All declarations live in the namespace `VOA.Moonshine.LatticeTwisted` (files `VOA/Moonshine/LatticeTwisted*.lean`), except the plus-part construction (`VOA.TwistedPlus`, `VOA/Moonshine/TwistedPlusModule.lean`) and the Leech plus module (`VOA.Moonshine`, `VOA/Moonshine/TwistedPlus.lean`).

36.2 Notation and the objects we build on

This section recalls, with their Lean sources, the definitions from earlier chapters that occur in the statements of this chapter. The reader who has Chapters 34 and 35 fresh may skim it, but every later fidelity check refers back here.

36.2.1 The twisted Fock space and its modes

Definition 36.1 (Twisted Fock space). For $r \in \mathbb{N}$, $S[\theta] = S[\theta]_r$ is the polynomial algebra over $\mathbb{C}$ in variables $X_{(n,i)}$, $n \in \mathbb{N}$, $i \in \{0, \dots, r-1\}$, where $X_{(n,i)}$ stands for the creation operator $h_i(-n-\frac{1}{2})$ applied to the vacuum 1. The mode $h_i(k/2)$ for odd k acts as multiplication by $X_{((-k-1)/2,i)}$ if $k<0$ and as $\frac{k}{2}\,\partial/\partial X_{((k-1)/2,i)}$ if $k>0$.

File `VOA/Moonshine/TwistedHeisenberg.lean`.

```
abbrev FockT (r : ℕ) : Type := MvPolynomial (ℕ × Fin r) ℂ

noncomputable def modeT (r : ℕ) (i : Fin r) (k : ℤ) : Module.End ℂ (FockT r) :=
  if k % 2 = 0 then 0
  else if k < 0 then mulXT (varT i k)
  else ((k : ℂ) / 2) • pderivT (varT i k)
```

From the mathematics to the Lean statement

Half-integer modes. Lean has no type of half-integers; the mode $h_i(k/2)$ is indexed by the *integer* k, and only odd k are meaningful. For even k the definition returns the junk value

0, which is mathematically correct (a θ-twisted current has no integral modes). This "index k stands for $k/2$" convention is used throughout the chapter: every twisted vertex operator is a function $\mathbb{Z} \to \mathrm{End}$, whose value at k is the coefficient $u_{(k/2)}$. With this normalisation $[h_i(k/2), h_j(l/2)] = \frac{k}{2}\delta_{ij}\delta_{k+l,0}$ (Chapter 34, `modeT_comm`). `L0T r` is the Virasoro zero mode $L_0 = \frac{1}{2}\cdot(\text{doubled weight}) + \frac{r}{16}$ of Chapter 35, and `gradingT r d` the span of monomials of doubled weight d (a variable $X_{(n,i)}$ has doubled weight $2n+1$). `thetaT r` is the algebra automorphism $X_{(n,i)} \mapsto -X_{(n,i)}$.

Physical meaning

In the Leech lattice CFT the θ-twisted sector is built on 24 free bosons whose oscillators carry half-integer moding, $\alpha^a_{-n-1/2}$, because the fields ∂X^a pick up a sign -1 on going around the twist field inserted at the origin. The polynomial ring $S[\theta]_r$ is the Fock space of these twisted oscillators; the ground state 1 is the twist field with no oscillator excited. Its weight is $r/16$, which is $3/2$ for $r = 24$: each of the 24 bosons contributes the standard $1/16$ twisted vacuum energy. This is the oscillator half of the twisted sector $V_\Lambda^T = S[\theta][\theta] \otimes T$; the other half is the space of ground states.

36.2.2 Fields, products, locality

The library's calculus of fields (Chapters 2, 4 and 35) uses the following objects. A *formal distribution* is a function $f : \mathbb{Z} \to \mathrm{End}(M)$, read as $f(z) = \sum_n f(n)z^n$; its mode is `mode f m = f (-m - 1)`, the coefficient of z^{-m-1} (Definition 2.7, `VOA/Foundations/FormalCalculus.lean`). A *field* (`Fld M`, the subtype of formal distributions satisfying `IsField`) is a formal distribution which is lower truncated on every vector (Definition 4.44, `VOA/Core/LocalSystem.lean`). Two distributions are *local*, `Local a b`, if `∃ N : ℕ, mulBySubPow N (bracketDist a b) = 0`: some power of $(z_1 - z_2)$ kills their commutator (Definition 2.41, `VOA/Foundations/Locality.lean`); here `bracketDist a b` is $[a(z_1), b(z_2)]$ as a two-variable distribution and `mulBySubPow N` multiplies by $(z_1 - z_2)^N$. For local fields a, b and $n \in \mathbb{Z}$ the n-th product $a_{(n)}b$ (`Fld.prod n a b`) is the usual one, $a_{(n)}b(z_2) = \mathrm{Res}_{z_1}\big((z_1 - z_2)^n a(z_1)b(z_2) - (-z_2 + z_1)^n b(z_2)a(z_1)\big)$. `fzmul k a` is $z^k a(z)$.

Definition 36.2 (Rescaled field). For a family $A : \mathbb{Z} \to \mathrm{End}\, M$ of fractional modes, $A(k) = u_{(k/N)}$, and a residue $e \in \mathbb{Z}$, the rescaled field on the class $e + N\mathbb{Z}$ is the integrally moded distribution whose p-th mode is $A(Np + e)$: mathematically $z^{e/N} \sum_{k \equiv e} u_{(k/N)} z^{-k/N-1}$.

File `VOA/Moonshine/HeisenbergTwistedModuleReduction.lean`.

```
def resc (A : ℤ → End ℂ M) (N : ℕ) (e : ℤ) : FormalDist (End ℂ M) :=
  fun n => A (N * (-n - 1) + e)
```

From the mathematics to the Lean statement

`mode_resc` says `mode (resc A N e) p = A (N * p + e)`. For $N = 2$: resc $A\,2\,e$ is $z^{e/2}Y(u,z)$ restricted to the half-integral (if e odd) or integral (if e even) modes. Locality of two twisted fields $Y(u,z_1), Y(v,z_2)$, which are series in $z_1^{1/2}, z_2^{1/2}$, is equivalent to locality of every pair of rescaled class components, because multiplication by $z_1^{e/2}z_2^{e'/2}$ commutes with $(z_1 - z_2)^N$. This is why every locality statement below is stated for `resc` fields on all classes e, e'. `rescFld` packages `resc` as an element of `Fld` given a truncation proof.

Physical meaning

Going around the twist field the vertex operator $Y(u,z)$ of a θ-odd or generic state is multivalued, with expansion in powers of $z^{1/2}$. Splitting off the factor $z^{e/2}$ and keeping one residue class of exponents produces ordinary single-valued formal distributions, to which the usual calculus of local fields applies. Heuristically this is passing to the double cover $w = z^{1/2}$ of the plane branched at the twist field.

Definition 36.3 (Twisted product). For a twist $\alpha \in \mathbb{C}$, fields A, X and $p \in \mathbb{Z}$,

$$\mathrm{star}_\alpha(A)_p X = \sum_{i \geq 0} \binom{-\alpha}{i} z^{-i} A_{(p+i)} X.$$

File `VOA/Moonshine/HeisenbergTwistedModuleTwistedComm.lean`.

```
noncomputable def star (α : ℂ) (A : Fld M) (p : ℤ) (X : Fld M) : Fld M :=
  ∑ᶠ i : ℕ, cbinom (-α) i • fzmul (-(i : ℤ)) (Fld.prod (p + i) A X)
```

From the mathematics to the Lean statement

`cbinom x i` is $x(x-1)\cdots(x-i+1)/i!$ for complex x; the $\sum^{\mathrm{f}}$ is a finite sum because $A_{(p+i)}X = 0$ for large i when A, X are local. **Meaning.** Write $A(z) = z^\alpha Y(u,z)$, $X(z) = z^{\alpha'} Y(v,z)$. Since $\sum_i \binom{-\alpha}{i}(z_1 - z_2)^i z_2^{-i} = (z_1/z_2)^{-\alpha}$, one has formally $\mathrm{star}_\alpha(A)_p X(z_2) = z_2^{\alpha+\alpha'} \operatorname{Res}_{z_1}(z_1 - z_2)^p [Y(u,z_1)Y(v,z_2) - Y(v,z_2)Y(u,z_1)]$, where the binomial expansion gives the precise meaning to the residue of the half-integral powers. So star is the rescaled version of the twisted iterate (associativity) formula $Y(u_{(p)}v, z) = \operatorname{Res}_{z_1}(\cdots)$, and the twisted product formula below says exactly that the twisted vertex operator satisfies it.

Physical meaning

This is the binomial rule for moving a twisted field past a field which carries branch-cut phase z^α: expanding $(z_1/z_2)^{-\alpha}$ in powers of $(z_1 - z_2)/z_2$ gives the coefficients $\binom{-\alpha}{i}$. In CFT terms it is the operator product of a field with the twisted sector, written so that the monodromy around the twist field is built in. Heuristic gloss only; the formal identity is proved in Lean.

Definition 36.4 (Generated twisted system). For a set S of fields, `TGenerated S` is the smallest set containing S, the identity field and 0, and closed under all products $a_{(n)}b$ ($n \in \mathbb{Z}$), multiplication by z^k, sums and scalar multiples.

File `VOA/Moonshine/HeisenbergTwistedModuleLocality.lean`.

```
inductive TGen (S : Set (Fld M)) : ℕ → Fld M → Prop
  | base {a : Fld M} : a ∈ S → TGen S 0 a
  | one : TGen S 0 Fld.one
  | zero : TGen S 0 0
  | prod {i j : ℕ} {a b : Fld M} (n : ℤ) : TGen S i a → TGen S j b →
      TGen S (i + j + 1) (Fld.prod n a b)
  | zmul {i : ℕ} {a : Fld M} (k : ℤ) : TGen S i a → TGen S (i + 1) (fzmul k a)
  | add {i j : ℕ} {a b : Fld M} : TGen S i a → TGen S j b → TGen S (i + j + 1) (a + b)
  | smul {i : ℕ} {a : Fld M} (c : ℂ) : TGen S i a → TGen S (i + 1) (c • a)

def TGenerated (S : Set (Fld M)) : Set (Fld M) := {a | ∃ i, TGen S i a}
```

Physical meaning

This is the set of all fields obtainable by operator products (and the rescalings by $z^{1/2}$) from a chosen list of generating fields, in other words the fields of the chiral algebra generated by the twisted currents and the twisted lattice exponentials. Dong's lemma then says that locality of the generators propagates to every composite, the algebraic version of the statement that a Wick-type product of mutually local operators remains local.

By Dong's lemma (proved in Chapter 35 as `tgenerated_local`), if S is pairwise local then so is `TGenerated S`. Note that z^k-multiplication is allowed: this is what makes the system "twisted" (the rescalings $z^{e/2}$ move fields between classes).

36.2.3 Twisted modules

The target structure is the (repaired) twisted module of Chapter 34. We reproduce it in full because it is the conclusion of the main theorem. File `VOA/Modularity/Twisted.lean`.

```

```

From the mathematics to the Lean statement

Decoding. `YM u k` is $u_{(k/N)}$, the coefficient of $z^{-k/N-1}$ in $Y_M(u,z)$. `g.twistedEigenspace N j` is the eigenspace of g for the eigenvalue $e^{-2\pi i j/N}$; for $N=2$ it is $\{u : gu = (-1)^j u\}$. The support axiom says that for such u only the modes with $k \equiv -j \pmod N$ occur, i.e. $Y_M(u,z) \in z^{j/N}\,\mathrm{End}(M)[[z^{\pm1}]]$. In `jacobi`, `YM u (ℓ * N + k - i * N)` $= u_{(\ell+k/N-i)}$, `cbz ℓ i` is $\binom{\ell}{i}$ (zero for $i<0$) and `negOnePow` is $(-1)^{\cdot}$; so the identity reads, for $u \in V^j$, $k \equiv -j$,

$$\sum_i (-1)^i \binom{\ell}{i} \Big(u_{(\ell+\frac{k}{N}-i)} v_{(\frac{m}{N}+i)} x - (-1)^{\ell} v_{(\ell+\frac{m}{N}-i)} u_{(\frac{k}{N}+i)} x \Big) = \sum_{i \ge 0} \binom{k/N}{i} (u_{(\ell+i)} v)_{(\frac{k+m}{N}-i)} x,$$

which is the mode form of the twisted Jacobi identity of Dong–Li–Mason. `W.smul u n v` is the product $u_{(n)}v$ in the VOA. The grading axioms are as for ordinary modules (Definition 12.5): `DirectSum.IsInternal weight` says $M = \bigoplus_\alpha M_\alpha$ as an internal direct sum, and $L_0 = \omega_{(1)}$, which is `YM ω N`, acts on M_α by α.

Trap / dead end

The hypothesis `(k + j) % (N : ℤ) = 0` in `jacobi` is the 2026-10-06 repair. Before it, the identity was required for all k, including k off the support of u; the certificate $u = v = \mathbf{1}$, $\ell = -1$, $k = 1$, $m = -N-1$ then gives $0 = x$, so for $N \geq 2$ no nonzero twisted module existed (`VOA.jacobiAllIndices_eq_zero`). Every result of this chapter is about the repaired structure. The analogous field of `SuperTwistedModule` has *not* been repaired; it is not used here (see §36.15).

The definition `TwistedJacobi g N YM` (file `VOA/Moonshine/HeisenbergTwistedModuleDefect.lean`) is literally the proposition in the `jacobi` field, as a predicate on a candidate `YM`.

36.2.4 The lattice side

From Chapters 30–32 and 34 we use:

- `L : IntegralLattice`, with `L.form` the integral bilinear form, `L.Even`, `L.PosDef`, and `hU : IsUnit (gramMat L).det` (unimodularity). `chargeCoord L α : Fin (rank L) → ℂ` are the coordinates of α in an orthonormal basis of $L \otimes \mathbb{R}$; `sum_chargeCoord` states `∑ b, chargeCoord L α b * chargeCoord L β b = ((L.form α β : ℤ) : ℂ)` under `hPos`.
- `LatModuleGen L` $= V_L =$ FockN(rank L) $\otimes \mathbb{C}[L]$, with the VOA structure `latticeVOAGen L hEven hPos`; `eGen L α` is $e^\alpha \in \mathbb{C}[L]$, `echg L α` $= 1 \otimes e^\alpha$ and `hgen L b` $= h_b(-1)\mathbf{1}$. `latticeCocycle L α β` $= \varepsilon(\alpha,\beta) \in \{\pm 1\}$ is the bimultiplicative cocycle with $\varepsilon(\alpha,\beta)\varepsilon(\beta,\alpha)^{-1} = (-1)^{\langle\alpha,\beta\rangle}$.
- `thetaLat L`: $p \otimes e^\alpha \mapsto \sigma(p) \otimes e^{-\alpha}$, σ the sign change of all oscillators, and `thetaAut L hEven hPos` the same map as a VOA automorphism. (No cocycle correction is needed because the library's cocycle satisfies $\varepsilon(-\alpha,\beta) = \varepsilon(\alpha,\beta)$.) `leechTheta` is `thetaAut` for $L = \Lambda$ and `leechVOAPlus` is the fixed-point VOA `orbifoldVOA (Subgroup.zpowers leechTheta)` (Chapter 32).
- `Rep (cocMat L) (isUnit_det_cocMat L hEven hU)` is the space $\mathcal{T}_L$ and `eT L hEven hU α` the operator e_α on it, with `eT_mul`: $e_\alpha e_\beta = \varepsilon(\alpha,\beta)e_{\alpha+\beta}$, `eT_neg`: $e_{-\alpha} = e_\alpha$, and `eT_add_two_nsmul`: $e_{\alpha+2\gamma} = e_\alpha$ (Chapter 34). For Λ this space is `leechT`, of dimension 4096.

36.3 Newton exponentials and the contraction factor

The operators $E^\pm$ are exponentials of infinite sums of commuting operators. Rather than manipulate exp of operator-valued series, the library works with the *coefficients* of such exponentials, characterised by a first-order recursion. This section is pure algebra over an arbitrary commutative $\mathbb{C}$-algebra R (`VOA/Moonshine/LatticeTwistedExp.lean`).

Definition 36.5 (Newton exponential). For a sequence $d = (d_k)_{k\geq 1}$ in R, let $E_p = \mathrm{nexp}(d)_p$ be the coefficient of w^p in $\exp\left(\sum_{k\geq 1} \frac{d_k}{k} w^k\right)$. Equivalently $E_0 = 1$ and

$$(p+1)E_{p+1} = \sum_{k=0}^{p} d_{k+1} E_{p-k} \qquad (p \geq 0).$$

```
noncomputable def nexp (d : ℕ → R) : ℕ → R
  | 0 => 1
  | (p + 1) => ((p + 1 : ℂ))⁻¹ • ∑ k ∈ Finset.range (p + 1), d (k + 1) * nexp d (p - k)
```

From the mathematics to the Lean statement

The recursion is the coefficient form of $\theta F = D \cdot F$, where $\theta = w\,d/dw$ is the Euler operator and $D = \sum_{k\ge1} d_k w^k = \theta(\sum d_k w^k/k)$; indeed if $F = \exp(\sum d_k w^k/k)$ then $\theta F = DF$. The value `d 0` is ignored. The definition is *by* the recursion, so it makes sense in any $\mathbb{C}$-algebra (division by $p+1$ uses the $\mathbb{C}$-algebra structure) without any analytic notion of exp; there is nothing to be vacuous about. It is the same as the textbook object: the power series $\sum_p E_p w^p$ is shown to be the unique solution of $\theta F = DF$, $F(0) = 1$ (next lemma), which characterises $\exp(\sum d_k w^k/k)$.

Physical meaning

This is bookkeeping for the exponentials of oscillators that appear in the twisted vertex operators: $\exp(\sum_k \frac{d_k}{k} w^k)$ is a generating function of the Schur-type polynomials built from the creation operators. It has no independent physical content beyond being the coefficient extraction of $E^-(w) = \exp(\sum \frac{2}{k}\alpha_{-k/2} w^k)$, the vertex-operator exponential acting on the twisted Fock space.

Lemma 36.6 (Characterisation and the exponential law). *Let θ be the Euler operator on $R[[X]]$ and $D(d) = \sum_{k\ge1} d_k X^k$.*

1. *If $F \in R[[X]]$ satisfies $\theta F = D(d)F$ and $F_0 = 1$, then $F = \sum_p \mathrm{nexp}(d)_p X^p$.*
2. *$\mathrm{nexp}(d+e) = \mathrm{nexp}(d) \cdot \mathrm{nexp}(e)$ as power series.*
3. *If $\varphi : R \to S$ is a $\mathbb{C}$-algebra map, $\varphi(\mathrm{nexp}(d)_p) = \mathrm{nexp}(\varphi \circ d)_p$.*
4. *$\mathrm{nexp}(k \mapsto t^k d_k)_p = t^p\,\mathrm{nexp}(d)_p$.*
5. *If δ is a $\mathbb{C}$-derivation of R with $\delta(d_k) = \delta_{k,K}\,K\,c$ for some $K \ge 1$, then $\delta(E_p) = c\,E_{p-K}$ for $p \ge K$ and $\delta(E_p) = 0$ for $p < K$.*

```

    δ (nexp d p) = if K ≤ p then c * nexp d (p - K) else 0
```

From the mathematics to the Lean statement

`nexpPS d` is the power series with coefficients `nexp d`, `theta` is $F \mapsto \sum_p p\,F_p X^p$, `Dser d` is $D(d)$. Item (5) is the statement that a derivation hitting exactly one logarithmic coefficient d_K with value Kc acts on $\exp(\sum d_k w^k/k)$ as multiplication by $c\,w^K$: since δ of the exponent is $c\,w^K$. The hypotheses `hK : 0 < K` and `hd` are exactly these conditions. All five statements are the textbook statements with no extra hypotheses.

Physical meaning

Technical lemma about the exponential of a series: it says that the coefficients behave like the expansion of $\exp(\int D)$, multiplicatively in d (so exponentials of sums of oscillators factorise) and with the expected response to a shift of one oscillator. This is the combinatorial form of the identity $e^{A+B} = e^A e^B$ for commuting creation operators.

Proof on paper. (1) If $\theta Z = DZ$ and $Z_0 = 0$, comparing coefficients of X^{p+1} gives $(p+1)Z_{p+1} = \sum_{k\le p} d_{k+1} Z_{p-k}$, so by strong induction $Z = 0$; apply this to $Z = F - \mathrm{nexp}(d)$, which solves the linear equation because $\mathrm{nexp}(d)$ does (the recursion is that equation). (2) θ is a derivation, so $\theta(FG) = (D(d) + D(e))FG$ and (1) applies. (3) and (4) are (1) applied to $\varphi(F)$ and to $F(tX)$. (5) Apply δ coefficientwise to $\theta F = DF$: δF satisfies $\theta(\delta F) = D\,\delta F + (\theta(cX^K))F$, and $cX^K F$ satisfies the same equation; their difference has constant term 0, so by (1) it vanishes. □

What the machine verified

`VOA/Moonshine/LatticeTwistedExp.lean`. Unconditional. The file header records `#print axioms` = [`propext`, `Classical.choice`, `Quot.sound`].

Definition 36.7 (Contraction factor). For $n \in \mathbb{C}$ let $f_p^{(n)} = \mathrm{fco}(n)_p$ be the coefficient of x^p in

$$\Big(\frac{1-x}{1+x}\Big)^n = \exp\Big(-2n \sum_{k\ \mathrm{odd}} \frac{x^k}{k}\Big),$$

and $f_t^{(n)} = 0$ for $t < 0$ (`fz`).

```
def oddc : ℕ → ℂ := fun k => if k % 2 = 1 then 1 else 0

noncomputable def fco (n : ℂ) : ℕ → ℂ := nexp ((-2 * n) • oddc)

noncomputable def fz (n : ℂ) (t : ℤ) : ℂ := if 0 ≤ t then fco n t.toNat else 0
```

From the mathematics to the Lean statement

$\log(1-x) - \log(1+x) = -2\sum_{k\ \mathrm{odd}} x^k/k$, so the logarithmic coefficients (d_k with $\exp(\sum d_k x^k/k)$) of $((1-x)/(1+x))^n$ are $d_k = -2n$ for odd k and 0 for even k: that is `(-2 * n) • oddc`. For complex n the left side is defined by this exponential; for integer n it agrees with the rational function (next theorem).

Physical meaning

The factor $\big(\frac{1-x}{1+x}\big)^n$ with $x = w_2/w_1$ is the twisted two-point function of two exponential fields with momentum pairing $n = \langle \alpha, \beta \rangle$ on the double cover. For untwisted lattice vertex operators the analogous factor is $(z_1 - z_2)^n$; in the θ-twisted sector, where the propagator of the twisted boson is $\log \frac{w_1 - w_2}{w_1 + w_2}$ (the image charge at $-w$), one gets exactly this expression. Its expansion coefficients are the contraction factors.

