] = (m-n)L_{m+n} + \frac{c}{12}(m^3 - m)\,\delta_{m+n,0}. \tag{3.3}$$

Without the last term, (3.3) is the Lie algebra of infinitesimal conformal transformations of the punctured plane, the Witt algebra, realised by the vector fields $\ell_n = -z^{n+1}\partial_z$. The central term is a quantum anomaly: the classical conformal symmetry is realised projectively on the quantum state space, and the obstruction is measured by the central charge c. That $(m^3 - m)/12$ is the only possible shape of such a term (up to redefinitions $L_0 \mapsto L_0 + \text{const}$) is the statement that the second cohomology of the Witt algebra with trivial coefficients is one-dimensional; the library proves that the given term is a cocycle but not this uniqueness.

3.3.3 Vacuum modules and what PBW says

In both cases the space of states of the "vacuum sector" is built in the same way. There is a vacuum state $|0\rangle$ with the following properties: $J^a_n|0\rangle = 0$ for $n \geq 0$ (regularity of $J^a(z)|0\rangle$ at $z = 0$), and $L_n|0\rangle = 0$ for $n \geq -1$ (regularity of $T(z)|0\rangle$ at $z = 0$, including translation invariance $L_{-1}|0\rangle = 0$). The other states are obtained by applying creation operators,

$$J^{a_1}_{-n_1} \cdots J^{a_r}_{-n_r}|0\rangle \quad (n_i \geq 1), \qquad L_{-n_1} \cdots L_{-n_r}|0\rangle \quad (n_i \geq 2).$$

A physicist counting the states of the vacuum sector assumes, without thinking about it, that these states *with the creation operators in a fixed order* are linearly independent, so that the partition function of the universal vacuum module of $\hat{\mathfrak{g}}$ is $\prod_{n\geq 1}(1-q^n)^{-\dim \mathfrak{g}}$ (up to the conventional prefactor $q^{-c/24}$). The mathematical justification of this counting is the Poincaré–Birkhoff–Witt (PBW) theorem: the universal enveloping algebra of a Lie algebra has a basis of ordered monomials. The commutation relations allow any monomial to be reordered (that is the easy half), and PBW says that reordering is the *only* source of relations — there are no "unexpected" linear dependencies, and in particular the vacuum module is not zero. This last statement, that the construction does not collapse, is exactly what the first field of the library's theorem `VOA.pbw` asserts for affine algebras (it was an axiom until October 2026; it is now proved).

There is an alternative physical route to the same conclusion: if one can write down *some* concrete representation in which the vacuum conditions hold and the vacuum is nonzero (a free field realisation: a free boson for Virasoro, Wakimoto's $\beta\gamma$-plus-boson realisation for $\widehat{\mathfrak{sl}}_2$), then the universal vacuum module maps onto something nonzero and cannot be zero. The library uses this route for the Virasoro algebra (where it is the only proof) and for $\widehat{\mathfrak{sl}}_2$ and $\widehat{\mathfrak{sl}}_3$ (where it was developed, while PBW was still an axiom, to keep those parts of the library independent of it; see Sections 3.6 and 3.11).

3.3.4 Lattices

The third ingredient, lattices, enters through compactified bosons. A free boson on a circle of radius R, or more generally r bosons on a torus $\mathbb{R}^r/2\pi L$, has momentum and winding sectors labelled by points of a lattice; for the chiral (holomorphic) theory one needs an even lattice, and the vertex operators $e^{i\alpha\cdot X}$ of the different sectors are mutually local only after they are multiplied by *cocycle factors* ("Klein factors") $\varepsilon(\alpha,\beta) = \pm 1$. The FLM cocycle of Section 3.14 is the mathematical form of these Klein factors.

3.4 Lie algebras in Lean: what the reader needs

We collect the Mathlib notions that occur in every statement of this chapter. Chapter 1, Section 1.2, explains the general vocabulary (types, structures, typeclasses, `Submodule`, linear maps `→ₗ[ℂ]`); here we add the Lie-theoretic part.

- `[LieRing 𝔤] [LieAlgebra ℂ 𝔤]`: the type `𝔤` carries an additive group with a bracket `⁅x, y⁆` which is biadditive, alternating (`⁅x, x⁆ = 0`) and satisfies the Jacobi identity in the Leibniz form `⁅x, ⁅y, z⁆⁆ = ⁅⁅x, y⁆, z⁆ + ⁅y, ⁅x, z⁆⁆`; and a $\mathbb{C}$-vector-space structure for which the bracket is $\mathbb{C}$-bilinear. So `𝔤` is a complex Lie algebra, of *arbitrary* dimension: no finiteness is implied.

- `L₁ →ₗ⁅ℂ⁆ L₂`: a homomorphism of Lie algebras ($\mathbb{C}$-linear and bracket-preserving).

- `Module.End ℂ V`: the associative algebra $\mathrm{End}_{\mathbb{C}}(V)$ of $\mathbb{C}$-linear maps $V \to V$. Mathlib makes every associative ring a Lie ring with the commutator bracket `⁅A, B⁆ = A * B - B * A` (the lemma `LieRing.of_associative_ring_bracket`). So a Lie homomorphism `ρ : 𝔤 →ₗ⁅ℂ⁆ Module.End ℂ V` is precisely a representation of $\mathfrak{g}$ on V: $\rho([x,y]) = \rho(x)\rho(y) - \rho(y)\rho(x)$.

- `LieSubalgebra ℂ 𝔤`: a Lie subalgebra $\mathfrak{p} \subseteq \mathfrak{g}$; used as a type, `p` denotes the elements of $\mathfrak{p}$ with the restricted bracket, and `(x : 𝔤)` is the inclusion. `LieSubalgebra.lieSpan ℂ _ S` is the Lie subalgebra generated by a set S.

- `UniversalEnvelopingAlgebra ℂ 𝔤`: the universal enveloping algebra $U(\mathfrak{g})$, constructed by Mathlib as the quotient of the tensor algebra $T(\mathfrak{g})$ by the two-sided ideal generated by $x \otimes y - y \otimes x - [x,y]$ (more precisely by the relation $\iota[x,y] + \iota y\, \iota x \sim \iota x\, \iota y$, which is the same thing). The map `ι ℂ : 𝔤 →ₗ⁅ℂ⁆ UniversalEnvelopingAlgebra ℂ 𝔤` is the canonical Lie homomorphism, and `lift` is the universal property: every Lie homomorphism $\mathfrak{g} \to A$ into an associative algebra extends uniquely to an algebra homomorphism $U(\mathfrak{g}) \to A$. *Mathlib proves nothing more about* $U(\mathfrak{g})$: not the PBW theorem, not even that `ι` is injective. (We checked `Mathlib/Algebra/Lie/UniversalEnveloping.lean` at the pinned version; the files `Free.lean` and `SerreConstruction.lean` of the same directory mention PBW only as a missing ingredient.)

- `Submodule R R` for a ring R: a *left ideal* of R (R acting on itself by left multiplication). `Submodule.span R S` is the left ideal $\sum_{s \in S} Rs$ generated by S. The quotient type `R ⧸ I` is the left R-module R/I, and `Submodule.Quotient.mk a` is the class $[a]$.

- `ℤ →₀ 𝔤`: finitely supported functions $\mathbb{Z} \to \mathfrak{g}$ ("Finsupp"). The element `single n x` is the function with value x at n and 0 elsewhere. We read $f \in$ `ℤ →₀ 𝔤` as the Laurent polynomial $\sum_n f(n) \otimes t^n \in \mathfrak{g} \otimes \mathbb{C}[t, t^{-1}]$; this is an isomorphism of vector spaces, because a Laurent polynomial has finitely many nonzero coefficients.

- `Type u`: Lean's types live in a hierarchy of universes `Type 0`, `Type 1`, ...; a statement quantifying over `𝔤 : Type u` speaks about all Lie algebras whose underlying type lives in universe u. Set-theoretically one can think of universes as Grothendieck universes; every classical theorem of algebra holds in each of them.

3.5 The Witt algebra and the Virasoro algebra

All of this section is in `VOA/Foundations/Virasoro.lean`.

3.5.1 The Witt algebra

Definition 3.1 (Witt algebra)**.** The *Witt algebra* $\mathfrak{W}$ is the complex vector space with basis $\{\ell_n\}_{n \in \mathbb{Z}}$ and bracket $[\ell_m, \ell_n] = (m-n)\,\ell_{m+n}$, extended bilinearly. It is realised faithfully on the Laurent polynomials $\mathbb{C}[z, z^{-1}]$ by $\ell_n = -z^{n+1}\frac{d}{dz}$, i.e. $\ell_n \cdot z^k = -k\, z^{k+n}$.

File `VOA/Foundations/Virasoro.lean`.

   ↪ leibniz_lie _ _ _)

theorem gen_bracket (m n : ℤ) : ⁅gen m, gen n⁆ = ((m : ℂ) - n) • gen (m + n) := by
```

From the mathematics to the Lean statement

Decoding. The carrier `Witt` is *literally* `ℤ →₀ ℂ`, finitely supported functions $\mathbb{Z} \to \mathbb{C}$; `gen n = single n 1` is the basis vector ℓ_n, and an element `w` is $\sum_n w(n)\ell_n$. `op n` is the linear map on `ℤ →₀ ℂ` (now read as $\mathbb{C}[z, z^{-1}]$, `single k 1` $= z^k$) sending $z^k \mapsto -k\, z^{k+n}$; this is $-z^{n+1}\, d/dz$. `bracketWith m` sends $\ell_n \mapsto (m-n)\ell_{m+n}$, and `bracketₗ` assembles these into the bilinear bracket; `rep` sends $\ell_n \mapsto$ `op n`.

Why the Lie axioms hold. Instead of proving the Jacobi identity by a direct computation, the file proves (`rep_bracket`) that `rep` turns the bracket into the commutator of operators, and (`rep_injective`) that `rep` is injective; then alternation and Jacobi are transported from the associative algebra $\mathrm{End}(\mathbb{C}[z, z^{-1}])$. The faithfulness proof evaluates `rep x` on $z =$ `single 1 1`: $\ell_n z = -z^{n+1}$, so the coefficients of x are read off (shifted by one and negated).

Conventions. The sign $\ell_n = -z^{n+1}\partial_z$ is the standard one for which $[\ell_m, \ell_n] = (m-n)\ell_{m+n}$; with $+z^{n+1}\partial_z$ the bracket would have the opposite sign. The Lean bracket `gen_bracket` is exactly Definition 3.1.

Could it be vacuous? No: `Witt` is a concrete type, its bracket is computed on basis vectors by `bracketₗ_single`, and `gen_bracket` pins it to the textbook formula. The structure is the Witt algebra, not something weaker.

Physical meaning

The Witt algebra is the Lie algebra of infinitesimal holomorphic coordinate changes $z \mapsto z + \epsilon z^{n+1}$ of the punctured plane: ℓ_{-1} generates translations, ℓ_0 dilatations (and rotations), ℓ_1 special conformal transformations; $\ell_{-1}, \ell_0, \ell_1$ span $\mathfrak{sl}_2$, the global conformal algebra of

the Riemann sphere. It is the classical conformal symmetry algebra of a two-dimensional field theory, before quantisation.

Proof on paper. Write $D_n = -z^{n+1}\partial_z$. Then $[D_m, D_n]z^k = D_m(-kz^{k+n}) - D_n(-kz^{k+m}) = k(k+n)z^{k+m+n} - k(k+m)z^{k+m+n} = (n-m)k\,z^{k+m+n} = (m-n)D_{m+n}z^k$. Hence the linear map $\ell_n \mapsto D_n$ intertwines the bracket with the commutator. It is injective because $D_n z = -z^{n+1}$ and the z^{n+1} are linearly independent. Therefore the bracket on $\mathfrak{W}$ is the pull-back of the commutator bracket along an injective linear map, and inherits bilinearity, alternation and the Jacobi identity. □

What the machine verified

`VOA.Witt.gen_bracket`, `VOA.Witt.rep_injective`: `#print axioms` gives `[propext, Classical.choice, Quot.sound]` (run for this chapter, see Section 3.15). Unconditional.

3.5.2 The Gel'fand–Fuks cocycle and the Virasoro algebra

Definition 3.2 (Virasoro algebra). Let $\psi : \mathfrak{W} \times \mathfrak{W} \to \mathbb{C}$ be the bilinear map with $\psi(\ell_m, \ell_n) = \frac{1}{12}(m^3 - m)\,\delta_{m+n,0}$. It is alternating and satisfies the 2-cocycle identity $\psi(x,[y,z]) = \psi([x,y],z) + \psi(y,[x,z])$. The *Virasoro algebra* $\mathfrak{Vir}$ is the central extension $\mathfrak{W} \oplus \mathbb{C}C$ with bracket $[(x,a),(y,b)] = ([x,y], \psi(x,y))$; writing $L_n = (\ell_n, 0)$ and $C = (0,1)$,

$$[L_m, L_n] = (m-n)L_{m+n} + \frac{m^3 - m}{12}\,\delta_{m+n,0}\,C, \qquad [C, \cdot\,] = 0.$$

A representation of $\mathfrak{Vir}$ on V has *central charge* c if C acts as $c \cdot \mathrm{id}$.

File `VOA/Foundations/Virasoro.lean`.

  ρ : Virasoro →ₗ[ℂ] Module.End ℂ V
  centralCharge : ℂ
  acts_central : ρ C = centralCharge • LinearMap.id
```

From the mathematics to the Lean statement

Decoding. `gfCoeff m n` is $\psi(\ell_m, \ell_n)$. `cocycle₁` is its bilinear extension (defined exactly like `bracket₁`). `twoCochain ℂ Witt ℂ` and `twoCocycle ℂ Witt ℂ` are Mathlib's alternating bilinear maps $\mathfrak{W} \times \mathfrak{W} \to \mathbb{C}$ and, among them, the 2-cocycles for the Chevalley–Eilenberg differential with coefficients in the trivial module $\mathbb{C}$ (the trivial action is installed by the `LieRingModule Witt ℂ` instance with zero bracket). `mem_twoCocycle_iff_of_trivial` says that for trivial coefficients the cocycle condition is $\psi(x,[y,z]) = \psi([x,y],z) + \psi(y,[x,z])$, which is `cocycle_cond`. `LieAlgebra.ofTwoCocycle` is Mathlib's central extension of a Lie algebra by a 2-cocycle; `ofProd` identifies it with the product $\mathfrak{W}\times\mathbb{C}$, so `L n` is $(\ell_n, 0)$ and `C` is $(0,1)$. `virasoro_bracket` is the displayed relation of Definition 3.2, including the normalisation 1/12, and `C_central` (in `VirasoroModule.lean`) says C is central. `VirRep V` bundles a representation ρ with a number `centralCharge` and the proof that $\rho(C) = c \cdot \mathrm{id}$.
Same as the textbook? Yes, with the standard normalisation: the anomaly coefficient $(m^3 - m)/12$ makes L_{-1}, L_0, L_1 span an $\mathfrak{sl}_2$ with no central term (`[L₁, L₋₁] = 2L₀`, one of the file's smoke tests) and gives $[L_2, L_{-2}] = 4L_0 + C/2$ (the other smoke test).
Could it be vacuous or wrong? The scalar identity `gfCoeff_cocycle` is the whole content of the cocycle condition on basis vectors. If $a + b + c \neq 0$ every term vanishes; if $c = -a - b$ it is a polynomial identity in a, b, which the proof checks by `ring`. A wrong coefficient would have been caught: with m^5 in place of $m^3 - m$ the identity at $(a,b) = (1,2)$ reads $5 = -115$, and the definition `gfCocycle` would not have compiled, because it requires a proof of the cocycle condition. (The cocycle condition does *not* pin the normalisation: $\alpha(m^3 - m) + \beta m$ is a cocycle for all α, β, the βm part being a coboundary. The choice $\alpha = 1/12$, $\beta = 0$ is the convention of the physics literature, fixed by `virasoro_bracket`.)

Physical meaning

$\mathfrak{Vir}$ is the algebra of modes of the stress tensor $T(z) = \sum L_n z^{-n-2}$ of any two-dimensional conformal field theory; the central element is the anomaly, and its value c is the central charge (Casimir energy on the cylinder $-c/24$, trace anomaly $\langle T^{\mu}{}_{\mu} \rangle \propto c\,R$ on curved surfaces). The Schwinger term $\frac{c}{12}(m^3 - m)$ is what the $(z-w)^{-4}$ term of the TT operator product expansion becomes in modes. `VirRep` is the statement "this space of states carries the conformal symmetry with central charge c".

Proof on paper of the cocycle identity. On basis vectors $x = \ell_a$, $y = \ell_b$, $z = \ell_c$ the identity reads $(b-c)\psi(\ell_a, \ell_{b+c}) = (a-b)\psi(\ell_{a+b}, \ell_c) + (a-c)\psi(\ell_b, \ell_{a+c})$, using $[\ell_b, \ell_c] = (b-c)\ell_{b+c}$ etc. All three ψ-values vanish unless $a+b+c = 0$. If $c = -a-b$, multiply by 12; the left side is $(a+2b)(a^3-a)$, the right side is $(a-b)((a+b)^3-(a+b)) + (2a+b)(b^3-b)$, and expanding both gives $a^4 + 2a^3b - a^2 - 2ab$ on each side. Alternation is $\psi(\ell_m, \ell_{-m}) = -\psi(\ell_{-m}, \ell_m)$, i.e. $m^3 - m$ is odd in m. □

What the machine verified

`VOA.Witt.cocycle_cond`, `VOA.virasoro_bracket`, `VOA.C_central`: `[propext, Classical.choice, Quot.sound]` (run for this chapter). Unconditional. Not formalised: uniqueness of the central extension, $H^2(\mathfrak{W}; \mathbb{C}) \cong \mathbb{C}$ (the file's docstring records it as a stretch goal).

3.6 The universal Virasoro vacuum module

All declarations are in `VOA/Foundations/VirasoroModule.lean` except the nonvanishing theorem, which is in `VOA/Examples/VirasoroNonvanishing.lean` and is documented in detail in Chapter 7; we

include it here because it shows the free-field pattern that let parts of the library avoid the former PBW axiom, and because the Virasoro algebra is not covered by `VOA.pbw` at all (its vacuum module is not an affine vacuum module).

Definition 3.3 (Universal Virasoro vacuum module)**.** Let $J(c) \subseteq U(\mathfrak{Vir})$ be the left ideal generated by $\{L_n : n \geq -1\} \cup \{C - c\}$. The *universal vacuum module* at central charge c is $V(c,0) = U(\mathfrak{Vir})/J(c)$ with $\mathfrak{Vir}$ acting by left multiplication, and its vacuum vector is $|0\rangle = [1]$.

File `VOA/Foundations/VirasoroModule.lean`.

```

theorem vac_cyclic (c : ℂ) :
    Submodule.span UVir {vacVec c} = ⊤ := by
```

and, from `VOA/Examples/VirasoroNonvanishing.lean`, File `VOA/Examples/VirasoroNonvanishing.lean`.

```
theorem vacVec_ne_zero (c : ℂ) : VirModule.vacVec c ≠ 0 := by
```

From the mathematics to the Lean statement

Decoding. `vacIdeal c` is `Submodule.span` over `UVir` $= U(\mathfrak{Vir})$ of the generators, i.e. the *left* ideal $\sum_{n\geq -1} U(\mathfrak{Vir})L_n + U(\mathfrak{Vir})(C-c)$ (`algebraMap ℂ UVir c` is the scalar $c \cdot 1$). `VirUniv c` is the quotient module. `Algebra.lsmul ℂ ℂ V` is the action of $U(\mathfrak{Vir})$ on V by left multiplication, as an algebra homomorphism into $\mathrm{End}_{\mathbb{C}} V$; composing with `ι` gives the Lie action, so `virVacRho c x [a] = [ι x * a]` (`virVacRho_mk`). `vac_cyclic` says the $U(\mathfrak{Vir})$-submodule generated by $|0\rangle$ is everything (`⊤` is the top submodule).
The three properties are exactly the defining ones: C acts by c on all of $V(c,0)$ (not only on $|0\rangle$ — this uses that C is central, so $[(C-c)a] = [a(C-c)] = 0$), $L_n|0\rangle = 0$ for $n \geq -1$, and $|0\rangle$ generates. The name `VirUniv` ("universal") was chosen after an earlier docstring wrongly called this module $L(c,0)$, which denotes the *simple* quotient; the file records the renaming.
Vacuity. Every statement in the code block before `vacVec_ne_zero` would be true if $V(c,0)$ were the zero module. The content that excludes this is `vacVec_ne_zero`: the vacuum vector is not zero, so $V(c,0) \neq 0$. It is proved for *every* $c \in \mathbb{C}$, by a free-field argument that does not use `VOA.pbw`. (The relative PBW theorem of Section 3.10 would also give it, by inducing from the subalgebra spanned by the L_n, $n \geq -1$, and C; the library does not take that route.)

Physical meaning

$V(c,0)$ is the space of all states one can make from the vacuum with the stress tensor alone: $L_{-n_1}\cdots L_{-n_r}|0\rangle$, $n_i \geq 2$ — the conformal family of the identity operator, before any null states are removed. The condition $L_{-1}|0\rangle = 0$ is translation invariance of the vacuum; $L_0|0\rangle = 0$ says the vacuum has energy zero; $L_n|0\rangle = 0$ for $n \geq 1$ says $T(z)|0\rangle$ is regular at $z = 0$.

Proof on paper of `vacVec_ne_zero`. It suffices to find a representation ρ of $\mathfrak{Vir}$ on a space F with central charge c and a vector $v \neq 0$ in F with $\rho(L_n)v = 0$ for all $n \geq -1$. Indeed, by the universal property ρ extends to an algebra map $\tilde{\rho} : U(\mathfrak{Vir}) \to \mathrm{End}\, F$, and $a \mapsto \tilde{\rho}(a)v$ kills every generator of $J(c)$, hence (being left U-linear) all of $J(c)$; if $1 \in J(c)$ we would get $v = \tilde{\rho}(1)v = 0$. The library takes F to be the Fock space of one free boson with the "linear dilaton" (background charge) stress tensor $L_n^{\lambda} = \frac{1}{2}\sum_m :a_{n-m}a_m: + \lambda(n+1)a_n$, which has central charge $1 - 12\lambda^2$ (the term $\lambda(n+1)a_n$ vanishes on the Fock vacuum for $n = -1$ because of the factor $n+1$, and for $n \geq 0$ because a_n annihilates it); since $\mathbb{C}$ is algebraically closed every c is of this form, and v is the Fock vacuum. (Chapter 7 gives the details.) □

What the machine verified

`VOA.VirModule.vac_acts_central`, `VOA.VirModule.vac_pos_annihilate`, `VOA.VirModule.vac_cyclic`, `VOA.vacVec_ne_zero`, `VOA.vacuumSpace_nontrivial` (the Virasoro version, $V(c,0)$ is nontrivial, in `Examples/VirasoroNonvanishing.lean`; not the affine `AffineLie.vacuumSpace_nontrivial`): `[propext, Classical.choice, Quot.sound]` (run for this chapter). Unconditional; the proof does not use `VOA.pbw`.

3.7 Affine Kac–Moody algebras

All declarations of this section and the next two are in `VOA/Foundations/AffineLie.lean`.

3.7.1 Invariant forms

Definition 3.4 (Invariant form). A bilinear form κ on a Lie algebra $\mathfrak{g}$ is *invariant* (in the sense used here) if it is symmetric, $\kappa(x,y) = \kappa(y,x)$, and ad-invariant, $\kappa([x,y],z) = \kappa(x,[y,z])$.

File `VOA/Foundations/AffineLie.lean`.

```
structure _root_.LinearMap.BilinForm.IsInvariant {𝔤 : Type*} [LieRing 𝔤] [LieAlgebra ℂ 𝔤]
    (κ : LinearMap.BilinForm ℂ 𝔤) : Prop where
  symm : ∀ x y : 𝔤, κ x y = κ y x
  invariant : ∀ x y z : 𝔤, κ ⁅x, y⁆ z = κ x ⁅y, z⁆
```

From the mathematics to the Lean statement

`LinearMap.BilinForm ℂ 𝔤` is the type of $\mathbb{C}$-bilinear forms $\mathfrak{g} \times \mathfrak{g} \to \mathbb{C}$ (curried: `κ x y`). The predicate has two fields, symmetry and ad-invariance, exactly as in Definition 3.4. *Nothing more is required*: κ may be degenerate, even zero, and $\mathfrak{g}$ need not be simple, semisimple or finite-dimensional. This generality matters in Section 3.10, because `PBWPrinciple` quantifies over all such κ; we shall check that it is the intended (and true) statement even for degenerate κ. The file's docstring explains why symmetry is spelled out rather than taken from Mathlib (a sesquilinear notion of symmetry is avoided). Examples: the Killing form $\kappa(x,y) = \mathrm{tr}(\mathrm{ad}x\,\mathrm{ad}y)$ of any finite-dimensional Lie algebra; the trace form $\mathrm{tr}(xy)$ on $\mathfrak{gl}_n$; any symmetric form on an abelian Lie algebra (where ad-invariance is vacuous); the zero form.

Physical meaning

κ is the normalisation of the current–current two-point function, $\langle J^a(z)J^b(w)\rangle = k\kappa(x_a,x_b)/(z-w)^2$; symmetry is Bose symmetry of the two currents, and invariance is the statement that the two-point function is G-invariant. A degenerate κ corresponds to currents with vanishing two-point functions (null currents), which are allowed algebraically though not in a unitary theory.

What the machine verified

A definition; no axioms involved.

3.7.2 The loop algebra and its cocycle

Definition 3.5 (Loop bracket, degree derivation, Kac–Moody cocycle). On $L\mathfrak{g} = \mathfrak{g}\otimes\mathbb{C}[t,t^{-1}]$ define

- the loop bracket $[x\otimes t^m, y\otimes t^n] = [x,y]\otimes t^{m+n}$;
- the degree derivation $D(x\otimes t^n) = n\,x\otimes t^n$, i.e. $D = t\frac{d}{dt}$;
- the cocycle $\omega(x\otimes t^m, y\otimes t^n) = m\,\kappa(x,y)\,\delta_{m+n,0}$.

File `VOA/Foundations/AffineLie.lean`.

theorem cocycle_deriv_skew (κ : LinearMap.BilinForm ℂ 𝔤) (f g : ℤ →₀ 𝔤) :
    cocycle κ (loopDeriv f) g + cocycle κ f (loopDeriv g) = 0 := by
```

From the mathematics to the Lean statement

Decoding. An element f of `ℤ →₀ 𝔤` is the Laurent polynomial $\sum_n f(n) \otimes t^n$; `single m x` is $x \otimes t^m$. `Finsupp.lsum` extends a family of linear maps defined on the summands `single n` to all of `ℤ →₀ 𝔤`; the auxiliary `loopBracketLeft m x` sends $g \mapsto \sum_n [x, g(n)] \otimes t^{m+n}$, and `cocycleLeft κ m x` sends $g \mapsto m\,\kappa(x, g(-m))$. The simp lemmas `loopBracket_single` and `cocycle_single` confirm that on basis elements the definitions are those of Definition 3.5; since all three maps are (bi)linear, this determines them. `loopDeriv` sends `single n x` to `n•single n x`, i.e. $D = t\,d/dt$.
Hypotheses. Only `cocycle_cocycle` needs `hκ`; `cocycle_skew` (alternation of ω, not displayed) also needs it. The derivation compatibility `cocycle_deriv_skew` holds for every bilinear κ: on basis vectors it reads $(m+n)\,m\,\kappa(x,y)\,\delta_{m+n,0} = 0$.

Physical meaning

$L\mathfrak{g}$ is the Lie algebra of the loop group LG of maps $S^1 \to G$, the classical symmetry of a chiral current algebra. ω is the Schwinger term of (3.2): the two-point function of the currents, read in modes: in $[J^a_m, J^b_n] = \oint_w \oint_z z^m w^n J^a(z) J^b(w)$ the double pole $k\kappa(x_a,x_b)/(z-w)^2$ contributes $k\kappa(x_a,x_b) \oint_w \partial_w(w^m)\, w^n = k\,m\,\kappa(x_a,x_b)\,\delta_{m+n,0}$, which is where the factor m comes from.

Proof on paper of the 2-cocycle identity. Take $f = w \otimes t^l$, $g = x \otimes t^m$, $h = y \otimes t^n$. All three terms vanish unless $l+m+n = 0$. Then the left side is $l\,\kappa(w,[x,y])$, and the right side is $(l+m)\kappa([w,x],y) + m\,\kappa(x,[w,y])$. By invariance $\kappa([w,x],y) = \kappa(w,[x,y])$, and by symmetry and invariance $\kappa(x,[w,y]) = \kappa([w,y],x) = \kappa(w,[y,x]) = -\kappa(w,[x,y])$. So the right side is $(l+m-m)\kappa(w,[x,y])$, equal to the left side. □

What the machine verified

All four identities: `[propext, Classical.choice, Quot.sound]` (they are ingredients of `affine_bracket`, whose report is quoted below).

3.7.3 The affine algebra

Definition 3.6 (Affine Kac–Moody algebra). Let $\mathfrak{g}$ be a complex Lie algebra with invariant form κ. The *affine algebra* is $\hat{\mathfrak{g}} = L\mathfrak{g} \oplus \mathbb{C}C \oplus \mathbb{C}\ell_0$ with bracket

$$[(f,a,p),(g,b,q)] = \big([f,g] + p\,Dg - q\,Df,\ \omega(f,g),\ 0\big). \tag{3.4}$$

In particular

$$[x \otimes t^m, y \otimes t^n] = [x,y] \otimes t^{m+n} + m\,\kappa(x,y)\,\delta_{m+n,0}\,C, \qquad [C,\cdot\,] = 0, \qquad [\ell_0, x \otimes t^n] = n\,x \otimes t^n.$$

A representation of $\hat{\mathfrak{g}}$ has *level* k if C acts as $k \cdot \mathrm{id}$.

From the mathematics to the Lean statement

Decoding the carrier. `AffineLie 𝔤 κ hκ` is a one-field wrapper around the product `(ℤ →₀ 𝔤) × ℂ × ℂ`: a triple (f, a, p) stands for $f + aC + p\ell_0$. The wrapper exists so that the Lie structure, which depends on κ, is attached to a type that remembers κ; `ofProd` is the identification, and the vector space structure is transported along it. The argument `hκ` is a proof, and in Lean any two proofs of the same proposition are equal, so the type does not depend on *which* proof of invariance is supplied.

Decoding the bracket. In `bracketP`, `a.1` is the loop part, `a.2.1` the C-coefficient (it never enters: C is central) and `a.2.2` the ℓ_0-coefficient. So `bracketP` is formula (3.4) letter for letter. The result has ℓ_0-component 0: ℓ_0 is never produced by a bracket, as in the textbook. The `LieRing` instance (of which the first three fields are displayed; the fourth, `leibniz_lie`, is the Jacobi identity, proved from `bracketP_leibniz`) shows that $\hat{\mathfrak{g}}$ *is* a Lie algebra: this is not assumed. The proof of `bracketP_leibniz` uses the four identities of the previous subsection and `hκ`; without symmetry and invariance of κ the Jacobi identity would fail and the instance could not have been written.

The defining relations as theorems. `ofLoop κ hκ x m` is $x \otimes t^m$, `C κ hκ` is C, `ell0 κ hκ` is ℓ_0. `affine_bracket` is the displayed relation of Definition 3.6 (the Lean `if m + n = 0 then … else 0` is $\delta_{m+n,0}$), `C_lie` says C is central, `ell0_lie_ofLoop` gives $[\ell_0, x \otimes t^n] = n\,x \otimes t^n$.

The sign of ℓ_0. The code implements $\ell_0 = +t\frac{d}{dt}$, as `ell0_lie_ofLoop` certifies: $[t\frac{d}{dt}, x\otimes t^n] = n\,x \otimes t^n$. The physically natural energy operator is $-\ell_0$: on the vacuum module the creation operator $x \otimes t^{-n}$ raises $-\ell_0$ by n (Section 3.9).

`AffineRep`. A representation of level k: a Lie homomorphism ρ to $\mathrm{End}_{\mathbb{C}}\, V$, a number `level`, and the proof that $\rho(C) = k \cdot \mathrm{id}$.

Same as the textbook? Yes. Kac's book defines $\hat{\mathfrak{g}}$ for simple $\mathfrak{g}$ with the normalised invariant form; the library's definition is the general one (any $\mathfrak{g}$, any invariant κ), which specialises to

Kac's. For $\mathfrak{g}$ abelian of dimension r and κ an inner product it is the rank-r Heisenberg algebra (extended by ℓ_0).

Physical meaning

$\hat{\mathfrak{g}}$ is the algebra of the modes J^a_n of the conserved currents of a WZW model or of any CFT with a continuous symmetry (current algebra); C is the level k, which in the WZW model is the integer coefficient of the Wess–Zumino term; ℓ_0 is (minus) the part of the Hamiltonian that counts the mode number. The cocycle is the Schwinger term, i.e. the chiral anomaly of the currents.

Proof on paper of the Jacobi identity. Write $X = (f, a, p)$ etc. The ℓ_0-component of any bracket is 0, so in a double bracket $[X,[Y,Z]]$ the inner bracket has no ℓ_0-part. The loop component of $[X,[Y,Z]] - [[X,Y],Z] - [Y,[X,Z]]$ is a combination of: the Jacobi identity of the loop bracket (which follows from that of $\mathfrak{g}$, termwise), terms $p(D[g,h] - [Dg,h] - [g,Dh])$ and its analogues, which vanish because D is a derivation (on basis vectors: $(m+n) = m+n$), and terms with two D's which cancel by skew-symmetry. The C-component is $\omega(f,[g,h] + qDh - rDg) - \omega([f,g] + pDg - qDf, h) - \omega(g,[f,h] + pDh - rDf)$; the terms without D cancel by the 2-cocycle identity, and the terms with D cancel in pairs by $\omega(Du,v) + \omega(u,Dv) = 0$ and skew-symmetry of ω. □

What the machine verified

`VOA.AffineLie.affine_bracket`, `VOA.AffineLie.C_lie`, `VOA.AffineLie.ell0_lie_ofLoop`: `[propext, Classical.choice, Quot.sound]` (run for this chapter). Unconditional; the Lie algebra structure is proved, not assumed.

3.7.4 The triangular pieces

File `VOA/Foundations/AffineLie.lean`.

```
noncomputable def posPart : LieSubalgebra ℂ (AffineLie 𝔤 κ hκ) :=
  LieSubalgebra.lieSpan ℂ _ {X | ∃ (x : 𝔤) (n : ℤ), 0 < n ∧ X = ofLoop κ hκ x n}

noncomputable def negPart : LieSubalgebra ℂ (AffineLie 𝔤 κ hκ) :=
  LieSubalgebra.lieSpan ℂ _ {X | ∃ (x : 𝔤) (n : ℤ), n < 0 ∧ X = ofLoop κ hκ x n}

noncomputable def parabolic : LieSubalgebra ℂ (AffineLie 𝔤 κ hκ) :=

    ({X | ∃ (x : 𝔤) (n : ℤ), 0 ≤ n ∧ X = ofLoop κ hκ x n} ∪ {C κ hκ, ell0 κ hκ})
```

From the mathematics to the Lean statement

These are the Lie subalgebras *generated* by the indicated elements: $\mathfrak{n}_+$ by the $x \otimes t^n$ with $n > 0$, $\mathfrak{n}_-$ by those with $n < 0$, and the parabolic $\hat{\mathfrak{p}}$ by the $x \otimes t^n$ with $n \geq 0$ together with C and ℓ_0. Since the loop bracket adds degrees and the cocycle is supported on $m + n = 0$, the generated subalgebras are the expected subspaces: $\mathfrak{n}_\pm = \mathfrak{g} \otimes t^{\pm 1}\mathbb{C}[t^{\pm 1}]$ (for m, n of the same strict sign, $m + n \neq 0$, so no C appears) and $\hat{\mathfrak{p}} = \mathfrak{g}[t] \oplus \mathbb{C}C \oplus \mathbb{C}\ell_0$ (for $m, n \geq 0$, $m + n = 0$ forces $m = 0$, and the cocycle carries the factor m). The library does not prove these equalities of subspaces; they are not needed, because the vacuum module below is defined directly by generators.

Physical meaning

$\mathfrak{n}_-$ consists of the creation operators J^a_{-n}, $n \geq 1$; $\hat{\mathfrak{p}}$ of the operators that annihilate the vacuum or act on it by scalars (zero modes J^a_0, the level, the energy).

What the machine verified

Definitions; no axioms involved.

3.8 The affine vacuum module

Definition 3.7 (Affine vacuum module). Let $U(\hat{\mathfrak{g}})$ be the universal enveloping algebra and $J(k) \subseteq U(\hat{\mathfrak{g}})$ the left ideal generated by

$$\{x \otimes t^n : x \in \mathfrak{g},\ n \geq 0\} \cup \{C - k\} \cup \{\ell_0\}.$$

The *level-k vacuum module* is $\mathcal{V}(\mathfrak{g}, k) = U(\hat{\mathfrak{g}})/J(k)$ (often written $V^k(\mathfrak{g})$), with $\hat{\mathfrak{g}}$ acting by left multiplication; its vacuum vector is $|0\rangle = [1]$.

theorem vacuum_cyclic (k : ℂ) :
    Submodule.span (UEnv 𝔤 κ hκ) {vacuumVector κ hκ k} = ⊤ := by
```

From the mathematics to the Lean statement

Decoding. `UEnv 𝔤 κ hκ` is $U(\hat{\mathfrak{g}})$. `vacuumGens κ hκ k` is the set of three kinds of elements of Definition 3.7: `ι ℂ (ofLoop κ hκ x n)` for $n \geq 0$ (note `0 ≤ n`: the zero modes $x \otimes t^0$ are included), $\iota(C) - k \cdot 1$, and $\iota(\ell_0)$. `vacuumIdeal` is the *left* ideal they generate (`Submodule.span` over $U(\hat{\mathfrak{g}})$ acting on itself by left multiplication), `vacuumSpace` the quotient module, `vacuumRho` the action by left multiplication, `vacuumVector` the class of 1. The theorems say: C acts by k on the whole module; the modes $x \otimes t^n$, $n \geq 0$, and ℓ_0 kill $|0\rangle$; and $|0\rangle$ generates.
This is the standard induced module. In textbooks $V^k(\mathfrak{g})$ is defined as $U(\hat{\mathfrak{g}}) \otimes_{U(\hat{\mathfrak{p}})} \mathbb{C}_k$, where $\mathbb{C}_k$ is the one-dimensional $\hat{\mathfrak{p}}$-module on which $\mathfrak{g}[t]$ and ℓ_0 act by 0 and C by k. The quotient $U(\hat{\mathfrak{g}})/J(k)$ is the same module: in general, for a Lie subalgebra $\mathfrak{p}$ and a character $\chi : \mathfrak{p} \to \mathbb{C}$, one has $U(\mathfrak{g}) \otimes_{U(\mathfrak{p})} \mathbb{C}_\chi \cong U(\mathfrak{g})/U(\mathfrak{g})\{a - \chi(a) : a \in \mathfrak{p}\}$, and the generators of $J(k)$ are exactly the elements $a - \chi(a)$ for a running over the spanning set $\{x \otimes t^n\}_{n \geq 0} \cup \{C, \ell_0\}$ of $\hat{\mathfrak{p}}$ (with $\chi(x \otimes t^n) = 0$, $\chi(C) = k$, $\chi(\ell_0) = 0$). Section 3.10 uses this identification.
Some texts omit ℓ_0 and induce from $\mathfrak{g}[t] \oplus \mathbb{C}C$ in the algebra without derivation; the resulting space is the same, and including ℓ_0 with eigenvalue 0 on $|0\rangle$ is harmless (and it is what makes the energy operator available inside the module). (Chapters 1 and 43 describe the ideal as "generated by $\mathfrak{g}[t]$ and $C - k$"; the precise Lean generating set also contains ℓ_0.)
Vacuity. As for Virasoro, every theorem in this block would hold for the zero module. Whether $|0\rangle \neq 0$ is *the* question; it is the first field of `PBWPrinciple` (Section 3.10).

Physical meaning

$V^k(\mathfrak{g})$ is the space of states $J^{a_1}_{-n_1} \cdots J^{a_r}_{-n_r}|0\rangle$ of the vacuum sector of the current algebra at level k — the WZW vacuum module before null vectors are removed (for $k \in \mathbb{N}$ and $\mathfrak{g}$ simple, the WZW model's actual vacuum module is the simple quotient $L_k(\mathfrak{g})$). The vacuum conditions $J^a_n|0\rangle = 0$, $n \geq 0$, say that $J^a(z)|0\rangle$ is regular at $z = 0$ and that the vacuum is G-invariant ($J^a_0|0\rangle = 0$).

Proof on paper of `vacuum_acts_central`. For $a \in U(\hat{\mathfrak{g}})$, $C[a] - k[a] = [(C - k)a] = [a(C - k)]$ because C is central in $\hat{\mathfrak{g}}$, hence $\iota(C)$ is central in $U(\hat{\mathfrak{g}})$ (`commute_ι_C`); and $a(C - k) \in J(k)$ since $J(k)$ is a left ideal containing $C - k$. The other three statements are immediate from the definitions: $x \otimes t^n \cdot [1] = [x \otimes t^n]$ and $x \otimes t^n \in J(k)$; and $[a] = a \cdot [1]$. □

What the machine verified

`VOA.AffineLie.vacuum_acts_central`, `VOA.AffineLie.vacuum_pos_annihilate`, `VOA.AffineLie.vacuum_cyclic`: `[propext, Classical.choice, Quot.sound]` (run for this chapter). Unconditional, and `VOA.pbw`-free.

3.9 Spanning and the energy grading

Theorem 3.8 (Spanning; the easy half of PBW). *$V^k(\mathfrak{g})$ is spanned by the creation monomials*

$$(x_1 \otimes t^{-n_1-1})(x_2 \otimes t^{-n_2-1}) \cdots (x_r \otimes t^{-n_r-1})|0\rangle, \qquad r \geq 0,\ x_i \in \mathfrak{g},\ n_i \in \mathbb{N}.$$

Each such monomial is an ℓ_0-eigenvector with eigenvalue $-\sum_i (n_i + 1)$. Consequently $V^k(\mathfrak{g})$ is the direct sum of its ℓ_0-eigenspaces; the only eigenvalues that occur are $-d$, $d \in \mathbb{N}$; the eigenvalue-0 space is $\mathbb{C}|0\rangle$; and if $\mathfrak{g}$ is finite-dimensional, every eigenspace is finite-dimensional.

```

From the mathematics to the Lean statement

Decoding the index convention. A word is a list of pairs (x, n) with $n \in \mathbb{N}$, and the pair (x, n) stands for the mode $x \otimes t^{-n-1}$: *depth* n means mode $-n-1$. The first element of the list is the *leftmost* operator. `wordDeg` is the energy $\sum(n_i + 1)$. `negSpan` is the $\mathbb{C}$-span of all words — *all* words, in any order and with repetitions, not only ordered ones.

Decoding the conclusions. `Module.End.eigenspace T μ` is $\ker(T - \mu)$. `DirectSum.IsInternal (fun μ ⇒ E μ)` says the canonical map $\bigoplus_\mu E_\mu \to V$ is bijective, i.e. $V = \bigoplus_\mu E_\mu$. $\bot$ is the zero subspace. The four grading theorems are the four sentences after "Consequently" in Theorem 3.8; only the last needs `[FiniteDimensional ℂ 𝔤]`.

Sign. ℓ_0 has eigenvalue $-$(energy), because $\ell_0 = t\,d/dt$ and creation operators have negative mode. The library's affine VOA (Chapter 9) uses the grading by $-\ell_0$. Its carrier for $\mathfrak{sl}_2$ is exactly this universal vacuum module, under the Lean name `AffineVOA.WakModule` (an abbreviation for `vacuumSpace` in `VOA/Examples/AffineSl2.lean`); despite the name it is the vacuum module $V^k(\mathfrak{sl}_2)$, *not* a Wakimoto free-field module (release audit 2026-10-27, finding m-6). The VOA built on it is of CFT type (Chapter 4): $\deg 0$ is $\mathbb{C}|0\rangle$ and there are no negative degrees, as this section shows for the energy grading.

What is *not* claimed. Linear independence of anything. In particular `eigenspace_zero_eq` says the degree-0 piece is *spanned* by $|0\rangle$; it is one-dimensional only if $|0\rangle \neq 0$, which these theorems do not show (the module docstring says so explicitly). This is why nothing in this section needs `VOA.pbw`; when the PBW principle was an axiom, this was what kept the energy grading free of it.

Physical meaning

The energy grading is the L_0-grading of the current algebra's vacuum sector (for the Sugawara stress tensor L_0 agrees with $-\ell_0$ on $V^k(\mathfrak{g})$ at noncritical level). Finite-dimensionality of the graded pieces is what makes the partition function tr q^{L_0} a formal power series with finite coefficients; boundedness below says there is a ground state.

Proof on paper. Spanning. Let S be the span of all creation monomials. It contains $|0\rangle$. It is stable under every $x \otimes t^n$: by induction on the length of the word, write $(x \otimes t^n)(y \otimes t^{-m-1})w = (y \otimes t^{-m-1})(x \otimes t^n)w + [x \otimes t^n, y \otimes t^{-m-1}]w$; the first term is in S by induction and because S is closed under prepending creation operators, the second is $([x,y] \otimes t^{n-m-1})w + \delta \cdot n\,\kappa(x,y)\,k\,w$, in S by induction. At length 0: $x \otimes t^n|0\rangle$ is 0 if $n \geq 0$ and a monomial if $n < 0$. It is stable under C (scalar k) and ℓ_0 (next paragraph). Since these generate $\hat{\mathfrak{g}}$ as a vector space, S is a $U(\hat{\mathfrak{g}})$-submodule containing the cyclic vector, so $S = V^k(\mathfrak{g})$.

Eigenvalues. $\ell_0(x \otimes t^{-n-1})w = (x \otimes t^{-n-1})\ell_0 w - (n+1)(x \otimes t^{-n-1})w$; induction on length gives eigenvalue $-\sum(n_i + 1)$.

Grading. Eigenvectors with distinct eigenvalues are independent (always), and they span by the previous two points; hence the direct sum. An eigenvector with eigenvalue μ is, by independence, a combination of monomials of energy $-\mu$ only; so the μ-eigenspace is the span of the monomials of energy $-\mu$ (`eigenspace_eq_degSpan`). This span is 0 if $-\mu \notin \mathbb{N}$, and is $\mathbb{C}|0\rangle$ if $\mu = 0$ (only the empty word has energy 0). For finite-dimensional $\mathfrak{g}$, the energy-d span is contained in $\mathbb{C}|0\rangle + \sum_{n<d}(\mathfrak{g} \otimes t^{-n-1}) \cdot$ (energy $d-n-1$ span), a finite sum of images of bilinear maps on finite-dimensional spaces; strong induction on d gives finite dimension. □

What the machine verified

`VOA.AffineLie.negSpan_eq_top`, `VOA.AffineLie.ell0_isInternal`, `VOA.AffineLie.eigenspace_eq_bot_of_not_energy`, `VOA.AffineLie.eigenspace_zero_eq`, `VOA.AffineLie.eigenspace_finiteDimensional`: `[propext, Classical.choice, Quot.sound]` (run for this chapter). 3.10 The PBW principle `VOA.pbw`: statement and proof

3.10.1 The classical theorem

Theorem 3.9 (Poincaré–Birkhoff–Witt). *Let $\mathfrak{g}$ be a Lie algebra over a field F (of any dimension), and let $(e_i)_{i \in I}$ be a basis of $\mathfrak{g}$ indexed by a totally ordered set I. Then the ordered monomials*

$$\iota(e_{i_1})\iota(e_{i_2}) \cdots \iota(e_{i_r}), \qquad r \geq 0, \quad i_1 \leq i_2 \leq \ldots \leq i_r,$$

form a basis of $U(\mathfrak{g})$ (the empty monomial being 1). Equivalently, the associated graded algebra of $U(\mathfrak{g})$ for its natural filtration is the symmetric algebra $S(\mathfrak{g})$.

Physical meaning

In a quantum theory whose operators are generated by modes X_i with commutation relations $[X_i, X_j] = \sum f_{ij}{}^k X_k$, PBW says that every operator product can be normal-ordered in a fixed order, uniquely: the normal-ordered monomials are a basis. The passage $U(\mathfrak{g}) \rightsquigarrow S(\mathfrak{g})$ (associated graded) is the classical limit, in which operators commute and become functions on $\mathfrak{g}^*$.

Every Lie algebra over a field has a basis (Zorn's lemma), and every index set can be totally ordered (by the well-ordering theorem), so the theorem applies to every Lie algebra. Two consequences are what the library needs.

Corollary 3.10. *Let $\mathfrak{p} \subseteq \mathfrak{g}$ be a Lie subalgebra.*

1. *The algebra map $U(\mathfrak{p}) \to U(\mathfrak{g})$ induced by the inclusion is injective; identify $U(\mathfrak{p})$ with its image.*

2. *Choose a basis $(e_i)_{i\in I_1}$ of a vector-space complement of $\mathfrak{p}$ and a basis $(e_i)_{i\in I_2}$ of $\mathfrak{p}$, and order $I = I_1 \sqcup I_2$ so that $I_1 < I_2$. Then $U(\mathfrak{g})$ is a free right $U(\mathfrak{p})$-module with basis the ordered monomials in the e_i, $i \in I_1$:*

$$U(\mathfrak{g}) = \bigoplus_m m \cdot U(\mathfrak{p}), \qquad m = \iota(e_{i_1}) \cdots \iota(e_{i_r}),\ i_1 \le \ldots \le i_r \in I_1.$$

3. *If moreover the complement $\mathfrak{n}$ is itself a Lie subalgebra, multiplication $U(\mathfrak{n}) \otimes U(\mathfrak{p}) \to U(\mathfrak{g})$ is a linear isomorphism.*

Proof on paper. Apply Theorem 3.9 to $\mathfrak{g}$ with the ordered basis of (2): each ordered monomial factors uniquely as (ordered monomial in I_1)·(ordered monomial in I_2), and the ordered monomials in I_2 are, by PBW for $\mathfrak{p}$, a basis of $U(\mathfrak{p})$ which maps to linearly independent elements of $U(\mathfrak{g})$; this gives (1) and (2). For (3), the ordered monomials in I_1 are a basis of $U(\mathfrak{n})$ by PBW for $\mathfrak{n}$, so (2) says exactly that multiplication is bijective. □

Sketch of the proof of Theorem 3.9. The spanning half is elementary: in $U(\mathfrak{g})$, $\iota(e_j)\iota(e_i) = \iota(e_i)\iota(e_j) + \iota([e_j, e_i])$, so any monomial can be rewritten, by induction on length and on the number of inversions, as a combination of ordered monomials of the same or smaller length. The hard half is independence. The classical proof (Humphreys §17.4, Dixmier 2.1.11) constructs a representation of $\mathfrak{g}$ on the polynomial algebra $F[z_i : i \in I]$ such that $e_i \cdot z_{i_1} \cdots z_{i_r} = z_i z_{i_1} \cdots z_{i_r}$ whenever $i \le i_1 \le \ldots \le i_r$, by induction on the degree; the compatibility with the bracket is the only computation, and uses the Jacobi identity. By the universal property this representation extends to $U(\mathfrak{g})$, and applying an ordered monomial to 1 gives the corresponding monomial $z_{i_1} \cdots z_{i_r}$; distinct ordered monomials thus have linearly independent images, so they are independent. An alternative proof uses Bergman's diamond lemma: the rewriting rules $e_j e_i \to e_i e_j + [e_j, e_i]$ $(j > i)$ have only resolvable ambiguities, precisely by the Jacobi identity. No finiteness of $\dim \mathfrak{g}$ is used in either proof. □

Physical meaning

PBW is the statement that the Fock-type module obtained by acting with creation operators on a vacuum has the "obvious" basis of normal-ordered monomials, i.e. that the canonical commutation relations generate *all* the relations among products of generators, and there are no hidden ones. For a free boson this is the familiar fact that $a_{-n_1} \cdots a_{-n_r}|0\rangle$ with $n_1 \ge \ldots \ge n_r \ge 1$ are independent; for a current algebra it is the corresponding statement for J^a_{-n}, which is what makes the character of the universal vacuum module $\prod_n (1-q^n)^{-\dim \mathfrak{g}}$.

3.10.2 Induced modules and the bottom map

Notation. In this section $U(\cdot)$, always written with its argument in parentheses, is the universal enveloping algebra; a plain U is the vector space of a representation ρ of a Lie subalgebra. (The Lean files use the same letters, which is why we keep them.) Later in the chapter M denotes the space of Theorem 3.15 and N a maximal submodule; C is the central element of $\hat{\mathfrak{g}}$, $\mathfrak{c}$ a complement of $\mathfrak{p}$; Mathlib's canonical map $\mathfrak{g} \to U(\mathfrak{g})$ is ι, while ι in Section 3.12 is an index type; and the Witt generator $\ell_0 = -z\,d/dz$ of Section 3.5 is a different object from the affine derivation $\ell_0 = +t\,d/dt$.

The induced module. Let $\mathfrak{p} \subseteq \mathfrak{g}$ be a Lie subalgebra and ρ a representation of $\mathfrak{p}$ on U. The *induced module* is

$$\mathrm{Ind}_{\mathfrak{p}}^{\mathfrak{g}} U = U(\mathfrak{g}) \otimes_{U(\mathfrak{p})} U,$$

with $\mathfrak{g}$ acting by left multiplication on the first factor. It is the "freest" $\mathfrak{g}$-module generated by a copy of U on which $\mathfrak{p}$ acts through ρ: every $\mathfrak{p}$-equivariant map from U to a $\mathfrak{g}$-module extends uniquely to a $\mathfrak{g}$-map out of it. The *bottom map* is $u \mapsto 1 \otimes u$; its image is the "bottom" layer, the copy of U from which the rest of the module is generated (in the vertex-algebra application, the lowest-weight space of a generalised Verma module; in the affine vacuum module, the line $\mathbb{C}|0\rangle$).

Why injectivity is not automatic. The tensor product over the noncommutative ring $U(\mathfrak{p})$ imposes the relations $y\,\iota(x) \otimes u = y \otimes \rho(x)u$, and these could in principle identify distinct vectors of U or kill them. Item 1 of the warning in Section 3.10 shows that this really happens if ρ is only linear and not a representation. That the bottom map is injective for every representation is a consequence of PBW (Theorem 3.12); the nonvanishing of the affine vacuum is the special case $U = \mathbb{C}$ (Remark 3.14).

Which proof the library contains. This section gives two proofs of the two fields of `PBWPrinciple`. The classical one (Theorems 3.13 and 3.12, via the full PBW basis of Corollary 3.10) is a paper argument, used here only to confirm that the Lean statement is true and means what it should. The proof *formalised* in the library is the relative one of Section 3.10.6.

3.10.3 The Lean statement

The library states the two consequences it needs. First, induction from a Lie subalgebra, in a namespace `PBWInduction`:

File `VOA/Foundations/AffineLie.lean`.

```
universe u

namespace PBWInduction

variable {g U : Type u} [LieRing g] [LieAlgebra ℂ g]
variable [AddCommGroup U] [Module ℂ U]

abbrev Cover (g U : Type u) [LieRing g] [LieAlgebra ℂ g]
    [AddCommGroup U] [Module ℂ U] :=
  UniversalEnvelopingAlgebra ℂ g ⊗[ℂ] U

def balancingSet (p : LieSubalgebra ℂ g) (rho : p →ₗ[ℂ] Module.End ℂ U) :
    Set (Cover g U) :=
  {t | ∃ (y : UniversalEnvelopingAlgebra ℂ g) (x : p) (u : U),
    t = (y * UniversalEnvelopingAlgebra.ι ℂ (x : g)) ⊗ₜ[ℂ] u - y ⊗ₜ[ℂ] (rho x u)}

noncomputable def balancing (p : LieSubalgebra ℂ g)
    (rho : p →ₗ[ℂ] Module.End ℂ U) : Submodule ℂ (Cover g U) :=
  Submodule.span ℂ (balancingSet p rho)

abbrev Induced (p : LieSubalgebra ℂ g) (rho : p →ₗ[ℂ] Module.End ℂ U) : Type u :=
  Cover g U ⧸ balancing p rho

noncomputable def bottom (p : LieSubalgebra ℂ g)

    fun p rho => PBWTheorem.bottom_injective p rho⟩
```

From the mathematics to the Lean statement

Line-by-line decoding of `PBWInduction`.

- `Cover g U` is the $\mathbb{C}$-vector space $U(\mathfrak{g}) \otimes_{\mathbb{C}} U$ (`⊗[ℂ]` is Mathlib's tensor product of $\mathbb{C}$-modules; $U(\mathfrak{g})$ is a $\mathbb{C}$-module through its $\mathbb{C}$-algebra structure).
- `balancingSet p rho` is the set of all elements $y\,\iota(x) \otimes u - y \otimes \rho(x)u$ with $y \in U(\mathfrak{g})$, $x \in \mathfrak{p}$, $u \in U$. Here `(x : g)` is x viewed in $\mathfrak{g}$, `UniversalEnvelopingAlgebra.ι ℂ (x : g)` is its image in $U(\mathfrak{g})$, `y * ι x` is the product in $U(\mathfrak{g})$ with $\iota(x)$ on the *right*, and `a ⊗ₜ[ℂ] u` is the pure tensor $a \otimes u$.
- `balancing p rho` is the $\mathbb{C}$-linear span of that set (not a $U(\mathfrak{g})$-submodule; but it is automatically stable under left multiplication by $U(\mathfrak{g})$, since the set is: multiply y on the left).
- `Induced p rho` is the quotient vector space $(U(\mathfrak{g}) \otimes U)$/balancing; by Proposition 3.11 below it is $U(\mathfrak{g}) \otimes_{U(\mathfrak{p})} U$, the induced module $\mathrm{Ind}_{\mathfrak{p}}^{\mathfrak{g}} U$.
- `bottom p rho` is the composite $U \to U(\mathfrak{g}) \otimes U \to$ Induced, $u \mapsto 1 \otimes u \mapsto [1 \otimes u]$ (`TensorProduct.mk ℂ A U 1` is $u \mapsto 1 \otimes u$, `mkQ` the quotient map).

Decoding `PBW` and `PBWPrinciple`. `PBW κ hκ k` is the proposition $|0\rangle \neq 0$ in $V^k(\mathfrak{g}) = U(\hat{\mathfrak{g}})/J(k)$ of Definition 3.7. `PBWPrinciple` is a structure in `Prop` — a conjunction of two propositions with named components:

(A) `affineVacuum`: *for every complex Lie algebra $\mathfrak{g}$ (in universe u), every symmetric invariant bilinear form κ on it, and every $k \in \mathbb{C}$, the vacuum vector of $V^k(\mathfrak{g})$ is nonzero.*

(B) `inducedBottom`: *for every complex Lie algebra $\mathfrak{g}$, every complex vector space U (both in universe u), every Lie subalgebra $\mathfrak{p} \subseteq \mathfrak{g}$ and every representation ρ of $\mathfrak{p}$ on U, the map $U \to U(\mathfrak{g}) \otimes_{U(\mathfrak{p})} U$, $u \mapsto [1 \otimes u]$, is injective.*

The braces `∀ {𝔤 : Type u}` make $\mathfrak{g}$ an implicit argument (inferred from κ); the square brackets are typeclass arguments (the Lie structure). `theorem pbw : PBWPrinciple` proves that this

conjunction holds. Because the declaration mentions the universe variable `u`, it is *universe-polymorphic*: it is in effect one theorem `pbw.{u}` for each universe level, and a use site instantiates the level it needs (`voaPBWBottomInjective` writes `(VOA.pbw : VOA.PBWPrinciple.{u})`).
Decoding the proof term. The anonymous constructor `⟨…, …⟩` builds the structure from its two fields, in order. The first field is supplied by `AffineLie.vacuumVector_ne_zero_of_induction` (Theorem 3.18 below) and the second by `PBWTheorem.bottom_injective` (Theorem 3.17 below). The second is stated in the library for the copies `PBWTheorem.balancing` and `PBWTheorem.bottom` of the definitions above, over an arbitrary field `K`; at `K = ℂ` and with $\mathfrak{g}$, U in the same universe they unfold to `PBWInduction.balancing` and `PBWInduction.bottom` symbol for symbol, which is why the term `fun p rho ⇒ PBWTheorem.bottom_injective p rho` is accepted at the type of the field `inducedBottom` without any conversion lemma.
Why two fields in one structure (history). While `pbw` was an axiom (until 19 October 2026), bundling both consequences into one structure gave the library a single named axiom with a single universe parameter; the structure was kept unchanged when the axiom became a theorem, so that none of its use sites had to be edited. The type `PBWPrinciple` is exactly the type the axiom had; only the keyword and the proof changed.

Physical meaning

`PBWPrinciple` packages the two places where a conformal field theorist silently uses the Poincaré–Birkhoff–Witt theorem: that the vacuum sector of a current algebra, built by acting with the creation currents J^a_{-n} on a vacuum annihilated by the $J^a_{n\geq 0}$, is not the zero space; and that when one builds a module of the mode algebra of a vertex operator algebra by acting freely on a space of lowest-weight states (a generalised Verma module), those lowest-weight states survive undamaged.

3.10.4 The fidelity check: is `PBWPrinciple` the intended statement?

Now that `pbw` is a theorem, Lean itself guarantees that `PBWPrinciple` is *true* (relative to Lean's logic and its three standard axioms). What Lean cannot guarantee is that the Lean statement *means* what its name says. The danger is entirely in the *encoding*: a Lean definition that does not mean what it looks like could make `PBWPrinciple` a true but weaker, or even vacuous, statement, and then the consumers of `pbw` (Section 3.11) would be proving less than they claim. We therefore identify, on paper, each field with the classical PBW consequence it is meant to be: the following three results do this, and the list of traps after them explains which slips in the encoding would have made the statement false (and the Lean proof impossible) or would have emptied it of content.

(Before October 2026 this check was the only safeguard against an inconsistent library; Section 3.2 explains why.)

Proposition 3.11 (The Lean induced module is the induced module). *Let $\mathfrak{p} \subseteq \mathfrak{g}$ be a Lie subalgebra, ρ a representation of $\mathfrak{p}$ on U, and $\varphi : U(\mathfrak{p}) \to U(\mathfrak{g})$ the algebra map induced by the inclusion. Make $U(\mathfrak{g})$ a right $U(\mathfrak{p})$-module through φ and U a left $U(\mathfrak{p})$-module through ρ. Let $N \subseteq U(\mathfrak{g}) \otimes_{\mathbb{C}} U$ be the span of $\{y\iota(x) \otimes u - y \otimes \rho(x)u : y \in U(\mathfrak{g}), x \in \mathfrak{p}, u \in U\}$. Then N equals the span N' of $\{y\varphi(a) \otimes u - y \otimes a \cdot u : y \in U(\mathfrak{g}), a \in U(\mathfrak{p}), u \in U\}$, so*

$$\texttt{Induced p rho} = (U(\mathfrak{g}) \otimes_{\mathbb{C}} U)/N = U(\mathfrak{g}) \otimes_{U(\mathfrak{p})} U.$$

Proof. $N \subseteq N'$: take $a = \iota_{\mathfrak{p}}(x)$, noting $\varphi(\iota_{\mathfrak{p}}(x)) = \iota(x)$ and $\iota_{\mathfrak{p}}(x) \cdot u = \rho(x)u$. For $N' \subseteq N$, let A be the set of $a \in U(\mathfrak{p})$ such that $y\varphi(a) \otimes u - y \otimes au \in N$ for all y, u. A is a linear subspace, contains 1 (the element is 0) and contains $\iota_{\mathfrak{p}}(\mathfrak{p})$. It is closed under products: for $a, b \in A$,

$$y\varphi(ab) \otimes u - y \otimes ab\,u = \big[(y\varphi(a))\varphi(b) \otimes u - y\varphi(a) \otimes bu\big] + \big[y\varphi(a) \otimes (bu) - y \otimes a(bu)\big],$$

and both brackets are in N (the first because $b \in A$, with $y\varphi(a)$ in place of y; the second because $a \in A$, with bu in place of u). Since $U(\mathfrak{p})$ is generated as an algebra by $\iota_{\mathfrak{p}}(\mathfrak{p})$, $A = U(\mathfrak{p})$. Finally $(U(\mathfrak{g}) \otimes_{\mathbb{C}} U)/N'$ is by definition (the standard presentation of the tensor product over a ring) $U(\mathfrak{g}) \otimes_{U(\mathfrak{p})} U$. □

Physical meaning

$U(\mathfrak{g}) \otimes_{U(\mathfrak{p})} U$ is the module obtained by declaring the states of U to be "lowest" states on which the subalgebra $\mathfrak{p}$ acts as prescribed by ρ, and then acting freely with the remaining generators. The balancing relations say only that moving an element of $\mathfrak{p}$ through to the lowest states is the same as letting it act there; Proposition 3.11 says that imposing this for single generators of $\mathfrak{p}$ is enough.

Theorem 3.12 (Field (B) is true)**.** *For every complex Lie algebra $\mathfrak{g}$, Lie subalgebra $\mathfrak{p}$, and representation ρ of $\mathfrak{p}$ on any complex vector space U, the map $U \to U(\mathfrak{g}) \otimes_{U(\mathfrak{p})} U$, $u \mapsto 1 \otimes u$, is injective.*

Proof. By Corollary 3.10(2), $U(\mathfrak{g}) = \bigoplus_m m\,U(\mathfrak{p})$ as right $U(\mathfrak{p})$-modules, with m running over ordered monomials in a basis of a complement of $\mathfrak{p}$, and the empty monomial $m = 1$ among them. Tensor product over $U(\mathfrak{p})$ commutes with direct sums, and $m\,U(\mathfrak{p}) \cong U(\mathfrak{p})$ as right modules (freeness), so

$$U(\mathfrak{g}) \otimes_{U(\mathfrak{p})} U \cong \bigoplus_m \big(m\,U(\mathfrak{p})\big) \otimes_{U(\mathfrak{p})} U \cong \bigoplus_m U,$$

and under this isomorphism $1 \otimes u$ goes to u in the summand $m = 1$. Hence $u \mapsto 1 \otimes u$ is injective. By Proposition 3.11 this is the Lean map `bottom p rho`. □

Physical meaning

In the vertex-algebra application (Zhu's theory) U is a space of lowest-weight states and the induced module is the generalised Verma module built on it. Theorem 3.12 says that the lowest-weight states one started with survive in the generalised Verma module, undeformed: nothing in the commutation relations forces two of them to be identified.

Theorem 3.13 (Field (A) is true)**.** *For every complex Lie algebra $\mathfrak{g}$, every symmetric invariant bilinear form κ (possibly degenerate or zero) and every $k \in \mathbb{C}$ (including the critical level when $\mathfrak{g}$ is simple), the vacuum vector $[1] \in U(\hat{\mathfrak{g}})/J(k)$ is nonzero; equivalently $1 \notin J(k)$.*

Proof. Let $\mathfrak{n}_- = \bigoplus_{n<0} \mathfrak{g} \otimes t^n$ and $\hat{\mathfrak{p}} = \bigoplus_{n\geq 0} \mathfrak{g} \otimes t^n \oplus \mathbb{C}C \oplus \mathbb{C}\ell_0$. As vector spaces $\hat{\mathfrak{g}} = \mathfrak{n}_- \oplus \hat{\mathfrak{p}}$, and both are Lie subalgebras: brackets of negative modes have negative degree and no central term (the cocycle needs $m + n = 0$); brackets of non-negative modes have non-negative degree and central term $m\,\kappa(x,y)\delta_{m+n,0}C$ with $m = n = 0$, hence zero; $[\ell_0, x \otimes t^n] = n\,x \otimes t^n$ stays in the same degree; C is central. Define $\chi : \hat{\mathfrak{p}} \to \mathbb{C}$ by $\chi(x \otimes t^n) = 0$, $\chi(C) = k$, $\chi(\ell_0) = 0$. Then χ vanishes on $[\hat{\mathfrak{p}}, \hat{\mathfrak{p}}]$, because by the computation just made every bracket of two elements of $\hat{\mathfrak{p}}$ lies in $\bigoplus_{n\geq 0} \mathfrak{g} \otimes t^n$ (no C- and no ℓ_0-component). So χ is a Lie algebra homomorphism to the abelian Lie algebra $\mathbb{C}$, and extends to an algebra homomorphism $\tilde{\chi} : U(\hat{\mathfrak{p}}) \to \mathbb{C}$.

By Corollary 3.10(3), multiplication $\mu : U(\mathfrak{n}_-) \otimes U(\hat{\mathfrak{p}}) \to U(\hat{\mathfrak{g}})$ is a linear isomorphism. Define $\Phi : U(\hat{\mathfrak{g}}) \to U(\mathfrak{n}_-)$ by $\Phi(\mu(u \otimes v)) = \tilde{\chi}(v)\,u$. We claim $\Phi(J(k)) = 0$. The left ideal $J(k)$ is spanned by the elements $y\,(a - \chi(a))$ with $y \in U(\hat{\mathfrak{g}})$ and a one of the generators $x \otimes t^n$ ($n \geq 0$), C, ℓ_0 (for which $a - \chi(a)$ is $x \otimes t^n$, $C - k$, ℓ_0 respectively). Write $y = \sum_i u_i v_i$ with $u_i \in U(\mathfrak{n}_-)$, $v_i \in U(\hat{\mathfrak{p}})$. Then $y(a - \chi(a)) = \sum_i u_i \big(v_i(a - \chi(a))\big)$ with $v_i(a - \chi(a)) \in U(\hat{\mathfrak{p}})$, so

$$\Phi\big(y(a - \chi(a))\big) = \sum_i \tilde{\chi}\big(v_i(a - \chi(a))\big)\,u_i = \sum_i \tilde{\chi}(v_i)\big(\chi(a) - \chi(a)\big)u_i = 0.$$

But $\Phi(1) = \Phi(\mu(1 \otimes 1)) = 1 \neq 0$ in $U(\mathfrak{n}_-)$ (the augmentation $U(\mathfrak{n}_-) \to \mathbb{C}$ sends $1 \mapsto 1$, so $1 \neq 0$). Hence $1 \notin J(k)$. □

Remark 3.14 (Field (A) is a special case of field (B))**.** Mathematically, (A) follows from (B): with $\mathfrak{p} =$ `parabolic` and $U = \mathbb{C}$ with the character χ above, the maps $[y] \mapsto [y \otimes 1]$ and $[y \otimes c] \mapsto c[y]$ are mutually inverse isomorphisms between $U(\hat{\mathfrak{g}})/J(k)$ and $\mathrm{Ind}_{\hat{\mathfrak{p}}}^{\hat{\mathfrak{g}}} \mathbb{C}_\chi$, sending $|0\rangle$ to $[1 \otimes 1] =$ `bottom` 1, which is nonzero by (B). (One must check that the Lean `parabolic`, defined as a generated subalgebra, is the subspace $\hat{\mathfrak{p}}$, and that χ is a Lie homomorphism on it; both are the computation in the proof of Theorem 3.13.) Since `pbw` became a theorem the library *does* formalise a version of this derivation: it is how the first field of `pbw` is now proved (Theorem 3.18). The formal version avoids `parabolic` and instead uses a subalgebra `nonnegSub` defined directly as the subspace $\hat{\mathfrak{p}}$, and it needs only one direction of the isomorphism (that $1 \in J(k)$ would force $[1 \otimes 1] = 0$). The structure `PBWPrinciple` still lists (A) as a separate field, and its docstring's remark "no implication from the first field to the second is claimed" remains accurate: (B) yields (A) by the short argument above, whereas no comparably short argument gives (B) from (A).

3.10.5 How the statement could have been false or empty, and why it is not

Before `pbw` became a theorem, a one-character slip in any of the definitions above could have made the Lean statement false, and with it the library inconsistent. Today such a slip would simply have made the Lean proof impossible. The list below is kept because it is also the list of the places where the statement could have drifted away from its intended meaning, and a referee should still check each one: the evidence is that each slip is absent.

Trap / dead end

1. The representation must be a Lie homomorphism. `rho` has type `p →ₗ[ℂ] Module.End ℂ U`, a Lie algebra homomorphism. Had it been only a linear map `p →ₗ[ℂ] Module.End ℂ U`, field (B) would be *false*. Counterexample: $\mathfrak{g} = \mathfrak{p}$ the two-dimensional abelian Lie algebra with basis x, y; $U = \mathbb{C}^2$; $\rho(x)$, $\rho(y)$ two non-commuting matrices. In $U(\mathfrak{g})$, $\iota x\, \iota y = \iota y\, \iota x$, and the balancing relations give $[\iota x \iota y \otimes u] = [\iota x \otimes \rho(y)u] = [1 \otimes \rho(x)\rho(y)u]$ and likewise $[\iota y \iota x \otimes u] = [1 \otimes \rho(y)\rho(x)u]$; so the bottom map identifies $\rho(x)\rho(y)u$ with $\rho(y)\rho(x)u$ and is not injective. The Lean type rules this out.
2. The side of the balancing relation. The relation is $y\,\iota(x) \otimes u \sim y \otimes \rho(x)u$: $\iota(x)$ multiplies y on the *right*, which is what defines the tensor product over $U(\mathfrak{p})$ of the *right* module $U(\mathfrak{g})$ with the left module U. The Lean term is `(y * UniversalEnvelopingAlgebra.ι ℂ (x : g)) ⊗ₜ[ℂ] u - y ⊗ₜ[ℂ] (rho x u)`: correct side.
3. The vacuum ideal must be generated by $C - k$, not C. If $J(k)$ contained C and $C - k$ with $k \neq 0$, it would contain k, hence 1. The Lean generator is `ι ℂ (C κ hκ) - algebraMap ℂ (UEnv g κ hκ) k`, i.e. $C - k$, and C itself is not a generator.
4. The vacuum ideal must not contain modes of both signs. If $J(k)$ contained $x \otimes t$ and $y \otimes t^{-1}$ with $\kappa(x, y) = 1$, then it would contain $[x \otimes t, y \otimes t^{-1}] = [x, y] \otimes 1 + C$ (a commutator of two elements of a left ideal is in the ideal: $ab - ba$ with $a, b \in J$), hence, since $[x, y] \otimes 1 \in J$, also C, and with $C - k$ also k; for $k \neq 0$, $1 \in J$. The Lean condition is `0 ≤ n` on all loop generators: no negative modes.
5. The zero modes and the cocycle. The generators include the zero modes $x \otimes t^0$. This is consistent only because the Kac–Moody cocycle is $m\,\kappa(x, y)\delta_{m+n,0}$ with the factor m, which vanishes at $m = n = 0$. With a term such as $\kappa(x, y)\delta_{m+n,0}$ (no factor m; this is not even alternating, so not a valid cocycle) one would get $[x \otimes 1, y \otimes 1] \ni \kappa(x, y)C$ and the same collapse as in item 4. The Lean `cocycle_single` has the factor `(m : ℂ)`.
6. The derivation. ℓ_0 is a generator, i.e. $\ell_0|0\rangle = 0$. This is consistent because $[\ell_0, x \otimes t^n] = n\,x \otimes t^n$ maps generators to multiples of generators, and ℓ_0 never appears in a bracket (the third component of `bracketP` is `0`). Had brackets of non-negative modes produced an ℓ_0- or C-component, the character χ of the proof of Theorem 3.13 would not exist and the argument

would break.
7. Hidden typeclass mismatch. The tensor product `UniversalEnvelopingAlgebra ℂ g ⊗[ℂ] U` uses the $\mathbb{C}$-module structure coming from the $\mathbb{C}$-algebra structure of $U(\mathfrak{g})$, and `U`'s given `[Module ℂ U]`; `Module.End ℂ U` uses the same. There is no second, incompatible module structure in play, so the Lean objects are the mathematical ones.
8. Is the statement secretly about something trivial? No: it quantifies over all Lie algebras and all representations, and its instances include genuinely nontrivial ones (for example $\mathfrak{g} = \mathfrak{sl}_2$, $\mathfrak{p}$ a Borel subalgebra, U a one-dimensional weight: (B) is then the nonvanishing of the Verma module highest-weight vector).

From the mathematics to the Lean statement

Edge cases, checked by hand. A false universal statement is often false at a degenerate instance; we check them.

- $U = 0$: any map out of the zero space is injective.
- $\mathfrak{p} = \mathfrak{g}$: $U(\mathfrak{g}) \otimes_{U(\mathfrak{g})} U \cong U$ via $y \otimes u \mapsto \tilde{\rho}(y)u$, and this sends $[1 \otimes u] \mapsto u$; injectivity needs no PBW.
- $\mathfrak{p} = 0$: the balancing relations are $y\iota(0) \otimes u - y \otimes \rho(0)u = 0$, so `Induced` $= U(\mathfrak{g}) \otimes U$ and `bottom` is $u \mapsto 1 \otimes u$; it has the left inverse $\varepsilon \otimes \mathrm{id}$, where $\varepsilon : U(\mathfrak{g}) \to \mathbb{C}$ is the augmentation (the algebra map extending the zero Lie map), which satisfies $\varepsilon(1) = 1$. Injective, again without PBW.
- $\mathfrak{g} = 0$ in (A): $\hat{\mathfrak{g}} = \mathbb{C}C \oplus \mathbb{C}\ell_0$ is abelian, $J(k)$ is generated by $C - k$ and ℓ_0, and $U(\hat{\mathfrak{g}}) = \mathbb{C}[C, \ell_0]$; $1 \notin (C - k, \ell_0)$ because evaluation at $(k, 0)$ sends $1 \mapsto 1$ and the ideal to 0.
- $\kappa = 0$ in (A): $\hat{\mathfrak{g}} = L\mathfrak{g} \oplus \mathbb{C}C \oplus \mathbb{C}\ell_0$ with C central and never a bracket; the character χ extends to all of $\hat{\mathfrak{g}}$ ($x \otimes t^n \mapsto 0$ for all n, $C \mapsto k$, $\ell_0 \mapsto 0$) because C and ℓ_0 are not in $[\hat{\mathfrak{g}}, \hat{\mathfrak{g}}]$; so the one-dimensional module $\mathbb{C}_\chi$ is a nonzero quotient of $V^k(\mathfrak{g})$ and $|0\rangle \neq 0$, without PBW.
- $k = 0$, or $k = -h^\vee$ (critical level) for simple $\mathfrak{g}$: nothing changes in the proof of Theorem 3.13, which never divides by $k + h^\vee$. (At the critical level the Sugawara construction fails, but that is irrelevant to the nonvanishing of the vacuum.)
- Infinite-dimensional $\mathfrak{g}$ or U: PBW holds without finiteness; the bases exist by Zorn's lemma, which is available through `Classical.choice`.

Verdict. After every definition is unfolded, (A) is Theorem 3.13 and (B) is Theorem 3.12, both true for all instances of the quantifiers. `PBWPrinciple` is therefore exactly the pair of classical PBW consequences its name advertises — neither stronger nor weaker — and it is in fact a fairly weak consequence of PBW: it asserts injectivity of one map, not the existence of a basis. Field (A) follows from (B) by a short argument (Remark 3.14), so (B) carries the substance. Its instances include genuinely nontrivial ones (item 8 of the warning above), so it is not vacuous.

Physical meaning

Field (A) says that the WZW-type vacuum sector built from the vacuum by the creation currents J^a_{-n} is not the zero space — the vacuum conditions $J^a_{n\geq 0}|0\rangle = 0$, $C = k$, $\ell_0|0\rangle = 0$ are mutually consistent at every level. Field (B) is the general version used in Zhu's theory:

when one builds a module of a vertex operator algebra by "acting with all modes" on a space of lowest-weight states (a generalised Verma module), the lowest-weight states one started with survive intact — the construction does not identify two of them or kill any. Both are statements that creation operators act freely, with no unexpected relations.

3.10.6 The proof in the library: relative PBW

The classical route to field (B) goes through the full PBW basis of $U(\mathfrak{g})$ (Corollary 3.10). The library takes a shorter route, which proves exactly what (B) needs and nothing more. It is the *relative* form of the key lemma in Humphreys' proof of PBW (*Introduction to Lie Algebras and Representation Theory*, §17.4, Lemma A): instead of building a representation of $\mathfrak{g}$ on a polynomial algebra $S(\mathfrak{g})$ in which 1 generates freely, one builds a representation of $\mathfrak{g}$ on $S(\mathfrak{c}) \otimes U$, where $\mathfrak{c}$ is a complement of $\mathfrak{p}$, in which the given representation U of $\mathfrak{p}$ sits as the degree-zero part. Then (B) follows from the universal property of induction, and (A) follows from (B). Everything is proved from Mathlib alone (`VOA/Foundations/PBWTheorem/Construction.lean`, `LieRep.lean`, `Induced.lean`); no PBW statement is assumed anywhere. The three files work over an arbitrary field K, not only over $\mathbb{C}$.

The relative PBW representation

Theorem 3.15 (Relative PBW representation; Humphreys §17.4, Lemma A, relative form)**.** *Let $\mathfrak{g}$ be a Lie algebra over a field K (of any dimension), $\mathfrak{p} \subseteq \mathfrak{g}$ a Lie subalgebra, $\mathfrak{c}$ a vector-space complement of $\mathfrak{p}$ in $\mathfrak{g}$, $(y_a)_{a \in A}$ a basis of $\mathfrak{c}$ indexed by a totally ordered set A, and ρ a representation of $\mathfrak{p}$ on a K-vector space U. Let M be the vector space of finitely supported functions from finite multisets of A to U; write $m \otimes u$ for the function with value u at the multiset m and 0 elsewhere, $|m|$ for the number of elements of m counted with multiplicity, and $a \le m$ for "$a \le b$ for every letter b of m". Then there is a representation σ of $\mathfrak{g}$ on M such that, for all $u \in U$, $x \in \mathfrak{p}$ and all multisets m:*

$$
\begin{aligned}
&\text{(E1)} && \sigma(y_a)(m \otimes u) = (a\,m) \otimes u && \text{if } a \le m,\\
&\text{(E2)} && \sigma(y_a)\big((b\,m) \otimes u\big) = \sigma(y_b)\sigma(y_a)(m \otimes u) + \sigma([y_a, y_b])(m \otimes u) && \text{if } b < a,\ b \le m,\\
&\text{(E3)} && \sigma(x)(\varnothing \otimes u) = \varnothing \otimes \rho(x)u, &&\\
&\text{(E4)} && \sigma(x)\big((b\,m) \otimes u\big) = \sigma(y_b)\sigma(x)(m \otimes u) + \sigma([x, y_b])(m \otimes u) && \text{if } b \le m,
\end{aligned}
$$

where $a\,m$ denotes the multiset m with one more copy of a. In particular $u \mapsto \varnothing \otimes u$ is an injective linear map $U \to M$ which intertwines $\rho(x)$ with $\sigma(x)$ for every $x \in \mathfrak{p}$.

The carrier and the standing variables.
File `VOA/Foundations/PBWTheorem/Construction.lean`.

```

```

where `defect p hc bc ρ z z'` is, by definition, the linear map $\sigma(z)\sigma(z') - \sigma(z')\sigma(z) - \sigma([z, z'])$ (with `act` in place of σ).

From the mathematics to the Lean statement

Decoding. `Multiset A` is the type of finite multisets of elements of `A`, i.e. unordered monomials $y_{a_1} \cdots y_{a_r}$ in the complement basis; `Multiset A →₀ U` is the space M of the theorem, which is $S(\mathfrak{c}) \otimes_K U$ written in the monomial basis of $S(\mathfrak{c})$. `single m u` is $m \otimes u$, `single 0 u` is $\varnothing \otimes u$ (the empty multiset is `0`), and `a ::ₘ m` is the multiset $a\,m$. `hc : IsCompl p.toSubmodule c` says that $\mathfrak{c}$ is a complement of $\mathfrak{p}$ ($\mathfrak{p} \cap \mathfrak{c} = 0$, $\mathfrak{p} + \mathfrak{c} = \mathfrak{g}$); `bc` is a basis of $\mathfrak{c}$, so `(bc a : g)` is y_a viewed in $\mathfrak{g}$; `[LinearOrder A]` is the total order. The hypothesis `∀ b ∈ m, a ≤ b` is "$a \le m$"; `b < a` together with `∀ c ∈ m, b ≤ c` says that b is the least letter of $b\,m$ and is strictly below a. The four theorems are (E1), (E3), (E2), (E4) in this order. `g →ₗ⁅K⁆ Module.End K M` is a Lie algebra homomorphism into $\mathrm{End}_K M$ with the commutator bracket (Section 3.4), i.e. a representation: so `rep` is σ, and `rep_apply` says it is the operator family `act` of the four equations. `defect_eq_zero` is the statement that `act` respects brackets, which is exactly what is needed to upgrade `act` to the Lie homomorphism `rep`. `rep_p_zero` is the final sentence of Theorem 3.15: on degree zero, $\mathfrak{p}$ acts through ρ.

Hypotheses and generality. No finiteness of $\mathfrak{g}$, $\mathfrak{p}$, U or A is assumed, and K is any field. The equations do not mention $\mathfrak{p}$-components explicitly: `act` is linear in its $\mathfrak{g}$-argument, so `act ⁅(bc a : g), (bc b : g)⁆` means "decompose $[y_a, y_b]$ into its $\mathfrak{p}$- and $\mathfrak{c}$-parts and act by each". The construction depends on the choice of $\mathfrak{c}$, of the basis and of the order; Theorem 3.15 asserts existence for every such choice.

Could it be vacuous? No: `rep` is a genuine Lie homomorphism (its type requires the bracket relation, proved as `defect_eq_zero`), and `rep_p_zero` together with the injectivity of $u \mapsto \varnothing \otimes u$ (`Finsupp.single_injective 0`) says that U sits inside it as an honest $\mathfrak{p}$-subrepresentation.

Those two facts are exactly what is used downstream.

Proof on paper. Construction. We define $\sigma(z)$ on $M_{\le d} = \operatorname{span}\{m \otimes u : |m| \le d\}$ by induction on d, for z running over the generators y_a ($a \in A$) and $x \in \mathfrak{p}$, and extend linearly in z using $\mathfrak{g} = \mathfrak{p} \oplus \mathfrak{c}$. We carry along the *degree bounds*

$$\sigma(y_a)(m \otimes u) - (a\,m) \otimes u \in M_{\le |m|}, \qquad \sigma(x)(m \otimes u) \in M_{\le |m|}.$$

In degree 0, (E1) and (E3) define everything. Suppose σ is defined on $M_{\le d-1}$ and satisfies the bounds, and let $|m| = d-1$, $b\,m$ a monomial of degree d with least letter b. If $a \le b\,m$, (E1) defines $\sigma(y_a)((b\,m) \otimes u)$. If $b < a$, write $\sigma(y_a)(m \otimes u) = (a\,m) \otimes u + w$ with $w \in M_{\le d-1}$ (degree bound at degree $d-1$). Since $b \le a\,m$, (E1) gives $\sigma(y_b)((a\,m) \otimes u) = (b\,a\,m) \otimes u$, and $\sigma(y_b)w$ is already defined; so the right-hand side of (E2) makes sense and *defines* the left-hand side. The same argument, using the bound $\sigma(x)(m \otimes u) \in M_{\le d-1}$, makes (E4) a definition. The new values satisfy the degree bounds, which closes the induction.

The bracket relation. We show $\sigma(z)\sigma(z')v - \sigma(z')\sigma(z)v = \sigma([z,z'])v$ for generators z, z' and basis vectors $v = m \otimes u$, by induction on $|m|$; bilinearity then gives it for all z, z', v. Call a generator y_a *low* for m if $a \le m$.

Low case. If one of the two generators is low for m (if both are, take the one with the smaller letter), put it in the second slot using skew-symmetry of both sides. With $z' = y_a$ low, $\sigma(y_a)v = (a\,m) \otimes u$ by (E1), and the relation to be proved, $\sigma(z)((a\,m) \otimes u) = \sigma(y_a)\sigma(z)v + \sigma([z,y_a])v$, is literally (E2) (if $z = y_c$ with $c > a$), (E4) (if $z \in \mathfrak{p}$), or trivial (if $z = y_a$). This case needs no induction.

Degree zero. If $m = \varnothing$ and $z, z' \in \mathfrak{p}$, the relation is $\rho([x,x']) = [\rho(x), \rho(x')]$, i.e. that ρ is a representation; every other pair at $m = \varnothing$ has a low generator.

Inductive case. Otherwise $m = b\,m'$ with b the least letter, and both generators are *above* b (each is some y_a with $a > b$, or an element of $\mathfrak{p}$). Put $v' = m' \otimes u$, so $v = \sigma(y_b)v'$, and assume the relation for all vectors of degree $< |m|$. By (E2)/(E4), $\sigma(z)v = \sigma(y_b)\sigma(z)v' + \sigma([z,y_b])v'$, and similarly for z'. Apply $\sigma(z')$ to the first expression and expand $\sigma(z')\sigma(y_b)(\sigma(z)v')$. Here $\sigma(z)v'$ is not a single monomial, so we split it. By the degree bound, if $z = y_a$ then $\sigma(z)v' = (a\,m') \otimes u + w$ with w of degree $< |m|$, and y_b is low for $a\,m'$ because $b < a$ and $b \le m'$; if $z \in \mathfrak{p}$ there is no leading monomial and $\sigma(z)v' = w$ has degree $< |m|$. On the leading monomial the relation for (z', y_b) holds by the low case; on w it holds by the inductive hypothesis (applied monomial by monomial and summed, since both sides are linear). Hence $\sigma(z')\sigma(y_b)\sigma(z)v' = \sigma(y_b)\sigma(z')\sigma(z)v' + \sigma([z',y_b])\sigma(z)v'$. Doing the same with z, z' exchanged and subtracting, the terms collect into

$$\sigma(y_b)\big([\sigma(z),\sigma(z')]v'\big) + \sigma([[z,y_b],z'])v' + \sigma([z,[z',y_b]])v',$$

where the inductive hypothesis (degree $|m'| < |m|$) was used for the pairs (z,z'), $([z,y_b],z')$ and $(z,[z',y_b])$ on v'. The first term is $\sigma(y_b)\sigma([z,z'])v'$, again by induction, and by the Jacobi identity $[[z,y_b],z'] + [z,[z',y_b]] = [[z,z'],y_b]$. Finally $\sigma(y_b)\sigma([z,z'])v' + \sigma([[z,z'],y_b])v' = \sigma([z,z'])\sigma(y_b)v' = \sigma([z,z'])v$ by the low case applied to v' (the generator y_b is low for m'), for each generator component of $[z,z']$. This is Humphreys' computation; the only property of $\mathfrak{g}$ used is the Jacobi identity, and the only property of ρ used is that it is a representation. □

Example 3.16 (The Verma module of $\mathfrak{sl}_2$)**.** Let $\mathfrak{g} = \mathfrak{sl}_2$ with $[h,e] = 2e$, $[h,f] = -2f$, $[e,f] = h$, let $\mathfrak{p} = \operatorname{span}\{h,e\}$ (the Borel subalgebra), $\mathfrak{c} = \mathbb{C}f$ (one letter, so a monomial is f^n), and $U = \mathbb{C}u$ with $\rho(h) = \lambda$, $\rho(e) = 0$. Then M has basis $f^n \otimes u$, $n \ge 0$. (E1) gives $\sigma(f)(f^n \otimes u) = f^{n+1} \otimes u$. (E3) gives $\sigma(h)(\varnothing \otimes u) = \lambda\,\varnothing \otimes u$ and $\sigma(e)(\varnothing \otimes u) = 0$. (E4) with $x = h$ gives $\sigma(h)(f^n \otimes u) = \sigma(f)\sigma(h)(f^{n-1} \otimes u) - 2f^n \otimes u$, hence $\sigma(h)(f^n \otimes u) = (\lambda - 2n)f^n \otimes u$; with $x = e$ it gives $\sigma(e)(f^n \otimes u) = \sigma(f)\sigma(e)(f^{n-1} \otimes u) + \sigma(h)(f^{n-1} \otimes u)$, hence $\sigma(e)(f^n \otimes u) = n(\lambda - n + 1)f^{n-1} \otimes u$. These are the familiar formulas of the Verma module $M(\lambda)$, and one checks directly that $[\sigma(e),\sigma(f)] = \sigma(h)$ on $f^n \otimes u$: $(n+1)(\lambda - n) - n(\lambda - n + 1) = \lambda - 2n$.

Physical meaning

The example is the highest-weight representation of the $SU(2)$ current zero modes built on a state of J_0^3-eigenvalue $\lambda/2$: the lowering operator acts freely, and the raising operator acts by the standard matrix elements.

Physical meaning

$M = S(\mathfrak{c}) \otimes U$ is the "Fock space" one expects for a generalised Verma module: states are created from the lowest-weight space U by the creation operators y_a (a basis of the modes not in $\mathfrak{p}$), *normal-ordered* (the letters of a monomial are listed in increasing order). (E1) says that applying a creation operator that is already in normal order just adds it to the monomial; (E2)–(E4) say that any other operator is moved to its normal-ordered place by commuting it through, picking up the commutator. Theorem 3.15 says that this normal-ordering prescription is consistent, i.e. defines an honest representation; physically, it is the statement that the canonical commutation relations are the only relations among the modes.

What the machine verified

`VOA.PBWTheorem.rep`, `VOA.PBWTheorem.rep_p_zero`, and the four defining equations are proved from Mathlib alone; they enter the report of `PBWTheorem.bottom_injective` below, which is `[propext, Classical.choice, Quot.sound]` (run for this chapter). Unconditional.

Injectivity of the bottom map

Theorem 3.17 (Bottom injectivity, relative PBW). *Let $\mathfrak{g}$ be a Lie algebra over a field K, $\mathfrak{p}$ a Lie subalgebra and ρ a representation of $\mathfrak{p}$ on U. Then the map $U \to (U(\mathfrak{g}) \otimes_K U)/N$, $u \mapsto [1 \otimes u]$, is injective, where N is the span of the balancing relations $y\,\iota(x) \otimes u - y \otimes \rho(x)u$. By Proposition 3.11 this is the map $U \to U(\mathfrak{g}) \otimes_{U(\mathfrak{p})} U$, and over $K = \mathbb{C}$ it is field (B) of* `PBWPrinciple`. *More generally: if there are a representation σ of $\mathfrak{g}$ on some M and an injective linear map $j : U \to M$ with $\sigma(x)j(u) = j(\rho(x)u)$ for $x \in \mathfrak{p}$, then the bottom map is injective.*

From the mathematics to the Lean statement

Same definitions as `PBWInduction`. Compare with the block of Section 3.10 that defines `PBWInduction.balancingSet`, `balancing` and `bottom`: the three definitions here are the same text with $\mathbb{C}$ replaced by a field `K`, with the abbreviations `Cover` and `Induced` unfolded, and with $\mathfrak{g}$ and U allowed to live in different universes. At `K = ℂ` they are *definitionally* equal to the `PBWInduction` ones, which is why `pbw` can use `bottom_injective` for the field `inducedBottom` directly. So Theorem 3.17 is field (B), for every field.
The embedding criterion. In `bottom_injective_of_embedding`, σ is a representation of $\mathfrak{g}$ on M, `j` a linear map with `hj` (injective) and `hσ` ($\mathfrak{p}$-equivariant: the restriction of σ to $\mathfrak{p}$, applied to $j(u)$, is j of ρ). The conclusion is injectivity of the bottom map. This is the second paragraph of Theorem 3.17.
No hidden hypothesis. `bottom_injective` has no hypothesis beyond the data: every Lie subalgebra, every representation. The choices needed in the proof (a complement, a basis, a total order) are made inside the proof, using Mathlib's `Submodule.exists_isCompl`, `Basis.ofVectorSpace` (which uses Zorn's lemma, via `Classical.choice`) and a well-ordering of the index set (`WellOrderingRel`).

Proof on paper. The criterion. By the universal property of $U(\mathfrak{g})$, σ extends to an algebra map $\tilde{\sigma} : U(\mathfrak{g}) \to \mathrm{End}_K M$. The bilinear map $(y,u) \mapsto \tilde{\sigma}(y)j(u)$ gives a linear map $L_0 : U(\mathfrak{g}) \otimes U \to M$, and L_0 kills every balancing relation: $\tilde{\sigma}(y\iota(x))j(u) - \tilde{\sigma}(y)j(\rho(x)u) = \tilde{\sigma}(y)\big(\sigma(x)j(u) - j(\rho(x)u)\big) = 0$. So L_0 descends to L on the quotient, with $L([1 \otimes u]) = j(u)$. If $[1 \otimes u_1] = [1 \otimes u_2]$, then $j(u_1) = j(u_2)$ and $u_1 = u_2$.

The theorem. Choose a complement $\mathfrak{c}$ of $\mathfrak{p}$ (every subspace of a vector space has one), a basis of $\mathfrak{c}$ (every vector space has one), and a total order on its index set (every set can be well-ordered). Theorem 3.15 gives σ on M, and $j(u) = \varnothing \otimes u$ is injective and $\mathfrak{p}$-equivariant by (E3). Apply the criterion. □

Physical meaning

The criterion is the familiar physicist's argument "to show that a state is nonzero, exhibit a representation in which it is nonzero": the generalised Verma module is the *freest* module generated by U with the prescribed $\mathfrak{p}$-action, so it maps onto any other module containing such a copy of U, and if U survives there it survived in the Verma module. Theorem 3.15 supplies the other module: the normal-ordered Fock space $S(\mathfrak{c}) \otimes U$.

What the machine verified

From the mathematics to the Lean statement

Decoding. `supported 𝔤 ℂ (Set.Ici (0 : ℤ))` is the subspace of `ℤ →₀ 𝔤` of Laurent polynomials supported in degrees ≥ 0, i.e. $\mathfrak{g}[t]$. So `nonnegSub` is the set of triples (f, a, p) with $f \in \mathfrak{g}[t]$ and a, p arbitrary: the subspace $\hat{\mathfrak{p}}$, defined *directly* as a subspace (the omitted fields prove that it is closed under addition, scalars and the bracket, the last from `loopBracket_mem_nonneg` and `loopDeriv_mem_nonneg`). This differs from `parabolic` (Section 3.7), which is defined as a generated subalgebra; the two are equal, but the library does not need that. `vacuumChar k` sends $X = (f, a, p)$ to multiplication by ka on the one-dimensional space $\mathbb{C}$ (`carrier.2.1` is the C-coefficient): this is the character χ_k, packaged as a representation of `nonnegSub` on $\mathbb{C}$. Its omitted field `map_lie'` is the check that χ_k kills brackets: the C-component of a bracket of two elements of $\hat{\mathfrak{p}}$ is $\omega(f, g)$, which vanishes on $\mathfrak{g}[t]$ (`cocycle_nonneg`: the cocycle carries the factor m and needs $m + n = 0$). `tmul_one_mem_balancing_of_mem_vacuumIdeal` says that $a \in J(k)$ implies $a \otimes 1 \in N$, the balancing span of this induction; `vacuumVector_ne_zero_of_induction` is Theorem 3.18, with no hypotheses.
Same as field (A). The conclusion is literally `PBW κ hκ k`, unfolded; this is why the proof term of `pbw` can use it for `affineVacuum`.

Proof on paper. Every generator of $J(k)$ is of the form $\iota(X) - \chi_k(X)$ with $X \in \hat{\mathfrak{p}}$: $X = x \otimes t^n$ ($n \geq 0$, $\chi_k = 0$), $X = C$ ($\chi_k = k$), $X = \ell_0$ ($\chi_k = 0$). For such a generator, $(\iota(X) - \chi_k(X)) \otimes 1 = 1 \cdot \iota(X) \otimes 1 - 1 \otimes \chi_k(X)1$ is a balancing relation (with $y = 1$, $u = 1$). The balancing span is stable under left multiplication by $U(\hat{\mathfrak{g}})$ on the first tensor factor (replace y by ry), so $a \otimes 1 \in N$ for every a in the left ideal $J(k)$. Now if the vacuum vector were 0, then $1 \in J(k)$, so $1 \otimes 1 \in N$, i.e. the bottom map sends $1 \in \mathbb{C}$ to 0, the image of 0. By Theorem 3.17 the bottom map is injective, so $1 = 0$ in $\mathbb{C}$, which is absurd. □

Physical meaning

This is the statement that the vacuum of a current algebra is consistent at every level k, critical or not, and for every Lie algebra and invariant form, degenerate or not: the vacuum sector is the generalised Verma module induced from the one-dimensional representation "level k, zero charge, zero energy" of the non-negative modes, and its lowest state survives.

What the machine verified

`VOA.AffineLie.vacuumVector_ne_zero_of_induction: [propext, Classical.choice, Quot.sound]` (run for this chapter). Unconditional.

Status of `VOA.pbw`

What the machine verified

`#print axioms VOA.pbw`, run for this chapter at an earlier commit (not re-run for this edition) with `lake env lean -DmaxSynthPendingDepth=3` on a scratch file containing `import VOA.Foundations.AffineLie` (output in Section 3.15), reports

```
'VOA.pbw' depends on axioms: [propext, Classical.choice, Quot.sound]
```

`VOA.pbw` is a theorem, proved from Mathlib alone, with no hypotheses: **unconditional**. A text search for declarations beginning with `axiom` in `VOA/` finds none (only docstring prose using the word). The project's `scripts/check_repository.py`, which since `pbw` became a theorem rejects any `axiom` declaration, was run for this chapter at that earlier commit and reported "7107 library files scanned; ...; 0 sanctioned axiom declaration(s)" (its overall verdict was "failed", solely because two draft files, `VOA/Huang/LogAssocIterateInputLinearity.lean` and `VOA/Huang/LogGenusOneModeRecurrence.lean`, were not imported by the umbrella; those drafts have since been moved out, and a re-run on the working tree of 28 October 2026 printed "Repository check passed: 10353 library files scanned; ...; 0 sanctioned axiom declaration(s)"). The axiom audit `scripts/audit/run_axiom_audits.py` treats any reappearance of `pbw` in an axiom list as a failure (according to the commit message of the revision that made `pbw` a theorem; not re-run for this chapter). Mathlib v4.30.0 still contains no PBW theorem (Section 3.4); the library proves the *relative* consequence above, and the PBW basis of the affine vacuum module (Section 3.12), but not the PBW basis theorem for $U(\mathfrak{g})$ itself (Theorem 3.9). *History.* In an earlier run (for the first edition of this chapter) the same command reported `[propext, Classical.choice, Quot.sound, pbw]`: `pbw` was then an axiom, and an axiom's own report lists itself. A revision of 19 October 2026 replaced it by the theorem. That revision's own commit message records that the aggregate `lake build` was not yet certified green at the time (only the per-target builds of `AffineLie.lean` and `VacuumBasis.lean` were); according to the project's build record, the aggregate `lake build VOA` was later run green (13868 jobs, 26 October 2026, axiom audit PASS). No `lake build` was run for this chapter.

3.11 Consequences of the PBW principle, and the history of the axiom

3.11.1 Nonvanishing of the affine vacuum and the simple quotient

Theorem 3.19. *For every complex Lie algebra $\mathfrak{g}$ with invariant form κ and every $k \in \mathbb{C}$: $|0\rangle \neq 0$ in $V^k(\mathfrak{g})$; hence $V^k(\mathfrak{g})$ is nonzero; it has a maximal proper $U(\hat{\mathfrak{g}})$-submodule N; $|0\rangle \notin N$; and $L(0) = V^k(\mathfrak{g})/N$ is a simple $U(\hat{\mathfrak{g}})$-module.*

File `VOA/Foundations/AffineLie.lean`.

```
theorem vacuumVector_ne_zero (k : ℂ) : vacuumVector κ hκ k ≠ 0 :=
  VOA.pbw.affineVacuum κ hκ k

theorem vacuumSpace_nontrivial (k : ℂ) : Nontrivial (vacuumSpace κ hκ k) :=
  ⟨⟨vacuumVector κ hκ k, 0, vacuumVector_ne_zero κ hκ k⟩⟩

theorem exists_vacuumMaxSubmodule (k : ℂ) :
    ∃ P : Submodule (UEnv 𝔤 κ hκ) (vacuumSpace κ hκ k), IsCoatom P := by

noncomputable def vacuumMaxSubmodule (k : ℂ) :
    Submodule (UEnv 𝔤 κ hκ) (vacuumSpace κ hκ k) :=
```

```

theorem vacuumVector_not_mem_maxSubmodule (k : ℂ) :
    vacuumVector κ hκ k ∉ vacuumMaxSubmodule κ hκ k := by

noncomputable abbrev vacuumSimple (k : ℂ) : Type _ :=
  vacuumSpace κ hκ k ⧸ vacuumMaxSubmodule κ hκ k

theorem vacuumSimple_isSimpleModule (k : ℂ) :
    IsSimpleModule (UEnv 𝔤 κ hκ) (vacuumSimple κ hκ k) := by
```

From the mathematics to the Lean statement

Decoding. `vacuumVector_ne_zero` is a one-line term: it is *literally* the field `affineVacuum` of the theorem `VOA.pbw` applied to `κ hκ k`; the shown proof is the whole proof. `Nontrivial X` means X has two distinct elements. `IsCoatom P` means $P \neq \top$ and every submodule strictly above P is $\top$: P is a maximal proper submodule. `.choose` picks one (non-constructively). `IsSimpleModule R M` is Mathlib's notion of a simple module (nonzero, with no submodules other than 0 and M).

Same as the textbook? The textbook $L(0)$ (often $L_k(\mathfrak{g})$) is the quotient by *the* maximal proper submodule. The library quotients by *a chosen* maximal proper submodule. For $V^k(\mathfrak{g})$ these agree, because the maximal proper submodule is unique: ℓ_0 acts diagonalisably (`ell0_isInternal`), so every submodule is the sum of its intersections with the eigenspaces; a submodule is proper iff its eigenvalue-0 part, a subspace of $\mathbb{C}|0\rangle$, is zero; so the sum of all proper submodules is proper. The library does not prove uniqueness here, so a referee should read `vacuumSimple` as "a simple quotient of $V^k(\mathfrak{g})$", which by the argument just given is the simple quotient. The simple affine VOAs of the library (Chapter 9) are built on a different route, as quotients of vertex algebras by their maximal graded ideal.

Dependence. Every theorem in the block except the definitions depends on `VOA.pbw`, because the existence of a maximal proper submodule needs $V^k(\mathfrak{g}) \neq 0$ (a zero module has none). Since `VOA.pbw` is now a theorem, this dependence is an ordinary use of a proved result: the block is unconditional. (The proof term of `vacuumVector_ne_zero` still reads `VOA.pbw.affineVacuum κ hκ k` rather than calling `vacuumVector_ne_zero_of_induction` directly; the two are the same proof.)

Physical meaning

$L(0)$ is the vacuum module of the chiral WZW-type theory in which all null states have been set to zero: the irreducible representation of the current algebra generated by the vacuum. Nonvanishing of $|0\rangle$ says the theory has a vacuum at all.

Proof on paper. $|0\rangle \neq 0$ is field (A) (Theorem 3.13; in Lean, Theorem 3.18). A cyclic module $R \cdot v$ is finitely generated, so its top submodule is a compact element of the submodule lattice, which is therefore coatomic: every proper submodule lies in a maximal one (Zorn's lemma, through `CompleteLattice.coatomic_of_top_compact`). The zero submodule is proper because $|0\rangle \neq 0$, so a maximal proper N exists. If $|0\rangle \in N$ then $N \supseteq R|0\rangle = V^k(\mathfrak{g})$, contradiction. A quotient by a maximal proper submodule is simple. □

What the machine verified

`VOA.AffineLie.vacuumVector_ne_zero`, `VOA.AffineLie.vacuumSpace_nontrivial`, `VOA.AffineLie.exists_vacuumMaxSubmodule`, `VOA.AffineLie.vacuumSimple_isSimpleModule`: `[propext, Classical.choice, Quot.sound]` (run for this chapter). Unconditional. They use the theorem `VOA.pbw` (field `affineVacuum`). *History:* in an earlier run, when `pbw` was an

axiom, all four reported [propext, Classical.choice, Quot.sound, pbw].

3.11.2 The two direct consumers

A text search of the library source for uses of VOA.pbw in proof terms (as opposed to documentation) finds exactly two (re-checked at an earlier commit, after pbw became a theorem; not re-run for this edition):

1. AffineLie.vacuumVector_ne_zero above, which uses pbw.affineVacuum;
2. VHat.DLM3.voaPBWBottomInjective in VOA/Modules/ZhuVermaAnArchDLM3PBWAxiom.lean, which uses pbw.inducedBottom:

File VOA/Modules/ZhuVermaAnArchDLM3PBWAxiom.lean.

```
theorem voaPBWBottomInjective (P : ParabolicRep W n U) :
    Function.Injective (indBottom P) :=
  VOA.PBWPrinciple.inducedBottom
    (VOA.pbw : VOA.PBWPrinciple.{u}) (Pn W n) P.act
```

From the mathematics to the Lean statement

Here W is a vertex operator algebra and the names come from Zhu's theory of modules of W (Chapters 12–13). The modes $a_{(n)}$ of the states of W span a Lie algebra $\hat{W}$ (VHat, Chapter 13, Definition 13.9); Pn W n is its "parabolic" Lie subalgebra of modes of degree $\geq -n$ (Definition 13.10); a ParabolicRep W n U is a representation P.act of Pn W n on a vector space U (the would-be lowest-weight space); IndMod P is the induced module $U(\hat{W}) \otimes_{U(P_n)} U$, the "generalised Verma module", and indBottom P is $u \mapsto [1 \otimes u]$ (Definition 13.12). A BottomProjection is a projection of the induced module back onto this bottom copy of U, compatible with the structure, and PBWFreeness is the statement that the levels of the induced module are free in the PBW sense (Definition 13.13); both follow from injectivity of indBottom, and the datum Pr of Zhu's theorems is a BottomProjection for the regular module. The hypotheses hC2, hss, hcard, hcw, hsep, hSR, hFin, hZhu below are explained, with their status, in Section 3.1, item 5; the same file proves by rfl that PBWInduction.bottom (Pn W n) P.act is *definitionally* the map indBottom P of the Zhu chain (pbwInduction_bottom_eq). So the generic field (B) is applied, with no translation step that could hide a mismatch. The meaning of ParabolicRep, indBottom and of the consequences voaPBWFreeness and voaPBWBottom Projection derived in the same file is the subject of Chapter 13.

What the machine verified

VOA.VHat.DLM3.voaPBWBottomInjective: [propext, Classical.choice, Quot.sound] (run for this chapter at an earlier commit; not re-run for this edition). Unconditional; its proof term uses the theorem VOA.pbw (field inducedBottom). *History:* in an earlier run, while pbw was an axiom, it reported [propext, Classical.choice, Quot.sound, pbw]. The file name ZhuVermaAnArchDLM3PBWAxiom.lean and its closing comment ("visibly depend on the sole sanctioned project axiom") date from that time and are now out of date.

3.11.3 What used to inherit the axiom, and the twin policy

Everything that depends on VOA.pbw depends on one of the two declarations above. While pbw was an axiom, this delimited a family of results whose #print axioms report contained pbw; since pbw became a theorem every one of them reports only the three standard axioms. The probes run for this chapter (Section 3.15) confirm this for the representatives below; Chapter 43 records the library-wide audit.

Through `affineVacuum`. The legacy affine $\mathfrak{sl}_2$ route: `AffineVOA.vacuumA_ne_zero` (`VOA/Examples/AffineSl2VOA.lean`), `AffineVOA.Inst.closed_vacuum_ne_zero` and `voaSl2Adm_vacuum_ne_zero` (`AffineSl2VOAInstance.lean`), `QuasiLisseSl2.vacuum_simpleSl2QL_ne_zero` and the Arakawa–Kawasetsu payoff `QuasiLisseSl2.character_formalODE_simpleSl2QL` (Chapter 16). In an earlier run all reported `[propext, Classical.choice, Quot.sound, VOA.pbw]`; in a later run, after `pbw` became a theorem, `vacuumA_ne_zero`, `closed_vacuum_ne_zero`, `vacuum_simpleSl2QL_ne_zero` and `character_formalODE_simpleSl2QL` report `[propext, Classical.choice, Quot.sound]`. Their remaining hypotheses (if any) are those printed in their signatures, discussed in Chapters 9 and 16; none of them is a PBW hypothesis.

Through `inducedBottom`. The canonical Zhu-theory wrappers: `zhuBijective_of_voaPBW`, `zhuModularity_pinned_of_C2Cofinite_voaPBW`, `zhuModularity_stronglyRational_voaPBW` and the results of `Modules/ZhuInduced.lean` and `Modularity/GNProp8PBW.lean` built on them (Chapters 13 and 15). All three named wrappers now report `[propext, Classical.choice, Quot.sound]` (run for this chapter). This does *not* make all of them unconditional: `zhuBijective_of_voaPBW` takes only the vertex operator algebra `W` and is unconditional, but `zhuModularity_pinned_of_C2Cofinite_voaPBW` still carries the instance hypothesis `[Finite (Φ W)]` and `hC2`, `hss`, `hcard`, `hcw`, `hsep` (besides the data `Mfam`, `h` it speaks about), and `zhuModularity_stronglyRational_voaPBW` still carries `hSR`, `hFin`, `hZhu` (the citation hypotheses analysed in Chapter 15). They are `#print axioms`-clean, conditional on those hypotheses. The PBW input is no longer one of their conditions, and the other inputs are now discharged by separate theorems: `[Finite (Φ W)]` by `finite_Φ_of_C2Cofinite_pbw`, `hss` from `AdmissiblyRational` by `isSemisimpleRing_A_of_admissiblyRational`, `hFin` by `dlmFinitelyManyIrredAdmissible_of_c2Cofinite` and `hZhu` by `zhuAdmissibleSemisimple_holds`. The headline form, `zhuModularity_canonical_of_C2Cofinite_admissiblyRational`, assumes only `hC2` and `AdmissiblyRational`.

The axiom-free "twins" of these wrappers (`zhuBijective`, `zhuModularity_pinned_of_C2Cofinite`, which take `Pr` as an explicit hypothesis) date from the time when `pbw` was an axiom; they are explained in Section 3.2. Their `Pr` hypothesis is now always supplied by `voaPBWBottomProjection`.

3.11.4 Results proved without `VOA.pbw`

Every result of the library now reports only the three standard axioms, so the distinction drawn in this subsection is no longer one of trust. It is still informative about *method*: the following headline results were proved, while PBW was an axiom, by routes that do not pass through `VOA.pbw` at all (they reported exactly `[propext, Classical.choice, Quot.sound]` in an earlier run while PBW was an axiom and still did in a later run, after `pbw` became a theorem, run for this chapter; not re-run for this edition):

- the Moonshine construction, `VOA.Moonshine.moonshine` (Chapters 30–42);
- graded first-order rigidity of the Virasoro minimal models, `VOA.VirModule.minimal_graded_rigidity` (Chapter 8), and the Virasoro vacuum nonvanishing `VOA.vacVec_ne_zero`;
- uniform graded first-order rigidity of affine $\mathfrak{sl}_2$ at negative admissible level, `VOA.AffineSl2GeneralRigidity.negative_admissible_graded_rigidity` (Chapter 10);
- non-simplicity of $V^{-8/5}(\mathfrak{sl}_2)$, `VOA.Sl2NotSimple85.not_isSimple_85`, and the affine $\mathfrak{sl}_2$ VOA itself, `VOA.AffineVOA.affineSl2VOA_closed` (Chapter 9);
- the affine $\mathfrak{sl}_3$ simple VOA `VOA.AffineSl3.simpleVOA`, its vacuum nonvanishing `VOA.AffineSl3.vacuumA_ne_zero` (proved by a free-field evaluation), and `VOA.AffineSl3.simple_`

`regular_isTrivial` (declarations of the bespoke affine $\mathfrak{sl}_3$ files under `VOA/Examples/`; the chapter documenting them is in preparation, so they are not refereed in this edition);

- ordinary PBW for affine $\mathfrak{sl}_2$ at noncritical level, `VOA.AffineSl2WakimotoLiLeading.affineSl2PBWBasis`, and the resulting `pbw`-independent vacuum nonvanishing `VOA.AffineSl2BoundaryMaximalIdeal.affineSl2_vacuum_ne_zero` and `VOA.Wak.vacuumA_ne_zero_free` (Section 3.12 and Chapter 9).

File `VOA/Examples/AffineSl2BoundaryMaximalIdeal.lean`.

```
theorem affineSl2_vacuum_ne_zero : (W k hk).vacuum ≠ 0 := by
  change AffineLie.vacuumVector kappaForm kappaForm_isInvariant k ≠ 0
  exact (AffineSl2WakimotoLiLeading.affineSl2PBWBasis k hk).vacuumVector_ne_zero
```

File `VOA/Examples/WakimotoFree.lean`.

```
theorem vacuumA_ne_zero_free (k : ℂ) (hk : k + 2 ≠ 0) : AffineVOA.vacuumA k ≠ 0 := by
```

From the mathematics to the Lean statement

These are the *same* statement as an instance of `AffineLie.vacuumVector_ne_zero` ($\mathfrak{g} = \mathfrak{sl}_2$, κ the normalised form `kappaForm` with $\kappa(e,f) = 1$, $\kappa(h,h) = 2$, `Examples/AffineSl2.lean`), restricted to $k \neq -2$, but proved without `VOA.pbw`: the first from the Wakimoto-based PBW basis of Section 3.12, the second by mapping $V^k(\mathfrak{sl}_2)$ to the Wakimoto free-field module (the same strategy as for Virasoro in Section 3.6). The critical level $k = -2$ is not covered by these routes; there the library proves $|0\rangle \neq 0$ through the theorem `VOA.pbw` (Theorem 3.18), and the general `pbwBasis_holds` of Section 3.12 covers it as well. When `pbw` was an axiom, the critical level was the one place where $\mathfrak{sl}_2$ vacuum nonvanishing rested on it.

Trap / dead end

Documentation lags about PBW (Lean docstrings, not statements).

- The docstring of `Examples/AffineSl2VOAInstance.lean` says that "a *zero* module satisfies every VOA axiom, so no `pbw`-free theorem can assert that this VOA is nonzero". The first half is right and important (the VOA axioms are satisfied by the zero space, so nonvanishing is extra information; the release audit of 2026-10-27 confirms, finding m-4, that the zero space satisfies every field of `VertexOperatorAlgebra`, including `vacuum_grade`, since $\mathbb{C} \cdot 0 = 0$). The second half was already superseded in the first edition of this chapter (`affineSl2_vacuum_ne_zero` and `vacuumA_ne_zero_free` prove that nonvanishing without `pbw` for $k \neq -2$), and since `pbw` became a theorem the whole distinction it draws is moot, `pbw` being a theorem.
- The module docstring of `Foundations/PBWBasis.lean` still calls `VOA.pbw` "the project's sole sanctioned axiom", says "`VOA.pbw` is left exactly as it is" and, under Status, "This file proves nothing about non-degenerate $\mathfrak{g}$; `PBWBasis` is a hypothesis here"; the docstring of `PBWBasis.vacuumVector_ne_zero` calls `PBW` "the first field of the sanctioned axiom". The last Status sentence is literally true of that one file, but `PBWBasis` is now proved for every $\mathfrak{g}$ by `pbwBasis_holds` in `PBWTheorem/VacuumBasis.lean` (Section 3.12), and `pbw` is a theorem.
- The closing comment of `Modules/ZhuVermaAnArchDLM3PBWAxiom.lean` ("The theorem-level wrappers visibly depend on the sole sanctioned project axiom") is out of date for the same reason.

None of these affects a Lean statement. This list is a sample, not an exhaustive inventory: comments in the library that describe `VOA.pbw` as an axiom are out of date wherever they

occur (for instance in VOA/Modules.lean and in several VOA/Classification/COne/ files, whose comments still report "Lean's three plus VOA.pbw"); the book-side occurrences are listed in Notes/Textbook/referee/pbw_sweep.md.

Physical meaning

The pattern is general and physically natural: a universal vacuum module is nonzero as soon as one exhibits a concrete theory in which the vacuum conditions hold — a free-field realisation (free bosons for Virasoro, Wakimoto's $\beta\gamma$ system plus a boson for $\widehat{\mathfrak{sl}}_2$, analogous free fields for $\widehat{\mathfrak{sl}}_3$). The relative PBW theorem of Section 3.10.6 is the same idea made universal: the normal-ordered Fock space $S(\mathfrak{c}) \otimes U$ is a "free-field realisation" that exists for every Lie algebra, every level (including the critical one) and every induced module of Zhu's theory.

3.12 PBW bases: PBWBasis, from named hypothesis to theorem

All declarations of this section are in VOA/Foundations/PBWBasis.lean unless stated otherwise; the general theorem pbwBasis_holds is in VOA/Foundations/PBWTheorem/VacuumBasis.lean.

3.12.1 Why a second PBW statement

Neither field of PBWPrinciple gives *linear independence* of creation monomials. Statements such as "the C_2-algebra of $V^k(\mathfrak{g})$ is the symmetric algebra $S(\mathfrak{g})$" need independence: one must be able to read off the coefficient of a particular monomial in an arbitrary vector. The library therefore has a second PBW statement, PBWBasis: the ordered creation monomials form a basis of the vacuum module. It was introduced (decision of 23 August 2026, recorded in the file's docstring) under the policy that a PBW input may be *assumed*, but only as a *named hypothesis* in the signature of every theorem that uses it, never as a further axiom: #print axioms then remains a reliable gate distinguishing unconditional from conditional results; a hypothesis is visible in the signature, where every previous vacuity failure of the project was found; and a hypothesis claims less ("if PBW, then ..."). Since pbw became a theorem that hypothesis is a *theorem* for every $\mathfrak{g}$, every invariant form, every ordered basis and every level (pbwBasis_holds, Section 3.12.3). The definition and the consequences below are unchanged; what has changed is that every hypothesis h : PBWBasis κ hκ b k in the library can now be discharged.

Definition 3.20 (Ordered creation word; PBW basis hypothesis)**.** Let $(b_i)_{i\in I}$ be a basis of $\mathfrak{g}$ indexed by a totally ordered set I, and order $I \times \mathbb{N}$ lexicographically. For a finitely supported exponent function $\mu : I \times \mathbb{N} \to \mathbb{N}$, the *ordered creation word* lists the pairs (i, n) in the support in increasing order, each repeated $\mu(i, n)$ times; the corresponding *ordered creation monomial* is

$$v_\mu = \prod_{(i,n)\ \text{increasing}} (b_i \otimes t^{-n-1})^{\mu(i,n)}|0\rangle \ \in V^k(\mathfrak{g}),$$

with the smallest pair leftmost. PBWBasis(κ, b, k) is the statement that $(v_\mu)_\mu$ is a basis of $V^k(\mathfrak{g})$.

File VOA/Foundations/PBWBasis.lean.

      ↔ AffineLie.vacuumVector κ hκ k ≠ 0 :=
```

From the mathematics to the Lean statement

Decoding. `Module.Basis ι ℂ 𝔤` is a basis of $\mathfrak{g}$ indexed by ι (a linear equivalence with `ι →₀ ℂ`); `[LinearOrder ι]` orders the index set. `ι ×ₗ ℕ` is the product with the *lexicographic* order (`×ₗ` is Mathlib's `Lex` synonym, and `ofLex` forgets the order). `(ι ×ₗ ℕ) →₀ ℕ` are the exponent functions μ. In `pbwWord`, `μ.support.sort (· ≤ ·)` lists the support in increasing order, and each $p = (i, n)$ contributes `μ p` copies of the pair (b_i, n); recall from Section 3.9 that (x, n) stands for $x \otimes t^{-n-1}$ and that the head of the list is the leftmost operator. `PBWBasis κ hκ b k` asserts that there is a basis `B` of $V^k(\mathfrak{g})$ indexed by exponent functions whose μ-th vector is the ordered creation monomial v_μ. This is Definition 3.20.

Hypotheses of the consequences. The theorems take `h : PBWBasis κ hκ b k` as an explicit hypothesis; nothing in this file is an axiom, and nothing in it uses `VOA.pbw`. `linearIndependent` extracts independence; `span_eq_top` (not displayed) extracts spanning by *ordered* words, a strengthening of `negSpan_eq_top`, which spans by *all* words; `vacuumVector_ne_zero` shows $|0\rangle = v_0 \neq 0$, i.e. `PBWBasis` implies field (A) of `PBWPrinciple` at the given $(\mathfrak{g}, \kappa, k)$.

Is `PBWBasis` true? Yes, for every $\mathfrak{g}$, κ, ordered basis b and k. By Theorem 3.13's proof, $V^k(\mathfrak{g}) \cong U(\mathfrak{n}_-)$ via $u \mapsto u|0\rangle$ (the map Φ there is inverse to it), and $\{b_i \otimes t^{-n-1}\}_{(i,n)}$ is a basis of $\mathfrak{n}_-$, ordered lexicographically; PBW for $\mathfrak{n}_-$ (Theorem 3.9) says the ordered monomials in this basis form a basis of $U(\mathfrak{n}_-)$. Any total order would do; the lexicographic one is the library's choice. So `PBWBasis` is a true hypothesis, never a vacuous one — and since `pbw` became a theorem the library proves it (Section 3.12.3). It is *logically stronger* than field (A) (it implies (A) for its instance, and asserts a whole basis), which is the sense of the docstring's "strictly stronger"; both are now theorems.

Positive control. A hypothesis of the form "there is a basis such that…" could be unsatisfiable through a badly chosen index type (two indices forced to the same vector). The theorem `pbwBasis_iff_of_subsingleton` shows that for the zero Lie algebra (with the empty basis, so a single exponent function) `PBWBasis` holds *exactly* when $|0\rangle \neq 0$; so the shape is satisfiable whenever the module is nonzero. It is a sanity check of the shape, not a proof of PBW.

Physical meaning

`PBWBasis` is the precise form of the physicist's counting of states in the vacuum sector of a current algebra: a basis is given by the normal-ordered products of the creation modes J^i_{-n-1}, ordered first by colour i and then by depth. Its graded dimension is $\prod_{n\geq 1}(1-q^n)^{-\dim \mathfrak{g}}$.

Proof on paper of `pbwBasis_iff_of_subsingleton`. If $\mathfrak{g} = 0$, every nonempty creation word is 0 (each mode is $0 \otimes t^{-n-1} = 0$), so $V^k(\mathfrak{g}) = \mathbb{C}|0\rangle$ by spanning; there is a single exponent function

$\mu = 0$, with $v_0 = |0\rangle$. A single vector is a basis of the space it spans iff it is nonzero. □

What the machine verified

`VOA.PBWBasis.linearIndependent`, `VOA.PBWBasis.vacuumVector_ne_zero`, `VOA.pbwBasis_iff_of_subsingleton`: `[propext, Classical.choice, Quot.sound]` (run for this chapter). Unconditional as implications. `PBWBasis` itself is a definition (a proposition), proved for all data by `pbwBasis_holds`; a library theorem that takes `h : PBWBasis κ hκ b k` as a hypothesis is therefore unconditional in substance, though its Lean statement still displays the (now redundant) hypothesis.

3.12.2 The hypothesis discharged for $\widehat{\mathfrak{sl}}_2$

Before the general theorem of Section 3.12.3, the hypothesis was first discharged for $\widehat{\mathfrak{sl}}_2$ at noncritical level, by a free-field argument that is still in the library and still consumed:

File `VOA/Examples/AffineSl2WakimotoLiLeading.lean`.

```
theorem affineSl2PBWBasis (k : ℂ) (hk : k + 2 ≠ 0) :
    PBWBasis AffineVOA.kappaForm AffineVOA.kappaForm_isInvariant
      (Pi.basisFun ℂ (Fin 3)) k :=
  pbwBasis_of_wakimotoOrderedCreationState_linearIndependent k hk
    (wakimotoOrderedCreationState_linearIndependent k)
```

and it is consumed, e.g., by `universalSymbolAlg_injective` in the same file (injectivity of the C_2 symbol map of $V^k(\mathfrak{sl}_2)$) and by `Examples/AffineSl2JointPBW.lean`.

From the mathematics to the Lean statement

$\mathfrak{sl}_2$ is modelled in the library as `Fin 3 → ℂ` with the bracket given by structure constants in the basis (e, f, h) (indices $0, 1, 2$; `Examples/AffineSl2.lean`), so `Pi.basisFun ℂ (Fin 3)` is the basis (e, f, h) with the order $e < f < h$ of `Fin 3`. `kappaForm` is the normalised invariant form. The hypothesis `hk : k + 2 ≠ 0` excludes the critical level $k = -h^\vee = -2$. The theorem is the instance of Definition 3.20 for $\mathfrak{sl}_2$ at every noncritical level, proved without any hypothesis. Its proof (detailed in Chapter 9) maps $V^k(\mathfrak{sl}_2)$ to the Wakimoto free-field module and shows that the images of the ordered creation monomials are linearly independent by a leading-term (triangularity) argument; the noncriticality is used by the Wakimoto realisation, not by PBW, which holds at $k = -2$ too.

Physical meaning

The Wakimoto realisation writes the $\widehat{\mathfrak{sl}}_2$ currents in terms of a $\beta\gamma$ system and a free boson with background charge depending on $k+2$. Since a free-field Fock space has a manifest basis, independence of the images of the PBW monomials can be checked there; that independence then holds in $V^k(\mathfrak{sl}_2)$ itself.

What the machine verified

`VOA.AffineSl2WakimotoLiLeading.affineSl2PBWBasis`: `[propext, Classical.choice, Quot.sound]` (run for this chapter). Unconditional for $k \neq -2$; does not use `VOA.pbw`. It is now a special case of `pbwBasis_holds` below (which also covers $k = -2$ and every ordered basis), but it is a separate proof, and the files that consume it were not rewired.

3.12.3 The hypothesis proved for every $\mathfrak{g}$

Theorem 3.21 (PBW basis of the affine vacuum module)**.** *For every complex Lie algebra $\mathfrak{g}$ (of any dimension), every symmetric invariant bilinear form κ, every basis $(b_i)_{i\in I}$ of $\mathfrak{g}$ indexed by a totally ordered set, and every $k \in \mathbb{C}$ (including the critical level),* PBWBasis(κ, b, k) *holds: the ordered creation monomials v_μ of Definition 3.20 form a basis of $V^k(\mathfrak{g})$. More precisely, the linear map $\Phi : V^k(\mathfrak{g}) \to S(\mathfrak{n}_-)$, $[a] \mapsto a\cdot 1$, given by the relative PBW representation of $\hat{\mathfrak{g}}$ on $S(\mathfrak{n}_-)\otimes\mathbb{C}_{\chi_k} \cong S(\mathfrak{n}_-)$, is a linear isomorphism.*

From the mathematics to the Lean statement

Decoding. `yMode a`, for `a = (i, n)` in `ι ×ₗ ℕ`, is the creation mode $b_i \otimes t^{-n-1}$ (depth n means mode $-n-1$, as in Section 3.9). `negComp` is their span, i.e. $\mathfrak{n}_- = \mathfrak{g}\otimes t^{-1}\mathbb{C}[t^{-1}]$, and `negComp_isCompl` says it is a vector-space complement of `nonnegSub` $= \hat{\mathfrak{p}}$ in $\hat{\mathfrak{g}}$; the omitted `negBasis` is the basis $(y_{(i,n)})$ of this complement, indexed by the lexicographically ordered `ι ×ₗ ℕ`. With these choices and the character `vacuumChar k` on the one-dimensional $U = \mathbb{C}$, the relative PBW representation of Theorem 3.15 acts on `Multiset (ι ×ₗ ℕ) →₀ ℂ`, which is $S(\mathfrak{n}_-)$ in its monomial basis; `ACT` is local notation for that action. `Φ` sends the class of $a \in U(\hat{\mathfrak{g}})$ to a applied to the vector $\varnothing \otimes 1$ (the omitted body checks that $J(k)$ acts by zero on it); `Φ_rho` says Φ is $\hat{\mathfrak{g}}$-equivariant. `ΦEquiv` upgrades Φ to a linear equivalence (`≃ₗ[ℂ]`) with inverse `Ψ`, which sends a monomial m to the sorted creation monomial of m applied to $|0\rangle$. `pbwBasis_holds` is the theorem, with *no* hypotheses beyond the data; its statement is literally `PBWBasis κ hκ b k` of Definition 3.20.

Same as the textbook? Yes, and in the strongest form: any $\mathfrak{g}$ (no finiteness), any invariant κ (possibly degenerate), any ordered basis, any k. The order on `ι ×ₗ ℕ` used to sort is the same lexicographic order in which `pbwWord` lists letters, so the basis vectors are exactly the v_μ of the definition.

Could it be vacuous? No: the conclusion is the existence of a basis *equal* to the given family of creation monomials, which pins every basis vector; and $\Phi(|0\rangle) = \varnothing \otimes 1 \neq 0$ (`Φ_vacuum`).

Proof on paper. Write ρ_Φ for the relative PBW representation of $\hat{\mathfrak{g}}$ on $S(\mathfrak{n}_-) = \bigoplus_m \mathbb{C}\,m$ built from $\hat{\mathfrak{p}}$, its complement $\mathfrak{n}_-$ with the ordered basis $y_{(i,n)}$, and the character χ_k on $\mathbb{C}$ (Theorem 3.15). Extend

it to $U(\hat{\mathfrak{g}})$ and set $\Phi([a]) = a \cdot \varnothing$. This is well defined: each generator $X - \chi_k(X)$ of $J(k)$ ($X \in \hat{\mathfrak{p}}$) kills $\varnothing$ by (E3), hence so does the left ideal $J(k)$. Φ is $\hat{\mathfrak{g}}$-equivariant by construction. By (E1), applying an ordered creation monomial $y_{a_1} \cdots y_{a_r}$ with $a_1 \le \ldots \le a_r$ to $\varnothing$ gives the monomial $a_1 \cdots a_r$; so $\Phi(v_\mu)$ = the basis monomial of $S(\mathfrak{n}_-)$ with exponents μ.

Conversely define $\Psi(m)$ = (the sorted creation monomial of m)$\cdot|0\rangle$, i.e. for $m = a_1 \cdots a_r$ with $a_1 \le \ldots \le a_r$, $\Psi(m) = y_{a_1} \cdots y_{a_r}|0\rangle$. We show $\Psi(\sigma(z)(m \otimes 1)) = z \cdot \Psi(m)$ for every generator z of $\hat{\mathfrak{g}}$ (a y_a or an element of $\hat{\mathfrak{p}}$) by induction on $|m|$, following the four equations. (E1): if $a \le m$, then $\Psi((a\,m) \otimes 1) = y_a\, y_{a_1} \cdots y_{a_r}|0\rangle = y_a \Psi(m)$ by definition of the sorted monomial. (E3): for $X \in \hat{\mathfrak{p}}$, $X|0\rangle = \chi_k(X)|0\rangle$ because $X - \chi_k(X) \in J(k)$, which matches $\sigma(X)(\varnothing \otimes 1) = \chi_k(X)\varnothing \otimes 1$. (E2): for $b < a$, $b \le m$, the left side is Ψ of the right side of (E2), which by induction (the vectors involved have degree $\le |m|$ and the y_b applied last is low) equals $y_b\, y_a \Psi(m) + [y_a, y_b]\Psi(m)$; in $U(\hat{\mathfrak{g}})$ we have $y_a y_b = y_b y_a + [y_a, y_b]$, so this is $y_a\, y_b \Psi(m) = y_a \Psi((b\,m) \otimes 1)$. (E4) is the same computation with $x \in \hat{\mathfrak{p}}$ in place of y_a, using $x y_b = y_b x + [x, y_b]$. Since every $\sigma(z)$ is determined by these equations, Ψ intertwines σ with the action of $\hat{\mathfrak{g}}$ on $V^k(\mathfrak{g})$. Then $\Phi \circ \Psi = \mathrm{id}$ on monomials (by the previous paragraph), and $\Psi \circ \Phi = \mathrm{id}$ on every creation word $w|0\rangle$: writing $w = z_1 \cdots z_r$, equivariance of Φ and of Ψ gives $\Psi\Phi(z_1 \cdots z_r|0\rangle) = z_1 \cdots z_r\, \Psi\Phi(|0\rangle)$, and $\Psi\Phi(|0\rangle) = \Psi(\varnothing) = |0\rangle$, hence on all of $V^k(\mathfrak{g})$ by the spanning theorem `negSpan_eq_top` (Theorem 3.8). So Φ is an isomorphism, and the pull-back of the monomial basis of $S(\mathfrak{n}_-)$ is the family (v_μ), which is therefore a basis. □

Physical meaning

This is the precise statement behind the physicist's character formula $\mathrm{tr}_{V^k(\mathfrak{g})}\, q^{L_0} = \prod_{n \ge 1}(1 - q^n)^{-\dim \mathfrak{g}}$ (for finite-dimensional $\mathfrak{g}$, up to the prefactor $q^{-c/24}$): the vacuum sector of a current algebra is a Fock space of $\dim \mathfrak{g}$ bosonic oscillators per mode number, with no relations among normal-ordered states, at every level including the critical one. The map Φ is the identification of the vacuum sector with that Fock space.

What the machine verified

`VOA.pbwBasis_holds`, `VOA.VacuumBasis.ΦEquiv`: `[propext, Classical.choice, Quot.sound]` (run for this chapter, Section 3.15). Unconditional. It makes every `h : PBWBasis …` hypothesis in the library dischargeable (the project lists removing such now-redundant hypotheses, e.g. in `Examples/AffineSl2UniversalC2PBW.lean`, as optional clean-up, not done when checked at an earlier commit; not re-checked for this edition).

3.13 Root data, affine Verma modules and the integrability target

All declarations of this section are in `VOA/Foundations/RootDatum.lean`. The file is scaffolding for the representation theory of affine algebras at general highest weight; little of it is consumed elsewhere, and its main theorems are either thin wrappers around Mathlib's root theory or explicitly conditional.

3.13.1 The finite root datum

Definition 3.22. Let $\mathfrak{g}$ be finite-dimensional with nondegenerate Killing form, and $\mathfrak{h} \subseteq \mathfrak{g}$ a splitting Cartan subalgebra. The roots of $(\mathfrak{g}, \mathfrak{h})$ form a reduced crystallographic root system Φ; it has a base (system of simple roots); for each root α there are $e_\alpha \in \mathfrak{g}_\alpha$, $f_\alpha \in \mathfrak{g}_{-\alpha}$ such that $(\alpha^\vee, e_\alpha, f_\alpha)$ is an $\mathfrak{sl}_2$-triple, $\alpha^\vee$ the coroot; $\beta(\alpha^\vee) \in \mathbb{Z}$ for roots α, β; a *highest root* θ is a positive root of maximal height; the *affine node* is $e_0 = f_\theta \otimes t$, $f_0 = e_\theta \otimes t^{-1}$.

From the mathematics to the Lean statement

Hypotheses. `[LieAlgebra.IsKilling ℂ 𝔤]` says the Killing form is nondegenerate (true for semisimple $\mathfrak{g}$); `H.IsCartanSubalgebra` that H is a Cartan subalgebra; `IsTriangularizable` that $\operatorname{ad} H$ is triangularisable (automatic over $\mathbb{C}$). `rootSystem H`, `coroot`, `rootSpace`, `Weight ℂ H 𝔤`, `IsSl2Triple`, `H.root`, `.Base`, `b.IsPos`, `b.height` are Mathlib's root-system vocabulary: the root system, the coroot $\alpha^\vee \in H$, the root space $\mathfrak{g}_\alpha$, a weight of H on $\mathfrak{g}$, an $\mathfrak{sl}_2$-triple $[h,e]=2e$, $[h,f]=-2f$, $[e,f]=h$, the finite type of roots, a base, positivity and height with respect to the base. `α.IsNonZero` excludes the zero weight (whose "root space" is H).

Content. `nonempty_base`, `exists_chevalleyTriple` and `cartanInteger` are restatements of Mathlib theorems (`RootPairing.nonempty_base`, `exists_isSl2Triple_of_weight_isNonZero`, `apply_coroot_eq_cast`); the library adds only the packaging. The highest root is defined as a positive root of maximal height (a choice, via `Finset.exists_max_image`); `[Nonempty H.root]` excludes the case with no roots. For simple $\mathfrak{g}$ the root of maximal height is unique, so this is *the* highest root, but uniqueness is not proved here. `affineEZero_bracket_affineFZero` is `affine_bracket` at $m=1, n=-1$: $[f_\theta\otimes t, e_\theta\otimes t^{-1}] = [f_\theta,e_\theta]\otimes 1 + \kappa(f_\theta,e_\theta)C$. The textbook form $[e_0,f_0]=C-\theta^\vee$ would need the normalisation $\kappa(f_\theta,e_\theta)=1$, which is not imposed (the docstring says so).

Physical meaning

The finite root datum classifies the symmetry algebra of the WZW model; the affine node e_0, f_0 is the extra $\mathfrak{sl}_2$ that mixes zero modes with modes ± 1, and integrability under it is the origin of the level-k truncation of the WZW spectrum (only representations with $\theta(\lambda) \le k$ appear).

What the machine verified

`VOA.RootDatum.exists_chevalleyTriple`, `VOA.RootDatum.cartanInteger`, `VOA.RootDatum.highestRoot_isNonZero`, `VOA.RootDatum.affineEZero_bracket_affineFZero`: `[propext, Classical.choice, Quot.sound]` (run for this chapter).

3.13.2 Affine Verma modules at general highest weight

Definition 3.23 (Affine Verma module). An *affine Cartan weight* λ consists of a linear form λ_{fin} on $\mathfrak{h}$, a level $\lambda(C)$ and an energy $\lambda(\ell_0)$. With a base fixed, the *Verma module* is $M(\lambda) = U(\hat{\mathfrak{g}})/I(\lambda)$, where $I(\lambda)$ is the left ideal generated by $x \otimes t^n$ ($n > 0$), the positive root vectors $x \otimes t^0$ ($x \in \mathfrak{g}_\alpha$, $\alpha > 0$), $h \otimes t^0 - \lambda_{\mathrm{fin}}(h)$ ($h \in \mathfrak{h}$), $C - \lambda(C)$ and $\ell_0 - \lambda(\ell_0)$; its highest-weight vector is $v_\lambda = [1]$.

File `VOA/Foundations/RootDatum.lean`.

```

```

From the mathematics to the Lean statement

Decoding. The five disjuncts of `vermaGens` are the five kinds of generator of Definition 3.23, in order; `vermaIdeal` is their left span. Note `0 < n` for the loop modes (the zero modes enter only through the positive root vectors and the Cartan relations), which is the Borel-type condition. `simpleHWOf h` is defined only *given* a proof `h : highestVector … ≠ 0`; every theorem about it carries this hypothesis.

The hypothesis is open in the library, though true. $v_\lambda \neq 0$ holds for every λ: it is field

(B) of `PBWPrinciple` (now the theorem `PBWTheorem.bottom_injective`) for the Borel-type subalgebra $\hat{\mathfrak{b}} = \mathfrak{n}_+ \oplus \mathfrak{h} \oplus \mathbb{C}C \oplus \mathbb{C}\ell_0$ (with $\mathfrak{n}_+$ now including the positive root spaces at mode 0) and its one-dimensional character λ, by the argument of Remark 3.14, which the library formalises for $\lambda = 0$ (Theorem 3.18) but not for general λ; the docstring of `exists_simpleHWMaxSubmodule_of_highestVector_ne_zero` calls it "the arbitrary-λ PBW nonvanishing result not yet derived here from `pbw.inducedBottom`". So the results of this subsection are `#print axioms`-clean *conditional on* $v_\lambda \neq 0$.

Physical meaning

$M(\lambda)$ is the space of all states of a current-algebra primary of weight λ and its descendants $J_{-n_1}^{a_1} \cdots v_\lambda$ before null states are removed; $L(\lambda)$, here `simpleHWOf`, is the irreducible representation, i.e. the conformal family of the primary in a theory where all nulls decouple.

What the machine verified

`VOA.AffineLie.simpleHWOf_isSimpleModule, VOA.AffineLie.simpleHighestVectorOf_ne_zero: [propext, Classical.choice, Quot.sound]` (run for this chapter), **conditional on** `highestVector H κ hκ b lam ≠ 0`, which is not discharged in the library.

3.13.3 The integrability target

File `VOA/Foundations/RootDatum.lean`.

```
def LocallyNilpotentEnd {V : Type*} [AddCommMonoid V] [Module ℂ V]
    (T : Module.End ℂ V) : Prop :=
  ∀ v : V, ∃ n : ℕ, (T ^ n) v = 0

def SimpleHWIntegrable [Nonempty H.root] (hnz : highestVector H κ hκ b lam ≠ 0) : Prop :=
  Integrable κ hκ (simpleHWOf H κ hκ b lam hnz) (simpleHWRhoOf H κ hκ b lam hnz)
    (chevalleyGeneratorSet H κ hκ b)

theorem simpleHWOf_integrable_of_chevalley_locallyNilpotent [Nonempty H.root]
    (hnz : highestVector H κ hκ b lam ≠ 0)
    (hKG : ∀ X ∈ chevalleyGeneratorSet H κ hκ b,
      LocallyNilpotentEnd (simpleHWRhoOf H κ hκ b lam hnz X)) :
    SimpleHWIntegrable H κ hκ b lam hnz := by
  exact hKG
```

Trap / dead end

A tautological wiring lemma. `Integrable … S` is defined as "every $X \in S$ acts locally nilpotently", and `SimpleHWIntegrable` is `Integrable` for the set of Chevalley generators (all e_α, f_α at mode 0 and e_0, f_0). The theorem `simpleHWOf_integrable_of_chevalley_locallyNilpotent` takes exactly that statement as its hypothesis `hKG` and returns it (`exact hKG`). It has no mathematical content; it records the shape of the open target (the Kac–Garland theorem: $L(\lambda)$ is integrable for dominant integral λ at level $\lambda(C) \in \mathbb{N}$). Integrability of $L(\lambda)$ is **not proved** in the library. A referee should not count this lemma as a result.

Physical meaning

Integrability is the algebraic shadow of unitarity of the WZW model: the representations of $\hat{\mathfrak{g}}$ that appear in the level-k WZW model are exactly the integrable ones, in which every $\mathfrak{sl}_2$-subalgebra attached to a simple root acts through finite-dimensional representations.

What the machine verified

`VOA.AffineLie.simpleHWOf_integrable_of_chevalley_locallyNilpotent: [propext, Classical.choice, Quot.sound]` (run for this chapter); a tautology.

3.14 Lattices, cocycles and parity

The five remaining files supply the data from which lattice vertex algebras (and through them the Moonshine module) are built, and the sign bookkeeping of super vertex algebras. They are presented in full, with their use, in Chapter 30 (Section 30.3.2, integral lattices), Chapter 31 (Sections 31.4 and 31.5, the cocycle and the orthonormal frame) and Chapter 1 (Section 1.2.14, parity). Here we give the statements, their meaning, and their machine status, so that this chapter covers its files; all of them report only the three standard axioms and none of them involves PBW.

3.14.1 Integral lattices

Definition 3.24 (Integral lattice). An *integral lattice* is a free $\mathbb{Z}$-module L of finite rank with a symmetric $\mathbb{Z}$-valued bilinear form $\langle\cdot,\cdot\rangle$. It is *even* if $\langle v, v\rangle \in 2\mathbb{Z}$ for all v, *positive definite* if $\langle v, v\rangle > 0$ for $v \neq 0$. Its *dual* is $L^* = \{x \in L \otimes \mathbb{R} : \langle x, v\rangle \in \mathbb{Z}\ \forall v \in L\}$, and L is *self-dual* (unimodular) if $L = L^*$.

File `VOA/Foundations/Lattices.lean`.

```

From the mathematics to the Lean statement

`IntegralLattice` bundles a type with its $\mathbb{Z}$-module structure, freeness, finite generation, the form and its symmetry; the bracketed fields are made instances. `L.dual` is defined (not shown) as the additive subgroup of `ℝ ⊗[ℤ] L.carrier` of elements whose real pairing with every `toReal v` $= 1 \otimes v$ is an integer, and `SelfDual` says it is exactly the image of L. **One difference from the textbook**: `PosDef` is positivity on *integer* points; for an integral form this is equivalent to positive definiteness over $\mathbb{R}$ (positivity on $\mathbb{Q}^r \setminus 0$ gives semidefiniteness over $\mathbb{R}$ by density, and a real null direction of an integral form would be a rational one, since the kernel of an integer matrix is defined over $\mathbb{Q}$). The library proves the needed consequence (Theorem 3.26 below), so nothing rests on this remark. Nondegeneracy is not part of `IntegralLattice`; it follows from `PosDef` when that is assumed. `latticeAlgebra L` is the group algebra $\mathbb{C}[L]$ with $e^u e^v = e^{u+v}$ (untwisted).

Physical meaning

L is the momentum (charge) lattice of r chiral bosons compactified on the torus $L \otimes \mathbb{R}/L$; evenness makes all vertex operators $e^{i\alpha\cdot X}$ have integer conformal weight $\langle\alpha,\alpha\rangle/2$ (bosonic statistics), self-duality makes the chiral theory modular invariant on its own (holomorphic).

What the machine verified

`VOA.IntegralLattice.le_dual, VOA.stdLattice_selfDual: [propext, Classical.choice, Quot.sound]` (run for this chapter).

3.14.2 The FLM cocycle and the twisted group algebra

Theorem 3.25 (FLM cocycle). *Let L have $\mathbb{Z}$-basis $B_1,\dots,B_n$ and put $\mathrm{coc}(\alpha,\beta)=\sum_{j<i}\langle B_i,B_j\rangle\alpha_i\beta_j$ (coordinates in the basis) and $\varepsilon(\alpha,\beta)=(-1)^{\mathrm{coc}(\alpha,\beta)}$. Then ε is bimultiplicative, normalised ($\varepsilon(0,\cdot)=\varepsilon(\cdot,0)=1$), a 2-cocycle, $\varepsilon(\alpha,\beta)\varepsilon(\alpha+\beta,\gamma)=\varepsilon(\beta,\gamma)\varepsilon(\alpha,\beta+\gamma)$, and, if L is even, $\varepsilon(\alpha,\beta)\varepsilon(\beta,\alpha)=(-1)^{\langle\alpha,\beta\rangle}$. Consequently the product $e^\alpha\star e^\beta=\varepsilon(\alpha,\beta)e^{\alpha+\beta}$ on $\mathbb{C}[L]$ is associative with unit e^0.*

File `VOA/Foundations/LatticeCocycle.lean`. The section variables are

```
variable (L : IntegralLattice) {n : ℕ} (B : Basis (Fin n) ℤ L.carrier)
```

and, with them, the general cocycle and its properties:

```
noncomputable def cocExp (α β : L.carrier) : ℤ :=

```

From the mathematics to the Lean statement

Context. `L : IntegralLattice` is an integral lattice (Definition 3.24); `L.carrier` is its underlying free $\mathbb{Z}$-module and `L.form` its $\mathbb{Z}$-valued symmetric form. `n` is the rank, and `B : Basis (Fin n) ℤ L.carrier` is a $\mathbb{Z}$-basis $B_0, \dots, B_{n-1}$ of L indexed by `Fin n` $= \{0, \dots, n-1\}$ with its usual order (the order enters through `j < i`). The general theorems hold for *every* such basis. **Matching the theorem.** `cocycle_add_left`, `cocycle_add_right` are bimultiplicativity, `cocycle_zero_left`, `cocycle_zero_right` normalisation, `cocycle_cocycleLaw` the 2-cocycle law, `cocycle_comm` the commutator property. `latticeBasis L` is a basis chosen once and for all (from Mathlib's `Module.Free.chooseBasis`, reindexed by `Fin`); `latticeCocycle` is `cocycle` at that basis, and its theorems are, by their one-line proof terms, literally the general theorems instantiated at `B := latticeBasis L`. `B.repr α i` is the i-th coordinate of α in the basis `B`; `cocExp` is the "upper-triangular Gram" exponent; `(-1 : ℂ) ^ z` with $z \in \mathbb{Z}$ is an integer power, so ε is ± 1 (`cocycle_sq`). `latticeCocycle` fixes the basis `latticeBasis L` (a chosen basis); all properties hold for every basis. `cocycle_comm` needs `hEven`: the diagonal terms $\langle B_i, B_i\rangle \alpha_i \beta_i$ are dropped from coc, which is harmless exactly when they are even. The FLM requirement is $\varepsilon(\alpha,\beta)/\varepsilon(\beta,\alpha) = (-1)^{\langle\alpha,\beta\rangle}$; since $\varepsilon = \pm 1$, quotient and product agree. `twMul` is the bilinear extension of $e^\alpha \star e^\beta = \varepsilon(\alpha,\beta) e^{\alpha+\beta}$ (`twMul_e`), kept as an operation rather than a ring instance so as not to clash with the untwisted product on the same carrier.

Physical meaning

$\varepsilon(\alpha,\beta)$ are the Klein factors (cocycle factors) of the compactified boson: without them, vertex operators $e^{i\alpha X}$, $e^{i\beta X}$ with odd $\langle\alpha,\beta\rangle$ would anticommute instead of commute (their operator product picks up $(-1)^{\langle\alpha,\beta\rangle}$ under exchange), and the lattice theory would not be a consistent bosonic chiral algebra. The twisted group algebra $\mathbb{C}_\varepsilon[L]$ is the algebra of the charge-shift (zero-mode) operators.

Proof on paper. coc is $\mathbb{Z}$-bilinear, so ε is bimultiplicative, and both sides of the cocycle law equal $(-1)^{\mathrm{coc}(\alpha,\beta)+\mathrm{coc}(\alpha,\gamma)+\mathrm{coc}(\beta,\gamma)}$. For the commutator, $\mathrm{coc}(\alpha,\beta)+\mathrm{coc}(\beta,\alpha) = \sum_{i\neq j}\langle B_i,B_j\rangle\alpha_i\beta_j = \langle\alpha,\beta\rangle - \sum_i \langle B_i,B_i\rangle\alpha_i\beta_i$ (using symmetry), and the last sum is even when L is even. Associativity of $\star$ on basis vectors is the cocycle law; normalisation gives the unit. □

What the machine verified

`VOA.IntegralLattice.latticeCocycle_cocycleLaw`, `VOA.IntegralLattice.latticeCocycle_comm`, `VOA.IntegralLattice.twMul_assoc`, `VOA.IntegralLattice.one_twMul`: `[propext, Classical.choice, Quot.sound]` (run for this chapter). Likewise `VOA.IntegralLattice.cocycle_add_left`, `cocycle_add_right`, `cocycle_zero_left`, `cocycle_zero_right`, `cocycle_sq` (separate probe at an earlier commit, not re-run for this edition, importing `VOA.Foundations.LatticeCocycle`). Unconditional.

3.14.3 Finiteness of bounded vectors and the orthonormal frame

Theorem 3.26. *If L is positive definite, then for every $N \in \mathbb{Z}$ the set $\{\alpha \in L : \langle\alpha,\alpha\rangle \le N\}$ is finite. Moreover, writing G for the real Gram matrix in the chosen basis and $C = \sqrt{G}$ (its positive square root), the real coordinates $\tilde\alpha = C \cdot \mathrm{coord}(\alpha)$ satisfy $\sum_a \tilde\alpha_a\tilde\beta_a = \langle\alpha,\beta\rangle$.*

File `VOA/Foundations/LatticeCocycle.lean`.

```

```
theorem boundedFinite (hPos : L.PosDef) : BoundedFinite L :=
  boundedFinite_of_coercive L hPos (coercive L hPos)
```

File `VOA/Foundations/LatticeOrthoFrame.lean`.

```
noncomputable def frame : Matrix (Fin (latRank L)) (Fin (latRank L)) ℝ := CFC.sqrt (gramR
 ↪  L)

noncomputable def orthCoord (α : L.carrier) : Fin (latRank L) → ℝ := frame L *ᵥ coordR L α

theorem orthCoord_inner (hPos : L.PosDef) (α β : L.carrier) :
    ∑ a, orthCoord L α a * orthCoord L β a = ((L.form α β : ℤ) : ℝ) := by
```

From the mathematics to the Lean statement

`BoundedFinite` is the finiteness statement; `boundedFinite` derives it from integer positivity through real coercivity ($\exists m > 0,\ m\|c\|^2 \le Q(c)$), proving along the way exactly the $\mathbb{Z} \Rightarrow \mathbb{R}$ positivity bridge discussed after Definition 3.24. `CFC.sqrt` is Mathlib's continuous-functional-calculus square root; `*ᵥ` is matrix–vector multiplication; `coordR α` the real-cast coordinates. `orthCoord_inner` is the second sentence of the theorem, with the hypothesis `hPos` needed for $C^2 = G$.

Physical meaning

Finiteness of bounded vectors makes each L_0-eigenspace of the lattice VOA finite-dimensional (finitely many momenta below any energy), so that the partition function $\theta_L(q)/\eta(q)^r$ is well defined. The orthonormal frame expresses the lattice bosons $\alpha(z) = \sum_a \tilde\alpha_a\,\partial X^a(z)$ in terms of r canonically normalised free bosons.

What the machine verified

`VOA.IntegralLattice.boundedFinite`, `VOA.IntegralLattice.orthCoord_inner`: `[propext, Classical.choice, Quot.sound]` (run for this chapter).

3.14.4 Parity and the Koszul sign

Definition 3.27. For $p, q \in \mathbb{Z}/2$ let $(-1)^p$ be the sign character and $\epsilon(p,q) = (-1)^{pq}$ the Koszul sign. A *parity grading* of a vector space is a decomposition $V = V_{\bar{0}} \oplus V_{\bar{1}}$; its *fermion-number involution* $(-1)^F$ is $+1$ on $V_{\bar{0}}$ and -1 on $V_{\bar{1}}$.

File `VOA/Foundations/Parity.lean`.

```
def parSign (p : ZMod 2) : ℂ := if p = 0 then 1 else -1

def koszul (p q : ZMod 2) : ℂ := parSign (p * q)

theorem koszul_add_left (p p' q : ZMod 2) :
    koszul (p + p') q = koszul p q * koszul p' q := by

structure ParityGrading (𝒱 : Type*) [AddCommGroup 𝒱] [Module ℂ 𝒱] where
  parity : ZMod 2 → Submodule ℂ 𝒱
  isInternal : DirectSum.IsInternal parity

noncomputable def parityInvol (P : ParityGrading 𝒱) : Module.End ℂ 𝒱 :=
  (2 : ℂ) • ((P.parity 0).projection (P.parity 1) P.isCompl01) - LinearMap.id

theorem koszulOp_homog (P : ParityGrading 𝒱) (p : ZMod 2) {q : ZMod 2} {u : 𝒱}
    (hu : u ∈ P.parity q) : P.koszulOp p u = koszul p q • u := by
```

From the mathematics to the Lean statement

`ZMod 2` is $\mathbb{Z}/2$. `parSign p` is $(-1)^p$ and `koszul p q` is $(-1)^{pq}$. `ParityGrading` is an internal direct-sum decomposition indexed by $\mathbb{Z}/2$; it is deliberately independent of the conformal-weight grading (no spin–statistics relation is imposed, so that the $\beta\gamma$ and bc systems fit). `parityInvol` is $2\pi_0 - \mathrm{id}$ with π_0 the projection onto $V_{\bar{0}}$ along $V_{\bar{1}}$, i.e. $(-1)^F$; `koszulOp p` is id for $p = 0$ and $(-1)^F$ for $p = 1$, and `koszulOp_homog` says it multiplies a vector of parity q by $(-1)^{pq}$.

Physical meaning

The Koszul sign is Fermi statistics: exchanging two odd (fermionic) fields costs a sign. $(-1)^F$ is the fermion-number operator, which also implements the Neveu–Schwarz/Ramond twist in super vertex algebras (Chapter 17).

What the machine verified

`VOA.koszul_add_left`, `VOA.ParityGrading.koszulOp_homog`: `[propext, Classical.choice, Quot.sound]` (run for this chapter).

3.15 The verification record

The following was run by the author of this chapter at an earlier commit, after `pbw` became a theorem (not re-run for this edition), on three scratch files, with the command

```
lake env lean -DmaxSynthPendingDepth=3 PbwProbe.lean
```

(never a bare `lake env lean`, which can silently change elaboration; see Chapter 43). The compiled library was already present and its `.olean` files were checked to be newer than the corresponding sources; no `lake build` was run for this chapter. The first file contained exactly

```
import VOA.Foundations.AffineLie
#print axioms VOA.pbw
#print axioms VOA.PBWTheorem.bottom_injective
#print axioms VOA.AffineLie.vacuumVector_ne_zero_of_induction
#print axioms VOA.AffineLie.vacuumVector_ne_zero
#print axioms VOA.AffineLie.vacuumSpace_nontrivial
#print axioms VOA.AffineLie.exists_vacuumMaxSubmodule
#print axioms VOA.AffineLie.vacuumSimple_isSimpleModule
```

and its complete output was

```

Together the three files cover every declaration named in a status box of this chapter except the five cocycle lemmas `cocycle_add_left`, `cocycle_add_right`, `cocycle_zero_left`, `cocycle_zero_right`, `cocycle_sq`, which were checked by a separate probe (Section 3.14); the 73 displayed probes all report exactly `[propext, Classical.choice, Quot.sound]`. A text search for uses of `VOA.pbw` in proof terms at that commit finds exactly the two direct consumers of Section 3.11. According to the project's build record, the aggregate `lake build VOA` was last run green on 26 October 2026 (13868 jobs) with the axiom audit passing; this was not re-run here.

Release audit 2026-10-27. `Notes/Textbook/referee/RELEASE_AUDIT_FOUNDATIONS.md` independently re-ran `#print axioms VOA.pbw` (the three standard axioms) and confirmed that `VOA.pbw` is a theorem at `VOA/Foundations/AffineLie.lean` and that the repository declares no axiom. Its findings bearing on this chapter: `AffineVOA.WakModule` is the universal vacuum module $V^k(\mathfrak{sl}_2)$ of this chapter, not a Wakimoto module; the derivation ℓ_0 is killed by the vacuum ideal, which gives the same vacuum module; the Virasoro VOA's carrier is `VirUniv c`, the universal $V(c,0)$; and the zero space counts as a VOA, so nonvanishing results such as `vacuumVector_ne_zero` carry real content.

Historical record (first edition). The first edition's probe, on a scratch file importing `VOA`, gave the following (abridged to one line per declaration). It is kept because it documents what depended on the axiom while there was one.

```

A second probe then gave `[propext, Classical.choice, Quot.sound]` for `VOA.Wak.vacuumA_ne_zero_free`, `VOA.zhuModularity_pinned_of_C2Cofinite`, `VOA.AffineSl3.simpleVOA`, `VOA.AffineSl3.simple_regular_isTrivial`, `VOA.AffineSl3.vacuumA_ne_zero`, and `[propext, Classical.choice, Quot.sound, VOA.pbw]` for `VOA.AffineVOA.vacuumA_ne_zero`, `VOA.QuasiLisseSl2.vacuum_simpleSl2QL_ne_zero`, `VOA.QuasiLisseSl2.character_formalODE_simpleSl2QL` and `VOA.zhuModularity_pinned_of_C2Cofinite_voaPBW` (58 declarations were probed in all).

3.16 Referee's checklist

The table lists the chapter's headline declarations with their intended meaning, their hypotheses and machine status, and the place where the fidelity check is carried out. Every declaration listed reports

exactly [propext, Classical.choice, Quot.sound] (Section 3.15); the library has no project axiom. Entries in bold mark a condition not discharged in the library, or a tautology.

Lean declaration	Intended meaning	Hypotheses / status	Fidelity check
VOA.pbw (PBWPrinciple)	(A) affine vacuum $\neq 0$ for all $\mathfrak{g}, \kappa, k$; (B) $U \to U(\mathfrak{g}) \otimes_{U(\mathfrak{p})} U$ injective for all $\mathfrak{g}, \mathfrak{p}, \rho$	theorem, unconditional (formerly a project axiom)	§3.10
PBWTheorem.rep, rep_p_zero	relative PBW representation on $S(\mathfrak{c}) \otimes U$	unconditional, any field	Thm. 3.15
PBWTheorem.bottom_injective	field (B), any field	unconditional	Thm. 3.17
AffineLie.vacuumVector_ne_zero_of_induction	field (A) from (B)	unconditional	Thm. 3.18
PBWInduction.Induced, bottom	induced module, $u \mapsto [1 \otimes u]$	definitions	Prop. 3.11
AffineLie.vacuumVector_ne_zero	$\|0\rangle \neq 0$ in $V^k(\mathfrak{g})$	none; via theorem VOA.pbw	§3.11
AffineLie.vacuumSimple_isSimpleModule	$L(0)$ simple	none; chosen coatom	§3.11
VHat.DLM3.voaPBWBottomInjective	bottom of DLM induced module embeds	none; via theorem VOA.pbw	§3.11
Witt.gen_bracket	$[\ell_m, \ell_n] = (m-n)\ell_{m+n}$	unconditional	§3.5
virasoro_bracket	Virasoro relation, $c/12\,(m^3-m)$	unconditional	§3.5
vacVec_ne_zero	Virasoro vacuum $\neq 0$	unconditional, pbw-free	§3.6
AffineLie.affine_bracket	affine relation with $m\kappa\delta C$	hκ (invariance)	§3.7
AffineLie.vacuum_cyclic etc.	vacuum conditions, cyclicity	unconditional	§3.8
AffineLie.negSpan_eq_top	creation monomials span	unconditional	§3.9
AffineLie.ell0_isInternal, eigenspace_zero_eq, eigenspace_finiteDimensional	energy grading, $V_0 = \mathbb{C}\|0\rangle$ (spanned), finite pieces	last needs $\dim \mathfrak{g} < \infty$	§3.9
PBWBasis	ordered monomials form a basis	definition (a proposition); proved by pbwBasis_holds	§3.12
pbwBasis_holds	PBW basis of $V^k(\mathfrak{g})$, all $\mathfrak{g}, \kappa, b, k$	unconditional	Thm. 3.21
PBWBasis.vacuumVector_ne_zero	PBWBasis $\Rightarrow \|0\rangle \neq 0$	h : PBWBasis …	§3.12
pbwBasis_iff_of_subsingleton	shape is satisfiable	$\mathfrak{g} = 0$	§3.12
affineSl2PBWBasis	PBW basis for $\widehat{\mathfrak{sl}}_2$	$k \neq -2$; Wakimoto proof, no VOA.pbw	§3.12
RootDatum.exists_chevalleyTriple, cartanInteger	root datum	IsKilling, Cartan	§3.13
AffineLie.simpleHWOf_isSimpleModule	$L(\lambda)$ simple	**conditional** on $v_\lambda \neq 0$ (open in library)	§3.13
simpleHWOf_integrable_of_chevalley_locallyNilpotent	integrability	**tautology**; Kac–Garland open	§3.13
stdLattice_selfDual	$\mathbb{Z}^n$ unimodular	unconditional	§3.14
latticeCocycle_comm	$\varepsilon(\alpha,\beta)\varepsilon(\beta,\alpha) = (-1)^{\langle\alpha,\beta\rangle}$	L.Even	§3.14

Lean declaration	Intended meaning	Hypotheses / status	Fidelity check
`twMul_assoc`	$\mathbb{C}_\varepsilon[L]$ associative	unconditional	§3.14
`boundedFinite`	finitely many short vectors	`L.PosDef`	§3.14
`orthCoord_inner`	orthonormal frame realises form	`L.PosDef`	§3.14
`koszulOp_homog`	$(-1)^{pq}$ on homogeneous vectors	unconditional	§3.14

Points the referee should take away:

1. The library has *no* project axiom. `VOA.pbw`, formerly the project's sole axiom, is now a theorem proved from Mathlib alone by relative PBW (Section 3.10.6); `#print axioms VOA.pbw` reports the three standard axioms.

2. `PBWPrinciple` is the intended statement: Section 3.10 unfolds each definition it mentions, identifies its two fields with classical consequences of PBW, and lists the slips that would have made it false or empty.

3. `VOA.pbw` is used directly in exactly two places. The results that used to inherit the axiom (the `_voaPBW` wrappers and the legacy affine $\mathfrak{sl}_2$ nonvanishing route) are now `#print axioms`-clean; those that carry other hypotheses (e.g. `hC2`, `hSR`, `hFin`, `hZhu`) remain conditional on them as stated. Of these, `hFin`, `hZhu`, `hss` and `[Finite (Φ W)]` are now discharged by library theorems, and Zhu's theorem holds for every C_2-cofinite `AdmissiblyRational` VOA (`zhuModularity_canonical_of_C2Cofinite_admissiblyRational`); only the relation of `AdmissiblyRational` to Dong–Li–Mason rationality is open. The axiom-free twins with `Pr : BottomProjection …`, `PBWFreeness` or `h : PBWBasis …` hypotheses are historical; those hypotheses are now always dischargeable.

4. `PBWBasis`, introduced as a named hypothesis, is a theorem for every $\mathfrak{g}$, κ, ordered basis and level (`pbwBasis_holds`).

5. Documentation lags found (a sample, not an exhaustive list): the `PBWBasis.lean` module docstring, which still calls `pbw` an axiom and `PBWBasis` an unproved hypothesis; the `AffineSl2VOAInstance.lean` remark that no pbw-free proof of nonvanishing is possible; and the closing comment of `ZhuVermaAnArchDLM3PBWAxiom.lean`. Comments calling `VOA.pbw` an axiom are out of date throughout the library (Notes/Textbook/referee/pbw_sweep.md lists the book-side occurrences). None affects a Lean statement.

6. Two results of `RootDatum.lean` are conditional on an undischarged (but true) hypothesis, and one is a tautology; none of them is used by a headline theorem.

3.17 Notes and references

PBW. The theorem goes back to H. Poincaré (1900), G. Birkhoff (1937) and E. Witt (1937). Our proof sketch follows J. E. Humphreys, *Introduction to Lie Algebras and Representation Theory*, Graduate Texts in Mathematics 9, Springer, 1972, §17.3–17.4; the general (any dimension, any field) statement and the freeness of $U(\mathfrak{g})$ over $U(\mathfrak{p})$ are in J. Dixmier, *Enveloping Algebras*, North-Holland, 1977 (reprinted by the AMS, Graduate Studies in Mathematics 11, 1996), §2.1 (Theorem 2.1.11, the reference cited in the library's docstrings) and §2.2. Chapter 4

Vertex algebra axioms, the Borcherds identity, and reconstruction

This chapter documents the release of the LeanVOA library named in the front matter. Every Lean quotation below is checked by `scripts/textbook/sync.py` to occur verbatim (up to whitespace and comments) in the source files of that release. Checks that were run at an earlier state of the library and not re-run for this edition are marked as such. The chapter covers the twenty-seven files assigned to it in `Notes/Textbook/assignment.txt`, all in `VOA/Core/`: `BareVA`, `VertexAlgebra`, `VertexOperatorAlgebra`, `Fields`, `Identities`, `OPE`, `Goddard`, `Dong`, `FieldOps`, `FieldCombinatorics`, `Reconstruction`, `BorcherdsIdentity`, `Borcherds`, `Skew`, `WeakAssoc`, `SkewSymmetry`, `FLM`, `Commutativity`, `ReconstructionExistence`, `TensorFieldLift`, the five `LocalSystem*` files, `FieldProductIterate` and `JacobiLocal` (each with suffix `.lean`).

4.1 What this chapter is about, and what it found

Chapter 1 stated the library's structures `PreVertexAlgebra` (Gannon's axioms VA1–VA5 on a graded space, which, as this chapter shows, do *not* make a vertex algebra in the standard sense; hence the prefix) and `VertexOperatorAlgebra` (the Lepowsky–Li/FLM vertex operator algebra, or VOA, *of CFT type*, the CFT-type layer over the general notion `GradedVertexOperatorAlgebra`), and it stated the most important theorems about them — the Borcherds identity, skew-symmetry, Goddard uniqueness, Dong's lemma, the reconstruction theorem — with short proofs. Chapter 2 develops the formal calculus (formal distributions, the delta function, locality, the decomposition of a local distribution into derivatives of the delta function) on which all of this rests. The present chapter goes one level deeper. It has four jobs.

1. **Audit the axioms.** We compare the library's structures `PreVertexAlgebra`, `BarePreVA` and `VertexOperatorAlgebra` with the textbook definitions of Borcherds, Frenkel–Lepowsky–Meurman (FLM), Kac, Frenkel–Ben-Zvi and Lepowsky–Li, axiom by axiom: is the translation operator part of the data or derived? is truncation required for all pairs? is the Jacobi identity an axiom, and if not, is it proved in all indices?

2. **Present the derivation of the Borcherds identity** from locality, step by step, as the library actually carries it out: Goddard uniqueness, Dong's lemma, translation covariance, the field n-th product theorem for $n \geq 0$ and $n < 0$, the iterate formula for all ℓ, and the Pascal-recursion argument that assembles the full three-index identity.

3. **Present the further structure theory** proved in these files: skew-symmetry and the weak-associativity argument behind it, the FLM associativity formula, commutative vertex algebras, the operator-first reconstruction theorem, the tensor-product lift of fields, Li's local systems

of weak vertex operators (including a Borcherds identity for an arbitrary pair of local fields on an arbitrary vector space), and the localisation of the first-order Jacobi identity used in deformation theory.

4. **Record precisely what is conditional, what is incomplete, and where the library's documentation over-claims.**

The main finding of this chapter: Gannon's axioms, `PreVertexAlgebra`, do not give a vertex algebra in the textbook sense

The library's structure `VOA.PreVertexAlgebra` transcribes Gannon's Definition 5.1.3(a): a graded space with a state–field map satisfying vacuum, creation, locality and truncation. It has **no translation-covariance axiom**. The textbook definitions (Kac, Frenkel–Ben-Zvi) include a translation operator T with $[T, Y(u,z)] = \partial_z Y(u,z)$ as part of the data; the FLM/Lepowsky–Li definitions take the Jacobi identity as an axiom, from which translation covariance follows. Without it, *the Borcherds identity does not follow.* We exhibit in Section 4.5 a three-dimensional graded space satisfying every field of `PreVertexAlgebra` on which the Borcherds identity, skew-symmetry and the derivative property $Y(Tu,z) = \partial_z Y(u,z)$ all fail. The counterexample was checked in Lean for this chapter, axiom-clean, and has since been vendored into the library as `VOA.TranslationCovariantCounterexample.VA`, with `not_isTranslationCovariant` and `jacobi_fails` (file `VOA/Core/TranslationCovariant.lean`).

The library itself is consistent with this: every theorem that needs translation covariance (the Borcherds identity, skew-symmetry, the duality formulas, the commutative-algebra theorem) is stated for `VertexOperatorAlgebra`, whose axiom (VOA3), $Y(L_{-1}v,z) = \partial_z Y(v,z)$, supplies exactly the missing ingredient. What was wrong is *documentation*: (i) an earlier docstring of `VOA/Core/BareVA.lean` asserted that the axioms VA2–VA5 are "all the Borcherds/Jacobi derivation actually consumes" and planned to restate the Borcherds chain over `BarePreVA`; this is false, and the plan is a dead end unless a translation axiom is added. The current docstring has been corrected: it carries a **Warning** that VA2–VA5 alone do not imply the Borcherds/Jacobi identity, cites the counterexample of Section 4.5, and calls the restatement over `BarePreVA` a dead end. (ii) An earlier version of the fidelity check of the vertex-algebra definition in Chapter 1 called the library's definition "stronger" than Kac's and said that locality and Jacobi are equivalent "for vertex algebras" (Chapter 1 now corrects this); the first claim is incorrect (the two definitions are incomparable: the library's has an extra grading but lacks translation covariance), and the second holds only in the presence of translation covariance, hence for the library's VOAs but not for its `PreVertexAlgebra`s. For VOAs, we show (on paper, Section 4.4) that the library's definition is exactly the Lepowsky–Li definition plus the CFT-type condition; only the direction "library VOA ⇒ Lepowsky–Li VOA" is machine-checked.

The release audit of 2026-10-27 (`Notes/Textbook/referee/RELEASE_AUDIT_FOUNDATIONS.md`, finding M-1) recompiled the counterexample and confirmed this finding. Its wording, which this chapter adopts: the library's `VertexOperatorAlgebra` is the Lepowsky–Li/FLM VOA **of CFT type** ($V_0 = \mathbb{C}\mathbf{1}$, $V_n = 0$ for $n < 0$, integer grading, finite-dimensional pieces), so every theorem about `VertexOperatorAlgebra` is a theorem about VOAs of CFT type only; `PreVertexAlgebra` and `BarePreVA` are **not** vertex algebras in the standard sense, and the Borcherds identity, a theorem for `VertexOperatorAlgebra`, fails for them. Where this chapter says "vertex algebra in the library's sense" or "bare vertex algebra" it means these weaker structures ("graded VA1–VA5 data"), never the textbook notion, and never the library's `VertexAlgebra` described next.

The library's response: names that say what the structures are. After this finding the library renamed its structures (28 October 2026). The structure transcribing Gannon's axioms, formerly called `VertexAlgebra`, is now `PreVertexAlgebra` (pro-

jection `toPreVertexAlgebra`); its ungraded companion, formerly `BareVA`, is `BarePreVA`. The name `VertexAlgebra` now denotes the genuine notion: a `PreVertexAlgebra` together with the field `translation_covariant`, which says $Y(Tu,z) = \partial_z Y(u,z)$ for the intrinsic translation operator $Tu = u_{(-2)}\mathbf{1}$ (file `VOA/Core/GenuineVertexAlgebra.lean`). On the conformal side there are two layers: `GradedVertexOperatorAlgebra` extends `PreVertexAlgebra` by a conformal vector, the axioms (VOA1)–(VOA3) and truncation from below ($V_n = 0$ for $n \ll 0$), which is the FLM/Lepowsky–Li notion (written with locality in place of the Jacobi identity); `VertexOperatorAlgebra` extends it by the two CFT-type fields `vacuum_grade` and `positivity`, i.e. (VOA4). Every VOA is a vertex algebra in the new sense, by `VertexOperatorAlgebra.toVertexAlgebra`, whose covariance field is `VertexOperatorAlgebra.isTranslationCovariant`. The structure theory of this chapter (Borcherds identity, skew-symmetry, FLM associativity, ...) is proved for `VertexOperatorAlgebra`; the library does not restate it for `VertexAlgebra` or for `GradedVertexOperatorAlgebra`.

How the chapter is organised. Section 4.2 recalls the conventions (modes, locality, fields, normal ordering) in the form used below. Section 4.3 presents the three structures and Section 4.4 compares them with the literature; Section 4.5 gives the counterexample. Sections 4.6–4.9 treat what holds at the level of the weak structures `PreVertexAlgebra`/`BarePreVA`: product fields, the operator product expansion, Goddard uniqueness and Dong's lemma. Section 4.10 is the "reconstruction cascade" at the VOA level, Section 4.11 the full Borcherds identity, Section 4.12 skew-symmetry, Section 4.13 the FLM associativity formula, and Section 4.14 commutative vertex algebras. Sections 4.15–4.17 treat the existence side: reconstruction, tensor lifts, local systems and the localised Jacobi identity. The chapter ends with the referee's checklist and the notes.

The logical skeleton in one paragraph. At the bare level one has: (a) the iterated product $Y(u,z_1)Y(v,z_2)x$ lies in $V((z_1))((z_2))$, on which $z_1 - z_2$ is not a zero divisor; (b) hence a field local with every $Y(b,\cdot)$ is determined by what it does to the vacuum (Goddard); (c) locality is preserved by all field products (Dong). At the VOA level one adds: (d) $Y(u,z)\mathbf{1} = e^{zT}u$ (from VOA3); then (e) every field product $Y(u,\cdot)_{(n)}Y(v,\cdot)$ is local with all $Y(b,\cdot)$ by (c) and creates $u_{(n)}v$ by (d), so equals $Y(u_{(n)}v,\cdot)$ by (b) — this is the *duality* or *n-th product theorem*; (f) its $n \geq 0$ case gives the commutator formula, its all-n case gives the iterate formula, and a Pascal recursion glues these into the Borcherds identity; (g) skew-symmetry is again (b), applied to the field $v \mapsto e^{zT}Y(v,-z)u$, whose locality is the hard computation.

4.2 Conventions recalled

We use the conventions of Chapter 1 and Chapter 2 throughout. Since every fidelity check below depends on them, we restate the four that matter most.

Distributions are indexed by powers of z; modes by the shifted index. A formal distribution with coefficients in a space W is a function $f : \mathbb{Z} \to W$, read as $\sum_k f(k)z^k$ (`VOA.FormalDist`, written `W⟦z^±⟧`). The *mode* is `mode f n = f (-n - 1)`, so that for $f = Y(u,z) = \sum_n u_{(n)}z^{-n-1}$ one has `mode (Y u) n` $= u_{(n)}$, while `(Y u) k` is the coefficient of z^k, i.e. $u_{(-k-1)}$. Both indexings occur in the statements below and we decode each occurrence. The n-th product is `V.smul u n v := mode (V.Y u) n v` $= u_{(n)}v$ (the name `smul` has nothing to do with scalar multiplication). The derivative is `deriv f k = (k+1) • f (k+1)`, the coefficientwise ∂_z; in modes, $(\partial_z f)_{(m)} = -m\, f_{(m-1)}$.

Two-variable distributions and locality. A two-variable distribution is $F : \mathbb{Z} \to \mathbb{Z} \to W$, $F(m,n)$ being the coefficient of $z_1^m z_2^n$ (`FormalDist₂`). Multiplication by $z_1 - z_2$ is `mulBySub F m n = F (m-1) n - F m (n-1)` and `mulBySubPow N` is its N-th iterate. The commutator of two operator-

valued distributions is `bracketDist a b m n = a m * b n - b n * a m`, and

$$\texttt{Local a b} \quad :\Longleftrightarrow \quad \exists N \in \mathbb{N},\ (z_1 - z_2)^N [a(z_1), b(z_2)] = 0.$$

The j-th *OPE coefficient* of a two-variable distribution is `cCoeff j F`$(w) = \mathrm{Res}_{z_1}(z_1 - w)^j F(z_1, w)$, i.e. `cCoeff j F n = mulBySubPow j F (-1) n` (no factorial). Chapter 2 proves (`local_iff_deltaSum`, Gannon Prop. 5.1.2) that $(z_1 - z_2)^N F = 0$ if and only if $F = \sum_{j<N} c_j(z_2)\partial_{z_2}^j \delta(z_1/z_2)$ for some one-variable c_j, where the building block `deltaDeriv j c` has $z_1^m z_2^n$-coefficient $\big(\prod_{i<j}(-m-1-i)\big)\, c(m+n+1+j)$; and then $c_j = \frac{1}{j!}$ `cCoeff j F`.

Fields and lower truncation. The library's predicate is

```
def IsField (a : FormalDist (End ℂ V)) : Prop :=
  ∀ x : V, ∃ B : ℤ, ∀ n : ℤ, n < B → a n x = 0
```

File `VOA/Core/Dong.lean` (`VOA.IsField`). In modes: for each vector x, $a_{(m)}x = 0$ for $m \gg 0$, i.e. $a(z)x \in V((z))$. This is Kac's notion of field and Lepowsky–Li's "truncation".

Normal ordering. The two-variable normal-ordered product is `normalOrdered a b m n = if 0 ≤ m then a m * b n else b n * a m`: the coefficients of *nonnegative* powers of z_1 (the modes $a_{(k)}$ with $k \le -1$, which create states) go to the left. The same-variable product $:a(z)b(z):$ of two fields is `nprod ha hb`, with z^s-coefficient $\sum_m$ `normalOrdered a b m (s-m)` (a finite sum on each vector), and the negative products are

```
noncomputable def negProd {a b : FormalDist (End ℂ V)} (ha : IsField a) (hb : IsField b)
    (m : ℕ) : FormalDist (End ℂ V) :=
  (m.factorial : ℂ)⁻¹ • nprod (ha.deriv_iterate m) hb
```

File `VOA/Core/Dong.lean`. So `negProd ha hb m` $= \frac{1}{m!}:(\partial_z^m a)(z)\, b(z):$, the field product $a_{(-m-1)}b$ of Kac (§2.3).

From the mathematics to the Lean statement

Why these conventions are the standard ones. For $n \ge 0$ Kac defines the field product $a(w)_{(n)}b(w) = \mathrm{Res}_z \big(a(z)b(w)\iota_{z,w}(z-w)^n - b(w)a(z)\iota_{w,z}(z-w)^n\big)$; for $n \ge 0$ the two expansions of $(z-w)^n$ agree (it is a polynomial), so this is $\mathrm{Res}_z(z-w)^n[a(z), b(w)]$, which is `cCoeff n (bracketDist a b)`. For $n = -m-1 < 0$ Kac's formula gives $\frac{1}{m!}:\partial^m a(w)\, b(w):$, which is `negProd`. Hence the library's pair (`cCoeff`, `negProd`) is exactly Kac's family of n-th products of fields. The z-power indexing of distributions is Gannon's; the $+1$ shift between powers and modes is the source of most sign and index decoding in this chapter, and we redo it in every fidelity check.

Physical meaning

These conventions are the algebraic shadow of the operator product expansion of two chiral fields, $a(z)b(w) = \sum_{n\ge 0} \frac{(a_{(n)}b)(w)}{(z-w)^{n+1}} + :a(z)b(w):$. The singular terms are the OPE coefficients $a_{(n)}b$ with $n \ge 0$; they are extracted by contour integrals $\oint_w dz\,(z-w)^n a(z)b(w)$, which is what $\mathrm{Res}_z(z-w)^n[a(z), b(w)]$ computes (the commutator is the difference of the two radially ordered expansions, i.e. the contour around w). The regular part at $z = w$ is the normal-ordered product, and its Taylor coefficients are the $a_{(-m-1)}b = \frac{1}{m!}:\partial^m a\, b:$. A field is an operator whose OPE with any state has a pole of finite order: in radial quantisation, $a(z)$ applied to a state of bounded energy produces only finitely many states of lower energy.

4.3 The three structures

4.3.1 `PreVertexAlgebra`: Gannon's Definition 5.1.3(a)

Definition 4.1 (The library's `PreVertexAlgebra`: graded VA1–VA5 data)**.** A *pre-vertex algebra* (Gannon's "vertex algebra"; in this book also called, for historical reasons, "a vertex algebra in the library's sense"; it is *not* a vertex algebra in the standard sense of Kac, Frenkel–Ben-Zvi or Lepowsky–Li, since it lacks translation covariance, see Section 4.5) is a complex vector space V with a $\mathbb{Z}$-grading $V = \bigoplus_{n\in\mathbb{Z}} V_n$ by finite-dimensional subspaces, a linear map $Y : V \to \mathrm{End}(V)[[z^{\pm 1}]]$, $u \mapsto Y(u,z) = \sum_n u_{(n)} z^{-n-1}$, and a vector $\mathbf{1} \in V_0$, such that for all $u, v \in V$:

(VA1) $u \in V_k, v \in V_\ell \Rightarrow u_{(n)}v \in V_{k+\ell-n-1}$ for all $n \in \mathbb{Z}$;

(VA2) $Y(\mathbf{1}, z) = \mathrm{id}_V$;

(VA3) $u_{(-1)}\mathbf{1} = u$ and $u_{(n)}\mathbf{1} = 0$ for $n \geq 0$;

(VA4) $Y(u,z)$ and $Y(v,z)$ are mutually local;

(VA5) there is $N = N(u,v) \in \mathbb{Z}$ with $u_{(n)}v = 0$ for all $n \geq N$.

```
structure PreVertexAlgebra (𝒱 : Type u) [AddCommGroup 𝒱] [Module ℂ 𝒱] where
  grading : ℤ → Submodule ℂ 𝒱
  isInternal : DirectSum.IsInternal grading
  finrank : ∀ n, FiniteDimensional ℂ (grading n)
  Y : 𝒱 →ₗ[ℂ] (End ℂ 𝒱)⟦z^±⟧
  vacuum : 𝒱
  vacuum_mem : vacuum ∈ grading 0

  locality : ∀ u v : 𝒱, Local (Y u) (Y v)
  regularity : ∀ u v : 𝒱, ∃ N : ℤ, ∀ n : ℤ, N ≤ n → mode (Y u) n v = 0
```

File `VOA/Core/VertexAlgebra.lean` (`VOA.PreVertexAlgebra`; field docstrings removed).

From the mathematics to the Lean statement

Chapter 1 decodes every field; we add only what the audit needs.

- **The data** are the grading (three fields: a family of submodules, the internal direct-sum property `DirectSum.IsInternal` — every vector is uniquely a finite sum of homogeneous components — and finite-dimensionality of each piece), the map `Y` and the vector `vacuum`. **There is no translation operator among the data, and no axiom mentions a derivative.**
- **Truncation is for all pairs**: `regularity` is quantified over all u, v, and the bound N may depend on both. Applied for fixed u and all v it says that $Y(u,z)$ is a field (`isField_Y` below).
- **Locality is for all pairs, including $u = v$**, with an order N depending on the pair (the existential is inside `Local`).
- **Vacuum**: `1` is the library's own unit distribution (coefficient id at z^0, zero elsewhere), so `vacuum_Y` is $Y(\mathbf{1}, z) = \mathrm{id}$, not the constant series $\delta(z)$.
- **No Jacobi identity** is assumed, and **no axiom relates $u_{(-2)}\mathbf{1}$ to anything**.

How the definition compares with the literature is the subject of Section 4.4.

Physical meaning

The five axioms are the minimal chiral-algebra data a physicist writes down: a space of states graded by scaling dimension with finite degeneracies (VA1), the identity operator corresponding to the vacuum (VA2), the state–operator map $u = \lim_{z\to 0} Y(u,z)\mathbf{1}$ (VA3), commutativity of chiral fields at distinct points, i.e. single-valuedness of radially ordered correlators $\langle \cdots a(z)b(w)\cdots\rangle$ up to poles on the diagonal (VA4), and finite-order poles in the OPE (VA5). What is *missing* is the statement that the field at z is the translate of the field at 0, i.e. that the Hamiltonian-like operator L_{-1} generating translations acts as ∂_z on fields. Section 4.5 shows that this is not a cosmetic omission.

Definition 4.2 (The n-th product and the translation operator)**.** In a vertex algebra in the library's sense, $u_{(n)}v :=$ `V.smul u n v`, and the *translation operator* is the linear map $T : V \to V$, $Tu := u_{(-2)}\mathbf{1}$. One has $T\mathbf{1} = 0$ and $T(V_k) \subseteq V_{k+1}$.

```
def smul (V : PreVertexAlgebra 𝒱) (u : 𝒱) (n : ℤ) (v : 𝒱) : 𝒱 := mode (V.Y u) n v

def T (V : PreVertexAlgebra 𝒱) : 𝒱 →ₗ[ℂ] 𝒱 where
  toFun u := V.smul u (-2) V.vacuum

@[simp] theorem T_vacuum (V : PreVertexAlgebra 𝒱) : V.T V.vacuum = 0

theorem T_mem_grading (V : PreVertexAlgebra 𝒱) {k : ℤ} {u : 𝒱} (hu : u ∈ V.grading k) :
    V.T u ∈ V.grading (k + 1)
```

File `VOA/Core/VertexAlgebra.lean` (`smul`) and `VOA/Core/Identities.lean` (`T`, `T_vacuum`, `T_mem_grading`; linearity proofs omitted).

From the mathematics to the Lean statement

T is *defined*, not postulated, and defined by the formula that holds in every textbook vertex algebra ($Y(u,z)\mathbf{1} = e^{zT}u$ gives $u_{(-2)}\mathbf{1} = Tu$). `T_vacuum` is VA2: $\mathbf{1}_{(-2)} = \delta_{-2,-1}\mathrm{id} = 0$. `T_mem_grading` is VA1 with $\mathbf{1} \in V_0$ and $n = -2$: $k + 0 + 2 - 1 = k + 1$. Nothing about T beyond these two facts holds in general (Section 4.5).

Physical meaning

T is meant to be the generator of translations, L_{-1}, which raises the scaling dimension by one (∂_z has dimension one) and annihilates the translation-invariant vacuum. In a genuine CFT Tu is the state of the derivative field $\partial u(z)$.

4.3.2 `BarePreVA`: the axioms without the grading

Definition 4.3 (Bare pre-vertex algebra (the library's `BarePreVA`))**.** A *bare pre-vertex algebra* (in this book also "bare vertex algebra"; not a vertex algebra in the standard sense: like `PreVertexAlgebra` it has no translation-covariance axiom, and the Borcherds identity fails for it) is a complex vector space with Y and $\mathbf{1}$ as above satisfying (VA2)–(VA5), with no grading. Every pre-vertex algebra gives one by forgetting the grading.

```
structure BarePreVA (𝒱 : Type u) [AddCommGroup 𝒱] [Module ℂ 𝒱] where
  Y : 𝒱 →ₗ[ℂ] (End ℂ 𝒱)⟦z^±⟧
  vacuum : 𝒱
```

```
  vacuum_Y : Y vacuum = (1 : (End ℂ 𝒱)⟦z^±⟧)
  creation : ∀ u : 𝒱, mode (Y u) (-1) vacuum = u ∧ ∀ n : ℤ, 0 ≤ n → mode (Y u) n vacuum = 0
  locality : ∀ u v : 𝒱, Local (Y u) (Y v)
  regularity : ∀ u v : 𝒱, ∃ N : ℤ, ∀ n : ℤ, N ≤ n → mode (Y u) n v = 0

def PreVertexAlgebra.toBarePreVA (V : PreVertexAlgebra 𝒱) : BarePreVA 𝒱 where

theorem isField_Y (V : BarePreVA 𝒱) (u : 𝒱) : IsField (V.Y u)
```

File `VOA/Core/BareVA.lean` (`VOA.BarePreVA`, `VOA.PreVertexAlgebra.toBarePreVA`, `VOA.BarePreVA.isField_Y`; the body of `toBarePreVA` copies the five fields). The same file also defines `VertexOperatorAlgebra.toBarePreVA` through the underlying vertex algebra.

From the mathematics to the Lean statement

The fields are those of `PreVertexAlgebra` minus `grading`, `isInternal`, `finrank`, `vacuum_mem`, `grading_mode`, verbatim otherwise. `isField_Y`: VA5 for the pair (u, x) gives N with $u_{(n)}x = 0$ for $n \geq N$; in z-power indexing the coefficient `(Y u) k x` $= u_{(-k-1)}x$ vanishes for $k < -N$, which is `IsField` with $B = -N$.

The file's motivation, and why its original plan fails. An earlier docstring explained that the grading is "dead weight" for the Borcherds theory — correctly: none of the Borcherds files uses the grading — and that the Borcherds chain should be restated over `BarePreVA` so that it can be applied to Li's local systems (Section 4.16), which carry no grading. It asserted that VA2–VA5 are "all the Borcherds/Jacobi derivation actually consumes". The current docstring reverses this: under the heading **Warning** it says that VA2–VA5 alone do not imply the Borcherds/Jacobi identity, because neither `PreVertexAlgebra` nor `BarePreVA` has a translation-covariance axiom; it cites the counterexample of Section 4.5; it calls the restatement over `BarePreVA` a dead end; and its status note says that nothing Borcherds-related is proved over `BarePreVA`. The old sentence was false: the derivation also consumes translation covariance, which the library takes from the VOA axiom (VOA3). The counterexample of Section 4.5 is a `PreVertexAlgebra`, hence (by `toBarePreVA`) a `BarePreVA`, violating the Borcherds identity. The restatement plan can only succeed if a translation operator with $[T, Y(u,z)] = \partial_z Y(u,z)$ and $T\mathbf{1} = 0$ is added to `BarePreVA`. (For the local-system application this is harmless: a local system has the natural translation $a \mapsto \partial a$, see `LocalFieldSystem.translation_val` in Section 4.16.)

Physical meaning

Removing the grading means forgetting the scaling dimensions, keeping only the operator algebra. That is the natural setting for, e.g., the algebra of all chiral fields acting on a single sector (a module), where no vacuum-module grading is available.

What the machine verified

`BarePreVA` and `toBarePreVA` are definitions; `BarePreVA.isField_Y` is proved, `#print axioms` = `[propext, Classical.choice, Quot.sound]` (run for this chapter). No Borcherds-type theorem is stated over `BarePreVA` at this commit.

4.3.3 `VertexOperatorAlgebra`

Definition 4.4 (Vertex operator algebra of CFT type, the library's `VertexOperatorAlgebra`)**.** A VOA (in the library's sense: a Lepowsky–Li/FLM VOA *of CFT type*) is a structure as in Definition 4.1 with $\omega \in V_2$ and $c \in \mathbb{C}$ such that, with $L_n := \omega_{(n+1)}$: (VOA1) the Virasoro relations with central charge

c; (VOA2) $L_0 = n$ on V_n; (VOA3) $Y(L_{-1}v, z) = \partial_z Y(v, z)$ for all v; (VOA4) $V_0 = \mathbb{C}\mathbf{1}$ and $V_n = 0$ for $n < 0$.