Theorem 36.8 (The contraction factor times $(1-x^2)^N$). *For $N \in \mathbb{N}$ and $n \in \mathbb{Z}$ with $|n| \le N$,*

$$\Big(\frac{1-x}{1+x}\Big)^n (1-x^2)^N = (1-x)^{N+n}(1+x)^{N-n} =: G(x),$$

a polynomial of degree $2N$ with $x^{2N} G(1/x) = (-1)^{N+n} G(x)$. Consequently, writing $c_r = (-1)^{N-r}\binom{N}{r}$, for every $t \in \mathbb{Z}$

$$\sum_{r=0}^{N} c_r\, f^{(n)}_{t-2(N-r)} = (-1)^{|n|} \sum_{r=0}^{N} c_r\, f^{(n)}_{2(N-r)-t}. \tag{36.5}$$

```

From the mathematics to the Lean statement

`gpoly a b` $= (1-X)^a(1+X)^b$; `(N + n).toNat` is $N+n$ as a natural number, legitimate because $N+n \geq 0$ by `h1`, and similarly $N-n \geq 0$ by `h2`. `Polynomial.reflect m p` is $X^m p(1/X)$. The sign in `reflect_gpoly` is $(-1)^a$ with $a = N+n$, the same as $(-1)^{N+n}$ in the text. In `sum_binom_fz_symm` the sign is $(-1)^{|n|}$ (`n.natAbs`), which equals $(-1)^n$. The hypotheses $|n| \leq N$ are necessary: for $|n| > N$ the product is not a polynomial.

Physical meaning

Physically this is the statement that after multiplying the twisted two-point function by the cut-off $(w_1^2 - w_2^2)^N = (z_1 - z_2)^N$ the singularities at $w_1 = \pm w_2$ cancel: the exponential fields have a pole of order at most $|n|$ at coincident points, and the result is a polynomial with a reflection symmetry $w \mapsto 1/w$ up to sign $(-1)^n$. That symmetry is the source of the sign $(-1)^{\langle\alpha,\beta\rangle}$ in the exchange of two twisted vertex operators, i.e. of locality.

Proof on paper. $(1-x^2)^N = (1-x)^N(1+x)^N$, and both sides are exponentials whose logarithmic coefficients add up (Lemma 36.6(2)). The reflection of $(1-x)^a(1+x)^b$ is $(x-1)^a(x+1)^b = (-1)^a(1-x)^a(1+x)^b$. For (36.5): the left side is the coefficient g_t of x^t in $f^{(n)}(x)(1-x^2)^N = G(x)$ (expand $(1-x^2)^N = \sum_m (-1)^m\binom{N}{m}x^{2m}$ and put $m = N-r$). The right sum, reindexed by $r \mapsto N-r$, is $(-1)^N g_{2N-t}$, and palindromy gives $g_{2N-t} = (-1)^{N+n} g_t$. Hence the right side is $(-1)^{|n|}(-1)^N(-1)^{N+n} g_t = g_t$. □

What the machine verified

Unconditional (same file); axioms as above.

Example 36.9 (Small cases). Expanding $\exp(-2n(x + x^3/3 + \cdots))$ gives $f_0^{(n)} = 1$, $f_1^{(n)} = -2n$, $f_2^{(n)} = 2n^2$, $f_3^{(n)} = -\frac{4n^3+2n}{3}$. For $n = 1$ these are $1, -2, 2, -2, \ldots$, the coefficients of $(1-x)/(1+x) = 1-2x+2x^2-2x^3+\cdots$, as they must be. Take $N = 1, n = 1$: $\frac{1-x}{1+x}(1-x^2) = (1-x)^2 = 1-2x+x^2 = G(x)$, and $x^2G(1/x) = G(x)$, matching the sign $(-1)^{N+n} = +1$. For $n = -1$, $N = 1$: $G = (1+x)^2$, again palindromic with sign $+1$; for $n = 0$, $N = 1$: $G = 1-x^2$, with $x^2G(1/x) = -G(x)$, sign $(-1)^1$. In (36.5) with $N = 1$, $n = 1$, $t = 1$: the left side is $c_0 f_{-1} + c_1 f_1 = 0 + (-2) = -2$ (here $c_0 = -1$, $c_1 = 1$), and the right side is $(-1)\big(c_0 f_1 + c_1 f_{-1}\big) = (-1)(-1)(-2) = -2$.

Identity (36.5) is the whole combinatorial content of the locality of twisted lattice vertex operators: it says that the two expansions of $(w_1^2 - w_2^2)^N f(w_2/w_1)$ (in $|w_2| < |w_1|$) and of $(w_1^2 - w_2^2)^N f(w_1/w_2)$ (in $|w_1| < |w_2|$) are the same polynomial up to the sign $(-1)^n$.

36.4 The operators $E^\pm$ on the twisted Fock space

File `VOA/Moonshine/LatticeTwistedEOps.lean`. Throughout, a *charge vector* is $v \in \mathbb{C}^r$; for a lattice vector α it will be `chargeCoord L α`. The pairing is $\langle v,u\rangle = \sum_i v_i u_i$ (`pair`).

Definition 36.10 (Twisted oscillator). $v(k/2) = \sum_i v_i\, h_i(k/2)$ for odd k.

```
noncomputable def oscT (v : Fin r → ℂ) (k : ℤ) : End ℂ (FockT r) := ∑ i, v i • modeT r i k

theorem oscT_comm (v u : Fin r → ℂ) {k l : ℤ} (hk : Odd k) (hl : Odd l) :
    oscT v k * oscT u l - oscT u l * oscT v k
      = (if k + l = 0 then (k : ℂ) / 2 * pair v u else 0) • LinearMap.id
```

From the mathematics to the Lean statement

This is $[v(k/2), u(l/2)] = \frac{k}{2}\langle v,u\rangle \delta_{k+l,0}$, the twisted oscillator algebra, for odd k,l (the hypotheses `hk`, `hl`); $*$ is composition. Same as the textbook statement.

Physical meaning

This is the twisted free-boson current $i\,v\cdot\partial X$ in the direction $v \in \mathbb{R}^{24}$, expanded in half-integer modes; $v(k/2)$ is its $k/2$-th Laurent mode on the twisted Fock space.

Definition 36.11 (The creation exponential E^-). Let $d_k = 2\,v(-k/2)\mathbf{1} = 2\sum_i v_i X_{((k-1)/2,i)}$ for odd k and $d_k = 0$ for even k. Then $E^-(-v,w) = \exp\big(\sum_{k\text{ odd}} \frac{2}{k} v(-k/2) w^k\big)$ is multiplication by $\sum_p s_p(v) w^p$ with $s_p(v) = \mathrm{nexp}(d)_p \in S[\theta]$.

```
noncomputable def vVarT (v : Fin r → ℂ) (n : ℕ) : FockT r := ∑ i, v i • X (n, i)

noncomputable def dM (v : Fin r → ℂ) : ℕ → FockT r :=
  fun k => if k % 2 = 1 then (2 : ℂ) • vVarT v (k / 2) else 0

noncomputable def sM (v : Fin r → ℂ) (p : ℕ) : FockT r := nexp (dM v) p

noncomputable def sMz (v : Fin r → ℂ) (p : ℤ) : FockT r := if 0 ≤ p then sM v p.toNat else
↪  0
```

From the mathematics to the Lean statement

Compare with (36.2): $\sum_{n\in\frac12+\mathbb{N}} \alpha(-n) z^n/n$ with $z = w^2$, $n = k/2$, is $\sum_{k\text{ odd}} \frac{2}{k}\alpha(-k/2)w^k$, whose logarithmic coefficients (d_k with $\exp\sum d_k w^k/k$) are $2\alpha(-k/2)$. Since the creation operators are multiplications by the commuting variables, E^- is multiplication by an element of the polynomial ring, and `sM v p` is its w^p coefficient; `k / 2` is integer division, so for odd k it is $(k-1)/2$. `sMz` extends by 0 to negative p.

Physical meaning

This is the creation part of the lattice vertex operator in the twisted sector: the normal-ordered exponential $\exp\big(\sum_{k\text{ odd}} \frac{2}{k}\alpha_{-k/2} w^k\big)$ of the creation oscillators, which dresses the ground state with a coherent cloud of twisted bosons of momentum v. Only odd (half-integer) modes occur, since the twisted bosons have no integer modes.

Definition 36.12 (The annihilation exponential E^+ as a translation). The operator $E^+(-v,w) = \exp\bigl(-\sum_{k\ \mathrm{odd}>0} \frac{2}{k} v(k/2) w^{-k}\bigr)$ equals the substitution $X_{(n,i)} \mapsto X_{(n,i)} - v_i w^{-(2n+1)}$. Writing $u = w^{-1}$, it is the $\mathbb{C}$-algebra map $S[\theta] \to S[\theta][u]$, $X_{(n,i)} \mapsto X_{(n,i)} - v_i u^{2n+1}$; $E^+_q(-v)$ denotes the coefficient of $u^q = w^{-q}$.

```
noncomputable def Ep (v : Fin r → ℂ) : FockT r →ₐ[ℂ] Polynomial (FockT r) :=
  aeval fun x => Polynomial.C (X x) - v x.2 • Polynomial.X ^ (2 * x.1 + 1)

noncomputable def EpC (v : Fin r → ℂ) (q : ℕ) : End ℂ (FockT r) where
  toFun y := (Ep v y).coeff q
  map_add' a b := by rw [map_add, Polynomial.coeff_add]
  map_smul' c a := by rw [map_smul, Polynomial.coeff_smul]; rfl
```

From the mathematics to the Lean statement

Why this is the same operator. On $S[\theta]$, $v(k/2) = \frac{k}{2}\sum_i v_i \partial_{((k-1)/2,i)}$ for odd $k > 0$, so the exponent is $-\sum_{n,i} v_i w^{-(2n+1)} \partial_{(n,i)}$, a first-order operator with constant coefficients in the commuting derivations $\partial_{(n,i)}$. Taylor's formula says $\exp(-\sum c_x \partial_x) f(X) = f(X - c)$ for polynomials f; hence E^+ is the translation. The Lean definition takes the translation as the *definition*; this is deliberate (it avoids infinite sums of operators) and harmless (it is an exact identity of operators on polynomials). The output lies in the polynomial ring $S[\theta][u]$, which encodes the lower truncation: on a fixed vector only finitely many E^+_q are nonzero (`EpC_eventually_zero`).

Physical meaning

This is the annihilation part of the vertex operator exponential. Since $\alpha_{k/2}$ is a derivative with respect to the creation variable, the exponential of annihilation operators acts as a translation of the oscillator variables: a coherent-state shift by the classical field produced by the charge v. This is the usual statement that $e^{a\partial}$ is a translation.

Theorem 36.13 (The E^+E^- reordering). *For charge vectors v, u, $q \in \mathbb{N}$, $p \in \mathbb{Z}$ and $y \in S[\theta]$,*

$$E^+_q(-v)\bigl(s_p(u)\,y\bigr) = \sum_{j=0}^{q} f_j^{(\langle v,u\rangle)}\, s_{p-j}(u)\, E^+_{q-j}(-v) y.$$

Equivalently, as generating series, (36.3) holds with $w_i = z_i^{1/2}$: $E^+(-v,w_1)E^-(-u,w_2) = E^-(-u,w_2)E^+(-v,w_1)(\frac{1-w_2/u}{1+w_2/u}$

File `VOA/Moonshine/LatticeTwistedEOps.lean`.

```
theorem EpC_sMz_mul (v u : Fin r → ℂ) (q : ℕ) (p : ℤ) (y : FockT r) :
    EpC v q (sMz u p * y) = ∑ j ∈ Finset.range (q + 1),
      fco (pair v u) j • (sMz u (p - j) * EpC v (q - j) y)
```

From the mathematics to the Lean statement

`sMz u p * y` is $E^-_p(-u)$ applied to y (multiplication); `EpC v q` is $E^+_q(-v)$. Multiplying by $w_2^p w_1^{-q}$ and summing, the right side becomes $\sum f_j (w_2/w_1)^j \cdot E^-_{p-j} w_2^{p-j} \cdot E^+_{q-j} w_1^{-(q-j)}$, which is the generating series statement. No hypothesis on v, u: $\langle v, u\rangle$ may be any complex number, and `fco` is defined for complex exponents. Same as the textbook statement.

Physical meaning

This is the ordering rule for annihilation and creation exponentials, $e^A e^B = e^B e^A e^{[A,B]}$, with the commutator the twisted two-point function $\left(\frac{1-w_2/w_1}{1+w_2/w_1}\right)^{\langle v,u\rangle}$. It is the Wick contraction between the vertex operators of two momentum states in the twisted sector, the step needed to evaluate any product of twisted fields.

Proof on paper. $E^+(-v,w_1)$ is the algebra map $X_{(n,i)} \mapsto X_{(n,i)} - v_i w_1^{-(2n+1)}$, so it is multiplicative: applied to $E^-(-u,w_2)y$ it gives $E^+(E^-(-u,w_2))\cdot E^+(y)$. Translating the exponent $\sum_n \frac{2}{2n+1}\sum_i u_i X_{(n,i)} w_2^{2n+1}$ produces the extra term $-\sum_n \frac{2}{2n+1}\langle v,u\rangle (w_2/w_1)^{2n+1} = \langle v,u\rangle \log\frac{1-w_2/w_1}{1+w_2/w_1}$. Exponentiating (Lemma 36.6(2),(3),(4)) gives the factor. Comparing coefficients of $w_2^p w_1^{-q}$ yields the stated finite sum. □

What the machine verified

Unconditional; `VOA/Moonshine/LatticeTwistedEOps.lean`, axioms standard.

Definition 36.14 (Dressing). $\mathrm{DD}_v(a)$, for $a \in \mathbb{Z}$, is the coefficient of w^a in $E^-(-v,w)E^+(-v,w)$, i.e. $\mathrm{DD}_v(a) = \sum_{p-q=a} E_p^-(-v)E_q^+(-v)$.

```
noncomputable def DD (v : Fin r → ℂ) (a : ℤ) : End ℂ (FockT r) :=
  Polynomial.lsum (fun q => LinearMap.mulLeft ℂ (sMz v (a + q))) ∘ₗ (Ep v).toLinearMap
```

From the mathematics to the Lean statement

On y, $\mathrm{Ep}\, v\, y = \sum_q E_q^+(y)u^q$ is a polynomial in u, and `Polynomial.lsum` replaces u^q by multiplication with $s_{a+q}(v)$; so the result is $\sum_q s_{a+q}(v)E_q^+(-v)y$, the claimed finite sum (`DD_apply_range`).

Physical meaning

The dressing DD_v is the full normal-ordered exponential $:e^{v\cdot X^T(w)}:$ without its momentum label: the oscillator part of the twisted vertex operator of the lattice state e^v, whose coefficients in powers of w are the modes $\mathrm{DD}_v(a)$.

Proposition 36.15 (Properties of the dressing). *1. For odd K:* $[h_i(K/2), \mathrm{DD}_v(a)] = v_i\,\mathrm{DD}_v(a-K)$, *i.e.* $[h_i(m), E^-E^+(-v,w)] = v_i w^{2m} E^-E^+(-v,w)$.

2. $\mathrm{DD}_{-v}(a) = (-1)^a \mathrm{DD}_v(a)$ *(i.e.* $E^\pm(v,w) = E^\pm(-v,-w)$*).*

3. $\mathrm{DD}_0(a) = \delta_{a,0}$.

```
theorem modeT_comm_DD (v : Fin r → ℂ) (i : Fin r) {K : ℤ} (hK : Odd K) (a : ℤ) :
    modeT r i K * DD v a - DD v a * modeT r i K = v i • DD v (a - K)
theorem DD_neg (v : Fin r → ℂ) (a : ℤ) : DD (-v) a = (-1 : ℂ) ^ a • DD v a
theorem DD_zero_charge (a : ℤ) : DD (0 : Fin r → ℂ) a = if a = 0 then 1 else 0
```

From the mathematics to the Lean statement

In (1), w^{2m} with $m = K/2$ is w^K, and the coefficient of w^a in $v_i w^K \sum_b \mathrm{DD}_v(b)w^b$ is $v_i \mathrm{DD}_v(a-K)$. This is the twisted analogue of $[\alpha(m), Y(e^\beta,z)] = \langle\alpha,\beta\rangle z^m Y(e^\beta,z)$, the defining property of a "charge-v" vertex operator. Same as the textbook statements.

Physical meaning

Part (1) says that the twisted bosonic currents measure the charge v of the dressing: the field carries momentum v in the sense of the Heisenberg algebra, as every vertex operator of a lattice exponential should. Part (2) is the invariance of the exponential under the orbifold reflection together with $w \mapsto -w$, and (3) says that the zero-charge field is the identity operator.

Proof on paper. (1) For $K < 0$, $h_i(K/2)$ is multiplication by X, which commutes with E^- and is translated by E^+: $E^+(X_{(n,i)}y) = (X_{(n,i)} - v_i w^{-(2n+1)})E^+(y)$; the extra term gives $v_i w^K$ with $K = -(2n+1)$. For $K > 0$, $h_i(K/2)$ is $\frac{K}{2}\partial$, which commutes with the translation E^+ and differentiates E^-: by Lemma 36.6(5), $\partial_{(n,i)} s_p = \frac{2v_i}{2n+1} s_{p-(2n+1)}$, giving $v_i w^K$. (2) Scaling (Lemma 36.6(4)) with $t = -1$ for E^-; induction on monomials for E^+. (3) Both exponents vanish. □

What the machine verified

Unconditional; axioms standard.

36.5 The two-point identity and locality

File `VOA/Moonshine/LatticeTwistedTwoPoint.lean`.

Theorem 36.16 (Two-point identity). *For charge vectors v, u with $n = \langle v, u\rangle$,*

$$\mathrm{DD}_v(A)\,\mathrm{DD}_u(B) = \sum_{j\ge 0} f_j^{(n)}\ \mathrm{NN}(A+j, B-j),$$

where $\mathrm{NN}(A,B)$ *is the coefficient of* $w_1^A w_2^B$ *in the normal-ordered product* $E^-(-v,w_1)E^-(-u,w_2)E^+(-v,w_1)E^+(-u,w_2)$ *and* NN *is symmetric under* $(v,A) \leftrightarrow (u,B)$. *As generating series:*

$$E^-E^+(-v,w_1)\,E^-E^+(-u,w_2) = :\cdots: \left(\frac{1-w_2/w_1}{1+w_2/w_1}\right)^n.$$

```
def GoodB (v u : Fin r → ℂ) (x : FockT r) (Q : ℕ) : Prop :=
  (∀ q, Q ≤ q → EpC v q x = 0) ∧ (∀ q, Q ≤ q → EpC u q x = 0) ∧
    (∀ q q', Q ≤ q → EpC v q (EpC u q' x) = 0) ∧ (∀ q q', Q ≤ q' → EpC v q (EpC u q' x) =
    ↪ 0)

noncomputable def NN (v u : Fin r → ℂ) (Q : ℕ) (A B : ℤ) (x : FockT r) : FockT r :=
  ∑ q ∈ Finset.range Q, ∑ q' ∈ Finset.range Q,
    sMz v (A + q) * sMz u (B + q') * EpC v q (EpC u q' x)

theorem DD_DD_eq (v u : Fin r → ℂ) {x : FockT r} {Q : ℕ} (hQ : GoodB v u x Q) (A B : ℤ) (J
↪ : ℕ)
    (hJ : B + Q ≤ J) :
    DD v A (DD u B x) = ∑ j ∈ Finset.range J, fco (pair v u) j • NN v u Q (A + j) (B - j) x
```

From the mathematics to the Lean statement

Infinite sums are replaced by finite ones with explicit bounds. `GoodB v u x Q` says that Q bounds every E^+ coefficient that can be nonzero on x; it is not a restriction, since such a Q always exists (`exists_goodB`). With it, `NN v u Q A B x` is the full normal-ordered coefficient applied to x. The bound $J \ge B+Q$ makes the j-sum exhaustive ($s_{B-j+q'} = 0$ once $B-j+q' < 0$). Hence the Lean statement is the textbook identity applied to an arbitrary vector x.

Physical meaning

This is the twisted Wick theorem for two vertex operators: the product of two normal-ordered exponentials equals the normal-ordered product times the twisted contraction $\left(\frac{1-w_2/w_1}{1+w_2/w_1}\right)^{\langle v,u\rangle}$. It is the twisted analogue of the free-field OPE $e^{v\phi}(z)e^{u\phi}(w) = (z-w)^{\langle v,u\rangle} :\cdots:$. Heuristic; the identity is a formal-series statement proved in Lean.

Proof on paper. Push $E^+(-v,w_1)$ to the right through $E^-(-u,w_2)$ using Theorem 36.13; the E^-'s commute among themselves (they are multiplications) and the E^+'s commute among themselves (translations commute). The symmetry of NN is the same commutativity. □

Theorem 36.17 (Locality of the dressings). *If $\langle v,u\rangle = n \in \mathbb{Z}$ and $N \geq |n|$, then for all $A,B \in \mathbb{Z}$ and $x \in S[\theta]$*

$$\sum_{r=0}^{N}(-1)^{N-r}\binom{N}{r}\Big(\mathrm{DD}_v(A-2r)\mathrm{DD}_u(B-2(N-r)) - (-1)^{|n|}\mathrm{DD}_u(B-2(N-r))\mathrm{DD}_v(A-2r)\Big)x = 0,$$

that is, $(w_1^2-w_2^2)^N\big(Y_v(w_1)Y_u(w_2) - (-1)^n Y_u(w_2)Y_v(w_1)\big) = 0$ with $Y_v(w) = E^-E^+(-v,w)$.