Axiom (VOA4) is the CFT-type condition (Lean fields `vacuum_grade` and `positivity`). It is a *restriction* relative to FLM and Lepowsky–Li, who require only $\dim V_n < \infty$ and $V_n = 0$ for $n \ll 0$: it excludes VOAs with $\dim V_0 > 1$ (for example non-simple direct sums), VOAs with negative weights (the $\beta\gamma$ system in its standard grading, shifted conformal vectors) and indefinite-lattice examples. Within CFT type the definition imposes no further restriction. Every theorem the library proves about `VertexOperatorAlgebra` is therefore a theorem about VOAs of CFT type. Note also that the zero space satisfies every axiom (if $\mathbf{1} = 0$, creation forces $V = 0$, and $V_0 = \mathbb{C} \cdot 0 = 0$ is allowed); the literature differs on whether to admit it, and statements meant for nonzero VOAs must assume $\mathbf{1} \neq 0$ or `Nontrivial` (release audit 2026-10-27, finding m-4). The library keeps the two layers apart. `VOA.GradedVertexOperatorAlgebra` extends `PreVertexAlgebra` by ω, c, (VOA1)–(VOA3) and the FLM/Lepowsky–Li truncation $V_n = 0$ for $n \ll 0$ (field `grading_bounded_below`); `VOA.VertexOperatorAlgebra` extends it by (VOA4), and its truncation field is filled automatically ($N = 0$). So `VertexOperatorAlgebra` is of CFT type *by definition*, and the general notion is `GradedVertexOperatorAlgebra`; for the latter the library provides the L_n form of (VOA1)–(VOA3) and the map `GradedVertexOperatorAlgebra.toNearVOA`, while every theorem of this chapter is stated for `VertexOperatorAlgebra`. Both structures are printed in Chapter 1. The Lean structure `VOA.VertexOperatorAlgebra` (file `VOA/Core/VertexOperatorAlgebra.lean`) is printed and decoded in full in Chapter 1; for the audit we need only the translation field:

```
translation : ∀ v : V, Y (mode (Y conformalVector) 0 v) = deriv (Y v)
```

File `VOA/Core/VertexOperatorAlgebra.lean`: `mode (Y ω) 0` $= \omega_{(0)} = L_{-1}$, and `deriv` is ∂_z; so this is the L_{-1}-derivative property of Lepowsky–Li and FLM, stated as an equality of fields for every v.

Physical meaning

The conformal vector is the stress tensor $T(z) = Y(\omega, z) = \sum L_n z^{-n-2}$. Axiom (VOA3) is the translation Ward identity: $L_{-1} = \oint T(z)\,dz$ generates $z \mapsto z + \epsilon$, and the state $L_{-1}v$ corresponds to the field $\partial v(z)$. It is precisely this axiom that the bare definition lacks, and it is through it that all of the structure theory of this chapter enters.

(`VOA.NearVOA`, the same axioms without finite-dimensionality and without (VOA4), is described in Chapter 1; no theorem of this chapter is stated for it.)

4.4 Comparison with the textbook definitions

The standard definitions differ in which properties are axioms and which are theorems. We summarise them, then compare.

- **Borcherds (1986)**: a vector space with bilinear products $u_{(n)}v$ ($n \in \mathbb{Z}$), a vacuum, $u_{(n)}v = 0$ for $n \gg 0$, $\mathbf{1}_{(n)}v = \delta_{n,-1}v$, $u_{(-1)}\mathbf{1} = u$, $u_{(n)}\mathbf{1} = 0$ ($n \geq 0$), and the Borcherds identity in all three indices as the main axiom. (Borcherds originally wrote it with a derivation D, $Du = u_{(-2)}\mathbf{1}$, and skew-symmetry among the axioms; the identity in all indices implies both.)

- **FLM (1988) and Lepowsky–Li (2004, Def. 3.1.1)**: $(V, Y, \mathbf{1})$ with truncation for all pairs, vacuum property, creation property, and the Jacobi identity (4.1) for all u, v; the D-derivative property is a consequence (Lepowsky–Li, §3.1). A VOA (LL Def. 3.1.22) adds a $\mathbb{Z}$-grading with finite-dimensional pieces, $V_n = 0$ for $n \ll 0$, $\omega \in V_2$ with Virasoro relations, L_0-grading and the L_{-1}-derivative property.

- **Kac (1998, Def. 1.3) and Frenkel–Ben-Zvi (2004, Def. 1.3.1)**: $(V, \mathbf{1}, T, Y)$ with $T \in \operatorname{End} V$ *part of the data*; each $Y(u,z)$ a field; vacuum axiom $Y(\mathbf{1},z) = \mathrm{id}$, $Y(u,z)\mathbf{1} \in V[[z]]$ with constant term u; *translation axiom* $[T, Y(u,z)] = \partial_z Y(u,z)$ and $T\mathbf{1} = 0$; locality. No grading.
- **Gannon (2006, Def. 5.1.3(a))**: as Definition 4.1, with grading and locality, without T and without Jacobi.

The Jacobi identity referred to is

$$z_0^{-1}\delta\Big(\tfrac{z_1-z_2}{z_0}\Big)Y(u,z_1)Y(v,z_2) - z_0^{-1}\delta\Big(\tfrac{z_2-z_1}{-z_0}\Big)Y(v,z_2)Y(u,z_1) = z_2^{-1}\delta\Big(\tfrac{z_1-z_0}{z_2}\Big)Y(Y(u,z_0)v,z_2), \quad (4.1)$$

whose $z_0^{-\ell-1}z_1^{-m-1}z_2^{-n-1}$-coefficient is the Borcherds identity (4.2). (To extract it, multiply by $z_0^{\ell}z_1^{m}z_2^{n}$, take $\operatorname{Res}_{z_0}\operatorname{Res}_{z_1}\operatorname{Res}_{z_2}$, and expand each δ-function binomially in the direction fixed by its argument; this is the standard computation behind Kac (4.8.3). The library states and proves only the coefficient form, Theorem 4.26.)

Ingredient	Kac / FBZ	FLM / LL	library `PreVertexAlgebra` (`VOA`)
grading, $\dim V_n < \infty$	no (VA); yes (VOA)	VOA only	required (both)
translation T	data, axiom $[T,Y] = \partial Y$	derived, theorem	derived $Tu = u_{(-2)}\mathbf{1}$; **no axiom** (VOA: from (VOA3))
truncation, all pairs	yes ("field")	yes	yes (`regularity`)
vacuum, creation	yes	yes	yes
locality	axiom	theorem	axiom
Jacobi / Borcherds	theorem	axiom	**not implied**; theorem for VOAs, all (ℓ, m, n)
skew-symmetry	theorem	theorem	**not implied**; theorem for VOAs
CFT type	—	no ($V_n = 0$ for $n \ll 0$)	VOA: $V_0 = \mathbb{C}\mathbf{1}$, $V_{<0} = 0$

Proposition 4.5 (The library's VOA is the Lepowsky–Li VOA of CFT type)**.** *Let $(V, Y, \mathbf{1}, \omega)$ be a graded vector space with a state–field map, vacuum and conformal vector. The following are equivalent:*

(a) it is a `VertexOperatorAlgebra` *(Definition 4.4);*

(b) it is a VOA in the sense of Lepowsky–Li Definition 3.1.22, with $V_0 = \mathbb{C}\mathbf{1}$ and $V_n = 0$ for $n < 0$.

Direction (a)⇒(b) is formalised (through `jacobi`*); direction (b)⇒(a), "every standard Lepowsky–Li VOA of CFT type is a library VOA", is* ***proved on paper only****.*

Physical meaning

The proposition says that, at the level of chiral algebras with a stress tensor, the library axiomatises exactly the standard object: a holomorphic CFT chiral algebra whose spectrum of L_0 is nonnegative with a unique vacuum. The extra condition (CFT type) excludes chiral algebras with negative-dimension states (some non-unitary and logarithmic theories, the $\beta\gamma$ system in its standard grading) and those with several dimension-zero states.

Proof on paper. (a)⇒(b): truncation, vacuum, creation, the grading, Virasoro, L_0- and L_{-1}-properties are fields of the structure, and $V_n = 0$ for $n < 0$ is (VOA4). The Jacobi identity is

the content of the theorem `jacobi` (Section 4.11), whose mode form for all ℓ, m, n is equivalent to (4.1) coefficient by coefficient. (b)⇒(a): the only fields of the library structure that are not literally LL axioms are VA1 (`grading_mode`) and VA4 (`locality`). Locality follows from Jacobi by the classical argument (Lepowsky–Li, §3.2: multiply (4.1) by z_0^N with N beyond the truncation order of $u_{(n)}v$ and take Res_{z_0}). VA1 follows from the commutator formula with $u = \omega$, $m = 1$: $[L_0, v_{(n)}] = (L_{-1}v)_{(n+1)} + (L_0 v)_{(n)} = (-n - 1 + \mathrm{wt}\, v)\, v_{(n)}$ (using $(L_{-1}v)_{(n+1)} = -(n+1)v_{(n)}$, the derivative property), so $v_{(n)}$ shifts the L_0-eigenvalue by $\mathrm{wt}\, v - n - 1$, and the grading is the L_0-eigenspace grading by (VOA2). □

What the machine verified

Direction (a)⇒(b) is machine-checked in the sense that every LL axiom is either a field of `VertexOperatorAlgebra` or the theorem `VOA.VertexOperatorAlgebra.jacobi` (axiom-clean). Direction (b)⇒(a) is argued on paper only: the library contains no structure in the Lepowsky–Li form, so there is nothing to state; in particular the release audit of 2026-10-27 (finding m-2) found no Lean declaration deriving `Local` from the Jacobi identity. The claim "every standard VOA of CFT type is an instance of `VertexOperatorAlgebra`" therefore rests on the literature (FLM, Lepowsky–Li), not on the machine.

Remark 4.6. Dropping (VOA4) on both sides, the same argument identifies `GradedVertexOperatorAlgebra` with the VOA of Lepowsky–Li Definition 3.1.22 on paper. Neither direction of that statement is formalised: the theorem `jacobi` is proved only for `VertexOperatorAlgebra`.

4.5 A vertex algebra in the library's sense that violates the Borcherds identity

Theorem 4.7 (Gannon's axioms do not imply translation covariance). *Let $A = \mathbb{C}\mathbf{1} \oplus \mathbb{C}x \oplus \mathbb{C}y$ be the commutative unital algebra with $x^2 = xy = y^2 = 0$, graded by $\deg \mathbf{1} = \deg x = 0$, $\deg y = 2$. For $u = a\mathbf{1} + bx + cy$ put $\varphi_z(u) := u + bz^2 y \in A[z]$ and let $Y(u,z)$ be multiplication by $\varphi_z(u)$:*

$$Y(u,z)v = \varphi_z(u)\, v, \qquad \text{so} \quad Y(\mathbf{1},z) = \mathrm{id}, \quad Y(x,z) = x\cdot + z^2\, y\cdot, \quad Y(y,z) = y\cdot.$$

Then $(A, Y, \mathbf{1})$ with this grading satisfies (VA1)–(VA5), i.e. it is a `PreVertexAlgebra`. *But $Tx = x_{(-2)}\mathbf{1} = 0$ while $\partial_z Y(x,z) = 2z\, y\cdot \neq 0$, so $Y(Tx,z) \neq \partial_z Y(x,z)$; there is* no *operator T' with $[T', Y(u,z)] = \partial_z Y(u,z)$ for all u; and the Borcherds identity (4.2) fails for $(u, v, w, \ell, m, n) = (x, \mathbf{1}, \mathbf{1}, -2, 0, -2)$: its left side is $2y$ and its right side is 0. Consequently skew-symmetry fails as well: $Y(x,z)\mathbf{1} = x + z^2 y$, whereas $e^{zT}Y(\mathbf{1}, -z)x = x$.*

Physical meaning

Physically this is an "operator algebra" in which the field attached to x at the point z is *not* the translate of the field at the origin: $Y(x,z) = x + z^2 y$ instead of $e^{zL_{-1}}$ acting. All fields commute, so locality is trivially satisfied, and the vacuum reproduces every state; but there is no consistent notion of moving an operator, so OPE associativity (crossing symmetry) and Bose exchange symmetry fail. In conformal field theory translation invariance is always present (it is the L_{-1} Ward identity), so physicists never meet this pathology; it is a reminder that the bare axioms VA1–VA5 are not a complete axiomatisation of a chiral algebra.

Proof on paper. The modes of $Y(u,z) = u\cdot + bz^2 y\cdot$ are $u_{(-1)} = u\cdot$, $u_{(-3)} = b\, y\cdot$ and $u_{(n)} = 0$ otherwise (the coefficient of z^k is $u_{(-k-1)}$).

(VA2): $\varphi_z(\mathbf{1}) = \mathbf{1}$. (VA3): $u_{(-1)}\mathbf{1} = u$, and $u_{(n)} = 0$ for $n \geq 0$. (VA5): $u_{(n)}v = 0$ for $n \geq 0$. (VA4): all $Y(u,z)$ are multiplication operators by elements of the commutative algebra $A[z]$, so

$[Y(u,z_1),Y(v,z_2)]=0$, local with order 0. (VA1): it suffices to check homogeneous u,v and the two nonzero modes. For $n=-1$ the target degree is $\deg u+\deg v$, and $u\cdot v$ is homogeneous of that degree because A is a graded algebra (deg is additive on the nonzero products $\mathbf{1}\cdot w=w$). For $n=-3$ the target is $\deg u+\deg v+2$; the mode is $b\,y\cdot$ with b the x-coefficient of u, nonzero only for $u\in\mathbb{C}x$ (degree 0), and $y\cdot v$ is nonzero only for $v\in\mathbb{C}\mathbf{1}$, giving y of degree $2=0+0+2$. The pieces $V_0=\operatorname{span}(\mathbf{1},x)$ and $V_2=\mathbb{C}y$ are finite-dimensional and $\mathbf{1}\in V_0$.

Failure of translation covariance: $Tx=x_{(-2)}\mathbf{1}$ is the z^1-coefficient of $\varphi_z(x)\mathbf{1}=x+z^2y$, which is 0; so $Y(Tx,z)=0$, while $\partial_z Y(x,z)$ has z^1-coefficient $2y\cdot\neq 0$. For an arbitrary T', the z^1-coefficient of $[T',Y(x,z)]$ is $[T',x_{(-2)}]=[T',0]=0$, again different from $2y\cdot$.

Failure of Borcherds: with $u=x$, $v=w=\mathbf{1}$, $\ell=-2$, $m=0$, $n=-2$, the left side of (4.2) is $\sum_{i\geq 0}(-1)^i\binom{-2}{i}\big(x_{(-2-i)}\mathbf{1}_{(-2+i)}\mathbf{1}-\mathbf{1}_{(-4-i)}x_{(i)}\mathbf{1}\big)$. The second term vanishes ($x_{(i)}\mathbf{1}=0$ for $i\geq 0$), and $\mathbf{1}_{(-2+i)}\mathbf{1}=\delta_{i,1}\mathbf{1}$; so only $i=1$ survives, giving $(-1)\binom{-2}{1}x_{(-3)}\mathbf{1}=2y$. The right side is $\sum_i\binom{0}{i}(x_{(-2+i)}\mathbf{1})_{(-2-i)}\mathbf{1}=(x_{(-2)}\mathbf{1})_{(-2)}\mathbf{1}=0_{(-2)}\mathbf{1}=0$. Skew-symmetry: $T=0$ on x and $Y(\mathbf{1},-z)=\mathrm{id}$. □

From the mathematics to the Lean statement

Why this example is the general mechanism. For a *commutative* vertex algebra in the library's sense (all fields commute and have no negative powers of z), $Y(u,z)=\varphi_z(u)\cdot$ for a map $\varphi_z : A\to A[[z]]$ which the axioms force to be an algebra homomorphism with $\varphi_0=\mathrm{id}$ — a *Hasse–Schmidt derivation*. The Borcherds identity at $m=0$, $\ell<0$ says $Y(u_{(\ell)}v,z)=Y(u,\cdot)_{(\ell)}Y(v,\cdot)$, which here is the group law $\varphi_w\circ\varphi_z=\varphi_{z+w}$, i.e. $\varphi_z=e^{zT}$ for an ordinary derivation T. A Hasse–Schmidt derivation that is not exponential (here $\varphi_z=\mathrm{id}+z^2D$ with $D(x)=y$, $D(\mathbf{1})=D(y)=0$) satisfies VA1–VA5 and nothing more. In particular the correspondence behind Gannon's Theorem 5.1.4 — a commutative vertex algebra *is* a commutative algebra with a derivation T, via $Y(u,z)v=(e^{zT}u)\,v$ — fails for Gannon's own definition: the example is commutative, its product $u_{(-1)}v$ is commutative and associative, its T is 0, yet $Y(x,z)\neq x\cdot$. The library proves the theorem only for VOAs (Section 4.14), and only the three conditions, not the reconstruction of Y from (A,T).

The machine check. For this chapter the example was formalised in Lean outside the library (not built by `lake build`, compiled with `lake env lean -DmaxSynthPendingDepth=3` at an earlier commit, when this chapter was first written, and not re-run for this edition; the check is not part of this release) as an inhabitant `L03Counter.VA : PreVertexAlgebra (Fin 3 → ℂ)` together with two refutations, `jacobi_fails` and `translation_fails`, all depending only on the axioms `propext`, `Classical.choice` and `Quot.sound`. The library's own copy, `VOA.TranslationCovariantCounterexample`, is described in the warning of Section 4.1. Here `V = Fin 3 → ℂ` with coordinates $(\mathbf{1},x,y)$, `grading 0 = {v | v 2 = 0}`, `grading 2 = {v | v 0 = 0 ∧ v 1 = 0}`, all other pieces $\bot$; `jacobi_fails` is the negation of the conclusion of `VertexOperatorAlgebra.jacobi` (Theorem 4.26) at fixed indices, with `VA.smul` in place of `W.smul`.

What the machine verified

Machine-checked for this chapter in a scratch file (not in the library, not part of the aggregate build); axiom-clean. The paper proof is complete and independent of the scratch file.

Consequences for the reader

1. *Do not read "vertex algebra" in a Lean statement as the textbook notion.* A theorem with hypothesis `V : PreVertexAlgebra V` is a theorem about Gannon-style graded local state–field systems, a class strictly larger than that of the vertex algebras of Kac or Lepowsky–Li equipped with a compatible grading (every such graded vertex algebra is

a `PreVertexAlgebra`, but not conversely). The theorems of this chapter stated at that level (Goddard uniqueness, the OPE decomposition, Dong's lemma, product fields) are true in the larger class, so nothing false is proved.

2. *Theorems that need translation covariance are, correctly, stated for VOAs.* The Borcherds identity, skew-symmetry, the duality formulas and Theorem 5.1.4 are all hypothesised on `VertexOperatorAlgebra`. In the source, the docstrings of `VOA/Core/Identities.lean` say this explicitly ("at the bare-VA level $Y(Tu,z) = \partial_z Y(u,z)$ is circular"); the counterexample shows it is not merely circular but false.

3. *Dead end.* Restating the Borcherds chain over `BarePreVA` (the plan of an earlier docstring of `BareVA.lean`; the current docstring records it as a dead end) cannot succeed without adding a translation axiom.

4.6 What holds at the bare level: product fields and the cancellation principle

Everything in this and the next three sections is proved for an arbitrary `PreVertexAlgebra` (and, where noted, for arbitrary distributions on an arbitrary vector space); by Section 4.5 none of it needs, or yields, translation covariance.

4.6.1 The vertex operators are fields

Theorem 4.8. *In a vertex algebra in the library's sense, every $Y(u,z)$ is a field.*

```
theorem isField_Y {𝒱 : Type u} [AddCommGroup 𝒱] [Module ℂ 𝒱] (V : PreVertexAlgebra 𝒱) (u :
↪  𝒱) :
    IsField (V.Y u)
```

File `VOA/Core/Reconstruction.lean` (`VOA.PreVertexAlgebra.isField_Y`).

From the mathematics to the Lean statement

Same content as `BarePreVA.isField_Y`; the proof converts VA5 for (u,x) to the z-power indexing (bound $B = -N$). The only hypothesis is the structure.

Physical meaning

Every chiral operator has finite-order poles against every state; this is what allows normal ordering $:u(z)v(z):$ to be defined at all.

Proof on paper. If $u_{(n)}x = 0$ for $n \geq N$, then the z^k-coefficient $u_{(-k-1)}x$ vanishes for $-k-1 \geq N$, i.e. $k < -N$ (indeed $k \leq -N-1$). □

4.6.2 The iterated product field and the cancellation principle

Definition 4.9 (Iterated product field). For $u, v, x \in V$, $Y(u,z_1)Y(v,z_2)x$ is the two-variable distribution whose $z_1^m z_2^n$-coefficient is $u_{(-m-1)}v_{(-n-1)}x$.

```
def Yprod (V : PreVertexAlgebra 𝒱) (u v x : 𝒱) : FormalDist₂ 𝒱 :=
  fun m n => (V.Y u) m ((V.Y v) n x)
```

File `VOA/Core/Fields.lean` (`VOA.PreVertexAlgebra.Yprod`).

From the mathematics to the Lean statement

`(V.Y u) m` is the coefficient of z_1^m in $Y(u, z_1)$, i.e. $u_{(-m-1)}$; similarly for v. No hypothesis; this is a definition, and each coefficient is a single vector (no sum).

Physical meaning

$Y(u, z_1)Y(v, z_2)x$ is the radially ordered product $|z_1| > |z_2|$ of two operators acting on the state x: the formal-series counterpart of a three-point function $\langle x'|u(z_1)v(z_2)|x\rangle$ expanded in the region $|z_1| > |z_2|$.

Definition 4.10 (Lower truncation in the second variable)**.** A two-variable distribution F is *lower-truncated in z_2* if there is B with $F(m, n) = 0$ for all m and all $n < B$. Such distributions form the space $W((z_1))((z_2))$ *only in the second variable*; nothing is assumed in z_1.

```
def IsBddBelow₂ (f : FormalDist₂ 𝒲) : Prop := ∃ B : ℤ, ∀ m n : ℤ, n < B → f m n = 0
```

File `VOA/Foundations/IteratedLaurent.lean` (`VOA.IsBddBelow₂`; treated in Chapter 2).

Physical meaning

Lower truncation in z_2 uniformly in z_1 is the formal analogue of analyticity of a correlator near $z_2 = 0$ in the domain $|z_1| > |z_2|$: the inner operator, acting on a fixed state, has a pole of bounded order.

Theorem 4.11 (The product field is lower-truncated; cancellation)**.** *For all u, v, x, $Y(u, z_1)Y(v, z_2)x$ is lower-truncated in z_2. Consequently, if $(z_1-z_2)^N Y(u, z_1)Y(v, z_2)x = (z_1-z_2)^N Y(u', z_1)Y(v', z_2)x'$ for some N, then $Y(u, z_1)Y(v, z_2)x = Y(u', z_1)Y(v', z_2)x'$.*

```
theorem Yprod_bddBelow (V : PreVertexAlgebra 𝒱) (u v x : 𝒱) : IsBddBelow₂ (V.Yprod u v x)

theorem Yprod_ext (V : PreVertexAlgebra 𝒱) {u v x u' v' x' : 𝒱} (N : ℕ)
    (h : mulBySubPow N (V.Yprod u v x) = mulBySubPow N (V.Yprod u' v' x')) :
    V.Yprod u v x = V.Yprod u' v' x'
```

File `VOA/Core/Fields.lean`. The engine is the cancellation lemma of Chapter 2:

```
theorem eq_zero_of_mulBySubPow_of_bddBelow :
    ∀ (N : ℕ) (f : FormalDist₂ 𝒲), mulBySubPow N f = 0 → IsBddBelow₂ f → f = 0
```

File `VOA/Foundations/IteratedLaurent.lean`.

From the mathematics to the Lean statement

`Yprod_bddBelow`: the bound is uniform in m (the z_1-power) because it comes from VA5 for the single pair (v, x): if $v_{(n)}x = 0$ for $n \geq N$, the whole z_2^q-column vanishes for $q < -N$. `Yprod_ext`: the hypothesis is one equation between two-variable distributions; the six vectors are arbitrary. The cancellation lemma is the precise statement "$z_1 - z_2$ is a non-zero divisor on $W((z_1))((z_2))$"; without the truncation hypothesis it is false ($(z_1 - z_2)\delta(z_1/z_2) = 0$).

Physical meaning

The cancellation principle is the formal version of a familiar analytic fact: two functions holomorphic in the annulus region $|z_1| > |z_2|$ that agree after multiplication by $(z_1 - z_2)^N$ agree. The point of formal calculus is that this fails for distributions supported on the diagonal ($\delta(z_1/z_2)$ is the formal "contact term"), and truncation in z_2 excludes exactly those.

Proof on paper. Truncation is explained in the dictionary. For cancellation, let $f \neq 0$ be lower-truncated in z_2 with $(z_1 - z_2)f = 0$, and let q be the least z_2-power that occurs. The $z_1^{m+1}z_2^q$-coefficient of $(z_1 - z_2)f$ is $f(m,q) - f(m+1,q-1) = f(m,q)$, so $f(m,q) = 0$ for all m, contradicting the choice of q. Induction on N handles $(z_1 - z_2)^N$, and `Yprod_ext` applies this to the difference of the two product fields, which is again lower-truncated. □

What the machine verified

`Yprod_bddBelow`, `Yprod_ext`, `eq_zero_of_mulBySubPow_of_bddBelow`: unconditional; `#print axioms VOA.PreVertexAlgebra.Yprod_ext = [propext, Classical.choice, Quot.sound]` (run for this chapter).

4.6.3 The vacuum expansion

Lemma 4.12. *$Y(b,w)\mathbf{1}$ has no negative powers of w, and its w^0-coefficient is b.*

```
theorem Y_apply_vacuum_eq_zero (V : PreVertexAlgebra 𝒱) (b : 𝒱) {n : ℤ} (hn : n < 0) :
    (V.Y b) n V.vacuum = 0

theorem Y_apply_vacuum_zero (V : PreVertexAlgebra 𝒱) (b : 𝒱) : (V.Y b) 0 V.vacuum = b
```

File `VOA/Core/Goddard.lean`.

From the mathematics to the Lean statement

`(V.Y b) n` with $n < 0$ is the mode $b_{(-n-1)}$ with $-n-1 \geq 0$, killed on $\mathbf{1}$ by VA3; `(V.Y b) 0` is $b_{(-1)}$, and $b_{(-1)}\mathbf{1} = b$. This is all of VA3, re-indexed. The higher coefficients $b_{(-k-1)}\mathbf{1}$, $k \geq 1$, are *not* determined at this level (in the counterexample $x_{(-3)}\mathbf{1} = y$ while $T^2x/2 = 0$).

Physical meaning

$\lim_{w\to 0} Y(b,w)\mathbf{1} = b$: inserting the operator at the origin creates the state. In a genuine CFT the full expansion is $Y(b,w)\mathbf{1} = e^{wL_{-1}}b$; only its constant term is an axiom here.

4.7 The operator product expansion

Theorem 4.13 (OPE decomposition and the structural commutator formula)**.** *For all u, v in a vertex algebra in the library's sense there are N and one-variable distributions $c_0, \dots, c_{N-1}$ with*

$$[Y(u,z_1), Y(v,z_2)] = \sum_{j<N} c_j(z_2)\,\partial_{z_2}^{j}\delta(z_1/z_2),$$

and then, for all $a, b \in \mathbb{Z}$,

$$[u_{(a)}, v_{(b)}] = \sum_{j<N} a(a-1)\cdots(a-j+1)\,(c_j)_{(a+b-j)}.$$

```
theorem bracket_deltaSum (V : PreVertexAlgebra 𝒱) (u v : 𝒱) :
    ∃ (N : ℕ) (c : Fin N → FormalDist (End ℂ 𝒱)),
      bracketDist (V.Y u) (V.Y v) = ∑ j : Fin N, deltaDeriv (j : ℕ) (c j)

theorem mode_bracket_ope (V : PreVertexAlgebra 𝒱) (u v : 𝒱) {N : ℕ}
    {c : Fin N → FormalDist (End ℂ 𝒱)}
    (h : bracketDist (V.Y u) (V.Y v) = ∑ j : Fin N, deltaDeriv (j : ℕ) (c j)) (a b : ℤ) :
    ⁅mode (V.Y u) a, mode (V.Y v) b⁆ = ∑ j : Fin N,
```

```
      (∏ i ∈ Finset.range (j : ℕ), (a - (i : ℤ))) • mode (c j) (a + b - ((j : ℕ) : ℤ))

theorem mode_commutator_structural (V : PreVertexAlgebra 𝒱) (u v : 𝒱) (a b : ℤ) :
    ∃ (N : ℕ) (c : Fin N → FormalDist (End ℂ 𝒱)),
      bracketDist (V.Y u) (V.Y v) = ∑ j : Fin N, deltaDeriv (j : ℕ) (c j) ∧
      ⁅mode (V.Y u) a, mode (V.Y v) b⁆ = ∑ j : Fin N,
        (∏ i ∈ Finset.range (j : ℕ), (a - (i : ℤ))) • mode (c j) (a + b - ((j : ℕ) : ℤ))
```

File `VOA/Core/OPE.lean`.

From the mathematics to the Lean statement

`Fin N` is $\{0, \dots, N-1\}$; `deltaDeriv j c` is $c(z_2)\partial_{z_2}^{j}\delta(z_1/z_2)$ with *no* $1/j!$ (Section 4.2); $[\cdot,\cdot]$ is the commutator in End V; the product $\prod_{i<j}(a-i)$ is the falling factorial $a^{\underline{j}}$, an integer acting by $\bullet$. The decomposition is `local_iff_deltaSum` (Chapter 2) applied to VA4.

What is not claimed. The coefficients c_j are *not* identified with $\frac{1}{j!}Y(u_{(j)}v,z)$ here; they are only existential. The identification is the duality theorem `nth_product` (Theorem 4.20), proved for VOAs. Hence this theorem is the commutator formula "up to the identification of the OPE coefficients", which is why the library calls it *structural*.

Physical meaning

This is the singular part of the OPE in its commutator form: the commutator of two chiral fields is supported on the diagonal, a finite sum of derivatives of the delta function whose coefficients are the residues $\oint_w (z-w)^j u(z)v(w)\,dz$, i.e. the pole coefficients of $u(z)v(w) \sim \sum_j \frac{(u_{(j)}v)(w)}{(z-w)^{j+1}}$. The mode formula is the familiar recipe "the OPE poles determine the commutation relations of the modes", e.g. $J(z)J(w) \sim \frac{k}{(z-w)^2}$ giving $[J_m, J_n] = km\,\delta_{m+n,0}$.

Proof on paper. The decomposition is VA4 plus Gannon's Prop. 5.1.2. For the modes: the $z_1^{-a-1}z_2^{-b-1}$-coefficient of the commutator is $[u_{(a)}, v_{(b)}]$; that of $c(z_2)\partial_{z_2}^{j}\delta(z_1/z_2) = \sum_k c(z_2)\,\partial_{z_2}^{j}(z_1^k z_2^{-k-1})$ is $\prod_{i<j}(a-i)$ times the $z_2^{-a-b+j-1}$-coefficient of c, i.e. $a^{\underline{j}}c_{(a+b-j)}$ (the library's formula with $m=-a-1$: $\prod_{i<j}(-m-1-i) = \prod_{i<j}(a-i)$). □

What the machine verified

All three unconditional, axiom-clean (`#print axioms VOA.bracket_deltaSum` run for this chapter).

4.8 Goddard uniqueness

Goddard's theorem is the engine of everything that follows. Its in-algebra version is form (i) of Theorem 4.14 below; we present all three versions the library proves, because each is used.

Theorem 4.14 (Goddard uniqueness, three forms)**.** *Let V be a vertex algebra in the library's sense, $a \in V$ and $A(z) \in \mathrm{End}(V)[[z^{\pm 1}]]$ with $A(z)\mathbf{1} = Y(a,z)\mathbf{1}$ coefficientwise.*

(i) If A is local with every $Y(b,z)$, then $A = Y(a,\cdot)$.

(ii) It suffices that for every b some $(z_1-z_2)^N$ kills $[A(z_1), Y(b,z_2)]\mathbf{1}$ (the commutator applied to the vacuum only).

*(iii) (*Abstract test fields.*) Let V be any vector space with a vector $\mathbf{1}$, A a distribution with $A(z)\mathbf{1} = 0$, and $(G_b)_{b\in V}$ distributions with $G_b(w)\mathbf{1} \in V[[w]]$ of constant term b. If A is local with every G_b, then $A = 0$.*

```
theorem goddard_uniqueness (V : PreVertexAlgebra 𝒱) (A : FormalDist (End ℂ 𝒱)) (a : 𝒱)
    (hAloc : ∀ b : 𝒱, Local A (V.Y b))
    (hAvac : ∀ m : ℤ, A m V.vacuum = (V.Y a) m V.vacuum) :
    A = V.Y a

theorem goddard_zero (vac : 𝒱) (A : FormalDist (End ℂ 𝒱)) (G : 𝒱 → FormalDist (End ℂ 𝒱))
    (hloc : ∀ b, Local A (G b))
    (hcre0 : ∀ b, (G b) 0 vac = b)
    (hcreneg : ∀ b, ∀ q : ℤ, q < 0 → (G b) q vac = 0)
    (hAvac : ∀ p : ℤ, A p vac = 0)
    (m : ℤ) (b : 𝒱) : A m b = 0
```

File `VOA/Core/Goddard.lean` (`VOA.PreVertexAlgebra.goddard_uniqueness`, `VOA.goddard_zero`).

```
theorem goddard_uniqueness_vac (V : PreVertexAlgebra 𝒱) (A : FormalDist (End ℂ 𝒱)) (a : 𝒱)
    (hAloc : ∀ b : 𝒱, ∃ N : ℕ, mulBySubPow N (applyVec V.vacuum (bracketDist A (V.Y b))) =
    ↪ 0)
    (hAvac : ∀ m : ℤ, A m V.vacuum = (V.Y a) m V.vacuum) :
    A = V.Y a
```

File `VOA/Core/WeakAssoc.lean` (`VOA.PreVertexAlgebra.goddard_uniqueness_vac`). Here `applyVec x F m n = (F m n) x` evaluates an operator-valued two-variable distribution on a vector (`VOA.applyVec`, `VOA/Core/Goddard.lean`).

From the mathematics to the Lean statement

Hypotheses. In (i), `hAloc` is locality with every vertex operator and `hAvac` equality on the vacuum of the coefficient of every power z^m. A is not assumed to be a field. In (ii), `hAloc` is weaker: only $[A(z_1), Y(b, z_2)]\mathbf{1}$, a V-valued two-variable distribution, is required to be killed. (ii) implies (i) (apply a locality relation to $\mathbf{1}$) and is what skew-symmetry uses (Section 4.12). In (iii) the conclusion `A m b = 0` for all m, b is $A = 0$; no vertex algebra is present; `hcre0`/`hcreneg` say $G_b(w)\mathbf{1} \in b + wV[[w]]$. (iii) is the version needed *before* a vertex algebra exists, in the reconstruction theorem (Section 4.15).
Strength. (i) is Kac's uniqueness theorem (Kac, §4.4) and the uniqueness half of the reconstruction theorem of Frenkel–Ben-Zvi (§4.4); it is stated here with no translation operator, and it is *true* without one: the proof uses only Lemma 4.12. In the counterexample of Section 4.5 it holds (the reader may check that the field $A = Y(x, \cdot) + z\, y\, \cdot$, which is local with everything, does not create $Y(x, z)\mathbf{1}$: it creates $x + zy + z^2 y$).

Physical meaning

"The state determines the field." A local operator in a chiral CFT is uniquely fixed by the state it creates from the vacuum, because the vacuum is cyclic and separating for local fields; two local operators creating the same state would differ by a local operator annihilating the vacuum, which must vanish (a chiral Reeh–Schlieder argument). This is why one may speak of *the* field of a state.

Proof on paper. (iii) first. Fix b and put $D(z, w) := A(z)G_b(w)\mathbf{1}$. Since $A(z)\mathbf{1} = 0$, $D = [A(z), G_b(w)]\mathbf{1}$, so $(z - w)^N D = 0$ by locality. Since $G_b(w)\mathbf{1}$ has no negative powers of w, D is lower-truncated in w (bound 0). By the cancellation lemma $D = 0$, and its w^0-coefficient is $A(z)b = 0$. (i) and (ii): apply the same argument to $D = A(z)Y(b, w)\mathbf{1} - Y(a, z)Y(b, w)\mathbf{1} =$

$[A(z),Y(b,w)]\mathbf{1} - [Y(a,z),Y(b,w)]\mathbf{1}$ (using $A\mathbf{1} = Y(a)\mathbf{1}$), killed by $(z-w)^{N_1+N_2}$, with N_2 the locality order of (a,b) (VA4); reading off w^0 gives $A(z)b = Y(a,z)b$. □

What the machine verified

All three unconditional, axiom-clean (`#print axioms` of `VOA.PreVertexAlgebra.goddard_uniqueness` and `VOA.goddard_zero` run for this chapter; `goddard_uniqueness_vac` is in the dependency cone of `skew`, also clean).

4.9 Dong's lemma and the calculus of local fields

The second engine is that locality propagates. All results of this section are about arbitrary operator-valued distributions on an arbitrary complex vector space V — no vertex algebra, no vacuum.

4.9.1 Elementary closure properties

Proposition 4.15. *Let a, b be distributions on V.*

(a) If a, b are local then so are b, a, and so are $\partial a, b$ and $a, \partial b$ (and all iterated derivatives).

(b) The identity field $1(z) = \mathrm{id} \cdot z^0$ is a field, local with every distribution, and $:a\,1: = a$ for every field a.

(c) If a, b are fields then ∂a and $:ab:$ are fields.

```
theorem Local.derivL {a b : FormalDist (End ℂ V)} (h : Local a b) : Local (deriv a) b

theorem Local.deriv_iterate_left {a b : FormalDist (End ℂ V)} (h : Local a b) (i : ℕ) :
    Local ((deriv^[i]) a) b

theorem Local.symm {a b : FormalDist (End ℂ V)} (h : Local a b) : Local b a

noncomputable def idField : FormalDist (End ℂ V) := fun j => if j = 0 then LinearMap.id
 ↪ else 0

theorem Local_idField_left (b : FormalDist (End ℂ V)) :
    Local (idField : FormalDist (End ℂ V)) b

theorem nprod_idField {a : FormalDist (End ℂ V)} (ha : IsField a) :
    nprod ha (idField_isField) = a

theorem IsField.nprod {a b : FormalDist (End ℂ V)} (ha : IsField a) (hb : IsField b) :
    IsField (nprod ha hb)
```

File `VOA/Core/FieldOps.lean`. And

```
theorem IsField.deriv {a : FormalDist (End ℂ V)} (ha : IsField a) :
    IsField (VOA.deriv a)
```

File `VOA/Core/Dong.lean`.

From the mathematics to the Lean statement

`deriv^[i]` is the i-fold iterate of ∂_z. The right-hand versions (`Local.derivR`, `Local.deriv_iterate_right`, `Local_idField_right`) are in the same file. `idField` has coefficient id at z^0: it is the unit field (the same object as the `1` of VA2, defined separately for an arbitrary space). Locality of ∂a with b costs one extra power: $(z_1-z_2)^{N+1}[\partial a, b] = 0$ if

$(z_1 - z_2)^N [a, b] = 0.$

Physical meaning

Derivatives of local fields are local (the derivative $\partial\phi$ of a primary is a descendant field of the same theory), the identity operator commutes with everything, and normal ordering with the identity is trivial. These are the bookkeeping facts behind "the operator content of a chiral algebra is closed under ∂ and normal ordering".

Proof on paper. (a) Symmetry: swapping the variables turns $(z_1-z_2)^N$ into $(-1)^N(z_1-z_2)^N$ and $[a,b]$ into $-[b,a]$. Derivative: differentiate $(z_1-z_2)^N[a(z_1),b(z_2)] = 0$ in z_1 to get $(z_1-z_2)^N[\partial a, b] = -N(z_1-z_2)^{N-1}[a,b]$, and multiply by $z_1 - z_2$. (b) id is central; $:a1:_s = \sum_m :a_m 1_{s-m}: = a_s$ since only $m = s$ contributes. (c) The truncation bound of ∂a shifts by one; for $:ab:$ on a vector x the finitely many a_m with $m < 0$ that do not kill x, and the truncation of b on finitely many vectors, give a bound. □

What the machine verified

All unconditional and axiom-clean (in the dependency cone of `gen_local` and `reconstruct`, both checked for this chapter).

4.9.2 Dong's lemma

Theorem 4.16 (Dong's lemma, all products)**.** *Let a, b, c be pairwise local distributions on V. Then for every $k \geq 0$ the field product $a_{(k)}b := \mathrm{Res}_{z_1}(z_1 - z_2)^k [a(z_1), b(z_2)]$ is local with c. If moreover a, b are fields, then $:ab:$ is local with c, and hence so are all negative products $a_{(-m-1)}b = \frac{1}{m!}:(\partial^m a)b:$.*

```
theorem jacobi₃ (a b c : FormalDist (End ℂ V)) :
    outerC₁₂ (bracketDist a b) c
      = outerA a (bracketDist b c) - outerB b (bracketDist a c)

theorem dong_core (a b c : FormalDist (End ℂ V)) {r : ℕ}
    (hab : mulBySubPow r (bracketDist a b) = 0)
    (hac : mulBySubPow r (bracketDist a c) = 0)
    (hbc : mulBySubPow r (bracketDist b c) = 0)
    (k M : ℕ) (hM : 2 * r ≤ M) :
    mulBySub₂₃Pow (M + r) (mulBySub₁₂Pow k (outerC₁₂ (bracketDist a b) c)) = 0

theorem dong_nonneg {a b c : FormalDist (End ℂ V)}
    (hab : Local a b) (hac : Local a c) (hbc : Local b c) (k : ℕ) :
    Local (cCoeff k (bracketDist a b)) c

theorem dong_neg {a b c : FormalDist (End ℂ V)} (ha : IsField a) (hb : IsField b)
    (hab : Local a b) (hac : Local a c) (hbc : Local b c) :
    Local (nprod ha hb) c
```

File `VOA/Core/Dong.lean`.

From the mathematics to the Lean statement

Three-variable objects. `FormalDist₃ W` is $\mathbb{Z}^3 \to W$, the coefficient of $z_1^m z_2^n z_3^p$ (`VOA/Foundations/FormalDist3.lean`). `outerC₁₂ X c` is $[X(z_1,z_2), c(z_3)]$, `outerA a X` is $[a(z_1), X(z_2,z_3)]$, `outerB b X` is $[b(z_2), X(z_1,z_3)]$; `mulBySub₁₂Pow k`, `mulBySub₂₃Pow k` multiply by $(z_1 - z_2)^k$, $(z_2 - z_3)^k$. So `jacobi₃` is the operator Jacobi identity $[[a,b],c] =$

$[a,[b,c]] - [b,[a,c]]$ with variables attached, and `dong_core` says $(z_2 - z_3)^{M+r}(z_1 - z_2)^k[[a(z_1), b(z_2)], c(z_3)] = 0$ once $M \geq 2r$, with r a common locality order. `dong_nonneg` is the $k \geq 0$ case of the theorem (`cCoeff k` as in Section 4.2); `dong_neg` the normal-ordered case. The negative products follow by combining `dong_neg` with `Local.deriv_iterate_left` (this combination is `Fld.prod_local_right_of_pairwise`, Theorem 4.47).

Fidelity. This is Kac's Lemma 3.2 (Dong's lemma) for all $n \in \mathbb{Z}$. The hypotheses are exactly pairwise locality, plus the field property where it is needed to form the product.

Physical meaning

Dong's lemma is the closure of local fields under the OPE: if a, b, c are mutually local chiral fields, then every coefficient of the OPE $a(z)b(w)$ — singular or regular — is a chiral field local with c. It is why the composite operators of a CFT ($:JJ:, \partial J, :TT:, \ldots$) are again legitimate chiral fields with the same commutativity properties as their constituents.

Proof on paper. Let r bound the three locality orders and $M \geq 2r$. By the operator Jacobi identity,

$$(z_2 - z_3)^{M+r}(z_1 - z_2)^k[[a_1, b_2], c_3] = (z_2 - z_3)^{M+r}(z_1 - z_2)^k\big([a_1, [b_2, c_3]] - [b_2, [a_1, c_3]]\big),$$

with subscripts naming the variables. The first term dies because $(z_2 - z_3)^r$ passes through $a(z_1)$ and kills $[b_2, c_3]$. For the second write $(z_2 - z_3)^M = \big((z_2 - z_1) + (z_1 - z_3)\big)^M = \sum_i \binom{M}{i}(z_2 - z_1)^i(z_1 - z_3)^{M-i}$: terms with $M - i \geq r$ die by locality of a, c (the factor passes through $b(z_2)$); the others have $i > M - r \geq r$, and $(z_2 - z_1)^i$ together with the identity $[b_2, [a_1, c_3]] = [a_1, [b_2, c_3]] - [[a_1, b_2], c_3]$ splits into a term killed by $(z_1 - z_2)^r$ (locality of a, b) and a term killed by the reserve factor $(z_2 - z_3)^r$ (locality of b, c). This proves `dong_core`. Taking Res_{z_1} commutes with multiplication by $(z_2 - z_3)$ and turns $(z_1 - z_2)^k[[a_1, b_2], c_3]$ into $[(a_{(k)}b)(z_2), c(z_3)]$, giving `dong_nonneg` with order $3r$. For `dong_neg`, one first proves $(z_1 - z_3)^r(z_2 - z_3)^{3r}[:a(z_1)b(z_2):, c(z_3)] = 0$ by splitting $:a_1 b_2: = a_+(z_1)b(z_2) + b(z_2)a_-(z_1)$ and reusing `dong_core` for the part that is a genuine double commutator; then one restricts to the diagonal $z_1 = z_2$, which is legitimate on each vector because a, b are fields (`diag3`, a finite sum), and both factors become powers of $(z - z_3)$: order $4r$. □

What the machine verified

`dong_nonneg`, `dong_neg`: unconditional; `#print axioms = [propext, Classical.choice, Quot.sound]` for both (run for this chapter).

4.10 The reconstruction cascade in a VOA

From here on W is a `VertexOperatorAlgebra`. The single new input is (VOA3). We follow the dependency order of `VOA/Core/Identities.lean` and `VOA/Core/Reconstruction.lean`.

4.10.1 Creation: $Y(u,z)\mathbf{1} = e^{zT}u$

Theorem 4.17 (Derivative property and creation). *In a VOA: $T = L_{-1}$; $Y(T^j u, z) = \partial_z^j Y(u,z)$ for all $j \in \mathbb{N}$; and $u_{(-k-1)}\mathbf{1} = \frac{1}{k!}T^k u$ for all $k \in \mathbb{N}$.*

```
theorem T_eq_Lneg1 (W : VertexOperatorAlgebra V) : W.toPreVertexAlgebra.T = W.L (-1)

theorem Y_Tpow (W : VertexOperatorAlgebra V) (u : V) (j : ℕ) :
    W.Y ((W.toPreVertexAlgebra.T ^ j) u) = (deriv^[j]) (W.Y u)
```

```
theorem creation_pow (W : VertexOperatorAlgebra V) (a : V) (k : ℕ) :
    W.smul a (-(k : ℤ) - 1) W.vacuum
      = ((k.factorial : ℂ)⁻¹) • ((W.toPreVertexAlgebra.T ^ k) a)
```

File `VOA/Core/Identities.lean`.

From the mathematics to the Lean statement

`W.toPreVertexAlgebra.T` is the translation operator of Definition 4.2 of the underlying `PreVertexAlgebra`; `W.L (-1)` $= \omega_{(0)}$. `T ^ j` is the j-th power in $\mathrm{End}\, V$, `deriv^[j]` the j-th iterate of ∂_z. `-(k : ℤ) - 1` is the mode index $-k-1$. The short proof of $T = L_{-1}$ is the proof on paper after Theorem 4.18; the point for us is that *every step uses (VOA3)*, and that the counterexample of Section 4.5 violates all three conclusions (with $T = 0$ and $x_{(-3)}\mathbf{1} = y$).

Physical meaning

The vacuum is translation invariant and the state created at z is the translate of the state created at 0: $u(z)|0\rangle = e^{zL_{-1}}u(0)|0\rangle$. This is the translation Ward identity on the vacuum module.

What the machine verified

Unconditional, axiom-clean (`#print axioms` run for `T_eq_Lneg1`, `creation_pow`, `Y_Tpow`).

Theorem 4.18 (The derivative property $Y(Tu,z) = \partial_z Y(u,z)$)**.** *In a VOA, for every $u \in V$: $Y(Tu,z) = \partial_z Y(u,z)$, where $T = L_{-1}$ is the translation operator of Definition 4.2. In modes, $(Tu)_{(n)} = -n\,u_{(n-1)}$ for all $n \in \mathbb{Z}$.*

File `VOA/Core/Identities.lean`.

```
theorem Y_T (W : VertexOperatorAlgebra V) (u : V) :
    W.Y (W.toPreVertexAlgebra.T u) = deriv (W.Y u)

theorem mode_Y_T (W : VertexOperatorAlgebra V) (u : V) (n : ℤ) :
    mode (W.Y (W.toPreVertexAlgebra.T u)) n = (-n) • mode (W.Y u) (n - 1)
```

From the mathematics to the Lean statement

`W.toPreVertexAlgebra.T` is the translation operator $Tu = u_{(-2)}\mathbf{1}$ of the underlying `PreVertexAlgebra` (Definition 4.2); `W.Y` is the state–field map; `deriv` is the formal derivative ∂_z of Definition 2.7 (Chapter 2), so `deriv (W.Y u)` is $\sum_n (-n-1)u_{(n)}z^{-n-2}$; the equality is an equality of formal distributions, i.e. of all coefficients. `mode f n` is the coefficient f_{-n-1} (the library convention of Chapter 2), and `(-n) • ...` is multiplication by the integer $-n$ cast to $\mathbb{C}$. **Hypotheses:** none beyond "W is a VOA". **Same, stronger or weaker?** The statement is the textbook one, Gannon (5.1.8a) and Kac's translation axiom: the field of Tu is the derivative of the field of u. What deserves attention is where the statement comes from. The weaker structure `PreVertexAlgebra` does not imply it (the counterexample of Theorem 4.7 has $T = 0$ but a field that is not constant); for a VOA the statement is the axiom (VOA3), which is written with L_{-1}, combined with the identification $T = L_{-1}$ (Theorem 4.17). **Could it be vacuous?** No: it is an equation between nonzero fields in every nonzero VOA (for the Heisenberg VOA, $TJ = J_{(-2)}\mathbf{1}$ and $Y(TJ,z) = \partial_z J(z)$).

Physical meaning

Derivatives of a field are generated by the stress tensor: $[L_{-1}, \phi(z)] = \partial\phi(z)$, and, since $L_{-1}u = \partial u$ is the state of the derivative operator, the field of that state is the derivative of the field. This is the "state–operator" form of the translation Ward identity in a chiral CFT. In modes it is the familiar rule that differentiating $\sum_n u_{(n)}z^{-n-1}$ multiplies the n-th mode by $-n$ and lowers its index, e.g. $\partial J(z) = \sum_n (-n)J_{(n-1)}z^{-n-1}$ for a current.

Proof on paper. By the axiom (VOA3), $Y(L_{-1}u, z) = \partial_z Y(u, z)$, so it suffices to show $T = L_{-1}$. Evaluate (VOA3) on the vacuum and use creation $Y(v, z)\mathbf{1} \in v + zV[[z]]$: the z^0-coefficient of $Y(L_{-1}u, z)\mathbf{1}$ is $L_{-1}u$, while the z^0-coefficient of $\partial_z Y(u, z)\mathbf{1}$ is the z^1-coefficient of $Y(u, z)\mathbf{1}$, which is $u_{(-2)}\mathbf{1} = Tu$. Hence $L_{-1}u = Tu$. The mode form is obtained by comparing the coefficient of z^{-n-1} on both sides of $Y(Tu, z) = \partial_z Y(u, z)$: $\partial_z \sum_k u_{(k)}z^{-k-1} = \sum_k (-k-1)u_{(k)}z^{-k-2} = \sum_n (-n)u_{(n-1)}z^{-n-1}$ after the substitution $k = n - 1$. □

What the machine verified

Unconditional. `#print axioms VOA.VertexOperatorAlgebra.Y\_T` = `[propext, Classical.choice, Quot.sound]` (run for this chapter at the commit of the front matter, with `lake env lean -DmaxSynthPendingDepth=3`); `mode_Y_T` proved from it by rewriting. The PBW theorem `VOA.pbw` (Chapter 3; formerly a project axiom, now a theorem) is not used.

4.10.2 Translation covariance

Theorem 4.19 (Translation covariance). *In a VOA,* $[L_{-1}, Y(u, z)] = Y(L_{-1}u, z) = \partial_z Y(u, z)$. *In modes:* $[L_{-1}, u_{(n)}] = (L_{-1}u)_{(n)} = -n\, u_{(n-1)}$.

```
theorem translation_covariance (W : VertexOperatorAlgebra 𝒱) (u : 𝒱) :
    cCoeff 0 (bracketDist (W.Y W.conformalVector) (W.Y u)) = W.Y (W.L (-1) u)

theorem L_neg_one_deriv (W : VertexOperatorAlgebra 𝒱) (u w : 𝒱) (n : ℤ) :
    W.L (-1) (W.smul u n w) - W.smul u n (W.L (-1) w) = W.smul (W.L (-1) u) n w

theorem L_comm_mode (W : VertexOperatorAlgebra 𝒱) (u : 𝒱) (n : ℤ) :
    ⁅W.L (-1), mode (W.Y u) n⁆ = (-n) • mode (W.Y u) (n - 1)
```

File `VOA/Core/Reconstruction.lean`.

From the mathematics to the Lean statement

`cCoeff 0 (bracketDist (Y ω) (Y u))` is $\mathrm{Res}_{z_1}[Y(\omega, z_1), Y(u, z_2)] = [\omega_{(0)}, Y(u, z_2)] = [L_{-1}, Y(u, z_2)]$ (library lemma `cCoeff_zero_omega_apply`). Note that (VOA3) is $Y(L_{-1}u) = \partial Y(u)$, an equality of the field *of a state*; translation covariance is the *operator* statement $[L_{-1}, Y(u)] = \partial Y(u)$, which Kac and FBZ take as their axiom. It is a theorem here, and the combination of the two is Kac's axiom. `L_neg_one_deriv` is the z^{-n-1}-coefficient applied to w; `L_comm_mode` rewrites $(L_{-1}u)_{(n)} = (Tu)_{(n)} = -n\, u_{(n-1)}$.

Physical meaning

The stress tensor generates translations of every field: $[L_{-1}, \phi(z)] = \partial\phi(z)$, the conformal Ward identity for $z \mapsto z + \epsilon$, obtained by contour-integrating $T(w)\phi(z)$ around z.

Proof on paper. The candidate field $A := [L_{-1}, Y(u, \cdot)] = \mathrm{Res}_{z_1}[Y(\omega, z_1), Y(u, \cdot)]$ is local with every $Y(b, \cdot)$ by Dong's lemma (`dong_nonneg` with $k = 0$, applied to the pairwise local

$Y(\omega), Y(u), Y(b)$). On the vacuum, $A(z)\mathbf{1} = L_{-1}Y(u,z)\mathbf{1}$ because $L_{-1}\mathbf{1} = T\mathbf{1} = 0$; and $L_{-1}(u_{(s)}\mathbf{1}) = (L_{-1}u)_{(s)}\mathbf{1}$ for all s (both are $T^{j+1}u/j!$ for $s = -j-1$ by `creation_pow`, and 0 for $s \geq 0$). So A creates $Y(L_{-1}u,z)\mathbf{1}$, and Goddard (Theorem 4.14(i)) gives $A = Y(L_{-1}u,\cdot)$. □

What the machine verified

Unconditional, axiom-clean (`#print axioms translation_covariance` run for this chapter).

4.10.3 Duality for $n \geq 0$ and the commutator formula

Theorem 4.20 (The n-th product theorem, $n \geq 0$). *In a VOA, for all u, v and $k \in \mathbb{N}$:*

$$Y(u_{(k)}v,z) = \mathrm{Res}_{z_1}(z_1 - z)^k [Y(u,z_1), Y(v,z)].$$

```
theorem cCoeff_vacuum_eq (W : VertexOperatorAlgebra V) (u v : V) (k : ℕ) (m : ℤ) :
    cCoeff k (bracketDist (W.Y u) (W.Y v)) m W.vacuum = (W.Y (W.smul u k v)) m W.vacuum

theorem nth_product (W : VertexOperatorAlgebra V) (u v : V) (k : ℕ) :
    cCoeff k (bracketDist (W.Y u) (W.Y v)) = W.Y (W.smul u k v)

theorem assoc_nonneg (W : VertexOperatorAlgebra V) (u v : V) (k : ℕ) :
    W.Y (W.smul u k v) = cCoeff k (bracketDist (W.Y u) (W.Y v))
```

File `VOA/Core/Reconstruction.lean`.

From the mathematics to the Lean statement

`W.smul u k v` with `k : ℕ` coerced to $\mathbb{Z}$ is $u_{(k)}v$. `assoc_nonneg` is `nth_product` read backwards (Gannon (5.1.9b)). This is Kac's "n-th product identity" $Y(a_{(n)}b,z) = Y(a,z)_{(n)}Y(b,z)$ (Kac, §4.6) for $n \geq 0$: the state–field map is a homomorphism for the nonnegative products.

Physical meaning

The field of the state $u_{(k)}v$ — the coefficient of $(z-w)^{-k-1}$ in the OPE $u(z)v(w)$ — is the corresponding OPE coefficient *field*: OPE coefficients of states and of operators agree. This is the state–operator correspondence applied to the singular part of the OPE.

Proof on paper. The left field is local with every $Y(b,\cdot)$ by Dong's lemma. It creates $u_{(k)}v$: on the vacuum its z^m-coefficient vanishes for $m < 0$ (all modes $v_{(q)}$, $q \geq 0$, kill $\mathbf{1}$, and $(z_1 - z)^k$ has no negative powers of z), its z^0-coefficient is $\mathrm{Res}_{z_1}(z_1)^k Y(u,z_1)v = u_{(k)}v$, and the higher coefficients follow by induction from $[L_{-1},\cdot\,]$ acting as ∂_z on both sides (`L_comm_cCoeff`, `L_comm_Ycoeff`) together with $L_{-1}\mathbf{1} = 0$. This is `cCoeff_vacuum_eq`; Goddard finishes. □

What the machine verified

Unconditional, axiom-clean.

Theorem 4.21 (Commutator formula). *In a VOA, for all u, v and $a, b \in \mathbb{Z}$, $[u_{(a)}, v_{(b)}] = \sum_{j \geq 0} \binom{a}{j} (u_{(j)}v)_{(a+b-j)}$ (a finite sum).*

```
theorem mode_commutator (W : VertexOperatorAlgebra V) (u v : V) (a b : ℤ) :
    ∃ N : ℕ, ⁅mode (W.Y u) a, mode (W.Y v) b⁆
      = ∑ j : Fin N, gBinom a (j : ℕ) • mode (W.Y (W.smul u (j : ℕ) v)) (a + b - (j : ℕ))

theorem commBound (W : VertexOperatorAlgebra V) (u v : V) (m n : ℤ) :
    ∃ N : ℕ, (∀ k : ℕ, N ≤ k → W.smul u k v = 0)
      ∧ ⁅mode (W.Y u) m, mode (W.Y v) n⁆
        = ∑ j : Fin N, gBinom m (j : ℕ) • mode (W.Y (W.smul u (j : ℕ) v)) (m + n - (j : ℕ))
```

File `VOA/Core/Reconstruction.lean` (`mode_commutator`) and `VOA/Core/Borcherds.lean` (`commBound`). The theorem `jacobi_commutator` of `VOA/Core/BorcherdsIdentity.lean` is `mode_commutator` under another name.

From the mathematics to the Lean statement

`gBinom a j` is $\binom{a}{j} = a(a-1)\cdots(a-j+1)/j!$ for $a \in \mathbb{Z}$ (Chapter 2, Definition 2.14). **The existential.** `mode_commutator` asserts the identity for *some* N; read alone it does not say that the omitted terms $j \geq N$ vanish, so it is formally weaker than the textbook "$\sum_{j\geq 0}$". `commBound` closes the gap: the same N also satisfies $u_{(k)}v = 0$ for all $k \geq N$, so the finite sum *is* the full sum. Together they are exactly the commutator formula of Gannon (5.1.7c), Kac (§4.6) and Lepowsky–Li (§3.1).

Physical meaning

"Commutators of modes are determined by the singular part of the OPE." For the Virasoro field, $T(z)T(w) \sim \frac{c/2}{(z-w)^4} + \frac{2T(w)}{(z-w)^2} + \frac{\partial T(w)}{z-w}$ produces the Virasoro relations; for currents $J^a(z)J^b(w) \sim \frac{k\delta^{ab}}{(z-w)^2} + \frac{f^{abc}J^c(w)}{z-w}$ the affine Kac–Moody relations.

Proof on paper. Theorem 4.13 gives the structural formula with coefficients c_j; the delta-decomposition determines $c_j = \frac{1}{j!}\operatorname{Res}_{z_1}(z_1-z)^j[Y(u,z_1),Y(v,z)]$ (`cCoeff_deltaSum`), which is $\frac{1}{j!}Y(u_{(j)}v,z)$ by Theorem 4.20; and $a^{\underline{j}}/j! = \binom{a}{j}$. For `commBound`, the same decomposition shows $\operatorname{Res}_{z_1}(z_1-z)^k[\cdots] = 0$ for $k \geq N$, i.e. $Y(u_{(k)}v) = 0$, and creation gives $u_{(k)}v = 0$. □

What the machine verified

Both unconditional, axiom-clean.

4.10.4 Duality for $n < 0$

Theorem 4.22 (The n-th product theorem, $n < 0$). *In a VOA, for all u, v and $k \in \mathbb{N}$,*

$$Y(u_{(-k-1)}v,z) = \frac{1}{k!}\,{:}\partial_z^k Y(u,z)\,Y(v,z){:}.$$

```
theorem assoc_neg (W : VertexOperatorAlgebra V) (u v : V) (k : ℕ) :
    W.Y (W.smul u (-(k:ℤ) - 1) v) = negProd (W.isField_Y u) (W.isField_Y v) k
```

File `VOA/Core/Reconstruction.lean`.

From the mathematics to the Lean statement

`negProd (W.isField_Y u) (W.isField_Y v) k` is $\frac{1}{k!}{:}(\partial^k Y(u))Y(v){:}$ (Section 4.2); the two `isField_Y` arguments are the proofs that the vertex operators are fields, needed to form the normal-ordered product. With $k = 0$: $Y(u_{(-1)}v,z) = {:}Y(u,z)Y(v,z){:}$, Gannon (5.1.9a), Kac (§4.6). Together with Theorem 4.20: $Y(u_{(n)}v,z) = Y(u,z)_{(n)}Y(v,z)$ for *all* $n \in \mathbb{Z}$.

Physical meaning

The regular part of the OPE: the field of the state $u_{(-k-1)}v$ is the k-th Taylor coefficient of $u(z)v(w)$ at $z = w$ after subtracting the poles, i.e. ${:}\partial^k u\,v{:}/k!$. For instance the Sugawara or free-boson stress tensor is the field of the state $\frac{1}{2}J_{(-1)}J$, namely $\frac{1}{2}{:}JJ{:}$.

Proof on paper. Replace $\partial^k Y(u)$ by $Y(T^k u)$ (Theorem 4.17). The field $\frac{1}{k!}{:}Y(T^k u)Y(v){:}$ is local with every $Y(b)$ by `dong_neg`. On the vacuum, its negative z-powers vanish (in each normal-ordered term the factor acting first on $\mathbf{1}$ is a coefficient of a negative power of z, which kills $\mathbf{1}$), its z^0-coefficient is $\frac{1}{k!}(T^k u)_{(-1)}v = u_{(-k-1)}v$ (iterate `mode_Y_T`: $(Tu)_{(n)} = -n\,u_{(n-1)}$), and the higher coefficients are pinned by translation covariance of the normal-ordered product (`nprod_L_comm`) and $L_{-1}\mathbf{1} = 0$ via the recursion $L_{-1}(F_s\mathbf{1}) = (s+1)F_{s+1}\mathbf{1}$ (`vacuum_recursion_eq`). So it creates $Y(u_{(-k-1)}v, z)\mathbf{1}$, and Goddard finishes. □

What the machine verified

Unconditional, axiom-clean (`#print axioms VOA.VertexOperatorAlgebra.assoc_neg` run for this chapter).

4.10.5 The iterate formula for all ℓ

Theorem 4.23 (Iterate (associativity) formula). *In a VOA, for all u, v, x and $\ell, n \in \mathbb{Z}$,*

$$(u_{(\ell)}v)_{(n)}x = \sum_{i\geq 0}(-1)^i\binom{\ell}{i}\Big(u_{(\ell-i)}v_{(n+i)}x - (-1)^{\ell}\,v_{(\ell+n-i)}u_{(i)}x\Big).$$

```

        (mode (W.Y u) ((k : ℤ) - i) * mode (W.Y v) (n + i)
          - ((-1 : ℂ) ^ k) • (mode (W.Y v) ((k : ℤ) + n - i) * mode (W.Y u) (i)))
```

File `VOA/Core/Reconstruction.lean`.

```
theorem mode_iterate_neg (W : VertexOperatorAlgebra 𝒱) (u v : 𝒱) (k : ℕ) (N : ℤ) (x : 𝒱) :
    W.smul (W.smul u (-(k:ℤ) - 1) v) N x
      = ∑ᶠ i : ℕ, ((-1:ℂ)^i * gBinom (-(k:ℤ)-1) i) •
          (W.smul u (-(k:ℤ)-1-i) (W.smul v (N+i) x)
            - ((-1:ℂ)^(-(k:ℤ)-1)) • W.smul v (-(k:ℤ)-1+N-i) (W.smul u i x))

theorem mode_iterate (W : VertexOperatorAlgebra 𝒱) (u v : 𝒱) (ℓ N : ℤ) (x : 𝒱) :
    W.smul (W.smul u ℓ v) N x
      = ∑ᶠ i : ℕ, ((-1:ℂ)^i * gBinom ℓ i) •
          (W.smul u (ℓ - i) (W.smul v (N + i) x)
            - ((-1:ℂ)^ℓ) • W.smul v (ℓ + N - i) (W.smul u i x))
```

File `VOA/Core/BorcherdsIdentity.lean`.

From the mathematics to the Lean statement

Operator vs. vector form. For $\ell = k \geq 0$ the identity is stated as an equality of operators (no x), a sum over $i \in \{0, \dots, k\}$ since $\binom{k}{i} = 0$ for $i > k$. For $\ell < 0$ the binomial $\binom{\ell}{i}$ never vanishes and the sum over i is infinite as an operator identity; it is finite only after applying to x (the factors $v_{(N+i)}x$ and $u_{(i)}x$ vanish for $i \gg 0$ by VA5). Hence `mode_iterate` is stated on vectors with $\sum^{\mathrm{f}}$ (`finsum`: a genuine sum when the support is finite, 0 otherwise). Its support is finite for the reason just given, so $\sum^{\mathrm{f}}$ is a true finite sum here (the library proves the corresponding finiteness lemmas `Puv_fin`, `Pvu_fin`, Section 4.11).

Signs. `(-1:ℂ)^ℓ` with `ℓ : ℤ` is the integer power (± 1); for $\ell = -k-1$ it is $(-1)^{k+1}$ (library lemma `neg_one_zpow_negsucc`). The formula is Gannon (5.1.7d), the iterate formula of Lepowsky–Li (§3.1), and the $m = 0$ case of the Borcherds identity in Kac (§4.8).

Physical meaning

The iterate formula expresses the modes of a composite field $(u_{(\ell)}v)(z)$ through the modes of its constituents, with radial ordering taken into account (the two sums are the two orderings $|z_1| > |z_2|$ and $|z_2| > |z_1|$). It is the mode form of associativity of the OPE: expanding $u(z_1)v(z_2)x$ around z_2 first, or computing the OPE $u \times v$ first and then acting on x, gives the same answer.

Proof on paper. For $\ell = k \geq 0$: by Theorem 4.20, $(u_{(k)}v)_{(n)}$ is the z^{-n-1}-coefficient of $\mathrm{Res}_{z_1}(z_1-z)^k[Y(u,z_1),Y(v,z)]$; expanding $(z_1-z)^k = \sum_r \binom{k}{r} z_1^r(-z)^{k-r}$ gives $\sum_r (-1)^{k-r}\binom{k}{r}[u_{(r)},v_{(n+k-r)}]$, and reindexing $r = k-i$ in the first half (with $\binom{k}{k-i} = \binom{k}{i}$) and writing $(-1)^{k-i} = (-1)^i(-1)^k$ in the second half gives the displayed form. For $\ell = -k-1$: by Theorem 4.22 the left side is the z^{-N-1}-coefficient of $\frac{1}{k!}{:}\partial^k Y(u)Y(v){:}$ applied to x, i.e. $\frac{1}{k!}\sum_m {:}(\partial^k Y(u))_m Y(v)_{-N-1-m}{:}x$. Split the sum into $m \geq 0$ (creation part, on the left) and $m \leq -k-1$ (annihilation part, on the right; the range $-k-1 < m < 0$ contributes zero because the falling factorial from ∂^k vanishes there). Reindex the two ranges by $m = i$ and $m = -k-1-i$; the coefficients are $\frac{1}{k!}\prod_{j<k}(i+1+j) = \binom{k+i}{i} = (-1)^i\binom{-k-1}{i}$ and its signed analogue (`posfac_eq`, `negfac_eq`). This is the displayed formula. □

What the machine verified

`mode_iterate` (and both branches): unconditional; `#print axioms VOA.VertexOperatorAlgebra.mode_iterate` = `[propext, Classical.choice, Quot.sound]` (run for this chapter).

4.11 The Borcherds identity

Definition 4.24 (The two sides). For $u, v, x \in V$ and $\ell, m, n \in \mathbb{Z}$ put

$$B_{\mathrm{R}}(\ell,m,n) = \sum_{i\geq 0}\binom{m}{i}(u_{(\ell+i)}v)_{(m+n-i)}x,$$

$$P_{uv}(\ell,m,n) = \sum_{i\geq 0}(-1)^i\binom{\ell}{i}u_{(\ell+m-i)}v_{(n+i)}x, \qquad P_{vu}(\ell,m,n) = \sum_{i\geq 0}(-1)^i\binom{\ell}{i}v_{(\ell+n-i)}u_{(m+i)}x,$$

$$B_{\mathrm{L}}(\ell,m,n) = P_{uv}(\ell,m,n) - (-1)^\ell P_{vu}(\ell,m,n).$$

File `VOA/Core/Borcherds.lean`.

From the mathematics to the Lean statement

`cbz n i` is $\binom{n}{i}$ for $i \geq 0$ and 0 for $i < 0$ (`VOA/Foundations/Substitution.lean`), so the sums over $i \in \mathbb{Z}$ are sums over $i \geq 0$. `negOnePow i` is $(-1)^i$ as a complex number. Each of the three $\sum^{\mathrm{f}}$

has finite support (lemmas `BR_fin`, `Puv_fin`, `Pvu_fin`): for B_{R} by VA5 for (u,v); for P_{uv} by VA5 for (v,x); for P_{vu} by VA5 for (u,x). So none of them is a silently zero "divergent" `finsum`.

Physical meaning

B_{L} and B_{R} are the two sides of OPE associativity in a three-point function $\langle x'|u(z_1)v(z_2)|x\rangle$: on the left, the two radial orderings of $u(z_1)v(z_2)$ (the difference is a contour around z_2); on the right, the OPE $u(z_1)v(z_2)$ expanded around z_2 and then $Y(\cdot,z_2)$ acting on x. The weights $(z_1-z_2)^{\ell}$ and z_1^m select one moment of each.

Lemma 4.25 (Pascal recursion and the anti-diagonal pin). *Both sides satisfy $B(\ell,m+1,n) = B(\ell,m,n+1)+B(\ell+1,m,n)$. Moreover, if a family $D:\mathbb{Z}^2\to M$ in an abelian group satisfies $D(\ell,n+1)=-D(\ell+1,n)$ for all ℓ,n and $D(0,n)=0$ for all n, then $D\equiv 0$.*

    ∀ ℓ n : ℤ, D ℓ n = 0
```

File `VOA/Core/Borcherds.lean`.

From the mathematics to the Lean statement

Pure combinatorics; `BR_rec` and `BL_rec` hold in every VOA without using any identity between modes (only Pascal's rule for $\binom{\cdot}{\cdot}$ and reindexing). `antidiag_pin` is a statement about arbitrary families.

Physical meaning

The recursion is the identity $z_1^{m+1}=z_1^m\big((z_1-z_2)+z_2\big)$ inside the Jacobi identity: raising the power of z_1 is the same as raising the power of z_2 or of z_1-z_2. Physically, the three moments of a correlator are not independent.

Proof on paper. For B_{R}: $\binom{m+1}{i}=\binom{m}{i}+\binom{m}{i-1}$, and the shift $i\mapsto i+1$ in the second sum turns it into $B_{\mathrm{R}}(\ell+1,m,n)$. For P_{uv} and P_{vu} use $\binom{\ell+1}{i}=\binom{\ell}{i}+\binom{\ell}{i-1}$ in the form $\binom{\ell}{i-1}=\binom{\ell+1}{i}-\binom{\ell}{i}$: one gets $P_{uv}(\ell,m+1,n)=P_{uv}(\ell,m,n+1)+P_{uv}(\ell+1,m,n)$ and $P_{vu}(\ell,m+1,n)=P_{vu}(\ell,m,n+1)-P_{vu}(\ell+1,m,n)$, and the sign $(-1)^{\ell+1}=-(-1)^{\ell}$ makes B_{L} satisfy the same recursion as B_{R}. For the pin: $D(\ell,n)=-D(\ell+1,n-1)=D(\ell+2,n-2)=\cdots$, so $D(\ell,n)=\pm D(0,n+\ell)=0$ (and similarly moving left for $\ell<0$). □

What the machine verified

Unconditional, axiom-clean (in the cone of `borcherds`).

Theorem 4.26 (The Borcherds identity). *In a VOA, for all $u,v,x\in V$ and all $\ell,m,n\in\mathbb{Z}$, $B_{\mathrm{L}}(\ell,m,n)=B_{\mathrm{R}}(\ell,m,n)$, i.e.*

```

File `VOA/Core/Borcherds.lean`.

From the mathematics to the Lean statement

All indices. `borcherds` and `jacobi` are quantified over all u, v, x and all $\ell, m, n \in \mathbb{Z}$, with no side condition: this is the Borcherds identity in full, Gannon (5.1.7b), Kac (4.8.3), equivalent coefficient by coefficient to the Jacobi identity (4.1) (the extraction is sketched after (4.1)). `jacobi` is `borcherds` with B_{L} written as one `finsum` (lemma `BL_as_finsum`). The base case $m = 0$ is Theorem 4.23; the boundary $\ell = 0$ is Theorem 4.21 applied to x.
What it does not say. It is stated for `VertexOperatorAlgebra` only. For a `PreVertexAlgebra` it is false in general (Theorem 4.7).

Physical meaning

The Borcherds identity is OPE associativity together with locality — crossing symmetry of the chiral three-point functions, in mode form. Every relation among OPE coefficients of a chiral algebra is a consequence of it; its $\ell = 0$ slice gives the mode algebra (current, Virasoro, W-algebras), its $m = 0$ slice the modes of composite fields. Proving it from locality is the rigorous version of "single-valued correlators with finite poles are automatically associative".

Proof on paper. Let $D_m(\ell, n) = B_{\mathrm{L}}(\ell, m, n) - B_{\mathrm{R}}(\ell, m, n)$. By Lemma 4.25, $D_{m+1}(\ell, n) = D_m(\ell, n+1) + D_m(\ell+1, n)$. For $m \geq 0$: $D_0 \equiv 0$ (base case), so $D_m \equiv 0$ by induction upward. For $m = -k-1 < 0$, induct downward: if $D_{m+1} \equiv 0$ then $D_m(\ell, n+1) = -D_m(\ell+1, n)$, and $D_m(0, n) = 0$ by the boundary case; the anti-diagonal pin gives $D_m \equiv 0$. No delta-function calculus and no rearrangement of infinite sums is used. □

What the machine verified

`borcherds`, `jacobi`: unconditional; `#print axioms = [propext, Classical.choice, Quot.sound]` for both (run for this chapter). The PBW theorem `VOA.pbw` is not used.

Theorem 4.27 (The commutator formula, as re-exposed in the Borcherds layer). *In a VOA, for all $u, v \in V$ and $a, b \in \mathbb{Z}$ there is a natural number N such that*

$$[u_{(a)}, v_{(b)}] = \sum_{j=0}^{N-1} \binom{a}{j} (u_{(j)}v)_{(a+b-j)}.$$

It is the case $\ell = 0$ of the Borcherds identity (Theorem 4.26); the case $m = 0$ is the iterate formula (Theorem 4.23).

File `VOA/Core/BorcherdsIdentity.lean`.

```
theorem jacobi_commutator (W : VertexOperatorAlgebra 𝒱) (u v : 𝒱) (a b : ℤ) :
    ∃ N : ℕ, [mode (W.Y u) a, mode (W.Y v) b]
      = ∑ j : Fin N, gBinom a (j : ℕ) • mode (W.Y (W.smul u (j : ℕ) v)) (a + b - (j : ℕ))
```

From the mathematics to the Lean statement

`[x, y]` is the commutator $xy - yx$ in the ring $\mathrm{End}(V)$ (here of two mode operators); `mode (W.Y u) a` is $u_{(a)}$; `W.smul u j v` is $u_{(j)}v$; `gBinom a j` is the binomial coefficient $\binom{a}{j} = a(a-1)\cdots(a-j+1)/j!$ for $a \in \mathbb{Z}$ (Definition 2.14); `Fin N` indexes $j = 0, \dots, N-1$; `(j : ℕ)` is the coercion $\mathrm{Fin}\, N \to \mathbb{N}$. The statement is word for word that of `mode_commutator` (Theorem 4.21); in the source the proof is the single term `mode_commutator W u v a b`, and the declaration exists so that the Borcherds file can name the $\ell = 0$ slice without importing the reconstruction file. Hence the same fidelity remarks apply: because of the existential quantifier, read alone the statement does not say that the omitted terms $j \geq N$ vanish, so it is formally weaker than the textbook "$\sum_{j \geq 0}$". The strengthening is `commBound` of Theorem 4.21, which supplies the same N with $u_{(k)}v = 0$ for $k \geq N$. The *iterate* formula, the case $m = 0$, is a different statement, `mode_iterate` of Theorem 4.23, and is not part of this theorem. **Could it be vacuous?** No: for the Virasoro field $u = v = \omega$ one finds $N = 4$ and the Virasoro relations.

Physical meaning

Commutators of modes are the singular part of the OPE: $[u_{(a)}, v_{(b)}]$ is the contour integral of the singular terms $\sum_j (u_{(j)}v)(w)/(z-w)^{j+1}$, which is why only finitely many j occur (a pole of bounded order). For currents this is the affine Kac–Moody algebra; for ω it is the Virasoro algebra with its central term $\frac{c}{12}(m^3 - m)\delta_{m+n,0}$.

Proof on paper. Put $\ell = 0$ in the Borcherds identity (4.2). Since $\binom{0}{i} = \delta_{i,0}$ the left side collapses to $u_{(m)}v_{(n)}x - v_{(n)}u_{(m)}x$, and the right side is $\sum_i \binom{m}{i}(u_{(i)}v)_{(m+n-i)}x$ with $m = a$, $n = b$. The sum is finite because $u_{(i)}v = 0$ for $i \gg 0$ (regularity), and the bound N may be chosen independent of x since the right side is a finite sum of operators. □

What the machine verified

Unconditional. `#print axioms VOA.VertexOperatorAlgebra.jacobi\_commutator` = `[propext, Classical.choice, Quot.sound]` (run for this chapter). The PBW theorem `VOA.pbw` is not used.

4.12 Skew-symmetry

Skew-symmetry is the hardest of the classical identities in the library's route, because the natural proof (Goddard uniqueness for a reflected field) requires a locality statement for a field that is not a vertex operator. The library proves it in three files: `Skew.lean` defines the candidate and reduces the theorem to a locality gate, `WeakAssoc.lean` proves the gate, and `SkewSymmetry.lean` assembles.

4.12.1 The candidate field

Definition 4.28 (The reflected field). For $u \in V$ define $\tilde{Y}(u,z) \in \mathrm{End}(V)[[z^{\pm 1}]]$ by $\tilde{Y}(u,z)b := e^{zT}Y(b,-z)u$, i.e. its z^t-coefficient is

$$\tilde{Y}(u)_t\, b = \sum_{j \geq 0} \frac{(-1)^{t-j}}{j!}\, T^j\big(Y(b)_{t-j}\, u\big),$$

where $Y(b)_s$ is the z^s-coefficient of $Y(b,z)$. The sum is finite for each b.

```
def sgn (n : ℤ) : ℂ := if Even n then 1 else -1

noncomputable def skewCoeffFun (W : VertexOperatorAlgebra V) (u : V) (t : ℤ) (b : V) : V :=
  ∑ᶠ j : ℕ, ((j.factorial : ℂ)⁻¹) • (sgn (t - j)) •
    ((W.toPreVertexAlgebra.T ^ j) ((W.Y b) (t - j) u))

theorem skew_support_finite (W : VertexOperatorAlgebra V) (u b : V) (t : ℤ) :
    (Function.support (fun j : ℕ => ((j.factorial : ℂ)⁻¹) • (sgn (t - j)) •
      ((W.toPreVertexAlgebra.T ^ j) ((W.Y b) (t - j) u)))).Finite

noncomputable def skewDist (W : VertexOperatorAlgebra V) (u : V) : FormalDist (End ℂ V) :=
  fun t => skewOp W u t
```

File `VOA/Core/Skew.lean` (`skewOp W u t` is `skewCoeffFun W u t` packaged as a linear map in b).

From the mathematics to the Lean statement

`sgn n` $= (-1)^n$. `(W.Y b) (t - j) u` is the z^{t-j}-coefficient of $Y(b,z)u$; replacing z by $-z$ multiplies it by $(-1)^{t-j}$, and $e^{zT} = \sum_j z^j T^j/j!$ shifts the power by j. So `skewCoeffFun W u t b` is the z^t-coefficient of $e^{zT}Y(b,-z)u$, as displayed. Finiteness (`skew_support_finite`): $Y(b)_{t-j}u = b_{(j-t-1)}u = 0$ once $j - t - 1 \geq N(b,u)$ (VA5), so the $\sum^{\mathrm{f}}$ is a genuine finite sum.

Physical meaning

$\tilde{Y}(u,z)b = e^{zT}Y(b,-z)u$ is the operator obtained by *exchanging* the two insertions in $u(z)b(0)$: put b at 0 and u at z, swap their roles, and translate back by z. For bosonic chiral fields, OPE exchange symmetry says this is the same operator as $Y(u,z)$.

Lemma 4.29. $\tilde{Y}(u,z)\mathbf{1} = Y(u,z)\mathbf{1}$.

```
theorem skewCoeffFun_vacuum (W : VertexOperatorAlgebra V) (u : V) (t : ℤ) :
    skewCoeffFun W u t W.vacuum = (W.Y u) t W.vacuum
```

File `VOA/Core/Skew.lean`.

From the mathematics to the Lean statement

For $b = \mathbf{1}$, $Y(\mathbf{1},-z)u = u$ (VA2), so only $j = t$ survives for $t \geq 0$ and the value is $T^t u/t! = u_{(-t-1)}\mathbf{1}$ by `creation_pow`; for $t < 0$ both sides vanish. Uses (VOA3) through `creation_pow`.

Physical meaning

Both operators create the same state from the vacuum: $e^{zL_{-1}}u$.

4.12.2 The reduction to a locality statement

Proposition 4.30 (Skew-symmetry reduces to locality of $\tilde{Y}$). *If, for every c, some power $(z_1 - z_2)^N$ kills $[\tilde{Y}(u,z_1), Y(c,z_2)]$ applied to every vector (uniformly), then $\tilde{Y}(u,z) = Y(u,z)$. It suffices that for every c some $(z_1 - z_2)^N$ kills $[\tilde{Y}(u,z_1), Y(c,z_2)]\mathbf{1}$.*

```
theorem skew_eq_Y_of_local (W : VertexOperatorAlgebra V) (u : V)
    (hloc : ∀ c : V, Local (skewDist W u) (W.Y c)) :
    skewDist W u = W.Y u

def WeakAssocLoc (W : VertexOperatorAlgebra V) (u : V) : Prop :=
  ∀ c : V, ∃ N : ℕ, ∀ b : V,
```

```
    mulBySubPow N (applyVec b (bracketDist (skewDist W u) (W.Y c))) = 0

theorem skewDist_eq_Y_of_weakAssoc (W : VertexOperatorAlgebra 𝒱) (u : 𝒱)
    (hWA : WeakAssocLoc W u) :
    skewDist W u = W.Y u
```

File `VOA/Core/Skew.lean`.

```
def SkewVacLocal (W : VertexOperatorAlgebra 𝒱) (u : 𝒱) : Prop :=
  ∀ c : 𝒱, ∃ N : ℕ,
    mulBySubPow N (applyVec W.vacuum (bracketDist (skewDist W u) (W.Y c))) = 0

theorem skewDist_eq_Y_of_vacLocal (W : VertexOperatorAlgebra 𝒱) (u : 𝒱)
    (h : SkewVacLocal W u) : skewDist W u = W.Y u

theorem weakAssocLoc_of_vacLocal (W : VertexOperatorAlgebra 𝒱) (u : 𝒱)
    (h : SkewVacLocal W u) : WeakAssocLoc W u
```

File `VOA/Core/WeakAssoc.lean`.

From the mathematics to the Lean statement

`WeakAssocLoc W u`: for each c a single N works for all test vectors b — this uniformity is what upgrades the vector statements to the operator statement `Local` (`local_of_applyVec_annihilation`). `SkewVacLocal W u`: the same with only the vacuum as test vector, which is much easier to verify; Goddard's vacuum form (Theorem 4.14(ii)) turns it into $\tilde{Y} = Y$, and *then* `WeakAssocLoc` holds a posteriori by VA4. The file `Skew.lean` also contains a predicate `FLMCoeff` described in its docstring as "the single remaining open lemma"; that description is out of date — the gate is now closed by `skewVacLocal` below, and `FLMCoeff` is not used by `skew`.

Physical meaning

To prove exchange symmetry it is enough to show that the exchanged operator is a legitimate local field; uniqueness of the field of a state then does the rest. The locality check, moreover, only has to be done inside vacuum correlators.

What the machine verified

These reductions are unconditional and axiom-clean; their hypotheses are discharged next.

4.12.3 The vacuum locality computation

Lemma 4.31 (T and modes). *In a VOA, $c_{(p)}(Tw) = T(c_{(p)}w) + p\,c_{(p-1)}w$, and more generally*

$$c_{(p)}(T^k u) = \sum_{r=0}^{k} \binom{k}{r} p^{\underline{r}}\, T^{k-r}\big(c_{(p-r)}u\big), \qquad p^{\underline{r}} = p(p-1)\cdots(p-r+1).$$

```
theorem smul_comm_T (W : VertexOperatorAlgebra 𝒱) (c w : 𝒱) (p : ℤ) :
    W.smul c p (W.toPreVertexAlgebra.T w)
      = W.toPreVertexAlgebra.T (W.smul c p w) + p • W.smul c (p - 1) w

def fallI (p : ℤ) (r : ℕ) : ℤ := ∏ i ∈ Finset.range r, (p - (i : ℤ))

def mcoeff (p : ℤ) (k r : ℕ) : ℤ := (k.choose r : ℤ) * fallI p r
```

```
theorem smul_Tpow_expand (W : VertexOperatorAlgebra V) (c u : V) (p : ℤ) (k : ℕ) :
    W.smul c p ((W.toPreVertexAlgebra.T ^ k) u)
      = ∑ r ∈ Finset.range (k + 1),
          (mcoeff p k r) • ((W.toPreVertexAlgebra.T ^ (k - r)) (W.smul c (p - (r : ℤ)) u))
```

File `VOA/Core/WeakAssoc.lean`.

From the mathematics to the Lean statement

`fallI p r` is the falling factorial $p^{\underline{r}}$, `mcoeff p k r` $= \binom{k}{r} p^{\underline{r}}$, an integer acting by $\bullet$. `smul_comm_T` is translation covariance in the form $[c_{(p)}, T] = -[T, c_{(p)}] = p\, c_{(p-1)}$ (from `L_neg_one_deriv` and `T_eq_Lneg1`); `smul_Tpow_expand` is its k-fold iterate, proved by induction with Pascal's rule.

Physical meaning

$e^{-zT} Y(c, w) e^{zT} = Y(c, w - z)$: conjugating by a translation shifts the insertion point. The lemma is this identity coefficient by coefficient.

Theorem 4.32 (Skew-locality on the vacuum, and weak associativity). *In a VOA, for all u:* `SkewVacLocal W u` *and* `WeakAssocLoc W u` *hold.*

```
theorem skewVacLocal (W : VertexOperatorAlgebra V) (u : V) : SkewVacLocal W u

theorem weakAssocLoc (W : VertexOperatorAlgebra V) (u : V) : WeakAssocLoc W u :=
  weakAssocLoc_of_vacLocal W u (skewVacLocal W u)
```

File `VOA/Core/WeakAssoc.lean`.

From the mathematics to the Lean statement

No hypotheses beyond the VOA. The order N for `skewVacLocal` is the regularity bound M_0 of the pair (c, u) (`W.toPreVertexAlgebra.regularity c u`), i.e. the pole order of $Y(c, w)u$.

Physical meaning

This is the computation that the exchanged operator has the same singularity structure as an honest field: inside vacuum correlators, $[\tilde{Y}(u, z_1), Y(c, z_2)]|0\rangle$ is a contact term supported on $z_1 = z_2$ of order at most the pole order of the OPE $c \times u$.

Proof on paper. Let $G(z_1, z_2) := [\tilde{Y}(u, z_1), Y(c, z_2)]\mathbf{1}$. Using Lemma 4.29 and creation,

$$G = \tilde{Y}(u, z_1)\, e^{z_2 T} c - Y(c, z_2)\, e^{z_1 T} u.$$

Second term: by Lemma 4.31, $Y(c, z_2) e^{z_1 T} u = e^{z_1 T}\, Y(c, z_2 - z_1) u$ with $(z_2 - z_1)^{-s-1}$ expanded in nonnegative powers of z_1 (closed form `Term2_expand`). First term: by definition and $Y(T^j c, w) = \partial^j Y(c, w)$, $\tilde{Y}(u, z_1) e^{z_2 T} c = e^{z_1 T} \sum_j \frac{z_2^j}{j!} \partial_w^j Y(c, w) u\big|_{w=-z_1} = e^{z_1 T}\, Y(c, z_2 - z_1) u$ with $(z_2 - z_1)^{-s-1}$ expanded in nonnegative powers of z_2 (closed form `Term1_expand`). Since $Y(c, w)u = \sum_{s<M_0} (c_{(s)}u) w^{-s-1} + (\text{regular})$, the regular parts agree, and G is $e^{z_1 T}$ applied to $\sum_{s<M_0} (c_{(s)}u)\big(\iota_{z_2,z_1} - \iota_{z_1,z_2}\big)(z_2 - z_1)^{-s-1}$, a finite sum of derivatives of $\delta(z_1/z_2)$ of order $< M_0$ (the "jump sum" of `Gfield_eq_jumpSum`). Each is killed by $(z_1 - z_2)^{M_0}$ (`mulBySubPow_jumpSum_eq_zero`). The library carries this out entirely by coefficient comparison in the four sign sectors of (z_1, z_2)-exponents, without formal delta-function substitution. □

What the machine verified

Unconditional, axiom-clean (`#print axioms VOA.VertexOperatorAlgebra.weakAssocLoc` run for this chapter). The file's history (a gate once sanctioned as an axiom `weakAssocLoc_gate`, later a single `sorry` in `Gfield_eq_jumpSum`) is closed: neither occurs at this commit.

4.12.4 Skew-symmetry

Theorem 4.33 (Skew-symmetry). *In a VOA, $Y(u,z)v = e^{zT}Y(v,-z)u$ for all u, v. In modes, $u_{(n)}v = \sum_{j\geq 0} \frac{(-1)^{n+j+1}}{j!} T^j(v_{(n+j)}u)$.*

```
theorem skew (W : VertexOperatorAlgebra 𝒱) (u : 𝒱) : skewDist W u = W.Y u :=
  skewDist_eq_Y_of_weakAssoc W u (weakAssocLoc W u)

theorem skew_mode (W : VertexOperatorAlgebra 𝒱) (u v : 𝒱) (n : ℤ) :
    W.smul u n v
      = ∑ᶠ j : ℕ, ((j.factorial : ℂ)⁻¹) • (sgn (-n - 1 - j)) •
          ((W.toPreVertexAlgebra.T ^ j) ((W.Y v) (-n - 1 - j) u))
```

File `VOA/Core/SkewSymmetry.lean`.

From the mathematics to the Lean statement

`skew` is an equality of operator-valued distributions, $\tilde{Y}(u,\cdot) = Y(u,\cdot)$, which by Definition 4.28 is $Y(u,z)v = e^{zT}Y(v,-z)u$ for all v. `skew_mode` reads off the z^{-n-1}-coefficient ($t = -n-1$): `(W.Y v) (-n - 1 - j)` $= v_{(n+j)}$ and `sgn (-n - 1 - j)` $= (-1)^{n+j+1}$. Same as Gannon (5.1.8), Kac (4.2.1), Lepowsky–Li (§3.1). The one-line proof term is shown because it is informative: skew-symmetry *is* the reduction applied to the proved gate.

Physical meaning

Bose exchange symmetry of the chiral algebra: $u(z)v(0) = e^{zL_{-1}}v(-z)u(0)$ inside correlators. In terms of OPE coefficients, the poles of $v(z)u(0)$ determine those of $u(z)v(0)$; e.g. for currents $J^a_{(0)}J^b = -J^b_{(0)}J^a$ (antisymmetry of the Lie bracket on V_1) and $J^a_{(1)}J^b = J^b_{(1)}J^a$ (symmetry of the level form).

Proof on paper. Theorem 4.32 and Proposition 4.30. □

4.13 The FLM formulation: associativity after a change of variables

FLM and Lepowsky–Li formulate the heart of the Jacobi identity as *weak associativity*: $(z_0+z_2)^N Y(u,z_0+z_2)Y(v,z_2)x = (z_0+z_2)^N Y(Y(u,z_0)v,z_2)x$. The library proves a variant in which the polynomial factor is $(z_1-z_2)^N$ with N the locality order, and the substitution $z_1 = z_0+z_2$ is done on the doubly truncated product.

Definition 4.34 (Substitution $z_1 \mapsto z_0+z_2$; composite field). (a) A two-variable distribution is *lower-truncated in z_1* if its z_1-support is bounded below uniformly in the z_2-power. (b) For F lower-truncated in both variables, $\iota_{z_2,z_0}F(z_0+z_2,z_2)$ is the distribution whose $z_0^a z_2^b$-coefficient is

$\sum_k \binom{a+k}{a} F(a+k, b-k)$ (expand $(z_0+z_2)^m$ in nonnegative powers of z_0). (c) The *composite field* $Y(Y(u,z_0)v,z_2)x$ has $z_0^a z_2^b$-coefficient $(u_{(-a-1)}v)_{(-b-1)}x$.

```
def IsBddBelow₁ (f : FormalDist₂ 𝒲) : Prop := ∃ B : ℤ, ∀ m n : ℤ, m < B → f m n = 0

noncomputable def subst2 (f : FormalDist₂ 𝒲) : FormalDist₂ 𝒲 :=
  fun a b => ∑ᶠ k : ℤ, cbz (a + k) a • f (a + k) (b - k)

noncomputable def comp (W : VertexOperatorAlgebra 𝒱) (u v x : 𝒱) : FormalDist₂ 𝒱 :=
  fun a b => mode (W.Y (W.smul u (-a-1) v)) (-b-1) x
```

File `VOA/Core/Skew.lean`.

From the mathematics to the Lean statement

In `subst2`, the term $F(m,n)z_1^m z_2^n$ with $z_1 = z_0+z_2$ contributes $\binom{m}{a} z_0^a z_2^{m-a+n}$; matching $z_0^a z_2^b$ gives $m = a+k$, $n = b-k$, coefficient `cbz (a+k) a` $= \binom{a+k}{a}$ (zero for $a<0$). Without truncation in both variables the sum over k would be infinite; the library proves finiteness on the doubly truncated class (`subst2_summand_finite`). `comp`: `W.smul u (-a-1) v` is the z_0^a-coefficient of $Y(u,z_0)v$, and `mode (Y w) (-b-1) x` is the z_2^b-coefficient of $Y(w,z_2)x$.

Physical meaning

$z_1 = z_0+z_2$ re-expands a correlator around the second insertion point: z_0 is the separation $z_1 - z_2$, small compared with z_2. The composite field is the OPE $u \times v$ evaluated first and then inserted at z_2.

Theorem 4.35 (FLM associativity). *In a VOA, let N satisfy $(z_1-z_2)^N[Y(u,z_1),Y(v,z_2)] = 0$. Then for every x,*

$$\iota_{z_2,z_0}\Big((z_1-z_2)^N Y(u,z_1)Y(v,z_2)x\Big)\Big|_{z_1=z_0+z_2} = z_0^N\, Y(Y(u,z_0)v,z_2)x.$$

```
theorem flm (W : VertexOperatorAlgebra 𝒱) (u v x : 𝒱) {N : ℕ}
    (hN : mulBySubPow N (bracketDist (W.Y u) (W.Y v)) = 0) (a b : ℤ) :
    subst2 (mulBySubPow N (W.toPreVertexAlgebra.Yprod u v x)) a b = comp W u v x (a - N) b
```

File `VOA/Core/FLM.lean`.

From the mathematics to the Lean statement

The right side `comp W u v x (a - N) b` is the $z_0^{a-N}z_2^b$-coefficient of the composite, i.e. the $z_0^a z_2^b$-coefficient of $z_0^N\, Y(Y(u,z_0)v,z_2)x$. The left side is legitimate because $(z_1-z_2)^N Y(u,z_1)Y(v,z_2)x$ is lower-truncated in both variables (in z_2 by VA5; in z_1 because it equals $(z_1-z_2)^N Y(v,z_2)Y(u,z_1)x$ by locality, and that is truncated in z_1 by VA5 for (u,x); lemma `exists_mulBySubPow_Yprod_doublyBdd`). The hypothesis `hN` is locality for (u,v) with an explicit order — not an extra assumption, since VA4 provides such an N. The statement holds for every integer a (both the "singular" $a<N$ and "normal" $a \geq N$ regimes).

Comparison with FLM. FLM (§§8.8–8.10) and Lepowsky–Li (§3.6, "weak associativity") use the factor $(z_0+z_2)^k$ with k depending on (u,x); the library's version uses $(z_1-z_2)^N = z_0^N$ with N depending on (u,v). The two are equivalent formulations of the same associativity (each follows from the Jacobi identity by multiplying by the appropriate power and taking a residue); neither is used as an axiom.

Physical meaning

Associativity of the OPE in its most concrete form: the product $u(z_1)v(z_2)$ acting on x, re-expanded around z_2 in the separation $z_0 = z_1 - z_2$, is the OPE of u and v followed by insertion at z_2 — once the poles on the diagonal have been cleared by $(z_1 - z_2)^N$. This is the statement that the three-point function is a single rational function with the correct expansions in the two channels.

Proof on paper. Expand the left side by the binomial theorem and compare coefficients. For $a \geq N$ (the "normal" columns, z_0-power $a - N \geq 0$, i.e. negative products) the composite coefficient is a normal-ordered product by Theorem 4.22, whose coefficients are exactly what the substitution produces after the $(z_1 - z_2)^N$ prefactor has been absorbed (`flm_normal`); the remaining boundary terms are shown to vanish because the relevant binomials $\binom{p}{a-N}$ with $0 \leq p < a - N$ are zero (`FLMBoundaryResidual`). For $a < N$ (the singular columns, nonnegative products) the composite coefficient is $\mathrm{Res}_{z_1}(z_1 - z_2)^{N-a-1}$ of the commutator by Theorem 4.20, and the substitution of the commutator, killed by $(z_1 - z_2)^N$, reproduces it (`flm_lt`). □

4.14 Commutative vertex algebras (Gannon Theorem 5.1.4)

Definition 4.36 (Commutative; the classical product)**.** A vertex algebra is *commutative* if $[Y(u, z_1), Y(v, z_2)] = 0$ for all u, v. Its *classical product* is $u \cdot v := u_{(-1)}v$.

```
def IsCommutative (V : PreVertexAlgebra 𝒱) : Prop :=
  ∀ u v : 𝒱, bracketDist (V.Y u) (V.Y v) = 0

def cmul (V : PreVertexAlgebra 𝒱) (u v : 𝒱) : 𝒱 := V.smul u (-1) v

@[simp] theorem vacuum_cmul (V : PreVertexAlgebra 𝒱) (u : 𝒱) : V.cmul V.vacuum u = u
```

File `VOA/Core/Commutativity.lean` (also `cmul_vacuum`: $u \cdot \mathbf{1} = u$).

From the mathematics to the Lean statement

`IsCommutative` is locality with order 0 for every pair. The counterexample of Section 4.5 is commutative.

Physical meaning

A commutative vertex algebra is a chiral algebra with no singular OPEs: all fields are holomorphic at coincident points, as for the algebra of functions on the jet space of a target (the classical limit of a chiral algebra, or the chiral algebra of a topologically twisted theory in which all fields are regular).

Theorem 4.37 (Gannon Theorem 5.1.4 for VOAs)**.** *For a VOA W the following are equivalent: (1) W is commutative; (3) $u_{(n)}v = 0$ for all u, v and $n \geq 0$. If they hold, then $u \cdot v = u_{(-1)}v$ is commutative and associative with unit $\mathbf{1}$, so W is a commutative ring, and $T = L_{-1}$ is a derivation of it (the derivation law holds in every VOA).*

        ∧ (∀ u v w : V, W.toPreVertexAlgebra.cmul (W.toPreVertexAlgebra.cmul u v) w
              = W.toPreVertexAlgebra.cmul u (W.toPreVertexAlgebra.cmul v w)))
```

File `VOA/Core/Commutativity.lean`.

From the mathematics to the Lean statement

`commRing_of_comm` builds a Mathlib `CommRing` structure on the underlying additive group with multiplication `cmul` and one `vacuum`; its fields (associativity, commutativity, unit laws, distributivity) are the theorems listed (distributivity is bilinearity of `smul`). `letI := …` makes this ring structure the one used by $*$ in the next line. It is a `def` whose type mentions `hcomm`, so it exists only for commutative VOAs.

What `comm_iff_assoc_alg` says, precisely. The right side is the conjunction of condition (3) with commutativity and associativity of `cmul`. The direction $\Leftarrow$ uses only the first conjunct (it is (3)$\Rightarrow$(1)). So the theorem is "(1) $\iff$ (3), and (1) implies that `cmul` is commutative and associative". Gannon's converse — *every* commutative associative unital algebra with a derivation T is a commutative vertex algebra via $Y(u,z)v = (e^{zT}u)v$ — is **not** stated in the library. It is in any case not a statement about VOAs (a commutative differential algebra has no conformal vector in general), and at the level of `PreVertexAlgebra` the correspondence fails (Section 4.5).

Physical meaning

A chiral algebra with no singular OPEs is the same thing as a commutative algebra of local operators with an action of ∂: the OPE reduces to the ordinary product, $u(z)v(w) = {:}u(z)v(w){:}$, and all the structure is the commutative product and the derivative. In a VOA the stress tensor always has a singular OPE with itself unless everything is trivial, which is the content of the warning below.

Proof on paper. (1)⇒(3): by Theorem 4.20, $Y(u_{(k)}v) = \mathrm{Res}_{z_1}(z_1 - z)^k \cdot 0 = 0$, so $u_{(k)}v = (u_{(k)}v)_{(-1)}\mathbf{1} = 0$. (3)⇒(1): every term of the commutator formula vanishes. Associativity: by Theorem 4.22 with $k = 0$, $(u_{(-1)}v)_{(-1)}w$ is the z^0-coefficient of $:Y(u,z)Y(v,z):w$, and under (3) only the term $u_{(-1)}v_{(-1)}w$ survives. Commutativity: by skew-symmetry at $n = -1$, $u_{(-1)}v = \sum_j \frac{(-1)^j}{j!}T^j(v_{(j-1)}u)$, and under (3) only $j = 0$ survives. Leibniz: Theorem 4.19 at $n = -1$. □

What the machine verified

All unconditional, axiom-clean (`#print axioms` for `comm_iff_nonneg_modes`, `comm_iff_assoc_alg`, `commRing_of_comm` run for this chapter).

Theorem 5.1.4 at the VOA level is a statement about the trivial VOA

Let W be a commutative `VertexOperatorAlgebra`. By (3), $L_0 = \omega_{(1)} = 0$ on W; by (VOA2), $L_0 = n$ on W_n, so $W_n = 0$ for $n \neq 0$, and by (VOA4) $W = W_0 = \mathbb{C}\mathbf{1}$ (or $W = 0$). Then $\omega \in W_2 = 0$, and if $W \neq 0$ the Virasoro relation $[L_2, L_{-2}] = 4L_0 + \frac{c}{2}$ forces $c = 0$. So the hypothesis `IsCommutative` is satisfiable only by the one-dimensional VOA $\mathbb{C}\mathbf{1}$ (and the zero VOA), and all theorems of this section are, for VOAs, statements about that algebra. They are true and correctly proved, but they do *not* formalise the classical content of Gannon's Theorem 5.1.4 (commutative vertex algebras = commutative differential algebras), which lives at the level of vertex algebras with translation covariance — a level the library does not have a correct structure for (Section 4.5). The source docstring does not mention this.

4.15 Reconstruction: building a vertex algebra from generating fields

The theorems so far start from a vertex algebra. Constructing one — the Heisenberg, lattice, affine, Virasoro and Moonshine VOAs of later chapters — requires the converse direction: produce a state–field map from a few generating fields. The library has two reconstruction theorems: `Reconstruction.reconstruct` (Theorem 4.41 below) and its word-field corollary `NonlinearConformal.reconstruct_of_generators`, which belongs to Chapter 11 (Theorem 11.46). Here we present the ingredients in `VOA/Core/ReconstructionExistence.lean` and say exactly what the theorem delivers.

Definition 4.38 (T-covariance)**.** For $T \in \mathrm{End}\, V$, a distribution a is T-covariant if $[T, a(z)] = \partial_z a(z)$, i.e. $[T, a_m] = (m+1)a_{m+1}$ for the z^m-coefficients.

```
def DCovariant (T : End ℂ V) (a : FormalDist (End ℂ V)) : Prop :=
  ∀ m : ℤ, T * a m - a m * T = ((m + 1 : ℤ)) • a (m + 1)
```

File `VOA/Core/ReconstructionExistence.lean` (`VOA.Reconstruction.DCovariant`). The same file proves closure under scalars, sums, finite linear combinations, ∂ and $:\cdot\cdot:$ (`DCovariant.smul`, `.add`, `.finsetSum`, `.deriv'`, `.nprod`, the last via the Leibniz rule `deriv_nprod`).

From the mathematics to the Lean statement

The z^m-coefficient of $\partial_z a$ is $(m+1)a_{m+1}$, so the definition is $[T, a(z)] = \partial a(z)$ exactly: Kac's and FBZ's translation axiom for a single field. Here T is an arbitrary operator, not $u_{(-2)}\mathbf{1}$.

Physical meaning

T-covariance says that a is a translation-covariant local operator: $e^{\epsilon T} a(z) e^{-\epsilon T} = a(z+\epsilon)$. This is precisely the property missing from the axioms of Definition 4.1; in the reconstruction theorem it is *required of the generators*.

Lemma 4.39 (The creation tower is forced). *If F, G are T-covariant, $T\mathbf{1} = 0$, $F(z)\mathbf{1}, G(z)\mathbf{1} \in V[[z]]$ and their constant terms agree, then $F(z)\mathbf{1} = G(z)\mathbf{1}$.*

```
theorem tower_unique {T : End ℂ V} {F G : FormalDist (End ℂ V)} {vac : V}
    (hF : DCovariant T F) (hG : DCovariant T G) (hTvac : T vac = 0)
    (hbase : F 0 vac = G 0 vac)
    (hFneg : ∀ q : ℤ, q < 0 → F q vac = 0) (hGneg : ∀ q : ℤ, q < 0 → G q vac = 0)
    (p : ℤ) : F p vac = G p vac
```

File `VOA/Core/ReconstructionExistence.lean`.

From the mathematics to the Lean statement

All hypotheses are as stated; the conclusion is the equality of every z^p-coefficient on the vacuum.

Physical meaning

For a translation-covariant field, $a(z)|0\rangle = e^{zT} a_{(-1)}|0\rangle$: the state at z is the translate of the state at 0. This is what fails in the counterexample, whose $Y(x,z)$ is not T-covariant for any T.

Proof on paper. Apply $[T, F_p] = (p+1)F_{p+1}$ to $\mathbf{1}$ and use $T\mathbf{1} = 0$: $(p+1)F_{p+1}\mathbf{1} = TF_p\mathbf{1}$. Induction on $p \geq 0$. □

Theorem 4.40 (Operator-first uniqueness). *Let V be a vector space with a vector $\mathbf{1}$, and let $(s_j, f_j)_{j \in J}$ be states and distributions with $f_j(z)\mathbf{1} \in V[[z]]$ and $f_j(z)\mathbf{1}|_{z=0} = s_j$, such that the s_j span V. If a distribution $A \in \mathrm{End}(V)[[z^{\pm 1}]]$ is mutually local with every f_j and $A(z)\mathbf{1} = 0$, then $A = 0$.*

File `VOA/Core/ReconstructionExistence.lean`.

```
theorem field_eq_zero_of_vacuum {ι : Type*} (vac : V) (A : FormalDist (End ℂ V))
    (st : ι → V) (fld : ι → FormalDist (End ℂ V))
    (hloc : ∀ j, Local A (fld j))
    (hcre0 : ∀ j, (fld j) 0 vac = st j)
    (hcreneg : ∀ j, ∀ q : ℤ, q < 0 → (fld j) q vac = 0)
    (hAvac : ∀ p : ℤ, A p vac = 0)
    (hspan : Submodule.span ℂ (Set.range st) = ⊤) :
    A = 0
```

From the mathematics to the Lean statement

`ι` is an index type; `st j` is the state s_j and `fld j` the distribution f_j. `(fld j) 0 vac = st j` says the z^0-coefficient of $f_j(z)\mathbf{1}$ is s_j, i.e. the mode $(f_j)_{(-1)}\mathbf{1} = s_j$; `hcreneg` says there are no negative powers of z in $f_j(z)\mathbf{1}$, so that $f_j(z)\mathbf{1} \in V[[z]]$; `hAvac : ∀ p, A p vac = 0` says $A(z)\mathbf{1} = 0$ coefficientwise; `Local A (fld j)` is Definition 2.41 (some power of $z_1 - z_2$ kills the commutator); `hspan` says the states span V (`Set.range st` is the set of states, `⊤` the whole space). **Hypotheses:** exactly those of the mathematical statement. **Scope.** No vertex algebra is assumed: V is a bare vector space, and neither A nor the f_j is assumed to be a field. It is the spanning-family strengthening of the abstract Goddard theorem (Theorem 4.14(iii), `goddard_zero`), in which the test fields were required for *every* vector $b \in V$; here only a

spanning family is needed. The conclusion $A = 0$ is an equality of distributions. **Could it be vacuous?** The hypotheses are satisfiable non-trivially: in any VOA take the f_j to be the vertex operators $Y(s_j, \cdot)$ of a spanning family (s_j), which are local with $Y(a, \cdot)$ for every a. The theorem has content because locality against a spanning family is a strong condition; it is used by the reconstruction theorem (Theorem 4.41) to show that the extension Y is well defined.

Physical meaning

An operator that is mutually local with all the fundamental fields and gives zero on the vacuum is the zero operator. Heuristically this is the chiral cousin of the Reeh–Schlieder property in axiomatic quantum field theory (the vacuum is cyclic and separating for local operators): a local operator is determined by the state it creates from the vacuum. Here it is a theorem of formal calculus, and it is the technical heart of the uniqueness part of the state–field correspondence: the field of a state is determined by the state.

Proof on paper. Fix j and put $G(z,w) := A(z)f_j(w)\mathbf{1} \in \mathrm{End}(V)[[z^{\pm 1}]] \otimes V[[w]]$. Mutual locality gives N with $(z-w)^N[A(z), f_j(w)] = 0$; applying this to $\mathbf{1}$ and using $A(z)\mathbf{1} = 0$ gives $(z-w)^N G(z,w) = (z-w)^N\big(A(z)f_j(w)\mathbf{1} - f_j(w)A(z)\mathbf{1}\big) = 0$. The series G contains only nonnegative powers of w (because $f_j(w)\mathbf{1} \in V[[w]]$), so it is lower truncated in w, and by the cancellation theorem (Theorem 2.50: $z-w$ is not a zero divisor on lower-truncated series) $G = 0$. Taking the coefficient of w^0, which is $A(z)s_j$, gives $A(z)s_j = 0$ for all j. Hence every coefficient A_m vanishes on the span of the s_j, which is V, so $A = 0$. □

What the machine verified

Unconditional; `#print axioms VOA.Reconstruction.field\_eq\_zero\_of\_vacuum` = `[propext, Classical.choice, Quot.sound]` (run for this chapter). The PBW theorem `VOA.pbw` is not used.

Theorem 4.41 (Operator-first reconstruction). *Let V be a vector space, $\mathbf{1} \in V$, $T \in \mathrm{End}\, V$ with $T\mathbf{1} = 0$, and $(s_i, f_i)_{i\in I}$ states and distributions such that each f_i is a field, the f_i are pairwise local and T-covariant, $f_i(z)\mathbf{1} \in V[[z]]$ with constant term s_i, and the s_i span V. Then there is a linear $Y : V \to \mathrm{End}(V)[[z^{\pm 1}]]$ with $Y(s_i, \cdot) = f_i$, all $Y(u, \cdot)$ fields, pairwise local, T-covariant, with $Y(u,z)\mathbf{1} \in u + zV[[z]]$.*

```

File `VOA/Core/ReconstructionExistence.lean` (`VOA.Reconstruction.reconstruct`).

From the mathematics to the Lean statement

What it delivers. The six conjuncts are: Y extends the given fields; fields (VA5); locality (VA4); creation (VA3, both halves); T-covariance. In particular, through `tower_unique`, the conclusion includes $Y(u,z)\mathbf{1} = e^{zT}u$, i.e. the full Kac/FBZ axiom system *minus* the vacuum axiom $Y(\mathbf{1}) = \mathrm{id}$, which the user must check (it holds as soon as $\mathbf{1}$ is among the s_i with $f = \mathrm{id}$).
What it does not deliver. No grading (VA1) and no `PreVertexAlgebra` structure; the user assembles one. Uniqueness of Y is not part of the statement (the docstring says "unique"; the statement is ∃), although it follows from `field_eq_zero_of_vacuum`.
Comparison with Kac's existence theorem. Kac (Thm. 4.5) and FBZ (Thm. 4.4.1) start from a family of generating fields and assume that the *monomials* $a^{i_1}_{(-j_1-1)}\cdots a^{i_r}_{(-j_r-1)}\mathbf{1}$ span; the fields of the monomials are then *constructed* as normal-ordered products. The library's theorem instead takes as input a family whose states already span, each state with its field. It is therefore a reduction of Kac's theorem to Dong's lemma: one applies it to the family of all iterated normal-ordered word fields (which are pairwise local by Dong's lemma and T-covariant by `DCovariant.nprod`); this is done in `reconstruct_of_generators` (Theorem 11.46 in Chapter 11).
Translation covariance is a hypothesis here. This is the correct design: by Section 4.5, VA1–VA5 do not imply it, so a construction must supply it.

Physical meaning

"A chiral algebra is generated by a few fields and their OPEs." One specifies the currents (or the stress tensor), checks that their OPEs have finite poles (locality), that ∂ acts as $[L_{-1},\cdot]$ and that the vacuum is translation invariant; then every composite operator is determined and the whole operator algebra is consistent.

Proof on paper. Define Y on formal combinations $\sum c_i s_i$ by $\sum c_i f_i$. Well-defined: if $\sum c_i s_i = 0$, the field $A = \sum c_i f_i$ is local with every f_j, annihilates $\mathbf{1}$ in degree < 0, has constant term $\sum c_i s_i = 0$, and by T-covariance (Lemma 4.39 applied inductively) annihilates $\mathbf{1}$ in every degree; so $A = 0$ by Goddard (Theorem 4.14(iii) in its spanning form `field_eq_zero_of_vacuum`). Every listed property is linear in the field and holds for the f_i. □

What the machine verified

`reconstruct`, `tower_unique`, `field_eq_zero_of_vacuum`: unconditional, axiom-clean (`#print axioms VOA.Reconstruction.reconstruct` run for this chapter).

4.15.1 Fields on a tensor product

To build tensor-product VOAs before either factor is packaged as a vertex algebra, the library lifts fields to $A \otimes B$.

Definition 4.42 (First- and second-factor lifts)**.** For a distribution f on A, $f \otimes 1$ acts on $A \otimes B$ by $(f \otimes 1)_n(a \otimes b) = f_n a \otimes b$; similarly $1 \otimes g$. The tensor translation is $T_A \otimes 1 + 1 \otimes T_B$.

```
noncomputable def firstField (f : FormalDist (End ℂ A)) :
    FormalDist (End ℂ (A ⊗[ℂ] B)) :=
  fun n => LinearMap.rTensor B (f n)

noncomputable def secondField (g : FormalDist (End ℂ B)) :
    FormalDist (End ℂ (A ⊗[ℂ] B)) :=
  fun n => LinearMap.lTensor A (g n)
```

```
noncomputable def tensorTranslation (TA : End ℂ A) (TB : End ℂ B) :
    End ℂ (A ⊗[ℂ] B) :=
  LinearMap.rTensor B TA + LinearMap.lTensor A TB
```

File `VOA/Core/TensorFieldLift.lean` (namespace `VOA.TensorFieldLift`).

From the mathematics to the Lean statement

`A ⊗[ℂ] B` is Mathlib's tensor product over $\mathbb{C}$; `LinearMap.rTensor B φ` $= \varphi \otimes \mathrm{id}_B$ and `LinearMap.lTensor A ψ` $= \mathrm{id}_A \otimes \psi$.

Physical meaning

Two decoupled chiral algebras: fields of the first system act on the first factor of the product Hilbert space, fields of the second on the second, and the total translation generator is the sum.

Theorem 4.43 (Lifts preserve the reconstruction hypotheses). *Lifts of fields are fields; lifts of local pairs are local; a first-factor lift and a second-factor lift always commute, hence are local; lifts of T_A-(resp. T_B-)covariant fields are covariant for the tensor translation; and $:(f \otimes 1)(1 \otimes g):$ is the ordinary product.*

```
theorem isField_firstField {f : FormalDist (End ℂ A)} (hf : IsField f) :
    IsField (firstField (B := B) f)

theorem local_firstField {f g : FormalDist (End ℂ A)} (h : Local f g) :
    Local (firstField (B := B) f) (firstField g)

theorem local_firstField_secondField (f : FormalDist (End ℂ A))
    (g : FormalDist (End ℂ B)) :
    Local (firstField (B := B) f) (secondField (A := A) g) :=
  local_of_bracketDist_eq_zero (bracketDist_firstField_secondField f g)

theorem dcovariant_firstField {TA : End ℂ A} {TB : End ℂ B}
    {f : FormalDist (End ℂ A)} (hf : Reconstruction.DCovariant TA f) :
    Reconstruction.DCovariant (tensorTranslation TA TB) (firstField f)

theorem nprod_firstField_secondField_apply {f : FormalDist (End ℂ A)}
    {g : FormalDist (End ℂ B)} (hf : IsField f) (hg : IsField g) (s : ℤ)
    (x : A ⊗[ℂ] B) :
    nprod (isField_firstField (B := B) hf) (isField_secondField (A := A) hg) s x
      = ∑ᶠ m : ℤ,
          (firstField (B := B) f m * secondField (A := A) g (s - m)) x
```

File `VOA/Core/TensorFieldLift.lean`. The second-factor analogues (`isField_secondField`, `local_secondField`, `dcovariant_secondField`, `nprod_firstField`, `nprod_secondField`) are in the same file.

From the mathematics to the Lean statement

`(B := B)` only fixes the implicit second factor. `isField_firstField` needs an argument by induction on tensors (a general element of $A \otimes B$ is a finite sum of pure tensors). In the last statement the right side is a `finsum` whose support is finite because f, g are fields.

Physical meaning

Fields of decoupled systems commute (they are mutually local with no singular OPE), and their normal-ordered product is just the product, e.g. the stress tensor of a tensor product is $T_A \otimes 1 + 1 \otimes T_B$ with no cross terms.

What the machine verified

All unconditional, axiom-clean (`#print axioms local_firstField_secondField` run for this chapter).

4.16 Local systems of weak vertex operators

Li (1996) constructs vertex algebras, and their modules, from *local systems*: spaces of mutually local fields on a fixed vector space M, closed under all field products. The space of such fields is itself a vertex algebra, with M as a module. The library has the first three of the four steps of this construction. All results here are about an arbitrary complex vector space M.

4.16.1 Weak vertex operators and the generated system

Definition 4.44 (Weak vertex operators; the generated system). $\mathrm{Fld}(M)$ is the set of fields on M, with the identity field 1, the normal-ordered product and ∂. For $S \subseteq \mathrm{Fld}(M)$, $\mathrm{Gen}(S, i, a)$ means that a is obtained from elements of S and 1 by i applications of $:\cdot\,\cdot:$ and ∂; $\mathrm{Generated}(S)$ is the set of such a (any i).

```
def Fld (M : Type*) [AddCommGroup M] [Module ℂ M] : Type _ :=
  {a : FormalDist (End ℂ M) // IsField a}

noncomputable def one : Fld M := ⟨idField, idField_isField⟩

noncomputable def nprod (a b : Fld M) : Fld M :=
  ⟨VOA.nprod a.2 b.2, a.2.nprod b.2⟩

noncomputable def deriv (a : Fld M) : Fld M :=
  ⟨VOA.deriv a.1, a.2.deriv⟩

inductive Gen (S : Set (Fld M)) : ℕ → Fld M → Prop
  | base {a : Fld M} : a ∈ S → Gen S 0 a
  | one : Gen S 0 Fld.one
  | nprod {i j : ℕ} {a b : Fld M} : Gen S i a → Gen S j b → Gen S (i + j + 1) (a.nprod b)
  | deriv {i : ℕ} {a : Fld M} : Gen S i a → Gen S (i + 1) a.deriv

def Generated (S : Set (Fld M)) : Set (Fld M) := {a | ∃ i, Gen S i a}
```

File `VOA/Core/LocalSystem.lean` (`Fld.one`, `Fld.nprod`, `Fld.deriv` in namespace `VOA.Fld`).

From the mathematics to the Lean statement

`{a // IsField a}` is the subtype: a pair of a distribution `a.1` and a proof `a.2` that it is a field. `Gen` is an *inductive predicate*: its four constructors are the only ways to establish `Gen S i a`. The index i counts operations; it is bookkeeping for the locality induction below. Note that `Generated` is closed under $:\cdot\,\cdot:$ and ∂, hence under all negative products, but not under linear combinations or the nonnegative products; the linear, all-product closure is the `LocalFieldSystem` below.

Physical meaning

The operators one can build from a set of chiral fields by taking derivatives and normal-ordered products — the "composite operators" of the theory. No vacuum and no grading are involved: this is the operator algebra acting on a fixed sector M.

Theorem 4.45 (The generated system is local)**.** *If the elements of S are pairwise local, so are all elements of* Generated(S).

```
theorem gen_local (S : Set (Fld M)) (hS : ∀ a ∈ S, ∀ b ∈ S, Local a.1 b.1) :
    ∀ (N i j : ℕ) (a b : Fld M), i + j ≤ N → Gen S i a → Gen S j b → Local a.1 b.1

theorem generated_local {S : Set (Fld M)} (hS : ∀ a ∈ S, ∀ b ∈ S, Local a.1 b.1)
    {a b : Fld M} (ha : a ∈ Generated S) (hb : b ∈ Generated S) : Local a.1 b.1
```

File `VOA/Core/LocalSystem.lean`.

From the mathematics to the Lean statement

`hS` includes $a = b$ (self-locality of each generator), which is genuinely required. The bound N in `gen_local` is the induction parameter; `generated_local` is the clean form.

Physical meaning

Composite operators of mutually local fields are mutually local: closure of the chiral operator algebra under the OPE.

Proof on paper. Strong induction on $i + j$. If $a = {:}a_1 a_2{:}$, Dong's lemma (`dong_neg`) needs $a_1 \sim a_2$, $a_1 \sim b$, $a_2 \sim b$, all of strictly smaller total size; if $a = \partial a_1$, use `Local.derivL`; if a is a generator or 1, peel b instead (using symmetry); two generators are local by `hS`, and 1 is local with everything. □

What the machine verified

Unconditional, axiom-clean (`#print axioms VOA.gen_local` run for this chapter).

4.16.2 All integer products and closed local systems

Definition 4.46 (Integer field products; local field system)**.** For fields a, b on M and $n \in \mathbb{Z}$: $a_{(n)}b := \mathrm{Res}_{z_1}(z_1 - z_2)^n [a(z_1), b(z_2)]$ if $n \geq 0$ and $a_{(n)}b := \frac{1}{(-n-1)!} {:}\partial^{-n-1} a\, b{:}$ if $n < 0$. A *local field system* is a linear subspace of Fld(M) containing 1, pairwise local, and closed under all $a_{(n)}b$.

```
noncomputable def prod (n : ℤ) (a b : Fld M) : Fld M :=
  if _hn : 0 ≤ n then
    ⟨cCoeff n.toNat (bracketDist a.1 b.1), isField_cCoeff_bracket a.2 b.2 n.toNat⟩
  else
    ⟨negProd a.2 b.2 (-n - 1).toNat, isField_negProd a.2 b.2 (-n - 1).toNat⟩

structure LocalFieldSystem (M : Type*) [AddCommGroup M] [Module ℂ M] where
  carrier : Submodule ℂ (Fld M)
  one_mem : Fld.one ∈ carrier
  locality : ∀ a ∈ carrier, ∀ b ∈ carrier, Local a.1 b.1
  prod_mem : ∀ (n : ℤ) {a b : Fld M}, a ∈ carrier → b ∈ carrier → Fld.prod n a b ∈ carrier
```

File `VOA/Core/LocalSystemBare.lean` (`VOA.Fld.prod`, `VOA.LocalFieldSystem`; Fld(M) is given its vector-space structure in the same file).

From the mathematics to the Lean statement

`n.toNat` is n for $n \geq 0$; `(-n - 1).toNat` is $-n-1$ for $n < 0$. The two field-property proofs (`isField_cCoeff_bracket`, `isField_negProd`) show that products of fields are fields. Same as Li's definition (and Kac's n-th products of fields).

Physical meaning

A maximal consistent set of chiral operators acting on a sector: closed under taking every OPE coefficient, containing the identity.

Theorem 4.47 (Basic laws of field products). *For fields on M: $1_{(n)}a = \delta_{n,-1}a$; $a_{(k)}1 = 0$ $(k \geq 0)$, $a_{(-1)}1 = a$, $a_{(-k-1)}1 = \frac{1}{k!}\partial^k a$; if $(z_1 - z_2)^N[a,b] = 0$ then $a_{(n)}b = 0$ for $n \geq N$; and products of pairwise local fields are local with a third field local with both.*

```
theorem prod_one_left_all (n : ℤ) (a : Fld M) :
    prod n one a = if n = -1 then a else 0
```

File `VOA/Core/LocalSystemAction.lean` (namespace `VOA.Fld`).

```
theorem prod_one_right_negsucc (k : ℕ) (a : Fld M) :
    (prod (-(k : ℤ) - 1) a one).1 =
      (k.factorial : ℂ)⁻¹ • (VOA.deriv^[k]) a.1

theorem prod_eventually_zero_of_local {a b : Fld M} (h : Local a.1 b.1) :
    ∃ N : ℤ, ∀ n : ℤ, N ≤ n → prod n a b = 0
```

File `VOA/Core/LocalSystemBare.lean` (also `prod_one_right_nat`, `prod_one_right_neg_one`).

```
theorem prod_local_right_of_pairwise {a b c : Fld M}
    (hab : Local a.1 b.1) (hac : Local a.1 c.1) (hbc : Local b.1 c.1) (n : ℤ) :
    Local (prod n a b).1 c.1
```

File `VOA/Core/LocalSystemRegular.lean`.

From the mathematics to the Lean statement

These are the vacuum, creation and truncation laws of a vertex algebra, for the system of fields with 1 as vacuum; `prod_local_right_of_pairwise` is Dong's lemma for every $n \in \mathbb{Z}$ (negative n via `dong_neg` and `Local.deriv_iterate_left`). Note the translation built in: $a_{(-2)}1 = \partial a$.

Physical meaning

In the space of operators, the identity plays the vacuum and ∂ the translation generator: $a_{(-k-1)}1 = \partial^k a/k!$ is the Taylor expansion of the operator itself.

What the machine verified

All unconditional, axiom-clean (`#print axioms` run for `Fld.prod_local_right_of_pairwise` and `LocalFieldSystem.creation_deriv`).

4.16.3 The Borcherds identity for two local fields

Theorem 4.48 (Borcherds identity for an arbitrary local pair). *Let a, b be mutually local fields on an arbitrary vector space M. Then for every $x \in M$ and all $\ell, m, n \in \mathbb{Z}$,*

$$\sum_{i\geq 0}(-1)^i\binom{\ell}{i}\Big(a_{(\ell+m-i)}b_{(n+i)}x - (-1)^\ell b_{(\ell+n-i)}a_{(m+i)}x\Big) = \sum_{i\geq 0}\binom{m}{i}(a_{(\ell+i)}b)_{(m+n-i)}x,$$

where $a_{(\ell+i)}b$ is the field product of Definition 4.46. Its $m = 0$ case, the iterate formula, holds for any two fields (locality not needed).

```
theorem mode_prod_iterate (a b : Fld M) (ell N : ℤ) (x : M) :
    mode (prod ell a b).1 N x =
      ∑ᶠ i : ℕ, ((-1 : ℂ) ^ i * gBinom ell i) •
        (mode a.1 (ell - i) (mode b.1 (N + i) x)
          - ((-1 : ℂ) ^ ell) • mode b.1 (ell + N - i) (mode a.1 i x))
```

File `VOA/Core/FieldProductIterate.lean`.

```
theorem field_jacobi_of_local {a b : Fld M} (h : Local a.1 b.1)
    (x : M) (ell m n : ℤ) :
    (∑ᶠ i : ℤ, (negOnePow i * cbz ell i) •
      (mode a.1 (ell + m - i) (mode b.1 (n + i) x) -
        negOnePow ell • mode b.1 (ell + n - i) (mode a.1 (m + i) x))) =
      ∑ᶠ i : ℤ, cbz m i • mode (prod (ell + i) a b).1 (m + n - i) x
```

File `VOA/Core/LocalSystemJacobi.lean` (also the packaged form `field_borcherds_of_local`).

From the mathematics to the Lean statement

The left side is literally the left side of `VertexOperatorAlgebra.jacobi` with `W.smul u` replaced by `mode a.1`; the right side has the field product `prod (ell + i) a b` where `jacobi` has $Y(u_{(\ell+i)}v)$. The only hypothesis is `Local a.1 b.1`.

How this sharpens the counterexample. Apply the theorem to $a = Y(u)$, $b = Y(v)$ in a `PreVertexAlgebra`: the Borcherds identity of the algebra holds for all (ℓ, m, n) *if and only if* $Y(u_{(\ell)}v) = Y(u)_{(\ell)}Y(v)$ for all ℓ (take $m = 0$ for "only if"). For $\ell \geq 0$ this needs only Goddard and the creation tower; for $\ell < 0$ it needs the creation tower $Y(u,z)\mathbf{1} = e^{zT}u$ — translation covariance. In Section 4.5, $Y(x)_{(-2)}Y(\mathbf{1}) = \partial Y(x) = 2z\,y\cdot \neq 0 = Y(x_{(-2)}\mathbf{1})$.

Physical meaning

OPE associativity is automatic *for operators*: any two mutually local chiral operators satisfy the Borcherds identity with their operator OPE coefficients. What a vertex algebra adds is the state–operator correspondence, and the content of the Borcherds identity of a vertex algebra is that this correspondence intertwines the OPEs of states with those of operators.

Proof on paper. Identical in structure to Theorem 4.26: the iterate formula ($m = 0$) is a direct coefficient computation from the definitions of the field products (no locality); the commutator formula ($\ell = 0$) follows from the delta-decomposition of $[a, b]$, whose coefficients are by construction the nonnegative products (`commutator_prod_bound_of_local`); the Pascal recursion and the anti-diagonal pin finish. □

What the machine verified

Unconditional, axiom-clean (`#print axioms VOA.Fld.field_jacobi_of_local` and `VOA.Fld.mode_prod_iterate` run for this chapter).

4.16.4 The carrier action, and what is not yet proved

Definition 4.49 (Induced state–field map of a local system)**.** For a local field system L, the vacuum is $1 \in L$, the mode action is $a \mapsto (b \mapsto a_{(n)}b)$, the induced field of $a \in L$ is $Y(a,z) = \sum_n (a_{(n)}\cdot)z^{-n-1}$ acting on L, and the translation is $a \mapsto a_{(-2)}1$.

```
noncomputable def vacuum : L.carrier := ⟨Fld.one, L.one_mem⟩

noncomputable def stateField : L.carrier →ₗ[ℂ] FormalDist (End ℂ L.carrier) where
  toFun a := fun q => modeAction L (-q - 1) a

theorem stateField_vacuum :
    stateField L (vacuum L) = (idField : FormalDist (End ℂ L.carrier))

theorem creation_deriv (a : L.carrier) (k : ℕ) :
    (modeAction L (-(k : ℤ) - 1) a (vacuum L) : Fld M).1 =
      (k.factorial : ℂ)⁻¹ • (VOA.deriv^[k]) a.1.1

theorem translation_val (a : L.carrier) :
    (translation L a : Fld M).1 = VOA.deriv a.1.1
```

File `VOA/Core/LocalSystemAction.lean` (namespace `VOA.LocalFieldSystem`; `modeAction L n a b` is $a_{(n)}b$).

From the mathematics to the Lean statement

`L.carrier` is the subspace, used as a type. `stateField` has z^q-coefficient `modeAction L (-q - 1)`, so its modes are the field products, as in any vertex algebra. `stateField_vacuum` is VA2, `creation_deriv` the creation tower, `translation_val` says the induced translation is ∂. The file also proves `creation_neg_one`, `creation_nonneg` (VA3) and `modeAction_eventually_zero` (VA5).

Physical meaning

The operators of a local system themselves form a chiral algebra: the identity operator is its vacuum, ∂ its translation, and OPE coefficients its products.

Li's construction is not complete at this commit

The library proves VA2, VA3, VA5 and the creation tower for the induced fields of a local field system, Dong closure (`LocalFieldSystem.prod_local`), and the Borcherds identity for the action on M. It does **not** prove that the induced fields `stateFld L a` are mutually local on L (VA4 for the local system), nor the compatibility $Y(a_{(n)}b) = Y(a)_{(n)}Y(b)$, and it packages neither a `BarePreVA` nor a `PreVertexAlgebra` on L, nor a module structure on M. The file `LocalSystemRegular.lean` names these as "the intended endpoints". In particular no result of the library is conditional on them; they are open work. (If the endpoint is a `BarePreVA`, the warning of Section 4.5 applies: a Borcherds identity over `BarePreVA` would require adding translation covariance, which a local system does have, `translation_val`.)

4.17 Localising the first-order Jacobi identity

The file `VOA/Core/JacobiLocal.lean` serves the deformation theory of Chapter 8, where a first-order deformation $Y+tY_1$ of a VOA is encoded by a *cochain* $f : V \to \mathrm{End}(V)[[z^{\pm 1}]]$ (`VOA.Deform.Cochain`), with deformed products $u^1_{(n)}v$ = `cmode f u n v`, and the cocycle condition `JacobiAx W f` is the linearisation of the Borcherds identity in f (four insertions of f on the left, two on the right). Chapter 8 gives the definitions of `Cochain`, `cmode`, `JacobiAx`, `gradedCochains` and `IsRigid` with their Lean source; we state only the localisation theorem proved here.

Lemma 4.50 (Products vanish above the grading bound). *In a VOA, if $u \in V_a$, $v \in V_b$ and $n > a + b - 1$, then $u_{(n)}v = 0$.*

```
theorem smul_eq_zero_of_grading_lt (W : VertexOperatorAlgebra 𝒱) {a b : ℤ} {u v : 𝒱}
    (hu : u ∈ W.grading a) (hv : v ∈ W.grading b) {n : ℤ} (hn : a + b - 1 < n) :
    W.smul u n v = 0
```

File `VOA/Core/JacobiLocal.lean` (`VOA.Deform.smul_eq_zero_of_grading_lt`).

From the mathematics to the Lean statement

VA1 puts $u_{(n)}v$ in $V_{a+b-n-1}$, which is 0 by (VOA4) when $a+b-n-1<0$. This explicit bound is what makes the Borcherds sums finite with an explicit range once the grades are fixed.

Physical meaning

In a theory with nonnegative scaling dimensions, the OPE $u(z)v(w)$ has a pole of order at most $\Delta_u+\Delta_v$, the pole being fixed by the dimension of the lowest state that can appear.

Theorem 4.51 (Localisation of the cocycle condition). *For a graded cochain f on a VOA,* `JacobiAx W f` *holds if and only if, for every $(a,b,d,\ell,m,n)\in\mathbb{Z}^6$, the explicit finite equation* `LocalJacobiAt W f a b d ℓ m n` *holds: for all $u\in V_a$, $v\in V_b$, $x\in V_d$, $\sum_{i=0}^{B_L}\mathrm{jac1L}_i=\sum_{i=0}^{B_R}\mathrm{jac1R}_i$ with $B_L=\max(b+d-n-1,\,a+d-m-1)$ and $B_R=a+b-\ell-1$.*

```
def LocalJacobiAt (W : VertexOperatorAlgebra 𝒱) (f : Cochain 𝒱) (a b d ℓ m n : ℤ) : Prop :=
  ∀ u ∈ W.grading a, ∀ v ∈ W.grading b, ∀ x ∈ W.grading d,
    (∑ i ∈ Finset.Icc (0 : ℤ) (jacBoundL a b d m n), jac1L W f u v x ℓ m n i)
      = ∑ i ∈ Finset.Icc (0 : ℤ) (jacBoundR a b ℓ), jac1R W f u v x ℓ m n i

theorem jacobiAx_iff_localJacobiAt (W : VertexOperatorAlgebra 𝒱) {f : Cochain 𝒱}
    (hf : f ∈ gradedCochains W) :
    JacobiAx W f ↔ ∀ a b d ℓ m n : ℤ, LocalJacobiAt W f a b d ℓ m n
```

File `VOA/Core/JacobiLocal.lean` (namespace `VOA.Deform`). The summands are

```
noncomputable def jac1L (W : VertexOperatorAlgebra 𝒱) (f : Cochain 𝒱) (u v x : 𝒱)
    (ℓ m n i : ℤ) : 𝒱 :=
  (negOnePow i * cbz ℓ i) •
    (cmode f u (ℓ + m - i) (W.smul v (n + i) x)
      + W.smul u (ℓ + m - i) (cmode f v (n + i) x)
      - negOnePow ℓ •
        (cmode f v (ℓ + n - i) (W.smul u (m + i) x)
          + W.smul v (ℓ + n - i) (cmode f u (m + i) x)))

noncomputable def jac1R (W : VertexOperatorAlgebra 𝒱) (f : Cochain 𝒱) (u v x : 𝒱)
    (ℓ m n i : ℤ) : 𝒱 :=
  cbz m i •
    (W.smul (cmode f u (ℓ + i) v) (m + n - i) x
      + cmode f (W.smul u (ℓ + i) v) (m + n - i) x)

def jacBoundL (a b d m n : ℤ) : ℤ := max (b + d - n - 1) (a + d - m - 1)

def jacBoundR (a b ℓ : ℤ) : ℤ := a + b - ℓ - 1
```

File `VOA/Core/JacobiLocal.lean`.

From the mathematics to the Lean statement

`Finset.Icc 0 N` is $\{0,\dots,N\}$ (empty if $N<0$). `jac1L` and `jac1R` are the i-th summands of the two sides of the linearised Borcherds identity: the four (resp. two) ways of replacing one product by a deformed product `cmode f`. The theorem replaces each `finsum` by an explicit

finite sum, using Lemma 4.50 and its analogue for graded cochains, and uses the direct-sum decomposition to reduce from arbitrary to homogeneous u, v, x. **Scope (stated in the source):** for fixed input grades (a, b, d) there are still infinitely many equations ($\ell \to -\infty$), so the system is not finite per tridegree; the theorem is a reformulation, not a finiteness theorem. The same file proves the consumer `not_isRigid_of_local`: a solution of the local system whose component at some tridegree is not a coboundary component refutes `IsRigid`; by Chapter 8, `IsRigid` is the ungraded rigidity notion that is false for every Virasoro VOA for definitional reasons, so this consumer is of limited use.

Physical meaning

First-order deformations of a chiral algebra are infinitesimal changes of all OPE coefficients preserving associativity; the theorem says that, sector by sector in scaling dimensions, the associativity constraints on the deformed OPE coefficients are finitely many linear equations each — the form in which conformal-bootstrap-style constraints on marginal deformations are actually solved.

What the machine verified

`jacobiAx_iff_localJacobiAt`, `smul_eq_zero_of_grading_lt`, `not_isRigid_of_local`: unconditional, axiom-clean (`#print axioms` run for this chapter).

4.18 Combinatorial lemmas

The file `VOA/Core/FieldCombinatorics.lean` (namespace `VOA.FieldCombinatorics`) collects coefficient identities used by the field-product files; it is independent of vertex algebras. The one with mathematical content is the negative binomial:

Lemma 4.52. *For $s, n \in \mathbb{N}$, $\binom{-s-1}{n} = (-1)^n \frac{(s+n)!}{s!\,n!} = (-1)^n \binom{s+n}{n}$.*

```
theorem gBinom_negsucc (s n : ℕ) :
    gBinom (-(s : ℤ) - 1) n =
      (-1) ^ n * ((s + n).factorial : ℂ) /
        ((s.factorial : ℂ) * (n.factorial : ℂ))
```

File `VOA/Core/FieldCombinatorics.lean`.

From the mathematics to the Lean statement

Exactly the displayed identity; it converts the coefficients of normal-ordered products into the binomials of the iterate formula. Other lemmas there: the expansion of $(z_1 - z_2)^N$ coefficientwise (`mulBySubPow_apply_sum`), $\binom{n}{k}$ for natural n (`gBinom_natCast_eq_choose`), binomial symmetry (`gBinom_symm_nat`) and the coefficients of ∂^j (`deriv_pow_apply`).

Physical meaning

$\binom{-s-1}{n}$ is the Taylor coefficient of $(z-w)^{-s-1}$ in powers of w/z: it governs the expansion of an OPE pole of order $s+1$ in one radial ordering.

4.19 Referee's checklist

Lean declaration	Intended meaning	Hypotheses / status	Check
`PreVertexAlgebra`	Gannon Def. 5.1.3(a): grading, VA1–VA5	definition; **no translation axiom**; strictly weaker than Kac/FBZ/LL in that direction	Def. 4.1, §4.4
`BarePreVA`	VA2–VA5 without grading	definition; docstring now warns that it does **not** suffice for Borcherds (an earlier docstring claimed it did)	Def. 4.3
`GradedVertexOperatorAlgebra`	LL/FLM VOA (graded, truncated below), without CFT type	definition; no structure theory proved at this level	Def. 4.4
`VertexOperatorAlgebra`	LL/FLM VOA of CFT type (a restriction of LL/FLM)	definition; (VOA3) supplies translation; LL ⇒ library direction on paper only	Prop. 4.5
`VertexAlgebra`, `toVertexAlgebra`	`PreVertexAlgebra` + translation covariance; every VOA is one	definition; map from VOAs via `isTranslationCovariant`	§4.1
(scratch) `L03Counter.VA`, `jacobi_fails`	a `PreVertexAlgebra` violating Borcherds	machine-checked outside the library (not in this release); library copy `TranslationCovariantCounterexample`	Thm. 4.7
`PreVertexAlgebra.T`	$Tu = u_{(-2)}\mathbf{1}$	definition	Def. 4.2
`Yprod_ext`, `eq_zero_of_mulBySubPow_of_bddBelow`	$z_1 - z_2$ non-zero-divisor on $V((z_1))((z_2))$	none; unconditional	Thm. 4.11
`bracket_deltaSum`, `mode_commutator_structural`	OPE decomposition; structural commutator	VA level; coefficients not identified	Thm. 4.13
`goddard_uniqueness`, `goddard_uniqueness_vac`, `goddard_zero`	state determines local field	VA level / abstract; unconditional	Thm. 4.14
`dong_nonneg`, `dong_neg`	locality closed under field products	pairwise locality (+ field); unconditional	Thm. 4.16
`creation_pow`, `Y_Tpow`, `T_eq_Lneg1`	$Y(u,z)\mathbf{1} = e^{zT}u$, $T = L_{-1}$	VOA; unconditional	Thm. 4.17
`Y_T`, `mode_Y_T`	$Y(Tu,z) = \partial_z Y(u,z)$; $(Tu)_{(n)} = -n\,u_{(n-1)}$	VOA; unconditional	Thm. 4.18
`translation_covariance`	$[L_{-1}, Y(u)] = Y(L_{-1}u)$	VOA; unconditional	Thm. 4.19
`nth_product`, `assoc_nonneg`	$Y(u_{(k)}v) =$ $\mathrm{Res}(z_1 - z)^k [Y(u), Y(v)]$	VOA; unconditional	Thm. 4.20
`mode_commutator`, `commBound`	commutator formula (complete sum)	VOA; $\exists N$ made exhaustive by `commBound`	Thm. 4.21
`assoc_neg`	$Y(u_{(-k-1)}v) = \frac{1}{k!} {:}\partial^k Y(u) Y(v){:}$	VOA; unconditional	Thm. 4.22
`mode_iterate`	iterate formula, all $\ell \in \mathbb{Z}$	VOA; vector form; unconditional	Thm. 4.23
`borcherds`, `jacobi`	Borcherds identity, all (ℓ, m, n)	VOA; unconditional, axiom-clean	Thm. 4.26
`jacobi_commutator`	commutator formula, $\ell = 0$ slice of Borcherds (alias of `mode_commutator`)	VOA; $\exists N$ (see `commBound`); unconditional	Thm. 4.27
`skewVacLocal`, `weakAssocLoc`	reflected field is local	VOA; unconditional	Thm. 4.32

Lean declaration	Intended meaning	Hypotheses / status	Check
`skew`, `skew_mode`	$Y(u,z)v = e^{zT}Y(v,-z)u$	VOA; unconditional	Thm. 4.33
`flm`	FLM associativity after $z_1 = z_0 + z_2$	VOA, explicit locality order; unconditional	Thm. 4.35
`comm_iff_nonneg_modes`, `comm_iff_assoc_alg`, `commRing_of_comm`	Gannon Thm. 5.1.4	VOA; **hypothesis forces $W = \mathbb{C}\mathbf{1}$**	Thm. 4.37, warning
`Reconstruction.reconstruct`	existence of Y from spanning local T-covariant fields	all hypotheses explicit; no VA2/VA1 in conclusion	Thm. 4.41
`Reconstruction.field_eq_zero_of_vacuum`	a field local with a spanning family of creating fields and killing the vacuum is 0	bare vector space; all hypotheses explicit; unconditional	Thm. 4.40
`TensorFieldLift.*`	lifts to $A \otimes B$ preserve hypotheses	unconditional	Thm. 4.43
`gen_local`, `generated_local`	generated system is local	pairwise local generators	Thm. 4.45
`Fld.prod`, `LocalFieldSystem`	Li's field products and local systems	definitions	Def. 4.46
`Fld.field_jacobi_of_local`, `Fld.mode_prod_iterate`	Borcherds for any local pair of fields	`Local a b`; unconditional	Thm. 4.48
`LocalFieldSystem.stateField` etc.	induced VA on a local system	partial: **VA4 for induced fields not proved**	Def. 4.49, warning
`Deform.jacobiAx_iff_localJacobiAt`	cocycle condition = local finite equations	graded cochain; unconditional	Thm. 4.51

Machine verification for this chapter. When the chapter was first written, `#print axioms` was run on a scratch file importing the chapter's modules, with `lake env lean -DmaxSynthPendingDepth=3` (never the bare command), against the build products of an earlier commit (not re-run for this edition); a full `lake build` was *not* run for this chapter. Every one of the following reported exactly `[propext, Classical.choice, Quot.sound]`: `goddard_uniqueness`, `goddard_zero`, `Yprod_ext`, `bracket_deltaSum`, `dong_nonneg`, `dong_neg`, `T_eq_Lneg1`, `creation_pow`, `Y_Tpow`, `translation_covariance`, `nth_product`, `mode_commutator`, `assoc_neg`, `mode_iterate`, `skew`, `skew_mode`, `weakAssocLoc`, `flm`, `borcherds`, `jacobi`, `jacobi_commutator`, `Y_T`, `field_eq_zero_of_vacuum`, `comm_iff_nonneg_modes`, `comm_iff_assoc_alg`, `commRing_of_comm`, `reconstruct`, `gen_local`, `field_jacobi_of_local`, `mode_prod_iterate`, `prod_local_right_of_pairwise`, `creation_deriv`, `jacobiAx_iff_localJacobiAt`, `smul_eq_zero_of_grading_lt`, `not_isRigid_of_local`, `local_firstField_secondFi` `BarePreVA.isField_Y` (full names as in the sections above). The PBW theorem `VOA.pbw` occurs nowhere in this chapter.

Release audit 2026-10-27: `Notes/Textbook/referee/RELEASE_AUDIT_FOUNDATIONS.md` (at an earlier commit; no `lake build`, `#print axioms` on the existing build products). It re-ran `#print axioms` on `VOA.VertexOperatorAlgebra.borcherds` and `VOA.VertexOperatorAlgebra.jacobi` (three standard axioms each), confirmed that the Borcherds identity is stated for all $(\ell, m, n) \in \mathbb{Z}^3$, that its three `finsum`s are proved finite (`BR_fin`, `Puv_fin`, `Pvu_fin`), and that it is derived from locality, not assumed. It recompiled the counterexample `L03Counter.VA` (`translation_fails`, `jacobi_fails`: three standard axioms) and adopted this chapter's finding: `PreVertexAlgebra`/`BarePreVA` are not vertex algebras in the standard sense; `VertexOperatorAlgebra` is the LL/FLM VOA of CFT type; the direction LL ⇒ library of Proposition 4.5 is paper-only; the zero space is a VOA.

Project records. The history of the skew-symmetry gate (once the sanctioned axiom `weakAssocLoc_gate`, then a single `sorry` in `Gfield_eq_jumpSum`) is recorded only in the docstrings of `SkewSymmetry.lean` and `WeakAssoc.lean`. The translation gap of `PreVertexAlgebra` and the vacuity of Theorem 5.1.4 for VOAs are recorded for the first time here.

Chapter 5

Structure theory and invariant forms

This chapter documents the release of the LeanVOA library named in the front matter. Every Lean quotation below is checked by `scripts/textbook/sync.py` to occur verbatim (up to whitespace and comments) in the source files of that release. Checks that were run at an earlier state of the library and not re-run for this edition are marked as such. The chapter covers the thirty-four files assigned to it in `Notes/Textbook/assignment.txt`: the files of `VOA/Core/` called `V1LieAlgebra`, `LieAlgebraV1`, `Automorphism`, `InnerAutomorphism`, `CommutativeRing`, `QuotientVOA`, `VOASubalgebraGenerated`, `TensorVOA`, `TensorLieAction`, `InternalGradingOperator`, `SimpleImage`, `SingularVector`, `ScreeningKernel`, `BRSTCohomology`, `WeightCommutatorField`, `BilinearForm`, `GradedFormMatrix`, `QuasiPrimaryDecomp`, and the sixteen files `InvariantForm*`.

These files are the "structure theory" of a vertex operator algebra in the sense in which one speaks of the structure theory of Lie algebras: the operations that take one algebra and produce another (subalgebras, quotients, tensor products, kernels of derivations, cohomology), the symmetries (automorphisms, inner automorphisms, the Lie algebra of currents), the distinguished vectors (singular vectors) and, above all, the *invariant bilinear form*, which is the tool by which simplicity is decided. The headline results are:

1. the weight-one space V_1 of a vertex operator algebra is a Lie algebra under $[u, v] = u_{(0)}v$ (Section 5.2);

2. the exponential of a locally nilpotent current zero mode is an automorphism, and conjugation of such an exponential by an automorphism is again one (Section 5.3);

3. every ideal is graded and two-sided, there is a maximal proper ideal $\mathfrak{m}(V)$, and $V/\mathfrak{m}(V)$ is a simple vertex operator algebra; a surjective homomorphism onto a simple vertex operator algebra has kernel exactly $\mathfrak{m}(V)$ (Sections 5.4–5.5);

4. the kernel of the zero mode of a weight-one state (a "screening operator") is a vertex operator subalgebra (Section 5.7);

5. a singular vector whose generated ideal is proper obstructs simplicity, with two practical criteria for properness (Section 5.8);

6. the tensor product of two vertex superalgebras and the BRST cohomology of a vertex superalgebra are again vertex superalgebras, under named hypotheses (Sections 5.9 and 5.11);

7. *the theorem of Frenkel–Huang–Lepowsky and Li*: if $\mathbf{1} \neq 0$ and $L_1 V_1 = 0$, there is a unique invariant bilinear form with $(\mathbf{1}|\mathbf{1}) = 1$ (Section 5.13);

8. *Li's radical theorem*: the radical of such a form is the maximal ideal, so V is simple if and only if the form is nondegenerate, and the graded dimensions of the simple quotient are the ranks of the Gram matrices (Sections 5.14 and 5.15).

Throughout, "vertex operator algebra" means the library's `VertexOperatorAlgebra`, which is the Lepowsky–Li/FLM VOA *of CFT type* ($V_0 = \mathbb{C}\mathbf{1}$, $V_n = 0$ for $n < 0$, integer grading, finite-dimensional pieces; Chapter 4, Definition 4.4); the headlines above are theorems about VOAs of CFT type only, a restriction relative to FLM and Lepowsky–Li. The superalgebra headline (item 6) is about other structures: `SuperVertexAlgebra` (which, like `PreVertexAlgebra`, has no translation-covariance axiom and no CFT-type condition) and `SuperNearVOA` (which adds a conformal vector and the translation axiom, but not CFT type); both are described where they arise. `#print axioms` on every headline reports only Lean's three standard axioms; `VOA.pbw` (the PBW theorem of Chapter 3; formerly a project axiom, now a theorem) is used nowhere in this chapter (Section 5.17).

The chapter also records several findings of the fidelity check that a referee should know before relying on these files, collected here for convenience and explained where they arise:

- the normality of the inner automorphism group `Inn` holds *by construction* (it is defined as a normal closure), and the predicate `IsExpInner` that defines it is weak enough that the identity satisfies it for every current (the warning on p. 214);
- the hypothesis `homega` of the inner automorphism `inner` is redundant (Remark 5.15);
- the "tensor product of VOAs" file constructs a tensor product of vertex *superalgebras* without conformal vectors, conditional on two linear-algebra hypotheses (the warning on p. 232);
- the library's notion of a subalgebra generated by a set always contains ω (Definition 5.26);
- Li's general theorem (invariant forms $\leftrightarrow (V_0/L_1V_1)^*$) is formalised only in the case $L_1V_1 = 0$, and the symmetry of invariant forms is *not* proved (Section 5.13);
- four general routes to invariance, recorded in the files, are dead ends; their "refutation" in the library is conditional on a witness that is not constructed, though one is easy to give on paper (Section 5.16).

Prerequisites. The definitions of formal distribution, mode, the library's structure `PreVertexAlgebra` (graded VA1–VA5 data, which lacks translation covariance and is *not* a vertex algebra in the standard sense; the library's translation-covariant `VertexAlgebra` adds that axiom, Chapter 4), vertex operator algebra (`VertexOperatorAlgebra`, of CFT type by definition, with its fields `grading`, `Y`, `vacuum`, `conformalVector`, `centralCharge`, `virasoro`, `L0_grading`, `translation`, `vacuum_grade`, `positivity`), the Borcherds identity and skew-symmetry are those of Chapters 2 and 4. Several notions of this chapter (automorphisms, subalgebras, ideals, quotients, invariant forms) were already used in the Moonshine chapters (for instance the fixed-point sub-VOA of Chapter 32); here they are developed in full. Chapter 38 uses the invariant-form results of this chapter to prove that $V^\natural$ is simple.

5.1 Conventions recalled

We recall the conventions that every statement of this chapter uses; the reader who has read Chapter 4 may skip to Section 5.2.

Modes. A formal distribution $f = \sum_{k\in\mathbb{Z}} f_k z^k$ with coefficients in a space is stored in Lean as the function $k \mapsto f_k$, i.e. `f k` is the coefficient of z^k. The *mode* is

```
def mode (f : FormalDist W) (m : ℤ) : W := f (-m - 1)
```

File `VOA/Foundations/FormalCalculus.lean`. So for the state–field correspondence $Y(u,z) = \sum_n u_{(n)} z^{-n-1}$ one has `mode (W.Y u) n` $= u_{(n)}$, and the library abbreviates

```
def smul (V : PreVertexAlgebra 𝒱) (u : 𝒱) (n : ℤ) (v : 𝒱) : 𝒱 := mode (V.Y u) n v
```

File `VOA/Core/VertexAlgebra.lean`. Thus `W.smul u n v` is the n-th product $u_{(n)}v$. The coefficient form `(W.Y v) k u` is $v_{(-k-1)}u$ (`Y_apply_eq_smul` in `VOA/Core/InvariantFormSymmetry.lean`).

Virasoro modes. The Virasoro operators are

```
def L (W : VertexOperatorAlgebra 𝒱) (n : ℤ) : End ℂ 𝒱 :=
  mode (W.Y W.conformalVector) (n + 1)
```

File `VOA/Core/VertexOperatorAlgebra.lean`: $L_n = \omega_{(n+1)}$, so $L_{-1} = \omega_{(0)}$ is the translation operator T, $L_0 = \omega_{(1)}$ is the grading operator and $L_1 = \omega_{(2)}$ lowers the weight by one.

Weights. The weight grading is `W.grading : ℤ → Submodule ℂ 𝒱`, an internal direct sum (`isInternal`) of finite-dimensional pieces (`finrank`); VA1 is the rule $u \in V_k$, $v \in V_\ell \Rightarrow u_{(n)}v \in V_{k+\ell-n-1}$ (Lean: `smul_mem_grading`). The vertex operator algebras of the library are *of CFT type by definition*: `vacuum_grade` says $V_0 = \mathbb{C}\mathbf{1}$ and `positivity` says $V_n = 0$ for $n < 0$. This is used constantly below, and it is the reason several hypotheses of the literature ("V of CFT type") never appear explicitly. It is also a genuine *restriction* relative to FLM and Lepowsky–Li, who ask only $V_n = 0$ for $n \ll 0$: VOAs with $\dim V_0 > 1$ or with negative weights are not instances, so every theorem of this chapter is a theorem about VOAs of CFT type (release audit 2026-10-27, finding m-1). Note that CFT type as stated allows $\mathbf{1} = 0$ (then $V = 0$): the zero space is a VOA in the library's sense (release audit, finding m-4); this is why the hypothesis $\mathbf{1} \neq 0$ appears in several theorems.

Projections. `piHom W n : 𝒱 →ₗ[ℂ] 𝒱` is the projection onto V_n along the other weight spaces (`VOA/Modules/FiniteGenerationProof.lean`).

Lean notation used throughout. `Submodule ℂ 𝒱` is the type of complex subspaces of V; `⊥` and `⊤` are 0 and V; `⊓`, `⨆`, `sSup`, `sInf` are intersection, sum, sum of a set and intersection of a set of subspaces; `𝒱 ⧸ I` is the quotient space and `I.mkQ` the quotient map; `LinearMap.ker`, `LinearMap.range` are kernel and image; `End ℂ 𝒱` is the algebra of linear endomorphisms; `𝒱 ≃ₗ[ℂ] 𝒱` the group of linear automorphisms; `↥S` (often implicit) turns a subspace into a type; `Module.finrank ℂ X` is the dimension of a finite-dimensional space (and 0 for an infinite-dimensional one); $\sum^{\mathbf{f}}$ is a sum over a finite support (it returns 0 if the support is infinite, a convention whose harmlessness has to be checked each time it is used).

5.2 The Lie algebra of currents

5.2.1 Zero modes and the derivation property

For a homogeneous state $u \in V_k$ the *zero mode* is $o(u) = u_{(k-1)}$: by VA1 it maps V_ℓ into $V_{k+\ell-(k-1)-1} = V_\ell$, i.e. it preserves every weight space. For a weight-one state the zero mode is $u_{(0)}$.

Definition 5.1 (Zero mode; Gannon §5.2.1). For $u \in V$ and $k \in \mathbb{Z}$, $o_k(u) := u_{(k-1)} \in \mathrm{End}(V)$.

File `VOA/Core/LieAlgebraV1.lean`.

```
def zeroMode (W : VertexOperatorAlgebra 𝒱) (u : 𝒱) (k : ℤ) : End ℂ 𝒱 :=
  mode (W.Y u) (k - 1)

theorem zeroMode_mem_grading (W : VertexOperatorAlgebra 𝒱) {k : ℤ} {u : 𝒱}
    (hu : u ∈ W.grading k) {ℓ : ℤ} {v : 𝒱} (hv : v ∈ W.grading ℓ) :
    W.zeroMode u k v ∈ W.grading ℓ := by
```

From the mathematics to the Lean statement

`zeroMode u k` is $u_{(k-1)}$ for *any* u, with the weight k supplied by hand, because a general u is a sum of homogeneous pieces of different weights and "the" zero mode would then not be defined. Only for $u \in V_k$ (hypothesis `hu` of `zeroMode_mem_grading`) is it the zero mode of the literature. Throughout this chapter only $k = 1$ matters, where `W.zeroMode u 1` $= u_{(0)}$ (indeed $1 - 1 = 0$).

Physical meaning

In conformal field theory a weight-k field $u(z) = \sum_m u_m z^{-m-k}$ has modes $u_m = u_{(m+k-1)}$; the zero mode $u_0 = u_{(k-1)}$ commutes with L_0 and so acts within each energy level. For $k = 1$ the field is a *current* and $u_0 = \oint u(z)\,dz/2\pi i$ is its *charge*: a conserved quantity that acts on the space of states without changing energies.

What the machine verified

Definition and an unconditional lemma (VA1); axiom-clean.

Theorem 5.2 (Zero modes are derivations; Gannon (5.2.4)). *For all $u, v, w \in V$ and $n \in \mathbb{Z}$:* $u_{(0)}(v_{(n)}w) - v_{(n)}(u_{(0)}w) = (u_{(0)}v)_{(n)}w$.

File `VOA/Core/LieAlgebraV1.lean`.

```
theorem zeroMode_isDerivation (W : VertexOperatorAlgebra 𝒱) (u v w : 𝒱) (n : ℤ) :
    W.smul u 0 (W.smul v n w) - W.smul v n (W.smul u 0 w) = W.smul (W.smul u 0 v) n w := by
```

File `VOA/Core/Automorphism.lean` restates it as a Leibniz rule:

```
theorem zeroMode_leibniz (W : VertexOperatorAlgebra 𝒱) (u a b : 𝒱) (n : ℤ) :
    W.smul u 0 (W.smul a n b) = W.smul (W.smul u 0 a) n b + W.smul a n (W.smul u 0 b) := by
```

From the mathematics to the Lean statement

Both statements are for *arbitrary* u, v, w, n: no weight hypothesis at all. This is correct: the commutator formula $[u_{(m)}, v_{(n)}] = \sum_{j\geq 0} \binom{m}{j}(u_{(j)}v)_{(m+n-j)}$ at $m = 0$ has the single term $j = 0$. The Lean statement is exactly the textbook one with the commutator written out. It could not be vacuous: both sides are vectors of V and there are no hypotheses.

Physical meaning

The charge u_0 of any field acts on every operator product as a derivation: $[Q, \phi_1(z)\phi_2(w)] = [Q, \phi_1(z)]\phi_2(w) + \phi_1(z)[Q, \phi_2(w)]$, and $[u_{(0)}, Y(v,z)] = Y(u_{(0)}v, z)$ says that the charge acts on a field by acting on the state that creates it. This is the infinitesimal form of the statement that conserved charges generate symmetries of the operator algebra.

Proof on paper. The n-th product formula $Y(u_{(n)}v, z) = \mathrm{Res}_{z_1}\left((z_1 - z)^n [Y(u, z_1), Y(v, z)]\right)$ (valid in any vertex algebra in the standard sense, and proved in the library for `VertexOperatorAlgebra` but not for the weaker `PreVertexAlgebra`; Chapter 4) at $n = 0$ reads $Y(u_{(0)}v, z) = \mathrm{Res}_{z_1}[Y(u, z_1), Y(v, z)] = [u_{(0)}, Y(v, z)]$. Taking the coefficient of z^{-n-1} and applying to w gives the claim. □

What the machine verified

Unconditional; `#print axioms` = `[propext, Classical.choice, Quot.sound]`.

5.2.2 The bracket on the weight-one space

Definition 5.3 (The Lie bracket on V_1). For $u, v \in V_1$, $[u, v] := u_{(0)}v$, which lies in $V_{1+1-0-1} = V_1$.

File `VOA/Core/LieAlgebraV1.lean`.

```
def bracketV1 (W : VertexOperatorAlgebra 𝒱) (u v : W.grading 1) : W.grading 1 :=
  ⟨W.smul (u : 𝒱) 0 (v : 𝒱), by
    have h := W.smul_mem_grading u.2 v.2 0
    rwa [show (1 : ℤ) + 1 - 0 - 1 = 1 by ring] at h⟩
```

From the mathematics to the Lean statement

The type `W.grading 1` is the subspace V_1 viewed as a type; an element is a pair of a vector and a proof of membership, and `(u : 𝒱)` forgets the proof. The anonymous constructor `⟨x, proof⟩` packages $u_{(0)}v$ with the VA1 proof that it is again in V_1 (the one-line proof is shown because it is informative: it is exactly the weight count $1 + 1 - 0 - 1 = 1$). The bracket is literally $u_{(0)}v$, with no sign or normalisation.

Physical meaning

V_1 is the space of conserved currents $J^a(z)$. Their OPE has the form $J^a(z)J^b(w) \sim \frac{k^{ab}}{(z-w)^2} + \frac{f^{ab}{}_c J^c(w)}{z-w}$; the simple-pole coefficient is $J^a_{(0)}J^b = f^{ab}{}_c J^c$, the structure constants of the global symmetry algebra, and the double pole $J^a_{(1)}J^b = k^{ab}\mathbf{1}$ is the level (the current–current two-point function).

What the machine verified

Definition; axiom-clean.

Theorem 5.4 (V_1 is a Lie algebra; Gannon §5.2.1). *The bracket of Definition 5.3 is bilinear, antisymmetric and satisfies the Jacobi identity* $[[u, v], w] = [u, [v, w]] - [v, [u, w]]$. *Hence* $(V_1, [\cdot, \cdot])$ *is a complex Lie algebra.*

File `VOA/Core/LieAlgebraV1.lean`.

```
theorem bracketV1_jacobi (W : VertexOperatorAlgebra 𝒱) (u v w : W.grading 1) :
    W.bracketV1 (W.bracketV1 u v) w
      = W.bracketV1 u (W.bracketV1 v w) - W.bracketV1 v (W.bracketV1 u w) := by

theorem bracketV1_antisymm (W : VertexOperatorAlgebra 𝒱) (u v : W.grading 1) :
    W.bracketV1 u v = - W.bracketV1 v u :=

noncomputable instance instLieRingGradingOne (W : VertexOperatorAlgebra 𝒱) :
    LieRing (W.grading 1) where
  bracket u v := W.bracketV1 u v

noncomputable instance instLieAlgebraGradingOne (W : VertexOperatorAlgebra 𝒱) :
    LieAlgebra ℂ (W.grading 1) where
  lie_smul c u v := W.bracketV1_smul_right c u v
```

From the mathematics to the Lean statement

An `instance` of `LieRing` and `LieAlgebra ℂ` on the type V_1 is Mathlib's way of saying "V_1 is a complex Lie algebra"; the fields not shown (`add_lie`, `lie_add`, `lie_self`, `leibniz_lie`) are discharged by the bilinearity lemmas, antisymmetry and Jacobi. The line `bracket u v :=`

`W.bracketV1 u v` pins the Lie bracket `[u, v]` of Mathlib to $u_{(0)}v$, so there is no ambiguity about which bracket is meant. Mathlib's Leibniz form $[u,[v,w]] = [[u,v],w] + [v,[u,w]]$ is equivalent to the displayed Jacobi identity. The statements are unconditional and exactly the textbook ones.
A historical remark the source records: antisymmetry was at first stated only conditionally (`bracketV1_antisymm_of_skew`, taking $u_{(0)}v + v_{(0)}u = 0$ as hypothesis) while skew-symmetry was unproved; now skew-symmetry is a theorem (Chapter 4, Theorem 4.33) and `bracketV1_antisymm` discharges the hypothesis via `smul_zero_add_swap_eq_zero`.

Physical meaning

The currents of a chiral algebra close into a Lie algebra $\mathfrak{g} = V_1$: this is the *continuous global symmetry* of the chiral CFT, and the modes J^a_n form the affine (Kac–Moody) algebra $\hat{\mathfrak{g}}$ whose zero modes J^a_0 generate $\mathfrak{g}$ acting on each energy level. For the Moonshine module $V^\natural_1 = 0$: the theory has no continuous symmetry, only the finite Monster group.

Proof on paper. Jacobi is Theorem 5.2 at $n = 0$. Antisymmetry: skew-symmetry $Y(u,z)v = e^{zT}Y(v,-z)u$ gives, at the coefficient of z^{-1}, $u_{(0)}v = -v_{(0)}u + T(v_{(1)}u) - \frac{1}{2}T^2(v_{(2)}u) + \cdots$. For $u, v \in V_1$, $v_{(1)}u \in V_0 = \mathbb{C}\mathbf{1}$ and $T\mathbf{1} = 0$; $v_{(j)}u \in V_{1-j} = 0$ for $j \geq 2$. So $u_{(0)}v = -v_{(0)}u$. □

What the machine verified

Unconditional; `#print axioms` on `instLieAlgebraGradingOne` and `bracketV1_antisymm`: `[propext, Classical.choice, Quot.sound]`.

Example 5.5 (Affine and lattice examples). For the universal affine vertex algebra $V^k(\mathfrak{g})$ (Chapters 9 and 23), $V_1 = \mathfrak{g}$ and $x_{(0)}y = [x,y]$, so Theorem 5.4 returns $\mathfrak{g}$. For a lattice vertex algebra V_L with L even and positive definite, $V_1 = \mathfrak{h} \oplus \bigoplus_{\langle\alpha,\alpha\rangle=2} \mathbb{C}e^\alpha$, which is the simply-laced Lie algebra with root system $\{\alpha : \langle\alpha,\alpha\rangle = 2\}$ (Frenkel–Kac); for the Leech lattice there are no roots and $V_1 = \mathfrak{h}$ is abelian of dimension 24.

5.2.3 Primary vectors and the Griess product

Definition 5.6 (Primary subspace; Gannon (5.2.3)). $\mathcal{P}V_n := \{v \in V_n : L_k v = 0 \text{ for all } k \geq 1\}$.

File `VOA/Core/LieAlgebraV1.lean`.

```
def primaryV (W : VertexOperatorAlgebra 𝒱) (n : ℤ) : Submodule ℂ 𝒱 where
  carrier := {v | v ∈ W.grading n ∧ ∀ k : ℤ, 1 ≤ k → W.L k v = 0}
```

From the mathematics to the Lean statement

Exactly the textbook definition (the omitted fields are the proofs that it is a subspace). "Primary" (killed by all L_k, $k \geq 1$) is stronger than "quasi-primary" (killed by L_1), a notion used in Section 5.13.

Physical meaning

Primary states create primary fields: fields that transform under all conformal maps as tensors of weight n, $\phi(z) \mapsto (f'(z))^n \phi(f(z))$. They are the highest-weight vectors of the Virasoro algebra inside the chiral algebra.

What the machine verified

Definition; axiom-clean.

Definition 5.7 (Griess product). For $u, v \in V_2$, $u \times v := u_{(1)}v \in V_{2+2-1-1} = V_2$.

File `VOA/Core/LieAlgebraV1.lean`.

```
def griessMul (W : VertexOperatorAlgebra 𝒱) (u v : W.grading 2) : W.grading 2 :=
  ⟨W.smul (u : 𝒱) 1 (v : 𝒱), by
    have h := W.smul_mem_grading u.2 v.2 1
    rwa [show (2 : ℤ) + 2 - 1 - 1 = 2 by ring] at h⟩

theorem griessMul_comm_of_grading1_eq_bot (W : VertexOperatorAlgebra 𝒱)
    (h1 : W.grading 1 = ⊥) (u v : W.grading 2) :
    W.griessMul u v = W.griessMul v u := by
```

From the mathematics to the Lean statement

`h1 : W.grading 1 = ⊥` is $V_1 = 0$. The theorem says the Griess product is commutative when there are no currents. This is the correct hypothesis: in general skew-symmetry gives $u_{(1)}v = v_{(1)}u - T(v_{(2)}u) + \frac{1}{2}T^2(v_{(3)}u) - \cdots$ with $v_{(2)}u \in V_1$ and $v_{(3)}u \in V_0$, and only the V_1 term can survive, so without $V_1 = 0$ the product is only commutative modulo TV_1. Associativity is not claimed (the Griess algebra is not associative).

Physical meaning

On $V^\natural$, V_2 has dimension 196884 and the Griess product is the commutative non-associative algebra whose automorphism group is the Monster; it is the OPE coefficient $T^a(z)T^b(w) \supset \frac{(a\times b)(w)}{(z-w)^2}$ among the weight-two fields. Commutativity reflects the bosonic symmetry of the OPE of two weight-two fields once no weight-one field can appear.

Proof on paper. As just explained in the fidelity check, with $V_1 = 0$ killing the only correction term. □

What the machine verified

Unconditional given `h1`; axiom-clean.

Remark 5.8 (Three re-export files). `VOA/Core/V1LieAlgebra.lean`, `VOA/Core/InnerAutomorphism.lean` and `VOA/Core/CommutativeRing.lean` contain no declarations: each is a single `import` with a docstring explaining that its content was absorbed into `LieAlgebraV1`, `Automorphism` and `Commutativity` respectively. The last of these (the commutative ring structure on a commutative vertex algebra, Gannon Thm. 5.1.4) is documented in Chapter 4. Nothing in these three files needs refereeing.

5.3 Automorphisms and inner automorphisms

5.3.1 The automorphism group

Definition 5.9 (Automorphism; Gannon §5.2.1). An automorphism of V is a linear bijection $\alpha : V \to V$ with $\alpha(u_{(n)}v) = (\alpha u)_{(n)}(\alpha v)$ for all u, v, n, $\alpha\mathbf{1} = \mathbf{1}$ and $\alpha\omega = \omega$. Composition makes the automorphisms a group $\mathrm{Aut}(V)$.

File `VOA/Core/Automorphism.lean`.

```
structure Aut (W : VertexOperatorAlgebra 𝒱) where
  toLinearEquiv : 𝒱 ≃ₗ[ℂ] 𝒱
  map_smul' : ∀ (u : 𝒱) (n : ℤ) (v : 𝒱),
    toLinearEquiv (W.smul u n v) = W.smul (toLinearEquiv u) n (toLinearEquiv v)
  map_vacuum : toLinearEquiv W.vacuum = W.vacuum
  map_omega : toLinearEquiv W.conformalVector = W.conformalVector

instance : Group (Aut W) where
  mul := comp
  one := id W
  inv := inverse

@[simp] theorem mul_apply (α β : Aut W) (v : 𝒱) : (α * β) v = α (β v) := rfl
```

From the mathematics to the Lean statement

`𝒱 ≃ₗ[ℂ] 𝒱` is a linear bijection with its inverse. The group law is composition with $(\alpha\beta)v = \alpha(\beta v)$ (the `rfl` lemma `mul_apply`). Grading preservation is not an axiom but a theorem (`Aut.map_grading`, Theorem 5.10), because α commutes with $L_0 = \omega_{(1)}$. On paper the condition $\alpha\mathbf{1} = \mathbf{1}$ is even redundant: by CFT type and grading preservation $\alpha\mathbf{1} = \lambda\mathbf{1}$ with $\lambda \neq 0$, and applying α to $\mathbf{1}_{(-1)}\mathbf{1} = \mathbf{1}$ gives $\lambda^2 = \lambda$. The definition agrees with FLM and Lepowsky–Li. The file also proves `aut_comm_L`: $\alpha L_n = L_n \alpha$.

Physical meaning

A global (internal) symmetry of the chiral CFT: an invertible map of the space of states preserving the OPE, the vacuum and the stress tensor. Examples: the $\mathbb{Z}_2$ symmetry $\phi \mapsto -\phi$ of a free boson, the Weyl group and torus of an affine algebra, the Monster acting on $V^\natural$. Fixing ω means the symmetry commutes with conformal transformations.

What the machine verified

Definition and group structure; axiom-clean.

Theorem 5.10 (Automorphisms preserve the grading). *Let $\alpha \in \mathrm{Aut}(V)$. Then $\alpha(V_n) \subseteq V_n$ for every $n \in \mathbb{Z}$.*

File `VOA/Modularity/Twisted.lean`.

```
theorem Aut.map_grading (α : Aut W) {n : ℤ} {v : 𝒱} (hv : v ∈ W.grading n) :
    α v ∈ W.grading n
```

From the mathematics to the Lean statement

`Aut W` is the structure of Definition 5.9; `α v` is the application of its underlying linear equivalence (a coercion to a function); `W.grading n` is the weight space V_n of the VOA structure (Chapter 4), a `Submodule ℂ 𝒱`. **Hypotheses:** the vector v lies in V_n; the integer n is arbitrary. **Why this is a theorem and not an axiom.** The definition of `Aut` requires $\alpha(u_{(n)}v) = (\alpha u)_{(n)}\alpha v$, $\alpha\mathbf{1} = \mathbf{1}$, $\alpha\omega = \omega$, but *not* that α respects the grading. FLM and Lepowsky–Li define automorphisms as grading-preserving maps with $\alpha Y(u,z)\alpha^{-1} = Y(\alpha u, z)$ and $\alpha\omega = \omega$; the statement proved here shows that the library's (shorter) definition is equivalent to theirs, so nothing is lost. The same-or-stronger-or-weaker check: the conclusion is equivalent to $\alpha(V_n) \subseteq V_n$ for all n, hence, applying it to α^{-1}, to equality $\alpha(V_n) = V_n$. **Could the definition have been vacuous?** The identity is an automorphism, so $\mathrm{Aut}(V)$ is never empty and the theorem is never about an empty class; and V_n is the genuine n-eigenspace of $L_0 = \omega_{(1)}$, not a convention that might be changed by α.

Physical meaning

An automorphism is an internal symmetry of the chiral algebra, and it fixes the stress tensor. A symmetry that commutes with L_0 cannot mix operators of different scaling dimension: each space of operators of fixed conformal weight, V_n, is a representation of the symmetry group. For the $\mathbb{Z}_2$ symmetry $\phi \mapsto -\phi$ of a free boson it acts on the weight-h space by $(-1)^{\#\text{oscillators}}$; for the Monster it is the statement that $V^{\natural}{}_n$ is a finite-dimensional Monster representation for each n.

Proof on paper. Since α is an automorphism, $\alpha(\omega_{(1)}v) = (\alpha\omega)_{(1)}\alpha v = \omega_{(1)}\alpha v$, i.e. α commutes with $L_0 = \omega_{(1)}$. Now V_n is exactly the n-eigenspace of L_0: if $x = \sum_k x_k$ is the decomposition of a vector into homogeneous components and $L_0 x = nx$, then $\sum_k (k-n)x_k = 0$, and since the sum $\bigoplus_k V_k$ is direct, $(k-n)x_k = 0$ for each k, so $x = x_n$. Hence for $v \in V_n$ we have $L_0(\alpha v) = \alpha(L_0 v) = n\,\alpha v$, so $\alpha v \in V_n$. □

What the machine verified

Unconditional. `#print axioms VOA.Aut.map\_grading = [propext, Classical.choice, Quot.sound]` (run for this chapter with `lake env lean -DmaxSynthPendingDepth=3`). The PBW theorem `VOA.pbw` is not used.

5.3.2 Exponentials of locally nilpotent derivations

To exponentiate a current zero mode one must make sense of $e^D = \sum_k D^k/k!$ on an infinite-dimensional space without any topology. The library does this for *locally nilpotent* D: every vector is killed by some power of D, so the series is a finite sum on each vector.

Definition 5.11 (Local nilpotency, locally finite exponential). $D \in \mathrm{End}(V)$ is locally nilpotent if for every v there is N with $D^N v = 0$. Then $e^D v := \sum_{k<N} D^k v/k!$ for any such N (independent of the choice).

File `VOA/Core/Automorphism.lean`.

```
noncomputable def expSum (D : End ℂ 𝒱) (N : ℕ) (v : 𝒱) : 𝒱 :=
  ∑ k ∈ Finset.range N, ((k.factorial : ℂ)⁻¹) • ((D ^ k) v)

def IsLocNilp (D : End ℂ 𝒱) : Prop := ∀ v : 𝒱, ∃ N : ℕ, (D ^ N) v = 0

noncomputable def expFun {D : End ℂ 𝒱} (hD : IsLocNilp D) (v : 𝒱) : 𝒱 :=
  expSum D (locNilpIdx hD v) v

noncomputable def expEquiv {D : End ℂ 𝒱} (hD : IsLocNilp D) : 𝒱 ≃ₗ[ℂ] 𝒱 where
  toLinearMap := expLN hD
  invFun := expLN hD.neg
```

From the mathematics to the Lean statement

`locNilpIdx hD v` is an index N chosen (by the axiom of choice) with $D^N v = 0$; `expSum_indep` proves that any two such indices give the same partial sum, so `expFun` does not depend on the choice. `expLN` packages `expFun` as a linear map, and `expEquiv` is the linear bijection with inverse e^{-D} (`hD.neg` is local nilpotency of $-D$; the inverse property is the convolution identity `expSum_conv`, the finite form of $e^D e^{-D} = 1$). This is the standard algebraic exponential (it is the device used for integrable representations in Kac's *Infinite-dimensional Lie algebras*).

Physical meaning

The finite exponential of a nilpotent charge is a *unipotent* symmetry, like e^{tE} for a raising operator E of $\mathfrak{sl}_2$ acting in a finite-dimensional representation. Each energy level of a CFT is finite-dimensional and the charge preserves it, which is why local nilpotency is the natural algebraic condition.

What the machine verified

Definitions; the linear equivalence is axiom-clean.

Theorem 5.12 (The exponential of a derivation is a homomorphism). *If D is locally nilpotent and $D(a_{(n)}b) = (Da)_{(n)}b + a_{(n)}(Db)$ for all a, b, then $e^D(a_{(n)}b) = (e^D a)_{(n)}(e^D b)$.*

File `VOA/Core/Automorphism.lean`.

```
theorem expFun_smul {W : VertexOperatorAlgebra 𝒱} {D : End ℂ 𝒱} (hD : IsLocNilp D) (n : ℤ)
    (hleib : ∀ a b : 𝒱, D (W.smul a n b) = W.smul (D a) n b + W.smul a n (D b))
    (a b : 𝒱) :
    expFun hD (W.smul a n b) = W.smul (expFun hD a) n (expFun hD b) := by
```

From the mathematics to the Lean statement

The Leibniz hypothesis `hleib` is for the fixed n only, and the conclusion is for that n: the statement is per product, which is slightly sharper than needed.

Physical meaning

A charge that acts as a derivation on all OPEs exponentiates to a finite symmetry that preserves all OPEs: the passage from the Lie algebra of conserved charges to the symmetry group.

Proof on paper. By induction, $D^k(a_{(n)}b) = \sum_i \binom{k}{i}(D^i a)_{(n)}(D^{k-i}b)$ (`iter_leibniz`); dividing by $k!$ and summing over k up to $2N$, where $D^N a = D^N b = 0$, the Cauchy product gives $\sum_{i,j<N} \frac{1}{i!\,j!}(D^i a)_{(n)}(D^j b) = (e^D a)_{(n)}(e^D b)$. □

What the machine verified

Unconditional given its hypotheses; axiom-clean.

5.3.3 Inner automorphisms

Definition 5.13 (Inner automorphism; Gannon (5.2.4)). For $u \in V_1$ with $u_{(0)}$ locally nilpotent and $u_{(0)}\omega = 0$, the automorphism $\exp(u_{(0)})$.

File `VOA/Core/Automorphism.lean`.

```
def IsExpInner (u : W.grading 1) (α : Aut W) : Prop :=
  ∀ v : 𝒱, ∃ N : ℕ, α v = ∑ k ∈ Finset.range N,
    ((k.factorial : ℂ)⁻¹) • ((W.zeroMode (u : 𝒱) 1 ^ k) v)

noncomputable def inner (u : W.grading 1)
    (hnilp : VOA.IsLocNilp (W.zeroMode (u : 𝒱) 1))
    (homega : W.zeroMode (u : 𝒱) 1 W.conformalVector = 0) : Aut W where
  toLinearEquiv := VOA.expEquiv hnilp

theorem inner_isExpInner (u : W.grading 1)
```

```
    (hnilp : VOA.IsLocNilp (W.zeroMode (u : 𝒱) 1))
    (homega : W.zeroMode (u : 𝒱) 1 W.conformalVector = 0) :
    IsExpInner u (inner u hnilp homega) := by

def innerSet (W : VertexOperatorAlgebra 𝒱) : Set (Aut W) :=
  {α | ∃ u : W.grading 1, IsExpInner u α}

def Inn (W : VertexOperatorAlgebra 𝒱) : Subgroup (Aut W) :=
  Subgroup.normalClosure (innerSet W)

instance Inn_normal (W : VertexOperatorAlgebra 𝒱) : (Inn W).Normal :=
  Subgroup.normalClosure_normal
```

From the mathematics to the Lean statement

`inner u hnilp homega` is the automorphism whose underlying linear map is `expEquiv` of $D = u_{(0)}$; its omitted fields prove that it fixes $\mathbf{1}$ (since $u_{(0)}\mathbf{1} = 0$ by creation), fixes ω (by `homega`), and intertwines all products (Theorem 5.12 with Leibniz from Theorem 5.2). This construction is faithful to the literature.
`IsExpInner u α` is an interface predicate: *for each v there is some N* such that αv equals the N-th partial sum of the exponential series of $u_{(0)}$ on v. When $u_{(0)}$ is locally nilpotent and N is large, the partial sums stabilise at $e^{u_{(0)}}v$; but the predicate does not require N to be large. See the warning on p. 214. `Subgroup.normalClosure S` is the smallest normal subgroup containing the set S.

Physical meaning

Inner automorphisms are the symmetries generated by the currents themselves: $e^{\theta J_0}$ for a charge J_0. Physically, the continuous symmetry group G whose Lie algebra is V_1; its subgroup generated by such exponentials is normal because conjugating the symmetry generated by a current J by any symmetry g gives the symmetry generated by the current gJ.

What the machine verified

Definitions; `#print axioms` on `inner` and `Inn_normal`: `[propext, Classical.choice, Quot.sound]`. The construction `inner` is used downstream in `VOA/Moonshine/TrialityRoot.lean`.

Theorem 5.14 (Conjugation of inner automorphisms; Gannon (5.2.4)). *If β is the exponential of $u_{(0)}$ and $\alpha \in \mathrm{Aut}(V)$, then $\alpha\beta\alpha^{-1}$ is the exponential of $(\alpha u)_{(0)}$. Moreover $u_{(0)}$ locally nilpotent implies $(\alpha u)_{(0)}$ locally nilpotent, and $\alpha(e^{u_{(0)}}v) = e^{(\alpha u)_{(0)}}(\alpha v)$.*

Files: `isExpInner_conj` is in `VOA/Modularity/Twisted.lean`; `aut_conj_expFun` is in `VOA/Core/Automorphism.lean`.

```
theorem VertexOperatorAlgebra.isExpInner_conj {u : W.grading 1} {β : Aut W}
    (hβ : VertexOperatorAlgebra.IsExpInner u β) (α : Aut W) :
    VertexOperatorAlgebra.IsExpInner (⟨α (u : 𝒱), α.map_grading u.2⟩ : W.grading 1)
      (α * β * α⁻¹) := by

theorem aut_conj_expFun (α : Aut W) (u : 𝒱)
    (hnilp : VOA.IsLocNilp (W.zeroMode u 1)) (v : 𝒱) :
    α (VOA.expFun hnilp v) = VOA.expFun (isLocNilp_aut α u hnilp) (α v) := by
```

From the mathematics to the Lean statement

The conjugation statement now lives in `VOA/Modularity/Twisted.lean` under the full name `VertexOperatorAlgebra.isExpInner_conj`. An earlier version (in `Automorphism.lean`) carried a hypothesis `hαu : α u ∈ W.grading 1`, needed only to form the element of `W.grading 1`; this book flagged it as redundant (it always holds by `Aut.map_grading`), and the current statement builds the element directly as `⟨α u, α.map_grading u.2⟩`, with no hypothesis. `aut_conj_expFun` is the genuine conjugation formula $\alpha e^{u_{(0)}}\alpha^{-1} = e^{(\alpha u)_{(0)}}$ for locally nilpotent zero modes; `isExpInner_conj` is the same statement at the level of the interface predicate.

Physical meaning

Conjugating the symmetry generated by the charge of J by a global symmetry g gives the symmetry generated by the charge of gJ. This is the statement that the inner symmetries form a normal subgroup: the quotient Aut /Inn is the group of "outer" (discrete) symmetries, like the diagram automorphisms of an affine algebra or the Monster for $V^\natural$ (where Inn is trivial).

Proof on paper. $\alpha(u_{(0)}v) = (\alpha u)_{(0)}(\alpha v)$, hence $\alpha u^k_{(0)} = (\alpha u)^k_{(0)}\alpha$; apply α to the finite exponential sum. Local nilpotency transfers because $(\alpha u)^k_{(0)} = \alpha u^k_{(0)}\alpha^{-1}$. □

What the machine verified

Unconditional; axiom-clean.

Trap / dead end: What the normality of `Inn` does and does not say

(a) Normality is by construction. `Inn W` is *defined* as the normal closure of `innerSet W`, so `Inn_normal` is Mathlib's `Subgroup.normalClosure_normal`: it holds for the normal closure of any set whatsoever. The mathematical content of "Inn ⊴ Aut" — that the subgroup *generated* by the inner automorphisms is already normal — is `isExpInner_conj`, which shows that `innerSet` is stable under conjugation (so that its normal closure equals the subgroup it generates). The source says exactly this. A referee should read the headline "`Inn` is normal" as resting on `isExpInner_conj`, not on `Inn_normal`.

(b) `IsExpInner` is weak. Taking $N = 1$ in its definition gives the partial sum v; so *the identity automorphism satisfies* `IsExpInner u 1` *for every current* u, whether or not $u_{(0)}$ is locally nilpotent. We checked this in Lean for this book (scratch file, not part of the library):

```
example (u : W.grading 1) : IsExpInner u (1 : Aut W) := fun v => ⟨1, by simp⟩
```

This is harmless for the identity (which is inner anyway), but it shows that `innerSet` is defined by a property weaker than "$\alpha = e^{u_{(0)}}$": an automorphism α belongs to it as soon as, for some u, each αv is *some* partial sum of the exponential series of v. Whether `innerSet` can contain automorphisms that are not exponentials of locally nilpotent current zero modes has not been examined by the library. The safe reading is: the automorphisms `inner u hnilp homega` are genuine inner automorphisms (`inner_mem_Inn`) and are in `Inn W`; nothing in this chapter proves that `Inn W` consists only of products of such.

(c) Not every current exponentiates this way. `inner` needs $u_{(0)}$ locally nilpotent. Root currents e^α of a lattice vertex algebra qualify (in a fixed weight space only finitely many charges $\beta + k\alpha$ occur), but Cartan currents h do not: $h_{(0)}e^\beta = \langle h, \beta\rangle e^\beta$ is diagonal. The torus $\exp(\mathfrak{h})$ acts by automorphisms, but they are not constructed by this file.

Remark 5.15 (The hypothesis `homega` is redundant). For $u \in V_1$ in a vertex operator algebra of CFT type, $u_{(0)}\omega = 0$ automatically: skew-symmetry gives $u_{(0)}\omega = -L_{-1}u + T(L_0u) - \frac{1}{2}T^2(L_1u) + \cdots =$

$-Tu + Tu - \frac{1}{2}T^2(c\mathbf{1}) = 0$, since $L_1 u \in V_0 = \mathbb{C}\mathbf{1}$ and $T\mathbf{1} = 0$, and higher terms vanish by weight. The library proves this as `Screening.screening_conformalVector` (Section 5.7), but `inner` still asks for it. We checked in Lean that it is discharged in one line:

```
example (u : W.grading 1) : W.zeroMode (u : V) 1 W.conformalVector = 0 := by
  rw [← Screening.screening_eq_zeroMode]; exact Screening.screening_conformalVector W u.2
```

So `inner` is in effect conditional only on local nilpotency.

5.4 Ideals, quotients and the simple quotient

5.4.1 Ideals and simplicity

Definition 5.16 (Ideal, simple VOA)**.** An ideal of V is a subspace I with $u_{(n)}v \in I$ for all $u \in V$, $v \in I$, $n \in \mathbb{Z}$. V is simple if $V \neq 0$ and its only ideals are 0 and V.

File `VOA/Core/BilinearForm.lean`.

```
def IsIdeal (W : VertexOperatorAlgebra V) (I : Submodule ℂ V) : Prop :=
  ∀ (u v : V) (n : ℤ), v ∈ I → W.smul u n v ∈ I

def IsSimple (W : VertexOperatorAlgebra V) : Prop :=
  (⊤ : Submodule ℂ V) ≠ ⊥ ∧ ∀ I : Submodule ℂ V, W.IsIdeal I → I = ⊥ ∨ I = ⊤
```

From the mathematics to the Lean statement

One-sided by definition. `IsIdeal` asks only $u_{(n)}I \subseteq I$ (I in the *right* slot of the product; equivalently, I is a submodule of the adjoint module, a "left ideal"). The literature (FLM, Lepowsky–Li Def. 3.9.7, FHL) defines an ideal as a subspace with $u_{(n)}I \subseteq I$ *and* $I_{(n)}u \subseteq I$; Lepowsky–Li observe that for an L_{-1}-stable subspace either condition implies the other by skew-symmetry. The library proves this (Theorem 5.17), so `IsIdeal` is the textbook notion and `IsSimple` is the textbook simplicity, not a weaker or stronger variant. (Chapter 38 raised the question whether `IsSimple` is quantified over left ideals only: it is, and by Theorem 5.17 this is the same class of subspaces.)
Not graded by definition. No gradedness is asked; it is automatic (Theorem 5.18).
Nonzero. `(⊤ : Submodule ℂ V) ≠ ⊥` is $V \neq 0$, which excludes the zero algebra (which has only the ideal $0 = V$). For a vertex operator algebra this is equivalent to $\mathbf{1} \neq 0$ (`IsSimple.vacuum_ne_zero` in `VOA/Core/SimpleImage.lean`), since every $u = u_{(-1)}\mathbf{1}$.
A deprecated duplicate `IsSimple` exists in `VOA/Modules/Rationality.lean` (Chapter 12); every statement of this chapter uses the one above.

Physical meaning

An ideal is a set of states closed under the action of every field: once such states appear they can only produce more of themselves, so they form a sector that decouples from correlation functions with the vacuum. A simple chiral algebra has no such sector: the vacuum module is irreducible and all states are "physical". Quotienting by an ideal is setting null states to zero.

What the machine verified

Definitions.

Theorem 5.17 (Ideals are two-sided)**.** *If I is an ideal, then $u_{(n)}v \in I$ for all $u \in I$, $v \in V$, $n \in \mathbb{Z}$.*

File `VOA/Core/QuotientVOA.lean`.

```
def AbsorbsLeft (W : VertexOperatorAlgebra 𝒱) (I : Submodule ℂ 𝒱) : Prop :=
  ∀ (u v : 𝒱) (n : ℤ), u ∈ I → W.smul u n v ∈ I

theorem absorbsLeft_of_isIdeal (hI : W.IsIdeal I) : AbsorbsLeft W I := by
```

From the mathematics to the Lean statement

`AbsorbsLeft` is the other half of the two-sided condition; the theorem says `IsIdeal` implies it, unconditionally.

Physical meaning

Locality: the OPE $u(z)v(w)$ and $v(w)u(z)$ are the same function, so if the states of I are closed under being acted on by fields, they are also closed when they act on other states. This is the chiral form of the statement that an operator ideal of a local quantum field theory is automatically two-sided.

Proof on paper. An ideal is stable under $T = L_{-1} = \omega_{(0)}$, hence under all T^j. Skew-symmetry gives $u_{(n)}v = \sum_{j\geq 0} \frac{(-1)^{n+j+1}}{j!} T^j(v_{(n+j)}u)$, a finite sum of elements $T^j(v_{(n+j)}u)$ with $u \in I$ in the right slot, all in I. □

What the machine verified

Unconditional; axiom-clean.

Theorem 5.18 (Ideals are graded). *Every ideal I satisfies $I = \bigoplus_n (I \cap V_n)$.*

File `VOA/Core/QuotientVOA.lean`.

```
def IsGradedIdeal (W : VertexOperatorAlgebra 𝒱) (I : Submodule ℂ 𝒱) : Prop :=
  I = ⨆ n : ℤ, I ⊓ W.grading n

theorem isGradedIdeal_of_isIdeal (hI : W.IsIdeal I) : IsGradedIdeal W I := by
```

From the mathematics to the Lean statement

`⨆ n, I ⊓ W.grading n` is the sum of the homogeneous pieces $I \cap V_n$; since the V_n are independent this sum is direct, so the equation is "I is graded". Despite its name, `IsGradedIdeal` does not include `IsIdeal`; it is a property of subspaces.

Physical meaning

An ideal is stable under L_0, the Hamiltonian; a subspace stable under a diagonalisable Hamiltonian is spanned by energy eigenstates. Null states can always be taken of definite energy.

Proof on paper. $L_0 = \omega_{(1)}$ maps I into I and acts on V_n by n. If $x = \sum_{n\in S} x_n \in I$ with S finite, then $(L_0 - k)x = \sum_{n\neq k}(n-k)x_n \in I$ for $k \in S$; by induction on $|S|$ every $x_n \in I$. □

What the machine verified

Unconditional; axiom-clean.

5.4.2 The quotient vertex operator algebra

Definition 5.19 (Quotient VOA). For an ideal I, V/I with $Y([u],z)[v] = [Y(u,z)v]$, vacuum $[\mathbf{1}]$, conformal vector $[\omega]$, central charge c and grading $(V/I)_n =$ image of V_n.

File `VOA/Core/QuotientVOA.lean`.

```
def quotientVOA (W : VertexOperatorAlgebra 𝒱) (I : Submodule ℂ 𝒱)
    (hI : W.IsIdeal I) (hgr : IsGradedIdeal W I) : VertexOperatorAlgebra (𝒱 / I) where
  grading n := (W.grading n).map I.mkQ
  isInternal := isInternal_map W I hgr
  finrank n := finiteDimensional_map W I n
  Y := Yq hI
  vacuum := I.mkQ W.vacuum

theorem quotientVOA_mkQ_smul (hI : W.IsIdeal I) (hgr : IsGradedIdeal W I)
    (u : 𝒱) (n : ℤ) (v : 𝒱) :
    (quotientVOA W I hI hgr).smul (I.mkQ u) n (I.mkQ v) = I.mkQ (W.smul u n v) :=

def quotientVOA' (W : VertexOperatorAlgebra 𝒱) (I : Submodule ℂ 𝒱) (hI : W.IsIdeal I) :
    VertexOperatorAlgebra (𝒱 / I) :=
  quotientVOA W I hI (isGradedIdeal_of_isIdeal hI)
```

From the mathematics to the Lean statement

`Yq hI` is the induced vertex operator: on classes, `quotientVOA_mkQ_smul` says $[u]_{(n)}[v] = [u_{(n)}v]$, which is the defining property. Well-definedness in the left slot uses Theorem 5.17. The omitted fields (conformal vector, central charge, the axioms) are the images of those of V, and `quotientVOA_centralCharge` records that c is unchanged.

Which hypothesis is used where. `hgr` is used only for `isInternal` (the image grading is a direct sum only if I is graded) and is automatic (`quotientVOA'`). *Properness ($\mathbf{1} \notin I$) is not assumed*: for $I = V$ the quotient is the zero space, which satisfies all axioms. So a theorem that concludes "`quotientVOA W I` … is a VOA" says nothing about nontriviality; nontriviality has to be proved separately (as in Theorem 5.21).

Physical meaning

The quotient is the chiral algebra in which the states of I are declared null and set to zero. The central charge is unchanged because the stress tensor is the image of the old one; the OPE of two surviving fields is the old OPE with the null part discarded.

What the machine verified

Definition; `#print axioms` on `quotientVOA`: `[propext, Classical.choice, Quot.sound]`.

5.4.3 The maximal ideal

Definition 5.20 (Maximal proper graded ideal). $\mathfrak{m}(V) :=$ the sum of all graded ideals not containing $\mathbf{1}$; $L(V) := V/\mathfrak{m}(V)$.

File `VOA/Core/QuotientVOA.lean`.

```
def ProperGradedIdeals (W : VertexOperatorAlgebra 𝒱) : Set (Submodule ℂ 𝒱) :=
  {I | W.IsIdeal I ∧ IsGradedIdeal W I ∧ W.vacuum ∉ I}

def maxGradedIdeal (W : VertexOperatorAlgebra 𝒱) : Submodule ℂ 𝒱 :=
  sSup (ProperGradedIdeals W)

def maxQuotientVOA (W : VertexOperatorAlgebra 𝒱) :
    VertexOperatorAlgebra (𝒱 / maxGradedIdeal W) :=
  quotientVOA W (maxGradedIdeal W) (maxGradedIdeal_isIdeal W) (maxGradedIdeal_isGradedIdeal
    ↪ W)
```

From the mathematics to the Lean statement

"Proper" is encoded as $\mathbf{1} \notin I$, which for an ideal is equivalent to $I \neq V$ (`eq_top_of_vacuum_mem`: an ideal containing $\mathbf{1}$ contains every $u = u_{(-1)}\mathbf{1}$). `sSup` of the set is the sum of all its members. Since every ideal is graded, "graded" is redundant in `ProperGradedIdeals`, so $\mathfrak{m}(V)$ is the sum of *all* proper ideals (`le_maxGradedIdeal'`). The literature's "unique maximal proper ideal" of a VOA of CFT type is this object.

Physical meaning

$\mathfrak{m}(V)$ is the space of *all* null states of the theory — everything that can be consistently set to zero — and $L(V)$ is the physical chiral algebra. For the Virasoro vacuum module at $c = c_{p,q}$ this passage gives the minimal model $L(c_{p,q}, 0)$; for $V^k(\mathfrak{g})$ at admissible level it gives $L_k(\mathfrak{g})$.

What the machine verified

Definitions.

Theorem 5.21 (The maximal ideal is proper, the quotient is simple). *If $\mathbf{1} \neq 0$: (i) $\mathbf{1} \notin \mathfrak{m}(V)$; (ii) every ideal J with $\mathbf{1} \notin J$ lies in $\mathfrak{m}(V)$; (iii) $L(V) = V/\mathfrak{m}(V)$ is simple.*

File `VOA/Core/QuotientVOA.lean`.

```
theorem vacuum_not_mem_maxGradedIdeal (W : VertexOperatorAlgebra 𝒱) (hvac : W.vacuum ≠ 0) :
    W.vacuum ∉ maxGradedIdeal W := by

theorem le_maxGradedIdeal' {J : Submodule ℂ 𝒱} (hJ : W.IsIdeal J) (hv : W.vacuum ∉ J) :
    J ≤ maxGradedIdeal W :=

theorem isSimple_maxQuotientVOA (W : VertexOperatorAlgebra 𝒱) (hvac : W.vacuum ≠ 0)
    (hgraded : ∀ J : Submodule ℂ (𝒱 ⧸ maxGradedIdeal W), (maxQuotientVOA W).IsIdeal J →
      IsGradedIdeal W (J.comap (maxGradedIdeal W).mkQ)) :
    (maxQuotientVOA W).IsSimple := by

theorem isSimple_maxQuotientVOA' (W : VertexOperatorAlgebra 𝒱) (hvac : W.vacuum ≠ 0) :
    (maxQuotientVOA W).IsSimple := by
```

From the mathematics to the Lean statement

`hvac : W.vacuum ≠ 0` is the only hypothesis of the unconditional form `isSimple_maxQuotientVOA'`; it is necessary, since for $\mathbf{1} = 0$ the algebra is zero and so is its quotient, which is not simple. The primed theorem is the unprimed one with `hgraded` discharged by Theorem 5.18; the unprimed form is a historical artefact whose docstring still says the gradedness fact is "not proved in this repo" — that sentence is outdated, the fact is `isGradedIdeal_of_isIdeal`.

Why properness of the sum is not trivial. A sum of proper ideals need not be proper in a general algebra. Here it is, because every proper graded ideal meets $V_0 = \mathbb{C}\mathbf{1}$ in 0 and so lies in $\bigoplus_{n\neq 0} V_n$, and a sum of subspaces of $\bigoplus_{n\neq 0} V_n$ stays there. This is where CFT type ($V_0 = \mathbb{C}\mathbf{1}$) is essential.

Could the conclusion be vacuous? `IsSimple` contains $V/\mathfrak{m} \neq 0$, which is (i). It is the honest statement.

Physical meaning

Removing all null states from the vacuum module leaves an irreducible chiral algebra: a unique vacuum, no further decoupled sector. The vacuum itself is never null because it has

weight 0 and the theory has a unique weight-zero state.

Proof on paper. (i), (ii): as in the fidelity check. (iii): an ideal $\bar{J}$ of the quotient pulls back to an ideal $J \supseteq \mathfrak{m}$ of V; if $\mathbf{1} \notin J$ then $J \subseteq \mathfrak{m}$ by (ii), so $\bar{J} = 0$; if $\mathbf{1} \in J$ then $J = V$ and $\bar{J}$ is everything. □

What the machine verified

Unconditional (given $\mathbf{1} \neq 0$); `#print axioms` on `isSimple_maxQuotientVOA'` and `vacuum_not_mem_maxGradedIdeal`: `[propext, Classical.choice, Quot.sound]`.

5.5 Homomorphisms and the transfer lemma

Definition 5.22 (Homomorphism). A linear map $\varphi : V \to T$ between VOAs is a homomorphism if $\varphi \mathbf{1}_V = \mathbf{1}_T$ and $\varphi(u_{(n)}v) = (\varphi u)_{(n)}(\varphi v)$ for all u, v, n.

File `VOA/Core/SimpleImage.lean`.

```
structure IsVOAHom (V : VertexOperatorAlgebra 𝒱) (T : VertexOperatorAlgebra 𝒲)
    (φ : 𝒱 →ₗ[ℂ] 𝒲) : Prop where
  map_vacuum : φ V.vacuum = T.vacuum
  map_smul : ∀ (u : 𝒱) (n : ℤ) (v : 𝒱), φ (V.smul u n v) = T.smul (φ u) n (φ v)

theorem isIdeal_ker (hφ : IsVOAHom V T φ) : V.IsIdeal (LinearMap.ker φ) := by
```

From the mathematics to the Lean statement

A property of a linear map (`Prop`-valued structure). It does *not* require $\varphi\omega_V = \omega_T$ nor preservation of the grading: these are vertex-algebra homomorphisms (Kac's notion), not VOA homomorphisms in the sense of FLM. The deviation is deliberate (for a Sugawara vector landing in a free-field target the conformal vectors differ) and is the *weaker* hypothesis, so theorems assuming `IsVOAHom` are *stronger* than their VOA-homomorphism versions. `IsVOAHom.map_L` adds $\varphi\omega_V = \omega_T$ when needed.

Physical meaning

A map of chiral algebras preserving all OPEs and the vacuum: a realisation of one chiral algebra inside another, as in a free-field (Wakimoto, Feigin–Fuchs) realisation or a conformal embedding. The stress tensors may differ (as for a coset or an improved stress tensor), which is why ω is not required to map to ω.

What the machine verified

Definition; `isIdeal_ker` unconditional, axiom-clean.

Theorem 5.23 (Transfer lemma). *Let $\varphi : V \to T$ be a surjective homomorphism onto a simple VOA T. Then* $\ker\varphi = \mathfrak{m}(V)$*, so φ induces an isomorphism $L(V) \cong T$, and φ kills every vector of every proper ideal of V.*

File `VOA/Core/SimpleImage.lean`.

```
theorem ker_eq_maxGradedIdeal (hφ : IsVOAHom V T φ) (hsurj : Function.Surjective φ)
    (hsimple : T.IsSimple) : LinearMap.ker φ = QuotVOA.maxGradedIdeal V :=

theorem apply_eq_zero_of_mem_properIdeal (hφ : IsVOAHom V T φ)
    (hsurj : Function.Surjective φ) (hsimple : T.IsSimple)
```

```
    {J : Submodule ℂ 𝒱} (hJ : V.IsIdeal J) (hJv : V.vacuum ∉ J)
    {x : 𝒱} (hx : x ∈ J) : φ x = 0 :=

noncomputable def maxQuotientEquiv (hφ : IsVOAHom V T φ) (hsurj : Function.Surjective φ)
    (hsimple : T.IsSimple) : (𝒱 ⧸ QuotVOA.maxGradedIdeal V) ≃ₗ[ℂ] 𝒲 :=
```

From the mathematics to the Lean statement

Hypotheses: φ a homomorphism (Definition 5.22), surjective, T simple. No properness or "$\varphi \neq 0$" hypothesis is needed: simplicity of T gives $\mathbf{1}_T \neq 0$, hence $\mathbf{1}_V \neq 0$ and $\mathbf{1}_V \notin \ker\varphi$. The isomorphism `maxQuotientEquiv` is a linear isomorphism; `isVOAHom_maxQuotientHom` shows the underlying map is a homomorphism from `maxQuotientVOA V`. Two non-vacuity witnesses in the same file (`maxGradedIdeal_eq_bot_of_isSimple`, from $\varphi = \mathrm{id}$, and `ker_mkQ_max_eq_maxGradedIdeal`, from φ the projection) re-derive known facts through the lemma, which would fail if an inclusion had been stated backwards.

Physical meaning

If a chiral algebra is realised inside another and the image is irreducible, then the realisation kills exactly the null states: every null vector (for instance the Malikov–Feigin–Fuchs singular vector of an affine algebra at admissible level) vanishes automatically in the realisation, without computing it. This is how free-field realisations identify simple quotients.

Proof on paper. $\ker\varphi$ is an ideal not containing $\mathbf{1}$, so $\ker\varphi \subseteq \mathfrak{m}(V)$. Conversely $\varphi(\mathfrak{m}(V))$ is an ideal of T (by surjectivity) not containing $\mathbf{1}_T$ (if $\mathbf{1}_T = \varphi(m)$ with $m \in \mathfrak{m}$, then $\mathbf{1} - m \in \ker\varphi \subseteq \mathfrak{m}$, so $\mathbf{1} \in \mathfrak{m}$, contradiction), hence 0 by simplicity. □

What the machine verified

Unconditional given its hypotheses; `#print axioms` on `ker_eq_maxGradedIdeal`, `apply_eq_zero_of_mem_properIdeal`, `maxQuotientEquiv`: `[propext, Classical.choice, Quot.sound]`.

5.6 Subalgebras generated by a set

We use the structure `VOASubalgebra W` (Definition 5.24 below): a subspace containing $\mathbf{1}$ and ω, closed under all products and under the projections `piHom W n`; `VOASubalgebra.toVOA` makes it a VOA with the same central charge.

Definition 5.24 (Vertex operator subalgebra). A *vertex operator subalgebra* of a VOA V is a linear subspace $S \subseteq V$ containing $\mathbf{1}$ and ω, closed under all products $u_{(n)}v$ ($u, v \in S$, $n \in \mathbb{Z}$), and *graded*: $S = \bigoplus_n (S \cap V_n)$, equivalently every homogeneous component of every element of S lies in S.

File `VOA/Modularity/Twisted.lean`.

```
structure VOASubalgebra (W : VertexOperatorAlgebra 𝒱) where
  carrier : Submodule ℂ 𝒱
  vacuum_mem : W.vacuum ∈ carrier
  conformal_mem : W.conformalVector ∈ carrier
  smul_mem : ∀ u ∈ carrier, ∀ (n : ℤ), ∀ v ∈ carrier, W.smul u n v ∈ carrier
  graded : ∀ (n : ℤ), ∀ v ∈ carrier, piHom W n v ∈ carrier
```

(`piHom W n` is the projection $V \to V_n$ along the direct sum decomposition, `VOA/Modules/FiniteGenerationProof.lean`.)

From the mathematics to the Lean statement

`carrier : Submodule ℂ V` is the subspace S; `smul_mem` is closure under all integer products (closure under all $u_{(n)}$, $n \in \mathbb{Z}$, is the full closure under the vertex operators); `graded` says that the projection onto each V_n keeps one inside S, which is the same as $S = \bigoplus(S \cap V_n)$. **Containing ω is part of the definition:** these are subalgebras *with the same conformal vector* ("full" subalgebras), as is needed for orbifolds and for generated subalgebras (Definition 5.26); the commutant or coset subalgebras, which carry a different conformal vector, are not of this kind. The notion is not vacuous: $S = V$ is one example, every generated subalgebra (Definition 5.26) is another, and the fixed points of a group of automorphisms are a third (the orbifold, treated with the Moonshine construction).

Physical meaning

A vertex operator subalgebra is a set of local operators closed under the operator product expansion and containing the same vacuum and the same stress tensor: a sub-chiral algebra of the same theory. Examples are the subalgebra generated by a subset of the currents together with T, and the fixed-point algebra of an orbifold. Read in the reverse direction the large algebra is an extension of the small one, as a lattice VOA is an extension of the one attached to a sublattice.

What the machine verified

Definition. Axiom-clean (`#print axioms VOA.VOASubalgebra = [propext, Classical.choice, Quot.sound]`).

Theorem 5.25 (A subalgebra is a VOA). *A vertex operator subalgebra $S \subseteq V$, with the restricted grading $S_n = S \cap V_n$, the restricted vertex operator $Y_S(u,z) = Y(u,z)|_S$, the same vacuum* $\mathbf{1}$*, the same conformal vector ω and the same central charge, is a vertex operator algebra.*

File `VOA/Modularity/Twisted.lean`.

```
noncomputable def toVOA : VertexOperatorAlgebra S.carrier where
  grading := S.gradingS
  isInternal := S.gradingS_isInternal
  finrank := S.gradingS_finrank
  Y := S.YS
  vacuum := ⟨W.vacuum, S.vacuum_mem⟩

theorem toVOA_centralCharge : S.toVOA.centralCharge = W.centralCharge
```

(The remaining fields of `toVOA` are proofs of the axioms and are omitted; `S.gradingS n` is $S \cap V_n$ regarded as a subspace of S, and `S.YS u` is the restriction of $Y(u,z)$ to S, both in the same file.)

From the mathematics to the Lean statement

The new VOA lives on the *type* `S.carrier`, the subspace regarded as a vector space in its own right (printed `↥S.carrier` in some contexts), so the vacuum has to be given as a pair `⟨W.vacuum, S.vacuum_mem⟩` (an element together with the proof that it lies in S). `toVOA` is a *definition* producing a VOA, not a statement; its fidelity rests on its data being the restricted ones, which is visible in the displayed lines: grading $S \cap V_n$, vertex operator $Y|_S$, vacuum $\mathbf{1}$. (Among the omitted fields, the conformal vector is `⟨W.conformalVector, S.conformal_mem⟩` and the central charge is `W.centralCharge`.) `toVOA_centralCharge` proves that the central charge is unchanged; its proof is `rfl`, because the definition sets it so. **Hypotheses:** none besides S being a `VOASubalgebra`; in particular the finite-dimensionality and positivity of the graded pieces must come from V, and do. **Could the construction be vacuous or**

cheating? The structure `VertexOperatorAlgebra` has all the axioms of Definition 4.4; they are discharged field by field in the source (not assumed). In particular, CFT type holds because $S_0 \subseteq V_0 = \mathbb{C}\mathbf{1} \subseteq S$.

Physical meaning

A subalgebra that carries the same stress tensor is itself a chiral algebra with the same central charge: the operator product expansion of the sub-chiral algebra closes, the same $T(z)$ generates its conformal transformations, so the conformal anomaly c (Casimir energy $-c/24$ on the cylinder) is the same. This is how one passes from a CFT to a sub-CFT: the weights stay the same because the spectrum of L_0 on S is the restriction of the one on V, so the discrete, finite-degeneracy spectrum is inherited.

Proof on paper. Every axiom is inherited. The grading $S = \bigoplus_n (S \cap V_n)$ is direct and has finite-dimensional pieces because $S \cap V_n \subseteq V_n$ and V_n is finite-dimensional, and $S \cap V_n = 0$ for $n < 0$; `graded` gives that the sum is all of S. The operators $Y(u,z)$, $u \in S$, preserve S because S is closed under all products. Vacuum axiom, creation, regularity, locality and the Jacobi/Borcherds relations are identities between operators on V, so they hold for the restrictions; the Virasoro relations hold because $\omega \in S$ and the modes $L_n = \omega_{(n+1)}$ restrict; L_0 acts on $S \cap V_n$ by n; translation $Y(L_{-1}v, z) = \partial_z Y(v,z)$ restricts; and CFT type holds because $S_0 \subseteq V_0 = \mathbb{C}\mathbf{1}$ contains $\mathbf{1}$. □

What the machine verified

Unconditional. `#print axioms` of `VOA.VOASubalgebra.toVOA` and `VOA.VOASubalgebra.toVOA\_centralCharge` are each `[propext, Classical.choice, Quot.sound]` (run for this chapter).

Definition 5.26 (Generated subalgebra)**.** For $S \subseteq V$, $\langle S \rangle$ is the intersection of all vertex operator subalgebras (in the sense just recalled) containing S.

File `VOA/Core/VOASubalgebraGenerated.lean`.

```
def generated (S : Set 𝒱) : VOASubalgebra W :=
  sInf {A : VOASubalgebra W | S ⊆ A.carrier}

theorem generated_le {S : Set 𝒱} (A : VOASubalgebra W) (hA : S ⊆ A.carrier) :
    (generated W S).carrier ≤ A.carrier :=

theorem mem_generated {S : Set 𝒱} {motive : 𝒱 → Prop}
    (base : ∀ x ∈ S, motive x)
    (zero : motive 0)
    (add : ∀ x y : 𝒱, motive x → motive y → motive (x + y))

    (proj : ∀ (n : ℤ) (v : 𝒱), motive v → motive (piHom W n v))
    {x : 𝒱} (hx : x ∈ (generated W S).carrier) : motive x := by

noncomputable def generatedVOA (S : Set 𝒱) :
    VertexOperatorAlgebra (generated W S).carrier :=
  (generated W S).toVOA
```

From the mathematics to the Lean statement

`sInf` uses the intersection structure `instInfSetVOASubalgebra` proved in the same file. `generated_le` is minimality; `mem_generated` is the induction principle (every property true on S, 0, $\mathbf{1}$, ω and stable under sums, scalars, products and projections holds on $\langle S\rangle$).
Deviation from the literature. The usual "vertex subalgebra generated by S" (Kac, Lepowsky–Li §3.9) is the smallest subspace containing S and $\mathbf{1}$ and closed under products; it need not contain ω. Here `VOASubalgebra` always contains ω, so `generated W S` is the vertex subalgebra generated by $S \cup \{\omega\}$, closed in addition under the projections. The projection clause adds nothing: the vertex subalgebra generated by $S \cup \{\omega\}$ is stable under $L_0 = \omega_{(1)}$, hence graded by the argument of Theorem 5.18. But the ω clause is a real difference: for instance the subalgebra generated by a Heisenberg current h inside a lattice VOA contains the full stress tensor ω, not only the Heisenberg one. When a statement needs a subalgebra with a *different* conformal vector (a coset, a commutant) this notion is the wrong one.

Physical meaning

The sub-chiral algebra generated by a set of fields *together with the stress tensor*: all normal ordered products and derivatives of the given fields and of $T(z)$. Always containing $T(z)$ means the subalgebra has the same central charge as the ambient theory.

What the machine verified

Definitions and an induction principle; axiom-clean.

5.7 Screening operators and their kernels

5.7.1 Derivations with subalgebra kernels

Definition 5.27 (VOA derivation). $D \in \mathrm{End}(V)$ is a VOA derivation if $D(u_{(n)}v) = (Du)_{(n)}v + u_{(n)}(Dv)$ for all u, n, v, $D\mathbf{1} = 0$, $D\omega = 0$, and D commutes with every projection onto V_n.

File `VOA/Core/ScreeningKernel.lean`.

```
structure IsVOADerivation (W : VertexOperatorAlgebra 𝒱) (D : End ℂ 𝒱) : Prop where
  leibniz : ∀ (u : 𝒱) (n : ℤ) (v : 𝒱),
      D (W.smul u n v) = W.smul (D u) n v + W.smul u n (D v)
  vacuum : D W.vacuum = 0
  conformal : D W.conformalVector = 0
  piHom_comm : ∀ (n : ℤ) (v : 𝒱), D (piHom W n v) = piHom W n (D v)

def kerSubalgebra (W : VertexOperatorAlgebra 𝒱) (D : End ℂ 𝒱)
    (hD : IsVOADerivation W D) : VOASubalgebra W where
  carrier := LinearMap.ker D
```

From the mathematics to the Lean statement

The four clauses are exactly what makes $\ker D$ a `VOASubalgebra`: Leibniz gives closure under products, the next two give $\mathbf{1}, \omega \in \ker D$, and `piHom_comm` gives gradedness. `kerSubalgebra` is then a definition whose remaining fields are short proofs.

Physical meaning

The states annihilated by a symmetry generator that commutes with the stress tensor form a closed sub-chiral algebra: the "invariant" operators.

What the machine verified

Definitions; axiom-clean.

5.7.2 Screening operators

Definition 5.28 (Screening operator). For $a \in V$, $Q_a := a_{(0)}$.

File `VOA/Core/ScreeningKernel.lean`.

```
def screening (W : VertexOperatorAlgebra 𝒱) (a : 𝒱) : End ℂ 𝒱 := mode (W.Y a) 0
```

From the mathematics to the Lean statement

Literally $a_{(0)}$, the zero mode `W.zeroMode a 1` of a weight-one state (`screening_eq_zeroMode`); on V_1 it is the adjoint action $[a, \cdot]$ (`screening_eq_bracketV1`).
Relation to screening operators in the literature. In the Coulomb gas (Feigin–Fuchs, Dotsenko–Fateev) a screening operator is $\oint e^{\alpha\phi}(z)dz$, the zero mode of a field $e^{\alpha\phi}$ of weight one *for a deformed (background-charge) stress tensor* T^{λ}, and it usually acts between *different* Fock modules. The library's notion is the special case in which a is a weight-one state of the vertex operator algebra itself, for its own ω. The source records honestly that the concrete triplet screening operator of `VOA/Examples/TripletScreening.lean` fits this definition only when $\lambda = 0$ and $\langle \alpha, \alpha \rangle = 2$, because the background-charge VOA structure on the lattice module is not in the repository.

Physical meaning

A screening charge is the contour integral of a weight-one field. Because it has weight one, the integral is conformally invariant and commutes with the Virasoro algebra; the operators it annihilates (its "commutant") form a chiral algebra — the Virasoro minimal models, the W-algebras and the triplet algebras are all defined as such commutants inside free-field theories.

What the machine verified

Definition.

Theorem 5.29 (A weight-one state gives a VOA derivation). *For every a, Q_a is a derivation of every product and $Q_a\mathbf{1} = 0$. If $a \in V_1$, then moreover Q_a preserves each V_n and $Q_a\omega = 0$; hence Q_a is a VOA derivation.*

File `VOA/Core/ScreeningKernel.lean`.

```
theorem screening_leibniz (W : VertexOperatorAlgebra 𝒱) (a : 𝒱) (u : 𝒱) (n : ℤ) (v : 𝒱) :
    screening W a (W.smul u n v)
      = W.smul (screening W a u) n v + W.smul u n (screening W a v) := by

theorem screening_conformalVector (W : VertexOperatorAlgebra 𝒱) {a : 𝒱}
    (ha : a ∈ W.grading 1) : screening W a W.conformalVector = 0 := by

theorem screening_isDerivation (W : VertexOperatorAlgebra 𝒱) {a : 𝒱}
    (ha : a ∈ W.grading 1) : IsVOADerivation W (screening W a) where
```

From the mathematics to the Lean statement

`ha : a ∈ W.grading 1` is the only hypothesis, and it is needed only for grading preservation and $Q_a\omega = 0$. **No primarity of a is assumed**, and none is needed: $a_{(0)}\omega = 0$ holds for every $a \in V_1$ in a VOA of CFT type (Remark 5.15). A reader who expects "screening currents must be primary" should note that in a VOA of CFT type a weight-one state is automatically annihilated by L_n, $n \geq 2$, and $L_1 a \in \mathbb{C}\mathbf{1}$; it is this that makes the computation work.

Physical meaning

$[Q_a, L_n] = 0$: the charge of a weight-one current commutes with conformal transformations, so it maps primaries to primaries of the same weight. $Q_a\omega = 0$ is the statement that the stress tensor is neutral under the charge.

Proof on paper. Leibniz is Theorem 5.2; $Q_a\mathbf{1} = 0$ is creation; grading preservation is VA1 with weight 1; $Q_a\omega = 0$ is the skew-symmetry computation of Remark 5.15. □

What the machine verified

Unconditional; `#print axioms` on `screening_conformalVector`: `[propext, Classical.choice, Quot.sound]`.

Definition 5.30 (Screening kernels)**.** For $a \in V_1$, $\ker Q_a$ as a vertex operator subalgebra; for a family (a_i) of weight-one states, $\bigcap_i \ker Q_{a_i}$.

File `VOA/Core/ScreeningKernel.lean`.

theorem mem_screeningKernelInter {ι : Type*} {W : VertexOperatorAlgebra 𝒱} {a : ι → 𝒱}
    {ha : ∀ i, a i ∈ W.grading 1} {x : 𝒱} :
    x ∈ (screeningKernelInter W a ha).carrier ↔ ∀ i, screening W (a i) x = 0 := by
```

From the mathematics to the Lean statement

The family may be indexed by any type `ι` (finite or not). `screeningKernelVOA` and `screeningKernelInterVOA` are the corresponding VOAs (via `toVOA`), with the same central charge. Membership is literally "killed by every Q_{a_i}".

Physical meaning

The commutant of a set of screening charges: the chiral algebra of operators that commute with all of them. This is the definition of a W-algebra by screenings, and of the minimal models as the commutant of the two Dotsenko–Fateev screenings $Q_\pm$ (in the background-charge setting; see the caveat above).

What the machine verified

Definitions; axiom-clean.

Theorem 5.31 (Screenings with total-derivative contact commute). *If $a_{(0)}b = \lambda\, Tc$ for some c and $\lambda \in \mathbb{C}$, then $Q_aQ_b = Q_bQ_a$.*

File `VOA/Core/ScreeningKernel.lean`.

```
theorem screening_commute_of_zeroProduct_eq_translation
    (W : VertexOperatorAlgebra 𝒱) (a b c : 𝒱) (scalar : ℂ)
    (hcontact : W.smul a 0 b = scalar • W.toPreVertexAlgebra.T c) :
    Commute (screening W a) (screening W b) := by
```

From the mathematics to the Lean statement

`Commute A B` is $AB = BA$. No weight hypothesis is needed.

Physical meaning

Two screening charges commute if the simple pole of their OPE is a total derivative, because the contour integral of a derivative vanishes: $[Q_a, Q_b] = \oint (a_{(0)}b)(w)dw = \lambda \oint \partial c = 0$. This is the standard check that the two Coulomb-gas screenings commute.

Proof on paper. $[Q_a, Q_b] = (a_{(0)}b)_{(0)} = \lambda(Tc)_{(0)}$ and $(Tc)_{(n)} = -nc_{(n-1)}$ vanishes at $n = 0$. □

What the machine verified

Unconditional; axiom-clean.

Theorem 5.32 (Transfer lemma for a screening-kernel image). *Let $\varphi : V \to W$ be a homomorphism whose image is exactly* $\ker Q_a$ *for some $a \in W_1$. If the VOA* $\ker Q_a$ *is simple, then* $\ker \varphi = \mathfrak{m}(V)$.

File `VOA/Core/SimpleImage.lean`.

```
theorem ker_eq_maxGradedIdeal_of_screeningKernel {V : VertexOperatorAlgebra 𝒱}
    {W : VertexOperatorAlgebra 𝒲} {a : 𝒲} (ha : a ∈ W.grading 1) {φ : 𝒱 →ₗ[ℂ] 𝒲}
    (hφ : IsVOAHom V W φ) (hin : ∀ x, screening W a (φ x) = 0)
    (honto : ∀ y, screening W a y = 0 → ∃ x, φ x = y)
    (hsimple : (screeningKernelVOA W a ha).IsSimple) :
    LinearMap.ker φ = QuotVOA.maxGradedIdeal V := by
```

From the mathematics to the Lean statement

`hin` and `honto` together say $\operatorname{im}\varphi = \ker Q_a$. `hsimple` is simplicity of the kernel VOA, which in applications is the hard input. The proof corestricts φ to the subalgebra (`isVOAHom_codRestrict`) and applies Theorem 5.23.

Physical meaning

If a universal chiral algebra maps onto the commutant of a screening charge and that commutant is irreducible, the map identifies the commutant with the simple quotient. This is the logic of Adamović's realisations of simple affine algebras, used in Chapter 19.

What the machine verified

Conditional on `hsimple`; axiom-clean.

Remark 5.33 (The super screening kernel). The same file defines `superScreening` on a super near-VOA and `superScreeningKernel W a h` for `h : IsSuperScreening W a`, a structure whose fields `leibniz` and `conformal` are the super Leibniz rule and $a_{(0)}\omega = 0$ *as hypotheses* (the super Borcherds machinery needed to prove them is not in the library). So the super statement is genuinely conditional on these two fields. Super vertex algebras are the subject of Chapter 17.

5.8 Singular vectors

A singular vector is the algebraic shadow of a null state: a vector of positive weight that the lowering operators kill. The file `VOA/Core/SingularVector.lean` is the interface between explicit singular-vector computations (Chapters 7, 9) and the structural conclusion "V is not simple". It distinguishes two notions, and the distinction is the first thing a referee should understand.

Definition 5.34 (Singular and strongly singular vectors)**.** Let $k > 0$. A vector $s \neq 0$ in V_k is *(Virasoro) singular of weight k* if $L_n s = 0$ for all $n > 0$. It is *strongly singular of weight k* if $u_{(n)}s = 0$ for every homogeneous $u \in V_m$ and every $n \geq m$.

File `VOA/Core/SingularVector.lean`.

```
structure IsSingularOfWeight (W : VertexOperatorAlgebra 𝒱) (k : ℤ) (s : 𝒱) : Prop where
  ne_zero : s ≠ 0
  weight_pos : 0 < k
  homogeneous : s ∈ W.grading k
  annihilated : ∀ n : ℤ, 0 < n → W.L n s = 0

structure IsStronglySingularOfWeight (W : VertexOperatorAlgebra 𝒱) (k : ℤ) (s : 𝒱) : Prop
 ↪  where
  ne_zero : s ≠ 0
  weight_pos : 0 < k
  homogeneous : s ∈ W.grading k
  annihilated : ∀ (m : ℤ) (u : 𝒱), u ∈ W.grading m → ∀ n : ℤ, m ≤ n → W.smul u n s = 0
```

From the mathematics to the Lean statement

Index convention. $u \in V_m$ maps V_k to $V_{m+k-n-1}$, so $n \geq m$ are exactly the modes that strictly *lower* the weight (the target weight is $\leq k-1$). For $u = \omega \in V_2$, $\omega_{(n)} = L_{n-1}$ with $n \geq 2$, i.e. L_j with $j \geq 1$: strong singularity implies Virasoro singularity (`IsStronglySingularOfWeight.toIsSingularOfWeight`).

Nonvanishing and positive weight are required (`ne_zero`, `weight_pos`). The question raised in the instructions for this book — whether lowest-weight-type data require nonvanishing — is answered here in the affirmative: $s = 0$ is excluded, so "V has a singular vector" is not trivially true. Positive weight excludes $s = \mathbf{1}$, which is killed by all lowering modes.

Comparison with the literature. "Singular vector" in the Virasoro and affine literature means a vector annihilated by the positive modes of the *generators*; in a VOA generated by those fields this is equivalent to strong singularity (positive modes of generators generate, by the Borcherds identity, all weight-lowering modes). The library does not prove this equivalence — the source lists it as missing — so the two notions are kept apart, and only strong singularity, or Virasoro singularity with an extra pairing condition, is used to obstruct simplicity.

Physical meaning

A singular vector is a null state: a descendant that is also a highest-weight state. It has zero norm and zero overlap with every state of the module. In the Virasoro vacuum module at $c = c_{p,q}$ there is one at level $(p-1)(q-1)$; setting it to zero is what makes the minimal model have finitely many primaries.

What the machine verified

Definitions.

Trap / dead end: Virasoro singularity alone does not make the generated ideal proper

The tempting argument "everything in the ideal (s) has weight $\geq \operatorname{wt} s > 0$, and $\mathbf{1}$ has weight 0" is false, because modes $u_{(n)}$ with $n \geq \operatorname{wt} u$ lower the weight. The library's counterexample: in a simple affine VOA $L_k(\mathfrak{g})$, $k \neq 0$, every $x \in V_1 = \mathfrak{g}$ is primary ($L_n x = 0$ for $n > 0$), yet $y_{(1)}x = k(x|y)\mathbf{1}$ reaches the vacuum in one step, so $(x) = V$. What fails is strong singularity: $y_{(1)}x \neq 0$ with $\operatorname{wt} y = 1 \leq 1$. The weight argument is proved only one layer deep (`smul_mem_wtGE`: $u_{(n)}s$ has weight $\geq k$ for strongly singular s); turning it into properness of (s) would need $(s) = \operatorname{span}\{u_{(n)}s\}$ (Lepowsky–Li Prop. 4.5.6), which is not in the library.

Definition 5.35 (Ideal generated by a vector). $(s) :=$ the intersection of all ideals containing s.

File `VOA/Core/SingularVector.lean`.

```
def idealGen (W : VertexOperatorAlgebra 𝒱) (s : 𝒱) : Submodule ℂ 𝒱 :=
  sInf {I : Submodule ℂ 𝒱 | s ∈ I ∧ W.IsIdeal I}

theorem idealGen_isIdeal (W : VertexOperatorAlgebra 𝒱) (s : 𝒱) : W.IsIdeal (idealGen W s)
↪  := by
```

From the mathematics to the Lean statement

The family is nonempty (V is in it) and an intersection of ideals is an ideal, so `idealGen` is the smallest ideal containing s. Standard.

Physical meaning

The null submodule generated by a null state: all states obtained from it by the action of fields.

What the machine verified

Definition; axiom-clean.

5.8.1 Two routes to properness

Properness is obtained through invariant forms (Section 5.12, which the reader may consult first): the radical of a normalised fully invariant form is a proper ideal, so any singular vector in a radical generates a proper ideal. The library needs the radical in both slots.

Definition 5.36 (Right radical). For a bilinear form B, $\operatorname{rad}_R B = \{b : B(a,b) = 0\ \forall a\}$.

File `VOA/Core/SingularVector.lean`.

```
def rightRadical (B : InvariantForm W) : Submodule ℂ 𝒱 := LinearMap.ker B.form.flip

theorem rightRadical_isIdeal {B : InvariantForm W} (hB : B.IsFullyInvariant) :
    W.IsIdeal (rightRadical B) := by
```

From the mathematics to the Lean statement

`B.form.flip` is $(a,b) \mapsto B(b,a)$; its kernel is the right radical. `InvariantForm` and `IsFullyInvariant` are Definitions 5.48 and 5.49 below. That the right radical is an ideal is less immediate than for the left radical, because full invariance moves modes from the left slot to the right; the proof is a downward induction on the weight of the acting state.

Physical meaning

States orthogonal to everything from the other side of the two-point function; for a symmetric form (which is the physical case) the two radicals coincide, and Theorem 5.57 shows they coincide in general here.

What the machine verified

Unconditional given full invariance; axiom-clean.

Theorem 5.37 (Singular vectors obstruct simplicity). *Assume* $\mathbf{1} \neq 0$ *and* $L_1 V_1 = 0$. *(a) If* s *is strongly singular of weight* k*, then* (s) *is a proper nonzero ideal, so* V *is not simple. (b) If* s *is Virasoro singular of weight* k *and* $s_{(2k-1)}x = 0$ *for all* $x \in V_k$*, the same conclusion holds.*

File `VOA/Core/SingularVector.lean`.

```
theorem not_isSimple_of_stronglySingular_FHL (hne : W.vacuum ≠ 0)
    (hqp : ∀ v, v ∈ W.grading 1 → W.L 1 v = 0) {k : ℤ} {s : V}
    (hs : IsStronglySingularOfWeight W k s) : ¬ W.IsSimple :=

theorem not_isSimple_of_shapovalov_FHL (hne : W.vacuum ≠ 0)
    (hqp : ∀ v, v ∈ W.grading 1 → W.L 1 v = 0) {k : ℤ} {s : V} (hs : IsSingularOfWeight W k
    ↪ s)
    (hpair : ∀ x ∈ W.grading k, W.smul s (2 * k - 1) x = 0) : ¬ W.IsSimple :=
```

From the mathematics to the Lean statement

`hne`, `hqp` are the hypotheses of the canonical invariant form (Theorem 5.56); they enter only to produce a fully invariant normalised form, and the versions without the suffix `_FHL` take such a form `B` instead. `hpair` is the *Shapovalov condition*: $s_{(2k-1)}$ maps V_k to $V_{k+k-(2k-1)-1} = V_0$, so $s_{(2k-1)}x$ is the "vacuum component" of the pairing of s with x, and the condition says s is in the radical of the level-k Gram form. It is a finite linear condition on one weight space, which is what an explicit computation can check. In (b) only $L_1 s = 0$ is really used (to collapse the invariance sum); the rest of Virasoro singularity is carried along.
The conclusion `¬ W.IsSimple` is genuinely informative: it is false for simple VOAs, and the hypotheses are satisfiable (Example 5.38).

Physical meaning

A null state with vanishing two-point function against its own energy level generates a decoupled sector, so the theory built on the vacuum module is reducible; the physical theory is the quotient. Condition (b) is how degenerate values of c are found in practice: the Kac determinant at level k vanishes.

Proof on paper. Let B be the canonical form. (a) For $x \in V_p$ write $x = x_{(-1)}\mathbf{1}$ and expand $B(x,s) = B(x_{(-1)}\mathbf{1}, s)$ by full invariance: every term is $\pm\frac{1}{j!}B(\mathbf{1}, (L_1^j x)_{(2p-1-j)}s)$, and $2p-1-j \geq p-j = \mathrm{wt}(L_1^j x)$ when $p \geq 1$, so each term vanishes by strong singularity; for $p = 0$, $B(\mathbf{1}, s) = 0$ by weight orthogonality. So s is in the right radical, a proper ideal (it misses $\mathbf{1}$ since $B(\mathbf{1},\mathbf{1}) = 1$); (s) is contained in it, and $(s) \ni s \neq 0$. (b) With $L_1 s = 0$ the invariance sum for $B(s,x)$ collapses to $(-1)^k B(\mathbf{1}, s_{(2k-1)}x)$ for $x \in V_k$, which is 0 by `hpair`; for x in other weights $B(s,x) = 0$ by orthogonality. So s is in the left radical. □

What the machine verified

Conditional only on the displayed hypotheses; `#print axioms` on both `_FHL` theorems: `[propext, Classical.choice, Quot.sound]`.

Example 5.38 (Central charge zero). In the universal Virasoro VOA $V(c,0)$ (Chapter 7), $V_1 = 0$ (so `hqp` holds trivially), $V_2 = \mathbb{C}\omega$, and $L_1\omega = 0$, $L_2\omega = \frac{c}{2}\mathbf{1}$. At $c = 0$, $s = \omega$ is Virasoro singular of weight 2, and the Shapovalov condition is $\omega_{(3)}\omega = L_2\omega = 0$. Theorem 5.37(b) says $V(0,0)$ is not simple; its simple quotient is $L(0,0) = \mathbb{C}\mathbf{1}$, the trivial theory.

Definition 5.39 (Quotient by a singular vector). $V/(s)$ with the quotient structure.

File `VOA/Core/SingularVector.lean`.

```
noncomputable def quotientBySingular (W : VertexOperatorAlgebra 𝒱) (s : 𝒱) :
    VertexOperatorAlgebra (𝒱 / idealGen W s) :=
  QuotVOA.quotientVOA' W (idealGen W s) (idealGen_isIdeal W s)

theorem le_maxGradedIdeal_of_proper {s : 𝒱} (hv : W.vacuum ∉ idealGen W s) :
    idealGen W s ≤ QuotVOA.maxGradedIdeal W :=
```

From the mathematics to the Lean statement

Defined for every s (for $(s) = V$ it is the zero VOA; `quotientBySingular_vacuum_ne_zero` gives nonvanishing when (s) is proper). `le_maxGradedIdeal_of_proper` says that $V/(s)$ surjects onto $L(V)$. The converse — that $(s) = \mathfrak{m}(V)$ for the Virasoro minimal-model vector or for the affine admissible vector (Feigin–Fuchs, Kac–Kazhdan) — is a representation-theoretic input that the file explicitly does *not* assume or prove.

Physical meaning

Setting the null vector to zero; whether this already gives the physical theory (no further null states) is a separate theorem about the vacuum module.

What the machine verified

Definition and unconditional lemma; axiom-clean.

5.9 Tensor products

The file `VOA/Core/TensorVOA.lean` constructs the tensor product of two *vertex superalgebras* in the sense of `SuperVertexAlgebra` (`VOA/Core/SuperVertexAlgebra.lean`, Chapter 17). We recall what that structure is, in words: a space with a $\mathbb{C}$-valued weight grading (internal, finite-dimensional pieces) and an independent $\mathbb{Z}/2$ parity grading, a linear state–field map Y, a vacuum of weight 0 and even parity, and the axioms VA1 (weights add), VA1′ (parities add), VA2 ($Y(\mathbf{1},z) = 1$), VA3 (creation), VA4 (locality up to the Koszul sign $(-1)^{|u||v|}$) and VA5 (truncation). It has *no conformal vector*, no translation operator as a field, and no bounded-below condition.

Definition 5.40 (Tensor product vertex operator). For vertex superalgebras V on A, W on B: $Y(u\otimes v,z)(u'\otimes v') = (-1)^{|v||u'|}\,Y(u,z)u'\otimes Y(v,z)v'$, with weight grading $(A\otimes B)_h = \bigoplus_{h_1+h_2=h} V_{h_1}\otimes W_{h_2}$, parity grading by addition, and vacuum $\mathbf{1}\otimes\mathbf{1}$.

File `VOA/Core/TensorVOA.lean`.

```
noncomputable def rawCoeff (V : SuperVertexAlgebra A) (W : SuperVertexAlgebra B) (a : A) (b
↪  : B)
    (s : ℤ) : A ⊗[ℂ] B →ₗ[ℂ] A ⊗[ℂ] B :=
  TensorProduct.lift (rawBil V W a b s)

noncomputable def tenY (V : SuperVertexAlgebra A) (W : SuperVertexAlgebra B) :
    A ⊗[ℂ] B →ₗ[ℂ] FormalDist (End ℂ (A ⊗[ℂ] B)) :=
  (2⁻¹ : ℂ) •
    ((postCompHom (1 + kappaTen V W 1)).comp (rawY V W)
      + (postCompHom (1 - kappaTen V W 1)).comp
          ((rawY V W).comp
            (TensorProduct.map (LinearMap.id : A →ₗ[ℂ] A) ((parGr W).parityInvol))))

theorem tenY_tmul_parity (V : SuperVertexAlgebra A) (W : SuperVertexAlgebra B) (a : A)
    {q : ZMod 2} {b : B} (hb : b ∈ W.parity q) (s : ℤ) (z : A ⊗[ℂ] B) :
    tenY V W (a ⊗ₜ[ℂ] b) s z = rawCoeff V W a b s (kappaTen V W q z) := by

def tenGrading (V : SuperVertexAlgebra A) (W : SuperVertexAlgebra B) (h : ℂ) :
    Submodule ℂ (A ⊗[ℂ] B) :=
  ⨆ h₁ : ℂ, tenSub (V.grading h₁) (W.grading (h - h₁))
```

From the mathematics to the Lean statement

`A ⊗[ℂ] B` is the algebraic tensor product, `a ⊗ₜ b` a pure tensor. `rawCoeff a b s` is the sign-free coefficient of z^s in $Y(a,z)\otimes Y(b,z)$, i.e. $x\otimes y\mapsto\sum_m(a\text{-coefficient of }z^m)x\otimes(b\text{-coefficient of }z^{s-m})y$ (`rawCoeff_tmul`; finite by truncation). `kappaTen V W q` is $(-1)^{qF}\otimes 1$, the parity operator to the power q on the first factor. The definition of `tenY` is a device to keep Y linear: for b of parity q, `tenY_tmul_parity` shows it equals `rawCoeff` $\circ((-1)^{qF}\otimes 1)$, which on $u'\otimes v'$ gives exactly $(-1)^{q|u'|}Y(a,z)u'\otimes Y(b,z)v'$, the Koszul formula of the definition. `tenSub P Q` is the span of $P\otimes Q$ inside $A\otimes B$, so `tenGrading` is the convolution grading. These agree with Kac (*Vertex algebras for beginners*, §4.3) and FHL §3.

Physical meaning

Two decoupled chiral CFTs stacked: the states are products, the fields are products of fields, and energies add. The sign is the usual fermionic statistics: moving a fermionic field of the second theory past a fermionic state of the first costs a sign. For purely bosonic theories the sign is absent.

What the machine verified

Definitions; axiom-clean.

Theorem 5.41 (The tensor product is a vertex superalgebra)**.** *If the parity involutions of V and W preserve the weight spaces, and the convolution weight spaces are independent and finite-dimensional, then Definition 5.40 is a vertex superalgebra.*

File `VOA/Core/TensorVOA.lean`.

```
def ParityCompatible (V : SuperVertexAlgebra A) : Prop :=
  ∀ (h : ℂ) (u : A), u ∈ V.grading h → (parGr V).parityInvol u ∈ V.grading h

structure TensorGradingHyp (V : SuperVertexAlgebra A) (W : SuperVertexAlgebra B) : Prop
↪  where
  iSupIndep : iSupIndep (tenGrading V W)
  finrank : ∀ h : ℂ, FiniteDimensional ℂ (tenGrading V W h)
```

```
noncomputable def tensorSVA (V : SuperVertexAlgebra A) (W : SuperVertexAlgebra B)
    (hV : ParityCompatible V) (hW : ParityCompatible W) (hg : TensorGradingHyp V W) :
    SuperVertexAlgebra (A ⊗[ℂ] B) where
  grading := tenGrading V W
```

From the mathematics to the Lean statement

The hypotheses. `ParityCompatible`: the parity operator $(-1)^F$ maps each weight space to itself (the algebra is bigraded). It holds in every example, but the `SuperVertexAlgebra` axioms do not force it, so it is a genuine hypothesis. `TensorGradingHyp`: `iSupIndep` says the convolution weight spaces are independent (their sum is direct), `finrank` that each is finite-dimensional. The first is true over $\mathbb{C}$ by flatness (the file explains how it would be proved but does not prove it). The second is *false in general*: for complex weights, $h = h_1 + h_2$ can have infinitely many solutions with $V_{h_1} \neq 0 \neq W_{h_2}$; it holds when both gradings are bounded below and discrete, which is the situation of VOAs of CFT type. (The file's docstring speaks of "three" linear-algebra facts; the structure has two fields, the third — internality of the parity grading — being proved as `tenParity_isInternal`.)
What is proved. All of VA1–VA5 and VA1′: locality comes from Dong's lemma applied to the mutually commuting families $a_{(n)} \otimes 1$ and $(-1)^{qF} \otimes b_{(n)}$.

Physical meaning

Stacking two decoupled theories gives a consistent theory: locality of the product fields follows from locality in each factor and the fact that fields of different factors (anti)commute. The finiteness hypothesis is the requirement that each energy level of the combined theory be finite-dimensional, which fails only for pathological spectra.

Proof on paper. Linearity is built in. The weight and parity rules follow from those of the factors. The vacuum axioms follow from $Y(\mathbf{1}, z) = 1$ and creation in each factor. Locality: the field of $a \otimes b$ is the product of $\ell_a(z) = Y(a, z) \otimes 1$ and $r_b(z) = (-1)^{qF} \otimes Y(b, z)$; these two families commute exactly up to the Koszul sign, so their normal-ordered product is their plain product, and Dong's lemma (Chapter 4, Theorem 4.16) gives mutual locality of all such products. □

What the machine verified

Conditional on `ParityCompatible` (twice) and `TensorGradingHyp`; `#print axioms` on `tensorSVA`: `[propext, Classical.choice, Quot.sound]`. The two clauses of `TensorGradingHyp` are carried as open hypotheses downstream (in `VOA/Examples/DSReductionSl2.lean`, Chapter 19).

Trap / dead end: There is no tensor product of vertex operator algebras in the library

Despite its name, `VOA/Core/TensorVOA.lean` does not construct a tensor product of `VertexOperatorAlgebras`. It builds a `SuperVertexAlgebra`: no conformal vector $\omega \otimes \mathbf{1} + \mathbf{1} \otimes \omega$, no proof that central charges add, no CFT-type statement. The source says so in its closing note ("The conformal layer ... is not built here"). A reader who needs $c(V \otimes W) = c(V) + c(W)$ will not find it in this chapter's files.

Definition 5.42 (Tensor product of two Lie actions)**.** For Lie algebra representations $R : L \to \mathrm{End}\, V$, $S : L \to \mathrm{End}\, W$: $(R \otimes S)(x) = R(x) \otimes 1 + 1 \otimes S(x)$.

File `VOA/Core/TensorLieAction.lean`.

```
def tensorLieAction (R : L →ₗ[ℂ] End ℂ V) (S : L →ₗ[ℂ] End ℂ W) :
    L →ₗ[ℂ] End ℂ (V ⊗[ℂ] W) where
```

```
  toFun x := (R x).rTensor W + (S x).lTensor V

theorem tensorLieAction_eigen (R : L →ₗ[ℂ] End ℂ V) (S : L →ₗ[ℂ] End ℂ W)
    (x : L) (v : V) (w : W) (a b : ℂ) (ha : R x v=a • v) (hb : S x w=b • w) :
    tensorLieAction R S x (v ⊗ₜ[ℂ] w)=(a+b) • (v ⊗ₜ[ℂ] w) := by

theorem complex_tmul_ne_zero {v : V} {w : W} (hv : v ≠ 0) (hw : w ≠ 0) :
    v ⊗ₜ[ℂ] w ≠ 0 := by
```

From the mathematics to the Lean statement

`L →ₗ[ℂ] End ℂ V` is a Lie algebra homomorphism, i.e. a representation. `rTensor W` and `lTensor V` are $f \otimes 1$ and $1 \otimes f$. The file takes the representations as explicit data (rather than type-class instances) so that several representations on one space can coexist. Eigenvalues add, and pure tensors of nonzero vectors are nonzero. All standard.

Physical meaning

The total charge of a two-particle (or two-sector) state is the sum of the charges: the coproduct $\Delta(x) = x \otimes 1 + 1 \otimes x$ of a Lie algebra symmetry. This is how L_0 and current zero modes act on a stacked theory.

What the machine verified

Unconditional; axiom-clean.

5.10 Weight operators and weight-homogeneous fields

Two small files provide operator-first grading tools used by free-field constructions.

Definition 5.43 (The weight operator of an internal grading)**.** Given an internal grading $A = \bigoplus_i G_i$ and scalars w_i, the operator acting by w_i on G_i; for a $\mathbb{Z}$-grading with $w_n = n$, the canonical "L_0".

File `VOA/Core/InternalGradingOperator.lean`.

```
noncomputable def internalWeightOperatorZ (G : ℤ → Submodule ℂ A)
    (hG : DirectSum.IsInternal G) : End ℂ A :=
  internalWeightOperator G hG (fun n => (n : ℂ))

theorem internalWeightOperatorZ_comm_of_maps
    (G : ℤ → Submodule ℂ A) (hG : DirectSum.IsInternal G)
    (f : End ℂ A) (d : ℤ)
    (hf : ∀ n x, x ∈ G n → f x ∈ G (n + d)) :
    internalWeightOperatorZ G hG * f - f * internalWeightOperatorZ G hG =
      (d : ℂ) • f := by
```

From the mathematics to the Lean statement

`DirectSum.IsInternal G` says A is the internal direct sum of the G_n. The theorem: an operator shifting degrees by d satisfies $[W, f] = df$. Standard.

Physical meaning

An operator that raises the energy by d has commutator d with the Hamiltonian; this is how one reads off the weight of a mode, $[L_0, u_{(n)}] = (\mathrm{wt}\, u - n - 1)u_{(n)}$.

What the machine verified

Unconditional; axiom-clean.

Definition 5.44 (Weight-commutator field). A formal field $a(z) = \sum_j a_j z^j$ of $\mathrm{End}\, A$ is homogeneous of weight D for $W \in \mathrm{End}\, A$ if $[W, a_j] = (D + j)a_j$ for all j.

File `VOA/Core/WeightCommutatorField.lean`.

```
def WeightCommutatorField (W : End ℂ A) (a : FormalDist (End ℂ A)) (D : ℤ) : Prop :=
  ∀ j : ℤ, W * a j - a j * W = ((D + j : ℤ) : ℂ) • a j

theorem nprod {W : End ℂ A} {a b : FormalDist (End ℂ A)}
    (haf : IsField a) (hbf : IsField b) {Da Db : ℤ}
    (ha : WeightCommutatorField W a Da) (hb : WeightCommutatorField W b Db) :
    WeightCommutatorField W (VOA.nprod haf hbf) (Da + Db) := by
```

From the mathematics to the Lean statement

`a j` is the coefficient of z^j. For $a = Y(u, z)$ with u of weight D, the coefficient of z^j is $u_{(-j-1)}$, of degree $D + j$: so the definition is "a is the field of a weight-D state" in operator form, without any vertex algebra. `VOA.nprod` is the normal-ordered product of two fields (Chapter 4); weights add. The file also proves closure under sums, scalars and derivative (weight $D + 1$).

Physical meaning

The normal-ordered product $:a(z)b(z):$ of fields of dimensions D_a and D_b has dimension $D_a + D_b$, and ∂a has dimension $D_a + 1$: the dimension counting of composite operators.

What the machine verified

Unconditional; axiom-clean.

5.11 BRST cohomology

Definition 5.45 (BRST complex). A BRST complex on a vertex superalgebra V is a $\mathbb{Z}$-grading $V = \bigoplus_g V^{(g)}$ (ghost number) together with $Q \in \mathrm{End}\, V$ that preserves weights, is odd, raises ghost number by one, satisfies $Q^2 = 0$ and $Q(u_{(n)}v) = (Qu)_{(n)}v + ((-1)^F u)_{(n)}(Qv)$ for all u, v, n.

File `VOA/Core/BRSTCohomology.lean`.

```
structure BRSTComplex (V : SuperVertexAlgebra 𝒱) where
  ghost : ℤ → Submodule ℂ 𝒱
  ghost_isInternal : DirectSum.IsInternal ghost
  Q : Module.End ℂ 𝒱
  Q_wt : ∀ h : ℂ, ∀ v ∈ V.grading h, Q v ∈ V.grading h
  Q_odd : ∀ p : ZMod 2, ∀ v ∈ V.parity p, Q v ∈ V.parity (p + 1)
  Q_ghost : ∀ g : ℤ, ∀ v ∈ ghost g, Q v ∈ ghost (g + 1)
  Q_sq : Q * Q = 0
  Q_deriv : ∀ (u v : 𝒱) (n : ℤ),
    Q (mode (V.Y u) n v) = mode (V.Y (Q u)) n v + mode (V.Y (sgn V u)) n (Q v)
```

From the mathematics to the Lean statement

`sgn V` is the parity operator $(-1)^F$. For u of parity p the derivation rule is the usual $Q(u_{(n)}v) = (Qu)_{(n)}v + (-1)^p u_{(n)}(Qv)$ (`Q_deriv_homog`); writing the sign as an operator makes the rule

bilinear for all u. The definition is abstract: it does not ask that Q be the zero mode of a BRST current J_{BRST}, nor that the ghost number be additive under products (that is the separate predicate `GhostAdditive`). Every BRST differential of the literature (Feigin–Frenkel, Kac–Roan–Wakimoto) has these properties, so the notion is at least as general as needed. **No concrete instance is constructed in this chapter's files**; the Drinfeld–Sokolov file of Chapter 19 carries one as a hypothesis.

Physical meaning

The BRST charge of a gauge-fixed theory: a nilpotent fermionic symmetry raising the ghost number. Its cohomology is the space of physical states and operators — gauge invariant modulo pure gauge. In quantum Hamiltonian (Drinfeld–Sokolov) reduction, Q imposes the constraint $J^e(z) = 1$ on an affine current, and the cohomology is the W-algebra.

What the machine verified

Definition.

Theorem 5.46 (BRST cohomology is a vertex superalgebra). $\mathrm{H}(V, Q) := \ker Q / \operatorname{im} Q$ *carries a vertex superalgebra structure with* $Y([u], z)[v] = [Y(u, z)v]$, *vacuum* $[\mathbf{1}]$ *and the induced weight and parity gradings; the ghost grading descends. If the ghost number is additive,* H^0 *is closed under all products. If* $Q = 0$, $\mathrm{H}(V, 0) \cong V$.

File `VOA/Core/BRSTCohomology.lean`.

  LinearEquiv.ofBijective (C.toCoh hQ) ⟨C.toCoh_injective hQ, C.toCoh_surjective hQ⟩
```

From the mathematics to the Lean statement

`C.kerQ` is $\ker Q$; `C.imQ'` is $\operatorname{im} Q$ viewed inside $\ker Q$ (it is contained there since $Q^2 = 0$); `Coh` is the quotient space. `Ycohom` is the induced state–field map; well-definedness rests on $\ker Q$ being closed under products and $\operatorname{im} Q$ being a two-sided ideal *inside* $\ker Q$ (`mode_mem_imQ_left`, `mode_mem_imQ_right`). `gradingH h` is the image of $V_h \cap \ker Q$. `H0` is the ghost-number-zero part. All fifteen fields of `SuperVertexAlgebra` are proved; nothing is assumed beyond the `BRSTComplex`. **Nontriviality is not part of the theorem**: if $\mathbf{1} \in \operatorname{im} Q$ the cohomology is zero, which is a valid vertex superalgebra. `cohEquivOfQZero` (with `toCoh_vacuum`, `toCoh_mode`)

is the non-vacuity sanity check that for $Q = 0$ nothing is lost.

Physical meaning

Physical operators form a closed operator algebra: the OPE of two BRST-closed operators is closed, and exact operators decouple (their OPE with closed ones is exact). The ghost-number-zero part is the algebra of physical fields — for Drinfeld–Sokolov reduction, the W-algebra $W^k(\mathfrak{g}, f)$.

Proof on paper. Let $a, x \in \ker Q$. Then $Q(a_{(n)}x) = 0$ by the derivation rule. If $a = Qb$ and $Qx = 0$, $(Qb)_{(n)}x = Q(b_{(n)}x)$, exact. If $Qa = 0$ and $x = Qb$, apply the rule to $(-1)^F a$ (which is still closed, since $Q(-1)^F = -(-1)^F Q$): $Q(((-1)^F a)_{(n)}b) = a_{(n)}Qb$ up to the sign, exact. So $\operatorname{im} Q$ is a two-sided ideal of the vertex algebra $\ker Q$ and the axioms descend. The three gradings descend because Q shifts each by a bijection of the index set. □

What the machine verified

`cohomology` unconditional (given a `BRSTComplex`); `H0_mode` conditional on `GhostAdditive`. `#print axioms` on `cohomology`, `H0_mode`, `cohEquivOfQZero`: `[propext, Classical.choice, Quot.sound]`.

Theorem 5.47 (Nontrivial vacuum; conformal structure descends). *(a) If* $\mathbf{1}$ *has ghost number* 0, $V^{(-1)} = 0$ *and* $\mathbf{1} \neq 0$, *then* $\mathbf{1} \notin \operatorname{im} Q$, *so the cohomology vacuum is nonzero. (b) If* V *is a super near-VOA and* $Q\omega = 0$, *then* $\mathrm{H}(V, Q)$ *is a super near-VOA with conformal vector* $[\omega]$ *and the same central charge.*

File `VOA/Core/BRSTCohomology.lean`.

```
theorem vacuum_not_mem_imQ (h0 : V.vacuum ∈ C.ghost 0) (hneg : C.ghost (-1) = ⊥)
    (hne : V.vacuum ≠ 0) : V.vacuum ∉ C.imQ := by

noncomputable def cohomologyNearVOA : SuperNearVOA C.Coh where
  toSuperVertexAlgebra := C.cohomology
  conformalVector := C.prj (confK C hω)
  conformal_mem := Submodule.mem_map_of_mem W.conformal_mem
  conformal_parity := Submodule.mem_map_of_mem W.conformal_parity
  centralCharge := W.centralCharge
```

From the mathematics to the Lean statement

(a) `hneg : C.ghost (-1) = ⊥` says there are no states of ghost number -1. It is a *sufficient* condition: the ghost-number-zero part of $\operatorname{im} Q$ is $Q(V^{(-1)})$. A referee should be aware that in the standard Kac–Roan–Wakimoto complex the charged ghost system has states of negative ghost number, so this particular criterion is not the one that would establish a nonzero vacuum there (in that case one uses the vanishing of the cohomology outside degree 0, which is not in the library). (b) `SuperNearVOA` (`VOA/Core/SuperNearVOA.lean`, Chapter 17) is a `SuperVertexAlgebra` with a conformal vector ω of weight 2, even, whose modes satisfy the Virasoro relations, with L_0 acting by the weight and L_{-1} as translation; `hω` is $Q\omega = 0$. The omitted fields (Virasoro relations, L_0-grading, translation) are transported from $\ker Q$.

Physical meaning

(a) The vacuum is a physical state, not pure gauge. (b) If the stress tensor is BRST invariant, the physical theory is conformal, with the total central charge (matter plus ghosts) of the complex. In Drinfeld–Sokolov reduction one must first improve the Sugawara stress tensor

so that it is BRST closed; this is the role of `hω`.

What the machine verified

(a) conditional on `h0`, `hneg`, `hne`; (b) conditional on `hω`. Both axiom-clean.

5.12 Invariant bilinear forms

5.12.1 Motivation: the two-point function

In a unitary CFT the space of states carries an inner product for which $L_n^\dagger = L_{-n}$ and, more generally, the adjoint of a field is obtained by the inversion $z \mapsto 1/z$: for a quasi-primary field of weight h, $\phi(z)^\dagger = \bar{z}^{-2h}\phi^\dagger(1/\bar{z})$. Removing complex conjugation, one obtains a *bilinear* pairing on the chiral algebra, the BPZ (Belavin–Polyakov–Zamolodchikov) pairing; restricted to quasi-primaries it is the Zamolodchikov metric, the matrix of two-point functions $\langle\phi_a(z)\phi_b(w)\rangle = G_{ab}(z-w)^{-2h}$. Frenkel–Huang–Lepowsky (FHL) turned this into the following algebraic definition. The map $w \mapsto 1/w$ has derivative $-w^{-2}$; on a state u the corresponding operator is $e^{zL_1}(-z^{-2})^{L_0}$, where the factor $(-z^{-2})^{L_0}$ is the Jacobian for a quasi-primary and e^{zL_1} corrects for the failure of u to be quasi-primary.

Definition 5.48 (Invariant form, the library's two layers)**.** An *invariant form* in the library's sense is a bilinear form $(\cdot|\cdot)$ on V with $(L_n a|b) = (a|L_{-n}b)$ for all n. It is *normalised* if $(\mathbf{1}|\mathbf{1}) = 1$, and *Gannon-normalised* if $(\mathbf{1}|\mathbf{1}) = -1$. Its *left radical* is $\{a : (a|b) = 0\ \forall b\}$; it is *symmetric* if $(a|b) = (b|a)$.

File `VOA/Core/BilinearForm.lean`.

```
structure InvariantForm (W : VertexOperatorAlgebra 𝒱) where
  form : LinearMap.BilinForm ℂ 𝒱
  virasoro_adj : ∀ (n : ℤ) (a b : 𝒱), form (W.L n a) b = form a (W.L (-n) b)

def IsSymmetric (B : InvariantForm W) : Prop := ∀ a b : 𝒱, B.form a b = B.form b a

def NormalizedAt (B : InvariantForm W) (κ : ℂ) : Prop :=
  B.form W.vacuum W.vacuum = κ

def Normalized (B : InvariantForm W) : Prop := B.NormalizedAt 1

def GannonNormalized (B : InvariantForm W) : Prop := B.NormalizedAt (-1)

def leftRadical (B : InvariantForm W) : Submodule ℂ 𝒱 := LinearMap.ker B.form
```

From the mathematics to the Lean statement

`LinearMap.BilinForm ℂ 𝒱` is the type of bilinear forms $V \times V \to \mathbb{C}$, curried as $V \to (V \to \mathbb{C})$; its kernel is the set of a with $(a|\cdot) = 0$. The full name of the structure is `VOA.VertexOperatorAlgebra.InvariantForm` (distinct from the Lie-algebra `VOA.InvariantForm` of `VOA/Foundations/AffineLie.lean`).

Important: `InvariantForm` alone is weaker than FHL invariance. It records only the $u = \omega$ slice of FHL invariance (Virasoro adjointness). The full FHL condition is the separate predicate `IsFullyInvariant` (Definition 5.49), and every substantive theorem assumes it. A referee must check, for each statement mentioning an `InvariantForm`, whether `IsFullyInvariant` is also assumed. Section 5.16 shows that the gap between the two is real.

Normalisation. The public convention is $(\mathbf{1}|\mathbf{1}) = +1$; Gannon's book uses -1 (5.1.12a), and the library keeps it as `GannonNormalized`.

Physical meaning

The bilinear BPZ pairing: $(a|b)$ is the coefficient of the two-point function of the fields of a and b with a inserted at infinity. Virasoro adjointness $L_n^\dagger = L_{-n}$ is the statement that the stress tensor is self-conjugate.

What the machine verified

Definitions.

Definition 5.49 (Full (FHL) invariance). $(Y(u,z)a|b) = (a|Y(e^{zL_1}(-z^{-2})^{L_0}u, z^{-1})b)$ for all u, a, b; in modes, for $u \in V_{\mathrm{wt}}$,

$$(u_{(n)}a|b) = (-1)^{\mathrm{wt}} \sum_{j=0}^{\mathrm{wt}} \frac{1}{j!}\big(a \,|\, (L_1^j u)_{(2\mathrm{wt}-n-2-j)}b\big). \tag{5.1}$$

File `VOA/Core/BilinearForm.lean`.

```
abbrev IsFullyInvariant (B : InvariantForm W) : Prop :=
  ∀ (wt : ℤ) (u : V), u ∈ W.grading wt → ∀ (n : ℤ) (a b : V),
    B.form (W.smul u n a) b
      = (-1 : ℂ) ^ wt • ∑ j ∈ Finset.range (wt.toNat + 1), ((j.factorial : ℂ)⁻¹) •
          B.form a (W.smul (((W.L 1) ^ j) u) (2 * wt - n - 2 - (j : ℤ)) b)
```

From the mathematics to the Lean statement

Derivation of the mode form. $(-z^{-2})^{L_0}u = (-1)^{\mathrm{wt}}z^{-2\mathrm{wt}}u$; e^{zL_1} contributes $\sum_j z^j L_1^j/j!$; $Y(v,z^{-1}) = \sum_k v_{(k)}z^{k+1}$. The total power of z is $-2\mathrm{wt}+j+k+1$, which equals $-n-1$ exactly when $k = 2\mathrm{wt}-n-2-j$. The sum stops at $j = \mathrm{wt}$ because $L_1^j u \in V_{\mathrm{wt}-j} = 0$ for $j > \mathrm{wt}$ (CFT type; `L_one_pow_eq_zero`). So the Lean term is exactly (5.1), with `(-1 : ℂ) ^ wt` $= (-1)^{\mathrm{wt}}$ (a `zpow`, harmless since only $\mathrm{wt} \geq 0$ has $u \neq 0$), `Finset.range (wt.toNat + 1)` $= \{0, \dots, \mathrm{wt}\}$ and `((W.L 1) ^ j) u` $= L_1^j u$.
Quantifiers. For each weight and each homogeneous u; general u follows by linearity. For $\mathrm{wt} < 0$ the hypothesis forces $u = 0$ and both sides vanish.
Same as FHL. This is FHL (5.2.1) / Gannon (5.1.11a) verbatim. **A documentation slip:** the docstring above `IsFullyInvariant` writes the right side as "$((L_1^j u)_{(.)}a|b)$"; the Lean term has `B.form a (W.smul … b)`, i.e. $(a|(L_1^j u)_{(.)}b)$, which is the correct formula. The statement, not the comment, is what is used. The `virasoro_adj` field is the slice $u = \omega$ (where $L_1\omega = 0$, `L1_conformal_zero`).

Physical meaning

The adjoint of the field of u is the field of the BPZ conjugate state at the inverted point. For a quasi-primary current J of weight 1 it reads $(J_n a|b) = -(a|J_{-n}b)$: the bilinear form makes J_n anti-adjoint to J_{-n}. (The positive-definite Hermitian inner product of a unitary theory is obtained by composing with an antilinear involution that sends J to $-\bar{J}$; this is why signs like $(h|h) = -k$ below are not a contradiction with unitarity.)

What the machine verified

Definition.

5.12.2 Elementary consequences

Theorem 5.50 (Orthogonality, radical, uniqueness, nondegeneracy, evaluation on V_1). *Let B be an invariant form. (i) $(V_m|V_n) = 0$ for $m \neq n$. Now let B be fully invariant. (ii) Its left radical is an ideal. (iii) If B_1, B_2 are fully invariant and normalised, $B_1 = B_2$. (iv) If V is simple and B is fully invariant and normalised, its radical is 0. (v) If B is fully invariant and normalised, $u_{(1)}v = -(u|v)\mathbf{1}$ for $u, v \in V_1$.*

File `VOA/Core/BilinearForm.lean`.

```

    (hn : B.Normalized) {u v : 𝒱} (hu : u ∈ W.grading 1) (hv : v ∈ W.grading 1) :
    W.smul u 1 v = -B.form u v • W.vacuum := by
```

From the mathematics to the Lean statement

All are the textbook statements (Gannon 5.1.11b, 5.1.12b), with these precisions. (i) needs only `virasoro_adj` at $n = 0$. (iii) is uniqueness *with normalisation*, i.e. equality, not "up to a scalar"; it needs no simplicity and no $L_1V_1 = 0$ — if two such forms exist they agree. (iv) derives nondegeneracy from simplicity; the converse is Theorem 5.57. (v) has a minus sign because of the public normalisation $(\mathbf{1}|\mathbf{1}) = 1$ and the $(-1)^{\mathrm{wt}}$ of FHL; in Gannon's normalisation it reads $u_{(1)}v = (u|v)\mathbf{1}$.

Physical meaning

(i) Energy eigenstates of different energy are orthogonal. (ii) Null states (zero overlap with everything) form a decoupled sector. (iii) Two-point functions are fixed by the OPE and the vacuum normalisation. (iv) An irreducible theory has a nondegenerate Zamolodchikov metric. (v) The double pole of two currents is their two-point function: for a free boson $h(z)h(w) \sim k/(z-w)^2$ one has $h_{(1)}h = k\mathbf{1}$ and so $(h|h) = -k$.

Proof on paper. (i) $m(a|b) = (L_0a|b) = (a|L_0b) = n(a|b)$. (ii) If $(a|\cdot) = 0$, then $(u_{(n)}a|b)$ is by (5.1) a combination of $(a|\cdots) = 0$. (iii) $D = B_1 - B_2$ is fully invariant with $(\mathbf{1}|\mathbf{1})_D = 0$; by (i) and $V_0 = \mathbb{C}\mathbf{1}$, $\mathbf{1} \in \operatorname{rad} D$; the radical is an ideal containing $\mathbf{1}$, hence V, so $D = 0$. (iv) The radical is an ideal; it is not V since $(\mathbf{1}|\mathbf{1}) = 1$. (v) Write $u = u_{(-1)}\mathbf{1}$ and apply (5.1) with $\mathrm{wt} = 1$, $n = -1$: $(u|v) = -\big((\mathbf{1}|u_{(1)}v) + (\mathbf{1}|(L_1u)_{(0)}v)\big)$; the second term vanishes since $L_1u \in \mathbb{C}\mathbf{1}$ and $\mathbf{1}_{(0)} = 0$; and $u_{(1)}v = \mu\mathbf{1}$ gives $(\mathbf{1}|u_{(1)}v) = \mu$. □

What the machine verified

Unconditional given the displayed hypotheses; `#print axioms` on `radical_isIdeal` and `invariantForm_unique`: `[propext, Classical.choice, Quot.sound]`.

Theorem 5.51 (Symmetry of the (1)-pairing on V_1). *For $u, v \in V_1$: $u_{(1)}v = v_{(1)}u$ and $u_{(0)}v + v_{(0)}u = 0$.*

File `VOA/Core/InvariantFormSymmetry.lean`.

```
theorem oneMode_symm_grading1 (W : VertexOperatorAlgebra 𝒱) {u v : 𝒱}
    (hu : u ∈ W.grading 1) (hv : v ∈ W.grading 1) :
    W.smul u 1 v = W.smul v 1 u := by

theorem zeroMode_antisymm_grading1 (W : VertexOperatorAlgebra 𝒱) {u v : 𝒱}
    (hu : u ∈ W.grading 1) (hv : v ∈ W.grading 1) :
    W.smul u 0 v + W.smul v 0 u = 0 := by
```

From the mathematics to the Lean statement

Unconditional consequences of skew-symmetry; with Theorem 5.50(v) they make every fully invariant normalised form symmetric *on* V_1. Symmetry of the whole form is a theorem of FHL (Prop. 5.3.6) and Li, but it is **not proved in the library** for any form, including the canonical one; the file's closing comment states the gap. Downstream statements never assume symmetry without saying so.

Physical meaning

The level matrix k^{ab} in $J^a(z)J^b(w) \sim k^{ab}/(z-w)^2$ is symmetric, because the double pole of a bosonic OPE is symmetric under exchange.

Proof on paper. Skew-symmetry at $n = 1$ and $n = 0$; the correction terms $T^j(v_{(1+j)}u)$ lie in $T^j V_{-j}$, which is 0 for $j \geq 1$ (or $T\mathbb{C}\mathbf{1} = 0$). □

What the machine verified

Unconditional; axiom-clean.

5.13 The canonical invariant form (FHL, Li)

5.13.1 The construction

Li's idea: if a normalised fully invariant form exists, then putting $a = \mathbf{1}$ in (5.1) shows $(x|b)$ is forced to be the vacuum coefficient of a certain mode product. One therefore *defines* the form by that formula and proves invariance.

Definition 5.52 (Vacuum coordinate and the canonical pairing)**.** Let $\varepsilon : V \to \mathbb{C}$ be the coefficient of $\mathbf{1}$ in the weight-zero component. For homogeneous $a \in V_p$ put

$$\mathrm{adjPair}_p(a,b) = (-1)^p \sum_{j=0}^{p} \frac{1}{j!}\,\varepsilon\big((L_1^j a)_{(2p-1-j)}b\big),$$

and extend to $\mathrm{canBilin}(a,b) = -\sum_p \mathrm{adjPair}_p(a_p,b)$ over the homogeneous components a_p of a.

File `VOA/Core/InvariantFormCanonical.lean`.

```
noncomputable def vacCoord (W : VertexOperatorAlgebra V) (hne : W.vacuum ≠ 0) : V →ₗ[ℂ] ℂ
 ↪  :=
  ((LinearEquiv.toSpanNonzeroSingleton ℂ V W.vacuum hne).symm.toLinearMap).comp

    V →ₗ[ℂ] (V →ₗ[ℂ] ℂ) :=
  letI : DirectSum.Decomposition W.grading := W.isInternal.chooseDecomposition
  (DirectSum.toModule ℂ ℤ (V →ₗ[ℂ] ℂ) (bSlotOfGrade W hne)).comp
    (DirectSum.decomposeLinearEquiv W.grading).toLinearMap
```

From the mathematics to the Lean statement

`grade0 W` is the projection to V_0, `grade0ToSpan` rewrites $V_0 = \mathbb{C}\mathbf{1}$, and `toSpanNonzeroSingleton … hne` identifies $\mathbb{C}\mathbf{1}$ with $\mathbb{C}$ via $c\mathbf{1} \mapsto c$, which needs $\mathbf{1} \neq 0$ (`hne`). So `vacCoord` is ε. The mode index $2p-1-j$ is $2\mathrm{wt}-n-2-j$ at $n=-1$: $\mathrm{adjPair}_p(a,b)$ is the value of the right side of (5.1) at $u=a$, $n=-1$, read against $\mathbf{1}$, i.e. "$(a_{(-1)}\mathbf{1}|b)$ if the form existed". `canBilin` glues these over the decomposition of a (`bSlotOfGrade` is the weight-p piece $-\mathrm{adjPair}_p$, `canBilin_homog`). The leading minus makes $\mathrm{canBilin}(\mathbf{1},\mathbf{1}) = -1$ (`canBilin_vacuum`), Gannon's normalisation; the public form is its negative.

Physical meaning

$(a|b)$ is read off as the vacuum component of the BPZ-conjugate of a acting on b: "$\langle 0|a^\dagger b\rangle$". The chiral two-point function is computed by bringing one operator to infinity and taking the vacuum expectation value.

What the machine verified

Definitions; axiom-clean.

Theorem 5.53 (Why $L_1V_1=0$ is needed). *For every b:* $\mathrm{canBilin}(L_{-1}\mathbf{1},b)=0$ *and* $\mathrm{canBilin}(\mathbf{1},L_1b)=-\varepsilon(L_1b)$. *Hence the $n=-1$ Virasoro adjointness of canBilin at $a=\mathbf{1}$ holds if and only if $\varepsilon(L_1b)=0$ for all b, i.e. iff $L_1V_1=0$.*

File `VOA/Core/InvariantFormCanonicalFHL.lean`.

```
theorem virSlice_vacuum (hne : W.vacuum ≠ 0) (b : V) :
    canBilin W hne (W.L (-1) W.vacuum) b = 0
      ∧ canBilin W hne W.vacuum (W.L 1 b) = - vacCoord W hne (W.L 1 b) := by
```

From the mathematics to the Lean statement

The Lean statement is the two displayed equalities; the "iff" is the one-line consequence (since L_1b has weight-zero component L_1b_1, the condition is $L_1V_1=0$, proved as `vacCoord_L1_eq_zero` in `VOA/Core/InvariantFormCanonicalVir.lean`). It is the library's certificate that the hypothesis `hqp` of Theorem 5.56 cannot be dropped for this construction. More is true on paper: *any* normalised form satisfying the $n=1$ Virasoro adjointness has $(\mathbf{1}|L_1v)=(L_{-1}\mathbf{1}|v)=0$ for $v\in V_1$, and $L_1v\in\mathbb{C}\mathbf{1}$, so $L_1V_1=0$ is necessary for the existence of a normalised invariant form at all. That converse is not stated in the library.

Physical meaning

$L_1V_1=0$ says the currents are quasi-primary. When it fails — e.g. the free boson with background charge, $T=\frac{1}{2}(\partial\phi)^2+\lambda\partial^2\phi$, where $L_1(\partial\phi)\propto\lambda\mathbf{1}$ — the vacuum is not self-conjugate: the Coulomb-gas two-point function $\langle V_\alpha V_\beta\rangle$ is nonzero only for $\alpha+\beta=2\alpha_0$, and the BPZ pairing pairs the theory with a twisted version of itself. No normalised invariant form exists then.

What the machine verified

Unconditional; axiom-clean.

5.13.2 The proof of invariance

The proof that canBilin is fully invariant under $L_1V_1 = 0$ occupies most of the `InvariantForm*` files. Mathematically it has three steps.

Step 1: reduction to the diagonal. By weight orthogonality and bilinearity it suffices to prove (5.1) for homogeneous $u \in V_{\mathrm{wt}}$, $a \in V_p$, $b \in V_q$ at the one mode $n = p + \mathrm{wt} - q - 1$ for which $u_{(n)}a \in V_q$ (all other modes give $0 = 0$). This is the predicate `CanDiagonal`.

Step 2: the quasi-primary decomposition. Under $L_1V_1 = 0$, every $a \in V_p$, $p \geq 1$, is $a_0 + L_{-1}c$ with $L_1a_0 = 0$ and $c \in V_{p-1}$ (Theorem 5.54). Both sides of (5.1) obey the same L_{-1}-covariance recursion in a (from $[L_{-1}, u_{(n)}] = -nu_{(n-1)}$ and the Virasoro adjointness $\mathrm{canBilin}(L_{-1}a, b) = \mathrm{canBilin}(a, L_1b)$, the latter proved under `hqp` as `canBilin_Lneg1_adj`), so it suffices to treat quasi-primary a, and similarly quasi-primary u.

Step 3: the quasi-primary matching identity (Li, Prop. 2.6). For quasi-primary $u \in V_w$ and $a \in V_p$, $\mathrm{canBilin}(u_{(n)}a, b) = (-1)^w \mathrm{canBilin}(a, u_{(2w-n-2)}b)$, proved by a direct computation with the vacuum coordinate: skew-symmetry shows $\varepsilon(u_{(n)}v) = \pm\varepsilon(v_{(n)}u)$ (the T-tower dies under ε), and a raising identity $(2p - M - 2)\varepsilon(a_{(M+1)}X) = -\varepsilon(a_{(M)}L_1X)$ for quasi-primary a kills low modes.

Theorem 5.54 (Quasi-primary decomposition). *If $L_1V_1 = 0$ and $p \geq 1$, every $a \in V_p$ can be written $a = a_0 + L_{-1}c$ with $a_0 \in V_p$, $L_1a_0 = 0$, $c \in V_{p-1}$.*

File `VOA/Core/QuasiPrimaryDecomp.lean`.

```
theorem qpDecomp (W : VertexOperatorAlgebra V)
    (hqp : ∀ v, v ∈ W.grading 1 → W.L 1 v = 0)

     ↪ c := by
```

From the mathematics to the Lean statement

The statement asserts existence of a decomposition (the sum $\mathcal{Q}\mathcal{P}_p + L_{-1}V_{p-1}$ is everything), not directness; directness also holds for $p \geq 2$ but is not needed. The hypothesis `hqp` is used exactly at $p = 1$, where $L_{-1}V_0 = L_{-1}\mathbb{C}\mathbf{1} = 0$ forces $V_1 = \mathcal{Q}\mathcal{P}_1$. The docstring's "$V_p = \mathcal{P}V_p \oplus L_{-1}V_{p-1}$" should be read with $\mathcal{P}$ meaning quasi-primary, not primary.

Physical meaning

Every state is a quasi-primary or a derivative: under the global conformal group SL_2 (generated by L_{-1}, L_0, L_1) each energy level decomposes into lowest-weight vectors (quasi-primaries) and their L_{-1}-descendants. Quasi-primary fields are those that transform simply under global conformal transformations, $\phi(z) \mapsto (cz + d)^{-2h}\phi(\frac{az+b}{cz+d})$.

Proof on paper. For quasi-primary $v \in V_m$, $L_1L_{-1}^{j+1}v = (j + 1)(2m + j)L_{-1}^j v$ (the $\mathfrak{sl}_2$ tower). By induction on q, every $b \in V_q$ is a finite sum $\sum_k L_{-1}^k w_k$ with $w_k \in V_{q-k}$ quasi-primary (`tower_sum_exists`): given b, $L_1b \in V_{q-1}$ has such an expansion, and one inverts L_1L_{-1} term by term (the coefficient $(k+1)(2q-k)$ vanishes only where the base vector is 0) to find c with $L_1(b - L_{-1}c) = 0$. □

What the machine verified

Conditional on hqp; `#print axioms`: `[propext, Classical.choice, Quot.sound]`.

Theorem 5.55 (The diagonal identity, unconditionally under $L_1V_1 = 0$). *If* $\mathbf{1} \neq 0$ *and* $L_1V_1 = 0$, *canBilin satisfies* (5.1) *at every matching mode.*

    (fun {_w} {_u} hu hqpu {_p} {_a} ha hqpa n b => canBilin_qp_qp_adj hne hqp hu hqpu ha
     ↪ hqpa n b)
```

From the mathematics to the Lean statement

`canRHS hne u a b wt n` is the right side of (5.1) for canBilin (same file). The one-line proof of `canDiagonal_unconditional` is shown because it is informative: it is the assembly lemma `canDiagonal_holds` fed with the two genuine inputs, Theorem 5.54 and the quasi-primary matching identity `canBilin_qp_qp_adj` (Step 3, for quasi-primary u and a, all modes). "Unconditional" in the name means "no hypothesis beyond `hne`, `hqp`".

Physical meaning

The two-point function of two quasi-primaries of weights w and p transforms covariantly under inversion; everything else follows by global conformal invariance, because descendants are derivatives of quasi-primaries.

What the machine verified

Conditional only on `hne`, `hqp`; `#print axioms` on `canDiagonal_unconditional` and `canBilin_qp_qp_adj`: `[propext, Classical.choice, Quot.sound]`.

Theorem 5.56 (FHL, Li: existence and uniqueness of the invariant form). *Let V be a VOA (of CFT type) with* $\mathbf{1} \neq 0$ *and* $L_1V_1 = 0$. *There is a fully invariant form with* $(\mathbf{1}|\mathbf{1}) = 1$; *every fully invariant normalised form equals it; it is nondegenerate if V is simple; and* $u_{(1)}v = -(u|v)\mathbf{1}$ *on* V_1.

From the mathematics to the Lean statement

Hypotheses. `hne`: $\mathbf{1} \neq 0$ (equivalently $V \neq 0$). `hqp`: $L_1 V_1 = 0$. CFT type is built into `VertexOperatorAlgebra`. `canFormFHL` is the negative of the Gannon-normalised form `canForm` built from canBilin and the Virasoro adjointness it inherits from `CanDiagonal` (the $u = \omega$ slice, using $L_1\omega = 0$).

Is the definition meaningful? `canonicalInvariantForm` is a `def`, so its existence says nothing; the content is in `_isFullyInvariant` and `_normalized`, which hold with no further hypotheses. Normalisation excludes the zero form.

Same, stronger or weaker than Li? Li (JPAA 96, 1994) proves, for a vertex operator algebra in his setting, that the space of invariant bilinear forms is linearly isomorphic to $(V_0/L_1V_1)^*$, and that every invariant form is symmetric. The library proves the case $V_0 = \mathbb{C}\mathbf{1}$, $L_1V_1 = 0$, in which $(V_0/L_1V_1)^* = \mathbb{C}$: existence and uniqueness up to the normalisation. **It does not prove** (a) the general isomorphism with $(V_0/L_1V_1)^*$ (when $L_1V_1 = \mathbb{C}\mathbf{1}$ the space of forms is 0; the library only has the necessity witness of Theorem 5.53), nor (b) symmetry of the form. So the Lean result is *weaker* than Li's theorem in these two respects and *the same* in the case it treats. Neither omission affects the uses in this book: $V^\natural$ has $V_1 = 0$, and nothing downstream depends on symmetry being proved; where it is needed (Chapter 8, `form_globalTowers_eq_zero` and `form_globalTowers_eq_zero_of_ne` in `VOA/Core/GlobalConformalTowers.lean`) it is an explicit hypothesis `hB : B.IsSymmetric`.

Physical meaning

A chiral CFT whose currents are quasi-primary has a canonical two-point function, unique once the vacuum is normalised: the BPZ metric is determined by the OPE. For $V^\natural$ ($V_1 = 0$) the condition is vacuous; for the free boson h with $T = \frac{1}{2}h^2$ it holds, and fails as soon as a background charge is turned on.

Proof on paper. Existence: Steps 1–3 above (Theorems 5.54, 5.55); the negative of canBilin has $(\mathbf{1}|\mathbf{1}) = 1$. Uniqueness, nondegeneracy, evaluation: Theorem 5.50(iii)–(v). □

What the machine verified

Conditional only on `hne`, `hqp`, which are the theorem's genuine hypotheses (and `hsimple` for nondegeneracy). `#print axioms` on all six declarations: `[propext, Classical.choice, Quot.sound]`.

Trap / dead end: Stale status lines in the intermediate files

The docstrings of `VOA/Core/InvariantFormCanonical.lean`, `…CanonicalFHL.lean`, `…CanonicalVir.lean` and `…CanonicalPStep.lean` still carry a status "(half-filled circle) bottoms out at the unproved residual" `CanVirasoroAdj`, `CanDiagonal` or `CanPStep` "(→ Li 1994)". These were the open residuals of the construction while it was being built; they are now all discharged by `canDiagonal_unconditional` (and `canVirasoroAdj_of_diagonal`), as the header of `InvariantFormFHL2.lean` states. The residual predicates remain as definitions; no theorem of this chapter depends on them as hypotheses. A referee reading those files should not conclude that Theorem 5.56 is conditional.

5.14 Li's radical theorem: simplicity is nondegeneracy

Theorem 5.57 (Li, Cor. 3.2). *Let B be a fully invariant normalised form on V. Then*

1. $\mathrm{rad}_L B = \mathfrak{m}(V) = \mathrm{rad}_R B$*;*
2. *V is simple if and only if* $\mathrm{rad}_L B = 0$*;*
3. *for homogeneous $x \in V_n$: $x \in \mathfrak{m}(V) \iff (x|y) = 0$ for all $y \in V_n$; equivalently, the weight-n part of $\mathfrak{m}(V)$ is the radical of the restriction of B to $V_n \times V_n$.*

File `VOA/Core/InvariantFormRadical.lean`.

```

    (n : ℤ) :
    LinearMap.ker (gradedForm B n) = (QuotVOA.maxGradedIdeal W).comap (W.grading n).subtype
     ↪  := by
```

From the mathematics to the Lean statement

Hypotheses. Only full invariance and normalisation of the given B. In particular no $L_1V_1 = 0$ is needed — if some such B exists the theorem applies; $\mathbf{1} \neq 0$ follows from normalisation (`vacuum_ne_zero_of_normalized`); CFT type is built in. **Notation.** `gradedForm B n` is B restricted to V_n (`compl₁₂` composes both slots with the inclusion $V_n \hookrightarrow V$); `comap` pulls the subspace $\mathfrak{m}(V)$ back along that inclusion. So `ker_gradedForm` is (3) as an equality of subspaces of V_n; `maxGradedIdeal_inf_grading` and `maxGradedIdeal_inf_grading_eq_bot_iff`

restate it as $\mathfrak{m} \cap V_n =$ image of the radical, and $\mathfrak{m} \cap V_n = 0 \iff$ the level-n form is nondegenerate. The `_canonical` corollaries (`leftRadical_canonical_eq_maxGradedIdeal`, `isSimple_iff_canonical_nondegenerate`, ...) instantiate B at Theorem 5.56, at the cost of `hne`, `hqp`.
Strength. (2) is an equivalence, strictly more than Theorem 5.50(iv). (1) includes the equality of the two radicals, a shadow of the (unproved) symmetry of B. (3) is the statement that makes simplicity *computable*: membership in the abstract supremum $\mathfrak{m}(V)$ is decided by a finite Gram matrix. **Vacuity.** The theorem is used to prove $V^\natural$ simple (Chapter 38) and is false for the square-zero impostor of that chapter, whose analogous form has the twisted sector in its radical.

Physical meaning

A chiral CFT is irreducible exactly when its Zamolodchikov metric is nondegenerate: a state with zero two-point function against every state is a null state, and null states are exactly what generates a decoupled ideal. Moreover null states can be found level by level, because the metric is block diagonal in the energy: the null states at level n are the kernel of the level-n Gram matrix. This is the Kac determinant method of Virasoro representation theory, here for an arbitrary chiral algebra.

Proof on paper. $\mathrm{rad}_L B$ is an ideal (Theorem 5.50(ii)) not containing $\mathbf{1}$, so $\mathrm{rad}_L B \subseteq \mathfrak{m}$. Conversely let I be a proper ideal. First $(\mathbf{1}|z) = 0$ for $z \in I$: the homogeneous components of z lie in I (Theorem 5.18); those of nonzero weight are orthogonal to $\mathbf{1}$, and $I \cap V_0 = 0$ by properness. Next, for homogeneous $x \in I \cap V_p$, write $x = x_{(-1)}\mathbf{1}$ and expand: $(x|b) = (-1)^p \sum_j \frac{1}{j!}(\mathbf{1}|(L_1^j x)_{(2p-1-j)}b)$. Each $L_1^j x \in I$, so $(L_1^j x)_{(m)}b \in I$ by two-sidedness (Theorem 5.17), and each term vanishes. So $I \subseteq \mathrm{rad}_L B$. The right radical is handled the same way with the slots exchanged. (2) is (1) with Theorem 5.21. (3): pairings of $x \in V_n$ with other weights vanish by orthogonality. □

What the machine verified

Conditional only on `hB`, `hn`; `#print axioms` on `leftRadical_eq_maxGradedIdeal`, `isSimple_iff_leftRadical_eq_bot`, `mem_maxGradedIdeal_iff_grading`, `leftRadical_eq_rightRadical`, `isSimple_iff_canonical_nondegenerate`: `[propext, Classical.choice, Quot.sound]`. The source records an independent validation at $c = -22/5$ (Lee–Yang): the level-4 radical is one-dimensional, matching $\dim V(-\frac{22}{5}, 0)_4 = 2$ and $\dim L(-\frac{22}{5}, 0)_4 = 1$; that check uses `Examples` files and is not part of this file.

5.15 Gram matrices: rank computes the simple quotient

Definition 5.58 (Level-n Gram matrix). For a basis (e_i) of V_n, $G_n = (B(e_i, e_j))_{i,j}$; for the canonical form, canGram.

File `VOA/Core/GradedFormMatrix.lean`.

```
noncomputable def gramMatrix (B : InvariantForm W) (n : ℤ) (e : Basis ι ℂ (W.grading n)) :
    Matrix ι ι ℂ :=
  LinearMap.BilinForm.toMatrix e (gradedForm B n)

noncomputable def canGram : Matrix ι ι ℂ := gramMatrix (canonicalInvariantForm hne hqp) n e
```

From the mathematics to the Lean statement

`Basis ι ℂ (W.grading n)` is a basis of V_n indexed by a finite type `ι` (`[Fintype ι]`); `toMatrix e` is the matrix of a bilinear form in that basis. `canGram` takes `hne`, `hqp`, `n`, `e` as section variables.

Physical meaning

The matrix of inner products of the states at energy level n — the Kac (Shapovalov) matrix of the vacuum module, computed with the BPZ form.

What the machine verified

Definitions.

Theorem 5.59 (Rank, determinant and the simple quotient). *Let B be fully invariant and normalised. Then* $\det G_n \neq 0 \iff \mathfrak{m} \cap V_n = 0$, *and* $\operatorname{rank} G_n + \dim(\mathfrak{m} \cap V_n) = \dim V_n$. *For the canonical form,* $\dim L(V)_n = \operatorname{rank} \mathrm{canGram}_n$; *if* $\det \mathrm{canGram}_n = 0$ *then* $\dim L(V)_n < \dim V_n$.

    (hdet : (canGram hne hqp n e).det = 0) :
    finrank ℂ ((QuotVOA.maxQuotientVOA W).grading n) < finrank ℂ (W.grading n) := by
```

From the mathematics to the Lean statement

`finrank ℂ X` is $\dim X$; `(QuotVOA.maxQuotientVOA W).grading n` is $L(V)_n$, which by definition (`maxQuotientVOA_grading_eq`, `rfl`) is the image of V_n in the quotient. `Matrix.rank` is the rank over $\mathbb{C}$. Finite-dimensionality of V_n is a structure field, so no finiteness hypothesis appears; the basis `e` is supplied by the caller. **Rank, not determinant.** The source stresses (and we repeat) that $\dim L(V)_n$ is the rank of the Gram matrix of *this* form; a matrix of a different form with proportional determinant has the same zero set but can have a different rank. In particular the "top-mode" Shapovalov form `RigidBridge.shapForm` of Chapter 8 agrees with `gradedForm` only up to the sign $(-1)^n$ and only on quasi-primary vectors (`gradedForm_eq_signed_shapForm_of_quasiPrimary`); at level 4 of a Virasoro VOA no basis is quasi-primary, and the two Gram determinants differ by the constant 21.

Physical meaning

The number of physical (non-null) states at level n is the rank of the Kac matrix; a zero of the Kac determinant signals that a null state appears at that level and the character of the physical theory drops there. This is how the characters of minimal models are computed.

Proof on paper. Theorem 5.57(3) identifies $\mathfrak{m} \cap V_n$ with the kernel of the restricted form, whose dimension is $\dim V_n - \operatorname{rank} G_n$; the quotient map $V_n \to L(V)_n$ is surjective with that kernel. A zero determinant means a nonzero kernel. □

What the machine verified

Conditional only on the displayed hypotheses; `#print axioms` on all four: `[propext, Classical.choice, Quot.sound]`.

Example 5.60 (Level two of the Virasoro vacuum module). In $V(c,0)$, $V_2 = \mathbb{C}\omega$ with $\omega = L_{-2}\mathbf{1}$, and $(\omega|\omega) = (\mathbf{1}|L_2L_{-2}\mathbf{1}) = (\mathbf{1}|(4L_0 + \frac{c}{2})\mathbf{1}) = \frac{c}{2}$. So $\mathrm{canGram}_2 = (c/2)$: for $c \neq 0$, $\dim L(c,0)_2 = 1$; for $c = 0$, $\dim L(0,0)_2 = 0$, consistent with Example 5.38. At level 4 the Gram matrix in the basis $L_{-4}\mathbf{1}, L_{-2}^2\mathbf{1}$ has determinant proportional to $c^2(5c+22)$, whose root $c = -\frac{22}{5}$ is the Lee–Yang model (Chapter 7).

5.16 Dead ends: four general routes to full invariance

Before the canonical construction succeeded, the project tried to prove that *every* `InvariantForm` — every Virasoro-adjoint bilinear form — is fully invariant, reducing the claim in four successive files to sharper and sharper residual predicates:

file	reduction theorem	residual hypothesis
`InvariantFormFHL`	`isFullyInvariant_of_propagation`	`hstep` (weight propagation)
`InvariantFormDiagonal`	`isFullyInvariant_of_diagonal`	`DiagonalFHL B`
`InvariantFormPStep`	`isFullyInvariant_of_pstep`	`PStep B`
`InvariantFormFHLClosure`	`isFullyInvariant_of_inputs`	`GoodBound B`, `CreationVanish B`

Files `VOA/Core/InvariantFormDiagonal.lean`, `VOA/Core/InvariantFormPStep.lean`, `VOA/Core/InvariantFormFHLClosure.lean`.

```
def DiagonalFHL (B : InvariantForm W) : Prop :=
  ∀ (wt p q : ℤ) (u a b : 𝒱), u ∈ W.grading wt → a ∈ W.grading p → b ∈ W.grading q →
    B.form (W.smul u (p + wt - q - 1) a) b = fhlRHS B u a b wt (p + wt - q - 1)

theorem isFullyInvariant_of_diagonal (B : InvariantForm W) (hdiag : DiagonalFHL B) :
    B.IsFullyInvariant :=

def PStep (B : InvariantForm W) : Prop :=
  ∀ (wt q : ℤ), 0 ≤ wt → 0 ≤ q → (∀ q' : ℤ, q' < q → DiagAt B wt q') → DiagAt B wt q

theorem isFullyInvariant_of_inputs (B : InvariantForm W) (hG : GoodBound B) (hC :
↪  CreationVanish B) :
    B.IsFullyInvariant :=
```

All four reductions are proved and axiom-clean, but the universal statements they reduce to are false.

Theorem 5.61 (Conditional delimitation). *Assume $L_1V_1 = 0$. A fully invariant form is symmetric on V_1. Hence, if some invariant form B_0 satisfies $B_0(u_0,v_0) \neq B_0(v_0,u_0)$ for some $u_0, v_0 \in V_1$, then not every invariant form is fully invariant, and none of the four residual predicates holds universally.*

File `VOA/Core/InvariantFormDelimitation.lean`.

From the mathematics to the Lean statement

The four theorems `general_fullyInvariant_not_a_theorem`, `general_diagonalFHL_not_a_theorem`, `general_pstep_not_a_theorem`, `general_fhlClosure_not_a_theorem` all take the witness `B₀`, `u₀`, `v₀`, `hasym` as hypotheses. **The library does not construct such a witness**; the files say so. The library map's phrase "four general invariant-form routes refuted" must therefore be read as "refuted conditionally". The companion `VOA/Core/InvariantFormTranspose.lean` shows that the transpose $B^{\mathsf{T}}(a,b) = B(b,a)$ of an invariant form is again one (`InvariantForm.transpose`) and that the skew-symmetry identity `form_smul_skew` holds for both, so the general toolkit cannot distinguish B from B^{T} (`no_structural_symmetry_of_antisymmetrize_ne`).

Physical meaning

Virasoro covariance alone does not fix the two-point functions of a theory with several currents: one can rotate the currents before pairing. Only covariance under the whole chiral algebra does.

Proof on paper. By (5.1) at wt $= 1$, $n = -1$, $a = \mathbf{1}$, with $L_1 u = 0$: $(u|v) = -(\mathbf{1}|u_{(1)}v)$; by Theorem 5.51, $u_{(1)}v = v_{(1)}u$. □

What the machine verified

Unconditional (`fullyInvariant_forces_v1_symm`) and conditional on an unconstructed witness (the four `…_not_a_theorem`); axiom-clean.

Trap / dead end: A witness exists on paper; do not re-attempt the general route

The missing witness is easy to give mathematically (this argument is not formalised). Let V be the rank-two Heisenberg VOA with currents h^1, h^2, $T = \frac{1}{2}((h^1)^2 + (h^2)^2)$, so $L_1 V_1 = 0$, and let B be its canonical form, with $B(h^i, h^j) = -\delta^{ij}$. The rotation g by 90° in the (h^1, h^2)-plane extends to an automorphism of V; it commutes with every L_n. Then $B_0(a,b) := B(a, gb)$ is Virasoro adjoint: $B_0(L_n a, b) = B(a, L_{-n} gb) = B(a, gL_{-n}b) = B_0(a, L_{-n}b)$. With $gh^1 = h^2$, $gh^2 = -h^1$ one gets $B_0(h^1, h^2) = B(h^1, -h^1) = 1$ but $B_0(h^2, h^1) = B(h^2, h^2) = -1$, so B_0 is not symmetric on V_1. By Theorem 5.61, the universal general-B statement is false for this V. The moral recorded by the project: *full invariance cannot be derived from Virasoro adjointness*; the canonical-form route of Section 5.13 is the only one, and the four general reductions should not be revived.

5.17 Machine verification for this chapter

For this book (when the chapter was first written, at an earlier commit; not re-run for this edition) we ran `#print axioms` on seventy-one declarations of the chapter's files, from a scratch file importing the relevant modules of the built tree, with

```
export PATH="$HOME/.elan/bin:$PATH"
lake env lean -DmaxSynthPendingDepth=3 Axioms.lean
```

(the flag avoids the audit trap of Section 43.1.6: a bare `lake env lean` drops `maxSynthPendingDepth`). Every one reported exactly

```
depends on axioms: [propext, Classical.choice, Quot.sound]
```

including `instLieAlgebraGradingOne`, `inner`, `isExpInner_conj`, `expFun_smul`, `quotientVOA`, `isGradedIdeal_of_isIdeal`, `isSimple_maxQuotientVOA'`, `ker_eq_maxGradedIdeal`, `screeningKernel`, `screening_conformalVector`, `ker_eq_maxGradedIdeal_of_screeningKernel`, `generated`, `tensorSVA`, `not_isSimple_of_stronglySingular_FHL`, `not_isSimple_of_shapovalov_FHL`, `BRSTComplex.cohomology`, `cohomologyNearVOA`, `canonicalInvariantForm_isFullyInvariant`, `invariantForm_unique_FHL`, `qpDecomp`, `canBilin_qp_qp_adj`, `leftRadical_eq_maxGradedIdeal`, `isSimple_iff_leftRadical_eq_bot`, `finrank_maxQuotient_grading`, `general_fullyInvariant_not_a_theorem`. The PBW theorem `VOA.pbw` appears nowhere. We did *not* re-run the aggregate `lake build`. The two Lean checks quoted in the warning on p. 214 and Remark 5.15 were compiled the same way in a separate scratch file and are not part of the library.

Release audit 2026-10-27. `Notes/Textbook/referee/RELEASE_AUDIT_FOUNDATIONS.md`. Its findings bearing on this chapter: `VertexOperatorAlgebra` is the LL/FLM VOA of CFT type, so every result here (the Lie algebra V_1, quotients, simplicity, the FHL–Li invariant form) is a result about VOAs of CFT type; the zero space is a VOA, so the nonvanishing hypotheses $\mathbf{1} \neq 0$ in this chapter are needed; the Borcherds identity used in the proofs is a theorem for `VertexOperatorAlgebra`, not for `PreVertexAlgebra`.

5.18 Referee's checklist

All entries are `#print axioms`-clean (standard axioms only, no `VOA.pbw`).

Lean declaration	Intended meaning	Hypotheses / status	Check
`zeroMode_isDerivation`	$u_{(0)}$ is a derivation of every product	none; unconditional	Thm. 5.2
`instLieAlgebraGradingOne`	V_1 is a Lie algebra, $[u,v] = u_{(0)}v$	none; unconditional	Thm. 5.4
`griessMul_comm_of_grading1_eq_bot`	Griess product commutative	$V_1 = 0$	Def. 5.7
`Aut`, `Group (Aut W)`	automorphism group	definition	Def. 5.9
`Aut.map_grading`	$\alpha(V_n) \subseteq V_n$	none; unconditional	Thm. 5.10
`VOASubalgebra`, `VOASubalgebra.toVOA`, `toVOA_centralCharge`	graded subspace containing $\mathbf{1}, \omega$, closed under products; it is a VOA of the same central charge	definition; $\omega \in S$ required; unconditional	Def. 5.24, Thm. 5.25
`expFun_smul`	e^D of a derivation is a homomorphism	D loc. nilpotent, Leibniz	Thm. 5.12
`inner`	$\exp(u_{(0)}) \in \mathrm{Aut}$	$u_{(0)}$ loc. nilp.; `homega` redundant	Def. 5.13, Rem. 5.15
`isExpInner_conj`, `aut_conj_expFun`	$\alpha e^{u_{(0)}} \alpha^{-1} = e^{(\alpha u)_{(0)}}$	none (former redundant `hαu` removed)	Thm. 5.14
`Inn`, `Inn_normal`	inner automorphisms normal	**normal by construction**; weak predicate	p. 214
`IsIdeal`, `IsSimple`	ideal, simple VOA	left ideals = two-sided	Def. 5.16
`absorbsLeft_of_isIdeal`	ideals are two-sided	none	Thm. 5.17
`isGradedIdeal_of_isIdeal`	ideals are graded	none	Thm. 5.18
`quotientVOA`, `quotientVOA'`	V/I is a VOA	I ideal; properness not assumed	Def. 5.19

Lean declaration	Intended meaning	Hypotheses / status	Check
`maxGradedIdeal`, `isSimple_maxQuotientVOA'`	$V/\mathfrak{m}$ is simple	$\mathbf{1} \neq 0$	Thm. 5.21
`IsVOAHom`	homomorphism	ω not required to be preserved	Def. 5.22
`IsVOAHom.ker_eq_maxGradedIdeal`	surjection onto simple has kernel $\mathfrak{m}$	surjective, target simple	Thm. 5.23
`VOASubalgebra.generated`	subalgebra generated by S	**always contains** ω	Def. 5.26
`screening_isDerivation`, `screeningKernel`	$\ker a_{(0)}$ is a subVOA	$a \in V_1$ (no primarity)	Thm. 5.29, Def. 5.30
`Screening.ker_eq_maxGradedIdeal_of_screeningKernel`	screening-kernel image is $L(V)$	image $= \ker Q_a$, kernel simple	Thm. 5.32
`superScreeningKernel`	super analogue	Leibniz, $Q\omega = 0$ **assumed**	Rem. 5.33
`IsSingularOfWeight`, `IsStronglySingularOfWeight`	singular vectors	$s \neq 0$, weight > 0	Def. 5.34
`not_isSimple_of_stronglySingular_FHL`	strongly singular $\Rightarrow$ not simple	$\mathbf{1} \neq 0$, $L_1V_1 = 0$	Thm. 5.37
`not_isSimple_of_shapovalov_FHL`	singular + Shapovalov $\Rightarrow$ not simple	same + pairing condition	Thm. 5.37
`tensorSVA`	tensor product of vertex superalgebras	`ParityCompatible`, `TensorGradingHyp`; **no** ω	Thm. 5.41, p. 232
`BRSTComplex.cohomology`	$\ker Q/\operatorname{im} Q$ is a vertex superalgebra	a `BRSTComplex`; nontriviality not claimed	Thm. 5.46
`cohomologyNearVOA`	conformal structure descends	$Q\omega = 0$	Thm. 5.47
`InvariantForm`, `IsFullyInvariant`	Virasoro-adjoint form; FHL invariance	**two layers**; check which is assumed	Defs. 5.48, 5.49
`invariantForm_unique`	normalised fully invariant forms coincide	none	Thm. 5.50
`qpDecomp`	$V_p = \mathcal{Q}\mathcal{P}_p + L_{-1}V_{p-1}$	$L_1V_1 = 0$	Thm. 5.54
`canonicalInvariantForm (+ _ isFullyInvariant, _normalized)`	FHL/Li canonical form exists	$\mathbf{1} \neq 0$, $L_1V_1 = 0$; symmetry **not proved**	Thm. 5.56
`invariantForm_unique_FHL`	uniqueness	same	Thm. 5.56
`virSlice_vacuum`	$L_1V_1 = 0$ is necessary	none	Thm. 5.53
`LiRadical.leftRadical_eq_maxGradedIdeal`	radical $= \mathfrak{m}(V)$	B fully inv., normalised	Thm. 5.57
`LiRadical.isSimple_iff_leftRadical_eq_bot`	simple $\iff$ nondegenerate	same	Thm. 5.57
`LiRadical.mem_maxGradedIdeal_iff_grading`	level-n criterion	same	Thm. 5.57
`GramMat.finrank_maxQuotient_grading`	$\dim L(V)_n = \operatorname{rank} \mathrm{canGram}_n$	$\mathbf{1} \neq 0$, $L_1V_1 = 0$, basis	Thm. 5.59
`general_fullyInvariant_not_a_theorem`	general route false	**conditional on unconstructed witness**	Thm. 5.61, p. 249

5.19 Notes and references

The invariant bilinear form and its mode formula are due to I. B. Frenkel, Y.-Z. Huang and J. Lepowsky, *On axiomatic approaches to vertex operator algebras and modules*, Memoirs of the American Mathematical Society 104 (1993), no. 494 (Section 5.2 for contragredient modules and invariant

forms, Prop. 5.3.6 for symmetry, Section 3 for tensor products). The existence-and-uniqueness theorem, the identification of the space of invariant forms with $(V_0/L_1V_1)^*$, and the corollary relating the radical to the maximal ideal are in H.-S. Li, *Symmetric invariant bilinear forms on vertex operator algebras*, Journal of Pure and Applied Algebra 96 (1994) 279–297. The library's docstrings cite these, and the textbook account of T. Gannon, *Moonshine beyond the Monster*, Cambridge University Press (2006), §5.1.3 and §5.2.1, for the conventions (equations (5.1.11)–(5.1.12), (5.2.1)–(5.2.4)).

General structure theory (ideals, quotients, simplicity, the V_1 Lie algebra, skew-symmetry) follows J. Lepowsky and H. Li, *Introduction to Vertex Operator Algebras and Their Representations*, Progress in Mathematics 227, Birkhäuser (2004), Chapter 3; I. Frenkel, J. Lepowsky and A. Meurman, *Vertex Operator Algebras and the Monster*, Academic Press (1988); and V. Kac, *Vertex Algebras for Beginners*, 2nd ed., University Lecture Series 10, AMS (1998), §4.3 for tensor products. The automorphism groups and inner automorphisms of VOAs, and the role of V_1, are discussed in C. Dong and G. Mason, *Rational vertex operator algebras and the effective central charge*, International Mathematics Research Notices 2004, and in Dong–Mason's work on the structure of V_1 (*Integrability of C_2-cofinite vertex operator algebras*, IMRN 2006), where V_1 is shown to be reductive under rationality assumptions — a result the library does not formalise.

Screening operators and free-field realisations: B. Feigin and D. Fuchs, *Representations of the Virasoro algebra*, in Representations of Lie groups and related topics, Gordon and Breach (1990); Vl. S. Dotsenko and V. A. Fateev, Nuclear Physics B 240 (1984) 312; D. Adamović, *Realizations of simple affine vertex algebras and their modules: the cases $\widehat{sl(2)}$ and $\widehat{osp(1,2)}$*, Communications in Mathematical Physics 366 (2019) 1025–1067. BRST cohomology and the Drinfeld–Sokolov reduction: B. Feigin and E. Frenkel, *Quantization of the Drinfeld–Sokolov reduction*, Physics Letters B 246 (1990) 75–81; V. Kac, S.-S. Roan and M. Wakimoto, *Quantum reduction for affine superalgebras*, Communications in Mathematical Physics 241 (2003) 307–342 (arXiv:math-ph/0302015); E. Frenkel and D. Ben-Zvi, *Vertex Algebras and Algebraic Curves*, 2nd ed., Mathematical Surveys and Monographs 88, AMS (2004), Chapter 15. The physical picture of the BPZ pairing is that of A. A. Belavin, A. M. Polyakov and A. B. Zamolodchikov, Nuclear Physics B 241 (1984) 333–380, and of P. Di Francesco, P. Mathieu and D. Sénéchal, *Conformal Field Theory*, Springer (1997), Chapters 6–7. The singular-vector criterion through invariant forms and the Gram-rank formula are the library's own packaging of these classical facts; the Kac determinant itself is the subject of Chapter 7.

Part II

Examples, deformations and rigidity

Chapter 6

Heisenberg and lattice vertex algebras in the library

This chapter documents the release of the LeanVOA library named in the front matter. Every Lean quotation below is checked by `scripts/textbook/sync.py` to occur verbatim (up to whitespace and comments) in the source files of that release. Checks that were run at an earlier state of the library and not re-run for this edition are marked as such. The chapter covers the files assigned to it in `Notes/Textbook/assignment.txt`: the rank-one Heisenberg files `VOA/Examples/Heisenberg*.lean`, the rank-r files `VOA/Examples/HeisenbergN*.lean`, the lattice files `VOA/Examples/Lattice*.lean` and `VOA/Examples/LatticeGen*.lean` (but not the super-lattice files `LatticeSuper*`, which belong to Chapter 17), the two Fock base-change files `VOA/Examples/Fock*.lean`, and `VOA/Examples/FreeBosonGeneralC.lean`. In total these are 76 files. We also present the *trivial* vertex operator algebra, which the library defines as the lattice vertex operator algebra of the rank-zero lattice; its file `VOA/Examples/ZhuInstantiation.lean` and the three `Trivial*.lean` files are assigned to Chapter 15, where the trivial algebra was the first non-vacuity witness of Zhu's modularity theorem, but its definition is a lattice construction and belongs here. Nontrivial instances are now proved as well: `zhuModularity_V2m` (the rank-one lattice VOA $V_{\sqrt{2m}\mathbb{Z}}$, every $m \geq 1$) and `zhuModularity_V2mPlus` (its $\mathbb{Z}_2$-orbifold, $m \geq 2$) (Chapters 15 and 22).

Relation to Chapter 31. The Moonshine part of the book already contains a long chapter on Heisenberg and lattice vertex operator algebras (Chapter 31). That chapter is written for the Leech lattice: it develops the rank-r Fock space `HeisenbergN.FockN`, the FLM cocycle, the orthonormal frame, the vertex operators $Y(e^{\alpha}, z)$, their locality, the reconstruction theorem and the general instance `LatGen.latticeVOAGen`, and then specialises to Λ. We do *not* repeat that material. Where a statement of this chapter uses one of those objects we recall it in a sentence and point to the exact definition or theorem of Chapter 31. What is new here is everything that Chapter 31 did not need:

- the *rank-one Heisenberg vertex operator algebra at an arbitrary nonzero level k*, `heisenbergVOA`, which is a separate implementation on a separate type (Section 6.3);
- the theorem that this algebra is *not C_2-cofinite*, `heisenberg_not_C2Cofinite`, the library's basic example of an irrational vertex operator algebra (Section 6.4);
- the Heisenberg instance of the "PBW boundary" of Zhu's bijection, `heisenbergAdjointBottomProjection` (Section 6.5);
- the *free boson with background charge*, a family of vertex operator algebra structures on the same Fock space with central charge $1 - 12\lambda^2$, realising every complex central charge (Section 6.6);

- a fidelity analysis of the general lattice theorem: which lattices are allowed, what the central charge and the grading are, and the rank-zero case (Section 6.7);
- the older, independent construction of the A_1 lattice vertex operator algebra `latticeVOA_A1`, which predates the general one, together with two *placeholder* declarations in the same files that a referee must not mistake for theorems (Section 6.8);
- the *charge-zero subalgebra* `chargeZeroSubVOA` of a lattice vertex operator algebra and the resulting Heisenberg-module structure on V_L (Section 6.9);
- background-charge deformations of the conformal vector of V_L, and the $\mathbb{Q}$-valued gradings they require (Section 6.10);
- the open "Li conjugation identity" for spectral flow on the Fock space (Section 6.11).

Trust summary. Every headline of this chapter was re-checked for this book with `#print axioms` (Section 6.13); each reports exactly `[propext, Classical.choice, Quot.sound]`, Lean's three standard axioms. In particular `VOA.pbw` (the PBW theorem of Chapter 3; formerly a project axiom, now a theorem) is **not** used anywhere in this chapter, not even by the "PBW" instance of Section 6.5, which was written to be `pbw`-free while `VOA.pbw` was still an axiom. The only hypotheses of the headline constructions are the natural ones: $k \neq 0$ for the Heisenberg algebra, and evenness plus positive-definiteness for a lattice. Every "vertex operator algebra" in these headlines is an instance of the library's `VertexOperatorAlgebra`, which is the Lepowsky–Li/FLM VOA *of CFT type* ($V_0 = \mathbb{C}\mathbf{1}$, $V_n = 0$ for $n < 0$, integer grading, finite-dimensional pieces), a restriction relative to FLM/LL (Definition 4.4); for $M(1)$ and V_L (L even, positive definite) CFT type holds, so nothing is lost. The release audit of 2026-10-27 judged `heisenbergVOA` and `LatGen.latticeVOAGen` **genuine**: every structure field is filled by a proved theorem, the carriers are the standard ones ($M(1) =$ `MvPolynomial ℕ ℂ`, and $M(1)^{\otimes r} \otimes \mathbb{C}[L]$ with the FLM cocycle), and the only hypotheses are $k \neq 0$, respectively evenness and `PosDef` over $\mathbb{Z}$ (for an integral form equivalent to positive definiteness over $\mathbb{R}$). One statement of the chapter is *open*: the proposition `LiConjugation` of Section 6.11 is defined but not proved.

Prerequisites. We use the definitions of Chapters 2–5: formal distributions and the mode convention `mode f n = f (-n-1)` (Definition 2.7), locality (Definition 2.41), fields (Definition 2.43), the normal-ordered product `nprod` (Chapter 4), the library's structures `PreVertexAlgebra` (graded VA1–VA5 data without translation covariance, *not* a vertex algebra in the standard sense; the library's translation-covariant notion is `VertexAlgebra`) and `VertexOperatorAlgebra` (VOAs, of CFT type by definition) (Definitions 4.1 and 4.4), Goddard's uniqueness theorem (Theorem 4.14), Dong's lemma (Theorem 4.16), weak modules (Definition 12.1) and vertex operator subalgebras (Definition 5.24). We recall each one briefly where it is used.

6.1 The physical picture

6.1.1 One free boson

The simplest two-dimensional conformal field theory is a single massless scalar field $X(z, \bar{z})$ with action $\frac{1}{4\pi} \int \partial X \bar{\partial} X$ (in one common normalisation). Its equation of motion $\partial\bar{\partial}X = 0$ says that ∂X is holomorphic: the *current* $J(z) = i\partial X(z)$ depends on z only, and it is a chiral field of conformal weight one. All the holomorphic ("chiral") information of the theory is encoded in the operator product expansion

$$J(z)J(w) \sim \frac{k}{(z-w)^2}, \tag{6.1}$$

where k is a normalisation constant, the *level*. Expanding $J(z) = \sum_n a_n z^{-n-1}$, the OPE (6.1) is equivalent to the commutation relations

$$[a_m, a_n] = m\,k\,\delta_{m+n,0} \qquad (m, n \in \mathbb{Z}), \tag{6.2}$$

which define the *Heisenberg Lie algebra* (with its central element set to the scalar k). For $n > 0$ the operators a_{-n} create and a_n annihilate a quantum of energy n; a_0 is the momentum and commutes with everything. The space of states of zero momentum built from the vacuum $\mathbf{1}$ (annihilated by all a_n, $n \geq 0$) is the *Fock space*

$$\mathcal{F} = \mathbb{C}[a_{-1}, a_{-2}, a_{-3}, \ldots]\,\mathbf{1},$$

a polynomial ring in infinitely many variables. It carries a vertex operator algebra structure, the *Heisenberg vertex operator algebra* $M(1)$ (or $\mathcal{V}(\hat{\mathfrak{h}}, k)$ in Gannon's notation): the field of $a_{-1}\mathbf{1}$ is $J(z)$, the field of a monomial is a normal-ordered product of derivatives of J, and the stress tensor is the Sugawara field

$$T(z) = \frac{1}{2k} :J(z)J(z):, \qquad c = 1. \tag{6.3}$$

The central charge is 1 for every $k \neq 0$: T is quadratic in J, so rescaling J rescales $1/k$ and leaves T unchanged. The level is therefore a normalisation, not a parameter of the theory; the library nevertheless keeps k as an explicit argument, because some later constructions (the A_1 lattice of Section 6.8) use $k = 2$.

6.1.2 The non-compact boson has a continuum of sectors

If X takes values in $\mathbb{R}$ (the "non-compact" boson) then every real momentum p is allowed. The Heisenberg algebra then has, besides the vacuum module $\mathcal{F} = \mathcal{F}_0$, one irreducible module $\mathcal{F}_p$ for every $p \in \mathbb{C}$, on which a_0 acts by p; its lowest state e^p has conformal weight $p^2/(2k)$. There are uncountably many inequivalent sectors, so the free boson is the prototype of an *irrational* conformal field theory. Algebraically this shows up as the failure of C_2*-cofiniteness*: the Poisson algebra $A_2(M(1)) = M(1)/O_2(M(1))$ is a polynomial ring $\mathbb{C}[x]$, the coordinate ring of the line of momenta, which is infinite-dimensional (Section 6.4). C_2-cofiniteness is the algebraic substitute for "finitely many sectors"; Zhu's modularity theorem (Chapter 15) needs it.

6.1.3 Compactification and lattices

If instead X lives on a torus $\mathbb{R}^r/2\pi\Gamma$, momenta are quantised, and the chiral algebra of the theory is enlarged by the vertex operators $:e^{i\alpha\cdot X}:$ for α in a lattice L of allowed chiral momenta. The resulting *lattice vertex operator algebra* V_L has state space $\mathcal{F}^{\otimes r} \otimes \mathbb{C}[L]$, and the state e^α has conformal weight $\frac{1}{2}\langle\alpha,\alpha\rangle$. For this to be a (bosonic, integer-graded) vertex operator algebra one needs L *even*; for the weights to be bounded below with finite multiplicities one needs L *positive-definite*. These are exactly the hypotheses of the library's general theorem (Section 6.7). The central charge stays $r = \operatorname{rank} L$: compactification adds states and fields but does not change the stress tensor.

The simplest compact example is $L = A_1 = \mathbb{Z}\alpha$ with $\langle\alpha,\alpha\rangle = 2$: one boson at the self-dual radius. Its weight-one space is spanned by $a_{-1}\mathbf{1}$, e^α and $e^{-\alpha}$, three currents that close into the affine Lie algebra $\widehat{\mathfrak{sl}_2}$ at level one (Frenkel–Kac). Thus V_{A_1} is the chiral algebra of the $SU(2)$ level-one Wess–Zumino–Witten model; this is the classical example of an *enhanced symmetry point* of a compactification. (The identification $V_{A_1} \cong L_{\widehat{\mathfrak{sl}_2}}(1,0)$ is mathematics the library does *not* formalise; see Section 6.8.)

6.1.4 Background charge

Finally, one may keep the free-boson vertex algebra but change the stress tensor:

$$T_\lambda(z) = \frac{1}{2} :J(z)^2: + \mu\,\partial J(z) \qquad (k = 1). \tag{6.4}$$

The extra term is a total derivative, so T_λ still generates translations (L_{-1} is unchanged), and on the zero-momentum Fock space L_0 is unchanged too. But the central charge moves: the double contraction of $\mu\partial J$ with itself contributes $-12\mu^2$, so $c = 1 - 12\mu^2$. In the library's sign convention $\mu = -\lambda$ and $c = 1 - 12\lambda^2$. This is the *Coulomb gas* or *Feigin–Fuchs* free field, physically a boson coupled to background curvature (the *linear dilaton*); with real λ one gets $c < 1$ (the free-field realisation of the Virasoro minimal models, Dotsenko–Fateev), with imaginary λ one gets $c > 1$ (the linear dilaton of non-critical string theory). In the normalisation in which the background charge α_0 is the coefficient of ∂J one writes $c = 1 - 12\alpha_0^2$; the Dotsenko–Fateev normalisation $T = -\frac{1}{4}(\partial\varphi)^2 + i\alpha_0\partial^2\varphi$ gives $c = 1 - 24\alpha_0^2$ instead. These are the same family with α_0 rescaled by $\sqrt{2}$.

6.2 The files and the two implementations

The library contains *two* independent implementations of the Heisenberg vertex operator algebra and *two* independent implementations of lattice vertex operator algebras. A referee must keep them apart, because they live on different Lean types and no isomorphism between them is proved.

Object	Lean name / type	Files and remarks
rank-one Heisenberg, level k	`VOA.heisenbergVOA k hk` on `VOA.Fock = MvPolynomial ℕ ℂ`	`HeisenbergFock`, `HeisenbergVertex`, `HeisenbergVirasoro`, `HeisenbergCentral`, `HeisenbergCreation`, `HeisenbergGrading`, `HeisenbergStructure`, `HeisenbergConformal`, `HeisenbergVOA`. This chapter.
rank-r Heisenberg, level k	`VOA.HeisenbergN.heisenbergNVOA r k hk` on `FockN r = MvPolynomial (ℕ × Fin r) ℂ`	`HeisenbergN*`. Chapter 31, Theorem 31.8; the alias `heisenbergVOA' n` (level 1) is in `Heisenberg.lean`.
general even lattice	`VOA.LatGen.latticeVOAGen L hEven hPos` on `LatModuleGen L`	`LatticeGen*`, `LatticeGeneralLocality`. Chapter 31, Theorem 31.27; fidelity in Section 6.7.
A_1 lattice	`VOA.LatExp.latticeVOA_A1` on `LatticeVOA.LatModule`	`LatticeA1`, `LatticeExp`, `LatticeFields`, `LatticeChargeM*`, `Lattice*Locality*`, `LatticeVOAInstance`, `LatticeA1VOA`, `Lattice.lean`. Section 6.8.
charge-zero subalgebra	`VOA.LatGen.chargeZeroSubVOA`	`LatticeCharge`. Section 6.9.
free boson, background charge	`VOA.FBgc.freeBosonVOA lam` on `VOA.Fock`	`FreeBosonGeneralC`. Section 6.6.
lattice background charge	`VOA.LatGen.BgA.LBg`, `VOA.LatGen.BgB.LBG`	`LatticeBackgroundChargeA`, `LatticeBackgroundChargeB`, `LatticeQuadRefine`. Section 6.10.
non-C_2-cofiniteness	`VOA.heisenberg_not_C2Cofinite`	`HeisenbergC2`. Section 6.4.
PBW boundary	`VOA.VHat.DLM3.heisenbergAdjointBoundaryPBWEtc`	`HeisenbergPBWEtcBoundary`. Section 6.5.
spectral flow (open)	`VOA.Heisenberg.LiConjugation`	`FockBaseChange`, `FockBC2`. Section 6.11.

The historical reason for the duplication is that the rank-one Heisenberg algebra and the A_1 lattice were the project's first test cases ("Phase 3" in the source comments), built before the general machinery existed. The general constructions (rank r, arbitrary even lattice) were then written by "lifting" the rank-one proofs; the rank-one files were kept because other parts of the library (the Virasoro chapter, Chapter 7; the $\mathfrak{sl}_2$ chapters; the C_2 theory) refer to them. Nothing in the library

identifies `heisenbergVOA 1 _` with `heisenbergNVOA 1 1 _`, nor `latticeVOA_A1` with `latticeVOAGen` of a rank-one lattice with Gram matrix (2); on paper both identifications are obvious (rename the polynomial variables), and nothing depends on them.

6.3 The rank-one Heisenberg vertex operator algebra at level k

All declarations of this section live in the namespace `VOA` and in the files `VOA/Examples/HeisenbergFock.lean` through `VOA/Examples/HeisenbergVOA.lean`. The construction is the rank-one, level-k version of the rank-r construction of Chapter 31, Section 31.3; we present it in full because it is the object on which the C_2 theorem, the PBW instance, the background-charge family and several Virasoro results of Chapter 7 are stated.

6.3.1 The Fock space and the oscillators

Definition 6.1 (Fock space, oscillators, vacuum)**.** Let $\mathcal{F} = \mathbb{C}[X_0, X_1, X_2, \dots]$ be the polynomial ring in countably many variables. The variable X_i stands for the state $a_{-(i+1)}\mathbf{1}$. For $k \in \mathbb{C}$ and $n \in \mathbb{Z}$ define $a_n =$ `osc k n` $\in \operatorname{End}\mathcal{F}$ by

$$a_n = \begin{cases} \text{multiplication by } X_{-n-1}, & n < 0, \\ 0, & n = 0, \\ n\,k\,\dfrac{\partial}{\partial X_{n-1}}, & n > 0, \end{cases}$$

and let the vacuum be $\mathbf{1} = 1$, the constant polynomial.

File `VOA/Examples/HeisenbergFock.lean`.

```
abbrev Fock : Type := MvPolynomial ℕ ℂ

noncomputable def mulX (i : ℕ) : Fock →ₗ[ℂ] Fock :=

  else if 0 < n then (n : ℂ) • k • pderivLM (n - 1).toNat
  else 0

noncomputable def vacuum : Fock := (1 : Fock)
```

From the mathematics to the Lean statement

Decoding. `MvPolynomial ℕ ℂ` is Mathlib's ring of complex polynomials in variables indexed by the natural numbers; `X i` is the variable X_i. `abbrev` makes `Fock` a transparent synonym, so all of Mathlib's polynomial API applies. `Fock →ₗ[ℂ] Fock` is the type of $\mathbb{C}$-linear endomorphisms. `LinearMap.mul ℂ Fock (X i)` is left multiplication by X_i (the composition with `LinearMap.id` is cosmetic). `pderiv i` is Mathlib's partial derivative $\partial/\partial X_i$, a derivation, turned into a linear map. `(-n - 1).toNat` converts the integer $-n-1$ to a natural number; in the branch $n < 0$ it is non-negative, so no truncation occurs. In the branch $n > 0$, `(n - 1).toNat` $= n - 1$. The scalar is $n \cdot k$.

Same as the textbook? Yes, with one presentational difference: the textbook defines $\mathcal{F}$ as the module induced from the one-dimensional representation of the non-negative part of the

Heisenberg algebra, and *proves* (by Poincaré–Birkhoff–Witt) that it is a polynomial ring. The library *defines* $\mathcal{F}$ to be the polynomial ring and then proves that the operators a_n satisfy the Heisenberg relations (Theorem 6.2) and that $\mathbf{1}$ is annihilated by a_n, $n \geq 0$. For $k \neq 0$ these two facts characterise the induced module up to isomorphism, so nothing is lost, and no PBW theorem is needed (this is why the Heisenberg algebra never needed `VOA.pbw`).

The zero mode is zero by definition. The third branch makes $a_0 = 0$. This is correct for the *vacuum* module (zero momentum), and it is a load-bearing fact later: it is why the background charge does not move L_0 (Section 6.6) and why charged modules need a separate construction (Section 6.11). It also means that `Fock` can never be used as a model of a charged Fock module $\mathcal{F}_p$, $p \neq 0$.

The level. No hypothesis is placed on k; at $k = 0$ all annihilators vanish and the definition still makes sense (but the vertex operator algebra will need $k \neq 0$).

Physical meaning

$\mathcal{F}$ is the space of finite-energy states of one chiral free boson at zero momentum. The variable X_i is one quantum in the oscillator mode of energy $i+1$, a monomial is a multi-particle state, and the constant 1 is the SL_2-invariant vacuum. The operators a_n are the Laurent modes of the current $J = i\partial X$: for $n < 0$ they create a quantum (multiplication), for $n > 0$ they annihilate one (a derivative, weighted so that the canonical commutator comes out as nk), and a_0 is the momentum, which vanishes on this sector.

What the machine verified

Definitions; no proof obligations. `HeisenbergFock.lean` records `#print axioms = [propext, Classical.choice, Quot.sound]` for all of its declarations.

Theorem 6.2 (Heisenberg relations; vacuum). *For all $k \in \mathbb{C}$ and $m, n \in \mathbb{Z}$, $[a_m, a_n] = m\,k\,\delta_{m+n,0}\,\mathrm{id}_{\mathcal{F}}$. Moreover $a_n\mathbf{1} = 0$ for every $n \geq 0$.*

File `VOA/Examples/HeisenbergFock.lean`.

```
theorem osc_comm (k : ℂ) (m n : ℤ) :
    osc k m * osc k n - osc k n * osc k m
      = (if m + n = 0 then (m : ℂ) * k else 0) • LinearMap.id

theorem osc_vacuum (k : ℂ) (n : ℤ) (hn : 0 ≤ n) : osc k n vacuum = 0
```

From the mathematics to the Lean statement

In `Module.End ℂ Fock` the product `*` is composition, so the left side is the commutator $a_m a_n - a_n a_m$. The right side is the scalar mk if $m + n = 0$ and 0 otherwise, times the identity. This is (6.2) exactly; it is quantified over all integers, zero modes included. Note that when $m + n = 0$ the scalar is mk, which is 0 for $m = 0$, as it must be.

Proof on paper. This is the rank-one case of Chapter 31, Theorem 31.3, and the proof is the same case analysis. Two creation operators are multiplications, which commute; two annihilators are multiples of partial derivatives, which commute; a zero mode is 0. In all these cases $m + n \neq 0$ or $m = 0$, so the right side vanishes too. If $m < 0 < n$, then a_m is multiplication by X_{-m-1} and a_n is $nk\,\partial/\partial X_{n-1}$; these commute unless $-m - 1 = n - 1$, i.e. $m + n = 0$, and then $[X, \partial_X] = -1$ gives $[a_m, a_n] = -nk = mk$. The case $m > 0 > n$ is symmetric. The vacuum statement holds because $a_0 = 0$ and the derivative of a constant is zero. □

Physical meaning

These are the canonical commutation relations of an infinite family of harmonic oscillators, one per positive mode number, equivalently the current–current OPE (6.1). The vacuum condition says that **1** is the ground state: it is annihilated by every lowering operator and has zero momentum.

What the machine verified

Proved, unconditional (no hypothesis on k). `#print axioms VOA.osc_comm` = `[propext, Classical.choice, Quot.sound]`, re-checked for this book.

6.3.2 The current and its locality

Definition 6.3 (The current). The basic current is the formal distribution $\alpha(z) = \sum_{n\in\mathbb{Z}} a_n z^{-n-1}$. In the library's indexing by powers of z, its z^j-coefficient is a_{-j-1}.

File `VOA/Examples/HeisenbergFock.lean`.

```
noncomputable def current (k : ℂ) : FormalDist (Module.End ℂ Fock) := fun j => osc k (-j -
↪ 1)

theorem current_mode (k : ℂ) (m : ℤ) : mode (current k) m = osc k m

theorem bracketDist_current_eq_deltaDeriv (k : ℂ) :
    bracketDist (current k) (current k) = deltaDeriv 1 (opeCoeff k)

theorem current_local (k : ℂ) : Local (current k) (current k)
```

From the mathematics to the Lean statement

`FormalDist (Module.End ℂ Fock)` is the type of two-sided formal series $\sum_{j\in\mathbb{Z}} f_j z^j$ with coefficients in $\mathrm{End}\,\mathcal{F}$, stored as the function $j \mapsto f_j$ (Chapter 2, Definition 2.1). `mode f m` is f_{-m-1}, the coefficient of z^{-m-1} (Definition 2.7); so `current_mode` says that the m-th mode of $\alpha(z)$ in the vertex-algebra sense is the oscillator a_m, which pins the index convention down. `bracketDist` is the commutator $[\alpha(z_1), \alpha(z_2)]$ as a two-variable distribution; `deltaDeriv 1 c` is $c(z_2)\,\partial_{z_2}\delta(z_1/z_2)$ and `opeCoeff k` is the constant distribution $k\cdot\mathrm{id}$. So the third statement is the identity $[\alpha(z_1), \alpha(z_2)] = k\,\partial_{z_2}\delta(z_1 - z_2)$, the algebraic form of (6.1). `Local a b` is mutual locality, $(z_1 - z_2)^N [a(z_1), b(z_2)] = 0$ for some N (Definition 2.41); here $N = 2$ works.

Physical meaning

$\alpha(z)$ is the chiral current $J(z) = i\partial X(z)$. Its self-commutator is a derivative of a delta function, which is the statement that the only singularity of $J(z)J(w)$ is the double pole $k/(z-w)^2$, with a c-number coefficient. Locality with $N = 2$ is the order of that pole.

What the machine verified

Proved, unconditional, axiom-clean (`HeisenbergFock.lean`).

6.3.3 The conformal-weight grading

Definition 6.4 (Weight spaces). Give X_i the weight $i + 1$. For $w \in \mathbb{N}$ let $\mathcal{F}_w$ be the span of the monomials $\prod_i X_i^{e_i}$ of total weight $\sum_i (i+1)e_i = w$. For $n \in \mathbb{Z}$ put $\mathcal{F}_{(n)} = \mathcal{F}_n$ if $n \geq 0$ and $\mathcal{F}_{(n)} = 0$ if $n < 0$.

Files `VOA/Examples/HeisenbergFock.lean` and `VOA/Examples/HeisenbergGrading.lean`.

```
def weightFn : ℕ → ℕ := fun i => i + 1

def gradingW (w : ℕ) : Submodule ℂ Fock :=
  weightedHomogeneousSubmodule ℂ weightFn w

noncomputable def gradingZ (n : ℤ) : Submodule ℂ Fock :=
  if 0 ≤ n then gradingW n.toNat else ⊥
```

From the mathematics to the Lean statement

`weightedHomogeneousSubmodule ℂ weightFn w` is Mathlib's subspace of polynomials all of whose monomials have weighted degree w, where the variable X_i has weight `weightFn i` $= i+1$. A `Submodule ℂ Fock` is a complex linear subspace, and `⊥` is the zero subspace. The $\mathbb{Z}$-indexed version is needed because the library's `PreVertexAlgebra` is $\mathbb{Z}$-graded (Definition 4.1).

Physical meaning

The weight of X_i is the energy $i+1$ of the mode $a_{-(i+1)}$, so $\mathcal{F}_w$ is the space of states of energy w (the eigenvalue of L_0, proved below). Its dimension is the number of partitions of w, and the graded dimension is $\prod_{n\geq 1}(1-q^n)^{-1} = q^{1/24}/\eta(\tau)$, the partition function of one chiral boson at zero momentum.

Theorem 6.5 (Graded structure of CFT type). *$\mathcal{F} = \bigoplus_{n\in\mathbb{Z}} \mathcal{F}_{(n)}$; each $\mathcal{F}_{(n)}$ is finite-dimensional; $\mathcal{F}_{(0)} = \mathbb{C}\mathbf{1}$; and $\mathcal{F}_{(n)} = 0$ for $n < 0$.*

File `VOA/Examples/HeisenbergStructure.lean`.

```
theorem gradingZ_isInternal : DirectSum.IsInternal gradingZ :=
  DirectSum.isInternal_submodule_of_iSupIndep_of_iSup_eq_top

theorem gradingZ_finrank (n : ℤ) : FiniteDimensional ℂ (gradingZ n)

theorem gradingZ_zero_eq_span_vacuum : gradingZ 0 = ℂ • vacuum

theorem gradingZ_positivity (n : ℤ) (hn : n < 0) : gradingZ n = ⊥ := gradingZ_of_neg hn
```

From the mathematics to the Lean statement

`DirectSum.IsInternal g` says that the canonical map $\bigoplus_n g_n \to \mathcal{F}$ is a linear isomorphism, i.e. $\mathcal{F}$ is the internal direct sum of the g_n. `FiniteDimensional ℂ S` is finite-dimensionality of the subspace S. `ℂ • vacuum` is the line spanned by the vacuum. These four statements are exactly the grading fields `isInternal`, `finrank`, `vacuum_grade`, `positivity` of Definitions 4.1 and 4.4.

Proof on paper. Mathlib provides the decomposition of a polynomial ring into weighted-homogeneous components; adding zero pieces in negative degree does not affect independence or spanning. A monomial of weight w only involves variables X_i with $i+1 \leq w$ and exponents $\leq w$, so there are finitely many of them. A monomial of weight 0 is the constant monomial. □

Physical meaning

These are the requirements that the spectrum of the chiral theory be discrete, with finite degeneracies, bounded below, and with a unique vacuum: the conditions under which characters $\mathrm{Tr}\, q^{L_0 - c/24}$ make sense.

What the machine verified

Proved, unconditional, axiom-clean (`HeisenbergStructure.lean`).

6.3.4 The vertex operators

Definition 6.6 (Vertex operators of the rank-one Fock space). For $i \in \mathbb{N}$ put $g_i(z) = \frac{1}{i!}\partial_z^i \alpha(z)$. For a list $l = [i_1, \dots, i_s]$ define the right-nested normal-ordered product

$$Y_l(z) = {:}g_{i_1}(z){:}\,{:}g_{i_2}(z){:}\cdots{:}g_{i_s}(z)\,\mathrm{id}{:}\cdots{:}, \qquad Y_{[\,]} = \mathrm{id}.$$

For a monomial $X^e = \prod_i X_i^{e_i}$ let $l(e)$ be the list in which each i occurs e_i times, in increasing order, and define $Y(X^e, z) = Y_{l(e)}(z)$; extend Y linearly to all of $\mathcal{F}$.

File `VOA/Examples/HeisenbergVertex.lean`.

```

noncomputable def Ymon (k : ℂ) (a : ℕ →₀ ℕ) : FormalDist (End ℂ Fock) :=
  Yword k (monoWord a)

noncomputable def Y (k : ℂ) : Fock →ₗ[ℂ] FormalDist (End ℂ Fock) :=
  Finsupp.linearCombination ℂ (Ymon k)
```

From the mathematics to the Lean statement

Decoding. `deriv^[j]` is the j-fold iterate of the formal derivative ∂_z; `i.factorial` is $i!$. `{ f // IsField f }` is the type of pairs (distribution, proof that it is a field), needed because `nprod` (the normal-ordered product ${:}a(z)b(z){:}$ of Chapter 4) is only defined for fields; the recursion carries the proof along. `idField` is the identity field $\mathrm{id} \cdot z^0$. An exponent vector `a : ℕ →₀ ℕ` is a finitely supported function, i.e. a monomial; `a.support.sort (· ≤ ·)` lists the variables that occur in increasing order, and `List.replicate (a i) i` repeats i as often as its exponent. Mathlib stores a polynomial as a finitely supported function from exponent vectors to coefficients, so `Finsupp.linearCombination ℂ (Ymon k)` is the linear map $\sum_e c_e X^e \mapsto \sum_e c_e\, Y_{l(e)}$.

Is this the right Y? Two features could worry a referee. (i) The *order* of the factors: the rank-one implementation sorts the variables, so Y is a deterministic function; in the rank-r implementation of Chapter 31 the order is the unspecified order of `Finset.toList`. In both cases the order is irrelevant on paper, because the g_i are mutually local with scalar commutators, so nested normal-ordered products of them commute. (ii) Whether Y is "the" vertex operator at all: this is settled by the theorems below. `Y_creation` shows $Y(u,z)\mathbf{1}|_{z=0} = u$

for every u, and `Y_local` shows that all $Y(u,z)$ are mutually local; by Goddard's uniqueness theorem (Theorem 4.14) these two properties determine $Y(u,z)$ uniquely. So no other choice could satisfy the axioms.

Physical meaning

This is the free-field rule for local operators: the operator creating $a_{-i_1-1}\cdots a_{-i_s-1}\mathbf{1}$ from the vacuum is the normal-ordered product $:\partial^{i_1}J\cdots\partial^{i_s}J:$, divided by the factorials. Normal ordering (annihilators to the right) is the standard way to make a product of free fields at the same point finite; Wick's theorem then computes all OPEs.

Theorem 6.7 (The axioms VA1–VA5 of the library's `PreVertexAlgebra`). *For every $k\in\mathbb{C}$: $Y(\mathbf{1},z)=\mathrm{id}$; $Y(a_{-1}\mathbf{1},z)=\alpha(z)$; for every u, $u_{(-1)}\mathbf{1}=u$ and $u_{(n)}\mathbf{1}=0$ for $n\geq 0$; any two $Y(u,z)$, $Y(v,z)$ are mutually local; for all u,v there is N with $u_{(n)}v=0$ for $n\geq N$; and if $u\in\mathcal{F}_{(p)}$, $v\in\mathcal{F}_{(q)}$ then $u_{(n)}v\in\mathcal{F}_{(p+q-n-1)}$.*

Files `VOA/Examples/HeisenbergVertex.lean`, `VOA/Examples/HeisenbergCreation.lean`, `VOA/Examples/HeisenbergStructure` `VOA/Examples/HeisenbergGrading.lean`.

```

theorem va1_grading_mode (kk : ℂ) {k ℓ : ℤ} (u : Fock) (hu : u ∈ gradingZ k)
    (v : Fock) (hv : v ∈ gradingZ ℓ) (n : ℤ) :
    mode (Y kk u) n v ∈ gradingZ (k + ℓ - n - 1)
```

From the mathematics to the Lean statement

`mode (Y k u) n v` is $u_{(n)}v$. In `va1_grading_mode` the level is renamed `kk` because `k` is used for a weight; the statement is VA1 of Definition 4.1. None of these theorems assumes $k\neq 0$: the axioms VA1–VA5 of `PreVertexAlgebra` hold at every level, including $k=0$ (where the algebra is commutative). Only the conformal structure needs $k\neq 0$. These five axioms do *not* include translation covariance (Chapter 4, Section 4.5), so by themselves they do not certify a vertex algebra in the standard sense; translation covariance is the field `translation` of the VOA of Theorem 6.10, proved for $k\neq 0$.

Proof on paper. *Vacuum and current.* The vacuum is the empty monomial, whose word is empty, so $Y(\mathbf{1},z)$ is the identity field; $a_{-1}\mathbf{1}=X_0$ has word $[0]$ and $g_0=\alpha$. *Creation.* Each $g_i(z)$ has the property that its coefficients of negative powers of z kill the vacuum, and its z^0-coefficient on $\mathbf{1}$ is $\frac{1}{i!}\cdot i!\,a_{-i-1}\mathbf{1}=X_i$. For a normal-ordered product $:a(z)b(z):$ in which a has this property and $b(z)\mathbf{1}$ is regular, the product applied to the vacuum is regular with constant term $a_{(-1)}(b_{(-1)}\mathbf{1})$; induction along the word gives $Y(X^e,z)\mathbf{1}=X^e+O(z)$. *Locality.* The currents g_i are mutually local (derivatives of a self-local field are mutually local). By Dong's lemma (Theorem 4.16), if a,b,c are pairwise local then $:ab:$ is local with c; iterating along the words shows all Y_l are pairwise local, and locality is bilinear. *Regularity* is the field property of $Y(u,z)$ applied to v. *Grading.* g_i shifts the weight of a

state by $i+1$ in the appropriate sense (it is a "graded field of weight $i+1$"), normal-ordered products of graded fields are graded with additive weights, and the weight of the word of X^e equals the weight of X^e. □

Physical meaning

Together these statements say that the free-boson local operators form a consistent operator algebra: the identity operator corresponds to the vacuum, J is the field of the one-particle state, each state is created from the vacuum by its own field, OPEs have poles of finite order, and OPE coefficients respect scaling dimensions.

What the machine verified

Proved, unconditional, axiom-clean. The six statements are packaged as the `PreVertexAlgebra` `heisVA` of Theorem 6.10. As a Lean statement `heisVA` certifies only the weak structure (no translation covariance; release audit 2026-10-27, finding M-1); for $k \neq 0$ it underlies the genuine VOA `heisenbergVOA`, so it is mathematically a vertex algebra, but the Lean statement says less.

6.3.5 The Sugawara conformal vector

Definition 6.8 (Sugawara field and conformal vector). For $k \neq 0$ put $T(z) = \frac{1}{2k}{:}\alpha(z)\alpha(z){:} = \sum_m L_m z^{-m-2}$, i.e. $L_m = \frac{1}{2k}\sum_j {:}a_{m-j}a_j{:}$, and $\omega = \frac{1}{2k}a_{-1}a_{-1}\mathbf{1} = \frac{1}{2k}X_0^2$.

File `VOA/Examples/HeisenbergVirasoro.lean`.

```
noncomputable def sugawaraField (k : ℂ) : FormalDist (End ℂ Fock) :=
  (1 / (2 * k)) • nprod (isField_current k) (isField_current k)

noncomputable def Lvir (k : ℂ) (m : ℤ) : End ℂ Fock :=
  (1 / (2 * k)) • nprod (isField_current k) (isField_current k) (-m - 2)

noncomputable def ω (k : ℂ) : Fock := (1 / (2 * k)) • osc k (-1) (osc k (-1) vacuum)
```

From the mathematics to the Lean statement

The field ${:}\alpha\alpha{:}$ has conformal weight 2, so its coefficient of z^{-m-2} is the mode L_m (up to the factor); `nprod … (-m - 2)` is that coefficient. In Lean, $1/(2k)$ is defined for $k = 0$ as 0 (division by zero is zero in Mathlib), so the definitions make sense for all k but are meaningful only for $k \neq 0$; every theorem about them assumes `hk : k ≠ 0`.

Physical meaning

T is the stress tensor of the free boson, the Sugawara construction for the abelian current algebra. The conformal vector is the state $T(z)\mathbf{1}|_{z=0} = L_{-2}\mathbf{1}$ (library lemma `Lvir_neg_two_vacuum`).

Theorem 6.9 (Virasoro relations with $c = 1$). *Let $k \neq 0$. Then $[L_m, a_n] = -n\,a_{m+n}$ and $[L_m, L_n] = (m-n)L_{m+n} + \delta_{m+n,0}\frac{m^3-m}{12}\mathrm{id}$ for all $m, n \in \mathbb{Z}$; and $L_2\omega = \frac{1}{2}\mathbf{1}$.*

Files `VOA/Examples/HeisenbergVirasoro.lean`, `VOA/Examples/HeisenbergCentral.lean`.

```
theorem L_comm_osc (k : ℂ) (hk : k ≠ 0) (m n : ℤ) :
    Lvir k m * osc k n - osc k n * Lvir k m = (-(n : ℂ)) • osc k (m + n)
```

```
theorem L_two_omega (k : ℂ) (hk : k ≠ 0) :
    Lvir k 2 (ω k) = ((1 : ℂ) / 2) • vacuum

theorem L_virasoro (k : ℂ) (hk : k ≠ 0) (m n : ℤ) :
    Lvir k m * Lvir k n - Lvir k n * Lvir k m
      = ((m : ℂ) - n) • Lvir k (m + n)
        + (if m + n = 0 then ((m : ℂ)^3 - m) / 12 else 0) • (LinearMap.id : End ℂ Fock)
```

From the mathematics to the Lean statement

The central term is $\frac{m^3-m}{12}$ with no factor c, i.e. $c = 1$. `L_two_omega` is the standard way to read off the central charge: $[L_2, L_{-2}]\mathbf{1} = \frac{c}{2}\mathbf{1}$ and $L_{-2}\mathbf{1} = \omega$. The level k enters only through `hk`: the statements are the same for all nonzero k.

Proof on paper. $[L_m, a_n]$: commute a_n through each quadratic term $:a_{m-j}a_j:$ using (6.2); only the two terms with $j = -n$ or $m-j = -n$ contribute, each giving $-\frac{n}{2}a_{m+n}$. For $[L_m, L_n]$, apply $[L_m, \cdot]$ to the defining sum of L_n using the first relation; the result is $(m-n)L_{m+n}$ up to the cost of re-normal-ordering, which is a finite "window" sum of scalars; evaluating it with the power sums $\sum i = \frac{N(N-1)}{2}$ and $\sum i^2 = \frac{N(N-1)(2N-1)}{6}$ gives $\frac{m^3-m}{12}\delta_{m+n,0}$. Finally $L_2(a_{-1}a_{-1}\mathbf{1}) = \frac{1}{2k}a_1a_1a_{-1}a_{-1}\mathbf{1} = \frac{1}{2k}\cdot 2k^2\mathbf{1}$, so $L_2\omega = \frac{1}{2k}\cdot\frac{1}{2k}\cdot 2k^2\mathbf{1} = \frac{1}{2}\mathbf{1}$. □

Physical meaning

$[L_m, a_n] = -na_{m+n}$ says that J is a primary field of weight one. The central term is the conformal anomaly of one free boson, $c = 1$, coming from the double Wick contraction in $T(z)T(w)$. It is independent of the normalisation k of the current, as it must be, since c counts degrees of freedom.

What the machine verified

Proved, conditional only on $k \neq 0$. `#print axioms VOA.L_virasoro` = `[propext, Classical.choice, Quot.sound]`.

6.3.6 The vertex operator algebra

Theorem 6.10 (The Heisenberg vertex operator algebra at level k). *For every $k \in \mathbb{C}\setminus\{0\}$, $(\mathcal{F}, Y, \mathbf{1}, \omega)$ with the grading $(\mathcal{F}_{(n)})_{n\in\mathbb{Z}}$ is a vertex operator algebra of CFT type with central charge* 1.

File `VOA/Examples/HeisenbergVOA.lean`.

From the mathematics to the Lean statement

Every field is a theorem. To write down a term of type `VertexOperatorAlgebra Fock`, Lean demands a value for every field of the structure of Definition 4.4, including the proof fields. The quoted definitions fill each one with a named theorem: the grading fields with Theorem 6.5, the vertex algebra axioms with Theorem 6.7, `virasoro` with `conf_virasoro` (which is `L_virasoro` transported through the identification $\omega_{(m+1)} = L_m$, library lemma `Lvir_eq_mode_Y_omega`), `L0_grading` with `conf_L0_grading` (L_0 acts on $\mathcal{F}_{(n)}$ by n), and `translation` with `conf_translation` ($Y(L_{-1}v, z) = \partial_z Y(v, z)$). The vertex-algebra hypothesis `_hk` of `heisVA` is unused (the underscore says so); it is there only so that `heisVA k hk` and `heisenbergVOA k hk` take the same arguments.

The central charge. `heisenberg_central_charge` is proved by `rfl`: it reads off the field `centralCharge := 1`. This is *not* circular, because the field `virasoro` must be proved with that same value; a wrong value would make the structure impossible to build. In addition `L_two_omega` computes $c/2 = \frac{1}{2}$ directly.

How the statement could have been weaker. A vertex operator algebra in this library is of CFT type, so the theorem includes $V_0 = \mathbb{C}\mathbf{1}$ and $V_n = 0$ for $n < 0$; these are true of $M(1)$. The level is any nonzero complex number; nothing requires $k = 1$ or k real. The theorem does *not* say that the algebras for different k are isomorphic (they are, via $X_i \mapsto \sqrt{k'/k}\, X_i$ on paper), nor that `heisenbergVOA 1 _` is isomorphic to `heisenbergNVOA 1 1 _` of Chapter 31 (it is, by renaming variables). It also does not assert simplicity of $M(1)$, which is true (for $k \neq 0$ the Fock space is irreducible under the Heisenberg algebra) but not stated in these files.

Could it be vacuous? No: the carrier is the infinite-dimensional polynomial ring, $\omega \neq 0$ for $k \neq 0$, and $L_2\omega = \frac{1}{2}\mathbf{1} \neq 0$.

Proof on paper. All fields except `translation` are the theorems listed above. Translation, $Y(L_{-1}v, z) = \partial_z Y(v, z)$, is proved by Goddard's uniqueness theorem: both sides are fields local with every $Y(b, z)$, and they agree on the vacuum. The latter is shown by an induction over the powers of z, using that every $Y(v, z)$ is L_{-1}-covariant, $[L_{-1}, Y(v, z)] = \partial_z Y(v, z)$ (`Y_DCovariant`). That covariance holds for the current (it is the case $m = -1$ of $[L_m, a_n] = -na_{m+n}$), is preserved by derivatives, and is preserved by normal-ordered products by the Leibniz rule $\partial{:}ab{:} = {:}(\partial a)b{:} + {:}a\,\partial b{:}$. □

Physical meaning

This is the statement that the chiral free boson is a consistent chiral conformal field theory with $c = 1$: a space of states, a vacuum, local fields for every state, a stress tensor generating the conformal symmetry, and a grading by energy. Its character is $\operatorname{Tr} q^{L_0 - 1/24} = 1/\eta(\tau)$. Because it has a continuum of irreducible modules (Section 6.4), it is the basic example of an irrational vertex operator algebra.

What the machine verified

Proved, conditional only on $k \neq 0$. `#print axioms VOA.heisenbergVOA` = [propext, Classical.choice, Quot.sound], re-checked for this book; `VOA.pbw` is not used.

Definition 6.11 (The rank-n alias at level one). `heisenbergVOA' n` is the rank-n Heisenberg vertex operator algebra of Chapter 31, Theorem 31.8, at level $k = 1$; its central charge is n.

File `VOA/Examples/Heisenberg.lean`.

```
noncomputable def heisenbergVOA' (n : ℕ) : VertexOperatorAlgebra (HeisenbergN.FockN n) :=
  HeisenbergN.heisenbergNVOA n 1 one_ne_zero

theorem heisenbergVOA'_centralCharge (n : ℕ) :
    (heisenbergVOA' n).centralCharge = (n : ℂ) := rfl
```

From the mathematics to the Lean statement

`one_ne_zero` is the proof that $1 \neq 0$, discharging the level hypothesis. The carrier is `FockN n` = `MvPolynomial (ℕ × Fin n) ℂ`, a *different type* from `Fock`; in particular `heisenbergVOA' 1` and `heisenbergVOA 1 _` are different Lean objects with no isomorphism proved between them.

Physical meaning

n independent free bosons, the oscillator part of a string on an n-torus; the central charges add.

What the machine verified

Definition by alias; axiom-clean.

6.4 The free boson is not C_2-cofinite

6.4.1 C_2-cofiniteness

Definition 6.12 (O_2, A_2, C_2-cofiniteness; Zhu). For a vertex operator algebra V let $O_2(V)$ be the linear span of all $u_{(-2)}v$, $u, v \in V$, and $A_2(V) = V/O_2(V)$. V is *C_2-cofinite* if $A_2(V)$ is finite-dimensional.

File `VOA/Modules/C2Cofinite.lean`.

```
def O₂ (W : VertexOperatorAlgebra 𝒱) : Submodule ℂ 𝒱 :=
  Submodule.span ℂ {x | ∃ u v : 𝒱, x = W.smul u (-2) v}

abbrev A₂ (W : VertexOperatorAlgebra 𝒱) : Type u := 𝒱 ⧸ O₂ W

def mk₂ (W : VertexOperatorAlgebra 𝒱) : 𝒱 →ₗ[ℂ] A₂ W := (O₂ W).mkQ

def C2Cofinite (W : VertexOperatorAlgebra 𝒱) : Prop := FiniteDimensional ℂ (A₂ W)
```

From the mathematics to the Lean statement

`W.smul u (-2) v` is $u_{(-2)}v$ (Definition 4.1). `Submodule.span ℂ S` is the linear span; `𝒱 ⧸ O₂ W` is the quotient vector space and `mkQ` the quotient map. The definition is Zhu's (and Gannon's Definition 5.3.5) verbatim. This notion is developed in Chapter 12; here we only need the definition.

Physical meaning

$A_2(V)$ is the "classical limit" of the chiral algebra: in it, all derivatives of fields are set to zero, and what remains is a commutative Poisson algebra, the ring of functions on the *associated variety* of V. C_2-cofiniteness says this variety is a point (finitely many states survive). It is the algebraic avatar of having finitely many sectors: C_2-cofiniteness alone gives finitely many irreducible modules, and for rational C_2-cofinite V their characters span a representation of $SL_2(\mathbb{Z})$ (Zhu). Rationality is needed: for the C_2-cofinite but irrational triplet algebras $\mathcal{W}(p)$ the ordinary characters do not close under $SL_2(\mathbb{Z})$, and pseudo-traces must be added. The library's forms of Zhu's theorem accordingly assume C_2-cofiniteness together with a rationality hypothesis: `zhuModularity_canonical_of_C2Cofinite_admissiblyRational` (`C2Cofinite W` and `AdmissiblyRational W`) and `zhuModularity_stronglyRational` (`StronglyRational W`), Chapter 15.

6.4.2 The theorem

Theorem 6.13 (Zhu; Gaberdiel–Neitzke). *For every $k \neq 0$ the Heisenberg vertex operator algebra $M(1) =$ `heisenbergVOA k hk` is not C_2-cofinite. More precisely, the classes of $X_0^n = (a_{-1})^n\mathbf{1}$, $n \in \mathbb{N}$, are linearly independent in $A_2(M(1))$.*

File `VOA/Examples/HeisenbergC2.lean`.

```
theorem constantCoeff_smul_neg_two_eq_zero (k : ℂ) (hk : k ≠ 0) (u v : Fock) :

theorem coeff_single0_eq_zero_of_mem_O₂ (k : ℂ) (hk : k ≠ 0) (n : ℕ) {p : Fock}
    (hp : p ∈ O₂ (heisenbergVOA k hk)) :
    MvPolynomial.coeff (Finsupp.single 0 n) p = 0

theorem heisenberg_A2_tower_linearIndependent (k : ℂ) (hk : k ≠ 0) :
    LinearIndependent ℂ (fun n : ℕ => mk₂ (heisenbergVOA k hk) ((X 0 : Fock) ^ n))

theorem heisenberg_not_C2Cofinite (k : ℂ) (hk : k ≠ 0) :
    ¬ C2Cofinite (heisenbergVOA k hk)
```

From the mathematics to the Lean statement

Decoding. `MvPolynomial.constantCoeff p` is the constant term of p, an algebra map $\mathcal{F} \to \mathbb{C}$ (the *augmentation* ε). `Finsupp.single 0 n` is the exponent vector of X_0^n, so `MvPolynomial.coeff (Finsupp.single 0 n) p` is the coefficient of X_0^n in p. `LinearIndependent ℂ f` says the family $f : \mathbb{N} \to A_2$ is linearly independent (every finite linear relation is trivial). `¬` is negation.

Strength. The headline is the negation of Definition 6.12 for the Heisenberg algebra at every nonzero level; the intermediate statement `heisenberg_A2_tower_linearIndependent` is stronger (it exhibits an explicit infinite independent family). The full description $A_2(M(1)) \cong \mathbb{C}[x]$ (the images of X_0^n *span* as well) is not stated in the library, and neither is the corresponding fact for Zhu's algebra $A(M(1)) \cong \mathbb{C}[x]$; only the lower bound needed for the negation is proved.

Could it be vacuous? A theorem of the form $\neg P(V)$ is only interesting if V is the intended object. Here V is the algebra of Theorem 6.10, and `C2Cofinite` is used positively elsewhere in the library (for example the trivial algebra of Section 6.7.4 is proved C_2-cofinite in `ZhuInstantiation.lean`), so the predicate is not identically false.

Proof on paper. Step 1: $O_2 \subseteq \ker \varepsilon$. Let u, v be monomials, of weights p and q. By VA1, $u_{(-2)}v$ has weight $p + q + 1 \geq 1$, so it is a combination of non-constant monomials and its constant term vanishes. By bilinearity $\varepsilon(u_{(-2)}v) = 0$ for all u, v, and $\ker \varepsilon$ is a subspace, so $O_2 \subseteq \ker \varepsilon$. In particular $\mathbf{1} \notin O_2$ since $\varepsilon(1) = 1$.

Step 2: a_1 preserves O_2. The mode a_1 is $(a_{-1}\mathbf{1})_{(1)}$, and the commutator formula (Theorem 4.21) gives $[a_1, v_{(-2)}] = (a_0 v)_{(-1)} + (a_1 v)_{(-2)} = (a_1 v)_{(-2)}$ because $a_0 = 0$ on $\mathcal{F}$. Hence $a_1(v_{(-2)}w) = (a_1 v)_{(-2)}w + v_{(-2)}(a_1 w) \in O_2$. Since $a_1 = k\,\partial/\partial X_0$ and $k \neq 0$, $\partial/\partial X_0$ preserves O_2 too.

Step 3: the X_0^n-coefficient vanishes on O_2. For any polynomial p, the constant term of $(\partial/\partial X_0)^n p$ is $n!$ times the coefficient of X_0^n in p. If $p \in O_2$ then $(\partial/\partial X_0)^n p \in O_2 \subseteq \ker \varepsilon$ by Steps 1–2, so that coefficient is 0.

Step 4: independence. If $\sum_n \ell_n [X_0^n] = 0$ in A_2, then $q = \sum_n \ell_n X_0^n \in O_2$, and by Step 3 every coefficient ℓ_m of q vanishes. An infinite linearly independent family cannot live in a finite-dimensional space, which contradicts `C2Cofinite`. □

Physical meaning

The surviving classes $[(a_{-1})^n\mathbf{1}]$ are the classical functions x^n of the zero mode of the boson, the coordinate on the (non-compact) target line. Physically the theorem says that the free boson on $\mathbb{R}$ has a continuous spectrum of sectors: for every momentum p there is a module $\mathcal{F}_p$ of lowest weight $p^2/2k$, and Zhu's correspondence identifies the lowest-weight data with points of a line. Compactifying (Section 6.7) discretises the momenta and restores finiteness: lattice vertex operator algebras of positive-definite even lattices are C_2-cofinite (proved in the library as `latticeVOAGen_c2Cofinite`, in `VOA/Classification/COne/LatticeC2.lean`, Chapter 22).

What the machine verified

Proved, conditional only on $k \neq 0$. `#print axioms VOA.heisenberg_not_C2Cofinite` = `[propext, Classical.choice, Quot.sound]`, re-checked for this book.

6.5 The Heisenberg instance of the PBW boundary

This section concerns one file, `VOA/Examples/HeisenbergPBWFreeness.lean`, whose role is entirely internal to the library's proof of Zhu's bijection (Chapter 13). We explain just enough of that context to state what is proved and, more importantly, what is *not*.

6.5.1 Context

Zhu's theorem identifies irreducible modules of a vertex operator algebra W with irreducible modules of its Zhu algebra $A(W)$. The hard direction starts from an $A(W)$-module U and constructs a W-module whose lowest-weight space is U. Following Dong–Li–Mason, the library forms an induced ("generalized Verma") module $M(U) = \mathcal{U}(\hat{W}) \otimes_{\mathcal{U}(P)} U$, where $\hat{W}$ is the Lie algebra of modes of W and P a parabolic subalgebra, and it needs the *bottom map* $u \mapsto [1 \otimes u]$ to be injective and to admit a projection back. In the classical setting this follows from the Poincaré–Birkhoff–Witt theorem, which the library now proves in the relative form needed (`VOA.pbw`, a formerly a project axiom, now a theorem; Chapter 3, Section 3.10.6). While it was an axiom, every `pbw`-dependent result had an axiom-free twin taking the needed conclusion as an explicit hypothesis, a `BottomProjection`; those twins remain in the library, with that hypothesis now always dischargeable (Chapter 3, Section 3.2).

Definition 6.14 (Bottom projection; PBW freeness)**.** Let P be a parabolic representation on a vector space U (in the case used below: an $A(W)$-module viewed as a representation of the degree-zero modes), $M(U)$ the induced module and $\iota : U \to M(U)$ the bottom map. A *bottom projection* is a

linear map $\pi : M(U) \to U$ with $\pi \circ \iota = \mathrm{id}_U$ that vanishes on every level of $M(U)$ other than the bottom one. *PBW freeness* means that ι is injective and the levels of $M(U)$ are independent.

Files `VOA/Modules/ZhuVermaAnArchDLM3Survival.lean`, `VOA/Modules/ZhuVermaAnArchDLM3PBWSplit.lean`.

```
structure BottomProjection (P : ParabolicRep W n U) where
  proj : IndMod P →ₗ[ℂ] U
  proj_bottom : ∀ u : U, proj (indBottom P u) = u
  proj_levCover : ∀ ⦃k : ℤ⦄, k ≠ (n : ℤ) → ∀ ⦃z : IndMod P⦄, z ∈ levCover P k → proj z = 0

structure PBWFreeness (P : ParabolicRep W n U) : Prop where
  bottom_injective : Function.Injective (indBottom P)
  levels_iSupIndep : iSupIndep (levCover P)
```

From the mathematics to the Lean statement

`IndMod P` is the induced module $M_n(U)$, `indBottom P` the bottom map ι, and `levCover P k` the level-k part of $M_n(U)$ (spanned by $[y \otimes u]$ with y of degree $k-n$ in the universal enveloping algebra). `iSupIndep` is independence of a family of subspaces (each meets the sum of the others in 0). These objects are defined and studied in Chapter 13; for this chapter the only point is that `BottomProjection` is *data* (a map with two properties) and `PBWFreeness` a *proposition*. A bottom projection forces `indBottom` to be injective (`BottomProjection.indBottom_injective`).

Physical meaning

The induced module is the chiral-algebra analogue of a Verma module: one takes a space of ground states and acts freely with all energy-raising modes. The bottom projection projects onto the ground states. Its existence says that the ground states are not destroyed by the construction, i.e. that the "Verma module" really has the prescribed ground states, which is what physicists assume tacitly when they build a representation from its highest-weight space.

6.5.2 The Heisenberg instance

Theorem 6.15 (A nonzero Heisenberg instance). *Let $k \neq 0$, $W = M(1)$ the Heisenberg algebra at level k, and $U = W_0 = \mathbb{C}\mathbf{1}$ its weight-zero subspace, viewed as a module for Zhu's algebra. Then the induced module of U has a bottom projection and is PBW-free; the vacuum is a nonzero vector of U and its image in the induced module is nonzero.*

Files `VOA/Examples/HeisenbergPBWFreeness.lean` and `VOA/Modules/ZhuVermaAnArchDLM3AdjointBottom.lean`.

```
def adjointPBWFreeness (W : VertexOperatorAlgebra 𝒱) :

        (parabolicRepOfAMod (heisenbergVOA k hk) (adjointBottomAMod (heisenbergVOA k hk)))
        (heisenbergAdjointBottomVacuum k hk) ≠ 0
```

From the mathematics to the Lean statement

What the Heisenberg declarations are. The first two quoted declarations hold for *every* vertex operator algebra W: `adjointBottomAMod W` is the weight-zero subspace of the adjoint module, made into an $A(W)$-module, and `parabolicRepOfAMod` turns it into a parabolic representation. The Heisenberg declarations are their specialisations to $W = M(1)$; a Lean check made for this book (not part of this release) confirms that `heisenbergAdjointBottomProjection k hk` is *definitionally equal* to `adjointBottomProjection (heisenbergVOA k hk)`. The only genuinely Heisenberg-specific content is the pair of non-vanishing theorems: the bottom space contains the nonzero vector `vacuum` (the polynomial 1), and its image in the induced module is nonzero. These guard against the instance being satisfied on a zero carrier.
What is not claimed. The module docstring is explicit and we repeat it: this is a *satisfiability* witness for the abstract structures, *not* a discharge of the hypothesis that the downstream Zhu bijection needs. That hypothesis concerns the *regular* module `regularAMod W`, not the adjoint bottom `adjointBottomAMod W`, and no identification of these two $A(W)$-modules is asserted. In particular this file does not make any `pbw`-dependent theorem unconditional, for Heisenberg or for anything else.

Proof on paper. The weight-zero space of the adjoint module embeds into W, and that inclusion is equivariant for the Frenkel–Zhu action of the parabolic subalgebra. By the universal property of the induced module the inclusion extends to a map $M(U) \to W$ whose composite with ι is the inclusion, which is injective; hence ι is injective. Level independence holds for every parabolic representation (an Euler-operator argument proved in Chapter 13), and injectivity plus independence gives the projection. For Heisenberg, the vacuum 1 has weight 0 and is nonzero, and injectivity of ι transfers non-vanishing to its image. □

Physical meaning

For the free boson the statement is the expected one: the induced module generated from the vacuum is the vacuum module, its ground state is the vacuum, and the vacuum survives. The interest is purely structural: it shows the abstract hypotheses of the `Pr`-hypothesis form of Zhu's theorem can be met by a nonzero example.

What the machine verified

Proved, conditional only on $k \neq 0$. `#print axioms` for `heisenbergAdjointBottomProjection`, `heisenbergAdjointPBWFreeness`, `heisenberg_indBottom_vacuum_ne_zero`: `[propext, Classical.choice, Quot.sound]` in each case. `VOA.pbw` is not used.

6.6 The free boson with background charge

The file `VOA/Examples/FreeBosonGeneralC.lean` turns the rank-one Heisenberg algebra at level 1 into a one-parameter family of vertex operator algebras with central charge $1 - 12\lambda^2$, $\lambda \in \mathbb{C}$. The

Virasoro relation it relies on is proved in `VOA/Examples/VirasoroFock.lean` (a Chapter 7 file); we quote it because the construction depends on it.

Definition 6.16 (Linear-dilaton modes). For $\lambda \in \mathbb{C}$ and $n \in \mathbb{Z}$ put $L^{\lambda}_n = L_n + \lambda(n+1)a_n$ on $\mathcal{F}$, where L_n and a_n are the level-one Sugawara modes and oscillators of Section 6.3.

File `VOA/Examples/VirasoroFock.lean`.

```
noncomputable def Lld (lam : ℂ) (n : ℤ) : End ℂ Fock :=
  Lvir 1 n + (lam * ((n : ℂ) + 1)) • osc 1 n

theorem Lld_virasoro (lam : ℂ) (m n : ℤ) :
    Lld lam m * Lld lam n - Lld lam n * Lld lam m
      = ((m : ℂ) - n) • Lld lam (m + n)
        + (if m + n = 0 then ((m : ℂ) ^ 3 - m) / 12 * (1 - 12 * lam ^ 2) else 0)
            • (LinearMap.id : End ℂ Fock)
```

From the mathematics to the Lean statement

`Lvir 1 n` is L_n at level $k = 1$ and `osc 1 n` is a_n. The relation is the Virasoro algebra with central charge $1 - 12\lambda^2$. No hypothesis on λ.

Physical meaning

These are the modes of $T_\lambda(z) = \frac{1}{2}{:}J^2{:} - \lambda\,\partial J$: the mode of ∂J at z^{-n-2} is $-(n+1)a_n$. The shift of the central charge by $-12\lambda^2$ comes from the double contraction $\lambda^2\langle\partial J(z)\partial J(w)\rangle = -6\lambda^2/(z-w)^4$; the cross terms $\langle {:}J^2{:}\,\partial J\rangle$ vanish because a three-point function of an odd number of free-field currents is zero.

What the machine verified

Proved, unconditional (`VirasoroFock.lean`, Chapter 7); axiom-clean.

Definition 6.17 (Deformed conformal vector). $\omega^{\lambda} = \omega - \lambda\, a_{-2}\mathbf{1} = \frac{1}{2}X_0^2 - \lambda X_1 \in \mathcal{F}_2$, with ω the level-one Heisenberg conformal vector.

File `VOA/Examples/FreeBosonGeneralC.lean`.

```
noncomputable def omegaLD (lam : ℂ) : Fock := ω 1 - lam • osc 1 (-2) vacuum

theorem mode_Y_omegaLD (lam : ℂ) (n : ℤ) :
    mode (Y 1 (omegaLD lam)) (n + 1) = Lld lam n

theorem Lld_zero (lam : ℂ) : Lld lam 0 = Lvir 1 0

theorem Lld_neg_one (lam : ℂ) : Lld lam (-1) = Lvir 1 (-1)
```

From the mathematics to the Lean statement

`osc 1 (-2) vacuum` is $a_{-2}\mathbf{1} = X_1$, whose field is $\partial\alpha(z)$; since mode$(\partial\alpha)(n+1) = -(n+1)a_n$, the minus sign in ω^{λ} is exactly what makes $\omega^{\lambda}_{(n+1)} = L^{\lambda}_n$ (`mode_Y_omegaLD`). This is the bridge between the operator family of Definition 6.16 and the state–field correspondence. `Lld_zero` and `Lld_neg_one` say that L_0 and L_{-1} are *not* deformed: $a_0 = 0$ on $\mathcal{F}$, and the coefficient $\lambda(n+1)$ vanishes at $n = -1$.

Physical meaning

ω^λ is the state of the improved stress tensor T_λ. The improvement term is a total derivative, so it does not change the generator of translations L_{-1}, and on the zero-momentum sector it does not change the energy L_0. It does change which fields are primary: for example $L_1^\lambda(a_{-1}\mathbf{1}) = 2\lambda\mathbf{1} \neq 0$, so for $\lambda \neq 0$ the current is no longer a primary field (it acquires an anomalous transformation law, the hallmark of a background charge at infinity).

What the machine verified

Proved, unconditional, axiom-clean.

Theorem 6.18 (The free boson at general central charge). *For every $\lambda \in \mathbb{C}$, the vertex algebra $\mathcal{F}$ of Theorem 6.10 at level 1, with conformal vector ω^λ, is a vertex operator algebra of CFT type with central charge $1 - 12\lambda^2$; its vertex algebra, its grading, L_0 and L_{-1} are those of the undeformed algebra. Consequently every complex number is the central charge of a vertex operator algebra structure on $\mathcal{F}$.*

File `VOA/Examples/FreeBosonGeneralC.lean`.

```

theorem centralCharge_surjective :
    Function.Surjective (fun lam : ℂ => (freeBosonVOA lam).centralCharge) :=
  fun c => exists_centralCharge c
```

From the mathematics to the Lean statement

What changes and what does not. The underlying `PreVertexAlgebra` is literally `heisVA 1 _` (`freeBosonVOA_toPreVertexAlgebra` is `rfl`); so Y, the vacuum, the grading by oscillator level and all vertex algebra axioms are those of $M(1)$ at level 1. Only `conformalVector`, `conformal_mem`, `centralCharge` and `virasoro` change; `L0_grading` and `translation` are the undeformed proofs after rewriting with `Lld_zero` and `Lld_neg_one`. `(freeBosonVOA lam).L 0` is $L_0^\lambda = \omega_{(1)}^\lambda$, and `freeBosonVOA_L_zero` says it is the undeformed L_0.
Is the grading the expected one? Yes, for the vacuum module: the conformal weight of X^e is still $\sum(i+1)e_i$, since $L_0^\lambda = L_0$. (On a charged module $\mathcal{F}_p$ the weights would shift to

$\frac{1}{2}p^2 + \lambda p$ in this sign convention, cf. the lattice version in Section 6.10, but charged modules are not part of this file.)

The central charge is not a free label. As in Theorem 6.10, the `rfl` proof of `freeBosonVOA_centralCharge` is meaningful because `virasoro` is proved with that value. A Lean check made for this book (not part of this release) confirms the triplet value $c($`freeBosonVOA (1/2)`$) = -2$ and that the vertex algebra does not depend on λ.

`exists_centralCharge`. This is the elementary fact that $1 - 12\lambda^2 = c$ has a solution $\lambda \in \mathbb{C}$ for every c ($\mathbb{C}$ is algebraically closed). It says that the conformal vector, not the vertex algebra, carries the central charge: one and the same vertex algebra admits conformal vectors of every central charge. It is *not* a statement about unitary or rational theories.

Two sign conventions in the library. Here $\omega^\lambda = \omega - \lambda a_{-2}\mathbf{1}$ and $L^\lambda_n = L_n + \lambda(n+1)a_n$. The lattice files of Section 6.10 use the opposite sign, $\omega_\lambda = \omega + \lambda(-2)\mathbf{1}$ and $L^\lambda_n = L_n - (n+1)\lambda(n)$. The two families are related by $\lambda \mapsto -\lambda$; the central charge is even in λ and does not see the difference, but the deformed weights do. A referee comparing statements across files should keep this in mind.

Proof on paper. The vertex algebra axioms are inherited. *VOA1*: by `mode_Y_omegaLD` the modes of ω^λ are L^λ_n, which satisfy the Virasoro relation with $c = 1 - 12\lambda^2$ (`Lld_virasoro`). The latter is proved by expanding $[L_m + \lambda(m+1)a_m,\ L_n + \lambda(n+1)a_n]$ into four commutators: $[L_m, L_n]$ gives $(m-n)L_{m+n} + \frac{m^3-m}{12}\delta_{m+n,0}$; the two cross terms give, by $[L_m, a_n] = -na_{m+n}$, $-\lambda(n+1)n\,a_{m+n} + \lambda(m+1)m\,a_{m+n} = \lambda(m-n)(m+n+1)a_{m+n}$, which is exactly the a-part of $(m-n)L^\lambda_{m+n}$; and $\lambda^2(m+1)(n+1)[a_m, a_n] = \lambda^2(m+1)(1-m)m\,\delta_{m+n,0} = -\lambda^2(m^3-m)\delta_{m+n,0}$, which is $\frac{m^3-m}{12}(-12\lambda^2)$. *VOA2, VOA3*: $L^\lambda_0 = L_0$, $L^\lambda_{-1} = L_{-1}$. *CFT type*: unchanged. Finally $\omega^\lambda \in \mathcal{F}_2$ since X_0^2 and X_1 have weight 2. □

Physical meaning

This is the Coulomb-gas (Feigin–Fuchs, Dotsenko–Fateev) free field, or the linear dilaton of string theory: a free boson whose stress tensor is improved by $-\lambda\partial J$. Real λ gives $c < 1$; the Virasoro minimal model $M(p,q)$ with $c_{p,q} = 1 - 6(p-q)^2/(pq)$ is realised at $\lambda^2 = (p-q)^2/(2pq)$, its primaries arising from vertex operators with special momenta and its null vectors from screening charges (Chapter 7). Imaginary λ gives $c > 1$, as for the Liouville and linear-dilaton theories. The value $\lambda = \frac{1}{2}$, $c = -2$, is the symplectic-fermion/triplet point (Chapter 18). Physically the background charge is a charge placed at infinity on the sphere, which is why the $U(1)$ charge conservation of correlators is shifted and the current is no longer primary.

What the machine verified

Proved, unconditional (no hypothesis on λ). `#print axioms` for `VOA.FBgc.freeBosonVOA`, `exists_centralCharge`, `centralCharge_surjective`: `[propext, Classical.choice, Quot.sound]`.

6.7 Lattice vertex operator algebras in general: what exactly is proved

The construction of V_L for an even positive-definite lattice L is presented in full in Chapter 31 (Sections 31.4–31.9), with every definition and the locality and reconstruction theorems. Here we restate the headline and carry out the fidelity analysis the task of this chapter calls for: *which lattices are allowed, what the central charge is, and whether the grading is the expected one.*

6.7.1 Lattices

Definition 6.19 (Integral lattice; even; positive-definite; rank). An integral lattice is a finitely generated free abelian group L with a symmetric $\mathbb{Z}$-valued bilinear form. It is even if $\langle v, v\rangle \in 2\mathbb{Z}$ for all v, positive-definite if $\langle v, v\rangle > 0$ for $v \neq 0$, and its rank is its rank as a free $\mathbb{Z}$-module. (Chapter 31, Definition 31.9.)

Files `VOA/Foundations/Lattices.lean` and `VOA/Foundations/LatticeCocycle.lean`.

```
structure IntegralLattice where
  carrier : Type u
  [addCommGroup : AddCommGroup carrier]
  [free : Module.Free ℤ carrier]
  [finite : Module.Finite ℤ carrier]
  form : LinearMap.BilinForm ℤ carrier
  isSymm : form.IsSymm

def Even : Prop := ∀ v : L.carrier, 2 ∣ L.form v v

def PosDef : Prop := ∀ v : L.carrier, v ≠ 0 → 0 < L.form v v

noncomputable def rank : ℕ := Module.finrank ℤ L.carrier
```

From the mathematics to the Lean statement

The fields `free` and `finite` make the carrier isomorphic to $\mathbb{Z}^n$ without fixing a basis. `2 ∣ x` is divisibility. Nothing requires the form to be non-degenerate or unimodular; positive-definiteness implies non-degeneracy. The rank may be 0.

Physical meaning

L is the lattice of chiral momenta of r compactified bosons. Evenness makes every vertex operator $:e^{i\alpha\cdot X}:$ bosonic with integer weight, positive-definiteness makes the energy $\frac{1}{2}\langle\alpha,\alpha\rangle$ positive (a Euclidean target torus). Unimodularity, not required here, is what modular invariance of the chiral partition function would need.

6.7.2 The state space and the grading

Recall from Chapter 31 (Definitions 31.17 and 31.18) that $V_L = \mathcal{F}_r \otimes \mathbb{C}[L]$, $r = \operatorname{rank} L$, with $\mathcal{F}_r =$ `FockN r` the rank-r Fock space and $\mathbb{C}[L]$ the vector space with basis e^α; that `halfNorm L α` is $\langle\alpha,\alpha\rangle/2$ (integer division); and that the weight-n space is $\sum_\alpha (\mathcal{F}_r)_{n-\langle\alpha,\alpha\rangle/2} \otimes e^\alpha$.
Files `VOA/Examples/LatticeGenGrading.lean`, `VOA/Examples/LatticeQuadRefine.lean`.

```
noncomputable def halfNorm (α : L.carrier) : ℤ := L.form α α / 2

noncomputable def bigradα (wα : ℤ × L.carrier) : Submodule ℂ (LatModuleGen L) :=

  ⨆ α : L.carrier, bigradα L (k - halfNorm L α, α)

theorem gradingLatGen_isInternal_free : DirectSum.IsInternal (gradingLatGen L)
```

Theorem 6.20 (The grading is the expected one). *For any integral lattice L, $V_L = \bigoplus_n (V_L)_n$ (no hypothesis). If L is even and positive-definite, then for every $\alpha \in L$ the charged vacuum $e^\alpha = 1 \otimes e^\alpha$ lies in the weight space $(V_L)_{\langle\alpha,\alpha\rangle/2}$ of the vertex operator algebra V_L; more generally $p \otimes e^\alpha$ with p of oscillator level w has weight $w + \frac{1}{2}\langle\alpha,\alpha\rangle$.*

File `VOA/Examples/LatticeGenGrading.lean`.

```
theorem bigradα_le_gradingLatGen (w : ℤ) (α : L.carrier) :
    bigradα L (w, α) ≤ gradingLatGen L (w + halfNorm L α)
```

From the mathematics to the Lean statement

`bigradα L (w, α)` is $(\mathcal{F}_r)_w \otimes e^\alpha$; the library lemma says it sits in weight $w + \mathtt{halfNorm}(\alpha)$. A Lean check made for this book (`latChargeGen_mem_grading`, not part of this release) specialises to $w = 0$, $p = 1$ and reads the result inside the `grading` field of `latticeVOAGen`, so it is a statement about the vertex operator algebra and not only about an auxiliary family of subspaces. For even L, `halfNorm` is exactly $\langle\alpha,\alpha\rangle/2$ (`two_halfNorm`, Chapter 31); without evenness integer division would round, which is one of the reasons evenness is a hypothesis. `gradingLatGen_isInternal_free` (in `LatticeQuadRefine.lean`) shows that the direct-sum decomposition itself needs *no* hypothesis; evenness and positivity are needed for finite-dimensionality, for the absence of negative weights, and for $V_0 = \mathbb{C}\mathbf{1}$ (Chapter 31, Theorem 31.19). The module docstring of `LatticeGenGrading.lean` still calls the finiteness of bounded vectors an "isolated crux"; that is stale, the crux is discharged (`IntegralLattice.boundedFinite`).

Proof on paper. Internality: $V_L = \bigoplus_{(w,\alpha)} (\mathcal{F}_r)_w \otimes e^\alpha$ because both tensor factors are graded, and regrouping the pieces of a direct sum along any map of index sets (here $(w,\alpha) \mapsto w + \langle\alpha,\alpha\rangle/2$) keeps it a direct sum. The weight of the vacuum $1 \in \mathcal{F}_r$ is 0, so $1 \otimes e^\alpha$ has weight $\langle\alpha,\alpha\rangle/2$. □

Physical meaning

The conformal weight $h = w + \frac{1}{2}p^2$ is oscillator energy plus the kinetic energy of the zero mode. The graded dimension is $\theta_L(q)/\prod(1-q^n)^r$, the torus partition function of the chiral bosons at the lattice point L.

What the machine verified

`gradingLatGen_isInternal_free`: proved, unconditional. `latChargeGen_mem_grading`: checked in Lean against the library (the check is not part of this release), compiled with `lake env lean -DmaxSynthPendingDepth=3; #print axioms = [propext, Classical.choice, Quot.sound]`.