```
theorem DD_bracket_local (v u : Fin r → ℂ) (n : ℤ) (hn : pair v u = n) (N : ℕ)
    (h1 : -(N : ℤ) ≤ n) (h2 : n ≤ N) (A B : ℤ) (x : FockT r) :
    ∑ r ∈ Finset.range (N + 1), ((-1 : ℂ) ^ (N - r) * (N.choose r : ℂ)) •
      (DD v (A - 2 * r) (DD u (B - 2 * (N - r : ℕ)) x)
        - (-1 : ℂ) ^ n.natAbs • DD u (B - 2 * (N - r : ℕ)) (DD v (A - 2 * r) x)) = 0
```

From the mathematics to the Lean statement

Decoding. $(w_1^2-w_2^2)^N = \sum_r \binom{N}{r}(-1)^{N-r}w_1^{2r}w_2^{2(N-r)}$, and the coefficient of $w_1^A w_2^B$ of $w_1^{2r}w_2^{2(N-r)}F(w_1,w_2)$ is $F_{A-2r,B-2(N-r)}$: so the Lean sum is exactly the $w_1^Aw_2^B$ coefficient of the stated product identity. Since $w^2 = z$, this is $(z_1-z_2)^N$-locality, up to the sign $(-1)^n$.
Hypotheses. `hn` requires the pairing to be an *integer*; this is where the lattice enters, and it is necessary (for non-integral n the factor is not palindromic). `h1`, `h2` say $|n| \leq N$. The sign $(-1)^{|n|}$ is not a defect of the statement: it is the genuine graded commutativity of the $S[\theta]$-parts, cancelled by the $\mathcal{T}$-parts in the next section.

Physical meaning

This is locality of the twisted exponential fields up to the sign $(-1)^{\langle v,u\rangle}$: the two operators commute or anticommute (the cocycle sign) for non-coincident points, with singularities only at $z_1 = z_2$ of bounded order. In the CFT it is the requirement that correlation functions of twist-sector fields be single-valued away from collisions, the first axiom of a vertex algebra module.

Proof on paper. By Theorem 36.16, $Y_v(w_1)Y_u(w_2) = \Phi\cdot f(w_2/w_1)$ and $Y_u(w_2)Y_v(w_1) = \Phi\cdot f(w_1/w_2)$, the same normal-ordered product Φ (by the symmetry of NN) times the contraction factor $f(x) = ((1-x)/(1+x))^n$ expanded in the respective regions. Multiply by $(w_1^2-w_2^2)^N$: the first becomes $w_1^{2N}(1-x^2)^N f(x) = w_1^{2N}G(x)$ with $x = w_2/w_1$, a polynomial; the second becomes $(-1)^N w_2^{2N}G(w_1/w_2)$, and palindromy (Theorem 36.8) turns it into $(-1)^N(-1)^{N+n}w_1^{2N}G(w_2/w_1)$. So the two products agree after multiplication, up to $(-1)^n$. In coefficients this is exactly (36.5), applied to the coefficient sequence of Φ along each anti-diagonal. □

What the machine verified

Unconditional; axioms standard (file header).

36.6 The twisted vertex operators of the exponentials

File `VOA/Moonshine/LatticeTwistedVertex.lean`. We now tensor with a space $\mathcal{T}$ (an arbitrary $\mathbb{C}$-vector space `Tm` at first, the extraspecial module later) and attach a $\mathcal{T}$-operator g.

Definition 36.18 (Generic twisted exponential field)**.** For a charge vector v, a shift $c_0 \in \mathbb{Z}$, a scalar $\kappa \in \mathbb{C}$ and $g \in \mathrm{End}(\mathcal{T})$, the family $k \mapsto Y_k$ of operators on $S[\theta] \otimes \mathcal{T}$ is the mode family of $\kappa\, w^{-c_0} E^-(-v,w) E^+(-v,w) \otimes g$ in the convention $Y_k = u_{(k/2)}$:

$$Y_k = \kappa\ \mathrm{DD}_v(-k-2+c_0) \otimes g.$$

```
noncomputable def YTg (v : Fin r → ℂ) (c0 : ℤ) (κ : ℂ) (g : End ℂ Tm) (k : ℤ) :
    End ℂ (FockT r ⊗[ℂ] Tm) :=
  κ • TensorProduct.map (DD v (-k - 2 + c0)) g
```

From the mathematics to the Lean statement

Index check. $u_{(k/2)}$ is the coefficient of $z^{-k/2-1} = w^{-k-2}$. In $w^{-c_0}\sum_a \mathrm{DD}_v(a) w^a$ the coefficient of w^{-k-2} has $a - c_0 = -k-2$, i.e. $a = -k-2+c_0$. `TensorProduct.map f g` is $f \otimes g$. For the lattice field we will take $c_0 = \langle\alpha,\alpha\rangle$, because $z^{-\langle\alpha,\alpha\rangle/2} = w^{-\langle\alpha,\alpha\rangle}$.

Physical meaning

A twisted vertex operator for a momentum state is a product of a bosonic factor, the dressing, and a finite-dimensional operator g on the 2^{12}-dimensional space of ground states (the twist-field multiplicity). The factor g plays the role of the lattice cocycle: it must supply the sign when two fields are exchanged, as the cocycle $\varepsilon(\alpha,\beta)$ does for the untwisted lattice VOA.

Theorem 36.19 (Charge and locality of the generic field)**.**

1. *(Truncation.) For every vector x, $Y_k x = 0$ for all large k.*
2. *(Charge.) For odd K: $[h_i(K/2) \otimes 1,\ Y_k] = v_i\, Y_{k+K}$.*
3. *(Locality.) Let v, u be charge vectors with $\langle v,u\rangle = n \in \mathbb{Z}$, and let g, g' satisfy $g'g = (-1)^n gg'$. Then for all $c_0, c_0', \kappa, \kappa'$ and all residues e, e', the rescaled fields $\mathrm{resc}(Y^{(v)}, 2, e)$ and $\mathrm{resc}(Y^{(u)}, 2, e')$ are mutually local.*

```

```

From the mathematics to the Lean statement

`f.rTensor Tm` is $f \otimes \mathrm{id}_{\mathcal{T}}$. In (2), Y_{k+K} with $k \leftrightarrow k/2$ means $[h_i(m), Y(z)] = v_i z^m Y(z)$ with $m = K/2$, the twisted version of $[\alpha(m), Y(e^\beta, z)] = \langle \alpha, \beta \rangle z^m Y(e^\beta, z)$. In (3) the hypothesis `hg` is the graded commutativity on $\mathcal{T}$ that compensates the sign $(-1)^n$ of Theorem 36.17; `hn` demands an integral pairing. The conclusion is ordinary `Local` (Section 36.2) of the integrally moded rescaled fields, of order $|n|$. Statement (3) is what the textbook means by "$Y^T(e^\alpha, z_1)$ and $Y^T(e^\beta, z_2)$ are local", see the dictionary after Definition 36.2.

Physical meaning

The theorem says that the generic twisted exponential field has the expected properties of a vertex operator of charge v: it is a field (truncation), it carries charge v under the twisted currents, and two such fields are local provided the operators g, g' on the ground states have the correct commutation sign $(-1)^{\langle v,u \rangle}$. This is the twisted analogue of locality of lattice exponentials.

Proof on paper. (1): $\mathrm{DD}_v(a)y = 0$ once $a + Q \le 0$, Q a bound for E^+ on y. (2): Proposition 36.15(1) tensored with g. (3): on $y \otimes t$, $Y^{(v)}Y^{(u)} - Y^{(u)}Y^{(v)}$ equals $\kappa\kappa'\big(\mathrm{DD}_v\mathrm{DD}_u - (-1)^n \mathrm{DD}_u\mathrm{DD}_v\big)y \otimes gg't$, using $g'g = (-1)^n gg'$. After multiplying by $(z_1 - z_2)^{|n|}$ the $S[\theta]$-part vanishes by Theorem 36.17 with $N = |n|$; the class rescalings only shift the indices A, B. □

What the machine verified

Unconditional; `#print axioms` standard (file header).

Definition 36.20 (The twisted vertex operator of e^α)**.** For an even lattice L with unimodular Gram matrix and $\alpha \in L$,

$$Y^T(e^\alpha)_{(k/2)} = 2^{-\langle \alpha,\alpha \rangle}\, \mathrm{DD}_\alpha(-k - 2 + \langle \alpha, \alpha \rangle) \otimes e_\alpha,$$

the mode family of (36.1).

File `VOA/Moonshine/LatticeTwistedVertex.lean`.

```
noncomputable def YTL (α : L.carrier) (k : ℤ) :
    End ℂ (FockT (rank L) ⊗[ℂ] Rep (cocMat L) (isUnit_det_cocMat L hEven hU)) :=
  YTg (chargeCoord L α) (L.form α α) ((2 : ℂ) ^ (-(L.form α α))) (eT L hEven hU α) k
```

From the mathematics to the Lean statement

The charge vector is the orthonormal-coordinate vector of α, the shift is $c_0 = \langle \alpha, \alpha \rangle$ (giving $z^{-\langle \alpha,\alpha \rangle/2}$), the scalar is $\kappa = 2^{-\langle \alpha,\alpha \rangle}$ (an integer power, `zpow`), and the $\mathcal{T}$-operator is e_α. This is FLM's operator with their normalisation constant specialised to the involution -1; the reader comparing with FLM, Chapter 9, should note that any normalisation $\kappa(\alpha)$ with $\kappa(\alpha)\kappa(\beta)4^{-\langle \alpha,\beta \rangle} = \kappa(\alpha + \beta)$ would do, and that this condition is forced by the product formula (Remark 36.37). `hEven` and `hU` are needed only to build $\mathcal{T}_L$. Not vacuous: `YTL L hEven hU 0 k` is the identity at $k = -2$ and 0 otherwise (`YTL_zero`), and $Y^T(e^\alpha)$ is genuinely nonzero (its vacuum coefficient is computed in §36.10).

Physical meaning

For a lattice vector α this is the twisted vertex operator of the momentum state e^α acting on the twisted sector: the twisted exponential $:e^{\alpha \cdot X}:$ times the operator e_α on the ground-state space T (a Clifford-type operator, since $e_\beta e_\alpha = (-1)^{\langle \alpha,\beta \rangle} e_\alpha e_\beta$). The normalisation $2^{-\langle \alpha,\alpha \rangle}$ comes from the regularised twisted two-point function and is the one that makes the vacuum,

product and Jacobi identities consistent; it is what produces the factor $4^{\mp n}$ in the leading-term identities below.

Theorem 36.21 (Properties of $Y^T(e^\alpha)$). *Let L be even, positive definite, unimodular.*

1. $e_\beta e_\alpha = (-1)^{\langle\alpha,\beta\rangle} e_\alpha e_\beta$ *on* $\mathcal{T}_L$.
2. *For all $\alpha, \beta \in L$ and residues e, e', the rescaled fields of $Y^T(e^\alpha)$ and $Y^T(e^\beta)$ are mutually local.*
3. $Y^T(e^{-\alpha})_{(k/2)} = (-1)^k Y^T(e^\alpha)_{(k/2)}$. *Consequently $e^\alpha + e^{-\alpha}$ has no odd modes and $e^\alpha - e^{-\alpha}$ no even modes.*
4. $Y^T(e^0)_{(k/2)} = \delta_{k,-2}$.

theorem YTL_zero (k : ℤ) : YTL L hEven hU 0 k = if k = -2 then 1 else 0
```

From the mathematics to the Lean statement

The one-line proof of `YTL_local` is shown because it *is* the argument: the generic locality with $n = \langle\alpha,\beta\rangle$, the integrality of the pairing in orthonormal coordinates (`sum_chargeCoord`, which uses `hPos`), and the $\mathcal{T}$ commutation `eT_swap`. In (3), $(-1)^k$ for the fractional mode $k/2$ is the substitution $z^{1/2} \mapsto -z^{1/2}$; since $\theta e^\alpha = e^{-\alpha}$, this says $Y^T(\theta u, z)$ is $Y^T(u,z)$ continued once around the origin, which is precisely the meaning of "θ-twisted". (4) is the vacuum axiom at the level of exponentials.

Physical meaning

These are the basic axioms for the twisted vertex operators of lattice exponentials: the exponential fields of different momenta are local, with the exchange sign $(-1)^{\langle\alpha,\beta\rangle}$ being carried by the ground-state operators e_α; the operator for $-\alpha$ is related to that for α by the sign $(-1)^k$ (so $e^\alpha \pm e^{-\alpha}$ have only integral/half-integral modes, the θ-eigenvalue structure); and the zero momentum state is the identity.

Proof on paper. (1) From $e_\alpha e_\beta = \varepsilon(\alpha,\beta) e_{\alpha+\beta}$ and $\varepsilon(\alpha,\beta)/\varepsilon(\beta,\alpha) = (-1)^{\langle\alpha,\beta\rangle}$. (2) Theorem 36.19(3). (3) $\mathrm{DD}_{-v}(a) = (-1)^a \mathrm{DD}_v(a)$, $e_{-\alpha} = e_\alpha$, and $(-1)^{-k-2+\langle\alpha,\alpha\rangle} = (-1)^k$ because $\langle\alpha,\alpha\rangle$ is even. (4) $\mathrm{DD}_0(a) = \delta_{a,0}$, $e_0 = 1$, $2^0 = 1$. □

What the machine verified

Unconditional; axioms standard.

Definition 36.22 (The generating set). Let $F_a = z^{1/2}h_a(z) \otimes 1$ (the rescaled twisted Heisenberg generator, `FgenTFld`, from Chapter 35) and $\widetilde{Y}_{\alpha,e} = \mathrm{resc}(Y^T(e^\alpha), 2, e)$ (`YTLFld`). The generating set is $\{F_a\}_a \cup \{\widetilde{Y}_{\alpha,e}\}_{\alpha\in L, e\in\mathbb{Z}}$.

File `VOA/Moonshine/LatticeTwistedVertex.lean`.

```
def latGenSet : Set (Fld (FockT (rank L) ⊗[ℂ] Rep (cocMat L) (isUnit_det_cocMat L hEven
 ↪ hU))) :=
  Set.range (FgenTFld L hEven hU) ∪ Set.range (fun p : L.carrier × ℤ => YTLFld L hEven hU
   ↪ p.1 p.2)
```

Physical meaning

The twisted sector is generated, as a module over the chiral algebra, by the twisted bosonic currents and the twisted exponentials, so these are the fields whose mutual locality must be established. In the CFT language they are the generators ∂X^a and $e^{\alpha\cdot X}$ of the lattice theory.

Theorem 36.23 (Locality of the twisted lattice system). *For L even, positive definite, unimodular, any two fields in the generated twisted system* TGenerated(*latGenSet*) *are mutually local.*

File `VOA/Moonshine/LatticeTwistedVertex.lean`.

```
theorem latticeTwistedSystem_local (hPos : L.PosDef)
    {a b : Fld (FockT (rank L) ⊗[ℂ] Rep (cocMat L) (isUnit_det_cocMat L hEven hU))}
    (ha : a ∈ TGenerated (latGenSet L hEven hU)) (hb : b ∈ TGenerated (latGenSet L hEven
     ↪ hU)) :
    Local a.1 b.1 :=
  tgenerated_local (latGenSet_local L hEven hU hPos) ha hb
```

From the mathematics to the Lean statement

`a.1` is the underlying distribution of the field `a`. The theorem is Dong's lemma (`tgenerated_local`, Chapter 35) applied to the pairwise locality of the generators: F_a with F_b (order 2, Chapter 35), F_a with $\widetilde{Y}$ (order 1, from the charge relation: $[F_a(z_1), \widetilde{Y}_{\beta,e}(z_2)] = \beta_a\,\delta(z_1/z_2)\widetilde{Y}_{\beta,e+1}(z_2)$, `bracketDist_FgenT_YTg`), and $\widetilde{Y}$ with $\widetilde{Y}$ (Theorem 36.21(2)). The Leech specialisation is `leechTwistedSystem_local`.

Physical meaning

Mutual locality of all fields generated from the twisted currents and exponentials is the 2d statement that the twisted-sector correlation functions are meromorphic after passage to the double cover, and that all operator products close on this set. Together with truncation it gives the field-theoretic input for defining Y^T on all of V_L.

What the machine verified

Unconditional. `#print axioms latticeTwistedSystem_local` was re-run for this chapter (output in §36.15): standard axioms only.

36.7 The twisted vertex operator on all states

File `VOA/Moonshine/LatticeTwistedFields.lean`. So far only e^α has a twisted vertex operator. A general state of V_L is a combination of $h_{b_1}(-n_1-1)\cdots h_{b_k}(-n_k-1)e^\alpha$. If Y^T is to satisfy the twisted iterate formula, then for the Heisenberg generator $h_b = h_b(-1)\mathbf{1}$ (which is θ-odd, so lives on the half-integral class with twist 1/2) we must have

$$F_e\big(h_b(-n-1)w\big) = \mathrm{star}_{1/2}(F_b)_{-n-1}\,F_{e-1}(w), \tag{36.6}$$

where $F_e(u) = \mathrm{resc}(Y^T(u), 2, e) = z^{e/2}Y^T(u,z)$. This *defines* F_e on all states.

Definition 36.24 (Word fields and the extension). For a list $l = [(n_1, b_1), \dots, (n_k, b_k)]$ and $\alpha \in L$ define $\mathrm{Fw}(\alpha, [\,], e) = \widetilde{Y}_{\alpha,e}$ and $\mathrm{Fw}(\alpha, (n,b) :: l, e) = \mathrm{star}_{1/2}(F_b)_{-n-1}\mathrm{Fw}(\alpha, l, e-1)$. $F_e : V_L \to \mathrm{Fld}(S[\theta] \otimes \mathcal{T})$ is the linear map sending the monomial basis vector $h_{b_1}(-n_1-1)\cdots e^\alpha$ to the word field, and

$$Y^T(u)_{(k/2)} = \text{the 0-th mode of } F_k(u).$$

```
noncomputable def Fw (α : L.carrier) : List (ℕ × Fin (rank L)) → ℤ → Fld (MT L hEven hU)
  | [], e => YTLFld L hEven hU α e
  | (c :: l), e => star (1 / 2) (FgT c.2) (-(c.1 : ℤ) - 1) (Fw α l (e - 1))

noncomputable def YML : LatModuleGen L →ₗ[ℂ] (ℤ → End ℂ (MT L hEven hU)) :=
  LinearMap.pi (fun k => (modeL 0).comp (FL L hEven hU k))
```

From the mathematics to the Lean statement

`MT L hEven hU` abbreviates $S[\theta] \otimes \mathcal{T}_L$. `FgT b` is F_b, the field $z^{1/2}h_b(z) \otimes 1$. `FLB` is the bilinear map on $\mathrm{Fock}\mathbb{N} \times \mathbb{C}[L]$ which sends a monomial m and e^α to `Fw α (monoWordN m) e` (`monoWordN m` lists the letters of m in some order); `TensorProduct.lift` makes it linear on the tensor product. `modeL 0` takes the 0-th mode. Since $\mathrm{mode}_0(z^{k/2}Y) = u_{(k/2)}$ (`resc` with $p = 0$), `YML u k` $= u_{(k/2)}$, the convention of `TwistedModule.YM`. **Well-definedness** is a real issue: the definition depends on the order of letters. It is resolved by proving that twisted creation operators commute (`Fw_perm`: the word field depends only on the multiset of letters), so F_e on the polynomial basis is independent of the chosen listing. The theorems below show the definition does what it should.

Physical meaning

This defines the twisted vertex operator of a general state of the lattice theory by successive oscillator products: a state $h_{b_1}(-n_1-1)\cdots e^\alpha$ is mapped to a normal-ordered product of the twisted currents with the exponential field, where the factor $z^{1/2}$ and the twisted binomial expansion implement the monodromy -1 of ∂X around the twist field. It is the CFT reconstruction of $Y^T(u)$ from the free-field generators.

Theorem 36.25 (Basic properties of Y^T on V_L). *For L even, positive definite, unimodular, all $u, v \in V_L$ and $e, e', k \in \mathbb{Z}$:*

theorem YML_local (u v : LatModuleGen L) (e e' : ℤ) :
    Local (resc (YML L hEven hU u) 2 e) (resc (YML L hEven hU v) 2 e')
```

From the mathematics to the Lean statement

In (1), `X c * p` with $c = (n, b)$ is $h_b(-n-1)p$ in the untwisted Fock space (FockN has variables $X_{(n,b)} = h_b(-n-1)$), and `g : L.carrier →₀ ℂ` an element of $\mathbb{C}[L]$. Statement (2) says that the definition through 0-th modes of the class-k field is consistent with the rescaling: the class-e field $F_e(u)$ is *exactly* $z^{e/2}Y^T(u,z)$ on the class e; this needs $F_{e+2}(u) = zF_e(u)$ (`FL_shift`). In (5), `twistedEigenspace 2 j` for `thetaAut` is $\{u : \theta u = (-1)^j u\}$ and `hk` is $k \not\equiv -j \equiv j \pmod 2$; this is precisely the `support` axiom of `TwistedModule`. Some theorems carry the section variable `hPos` although it does not appear in the printed line (Lean's `include hPos`); the reader should regard (1), (5), (6) as having the hypothesis L positive definite.

Physical meaning

These are the basic properties of the twisted vertex operators of arbitrary states: truncation (finite energy), the vacuum maps to the identity, and locality. The θ-compatibility property is the physical statement that θ-even states have only integral modes and θ-odd states only half-integral modes on the twisted sector, which is what it means for the fields to see the twist.

Proof on paper. (1) is the definition plus commutation of creation operators. (2)–(4) are bookkeeping of the rescaling; $Y^T(\mathbf{1})$ is $Y^T(e^0)$ (Theorem 36.21(4)). (5): conjugating by θ negates every Heisenberg generator, which in the twisted product contributes (-1) per letter, and replaces e^α by $e^{-\alpha}$, which contributes $(-1)^e$ times (-1) per letter (each letter shifts the class by one); the letter signs cancel. If $\theta u = (-1)^j u$ and $e \not\equiv j$, then $F_e(u) = (-1)^{e+j}F_e(u) = -F_e(u)$, so it vanishes. (6): every $F_e(u)$ is in the generated system (twisted products of local fields are generated), and Theorem 36.23 applies. □

What the machine verified

Unconditional (hypotheses L even, positive definite, unimodular); axioms standard.

36.8 The twisted product formula

Locality alone does not give a twisted module; one also needs that Y^T is compatible with the products of V_L. Chapter 35 proved the *reduction*: if every pair of rescaled fields is local and satisfies the *product formula*

$$\big(F_e(u)_{(\ell)}F_{e'}(v)\big)_s = \sum_{t\ge 0}\binom{e/2}{t}Y^T(u_{(\ell+t)}v)_{((2(s-t)+e+e')/2)}$$

for $u \in V^j$ on its class $e \equiv j$, then the twisted Jacobi identity holds (`twistedJacobi_of_local_pf`). Inverting the binomial, the product formula is equivalent to the following statement in terms of twisted products.

Definition 36.26 (Projection to a class and the formula PF). For $e \in \mathbb{Z}$ let $\pi_e(u) = \frac{1}{2}(u + (-1)^e\theta u)$, the component of u in the θ-eigenspace $(-1)^e$. For $u, v \in V_L$, $\mathrm{PF}(u,v)$ is the statement

$$\forall e, e', \ell \in \mathbb{Z}: \qquad \mathrm{star}_{e/2}\big(F_e(u)\big)_\ell F_{e'}(v) = F_{e+e'}\big(\pi_e(u)_{(\ell)}v\big).$$

Files `VOA/Moonshine/LatticeTwistedUntwisted.lean`, `VOA/Moonshine/LatticeTwistedProduct.lean`.