6.7.3 The theorem

Theorem 6.21 (Lattice vertex operator algebras). *Let L be an even positive-definite integral lattice of rank $r \geq 0$. Then V_L, with the FLM vertex operators, vacuum $1 \otimes e^0$, conformal vector $\omega = \frac{1}{2}\sum_{a=1}^{r} h_a(-1)^2\mathbf{1} \otimes e^0$ and the grading of Theorem 6.20, is a vertex operator algebra of CFT type with central charge r.*

```

From the mathematics to the Lean statement

Which lattices. Exactly the even, positive-definite ones, of any rank including 0. The rank is not bounded and unimodularity is not assumed: A_1, $\sqrt{2}\mathbb{Z}$, E_8, Λ and the rank-zero lattice are all covered. Odd lattices are excluded (they give vertex *super*algebras, Chapter 17); for example the standard lattice $\mathbb{Z}^1$ is not even (checked in Lean, `std1_not_even`; the check is not part of this release). Indefinite lattices are excluded (their V_L has infinite-dimensional weight spaces and is not a vertex operator algebra in the sense of Definition 4.4; the library's `NearVOA` is meant for them).

The central charge is `rank L`, the rank as a free $\mathbb{Z}$-module (`Module.finrank ℤ`), as it should be.

The vertex operators. `YfullGen` is obtained from the reconstruction theorem by choice (`.choose`); it is nevertheless unique, by Goddard's theorem, and its values on the generating fields are the explicit FLM formulas $Y(e^\alpha, z) = E^-(\alpha, z)E^+(\alpha, z)e_\alpha z^{\alpha(0)}$ with the cocycle ε (Chapter 31, Theorems 31.26 and Definition 31.21). The cocycle is built on a basis chosen by `Module.Free.chooseBasis`; different choices give isomorphic algebras (Chapter 31, Theorem 31.36).

A non-vacuity sanity check. A Lean check made for this book (not part of this release) instantiates the theorem at the rank-one lattice `sqrt2Lattice` $= \sqrt{2}\mathbb{Z}$ (form $\langle v, w\rangle = 2vw$), proving its evenness and positivity and that the resulting algebra `latticeVOA_sqrt2` has central charge 1. This is a *second*, independent A_1 lattice vertex operator algebra, besides the one of Section 6.8.

What is not in these files. Simplicity of V_L, its modules $V_{L+\lambda}$ for $\lambda \in L^*$, the rationality and C_2-cofiniteness of V_L, and the description of $(V_L)_1$ as a Lie algebra for general L are not stated in this chapter's files. Two of these are proved elsewhere: C_2-cofiniteness for every even positive-definite L (`latticeVOAGen_c2Cofinite`), and strong rationality in rank one (`V2m_stronglyRational`, for $V_{\sqrt{2m}\mathbb{Z}}$); see Chapter 22. The Moonshine part proves the facts it needs for Λ (rootlessness: Chapter 31, Theorem 31.29; invariant forms: Chapter 32).

Proof on paper. See Chapter 31, Sections 31.4–31.9: the charge oscillators satisfy the Heisenberg relations with the lattice form; the FLM vertex operators are mutually local because the boson reordering produces $(z_1 - z_2)^{\langle\alpha,\beta\rangle}$ and the cocycle supplies the sign $(-1)^{\langle\alpha,\beta\rangle}$; the reconstruction theorem builds Y for all states from the generating fields; the Sugawara vector gives the Virasoro algebra with $c = r$, and the grading identities follow from $\frac{1}{2}|\alpha+\beta|^2 = \frac{1}{2}|\alpha|^2 + \frac{1}{2}|\beta|^2 + \langle\alpha,\beta\rangle$. □

Physical meaning

V_L is the chiral algebra of r bosons compactified on the torus dual to L (Frenkel–Kac, Segal, FLM, Borcherds). Its weight-one space contains the r abelian currents and one current e^α for every root $\langle\alpha,\alpha\rangle = 2$; when roots exist the $U(1)^r$ symmetry is enhanced to a non-abelian simply-laced current algebra at level one. For unimodular L (e.g. E_8, Λ) the theory is holomorphic.

What the machine verified

Proved, conditional only on `hEven` and `hPos`. `#print axioms VOA.LatGen.latticeVOAGen` = `[propext, Classical.choice, Quot.sound]` (re-checked); `VOA.pbw` not used.

6.7.4 The rank-zero lattice: the trivial vertex operator algebra

Definition 6.22 (Trivial vertex operator algebra)**.** `trivialVOA` $= V_{\{0\}}$, the lattice vertex operator algebra of the rank-zero lattice $\mathbb{Z}^0$. Its carrier is $\mathcal{F}_0 \otimes \mathbb{C}[\{0\}] \cong \mathbb{C}$, spanned by the vacuum; its central charge is 0.

Files `VOA/Foundations/Lattices.lean`, `VOA/Examples/ZhuInstantiation.lean`.

```
noncomputable def stdLattice (n : ℕ) : IntegralLattice where
  carrier := Fin n → ℤ
  form := Matrix.toBilin' (1 : Matrix (Fin n) (Fin n) ℤ)

theorem std0_even : (stdLattice 0).Even

theorem std0_posDef : (stdLattice 0).PosDef

noncomputable def trivialVOA : VertexOperatorAlgebra (LatGen.LatModuleGen (stdLattice 0))
 ↪  :=
  LatGen.latticeVOAGen (stdLattice 0) std0_even std0_posDef

noncomputable def trivialCarrierEquiv : LatGen.LatModuleGen (stdLattice 0) ≃ₗ[ℂ] ℂ :=
  (TensorProduct.congr fockZeroEquiv chargeZeroEquiv).trans (TensorProduct.lid ℂ ℂ)

theorem trivial_finrank : Module.finrank ℂ (LatGen.LatModuleGen (stdLattice 0)) = 1
```

From the mathematics to the Lean statement

`stdLattice n` is $\mathbb{Z}^n$ with the identity Gram matrix (`Matrix.toBilin'` turns a matrix into a bilinear form). It is even only for $n = 0$, where both evenness and positivity hold vacuously. `≃ₗ[ℂ]` is a linear isomorphism; `trivialCarrierEquiv` identifies the carrier with $\mathbb{C}$, and `trivial_finrank` says it is one-dimensional. The central charge is `rank (stdLattice 0)` $= 0$ (checked in Lean; not part of this release). So `trivialVOA` is the vertex operator algebra $\mathbb{C}\mathbf{1}$ with $\omega = 0$ and $c = 0$, as intended. It was used in Chapter 15 as the first non-vacuity witness for Zhu's modularity theorem, where it is proved C_2-cofinite, regular and rational; nontrivial instances (`zhuModularity_V2m`, every $m \geq 1$, and `zhuModularity_V2mPlus`) are now proved as well (Chapters 15 and 22).

The zero space is also a VOA. The library's axioms are satisfied by the zero space ($\mathbf{1} = 0$, and $V_0 = \mathbb{C} \cdot 0 = 0$ is allowed; release audit 2026-10-27, finding m-4). So a non-vacuity witness must be visibly nonzero; `trivial_finrank` shows that `trivialVOA` is one-dimensional, not zero, and hence is a genuine witness.

Physical meaning

The trivial chiral algebra is the theory with no degrees of freedom: one state, no fields but the identity, $c = 0$, character 1. It is the unit for tensor products of chiral algebras, and the simplest (degenerate) rational, holomorphic vertex operator algebra.

What the machine verified

`trivialVOA`: `#print axioms` = `[propext, Classical.choice, Quot.sound]`. The file is assigned to Chapter 15.

6.8 The A_1 lattice vertex operator algebra

Before the general construction existed, the library built the lattice vertex operator algebra of the A_1 root lattice $\mathbb{Z}\alpha$, $\langle\alpha,\alpha\rangle = 2$, by hand. That construction is complete and closed, and the general one was obtained by "lifting" its proofs. It lives in the namespaces `VOA.LatticeVOA` and `VOA.LatExp`. Its distinctive design choice is a normalisation without $\sqrt{2}$: the single boson is taken at *level* $k = 2$, so that the oscillator algebra is $[\alpha_m, \alpha_n] = 2m\delta_{m+n,0}$, i.e. the lattice norm *is* the level.

6.8.1 The state space, the cocycle and the boson

Definition 6.23 (State space of V_{A_1}). $V_{A_1} = \mathcal{F}_1 \otimes \mathbb{C}[\mathbb{Z}]$, where $\mathbb{C}[\mathbb{Z}]$ has basis $e^{n\alpha}$ ($n \in \mathbb{Z}$); the vacuum is $1 \otimes e^0$; the form is $\langle m\alpha, n\alpha\rangle = 2mn$; the cocycle is $\varepsilon \equiv 1$; the oscillators are those of the rank-one Heisenberg algebra `FockN 1` at level 2.

Files `VOA/Examples/LatticeA1.lean`, `VOA/Examples/LatticeExp.lean`.

```

noncomputable abbrev B : Type := FockN 1

noncomputable def α (m : ℤ) : End ℂ B := oscN 1 2 0 m
```

From the mathematics to the Lean statement

`AddMonoidAlgebra ℂ ℤ` is the group algebra of $(\mathbb{Z}, +)$; `single n 1` is the basis vector $e^{n\alpha}$. `⊗[ℂ]` is the algebraic tensor product and `p ⊗ₜ[ℂ] x` a pure tensor. `oscN 1 2 0 m` is the oscillator $h_0(m)$ of the rank-one Fock space `FockN 1` (Chapter 31, Definition 31.2) at level 2. The cocycle is identically 1: this is legitimate for A_1 because $\langle m\alpha, n\alpha\rangle = 2mn$ is even, so the required commutator sign $(-1)^{\langle\cdot,\cdot\rangle}$ is $+1$ and the trivial cocycle works (library lemmas `cocycle_cocycle`, `cocycle_comm`). It would be wrong for a lattice with odd inner products, which is why the general construction needs the FLM cocycle.

Physical meaning

One boson at the self-dual radius, with momentum lattice $\mathbb{Z}\alpha$. Normalising the current so that $J(z)J(w) \sim 2/(z-w)^2$ makes the momentum of $e^{n\alpha}$ equal to $2n$ (the eigenvalue of the zero mode α_0) and its energy $n^2 = \frac{1}{4}(2n)^2$, matching $\frac{1}{2}\langle n\alpha, n\alpha\rangle$.

What the machine verified

Definitions; the cocycle identities are proved, axiom-clean.

6.8.2 The vertex operators

Definition 6.24 ($Y(e^{m\alpha}, z)$). For $c \in \mathbb{C}$ let $E^-(c\alpha, z) = \exp\big(c\sum_{n\geq 1}\frac{\alpha_{-n}}{n}z^n\big)$ (multiplication by Schur-type polynomials $p_N^{(c)}$ at z^N) and $E^+(c\alpha, z) = \exp\big(-c\sum_{n\geq 1}\frac{\alpha_n}{n}z^{-n}\big)$, both defined by Newton recursions, and $EE(c\alpha, z) = {:}E^-(c\alpha, z)E^+(c\alpha, z){:}$. For $m \in \mathbb{Z}$, the vertex operator $Y(e^{m\alpha}, z)$ acts on $p \otimes e^{n\alpha}$ by

$$Y(e^{m\alpha}, z)(p \otimes e^{n\alpha}) = z^{2mn}\big(EE(m\alpha, z)p\big) \otimes e^{(n+m)\alpha}.$$

Files `VOA/Examples/LatticeChargeM.lean`, `VOA/Examples/LatticeChargeMFields.lean`.

    Yemα m t (p ⊗ₜ[ℂ] eVec n) = (EEC (m : ℂ) (t - 2 * m * n) p) ⊗ₜ[ℂ] eVec (n + m)
```

From the mathematics to the Lean statement

Decoding. `cVar m` is the variable $X_{(m,0)}$, i.e. $\alpha_{-m-1}\mathbf{1}$. The recursion for `cSchurC c` is Newton's identity for the coefficients of $\exp(c\sum_n \alpha_{-n}z^n/n)$: $(N+1)p_{N+1} = c\sum_{m=0}^{N} p_{N-m}X_{(m,0)}$. Similarly `aExpC c N` is the coefficient of z^{-N} in $\exp(-c\sum_n \alpha_n z^{-n}/n)$. `EminusOpC c N` is multiplication by `cSchurC c N`. As formal distributions indexed by powers of z, E^- lives in non-negative and E^+ in non-positive powers. `Yemα m t` is the coefficient of z^t of $Y(e^{m\alpha}, z)$; by `Yemα_tmul` it sends $p \otimes e^{n\alpha}$ to $EE(m\alpha)_{t-2mn}\,p \otimes e^{(n+m)\alpha}$, which is the z^t-coefficient of $z^{2mn}EE(m\alpha, z)p \otimes e^{(n+m)\alpha}$. The factor z^{2mn} is z^{α_0} acting on $e^{n\alpha}$ (with $\alpha_0 = 2n$ there, scaled by m), the shift $e^{n\alpha} \mapsto e^{(n+m)\alpha}$ carries the trivial cocycle. This is the FLM formula $Y(e^\beta, z) = E^-(\beta, z)E^+(\beta, z)e_\beta z^{\beta(0)}$ for $\beta = m\alpha$, with the library's naming $E^\mp(\beta)$ for FLM's

$E^{\mp}(-\beta)$ (Chapter 31).

Physical meaning

$Y(e^{m\alpha}, z) = :e^{im\alpha\cdot X(z)}:$, the vertex operator of charge m. Its conformal weight is $\frac{1}{2}\langle m\alpha, m\alpha\rangle = m^2$; the charges ± 1 have weight one and are the currents $J^{\pm}$ of $\widehat{\mathfrak{sl}}_{2_1}$. The factor z^{2mn} produces the OPE singularity $(z-w)^{2mn}$ between charges m and n: for $mn < 0$ a pole, for $mn > 0$ a zero.

What the machine verified

Definitions; `Yemα_tmul` proved, axiom-clean.

6.8.3 Locality and the instance

Theorem 6.25 (V_{A_1}). *The vertex operators $Y(e^{m\alpha}, z)$, $m \in \mathbb{Z}$, are pairwise mutually local. Consequently V_{A_1}, with the vertex map reconstructed from the boson current and the $Y(e^{m\alpha}, z)$, the vacuum $1 \otimes e^0$, the conformal vector $\omega = \frac{1}{4}\alpha_{-1}^2\mathbf{1} \otimes e^0$ and the grading in which $p \otimes e^{n\alpha}$ (p of level w) has weight $w + n^2$, is a vertex operator algebra of CFT type with central charge* 1.

From the mathematics to the Lean statement

The grading. `bigrad (w, n)` is $(\mathcal{F}_1)_w \otimes e^{n\alpha}$ and `gradingLat k` collects the pieces with $w + n^2 = k$. Since $\frac{1}{2}\langle n\alpha, n\alpha\rangle = n^2$, this is the expected weight $w + \frac{1}{2}\langle\beta,\beta\rangle$, specialised to A_1.
The conformal vector. `HeisenbergN.ωN 1 2` is $\frac{1}{2k}h(-1)^2\mathbf{1}$ at $k = 2$, i.e. $\frac{1}{4}\alpha_{-1}^2\mathbf{1}$, the Sugawara vector of a level-2 current (Chapter 31, (31.7)); `mkE 0` places it in the charge-zero sector.
The gate. `latticeVOA_A1_of_locality` takes the locality of all charged generators as a hypothesis `hYloc`; `Yfull` is the vertex map produced from that hypothesis by the reconstruction theorem (Chapter 4, Theorem 4.41) via `.choose`. The elided fields `(...)` are `vacuum_mem`, `grading_mode`, `vacuum_Y`, `creation`, `locality`, `regularity`, each a named theorem in the same file taking `hYloc`. The gate is discharged by the theorem `Yemα_local`, so `latticeVOA_A1` has *no* hypotheses. The same definition is re-exported as `VOA.latticeVOA_A1` in `Lattice.lean`.
What is not proved. The identification $V_{A_1} \cong L_{\hat{\mathfrak{sl}}_2}(1,0)$ with the simple affine vertex operator algebra of level one (Frenkel–Kac) is not in the library; the module docstring of `LatticeA1.lean` mentions "$= \widehat{\mathfrak{sl}_2}$ level 1" as motivation only. Nor is it proved that $\dim(V_{A_1})_1 = 3$ or that $(V_{A_1})_1 \cong \mathfrak{sl}_2$, nor that `latticeVOA_A1` is isomorphic to the general construction at $\sqrt{2}\mathbb{Z}$ (`latticeVOA_sqrt2`, Section 6.7). Both statements are true on paper.

Proof on paper. Locality. For $m = 0$, $Y(e^0, z)$ is the identity field. For $mm' \geq 1$ (same sign), the boson reordering $E^+(m\alpha, z_1)E^-(m'\alpha, z_2) = (1 - z_2/z_1)^{2mm'}E^-(m'\alpha, z_2)E^+(m\alpha, z_1)$ is a finite binomial expansion, and the two operator orders differ by $(-1)^{2mm'} = 1$, so the operators commute exactly (bound 0). For $mm' \leq -1$ the reordering factor $(1 - z_2/z_1)^{2mm'}$ is an infinite geometric-type series, and multiplying by $(z_1 - z_2)^{2|mm'|}$ collapses both orders to the same normal-ordered four-fold product, giving locality with bound $2|mm'|$. *Instance.* Exactly as in the general case (Chapter 31): the boson current is local with itself and with every $Y(e^{m\alpha}, z)$ (a simple pole with residue the charge $2m$); Dong's lemma propagates locality to all word fields; reconstruction produces Y; the Sugawara vector at level 2 gives $c = 1$ and L_0 acting by $w + n^2$. □

Physical meaning

V_{A_1} is the chiral algebra of the compact boson at the self-dual radius, equivalently the $SU(2)$ level-one WZW model: the three weight-one states $\alpha_{-1}\mathbf{1}$, e^{α}, $e^{-\alpha}$ give the currents $J^3, J^{\pm}$ and V_{A_1} is the vacuum module of $\widehat{\mathfrak{sl}_2}_1$ (Frenkel–Kac). Its character is $\theta_{A_1}(\tau)/\eta(\tau) = \sum_n q^{n^2}/\eta(\tau)$, the level-one $SU(2)$ vacuum character. Since A_1 has determinant 2, V_{A_1} has exactly two irreducible modules, V_{A_1} and $V_{A_1+\alpha/2}$ (spin 0 and spin $\frac{1}{2}$), as the $SU(2)_1$ WZW model does.

What the machine verified

Proved, unconditional. `#print axioms` for `VOA.LatExp.latticeVOA_A1`, `VOA.latticeVOA_A1`, `VOA.LatExp.Yemα_local`: `[propext, Classical.choice, Quot.sound]`, pbw-free.

6.8.4 Two placeholders in the same files

Trap / dead end

The superseded operator `LatticeVOA.Yeα`. `VOA/Examples/LatticeA1.lean` defines an early "lattice vertex operator" whose boson factor is replaced by the identity in degree 0:

```
noncomputable def EminusOp : FormalDist (End ℂ LatModule) :=
  fun t => if t = 0 then LinearMap.id else 0

noncomputable def Yeα : FormalDist (End ℂ LatModule) :=
  fun t => if t = 0 then (eShift 1).comp (EminusOp 0) else (eShift 1).comp (EminusOp
   ↪ t)
```

This operator is e_α concentrated in z^0; it has no oscillator dressing and is *not* the lattice vertex operator. (The same file's `alphaCur`/`expoNeg` also use level 1, the wrong normalisation for A_1.) The module docstring of `Lattice.lean` says explicitly that it "is superseded by the genuine boson-dressed `LatExp.Yeα`". Nothing downstream uses it; `latticeVOA_A1` uses `LatExp.Yemα`. A referee should not read the lemma `Yeα_creation_z0` as a statement about V_{A_1}.

Trap / dead end

`OPEStructure` and `latticeA1_local_of_nonneg` say nothing about operators. The predicate

```
def OPEStructure (m n : ℤ) : Prop :=
  ∃ N : ℕ, (latForm m n : ℤ) = (N : ℤ) ∧
    mulBySubPow N (expandPos (-(N : ℤ))) = expandPos 0

theorem latticeA1_local_of_nonneg {m n : ℤ} (h : 0 ≤ LatticeVOA.latForm m n) :
    LatticeVOA.OPEStructure m n :=
  LatticeVOA.OPEStructure_of_nonneg h
```

(`VOA/Examples/LatticeA1.lean`, `VOA/Examples/Lattice.lean`) mentions only the integer $2mn$ and the scalar distribution $\iota_{12}(z_1-z_2)^{-N}$: it says "$2mn$ is a natural number N and $(z_1-z_2)^N\iota_{12}(z_1-z_2)^{-N}=1$". The second clause is a general identity of formal calculus. A Lean check made for this book (`OPEStructure_iff`, not part of this release) proves that `LatticeVOA.OPEStructure m n` holds if and only if `0 ≤ LatticeVOA.latForm m n`, so `latticeA1_local_of_nonneg` is the tautology "if $2mn \geq 0$ then $2mn \geq 0$". Its docstring ("so the two lattice VOs are mutually local") over-claims. The genuine locality theorem is `LatExp.Yemα_local` above. Likewise the theorem named `latticeA1_centralCharge` in `Lattice.lean` states `(heisenbergVOA' 1).centralCharge = 1`, a fact about the rank-one Heisenberg algebra, not about V_{A_1}; the lattice statement is `latticeVOA_A1_centralCharge`.

6.9 Charge sectors and the charge-zero subalgebra

The file `VOA/Examples/LatticeCharge.lean` proves that every vertex operator of V_L shifts the momentum by the momentum of its state, deduces that the momentum-zero sector is a vertex operator subalgebra, and obtains from it the first "non-adjoint" modules of the library.

6.9.1 Charge sectors

Definition 6.26 (Charge sectors; charge shift). For $\gamma \in L$ the *charge-γ sector* of V_L is $\mathcal{F}_r \otimes e^\gamma$. A formal distribution $f(z) = \sum_j f_j z^j$ with coefficients in $\mathrm{End}\, V_L$ *shifts charge by α* if every f_j maps

$\mathcal{F}_r \otimes e^{\beta}$ into $\mathcal{F}_r \otimes e^{\alpha+\beta}$, for every $\beta \in L$.

File `VOA/Examples/LatticeCharge.lean`.

```
noncomputable def chargeSec (γ : L.carrier) : Submodule ℂ (LatModuleGen L) :=
  LinearMap.range (mkEα L γ)

def ShiftsCharge (f : FormalDist (Module.End ℂ (LatModuleGen L))) (α : L.carrier) : Prop :=
  ∀ (β : L.carrier) (k : ℤ), ∀ x ∈ chargeSec L β, f k x ∈ chargeSec L (α + β)
```

From the mathematics to the Lean statement

`mkEα L γ` is the linear map $p \mapsto p \otimes e^{\gamma}$ (Chapter 31), and `LinearMap.range` its image, so `chargeSec L γ` $= \mathcal{F}_r \otimes e^{\gamma}$. In `ShiftsCharge` the integer `k` indexes powers of z, but since the condition is required for all `k` this makes no difference. The quantifiers are as in the definition.

Physical meaning

$V_L = \bigoplus_{\gamma} \mathcal{F}_r \otimes e^{\gamma}$ is the decomposition of the Hilbert space by the $U(1)^r$ momentum charges. A field shifts charge by α when it has definite charge α; charge conservation says that the field of a state of charge α does exactly that.

Theorem 6.27 (Charge additivity). *Let L be even and positive-definite. The boson currents shift charge by 0, $Y(e^{\alpha}, z)$ shifts charge by α, and for every state u in the charge-α sector, $Y(u, z)$ shifts charge by α.*

File `VOA/Examples/LatticeCharge.lean`.

```
theorem alphaLatGen_shiftsCharge (a : Fin (rank L)) :
    ShiftsCharge L (alphaLatGen L a) 0

theorem Yeαvec_shiftsCharge (α : L.carrier) :
    ShiftsCharge L (Yeαvec L α) α

theorem YfullGen_shiftsCharge (hEven : L.Even) (hPos : L.PosDef) (α : L.carrier)
    {u : LatModuleGen L} (hu : u ∈ chargeSec L α) :
    ShiftsCharge L (YfullGen L hEven hPos u) α
```

From the mathematics to the Lean statement

`alphaLatGen L a` is the direction-a boson current of V_L including its momentum zero mode (Chapter 31); `Yeαvec L α` is $Y(e^{\alpha}, z)$ (Definition 31.21); `YfullGen` is the vertex map of `latticeVOAGen`. The last statement is the one that matters: it is about the actual vertex operators of the vertex operator algebra of Theorem 6.21, for every state of definite charge.

Proof on paper. The boson current acts on the Fock factor only, and its zero mode multiplies $p \otimes e^{\beta}$ by a scalar; so it preserves each sector. $Y(e^{\alpha}, z)$ sends $p \otimes e^{\beta}$ to a multiple of $(\ldots) \otimes e^{\alpha+\beta}$ by its defining formula. The property "shifts charge by α" is preserved by derivatives, scalar multiples and sums, and if a shifts by α and b by α' then every coefficient of $:ab:$ is a sum of composites $a_m b_n$ or $b_n a_m$, which shift by $\alpha + \alpha'$. Hence every word field $:\partial^{i_1} h_{a_1} \cdots Y(e^{\alpha}):$ shifts by α. Finally the charge-α sector is spanned by the charge-α word states, the vertex map sends each word state to its word field, and the vertex map is linear. □

Physical meaning

This is $U(1)^r$ charge conservation in operator form: the OPE of a charge-α field with a charge-β field contains only charge-$(\alpha+\beta)$ fields.

What the machine verified

Proved, conditional on `hEven`, `hPos` for the last statement (the first two need no hypothesis). `#print axioms VOA.LatGen.YfullGen_shiftsCharge` = `[propext, Classical.choice, Quot.sound]`.

6.9.2 The charge-zero subalgebra

Recall (Chapter 5, Definition 5.24) that a vertex operator subalgebra of W is a subspace containing the vacuum and the conformal vector, closed under all products $u_{(n)}v$, and graded (stable under the projections onto the weight spaces). By Theorem 5.25 it is itself a vertex operator algebra (`VOASubalgebra.toVOA`) with the same central charge.
File `VOA/Modularity/Twisted.lean`.

```
structure VOASubalgebra (W : VertexOperatorAlgebra 𝒱) where
  carrier : Submodule ℂ 𝒱
  vacuum_mem : W.vacuum ∈ carrier
  conformal_mem : W.conformalVector ∈ carrier
  smul_mem : ∀ u ∈ carrier, ∀ (n : ℤ), ∀ v ∈ carrier, W.smul u n v ∈ carrier
  graded : ∀ (n : ℤ), ∀ v ∈ carrier, piHom W n v ∈ carrier
```

Definition 6.28 (The charge-zero subalgebra)**.** For L even and positive-definite, $V_L^{(0)} = \mathcal{F}_r \otimes e^0 \subseteq V_L$, as a vertex operator subalgebra.

File `VOA/Examples/LatticeCharge.lean`.

```
theorem chargeSec_zero_smul_mem (hEven : L.Even) (hPos : L.PosDef)
    {u : LatModuleGen L} (hu : u ∈ chargeSec L 0) (n : ℤ)
    {v : LatModuleGen L} (hv : v ∈ chargeSec L 0) :
    (latticeVOAGen L hEven hPos).smul u n v ∈ chargeSec L 0

theorem chargeSec_zero_graded (hEven : L.Even) (hPos : L.PosDef)
    (n : ℤ) {v : LatModuleGen L} (hv : v ∈ chargeSec L 0) :
    piHom (latticeVOAGen L hEven hPos) n v ∈ chargeSec L 0

noncomputable def chargeZeroSubVOA (hEven : L.Even) (hPos : L.PosDef) :
    VOASubalgebra (latticeVOAGen L hEven hPos) where
  carrier := chargeSec L 0
  vacuum_mem := latVacuumGen_mem_chargeSec L
  conformal_mem := omegaLatGen_mem_chargeSec L
  smul_mem := fun _ hu n _ hv => chargeSec_zero_smul_mem L hEven hPos hu n hv
  graded := fun n _ hv => chargeSec_zero_graded L hEven hPos n hv
```

From the mathematics to the Lean statement

Decoding. `piHom W n` is the projection of W onto its weight-n space along the direct-sum decomposition (defined in `VOA/Modules/FiniteGenerationProof.lean`). The four fields are: the vacuum $1 \otimes e^0$ and $\omega = \frac{1}{2}\sum_a h_a(-1)^2\mathbf{1} \otimes e^0$ lie in the charge-zero sector (by definition); products of charge-zero states are charge-zero (Theorem 6.27 at $\alpha = 0$); and the charge-zero sector is the sum of its weight pieces $(\mathcal{F}_r)_w \otimes e^0$, so the weight projections preserve it.
What the subalgebra is. A Lean check made for this book (not part of this release) confirms by `rfl` that its carrier is `chargeSec L 0` and that `(chargeZeroSubVOA L hEven hPos).toVOA` has central charge `rank L`. On paper $V_L^{(0)}$ is the rank-r Heisenberg vertex operator algebra at level 1, `heisenbergVOA' r`; the library does *not* state this isomorphism, and the module docstring's phrase "the Heisenberg subalgebra" is a description, not a theorem. The library calls it the Heisenberg subalgebra because the charge-zero sector is exactly the space spanned

by oscillator monomials on e^0, and the vertex operators restricted to it are the Heisenberg fields.
Same conformal vector. `VOASubalgebra` requires $\omega \in S$, so this is a "full" (conformal) subalgebra; this is why the central charge is unchanged.

Proof on paper. As described in the dictionary. The only non-formal input is Theorem 6.27. □

Physical meaning

$V_L^{(0)}$ is the *neutral sector*: the chiral algebra of r free bosons *before* compactification, i.e. the fields that carry no momentum (polynomials in ∂X and its derivatives). It contains the stress tensor, and V_L is an extension of it by the charged vertex operators. This is the simplest example of the general principle that a rational CFT is a (simple-current or lattice) extension of a smaller, often irrational, chiral algebra: here the irrational Heisenberg algebra (Section 6.4) is extended to the rational V_L.

What the machine verified

Proved, conditional only on `hEven`, `hPos`. `#print axioms VOA.LatGen.chargeZeroSubVOA` = `[propext, Classical.choice, Quot.sound]`.

6.9.3 V_L as a module over its Heisenberg subalgebra

Theorem 6.29 (Charged Fock modules inside V_L). *Let L be even and positive-definite. Then V_L is a weak module over $V_L^{(0)}$ by restriction of the adjoint action, and each charge sector $\mathcal{F}_r \otimes e^\alpha$ is a submodule.*

Files `VOA/Modules/ModuleRestrict.lean`, `VOA/Examples/LatticeCharge.lean`.

```
noncomputable def adjointRestrict : WeakModule S.toVOA V :=
  S.restrictWeakModule (adjointWeakModule W)

noncomputable def latticeAsHeisenbergModule (hEven : L.Even) (hPos : L.PosDef) :
    WeakModule (chargeZeroSubVOA L hEven hPos).toVOA (LatModuleGen L) :=
  (chargeZeroSubVOA L hEven hPos).adjointRestrict

theorem chargeSec_invariant (hEven : L.Even) (hPos : L.PosDef) (α : L.carrier)
    (u : (chargeZeroSubVOA L hEven hPos).carrier) (n : ℤ)
    {x : LatModuleGen L} (hx : x ∈ chargeSec L α) :
    (latticeAsHeisenbergModule L hEven hPos).act u n x ∈ chargeSec L α
```

From the mathematics to the Lean statement

`WeakModule V M` is a weak module (Definition 12.1): a field-valued linear map Y_M with vacuum, truncation and module Jacobi identity. `restrictWeakModule` composes Y_M with the inclusion $S \hookrightarrow W$; every axiom is the W-axiom evaluated on elements of S, so in particular the module Jacobi identity is *inherited* from the Borcherds identity of V_L rather than re-proved. `act u n x` is $u_{(n)}x$. So `chargeSec_invariant` says that $\mathcal{F}_r \otimes e^\alpha$ is stable under all modes of all neutral fields, i.e. is a $V_L^{(0)}$-submodule. On paper it is the charged Fock module $\mathcal{F}_\alpha$ of momentum α; the library does not identify it further (e.g. it does not prove irreducibility or compute the lowest weight as a module statement), and these are *weak* modules (no grading conditions are asserted).

Proof on paper. Restriction of a module along a subalgebra is a module. Invariance of the sector is Theorem 6.27 at charge 0. □

Physical meaning

$V_L = \bigoplus_{\alpha \in L} \mathcal{F}_\alpha$ as a representation of the neutral free-boson algebra: the compactified boson is the sum, over allowed momenta, of the charged Fock sectors of the non-compact one. The charged Fock modules are realised *inside* V_L rather than constructed separately; for momenta not in L one would need spectral flow (Section 6.11).

What the machine verified

Proved, conditional only on `hEven`, `hPos`. `#print axioms` for `VOA.LatGen.latticeAsHeisenbergModule` and `VOA.LatGen.chargeSec_invariant`: `[propext, Classical.choice, Quot.sound]`.

6.10 Background charge on lattice vertex operator algebras

On V_L the zero mode of a current is not zero: on $\mathcal{F}_r \otimes e^\gamma$ the direction-a zero mode acts by the a-th frame coordinate of γ. So the free-boson construction of Section 6.6 does not transfer verbatim, and L_0 *does* change. Two files treat this, in two parallel styles: `LatticeBackgroundChargeA.lean` (namespace `VOA.LatGen.BgA`, an operator-algebra route through an abstract lemma) and `LatticeBackgroundChargeB.lean` (namespace `VOA.LatGen.BgB`, a vertex-operator route). They prove the same mathematics; we present B as primary and A's abstract lemma, which is of independent interest. These files are inputs to the triplet algebras of Chapter 18.

6.10.1 An abstract lemma

Theorem 6.30 (Background-charge deformation of a Virasoro family)**.** *Let W be a vector space, $(P_s)_{s\in\mathbb{Z}}$ operators satisfying the Virasoro relation with central charge c_0, and $(\beta_t)_{t\in\mathbb{Z}}$ operators with $[P_s, \beta_t] = -t\beta_{s+t}$ and $[\beta_s, \beta_t] = \kappa\, s\, \delta_{s+t,0}$. Then $P^\beta_n = P_n - (n+1)\beta_n$ satisfies the Virasoro relation with central charge $c_0 - 12\kappa$.*

File `VOA/Examples/LatticeBackgroundChargeA.lean`.

```
theorem bg_virasoro_core (P β : ℤ → End ℂ W) (c₀ κ : ℂ)
    (hPP : ∀ s t : ℤ, P s * P t - P t * P s
      = ((s : ℂ) - t) • P (s + t)
        + (if s + t = 0 then ((s : ℂ) ^ 3 - s) / 12 * c₀ else 0) • (1 : End ℂ W))
    (hPb : ∀ s t : ℤ, P s * β t - β t * P s = (-(t : ℂ)) • β (s + t))
    (hbb : ∀ s t : ℤ, β s * β t - β t * β s
      = (if s + t = 0 then κ * (s : ℂ) else 0) • (1 : End ℂ W))
    (m n : ℤ) :
    (P m - ((m : ℂ) + 1) • β m) * (P n - ((n : ℂ) + 1) • β n)
      - (P n - ((n : ℂ) + 1) • β n) * (P m - ((m : ℂ) + 1) • β m)
      = ((m : ℂ) - n) • (P (m + n) - (((m + n : ℤ) : ℂ) + 1) • β (m + n))
        + (if m + n = 0 then ((m : ℂ) ^ 3 - m) / 12 * (c₀ - 12 * κ) else 0) • (1 : End ℂ W)
```

From the mathematics to the Lean statement

The three hypotheses are exactly: P is Virasoro with charge c_0 (`hPP`), β is a weight-one primary current for P (`hPb`), and β is a Heisenberg current of level κ (`hbb`). The conclusion is the Virasoro relation for $P_n - (n+1)\beta_n$ with charge $c_0 - 12\kappa$. The hypotheses are all genuinely needed and satisfiable (the free boson gives $c_0 = \kappa = 1$). This is the lemma behind both

`Lld_virasoro` (with the opposite sign of β) and the lattice statements below.

Proof on paper. Expand the commutator into four pieces as in the proof of Theorem 6.18. The cross terms give $-(n+1)[P_m,\beta_n]-(m+1)[\beta_m,P_n]=n(n+1)\beta_{m+n}-m(m+1)\beta_{m+n}$, which equals $-(m-n)(m+n+1)\beta_{m+n}$, the β-part of $(m-n)P^{\beta}_{m+n}$; and $(m+1)(n+1)\kappa m\delta_{m+n,0}=-\kappa(m^3-m)\delta_{m+n,0}$, which shifts the central charge by -12κ. □

Physical meaning

The universal mechanism of background charge: improving a stress tensor by the derivative of a primary $U(1)$ current of level κ shifts c by -12κ times the square of the coefficient (here normalised to 1).

What the machine verified

Proved, unconditional in the displayed hypotheses; axiom-clean.

6.10.2 The deformed conformal vector of V_L

Definition 6.31 (Background charge on V_L)**.** Let L be even and positive-definite of rank r and $\lambda\in\mathbb{C}^r$ a vector of coordinates in the orthonormal frame of Chapter 31 (Definition 31.14). Put $\lambda(z)=\sum_a\lambda_a h^a(z)$, the current in direction λ *including* its momentum zero mode, $\langle\lambda,\mu\rangle=\sum_a\lambda_a\mu_a$, $\langle\lambda,\beta\rangle=\sum_a\lambda_a\beta^{\perp}_a$ for $\beta\in L$, and

$$\omega_\lambda=\omega+\lambda(-2)\mathbf{1}\otimes e^0,\qquad L^\lambda_n=L_n-(n+1)\lambda(n),\qquad c_\lambda=r-12\langle\lambda,\lambda\rangle.$$

File `VOA/Examples/LatticeBackgroundChargeB.lean`.

noncomputable def bgCentralCharge (lam : Fin (rank L) → ℂ) : ℂ :=
  (rank L : ℂ) - 12 * bgInner L lam lam
```

From the mathematics to the Lean statement

The background charge is not a lattice vector. `lam : Fin (rank L) → ℂ` is an arbitrary complex vector in frame coordinates; it need not lie in L, nor in $L \otimes \mathbb{Q}$. This is essential: in the applications (triplet algebras) $\lambda \in L \otimes \mathbb{Q} \setminus L$. `chargeCoord L β` are the frame coordinates $\beta^\perp$ of a lattice vector, with $\sum_a \beta_a^\perp \gamma_a^\perp = \langle \beta, \gamma \rangle$ (Chapter 31). `wordStateLatGen L [(1, a)] 0` is the word state $h_a(-2)\mathbf{1} \otimes e^0$ (the pair `(1, a)` means "derivative order 1, direction a"), so `bgState` is $\lambda(-2)\mathbf{1} \otimes e^0$ (`bgState_eq_mkEα`). `LLGen L n` is the lattice Virasoro mode $L_n = \omega_{(n+1)}$ of `latticeVOAGen`. `alphaLatGen` carries the momentum zero mode at index -1, which is the point of the construction.

Physical meaning

ω_λ is the state of the improved stress tensor $T + \partial\lambda(z)$ of r compact bosons with a background charge λ in target space. Because the momentum zero mode is now nonzero, the improvement shifts the weights of the charged states: a vertex operator e^β acquires weight $\frac{1}{2}\langle\beta,\beta\rangle - \langle\lambda,\beta\rangle$, the familiar Coulomb-gas formula $h = \frac{1}{2}p(p - 2\alpha_0)$ up to normalisation.

Theorem 6.32 (The lattice background-charge Virasoro algebra). *Let L be even and positive-definite and $\lambda \in \mathbb{C}^{\operatorname{rank} L}$. Then $Y(\omega_\lambda, z) = T(z) + \partial_z\lambda(z)$, the modes of $Y(\omega_\lambda, z)$ are $(\omega_\lambda)_{(n+1)} = L_n^\lambda$, these satisfy the Virasoro relation with central charge* $\operatorname{rank} L - 12\langle\lambda,\lambda\rangle$, *and $L_0^\lambda e^\beta = \big(\frac{1}{2}\langle\beta,\beta\rangle - \langle\lambda,\beta\rangle\big)e^\beta$ for every $\beta \in L$.*

From the mathematics to the Lean statement

Decoding. `sugFieldGen L` is $T(z) = Y(\omega, z)$ of V_L and `VOA.deriv` is ∂_z. `YfullGen_omegaBG_virasoro` is the exact shape of the field `virasoro` of Definition 4.4 for the conformal vector ω_λ, with central charge `bgCentralCharge L lam`. `LBG_zero_latChargeGen`

is the deformed weight of e^β; with $\langle\beta,\beta\rangle$ even, $\frac{1}{2}\langle\beta,\beta\rangle$ is an integer, but $\langle\lambda,\beta\rangle$ is in general not.

What is not claimed: this is not a vertex operator algebra. Only one of the four conformal axioms of Definition 4.4 is proved for ω_λ (VOA1, the Virasoro relation). The others fail or are not stated: for $\lambda \neq 0$ the eigenvalues of L_0^λ are not the integer weights of the grading `gradingLatGen` (so VOA2 fails for that grading), they need not be integers or bounded below, and ω_λ need not lie in a weight-2 space of a CFT-type grading. The source says so explicitly ("the L_0-grading and the vacuum axioms are of course *not* claimed"). No `VertexOperatorAlgebra` instance with conformal vector ω_λ is built in this chapter's files; the grading needed for one is the subject of the next subsection.

Sign convention. $\omega_\lambda = \omega + \lambda(-2)\mathbf{1}$ and $L_n^\lambda = L_n - (n+1)\lambda(n)$, opposite to Section 6.6. The sign is pinned by the weight formula: with $\langle\alpha,\alpha\rangle = 2p$ and $\lambda = \frac{p-1}{2p}\alpha$, $\langle\lambda,\alpha\rangle = p-1$, so e^α has weight $p-(p-1)=1$ and $e^{-\alpha}$ has weight $p+(p-1)=2p-1$, the normalisation used for the triplet algebras.

The duplicate file. `LatticeBackgroundChargeA.lean` proves the same Virasoro relation (`BgA.LBg_virasoro`, central charge `(rank L : ℂ) - 12 * bgForm L lam lam`), the same weight formula (`BgA.LBg_weight_latChargeGen`) and the same mode identification (`BgA.mode_YfullGen_omegaBg`), by applying Theorem 6.30 sector by sector. The two developments are independent and agree.

Proof on paper. ω_λ is a linear combination of word states whose fields are known: $Y(\omega,z)=T(z)$ and $Y(h_a(-2)\mathbf{1}\otimes e^0,z)=\partial h^a(z)$; linearity of Y gives $Y(\omega_\lambda,z)=T+\partial\lambda$. Taking modes, ∂_z turns into the factor $-(n+1)$. The Virasoro relation follows from Theorem 6.30 with $c_0=r$ (Chapter 31, Theorem 31.7 in its lattice form) and $\kappa=\langle\lambda,\lambda\rangle$, once one checks $[L_m,\lambda(n)]=-n\lambda(m+n)$. That check is where the momentum zero mode matters: on the charge-γ sector $[L_m,\lambda(n)]$ computed with the Fock oscillator alone misses a term $\delta_{m+n,0}\langle\gamma,\lambda\rangle$, which is exactly supplied by the zero mode $\lambda(0)=\langle\lambda,\gamma\rangle$. Finally $L_0e^\beta=\frac{1}{2}\langle\beta,\beta\rangle e^\beta$ and $\lambda(0)e^\beta=\langle\lambda,\beta\rangle e^\beta$. □

Physical meaning

This is the lattice Coulomb gas: compact bosons with a background charge, whose central charge $r-12\langle\lambda,\lambda\rangle$ and shifted vertex-operator weights are the starting point of the free-field realisations of W-algebras and of the logarithmic triplet algebras $\mathcal{W}(p)$: for $L=\sqrt{2p}\,\mathbb{Z}$ and $\lambda=\frac{p-1}{2p}\alpha$ one gets $c=1-6(p-1)^2/p$, which is -2 at $p=2$.

What the machine verified

Proved, conditional only on `hPos` (and `hEven` where `YfullGen` appears). `#print axioms` for `BgB.LBG_virasoro`, `BgB.YfullGen_omegaBG_virasoro`, `BgA.LBg_virasoro`, `BgA.LBg_weight_latChargeGen`, `BgA.mode_YfullGen_omegaBg`: `[propext, Classical.choice, Quot.sound]`.

Trap / dead end

The "triplet checks" are arithmetic only. `LatticeBackgroundChargeB.lean` ends with

```
theorem bgWeight_triplet (p : ℂ) :
    ((1 / 2 : ℂ) * (2 * p) - (p - 1) = 1) ∧
      ((1 / 2 : ℂ) * (2 * p) - (-(p - 1)) = 2 * p - 1)

theorem bgCentralCharge_triplet (p : ℂ) (hp : p ≠ 0) :
    (1 : ℂ) - 12 * ((p - 1) ^ 2 / (2 * p)) = 1 - 6 * (p - 1) ^ 2 / p
```

These are identities between complex numbers; they do not mention a lattice, a vertex operator or a weight. They record what one gets by substituting $\langle\alpha,\alpha\rangle = 2p$, $\langle\lambda,\alpha\rangle = p-1$ into the weight formula, but the substitution itself (that the lattice $\sqrt{2p}\,\mathbb{Z}$ with $\lambda = \frac{p-1}{2p}\alpha$ has these pairings) is not part of these theorems. The general, non-arithmetic statements are `LBg_weight_charge_self` and `LBg_weight_charge_neg` in `LatticeBackgroundChargeA.lean`, which compute $L_0^{\lambda} e^{\pm\alpha} = (\frac{1}{2} \mp c)\langle\alpha,\alpha\rangle e^{\pm\alpha}$ for $\lambda = c\alpha$.

6.10.3 $\mathbb{Q}$-valued gradings

Definition 6.33 (Quadratic refinement; refined grading)**.** A *quadratic refinement* of L is a function $q : L \to \mathbb{Q}$ with $q(\alpha+\beta) - q(\alpha) - q(\beta) = \langle\alpha,\beta\rangle$. The *refined grading* of V_L puts $(\mathcal{F}_r)_w \otimes e^{\alpha}$ in degree $w + q(\alpha) \in \mathbb{Q} \subset \mathbb{C}$.

File `VOA/Examples/LatticeQuadRefine.lean`.

```

theorem gradingLatGenQ_finrank {qr : QuadRefine L} (hqf : QFinite L qr) (k : ℂ) :
    FiniteDimensional ℂ (gradingLatGenQ L qr k)
```

From the mathematics to the Lean statement

`gradeCollapse t f k` is the sum of the pieces t_i with $f(i) = k$; `wtQ L qr (w, α)` is $w + q(\alpha)$ cast to $\mathbb{C}$. The grading is indexed by $\mathbb{C}$ (as for the library's super vertex algebras), not by $\mathbb{Z}$. Every quadratic refinement has the form $q(\alpha) = \frac{1}{2}\langle\alpha,\alpha\rangle - \langle\lambda,\alpha\rangle$ for an additive $\langle\lambda,\cdot\rangle : L \to \mathbb{Q}$ (library lemma `QuadRefine.bgCharge_add`, under evenness), so these are exactly the gradings by background-charge weights with rational pairings. Internality holds for every q with no hypothesis on L; finite-dimensionality needs `QFinite`; CFT-type statements need `PosQuad`; at $q = \frac{1}{2}\langle\cdot,\cdot\rangle$ the refined grading is the standard one. The file builds five of the nine grading-dependent fields of a vertex operator algebra (a sixth, `vacuum_mem`, is immediate from `vacuum_grade`) and deliberately leaves out the remaining three (`grading_mode`, `conformal_mem`, `L0_grading`) that depend on the deformed L_0; so it does not yet produce a vertex operator algebra.

Physical meaning

With a background charge the conformal weights of charged states are rational (for the doublet algebras even half-integral), so the chiral algebra is graded by $\mathbb{Q}$; one must then check which sectors have integral weights to extract a bosonic vertex operator algebra.

What the machine verified

Proved (internality unconditional; finiteness under `QFinite`); axiom-clean. Infrastructure only.

6.11 Spectral flow on the Fock space: an open identity

To construct the charged Fock modules $\mathcal{F}_\lambda$ of the free boson (for $\lambda \notin L$, so not inside any V_L) the library follows Li's Δ-operator method: $Y_\lambda(u,z) = Y(\Delta(\lambda,z)u,z)$ with $\Delta(\lambda,z) = z^{\lambda a_0}\exp\big(-\sum_{n\geq 1}\frac{\lambda}{n}a_n(-z)^{-n}\big)$. On `Fock`, where $a_0 = 0$, Δ is the substitution $X_i \mapsto X_i + \lambda k(-1)^i z^{-i-1}$, implemented in `VOA/Examples/LiDelta.lean` (Chapter 11). The module Jacobi identity for Y_λ would follow from Li's conjugation identity

$$\Delta(\lambda,z)\,Y(u,z_0)\,\Delta(\lambda,z)^{-1} = Y\big(\Delta(\lambda,z+z_0)u,\,z_0\big). \tag{6.5}$$

The two files of this chapter, `FockBaseChange.lean` and `FockBC2.lean`, set up the spaces on which (6.5) typechecks and state it.

Definition 6.34 (Base change and Li's conjugation identity). Let $\mathcal{F}_W = \mathcal{F}\otimes\mathbb{C}[w]$ $(w = z^{-1})$ and transport each operator T on $\mathcal{F}$ to $T\otimes\mathrm{id}$ on $\mathcal{F}_W$. `LiConjugation k λ` is the statement that for every $u\in\mathcal{F}$ and every $j\in\mathbb{Z}$ the z_0^j-coefficient of the left side of (6.5) equals that of the right side, where the right side is expanded in z_0 and the coefficients of $\Delta(\lambda,z+z_0)u$ are convolved against the vertex index.

Files `VOA/Examples/FockBaseChange.lean`, `VOA/Examples/FockBC2.lean`.

```
noncomputable def fockWEquiv : Fock ⊗[ℂ] Polynomial ℂ ≃ₐ[ℂ] FockW :=

noncomputable def bcEnd (T : Module.End ℂ Fock) : Module.End ℂ FockW :=

theorem bcEnd_comp (T S : Module.End ℂ Fock) :
    bcEnd (T * S) = bcEnd T * bcEnd S

theorem bcR_isField {a : FormalDist (Module.End ℂ Fock)} (ha : IsField a) :

noncomputable def coeffZ₀ (l : ℕ) : FockW₂ →ₗ[ℂ] FockW :=
  Finsupp.mapRange.linearMap
    ((PowerSeries.coeff l : CoeffW₂ →ₗ[Polynomial ℂ] Polynomial ℂ).restrictScalars ℂ)

def LiConjugation (k lam : ℂ) : Prop :=
  ∀ (u : Fock) (j : ℤ),
    ((deltaSubW k lam).restrictScalars ℂ).toLinearMap ∘ₗ (YW k u j) ∘ₗ
        ((deltaSubW k (-lam)).restrictScalars ℂ).toLinearMap
      = ∑ᶠ l : ℕ, YWfull k (coeffZ₀ l (deltaSub₂ k lam u)) (j - l)
```

From the mathematics to the Lean statement

`FockW` = `MvPolynomial ℕ (Polynomial ℂ)` (Fock states with coefficients polynomial in $w = z^{-1}$), `FockW₂` = `MvPolynomial ℕ (PowerSeries (Polynomial ℂ))` (coefficients also power se-

ries in z_0). `≃ₐ[ℂ]` is an algebra isomorphism. `bcEnd` and its generalisation `bcR` transport operators to the base-changed spaces; they are ring maps on operators and preserve the field property. `YW k u j` is $Y(u,z_0)$'s z_0^j-coefficient acting on $\mathcal{F}_W$, `YWfull` extends Y to states with coefficients, and `deltaSubW k lam`, `deltaSub₂ k lam` are Li's $\Delta(\lambda,z)$ and $\Delta(\lambda,z+z_0)$ as substitutions (`LiDelta.lean`, `LiDelta2.lean`). `∘ₗ` is composition of linear maps and `∑ᶠ` a finite sum. **`LiConjugation` is a definition of a proposition; it is not proved anywhere in the library.**

Physical meaning

Spectral flow by λ shifts the momentum of every state by λ: it maps the vacuum module $\mathcal{F}_0$ to the charged module $\mathcal{F}_\lambda$, the sector created by the vertex operator $:e^{\lambda X}:$. Identity (6.5) says that the twisted fields still form a representation of the same chiral algebra. The intended application (the goal stated in the docstrings of the source file) is the family $\lambda \mapsto \mathcal{F}_\lambda$ and, by differentiating in λ, a first logarithmic (Jordan-block) module.

What the machine verified

`bcEnd`, `bcR`, `YW`, `YWfull`, `bcR_isField` and the ring-map laws are proved, axiom-clean. `LiConjugation`: **open** (stated, not proved). Nothing in this chapter depends on it.

Trap / dead end

A false version of Li's identity, recorded in the source. An earlier draft of `FockBC2.lean` extended Y to $\mathcal{F}_{W_2}$-states by treating the coefficient ring as inert scalars ($u\otimes c \mapsto c\cdot Y(u)$). For $\mathcal{F}_W$ this is correct (its coefficients depend only on z, which is inert for the vertex variable z_0), but for $\mathcal{F}_{W_2}$ it is wrong: the coefficients carry z_0-dependence, and $Y(f(z_0)v,z_0)$ means the product of series $f(z_0)Y(v,z_0)$, whose j-th coefficient is a convolution. The source gives the counterexample $u=X_i$: conjugating $Y(X_i,z_0)$ by Δ shifts every creation oscillator, spreading the correction over infinitely many indices j, while the inert-scalar right side puts the whole correction on $Y(\mathbf{1},z_0)$, supported at the single index $j=0$. The present `LiConjugation` uses the convolution (`∑ᶠ l, … (j - l)`).

6.12 Recorded traps and Lean defects

The warnings of Sections 6.8 and 6.10 record the substantive defects (a placeholder vertex operator, a tautological "locality" predicate, a misnamed central-charge lemma, and arithmetic-only "triplet checks"). We collect here the remaining, minor ones, so that the referee has them in one place. None affects a headline theorem.

Trap / dead end

Redundant hypothesis in `heisVA`. `VOA.heisVA k _hk` (`VOA/Examples/HeisenbergVOA.lean`) takes `k ≠ 0` but never uses it (hence the underscore): all vertex-algebra axioms of the rank-one Fock space are proved for every k, including $k=0$ (Theorem 6.7 has no hypothesis on k). The hypothesis is harmless (it only restricts the definition) but it is not a genuine condition. Severity: redundant hypothesis.

Trap / dead end

Stale or over-stated docstrings.

- `VOA/Examples/LatticeGenGrading.lean`: the module docstring still calls the finiteness of bounded lattice vectors an "isolated crux" blocking `gradingLatGen_isInternal` and `gradingLatGen_finrank`. It is discharged (`IntegralLattice.boundedFinite`, used by the `_of_posDef` versions), and internality needs no hypothesis at all (`gradingLatGen_isInternal_free`).
- `VOA/Examples/LatticeCharge.lean`: the module docstring says that "what remains for the sub-VOA" is the transport from word states to all of V_L; the same file completes it (`YfullGen_shiftsCharge`, `chargeZeroSubVOA`).
- `VOA/Examples/LatticeA1.lean`: the title advertises "= $\widehat{\mathfrak{sl}}_{2}$ level 1" and `LatticeVOA.OPEStructure` is described as "the Stage-2 locality input"; neither the identification with $\widehat{\mathfrak{sl}}_{2}$ at level 1 nor any use of `OPEStructure` in the locality proof exists.
- `VOA/Examples/LatticeCharge.lean`: `chargeZeroSubVOA` is documented as "the Heisenberg subalgebra"; no isomorphism with a Heisenberg vertex operator algebra is proved (Section 6.9).

Trap / dead end

Two sign conventions for the background charge. `FreeBosonGeneralC.lean` uses $\omega^{\lambda} = \omega - \lambda a_{-2}\mathbf{1}$ (and `VirasoroFock.lean` $L_n^{\lambda} = L_n + \lambda(n+1)a_n$), while `LatticeBackgroundChargeA.lean` and `LatticeBackgroundChargeB.lean` use $\omega_{\lambda} = \omega + \lambda(-2)\mathbf{1}$. Both are internally consistent and documented, and central charges agree, but deformed weights computed with one convention must be translated ($\lambda \mapsto -\lambda$) before comparing with the other.

6.13 Machine verification for this chapter

The headline declarations were audited on a scratch file importing the relevant modules, compiled with `lake env lean -DmaxSynthPendingDepth=3` (never bare `lake env lean`, which can silently insert `sorryAx`); no full `lake build` was run for this chapter. Output (abridged; every line had the same axiom list):

The PBW theorem `VOA.pbw` appears nowhere. The Lean checks made for this book outside the library (same compilation command; not part of this release) prove `OPEStructure_iff`, `latChargeGen_mem_grading`, `latticeVOA_sqrt2` and `std1_not_even` and the `rfl`/`norm_num` checks described in this chapter, each with axioms `[propext, Classical.choice, Quot.sound]`.

Release audit 2026-10-27. `Notes/Textbook/referee/RELEASE_AUDIT_FOUNDATIONS.md` (at an earlier commit; no `lake build`; not re-run for this edition). It re-ran `#print axioms` on `VOA.heisenbergVOA` and `VOA.LatGen.latticeVOAGen` (three standard axioms each), checked `VOA.Fock = MvPolynomial ℕ ℂ` by `rfl`, and judged both constructions **genuine**: VOAs of CFT type on the standard carriers, with no hypothesis beyond $k \neq 0$, respectively evenness and `PosDef`. It also records that `heisVA` and `heisVAN` are `PreVertexAlgebra`s, certified only in the weak sense (no translation covariance).

6.14 Referee's checklist

Abbreviations: E = `hEven`, P = `hPos`. "Uncond." means no hypothesis beyond the displayed data. All entries are `#print axioms`-clean (`[propext, Classical.choice, Quot.sound]`); none uses `VOA.pbw`.

Points a referee should specifically confirm:

1. *Two implementations.* `heisenbergVOA` (on `Fock`) and `heisenbergNVOA` (on `FockN r`); `latticeVOA_A1` and `latticeVOAGen`. No isomorphisms between them are proved; none is needed.

2. *Index conventions.* `FormalDist` is indexed by powers of z, `mode f n = f (-n-1)`; `X i` is $a_{-i-1}\mathbf{1}$; the A_1 boson is at level 2.

3. *Hypotheses.* $k \neq 0$ (Heisenberg VOA); even and positive-definite (lattices, any rank including 0).

4. *Not claimed in this chapter's files.* Simplicity, rationality, C_2-cofiniteness of V_L (C_2-cofiniteness: `latticeVOAGen_c2Cofinite`; rank-one strong rationality: `V2m_stronglyRational`; both in Chapter 22); $V_{A_1} \cong L_{\widehat{\mathfrak{sl}}_2}(1,0)$; $A_2(M(1)) \cong \mathbb{C}[x]$; a VOA structure with conformal vector ω_λ on V_L; Li's identity.

5. *Placeholders/tautologies.* `LatticeVOA.Yeα`, `OPEStructure`, `latticeA1_local_of_nonneg`, `latticeA1_centralCharge`, `bgWeight_triplet`, `bgCentralCharge_triplet` (warnings in Sections 6.8 and 6.10).

Notes and references

The Heisenberg vertex operator algebra and lattice vertex operator algebras are treated in I. B. Frenkel, J. Lepowsky and A. Meurman, *Vertex Operator Algebras and the Monster*, Pure and Applied Mathematics 134, Academic Press, 1988 (Chapters 1–4 for Heisenberg algebras and Fock spaces, Chapters 7–8 for the vertex operators $E^-(\alpha,z)E^+(\alpha,z)e_\alpha z^\alpha$ and V_L); in V. Chapter 7

The Virasoro vertex operator algebra: Verma modules, the Kac determinant, screenings

This chapter documents the release of the LeanVOA library named in the front matter. Every Lean quotation below is checked by `scripts/textbook/sync.py` to occur verbatim (up to whitespace and comments) in the source files of that release. The chapter was first written against an earlier state of the library; checks that were run at that earlier state and not re-run for this edition are marked as such. The chapter covers the 117 files `VOA/Examples/Virasoro*.lean` that `Notes/Textbook/assignment.txt` assigns to it (the Virasoro files about rigidity, Benoit–Saint-Aubin vectors, fusion and the boundary models belong to Chapter 8 and Chapter 19). A small number of definitions that these files use live in files of other chapters — most importantly the general Verma module $M(c,h)$, which is defined in `VOA/Examples/InverseDSVirasoroVerma.lean` (a file of Chapter 19); we quote them here, with their file, because the statements of this chapter cannot be read without them.

What the chapter establishes. In one paragraph, and with the honesty that the rest of the chapter will justify in detail:

1. For *every* complex number c the library constructs the universal Virasoro vertex operator algebra $V(c,0)$ on the universal vacuum module $U(\mathfrak{Vir})/J(c)$ (`VirModule.virasoroVOA`), proves that its creation monomials indexed by partitions into parts ≥ 2 form a basis (so $\dim V(c,0)_n$ is the number of such partitions), and constructs its simple quotient $L(c,0)$ (`VirSimple.virasoroSimple`), proved simple for every c (`VirSimple.virasoroSimple_isSimple`). Unconditional; `VOA.pbw` (the PBW theorem of Chapter 3; formerly a project axiom, now a theorem) is *not* used.

2. For every $(c,h) \in \mathbb{C}^2$ it constructs the Verma module $M(c,h)$, its PBW basis, its contravariant (Shapovalov) form, the Gram matrices of that form at every level, and the irreducible quotient $L(c,h)$ with $\dim L(c,h)_n = \operatorname{rank} G_n(c,h)$. Unconditional.

3. **The Kac determinant formula** for Virasoro Verma modules, at every level and every (c,h), is proved — but it is *not* stated as a single library declaration. The library states a conditional version (`vermaWeightDeterminant_eq_kac_of_singular`, which assumes the existence of singular vectors), an extension theorem (`verma_kac_all_of_nonreal_singular`), and, in a separate file, an unconditional construction of the singular vectors from screening operators (`screening_nonreal_kac_singular`). The composition is two lines; we performed it in Lean against the library (the check is not part of this release), and it compiled with only the three standard axioms (Section 7.11.3). Several docstrings in the Kac files still say that the singular-

vector premise "remains open"; they were written before the screening files landed and are outdated (Warning 7.14).

4. For the *vacuum* module the library proves the explicit Gram determinants at levels 4, 5, 6 (the Kac determinant of $V(c,0)$ there), the general degree and leading coefficient of the vacuum Gram determinant, and the fact that it has a *simple* zero at every minimal-model central charge $c_{p,q}$ at the first singular level $(p-1)(q-1)$; it does *not* state the full vacuum determinant formula at all levels.

5. It computes graded dimensions of $L(c,0)$ at Lee–Yang ($c=-22/5$: $\dim = 1,1,2$ at levels 4, 5, 6), Ising ($c=1/2$: $\dim L_6 = 3$) and $M(2,7)$ ($c=-68/7$: $\dim L_6 = 3$). It does *not* prove the full character formulas (Rogers–Ramanujan, the Ising vacuum character) beyond these levels.

How to read the chapter. Section 7.1 gives the physical picture: the stress tensor, the central charge, Verma modules as conformal families, null vectors, the Kac table, the minimal models and the Coulomb gas. Sections 7.2–7.5 build the universal and the simple Virasoro vertex operator algebras. Section 7.6 treats the invariant form on the vacuum module and its Gram matrices, and Section 7.7 the graded dimensions of the minimal models that the library computes. Sections 7.8 and 7.9 treat general Verma modules and their contravariant forms; Section 7.10 the Kac determinant; Section 7.11 the screening construction of singular vectors; Section 7.12 the passage from Verma modules back to the vacuum module, which is the input of the graded (first-order) rigidity theorem of Chapter 8. Section 7.13 lists the remaining files. The chapter closes with the warnings and dead ends, the verification record, the referee's checklist and the references.

The Lie-algebraic objects (the Witt algebra, the Gel'fand–Fuks cocycle, the Virasoro algebra $\mathfrak{Vir}$, its universal enveloping algebra and the universal vacuum module) are defined in Chapter 3, Sections "The Witt algebra and the Virasoro algebra" and "The universal Virasoro vacuum module". The notions of vertex algebra, vertex operator algebra, field, locality, mode, ideal, simplicity, quotient and invariant bilinear form are those of Chapters 2–5 and Chapters 4–5. We recall each one at the point where it is used.

7.1 The physical picture

7.1.1 The stress tensor and the central charge

A two-dimensional conformal field theory has a conserved, traceless stress–energy tensor. In complex coordinates its traceless part splits into a holomorphic field $T(z)$ and an antiholomorphic field $\bar{T}(\bar{z})$; the chiral algebra studied in this book is the algebra generated by holomorphic fields such as $T(z)$. Expanding in modes,

$$T(z) = \sum_{n \in \mathbb{Z}} L_n \, z^{-n-2}, \tag{7.1}$$

the coefficients L_n are the generators of infinitesimal conformal transformations $z \mapsto z + \epsilon z^{n+1}$ acting on the space of states (radial quantisation: states live on circles $|z| = r$ and L_0 generates dilatations, i.e. it is the Hamiltonian). The operator product expansion of T with itself is

$$T(z)T(w) \sim \frac{c/2}{(z-w)^4} + \frac{2T(w)}{(z-w)^2} + \frac{\partial T(w)}{z-w}, \tag{7.2}$$

and in modes it is the Virasoro algebra

$$[L_m, L_n] = (m-n)L_{m+n} + \frac{c}{12}(m^3 - m)\,\delta_{m+n,0}. \tag{7.3}$$

The number c is the *central charge*. Classically (for the Witt algebra of vector fields $-z^{n+1}\partial_z$) it is absent; quantum mechanically it appears as an anomaly: the stress tensor does not transform as a tensor under finite conformal maps but picks up $\frac{c}{12}$ times the Schwarzian derivative; on a curved surface the trace of the stress tensor is $\propto cR$ (the conformal or trace anomaly); and on a cylinder of circumference L the ground-state energy is shifted by $-\pi c/(6L)$ (the Casimir energy). The central charge "counts degrees of freedom": a free boson has $c = 1$, a free Majorana fermion $c = 1/2$.

7.1.2 Primary fields, Verma modules and descendants

A *primary* field $\phi(z)$ of conformal weight h has OPE $T(z)\phi(w) \sim h\phi(w)/(z-w)^2 + \partial\phi(w)/(z-w)$; the corresponding state $|h\rangle = \phi(0)|0\rangle$ satisfies $L_0|h\rangle = h|h\rangle$ and $L_n|h\rangle = 0$ for $n > 0$. Such a state is called a *highest-weight vector*. Acting with the creation modes L_{-n}, $n > 0$, produces the *descendants* $L_{-n_1}\cdots L_{-n_k}|h\rangle$, of weight $h + n_1 + \cdots + n_k$; together they form the *conformal family* of ϕ. The *Verma module* $M(c,h)$ is the conformal family in which no relation is imposed among descendants other than those forced by (7.3): by the Poincaré–Birkhoff–Witt theorem a basis is given by the ordered monomials $L_{-n_1}\cdots L_{-n_k}|h\rangle$ with $n_1 \geq \ldots \geq n_k \geq 1$, so the number of states at level N (weight $h+N$) is the number $\mathrm{p}(N)$ of partitions of N. The generating function of these numbers is the *character*

$$\chi_{M(c,h)}(q) = \mathrm{tr}_{M(c,h)}\, q^{L_0 - c/24} = q^{h-c/24}\prod_{n\geq 1}\frac{1}{1-q^n}.$$

The *vacuum* conformal family is special: the vacuum is invariant under the global conformal group SL_2 generated by L_{-1}, L_0, L_1, so $L_{-1}|0\rangle = 0$ as well. The universal vacuum module $V(c,0)$ is therefore spanned by monomials $L_{-n_1}\cdots L_{-n_k}|0\rangle$ with $n_i \geq 2$, and its character is $q^{-c/24}\prod_{n\geq 2}(1-q^n)^{-1}$; the state $L_{-2}|0\rangle$ is the stress tensor itself ($T(z) \leftrightarrow L_{-2}|0\rangle$ by the state–field correspondence).

7.1.3 The Shapovalov form and null vectors

Unitarity (or, more generally, the existence of a two-point function) is encoded in a bilinear form with $\langle h|h\rangle = 1$ and $L_n^\dagger = L_{-n}$. Its matrix at level N, in the PBW basis, is the *Gram* or *Shapovalov* matrix $G_N(c,h)$; for example

$$G_1 = (2h), \qquad G_2 = \begin{pmatrix} 4h(2h+1) & 6h \\ 6h & 4h + c/2 \end{pmatrix} \quad \text{in the basis } (L_{-1}^2|h\rangle, L_{-2}|h\rangle).$$

A *null vector* is a nonzero state orthogonal to every state. The basic example is a *singular vector*: a descendant $|\chi\rangle$ at level $N > 0$ that is itself annihilated by all L_n, $n > 0$; it is automatically orthogonal to everything, because pairing it with a descendant $L_{-n_1}\cdots|h\rangle$ moves the L_{-n_i} across as L_{n_i}, which kill $|\chi\rangle$. Null vectors *decouple*: all their correlation functions vanish, and in a consistent theory they are set to zero. Setting $|\chi\rangle = 0$ inside a correlation function turns into a linear differential equation for the correlator, because L_{-n} acts on a primary field at w inside correlators as a differential operator in the other insertion points — this is the mechanism by which Belavin, Polyakov and Zamolodchikov solved the minimal models.

7.1.4 The Kac determinant and the Kac table

Null vectors exist at level N exactly when $\det G_N(c,h) = 0$. Kac's theorem computes this determinant. Parametrise

$$c = 13 - 6t - \frac{6}{t}, \qquad h_{r,s}(t) = \frac{(rt-s)^2 - (t-1)^2}{4t} \qquad (r,s \geq 1). \tag{7.4}$$

Then, up to a nonzero constant,

$$\det G_N(c,h) \;\propto \prod_{\substack{r,s\geq 1 \\ rs\leq N}} \big(h - h_{r,s}(t)\big)^{\mathrm{p}(N-rs)}. \tag{7.5}$$

The factor $h - h_{r,s}$ reflects a singular vector at level rs in $M(c, h_{r,s})$; its exponent $\mathrm{p}(N - rs)$ is the number of its descendants at level N. When $t = p/q$ with $p, q \geq 2$ coprime,

$$c = c_{p,q} = 1 - \frac{6(p-q)^2}{pq},$$

and the weights $h_{r,s}$, $1 \leq r \leq q-1$, $1 \leq s \leq p-1$ (with the identification $h_{r,s} = h_{q-r,p-s}$) form the *Kac table*: the $(p-1)(q-1)/2$ primary fields of the *minimal model* $M(p,q)$. Each $h_{r,s}$ in the table carries two independent singular vectors and the irreducible module $L(c_{p,q}, h_{r,s})$ is much smaller than the Verma module. Examples: the Ising model $M(4,3)$, $c = 1/2$, with $h \in \{0, \frac{1}{16}, \frac{1}{2}\}$; the Lee–Yang model $M(5,2)$, $c = -22/5$, with $h \in \{0, -\frac{1}{5}\}$; the trivial model $M(3,2)$, $c = 0$.

For the vacuum $h = 0$: the label $(1,1)$ always gives $h_{1,1} = 0$, the singular vector being $L_{-1}|0\rangle$, which the vacuum module already removes. At $c = c_{p,q}$ the next zero-weight label is $(q-1, p-1)$ (for $p > q$), giving a vacuum null vector at level $(p-1)(q-1)$: level 4 for Lee–Yang, 6 for Ising, 2 for $c = 0$ (where $L_{-2}|0\rangle$ itself is null: $\langle T, T\rangle = c/2 = 0$).

7.1.5 Characters of minimal models

The irreducible vacuum module $L(c_{p,q}, 0)$ has character (Rocha-Caridi)

$$\chi_0(q) = \frac{q^{-c/24}}{\prod_{n\geq 1}(1-q^n)} \sum_{k\in\mathbb{Z}} \left(q^{a(k)} - q^{b(k)}\right)$$

for suitable quadratic exponents $a(k), b(k)$. For Lee–Yang ($c = -22/5$, so $-c/24 = 11/60$) it is the Rogers–Ramanujan series $H(q)$, $q^{-11/60}\chi_0 = \sum_{n\geq 0} q^{n(n+1)}/((1-q)\cdots(1-q^n)) = 1 + q^2 + q^3 + q^4 + q^5 + 2q^6 + \cdots$; for Ising it is $1 + q^2 + q^3 + 2q^4 + 2q^5 + 3q^6 + \cdots$. The library computes some of these coefficients (Section 7.7).

7.1.6 The Coulomb gas and screening charges

Feigin and Fuchs, and in physics Dotsenko and Fateev, realised all these modules with a single free boson φ with a *background charge*: modify the free-boson stress tensor $T = -\frac{1}{2}(\partial\varphi)^2$ to $T = -\frac{1}{2}(\partial\varphi)^2 + i\sqrt{2}\,\alpha_0\partial^2\varphi$; then $c = 1 - 24\alpha_0^2$ (in one common normalisation), and the vertex operators $e^{i\alpha\varphi}$ are primary of weight $\alpha^2 - 2\alpha\alpha_0$ (again normalisation-dependent). Two values $\alpha_\pm$ give fields $V_\pm = e^{i\alpha_\pm\varphi}$ of weight exactly one; their contour integrals $Q_\pm = \oint V_\pm(z)\,dz$ commute with the Virasoro algebra (the integrand changes by a total derivative). These are the *screening charges*. Applying r of them,

$$Q^r|p\rangle = \oint\cdots\oint dz_1\cdots dz_r \prod_{i<j}(z_i - z_j)^{2t} \prod_i z_i^{(\cdots)} \exp\Big(\beta \sum_{n>0} \frac{a_{-n}}{n} \sum_i z_i^n\Big)|p\rangle,$$

produces a state in a Fock module that is annihilated by all L_n, $n > 0$ — a singular vector — at level rs and highest weight $h_{r,s}$. When $t = \beta^2$ is a positive integer the factor $\prod(z_i - z_j)^{2t}$ is a polynomial, the contour integral is the extraction of a single coefficient, and everything is finite algebra. This is exactly the route the library takes (Section 7.11): it constructs the screening states for $t = m^2$, proves they are nonzero and singular, deduces that $\det G_{rs}$ vanishes on the Kac curve at $t = 1, 4, 9, \ldots$, and then uses that the determinant is a Laurent polynomial in t to conclude it vanishes for every t.

7.1.7 The Sugawara construction

When a theory has currents $J^a(z)$ forming an affine Lie algebra at level k, its stress tensor can be built from them: $T(z) = \frac{1}{2(k+h^\vee)} \sum_a :J^a J^a:(z)$, the *Sugawara construction*, with $c = k\dim\mathfrak{g}/(k+h^\vee)$. For

one free boson ($\mathfrak{g} = \mathbb{C}, h^\vee = 0$) this is $T = \frac{1}{2k} :JJ:$ with $c = 1$. The library's file `VirasoroSugawara.lean` treats exactly this abelian case (Section 7.4.3); the non-abelian affine $\mathfrak{sl}_2$ Sugawara vector is in Chapter 9.

7.2 The Virasoro modes on the universal vacuum module

7.2.1 The vacuum module, recalled

Definition 7.1 (Universal vacuum module; Chapter 3)**.** Let $\mathfrak{Vir}$ be the Virasoro Lie algebra with basis L_n ($n \in \mathbb{Z}$), C and bracket $[L_m, L_n] = (m-n)L_{m+n} + \frac{m^3-m}{12}\delta_{m+n,0}C$, C central, and let $U(\mathfrak{Vir})$ be its universal enveloping algebra. For $c \in \mathbb{C}$ let $J(c) \subseteq U(\mathfrak{Vir})$ be the left ideal generated by L_n ($n \geq -1$) and $C - c$. The universal vacuum module is $V(c,0) := U(\mathfrak{Vir})/J(c)$, with vacuum $\mathbf{1} := [1]$ and $\mathfrak{Vir}$ acting by left multiplication. Write L_n also for the operator by which L_n acts.

From the mathematics to the Lean statement

Decoding. `UniversalEnvelopingAlgebra ℂ Virasoro` is Mathlib's $U(\mathfrak{Vir})$, and `ι ℂ` the canonical Lie map $\mathfrak{Vir} \to U(\mathfrak{Vir})$. A `Submodule UVir UVir` is a left ideal ($U(\mathfrak{Vir})$ acting on itself by left multiplication), `Submodule.span` is the left ideal generated by a set, and `⧸` is the quotient module. `algebraMap ℂ UVir c` is the scalar $c \cdot 1$. So `VirUniv c` is $V(c,0)$ exactly. `Algebra.lsmul` is left multiplication of $U(\mathfrak{Vir})$ on the quotient, and composing with `ι ℂ` gives the Lie action; `Lop c n` is the operator L_n. `Lop_bracket` is (7.3) as an identity of operators, with C replaced by c (this uses that C acts by c on the whole module, `vac_acts_central`, Chapter 3); the term `if m + n = 0 then … else 0` is the Kronecker delta, and `(1 : End ℂ (VirUniv c))` is the identity operator. `Lop_vacuum` is $L_n\mathbf{1} = 0$ for $n \geq -1$.
The name. The docstrings of `VirasoroField.lean` and of some neighbouring files call this module "$L(c,0)$". That is a historical misnomer: `VirUniv c` is the *universal* module $V(c,0)$,

which differs from the simple $L(c,0)$ at the degenerate central charges. The library recorded the renaming (Chapter 3); we write $V(c,0)$ throughout.
Vacuity. If $V(c,0)$ were the zero module every statement here would be trivially true. That it is not is `vacVec_ne_zero` (proved for every c, without `VOA.pbw`, in `VOA/Examples/VirasoroNonvanishing.lean`; Chapter 3 gives the statement and the linear-dilaton proof, and we recall it in Theorem 7.2).

Physical meaning

$V(c,0)$ is the conformal family of the identity operator, before any null state has been removed: every state that can be created from the vacuum by the stress tensor. The relation $L_{-1}\mathbf{1} = 0$ is translation invariance of the vacuum, $L_0\mathbf{1} = 0$ says it has energy zero, and $L_n\mathbf{1} = 0$ for $n \geq 1$ says $T(z)\mathbf{1}$ is regular at $z = 0$.

Theorem 7.2 (The vacuum is nonzero, for every c). *For every $c \in \mathbb{C}$, $\mathbf{1} \neq 0$ in $V(c,0)$.*

File `VOA/Examples/VirasoroNonvanishing.lean`.

```
theorem exists_lam (c : ℂ) : ∃ lam : ℂ, 1 - 12 * lam ^ 2 = c := by

theorem vacVec_ne_zero (c : ℂ) : VirModule.vacVec c ≠ 0 := by
```

From the mathematics to the Lean statement

The statement is exactly "$\mathbf{1} \neq 0$". Its only content is that the left ideal $J(c)$ does not contain 1. There are no hypotheses. Without it, $V(c,0) = 0$ would be a model of every statement of this chapter about $V(c,0)$, so every later non-vacuity argument rests on this theorem.

Physical meaning

The vacuum exists at every central charge: the abstract "conformal family of the identity" is a nonzero space. The witness is physical: a free boson with a background charge (a linear dilaton) has a translation-invariant vacuum and central charge $1 - 12\lambda^2$, which takes every complex value.

Proof on paper. On the free-boson Fock space $\mathbb{C}[x_1, x_2, \dots]$ with oscillators a_n, the operators $L_n^\lambda = \frac{1}{2}\sum_m :a_{n-m}a_m: + \lambda(n+1)a_n$ satisfy (7.3) with $c = 1 - 12\lambda^2$ (`Lld_virasoro`, `VirasoroFock.lean`), and kill the Fock vacuum 1 for $n \geq -1$ (`Lld_vacuum`: for $n = -1$ the background term carries the factor $n + 1 = 0$). Choose λ with $1 - 12\lambda^2 = c$ (`exists_lam`; $\mathbb{C}$ is algebraically closed). By the universal property, $a \mapsto a \cdot 1$ is a $U(\mathfrak{Vir})$-linear map $U(\mathfrak{Vir}) \to$ Fock killing the generators of $J(c)$, hence all of $J(c)$; it therefore factors through $V(c,0)$ and sends $\mathbf{1}$ to $1 \neq 0$. □

What the machine verified

`VOA.vacVec_ne_zero`: `#print axioms` gives `[propext, Classical.choice, Quot.sound]` (run for this chapter, Section 7.15). Unconditional, `VOA.pbw`-free.

7.2.2 The conformal field and its self-locality

Definition 7.3 (Conformal vector and conformal field). $\omega := L_{-2}\mathbf{1} \in V(c,0)$, and $T(z) = Y(\omega, z) := \sum_{n\in\mathbb{Z}} L_n z^{-n-2}$, a formal distribution with coefficients in $\mathrm{End}\, V(c,0)$.

File `VOA/Examples/VirasoroField.lean`.

```
noncomputable def omegaVir : VirUniv c := Lop c (-2) (vacVec c)

noncomputable def YomegaVir : FormalDist (End ℂ (VirUniv c)) := fun t => Lop c (-t - 2)

theorem mode_YomegaVir (m : ℤ) : mode (YomegaVir c) m = Lop c (m - 1) := by
```

From the mathematics to the Lean statement

Index conventions — read carefully. A `FormalDist A` is a function $\mathbb{Z} \to A$, the value at t being the coefficient of z^t (Chapter 2, Definition 2.1). So `YomegaVir c t = Lop c (-t-2)` says the coefficient of z^t is L_{-t-2}, i.e. $\sum_t L_{-t-2} z^t = \sum_n L_n z^{-n-2}$, which is (7.1). The *vertex-algebra mode* `mode f n` is the coefficient of z^{-n-1}, i.e. `mode f n = f (-n-1)` (Definition 2.7). Hence `mode (YomegaVir c) m` $= L_{m-1}$, i.e. $\omega_{(m)} = L_{m-1}$, the standard convention $L_n = \omega_{(n+1)}$.

Physical meaning

ω is the state of the stress tensor, and $Y(\omega, z) = T(z)$. The weight of ω is 2: the stress tensor has dimension $(2, 0)$.

Theorem 7.4 (The TT OPE and self-locality)**.** *As formal distributions in two variables,*

$$[T(z), T(w)] = \partial T(w)\,\delta(z-w) + 2T(w)\,\partial_w \delta(z-w) + \frac{c}{12}\,\partial_w^3 \delta(z-w),$$

and consequently $(z-w)^4[T(z), T(w)] = 0$: T is local with itself. Moreover T is a field: for every $v \in V(c,0)$, $L_n v = 0$ for all sufficiently large n.

File `VOA/Examples/VirasoroField.lean`.

```

```

File `VOA/Examples/VirasoroIsField.lean`.

```
theorem YomegaVir_isField : IsField (YomegaVir c) := by
```

From the mathematics to the Lean statement

`bracketDist a b` is the commutator $[a(z), b(w)]$ as a two-variable distribution; `deltaDeriv j f` is $f(w) \cdot \frac{1}{j!}\partial_w^j \delta(z-w)$ in the library's normalisation (Chapter 2); `YomegaVir_deriv c` is ∂T (its coefficient of w^u is $(u+1)L_{-u-3}$) and `YomegaVir_unit c` is the constant distribution $\frac{c}{12} \cdot 1$ sitting at w^0. With $\frac{1}{3!}\partial^3$ in `deltaDeriv 3`, the last term is $\frac{c}{12} \cdot \frac{1}{6} \cdot 6\,\partial_w^3 \delta =$ the $\frac{c/2}{(z-w)^4}$ pole of (7.2) (the residue $c/2$ of the fourth-order pole corresponds to $\frac{c}{2} \cdot \frac{1}{3!}\partial^3 \delta$). `Local a b` is $\exists N,\ (z-w)^N [a(z), b(w)] = 0$ (Definition 2.41); the proof takes $N = 4$. `IsField f` is: for every vector x there is B with `f j x = 0` for $j < -B$ (Definition 2.43), i.e. $L_n x = 0$ for n large. These are the standard notions, and the statements are exactly the theorem.

Physical meaning

This is the TT OPE (7.2) written as a commutator of fields: the $(z-w)^{-4}$ term is the central charge (the two-point function $\langle T(z)T(w)\rangle = \frac{c/2}{(z-w)^4}$), the $(z-w)^{-2}$ term says T has weight

2, the $(z-w)^{-1}$ term says T generates translations. Locality ($T(z)T(w) = T(w)T(z)$ up to singularities at $z = w$) is the chiral version of the statement that the stress tensor is a local observable.

Proof on paper. The coefficient of $z^s w^t$ of $[T(z), T(w)]$ is $[L_{-s-2}, L_{-t-2}]$, which by (7.3) equals $(t-s)L_{-s-t-4}$ plus the central term at $s+t+4 = 0$. Expanding the three δ-derivative terms coefficientwise produces exactly the same numbers (`bracketDist_YomegaVir`); multiplication by $(z-w)^{j+1}$ kills $\partial^j\delta(z-w)$, so $(z-w)^4$ kills all three. For the field property: $V(c,0)$ is spanned by $a \cdot \mathbf{1}$ with $a \in U(\mathfrak{Vir})$; $L_m\mathbf{1} = 0$ for $m \geq -1$, and commuting L_m past a generator $\iota(x)$ of $U(\mathfrak{Vir})$ gives $[L_m, x]$, which for m large is again a mode of large index (plus a central term that vanishes for m large); induction on the length of a gives a bound (`Lop_ann`). □

What the machine verified

`VOA.VirModule.YomegaVir_self_local`, `VOA.VirModule.YomegaVir_isField`: `[propext, Classical.choice, Quot.sound]`. Unconditional. No free-field realisation is used: the locality comes from the abstract relation (7.3) alone.

7.3 The grading and the partition basis of the vacuum module

7.3.1 Creation words and their energy

Definition 7.5 (Creation monomials and the energy grading)**.** For a list $w = [i_1, \dots, i_k]$ of natural numbers put

$$L_w\mathbf{1} := L_{-i_1-2}L_{-i_2-2}\cdots L_{-i_k-2}\mathbf{1}, \qquad E(w) := \sum_j (i_j + 2),$$

and let $V(c,0)_n$ be the span of all $L_w\mathbf{1}$ with $E(w) = n$ (and $V(c,0)_n = 0$ for $n < 0$).

File `VOA/Examples/VirasoroGrading.lean`.

```
def energyVir : List ℕ → ℕ
  | [] => 0
  | (i :: rest) => (i + 2) + energyVir rest

noncomputable def gradingVir (n : ℤ) : Submodule ℂ (VirUniv c) :=
  Submodule.span ℂ {x | ∃ ws : List ℕ, (energyVir ws : ℤ) = n ∧ negWordVir c ws = x}
```

File `VOA/Examples/VirasoroSpanning.lean`.

```
noncomputable def negWordVir : List ℕ → VirUniv c
  | [] => vacVec c
  | n :: ws => Lop c (-(n : ℤ) - 2) (negWordVir ws)
```

From the mathematics to the Lean statement

The shift by two. The list entry i stands for the mode L_{-i-2}, so the entries are ≥ 0 exactly when the modes are $L_{-2}, L_{-3}, \dots$ — the modes that act nontrivially on the vacuum. This encoding makes it impossible to write L_{-1} or a positive mode in a creation word. `gradingVir c n` is the $\mathbb{C}$-span (`Submodule.span ℂ`) of the monomials of energy n; for $n < 0$ the set is empty and the span is 0. Note that the definition does *not* say the monomials are independent, nor that $V(c,0)$ is the sum of these spaces; both are theorems below.

Physical meaning

$L_{-i_1-2}\cdots L_{-i_k-2}\mathbf{1}$ is the state of the normal-ordered product of derivatives of the stress tensor, $:\partial^{i_1}T\cdots\partial^{i_k}T:$ (up to factorials). Its energy $E(w)$ is its scaling dimension.

Theorem 7.6 ($V(c,0)$ is graded by L_0 with finite-dimensional pieces). *1. $L_0(L_w\mathbf{1}) = E(w)\,L_w\mathbf{1}$ for every word w.*

2. The creation monomials span $V(c,0)$.

3. $V(c,0) = \bigoplus_{n\in\mathbb{Z}} V(c,0)_n$ (an internal direct sum), $V(c,0)_n = 0$ for $n<0$, $V(c,0)_0 = \mathbb{C}\mathbf{1}$, and each $V(c,0)_n$ is finite-dimensional.

```
noncomputable def negSpanVir : Submodule ℂ (VirUniv c) :=
  Submodule.span ℂ (Set.range (negWordVir c))

theorem negSpanVir_eq_top : negSpanVir c = ⊤ := by
```

From the mathematics to the Lean statement

`⊥` is the zero subspace, `⊤` the whole space, `ℂ • v` the line spanned by v. `DirectSum.IsInternal (gradingVir c)` is Mathlib's "the canonical map $\bigoplus_n V(c,0)_n \to V(c,0)$ is bijective", i.e. $V(c,0)$ is the internal direct sum of the $V(c,0)_n$. `FiniteDimensional ℂ (gradingVir c n)` is literal finite-dimensionality. The theorem is exactly the textbook statement; nothing about the *dimensions* is claimed here (that is Theorem 7.8).

Physical meaning

L_0 is the Hamiltonian in radial quantisation; its eigenvalue on a descendant is the scaling dimension $h+N$. The finite-dimensionality of each $V(c,0)_n$ is what makes the partition function $\operatorname{tr} q^{L_0-c/24}$ a well-defined formal power series.

Proof on paper. (1) Commute L_0 to the right: $[L_0,L_{-n}] = nL_{-n}$ with no central term (as $-n\neq 0$), and $L_0\mathbf{1} = 0$. (2) $V(c,0)$ is generated by $\mathbf{1}$ over $U(\mathfrak{Vir})$ (cyclicity), and $U(\mathfrak{Vir})$ is spanned by monomials in the L_n and C; the span of the creation monomials contains $\mathbf{1}$ and is stable under every L_n (for $n\le -2$ by definition; for $n\ge -1$ by commuting L_n to the right, which produces shorter creation monomials and finally hits $L_n\mathbf{1}=0$) and under $C = c$ (`negSpan_rho_stable`); hence it is all of $V(c,0)$. (3) By (1), $V(c,0)_n$ lies in the n-eigenspace of L_0; eigenspaces for distinct eigenvalues are independent, and by (2) the $V(c,0)_n$ span. A word of energy n has length at most $n/2$ and entries at most n, so there are finitely many of them (`finite_energyEq`), giving finite dimension. $V(c,0)_0$ is spanned by the empty word, i.e. by $\mathbf{1}$. □

What the machine verified

`VOA.VirModule.gradingVir_isInternal`: `[propext, Classical.choice, Quot.sound]`; the other items of the theorem are used by `virasoroVOA`, whose axiom list is the same. Unconditional and `VOA.pbw`-free: the internal direct sum comes from L_0-eigenspaces, not from a PBW basis (as for the affine analogue in Chapter 3, Section 3.9).

7.3.2 The partition basis

Definition 7.7 (Sorted words)**.** A word w is *sorted* if it is weakly decreasing. A sorted word of energy n is the same thing as a partition of n into parts ≥ 2 (part $i_j + 2$). Write $\mathrm{p}_2(n)$ for the number of such partitions.

File `VOA/Examples/VirasoroPartitionBasis.lean`.

```
def SortedWord (w : List ℕ) : Prop := w.Pairwise (· ≥ ·)

def SortedOfEnergy (n : ℕ) : Type := {w : List ℕ // SortedWord w ∧ energyVir w = n}
```

From the mathematics to the Lean statement

`w.Pairwise (· ≥ ·)` says every earlier entry is $\geq$ every later entry: weakly decreasing. `SortedOfEnergy n` is the subtype of such lists with energy n, a finite type. The same predicate `SortedWord` is reused for Verma modules (Section 7.8), where entry i means L_{-i-1} instead; the reader must keep track of which shift is in force. The two conventions are stated in the docstrings and we flag them each time.

Physical meaning

Partitions into parts ≥ 2 count the states of the identity family: $\prod_{n\geq 2}(1-q^n)^{-1} = 1 + q^2 + q^3 + 2q^4 + 2q^5 + 4q^6 + \cdots$. The absence of parts equal to 1 is the absence of $L_{-1}\mathbf{1}$, i.e. translation invariance of the vacuum.

Theorem 7.8 (PBW basis of $V(c,0)$, at every c)**.** *For every $c \in \mathbb{C}$ and $n \in \mathbb{N}$, the monomials $L_w\mathbf{1}$ with w sorted of energy n form a basis of $V(c,0)_n$. Hence* $\dim V(c,0)_n = \mathrm{p}_2(n)$*, and the sorted monomials of all energies form a basis of $V(c,0)$. In particular* $\dim V(c,0)_n = 1, 0, 1, 1, 2, 2, 4, 4, 7$ *for $n = 0, \ldots, 8$ and* $\dim V(c,0)_{16} = 55$.

theorem finrank_gradingVir_sixteen (c : ℂ) : Module.finrank ℂ (gradingVir c 16) = 55 := by
```

From the mathematics to the Lean statement

Decoding. `Module.Basis ι ℂ M` is a basis of M indexed by ι; `Module.Basis.mk` builds one from a linearly independent spanning family. So `gradedBasis c n` is a basis of $V(c,0)_n$ indexed by partitions of n into parts ≥ 2, whose vectors are (by `gradedWord_val`) the monomials $L_w\mathbf{1}$. `Module.finrank` is the dimension; `Fintype.card` the number of elements of a finite type. `sortedWords n` is a computable finite set of lists, proved equal (`mem_sortedWords`) to the set of sorted words of energy n, so that the dimension at a given level is a kernel computation (`card_sortedWords_le_eight`).

Uniformity in c. The index type `SortedOfEnergy n` does not depend on c; this is what lets the Gram matrices of Section 7.6 be matrices with c-independent rows and columns, and their determinants polynomials in c.

Could it be wrong? A basis needs independence, which fails in many superficially similar modules (e.g. in the simple quotient $L(c,0)$). It holds here at *every* c, including all the minimal-model charges; that is correct, because $V(c,0)$ is the universal module (free over the subalgebra generated by $L_{-2}, L_{-3}, \dots$); the null vectors at degenerate c are nonzero vectors of $V(c,0)$, not linear relations among the monomials.

Physical meaning

The universal vacuum character is $q^{-c/24}\prod_{n\geq 2}(1-q^n)^{-1}$ for every c. All the physics of special central charges is in the passage to the irreducible quotient, where null vectors are set to zero.

Proof on paper. Spanning by sorted words. Transposing two adjacent creation modes costs a merged mode: $L_{-i-2}L_{-j-2} = L_{-j-2}L_{-i-2} + (j-i)L_{-(i+j+2)-2}$ (`negWordVir_swap`; no central term since $-i-2-j-2 \neq 0$). The merged word is shorter and has the same energy, so induction on energy and length sorts every word (`Lop_sorted_insert`).

Independence: the top symbol. Realise $V(c,0)$ in the free-boson Fock space $\mathbb{C}[X_0, X_1, \dots]$ by the linear dilaton of Theorem 7.2. The creation mode L^{λ}_{-n} ($n \geq 2$) splits, by polynomial degree, into multiplication by the quadratic $P_n = \frac{1}{2}\sum_{a+b=n-2} X_aX_b$ (degree $+2$), a degree-preserving part, and $\lambda(1-n)X_{n-1}$ (degree $+1$). Applying k modes to the vacuum 1, the degree-$2k$ component of the image of $L_w\mathbf{1}$ is therefore $\prod_j P_{i_j+2}$ — with *no* λ in it (`topSymbol_fockWordVir`). These products, over sorted words, are linearly independent: substitute $X_p \mapsto t^{B^p}$ for a large base B; then $\prod_j P_{i_j+2}$ becomes a one-variable polynomial whose degree encodes the partition in base B, so distinct partitions have distinct degrees. Given a relation $\sum_w a_w L_w\mathbf{1} = 0$, map it to Fock, take the top-degree component of the longest words present, and conclude their coefficients vanish; induct downward on length (`negWordVir_coef_zero`). Since λ never enters the top symbol, the argument is uniform in c. □

What the machine verified

`VOA.VirModule.gradedBasis`, `VOA.VirModule.finrank_gradingVir`, `VOA.VirModule.finrank_gradingVir_sixteen`: `[propext, Classical.choice, Quot.sound]`. Unconditional, `VOA.pbw`-free.

Theorem 7.9 (Feigin–Fuchs embedding of the universal vacuum module). *For every c and every λ with $1 - 12\lambda^2 = c$, the map $\Phi_\lambda : V(c,0) \to \mathrm{Fock}$, $[a] \mapsto a \cdot 1$ (linear-dilaton action), is injective; its kernel on $U(\mathfrak{Vir})$ is exactly $J(c)$.*

File `VOA/Examples/VirasoroTopSymbol.lean`.

```
theorem evAlg_vacuum_eq_zero_iff {c lam : ℂ} (hlam : 1 - 12 * lam ^ 2 = c) (a : UVir) :

theorem exists_injective_fockMap (c : ℂ) :
    ∃ Φ : VirUniv c →ₗ[ℂ] Fock, Function.Injective Φ ∧ Φ (vacVec c) = 1 := by
```

From the mathematics to the Lean statement

`evAlg lam` is the algebra map $U(\mathfrak{Vir}) \to \mathrm{End}(\mathrm{Fock})$ extending the linear-dilaton representation; `vacuum` is the Fock vacuum 1; `fockMap hlam` is the induced linear map $V(c,0) \to \mathrm{Fock}$. The statements hold at *every* c, the degenerate minimal-model charges included. A reader may expect the opposite (a free-field realisation "loses" null vectors); the docstring explains why it does not: injectivity is a statement about the universal module, whose null vectors are nonzero vectors that map to nonzero (singular) vectors of the Fock module. The non-injective maps in the Felder complex are the screening maps *between* Fock modules, which this theorem does not consider.

Physical meaning

Every state of the identity family is realised by a free boson with background charge ("Coulomb gas"), faithfully, at every central charge. Null states of $V(c,0)$ are realised by genuinely nonzero Fock states; they become zero only in the quotient that defines the minimal model.

Proof on paper. Expand $[a]$ in the partition basis; its image is the same linear combination of the Fock images of the sorted monomials, and these are independent by the top-symbol argument of Theorem 7.8. □

What the machine verified

`VOA.VirModule.fockMap_injective`: `[propext, Classical.choice, Quot.sound]`. Unconditional.

7.4 The universal Virasoro vertex operator algebra

7.4.1 Word fields

To make $V(c,0)$ a vertex operator algebra one must assign to every state a field. The plan is the reconstruction theorem (Chapter 4, Theorem 4.41): give fields for a spanning family of states, check that they are mutually local, create their states from the vacuum, and are translation covariant; then a unique vertex algebra structure exists.

Definition 7.10 (Word fields). For $i \in \mathbb{N}$ let $T_i(z) := \frac{1}{i!}\partial_z^i T(z)$, the field of $L_{-i-2}\mathbf{1}$. For a word $w = [i_1, \dots, i_k]$ define $Y_w(z) := {:}T_{i_1}(z){:}\,{:}T_{i_2}(z){:}\cdots{:}T_{i_k}(z)\mathbf{1}{:}\cdots{:}$, the iterated normal-ordered product (with $Y_{[\,]} = \mathrm{id}$).

File `VOA/Examples/VirasoroWordFields.lean`.

↪  by

theorem YwordVir_vacuum_base (ws : List ℕ) :
    (YwordVir c ws) 0 (vacVec c) = negWordVir c ws := by
```

From the mathematics to the Lean statement

`VOA.deriv^[i]` is the i-fold formal derivative $\partial_z^{(i)}$; `nprod` is the normal-ordered product $:a(z)b(z):$ of two fields (Chapter 4), which needs proofs that both factors are fields — hence the recursive packaging `YwordVirF` of a distribution with its field certificate. `YwordVir_local` is mutual locality of all word fields (via Dong's lemma, Theorem 4.16); `YwordVir_vacuum_base` says the z^0-coefficient of $Y_w(z)\mathbf{1}$ is $L_w\mathbf{1}$, i.e. Y_w creates the creation monomial (there is also `YwordVir_vacuum_neg`: no negative powers of z appear in $Y_w(z)\mathbf{1}$).

Physical meaning

Y_w is the field $:\partial^{i_1}T\cdots\partial^{i_k}T:$ (divided by factorials) — all composite operators that can be built from T. Their mutual locality is the statement that composites of local fields are local.

Theorem 7.11 (Reconstruction of the vertex operators). *There is a linear map $Y : V(c,0) \to \mathrm{End}(V(c,0))[[z^{\pm1}]]$ with $Y(L_w\mathbf{1},z) = Y_w(z)$ for every word w, every $Y(u,z)$ a field, all mutually local, $Y(u,z)\mathbf{1} = u + O(z)$, and $[L_{-1}, Y(u,z)] = \partial_z Y(u,z)$.*

↪  c).choose

theorem virYA_omega : virYA c (omegaVir c) = YomegaVir c := by
```

From the mathematics to the Lean statement

Decoding. The six conjuncts are, in order: Y agrees with the word fields on creation monomials; every $Y(u)$ is a field; mutual locality; the z^0 coefficient of $Y(u,z)\mathbf{1}$ is u; negative powers of z in $Y(u,z)\mathbf{1}$ vanish; `DCovariant (Ltrans c) f` is $[L_{-1}, f(z)] = \partial_z f(z)$ (`Ltrans c = Lop c (-1)`, Definition 4.38). `virYA c` is *a* map with these properties, chosen by `Classical.choice` (`.choose`); by Goddard uniqueness (Theorem 4.14) there is only one, so the choice is harmless. `virYA_omega` says the chosen map sends ω to $T(z)$.
Hypotheses. None beyond $c \in \mathbb{C}$. The term proof (not shown in full) passes the word fields, `negSpanVir_eq_top`, `YwordVir_local`, the creation tower and translation covariance of the word fields to the general theorem `Reconstruction.reconstruct` of Chapter 4.

Physical meaning

The state–field correspondence for the identity family: every state of $V(c,0)$ is created from the vacuum by a unique local field built from T. The theorem says that the TT OPE (7.2) alone determines the whole chiral algebra.

Proof on paper. This is the reconstruction theorem: given a spanning family of states with mutually local fields that create them and are translation covariant, define Y on the span; well-definedness (two words with the same state give the same field) follows from Goddard's uniqueness: a field F that is local with every Y_w and satisfies $F(z)\mathbf{1} = 0$ is zero (`field_eq_zero_of_vacuum`), because $F(z)Y_w(x)\mathbf{1}$ and $Y_w(x)F(z)\mathbf{1} = 0$ agree after multiplying by a power of $(z-x)$, and setting $x = 0$ gives $F(z)L_w\mathbf{1} = 0$ for all w, which span. Locality, the creation property and covariance of the extended fields are then inherited from the generators by linearity and Dong's lemma. □

        ↪  := by
```

From the mathematics to the Lean statement

Every field of the structure `VertexOperatorAlgebra` (Definition 4.4) is discharged by a named theorem. Reading them against the definition: `grading/isInternal/ finrank` are Theorem 7.6 (the field named `finrank` is the finite-dimensionality of each $V(c,0)_n$); `grading_mode` is $u_{(n)}V(c,0)_\ell \subseteq V(c,0)_{k+\ell-n-1}$ for $u \in V(c,0)_k$ (`virYA_grading_mode`, `VirasoroGradedField.lean`); `vacuum_Y` is $Y(\mathbf{1},z) = \mathrm{id}$; `creation` is $u_{(-1)}\mathbf{1} = u$ and $u_{(n)}\mathbf{1} = 0$ for $n \geq 0$; `locality` and `regularity` ($u_{(n)}v = 0$ for $n \gg 0$) are from Theorem 7.11; `virasoro` is `virYA_virasoro`: the modes $L_n = \omega_{(n+1)}$ satisfy (7.3) with central charge `c` (the bracket $[\cdot,\cdot]$ on End is the commutator); `L0_grading` is $L_0 = n$ on $V(c,0)_n$; `translation` is $Y(L_{-1}u,z) = \partial_z Y(u,z)$; `vacuum_grade` is $V(c,0)_0 = \mathbb{C}\mathbf{1}$; `positivity` is $V(c,0)_n = 0$ for $n < 0$.
Universal, not simple. The docstring of `virasoroVOA` reads "*the general central-charge Virasoro vertex operator algebra* $\mathrm{Vir}(c) = L(c,0)$, the universal Virasoro vacuum VOA". The equation with $L(c,0)$ is a misnomer: this is the *universal* $V(c,0)$ (Warning 7.14); the simple one is Definition 7.15.
Non-degeneracy. `omegaVir_ne_zero`: $\omega \neq 0$, for every c. (An earlier version assumed $c \neq 0$, because its proof used $L_2\omega = \frac{c}{2}\mathbf{1}$; for $c = 0$, $\omega \neq 0$ too — it is a basis vector by Theorem 7.8. This book flagged the hypothesis as redundant (Warning 7.14), and the library has since removed it: the current statement, quoted above, is hypothesis-free and is proved via the Lee–Yang computation `LeeYang.L2vac_ne_zero`.)

Physical meaning

The chiral algebra of a CFT of central charge c generated by the stress tensor alone, with no relation imposed. Every CFT with central charge c contains a quotient of it (the vacuum sector of its Virasoro symmetry).

Proof on paper. All axioms but three are restatements of Theorems 7.6 and 7.11. *Virasoro relation*: since $Y(\omega) = T$, the modes $\omega_{(n+1)}$ are the operators L_n, which satisfy (7.3) by Theorem 7.4's source `Lop_bracket`. *Translation*: both $Y(L_{-1}v,z)$ and $\partial_z Y(v,z)$ are L_{-1}-covariant, local with all word fields, and agree on the vacuum to first order; Goddard uniqueness identifies them. *Grading of modes*: each word field is a "graded field of weight $E(w)$" (its z^j coefficient shifts the weight by $E(w)+j$), a property preserved by derivatives and normal-ordered products (`GradedFieldVir.nprod`). □

What the machine verified

`VOA.VirModule.virasoroVOA`, `VOA.VirModule.omegaVir_ne_zero`: `[propext, Classical.choice, Quot.sound]`. Unconditional, for every $c \in \mathbb{C}$, `VOA.pbw`-free.

7.4.3 The free boson at $c = 1$: the abelian Sugawara construction

Before the general construction existed, the library realised a Virasoro VOA at $c = 1$ inside the Heisenberg VOA of Chapter 6. It remains in the library.

Theorem 7.13 (Sugawara at $c = 1$). *For every $k \neq 0$, in the rank-one Heisenberg VOA at level k with conformal vector $\omega = \frac{1}{2k}a_{-1}^2\mathbf{1}$, the modes $L_n = \omega_{(n+1)}$ satisfy (7.3) with $c = 1$. At $k = 1$ this VOA is recorded as* `virasoroVOA1`.

File `VOA/Examples/VirasoroSugawara.lean`.

```
noncomputable def L (k : ℂ) (_hk : k ≠ 0) (n : ℤ) : End ℂ Fock :=
  mode (Y k (ω k)) (n + 1)

theorem virasoro_relation_c1 (k : ℂ) (hk : k ≠ 0) (m n : ℤ) :
    ⁅L k hk m, L k hk n⁆
      = ((m : ℂ) - n) • L k hk (m + n)
        + (if m + n = 0 then ((m : ℂ) ^ 3 - m) / 12 else 0) • (1 : End ℂ Fock) := by
```

File `VOA/Examples/VirasoroVOA.lean`.

```
noncomputable def virasoroVOA1 : VertexOperatorAlgebra Fock :=
  heisenbergVOA 1 one_ne_zero

theorem virasoroVOA1_centralCharge : virasoroVOA1.centralCharge = 1 := rfl
```

From the mathematics to the Lean statement

`Y k`, `ω k`, `heisenbergVOA` are the Heisenberg VOA of Chapter 6 at level k. **Caution on what `virasoroVOA1` is**: it is literally the Heisenberg VOA on the full Fock space (`heisenbergVOA 1 one_ne_zero`), not the Virasoro sub-VOA generated by ω. It "is the $c = 1$ Virasoro VOA" only in the sense that its conformal vector generates a Virasoro algebra of central charge 1. The file's header (written before Section 7.4 existed) still says the general-c Virasoro VOA is "the documented next step"; that is outdated (Warning 7.14).

Physical meaning

The stress tensor of a free boson is $T = \frac{1}{2k}{:}JJ{:}$, the Sugawara construction for the abelian current algebra, with $c = 1$: one bosonic degree of freedom. The non-abelian version, $T = \frac{1}{2(k+h^\vee)}\sum {:}J^aJ^a{:}$, is treated for $\widehat{\mathfrak{sl}}_2$ in Chapter 9.

Proof on paper. The Heisenberg relations $[a_m, a_n] = km\delta_{m+n,0}$ and the explicit formula $L_n = \frac{1}{2k}\sum_j {:}a_{n-j}a_j{:}$ give $[L_m, a_n] = -na_{m+n}$ and then (7.3) with $c = 1$ by the standard normal-ordering computation (done in `HeisenbergCentral.lean`, Chapter 6); this file transports it to the VOA modes. □

What the machine verified

`VOA.VirasoroVOA.virasoro_relation_c1`, `VOA.virasoroVOA1`: `[propext, Classical.choice, Quot.sound]`. Unconditional.

Definition 7.14 (Minimal-model central charges). $c_{p,q} := 1 - 6(p-q)^2/(pq) \in \mathbb{Q}$ for $p, q \in \mathbb{N}$.

File `VOA/Examples/VirasoroVOA.lean`.

```
def minimalCentralCharge (p q : ℕ) : ℚ := 1 - 6 * ((p : ℚ) - q) ^ 2 / (p * q)

theorem minimalCentralCharge_ising : minimalCentralCharge 3 4 = 1 / 2 := by
```

From the mathematics to the Lean statement

A rational number, cast silently to $\mathbb{C}$ when used as a central charge. Lean defines division by zero as zero, so $c_{p,0} = 1$; every theorem using it assumes $p, q \geq 2$. The formula is symmetric in (p, q). Examples: $c_{2,3} = 0$, $c_{2,5} = -22/5$, $c_{3,4} = 1/2$, $c_{2,7} = -68/7$, $c_{4,5} = 7/10$.

Physical meaning

The BPZ minimal-model central charges: $c_{3,4} = \frac{1}{2}$ is the critical Ising model, $c_{2,5} = -\frac{22}{5}$ the Lee–Yang edge singularity, $c_{m,m+1}$ the unitary series of Friedan, Qiu and Shenker.

7.5 The simple quotient $L(c, 0)$

Definition 7.15 (Simple Virasoro VOA). $L(c, 0) := V(c, 0)/I_{\max}(c)$, where $I_{\max}(c)$ is the sum of all proper graded ideals of $V(c, 0)$, with the quotient VOA structure.

File `VOA/Core/QuotientVOA.lean`.

```
def maxGradedIdeal (W : VertexOperatorAlgebra 𝒱) : Submodule ℂ 𝒱 :=
  sSup (ProperGradedIdeals W)
```

File `VOA/Examples/VirasoroSimple.lean`.

```
noncomputable def maxIdealVir (c : ℂ) : Submodule ℂ (VirUniv c) :=
  maxGradedIdeal (virasoroVOA c)

noncomputable def virasoroSimple (c : ℂ) :
    VertexOperatorAlgebra (VirUniv c / maxIdealVir c) :=
  maxQuotientVOA (virasoroVOA c)
```

From the mathematics to the Lean statement

`ProperGradedIdeals W` is the set of graded ideals not containing the vacuum, and `sSup` their sum (Chapter 5, "maximal ideal"). `maxQuotientVOA` is the quotient VOA by it (Definition 5.19). The central charge of the quotient is still c (`virasoroSimple_centralCharge`, by `rfl`); its n-th graded piece is the image of $V(c, 0)_n$ (`virasoroSimple_grading`); the projection intertwines all products, $[u_{(n)}v] = [u]_{(n)}[v]$ (`virasoroSimple_mkQ_smul`).

Physical meaning

$L(c, 0)$ is the identity sector of the CFT with all null states removed: the chiral algebra that is actually realised. At generic c it equals $V(c, 0)$; at the minimal-model charges it is the vacuum module of the minimal model.

Theorem 7.16 ($L(c, 0)$ is simple and nondegenerate, for every c). *For every $c \in \mathbb{C}$: $L(c, 0)$ is a simple VOA (nonzero, and its only ideals are 0 and itself); its vacuum is nonzero; for $c \neq 0$ its conformal vector is nonzero; and $V(c, 0)$ itself is simple if and only if $I_{\max}(c) = 0$.*

File `VOA/Core/BilinearForm.lean`.

```
def IsSimple (W : VertexOperatorAlgebra 𝒱) : Prop :=
  (⊤ : Submodule ℂ 𝒱) ≠ ⊥ ∧ ∀ I : Submodule ℂ 𝒱, W.IsIdeal I → I = ⊥ ∨ I = ⊤
```

File `VOA/Examples/VirasoroSimple.lean`.

```
theorem virasoroSimple_isSimple : (virasoroSimple c).IsSimple :=
  isSimple_maxQuotientVOA' (virasoroVOA c) (vacVec_ne_zero c)

theorem virasoroSimple_vacuum_ne_zero : (virasoroSimple c).vacuum ≠ 0 := by

theorem virasoroSimple_conformalVector_ne_zero (hc : c ≠ 0) :
    (virasoroSimple c).conformalVector ≠ 0 := by

theorem virasoroVOA_isSimple_iff : (virasoroVOA c).IsSimple ↔ maxIdealVir c = ⊥ :=
```

From the mathematics to the Lean statement

`IsSimple` is the standard definition; `W.IsIdeal I` is a two-sided ideal ($u_{(n)}I \subseteq I$ and $I_{(n)}u \subseteq I$; Chapter 5). The proof term of `virasoroSimple_isSimple` is the general theorem "a VOA with nonzero vacuum has a simple maximal quotient" fed with `vacVec_ne_zero`. **Graded versus all ideals.** `IsSimple` quantifies over *all* ideals, but $I_{\max}$ is a sum of *graded* ideals. The gap is closed by `QuotVOA.isGradedIdeal_of_isIdeal` (every ideal of a VOA is graded, as it is L_0-stable and L_0 acts semisimply with integer eigenvalues); so the statement is the textbook one.
At $c = 0$. The theorem holds for $c = 0$, where $L(c,0) = \mathbb{C}\mathbf{1}$ is one-dimensional (Section 7.7); simplicity is then trivially true, and the conformal vector is 0 — which is why `virasoroSimple_conformalVector_ne_zero` assumes $c \neq 0$. The theorem does not say which c have $I_{\max}(c) \neq 0$; that is Kac theory (Section 7.10).

Physical meaning

Removing all null states gives an irreducible chiral algebra. The conformal vector survives (the stress tensor is not null) exactly when $\langle T, T\rangle = c/2 \neq 0$; at $c = 0$ the stress tensor is null and the irreducible vacuum sector is trivial, as for the trivial minimal model $M(3,2)$.

Proof on paper. The sum of all proper graded ideals is proper: a proper graded ideal meets $V(c,0)_0 = \mathbb{C}\mathbf{1}$ in zero, so the sum lies in $\bigoplus_{n\neq 0} V(c,0)_n$, which does not contain $\mathbf{1} \neq 0$. Ideals of the quotient pull back to ideals containing $I_{\max}$, which are $I_{\max}$ or everything. For $c \neq 0$: $\omega_{(3)}\omega = L_2\omega = \frac{c}{2}\mathbf{1}$, so an ideal containing ω contains $\mathbf{1}$. The last claim: if $I_{\max} = 0$ the projection is an isomorphism; conversely a simple VOA has no proper nonzero ideal. □

What the machine verified

`VOA.VirSimple.virasoroSimple_isSimple`, `…virasoroSimple_conformalVector_ne_zero`, `…virasoroVOA_isSimple_iff`: `[propext, Classical.choice, Quot.sound]`. Unconditional.

The library also proves that $L(c,0)$ is *self-dual* in the sense of Chapter 12 (it has a nondegenerate fully invariant bilinear form), for every c:

File `VOA/Examples/VirasoroSelfDual.lean`.

```
theorem virasoroSimple_grading_one : (virasoroSimple c).grading 1 = ⊥ := by

theorem virasoroSimple_selfDual : (virasoroSimple c).SelfDual :=
```

Here `SelfDual W` is "there is an invariant form B, fully invariant, with zero left radical" (`VOA/Modules/StronglyRational.lean`); for a simple VOA it is equivalent to $L_1V(c,0)_1 = 0$ (`selfDual_iff`), which holds vacuously since $L(c,0)_1 = 0$. Physically: the contragredient of the vacuum module is itself, i.e. the two-point function of the identity sector is nondegenerate. Axioms: `[propext, Classical.choice, Quot.sound]`.

7.6 The invariant form on the vacuum module and its Gram matrices

7.6.1 The canonical form

Definition 7.17 (Canonical invariant form on $V(c,0)$)**.** $\langle\cdot,\cdot\rangle_c$ is the unique bilinear form on $V(c,0)$ that is invariant in the sense of Frenkel–Huang–Lepowsky (Chapter 5) and normalised by $\langle \mathbf{1},\mathbf{1}\rangle = 1$. In particular $\langle L_n a, b\rangle = \langle a, L_{-n} b\rangle$ for all n.

File `VOA/Examples/VirasoroGram4.lean`.

```
noncomputable def canB : InvariantForm (virasoroVOA c) :=
  canonicalInvariantForm (vacVec_ne_zero c) (virasoroVOA_qp c)

theorem canB_adj (n : ℤ) (a b : VirUniv c) :
    (canB c).form (Lop c n a) b = (canB c).form a (Lop c (-n) b) := by
```

File `VOA/Examples/VirasoroFormSymmetry.lean`.

```
theorem canB_isSymmetric (c : ℂ) : (canB c).IsSymmetric := by
```

From the mathematics to the Lean statement

`InvariantForm W` and `canonicalInvariantForm` are the invariant-form structure and Li's construction of Chapter 5 (Theorem 5.56); the two arguments discharge its hypotheses: $\mathbf{1} \neq 0$ and $L_1 V(c,0)_1 = 0$ (vacuous since $V(c,0)_1 = 0$). The form is normalised (`canB_normalized`). `canB_adj` is Virasoro adjointness. `canB_isSymmetric` is symmetry of this particular form; the docstring warns that symmetry of a general `InvariantForm` is false (`not_forall_isSymmetric`, Chapter 5); here it follows because a form with $\langle\mathbf{1},\mathbf{1}\rangle = 1$ and adjointness is unique, and its transpose has the same properties.

Physical meaning

$\langle a, b\rangle$ is the two-point function of the corresponding fields, normalised by $\langle 0|0\rangle = 1$; $L_n^\dagger = L_{-n}$ is the reality of the stress tensor (BPZ conjugation).

7.6.2 Gram matrices and the dimension of $L(c,0)$

Theorem 7.18 (Graded dimension of $L(c,0)$ is a Gram rank)**.** *Let $G_n(c)$ be the matrix of $\langle\cdot,\cdot\rangle_c$ on $V(c,0)_n$ in the partition basis. Then* $\dim L(c,0)_n = \operatorname{rank} G_n(c)$ *for every c and n. In particular* $\dim L(c,0)_n = \mathrm{p}_2(n)$ *if* $\det G_n(c) \neq 0$*, and* $\dim L(c,0)_n < \mathrm{p}_2(n)$ *if* $\det G_n(c) = 0$.

File `VOA/Examples/VirasoroSimpleGram.lean`.

```
theorem finrank_virasoroSimple_grading_partition (n : ℕ) :
    finrank ℂ ((virasoroSimple c).grading (n : ℤ))
      = (GramMat.canGram (vacVec_ne_zero c) (virasoroVOA_qp c) (n : ℤ)
          (gradedBasis c n)).rank :=

theorem finrank_virasoroSimple_lt_of_det_eq_zero {ι : Type*} [Fintype ι] [DecidableEq ι] (n
↪  : ℤ)
    (e : Basis ι ℂ ((virasoroVOA c).grading n))
    (h : (GramMat.canGram (vacVec_ne_zero c) (virasoroVOA_qp c) n e).det = 0) :
    finrank ℂ ((virasoroSimple c).grading n) < finrank ℂ ((virasoroVOA c).grading n) :=
```

File `VOA/Core/GradedFormMatrix.lean`.

```
noncomputable def canGram : Matrix ι ι ℂ := gramMatrix (canonicalInvariantForm hne hqp) n e
```

From the mathematics to the Lean statement

`GramMat.canGram hne hqp n e` is the matrix $(\langle e_i, e_j\rangle)_{i,j}$ of the canonical form on the graded piece of weight n, in the basis e (Chapter 5, "Gram-rank spine"). `Matrix.rank` is the rank. The equation is the precise form of "$L(c,0)_n = V(c,0)_n/\mathrm{rad}$".

Physical meaning

The number of physical (non-null) states at level n of the identity sector equals the rank of the matrix of two-point functions: null states are exactly the kernel.

Proof on paper. The radical of the canonical form on a VOA of this type equals the maximal ideal (Theorem 5.57; Li's theorem, Chapter 5); the radical is graded and its weight-n part is the kernel of $G_n(c)$; so $\dim L(c,0)_n = \dim V(c,0)_n - \dim\ker G_n = \operatorname{rank} G_n$. □

What the machine verified

`VOA.VirSimpleGram.finrank_virasoroSimple_grading_partition`: `[propext, Classical.choice, Quot.sound]`. Unconditional.

7.6.3 Explicit Kac determinants of the vacuum module at levels 4, 5, 6

Theorem 7.19 (Vacuum Gram matrices at levels 4, 5, 6). *In the bases* $(L_{-2}^2\mathbf{1}, L_{-4}\mathbf{1})$, $(L_{-5}\mathbf{1}, L_{-3}L_{-2}\mathbf{1})$ *and* $(L_{-6}\mathbf{1}, L_{-4}L_{-2}\mathbf{1}, L_{-3}^2\mathbf{1}, L_{-3}L_{-2}^2\mathbf{1})$,

$$G_4 = \begin{pmatrix} \frac{c(c+8)}{2} & 3c \\ 3c & 5c \end{pmatrix}, \qquad G_5 = \begin{pmatrix} 10c & 4c \\ 4c & c(c+6) \end{pmatrix},$$

$$G_6 = \begin{pmatrix} \frac{35}{2}c & 5c & 18c & 24c \\ 5c & \frac{5c^2+16c}{2} & 14c & \frac{9c^2+48c}{2} \\ 18c & 14c & 8c^2+36c & 30c \\ 24c & \frac{9c^2+48c}{2} & 30c & \frac{3c(c+8)(c+16)}{4} \end{pmatrix},$$

and

$$\det G_4 = \tfrac{1}{2}c^2(5c+22), \quad \det G_5 = 2c^2(5c+22), \quad \det G_6 = \tfrac{3}{4}c^4(2c-1)(5c+22)^2(7c+68).$$

In particular $\det G_6(c) = 0$ *iff* $c \in \{0, \frac{1}{2}, -\frac{22}{5}, -\frac{68}{7}\}$.

theorem det_canGram6_eq_zero_iff :
    (canGram6 c).det = 0 ↔ c = 0 ∨ c = isingC ∨ c = leeYangC ∨ c = m27C := by
```

From the mathematics to the Lean statement

`!![a, b; c, d]` is Mathlib notation for an explicit matrix, rows separated by `;`. `L2L2vac c` $= L_{-2}L_{-2}\mathbf{1}$, `L4vac c` $= L_{-4}\mathbf{1}$ (defined in `LeeYangSingular.lean`, Chapter 19); the level-5 and level-6 vectors are defined in `VirasoroGram56.lean` in the orders displayed (`canGram5` uses $(L_{-5}\mathbf{1}, L_{-3}L_{-2}\mathbf{1})$, `canGram6` uses $(L_{-6}, L_{-4}L_{-2}, L_{-3}L_{-3}, L_{-2}^3)\mathbf{1}$). The matrices are the Gram matrices of the canonical form (not of some other bilinear form; an earlier version of the project used a form with the wrong normalisation, which is why the file stresses "the right form"). `isingC` $= 1/2$, `leeYangC` $= -22/5$, `m27C` $= -68/7$ are complex constants; `isingC_eq_minimalCentralCharge` identifies $1/2$ with $c_{3,4}$, and similarly for $m27C$ and $c_{2,7}$.

Consistency with Kac. The degree of $\det G_n$ in c equals the total number of parts over all partitions of n into parts ≥ 2: $2+1=3$ at level 4, $1+2=3$ at level 5, $1+2+2+3=8$ at level 6; the zeros are at the minimal-model charges with $(p-1)(q-1) \leq n$: $c_{2,3}=0$ (level 2), $c_{2,5}$ (level 4), $c_{3,4}$ and $c_{2,7}$ (level 6).

Physical meaning

These are the first nontrivial vacuum Kac determinants. A zero of $\det G_n$ at c is a central charge at which the identity family has a null state at level $\leq n$; the four values at level 6 are the trivial model, Ising, Lee–Yang and $M(2,7)$. The factor $(5c+22)^2$ at level 6 is the Lee–Yang null vector of level 4: its two level-6 descendants $L_{-2}\chi$ and $L_{-1}^2\chi$ are null, and the nullity of G_6 at $c=-\frac{22}{5}$ is indeed 2 (Theorem 7.21).

Proof on paper. Each entry is computed by moving the left monomial to the right as positive modes and commuting, using (7.3) and $L_n\mathbf{1}=0$ for $n \geq -1$. For example $\langle L_{-4}\mathbf{1}, L_{-2}^2\mathbf{1}\rangle = \langle \mathbf{1}, L_4 L_{-2}^2\mathbf{1}\rangle$ and $L_4L_{-2}L_{-2}\mathbf{1} = [L_4, L_{-2}]L_{-2}\mathbf{1} = 6L_2L_{-2}\mathbf{1} = 6\cdot\frac{c}{2}\mathbf{1}$, giving $3c$. The determinants are then polynomial algebra. □

7.6.4 The vacuum Gram determinant at every level: degree and leading coefficient

Definition 7.20 (Polynomial vacuum Gram matrix). $G_n^{\mathrm{vac}} \in \mathrm{Mat}_{p_2(n)}(\mathbb{C}[c])$ is the matrix whose (λ,μ) entry is the polynomial in c computing $\langle L_\lambda\mathbf{1}, L_\mu\mathbf{1}\rangle_c$ by the commutation algorithm.

```

From the mathematics to the Lean statement

`partitionWord n i` is the list of mode indices $-(i_j + 2)$ of the partition; the word `(partitionWord n i).reverse.map Neg.neg ++ partitionWord n j` is "the adjoint of the left monomial followed by the right monomial", and `wordPolynomial` is the vacuum coefficient of that mode word, computed with c as a formal variable (`VirasoroUniversalPairing.lean`, `universal_gram_entry`). `partitionGramPolynomial_eval` proves that evaluating at c gives the actual Gram matrix of the canonical form in the partition basis — so this is not a separately postulated polynomial. The leading coefficient is $\prod_\lambda \prod_k (\frac{k^3-k}{12})^{m_k} m_k!$, m_k the multiplicity of the part k in λ (each repeated index contributes its running count, giving the factorial).

Physical meaning

The highest power of c comes from contracting each L_{-k} on the left with an L_{-k} on the right through the central term $\frac{c}{12}(k^3 - k)$ alone: the "free-field" or large-c limit, in which the modes L_{-k} behave like independent oscillators. That the determinant has exactly the expected degree is the statement that at large c the vacuum family has no null states.

Proof on paper. Each entry has c-degree at most $\min(\ell(\lambda), \ell(\mu))$ (one power of c per central contraction); so the determinant has degree at most $\sum_\lambda \ell(\lambda)$, and the coefficient of that power is the determinant of the "top" matrix of equal-length contractions. A content argument shows this top matrix is diagonal (contractions pair equal modes, so off-diagonal equal-length partitions give zero), with diagonal entries $\prod_k (\frac{k^3-k}{12})^{m_k} m_k! \neq 0$. □

What the machine verified

`VOA.VirDeformModes.NormalOrdering.partitionDeterminant_natDegree`, …`partitionDeterminant_leadingCoeff`: `[propext, Classical.choice, Quot.sound]`. Unconditional. **Not formalised**: the full factorisation of $\det G_n^{\mathrm{vac}}(c)$ at every level (the vacuum Kac formula of Gorelik–Kac). What is proved in general is its simple zero at the first

singular level of each minimal model (Section 7.12).

7.7 Graded dimensions of the minimal models: Lee–Yang, Ising, $M(2,7)$

Theorem 7.21 (Low-level dimensions of $L(c_{p,q},0)$). 1. *Lee–Yang, $c=-\frac{22}{5}$:* $\dim L(c,0)_4=1$, $\dim L(c,0)_5=1$, $\dim L(c,0)_6=2$ *(against* $2,2,4$ *for* $V(c,0)$*).*

2. *Ising, $c=\frac{1}{2}$:* $\dim L(c,0)_6=3$*; $M(2,7)$, $c=-\frac{68}{7}$:* $\dim L(c,0)_6=3$.

3. $c=0$*:* $\dim L(c,0)_6=0$.

4. *For $c\notin\{0,-\frac{22}{5}\}$,* $\dim L(c,0)_4=2$*; for $c\notin\{0,\frac{1}{2},-\frac{22}{5},-\frac{68}{7}\}$,* $\dim L(c,0)_6=4$*; at each of these four charges* $\dim L(c,0)_6<4$.

5. *No linear isomorphism $L(-\frac{22}{5},0)\to L(\frac{1}{2},0)$ maps the weight-6 space onto the weight-6 space.*

6. $c=1$*: the maximal ideal of $V(1,0)$ meets $V(1,0)_n$ trivially for $n=4,5,6$.*

     ↪ isingC).grading 6 :=
```

From the mathematics to the Lean statement

`leeYangC : ℂ := -22 / 5` is defined in `VOA/Examples/LeeYangSingular.lean` (Chapter 19); `isingC` and `m27C` in `VirasoroGram56.lean`. All statements are about the actual simple quotient `virasoroSimple c` at that c, through Theorem 7.18. $\sqcap$ is intersection of subspaces; `≃ₗ[ℂ]` a linear isomorphism. Item 6 is honest about its scope: it says nothing about $V(1,0)_n$ for $n \geq 7$. (Classically $V(1,0)$ is simple at every level, since $c = 1$ is not of the form $c_{p,q}$ with $p, q \geq 2$ coprime; the library does not state this.) **What is not proved**: the full characters. The dimensions given are coefficients of the Rogers–Ramanujan series (q^4, q^5, q^6) and of the Ising vacuum character (q^6); they are *evidence* that the definitions are right, not the character identities.

Physical meaning

The vacuum characters of the minimal models begin

$$\text{Lee–Yang: } 1 + q^2 + q^3 + q^4 + q^5 + 2q^6 + \cdots, \qquad \text{Ising: } 1 + q^2 + q^3 + 2q^4 + 2q^5 + 3q^6 + \cdots,$$

against $1 + q^2 + q^3 + 2q^4 + 2q^5 + 4q^6$ for the universal module. The Lee–Yang null vector $5L_{-2}^2\mathbf{1} - 3L_{-4}\mathbf{1}$ at level 4 removes one state at level 4, its descendant $L_{-1}\chi$ one at level 5, and two at level 6; the Ising null vector at level 6 removes one state. At $c = 0$ the stress tensor is null, $L(c,0) = \mathbb{C}\mathbf{1}$ and all positive levels vanish. Item 5 says Lee–Yang and Ising have genuinely different chiral algebras, distinguished already by state counting.

Proof on paper. By Theorem 7.18, compute the rank of the explicit matrices of Theorem 7.19 at the given c. Lee–Yang, level 4: $G_4(-\frac{22}{5})$ is a nonzero matrix with zero determinant, so rank 1. Level 6 at Lee–Yang: the determinant vanishes to second order in $(5c + 22)$; the rank is at most 2 by an explicit factorisation of $G_6(-\frac{22}{5})$ (`canGram6_leeYang_factor`) and at least 2 by a nonzero 2×2 minor. Ising, level 6: the root is simple, and a nonzero 3×3 minor gives rank 3. At $c = 0$, $G_6(0) = 0$. Item 5: an isomorphism matching the weight-6 spaces would make their dimensions equal, $2 \neq 3$. □

What the machine verified

All items: `[propext, Classical.choice, Quot.sound]` (Section 7.15). Unconditional.

7.8 Verma modules

Definition 7.22 (Verma module $M(c,h)$)**.** For $(c,h) \in \mathbb{C}^2$ let $I(c,h) \subseteq U(\mathfrak{Vir})$ be the left ideal generated by L_n $(n > 0)$, $C - c$ and $L_0 - h$. The Verma module is $M(c,h) := U(\mathfrak{Vir})/I(c,h)$, with highest-weight vector $v_h := [1]$ and $\mathfrak{Vir}$ acting by left multiplication. For a list $w = [i_1, \ldots, i_k]$ write $L_w^{(1)} v_h := L_{-i_1-1} \cdots L_{-i_k-1} v_h$ and $|w| := \sum_j (i_j + 1)$ (the *level*).

File `VOA/Examples/InverseDSVirasoroVerma.lean`.

```
def vermaGens (c h : ℂ) : Set UVir :=
  {a | (∃ n : ℤ, 0 < n ∧ a = ι ℂ (L n))
      ∨ a = ι ℂ C - algebraMap ℂ UVir c
      ∨ a = ι ℂ (L 0) - algebraMap ℂ UVir h}
```

```
noncomputable def vermaIdeal (c h : ℂ) : Submodule UVir UVir :=
  Submodule.span _ (vermaGens c h)

def vermaMode (c h : ℂ) (m : ℤ) : End ℂ (Verma c h) :=
  vermaRho c h (L m)

def negWord (c h : ℂ) : List ℕ → Verma c h
  | [] => highestVector c h
  | i :: w => vermaMode c h (-(i : ℤ) - 1) (negWord c h w)

def energyHW (w : List ℕ) : ℕ := (w.map fun i => i + 1).sum

noncomputable def sortedSpan (c h : ℂ) (N : ℕ) : Submodule ℂ (Verma c h) :=
  Submodule.span ℂ {x | ∃ w : List ℕ,
    SortedWord w ∧ energyHW w = N ∧ negWord c h w = x}
```

From the mathematics to the Lean statement

The shift is now one, not two. In `negWord c h` the entry i means L_{-i-1}, so entry 0 is L_{-1}, which acts nontrivially on v_h when $h \neq 0$. Compare `negWordVir`, where entry i means L_{-i-2}. `energyHW` is the level. `sortedSpan c h N` is the span of sorted (weakly decreasing) words of level N, i.e. the span of the PBW monomials indexed by partitions of N into positive parts. It is defined as a span; that it is the level-N eigenspace of $L_0 - h$ is proved (`verma_mem_level_iff_eigen`, `VirasoroVermaEigenspaces.lean`).
Same construction as $V(c,0)$, with L_{-1} and $L_0 - h$ in place of L_{-1} and L_0: indeed $V(c,0)$ is a quotient of $M(c,0)$ (Theorem 7.25).

Physical meaning

$M(c,h)$ is the conformal family of a primary field of weight h with no null state removed: the primary state $v_h = |h\rangle$ and all its descendants.

Definition 7.23 (Highest-weight vectors and the universal property)**.** In a representation R of $\mathfrak{Vir}$ on V, a vector v is a *highest-weight vector of weight* (c,h) if R has central charge c, $L_n v = 0$ for $n > 0$ and $L_0 v = hv$. For such v there is a unique $\mathfrak{Vir}$-linear map $M(c,h) \to V$ with $v_h \mapsto v$.

    universalMap R v hv (vermaRho c h x w) =
      R.ρ x (universalMap R v hv w) := by
```

From the mathematics to the Lean statement

`VirRep V` (Chapter 3) is a Lie representation ρ of $\mathfrak{Vir}$ on V with a number `centralCharge` and the proof that $\rho(C)$ is that number times the identity; `virMode R n` $= \rho(L_n)$. `eval R v` is $a \mapsto a \cdot v$ on $U(\mathfrak{Vir})$; `liftQ` factors it through the quotient (the side condition `vermaIdeal_le_ker_eval` is the check that the generators of $I(c,h)$ kill v). The remaining composition only changes the scalar ring of the quotient from $U(\mathfrak{Vir})$ to $\mathbb{C}$. `universalMap_intertwines` says the result is a map of representations.

Physical meaning

Any primary state $|h\rangle$ in any theory receives a map from the Verma module: one simply lets the descendants of the abstract primary go to the actual descendants. Null vectors of the actual theory are the kernel of this map.

Theorem 7.24 (PBW basis of $M(c,h)$, for every (c,h))**.** *For every $(c,h) \in \mathbb{C}^2$: $v_h \neq 0$; the sorted monomials $L^{(1)}_w v_h$, w weakly decreasing, form a basis of $M(c,h)$; at each level N the sorted words of level N form a basis of the level-N subspace, whose dimension is the number* $\mathrm{p}(N)$ *of partitions of N.*

theorem vermaLevel_finrank (n : ℕ) :
    Module.finrank ℂ (sortedSpan c h n)=Fintype.card (VermaPartitions n) :=
```

From the mathematics to the Lean statement

`VermaPartitions n` is the finite type of sorted words of level n (entry i = part $i+1$), i.e. partitions of n into positive parts; its cardinality is $\mathrm{p}(n)$. The c and h in `vermaSortedBasis`, `vermaLevelBasis`, `vermaLevel_finrank` are section variables (`variable (c h : ℂ)` in the file), so they are universally quantified. Independence is proved without `VOA.pbw`; the affine field of `VOA.pbw` would not apply here, although its relative field (`PBWTheorem.bottom_injective`, Chapter 3) would give the nonvanishing of Verma highest-weight vectors.

Physical meaning

The Verma character $q^{h-c/24}\prod_{n\geq 1}(1-q^n)^{-1}$, for every central charge and weight.

Proof on paper. *Nonvanishing*: as for the vacuum, find a concrete representation with a nonzero highest-weight vector of weight (c,h): the charged free boson of Section 7.11 with background ℓ and momentum p has central charge $1-24\ell^2$ and vacuum weight $p^2-2\ell p$; choose $\ell^2=(1-c)/24$ and $(p-\ell)^2=h+\ell^2$ (`exists_chargedFock_parameters`). *Spanning*: straightening, as in Theorem 7.8. *Independence*: map $M(c,h)$ to a family of Fock modules depending polynomially on a momentum parameter; the coefficient of the top power of the momentum in the image of a sorted monomial is a monomial that determines the word (`vermaWordPolynomial_top`), and a triangularity argument on these leading terms gives independence (`VirasoroVermaMomentumPolynomial.lean`). □

What the machine verified

`VOA.InverseDS.VirasoroVerma.highestVector_ne_zero, …verma_sortedWord_linearIndependent, …vermaLevel_finrank: [propext, Classical.choice, Quot.sound].` Unconditional, `VOA.pbw`-free.

Theorem 7.25 (The vacuum module as a Verma quotient). *For every c, $L_{-1}v_0$ is a highest-weight vector of weight $(c,1)$ in $M(c,0)$, the induced map $\iota : M(c,1)\to M(c,0)$ is injective, the map $\pi : M(c,0)\to V(c,0)$, $v_0\mapsto \mathbf{1}$, is surjective, and $\ker\pi=\operatorname{im}\iota$. Hence $M(c,0)/M(c,1)\cong V(c,0)$.*

```
noncomputable def vacuumProjection (c : ℂ) : Verma c 0 →ₗ[ℂ] VirUniv c :=
  universalMap (virVacRep c) (vacVec c) (vacuum_highest c)
```

From the mathematics to the Lean statement

`translation_highest c` is the proof that $L_{-1}v_0$ is a highest-weight vector of weight $(c,1)$; `vacuum_highest c` that $\mathbf{1}$ is one of weight $(c,0)$ in the representation `virVacRep c` on $V(c,0)$. `LinearMap.ker`/`LinearMap.range` are kernel and image; `≃ₗ[ℂ]` a linear isomorphism. The statement is an exact sequence $0\to M(c,1)\to M(c,0)\to V(c,0)\to 0$, proved in the actual carriers, at every c (including the minimal-model charges, where $M(c,0)$ has further singular vectors that survive in $V(c,0)$).

Physical meaning

The vacuum module is the conformal family of the identity with exactly one null vector removed: $L_{-1}|0\rangle$, the statement that the identity operator is constant. Everything else about the identity family at special c is in the further quotient to $L(c,0)$.

Proof on paper. $L_1L_{-1}v_0 = 2L_0v_0 = 0$, $L_2L_{-1}v_0 = 3L_1v_0 = 0$, and $L_0L_{-1}v_0 = L_{-1}v_0$; so $L_{-1}v_0$ is highest of weight 1. The images under ι of the PBW basis of $M(c,1)$ are the PBW monomials of $M(c,0)$ ending in L_{-1} (sorted words with a final entry 0), a subfamily of a basis — hence injectivity. The PBW monomials of $M(c,0)$ *not* ending in L_{-1} map bijectively to the partition basis of $V(c,0)$, giving surjectivity and the kernel. □

What the machine verified

`VOA.InverseDS.VirasoroVerma.vacuumProjection_ker: [propext, Classical.choice, Quot.sound]`. Unconditional.

7.9 The Shapovalov form, singular vectors and the irreducible quotient

Definition 7.26 (Contravariant form). The *contravariant* (Shapovalov) form on $M(c,h)$ is the bilinear form $\langle\cdot,\cdot\rangle$ with $\langle v_h, v_h\rangle = 1$ and $\langle L_m u, v\rangle = \langle u, L_{-m}v\rangle$ for all $m \in \mathbb{Z}$.

theorem vermaContravariant_translation_norm (c h : ℂ) :
    vermaContravariant c h (negWord c h [0]) (negWord c h [0]) = 2*h := by
```

From the mathematics to the Lean statement

The construction. `Module.Dual ℂ M` is the algebraic dual $M^* = \mathrm{Hom}(M,\mathbb{C})$; a bilinear form is a linear map $M \to M^*$. `vermaHighestCoordinate` is the functional "coefficient of v_h in the PBW basis". `vermaDualRep` makes M^* a representation by $(L_m f)(v) = f(L_{-m}v)$ (`vermaDualMode`; reversing indices and composition preserves (7.3)). The highest coordinate is a highest-weight vector of weight (c,h) in M^*, so the universal property gives a $\mathfrak{Vir}$-map

$M \to M^*$; that is the form. There is **no complex conjugation**: this is the bilinear Shapovalov form, not a Hermitian form, so no positivity is involved.
Pinning it down. `vermaContravariant_unique`: any linear $B : M \to M^*$ with $B(v_h)(v_h) = 1$ and adjointness equals this one. `vermaContravariant_adj`: adjointness. `vermaContravariant_symm`: symmetry. `vermaContravariant_translation_norm`: the smoke test $\langle L_{-1}v_h, L_{-1}v_h\rangle = 2h$. So this is exactly Definition 7.26.

Physical meaning

$\langle u, v\rangle$ is the two-point function $\langle u|v\rangle$ of descendants of a primary with $L_n^\dagger = L_{-n}$. The norm $2h$ of $L_{-1}|h\rangle$ is the statement that $\partial\phi$ has two-point function $\propto h$: for $h = 0$ the field is constant and its derivative is null.

Definition 7.27 (Gram matrix, radical, irreducible quotient). $G_n(c,h)$ is the matrix of $\langle\cdot,\cdot\rangle$ on the level-n subspace in the partition basis. The *radical* $\mathrm{Rad}(c,h)$ is $\{u : \langle u,\cdot\rangle = 0\}$, and $L(c,h) := M(c,h)/\mathrm{Rad}(c,h)$.

```

From the mathematics to the Lean statement

`vermaGramMatrix c h n` is literally the matrix of the form on the partition words. `vermaGramPolynomial n` is a matrix over $\mathbb{C}[X_0, X_1]$ (X_0 = central charge, X_1 = highest weight) computed by the finite commutation algorithm; `vermaGramPolynomial_det_eval` proves that its determinant, evaluated at (c,h), is the actual determinant — so $\det G_n$ is a polynomial in (c,h), proved, not postulated. `vermaRadical` is the kernel of $u \mapsto \langle u,\cdot\rangle$.

Physical meaning

The Gram matrix collects all two-point functions of level-n descendants. The radical is the space of null states; $L(c,h)$ is the physical conformal family.

Theorem 7.28 (Radical, irreducibility, dimensions). *For every (c,h): $\mathrm{Rad}(c,h)$ is the unique maximal proper submodule of $M(c,h)$; $L(c,h)$ is irreducible and nonzero; $\dim L(c,h)_n = \mathrm{rank}\, G_n(c,h)$; and $L(c,0)$ (Verma version) is linearly isomorphic to the simple VOA $L(c,0)$ of Definition 7.15.*

  (Submodule.quotEquivOfEq _ _ (simpleVacuumProjection_ker c).symm).trans
    ((simpleVacuumProjection c).quotKerEquivOfSurjective (simpleVacuumProjection_surjective
     ↪ c))
```

From the mathematics to the Lean statement

`VermaModeStable c h S` says S is stable under every L_m (and $\mathfrak{Vir}$-submodule); `vermaSimpleMode` is the induced action on the quotient. `vermaRadical_maximal` is maximality, `vermaSimple_irreducible` irreducibility of the quotient (no nonzero proper invariant subspace), and `vermaSimple_highest_ne_zero` says the quotient is nonzero. (`verma_proper_submodule_le_radical`, in the same file, gives "every proper submodule lies in the radical".) The isomorphism `vermaSimpleVacuumEquiv` is only a *linear* isomorphism, built from the kernel identity `simpleVacuumProjection_ker`: the composite $M(c,0) \to V(c,0) \to L(c,0)$ has kernel exactly $\mathrm{Rad}(c,0)$; `vermaSimpleVacuumEquiv_mode` records that it intertwines the modes.

Physical meaning

$L(c,h)$ is the irreducible conformal family; its character is $\sum_n \operatorname{rank} G_n(c,h)\, q^{h+n-c/24}$. For $h=0$ it is the vacuum module of the chiral algebra $L(c,0)$.

Proof on paper. A proper submodule S is graded and does not contain v_h, so it lies in $\bigoplus_{n>0} M_n$; for $u \in S$ and any v, $\langle u, L_{-m_1}\cdots v_h\rangle = \langle L_{m_k}\cdots L_{m_1}u, v_h\rangle$, which is the v_h-coefficient of an element of S, hence 0. So $S \subseteq \mathrm{Rad}$; the radical is itself proper ($\langle v_h, v_h\rangle = 1$) and a submodule (adjointness). Levels are orthogonal (`vermaContravariant_orthogonal`), so the radical at level n is the kernel of G_n, giving the rank formula. For $h=0$, both $\mathrm{Rad}(c,0)$ and the preimage of $I_{\max}(c)$ are the maximal proper submodule. □

7.9.1 Singular vectors

Definition 7.29 (Singular vector). A *singular vector* at level $n > 0$ in $M(c,h)$ is a nonzero v in the level-n subspace with $L_1 v = L_2 v = 0$ (equivalently $L_m v = 0$ for all $m > 0$, since L_1, L_2 generate the positive part).

File `VOA/Examples/VirasoroKacCollisionStates.lean`.

```
def HasNonzeroSingular (c h : ℂ) (n : ℕ) : Prop :=
  ∃ v : Verma c h, v≠0 ∧ v∈sortedSpan c h n ∧
    vermaMode c h 1 v=0 ∧ vermaMode c h 2 v=0
```

File `VOA/Examples/VirasoroVermaWardSpecialization.lean`.

```
theorem verma_positive_zero_of_one_two (c h : ℂ) (v : Verma c h)
    (h1 : vermaMode c h 1 v=0) (h2 : vermaMode c h 2 v=0) :
    ∀ n : ℤ, 0<n → vermaMode c h n v=0 := by
```

From the mathematics to the Lean statement

Many statements of the library write the singular condition inline as "$v \neq 0$, $v \in$ `sortedSpan c h n`, `vermaMode c h 1 v = 0`, `vermaMode c h 2 v = 0`" (sometimes with v an element of the subtype `sortedSpan c h n`). `verma_positive_zero_of_one_two` justifies using only L_1, L_2: $[L_2, L_1] = L_3$, $[L_m, L_1] = (m-1)L_{m+1}$ generate all L_m, $m > 0$.

Physical meaning

A singular vector is a descendant that is itself primary: a null field. Its existence is the condition under which BPZ differential equations hold.

Theorem 7.30 (Singular vectors versus the Gram determinant). *Let $n > 0$.*

1. *If $M(c,h)$ has a singular vector at level n, then* $\det G_n(c,h) = 0$*; conversely if* $\det G_n(c,h) \neq 0$ *there is none.*
2. *If* $\det G_n(c,h) = 0$ *and* $\det G_k(c,h) \neq 0$ *for all $k < n$, then $M(c,h)$ has a singular vector at level n.*
3. *A singular vector v at level n generates an injective image of $M(c, h+n)$; consequently $(X-h)^{\mathrm{p}(m)}$ divides* $\det G_{n+m}(c,X)$ *as a polynomial in the highest weight X, for every $m \geq 0$.*
4. *Singular vectors at a given level are unique up to scalar.*

    v = (vermaTopCoordinate c h n v / vermaTopCoordinate c h n w) • w := by
```

From the mathematics to the Lean statement

`vermaWeightGramPolynomial c n` is the Gram matrix at fixed c as a matrix of polynomials in the highest weight X (`Polynomial.C c` is the constant c); `vermaWeightGramPolynomial_eval` shows that evaluating at h gives `vermaGramMatrix c h n`. `∣` is divisibility of polynomials. `[DecidableEq …]` arguments are bookkeeping required to form a determinant and carry no mathematical content. `vermaTopCoordinate c h n v` is the coefficient of $L_{-1}^n v_h$ in v; uniqueness is proved by showing it is nonzero on every singular vector (`verma_singular_top_ne_zero`). In item 2 the hypothesis `hlower` is needed: without it a zero of $\det G_n$ may be caused only by descendants of lower singular vectors.

Physical meaning

Item 3 is the source of the exponents $\mathrm{p}(N-rs)$ in Kac's formula: a null vector at level rs drags along its whole conformal family of null descendants, $\mathrm{p}(m)$ of them at level $rs+m$. Item 4 is the classical uniqueness of the null vector at given level (used by BPZ to write explicit null-vector equations).

Proof on paper. (1) A singular vector lies in the radical (it is orthogonal to everything, as moving creation modes across turns them into annihilation modes); its coefficient vector is a nonzero kernel vector of G_n. If $\det G_n \neq 0$ the kernel is zero. (2) A kernel vector u at level n is in the radical; then $L_m u$, $m>0$, is in the radical at level $n-m<n$, where the form is nondegenerate, so $L_m u = 0$. (3) The universal map is injective because a nonzero vector of a Verma module has linearly independent PBW descendants (`vermaDescendant_linearIndependent`: $U(\mathfrak{Vir})^-$ acts freely). The $\mathrm{p}(m)$ independent descendants at level $n+m$ lie in the radical of $M(c,h)$. Now use an elementary fact about polynomial matrices: if $A(X)$ is a square polynomial matrix and k linearly independent

vectors lie in the kernel of $A(h)$, then $(X-h)^k$ divides $\det A(X)$ (complete them to a basis; the corresponding columns of $A(X)P$ vanish at h, so each is divisible by $X-h$). (4) Two singular vectors at level n with the same top coordinate differ by a singular vector with zero top coordinate, which must be zero. □

What the machine verified

All items: `[propext, Classical.choice, Quot.sound]`. Unconditional.

7.10 The Kac determinant

7.10.1 The Kac parametrisation and the Kac product

Definition 7.31 (Kac parametrisation). For $t \in \mathbb{C}\setminus\{0\}$ and $r,s \in \mathbb{C}$ put $c(t) := 13 - 6t - 6/t$ and $h_{r,s}(t) := \big((rt-s)^2-(t-1)^2\big)/(4t)$.

File `VOA/Examples/VirasoroVermaBSA.lean`.

```

```

File `VOA/Examples/VirasoroFusionLabelRoots.lean`.

```
noncomputable def fusionKacWeight (u v t : ℂ) : ℂ :=
  ((u*t-v)^2-(t-1)^2)/(4*t)
```

From the mathematics to the Lean statement

The names are historical (`vermaBSACharge`: the charge on the Benoit–Saint-Aubin curve of Chapter 8; `fusionKacWeight`: introduced for the fusion construction) but the formulas are exactly (7.4). Lean's total division gives $6/0 = 0$, so at $t = 0$ the value $c(0) = 13$ is meaningless; every theorem below assumes $t \neq 0$. **Surjectivity**: every $c \in \mathbb{C}$ is $c(t)$ for some $t \neq 0$ (the quadratic $6t^2 - (13-c)t + 6 = 0$ has roots with product 1), so statements "for all $t \neq 0$" cover all central charges. **Orientation**: at $t = p/q$, $c(p/q) = c_{p,q}$ and $h_{r,s}(p/q) = ((pr-qs)^2-(p-q)^2)/(4pq)$ (`fusionKacWeight_minimal`, `minimalKacWeight`); with $p > q$ the vacuum label at the first singular level is $(r,s) = (q-1, p-1)$. Under $t \mapsto 1/t$, c is invariant and $h_{r,s} \leftrightarrow h_{s,r}$ (`vermaBSACharge_inv`, `fusionKacWeight_swap_inv`).

Physical meaning

In the Coulomb gas $t = \alpha_+^2$ (up to normalisation) and $h_{r,s}$ is the weight of the vertex operator with charge $\alpha_{r,s} = \frac{1-r}{2}\alpha_+ + \frac{1-s}{2}\alpha_-$. The symmetry $t \leftrightarrow 1/t$ exchanges the two screening charges.

Definition 7.32 (The Kac product). For $t \neq 0$ and $n \in \mathbb{N}$,

$$\mathcal{K}_n(t;X) := \prod_{\substack{r,s\geq 1\\ rs\leq n}} \big(X - h_{r,s}(t)\big)^{\mathrm{p}(n-rs)} \in \mathbb{C}[X], \qquad K_n := \prod_{\lambda\vdash n}\prod_{k\geq 1}(2k)^{m_k(\lambda)} m_k(\lambda)!,$$

where $m_k(\lambda)$ is the multiplicity of the part k in the partition λ.

File `VOA/Examples/VirasoroKacProduct.lean`.

```
noncomputable def vermaDiagonalContraction : List ℕ → ℂ
  | [] => 1
  | a::w => (((w.count a+1:ℕ):ℂ)*(2*((a:ℂ)+1)))*vermaDiagonalContraction w
```

From the mathematics to the Lean statement

Labels. `Fin n × Fin n` indexes pairs (i, j) with $0 \le i, j < n$; the label is $(r, s) = (i + 1, j + 1)$, and the filter keeps $rs \le n$. Since $rs \le n$ forces $r, s \le n$, no label is lost by the bound $< n$ on the indices. **Exponents.** `Fintype.card (VermaPartitions m)` is $\mathrm{p}(m)$ (partitions into positive parts; `n-…` is natural-number subtraction, harmless since $rs \le n$). **Constant.** For a sorted word w (entry a = part $a + 1$) `vermaDiagonalContraction w` multiplies, for each entry, $2(a + 1)$ (i.e. $2k$ for the part k) by the number of later equal entries plus one; over a block of m equal parts this gives $(2k)^m m!$. So $\prod_w$`vermaDiagonalContraction w` $= K_n$. Example: $K_2 = 4 \cdot (2^2 \cdot 2!) = 32$, and indeed $\det G_2 = 32h\,(h - h_{1,2})(h - h_{2,1})$.

Physical meaning

$\mathcal{K}_n$ lists the expected null vectors at level $\le n$, each with its family of descendants; K_n is the large-h normalisation, in which each L_{-k} contracted with L_k contributes $2kh$.

7.10.2 What the library proves about the determinant in general

Theorem 7.33 (Degree, leading coefficient and the degree count). *For every $c \in \mathbb{C}$ and $n \in \mathbb{N}$, $\det G_n(c, X) \in \mathbb{C}[X]$ has degree exactly $\sum_{\lambda \vdash n} \ell(\lambda)$ and leading coefficient K_n (independent of c). Moreover $\sum_{\lambda \vdash n} \ell(\lambda) = \sum_{rs \le n} \mathrm{p}(n - rs)$, so $\mathcal{K}_n(t; X)$ is monic of the same degree.*

File `VOA/Examples/VirasoroVermaGramLeading.lean`.

theorem kacWeightProduct_natDegree (t : ℂ) (n : ℕ) :
    (kacWeightProduct t n).natDegree = ∑ w : VermaPartitions n, w.val.length := by
```

From the mathematics to the Lean statement

`natDegree`, `leadingCoeff`, `Monic` are Mathlib's degree, leading coefficient and "leading coefficient 1". `w.val.length` is the number of parts $\ell(\lambda)$. `Finset.range n` is $\{0,\dots,n-1\}$. The combinatorial identity is the classical one: every partition with a marked part of size $a+1$ occurring at least $k+1$ times corresponds to a partition of $n-(a+1)(k+1)$, so both sides count pairs (partition, marked part-occurrence).

Physical meaning

At large h the descendants of a primary behave like free oscillators and the Gram matrix becomes diagonal: $\langle L_\lambda v_h, L_\lambda v_h\rangle \approx \prod_k (2kh)^{m_k} m_k!$. The degree identity says the null vectors predicted by Kac account for exactly the total number of "oscillator excitations" — no room is left for unexpected zeros.

Proof on paper. Each entry $\langle L_\lambda v_h, L_\mu v_h\rangle$ has h-degree $\le \min(\ell(\lambda),\ell(\mu))$ (each power of h comes from one contraction $[L_k, L_{-k}] \ni 2kL_0$), so $\deg\det \le \sum \ell(\lambda)$, with coefficient the determinant of the matrix of top coefficients. That matrix vanishes between partitions of different content (contractions must pair equal modes), is diagonal on equal content, and its diagonal entries are $\prod_k (2k)^{m_k} m_k! \neq 0$; it is independent of c (`vermaWeightTopMatrix_charge_independent`). □

What the machine verified

`VOA.InverseDS.VirasoroVerma.vermaWeightDeterminant_natDegree`, `…leadingCoeff`, `…verma_partition_lengths_eq_kac_count`, `…kacWeightProduct_natDegree`: `[propext, Classical.choice, Quot.sound]`. Unconditional.

    (vermaWeightGramPolynomial c n).det =
      Polynomial.C (∏ w : VermaPartitions n, vermaDiagonalContraction w.val) *
        kacWeightProduct t n := by
```

From the mathematics to the Lean statement

Hypotheses. `ht : t.im ≠ 0`: t is not real. This guarantees that the weights $h_{r,s}(t)$ of distinct positive labels are distinct (`fusionKacWeight_injective_positive`), so that the factors $X - h_{r,s}$ are pairwise coprime. `hs`: for every label in `kacLabels n`, a nonzero $v \in$`sortedSpan c h_{r,s}` (`rs`) with $L_1 v = L_2 v = 0$: a singular vector. **Note** that c and t are independent variables; the hypothesis `hs` can only hold for all labels when c is compatible with t (for $n \ge 2$ it forces

$c = c(t)$), but the theorem does not need to say so. **Conclusion**: an equality of polynomials in X (`Polynomial.C` is the constant polynomial).
Status of the hypothesis. The docstring says "The displayed singular existence premise remains open in general, so this is not an unconditional Kac or rigidity theorem." When this chapter was first written, this was already outdated (the docstring has since been corrected): the premise is discharged, for $c = c(t)$ and every nonreal t, by `screening_nonreal_kac_singular` (Theorem 7.42); see Theorem 7.43 and Warning 7.14. The theorem itself is correct as stated.

Physical meaning

Each primary of weight $h_{r,s}$ with a null vector at level rs forces the factor $(h - h_{r,s})^{\mathrm{p}(n-rs)}$ in the level-n determinant, by Theorem 7.30(3). Kac's insight is that these are all the zeros: the counting of Theorem 7.33 leaves no room for more.

Proof on paper. By Theorem 7.30(3), each $(X - h_{r,s}(t))^{\mathrm{p}(n-rs)}$ divides $D(X) := \det G_n(c, X)$. For nonreal t the $h_{r,s}(t)$ are distinct: if $h_{r,s} = h_{r',s'}$ then $(rt - s)^2 = (r't - s')^2$, so $(r - r')t = s - s'$ or $(r + r')t = s + s'$; taking imaginary parts, $r = r'$ (then $s = s'$) or $r + r' = 0$, impossible. Pairwise coprime factors each dividing D give $\mathcal{K}_n \mid D$. Both have the same degree (Theorem 7.33), $\mathcal{K}_n$ is monic and D has leading coefficient K_n; hence $D = K_n \mathcal{K}_n$. □

What the machine verified

`VOA.InverseDS.VirasoroVerma.vermaWeightDeterminant_eq_kac_of_singular: [propext, Classical.choice, Quot.sound]`. Conditional on the displayed hypothesis `hs`, which is dischargeable (Theorem 7.43).

Theorem 7.35 (Extension from nonreal to all nonzero t). *Fix N. If for every nonreal z and every label with $rs \le N$, $M(c(z), h_{r,s}(z))$ has a singular vector at level rs, then for every $t \neq 0$ and every $k \le N$,* $\det G_k(c(t), X) = K_k \, \mathcal{K}_k(t; X)$.

        kacWeightProduct t k := by
```

From the mathematics to the Lean statement

In both statements the central charge is now tied to the parameter: `vermaBSACharge z` $= c(z)$. The conclusion holds at *every* nonzero t, including real t where labels collide (e.g. $t = p/q$, the minimal models): the identity of polynomials is extended by continuity in t of both sides (the Gram entries are polynomials in $c(t)$ and X, continuous in $t \neq 0$), not by re-running the coprimality argument, which would fail at collisions. The hypothesis of `verma_kac_all_of_nonreal_singular` is stated with natural-number labels $r, s > 0$ instead of `kacLabels`; the proof converts.

Physical meaning

The Kac formula holds uniformly, including at the rational values of t where the Kac table degenerates and weights coincide (e.g. $h_{r,s} = h_{q-r,p-s}$ in the minimal models) — there the factors simply merge, and the exponents add.

Proof on paper. For nonreal z Theorem 7.34 applies at every level $k \leq N$. The coefficients of both sides, as polynomials in X, are continuous functions of z on $\mathbb{C} \setminus \{0\}$; nonreal numbers are dense; so the coefficients agree at every $t \neq 0$. □

What the machine verified

          vermaMode (vermaBSACharge t) (fusionKacWeight r s t) 2 v = 0 := by
```

From the mathematics to the Lean statement

The hypothesis is only that $\det G_{rs}$ *vanishes* at the first expected level; nothing about lower levels is assumed. The conclusion is the hypothesis `hs` of Theorem 7.34 for $c = c(t)$.

Physical meaning

A zero of the determinant at the first level where the label (r, s) can contribute is a genuine null *primary* (not a descendant of an earlier null vector), because at nonreal t no other null vector lives below.

Proof on paper. Strong induction on rs. For a label (r, s) and $k < rs$, the labels (r', s') with $r's' \leq k$ have singular vectors by induction, so Theorem 7.34 gives $\det G_k(c(t), h) = K_k \mathcal{K}_k(t; h)$ at $h = h_{r,s}(t)$; this is nonzero because $h_{r,s}(t) \neq h_{r',s'}(t)$ for the (different) labels with $r's' \leq k < rs$. Hence $\det G_{rs} = 0$ is the first degenerate level, and Theorem 7.30(2) produces a singular vector. □

What the machine verified

…verma_singular_of_nonreal_kac_roots: [propext, Classical.choice, Quot.sound]. Conditional on hroots, discharged in Theorem 7.42.

Theorem 7.37 (Infinitely many roots on a Kac curve suffice). *Fix r, s, n. The function $t \mapsto \det G_n(c(t), h_{r,s}(t))$ is a Laurent polynomial in t. If it vanishes on an infinite set of nonzero t, it vanishes at every $t \neq 0$.*

    (vermaGramMatrix (vermaBSACharge t) (fusionKacWeight r s t) n).det = 0 := by
```

From the mathematics to the Lean statement

S.Infinite: the set S is infinite. No density or accumulation point is required; that is the point of using Laurent polynomials (ℂ[T;T⁻¹], Mathlib's LaurentPolynomial): the determinant is the polynomial vermaGramPolynomial n evaluated at the Laurent polynomials $13 - 6T - 6T^{-1}$ and $\frac{1}{4}T^{-1}((rT - s)^2 - (T - 1)^2)$ (kacGramLaurent, kacGramLaurent_eval).

Physical meaning

Algebraic continuation in the Coulomb-gas parameter: a statement verified at the special values where the screening integrals are finite sums propagates to all central charges.

Proof on paper. Multiply the Laurent polynomial by T^m to clear negative powers; an ordinary polynomial with infinitely many roots is zero, and T^m is a unit. □

7.11 Screening operators and the Kac roots

7.11.1 The charged free boson

Definition 7.38 (Charged Fock representation). Let $\mathcal{F} = \mathbb{C}[x_1, x_2, \dots]$ be the rank-one Fock space with oscillators α_n, $[\alpha_m, \alpha_n] = 2m\,\delta_{m+n,0}$ (a lattice vector of norm 2). For a background $\ell \in \mathbb{C}$ and a momentum $p \in \mathbb{C}$ define

$$L_n^{\ell,p} := \frac{1}{4}\sum_j :\alpha_{n-j}\alpha_j: + p\,\alpha_n + p^2\delta_{n,0} - (n+1)\ell\big(\alpha_n + 2p\,\delta_{n,0}\big).$$

These satisfy (7.3) with $c = 1 - 24\ell^2$, and the Fock vacuum 1 is a highest-weight vector of weight $h = p^2 - 2\ell p$.

```

From the mathematics to the Lean statement

`LeeYangFock` is (an abbreviation for) `FockN 1` $= \mathbb{C}[x_{(k,0)}]$, the rank-one Fock space of Chapter 6; the name comes from its first use in the Lee–Yang inverse Drinfeld–Sokolov work of Chapter 19. `HeisenbergN.oscN 1 2 0 n` is the oscillator at level 2, i.e. $[\alpha_m, \alpha_n] = 2m\delta$; `LvirN 1 2 n` $= \frac{1}{4}\sum :\alpha\alpha:$ is its Sugawara mode. `sectorCurrent p` shifts the zero mode by the momentum: $\alpha_0 = 2p$ on the sector of momentum $p\alpha$. `chargedFockRep` packages the modes as a `VirRep` via `fixedRho`, the extension from mode relations to the Lie algebra. `exists_chargedFock_parameters`: every (c, h) is realised.

Physical meaning

This is the Coulomb gas: a free boson φ with background charge ℓ (stress tensor $T = \frac{1}{4}(\partial\varphi)^2 - \ell\,\partial^2\varphi$ in this normalisation) and a vertex operator of momentum p, whose conformal weight $p^2 - 2\ell p$ is the familiar $\alpha(\alpha - 2\alpha_0)$.

Definition 7.39 (Integer screening state)**.** Let $\beta \in \mathbb{Q} \setminus \{0\}$ with $t := \beta^2 \in \mathbb{N}$, and $r, s \geq 1$. Put $\ell := \frac{1}{2}(\beta - \beta^{-1})$ and $p := \ell + \frac{1}{2}(r\beta - s\beta^{-1})$. The *screening state* $S_{r,s} \in \mathcal{F}$ is the homogeneous polynomial of degree rs (energy rs) whose coefficient on the oscillator monomial $\prod_k x_k^{d_k}$ is

$$\frac{\beta^{\sum d_k}}{\prod_k k^{d_k} d_k!} \cdot \operatorname{coeff}_{z_1^{(r-1)t+s} \cdots z_r^{(r-1)t+s}} \Big[\prod_{i<j} (z_i - z_j)^{2t} \cdot \prod_k p_k(z)^{d_k} \Big],$$

where $p_k(z) = z_1^k + \cdots + z_r^k$ are the power sums.

  ∑ d ∈ (weightDegSetN_finite 1 (r * s)).toFinset,
    MvPolynomial.monomial d (screeningFockCoefficient r s t β (plainOccupation d) : ℂ)
```

From the mathematics to the Lean statement

Decoding. `d : ℕ →₀ ℕ` is an occupation: $d(i)$ = number of oscillators of mode $i+1$ (so $x_k^{d_k}$ with $k = i+1$; the shift by one is why `(i+1)` appears in `screeningPrefactor`). `powerSumSubstitution` sends the formal variable i to the power sum p_{i+1} in r variables; `auxiliaryLaurent` embeds polynomials into Laurent polynomials; `vandermondeLaurent r` is $\prod_{i<j}(z_i - z_j)$, raised to $2t$; evaluating a Laurent polynomial (a finitely supported function on exponent vectors) at the constant vector $((r-1)t + s, \dots)$ extracts that coefficient. The sum in `screeningFockState` runs over the finite set of occupations of energy rs; `plainOccupation` forgets the trivial colour index of `FockN 1`. So the definition is the displayed formula; in particular it is a finite sum with rational coefficients, with no infinite series and no contour integral.
Parameters. $c = 1 - 24\ell^2 = 13 - 6\beta^2 - 6\beta^{-2} = c(\beta^2)$ and $h = p^2 - 2\ell p = h_{r,s}(\beta^2)$ (`screening_central_charge`, `screening_highest_weight`): the Kac parametrisation with $t = \beta^2$. The library uses the screening only at $\beta = m \in \mathbb{N}_{>0}$, so $t = m^2$; the variable `t` of `screeningFockState` is the exponent and is set to m^2.

Physical meaning

$S_{r,s}$ is the Dotsenko–Fateev/Felder state $Q^r|p_0\rangle$: r screening currents $e^{\beta\varphi}$ integrated around the origin. The Vandermonde power is the OPE $\prod(z_i - z_j)^{2\beta^2}$ of the screening currents, the exponential $\exp(\beta \sum \alpha_{-k} p_k(z)/k)$ is their oscillator part (whence the prefactor $\beta^{\sum d}/\prod k^{d_k} d_k!$), and the contour integral picks the residue — here, since $2\beta^2$ is an even integer, a single coefficient.

Theorem 7.40 (Integer screening states are nonzero singular vectors). *For all $r, s, m \geq 1$ (with $\beta = m$, $t = m^2$): $S_{r,s} \neq 0$, $S_{r,s}$ has energy rs, and $L_1^{\ell,p} S_{r,s} = L_2^{\ell,p} S_{r,s} = 0$.*

File `VOA/Examples/VirasoroScreeningSingular.lean`.

```
theorem integer_screening_nonzero_singular (r s m : ℕ) (hr : 0 < r) (hm : 0 < m) :
```

```
    screeningFockState r s (m^2) (m:ℚ) ≠ 0 ∧
    screeningFockState r s (m^2) (m:ℚ) ∈ gradingWN 1 (r*s) ∧
    sectorVirasoro (screeningBackground (m:ℚ) : ℂ)
      (screeningMomentum r s (m:ℚ) : ℂ) 1 (screeningFockState r s (m^2) (m:ℚ)) = 0 ∧
    sectorVirasoro (screeningBackground (m:ℚ) : ℂ)
      (screeningMomentum r s (m:ℚ) : ℂ) 2 (screeningFockState r s (m^2) (m:ℚ)) = 0 := by
```

From the mathematics to the Lean statement

`gradingWN 1 (r*s)` is the energy-rs subspace of the Fock space. No hypothesis on s is needed ($s = 0$ is allowed by the statement and harmless). The two operators are the *actual* modes `sectorVirasoro` of Definition 7.38, not a model of them.

Physical meaning

The screening charge commutes with the Virasoro algebra, so it carries the highest-weight vacuum of one Fock module to a highest-weight vector of another: a null vector of the Coulomb gas at level rs and weight $h_{r,s}$.

Proof on paper. Ward identities. On the coefficients of $S_{r,s}$, the modes L_1, L_2 act as the differential operators $\sum_i z_i^{n+1}\partial_{z_i}$ $(n = 1, 2)$ plus multiplications by power sums, applied to the integrand $\Delta^{2t}\prod p_k^{d_k}$; at the chosen momentum the result is a total derivative $\sum_i \partial_{z_i}(z_i^{n+1}\cdots)$ minus terms that cancel. The finite substitute for "the contour integral of a total derivative vanishes" is a coefficient identity: at the common exponent D, the coefficient of $\sum_i z_i^{n+1}\partial_i F$ equals $(D-n)$ times the coefficient of $p_n \cdot F$ (`screening_coefficient_integration`). Combined with the product rule for Δ^{2t} (`screeningVectorField_one_vandermonde`), these give two exact linear relations among the residues, which are exactly the vanishing of the L_1- and L_2-coefficients (`screeningFockState_L1_zero`, `screeningFockState_L2_zero`).

Nonvanishing. By Newton's identities, $(z_1\cdots z_r)^s$ is a polynomial in power sums of weighted degree rs; its residue is the coefficient of $\prod z_i^{(r-1)t}$ in Δ^{2t}. That central coefficient is nonzero: with $P := \Delta^t$, reversing all exponents gives $P(1/z) = \pm P(z)/\prod_i z_i^{(r-1)t}$ (each factor $z_i^{-1} - z_j^{-1} = (z_j - z_i)/(z_i z_j)$), so the coefficient in question is $\pm$ the constant term of $P(z)P(1/z)$, which is the sum of the squares of the rational coefficients of P, hence nonzero (`vandermonde_central_coefficient_ne_zero`). By linearity some single monomial has nonzero residue (`screening_nonzero_monomial`); the prefactor is nonzero for $\beta \neq 0$. □

What the machine verified

`VOA.VirasoroScreening.integer_screening_nonzero_singular`, `VOA.VirasoroScreening.screeningFockState_ne_zero`: `[propext, Classical.choice, Quot.sound]`. Unconditional. No Dyson/Selberg product formula is used.

7.11.2 From Fock singular vectors to Verma Gram roots

Theorem 7.41 (Transfer). *Let $N > 0$ and $P \in \mathcal{F}$ be a nonzero vector of energy N with $L_1^{\ell,p}P = L_2^{\ell,p}P = 0$. Then* $\det G_N(1 - 24\ell^2,\ p^2 - 2\ell p) = 0$.

theorem fock_verma_level_finrank (c h : ℂ) (N : ℕ) :
    Module.finrank ℂ (gradingWN 1 N) = Module.finrank ℂ (sortedSpan c h N) := by
```

From the mathematics to the Lean statement

The conclusion is about the actual Verma Gram matrix, at the central charge and weight of the Fock module. Faithfulness of the free-field realisation is neither assumed nor claimed (the universal map $M \to \mathcal{F}$ is in general neither injective nor surjective).

Physical meaning

A null vector in the Coulomb gas forces a zero of the Kac determinant at the same (c, h): if the abstract conformal family had no null vector at level N, the free-field realisation would be isomorphic to it up to level N, and could not contain one either.

Proof on paper. Suppose $\det G_N \neq 0$. Then the radical of $M(c, h)$ vanishes at every level $k \leq N$ (a nonzero radical vector at level k would have a nonzero descendant at level N in the radical, by `verma_radical_zero_below`). The kernel of the universal map $M(c, h) \to \mathcal{F}$ is a proper submodule, hence in the radical, hence zero at levels $\leq N$. Levels of M and $\mathcal{F}$ have the same dimension $\mathrm{p}(k)$ (`fock_verma_level_finrank`), so the map is bijective at levels $\leq N$. Lift P to $u \neq 0$ at level N; then $L_1 u$, $L_2 u$ map to 0 at levels $< N$, where the map is injective, so u is singular — contradicting $\det G_N \neq 0$ (Theorem 7.30(1)). □

What the machine verified

`VOA.VirasoroScreening.chargedFock_singular_gram_root: [propext, Classical.choice, Quot.sound]`. Unconditional.

Theorem 7.42 (Kac roots and singular vectors at all labels). *For all $r, s \geq 1$:*

1. *for every integer $m \geq 1$, $\det G_{rs}(c(m^2), h_{r,s}(m^2)) = 0$;*
2. *hence for every $t \neq 0$, $\det G_{rs}(c(t), h_{r,s}(t)) = 0$;*
3. *for every nonreal t, $M(c(t), h_{r,s}(t))$ has a singular vector at level rs.*

        vermaMode (vermaBSACharge t) (fusionKacWeight r s t) 2 v = 0 := by
```

From the mathematics to the Lean statement

The set S of `infinite_integer_screening_roots` is $\{1, 4, 9, \dots\}$. Item 3 is *exactly* the hypothesis `hs` of `verma_kac_all_of_nonreal_singular` (for any N), and its specialisation is the hypothesis of `vermaWeightDeterminant_eq_kac_of_singular` with $c = c(t)$.

Physical meaning

Every entry of the (infinite) Kac table gives a zero of $\det G_{rs}$ at every central charge, and a singular vector at level rs at every nonreal t — proved by building the null vectors in the Coulomb gas at the special values $t = 1, 4, 9, \dots$ and continuing algebraically. At real t, which includes all minimal models, the theorem gives only the vanishing of the determinant.

Proof on paper. (1) Theorems 7.40 and 7.41 with $\beta = m$. (2) Theorem 7.37 with $S = \{m^2\}$. (3) Theorem 7.36, whose hypothesis is (2). □

What the machine verified

All four: `[propext, Classical.choice, Quot.sound]`. Unconditional.

7.11.3 The Kac determinant formula, unconditionally

Theorem 7.43 (Kac determinant formula). *For every $t \in \mathbb{C} \setminus \{0\}$, every $n \in \mathbb{N}$ and every $h \in \mathbb{C}$,*

$$\det G_n\big(c(t), h\big) = K_n \prod_{\substack{r,s \geq 1 \\ rs \leq n}} \big(h - h_{r,s}(t)\big)^{\mathrm{p}(n-rs)}.$$

Since every $c \in \mathbb{C}$ is some $c(t)$, this is the Kac determinant for all Virasoro Verma modules.

This theorem is **not** a declaration of the library. It is the composition of Theorem 7.35 and Theorem 7.42(3): applying `verma_kac_all_of_nonreal_singular` to the singular vectors `screening_nonreal_kac_singular` gives the identity of polynomials in h, and evaluating it (`vermaWeightDeterminant_eval`) gives the displayed formula. We performed this composition in Lean against the library, as two theorems `kac_determinant` and `kac_determinant_eval`; the check is not part of this release.

From the mathematics to the Lean statement

The identity is stated with symbols defined above: `vermaWeightGramPolynomial` (Theorem 7.30), `vermaBSACharge` (Definition 7.31), `vermaDiagonalContraction` and `kacWeightProduct` (Definition 7.32). The only hypothesis is $t \neq 0$. The check was compiled against an earlier commit, when this chapter was first written (not re-run for this edition), and `#print axioms` reports `[propext, Classical.choice, Quot.sound]` for both theorems. Why it is not trivially true: the left side is the determinant of the actual Shapovalov form, computed by an independent algorithm, and the right side is an explicit product; the degree and leading coefficient match by Theorem 7.33, so any error would show up as a wrong root.

Physical meaning

This is Kac's theorem (1979), proved by Feigin–Fuchs (1982–84) via the Coulomb gas: it identifies all the central charges and weights at which conformal families contain null states, and is the basis of the classification of minimal models.

Proof on paper. Combine: singular vectors at nonreal t (Theorem 7.42) give the formula at nonreal t (Theorem 7.34), which extends to all $t \neq 0$ by continuity (Theorem 7.35). □

What the machine verified

Checked in Lean against the library (not a library declaration; the check is not part of this release), axioms `[propext, Classical.choice, Quot.sound]`. **Unconditional**. The library additionally contains older partial results that this subsumes: the formula at levels < 9 (`vermaWeightDeterminant_kac_below_nine_all`, via Benoit–Saint-Aubin vectors for labels with a part ≤ 2), singular vectors at $t = \pm 1$ for all labels (`kacSingular_at_one`, `kacSingular_at_neg_one`), and the Benoit–Saint-Aubin factors $(X - h_{1,N})^{\mathrm{p}(m)}$ for all $t \neq 0$ (`vermaWeightDeterminant_bsa_factor_all`).

7.12 From Verma modules back to the vacuum: the simple zero at $c_{p,q}$

The graded (first-order) rigidity theorem of Chapter 8 needs one fact about the *vacuum* Gram determinant $D_n(c) := \det G_n^{\mathrm{vac}}(c)$ (Definition 7.20): at $c = c_{p,q}$ and the first singular level $n = (p-1)(q-1)$, D_n has a *simple* zero. This section explains how the library derives it from the Verma determinant.

Theorem 7.44 (Vacuum block of the Verma determinant). *For every c and n:*

1. *the vacuum Gram matrix $G_n^{\mathrm{vac}}(c)$ is the submatrix of the Verma Gram matrix $G_n(c,0)$ on the partitions without parts equal to 1;*

2. *the coefficient of $X^{\mathrm{p}(n)}$ in $\det G_{n+1}(c,X)$ equals $D_{n+1}(c) \cdot \det T_n(c)$, where $T_n(c)$ is the first-order (in X) block of the Gram matrix on the words ending with L_{-1}.*

File `VOA/Examples/VirasoroVermaVacuumForm.lean`.

theorem vermaWeightDeterminant_vacuum_first (c : ℂ) (n : ℕ) :
    (vermaWeightGramPolynomial c (n+1)).det.coeff (Fintype.card (VermaPartitions n)) =
      ((partitionGramPolynomial (n+1)).map (Polynomial.eval c)).det *
        (translationFirstGram c n).det := by
```

From the mathematics to the Lean statement

`vacuumVermaPartition n` sends a vacuum partition (entries i meaning L_{-i-2}) to the same modes in the Verma convention (entries $i+1$ meaning L_{-i-2}); `submatrix` restricts rows and columns. `translationVermaPartition n` appends an L_{-1} to a level-n word. `.coeff k` is the coefficient of X^k. Since $\det G_{n+1}(c,X)$ is divisible by $X^{\mathrm{p}(n)}$ (the factor of the label $(1,1)$), item 2 identifies its first possibly nonzero coefficient.

Physical meaning

At $h \to 0$ the descendants $L_{-1}(\dots)$ become null (they are descendants of the null vector $L_{-1}|0\rangle$); the leading behaviour of the determinant as $h \to 0$ factors into the norm of the genuine vacuum states times the norm of these "translation" states, which behaves like h times the Gram matrix of $M(c,1)$.

Proof on paper. Order the partition basis of level $n+1$ as (words without L_{-1}) $\sqcup$ (words ending in L_{-1}). Entries pairing a word ending in L_{-1} with anything are divisible by X (move the L_{-1} across as L_1, which acts on v_h-descendants producing a factor that vanishes with h); so the matrix has the block form $\begin{pmatrix} A(X) & XB(X) \\ XB'(X) & XT(X) \end{pmatrix}$ and the coefficient of $X^{p(n)}$ in its determinant is $\det A(0) \det T(0)$, with $A(0) = G^{\mathrm{vac}}_{n+1}(c)$ by item 1. □

What the machine verified

Both items: `[propext, Classical.choice, Quot.sound]`. Unconditional.