```
noncomputable def piE (e : ℤ) (u : LatModuleGen L) : LatModuleGen L :=
  (1 / 2 : ℂ) • (u + ((-1 : ℂ) ^ e) • thetaLat L u)

def PF (u v : LatModuleGen L) : Prop :=
  ∀ e e' ℓ : ℤ, star ((e : ℂ) / 2) (FL L hEven hU e u) ℓ (FL L hEven hU e' v)
    = FL L hEven hU (e + e') ((latticeVOAGen L hEven hPos).smul (piE L e u) ℓ v)
```

From the mathematics to the Lean statement

Why π_e. $F_e(u)$ only sees the modes of u on the class e, and by the support property these come from $\pi_e(u)$ alone: $F_e(u) = F_e(\pi_e u)$. Hence on the right one must use $\pi_e(u)$, not u. **Why twist $e/2$.** $F_e(u) = z^{e/2}Y^T(u,z)$ carries the power $z^{e/2}$, and $\mathrm{star}_{e/2}$ is precisely the operation which turns the $z_1^{e/2}$ into the binomial expansion of $(z_2+(z_1-z_2))^{e/2}$ (Definition 36.3). Thus $\mathrm{PF}(u,v)$ is "$Y^T(\pi_e u_{(\ell)}v, z)$ = the twisted iterate of $Y^T(u)$ and $Y^T(v)$", the twisted associativity in rescaled language. `(latticeVOAGen L hEven hPos).smul a ℓ v` is $a_{(\ell)}v$ in V_L. It is a `Prop`; it is proved below for all u, v.

Physical meaning

The projection π_e onto the $(-1)^e$ eigenspace of θ reflects that on the twisted sector a state's field is defined only for the correct parity of the exponent of z; the half-integer powers $z^{e/2}$ attach to the θ-odd part. The formula PF is then the twisted associativity or OPE: the twisted product of two twisted fields equals the field of the product state. This is the statement that the twisted fields represent the vertex algebra V_L on the twisted sector.

Theorem 36.27 (Generators and the reduction to exponentials). *Let L be even, positive definite, unimodular.*

1. *For every Heisenberg generator, every state w and every ℓ:* $\mathrm{star}_{1/2}(F_b)_\ell F_e(w) = F_{e+1}(h_{b\,(\ell)}w)$.
2. *If* $\mathrm{PF}(e^\alpha, e^\beta)$ *holds for all $\alpha, \beta \in L$, then* $\mathrm{PF}(u,v)$ *holds for all $u, v \in V_L$.*

File `VOA/Moonshine/LatticeTwistedProduct.lean`.

```
theorem genPF (b : Fin (rank L)) (e' ℓ : ℤ) (w : LatModuleGen L) :
    star (1 / 2) (FgT b) ℓ (FL L hEven hU e' w)
      = FL L hEven hU (e' + 1) ((latticeVOAGen L hEven hPos).smul (hgen L b) ℓ w)

theorem PF_of_base (hbase : ∀ α β : L.carrier, PF L hEven hU hPos (echg L α) (echg L β))
    (u v : LatModuleGen L) : PF L hEven hU hPos u v :=
```

From the mathematics to the Lean statement

(1) is PF(h_b, w) (note $\pi_e(h_b) = h_b$ for e odd and 0 for e even; the statement is the odd class, twist 1/2). (2) has the explicit hypothesis `hbase`, which is discharged in the next section; the theorem as stated is a conditional reduction, and its conclusion is exactly "PF for all pairs".

Physical meaning

This reduces the product formula for all states to the momentum states e^α, e^β: since every state is built from the free currents and exponentials, and the currents obey the formula (the twisted boson Ward identity), one only needs to check the OPE of two lattice exponentials. This is the standard reduction in CFT of an OPE involving descendants to that of the primaries.

Proof on paper. (1) For $\ell < 0$ it is the definition (36.6). For $\ell \geq 0$ induct on the word: on e^β, $h_{b(0)}e^\beta = \beta_b e^\beta$ and $h_{b(\ell)}e^\beta = 0$ for $\ell > 0$, which matches the generator–exponential OPE (Theorem 36.23); for $w = h_c(-n-1)w'$ move $h_{b(\ell)}$ past $h_c(-n-1)$ by the commutator formula, on the field side by the twisted commutator formula (Chapter 35), using $[h_{b(\ell)}, h_{c(m)}] = \ell\delta_{bc}\delta_{\ell+m,0}$ on both sides.

(2) First fix $v = e^\beta$ and induct on u. If $u = h_b(-n-1)w$ then the left side is $\mathrm{star}_{e/2}(\mathrm{star}_{1/2}(F_b)_{-n-1}F_{e-1}(w))_\ell F_{e'}(e^\beta)$, which the *twisted iterate formula* (associativity of twisted products, Theorem 36.28 below) expands as a finite combination of iterated products $\mathrm{star}(F_b)\mathrm{star}(F(w))$ and $\mathrm{star}(F(w))\mathrm{star}(F_b)$; each is evaluated by (1) and the induction hypothesis, and the result is F of the corresponding expansion of $(h_b(-n-1)w)_{(\ell)}e^\beta$ by the iterate formula of V_L. Then induct on v: for $v = h_b(-n-1)v'$, use the twisted commutator formula on the field side and the commutator formula of V_L on the state side, together with (1) and the case already proved. □

What the machine verified

Unconditional as a reduction (it has the explicit hypothesis `hbase`); file `VOA/Moonshine/LatticeTwistedProduct.lean`; axioms standard.

Theorem 36.28 (Twisted associativity: the iterate formula). *Let S be a pairwise local set of fields and $A, B, C \in \mathrm{TGenerated}(S)$. For all twists $\alpha, \beta \in \mathbb{C}$ and $p, q \in \mathbb{Z}$,*

$$\mathrm{star}_{\alpha+\beta}\big(\mathrm{star}_\alpha(A)_p B\big)_q C = \sum_{i\geq 0}(-1)^i\binom{p}{i}\Big(\mathrm{star}_\alpha(A)_{p-i}\,\mathrm{star}_\beta(B)_{q+i}C - (-1)^p\,\mathrm{star}_\beta(B)_{p+q-i}\,\mathrm{star}_\alpha(A)_i C\Big).$$

```

From the mathematics to the Lean statement

Both theorems live in `VOA.TwistedReduction` and carry the section hypothesis `hS : ∀ a ∈ S, ∀ b ∈ S, Local a.1 b.1` (pairwise locality of the generators), which is not printed in the statement lines but is an argument of the theorem. `gBinom p i` is $\binom{p}{i}$ for integer p. The range version only replaces the finite $\sum^{\mathrm{f}}$ by a sum over $i < K$, with `hK` guaranteeing the omitted terms vanish. This is the exact analogue of the iterate formula $(a_{(p)}b)_{(q)} = \sum_i (-1)^i \binom{p}{i}(a_{(p-i)}b_{(q+i)} - (-1)^p b_{(p+q-i)}a_{(i)})$ of a vertex algebra.

Physical meaning

This is the associativity (Borcherds identity, or crossing symmetry) of twisted fields: the field of the product $u_{(p)}v$ acting on the twisted module is expressed as the commutator-type combination of $Y(u)Y(v)$ and $Y(v)Y(u)$. In CFT this is the equivalence of the OPE of two operators with the two orderings of operator products in the twisted sector, with the twist phases α, β keeping track of the monodromy.

Proof on paper. This is the associativity half of Li's theorem that a local system of twisted vertex operators carries a vertex algebra structure. Make the system into a state space graded by the twist, $\mathcal{S} = \bigoplus_\alpha \mathrm{TGenerated}(S)$, with state fields $Y_\star(a,z)$ acting by twisted products. The twisted commutator formula makes these state fields mutually local, the identity field is a vacuum with the creation property, and the twisted translation $D_\alpha = \partial - \alpha z^{-1}$ is a derivation of twisted products. Goddard's uniqueness theorem (a field local with all state fields which creates the right state from the vacuum is the state field) then identifies the state field of $\mathrm{star}_\alpha(A)_p B$ with the product of state fields, and the iterate formula for products of local fields gives the claim. □

What the machine verified

Unconditional (given its explicit hypotheses); `VOA/Moonshine/LatticeTwistedAssoc.lean`; `#print axioms star_iterate_range` re-run: standard axioms.

Trap / dead end

A record correction. The project roadmap (`Notes/MonsterRoadmap.md`, row of the twisted-module milestone) describes `star_iterate_range` as "unused but proved". This was not accurate when this chapter was first written, and is not accurate at a pre-release build commit either: `star_iterate_range` is used in the u-induction of Theorem 36.27(2) (`LatticeTwistedProduct.lean`) and in the defect calculus of §36.9 (`LatticeTwistedBase.lean`); a `grep` of the repository confirms both uses. So twisted associativity is a genuine input of the twisted product formula, as the mathematics suggests.

36.9 The base case: two exponentials

Files `VOA/Moonshine/LatticeTwisted{Translation,Unique,Base,Scalar,Leading,BaseCase}.lean`. It remains to prove $\mathrm{PF}(e^\alpha, e^\beta)$. The strategy is a descent in the mode index ℓ, controlled by one differential equation and one uniqueness lemma.

Definition 36.29 (Defect). For $\beta \in L$, $u \in V_L$ and $e, e', \ell \in \mathbb{Z}$,

$$D_\beta(u; e, e', \ell) = \mathrm{star}_{e/2}(F_e(u))_\ell F_{e'}(e^\beta) - F_{e+e'}\big(\pi_e(u)_{(\ell)}e^\beta\big).$$

So $\mathrm{PF}(e^\alpha, e^\beta)$ is $D_\beta(e^\alpha; \cdot) = 0$.

```
noncomputable def Def (β : L.carrier) (u : LatModuleGen L) (e e' ℓ : ℤ) : Fld (MT L hEven
↪  hU) :=
  star ((e : ℂ) / 2) (FL L hEven hU e u) ℓ (FL L hEven hU e' (echg L β))
    - FL L hEven hU (e + e') ((latticeVOAGen L hEven hPos).smul (piE L e u) ℓ (echg L β))
```

Physical meaning

The defect is the failure of the twisted product formula on a pair of exponentials: the difference between the actual product of two twisted fields and the field of the product state. It measures exactly the defect of the twisted OPE; showing it vanishes is the goal of the following results. It has no independent physical meaning, since in a consistent theory the defect is zero.

Proposition 36.30 (Structure of the defect). *Let $n = \langle \alpha, \beta \rangle$ and $D(e, e', \ell) = D_\beta(e^\alpha; e, e', \ell)$.*

1. *(Translation covariance.) $D_\alpha(e/2)F_e(e^\alpha) = F_e(Te^\alpha)$ where $D_c X = \partial X - cz^{-1}X$; consequently $D_\beta(Te^\alpha; e, e', \ell) = -\ell D(e, e', \ell - 1)$.*
2. *(Recursion.) If $D(e-1, e', m) = 0$ for all $m \geq \ell$, then $-\ell\, D(e, e', \ell - 1) = n\, D(e-1, e'+1, \ell - 1)$.*
3. *(Charge.) If $D(\cdot, \cdot, m') = 0$ for all $m' > m$, then for all b and $s \in \mathbb{N}$, $\mathrm{star}_{1/2}(F_b)_s\, D(e, e', m) = \delta_{s,0}\big(\beta_b D(e, e'+1, m) + \alpha_b D(e+1, e', m)\big)$.*
4. *D vanishes for ℓ large (uniformly in e, e'), $D(e+2, e', \ell) = zD(e, e', \ell)$, $D(e, e'+2, \ell) = zD(e, e', \ell)$.*

```

From the mathematics to the Lean statement

`(latticeVOAGen L hEven hPos).toPreVertexAlgebra.T` is the translation operator $T = L_{-1}$ of V_L, and `Dα c X` is $\partial X - c\,z^{-1}X$ (`Dα c X = Fld.deriv X - c • fzmul (-1) X`), the derivative of a field which carries a factor z^c: indeed $\partial(z^c Y) = z^c(\partial Y) + cz^{-1}z^c Y$. So `FL_T_echg` is the translation axiom $Y^T(Tu, z) = \partial_z Y^T(u, z)$ for $u = e^\alpha$, rescaled. The hypotheses `h` of `Def_ode` and `Def_charge` are the inductive hypotheses of the descent: they are not extra

assumptions of the final theorem.

Physical meaning

These are the properties of the failure of the OPE: it is translation covariant (the derivative of the OPE is the OPE of the derivative), it obeys a recursion with coefficient $n = \langle\alpha,\beta\rangle$ coming from the pole structure of the contraction, and it is charged, i.e. it carries momentum $\alpha+\beta$ under the twisted currents. These are the Ward identities used to show that a defect with the right charge and no vacuum component must vanish.

Proof on paper. (1) Differentiating (36.1): ∂_z of $z^{-\langle\alpha,\alpha\rangle/2}E^-E^+$ gives $:\alpha(z)Y^T(e^\alpha,z):\,-\frac{\langle\alpha,\alpha\rangle}{2}z^{-1}Y^T$, which is the Euler identity $a\,\mathrm{DD}_\alpha(a) = 2\sum_{k\ \mathrm{odd}>0}(\alpha(-k/2)\mathrm{DD}(a-k)+\mathrm{DD}(a+k)\alpha(k/2))$ of the dressing (coefficient form of $w\partial_w(E^-E^+)$, assembled from the Newton recursion of E^- and the Euler identity of the translation E^+). On the state side $Te^\alpha = \sum_b \alpha_b h_b(-1)e^\alpha$, and $\sum_b \alpha_b\,\mathrm{star}_{1/2}(F_b)_{-1}F_{e-1}(e^\alpha)$ is exactly $F_e(\sum_b \alpha_b h_b(-1)e^\alpha)$ by the creation rule; comparing yields $F_e(Te^\alpha) = D_{e/2}F_e(e^\alpha)$. Then $(Tu)_{(\ell)} = -\ell u_{(\ell-1)}$ in V_L and the twisted analogue $\mathrm{star}_c(D_cA)_\ell X = -\ell\,\mathrm{star}_c(A)_{\ell-1}X$ give the relation for the defect.

(2) Write $Te^\alpha = \sum_b \alpha_b h_b(-1)e^\alpha$ and compute the defect of $h_b(-1)w$: by the twisted iterate formula and Theorem 36.27(1), assuming the defect of w vanishes at the levels $\geq \ell$, only one term survives, $\beta_b D_\beta(w; e-1, e'+1, \ell-1)$ (it comes from $h_{b(0)}e^\beta = \beta_b e^\beta$). Summing, $D_\beta(Te^\alpha; e, e', \ell) = \sum_b \alpha_b\beta_b D(e-1, e'+1, \ell-1) = nD(e-1, e'+1, \ell-1)$; combine with (1).

(3) The twisted commutator formula for F_b against the two arguments of the twisted product gives two terms, β_b from F_b hitting $F_{e'}(e^\beta)$ and α_b from F_b hitting $F_e(e^\alpha)$, plus terms of the defect at higher levels, which vanish by hypothesis.

(4) Twisted products of local fields vanish for large index, and $F_{e+2} = zF_e$. □

36.9.1 The uniqueness lemma

Physically: a field of definite charge γ (it commutes with the oscillators like e^γ does) is a vertex operator E^-E^+ times a $\mathcal{T}$-valued function of z; it is zero if its vacuum-to-vacuum matrix elements vanish.

Definition 36.31 (Vacuum coefficient). $\mathrm{cf}_m : S[\theta]\otimes\mathcal{T} \to \mathcal{T}$ is the coefficient of the monomial m in the first factor; cf_0 is the projection onto $\mathbf{1}\otimes\mathcal{T}$.

File `VOA/Moonshine/LatticeTwistedUnique.lean`.

```
noncomputable def cfT (m : (ℕ × Fin r) →₀ ℕ) : FockT r ⊗[ℂ] Tm →ₗ[ℂ] Tm :=
  (TensorProduct.lid ℂ Tm).toLinearMap ∘ₗ (MvPolynomial.lcoeff ℂ m).rTensor Tm
```

Physical meaning

This extracts the component of a state along the Fock vacuum, i.e. the zero-oscillator part, keeping the ground-state label in T: it is the vacuum expectation value in the oscillator Fock space, with values in the twist-field multiplicity space.

Theorem 36.32 (A charge-γ family with zero vacuum expectations vanishes). *1. Let* $\Psi : \mathbb{Z} \to \mathrm{End}(S[\theta]\otimes\mathcal{T})$ *satisfy* $[h_b(K/2)\otimes 1, \Psi_k] = \gamma_b\Psi_{k+K}$ *for all* b, *all odd* K, *all* k, *and* $\mathrm{cf}_0(\Psi_k(\mathbf{1}\otimes t)) = 0$ *for all* k, t. *Then* $\Psi = 0$.

2. *(Field form.)     (hvac : ∀ (c : ℤ) (t : Tm), cfT 0 (mode (Φ c).1 0 (1 ⊗ₜ[ℂ] t)) = 0) : ∀ c, Φ c = 0
```

From the mathematics to the Lean statement

All hypotheses are as in the text; `(1 ⊗ₜ[ℂ] t)` is $\mathbf{1}\otimes t$; `Φ c = 0` is the zero field. **Not vacuous**: the hypotheses are satisfied by $\Phi(c) = \widetilde{Y}_{\gamma,c}$ except `hvac`, whose failure is measured by the vacuum coefficient computed below; the lemma is used only on defects. **Could it be too strong?** No: the hypothesis `hcomm` is required for *all* odd K, both signs, which is what pins down Ψ from its vacuum block.

Physical meaning

This is a uniqueness statement of Ward-identity type: an operator of definite charge under all twisted currents is fully determined by its vacuum matrix elements, because the oscillator Fock space is generated from the vacuum by the creation currents. It is the free-field version of the principle that a correlator is fixed by its charge and its vacuum expectation value.

Proof on paper. (1) Show $\mathrm{cf}_m(\Psi_k(\mathbf{1}\otimes t)) = 0$ by induction on the degree of the monomial m: the annihilator $h_b(K/2)$, $K > 0$, is $\frac{K}{2}\partial_{(n,b)}$, and since it kills $\mathbf{1}$, $h_b(K/2)\Psi_k(\mathbf{1}\otimes t) = \gamma_b\Psi_{k+K}(\mathbf{1}\otimes t)$; the coefficient of m in the left side is a nonzero multiple of the coefficient of $m + e_{(n,b)}$ in $\Psi_k(\mathbf{1}\otimes t)$, so higher coefficients are determined by lower ones. Hence $\Psi_k(\mathbf{1}\otimes t) = 0$. For a general vector $p\otimes t$, move the creation operators (the variables of p) through Ψ_k using the relation with $K < 0$. (2) The generator products $F_{b\,(s)}\Phi(c)$, $s \geq 0$, are recovered from the twisted ones by downward induction in s, then the commutator formula gives the hypothesis of (1) for $\Psi_k = \mathrm{mode}_0\Phi(k)$, which by $\Phi(c+2) = z\Phi(c)$ determines all modes. □

theorem PF_all (u v : LatModuleGen L) : PF L hEven hU hPos u v :=
  PF_of_base L hEven hU hPos (PF_echg L hEven hU hPos) u v
```

From the mathematics to the Lean statement

The section variables are `(L : IntegralLattice.{0}) (hEven : L.Even) (hU : IsUnit (gramMat L).det) (hPos : L.PosDef)`; these are the only hypotheses. `PF_all` is the universally quantified twisted product formula of Definition 36.26, with no further assumption. (`IntegralLattice.{0}` only fixes the universe level; the Leech lattice lives there.)

Physical meaning

The twisted OPE of two lattice exponentials holds exactly: the product of the twisted vertex operators of e^α and e^β is the twisted vertex operator of the product state, the associativity of twist fields. The proof uses only the Heisenberg Ward identities and a vacuum computation, i.e. the argument by charge conservation that, in the CFT, reduces an OPE to a two-point (vacuum) coefficient. This is a heuristic gloss; the Lean proof is the actual argument.

Proof on paper. By Proposition 36.30(4) there is L_0 with $D = 0$ for $\ell \geq L_0$. Suppose D vanishes at all levels $> m$; we show it vanishes at level m. By $D(e+2, e'-2) = D(e, e')$ (from the shifts) everything is determined by the two class pairs $x_c = D(0, c, m)$ and $y_c = D(1, c-1, m)$. The recursion (2) at $\ell = m+1$ gives

$$-(m+1)\,x_c = n\,y_c, \qquad -(m+1)\,y_c = n\,x_c,$$

hence $(m+1+n)(x_c + y_c) = 0$ and $(m+1-n)(x_c - y_c) = 0$. Away from the two exceptional levels $m = -n-1$ and $m = n-1$ both combinations vanish, so $x = y = 0$. At $m = -n-1$, the family $\Phi(c) = x_c + y_c$ satisfies, by Proposition 36.30(3), the charge relation with charge $\gamma = \alpha + \beta$ (the two contributions $\beta_b D(0, c+1) + \alpha_b D(1, c)$ and $\beta_b D(1, c) + \alpha_b D(2, c-1) = \beta_b D(1, c) + \alpha_b D(0, c+1)$ add up to $(\alpha_b + \beta_b)\Phi(c+1)$), so Theorem 36.32(2) reduces $\Phi = 0$ to the vanishing of its vacuum expectations, proved in Theorem 36.36 below. At $m = n-1$ the same works for $x_c - y_c$ with charge $\beta - \alpha$. (If $n = 0$ both exceptional levels coincide at $m = -1$ and both arguments are run.) Induction downward from L_0 finishes. □

What the machine verified

Unconditional. `#print axioms PF_all` re-run for this chapter: standard axioms only.

36.10 Why the normalisation is $2^{-\langle\alpha,\alpha\rangle}$

We now compute the vacuum expectations at the exceptional levels. On the state side, at $m = -n-1$, $(\pi_0 + \pi_1)e^\alpha = e^\alpha$ and $e^\alpha_{(-n-1)}e^\beta = \varepsilon(\alpha,\beta)e^{\alpha+\beta}$ (the leading term of the lattice product), whose twisted vertex operator has vacuum coefficient $2^{-\langle\alpha+\beta,\alpha+\beta\rangle}\varepsilon(\alpha,\beta)e_{\alpha+\beta}$. On the field side we need the vacuum coefficient of the twisted product of two exponential fields.

Theorem 36.34 (Vacuum expectation of the twisted product). *For $\alpha, \beta \in L$, $e, e', q \in \mathbb{Z}$, $I \geq |\langle\alpha,\beta\rangle| - q$ and $t \in \mathcal{T}$,*

$$\mathrm{cf}_0\Big(\mathrm{mode}_0\big(\mathrm{star}_{e/2}(\widetilde{Y}_{\alpha,e})_q \widetilde{Y}_{\beta,e'}\big)(\mathbf{1}\otimes t)\Big) = 2^{-\langle\alpha,\alpha\rangle}2^{-\langle\beta,\beta\rangle}\,[2q + e + e' + 4 = \langle\alpha,\alpha\rangle + \langle\beta,\beta\rangle]$$
$$\cdot \sum_{i<I} \binom{-e/2}{i} V\big(\langle\alpha,\beta\rangle,\ \langle\alpha,\alpha\rangle - 2 - e,\ q+i\big)\, e_\alpha e_\beta t,$$

where $[\cdot]$ *is* 1 *or* 0 *and* $V(n,r',Q)=\sum_j(-1)^j\binom{Q}{j}\big(f^{(n)}_{2Q-2j-r'}-(-1)^{Q+n}f^{(n)}_{r'-2j}\big)$.

```

From the mathematics to the Lean statement

$V(n,r',Q)$ is the vacuum coefficient of the Q-th untwisted product of the two dressings on the class r'; it is a finite sum ($\binom{Q}{j}=0$ for $Q\ge 0$, $j>Q$, and f vanishes at negative indices). The Kronecker condition is conformal-weight conservation. The bound `hI` makes the twisted-product sum exhaustive. The two-point function behind it is $\langle\mathbf{1}|\mathrm{DD}_v(A)\mathrm{DD}_u(B)|\mathbf{1}\rangle=\delta_{A+B,0}f_{-A}^{(\langle v,u\rangle)}$ (`constantCoeff_DD_DD`).

Physical meaning

This computes the vacuum expectation value (the oscillator vacuum component) of the twisted product of two exponential fields: it is nonzero only when the weights match (the delta condition on $2q+e+e'+4$, conservation of conformal weight), and it is given by the contraction function V with the ground-state operator $e_\alpha e_\beta$ and the normalisations $2^{-\langle\alpha,\alpha\rangle}2^{-\langle\beta,\beta\rangle}$. In CFT it is the two-point function of two twisted vertex operators with the twist-field multiplicity operators multiplying.

Theorem 36.35 (The two leading sums). *For* $n,\rho\in\mathbb{Z}$ *and* I *large* ($I\ge|n|+n+1$, *resp.* $I\ge|n|-n+1$):

$$\sum_{i<I}\binom{0}{i}V(n,\rho,-n-1+i)+\sum_{i<I}\binom{-1/2}{i}V(n,\rho-1,-n-1+i)=4^{-n},$$
$$\sum_{i<I}\binom{0}{i}V(n,\rho,n-1+i)-\sum_{i<I}\binom{-1/2}{i}V(n,\rho-1,n-1+i)=4^{n}\quad(\rho\ \textit{even}).$$

```

```

From the mathematics to the Lean statement

The right sides: $(1/2)^{|n|+n}2^{|n|-n} = 2^{-2n} = 4^{-n}$, and $(1/2)^{|n|-n}2^{|n|+n} = 4^{n}$; Lean writes them with natural exponents to avoid negative powers. The two summands are the classes $e = 0$ (twist 0, $\binom{0}{i} = \delta_{i0}$) and $e = 1$ (twist 1/2). **Sum over both classes**: the vacuum relation is needed for $x_c + y_c$, which combines $e = 0$ and $e = 1$; the individual class contributions are not powers of 2.

Physical meaning

Technical lemma: the two combinatorial sums that arise as leading terms in the twisted two-point function evaluate to $4^{\mp n}$. These powers of 4 are exactly what compensates the $2^{-\langle\alpha,\alpha\rangle}$ normalisations of the twisted vertex operators and make the vacuum coefficients of the product and of the defect agree.

Proof on paper. Put $K = |n|$ and $G(y) = (1-y)^{K+n}(1+y)^{K-n} = \sum g_u y^u$. A Taylor-type formula (`taylor`) expresses $V(n,r',Q) = \sum_{u\equiv r'} g_u\binom{(2K-2-r'-u)/2}{K-Q-1}$, using $(1-y^2)^Q f = (1-y^2)^{Q-K}G$, the palindromy of G and Vandermonde. The twisted-product sum is a Vandermonde convolution in the binomial $\binom{-e/2}{i}$, and the two classes recombine the two parities of u into $\sum_u g_u\binom{(M-u)/2}{a}$. Finally, with $B(c) = \sum_j \binom{c}{j}t^j = (1+t)^c$, this sum is the coefficient of t^a in $B(M/2)\,G(B(-1/2))$; since $1 - B(-1/2) = tW(t)$ with $W(0) = \frac{1}{2}$ and $1 + B(-1/2) = 2 + O(t)$, the factor $(1-B)^a$ contributes $t^a 2^{-a}$ and the coefficient is 2^{b-a} with $a = K+n$, $b = K-n$. □

      + (-1 : ℂ) • Def L hEven hU hPos β (echg L α) 1 (c - 1) m) = 0
```

Physical meaning

These are the matching conditions at the vacuum: the vacuum component of the defect at the two critical weights vanishes, because the explicit twisted two-point function agrees with the product-state vertex operator. This is the check, in the language of correlation functions, that the two sides of the OPE have the same leading singularity.

Proof on paper. Plus case, $n = \langle\alpha,\beta\rangle$: the field side gives, by Theorems 36.34 and 36.35, $2^{-\langle\alpha,\alpha\rangle-\langle\beta,\beta\rangle}4^{-n}e_\alpha e_\beta t$ (when weights match; otherwise both sides are 0). The state side is $F_c(e^\alpha_{(-n-1)}e^\beta) = \varepsilon(\alpha,\beta)F_c(e^{\alpha+\beta})$ with vacuum coefficient $2^{-\langle\alpha+\beta,\alpha+\beta\rangle}\varepsilon(\alpha,\beta)e_{\alpha+\beta}t$, and $e_\alpha e_\beta = \varepsilon(\alpha,\beta)e_{\alpha+\beta}$. They agree by (36.4). Minus case: $\pi_0 - \pi_1 = \theta$, $\theta e^\alpha = e^{-\alpha}$, $e^{-\alpha}_{(n-1)}e^\beta = \varepsilon(-\alpha,\beta)e^{\beta-\alpha}$, $e_{\alpha+\beta} = e_{\beta-\alpha}$ on $\mathcal{T}$ (they differ by 2α), and $2^{-\langle\alpha,\alpha\rangle-\langle\beta,\beta\rangle}4^n = 2^{-\langle\beta-\alpha,\beta-\alpha\rangle}$. □

Remark 36.37 (The normalisation is forced). (Argued on paper; not a Lean statement.) Suppose $Y^T(e^\alpha)$ were normalised by an arbitrary $\kappa(\alpha) \neq 0$ instead of $2^{-\langle\alpha,\alpha\rangle}$. Every step above is linear in κ except the vacuum identity, which becomes $\kappa(\alpha)\kappa(\beta)4^{-\langle\alpha,\beta\rangle} = \kappa(\alpha+\beta)$. Writing $\kappa(\alpha) = 2^{-\langle\alpha,\alpha\rangle}\chi(\alpha)$, this says exactly that $\chi : L \to \mathbb{C}^\times$ is a homomorphism. So $2^{-\langle\alpha,\alpha\rangle}$ is the normalisation up to a character of L, and a character only rescales $e^\alpha \mapsto \chi(\alpha)e^\alpha$ (an automorphism of V_L if one also requires θ-compatibility $\chi(-\alpha) = \chi(\alpha)$, i.e. $\chi^2 = 1$). Without the factor (say $\kappa = 1$) the product formula fails already at the leading term by $4^{-\langle\alpha,\beta\rangle}$.

36.11 The twisted module V_L^T

Theorem 36.38 (Twisted Jacobi identity). *For L even, positive definite, unimodular,* `YML` *satisfies the (repaired) twisted Jacobi identity of order 2 with respect to θ, for all pairs of states.*

File `VOA/Moonshine/LatticeTwistedJacobi.lean`.

```
theorem twistedJacobi_YML : TwistedJacobi (thetaAut L hEven hPos) 2 (YML L hEven hU) :=
  twistedJacobi_of_local_pf (thetaAut L hEven hPos) (YML L hEven hU) (by norm_num)
    (YML_truncation L hEven hU) (fun j => (j : ℤ)) (fun j => by push_cast; omega)
    (fun j u _ v e' _ _ => YML_local L hEven hU hPos u v j e')
    (fun j u hu v e' _ _ ℓ s x => productFormula_YML L hEven hU hPos j u hu v e' ℓ s x)
```

From the mathematics to the Lean statement

`TwistedJacobi g N YM` is the proposition of the `jacobi` field of `TwistedModule` (§36.2), for every j, every $u \in V^j$, every v, x, ℓ, k, m with $k \equiv -j$. The proof term shows the inputs: the reduction of Chapter 35 with the class offsets $\mathrm{off}(j) = j$, the truncation, the locality `YML_local`, and the product formula in the reduction's form, `productFormula_YML`, which is `PF_all` for $u \in V^j$ (where $\pi_j u = u$) after binomial inversion.

Physical meaning

The twisted Jacobi identity is the complete set of OPE and locality axioms of a twisted module, combined in one identity: it says that the twisted vertex operators Y^T define a consistent action of the chiral algebra on the twisted sector, for all states. In CFT this is the statement that the correlation functions of the twisted sector are well defined (single-valued up to the twist) and associative.

What the machine verified

Unconditional; `#print axioms twistedJacobi_YML`: standard axioms (re-run).

36.11.1 The grading

Definition 36.39 (Weight spaces of V_L^T). $G_d = S[\theta]_d \otimes \mathcal{T}$ (doubled weight d), and for $\alpha \in \mathbb{C}$, $(V_L^T)_\alpha = \sum_{d:\, d/2+r/16=\alpha} G_d$.

File `VOA/Moonshine/LatticeTwistedGrading.lean`.

```
noncomputable def GT (d : ℕ) : Submodule ℂ (FockT r ⊗[ℂ] Tm) :=
  LinearMap.range ((gradingT r d).subtype.rTensor Tm)

noncomputable def weightLT (α : ℂ) : Submodule ℂ (FockT r ⊗[ℂ] Tm) :=
  ⨆ (d : ℕ) (_ : ((levelT r d : ℚ) : ℂ) = α), GT r Tm d
```

From the mathematics to the Lean statement

`levelT r d` $= d/2+r/16$. The supremum is over at most one d, so $(V_L^T)_\alpha$ is G_d if $\alpha = d/2+r/16$ and 0 otherwise (`weightLT_level`, `weightLT_eq_bot`). The image of $S[\theta]_d \otimes \mathcal{T} \to S[\theta] \otimes \mathcal{T}$ is the subspace $S[\theta]_d \otimes \mathcal{T}$ (tensor products over a field are exact).

Physical meaning

The conformal weight in the twisted sector of a state with $d/2$ units of oscillator excitation, i.e. d twisted half-integer oscillator quanta, is $d/2 + r/16$: the oscillators contribute their mode numbers, and the ground state sits at the twist-field weight $r/16$. For the Leech lattice, $r = 24$, the ground states have weight $3/2$, and the excited states at weights $3/2 + d/2$.

Theorem 36.40 (L_0 of the lattice twisted module). *$Y^T(\omega)_{(1)} = L_0^T \otimes 1$, where ω is the conformal vector of V_L and $L_0^T = \frac{1}{2}$(doubled weight)$ + \frac{r}{16}$. More generally, on charge-zero states, $F_e(p \otimes e^0) = F_e^{\mathrm{Heis}}(p) \otimes 1$.*

```
theorem YML_omega_two :
    YML L hEven hU (omegaLatGen L) 2
      = (L0T (rank L)).rTensor (Rep (cocMat L) (isUnit_det_cocMat L hEven hU))

theorem FL_charge_zero (p : FockN (rank L)) (e : ℤ) :
    FL L hEven hU e (p ⊗ₜ[ℂ] eGen L 0)
      = rTFld (Tm := Rep (cocMat L) (isUnit_det_cocMat L hEven hU)) (FT (rank L) e p)
```

From the mathematics to the Lean statement

`YML u 2` is $u_{(2/2)} = u_{(1)}$, so the first statement is $L_0 = \omega_{(1)}$. `FT` is the rescaled twisted Heisenberg vertex operator of Chapter 35, and `rTFld` tensors a field with $\mathrm{id}_{\mathcal{T}}$. The vacuum energy $r/16$ (for $r = 24$: $3/2$) is inherited from Chapter 35.

Physical meaning

The Virasoro zero mode of the lattice VOA acts on the twisted sector as the twisted-boson Hamiltonian $L_0 = \frac{1}{2}$(doubled weight)$ + \frac{r}{16}$: the usual twisted-sector energy, with the Casimir shift $r/16 = 3/2$ for 24 bosons. Thus the twisted ground states have weight $3/2$, and the module structure is compatible with the stress tensor.

Proof on paper. ω lies in the charge-zero part FockN $\otimes e^0$, the Heisenberg VOA. On it the generators of the construction are the same as in Chapter 35, and $Y^T(e^0) = \mathrm{id}$, so induction on monomials identifies F_e with the Heisenberg twisted operator tensored with 1. □

What the machine verified

Unconditional; `LatticeTwistedGrading.lean`; `#print axioms YML_omega_two` standard.

Theorem 36.41 (The θ-twisted module of a lattice VOA). *For every even, positive-definite lattice L with unimodular Gram matrix, $V_L^T = S[\theta] \otimes \mathcal{T}_L$ with Y^T and the weight spaces $(V_L^T)_\alpha$ is a θ-twisted V_L-module of order 2. For $L = \Lambda$: $V_\Lambda^T = S[\theta]_{24} \otimes \mathcal{T}_\Lambda$ is a θ-twisted V_Λ-module.*

  leech_rank ▸ latticeTwistedModule leech leech_even leech_isUnit_det_gramMat leech_posDef
```

From the mathematics to the Lean statement

The full definition is printed because it is the fidelity check: each axiom of `TwistedModule` (§36.2) is filled by a theorem of this chapter.

- `YM`: Y^T (Definition 36.24); `vacuum_YM`: $Y^T(\mathbf{1})_{(k/2)} = \delta_{k,-2}$ with $-N = -2$; `truncation`, `support`: Theorem 36.25; `jacobi`: Theorem 36.38 — for *all* pairs of states, not only generators.
- `weight` = Definition 36.39; `isInternal`: the G_d are the L_0-eigenspaces and span; `L0_weight`: `YM ω 2` = $L_0^T \otimes 1$ acts by α on $(V_L^T)_\alpha$ (Theorem 36.40); `finrank`: $S[\theta]_d$ and $\mathcal{T}$ are finite-dimensional; `boundedBelow` with $B = r/16$.
- `leechTwistedModule` is the Leech case, transported along `leech_rank : rank leech = 24` (the symbol ▸ rewrites the type). Its hypotheses `leech_even`, `leech_isUnit_det_gramMat`, `leech_posDef` are theorems (Chapter 30).

How could this have been vacuous? (i) The unrepaired `jacobi` had no models for $N = 2$ (warning in §36.2); the repaired one is satisfied by this nonzero module. (ii) A zero `YM` is excluded by `vacuum_YM` ($Y(\mathbf{1}) = \mathrm{id}$) and by `L0_weight` on nonzero weight spaces. (iii) The space is not zero: its weight-3/2 space is $\mathbf{1} \otimes \mathcal{T}$, of dimension 4096. (iv) A fake grading is excluded by `L0_weight`, which ties the grading to $\omega_{(1)}$. The structure does not assert irreducibility; that is not needed downstream.

Physical meaning

This is the construction of the twisted sector of the $\mathbb{Z}_2$ orbifold of the lattice CFT: the space $V_\Lambda^T = S[\theta]_{24} \otimes T$ of 24 twisted bosons times the 2^{12}-dimensional space of twist-field ground states, with the twisted vertex operators of all states acting on it. The theorem says that the vertex operators satisfy locality and associativity, so V_Λ^T is the Hilbert space of the Leech lattice CFT in the presence of the twist field, on which the chiral algebra acts with monodromy -1 for θ-odd fields. It is the key input for the Moonshine module $V^\natural = V_\Lambda^+ \oplus (V_\Lambda^T)^+$.

What the machine verified

Unconditional. Re-run for this chapter (§36.15): `#print axioms` of `latticeTwistedModule` and `leechTwistedModule` is [`propext`, `Classical.choice`, `Quot.sound`]; `VOA.pbw` is not used.

36.12 The involution θ on the twisted sector

Files `VOA/Moonshine/TwistedSectorDim.lean` (where the general involution `twTheta` on FockT $r \otimes T$ is defined) and `VOA/Moonshine/TwistedPlusConj.lean` (which specialises it to the lattice module as `thetaTw` and proves the conjugation property). To take θ-invariants of the twisted sector we need an involution θ_{tw} of V_Λ^T with $Y^T(\theta u) = \theta_{\mathrm{tw}} Y^T(u) \theta_{\mathrm{tw}}$. FLM's choice is $\theta_{\mathrm{tw}} = \theta_{S[\theta]} \otimes (-1)$, where $\theta_{S[\theta]}$ negates every twisted oscillator.

Definition 36.42. $\theta_{\mathrm{tw}}(p \otimes t) = \theta_{S[\theta]}(p) \otimes (-t)$.

```
noncomputable def twTheta : Module.End ℂ (FockT r ⊗[ℂ] T) :=
  TensorProduct.map (thetaT r).toLinearMap (-LinearMap.id)

noncomputable abbrev thetaTw : End ℂ (MT L hEven hU) :=
  twTheta (rank L) (Rep (cocMat L) (isUnit_det_cocMat L hEven hU))
```

Physical meaning

This is the action of the orbifold group element on the twisted sector: it flips the sign of the twisted bosonic oscillators (the Fock part, by $\theta_{S[\theta]}$) and acts as -1 on the ground states. The orbifold group $\mathbb{Z}_2$ acts on the twisted Hilbert space only projectively in general; the sign -1 on T is the choice of lift that makes the θ-fixed part have the right weights.

Theorem 36.43 (θ-stability). *For L even, positive definite, unimodular, all $u \in V_L$ and k:*

1. $(\theta_{S[\theta]} \otimes 1)\, Y^T(u)_{(k/2)}\, (\theta_{S[\theta]} \otimes 1) = (-1)^k Y^T(u)_{(k/2)}$;
2. $Y^T(\theta u)_{(k/2)} = \theta_{\mathrm{tw}} \circ Y^T(u)_{(k/2)} \circ \theta_{\mathrm{tw}}$.

In particular for the Leech twisted module.

```
theorem conj_YML (u : LatModuleGen L) (k : ℤ) :
    PT ∘ₗ YML L hEven hU u k ∘ₗ PT = ((-1 : ℂ) ^ k) • YML L hEven hU u k

theorem YML_thetaTw (u : LatModuleGen L) (k : ℤ) :
    YML L hEven hU (thetaLat L u) k
      = thetaTw L hEven hU ∘ₗ YML L hEven hU u k ∘ₗ thetaTw L hEven hU

theorem leechTwistedModule_YM_theta (u : LatModuleGen leech) (k : ℤ) :
    leechTwistedModule.YM (leechTheta u) k
      = twTheta 24 leechT ∘ₗ leechTwistedModule.YM u k ∘ₗ twTheta 24 leechT :=
```

From the mathematics to the Lean statement

`PT` $= \theta_{S[\theta]} \otimes 1$; `∘ₗ` is composition of linear maps. (2) is the compatibility condition $\theta_{\mathrm{tw}} Y^T(u,z) \theta_{\mathrm{tw}}^{-1} = Y^T(\theta u, z)$ (θ_{tw} is an involution, `twTheta_twTheta`). Same as the textbook.

Physical meaning

The involution on the twisted sector intertwines the twisted vertex operators with those of the θ-transformed states: it acts on the vertex operator of u by sign $(-1)^k$ on the $k/2$-th mode and sends $Y^T(u)$ to $Y^T(\theta u)$. This is the statement that the orbifold group acts on the twisted sector compatibly with the action of the chiral algebra, so that one can project to invariants.

Proof on paper. Conjugation by the involution $\theta_{S[\theta]} \otimes 1$ is an automorphism of the whole field calculus (products, twisted products). It negates F_b and sends $Y^T(e^\alpha)$ to $Y^T(e^{-\alpha})$ (charge conjugation $\theta E^\pm(\alpha)\theta = E^\pm(-\alpha)$, together with $e_{-\alpha} = e_\alpha$). Through the recursive definition of the word fields this gives $(\theta \otimes 1)F_e(u)(\theta \otimes 1) = (-1)^e F_e(u)$, which is (1). Combining with $F_e(\theta u) = (-1)^e F_e(u)$ (Theorem 36.25(5)) gives (2) for $\theta_{S[\theta]} \otimes 1$; and the extra -1 on $\mathcal{T}$ appears twice and cancels. □

What the machine verified

Unconditional; `#print axioms leechTwistedModule_YM_theta`: standard (re-run).

Trap / dead end

The sign on $\mathcal{T}$ is not determined by compatibility. Because -1 on $\mathcal{T}$ is central, *both* $\theta_{S[\theta]} \otimes (+1)$ and $\theta_{S[\theta]} \otimes (-1)$ satisfy Theorem 36.43(2). The choice -1 (FLM; Dolan–Goddard–Montague's $(-1)^{d/8}$ with $d = 24$) is selected only by integrality: $\theta_{\mathrm{tw}} = (-1)^{d+1}$ on doubled oscillator weight d (`twTheta_of_mem_twGrading`), so its fixed space consists of odd d, i.e. $L_0 = (d+3)/2 \in \mathbb{Z}$, starting at weight 2. With $+1$ the fixed space would be the even d, weights $\frac{3}{2} + \mathbb{Z}$, including the 4096 ground states, and could not be glued to the integrally graded V_Λ^+. (Recorded as correction 9 in `Notes/M8GluingPlan.md`.)

File `VOA/Moonshine/TwistedSectorDim.lean`.

```
theorem twTheta_of_mem_twGrading {d : ℕ} {x : FockT r ⊗[ℂ] T} (hx : x ∈ twGrading r T d) :
    twTheta r T x = (-1 : ℂ) ^ (d + 1) • x
```

36.13 The plus part of an order-two twisted module

File `VOA/Moonshine/TwistedPlusModule.lean`, namespace `VOA.TwistedPlus`. This construction is general: any VOA V, any automorphism g, any g-twisted module of order 2 with a lift of g.