Theorem 7.45 (Simple zero of the vacuum determinant at the minimal models). *Let $p > q \geq 2$ be coprime and $N = (p-1)(q-1)$. Then $D_N(c_{p,q}) = 0$ and $D'_N(c_{p,q}) \neq 0$.*

```

From the mathematics to the Lean statement

Hypotheses. `hq`, `hpq`, `hcop`: $2 \leq q < p$, coprime — the minimal-model labels with the order fixed (the symmetric case $p < q$ follows by $c_{p,q} = c_{q,p}$). `hn`: $n+1 = N$. `hk`: the Kac formula at every $z \neq 0$ and every level $\leq N$ — which is Theorem 7.43, hence dischargeable. **Conclusion**: $P = D_N$ as a polynomial in c; `P.derivative` is its derivative; evaluated at `vermaBSACharge (p/q)` $= c_{p,q}$. `kacVacuumScalar t n` is $\mathcal{K}_N(t;0)$ with the factor of the label $(1,1)$ removed (the `.erase (0,0)`); `_root_.deriv` is the complex derivative.

Docstrings. Both docstrings say the Kac identity "remains the missing ordinary representation-theory input" / "still requires the missing general ordinary Kac represen-

tation input". Outdated (Warning 7.14).
Unconditional form. Composing `vacuum_simple_of_verma_kac` with the Kac formula (Theorem 7.43, which supplies `hk`) gives the theorem without `hk`; this composition, `vacuum_simple_zero`, was checked in Lean against the library (the check is not part of this release), with axioms `[propext, Classical.choice, Quot.sound]`. The library's own unconditional consumer of this chain is `minimal_graded_rigidity` (Chapter 8), which takes the equivalent route through `infinite_integer_screening_roots`.

Physical meaning

At a minimal-model central charge the vacuum family acquires exactly one new null vector at level $(p-1)(q-1)$ — the field whose decoupling defines the minimal model — and its norm, as a function of c, crosses zero linearly. That is why the central charge cannot be moved while keeping the null relation (Chapter 8).

Proof on paper. Set t near p/q and $n+1=N$. By Theorem 7.44(2) and the Kac formula, comparing coefficients of $X^{\mathrm{p}(n)}$: $2^{\mathrm{p}(n)}D_N(c(t))\det G_n(c(t),1) = K_N\cdot\mathcal{K}'_N(t)$, where $\mathcal{K}'_N(t)$ is `kacVacuumScalar` (`vacuumDeterminant_kac_coefficient`). At $t=p/q$: the label $(q-1,p-1)$ has $h_{q-1,p-1}(p/q)=0$ with nonzero t-derivative (`fusionKacWeight_minimal_derivative`) and exponent $\mathrm{p}(0)=1$; every other label $(r,s)\neq(1,1)$ with $rs\le N$ has $h_{r,s}(p/q)\neq 0$ (`minimalKacWeight_zero_before_first`, a Diophantine argument using coprimality). Hence $\mathcal{K}'_N$ has a simple zero at p/q. Also $\det G_n(c(p/q),1)\neq 0$, because $1=h_{r,s}(p/q)$ does not happen for $rs\le n<N$ (`kacWeightProduct_one_minimal_ne`). The map $t\mapsto c(t)$ has $c'(p/q)=-6+6q^2/p^2\neq 0$. By the chain rule (`polynomial_simple_of_curve_product`), $D_N(c_{p,q})=0$ and $D'_N(c_{p,q})\neq 0$. □

What the machine verified

`VOA.InverseDS.VirasoroVerma.vacuum_simple_of_verma_kac`, `…kacVacuumScalar_minimal_simple`: `[propext, Classical.choice, Quot.sound]`; the first is conditional on `hk`, discharged by composition with Theorem 7.43 (checked in Lean, not part of this release; unconditional, `[propext, Classical.choice, Quot.sound]`).

7.13 Other files of this chapter

The remaining files of the chapter are infrastructure for the theorems above or for the rigidity argument of Chapter 8. None introduces a hypothesis or axiom; all are `VOA.pbw`-free. We group them.

- *Normal ordering and universal pairings* (namespace `VirDeformModes.NormalOrdering`): `VirasoroNormalOrdering`, `VirasoroUniversalPairing`, `VirasoroCentralContractions`, `VirasoroContractionDiagonal`, `VirasoroContractionSupport`, `VirasoroGramDegree`, `VirasoroGramLeadingCoefficient`, `VirasoroGramDivisibility`, `VirasoroPartitionObstruction`, `VirasoroDeterminantObstruction`, `VirasoroDeterminantFirstBlock`, `VirasoroSingularGram`, `VirasoroSingularDescendants`, `VirasoroSingularSpecialization`, `VirasoroWordPairing`, `VirasoroFixedReconstruction`, `VirasoroVacuumEvaluation`. A formal normal-ordering algorithm for mode words with the central charge as a variable; the vacuum Gram polynomial (Definition 7.20) and its degree and leading coefficient; divisibility of determinants by $(X-c)^{\mathrm{nullity}}$; and the deformation-theoretic results `isTrivial_of_zero_central_variation`, `leeYang_graded_rigidity`, `graded_rigidity_of_simple_determinant`, `virWord_pairing_obstruction`, which are stated and explained in Chapter 8.

- *Verma infrastructure* (namespace `InverseDS.VirasoroVerma`): `VirasoroVermaEigenspaces`, `VirasoroVermaUniformStraightening`, `VirasoroVermaMomentumPolynomial`, `VirasoroVermaPositiveSymbols`, `VirasoroVermaDescendantSymbols`, `VirasoroVermaDescendantIndependence`, `VirasoroVermaHighestProjection`, `VirasoroVermaPolynomialWard`, `VirasoroVermaWeightContractions`, `VirasoroVermaGramDegree`, `VirasoroVermaTensorFock`, `VirasoroLeadingInvariants`, `VirasoroTopCoordinate`, `VirasoroVermaWardSpecialization`, `VirasoroWardClosedKernel` (a singular family at nonreal parameters extends by continuity: `verma_highest_of_nonreal`), `VirasoroVermaChargeTransport`, `VirasoroVermaChargeResponse` (Ward-type identities used in the fusion construction of Chapter 8).

- *Ward operators for descendant fields*: `VirasoroDescendantWard`, `VirasoroAllDescendantWard`, `VirasoroDescendantTriangular`, `VirasoroDescendantTower`. Coefficient sequences of a would-be intertwining (vertex) operator between Verma modules and the defects of the L_1, L_2 covariance identities (the conformal Ward identities $[L_m, \phi(z)] = z^m(z\partial + (m+1)\Delta)\phi(z)$ written coefficientwise). They support the fusion construction of singular vectors (Chapter 8); no fusion rule is assumed.

- *Screening auxiliaries*: `VirasoroScreening{Laurent, Vandermonde, Moment, Newton, Coefficient, Derivation, PowerSumDerivative, WardWeight, Integration, ResidueFunctional, Differentiation, Factorial, Migration, ShiftCoefficient, ModeCoefficients, PairSums}`, `VirasoroChargedFockGrading`, `VirasoroFockPositiveOperators`, `VirasoroFockShiftSum`, `VirasoroFockLevelDimension`: the finite residue calculus of Theorem 7.40.

- *Vacuum-module auxiliaries*: `VirasoroGradedField` (graded fields and the grading axiom), `VirasoroGoodFiltration`, `VirasoroFiltrationTranslation` (Li-type filtrations, used in Chapter 11), `VirasoroFockConjugation` (complex conjugation on Fock space, used for real structures in Chapter 19), `VirasoroQuotientForm` (the canonical form `Bsimp` on $L(c,0)$ and `gram_simple_negWord`: its Gram entries equal those of $V(c,0)$), `VirasoroFormSymmetry`, `VirasoroDescendantIndependence`, `VirasoroVacuumFourShift`, `VirasoroVacuumFourContinuant` (a finite continuant recurrence at the parameters $t = 4/p$ and a polynomial certificate relating p and $p+4$; the docstring states that the needed nonvanishing is neither assumed nor proved there; no headline theorem of this chapter depends on these files).

- *Kac arithmetic*: `VirasoroKacLabelSeparation` (`minimalKacWeight` and which labels have weight 0 or 1 at $t = p/q$), `VirasoroKacSmallLabels`, `VirasoroKacCollisionStates` (the partial results superseded by Theorem 7.43), `VirasoroKacSingularTransfer` (also containing the conditional graded-rigidity theorems, with conclusion `IsRigidGraded`, `minimal_rigidity_of_nonreal_kac_singular` and `minimal_graded_rigidity_of_kac_singular`), `VirasoroKacRootBootstrap` (`minimal_rigidity_of_infinite_kac_roots`, the form consumed by Chapter 8).

- *Combinatorics*: `VirasoroAdmissibleCombinatorics` — Salazar's n-admissible partitions (`IsNAdmissible`: $w_j \geq w_{j+n-1} + 2$) and their counts in lengths ≤ 2, the combinatorial side of the conjectural basis of the boundary models $L(c_{2,2n+1}, 0)$. The file asserts no basis theorem.

7.14 Warnings, recorded defects and dead ends

Outdated docstrings

Several docstrings, when this chapter was first written, described the state of the library before later files landed. The Lean *statements* are correct; the prose was wrong. At a pre-release build commit most of the wording quoted below has been corrected in the sources (the "Phase-4/5

target" remark in the header of `VirasoroVOA.lean` remains); the list is kept as a record.

1. *"The singular-existence premise remains open".* Module or declaration docstrings of `VirasoroKacProduct.lean` (`vermaWeightDeterminant_eq_kac_of_singular`), `VirasoroKacSingularTransfer.lean` (module header; `minimal_rigidity_of_nonreal_kac_singular`), `VirasoroKacVacuumTransfer.lean` (`vacuum_simple_of_verma_kac`, `graded_rigidity_of_verma_kac`), `VirasoroKacVacuumCoefficient.lean` (module header), `VirasoroKacScalarRoot.lean` (`kacVacuumScalar_minimal_simple`), `VirasoroKacRootBootstrap.lean` and `VirasoroKacLaurent.lean` (module headers), and `VirasoroKacLabelSeparation.lean` (line 191) say the singular-vector or root input is missing. It is supplied by `screening_nonreal_kac_singular` and `infinite_integer_screening_roots` (Theorem 7.42); the composition is Theorem 7.43.

2. *"General c is the next step".* The headers of `VirasoroVOA.lean` and `VirasoroSugawara.lean` say that a standalone Virasoro VOA for general c is "deferred"/"the documented next step". It exists: `VirModule.virasoroVOA` (Definition 7.12) and `VirSimple.virasoroSimple` (Definition 7.15). The same header calls the rationality of minimal models a "Phase-4/5 target"; it is not proved in this chapter.

3. *"$L(c,0)$" for the universal module.* The docstrings of `virasoroVOA` ("$\mathrm{Vir}(c) = L(c,0)$, the universal Virasoro vacuum VOA"), `VirasoroField.lean`, `VirasoroSpanning.lean`, `VirasoroWordFields.lean`, `VirasoroGrading.lean`, `VirasoroNonvanishing.lean` and `VirasoroFock.lean` call `VirUniv c` "$L(c,0)$". It is the universal $V(c,0)$; the simple $L(c,0)$ is `virasoroSimple c`. `VirasoroSimple.lean` records the intended renaming.

Severity: documentation only.

Redundant hypothesis $c \neq 0$ (since removed from `omegaVir_ne_zero`)

Update. Following this finding the library removed the hypothesis: `omegaVir_ne_zero` and `virasoroVOA_conformalVector_ne_zero` are now stated for every c (quoted in Section 7.4's dictionary). The text below records the situation when the chapter was written. `VirModule.omegaVir_ne_zero` and `VirModule.virasoroVOA_conformalVector_ne_zero` (`VirasoroInstance.lean`) assume `hc : c ≠ 0`. In the universal module the conclusion $\omega \neq 0$ holds for every c, because $\omega = L_{-2}\mathbf{1}$ is a partition-basis vector (`negWordVir_ne_zero`). A Lean check made for this book (not part of this release) proves `omegaVir_ne_zero_all (c : ℂ) : omegaVir c ≠ 0` in one line, axioms `[propext, Classical.choice, Quot.sound]`. (The hypothesis is *not* redundant for the simple quotient: `virasoroSimple_conformalVector_ne_zero` genuinely needs $c \neq 0$.) Severity: weaker than possible; harmless.

The Kac determinant is not a library declaration

A referee searching the library for "the Kac determinant formula" finds only conditional statements (`vermaWeightDeterminant_eq_kac_of_singular`, `verma_kac_all_of_nonreal_singular`, `vermaWeightDeterminant_kac_extend`) and the finite-level `vermaWeightDeterminant_kac_below_nine_all`. The unconditional formula at all levels is a two-line composition that the library never states; likewise the unconditional vacuum simple-zero theorem. Both were checked in Lean for this book (Theorems 7.43 and 7.45); the checks are not part of this release. Severity: conditional gap that is closed by composition.

Two word conventions, two free-field normalisations

(1) In the vacuum module a word entry i means L_{-i-2} (`negWordVir`, `SortedOfEnergy`); in Verma modules it means L_{-i-1} (`negWord`, `VermaPartitions`). The map `vacuumVermaPartition` adds one to each entry. (2) The linear-dilaton realisation of Theorem 7.2 uses $L_n = L_n^{\mathrm{Sug}} + \lambda(n+1)a_n$ at Heisenberg level 1 with $c = 1 - 12\lambda^2$; the charged realisation of Definition 7.38 uses level 2, a minus sign and $c = 1 - 24\ell^2$. Both are correct; the formulas must not be mixed.

Dead ends and expectations that turned out false

1. *Isolated collision parameters do not suffice.* Singular vectors constructed only at special parameters (e.g. $t = \pm 1$, `kacSingular_at_one`) cannot feed the Laurent interpolation of Theorem 7.37, which needs infinitely many roots; the docstring of `minimal_rigidity_of_infinite_kac_roots` records this. The integer screenings supply the infinite family $t \in \{1, 4, 9, \dots\}$.

2. *Benoit–Saint-Aubin vectors give only labels with a part ≤ 2.* The explicit BSA singular vectors (Chapter 8) cover labels $(1, N)$, $(N, 1)$ and (by composition) $(2, N)$; this gives the Kac formula only below level 9 (`vermaWeightDeterminant_kac_below_nine_all`), since $(3, 3)$ is the first label with both parts ≥ 3. The general case needed the screening construction.

3. *The free-field map of the vacuum module is injective at every c* (Theorem 7.9). The opposite expectation (that it "sees" the minimal-model null vectors as a kernel) is false; the kernels in the Felder complex belong to screening maps between Fock modules.

4. *Determinant versus rank.* A vanishing vacuum determinant only says "some null state"; the dimension of $L(c, 0)_n$ needs the rank (Theorem 7.18). The multiplicity of a root of $\det G_n$ bounds the nullity only from above (a root of order k allows nullity anywhere from 1 to k), so the library computes ranks directly, by explicit factorisations and nonzero minors, rather than reading them off root multiplicities.

7.15 Verification record

When this chapter was first written we ran `#print axioms` on the already-built tree at an earlier commit (not re-run for this edition; no new aggregate `lake build` was run), with a scratch file importing the relevant modules and

```
export PATH="$HOME/.elan/bin:$PATH"
lake env lean -DmaxSynthPendingDepth=3 Axioms.lean
```

(the flag avoids the audit trap of Section 43.1.6: a bare `lake env lean` drops `maxSynthPendingDepth`). All 69 declarations checked reported exactly

```
depends on axioms: [propext, Classical.choice, Quot.sound]
```

None uses `VOA.pbw` or `sorryAx`. The list:

`VirModule.virasoroVOA`, `virYA_exists`, `YomegaVir_self_local`, `YomegaVir_isField`, `gradingVir_isInternal`, `omegaVir_ne_zero`, `VOA.vacVec_ne_zero`, `gradedBasis`, `finrank_gradingVir`, `fockMap_injective`, `finrank_gradingVir_sixteen`; `VirSimple.virasoroSimple_isSimple`, `virasoroSimple_conformalVector_ne_zero`, `virasoroVOA_isSimple_iff`, `virasoroSimple_selfDual`; `VirGram4.canGram4_eq`, `det_canGram4`, `VirGram56.det_canGram5`, `det_canGram6`, `det_canGram6_eq_zero_iff`, `VirFormSym.canB_isSymmetric`; `VirSimpleGram.finrank_virasoroSimple_grading_partition`, `finrank_`

Chapter 8

First-order deformations and the graded first-order rigidity of Virasoro minimal models

This chapter documents the release of the LeanVOA library named in the front matter. Every Lean quotation below is checked by `scripts/textbook/sync.py` to occur verbatim (up to whitespace and comments) in the source files of that release. The chapter was first written against an earlier state of the library; checks that were run at that earlier state and not re-run for this edition are marked as such. The chapter covers the files assigned to it in `Notes/Textbook/assignment.txt`: the general first-order deformation theory in `VOA/Core/Deformation*.lean`, `VOA/Core/DeformedForm.lean`, `VOA/Core/RigidityBridge.lean` and a few auxiliary linear-algebra files, the example file `VOA/Examples/NonzeroDeformation.lean`, and the roughly eighty files `VOA/Examples/Virasoro*.lean` whose subject is the rigidity of the simple Virasoro vertex operator algebras.

The headline of the chapter is a single theorem, `VOA.VirModule.minimal_graded_rigidity`: *for every pair of coprime integers $p, q \geq 2$, every graded first-order deformation of the simple Virasoro vertex operator algebra $L(c_{p,q}, 0)$ of central charge $c_{p,q} = 1 - 6(p-q)^2/(pq)$ is trivial*, that is, it is undone by an infinitesimal change of coordinates. The theorem is proved without any hypothesis beyond the label conditions, and `#print axioms` reports only Lean's three standard axioms; in particular `VOA.pbw` (the PBW theorem of Chapter 3; formerly a project axiom, now a theorem) is not used.

Three qualifications travel with the headline everywhere in this chapter (they are the caveats of the release audit `Notes/Textbook/referee/RELEASE_AUDIT_RIGIDITY.md`). First, the theorem is *graded first-order* rigidity: the parameter ring is $\mathbb{C}[t]/(t^2)$, the vertex operation Y is deformed, the vacuum is held fixed, the deformation must respect the weight grading, and "trivial" means "the coboundary of a grade-preserving, vacuum-fixing φ". Nothing is claimed about formal ($\mathbb{C}[[t]]$), ungraded or grading-moving deformations; the library's *ungraded* notion `IsRigid` is false for every universal Virasoro VOA $V(c, 0)$, for a definitional reason (Warning 8.2.5), and is never quoted as true in this book. Second, the notion `IsRigidGraded` is not vacuous: the library constructs the c-derivative $\partial_c Y$ on the universal Virasoro VOA $V(c, 0)$ and proves `VOA.VirPoly.not_isRigidGraded_virasoroVOA`, i.e. $V(c, 0)$ is not graded first-order rigid, for every $c \in \mathbb{C}$ (Remark 8.6). The witness deformation moves the central charge, which the library's notion of first-order deformation allows (it is not required to preserve ω or c). This caveat of the release audit has therefore been discharged since the audit was written. Third, at $(p, q) = (2, 3)$ the central charge is $c_{2,3} = 0$ and $L(0, 0) = \mathbb{C}\mathbf{1}$, so that instance is trivially true; the content lies in the other labels.

The chapter has four jobs.

1. Explain from first principles what a first-order deformation of a vertex operator algebra is, what it means for one to be *trivial*, and what *rigidity* means, both mathematically (vanishing of

a second cohomology group, in the spirit of Gerstenhaber's deformation theory of associative algebras) and physically (absence of exactly marginal deformations of a chiral algebra: the theory is an isolated point of its moduli space).

2. Present the library's definitions — `FirstOrderDeformation`, `IsGraded`, `IsCoboundary`, `IsTrivial`, `IsRigid`, `IsRigidGraded` — with their verbatim Lean source, and run the fidelity check on them with particular care. This is the heart of the chapter: the referee must be convinced that `IsRigidGraded` is the rigidity notion the authors intended, must know exactly which deformations it quantifies over, and must know how it could have been vacuous and why it is not. We shall see that one of the two notions the library defines, `IsRigid`, is *false for every Virasoro vertex operator algebra for a definitional reason*, and that the library knows this and uses only `IsRigidGraded`.

3. Explain the proof of the headline theorem on paper. The proof has three steps that can be stated in a paragraph each: (a) a graded deformation of $L(c,0)$ has exactly one gauge-invariant parameter δ, the first-order change of the central charge; (b) if $\delta = 0$ the deformation is trivial (a reconstruction theorem using simplicity); (c) if $c = c_{p,q}$, a null vector of the universal vacuum module, whose norm has a *simple* zero at c, forces $\delta = 0$. Step (c) needs the Kac determinant of the vacuum module, which is the subject of the companion Chapter 7; we state precisely which results of that chapter are used.

4. Present the worked cases that the library proved on the way (central charge 0, Lee–Yang $-22/5$, Ising $1/2$, $M(2,7)$ at $-68/7$, tricritical Ising $7/10$, the families $M(2,q)$ and $M(p,3)$), the dead ends that were recorded (a tautological "structural" rigidity theorem, an unsatisfiable "bridge" hypothesis, the false belief that an isolated degenerate charge suffices), and close with the referee's checklist.

The foundations — formal distributions, modes $u_{(n)}$, the definitions of vertex algebra and vertex operator algebra, the Borcherds identity, ideals, simple quotients and invariant bilinear forms — are those of Chapters 2, 4 and 5, to which we point for every such notion. The Virasoro vertex operator algebra itself (its construction, its Verma modules, the Kac determinant) is the subject of Chapter 7; since that chapter is a companion rather than a prerequisite we recall in Section 8.3 every Virasoro definition our statements use, with its verbatim Lean source.

8.1 Why deformations, and why minimal models should be rigid

8.1.1 Deformations in algebra: Gerstenhaber's picture

Let A be an associative algebra over $\mathbb{C}$ with product $\mu(a,b) = ab$. A *first-order deformation* of A is an associative product on $A[t]/(t^2) = A \oplus tA$ of the form

$$\mu_t(a,b) = \mu(a,b) + t\,\mu_1(a,b),$$

extended $\mathbb{C}[t]/(t^2)$-bilinearly, where $\mu_1 : A \times A \to A$ is bilinear. Associativity of μ_t modulo t^2 is the condition

$$\mu_1(ab,c) + \mu_1(a,b)c = \mu_1(a,bc) + a\mu_1(b,c),$$

which says that μ_1 is a Hochschild 2-cocycle. Two deformations are *equivalent* if they differ by an infinitesimal change of coordinates $a \mapsto a + t\varphi(a)$ with $\varphi : A \to A$ linear; such a change transforms μ_1 into $\mu_1 + \delta\varphi$ with $(\delta\varphi)(a,b) = \varphi(a)b - \varphi(ab) + a\varphi(b)$, a Hochschild coboundary. A deformation is *trivial* if it is equivalent to the zero deformation, and A is *rigid* (to first order) if every first-order deformation is trivial; equivalently the second Hochschild cohomology $HH^2(A,A)$ vanishes. This is the theory created by Gerstenhaber in 1964. Two features of it will recur:

- *The cocycle condition is linear in μ_1.* The original axiom (associativity) is quadratic in the product; substituting $\mu + t\mu_1$ and discarding t^2 leaves the "derivative" of the axiom in the direction μ_1, which is linear. Hence the deformations form a vector space, and the trivial ones a subspace.
- *Rigidity is a statement about a quotient.* A nonzero μ_1 can be trivial; what is asked is that every cocycle is a coboundary. A rigidity theorem that forgot the quotient ("every μ_1 is zero") would be false for every algebra, since $\delta\varphi$ is almost never zero.

8.1.2 Deformations of vertex algebras

A vertex algebra (Definition 4.1 of Chapter 4) has infinitely many products $u_{(n)}v$, $n \in \mathbb{Z}$, packaged in the state–field correspondence $Y(u,z) = \sum_n u_{(n)}z^{-n-1}$, and its main identity, the Borcherds identity (Theorem 4.26), is quadratic in Y. Deforming Y to $Y + tY_1$ over the dual numbers and discarding t^2 therefore gives, exactly as for associative algebras, a linear "cocycle" condition on Y_1, and infinitesimal changes of coordinates $1 + t\varphi$ give "coboundaries". Cohomology theories for vertex algebras in which the second cohomology classifies such first-order deformations were developed by Huang (for grading-restricted vertex algebras) and by others; see the Notes at the end of the chapter. The library constructs no cohomology theory at all: it works with the cocycle and coboundary conditions directly, as elementary statements about modes. This is a deliberate design decision, recorded in the docstring of `VOA/Core/Deformation.lean`, and it makes the fidelity check easier, because nothing is hidden inside a homological construction.

8.1.3 The physical picture: moduli of conformal field theories

In two-dimensional conformal field theory one asks whether a given theory sits in a continuous family. The standard example is the compactified free boson: the radius R of the target circle can be varied continuously, and every value gives a consistent CFT; the operator that moves R is the "exactly marginal" operator $\partial X\bar{\partial}X$ of conformal weight $(1,1)$. A theory with no exactly marginal deformations is *isolated*: it is a point, not a curve, in the space of theories.

A vertex operator algebra is the *chiral algebra* of a CFT: the algebra of fields depending holomorphically on z, with their operator product expansions. Deforming the vertex algebra means deforming the OPE coefficients of the chiral fields while keeping the space of states fixed. For the free boson the chiral algebra is the Heisenberg vertex operator algebra, generated by a current $J(z)$ with $J(z)J(w) \sim k/(z-w)^2$; changing k looks like a deformation, but it is undone by rescaling $J \mapsto \lambda J$, i.e. by a change of coordinates, so it is trivial. For the Virasoro algebra the analogous parameter is the central charge in

$$T(z)T(w) \sim \frac{c/2}{(z-w)^4} + \frac{2T(w)}{(z-w)^2} + \frac{\partial T(w)}{z-w},$$

and here rescaling T does *not* undo a change of c: rescaling $T \mapsto \lambda T$ changes the coefficient 2 of the second-order pole, which is fixed by the requirement that T generate the conformal symmetry. So the universal Virasoro vertex operator algebra $V(c,0)$ has a genuine one-parameter family of deformations, $c \mapsto c + t$. (We shall see that the library proves the "coordinate change cannot move c" half of this statement as a theorem, Theorem 8.14, and also constructs the deformation ∂_c itself, `VOA.VirPoly.cDeformation`; Section 8.2.7.)

8.1.4 Why the minimal models should be rigid

The *minimal models* of Belavin, Polyakov and Zamolodchikov are the CFTs whose chiral algebra is the simple quotient $L(c,0)$ of $V(c,0)$ at one of the special central charges

$$c_{p,q} = 1 - \frac{6(p-q)^2}{pq}, \qquad p,q \geq 2,\ \gcd(p,q) = 1.$$

(Examples: $c_{2,3} = 0$, the Lee–Yang model $c_{2,5} = -22/5$, the Ising model $c_{3,4} = 1/2$, the tricritical Ising model $c_{4,5} = 7/10$.) At these values, and only there, the vacuum module $V(c,0)$ contains a *null vector* — a nonzero state s of positive weight orthogonal to everything for the invariant form — and $L(c,0) = V(c,0)/\langle s\rangle$. The lowest one sits at weight $(p-1)(q-1)$. The physical heuristic for rigidity is then:

1. The chiral algebra $L(c,0)$ is generated by T, and the only parameter in the TT OPE is c. So any deformation of $L(c,0)$, after a change of coordinates, can only move c, to $c + t\delta$.
2. In $L(c,0)$ the null vector is *zero*: $s = 0$ is a relation of the algebra. A deformation must keep this relation (to first order, after correcting s by ts').
3. But the norm $\langle s, s\rangle$ of the corresponding universal state, as a function of the central charge, vanishes at $c = c_{p,q}$ to *first* order. Moving c to $c + t\delta$ changes the norm by $t\delta \cdot \frac{d}{dc}\langle s, s\rangle \neq 0$ unless $\delta = 0$, and a state with nonzero norm cannot be zero. Hence $\delta = 0$, and by step 1 the deformation is trivial.

That is the whole idea, and the Lean proof follows it faithfully. The work is in making each step precise: in step 1, "after a change of coordinates" and "generated by T" become a reconstruction theorem (Section 8.5); in step 2, "keep the relation" becomes a pairing identity over the dual numbers (Section 8.6); in step 3 one needs to know that a suitable norm, or the vacuum Gram determinant, has a *simple* zero at $c_{p,q}$ (Section 8.8). The word "simple" is essential: the minimal-model charges accumulate at $c = 1$, so "$c_{p,q}$ is an isolated degenerate value" is not even true across all levels, and at a fixed level an isolated root of multiplicity two would *not* obstruct a first-order motion (Warning 8.6.4).

The physical statement is about first order only, and so is the theorem. It says nothing about analytic families, about the full (non-chiral) CFT, or about the modules of $L(c,0)$; we list precisely what it does and does not say in Section 8.2.6.

8.2 First-order deformations of a vertex operator algebra

Throughout, W is a vertex operator algebra in the sense of Definition 4.4 of Chapter 4, with state space $\mathcal{V} = \bigoplus_{n\geq 0} \mathcal{V}_n$ (CFT type: $\mathcal{V}_0 = \mathbb{C}\mathbf{1}$, $\mathcal{V}_n = 0$ for $n < 0$), state–field map Y, vacuum $\mathbf{1}$, conformal vector ω and central charge c. We write $u_{(n)}v$ for the n-th product (`W.smul u n v` in Lean) and $L_n = \omega_{(n+1)}$.

8.2.1 Derivation of the axioms

Let $R = \mathbb{C}[t]/(t^2)$, the ring of dual numbers, and let $\mathcal{V}_R = R \otimes_{\mathbb{C}} \mathcal{V} = \mathcal{V} \oplus t\mathcal{V}$. We look for a vertex algebra structure on $\mathcal{V}_R$ over R, with the same vacuum, of the form

$$Y^t(u,z)v = Y(u,z)v + t\,Y_1(u,z)v, \qquad \text{i.e.} \qquad u^t_{(n)}v = u_{(n)}v + t\,u^1_{(n)}v, \tag{8.1}$$

where $Y_1 : \mathcal{V} \to \mathrm{End}(\mathcal{V})[[z^{\pm 1}]]$ is $\mathbb{C}$-linear, $u^1_{(n)}v$ denotes the coefficient of z^{-n-1} in $Y_1(u,z)v$, and everything is extended R-bilinearly. Each vertex-algebra axiom for $(\mathcal{V}_R, Y^t, \mathbf{1})$ splits into a t^0 part, which is the axiom for W and holds automatically, and a t^1 part, which is a condition on Y_1:

(D1) *Truncation* (VA5). $u^t_{(n)}v = 0$ for $n \gg 0$; at order t: for all u, v there is N with $u^1_{(n)}v = 0$ for $n \geq N$.

(D2) *Vacuum field* (VA2). $Y^t(\mathbf{1},z) = \mathrm{id}$; the right side has no t, so $Y_1(\mathbf{1},z) = 0$.

(D3) *Creation* (VA3). $u^t_{(n)}\mathbf{1} = 0$ for $n \geq 0$ and $u^t_{(-1)}\mathbf{1} = u$; the vector u on the right has no t-component (we deform Y, not the space), so $u^1_{(n)}\mathbf{1} = 0$ for all $n \geq -1$.

(D4) *Borcherds identity.* Every term of (4.2) contains exactly two modes. Substituting $u_{(k)} \mapsto u_{(k)} + t u^1_{(k)}$ and keeping the coefficient of t gives, for all $u, v, x \in \mathcal{V}$ and $\ell, m, n \in \mathbb{Z}$,

$$\sum_{i\geq 0}(-1)^i\binom{\ell}{i}\Big(u^1_{(\ell+m-i)}v_{(n+i)}x + u_{(\ell+m-i)}v^1_{(n+i)}x - (-1)^{\ell}\big(v^1_{(\ell+n-i)}u_{(m+i)}x + v_{(\ell+n-i)}u^1_{(m+i)}x\big)\Big)$$
$$= \sum_{i\geq 0}\binom{m}{i}\Big((u^1_{(\ell+i)}v)_{(m+n-i)}x + (u_{(\ell+i)}v)^1_{(m+n-i)}x\Big). \tag{8.2}$$

On each side one sums over the two ways of placing a single Y_1. This is the "Y_1 is a 2-cocycle" condition, and it is linear in Y_1.

Locality (VA4) is not imposed separately: over a commutative base ring the Borcherds identity together with vacuum, creation and truncation is equivalent to the full set of vertex-algebra axioms (this is the Jacobi-identity definition of Frenkel–Lepowsky–Meurman and Lepowsky–Li, and its equivalence with the locality definition; for the library's own axioms over $\mathbb{C}$ see Chapter 4). The grading axiom (VA1) is *not* imposed at this stage; its first-order part will be the separate predicate `IsGraded` below.

8.2.2 The definition

Definition 8.1 (First-order deformation)**.** A *first-order deformation* of W is a $\mathbb{C}$-linear map $Y_1 : \mathcal{V} \to \mathrm{End}(\mathcal{V})[[z^{\pm 1}]]$ satisfying (D1)–(D4). We write $u^1_{(n)}v := (Y_1(u))_{(n)}v$ for its products.

```

(`VOA.Deform.FirstOrderDeformation`, `VOA.Deform.FirstOrderDeformation.smul₁`, `VOA/Core/Deformation.lean`; the ambient context is `variable {𝒱 : Type u} [AddCommGroup 𝒱] [Module ℂ 𝒱]`, i.e. $\mathcal{V}$ is a complex vector space; field docstrings removed.)

From the mathematics to the Lean statement

Decoding.

- `Y1 : 𝒱 →ₗ[ℂ] (End ℂ 𝒱)⟦z^±⟧` is a $\mathbb{C}$-linear map from $\mathcal{V}$ to formal distributions with coefficients in $\mathrm{End}_{\mathbb{C}}(\mathcal{V})$ — *exactly the type* of the undeformed `W.Y` (Chapter 4, Definition 4.1). Linearity in u is built into `→ₗ[ℂ]`; linearity of each $u^1_{(n)}$ in v is built into `End ℂ 𝒱`. So Y_1 is a bilinear family of products, with nothing assumed beyond bilinearity.
- `mode (Y1 u) n v` is $u^1_{(n)}v$, by the convention `mode f n = f (-n-1)` of Definition 2.7:

the coefficient of z^{-n-1}. `smul₁ D u n v` is the same thing with a name, mirroring `W.smul u n v` $= u_{(n)}v$.

- `truncation` is (D1), with N depending on u, v. `vacuum_Y1` is (D2): `Y1 W.vacuum = 0` means the whole distribution $Y_1(\mathbf{1}, z)$ is zero. `creation` is (D3): $u^1_{(n)}\mathbf{1} = 0$ for every $n \geq -1$ — note *including* $n = -1$, which is the first-order part of $u_{(-1)}\mathbf{1} = u$.

- `jacobi` is (8.2). `negOnePow i` is $(-1)^i$, `cbz ℓ i` is the binomial coefficient $\binom{\ell}{i}$ with integer lower index, *zero for* $i < 0$ (Definition 2.14), so the sums over all $i \in \mathbb{Z}$ are the sums over $i \geq 0$ of the displayed formula. The left side has four terms: u^1v, uv^1, v^1u, vu^1; the right side has two: $(u^1_{(\ell+i)}v)_{(m+n-i)}x$ and $(u_{(\ell+i)}v)^1_{(m+n-i)}x$. This is term-by-term the Leibniz derivative of the library's undeformed Borcherds identity `VertexOperatorAlgebra.jacobi` (Theorem 4.26), whose summands are $u_{(\ell+m-i)}v_{(n+i)}x - (-1)^\ell v_{(\ell+n-i)}u_{(m+i)}x$ and $\binom{m}{i}(u_{(\ell+i)}v)_{(m+n-i)}x$.

- $\sum^{\mathrm{f}}$ is Mathlib's `finsum`: the sum of a family with finite support, and *by definition* 0 *if the support is infinite*.

Could `jacobi` be vacuous? Yes, in principle, through `finsum`: if one of the two families had infinite support, its `finsum` would be 0 by fiat and the axiom would degenerate. The library proves that this does not happen: `jacobiLHS_support_finite` and `jacobiRHS_support_finite` (same file) show both supports are finite, using `truncation` and the undeformed VA5. (Negative i are killed by `cbz`; large i by truncation.) So `jacobi` is a genuine finite identity, the one displayed.

What is fixed and what is deformed.

- The *state space* is fixed: $\mathcal{V}_R = \mathcal{V} \oplus t\mathcal{V}$, a free R-module. Deformations that change the underlying graded dimensions (as happens at a jump of the family $c \mapsto L(c, 0)$) are *not* first-order deformations in this sense; this is the standard convention of algebraic deformation theory.

- The *vacuum* is fixed. The source records why this loses nothing: a deformed vacuum $\mathbf{1} + t\mathbf{1}'$ can be moved back to $\mathbf{1}$ by the coordinate change of $\varphi = -(\, v \mapsto \mathbf{1}'_{(-1)}v\,)$. We have not checked this remark in Lean; it is not used.

- The *conformal vector* is **not** part of the data. Nothing requires Y^t to have a conformal vector, let alone ω. So these are deformations of the *vertex algebra* underlying W, not of the vertex operator algebra. For the rigidity question this is the *harder* (larger) class: every deformation of W as a VOA (moving Y and possibly ω) gives a deformation of the vertex algebra by forgetting ω.

- The *translation operator* is not mentioned. In a vertex algebra it is determined by $Tu = u_{(-2)}\mathbf{1}$, so the deformed one is $T + tT_1$ with $T_1u = u^1_{(-2)}\mathbf{1}$; (D3) does not force $T_1 = 0$ because it constrains only $n \geq -1$. Similarly skew-symmetry is not an axiom; it follows from (D4) as it does in the undeformed case.

- The *base ring* is the dual numbers only. This is "first order". There is no statement over $\mathbb{C}[t]/(t^3)$ or $\mathbb{C}[[t]]$.

Same as the literature? With these conventions, a `FirstOrderDeformation` is exactly a vertex algebra structure on $R \otimes \mathcal{V}$ over R reducing to W modulo t and having vacuum $\mathbf{1}$: (D1)–(D4) are necessary (they are the order-t parts of axioms that any such structure satisfies) and, by the Jacobi-identity form of the axioms, sufficient. The direction that matters for rigidity is the first: *no genuine first-order deformation is excluded by the definition*, so a rigidity theorem quantifying over `FirstOrderDeformation` is not weakened by a too-narrow notion of deformation.

What the machine verified

A definition. The support-finiteness lemmas `jacobiLHS_support_finite`, `jacobiRHS_support_finite` and the linearity lemmas for $\mathtt{smul}_1$ ($\mathtt{smul}_1_\mathtt{add_left}$, $\mathtt{smul}_1_\mathtt{smul_right}$, ...) are proved in the same file, axiom-clean.

Physical meaning

A first-order deformation is the chiral-algebra version of perturbing a CFT by an infinitesimal amount: one keeps the space of states and the vacuum and changes every operator product expansion coefficient C_{uv}^{w} by $t\,\delta C_{uv}^{w}$, discarding t^2. Conditions (D1)–(D4) say that the perturbed OPEs are still consistent: the OPE of two fields is still a Laurent series (truncation), the identity field is still the identity (vacuum), the state–operator map still sends u to the field creating u from the vacuum (creation), and the perturbed OPE is still associative and local (Borcherds). In conformal perturbation theory such a change is produced by integrating a *marginal* operator over the plane; for a purely chiral algebra the analogous objects are changes of the OPE structure constants, and the question whether they are "exactly marginal" is the question whether they integrate to a family. The definition does not require the perturbed theory to keep a stress tensor; that only enlarges the class of perturbations considered.

8.2.3 Graded deformations

Definition 8.2 (Graded deformation)**.** A first-order deformation is *graded* if $u^1_{(n)}v \in \mathcal{V}_{k+\ell-n-1}$ whenever $u \in \mathcal{V}_k$, $v \in \mathcal{V}_\ell$, $n \in \mathbb{Z}$; that is, each $u^1_{(n)}$ shifts the weight exactly as $u_{(n)}$ does (VA1 at order t).

```
def IsGraded (D : FirstOrderDeformation W) : Prop :=
  ∀ (k ℓ : ℤ) (u : 𝒱), u ∈ W.grading k → ∀ (v : 𝒱), v ∈ W.grading ℓ → ∀ (n : ℤ),
    D.smul₁ u n v ∈ W.grading (k + ℓ - n - 1)
```

(`VOA.Deform.FirstOrderDeformation.IsGraded`, `VOA/Core/Deformation.lean`.)

From the mathematics to the Lean statement

`W.grading k` is the subspace $\mathcal{V}_k$ (the field `grading` of Definition 4.1). The quantifiers are over all integers k, ℓ, n and all homogeneous u, v; for $k < 0$ or $\ell < 0$ the hypothesis forces $u = 0$ or $v = 0$ (CFT type) and the condition is empty. The predicate is exactly VA1 for the t-component.

Why a predicate and not a field. The source explains: an ungraded first-order deformation is a legitimate object, and making gradedness a field would silently strengthen `FirstOrderDeformation`. We shall see in Warning 8.2.5 that this choice has a consequence for the *ungraded* rigidity notion `IsRigid`, which the library acknowledges and avoids.

What gradedness buys. For graded Y_1 the mode index is determined by three weights: $u^1_{(n)}$ maps $\mathcal{V}_a \otimes \mathcal{V}_b$ to $\mathcal{V}_{a+b-n-1}$, so the component of Y_1 from $\mathcal{V}_a \otimes \mathcal{V}_b$ to $\mathcal{V}_d$ lives in the single mode $n = a + b - d - 1$, and is a bilinear map between finite-dimensional spaces. Since $\mathcal{V}_d = 0$ for $d < 0$, truncation (D1) is then automatic (`Deform.truncated_of_graded` in `VOA/Core/DeformationGraded.lean`).

Physical meaning

Gradedness says the perturbation preserves conformal weights: the field of a state of weight k acting on a state of weight ℓ still produces, at the pole $(z-w)^{-n-1}$, states of weight $k+\ell-n-1$. Physically this is the requirement that the perturbation commutes with dilatations $z \mapsto \lambda z$,

i.e. is *marginal* rather than relevant or irrelevant: a perturbation by an operator of the wrong weight would introduce a scale and break conformal invariance. (Heuristic: a CFT perturbed by a marginal operator stays conformal to first order; that is what gradedness models here.)

8.2.4 Trivial deformations

Let $\varphi : V \to V$ be linear and consider the R-linear automorphism $g = 1 + t\varphi$ of V_R, with inverse $1 - t\varphi$. Transporting Y along g gives the vertex algebra structure $Y^g(u,z) = g^{-1}Y(gu,z)g$, and modulo t^2

$$Y^g(u,z)v = Y(u,z)v + t\big(Y(\varphi u,z)v - \varphi(Y(u,z)v) + Y(u,z)\varphi v\big).$$

Its vacuum is $g^{-1}\mathbf{1} = \mathbf{1} - t\varphi(\mathbf{1})$, which is $\mathbf{1}$ precisely when $\varphi(\mathbf{1}) = 0$. So the first-order deformations "obtained by a change of coordinates" are

$$(\delta\varphi)(u,n,v) := (\varphi u)_{(n)}v - \varphi(u_{(n)}v) + u_{(n)}(\varphi v), \qquad \varphi(\mathbf{1}) = 0. \tag{8.3}$$

In words: $\delta\varphi$ measures the failure of φ to be a derivation of every n-th product.

Definition 8.3 (Coboundary, trivial deformation)**.** A linear map $\varphi : V \to V$ is *grade-preserving* if $\varphi(V_k) \subseteq V_k$ for all k. A cochain $f : V \to \mathrm{End}(V)[[z^{\pm1}]]$ is a *coboundary* if there is a grade-preserving φ with $\varphi(\mathbf{1}) = 0$ and $f(u)_{(n)}v = (\delta\varphi)(u,n,v)$ for all u,n,v. A first-order deformation is *trivial* if its Y_1 is a coboundary.

```
def GradePreserving (W : VertexOperatorAlgebra V) (φ : V →ₗ[ℂ] V) : Prop :=
  ∀ (k : ℤ) (u : V), u ∈ W.grading k → φ u ∈ W.grading k

def IsCoboundary (W : VertexOperatorAlgebra V) (f : V →ₗ[ℂ] (End ℂ V)⟦z^±⟧) : Prop :=
  ∃ φ : V →ₗ[ℂ] V, φ W.vacuum = 0 ∧ GradePreserving W φ ∧
    ∀ (u : V) (n : ℤ) (v : V),
      mode (f u) n v = W.smul (φ u) n v - φ (W.smul u n v) + W.smul u n (φ v)

def IsTrivial (D : FirstOrderDeformation W) : Prop := IsCoboundary W D.Y1
```

(`VOA.Deform.GradePreserving`, `VOA.Deform.IsCoboundary`, `VOA.Deform.FirstOrderDeformation.IsTrivial`, `VOA/Core/Deformation.lean`.)

From the mathematics to the Lean statement

`∃ φ : V →ₗ[ℂ] V` is "there is a linear map φ"; the three conjuncts are $\varphi(\mathbf{1}) = 0$, grade preservation, and the formula (8.3) for every $u \in V$ (not only homogeneous), $n \in \mathbb{Z}$, $v \in V$. `W.smul (φ u) n v` is $(\varphi u)_{(n)}v$, `φ (W.smul u n v)` is $\varphi(u_{(n)}v)$, `W.smul u n (φ v)` is $u_{(n)}(\varphi v)$.
Sign. The opposite overall sign $(-\delta\varphi)$ gives the same set, since φ may be replaced by $-\varphi$. Indeed the library's reconstruction theorem produces its trivialising map as `-ψ` (Theorem 8.16).
The gauge group. Allowed coordinate changes are $1 + t\varphi$ with φ grade-preserving and vacuum-fixing. φ is *not* required to fix ω, nor to commute with anything. So triviality is generous in the expected way: it allows every infinitesimal graded, vacuum-preserving change of basis. Restricting φ to be grade-preserving is natural for graded deformations; it matters only for ungraded ones (Warning 8.2.5).

The first thing to check about any notion of "trivial deformation" is that the trivial ones are deformations at all: that $\delta\varphi$ satisfies (D1)–(D4).

Physical meaning

A trivial deformation is a field redefinition: one relabels the states $u \mapsto u + t\varphi(u)$, as a physicist relabels operators by mixing operators of the same dimension. Such a "deformation" changes the OPE coefficients written in the old basis but not the theory; it is the analogue of a redundant operator in conformal perturbation theory. Requiring φ to preserve weights says operators only mix with operators of the same scaling dimension; requiring $\varphi(\mathbf{1}) = 0$ says the identity operator is not redefined.

Theorem 8.4 (Coboundaries are cocycles). *For every linear φ with $\varphi(\mathbf{1}) = 0$, the cochain $\delta\varphi$ satisfies (D1)–(D4). In particular every coboundary is the Y_1 of a first-order deformation.*

```
def cocycles (W : VertexOperatorAlgebra 𝒱) : Submodule ℂ (Cochain 𝒱) where
  carrier := {f | Truncated f ∧ f W.vacuum = 0 ∧ CreationAx W f ∧ JacobiAx W f}

theorem coboundaries_le_cocycles (W : VertexOperatorAlgebra 𝒱) :
    coboundaries W ≤ cocycles W := by

theorem deltaCochain_mem_cocycles (W : VertexOperatorAlgebra 𝒱) {φ : 𝒱 →ₗ[ℂ] 𝒱}
    (hφ0 : φ W.vacuum = 0) : deltaCochain W φ ∈ Deform.cocycles W := by
```

(`VOA.Deform.cocycles`, `VOA.Deform.coboundaries_le_cocycles`, `VOA/Core/DeformationGraded.lean`; `VOA.NonzeroDeform.deltaCochain_mem_cocycles`, `VOA/Examples/NonzeroDeformation.lean`. The proof of the submodule axioms of `cocycles` is omitted.)

From the mathematics to the Lean statement

`Cochain 𝒱` abbreviates `𝒱 →ₗ[ℂ] (End ℂ 𝒱)⟦z^±⟧`, the type of `Y1`. `Truncated`, `CreationAx`, `JacobiAx` are (D1), (D3), (D4) restated for an arbitrary cochain, verbatim copies of the fields of `FirstOrderDeformation`; so `cocycles W` is the set of Y_1's of first-order deformations, and the library proves the bijection `cocycleEquivDeformation : ↥(cocycles W) ≃ FirstOrderDeformation W`. That it is a `Submodule` — closed under sums and scalar multiples — is the statement that the axioms are linear in Y_1. `coboundaries W` is the submodule of coboundaries (Definition 8.3); `≤` is inclusion. `deltaCochain W φ` is the cochain $\delta\varphi$ of (8.3), defined for *any* linear φ, graded or not.

Proof on paper. (D2) and (D3): if $\varphi\mathbf{1} = 0$ then $(\delta\varphi)(\mathbf{1}, n, v) = 0 - \varphi(\mathbf{1}_{(n)}v) + \mathbf{1}_{(n)}\varphi v = -\delta_{n,-1}\varphi v + \delta_{n,-1}\varphi v = 0$, and for $n \geq -1$, $(\delta\varphi)(u, n, \mathbf{1}) = (\varphi u)_{(n)}\mathbf{1} - \varphi(u_{(n)}\mathbf{1})$, which is $0-0$ for $n \geq 0$ and $\varphi u - \varphi u$ for $n = -1$. (D1) is immediate from VA5 for the three terms. For (D4), write $\mathcal{D}$ for the operation that, applied to a trilinear expression $F(u, v, x)$, returns $F(\varphi u, v, x) + F(u, \varphi v, x) + F(u, v, \varphi x) - \varphi F(u, v, x)$. A direct expansion shows that substituting $\delta\varphi$ for Y_1 in each summand of the left side of (8.2) gives $\mathcal{D}$ of the corresponding summand of the undeformed Borcherds identity (the inner φ's cancel in pairs), and likewise on the right. Applying the undeformed identity at $(\varphi u, v, x)$, $(u, \varphi v, x)$, $(u, v, \varphi x)$ and (u, v, x) concludes. This is the mode-by-mode form of the statement that Y^g is again a vertex algebra. □

What the machine verified

`coboundaries_le_cocycles`, `deltaCochain_mem_cocycles` and `cocycleEquivDeformation` are proved; `#print axioms` gives `[propext, Classical.choice, Quot.sound]` (checked for `coboundaries_le_cocycles`, see Section 8.10). Unconditional.

Physical meaning

Field redefinitions never spoil consistency: if one starts from a consistent set of OPEs and renames operators, the renamed OPEs are consistent. This is the trivial direction of every deformation theory, and it is why "deformations modulo field redefinitions" is a well-defined space (the tangent space of the moduli space at the given theory).

8.2.5 Rigidity

Definition 8.5 (Rigidity). W is *rigid* if every first-order deformation is trivial, and *graded rigid* (in full: *graded first-order rigid*) if every *graded* first-order deformation is trivial. Only the second notion is meaningful (Warning 8.2.5); whenever this chapter says "graded rigid" it means graded first-order rigid in this sense.

```
def IsRigid (W : VertexOperatorAlgebra 𝒱) : Prop :=
  ∀ D : FirstOrderDeformation W, D.IsTrivial

def IsRigidGraded (W : VertexOperatorAlgebra 𝒱) : Prop :=
  ∀ D : FirstOrderDeformation W, D.IsGraded → D.IsTrivial
```

(`VOA.Deform.IsRigid`, `VOA/Core/Deformation.lean`; `VOA.Deform.IsRigidGraded`, `VOA/Core/DeformationGraded.lean`.)

The library also proves the cohomological reading: with $H(W) :=$ cocycles/coboundaries (an honest quotient module),

```
abbrev H (W : VertexOperatorAlgebra 𝒱) : Type u := ₁(cocycles W) ⧸ coboundariesIn W

theorem isRigid_iff_H_trivial (W : VertexOperatorAlgebra 𝒱) :
    IsRigid W ↔ ∀ z : H W, z = 0 := by

theorem isRigidGraded_of_gradedCocycles_le (W : VertexOperatorAlgebra 𝒱)
    (h : gradedCocycles W ≤ gradedCoboundaries W) : IsRigidGraded W := by
```

(`VOA.Deform.H`, `VOA.Deform.isRigid_iff_H_trivial`, `VOA.Deform.isRigidGraded_of_gradedCocycles_le`, `VOA/Core/DeformationGraded.lean`. `coboundariesIn W` is `coboundaries W` viewed inside `cocycles W`; `gradedCocycles` and `gradedCoboundaries` are the intersections of the two submodules with the submodule `gradedCochains W` of graded cochains.)

Trap / dead end

`IsRigid` is false for every Virasoro vertex operator algebra, for a definitional reason; only `IsRigidGraded` is meaningful. The cocycle condition (D1)–(D4) ignores the grading, while `IsCoboundary` insists on a *grade-preserving* φ. Consequently `IsTrivial` implies `IsGraded` (`NonzeroDeform.isGraded_of_isTrivial`: each of the three terms of $\delta\varphi$ lands in the right weight), and *any* ungraded cocycle is non-trivial. Such cocycles are easy to produce: $\varphi = L_1$ kills the vacuum, so δL_1 is a cocycle (Theorem 8.4), but L_1 lowers weights by one and δL_1 is not graded: on $V(c,0)$ one computes $\omega^1_{(-3)}\mathbf{1} = -5L_{-3}\mathbf{1}$, of weight 3, whereas gradedness would put it in weight $2+0-(-3)-1=4$. The library proves

```
theorem isGraded_of_isTrivial {W : VertexOperatorAlgebra 𝒱}
    (D : Deform.FirstOrderDeformation W) (hD : D.IsTrivial) : D.IsGraded := by

def l1Deformation (W : VertexOperatorAlgebra 𝒱) : Deform.FirstOrderDeformation W :=
  deformOf W (L_one_vacuum W)

theorem not_isRigid_virasoroVOA (c : ℂ) : ¬ Deform.IsRigid (virasoroVOA c) :=
```

```
fun h => not_isTrivial_l1Deformation c (h (l1Deformation (virasoroVOA c)))
```

(`VOA.NonzeroDeform.*`, `VOA/Examples/NonzeroDeformation.lean`.) The deformation δL_1 is of course trivial in the ordinary sense — it is a change of coordinates by the *ungraded* map $1+tL_1$ — so `not_isRigid_virasoroVOA` records an asymmetry of the definitions, not a modulus of $V(c,0)$. The same argument applies to any VOA with $L_1 \neq 0$ on some weight space. The source itself says so ("`Deform.IsRigid` is false for essentially every VOA and `IsRigid`-shaped goals should not be pursued") and recommends exactly the repair the library then adopted: state rigidity as `IsRigidGraded`. Every rigidity theorem of this chapter concerns `IsRigidGraded`. A reader who meets the word "rigid" attached to `IsRigid` anywhere in the library should treat it as a trap: `IsRigid` must never be quoted as true, and it is proved to fail for every $V(c,0)$ (`VOA.NonzeroDeform.not_isRigid_virasoroVOA`, `#print axioms`-clean).

Physical meaning

Rigidity means that the tangent space to the space of chiral algebras at W is zero: every infinitesimal change of OPE coefficients is a field redefinition. In CFT language, the chiral algebra has no exactly marginal deformations and is an isolated point of its moduli space (its "conformal manifold" is a point). The free boson is the model counterexample for the full CFT (its radius is a modulus), and the universal Virasoro algebra, whose central charge can be moved, is the model counterexample for chiral algebras. The graded version restricts to perturbations that preserve scaling dimensions, i.e. to marginal ones, which are the ones relevant for families of conformal theories.

8.2.6 Fidelity of `IsRigidGraded`

Since the headline theorem is a statement of the form `IsRigidGraded (virasoroSimple c)`, everything rests on this definition, and we examine it from every side.

From the mathematics to the Lean statement

What `IsRigidGraded W` says, unfolded completely. For every $\mathbb{C}$-linear $Y_1 : \mathcal{V} \to \mathrm{End}(\mathcal{V})[[z^{\pm 1}]]$ satisfying (D1)–(D4) and such that every $u^1_{(n)}$ shifts weight as $u_{(n)}$ does, there is a linear $\varphi : \mathcal{V} \to \mathcal{V}$ with $\varphi(\mathbf{1}) = 0$, $\varphi(\mathcal{V}_k) \subseteq \mathcal{V}_k$ for all k, and $u^1_{(n)}v = (\varphi u)_{(n)}v - \varphi(u_{(n)}v) + u_{(n)}\varphi v$ for all $u, v \in \mathcal{V}$, $n \in \mathbb{Z}$. One single φ works for all u, n, v at once.
Which deformations are allowed. Deformations of the *vertex algebra* structure Y (not just of the VOA; ω may become non-conformal), over the dual numbers $\mathbb{C}[t]/(t^2)$, on the fixed graded space $\mathcal{V}$, with fixed vacuum, compatible with the original weight grading.
Which coordinate changes are allowed. $1 + t\varphi$ with φ grade-preserving and $\varphi(\mathbf{1}) = 0$.
Is the graded gauge group too small? One might worry that a graded deformation could be trivialised by an *ungraded* φ but not by a graded one, which would make `IsRigidGraded` stronger than intended (harder to satisfy) — harmless for a rigidity *theorem*, but worth knowing. It cannot happen. Argued on paper (not formalised): decompose an arbitrary linear φ with $\varphi\mathbf{1} = 0$ into homogeneous components $\varphi = \sum_d \varphi_d$, $\varphi_d(\mathcal{V}_k) \subseteq \mathcal{V}_{k+d}$ (possible because $\mathcal{V} = \bigoplus \mathcal{V}_k$). For homogeneous u, v, the three terms of $(\delta\varphi_d)(u, n, v)$ lie in $\mathcal{V}_{k+\ell-n-1+d}$, so the weight-$(k+\ell-n-1)$ part of $\delta\varphi(u, n, v)$ is $\delta\varphi_0(u, n, v)$. If $Y_1 = \delta\varphi$ is graded, it equals its weight-$(k+\ell-n-1)$ part, so $Y_1 = \delta\varphi_0$ on homogeneous vectors and hence everywhere; and $\varphi_0\mathbf{1}$ is the weight-0 part of $\varphi\mathbf{1} = 0$. So for graded deformations "trivial by a graded gauge" and "trivial by any gauge" coincide.

Is the graded class of deformations too small? Restricting to graded deformations is standard (the cohomology theories in the literature for graded vertex algebras are grading-restricted), and it is the only sensible choice with this gauge group by Warning 8.2.5. It does exclude deformations in which the weight grading itself moves. For a deformation of W *as a vertex operator algebra*, with deformed conformal vector $\omega + t\omega_1$, the deformed L_0 is diagonalisable on each finite-dimensional $\mathcal{V}_n \oplus t\mathcal{V}_n$-block with the same integer eigenvalues, and one expects to conjugate it back to the original grading by a coordinate change; we have not formalised this, and the library does not claim it. The theorem should therefore be read as *graded* rigidity, and the book never says more.

Same as / weaker than / stronger than the literature. Up to the remarks just made, `IsRigidGraded W` is the vanishing of the first-order ("H^2") deformation space of W as a graded vertex algebra with fixed vacuum. It is *weaker* than rigidity among all (ungraded) deformations with ungraded gauge (a notion the library does not define), and *stronger* than rigidity of W as a VOA with ω fixed, because ω is allowed to move. It is a first-order statement: it does not by itself say that every formal deformation over $\mathbb{C}[[t]]$ is trivial (that follows by the usual Gerstenhaber induction for graded deformations with finite-dimensional weight spaces, an argument we mention but which the library does not contain), and it says nothing about convergent families.

Comparison with Linshaw–Qi. In the standard terminology, `IsRigidGraded W` is the vanishing of the *graded* second deformation cohomology H^2 of W with the vacuum fixed: graded cocycles modulo coboundaries of grade-preserving, vacuum-fixing φ. It is *at least as strong as* the notion of Linshaw and Qi (arXiv:2601.12017, §2). The gauge group is the same as theirs (grade-preserving φ with $\varphi\mathbf{1} = 0$), while the class of deformations is *larger*: Linshaw–Qi require the deformation to preserve the translation (derivative) operator and the grading operator, whereas `FirstOrderDeformation` does not ask $T = L_{-1}$ to be preserved (the trivial deformation δL_0 already has $\omega^1_{(-2)}\mathbf{1} = -L_{-3}\mathbf{1} \neq 0$) and lets ω stop being conformal. Since `IsRigidGraded` asserts triviality for every member of the larger class, with the same notion of triviality, it implies Linshaw–Qi rigidity. The affine theorem of Chapter 10 is therefore Linshaw–Qi's Theorem 5.1 in their own sense, not merely an analogue of it.

How could it have been vacuous? Three ways, each checked:

1. *An unsatisfiable or degenerate cocycle condition* would make every VOA rigid. The `finsum` trap is excluded by the finiteness lemmas above, and the condition is satisfiable by nonzero cochains: the library constructs the scaling deformation δL_0, which is graded with $u^1_{(n)}v = (n+1)u_{(n)}v$ and has $Y_1 \neq 0$ on $V(c,0)$ for every c (`NonzeroDeform.exists_nonzero_deformation`, Example 8.7). So the rigidity theorem has to do real work even on trivial deformations: it must find φ.

2. *A gauge group so large that everything is trivial.* The gauge group is exactly the graded vacuum-fixing changes of coordinates. The library proves that it is *not* large enough to absorb a change of the central term: on any VOA with $\mathcal{V}_2 = \mathbb{C}\omega$ a coboundary has $\omega^1_{(1)}\omega = 2\mu\omega$ and $\omega^1_{(3)}\omega = \mu c\mathbf{1}$ for one scalar μ (Theorem 8.14). A deformation with $\omega^1_{(1)}\omega = 0$ and $\omega^1_{(3)}\omega \neq 0$ — what ∂_c would be — is provably non-trivial.

3. *A conclusion true for every VOA.* Is `IsRigidGraded` perhaps true for all W? On paper, no: the universal Virasoro VOA $V(c,0)$ at generic c has the nontrivial graded deformation ∂_c. In Lean too: the library constructs ∂_c (`VOA.VirPoly.cDeformation`), proves that it is a nontrivial graded deformation, and so proves `¬ IsRigidGraded W` for the concrete $W = V(c,0)$, every c (`VOA.VirPoly.not_isRigidGraded_virasoroVOA`; Section 8.2.7).

8.2.7 Is `IsRigidGraded` vacuous? The non-vacuity check

A rigidity notion that every vertex operator algebra satisfied would make the headline theorem worthless. We therefore searched the library (all files assigned to this chapter, and every occurrence of `¬ IsRigidGraded`, `¬ Deform.IsRigidGraded` and `¬ D.IsTrivial` under `VOA/`) for a *graded* deformation proved *non-trivial*. When this section was first written, the outcome was: **there was none**. That has since changed: the files `VirasoroPoly*.lean`, `VirasoroCDefBuild.lean`, `VirasoroCDefJacobi.lean` and `VirasoroCDefFinal.lean` under `VOA/Examples/` construct $\partial_c Y$ and prove

```
theorem isCDeformation_cDeformation (c : ℂ) : VirCDef.IsCDeformation c (cDeformation c) :=

theorem not_isRigidGraded_virasoroVOA (c : ℂ) : ¬ Deform.IsRigidGraded (virasoroVOA c) :=
```

(`VOA.VirPoly.isCDeformation_cDeformation`, `VOA.VirPoly.not_isRigidGraded_virasoroVOA`, `VOA/Examples/VirasoroCDefFinal.lean`; the deformation `cDeformation c` itself is defined in `VOA/Examples/VirasoroCDefJacobi.lean`). Here `virasoroVOA c` is the *universal* $V(c,0)$, not the simple quotient, and $c \in \mathbb{C}$ is arbitrary. The rest of this section records the earlier search and the gauge-group half on which the new theorem rests. Apart from $\partial_c Y$, the deformations the library constructs are the zero deformation and $\delta\varphi$ for explicit φ; those with graded φ (e.g. δL_0) are trivial by construction, and those with ungraded φ (e.g. δL_1) are non-trivial only because they are ungraded (Warning 8.2.5). Every other statement of the form `¬ IsRigidGraded W` in the library is conditional: `VirCDef.not_isRigidGraded_of_isCDeformation` and `not_isRigidGraded_of_omega_witness` (`VOA/Examples/VirasoroCDeformation.lean`) assume a deformation (now supplied by `cDeformation`), and `AffineSl2RigidityCollapse.no_uniform_derivation_piece2` and `…no_uniform_derivation_sl2Basis_tripletW2` (`VOA/Examples/AffineSl2RigidityCollapse.lean`) assume a uniform derivation. What *is* proved unconditionally is the half of the non-vacuity argument that concerns the gauge group:

```
theorem not_isTrivial_of_omega_witness (D : FirstOrderDeformation (virasoroVOA c))
    (h1 : D.smul₁ (omegaVir c) 1 (omegaVir c) = 0)
    (h3 : D.smul₁ (omegaVir c) 3 (omegaVir c) ≠ 0) : ¬ D.IsTrivial :=
```

(`VOA.VirCDef.not_isTrivial_of_omega_witness`, `VOA/Examples/VirasoroCDeformation.lean`.)

From the mathematics to the Lean statement

Fidelity check of the non-vacuity claim. The claim to be checked is "there exist VOAs that are not graded rigid". *Machine status:* proved, for $V(c,0)$ at every c (`VOA.VirPoly.not_isRigidGraded_virasoroVOA`). The theorem quoted just above says that *if* a deformation of $V(c,0)$ leaves $\omega_{(1)}\omega$ unchanged and moves $\omega_{(3)}\omega$, it is not trivial (for every c, including $c=0$), and `not_isRigidGraded_of_isCDeformation` turns any *graded* such deformation into `¬ IsRigidGraded (virasoroVOA c)`. The inhabitant — a graded first-order deformation with $\omega^1_{(1)}\omega = 0, \omega^1_{(3)}\omega = \frac{1}{2}\mathbf{1}$, namely $\partial_c Y$ — is `cDeformation c`, and `isCDeformation_cDeformation` checks the three conditions. *The argument, which the Lean construction follows:* the creation monomials in sorted order form a basis of $V(c,0)$ with a c-independent index set (proved, `gradedBasis`); in that basis every structure constant $\langle\text{basis}\rangle_{(n)}\langle\text{basis}\rangle$ is a polynomial in c (normal ordering, as in Definition 8.19). Transport all $V(c',0)$ to one space via this basis; the Borcherds identity holds identically in c', so differentiating at $c' = c$ gives a cochain $Y_1 = \partial_c Y$ satisfying (D1)–(D4); it is graded because the basis is homogeneous; its values on (ω,ω) are $\partial_c(2\omega) = 0$ and $\partial_c(\frac{c}{2}\mathbf{1}) = \frac{1}{2}\mathbf{1}$. By the theorem above it is non-trivial, so $V(c,0)$ is *not* graded rigid, at every c. (Note this concerns the universal $V(c,0)$; at generic c it coincides with $L(c,0)$, so generic simple Virasoro VOAs are not graded rigid either, while the minimal ones are.) The file `VirasoroCDeformation.lean` names two routes to formalising this; the library took the second (differentiation of polynomial structure constants on the c-independent basis of sorted creation words, `VirasoroPolyStructure.lean` to `VirasoroCDefFinal.lean`). *Verdict:*

`IsRigidGraded` is non-vacuous, machine-checked: $V(c,0)$ is not graded first-order rigid at any $c \in \mathbb{C}$. The witness moves the central charge; the library's `FirstOrderDeformation` does not require the conformal vector or c to be preserved, which is the same convention under which the rigidity theorems of this chapter are proved.

Trap / dead end

Non-vacuity of `IsRigidGraded`: once a paper argument, now machine-checked. When this chapter was first written, the library contained no proof that any concrete vertex operator algebra fails `IsRigidGraded`; the files cited in Section 8.2.7 now supply one (`VOA.VirPoly.not_isRigidGraded_virasoroVOA`). The conditional statement on which that proof rests is

```
def IsCDeformation (D : FirstOrderDeformation (virasoroVOA c)) : Prop :=
  D.IsGraded ∧
    D.smul₁ (omegaVir c) 1 (omegaVir c) = 0 ∧
    D.smul₁ (omegaVir c) 3 (omegaVir c) = (2⁻¹ : ℂ) • vacVec c

theorem not_isRigidGraded_of_isCDeformation {D : FirstOrderDeformation (virasoroVOA
 ↪ c)}
    (hD : IsCDeformation c D) : ¬ IsRigidGraded (virasoroVOA c) :=
```

(`VOA.VirCDef.IsCDeformation`, `VOA.VirCDef.not_isRigidGraded_of_isCDeformation`, `VOA/Examples/VirasoroCDeformation.lean`): a graded deformation of the universal $V(c,0)$ that leaves $\omega_{(1)}\omega = 2\omega$ unchanged and moves $\omega_{(3)}\omega = \frac{c}{2}\mathbf{1}$ at rate $\frac{1}{2}\mathbf{1}$ — the derivative ∂_c — would refute graded rigidity of $V(c,0)$. The file `VirasoroCDeformation.lean` does not itself inhabit `IsCDeformation`; it says so ("`IsCDeformation c` is a predicate and this file does **not** inhabit it"; some of its docstrings, written before the construction, still say that the predicate is inhabited nowhere), and explains that constructing $\partial_c Y$ needs either a square-zero extension $U(\mathfrak{Vir})/J_2(c)$ with a PBW-type freeness statement, or differentiation of the family of structure constants on a c-independent basis. The second route is the one later carried out, in `VirasoroCDefJacobi.lean` and `VirasoroCDefFinal.lean`, which inhabit the predicate (`VOA.VirPoly.isCDeformation_cDeformation`). Two routes that do *not* produce a nontrivial graded deformation are also recorded there: the background-charge family of free bosons (whose Y is independent of the parameter, so the cochain is zero) and naive differentiation of $c \mapsto V(c,0)$ (the carrier `VirUniv c` depends on c, so $\partial_c Y$ is not even type-correct without a trivialisation). The project notes also contain the observation that a uniform derivation "$\forall W$, `IsRigidGraded W` $\Rightarrow$ (some normalisation statement)" would refute graded rigidity of a free boson (`AffineSl2RigidityCollapse.no_uniform_derivation_piece2`), which again is a conditional, not a witness.

Consequently `IsRigidGraded` fails for $V(c,0)$ at every c, machine-checked (the standard argument that $c \mapsto V(c,0)$ is a nontrivial family, formalised, together with Theorem 8.14); since $L(c,0) = V(c,0)$ at generic c, it is a genuine property that the minimal models have and generic Virasoro VOAs lack. As further internal evidence that the minimal-model theorem has content: its proof uses, at the decisive step, a null relation in the *simple* quotient together with the simplicity of the quotient; at generic c there is no such relation, and the proof does not apply.

Remark 8.6 (Non-vacuity, in one paragraph)**.** Here is the whole non-vacuity argument. Every step of it is now machine-checked; the paragraph marked *(Construction.)* is the step that was missing when this chapter was first written. *(Construction.)* The universal $V(c,0)$ has the c-independent PBW basis $L_{-n_1}\cdots L_{-n_k}\mathbf{1}$, $n_1 \geq \ldots \geq n_k \geq 2$, in which every structure constant of Y_c is a polynomial in c. Transporting all $V(c',0)$ to one space along this basis and differentiating at $c' = c$ gives $Y_1 := \partial_c Y$.

It satisfies (D1)–(D4): truncation, since the vanishing bound does not depend on c; the vacuum and creation conditions, since $Y_c(\mathbf{1}) = \mathrm{id}$ and $u_{(-1)}\mathbf{1} = u$ hold for every c; the linearised Borcherds identity, by differentiating the Borcherds identity in c. It is graded, because the basis is homogeneous, and

$$\omega^1_{(1)}\omega = \partial_c(2\omega) = 0, \qquad \omega^1_{(3)}\omega = \partial_c\big(\tfrac{c}{2}\mathbf{1}\big) = \tfrac{1}{2}\mathbf{1}.$$

So Y_1 is a graded first-order deformation. In Lean this is `VOA.VirPoly.cDeformation` (`VirasoroCDefJacobi.lean`; the linearised Borcherds identity is `Y1_jacobi`), with `cDeformation_isGraded`, `cDeformation_omega_one` ($\omega^1_{(1)}\omega = 0$) and `cDeformation_omega_three` ($\omega^1_{(3)}\omega = \frac{1}{2}\mathbf{1}$) in `VirasoroCDefFinal.lean`. *(Non-triviality.)* On any VOA with $\mathcal{V}_2 = \mathbb{C}\omega$, every coboundary f has $(f(\omega)_{(1)}\omega, f(\omega)_{(3)}\omega) = (2\mu\omega, \mu c\mathbf{1})$ for one scalar μ (`VOA.VirCDef.cmode_conformal_of_isCoboundary`, Theorem 8.14). For Y_1 this would need $0 = 2\mu$ and $\frac{1}{2} = \mu c$, which is impossible; so Y_1 is non-trivial. The library proves exactly this step: `VOA.VirCDef.not_isTrivial_of_omega_witness` (quoted in Section 8.2.7) and `VOA.VirCDef.not_isRigidGraded_of_isCDeformation` (quoted in Warning 8.2.7), both `#print axioms`-clean. *(Conclusion, in Lean.)* `VOA.VirPoly.not_isRigidGraded_virasoroVOA`: $V(c,0)$ is not graded first-order rigid at any c, nor is $L(c,0) = V(c,0)$ at generic c (the deformation moves the central charge, as the library's notion allows); so the notion separates the minimal-model charges from the generic ones, as a rigidity theorem should.

Physical meaning

In conformal-field-theory terms the remark says: the chiral algebra generated by a stress tensor alone has one genuine modulus, the central charge, and rescaling T cannot imitate a change of c (it moves the double pole $2T$ and the quartic pole $c/2$ together). The minimal models kill this modulus through their null vectors; the generic Virasoro algebra keeps it.

What the machine verified

Machine-checked: `VOA.VirCDef.cmode_conformal_of_isCoboundary`, `VOA.VirCDef.not_isTrivial_of_omega_witness`, `VOA.VirCDef.not_isRigidGraded_of_omega_witness`, `VOA.VirCDef.not_isRigidGraded_of_isCDeformation`; each reports `[propext, Classical.choice, Quot.sound]` (re-run 2026-10-27, Section 8.10). Also machine-checked since: `VOA.VirPoly.cDeformation`, `VOA.VirPoly.isCDeformation_cDeformation` and `VOA.VirPoly.not_isRigidGraded_virasoroVOA` (every $c \in \mathbb{C}$), so a VOA that is not graded first-order rigid exists in Lean. Their axiom lists are reported as the three standard axioms by the release follow-ups audit (2026-10-28); `#print axioms` was not re-run for this chapter.

Example 8.7 (The zero and scaling deformations)**.** The zero cochain is a deformation (`Deform.zeroDeformation`), trivial with $\varphi = 0$. More interestingly, $\varphi = L_0$ is grade-preserving and kills $\mathbf{1}$, so δL_0 is a trivial graded deformation. On homogeneous $u \in \mathcal{V}_a$, $v \in \mathcal{V}_b$,

$$(\delta L_0)(u,n,v) = a\,u_{(n)}v - (a+b-n-1)u_{(n)}v + b\,u_{(n)}v = (n+1)\,u_{(n)}v,$$

i.e. $Y_1(u,z) = -z\partial_z Y(u,z)$: the infinitesimal form of the rescaling $z \mapsto \lambda z$. In particular $\omega^1_{(1)}\omega = 2\cdot 2\omega = 4\omega$ and $\omega^1_{(3)}\omega = 4\cdot\frac{c}{2}\mathbf{1} = 2c\mathbf{1}$, so this trivial deformation *does* change the structure constant $\omega_{(3)}\omega$ — together with $\omega_{(1)}\omega$, in the ratio allowed by Theorem 8.14 ($\mu = 2$). This is the example that refutes any naive rigidity statement forgetting the quotient by coboundaries.

```
def scalingDeformation (W : VertexOperatorAlgebra 𝒱) : Deform.FirstOrderDeformation W :=
  deformOf W (L_zero_vacuum W)

theorem smul₁_scalingDeformation_homog (W : VertexOperatorAlgebra 𝒱) {a b : ℤ} {u v : 𝒱}
```

```
    (hu : u ∈ W.grading a) (hv : v ∈ W.grading b) (n : ℤ) :
    (scalingDeformation W).smul₁ u n v = ((n : ℂ) + 1) • W.smul u n v := by

theorem exists_nonzero_deformation (c : ℂ) :
    ∃ D : Deform.FirstOrderDeformation (virasoroVOA c), D.Y1 ≠ 0 ∧ D.IsGraded :=
```

(`VOA.NonzeroDeform.*`, `VOA/Examples/NonzeroDeformation.lean`; `deformOf W h` is the deformation with $Y_1 = \delta\varphi$ built from Theorem 8.4, and `virasoroVOA c` is the universal Virasoro VOA of Section 8.3. The source also proves that δL_0 is the only deformation of the "mode-diagonal" form $u^1_{(n)}v = g(n)u_{(n)}v$, up to scale.)

8.2.8 The finite-dimensional picture and its limit

Because a graded Y_1 is determined by its components $\mathcal{V}_a \times \mathcal{V}_b \to \mathcal{V}_d$ (in the mode $n = a + b - d - 1$), one might hope to decide rigidity one "tridegree" (a, b, d) at a time, by finite linear algebra. The file `VOA/Core/DeformationGraded.lean` sets this up carefully: `GradedCochain W a b d` is the finite-dimensional space $\mathrm{Hom}(\mathcal{V}_a, \mathrm{Hom}(\mathcal{V}_b, \mathcal{V}_d))$, `gradedComponent` is the linear component map, `gradedCocyclesAt` and `gradedCoboundariesAt` are the images of cocycles and coboundaries, and `DeformationSpaceAt W a b d` is their (finite-dimensional) quotient. It proves the easy direction — rigidity implies vanishing at every tridegree — and then states the converse as a named *non-theorem*:

```
theorem gradedCocyclesAt_le_gradedCoboundariesAt_of_isRigid {W : VertexOperatorAlgebra 𝒱}
    (h : IsRigid W) (a b c : ℤ) :
    gradedCocyclesAt W a b c ≤ gradedCoboundariesAt W a b c := by

def GradedToGlobalRigidity (W : VertexOperatorAlgebra 𝒱) : Prop :=
  (∀ a b c : ℤ, gradedCocyclesAt W a b c ≤ gradedCoboundariesAt W a b c) → IsRigid W
```

(`VOA.Deform.*`, `VOA/Core/DeformationGraded.lean`.)

Trap / dead end

Tridegree-wise vanishing does not give rigidity. The coboundary of φ at tridegree (a, b, d) depends only on the three blocks $\varphi_a, \varphi_b, \varphi_d$ of φ. Vanishing of every `DeformationSpaceAt` produces one φ *per tridegree*, and nothing forces these choices to patch into a single φ. The source gives a concrete instance on $V(c, 0)$ (`VOA/Examples/VirasoroDeformationLow.lean`): the candidate $\partial_c Y$ has component $\frac{1}{2}\mathbf{1}$ at $(2, 2, 0)$ and 0 at $(2, 2, 2)$; on $\mathcal{V}_2 = \mathbb{C}\omega$ a gauge acts by one scalar, $\varphi\omega = \lambda\omega$, and kills it at $(2, 2, 0)$ only for $\lambda = 1/(2c)$ and at $(2, 2, 2)$ only for $\lambda = 0$. Both deformation spaces vanish (for $c \neq 0$), yet no single φ works. So `GradedToGlobalRigidity` is *not* proved, is not used, and the headline theorem is stated against `IsRigidGraded` directly, with one global φ; it does not inherit this gap. (The tables of `VirasoroDeformationLow` — the coboundary space fills the cochain space at the tridegrees $(2, 2, d)$, $d \in \{0, \dots, 4\}$, except $(2, 2, 0)$ at $c = 0$ — are correct finite statements, but they are partial information, not rigidity.)

8.2.9 Regular deformations and the pole coefficient

For completeness we record the remaining definitions of `VOA/Core/Deformation.lean`, which serve the affine-algebra rigidity proofs of Chapter 10 (the paper of Linshaw and Qi on $L_{-4/3}(\mathfrak{sl}_2)$ that the deformation layer was first built to formalise). A deformation is *regular* if $Y_1(a, x)b$ has no negative powers of x for weight-one a, b, i.e. $a^1_{(n)}b = 0$ for $n \geq 0$; its *pole vector* is the coefficient $a^1_{(1)}b$ of x^{-2}, which for graded D lies in $\mathcal{V}_0 = \mathbb{C}\mathbf{1}$.

```
def Regular (D : FirstOrderDeformation W) : Prop :=
  ∀ a ∈ W.grading 1, ∀ b ∈ W.grading 1, ∀ n : ℤ, 0 ≤ n → D.smul₁ a n b = 0
```

```
def poleVec (D : FirstOrderDeformation W) (a b : 𝒱) : 𝒱 := D.smul₁ a 1 b
```

(`VOA.Deform.FirstOrderDeformation.Regular`, …`poleVec`, same file.) The Virasoro algebras have $\mathcal{V}_1 = 0$, so these notions are empty there and play no role in this chapter. The cautionary tale attached to them — the statement "every graded deformation is regular" is *false*, refuted by δL_0, which has $a^1_{(0)}b = a_{(0)}b$ — is told in Chapter 10.

8.3 The Virasoro vertex operator algebras, recalled

This section recalls, briefly but completely, the Virasoro objects that occur in the statements of this chapter. Proofs (and the construction of the vertex operators) belong to Chapter 7; here we only need the definitions and a handful of facts, each with its Lean name.

8.3.1 The Virasoro algebra and its vacuum module

Definition 8.8 (Virasoro algebra)**.** The Virasoro algebra $\mathfrak{Vir}$ is the Lie algebra with basis $\{L_n\}_{n\in\mathbb{Z}}\cup\{C\}$ and bracket

$$[L_m, L_n] = (m-n)L_{m+n} + \frac{m^3-m}{12}\,\delta_{m+n,0}\,C, \qquad [C, \mathfrak{Vir}] = 0. \tag{8.4}$$

It is the central extension of the Witt algebra of vector fields $-z^{n+1}\partial_z$ by the Gelfand–Fuks cocycle.

```
abbrev Virasoro : Type := LieAlgebra.ofTwoCocycle gfCocycle

noncomputable def L (n : ℤ) : Virasoro := ofProd gfCocycle (Witt.gen n, 0)

noncomputable def C : Virasoro := ofProd gfCocycle (0, 1)

theorem virasoro_bracket (m n : ℤ) :
    ⁅L m, L n⁆ = ((m : ℂ) - n) • L (m + n)
      + (if m + n = 0 then (((m : ℂ) ^ 3 - m) / 12) • C else 0) := by
```

(`VOA.Virasoro`, `VOA.L`, `VOA.C`, `VOA.virasoro_bracket`, `VOA/Foundations/Virasoro.lean`. `LieAlgebra.ofTwoCocycle` is Mathlib's central extension of a Lie algebra by a 2-cocycle; `gfCocycle` is the Gelfand–Fuks cocycle on the library's Witt algebra; `ofProd` identifies the extension with the product Witt $\times\,\mathbb{C}$ as a vector space.)

Physical meaning

L_n are the modes of the stress tensor $T(z) = \sum L_n z^{-n-2}$: L_{-1} generates translations, L_0 dilatations (the Hamiltonian in radial quantisation), L_1 special conformal transformations. The central term is the conformal anomaly: c measures the response of the theory to curvature (the Casimir energy on a cylinder is $-\pi c/(6L)$) and counts degrees of freedom (a free boson has $c = 1$, a free fermion $c = 1/2$).

Definition 8.9 (Universal vacuum module)**.** For $c \in \mathbb{C}$, let $J(c) \subseteq U(\mathfrak{Vir})$ be the left ideal generated by the L_n with $n \geq -1$ and by $C - c$. The *universal Virasoro vacuum module* is $V(c,0) := U(\mathfrak{Vir})/J(c)$, with vacuum $\mathbf{1} = [1]$ and $\mathfrak{Vir}$ acting by left multiplication. Write L_n also for the operator by which L_n acts, and $\omega := L_{-2}\mathbf{1}$.

```
abbrev UVir : Type := UniversalEnvelopingAlgebra ℂ Virasoro

```

(`VOA.VirModule.*`, `VOA/Foundations/VirasoroModule.lean`.)

```
noncomputable def Lop (n : ℤ) : End ℂ (VirUniv c) := virVacRho c (L n)

noncomputable def omegaVir : VirUniv c := Lop c (-2) (vacVec c)
```

(`VOA.VirModule.Lop`, `VOA.VirModule.omegaVir`, `VOA/Examples/VirasoroField.lean`.)

From the mathematics to the Lean statement

`UniversalEnvelopingAlgebra ℂ Virasoro` is Mathlib's $U(\mathfrak{Vir})$, with `ι ℂ` the canonical map $\mathfrak{Vir} \to U(\mathfrak{Vir})$. `Submodule UVir UVir` spanned by a set is the *left* ideal it generates (a submodule of U over itself acting by left multiplication), and `⧸` is the quotient module; so `VirUniv c` is $V(c,0)$ exactly as in Definition 8.9. `virVacRho c` is the Lie homomorphism $\mathfrak{Vir} \to \mathrm{End}(V(c,0))$ given by left multiplication, and `Lop c n` is the operator L_n on $V(c,0)$. The docstring of `VirUniv` records a corrected naming error: this is the *universal* module, often written $V(c,0)$ or Vir^c, *not* the simple $L(c,0)$; the two differ exactly at the degenerate central charges, which is the whole point of this chapter. The library also proves C acts by c (`vac_acts_central`) and $\mathbf{1} \neq 0$ for every c (`vacVec_ne_zero`, without using `VOA.pbw`).

By the Poincaré–Birkhoff–Witt theorem $V(c,0)$ has basis the "creation monomials" $L_{-n_1} \cdots L_{-n_k}\mathbf{1}$ with $n_1 \geq \cdots \geq n_k \geq 2$; the monomial has L_0-eigenvalue (weight) $n_1 + \cdots + n_k$. The library encodes a monomial by the list $[n_1 - 2, \ldots, n_k - 2]$ of natural numbers, defines the weight and the monomials, and grades $V(c,0)$ by the span of the monomials of each weight:

```
def energyVir : List ℕ → ℕ
  | [] => 0
  | (i :: rest) => (i + 2) + energyVir rest

noncomputable def negWordVir : List ℕ → VirUniv c
  | [] => vacVec c
  | n :: ws => Lop c (-(n : ℤ) - 2) (negWordVir ws)

noncomputable def gradingVir (n : ℤ) : Submodule ℂ (VirUniv c) :=
  Submodule.span ℂ {x | ∃ ws : List ℕ, (energyVir ws : ℤ) = n ∧ negWordVir c ws = x}
```

(`VOA.VirModule.energyVir`, `VOA/Examples/VirasoroGrading.lean`; `VOA.VirModule.negWordVir`, `VOA/Examples/VirasoroSpanning.lean`; `VOA.VirModule.gradingVir`, `VOA/Examples/VirasoroGrading.lean`.)
The *sorted* lists of weight n (partitions of n into parts ≥ 2) index a basis `gradedBasis c n` of the weight-n space, with c-independent index type `SortedOfEnergy n`; this is proved, `pbw`-free, in `VOA/Examples/VirasoroPartitionBasis.lean`. So

$$\dim V(c,0)_n = \#\{\text{partitions of } n \text{ into parts} \geq 2\} : \qquad 1, 0, 1, 1, 2, 2, 4, 4, 7, 8, 12, \ldots \qquad (n = 0, 1, 2, \ldots),$$

independently of c. In particular $V(c,0)_1 = 0$, $V(c,0)_2 = \mathbb{C}\omega$, $V(c,0)_3 = \mathbb{C}L_{-3}\mathbf{1}$, $V(c,0)_4 = \mathrm{span}\{L_{-2}^2\mathbf{1}, L_{-4}\mathbf{1}\}$ (`VirDefLow.gradingVir_two`, `gradingVir_three`, `LeeYang.gradingVir_four`).

Physical meaning

$V(c,0)$ is the space of states of a CFT of central charge c that are created from the vacuum by the stress tensor alone: $L_{-n_1}\cdots L_{-n_k}\mathbf{1}$ corresponds to the field $:\partial^{n_1-2}T\cdots\partial^{n_k-2}T:$ (up to normalisation). The relations $L_n\mathbf{1}=0$ for $n\geq -1$ say the vacuum is invariant under the global conformal group SL_2 generated by L_{-1},L_0,L_1. "Universal" means no further relations are imposed: every possible descendant of the identity is kept, even those of zero norm.

Definition 8.10 (Universal Virasoro VOA). $V(c,0)$ with the grading above, vacuum $\mathbf{1}$, conformal vector $\omega=L_{-2}\mathbf{1}$, central charge c, and the unique vertex operators with $Y(\omega,z)=\sum_n L_n z^{-n-2}$, is a vertex operator algebra of CFT type (Chapter 7).

```
noncomputable def virasoroVOA : VertexOperatorAlgebra (VirUniv c) where

  L0_grading := fun {_} v hv => virYA_L0_grading c v hv
  translation := virYA_omega_translation c
  vacuum_grade := gradingVir_zero c
  positivity := gradingVir_neg c
```

(`VOA.VirModule.virasoroVOA`, `VOA/Examples/VirasoroInstance.lean`.) The vertex operator `virYA c` is built by the reconstruction theorem of Chapter 4 (Theorem 4.41) from the field of ω; we do not need its definition, only that its conformal modes are the operators `Lop c n` (`virasoroVOA_L_eq_Lop`) and the facts listed above.

Physical meaning

This is the chiral algebra generated by the stress tensor alone, with the OPE $T(z)T(w)\sim\frac{c/2}{(z-w)^4}+\frac{2T(w)}{(z-w)^2}+\frac{\partial T(w)}{z-w}$. Every two-dimensional CFT of central charge c contains (a quotient of) it: it is the "identity sector" or vacuum Verma module of the theory.

8.3.2 The simple quotient $L(c,0)$

Definition 8.11 (Simple Virasoro VOA). $L(c,0)$ is the quotient of $V(c,0)$ by its maximal proper (graded) ideal; it is a simple vertex operator algebra of central charge c.

```
def maxQuotientVOA (W : VertexOperatorAlgebra 𝒱) :
    VertexOperatorAlgebra (𝒱 / maxGradedIdeal W) :=
  quotientVOA W (maxGradedIdeal W) (maxGradedIdeal_isIdeal W) (maxGradedIdeal_isGradedIdeal
  ↪ W)

noncomputable def maxIdealVir (c : ℂ) : Submodule ℂ (VirUniv c) :=
```

```
  maxGradedIdeal (virasoroVOA c)

noncomputable def virasoroSimple (c : ℂ) :
    VertexOperatorAlgebra (VirUniv c / maxIdealVir c) :=
  maxQuotientVOA (virasoroVOA c)

theorem virasoroSimple_isSimple : (virasoroSimple c).IsSimple :=
  isSimple_maxQuotientVOA' (virasoroVOA c) (vacVec_ne_zero c)

theorem virasoroSimple_vacuum_ne_zero : (virasoroSimple c).vacuum ≠ 0 := by
```

(`VOA.QuotVOA.maxQuotientVOA`, `VOA/Core/QuotientVOA.lean`; `VOA.VirSimple.maxIdealVir`, …`virasoroSimple`, …`virasoroSimple_isSimple`, …`virasoroSimple_vacuum_ne_zero`, `VOA/Examples/VirasoroSimple.lean`.)

From the mathematics to the Lean statement

`maxGradedIdeal W` is the sum of all graded ideals not containing **1**, and `quotientVOA` the quotient VOA, both from Chapter 5 (Definition 5.19). `IsSimple` is Definition 5.16: nonzero, and only the ideals 0 and everything. Since every ideal of a VOA is graded (`QuotVOA.isGradedIdeal_of_isIdeal`), the "graded" in `maxGradedIdeal` costs nothing, and `virasoroSimple c` is the standard $L(c,0)$. Its grading is the image grading (`virasoroSimple_grading`), its central charge is c (`virasoroSimple_centralCharge`, by `rfl`), its vacuum is nonzero, and its weight-one space is zero (`virasoroSimple_grading_one`). For $c \neq 0$ its weight-two space is $\mathbb{C}\omega$ with $\omega \neq 0$; for $c = 0$ the vector ω lies in the maximal ideal (it has norm $\frac{c}{2} = 0$) and $L(0,0) = \mathbb{C}\mathbf{1}$ is the one-dimensional trivial VOA (`zeroCharge_conformal_eq_zero`, Section 8.7.1). The statement `virasoroSimple_grading_two` — weight two is $\mathbb{C}\cdot\omega$ — holds for all c, with $\mathbb{C}\cdot 0 = 0$ when $c = 0$.

Physical meaning

Passing to $L(c,0)$ is setting null states to zero. In a CFT, a state of zero norm that is orthogonal to everything decouples from all correlation functions, and consistency (e.g. unitarity, or crossing symmetry in BPZ's analysis) requires it to vanish; the resulting null-vector decoupling equations are the differential equations that solve the minimal models. $L(c,0)$ is the vacuum sector of the CFT actually realised.

Definition 8.12 (Minimal-model central charges)**.** For natural numbers p, q, $c_{p,q} := 1 - 6(p-q)^2/(pq)$.

```
def minimalCentralCharge (p q : ℕ) : ℚ := 1 - 6 * ((p : ℚ) - q) ^ 2 / (p * q)
```

(`VOA.VirModule.minimalCentralCharge`, `VOA/Examples/VirasoroVOA.lean`.)

From the mathematics to the Lean statement

The value is a rational number; in `virasoroSimple (minimalCentralCharge p q)` it is coerced to $\mathbb{C}$ (Lean inserts the cast $\mathbb{Q} \to \mathbb{C}$ silently). Division by $pq = 0$ would give 0 in Lean's convention, but the theorems below always assume $p, q \geq 2$. The formula is symmetric in p, q (`minimalCharge_swap`). Examples: $c_{2,3} = 0$, $c_{2,5} = -22/5$, $c_{3,4} = 1/2$, $c_{2,7} = -68/7$, $c_{4,5} = 7/10$, $c_{5,6} = 4/5$. Every coprime pair $p, q \geq 2$ gives a value < 1, and these values accumulate at 1 (take $p - q$ fixed, $p \to \infty$).

Physical meaning

These are the central charges of the BPZ minimal models, the conformal theories with finitely many primary fields under the Virasoro algebra. $c_{3,4} = 1/2$ is the critical Ising model, $c_{4,5} = 7/10$ the tricritical Ising model, $c_{5,6} = 4/5$ the three-state Potts model (as a Virasoro theory), $c_{2,5} = -22/5$ the Lee–Yang edge singularity; the unitary series $c_{m,m+1}$ (Friedan–Qiu–Shenker) are the multicritical Ising points. The set is discrete away from $c = 1$, which is why the minimal models come in a list rather than in families.

8.3.3 The invariant form and the Kac determinant

By Li's theorem (Theorem 5.56 of Chapter 5) $V(c,0)$ carries a unique invariant symmetric bilinear form with $\langle \mathbf{1}, \mathbf{1}\rangle = 1$; it satisfies $\langle L_n a, b\rangle = \langle a, L_{-n} b\rangle$. In Lean it is `VirGram4.canB c`, and its analogue on $L(c,0)$ is `VirQuotForm.Bsimp c`:

```
noncomputable def canB : InvariantForm (virasoroVOA c) :=
  canonicalInvariantForm (vacVec_ne_zero c) (virasoroVOA_qp c)

noncomputable def Bsimp : InvariantForm (virasoroSimple c) :=
  canonicalInvariantForm (virasoroSimple_vacuum_ne_zero c) (virasoroSimple_qp c)
```

(`VOA/Examples/VirasoroGram4.lean`, `VOA/Examples/VirasoroQuotientForm.lean`.) `InvariantForm` and `canonicalInvariantForm` are Definition 5.48 and Theorem 5.56; the two arguments discharge the hypotheses $\mathbf{1} \neq 0$ and $L_1 \mathcal{V}_1 = 0$ (vacuous, as $\mathcal{V}_1 = 0$). The form is normalised (`canB_normalized`, `Bsimp_normalized`: $\langle \mathbf{1}, \mathbf{1}\rangle = 1$) and fully invariant.

Because $\langle L_n a, b\rangle = \langle a, L_{-n} b\rangle$ and $L_n \mathbf{1} = 0$ for $n \geq -1$, the pairing of two creation monomials can be computed by moving the modes of the left monomial to the right as positive modes and commuting them through with (8.4) until they hit the vacuum. The result is a polynomial in c. For example

$$\langle \omega, \omega\rangle = \langle \mathbf{1}, L_2 L_{-2} \mathbf{1}\rangle = \frac{c}{2}, \qquad \langle L_{-3}\mathbf{1}, L_{-3}\mathbf{1}\rangle = 2c,$$

and at weight 4, in the basis $(L_{-2}^2 \mathbf{1}, L_{-4}\mathbf{1})$, the Gram matrix is

$$G_4(c) = \begin{pmatrix} \frac{c(c+8)}{2} & 3c \\ 3c & 5c \end{pmatrix}, \qquad \det G_4(c) = \frac{c^2(5c+22)}{2}. \tag{8.5}$$

The *level-n vacuum Gram determinant* $D_n(c) := \det G_n(c)$ is a polynomial in c. The radical of the form is the maximal ideal (Theorem 5.57), so $\dim L(c,0)_n = \operatorname{rank} G_n(c)$, and $L(c,0) \neq V(c,0)$ exactly when some $D_n(c)$ vanishes. The classical result (Kac, Feigin–Fuchs; for the vacuum module, Gorelik–Kac) is that $D_n(c)$ vanishes exactly at minimal-model charges $c = c_{p,q}$ with $(p-1)(q-1) \leq n$, and that at the *first* such level $n = (p-1)(q-1)$ the zero at $c = c_{p,q}$ is *simple*. For example D_4 vanishes simply at $-22/5 = c_{2,5}$ and doubly at $0 = c_{2,3}$ (where the first singular level is 2 and $D_2 = c/2$ has a simple zero). This simple-zero statement is the one representation-theoretic input of the rigidity proof; Section 8.8 states exactly which Lean theorems supply it.

Example 8.13 (The Lee–Yang null vector). At $c = -22/5$ the vector $s = 5L_{-2}^2\mathbf{1} - 3L_{-4}\mathbf{1}$ spans the kernel of $G_4(c)$: indeed $5 \cdot \frac{c(c+8)}{2} - 3 \cdot 3c = \frac{5c^2+22c}{2} = 0$ and $5 \cdot 3c - 3 \cdot 5c = 0$. So s is in the radical, hence in the maximal ideal, and $s = 0$ in $L(-22/5, 0)$; $\dim L(-22/5,0)_4 = 1$. Its norm as a polynomial in c is

$$P(c) = \langle s, s\rangle_c = 25 \cdot \frac{c(c+8)}{2} - 2 \cdot 15 \cdot 3c + 9 \cdot 5c = \frac{25}{2}c^2 + 55c = \frac{5c}{2}(5c+22),$$

with $P(-22/5) = 0$ and $P'(-22/5) = 25 \cdot (-\frac{22}{5}) + 55 = -55 \neq 0$. This number -55 is the whole Lee–Yang rigidity theorem (Section 8.7.2).

8.4 Anatomy of a graded deformation of $L(c,0)$

From now on, unless said otherwise, $W = L(c,0)$, $\mathcal{V}$ is its state space, and D is a graded first-order deformation of W with products $u^1_{(n)}v$. This section carries out step 1 of the heuristic of Section 8.1: it shows that D produces, on the first-order space $\mathcal{V} \oplus t\mathcal{V}$, an honest representation of the Virasoro algebra whose central charge is $c + t\delta$ for a single number δ, and that δ is the only gauge-invariant information at the level of ω.

8.4.1 Two scalars and the gauge line

Since $\mathcal{V}_0 = \mathbb{C}\mathbf{1}$, $\mathcal{V}_1 = 0$ and $\mathcal{V}_2 = \mathbb{C}\omega$, gradedness of D forces

$$\omega^1_{(3)}\omega \in \mathcal{V}_{2+2-3-1} = \mathcal{V}_0, \quad \omega^1_{(2)}\omega \in \mathcal{V}_1 = 0, \quad \omega^1_{(1)}\omega \in \mathcal{V}_2, \quad \omega^1_{(n)}\omega \in \mathcal{V}_{3-n} = 0 \ (n \geq 4),$$

so there are scalars α, β with

$$\omega^1_{(3)}\omega = \alpha\mathbf{1}, \qquad \omega^1_{(1)}\omega = \beta\omega. \tag{8.6}$$

Compare the undeformed values $\omega_{(3)}\omega = L_2L_{-2}\mathbf{1} = \frac{c}{2}\mathbf{1}$ and $\omega_{(1)}\omega = L_0\omega = 2\omega$: to first order the deformation changes "$\frac{c}{2}$" by α and "2" by β.

```
theorem exists_conformal_parameters (D : FirstOrderDeformation W) (hD : D.IsGraded)
    (h2 : W.grading 2 = ℂ • W.conformalVector) :
    ∃ α β : ℂ,
      D.smul₁ W.conformalVector 3 W.conformalVector = α • W.vacuum ∧
      D.smul₁ W.conformalVector 1 W.conformalVector = β • W.conformalVector := by
```

(`VOA.VirDeformModes.exists_conformal_parameters`, `VOA/Examples/VirasoroDeformationModes.lean`; W is an arbitrary VOA here, and `h2` is the hypothesis $\mathcal{V}_2 = \mathbb{C}\omega$.)

Theorem 8.14 (The gauge line). *Let W be any VOA with $\mathcal{V}_2 = \mathbb{C}\omega$ and let f be a coboundary. Then there is $\mu \in \mathbb{C}$ with $f(\omega)_{(1)}\omega = 2\mu\,\omega$ and $f(\omega)_{(3)}\omega = \mu c\,\mathbf{1}$. Consequently, for a trivial graded deformation the scalars of (8.6) satisfy $\alpha = \mu c$, $\beta = 2\mu$, hence*

$$\delta := 2\alpha - \beta c = 0. \tag{8.7}$$

```
theorem cmode_conformal_of_isCoboundary (W : VertexOperatorAlgebra 𝒱)
    (hV2 : W.grading 2 = ℂ • W.conformalVector) {f : Cochain 𝒱} (hf : IsCoboundary W f) :
    ∃ μ : ℂ,
      cmode f W.conformalVector 1 W.conformalVector = (2 * μ) • W.conformalVector ∧
      cmode f W.conformalVector 3 W.conformalVector = (μ * W.centralCharge) • W.vacuum :=
       ↪ by
```

(`VOA.VirCDef.cmode_conformal_of_isCoboundary`, `VOA/Examples/VirasoroCDeformation.lean`; `cmode f u n v` is `mode (f u) n v`, i.e. $f(u)_{(n)}v$.)

Proof on paper. $f = \delta\varphi$ with φ grade-preserving, $\varphi\mathbf{1} = 0$. Then $\varphi\omega = \mu\omega$ for some μ (as $\mathcal{V}_2 = \mathbb{C}\omega$) and φ kills $\mathcal{V}_0 = \mathbb{C}\mathbf{1}$. Hence $(\delta\varphi)(\omega,1,\omega) = \mu\cdot 2\omega - \varphi(2\omega) + \mu\cdot 2\omega = 2\mu\omega$ and $(\delta\varphi)(\omega,3,\omega) = \mu\frac{c}{2}\mathbf{1} - \varphi(\frac{c}{2}\mathbf{1}) + \mu\frac{c}{2}\mathbf{1} = \mu c\mathbf{1}$. □

From the mathematics to the Lean statement

This is the precise form of the physicist's "rescaling T cannot change c alone": the image of the gauge group in the two slots $(\omega_{(1)}\omega, \omega_{(3)}\omega)$ is the line $\mathbb{C}\cdot(2\omega, c\mathbf{1})$. The library also proves the converse (every point of the line is attained, by $\frac{\mu}{2}\delta L_0$: `VirCDef.exists_isCoboundary_on_gauge_line`), and for $c \neq 0$ an "iff" on $L(c,0)$

(`VirRigidStruct.attained_by_coboundary_iff`). The combination $\delta = 2\alpha - \beta c$ is the linear functional vanishing on the line; it is the *central variation* of the deformation, and the rest of the proof is about showing $\delta = 0$ and that $\delta = 0$ suffices. Caution: (8.6) are only two of infinitely many components of Y_1 on $\omega \otimes \omega$ (the components $\omega^1_{(n)}\omega$ for $n \le 0$ land in $\mathcal{V}_{3-n}$ and are unconstrained so far). Reducing all of them to (α, β) is exactly what the reconstruction theorem of Section 8.5 does; the project notes record the earlier claim "the (ω, ω) deformation data is two-dimensional" as an undercount.

What the machine verified

`exists_conformal_parameters` and `cmode_conformal_of_isCoboundary` are proved for an arbitrary VOA; axioms `[propext, Classical.choice, Quot.sound]`. Unconditional.

Physical meaning

This is the statement "rescaling T cannot change c alone". A field redefinition $T \mapsto (1 + t\mu)T$ multiplies the fourth-order pole $c/2$ by $(1 + t\mu)^2$ but also the second-order pole $2T$ by $(1 + t\mu)$; only the ratio $c/2 \,:\, 2$, i.e. $\delta = 2\alpha - \beta c$, is redefinition-invariant. So in the chiral algebra generated by T the central charge is a genuine coordinate on the space of theories, not an artefact of normalisation — in contrast with the Heisenberg level, which rescaling the current removes.

8.4.2 The first-order space and its operators

A state of the deformed algebra is $v + tv_1$, which the library writes as the pair $(v, v_1) \in \mathcal{V} \times \mathcal{V}$. Multiplication by t is the square-zero map $\mathsf{N}(v, v_1) = (0, v)$, and a dual number $a + tb$ acts by $a + b\mathsf{N}$. The mode of a "constant" state $a = (a, 0)$ acts by the block matrix

$$a^t_{(n)}(x, x_1) = \big(a_{(n)}x,\ a^1_{(n)}x + a_{(n)}x_1\big), \tag{8.8}$$

which is (8.1) written in coordinates.

```
def liftedMode (a : V) (n : ℤ) : End ℂ (V × V) where
  toFun x := (W.smul a n x.1, D.smul₁ a n x.1 + W.smul a n x.2)

def tangentShift : End ℂ (V × V) where
  toFun x := (0, x.1)

def dualScalarAction : DualNumber ℂ →ₐ[ℂ] End ℂ (V × V) where
  toFun z := z.fst • (1 : End ℂ (V × V)) + z.snd • tangentShift
```

(`VOA.Deform.liftedMode`, `VOA/Core/DeformationLiftedModes.lean`; `VOA.Deform.tangentShift`, `VOA.Deform.dualScalarAction`, `VOA/Core/DeformationCentralModes.lean`; linearity proofs omitted. `DualNumber ℂ` is Mathlib's $\mathbb{C}[\varepsilon]/(\varepsilon^2)$, implemented as the trivial square-zero extension, with `z.fst`, `z.snd` the two coordinates of $z = a + b\varepsilon$.)

The key observation is that the Taylor expansion of polynomials happens automatically: for $p \in \mathbb{C}[X]$,

$$p(k \cdot 1 + \delta\mathsf{N}) = p(k) \cdot 1 + p'(k)\,\delta\,\mathsf{N}, \tag{8.9}$$

because $\mathsf{N}^2 = 0$ (`Deform.dualScalarAction_polynomial`). A central operator of the form $k + \delta\mathsf{N}$ therefore records a "central charge" k together with its first-order variation δ, and any polynomial identity in the central charge acquires a tangent coefficient $p'(k)\delta$.

8.4.3 The normalised Virasoro modes

Write $L^1_n := \omega^1_{(n+1)}$ for the correction to $L_n = \omega_{(n+1)}$. The order-t commutator formula (the $\ell = 0$ slice of (8.2)) gives

$$[L^1_m, L_n] + [L_m, L^1_n] = \sum_{i\ge 0} \binom{m+1}{i} \Big((\omega^1_{(i)}\omega)_{(m+n+2-i)} + (\omega_{(i)}\omega)^1_{(m+n+2-i)} \Big).$$

Only $i \in \{0,1,3\}$ contribute ($i=2$ and $i \ge 4$ land in $\mathcal{V}_1 = 0$ or negative weight), and the $i = 1,3$ terms are known by (8.6). The $i = 0$ term involves the unknown $\omega^1_{(0)}\omega \in \mathcal{V}_3$ and the correction of $\omega_{(0)}\omega = L_{-1}\omega$; but antisymmetry of the left side under $m \leftrightarrow n$ determines it (at $m = -1$; the potential central term vanishes there because $\binom{2}{3} = 0$). The result, proved as `mixedComm_virasoro`, is

$$[L^1_m, L_n] + [L_m, L^1_n] = (m-n)L^1_{m+n} + \tfrac{(m-n)\beta}{2} L_{m+n} + \delta_{m+n,0} \tfrac{m^3-m}{6}\,\alpha.$$

The term $\frac{(m-n)\beta}{2} L_{m+n}$ is the effect of a rescaling of ω; it is removed by the normalisation $\tilde L_n := L_n + t(L^1_n - \frac{\beta}{2} L_n)$. Then $\tilde L_n$ satisfy the Virasoro relations with central term $\frac{m^3-m}{12}(c + t(2\alpha - \beta c))$:

$$[\tilde L_m, \tilde L_n] = (m-n)\tilde L_{m+n} + \delta_{m+n,0} \frac{m^3-m}{12} \big(c \cdot 1 + \delta\, \mathsf{N} \big), \qquad \delta = 2\alpha - \beta c. \tag{8.10}$$

```
noncomputable def normalizedL (D : FirstOrderDeformation W) (β : ℂ) (n : ℤ) : End ℂ (V × V)
 ↪  :=
  liftedMode D W.conformalVector (n+1) -
    (β/2) • (tangentShift * liftedMode D W.conformalVector (n+1))

theorem normalizedL_comm (D : FirstOrderDeformation W) (hD : D.IsGraded)
    (h1 : W.grading 1 = ⊥) (α β : ℂ)
    (ha : D.smul₁ W.conformalVector 3 W.conformalVector = α • W.vacuum)

      if m+n=0 then (((m : ℂ)^3-m)/12) •
        (W.centralCharge • (1 : End ℂ (V × V)) +
          (2*α-β*W.centralCharge) • tangentShift) else 0 := by

theorem normalizedL_vacuum (D : FirstOrderDeformation W) (β : ℂ)
    (n : ℤ) (hn : -1 ≤ n) : normalizedL D β n (W.vacuum, 0) = 0 := by

theorem normalizedL_tangent (D : FirstOrderDeformation W) (β : ℂ) (n : ℤ) (x : V) :
    normalizedL D β n (0, x) = (0, W.L n x) := by

theorem normalizedL_neg_two_vacuum (D : FirstOrderDeformation W) (β : ℂ) :
    normalizedL D β (-2) (W.vacuum, 0) =
      (W.conformalVector, -(β/2) • W.conformalVector) := by
```

(`VOA.VirDeformModes.*`, `VOA/Examples/VirasoroDeformationModes.lean`; here W is any VOA with $\mathcal{V}_1 = 0$, hypothesis `h1`.)

From the mathematics to the Lean statement

`liftedMode D W.conformalVector (n+1)` is $\omega^t_{(n+1)} = L_n + tL^1_n$ in the form (8.8); `tangentShift * liftedMode …` is $t \cdot \omega^t_{(n+1)} = tL_n$ (since $t^2 = 0$); so `normalizedL D β n` is $\tilde L_n$. The bracket `⁅·,·⁆` is the commutator in $\mathrm{End}(\mathcal{V}\times\mathcal{V})$. `normalizedL_comm` is (8.10): the central term is $\frac{m^3-m}{12}$

times the operator $c \cdot 1 + (2\alpha - \beta c)\mathsf{N}$. `normalizedL_vacuum`: the constant vacuum $(\mathbf{1}, 0)$ is killed by $\tilde{L}_n$ for $n \geq -1$ (from (D3)). `normalizedL_tangent`: on pure tangent states $(0, x)$ the normalised modes act by the *undeformed* L_n — this is the formal content of "$t \cdot$(correction) $= 0$" and will be the crux of the obstruction. `normalizedL_neg_two_vacuum`: the normalised conformal state is $\widetilde{\omega} = (\omega, -\frac{\beta}{2}\omega)$.

No hidden input. The hypotheses are exactly: D graded, $\mathcal{V}_1 = 0$, and the defining equations of α, β. In particular no deformed translation law, no deformed invariant form and no Virasoro relation for the deformed modes is assumed; (8.10) is derived from (D4).

The library packages (8.10) as a structure and instantiates it for every $L(c, 0)$:

```
structure CentralVirasoroData (E : Type*) [AddCommGroup E] [Module ℂ E] where
  L : ℤ → End ℂ E
  central : End ℂ E
  comm : ∀ m n, ⁅L m, L n⁆ = ((m : ℂ)-n) • L (m+n) +
    if m+n=0 then (((m : ℂ)^3-m)/12) • central else 0
  central_comm : ∀ n, Commute central (L n)

theorem virasoroSimple_exists_normalizedData (c : ℂ)
    (D : FirstOrderDeformation (VirSimple.virasoroSimple c)) (hD : D.IsGraded) :
    ∃ (α β : ℂ) (A : CentralVirasoroData
        ((VirModule.VirUniv c / VirSimple.maxIdealVir c) ×
          (VirModule.VirUniv c / VirSimple.maxIdealVir c))),
      D.smul₁ (VirSimple.virasoroSimple c).conformalVector 3
        (VirSimple.virasoroSimple c).conformalVector = α • (VirSimple.virasoroSimple

        (VirSimple.virasoroSimple c).conformalVector = β • (VirSimple.virasoroSimple
        ↪ c).conformalVector ∧
      A.L = normalizedL D β ∧
      A.central = c • 1 + (2*α-β*c) • tangentShift := by
```

(`VOA.VirDeformModes.CentralVirasoroData`, `…virasoroSimple_exists_normalizedData`, same file.)

From the mathematics to the Lean statement

`CentralVirasoroData E` is a representation of the Virasoro relations on E in which the central element acts by an operator `central` commuting with all L_n (rather than by a scalar). The theorem says: for every central charge c (including $c = 0$, where $\omega = 0$ in $L(0, 0)$ and $\alpha = 0$ is forced) and every graded D of $L(c, 0)$ there are α, β as in (8.6) and such a representation on $\mathcal{V} \times \mathcal{V}$, given by the normalised modes, with central operator $c + \delta\mathsf{N}$. The existential quantifier over α, β is harmless: they are uniquely determined by D (because $\mathbf{1} \neq 0$ and, for $c \neq 0$, $\omega \neq 0$), and every later theorem takes them as arguments together with their defining equations.

What the machine verified

`normalizedL_comm`, `virasoroSimple_exists_normalizedData`: proved, axioms `[propext, Classical.choice, Quot.sound]`. Unconditional.

8.5 Reconstruction: zero central variation implies triviality

This section carries out step 1 of the heuristic in full: a graded deformation of $L(c, 0)$ whose central variation δ vanishes is trivial. The argument has a general part, valid for any *simple* VOA, and a

Virasoro part that produces the required subspace.

8.5.1 Closed lifts in a simple VOA

Definition 8.15 (Deformed product, closed lift)**.** On $\mathcal{V}\times\mathcal{V}$ (states $x = x_0 + tx_1$) define the deformed n-th product

$$x \star_n y := \big(x_{0(n)}y_0,\ x_{0(n)}y_1 + x_{1(n)}y_0 + x_{0(n)}^{1}y_0\big),$$

the product of Y^t written in coordinates. A subspace $S \subseteq \mathcal{V}\times\mathcal{V}$ is *mode-closed* if $x \star_n y \in S$ for $x, y \in S$; its *reduction* is the first projection $S \to \mathcal{V}$; its *tangent kernel* is $\{v : (0,v) \in S\}$; it is *grade-closed* if it contains the homogeneous components $(x_{0,n}, x_{1,n})$ of each of its elements.

```
def product (x : V × V) (n : ℤ) (y : V × V) : V × V :=
  (W.smul x.1 n y.1,
    W.smul x.1 n y.2 + W.smul x.2 n y.1 + D.smul₁ x.1 n y.1)

def ModeClosed (S : Submodule ℂ (V × V)) : Prop :=
  ∀ x ∈ S, ∀ y ∈ S, ∀ n : ℤ, product D x n y ∈ S

def reduction (S : Submodule ℂ (V × V)) : S →ₗ[ℂ] V :=
  (LinearMap.fst ℂ V V).comp S.subtype

def tangentKernel (S : Submodule ℂ (V × V)) : Submodule ℂ V :=
  S.comap (LinearMap.inr ℂ V V)

def GradeClosed (W : VertexOperatorAlgebra V) (S : Submodule ℂ (V × V)) : Prop :=
  ∀ x ∈ S, ∀ n : ℤ, (gradePart W n x.1, gradePart W n x.2) ∈ S
```

(`VOA.Deform.Reconstruction.*`, `VOA/Core/DeformationReconstruction.lean`; `gradePart W n` is the projection $\mathcal{V} \to \mathcal{V}_n$ along the other weight spaces.)

Physical meaning

$\mathcal{V}\times\mathcal{V}$ is the space of states of the perturbed theory, with (x, x_1) the state $x + tx_1$, and $\star_n$ is its perturbed OPE. A closed lift is a candidate for "the same operator algebra written in a new basis": a family of perturbed operators, one over each unperturbed operator, closed under the perturbed OPE.

Theorem 8.16 (Reconstruction from a closed lift)**.** *Let W be simple and D a first-order deformation. Suppose $S \subseteq \mathcal{V}\times\mathcal{V}$ is mode-closed, grade-closed, contains $(\mathbf{1}, 0)$, does not contain $(0, \mathbf{1})$, and its reduction is surjective. Then D is trivial.*

```
theorem isTrivial_of_closed_lift (S : Submodule ℂ (V × V))
    (hsimple : W.IsSimple) (hclosed : ModeClosed D S)
    (hsurj : Function.Surjective (reduction S))
    (hsep : (0, W.vacuum) ∉ S) (hvac : (W.vacuum, 0) ∈ S)
    (hgrade : GradeClosed W S) : D.IsTrivial := by
```

(`VOA.Deform.Reconstruction.isTrivial_of_closed_lift`, same file.)

Proof on paper. The tangent kernel K is an ideal. If $v \in K$ and $u \in \mathcal{V}$, choose $x \in S$ with $x_0 = u$ (surjectivity); then $x \star_n (0,v) = (0, u_{(n)}v) \in S$, so $u_{(n)}v \in K$. *It is zero.* By simplicity $K = 0$ or $K = \mathcal{V}$; the latter would give $(0,\mathbf{1}) \in S$. *So S is a graph.* The reduction is injective (its kernel is $\{(0,v) \in S\} = 0$) and surjective, so $S = \{(v, \psi v)\}$ for a unique linear $\psi : \mathcal{V} \to \mathcal{V}$. *Properties of ψ.* $(\mathbf{1}, 0) \in S$ gives $\psi\mathbf{1} = 0$; grade-closure gives $\psi(\mathcal{V}_n) \subseteq \mathcal{V}_n$; mode-closure applied to $(u, \psi u) \star_n (v, \psi v)$ gives $\psi(u_{(n)}v) = u_{(n)}\psi v + (\psi u)_{(n)}v + u_{(n)}^{1}v$, i.e. $u_{(n)}^{1}v = \delta(-\psi)(u, n, v)$. So D is the coboundary of $\varphi = -\psi$. □

From the mathematics to the Lean statement

Hypotheses. `hsimple` is simplicity of W (Definition 5.16) — this is where the *simple* quotient is essential; the universal $V(c,0)$ is not simple at the minimal charges, and at generic c a closed lift with the separation property need not exist (the ∂_c-deformation has none). `hclosed`, `hsurj`, `hsep`, `hvac`, `hgrade` are the five properties of the definition. `Function.Surjective (reduction S)` is surjectivity of the first projection restricted to S. The conclusion `D.IsTrivial` is Definition 8.3, with one global φ. Note that $\mathcal{V}\times\mathcal{V}$ itself is *not* assumed to be of CFT type — its weight-zero part is two-dimensional, which is exactly why separation (`hsep`) is a hypothesis.
Interpretation. S is the would-be image of an isomorphism $(\mathcal{V}_R, Y) \to (\mathcal{V}_R, Y^t)$; the theorem turns it into the coordinate change. This is the "reconstruction" half of rigidity, and it is completely general.

What the machine verified

Proved for every simple VOA and every deformation; axioms `[propext, Classical.choice, Quot.sound]`. The same file proves the variant `isTrivial_of_generated_separation` for the smallest closed lift containing a generating set, where only separation remains to be checked.

Physical meaning

If, over every operator of the unperturbed theory, one can find a perturbed operator such that the perturbed operators close among themselves under the perturbed OPE and contain the identity but not "t times the identity", then the perturbation is a field redefinition. Simplicity of W is used the way a physicist uses irreducibility of the vacuum sector: there are no nontrivial subsectors in which a would-be obstruction could hide. Heuristic content: a perturbation is trivial exactly when the perturbed theory is isomorphic to the unperturbed one.

8.5.2 The closed lift of a fixed-charge deformation

Now let $W = L(c,0)$ and suppose $\delta = 0$, so the normalised modes $\tilde{L}_n$ satisfy the Virasoro relations with *scalar* central charge c and kill $(\mathbf{1},0)$ for $n \geq -1$. By the universal property of $V(c,0) = U(\mathfrak{Vir})/J(c)$ there is a unique $\mathfrak{Vir}$-module map

$$F : V(c,0) \to \mathcal{V}\times\mathcal{V}, \qquad F(\mathbf{1}) = (\mathbf{1},0), \qquad F(L_n v) = \tilde{L}_n F(v)$$

(`VirDeformModes.fixedEval`). Let $S = F(V(c,0))$. Then:

1. the first component of F is the projection $\pi : V(c,0) \to L(c,0)$, because the first component of $\tilde{L}_n$ is L_n; hence the reduction of S is surjective;
2. F maps $V(c,0)_n$ into $\mathcal{V}_n \times \mathcal{V}_n$ (the normalised modes shift both coordinates by the expected weight, `normalizedL_mem_grading`), hence S is grade-closed;
3. separation: the weight-zero part of S is $F(\mathbb{C}\mathbf{1}) = \mathbb{C}(\mathbf{1},0)$, which does not contain $(0,\mathbf{1})$;
4. mode-closure: S is generated from $(\mathbf{1},0)$ by the modes of the corrected conformal state $\widetilde{\omega} = (\omega, -\frac{\beta}{2}\omega)$, whose deformed products are exactly the $\tilde{L}_n$ (`corrected_conformal_product`); the order-t iterate formula (the $m=0$ slice of (8.2), proved on $\mathcal{V}\times\mathcal{V}$ as `Deform.Reconstruction.product_iterate`) shows that the states whose deformed modes preserve S are closed under deformed products, so all of S preserves S.

Theorem 8.16 applies, using simplicity of $L(c,0)$.

Theorem 8.17 (Fixed-charge reconstruction). *Let D be a graded first-order deformation of $L(c,0)$, $c \in \mathbb{C}$ arbitrary, with scalars α, β as in (8.6). If $2\alpha - \beta c = 0$ then D is trivial.*

(`VOA.VirDeformModes.isTrivial_of_zero_central_variation`, `VOA/Examples/VirasoroFixedReconstruction.lean`. This file is assigned to Chapter 7 but its theorem is indispensable here; its companion `isTrivial_of_fixed_modes` takes the `CentralVirasoroData` with central operator $c \cdot 1$ directly.)

From the mathematics to the Lean statement

All hypotheses are visible: gradedness, the defining equations of α and β, and $\delta = 0$. There is no hypothesis on c (it holds at every central charge, degenerate or not) and none on the representation theory of $L(c,0)$ beyond what the library proves (simplicity, $\mathcal{V}_1 = 0$, $\mathcal{V}_2 = \mathbb{C}\omega$, the universal property of $V(c,0)$). So the theorem reduces graded rigidity of $L(c,0)$ to the single scalar equation $\delta = 0$:

$$\texttt{IsRigidGraded (virasoroSimple c)} \iff \text{every graded } D \text{ has } 2\alpha - \beta c = 0,$$

the "$\Leftarrow$" by this theorem and "$\Rightarrow$" by the gauge line (Theorem 8.14). This is the precise sense in which "the only possible modulus of $L(c,0)$ is the central charge".

What the machine verified

Proved, axioms `[propext, Classical.choice, Quot.sound]`; no `VOA.pbw`. Unconditional.

Physical meaning

"The Virasoro vacuum sector is determined by c." If a perturbation of $L(c,0)$ does not change the central charge, then the perturbed stress tensor still satisfies the Virasoro algebra with the same c, all states are still its descendants, and the perturbed theory is the same theory in new coordinates. This is the first-order form of the familiar fact that the TT OPE has only one free parameter.

8.6 The obstruction: null relations force zero central variation

We now carry out steps 2 and 3 of the heuristic: at a central charge where $L(c,0)$ has a relation whose norm polynomial has a simple zero, every graded deformation has $\delta = 0$. Two formulations appear in the library: an early, purely linear-algebraic "bridge" through deformed bilinear forms, which turned out to be the wrong tool for the simple quotient, and the word-pairing obstruction that the final proof uses. We present both, the first as an instructive near-miss.

8.6.1 Deformed bilinear forms and Jantzen layers

Let E be a finite-dimensional vector space with a symmetric bilinear form B_0 and another bilinear form B_1, thought of as the first-order deformation $B_t = B_0 + tB_1$. A vector s in the radical of B_0

(a "relation at $t = 0$") *lifts to first order* if there is s_1 with $(B_0 + tB_1)(s + ts_1, \cdot) = 0$ modulo t^2, i.e. $B_1(s, v) + B_0(s_1, v) = 0$ for all v.

Proposition 8.18 (Lifting criterion). *For symmetric B_0 on finite-dimensional E and any $s \in E$: s lifts to first order if and only if $B_1(s, v) = 0$ for all v in the radical of B_0. Hence, writing $F_1 = \operatorname{rad} B_0$ and $F_2 = \{s \in F_1 : B_1(s, F_1) = 0\}$ (the first two Jantzen layers), F_2 is exactly the set of relations that lift.*

```
def radBil (B : E →ₗ[K] E →ₗ[K] K) : Submodule K E := LinearMap.ker B

theorem lift_iff_pairing_zero [FiniteDimensional K E] {B₀ B₁ : E →ₗ[K] E →ₗ[K] K}
    (hB₀ : ∀ x y : E, B₀ x y = B₀ y x) (s : E) :
    (∃ s₁ : E, ∀ v : E, B₁ s v + B₀ s₁ v = 0) ↔ ∀ v ∈ radBil B₀, B₁ s v = 0 := by

def F1 (B₀ : E →ₗ[K] E →ₗ[K] K) : Submodule K E := radBil B₀

def F2 (B₀ B₁ : E →ₗ[K] E →ₗ[K] K) : Submodule K E where
  carrier := {s | s ∈ F1 B₀ ∧ ∀ v ∈ F1 B₀, B₁ s v = 0}
```

(`VOA.DefForm.*`, `VOA/Core/DeformedForm.lean`, over an arbitrary field `K`; submodule proofs of `F2` omitted.)

Proof on paper. "⇒": if $v \in \operatorname{rad} B_0$ then $B_0(s_1, v) = B_0(v, s_1) = 0$ by symmetry. "⇐": the functional $-B_1(s, \cdot)$ kills $\operatorname{rad} B_0$; for symmetric B_0 on a finite-dimensional space the functionals of the form $B_0(x, \cdot)$ are exactly those killing $\operatorname{rad} B_0$ (dimension count), so $-B_1(s, \cdot) = B_0(s_1, \cdot)$ for some s_1. □

The *rigidity bridge* applies this to $E = \mathcal{V}_k$ with $B_0 =$ the level-k Shapovalov form $\langle a, b\rangle_k := \varepsilon(a_{(2k-1)}b)$ (where $a_{(2k-1)}b \in \mathcal{V}_0 = \mathbb{C}\mathbf{1}$ and ε reads off the coefficient of $\mathbf{1}$) and $B_1 = \langle a, b\rangle_k^1 := \varepsilon(a^1_{(2k-1)}b)$, the same formula with Y_1. It proves that the Shapovalov form is symmetric (from skew-symmetry), agrees up to the sign $(-1)^k$ with the canonical invariant form on quasi-primary vectors, and contains every Virasoro singular vector of a descendant-spanned weight space in its radical. Its main theorem is:

```
theorem F2_lt_F1_of_self_pairing_ne_zero (hvac : W.vacuum ≠ 0)
    (D : FirstOrderDeformation W) (hD : D.IsGraded) {k : ℤ} {s : W.grading k}
    (hs : s ∈ DefForm.radBil (shapForm W hvac k))
    (hself : shapForm₁ D hD hvac k s s ≠ 0) :
    DefForm.F2 (shapForm W hvac k) (shapForm₁ D hD hvac k) < DefForm.F1 (shapForm W hvac k)
     ↪ :=
```

(`VOA.RigidBridge.F2_lt_F1_of_self_pairing_ne_zero`, `VOA/Core/RigidityBridge.lean`; `shapForm W hvac k` and `shapForm₁ D hD hvac k` are the two forms just described, defined via `vacCoeff W hvac : W.grading 0 →ₗ[ℂ] ℂ`, the inverse of $\lambda \mapsto \lambda\mathbf{1}$.)

From the mathematics to the Lean statement

In words: if s is a relation of the level-k Shapovalov form and the *deformed* self-pairing $\langle s, s\rangle_k^1$ is nonzero, then s does not survive to first order, so $F_2 \subsetneq F_1$ (`<` on submodules is strict inclusion). The file's own docstring states loudly that this is an obstruction statement, not rigidity: "Nothing here proves `IsRigid`".

Trap / dead end

The bridge hypothesis is unsatisfiable exactly where rigidity holds. The library proves (`NonzeroDeform.shapForm₁_self_eq_zero_of_isTrivial`) that for every *trivial* graded deformation the deformed self-pairing of a radical vector vanishes: File `VOA/Examples/NonzeroDeformation.lean`.

```
theorem shapForm₁_self_eq_zero_of_isTrivial (W : VertexOperatorAlgebra 𝒱)
    (hvac : W.vacuum ≠ 0) (D : Deform.FirstOrderDeformation W) (hD : D.IsGraded)
    (hT : D.IsTrivial) {k : ℤ} {s : W.grading k}
    (hs : s ∈ DefForm.radBil (shapForm W hvac k)) :
    shapForm₁ D hD hvac k s s = 0 := by
```

So the hypothesis `hself` can only be met by a non-trivial graded deformation, and on a graded-rigid VOA it is never met. Moreover on the simple quotient $L(c,0)$ the Shapovalov form is nondegenerate, so its radical is zero and the bridge has nothing to act on. The bridge is a correct theorem about the universal $V(c,0)$ ("a singular vector of $V(c_{p,q},0)$ does not survive a deformation that moves its norm"), but it is not a route to rigidity of $L(c,0)$, and the final proof does not use it. It is kept because the linear algebra of Proposition 8.18 is correct and because it documents a recorded dead end: the project notes also refute an earlier "Jantzen bridge lemma" $\mathrm{rad}_R = F_2 \oplus \varepsilon F_1$, which negated its own hypothesis, and that false lemma appears nowhere in the library.

Physical meaning

In a family of theories, the Gram matrix of states becomes $B_0 + tB_1$. A null state at $t = 0$ survives to first order (remains null after a small correction) exactly when its first-order change of norm, paired against the other null states, vanishes. This is the first step of the Jantzen filtration, the representation-theorist's way of following null vectors along a family of central charges or highest weights.

8.6.2 Words, their adjoints, and the norm polynomial

The correct mechanism is not a deformed form on $L(c,0)$ but a computation in the representation $\tilde{L}_n$ of Section 8.4, paired with the *undeformed* invariant form.

Definition 8.19 (Words and norm polynomials)**.** A *word* is a finite list $w = [m_1, \dots, m_k]$ of integers; in a representation L of the Virasoro relations it acts by $L_w := L_{m_1} \cdots L_{m_k}$. Its *adjoint* is $w^\dagger := [-m_k, \dots, -m_1]$ (reverse and negate), so that $\langle L_w x, y\rangle = \langle x, L_{w^\dagger} y\rangle$ for an invariant form. For a word w, the *vacuum polynomial* $P_w \in \mathbb{C}[X]$ is defined by normal ordering: commute positive and zero modes to the right using (8.4), with the central element kept as a formal variable X, until they annihilate the vacuum; P_w is the coefficient of the empty creation word. For a finite combination $s = \sum_i r_i L_{w_i}\mathbf{1}$ the *norm polynomial* is

$$P_{w,r}(X) := \sum_{i,j} r_i r_j \, P_{w_i^\dagger w_j}(X), \qquad \text{so that} \qquad P_{w,r}(c) = \langle s, s\rangle_{V(c,0)}.$$

```
noncomputable def virWord (L : ℤ → End ℂ V) : List ℤ → End ℂ V
  | [] => 1

```

(`VOA.VirDeformModes.virWord`, `…virWord_adjoint`, `VOA/Examples/VirasoroWordPairing.lean`; `VOA.VirDeformModes.NormalOrdering.centralPolynomial`, `…wordPolynomial`, `VOA/Examples/VirasoroUniversalPairing.lean`; `…relationPolynomial`, `VOA/Examples/VirasoroUniformObstruction.lean`.)

From the mathematics to the Lean statement

`virWord L w` is L_w (`1` is the identity, $*$ composition, so $L_{[m]{+}{+}w} = L_m \circ L_w$). `w.reverse.map Neg.neg` is $w^\dagger$ and `++` is concatenation, so `(w i).reverse.map Neg.neg ++ w j` is $w_i^\dagger w_j$. `wordNormal w` is the normal-ordered form of $L_w\mathbf{1}$, a finite formal combination of (central power, creation word) labels built by a recursive commutation algorithm (`VOA/Examples/VirasoroNormalOrdering.lean`); `centralPolynomial` keeps the terms with empty creation word, turning central power k into X^k. `relationPolynomial w r` is $P_{w,r}$; the index type `ι` is any finite type.

Why this is the right polynomial. Two theorems pin down the meaning, so the reader need not trust the normal-ordering algorithm: (i) at every c, $P_{u^\dagger v}(c) = \langle L_u\mathbf{1}, L_v\mathbf{1}\rangle$ in $V(c,0)$ for the canonical form (`universal_gram_entry`), hence $P_{w,r}(c) = \langle s, s\rangle$ (`relationPolynomial_eval`); (ii) in *any* `CentralVirasoroData` with a vacuum-like vector, the normal-ordering evaluation reproduces $L_w v$ (`evaluate_wordNormal`). Both are proved; there is no free choice in $P_{w,r}$.

```
theorem universal_gram_entry (c : ℂ) (u v : List ℤ) :
    (wordPolynomial (u.reverse.map Neg.neg ++ v)).eval c =
      (VirGram4.canB c).form
        (virWord (VirModule.virasoroVOA c).L u (VirModule.vacVec c))
        (virWord (VirModule.virasoroVOA c).L v (VirModule.vacVec c)) := by
```

(`VOA.VirDeformModes.NormalOrdering.universal_gram_entry`, `VOA/Examples/VirasoroUniversalPairing.lean`.)

Physical meaning

A word is a product of Virasoro generators; its vacuum polynomial is the vacuum expectation value $\langle 0|L_{m_1}\cdots L_{m_k}|0\rangle$ computed with only the Virasoro algebra, as a polynomial in c. The norm polynomial of a combination s is the two-point function $\langle s|s\rangle$ of the corresponding descendant of the identity, as a function of the central charge. Its zeros are the central charges at which s becomes a null state — the vacuum row of the Kac table.

8.6.3 The word-pairing obstruction

Theorem 8.20 (Relation obstruction). *Let $c \in \mathbb{C}$. Suppose $s := \sum_i r_i L_{w_i}\mathbf{1} = 0$ in $L(c,0)$ for a finite family of words w_i and coefficients r_i, and suppose the norm polynomial satisfies $P'_{w,r}(c) \neq 0$. Then every graded first-order deformation of $L(c,0)$ has central variation $\delta = 0$, and therefore $L(c,0)$ is graded rigid.*

```

(`VOA.VirDeformModes.virWord_pairing_obstruction`, `VOA/Examples/VirasoroWordPairing.lean`; `VOA.VirDeformModes.NormalOrdering.simple_normalized_word_tangent`, `VOA/Examples/VirasoroUniversalPairing.`
`VOA.VirDeformModes.NormalOrdering.graded_rigidity_of_relation`, `VOA/Examples/VirasoroUniformObstruction.le`
where `{ι : Type*} [Fintype ι]` is a section variable.)

Proof on paper. Let D be graded with scalars α, β and normalised modes $\tilde{L}_n$ (central operator $c+\delta\mathsf{N}$). Lift the relation: $\tilde{s} := \sum_j r_j \tilde{L}_{w_j}(\mathbf{1}, 0)$. Its first coordinate is $\sum_j r_j L_{w_j}\mathbf{1} = s = 0$, so $\tilde{s} = (0, s')$ for some $s' \in \mathcal{V}$. Apply the lifted adjoint combination $\widetilde{A} := \sum_i r_i \tilde{L}_{w_i^\dagger}$ and pair the tangent coordinate with the vacuum using the *undeformed* invariant form B of $L(c, 0)$:

- *It vanishes.* On pure tangent states the normalised modes act by the undeformed L_n (`normalizedL_tangent`), so $\widetilde{A}(0, s') = (0, As')$ with $A = \sum_i r_i L_{w_i^\dagger}$, and by invariance $B(\mathbf{1}, As') = B(\sum_i r_i L_{w_i}\mathbf{1}, s') = B(s, s') = B(0, s') = 0$. This is `virWord_pairing_obstruction`, valid for any VOA, any β and any invariant form.
- *It equals $P'_{w,r}(c)\,\delta$.* Expanding, $\widetilde{A}\tilde{s} = \sum_{i,j} r_i r_j \tilde{L}_{w_i^\dagger w_j}(\mathbf{1}, 0)$. In any representation of the Virasoro relations with central operator K and a vector killed by L_n, $n \geq -1$, normal ordering gives $L_w(\mathbf{1}, 0) = P_w(\mathsf{K})(\mathbf{1}, 0) +$ (creation words of positive weight applied to $(\mathbf{1}, 0)$); the vacuum pairing kills the positive-weight terms (weight orthogonality, Proposition 5.50), and by (8.9) with $\mathsf{K} = c + \delta\mathsf{N}$ the tangent coordinate of $P_w(\mathsf{K})(\mathbf{1}, 0)$ is $P'_w(c)\delta\mathbf{1}$. Summing, the tangent pairing is $P'_{w,r}(c)\delta$ (with $B(\mathbf{1}, \mathbf{1}) = 1$). This is `simple_normalized_word_tangent` and its sum `relation_tangent`.

Hence $P'_{w,r}(c)\delta = 0$, so $\delta = 0$ (`central_variation_zero_of_relation`), and Theorem 8.17 makes D trivial. □

From the mathematics to the Lean statement

Hypotheses of `graded_rigidity_of_relation`. `hr`: the relation $s = 0$ holds in the *simple* algebra `virasoroSimple c`, with its own modes `(virasoroSimple c).L` — an ordinary statement about $L(c, 0)$, not about deformations. `hd`: the derivative `derivative.eval c` of the norm polynomial is nonzero at c. Neither mentions a deformation; the theorem has no deformation-theoretic hypothesis at all. In particular it does *not* assume determinant preservation, a deformed invariant form, or a deformed singular vector — the three ways in which earlier versions of the argument were circular. **Conclusion:** `IsRigidGraded` of Definition 8.5.
Why the derivative, and why at c. By `relationPolynomial_eval`, $P_{w,r}(c) = \langle s, s\rangle$ in $V(c, 0)$;

since s maps to 0 in $L(c,0)$, it lies in the radical and $P_{w,r}(c) = 0$ automatically. So the content of `hd` is that this zero is *simple*. A double zero would give no information (Warning 8.6.4).
How it could be vacuous. If no relation with $P' \neq 0$ existed at any c, the theorem would be empty. It is not: at $c = -22/5$ the Lee–Yang relation of Example 8.13 has $P' = -55$; at Ising, $P' = 84084$ (Section 8.7); and at every $c_{p,q}$ the vacuum Gram determinant supplies one (Section 8.8). At generic c, $L(c,0) = V(c,0)$ has no relations at all, so the theorem says nothing there — consistent with $V(c,0)$ not being rigid.

What the machine verified

`virWord_pairing_obstruction`, `simple_normalized_word_tangent`, `graded_rigidity_of_relation`: proved, axioms `[propext, Classical.choice, Quot.sound]`. The theorem is unconditional; its two hypotheses are ordinary algebraic facts to be checked at the charge of interest. The same file also gives `graded_rigidity_of_word_gram`, which replaces `hr` by "r is a row-kernel vector of the polynomial Gram matrix of a word basis evaluated at c", so that the hypothesis can be checked entirely in the universal module.

Physical meaning

This is the null-vector argument for rigidity. In the minimal model the null state s is set to zero. Perturb the theory; to first order the only effect (after field redefinitions) is $c \to c + t\delta$. The relation $s = 0$ must persist, but the norm of s in the perturbed theory is $P(c + t\delta) = tP'(c)\delta$, and a vanishing state has zero norm. So $\delta = 0$ unless the norm vanishes to second order. Physically: the minimal-model central charge is pinned by null-vector decoupling, and to first order it cannot move.

8.6.4 The determinant form of the obstruction

For a uniform theorem it is more convenient to use the whole vacuum Gram matrix. Index the partitions of n into parts ≥ 2 by `SortedOfEnergy n` and let $G_n(X)$ be the matrix of norm polynomials $P_{w_i^\dagger w_j}(X)$ of the corresponding creation words; $\det G_n(c) = D_n(c)$ is the vacuum Gram determinant of Section 8.3.3.

```
def partitionWord (n : ℕ) (w : SortedOfEnergy n) : List ℤ :=
  w.val.map (fun (i : ℕ) => -(i:ℤ)-2)

noncomputable def partitionGramPolynomial (n : ℕ) :
    Matrix (SortedOfEnergy n) (SortedOfEnergy n) (Polynomial ℂ) :=
  fun i j => wordPolynomial ((partitionWord n i).reverse.map Neg.neg ++ partitionWord n j)

theorem partitionGramPolynomial_eval (c : ℂ) (n : ℕ) :
    (partitionGramPolynomial n).map (Polynomial.eval c) =
      GramMat.gramMatrix (VirGram4.canB c) (n:ℤ) (gradedBasis c n) := by
```

(`VOA.VirDeformModes.NormalOrdering.*`, `VOA/Examples/VirasoroPartitionObstruction.lean`; `GramMat.gramMatrix B n e` is the matrix $(B(e_i, e_j))$ of a basis e of $\mathcal{V}_n$.)

Theorem 8.21 (Simple determinant root obstruction). *If $D_n(c) = 0$ and $D_n'(c) \neq 0$ for some n, then $L(c,0)$ is graded rigid.*

```
theorem actual_partition_determinant_zero (c : ℂ)
    (D : FirstOrderDeformation (virasoroSimple c)) (hD : D.IsGraded)
    (α β : ℂ)
    (ha : D.smul₁ (virasoroSimple c).conformalVector 3
```

```
      (virasoroSimple c).conformalVector = α • (virasoroSimple c).vacuum)
    (hb : D.smul₁ (virasoroSimple c).conformalVector 1
      (virasoroSimple c).conformalVector = β • (virasoroSimple c).conformalVector)
    (n : ℕ) (hroot : (partitionGramPolynomial n).det.eval c = 0) :
    (partitionGramPolynomial n).det.aeval (inl c + inr (2*α-β*c) : DualNumber ℂ) = 0 := by

theorem graded_rigidity_of_simple_determinant (c : ℂ) (n : ℕ)
    (hroot : (partitionGramPolynomial n).det.eval c = 0)
    (hsimple : (partitionGramPolynomial n).det.derivative.eval c ≠ 0) :
    IsRigidGraded (virasoroSimple c) := by
```

(`VOA.VirDeformModes.NormalOrdering.*`, `VOA/Examples/VirasoroDeterminantObstruction.lean`; `inl c + inr δ` is the dual number $c + \delta\varepsilon$ and `aeval` evaluates a polynomial at it.)

Proof on paper. Let D be graded. *Step 1: the determinant does not move.* Since $D_n(c) = 0$ there is a nonzero r with $\sum_i r_i \langle e_i, e_j\rangle = 0$ for all j, so $\sum_i r_i e_i$ lies in the radical and $\sum_i r_i \pi(e_i) = 0$ in $L(c,0)$. Lift: $\sum_i r_i \tilde{L}_{w_i}(\mathbf{1}, 0) = (0, x)$ with $x \in L(c,0)_n$. The ordinary words $\pi(e_j)$ span $L(c,0)_n$, so $x = \sum_j s_j \pi(e_j)$, and since $t \cdot (y, y_1) = (0, y)$ the dual-number vector $\rho = r - ts$ satisfies $\sum_i \rho_i \tilde{L}_{w_i}(\mathbf{1}, 0) = 0$. Pairing with the lifted adjoint rows as in the previous proof shows $\rho^T G_n(c + t\delta) = 0$ over the dual numbers. As $r \neq 0$, some ρ_i is a unit, so the matrix $G_n(c + t\delta)$ has a kernel vector with a unit entry and its determinant is zero. *Step 2: Taylor.* $0 = D_n(c + t\delta) = D_n(c) + tD_n'(c)\delta = tD_n'(c)\delta$, so $\delta = 0$ (`VirRigidTangent.tangent_eq_zero_of_simple_root`). *Step 3:* Theorem 8.17. □

From the mathematics to the Lean statement

`hroot` and `hsimple` are exactly "D_n has a simple zero at c"; nothing about deformations is assumed. Determinant preservation ($D_n(c + t\delta) = 0$) is a *conclusion* (`actual_partition_determinant_zero`), proved from the actual deformation, not a hypothesis. This is the "determinant" twin of Theorem 8.20, and it is the form used for the general theorem.

What the machine verified

Both theorems proved, axioms `[propext, Classical.choice, Quot.sound]`. Unconditional.

Trap / dead end

An isolated degenerate charge is not enough; the root must be simple. One might think that rigidity follows because $c_{p,q}$ is an isolated zero of the level-n determinant. It does not: over the dual numbers, X^2 has the nonzero root ε, although 0 is its only complex root. The library records this as a theorem,

```
theorem isolated_root_has_nonzero_tangent :
    (∀ c : ℂ, c ^ 2 = 0 ↔ c = 0) ∧
      (DualNumber.eps : DualNumber ℂ) ≠ 0 ∧
      (X ^ 2 : Polynomial ℂ).aeval (DualNumber.eps : DualNumber ℂ) = 0 := by
```

(`VOA.VirRigidTangent.isolated_root_has_nonzero_tangent`, `VOA/Examples/VirasoroRigidityTangent.lean`), and the theorem that is used is the simple-root test `tangent_eq_zero_of_simple_root`: if $p'(c) \neq 0$ and $p(c + \delta\varepsilon) = 0$ then $\delta = 0$. Concretely, $D_4(c) = c^2(5c + 22)/2$ has a *double* zero at $c = 0$, so level 4 says nothing at $c = 0$ (the useful level there is 2). A second, related trap is also recorded: "the degenerate locus is discrete" is false as a statement over all levels, since the charges $c_{p,q}$ accumulate at $c = 1$; the correct and sufficient statement is per level (for fixed n, D_n is a nonzero polynomial with finitely many roots), and the argument above uses only one level at a time.

Physical meaning

The determinant $D_n(c)$ is the Kac determinant of the vacuum module at level n; its zeros list the central charges where a null descendant of the identity appears. A simple zero means that, as c moves off the minimal value, exactly one state stops being null at first order. The theorem says the minimal model cannot be perturbed: any perturbation would have to move c, and moving c would turn the decoupled null state back into a physical state of nonzero norm.

8.7 Worked cases

Before the general theorem, the library proved graded rigidity case by case, each time by exhibiting a relation with a nonzero norm derivative and applying the mechanism of Theorem 8.20 (in the earliest cases, a hand-specialised version of it). These cases are worth reading: each is a complete, checkable instance of the argument, with explicit numbers, and together they show the mechanism is not vacuous. All of them are now also consequences of the general theorem of Section 8.8.

8.7.1 Central charge zero: $M(2,3)$

At $c = 0$ the conformal vector has norm $\langle\omega,\omega\rangle = c/2 = 0$ and spans $V(0,0)_2$, so it lies in the radical, i.e. in the maximal ideal: $\omega = 0$ in $L(0,0)$. Then $\alpha\mathbf{1} = \omega_{(3)}^{1}\omega = 0$, so $\alpha = 0$ and $\delta = 2\alpha - \beta\cdot 0 = 0$; Theorem 8.17 applies.

```
theorem zeroCharge_conformal_eq_zero : (virasoroSimple 0).conformalVector = 0 := by

theorem zeroCharge_graded_rigidity : Deform.IsRigidGraded (virasoroSimple 0) := by
```

(`VOA.VirDeformModes.*`, `VOA/Examples/VirasoroZeroChargeRigidity.lean`.)

From the mathematics to the Lean statement

In fact $L(0,0) = \mathbb{C}\mathbf{1}$ is the one-dimensional VOA (every positive-weight creation monomial contains a mode applied to $\omega = 0$, or more simply, $\omega = 0$ generates). Its graded rigidity is a triviality, and the library's proof is correspondingly short. It is included honestly: $c_{2,3} = 0$, so the minimal model $M(2,3)$ is the trivial theory, and the general theorem covers it with no exception (the vacuum Gram determinant $D_2(c) = c/2$ has a simple zero at 0).

Physical meaning

$M(2,3)$ is the trivial CFT with one state; its rigidity is the statement that a one-point theory cannot be deformed. It is included because the minimal-model list starts there, and because $c = 0$ is a point where the level-two null vector is T itself: at $c = 0$ the stress tensor of the vacuum sector has zero norm and decouples.

8.7.2 Lee–Yang: $M(2,5)$, $c = -22/5$

The relation is $s = 5L_{-2}^2\mathbf{1} - 3L_{-4}\mathbf{1} = 0$ in $L(-\frac{22}{5},0)$ (Example 8.13). In any representation with central operator K and a vacuum-like vector v, normal ordering gives the adjoint-word identity

$$(5L_2L_2 - 3L_4)(5L_{-2}L_{-2} - 3L_{-4})v = \left(\tfrac{25}{2}\mathsf{K}^2 + 55\mathsf{K}\right)v,$$

`vir_singular4_polynomial`. With $\mathsf{K} = -\frac{22}{5} + \delta\mathsf{N}$ the right side applied to $(\mathbf{1},0)$ is $(0, -55\delta\mathbf{1})$ (`leeYang_singular_central_polynomial`; the constant term vanishes because $-22/5$ is a root and the tangent term is $P'(-22/5) = -55$). The vanishing pairing forces $-55\delta = 0$.

```
theorem leeYang_singular_central_polynomial (δ : ℂ) (v : V) :
    let K : End ℂ (V × V) := LeeYang.leeYangC • 1 + δ • tangentShift
    (25/2 : ℂ) • K (K (v, 0)) + (55 : ℂ) • K (v, 0) =
      (0, (-55 * δ) • v) := by

theorem leeYang_graded_rigidity : Deform.IsRigidGraded (virasoroSimple LeeYang.leeYangC) :=
 ↪ by
```

(`VOA.VirDeformModes.leeYang_singular_central_polynomial`, `VOA/Examples/VirasoroDeformationGram4.lean`; `VOA.VirDeformModes.leeYang_graded_rigidity`, `VOA/Examples/VirasoroFixedReconstruction.lean`; `LeeYang.leeYangC` is `-22 / 5 : ℂ`.)

Physical meaning

The Lee–Yang model describes the edge singularity of the Ising model in an imaginary magnetic field; it is the simplest non-unitary CFT, with one nontrivial primary of weight $-1/5$. Its vacuum null vector at level four, $(L_{-2}^2 - \frac{3}{5}L_{-4})\mathbf{1}$, is the relation $:TT: \propto \partial^2 T$ among chiral fields; the number -55 measures how fast this relation fails when c moves off $-22/5$, and its nonvanishing pins c.

8.7.3 Ising and $M(2,7)$ at weight six

$c_{3,4} = \frac{1}{2}$ and $c_{2,7} = -\frac{68}{7}$ both have first singular level $(p-1)(q-1) = 6$. The weight-six space has the basis $L_{-6}\mathbf{1}$, $L_{-4}L_{-2}\mathbf{1}$, $L_{-3}^2\mathbf{1}$, $L_{-2}^3\mathbf{1}$, and the null relations have integral coefficients:

$$\text{Ising: } (-108, -264, 93, 64), \qquad M(2,7)\ :\ (-38, -77, -7, 49).$$

They are certified as row-kernel vectors of the canonical Gram matrix `canGram6` at the respective charge (`ising_gram6_row`, `m27_gram6_row`) and hence vanish in $L(c,0)$. The norm polynomials, computed by normal ordering with the central operator kept,

$$P_{\mathrm{Is}}(\mathsf{K}) = -83316\mathsf{K} + 165096\mathsf{K}^2 + 3072\mathsf{K}^3, \qquad P_{2,7}(\mathsf{K}) = 67830\mathsf{K} + \tfrac{48951}{2}\mathsf{K}^2 + \tfrac{7203}{4}\mathsf{K}^3,$$

vanish at their charges and have derivatives 84084 and 102102 there. (Check for Ising: $-83316 \cdot \frac{1}{2} + 165096 \cdot \frac{1}{4} + 3072 \cdot \frac{1}{8} = -41658 + 41274 + 384 = 0$ and $-83316 + 165096 + 3 \cdot 3072 \cdot \frac{1}{4} = 84084$.)

```
def weight6Words : Fin 4 → List ℤ := ![[-6],[-4,-2],[-3,-3],[-2,-2,-2]]

def isingCoefficients : Fin 4 → ℂ := ![-108,-264,93,64]

```

(`VOA.VirDeformModes.*`, `VOA/Examples/VirasoroWeight6Norm.lean` and `VOA/Examples/VirasoroWeight6Rigidity.lean`; `isingC` is `1 / 2`, `m27C` is `-68 / 7`, both in `VirGram56`.)

From the mathematics to the Lean statement

The normal forms were *proposed* by a Python script and each reduction step was then *proved* in Lean from the Virasoro commutators, with the central element kept as an operator so that the tangent coefficient is retained. Python is not trusted: it only suggests the identities that Lean checks. The source states this, and it matters for the trust model: no numerical evidence enters these theorems.

Physical meaning

The Ising CFT ($c = 1/2$, primaries $1, \sigma, \varepsilon$ of weights $0, \frac{1}{16}, \frac{1}{2}$) is the continuum limit of the critical two-dimensional Ising model, equivalently a free Majorana fermion. Heuristically, its vacuum relation at weight six reflects that, for a single real fermion ψ, products of $T = -\frac{1}{2}\psi\partial\psi$ satisfy an extra identity (from $\psi^2 = 0$); $M(2,7)$ is a non-unitary model with the same first singular level. The nonzero derivatives 84084 and 102102 say these relations cannot survive any change of c.

8.7.4 Tricritical Ising: $M(4,5)$, $c = 7/10$

Here the first singular level is $3 \cdot 4 = 12$, where $V(c,0)_{12}$ has dimension 21. The library certifies an explicit weight-twelve combination of the 21 partition words with integer coefficients, proves it is annihilated by L_1 and L_2 at $c = 7/10$ (hence lies in the maximal ideal and vanishes in $L(\frac{7}{10}, 0)$), proves it is nonzero at every charge (its "vacuum survival" value is 8000), and computes its norm polynomial, a polynomial of degree six whose derivative at 7/10 is 128451135137139360:

```
noncomputable def tricriticalC : ℂ := 7/10

theorem tricritical_weight12_central {V : Type*} [AddCommGroup V] [Module ℂ V]
    (δ : ℂ) (v : V) :
    let K : End ℂ (V × V) := tricriticalC • 1+δ • tangentShift
    (321372476328566880:ℂ) • K (v,0) +
      (-1083581144832396000:ℂ) • (K^2) (v,0) +
      (866474649917232000:ℂ) • (K^3) (v,0) +
      (362527767823200000:ℂ) • (K^4) (v,0) +
      (527065804800000:ℂ) • (K^5) (v,0) +
      (2949120000000:ℂ) • (K^6) (v,0) = (0,(128451135137139360*δ) • v) := by

theorem tricritical_graded_rigidity : Deform.IsRigidGraded (virasoroSimple tricriticalC) :=
↪  by

theorem minimal_four_five_graded_rigidity :
    Deform.IsRigidGraded (virasoroSimple (minimalCentralCharge 4 5)) := by
```

(`VOA.VirDeformModes.*`, `VOA/Examples/VirasoroTricriticalRigidity.lean`; the certificate, with 555 private ordered-word reductions, is in `VOA/Examples/VirasoroTricriticalNorm.lean`.)

Physical meaning

The tricritical Ising model ($c = 7/10$) describes the tricritical point of the Blume–Capel model and is the simplest superconformal minimal model; its first vacuum null vector sits at weight twelve, which is why the explicit certificate is large. Rigidity says the tricritical point is isolated among chiral algebras generated by T.

8.7.5 The families $M(2,q)$ and $M(p,3)$

Two infinite families were done uniformly before the general theorem, each by constructing the relevant null vector by an explicit recursion and proving its norm derivative nonzero.

$M(2,q)$, q odd. In Kac's parametrisation $c(t) = 13 - 6t - 6/t$, the choice $t = (N+1)/2$ makes the $(1,N)$ Kac weight $h_{1,N}(t) = \frac{(N-t)^2-(t-1)^2}{4t}$ equal to 0, and $c((N+1)/2) = c_{2,N+1}$ (`bsaCharge_eq_minimal`). The vacuum module therefore contains the $(1,N)$ singular vector of Benoit and Saint-Aubin, built by a finite recursion in the L_{-1}, L_{-2} (the library constructs it from the Ward identities for L_1, L_2, with only the denominators $r(N-r)$, without assuming a singular-vector formula). For even N the norm derivative is identified with a "diagonal response" computed by a three-term recurrence and a contiguous relation, and shown nonzero.

```
noncomputable def bsaCharge (N : ℕ) : ℂ :=
  13 - 3*((N:ℂ)+1) - 12/((N:ℂ)+1)

theorem bsa_even_graded_rigidity (k : ℕ) :
    Deform.IsRigidGraded (VirSimple.virasoroSimple (bsaCharge (2*(k+2)))) :=

theorem minimal_two_graded_rigidity (q : ℕ) (hq : 2≤q) (hcop : Nat.Coprime 2 q) :
    Deform.IsRigidGraded (VirSimple.virasoroSimple (minimalCentralCharge 2 q)) := by

theorem minimal_right_two_graded_rigidity (p : ℕ) (hp : 2≤p) (hcop : Nat.Coprime p 2) :
    Deform.IsRigidGraded (VirSimple.virasoroSimple (minimalCentralCharge p 2)) := by
```

(`VOA.VirModule.bsaCharge`, `VOA/Examples/VirasoroBSARecursion.lean`; the three theorems, `VOA/Examples/VirasoroBoundaryRigidity.lean`. `bsa_even_graded_rigidity k` covers $q = 2k+5$; $q = 3$ is the zero-charge case; coprimality with 2 supplies oddness.)

$M(p,3)$. At $t = 3/p$ the $(p-1,2)$ Kac weight is 0 and the first vacuum singular level is $2(p-1)$. The library constructs the singular vector by a "fusion" recursion (a triangular system dividing only by charge-independent nonzero diagonals, nonresonant by coprimality with 3), transports the construction to a moving charge, proves the moving-norm identity $\langle S(t), S(t)\rangle = -d_R(t)\,C(t)$ with d_R vanishing simply at $t_0 = 3/p$ and $C(t_0) \neq 0$ (the latter by a finite hypergeometric-resonance argument), and concludes that the norm derivative is nonzero.

```
theorem minimal_three_graded_rigidity (p : ℕ) (hp : 2≤p) (hcop : Nat.Coprime p 3) :
    Deform.IsRigidGraded (VirSimple.virasoroSimple (minimalCentralCharge p 3)) := by

theorem minimal_left_three_graded_rigidity (q : ℕ) (hq : 2≤q) (hcop : Nat.Coprime 3 q) :
    Deform.IsRigidGraded (VirSimple.virasoroSimple (minimalCentralCharge 3 q)) := by
```

(`VOA.InverseDS.VirasoroVerma.*`, `VOA/Examples/VirasoroMinimalThreeRigidity.lean`; the construction occupies the `VirasoroFusion*`, `VirasoroMinimalThree*`, `VirasoroThreeMoving*` and `VirasoroMovingNormDerivative` files of this chapter.)

What the machine verified

Every theorem of this section is proved; `#print axioms` gives `[propext, Classical.choice, Quot.sound]` for `zeroCharge_graded_rigidity`, `leeYang_graded_rigidity`, `ising_graded_rigidity`, `m27_graded_rigidity`, `tricritical_graded_rigidity`, `minimal_four_five_graded_rigidity`, `bsa_even_graded_rigidity`, `minimal_two_graded_rigidity`, `minimal_right_two_graded_rigidity`, `minimal_three_graded_rigidity` and `minimal_left_three_graded_rigidity` (Section 8.10). No `VOA.pbw`. All unconditional statements of graded first-order rigidity. Full names: the tricritical theorems are `VOA.VirDeformModes.tricritical_graded_rigidity` and `VOA.VirDeformModes.minimal_four_five_graded_rigidity`; the three-label theorems are `VOA.InverseDS.VirasoroVerma.minimal_three_graded_rigidity`

and `VOA.InverseDS.VirasoroVerma.minimal_left_three_graded_rigidity`; the two-label theorems are `VOA.VirModule.minimal_two_graded_rigidity` and `VOA.VirModule.minimal_right_two_graded_rigidity` (not all in `VOA.VirModule`, despite the headline's namespace).

Trap / dead end

A "structural" rigidity theorem that was a tautology. Before the cases above were proved, the file `VOA/Examples/VirasoroRigidityStructural.lean` stated rigidity of Ising, $M(2,7)$ and Lee–Yang from a graded-dimension jump, under a hypothesis

```
def RealisedByNondegenerate (U : VertexOperatorAlgebra 𝒰) (n : ℤ) (d : ℕ) : Prop :=
  (∃ D : FirstOrderDeformation U, D.IsGraded ∧ ¬ D.IsTrivial) → finrank ℂ (U.grading
  ↪ n) = d

theorem isRigidGraded_of_finrank_lt (U : VertexOperatorAlgebra 𝒰) (n : ℤ) (d : ℕ)
    (hE : RealisedByNondegenerate U n d) (hlt : finrank ℂ (U.grading n) < d) :
    IsRigidGraded U := by
```

intended to mean "a modulus would move U along the family $c \mapsto L(c,0)$, preserving graded dimensions". An adversarial audit showed that, given the (proved) jump `hlt`, the hypothesis `hE` is *logically equivalent to the conclusion*: `hE` unfolds to "a nontrivial graded deformation exists ⇒ (a false equation)", i.e. to `IsRigidGraded U`. The library now records the certificate

```
theorem realisedByNondegenerate_iff_isRigidGraded
    {V : Type*} [AddCommGroup V] [Module ℂ V] (W : VertexOperatorAlgebra V)
    (n : ℤ) (d : ℕ) (hlt : Module.finrank ℂ (W.grading n) < d) :
    VirRigidStruct.RealisedByNondegenerate W n d ↔ Deform.IsRigidGraded W := by
```

(`VOA.VirRigidTangent.realisedByNondegenerate_iff_isRigidGraded`, `VOA/Examples/VirasoroRigidityTangent.lean`). So the instances `isRigidGraded_virasoroSimple_ising` etc. in that file read "if $L(c,0)$ is graded rigid then it is graded rigid". They remain in the library (with honest docstrings) but are *not* the rigidity theorems; the unconditional theorems of this section are. The lesson, which the project applies throughout: a hypothesis must be checked for *uniform derivability from the conclusion*, not merely for truth. (The unconditional content of that file — the gauge line and the dimension jump $\dim L(\frac{1}{2},0)_6 < \dim L(1,0)_6$ — is correct.)

Physical meaning

$M(2,q)$ are the non-unitary "Lee–Yang series" (they include Lee–Yang at $q=5$); their vacuum null vector is of Benoit–Saint-Aubin type, the explicit $(1,s)$ null vectors found in the study of degenerate fields, whose decoupling gives order-s differential equations for correlators. $M(p,3)$ include the Ising model $M(4,3)$. In both families the physics is the same as in the single cases: the null vector pins the central charge to first order.

8.8 All minimal models

Theorem 8.22 (Graded first-order rigidity of the Virasoro minimal models). *Let $p,q \geq 2$ be coprime integers and $c_{p,q} = 1 - 6(p-q)^2/(pq)$. Every graded first-order deformation of the simple Virasoro vertex operator algebra $L(c_{p,q},0)$ is trivial: there is a grade-preserving linear map φ with $\varphi(\mathbf{1}) = 0$ such that $u^1_{(n)}v = (\varphi u)_{(n)}v - \varphi(u_{(n)}v) + u_{(n)}\varphi v$ for all u, v, n.*

```
theorem minimal_graded_rigidity (p q : ℕ) (hp : 2 ≤ p) (hq : 2 ≤ q)
    (hcop : p.Coprime q) :
    IsRigidGraded (virasoroSimple (minimalCentralCharge p q)) := by
  apply minimal_rigidity_of_infinite_kac_roots p q hp hq hcop
  intro r s hr hs _
  exact infinite_integer_screening_roots r s hr hs
```

(`VOA.VirModule.minimal_graded_rigidity`, `VOA/Examples/VirasoroMinimalRigidityComplete.lean`; the three-line proof is shown because it is informative: it is the composition of two named theorems.)

From the mathematics to the Lean statement

Decoding the statement.

- `(p q : ℕ)`: natural numbers; `hp`, `hq`: $p, q \geq 2$; `hcop : p.Coprime q`: $\gcd(p, q) = 1$. These are exactly the standard labels of the minimal models; the order of p, q is irrelevant (the formula is symmetric and both orders are allowed), and $p = q$ is excluded by coprimality. There is no unitarity assumption: non-unitary models such as Lee–Yang are included.
- `minimalCentralCharge p q` is Definition 8.12, a rational number, silently cast to $\mathbb{C}$.
- `virasoroSimple c` is $L(c, 0)$, the quotient of the universal vacuum VOA $V(c, 0)$ by its maximal proper ideal (Definition 8.11); it is simple, with nonzero vacuum, for every c.
- `IsRigidGraded` is Definition 8.5, examined in Section 8.2.6.

Every hypothesis is the intended one, and there are no others. The statement has no hypothesis about singular vectors, determinants, characters, vacuum survival, norm derivatives, or deformations; earlier versions of the theorem (`minimal_graded_rigidity_of_kac_singular`, `graded_rigidity_of_verma_kac`, `minimal_rigidity_of_infinite_kac_roots`) carried such inputs as explicit hypotheses, and the final theorem discharges them, as its displayed proof shows.

Same as the intended theorem? Yes, in the sense of Section 8.2.6: it is *graded* first-order rigidity of the vacuum VOA of every minimal model, over the dual numbers, modulo graded vacuum-preserving coordinate changes, with the conformal vector allowed to move. It does not assert rigidity among ungraded deformations (where the library's `IsRigid` is false for a definitional reason, Warning 8.2.5), higher-order or analytic rigidity, rigidity of the minimal-model modules or of the full non-chiral CFT, or the rationality of $L(c_{p,q}, 0)$ (which is Wang's theorem, a separate matter).

Could it be vacuous? The hypotheses are satisfiable ($p = 2, q = 3, \ldots$); the object $L(c_{p,q}, 0)$ is a genuine nonzero simple VOA (for $(p, q) \neq (2, 3), (3, 2)$ it is infinite-dimensional, with $\omega \neq 0$); the deformation notion contains every genuine graded first-order deformation and admits nonzero graded cocycles (e.g. δL_0); the conclusion is not a tautology of the definitions: it fails for $V(c, 0)$ at every c, machine-checked (`VOA.VirPoly.not_isRigidGraded_virasoroVOA`, Remark 8.6).

The label $(2, 3)$**.** At $(p, q) = (2, 3)$ (or $(3, 2)$) the central charge is $c_{2,3} = 0$, and $L(0, 0) = \mathbb{C}\mathbf{1}$ is the one-dimensional VOA (Section 8.7.1); its graded rigidity is trivially true, since $Y_1\mathbf{1} = 0$ is forced by (D2). This instance of the theorem carries no content. It is harmless: the other labels do.

Physical meaning

Every Virasoro minimal model — Ising, tricritical Ising, Potts, Lee–Yang and all non-unitary $M(p,q)$ — has a chiral algebra with no exactly marginal deformations (to first order, among weight-preserving perturbations): the minimal models are isolated points, not members of continuous families. This matches the physical picture in which c is quantised by null-vector decoupling and the Kac table, and the classification of minimal models as a discrete list. Honest caveats: this is a statement about the chiral vacuum algebra only (not about the full non-chiral CFT with its modular-invariant combination of sectors, nor about its modules), and about first order only. That the full CFT is isolated too is widely believed, but it is a different statement (about weight-$(1,1)$ fields of the non-chiral theory) and is not what is proved.

8.8.1 The proof on paper

Fix coprime $p, q \geq 2$, put $c_0 = c_{p,q}$ and $N = (p-1)(q-1)$, and let D be a graded first-order deformation of $L(c_0, 0)$.

1. *Normal form* (Section 8.4). D determines scalars α, β and normalised modes $\tilde{L}_n$ on $\mathcal{V} \oplus t\mathcal{V}$ satisfying the Virasoro relations with central operator $c_0 + \delta\mathsf{N}$, $\delta = 2\alpha - \beta c_0$.

2. *Reconstruction* (Theorem 8.17). If $\delta = 0$ then D is trivial.

3. *Obstruction* (Theorem 8.21). If the vacuum Gram determinant $D_N(c) = \det G_N(c)$ has a simple zero at c_0, then $\delta = 0$.

4. *Representation theory* (Chapter 7). $D_N(c_0) = 0$ and $D_N'(c_0) \neq 0$.

Steps 1–3 are this chapter's; step 4 is a statement purely about the universal Virasoro vacuum module, and is the deep input. In the literature it follows from the Kac determinant formula for the vacuum module (Gorelik and Kac): $D_N(c)$ is, up to a nonzero constant, $\prod (c - c_{a,b})^{\dim L(h;c_{a,b})_N}$ over primitive labels, and at the first level $N = (p-1)(q-1)$ the factor $c - c_{p,q}$ occurs exactly once (the lowest weight space of the irreducible quotient is one-dimensional) while every other factor is nonzero at c_0 (distinct coprime label pairs with ratios > 1 give distinct charges). The Lean proof does *not* cite this; it proves step 4 from scratch along the following route, all of which lives in files of Chapter 7:

(a) *Kac parametrisation.* $c(t) = 13 - 6t - 6/t$, $h_{r,s}(t) = \frac{(rt-s)^2-(t-1)^2}{4t}$; for $p > q$ one takes $t = p/q$, so that $c(p/q) = c_{p,q}$, and the label $(q-1, p-1)$ has $h = 0$ at level $(p-1)(q-1)$.

(b) *Gram roots from free fields.* For positive integers r, s, m, at $t = m^2$, an explicit finite "screening" polynomial in a rank-one charged Fock space is a nonzero state of energy rs annihilated by L_1 and L_2; a transfer argument (equal level dimensions of Fock and Verma, injectivity below the first degenerate level) turns it into a zero of the Verma Gram determinant at $(c(t), h_{r,s}(t))$ and level rs. This gives, for each label, the infinite family of roots $t \in \{1, 4, 9, \dots\}$: `infinite_integer_screening_roots`.

(c) *All parameters.* Along a Kac curve the determinant is a Laurent polynomial in t; infinitely many roots force it to vanish identically (`kacGram_root_of_infinite`). Strong induction on the level then produces actual nonzero singular vectors at nonreal t, and degree exhaustion $\sum_{\lambda \vdash n} \ell(\lambda) = \sum_{rs \leq n} p(n - rs)$ identifies the Verma determinant with the Kac product; continuity extends it to all $t \neq 0$.

(d) *From Verma to vacuum.* The coefficient of the top power of h in the level-$(n+1)$ Verma determinant equals $2^{p(n)} \det G^{\mathrm{vac}}_{n+1}(c) \det G^{\mathrm{Verma}}_n(c, 1)$; comparing with the Kac product, whose relevant

factor vanishes simply at $t = p/q$ (derivative $q(q-p)/(2p) \neq 0$) while the weight-one factor does not vanish, the chain rule gives $D_N(c_0) = 0 \neq D'_N(c_0)$ (`vacuum_simple_of_verma_kac`).

The two Lean theorems composed in the displayed proof are the end points of this route:

```
theorem minimal_rigidity_of_infinite_kac_roots (p q : ℕ) (hp : 2 ≤ p)
    (hq : 2 ≤ q) (hcop : p.Coprime q)
    (hroots : ∀ r s : ℕ, 0 < r → 0 < s → r*s ≤ (p-1)*(q-1) →
      ∃ S : Set ℂ, S.Infinite ∧ (∀ t ∈ S, t ≠ 0) ∧
        ∀ t ∈ S, (vermaGramMatrix (vermaBSACharge t)
          (fusionKacWeight r s t) (r*s)).det = 0) :
    IsRigidGraded (virasoroSimple (minimalCentralCharge p q)) := by

theorem infinite_integer_screening_roots (r s : ℕ) (hr : 0 < r) (hs : 0 < s) :
    ∃ S : Set ℂ, S.Infinite ∧ (∀ t ∈ S, t ≠ 0) ∧
      ∀ t ∈ S, (vermaGramMatrix (vermaBSACharge t)
        (fusionKacWeight r s t) (r*s)).det = 0 := by
```

(`VOA.InverseDS.VirasoroVerma.minimal_rigidity_of_infinite_kac_roots`, `VOA/Examples/VirasoroKacRootBootstrap.lean`; `VOA.VirasoroScreening.infinite_integer_screening_roots`, `VOA/Examples/VirasoroScreeningKacRoots.lean`; both files belong to Chapter 7.)

From the mathematics to the Lean statement

`vermaBSACharge t` is $c(t) = 13 - 6t - 6/t$ and `fusionKacWeight r s t` is $h_{r,s}(t)$; `vermaGramMatrix c h n` is the level-n Gram (Shapovalov) matrix of the Verma module $M(c,h)$ in the partition basis. The hypothesis `hroots` of the first theorem is a statement about Verma modules only — for each positive label (r,s) with $rs \leq (p-1)(q-1)$, infinitely many distinct nonzero parameters t at which $\det G^{\mathrm{Verma}}_{rs}(c(t), h_{r,s}(t)) = 0$ — and the second theorem supplies it for *all* positive labels, with $S = \{1, 4, 9, \dots\}$. The source of the first theorem notes that isolated collision parameters could not satisfy `hroots`; it genuinely requires infinitely many roots, and gets them. The internal route (a)–(d) replaces the external citation of Gorelik–Kac, which the project's paper note (`Notes/Virasoro_Uniform_Rigidity_Argument.tex`) keeps as an alternative exposition, not a proof dependency.

What the machine verified

`VOA.VirModule.minimal_graded_rigidity`: **graded first-order rigidity, proved, unconditional** (no hypotheses beyond the label conditions; the notion is non-vacuous, since $V(c,0)$ is proved not graded rigid, Remark 8.6). `#print axioms` (run on this commit, see Section 8.10):

```
'VOA.VirModule.minimal_graded_rigidity' depends on axioms: [propext,
 ↪  Classical.choice, Quot.sound]
```

`VOA.pbw` does *not* appear: the result does not use `VOA.pbw`. Its hypotheses are only the label conditions. (The project's build record reports an aggregate `lake build` of 9,874 jobs and a full sequential axiom audit with the same outcome at the time the theorem landed; for this book we re-ran `#print axioms` on the built tree and did not re-run the aggregate build.) The repository's `README.md` now records the theorem as proved, with the same graded first-order qualification.

8.9 Other files of this chapter

For completeness, here is what the remaining assigned files contain; none of them is needed for the statements above beyond what has been described.

- `Core/DeformationCurrentModes`, `Core/DeformationPoleForm`, `Core/DeformationNormalization`, and the current part of `Core/DeformationLiftedModes`, `Core/DeformationCentralModes`: the weight-one (affine) analogue of Section 8.4 — lifted current modes, the invariant pole pairing, the level variation $k + \delta\mathsf{N}$, and gauge normalisation via $H^2(\mathfrak{g}, \mathfrak{g}) = 0$. They serve the affine rigidity theorems of Chapter 10. `Core/DeformationIteration`: the iterate formula on $\mathcal{V} \times \mathcal{V}$ used in Section 8.5.

- `Core/RankOneTransfer` (completing the square for a positive-definite Hermitian matrix minus a rank-one term), `Core/GlobalConformalTowers` (norms of global descendants $\langle L_{-1}^r u, L_{-1}^r v\rangle = r!(2m)_r\langle u, v\rangle$ for quasi-primaries of weight m), `Core/HorizontalSaturation` ($\mathfrak{sl}_2$ ladder saturation): linear-algebra tools used by the graded-unitarity work of Chapter 19.

- `Examples/VirasoroDeformationLow`, `VirasoroRigidityGramLift`: the tridegree tables of Section 8.2.8 and the level-4/6 Gram matrices over $\mathbb{C}[X]$ evaluated at dual numbers. `VirasoroCDeformation`: the gauge line and the conditional non-rigidity of $V(c, 0)$. `VirasoroPolyStructure`, `VirasoroPolyFields`, `VirasoroPolyTensor`, `VirasoroPolyEnergy`, `VirasoroPolyDeriv`, `VirasoroCDefBuild`, `VirasoroCDefJacobi`, `VirasoroCDefFinal`: the structure constants of $V(c, 0)$ as polynomials in c on the sorted-word basis, their c-derivative $\partial_c Y$ (`cDeformation`), and the unconditional non-rigidity `not_isRigidGraded_virasoroVOA` (Section 8.2.7). (These files postdate the assignment list of the first edition.) `VirasoroDeformationReconstruction`: generation of $L(c, 0)$ by ω and the generated-carrier form of reconstruction.

- `VirasoroBSA*`, `VirasoroVermaBSA*`, `VirasoroDescendantBSATransport`: the Benoit–Saint-Aubin $(1, N)$ singular vectors, in the vacuum module and in general Verma modules (`vermaBSA_nonzero_highest_all`: a nonzero highest-weight vector at level N of $M(c(t), h_{1,N}(t))$ for every $t \neq 0$, $N > 0$). `VirasoroFusion*`, `VirasoroVacuumFusion*`, `VirasoroMinimalThree*`, `VirasoroThreeMoving*`, `VirasoroMovingNormDerivative`, `VirasoroMinimalFourVacuum`, `VirasoroMinimalFusionArithmetic`, `VirasoroMinimalChargeArithmetic`: the fusion construction of singular vectors and its arithmetic (nonresonance at prime-power labels; uniqueness of the primitive label of a charge). `VirasoroTranslationTangent`, `VirasoroTranslationFirstForm`: the translated first-order form, giving the Verma-to-vacuum coefficient identity of step (d).

- `VirasoroSalazarInterface`: definitions of predicates expressing Salazar's admissible-monomial basis theorem for the boundary simple Virasoro module, with implications between them; nothing is assumed or asserted, and no axiom is added.

Several of these files contain conditional theorems whose hypotheses were later discharged (for instance `graded_rigidity_of_bsa_scalar`, `minimal_graded_rigidity_of_kac_singular`, `graded_rigidity_of_verma_kac`); their docstrings say "this conditional theorem does not assert that the scalar input holds". They are correct as stated and are superseded by the unconditional theorems quoted in this chapter.

8.10 Verification record

When this chapter was first written we ran `#print axioms` on the headline declarations, on the already-built tree at an earlier commit (not re-run for this edition), with a scratch file importing the relevant modules and the command

```
export PATH="$HOME/.elan/bin:$PATH"
lake env lean -DmaxSynthPendingDepth=3 Axioms.lean
```

(the flag avoids the audit trap of Section 43.1.6: a bare `lake env lean` drops `maxSynthPendingDepth`). Every one of the following reported exactly

```
depends on axioms: [propext, Classical.choice, Quot.sound]
```

(All names in the `VOA` namespace.) The PBW theorem `VOA.pbw` appears in none of them. We did not re-run the aggregate `lake build` for this chapter; the tree had been built, and the `olean` files of the imported modules were present. A clean `#print axioms` does not report explicit hypotheses; here the headline theorems have none beyond the label conditions, so "unconditional" is justified for them, while the reduction theorems (`graded_rigidity_of_relation`, `graded_rigidity_of_simple_determinant`, `minimal_rigidity_of_infinite_kac_roots`, ...) are unconditional *implications* whose hypotheses are visible in their statements.

Re-run 2026-10-27. At a later commit (not re-run for this edition), with the same command on a scratch file, `#print axioms` again gave exactly `[propext, Classical.choice, Quot.sound]` for `VirModule.minimal_graded_rigidity`, `InverseDS.VirasoroVerma.minimal_three_graded_rigidity`, `InverseDS.VirasoroVerma.minimal_left_three_graded_rigidity`, `VirDeformModes.tricritical_graded_rigidit` `VirDeformModes.minimal_four_five_graded_rigidity`, `VirCDef.cmode_conformal_of_isCoboundary`, `VirCDef.not_isTrivial_of_omega_witness`, `VirCDef.not_isRigidGraded_of_omega_witness`, `VirCDef.not_isTrivial_of_isCDeformation`, `VirCDef.not_isRigidGraded_of_isCDeformation` and `NonzeroDeform.not_isRigid_virasoroVOA` (all in `VOA`). No aggregate `lake build` was run.

Release audit 2026-10-27: `Notes/Textbook/referee/RELEASE_AUDIT_RIGIDITY.md`. Its verdict on the headline and its special cases is "announceable with caveats"; the two caveats (graded first-order only; non-vacuity argued on paper only) are stated in the opening of the chapter, in Section 8.2.6 and in Remark 8.6. The second caveat has since been discharged by `VOA.VirPoly.not_isRigidGraded_virasoroVOA` (release follow-ups audit, `Notes/Textbook/referee/RELEASE_AUDIT_FOLLOWUPS.md`, 2026-10-28: "with caveats: holds for every c; the deformation moves c"; it reports standard axioms for `cDeformation`, `isCDeformation_cDeformation`, `cDeformation_isGraded` and `not_isRigidGraded_virasoroVOA`). We did not re-run `#print axioms` on these for this chapter. The remaining caveat is that rigidity is graded first-order only (plus the remark on the label $(2,3)$).

8.11 Referee's checklist

Lean declaration	Intended meaning	Hypotheses / status	Check
`Deform.FirstOrderDeformation`	$Y + tY_1$ is a VA over $\mathbb{C}[t]/t^2$, same space and vacuum	definition; (D1)–(D4), `finsum` non-vacuous	Def. 8.1

Lean declaration	Intended meaning	Hypotheses / status	Check
…FirstOrderDeformation.IsGraded	Y_1 respects weights (VA1 at order t)	definition (predicate)	Def. 8.2
Deform.IsCoboundary, …IsTrivial	$Y_1 = \delta\varphi$, φ graded, $\varphi\mathbf{1} = 0$	definition	Def. 8.3
Deform.coboundaries_le_cocycles	field redefinitions are deformations	none; unconditional	Thm. 8.4
Deform.IsRigid	every deformation trivial	definition; **TRAP**: false for every $V(c,0)$ (definitional)	Warn. 8.2.5
Deform.IsRigidGraded	every graded first-order deformation trivial (graded $H^2 = 0$, vacuum fixed; ≥ Linshaw–Qi)	definition; the notion used	Def. 8.5, §8.2.6
Deform.isRigid_iff_H_trivial	rigidity $\iff$ $H = 0$	none; unconditional	§8.2
Deform.GradedToGlobalRigidity	tridegree-wise ⇒ global	**named target, not proved**, unused	Warn. 8.2.8
VirCDef.not_isRigidGraded_of_isCDeformation	∂_c would refute rigidity of $V(c,0)$	conditional; the predicate is inhabited by VirPoly.cDeformation	Warn. 8.2.7
VirPoly.not_isRigidGraded_virasoroVOA	$V(c,0)$ is not graded first-order rigid, every c	none; unconditional (the witness $\partial_c Y$ moves c)	§8.2.7
VOA.VirCDef.not_isTrivial_of_omega_witness	a deformation of $V(c,0)$ with $\omega^1_{(1)}\omega = 0 \neq \omega^1_{(3)}\omega$ is non-trivial	the two ω-values; unconditional	Rem. 8.6
VirCDef.cmode_conformal_of_isCoboundary	gauge line: coboundaries have $\delta = 0$	$\mathcal{V}_2 = \mathbb{C}\omega$; unconditional	Thm. 8.14
VirDeformModes.normalizedL_comm	normalised modes: Virasoro with centre $c + \delta\mathsf{N}$	graded, $\mathcal{V}_1 = 0$; unconditional	§8.4
Deform.Reconstruction.isTrivial_of_closed_lift	closed separated lift ⇒ trivial	W simple + 5 lift properties	Thm. 8.16
VirDeformModes.isTrivial_of_zero_central_variation	$\delta = 0$ ⇒ trivial, any c	graded; unconditional	Thm. 8.17
DefForm.lift_iff_pairing_zero	lifting criterion for null vectors	B_0 symmetric, fin.-dim.; unconditional	Prop. 8.18
RigidBridge.F2_lt_F1_of_self_pairing_ne_zero	a null vector with $\langle s,s\rangle^1 \neq 0$ does not lift	hypothesis unsatisfiable for trivial D; not used	Warn. 8.6.1
…NormalOrdering.graded_rigidity_of_relation	relation with simple-zero norm ⇒ rigid	relation in $L(c,0)$, $P'(c) \neq 0$; unconditional	Thm. 8.20
…NormalOrdering.graded_rigidity_of_simple_determinant	simple zero of D_n ⇒ rigid	$D_n(c) = 0 \neq D_n'(c)$; unconditional	Thm. 8.21
VirRigidTangent.isolated_root_has_nonzero_tangent	isolated root ⇏ rigid	none	Warn. 8.6.4
VirRigidStruct.isRigidGraded_of_finrank_lt	"dimension jump" rigidity	**TAUTOLOGY**: hypothesis $\iff$ conclusion	Warn. 8.7.5
VOA.VirDeformModes.zeroCharge_graded_rigidity	$M(2,3)$, $c = 0$, $L(0,0) = \mathbb{C}\mathbf{1}$: trivially rigid	none; unconditional	§8.7.1
VirDeformModes.leeYang_graded_rigidity	Lee–Yang $c = -22/5$	none; unconditional	§8.7.2

Lean declaration	Intended meaning	Hypotheses / status	Check
`VirDeformModes.ising_graded_rigidity`, `m27_graded_rigidity`	Ising, $M(2,7)$	none; unconditional	§8.7
`VOA.VirDeformModes.tricritical_graded_rigidity` (+ `minimal_four_five`)	$M(4,5)$	none; unconditional	§8.7
`VOA.VirModule.minimal_two_graded_rigidity` (+ `right`)	$M(2,q)$, $M(p,2)$	labels; unconditional	§8.7
`VOA.InverseDS.VirasoroVerma.minimal_three_graded_rigidity` (+ `left`)	$M(p,3)$, $M(3,q)$	labels; unconditional	§8.7
`…minimal_rigidity_of_infinite_kac_roots`	infinitely many Verma Gram roots ⇒ rigid	`hroots` (supplied by screening)	§8.8
`VirModule.minimal_graded_rigidity` (headline)	every graded first-order deformation of every minimal model $L(c_{p,q},0)$ is trivial	$p,q\geq 2$ coprime; **unconditional**, no `pbw`; non-vacuity machine-checked ($V(c,0)$ not graded rigid)	Thm. 8.22

8.12 Notes and references

Deformation theory. The cohomological theory of deformations of associative algebras is due to M. Gerstenhaber, "On the deformation of rings and algebras", *Annals of Mathematics* 79 (1964), 59–103; the Lie-algebra analogue to A. Nijenhuis and R. W. Richardson, "Cohomology and deformations in graded Lie algebras", *Bull. Amer. Math. Soc.* 72 (1966), 1–29. For vertex algebras, a cohomology theory in which the second cohomology classifies first-order deformations of grading-restricted vertex algebras was developed by Y.-Z. Huang, "A cohomology theory of grading-restricted vertex algebras", *Comm. Math. Phys.* 327 (2014), 279–307, and "First and second cohomologies of grading-restricted vertex algebras", *Comm. Math. Phys.* 327 (2014), 261–278. The library constructs no cohomology theory and no comparison with Huang's is formalised.

The target statements. The affine counterpart, rigidity of $L_{-4/3}(\mathfrak{sl}_2)$, is the subject of the paper of A. Linshaw and F. Qi, arXiv:2601.12017v2 (2026), whose Theorem 3.1 setting (regular deformations, pole coefficient) is formalised in `VOA/Core/Deformation.lean`; see Chapter 10. The Virasoro theorem of this chapter was formulated within the project; the project's working note `Notes/Virasoro_Uniform_Rigidity_Argument.tex` gives a short paper proof using the vacuum Kac determinant of M. Gorelik and V. Kac, "On simplicity of vacuum modules", *Advances in Mathematics* 211 (2007), 621–677, arXiv:math-ph/0606002, Theorem 4.2.1; the Lean proof does not depend on that citation.

Virasoro representation theory. The Kac determinant: V. G. Kac, "Contravariant form for infinite-dimensional Lie algebras and superalgebras", in *Group Theoretical Methods in Physics*, Lecture Notes in Physics 94, Springer (1979), 441–445; B. L. Feigin and D. B. Fuchs, "Verma modules over the Virasoro algebra", in *Topology* (Leningrad 1982), Lecture Notes in Mathematics 1060, Springer (1984), 230–245. The Benoit–Saint-Aubin null vectors: L. Benoit and Y. Saint-Aubin, "Degenerate conformal field theories and explicit expressions for some null vectors", *Phys. Lett. B* 215 (1988), 517–522. Fusion constructions of singular vectors: e.g. A. Kent, "Singular vectors of the Virasoro algebra", *Phys. Lett. B* 273 (1991), 56–62. Free-field (screening) realisations: V. S. Dotsenko and V. A. Fateev, "Conformal algebra and multipoint correlation functions in 2D statistical models", *Nucl. Phys. B* 240 (1984), 312–348.

Vertex operator algebras of Virasoro type. I. B. Frenkel and Y. Zhu, "Vertex operator algebras

associated to representations of affine and Virasoro algebras", *Duke Math. J.* 66 (1992), 123–168, construct $V(c,0)$ and $L(c,0)$ as VOAs; W. Wang, "Rationality of Virasoro vertex operator algebras", *Int. Math. Res. Notices* 1993, no. 7, 197–211, proves that $L(c_{p,q},0)$ is rational with irreducible modules given by the Kac table. Neither rationality nor the module classification is used or proved in this chapter.

Physics. The minimal models: A. A. Belavin, A. M. Polyakov and A. B. Zamolodchikov, "Infinite conformal symmetry in two-dimensional quantum field theory", *Nucl. Phys. B* 241 (1984), 333–380; the unitary series: D. Friedan, Z. Qiu and S. Shenker, "Conformal invariance, unitarity, and critical exponents in two dimensions", *Phys. Rev. Lett.* 52 (1984), 1575–1578. For conformal perturbation theory and marginal deformations see P. Di Francesco, P. Mathieu and D. Sénéchal, *Conformal Field Theory*, Springer (1997), and for the Lee–Yang model J. L. Cardy, "Conformal invariance and the Yang–Lee edge singularity in two dimensions", *Phys. Rev. Lett.* 54 (1985), 1354–1356. Standard VOA background: T. Gannon, *Moonshine beyond the Monster*, Cambridge University Press (2006), §§3.1, 5.1; J. Lepowsky and H. Li, *Introduction to Vertex Operator Algebras and Their Representations*, Birkhäuser (2004).

Project records. The dead ends of Warnings 8.2.5–8.7.5 are also recorded in the project's internal records; the book's own catalogue of dead ends is Section 43.2.

Chapter 9

Affine $\mathfrak{sl}_2$: construction, Verma modules, Wakimoto realisation, screening, non-simplicity

This chapter documents the release of the LeanVOA library named in the front matter. Every Lean quotation in a `leancode` box is checked by `scripts/textbook/sync.py` to occur verbatim in the source files of that release (up to whitespace; docstrings and comments are omitted from the quotations, never code). The chapter was first written against an earlier state of the library ("the snapshot" below); checks that were run at an earlier state of the library and not re-run for this edition are marked as such. Tool output and shell commands are printed in plain boxes. The chapter covers the 133 files assigned to it in `Notes/Textbook/assignment.txt`: `VOA/Examples/Affine.lean`, `VOA/Examples/AffineSimpleQuotient.lean`, the files `VOA/Examples/AffineSl2*.lean` not assigned to Chapters 10 and 16, and the files `VOA/Examples/Wakimoto*.lean`.

What the chapter is about. The affine Lie algebra $\widehat{\mathfrak{sl}}_2$ is the symmetry algebra of the $SU(2)$ Wess–Zumino–Witten (WZW) model, and the vertex operator algebras built from it — the *universal affine VOA* $V^k(\mathfrak{sl}_2)$ and its *simple quotient* $L_k(\mathfrak{sl}_2)$ — are the chiral algebras of that model at level k. They are also the simplest non-abelian VOAs, and the testing ground for almost every structural question about VOAs. The library contains a complete construction of $V^k(\mathfrak{sl}_2)$ and a substantial body of representation theory around it. Concretely, this chapter presents:

1. the **universal affine VOA** $V^k(\mathfrak{sl}_2)$ at every non-critical level $k \neq -2$, with the **Sugawara conformal vector** and central charge $c = 3k/(k+2)$, as a genuine instance of the library's `VertexOperatorAlgebra` structure (`AffineVOA.affineSl2VOA_closed`, Section 9.4);
2. the **Wakimoto free-field realisation** of $\widehat{\mathfrak{sl}}_2$ on a $\beta\gamma$ system tensored with a free boson, built as an honest Lie-algebra representation on a polynomial ring (`Wak.wakRho`, Section 9.6);
3. the **Poincaré–Birkhoff–Witt basis** of $V^k(\mathfrak{sl}_2)$ at every non-critical level, proved without `VOA.pbw` (then an axiom; it is now a theorem, and its corollary `pbwBasis_holds` gives the PBW basis for every $\mathfrak{g}$ and every level, Chapter 3), by a leading-term argument in the Wakimoto realisation (`AffineSl2WakimotoLiLeading.affineSl2PBWBasis`, Section 9.7);
4. explicit **singular vectors** of $V^k(\mathfrak{sl}_2)$ at the admissible levels $k = -4/3$ (weight 3) and $k = -8/5$ (weight 5), each with the theorem that *the level is forced*, their nonvanishing via the Wakimoto realisation, and their C_2 symbols (powers of the Casimir); and, checked in Lean for this chapter outside the library, the integrable-level vector $e_{-1}^{N+1}|0\rangle$ (Section 9.8);
5. the theorem that $V^{-8/5}(\mathfrak{sl}_2)$ **is not simple** (`Sl2NotSimple85.not_isSimple_85`), i.e. that $L_{-8/5}(\mathfrak{sl}_2)$ is a proper quotient, `pbw`-free (Section 9.9);

6. **Verma modules** $M(k,\lambda)$ of $\widehat{\mathfrak{sl}}_2$ at every pair of complex parameters, their PBW bases, their contravariant (Shapovalov) forms, **screening** constructions of singular vectors, and the full **Kac–Kazhdan determinant formula** for $\widehat{\mathfrak{sl}}_2$ at every complex level, including its vacuum specialisation used in Chapter 10 (Sections 9.10–9.12).

What the machine verified

Trust summary (details in Section 9.15). `#print axioms` was run for this chapter on 96 headline declarations with `lake env lean -DmaxSynthPendingDepth=3` against the built tree. Every result listed above reports exactly `[propext, Classical.choice, Quot.sound]`: the closed VOA, the Wakimoto representation, the PBW basis, the singular vectors and their nonvanishing, non-simplicity at $k=-8/5$, the Verma and Kac-determinant theorems. At the snapshot, `VOA.pbw` (then an axiom) appeared in exactly the declarations that use the lemma `AffineVOA.vacuumA_ne_zero` (a restatement of `AffineLie.vacuumVector_ne_zero`, i.e. the field `affineVacuum` of `VOA.pbw`): that lemma itself, `AffineVOA.Inst.closed_vacuum_ne_zero` and `voaSl2Adm_vacuum_ne_zero`, the independence lemmas of `VOA/Examples/AffineSl2Indep.lean`, and `Wak.M_indep_sing` which uses one of them. Each of these has a `pbw`-free replacement elsewhere in the chapter. In a later run, after `VOA.pbw` became a theorem (not re-run for this edition), all of them reported the three standard axioms only (re-probed: `vacuumA_ne_zero`, `closed_vacuum_ne_zero`, `voaSl2Adm_vacuum_ne_zero`, `Sl2Indep.Q_indep`, `indep_iff_sl2Singular_ne_zero`, `Wak.M_indep_sing`), because `VOA.pbw` is a theorem. The affine $\mathfrak{sl}_2$ files use it only through `vacuumVector_ne_zero`.

How to read this chapter. Every definition and theorem is presented as in the rest of the book: mathematical statement, the Lean source (with its file), a box *From the mathematics to the Lean statement* that decodes it and checks it against the intended statement, a *Physical meaning* box, a proof on paper, and a *What the machine verified* box. The files contain several thousand declarations; we present every definition on which a headline depends and the headline theorems, and summarise the supporting infrastructure in Section 9.13. Prerequisites: vertex algebras, modes, fields and locality (Chapters 2 and 4); the affine Kac–Moody algebra, its vacuum module, the PBW theorem `VOA.pbw` and `PBWBasis` (now proved by `pbwBasis_holds`) (Chapter 3); reconstruction (Chapter 4); ideals, maximal quotients, invariant forms and singular vectors (Chapter 5). Chapter 10 (rigidity) builds on this one and recalls some of its definitions.

A physicist's preview. The $SU(2)$ WZW model at level k has three holomorphic currents $J^a(z)$, $a\in\{e,f,h\}$, with operator product expansion

$$J^a(z)\,J^b(w)\sim\frac{k\,\kappa(a,b)}{(z-w)^2}+\frac{\sum_c f^{ab}{}_c\,J^c(w)}{z-w}, \tag{9.1}$$

where $f^{ab}{}_c$ are the structure constants of $\mathfrak{sl}_2$ and κ its normalised Killing form. The double pole is a *Schwinger term*; its coefficient is the level. In modes $J^a(z)=\sum_n J^a_n z^{-n-1}$ the OPE is the affine bracket

$$[J^a_m,J^b_n]=\sum_c f^{ab}{}_c\,J^c_{m+n}+m\,k\,\kappa(a,b)\,\delta_{m+n,0}. \tag{9.2}$$

The stress tensor is quadratic in the currents (Sugawara): $T(z)=\frac{1}{2(k+2)}\sum_{a,b}\kappa^{ab}(J^aJ^b)(z)$, with central charge $c=3k/(k+2)$; the denominator $k+h^\vee=k+2$ shows that at the *critical level* $k=-2$ there is no stress tensor. At non-negative integer k the theory is unitary and rational; its chiral algebra is $L_k(\mathfrak{sl}_2)$, obtained from $V^k(\mathfrak{sl}_2)$ by setting the null state $(J^e_{-1})^{k+1}|0\rangle$ to zero, which truncates the allowed spins to $0,\frac12,\dots,\frac{k}{2}$ (the *fusion rules*). At the *admissible* fractional levels of Kac–Wakimoto (such as $k=-4/3$ and $k=-8/5$) there are null vectors too, at higher weight.

Wakimoto discovered that all of this can be written in terms of free fields: a bosonic ghost pair β, γ and one free boson ϕ; null vectors are then produced by *screening operators*, contour integrals of free-field currents that commute with $\widehat{\mathfrak{sl}}_2$. The library formalises each of these physical statements as a theorem; the chapter explains which, in what form, and with what status.

9.1 The current algebra on the vacuum module

9.1.1 The Lie algebra $\mathfrak{sl}_2$ in coordinates

Definition 9.1 ($\mathfrak{sl}_2$, its structure constants and normalised Killing form)**.** $\mathfrak{sl}_2$ is the complex Lie algebra with basis e, f, h and brackets $[h,e] = 2e$, $[h,f] = -2f$, $[e,f] = h$. Writing $[x_a, x_b] = \sum_c f^{ab}{}_c\, x_c$ for $(x_0, x_1, x_2) = (e, f, h)$, the nonzero structure constants are $f^{he}{}_e = 2$, $f^{eh}{}_e = -2$, $f^{hf}{}_f = -2$, $f^{fh}{}_f = 2$, $f^{ef}{}_h = 1$, $f^{fe}{}_h = -1$. The *normalised Killing form* is the symmetric invariant form with $\kappa(e,f) = \kappa(f,e) = 1$, $\kappa(h,h) = 2$ and all other basis pairings zero; it equals the trace form $\mathrm{tr}(xy)$ in the defining representation and $\frac{1}{4}$ of the Killing form $\mathrm{tr}(\mathrm{ad}\, x\ \mathrm{ad}\, y)$.

  vacuumRho kappaForm kappaForm_isInvariant k (ofLoop kappaForm kappaForm_isInvariant
  ↪ (basis a) m)
```

From the mathematics to the Lean statement

The Lie algebra. `Sl2 := Fin 3 → ℂ` is $\mathbb{C}^3$ with coordinates indexed by `Fin 3` $= \{0,1,2\}$, read as (e,f,h); `basis a` is the a-th standard basis vector (`Pi.single a 1`). The bracket is defined (instance `Bracket Sl2 Sl2`, not displayed) by `⁅x, y⁆c = brComp x y c` $= \sum_{a,b} x_a y_b f^{ab}{}_c$, and the file proves the Lie axioms (`lie_self_sl2`, `leibniz_lie_sl2`) by a finite case analysis, producing Mathlib instances `LieRing Sl2`, `LieAlgebra ℂ Sl2`. The table `fabc` is exactly the list in Definition 9.1 (the comments in the source spell out each line). `kappaForm` (not displayed; it is the bilinear form $\kappa(x,y) = \sum_{a,b} x_a y_b$ `kappa a b`) is proved symmetric and invariant, $\kappa([x,y],z) = \kappa(x,[y,z])$, as `kappaForm_isInvariant`.

The affine algebra and the vacuum module. `AffineLie 𝔤 κ hκ` is the affine Kac–Moody algebra $\hat{\mathfrak{g}} = \mathfrak{g}\otimes\mathbb{C}[t,t^{-1}]\oplus\mathbb{C}C\oplus\mathbb{C}\ell_0$ of Chapter 3 (Definition 3.6); `ofLoop κ hκ x m` is $x\otimes t^m$. `vacuumSpace κ hκ k` is the vacuum module $V^k(\mathfrak{g}) = U(\hat{\mathfrak{g}})/J(k)$, where the left ideal $J(k)$ is generated by $x\otimes t^n$ $(n\geq 0)$, $C-k$ and ℓ_0 (Definition 3.7), and `vacuumRho` is the action of $\hat{\mathfrak{g}}$ on it by left multiplication. So `J k a m` is the operator J^a_m by which $x_a\otimes t^m$ acts on $V^k(\mathfrak{sl}_2)$.

A misleading name. `WakModule k` is *not* a Wakimoto module. It is the universal vacuum module $V^k(\mathfrak{sl}_2)$; the name is historical. The Wakimoto (free-field) module is the polynomial ring `Wak.WakFock` of Section 9.6.

Same as the textbook? Yes. The only conventions to keep in mind are the colour labels $0,1,2 = e,f,h$ (`colE`, `colF`, `colH`) and the normalisation of κ, which fixes what "level k" means: with this κ, $k\in\mathbb{Z}_{\geq 0}$ are the integrable levels and the dual Coxeter number is $h^\vee = 2$, as in Kac's book and in Di Francesco–Mathieu–Sénéchal.

Physical meaning

e,f,h are the raising, lowering and Cartan generators of the complexified $SU(2)$ symmetry; $\frac{1}{2}h$ is the spin projection J^3, so a state of h-eigenvalue $2j$ has $J^3 = j$. The form κ is the normalisation in which the root α (the h-eigenvalue of e) has length squared 2. The vacuum module $V^k(\mathfrak{sl}_2)$ is the space of states generated from the vacuum by the current modes J^a_{-n}, $n\geq 1$, with no relation imposed beyond the current algebra itself — the "Verma module of the vacuum" of the WZW model.

What the machine verified

Definitions. `kappaForm_isInvariant`: `[propext, Classical.choice, Quot.sound]` (run for this chapter).

9.1.2 The affine commutator

Theorem 9.2 (The affine bracket on $V^k(\mathfrak{sl}_2)$). *For every $k\in\mathbb{C}$, all colours a,b and all $m,n\in\mathbb{Z}$, as operators on $V^k(\mathfrak{sl}_2)$,*

$$J^a_m J^b_n - J^b_n J^a_m = \sum_c f^{ab}{}_c J^c_{m+n} + \delta_{m+n,0}\, m\, k\, \kappa(a,b)\,\mathrm{id}.$$

File `VOA/Examples/AffineSl2.lean`.

```
theorem current_comm (k : ℂ) (a b : Fin 3) (m n : ℤ) :
    J k a m * J k b n - J k b n * J k a m
      = (∑ c, fabc a b c • J k c (m + n))
        + (if m + n = 0 then ((m : ℂ) * k * kappa a b) • LinearMap.id else 0) := by
```

From the mathematics to the Lean statement

$*$ on `Module.End ℂ (WakModule k)` is composition, so the left side is the commutator $[J^a_m, J^b_n]$. $\bullet$ is scalar multiplication and `LinearMap.id` the identity. The central term carries the factor m of the *left* mode; for $[f_m, e_n]$ this gives $-h_{m+n} + m\,k\,\delta_{m+n,0}$, a convention the singular-vector files flag as the one place where a slip would flip a sign. The statement holds for *every* k, including the critical level; it is a statement about the module $U(\widehat{\mathfrak{sl}}_2)/J(k)$, which is nonzero (Section 9.2), so it is not vacuous.

Physical meaning

This is the mode form (9.2) of the current OPE (9.1): the first term is the classical Poisson bracket of $SU(2)$ charges, the second the quantum anomaly (Schwinger term) whose coefficient k is the level. In the WZW model on $SU(2)$, k is the integer coefficient of the Wess–Zumino term.

Proof on paper. `vacuumRho` is a Lie algebra homomorphism, so $[J^a_m, J^b_n]$ is the action of $[x_a \otimes t^m, x_b \otimes t^n] = [x_a, x_b] \otimes t^{m+n} + m\,\kappa(x_a, x_b)\delta_{m+n,0} C$ (the affine bracket of Chapter 3). Expand $[x_a, x_b] = \sum_c f^{ab}{}_c x_c$; and C acts on the vacuum module as k, because $C - k$ lies in the defining ideal and C is central. □

What the machine verified

`VOA.AffineVOA.current_comm: [propext, Classical.choice, Quot.sound]` (run for this chapter). Unconditional; `pbw`-free.

9.1.3 Current fields and locality

Definition 9.3 (Current field). $J^a(z) := \sum_{m\in\mathbb{Z}} J^a_m z^{-m-1}$, a formal distribution with coefficients in $\mathrm{End}\, V^k(\mathfrak{sl}_2)$.

File `VOA/Examples/AffineSl2.lean`.

```
noncomputable def Jfield (k : ℂ) (a : Fin 3) : FormalDist (Module.End ℂ (WakModule k)) :=
  fun j => J k a (-j - 1)

theorem Jfield_mode (k : ℂ) (a : Fin 3) (m : ℤ) : mode (Jfield k a) m = J k a m := by
```

From the mathematics to the Lean statement

A `FormalDist A` is a function $\mathbb{Z} \to A$ indexed by the *exponent of* z (Chapter 2, Definition 2.1); the library's mode convention is `mode f n = f (-n-1)` (Definition 2.7). Here the coefficient of z^j is J^a_{-j-1}, so the coefficient of z^{-m-1} is J^a_m, and `Jfield_mode` records `mode (Jfield k a) m` $= J^a_m$. This is the textbook field.

Physical meaning

$J^a(z)$ is the holomorphic current of the WZW model; J^a_m is its m-th Fourier mode on the cylinder. Modes with $m < 0$ create states, modes with $m > 0$ annihilate the vacuum.

What the machine verified

Definition; `Jfield_mode` is axiom-clean.

Theorem 9.4 (Mutual locality of the currents). *For all colours* a, b: $[J^a(z), J^b(w)] = \sum_c f^{ab}{}_c J^c(w)\,\delta(z/w) + k\,\kappa(a,b)\,\partial_w \delta(z/w)$, *and consequently* $(z-w)^2[J^a(z), J^b(w)] = 0$.

File `VOA/Examples/AffineSl2.lean`.

```
theorem bracketDist_Jfield_eq (k : ℂ) (a b : Fin 3) :
    bracketDist (Jfield k a) (Jfield k b)
      = deltaDeriv 0 (opeCoeff0 k a b) + deltaDeriv 1 (opeCoeff1 k a b) := by

theorem Jfield_self_local (k : ℂ) (a b : Fin 3) :
    mulBySubPow 2 (bracketDist (Jfield k a) (Jfield k b)) = 0 := by

theorem Jfield_local (k : ℂ) (a b : Fin 3) : Local (Jfield k a) (Jfield k b) :=
  ⟨2, Jfield_self_local k a b⟩
```

From the mathematics to the Lean statement

`bracketDist a b` is the two-variable distribution $[a(z), b(w)]$; `deltaDeriv j c` is $c(w)\,\partial_w^{(j)}\delta(z/w)$ in the divided-power normalisation; `mulBySubPow N` multiplies by $(z-w)^N$; `Local a b` says some power of $(z-w)$ kills the commutator (Chapter 2, Definition 2.41). `opeCoeff0 k a b` is the distribution $\sum_c f^{ab}{}_c J^c(w)$ and `opeCoeff1 k a b` the constant $k\,\kappa(a,b)$ id (defined in the same file). So the first theorem is the OPE (9.1) in its delta-function form, and `Jfield_local` is locality with order 2.

Physical meaning

The two terms are the simple and double poles of the current–current OPE. Locality of order two says the OPE has at most a double pole — currents have conformal weight one.

Proof on paper. Coefficientwise, the commutator of the z^m and w^n coefficients is the affine bracket of Theorem 9.2, which is the coefficient of $z^m w^n$ in the right side. $(z-w)\delta(z/w) = 0$ and $(z-w)^2\partial_w\delta(z/w) = 0$. □

What the machine verified

`VOA.AffineVOA.Jfield_local`: `[propext, Classical.choice, Quot.sound]` (run for this chapter).

9.2 The energy grading, the vacuum, and where the PBW theorem enters

Definition 9.5 (Energy grading of $V^k(\mathfrak{sl}_2)$). ℓ_0 acts on $V^k(\mathfrak{sl}_2)$ diagonalisably with eigenvalues $-d$, $d \in \mathbb{Z}_{\geq 0}$ (Chapter 3, Section 3.9). For $n \in \mathbb{Z}$ let V^k_n be the ℓ_0-eigenspace of eigenvalue $-n$: the states of *conformal weight* (energy) n. The vacuum is $|0\rangle$, the class of $1 \in U(\widehat{\mathfrak{sl}}_2)$.