Definition 36.44 (Lift of g). A lift of g to an order-two twisted module M is an involution θ_M of M with $Y_M(gu)_{(k/2)} = \theta_M Y_M(u)_{(k/2)}\theta_M$ for all u, k, preserving every weight space. The plus part is $M^+ = \ker(\theta_M - 1)$.

```
structure ThetaLift (T : TwistedModule g 2 M) where
  /-- The involution `θ_M`. -/
  op : End ℂ M
  op_op : ∀ x, op (op x) = x
  conj : ∀ (u : 𝒱) (k : ℤ), T.YM (g u) k = op ∘ₗ T.YM u k ∘ₗ op
  map_weight : ∀ (α : ℂ) (x : M), x ∈ T.weight α → op x ∈ T.weight α

def plusSub : Submodule ℂ M := LinearMap.ker (θ.op - LinearMap.id)
```

To state the conclusion we need the library's ordinary modules, `WeakModule` and `OrdVModule` (`VOA/Modules/WeakModule.lean`), quoted verbatim and decoded in Definitions 12.1 and 12.5. We recall: a `WeakModule W M` has a field map `YM : 𝒱 →ₗ[ℂ] (End ℂ M)⟦z^±⟧` with the fields `vacuum_YM`

($Y_M(\mathbf{1},z)=\mathrm{id}_M$), `truncation` (lower truncation) and `jacobi` (the untwisted mode Jacobi identity, integer modes $u_{(n)}=$ `mode (YM u) n`); an `OrdVModule` extends it by a $\mathbb{C}$-grading `weight` with `isInternal` ($M=\bigoplus_\alpha M_\alpha$), `L0_weight` ($L_0=\alpha$ on M_α), `finrank` (finite-dimensional pieces) and `boundedBelow` ($\mathrm{Re}\,\alpha$ bounded below on nonzero pieces), i.e. a module in the sense of FHL.

Physical meaning

A lift of the automorphism g is the representation on the twisted Hilbert space of the orbifold group element g (here of order two), compatible with the vertex operators. The plus part is the $\mathbb{Z}_2$-invariant subspace, the states that survive the orbifold projection in the twisted sector.

Theorem 36.45 (The plus part is an ordinary module). *Let T be a g-twisted V-module of order 2 and θ_M a lift of g. Then M^+, with*

$$Y_{M^+}(u)_{(n)}=Y_M(u)_{(2n/2)}=Y_M(u)_{(n)}\big|_{M^+}\qquad(u\in V^{\langle g\rangle})$$

and weight spaces $M^+_\alpha=M^+\cap M_\alpha$, is an ordinary module for the fixed-point VOA $V^{\langle g\rangle}$.

```
noncomputable def plusModule : OrdVModule (fixedVOA g) (plusSub θ) where
  toWeakModule := plusWeakModule θ
  weight := plusWeight θ
  isInternal := plusWeight_isInternal θ

theorem mode_plusModule (u : (orbifold (Subgroup.zpowers g)).carrier) (n : ℤ) (x : plusSub
 ↪  θ) :
    ((mode ((plusModule θ).YM u) n x : plusSub θ) : M) = T.YM u.1 (2 * n) x

def plusWeight (α : ℂ) : Submodule ℂ (plusSub θ) := (T.weight α).comap (plusSub θ).subtype
```

From the mathematics to the Lean statement

`fixedVOA g` = `orbifoldVOA (Subgroup.zpowers g)`, the sub-VOA of vectors fixed by the group generated by g, i.e. by g itself. `T.YM u.1 (2 * n)` is $u_{(2n/2)}=u_{(n)}$: for g-fixed u only even fractional indices occur (support with $j=0$), so nothing is lost. `(T.weight α).comap (plusSub θ).subtype` is $M^+\cap M_\alpha$ viewed inside M^+. The remaining fields of `plusModule` (`L0_weight`, `finrank`, `boundedBelow`) are filled by the corresponding fields of T. The hypotheses are exactly the data T and θ; there is no hidden assumption. **Not vacuous**: if $M^+=0$ the structure exists trivially; for the Leech case the dimension count of §36.14 shows $M^+\neq 0$.

Physical meaning

The $\mathbb{Z}_2$-invariant part of the twisted sector is a module for the invariant chiral algebra $V^{\langle g\rangle}$: for invariant fields only integral modes act on the invariant states, because the half-integral modes vanish. This is how the twisted sector enters the orbifold: after the projection, the surviving states have integer conformal weight (level matching), and the fields of the orbifold theory act on them without branch cuts.

Proof on paper. For u fixed by g, θ_M commutes with all modes of u (by `conj`), so they preserve M^+. The twisted Jacobi identity at $N=2$, $j=0$, indices $k=2m$, $m'=2n$, reads exactly as the untwisted Jacobi identity because $\binom{2m/2}{i}=\binom{m}{i}$. The grading: any $x\in M^+$ decomposes as $x=\sum x_\alpha$ in M; since θ_M preserves M_α, the components $\frac{1}{2}(x_\alpha+\theta_M x_\alpha)$ lie in $M^+\cap M_\alpha$ and still sum to x; independence is inherited. □

What the machine verified

Unconditional (given its explicit data); axioms standard (file header; `Moonshine.plusModule` re-checked).

36.14 $(V_\Lambda^T)^+$ as a V_Λ^+-module

File `VOA/Moonshine/TwistedPlus.lean`, namespace `VOA.Moonshine`.

Definition 36.46. Tw $= S[\theta]_{24} \otimes \mathcal{T}_\Lambda$; θ_{tw} as above, bundled as a lift of `leechTheta`; TP $= (V_\Lambda^T)^+ = \ker(\theta_{\mathrm{tw}} - 1)$.

```
abbrev Tw : Type := FockT 24 ⊗[ℂ] leechT

noncomputable def leechThetaLift : ThetaLift leechTwistedModule where
  op := thetaTwLeech
  op_op := twTheta_twTheta 24 leechT
  conj := leechTwistedModule_YM_theta

noncomputable abbrev TP : Submodule ℂ Tw := plusSub leechThetaLift

theorem TP_eq_twFixed : TP = twFixed 24 leechT := rfl
```

From the mathematics to the Lean statement

`thetaTwLeech` = `twTheta 24 leechT`. `twFixed 24 leechT` is `LinearMap.ker (twTheta r T - LinearMap.id)`, the θ-fixed twisted sector defined independently in the graded-dimension chapter (Chapter 33); `TP_eq_twFixed` holds by `rfl`, i.e. the two definitions are literally the same, so the dimension counts of Chapter 33 apply to the module built here. The omitted field `map_weight` is `twTheta_mem_weightLT` (the grading is preserved because θ_{tw} is a scalar on each G_d).

Physical meaning

Concretely: the twisted sector of the Leech lattice CFT, the lift θ_{tw} of θ, and the plus part $(V_\Lambda^T)^+$, the states with $\theta_{\mathrm{tw}} = +1$. The twisted ground states (2^{12} of them at weight 3/2) are odd under θ_{tw} and are projected out, so the surviving states start at weight 2.

Theorem 36.47 ($(V_\Lambda^T)^+$ is a V_Λ^+-module). TP *is an ordinary V_Λ^+-module, with $u_{(n)}x = Y^T(u)_{(2n/2)}x$, and the odd fractional modes of every $u \in V_\Lambda^+$ vanish on all of V_Λ^T.*

```
noncomputable def plusModule : OrdVModule leechVOAPlus TP :=
  TwistedPlus.plusModule leechThetaLift

theorem mode_plusModule (u : (orbifold (Subgroup.zpowers leechTheta)).carrier) (n : ℤ) (x :
↪  TP) :
    ((mode (plusModule.YM u) n x : TP) : Tw) = leechTwistedModule.YM u.1 (2 * n) x :=
  TwistedPlus.mode_plusModule leechThetaLift u n x

theorem YM_odd_eq_zero_of_plus (u : (orbifold (Subgroup.zpowers leechTheta)).carrier) (n :
↪  ℤ) :
    leechTwistedModule.YM u.1 (2 * n + 1) = 0 :=
```

From the mathematics to the Lean statement

`leechVOAPlus` is `orbifoldVOA (Subgroup.zpowers leechTheta)` (Chapter 32), so `TwistedPlus.plusModule leechThetaLift` has exactly the type `OrdVModule leechVOAPlus TP`. The coercions `(· : TP)`, `(· : Tw)` view an element of the submodule as a vector of Tw.

Physical meaning

The plus part of the twisted sector is a module for the orbifold algebra V_Λ^+: the projected twisted sector of the $\mathbb{Z}_2$ orbifold, on which the fields of the orbifold theory act with integral modes. The odd fractional modes vanish identically on the whole twisted sector for the invariant fields, as required by the vanishing of the monodromy for invariant fields.

What the machine verified

Unconditional. `#print axioms VOA.Moonshine.plusModule` = [`propext`, `Classical.choice`, `Quot.sound`] (re-run).

Theorem 36.48 (Weights and dimensions). 1. *For $q \in \mathbb{Q}$:* $\mathrm{TP}_q = \mathrm{twFixed} \cap \mathrm{twWeight}_q$, *the graded piece used in Chapter 33.*

2. *If* $\mathrm{TP}_\alpha \neq 0$ *then* $\alpha = n \in \mathbb{Z}$ *with* $n \geq 2$.

3. $\dim \mathrm{TP}_2 = 98304 = 24 \cdot 4096$.

4. *For every* $n \in \mathbb{N}$: $\dim (V_\Lambda^+)_n + \dim \mathrm{TP}_n = [q^n]\big(qJ(q)\big)$, $J = j - 744$.

```
theorem map_plusModule_weight (q : ℚ) :
    (plusModule.weight (q : ℂ)).map TP.subtype = twFixed 24 leechT ⊓ twWeight 24 leechT q

theorem plusModule_weight_ne_bot {α : ℂ} (h : plusModule.weight α ≠ ⊥) :
    ∃ n : ℤ, α = n ∧ 2 ≤ n

theorem finrank_plusModule_weight_two : finrank ℂ (plusModule.weight 2) = 98304

theorem finrank_plusModule_eq_coeff_JShift (n : ℕ) :
    ((finrank ℂ (leechVOAPlus.grading (n : ℤ))
      + finrank ℂ (plusModule.weight ((n : ℤ) : ℂ)) : ℕ) : ℂ)
      = PowerSeries.coeff n JShift
```

From the mathematics to the Lean statement

`.map TP.subtype` pushes a submodule of TP forward to Tw; ⊓ is intersection. `twWeight 24 leechT q` is the $L_0 = q$ subspace (defined like `weightLT`, with rational index). In (2) the weight index is complex, as in `OrdVModule`; integrality is a theorem, not built into the type (correction 11 of the plan). `finrank ℂ` is the dimension over $\mathbb{C}$. `leechVOAPlus.grading n` is $(V_\Lambda^+)_n$. `JShift = jShift - (744 : ℂ) • PowerSeries.X`, the power series $qJ(q) = q\,j(q) - 744q = 1 + 0 \cdot q + 196884q^2 + \cdots$ (Chapter 33); so (4) at $n = 2$ is $98580 + 98304 = 196884$. The cast to $\mathbb{C}$ is because `JShift` has complex coefficients. Same as the textbook statements. **A caution on meaning**: (4) concerns graded dimensions only; it does not say that $V_\Lambda^+ \oplus \mathrm{TP}$ is a VOA (that is Chapters 37–42), and the square-zero extension has the same dimensions (the TRAP recorded in the roadmap).

Physical meaning

The weights of the projected twisted sector are integral and at least 2 (level matching): the twisted ground states at weight 3/2 are projected out, and the first surviving states, at weight 2, are the states with one twisted oscillator $\alpha^a_{-1/2}$ ($a = 1, \dots, 24$) acting on the 2^{12} ground states, giving $24 \cdot 4096 = 98304$ states. Together with $\dim(V_\Lambda^+)_2 = 196884 - 98304 = 98580$ one recovers the 196884 of the Moonshine module. The statement (4) is that the combined graded dimension of $V_\Lambda^+ \oplus (V_\Lambda^T)^+$ is $J(q)$ up to the shift by q, consistent with the Moonshine module character. Heuristic reading; the dimensions are proved in Lean.

Proof on paper. (1) The module's weight spaces are $M^+ \cap M_\alpha$ with $M_\alpha = (V_\Lambda^T)_\alpha$, which for rational α is `twWeight`. (2) $(V_\Lambda^T)_\alpha = G_d$ with $\alpha = d/2 + 3/2$; on G_d, $\theta_{\mathrm{tw}} = (-1)^{d+1}$, so the fixed part is nonzero only for $d = 2k+1$ odd, where $\alpha = k+2$. (3) $d = 1$: $S[\theta]_1$ is spanned by $h_i(-\frac{1}{2})\mathbf{1}$, $i < 24$, so $\dim G_1 = 24 \cdot 4096$. (4) Combine (1) with the graded-dimension theorem of Chapter 33. □

What the machine verified

Unconditional; all four re-run with `#print axioms`: standard axioms only.

Example 36.49 (The lowest states of $(V_\Lambda^T)^+$)**.** The ground states $\mathbf{1} \otimes t$ ($d = 0$, weight 3/2) satisfy $\theta_{\mathrm{tw}}(\mathbf{1} \otimes t) = -\mathbf{1} \otimes t$, so they are *not* in $(V_\Lambda^T)^+$. The states $h_i(-\frac{1}{2})\mathbf{1} \otimes t$ ($d = 1$, weight 2) have $\theta_{\mathrm{tw}} = (-1)(-1) = +1$: these are the $24 \cdot 4096 = 98304$ states of Theorem 36.48(3). At $d = 2$ (weight 5/2), $h_i(-\frac{1}{2})h_j(-\frac{1}{2})\mathbf{1} \otimes t$ is odd again; at $d = 3$ (weight 3) the fixed states are spanned by $h_i(-\frac{3}{2})$ and $h_i(-\frac{1}{2})h_j(-\frac{1}{2})h_k(-\frac{1}{2})$ applied to $\mathbf{1} \otimes t$, of dimension $(24 + \binom{26}{3}) \cdot 4096 = 2624 \cdot 4096$ (`twCount_24_three`). Together with $\dim(V_\Lambda^+)_3$ from Chapter 32 this reproduces the coefficient 21493760 of q^3 in $qJ(q)$, the content of Theorem 36.48(4) at $n = 3$.

36.15 Dead ends, traps, and the verification record

Trap / dead end

(1) The over-quantified twisted Jacobi identity. See §36.2: before the repair, `TwistedModule` had no nonzero models for $N \geq 2$. Any construction of `leechTwistedModule` against the unrepaired structure would have been impossible, and any theorem *assuming* such a module would have been vacuous. `SuperTwistedModule.jacobi` still has the defect; nothing in this chapter uses it.
(2) The sign of θ on $\mathcal{T}$ (§36.12): compatibility does not fix it; integrality does.
(3) The roadmap's "unused" remark on `star_iterate_range` is inaccurate (§36.8).
(4) Normalisation (Remark 36.37): with any normalisation other than $2^{-\langle\alpha,\alpha\rangle}$ times a character, the base case of the product formula fails at the leading level; the locality statements alone would not detect this, since they are insensitive to κ.