File `VOA/Examples/AffineSl2VOA.lean`.

```

  Module.End.eigenspace (ell0OpA k) (-(n : ℂ))

noncomputable def vacuumA (k : ℂ) : WakModule k :=
  vacuumVector kappaForm kappaForm_isInvariant k

theorem gradingZA_isInternal (k : ℂ) : DirectSum.IsInternal (gradingZA k) :=
```

```
theorem gradingZA_finiteDimensional (k : ℂ) (n : ℤ) :
    FiniteDimensional ℂ (gradingZA k n) :=

theorem gradingZA_zero_eq_smul_vacuum (k : ℂ) :
    gradingZA k 0 = (ℂ • vacuumA k) :=

theorem gradingZA_positivity (k : ℂ) (n : ℤ) (hn : n < 0) : gradingZA k n = ⊥ := by
```

From the mathematics to the Lean statement

`Module.End.eigenspace T μ` is $\ker(T-\mu)$. The sign is deliberate: ℓ_0 is the *degree derivation*, $[\ell_0, x\otimes t^m] = m\,x\otimes t^m$, so a creation mode J^a_{-m} lowers the ℓ_0-eigenvalue by m; the energy is $-\ell_0$. `DirectSum.IsInternal` says $V^k = \bigoplus_n V^k_n$ (Mathlib's internal direct sum). `ℂ • v` is the line spanned by v; `⊥` is the zero subspace. So the four theorems say: the grading is a direct-sum decomposition with finite-dimensional pieces, $V^k_0 = \mathbb{C}|0\rangle$, and $V^k_n = 0$ for $n<0$ — the CFT-type conditions of Chapter 4 (Definition 4.4, (VOA4)). None of these needs $|0\rangle \neq 0$: if the module were zero they would hold trivially.

Physical meaning

V^k_n is the space of states of energy $L_0 = n$ in the vacuum sector; its dimension is the coefficient of q^n in the vacuum character $\prod_{m\geq 1}(1-q^m)^{-3}$ (for the universal algebra). Finite-dimensionality and boundedness below are what make the character a q-series.

What the machine verified

All four: `[propext, Classical.choice, Quot.sound]`; definitions axiom-free.

Theorem 9.6 (Nonvanishing of the vacuum, via `VOA.pbw`). *$|0\rangle \neq 0$ in $V^k(\mathfrak{sl}_2)$ for every $k \in \mathbb{C}$.*

File `VOA/Examples/AffineSl2VOA.lean`.

```
theorem vacuumA_ne_zero (k : ℂ) : vacuumA k ≠ 0 :=
  vacuumVector_ne_zero kappaForm kappaForm_isInvariant k
```

From the mathematics to the Lean statement

The proof term is the whole proof: it is the library lemma `AffineLie.vacuumVector_ne_zero` of Chapter 3 (Theorem 3.19), which in turn is *literally* the field `affineVacuum` of the theorem `VOA.pbw` (formerly a project axiom, now a theorem; proved by relative PBW, Chapter 3, Theorem 3.18). It is valid at every k, including $k=-2$.

Physical meaning

The universal current algebra has a vacuum. Physically obvious; mathematically, a quotient of $U(\widehat{\mathfrak{sl}}_2)$ by a left ideal could be zero, and ruling this out is the PBW theorem.

The zero module satisfies every VOA axiom

The library's `VertexOperatorAlgebra` structure (Chapter 4, Definition 4.4) has no field asserting $|0\rangle \neq 0$. On the zero vector space every axiom holds. A theorem about $V^k(\mathfrak{sl}_2)$ that silently relied on a degenerate carrier would be vacuous. Nonvanishing is therefore always a separate, explicit statement, and this chapter tracks which proof of it each result uses:

- `AffineVOA.vacuumA_ne_zero` (above) uses `VOA.pbw`;
- `Wak.vacuumA_ne_zero_free` (Theorem 9.21) proves the same for $k \neq -2$ from the Waki-

moto realisation, without `VOA.pbw`;

- `AffineSl2WakimotoLiLeading.affineSl2PBWBasis` (Theorem 9.25) gives a full basis for $k \neq -2$, again without `VOA.pbw`.

At the critical level $k = -2$ the library's proofs of $|0\rangle \neq 0$ are `vacuumA_ne_zero` (through the theorem `VOA.pbw`) and `pbwBasis_holds`.

What the machine verified

`VOA.AffineVOA.vacuumA_ne_zero`: `[propext, Classical.choice, Quot.sound, VOA.pbw]` (run for this chapter at the snapshot, when `VOA.pbw` was an axiom); re-probed at a later commit, after `VOA.pbw` became a theorem (not re-run for this edition): `[propext, Classical.choice, Quot.sound]`. Uses the theorem `VOA.pbw`.

Proposition 9.7 (Current modes shift the weight; regularity). *J^a_m maps V^k_n into V^k_{n-m}; hence $J^a_m v = 0$ when $v \in V^k_n$ and $m > n$, and for every state v there is B with $J^a_m v = 0$ for all $m \geq B$.*

File `VOA/Examples/AffineSl2VOA.lean`.

```
theorem J_mem_gradingZA (k : ℂ) (a : Fin 3) (m n : ℤ) {v : WakModule k}
    (hv : v ∈ gradingZA k n) : J k a m v ∈ gradingZA k (n - m) := by

theorem J_gradingZA_eq_zero (k : ℂ) (a : Fin 3) {m n : ℤ} (hmn : n < m) {v : WakModule k}
    (hv : v ∈ gradingZA k n) : J k a m v = 0 := by
```

From the mathematics to the Lean statement

Exactly as stated. The second follows from the first and `gradingZA_positivity`. The arbitrary-state version is `J_regularity` in the same file, which makes `Jfield k a` a *field* in the sense of Chapter 2 (Definition 2.43): applied to any state, only finitely many negative powers of z survive.

Physical meaning

J^a_m carries energy $-m$: annihilation modes lower the energy, and nothing has negative energy.

Proof on paper. $[\ell_0, J^a_m] = mJ^a_m$; if $\ell_0 v = -nv$ then $\ell_0 J^a_m v = (m-n)J^a_m v$. □

What the machine verified

Both: `[propext, Classical.choice, Quot.sound]`.

9.3 The Sugawara construction

9.3.1 The Sugawara field and the central charge

Definition 9.8 (Sugawara field, Virasoro modes, conformal vector, central charge). Let κ^{ab} be the inverse matrix of κ: $\kappa^{ef} = \kappa^{fe} = 1, \kappa^{hh} = \frac{1}{2}$. For $k \neq -2$ the *Sugawara field* is

$$T(z) = \frac{1}{2(k+h^\vee)} \sum_{a,b} \kappa^{ab} :J^a(z)J^b(z): = \frac{1}{2(k+2)}\Big(:J^eJ^f: + :J^fJ^e: + \frac{1}{2}:J^hJ^h:\Big)(z), \tag{9.3}$$

with $h^\vee = 2$ the dual Coxeter number of $\mathfrak{sl}_2$. Its modes are L_n, $T(z) = \sum_n L_n z^{-n-2}$. The conformal vector is $\omega = L_{-2}|0\rangle$, and the central charge is $c(k) = \dfrac{k \dim \mathfrak{sl}_2}{k+h^\vee} = \dfrac{3k}{k+2}$.

File `VOA/Examples/AffineSl2VOA.lean`.

```
noncomputable def kappaInv : Fin 3 → Fin 3 → ℂ

noncomputable def omegaA (k : ℂ) : WakModule k := Lsug k (-2) (vacuumA k)

noncomputable def centralChargeA (k : ℂ) : ℂ := dimSl2 * k / (k + dualCoxeter)

theorem centralChargeA_eq (k : ℂ) : centralChargeA k = 3 * k / (k + 2) := by
```

From the mathematics to the Lean statement

`nprod ha hb` is the normally ordered product $:a(z)b(z):$ of two fields (Chapter 4; it needs the witnesses `Jfield_isField` that the currents are fields, Proposition 9.7). `kappaInv` is the inverse of the matrix `kappa` (`kappaInv_kappa` proves $\sum_b \kappa(a,b)\kappa^{bc} = \delta_{ac}$). The prefactor `(2 * (k + dualCoxeter))⁻¹` is $1/(2(k+2))$.

Mode indices. T has conformal weight 2, so L_n is the coefficient of z^{-n-2}, which in the library's convention is `mode T (n + 1)`: indeed `mode T (n+1)` is the coefficient of $z^{-(n+1)-1}$. Hence `Lsug k n` $= L_n$ and `omegaA k` $= L_{-2}|0\rangle$, the state $\omega = \frac{1}{2(k+2)}\sum_{a,b}\kappa^{ab}J^a_{-1}J^b_{-1}|0\rangle$ (proved as `omegaA_creation_form` in `VOA/Examples/AffineSl2Virasoro.lean`).

The critical level. In Lean, $0^{-1} = 0$. At $k = -2$ the definition therefore does *not* fail; it silently produces $T = 0$. Every theorem below about T carries the hypothesis `hk : k + 2 ≠ 0`, and at $k = -2$ the Sugawara identities are false for this T (see the warning after Theorem 9.9). `centralChargeA_eq` holds for all k in the same convention (both sides are 0 at $k = -2$).

Physical meaning

Equation (9.3) is the Sugawara stress tensor of the WZW model. The shift $k \mapsto k + h^\vee$ in the denominator is a quantum effect: classically one would write $1/(2k)$; the normal ordering of the double pole of J^aJ^b produces the Casimir of the adjoint representation, $2h^\vee$, which renormalises it. For $k \in \mathbb{Z}_{\geq 0}$ one gets $c = 0, 1, \frac{3}{2}, \frac{9}{5}, 2, \ldots$; $c = 1$ at $k = 1$ is the $SU(2)_1$ theory of a free boson at the self-dual radius. At $k = -4/3$, $c = -6$; at $k = -8/5$, $c = -12$.

What the machine verified

Definitions. `centralChargeA_eq`: `[propext, Classical.choice, Quot.sound]`.

9.3.2 The Sugawara operators act as derivations on the currents

Theorem 9.9 (Translation covariance of the currents). *Let $k \neq -2$. Then $[L_{-1}, J^c_\mu] = -\mu\, J^c_{\mu-1}$ for every colour c and $\mu \in \mathbb{Z}$. Equivalently, $[L_{-1}, J^c(z)] = \partial_z J^c(z)$.*

```
def DCovariant (T : End ℂ V) (a : FormalDist (End ℂ V)) : Prop :=
  ∀ m : ℤ, T * a m - a m * T = ((m + 1 : ℤ)) • a (m + 1)
```

From the mathematics to the Lean statement

`Ltrans k` $= L_{-1}$. `DCovariant T a` says $[T, a_m] = (m+1)a_{m+1}$ for the coefficient a_m of z^m; since $\partial_z \sum_m a_m z^m = \sum_m (m+1) a_{m+1} z^m$, this is $[T, a(z)] = \partial_z a(z)$ (Chapter 4, Definition 4.38). With $a = J^c$ and $a_m = J^c_{-m-1}$ it is $[L_{-1}, J^c_{-m-1}] = (m+1) J^c_{-m-2}$, i.e. `Lcomm_current` with $\mu = -m-1$. The hypothesis $k + 2 \neq 0$ is necessary, see the warning.

Physical meaning

L_{-1} generates translations $z \mapsto z + \epsilon$; the theorem says the currents transform as fields under translation. Together with Theorem 9.10 below it says $J^a(z)$ is a primary field of conformal weight one with respect to the Sugawara stress tensor — the defining property of the WZW currents, and the reason the Sugawara T is "the" stress tensor.

Proof on paper. Write $L_{-1} = \frac{1}{2(k+2)} \sum_{a,b} \kappa^{ab} \sum_p {:}J^a_{-1-p} J^b_p{:}$ and compute $[L_{-1}, J^c_\mu]$ with the Leibniz rule and Theorem 9.2. Two contributions arise. The *central* terms give $2\mu k\, J^c_{\mu-1}$ (each of the two factors of the quadratic contributes $\mu k \kappa(\cdot, c)$, contracted with κ^{ab}). The *structure-constant* terms give $\sum_{a,b} \kappa^{ab} f^{\cdot\cdot}{}_{\cdot}$-contractions; naively they cancel by antisymmetry of f against symmetry of κ^{ab}, but normal ordering spoils the cancellation on a finite "band" of μ modes, and re-ordering those produces the quadratic Casimir of the adjoint representation, $\sum_{a,b,d} \kappa^{ab} f^{ad}{}_e f^{bc}{}_d$-type contraction $= 2h^\vee = 4$, times $\mu J^c_{\mu-1}$. Altogether $[\sum \kappa^{ab} {:}J^a J^b{:}_{-1}, J^c_\mu] = -2\mu(k+2) J^c_{\mu-1}$, and the prefactor $\frac{1}{2(k+2)}$ gives $-\mu J^c_{\mu-1}$. (The source calls the band computation the *flip-band telescoping*; it lives in `VOA/Examples/AffineSl2CurrentCovStruct.lean`.) □

The critical level

The file `AffineSl2CurrentCov.lean` records that the covariance identity is *false* at $k = -2$ (checked independently in Mathematica on 168 cases, per the source): there the prefactor is $(2 \cdot 0)^{-1} = 0$ in Lean, so $L_{-1} = 0$, while $-\mu J^c_{\mu-1} \neq 0$. This is the formal shadow of the physical fact that at the critical level the Sugawara vector is *central* (it commutes with all currents) rather than a stress tensor. The hypothesis `hk` is therefore not a convenience; it is the correct hypothesis.

What the machine verified

`VOA.AffineVOA.SugawaraCov.Lcomm_current`, `VOA.AffineVOA.SugawaraCov.Jfield_DCovariant`: `[propext, Classical.choice, Quot.sound]` (run for this chapter). Unconditional for $k \neq -2$.

Theorem 9.10 (The Sugawara L_0 is the energy). *Let $k \neq -2$. Then $L_0 = -\ell_0$ on $V^k(\mathfrak{sl}_2)$; equivalently $L_0 v = nv$ for $v \in V^k_n$.*

File `VOA/Examples/AffineSl2L0Cov.lean`.

```
theorem Lsug0_comm_current (k : ℂ) (hk : k + 2 ≠ 0) (c : Fin 3) (μ : ℤ) (x : WakModule k) :
    (Lsug k 0 * J k c μ - J k c μ * Lsug k 0) x = ((-μ : ℤ) : ℂ) • J k c μ x := by

theorem Lsug0_eq_negEll0OpA (k : ℂ) (hk : k + 2 ≠ 0) : Lsug k 0 = -ell0OpA k := by

theorem hYA_L0 (k : ℂ) (hk : k + 2 ≠ 0) {n : ℤ} (v : WakModule k) (hv : v ∈ gradingZA k n)
  ↪ :
    mode (YA k hk (omegaA k)) 1 v = (n : ℂ) • v := by
```

From the mathematics to the Lean statement

`Lsug0_comm_current` is $[L_0, J^c_\mu] = -\mu J^c_\mu$: the currents have weight one. `Lsug0_eq_negEll0OpA` is the operator identity $L_0 = -\ell_0$. `hYA_L0` is the form consumed by the VOA axiom (VOA2): `YA k hk` is the vertex map of Section 9.4, and `mode (YA k hk (omegaA k)) 1` $= \omega_{(1)} = L_0$ (the file proves `YA k hk (omegaA k)` is the Sugawara field).

Physical meaning

The Sugawara L_0 counts energy: the stress tensor built from the currents generates the same time translations as the grading by mode number. This is why the WZW Hamiltonian is quadratic in the currents.

Proof on paper. The same computation as Theorem 9.9, for the mode L_0, gives $[L_0, J^c_\mu] = -\mu J^c_\mu$ (the central contribution is $2\mu k$, the Casimir contribution 4μ, total $2\mu(k+2)$, divided by $2(k+2)$). $L_0|0\rangle = 0$ since every term of L_0 has an annihilation mode on the right after normal ordering. The creation monomials $J^{a_1}_{-n_1} \cdots J^{a_r}_{-n_r}|0\rangle$ span V^k (Chapter 3, Theorem 3.8); on them both L_0 and $-\ell_0$ act by $\sum n_i$, by induction on r. □

What the machine verified

All three: `[propext, Classical.choice, Quot.sound]`; unconditional for $k \neq -2$.

9.4 The universal affine VOA $V^k(\mathfrak{sl}_2)$

9.4.1 Reconstruction of the vertex map

A VOA needs a vertex operator $Y(v,z)$ for *every* state v, not just for the currents. The textbook construction (reconstruction theorem; Chapter 4, Theorem 4.41) assigns to the creation monomial $J^{a_1}_{-i_1-1} \cdots J^{a_r}_{-i_r-1}|0\rangle$ the iterated normal-ordered product $:\partial^{(i_1)}J^{a_1}(z) \cdots \partial^{(i_r)}J^{a_r}(z):$, where $\partial^{(i)} = \partial^i/i!$. The difficulty is well-definedness: monomials are not linearly independent (they satisfy the affine relations), so the assignment must respect relations. The library's reconstruction theorem needs only that the monomials *span* and that the candidate fields are mutually local and translation-covariant; well-definedness then follows from Goddard's uniqueness theorem.

Definition 9.11 (Creation words and their fields). For a list $\ell = [(a_1, i_1), \dots, (a_r, i_r)]$ of colours and depths, the *word state* is $J^{a_1}_{-i_1-1} \cdots J^{a_r}_{-i_r-1}|0\rangle$ and the *word field* is $:\partial^{(i_1)}J^{a_1}(z)\cdots:\partial^{(i_r)}J^{a_r}(z)\,\mathrm{id}:\cdots:$ (right-nested normal ordering, ending with the identity field).

File `VOA/Examples/AffineSl2VOA.lean`.

```
noncomputable def wordStateA (k : ℂ) : List (Fin 3 × ℕ) → WakModule k
  | [] => vacuumA k
  | (ai :: rest) => J k ai.1 (-(ai.2 : ℤ) - 1) (wordStateA k rest)

noncomputable def YwordA (k : ℂ) (l : List (Fin 3 × ℕ)) :
    FormalDist (End ℂ (WakModule k)) := (YwordAF k l).1
```

From the mathematics to the Lean statement

A pair `(a, i)` stands for the creation mode J^a_{-i-1}; the head of the list is the leftmost (outermost) operator. `YwordAF` (same file, not displayed) builds the right-nested normal-ordered product of the scaled derivatives `genFieldA k a i` $= \frac{1}{i!}\partial_z^i J^a(z)$, starting from the identity field `idFieldA`, together with a proof that the result is a field; `YwordA` forgets the proof.

Physical meaning

State–field correspondence: the state $J^a_{-i-1}|0\rangle$ corresponds to the field $\frac{1}{i!}\partial^i J^a(z)$, and products of creation modes correspond to normal-ordered products of fields.

What the machine verified

Definitions; axiom-free.

Theorem 9.12 (Existence of the vertex map). *Let $k \neq -2$. There is a linear map $Y : V^k(\mathfrak{sl}_2) \to \mathrm{End}(V^k(\mathfrak{sl}_2))[[z^{\pm1}]]$ such that $Y(\text{word state}) = \text{word field}$ for every word; every $Y(u,z)$ is a field; all $Y(u,z)$ are mutually local; $Y(u,z)|0\rangle = u + O(z)$ (creation); and $[L_{-1}, Y(u,z)] = \partial_z Y(u,z)$.*

File `VOA/Examples/AffineSl2Reconstruction.lean`.

```
theorem affineYA_of_currentCov (k : ℂ)
    (hJ : ∀ a : Fin 3, Reconstruction.DCovariant (Ltrans k) (Jfield k a)) :
    ∃ YA : WakModule k →ₗ[ℂ] FormalDist (End ℂ (WakModule k)),

      (∀ u : WakModule k, Reconstruction.DCovariant (Ltrans k) (YA u)) :=
```

File `VOA/Examples/AffineSl2Assembly.lean`.

```
noncomputable def YAspec (k : ℂ) (hk : k + 2 ≠ 0) :=
  affineYA_of_currentCov k (fun a => SugawaraCov.Jfield_DCovariant k hk a)

noncomputable def YA (k : ℂ) (hk : k + 2 ≠ 0) :
    WakModule k →ₗ[ℂ] FormalDist (End ℂ (WakModule k)) :=
  (YAspec k hk).choose
```

From the mathematics to the Lean statement

`→ₗ[ℂ]` is a $\mathbb{C}$-linear map. `(YA u) 0 (vacuumA k) = u` reads: the coefficient of z^0 of $Y(u,z)|0\rangle$ is u; `(YA u) q (vacuumA k) = 0` for $q < 0$: no negative powers. Together this is the creation axiom $Y(u,z)|0\rangle \in u + zV[[z]]$. The hypothesis `hJ` of `affineYA_of_currentCov` is exactly the covariance of Theorem 9.9, which `YAspec` supplies for $k \neq -2$; so `YA k hk` is unconditional. `.choose` picks the witness (it is unique by Goddard uniqueness, though uniqueness is not needed). The file `AffineSl2Reconstruction.lean` is assigned to Chapter 10 but its single theorem is quoted here because the construction depends on it; its proof is one application of the generic `Reconstruction.reconstruct` of Chapter 4, fed with spanning (`wordStateA_span`), locality (Dong's lemma applied to Theorem 9.4) and the vacuum properties.

Physical meaning

Every state of the WZW vacuum sector has a local field, and all these fields are mutually local: the chiral algebra is closed under OPE.

Proof on paper. This is the reconstruction theorem (Kac, *Vertex algebras for beginners*, Thm. 4.5): a cyclic module spanned by monomials in the modes of mutually local, translation-covariant fields that create the generating states from the vacuum carries a unique vertex algebra structure with those fields. Well-definedness: if a linear combination of word states vanishes, the corresponding combination of word fields is a translation-covariant field that annihilates the vacuum at z^0, hence is zero by Goddard uniqueness. □

What the machine verified

`VOA.AffineVOA.affineYA_of_currentCov`, `VOA.AffineVOA.YA`: `[propext, Classical.choice, Quot.sound]` (run for this chapter).

9.4.2 The Virasoro relations and the closed instance

Theorem 9.13 (Currents are primary; the Sugawara Virasoro algebra). *Let $k \neq -2$ and $L_n = \omega_{(n+1)}$ for the vertex map of Theorem 9.12. Then $L_1 J^c_{-1}|0\rangle = 0$ for every colour c, and*

$$[L_m, L_n] = (m-n)L_{m+n} + \delta_{m+n,0}\frac{m^3-m}{12}\,c(k), \qquad c(k) = \frac{3k}{k+2}.$$

File `VOA/Examples/AffineSl2Virasoro.lean`.

```
theorem current_primary (k : ℂ) (hk : k + 2 ≠ 0) (c : Fin 3) :
    mode (YA k hk (omegaA k)) 2 (J k c (-1) (vacuumA k)) = 0 := by

theorem hYA_virasoro (k : ℂ) (hk : k + 2 ≠ 0) (m n : ℤ) :
    ⁅mode (YA k hk (omegaA k)) (m + 1), mode (YA k hk (omegaA k)) (n + 1)⁆
      = ((m : ℂ) - n) • mode (YA k hk (omegaA k)) (m + n + 1)
        + (if m + n = 0 then
            (((m : ℂ) ^ 3 - m) / 12 * centralChargeA k) • (1 : End ℂ (WakModule k))
           else 0) := by
```

From the mathematics to the Lean statement

`mode (YA k hk (omegaA k)) (m + 1)` is $\omega_{(m+1)} = L_m$; `⁅·,·⁆` is the commutator of endomorphisms. The statement is *verbatim* the field `virasoro` of the library's `VertexOperatorAlgebra` structure (Definition 4.4), with `centralChargeA k` $= 3k/(k+2)$. `current_primary` is $L_1 J^c_{-1}|0\rangle = 0$ (mode index 2 is $\omega_{(2)} = L_1$).

Physical meaning

The stress tensor built from the currents satisfies the Virasoro algebra with the WZW central charge $c = k\dim\mathfrak{g}/(k+h^\vee)$. For $k\to\infty$, $c\to 3$: three free bosons (the semiclassical limit of the sigma model on S^3).

Proof on paper. By the Borcherds commutator formula (Chapter 4, Theorem 4.21), $[L_m,L_n]=\sum_{j\ge 0}\binom{m+1}{j}(\omega_{(j)}\omega)_{(m+n+2-j)}$, and $\omega_{(j)}\omega$ has weight $3-j$, so only $j\le 3$ contribute. One computes the four OPE coefficients: $\omega_{(0)}\omega=L_{-1}\omega$ (translation), $\omega_{(1)}\omega=2\omega$ (Theorem 9.10), $\omega_{(2)}\omega=0$, and $\omega_{(3)}\omega=\frac{c}{2}|0\rangle$. For the last two, write $\omega=\frac{1}{2(k+2)}\sum\kappa^{ab}J^a_{-1}J^b_{-1}|0\rangle$ and use that the currents are primary of weight one ($[L_m,J^c_\mu]=-\mu J^c_{m+\mu}$, derived from L_{-1}-covariance, L_0-grading and $L_1J^c_{-1}|0\rangle=0$): $L_2(J^a_{-1}J^b_{-1}|0\rangle)=k\kappa(a,b)|0\rangle$, so $\omega_{(3)}\omega=L_2\omega=\frac{k}{2(k+2)}\sum_{a,b}\kappa^{ab}\kappa(a,b)|0\rangle=\frac{3k}{2(k+2)}|0\rangle$; and $L_1(J^a_{-1}J^b_{-1}|0\rangle)=\sum_d f^{ab}{}_dJ^d_{-1}|0\rangle$, which is killed by the symmetric contraction with κ^{ab}. Substituting gives the Virasoro relation. □

What the machine verified

`VOA.AffineVOA.Vir.current_primary`, `VOA.AffineVOA.Vir.hYA_virasoro`: `[propext, Classical.choice, Quot.sound]` (run for this chapter).

Definition 9.14 (The universal affine VOA $V^k(\mathfrak{sl}_2)$). For $k\neq -2$, $V^k(\mathfrak{sl}_2)$ is the vertex operator algebra on the vacuum module with grading V^k_n, vacuum $|0\rangle$, vertex map Y of Theorem 9.12, conformal vector ω and central charge $3k/(k+2)$.

File `VOA/Examples/AffineSl2VOA.lean`.

```

From the mathematics to the Lean statement

The shell and the closed instance. `affineSl2VOA` (only its first hypotheses are shown; the remaining ones are `hYA_virasoro`, `hYA_L0`, `hYA_translation`, of exactly the shape of the corresponding `VertexOperatorAlgebra` fields) is a *constructor*: given a vertex map and proofs of the nine Y-dependent axioms, it fills in every other field with the proved data of Section 9.2 (grading, finite dimensionality, vacuum, $V_0 = \mathbb{C}|0\rangle$, positivity, conformal vector `omegaA k`, central charge `centralChargeA k`). The closed instance `affineSl2VOA_closed k hk` supplies all nine hypotheses with proved theorems; there is *no* remaining hypothesis except $k + 2 \neq 0$. The hypothesis `_hk` of the shell is unused in its body (hence the underscore); it is used by the proofs fed to it.

Is it the textbook $V^k(\mathfrak{sl}_2)$? The carrier is $U(\widehat{\mathfrak{sl}}_2)/J(k)$, the vacuum is the class of 1, the grading is by $-\ell_0$, the conformal vector is the Sugawara vector, and $Y(J^a_{-1}|0\rangle, z) = J^a(z)$ (Theorem 9.15 below). By the uniqueness part of reconstruction there is only one vertex algebra structure on this module with these generating fields, so this is Frenkel–Zhu's $V^k(\mathfrak{sl}_2)$ (often written $V_k(\mathfrak{g})$ or $N_{\mathfrak{g}}(k, 0)$).

The Affine.lean theorem. `affineSl2VOA_centralCharge` in `VOA/Examples/Affine.lean` (namespace `VOA`) restates `centralChargeA_eq`; the module docstring of that file is *stale* (it still describes the reconstruction as missing and the vacuum as pbw-dependent), see Section 9.14.

Physical meaning

$V^k(\mathfrak{sl}_2)$ is the chiral algebra of the $SU(2)$ WZW model *before* null vectors are removed: it is consistent as an algebra of local fields at every non-critical level, but at special levels (integrable, admissible) it is reducible, and the physical theory uses its simple quotient.

What the machine verified

`VOA.AffineVOA.affineSl2VOA_closed`, `VOA.AffineVOA.affineSl2VOA_closed_central_charge`, `VOA.affineSl2VOA_centralCharge`: `[propext, Classical.choice, Quot.sound]` (run for this chapter). **The closed VOA does not use `VOA.pbw`.** (An older docstring claimed it did; the source records the correction of 22 August 2026, and the audit above confirms it.)

9.4.3 Non-degeneracy checks

Because the zero module satisfies every axiom, a referee should ask whether the closed instance could be degenerate in some other way — for instance a vertex map that collapses states. The library answers this directly.

Theorem 9.15 (The vertex map is faithful and restricts to the currents). *Let $k \neq -2$. (i) Y is injective. (ii) $Y(|0\rangle, z) = \mathrm{id}$ and $Y(J^a_{-1}|0\rangle, z) = J^a(z)$; hence $(J^a_{-1}|0\rangle)_{(n)} = J^a_n$. (iii) The VOA modes of the current states satisfy the affine bracket.*

File `VOA/Examples/AffineSl2VOAInstance.lean`.

```

        ((affineSl2VOA_closed k hk).smul (currentState k a) m v)
      = (∑ c, fabc a b c • J k c (m + n) v)
        + (if m + n = 0 then ((m : ℂ) * k * kappa a b) • v else 0) := by
```

From the mathematics to the Lean statement

The file works under `variable (k : ℂ) (hk : k + 2 ≠ 0)`. `W.smul u n v` is $u_{(n)}v$ (Chapter 4). (i) holds because u is recovered from $Y(u,z)$ as the z^0 coefficient of $Y(u,z)|0\rangle$. (ii)–(iii) tie the abstract VOA structure back to the affine Lie algebra. The companion `closed_vacuum_ne_zero` (same file) is `vacuumA_ne_zero k` and therefore uses `VOA.pbw`; downstream results that need $|0\rangle \neq 0$ were written, while `VOA.pbw` was an axiom, to use a Wakimoto-side statement instead (they do; Sections 9.6–9.9).

Physical meaning

The state $J^a_{-1}|0\rangle$ corresponds to the field $J^a(z)$ — the most basic instance of the state–field correspondence in a current algebra; and the OPE of the corresponding fields reproduces the current algebra.

What the machine verified

All displayed: `[propext, Classical.choice, Quot.sound]` (run for this chapter). `VOA.AffineVOA.Inst.closed_vacuum_ne_zero: [propext, Classical.choice, Quot.sound, VOA.pbw]` at the snapshot, when `VOA.pbw` was an axiom; re-probed at a later commit, after `VOA.pbw` became a theorem (not re-run for this edition): `[propext, Classical.choice, Quot.sound]`. Uses the theorem `VOA.pbw`. The file also instantiates $k = -4/3$ as `voaSl2Adm` with `voaSl2Adm_centralCharge : voaSl2Adm.centralCharge = -6` (axiom-clean).

9.5 The simple quotient and the singular-vector bridge

The simple quotient is defined, for every VOA, as the quotient by the maximal proper graded ideal `QuotVOA.maxGradedIdeal` (Chapter 5). For $V^k(\mathfrak{sl}_2)$ the library's object is `AffineSl2GeneralRigidity.simple k hk := QuotVOA.maxQuotientVOA (affineSl2VOA_closed k hk)`, recalled with its Lean source in Chapter 10 (Definition 10.2). It is proved simple and nonzero for every $k \neq -2$ without `VOA.pbw`. The file `VOA/Examples/AffineSimpleQuotient.lean` of this chapter supplies the generic link between singular vectors and that maximal ideal.

Theorem 9.16 (Properness test and singular-vector bridge). *Let W be a VOA with $|0\rangle \neq 0$. (i) An ideal I is proper iff $|0\rangle \notin I$ iff $I \cap W_0 = 0$. (ii) If moreover $L_1 W_1 = 0$ and s is a strongly singular vector of some positive weight, then s lies in the maximal ideal, maps to 0 in the simple quotient, the maximal ideal is nonzero, and the quotient map $W \to W/\max$ is not injective.*

File `VOA/Examples/AffineSimpleQuotient.lean`.

```
theorem tfae_proper (hI : W.IsIdeal I) (hvac : W.vacuum ≠ 0) :

    (hs : IsStronglySingularOfWeight W k s) :
    ¬ Function.Injective (maxGradedIdeal W).mkQ := by
```

From the mathematics to the Lean statement

`IsStronglySingularOfWeight W k s` (Chapter 5, Definition 5.34) says $s \neq 0$, $k > 0$, $s \in W_k$, and $u_{(n)}s = 0$ for every $u \in W_m$ and $n \geq m$ (every mode that does not raise the weight kills s). `(maxGradedIdeal W).mkQ` is the quotient map onto the simple quotient. `hqp` ($L_1 W_1 = 0$) is needed to build the canonical invariant bilinear form whose radical is the maximal ideal (Li's theorem, Chapter 5, Theorem 5.57). `List.TFAE` says the listed propositions are pairwise equivalent; `⊤` is the whole space. All hypotheses are explicit and are discharged for $V^k(\mathfrak{sl}_2)$ in Section 9.9.

Physical meaning

A null state — one orthogonal to every state under the two-point function — is set to zero in the physical theory; the simple quotient is the chiral algebra with all null states removed. The theorem says that a highest-weight state of positive weight is null and is removed.

Proof on paper. (i) An ideal containing a nonzero vector of $W_0 = \mathbb{C}|0\rangle$ contains $|0\rangle$, and then $u = u_{(-1)}|0\rangle$ for all u. (ii) For strongly singular s, invariance of the canonical form moves every mode to the other side and lowers weight, so s pairs to zero with everything; it is in the radical, which is the maximal ideal (Li). □

What the machine verified

`VOA.SimpleQuot.mkQ_eq_zero_of_stronglySingular`, `VOA.SimpleQuot.maxQuotientVOA_vacuum_ne_zero`: `[propext, Classical.choice, Quot.sound]` (run for this chapter); the others in the block share the same proof route.

A documentation-only definition of $L_k(\mathfrak{sl}_2)$

The text of `VOA/Examples/AffineSimpleQuotient.lean` contains a section "§4 The recipe" with apparently Lean declarations `AffineSimple.affineSl2Simple`, `affineSl2Simple_isSimple`, `maxIdealAff`, ..., using `vacuumA_ne_zero`. **These are inside a docstring** (a Markdown code block in a `/-! ... -/` comment); they are not compiled, and no declaration named `affineSl2Simple` exists in the library (a search of all `VOA/` sources confirms it). A referee must not cite them. The compiled simple quotient is `AffineSl2GeneralRigidity.simple` (Chapter 10), whose nonvanishing is `AffineSl2BoundaryMaximalIdeal.affineSl2_vacuum_ne_zero`, derived from the Wakimoto PBW basis of Theorem 9.25. Had the recipe been compiled as written, it would have used `VOA.pbw` (at the time an axiom).

9.6 The Wakimoto free-field realisation

9.6.1 Why free fields

Every positive statement about $V^k(\mathfrak{sl}_2)$ — that a vector is nonzero, that some vectors are linearly independent — is hard to prove inside $U(\widehat{\mathfrak{sl}}_2)/J(k)$, because elements of a quotient are only known up to the ideal. Wakimoto's idea (1986), developed by Feigin and Frenkel, is to represent $\widehat{\mathfrak{sl}}_2$ on a *free* Fock space, where vectors are polynomials and nonvanishing can be read off coefficients. If a representation ρ on a Fock space $\mathcal{F}$ has a vector Ω satisfying the vacuum conditions, then $u|0\rangle \mapsto \rho(u)\Omega$ is a well-defined $\widehat{\mathfrak{sl}}_2$-map $V^k(\mathfrak{sl}_2) \to \mathcal{F}$, and any vector with nonzero image is nonzero. The library builds this map, and then pushes it all the way to a PBW basis.

9.6.2 The free fields

Definition 9.17 (The Wakimoto Fock space and the free-field modes)**.** Let $\mathcal{F} = \mathbb{C}[b_1, b_2, \dots ; c_0, c_1, \dots ; A_1, A_2, \dots]$, the polynomial ring in three infinite families of variables. Define operators

$$\beta_m = \begin{cases} b_{-m}\cdot & m \le -1, \\ \partial/\partial c_m & m \ge 0, \end{cases} \qquad \gamma_n = \begin{cases} c_{-n}\cdot & n \le 0, \\ -\partial/\partial b_n & n \ge 1, \end{cases}$$

$$a_m = \begin{cases} A_{-m}\cdot & m \le -1, \\ 2(k+2)\,m\,\partial/\partial A_m & m \ge 0. \end{cases}$$

Then $[\beta_m, \gamma_n] = \delta_{m+n,0}$, $[a_m, a_n] = 2(k+2)\,m\,\delta_{m+n,0}$, and all other brackets of free-field modes vanish. The Fock vacuum is the constant polynomial 1.

From the mathematics to the Lean statement

`MvPolynomial (Fin 3 × ℕ) ℂ` is the polynomial ring in variables `X (a, i)`: family $a = 0$ is b_{i+1}, family 1 is c_i, family 2 is A_{i+1} (note the shift by one in families 0 and 2, handled by `bV`, `aV`, which return 0 for out-of-range indices). `mulL Q` is multiplication by Q; `bD i`, `cD j`, `aD i` are the partial derivatives $\partial/\partial b_i$, $\partial/\partial c_j$, $\partial/\partial A_i$, extended by 0. So `Bet`, `Gam`, `Aos` are exactly β, γ, a of Definition 9.17 (including $a_0 = 0$: the boson has zero momentum on this module). The theorems are the canonical commutation relations.

Physical meaning

$\beta(z), \gamma(z)$ are a bosonic ghost system of weights $(1, 0)$ — equivalently, coordinates on the flag manifold $SL_2/B \supset \mathbb{C}$ and its conjugate momentum — and $a(z) = \sqrt{2(k+2)}\,\partial\phi(z)$ is a rescaled free boson. The rescaling removes all square roots, so every structure constant is a polynomial in k with integer coefficients. Note that γ_0 is a *creation* operator (multiplication by c_0): the Wakimoto vacuum is the module of polynomial functions on the big cell.

What the machine verified

`Bet_Gam_lie`, `Aos_Aos_lie`: `[propext, Classical.choice, Quot.sound]` (run for this chapter).

9.6.3 The Wakimoto currents

Definition 9.18 (Wakimoto currents). With normal-ordered composites $:\beta\gamma:_n$, $:\gamma\gamma:_n$, $:a\gamma:_n$, $:\beta\gamma\gamma:_n$ (creation modes to the left), set

$$e_n = \beta_n, \qquad h_n = -2:\beta\gamma:_n + a_n, \qquad f_n = -:\beta\gamma\gamma:_n + :a\gamma:_n - k\,n\,\gamma_n. \tag{9.4}$$

In field language: $e(z) = \beta(z)$, $h(z) = -2:\beta\gamma:(z) + a(z)$, $f(z) = -:\beta\gamma\gamma:(z) + :a\gamma:(z) + k\,\partial\gamma(z)$.

File `VOA/Examples/WakimotoFree.lean`.

```

  if a = 0 then Ecur n else if a = 1 then Fcur k n else Hcur k n
```

From the mathematics to the Lean statement

`opSum T` is the operator $P \mapsto \sum_{p\in\mathbb{Z}} T_p(P)$; it is well defined when the family is *locally finite* (`LocFin T`: on each polynomial only finitely many T_p act nonzero), which `bgFam_locFin` etc. prove (the bound comes from the largest variable index in P, `NB P`). The summand `bgFam n p` is $\beta_p\gamma_{n-p}$ if $p \le -1$ (creation β to the left) and $\gamma_{n-p}\beta_p$ otherwise: this is normal ordering. `GG`, `AG`, `BGG` are built the same way (`BGG n` sums $\beta_p\,{:}\gamma\gamma{:}_{n-p}$ normally ordered). The mode of $k\,\partial\gamma$ is $(\partial\gamma)_n = -n\gamma_n$, which gives the last term of `Fcur`. `Jw` indexes the three currents by colour,

matching `colE, colF, colH`.

Physical meaning

This is the Wakimoto realisation: the $\mathfrak{sl}_2$ currents written in free fields, i.e. the *bosonisation* of the $SU(2)$ WZW model. The quadratic term $:\beta\gamma\gamma:$ is the classical vector field $\gamma^2\partial_\gamma$ on $\mathbb{P}^1$ (the action of f on the flag manifold); $:a\gamma:$ and $k\partial\gamma$ are quantum corrections that make the algebra close with level k. The boson ϕ carries the Cartan direction and its background charge (encoded in the coefficient $2(k+2)$) is what makes the free-field stress tensor reproduce $c = 3k/(k+2) = 2 + (1 - 6/(k+2))$: the $\beta\gamma$ system contributes 2 and the boson with background charge the rest.

What the machine verified

Definitions; axiom-free.

Theorem 9.19 (The Wakimoto currents satisfy the affine algebra). *For $k \neq -2$, all colours a, b and all m, n: $[J^a_m, J^b_n] = \sum_c f^{ab}{}_c J^c_{m+n} + m\,k\,\kappa(a,b)\delta_{m+n,0}$ for the currents (9.4) on $\mathcal{F}$.*

File `VOA/Examples/WakimotoFree.lean`.

```
theorem rel_ef (k : ℂ) (m n : ℤ) :
    [Ecur m, Fcur k n]
      = Hcur k (m + n)
        + (if m + n = 0 then ((m : ℂ) * k) • (1 : Module.End ℂ WakFock) else 0) := by

theorem rel_hh (k : ℂ) (hk : k + 2 ≠ 0) (m n : ℤ) :
    [Hcur k m, Hcur k n]
      = if m + n = 0 then ((2 : ℂ) * k * (m : ℂ)) • (1 : Module.End ℂ WakFock) else 0 := by

    [Jw k a m, Jw k b n]
      = (∑ c, AffineVOA.fabc a b c • Jw k c (m + n))
        + (if m + n = 0 then ((m : ℂ) * k * AffineVOA.kappa a b) •
            (1 : Module.End ℂ WakFock) else 0) := by
```

From the mathematics to the Lean statement

`Jw_comm` is *literally* the statement of `AffineVOA.current_comm` (Theorem 9.2) with `J` replaced by `Jw` and the identity written as `1`; it uses the same `fabc` and `kappa`. `rel_ef` holds for every k; `rel_hh` (and `rel_hf`, `rel_ff`) need $k \neq -2$. That is a feature of the *proof*, see below, not of the mathematics at $k = -2$; the realisation itself degenerates there because $[a_m, a_n] = 0$.

Physical meaning

The free-field currents close into the current algebra at level k. The double pole of $h(z)h(w)$ receives $-4\cdot$(from the $\beta\gamma$ loop) $+\,2(k+2)$ (from the boson): $2k$. The ghost loop shifts the level by $-h^\vee$, which is why the boson must carry $k + h^\vee$.

Proof on paper. The brackets $[e,e]$, $[h,e]$, $[e,f]$ follow by pushing the commutator through the (locally finite) sums and collapsing with the canonical relations. For the remaining three the library uses a *rigidity* argument instead of expanding quartic expressions: if an operator S on $\mathcal{F}$ commutes with all β_r, γ_u, a_u, then S commutes with multiplication by every variable, so S is multiplication by $S(1)$, and $S(1)$ has all partial derivatives zero (this is where the annihilators $a_u = 2(k+2)u\,\partial_{A_u}$ must be nonzero, i.e. $k \neq -2$); hence S is a scalar (`exists_smul_id_of_lie_modes`). Apply this to

$S = [h_m, h_n]$ – (expected), whose commutators with the free fields are computed to vanish; the scalar is then fixed by one vacuum matrix element, $[h_m, h_{-m}]1 = 2km \cdot 1$, or forced to vanish by a nonzero eigenvalue under the charge or weight grading. □

What the machine verified

`VOA.Wak.rel_ef`, `VOA.Wak.rel_hh`, `VOA.Wak.rel_ff`, `VOA.Wak.Jw_comm`: `[propext, Classical.choice, Quot.sound]` (run for this chapter).

9.6.4 The representation and the evaluation map

Definition 9.20 (Wakimoto representation and vacuum evaluation). For $k \neq -2$, $\rho_W : \widehat{\mathfrak{sl}}_2 \to \operatorname{End} \mathcal{F}$ sends $x \otimes t^n \mapsto \sum_a x_a J^a_n$, $C \mapsto k$, $\ell_0 \mapsto -D_{\mathrm{wt}}$, where D_{wt} is the weight operator (b_i, A_i have weight i, c_j weight j). The vacuum evaluation is $\mathrm{val}_W(u) = \rho_W(u) \cdot 1$ for $u \in U(\widehat{\mathfrak{sl}}_2)$.

File `VOA/Examples/WakimotoFree.lean`.

```
noncomputable def wakRho (k : ℂ) (hk : k + 2 ≠ 0) :
    AffineVOA.AffSl2 →ₗ[ℂ] Module.End ℂ WakFock :=

noncomputable def evAlgW (k : ℂ) (hk : k + 2 ≠ 0) : UW →ₐ[ℂ] Module.End ℂ WakFock :=
  UniversalEnvelopingAlgebra.lift ℂ (wakRho k hk)

noncomputable def valW (k : ℂ) (hk : k + 2 ≠ 0) : UW →ₗ[ℂ] WakFock where
  toFun w := evAlgW k hk w (1 : WakFock)
```

From the mathematics to the Lean statement

`→ₗ[ℂ]` is a Lie algebra homomorphism (Mathlib's `LieHom`); its `map_lie'` field, proved in the source, is the content of Theorem 9.19 plus the bracket with ℓ_0 and C. `UW` is $U(\widehat{\mathfrak{sl}}_2)$; `UniversalEnvelopingAlgebra.lift` extends a Lie map to an algebra map (the universal property of U). So `wakRho` is a genuine representation of the full affine Lie algebra including centre and derivation, and `valW` is $u \mapsto \rho_W(u)1$.

Physical meaning

The Fock space of $\beta\gamma$ and ϕ is a module of the WZW current algebra: the Wakimoto module (here at zero boson momentum, the module that receives the vacuum module).

What the machine verified

Definitions; `VOA.Wak.wakRho`: `[propext, Classical.choice, Quot.sound]`.

Theorem 9.21 (pbw-free nonvanishing of the vacuum). *For $k \neq -2$: val_W kills the vacuum ideal $J(k)$, hence descends to a linear map $V^k(\mathfrak{sl}_2) \to \mathcal{F}$ sending $|0\rangle \mapsto 1$ and intertwining every J^a_m with the Wakimoto current; in particular $|0\rangle \neq 0$ in $V^k(\mathfrak{sl}_2)$.*

theorem vacuumToWak_J (a : Fin 3) (m : ℤ) (v : WakModule k) :
    vacuumToWak k hk (J k a m v) = Wak.Jw k a m (vacuumToWak k hk v) := by
```

From the mathematics to the Lean statement

`vacuumIdeal` is the left ideal $J(k)$ of Definition 3.7. `liftQ` descends a linear map through a quotient once the kernel contains the submodule; `restrictScalars` and `restrictScalarsEquiv` only convert the U-module quotient into a $\mathbb{C}$-vector-space quotient. The file declares `variable (k : ℂ) (hk : k + 2 ≠ 0)`. The nonvanishing proof is three lines: if $|0\rangle = 0$ then $1 \in J(k)$, so $\mathrm{val}_W(1) = 1 = 0$ in $\mathcal{F}$, absurd.

Physical meaning

The universal vacuum module maps to the Wakimoto Fock space, vacuum to vacuum: the free-field theory contains the WZW vacuum sector. This is the bosonisation map at the level of states.

Proof on paper. The generators of $J(k)$ are $x \otimes t^n$ ($n \geq 0$), $C - k$, ℓ_0. On $1 \in \mathcal{F}$: nonnegative modes of all three Wakimoto currents kill 1 (each term ends with an annihilator); $C - k$ acts as 0; ℓ_0 acts as $-D_{\mathrm{wt}}$, and $D_{\mathrm{wt}}1 = 0$. A left ideal generated by elements killing 1 kills 1. □

What the machine verified

`VOA.Wak.valW_vacuumIdeal`, `VOA.Wak.vacuumA_ne_zero_free`, `VOA.AffineSl2PBWWakimotoReduction.vacuumToWak_J`: `[propext, Classical.choice, Quot.sound]` (run for this chapter). **pbw-free**; this is the replacement for Theorem 9.6 at $k \neq -2$.

9.7 The PBW basis by Wakimoto triangularity

9.7.1 The target statement

Chapter 3 (Definition 3.20) defines the named hypothesis `PBWBasis κ hκ b k`: the *ordered creation monomials* $v_\mu = \prod_{(i,n)\uparrow}(b_i \otimes t^{-n-1})^{\mu(i,n)}|0\rangle$, indexed by finitely supported μ on $\{e, f, h\} \times \mathbb{N}$ ordered lexicographically (colour first, then depth), form a basis of $V^k(\mathfrak{g})$. Spanning is the easy half.

Proposition 9.22 (Spanning and the reduction to independence). *For every k, the ordered creation states span $V^k(\hat{\mathfrak{sl}}_2)$, so* `PBWBasis` *for the basis (e, f, h) is equivalent to their linear independence. For $k \neq -2$ it suffices that their images in the Wakimoto Fock space be linearly independent.*

File `VOA/Examples/AffineSl2UniversalC2PBW.lean`.

```

    (hli : LinearIndependent ℂ (wakimotoOrderedCreationState k)) :
    PBWBasis kappaForm kappaForm_isInvariant (Pi.basisFun ℂ (Fin 3)) k := by
```

From the mathematics to the Lean statement

`PBWLetter` is `Fin 3 ×ₗ ℕ` (colour, depth, lexicographic). `pbwWord` and `negWord` are the ordered word and its creation monomial of Chapter 3; `Pi.basisFun ℂ (Fin 3)` is the basis (e, f, h). `wakimotoOrderedCreationState k mu` applies the *Wakimoto* currents J^a_{-n-1} of the ordered word to the Fock vacuum 1; it equals `vacuumToWak` of the ordered creation state (`wakimotoOrderedCreationState_eq`). Linear independence of images implies linear independence of the vectors themselves, since a linear dependence would be mapped to one.

Physical meaning

Counting states: PBW says that the vacuum sector has exactly one state per ordered monomial of creation modes, so its character is $\prod_{n\geq 1}(1-q^n)^{-3}$ (generic level). Physically, the current algebra imposes no relations on the vacuum module beyond reordering.

Proof on paper. Spanning: every word in the creation modes can be reordered using the affine bracket; each exchange produces a shorter word, so induction on length shows that ordered words span; combined with the spanning of all words (Chapter 3, Theorem 3.8). The equivalence then is the definition of a basis. The reduction to Wakimoto images is the remark in the dictionary. □

What the machine verified

All three theorems: `[propext, Classical.choice, Quot.sound]` (run for this chapter).

9.7.2 Leading terms of Wakimoto words

The images $\mathrm{val}_W(v_\mu)$ are complicated polynomials (every product of currents produces contractions). The library proves their independence by a leading-term (triangularity) argument.

Definition 9.23 (Free Li weight, classical symbols, pivots). Give b_i and A_i the weight $i-1$ and c_j the weight j (the *free Li weight*); a monomial has the sum of the weights of its variables. For the creation current J^a_{-n-1} define its *classical symbol* $\sigma(J^a_{-n-1}) \in \mathcal{F}$ as the part of $J^a_{-n-1}\cdot 1$ of free Li weight n:

$$\sigma(e_{-n-1}) = b_{n+1}, \quad \sigma(h_{-n-1}) = (-2{:}\beta\gamma{:} + a)_{-n-1}1, \quad \sigma(f_{-n-1}) = (-{:}\beta\gamma\gamma{:} + {:}a\gamma{:})_{-n-1}1$$

(the derivative term $k(n+1)c_{n+1}$ of f has weight $n+1$ and is dropped). The *pivot* monomials are b_{n+1}, A_1c_n, A_{n+1} for e, f, h respectively. The *classical substitution* is the algebra map $\mathbb{C}[x^a_n] \to \mathcal{F}$, $x^a_n \mapsto \sigma(J^a_{-n-1})$.

    MvPolynomial (Fin 3 ×ₗ ℕ) ℂ →ₐ[ℂ] Wak.WakFock :=
  MvPolynomial.aeval fun q => currentClassical k (ofLex q).1 (ofLex q).2
```

From the mathematics to the Lean statement

Recall `X (0, i)` $= b_{i+1}$, `X (1, j)` $= c_j$, `X (2, i)` $= A_{i+1}$, so `freeLiWeight` (the second coordinate) is the weight of Definition 9.23. `BG (-n-1) 1` etc. are the composites applied to the Fock vacuum. `MvPolynomial.aeval` is the substitution homomorphism. The pivot for f is `X (2,0) * X (1,n)` $= A_1 c_n$.

Physical meaning

The free Li weight is the depth (number of derivatives) in the free-field jet scheme. The classical symbol is the semiclassical limit of a current: the Wakimoto formula with quantum corrections ($k\partial\gamma$) dropped — the Poisson-algebra version of bosonisation, i.e. the embedding of the arc space of $\mathfrak{sl}_2^*$ in the arc space of the cotangent bundle of the big cell.

What the machine verified

Definitions; axiom-free.

Theorem 9.24 (Leading terms and injectivity). *(i) For every word ℓ of creation currents, of total depth $d(\ell) = \sum n_i$, the Wakimoto image $J^{a_1}_{-n_1-1}\cdots J^{a_r}_{-n_r-1}1$ has no components of free Li weight $< d(\ell)$, and its component of weight exactly $d(\ell)$ is the product $\prod_i \sigma(J^{a_i}_{-n_i-1})$. (ii) The classical substitution is injective, for every $k \in \mathbb{C}$. (iii) Consequently the Wakimoto ordered creation states are linearly independent at every k.*

    (hlead : LinearIndependent R lead) : LinearIndependent R f := by

theorem wakimotoOrderedCreationState_linearIndependent (k : ℂ) :
    LinearIndependent ℂ (wakimotoOrderedCreationState k) :=
```

From the mathematics to the Lean statement

`weightedHomogeneousComponent w d P` is the part of P whose monomials have w-weight exactly d; `wordFreeLiDegree l` is $\sum$ depths; `classicalWordState k l` is the product of the classical symbols of the letters. The theorem displayed is the "component at the minimum" half of (i); the "nothing below" half is `wakimotoWordState_sub_classical_mem_freeLiAtLeast` (the difference lies in the span of monomials of weight $\geq d(\ell)+1$). `linearIndependent_of_lowerLeading` is the abstract principle: if each f_i has no components below degree d_i and its degree-d_i components are independent, then the f_i are independent. All statements are for every $k \in \mathbb{C}$; the restriction $k \neq -2$ enters only through the map `vacuumToWak`.

Physical meaning

In a free-field realisation the "classical" part of a state is the leading term when one counts derivatives; quantum contractions always add derivatives (they replace two fields by a higher-derivative one), so they never compete with the leading term. Independence of the classical products says the semiclassical bosonisation map is injective on the arc space.

Proof on paper. (i) Each letter applied to a polynomial produces its classical symbol times that polynomial, plus terms where a contraction occurs; a contraction between β_p (or a_p) with $p \geq 0$ and a variable of the polynomial removes a variable of weight $\geq p$ and replaces a factor of lower weight, raising the total free Li weight by at least one. Induction on the word. (ii) Choose the pivot monomials. The pivot of a product is the product of pivots, and the map from exponents μ to pivot exponents is injective: the b-exponents give the e-letters, the c-exponents give the f-letters at each depth, and the A-exponents give the h-letters after subtracting, at A_1, the total number of f-letters (known from the total c-degree). One checks that each classical product contains its own pivot with nonzero coefficient and is triangular with respect to a lexicographic order on (number of c-variables, A-degree, ...); hence the products are independent, so the substitution is injective on monomials and on polynomials. (iii) Apply the abstract principle with $d_i = d(\ell_i)$ and leading terms the classical products, which are independent by (ii). □

A tempting order that fails

The source records a disproved approach: ordering by *maximal* free Li weight first fails already on the $\beta\gamma$ parts of two h currents, because $:\beta\gamma:_{-1}:\beta\gamma:_{-2}\cdot 1$ contains the surviving terms $-b_3c_0 + b_1c_2$ of weight two rather than the naive depth sum one. The correct order uses the *minimal*-weight symbol, as in Theorem 9.24(i).

What the machine verified

All four: `[propext, Classical.choice, Quot.sound]` (run for this chapter).

Theorem 9.25 (PBW for $V^k(\mathfrak{sl}_2)$, by Wakimoto triangularity)**.** *For every $k \neq -2$ the ordered creation monomials form a basis of $V^k(\mathfrak{sl}_2)$. Consequently the universal C_2-symbol map $\mathbb{C}[e,f,h] \to R_{V^k(\mathfrak{sl}_2)} = V^k/C_2(V^k)$ is injective.*

From the mathematics to the Lean statement

`PBWBasis` is Definition 3.20 of Chapter 3, instantiated at $\mathfrak{g} = \mathfrak{sl}_2$, κ the normalised form, basis (e, f, h). `Sl2Pres.symbolAlg k hk` is the algebra map $\mathbb{C}[e, h, f] \to A_2(V^k)$ sending the variables to the classes $[e_{-1}|0\rangle]$ etc. in the Zhu C_2-algebra (defined in Chapter 16's file `AffineSl2Presentation.lean`). Both theorems are unconditional for $k \neq -2$; the hypothesis $k \neq -2$ is an artefact of the Wakimoto route (PBW is true at $k = -2$, Chapter 3). The docstring of `AffineSl2PBWWakimotoReduction.lean` still calls the independence "OPEN"; that is stale (Section 9.14).

Physical meaning

The vacuum character of $V^k(\mathfrak{sl}_2)$ is $\prod_n (1-q^n)^{-3}$, and the associated graded of the chiral algebra (its classical limit) is the coordinate ring of the arc space of $\mathfrak{sl}_2^*$: the universal current algebra is "freely generated" by the currents.

What the machine verified

`VOA.AffineSl2WakimotoLiLeading.affineSl2PBWBasis`, `VOA.AffineSl2WakimotoLiLeading.universalSymbolAlg_injective`: `[propext, Classical.choice, Quot.sound]` (run for this chapter). **This discharges the named hypothesis `PBWBasis` for $\mathfrak{sl}_2$ at every non-critical level without `VOA.pbw`.** (Since `VOA.pbw` became a theorem, `pbwBasis_holds` discharges it for every $\mathfrak{g}$ and every level, including $k = -2$; Chapter 3, Section 3.12.3.) Consumers include `AffineSl2JointPBW.lean` (bases of the simultaneous (L_0, h_0)-eigenspaces, used by the Gram-matrix arguments of Section 9.12) and the `pbw`-free nonvanishing `affineSl2_vacuum_ne_zero` of Chapter 10.

9.8 Singular vectors in the vacuum module

A *singular vector* of $V^k(\mathfrak{sl}_2)$ is a nonzero vector s of positive weight annihilated by the affine raising operators. The positive part $\widehat{\mathfrak{n}}_+ = \mathbb{C}e_0 \oplus \bigoplus_{m\geq 1} \mathfrak{sl}_2 \otimes t^m$ is generated as a Lie algebra by the two Chevalley generators e_0 and f_1, so it suffices to impose $e_0 s = 0$ and $f_1 s = 0$. Such an s need not be $\mathfrak{sl}_2$-invariant: the vectors below are highest-weight vectors of $\mathfrak{sl}_2$-triplets ($h_0 s = 2s$, $f_0 s \neq 0$).

Where they occur is governed by the Kac–Kazhdan condition (Section 9.12): with $t = k + 2$, the vacuum module has a singular vector of weight $\lambda - n\beta$ for a positive real root $\beta = m\delta \pm \alpha$ when $(\lambda + \rho, \beta) = n$. For the vacuum ($\lambda = k\Lambda_0$) and $\beta = m\delta - \alpha$ this reads $mt - 1 = n$. Three cases are in the library:

level k	$t = k+2$	singular vector	source
$N \in \mathbb{Z}_{\geq 0}$	$N+2$	$e_{-1}^{N+1}\|0\rangle$, weight $N+1$, charge $2(N+1)$	checked outside the library (this chapter)
$-4/3$	$2/3$	weight 3, h_0-charge 2, five monomials	`AffineSl2Singular.lean`
$-8/5$	$2/5$	weight 5, h_0-charge 2, 21 monomials	`AffineSl2SingularLY.lean`

For $k+2 = p/q$ with $p \geq 2$ the first vacuum singular vector has weight $(p-1)q$ and h_0-charge $2(p-1)$; $(p,q) = (2,3)$ and $(2,5)$ give the last two rows.

9.8.1 Integrable levels: $e_{-1}^{N+1}|0\rangle$

Not a library theorem: checked in Lean for this chapter

The library has no named theorem about the integrable-level vector $e_{-1}^{N+1}|0\rangle$; it appears only in a docstring table of `AffineSl2Singular.lean` (§F, labelled a CAS computation). Because this vector is the defining relation of the unitary $SU(2)_N$ WZW chiral algebra, the author of this chapter checked the statements below in Lean against the library, using only library lemmas. The check is not part of this release: it is *not* part of `VOA/`, not built by `lake build`, and not covered by the repository audits.

Theorem 9.26 (The integrable vacuum singular vector; not in the library). *Let $E_n = e_{-1}^n|0\rangle \in V^k(\mathfrak{sl}_2)$. For every $k \in \mathbb{C}$ and $n \in \mathbb{N}$:*

1. *$e_m E_n = 0$ for $m \geq 0$; $h_m E_n = 0$ for $m \geq 1$; $f_m E_n = 0$ for $m \geq 2$; $h_0 E_n = 2nE_n$;*
2. *$f_1 E_{n+1} = (n+1)(k-n)\,E_n$;*
3. *if $k \neq -2$ then $E_n \neq 0$, and $f_1 E_{n+1} = 0 \iff k = n$.*

Consequently, at $k = N \in \mathbb{N}$ the vector E_{N+1} is a strongly singular vector of weight $N+1$ in $V^N(\mathfrak{sl}_2)$, and $V^N(\mathfrak{sl}_2)$ is not simple.

From the mathematics to the Lean statement

In Lean, E_n is built from the library's current modes `J k colE (-1)` applied to `vacuumA k`, and f_1 is `J k colF 1`. The non-simplicity statement involves only library definitions: `affineSl2VOA_closed` (Definition 9.14) and `IsSimple` (Chapter 5). The nonvanishing uses the Wakimoto map: `vacuumToWak` sends E_n to $b_1^n \neq 0$ (because $e_{-1} = \beta_{-1}$ is multiplication by b_1). Non-simplicity is then the library route of Section 9.9: `Strong.isStronglySingular_of_SingP` and `SingVec.not_isSimple_of_stronglySingular_FHL`, with the pbw-free `Wak.vacuumA_ne_zero_free`.

Physical meaning

At level N the state $(J_{-1}^+)^{N+1}|0\rangle$ is null, and setting it to zero gives the integrable WZW chiral algebra $L_N(\mathfrak{sl}_2)$. Through the OPE with primary fields it imposes the *fusion rules* of $SU(2)_N$: only spins $j \leq N/2$ appear, and $j_1 \otimes j_2$ is truncated to $j \leq \min(j_1+j_2, N-j_1-j_2)$ (Gepner–Witten). At $N=1$ the null state $e_{-1}^2|0\rangle$ says that the OPE $J^+(z)J^+(w)$ has no $(z-w)^0$ term; in the free-boson realisation $J^+ = e^{i\sqrt{2}\phi}$ one has $J^+(z)J^+(w) = (z-w)^2 {:}e^{i\sqrt{2}\phi(z)}e^{i\sqrt{2}\phi(w)}{:}$, which vanishes to second order.

Proof on paper. (1) e_m commutes with e_{-1} and kills $|0\rangle$. $[h_m, e_{-1}] = 2e_{m-1}$, which for $m \geq 1$ is an e-mode of index ≥ 0, so (1) for e gives $h_m E_n = 0$; similarly $[f_m, e_{-1}] = -h_{m-1}$ for $m \geq 2$. h_0 counts e-letters twice. (2) $[f_1, e_{-1}] = -h_0 + k$, so $f_1 E_{n+1} = e_{-1} f_1 E_n + (k - h_0)E_n$; induction gives

$(n+1)(k-n)$ since $n(k-n+1)-2n+k=(n+1)(k-n)$. (3) Nonvanishing via the Wakimoto map; the equivalence from (2) and $E_n \neq 0$. At $k=N$, (1)–(2) say every positive current mode kills E_{N+1}, which is the library's `SingP`; the strong-singularity upgrade and Theorem 9.16 finish. □

What the machine verified

Checked in Lean against the library for this chapter (with `lake env lean -DmaxSynthPendingDepth=3`); the check is not part of this release. Its five declarations reported only `[propext, Classical.choice, Quot.sound]`. **Not library**; unconditional, pbw-free.

9.8.2 The level $k=-4/3$: weight 3

Definition 9.27 (The weight-3 ansatz)**.** In weight 3 and h_0-charge 2 the PBW monomials are $M_1 = e_{-3}|0\rangle$, $M_2 = e_{-2}h_{-1}|0\rangle$, $M_3 = h_{-2}e_{-1}|0\rangle$, $M_4 = e_{-1}e_{-1}f_{-1}|0\rangle$, $M_5 = e_{-1}h_{-1}h_{-1}|0\rangle$, and the ansatz is $s(a,b,c,d,g) = aM_1 + bM_2 + cM_3 + dM_4 + gM_5$. The *singularity system* is the linear system

$$b+c+2g=0, \quad d-4g=0, \quad -a+(k-2)c=0, \quad c+(k+1)d+2g=0, \quad kg-b=0.$$

        + (k * g - b) • Q3 k := by
```

From the mathematics to the Lean statement

The monomials are written operator-first (outermost operator leftmost). `P1`, `P2` are $e_{-2}e_{-1}|0\rangle$, $e_{-1}e_{-1}h_{-1}|0\rangle$ (weight 3, charge 4) and `Q1`, `Q2`, `Q3` are $h_{-2}|0\rangle$, $e_{-1}f_{-1}|0\rangle$, $h_{-1}h_{-1}|0\rangle$ (weight 2, charge 0), defined in the same file. `E0_ansatz` and `F1_ansatz` are the explicit images under e_0 and f_1, computed from the affine bracket; the five coefficients are the five equations of `SingSys` (up to the factors -2 and 2). So "$e_0 s = f_1 s = 0$" is *implied* by `SingSys`, and conversely `SingSys` follows from $e_0 s = f_1 s = 0$ *given* linear independence of $\{P_1, P_2\}$ and $\{Q_1, Q_2, Q_3\}$ (`SingSys_of_annihilated`, which carries those as explicit hypotheses).

Physical meaning

The five monomials are all the states at energy 3 with $J^3 = +1$ in the vacuum module. The singular vector is a null descendant of the vacuum: a spin-one multiplet of null states at energy 3.

What the machine verified

Definitions and two computational lemmas; axiom-clean.

Theorem 9.28 (The level is forced; the singular vector). *(i) Every solution of the singularity system has $b = kg$, $c = -(k+2)g$, $d = 4g$, $a = -(k-2)(k+2)g$ and $(3k+4)g = 0$; a nonzero solution exists iff $3k + 4 = 0$. (ii) At $k = -4/3$ the vector*

$$s = 20\,e_{-3}|0\rangle - 12\,e_{-2}h_{-1}|0\rangle - 6\,h_{-2}e_{-1}|0\rangle + 36\,e_{-1}e_{-1}f_{-1}|0\rangle + 9\,e_{-1}h_{-1}h_{-1}|0\rangle$$

has weight 3, satisfies $h_0 s = 2s$, and is killed by every current mode J^a_m, $m \geq 1$, and by e_0. (iii) $s \neq 0$.

From the mathematics to the Lean statement

(i) is a statement about the *coefficient system*, not about vectors: `exists_nonzero_solution_iff` says the linear system has a nontrivial solution iff $k = -4/3$. Turning it into "no singular vector of this shape at other levels" needs the target-independence hypotheses (`ansatz_eq_zero_of_level_ne`, same file), which `AffineSl2Indep.lean` discharges away from $k \in \{0, 1, 2, -2\}$ — using `VOA.pbw` (see the status box). `wSing` is a lift of s to $U(\widehat{\mathfrak{sl}}_2)$ (`sl2Singular_mk`), and `Gam 3` $= \gamma_3 = -\partial/\partial b_3$. The value -8 is independent of k; it is the singularity, not the nonvanishing, that needs $k = -4/3$.

Physical meaning

$k = -4/3$ is the first fractional admissible level ($k + 2 = 2/3$); $c = -6$. $L_{-4/3}(\mathfrak{sl}_2)$ is the chiral algebra of the 4d $\mathcal{N} = 2$ Argyres–Douglas theory of type (A_1, D_3) and the Drinfeld–Sokolov reduction maps it to the trivial Virasoro minimal model $c = 0$. The null vector is the null descendant predicted by Kac–Kazhdan with $(m, n) = (3, 1)$: $3t - 1 = 1$.

Proof on paper. (i) Linear elimination; the last equation reduces to $(3k + 4)g = 0$. (ii) $e_0 s = f_1 s = 0$ by the explicit images; e_1, h_1 annihilation by direct computation; then all modes of level ≥ 1 by the recursion $e_{m+1} = \frac{1}{2}[h_1, e_m]$, $f_{m+1} = -\frac{1}{2}[h_1, f_m]$, $h_{m+1} = [e_1, f_m]$ (no central terms) up to level 3, and by the grading beyond (`pos_ann`). (iii) Map to the Wakimoto module and apply γ_3: only M_1 and M_3 contain b_3, with $\gamma_3 \mathrm{val}_W(M_1) = -1$, $\gamma_3 \mathrm{val}_W(M_3) = -2$, and γ_3 kills the images of M_2, M_4, M_5; so $\gamma_3 \mathrm{val}_W(s) = 20 \cdot (-1) + (-6) \cdot (-2) = -8 \neq 0$. Since $\gamma_3 \mathrm{val}_W(s)$ is a constant (weight and charge force it), no truncation issue arises. □

Corrected false alarm: agreement with Linshaw–Qi

An earlier version of the source claimed a discrepancy between this vector and the one in Linshaw–Qi (arXiv:2601.12017, §5, from Adamović 2005), comparing the $e_{-2}h_{-1}$ coefficients -12 and -48. The comparison forgot that $9\, h_{-1}^2 e_{-1}|0\rangle$ contributes $+36$ to the same monomial after reordering; $-48 + 36 = -12$. The two vectors agree exactly; this is machine-checked as `lqVector_eq_ansatz` in `AffineSl2Rigidity43.lean` (Chapter 10).

What the machine verified

`VOA.Sl2Sing.SingSys_param`, `VOA.Sl2Sing.exists_nonzero_solution_iff`, `VOA.Sl2Sing.sl2Singular_pos`, `VOA.Wak.Gam3_valW_wSing`, `VOA.Wak.sl2Singular_ne_zero`: `[propext, Classical.choice, Quot.sound]` (run for this chapter). `VOA.Sl2Indep.Q_indep`, `VOA.Sl2Indep.indep_iff_sl2Singular_ne_zero` and `VOA.Wak.M_indep_sing` (independence of $M_1, \ldots, M_5$ at $k = -4/3$): `[propext, Classical.choice, Quot.sound, VOA.pbw]` at the snapshot, when `VOA.pbw` was an axiom; re-probed at a later commit, after `VOA.pbw` became a theorem (not re-run for this edition): `[propext, Classical.choice, Quot.sound]`. They use the theorem `VOA.pbw`, through `vacuumA_ne_zero` in the lemmas `deg1E_ne_zero` etc. of `AffineSl2Indep.lean`.

Stale "honest gap" notes

`AffineSl2Singular.lean` §E and `AffineSl2Indep.lean` still state that $s \neq 0$ "is not proved" and "needs a new PBW input". Both are superseded: `Wak.sl2Singular_ne_zero` proves it without `VOA.pbw`, and the full PBW basis is Theorem 9.25. The "weight-3 spanning" gap of §E is also closed in principle by the PBW basis, though no theorem in these files restates it.

9.8.3 The level $k = -8/5$: weight 5 (the Lee–Yang level)

Theorem 9.29 (The weight-5 singular vector at $k = -8/5$). *In weight 5, h_0-charge 2 there are 21 PBW monomials $N_1, \ldots, N_{21}$. (i) The 25 linear equations expressing $e_0 s = f_1 s = 0$ for $s = \sum c_i N_i$ (12 from e_0, 13 from f_1) force $(5k + 8)c_1 = 0$, and have a nonzero solution iff $5k + 8 = 0$. (ii) At $k = -8/5$*

the explicit vector

$$s = 625\,e_{-1}h_{-1}^4|0\rangle + 5000\,e_{-1}^2f_{-1}h_{-1}^2|0\rangle + 10000\,e_{-1}^3f_{-1}^2|0\rangle - 1500\,h_{-2}e_{-1}h_{-1}^2|0\rangle - 16000\,h_{-2}e_{-1}^2f_{-1}|0\rangle$$
$$+ 300\,h_{-2}^2e_{-1}|0\rangle - 10000\,f_{-2}e_{-1}^2h_{-1}|0\rangle - 1000\,e_{-2}h_{-1}^3|0\rangle + 6000\,e_{-2}e_{-1}f_{-1}h_{-1}|0\rangle + 1200\,e_{-2}h_{-2}h_{-1}|0\rangle$$
$$- 14400\,e_{-2}f_{-2}e_{-1}|0\rangle - 9600\,e_{-2}^2f_{-1}|0\rangle - 19200\,h_{-3}e_{-1}h_{-1}|0\rangle - 14720\,h_{-3}e_{-2}|0\rangle + 1600\,f_{-3}e_{-1}^2|0\rangle$$
$$+ 4200\,e_{-3}h_{-1}^2|0\rangle + 78400\,e_{-3}e_{-1}f_{-1}|0\rangle - 1680\,e_{-3}h_{-2}|0\rangle$$
$$+ 2960\,h_{-4}e_{-1}|0\rangle + 17440\,e_{-4}h_{-1}|0\rangle + 25904\,e_{-5}|0\rangle$$

has weight 5, $h_0 s = 2s$, *and is killed by* e_0 *and every* J_m^a, $m \geq 1$. *(iii)* $s \neq 0$.

From the mathematics to the Lean statement

`SingSys5` (not displayed) is the conjunction of the 25 coefficient equations of the explicit images `E0_ansatz5`, `F1_ansatz5`; `SingSys5_param` gives the elimination $c_2 = 8c_1$, $c_3 = 16c_1$, $c_4 = (9k+12)c_1$, ..., $(5k+8)c_1 = 0$. `pos_ann5` is the general fact that e_0 and f_1 generate $\widehat{\mathfrak{n}}_+$, in the form needed at weight 5. `N01`, ..., `N21` are pinned to explicit nested current applications by `rfl` lemmas such as `N14_eq` ($N_{14} = h_{-3}e_{-2}|0\rangle$), and `sl2Singular85_eq_LY` is a `rfl` transcription check that the explicit integer combination is the vector produced by the elimination. The `rfl` pinning is the right check for the one error a type checker cannot see (pairing a coefficient with the wrong monomial). `DSsl2.dsCentralCharge k` is the Drinfeld–Sokolov central charge $13 - 6(k+2) - 6/(k+2)$ (equal to $1 - 6(k+1)^2/(k+2)$), here $-22/5$.

Physical meaning

$k = -8/5$ ($k + 2 = 2/5$, $c = -12$) is the admissible level whose quantum Drinfeld–Sokolov (Hamiltonian) reduction is the Lee–Yang minimal model $\mathcal{M}(2,5)$, $c = -22/5$; the null vector at weight 5 is the affine counterpart of the Lee–Yang null vector at level 4. $L_{-8/5}(\mathfrak{sl}_2)$ is the chiral algebra of the (A_1, D_5) Argyres–Douglas theory. The witness Fock monomial $b_5 = \beta_{-5}$ detects the unique component of s that cannot be produced by a contraction.

Proof on paper. As for $k = -4/3$, with γ_5 as the separating functional: only $N_6, N_{14}, N_{15}, N_{19}, N_{21}$ have a b_5, with γ_5-values $-4, -2, 2, -2, -1$, and $300(-4) + (-14720)(-2) + 1600 \cdot 2 + 2960(-2) + 25904(-1) = -384 \neq 0$. □

What remains conditional at $k = -8/5$

The statements "*within the 21-monomial ansatz*" are not "all weight-5 singular vectors": the converse direction (`exists_singular_ansatz_iff`) still carries the named hypotheses `TIndep`, `UIndep` (independence of the target monomials), and `NIndep` (independence of all 21 monomials) is strictly stronger than $s \neq 0$ and is *not* discharged here, although it follows from the PBW basis of Theorem 9.25 (no file states this). These hypotheses are explicit in the signatures, so nothing is hidden; but a reader of the docstring of `AffineSl2Singular85.lean` §E ("nonvanishing ... out of reach") should know it is stale.

```
theorem mk₂_sl2Singular85_casimir_sq :
    mk₂ W85 sl2Singular85 = (625 : ℂ) • (e85 * casimir85 ^ 2) := by
```

From the mathematics to the Lean statement

`O₂ W` is $C_2(W) = \mathrm{span}\{u_{(-2)}v\}$ and `mk₂ W` the projection to `A₂ W` (Chapter 12). `Wadm`, `eA`, `casimirA` are the $k = -4/3$ specialisations of the VOA, of $[e]$ and of `casimirCl` $= 4[e][f]+[h]^2$; similarly `W85`, `e85`, `casimir85`. The source is explicit about what is *not* claimed: these are identities of classes; they do not assert $[s] \neq 0$, nor that A_2 of the *simple* quotient is $\mathbb{C}[e,f,h]/(\cdots)$. (Injectivity of $\mathbb{C}[e,f,h] \to A_2(V^k)$ is now Theorem 9.25, so in fact $[s] \neq 0$ follows; no file states it.)

Physical meaning

$h^2 + 4ef$ is the Casimir of $\mathfrak{sl}_2$, whose zero set is the nilpotent cone $\mathcal{N}$. The symbol of the null vector generates (part of) the ideal defining the associated variety of $L_k(\mathfrak{sl}_2)$; at admissible level Arakawa's theorem says that variety is $\mathcal{N}$, so L_k is quasi-lisse but not lisse — consistent with its role as an Argyres–Douglas chiral algebra (Higgs branch $= \mathcal{N}$ for (A_1, D_{2n+1})).

Proof on paper. $J^a_n = (J^a_{-1}|0\rangle)_{(n)}$ and $u_{(n)}v \in C_2$ for $n \leq -2$. Of the monomials of s, only those built from (-1)-modes survive; they are iterated products of $[e], [f], [h]$. Collect and factor. □

9.9 $V^{-8/5}(\mathfrak{sl}_2)$ is not simple

9.9.1 From positive current modes to strong singularity

Theorem 9.31 (Strong singularity from the currents). *Let $k \neq -2$. (i) $L_1 v = 0$ for all $v \in V^k_1$. (ii) If every current mode J^a_i, $i \geq 1$, kills t, then every mode $u_{(N)}$ of every homogeneous state $u \in V^k_m$ with $N \geq m$ kills t. In particular, a nonzero such t of weight $w > 0$ is strongly singular of weight w.*

File `VOA/Examples/AffineSl2Strong.lean`.

```
theorem affineSl2_qp (k : ℂ) (hk : k + 2 ≠ 0) :

    SingVec.IsStronglySingularOfWeight (affineSl2VOA_closed k hk) w t where
```

From the mathematics to the Lean statement

`W.L 1` is $L_1 = \omega_{(2)}$. `SingP k t` is exactly "every positive current mode kills t", the output of the explicit computations above (no weight hypothesis). The conclusion of `isStronglySingular_of_SingP` is the structure `IsStronglySingularOfWeight` of Chapter 5, whose `ne_zero`, `weight_pos`, `homogeneous` fields are the hypotheses `hne`, `hw`, `hmem`.

Physical meaning

For a current algebra, "highest weight with respect to the currents" implies "highest weight with respect to every field", because every field is a normal-ordered product of currents and their derivatives.

Proof on paper. (i) V_1^k is spanned by $J^a_{-1}|0\rangle$, which are primary (Theorem 9.13). (ii) Induction on creation words $u = J^{a_1}_{-n_1}\cdots|0\rangle$ using the iterate formula. The naive induction with t fixed fails: expanding $(J^a_{-n-1}w)_{(N)}t$ produces $w_{(\cdot)}(J^a_0 t)$, and $J^a_0 t \neq 0$ in general (for the $k=-8/5$ vector, $h_0 t = 2t$, $f_0 t \neq 0$). The repair is to induct over the set of all t satisfying `SingP`, which is stable under the zero modes: for $i \geq 1$, $J^b_i J^a_0 t = J^a_0 J^b_i t + \sum_c f^{ba}{}_c J^c_i t = 0$ (no central term since $i+0 \neq 0$). □

An overclaim corrected in the source

An earlier version of `AffineSl2Strong.lean` asserted that the general Core-level statement "positive modes of a generating set kill $s \Rightarrow s$ strongly singular" is *false* for generators of weight ≥ 2. What is established is only that *this induction* does not close there; the abstract statement is neither proved nor refuted. The source now says so.

What the machine verified

`VOA.AffineVOA.Strong.affineSl2_qp`, `VOA.AffineVOA.Strong.isStronglySingular_of_SingP`: `[propext, Classical.choice, Quot.sound]` (run for this chapter).

9.9.2 The theorem

Theorem 9.32 ($V^{-8/5}(\mathfrak{sl}_2)$ is not simple). *The universal affine VOA $V^{-8/5}(\mathfrak{sl}_2)$ is not simple. Equivalently, the weight-5 singular vector lies in its maximal ideal, maps to 0 in $L_{-8/5}(\mathfrak{sl}_2)$, the maximal ideal is nonzero, and $L_{-8/5}(\mathfrak{sl}_2)$ is a proper quotient of $V^{-8/5}(\mathfrak{sl}_2)$.*

```

From the mathematics to the Lean statement

`IsSimple` (Chapter 5, Definition 5.16) requires the algebra to be nonzero and to have no ideals other than 0 and everything; so `¬ IsSimple` is informative only if the algebra is nonzero, which `vacuum85_ne_zero` supplies — through the Wakimoto realisation (`vacuumA85_ne_zero` = `vacuumA_ne_zero_free` at $k = -8/5$), *not* through `closed_vacuum_ne_zero`, which would have imported `VOA.pbw`. `qp85` is `affineSl2_qp` at $k = -8/5$. `SingVec.not_isSimple_of_stronglySingular_FHL` is Theorem 5.37 of Chapter 5. The proved ideal is a proper nonzero ideal; the theorem does not identify it with the ideal generated by s, nor claim that s generates the maximal ideal (that is Adamović–Milas, an external input in Chapter 10). The analogous statements at $k = -4/3$ are `LQ43.maxGradedIdeal_ne_bot` in Chapter 10, and at integrable levels Theorem 9.26 (checked outside the library).

Physical meaning

At $k = -8/5$ the current algebra has a null state at energy 5; the chiral algebra with a nondegenerate two-point function, $L_{-8/5}(\mathfrak{sl}_2)$, differs from the universal one. This is the statement that the (A_1, D_5) Argyres–Douglas chiral algebra satisfies a relation among the moment map operators (heuristically, a Higgs branch chiral ring relation).

Proof on paper. $s \neq 0$ (Theorem 9.29) and `SingP` holds, so s is strongly singular of weight 5 (Theorem 9.31). With $|0\rangle \neq 0$ and $L_1 V_1 = 0$, the canonical invariant form exists, s is in its radical, and the radical is a proper nonzero ideal (Theorem 9.16). □

A superseded "not reachable" note

`WakimotoEightFifths.lean` §8 previously said that properness of the ideal (s) "remains out of reach" because it needs the triangular decomposition $U = U(\widehat{\mathfrak{n}}_-)U(\mathfrak{h})U(\widehat{\mathfrak{n}}_+)$. The invariant-form route needs no PBW at all; the preamble has been corrected in the source.

What the machine verified

`VOA.Sl2NotSimple85.stronglySingular85`, `VOA.Sl2NotSimple85.not_isSimple_85`, `VOA.Sl2NotSimple85.mkQ_sl2Singular85_eq_zero`, `VOA.Sl2NotSimple85.maxGradedIdeal_85_ne_bot`, `VOA.Sl2NotSimple85.mkQ_85_not_injective`, `VOA.WakLY.vacuumA85_ne_zero`: `[propext, Classical.choice, Quot.sound]` (run for this chapter). **Unconditional, pbw-free.** The level is $k = -8/5$, i.e. $k + 2 = 2/5$.

9.10 Verma modules of $\widehat{\mathfrak{sl}}_2$

The vacuum module is one member of a two-parameter family. For $k, \lambda \in \mathbb{C}$ the *Verma module* $M(k, \lambda)$ is generated by a vector v_λ with $e_0 v_\lambda = 0$, $J^a_m v_\lambda = 0$ for $m > 0$, $h_0 v_\lambda = \lambda v_\lambda$, $C = k$, $\ell_0 v_\lambda = 0$, and no other relations. The vacuum module is the quotient of $M(k, 0)$ by the extra relation $f_0 v_0 = 0$.

The Kac–Kazhdan determinant formula, which locates all singular vectors, is a statement about the contravariant forms on all $M(k,\lambda)$, so the library develops these modules in full. (Chapter 3, Definition 3.23, has a general-$\mathfrak{g}$ Verma module; the files of this section use a separate, $\mathfrak{sl}_2$-specific construction.)

Definition 9.33 (Affine $\mathfrak{sl}_2$ Verma module)**.** Call a mode (a,n) *lower* if $n<0$, or $n=0$ and $a=f$. $M(k,\lambda)=U(\widehat{\mathfrak{sl}}_2)/I(k,\lambda)$, where the left ideal $I(k,\lambda)$ is generated by $x_a\otimes t^n-\delta_{n,0}\delta_{a,h}\lambda$ for all non-lower (a,n), by $C-k$ and by ℓ_0. The highest vector v_λ is the class of 1. A vector v in a $\widehat{\mathfrak{sl}}_2$-module E is *highest of type* (k,λ) if it satisfies the same relations.

File `VOA/Examples/AffineSl2HighestNormalOrdering.lean`.

  modes : ∀ a n,¬IsLower a n → R (modeElement a n) v=
    if n=0 ∧ a=2 then h • v else 0
```

From the mathematics to the Lean statement

In these files the highest weight is called `h`; we write λ to avoid a clash with the generator h. `U` is $U(\widehat{\mathfrak{sl}}_2)$ (including C and ℓ_0), `ι ℂ` the inclusion $\widehat{\mathfrak{sl}}_2\to U$, `modeElement a n` $=x_a\otimes t^n$, `algebraMap ℂ U` the scalars. So `highestGens` is the list of generators of Definition 9.33, `Verma k h` is $M(k,\lambda)$, and `mode k h a n` is the action of $x_a\otimes t^n$. `IsHighest R v k h` is exactly "v is highest of type (k,λ) for the representation R". The universal property (`universalMap`, `universalMap_highest`, `universalMap_intertwines`, same file) gives the unique $\widehat{\mathfrak{sl}}_2$-map $M(k,\lambda)\to E$ sending $v_\lambda\mapsto v$.

Physical meaning

$M(k,\lambda)$ is the module of all descendants of a WZW primary field of spin $j=\lambda/2$ (its ground states form the $\mathfrak{sl}_2$-Verma module of highest weight λ), before any null vector is removed. For the integrable representations $\lambda\in\{0,\dots,k\}$; at admissible level λ takes fractional admissible values.

What the machine verified

Definitions; axiom-free.

Theorem 9.34 (PBW for Verma modules, at every (k,λ)). *For every $k,\lambda\in\mathbb{C}$: $v_\lambda\neq 0$; the* occupation words *— one fixed product of lower modes for each finite multiset of lower modes — form a basis of $M(k,\lambda)$; and for every nonzero $v\in M(k,\lambda)$ the vectors (occupation word)$\cdot v$ are linearly independent.*

    LinearIndependent ℂ (fun d : Occupation => currentWord (mode k h) (occupationWord d) v)
    ↪  := by
```

From the mathematics to the Lean statement

`Occupation` = `(Fin 3×ℕ)→₀ℕ` (`WakimotoJointFockSpace.lean`) is a finite multiset of oscillator labels; `lowerLetter` translates the label (a,j) into the lower mode e_{-j-1} $(a=0)$, f_{-j} $(a=1$, so $j=0$ is the horizontal f_0), h_{-j-1} $(a=2)$. These labels deliberately match the Wakimoto variables b_{j+1}, c_j, A_{j+1}. `occupationWord d` lists the letters of d in the order chosen by `Multiset.toList` — an arbitrary but fixed order; the straightening file proves spanning for exactly these representatives, so no "sorted order" assumption is hidden. `currentWord R w v` applies the modes of the list w to v (head leftmost). `Module.Basis.mk` builds a basis from independence and spanning, so `occupationBasis` *is* a PBW theorem. The independence proof needs no hypothesis on k: the critical level is included.

Physical meaning

States in the highest-weight representation are counted by free oscillators, one for each lower mode; the character of $M(k,\lambda)$ is $q^{h_\lambda}\prod_{n\geq 1}(1-q^n)^{-1}(1-zq^n)^{-1}(1-z^{-1}q^{n-1})^{-1}$ (in the variable z for h_0).

Proof on paper. Independence: construct an explicit module in which the images are visibly independent. The library uses a triple tensor product of shifted Wakimoto vacuum modules: for $d\geq 2$, $E_n\mapsto E_{dn+1}, F_n\mapsto F_{dn-1}, H_n\mapsto H_{dn}+(\text{old level})\delta_{n,0}$ is a Lie map from $\widehat{\mathfrak{sl}}_2$ at level ℓ to $\widehat{\mathfrak{sl}}_2$ at level $d\ell$ that sends *every* lower mode, including f_0, to a strictly negative mode (`WakimotoShiftedVacuum.lean`); tensoring three such pullbacks with dilations $2,3,4$ and a free auxiliary parameter realises any prescribed (k,λ) (`AffineSl2TensorHighest.lean`), and projecting to the first factor reduces independence to the vacuum independence of Theorem 9.24 (via the injective relabelling $j\mapsto 2j$ or $2j+1$). Spanning: normal ordering, by induction on word length. Descendant independence for arbitrary

$v \neq 0$: the same model gives an injective intertwiner (`exists_injective_creation_model`), and in the polynomial ring the leading symbol of a word times the first nonzero component of the image of v is nonzero, the polynomial ring being a domain. □

What the machine verified

`VOA.AffineVOA.HighestModule.highestVector_ne_zero`, `occupationWords_independent`, `occupationBasis`, `descendants_independent`: `[propext, Classical.choice, Quot.sound]` (run for this chapter). Unconditional at every (k, λ), critical level included.

Theorem 9.35 (The vacuum module is $M(k,0)/M(k,-2)$). *For every $k \in \mathbb{C}$: $f_0 v_0 \in M(k,0)$ is a nonzero highest vector of type $(k,-2)$; the induced map $M(k,-2) \to M(k,0)$ is injective; the canonical map $M(k,0) \to V^k(\mathfrak{sl}_2)$ is surjective with kernel exactly its image. That is, $0 \to M(k,-2) \to M(k,0) \to V^k(\mathfrak{sl}_2) \to 0$ is exact.*

File `VOA/Examples/AffineSl2VacuumProjection.lean`.

```

File `VOA/Examples/AffineSl2VacuumExactSequence.lean`.

```
theorem vacuumProjection_ker (k : ℂ) :
    LinearMap.ker (vacuumProjection k)=LinearMap.range (horizontalEmbedding k) := by
```

From the mathematics to the Lean statement

`mode k 0 1 0` is f_0 on $M(k,0)$. Note that injectivity of the horizontal embedding and the nonvanishing of $f_0 v_0$ use Theorem 9.34 (not `VOA.pbw`), and the kernel computation is an induction in the enveloping algebra, valid at every k, without any character or determinant input.

Physical meaning

The vacuum primary is an $SU(2)$ singlet: the state $J_0^-|0\rangle$ of the Verma module is null at every level and generates a copy of the spin -1 Verma module; removing it gives the vacuum module.

Proof on paper. $e_0 f_0 v_0 = h_0 v_0 = 0$ and $h_0 f_0 v_0 = -2 f_0 v_0$, so $f_0 v_0$ is highest of weight -2. The vacuum ideal is $I(k,0) + U f_0$, so the kernel of $M(k,0) \to V^k$ is $U \cdot f_0 v_0$, which is the image of the embedding. Injectivity: the embedding sends occupation-word basis vectors of $M(k,-2)$ to descendants of the nonzero vector $f_0 v_0$, independent by Theorem 9.34. □

```

From the mathematics to the Lean statement

`Module.Dual ℂ M` is the dual space; a linear map $M \to M^*$ is a bilinear form. `dualRho k h` is the representation on M^* by transposes of the Chevalley adjoints (`AffineSl2VermaDual.lean`); `highestCoordinate k h` is the coefficient of v_λ in the occupation basis, proved to be a highest vector of type (k,λ) in M^*; the form is the universal map $M \to M^*$. Normalisation, adjointness and symmetry are *consequences* of the construction, not assumptions. No complex conjugation occurs: this is the bilinear (Shapovalov) form, the right object for determinants at complex parameters. The *radical* of the form (vectors pairing to zero with everything) is a submodule (`contravariant_radical_mode`).

Physical meaning

At real level and weight, the Hermitian version of this form is the inner product on the Hilbert space of the WZW model; null states are its zero-norm states; the theory is unitary iff the form is positive semi-definite (integrable k,λ).

What the machine verified

`contravariant_normalized`, `contravariant_adj`, `contravariant_symm`: `[propext, Classical.choice, Quot.sound]` (run for this chapter).

Definition 9.37 (Joint weight spaces and the Gram matrices). An occupation d has *energy* $\sum_v d(v)\varepsilon(v)$ and *charge* $\sum_v d(v)\chi(v)$ with $\varepsilon(b_{j+1}) = j{+}1, \varepsilon(c_j) = j, \varepsilon(A_{j+1}) = j{+}1$ and $\chi = +1, -1, 0$ on the three families. The *joint index* $\mathcal{J}(n,c)$ is the (finite) set of occupations of energy n and charge c. The *Gram matrix* $G_{n,c}(k,\lambda)$ is the matrix of the contravariant form on the occupation basis vectors indexed by $\mathcal{J}(n,c)$; $D_{n,c}(k,\lambda) = \det G_{n,c}(k,\lambda)$. For fixed k it is a polynomial in λ, the *weight determinant*.

def weightDeterminant (k : ℂ) (n : ℕ) (c : ℤ) : Polynomial ℂ :=
  (weightGramPolynomial k n c).det
```

From the mathematics to the Lean statement

`occupationEnergy`, `occupationCharge` are the additive extensions (`Finsupp.weight`) of `oscillatorEnergy`, `oscillatorCharge`. The charge counts e-letters minus f-letters, so a vector of charge c in $M(k,\lambda)$ has h_0-eigenvalue $\lambda + 2c$. `highestGramPolynomial n c` is a matrix of polynomials in two variables (k,λ) obtained by normal ordering; the theorem `highestGramPolynomial_verma` says that evaluating it at (k,λ) gives the actual Gram matrix of the actual form, at *all* parameters (no non-critical hypothesis). `weightDeterminant k n c` substitutes k and keeps λ as the variable `X`. So the determinant studied below is a genuine Gram determinant, not a formal expression.

Physical meaning

$G_{n,c}$ is the matrix of two-point functions of the descendants at energy n and spin projection $\frac{1}{2}\lambda + c$. Its determinant vanishes exactly when a null state exists in that sector.

What the machine verified

Definitions; `highestGramPolynomial_verma`: `[propext, Classical.choice, Quot.sound]`.

9.11 Screening operators and singular vectors in Verma modules

9.11.1 The charged Wakimoto module

Definition 9.38 (Wakimoto module of highest weight λ). On the same Fock space $\mathcal{F}$ set $H_n = h_n + \lambda\delta_{n,0}$ and $F_n = f_n + \lambda\gamma_n$, $E_n = e_n$. For $k \neq -2$ this is a representation of $\widehat{\mathfrak{sl}}_2$ at level k, and 1 is a highest vector of type (k,λ).

File `VOA/Examples/WakimotoCharged.lean`.

```

noncomputable def rho (k lam : ℂ) (hk : k + 2 ≠ 0) :
    AffSl2 →ₗ[ℂ] Module.End ℂ WakFock := (currentData k lam hk).rho
```

From the mathematics to the Lean statement

This is the Wakimoto module with boson momentum λ (namespace `Wak.Charged`): shifting the boson zero mode by λ adds λ to h_0 and $\lambda\gamma$ to f. `currentData` packages the proved commutators into the generic interface `AffineCentralCurrentData` (Section 9.13), which produces the Lie map.

Physical meaning

The Wakimoto module W_λ is the Fock module of $\beta\gamma$ and of the boson with momentum $p \propto \lambda$: the free-field representative of the WZW primary of spin $\lambda/2$. It is generally not isomorphic to $M(k,\lambda)$ (it is a "twisted dual"), but it receives the highest vector.

What the machine verified

Definitions; axiom-free.

9.11.2 Screening vectors

Physically, the screening current of the Wakimoto realisation is $S(z) = \beta(z)\, e^{-\frac{2}{\alpha_+}\phi(z)}$ with $\alpha_+^2 = 2(k+2)$; its contour integral commutes with $\widehat{\mathfrak{sl}}_2$. An r-fold integral of products of screening currents applied to a Fock vector produces singular vectors. When $k+2 = 1/M$ for a positive integer M the integrand is single-valued, $\prod_{i<j}(z_i - z_j)^{2M} \prod_i \beta(z_i) \exp(-M \sum_m \frac{p_m(z)}{m} a_{-m})$, and the integral is a coefficient extraction. The library implements exactly this, with all series truncated.

Definition 9.39 (The integer screening state). For $r, q, M \geq 1$ let $\mathrm{state}(r,q,M) \in \mathcal{F}$ be the coefficient of $z_1^{(r-1)M+q-1} \cdots z_r^{(r-1)M+q-1}$ in the finite Laurent polynomial

$$\Delta(z)^{2M} \prod_{i=1}^{r} \Big(\sum_{j=0}^{D} b_{j+1} z_i^j \Big) \prod_{m=1}^{D} \sum_{\ell=0}^{D} \frac{1}{\ell!} \Big(-\frac{M}{m} \Big)^{\ell} \Big(A_m \sum_i z_i^m \Big)^{\ell}, \qquad D = r(q-1),$$

with Δ the Vandermonde (the Laurent Vandermonde of `VOA/Examples/VirasoroScreeningVandermonde.lean`, Chapter 7).

File `VOA/Examples/AffineSl2ScreeningPolynomial.lean`.

```

    ∏ m ∈ Finset.range (r*(q-1)), exponentialFactor r (r*(q-1)) M (m+1)

noncomputable def state (r q M : ℕ) : WakFock :=
  integrand r q M (fun _ => (((r-1)*M+q-1 : ℕ) : ℤ))
```

From the mathematics to the Lean statement

`Auxiliary r` = `AddMonoidAlgebra WakFock (Fin r →₀ ℤ)` is the ring of Laurent polynomials in $z_1, \dots, z_r$ with coefficients in $\mathcal{F}$; `single e P` is Pz^e; `unitExponent r i` is the exponent of z_i; `bosonPower r m` is $A_m \sum_i z_i^m$; `delta r` is the Vandermonde. Applying an element of `Auxiliary r` to an exponent extracts that coefficient. Everything is finite, so there is no analytic content and no convergence issue; the truncation degree $D = r(q-1)$ is exactly what the selected coefficient can see (`AffineSl2ScreeningSupport.lean`).

Physical meaning

state(r, q, M) is $\oint \cdots \oint S(z_1) \cdots S(z_r)\, dz$ applied to a Fock vacuum: r screening charges. The Vandermonde power is the free-boson two-point function $\prod (z_i - z_j)^{2M}$, the β factors come from $\beta(z_i)$, and the exponential is the creation part of $e^{-2\phi/\alpha_+}$.

What the machine verified

Definitions; axiom-free.

Theorem 9.40 (Screening singular vectors). *Let $r, q, M \geq 1$ and k with $M(k+2) = 1$. Put $\lambda = q(k+2) - r - 1$. Then* state$(r, q, M) \neq 0$*, it has energy rq, it satisfies $H_0\, s = (q(k+2) + r - 1)s$ (i.e. charge $+r$ relative to λ), $E_0 s = 0$, and every positive current mode of the charged representation kills it.*

File `VOA/Examples/AffineSl2ScreeningSingular.lean`.

```
theorem exists_nonzero_screening_highest (r q M : ℕ) (hr : 0<r) (hq : 0<q)
    (k : ℂ) (hMk : (M : ℂ)*(k+2)=1) :

        ((q : ℂ)*(k+2)+(r : ℂ)-1) • v ∧
      Ecur 0 v=0 ∧
      ∀ (a : Fin 3) (n : ℤ),0<n →
        Charged.J k ((q : ℂ)*(k+2)-(r : ℂ)-1) a n v=0 := by
```

From the mathematics to the Lean statement

`Dwt` is the energy operator. The level is restricted to $k + 2 = 1/M$ (reciprocal positive integers); the witness is `state r q M`. The statement is about the Wakimoto module, not yet about $M(k, \lambda)$; the next section transfers it. Note that all three conditions are *proved*; the source stresses that no "screening Ward identity" is assumed — the proof is a long sequence of finite integration-by-parts identities in `Auxiliary r` (the 27 files `AffineSl2Screening*.lean`).

Physical meaning

This is the Feigin–Frenkel mechanism: screening operators commute with the current algebra, so they map highest vectors to highest vectors; acting r times on the Fock vacuum of momen-

tum λ they produce the Malikov–Feigin–Fuchs singular vector of $M(k,\lambda)$ at $\lambda = q(k+2)-r-1$, the Kac–Kazhdan condition for the root $q\delta-\alpha$ with multiplicity r.

Proof on paper. Nonvanishing: set $b_q = 1$ and all other variables 0; the value is the central coefficient of $\Delta^{2M}\prod z_i^{q-1}$, a nonzero constant-term identity (Dyson's constant term). Raising modes: the integrand contains only b and A variables, so $E_n = \partial/\partial c_n$ ($n \geq 0$) kills it. Positive H_n: direct computation, the $\beta\gamma$ and boson contributions cancel after finite integration by parts. F_1: the hardest, a weighted Vandermonde derivative identity plus pair counting at the screening charge; higher F_n from $[H_{n-1}, F_1]$. □

What the machine verified

`VOA.Wak.Screening.exists_nonzero_screening_highest: [propext, Classical.choice, Quot.sound]` (run for this chapter).

9.12 The Kac–Kazhdan determinant

9.12.1 The classical formula

For $\widehat{\mathfrak{sl}}_2$ with $t = k+2$, the positive real roots are $\beta = m\delta-\alpha$ ($m \geq 1$) and $\beta = m\delta+\alpha$ ($m \geq 0$), with $(\lambda+\rho, m\delta \mp \alpha) = mt \mp (\lambda+1)$ for the highest weight (k,λ). The Kac–Kazhdan formula says that, up to a nonzero constant and powers of t coming from the imaginary roots,

$$\det G_\eta(k,\lambda) \;\propto\; \prod_{\beta>0 \text{ real}} \prod_{n\geq 1} \big((\lambda+\rho,\beta)-n\big)^{P(\eta-n\beta)}, \tag{9.5}$$

where η is the weight of the block and P the Kostant partition function (here: the number of occupations of the shifted energy and charge). As a polynomial in λ at fixed k the real-root factors are linear: $\lambda-(mt-n-1)$ for $\beta = m\delta-\alpha$ and $\lambda-(n-1-mt)$ for $\beta = m\delta+\alpha$; the latter with $m=0$ is the horizontal family, $f_0^n v_\lambda$ singular at $\lambda = n-1$.

9.12.2 The library's statement

Definition 9.41 (Real-root labels, weights, multiplicities, the Kac product). A *label* is $i = ((a,j),r)$ with $a \in \{0,1\}$ (an oscillator of colour β or γ at depth j) and $r \geq 0$ (the occurrence $n = r+1$). Its *real-root weight* at t is $w_t(i) = s(a,j)\,t + o(a,j,r)$ with slope $s = j+1$, offset $-r-2$ for $a=0$ (the root $(j+1)\delta-\alpha$), and slope $-j$, offset r for $a=1$ (the root $j\delta+\alpha$). For a block (n,c) the label set $\mathcal{L}(n,c)$ consists of the labels in the finite oscillator box with $(r+1)\cdot\mathrm{energy}(a,j) \leq n$, and the multiplicity of i is $|\mathcal{J}(n-(r+1)\varepsilon, c-(r+1)\chi)|$. The *Kac product* is $K_{n,c}(t)(X) = \prod_{i\in\mathcal{L}(n,c)}(X-w_t(i))^{\mathrm{mult}(i)}$.

def annihilationWeight (k : ℂ) (v : Fin 3×ℕ) : ℂ :=
  if v.1=0 then -1 else if v.1=1 then 1 else 2*(k+2)*(v.2+1)
```

From the mathematics to the Lean statement

`realRootModes n c` is the set of β- and γ-oscillators (colours 0, 1; bosons excluded) of depth at most $2n-c$; the factor `Finset.range (2*n-c)` bounds r by the principal weight. Neither bound excludes a genuine factor: a label outside them has multiplicity zero. The integer casts and natural subtraction in `affineKacMultiplicity` are harmless because the filter guarantees $(r+1)\varepsilon \le n$. The constant: `derivativeMultiplier k w e` is a product of `annihilationWeights`, which are ∓ 1 for the ghosts and $2(k+2)(j+1)$ for the boson at depth j — the imaginary-root factors of the Kac–Kazhdan formula, powers of $t = k+2$.

Physical meaning

Each label is a null vector: the $r+1$-st power of a lowering operator associated with the real root becomes null when the momentum of the Wakimoto boson sits at the corresponding position of the Kac table; its multiplicity is the number of descendants of that null vector in the block.

What the machine verified

Definitions; axiom-free.

Theorem 9.42 (Kac–Kazhdan determinant formula for $\widehat{\mathfrak{sl}}_2$, every level). *For every $t \in \mathbb{C}$, every energy n and charge c, as polynomials in λ,*

$$\det G_{n,c}(t-2,\lambda) = C_{n,c}(t)\cdot K_{n,c}(t)(\lambda), \qquad C_{n,c}(t) = \prod_{i\in\mathcal{J}(n,c)} \mathrm{derivativeMultiplier}(t-2,\dots).$$

$K_{n,c}(t)$ is monic of degree rowDegree+creationDegree, *and $C_{n,c}(t) \neq 0$ for $t \neq 0$; so at non-critical level the roots of the Gram determinant in λ are exactly the real-root weights, with the stated multiplicities.*

    (weightDeterminant k n c).leadingCoeff=
      ∏ i : JointIndex n c,derivativeMultiplier k i.val.toMultiset.toList.reverse 0 := by
```

From the mathematics to the Lean statement

`t.im≠0` restricts the first version to non-real t; `_all` removes the restriction. The argument `i.val.toMultiset.toList.reverse` is the reversed occupation word of the basis index i (the adjoint row), and 0 the empty starting occupation. `rowDegree`, `creationDegree` count lowering letters in the adjoint and creation words. So `weightDeterminant_eq_affineKacProduct_all` is exactly the displayed formula, as an identity in $\mathbb{C}[\lambda]$ for every complex t — including $t = 0$, where C may vanish and the identity is the true but uninformative $0 = 0$ (the source says so explicitly: "no noncritical nondegeneracy is asserted there"). `affineKac_factor` is the individual divisibility for every t. Compared with the textbook (9.5): same factors, same multiplicities (Kostant partition function = occupation count), constant identified explicitly. **How could it have been vacuous?** If `weightDeterminant` were not the determinant of the actual form, the identity would be about a formal object; Definition 9.37 and `highestGramPolynomial_verma` close that gap. If the occupation words were not a basis, the Gram matrix would not represent the form; Theorem 9.34 closes that gap.

Physical meaning

The Kac determinant tells, for each level and spin, exactly where null states appear in the WZW representation theory: at $\lambda = mt - n - 1$ (descendants of $(J^+_{-m})^n$-type null vectors) and $\lambda = n - 1 - mt$. Integrable representations ($t = N + 2, \lambda \in \{0, \dots, N\}$) sit on the intersection of the lines $m = 0$ (horizontal, $n = \lambda + 1$) and $m = 1, n = N + 1 - \lambda$: the two null vectors $f_0^{\lambda+1}v$ and $e_{-1}^{N+1-\lambda}v$ whose removal gives the unitary modules and the fusion rules. Admissible levels are where two families of lines meet rationally.

Proof on paper. Three ingredients. (a) *Degree and leading coefficient*: the Gram matrix factors through the charged Wakimoto Fock space as (adjoint-row matrix)×(creation matrix); both factors are polynomial in λ and triangular in boson count with explicit diagonals; this gives $\deg_\lambda \det$ = rowDegree + creationDegree and the leading coefficient $C_{n,c}$. (b) *Roots with multiplicity*: for $t = 1/M$ the screening vectors of Theorem 9.40 give kernel vectors of the Fock row matrix, hence Gram-determinant roots at $\lambda = qt - r - 1$ (`highestDeterminant_screening_root`); since the determinant is polynomial in (t, λ) and vanishes on the line $\lambda = qt - r - 1$ for infinitely many t,

it vanishes on the whole line (`highestDeterminant_kac_root`). The opposite family comes from the diagram automorphism of $\widehat{\mathfrak{sl}}_2$ ($E_n \mapsto F_{n+1}, F_n \mapsto E_{n-1}, \lambda \mapsto k - \lambda$), realised on the Wakimoto module (`WakimotoDiagramAction.lean`, `highestDeterminant_opposite_kac_root`). A radical vector in block (n, c) has an independent family of descendants (Theorem 9.34) lying in the radical, giving the factor with multiplicity $|\mathcal{J}(m, d)|$ (`weightDeterminant_factor_of_radical`, `weightDeterminant_positive_factor`, `weightDeterminant_negative_factor`). (c) *Counting*: at non-real t the real-root weights of distinct labels are distinct (integer linear functions of a non-real number agree only if their coefficients agree), so the product divides; its degree equals the determinant's (exact occupation count), and both are compared via leading coefficients. Finally both sides are continuous in t and agree on the dense set of non-real t, so they agree everywhere — this preserves multiplicities of colliding factors without counting null spaces. □

What the machine verified

`VOA.Wak.Charged.weightDeterminant_eq_affineKacProduct`, `VOA.Wak.Charged.weightDeterminant_eq_affineKacProduct_all`, `VOA.Wak.Charged.highestDeterminant_screening_root`, `highestDeterminant_kac_root`, `highestDeterminant_opposite_kac_root`, and `VOA.AffineVOA.HighestModule.weightDeterminant_natDegree`, `weightDeterminant_leadingCoeff`, `weightDeterminant_factor_of_radical`, `weightDeterminant_positive_factor`, `weightDeterminant_negative_factor`: all `[propext, Classical.choice, Quot.sound]` (run for this chapter). **Unconditional, every complex level.**

9.12.3 The vacuum specialisation

At $\lambda = 0$ the horizontal factor X of $K_{n,c}$ vanishes identically in t, reflecting the null vector $f_0 v_0$. The vacuum module's own Gram determinant is obtained by removing it.

Theorem 9.43 (Vacuum coefficient identity). *For $2n - c > 0$, as polynomials in k,*

$$\det V_{n,c}(k) \cdot \det G_{n,c+1}(k, -2) = \sigma_{n,c}\, \Lambda_{n,c}(k) \prod_{i \in \mathcal{L}(n,c) \setminus \{\mathit{horizontal}\}} \big(-w_{k+2}(i)\big)^{\mathrm{mult}(i)},$$

where $V_{n,c}(k)$ is the Gram matrix of the vacuum module (VOA convention, charge $2c$) in an adapted basis, $\sigma_{n,c} \neq 0$ a constant, and $\Lambda_{n,c}(k) \neq 0$ for $k \neq -2$.

File `VOA/Examples/AffineSl2KacVacuumCoefficient.lean`.

```

      Polynomial.C (vacuumDeterminantScale n c)*affineLeadingPolynomial n
      ↪ c*affineVacuumProduct n c := by
```

From the mathematics to the Lean statement

`((1,0),0)` is the horizontal label (γ at depth 0, first occurrence: $f_0 v$). The variable `X` is now the level k (so $t = X+2$). `vacuumChevalleyPolynomial n c` (`AffineSl2VacuumFirstBlock.lean`) is the Gram matrix of the universal vacuum module on adapted PBW words, written in the VOA bilinear convention via the Chevalley involution (`AffineSl2VacuumChevalley*.lean`); `vacuumDeterminantScale` is the square of a constant change-of-basis determinant, nonzero (`vacuumDeterminantScale_ne_zero`). This identity is the input that Chapter 10 uses to locate a *simple* root of the vacuum determinant at every negative admissible level.

Physical meaning

The vacuum Kac determinant: null states of the WZW vacuum module occur exactly at the levels where a non-horizontal real-root factor vanishes at $\lambda = 0$, i.e. $m(k+2) - n - 1 = 0$ — the integrable ($m = 1$, $k = n-1$) and admissible ($k+2 = (n+1)/m$) levels.

Proof on paper. By the exact sequence (Theorem 9.35) the weight-0 Verma block splits, in an adapted basis, into a vacuum part and the horizontal radical $M(k,-2)$. Expanding $\det G_{n,c}(k,\lambda)$ at $\lambda = 0$, the first nonvanishing coefficient (of order $\lambda^{|\mathcal{J}(n,c+1)|}$) is $\det V \cdot \det G(k,-2)$ (the first-order form on the horizontal radical is the actual form on $M(k,-2)$, `AffineSl2HorizontalFirstForm.lean`). On the other side it is the corresponding coefficient of $C \cdot K$, i.e. C times the product of the remaining factors at $\lambda = 0$. □

What the machine verified

`VOA.Wak.Charged.affine_vacuum_polynomial_identity, affineLeadingPolynomial_eval_ne_zero: [propext, Classical.choice, Quot.sound]` (run for this chapter).

9.13 Supporting infrastructure

The remaining files serve the headlines above or Chapter 10. They are summarised here by group; none contains an axiom, and none introduces a hypothesis that a headline depends on.

Assembling representations from current data. `AffineSl2CentralCurrentRealization.lean` (`AffineCentralCurrentData`: loop modes, a degree operator and a *possibly non-scalar* central operator satisfying the affine relations assemble to a Lie map $\widehat{\mathfrak{sl}}_2 \to \operatorname{End} E$; used for first-order deformations where the centre is $k + \delta N$, $N^2 = 0$), `AffineSl2CurrentRealization.lean` (`AffineCurrentData`, scalar level), `AffineSl2CurrentOPEBridge.lean` (`AffineCurrentFieldData`: from current OPEs to such data), `AffineSl2VacuumEvaluation.lean` (`VacuumCurrentRealization`: a representation with a vector satisfying the vacuum conditions receives a map from $V^k(\mathfrak{sl}_2)$, `VacuumCurrentRealization.eval`). These generalise the Wakimoto evaluation of Theorem 9.21 and are consumed by the inverse Drinfeld–Sokolov programme (Chapter 19).

Normal ordering and pairings. `AffineSl2NormalOrdering.lean` (normal forms with an operator-valued level), `AffineSl2HighestNormalOrdering.lean` (the same retaining f_0 and powers of λ), `AffineSl2UniversalPairing.lean`, `AffineSl2UniversalGram.lean` (vacuum-pairing polynomials are the actual universal Gram entries, `wordGramPolynomial_universal`), `AffineSl2HighestPairingPolynomial.lean`, `AffineSl2SingularNorm.lean`, `AffineSl2SingularLift.lean` (deformation-side pairings; Chapter 10).

Joint eigenspaces and Gram blocks of the vacuum module. `AffineSl2JointPBW.lean` (bases of simultaneous (L_0, h_0)-eigenspaces from Theorem 9.25), `AffineSl2JointGram.lean` (the canonical form pairs energy n, charge h with energy n, charge $-h$; a row relation of a Gram block lies in the maximal ideal, `jointGram_row_relation`), `AffineSl2JointChargeFlip.lean`, `AffineSl2JointContractionDiagonal.lean`, `AffineSl2JointGramDegree.lean`, `AffineSl2JointGramLeading.lean`, `AffineSl2GramDegree.lean`, `AffineSl2CentralContractions.lean`, `AffineSl2ContractionMultiset.lean` (leading terms in k: exact degree and nonzero leading coefficient of the joint determinants), and the two rigidity criteria `graded_rigidity_of_joint_simple_root` (`AffineSl2JointSimpleRoot.lean`) and `graded_rigidity_of_vacuum_simple_root` (`AffineSl2VacuumSimpleRoot.lean`), which Chapter 10 presents.

The Verma/Kac machinery. `AffineSl2Verma*.lean`, `AffineSl2Highest*.lean`, `AffineSl2Horizontal*.lean`, `AffineSl2Vacuum*.lean`, `AffineSl2Kac*.lean`, `AffineSl2Fock*.lean`, `AffineSl2ChargedPolynomial*.lean`, `AffineSl2CreationWeightLeading.lean`, `AffineSl2AnnihilationWeightLeading.lean`, `AffineSl2Occupation*.lean`, `AffineSl2OscillatorWordPairing.lean`, `AffineSl2BosonFiltration.lean`, `AffineSl2DiagramGramRoots.lean`, `AffineSl2TensorHighest.lean`, `AffineSl2WakimotoDescendants.lean`, `Wakimoto*.lean` other than `WakimotoFree` and `WakimotoEightFifths`: the steps of the proofs of Theorems 9.34, 9.35, 9.40, 9.42, 9.43.

Sugawara internals. `AffineSl2CurrentCov.lean`, `AffineSl2CurrentCovStruct.lean`, `AffineSl2L0Cov.lean`, `AffineSl2Assembly.lean`, `AffineSl2Virasoro.lean` (Section 9.3–9.4).

Filtrations and norms. `AffineSl2GoodFiltration.lean` constructs the "corrected R-filtration" on $V^k(\mathfrak{sl}_2)$ in which both the currents and the Sugawara vector have degree one (`correctedAffineGoodFiltration`, a `GoodFiltration` in the sense of Chapter 11); it descends to every graded quotient. The source says explicitly what it does not claim (no identification with an intrinsic filtration on a quotient, no inverse-DS strictness). `AffineSl2HarmonicNorm.lean` computes a multiplicity-free family of norms (`canonical_compactHarmonicDiagonal_eq`) and their signs at negative real level, for the graded unitarity programme of Chapter 19. `AffineSl2Indep.lean` (the `pbw`-dependent independence lemmas of Section 9.8) and `AffineSl2UniversalC2PBW.lean` (the C_2-symbol reduction) complete the list.

What the machine verified

`VOA.AffineVOA.CorrectedR.correctedAffineGoodFiltration`: `[propext, Classical.choice, Quot.sound]` (run for this chapter). The other declarations of this section were not individually audited for this chapter; the library's own audit (`scripts/audit/run_axiom_audits.py`) is the record for them.

9.14 Documentation defects found while writing this chapter

Stale or incorrect docstrings (severity: documentation)

1. `VOA/Examples/Affine.lean`, module docstring: describes the affine VOA as "assembled down to a single reconstruction input" with status "Phase 3, needs the module-polymorphic reconstruction theorem" and vacuum "nonzero via `pbw`". All superseded: `affineSl2VOA_closed` exists and is `pbw`-free (Definition 9.14).

2. `VOA/Examples/AffineSl2VOA.lean`, section "Axioms": says the current-algebra inputs

`current_comm`, `Jfield_local` "carry the sanctioned `VOA.pbw`". False: both are axiom-clean (Section 9.15). Only `vacuumA_ne_zero` in that file uses `VOA.pbw` (now a theorem).

3. `VOA/Examples/AffineSimpleQuotient.lean` §4: a documentation-only "definition" of `AffineSimple.affineSl2Simple` that is not compiled and would depend on `pbw` (Section 9.5).

4. `VOA/Examples/AffineSl2PBWWakimotoReduction.lean`, "Status": calls the Wakimoto independence "OPEN"; it is proved (`wakimotoOrderedCreationState_linearIndependent`).

5. `VOA/Examples/AffineSl2Singular.lean` §E, `AffineSl2Singular85.lean` §E, `AffineSl2SingularLY.lean` §E, `AffineSl2Indep.lean`, `AffineSl2Symbol.lean`, `AffineSl2VOAInstance.lean`: "$s \neq 0$ needs PBW independence / is out of reach", "no `pbw`-free theorem can assert that this VOA is nonzero", "the repository does not yet have" a PBW coordinate functional. All superseded by `Wak.sl2Singular_ne_zero`, `WakLY.sl2SingularLY_ne_zero`, `Wak.vacuumA_ne_zero_free` and `affineSl2PBWBasis`.

6. `AffineSl2VOA.lean`, `AffineSl2VOAInstance.lean`, `Affine.lean`: docstrings still describe `pbw` as the sanctioned axiom; superseded by a later revision of the library, which made `VOA.pbw` a theorem.

7. `VOA/Examples/AffineSl2VOAInstance.lean`: says $L_n s = 0$ for $n = 1, 2, 3$ is missing because the general Sugawara commutator $[L_n, J^c_\mu]$ is proved only for $n = -1, 0$. Superseded: `Vir.Lcomm_J` (`AffineSl2Virasoro.lean`) proves it for all n.

None of these affects a Lean statement; they affect a reader who trusts the comments.

9.15 Verification record

All axiom checks were run for this chapter on a scratch file importing the relevant modules of the already-built tree (no full `lake build` was run):

```
export PATH="$HOME/.elan/bin:$PATH"
lake env lean -DmaxSynthPendingDepth=3 <scratchpad>/L08/Ax.lean
```

The file contains 96 `#print axioms` commands; all elaborated without error. Output, joined per line and grouped:

```

In a later run, after `VOA.pbw` became a theorem (not re-run for this edition), all five report `[propext, Classical.choice, Quot.sound]` (re-probed). The Lean check of Theorem 9.26 (not part of this release) was compiled with the same command; its five `#print axioms` lines all report `[propext, Classical.choice, Quot.sound]`.

Where `VOA.pbw` enters. A text search of the code (comments stripped) of the 133 files of this chapter for uses of `vacuumA_ne_zero`, `vacuumVector_ne_zero`, `closed_vacuum_ne_zero`, `voaSl2Adm_vacuum_ne_zero` and the `Sl2Indep` lemmas finds direct uses only in `AffineSl2VOA.lean` (`vacuumA_ne_zero` itself), `AffineSl2VOAInstance.lean` (`closed_vacuum_ne_zero`, `voaSl2Adm_vacuum_ne_zero`), `AffineSl2Indep.lean` (the lemmas `deg1E_ne_zero`, `deg1F_ne_zero`, `deg1H_ne_zero` and everything built on them) and `WakimotoFree.lean` (`M_indep_sing`). Every route ends at `AffineLie.vacuumVector_ne_zero`, i.e. the field `affineVacuum` of the theorem `VOA.pbw`. This confirms the claim of Chapter 3.

The library's own record at the snapshot: the commit message of that snapshot reports an aggregate build of 10,343 jobs with `check_repository.py` and `run_axiom_audits.py` passing. That is the source's claim; the axiom lists above are what this chapter's author re-confirmed.

9.16 Referee's checklist

"Uncond." means the listed hypotheses are ordinary mathematical hypotheses with no unestablished datum; $*$ marks a `#print axioms` run for this chapter with result `[propext, Classical.choice, Quot.sound]`; † marks a result whose proof goes through `VOA.pbw` (an axiom at the snapshot, a theorem now; all such results now report the three standard axioms). Namespaces: `AV` = `VOA.AffineVOA`, `HM` = `VOA.AffineVOA.HighestModule`, `WC` = `VOA.Wak.Charged`.

`WC.affine_vacuum_polynomial_identity*`	vacuum Kac coefficient	$2n>c$	uncond.; Thm. 9.43

Points a referee should weigh. (1) The VOA structure has no nonvanishing field; check which nonvanishing proof each result uses (Section 9.2). Every headline uses a `pbw`-free one. (2) The "level is a theorem" results are about coefficient systems within a fixed ansatz; the converse statements about all vectors carry explicit independence hypotheses. (3) `AffineSimple.affineSl2Simple` is documentation, not code (Section 9.5). (4) The integrable-level singular vector is not in the library; the chapter supplies a Lean check that is not part of this release. (5) The Kac formula is stated as a polynomial identity in λ at every complex t; at the critical level it degenerates honestly. (6) `WakModule` is the universal vacuum module, not a Wakimoto module.

Chapter 10

Graded first-order rigidity of affine $\mathfrak{sl}_2$: Linshaw–Qi and admissible levels

This chapter documents the release of the library named in the front matter. The chapter was first written against an earlier commit (the "documented commit" of the historical records below); the mathematics it describes was completed in the commit immediately before that one ("Prove uniform negative-admissible affine sl2 graded rigidity"). Quotations from the repository are printed in `leancode` boxes, which `scripts/textbook/sync.py` checks to occur verbatim in the source files of the release (docstrings and comments are omitted from the quotations, never the code); tool output is printed in plain boxes.

The question of this chapter is easy to state. Take the simple affine vertex operator algebra $L_k(\mathfrak{sl}_2)$ — the chiral algebra of the $SU(2)$ Wess–Zumino–Witten model at level k — and ask whether its operator product expansion can be deformed. Not deformed by a change of coordinates (renaming the fields, which changes nothing), but genuinely: is there a one-parameter family of vertex algebras V_t, with $V_0 = L_k(\mathfrak{sl}_2)$, that is not just $L_k(\mathfrak{sl}_2)$ in disguise? A VOA with no such infinitesimal family is called *rigid*. The library works to first order and with gradings: its notion is *graded first-order rigidity* (deformations over $\mathbb{C}[t]/(t^2)$, the vertex operation deformed, the vacuum fixed, the weight grading respected; a deformation is trivial when it is the coboundary of a grade-preserving, vacuum-fixing φ). Every rigidity statement in this chapter is meant in that sense, and nothing is claimed about formal, ungraded or grading-moving deformations. The library proves:

Theorem 10.1 (informal; precise form in Theorem 10.15)**.** *Let p, q be coprime positive integers with $2 \le p < 2q$, and put $k = p/q - 2$. Then every graded first-order deformation of the simple affine VOA $L_k(\mathfrak{sl}_2)$ is trivial.*

Physical meaning

The $SU(2)$ WZW model at level k is the CFT of a string moving on the group manifold $SU(2) \cong S^3$ with k units of H-flux; its holomorphic currents $J^a(z)$ generate $L_k(\mathfrak{sl}_2)$. At negative fractional k the corresponding CFTs are non-unitary (negative central charge $c = 3k/(k+2)$, e.g. $c = -6$ at $k = -4/3$). The theorem says such a chiral algebra admits no infinitesimal change of its OPEs other than field redefinitions: there is no "chiral conformal manifold" through it. A physicist expects this because the only continuous parameter of the current OPE (10.1) is k, and at admissible k the null-vector relations exist only at that value. This is a heuristic; the proof is below.

The levels covered are exactly the *negative admissible* levels of Kac and Wakimoto: $k = -4/3$, $-1/2$, $-8/5$, $-2/3$, $-12/7$, $-5/4$, … (every rational number $k \in (-2, 0)$ whose shifted level $k + 2$ has numerator at least 2 in lowest terms). The case $k = -4/3$ is Theorem 5.1 of Linshaw and Qi (arXiv:2601.12017); the uniform statement is new in this library.

What the machine verified

The headline is `VOA.AffineSl2GeneralRigidity.negative_admissible_graded_rigidity` in `VOA/Examples/AffineSl2AdmissibleRigidity.lean`. Its only hypotheses are the four numerical conditions $2 \le p$, $0 < q$, $\gcd(p,q) = 1$, $p < 2q$; no singular-vector, determinant, character, representation-theoretic or reconstruction premise remains. The Linshaw–Qi level is separately `VOA.LQ43.L43_graded_rigidity` (no hypotheses at all). While writing this chapter, `#print axioms` was re-run on both (with `lake env lean -DmaxSynthPendingDepth=3` against the built tree), and on every other headline declaration of the chapter; the answer was in every case `[propext, Classical.choice, Quot.sound]`. The PBW theorem `VOA.pbw` (Chapter 3; formerly a project axiom, now a theorem) is *not* used anywhere in this chapter's results, even though they concern an affine Lie-algebra construction: the affine vacuum module is shown nonzero through a PBW theorem *proved* by Wakimoto triangularity, not through `VOA.pbw`. Both theorems are therefore *unconditional* statements of graded first-order rigidity. Two caveats from the release audit (`Notes/Textbook/referee/RELEASE_AUDIT_RIGIDITY.md`) accompany them: only graded first-order deformations are covered, and the non-vacuity of the rigidity notion (that some VOA fails it) was argued on paper only. The second caveat has since been discharged: the library proves that the universal Virasoro VOA $V(c,0)$ is not graded rigid, for every c (`VOA.VirPoly.not_isRigidGraded_virasoroVOA`; the witness $\partial_c Y$ moves the central charge, which `FirstOrderDeformation` permits; Section 10.3, second warning). The full record is in Section 10.11.

How to read this chapter. Every definition and theorem appears as a mathematical statement, then its Lean declaration copied verbatim, then a fidelity-check box (titled *From the mathematics to the Lean statement*) that decodes the Lean, lists every hypothesis, traces every defined term to its definition, compares with the literature, and says how the statement could have been wrong or vacuous. Proofs are explained on paper. Sections 10.1–10.3 set up the objects (affine $\mathfrak{sl}_2$, admissible levels, deformations); Section 10.4 is the Lie-algebra cohomology needed to normalise a deformation; Section 10.5 is the story of Linshaw–Qi's Theorem 5.1, including the *tautological bundled hypothesis* that an earlier revision of the library carried and how it was removed; Sections 10.6–10.8 give the uniform proof; Section 10.9 describes the (conditional) boundary-level C_2 programme that lives in the same files. The chapter ends with the verification record, the referee's checklist, and notes and references.

A physicist's preview. In a two-dimensional conformal field theory, the chiral algebra is the algebra of holomorphic fields and their operator product expansions (OPEs). For the $SU(2)$ WZW model the chiral algebra is generated by three currents $J^e(z), J^h(z), J^f(z)$ with OPE

$$J^a(z)J^b(w) \sim \frac{k\,\kappa(a,b)}{(z-w)^2} + \frac{J^{[a,b]}(w)}{z-w}, \tag{10.1}$$

where κ is the normalised Killing form. The OPE has exactly two pieces of data: the structure constants of $\mathfrak{sl}_2$ (which cannot change continuously — $\mathfrak{sl}_2$ is rigid as a Lie algebra) and the number k in the double pole. A first-order deformation of the OPE therefore has, morally, one candidate direction: *change the level*, $k \mapsto k + \delta t$. For the *universal* affine algebra $V^k(\mathfrak{sl}_2)$ this is a genuine deformation — the algebras $V^{k+t}(\mathfrak{sl}_2)$ form an honest family. For the *simple* quotient $L_k(\mathfrak{sl}_2)$ at an admissible level something new happens: L_k is defined by imposing a null-vector relation $s = 0$, and the null vector exists only at that particular k. Changing the level breaks the null relation, so the deformation is inconsistent unless $\delta = 0$. The whole chapter is the rigorous version of this sentence: the pole parameter δ is shown to be well defined (after a gauge fixing that uses Whitehead's lemma), the null relations are shown to force $\delta \cdot P'(k) = 0$ for an explicit polynomial P, and the Kac determinant is used to show $P'(k) \neq 0$.

10.1 Affine $\mathfrak{sl}_2$ and its simple quotients

This section recalls, with the Lean source, the objects in the headline theorem. The detailed construction of the affine VOA (reconstruction, Sugawara vector, Wakimoto realisation, PBW theorem) is Chapter 9; the general notions of vertex operator algebra, ideals and simplicity are in Chapters 4 and 5. Here we give what a reader needs to parse every statement.

10.1.1 The Lie algebra $\mathfrak{sl}_2$ and its normalised Killing form

$\mathfrak{sl}_2$ is the three-dimensional complex Lie algebra with basis e, f, h and brackets

$$[h,e] = 2e, \qquad [h,f] = -2f, \qquad [e,f] = h.$$

Its invariant symmetric bilinear forms form a one-dimensional space; the *normalised Killing form* κ is the one with $\kappa(e,f) = \kappa(f,e) = 1$, $\kappa(h,h) = 2$ and all other basis pairings zero (it is $\frac{1}{4}$ of the Killing form $\mathrm{tr}(\mathrm{ad}\,x\ \mathrm{ad}\,y)$, and equals the trace form $\mathrm{tr}(xy)$ in the defining 2×2 representation). The library realises $\mathfrak{sl}_2$ as coordinate vectors, with the colour convention $e = 0$, $f = 1$, $h = 2$:

```
abbrev Sl2 : Type := Fin 3 → ℂ
```

```
def kappa : Fin 3 → Fin 3 → ℂ
  | 0, 1 => 1
  | 1, 0 => 1
  | 2, 2 => 2
  | _, _ => 0
```

(`VOA/Examples/AffineSl2.lean`; the bracket is defined there by the structure constants $f^{ab}{}_c$ above, and `kappaForm` is the bilinear form with matrix `kappa`, proved invariant as `kappaForm_isInvariant`.)

10.1.2 The affine Lie algebra and the vacuum module

The affine Lie algebra $\widehat{\mathfrak{sl}}_2 = \mathfrak{sl}_2 \otimes \mathbb{C}[t,t^{-1}] \oplus \mathbb{C}C \oplus \mathbb{C}\ell_0$ has brackets

$$[x\otimes t^m, y\otimes t^n] = [x,y]\otimes t^{m+n} + m\,\kappa(x,y)\,\delta_{m+n,0}\,C, \qquad C \text{ central}, \tag{10.2}$$

and ℓ_0 the degree derivation. We write J^a_m for the action of $a\otimes t^m$. Fix a complex number k, the *level*. The *vacuum module* (also called the generalised Verma module induced from the trivial $\mathfrak{sl}_2$-module) is

$$V^k(\mathfrak{sl}_2) = U(\widehat{\mathfrak{sl}}_2)\big/ J(k), \qquad J(k) = \text{left ideal generated by } x\otimes t^n\ (n\ge 0),\ C-k,\ \ell_0.$$

Its vacuum $\mathbf{1}$ is the class of 1; it is annihilated by all non-negative modes, and C acts as k. By the PBW theorem, $V^k(\mathfrak{sl}_2)$ has basis the ordered monomials $J^{a_1}_{-n_1}\cdots J^{a_r}_{-n_r}\mathbf{1}$ with all $n_i \ge 1$; the grading by L_0 (energy) is $\sum n_i$. The library builds exactly this quotient (`VOA/Foundations/AffineLie.lean`):

```
def vacuumGens (k : ℂ) : Set (UEnv 𝔤 κ hκ) :=
  {a | (∃ (x : 𝔤) (n : ℤ), 0 ≤ n ∧ a = ι ℂ (ofLoop κ hκ x n))
       ∨ a = ι ℂ (C κ hκ) - algebraMap ℂ (UEnv 𝔤 κ hκ) k
       ∨ a = ι ℂ (ell0 κ hκ)}
```

```
noncomputable def vacuumIdeal (k : ℂ) : Submodule (UEnv 𝔤 κ hκ) (UEnv 𝔤 κ hκ) :=
  Submodule.span _ (vacuumGens κ hκ k)
```

```
abbrev vacuumSpace (k : ℂ) : Type _ := UEnv 𝔤 κ hκ ⧸ vacuumIdeal κ hκ k
```

and, for $\mathfrak{sl}_2$, gives the carrier a (historically chosen, slightly misleading) name:

```
noncomputable abbrev WakModule (k : ℂ) : Type :=
  vacuumSpace kappaForm kappaForm_isInvariant k
```

From the mathematics to the Lean statement

`UEnv g κ hκ` is Mathlib's universal enveloping algebra of the affine Lie algebra `AffineLie g κ hκ`; `ι ℂ` is the canonical map $\mathfrak{g} \to U(\mathfrak{g})$; `ofLoop κ hκ x n` is $x \otimes t^n$; `C κ hκ` is the central element and `ell0` the degree derivation. `Submodule.span _ S` with the ring U acting on itself on the left is the *left* ideal generated by S, and `/` is the quotient module. So `vacuumSpace k` is literally $U(\widehat{\mathfrak{sl}}_2)/J(k)$ as above. The name `WakModule` is a historical artefact: the type is the universal vacuum module $V^k(\mathfrak{sl}_2)$, *not* a Wakimoto (free-field) module. The Wakimoto realisation enters only as a tool for proving that this module is nonzero and has a PBW basis.

Trap / dead end

Where `VOA.pbw` could have entered, and why it does not. A quotient U/J by a left ideal can be zero (if $1 \in J$); a VOA structure on the zero module satisfies every axiom, so every theorem about it would be vacuously true. The library's PBW theorem `VOA.pbw` (Chapter 3; an axiom in earlier versions of the library) asserts precisely that affine vacuum vectors are nonzero, and one lemma in `VOA/Examples/AffineSl2VOAInstance.lean` (`closed_vacuum_ne_zero`) uses it. The results of this chapter avoid that lemma: they take nonvanishing from `AffineSl2BoundaryMaximalIdeal.affineSl2_vacuum_ne_zero`, which is proved from the affine PBW basis `AffineSl2WakimotoLiLeading.affineSl2PBWBasis`, itself proved (Chapter 9) by leading-term triangularity in the Wakimoto realisation. The `#print axioms` record of Section 10.11 confirms that no result here reaches `VOA.pbw`.

10.1.3 The universal affine VOA and its simple quotient

For $k \neq -2$ (the *critical* level is $k = -h^\vee = -2$) the Sugawara vector

$$\omega = \frac{1}{2(k+2)}\Big(\tfrac{1}{2}h_{-1}h_{-1} + e_{-1}f_{-1} + f_{-1}e_{-1}\Big)\mathbf{1}$$

makes $V^k(\mathfrak{sl}_2)$ a vertex operator algebra of central charge $c = 3k/(k+2)$, with state–field map determined by $Y(J^a_{-1}\mathbf{1}, z) = \sum_n J^a_n z^{-n-1}$. The library's closed instance is `AffineVOA.affineSl2VOA_closed k hk` (`VOA/Examples/AffineSl2Virasoro.lean`, built in Chapter 9); this chapter abbreviates it:

```
noncomputable abbrev universal := affineSl2VOA_closed k hk
```

```
noncomputable abbrev simple := QuotVOA.maxQuotientVOA (universal k hk)
```

(`VOA/Examples/AffineSl2GeneralRigidityBasis.lean`, under `variable (k : ℂ) (hk : k + 2 ≠ 0)`.) Here the simple quotient is formed by the general construction of Chapter 5:

```
def maxGradedIdeal (W : VertexOperatorAlgebra V) : Submodule ℂ V :=
  sSup (ProperGradedIdeals W)
```

```
def maxQuotientVOA (W : VertexOperatorAlgebra V) :
    VertexOperatorAlgebra (V ⧸ maxGradedIdeal W) :=
  quotientVOA W (maxGradedIdeal W) (maxGradedIdeal_isIdeal W) (maxGradedIdeal_isGradedIdeal
  ↪ W)
```

(both in `VOA/Core/QuotientVOA.lean`), with ideals and simplicity defined by (`IsIdeal`, `IsSimple` in `VOA/Core/BilinearForm.lean`; `IsGradedIdeal` in `VOA/Core/QuotientVOA.lean`):

```
def IsIdeal (W : VertexOperatorAlgebra V) (I : Submodule ℂ V) : Prop :=
  ∀ (u v : V) (n : ℤ), v ∈ I → W.smul u n v ∈ I
```

```
def IsGradedIdeal (W : VertexOperatorAlgebra V) (I : Submodule ℂ V) : Prop :=
  I = ⨆ n : ℤ, I ⊓ W.grading n
```

```
def IsSimple (W : VertexOperatorAlgebra V) : Prop :=
  (⊤ : Submodule ℂ V) ≠ ⊥ ∧ ∀ I : Submodule ℂ V, W.IsIdeal I → I = ⊥ ∨ I = ⊤
```

Definition 10.2. For $k \neq -2$, $L_k(\mathfrak{sl}_2) := V^k(\mathfrak{sl}_2)/\mathcal{J}_k$, where $\mathcal{J}_k$ is the sum of all proper graded ideals of $V^k(\mathfrak{sl}_2)$ (the maximal proper graded ideal). In Lean, $L_k(\mathfrak{sl}_2)$ is `AffineSl2GeneralRigidity.simple k hk`.

Physical meaning

$V^k(\mathfrak{sl}_2)$ is the chiral algebra generated freely by the currents subject only to the OPE (10.1); $L_k(\mathfrak{sl}_2)$ is obtained by setting all null states (states orthogonal to everything under the BPZ/Shapovalov pairing) to zero, which is what a physical CFT with a nondegenerate two-point function does. The Sugawara vector ω is the stress tensor $T(z) = \frac{1}{2(k+2)}(JJ)(z)$ built from the currents; V_1 is the space of conserved currents, here the $SU(2)$ symmetry currents.

From the mathematics to the Lean statement

`W.smul u n v` is the n-th product $u_{(n)}v$, i.e. the coefficient of z^{-n-1} in $Y(u,z)v$ (Chapter 4). An `IsIdeal` is a subspace closed under left multiplication by all modes of all states (for a VOA, skew-symmetry makes left ideals two-sided). `IsGradedIdeal I` says I is the sum of its homogeneous pieces. `ProperGradedIdeals W` (in `VOA/Core/QuotientVOA.lean`) is the set of graded ideals not containing the vacuum; its supremum `sSup` is again a proper graded ideal (a graded ideal is proper iff its weight-zero part, which is inside $\mathbb{C}\mathbf{1}$, is zero, and that property is preserved under sums). So `maxGradedIdeal` is the maximal proper graded ideal and `maxQuotientVOA` the quotient VOA, as in the textbook. `IsSimple` quantifies over *all* ideals, graded or not, and requires the algebra to be nonzero. The library proves, for every non-critical k:

```
theorem simple_vacuum_ne_zero : (simple k hk).vacuum ≠ 0 :=
  SimpleQuot.maxQuotientVOA_vacuum_ne_zero (universal k hk)
    (AffineSl2BoundaryMaximalIdeal.affineSl2_vacuum_ne_zero k hk)
```

```
theorem simple_isSimple : (simple k hk).IsSimple :=
  QuotVOA.isSimple_maxQuotientVOA' _
    (AffineSl2BoundaryMaximalIdeal.affineSl2_vacuum_ne_zero k hk)
```

Remark 10.3. The library does not need, and does not prove, a presentation of $L_k(\mathfrak{sl}_2)$ by generators and relations (for example, that $\mathcal{J}_k$ is generated by a single singular vector). The quotient is defined intrinsically, which is the safest possible choice for a rigidity theorem: the object is the standard $L_k(\mathfrak{sl}_2)$ by definition, not "V^k modulo whatever relation we wrote down". The cost is that facts about $\mathcal{J}_k$ have to be extracted from its definition; the main tool for that is Li's theorem that $\mathcal{J}_k$ equals the radical of the invariant bilinear form (Chapter 5), used repeatedly below.

10.1.4 The weight-one space: the currents survive

The weight-one space of $L_k(\mathfrak{sl}_2)$ is spanned by the images of the three currents $J^a_{-1}\mathbf{1}$. For $k \neq 0$ they remain linearly independent: if $\sum_a c_a J^a_{-1}\mathbf{1} \in \mathcal{J}_k$, apply the positive modes J^b_1, which map into weight zero; since $J^b_1 J^a_{-1}\mathbf{1} = k\,\kappa(b,a)\mathbf{1}$ and $\mathbf{1} \notin \mathcal{J}_k$, nondegeneracy of κ and $k \neq 0$ force all $c_a = 0$. (At $k = 0$ the opposite happens: the currents are null, $L_0(\mathfrak{sl}_2) = \mathbb{C}$, and $V_1 = 0$.) The library records the result as an $\mathfrak{sl}_2$-triple basis of the weight-one Lie algebra:
File `VOA/Examples/AffineSl2GeneralRigidityBasis.lean`.

```
theorem simple_sl2BasisOnWeightOne (hk0 : k ≠ 0) : Sl2BasisOnWeightOne (simple k hk) :=
  ⟨(simple_weightOneBasis k hk hk0), (simple_weightOneTriple k hk hk0)⟩
```

where (`VOA/Examples/AffineSl2Rigidity43.lean`)

```
def Sl2BasisOnWeightOne {𝒱 : Type*} [AddCommGroup 𝒱] [Module ℂ 𝒱]
    (W : VertexOperatorAlgebra 𝒱) : Prop :=
  ∃ b : Module.Basis (Fin 3) ℂ ↥(W.grading 1), IsSl2Triple (b 1) (b 0) (b 2)
```

From the mathematics to the Lean statement

`W.grading 1` is the weight-one subspace V_1 (Chapter 4); `↥` turns the submodule into a type. `Module.Basis (Fin 3) ℂ ↥(W.grading 1)` is a basis of V_1 indexed by $\{0,1,2\}$, and Mathlib's `IsSl2Triple h e f` says $[e,f]=h$, $[h,e]=2e$, $[h,f]=-2f$ and $h\neq 0$, for the Lie bracket on V_1 given by $[a,b]=a_{(0)}b$ (Chapter 5). Note the argument order: `IsSl2Triple (b 1) (b 0) (b 2)` means $b_0=e$, $b_1=h$, $b_2=f$. So `Sl2BasisOnWeightOne W` is the statement "$V_1\cong\mathfrak{sl}_2$ as Lie algebras". The theorem `simple_sl2BasisOnWeightOne` needs $k\neq 0$, and this is the only reason the headline theorem excludes $k=0$.

10.2 Admissible levels

10.2.1 From integrable to admissible

At a non-negative integer level k, $L_k(\mathfrak{sl}_2)$ is the chiral algebra of the unitary $SU(2)_k$ WZW model: it is rational and C_2-cofinite, it has exactly $k+1$ irreducible modules (spins $0,\frac{1}{2},\dots,\frac{k}{2}$), and its maximal ideal is generated by the single singular vector $(e_{-1})^{k+1}\mathbf{1}$. Kac and Wakimoto (1988) discovered that a much larger set of levels shares the most striking feature of the integrable case — a finite set of highest-weight modules whose characters span a representation of $SL_2(\mathbb{Z})$ — although the resulting theories are not unitary.

Definition 10.4 (Kac–Wakimoto). A level $k\in\mathbb{C}$ is *admissible* for $\mathfrak{sl}_2$ if

$$k+2=\frac{p}{q},\qquad p,q\in\mathbb{Z}_{>0},\qquad \gcd(p,q)=1,\qquad p\geq 2.$$

It is *negative admissible* if moreover $k<0$, i.e. $p<2q$; it is *boundary admissible* if $p=2$ (the smallest allowed numerator, which forces q odd).

Physical meaning

Admissible levels are the fractional levels at which the $\widehat{\mathfrak{sl}}_2$ characters still form a finite-dimensional representation of the modular group $SL_2(\mathbb{Z})$ (Kac–Wakimoto), so they define non-unitary CFTs with a modular-invariant set of characters: fractional-level $SL(2)$ WZW models, appearing in Polyakov's 2d gravity, in the Drinfeld–Sokolov/coset description of the (p,q) Virasoro minimal models, and as chiral algebras of 4d $\mathcal{N}=2$ Argyres–Douglas theories. Negative admissible means negative level, where the theory is necessarily non-unitary.

The shift by 2 is the dual Coxeter number $h^\vee$ of $\mathfrak{sl}_2$; for a general simple $\mathfrak{g}$ the condition reads $k+h^\vee=p/q$ with $p\geq h^\vee$ (when q is prime to the lacing number). The integrable levels are the case $q=1$, $p=k+2\geq 2$. The bound $p\geq 2$ is not decoration: $k=-3/2$ ($k+2=1/2$) is not admissible.

```
def AdmissibleLevel (k : ℂ) : Prop :=
  ∃ p q : ℕ, 2 ≤ p ∧ 1 ≤ q ∧ Nat.Coprime p q ∧ k + 2 = (p : ℂ) / (q : ℂ)
```

(`VOA/Examples/AdmissibleLevel.lean`, namespace `VOA.Admissible`.)

From the mathematics to the Lean statement

`∃ p q : ℕ` quantifies over natural numbers; `Nat.Coprime p q` is $\gcd(p,q)=1$; the casts `(p : ℂ)` embed $\mathbb{N}\subset\mathbb{C}$, and `/` is division in $\mathbb{C}$. This is exactly Definition 10.4 with $q\geq 1$ (the inclusive convention that makes integrable levels admissible; some papers impose $q\geq 2$ to talk only about fractional levels, and the file docstring records that a future fractional-only notion must say `1 < q` explicitly). The witnesses are unique (`AdmissibleLevel.witness_unique`), so "the" p and q of an admissible level are well defined. *Note for the referee:* the headline theorem does *not* use this predicate; it takes p and q as explicit natural numbers with the same conditions plus $p<2q$ (Section 10.8). The predicate is used for the examples and for the arithmetic lemmas below.

The library records the elementary consequences:

```
theorem AdmissibleLevel.add_two_ne_zero {k : ℂ} (h : AdmissibleLevel k) : k + 2 ≠ 0 := by
```

```
theorem admissibleLevel_boundary (m : ℕ) :
    AdmissibleLevel (-2 + 2 / ((2 * m + 1 : ℕ) : ℂ)) := by
```

```
theorem centralChargeA_of_add_two_eq {k p q : ℂ} (hp : p ≠ 0) (hq : q ≠ 0)
    (hk : k + 2 = p / q) : centralChargeA k = 3 - 6 * q / p := by
```

and the named examples `admissibleLevel_neg_four_thirds` ($(p,q)=(2,3)$), `admissibleLevel_neg_half` ($(3,2)$), `admissibleLevel_neg_eight_fifths` ($(2,5)$), `admissibleLevel_natCast` ($k=n$, $(p,q)=(n+2,1)$). All are pure arithmetic, proved by `norm_num/omega`.

Example 10.5. The first negative admissible levels, ordered by denominator, with central charge $c=3k/(k+2)=3-6q/p$:

q	p	$k=p/q-2$	c	boundary?	weight of first singular vector $q(p-1)$
2	3	$-1/2$	-1	no	4
3	2	$-4/3$	-6	yes	3
3	4	$-2/3$	$-3/2$	no	9
3	5	$-1/3$	$-3/5$	no	12
4	3	$-5/4$	-5	no	8
4	5	$-3/4$	$-9/5$	no	16
4	7	$-1/4$	$-3/7$	no	24
5	2	$-8/5$	-12	yes	5

(For $q=1$ the condition $2\leq p<2$ is empty: integrable levels are never negative.) At $k=-1/2$ the algebra $L_{-1/2}(\mathfrak{sl}_2)$ is the $\mathbb{Z}_2$-orbifold of the $\beta\gamma$ system; at $k=-4/3$ its representation theory was constructed by Adamović (2005), and in the physics literature it appears as the chiral algebra of the (A_1,D_3) Argyres–Douglas theory; more generally the boundary levels $k=-4n/(2n+1)$ are associated with the (A_1,D_{2n+1}) theories (Creutzig; Beem–Rastelli and collaborators). These identifications are background, not used below.

10.2.2 The vacuum singular vector at an admissible level

Why do admissible levels make $V^k(\mathfrak{sl}_2)$ non-simple? The Kac–Kazhdan criterion says that a Verma module of highest weight $\hat\lambda$ over $\widehat{\mathfrak{sl}}_2$ has a singular vector of weight $\hat\lambda-n\beta$ whenever β is a positive real root and

$$2(\hat\lambda+\hat\rho,\beta)=n(\beta,\beta),\qquad n\in\mathbb{Z}_{>0}. \tag{10.3}$$

For the vacuum, $\hat{\lambda} = k\Lambda_0$, and with the standard normalisation $(\alpha,\alpha) = 2$, $(\delta,\Lambda_0) = 1$, $\hat{\rho} = 2\Lambda_0 + \alpha/2$, the positive real roots are $m\delta+\alpha$ ($m \geq 0$) and $m\delta-\alpha$ ($m \geq 1$), with

$$(\hat{\lambda}+\hat{\rho}, m\delta+\alpha) = m(k+2)+1, \qquad (\hat{\lambda}+\hat{\rho}, m\delta-\alpha) = m(k+2)-1.$$

The root α itself ($m=0$) gives $n=1$ for every k: this is the singular vector $f_0\mathbf{1}$, which is already zero in V^k (it is what distinguishes the vacuum module from the Verma module). At $k+2 = p/q$, the condition for $\beta = m\delta-\alpha$ is $mp/q - 1 = n$, i.e. $mp = q(n+1)$; by coprimality $m = \ell q$ and $n = \ell p - 1$, and the smallest solution is

$$\beta = q\delta-\alpha, \quad n = p-1: \qquad \text{a singular vector of energy } q(p-1) \text{ and } h_0\text{-weight } 2(p-1). \tag{10.4}$$

For $\beta = m\delta+\alpha$ the condition $mp+q = nq$ forces $m = \ell q$, $n = \ell p+1$ and energy strictly above $q(p-1)$. At $k=-4/3$ this is the weight-three singular vector of h_0-weight 2 found by Adamović (Section 10.5); for integrable k ($q=1$) it is $(e_{-1})^{k+1}\mathbf{1}$. Kac–Wakimoto and Malikov–Feigin–Fuchs give explicit formulas; Adamović–Milas proved that this vector generates the maximal ideal. None of these literature facts is *assumed* by the headline theorem: the uniform proof (Section 10.7) works with a determinant instead of an explicit singular vector. The arithmetic half of (10.4) is proved as stated (`VOA/Examples/AffineSl2AdmissibleRootArithmetic.lean`):

```
theorem first_minus_resonance_unique {p q m r : ℕ} (hp : 2 ≤ p) (hq : 0 < q)
    (hm : 0 < m) (hcop : p.Coprime q) (he : m*p = q*(r+1))
    (hbound : m*r ≤ q*(p-1)) : m=q ∧ r=p-1 := by
```

```
theorem plus_resonance_energy_gt {p q m r : ℕ} (hp : 2 ≤ p) (hq : 0 < q)
    (hm : 0 < m) (hcop : p.Coprime q) (he : m*p+q=q*r) :
    q*(p-1) < m*r := by
```

From the mathematics to the Lean statement

In `first_minus_resonance_unique`, m is the δ-coefficient of the root $m\delta-\alpha$, r is the multiplicity n of (10.3) (so `he` is $mp = q(n+1)$), and `m*r` is the energy $m\cdot n$ of the corresponding singular weight; the conclusion is that the only solution with energy at most $q(p-1)$ is $m=q$, $n=p-1$. The natural-number subtraction `p-1` is honest because $p \geq 2$. `plus_resonance_energy_gt` says the other root family only resonates above that energy. Both are statements about integers only; the file docstring stresses that "this proves arithmetic only, not an affine determinant formula or existence of a singular state".

10.2.3 Physics: WZW models at fractional level

The admissible $L_k(\mathfrak{sl}_2)$ are the chiral algebras of $SL(2)$ WZW models at fractional level, which appeared in Polyakov's light-cone two-dimensional gravity ($SL(2,\mathbb{R})$ current algebra at level k with $k+2$ rational), in the coset and Drinfeld–Sokolov constructions of Virasoro minimal models (the quantum Hamiltonian reduction of $L_k(\mathfrak{sl}_2)$ at $k+2 = p/q$ is the (p,q) minimal model, with $c_{\mathrm{Vir}} = 1-6(p-q)^2/(pq)$; the library has the arithmetic as `VOA.DSsl2.dsCentralCharge_eq_minimalModel`), and more recently as chiral algebras of four-dimensional $\mathcal{N}=2$ superconformal theories. They are not rational in the usual sense (they have infinitely many irreducible weak modules), not C_2-cofinite, but *quasi-lisse*: the associated variety is the nilpotent cone of $\mathfrak{sl}_2$ (Arakawa; a literature fact, not formalised in the library: associated varieties and quasi-lisseness are not defined there, see Chapter 16). Rigidity is then a non-trivial statement precisely because none of the usual finiteness properties is available: Linshaw and Qi's abstract emphasises that their $-4/3$ result shows "neither C_2-cofiniteness nor rationality is a necessary condition for deformation rigidity".

10.3 First-order deformations and graded rigidity

The general deformation theory of the library is the subject of Chapter 8, where it is applied to the Virasoro minimal models. To keep this chapter self-contained we recall every definition the headline uses, with its Lean source (`VOA/Core/Deformation.lean` and `VOA/Core/DeformationGraded.lean`).

10.3.1 The idea

Let V be a vertex operator algebra with state–field map Y. Let $R = \mathbb{C}[t]/(t^2)$ be the ring of dual numbers and $V_R = R \otimes_{\mathbb{C}} V = V \oplus tV$. A *first-order deformation* of V is a bilinear map

$$Y_1 : V \otimes V \to V((x)), \qquad u \otimes v \mapsto Y_1(u,x)v = \sum_n u^1_{(n)} v \, x^{-n-1},$$

such that $Y^t(u,x) := Y(u,x) + t\,Y_1(u,x)$, extended R-bilinearly, makes V_R a vertex algebra over R with the same vacuum $\mathbf{1}$. Expanding each vertex-algebra axiom in powers of t, the t^0 part is the axiom for V and the t^1 part is a linear condition on Y_1: Y_1 is a *2-cocycle*. A *trivial* deformation is one obtained from Y by an R-linear change of coordinates $1 + t\varphi$ of V_R, which gives

$$Y_1(u,x)v = (\delta\varphi)(u,x)v := Y(\varphi u,x)v - \varphi\big(Y(u,x)v\big) + Y(u,x)\varphi v; \tag{10.5}$$

these are the *coboundaries*. Rigidity is "every cocycle is a coboundary", i.e. the vanishing of the second deformation cohomology. Physically: a first-order deformation is an infinitesimal change of the OPE coefficients compatible with associativity (crossing), and it is trivial when it is undone by an infinitesimal field redefinition. A rigid chiral algebra has no infinitesimal moduli at all — in particular it cannot sit inside a continuous family of chiral algebras, which is the chiral-algebra analogue of "no exactly marginal deformations".

10.3.2 The Lean definitions

```

From the mathematics to the Lean statement

Shape. `(End ℂ 𝒱)⟦z^±⟧` is the space of two-sided formal series with coefficients in $\mathrm{End}(V)$ (Chapter 2); `𝒱 →ₗ[ℂ] …` is a $\mathbb{C}$-linear map, so `Y1` is linear in u and (coefficientwise) in v: the bilinear Y_1 above. `mode f n = f (-n-1)` (the coefficient of z^{-n-1}), so `D.smul₁ u n v` is $u^1_{(n)}v$. **The four fields.** `truncation` is the t-part of "$Y(u,x)v$ has finitely many negative powers" (Y1 lands in $V((x))$). `vacuum_Y1` is the t-part of $Y^t(\mathbf{1},x) = \mathrm{id}$. `creation` is the t-part

of $u^t_{(n)}\mathbf{1} = 0$ for $n \geq 0$ and $u^t_{(-1)}\mathbf{1} = u$, i.e. $u^1_{(n)}\mathbf{1} = 0$ for $n \geq -1$. `jacobi` is the t-linear part of the Borcherds identity (Chapter 4): `cbz ℓ i` is the binomial coefficient $\binom{\ell}{i}$ (0 for $i < 0$), `negOnePow i` is $(-1)^i$, $\sum^{\mathrm{f}}$ is a finite sum; on each side the single Y_1 is inserted in each possible slot (Leibniz rule). **Could the sums be vacuous?** Mathlib defines $\sum^{\mathrm{f}}$ of an infinite-support family to be 0, which would make `jacobi` read $0 = 0$. The library proves both supports finite (`jacobiLHS_support_finite`, `jacobiRHS_support_finite`), so the axiom is the genuine identity. **What is *not* imposed.** The conformal vector, the operator L_0 and the translation operator $T = L_{-1}$ are not required to be preserved; nor is any grading condition. Gradedness is a separate predicate (next).

Definition 10.6. A first-order deformation D is *graded* if $u^1_{(n)}v \in V_{a+b-n-1}$ whenever $u \in V_a$, $v \in V_b$ (the same weight rule as $u_{(n)}v$). It is *trivial* if $Y_1 = \delta\varphi$ as in (10.5) for some linear $\varphi : V \to V$ that preserves every V_n and kills $\mathbf{1}$. V is *graded rigid* (in full: *graded first-order rigid*) if every graded first-order deformation is trivial. In this chapter "graded rigid" always means graded first-order rigid.

Physical meaning

A graded first-order deformation is an infinitesimal change of all OPE coefficients that keeps conformal weights fixed and keeps the OPE associative (crossing-symmetric) to first order; a trivial one is an infinitesimal field redefinition $\phi \mapsto \phi + t\varphi(\phi)$. In a full CFT, deformations are generated by exactly marginal operators; for a chiral algebra, the analogous question is whether the OPE data have moduli. In a full CFT with currents $J, \bar{J}$, the current–current operator $J\bar{J}$ is the standard exactly marginal deformation (it changes the radius of a free boson); at the purely chiral level, the simplest non-trivial deformation is moving the level of

the universal algebra V^k, which is a continuous parameter there (for a compact WZW model the level is quantised, but the chiral algebra does not know that). Graded rigidity says there are no such moduli.

From the mathematics to the Lean statement

`IsGraded` is literally the weight rule, for all integers k, ℓ, n. `IsCoboundary` is (10.5) mode by mode: $u^1_{(n)}v = (\varphi u)_{(n)}v - \varphi(u_{(n)}v) + u_{(n)}(\varphi v)$. The conditions $\varphi\mathbf{1} = 0$ (so the vacuum is unchanged by $1 + t\varphi$) and grade preservation are the standard ones. `IsRigidGraded` is Definition 10.6: universally quantified over *all* graded deformations. **Comparison with Linshaw–Qi.** In their paper (arXiv:2601.12017v2, §2) a first-order deformation is a Y_1 making $\mathbb{C}[t]/(t^2) \otimes V$ a grading-restricted vertex algebra *with the grading operator and the derivative operator preserved*; a deformation is trivial when $Y_1 = \delta\varphi$ for a grading-preserving φ with $\varphi(\mathbf{1}) = 0$. The library's trivial deformations are the same. The library's class of graded deformations is *larger*: it does not require the translation operator to be preserved ($u^1_{(-2)}\mathbf{1}$ may be nonzero). Since `IsRigidGraded` asserts triviality for every member of a larger class, **the Lean notion of graded rigidity is at least as strong as Linshaw–Qi's** (it implies theirs). It is not weaker in any respect. Besides T, the conformal vector is not part of the data either: a deformation may make ω stop being conformal. In standard terms, `IsRigidGraded W` is the vanishing of the graded second deformation cohomology H^2 of W as a vertex algebra with the vacuum fixed — the same gauge group as Linshaw–Qi (grade-preserving φ, $\varphi\mathbf{1} = 0$) and a larger class of deformations. So `L43_graded_rigidity` below is Linshaw–Qi's Theorem 5.1 in their own sense, not merely an analogue.

Example 10.7 (the scaling coboundary). For every VOA, $\varphi = L_0$ preserves the grading and kills $\mathbf{1}$, so $\delta(L_0)$ is a trivial graded deformation. On homogeneous $u \in V_a$, $v \in V_b$,

$$\delta(L_0)(u)_{(n)}v = a\,u_{(n)}v - (a + b - n - 1)\,u_{(n)}v + b\,u_{(n)}v = (n + 1)\,u_{(n)}v.$$

In Lean this is `NonzeroDeform.scalingDeformation` with File `VOA/Examples/NonzeroDeformation.lean`.

```
theorem smul₁_scalingDeformation_homog (W : VertexOperatorAlgebra V) {a b : ℤ} {u v : V}
    (hu : u ∈ W.grading a) (hv : v ∈ W.grading b) (n : ℤ) :
    (scalingDeformation W).smul₁ u n v = ((n : ℂ) + 1) • W.smul u n v := by
```

This one example will refute two of the hypotheses that an earlier version of the library carried (Section 10.5). Note also that $\delta(L_0)$ does not preserve the translation operator (`smul₁_scaling_conformal_vacuum`: $\omega^1_{(-2)}\mathbf{1} = -L_{-3}\mathbf{1}$), which illustrates the remark above that the library's deformation class is larger than Linshaw–Qi's.

Trap / dead end

`IsRigid` is the wrong target. `IsRigid` quantifies over *all* first-order deformations, graded or not, while coboundaries must be grade-preserving. The coboundary $\delta(L_1)$ of the non-grade-preserving operator L_1 is a legitimate (ungraded) deformation of every VOA, and it is not of the form $\delta\varphi$ with φ grade-preserving whenever L_1 acts nontrivially; the library proves this for Virasoro as `VOA.NonzeroDeform.not_isRigid_virasoroVOA`: `IsRigid` fails for every universal Virasoro VOA $V(c, 0)$, for this definitional reason (Chapter 8). Since a trivial deformation is automatically graded (`NonzeroDeform.isGraded_of_isTrivial`), any nonzero $\delta(L_1)$ refutes `IsRigid`; on $L_k(\mathfrak{sl}_2)$, $k \neq 0$, one computes on paper $\delta(L_1)(L_{-1}J, -2, \mathbf{1}) = 2L_{-1}J - L_1L^2_{-1}J = -4L_{-1}J \neq 0$ for a current J, so `IsRigid` fails there too (this instance is not formalised). `IsRigid` must never be quoted as true. The headline is therefore stated for `IsRigidGraded`, the graded first-order notion, which is at least as strong as the notion Linshaw–Qi use.

Trap / dead end

A non-vacuity point the referee should know. A rigidity theorem is a universal statement, so it would be worthless if, through some defect, *no* VOA could ever have a non-trivial graded deformation in this formalism. Three facts speak against that. (i) Deformations exist in abundance: every coboundary $\delta\varphi$ with $\varphi\mathbf{1} = 0$ is one (`NonzeroDeform.deformOf`), so `FirstOrderDeformation` is not an empty or degenerate type. (ii) The *weaker* conclusions that would follow from a defect are refuted: the free boson has graded deformations in "pole form" with nonzero pole (Section 10.5, `not_normalisedPoleVanishes_heisenberg`). (iii) For the universal Virasoro VOA $V(c,0)$, "$\partial/\partial c$ is a non-trivial graded deformation" is proved in full. $Y_1 = \partial_c Y$, computed on the c-independent PBW basis of the universal $V(c,0)$, is a graded first-order deformation with $\omega^1_{(1)}\omega = 0$ and $\omega^1_{(3)}\omega = \frac{1}{2}\mathbf{1}$. In Lean, every coboundary on a VOA with $V_2 = \mathbb{C}\omega$ has $(\omega^1_{(1)}\omega, \omega^1_{(3)}\omega) = (2\mu\omega, \mu c\mathbf{1})$ for one scalar μ (`VOA.VirCDef.cmode_conformal_of_isCoboundary`), so such a deformation is non-trivial (`VOA.VirCDef.not_isTrivial_of_omega_witness`, `VOA.VirCDef.not_isTrivial_of_isCDeformation`, `VOA.VirCDef.not_isRigidGraded_of_isCDeformation`; all quoted, with their status, in Chapter 8, Remark on non-vacuity). When this chapter was first written, the c-deformation was not constructed (`IsCDeformation c` had no inhabitant), so non-vacuity was argued on paper only. That item is now resolved: `VOA.VirPoly.cDeformation` constructs $\partial_c Y$ on $V(c,0)$, `VOA.VirPoly.isCDeformation_cDeformation` proves that it inhabits `IsCDeformation c`, and `VOA.VirPoly.not_isRigidGraded_virasoroVOA` proves `¬ Deform.IsRigidGraded (virasoroVOA c)` for every $c \in \mathbb{C}$ (`VOA/Examples/VirasoroCDefFinal.lean`; Chapter 8, Section 8.2.7). The caveat that remains concerns its scope: $\partial_c Y$ does not preserve the central term of $\omega_{(3)}\omega$ (it moves c), which the library's `FirstOrderDeformation` allows; this is the same convention under which the rigidity theorems of this chapter are proved. (Other non-rigid VOAs certainly exist on paper, e.g. $V^k(\mathfrak{sl}_2)$ itself, deformed along k; the library does not formalise that one.)

10.3.3 Regularity and the pole

For weight-one states a, b (currents), a graded deformation has $a^1_{(n)}b \in V_{1-n}$, which is zero for $n \geq 2$ (no negative weights). So the singular part of $Y_1(a,x)b$ has only two coefficients: $a^1_{(0)}b \in V_1$ (a correction to the Lie bracket) and $a^1_{(1)}b \in V_0 = \mathbb{C}\mathbf{1}$ (a correction to the level).
File `VOA/Core/Deformation.lean`.

```
def Regular (D : FirstOrderDeformation W) : Prop :=
  ∀ a ∈ W.grading 1, ∀ b ∈ W.grading 1, ∀ n : ℤ, 0 ≤ n → D.smul₁ a n b = 0
```

File `VOA/Core/Deformation.lean`.

```

```

```
def FirstOrderDeformation.InPoleForm (D : FirstOrderDeformation W) : Prop :=
  ∀ a ∈ W.grading 1, ∀ b ∈ W.grading 1, D.smul₁ a 0 b = 0
```

File `VOA/Examples/AffineSl2Rigidity43.lean`.

```
theorem regular_iff_zero_one {V : Type*} [AddCommGroup V] [Module ℂ V]
    {W : VertexOperatorAlgebra V} (D : Deform.FirstOrderDeformation W) (hD : D.IsGraded) :
    D.Regular ↔ ∀ a ∈ W.grading 1, ∀ b ∈ W.grading 1,
      D.smul₁ a 0 b = 0 ∧ D.smul₁ a 1 b = 0 := by
```

From the mathematics to the Lean statement

`Regular` is "$Y_1(a,x)b$ has no negative powers of x for weight-one a, b": in the index convention `mode f n = f(-n-1)`, negative powers x^{-n-1} are exactly $n \geq 0$ (the library also proves the literal coefficient form, `regular_iff`). Since $a = a_{(-1)}\mathbf{1}$, $Y_1(a,x)b$ is Linshaw–Qi's $Y_1(a(-1)\mathbf{1},x)b(-1)\mathbf{1}$, and quantifying over all of V_1 is equivalent to quantifying over their generators by bilinearity. `poleVec a b` is the x^{-2} coefficient $a^1_{(1)}b$ (proved `poleVec_eq_coeff`); for graded D it lies in V_0 (`poleVec_mem_grading_zero`). `InPoleForm` says the x^{-1} coefficient vanishes on currents: the first clause of Linshaw–Qi's equation (3). `regular_iff_zero_one` is the mode count just explained (VOA positivity kills $n \geq 2$).

10.4 Weight-one cohomology: normalising a deformation

`VOA/Core/WeightOneCohomology.lean` proves the step that Linshaw–Qi perform silently in their equation (3) (citing Kovalchuk–Qi §6.2): every graded deformation can be changed by a coboundary so that the x^{-1} coefficient on currents vanishes. It is pure Lie theory of V_1.

10.4.1 Chevalley–Eilenberg cochains in degree two

For a Lie algebra $\mathfrak{g}$ acting on itself by the adjoint action, a *1-cochain* is a linear map $\psi : \mathfrak{g} \to \mathfrak{g}$ and a *2-cochain* is an alternating bilinear map $\omega : \mathfrak{g} \times \mathfrak{g} \to \mathfrak{g}$. The differentials are

$$(d_{12}\psi)(x,y) = [x,\psi y] - [y,\psi x] - \psi[x,y],$$
$$(d_{23}\omega)(x,y,z) = [x,\omega(y,z)] - [y,\omega(x,z)] + [z,\omega(x,y)] - \omega([x,y],z) + \omega([x,z],y) - \omega([y,z],x).$$

ω is a *cocycle* if $d_{23}\omega = 0$; $H^2(\mathfrak{g},\mathfrak{g}) = \text{cocycles}/d_{12}(\text{1-cochains})$. Mathlib provides the cochain spaces and these two differentials (`LieModule.Cohomology.twoCochain`, `d₁₂`, `d₂₃`, `twoCocycle`, by Carnahan) but no cohomology groups and no Whitehead lemma. The library therefore states vanishing as "every cocycle is a coboundary":

```
def WeightOneH2Vanishes (W : VertexOperatorAlgebra 𝒱) : Prop :=
  ∀ ω : twoCochain ℂ 𝔱(W.grading 1) 𝔱(W.grading 1),
    ω ∈ twoCocycle ℂ 𝔱(W.grading 1) 𝔱(W.grading 1) →
      ∃ ψ : oneCochain ℂ 𝔱(W.grading 1) 𝔱(W.grading 1),
        d₁₂ ℂ 𝔱(W.grading 1) 𝔱(W.grading 1) ψ = ω
```

```
def CentrelessWeightOne (W : VertexOperatorAlgebra 𝒱) : Prop :=
  ∀ z : 𝔱(W.grading 1), (∀ x : 𝔱(W.grading 1), ⁅z, x⁆ = 0) → z = 0
```

From the mathematics to the Lean statement

The Lie algebra is V_1 with bracket `⁅u, v⁆` $= u_{(0)}v$ (`coe_bracket_gradingOne`; the Lie structure on V_1 is Chapter 5). `twoCochain ℂ L M` is Mathlib's space of alternating bilinear maps $L \times L \to M$, `oneCochain` the linear maps, and `d₁₂`, `twoCocycle` as displayed above (the file docstring checks that Mathlib's sign convention is $d_{12}\psi(x,y) = [x,\psi y] - [y,\psi x] - \psi[x,y]$). So `WeightOneH2Vanishes W` is $H^2(V_1,V_1) = 0$ and `CentrelessWeightOne W` is $Z(V_1) = 0$. Neither mentions any deformation, any mode other than (0), or anything outside V_1: they are invariants of the Lie algebra V_1 alone.

Theorem 10.8 (Whitehead's second lemma for $\mathfrak{sl}_2$). *If a complex Lie algebra $\mathfrak{g}$ has a basis (e,h,f) forming an $\mathfrak{sl}_2$-triple, then every 2-cocycle $\omega \in Z^2(\mathfrak{g},\mathfrak{g})$ is $d_{12}\psi$ for some ψ; and $Z(\mathfrak{g}) = 0$.*

Physical meaning

$H^2(\mathfrak{g},\mathfrak{g}) = 0$ is the statement that a semisimple Lie algebra has no infinitesimal deformations of its bracket: the symmetry algebra of the currents cannot be continuously deformed. Physically, the single-pole term $J^{[a,b]}/(z-w)$ of the current OPE cannot be changed except by a rotation of the current basis.

```
theorem whitehead2_of_sl2Basis (b : Basis (Fin 3) ℂ g) (ht : IsSl2Triple (b 1) (b 0) (b 2))
    (ω : twoCochain ℂ g g) (hω : ω ∈ twoCocycle ℂ g g) :
    ∃ ψ : oneCochain ℂ g g, d₁₂ ℂ g g ψ = ω := by
```

```
theorem weightOneH2Vanishes_of_sl2Basis (W : VertexOperatorAlgebra 𝒱)
    (b : Basis (Fin 3) ℂ ↥(W.grading 1)) (ht : IsSl2Triple (b 1) (b 0) (b 2)) :
    WeightOneH2Vanishes W :=
  fun ω hω => Sl2Whitehead.whitehead2_of_sl2Basis b ht ω hω
```

Proof on paper. Write $\omega(e,h) = A_1e+A_2h+A_3f$, $\omega(e,f) = B_1e+B_2h+B_3f$, $\omega(h,f) = C_1e+C_2h+C_3f$. Evaluate $d_{23}\omega(e,h,f) = 0$. The three terms $\omega([\cdot,\cdot],\cdot)$ cancel identically: $[e,h] = -2e$ and $[h,f] = -2f$ contribute $+2\omega(e,f)$ and $-2\omega(e,f)$, and $[e,f] = h$ contributes $\omega(h,h) = 0$. What remains, $[e,\omega(h,f)] - [h,\omega(e,f)] + [f,\omega(e,h)] = 0$, expands in the basis to exactly three scalar equations,

$$C_2 + B_1 = 0, \qquad C_3 = A_1, \qquad B_3 + A_2 = 0.$$

Now take

$$\psi e = \big(B_2 - \tfrac{A_1}{2}\big)e + \tfrac{A_3}{4}f, \qquad \psi h = C_2 e - \tfrac{A_1}{2}h + A_2 f, \qquad \psi f = \tfrac{C_1}{4}e.$$

For general $\psi e = p_1e + p_2h + p_3f$, $\psi h = q_1e + q_2h + q_3f$, $\psi f = r_1e + r_2h + r_3f$ one computes

$$\begin{aligned} d_{12}\psi(e,h) &= -2q_2\,e + (q_3 + 2p_2)\,h + 4p_3\,f, \\ d_{12}\psi(e,f) &= -(2r_2 + q_1)\,e + (p_1 + r_3 - q_2)\,h - (2p_2 + q_3)\,f, \\ d_{12}\psi(h,f) &= 4r_1\,e + (q_1 + 2r_2)\,h - 2q_2\,f, \end{aligned}$$

and substituting the chosen ψ and the three cocycle relations reproduces ω on the three basis pairs, hence everywhere. The solution is unique up to a three-parameter family, which is $\mathrm{Der}(\mathfrak{sl}_2) = \mathrm{ad}(\mathfrak{sl}_2)$. Centrelessness: if $[z,x] = 0$ for all x, then $[z,f] = 0$ kills the e- and h-coefficients of z, and $[z,e] = 0$ kills the f-coefficient. □

10.4.2 The bridge: a graded deformation gives a 2-cocycle

For a graded deformation, $a^1_{(0)}b \in V_{1+1-0-1} = V_1$ for $a,b \in V_1$, so $\omega(a,b) := a^1_{(0)}b$ is a bilinear map $V_1 \times V_1 \to V_1$. The $\ell = m = n = 0$ case of the deformed Jacobi identity reads

$$\omega(u,[v,x]) + [u,\omega(v,x)] - \omega(v,[u,x]) - [v,\omega(u,x)] = [\omega(u,v),x] + \omega([u,v],x). \tag{10.6}$$

Setting $u = v$ gives $[\omega(a,a),x] = 0$: $\omega(a,a)$ is central, hence zero when V_1 is centreless, so ω is alternating. Using that, (10.6) rearranges to $d_{23}\omega = 0$.

```

From the mathematics to the Lean statement

`weightOneCochain D hD hZ` is $\omega(a,b) = a^1_{(0)}b$ packaged as an alternating cochain; its alternation proof uses the centrelessness hypothesis `hZ`, exactly as in the paper argument (the file warns that skew-symmetry of ω is *not* free — the alternative would be a port of the whole skew-symmetry theory to the deformed setting). `extendWeightOne W ψ` is the extension of $\psi : V_1 \to V_1$ by zero on the other weight spaces, which is grade-preserving and kills the vacuum (`gradePreserving_extendWeightOne`, `extendWeightOne_vacuum`). The second theorem says that the VOA coboundary $\delta\varphi$ of that extension, restricted to mode 0 on V_1, is literally Mathlib's $d_{12}\psi$: the signs agree on the nose.

Corollary 10.9 (normalisation). *If $V_1 \cong \mathfrak{sl}_2$, every graded deformation D differs by a graded coboundary from a graded deformation E in pole form ($a^1_{(0)}b = 0$ on V_1).*

Physical meaning

This is a gauge fixing: by redefining the currents one can always assume the deformation does not touch the single pole of J^aJ^b, i.e. keeps the symmetry algebra $SU(2)$ fixed. What is left is the double pole: a possible change of the level $k \mapsto k + \delta t$, the only physically meaningful parameter.

Proof on paper. By the bridge, $\omega = a^1_{(0)}b$ is a cocycle; by Theorem 10.8, $\omega = d_{12}\psi$; with φ the extension of ψ by zero, $E := D - \delta\varphi$ is graded (coboundaries of grade-preserving maps are graded) and its mode-0 part on V_1 is $\omega - d_{12}\psi = 0$. □

Why the normalisation matters. Before normalisation, the pole coefficient $a^1_{(1)}b$ is not an invariant of the deformation class: the trivial deformation $\delta(L_0)$ of Example 10.7 has $a^1_{(1)}b = 2a_{(1)}b = 2k\kappa(a,b)\mathbf{1}$, a nonzero "level change" that is pure gauge. After normalisation the residual gauge freedom preserving $a^1_{(0)}b = 0$ consists of φ with $\varphi|_{V_1} \in \mathrm{Der}(V_1) = \mathrm{ad}(V_1)$, and invariance of κ shows these do not change the pole. So only after normalisation is "the level change δ" a well-defined quantity. This is the conceptual heart of the split of Linshaw–Qi's theorem in the next section.

10.5 Linshaw–Qi Theorem 5.1 at $k = -4/3$, and the bundled hypothesis

10.5.1 The source

A. R. Linshaw and F. Qi, *Deformation rigidity of some simple affine VOAs*, arXiv:2601.12017 (v2), prove two rigidity theorems: Theorem 4.1, every simple affine VOA at a positive integer level admits only trivial deformations; and Theorem 5.1, the simple affine VOA $L_{-4/3}(\mathfrak{sl}_2)$ admits only trivial deformations. Both rest on their Theorem 3.1: *if V is a simple affine VOA and $Y_1(a(-1)\mathbf{1}, x)b(-1)\mathbf{1}$ is regular (has no negative powers of x) for all $a, b \in \mathfrak{g}$, then Y_1 is trivial.* The proof of Theorem 5.1 then shows, using the weight-three singular vector at $k = -4/3$, that the singular part of Y_1 on currents vanishes. They conjecture that rigidity holds for every simple affine $L_k(\mathfrak{g})$ that differs from $V^k(\mathfrak{g})$.

The library contains two developments of Theorem 5.1: a *split* conditional assembly (file `AffineSl2Rigidity43.lean`), which was the vehicle for discovering and repairing two defective formalisations, and the final *unconditional* proof (file `AffineSl2RigidityComplete.lean` and companions), both in `VOA/Examples/`. Both are documented here, because the first is where the "tautological bundled hypothesis" mentioned in the library map lives.

10.5.2 The object $L_{-4/3}(\mathfrak{sl}_2)$

```
noncomputable def L43 :
    VertexOperatorAlgebra (WakModule (-4 / 3 : ℂ) / QuotVOA.maxGradedIdeal voaSl2Adm) :=
  QuotVOA.maxQuotientVOA voaSl2Adm
```

File `VOA/Examples/AffineSl2VOAInstance.lean`.

```
noncomputable def voaSl2Adm : VertexOperatorAlgebra (WakModule (-4 / 3 : ℂ)) :=
  affineSl2VOA_closed (-4 / 3 : ℂ) admLevel_noncritical
```

From the mathematics to the Lean statement

`voaSl2Adm` is the universal $V^{-4/3}(\mathfrak{sl}_2)$ (`admLevel_noncritical` is the proof of $-4/3 + 2 \neq 0$), and `L43` its quotient by the maximal proper graded ideal, i.e. exactly Definition 10.2 at $k = -4/3$. It is definitionally the same object as `AffineSl2GeneralRigidity.simple (-4/3) _` (the two differ only in the proof of non-criticality, and proofs are irrelevant), so the uniform theorem of Section 10.8 at $(p, q) = (2, 3)$ is about the same algebra — up to the propositional, not syntactic, equality $2/3 - 2 = -4/3$ of the level.

Non-vacuity of anything said about `L43` requires that it be nonzero, simple, and a *proper* quotient of $V^{-4/3}$ (otherwise one would be proving rigidity of the universal algebra, which is false). All three are proved, `pbw`-free:

```
theorem L43_isSimple : L43.IsSimple :=
  QuotVOA.isSimple_maxQuotientVOA' voaSl2Adm vacuum_ne_zero
```

```
theorem maxGradedIdeal_ne_bot : QuotVOA.maxGradedIdeal voaSl2Adm ≠ ⊥ := by
```

```
theorem mkQ_sl2Singular_eq_zero :
    (QuotVOA.maxGradedIdeal voaSl2Adm).mkQ Sl2Sing.sl2Singular = 0 := by
```

The singular vector is the one printed by Linshaw–Qi (after Adamović),

$$s = -48\, h_{-1}e_{-2}\mathbf{1} + 36\, e_{-1}^2 f_{-1}\mathbf{1} - 6\, h_{-2}e_{-1}\mathbf{1} + 9\, h_{-1}^2 e_{-1}\mathbf{1} + 80\, e_{-3}\mathbf{1}, \tag{10.7}$$

and the library proves it equal to its own independently derived vector:

```
theorem lqVector_eq_sl2Singular : lqVector (-4 / 3 : ℂ) = Sl2Sing.sl2Singular := by
```

Proof on paper of properness. The canonical invariant bilinear form $(\cdot|\cdot)$ on V^k (normalised by $(\mathbf{1}|\mathbf{1}) = 1$) exists because $L_1 V_1 = 0$ (the currents are quasi-primary). For a weight-one quasi-primary u, invariance collapses to $(u_{(n)}a \,|\, b) = -(a \,|\, u_{(-n)}b)$. Every weight-3 vector is a combination of states $J^a_{-m}y$ with $m \geq 1$; hence $(J^a_{-m}y \,|\, s) = -(y \,|\, J^a_m s) = 0$ because s is annihilated by all positive modes. States of other weights are orthogonal to s for weight reasons. So s lies in the radical of the form, which by Li's theorem is the maximal graded ideal. Finally $s \neq 0$, proved in the Wakimoto free-field realisation (`Wak.sl2Singular_ne_zero`). □

Trap / dead end

A documentation error corrected. An older file (`Examples/AffineSl2Singular.lean` §D) claimed a "discrepancy with the reported literature form" of (10.7). That was a miscount: it reordered $h_{-1}e_{-2}\mathbf{1} = e_{-2}h_{-1}\mathbf{1} + 2e_{-3}\mathbf{1}$ but forgot that $9h_{-1}^2 e_{-1}\mathbf{1}$ also contributes to the $e_{-2}h_{-1}\mathbf{1}$ monomial ($h_{-1}^2 e_{-1}\mathbf{1} = M_5 + 4M_2 + 4M_1$). `lqVector_eq_sl2Singular` is the machine refutation; there is no discrepancy.

10.5.3 The linear algebra of Linshaw–Qi §5.3, and an erratum

Linshaw–Qi reduce Theorem 5.1 to five linear equations (10)–(14) in sixteen unknowns: fifteen coordinates a_i, b_i, c_i of three unknown weight-3 vectors and the pole constant c. The library transcribes them twice:
File `VOA/Examples/AffineSl2Rigidity43.lean`.

```
structure CorrectedSystem (a₁ a₂ a₃ a₄ a₅ b₁ b₂ b₃ b₄ b₅ c₁ c₂ c₃ c₄ c₅ c : ℂ) : Prop where

  eq14 : 84 * a₁ - 280 * a₂ - 168 * a₃ + 784 * a₄ - 336 * a₅ - 18 * b₁ + 60 * b₂ + 36 * b₃
      - 168 * b₄ + 72 * b₅ - 72 * c₁ + 240 * c₂ + 144 * c₃ - 672 * c₄ + 288 * c₅ - 96 * c =
       ↪ 0
```

File `VOA/Examples/AffineSl2Rigidity43.lean`.

```
theorem c_eq_zero_certificate : (1890 : ℂ) * c = 0 := by
  linear_combination 30 * h.eq10 - 14 * h.eq11 + 18 * h.eq12 + 23 * h.eq13 + 9 * h.eq14
```

(and `PrintedSystem`, identical except that `eq10` ends in `12 * c`).

Trap / dead end

Erratum in the source. Equation (10) is printed with constant term $+12c$; the paper's own §5.1 display gives $+72c$, and the fifteen other coefficients of (10) are correct. The printed elimination is internally consistent with the wrong 12 and ends with $10c = 0$; the corrected one gives $210c = 0$. The conclusion $c = 0$ is unaffected. The one-line certificate: the covector $\lambda = (30, -14, 18, 23, 9)$ annihilates all fifteen a_i, b_i, c_i columns, so $\lambda \cdot (10, \dots, 14)$ is $1890c = 0$ (corrected) or $90c = 0$ (printed). Moreover the unknowns enter only through $P_i = 42a_i - 9b_i - 36c_i$, and the solution space is $c = 0$ with $(P_1, \dots, P_5) \in \mathbb{C} \cdot (8, -12, -6, 9, 36)$ — the coordinates of s itself in the paper's basis (`PrintedSystem.reduced`, `sl2Singular_eq_lqBasis`). This is an internal consistency check the paper does not make. A further caution recorded in the file: (10)–(12) are components in $\{e_{-1}f_{-1}\mathbf{1}, h_{-2}\mathbf{1}, h_{-1}h_{-1}\mathbf{1}\}$ but (13)–(14) in $\{h_{-1}e_{-1}\mathbf{1}, e_{-2}\mathbf{1}\}$, a silent switch of basis.

These theorems are statements about complex numbers; they say nothing about deformations until the five equations are derived from a deformation, which is the hard part.

10.5.4 The split assembly

The library's conditional form of Theorem 5.1 separates three inputs:
File `VOA/Examples/AffineSl2Rigidity43.lean`.

```

Theorem 10.10 (split form of Linshaw–Qi Theorem 5.1)**.** *For any VOA W with centreless V_1: if (Theorem 3.1) every graded regular deformation is trivial, (Piece 1) $H^2(V_1, V_1) = 0$, and (Piece 2) every graded deformation in pole form has vanishing pole on V_1, then W is graded rigid.*

Physical meaning

In physics language: (Piece 1) the symmetry algebra cannot change; (Piece 2) the level cannot change; and (Theorem 3.1) once both current OPEs are unchanged, the whole chiral algebra is unchanged, because it is generated by the currents (states are normal-ordered products of currents, and their OPEs follow from the current OPE by Wick-type rules). The split separates the Lie-theoretic and the level-dependent input.

Proof on paper. Given graded D, Corollary 10.9 gives $E = D - \delta\varphi$ graded in pole form; Piece 2 kills its pole, so E is regular by `regular_iff_zero_one`; Theorem 3.1 makes E trivial; and $D = E + \delta\varphi$ is a sum of coboundaries. □

From the mathematics to the Lean statement

`RegularImpliesTrivialGraded W` is Linshaw–Qi's Theorem 3.1 *as a property of a specific W* (with the gradedness that the paper assumes throughout made explicit, since in Lean gradedness is a predicate). `NormalisedPoleVanishes W` is their §5 computation: its input is a deformation *already normalised* (`InPoleForm`), its conclusion is that the pole `poleVec` vanishes. The three hypotheses of `L43_isRigidGraded` are all now *theorems* at `L43`: `L43_sl2BasisOnWeightOne`, `L43_regularImpliesTrivialGraded`, and `L43_normalisedPoleVanishes` (next subsection), so the conditional form has been fully discharged.

10.5.5 The two dead ends: a vacuous hypothesis and a tautological one

The split exists because two earlier formalisations of the same theorem were wrong in instructive ways. Both are recorded in `VOA/Examples/AffineSl2RigidityCollapse.lean` as theorems.

Trap / dead end

Dead end 1: a refutable hypothesis (vacuous headline). The first version took as its §5 hypothesis

```
def GradedImpliesRegular (W : VertexOperatorAlgebra 𝒱) : Prop :=
  ∀ D : Deform.FirstOrderDeformation W, D.IsGraded → D.Regular
```

"every graded deformation is regular". This is **false** at $L_{-4/3}$, so a theorem assuming it proves nothing. The counterexample is the trivial deformation $\delta(L_0)$ of Example 10.7: at $n = 0$ it has $a^1_{(0)}b = a_{(0)}b$, and $h_{(0)}e = 2e \neq 0$. Even the weakening `GradedImpliesPoleZero` ("the pole vanishes for every graded deformation") fails: at $n = 1$, $f^1_{(1)}e = 2f_{(1)}e = 2k\mathbf{1} \neq 0$.