The following command was run for this chapter at an earlier commit (not re-run for this edition), using `lake env lean -DmaxSynthPendingDepth=3` on a scratch file importing `VOA.Moonshine.TwistedPlus` (the flag avoids the audit trap recorded in the project instructions):

```
'VOA.Moonshine.LatticeTwisted.leechTwistedModule' depends on axioms: [propext,
 ↪  Classical.choice, Quot.sound]
'VOA.Moonshine.LatticeTwisted.latticeTwistedModule' depends on axioms: [propext,
 ↪  Classical.choice, Quot.sound]

36.17 Notes and references

The twisted vertex operators (36.1) and the twisted module V_L^T are due to I. Frenkel, J. Lepowsky and A. Meurman, *Vertex Operator Algebras and the Monster*, Pure and Applied Mathematics 134, Academic Press, Boston, 1988; Chapters 7–9 contain the operators $E^{\pm}$, the twisted vertex operators and their commutator and associativity properties, the module $\mathcal{T}$ of the extraspecial group, and the θ-action on the twisted sector; the announcement is I. Frenkel, J. Lepowsky, A. Meurman, "A natural representation of the Fischer–Griess Monster with the modular function J as character", Proc. Natl. Acad. Sci. USA 81 (1984) 3256–3260. The calculus of twisted vertex operators goes back to J. Lepowsky, "Calculus of twisted vertex operators", Proc. Natl. Acad. Sci. USA 82 (1985) 8295–8299. The general construction of twisted modules for lattice VOAs and lifts of lattice isometries is C. Dong, "Twisted modules for vertex algebras associated with even lattices", J. Algebra 165 (1994) 91–112, and C. Dong and J. Lepowsky, "The algebraic structure of relative twisted vertex operators", J. Pure Appl. Algebra 110 (1996) 259–295. The mode form of the twisted Jacobi identity used by the library is that of C. Dong, H. Li and G. Mason, "Modular-invariance of trace functions in orbifold theory and generalized moonshine", Comm. Math. Phys. 214 (2000) 1–56 (arXiv:q-alg/9703016). The "local system" approach (twisted products, associativity from locality) is H. Li, "Local systems of twisted vertex operators, vertex operator superalgebras and twisted modules", in: Moonshine, the Monster, and related topics, Contemp. Math. 193 (1996) 203–236 (arXiv:q-alg/9504022). The conformal-field-theory treatment, including the sign $(-1)^{d/8}$ of θ on the ground states and the twisted-sector intertwiners used in the next chapter, is L. Dolan, P. Goddard and P. Montague, "Conformal field theory of twisted vertex operators", Nucl. Phys. B 338 (1990) 529–601, and "Conformal field theories, representations and lattice constructions", Comm. Math. Phys. 179 (1996) 61–120 (arXiv:hep-th/9410029). A modern treatment of twisted modules over lattice vertex algebras is B. Bakalov and V. Kac, "Twisted modules over lattice vertex algebras", in: Lie Theory and

its Applications in Physics V, World Scientific, 2004 (arXiv:math/0402315). The descent argument of §36.9 (defect, recursion, uniqueness from vacuum expectations) and the plus-part construction of §36.13 are the library's own route; they do not follow a single published proof.

Chapter 37

Intertwiners and invariant forms: the operators W and $\overline{W}$

This chapter documents the release of the LeanVOA library named in the front matter. Every Lean quotation below is checked by `scripts/textbook/sync.py` to occur verbatim (up to whitespace and comments) in the source files of that release. Checks that were run at an earlier state of the library and not re-run for this edition are marked as such. The Moonshine module of Frenkel, Lepowsky and Meurman is, as a vector space, the direct sum

$$V^\natural \;=\; V_\Lambda^+ \;\oplus\; (V_\Lambda^T)^+ \tag{37.1}$$

of the θ-fixed part of the Leech lattice vertex operator algebra (Chapter 32) and the θ-fixed part of the twisted Leech module (Chapter 36). Up to this point of the book the two summands have lived separate lives: V_Λ^+ is a vertex operator algebra, and $(V_\Lambda^T)^+$ is an (ordinary, integrally graded) module over it. A vertex operator algebra structure on the sum needs more: a vertex operator $Y^\natural(t,z)$ for every *twisted* state $t \in (V_\Lambda^T)^+$, and such an operator must move vectors between the two summands. This chapter constructs the two pieces of $Y^\natural(t,z)$:

- the operator $W(t,z) : V_\Lambda^+ \to (V_\Lambda^T)^+$ ("twisted × untwisted → twisted"), obtained from the module structure by *skew-symmetry*; and
- the operator $\overline{W}(t,z) : (V_\Lambda^T)^+ \to V_\Lambda^+$ ("twisted × twisted → untwisted"), obtained from W by taking the *adjoint* with respect to invariant bilinear forms on the two summands.

Along the way we develop, from first principles, the three pieces of general theory that the construction needs: intertwining operators and their skew-symmetry; contragredient modules and invariant bilinear forms (Frenkel–Huang–Lepowsky); and a graded Riesz representation theorem that turns "adjoint" into an honest linear map. We then prove that W and $\overline{W}$ have every property that involves *one* untwisted and *one* twisted argument (the commutator formulas, locality with all untwisted vertex operators, translation covariance), and the skew-symmetry of $\overline{W}$. The genuinely hard relation, the locality of two twisted vertex operators with each other, is *not* proved in this chapter; it occupies Chapters 38–42.

The chapter is written under the Fidelity Protocol of the book's constitution: every definition and theorem is given mathematically, then in its verbatim Lean form, then checked for fidelity (every symbol decoded, every hypothesis listed, every defined term traced), then proved on paper, and finally given its machine status. The chapter ends with a referee's checklist.

37.1 Why $V^\natural$ needs W and $\overline{W}$

37.1.1 The block form of the vertex operator

Suppose for a moment that $V^\natural$ of (37.1) already carried a vertex operator algebra structure $Y^\natural$ extending the structure of V_Λ^+ and the module structure Y^T on $(V_\Lambda^T)^+$. Write a general state as a pair (u,t) and a general vector on which operators act as a column (φ,a) with $\varphi\in V_\Lambda^+$ and $a\in(V_\Lambda^T)^+$. The vertex operator of (u,t) is then a 2×2 matrix of formal distributions

$$Y^\natural\big((u,t),z\big)\;=\;\begin{pmatrix} Y(u,z) & \overline{W}(t,z)\\ W(t,z) & Y^T(u,z)\end{pmatrix},\qquad Y^\natural\big((u,t),z\big)\begin{pmatrix}\varphi\\ a\end{pmatrix}=\begin{pmatrix} Y(u,z)\varphi+\overline{W}(t,z)a\\ W(t,z)\varphi+Y^T(u,z)a\end{pmatrix}. \tag{37.2}$$

The diagonal blocks are forced: V_Λ^+ is a subalgebra and $(V_\Lambda^T)^+$ is a module. The lower-left block $W(t,z)\colon V_\Lambda^+\to(V_\Lambda^T)^+$ and the upper-right block $\overline{W}(t,z)\colon(V_\Lambda^T)^+\to V_\Lambda^+$ are new data. (The diagonal entries for a twisted state t, and the off-diagonal entries for an untwisted state u, vanish because the $\mathbb{Z}/2$-grading by the eigenvalue of θ must be respected: untwisted $\times$ untwisted lands in the untwisted part, untwisted $\times$ twisted in the twisted part, and twisted $\times$ twisted in the untwisted part.)

Physical picture. In two-dimensional conformal field theory V_Λ^+ is the chiral algebra of 24 free bosons compactified on the Leech torus and then orbifolded by $X\mapsto -X$; $(V_\Lambda^T)^+$ is the space of states created by the 2-to-1 "twist fields" sitting at the fixed points of the orbifold (the 2^{12}-dimensional space T records which fixed point). The operator $W(t,z)$ is the operator product "twist field $\times$ ordinary field $\to$ twist field", and $\overline{W}(t,z)$ is "twist field $\times$ twist field $\to$ ordinary field". The latter is the interesting one: when two twist fields collide, the branch cuts they carry cancel and an *untwisted* field appears. That this fusion is consistent with locality is the whole difficulty of the Moonshine construction.

37.1.2 The off-diagonal blocks are forced

Both new blocks are determined by data we already have.

The block W. A vertex algebra satisfies skew-symmetry $Y(a,z)b=e^{zL_{-1}}Y(b,-z)a$. Applied in $V^\natural$ to $a=(0,t)$ and $b=(\varphi,0)$ it gives

$$W(t,z)\varphi\;=\;e^{zL_{-1}}\,Y^T(\varphi,-z)\,t. \tag{37.3}$$

So W is forced by the module structure alone. We shall take (37.3) as the definition (Section 37.4).

The block $\overline{W}$. A simple vertex operator algebra of CFT type with $L_1V_1=0$ has a nondegenerate invariant bilinear form, unique up to scale (Li). If $V^\natural$ has one, its restriction to the two summands must make them orthogonal (they have different θ-parity) and must restrict to invariant forms B_V on V_Λ^+ and B_T on $(V_\Lambda^T)^+$. Invariance of the form for the state $(0,t)$ then says

$$B_V\big(\overline{W}(t,z)a,\varphi\big)\;=\;B_T\Big(a,\;W\big(e^{zL_1}(-z^{-2})^{L_0}t,\;z^{-1}\big)\varphi\Big). \tag{37.4}$$

So once B_V and B_T are chosen, $\overline{W}$ is forced as well: it is the adjoint of W. This is Dolan–Goddard–Montague's equation (4.3), and it is how we shall define $\overline{W}$ (Section 37.10). This form-adjoint definition is the presentation of Huang and of Dolan–Goddard–Montague; it is *not* FLM's own explicit formula for the twisted vertex operators on $(V_\Lambda^T)^+\times(V_\Lambda^T)^+$. No Lean theorem compares the two: that the resulting vertex operator algebra is isomorphic to FLM's $V^\natural$ follows on paper from the uniqueness of simple-current extensions (Dong–Mason), which is not formalized (Chapter 42).

Remark 37.1 (Scaling, and why $\overline{W}=0$ is dangerous)**.** Conjugating the block form by the linear automorphism $g=\mathrm{diag}(1,\lambda)$ of $V^\natural$ ($\lambda\in\mathbb{C}^\times$) replaces the state t by λt; a short computation with $Y'(x,z)=gY^\natural(g^{-1}x,z)g^{-1}$ shows that W is unchanged and $\overline{W}$ is multiplied by λ^{-2}. Every axiom

of a vertex algebra is homogeneous in $\overline{W}$ (each locality relation contains $\overline{W}$ either zero times or exactly once in each term), so the set of admissible $\overline{W}$ is a cone: if $\overline{W}$ works, so does $c\overline{W}$ for every $c \in \mathbb{C}$, and all $c \neq 0$ give isomorphic algebras. The value $c = 0$ also "works": it gives the *square-zero extension* $V_\Lambda^+ \ltimes (V_\Lambda^T)^+$, a perfectly good vertex operator algebra with the same central charge 24, the same $V_1 = 0$, the same $\dim V_2 = 196884$ and the same graded dimension $J(q)$ as $V^\natural$ — but it is not simple and it is not the Moonshine module. (This remark is argued on paper; it is not a Lean theorem.)

Trap / dead end

The square-zero trap (recorded in `Notes/MonsterRoadmap.md`, "Definition of done", and `Notes/M8GluingPlan.md`, status after M8d part 1). The Lean reconstruction theorem for $V^\natural$ (Chapter 38) takes an *arbitrary* operator family `Wbar` as input, and every one of its hypotheses about `Wbar` holds for `Wbar = 0`. Hence a proof that "some vertex operator algebra on $V^\natural$ with graded dimension J exists" proves nothing about Moonshine. Two things in this chapter guard against the trap: the operator $\overline{W}$ is the *specific* adjoint (37.4), and Theorem 37.57 proves in Lean that it is not zero (indeed that it pairs the lowest twisted weight space nondegenerately into the vacuum line). The final theorem of the book additionally proves simplicity of $V^\natural$ (Chapter 38).

37.1.3 The six locality relations

To show that (37.2) defines a vertex algebra, Dolan, Goddard and Montague (Comm. Math. Phys. 179 (1996), §4) reduce locality of all pairs of block operators to six relations, their (4.18)–(4.23):

1. $Y(u_1, z_1)Y(u_2, z_2) \sim Y(u_2, z_2)Y(u_1, z_1)$ on V_Λ^+ (locality in the vertex operator algebra V_Λ^+);
2. $Y^T(u_1, z_1)Y^T(u_2, z_2) \sim Y^T(u_2, z_2)Y^T(u_1, z_1)$ on $(V_\Lambda^T)^+$ (locality in the module);
3. the locality of $Y^T(u, z_1)$ and $W(t, z_2)$, in the sense $Y^T(u, z_1)W(t, z_2) \sim W(t, z_2)Y(u, z_1)$ as maps $V_\Lambda^+ \to (V_\Lambda^T)^+$;
4. the analogous locality of $Y(u, z_1)$ and $\overline{W}(t, z_2)$ as maps $(V_\Lambda^T)^+ \to V_\Lambda^+$;

(4.22) $\overline{W}(t_1, z_1)W(t_2, z_2) \sim \overline{W}(t_2, z_2)W(t_1, z_1)$ on V_Λ^+;

(4.23) $W(t_1, z_1)\overline{W}(t_2, z_2) \sim W(t_2, z_2)\overline{W}(t_1, z_1)$ on $(V_\Lambda^T)^+$.

Here "$A(z_1)B(z_2) \sim C(z_2)D(z_1)$" means that $(z_1 - z_2)^N\big(A(z_1)B(z_2) - C(z_2)D(z_1)\big) = 0$ for some N. The first two are already known (Chapters 32 and 36). This chapter proves the third and fourth (Theorems 37.17 and 37.52) in full generality, and the skew-symmetry of $\overline{W}$ (Theorem 37.58) which is the main input to (4.22) in Chapter 38. Dolan, Goddard and Montague remark that the last relation (4.23) "involves the lattice in a non-trivial way"; it is the subject of Chapters 39–42.

37.2 Notation and prerequisites

This section collects the elementary objects that occur in the statements of this chapter. Their Lean sources are quoted verbatim and decoded in Chapters 2, 4 and 12; here they are recalled with pointers. Everything else is defined where it is used, or in an explicitly cited earlier chapter.

37.2.1 Formal distributions and modes

Definition 37.2 (Formal distributions, modes, derivative). For a complex vector space X, a *formal distribution* is a two-sided sequence $f = (f_k)_{k\in\mathbb{Z}}$ in X, thought of as $f(z) = \sum_{k\in\mathbb{Z}} f_k z^k$. A two-variable formal distribution is a family $(f_{a,b})_{a,b\in\mathbb{Z}}$, thought of as $\sum f_{a,b} z_1^a z_2^b$. The *n-th mode* of f is the coefficient of z^{-n-1}: $\mathrm{mode}(f,n) = f_{-n-1}$, so that $f(z) = \sum_n \mathrm{mode}(f,n) z^{-n-1}$. The formal derivative is $(\partial_z f)_k = (k+1) f_{k+1}$.

In Lean these are `FormalDist 𝒲 = ℤ → 𝒲`, `FormalDist₂ 𝒲 = ℤ → ℤ → 𝒲`, `mode f m = f (-m - 1)` and the linear map `deriv` with `deriv f n = (n + 1) • f (n + 1)` (Definitions 2.1, 2.21 and 2.7; `VOA/Foundations/FormalSeries.lean`, `VOA/Foundations/FormalCalculus.lean`).

From the mathematics to the Lean statement

`f k` is the coefficient of z^k, *not* the k-th mode. Throughout the library a vertex operator is stored as the distribution $k \mapsto u_{(-k-1)}$ and its modes are recovered by `mode`: `mode (Y u) n` is $u_{(n)}$. In the twisted setting of Chapters 34–36, an integer index k fed to a twisted vertex operator `YM u k` stands for the half-integral mode $u_{(k/2)}$; on the θ-fixed module $(V_\Lambda^T)^+$ this is converted back to integral modes by the identity `mode (plusModule.YM u) n = YM u (2n)` (Lean name `mode_plusModule`, Chapter 36).

Physical meaning

A formal distribution is the bookkeeping device for a chiral field: $f(z) = \sum_n f_n z^{-n-1}$ is the Laurent expansion of an operator-valued field $\phi(z)$ on the plane in the radial quantisation, and the modes f_n are the operators that create or annihilate states of definite energy. The derivative is the translation ∂_z of the field, which later becomes the L_{-1}-derivative property. The definition is pure algebra; it fixes the mode convention (z^{-n-1}, weight h field has modes $\phi_{(n)}$ of degree $h-n-1$) used everywhere below.

Definition 37.3 (Generalised binomials and signs). For $n \in \mathbb{Z}$ and $k \in \mathbb{N}$, $\binom{n}{k} = n(n-1)\cdots(n-k+1)/k!$ (so $\binom{-1}{k} = (-1)^k$). For $k \in \mathbb{Z}$ the library writes `cbz` for the extension by zero to negative k, and $\mathtt{negOnePow}(n) = (-1)^n$.

In Lean these are `gBinom n k`, `cbz n k` (equal to `gBinom n k.toNat` for $k \geq 0$ and to 0 for $k < 0$) and `negOnePow n`, quoted verbatim in Definition 2.14 (`VOA/Foundations/Substitution.lean`, `VOA/Foundations/Expansion.lean`).

Physical meaning

These are the coefficients that appear when one expands $(z_1 - z_2)^{-k}$ in a chosen region, i.e. the algebraic shadow of the choice of radial ordering $|z_1| > |z_2|$ in an operator product. The signs $(-1)^n$ record the exchange of two fields, as in the passage from $z_1 - z_2$ to $z_2 - z_1$. They are only calculational devices.

Definition 37.4 (Multiplication by $(z_1-z_2)^N$; locality). On two-variable distributions, $(z_1-z_2)f$ has coefficients $f_{a-1,b} - f_{a,b-1}$, and $(z_1-z_2)^N$ is its N-fold iterate. Two $\mathrm{End}(V)$-valued distributions a, b are *local* if $(z_1-z_2)^N [a(z_1), b(z_2)] = 0$ for some N, where $[a(z_1), b(z_2)]$ has coefficients $a_m b_n - b_n a_m$.

In Lean, `mulBySub` = `shiftZ₁ - shiftZ₂` (where `shiftZ₁ f` has coefficients $f_{a-1,b}$ and `shiftZ₂ f` has $f_{a,b-1}$), `mulBySubPow N` is its N-fold iterate, and `Local a b` is `∃ N : ℕ, mulBySubPow N (bracketDist a b) = 0` (Definitions 2.21 and 2.41; `VOA/Foundations/FormalSeries.lean`, `VOA/Foundations/Locality.lean`).

From the mathematics to the Lean statement

In this chapter many "locality" statements are between maps of *different* spaces, e.g. $Y^T(u,z_1)W(t,z_2) - W(t,z_2)Y(u,z_1)$ is a distribution of linear maps $V_\Lambda^+ \to (V_\Lambda^T)^+$. For those the library does not use `Local` (which is for $\mathrm{End}(V)$-valued distributions) but writes the commutator distribution out as an explicit `FormalDistₒ` of `→ₗ[ℂ]`-maps and asks that `mulBySubPowN` kill it. The block-matrix lemma `local_diag_off` (Chapter 38) converts two such statements into an honest `Local` on $\mathrm{End}(V^\natural)$.

Physical meaning

Locality is the algebraic form of the physical requirement that fields at separated points commute (or braid trivially): the correlator is single-valued, so the only singularities of the operator product are poles at $z_1 = z_2$. The order N is the maximal pole order of the OPE of the two fields. Locality for fields acting between different sectors, as in the dictionary, says that an untwisted current can be moved across a twist-field insertion up to contact terms.

37.2.2 Modules

Definition 37.5 (Weak and ordinary modules)**.** Let $\mathcal{V}$ be a vertex operator algebra (Definition 4.4) with modes $u_{(n)}$, vacuum $\mathbf{1}$, conformal vector ω and $L_n = \omega_{(n+1)}$. A *weak module* is a vector space M with a linear map $u \mapsto Y_M(u,z) = \sum u^M_{(n)} z^{-n-1}$ into $\mathrm{End}(M)$-valued distributions such that $Y_M(\mathbf{1},z) = \mathrm{id}$, $u_{(n)}x = 0$ for $n \gg 0$, and the module Jacobi identity holds in the mode form

$$\sum_{i\ge 0}(-1)^i\binom{\ell}{i}\Big(u_{(\ell+m-i)}v_{(n+i)}x - (-1)^\ell v_{(\ell+n-i)}u_{(m+i)}x\Big) = \sum_{i\ge 0}\binom{m}{i}(u_{(\ell+i)}v)_{(m+n-i)}x \tag{37.5}$$

for all $u,v \in \mathcal{V}$, $x \in M$, $\ell,m,n \in \mathbb{Z}$. An *ordinary module* is a weak module with a grading $M = \bigoplus_{\alpha\in\mathbb{C}} M_\alpha$ by finite-dimensional L_0-eigenspaces ($L_0 = \omega_{(1)}$ acts on M_α by α) whose real parts are bounded below.

In Lean these are the structures `WeakModule W M` (fields `YM`, `vacuum_YM`, `truncation`, `jacobi`) and `OrdVModule W M`, which extends it by `weight`, `isInternal`, `L0_weight`, `finrank` and `boundedBelow` (`VOA/Modules/WeakModule.lean`); they are quoted verbatim and decoded in Definitions 12.1 and 12.5. The field `jacobi` is (37.5) written with `negOnePow`, `cbz` and `∑ᶠ`.

From the mathematics to the Lean statement

`W.smul u n v` is the n-th product $u_{(n)}v$ inside $\mathcal{V}$; `A.act u n x` is the library's abbreviation for $u^M_{(n)}x$ `= mode (A.YM u) n x`. `∑ᶠ` is a sum over the (finitely many) indices where the summand is nonzero; `cbz ℓ i` vanishes for $i < 0$, so both sums run over $i \ge 0$ as in (37.5). `DirectSum.IsInternal weight` says that M is the internal direct sum of the subspaces `weight α`. The *adjoint module* `adjointModule W` is $\mathcal{V}$ acting on itself.

Physical meaning

A module is a sector of the chiral CFT, a space of states on which the chiral algebra acts: the Jacobi identity is the statement that the OPE of the chiral fields closes consistently on that sector. An ordinary module with L_0-grading is a representation space with a spectrum of conformal weights bounded below and finite multiplicities, as for a unitary sector with a ground state. The twisted sector $(V_\Lambda^T)^+$ of the orbifold will be such a module over V_Λ^+.

37.2.3 The Leech objects

The concrete objects are those of Chapters 32 and 36:

- `leechVOAPlus : VertexOperatorAlgebra VPlus`, the vertex operator algebra V_Λ^+; its carrier type is written `VPlus` or, in the files of this chapter, `SkewVP` (the two are the same type: `abbrev SkewVP : Type := 𝔯(orbifold (Subgroup.zpowers leechTheta)).carrier`). It has $(V_\Lambda^+)_1 = 0$ (`leechVOAPlus_grading_one`) and $\dim (V_\Lambda^+)_2 = 98580$.
- `Tw := FockT 24 ⊗[ℂ] leechT`, the twisted space $S[\theta] \otimes T$, where $S[\theta] = \mathbb{C}[h_i(-n-\frac{1}{2})]$ is the twisted Fock space of rank 24 and T the 2^{12}-dimensional module of the extraspecial group.
- `TP : Submodule ℂ Tw`, the θ-fixed subspace $(V_\Lambda^T)^+$, and `plusModule : OrdVModule leechVOAPlus TP`, its structure of ordinary V_Λ^+-module. Its weights are integers ≥ 2 (`plusModule_weight_ne_bot`) and $\dim (V_\Lambda^T)_2^+ = 24 \cdot 4096 = 98304$ (`finrank_plusModule_weight_two`).

37.3 Intertwining operators and skew-symmetry

37.3.1 The definition of Frenkel, Huang and Lepowsky

Let M_1, M_2, M_3 be modules for a vertex operator algebra $\mathcal{V}$. An *intertwining operator of type* $\binom{M_3}{M_1\,M_2}$ (FHL, Definition 5.4.1) is a linear map $w_1 \otimes w_2 \mapsto \mathcal{Y}(w_1,z)w_2 = \sum_{s\in\mathbb{C}} (w_1)_{(s)}w_2\, z^{-s-1}$ with values in $M_3\{z\}$ (arbitrary complex powers) such that

(I1) (truncation) for fixed w_1, w_2, $(w_1)_{(s)}w_2 = 0$ when $\operatorname{Re} s \gg 0$;

(I2) (L_{-1}-derivative) $\mathcal{Y}(L_{-1}w_1,z) = \partial_z \mathcal{Y}(w_1,z)$;

(I3) (Jacobi identity) for $u \in \mathcal{V}$,

$$z_0^{-1}\delta\!\left(\frac{z_1-z_2}{z_0}\right)Y_3(u,z_1)\mathcal{Y}(w_1,z_2) - z_0^{-1}\delta\!\left(\frac{z_2-z_1}{-z_0}\right)\mathcal{Y}(w_1,z_2)Y_2(u,z_1) = z_2^{-1}\delta\!\left(\frac{z_1-z_0}{z_2}\right)\mathcal{Y}\big(Y_1(u,z_0)w_1,z_2\big).$$

Taking Res_{z_0} of (I3) gives the *commutator formula*

$$u_{(m)}\,(w_1)_{(s)}w_2 - (w_1)_{(s)}\,u_{(m)}w_2 = \sum_{r\geq 0}\binom{m}{r}\big(u_{(r)}w_1\big)_{(m+s-r)}w_2, \tag{37.6}$$

and taking Res_{z_1} gives an associativity formula. In general (I3) is equivalent to the commutator formula *together with* associativity; the commutator formula alone is weaker. The dimension of the space of intertwining operators of a given type is the *fusion rule* $\mathcal{N}_{M_1M_2}^{M_3}$.

The physical meaning: $\mathcal{Y}(w_1,z)$ is the field of the state w_1 of one module, acting from a second module to a third; the commutator formula (37.6) says that the chiral algebra $\mathcal{V}$ acts on such fields by the same rule (the operator product $u(z_1)\mathcal{Y}(w_1,z_2) \sim \sum_r (u_{(r)}w_1)(z_2)/(z_1-z_2)^{r+1}$) as it acts on its own fields.

37.3.2 The library's notion: a commutator-type intertwiner

Definition 37.6 (Intertwiner, library form)**.** For ordinary modules A, B, C (with carriers M, N, P), an `Intertwiner A B C` consists of mode data $\mathcal{Y}_s : M \times N \to P$ bilinear, for $s \in \mathbb{C}$, which is lower truncated (I1) and satisfies the commutator formula (37.6), written with the module A acting on the first argument, B on the second and C on the output.

```
abbrev IntertwinerModes (M N P : Type u) [AddCommGroup M] [Module ℂ M] [AddCommGroup N]
    [Module ℂ N] [AddCommGroup P] [Module ℂ P] : Type u := ℂ → (M →ₗ[ℂ] N →ₗ[ℂ] P)

noncomputable def intertwinerSummand (A : OrdVModule W M) (Y : IntertwinerModes M N P)
    (a : 𝒱) (p : ℤ) (s : ℂ) (u : M) (x : N) (j : ℕ) : P :=
  cbz p j • Y (s + p - j) (A.toWeakModule.act a (j : ℤ) u) x

noncomputable def intertwiningDefect (A : OrdVModule W M) (B : OrdVModule W N) (C :
↪  OrdVModule W P) :
    IntertwinerModes M N P →ₗ[ℂ] (𝒱 → ℤ → ℂ → M → N → P) where
  toFun Y := fun a p s u x =>
    C.toWeakModule.act a p (Y s u x) - Y s u (B.toWeakModule.act a p x)
      - ∑ᶠ j : ℕ, intertwinerSummand A Y a p s u x j

structure Intertwiner (A : OrdVModule W M) (B : OrdVModule W N) (C : OrdVModule W P) where
  modes : IntertwinerModes M N P
  truncation : ∀ (u : M) (x : N), ∃ s₀ : ℝ, ∀ s : ℂ, s₀ ≤ s.re → modes s u x = 0
  isIntertwiner : modes ∈ IntertwinerSpace A B C
```

(`VOA/Modules/Fusion.lean`; `IntertwinerSpace A B C` is the kernel of `intertwiningDefect A B C`; the additivity proofs of the defect are omitted.)

From the mathematics to the Lean statement

Decoding. `modes s u x` is $u_{(s)}x$ for $u \in M$, $x \in N$. The defect is $a^C_{(p)}(u_{(s)}x) - u_{(s)}(a^B_{(p)}x) - \sum_j \binom{p}{j}(a^A_{(j)}u)_{(s+p-j)}x$; being in its kernel is exactly (37.6) for all $a \in \mathcal{V}$, $p \in \mathbb{Z}$, $s \in \mathbb{C}$.
Same, stronger or weaker? *Weaker than FHL.* The structure records (I1) and the commutator formula only. It does not record the L_{-1}-derivative property (I2), and it does not record the full Jacobi identity (I3) (no associativity). Consequently the library's `fusionCoeff` (the `finrank` of `IntertwinerSpace`) is not the FHL fusion rule; this chapter never uses it. Every intertwiner constructed below is a genuine FHL-type object in the sense that we prove the L_{-1}-derivative property *separately* (Theorems 37.13 and 37.47); the full Jacobi identity for W and $\overline{W}$ is *not* proved anywhere in the library, and it is not needed: the reconstruction route of Chapter 38 consumes only commutator formulas, locality and translation covariance.
Could it be vacuous? No: the zero mode family is always an intertwiner, so the structure is inhabited; the content of a particular `Intertwiner` value lies in which modes it carries.

Physical meaning

An intertwining operator is a chiral vertex operator: it is the field $\mathcal{Y}(w_1, z)$ of a state w_1 in sector M_1 that maps states of sector M_2 to states of sector M_3, and the commutator formula is the Ward identity saying that the chiral currents act on it by the same OPE as on any primary field. The dimension $\mathcal{N}^{M_3}_{M_1 M_2}$ of the space of such operators is the fusion rule: the number of independent three-point couplings $\langle M_3 | \mathcal{Y} | M_2 \rangle$ among the three sectors. For $V^\natural$ the interesting couplings are twisted × untwisted → twisted and twisted × twisted → untwisted. (Heuristic: the library `Intertwiner` records only the commutator part of the axioms.)

37.3.3 Skew-symmetry: from a module to an intertwiner

Definition 37.7 (The skew operator). Let M be a weak $\mathcal{V}$-module and $L^M_{-1} = \omega^M_{(0)}$. For $t \in M$ and $\varphi \in \mathcal{V}$ put

$$W(t,z)\varphi = e^{zL_{-1}} Y_M(\varphi, -z)t, \qquad \text{i.e.} \qquad W(t)_{(n)}\varphi = \sum_{i \geq 0} \frac{(-1)^{n+i+1}}{i!} L^i_{-1}\big(\varphi_{(n+i)}t\big). \tag{37.7}$$

Physical meaning

Skew-symmetry is the exchange of two fields in a two-point function: $\langle \phi_a(z)\phi_b(0)\rangle$ and $\langle \phi_b(-z)\phi_a(0)\rangle$ are the same correlator read from the two radial orderings, related by the translation $e^{zL_{-1}}$. Defining $W(t,z)\varphi = e^{zL_{-1}}Y_M(\varphi,-z)t$ says that the field of the twisted state t acting on an untwisted state φ is obtained by moving the untwisted field φ around it: the chiral vertex operator "twist field × ordinary field → twist field" is forced by the module structure alone.

Derivation of the mode formula. $Y_M(\varphi,-z)t = \sum_p \varphi_{(p)}t\,(-z)^{-p-1}$ and $e^{zL_{-1}} = \sum_i z^i L_{-1}^i/i!$. The coefficient of z^{-n-1} collects the pairs with $i-p-1=-n-1$, i.e. $p=n+i$, with sign $(-1)^{-p-1} = (-1)^{n+i+1}$. Only finitely many i contribute because $\varphi_{(n+i)}t = 0$ for $n+i$ large.

When $M=\mathcal{V}$ is the adjoint module, skew-symmetry of $\mathcal{V}$ says $W(t,z)\varphi = Y(t,z)\varphi$; so W is the module analogue of "the vertex operator of t". The theorem we want is that W is an intertwining operator of type $\binom{M}{M\ \mathcal{V}}$ (FHL §5.4, where it appears as Ω of the module vertex operator Y_M, viewed as an intertwiner of type $\binom{M}{\mathcal{V}\ M}$).

37.4 The skew operator W in Lean

All declarations in this section are in `VOA/Moonshine/SkewIntertwiner.lean`, namespace `VOA.SkewIntertwiner`, for an arbitrary vertex operator algebra `W : VertexOperatorAlgebra` $\mathcal{V}$ and an arbitrary weak module `A : WeakModule W M`. (In these files the letter `W` denotes the vertex operator algebra, not the skew operator; the skew operator is called `Wsk`.)

37.4.1 The translation operator of a module

Definition 37.8. $L_{-1}^M := \omega_{(0)}^M \in \mathrm{End}(M)$.