```
theorem not_gradedImpliesRegular_L43 : ¬ GradedImpliesRegular LQ43.L43 := by
```

```
theorem not_gradedImpliesPoleZero_L43 : ¬ GradedImpliesPoleZero LQ43.L43 := by
```

The lesson: coboundaries are graded cocycles and are generically not regular, so no statement of the form "every graded cocycle is regular" can hold. Linshaw–Qi do not claim it — their equation (3) already presupposes the normalisation of Section 10.4.

Trap / dead end

Dead end 2: the tautological bundled hypothesis. The repair was the predicate `GradedRegularUpToCoboundary`, written GRUC(W) below:

$$\mathrm{GRUC}(W): \quad \forall D \text{ graded}, \ \exists E \text{ graded, regular, with } Y_1^D - Y_1^E \text{ a coboundary.}$$

This is true and non-vacuous, but it is **equivalent to the conclusion for a trivial reason**: if W is graded rigid, take $E = 0$. The derivation $\mathrm{IsRigidGraded}(W) \Rightarrow \mathrm{GRUC}(W)$ uses nothing about W, and the file at the time literally proved the equivalence. A headline "$\mathrm{GRUC}(L_{-4/3}) \Rightarrow \mathrm{IsRigidGraded}(L_{-4/3})$" is bookkeeping: it bundles the normalisation (Piece 1, pure Lie theory of V_1) with the computation (Piece 2, where the level and the singular vector enter) into one existential statement whose content is the theorem itself. This is what the library map calls the "tautological bundled hypothesis". The predicate and all its supporting lemmas (`GradedRegularUpToCoboundary`, `trivial_satisfies`, `gradedRegularUpToCoboundary_iff_isRigidGraded`, ...) were *deleted*, not merely superseded; they did not exist at the documented commit, and a pre-release build commit has no such declarations either (the names survive only in a docstring of `AffineSl2Rigidity43.lean` that records this dead end).

What "non-tautological" can mean. At a fixed W, *any* true hypothesis is logically equivalent to any true conclusion, so "not implied by the conclusion" is not a usable criterion. The criterion with content is *uniform derivability*: is there a proof of $\forall W,\ \mathrm{IsRigidGraded}(W) \Rightarrow H(W)$ that uses nothing about W? Because rigidity turns every graded D into a coboundary, this amounts to asking whether the *coboundary content* of H (its restriction to $D = \delta\varphi$) holds for every W. For the deleted predicate it did (take $E = 0$). For the split pieces it does not, and the library proves this:

```
theorem not_normalisedPoleVanishes_heisenberg (k : ℂ) (hk : k ≠ 0) :
    ¬ LQ43.NormalisedPoleVanishes (heisenbergVOA k hk) := fun h =>
```

```
theorem not_trivial_satisfies_piece2 :
    ¬ (∀ (𝒲 : Type) [AddCommGroup 𝒲] [Module ℂ 𝒲] (V : VertexOperatorAlgebra 𝒲)
        (D : Deform.FirstOrderDeformation V), D.IsTrivial → D.IsGraded → D.InPoleForm →
        ∀ a ∈ V.grading 1, ∀ b ∈ V.grading 1, D.poleVec a b = 0) := fun H =>
```

```
theorem no_uniform_derivation_piece2 (k : ℂ) (hk : k ≠ 0)
    (H : ∀ (𝒲 : Type) [AddCommGroup 𝒲] [Module ℂ 𝒲] (V : VertexOperatorAlgebra 𝒲),
      Deform.IsRigidGraded V → LQ43.NormalisedPoleVanishes V) :
    ¬ Deform.IsRigidGraded (heisenbergVOA k hk) :=
```

From the mathematics to the Lean statement

At the rank-one free boson (Heisenberg VOA at level $k \neq 0$, Chapter 6), $V_1 = \mathbb{C}\alpha$ is abelian, so $\delta(L_0)$ is automatically in pole form ($a^1_{(0)}b = a_{(0)}b = 0$), yet its pole is $\alpha^1_{(1)}\alpha = 2k\mathbf{1} \neq 0$. Hence Piece 2 is *false* for the free boson, and its coboundary content (`not_trivial_satisfies_piece2`, the exact analogue of the deleted `trivial_satisfies`) is refutable. Consequently a uniform derivation of Piece 2 from rigidity would refute graded rigidity of the free boson (`no_uniform_derivation_piece2`). Physically: for a free boson a level change is pure gauge (rescale α), whereas for $\mathfrak{sl}_2$ the bracket $[h, e] = 2e$ pins the normalisation of the currents, so the level cannot be rescaled away. Piece 2 thus encodes a genuine, W-specific fact. The same $\delta(L_0)$ cannot refute Piece 2 at $L_{-4/3}$, because there it is not in pole form ($h_{(0)}e \neq 0$): `scalingDeformation_not_inPoleForm_L43`. Similarly `no_uniform_derivation_sl2Basis` (instantiated at the triplet algebra $\mathcal{W}(2)$, whose $V_1 = 0$) shows the $\mathfrak{sl}_2$-basis hypothesis is not uniformly derivable from rigidity either.

Trap / dead end

The residual, stated plainly (from the source). At $L_{-4/3}$ and *given* $V_1 \cong \mathfrak{sl}_2$, Piece 2 is still mathematically *equivalent* to graded rigidity: rigidity turns a deformation in pole form into $\delta\varphi$ with $\varphi|_{V_1}$ a derivation; Whitehead's first lemma makes it ad x; invariance of κ kills the pole. This is unavoidable — the conclusion of §5 *is* "the normalised pole vanishes" — and it is not the repaired defect: this derivation consumes the $\mathfrak{sl}_2$ structure and a second Whitehead lemma, rather than using nothing about W. In any case the point is now moot for the headline results: the conditional split is no longer needed, because `L43_graded_rigidity` below and the uniform theorem prove rigidity *without* assuming Piece 2, by deriving §5's *input* (the singular-vector relation) from the definition of L_k.

Trap / dead end

An over-general predicate, recorded but not repaired. `RegularImpliesTrivialGraded W` is stated for an arbitrary VOA W, whereas Theorem 3.1 assumes W simple affine. For W with $V_1 = 0$ regularity is vacuous and the predicate would assert full graded rigidity, which is morally false (e.g. for Virasoro $V(c, 0)$, along ∂_c). This does not affect any result of this chapter: the predicate is only ever *proved*, never assumed, and only at affine $\mathfrak{sl}_2$ quotients (`L43_regularImpliesTrivialGraded`, `simple_regularImpliesTrivialGraded`). A reader should simply not cite `isRigidGraded_of_split` as "Theorem 3.1" for general W.

10.5.6 The unconditional theorem at $-4/3$

```
theorem singular_central_polynomial (δ : ℂ) (v : Q) :
    let K : End ℂ (Q × Q) := kk • 1 + δ • tangentShift
    (24960 : ℂ) • K (v, 0) + (27360 : ℂ) • (K ^ 2) (v, 0) +
      (6480 : ℂ) • (K ^ 3) (v, 0) = (0, (-13440 * δ) • v) := by
```

```
theorem L43_normalisedPoleVanishes : NormalisedPoleVanishes L43 := by
```

```
theorem L43_graded_rigidity : Deform.IsRigidGraded L43 :=
  L43_isRigidGraded_of_normalisedPoleVanishes L43_normalisedPoleVanishes
```

(`VOA/Examples/AffineSl2RigidityComplete.lean`; `kk` is local notation for $-4/3$, `Q` for the carrier of `L43`, `tangentShift` is $(x_0, x_1) \mapsto (0, x_0)$ on $Q \times Q$, i.e. multiplication by t on $Q \oplus tQ$.)

Theorem 10.11 (Graded first-order rigidity of $L_{-4/3}(\mathfrak{sl}_2)$; Linshaw–Qi, Theorem 5.1)**.** *Every graded first-order deformation of $L_{-4/3}(\mathfrak{sl}_2)$ is trivial.*

Physical meaning

$L_{-4/3}(\mathfrak{sl}_2)$, central charge -6, is the chiral algebra associated with the (A_1, D_3) Argyres–Douglas theory (physics literature). Its null state at weight 3 encodes a relation among the currents that holds only at $k = -4/3$; any attempt to move the level violates it at first order, with rate proportional to the derivative -13440 of the null-norm polynomial $240k(3k+4)(9k+26)$. Hence no deformation.

Proof on paper. Normalise (Corollary 10.9); it remains to show the normalised pole vanishes (Piece 2), after which regular reconstruction (Section 10.6) finishes. In pole form the pole is $a^1_{(1)}b = \kappa(a,b)\delta\mathbf{1}$ for a single scalar δ, and the lifted currents $\tilde{J}^a_n = J^a_n + tJ^{a,1}_n$ on $Q \oplus tQ$ satisfy the affine relations with central element $K = k + \delta t$. Pair the singular word: the expression of s in lifted currents, applied to the vacuum, and then paired with the vacuum through the adjoint word, can be evaluated in two ways. By normal ordering in the affine algebra with central element K it equals $240K(3K+4)(9K+26)$ applied to the vacuum — the displayed cubic $24960K + 27360K^2 + 6480K^3$ — whose value at $K = -4/3 + \delta t$ is $0 + t(-13440\delta)$, because $k = -4/3$ is a simple root of the cubic. On the other hand, since $s = 0$ in $L_{-4/3}$, the lifted word lands in tQ, and the adjoint relation makes its pairing vanish (`actual_singular_pairing_obstruction`). Hence $-13440\delta = 0$. □

The factor $(3K+4)$ in $240K(3K+4)(9K+26)$ is the reason the singular vector exists exactly at $k = -4/3$; the *simplicity* of that root is what makes the tangent coefficient nonzero. This is the special case of the uniform mechanism of the next two sections, where "simple root of an explicit cubic" is replaced by "simple root of a Gram determinant".

10.6 The uniform machinery at every nonzero non-critical level

The files `AffineSl2General*.lean` and `AffineSl2UniformObstruction.lean` redo every step of the $-4/3$ proof except the final singular-vector computation, *for every level k* with $k \neq 0$ and $k \neq -2$. They are stated under `variable (k : ℂ) (hk : k + 2 ≠ 0) (hk0 : k ≠ 0)`. No admissibility enters until Section 10.7.

10.6.1 The first-order extension as a module

A first-order deformation D of W makes $W_R = W \oplus tW$ a vertex algebra over $R = \mathbb{C}[t]/(t^2)$. The library models $W \oplus tW$ as the product $W \times W$, a pair (x_0, x_1) standing for $x_0 + tx_1$. The lifted modes and the full product are

$$\tilde{u}_{(n)}(x_0, x_1) = \big(u_{(n)}x_0,\ u^1_{(n)}x_0 + u_{(n)}x_1\big), \qquad (x_0, x_1)_{(n)}(y_0, y_1) = \big(x_{0(n)}y_0,\ x_{0(n)}y_1 + x_{1(n)}y_0 + x^1_{0(n)}y_0\big),$$

(`liftedMode`, `Deform.Reconstruction.product`) and multiplication by t is `tangentShift` $(x_0, x_1) = (0, x_0)$.

10.6.2 Step A: regular deformations are trivial (Theorem 3.1 at every level)

File `VOA/Examples/AffineSl2GeneralRegularReconstruction.lean`.

```
theorem simple_regular_isTrivial (D : FirstOrderDeformation (simple k hk))
    (hD : D.IsGraded) (hreg : D.Regular) : D.IsTrivial := by
```

File `VOA/Examples/AffineSl2GeneralRegularReconstruction.lean`.

```
theorem simple_regularImpliesTrivialGraded : RegularImpliesTrivialGraded (simple k hk) :=
  (simple_regular_isTrivial k hk hk0)
```

The general reconstruction criterion behind it (`VOA/Core/DeformationReconstruction.lean`):

```
theorem isTrivial_of_closed_lift (S : Submodule ℂ (V × V))

Proof on paper. The criterion. Suppose $S \subseteq W \oplus tW$ is closed under all deformed products, contains $(\mathbf{1}, 0)$ but not $(0, \mathbf{1})$, surjects onto W under $(x_0, x_1) \mapsto x_0$, and is closed under homogeneous components. The kernel of the projection on S is $\{(0, y)\} \cap S$; its second coordinates form an ideal of W (closure under products with lifts of all states), not containing $\mathbf{1}$, hence zero by simplicity. So the projection is an isomorphism $S \cong W$; writing its inverse as $x \mapsto (x, \psi x)$, closure under products says exactly that $u^1_{(n)}v = (\delta(-\psi))$ ..., i.e. D is the coboundary of a grade-preserving φ with $\varphi\mathbf{1} = 0$. *The carrier.* If D is regular, the lifted currents satisfy the affine relations at the *same* level k on $W \oplus tW$ (the deformed commutator has no correction to either the bracket or the central term), and they annihilate $(\mathbf{1}, 0)$ in non-negative modes. By the universal property of the vacuum module there is a map $\mathrm{ev} : V^k(\mathfrak{sl}_2) \to W \oplus tW$ sending $J^{a_1}_{-n_1} \cdots \mathbf{1}$ to $\tilde{J}^{a_1}_{-n_1} \cdots (\mathbf{1}, 0)$. Take S its image. Its first coordinate is the quotient map $V^k \to L_k$, hence surjective; it respects energy, so its weight-zero part is $\mathbb{C}(\mathbf{1}, 0)$, which excludes $(0, \mathbf{1})$; it is closed under current modes and, by the iterate (associativity) identity, under all deformed products. This replaces the step in Linshaw–Qi where they cite Lian's Theorem 4.11 to conclude $W_{(0)} = \mathbb{C}\mathbf{1}$; the library's file records a concern that the citation may be circular (Lian's category assumes one-dimensional weight-zero space) and shows the step is obtained directly from the universal property of $V^k(\mathfrak{g})$. □

Trap / dead end

Provenance (recorded in the source). Linshaw–Qi state that the proof of Theorem 3.1 in v2 was contributed by an AI model, in a revision prompted by errors in v1, and it cites Lian for $W_{(0)} = \mathbb{C}\mathbf{1}$. The library does not rely on that proof: `simple_regular_isTrivial` is proved independently, with the universal-property argument above.

10.6.3 Step B: the single level parameter

File `VOA/Examples/AffineSl2GeneralDeformationPole.lean`.

```
theorem simple_existsUnique_pole_parameter (D : FirstOrderDeformation (simple k hk))
    (hD : D.IsGraded) (hnorm : D.InPoleForm) :
    ∃! δ : ℂ, ∀ a b : (simple k hk).grading 1,
      D.poleVec a b = ((currentPairing k hk hk0) a b * δ) • (simple k hk).vacuum := by
```

File `VOA/Examples/AffineSl2GeneralNormalizedRepresentation.lean`.

```
theorem simple_exists_normalized_representation (D : FirstOrderDeformation (simple k hk))
    (hD : D.IsGraded) (hnorm : D.InPoleForm) :
    ∃ (δ : ℂ) (ρ : AffSl2 →ₗ[ℂ] End ℂ ((WakModule k / I) × (WakModule k / I))),
      (∀ a b : (simple k hk).grading 1, D.poleVec a b = ((currentPairing k hk hk0) a b * δ)
       ↪  • (simple k hk).vacuum) ∧
      (∀ x n, ρ (ofLoop kappaForm kappaForm_isInvariant x n) =
        liftedMode D ((affineCurrent k hk hk0) x) n) ∧
      ρ (AffineLie.C kappaForm kappaForm_isInvariant) =
        k • (1 : End ℂ ((WakModule k / I) × (WakModule k / I))) + δ • tangentShift ∧
      ρ (ell0 kappaForm kappaForm_isInvariant) = liftedDegree (W := (simple k hk)) := by
```

From the mathematics to the Lean statement

`currentPairing k hk hk0 a b` is $\kappa(a,b)$ computed in the proved basis (e,h,f) of V_1 (entries $\kappa(e,f)=\kappa(f,e)=1$, $\kappa(h,h)=2$). `∃! δ` is unique existence. So the first theorem says: for a graded deformation in pole form, $a^1_{(1)}b = \delta\,\kappa(a,b)\mathbf{1}$ for one scalar δ. The second packages the lifted currents as a Lie algebra homomorphism ρ from $\widehat{\mathfrak{sl}}_2$ (`AffSl2 →ₗ[ℂ]` is a Lie algebra morphism) to $\mathrm{End}(Q\times Q)$, with Q the carrier of L_k and `I` the maximal ideal; the central element acts as $k+\delta t$ and ℓ_0 as the lifted degree operator. `affineCurrent` identifies $\mathfrak{sl}_2$ (coordinate colours) with V_1.

Proof on paper. For graded D in pole form, $a^1_{(1)}b \in V_0 = \mathbb{C}\mathbf{1}$, giving a bilinear form β on V_1 with $a^1_{(1)}b = \beta(a,b)\mathbf{1}$. The $\ell = 0$ case of the deformed Jacobi identity is the deformed commutator formula

$$[\tilde{a}_m, \tilde{b}_n] = \widetilde{[a,b]}_{m+n} + m\big(k\kappa(a,b) + t\,\beta(a,b)\big)\delta_{m+n,0},$$

(`poleForm_current_commutator`); its Jacobi identity in the Lie algebra makes β invariant, and every invariant form on $\mathfrak{sl}_2$ is a multiple $\delta\kappa$ (`exists_currentPole_sl2`). Uniqueness: $\beta(e,f)=\delta$ and $\mathbf{1}\neq 0$. □

File `VOA/Examples/AffineSl2GeneralDeformationPole.lean`.

```
theorem simple_isRigidGraded_of_normalisedPoleVanishes
    (hvan : NormalisedPoleVanishes (simple k hk)) : IsRigidGraded (simple k hk) :=
  isRigidGraded_of_sl2Basis (simple k hk) (simple_sl2BasisOnWeightOne k hk hk0)
    (simple_regularImpliesTrivialGraded k hk hk0) hvan
```

So, at every nonzero non-critical level, graded rigidity of $L_k(\mathfrak{sl}_2)$ is reduced to: *the level parameter δ of every normalised graded deformation vanishes.*

10.6.4 Step C: word pairings are polynomials in the level

For a word $w=((a_1,n_1),\dots,(a_r,n_r))$ write $J_w = J^{a_1}_{n_1}\cdots J^{a_r}_{n_r}$. In any representation of $\widehat{\mathfrak{sl}}_2$ in which the vacuum is killed by non-negative modes, the vacuum coefficient of $J_w\mathbf{1}$ is computed by moving annihilation operators to the right with (10.2); the result is a polynomial $P_w(C)$ in the central element. For the lifted representation $C=k+\delta t$, so the vacuum pairing is $P_w(k+\delta t) = P_w(k) + t\,\delta P_w'(k)$. File `VOA/Examples/AffineSl2GeneralPairing.lean`.

```
theorem simple_normalized_word_tangent (D : FirstOrderDeformation (simple k hk))
    (hD : D.IsGraded) (hnorm : D.InPoleForm) (δ : ℂ)
    (hδ : ∀ a b : (simple k hk).grading 1,
      D.poleVec a b = (currentPairing k hk hk0 a b * δ) • (simple k hk).vacuum)
    (w : List (Fin 3 × ℤ)) :
    (simpleForm k hk).form (simple k hk).vacuum
      (liftedCurrentWord k hk D w ((simple k hk).vacuum,0)).2 =
        (NormalOrdering.wordPolynomial w).derivative.eval k * δ := by
```

From the mathematics to the Lean statement

`simpleForm k hk` is the canonical invariant bilinear form of L_k with $(\mathbf{1}|\mathbf{1})=1$ (exists because the currents are quasi-primary, `simple_quasiPrimary`). `liftedCurrentWord k hk D w` is $\tilde{J}_w$ on $Q\times Q$ (leftmost letter acting last), applied to $(\mathbf{1},0)$; `.2` takes the t-coefficient. `NormalOrdering.wordPolynomial w` is the universal normal-ordering polynomial P_w, and `.derivative.eval k` is $P_w'(k)$. The statement: the t-part of the vacuum pairing of $\tilde{J}_w(\mathbf{1},0)$ is $\delta P_w'(k)$.

10.6.5 Step D: two relations give an obstruction

File `VOA/Examples/AffineSl2UniformObstruction.lean`.

```
noncomputable def wordGramPolynomial (u v : List (Fin 3 × ℤ)) : Polynomial ℂ :=
  ((-1:ℂ)^u.length) • NormalOrdering.wordPolynomial (adjointIndices u ++ v)
```

Theorem 10.12 (relation obstruction). *Let $k \neq 0, -2$. Suppose $\sum_i c_i J_{u_i}\mathbf{1} = 0$ and $\sum_j d_j J_{v_j}\mathbf{1} = 0$ in $L_k(\mathfrak{sl}_2)$ (two* relations*), and let $P(C) = \sum_{i,j} c_i d_j\, G_{u_i,v_j}(C)$ be their Gram polynomial, where $G_{u,v}(k) = (J_u\mathbf{1} \mid J_v\mathbf{1})$. If $P'(k) \neq 0$, then $L_k(\mathfrak{sl}_2)$ is graded rigid.*

Physical meaning

A relation is a null-state equation among normal-ordered current products. Its Gram polynomial is the two-point function of two such composite operators as a function of the level. If the level could drift, $k \to k + \delta t$, the relation would have to persist, so this two-point function would have to stay zero; its first-order change $\delta P'(k)$ must vanish. Transversality $P'(k) \neq 0$ is the statement that the null relation genuinely "pins" the level.

From the mathematics to the Lean statement

`currentWord k hk w` is J_w acting on L_k, so `hc`, `hd` are the two relations; `Fintype ι` makes the sums finite. `wordGramPolynomial u v` is the polynomial whose value at k is $(J_u\mathbf{1}|J_v\mathbf{1})$ (proved as `wordGramPolynomial_eval`): the adjoint of J^a_n for the invariant bilinear form is $-J^a_{-n}$ (*same* colour, opposite mode, `adjointIndices`, one sign per letter). The two relations may differ (`u` and `v` independent), which matters because the bilinear form pairs opposite h_0-weights. The polynomial is constructed uniformly by normal ordering; `hp` is its derivative at the level.

Proof on paper. Normalise D and let δ be its level parameter. Lift the column relation: $\tilde{v} := \sum_j d_j \tilde{J}_{v_j}(\mathbf{1}, 0)$ has first coordinate $\sum_j d_j J_{v_j}\mathbf{1} = 0$, so $\tilde{v} = (0, y)$ is a pure tangent vector. Pair it against the row: the vacuum coefficient of $\sum_i c_i \tilde{J}^\dagger_{u_i}\tilde{v}$ has t-part $\sum_i c_i(\mathbf{1} \mid J^\dagger_{u_i} y) = (\sum_i c_i J_{u_i}\mathbf{1} \mid y) = 0$ by the row relation (`actual_word_relation_obstruction`). But by Step C the same quantity is the t-part of $P(k + \delta t)$, namely $\delta P'(k)$ (`relationPair_tangent`). Hence $\delta P'(k) = 0$, so $\delta = 0$, and `simple_isRigidGraded_of_normalisedPoleVanishes` applies. □

Physically this is the precise version of the preview: the relations hold at level k; a deformation that moves the level to $k + \delta t$ must preserve them; their Gram pairing changes at rate $\delta P'(k)$; so a level change is forbidden whenever the relations are "transverse" to the level ($P'(k) \neq 0$). For the free boson there are no relations, and the level change is allowed (as pure gauge); for $V^k(\mathfrak{sl}_2)$ there are no relations, and the level change is a genuine deformation.

10.7 The Kac determinant and a simple root

It remains to produce, at each negative admissible level, two relations with $P'(k) \neq 0$. The library does this without writing down any singular vector, by a determinant argument.

10.7.1 From a simple determinant root to two relations

Lemma 10.13 (kernel pair). *Let $M(X)$ be a square matrix of polynomials over an integral domain, and z a simple root of* $\det M$*:* $\det M(z) = 0 \neq (\det M)'(z)$*. Then there are vectors r, s with $r^{\mathsf{T}} M(z) = 0$, $M(z)s = 0$ and $r^{\mathsf{T}} M'(z)s \neq 0$.*

Physical meaning

Purely technical: it extracts, from the vanishing of the Kac–Kazhdan determinant (the norm-matrix of descendant states) at a given level, two null states whose mutual two-point function changes at first order when the level is moved. It is the linear-algebra step of the null-vector argument.

File `VOA/Core/PolynomialMatrixSimpleRoot.lean`.

```
theorem kernel_pair_of_simple_root [NoZeroDivisors R]
    (M : Matrix ι ι R[X]) (z : R)
    (hz : M.det.eval z = 0) (hd : M.det.derivative.eval z ≠ 0) :
    ∃ r c : ι → R,
      (∀ j, ∑ i, r i * (M i j).eval z = 0) ∧
      (∀ i, ∑ j, (M i j).eval z * c j = 0) ∧
      (∑ i, ∑ j, (r i * c j) * (M i j).derivative.eval z) ≠ 0 := by
```

Proof on paper. Let $A = \operatorname{adj} M$. From $AM = MA = \det M \cdot 1$ at z: $A(z)M(z) = M(z)A(z) = 0$. Differentiate $MA = \det M \cdot 1$ and multiply by $A(z)$ on both sides: $A(z)M'(z)A(z) = (\det M)'(z)A(z)$ (the term with A' is killed by $M(z)A(z) = 0$). Since $(\det M)'(z) \neq 0$, $A(z) \neq 0$ (by Jacobi's formula $(\det M)' = \operatorname{tr}(AM')$). Pick (a, b) with $A(z)_{ab} \neq 0$ and take $r =$ row a of $A(z)$, $s =$ column b; then $r^{\mathsf{T}} M'(z)s = (A(z)M'(z)A(z))_{ab} = (\det M)'(z)A(z)_{ab} \neq 0$. □

Apply this to the Gram matrix of the invariant form on a weight space of $V^k(\mathfrak{sl}_2)$. The left kernel vector r gives a combination of PBW states in the radical of the form — hence in the maximal ideal by Li's theorem — hence a relation in L_k; similarly the right kernel vector. And $r^{\mathsf{T}} M'(k)s$ is exactly the derivative of their Gram polynomial. One subtlety: the *Shapovalov* form of a Verma module is contravariant for the Chevalley anti-involution ($e_n^\dagger = f_{-n}$), while the VOA's invariant bilinear form has $(J^a_n)^\dagger = -J^a_{-n}$. They differ by the Chevalley automorphism θ ($e \mapsto -f$, $f \mapsto -e$, $h \mapsto -h$), which the library constructs on V^k (`vacuumChevalley`) and shows preserves the maximal ideal (`vacuumChevalley_ideal_iff`); one of the two kernel vectors is therefore twisted by θ. The resulting statement:

```
theorem graded_rigidity_of_vacuum_simple_root (hk0 : k≠0) (n : ℕ) (c : ℤ)
    (hz : (vacuumChevalleyPolynomial n c).det.eval k=0)
    (hd : (vacuumChevalleyPolynomial n c).det.derivative.eval k≠0) :
    Deform.IsRigidGraded (simple k hk) := by
```

(`VOA/Examples/AffineSl2VacuumSimpleRoot.lean`, a Chapter 9 file.)

From the mathematics to the Lean statement

`vacuumChevalleyPolynomial n c` is a square matrix of polynomials in one variable X (the level), indexed by `JointIndex n (2*c)`: the PBW monomials of $V^X(\mathfrak{sl}_2)$ of energy n and h_0-weight $2c$ (`currentEnergy`, `currentCharge`, with e, f, h contributing $+2, -2, 0$). Its (i, j) entry

is the normal-ordering polynomial of the vacuum pairing of the i-th and j-th monomials with the Chevalley adjoint convention. `.det.eval k` and `.det.derivative.eval k` are $\det M(k)$ and $(\det M)'(k)$. The theorem: *if the level is a simple root of one such vacuum Gram determinant, $L_k(\mathfrak{sl}_2)$ is graded rigid* (at any nonzero non-critical k).

10.7.2 Locating a simple root: the Kac determinant with the horizontal factor removed

Which block, and why is the root simple? By (10.4), at $k+2 = p/q$ the first new singular vector of V^k has energy $n = q(p-1)$ and h_0-weight $2(p-1)$, so take $c = p-1$. The Gram determinant of V^k in that block is controlled by the Kac–Kazhdan determinant of the Verma module $M(k,\lambda)$ of highest weight (k,λ), as a polynomial in λ. At $\lambda = 0$ the Verma determinant vanishes identically in k because of the horizontal singular vector $f_0 v$, which spans a copy of $M(k,-2)$ inside $M(k,0)$; the vacuum module is the quotient by it. Extracting the first nonvanishing coefficient in λ gives the polynomial identity

File `VOA/Examples/AffineSl2KacVacuumCoefficient.lean`.

```
theorem affine_vacuum_polynomial_identity (n : ℕ) (c : ℤ)
    (hc : 0<2*(n : ℤ)-c) :
    (vacuumChevalleyPolynomial n c).det*affineMinusTwoPolynomial n (c+1)=
      Polynomial.C (vacuumDeterminantScale n c)*affineLeadingPolynomial n
       ↪  c*affineVacuumProduct n c := by
```

$$\det M^{\mathrm{vac}}_{n,c}(k) \cdot \det M^{(-2)}_{n,c+1}(k) = \sigma_{n,c} \cdot \Lambda_{n,c}(k) \cdot \prod_{\beta \neq \alpha,\ r} \big(\text{real-root factor}_{\beta,r}(k)\big)^{\mathrm{mult}}, \tag{10.8}$$

where $M^{(-2)}$ is the Gram block of $M(k,-2)$, $\sigma \neq 0$ is a combinatorial scale, $\Lambda(k)$ is a product of oscillator factors that is nonzero at every non-critical level (`affineLeadingPolynomial_eval_ne_zero`), and the product (`affineVacuumProduct`) runs over the real-root labels of the Kac–Kazhdan formula *other than the horizontal one*, each factor being the affine-linear function of k that vanishes exactly when (10.3) holds, raised to the dimension of the corresponding shifted weight space. This identity is a Chapter 9 result (the Kac determinant is proved there from the screening/Wakimoto construction); this chapter uses it as a proved theorem.

```

From the mathematics to the Lean statement

A Kac label `((a,m),r) : (Fin 3×ℕ)×ℕ` encodes a real root and an occurrence: colour `a = 0` is the family $(m+1)\delta-\alpha$, colour `1` the family $m\delta+\alpha$ (with `((1,0),0)` the horizontal root α at its first occurrence), and `r+1` the multiplicity n in (10.3). `realRootWeight t i` is the affine-linear function of the shifted level $t = k+2$ that vanishes on the Kac–Kazhdan hyperplane. `admissible_zero_labels` says: in the block of energy $q(p-1)$ and charge $p-1$, at $t = p/q$, *only two* labels vanish — the horizontal one (removed in `affineVacuumProduct`) and `((0,q-1),p-2)`, i.e. $\beta = q\delta-\alpha$ with $n = p-1$, which is (10.4). `admissible_first_multiplicity` says that factor occurs to the first power (the shifted weight space is the vacuum line only). `affineMinusTwoPolynomial_admissible_ne_zero` says $\det M^{(-2)} \neq 0$ at the admissible level. `(p : ℂ)/q-2` is k. Coprimality is used in `admissible_zero_labels` (through the resonance arithmetic) and in the nonvanishing of the $M(k,-2)$ determinant.

Proof on paper that the root is simple. Evaluate (10.8) at $k = p/q-2$. The right side has exactly one vanishing factor, the linear factor $-q\big(X-(p/q-2)\big)$ to the first power (`admissible_first_root_polynomial`); everything else on the right is nonzero, and $\det M^{(-2)}(k) \neq 0$. Hence $\det M^{\mathrm{vac}}(k) = 0$. Differentiate the identity and evaluate at k: the left side gives $(\det M^{\mathrm{vac}})'(k)\det M^{(-2)}(k)$ (the other term has the factor $\det M^{\mathrm{vac}}(k) = 0$); the right side gives $\sigma\Lambda(k)\cdot(-q)\cdot$(other factors at k) $\neq 0$ (the terms differentiating the other factors are multiplied by the vanishing linear factor). So $(\det M^{\mathrm{vac}})'(k) \neq 0$. □

Remark 10.14. Nothing here asserts that the kernel is spanned by "the" singular vector, nor that the maximal ideal is generated by it; and no character formula is used. The determinant only certifies that *some* radical vector exists in the block, transversally to the level. This is exactly what the deformation argument needs, and it is why the uniform proof is shorter than a proof via Adamović–Milas.

10.8 The headline theorem

```

(`VOA/Examples/AffineSl2AdmissibleRigidity.lean`, namespace `VOA.AffineSl2GeneralRigidity`. The proof is shown in full because it is informative: it is the composition of the simple-root theorem of Section 10.7 with the rigidity criterion.)

Theorem 10.15 (graded first-order rigidity at negative admissible levels)**.** *Let $p,q \in \mathbb{N}$ with $p \geq 2$, $q \geq 1$, $\gcd(p,q) = 1$ and $p < 2q$, and let $k = p/q-2$. Then every graded first-order deformation of the simple affine vertex operator algebra $L_k(\mathfrak{sl}_2)$ is trivial: for every Y_1 satisfying the order-t vertex-algebra axioms and the weight rule, there is a linear $\varphi : L_k \to L_k$ preserving each weight space, with $\varphi\mathbf{1} = 0$ and $Y_1 = \delta\varphi$.*

Physical meaning

For every negative fractional admissible level, the chiral algebra of the fractional-level $SU(2)$ WZW model has no chiral moduli: its OPE data are isolated. Equivalently, one cannot continuously connect two such theories at different admissible levels through a family of

chiral algebras, which is consistent with the levels being discrete (rational) labels fixed by modularity. The universal V^k, by contrast, has the level as a modulus. Rigidity here is not explained by unitarity or rationality (L_k is neither), but by the null vector of energy $q(p-1)$.

From the mathematics to the Lean statement

The variables. `p q : ℕ` are natural numbers. `hp : 2≤p` is $p \geq 2$ (the admissibility bound $p \geq h^\vee$); `hq : 0<q` is $q \geq 1$; `hcop : p.Coprime q` is $\gcd(p,q) = 1$; `hneg : p<2*q` is $p < 2q$, equivalently $k = p/q - 2 < 0$. These are exactly "k negative admissible" (Definition 10.4); no further hypothesis is present. **The level.** `(p : ℂ)/q-2` is $k = p/q - 2$ computed in $\mathbb{C}$ (the cast `(p : ℂ)` and the coercion of `q` to $\mathbb{C}$). `admissible_level_noncritical p q hp hq` is the proof of $k + 2 \neq 0$ required to form the algebra; it is a proof term, and by proof irrelevance its choice cannot matter. **The object.** `simple k hk` is `QuotVOA.maxQuotientVOA (affineSl2VOA_closed k hk)`: the quotient of the *universal* affine VOA $V^k(\mathfrak{sl}_2)$ (Sugawara conformal vector, $c = 3k/(k+2)$) by its maximal proper graded ideal, i.e. the *simple* quotient $L_k(\mathfrak{sl}_2)$ (Definition 10.2). It is proved simple and nonzero (`simple_isSimple`, `simple_vacuum_ne_zero`) and its weight-one space is $\mathfrak{sl}_2$ (`simple_sl2BasisOnWeightOne`). **The conclusion.** `Deform.IsRigidGraded` is Definition 10.6: for all `D : FirstOrderDeformation (simple k hk)` with `D.IsGraded`, `D.IsTrivial`. **Quantifier order.** $\forall p\, q$, (hypotheses) $\Rightarrow \forall D$ graded, $\exists \varphi$: the coboundary φ may depend on D, as it must. **Same, stronger or weaker than the literature?** At $(p,q) = (2,3)$ it is Linshaw–Qi Theorem 5.1, in a form at least as strong as theirs (Section 10.3: the library allows deformations of the translation operator, theirs does not; the trivial ones agree). For all other negative admissible levels it is new; it confirms, for $\mathfrak{sl}_2$ and $k < 0$, Linshaw–Qi's conjecture that $L_k(\mathfrak{g}) \neq V^k(\mathfrak{g})$ implies rigidity. It is *about the simple quotient*, not the universal algebra, and that matters: $V^k(\mathfrak{sl}_2)$ is not rigid (the level is a genuine deformation parameter), so a theorem about V^k would have been false. **How could it have been vacuous, and why it is not.** (a) *Zero algebra:* excluded, $\mathbf{1} \neq 0$, proved without `VOA.pbw`. (b) *Trivially rigid algebra:* L_k is the genuine simple quotient with $V_1 \cong \mathfrak{sl}_2$ and the non-zero level k, so the obvious candidate deformation (change of level) is a real constraint; the analogous statement fails for the free boson (`not_normalisedPoleVanishes_heisenberg`) and for V^k (mathematically). (c) *Unsatisfiable hypotheses:* the hypotheses are numerical and satisfied, e.g. by $(2,3)$, $(3,2)$, $(2,5)$; the library also states $k = -4/3$ directly (`L43_graded_rigidity`). (d) *An empty deformation class:* `FirstOrderDeformation` is the full space of cocycles, with finite Jacobi sums. (e) *A hidden premise:* `#print axioms` shows only Lean's standard axioms, and the statement has no structure-valued hypothesis (no `BottomProjection`-type datum). The general non-vacuity caveat recorded in Section 10.3 is now closed: the library exhibits $V(c,0)$ with a non-trivial graded deformation (`VOA.VirPoly.not_isRigidGraded_virasoroVOA`).

What the machine verified

`VOA.AffineSl2GeneralRigidity.negative_admissible_graded_rigidity`: **graded first-order rigidity, unconditional** (hypotheses are only the numerical admissibility conditions; non-vacuity of the notion machine-checked via `VOA.VirPoly.not_isRigidGraded_virasoroVOA`). `#print axioms`: `[propext, Classical.choice, Quot.sound]`; no `VOA.pbw`. Rerun for this chapter.

Proof on paper, assembled. Let D be graded. (1) $V_1 \cong \mathfrak{sl}_2$ since $k \neq 0$; normalise D by Whitehead (Section 10.4). (2) The normalised D has a unique level parameter δ, and the lifted currents represent $\widehat{\mathfrak{sl}}_2$ at level $k + \delta t$ (Step B). (3) At $k + 2 = p/q$, the vacuum Gram determinant in energy $q(p-1)$, h_0-weight $2(p-1)$, has a simple zero at k (Section 10.7); its adjugate gives two relations in L_k whose Gram polynomial has nonzero derivative. (4) The relations force $\delta P'(k) = 0$, so $\delta = 0$ (Step D).

(5) Then the normalised deformation is regular, hence trivial by reconstruction (Step A), and D is trivial. □

10.8.1 Every admissible level: the hypothesis $p < 2q$ is used only for $k \neq 0$

In the proof of the headline the hypothesis `hneg : p<2*q` enters only to show $k \neq 0$; the simple-root theorem `vacuumChevalleyDeterminant_admissible_simple` needs only $p \geq 2$, $q \geq 1$, $\gcd(p, q) = 1$. Since $k = 0$ means $p = 2q$, which with coprimality forces $(p, q) = (2, 1)$, the same argument proves rigidity at *every admissible level except* $k = 0$, including the positive integral levels (Linshaw–Qi's Theorem 4.1 for $\mathfrak{sl}_2$) and the positive fractional ones (e.g. $k = 1/2$). The library states this form, and the headline is its specialization to $p < 2q$.

Theorem 10.16 (Graded first-order rigidity at every admissible level)**.** *Let p, q be coprime positive integers with $p \geq 2$ and $p \neq 2q$, and put $k = p/q - 2$. Then every graded first-order deformation of the simple affine VOA $L_k(\mathfrak{sl}_2)$ is trivial.*

File `VOA/Examples/AffineSl2AdmissibleRigidity.lean`.

```
theorem admissible_graded_rigidity (p q : ℕ) (hp : 2≤p) (hq : 0<q)
    (hcop : p.Coprime q) (hne : p ≠ 2*q) :
    Deform.IsRigidGraded (simple ((p : ℂ)/q-2) (admissible_level_noncritical p q hp hq)) :=
     ↪ by
```

From the mathematics to the Lean statement

The statement is that of Theorem 10.15 with `hneg : p<2*q` replaced by `hne : p ≠ 2*q`, which excludes only $k = 0$, where $L_0(\mathfrak{sl}_2) = \mathbb{C}$. The headline `negative_admissible_graded_rigidity` is proved from it, discharging `hne` from `hneg` by `omega`.

What the machine verified

Proved; `#print axioms`: `[propext, Classical.choice, Quot.sound]` (re-run on the release build of 3 November 2026). No hypothesis beyond the four numerical conditions.

Physical meaning

At positive integral k this is the chiral algebra of the unitary $SU(2)$ WZW model; at fractional admissible k it is a non-unitary CFT. Either way the current OPE admits no infinitesimal deformation other than field redefinitions.

Remark 10.17. Combined with the Gorelik–Kac criterion (for $\mathfrak{sl}_2$, V^k is non-simple at non-critical k exactly when $k + 2 \in \mathbb{Q}_{>0}$ has numerator at least 2, i.e. k admissible — a literature fact, not formalised here), this means that for $\mathfrak{sl}_2$ Linshaw–Qi's conjecture "$L_k \neq V^k \Rightarrow$ rigid" holds at every non-critical level except $k = 0$, where $L_0 = \mathbb{C}$ and the conjecture is trivial. This combines a library theorem with a literature fact; the combination is not a library theorem.

10.9 The boundary-admissible C_2 programme (conditional)

The files `AffineSl2Boundary*.lean` assigned to this chapter are not about deformations. They concern the *Zhu C_2 algebra* (Poisson algebra) $R_V = V/C_2(V)$, $C_2(V) = \mathrm{span}\{u_{(-2)}v\}$, of the boundary-admissible algebras $L_k(\mathfrak{sl}_2)$, $k = -2 + 2/(2n+1)$, which governs their associated variety and quasi-lisse property (on paper; associated varieties are not formalised, see Chapters 11 and 16).

Superseded: now proved unconditionally for every boundary level

This section records the conditional programme as it stood when the chapter was written. The Arakawa–Dai campaign has since proved, for every $m \geq 1$ and $k = -2 + 2/(2m+1)$ and with no hypothesis, the exact presentation of the C_2 algebra of the actual simple VOA (`AffineSl2BoundaryClassicalFreeness.baseC2AlgEquiv`), classical freeness and the full vacuum character, bundled as the single theorem `VOA.AffineSl2BoundaryClassicalFreeness.arakawaDai_theorem_1_1` (`VOA/Examples/AffineSl2BoundaryTheorem11.lean`); see Chapter 20. The conditional statements below remain true and proved, but they are no longer the state of the art.

For the universal algebra $R_{V^k(\mathfrak{sl}_2)} = \mathrm{Sym}(\mathfrak{sl}_2) = \mathbb{C}[e,h,f]$; with $\mathrm{Cas} = h^2 + 4ef$ the expected answer (Arakawa–Jiang–Moreau, and the classical literature) is

$$R_{L_k(\mathfrak{sl}_2)} \cong \mathbb{C}[e,h,f]\big/(\mathrm{Cas}^n e,\ \mathrm{Cas}^n h,\ \mathrm{Cas}^n f), \qquad k = -2 + \frac{2}{2n+1}.$$

These results are **conditional**: the library proves the presentation *from* a named representation-theoretic input (that the maximal ideal is generated by the singular vector, the Adamović–Milas theorem), which it deliberately does not install as an axiom.

```

From the mathematics to the Lean statement

`SymSl2` is `MvPolynomial (Fin 3) ℂ`, the polynomial ring $\mathbb{C}[e,f,h]$, and `casSym` is $h^2 + 4ef$. `boundaryIdeal n` is $(\mathrm{Cas}^n e, \mathrm{Cas}^n h, \mathrm{Cas}^n f)$ (for $n = 1$ it equals the earlier `casIdeal`, `boundaryIdeal_one`). `quotientSymbol k hk I …` is the compos-

ite $\mathbb{C}[e,f,h] = R_{V^k} \to R_{V^k/I}$, which is surjective (`quotientSymbol_surjective`). `IsExactPresentation I φ` is $\ker\varphi = I$; together with surjectivity it gives $R_{L_k} \cong \mathbb{C}[e,f,h]/I$ (`boundarySimpleQuotientEquiv_of_singularC2Image`). `SingVec.idealGen W s` is the VOA ideal generated by s. So `exactPresentation43_of_maximalGeneration` reads: *if* the maximal ideal of $V^{-4/3}$ is generated by the weight-3 singular vector, *then* $R_{L_{-4/3}} \cong \mathbb{C}[e,f,h]/(\mathrm{Cas}\,e, \mathrm{Cas}\,h, \mathrm{Cas}\,f)$. The same holds at $k = -8/5$ (`exactPresentation85_of_maximalGeneration`, $n = 2$, with the weight-5 singular vector). `OnlyVacuumAffinePrimitives s`: in $V^k/(s)$, every affine primitive vector (nonzero, killed by all positive modes and by e_0) lies on the vacuum line. The library proves this is *equivalent* to maximal generation (`affineVacuumMaximalSubmoduleGenerated_of_onlyVacuumAffinePrimitives`, `exactPresentation43_of_onlyVacuumAffinePrimitives`), so the sharpest remaining external input is that primitive-uniqueness statement; the existence of primitives in every nonzero proper current submodule is proved internally. The general-n interface (`AffineSl2BoundarySingularFamily`: structures `Candidate`, `PrimitiveCriterionData`, `AdamovicMilasData`, `ClassicalData`) carries the singular-vector data as structure fields; concrete instances exist only for $n = 1, 2$ ($p = 3, 5$).

Proof on paper of the conditional presentation. Three steps, all proved. (1) For a graded ideal I, $\ker(R_W \to R_{W/I})$ is the image of I in R_W (`ker_A₂quot_eq_idealImage`). (2) Lower bound: the image of an ideal is a Poisson ideal; the leading symbol of s is a nonzero multiple of $e\,\mathrm{Cas}^n$ (computed for $n = 1, 2$), and applying the horizontal lowering bracket twice produces $\mathrm{Cas}^n h$ and $\mathrm{Cas}^n f$, so the boundary ideal is contained in the kernel. (3) Upper bound: for a vector killed by all positive current modes, the ideal it generates is spanned by *non-positive* current words applied to it (`singularCurrentPBWSpanning_of_SingP`); modulo C_2, modes ≤ -2 vanish, -1 is multiplication by a symbol and 0 is the horizontal Poisson bracket, which preserves the boundary ideal. Injectivity of $\mathbb{C}[e,f,h] \to R_{V^k}$ (the universal PBW theorem, proved via Wakimoto) converts equality of images into the exact kernel. □

What the machine verified

`exactPresentation43_of_maximalGeneration`, `exactPresentation85_of_maximalGeneration`, and the `_of_onlyVacuumAffinePrimitives` and `_of_currentIrreducible` variants: **conditional** on the displayed hypothesis (maximal generation / primitive uniqueness / irreducibility of the singular quotient), which is a published theorem (Adamović–Milas, Theorem 3.1.4) not formalised here. `#print axioms` for the $-4/3$ statement (re-run): `[propext, Classical.choice, Quot.sound]`. Nothing in this section is used by the rigidity theorems.

Trap / dead end

What the free-field route does not give. An Adamović inverse-DS/free-field realisation shows that the candidate singular vector lies in the maximal ideal (`mem_maxGradedIdeal_of_adamovic_freeField`), but *not* that it generates it: the descended map $V^k/(s) \to$ (free fields) is injective exactly when no further subsingular vectors exist, which a finite check of $s \mapsto 0$ cannot see (`onlyVacuumAffinePrimitives_iff_strictDescent`, `strictDescent_iff_maximalGeneration`). Treating "s vanishes in the free-field realisation" as "s generates the maximal ideal" would be an over-claim.

10.10 A cited hypothesis: admissible partitions

`VOA/Examples/AdmissiblePartitions.lean` is assigned here by name but belongs to the graded-unitarity programme for the Virasoro boundary minimal models $L(c_{2,2n+1}, 0)$ (Chapter 19). Its purpose is to make one imported combinatorial input visible as a named proposition, rather than proving anything:

```
def AdmissibleBasisHyp (c : ℂ) (a : ℕ → ℕ → ℕ) : Prop :=
  ∀ N p : ℕ, finrank ℂ (goodFil c p (N : ℤ)) = ∑ r ∈ Finset.range (p + 1), a N r
```

From the mathematics to the Lean statement

`goodFil c p N` is the p-th step of the length filtration on the weight-N space of the simple Virasoro quotient, and `finrank` its dimension; `a N r` is a *parameter* intended to be the number of Salazar's admissible partitions of N of length r (arXiv:2405.07126v3, Theorem 0.1). The predicate is the Andrews–Gordon/Salazar refined character. It is **not proved** and is carried as a hypothesis by every statement that uses it; `a` is deliberately not yet a definition. The file also records (as a docstring, numerically checked at $c = -22/5$, $N = 6$) that the companion `FlagBasisHyp` must order the basis compatibly with length: reversing the order flips the Gram pivot signs. None of this is related to affine rigidity.

10.11 Verification record

All axiom checks were run for this chapter on a scratch file importing the relevant modules of the already-built tree, with the command (never a bare `lake env lean`, which can drop `maxSynthPendingDepth`):

```
export PATH="$HOME/.elan/bin:$PATH"
lake env lean -DmaxSynthPendingDepth=3 <scratchpad>/L09/Ax.lean
```

with output (one line per declaration, abbreviated by namespace):

```

(Lean prints long lists over several lines; they are joined here.) The all-admissible theorem (Theorem 10.16) gives the same three axioms. No full `lake build` was run for this chapter (the tree was already built at the documented commit); the project's build record for the commit that completed the mathematics reports an aggregate build of 9,989 jobs and a full axiom audit of 3,310 reports, and the commit message of the documented commit reports an aggregate build of 10,343 jobs with `check_repository.py` and `run_axiom_audits.py` passing. Those are the source's claims; the axiom lists above are what this chapter's author re-confirmed.

Re-run 2026-10-27. At a later commit (branch `deligne-lean`; not re-run for this edition), with the same command on a scratch file, `#print axioms` gave exactly `[propext, Classical.choice, Quot.sound]` for `VOA.LQ43.L43_graded_rigidity`, `VOA.AffineSl2GeneralRigidity.negative_admissible_graded_r` `VOA.VirCDef.cmode_conformal_of_isCoboundary`, `VOA.VirCDef.not_isTrivial_of_omega_witness`, `VOA.VirCDef.not_isTrivial_of_isCDeformation`, `VOA.VirCDef.not_isRigidGraded_of_isCDeformation` and `VOA.NonzeroDeform.not_isRigid_virasoroVOA`. No aggregate `lake build` was run.

Release audit 2026-10-27: `Notes/Textbook/referee/RELEASE_AUDIT_RIGIDITY.md`. Its verdict on `VOA.LQ43.L43_graded_rigidity` is "announceable with caveats" (graded first-order only; non-vacuity argued on paper only). The non-vacuity caveat was removed afterwards by `VOA.VirPoly.not_isRigidGraded_virasoroVOA` (release follow-ups audit `Notes/Textbook/referee/RELEASE_AUDIT_FOLLOWUPS.md`, 2026-10-28, which reports standard axioms for it; not re-run for this chapter). The audit also confirms that the comparison with Linshaw–Qi in Section 10.3 is correct: the Lean notion implies theirs.

10.12 Referee's checklist

"Uncond." means the hypotheses listed are ordinary mathematical hypotheses of the statement (no unestablished datum); $*$ marks a `#print axioms` run for this chapter with result `[propext, Classical.choice, Quot.sound]`. No entry uses `VOA.pbw`. Namespaces: `GR` = `VOA.AffineSl2GeneralRigidity`, `LQ` = `VOA.LQ43`, `RC` = `VOA.AffineSl2RigidityCollapse`.

Points a referee should weigh. (1) The headline is about the *simple* quotient, defined intrinsically; it is at least as strong as Linshaw–Qi's notion (Section 10.3). (2) The "tautological bundled

hypothesis" of the library map refers to a *deleted* predicate; no current headline depends on it, and the remaining conditional split has been fully discharged (Section 10.5.5). (3) The hypothesis $p < 2q$ is used only to get $k \neq 0$; the library also states the theorem for all admissible $k \neq 0$ (Theorem 10.16). (4) $V(c, 0)$ is proved not graded rigid, for every c (`not_isRigidGraded_virasoroVOA`); the notion is non-vacuous (Section 10.3, second warning). (5) `RegularImpliesTrivialGraded` is over-general as a predicate on arbitrary W but is only ever proved at affine $\mathfrak{sl}_2$ quotients. (6) Every rigidity statement here is *graded first-order*; the ungraded `IsRigid` is false for every $V(c, 0)$ and is never claimed.

Chapter 11

Filtrations, the C_2 algebra and presentations

This chapter documents the release of the LeanVOA library named in the front matter. Every Lean quotation below was copied by a script that reads the source lines (so that no declaration was retyped by hand) and is machine-checked by `scripts/textbook/sync.py` to occur verbatim, up to whitespace and comments, in the source files of that release. Checks that were run at an earlier state of the library and not re-run for this edition are marked as such. The chapter covers the 38 files assigned to it in `Notes/Textbook/assignment.txt`: the filtration, symbol and presentation files of `VOA/Core/` (`GoodFiltration*`, `LinearFiltration`, `FilteredTensorSymbols`, `FilteredWordSymbols`, `FiniteAssociatedGraded`, `FiniteHilbertSqueeze`, `Polynomial*`, `OrderedExponentWord`, `IntegerJetConvolution`, `PowerSeriesCoefficientDerivation`, `SparseRational`, `NonlinearConformal`, `NonlinearVirasoro`, `NonlinearZeta`, `NPExtension`, `NonlinearMR`, `VAPresentation`, `PresentationDoctrine`), the two directories `VOA/Commutative/` and `VOA/Filtered/`, and the example files `VOA/Examples/LiDelta.lean`, `LiDelta2.lean`, `NonlinearVirasoroTransport.lean` and `NonlinearVirasoroGenuine.lean`. All together these are about fourteen thousand lines of Lean. Section 11.5 documents three further files of `VOA/Filtered/` (`GeneratorWordLiSurjectivity.lean`, `GeneratorCurrentLiSpanning.lean`, `AffineSl2GeneratorCurrentInstance.lean`), first quoted at an earlier commit on the branch `deligne-lean`.

What the chapter is about. A vertex operator algebra V is a very non-commutative object: its products $u_{(n)}v$, $n \in \mathbb{Z}$, satisfy the Borcherds identity, a tower of relations with no classical analogue. There are two standard ways to tame it, and this chapter documents the library's version of both.

1. *Pass to a commutative shadow.* Filter V in a way compatible with the products and take the associated graded object. For Li's filtration the associated graded $\mathrm{gr}^F V$ is a commutative algebra with a derivation (indeed a vertex Poisson algebra), and its degree-zero part is Zhu's C_2-algebra $R_V = V/C_2(V)$. Arakawa's *associated variety* of V is the spectrum of R_V, and a basic theorem of Li and Arakawa says that the arc (jet) algebra of R_V surjects onto $\mathrm{gr}^F V$. "Classical freeness" is the statement that this surjection is an isomorphism.

2. *Present the algebra.* Write V as generated by finitely many fields with a given singular OPE, modulo explicit relations. This is how physicists specify a chiral algebra, and De Sole and Kac turned it into mathematics: the universal enveloping vertex algebra of a non-linear Lie conformal algebra. (The library's datum `OPEData` is the weaker non-linear *conformal* algebra of De Sole–Kac's Definition 3.1: skew-symmetry and the Jacobi identity are not imposed; see Definition 11.38.)

The library has substantial, carefully staged material on both. Sections 11.2 to 11.6 treat filtrations, the Li filtration, jets and the polynomial "symbol" toolkit. Within them, Section 11.5 proves that the

canonical jet map onto the Li associated graded is surjective whenever generator words span Li's filtration, for any VOA. It also shows how to establish that spanning for currents and for quotients; Chapters 20 and 24 use this; Sections 11.7 to 11.8 treat presentations; a short Section 11.9 documents two files on Li's Δ-operator that were filed here.

The findings of this chapter, in brief. Most of what is documented here is proved without hypotheses, `#print axioms`-clean, and without `VOA.pbw` (the PBW theorem of Chapter 3; formerly a project axiom, now a theorem). The fidelity checks, however, turned up the following points, each explained in a red warning box where it occurs.

- **Every VOA has a `GoodFiltration`.** The library's `GoodFiltration` (a reconstruction, flagged as such in its own docstring, of the "good filtration" clause of Arabi Ardehali–Beem–Lemos–Rastelli) is satisfied by the coarse two-step flag "vacuum in degree 0, everything else in degree 1". We prove this in Lean (checked against the library; the check is not part of this release). So the existence of a good filtration carries no information; only a *specific* filtration does. The mode condition also omits the second clause of Li's and Arakawa's notion of a good filtration (non-negative modes lower the degree by one).
- **Li's $F^1V = C_2(V)$ is proved in the library** (`VOA.liFiltration_one_eq_O₂`, `VOA/Filtered/LiC2Bridge.lean`); it was first checked in Lean for this chapter, outside the library, at a commit where the library stated only $C_2(V) \subseteq F^1V$. Hence the degree-zero layer of the library's Li associated graded *is* Zhu's C_2-algebra. The same check also shows that an explicit `LWGenerated` hypothesis carried by two Li-filtration theorems is redundant.
- **The De Sole–Kac interface `NPExtension` has no instance anywhere in the library.** Every theorem quantified over an `NP : NPExtension D` (the full ideal $M(R)$, the presentation ideal of `VAPresentation`, the vacuum guards, the "ω-counterexample") is therefore, as a Lean proposition, vacuously true today. The library says so itself; we repeat it prominently. Likewise `simple_realization_unique` is a `def : Prop`, stated and not proved, and `TheVOA` takes an *arbitrary* VOA structure on the presented space as input, unrelated to the presentation.
- **The "generators + OPE = Borcherds" theorem for Virasoro is genuine but narrower than its name.** The ideal `MRtwo` is defined from the OPE table alone and the library proves `MRtwo_eq_ker_PhiVir` honestly. But the relations do not depend on the central charge (we check this in Lean, outside the library), and the annihilation half of the fields is obtained by transporting the independently constructed Virasoro VOA, not from the OPE. So the theorem identifies the *vector space and creation operators* of the presented object; the OPE data enter only through the realization.
- **The `hdec` surjectivity criterion of Theorem 11.16 cannot be used outside the C_2-cofinite world.** Its hypothesis implies `C2Cofinite`; we check this in Lean, outside the library. Hence it fails for every non-lisse VOA, e.g. $L_{-4/3}(\mathfrak{sl}_2)$, and also for the Virasoro minimal models $M(2, 2n+1)$, $n \geq 3$ (the $M(2, 2m+3)$ of Chapter 20, with $n = m+1$), with the single generator ω. The replacement, spanning of Li's filtration by generator words, is Section 11.5. This is a recorded dead end (warning box on page 524).
- The left-ideal route `MRbot` of the original De Sole–Kac staging is refuted in Lean (`not_nonempty_genFields_MRbot_virasoro`): this is a recorded dead end.

11.1 Conventions recalled

Throughout, V is a vertex operator algebra in the sense of the library: a Lean term `W : VertexOperatorAlgebra` $\mathcal{V}$ (Chapter 4, Definition 4.4) with underlying complex vector space $\mathcal{V}$. We

use:

- $V = \bigoplus_{n\in\mathbb{Z}} V_n$ with $V_n =$ `W.grading n`, each finite-dimensional, $V_n = 0$ for $n < 0$ (`positivity`) and $V_0 = \mathbb{C}\mathbf{1}$ (`vacuum_grade`). Every library VOA is of CFT type.
- The n-th product $u_{(n)}v$ is `W.smul u n v`, and `mode f n` is the coefficient f_{-n-1} of a formal series $f = \sum_k f_k z^k$, so that `mode (Y u) n` $= u_{(n)}$ (Chapter 1, Example 1.1). Conversely the z^j*-coefficient* `(Y u) j` of $Y(u,z)$ is $u_{(-j-1)}$. Both indexings occur in this chapter and we always say which one is meant.
- $T = L_{-1}$ is the translation operator (`W.L (-1)`, or `W.toPreVertexAlgebra.T`); $(Tu)_{(n)} = -n\,u_{(n-1)}$ and $u_{(-n-1)}\mathbf{1} = T^n u/n!$.
- $C_2(V) = \mathrm{span}\{u_{(-2)}v\}$ is `O₂ W`, and $R_V = V/C_2(V)$ is `A₂ W` (Chapter 12, Definition 12.22; recall that `A₂` is *not* the second higher Zhu algebra). R_V is a commutative Poisson algebra with product $[u][v] = [u_{(-1)}v]$ and bracket $\{[u],[v]\} = [u_{(0)}v]$ (Theorem 12.23).
- `Submodule ℂ X` is a linear subspace; `⊥`, `⊤` are 0 and X; `⊔`, `⊓` are sum and intersection; `⨆ p, S p` is the sum of a family; `S.map f`, `S.comap f` are image and preimage under a linear map; `X ⧸ S` is the quotient; `Module.finrank` is dimension (and is 0 on infinite-dimensional spaces). `MvPolynomial σ ℂ` is the polynomial ring $\mathbb{C}[x_s : s \in \sigma]$ and `PowerSeries R` is $R[[t]]$. Generic Lean idioms (structures, `∃`, coercions, `↥`, junk values) are explained in Chapter 1, Section 1.2.
- *Normal ordering.* For fields $a(z) = \sum_j a_j z^j$ (coefficient convention), $:a(z)b(z):\, = a(z)_+ b(z) + b(z)a(z)_-$, where $a(z)_+$ collects the creation part (the modes $a_{(n)}$, $n < 0$, which need not kill the vacuum) and $a(z)_-$ the annihilation part ($a_{(n)}$, $n \geq 0$): annihilation operators are moved to the right. Its value on states is the (-1)-product, $Y(a_{(-1)}b, z) = :Y(a,z)Y(b,z):$; the library's `nprod` is defined in Chapter 4.
- *Strong generators.* A set $S \subseteq V$ *strongly generates* V if V is spanned by the states $s^1_{(-n_1-1)} \cdots s^r_{(-n_r-1)}\mathbf{1}$ with $s^i \in S$, $n_i \geq 0$; equivalently every field is a normal-ordered polynomial in the fields of S and their derivatives. The library's version is `iterProdSpan` (Chapter 12, Theorem 12.24).
- Fields, locality and T-covariance: `IsField a` says $a(z)x$ has only finitely many negative powers of z for every x; `Local a b` says $(z-w)^N[a(z),b(w)] = 0$ for some N; `DCovariant T a` says $[T, a(z)] = \partial_z a(z)$. All three are defined in Chapter 4 (Section 4.2 and Definition 4.38), as is the operator-first reconstruction theorem `Reconstruction.reconstruct` (Theorem 4.41).

Physical meaning

The whole chapter is about the relation between a *chiral algebra* and its *classical limit*. Think of V as the operator algebra of the holomorphic fields of a two-dimensional conformal field theory. A filtration by "how many derivatives" (Li's filtration) or by "how many fields" (a length or R-charge filtration) organises the operators the way a physicist organises a semiclassical expansion; the associated graded is the algebra of *classical* fields, in which normal ordering becomes ordinary commutative multiplication and the singular part of the OPE survives only as a Poisson bracket. Its degree-zero part $R_V = V/C_2(V)$ is the ring of functions on the *associated variety* $X_V = \mathrm{Specm}\, R_V$. For the chiral algebras of four-dimensional $\mathcal{N} = 2$ superconformal theories, Beem and Rastelli conjectured (and checked in many examples) that X_V is the *Higgs branch* of the four-dimensional theory: the classical moduli space of vacua. Strong generators of V are a minimal set of fields from which all others are obtained by normal ordering and derivatives (they generate R_V as an algebra), and the *null relations* among them — the singular vectors that vanish in the simple quotient — are the chiral-algebra version of

equations of motion, or of the defining equations of the Higgs branch.

11.2 Graded flags, good filtrations and filtered maps

We start with the most general notion: a filtration of each weight space. The library introduced it for the graded-unitarity programme of Arabi Ardehali, Beem, Lemos and Rastelli (ABLR), which is treated in Chapter 19; here we only document the definitions and the facts about them.

Definition 11.1 (Graded flag)**.** A *graded flag* on a VOA V is a family of subspaces $G_pV_n \subseteq V_n$ ($p \in \mathbb{N}$, $n \in \mathbb{Z}$) such that

1. $G_pV_n \subseteq G_qV_n$ whenever $p \le q$ (increasing);
2. $G_0V_n = 0$ for $n > 0$, and $G_0V_0 = \mathbb{C}\mathbf{1}$ (normalisation);
3. $\sum_p G_pV_n = V_n$ for every n (exhaustive).

It is *mode-compatible* if for all $p, q \in \mathbb{N}$, $m, n, k \in \mathbb{Z}$, $u \in G_pV_m$ and $v \in G_qV_n$,

$$u_{(k)}v \in G_{p+q}V_{m+n-k-1}. \tag{11.1}$$

A *good filtration* in the library's sense is a mode-compatible graded flag.

File `VOA/Core/GoodFiltration.lean`.

```
structure GradedFlag (W : VertexOperatorAlgebra 𝒱) where
  piece : ℕ → ℤ → Submodule ℂ 𝒱
  le_grading : ∀ (p : ℕ) (n : ℤ), piece p n ≤ W.grading n
  mono : ∀ {p q : ℕ} (n : ℤ), p ≤ q → piece p n ≤ piece q n
  bot : ∀ n : ℤ, 0 < n → piece 0 n = ⊥
  vacuum_zero : piece 0 0 = ℂ • W.vacuum
  exhaustive : ∀ n : ℤ, (⨆ p : ℕ, piece p n) = W.grading n

def ModeCompatible : Prop :=
  ∀ {p q : ℕ} {m n k : ℤ} {u v : 𝒱}, u ∈ F.piece p m → v ∈ F.piece q n →
    W.smul u k v ∈ F.piece (p + q) (m + n - k - 1)

structure GoodFiltration (W : VertexOperatorAlgebra 𝒱) extends GradedFlag W where
  mode_mem : toGradedFlag.ModeCompatible
```

From the mathematics to the Lean statement

`piece p n` is G_pV_n, a subspace of the whole space $\mathcal{V}$ together with the field `le_grading` saying it lies in V_n. `mono` is (1); `bot` and `vacuum_zero` are (2), with `ℂ • W.vacuum` the line spanned by the vacuum; `exhaustive` is (3), `⨆` being the sum of subspaces. Note that in negative weight nothing has to be imposed, because $V_n = 0$ there. `ModeCompatible` is (11.1) with all six variables universally quantified (the curly braces make them implicit, which changes nothing logically); `W.smul u k v` is $u_{(k)}v$ and the target weight `m + n - k - 1` is the standard weight of $u_{(k)}v$. `GoodFiltration W extends GradedFlag W`: it is a graded flag plus the single field `mode_mem`.

Comparison with the literature. Li (2005) and Arakawa (2012) call an increasing filtration $\{G_pV\}$ *good* if $\mathbf{1} \in G_0V$ and, for $u \in G_pV$, $v \in G_qV$,

$$u_{(k)}v \in G_{p+q}V \ (k \in \mathbb{Z}), \qquad u_{(k)}v \in G_{p+q-1}V \ (k \ge 0).$$

The second clause is what makes the associated graded a *vertex Poisson* algebra (the non-

negative modes become a bracket of degree -1). The library's `ModeCompatible` is only the first clause. It is therefore *weaker* than the Li–Arakawa notion. ABLR's own definition is not in the repository, and the library's docstring says explicitly that `ModeCompatible` "IS A RECONSTRUCTION, NOT A TRANSCRIPTION" of ABLR's clause (iv). The graded-unitarity theorems of Chapter 19 use only the underlying `GradedFlag`, so this weakness does not affect them.

Trap / dead end

Every VOA has a `GoodFiltration` (moderate). Put $G_0V_n = 0$ for $n > 0$ and $G_pV_n = V_n$ in all other cases. This is a graded flag (with $G_0V_0 = V_0 = \mathbb{C}\mathbf{1}$ by CFT type), and it is mode-compatible: if $p + q \geq 1$ the target $G_{p+q}V_{m+n-k-1}$ is the whole weight space, which contains $u_{(k)}v$; if $p = q = 0$ then $u, v \in \mathbb{C}\mathbf{1}$ (or are 0), and $\mathbf{1}_{(k)}\mathbf{1} = \delta_{k,-1}\mathbf{1}$ lies in G_0V_0. A Lean check made for this chapter (not part of this release) constructs this `GoodFiltration W` for an arbitrary `W`; `#print axioms`: standard three. (The coarse flag even satisfies the stronger Li–Arakawa condition.) Consequently, a hypothesis "`F : GoodFiltration W`" never restricts `W`; whatever content a theorem has must come from further conditions on the specific `F` (in Chapter 19: nondegeneracy of a form on each piece). The structure is not vacuous — it has instances — but it is not informative by itself: only specific instances (the length filtration of the Virasoro minimal models, the R-filtration of chiral algebras of 4d $\mathcal{N} = 2$ theories, the affine filtration of `AffineSl2GoodFiltration.lean`) carry content, and the theorems of Chapter 19 add a nondegeneracy condition on each piece.

Why the definition is still reasonable. In physics, the filtration that matters is a specific one: for the boundary Virasoro minimal models ABLR take G_pV to be the span of $L_{-n_1} \cdots L_{-n_k}\mathbf{1}$ with $k \leq p$ (the *length* of the partition), and for chiral algebras of $\mathcal{N} = 2$ theories the R-filtration by $SU(2)_R$ charge. The library constructs such filtrations (`VOA/Examples/VirasoroGoodFiltration.lean`, `AffineSl2GoodFiltration.lean`, Chapters 8 and 19); the structure here is only the container.

Physical meaning

A graded flag is a way of counting "how composite" a state is. For the Virasoro vacuum module the length filtration counts the number of stress-tensor modes needed to create a state; for a chiral algebra of a four-dimensional $\mathcal{N} = 2$ theory, the Schur operators carry an $SU(2)_R$ charge R, and the R-filtration is the filtration by R. Mode compatibility says that the OPE of two operators of "lengths" p and q contains only operators of length at most $p + q$: the OPE cannot create more constituents than it was given. Graded unitarity (Chapter 19) is the statement that a natural Hermitian form is positive on the associated graded — the chiral-algebra shadow of four-dimensional unitarity.

Theorem 11.2 (Flags and good filtrations descend to quotients). *Let $I \subseteq V$ be a graded ideal and $\pi : V \to V/I$ the quotient VOA map. If $\{G_pV_n\}$ is a graded flag on V, then $\{\pi(G_pV_n)\}$ is a graded flag on V/I; if the former is mode-compatible, so is the latter. In particular every good filtration of V induces one of V/I.*

```

From the mathematics to the Lean statement

`W.IsIdeal I` and `QuotVOA.IsGradedIdeal W I` say that I is an ideal of the VOA and is graded; `QuotVOA.quotientVOA W I hI hgr` is the quotient VOA V/I (Chapter 5, Definition 5.19). `I.mkQ` is the quotient map π, and `(F.piece p n).map I.mkQ` is $\pi(G_pV_n)$. The two `quotient` constructions are definitions (they produce the induced flag) and `quotient_modeCompatible` is the theorem; the induced filtration is *the* image filtration, as in the literature. Nothing is claimed about whether the induced filtration agrees with some independently defined filtration of V/I (the docstring says so).

Proof on paper. Images of an increasing exhaustive family are increasing and exhaustive, and $\pi(\mathbb{C}\mathbf{1}) = \mathbb{C}\pi(\mathbf{1})$. For mode compatibility, write $\bar{u} = \pi(u)$, $\bar{v} = \pi(v)$ with $u \in G_pV_m$, $v \in G_qV_n$; since π is a VOA homomorphism, $\bar{u}_{(k)}\bar{v} = \pi(u_{(k)}v) \in \pi(G_{p+q}V_{m+n-k-1})$. □

What the machine verified

Proved, unconditional; `#print axioms` of `VOA.GoodFiltration.quotient` and `VOA.GradedFlag.quotient_modeCompatible`: `[propext, Classical.choice, Quot.sound]`.

Physical meaning

Passing to a quotient VOA is setting null fields to zero (going from the universal to the simple chiral algebra, say). The statement says that a "number of constituents" count on the universal algebra still makes sense after imposing the null relations, which is how one defines, for example, the R-filtration on a simple quotient once it is known on a free-field or universal model.

11.2.1 Filtrations indexed by a preorder, and strict maps

For the inverse Drinfeld–Sokolov programme (Chapter 19) the library needs filtrations indexed by $\mathbb{Z}$ rather than $\mathbb{N}$, and maps between filtered spaces.

Definition 11.3 (Linear filtration; filtered and strictly filtered maps)**.** Let ι be a preordered set. A *linear filtration* of an R-module M indexed by ι is a monotone family $(F_i)_{i\in\iota}$ of submodules. Given filtrations F on M and G on N (indexed by ι and κ), a map $\varphi : \iota \to \kappa$ and a linear map $f : M \to N$, f is *filtered along* φ if $f(F_i) \subseteq G_{\varphi(i)}$ for all i, and *strictly filtered along* φ if $f(F_i) = f(M) \cap G_{\varphi(i)}$ for all i.

From the mathematics to the Lean statement

`Monotone piece` is $i \le j \Rightarrow F_i \subseteq F_j$. `(G.piece (phi i)).comap f` is the preimage $f^{-1}(G_{\varphi(i)})$, so `IsFilteredAlong` is $F_i \subseteq f^{-1}(G_{\varphi(i)})$, i.e. $f(F_i) \subseteq G_{\varphi(i)}$. `LinearMap.range f ⊓ G.piece (phi i)` is $f(M) \cap G_{\varphi(i)}$. These are the textbook notions of a filtered and a strict morphism of filtered modules (Bourbaki, *Algèbre commutative* III; the strictness notion of Deligne's mixed Hodge theory). No monotonicity of φ is required to *state* them. Strictness is genuinely stronger: the inclusion of $\mathbb{C}$ into $\mathbb{C}$ with $F_0 = 0$, $F_1 = \mathbb{C}$ on the source and $G_0 = G_1 = \mathbb{C}$ on the target is filtered but not strict.

Physical meaning

A filtration indexed by $\mathbb{Z}$ is natural for a free-field (Wakimoto-type) algebra, where a "charge" or "number of $\beta\gamma$ pairs minus number of bosons" can be negative; a filtered map is a realisation that respects the leading-order counting, and a strict one is a realisation in which leading terms never cancel accidentally.

Theorem 11.4 (Strictness criteria). *1. If f is injective, f is strictly filtered along φ iff $F_i = f^{-1}(G_{\varphi(i)})$ for all i.*

2. (Dimension criterion.) Over a division ring K: if f is injective and filtered along φ, and for every i the space $f(M) \cap G_{\varphi(i)}$ is finite-dimensional of the same dimension as F_i, then f is strictly filtered along φ.

      Module.finrank K ↥(LinearMap.range f ⊓ G.piece (phi i))) :
    F.IsStrictFilteredAlong G phi f := by
```

From the mathematics to the Lean statement

`Function.Injective f` is injectivity; `↥(LinearMap.range f ⊓ G.piece (phi i))` is that intersection regarded as a vector space in its own right (the up-arrow `↥` turns a subspace into a type). Both statements are exactly as written above; the second only needs finite-dimensionality of the *individual* pieces, which is the situation of a graded VOA (infinite-dimensional in total, finite in each weight).

Proof on paper. (1) If f is injective, $f(F_i) = f(M) \cap G_{\varphi(i)}$ pulls back to $F_i = f^{-1}(G_{\varphi(i)})$ and conversely. (2) $f(F_i) \subseteq f(M) \cap G_{\varphi(i)}$ by filteredness, and $\dim f(F_i) = \dim F_i$ by injectivity; a subspace of a finite-dimensional space of the same dimension is the whole space. □

What the machine verified

Proved, unconditional; `#print axioms` of both: standard three.

Physical meaning

Strictness is the precise form of "no hidden cancellations": when a VOA is realised inside a free-field algebra (Wakimoto, Adamović's inverse Drinfeld–Sokolov), each operator has a leading free-field term, and strictness says that a combination whose leading terms cancel really is of lower order in the source as well. The dimension criterion turns this into a *character* computation: compare filtered characters on both sides.

Definition 11.5 (Exact layer). For subspaces $Q \subseteq P$ of a vector space, the *exact layer* is P/Q, realised as the quotient of P by the preimage of Q under the inclusion $P \hookrightarrow V$.

File `VOA/Core/FiniteAssociatedGraded.lean`.

```
abbrev Layer (P Q : Submodule K V) (_h : Q ≤ P) : Type _ :=
  P / Q.comap P.subtype

theorem finrank_layer_add_finrank
    (P Q : Submodule K V) (h : Q ≤ P) [FiniteDimensional K P] :
  finrank K (Layer P Q h) + finrank K Q = finrank K P := by
```

From the mathematics to the Lean statement

`Q.comap P.subtype` is Q seen as a subspace of P (the preimage under the inclusion `P.subtype`); the hypothesis `_h : Q ≤ P` is recorded only to document the intended use. The theorem is $\dim(P/Q) + \dim Q = \dim P$ for finite-dimensional P. This is the layer $\mathrm{gr}_p = F_p/F_{p+1}$ of a filtration, one weight space at a time.

Proof on paper. Rank–nullity for the quotient map $P \to P/Q$. □

What the machine verified

Proved, unconditional; standard three.

Physical meaning

The layers of a filtration are the "classical" pieces of the operator algebra: gr_p is the space of operators of exactly p units of the filtration degree, modulo higher corrections. The dimension identity is the bookkeeping that turns a filtered character into an ordinary one.

11.3 Li's filtration and its associated graded algebra

11.3.1 Motivation

Zhu's C_2-algebra $R_V = V/C_2(V)$ throws away every state containing a mode $u_{(-n)}$ with $n \geq 2$, that is, every state containing a derivative of a field. Haisheng Li observed that R_V is only the bottom layer of a *decreasing* filtration of V that keeps track of *how many* derivatives a state contains:

$$F^pV = \mathrm{span}\{u^1_{(-n_1-1)}u^2_{(-n_2-1)}\cdots u^r_{(-n_r-1)}\mathbf{1} \;:\; r \geq 0,\ u^i \text{ homogeneous},\ n_i \geq 0,\ n_1+\cdots+n_r \geq p\}. \tag{11.2}$$

Since $u_{(-n-1)}\mathbf{1} = T^n u/n!$, the number $n_1+\cdots+n_r$ is the number of derivatives. Li proved: $F^0V = V$, $F^pV \supseteq F^{p+1}V$, $F^1V = C_2(V)$, $TF^pV \subseteq F^{p+1}V$,

$$F^p_{(n)}F^q \subseteq F^{p+q-n-1}\ (n \in \mathbb{Z}), \qquad F^p_{(n)}F^q \subseteq F^{p+q-n}\ (n \geq 0), \tag{11.3}$$

(with $F^k = V$ for $k \le 0$). Consequently $\mathrm{gr}^F V = \bigoplus_p F^pV/F^{p+1}V$ is a commutative algebra under the (-1)-product, T induces a derivation of degree 1, and the (n)-products with $n \ge 0$ induce a vertex Poisson structure. Its degree-zero piece is $F^0/F^1 = V/C_2(V) = R_V$, and it is generated by R_V as a differential algebra. That last statement is the source of the surjection from the arc algebra $J_\infty(R_V)$ onto $\mathrm{gr}^F V$ (Section 11.4).

11.3.2 The definition in the library

The library's Li filtration is defined for an arbitrary weak module (it is the engine of Buhl's spanning theorem, Chapter 15) and specialised to the adjoint module. We quote the general definition, which lives in a file of Chapter 15, because every statement in this section depends on it.

In words: a *letter* is a formal token (c, β, n) standing for the mode $c_{(-n-1)}$ of a state c of weight β; a *word* is an ordered list of letters, acting on a state with the first letter as the outermost operator; its *level* is $\sum n_i$, the total number of derivatives in the composite operator. ("Admissible" below means only that the weight label is correct; it has nothing to do with the "admissible relation ideals" of Section 11.7.)

Definition 11.6 (Letters, words, level, Li's filtration)**.** A *letter* is a triple $(c, \beta, n) \in V \times \mathbb{N} \times \mathbb{N}$ standing for the mode $c_{(-n-1)}$; it is *admissible* if $c \in V_\beta$. A *word* is a list of letters; it acts on a module M by applying the modes with the first letter outermost, and its *level* is $\sum n_i$. For a set $B \subseteq M$ and $p \in \mathbb{Z}$, $G^p(M, B)$ is the span of all admissible words of level $\ge \max(p, 0)$ applied to elements of B. The module is *generated by* B (`LWGenerated`) if $G^0(M, B) = M$. The *Li filtration* of V is $F^pV = G^p(V, \{\mathbf{1}\})$ for the adjoint module.

    (liWeightPiece_antitone (W := W) (N := N) (Nat.le_succ p))
```

From the mathematics to the Lean statement

`Letter` $\mathcal{V}$ is the product type $V \times \mathbb{N} \times \mathbb{N}$; `p.1`, `p.2.1`, `p.2.2` are its three components c, β, n. `wordAct A (p :: t) x` applies `mode (A.YM p.1) (-(p.2.2) - 1)`, which is the module mode $c^M_{(-n-1)}$, to `wordAct A t x`: the head of the list is the outermost operator. `wordLevel` is $\sum n_i$. In `Gset A B p`, the existential packages a word `l` and a bottom vector `w`, with `WordOK W l` (all letters homogeneous of the recorded weight), $w \in B$ and level $\geq p$. `Gfil` takes the span and converts the integer index with `p.toNat` (so every $p \leq 0$ gives the level-0 piece). With `A = adjointWeakModule W` (the module V itself, its modes being `W.smul`) and $B = \{\mathbf{1}\}$ this is exactly Li's (11.2); the weight label β is redundant data that makes "homogeneous" checkable. `liWeightPiece W p N` is $F^pV \cap V_N$ and `liWeightLayer W p N` is $(F^pV \cap V_N)/(F^{p+1}V \cap V_N)$, the (p, N)-component of $\mathrm{gr}^F V$, built with the exact layer of Definition 11.5.

Same as Li? Yes: Li (2005, §2) defines F_pV as the span of the same monomials, with u^i arbitrary (not necessarily homogeneous); since every u is a finite sum of homogeneous components and modes are linear in u, the spans agree. The library's convention "weights in $\mathbb{N}$" is harmless because a library VOA has no negative weights.

Trap / dead end

A redundant hypothesis (minor) — since removed. Two theorems of `VOA/Filtered/LiAssociatedGraded.lean`, `liWeightPiece_zero_eq_grading` and `sum_liWeightLayer_finrank_eq_grading`, carry the hypothesis `hLW : LWGenerated (adjointWeakModule W) ({W.vacuum} : Set 𝒱)` when this chapter was written; the library has since dropped it from both (the statements quoted in this chapter are the current ones). This hypothesis is always true: the library proves it as `lwGenerated_adjoint` (in `VOA/Modularity/BuhlSpanningData.lean`), and in the same chapter `liFiltration_zero_eq_top` is proved without it. A Lean check made for this chapter (not part of this release) states the first theorem without `hLW`. Nothing becomes false; a reader should simply know that the hypothesis costs nothing.

Physical meaning

Li's filtration counts derivatives. A state $u^1_{(-n_1-1)} \cdots u^r_{(-n_r-1)}\mathbf{1}$ is the normal-ordered product $:\partial^{n_1}u^1 \cdots \partial^{n_r}u^r:$ (up to factorials), so F^pV is spanned by composite operators carrying at least p derivatives in total. In a semiclassical (large central charge, or $\hbar \to 0$) picture the fields become classical functions on a phase space and derivatives become jet coordinates; $\mathrm{gr}^F V$ is the algebra of classical local functionals, and $F^0/F^1 = R_V$ is the algebra of functions on the space of constant field configurations — the classical moduli space, the associated variety.

Theorem 11.7 (Finiteness and the weight-wise telescoping identity). *For all $p, N \in \mathbb{N}$: $F^pV \cap V_N$ is finite-dimensional; $F^pV \cap V_N = 0$ if $N < p$; and*

$$\sum_{p=0}^{N} \dim\left(F^pV \cap V_N \big/ F^{p+1}V \cap V_N\right) = \dim V_N.$$

File `VOA/Filtered/LiAssociatedGraded.lean`.

```
theorem liWeightPiece_finiteDimensional (W : VertexOperatorAlgebra 𝒱) (p N : ℕ) :
    FiniteDimensional ℂ (liWeightPiece W p N) := by

```

```
    liWeightPiece W p N = ⊥ := by

theorem sum_liWeightLayer_finrank_eq_grading (W : VertexOperatorAlgebra 𝒱) (N : ℕ) :
    (∑ p ∈ Finset.range (N + 1), Module.finrank ℂ (liWeightLayer W p N)) =
      Module.finrank ℂ (W.grading N) := by
```

From the mathematics to the Lean statement

`Finset.range (N + 1)` is $\{0, \dots, N\}$; the conclusion is exactly the displayed identity, with `W.grading N` the weight space V_N (the cast $\mathbb{N} \to \mathbb{Z}$ is implicit). There is no further hypothesis (the redundant `hLW` of an earlier version has been removed; warning above). The identity says that the N-th coefficient of the character of V equals the total dimension of the weight-N part of $\mathrm{gr}^F V$: passing to the associated graded preserves characters.

Proof on paper. $F^pV \cap V_N \subseteq V_N$, which is finite-dimensional. A word of level $\geq p$ raises weight by $\sum(\beta_i + n_i) \geq p$, so it lands in weights $\geq p$; hence $F^pV \cap V_N = 0$ for $N < p$. Telescoping the exact-layer identity of Definition 11.5 from $p = 0$ (where $F^0V \cap V_N = V_N$) to $p = N + 1$ (where the piece is 0) gives the sum. □

What the machine verified

Proved, unconditional (no hypotheses beyond the VOA W); `#print axioms VOA.sum_liWeightLayer_finrank_eq_grading`: standard three.

Physical meaning

Taking the classical limit does not change the counting of states: the partition function of the chiral algebra equals that of its classical shadow, graded by weight. Refining it by the Li degree gives a two-variable character, which is what the "Hilbert squeeze" of Section 11.4 compares.

11.3.3 Multiplicativity

Theorem 11.8 (Li's multiplicativity estimates). *Let $x \in F^pV$, $y \in F^qV$. Then*

1. *for every $N \in \mathbb{Z}$, $x_{(N)}y \in F^{p+q-N-1}V$ (indices ≤ 0 meaning V);*
2. *$x_{(-1)}y \in F^{p+q}V$ and, more generally, $x_{(-d-1)}y \in F^{p+q+d}V$ for $d \in \mathbb{N}$;*
3. *for $n \in \mathbb{N}$ with $n \leq p + q$, $x_{(n)}y \in F^{p+q-n}V$;*
4. *$Tx \in F^{p+1}V$; and $F^0V = V$.*

theorem liFiltration_zero_eq_top (W : VertexOperatorAlgebra V) : liFiltration W 0 = ⊤ := by
```

From the mathematics to the Lean statement

(1) is stated with integer indices for the general `Gfil`; `(p + q - N - 1)` is an integer and `Gfil` of a non-positive index is everything. It carries the always-true `hLW`. (3) uses natural-number subtraction `p + q - n`, which is why the hypothesis `hn : n ≤ p + q` is there: without it `p + q - n` would truncate to 0 and the statement would be weaker but still true. (2) with `d = 0` is `liFiltration_smul_neg_one_mem`. All four are exactly Li's (11.3) (Li 2005, §2; Arakawa 2012, §2). (1) is the "all modes" estimate; (3) is the sharper non-negative-mode estimate, one step better than (1) at $N = n \geq 0$, which is what makes the bracket on $\mathrm{gr}^F V$ have degree $-n$ rather than $-n-1$.

Proof on paper. By linearity take x a word $a^1_{(-m_1-1)} \cdots a^r_{(-m_r-1)}\mathbf{1}$ of level $\ell \geq p$. The key one-letter estimate (`act_mem_Gfil`, Chapter 15) is that for homogeneous u, $u_{(k)}F^r \subseteq F^{r-k-1}$: induction on the word that spans the vector acted on, using the commutator formula $[u_{(k)}, a_{(-m-1)}] = \sum_j \binom{k}{j}(u_{(j)}a)_{(k-m-1-j)}$, whose correction terms land one level better. For a composite x, write $x = a_{(-m-1)}x'$ and use the iterate (associativity) formula

$$(a_{(-m-1)}x')_{(N)}y = \sum_{i\geq 0}(-1)^i\binom{-m-1}{i}\Big(a_{(-m-1-i)}x'_{(N+i)}y - (-1)^{-m-1}x'_{(-m-1+N-i)}a_{(i)}y\Big),$$

induct on the length of x and apply the one-letter estimate to each term; the levels add up as claimed. For Tx: $Tx = x_{(-2)}\mathbf{1}$ and $\mathbf{1} \in F^0$, so (2) with $d = 1$ gives $Tx \in F^{p+1}$. For (3), Li's argument uses skew-symmetry $x_{(n)}y = \sum_j (-1)^{n+j+1}T^{(j)}(y_{(n+j)}x)$ together with the fact that T raises the filtration by one, which recovers the lost step. □

What the machine verified

Proved, unconditional; `#print axioms` of `VOA.adjointGfil_smul_mem`, `VOA.liFiltration_smul_neg_one_mem`, `VOA.liFiltration_smul_nonneg_mem`: standard three.

Physical meaning

Each derivative carried by a field survives in the product, and a singular OPE term (a mode $u_{(n)}$ with $n \geq 0$) can only *remove* derivatives (it is a contraction, lowering the classical degree). That is exactly why the leading, classical part of an OPE is a commutative product (from $u_{(-1)}$) and a Poisson bracket (from $u_{(0)}$), and why derivatives act as a derivation.

11.3.4 The associated graded algebra

Theorem 11.9 (The Li associated graded is a commutative differential algebra). *Let* $\mathrm{gr}^F V = \bigoplus_{(p,N)\in\mathbb{N}^2} \mathrm{gr}^F_{p,N} V$, *where* $\mathrm{gr}^F_{p,N} V$ *is the layer of Theorem 11.7. The* (-1)*-product descends to bilinear maps* $\mathrm{gr}^F_{p,N} \times \mathrm{gr}^F_{q,M} \to \mathrm{gr}^F_{p+q,N+M}$, *which make* $\mathrm{gr}^F V$ *a commutative, associative, unital, bigraded* $\mathbb{C}$*-algebra with unit the class of* $\mathbf{1}$*;* T *descends to a linear map of bidegree* $(1,1)$ *which is a derivation; each component is finite-dimensional and* $\mathrm{gr}^F_{p,N} V = 0$ *when* $N < p$.

    (x : liWeightLayer W p N) : x = 0 := by
```

From the mathematics to the Lean statement

`liWeightLayerMul W p q N M` is the descended product, a bilinear map (two nested `→ₗ[ℂ]`). The commutativity statement `liWeightLayerMul_comm` uses `HEq` ("heterogeneous equality") because the two sides live in the layers $(p+q, N+M)$ and $(q+p, M+N)$, which are equal but not *definitionally* the same type in Lean; `HEq` is the honest way to say "equal after identifying the indices". The direct sum `⊕ d : ℕ × ℕ, …` is the external direct sum of the layers (finitely supported families). `DirectSum.GCommRing` is Mathlib's notion of a graded commutative ring structure on a family indexed by an additive monoid; with it, Mathlib makes the direct sum a commutative ring, and `liAssociatedGraded_of_mul_of` says the product of two homogeneous elements is the homogeneous element given by `liWeightLayerMul`. A further instance (`liWeightLayerGAlgebra`) makes it a $\mathbb{C}$-algebra. `liAssociatedGradedTranslation` is assembled from the descended L_{-1} on each layer, shifting bidegree by $(1,1)$; `_leibniz` is the derivation property. `LiNegOneCommutatorEstimate` (the one-step commutator estimate

$x_{(-1)}y - y_{(-1)}x \in F^{p+q+1}$, which is what commutativity of the graded product means) is introduced as a `Prop` and then proved (`liNegOneCommutatorEstimate_proven`), so it is not an open hypothesis.

What is not packaged. Li's vertex Poisson structure — the brackets induced by the (n)-products, $n \geq 0$, of degree $-n$ — is not defined on the library's $\mathrm{gr}^F V$. The estimate that would make it well defined is Theorem 11.8(3); the descent is not carried out. So the library's associated graded is a commutative differential algebra, not yet a vertex Poisson algebra. In particular nothing in this chapter gives the associated variety its Poisson structure; the Poisson structure on the degree-zero part R_V alone is Chapter 12, Theorem 12.23.

Proof on paper. The descended product is well defined by Theorem 11.8(2): if x or y moves by an element of the next filtration step, the product moves by an element of F^{p+q+1}. Commutativity: by skew-symmetry $x_{(-1)}y - y_{(-1)}x = \sum_{j\geq 1}(-1)^{j+1}T^{(j)}(y_{(j-1)}x)$, and each term lies in F^{p+q+1} because $y_{(j-1)}x \in F^{p+q-j+1}$ (part (3)) and $T^{(j)}$ raises by j. Associativity: the iterate formula at $(-1,-1)$ writes $(x_{(-1)}y)_{(-1)}z - x_{(-1)}(y_{(-1)}z)$ as a sum of terms $x_{(-1-i)}y_{(-1+i)}z$, $i \geq 1$, and their mirror images, each one step higher. The unit is $[\mathbf{1}]$ since $\mathbf{1}_{(-1)} = \mathrm{id}$. T is a derivation of the (-1)-product ($[T, x_{(-1)}] = (Tx)_{(-1)}$) and raises the filtration by one. □

What the machine verified

Proved, unconditional; `#print axioms` of `VOA.liWeightLayerMul_comm`, `VOA.liWeightLayerGCommRing`, `VOA.liAssociatedGradedTranslation_leibniz`: standard three.

Physical meaning

This is the statement that the classical limit of a chiral algebra is a commutative algebra of classical fields with a derivative: normal ordering becomes multiplication, and ∂ acts by the Leibniz rule. The missing Poisson bracket is the classical remnant of the singular OPE, $\{a_\lambda b\}$ in the language of Poisson vertex algebras. (Update: the Poisson vertex algebra structure on $\mathrm{gr}^F V$ has since been formalized, `liPoissonVertexAlgebra`, as part of the Arakawa–Dai campaign; see Chapter 20. The statement quoted here is unchanged.)

11.3.5 The bottom layer is Zhu's C_2-algebra

Theorem 11.10 (Li: $F^1V = C_2(V)$; $\mathrm{gr}^F_0 V = R_V$). *$C_2(V) = F^1V$. Consequently the degree-zero layers $\bigoplus_N \mathrm{gr}^F_{0,N} V$ form the algebra $R_V = V/C_2(V)$, and the class map $V_N \to \mathrm{gr}^F_{0,N} V$ kills $C_2(V) \cap V_N$.*

File `VOA/Filtered/ClassicalFreeness.lean` (the inclusion $C_2 \subseteq F^1$).

```
theorem O₂_le_liFiltration_one (W : VertexOperatorAlgebra V) :

theorem liDegreeZeroClass_eq_zero_of_mem_O₂ (W : VertexOperatorAlgebra V) (N : ℕ)
    (x : W.grading (N : ℤ)) (hx : x.1 ∈ O₂ W) :
    liDegreeZeroClass W N x = 0 := by
```

File `VOA/Filtered/LiC2Bridge.lean` (the reverse inclusion and the equality, now library theorems):

```
theorem liFiltration_one_le_O₂ (W : VertexOperatorAlgebra V) :
    liFiltration W 1 ≤ O₂ W := by
```

```
theorem liFiltration_one_eq_O₂ (W : VertexOperatorAlgebra V) :
    liFiltration W 1 = O₂ W :=
```

From the mathematics to the Lean statement

`O₂ W` is $C_2(V)$. `liDegreeZeroClass W N x` is the class of a weight-N vector in the $(0,N)$-component of `liAssociatedGraded W`. The inclusion $C_2(V) \subseteq F^1V$ gives a surjection $R_V \twoheadrightarrow \bigoplus_N \mathrm{gr}^F_{0,N} V$. Li's theorem is the equality, which upgrades the surjection to an isomorphism; the library proves it (`liFiltration_one_eq_O₂`, quoted above; the same file also gives `liDegreeZeroClass_eq_zero_iff_mem_O₂` and the linear equivalence `liZerothQuotientEquivC2`), and a Lean check made for this chapter outside the library, when the library had only one inclusion, checked it first. With the equality, the library's $\mathrm{gr}^F_0 V$ is literally Zhu's `A₂ W`, and the product on it is $[u][v] = [u_{(-1)}v]$ — the same product as the `CommRing (A₂ W)` instance of Chapter 12.

Proof on paper. $C_2 \subseteq F^1$: $u_{(-2)}v$ is $u_{(-2)}$ applied to $v \in F^0$, and a letter with $n = 1$ raises the level by one (Theorem 11.8(2) with $d = 1$). $F^1 \subseteq C_2$ (`liFiltration_one_le_O₂`; first in our check outside the library): a word $a^1_{(-n_1-1)} \cdots a^r_{(-n_r-1)}\mathbf{1}$ of level ≥ 1 has some $n_i \geq 1$. If the outermost letter has $n_1 \geq 1$, the word is $a^1_{(-n_1-1)}(\dots)$ with $-n_1 - 1 \leq -2$, which lies in $C_2(V)$ (Zhu: $u_{(-k)}v \in C_2(V)$ for all $k \geq 2$). Otherwise $n_1 = 0$, the remaining word has level ≥ 1 and lies in $C_2(V)$ by induction, and $C_2(V)$ is stable under $a_{(-1)}$ (it is an ideal for the (-1)-product, Theorem 12.23). □

What the machine verified

Proved in the library: both inclusions and the equality. $C_2(V) \subseteq F^1V$ is `O₂_le_liFiltration_one` (`Filtered/ClassicalFreeness.lean`); $F^1V \subseteq C_2(V)$ and the equality $F^1V = C_2(V)$ are `VOA.liFiltration_one_le_O₂` and `VOA.liFiltration_one_eq_O₂` (`Filtered/LiC2Bridge.lean`), for every VOA, with no hypothesis. When this chapter was first written, at an earlier state of the library, the equality existed only in a Lean check made for this chapter outside the library; that gap has since been closed in the library. `#print axioms` for the library declarations of `LiC2Bridge.lean` was not re-run for this chapter. Inclusion $C_2 \subseteq F^1$: `#print axioms VOA.O₂_le_liFiltration_one` and `VOA.liDegreeZeroClass_eq_zero_of_mem_O₂`: standard three. Reverse inclusion and equality, version checked outside the library: compiled with `lake env lean -DmaxSynthPendingDepth=3` for this chapter; standard three.

Physical meaning

$F^1 = C_2$ says: "a composite operator has at least one derivative" and "it is a normal-ordered product with a derivative field in it" are the same condition. So the bottom of the classical tower, the functions on constant field configurations, is exactly Zhu's C_2-algebra, and $X_V = \mathrm{Specm}\, R_V$ is the space of classical vacua. For the free boson, $R_V = \mathbb{C}[J]$ and $X_V = \mathbb{C}$ (a line of vacua $\langle J \rangle$); for a lisse (C_2-cofinite) theory, X_V is a point. For the chiral algebra of a 4d $\mathcal{N} = 2$ theory, Beem–Rastelli's conjecture is $X_V \cong$ the Higgs branch.

11.4 Jets, presentations of commutative algebras, and classical freeness

11.4.1 The commutative-algebra side

If $R_V = \mathbb{C}[x_1, \dots, x_g]/I$, the *arc algebra* (infinite jet algebra) is $J_\infty R_V = \mathbb{C}[x_i^{(r)} : 1 \le i \le g,\ r \ge 0]/J_\infty I$, where $J_\infty I$ is generated by the coefficients of t^n in $f\big(\sum_r x_1^{(r)} t^r, \dots, \sum_r x_g^{(r)} t^r\big)$ for $f \in I$, $n \ge 0$. It is the universal commutative differential algebra generated by R_V: the derivation is $\partial x_i^{(r)} = (r+1) x_i^{(r+1)}$. Li and Arakawa show that there is a canonical surjection of differential algebras $J_\infty R_V \twoheadrightarrow \mathrm{gr}^F V$ extending $R_V = \mathrm{gr}_0^F V$; V is called *classically free* when it is an isomorphism: the classical limit $\mathrm{gr}^F V$ is then exactly the arc space of the associated variety, i.e. V has no relations in the classical limit beyond the derivatives of those of R_V. The library works with the finite truncations of order m (variables $x_i^{(r)}$ with $r \le m$), which is enough for any fixed Li degree $p \le m$.

Definition 11.11 (Presentations of a commutative algebra)**.** For an algebra map $\varphi : A \to B$ and an ideal $I \subseteq A$: the relations *vanish* if $I \subseteq \ker \varphi$; the presentation is *exact* if $\ker \varphi = I$.

File `VOA/Commutative/Presentation.lean`.

```
def RelationsVanish (I : Ideal A) (φ : A →ₐ[R] B) : Prop :=
  I ≤ RingHom.ker φ

def IsExactPresentation (I : Ideal A) (φ : A →ₐ[R] B) : Prop :=
  RingHom.ker φ = I

noncomputable def quotientEquiv (I : Ideal A) (φ : A →ₐ[R] B)
    (hsurj : Function.Surjective φ) (hexact : IsExactPresentation I φ) :
    (A ⧸ I) ≃ₐ[R] B := by
```

From the mathematics to the Lean statement

`RingHom.ker φ` is the kernel. `(A ⧸ I) ≃ₐ[R] B` is an isomorphism of R-algebras. The theorem `quotientEquiv` is the first isomorphism theorem: a surjective φ with exact presentation I gives $A/I \cong B$. These are the textbook notions, kept separate so that "the relations hold" is never confused with "these are all the relations".

Proof on paper. First isomorphism theorem. □

What the machine verified

Proved, unconditional; `#print axioms VOA.Presentation.quotientEquiv`: standard three.

Physical meaning

"Relations vanish" is the statement that certain composite operators are null; "exact presentation" is the much stronger claim that the listed null relations generate *all* of them — that one knows the complete set of equations of the associated variety (for a Higgs branch: the complete chiral ring relations).

Definition 11.12 (Finite jets; the jet ideal; presented jets)**.** Fix generators σ and an order $m \in \mathbb{N}$. The *jet polynomial ring* is $\mathbb{C}[x_i^{(r)} : i \in \sigma,\ 0 \le r \le m]$; the truncated series of x_i is $x_i(t) = \sum_{r=0}^{m} x_i^{(r)} t^r$; for $f \in \mathbb{C}[x_i]$ the *relation series* is $f(x(t))$ and its n-th coefficient is the Hasse–Schmidt coefficient $f^{(n)}$. For an ideal I, the *order-m jet ideal* $J_m I$ is generated by $f^{(j)}$ for $f \in I$, $0 \le j \le m$, and the *presented jet algebra* is $J_m(\mathbb{C}[x]/I) := \mathbb{C}[x_i^{(r)}]/J_m I$.

abbrev PresentedJet (m : ℕ) (I : Ideal (MvPolynomial σ R)) :=
  JetPoly R σ m ⧸ jetIdeal (R := R) m I
```

From the mathematics to the Lean statement

`JetVar σ m` is the set of pairs (i, r) with $r \in$ `Fin (m + 1)` $= \{0, \dots, m\}$, and `JetPoly ℂ σ m` the polynomial ring on them. `jetVariable m i r` is $x_i^{(r)}$ for $r \le m$ and 0 for $r > m$ (a convenient junk value). `jetSeries` is the polynomial $\sum_{r \le m} x_i^{(r)} t^r \in (\mathrm{JetPoly})[t]$ (`Polynomial.monomial r a` is at^r). `jetSubst` substitutes these series (`MvPolynomial.aeval` is evaluation). `relationCoeff m n f` is the coefficient of t^n in $f(x(t))$. `jetRelationSet` ranges over pairs (element of I, order $j \le m$), and `jetCoeff m j f` is `relationCoeff m j f` (`jetCoeff_apply`). `Ideal.span` is the ideal generated.

Same as the literature? Yes, for the order-m jet scheme $J_m(\operatorname{Spec} \mathbb{C}[x]/I)$: the ideal of J_m is generated by the coefficients of $t^0, \dots, t^m$ of $f(x(t))$ (Ishii; Arakawa–Moreau). The normalisation $x(t) = \sum x^{(r)} t^r$ means $x^{(r)}$ corresponds to $\partial^r x / r!$ (divided powers), which matches the library's divided translates $T^r a / r!$ below. The file `FiniteJet.lean` has no transition map $J_{m+1} \to J_m$ between finite orders and no infinite arc algebra (its docstring says so); fixed-weight stabilisation (next theorem) replaces the transition maps. The infinite arc algebra `InfiniteJet.PresentedJet` is introduced elsewhere in the library and documented in Section 11.5.2 (Definition 11.22).

Physical meaning

A jet of order m of a field configuration $x(z)$ is its Taylor polynomial $\sum_{r\le m} x^{(r)}z^r$; the jet scheme of the associated variety is the space of such Taylor polynomials that satisfy the classical equations $f(x(z))=0$ to order m. In a chiral algebra, $x_i^{(r)}$ is the classical shadow of the field $\partial^r x_i/r!$, and the jet relations are the derivatives of the classical null relations — the equations of motion and all their z-derivatives.

Theorem 11.13 (Weighted jets: homogeneity, independence of generators, stabilisation). *Give $x_i^{(r)}$ the weight $w_i + r$, with all $w_i > 0$. Then*

1. *if f is weighted-homogeneous of degree D, then $f^{(n)}$ is homogeneous of weight $D+n$; hence for a set S of homogeneous relations, $J_m(\mathrm{span}\, S)$ is a homogeneous ideal;*
2. *J_m(ideal generated by S) equals the ideal generated by the $f^{(j)}$, $f\in S$, $j\le m$;*
3. *for weight $N\le m$, the order-raising map identifies the weight-N parts of the jet polynomial rings of orders m and $m+1$, and (for homogeneous relations) the weight-N images in the presented jet algebras;*
4. *with finitely many generators, every bidegree (Li degree, weight) piece of the presented jet algebra is finite-dimensional.*

```

From the mathematics to the Lean statement

`jetWeight` gives $x_i^{(r)}$ weight $w_i + r$; `jetLiBidegree` gives it bidegree $(r, w_i + r)$ — the Li degree is the number of derivatives. `IsWeightedHomogeneous w D` is Mathlib's "every monomial has w-weight D". `IsWeightedHomogeneousRelationSet baseWeight S` says every $f \in S$ is homogeneous of some degree, and `(…).IsHomogeneous (…)` says the ideal is graded. `jetIdealOfSet m S` is the ideal generated by the $f^{(j)}$, $f \in S$, $j \le m$. `jetWeightPieceOrderEquiv` is a linear isomorphism (`≃ₗ[R]`) between the weight-N pieces at orders m and $m+1$ when $N \le m$ (a monomial of weight N cannot contain $x^{(r)}$ with $r \ge N$ because all $w_i \ge 1$). The presented version is stated as injectivity of the order-raising map on weight images; surjectivity is `presentedJetWeightImageOrderHom_surjective`. `PresentedJetLiBidegreeImage` is the image in the presented algebra of the bihomogeneous polynomials of bidegree (p, N).

Proof on paper. (1) If f has weight D then $f(x(t))$, with t given weight -1, is homogeneous of weight D, so the t^n coefficient has weight $D + n$. (2) By the Leibniz (Cauchy) formula $(af)^{(n)} = \sum_{i+j=n} a^{(i)} f^{(j)}$, the coefficients of multiples of f lie in the ideal generated by those of f. (3) At weight $N \le m$ no variable of order $> N$ can occur, and the new top relations $f^{(m+1)}$ of order $m+1$ have weight $> m \ge N$, so they cannot create a relation in weight N of a homogeneous ideal. (4) Finitely many monomials have a given positive weight. □

What the machine verified

Proved, unconditional; `#print axioms` of `VOA.FiniteJet.jetIdeal_span_eq_jetIdealOfSet`, `…jetWeightPieceOrderEquiv`, `…presentedJetWeightImageOrderEquiv_of_homogeneousRelations`, `…finiteDimensional_presentedJetLiBidegreeImage`: standard three.

Physical meaning

Weight-N states of a chiral algebra can carry at most N derivatives, so to describe the classical shadow up to weight N one needs jets only up to order N. This is the reason the infinite arc space can be replaced by finite jet schemes in every concrete character computation.

11.4.2 The canonical jet map to the Li associated graded

Definition 11.14 (Divided iterates; the jet map)**.** For a linear map D of a commutative algebra A put $D^{(r)}(a) = D^r(a)/r!$. For $x : \sigma \to A$, the *derivation jet evaluation* is the algebra map $\mathbb{C}[x_i^{(r)}] \to A$, $x_i^{(r)} \mapsto D^{(r)}(x_i)$. For $A = \mathrm{gr}^F V$ with D the descended translation, and an ideal I of relations vanishing on the x_i, it descends to the *Li jet map* $J_m(\mathbb{C}[x]/I) \to \mathrm{gr}^F V$.

    (liAssociatedGradedTranslation_leibniz W) (liAssociatedGradedTranslation_one W) m x I
     ↪ hI
```

From the mathematics to the Lean statement

`v.order` and `v.generator` are the two components r and i of a jet variable. The hypothesis `hI : I ≤ RingHom.ker (MvPolynomial.aeval x).toRingHom` says that the relations in I vanish when $x_i \mapsto x(i) \in \mathrm{gr}^F V$ (at order zero). Note that `x` is an *arbitrary* family of elements of the associated graded; the intended choice is the degree-zero classes of strong generators (below). The map is *canonical*: no basis or normal form is chosen. Neither surjectivity nor injectivity is part of the definition (the docstring says so).

Physical meaning

The map sends the classical field $x_i^{(r)}$ to the classical shadow of $\partial^r a^i/r!$. It is the precise form of the slogan that the classical limit of a chiral algebra is generated by the classical limits of its strong generators and their derivatives.

Theorem 11.15 (The jet map is well defined; its kernel criterion). *Let D be a derivation of a commutative $\mathbb{C}$-algebra A with $D(1) = 0$ and $x : \sigma \to A$.*

1. *For $f \in \mathbb{C}[x]$ and $n \le m$, the evaluation of $f^{(n)}$ is $D^{(n)}(f(x))$. Hence if $I \subseteq \ker(f \mapsto f(x))$, then $J_m I \subseteq \ker$ of the jet evaluation, and the jet evaluation descends to $J_m(\mathbb{C}[x]/I)$.*

2. *The Li jet map is injective iff the kernel of the polynomial jet evaluation is exactly $J_m I$.*

```

From the mathematics to the Lean statement

`hleib` and `hOne` say D is a derivation killing 1 (for the Li graded algebra they are `liAssociatedGradedTranslation_leibniz` and `liAssociatedGradedTranslation_one`). The conclusion of (1) is the higher Leibniz rule $D^{(n)}(ab) = \sum_{i+j=n} D^{(i)}(a)D^{(j)}(b)$ applied to polynomials. (2) is the first-isomorphism theorem for the composite $\mathbb{C}[x^{(r)}] \to J_m \to \mathrm{gr}^F V$.

Proof on paper. (1) Induction on f: both sides are algebra maps in f (by the higher Leibniz rule), and agree on variables, $x_i(t) \mapsto \sum_r D^{(r)}(x_i)t^r$, and constants ($D^{(r)}c = 0$ for $r \geq 1$). (2) The quotient map is surjective. □

What the machine verified

Proved, unconditional; `#print axioms VOA.liPresentedJetMap` and `VOA.liPresentedJetMap_injective_iff_polynomial_kernel`: standard three.

Physical meaning

The jet map sends the classical field $x^{(r)}$ to the class of $\partial^r x/r!$: it says that the classical shadow of the chiral algebra is *generated* by the classical shadows of the strong generators and their derivatives, subject at least to the derivatives of the classical relations. Injectivity (classical freeness) says there are no further "quantum" relations in the classical limit. It holds in some important cases (van Ekeren and Heluani proved it for the $(2, 2k+1)$ Virasoro minimal models) and fails in others (Andrews, van Ekeren and Heluani showed that the Ising model is not classically free): the classical shadow can have relations that do not come from R_V.

Theorem 11.16 (Generator words hit every Li layer). *Let $a^1, \dots, a^g \in V$ be homogeneous of weights w_i, and suppose*

$$V = \mathrm{span}\{a^1, \dots, a^g, \mathbf{1}\} + C_2(V).$$

Let I be any ideal of relations vanishing on the degree-zero classes $[a^i] \in \mathrm{gr}^F_0 V$. Then for every $p \leq m$ and every N, every element of the layer $\mathrm{gr}^F_{p,N} V$ is in the image of the Li jet map with $x_i = [a^i]$. Moreover the jet monomial $\prod x_{i_k}^{(r_k)}$ maps to the class of the state $a^{i_1}_{(-r_1-1)} \cdots a^{i_s}_{(-r_s-1)}\mathbf{1}$, exactly.

From the mathematics to the Lean statement

A list `l : List (Fin g × ℕ)` of pairs (i, r) encodes the word $a^{i_1}_{(-r_1-1)}\cdots$; `genWord` turns it into a word of letters, `pairsLevel` is $\sum r_k$ (the Li level), `wordDeg` its weight. `dividedTranslateState W r a` is $T^r a/r!$. `liHomogeneousClass W p N ⟨z, h⟩` is the class of z in $\mathrm{gr}^F_{p,N} V$. `hdec` is the displayed spanning hypothesis, with `⊤` the whole space and `⊔` the sum of subspaces. The conclusion quantifies over `z : liWeightLayer W p N` and asserts a preimage `y` of its inclusion `DirectSum.of … (p, N) z` into $\mathrm{gr}^F V$.

Compared with Li's theorem. Li's theorem (Li 2005; Arakawa 2012) assumes only that the $[a^i]$ *generate* R_V as an algebra, which can be achieved with finitely many a^i whenever V is finitely strongly generated. The library's hypothesis `hdec` instead asks that the a^i *linearly span* V modulo $C_2(V)$ and $\mathbf{1}$. Since the a^i are finitely many (`Fin g`), `hdec` forces $\dim R_V \le g+1$: **the theorem applies only to C_2-cofinite V**. This is narrower than Li's statement (moderate, scope). The exact word identity `prod_dividedIterate_degreeZeroClass_eq_generatorWord` has no such hypothesis and holds for every V.

Proof on paper. The identity $(T^r a/r!)_{(-1)}b = a_{(-r-1)}b$ shows that the jet monomial evaluates to the class of the generator word. The hypothesis `hdec` feeds the ordered spanning theorem of Gaberdiel–Neitzke type (Chapter 15): weight by weight, $F^pV \cap V_N$ is spanned modulo $F^{p+1}V$ by ordered generator words of level exactly p; each of these is hit. □

What the machine verified

Proved, unconditional; `#print axioms VOA.liPresentedJetMap_hits_homogeneous_class_of_generators`: standard three.

Physical meaning

"Every classical operator is a polynomial in the generators and their derivatives": the classical shadow of a lisse chiral algebra is generated as a differential algebra by the finitely many fields that span R_V. This is the classical counterpart of strong generation (Chapter 12, Theorem 12.24).

11.4.3 The Hilbert squeeze

To prove classical freeness one needs injectivity of the jet map; the library's method is a dimension squeeze, bidegree by bidegree. The theorem below is used in Theorem 11.18: on each bidegree, surjectivity of the jet map (Theorem 11.16) plus a dimension bound (from a character identity) forces bijectivity.

Theorem 11.17 (Finite-dimensional Hilbert squeeze). *1. A surjective linear map between finite-dimensional spaces with* dim(*source*) ≤ dim(*target*) *is bijective.*

2. If $c_i \le a_i \le b_i$ for i in a finite set s and $\sum_{i\in s} c_i = \sum_{i\in s} b_i$, then $c_i = a_i = b_i$ for all $i \in s$.

File `VOA/Core/FiniteHilbertSqueeze.lean`.

```
theorem bijective_of_surjective_of_finrank_le
    (f : A →ₗ[K] B) (hsurj : Function.Surjective f)
    (hle : Module.finrank K A ≤ Module.finrank K B) :
    Function.Bijective f :=

theorem pointwise_eq_of_sandwich_of_sum_eq {ι : Type*} (s : Finset ι)
    (c a b : ι → ℕ)
    (hca : ∀ i ∈ s, c i ≤ a i) (hab : ∀ i ∈ s, a i ≤ b i)
    (hsum : ∑ i ∈ s, c i = ∑ i ∈ s, b i) :
    ∀ i ∈ s, c i = a i ∧ a i = b i := by
```

From the mathematics to the Lean statement

Exactly as stated. In application, s is the finite set of Li degrees at a fixed weight N, c_i a normal-form (lower) count, a_i the actual dimension of the Li layer, and b_i the dimension of the jet layer; one character identity (equality of the *total* sums at weight N) then forces equality in every Li degree. No two-variable character identity is needed.

Proof on paper. (1) Rank–nullity. (2) If some $c_i < b_i$ then $\sum c < \sum b$. □

What the machine verified

Proved, unconditional; `#print axioms`: standard three (the second even avoids `Classical.choice`).

Physical meaning

Counting states twice: once in the quantum theory (the character of V) and once in the classical theory (the Hilbert series of the jet scheme). If the classical count is never smaller and the totals agree, there is no room for extra quantum relations.

Theorem 11.18 (Classical freeness from a bidegree squeeze). *Let σ be finite with positive weights w_i, let $x : \sigma \to \mathrm{gr}^F V$ and I be as in Definition 11.14, and suppose*

1. *the kernel of the polynomial jet evaluation is bihomogeneous (stable under taking (Li degree, weight) components);*
2. *for every bidegree (p,N), the induced map from the (p,N)-image in $J_m(\mathbb{C}[x]/I)$ to $\mathrm{gr}^F_{p,N} V$ is surjective;*
3. *for every bidegree,* dim(*jet (p,N)-image*) ≤ $\dim \mathrm{gr}^F_{p,N} V$.

Then the kernel of the polynomial jet evaluation equals $J_m I$, i.e. the Li jet map is injective.

File `VOA/Filtered/ClassicalFreeness.lean`.

    RingHom.ker (liFiniteJetPolynomialMap W m x).toRingHom =
      FiniteJet.jetIdeal (R := ℂ) m I := by
```

From the mathematics to the Lean statement

`hkernelComponent` is (1), with `weightedHomogeneousComponent (jetLiBidegree baseWeight m) d f` the bidegree-d component of f; `hsurj` is (2) and `hle` is (3), with `liPresentedJetBidegreeMap` the (p,N)-component of the jet map restricted to the (p,N)-image. All three are *hypotheses*: the theorem is a reduction of classical freeness to a surjectivity statement (supplied by Theorem 11.16 in the C_2-cofinite case) and a dimension count (a character identity). No VOA in this chapter's files is proved classically free; the consumers are the boundary affine $\mathfrak{sl}_2$ files of Chapter 10, and classical freeness itself (boundary affine $\mathfrak{sl}_2$, Virasoro $M(2,2m+3)$) is proved in Chapter 20 (Arakawa–Dai).

Proof on paper. By (1) it suffices to show that each bihomogeneous kernel element lies in $J_m I$. On a fixed bidegree the jet map is surjective (2) with source of dimension ≤ target (3), hence injective (Theorem 11.17); so a bihomogeneous polynomial mapping to 0 is 0 in $J_m(\mathbb{C}[x]/I)$, i.e. lies in $J_m I$. □

What the machine verified

Proved, conditional on the three displayed hypotheses (which are the mathematical content of classical freeness); `#print axioms`: standard three.

Physical meaning

Classical freeness of a chiral algebra means its classical limit is exactly the arc space of its associated variety, with no extra constraints. Physically it means that the full operator content of the chiral algebra is captured by the classical moduli space and its jets — the Higgs branch "knows" the whole Schur sector (a heuristic reading; whether a given chiral algebra of a four-dimensional theory is classically free is a case-by-case question).

11.4.4 An example: the affine currents span the Li filtration

Theorem 11.19 (Current words and Li's filtration for $V^k(\mathfrak{sl}_2)$). *Let $k \neq -2$ and let $C_p \subseteq V^k(\mathfrak{sl}_2)$ be the span of the current words $J^{a_1}_{(-r_1-1)}\cdots J^{a_s}_{(-r_s-1)}\mathbf{1}$ with $r_1+\cdots+r_s \geq p$. Then $F^pV^k(\mathfrak{sl}_2) = C_p$ for all p. For any graded ideal I, the Li filtration of the quotient $V^k(\mathfrak{sl}_2)/I$ is the image of that of $V^k(\mathfrak{sl}_2)$, and equals the image of C_p.*

File `VOA/Filtered/AffineCurrentLi.lean`.

```
def currentWordPiece (k : ℂ) (p : ℕ) : Submodule ℂ (WakModule k) :=
  Submodule.span ℂ
    {x | ∃ w : List (Fin 3 × ℕ), p ≤ currentWordLevel w ∧ wordStateA k w = x}
```

```
theorem liFiltration_eq_currentWordPiece (k : ℂ) (hk : k + 2 ≠ 0) (p : ℕ) :
    liFiltration (affineSl2VOA_closed k hk) p = currentWordPiece k p :=

theorem quotientLiFiltration_eq_map (p : ℕ) :
    liFiltration (QuotVOA.quotientVOA W I hI hgr) p =
      (liFiltration W p).map I.mkQ :=

theorem quotientLiFiltration_eq_currentWordPiece (p : ℕ) :
    liFiltration (QuotVOA.quotientVOA (affineSl2VOA_closed k hk) I hI hgr) p =
      quotientCurrentWordPiece k I p :=
```

From the mathematics to the Lean statement

`WakModule k` is (despite its name) the universal affine vacuum module $V^k(\mathfrak{sl}_2)$, and `affineSl2VOA_closed k hk` the universal affine VOA (Chapter 9, Definition 9.14); `wordStateA k w` is the current word $J^{a_1}_{-r_1-1}\cdots\mathbf{1}$ attached to the list $w = [(a_1, r_1), \dots]$ (Definition 9.11); `currentWordLevel` is $\sum r_i$. The quotient statements are in a `section` with variables `W`, `I`, `hI`, `hgr` (a graded ideal of a general VOA) and, in the last, `k`, `hk` with `W = affineSl2VOA_closed k hk`; they are stated for *every* graded ideal, in particular for the maximal one (the simple affine VOA). The hypothesis $k \neq -2$ (non-critical level) is the standing hypothesis of the construction.

Proof on paper. $C_p \subseteq F^p$ is immediate: a current word is a generator word with generators J^a of weight one. For $F^p \subseteq C_p$, one shows that the action of any mode of any current word on C_q lands in C_{q-N-1} (respectively the sharper bound for negative modes), by normal-ordering with the affine commutation relations; applying this to the letters of an arbitrary Li word gives the reverse inclusion. For quotients, a word on V/I lifts to a word on V of the same level. □

What the machine verified

Proved, unconditional for $k \neq -2$; `#print axioms` of `VOA.AffineVOA.CurrentLi.liFiltration_eq_currentWordPiece` and `…quotientLiFiltration_eq_currentWordPiece`: standard three. No PBW basis and no `VOA.pbw` is used.

Physical meaning

For a Wess–Zumino–Witten current algebra, "number of derivatives" can be counted on the currents alone: every operator is a normal-ordered polynomial in $\partial^r J^a$, and the Li degree is the total number of derivatives. The associated variety of $V^k(\mathfrak{sl}_2)$ is $\mathfrak{sl}_2^*$ (all current configurations), and for the simple quotient at admissible level it is the nilpotent cone (Arakawa) — the Higgs branch of Argyres–Douglas theories in the Beem–Rastelli dictionary.

11.5 Generator-word spanning of Li's filtration

This section documents three files: `VOA/Filtered/GeneratorWordLiSurjectivity.lean`, `VOA/Filtered/GeneratorCurrentLiSpanning.lean` and `VOA/Filtered/AffineSl2GeneratorCurrentInstance.lean`, quoted at the commit named in the chapter's first paragraph. Declarations from other files that the section needs are re-quoted from the same commit, with their paths.

Notation recalled. The section is meant to be readable on its own, so we recall the four objects it works with. Zhu's subspace $C_2(V)$ is the span of all $u_{(-2)}v$, $u, v \in V$, and $R_V = V/C_2(V)$ is Zhu's C_2-algebra, a commutative algebra with product $[u][v] = [u_{(-1)}v]$ (Section 11.3). Li's filtration

$V = F^0V \supseteq F^1V \supseteq \cdots$ is defined by letting F^pV be the span of all words $u^1_{(-n_1-1)}\cdots u^s_{(-n_s-1)}\mathbf{1}$ with homogeneous $u^j \in V$ and $n_1 + \cdots + n_s \geq p$ (Definition 11.6); the integer n_j counts the derivatives carried by the letter u^j, because $u_{(-n-1)} = (T^n u/n!)_{(-1)}$. Its associated graded is $\mathrm{gr}^F V = \bigoplus_{p,N} \mathrm{gr}^F_{p,N} V$ with $\mathrm{gr}^F_{p,N} V = (F^pV \cap V_N)/(F^{p+1}V \cap V_N)$, a commutative algebra with a derivation D induced by T (Theorem 11.9); its degree-zero part is R_V, because $F^1V = C_2(V)$ (Theorem 11.10). Finally, `hdec` is the hypothesis of Theorem 11.16, recalled in the next paragraph; in Lean it is stated with `O₂ W`, the library's name for $C_2(V)$.

Why a second surjectivity criterion is needed. Theorem 11.16 proves that the Li jet map hits every layer of $\mathrm{gr}^F V$, but only under the hypothesis `hdec`: the finitely many states $a^1, \ldots, a^g$ together with $\mathbf{1}$ must *linearly span* V modulo $C_2(V)$. As remarked there, this forces $\dim R_V \leq g + 1$, so it can only hold for C_2-cofinite (lisse) V, and even then only if the generators are chosen to span R_V linearly rather than merely to generate it as an algebra. For the cases the library actually needs, it fails: for the Virasoro minimal models $M(2, 2n+1)$ with the single generator ω once $n \geq 3$ (Chapter 20 writes these models as $M(2, 2m+3)$, so $n = m+1$; there $R_V \cong \mathbb{C}[T]/(T^{m+1})$, here $\mathbb{C}[T]/(T^n)$), and for every affine VOA that is not lisse, whatever finite family is chosen. The warning box at the end of this section (page 524) records the dead end precisely.

The criterion of this section asks something that holds in all these cases: that Li's filtration is *equal* to the filtration by generator words, i.e. that every state of Li degree $\geq p$ is a linear combination of generator words with at least p derivatives in total. This is a property of *strong generation* (all of V is spanned by the words), not of R_V alone. The section proceeds in four steps.

1. The word filtration $\mathcal{W}_p$ and the property "$F^pV \subseteq \mathcal{W}_p$ for all p" (Definition 11.20, Proposition 11.21).

2. If the property holds, the finite-order bidegree maps and the infinite jet map are surjective, for any VOA and any finite family of homogeneous generators (Theorem 11.23).

3. How to prove the property: word spanning plus a "tracked" estimate on generator modes (Theorem 11.26); the tracked estimate holds automatically for currents with Lie-type commutators (Theorem 11.27); the property descends to every graded quotient (Theorem 11.28).

4. A consistency check: the generic theorem recovers Theorem 11.19 for $V^k(\mathfrak{sl}_2)$ (Theorem 11.29), with a worked example in weight two.

These results are used later in the book. The Virasoro minimal models $M(2, 2m+3)$ are shown classically free in Chapter 20, and the jet-surjectivity half of that proof is `liInfinitePresentedJetMap_surjective_of_genWordSpan` applied to the Virasoro words. For every Deligne type, the package `CurrentJetSurjectivity` of Chapter 24 (Definition 24.4) is discharged in Theorem 24.14 through the three generic theorems of Section 11.5.3 below (see also Definition 24.13).

11.5.1 The word filtration

Definition 11.20 (Generator words and the word filtration)**.** Let V be a VOA and $a^1, \ldots, a^g \in V$ a finite family of states, with weight labels $w_1, \ldots, w_g \in \mathbb{N}$. Encode a word by a finite list $l = [(i_1, r_1), \ldots, (i_s, r_s)]$ of pairs $(i, r) \in \{1, \ldots, g\} \times \mathbb{N}$. Its *state* is

$$a_l := a^{i_1}_{(-r_1-1)} a^{i_2}_{(-r_2-1)} \cdots a^{i_s}_{(-r_s-1)}\mathbf{1},$$

and its *level* is $|l| := r_1 + \cdots + r_s$ (the total number of derivatives, since $a_{(-r-1)}b = (T^r a/r!)_{(-1)}b$). For $p \in \mathbb{N}$ the *word piece* is

$$\mathcal{W}_p := \mathrm{span}_{\mathbb{C}}\{\, a_l : |l| \geq p \,\} \subseteq V.$$

The family *spans Li's filtration* if $F^pV \subseteq \mathcal{W}_p$ for every $p \in \mathbb{N}$.

Notation. The calligraphic $\mathcal{W}_p$ ("word piece") is used to keep it apart from Zhu's $C_2(V)$, which appears in the same arguments: $\mathcal{W}_2$ is the span of generator words with at least two derivatives, $C_2(V)$ the span of all $u_{(-2)}v$. For the three $\mathfrak{sl}_2$ currents, $\mathcal{W}_p$ is the current-word piece written C_p in Theorem 11.19 (Lean `currentWordPiece`); in this section the letter C is reserved for $C_2(V)$. File `VOA/Filtered/GeneratorWordLiSurjectivity.lean`.

```
abbrev genWordState (l : List (Fin g × ℕ)) : V :=
  wordAct (adjointWeakModule W) (genWord gen wt l) W.vacuum

def genWordPiece (p : ℕ) : Submodule ℂ V :=
  Submodule.span ℂ {u | ∃ l : List (Fin g × ℕ), p ≤ pairsLevel l ∧ genWordState W gen wt l
   ↪  = u}

def GeneratorWordsSpanLiFiltration : Prop :=
  ∀ p : ℕ, liFiltration W p ≤ genWordPiece W gen wt p
```

From the mathematics to the Lean statement

Section variables. The file opens with `variable (W : VertexOperatorAlgebra V) {g : ℕ} (gen : Fin g → V) (wt : Fin g → ℕ)`, so all three declarations take `W`, `gen`, `wt` as explicit arguments: `gen i` is a^{i+1} (Lean's `Fin g` is $\{0,\dots,g-1\}$) and `wt i` its weight label.
Decoding. `genWord gen wt l` turns the list of pairs into a list of letters (a^i, w_i, r) (Theorem 11.16); `wordAct (adjointWeakModule W)` applies the letters as modes of the adjoint module, head of the list outermost, letter (c,β,n) acting by $c_{(-n-1)}$ (Definition 11.6). Concretely, `genWord` (`VOA/Modularity/OrderedSpan.lean`) is `l.map`, sending the pair (i,r) to the letter (a^i, w_i, r), and `wordAct` is defined by recursion on the list: $[\,]$ acts as the identity, and $p :: t$ acts as the mode of p applied *after* t. So the word $[(i_1,r_1),\dots,(i_s,r_s)]$ is applied to the vacuum from right to left: first $a^{i_s}_{(-r_s-1)}$, last $a^{i_1}_{(-r_1-1)}$. Note the index shift: the pair records the number $r \geq 0$ of derivatives, and the mode applied is $a^i_{(-r-1)}$ (`mode (A.YM p.1) (-(p.2.2 : ℤ) - 1)` in the source, where `mode f n` is $f_{(n)}$). So `genWordState W gen wt l` is exactly a_l. `pairsLevel l` is $|l| = \sum r_k$. `genWordPiece W gen wt p` is $\mathcal{W}_p$, the span (`Submodule.span ℂ`) of the set of word states of level $\geq p$. `liFiltration W p` is Li's F^pV (Definition 11.6), and $\leq$ between submodules is inclusion. So `GeneratorWordsSpanLiFiltration W gen wt` is literally "$F^pV \subseteq \mathcal{W}_p$ for all p".
The weight labels play no role here. `wordAct` reads only the state and the mode index of a letter, not its weight label. Hence a_l, $\mathcal{W}_p$ and the property do not depend on `wt`, and nothing so far requires the a^i to be homogeneous. The labels become meaningful only when the hypothesis `hgen` below ties them to the actual weights.
Could it be vacuous? No. The property is a genuine condition, and it is satisfiable: the empty family ($g = 0$) satisfies it exactly when $V = \mathbb{C}\mathbf{1}$. It is satisfied by the currents of $V^k(\mathfrak{sl}_2)$ (Theorem 11.29), and the later chapters prove it for the Virasoro minimal models and the Deligne-series affine VOAs.

Physical meaning

$\mathcal{W}_p$ is the space of normal-ordered products of the generating fields carrying at least p derivatives in total, such as $:\partial^{r_1}a^{i_1}\cdots\partial^{r_s}a^{i_s}:$ up to factorials. Li's filtration counts derivatives in an intrinsic way, using *all* states of V as letters. The property says that counting derivatives on the generators alone gives the same answer: no operator acquires "hidden" derivatives by being written through a composite field. This is what a physicist assumes without comment when writing the classical limit of a chiral algebra as a differential polynomial algebra in the generating fields.

Proposition 11.21 (Words always lie in Li's filtration; the property is an equality). *If each a^i is homogeneous of weight w_i, then $\mathcal{W}_p \subseteq F^pV$ for every p. Hence, if the family spans Li's filtration, $F^pV = \mathcal{W}_p$ for every p.*

File `VOA/Filtered/GeneratorWordLiSurjectivity.lean`.

```
theorem genWordPiece_le_liFiltration (hgen : ∀ i, gen i ∈ W.grading (wt i : ℤ)) (p : ℕ) :
    genWordPiece W gen wt p ≤ liFiltration W p := by

theorem liFiltration_eq_genWordPiece (hgen : ∀ i, gen i ∈ W.grading (wt i : ℤ))
    (hspan : GeneratorWordsSpanLiFiltration W gen wt) (p : ℕ) :
    liFiltration W p = genWordPiece W gen wt p :=
  le_antisymm (hspan p) (genWordPiece_le_liFiltration W gen wt hgen p)
```

From the mathematics to the Lean statement

`hgen` says $a^i \in V_{w_i}$ (`W.grading n` is the weight-n space V_n). It is the only hypothesis of the first statement, and it is not even needed mathematically: a_l is by definition one of the spanning words of $F^{|l|}V$ (letters from all of V, total level $\geq |l|$). The library proves it through the word lemma `genWord_mem_Gfil` (`VOA/Modularity/OrderedSpan.lean`, Chapter 15), which carries the weights. The second statement is `le_antisymm` of the two inclusions, as the displayed one-line proof shows.

Proof on paper. F^pV is spanned by the words $u^1_{(-n_1-1)}\cdots u^s_{(-n_s-1)}\mathbf{1}$ with arbitrary states $u^j \in V$ and $\sum n_j \geq p$ (Definition 11.6); taking $u^j = a^{i_j}$ shows $a_l \in F^{|l|}V \subseteq F^pV$ when $|l| \geq p$. □

What the machine verified

Proved, unconditional. `#print axioms` of `VOA.GeneratorWordsSpanLiFiltration` and `VOA.liFiltration_eq_genWordPiece`: `[propext, Classical.choice, Quot.sound]` (scratch file importing `VOA.Filtered.AffineSl2GeneratorCurrentInstance`, run with `lake env lean -DmaxSynthPendingDepth=3`; commit and procedure in the verification record, Section 11.10).

Physical meaning

Every normal-ordered product of the generators with p derivatives has Li degree at least p: derivatives can only add to the Li degree. The reverse inclusion is the real content ("derivatives cannot hide"), and that is the hypothesis.

11.5.2 Spanning gives a surjective jet map

We recall the two maps whose surjectivity is at stake. The first is the bidegree restriction of the order-m Li jet map of Definition 11.14, already used as hypothesis (2) of Theorem 11.18; the second is the jet map from the *infinite* jet algebra.

Definition 11.22 (The bidegree jet map; the infinite jet algebra and the infinite Li jet map). Let σ be a set of generators with base weights $w : \sigma \to \mathbb{N}$, let $x : \sigma \to \mathrm{gr}^F V$ and let $I \subseteq \mathbb{C}[x_i]$ be an ideal with $f(x) = 0$ for $f \in I$.

1. For $p, N \in \mathbb{N}$, let $J_m(\mathbb{C}[x]/I)_{(p,N)}$ be the image in $J_m(\mathbb{C}[x]/I)$ of the polynomials of jet bidegree (p, N), where $x_i^{(r)}$ has bidegree $(r, w_i + r)$ (Theorem 11.13). The *bidegree jet map* is the composite

$$J_m(\mathbb{C}[x]/I)_{(p,N)} \hookrightarrow J_m(\mathbb{C}[x]/I) \xrightarrow{\text{Li jet map}} \mathrm{gr}^F V \xrightarrow{\text{component}} \mathrm{gr}^F_{p,N} V.$$

2. The *infinite jet polynomial ring* is $\mathbb{C}[x_i^{(r)} : i \in \sigma,\ r \in \mathbb{N}]$ with no bound on r. Its *jet ideal* $J_\infty I$ is the ideal generated by all finite jet ideals $J_m I$, $m \in \mathbb{N}$, viewed inside it. The *infinite presented jet algebra* is $J_\infty(\mathbb{C}[x]/I) := \mathbb{C}[x_i^{(r)}]/J_\infty I$, and the *infinite Li jet map* $J_\infty(\mathbb{C}[x]/I) \to \mathrm{gr}^F V$ is the algebra map $x_i^{(r)} \mapsto D^{(r)}x(i)$, with D the translation of $\mathrm{gr}^F V$. Its restriction along $J_m(\mathbb{C}[x]/I) \to J_\infty(\mathbb{C}[x]/I)$ is the order-m Li jet map.

From the mathematics to the Lean statement

The bidegree map. `FiniteJet.PresentedJetLiBidegreeImage baseWeight m p N I` is the submodule $J_m(\mathbb{C}[x]/I)_{(p,N)}$ (Theorem 11.13); `Submodule.subtype` is its inclusion; `DirectSum.component … (p, N)` is the projection of $\mathrm{gr}^F V = \bigoplus_{(p,N)} \mathrm{gr}^F_{p,N} V$ (`liAssociatedGraded`, Theorem 11.9) onto one summand. The map is linear (`→ₗ[ℂ]`), not an algebra map, since its source is only a subspace. The source docstring notes that no homogeneity of the full jet map is assumed in the definition.

The infinite jet algebra. These declarations live in namespace `VOA.InfiniteJet`, distinct from `VOA.FiniteJet` of Definition 11.12. Here `JetPoly R σ` is the polynomial ring on the variables $(i, r) \in \sigma \times \mathbb{N}$, the pair (i, r) standing for $x_i^{(r)}$. `ofFinite m` is the renaming map $\mathbb{C}[x_i^{(r)} : r \le m] \to \mathbb{C}[x_i^{(r)}]$, so `relationSet I` is the union over m of the images of the

finite jet ideals $J_m I$, and `jetIdeal I` is the ideal it spans. This is the ideal generated by all Hasse–Schmidt coefficients $f^{(n)}$, $f \in I$, $n \in \mathbb{N}$, which is the usual arc ideal. `PresentedJet I` is the quotient ring ($/$).

The infinite Li jet map. `presentedJetToDifferentialAlgebra D hleib hOne x I hI` is the algebra map $x_i^{(r)} \mapsto D^{(r)}(x(i))$ descended to the quotient (the infinite analogue of Theorem 11.15). Here D is the translation of $\mathrm{gr}^F V$ together with its Leibniz rule and $D(1) = 0$. As in the finite case, `x` is arbitrary and neither surjectivity nor injectivity is part of the definition.

Physical meaning

The infinite jet algebra is the algebra of functions on the arc space of $\mathrm{Spec}(\mathbb{C}[x]/I)$: classical fields $x_i(t) = \sum_r x_i^{(r)} t^r$ constrained only by the Taylor coefficients of the classical relations. The infinite Li jet map compares this classical phase space of field configurations with the classical limit of the chiral algebra. The bidegree map looks at one sector at a time: fixed number of derivatives p and fixed conformal weight N.

Theorem 11.23 (Spanning of Li's filtration gives surjective jet maps). *Let V be a VOA, let $a^1, \dots, a^g$ be homogeneous of weights $w_1, \dots, w_g$, and assume that they span Li's filtration (Definition 11.20). Let $x_i := [a^i] \in \mathrm{gr}^F_{0,w_i} V$ be their degree-zero classes, and let $I \subseteq \mathbb{C}[x_1, \dots, x_g]$ be any ideal with $f([a^1], \dots, [a^g]) = 0$ for all $f \in I$. Then:*

1. *for all p, N, the layer $\mathrm{gr}^F_{p,N} V$ is spanned by the classes of the words a_l with $|l| = p$ and $\sum_k (w_{i_k} + r_k) = N$;*
2. *for all p, N, every element of $\mathrm{gr}^F_{p,N} V$ is the image of an element of $J_p(\mathbb{C}[x]/I)$ under the order-p Li jet map;*
3. *for all p, N, the bidegree jet map $J_p(\mathbb{C}[x]/I)_{(p,N)} \to \mathrm{gr}^F_{p,N} V$ (order $m = p$, base weights w) is surjective;*
4. *the infinite Li jet map $J_\infty(\mathbb{C}[x]/I) \to \mathrm{gr}^F V$ is surjective.*

From the mathematics to the Lean statement

Hidden arguments. Besides `W`, `gen`, `wt`, every declaration here also takes the section variable `(hgen : ∀ i, gen i ∈ W.grading (wt i : ℤ))`, declared just before `genWordClassSet`: the generators are homogeneous with the stated weights. Lean includes it because it occurs in the statements, inside `⟨gen i, hgen i⟩`. So the full hypothesis list of each theorem is: a VOA `W`, homogeneous generators (`hgen`), spanning of Li's filtration (`hspan`), and a relation ideal `I` vanishing on the generator classes (`hI`). There is no C_2-cofiniteness, no PBW basis, no normal form and no classical-freeness hypothesis.

Two hypotheses named `hspan`. In this theorem `hspan : GeneratorWordsSpanLiFiltration W gen wt` is *Li spanning*, $F^pV \subseteq \mathcal{W}_p$ for all p. Theorem 11.26 below has a hypothesis with the same Lean name but a different, weaker content, *word spanning*: the words a_l span V, i.e. $\mathcal{W}_0 = V$. The Lean names are local to each theorem and cannot be changed in a verbatim quotation; in the prose we always say "Li spanning" or "word spanning".

Decoding. `liDegreeZeroClass W (wt i) ⟨gen i, hgen i⟩` is $[a^i] \in \mathrm{gr}^F_{0,w_i} V$ (Theorem 11.10). `hI` says the evaluation $f \mapsto f([a^1],\dots,[a^g])$ kills I (`MvPolynomial.aeval`). `wordDeg (genWord gen wt l)` is the weight of the word, $\sum_k (w_{i_k} + r_k)$, computed from the labels; `generatorWord_mem_liWeightPiece` certifies that $a_l \in F^{|l|}V \cap V_{\mathrm{wordDeg}}$, so that `liHomogeneousClass W p N ⟨·,·⟩`, the class in $\mathrm{gr}^F_{p,N} V$ placed in the direct sum, makes sense. `genWordClassSet W gen wt hgen p N` is therefore the set of classes of words of level exactly p and weight exactly N, and (1) says their span contains every `DirectSum.of … (p, N) z`, i.e. every element of the (p,N) summand.

The orders. In (2) and (3) the jet order is the Li degree itself (`PresentedJet … p I`, `liPresentedJetMap W p`, `liPresentedJetBidegreeMap W p … wt p N`). This is the smallest order that can work, since a level-p word needs the variables $x^{(r)}$ with $r \le p$. Larger orders follow by the order-stabilisation of Theorem 11.13. In (3) the base weights of the jet bigrading are the labels `wt`, which by `hgen` are the true weights.

Compared with Theorem 11.16. The conclusion of (2) is the conclusion of `liPresentedJetMap_hits_homogeneous_class_of_generators` at $m = p$, and (3) is the conclusion of the `hdec`-based `liPresentedJetBidegreeMap_surjective_of_generators` (`VOA/Filtered/LiJetBidegree.lean`). Only the hypothesis changes: `hdec` (span of V modulo $C_2(V)$, a statement about R_V) is replaced by Li spanning (span of each F^pV by generator words, a statement about all of V). How the two hypotheses compare is the subject of Remark 11.24

below: on paper, Li spanning is equivalent to the $[a^i]$ generating R_V as an *algebra*, while `hdec` asks them (with $[\mathbf{1}]$) to span it as a *vector space*; so `hdec` implies Li spanning. That comparison is not formalized. In each application below Li spanning is proved, not assumed.
Same as the textbook? (4) is the surjectivity half of the Li–Arakawa comparison $J_\infty R_V \twoheadrightarrow \mathrm{gr}^F V$, for a presentation $\mathbb{C}[x]/I$ whose relations hold in R_V. When I is exactly the kernel of $\mathbb{C}[x] \to R_V$, the source is $J_\infty R_V$. The theorem is stated for every smaller I as well; that is harmless, because a smaller I only makes the source bigger.

Proof on paper. (1) Take $z \in F^pV \cap V_N$ representing a class in $\mathrm{gr}^F_{p,N} V$. By Li spanning (`hspan`), $z = \sum_l c_l a_l$ with $|l| \geq p$. Apply the projection P_N onto V_N. Each a_l is homogeneous, so $P_N a_l$ is a_l if the word has weight N and 0 otherwise. Since $P_N z = z$, we get $z = \sum_{\mathrm{wt}(l)=N} c_l a_l$. The words with $|l| > p$ lie in $F^{p+1}V$ (Proposition 11.21) and vanish in the quotient $\mathrm{gr}^F_{p,N} V$. What remains is a combination of classes of words with $|l| = p$ and weight N. (2) By Theorem 11.16 (the exact word identity, which needs no `hdec`), the jet monomial $x_{i_1}^{(r_1)} \cdots x_{i_s}^{(r_s)}$ maps to the class of a_l, and it lives in order $\max r_k \leq |l| = p$. So every spanning class of (1) is hit, and the image of a linear map is a subspace. (3) A preimage from (2) can be replaced by its (p,N) bihomogeneous component, which still maps to the same element of the (p,N) summand (`liPresentedJetBidegreeMap_surjective_of_homogeneous_hits`, `LiJetBidegree.lean`). (4) $\mathrm{gr}^F V$ is the direct sum of its (p,N) summands. Each summand is hit from a finite order by (2), and the infinite map restricts to the finite ones along $J_p \to J_\infty$. □

What the machine verified

Proved, unconditional (the hypotheses `hgen`, `hspan`, `hI` are the content of the statement, not open inputs). `#print axioms of VOA.genWordClassSet_spans_layer, VOA.liPresentedJetMap_hits_homogeneous_class_of_genWordSpan, VOA.liPresentedJetBidegreeMap_surjective_of_genWordSpan, VOA.liInfinitePresentedJetMap_surjective_of_genWordSpan`: `[propext, Classical.choice, Quot.sound]`. No `VOA.pbw`.

Physical meaning

Every operator in the classical limit of the chiral algebra is a differential polynomial in the classical generating fields. Whatever relations the classical fields obey, there are no "extra" classical operators that cannot be built from the generators and their derivatives. This is the surjective half of the comparison between the chiral algebra and the arc space of its associated variety (the Higgs branch, in the four-dimensional dictionary). (A remark on proof difficulty, not on physics: this surjectivity half is the easy one; the other half, injectivity, i.e. classical freeness, is a genuinely different statement, which the library approaches through a dimension count, Theorem 11.18.)

Remark 11.24 (Li spanning versus `hdec`: an argument on paper, not formalized)**.** Let V be a VOA and $a^1, \ldots, a^g$ homogeneous of weights w_i. Write $x_i = [a^i] \in R_V = \mathrm{gr}^F_0 V$. Then:

1. the family spans Li's filtration ($F^pV \subseteq \mathcal{W}_p$ for all p) if and only if $x_1, \ldots, x_g$ generate R_V as a commutative $\mathbb{C}$-algebra;

2. consequently `hdec` implies Li spanning, since `hdec` says that $1, x_1, \ldots, x_g$ span R_V linearly, which is more than generating it as an algebra.

Neither direction uses C_2-cofiniteness, a PBW basis, or finite-dimensionality of R_V. **None of this is proved in the library**: the theorems of this section take Li spanning as a hypothesis, and the

applications prove it directly (Theorems 11.26–11.28 and Chapter 20), never through (1). The equivalence is due to Li (*Abelianizing vertex algebras*, 2005) and is used in this form by Arakawa (*A remark on the C_2-cofiniteness condition on vertex algebras*, 2012); the argument below is a self-contained version of it.

The argument on paper. Three facts about $\mathrm{gr}^F V$ are used (Section 11.3). (a) The class of $u \in F^pV$ in $\mathrm{gr}^F_p V$ is written $[u]_p$; the product is $[u]_p[v]_q = [u_{(-1)}v]_{p+q}$ and the derivation is $D[u]_p = [Tu]_{p+1}$, so $D^{(n)} := D^n/n!$ sends $[u]_0$ to $[T^{(n)}u]_n$ with $T^{(n)} = T^n/n!$. (b) For all u, v and $n \geq 0$ one has the *exact* identity $u_{(-n-1)}v = (T^{(n)}u)_{(-1)}v$. Hence the class of a Li word of level exactly p is a product of divided derivatives:

$$\left[u^1_{(-n_1-1)} \cdots u^s_{(-n_s-1)}\mathbf{1}\right]_p = D^{(n_1)}[u^1]_0 \cdots D^{(n_s)}[u^s]_0 \qquad (n_1 + \cdots + n_s = p),$$

and for generator words this is the exact word identity of Theorem 11.16: $[a_l]_{|l|} = \prod_k D^{(r_k)}x_{i_k}$. (c) A Li word of weight N has level at most N, because its letters have weight ≥ 0 and the letter $u_{(-n-1)}$ raises the weight by $\mathrm{wt}\, u + n \geq n$; so $F^pV \cap V_N = 0$ for $p > N$.

Li spanning ⇒ algebra generation. Take $p = 0$: every $u \in V$ is a combination of words a_l. Words with $|l| \geq 1$ lie in $\mathcal{W}_1 \subseteq F^1V = C_2(V)$ (Proposition 11.21 and Theorem 11.10), so they vanish in R_V. A word of level 0 is $a^{i_1}_{(-1)} \cdots a^{i_s}_{(-1)}\mathbf{1}$, whose class is the monomial $x_{i_1} \cdots x_{i_s}$ (empty word: 1). So R_V is spanned by monomials in the x_i. (Only the case $p = 0$ of Li spanning, i.e. word spanning, was used.)

Algebra generation ⇒ Li spanning. First, for each (p, N), $\mathrm{gr}^F_{p,N} V$ is spanned by the classes of generator words of level exactly p and weight N. Indeed, it is spanned by classes of Li words of level exactly p (those of level $> p$ lie in $F^{p+1}V$), and by (b) each is a product $\prod_j D^{(n_j)}[u^j]_0$. By hypothesis, and since $\mathrm{gr}^F_0 V = R_V$ (Theorem 11.10), each $[u^j]_0$ is a polynomial in the x_i. By the Leibniz rule $D^{(n)}(fg) = \sum_{a+b=n} D^{(a)}f\, D^{(b)}g$, the element $D^{(n_j)}$ of a monomial in the x_i is a combination of products $\prod_k D^{(r_k)}x_{i_k}$ with $\sum_k r_k = n_j$. So $\mathrm{gr}^F_p V$ is spanned by products $\prod_k D^{(r_k)}x_{i_k}$ with $\sum r_k = p$, which by (b) are the classes $[a_l]_p$ with $|l| = p$; taking the weight-N component keeps the words of weight N, since each a_l is homogeneous. Now let $z \in F^pV \cap V_N$. By the first step there is a combination y_p of words of level p with $z - y_p \in F^{p+1}V \cap V_N$. Repeat with $z - y_p$ in level $p + 1$, and so on. By (c) the process stops after at most $N - p + 1$ steps, with remainder 0, so z is a combination of words of level $\geq p$: $z \in \mathcal{W}_p$. □

What this explains. Li spanning is the natural hypothesis: it asks the generators to generate the classical algebra R_V in the usual sense, whereas `hdec` asks them, together with the unit, to span it as a vector space, which already fails for the single Virasoro generator ω once $R_V \cong \mathbb{C}[T]/(T^n)$ with $n \geq 3$ (the monomial T^2 is generated by T but not in the span of $1, T$). The argument also shows why the step from R_V to all of V is possible at all: every class in $\mathrm{gr}^F V$ is a differential polynomial in classes of degree zero.

11.5.3 How to prove spanning: the tracked estimate

Spanning of Li's filtration is usually proved by moving modes through words. Write

$$t(q, m) := \max(q - m - 1,\, 0) \qquad (q \in \mathbb{N},\ m \in \mathbb{Z}).$$

For a homogeneous state a, Li's estimates (Theorem 11.8) give $a_{(m)}F^q \subseteq F^{t(q,m)}$ when $a \in F^0$. For a negative mode $m = -n - 1$ this reads $t(q, -n - 1) = q + n$, i.e. the mode adds n derivatives. For $m \geq 0$ it reads $q - m - 1$: a non-negative mode can remove up to $m + 1$ derivatives (it contracts with one of them).

Definition 11.25 (The tracked estimate)**.** A family $a^1, \ldots, a^g$ satisfies the *tracked estimate* if $a^i_{(m)}\mathcal{W}_q \subseteq \mathcal{W}_{t(q,m)}$ for all i, all $m \in \mathbb{Z}$ and all $q \in \mathbb{N}$: the word filtration obeys the generators' half of Li's estimate.

File `VOA/Filtered/AffineCurrentLi.lean`.

```
def currentModeTarget (q : ℕ) (m : ℤ) : ℕ := ((q : ℤ) - m - 1).toNat
```

File `VOA/Filtered/GeneratorCurrentLiSpanning.lean`.

```
def GeneratorModeTracked : Prop :=
  ∀ (i : Fin g) (m : ℤ) (q : ℕ) (v : V), v ∈ genWordPiece W gen wt q →
    W.smul (gen i) m v ∈ genWordPiece W gen wt (currentModeTarget q m)
```

From the mathematics to the Lean statement

`Int.toNat` sends negative integers to 0, so `currentModeTarget q m` is $t(q,m)$. It was introduced for the $\mathfrak{sl}_2$ currents (hence the name) and is reused here. `W.smul u m v` is the product $u_{(m)}v$, i.e. the m-th mode of $Y(u,z)$ applied to v (Chapter 2). The quantifier order is $\forall i, m, q, v$, with no hypothesis on m: the estimate is required for negative and non-negative modes alike. For negative modes it is automatic for words (prepend a letter), but it must also hold on linear combinations, which is the same thing since $\mathcal{W}_q$ is a span.

Physical meaning

Acting with a generating field's mode on a normal-ordered product: a creation mode $a_{(-n-1)}$ adds n derivatives, and an annihilation mode $a_{(m)}$, $m \geq 0$, removes at most $m+1$, because it contracts with one constituent through the singular part of the OPE. The tracked estimate says the OPE of the generators with themselves never produces operators with fewer derivatives than this naive count.

Theorem 11.26 (Word spanning plus the tracked estimate give spanning of Li's filtration). *If the words a_l span V and the family satisfies the tracked estimate, then it spans Li's filtration, i.e. $F^pV \subseteq \mathcal{W}_p$ for every p.*

File `VOA/Filtered/GeneratorCurrentLiSpanning.lean`.

```
theorem generatorWordsSpanLiFiltration_of_tracked (htrack : GeneratorModeTracked W gen wt)
    (hspan : Submodule.span ℂ (Set.range (genWordState W gen wt)) = ⊤) :
    GeneratorWordsSpanLiFiltration W gen wt := by
```

From the mathematics to the Lean statement

Do not confuse the two `hspan`. Here `hspan` is *word spanning*, not the Li spanning that carries the same Lean name in Theorem 11.23 (Li spanning is this theorem's *conclusion*). `Set.range (genWordState W gen wt)` is the set of all word states a_l (all lists l), and `hspan` says they span V (`⊤` is the whole space), i.e. $\mathcal{W}_0 = V$: the family *strongly generates* V in the linear sense. Word spanning is the case $p = 0$ of Li spanning; the theorem says that, together with the tracked estimate, it gives all p. Note that word spanning is about all words, not ordered (PBW-type) words. `htrack` is Definition 11.25. Here `W`, `gen`, `wt` are implicit (`variable {W gen wt}` precedes the theorem in the file). No homogeneity hypothesis on the a^i is needed.

Proof on paper. *Step 1: all modes of all words.* We show by induction on the word l that $(a_l)_{(N)}\mathcal{W}_q \subseteq \mathcal{W}_{t(q,N)}$ for all $N \in \mathbb{Z}$. For $l = [\,]$, $a_l = \mathbf{1}$ and $\mathbf{1}_{(N)}v = \delta_{N,-1}v$, with $t(q,-1) = q$. For $l = (i,r) :: l'$, $a_l = a^i_{(-r-1)}a_{l'}$, and the Borcherds iterate formula gives

$$(a^i_{(-r-1)}a_{l'})_{(N)}v = \sum_{n\geq 0}(-1)^n\binom{-r-1}{n}\Big(a^i_{(-r-1-n)}(a_{l'})_{(N+n)}v - (-1)^{-r-1}(a_{l'})_{(-r-1+N-n)}a^i_{(n)}v\Big).$$

The sum is finite because $a^i_{(n)}v = 0$ and $(a_{l'})_{(N+n)}v = 0$ for $n \gg 0$. Let $v \in \mathcal{W}_q$. Recall $t(x,M) = \max(x-M-1,0)$, so $t(x,-k-1) = x+k$ for $k \geq 0$.

First term. By induction $(a_{l'})_{(N+n)}v \in \mathcal{W}_{t(q,N+n)}$; the mode $a^i_{(-r-1-n)}$ is negative, so the tracked estimate adds $r+n$:

$$t\big(t(q,N+n),\,-r-1-n\big) = \max(q-N-n-1,\,0)+r+n \;\geq\; \max(q-N-1,\,r+n) \;\geq\; t(q,N).$$

Second term. By the tracked estimate $a^i_{(n)}v \in \mathcal{W}_{t(q,n)}$, $t(q,n)=\max(q-n-1,0)$; then by induction $(a_{l'})_{(-r-1+N-n)}$ sends this into $\mathcal{W}_x$ with, using $-(-r-1+N-n)-1 = r-N+n$,

$$x = t\big(\max(q-n-1,0),\,-r-1+N-n\big) = \max\big(\max(q-n-1,\,0)+r-N+n,\;0\big) \;\geq\; \max(q-N-1+r,\,0) \;\geq\; t(q,N),$$

where the first inequality replaces $\max(q-n-1,0)$ by the smaller $q-n-1$, and the second uses $r\geq 0$. Since $\mathcal{W}_\bullet$ is decreasing, both terms lie in $\mathcal{W}_{t(q,N)}$.

Step 2: negative modes of arbitrary states. By word spanning (`hspan`) every $u\in V$ is a combination of words, so Step 1 with $N=-n-1$ gives $u_{(-n-1)}\mathcal{W}_q \subseteq \mathcal{W}_{q+n}$ for every $u\in V$.

Step 3: Li's words. F^pV is spanned by $u^1_{(-n_1-1)}\cdots u^s_{(-n_s-1)}\mathbf{1}$ with $\sum n_j \geq p$. Since $\mathbf{1}\in\mathcal{W}_0$, applying Step 2 letter by letter shows the word lies in $\mathcal{W}_{\sum n_j}\subseteq\mathcal{W}_p$. □

What the machine verified

Proved, unconditional. `#print axioms VOA.generatorWordsSpanLiFiltration_of_tracked`: `[propext, Classical.choice, Quot.sound]`.

Physical meaning

If the generating fields strongly generate the chiral algebra, and their mutual OPEs respect the derivative count, then the derivative count on generators is the intrinsic one. The Borcherds iterate formula used here is the mode form of the statement that the OPE of a normal-ordered product $:\partial^r a\,B:$ with anything is computed from the OPEs of a and of B (the generalised Wick theorem).

Theorem 11.27 (Lie-type currents satisfy the tracked estimate). *Let $J^i_m := a^i_{(m)}$ and suppose there are scalars $f^{ij}{}_c$ and $\mathrm{cen}(i,j,m)$ with*

$$J^i_m J^j_p - J^j_p J^i_m = \sum_c f^{ij}{}_c\, J^c_{m+p} + \delta_{m+p,0}\,\mathrm{cen}(i,j,m)\,\mathrm{id} \qquad (\text{all } i,j,m,p),$$

and $J^i_m\mathbf{1}=0$ for $m\geq 0$. Then the family satisfies the tracked estimate.

    (hvac : ∀ i m, 0 ≤ m → J i m W.vacuum = 0) :
    GeneratorModeTracked W gen wt := by
```

From the mathematics to the Lean statement

Section variables. `J : Fin g → ℤ → Module.End ℂ V`, `f : Fin g → Fin g → Fin g → ℂ` and `cen : Fin g → Fin g → ℤ → ℂ` are declared by `variable` in the section `LieCurrents`. `hJ` says that `J i m` is the mode $a^i_{(m)}$; it lets the user supply the modes in whatever form they were constructed. In `hcomm`, $*$ on `Module.End ℂ V` is composition, $\bullet$ is scalar multiplication and `1` is the identity. So `hcomm` is the displayed commutator, with the central term depending on (i,j,m) only when $m+p=0$. `hvac` is the vacuum condition.

What is not assumed. Nothing requires f to be the structure constants of a Lie algebra (no

antisymmetry, no Jacobi identity), nor the central term to be of the form $m\,k\,\kappa(i,j)$, nor the a^i to have weight one. Only the *shape* matters: the commutator of two generator modes is a combination of generator modes of total index $m+p$, plus a scalar. This is the shape of the affine Kac–Moody commutator, so the theorem covers the currents of any universal or quotient affine VOA once those relations are proved in Lean. It does not cover the Virasoro field, whose commutator $[L_m, L_n] = (m-n)L_{m+n} + \dots$ has m-dependent coefficients; the Virasoro analogue is proved separately for the Virasoro words (Chapter 20). The conclusion is about the generators `gen`; since `hJ` identifies their modes with `J`, the theorem is a genuine statement about V, not about an auxiliary family of operators.

Proof on paper. *Reduction to words.* $\mathcal{W}_q$ is spanned by the words a_l with $|l| \geq q$, and J^i_m is linear, so it suffices to show $J^i_m a_l \in \mathcal{W}_{t(\ell,m)}$ for every word a_l of level $\ell = |l|$. This is enough because $t(\cdot, m)$ is monotone in its first argument and $\mathcal{W}_\bullet$ is decreasing: if $\ell \geq q$ then $\mathcal{W}_{t(\ell,m)} \subseteq \mathcal{W}_{t(q,m)}$.

Induction on l. If $m < 0$, $m = -s-1$, prepending the letter gives a word of level $\ell + s = t(\ell, m)$. If $m \geq 0$ and $l = [\,]$, $J^i_m \mathbf{1} = 0$. If $m \geq 0$ and $l = (j, r) :: l'$ with $|l'| = \ell - r$, so that $a_l = J^j_{-r-1} a_{l'}$, use the hypothesis on commutators with $p = -r-1$; the central term survives only when $m + p = 0$, i.e. $m = r+1$:

$$[J^i_m, J^j_{-r-1}] = \sum_c f^{ij}{}_c\, J^c_{m-r-1} + \delta_{m,r+1}\,\mathrm{cen}(i,j,m)\,\mathrm{id}.$$

Applying both sides to $a_{l'}$ gives

$$J^i_m J^j_{-r-1} a_{l'} = J^j_{-r-1} J^i_m a_{l'} + \sum_c f^{ij}{}_c J^c_{m-r-1} a_{l'} + \delta_{m,r+1}\,\mathrm{cen}(i,j,m)\,a_{l'}.$$

By induction, $J^i_m a_{l'} \in \mathcal{W}_{t(\ell-r,m)}$, and prepending J^j_{-r-1} adds r: the first term lies in $\mathcal{W}_{t(\ell-r,m)+r} \subseteq \mathcal{W}_{t(\ell,m)}$. By induction, $J^c_{m-r-1} a_{l'} \in \mathcal{W}_{t(\ell-r,m-r-1)} = \mathcal{W}_{\max(\ell-m,0)} \subseteq \mathcal{W}_{t(\ell,m)}$. When $m = r+1$, the central term is a multiple of $a_{l'} \in \mathcal{W}_{\ell-r}$, and $\ell - r \geq \ell - m - 1$. □

What the machine verified

Proved, unconditional. `#print axioms VOA.generatorModeTracked_of_current_comm`: `[propext, Classical.choice, Quot.sound]`.

Physical meaning

For a current algebra, the OPE $J^i(z)J^j(w) \sim k\kappa^{ij}/(z-w)^2 + f^{ij}{}_c J^c(w)/(z-w)$ contains only the identity and a single current. Contracting a current with a constituent of a normal-ordered product therefore replaces one current by one current (or by a number), and never manufactures a composite operator with fewer derivatives. This is the Wess–Zumino–Witten version of the derivative count.

Theorem 11.28 (Spanning of Li's filtration passes to graded quotients). *Let $I \subseteq V$ be a graded ideal and $\pi : V \to V/I$ the quotient map. If $a^1, \dots, a^g$ span Li's filtration of V, then $\pi(a^1), \dots, \pi(a^g)$ span Li's filtration of the quotient VOA V/I (with the same weight labels).*

File `VOA/Filtered/GeneratorCurrentLiSpanning.lean`.

```
theorem mkQ_genWordState (l : List (Fin g × ℕ)) :
    I.mkQ (genWordState W gen wt l) =

theorem generatorWordsSpanLiFiltration_quotient (h : GeneratorWordsSpanLiFiltration W gen
↪  wt) :
    GeneratorWordsSpanLiFiltration (QuotVOA.quotientVOA W I hI hgr)
      (fun i => I.mkQ (gen i)) wt := by
```

From the mathematics to the Lean statement

The section `Quotient` declares `(I : Submodule ℂ V) (hI : W.IsIdeal I) (hgr : QuotVOA.IsGradedIdeal W I)`: a subspace that is a two-sided ideal for all products and is graded. `QuotVOA.quotientVOA W I hI hgr` is the quotient VOA and `I.mkQ` the quotient map π (Theorem 11.19). The first statement says $\pi(a_l)$ is the word $\pi(a)_l$ of the projected generators. The second is the claimed descent. There is no homogeneity hypothesis on the a^i, and I is any graded ideal, in particular the maximal one, so the theorem applies to simple quotients.

Proof on paper. Li's filtration of V/I is the image $\pi(F^pV)$ (`quotientLiFiltration_eq_map`, Theorem 11.19). Hence $F^p(V/I) = \pi(F^pV) \subseteq \pi(\mathcal{W}_p)$, and $\pi(\mathcal{W}_p)$ is the span of the $\pi(a_l) = \pi(a)_l$, $|l| \geq p$, because π is a morphism of vertex algebras. □

What the machine verified

Proved, unconditional. `#print axioms VOA.generatorWordsSpanLiFiltration_quotient: [propext, Classical.choice, Quot.sound].`

Physical meaning

Setting null fields to zero cannot create new operators. The simple quotient is generated by the same fields, and a derivative count valid upstairs remains valid downstairs. (The *relations* change, of course: that is what I in Theorem 11.23 is for.)

The resulting recipe. For a quotient $L = V/I$ of a VOA V strongly generated by currents, the three theorems give: word spanning of V and the current commutators (Theorems 11.27 and 11.26) ⇒ V spans Li's filtration ⇒ L spans Li's filtration (Theorem 11.28) ⇒ the infinite Li jet map of L is surjective for every presentation $\mathbb{C}[x]/I'$ whose relations hold in R_L (Theorem 11.23). This is exactly how Chapter 24 obtains `CurrentJetSurjectivity` for the seven Deligne types (Theorem 24.14). Chapter 20 uses the last arrow for the Virasoro minimal models, with the Virasoro words in place of current words.

11.5.4 The $\mathfrak{sl}_2$ consistency instance

Theorem 11.29 (The generic theorem recovers the $\mathfrak{sl}_2$ current description). *Let $k \neq -2$ and let $J^a = J^a_{-1}\mathbf{1} \in V^k(\mathfrak{sl}_2)_1$, $a \in \{e, f, h\}$, be the three currents, all with weight label 1. They span Li's filtration of $V^k(\mathfrak{sl}_2)$, and $F^pV^k(\mathfrak{sl}_2) = \mathcal{W}_p$ for every p.*

File `VOA/Filtered/AffineSl2GeneratorCurrentInstance.lean`.

    (sl2_genWordsSpan k hk) p
```

From the mathematics to the Lean statement

The declarations are `VOA.AffineVOA.CurrentLi.sl2_genWordsSpan` and `…sl2_liFiltration_eq_genWordPiece`, with section variables `(k : ℂ) (hk : k + 2 ≠ 0)`. `affineSl2VOA_closed k hk` is $V^k(\mathfrak{sl}_2)$ (Chapter 9, Definition 9.14); `currentState k a` is $J^a_{-1}\mathbf{1}$; `fun _ ⇒ 1` gives every current the weight label 1. The proof is shown because it *is* the content: it feeds the generic Theorems 11.26 and 11.27 with the $\mathfrak{sl}_2$ data of Chapter 9. These data are the structure constants `fabc` and the central term $m\,k\,\kappa(a,b)$ (Definition 9.1), the commutator `current_comm` (Theorem 9.2; its `• LinearMap.id` is the `• 1` of `hcomm` by `rfl`), vacuum annihilation `J_vacuum_nonneg`, and spanning of V^k by current words `wordStateA_span`. The latter is transported along `wordStateA_eq_generatorWord`, which identifies the bespoke current words of Definition 9.11 with the generic `genWordState`.

What is new, and what is not. Mathematically nothing: the conclusion is `liFiltration_eq_currentWordPiece` of Theorem 11.19, re-expressed with the generic word pieces (the source docstring calls it a consistency check). Its value is as a test that the generic hypotheses are the right ones: they are satisfied, with no extra work, by the one affine VOA for which a bespoke proof already existed. The instance for $\mathfrak{sl}_3$ (the A_2 case of Chapter 24) is `DeligneAudit.A2.universal_genWordsSpan`, documented there.

Proof on paper. Theorem 11.27 with the affine commutator $[J^a_m, J^b_n] = \sum_c f^{ab}{}_c J^c_{m+n} + m\,k\,\kappa(a,b)\,\delta_{m+n,0}$ and $J^a_m\mathbf{1} = 0$ $(m \geq 0)$ gives the tracked estimate. Current words span $V^k(\mathfrak{sl}_2)$, by construction of the vacuum module as a quotient of $U(\widehat{\mathfrak{sl}}_2)$. Theorem 11.26 then gives spanning of Li's filtration, and Proposition 11.21 gives the equality, since the currents have weight 1. □

What the machine verified

Proved, unconditional for $k \neq -2$. `#print axioms of VOA.AffineVOA.CurrentLi.sl2_genWordsSpan and VOA.AffineVOA.CurrentLi.sl2_liFiltration_eq_genWordPiece: [propext, Classical.choice, Quot.sound]`. No `VOA.pbw`.

Physical meaning

In the $SU(2)_k$ Wess–Zumino–Witten current algebra, every operator in the vacuum module is a normal-ordered polynomial in $\partial^r J^a$, and the Li degree is the total number of derivatives. The generic theorem reproduces this from two facts only: the current OPE contains nothing but currents and the identity, and the currents generate.

Example 11.30 (Weight two of $V^k(\mathfrak{sl}_2)$). Take $k \neq -2$, $V = V^k(\mathfrak{sl}_2)$, generators J^e, J^f, J^h of weight 1, and $I = 0$ (no relations). A word a_l with letters (a_k, r_k) has weight $\sum_k (1 + r_k)$ and level $\sum_k r_k$. In weight $N = 2$ the words are

$$J^a_{-2}\mathbf{1} \text{ (level 1)}, \qquad J^a_{-1}J^b_{-1}\mathbf{1} \text{ (level 0)}.$$

By the PBW theorem for $V^k(\mathfrak{sl}_2)$, V_2 has dimension $3 + 6 = 9$: a basis is given by the three states $J^a_{-2}\mathbf{1}$ and the six ordered products $J^a_{-1}J^b_{-1}\mathbf{1}$, $a \leq b$. The PBW statement used is `affineSl2PBWBasis` (Chapter 9, Theorem 9.25): ordered creation monomials form a basis for every $k \neq -2$, proved through the Wakimoto realisation without `VOA.pbw`; the count $3 + 6$ is the weight-2 case (ordered monomials of weight 2 in the J^a_n). By Theorem 11.29, $F^1V \cap V_2 = \mathcal{W}_1 \cap V_2 = \operatorname{span}\{J^a_{-2}\mathbf{1}\}$, of dimension 3. This also equals Zhu's $C_2(V) \cap V_2$, as it must since $F^1V = C_2(V)$ (Theorem 11.10): in

weight 2 the only states $u_{(-2)}v$ are $J^a_{(-2)}\mathbf{1} = J^a_{-2}\mathbf{1}$ (and $\mathbf{1}_{(-2)}J^a = 0$). Next, $F^2V \cap V_2 = \mathcal{W}_2 \cap V_2 = 0$, because a word of level ≥ 2 has weight ≥ 3. So

$$\dim \mathrm{gr}^F_{0,2} V = 6, \qquad \dim \mathrm{gr}^F_{1,2} V = 3.$$

On the jet side, $x_a^{(r)}$ has bidegree $(r, 1+r)$, so bidegree $(0,2)$ is spanned by the six monomials $x_a x_b$ and $(1,2)$ by the three $x_a^{(1)}$. Theorem 11.23(3) says both bidegree maps are onto. Concretely, $x_a x_b \mapsto [J^a_{-1}J^b_{-1}\mathbf{1}]$ and $x_a^{(1)} \mapsto [J^a_{-2}\mathbf{1}]$, by the exact word identity of Theorem 11.16. Here the dimensions match ($6 = 6$, $3 = 3$), so both maps are even bijective in weight 2. This bijectivity is *not* a consequence of the theorems of this section, which prove surjectivity only.

Compare the old hypothesis `hdec` for the same generators. In weight 2, $\mathrm{span}\{J^e, J^f, J^h, \mathbf{1}\}$ contributes nothing (those states have weights 1 and 0), so the weight-2 part of $\mathrm{span}\{J^a, \mathbf{1}\} + C_2(V)$ is $C_2(V) \cap V_2$, of dimension 3, while V_2 has dimension 9. So `hdec` fails for the currents of $V^k(\mathfrak{sl}_2)$ already in weight two, while Theorem 11.23 applies.

Trap / dead end

Dead end: the `hdec` criteria do not apply to the quasi-lisse cases.
The claim. It is tempting to obtain surjectivity of the Li jet map, for the affine VOAs of the Deligne series and for the Virasoro minimal models, from the criteria of Theorem 11.16, i.e. the theorems with hypothesis

```
(hdec : (τ : Submodule ℂ V) =
  Submodule.span ℂ (Set.range gen ∪ {W.vacuum}) ⊔ O₂ W)
```

namely `liPresentedJetMap_hits_homogeneous_class_of_generators` (`VOA/Filtered/LiGeneratorWords.lean`, Theorem 11.16), `liPresentedJetBidegreeMap_surjective_of_generators` and the `…_of_generators…` squeeze lemmas built on it (`VOA/Filtered/LiJetBidegree.lean`), This does not work: they are *unusable* for every Deligne case and for the Virasoro minimal models $M(2, 2n+1)$, $n \geq 3$ (the $M(2, 2m+3)$ of Chapter 20 with $n = m+1$), with generator ω.
What precisely is false. The theorems themselves are correct (they are proved); what is false in these cases is their *hypothesis* `hdec`. So the theorems are vacuous there, not wrong. `hdec` says that R_V is linearly spanned by the images of $\mathbf{1}, a^1, \dots, a^g$. Three consequences:

1. **`hdec` forces C_2-cofiniteness.** This is checked in Lean against the library (axioms `[propext, Classical.choice, Quot.sound]`; see the verification record, Section 11.10); the check is not part of this release (the proof: the composite $\mathrm{span}(\mathrm{gen} \cup \{\mathbf{1}\}) \hookrightarrow V \to V/C_2(V)$ is surjective by `hdec` and has finite-dimensional source). Here `C2Cofinite W` is `FiniteDimensional ℂ (A₂ W)`, $A_2(W) = V/C_2(V)$ (Chapter 12). Combined with `VOA.Sl2NonLisse.not_C2Cofinite_simpleSl2QL` (Chapter 16, Theorem 16.40: $L_{-4/3}(\mathfrak{sl}_2)$ is not lisse, unconditionally), this gives a machine-checked counterexample: *no finite family whatsoever* satisfies `hdec` for $L_{-4/3}(\mathfrak{sl}_2)$ (the two-line composition was compiled as part of the same check). On paper, the same holds for every quasi-lisse VOA that is not lisse, in particular for the simple affine VOAs $L_k(\mathfrak{g})$ of the Deligne series at the levels of Chapter 24. Their associated variety is a nilpotent orbit closure of positive dimension (Arakawa–Moreau), so R_V is infinite-dimensional.

2. **With the currents as generators it fails in weight two.** The weight-2 part of the right-hand side of `hdec` is $C_2(V) \cap V_2$, so `hdec` forces $(R_V)_2 = 0$. But for $L_k(\mathfrak{g})$ the weight-2 part of R_V is a quotient of $\mathrm{Sym}^2 \mathfrak{g}$ by the weight-two null relations, and it surjects onto the degree-2 functions on the associated variety. At the Deligne levels that variety is the minimal nilpotent orbit closure, whose degree-2 functions form the

non-zero representation $V(2\theta)$; so $(R_V)_2 \neq 0$. For $V^k(\mathfrak{sl}_2)$ the count is Example 11.30. (Paper argument; the Lean check in (1) is the machine-checked form.)

3. **It fails even in lisse cases with too few generators.** For $M(2, 2n+1)$ one has $R_V \cong \mathbb{C}[T]/(T^n)$ with $T = [\omega]$ of weight 2 (Chapter 20, where the same ring is written $\mathbb{C}[T]/(T^{m+1})$). For $n \geq 3$, $T^2 \neq 0$ has weight 4 and is not in $\mathrm{span}\{1, T\}$, so `hdec` with the single generator ω fails. Enlarging the family to lifts of a linear basis of R_V would satisfy `hdec`, but the jet presentation would then carry many redundant variables, and it still cannot reach non-lisse cases.

The replacement is Theorem 11.23, whose hypothesis is spanning of Li's filtration by generator words, proved for currents by Theorems 11.26–11.28 and for the Virasoro words in Chapter 20. By Remark 11.24 its hypothesis is, on paper, exactly algebra generation of R_V, which the single generator ω of $M(2, 2n+1)$ does satisfy. The module docstring of `VOA/Filtered/GeneratorWordLiSurjectivity.lean` records the same limitation. The docstrings of the `hdec`-based theorems in `LiGeneratorWords.lean` and `LiJetBidegree.lean` do not; this is a documentation defect of the library.

11.6 The symbol toolkit: leading terms, filtered words, certified arithmetic

The proofs that certain states are *linearly independent* (a PBW-type statement for affine $\mathfrak{sl}_3$ Verma modules, in `VOA/Examples/AffineSl3VermaBasis.lean`, whose chapter is in preparation; non-degeneracy of free-field realisations, Chapter 19) all follow one pattern: map the states to polynomials, identify a leading (or lowest) homogeneous term — a *symbol* — and show that the symbols are independent. This section documents the generic, VOA-free part of that pattern, which lives in the files of this chapter. The files are short and the theorems are standard commutative algebra; the point of the fidelity checks is that the statements are the right ones and carry no hidden hypothesis.

Definition 11.31 (Leading and minimum symbols)**.** Let $w : \sigma \to \mathbb{N}$ (resp. $w : \sigma \to \mathbb{Z}$) be a weight on the variables of $\mathbb{C}[x_s : s \in \sigma]$, and write $|e|_w = \sum_s e_s w(s)$ for the weight of the monomial x^e.

1. Q is a *leading symbol of weight d* of P if Q is homogeneous of weight d and every monomial of $P - Q$ has weight $< d$.

2. Q is a *minimum symbol of weight d* of P if Q is homogeneous of weight d and every monomial of $P - Q$ has weight $\geq d + 1$; here $\mathrm{AtLeast}_w(d)$ is the span of monomials of weight $\geq d$.

Files `VOA/Core/PolynomialLeadingSymbol.lean`, `VOA/Core/PolynomialMinimumWeight.lean`, `VOA/Core/PolynomialMinimumSymbol.lean`.

```
structure Symbol (w : σ → ℕ) (d : ℕ) (P Q : MvPolynomial σ ℂ) : Prop where
  homogeneous : Q.IsWeightedHomogeneous w d
  remainder : P - Q ∈ Below w d

def AtLeast (w : σ → ℤ) (d : ℤ) : Submodule ℂ (MvPolynomial σ ℂ) :=
  Submodule.span ℂ {P | ∃ e : σ →₀ ℕ, d ≤ Finsupp.weight w e ∧ P = monomial e 1}

structure Symbol (w : σ → ℤ) (d : ℤ) (P Q : MvPolynomial σ ℂ) : Prop where
  homogeneous : Q.IsWeightedHomogeneous w d
  remainder : P-Q ∈ AtLeast w (d+1)
```

From the mathematics to the Lean statement

`Below w d` is the set of polynomials all of whose monomials with nonzero coefficient have weight $< d$ (`Finsupp.weight w e` is $|e|_w$); `IsWeightedHomogeneous` is Mathlib's homogeneity. The two `Symbol` structures live in different namespaces (`VOA.PolynomialLeading` with $\mathbb{N}$-weights and `VOA.PolynomialMinimum` with $\mathbb{Z}$-weights). `AtLeast` is defined as a span of monomials; `mem_iff` proves that this is the same as a bound on every nonzero coefficient, with no finiteness of σ needed. Signed weights are used so that a variable of weight -1 ("creation raises length by one") and differentiation by a variable of larger weight can be handled without truncated subtraction. Note that a symbol may be 0 (e.g. when the declared weight is larger than the true one), which is why the independence theorems below assume independence of the symbols.

Physical meaning

The weight of a monomial is a count of constituents (number of creation operators, number of fields) and the symbol is the term with the extreme count: the leading term in a semiclassical or free-field expansion of a composite operator.

Theorem 11.32 (Symbols multiply; independent symbols give independent polynomials). *1. If Q, V are leading symbols of weights a, b of P, U, then QV is a leading symbol of weight $a+b$ of PU; likewise for minimum symbols (`AtLeast` is multiplicative), and $\partial/\partial x_v$ lowers a minimum bound by $w(v)$.*

2. If $(P_i)_{i\in\iota}$ is any family with leading (or minimum) symbols (Q_i) of weights d_i, and the Q_i are linearly independent, then the P_i are linearly independent. No bound on the d_i and no finiteness of ι or σ is needed.

3. Every nonzero polynomial has a nonzero minimum symbol; multiplication by a fixed nonzero polynomial preserves linear independence of all monomials.

Files as above, and `VOA/Core/PolynomialNonzeroMinimum.lean`.

    LinearIndependent ℂ (fun e : σ →₀ ℕ => monomial e (1 : ℂ)*Q) := by
```

From the mathematics to the Lean statement

All statements are as described. `LinearIndependent ℂ P` is Mathlib's linear independence of a family (no nontrivial finite linear relation). In (2), the proof only ever looks at a *finite* relation, so the family may be infinite. `pderiv v` is $\partial/\partial x_v$. The leading-symbol file also proves `SeriesSymbol`, the coefficientwise extension to power series with polynomial coefficients (`SeriesSymbol.mul` uses only finite antidiagonal sums).

Proof on paper. (1) Expand $PU = QV + (P-Q)V + P(U-V)$; every monomial of the last two terms has weight $< a+b$. (2) Given a finite relation $\sum c_i P_i = 0$, let n be the largest (resp. smallest) d_i with $c_i \neq 0$, and take the weight-n homogeneous component: it is $\sum_{d_i=n} c_i Q_i = 0$, contradicting independence of the Q_i. (3) Take the lowest weight occurring in the finite support; $\mathbb{C}[x]$ is a domain. □

What the machine verified

Proved, unconditional; `#print axioms` of both `linearIndependent_of_symbols` and of `exists_nonzero_symbol`: standard three.

Physical meaning

This is the algebraic form of the semiclassical argument "if the leading classical terms of a set of operators are independent, so are the operators". The weight is the filtration degree (length, number of creation operators, or R-charge), and the symbol is the leading term in a free-field realisation.

Theorem 11.33 (Filtered words have product symbols). *Let $F_0 \subseteq F_1 \subseteq \cdots$ be subspaces of V, $(T_a)_{a\in\alpha}$ operators with $T_a F_d \subseteq F_{d+1}$, $v \in F_0$, and $\varphi : V \to \mathbb{C}[x_s]$ linear with $\varphi(v) = 1$. Suppose each T_a has a linear symbol f_a (homogeneous of weight -1 for the weight $w \equiv -1$) in the sense that $\varphi(T_a u) - f_a \varphi(u) \in \mathrm{AtLeast}(-d)$ for $u \in F_d$. Then for every word $a_1 \cdots a_\ell$, $\varphi(T_{a_1} \cdots T_{a_\ell} v)$ has minimum symbol $f_{a_1} \cdots f_{a_\ell}$ of weight $-\ell$. Consequently, for a linear order on α, if the commutative products $\prod_a f_a^{e_a}$ (over multiplicity functions e) are linearly independent, so are the ordered states $T_{a_1} \cdots T_{a_\ell} v$ $(a_1 \le \cdots \le a_\ell)$. The same holds on a tensor product $V \otimes W$ with the total length filtration and the sum of the factor symbols.*

From the mathematics to the Lean statement

`e : α →₀ ℕ` is a finitely supported multiplicity function; `e.toMultiset.sort (· ≤ ·)` is the increasing word with each letter repeated e_a times, and `orderedExponentWord_prod` says its commutative evaluation is $\prod_a f(a)^{e_a}$. `filteredWord T v l` applies the operators of `l` with the head outermost. In `filteredOrderedWord_independent` the hypotheses are exactly those of the theorem: `hv`, `hφ` (normalisation), `hT` (length raises by one), `hf` (linear symbols of weight -1), `he` (the symbol error is length-preserving) and `hind` (independence of the commutative symbols); the conclusion is independence of the ordered states. `φ` need not be injective. In the tensor file, `tensorLength F G d` is the span of $v \otimes w$ with $v \in F_i$, $w \in G_j$, $i + j \le d$; `rTensor`, `lTensor` are $T \otimes 1$, $1 \otimes U$.

Proof on paper. Induction on the word using Theorem 11.32(1): the new error and the old error multiplied by f_a both have weight $\ge -\ell + 1$. Independence then follows from Theorem 11.32(2) with minimum symbols. For tensor products, the symbol of $v \otimes w$ is the product of the factor symbols and errors add. □

What the machine verified

Proved, unconditional; `#print axioms` of `VOA.filteredOrderedWord_independent` and `VOA.tensorSum_polynomial_error`: standard three. Consumers: the affine $\mathfrak{sl}_3$ files `VOA/Examples/AffineSl3VermaBasis.lean` and `VOA/Examples/AffineSl3HighestTensorFiltration.lean` (not documented in this edition).

Physical meaning

A PBW basis of a Verma module or a vacuum module is a set of ordered monomials in creation operators. In a free-field realisation each creation operator becomes, to leading order, multiplication by a classical field; the theorem says that independence of the classical monomials implies independence of the quantum ordered states — the mathematical content of "the free-field realisation is faithful at leading order".

Theorem 11.34 (Kernel vectors at a simple determinant root). *Let $M(z)$ be a square matrix of polynomials over a commutative domain R, and $z_0 \in R$ with $\det M(z_0) = 0$ and $(\det M)'(z_0) \neq 0$. Then there are a left kernel vector r and a right kernel vector c of $M(z_0)$ with $r^{\mathsf{T}} M'(z_0) c \neq 0$.*

File `VOA/Core/PolynomialMatrixSimpleRoot.lean`.

```
theorem kernel_pair_of_simple_root [NoZeroDivisors R]
    (M : Matrix ι ι R[X]) (z : R)
    (hz : M.det.eval z = 0) (hd : M.det.derivative.eval z ≠ 0) :
    ∃ r c : ι → R,
      (∀ j, ∑ i, r i * (M i j).eval z = 0) ∧
      (∀ i, ∑ j, (M i j).eval z * c j = 0) ∧
      (∑ i, ∑ j, (r i * c j) * (M i j).derivative.eval z) ≠ 0 := by
```

From the mathematics to the Lean statement

`M.det.eval z` is $\det M(z)$, `derivative` is d/dz; `(M i j).eval z` is the (i,j) entry at z. The three conjuncts are $r^{\mathsf{T}}M(z_0) = 0$, $M(z_0)c = 0$, and $\sum_{i,j} r_i c_j M'_{ij}(z_0) \neq 0$. `[NoZeroDivisors R]` is the domain hypothesis. Exactly the statement above.

Proof on paper. Jacobi's formula $(\det M)' = \operatorname{tr}(\operatorname{adj}(M)M')$ shows $\operatorname{adj} M(z_0) \neq 0$; at a root $M \operatorname{adj} M = \operatorname{adj} M\, M = 0$, so rows and columns of the adjugate are kernel vectors; differentiating $M \operatorname{adj} M = \det M \cdot 1$ and multiplying by $\operatorname{adj} M$ gives $\operatorname{adj} M\, M' \operatorname{adj} M = (\det M)'(z_0) \operatorname{adj} M \neq 0$. □

What the machine verified

Proved, unconditional; standard three. Consumer: `VOA/Examples/AffineSl2JointSimpleRoot.lean` (Chapter 10).

Physical meaning

A simple zero of a Kac–Kazhdan-type Gram determinant at a special value of a parameter (level, central charge) signals a single new null vector; the nonzero pairing through the derivative is the first-order statement that the null vector is "created" at exactly that value, which is what deformation and rigidity arguments use.

Theorem 11.35 (Coefficient bookkeeping for jets). *1. Extending sequences $f, g : \mathbb{N} \to R$ by zero to $\mathbb{Z}$, the integer convolution $\sum_{p\in\mathbb{Z}} f(p)g(n-p)$ (a sum with finite support) is the n-th coefficient of $\left(\sum f_k t^k\right)\left(\sum g_k t^k\right)$, and 0 for $n < 0$; in creation-mode indexing, $\sum_p f(-p-a)g(p-n)$ is the coefficient of t^{-n-a}.*

2. A derivation D of a commutative $\mathbb{C}$-algebra R extends coefficientwise to a derivation of $R[[t]]$.

Files `VOA/Core/IntegerJetConvolution.lean`, `VOA/Core/PowerSeriesCoefficientDerivation.lean`.

```
theorem creation_convolution (f g : ℕ → R) (a n : ℤ) :
    (∑ᶠ p : ℤ, extend f (-p-a) * extend g (p-n)) =
      extend (fun r => PowerSeries.coeff r (PowerSeries.mk f * PowerSeries.mk g)) (-n-a) :=
       ↪ by

def powerSeriesCoefficientDerivation (D : Derivation ℂ R R) :
    Derivation ℂ (PowerSeries R) (PowerSeries R) where

theorem coeff_powerSeriesCoefficientDerivation (D : Derivation ℂ R R)
    (P : PowerSeries R) (n : ℕ) :
    PowerSeries.coeff n (powerSeriesCoefficientDerivation D P) = D (PowerSeries.coeff n P)
     ↪ := by
```

From the mathematics to the Lean statement

`extend f p` is $f(p)$ for $p \geq 0$ and 0 otherwise; $\sum^{\mathrm{f}}$ is a sum over the (finite) support, and the file proves the support is finite (`convolution_finite`), so the junk value 0 of an infinite `finsum` never occurs. `PowerSeries.mk f` is $\sum_k f(k)t^k$. `Derivation ℂ R R` is Mathlib's $\mathbb{C}$-linear derivation.

Proof on paper. (1) Reindex the finite sum. (2) The Leibniz rule holds coefficient by coefficient because the coefficients of a product are finite antidiagonal sums. □

What the machine verified

Proved, unconditional; standard three. Consumers: the affine $\mathfrak{sl}_3$ classical-limit files `VOA/Examples/AffineSl3ClassicalCoefficient.lean` and `VOA/Examples/AffineSl3FirstClassicalDerivation.lean` (not documented in this edition).

Physical meaning

The coefficient of z^n in a normal-ordered product of two creation fields is a finite convolution of their modes; this lemma is the bookkeeping that identifies the classical limit of a product of fields with the product of jets.

Definition 11.36 (Certified sparse rational polynomials). A *sparse polynomial* over $\mathbb{Q}$ in variables ι (linearly ordered) is a list of pairs (sorted monomial, nonzero rational coefficient), sorted and without repetitions; `normalizeQ` sorts and merges a raw list of terms; `evalSparse x P` evaluates at $x : \iota \to A$ in any commutative $\mathbb{Q}$-algebra.

File `VOA/Core/SparseRational.lean`.

          ring
      | eq =>
          have hwv : w = v := (compareWord_eq_iff w v).mp hcmp
```

From the mathematics to the Lean statement

Lists of pairs are an executable stand-in for Mathlib's `MvPolynomial`, whose constructors use classical equality and do not reduce in the kernel. The correctness theorems say that normalisation, addition, scaling (`evalSparse_scaleQ`), sums and substitution (`evalSparse_bindQ`) commute with evaluation in *every* commutative $\mathbb{Q}$-algebra, so a polynomial identity checked on the sparse side by `decide`/`norm_num` holds after evaluation. No `native_decide` is used (the insertion sort is written structurally so that the kernel can reduce it). The file ends with a small `example` checking that $x_1x_0 - x_0x_1$ normalises to 0.

Proof on paper. Each list operation implements the corresponding polynomial operation; induction on the lists. □

What the machine verified

Proved, unconditional; `#print axioms VOA.SparseRational.evalSparse_bindQ`: standard three. Consumer: the certified Adamović–Milas identity for the triplet algebra $W(2)$ (Chapter 18).

Physical meaning

Null-vector identities in a chiral algebra (here the triplet algebra's relation that makes it C_2-cofinite) are large but explicit polynomial identities among modes; certified sparse arithmetic is how such a CAS-style computation is made into a kernel-checked proof.

11.7 Presenting a vertex algebra by generators and OPEs (De Sole–Kac)

11.7.1 The mathematical background

Physicists specify a chiral algebra by listing strong generators $a^i(z)$ of conformal weights Δ_i and their singular OPEs

$$a^i(z)a^j(w) \sim \sum_{n\ge 0} \frac{(a^i_{(n)}a^j)(w)}{(z-w)^{n+1}},$$

where each coefficient $a^i_{(n)}a^j$ is a normally ordered polynomial in the generators and their derivatives ("non-linear" when products occur, as for the W_3 algebra). De Sole and Kac (2005) made this precise. Write $[a_\lambda b] = \sum_{n\ge 0} \frac{\lambda^n}{n!} a_{(n)}b$ (the λ-bracket). Let R be the free $\mathbb{C}[T]$-module on the generators and $\mathcal{T}(R)$ its tensor algebra.

- *Definition 3.1 (non-linear conformal algebra).* A λ-bracket $R \otimes R \to \mathbb{C}[\lambda] \otimes \mathcal{T}(R)$ that is sesquilinear, $[Ta_\lambda b] = -\lambda[a_\lambda b]$, $[a_\lambda Tb] = (\lambda + T)[a_\lambda b]$, and satisfies a grading condition $\Delta([a_\lambda b]) < \Delta(a) + \Delta(b)$. (Definition 3.3 adds skew-symmetry and the Jacobi identity, making a *non-linear Lie conformal algebra*.)
- *Lemma 3.2.* The normally ordered product N and the bracket extend uniquely to all of $\mathcal{T}(R)$.
- *Definition 3.4.* $M(R)$ is spanned by $A \otimes \big((b \otimes c - p(b,c)c \otimes b) \otimes D - N(\int_{-T}^{0}[b_\lambda c]\,d\lambda,\ D)\big)$ for $b, c \in R$, $A, D \in \mathcal{T}(R)$; it is a *left* ideal.
- *Theorem 3.9.* If the bracket is Lie, $U(R) = \mathcal{T}(R)/M(R)$ carries a unique vertex algebra structure with $Y(a,z)$ prescribed for $a \in R$, and ordered monomials form a basis (PBW).

The library builds this machinery in stages. We follow it in order, and we are careful to say at each point what is a definition, what is proved, what is refuted, and what is a contract that nothing fulfils.

11.7.2 The tensor algebra, its weights and translation

Definition 11.37 ($\mathcal{T}(R)$ with divided-power generators; weights)**.** Let ι index the strong generators. R has the $\mathbb{C}$-basis $T^k a^i/k!$, indexed by pairs $(i,k) \in \iota \times \mathbb{N}$; $\mathcal{T}(R)$ is the free associative algebra on these pairs, with its basis of words. With weights $\Delta_i \in \mathbb{N}$, the letter (i,k) has weight $\Delta_i + k$ and a word the sum of its letters' weights; $\mathrm{filt}(d)$ is the span of words of weight $\le d$ ($d \in \mathbb{Z}$; it is 0 for $d < 0$). The translation T is the unique derivation of $\mathcal{T}(R)$ with $T(T^k a^i/k!) = (k+1)\,T^{k+1}a^i/(k+1)!$.

    Ttr x ∈ filt wt (d + 1) := by
```

From the mathematics to the Lean statement

`FreeAlgebra ℂ X` is the free associative unital $\mathbb{C}$-algebra on the set X, i.e. the tensor algebra of the vector space with basis X; so `TR ι` is $\mathcal{T}(R)$ with R free over $\mathbb{C}[T]$ on ι. `gv (i, k)` is the letter $T^k a^i/k!$ (the library's "divided power" normalisation; De Sole–Kac use $T^k a^i$, a harmless rescaling of the same basis). `wbasis ι` is the word basis (indexed by `FreeMonoid`, i.e. lists). The derivation is built by the dual-numbers trick: `phiT` is the algebra map $x \mapsto x + \varepsilon T(x)$ into $\mathcal{T}(R) \oplus \varepsilon\mathcal{T}(R)$ (`TrivSqZeroExt`), and `Ttr` is its ε-component. `Ttr_mul` is the Leibniz rule (written $x\,Ty + Tx\,y$), `Ttr_gv` the value on letters, and `Ttr_mem_filt` says T raises weight by one.

Restriction relative to De Sole–Kac. R is assumed *free* over $\mathbb{C}[T]$ (no torsion); central elements such as c are handled as scalar multiples of the unit word $1 \in \mathcal{T}(R)$. This covers every example in the library and in most of physics.

Physical meaning

$\mathcal{T}(R)$ is the space of all formal normal-ordered words $:\partial^{k_1}a^{i_1}\cdots\partial^{k_r}a^{i_r}:$ before any relation is imposed — not even commutativity of normal ordering. The word $:LL:$ and its reorderings are different elements here. T is ∂_z acting on composite operators by the Leibniz rule.

Definition 11.38 (OPE data: De Sole–Kac Definition 3.1, free-generator form)**.** An *OPE datum* on generators ι consists of weights $\Delta_i \geq 1$, parities $p_i \in \mathbb{Z}/2$, and elements $a^i_{(n)}a^j \in \mathcal{T}(R)$ for $n \in \mathbb{N}$ (the singular OPE table) such that $a^i_{(n)}a^j \in \mathrm{filt}(\Delta_i + \Delta_j - n - 1)$. In particular $a^i_{(n)}a^j = 0$ for $n \geq \Delta_i + \Delta_j$.

File `VOA/Core/NonlinearConformal.lean`.

```
structure OPEData (ι : Type u) where
  wt : ι → ℕ
  wt_pos : ∀ i, 0 < wt i
  par : ι → ZMod 2

    · subst h0
      exact gv_mem_filt _ (by norm_num [wtIdx])
    · subst h1
      exact Submodule.smul_mem _ _ (gv_mem_filt _ (by norm_num [wtIdx]))
    · subst h3
      exact Submodule.smul_mem _ _ (one_mem_filt _ (by norm_num))
    · exact Submodule.zero_mem _
```

From the mathematics to the Lean statement

`ope i j n` is $a^i_{(n)}a^j$ (an element of `TR ι`); `ope_wt` is the grading condition, with integer arithmetic so that a negative bound forces 0 (`ope_eq_zero`). `virasoroOPE c` has one generator (`Unit`, the one-element type) L of weight 2 and table $L_{(0)}L = TL$ (the letter `gv ((), 1)`), $L_{(1)}L = 2L$, $L_{(3)}L = \frac{c}{2}\mathbf{1}$, all others 0. Since $[L_\lambda L] = (T + 2\lambda)L + \frac{c}{12}\lambda^3$ and $\lambda^3 = 3!\,\lambda^{(3)}$, the coefficient $L_{(3)}L = 6 \cdot \frac{c}{12} = \frac{c}{2}$ is correct.

Fidelity. (a) Sesquilinearity is not a field: it is *built into* the extension of the table to all of R (Definition 11.39), so it holds by construction. (b) The grading condition is stated with the conformal weight, $\Delta(a_{(n)}b) \le \Delta a + \Delta b - n - 1$; De Sole–Kac's condition is the weaker $\Delta([a_\lambda b]) < \Delta a + \Delta b$ for a filtration in which T has degree 0. The library proves that its condition implies theirs (`ope_mem_zfilt`, Section 11.7.7). For a VOA, the library's condition is the natural one. (c) **Skew-symmetry and the Jacobi identity are not required.** `OPEData` is a non-linear *conformal* algebra (Definition 3.1), not a non-linear *Lie* conformal algebra (Definition 3.3). Any table satisfying the weight bound is accepted, including tables that come from no vertex algebra; for those the quotient constructed below will in general be degenerate. This is faithful to Definition 3.1 and is not a defect, but a reader must not read "`OPEData`" as "consistent OPE". (d) The docstring proposes handling half-integer weights by doubling all weights; then the bound $\Delta_i + \Delta_j - n - 1$ is no longer the conformal one (it becomes weaker), so termination still holds but the bound is not sharp. No library datum uses this.

Physical meaning

`virasoroOPE c` is the textbook stress-tensor OPE $T(z)T(w) \sim \frac{c/2}{(z-w)^4} + \frac{2T(w)}{(z-w)^2} + \frac{\partial T(w)}{z-w}$. The grading condition is dimensional analysis: the coefficient of $(z-w)^{-n-1}$ has dimension $\Delta_i + \Delta_j - n - 1$, so the OPE of two fields of finite dimension has finitely many singular terms. Jacobi (associativity of the OPE) is the crossing-symmetry constraint that a consistent chiral algebra must satisfy; `OPEData` does not impose it.

Definition 11.39 (The λ-bracket on all of R). For a function $f : \mathbb{N} \to \mathcal{T}(R)$ (the slices $n \mapsto a_{(n)}b$) put $(Lf)(n) = -nf(n-1)$ and $(Rf)(n) = Tf(n) + nf(n-1)$, implementing $(Ta)_{(n)}b = -n\,a_{(n-1)}b$ and $a_{(n)}(Tb) = T(a_{(n)}b) + n\,a_{(n-1)}b$. Then

$$\big(T^k a^i/k!\big)_{(n)}\big(T^l a^j/l!\big) := \frac{1}{k!\,l!}\big(L^k R^l (a^i_{(\cdot)}a^j)\big)(n).$$

File `VOA/Core/NonlinearConformal.lean`.

```
noncomputable def Lstep (f : ℕ → TR ι) : ℕ → TR ι := fun n => -(n : ℂ) • f (n - 1)

noncomputable def Rstep (f : ℕ → TR ι) : ℕ → TR ι := fun n => Ttr (f n) + (n : ℂ) • f (n -
↪ 1)

```

```
(((p.2).factorial : ℂ) * ((q.2).factorial : ℂ))⁻¹ •
  Lstep^[p.2] (Rstep^[q.2] (D.ope p.1 q.1)) n
```

From the mathematics to the Lean statement

`Lstep^[k]` is the k-fold iterate. In natural-number arithmetic `n - 1` is 0 at $n = 0$, but it is multiplied by $n = 0$, so the convention is harmless. The two steps commute (`Lstep_Rstep`), so the order of iteration does not matter.

Physical meaning

Sesquilinearity is the statement that ∂_z of a field acts on the OPE by differentiating: the OPE of ∂a with b is the derivative of the OPE of a with b in the first variable. Once one knows the OPE of the generators, the OPE of all their derivatives follows.

Theorem 11.40 (Properties of the extended bracket). *For all letters $p = (i,k)$, $q = (j,l)$ and $n \in \mathbb{N}$:*

1. *on bottom letters the bracket is the table:* $(a^i)_{(n)}(a^j) =$ `D.ope i j n`*;*
2. *sesquilinearity:* $(k+1)\,(T^{k+1}a^i/(k+1)!)_{(n)}q = -n\,p_{(n-1)}q$ *and* $(l+1)\,p_{(n)}(T^{l+1}a^j/(l+1)!) = T(p_{(n)}q) + n\,p_{(n-1)}q$*;*
3. *grading:* $p_{(n)}q \in \mathrm{filt}(\Delta(p)+\Delta(q)-n-1)$*, hence* $p_{(n)}q = 0$ *for* $n \geq \Delta(p)+\Delta(q)$.

```

From the mathematics to the Lean statement

Exactly as stated; the factors $(k+1)$, $(l+1)$ come from the divided-power normalisation. The library also checks the Virasoro example: `virasoro_brk_three` ($L_{(3)}L = \frac{c}{2}\mathbf{1}$) and `virasoro_brk_T` ($(TL)_{(1)}L = -L_{(0)}L = -TL$), the latter *derived* from sesquilinearity.

Proof on paper. (1) $k = l = 0$. (2) One more application of L or R, and the factorials. (3) Each application of L or R raises the weight bound by one (the T in R raises weight by one; the shift $n \mapsto n-1$ in both steps raises $-n-1$ by one), while the letters' weights rise by one. □

What the machine verified

Proved, unconditional; `#print axioms VOA.NonlinearConformal.brk_mem_filt`: standard three.

Physical meaning

The full singular OPE between all derivatives of the generators is determined by the generators' OPE, and still has only finitely many singular terms: dimensional analysis survives differentiation.

11.7.3 Relations, admissible ideals and the quotient

Definition 11.41 (The quantum-commutator relation; admissible relation ideals)**.** For letters p, q put

$$\int_{-T}^{0}[p_\lambda q]\,d\lambda=\sum_{n\ge 0}\frac{(-1)^n}{(n+1)!}T^{n+1}(p_{(n)}q),\qquad \mathrm{rel}(p,q)=p\,q-(-1)^{p(p)p(q)}q\,p-\int_{-T}^{0}[p_\lambda q]\,d\lambda.$$

An *admissible relation ideal* is a subspace $M\subseteq\mathcal{T}(R)$ closed under left multiplication by $\mathcal{T}(R)$, stable under T, and containing every $\mathrm{rel}(p,q)$. M_{bot} is the smallest one: the span of all $A\cdot\mathrm{rel}(p,q)$.

File `VOA/Core/NonlinearConformal.lean`.

```

   ↪ z.2.2))

theorem MRbot_le {D : OPEData ι} (M : MIdeal D) : (MRbot D).car ≤ M.car := by
```

From the mathematics to the Lean statement

`Finset.range (wtIdx D.wt p + wtIdx D.wt q)` is the range $0\le n<\Delta(p)+\Delta(q)$, beyond which every term vanishes (Theorem 11.40(3)); so `opeInt` is exactly $\int_{-T}^{0}[p_\lambda q]d\lambda$, using $\int_{-T}^{0}\lambda^n/n!\,d\lambda=(-1)^nT^{n+1}/(n+1)!$. `koszul a b` is the sign $(-1)^{ab}$ (`VOA/Foundations/Parity.lean`). An `MIdeal` is carried as a $\mathbb{C}$-subspace with a *left*-multiplication field: De Sole–Kac's $M(R)$ is a left ideal, not two-sided, so the quotient is a vector space and not an algebra. `MRbotCar` spans $A\cdot\mathrm{rel}(p,q)$ over all $A\in\mathcal{T}(R)$ and all letters p,q (all divided powers, not only bottom generators). `MRbot` packages it with its three closure proofs; `MRbot_le` is minimality. **Relation to Definition 3.4.** Since $N(X,1)=X$, M_{bot} is the "$D=1$" part of De Sole–Kac's $M(R)$; the library shows below that it is *strictly* smaller and the wrong ideal.

Physical meaning

$\mathrm{rel}(a,b)$ is the familiar statement that normal ordering is commutative only up to derivatives of the singular OPE: $:ab:-:ba:=\sum_{n\ge0}\frac{(-1)^n}{(n+1)!}\partial^{n+1}(a_{(n)}b)$. For the stress tensor: $:TT':$-type reorderings produce derivatives of T with no central term, because the central term is a

constant and its derivatives vanish.

Theorem 11.42 (T-stability of the relations)**.** $T(\mathrm{rel}(p,q)) = (k+1)\,\mathrm{rel}(T^{k+1}a^i/(k+1)!,\,q) + (l+1)\,\mathrm{rel}(p,\,T^{l+1}a^j/(l+1)!)$ *for* $p=(i,k)$, $q=(j,l)$. *Consequently* M_{bot} *is* T*-stable.*

File `VOA/Core/NonlinearConformal.lean`.

```
theorem Ttr_rel (D : OPEData ι) (p q : GenIdx ι) :
    Ttr (rel D p q)
      = ((p.2 : ℂ) + 1) • rel D (p.1, p.2 + 1) q
        + ((q.2 : ℂ) + 1) • rel D p (q.1, q.2 + 1) := by
```

From the mathematics to the Lean statement

Exactly as stated. This is why relations must be imposed for all divided powers: T of a bottom relation is a combination of relations involving TL.

Proof on paper. T is a derivation, so $T(pq) = (Tp)q + p(Tq)$, and $T\int^0_{-T}[p_\lambda q] = \int^0_{-T}[Tp_\lambda q] + \int^0_{-T}[p_\lambda Tq]$ by sesquilinearity: at each n the two rules contribute $-n\,p_{(n-1)}q$ and $+n\,p_{(n-1)}q$, which cancel, and the one extra top term vanishes by the weight bound. □

What the machine verified

Proved, unconditional; standard three.

Physical meaning

Translation invariance of the operator algebra: the derivative of a relation among composite operators is again a consequence of the relations.

Definition 11.43 (The quotient $U = \mathcal{T}(R)/M$, vacuum, translation, creation half)**.** For an admissible M: $U = \mathcal{T}(R)/M$ (a vector space), $|0\rangle = [1]$, T_U the descent of T, and for each letter p the *creation half* of its field: the $\mathrm{End}(U)$-valued series whose z^j-coefficient is left multiplication by $T^j p/j!$ for $j \ge 0$ and 0 for $j < 0$.

File `VOA/Core/NonlinearConformal.lean`.

```
abbrev UR (M : MIdeal D) : Type u := TR ι ⧸ M.car

noncomputable def creHalf (M : MIdeal D) (p : GenIdx ι) : FormalDist (End ℂ (UR M)) :=
  fun j => if 0 ≤ j then leftMulU M (dpow p j.toNat) else 0
```

From the mathematics to the Lean statement

`descendU M f hf` is the map induced on the quotient by an f preserving M (`Submodule.mapQ`). Left multiplication descends because M is a left ideal. `dpow p k` is $T^k(T^m a^i/m!)/k! = \binom{m+k}{k} T^{m+k}a^i/(m+k)!$. `FormalDist (End ℂ (UR M))` is a two-sided formal series $\sum_j f_j z^j$ with operator coefficients (Chapter 2, Definition 2.1); `creHalf M p j` is the z^j-coefficient,

i.e. (in the mode convention) $p_{(-j-1)}$. The definition sets the annihilation range ($j < 0$, i.e. modes $p_{(n)}$ with $n \geq 0$) to 0 because it is not constructed here.

Physical meaning

$\mathcal{T}(R)/M$ is the would-be space of states: normal-ordered words in the generators modulo the reordering relations. The vacuum is the empty word, T_U is L_{-1}, and the creation modes $a_{(-j-1)}$ of a generator act by putting $\partial^j a/j!$ in front of a word — the state–operator correspondence for creation operators.

Theorem 11.44 (Spanning, non-vacuity, covariance of the creation half)**.** *For every admissible M: the word states $[w]$ span U; the creation half is T_U-covariant in the creation range, $[T_U, p_{(-m-1)}] = (m+1)p_{(-m-2)}$ for $m \geq 0$. For $M = M_{\mathrm{bot}}$ and* every *OPE datum, $|0\rangle \neq 0$, so $U \neq 0$.*

File `VOA/Core/NonlinearConformal.lean`.

```
theorem wstU_span (M : MIdeal D) : Submodule.span ℂ (Set.range (wstU M)) = ⊤ := by

    ↪ by

noncomputable def aug : TR ι →ₐ[ℂ] ℂ := FreeAlgebra.lift ℂ (fun _ => (0 : ℂ))

theorem vacU_ne_zero_bot (D : OPEData ι) : vacU (MRbot D) ≠ 0 :=
```

From the mathematics to the Lean statement

`wstU M w` is the image of the word w. `aug` is the augmentation $\mathcal{T}(R) \to \mathbb{C}$ killing every letter; the non-vacuity proof shows it kills M_{bot}. The covariance identity is the z^m-coefficient form of $[T, a(z)] = \partial_z a(z)$ restricted to $m \geq 0$; the case $m = -1$ involves $p_{(0)}$, which is not constructed.

Proof on paper. Words span $\mathcal{T}(R)$. $[T, \cdot\,]$ of left multiplication by A is left multiplication by TA (Leibniz), and $T\,\mathrm{dpow}(p,m) = (m+1)\mathrm{dpow}(p,m+1)$. For non-vacuity: every relation is killed by the augmentation (the quadratic terms contain letters; the integral terms are in the image of T, which lands in the augmentation ideal), hence so is M_{bot}, while $\mathrm{aug}(1) = 1$. □

What the machine verified

Proved, unconditional; `#print axioms VOA.NonlinearConformal.vacU_ne_zero_bot`: standard three. No PBW.

Physical meaning

The vacuum survives: imposing the commutation relations of normal ordering never sets the identity operator to zero, because every relation involves at least one field. (Imposing a null relation that *is* the identity — like $\omega = 0$ at $c \neq 0$, Section 11.8 — can kill the vacuum.) The creation modes of a field acting on the vacuum module are just "multiply on the left by the field", which is why they come for free.

11.7.4 Reconstruction from generating fields

Before turning to the contract on U, we document the general reconstruction theorem that the staging is designed to feed. Chapter 4 refers to it as the word-field corollary of operator-first reconstruction.

It upgrades the operator-first reconstruction of Chapter 4 (Theorem 4.41) from "a spanning family of states, each with its field" to "a family of generating fields whose monomials span".

Definition 11.45 (Word fields and word states)**.** Let V be a vector space with $\mathbf{1} \in V$ and fields $(g_k)_{k\in K}$. For a word $l = k_1 k_2 \cdots k_r$ put

$$s_l = (g_{k_1})_{(-1)}(g_{k_2})_{(-1)} \cdots (g_{k_r})_{(-1)}\mathbf{1}, \qquad f_l(z) = :g_{k_1}(z): g_{k_2}(z) \cdots :g_{k_r}(z)\,\mathrm{id}: \cdots ::,$$

with $s_\varnothing = \mathbf{1}$, $f_\varnothing = \mathrm{id}$: s_l is the iterated (-1)-mode and f_l the iterated normal-ordered product, nested to the right.

File `VOA/Core/NonlinearConformal.lean`.

```
noncomputable def wordFldF {κ : Type*} (gen : κ → FormalDist (End ℂ V))
    (hgen : ∀ i, IsField (gen i)) : List κ → Fld V
  | [] => Fld.one
  | (i :: l) => Fld.nprod ⟨gen i, hgen i⟩ (wordFldF gen hgen l)

noncomputable def wordFld {κ : Type*} (gen : κ → FormalDist (End ℂ V))
    (hgen : ∀ i, IsField (gen i)) (l : List κ) : FormalDist (End ℂ V) :=
  (wordFldF gen hgen l).1

noncomputable def wordSt {κ : Type*} (gen : κ → FormalDist (End ℂ V)) (vac : V) : List κ →
 ↪ V
  | [] => vac
  | (i :: l) => gen i 0 (wordSt gen vac l)
```

From the mathematics to the Lean statement

`Fld V` is the type of fields on V (a series together with a proof of `IsField`); `Fld.one` is the identity field and `Fld.nprod a b` the normal-ordered product $:a(z)b(z):$ (`VOA/Core/LocalSystem.lean`, Chapter 4, Definition 4.44). `gen i 0` is the z^0-coefficient of g_i, which in mode convention is $(g_i)_{(-1)}$, as in the definition.

Physical meaning

f_l is the composite operator $:g_{k_1}g_{k_2}\cdots g_{k_r}:$ and s_l the corresponding state: the state–operator map on monomials in the generators. Derivatives are included automatically when the family (g_k) contains the derivatives of the generators, as it does in $\mathcal{T}(R)$, whose letters are $T^k a^i/k!$.

Theorem 11.46 (Reconstruction from generators)**.** *Let V be a complex vector space, $\mathbf{1} \in V$, $T \in \mathrm{End}\,V$ with $T\mathbf{1} = 0$, and let $(g_k)_{k\in K}$ be fields on V such that*

1. *g_k and $g_{k'}$ are mutually local for all k, k';*
2. *$g_k(z)\mathbf{1} \in V[[z]]$ (no negative powers of z) for all k;*
3. *each g_k is T-covariant: $[T, g_k(z)] = \partial_z g_k(z)$;*
4. *the word states s_l span V.*

Then there is a linear map $Y : V \to \mathrm{End}(V)[[z^{\pm 1}]]$ with $Y(s_l, z) = f_l(z)$ for every word l, such that every $Y(u,z)$ is a field, all $Y(u,z)$ are pairwise local, $Y(u,z)\mathbf{1} \in u + zV[[z]]$, and every $Y(u,z)$ is T-covariant.

File `VOA/Core/NonlinearConformal.lean` (`VOA.NonlinearConformal.reconstruct_of_generators`).

```
theorem reconstruct_of_generators {κ : Type*} (vac : V) (T : End ℂ V)
    (gen : κ → FormalDist (End ℂ V))
    (hgen : ∀ i, IsField (gen i))

    (fun l q hq => wordFld_vac_neg gen hgen vac hvn l q hq)
    hTvac (wordFld_cov gen hgen hcov)
```

From the mathematics to the Lean statement

`κ` is the index set K; `List κ` the words; `hgen` says each g_k is a field; `hloc` is (1); `hvn` is (2), since the z^q-coefficient with $q < 0$ applied to the vacuum must vanish; `hTvac` is $T\mathbf{1} = 0$; `hcov` is (3) (`DCovariant`, Definition 4.38); `hspan` is (4). The conclusion is an existential over a linear map `YA : V →ₗ[ℂ] FormalDist (End ℂ V)` with six conjuncts: $Y(s_l) = f_l$; fields; locality; $(YA\,u)_0\mathbf{1} = u$ (the z^0-coefficient on the vacuum is u); vanishing of negative powers on the vacuum; T-covariance. The term-mode proof is literally `reconstruct` applied to the family of all word states and word fields.

Comparison with the literature. This is the existence part of Kac's reconstruction theorem (*Vertex algebras for beginners*, Thm. 4.5) and of Frenkel–Ben-Zvi Thm. 4.4.1: from translation-covariant, mutually local generating fields whose monomials span, one gets a vertex algebra. Two differences. (i) Kac and FBZ use monomials in *all* negative modes $a^k_{(-j-1)}$; the library uses only (-1)-modes, so the family (g_k) must itself contain the derivatives (in U the letters are $T^j a/j!$, so this is automatic). (ii) The conclusion does not package a `PreVertexAlgebra`: no grading and no vacuum axiom $Y(\mathbf{1}) = \mathrm{id}$ are produced (the latter is the empty word: $Y(s_\varnothing) = f_\varnothing = \mathrm{id}$, so it does hold when $\mathbf{1}$ is a word state, which it always is). Uniqueness of Y is not stated; it follows from Goddard uniqueness. **Could it be vacuous?** No: the hypotheses are satisfiable by every library vertex algebra with its generating fields, and the library uses this theorem for the Moonshine fields (`VOA/Moonshine/VnatFields.lean` imports the file).

Proof on paper. Apply the operator-first reconstruction (Theorem 4.41) to the family $(s_l, f_l)_l$. Its hypotheses: the s_l span (4); each f_l is a field, because normal-ordered products of fields are fields; the f_l are pairwise local, because the set of fields generated from a pairwise-local set by normal-ordered products is pairwise local (Dong's lemma, packaged as `Core.LocalSystem.generated_local`, Chapter 4, Theorem 4.45); $f_l(z)\mathbf{1}$ has no negative powers and constant term s_l, by induction on l using (2) and the formula $:a(z)b(z):\mathbf{1} = a(z)_+b(z)\mathbf{1}$; and each f_l is T-covariant, because T-covariance is preserved by normal ordering (Leibniz rule for ∂_z). □

What the machine verified

Proved, unconditional; `#print axioms VOA.NonlinearConformal.reconstruct_of_generators`: standard three (run for this chapter).

Physical meaning

This is the form of reconstruction used whenever a chiral algebra is generated by finitely many fields: the states are the normal-ordered monomials $:g_{k_1}\cdots g_{k_r}:$ applied to the vacuum, which span the space of states. Every operator of the theory is a normal-ordered composite of the generating currents (for a W-algebra: of $T, W_3, \dots$, and their derivatives), and one has to check only the locality of the generators (finite-order poles in their OPEs), their translation covariance, and that the monomials span.

Two bridges, valid on any vector space, turn weight bookkeeping and an OPE table into the hypotheses of Theorem 11.46.

Theorem 11.47 (Fields from a weight filtration; locality from the OPE). 1. *If V is exhausted by subspaces F_d ($d \in \mathbb{Z}$) with $F_d = 0$ for $d < 0$, and the z^j-coefficient of a maps F_d into $F_{d+\Delta+j}$, then a is a field.*

2. *If $[a_{(m)}, b_{(n)}]$-type commutators are given by finitely many OPE coefficient fields $c_0, \dots, c_{N-1}$ through the falling-factorial (commutator) formula, then a and b are mutually local.*

File `VOA/Core/NonlinearConformal.lean`.

```
theorem isField_of_filt (a : FormalDist (End ℂ V)) (F : ℤ → Submodule ℂ V) (Δ : ℤ)
    (hbot : ∀ d : ℤ, d < 0 → F d = ⊥)
    (hcov : ∀ x : V, ∃ d : ℤ, x ∈ F d)
    (hmap : ∀ (j d : ℤ) (x : V), x ∈ F d → a j x ∈ F (d + Δ + j)) :
    IsField a := by

theorem local_of_ope (a b : FormalDist (End ℂ V)) (N : ℕ) (c : Fin N → FormalDist (End ℂ
↪  V))
    (h : ∀ m n : ℤ, a m * b n - b n * a m
        = ∑ j : Fin N, (∏ i ∈ Finset.range (j : ℕ), (-m - 1 - (i : ℤ))) • c j (m + n + 1 +
        ↪  j)) :
    Local a b := by
```

From the mathematics to the Lean statement

In (2), `a m`, `b n` are z^m-, w^n-coefficients; `∏ i ∈ Finset.range j, (-m - 1 - i)` is the falling factorial $(-m-1)(-m-2)\cdots(-m-j)$, i.e. $j!\binom{-m-1}{j}$; the hypothesis is the commutator formula $[a(z), b(w)] = \sum_{j<N} c_j(w)\partial_w^{(j)}\delta(z,w)$ written coefficientwise in the library's z-power indexing. `local_iff_deltaSum` (Chapter 2) converts it to locality of order N.

Proof on paper. (1) A vector of filtration degree d is killed by coefficients with $d + \Delta + j < 0$. (2) A finite sum of derivatives of $\delta(z-w)$ is annihilated by $(z-w)^N$. □

What the machine verified

Proved, unconditional; standard three. Neither bridge is used by the Virasoro instance below (which transports locality).

Physical meaning

(1) is the statement that a field of definite conformal weight acting on a state of finite energy can lower the energy only finitely often. (2) is the classic equivalence "finite singular OPE ⇔ locality".

11.7.5 The contract `GenFields`, and a refuted route

Definition 11.48 (Generating-field contract). For an admissible ideal M, a `GenFields M` is a family of fields $\{Y(p,z)\}$ on $U = \mathcal{T}(R)/M$, one per letter p, which are pairwise local, T_U-covariant, kill $|0\rangle$ in negative powers of z, and whose creation half is the one of Definition 11.43.

File `VOA/Core/NonlinearConformal.lean`.

```

From the mathematics to the Lean statement

The only freedom left in `fld` is the annihilation range (`cre` fixes all z^j, $j \geq 0$); `UR_YA` is Theorem 11.46 applied to `G.fld`, with spanning supplied by `wstU_span`. It is a theorem *conditional on a term* `G : GenFields M` (the `variable` binder). The only general witness, `emptyGenFields`, has no generators.

Physical meaning

`GenFields` is exactly what a physicist means by "the OPE defines the fields": it asks for the annihilation modes of each generator, compatible with the creation modes already present. Providing it for a nonlinear OPE in general is De Sole–Kac's Lemma 3.2 and §4 — the hard theorem.

Trap / dead end

Dead end: the left ideal M_{bot} is the wrong ideal (refuted in Lean). The original staging offered M_{bot} as the ideal over which to populate `GenFields`. For the Virasoro datum this is *false*:

```
theorem not_nonempty_genFields_MRbot_virasoro (c : ℂ) :
    ¬ Nonempty (GenFields (MRbot (virasoroOPE c))) := by
```

(`VOA/Core/NonlinearVirasoro.lean`). Reason: `cre` forces $L_{(-m-1)}$ to be left multiplication by $T^m L/m!$ for all $m \geq 0$, so $[L_{(-m-1)}, L_{(-n-1)}]$ is left multiplication by $g_m g_n - g_n g_m$ (with $g_k = T^k L/k!$). In a vertex algebra this commutator must be a finite combination of single modes, which requires the relation $\mathrm{rel}(g_m, g_n)$ to be usable *inside* a word, i.e. multiplied on the right. The coordinate of the length-three word $[g_{N+1}, g_0, g_0]$ vanishes on M_{bot} but locality of order N would force it to be ± 1. Accordingly M_{bot} is strictly smaller than the two-sided ideal (witness $\mathrm{rel}(L, TL) \cdot L$):

```
theorem MRbot_lt_MRtwo_virasoro (c : ℂ) :
    (MRbot (virasoroOPE c)).car < (MRtwo (virasoroOPE c)).car := by
```

Any theorem with a hypothesis `G : GenFields (MRbot _)` for the Virasoro datum is vacuous. Both statements: `#print axioms`: standard three. (In De Sole–Kac's own $M(R)$ the $D \neq 1$ generators supply exactly the missing right multiplications.)

Definition 11.49 (The two-sided relation ideal). M_{two} is the span of all $A \cdot \mathrm{rel}(p,q) \cdot B, A, B \in \mathcal{T}(R)$: the two-sided ideal generated by the relations. It is admissible.

noncomputable def MRtwo (D : OPEData ι) : MIdeal D where
```

From the mathematics to the Lean statement

For a *linear* datum (every OPE value in $\mathbb{C} \cdot 1 \oplus R$, as for Virasoro), De Sole–Kac's (3.1)–(3.2) give $N(X,D) = XD$ for $X \in R \oplus \mathbb{C}1$, so Definition 3.4 is exactly M_{two}; the library proves this reconciliation for any interface term (`MRfullCar_eq_MRtwoCar`, Section 11.8). For nonlinear data M_{two} is *not* De Sole–Kac's $M(R)$. The definition mentions only the OPE table (through `rel`): no model, no kernel of a map.

Physical meaning

For a Lie-algebra-like (linear) OPE such as Virasoro or affine currents, the presented chiral algebra is the universal enveloping algebra of the negative-mode Lie algebra: one may reorder modes anywhere inside a word using the commutation relations. That is exactly the two-sided ideal.

11.7.6 Generators plus OPE equals Borcherds, for Virasoro

Theorem 11.50 (The Virasoro relations in closed form; independence of c). *For the Virasoro datum and letters $g_k = T^k L/k!$:*

$$\mathrm{rel}(g_k, g_l) = g_k g_l - g_l g_k - (l-k)\, g_{k+l+2}.$$

In particular the relations, and hence M_{two}, do not depend on the central charge c.

File `VOA/Core/NonlinearVirasoro.lean`; the independence of M_{two} from c was checked in Lean against the library (the check is not part of this release).

```
theorem virasoro_rel (c : ℂ) (k l : ℕ) :
    rel (virasoroOPE c) ((), k) ((), l)
      = gv ((), k) * gv ((), l) - gv ((), l) * gv ((), k)
        - ((l : ℂ) - k) • gv ((), k + l + 2) := by
```

From the mathematics to the Lean statement

Under $g_k \mapsto L_{-k-2}$ this is the Witt bracket $[L_{-k-2}, L_{-l-2}] = (l-k)L_{-k-l-4}$ (no central term since $-k-l-4 \neq 0$). The central term of the OPE disappears because $\int_{-T}^{0}$ applies at least one T to $L_{(3)}L = \frac{c}{2} \cdot 1$, and $T1 = 0$. The check outside the library states the consequence: `MRtwoCar (virasoroOPE c) = MRtwoCar (virasoroOPE c')` for all c, c'.

Proof on paper. First take $l = 0$. By left sesquilinearity, $(g_k)_{(n)}L = \frac{(-1)^k}{k!} n(n-1)\cdots(n-k+1)\, L_{(n-k)}L$, so only $n = k$ ($L_{(0)}L = TL$), $n = k+1$ ($L_{(1)}L = 2L$) and $n = k+3$ (the central term)

contribute. Applying $\frac{(-1)^n}{(n+1)!}T^{n+1}$ gives $(k+2)g_{k+2}$, $-2(k+1)g_{k+2}$ and 0 (since $T^{k+4}1 = 0$), so $\int_{-T}^{0}[g_{k\,\lambda}L] = -k\,g_{k+2}$. The general case follows by induction on l using the T-equivariance of $\int_{-T}^{0}$ (the identity behind Theorem 11.42). □

What the machine verified

Proved, unconditional; standard three (library; the independence of M_{two} in the check outside the library).

Physical meaning

As a vector space, the universal Virasoro vacuum module is the same for all c (a PBW space on $L_{-2}, L_{-3}, \ldots$); the central charge lives entirely in the annihilation modes (L_n, $n \geq -1$) acting on it. So any "presentation" that only fixes the vector space and creation operators cannot see c.

Theorem 11.51 ($M_{\mathrm{two}} = \ker\Phi$; the presentation is the Virasoro VOA). *Let $\Phi : \mathcal{T}(R) \to V(c,0)$ be the linear map $g_{k_1}\cdots g_{k_r} \mapsto L_{-k_1-2}\cdots L_{-k_r-2}\mathbf{1}$ into the universal Virasoro vacuum module. Then:*

1. *$M_{\mathrm{two}} = \ker\Phi$; so $\bar{\Phi} : \mathcal{T}(R)/M_{\mathrm{two}} \to V(c,0)$ is a linear isomorphism;*
2. *the sorted word states $[g_{k_1}\cdots g_{k_r}]$, $k_1 \geq \cdots \geq k_r$, form a basis of $\mathcal{T}(R)/M_{\mathrm{two}}$ (spanning and independence);*
3. *there are generating fields* `genFieldsVirTwo c : GenFields (MRtwo (virasoroOPE c))`*, and an isomorphism $e : \mathcal{T}(R)/M_{\mathrm{two}} \to V(c,0)$ sending $|0\rangle \mapsto \mathbf{1}$, $T_U \mapsto L_{-1}$, and each generating field of g_k to $Y(L_{-k-2}\mathbf{1}, z)$ — in particular the field of g_0 to $Y(\omega, z)$;*
4. *the modes $L_m := (\text{field of } g_0)_{(m+1)}$ on $\mathcal{T}(R)/M_{\mathrm{two}}$ satisfy the Virasoro relations with central charge c, and $\mathcal{T}(R)/M_{\mathrm{two}}$ carries a* `PreVertexAlgebra` *structure whose vertex operator at g_k is the generating field (the library's pre-vertex algebra record* `PreVertexAlgebra`*, Chapter 4, which does not include translation covariance; it is not the library's translation-covariant* `VertexAlgebra` *of* `Core/GenuineVertexAlgebra.lean`*. Here it is transported from the VOA $V(c,0)$, so covariance holds by transport, but the type does not record it).*

From the mathematics to the Lean statement

`UVir` is the universal enveloping algebra of the Virasoro Lie algebra, `ι ℂ (L n)` the image of L_n in it, and `VirUniv c` the universal vacuum module $V(c,0)$ (Chapter 7, Definition 7.1); `psiVir` is the algebra map $g_k \mapsto L_{-k-2}$ and `PhiVir c X` the class of `psiVir X` applied to the vacuum. `wstUw c w` is the word state of the list w of indices; `SortedWord w` means w is weakly decreasing (Definition 7.7). `virYA c` is the vertex operator map of the universal Virasoro VOA (Theorem 7.11), `negWordVir c [k]` $= L_{-k-2}\mathbf{1}$, `Ltrans c` $= L_{-1}$, `virasoroVOA c` the universal Virasoro VOA (Definition 7.12). `conjDist e a` is the conjugated series $e^{-1} \circ a(z) \circ e$; `transportVA A e` transports a vertex algebra structure along a linear isomorphism.

What is genuine, and what is by construction. The ideal `MRtwo (virasoroOPE c)` is defined from the OPE table alone; (1) and (2) are honest theorems (spanning by a straightening argument in the quotient, which is where two-sidedness is used; independence imported from the `pbw`-free partition basis of Chapter 7). In (3)–(4), however, the fields are *defined* by conjugating the already constructed Y of $V(c,0)$ across $e = \tilde{\Phi}$ (`fldVirTwo`), and `virasoroURVATwo` is the transported `PreVertexAlgebra` (the library's record without translation covariance; it inherits covariance from $V(c,0)$ only because it is transported, and its type does not say so). So the field-matching clauses of `virasoro_presentation_equivalence_genuine` hold essentially by construction; their content is that the transported fields satisfy the contract — above all `cre`, which pins their creation half to left multiplication in the presentation (the numerical identity $\mathrm{dpow}((),k)\,n = \binom{k+n}{n} g_{k+n}$ against the coefficient of $\frac{1}{k!}\partial^k Y(\omega,z)$). The annihilation half is *not* derived from the OPE (De Sole–Kac Lemma 3.2 and §4 are not formalised; the docstrings say so), and `local_of_ope` is not used. Combined with Theorem 11.50, the honest summary is: *the vector space and the creation operators presented by one weight-two generator with the Virasoro OPE are those of $V(c,0)$, for every c; the vertex algebra structure on it is the transported one.* The theorem name "generators + OPE = Borcherds" (file headers) is therefore stronger than what is proved, though the proved statement is correct and non-circular.

Non-vacuity. $U \neq 0$ and the sorted monomials are independent, so the presentation is not the zero space; the Virasoro relations in (4) hold with the given c (this is where c re-enters, through the transported annihilation modes).

Proof on paper. Φ kills the relations because they are the Witt relations, which hold in $U(\mathrm{Vir})$;

and Φ is T-equivariant and left-$\mathcal{T}(R)$-linear, so $M_{\text{two}} \subseteq \ker\Phi$. For the converse, the swap identity $[g_n g_j W] = [g_j g_n W] + (j-n)[g_{n+j+2}W]$ in the quotient (a right multiple of a relation) and induction on the energy show that sorted words span $\mathcal{T}(R)/M_{\text{two}}$; their images $L_{-k_1-2}\cdots L_{-k_r-2}\mathbf{1}$ are linearly independent in $V(c,0)$ for every c (partition basis). So $\bar{\Phi}$ maps a spanning set bijectively onto an independent set: it is injective, and it is surjective because the creation monomials span $V(c,0)$. Everything else is transport of structure along $\bar{\Phi}$. □

What the machine verified

Proved, unconditional, pbw-free; `#print axioms` of `VOA.VirModule.MRtwo_eq_ker_PhiVir`, `…sortedWstUw_span`, `…sortedWordSt_linearIndependent_two`, `…virasoro_presentation_equivalence_genuine`, `…fldVirTwo_virasoro`, `…virasoroURVATwo`: standard three (run for this chapter). The earlier versions over `MVir c := ker Φ` (`virasoro_presentation_equivalence`, `genFieldsVir`; file `NonlinearVirasoroTransport.lean`) are circular by their own docstring and superseded by the "`Two`" versions.

Physical meaning

"The Virasoro algebra is generated by $T(z)$ with the TT OPE." What the library verifies is the counting half of that sentence: the states built from T and its derivatives, modulo the reordering relations dictated by the singular OPE, are exactly the Virasoro descendants of the vacuum, one for each partition into parts ≥ 2. The dynamical half — that the OPE alone determines the annihilation modes and their locality — is the content of the De Sole–Kac construction, which is staged but not completed.

11.7.7 Gradings on $\mathcal{T}(R)$: exact weight and the De Sole–Kac filtration

Definition 11.52 (Exact weight; conformal data; positive weight; the ζ-filtration). gr(d) is the span of words of weight exactly d; an OPE datum is *conformal* if $a^i_{(n)}a^j \in \mathrm{gr}(\Delta_i+\Delta_j-n-1)$; grPos is the span of words of positive weight. The ζ-*weight* of a letter $T^k a^i/k!$ is Δ_i (the power of T is ignored), and zfilt(d) is the span of words of ζ-weight $\leq d$.

Files `VOA/Core/NonlinearVirasoro.lean`, `VOA/Core/NonlinearZeta.lean`.

```
noncomputable def gr (wt : ι → ℕ) (d : ℕ) : Submodule ℂ (TR ι) :=
  Submodule.span ℂ (wbasis ι '' {w | wtWord wt w = d})

def OPEData.IsConformal (D : OPEData ι) : Prop :=
  ∀ i j (n : ℕ), D.ope i j n ∈ gr D.wt (D.wt i + D.wt j - n - 1)

noncomputable def grPos (wt : ι → ℕ) : Submodule ℂ (TR ι) :=
  Submodule.span ℂ (wbasis ι '' {w | 0 < wtWord wt w})

def zwtIdx : GenIdx ι → ℕ := fun p => wt p.1

noncomputable def zfilt (d : ℤ) : Submodule ℂ (TR ι) :=
  Submodule.span ℂ (wbasis ι '' {w | ((zwtWord wt w : ℤ)) ≤ d})
```

From the mathematics to the Lean statement

`IsConformal` is an *extra* predicate, so that genuinely non-conformal data (allowed by De Sole–Kac) remain expressible. In `IsConformal` the subtraction is in $\mathbb{N}$; for $n+1 > \Delta_i+\Delta_j$ the coefficient is already 0, so truncation imposes nothing.

Physical meaning

The exact weight is the conformal dimension L_0; positive weight means "not proportional to the identity". The ζ-weight counts how composite an operator is, ignoring derivatives.

Theorem 11.53 (Gradings: what holds). 1. *The Virasoro datum is conformal.*

2. *For conformal data,* $\mathrm{rel}(p,q)$ *is homogeneous of weight* $\Delta(p)+\Delta(q)$.

3. T *preserves* $\mathrm{zfilt}(d)$*, and the library's grading condition implies De Sole–Kac's:* $a^i_{(n)}a^j \in \mathrm{zfilt}(\Delta_i+\Delta_j-1)$.

4. $x \in \mathrm{grPos}$ *iff its weight-*0 *component vanishes.*

Files `VOA/Core/NonlinearVirasoro.lean`, `VOA/Core/NonlinearZeta.lean`.

```
theorem virasoroOPE_isConformal (c : ℂ) : (virasoroOPE c).IsConformal := by

theorem rel_mem_gr {D : OPEData ι} (hC : D.IsConformal) (p q : GenIdx ι) :
    rel D p q ∈ gr D.wt (wtIdx D.wt p + wtIdx D.wt q) := by

theorem mem_grPos_iff (wt : ι → ℕ) (x : TR ι) :
    x ∈ grPos wt ↔ grProj wt 0 x = 0 := by
```

From the mathematics to the Lean statement

`grProj wt 0 x` is the weight-0 component (a finite sum, computed from the word-basis coordinates). (3) is the precise sense in which `OPEData` feeds De Sole–Kac's Lemma 3.2 recursion, which runs on a filtration where T has degree 0: the library's conformal-weight filtration gives T degree $+1$, so a recursion on it could not terminate. The ζ results are unconditional but, by the file's own account, not yet used by any proof outside the interface fields `N_zfilt`, `P_zfilt` below.

Proof on paper. (1) Inspection of the table. (2) Each term of rel has weight $\Delta(p)+\Delta(q)$: the products by additivity, $T^{n+1}(p_{(n)}q)$ by the conformal condition plus $n+1$. (3) T changes only the T-power of a letter. Since $\zeta \le \Delta$ wordwise and $\Delta_i+\Delta_j-n-1 \le \Delta_i+\Delta_j-1$. (4) Decompose into weight components. □

What the machine verified

Proved, unconditional; standard three.

Physical meaning

Two different "sizes" of a composite operator: its conformal dimension (derivatives count) and its "number of constituents" weighted by the generators' dimensions (derivatives do not count). The second is the right induction parameter for constructing the normal-ordered product of composites, because differentiating does not make an operator more composite.

11.8 The non-linear layer: an interface with no instance

For OPE data whose singular terms contain genuine normally ordered products (the W_3 algebra, $\mathcal{N} = 2$ chiral algebras, nonlinear W-algebras), $M(R)$ cannot be written down without De Sole–Kac's Lemma 3.2. The library stages this "Stage A" as an *interface*: a structure listing all the properties of the extended normally ordered product N and bracket P, over which everything downstream is parametrised.

Trap / dead end

No instance of `NPExtension` exists anywhere in the library (open gap). A search of the whole of `VOA/` finds no term of type `NPExtension D` for any `D`; the existence–uniqueness theorem ("Stage B") is not formalised. Every theorem of this section that takes `NP : NPExtension D` as a hypothesis is therefore, as a Lean proposition, *vacuously true today*: it would remain provable if `NPExtension` were uninhabitable. The library's docstrings say exactly this ("every downstream statement quantified over `NP : NPExtension D` is a conditional whose antecedent nobody has supplied"). We have *not* checked that `NPExtension` is satisfiable; its 17 fields were audited against De Sole–Kac by the authors (per the docstring), and one near-inconsistency (the shared cutoff in `wickRight`) is documented there. A reader must treat this whole section as a precise *specification*, not as mathematics established in Lean.

Definition 11.54 (The extension interface, De Sole–Kac Lemma 3.2)**.** An `NPExtension D` consists of bilinear maps $N : \mathcal{T}(R) \times \mathcal{T}(R) \to \mathcal{T}(R)$ and $P : \mathcal{T}(R) \times \mathcal{T}(R) \to \mathcal{T}(R)^{\mathbb{N}}$ (the slices $P(A,B)(n) = A_{(n)}B$) satisfying: $N(1,A) = N(A,1) = A$; $N(a,B) = aB$ for a letter a; $P(1,A) = P(A,1) = 0$; P restricts to the OPE table on bottom letters; extended sesquilinearity $P(TA,B) = L(P(A,B))$, $P(A,TB) = R(P(A,B))$; T is a derivation of N; quasi-associativity, the left and right Wick formulas (De Sole–Kac (3.3), (3.6), (3.7), in slice form with explicit cutoffs); the grading bounds (3.8) in the ζ-filtration; and the conformal-weight termination bound $P(A,B)(n) \in \mathrm{filt}(\Delta A + \Delta B - n - 1)$.

```

From the mathematics to the Lean statement

`TR ι →ι[ℂ] TR ι →ι[ℂ] TR ι` is a bilinear map; `P A B n` is the coefficient of $\lambda^n/n!$ in $P_\lambda(A,B)$. `quasiAssoc`, `wickLeft` and `wickRight` transcribe (3.3), (3.6), (3.7) with finite cutoffs `m` justified by the vanishing hypotheses. The field docstring of `quasiAssoc` records a deliberate sign choice: the Koszul sign is $p(a,B)$ where De Sole–Kac's printed (3.3) has $p(a,b)$; the authors argue the printed sign is a misprint. `Tdiv k` is $T^k/k!$, `parWord D w` the parity of a word. The library derives `P_gv_eq_brk` (on letters, P is the bracket of Definition 11.39) and `P_eventually_zero` from these fields. **Fidelity.** 16 fields transcribe De Sole–Kac Lemma 3.2 / Lemma 4.2; `P_filt` is an addition (needed to make slices terminate). De Sole–Kac's Definition 3.1 also assumes the seed bracket is parity-preserving; `OPEData` does not, so the library names this as `OPEData.SeedParityCompatible` and proves it propagates to all letters (`brk_mem_parPiece`). Exact-weight gradedness of N, P is a separate mixin `NPGraded`.

Physical meaning

$N(A,B)$ is the normal-ordered product of two composite operators and $P(A,B)$ their full singular OPE; the Wick formulas are the rules for computing OPEs of composites (the "generalised Wick theorem" of Bais et al. used to compute W-algebra OPEs), and quasi-associativity is the rule for rebracketing nested normal-ordered products. Their existence and uniqueness for a non-linear Lie conformal algebra is the content of the De Sole–Kac construction.

Definition 11.55 (The full $M(R)$ over the interface). Given `NP`, the full Definition 3.4 generator is $\mathrm{relD}(p,q;B) = pqB - (-1)^{p(p)p(q)}qpB - N(\int_{-T}^{0}[p_\lambda q], B)$, and M_{full} is the span of all $A \cdot \mathrm{relD}(p,q;w)$ over words w.

theorem vacU_ne_zero_MRfull (hC : D.IsConformal) (hg : NPGraded NP) :
    vacU (MRfull NP).toMIdeal ≠ 0 :=
```

From the mathematics to the Lean statement

This is Definition 3.4 verbatim (with D ranging over the word basis, which suffices by linearity). For a linear datum (`IsLinear`: every OPE value in `linSub ι` $= \mathbb{C}1 \oplus \mathrm{span}\{\text{letters}\}$) the full ideal is M_{two}, for any interface term. `vacU_ne_zero_MRfull` is the graded non-vacuity guard, with hypotheses `IsConformal` and `NPGraded NP`. The closure of $M(R)$ under N and P on both sides (De Sole–Kac Cor. 4.5, which uses the Jacobi identity) is only stated, as the `Prop`-structure `NPClosure`. The docstring notes that the composite $M_{\text{full}} = \ker \Phi$ for Virasoro is not formalised (it would be one `Eq.trans` in an `Examples` file).

Proof on paper. For $X \in \mathbb{C}1 \oplus R$, $N(X, B) = XB$ by the two unit/letter axioms, and for linear data $\int_{-T}^{0}[p_\lambda q] \in \mathbb{C}1 \oplus R$, so $\mathrm{relD}(p, q; B) = \mathrm{rel}(p, q)B$. The augmentation kills positive-weight words. □

What the machine verified

Proved, *conditional on an* `NPExtension` *term, which does not exist*; `#print axioms` of `MRfullCar_eq_MRtwoCar`, `MRfull_virasoro`, `vacU_ne_zero_MRfull`: standard three. `virasoroOPE_isLinear` is unconditional.

Physical meaning

For a Lie-type OPE nothing nonlinear happens, and the general construction must reduce to the universal enveloping algebra of the mode Lie algebra; that consistency check is what is proved, modulo the existence of the general construction.

Definition 11.56 (Presentations with strong relations)**.** A `VAPresentation` is an OPE datum together with a finite list of homogeneous elements of $\mathcal{T}(R)$ of positive weight, the *strong relations* (null fields). Given `NP`, the relation ideal is the smallest subspace containing them and closed under T and under N and every slice of P on both sides; the presentation ideal is M_{full} + RelIdeal and the presented object is $\mathcal{T}(R)$ modulo it.

noncomputable def MPresCar : Submodule ℂ (TR ι) := MRfullCar NP ⊔ RelIdeal P NP

noncomputable abbrev UPres : Type u := UR (MPres P NP).toMIdeal
```

From the mathematics to the Lean statement

`relVal r` is the r-th relation as *literal data* (an explicit element of $\mathcal{T}(R)$, never a kernel); `relWt`, `relVal_homog` its weight and homogeneity. `relFin` (finiteness) is recorded but used by no theorem. `InRelIdeal` is an inductive predicate: the smallest set closed under the nine listed constructors. This is Linshaw's $M'(\mathcal{A})$-closure for degenerate non-linear conformal algebras.

Physical meaning

This is how a W-algebra or a quotient such as a minimal model is specified by physicists: generators, their OPEs, and the null fields that must be set to zero ("the null field $N = :TT: - \frac{3}{10}\partial^2 T$ vanishes" for Lee–Yang). The relation ideal is everything those null fields generate under OPE with anything.

Theorem 11.57 (L2 recovery; the vacuum guard and its counterexample)**.** *For every* `NP`*:*

1. *with no relations, the presentation ideal is M_{full}, and for linear data M_{two};*
2. *if the datum is conformal,* `NPGraded NP`*, and* `RelBracketVacuumFree` *(every bracket slice of an element of the relation ideal has no weight-0 component), then $|0\rangle \neq 0$ in the presented object;*
3. *for the Virasoro datum at $c \neq 0$ with the single relation ω (i.e. L),* $1 \in$ RelIdeal.

    (NP : NPExtension (virasoroOPE c)) :
    (1 : TR Unit) ∈ RelIdeal (omegaRelPresentation c) NP := by
```

From the mathematics to the Lean statement

In (3) the presentation `omegaRelPresentation c` lists L itself as a relation; then $P(L,L)(3) = \frac{c}{2} \cdot 1$ is in the relation ideal, so the vacuum dies. This refutes the design's "model-free" guard (conformal + homogeneous positive-weight relations $\Rightarrow 1 \notin M$), and shows that `RelBracketVacuumFree` is not implied by `IsConformal` and `NPGraded` (`not_relBracketVacuumFree_omegaRel`). **But** all four statements take `NP` as input, so — as the docstring stresses — as Lean propositions they "refute nothing by themselves" until an interface term exists. The mathematics behind (3) is unconditional: setting $T(z) = 0$ at $c \neq 0$ contradicts $T(z)T(w) \sim \frac{c/2}{(z-w)^4}$.

Proof on paper. (1) The inductive closure of the empty set is $\{0\}$. (2) Under the hypotheses, every generator of the presentation ideal lies in grPos, which the augmentation kills. (3) `pLeft` applied to the relation L with $A = L$, $n = 3$, and `P_bot`, give $\frac{c}{2} \cdot 1$; scale. □

What the machine verified

Proved, conditional on `NP : NPExtension …` (uninhabited); `#print axioms`: standard three. A recorded dead end (the model-free vacuum guard), refuted on paper unconditionally and in Lean conditionally.

Physical meaning

Imposing a null relation is safe only if the relation really is null in some consistent theory; an arbitrary positive-weight relation can generate the identity through its OPE. The stress tensor is the cleanest example: it is never null when $c \neq 0$.

Definition 11.58 (Evaluation, nullity certificates, `TheVOA`, realizations). For a VOA W and $g : \iota \to W$, $\mathrm{ev} : \mathcal{T}(R) \to W$ sends a word $(i_1, k_1) \cdots$ to $(T^{k_1} g_{i_1} / k_1!)_{(-1)} \cdots \mathbf{1}$. A relation is *null* for an invariant form B if its evaluation pairs to zero with everything. `TheVOA P NP W` is the simple quotient of a given VOA structure W on the presented space. A *realization* of a presentation in W is $g : \iota \to W$ with homogeneous images of the declared weights, satisfying the OPE list, killing the relations, and with spanning word states. `simple_realization_unique` is the proposition that any two simple realizations of a presentation are isomorphic as vertex algebras.

```

From the mathematics to the Lean statement

`InvariantForm W`, `IsFullyInvariant`, `Normalized` and Li's radical theorem are Chapter 5 (Definitions 5.48, 5.49, Theorem 5.57); `QuotVOA.maxGradedIdeal W` is the maximal proper graded ideal and `maxQuotientVOA` the simple quotient (Definition 5.20). `evTR` is defined by `Module.Basis.constr` on the word basis. `mem_maxGradedIdeal_of_null` is a genuine theorem: a null relation evaluates into the maximal ideal (Li's radical theorem).

Trap / dead end

`TheVOA` is not tied to its presentation (moderate), and the uniqueness statement is unproved (open gap). `TheVOA P NP W` takes as input an *arbitrary* `W : VertexOperatorAlgebra (UPres P NP)`: any VOA structure whatsoever on the underlying vector space of the presented object, with no requirement that its vertex operators extend the creation half, satisfy the OPE table, or kill the relations. Its value is `QuotVOA.maxQuotientVOA W`, which depends on `P` and `NP` only through the carrier type. So the name "THE vertex algebra of a presentation" is a convention attached to a datum the library cannot yet produce (the docstring says the structure "arrives via the `GenFields` contract and conformal data in later stages"), not a construction. And since `UPres P NP` needs `NP`, `TheVOA` has no instance at all. Separately, `simple_realization_unique` is a `def : Prop` — a statement, *not* a theorem — and nothing proves it; its intended proof route (universal property plus Li's theorem, after Roitman) is described only in prose. Note also that `RealizesPresentation` mentions only the non-negative products (`hOPE` for `n : ℕ`) and that the conclusion of `simple_realization_unique` preserves vacuum and all products but not the conformal vector.

Proof on paper (of `mem_maxGradedIdeal_of_null`). For a fully invariant normalised form, the radical is the maximal proper graded ideal (Li); a null vector lies in the radical. □

What the machine verified

`mem_maxGradedIdeal_of_null`, `relIdealNull_iff_forms_vanish`: proved; standard three. `TheVOA`: definition, no instance. `simple_realization_unique`: unproved proposition, no consumer.

Physical meaning

Nullity is the statement "this composite operator has zero two-point function with everything", which in a unitary or at least nondegenerate theory means it vanishes. "The" chiral algebra of a presentation is the simple quotient: the one in which every null field has been set to zero. Uniqueness of simple realizations is the mathematical form of "a chiral algebra is determined by its generators, their OPEs and its null relations" — believed by every physicist, and proved for lattice VOAs by Roitman, but not formalised here.

11.9 Li's Δ-operator on the Fock space

Two files filed with this chapter concern a different Li construction: the operator $\Delta(h,z)$ of Li (1997) that produces new (twisted, or charged) modules from old by $Y_\Delta(u,z) = Y(\Delta(h,z)u,z)$. On the rank-one Fock space $\mathbb{C}[X_0, X_1, \dots]$ of Chapter 6 (Definition 6.1), where $a_n = nk\,\partial/\partial X_{n-1}$ for $n \geq 1$

and $a_0 = 0$, $\Delta(\lambda, z) = z^{\lambda a_0}\exp\bigl(-\sum_{n\ge1}\frac{\lambda}{n}a_n(-z)^{-n}\bigr)$ is the substitution $X_i \mapsto X_i + \lambda k(-1)^i w^{i+1}$, $w = z^{-1}$.

Definition 11.59 (Li's Δ as a substitution, one and two variables). $\Delta_\lambda : \mathbb{C}[X_i] \to \mathbb{C}[w][X_i]$ is the algebra map $X_i \mapsto X_i + \lambda k(-1)^i w^{i+1}$. The two-variable version $\Delta^{(2)}_\lambda : \mathbb{C}[X_i] \to (\mathbb{C}[w][[z_0]])[X_i]$ substitutes the ι_{z,z_0}-expansion of $\lambda k(-1)^i (z+z_0)^{-i-1}$.

Files `VOA/Examples/LiDelta.lean`, `VOA/Examples/LiDelta2.lean`.

```
noncomputable def deltaCoeff (k lam : ℂ) (i : ℕ) : Polynomial ℂ :=
  Polynomial.C (lam * k * (-1) ^ i) * Polynomial.X ^ (i + 1)

noncomputable def deltaSub (k lam : ℂ) : Fock →ₐ[ℂ] FockW :=

noncomputable def deltaSub₂ (k lam : ℂ) : Fock →ₐ[ℂ] FockW₂ :=
  aeval fun i : ℕ => (X i : FockW₂) + MvPolynomial.C (deltaCoeff₂ k lam i)
```

From the mathematics to the Lean statement

`Polynomial.X` is w; `gBinom (-(i : ℤ) - 1) j` is $\binom{-i-1}{j}$, so `expandNegPow i` is $\sum_j \binom{-i-1}{j} w^{i+1+j} z_0^j = (z+z_0)^{-i-1}$ expanded in non-negative powers of z_0. The exponent check: $-\sum_n \frac{\lambda}{n} nk\,\partial_{X_{n-1}}(-1)^n z^{-n}$ translates X_{n-1} by $\lambda k(-1)^{n-1}w^n$, i.e. X_i by $\lambda k(-1)^i w^{i+1}$, matching `deltaCoeff`. Faithful.

Physical meaning

The substitution $X_i \mapsto X_i + \text{const}\cdot w^{i+1}$ is the effect of conjugating by a vertex operator of momentum λ: each oscillator acquires a classical background $\langle\partial^i\phi\rangle \propto \lambda z^{-i-1}$, the field of a charge at the origin.

Theorem 11.60 (Group law, inverse, specialisation). *$\Delta_\mu \circ \Delta_\lambda = \Delta_{\lambda+\mu}$ (as substitutions), Δ_0 is the inclusion, $\Delta_{-\lambda}\circ\Delta_\lambda$ is the inclusion, Δ_λ commutes with $\partial/\partial X_j$, and setting $z_0 = 0$ in $\Delta^{(2)}_\lambda$ gives Δ_λ.*

Files as above.

```
theorem deltaSubW_comp_deltaSub (k lam mu : ℂ) :
    ((deltaSubW k mu).restrictScalars ℂ).comp (deltaSub k lam) = deltaSub k (lam + mu) :=
    ↪ by

theorem deltaSubW_neg_comp_deltaSub (k lam : ℂ) :

theorem deltaSub_pderiv (k lam : ℂ) (j : ℕ) (p : Fock) :
    deltaSub k lam (MvPolynomial.pderiv j p)
      = MvPolynomial.pderiv j (deltaSub k lam p) := by

theorem deltaSub₂_specialize (k lam : ℂ) (p : Fock) :
    specializeZ₀ (deltaSub₂ k lam p) = deltaSub k lam p := by
```

From the mathematics to the Lean statement

`deltaSubW k μ` is the $\mathbb{C}[w]$-linear extension of Δ_μ to $\mathbb{C}[w][X_i]$; `restrictScalars ℂ` views it as $\mathbb{C}$-linear. `includeW` is the inclusion $\mathbb{C}[X] \to \mathbb{C}[w][X]$. `specializeZ₀` sets $z_0 = 0$ in the coefficients.

Proof on paper. Translations compose additively; partial derivatives commute with constant translations; $z_0 = 0$ in $(z + z_0)^{-i-1}$ gives z^{-i-1}. □

What the machine verified

Proved, unconditional; `#print axioms of VOA.Heisenberg.deltaSub₂_specialize, VOA.Heisenberg.deltaSubW_comp_deltaSub`: standard three. **Definitional layer only**: Li's conjugation identity $\Delta(\lambda, z)Y(u, z_0)\Delta(\lambda, z)^{-1} = Y(\Delta(\lambda, z + z_0)u, z_0)$ and the resulting charged module F_λ are not proved here (the file says so); consumers are `FockBC2.lean`, `FockBaseChange.lean` (Chapter 6).

Physical meaning

$\Delta(\lambda, z)$ is spectral flow by the $U(1)$ current: it shifts the zero mode a_0 by λk and turns the vacuum Fock module into the charged Fock module F_λ, the sector of momentum λ of the free boson. The group law is the additivity of momentum. It is the standard route to the first logarithmic modules (by differentiating in λ).

Lean declaration	Intended meaning	Hypotheses / status	Fidelity check
`PolynomialMatrix.kernel_pair_of_simple_root`	kernel pair at a simple determinant root	domain; unconditional	Thm. 11.34
`SparseRational.evalSparse_normalizeQ` etc.	certified sparse arithmetic	unconditional	Def. 11.36
`NonlinearConformal.OPEData`, `virasoroOPE`	De Sole–Kac Def. 3.1 (no Jacobi)	definition	Def. 11.38
`brk_mem_filt`, `Ttr_rel`	bracket grading; T-stability of relations	unconditional	Thms. 11.40, 11.42
`vacU_ne_zero_bot`	$\mathcal{T}(R)/M_{\mathrm{bot}} \neq 0$	unconditional	Thm. 11.44
`reconstruct_of_generators`	reconstruction from generating fields	local, covariant, spanning; unconditional	Thm. 11.46
`UR_YA`	vertex map on $\mathcal{T}(R)/M$	`G : GenFields M`	Def. 11.48
`not_nonempty_genFields_MRbot_virasoro`	refutes the M_{bot} route	**refutation**; unconditional	warning after Def. 11.48
`virasoro_rel` (+ c-independence checked outside the library)	Witt relations; c-independent	unconditional	Thm. 11.50
`VirModule.MRtwo_eq_ker_PhiVir`	presentation ideal $=\ker\Phi$	unconditional, `pbw`-free	Thm. 11.51
`VirModule.virasoro_presentation_equivalence_genuine`	$\mathcal{T}(R)/M_{\mathrm{two}} \cong V(c,0)$ with fields	unconditional; fields by transport	Thm. 11.51
`ope_mem_zfilt`, `rel_mem_gr`	gradings on $\mathcal{T}(R)$	unconditional (`IsConformal` for the latter)	Thm. 11.53
`NPExtension`	De Sole–Kac Lemma 3.2 interface	**no instance exists**	Def. 11.54
`MRfullCar_eq_MRtwoCar`, `vacU_ne_zero_MPres`, `one_mem_relIdeal_omegaRel`	full $M(R)$, vacuum guard, ω-counterexample	**vacuous today** (need `NP`)	Def. 11.55, Thm. 11.57
`mem_maxGradedIdeal_of_null`	null relations lie in the maximal ideal	fully invariant normalised form	Def. 11.58
`TheVOA`, `simple_realization_unique`	"the" VOA; uniqueness of simple realizations	**arbitrary input W; unproved `Prop`**	warning in §11.8
`Heisenberg.deltaSub`, `deltaSub₂_specialize`	Li's Δ (spectral flow) as substitution	unconditional; definitional layer	Thm. 11.60

Entries in **bold** in the third column are the ones a referee must not miss: a structure with no instance (so theorems over it are vacuous today), an unproved `Prop`, a refuted route, or a hypothesis narrower than the literature.

All `#print axioms` results quoted in this chapter were obtained at an earlier commit (the snapshot against which the chapter was first written; later re-probes are stated where they were made) by running scratch files that import the relevant modules, with `lake env lean -DmaxSynthPendingDepth=3` (never a bare `lake env lean`); they were not re-run for this edition, and no full `lake build` was run for this chapter. Every library declaration checked reports `[propext, Classical.choice, Quot.sound]` (one reports only `[propext, Quot.sound]`); none uses `VOA.pbw`. The Lean checks of this chapter made outside the library (the coarse good filtration, the first theorem without `hLW`, the c-independence of M_{two}, and $F^1V = C_2(V)$) compiled with the same command and the same three axioms; they are not part of this release.

The declarations of Section 11.5 were checked at an earlier commit on the branch `deligne-lean` (the commit at which that section's quotations were first taken), not re-run for this edition. A scratch file importing `VOA.Filtered.AffineSl2GeneratorCurrentInstance` was run with the same command; it printed the axioms of the eleven declarations named in that section's status boxes and

compiled the Lean check of the warning box (`hdec` forces C_2-cofiniteness). All report `[propext, Classical.choice, Quot.sound]`. That check is not part of this release.

Project records. The staging of the presentation layer (Stages A1–A5 and the deferred Stage B) is documented in the module docstrings of `NonlinearConformal.lean`, `NonlinearVirasoro.lean`, `NonlinearZeta.lean`, `NPExtension.lean`, `NonlinearMR.lean`,

`VAPresentation.lean`, `PresentationDoctrine.lean` and of the two Virasoro example files. The Lean checks of this chapter made outside the library are not part of this release.

Part III

Representation theory

Chapter 12

Modules, Zhu's algebra, and the rationality hierarchy

This chapter documents the release of the LeanVOA library named in the front matter; it was first written against an earlier state of the library ("the snapshot" below), and checks that were run at an earlier state of the library and not re-run for this edition are marked as such. Every Lean quotation below is taken from the files of the release and is machine-checked by `scripts/textbook/sync.py` to occur verbatim (up to whitespace and comments) in the source. The chapter covers the files assigned to it in `Notes/Textbook/assignment.txt`: all of `VOA/Modules/` except the roughly three hundred files `VOA/Modules/ZhuVerma*.lean` (the Frenkel–Zhu tower and the hard direction of Zhu's correspondence, Chapter 13), the super-module files `VOA/Modules/Super*.lean` (Chapter 17), the three Poisson-trace files (Chapter 16) and `VOA/Modules/FZBimodule.lean` (Chapter 42). About fifty files and sixteen thousand lines of Lean remain. Where a statement of this chapter needs a definition that lives in one of those other files (the Frenkel–Zhu spaces $A_n(V)$, the quotient $\mathrm{HP}_0(R_V)$ of Arakawa–Kawasetsu, the subspaces $C_m(V)$), we quote the definition here, with its file, so that the chapter is self-contained.

Release revision. The chapter was revised for the first public release, applying the release audit `Notes/Textbook/referee/RELEASE_AUDIT_ZHU.md` (2026-10-27). The changes concern the use made of this chapter's rationality predicates by Zhu's modularity theorem (Chapter 15) and the status of the two halves of Zhu's correspondence (Chapter 13); no quotation of this chapter changed.

Second release revision (2026-10-28). The chapter was revised again, applying finding F2 of `Notes/Textbook/referee/RELEASE_AUDIT_NEW_DECLS.md`. The first release revision said that the implication "rational $\Rightarrow$ $A(V)$ semisimple", this chapter's named predicate `ZhuAdmissibleSemisimple`, was unproved. That was false. The library proves it (`isSemisimpleRing_A_of_admissiblyRational` and `zhuAdmissibleSemisimple_of_Pr`, in `VOA/Huang/ZhuSemisimple.lean`), and Zhu's modularity theorem is now stated for C_2-cofinite rational V (Chapter 15). The new quotation (Theorem 12.39) was copied at that revision; no older quotation changed.

Third release revision (2026-10-28). The chapter was revised once more, for the file `VOA/Classification/COne/LiteratureInputsProved.lean`, which this chapter now documents. Earlier revisions said that the library does not prove the structure theorems of Dong–Li–Mason, Abe–Buhl–Dong and Li, and carries all seven of them as named hypotheses. That is no longer true. Of the seven named literature predicates of Section 12.9.3, six are theorems of the library: four for every VOA (`ABDWeakIsAdmissible`, `ABDIrreducibleWeakIsOrdinary`, `ABDRegularOfC2AndRational`, `ZhuAdmissibleSemisimple`) and two for every C_2-cofinite VOA (`DLMSimpleAdmissibleOrdinary`, `DLMFinitelyManyIrredAdmissible`); only `LiC2CofiniteOfRegular` (H. Li's "regular $\Rightarrow$ C_2-cofinite") is unproved, together with the two DLM predicates for VOAs that are not C_2-cofinite. The new material is Theorem 12.40; the status boxes of the rationality lattice and of strong rationality, and the checklist, were corrected accordingly. No older quotation changed.

Chapter 1 introduced, briefly, weak modules, ordinary modules, Zhu's product, the space $O(V)$,

Zhu's algebra $A(V)$, the zero-mode action on a lowest-weight space and the library's notion of intertwining operator. We do not repeat those definitions in full; we recall them in Section 12.1 and refer back. This chapter goes further in five directions:

1. the *full ladder of module categories* used in the literature — weak, admissible ($\mathbb{N}$-gradable), logarithmic (grading-restricted generalised) and ordinary — and the theorems relating them (Section 12.2);
2. the *associative algebra* $A(V)$, which the library proves associative unconditionally, its action on lowest-weight spaces, the forward half of Zhu's correspondence, and a Zhu-algebra simplicity criterion (Section 12.4);
3. C_2*-cofiniteness*, the Poisson algebra $V/C_2(V)$, finite generation, the Frenkel–Zhu and Dong–Li–Mason higher Zhu algebras $A_n(V)$ and their finiteness under C_2 (Sections 12.5 and 12.6);
4. the *contragredient module* M', which the library constructs in full (Section 12.7), and the library's fusion coefficient, which we prove to be identically zero (Section 12.8);
5. the *rationality hierarchy*: regular, admissibly rational ("rational"), Gannon-rational, holomorphic, strongly finite and strongly rational, and the implications among them, together with the structure theorems of Dong–Li–Mason, Abe–Buhl–Dong and Li, stated as named predicates; all but one of these (Li's theorem) are now proved in the library, the two DLM ones for C_2-cofinite V (Section 12.9).

The findings of this chapter, in brief. Most of what is documented here is faithful to the literature and is proved without hypotheses, axiom-clean, and without `VOA.pbw` (the PBW theorem of Chapter 3; formerly a project axiom, now a theorem). The fidelity checks did, however, turn up several definitions that do not mean what their names say. We list them here so that a reader skimming the chapter does not miss them; each is explained in a red warning box where it occurs.

- `VOA.fusionCoeff` is *identically zero*. Chapter 1 argued this on paper; we have now proved it in Lean (library theorem `fusionCoeff_eq_zero`, Theorem 12.33). No theorem of the library uses `fusionCoeff`, so nothing proved becomes false or vacuous.
- `VOA.Unitary` ("unitary module") is *unsatisfiable* on every module of dimension at least two (library theorem `old_unitary_isEmpty`, Proposition 12.31), and `VOA.SelfContragredient` is satisfied by *every* module (the library itself proves this). Neither has a consumer.
- `VOA.InducedAssignment`, the interface through which the file `VOA/Modules/ZhuInduced.lean` expresses "the hard direction of Zhu's correspondence", is *uninhabited* (the library proves `not_nonempty_inducedAssignment`), so the round-trip theorems stated with it are vacuous. The genuine bijection is proved elsewhere (Chapter 13).
- `VOA.IsLowestWeight N h` does not require $M_h \neq 0$, and requires *all* weights to lie in the single coset $h + \mathbb{N}$. Theorems with this hypothesis are true but become statements about the zero space when $M_h = 0$.
- **Rationality implies that $A(V)$ is semisimple, in Lean.** The named predicate `ZhuAdmissibleSemisimple` ("rational $\Rightarrow$ $A(V)$ semisimple") is a theorem, for every V: `isSemisimpleRing_A_of_admissiblyRational` (Theorem 12.39). So Zhu's modularity theorem (Chapter 15) holds in Lean for every C_2-cofinite V that satisfies the library's rationality predicate `AdmissiblyRational`, in particular for the strongly rational lattice VOAs $V_{\sqrt{2m}\mathbb{Z}}$ (Chapter 22). For C_2-cofinite V, Dong–Li–Mason rationality implies `AdmissiblyRational` (`admissiblyRational_of_dlmRational`, Theorem 12.36); what remains open is only the converse (Section 12.9.2). *Correction:* the first release revision of this chapter said that the implication was unproved and that $V_{\sqrt{2m}\mathbb{Z}}$ was not covered; both claims were wrong.

- **Six of the seven named literature predicates are theorems.** Abe–Buhl–Dong's Proposition 5.7, Corollary 5.8 and Theorem 4.5 (hard direction) and Zhu's semisimplicity theorem hold in Lean for every V; Dong–Li–Mason's Theorem 8.1(b),(c) hold for every C_2-cofinite V (Theorem 12.40). Consequently a strongly rational VOA is regular and Gannon-rational with no literature hypothesis (`StronglyRational.regular`, `StronglyRational.gannonRational'`). Only H. Li's "regular $\Rightarrow$ C_2-cofinite" (`LiC2CofiniteOfRegular`) remains a named, unproved hypothesis, and the one theorem of this chapter that uses it is the equivalence `regular_iff_c2Cofinite_and_admissiblyRational`.

- The library's $A_n(V)$ (file `VOA/Modules/ZhuVermaAn.lean`) omits the generators $(L_{-1}+L_0)u$ that Dong–Li–Mason include in $O_n(V)$, so it surjects onto, and may be larger than, the literature's $A_n(V)$; and the library's `A₂ W` is *not* the second higher Zhu algebra but Zhu's C_2-quotient $V/C_2(V)$.

12.1 Conventions recalled

Throughout, V denotes a vertex operator algebra in the sense of the library (the Lean `W : VertexOperatorAlgebra 𝒱` with underlying vector space $\mathcal{V}$); Chapter 1, Section 4.3, and Chapter 4 give the definition. We recall the features that matter in this chapter.

- $V = \bigoplus_{n\in\mathbb{Z}} V_n$ with each V_n finite-dimensional, $V_n = 0$ for $n < 0$ and $V_0 = \mathbb{C}\mathbf{1}$. These are *structure fields* of every library VOA (`positivity`, `vacuum_grade`, `finrank`); so every VOA in the library is of *CFT type*. Many literature theorems about modules assume CFT type; here it is automatic. In particular the zero vector space with $\mathbf{1} = 0$ is a library VOA (the "zero VOA"), which is why simplicity hypotheses often have to be carried to exclude it.

- The n-th product is $u_{(n)}v$, written `W.smul u n v`. For a formal series $f = \sum_k f_k z^k$ the library writes `mode f n` for the coefficient f_{-n-1}, so that `mode (Y u) n` is the operator $u_{(n)}$ in the expansion $Y(u,z) = \sum_n u_{(n)} z^{-n-1}$. The Virasoro operators are $L_n = \omega_{(n+1)}$, written `W.L n`; in particular $L_0 = \omega_{(1)}$ and $L_{-1} = \omega_{(0)}$.

- `cbz m i` is the generalised binomial coefficient $\binom{m}{i}$ for $m \in \mathbb{Z}$ and $i \in \mathbb{Z}$, equal to 0 when $i < 0$; `negOnePow i` is $(-1)^i$. A sum `∑ᶠ i, f i` is a sum over the (finite) support of f; Mathlib assigns it the value 0 if the support is infinite, so every time such a sum appears in an *axiom* one must check that the support is finite (the dictionary of Definition 12.1 does this for the module Jacobi identity).

- `Submodule ℂ X` is a linear subspace of X; `⊥` and `⊤` are the zero subspace and the whole space; `DirectSum.IsInternal w` says that X is the internal direct sum of the family of subspaces $w(\alpha)$; `FiniteDimensional ℂ X` and `Module.finrank ℂ X` are finite-dimensionality and dimension (Mathlib's convention: `finrank` of an *infinite*-dimensional space is 0). `X ⧸ S` is the quotient space.

From Chapter 1 we use: `WeakModule` (Definition 12.1), with action $u^M_{(n)}x$ = `A.act u n x` = `mode (A.YM u) n x`; `OrdVModule` (Definition 12.5) with weight spaces `N.weight α` $= M_\alpha$; the adjoint module (Definition 12.6); Zhu's product `zhuMul`, `O W`, `A W` (Definition 40.1); the zero mode `oMod` and `IsLowestWeight` (Definition 40.4); Zhu's multiplicativity theorem on the lowest-weight space (Theorem 12.16); and the library's intertwiners (Definition 12.32). Weak submodules `WeakModule.Submodule'` are subspaces stable under every $u^M_{(n)}$, and `WeakModule.Hom` are linear maps commuting with every $u^M_{(n)}$. A *sub-VOA* `VOASubalgebra W` (Chapter 1, Section 5.4) is a graded subspace containing $\mathbf{1}$ and ω and closed under all products; `S.toVOA` is the VOA it carries.

Physical meaning

Throughout, the physical dictionary is the one of Chapter 1, Section 1.7: V is the *chiral algebra* of a two-dimensional conformal field theory (the holomorphic fields and their operator product expansions), $u_{(n)}$ are the Laurent modes of the field $Y(u,z)$, L_0 measures conformal weight (energy on the cylinder is $L_0 - c/24$), and CFT type says that the vacuum is the unique state of weight 0 and that there are no states of negative energy. A *module* is a *sector* (a superselection sector, a representation of the chiral algebra on a space of states created by a non-vacuum primary field). This chapter is about the representation theory of the chiral algebra, i.e. about the *spectrum of sectors* of a CFT.

12.2 The ladder of module categories

The literature on vertex operator algebras uses (at least) four notions of "module", which form a chain of inclusions

$$\text{ordinary} \subseteq \text{logarithmic} \subseteq \text{admissible} \subseteq \text{weak}.$$

They differ only in what is demanded of a grading. A weak module has none. An admissible module has an auxiliary $\mathbb{N}$-grading compatible with the modes, but its pieces may be infinite-dimensional and L_0 need not act semisimply. A logarithmic module is graded by *generalised* eigenspaces of L_0, each finite-dimensional. An ordinary module is graded by honest eigenspaces of L_0, each finite-dimensional. Rationality conditions are statements of the form "every module of such-and-such kind is completely reducible", and the kind matters, so we must be precise about all four.

12.2.1 Weak modules and the derivative property

Physically, a module over a VOA V is a *sector* of the chiral CFT: a space of states on which all fields of V act, with the same operator product expansions, but which is not itself created from the vacuum. We begin with the weakest notion, which has no grading at all.

Definition 12.1 (Weak module; Gannon Def. 5.3.1, FHL). Let V be a VOA. A *weak V-module* is a vector space M together with a linear map $Y_M : V \to \mathrm{End}(M)[[z^{\pm 1}]]$, $Y_M(u,z) = \sum_{n \in \mathbb{Z}} u^M_{(n)} z^{-n-1}$, such that

(M1) $Y_M(\mathbf{1}, z) = \mathrm{id}_M$;

(M2) each $Y_M(u,z)$ is a field: for all $u \in V$ and $x \in M$, $u^M_{(n)} x = 0$ for $n \gg 0$;

(M3) the Borcherds (Jacobi) identity holds: for all $u, v \in V$, $x \in M$ and $\ell, m, n \in \mathbb{Z}$,

$$\sum_{i \geq 0} (-1)^i \binom{\ell}{i} \Big(u^M_{(\ell+m-i)} v^M_{(n+i)} x - (-1)^\ell v^M_{(\ell+n-i)} u^M_{(m+i)} x \Big) = \sum_{i \geq 0} \binom{m}{i} (u_{(\ell+i)} v)^M_{(m+n-i)} x.$$

File `VOA/Modules/WeakModule.lean`.

```

(`VOA.WeakModule`, `VOA.WeakModule.act`; `act` lies in the namespace `WeakModule`.)

From the mathematics to the Lean statement

`(End ℂ M)⟦z^±⟧` is the space `FormalDist (End ℂ M)` of doubly infinite series of endomorphisms (Definition 2.1); `mode (YM u) n` is $u^M_{(n)}$, the coefficient of z^{-n-1} (Definition 2.7); `YM W.vacuum = 1` uses the unit distribution $\mathrm{id}_M z^0$, i.e. (M1); `truncation` is (M2), the field condition (Definition 2.43) in mode indexing: "there is N such that $u_{(n)}x = 0$ for all $n \geq N$"; `jacobi` is (M3), word for word the same formula as `VertexOperatorAlgebra.jacobi` (Theorem 4.26), where the *algebra* product $u_{(\ell+i)}v$ on the right is `W.smul u (ℓ + i) v`. `negOnePow i * cbz ℓ i` is $(-1)^i\binom{\ell}{i}$ and `cbz m i` the binomial $\binom{m}{i}$ with the convention that it vanishes for $i < 0$ (Definition 2.14). `A.act u n x` is the module action $u^M_{(n)}x$.

The ∑ᶠ convention in an axiom. Here the Jacobi identity is an *axiom*, and an axiom stated with ∑ᶠ could be weaker than intended if a sum had infinite support (the sum would then be read as 0, and the axiom would assert $0 = \cdots$). It does not happen: both supports are finite for every weak module. On the left, $i < 0$ gives $\binom{\ell}{i} = 0$, for $i \geq 0$ large $v^M_{(n+i)}x = 0$ and $u^M_{(m+i)}x = 0$ by (M2). On the right, $i < 0$ gives $\binom{m}{i} = 0$ and $u_{(\ell+i)}v = 0$ for $i \gg 0$ by the regularity axiom of V. So the axiom is the intended one.

Why Jacobi rather than locality. For a module, locality of the fields $Y_M(u,z)$ together with (M1)–(M2) does *not* imply the Jacobi identity: the relation between $Y_M(u_{(n)}v,z)$ and $Y_M(u,z)$, $Y_M(v,z)$ is extra information, and there is no vacuum in M to run the Goddard argument (Theorem 4.14). The library therefore takes the Jacobi identity as the axiom, as do Frenkel–Huang–Lepowsky, Lepowsky–Li (Def. 4.1.1) and Gannon. This is the standard definition.

What is not required, and why that is harmless. No Virasoro axiom and no L_{-1}-derivative axiom is imposed on M. The Virasoro relations for $L^M_n = \omega^M_{(n+1)}$ follow from (M3) and the VOA axioms of V, and the L_{-1}-derivative property is proved below (Theorem 12.3). **Could the definition be vacuous?** The zero space is a weak module, and so is V itself (Definition 12.6); the axioms are consistent and have the intended examples. Weak homomorphisms (`WeakModule.Hom`: linear maps commuting with every $u_{(n)}$) and weak submodules (`WeakModule.Submodule'`: subspaces stable under every $u_{(n)}$) are defined in the same file in the evident way.

Physical meaning

A weak module is a space of states M on which the fields $Y_M(u,z)$ act with the same Jacobi identity as in the vacuum sector: an algebraic shadow of a superselection sector, namely the space generated from the origin by an operator that is not itself in the vacuum module. The Jacobi identity contains both the commutation relations of the modes and the operator product expansion (the right side involves the OPE coefficients $u_{(\ell+i)}v$ of V). It is "weak" because no energy grading is demanded, so it also admits unphysical sectors with energy unbounded below; the physical sectors are the graded modules of Definition 12.5.

What the machine verified

Definitions; axiom-clean (`#print axioms` of `VOA.WeakModule` and `VOA.WeakModule.act` is `[propext, Classical.choice, Quot.sound]`, run for this chapter with `lake env lean -DmaxSynthPendingDepth=3`). Satisfiable: the adjoint module is an instance.

Theorem 12.2 (Module commutator formula). *For a weak module M, all $u, v \in V$, $x \in M$ and $m, n \in \mathbb{Z}$,*

$$u^M_{(m)}v^M_{(n)}x - v^M_{(n)}u^M_{(m)}x \;=\; \sum_{i\geq 0}\binom{m}{i}(u_{(i)}v)^M_{(m+n-i)}x,$$

a finite sum.

File `VOA/Modularity/ZhuRecursionProof.lean`.

```
theorem mode_commutator (A : WeakModule W M) (u v : 𝒱) (x : M) (m n : ℤ) :
    mode (A.YM u) m (mode (A.YM v) n x) - mode (A.YM v) n (mode (A.YM u) m x)
      = ∑ᶠ i : ℤ, cbz m i • mode (A.YM (W.smul u i v)) (m + n - i) x
```

From the mathematics to the Lean statement

This is the formula $[u_{(m)}, v_{(n)}] = \sum_i \binom{m}{i}(u_{(i)}v)_{(m+n-i)}$ of Theorem 4.21 on M instead of V (the declaration is `VOA.mode_commutator`, to be distinguished from the VOA-level `VOA.VertexOperatorAlgebra.mode_commutator`). Unlike the VOA-level statement it is stated as an identity on a vector x with a $\sum^{\mathrm{f}}$, not with an existential bound N. The `finsum` is a genuine finite sum for the same reasons as in Definition 12.1: $\binom{m}{i} = 0$ for $i < 0$ and $u_{(i)}v = 0$ for $i \gg 0$. **Hypotheses:** M is a weak module; nothing else. The statement is the textbook one, FHL, Lepowsky–Li (§4.1) and Gannon (§5.3.1). A version with an explicit finite range is `act_comm` in `VOA/Moonshine/VnatBlock.lean`.

Physical meaning

The modes of the fields satisfy the same commutation relations on every sector as on the vacuum module: the current algebra $[J_m, J_n] = km\delta_{m+n}$ or the Virasoro algebra with the same central charge c acts on every representation. This is the statement that the operator product expansion of chiral fields is a property of the algebra of local operators and not of the state on which they act, and it is the origin of the universal Ward identities that hold in all sectors.

Proof on paper. Put $\ell = 0$ in (M3). Since $\binom{0}{i} = \delta_{i,0}$, the left side collapses to its $i = 0$ term, $u^M_{(m)}v^M_{(n)}x - v^M_{(n)}u^M_{(m)}x$, and the right side is $\sum_i \binom{m}{i}(u_{(i)}v)^M_{(m+n-i)}x$. □

What the machine verified

Unconditional. `#print axioms VOA.mode\_commutator = [propext, Classical.choice, Quot.sound]` (run for this chapter).

Recall the definition of a weak module (Definition 12.1): a linear map $Y_M : V \to \mathrm{End}(M)[[z^{\pm 1}]]$ with $Y_M(\mathbf{1}, z) = \mathrm{id}$, lower truncation, and the Jacobi (Borcherds) identity in all indices. No L_{-1}-derivative axiom is imposed, because it follows. The library proves this.

Theorem 12.3 (Derivative property on a weak module). *Let M be a weak V-module. For all $a \in V$, $n \in \mathbb{Z}$, $x \in M$,*

$$(L_{-1}a)^M_{(n)}x = -n\, a^M_{(n-1)}x,$$

i.e. $Y_M(L_{-1}a, z) = \partial_z Y_M(a, z)$.

File `VOA/Modules/Translation.lean`.

```
theorem act_T_covariance (A : WeakModule W M) (a : 𝒱) (n : ℤ) (x : M) :
    A.act (W.L (-1) a) n x = (-(n : ℂ)) • A.act a (n - 1) x := by
```

From the mathematics to the Lean statement

`A.act u n x` is $u^M_{(n)}x$; `W.L (-1) a` is $L_{-1}a$; `(-(n : ℂ)) • y` is $-n\,y$ (the integer n cast to $\mathbb{C}$). There are no hypotheses beyond "M is a weak module". The generating-function form: $\partial_z \sum_n a_{(n)}z^{-n-1} = \sum_n (-n-1)a_{(n)}z^{-n-2} = \sum_n (-n)a_{(n-1)}z^{-n-1}$, whose coefficient of z^{-n-1} is exactly the right-hand side. So the statement is the textbook one (Lepowsky–Li, Prop. 4.1.5; Frenkel–Huang–Lepowsky, §4.1), with no weakening.

Proof on paper. Put $m = 0$ in the module Jacobi identity. Since $\binom{0}{i} = \delta_{i,0}$, the right-hand side becomes $(u_{(\ell)}v)^M_{(n)}x$ and the identity is the *iterate formula*

$$(u_{(\ell)}v)^M_{(n)}x = \sum_{i\ge 0}(-1)^i\binom{\ell}{i}\Big(u^M_{(\ell-i)}v^M_{(n+i)}x - (-1)^\ell v^M_{(\ell+n-i)}u^M_{(i)}x\Big).$$

In V we have $L_{-1}a = a_{(-2)}\mathbf{1}$ (creation property). Take $u = a$, $v = \mathbf{1}$, $\ell = -2$. On a module $\mathbf{1}^M_{(k)} = \delta_{k,-1}$, so of the two infinite families only the term $i = -1-n$ of the first and $i = n-1$ of the second survive (when they have $i \ge 0$). Their coefficients are $(-1)^{-1-n}\binom{-2}{-1-n}$ and $-(-1)^{n-1}\binom{-2}{n-1}$, and using $\binom{-2}{j} = (-1)^j(j+1)$ one checks that in every case (whether $n \le -1$, $n \ge 1$ or $n = 0$) the total coefficient of $a^M_{(n-1)}x$ is $-n$. □

What the machine verified

Proved, no hypotheses. `#print axioms VOA.act_T_covariance` gives `[propext, Classical.choice, Quot.sound]` (run for this chapter).

Physical meaning

The derivative property says that the field $Y_M(L_{-1}a, z)$ of the descendant $L_{-1}a$ is the derivative of the field of a in *every* sector: L_{-1} generates translations $z \mapsto z + \epsilon$ in all representations, not only in the vacuum sector. Physically it is the statement that the stress tensor's L_{-1} is the momentum operator, and a sector that violated it would not be translation covariant. It is the module half of the conformal Ward identity.

12.2.2 Admissible ($\mathbb{N}$-gradable) modules

Definition 12.4 (Admissible module; Zhu 1996, §1.4; Dong–Li–Mason 1998, Def. 2.2)**.** An *admissible* V-module is a weak module M together with a decomposition $M = \bigoplus_{k\in\mathbb{N}} M(k)$ such that for every homogeneous $a \in V_w$, every $p \in \mathbb{Z}$ and every k,

$$a^M_{(p)}M(k) \subseteq M(k + w - p - 1)$$

(with $M(j) = 0$ for $j < 0$). It is *irreducible* if $M \neq 0$ and its only weak submodules are 0 and M; *completely reducible* if every weak submodule has a complementary weak submodule.

File `VOA/Modules/AdmissibleModule.lean`.

```
structure AdmissibleModule (W : VertexOperatorAlgebra 𝒱) (M : Type v)
    [AddCommGroup M] [Module ℂ M] extends WeakModule W M where

  isInternal : DirectSum.IsInternal lev
  act_lev : ∀ ⦃w p k : ℤ⦄ ⦃a : 𝒱⦄, a ∈ W.grading w → ∀ ⦃x : M⦄, x ∈ lev k →
    mode (YM a) p x ∈ lev (k + (w - p - 1))
```

```
def IsIrreducible (N : AdmissibleModule W M) : Prop :=
  Nontrivial M ∧ ∀ P : WeakModule.Submodule' N.toWeakModule, P.carrier = ⊥ ∨ P.carrier = ⊤

def IsCompletelyReducible (N : AdmissibleModule W M) : Prop :=
  ∀ P : WeakModule.Submodule' N.toWeakModule,
    ∃ Q : WeakModule.Submodule' N.toWeakModule, IsCompl P.carrier Q.carrier

def adjointAdmissibleModule (W : VertexOperatorAlgebra 𝒱) : AdmissibleModule W 𝒱 where
  toWeakModule := adjointWeakModule W
  lev := W.grading
```

From the mathematics to the Lean statement

Decoding. `extends WeakModule W M` means an admissible module *is* a weak module (its field `toWeakModule`) plus data. `lev k` is $M(k)$; the grading is indexed by $\mathbb{Z}$ with the negative pieces forced to be zero (`lev_eq_bot_of_neg`), which is an $\mathbb{N}$-grading in $\mathbb{Z}$ bookkeeping (it avoids truncated subtraction in $k + w - p - 1$). `a ∈ W.grading w` says $a \in V_w$. The binders ⦃ ⦄ are "strict implicit" arguments: the statement is the same universally quantified statement. `IsCompl P Q` says $P \cap Q = 0$ and $P + Q = M$. `Nontrivial M` says $M \neq 0$.
Same as the literature? The structure is DLM's Definition 2.2 (= Zhu's "$\mathbb{N}$-gradable weak module") with two conventions to note.

1. DLM sometimes add $M(0) \neq 0$ when $M \neq 0$ (a normalisation of the grading). The library does not; this only enlarges the class by allowing shifts of the grading, and changes nothing about which weak modules are admissible.

2. *Irreducible* and *completely reducible* quantify over *weak* submodules (any subspace stable under all modes), not over *graded* submodules. DLM's "simple admissible" means *graded*-simple ("0 and M are the only graded submodules"), and their complete reducibility means "direct sum of graded-simple admissible submodules". So the library's irreducibility is *stronger* than DLM's (fewer modules count as irreducible) and the relationship between the two complete-reducibility notions is discussed in the warning in Section 12.9.2 below.

The adjoint module V with $M(k) = V_k$ is admissible (`adjointAdmissibleModule`; the mode shift is the grading axiom of V), so the category is never empty.

Physical meaning

An admissible module is a sector whose states come in levels $M(0), M(1), \ldots$ above a ground floor, with modes $a_{(p)}$ of a weight-w field raising the level by $w - p - 1$ (so $a_{(w-1)}$, the zero mode, preserves it). It is the minimal structure one needs to talk about "the ground states" of a sector without yet assuming that the Hamiltonian L_0 is diagonalisable or that each level has finite degeneracy. In logarithmic CFT, where L_0 has Jordan blocks, admissible modules are the natural home of the indecomposable sectors.

What the machine verified

Definitions; the adjoint instance is proved. `#print axioms` of the file's declarations: `[propext, Classical.choice, Quot.sound]` (file docstring; we re-ran it for the downstream theorems below).

12.2.3 Ordinary modules, and the global lower bound

Definition 12.5 (Ordinary module; irreducible; completely reducible; Gannon Def. 5.3.1(c))**.** A *V-module* (an *ordinary* module) is a weak module M together with a decomposition $M = \bigoplus_{\alpha\in\mathbb{C}} M_\alpha$ such that $L_0^M = \omega_{(1)}^M$ acts on M_α as the scalar α, each M_α is finite-dimensional, and the real parts of the weights α with $M_\alpha \neq 0$ are bounded below. It is *irreducible* if $M \neq 0$ and its only weak submodules are 0 and M, and *completely reducible* if every weak submodule has a complementary weak submodule.

File `VOA/Modules/WeakModule.lean`.

```
structure OrdVModule (W : VertexOperatorAlgebra 𝒱) (M : Type v)
    [AddCommGroup M] [Module ℂ M] extends WeakModule W M where

    ∃ Q : WeakModule.Submodule' N.toWeakModule, IsCompl P.carrier Q.carrier
```

(`VOA.OrdVModule`, `VOA.OrdVModule.IsIrreducible`, `VOA.OrdVModule.IsCompletelyReducible`; the last two lie in the namespace `OrdVModule`.)

From the mathematics to the Lean statement

Name. `OrdVModule` ("ordinary V-module") avoids a clash with Mathlib's `Module`. `extends WeakModule W M` means that an ordinary module *is* a weak module (the field `toWeakModule`) together with the extra data. **Fields.** `weight α` is the subspace M_α; `isInternal` says that M is the internal direct sum of the M_α; `L0_weight` says $L_0^M = \alpha$ on M_α (`mode (YM ω) 1` is $\omega_{(1)}^M = L_0^M$); together these make M_α exactly the α-eigenspace of L_0^M, so that L_0^M is diagonalisable (if $L_0 x = \alpha x$ and $x = \sum x_\beta$, then $(\beta-\alpha)x_\beta = 0$ for all β, so $x = x_\alpha$); `finrank` gives finite-dimensional weight spaces; `boundedBelow` is a *global* real bound $B \le \operatorname{Re}\alpha$ on all occurring weights (`α.re` is the real part). **Predicates.** `Nontrivial M` says that M has two distinct elements, i.e. $M \neq 0$; `P.carrier = ⊥ ∨ P.carrier = ⊤` says that the underlying subspace of the weak submodule P is 0 or M; `IsCompl P Q` says $P \cap Q = 0$ and $P + Q = M$. Both `IsIrreducible` and `IsCompletelyReducible` quantify over *weak* submodules (`WeakModule.Submodule'`: subspaces stable under every $u_{(n)}$), not merely graded ones. For ordinary modules this is the standard meaning, since every weak submodule of an ordinary module is automatically graded (it is stable under $L_0 = \omega_{(1)}$, and L_0 is diagonalisable on M).

Fidelity. The same as the standard definition (FHL, Lepowsky–Li Def. 4.1.6, Gannon Def. 5.3.1(c)) with complex weights; some authors (Dong–Li–Mason) require weights in $h + \mathbb{N}$, which is a special case. The one deviation is the global lower bound (the warning in Section 12.2): the library demands one real bound for *all* weights, which is stronger than the coset-wise condition of FHL. A twisted sector with weights in $\frac{3}{2} + \frac{1}{2}\mathbb{Z}$ is *not* an `OrdVModule` of the untwisted algebra; it is a `TwistedModule` (Chapter 34). **Could the definition be vacuous?** The adjoint module (Definition 12.6) is an `OrdVModule`, and the Moonshine sectors are further examples, so the class is non-empty; and the notions `IsIrreducible`, `IsCompletelyReducible` are satisfiable (the adjoint module is irreducible exactly when V is simple, see Definition 12.34). The distinction from the admissible versions of the same names is in Definition 12.4.

Physical meaning

An ordinary module is a physical sector: a graded Hilbert space of states $M = \bigoplus_\alpha M_\alpha$ with M_α the eigenspace of L_0 of conformal weight α and finite degeneracy. The weights are the scaling dimensions of the primary and descendant states, and on the cylinder the energy of a state is $L_0 - c/24$. Irreducibility means that no proper subspace of states is closed under all the modes, i.e. the sector is a single irreducible representation of the chiral algebra and cannot be split into independent superselection sectors. For a rational CFT the irreducible modules are the finitely many superselection sectors, they label the primary fields, and their characters (Definition 12.13) are the building blocks of the partition function. Finite dimensionality of each M_α is the statement of a discrete spectrum with finite degeneracy.

Proof on paper. There is no theorem to prove: these are definitions. The only claim made in the dictionary, that every weak submodule of an ordinary module is graded, follows because a weak submodule P is stable under $L_0^M = \omega_{(1)}^M$; for $x = \sum_\alpha x_\alpha \in P$ the vectors $(L_0^M)^k x = \sum_\alpha \alpha^k x_\alpha$ lie in P, and a Vandermonde argument on the finitely many nonzero components shows that each $x_\alpha \in P$. □

What the machine verified

Definitions; axiom-clean (`#print axioms` of `VOA.OrdVModule`, `VOA.OrdVModule.IsIrreducible` and `VOA.OrdVModule.IsCompletelyReducible` is `[propext, Classical.choice, Quot.sound]`, run for this chapter). The global lower bound is a recorded design choice (moderate); see the warning in Section 12.2.

Definition 12.6 (Adjoint module)**.** Every VOA V is a module over itself, the *adjoint module*, with $Y_V = Y$ and weight spaces $V_\alpha = V_n$ if $\alpha = n \in \mathbb{Z}$ and $V_\alpha = 0$ if $\alpha \notin \mathbb{Z}$.

File `VOA/Modules/WeakModule.lean`.

```
def adjWeight (W : VertexOperatorAlgebra 𝒱) (α : ℂ) : Submodule ℂ 𝒱 :=
  ⨆ (n : ℤ) (_ : (n : ℂ) = α), W.grading n

def adjointWeakModule (W : VertexOperatorAlgebra 𝒱) : WeakModule W 𝒱 where
  YM := W.Y
  vacuum_YM := W.vacuum_Y
  truncation := fun u x => W.regularity u x
  jacobi := W.jacobi

def adjointModule (W : VertexOperatorAlgebra 𝒱) : OrdVModule W 𝒱 where
  toWeakModule := adjointWeakModule W
  weight := adjWeight W
```

(`VOA.adjWeight`, `VOA.adjointWeakModule`, `VOA.adjointModule`. The remaining fields of `adjointModule` (`isInternal`, `L0_weight`, `finrank`, `boundedBelow`) are proofs and are omitted.)

From the mathematics to the Lean statement

`adjWeight W α` is the supremum, over all integers n with $(n : \mathbb{C}) = \alpha$, of V_n: it equals V_n at $\alpha = n$ and 0 at every non-integer α (the library proves `adjWeight_cast` and `adjWeight_eq_bot`). This re-indexes the integer grading of V by the complex weights that an ordinary module requires. Here the one-line proof terms are informative: the Jacobi axiom of the adjoint weak module is *literally* the theorem `W.jacobi` (Theorem 4.26), the truncation axiom is VA5 (regularity), and `vacuum_YM` is the vacuum axiom $Y(\mathbf{1}, z) = \mathrm{id}$. The fields of `adjointModule` that were omitted use the VOA data: `isInternal` is the direct-sum decomposition of V, `L0_weight` is $L_0 v = nv$ on V_n, `finrank` is $\dim V_n < \infty$, and `boundedBelow` follows from $V_n = 0$

for $n < 0$ (CFT type). So the adjoint module is the honest one, and $u^V_{(n)}x = u_{(n)}x$.

Physical meaning

The adjoint module is the algebra acting on itself: the vacuum sector, whose states are those created from the vacuum by the fields of the algebra itself (the state–field correspondence). It is the identity sector among the superselection sectors (the vacuum representation), and in the fusion product it plays the role of the unit: $V \times M = M$.

Proof on paper. (That V is an ordinary module.) (M1) is the vacuum axiom of V, (M2) is regularity (VA5), (M3) is the Borcherds identity of Theorem 4.26, for which $Y_M = Y$ makes both sides literally the same. $L_0^V = \omega_{(1)}$ acts as n on V_n by the axiom (VOA2), the V_n are finite-dimensional by the VOA axioms, $V_n = 0$ for $n < 0$ gives the lower bound $B = 0$, and the sum is direct. □

What the machine verified

Unconditional. `#print axioms` of `VOA.adjointWeakModule` and `VOA.adjointModule` is `[propext, Classical.choice, Quot.sound]` (run for this chapter).

Ordinary modules (Lean `OrdVModule`) were defined in Definition 12.5: a weak module with $M = \bigoplus_{\alpha\in\mathbb{C}} M_\alpha$, $L_0 = \alpha$ on M_α, $\dim M_\alpha < \infty$, and $\exists B \in \mathbb{R}$ with $\operatorname{Re}\alpha \geq B$ whenever $M_\alpha \neq 0$. We add one fidelity remark that Chapter 1 did not make.

Trap / dead end

The lower bound is global, not per coset (moderate, design choice). Frenkel–Huang–Lepowsky and Lepowsky–Li require, for a module with complex weights, only that *for each* α one has $M_{\alpha+n} = 0$ for all sufficiently negative integers n ("truncation in each coset of $\mathbb{Z}$"). The library's field `boundedBelow` demands one real bound B for *all* weights. The two agree for modules whose weights lie in finitely many cosets $\alpha + \mathbb{Z}$ — in particular for every irreducible module and every finite direct sum of them — but an infinite direct sum $\bigoplus_{j\geq 1} M^{(j)}$ of irreducibles whose lowest weights h_j lie in distinct cosets with $\operatorname{Re} h_j \to -\infty$ is an FHL module and *not* an `OrdVModule`. Consequences: a statement "every `OrdVModule` is completely reducible" (Gannon's clause (1) below) quantifies over *fewer* modules than the FHL statement, hence is formally weaker. The library records the same choice for logarithmic modules (docstring of `VOA/Modules/LogVModule.lean`); for ordinary modules it is not mentioned. No theorem in this chapter depends on the difference.

Lemma 12.7 (Modes shift weights; lowering modes kill the bottom). *Let M be an ordinary module, $v \in V_\beta$, $x \in M_\alpha$, $n \in \mathbb{Z}$. Then $v^M_{(n)}x \in M_{\alpha+\beta-n-1}$. If moreover every weight of M lies in $h+\mathbb{N}$, $x \in M_h$ and $n \geq \beta$, then $v^M_{(n)}x = 0$.*

File `VOA/Modules/ZeroModeMult.lean`.

```
theorem mode_mem_weight (N : OrdVModule W M) {β : ℤ} {v : V} (hv : v ∈ W.grading β)
    {α : ℂ} {x : M} (hx : x ∈ N.weight α) (n : ℤ) :
    mode (N.YM v) n x ∈ N.weight (α + (β : ℂ) - n - 1) := by

theorem mode_lowering_vanish (N : OrdVModule W M) {h : ℂ} (hcw : IsLowestWeight N h)
    {β : ℤ} {v : V} (hv : v ∈ W.grading β) {x : M} (hx : x ∈ N.weight h) {n : ℤ}
    (hn : β ≤ n) : mode (N.YM v) n x = 0 := by
```

From the mathematics to the Lean statement

The first statement is the commutator $[L_0, v_{(n)}] = (\beta - n - 1)v_{(n)}$ on M in eigenvector form; the second uses `IsLowestWeight N h` (Definition 12.14 below): the target weight $h+\beta-n-1$ is not of the form $h + k$ with $k \in \mathbb{N}$ when $n \geq \beta$, so the target space is zero. Same as the textbook (it is the standard consequence of the commutator formula with ω; see Lepowsky–Li, §4.1, and the proof of Zhu 1996, Theorem 2.1.2).

Proof on paper. The module commutator formula (Theorem 12.2) with $u = \omega$, $m = 1$ gives $[L_0, v_{(n)}] = \sum_i \binom{1}{i}(\omega_{(i)}v)_{(n+1-i)} = (L_{-1}v)_{(n+1)} + (L_0 v)_{(n)} = (-(n+1) + \beta)v_{(n)}$ by Theorem 12.3. Hence $L_0 v_{(n)}x = (\alpha + \beta - n - 1)v_{(n)}x$, and since L_0 is diagonal with eigenspaces M_γ, an eigenvector of eigenvalue γ lies in M_γ (library lemma `eigenvector_mem_weight`). The vanishing statement follows. □

What the machine verified

Proved, no hypotheses beyond those displayed; axiom-clean (part of the dependency cone of `oMod_zhuMul_lowest_all`, whose `#print axioms` we ran).

Physical meaning

A mode $v_{(n)}$ of a field of weight β changes the energy by $\beta - n - 1$: modes with $n < \beta - 1$ create excitations, $n = \beta - 1$ is the zero mode (a conserved charge on each energy level) and $n > \beta - 1$ annihilate. On the ground states of a sector, all annihilation modes vanish: this is the defining property of a *primary* state, and it is what makes Zhu's algebra act on the ground states alone.

12.2.4 Logarithmic modules

In logarithmic conformal field theory L_0 is not diagonalisable on some sectors: it has Jordan blocks, and correlation functions acquire logarithms $\log z$. The appropriate module notion is the *grading-restricted generalised module* of Huang–Lepowsky–Zhang.

Definition 12.8 (Logarithmic module; Huang–Lepowsky–Zhang; McRae Def. 2.4)**.** A *logarithmic* V-module is a weak module M with $M = \bigoplus_{\alpha \in \mathbb{C}} M_{[\alpha]}$ such that every $x \in M_{[\alpha]}$ is annihilated by some power of $L_0 - \alpha$, every $M_{[\alpha]}$ is finite-dimensional, and $\operatorname{Re}\alpha$ is bounded below on the nonzero pieces.

File `VOA/Modules/LogVModule.lean`.

```
structure LogVModule (W : VertexOperatorAlgebra 𝒱) (M : Type v)
    [AddCommGroup M] [Module ℂ M] extends WeakModule W M where
  weight : ℂ → Submodule ℂ M
  isInternal : DirectSum.IsInternal weight
  weight_le_maxGenEigenspace :
    ∀ α : ℂ, weight α ≤ (mode (YM W.conformalVector) 1).maxGenEigenspace α
  finrank : ∀ α, FiniteDimensional ℂ (weight α)
  boundedBelow : ∃ B : ℝ, ∀ α : ℂ, weight α ≠ ⊥ → B ≤ α.re
```

From the mathematics to the Lean statement

`mode (YM W.conformalVector) 1` is $L_0^M = \omega_{(1)}^M$. For an endomorphism T, `T.maxGenEigenspace α` is Mathlib's *generalised eigenspace* $\{x : (T-\alpha)^k x = 0 \text{ for some } k\}$. The only difference from `OrdVModule` is that `weight_le_maxGenEigenspace` replaces "$L_0 = \alpha$ on M_α". Only one inclusion is demanded; the library proves the other (Theorem 12.9), so the

grading is not extra data. The lower bound is global, with the same caveat as for ordinary modules (the library's docstring records it): HLZ and McRae truncate per coset.
Same as the literature? Same as HLZ's grading-restricted generalised module and McRae's Definition 2.4, up to the global-versus-per-coset lower bound. The Jacobi identity is required in its usual form; the L_{-1}-derivative property, which HLZ list, is automatic (Theorem 12.3).
Could it be vacuous, or collapse to ordinary modules? Every ordinary module is logarithmic (`OrdVModule.toLog`), so the class is non-empty. Whether the library contains a module with $L_0^{\mathrm{nil}} \neq 0$ is the subject of the triplet chapter (Chapter 18); in this chapter we only use the definition.

Physical meaning

In a logarithmic CFT (the triplet models $W(p)$, symplectic fermions, critical percolation and polymers) the Hamiltonian L_0 has Jordan blocks: there are pairs of states (ϕ, ψ) with $L_0\phi = h\phi$ and $L_0\psi = h\psi + \phi$. The two-point function then contains $\log z$, and the partition function must be completed by *pseudo-traces*. A logarithmic module is a sector of such a theory; the generalised eigenspace $M_{[h]}$ collects all states whose energy is h "up to nilpotent mixing".

Theorem 12.9 (The logarithmic grading is canonical; Jordan decomposition of L_0)**.** *For a logarithmic module M: (i) $M_{[\alpha]}$ equals the full generalised α-eigenspace of L_0; (ii) writing L_0^{ss} for the operator acting as α on $M_{[\alpha]}$ and $L_0^{\mathrm{nil}} = L_0 - L_0^{\mathrm{ss}}$, the two commute, L_0^{nil} is locally nilpotent, and M is an ordinary module (with the same grading) if and only if $L_0^{\mathrm{nil}} = 0$.*

File `VOA/Modules/LogVModule.lean`.

```
theorem weight_eq_maxGenEigenspace (N : LogVModule W M) (α : ℂ) :

    N.IsL0Semisimple ↔ N.L0nil = 0 := by

def LogVModule.toOrd (N : LogVModule W M) (h : N.IsL0Semisimple) : OrdVModule W M where
```

From the mathematics to the Lean statement

`N.L0op` is L_0^M. `L0ss` is defined by decomposing $x = \sum_\beta x_\beta$ (the internal direct sum gives the components, by choice, hence `noncomputable`) and returning $\sum_\beta \beta x_\beta$: this is L_0^{ss}. $*$ on `Module.End` is composition. `toOrd` turns an L_0-semisimple logarithmic module into an ordinary one with the same weak module and grading, and the library proves the round trips

`toOrd_toLog`, `toLog_toOrd` by `rfl`. So ordinary modules are *exactly* the logarithmic modules with $L_0^{\mathrm{nil}} = 0$; this is the intended statement.

Proof on paper. (i) If y is a generalised α-eigenvector, decompose $y = \sum_\beta y_\beta$ along the grading; $y - y_\alpha$ is both a generalised α-eigenvector and a sum of generalised β-eigenvectors with $\beta \neq \alpha$. Generalised eigenspaces for distinct eigenvalues are independent, so $y = y_\alpha \in M_{[\alpha]}$. (ii) L_0 preserves each generalised eigenspace and L_0^{ss} is a scalar on it, so they commute; on $M_{[\alpha]}$, $L_0^{\mathrm{nil}} = L_0 - \alpha$, which is locally nilpotent there; and $L_0^{\mathrm{nil}} = 0$ says precisely that $L_0 = \alpha$ on each $M_{[\alpha]}$. □

What the machine verified

Proved, no hypotheses. `#print axioms` of `VOA.LogVModule.weight_eq_maxGenEigenspace` and `VOA.LogVModule.isL0Semisimple_iff_L0nil_eq_zero`: `[propext, Classical.choice, Quot.sound]`.

Physical meaning

$L_0 = L_0^{\mathrm{ss}} + L_0^{\mathrm{nil}}$ is the Jordan decomposition of the Hamiltonian. The torus amplitude of a logarithmic sector is tr $q^{L_0^{\mathrm{ss}} - c/24} e^{2\pi i \tau L_0^{\mathrm{nil}}}$-type expressions; the nilpotent part is what produces the factors of τ (equivalently $\log q$) in logarithmic characters, and its vanishing is exactly the statement that the sector is an ordinary, non-logarithmic one.

12.2.5 Every ordinary module is admissible

An ordinary module comes with a $\mathbb{C}$-grading, not an $\mathbb{N}$-grading. To compare rationality conditions over the two categories one needs to manufacture an admissible grading on the same weak module.

Theorem 12.10 (Ordinary $\subseteq$ admissible; Dong–Li–Mason, Lemma 3.4 at $g = 1$)**.** *Every ordinary module M admits an $\mathbb{N}$-grading $M = \bigoplus_k M(k)$, on the same weak module, satisfying the admissibility axiom of Definition 12.4.*

Files `VOA/Modules/AdmissibleRationality.lean` (the predicate) and `VOA/Modules/RationalityLattice.lean` (the theorem).

```
def OrdVModule.HasAdmissibleRefinement {W : VertexOperatorAlgebra 𝒱} {M : Type v}
    [AddCommGroup M] [Module ℂ M] (N : OrdVModule W M) : Prop :=
  ∃ lev : ℤ → Submodule ℂ M,
    (∀ k : ℤ, k < 0 → lev k = ⊥) ∧ DirectSum.IsInternal lev ∧
      ∀ ⦃w p k : ℤ⦄ ⦃a : 𝒱⦄, a ∈ W.grading w → ∀ ⦃x : M⦄, x ∈ lev k →
        mode (N.YM a) p x ∈ lev (k + (w - p - 1))

theorem OrdVModule.hasAdmissibleRefinement {W : VertexOperatorAlgebra 𝒱} {M : Type u}
    [AddCommGroup M] [Module ℂ M] (N : OrdVModule W M) : N.HasAdmissibleRefinement := by
```

From the mathematics to the Lean statement

`HasAdmissibleRefinement` lists exactly the three admissible-module fields for the weak module `N.toWeakModule`; it is stated as a proposition about the same weak module so that the two notions of complete reducibility are literally about the same subspaces. The carrier is required to live in the universe `Type u` of V (a bookkeeping restriction of Lean's type theory; every module of interest is there). Same as DLM Lemma 3.4 (untwisted case).

Proof on paper. Let B be the global lower bound. Put $M(k) = \bigoplus\{M_\alpha : \lfloor \mathrm{Re}\,\alpha - B \rfloor = k\}$. Nonzero pieces have $\mathrm{Re}\,\alpha \geq B$, so $M(k) = 0$ for $k < 0$. Regrouping an internal direct sum along any

map of index sets is again an internal direct sum. If $a \in V_w$ and $x \in M_\alpha$, then $a_{(p)}x \in M_{\alpha+w-p-1}$ (Lemma 12.7), and since $w-p-1$ is an *integer*, $\lfloor \mathrm{Re}(\alpha+w-p-1)-B \rfloor = \lfloor \mathrm{Re}\,\alpha - B \rfloor + w - p - 1$. □

(This is where the *global* bound is convenient: with a per-coset bound one would choose a base point in each coset of $\mathbb{C}/\mathbb{Z}$.) A related, weaker statement is in the same file: `OrdVModule.hasAdmissibleRefinement_of_isLowestWeight`, which takes $M(k) = M_{h+k}$ when all weights lie in $h + \mathbb{N}$.

What the machine verified

Proved, no hypotheses; `#print axioms VOA.OrdVModule.hasAdmissibleRefinement` = `[propext, Classical.choice, Quot.sound]`. The library also packages it as a definition `OrdVModule.toAdmissible : AdmissibleModule W M`.

Physical meaning

Every physical sector, with its energy grading, can be viewed as a sector with "levels": group the energy eigenspaces by the integer part of their energy above the vacuum floor. Since fields shift energies by integers, they shift levels by the same integers. This is why statements about all admissible sectors (rationality) automatically say something about all ordinary sectors.

12.2.6 Submodules, morphisms, exact sequences

Three small pieces of infrastructure are used later.

- **Submodules of ordinary modules are graded.** If P is a weak submodule of an ordinary module M, then $P = \bigoplus_\alpha (P \cap M_\alpha)$ and P is an ordinary module with these weight spaces (`OrdVModule.submodule` in `VOA/Modules/OrdSubmodule.lean`, proved, axiom-clean). The reason: P is L_0-stable, and an L_0-stable subspace of a space on which L_0 is diagonalisable with given eigenspaces contains the eigencomponents of each of its vectors (Vandermonde). Consequently, for *ordinary* modules "irreducible" and "completely reducible" mean the same whether one uses weak or graded submodules — the subtlety of the warning in Section 12.9.2 below is specific to admissible modules.

- **Morphisms and short exact sequences** are the subject of the next proposition.

Proposition 12.11 (Graded dimension is additive on short exact sequences). *If $0 \to A \xrightarrow{f} B \xrightarrow{g} C \to 0$ is a short exact sequence of ordinary modules with weight-preserving module maps, then $\dim B_\alpha = \dim A_\alpha + \dim C_\alpha$ for every α, i.e. $\chi_B = \chi_A + \chi_C$ as formal q-series.*

File `VOA/Modules/OrdinaryExact.lean`.

```
structure Hom (A : OrdVModule W M) (B : OrdVModule W N) where
  toWeakHom : A.toWeakModule.Hom B.toWeakModule
  map_weight : ∀ (α : ℂ) {m : M}, m ∈ A.weight α →
    toWeakHom.toLinearMap m ∈ B.weight α

structure ShortExact (f : Hom A B) (g : Hom B C) : Prop where
  injective : Function.Injective f.toLinearMap
  exactAt : ExactAt f g
  surjective : Function.Surjective g.toLinearMap

theorem gradedDim_eq_add (h : ShortExact f g) :
    gradedDim B = gradedDim A + gradedDim C := by
```

From the mathematics to the Lean statement

`ExactAt f g` is "range f = kernel g" pointwise (`exactAt_iff_range_eq_ker`). `gradedDim` is the formal character (Definition 12.13). Weight preservation is explicit data in `Hom`; it is in fact automatic for module maps between ordinary modules (they commute with L_0; compare `ModuleEquiv.maps_weight` below), so carrying it costs nothing. Same as the standard statement. The companion file `VOA/Modules/OrdinaryComplex.lean` develops cochain complexes of ordinary modules, weight homology, and a coefficientwise Euler–Poincaré identity (`EulerWindowSupport.eulerCharacter_eq`); exactness of any concrete resolution is *not* claimed there.

Proof on paper. Restricted to weight α the sequence is a short exact sequence of finite-dimensional vector spaces (weight preservation and the internal decompositions); apply rank–nullity. □

What the machine verified

Proved; `#print axioms VOA.OrdVModule.Hom.ShortExact.gradedDim_eq_add` = `[propext, Classical.choice, Quot.sound]`.

Physical meaning

Characters count states level by level, so they are additive in exact sequences: a sector built as an extension of two others has the sum of their partition functions. This is why characters cannot detect whether an extension splits, and why in logarithmic and non-rational theories the characters of irreducibles must be supplemented by finer data (pseudo-traces, or Euler characteristics of resolutions such as Felder's).

12.2.7 Restriction to a sub-VOA

Definition 12.12 (Restriction; Gannon §5.3). Let $S \subseteq V$ be a sub-VOA (containing $\mathbf{1}$ and the conformal vector ω). Any weak (resp. ordinary) V-module M becomes a weak (resp. ordinary) S-module by restricting Y_M to S, with the same weight spaces.

Files `VOA/Modules/ModuleRestrict.lean`, `VOA/Modules/ModuleRestrictOrd.lean`.

```
noncomputable def restrictWeakModule {M : Type v} [AddCommGroup M] [Module ℂ M]
    (A : WeakModule W M) : WeakModule S.toVOA M where
  YM := A.YM.comp S.carrier.subtype
  vacuum_YM := A.vacuum_YM
  truncation := fun u x => A.truncation (u : 𝒱) x
  jacobi := fun u v x ℓ m n => A.jacobi (u : 𝒱) (v : 𝒱) x ℓ m n

noncomputable def restrictOrdVModule {M : Type v} [AddCommGroup M] [Module ℂ M]
    (N : OrdVModule W M) : OrdVModule S.toVOA M where
  toWeakModule := S.restrictWeakModule N.toWeakModule
  weight := N.weight
  isInternal := N.isInternal
  L0_weight := N.L0_weight
  finrank := N.finrank
  boundedBelow := N.boundedBelow
```

From the mathematics to the Lean statement

These are full definitions, and every field is informative: `A.YM.comp S.carrier.subtype` is $Y_M \circ (S \hookrightarrow V)$; each axiom is the V-axiom evaluated on elements of S (written `(u : 𝒱)`,

the coercion of $u \in S$ into V). The Jacobi identity type-checks without change because the product of S is that of V. The L_0 field transfers because S has the *same* conformal vector as V (a field of `VOASubalgebra`). So this is restriction along a *conformal* sub-VOA, as in the literature; restriction along a vertex subalgebra with a different conformal vector (a coset construction) is not covered. The library also provides `adjointRestrict`, V as an S-module, and the inclusion $S \hookrightarrow V$ as a module map (`adjointInclusion`).

What the machine verified

Definitions with all proofs inlined above; `#print axioms` of `VOA.VOASubalgebra.restrictWeakModule` and `...restrictOrdVModule`: `[propext, Classical.choice, Quot.sound]`.

Physical meaning

Restriction is "forgetting symmetry": a sector of a CFT with chiral algebra V is in particular a representation of any smaller chiral algebra S with the same stress tensor. For the lattice VOA V_L and its Heisenberg subalgebra, the vacuum sector of V_L decomposes into the charged Fock sectors F_α, $\alpha \in L$ — the physicist's statement that the compactified boson's Hilbert space is a sum of momentum/winding sectors of the free boson. For an orbifold $V^G \subseteq V$, restriction gives the untwisted sectors of the orbifold theory.

12.3 Characters, zero modes, and lowest weights

Definition 12.13 (Character, zero mode, one-point function; Zhu 1996, §4)**.** Let M be an ordinary module and c the central charge of V.

1. The *character* (graded dimension) is the formal series $\chi_M(q) = \operatorname{tr}_M q^{L_0 - c/24} = \sum_\alpha (\dim M_\alpha)\, q^{\alpha - c/24}$, recorded as the function $e \mapsto \dim M_{e+c/24}$ (coefficient of q^e).

2. The *zero mode* of $v \in V_k$ is $o(v) = v^M_{(k-1)}$, extended linearly to all of V.

3. The *one-point function* is $\chi_M(v;q) = \operatorname{tr}_M o(v) q^{L_0 - c/24}$, the function $e \mapsto \operatorname{tr}_{M_{e+c/24}} o(v)$.

File `VOA/Modules/Character.lean`.

```
abbrev FormalQSeries : Type := ℂ → ℂ

noncomputable def weightBlock (N : OrdVModule W M) (T : End ℂ M) (α : ℂ) : End ℂ (N.weight
 ↪  α) :=
  (internalProjTo N.isInternal α).comp (T.comp (N.weight α).subtype)

noncomputable def gradedDim (N : OrdVModule W M) : FormalQSeries :=
  fun e => (Module.finrank ℂ (N.weight (e + W.centralCharge / 24)) : ℂ)

noncomputable def onePoint (N : OrdVModule W M) (v : 𝒱) : FormalQSeries :=
  fun e =>
    haveI := N.finrank (e + W.centralCharge / 24)
    LinearMap.trace ℂ _ (weightBlock N (oMod N v) (e + W.centralCharge / 24))

theorem onePoint_vacuum (N : OrdVModule W M) : onePoint N W.vacuum = gradedDim N := by
```

From the mathematics to the Lean statement

A `FormalQSeries` is any function $\mathbb{C} \to \mathbb{C}$, read as the formal sum $\sum_e f(e)q^e$ over complex exponents; no convergence is asserted (that is the business of Chapters 14–15). `weightBlock N T α` is the diagonal block $M_\alpha \to M \to M_\alpha$ of an operator T (inclusion, then T, then projection along the direct sum). `LinearMap.trace` is the trace, well defined because M_α is finite-dimensional (the `haveI` supplies that fact). `oMod N` is the zero mode of Definition 40.4. `onePoint_vacuum` says $\chi_M(\mathbf{1}; q) = \chi_M(q)$ because $o(\mathbf{1}) = \mathrm{id}$. The $q^{-c/24}$ shift is built into the indexing. Same as Zhu's definitions.

What the machine verified

Definitions; `#print axioms` of the lemmas `onePoint_vacuum`, `onePoint_add` is the standard three (file docstring).

Physical meaning

$\chi_M(q)$ is the torus partition function of the chiral sector M, tr $q^{L_0 - c/24}$ with $q = e^{2\pi i\tau}$; the shift $-c/24$ is the Casimir energy of the cylinder. The one-point function is the torus one-point function of the zero mode of a field — the expectation value of a conserved charge, weighted by the Boltzmann factor. Zhu's theorem says that for a rational C_2-cofinite theory these span a representation of $SL_2(\mathbb{Z})$, which is the mathematical form of modular invariance of the torus amplitudes. (The library proves it in Chapter 15 for one-point functions of C_2-cofinite V that are rational in its sense `AdmissiblyRational`, and more generally whenever $A(V)$ is semisimple.)

Definition 12.14 (Lowest weight; conformal weight)**.** An ordinary module M *has lowest weight* $h \in \mathbb{C}$ (library sense) if every α with $M_\alpha \neq 0$ is of the form $h + n$ with $n \in \mathbb{N}$. It *has conformal weight* h if moreover $M_h \neq 0$.

Files `VOA/Modules/ZeroModeMult.lean` and `VOA/Modules/Rationality.lean`.

```
def IsLowestWeight (N : OrdVModule W M) (h : ℂ) : Prop :=
  ∀ α : ℂ, N.weight α ≠ ⊥ → ∃ n : ℕ, α = h + n

def HasConformalWeight (N : OrdVModule W M) (h : ℂ) : Prop :=
  N.weight h ≠ ⊥ ∧ ∀ α : ℂ, N.weight α ≠ ⊥ → ∃ n : ℕ, α = h + n
```

From the mathematics to the Lean statement

`N.weight α ≠ ⊥` is "$M_\alpha \neq 0$". The two predicates differ exactly by the conjunct `N.weight h ≠ ⊥`.

Trap / dead end

`IsLowestWeight` does not require $M_h \neq 0$ (confirmed; moderate). This confirms, with a machine check, a defect suspected earlier in the project. Precisely:

- the zero module satisfies `IsLowestWeight N h` for *every* h;
- a module with lowest weight h in the usual sense also satisfies `IsLowestWeight N (h-1)`, `IsLowestWeight N (h-2)`, …, and for those values $M_{h-k} = 0$.

Theorems that take `hcw : IsLowestWeight N h` and conclude something about M_h (Zhu's multiplicativity $o(u*v) = o(u)o(v)$ on M_h, $O(V)M_h = 0$, the $A(V)$-module structure `moduleMh` on M_h) remain *true*; when $M_h = 0$ they are statements about the zero space, i.e. vacuous.

They are therefore no weaker as hypotheses, but a reader must not infer from them that M_h is the genuine bottom of M. Where the library needs a genuine bottom it adds the conjunct: `HasConformalWeight` above, and the field `realized : isMod.weight h ≠ ⊥` of the bundled `LWModule` (Definition 12.19).
There is a second, opposite difference from the informal phrase "M has lowest weight h": the library predicate requires *all* weights to lie in the single coset $h + \mathbb{N}$. A direct sum of two irreducible modules whose lowest weights differ by a non-integer satisfies `IsLowestWeight` for no h at all. In the literature Zhu's algebra acts on the "top level" $\Omega(M)$ of any admissible module, coset by coset; the library's statements cover modules with one coset of weights. For irreducible modules, the case that matters for Zhu's correspondence, all weights lie in one coset, so nothing is lost there.

Physical meaning

The lowest weight h is the conformal dimension of the primary field that creates the sector from the vacuum: the ground-state energy of the sector is $h - c/24$ on the cylinder. "Weights in $h + \mathbb{N}$" says that all other states are descendants with integer-spaced energies above the ground state, which is the spectrum of a single irreducible representation (one primary and its descendants). A sector made of several primaries with non-integer energy differences is a direct sum of representations and has no single "h".

Theorem 12.15 (T-periodicity of the character; Gannon Lemma 5.3.3)**.** *If M has conformal weight h then $\chi_M(\tau + 1) = e^{2\pi i(h-c/24)}\chi_M(\tau)$, i.e. the coefficient of q^e in χ_M is multiplied by $e^{2\pi ie}$ and this factor equals $e^{2\pi i(h-c/24)}$ on every nonzero coefficient.*

File `VOA/Modules/Rationality.lean`.

```
noncomputable def qShift (χ : FormalQSeries) : FormalQSeries :=
  fun e => Complex.exp (2 * (Real.pi : ℂ) * Complex.I * e) * χ e

theorem char_T_transform (N : OrdVModule W M) (h : ℂ) (hcw : HasConformalWeight N h) :
    qShift (gradedDim N)
      = (Complex.exp (2 * (Real.pi : ℂ) * Complex.I * (h - W.centralCharge / 24)))
          • gradedDim N := by

theorem conformalWeight_char_periodicity (N : OrdVModule W M)
    {h : ℂ} (hcw : HasConformalWeight N h) :
```

From the mathematics to the Lean statement

`qShift` implements $\tau \mapsto \tau+1$ on a formal series in $q = e^{2\pi i\tau}$: $q^e \mapsto e^{2\pi ie}q^e$. The only hypothesis of `char_T_transform` is `HasConformalWeight`; in fact only its second clause (weights in $h + \mathbb{N}$) is used. Same as Gannon's lemma.
Decorative hypotheses, since removed. The variant `conformalWeight_char_periodicity` used to carry `_hwr : GannonRational W` and `_hN : OrdVModule.IsIrreducible N` (the leading underscore is Lean's convention for an unused argument) so that it read like Gannon's lemma. The library has dropped them; the current statement, quoted above, has only `hcw`. The theorem is *not* conditional on rationality or irreducibility.

Proof on paper. If $M_{e+c/24} \neq 0$ then $e + c/24 = h + n$ with $n \in \mathbb{N}$, so $e^{2\pi ie} = e^{2\pi i(h-c/24)}e^{2\pi in} = e^{2\pi i(h-c/24)}$; where the coefficient is 0 both sides vanish. □

What the machine verified

Proved; `#print axioms VOA.char_T_transform` = `[propext, Classical.choice, Quot.sound]`. The *rationality* of h (Anderson–Moore, Dong–Li–Mason) is not proved in this file; its docstring calls it a "gate" to be supplied by modularity, and nothing is claimed.

Physical meaning

$\tau \mapsto \tau + 1$ is the Dehn twist of the torus, generated by $e^{2\pi i(L_0 - c/24)}$. On a sector of conformal weight h it acts by the phase $e^{2\pi i(h - c/24)}$, the eigenvalue of the modular T-matrix; the spin h mod 1 of the primary field is what this phase measures.

12.4 Zhu's algebra

Recall (Definition 40.1) that for homogeneous $u \in V_k$,

$$u * v = \operatorname{Res}_z Y(u,z)v\frac{(1+z)^k}{z} = \sum_{m=0}^{k}\binom{k}{m}u_{(m-1)}v,$$

extended bilinearly; $O(V)$ is the span of all $((L_{-1}+L_0)u) * v$, equivalently (Chapter 1) of all $u \circ v = \operatorname{Res}_z Y(u,z)v(1+z)^{\mathrm{wt}\,u}/z^2$; and $A(V) = V/O(V)$. Chapter 1 proved that $o(u*v) = o(u)o(v)$ on a lowest-weight space and that $O(V)$ acts there by zero (Theorem 12.16). What remains is the ring structure itself.

Theorem 12.16 (Zhu: zero modes act on the lowest-weight space through $A(V)$)**.** *Let M be an ordinary V-module with lowest weight h. For all $u, v \in V$ and $x \in M_h$, $o(u*v)x = o(u)o(v)x$. Moreover $o(O(V))M_h = 0$, so $u \mapsto o(u)|_{M_h}$ factors through $A(V) = V/O(V)$. For homogeneous $a \in V_M$ ($M \in \mathbb{N}$) and all $b \in V$, all the residues $\sum_i \binom{M+n}{i} a_{(i-2-n)}b$, $n \geq 0$, lie in $O(V)$.*

File `VOA/Modules/ZhuModule.lean`.

    (ha : a ∈ W.grading (M : ℤ)) (b : 𝒱) (n : ℕ) : Pres W M a b n ∈ O W
```

From the mathematics to the Lean statement

`oMod N u` is the zero mode $o(u)$ of Definition 12.13(2) (extended linearly from homogeneous u); `zhuMul W u v` is the Zhu product $u * v$ and `O W` the subspace $O(V)$ (Definition 40.1); `IsLowestWeight N h` is Definition 12.14; `N.weight h` is M_h. `rhoLW N h u` is the restriction of $o(u)$ to M_h: `weightBlock N T α` takes the diagonal block $M_\alpha \to M \to M_\alpha$ of an operator T (the library proves, as a separate lemma, that $o(u)$ preserves M_h, so the block loses nothing). `O W ≤ LinearMap.ker (rhoLW N h)` says every element of $O(V)$ acts as zero on M_h. `Pres W`

`M a b n` is the residue $\operatorname{Res}_z Y(a,z)b\,\frac{(1+z)^{M+n}}{z^{2+n}}$, written as a finite sum over $i \in \{0,\dots,M+n\}$ (the terms with larger i vanish since $\binom{M+n}{i} = 0$). **Hypotheses:** lowest weight h for the first three statements, which are quantified over *all* $u, v \in V$ (inhomogeneous vectors included, by bilinearity), and homogeneity of a in `Pres_mem_O`. **The trap of Definition 12.14:** `IsLowestWeight N h` does not require $M_h \neq 0$; if $M_h = 0$ the conclusions are statements about the zero space and are true but empty; the theorem is not weakened as a hypothesis, but it does not by itself say that M_h is the genuine bottom of M. Same as Zhu, *J. AMS* 9 (1996), Theorem 2.1.2 (the easy direction) and Frenkel–Zhu Lemma 2.1.2; and Gannon (5.3.9).

Physical meaning

Zhu's theorem says that the zero modes (charges) acting on the lowest-weight space M_h, the space of primary states, form a representation of the associative algebra $A(V)$: the product of zero modes is the Zhu product, and the null vectors in $O(V)$ act as zero. Physically this is the content of the null-vector (fusion) constraints on the weights of primary fields; for example, the Virasoro vacuum relation gives the Kac condition on h. This is the main tool for classifying the sectors of a rational CFT: the irreducible modules are produced from the irreducible representations of the finite-dimensional algebra $A(V)$.

Proof on paper. For $u \in V_k$, $v \in V_\ell$ and $x \in M_h$, modes $v_{(n)}$ with $n \geq \ell$ kill x (they would lower the weight below h; compare Lemma 12.7). Expand $o(u * v)x = \sum_m \binom{k}{m}(u_{(m-1)}v)_{(k+\ell-m-1)}x$ by the iterate formula (Theorem 4.23, in its module form obtained by putting $m = 0$ in (M3)); all terms with an annihilation mode acting first on x vanish, and the binomial sums collapse to $u_{(k-1)}v_{(\ell-1)}x = o(u)o(v)x$. For $O(V)$: $o((L_{-1}+L_0)u) = 0$ on any module, because $(L_{-1}u)_{(k)} = -k\,u_{(k-1)}$ (Theorem 12.3) cancels $L_0 u = ku$; combined with the multiplicativity on M_h this kills the generators $((L_{-1}+L_0)u) * v$ of $O(V)$. The residue statement is by induction on n: $n = 0$ is the case $u \circ v \in O(V)$, and the induction step is the integration-by-parts identity $(n+2)\operatorname{Pres}(n+1) = \operatorname{Pres}_{L_{-1}a}(n) + (M+n+1)\operatorname{Pres}(n)$, applied to a and to $L_{-1}a$. □

What the machine verified

Unconditional given the displayed hypotheses. `#print axioms` of `VOA.oMod\_zhuMul\_lowest\_all`, `VOA.rhoLW`, `VOA.O\_le\_ker\_rhoLW` and `VOA.Pres\_mem\_O` is `[propext, Classical.choice, Quot.sound]` for each (run for this chapter). The PBW theorem `VOA.pbw` is not used.

12.4.1 $A(V)$ is an associative algebra

Theorem 12.17 (Zhu 1996, Theorem 2.1.1). *For every VOA V: $O(V)$ is a two-sided ideal for $*$, the product $*$ is associative modulo $O(V)$, and the class of $\mathbf{1}$ is a two-sided unit. Hence $A(V)$ is an associative unital $\mathbb{C}$-algebra with product $[u][v] = [u * v]$.*

From the mathematics to the Lean statement

Decoding. `ZhuRingData W` is a proposition (a `structure ... : Prop`) bundling exactly the three facts of Zhu's theorem. `zhuRingData_holds` proves it for *every* `W` — there is no hypothesis. `instRingA` then builds a `Ring` structure on the quotient type `A W` whose multiplication is the descended Zhu product and whose unit is $[\mathbf{1}]$ (library lemmas `zhuMul_vacuum_left`, `zhuMul_vacuum_right` give the unit laws already in V), reusing the quotient's additive group (so "+" on $A(V)$ is the usual one). `instAlgebraA` adds the $\mathbb{C}$-algebra structure.
Why the ring is not a global instance. `instRingA` is a `def`, not an `instance`, and every statement that multiplies in $A(V)$ opens it locally (`letI := instRingA W`). This is a technicality of Lean's instance system; mathematically $A(V)$ simply *is* this ring.
Same as the literature? Yes: this is Zhu's Theorem 2.1.1 (and Frenkel–Zhu's), stated for VOAs of CFT type, which is every library VOA. The three named cores `ZhuHR.right_ideal_core` (right ideal, for homogeneous u, a) and `associator_core` (associativity for homogeneous u, v) are the genuine content; the left-ideal property is derived from associativity, and the reduction from homogeneous to arbitrary vectors is bilinearity.
Could it be vacuous? No: there are no hypotheses, and $A(V)$ is a genuine quotient (for the zero VOA it is the zero ring, which is correct).

Proof on paper. We follow Zhu. Write, for homogeneous u, $u * v = \operatorname{Res}_z Y(u,z)v\frac{(1+z)^{\mathrm{wt}\,u}}{z}$ and $u \circ v = \operatorname{Res}_z Y(u,z)v\frac{(1+z)^{\mathrm{wt}\,u}}{z^2}$.

1. *More of $O(V)$.* By induction on n, every residue $\operatorname{Res}_z Y(u,z)v\frac{(1+z)^{\mathrm{wt}\,u+n}}{z^{2+n}}$, $n \geq 0$, lies in $O(V)$: the case $n = 0$ is the definition, and integrating by parts with $Y(L_{-1}u,z) = \partial_z Y(u,z)$ relates the residue at $n+1$ to those at n for u and $L_{-1}u$ (library: `Pres_mem_O`, Theorem 12.16).

2. *Skew formula.* Using skew-symmetry $Y(u,z)v = e^{zL_{-1}}Y(v,-z)u$ one shows $u * v - v * u \equiv \operatorname{Res}_z Y(u,z)v(1+z)^{\mathrm{wt}\,u-1}$ modulo $O(V)$; in particular $O(V)$ is a left ideal once it is a right ideal.

3. *Right ideal.* For a homogeneous, $u * (a \circ b)$ is a residue in two variables; using the Jacobi identity to commute $Y(u,z_1)$ past $Y(a,z_2)$ one rewrites it as a combination of $a' \circ b'$ and of the residues of step 1, all in $O(V)$ (library: `ZhuHR.right_ideal_core`, off a binomial "linchpin" identity `zhu_right_binom`).

4. *Associativity.* $(u * v) * w - u * (v * w)$ is, by the iterate (associativity) formula of the Jacobi identity, a two-variable residue $\operatorname{Res}_{z_2}\operatorname{Res}_{z_1-z_2}$ minus $\operatorname{Res}_{z_1}\operatorname{Res}_{z_2}$; the difference of the two expansions is the residue of a function with a pole of order ≥ 2 at $z_2 = 0$ weighted by $(1+z)^{\mathrm{wt}}$, which step 1 places in $O(V)$ (library: `associator_core`, the longest file of this chapter, `VOA/Modules/ZhuAssociator.lean`).

5. *Unit.* $\mathbf{1} * v = \mathbf{1}_{(-1)}v = v$ and $v * \mathbf{1} = \sum_m \binom{k}{m} v_{(m-1)}\mathbf{1} = v$ (only $m = 0$ survives by the creation property).

Bilinearity of $*$ then lets the quotient inherit a ring structure. □

What the machine verified

Proved, unconditional. `#print axioms` (run for this chapter) of `VOA.zhuRingData\_holds`, `VOA.instRingA`, `VOA.associator\_core` and `ZhuHR.right\_ideal\_core`: `[propext, Classical.choice, Quot.sound]`. `VOA.pbw` is not used.

Physical meaning

$A(V)$ is the algebra of *zero modes acting on ground states*. In any sector, zero modes of fields preserve the space of ground states, and their products there are computed by the Zhu product — a deformation of the normal-ordered product $u_{(-1)}v$ that accounts for the reordering of modes. Associativity of $A(V)$ is the associativity of operator composition on ground states, which physically is inherited from associativity of the OPE. For the free boson $A(V) = \mathbb{C}[J_0]$ (the momentum), for an affine algebra $A(V)$ is a quotient of $U(\mathfrak{g})$ (the global charges), and for the Virasoro algebra $A(V)$ is a quotient of $\mathbb{C}[L_0]$ by the null-vector relation — the Kac-table equation.

Theorem 12.18 (Ground states form an $A(V)$-module; Zhu 1996, Theorem 2.1.2). *If M is an ordinary module with lowest weight h (library sense), then $[u] \cdot x = o(u)x$ is a well-defined unital $A(V)$-module structure on M_h.*

Files `VOA/Modules/ZhuModule.lean`, `VOA/Modules/ZhuRingInstance.lean`.

```
noncomputable def actA (N : OrdVModule W Mod) {h : ℂ} (hcw : IsLowestWeight N h) :
    A W →ₗ[ℂ] End ℂ (N.weight h) :=
  (O W).liftQ (rhoLW N h) (O_le_ker_rhoLW N hcw)

@[reducible] noncomputable def moduleMh (W : VertexOperatorAlgebra 𝒱) {N : OrdVModule W

    (hcw : IsLowestWeight N h) :
    letI := instRingA W; letI := instAlgebraA W; Module (A W) (N.weight h) :=
  AsModule (zhuRingData_holds W) hcw
```

From the mathematics to the Lean statement

`rhoLW N h u` is $o(u)$ restricted to M_h (Chapter 1). `(O W).liftQ f hf` is the map induced on the quotient $V/O(V)$ by a linear map f vanishing on $O(V)$; the vanishing is `O_le_ker_rhoLW` (Theorem 12.16). `moduleMh` upgrades the linear map $A(V) \to \mathrm{End}(M_h)$ to a module structure, using multiplicativity `oMod_zhuMul_lowest_all` and $o(\mathbf{1}) = \mathrm{id}$. Hypothesis: `IsLowestWeight N h` — see the warning in Section 12.3; if $M_h = 0$ the module is zero. Same as Zhu's theorem ("easy direction" of the correspondence).

What the machine verified

Proved, unconditional given `hcw`; `#print axioms VOA.moduleMh` = `[propext, Classical.choice, Quot.sound]`.

Physical meaning

The ground states of a sector carry a representation of the zero-mode algebra. For a primary field of weight h in a Virasoro minimal model, $[\omega]$ acts on the one-dimensional ground space by h, and the null-vector relation in $A(V)$ forces h into the Kac table: this is the algebraic version of the BPZ argument that null states restrict the allowed primaries.

12.4.2 The forward half of Zhu's correspondence

Definition 12.19 ($A(V)$-modules and lowest-weight modules, bundled)**.** An `AMod` is a vector space U with a linear map $\rho : A(V) \to \mathrm{End}\, U$ such that $\rho[\mathbf{1}] = 1$ and $\rho[u * v] = \rho[u]\rho[v]$. An `LWModule` is an ordinary module M with a number h such that all weights lie in $h + \mathbb{N}$ *and* $M_h \neq 0$. Isomorphism classes are taken with respect to linear isomorphisms intertwining the actions.

File `VOA/Modules/ZhuBijection.lean`.

```

  ρ_one : ρ (one W) = 1
  ρ_mul : ∀ u v : 𝒱, ρ (mk W (zhuMul W u v)) = ρ (mk W u) * ρ (mk W v)

structure LWModule where
  carrier : Type u
  [addCommGroup : AddCommGroup carrier]
  [module : Module ℂ carrier]
  isMod : OrdVModule W carrier
  h : ℂ
  isLow : IsLowestWeight isMod h
  realized : isMod.weight h ≠ ⊥

noncomputable def forwardMap : LWModuleIsoClass W → AModIsoClass W :=
  Quotient.lift (fun P => (Quotient.mk (AMod.setoid W) P.toAMod : AModIsoClass W))
    (fun _ _ ⟨e⟩ => Quotient.sound ⟨LWModule.isoToAModEquiv W e⟩)
```

From the mathematics to the Lean statement

`AMod`. A "bundled" module: the carrier type is a field. `mk W` is the projection $V \to A(V)$, `one W` is $[\mathbf{1}]$. Multiplicativity is required on classes of the form $[u * v]$, which is every product in $A(V)$; so an `AMod` is exactly a unital module over the ring $A(V)$, of any dimension, possibly zero, possibly reducible.

`LWModule`. Here `realized` adds the missing "$M_h \neq 0$"; an `LWModule` is not required to be irreducible.

`forwardMap`. `LWModuleIsoClass W` and `AModIsoClass W` are the quotients by isomorphism (`Quotient`); `Quotient.lift` defines a map on classes from a map on representatives, given a proof that isomorphic inputs give isomorphic outputs (`LWModule.isoToAModEquiv`: a module isomorphism preserves weight spaces, intertwines zero modes, and the two lowest weights agree because both bottoms are nonzero). The map is $[M] \mapsto [M_h]$. Zhu's theorem says its restriction to *irreducible* modules is a bijection onto irreducible $A(V)$-modules; that is Chapter 13: the uniqueness half for every V (`zhuBijective_of_voaPBW`; the codomain of `zhuBijective` is the image of the map), and the full bijection onto simple $A(V)$-modules for C_2-cofinite V (`zhuCorrespondence_of_C2Cofinite`).

What the machine verified

Definitions; `#print axioms VOA.forwardMap` = `[propext, Classical.choice, Quot.sound]`.

Physical meaning

The forward map sends a sector to its space of ground states with the action of the zero modes — in physics language, a representation of the chiral algebra to the representation of the "finite-dimensional" symmetry seen by its primaries. Zhu's correspondence is the statement that a primary field (an irreducible representation of the zero-mode algebra on ground states) generates exactly one irreducible sector.

Trap / dead end

`InducedAssignment` is uninhabited; the round-trip theorems built on it are vacuous (serious, recorded in the library; docstrings stale, documentation only). The file `VOA/Modules/ZhuInduced.lean` expresses the "hard direction" of Zhu's correspondence as the structure

```
structure InducedAssignment where
  realize : AMod W → LWModule W
  realizes : ∀ U : AMod W, AModEquiv W (realize U).toAMod U
  isoInvariant : ∀ U U' : AMod W, Nonempty (AModEquiv W U U') →
    LWModule.Iso W (realize U) (realize U')

theorem forwardMap_invFun (A : InducedAssignment W) (x : AModIsoClass W) :
    forwardMap W (A.invFun x) = x := by
```

It asks for a lowest-weight module realising *every* `AMod`, including the *zero* $A(V)$-module (carrier a point; $\rho[\mathbf{1}] = 1$ holds because the endomorphism ring of the zero space is the zero ring). But an `LWModule` has $M_h \neq 0$ (`realized`), and no nonzero space is isomorphic to zero. So no `InducedAssignment` exists, for any V. The library proves exactly this, in a file of Chapter 13 (`VOA/Modules/ZhuVermaAnArchZhu534.lean`):

```
theorem not_nonempty_inducedAssignment (W : VertexOperatorAlgebra 𝒱) :
    ¬ Nonempty (InducedAssignment W) := by
```

(`#print axioms`: standard three). Even for nonzero U a realisation can fail: $[\omega]$ acts on the bottom of an `LWModule` by the scalar h, so an $A(V)$-module on which $[\omega]$ is not scalar (e.g. a direct sum of two irreducibles with different h) has no realisation. Consequently `forwardMap_invFun`, `forwardMap_comp_invFun` (this file) and `forwardMap_invFun_ofPointwise` (`VOA/Modules/ZhuInducedPointwise.lean`) are true for the trivial reason that their hypothesis can never be supplied; the pointwise input `∀ U, HasInducedModule W U` is refuted by `not_forall_hasInducedModule`, and the file `ZhuInducedPointwise.lean` itself notes that its second input `BottomIsoLifts` is false (a generalised Verma module and its irreducible quotient have the same bottom). The docstrings of `ZhuInduced.lean` ("remains reusable API") and of `ZhuBijection.lean` ("the entire remaining content … is located in the single precise object `InducedAssignment`") are stale. The correct replacements are in Chapter 13: for C_2-cofinite V, the genuine bijection between $\Phi(V)$ and isomorphism classes of simple $A(V)$-modules is `zhuCorrespondence_of_C2Cofinite` (conditional only on C_2); for every V, the uniqueness half is `zhuBijective`, a bijection onto its image. The latter is conditional on an explicit datum `Pr : BottomProjection ...`, and its wrapper `zhuBijective_of_voaPBW` supplies `Pr` from the theorem `VOA.pbw` and is unconditional (`#print axioms` in a later run, after `pbw` became a theorem, not re-run for this edition: `[propext, Classical.choice, Quot.sound]`; at the snapshot, run for this chapter, the list also contained `pbw`, then an axiom).

12.4.3 Two consequences: bottoms are simple, and a Zhu-polynomial simplicity test

Theorem 12.20 (Simple bottoms). *Assume $A(V)$ is a semisimple ring and the PBW datum* `Pr` *of Chapter 13 is given. Then the bottom M_h of every irreducible lowest-weight module is a simple $A(V)$-module.*

File `VOA/Modules/ZhuBottomSimple.lean`.

```
theorem isSimpleAMod_of_irreducible_of_semisimple
    (Pr : BottomProjection (parabolicRepOfAMod W (regularAMod W)))
    (hss : letI := instRingA W; IsSemisimpleRing (A W))
    (P : LWModule W) (hP : P.IsIrreducibleLW) : IsSimpleAMod P.toAMod := by
```

From the mathematics to the Lean statement

`IsSemisimpleRing` is Mathlib's semisimplicity (every module is a direct sum of simple modules). `P.IsIrreducibleLW` is irreducibility of the underlying ordinary module, `IsSimpleAMod` is "nonzero with no proper nonzero $A(V)$-submodule". `Pr` is the canonical-bottom projection of the Dong–Jiang induced module (Chapter 13); it is an explicit hypothesis, not an axiom. In the literature this statement holds without semisimplicity and without `Pr` (Zhu 1996, Theorem 2.2.1: the top level of an irreducible module is an irreducible $A(V)$-module); the library's version is therefore *weaker* (more hypotheses) than Zhu's. **Superseded:** the general statement, with neither hypothesis, is now a library theorem, `VOA.Huang.LWBottomRecovery.isSimpleAMod_toAMod_of_irreducible` (via `allBottomRecovers`), presented in Chapter 13, Theorem 13.6 (standard three axioms, checked at an earlier commit, not re-run for this edition).

Proof on paper. A nonzero $A(V)$-submodule $S \subseteq M_h$ contains a simple submodule T (semisimplicity). The universal property of the induced module $\bar{M}(T)$ gives a module map $\bar{M}(T) \to M$ which is the inclusion on the bottom; its image is a nonzero submodule, hence all of M by irreducibility, and comparing bottoms gives $T = M_h$. □

What the machine verified

Proved, *conditional on* `Pr` and `hss`; `#print axioms` of `VOA.isSimpleAMod_of_irreducible_of_semisimple` = `[propext, Classical.choice, Quot.sound]`.

Physical meaning

The ground states of an irreducible sector form an irreducible multiplet of the zero-mode algebra: if they split, the descendants of one piece would form a smaller sector. This is the statement that each irreducible sector has "one primary" up to the zero-mode symmetry.

Theorem 12.21 (Zhu-polynomial simplicity criterion). *Let $V \neq 0$ with $V_1 = 0$, and let $P \in \mathbb{C}[x]$ satisfy $P([\omega]) = 0$ in $A(V)$. If the only non-negative integer roots of P are among $\{0, 1\}$, then V is simple.*

File `VOA/Modules/ZhuPolynomialSimplicity.lean`.

```
def ZhuPolynomialRelation (P : Polynomial ℂ) : Prop :=
  letI := instRingA W
  letI := instAlgebraA W
  Polynomial.aeval (mk W W.conformalVector) P = 0

theorem isSimple_of_zhuPolynomial
    (hneW : (⊤ : Submodule ℂ 𝒱) ≠ ⊥)
    (hV1 : W.grading 1 = ⊥)
```

```
    (P : Polynomial ℂ)
    (hpoly : ZhuPolynomialRelation W P)
    (hroots : ∀ n : ℕ, P.eval (n : ℂ) = 0 → n = 0 ∨ n = 1) :
    W.IsSimple := by
```

From the mathematics to the Lean statement

`Polynomial.aeval x P` is $P(x)$ evaluated in the algebra $A(V)$; `mk W W.conformalVector` is $[\omega]$. `W.IsSimple` is simplicity of the VOA: $V \neq 0$ and every ideal is 0 or V (Chapter 5; an ideal `W.IsIdeal I` is a subspace with $u_{(n)}I \subseteq I$). Hypotheses: $V \neq 0$, $V_1 = 0$, the polynomial relation, the root condition. The full Lean name is `VOA.ZhuPolynomialSimplicity.isSimple_of_zhuPolynomial`. This is a recognition principle formulated in the project (it is used for the triplet algebra $W(2)$, Chapter 18); it is a correct consequence of Zhu's theory, not a literature theorem to be compared.

Proof on paper. Let I be a nonzero proper ideal. It is a V-submodule of the adjoint module, graded, and has a least occupied weight $n \in \mathbb{N}$; then I is an ordinary module with lowest weight n and $I_n \neq 0$ (`idealOrdModule`, `idealBottomWeight`). By Theorem 12.18, $A(V)$ acts on I_n and $[\omega]$ acts by $L_0 = n$. Since $P([\omega]) = 0$, $P(n)I_n = 0$, so $P(n) = 0$ and $n \in \{0, 1\}$. But $n = 0$ would put $\mathbf{1}$ in I (as $V_0 = \mathbb{C}\mathbf{1}$) and then $I = V$; and $n = 1$ is impossible since $V_1 = 0$. □

What the machine verified

Proved; `#print axioms` = `[propext, Classical.choice, Quot.sound]`.

Physical meaning

An ideal of the chiral algebra would be a set of null fields; its lowest state would be a primary of some weight n in the vacuum module. Zhu's algebra lists the allowed weights of primaries (roots of P); if none of them is a positive integer ≥ 2, there is no room for a null primary, so the vacuum module is irreducible. This is the chiral-algebra version of "no null vectors at these levels".

12.5 C_2-cofiniteness and the Poisson algebra $V/C_2(V)$

Zhu introduced a finiteness condition under which the characters of modules converge, and, together with rationality, are modular. (The library proves convergence from C_2 alone, and modularity from C_2 together with rationality (`AdmissiblyRational`), or more generally with semisimplicity of $A(V)$; Chapter 15.) It is the cleanest "finitely many sectors" condition that can be checked on the vacuum module alone.

Definition 12.22 ($C_2(V)$, C_2-cofiniteness; Zhu 1996, §4.4). $C_2(V) = \mathrm{span}\{u_{(-2)}v : u, v \in V\}$, $R_V = V/C_2(V)$, and V is *C_2-cofinite* if $\dim R_V < \infty$.

File `VOA/Modules/C2Cofinite.lean`.

```
def O₂ (W : VertexOperatorAlgebra 𝒱) : Submodule ℂ 𝒱 :=
  Submodule.span ℂ {x | ∃ u v : 𝒱, x = W.smul u (-2) v}

abbrev A₂ (W : VertexOperatorAlgebra 𝒱) : Type u := 𝒱 ⧸ O₂ W

def poissonMul (W : VertexOperatorAlgebra 𝒱) (u v : 𝒱) : 𝒱 := W.smul u (-1) v

def poissonBracket (W : VertexOperatorAlgebra 𝒱) (u v : 𝒱) : 𝒱 := W.smul u 0 v

def C2Cofinite (W : VertexOperatorAlgebra 𝒱) : Prop := FiniteDimensional ℂ (A₂ W)
```

From the mathematics to the Lean statement

`O₂ W` is $C_2(V)$ (Zhu calls it $C_2(V)$; the library's "O_2" echoes Zhu's $O(V)$). `A₂ W` is the quotient $R_V = V/C_2(V)$. `C2Cofinite W` is $\dim R_V < \infty$. Same as Zhu's definition, and as Gaberdiel–Neitzke's and Arakawa's (R_V is Zhu's C_2-algebra, Li's $V/C_2(V)$, Arakawa's R_V). The standing CFT type is automatic.

Trap / dead end

Notation clash: `A₂` is not the second higher Zhu algebra (documentation only). In the literature, $A_n(V)$ (Dong–Li–Mason) denotes the n-th higher Zhu algebra (Section 12.6), and $A_2(V)$ would be the second one; Gaberdiel–Neitzke write $A_{[2]}(V)$ for $V/C_2(V)$, Arakawa writes R_V. The library's `A₂ W` is $V/C_2(V)$, the commutative Poisson algebra, while the higher Zhu algebras are `An W n`. A reader must not read `A₂ W` as `An W 2`.

Physical meaning

$C_2(V)$ is spanned by states containing at least one "derivative" or excited mode $u_{(-2)}$; the quotient R_V keeps only the "classical" part of the chiral algebra, the commutative algebra of fields modulo derivatives. It is the coordinate ring of the *associated variety*, the classical phase space of the chiral algebra. C_2-cofiniteness ("lisse") says that this phase space is a finite set of points (zero-dimensional): the theory has no continuous moduli of vacua, no free bosons, and — as Zhu, Gaberdiel–Neitzke, Abe–Buhl–Dong and Miyamoto show — finitely many irreducible sectors with convergent characters, modular in Zhu's sense when $A(V)$ is semisimple and in Miyamoto's pseudo-trace sense in general. The free boson fails it: $R_V = \mathbb{C}[J]$ is a line.

Theorem 12.23 (R_V is a Poisson algebra; Zhu, Li). *$C_2(V)$ is a two-sided ideal for both products $u_{(-1)}v$ and $u_{(0)}v$, and on R_V the product $[u][v] = [u_{(-1)}v]$ is commutative, associative and unital, the bracket $\{[u],[v]\} = [u_{(0)}v]$ is a Lie bracket, and the Leibniz rule $\{a,bc\} = \{a,b\}c + b\{a,c\}$ holds.*

Files `VOA/Modules/C2Cofinite.lean`, `VOA/Modules/PoissonDescent.lean`.

```
theorem poissonBracket_leibniz (W : VertexOperatorAlgebra 𝒱) (u v w : 𝒱) :
    poissonBracket W u (poissonMul W v w) - poissonMul W v (poissonBracket W u w)
      = poissonMul W (poissonBracket W u v) w := by

noncomputable instance A₂CommRing (W : VertexOperatorAlgebra 𝒱) : CommRing (A₂ W) :=

noncomputable instance A₂LieRing (W : VertexOperatorAlgebra 𝒱) : LieRing (A₂ W) :=
```

From the mathematics to the Lean statement

`CommRing (A₂ W)`: a commutative ring structure on the quotient whose product is $[u_{(-1)}v]$ and unit $[\mathbf{1}]$ (the definitions inside the instance use `A₂mul`, `A₂bracket`, the descents of `poissonMul`, `poissonBracket`). `LieRing (A₂ W)`: a Lie bracket with `A₂bracket`. The Leibniz rule is stated in V and holds *exactly* there (it is the derivation property of $u_{(0)}$), hence also in R_V. The library does not package a single "Poisson algebra" structure (Mathlib has no such class); the two instances plus Leibniz are its content. Same as Li's Poisson structure on $V/C_2(V)$.

Proof on paper. $u_{(-n)}v \in C_2(V)$ for every $n \geq 2$: by Theorem 12.3 applied to the adjoint module, $(L_{-1}u)_{(-n)} = n\,u_{(-n-1)}$, so $u_{(-n-1)}v = \frac{1}{n}(L_{-1}u)_{(-n)}v$ and induction on n applies. For the ideal property, the iterate formula writes $(a_{(-2)}b)_{(m)}x$ ($m \leq 0$) as a sum of terms with an outer mode ≤ -2, which lie in $C_2(V)$; commutativity $u_{(-1)}v - v_{(-1)}u \in C_2(V)$ and antisymmetry

$u_{(0)}v+v_{(0)}u \in C_2(V)$ follow from skew-symmetry $Y(u,z)v = e^{zL_{-1}}Y(v,-z)u$, since every correction term contains L_{-1}, and $L_{-1}V \subseteq C_2(V)$ ($L_{-1}x = x_{(-2)}\mathbf{1}$). Associativity modulo C_2 is the iterate formula at $\ell = -1$; the Jacobi identity for the bracket and the Leibniz rule are the statement that $u_{(0)}$ is a derivation of all products (commutator formula with $m = 0$). □

What the machine verified

Proved, unconditional; `#print axioms` of `VOA.A₂CommRing`, `VOA.A₂LieRing`, `VOA.poissonBracket\_leibniz`: standard three.

Physical meaning

The Poisson bracket $\{u,v\} = u_{(0)}v$ is the classical limit of the OPE's simple pole, i.e. of the charge commutators; the commutative product $u_{(-1)}v$ is the classical limit of normal ordering. R_V is thus the classical (semiclassical, $\hbar \to 0$) limit of the chiral algebra, and its Poisson structure records the leading-order Ward identities. Arakawa's associated variety is Specm R_V with this Poisson structure.

Theorem 12.24 (C_2-cofinite implies finitely strongly generated; Zhu, Gannon 5.3.11a)**.** *Let $S \subseteq V$ be a set of homogeneous vectors with $V = \operatorname{span} S + C_2(V)$. Then V is spanned by the vectors $s^1_{(-m_1)}\cdots s^k_{(-m_k)}\mathbf{1}$ with $s^i \in S$, $m_i \geq 1$, $k \geq 0$. In particular, if V is C_2-cofinite, lifts of a basis of R_V strongly generate V.*

Files `VOA/Modules/FiniteGeneration.lean`, `VOA/Modules/FiniteGenerationProof.lean`.

```
def IsHomog (W : VertexOperatorAlgebra 𝒱) (x : 𝒱) : Prop := ∃ n : ℤ, x ∈ W.grading n

inductive IsIterProd (W : VertexOperatorAlgebra 𝒱) (S : Set 𝒱) : 𝒱 → Prop
  | vacuum : IsIterProd W S W.vacuum
  | step (s : 𝒱) (hs : s ∈ S) (m : ℤ) (hm : 1 ≤ m) (x : 𝒱) (hx : IsIterProd W S x) :
      IsIterProd W S (W.smul s (-m) x)

def iterProdSpan (W : VertexOperatorAlgebra 𝒱) (S : Set 𝒱) : Submodule ℂ 𝒱 :=
  Submodule.span ℂ {x | IsIterProd W S x}

theorem iterProdSpan_eq_top (W : VertexOperatorAlgebra 𝒱) (S : Set 𝒱)
    (hShom : ∀ s ∈ S, IsHomog W s)
    (htop : (⊤ : Submodule ℂ 𝒱) = Submodule.span ℂ S ⊔ O₂ W) :
    iterProdSpan W S = ⊤ :=
```

From the mathematics to the Lean statement

`IsIterProd W S` is the smallest set containing $\mathbf{1}$ and closed under $x \mapsto s_{(-m)}x$ for $s \in S$, $m \geq 1$ (an `inductive` predicate: exactly the iterated words). $\sqcup$ is the sum of subspaces. The hypothesis `htop` is $V = \operatorname{span} S + C_2(V)$, which for C_2-cofinite V holds with S finite (`iterProdSpan_eq_top_of_finite`). The words are not required to be ordered, so this is the weak form of strong generation (Gaberdiel–Neitzke prove an ordered PBW-type refinement; the library's ordered version, needed for C_m, is in Chapter 15). Same as Gannon 5.3.11a / Zhu Lemma 4.4.1.

Proof on paper. Induction on the weight. Let $T =$ span of the words. Weight-n vectors are in $\operatorname{span} S + (C_2(V) \cap V_n)$, so it suffices to show the homogeneous generators $a_{(-2)}b$ of weight n lie in T, assuming $V_k \subseteq T$ for $k < n$. Write a itself modulo C_2 as a combination of S plus elements of $C_2(V)$ of the same weight $< n$, and peel the left factor with the iterate formula: an S-left factor gives a word step; a C_2-left factor recurses on a strictly smaller weight, and all right factors that appear have weight $< n$. (The library's double induction is "`genPeel_master`".) □

What the machine verified

Proved, unconditional; `#print axioms VOA.iterProdSpan_eq_top`: standard three. A companion, `iterProdSpan_smul_closed` (`VOA/Modules/PairClosure.lean`), shows that if all products $s_{(j)}t$, $j \geq 0$, of generators of weight ≥ 1 lie in the span of words, then that span is closed under *all* products; and `VOA/Modules/NilpotentGenerators.lean` proves the pure algebra fact that a commutative algebra generated by finitely many nilpotents g_i with $g_i^{m_i} = 0$ has dimension at most $\prod m_i$ (`NilpotentGenerators.finrank_le_prod`), the engine for proving C_2-cofiniteness of the triplet algebra (Chapter 18). Both axiom-clean.

Physical meaning

A lisse chiral algebra is generated, in the sense of normal-ordered products and derivatives, by finitely many fields (for the Virasoro minimal models, T alone; for the triplet, T and $W^{\pm,0}$). The OPEs among the generators then determine everything, which is why a CFT is specified by a finite OPE table.

Example 12.25 (Which VOAs are C_2-cofinite, in the library).

- The rank-one Heisenberg (free boson) VOA is *not* C_2-cofinite: `heisenberg_not_C2Cofinite` (`VOA/Examples/HeisenbergC2.lean`, Chapter 6), proved by exhibiting the linearly independent classes $[(a_{(-1)})^n \mathbf{1}]$ in R_V.
- The lattice triplet algebra $W(2)$ *is* C_2-cofinite and is *not* admissibly rational: `VOA.LatGen.Wp.tripletWVOA_two_c2Cofinite_and_not_admissiblyRational` (Chapter 18; `#print axioms` run for this chapter: standard three).
- Every VOA with $V = \mathbb{C}\mathbf{1}$ is C_2-cofinite (`c2Cofinite_of_span_vacuum`).
- Every lattice VOA V_L (L even, positive definite) is C_2-cofinite and strongly finite: `latticeVOAGen_c2Cofinite`, `latticeVOAGen_stronglyFinite` (`VOA/Classification/COne/LatticeC2.lean`, Chapter 22); in particular the rank-one $V_{\sqrt{2m}\mathbb{Z}}$ (`V2m_c2Cofinite`, `V2m_stronglyFinite`).

C_2-cofiniteness of $V^\natural$ is not proved in the library.

Physical meaning

The triplet example is the physically important one: $W(2)$ (symplectic fermions' even part, $c = -2$) is the prototype logarithmic CFT, with finitely many sectors (lisse) but indecomposable, non-semisimple sector structure. It shows that "finitely many sectors" does not imply "rational".

Definition 12.26 (Zeroth Poisson homology; Etingof–Schedler, Arakawa–Kawasetsu). $\mathrm{HP}_0(R_V) = R_V/\{R_V, R_V\}$, where $\{R_V, R_V\}$ is the span of all Poisson brackets. V is *Etingof-finite* if $\dim \mathrm{HP}_0(R_V) < \infty$.

File `VOA/Modules/PoissonTrace.lean` (assigned to Chapter 16).

```
noncomputable def poissonSpan (W : VertexOperatorAlgebra 𝒱) : Submodule ℂ (A₂ W) :=
  bilinSpan (A₂bracket W)

noncomputable abbrev HP₀ (W : VertexOperatorAlgebra 𝒱) : Type u := A₂ W / poissonSpan W

def EtingofFinite (W : VertexOperatorAlgebra 𝒱) : Prop := FiniteDimensional ℂ (HP₀ W)

theorem EtingofFinite_of_C2Cofinite (W : VertexOperatorAlgebra 𝒱) (h : C2Cofinite W) :
    EtingofFinite W := by
```

From the mathematics to the Lean statement

`bilinSpan (A₂bracket W)` is the span of the values $\{p, q\}$ of the descended bracket (library lemma `poissonSpan_def`). HP_0 is a vector space, not a ring. **Same as the literature?** Arakawa–Kawasetsu call V *quasi-lisse* if the associated variety $\operatorname{Specm} R_V$ has finitely many symplectic leaves; Etingof–Schedler show that this implies $\dim \mathrm{HP}_0(R_V) < \infty$, which is the only consequence Arakawa–Kawasetsu use for modularity. So `EtingofFinite` is *weaker* than (implied by) quasi-lisse. Under it the library proves the Arakawa–Kawasetsu MLDE (`IsSqPrimary.exists_monicMLDEOn_all_analyticBlocks_of_etingofFinite_uncond`, Chapter 16): conditional only on `EtingofFinite` (its former input `AKWeightGrading W` is now the theorem `akWeightGrading W`), one monic MLDE of unbounded order for all abstract analytic genus-one blocks. It has no Zhu-type modular-invariance theorem under it beyond the trivial VOA. The library proves C_2-cofinite $\Rightarrow$ Etingof-finite; strictness of the implication is shown in Chapter 16 (the simple affine $\mathfrak{sl}_2$ quotient at an admissible level).

Proof on paper (of the implication). $\mathrm{HP}_0(R_V)$ is a quotient of R_V. □

What the machine verified

Proved; `#print axioms VOA.EtingofFinite_of_C2Cofinite`: standard three.

Physical meaning

Quasi-lisse chiral algebras (Arakawa–Kawasetsu) are those whose classical phase space has finitely many symplectic leaves: the Higgs-branch chiral algebras of four-dimensional $\mathcal{N} = 2$ superconformal theories (Beem–Rastelli and collaborators) are the motivating examples. $\mathrm{HP}_0(R_V)^*$ is the space of Poisson traces, the classical shadow of torus one-point functions; its finite-dimensionality is what makes characters satisfy a modular linear differential equation even when the theory has continuous families of states.

12.6 Higher Zhu algebras and finiteness under C_2

Zhu's algebra sees only the ground states of a sector. To see the first n excited levels one uses the higher Zhu algebras.

Definition 12.27 (Higher Zhu algebras; Dong–Li–Mason 1998; the spaces $C_m(V)$)**.** For $n \in \mathbb{N}$ and homogeneous a,

$$a \circ_n b = \operatorname{Res}_z Y(a,z) b \frac{(1+z)^{\operatorname{wt} a + n}}{z^{2n+2}} = \sum_{i \geq 0} \binom{\operatorname{wt} a + n}{i} a_{(i-2n-2)} b,$$

extended bilinearly; $O_n^{\mathrm{lib}}(V) = \operatorname{span}\{a \circ_n b\}$ and $A_n^{\mathrm{lib}}(V) = V / O_n^{\mathrm{lib}}(V)$. Also $C_m(V) = \operatorname{span}\{u_{(-m)} v\}$.

Files `VOA/Modules/ZhuVermaAn.lean` (Chapter 13) and `VOA/Modularity/AnFiniteDim.lean` (Chapter 15).

```
noncomputable def circFamily (W : VertexOperatorAlgebra 𝒱) (n : ℕ) (b : 𝒱) (k : ℤ) :

abbrev An (W : VertexOperatorAlgebra V) (n : ℕ) : Type u := V ⧸ On W n

def CGen (W : VertexOperatorAlgebra V) (M : ℤ) : Submodule ℂ V :=
  Submodule.span ℂ {x | ∃ u v : V, x = W.smul u M v}
```

From the mathematics to the Lean statement

`circ W n a b` is $a \circ_n b$, assembled from homogeneous components exactly as `zhuMul` (Chapter 1 explains the `DFinsupp.lsum` pattern); the range $\{0, \dots, \mathrm{wt}\, a + n\}$ is where the binomial coefficient is nonzero. `CGen W (-m)` is $C_m(V)$; `CGen_neg_two : CGen W (-2) = O₂ W` holds by definition. At $n = 0$ the library proves `On_zero_eq_O : On W 0 = O W` (Chapter 13), so $A_0 = A(V)$.

Trap / dead end

The library's $O_n(V)$ omits generators (moderate), and the attribution is to DLM (documentation only). Dong–Li–Mason (*J. Algebra* 206, 1998), who introduced $A_n(V)$, define $O_n(V)$ as the span of the $a \circ_n b$ *and* of all $(L_{-1} + L_0)a$. At $n = 0$ the extra generators are redundant ($(L_{-1} + L_0)a = a \circ_0 \mathbf{1}$), which is why `On_zero_eq_O` holds; for $n \geq 1$, $a \circ_n \mathbf{1}$ is a different vector and the library does not prove that $(L_{-1} + L_0)a \in O_n^{\mathrm{lib}}(V)$ (its own comment in `VOA/Modules/ZhuVermaAnArch.lean` says this family "is what `On W n` omits"). Hence $O_n^{\mathrm{lib}} \subseteq O_n^{\mathrm{DLM}}$ and $A_n^{\mathrm{lib}}(V)$ *surjects onto* the literature's $A_n(V)$; it may be larger. For the finiteness theorem below this is harmless — finiteness of the larger space implies finiteness of DLM's — so that theorem is at least as strong as the literature's. But `An W n` must not be identified with DLM's $A_n(V)$ without an argument. The library's docstrings attribute A_n to Frenkel–Zhu; Frenkel–Zhu (1992) introduced the $A(V)$-bimodules $A(M)$, while the tower $A_n(V)$ is Dong–Li–Mason's.

Physical meaning

$A_n(V)$ is the algebra of all modes that map the first n excited levels of any sector to themselves; its representations classify sectors together with their low-lying descendants. Physically it records the level-truncated OPE algebra: how many and which states appear up to energy $h + n$.

Theorem 12.28 (C_2 controls the whole tower; Gaberdiel–Neitzke, Zhu, Dong–Li–Mason). *If V is C_2-cofinite then: (i) $V/C_m(V)$ is finite-dimensional for every $m \geq 1$; (ii) $A(V)$ is finite-dimensional; (iii) $A_n^{\mathrm{lib}}(V)$ is finite-dimensional for every $n \in \mathbb{N}$.*

```

From the mathematics to the Lean statement

Hypothesis: only `C2Cofinite W`; the conclusions are literal finite-dimensionality of the quotient spaces just defined. (i) at $m = 1$ is trivial ($C_1(V) = V$, since $v = \mathbf{1}_{(-1)}v$), at $m = 2$ it is the hypothesis, and for $m \geq 3$ it is the content (since $C_{m+1} \subseteq C_m$, larger m is *harder*). (ii) is Zhu's (and Gaberdiel–Neitzke's) theorem; the library's proof is the one-line alias of `finiteDimensional_A_of_C2Cofinite` (`VOA/Modularity/ZhuAlgebraFinite.lean`, Chapter 15). (iii) concerns the library's A_n (see the warning above); since it may be bigger than DLM's, the statement is at least as strong as the literature's "C_2-cofinite $\Rightarrow \dim A_n(V) < \infty$". The same file also proves finiteness of the Dong–Jiang bimodules $A_{n,0}(V)$ (`finiteDimensional_AnmFull_of_C2Cofinite`); their definition belongs to Chapter 13 and we do not present it.

Proof on paper. (ii): modulo $O(V)$, $u_{(-2)}v$ equals $u \circ v$ minus terms $u_{(i-2)}v$, $i \geq 1$, of strictly smaller weight; so by induction on weight, a finite set spanning V modulo $C_2(V)$ spans V modulo $O(V)$. (i): Gaberdiel–Neitzke's Proposition 8 refines Theorem 12.24: V is spanned by ordered words $s^1_{(-n_1)} \cdots s^k_{(-n_k)}\mathbf{1}$ with $n_1 > n_2 > \cdots > n_k > 0$ (strict decrease, achieved by the commutator formula and C_2-cofiniteness); a word with $n_1 \geq m$ lies in $C_m(V)$, and strictly decreasing words with all $n_i < m$ have length $< m$, so finitely many of them span V modulo $C_m(V)$ (their Theorem 11). (iii): $a \circ_n b = a_{(-2n-2)}b +$ terms of lower weight, so the same induction as in (ii), with C_{2n+2} in place of C_2, shows that a finite set spanning V modulo $C_{2n+2}(V)$ spans V modulo $O_n^{\mathrm{lib}}(V)$; apply (i) with $m = 2n + 2$. □

What the machine verified

Proved, unconditional given `hC2`; `#print axioms` of all three (run for this chapter): standard three, no `VOA.pbw`.

Physical meaning

In a lisse theory each energy window of each sector is described by a finite-dimensional algebra. Physically: finitely many generators with a finite OPE table can only produce finitely many independent "level-n multiplets", so the spectrum of sectors up to any fixed excitation is finite. This is the input to Zhu's proof that torus one-point functions satisfy a finite system of modular differential equations.

12.7 The contragredient module

Definition 12.29 (Restricted dual and contragredient action; FHL §5.2)**.** Let M be an ordinary module. Its *restricted dual* is $M' = \bigoplus_\alpha (M_\alpha)^*$. For $u \in V_{\mathrm{wt}\,u}$, $f \in M'$ and $x \in M$, the contragredient action is defined by

$$\langle Y'(u,z)f, x\rangle = \langle f, Y\big(e^{zL_1}(-z^{-2})^{L_0}u, z^{-1}\big)x\rangle,$$

whose mode form is

$$\langle u'_{(n)}f, x\rangle = (-1)^{\mathrm{wt}\,u}\sum_{j\geq 0}\frac{1}{j!}\langle f,\ (L_1^j u)_{(2\,\mathrm{wt}\,u-n-2-j)}x\rangle.$$

```

From the mathematics to the Lean statement

Decoding. `Module.Dual ℂ X` is the dual space X^*; `DirectSum ℂ F` is the external direct sum $\bigoplus_\alpha F(\alpha)$, so `RestrictedDual N` is $M' = \bigoplus_\alpha M^*_\alpha$ (not the full dual M^*, which is the direct *product*). `DirectSum.lof ... α` is the inclusion of the α-summand, so `RestrictedDual.weight N α` is $(M')_\alpha = M^*_\alpha$. `dualTargetOp N wt u n γ j` is $x \mapsto$ the M_γ-component of $(L_1^j u)_{(2\,\mathrm{wt}-n-2-j)}x$, and `LinearMap.lcomp` precomposes a functional $g \in M^*_\gamma$ with it. So `dualCompMap N wt u n γ g` is the functional $x \mapsto (-1)^{\mathrm{wt}\,u}\sum_{j=0}^{\mathrm{wt}\,u}\frac{1}{j!}\,g\big(\mathrm{pr}_\gamma(L_1^j u)_{(2\,\mathrm{wt}\,u-n-2-j)}x\big)$, exactly the mode formula (the sum stops at $j = \mathrm{wt}\,u$ because $L_1^j u \in V_{\mathrm{wt}\,u-j}$ vanishes for $j > \mathrm{wt}\,u$ by CFT type). `dualModeEndo` assembles these over all γ, putting the image of $g \in M^*_\gamma$ into the slot $\gamma+\mathrm{wt}\,u-n-1$ (`dualOutIdx`); `dualModeEndo_pairing_out` certifies that pairing the result with x in that slot gives back the formula, so nothing is lost by the reindexing. `YMdual` is the field $Y'(u,z) = \sum_n u'_{(n)}z^{-n-1}$ (`dualModeAt N n u` is $u'_{(n)}$, assembled over homogeneous components of u as for `zhuMul`).

Derivation of the mode formula. For u homogeneous, $(-z^{-2})^{L_0}u = (-1)^{\mathrm{wt}\,u}z^{-2\,\mathrm{wt}\,u}u$, and $e^{zL_1} = \sum_j z^j L_1^j/j!$. With $Y(w,z^{-1}) = \sum_m w_{(m)}z^{m+1}$, the coefficient of z^{-n-1} of $(-1)^{\mathrm{wt}\,u}\sum_j \frac{z^{j-2\,\mathrm{wt}\,u}}{j!}Y(L_1^j u, z^{-1})$ comes from $j-2\,\mathrm{wt}\,u+m+1 = -n-1$, i.e. $m = 2\,\mathrm{wt}\,u-n-2-j$. This is the Lean formula. So the definition is *the same* as FHL's (5.2.4) and Gannon's (5.1.11a), not a variant.

Physical meaning

The contragredient sector M' is the *charge conjugate* (antiparticle) sector: its states are the bras dual to the kets of M, and Y' is the field obtained by the BPZ conjugation $z \mapsto 1/z$ of the field acting on kets, with the factor $e^{zL_1}(-z^{-2})^{L_0}$ being the conformal transformation law of a quasi-primary under inversion. In a rational CFT the fusion rules satisfy $N^V_{MM'} = 1$: M' is the unique sector that fuses with M to the vacuum.

Theorem 12.30 (M' is an ordinary module; FHL Theorem 5.2.1)**.** *For every ordinary module M, (M', Y') is an ordinary V-module with $(M')_\alpha = M^*_\alpha$; in particular $\chi_{M'} = \chi_M$. Moreover, for quasi-primary $v \in V_n$ (that is, $L_1 v = 0$), $\chi_{M'}(v;q) = (-1)^n\chi_M(v;q)$.*

```

From the mathematics to the Lean statement

The Jacobi identity is proved, not assumed. `ContragredientJacobi N` is word for word the module Jacobi axiom for the field `YMdual N`, and `contragredientJacobi_holds` proves it for every N with no hypothesis. `contragredientModule N` is the unconditional ordinary module; the `rfl` lemma `contragredientModule_eq_contragredient` shows it is *definitionally* the module whose field is `YMdual N` and whose weight spaces are M^*_α (the remaining fields of `contragredientOrdVModule`: L_0 acts by α on M^*_α, finite-dimensionality, lower bound — proved in the same file). `contragredientFromResidual N` is another name for `contragredientModule N`.

Characters. `contragredientGradedDim N` is $e \mapsto \dim(M_{e+c/24})^*$, and the theorem says this equals $\dim M_{e+c/24}$ — a statement about vector spaces, independent of the action (so it holds equally for the module just built). `onePoint_contragredient_holds`: for $v \in V_n$ with $L_1 v = 0$, the one-point function of M' is $(-1)^n$ times that of M (`n.toNat` equals n for $n \geq 0$; for $n < 0$, $v = 0$ by CFT type and both sides vanish). For general v the formula has L_1-correction terms, which the library does not state.

Same as the literature? Yes: FHL Theorem 5.2.1 (and the evident equality $\chi_{M'} = \chi_M$, Gan-

non (5.3.4b)), and Zhu's $\mathrm{tr}_{M'} o(v)q^{L_0} = (-1)^n \mathrm{tr}_M o(v)q^{L_0}$ for quasi-primary v (the transpose of $o(v)$ is $(-1)^n o(v)$ up to L_1-terms). What the library does *not* prove: $M'' \cong M$, and that M' is irreducible when M is.

Proof on paper. Vacuum and truncation are immediate from the formula ($\mathbf{1}'_{(n)}$ is the transpose of $\mathbf{1}_{(-n-2)} = \delta_{n,-1}$; and $u'_{(n)}$ maps M^*_γ to $M^*_{\gamma+\mathrm{wt}\,u-n-1}$, which is 0 for n large by the lower bound of M). The Jacobi identity is FHL's argument: one must show that the conjugation $u \mapsto e^{zL_1}(-z^{-2})^{L_0}u$, $z \mapsto z^{-1}$ transforms the Jacobi identity of Y into that of Y'. The key identities are the conjugation formulas $e^{zL_1}(-z^{-2})^{L_0}\,Y(u,z_0)\,(-z^{-2})^{-L_0}e^{-zL_1} = Y\big(e^{(z+z_0)L_1}(-(z+z_0)^{-2})^{L_0}u, -z_0/(z(z+z_0))\big)$ and the change of variables in the formal delta functions. The library carries this out mode by mode: it reduces the identity to a residual (`DualAdjResidual`), proves the quasi-primary case, and then the general case by eliminating the comultiplication coefficient of e^{zL_1} in closed form and a Vandermonde convolution (`ContragredientClose.lean`). For the one-point function: on M^*_α the zero mode of a quasi-primary $v \in V_n$ is $(-1)^n$ times the transpose of $o(v)|_{M_\alpha}$, and a transpose has the same trace. □

What the machine verified

Proved, unconditional. `#print axioms` (run for this chapter) of `VOA.contragredientModule`, `VOA.contragredientJacobi\_holds`, `VOA.contragredient\_gradedDim`, `VOA.onePoint\_contragredient\_holds`: standard three; no `VOA.pbw`. The file `Contragredient.lean` still describes the action as "frontier" in one of its section comments; the status paragraph at the top of the same file says it is unconditional, which is correct.

Physical meaning

Charge conjugation preserves the spectrum: M' has the same energies and degeneracies as M. The one-point function of a quasi-primary field of weight n picks up $(-1)^n$, the parity of the field under the inversion that exchanges particles and antiparticles; for a current ($n = 1$) it is the statement that conjugate sectors carry opposite charges.

Trap / dead end

`SelfContragredient` is vacuous (serious, recorded in the library). In `VOA/Modules/Contragredient.lean`:

```
def SelfContragredient (N : OrdVModule W M) : Prop :=
  Nonempty (M ≃ₗ[ℂ] RestrictedDual N)
```

This asks only for a *linear* isomorphism $M \cong \bigoplus_\alpha M^*_\alpha$, which exists for every ordinary module (choose a basis of each finite-dimensional M_α). The library proves it: `selfContragredient_of_ordVModule (N : OrdVModule W M) : SelfContragredient N` (`VOA/Modules/StronglyRational.lean`; `#print axioms`: standard three). The literature's "$M \cong M'$" means an isomorphism *of V-modules* (with `contragredientModule N`), which the library does not define. The predicate has no consumer; the library's strong-rationality notions deliberately use `SelfDual` (Section 12.9.7) instead.

Proposition 12.31 (`Unitary` is unsatisfiable in dimension ≥ 2)**.** *The library's "unitary module" structure on an ordinary module M asks for a $\mathbb{C}$-bilinear form $(\cdot|\cdot)$ on M with $(u_{(n)}x|y) = (x|u_{(n)}y)$ for all u, n, x, y and $(x|x) \neq 0$ for every $x \neq 0$. If M contains two linearly independent vectors, no such structure exists.*

File `VOA/Modules/Contragredient.lean`; the proposition is the library theorem `VOA.old_unitary_`

`isEmpty` (`VOA/Modules/CoreFixUnitary.lean`).

```
structure Unitary [StarRing ℂ] (N : OrdVModule W M) where
  form : M →ₗ[ℂ] M →ₗ[ℂ] ℂ
  invariant : ∀ (u : 𝒱) (n : ℤ) (x y : M),
    form (N.toWeakModule.act u n x) y = form x (N.toWeakModule.act u n y)
  posDef : ∀ x : M, x ≠ 0 → form x x ≠ 0
```

From the mathematics to the Lean statement

Decoding. `M →ₗ[ℂ] M →ₗ[ℂ] ℂ` is a *bilinear* (not sesquilinear) form. The hypothesis `[StarRing ℂ]` asks for a star operation on $\mathbb{C}$ but nothing in the structure uses it; the docstring's "star involution $u \mapsto u^{*}$" does not appear in the fields. `posDef` is not positivity (which would need a real part) but non-isotropy: $(x|x) \neq 0$.

What is wrong (serious). Over $\mathbb{C}$, a quadratic form in two or more variables always has a nonzero zero: $q(ae_1+e_2) = a^2(e_1|e_1)+a\big((e_1|e_2)+(e_2|e_1)\big)+(e_2|e_2)$ is a quadratic polynomial in a, which has a root if $(e_1|e_1) \neq 0$, and if $(e_1|e_1) = 0$ then $x = e_1$ itself is isotropic. So `posDef` fails on every space of dimension ≥ 2, whatever the action. Independently, the `invariant` field is not the unitarity condition of the literature, which is $(u_{(n)}x|y) = (x|\theta(u)^{\dagger}_{(n)}y)$ with an *antilinear* involution θ and, for the Virasoro modes, $(L_n x|y) = (x|L_{-n}y)$; the library's condition pairs $u_{(n)}$ with itself. Unitarity in the sense of Dong–Lin (Hermitian, positive definite, θ-twisted invariance) is therefore not represented by this structure. It has no consumers (the only use is an `example` that it typechecks); graded unitarity in the sense of the rest of the library is a different notion (Chapter 19).

Proof on paper. The isotropic-vector argument just given; the Lean proof formalises it with Mathlib's quadratic-formula lemma `exists_quadratic_eq_zero` and the existence of square roots in $\mathbb{C}$. □

What the machine verified

Proved in the library (`old_unitary_isEmpty`). When this chapter was written the statement was checked in Lean outside the library, compiled with `lake env lean -DmaxSynthPendingDepth=3`; axioms `[propext, Classical.choice, Quot.sound]`. `#print axioms` for the library theorem was not re-run for this edition.

Physical meaning

In physics a unitary sector carries a positive-definite *Hermitian* inner product for which $L_n^{\dagger} = L_{-n}$ (and $J_n^{a\dagger} = J^a_{-n}$ for currents); unitarity of the minimal models singles out the FQS series. The library's structure, being bilinear and asking each mode to be its own adjoint, does not express this, and over the complex numbers no bilinear form can be "positive" on a space of dimension two or more.

12.8 Intertwining operators and the fusion coefficient

Definition 12.32 (The library's intertwining operators and intertwiner space)**.** Let M, N, P be ordinary V-modules. *Mode data* of type $\binom{P}{M}N$ is a family of bilinear maps $\mathcal{Y}_s : M \otimes N \to P$, $s \in \mathbb{C}$ (the coefficient of z^{-s-1} of a would-be field $\mathcal{Y}(u,z)x$ with arbitrary complex powers of z). Its *intertwining defect* is

$$\Delta(a,p,s,u,x) = a^P_{(p)}\mathcal{Y}_s(u)x - \mathcal{Y}_s(u)a^N_{(p)}x - \sum_{j\geq 0}\binom{p}{j}\mathcal{Y}_{s+p-j}(a^M_{(j)}u)x,$$

for $a \in V$, $p \in \mathbb{Z}$, $s \in \mathbb{C}$, $u \in M$, $x \in N$. The library's *intertwiner space* $\mathrm{Int}(M, N; P)$ is the subspace of mode data with $\Delta \equiv 0$; an `Intertwiner` is an element of it which in addition is lower truncated ($Y_s(u)x = 0$ for $\mathrm{Re}\, s \gg 0$); and fusionCoeff $= \dim \mathrm{Int}(M, N; P)$.

File `VOA/Modules/Fusion.lean`.

```

```

(`VOA.IntertwinerModes`, `VOA.intertwinerSummand`, `VOA.intertwiningDefect`, `VOA.IntertwinerSpace`, `VOA.Intertwiner`; the two linearity fields of `intertwiningDefect` are proofs and are omitted. The last declaration, `fusionCoeff`, is displayed in Theorem 12.33.)

From the mathematics to the Lean statement

`IntertwinerModes M N P` is the type of functions $\mathbb{C} \to (M \to_{\mathbb{C}} N \to_{\mathbb{C}} P)$; `Y s u x` is $Y_s(u)x$, the coefficient of z^{-s-1}. `A.toWeakModule.act a j u` is $a^M_{(j)}u$ (Definition 12.1), and `intertwinerSummand` is the single term $\binom{p}{j} Y_{s+p-j}(a^M_{(j)}u)x$ of the commutator sum; the sum over $j \in \mathbb{N}$ is a `finsum`, which is finite because $a^M_{(j)}u = 0$ for $j \gg 0$ (the library proves `intertwinerSummand_support_finite`), so it is the true sum. The defect is exactly the commutator formula $[a_{(p)}, Y(u,z)] = \sum_j \binom{p}{j} z^{p-j} Y(a_{(j)}u, z)$ written in modes: it is the $\ell = 0$ slice of the Jacobi identity for intertwining operators of Frenkel–Huang–Lepowsky. `IntertwinerSpace A B C` is the kernel of the linear map `intertwiningDefect A B C`, so it is a subspace of the mode data.

Same, stronger or weaker. *Weaker* than FHL's Definition 5.4.1: there is no iterate (associativity) part of the Jacobi identity, no L_{-1}-derivative property $Y(L_{-1}u, z) = \partial_z Y(u, z)$, and `IntertwinerSpace` does not even include the lower truncation (only the bundled `Intertwiner` does). So the library's intertwiner space *contains* the space of FHL intertwiners, possibly strictly. **Could the definition be wrong or vacuous?** It is not vacuous as a definition: the Moonshine construction's skew intertwiner W is an `Intertwiner` (Chapter 37). But the number `fusionCoeff` built from it is *not* a fusion rule, and in fact is 0 for all modules (Theorem 12.33); the discussion in that theorem applies.

Physical meaning

An intertwining operator is the algebraic form of a chiral vertex operator of CFT: the operator $Y(u,z)x$ that inserts a primary field of sector M and acts on states of sector N, landing in sector P. The operator product of fields from two sectors decomposes as the fusion product $M \times N = \bigoplus_P N_{MN}^P P$, and N_{MN}^P is the dimension of the space of intertwiners. The library's notion keeps only the commutator relations with the modes (the Ward identities for V) and drops associativity and the derivative property; so its dimension is an upper bound on the true fusion multiplicity and is not the fusion rule. The OPE of sectors becomes rigid only after the full Jacobi identity is imposed, which is what leads to the Verlinde formula.

Proof on paper. There is nothing to prove: these are definitions. The one claim made, that the vanishing of the defect is the commutator formula in modes, is the following: for an honest intertwining operator the $\ell = 0$ slice of its Jacobi identity reads $[a_{(p)}, Y(u,z)] = \sum_{j\geq 0} \binom{p}{j} z^{p-j} Y(a_{(j)}u, z)$, and comparing the coefficients of z^{-s-1} on both sides gives $a_{(p)}^P Y_s(u)x - Y_s(u)a_{(p)}^N x = \sum_j \binom{p}{j} Y_{s+p-j}(a_{(j)}^M u)x$, i.e. $\Delta = 0$. □

What the machine verified

Definitions. `#print axioms` of `VOA.IntertwinerModes`, `VOA.intertwiningDefect`, `VOA.IntertwinerSpace` is `[propext, Classical.choice, Quot.sound]` (run for this chapter). **Warning:** the derived number `fusionCoeff` is identically 0 (Theorem 12.33); do not read it as a fusion rule.

Definition 12.32 introduced the library's intertwining operators: mode data $Y_s : M \otimes N \to P$, $s \in \mathbb{C}$, subject only to the commutator condition

$$a_{(p)}^P Y_s(u)x - Y_s(u)a_{(p)}^N x = \sum_{j\geq 0} \binom{p}{j} Y_{s+p-j}(a_{(j)}^M u)x$$

for all $a \in V$, $p \in \mathbb{Z}$, $s \in \mathbb{C}$, $u \in M$, $x \in N$ (the kernel `IntertwinerSpace A B C` of the linear map `intertwiningDefect`), and `fusionCoeff A B C := Module.finrank ℂ (IntertwinerSpace A B C)`. In the literature (FHL Definition 5.4.1) an intertwining operator of type $\binom{P}{MN}$ must in addition satisfy lower truncation, the full Jacobi identity (with its iterate part) and the L_{-1}-derivative property $Y(L_{-1}u, z) = \partial_z Y(u,z)$; the fusion rule N_{MN}^P is the dimension of that space.

Theorem 12.33 (`fusionCoeff` is identically zero). *For all ordinary modules A, B, C,* `fusionCoeff A B C = 0`. *More precisely,* `IntertwinerSpace A B C` *is either the zero space or infinite-dimensional.*

Library file `VOA/Modules/Fusion.lean`; the result is the library theorem `VOA.fusionCoeff_eq_zero` (`VOA/Modules/CoreFixFusion.lean`).

```
noncomputable def fusionCoeff (A : OrdVModule W M) (B : OrdVModule W N) (C : OrdVModule W
↪  P) : ℕ :=
  Module.finrank ℂ (IntertwinerSpace A B C)
```

From the mathematics to the Lean statement

Status of the claim. Chapter 1 and Chapter 43 argued this on paper, and it had been recorded as a defect that was not yet formalised. It is now formalised, and the defect is *confirmed*. When this chapter was written it was checked in Lean outside the library, with the standard three axioms; `#print axioms` for the library theorem was not re-run for this edition.
Why this is a defect and not a theorem about fusion (serious). The true fusion rule N_{VV}^V of a simple VOA is 1, and $N_{MM'}^V = 1$; the library's number is 0 in all cases. The cause is the missing L_{-1}-derivative property and grading: without them the exponents s can be shifted

by any complex number.
Does this make any theorem vacuous? We searched the library: `fusionCoeff` and `IntertwinerSpace` are used nowhere outside `Fusion.lean` (the identically named `fusionCoeff` in `VOA/Examples/VirasoroFusion*.lean` is an unrelated local power-series coefficient). The bundled `Intertwiner` structure is used by the Moonshine construction (`skewIntertwiner`, `leechSkewIntertwiner`, Chapter 37); its fields are satisfiable (the skew intertwiner is a nonzero example), so no theorem stated with it is vacuous, and the Moonshine chapters prove the L_{-1}-property and all uniqueness statements separately. The "Verlinde apex" in the docstring of `Fusion.lean` ("`fusionCoeff` is exactly the interface they wire to") is not implemented and, with this definition, could not be (documentation only).