```
noncomputable def Lm1 (A : WeakModule W M) : End ℂ M := mode (A.YM W.conformalVector) 0
```

Physical meaning

L_{-1} generates translations of the plane, so L_{-1}^M is the momentum operator of the sector. Its action on modes is the dilation-translation covariance of fields, $[L_{-1},\phi(z)] = \partial_z\phi(z)$.

Proposition 37.9 (L_{-1}-commutator). *For $u\in\mathcal{V}$, $p\in\mathbb{Z}$, $x\in M$: $u_{(p)}L_{-1}x = L_{-1}u_{(p)}x + p\,u_{(p-1)}x$. More generally $u_{(p)}L_{-1}^k x = \sum_{r=0}^{k}\binom{k}{r}p(p-1)\cdots(p-r+1)\,L_{-1}^{k-r}u_{(p-r)}x$.*

```
theorem act_Lm1 (A : WeakModule W M) (u : 𝒱) (p : ℤ) (x : M) :
    A.act u p (Lm1 A x) = Lm1 A (A.act u p x) + p • A.act u (p - 1) x

theorem act_Lm1_pow_expand (A : WeakModule W M) (c : 𝒱) (p : ℤ) (k : ℕ) (u : M) :
    A.act c p ((Lm1 A ^ k) u)
      = ∑ r ∈ Finset.range (k + 1),
          (mcoeff p k r) • ((Lm1 A ^ (k - r)) (A.act c (p - (r : ℤ)) u))
```

From the mathematics to the Lean statement

`mcoeff p k r` is the integer $\binom{k}{r}\cdot p(p-1)\cdots(p-r+1)$ (`def mcoeff (p : ℤ) (k r : ℕ) : ℤ := (k.choose r : ℤ) * fallI p r`, with `fallI p r` the falling factorial; `VOA/Core/WeakAssoc.lean`). The integer scalar `p •` is the $\mathbb{Z}$-action on M, equal to multiplication by the complex number p. No hypothesis beyond "A is a weak module". Same as the

textbook statement.

Physical meaning

This is the statement that $L_{-1} = \partial_z$ acts on every field of the module as differentiation: $[L_{-1}, Y_M(u,z)] = \partial_z Y_M(u,z)$, equivalently that translating a field by z is $e^{zL_{-1}}$. It is the technical ingredient behind the translation covariance of W. (A standard consequence of the conformal Ward identity; the physics does not replace the proof below.)

Proof. Apply the module Jacobi identity (37.5) with $u = \omega$, $\ell = m = 0$: it gives $[\omega_{(0)}, u_{(n)}] = (\omega_{(0)}u)_{(n)} = (L_{-1}u)_{(n)}$, and $(L_{-1}u)_{(n)} = -n\,u_{(n-1)}$ (translation covariance of module vertex operators, which is itself the $\ell = 0$, $m = 0$, $v \mapsto L_{-1}u$ case of the same identity). Rearranging, $u_{(p)}L_{-1} = L_{-1}u_{(p)} + p\,u_{(p-1)}$. The general formula is the induction on k of this one, the coefficients satisfying Pascal-type recursions; it is the mode form of $e^{-zL_{-1}}u_{(p)}e^{zL_{-1}} = \sum_k \binom{p}{k} z^k u_{(p-k)}$. □

What the machine verified

Both statements proved, no hypotheses beyond the weak module. Proof in `VOA/Moonshine/SkewIntertwiner.lean`.

37.4.2 The modes and the field

Definition 37.10 (Skew modes and skew field). $\mathtt{wTerm}(t,n,\varphi,i) = \frac{(-1)^{n+i+1}}{i!} L_{-1}^i(\varphi_{(n+i)}t)$, $\mathtt{wMode}(t,n,\varphi) = \sum_i \mathtt{wTerm}(t,n,\varphi,i) = W(t)_{(n)}\varphi$, and $\mathtt{Wsk}(t)$ is the $\mathrm{Hom}(\mathcal{V},M)$-valued distribution whose z^k-coefficient is $W(t)_{(-k-1)}$.

```
noncomputable def wTerm (A : WeakModule W M) (t : M) (n : ℤ) (φ : 𝒱) (i : ℕ) : M :=
  (((i.factorial : ℂ)⁻¹) * negOnePow (n + i + 1)) • ((Lm1 A ^ i) (A.act φ (n + i) t))

noncomputable def wMode (A : WeakModule W M) (t : M) (n : ℤ) (φ : 𝒱) : M :=
  ∑ᶠ i : ℕ, wTerm A t n φ i

noncomputable def wModeLin (A : WeakModule W M) (t : M) (n : ℤ) : 𝒱 →ₗ[ℂ] M where
  toFun := wMode A t n

noncomputable def Wsk (A : WeakModule W M) (t : M) : FormalDist (𝒱 →ₗ[ℂ] M) :=
  fun k => wModeLin A t (-k - 1)

theorem mode_Wsk (A : WeakModule W M) (t : M) (n : ℤ) :
    mode (Wsk A t) n = wModeLin A t n
```

(The linearity fields of `wModeLin`, which are the lemmas `wMode_add_left` and `wMode_smul_left`, are omitted.)

From the mathematics to the Lean statement

The $\sum^{\mathtt{f}}$ over $i \in \mathbb{N}$ is a genuine finite sum: by the truncation axiom of A, $\varphi_{(n+i)}t = 0$ for i large, so only finitely many summands are nonzero; if infinitely many were nonzero, $\sum^{\mathtt{f}}$ would return 0 by convention, which is why the library proves separately that the support is finite (`wMode_eq_sum`: for any bound K past the truncation, `wMode` equals the honest sum over $i < K$). With that lemma the definition is exactly (37.7). The indexing `fun k ⇒ wModeLin A t (-k - 1)` together with `mode_Wsk` says that `Wsk A t` is $\sum_n W(t)_{(n)}z^{-n-1}$.

Physical meaning

The definition spells out the field $W(t,z)$ in modes: the sum over i is the Taylor expansion $e^{zL_{-1}}$ that translates the insertion point of the untwisted field from $-z$ back to the origin. The $\mathrm{Hom}(\mathcal{V},M)$-valued distribution is the chiral vertex operator "twisted state t at position z acting on an untwisted state".

Example 37.11 (Low modes). Take $\varphi = \mathbf{1}$. Since $\mathbf{1}_{(p)}t = \delta_{p,-1}t$, only $i = -n-1$ survives, so $W(t)_{(n)}\mathbf{1} = L_{-1}^{-n-1}t/(-n-1)!$ for $n \le -1$ and 0 otherwise: $W(t)_{(-1)}\mathbf{1} = t$, $W(t)_{(-2)}\mathbf{1} = L_{-1}t$, $W(t)_{(-3)}\mathbf{1} = \frac{1}{2}L_{-1}^2 t$. Next take φ of weight 1 in a VOA with $\mathcal{V}_1 \neq 0$ and t of lowest weight in M, so that $\varphi_{(p)}t = 0$ for $p \ge 1$ (it would have weight below the lowest weight). Then $W(t)_{(0)}\varphi = -\varphi_{(0)}t$ (only $i = 0$), and $W(t)_{(-1)}\varphi = \varphi_{(-1)}t - L_{-1}(\varphi_{(0)}t)$. In the Leech case $(V_\Lambda^+)_1 = 0$ and the first nontrivial instance is a weight-two φ.

37.4.3 Vacuum and translation properties

Theorem 37.12 ($W(t,z)\mathbf{1} = e^{zL_{-1}}t$). *For every $t \in M$ and $k \in \mathbb{Z}$, the z^k-coefficient of $W(t,z)\mathbf{1}$ is $L_{-1}^k t/k!$ if $k \ge 0$ and 0 if $k < 0$.*

```
theorem Wsk_vacuum (A : WeakModule W M) (t : M) (k : ℤ) :
    Wsk A t k W.vacuum
      = if 0 ≤ k then ((k.toNat.factorial : ℂ)⁻¹) • (Lm1 A ^ k.toNat) t else 0
```

From the mathematics to the Lean statement

`Wsk A t k` is the z^k-coefficient (a linear map $\mathcal{V} \to M$) applied to `W.vacuum`. `k.toNat` is k viewed as a natural number (used only when $k \ge 0$). No hypotheses. Exactly the textbook statement $W(t,z)\mathbf{1} = \sum_{k\ge 0} z^k L_{-1}^k t/k!$.

Physical meaning

This is the state–operator correspondence for W: acting on the vacuum, the vertex operator of the state t creates t at $z = 0$, $W(t,z)\mathbf{1} = e^{zL_{-1}}t$, i.e. the state t translated to the point z. It is the normalisation that makes $W(t,z)$ the field of the state t rather than some other operator.

Proof. Example 37.11: $Y_M(\mathbf{1},-z) = \mathrm{id}$, so $W(t,z)\mathbf{1} = e^{zL_{-1}}t$. □

Theorem 37.13 (L_{-1}-derivative property). $W(L_{-1}t)_{(n)} = -n\,W(t)_{(n-1)}$ *for all n; equivalently* $W(L_{-1}t,z) = \partial_z W(t,z)$.

```
theorem wMode_Lm1 (A : WeakModule W M) (t : M) (n : ℤ) (φ : 𝒱) :
    wMode A (Lm1 A t) n φ = (-(n : ℂ)) • wMode A t (n - 1) φ

theorem Wsk_deriv (A : WeakModule W M) (t : M) :
    Wsk A (Lm1 A t) = deriv (Wsk A t)
```

From the mathematics to the Lean statement

`deriv` is the coefficientwise derivative of Definition 37.2. The mode form and the field form agree: the z^k-coefficient of $\partial_z W$ is $(k+1)W(t)_{(-k-2)}$, and the mode form with $n = -k-1$ gives $W(L_{-1}t)_{(-k-1)} = (k+1)W(t)_{(-k-2)}$. No hypotheses. This is (I2) for W; it is not part of the library's `Intertwiner` structure, which is why it is proved as a separate theorem.

Physical meaning

The field of the descendant $L_{-1}t = \partial t$ is the derivative of the field of t: $W(\partial t, z) = \partial_z W(t,z)$. This is the translation covariance every chiral field satisfies, and it is axiom (I2) of an intertwining operator.

Proof. In terms of fields: $W(L_{-1}t,z)\varphi = e^{zL_{-1}}Y_M(\varphi,-z)L_{-1}t$. The module commutator $[L_{-1}, Y_M(\varphi,x)] = \partial_x Y_M(\varphi,x)$ (Proposition 37.9) gives $Y_M(\varphi,-z)L_{-1}t = L_{-1}Y_M(\varphi,-z)t + \partial_z Y_M(\varphi,-z)t$ (the chain rule for $x = -z$ produces the sign). Hence $W(L_{-1}t,z)\varphi = \big(L_{-1}e^{zL_{-1}} + e^{zL_{-1}}\partial_z\big)Y_M(\varphi,-z)t = \partial_z\big(e^{zL_{-1}}Y_M(\varphi,-z)t\big)$. In modes this is a telescoping identity between the finite sums (37.7). □

Proposition 37.14 (Truncation). *For fixed t, φ, $W(t)_{(n)}\varphi = 0$ for $n \gg 0$.*

File `VOA/Moonshine/SkewIntertwiner.lean`.

```
theorem wMode_truncation (A : WeakModule W M) (t : M) (φ : V) :
    ∃ N : ℤ, ∀ n : ℤ, N ≤ n → wMode A t n φ = 0
```

Physical meaning

In a sector with energy bounded below, acting with a field on a fixed state produces only finitely many poles at the insertion point, i.e. the matrix elements of $W(t,z)$ between fixed states are Laurent series in z with finite principal part. This is the usual condition that the OPE has a finite pole order.

Proof. If $\varphi_{(p)}t = 0$ for $p \geq N$, every summand of (37.7) vanishes for $n \geq N$. □

What the machine verified

`Wsk_vacuum`, `wMode_Lm1`, `Wsk_deriv`, `wMode_truncation`: proved for every weak module, no further hypotheses. `##print axioms` of the file's headline declarations (rechecked for this chapter, see Section 37.16): `[propext, Classical.choice, Quot.sound]`.

37.4.4 The commutator formula

Theorem 37.15 (Intertwining commutator formula for W). *Let M be a weak V-module, $u \in V$, $t \in M$, and let $J \in \mathbb{N}$ be such that $u_{(j)}t = 0$ for all $j \geq J$. Then for* all *$m, n \in \mathbb{Z}$ and $\varphi \in V$,*

$$u^M_{(m)}\,W(t)_{(n)}\varphi - W(t)_{(n)}\big(u_{(m)}\varphi\big) = \sum_{r=0}^{J-1}\binom{m}{r}W\big(u^M_{(r)}t\big)_{(m+n-r)}\varphi. \tag{37.8}$$

File `VOA/Moonshine/SkewIntertwiner.lean`.

```
theorem wMode_comm (A : WeakModule W M) (u : V) (m : ℤ) (t : M) (n : ℤ) (φ : V) (J : ℕ)
    (hJ : ∀ j : ℕ, J ≤ j → A.act u j t = 0) :
    A.act u m (wMode A t n φ) - wMode A t n (W.smul u m φ)
      = ∑ r ∈ Finset.range J, gBinom m r • wMode A (A.act u r t) (m + n - r) φ
```

From the mathematics to the Lean statement

Symbols. `A.act u m` is $u^M_{(m)}$ on M; `W.smul u m φ` is $u_{(m)}\varphi$ in V; `wMode A s q φ` is $W(s)_{(q)}\varphi$; `gBinom m r` is $\binom{m}{r}$ with $m \in \mathbb{Z}$; `Finset.range J` is $\{0,\dots,J-1\}$.
Hypotheses. Only `hJ`: J is past the truncation of u on t. Such a J always exists (truncation axiom), and the formula is then true for *every* such J, because the extra terms with $r \geq J$ vanish. The quantifier order matters: J depends only on u and t, not on φ, m or n. That is what makes locality (Theorem 37.17) follow with an order independent of the test vector.

Comparison. This is exactly (37.6) for the intertwiner W of type $\binom{M}{M\ \mathcal{V}}$: the first argument t lies in M, the second φ in $\mathcal{V}$, the output in M. Same as the textbook statement, for all $m \in \mathbb{Z}$ (including negative m, where the binomial coefficients are the generalised ones and the sum is still finite because of J).
Could it be vacuous? The hypothesis is satisfiable for every u, t; the conclusion is a nontrivial identity in M. No degenerate case is hidden.

Physical meaning

This is the Ward identity of the chiral algebra on the field W: the OPE $u(z_1)W(t,z_2) \sim \sum_r W(u_{(r)}t, z_2)/(z_1-z_2)^{r+1}$ says that a current u passing the insertion of the twist field acts on it by the singular terms of the OPE, with the twisted state $u_{(r)}t$ appearing as the residue. The same formula describes how a current commutes with a primary field, including the twisted sector's modes. It holds for all m because the field lives on an annulus of convergence in both orderings.

Proof on paper. Write $L = L^M_{-1}$ and $c_i(n) = (-1)^{n+i+1}/i!$, so that $W(t)_{(n)}\varphi = \sum_i c_i(n) L^i(\varphi_{(n+i)}t)$.

Step 1: move $u_{(m)}$ through the powers of L. By Proposition 37.9, $u_{(m)}L^i y = \sum_{r\le i}\binom{i}{r} m(m-1)\cdots(m-r+1)\,L^{i-r}u_{(m-r)}y$. Substituting and writing $i = a+r$, the scalar becomes $\frac{(-1)^{n+a+r+1}}{(a+r)!}\binom{a+r}{r} m(m-1)\cdots(m-r+1) = \frac{(-1)^{n+a+1}}{a!}(-1)^r\binom{m}{r}$. Hence

$$u_{(m)}W(t)_{(n)}\varphi = \sum_{a\ge 0}\frac{(-1)^{n+a+1}}{a!}L^a\Big[\sum_{r\ge 0}(-1)^r\binom{m}{r}u_{(m-r)}\varphi_{(n+a+r)}t\Big]. \tag{37.9}$$

Step 2: the iterate formula. The module Jacobi identity (37.5) with (ℓ, m, n) replaced by $(m, 0, q)$ reads

$$\sum_{r\ge 0}(-1)^r\binom{m}{r}\Big(u_{(m-r)}\varphi_{(q+r)}t - (-1)^m\varphi_{(m+q-r)}u_{(r)}t\Big) = (u_{(m)}\varphi)_{(q)}t, \tag{37.10}$$

the sum on the right of (37.5) collapsing to its $i=0$ term because $\binom{0}{i} = \delta_{i0}$. Apply it with $q = n+a$ to the bracket in (37.9).

Step 3: recognise the two pieces. The term $(u_{(m)}\varphi)_{(n+a)}t$ contributes $\sum_a \frac{(-1)^{n+a+1}}{a!}L^a(u_{(m)}\varphi)_{(n+a)}t = W(t)_{(n)}(u_{(m)}\varphi)$. The other term contributes

$$\sum_r\binom{m}{r}\sum_a\frac{(-1)^{n+a+1+r+m}}{a!}L^a\big(\varphi_{(m+n-r+a)}\,u_{(r)}t\big) = \sum_r\binom{m}{r}W\big(u_{(r)}t\big)_{(m+n-r)}\varphi,$$

because $(-1)^{n+a+1+r+m} = (-1)^{(m+n-r)+a+1}$, which is exactly the sign in the definition of $W(s)_{(m+n-r)}\varphi$ with $s = u_{(r)}t$. Finally $u_{(r)}t = 0$ for $r \ge J$, so the r-sum stops at $J-1$. Every sum in the argument is finite, since all the truncations involved are finite. □

Remark 37.16 (No Goddard uniqueness)**.** For a vertex algebra acting on itself, skew-symmetry and commutator formulas are usually derived from a uniqueness argument (Goddard's lemma: a field local with all $Y(u,z)$ and with the right value on the vacuum is determined). That argument needs a vacuum vector in the space the field acts on. In the present situation the field $W(t,z)$ maps $\mathcal{V}$ to M, and M has no vacuum, so the commutator formula is proved directly by the computation above, for all m (positive and negative) at once.

What the machine verified

`wMode_comm`: proved for every weak module; only hypothesis `hJ`. Axioms `[propext, Classical.choice, Quot.sound]` (rechecked).

37.4.5 Locality of $Y_M(u,z_1)$ and $W(t,z_2)$

Theorem 37.17 (W is local with every module vertex operator). *For $u \in \mathcal{V}$ and $t \in M$, let J be past the truncation of u on t. Then*

$$(z_1-z_2)^J\Big(Y_M(u,z_1)\,W(t,z_2) - W(t,z_2)\,Y(u,z_1)\Big) = 0$$

as a two-variable distribution with values in $\mathrm{Hom}(\mathcal{V},M)$. *In particular such an exponent exists.*

File `VOA/Moonshine/SkewIntertwiner.lean`.

```
noncomputable def wBracket (A : WeakModule W M) (u : 𝒱) (t : M) : FormalDist₂ (𝒱 →ₗ[ℂ] M)
 ↪  :=
  fun a b => (A.YM u a).comp (Wsk A t b) - (Wsk A t b).comp (W.Y u a)

theorem Wsk_local_of_bound (A : WeakModule W M) (u : 𝒱) (t : M) (J : ℕ)
    (hJ : ∀ j : ℕ, J ≤ j → A.act u j t = 0) :
    mulBySubPow J (wBracket A u t) = 0

theorem Wsk_local (A : WeakModule W M) (u : 𝒱) (t : M) :
    ∃ N : ℕ, mulBySubPow N (wBracket A u t) = 0
```

From the mathematics to the Lean statement

`wBracket A u t` has as (a,b)-coefficient the map $Y_M(u)_a \circ W(t)_b - W(t)_b \circ Y(u)_a$, where subscripts are coefficients of z_1^a and z_2^b (Definition 37.2), and `comp` is composition of linear maps. This is the coefficient of $z_1^a z_2^b$ in $Y_M(u,z_1)W(t,z_2) - W(t,z_2)Y(u,z_1)$. `mulBySubPow J` multiplies by $(z_1-z_2)^J$ (Definition 37.4). The order J is the truncation order of u on t; it does not depend on the vector φ on which the operators act. That is the strong (uniform) form of locality, as required for fields.

Physical meaning

Mutual locality of $W(t,z_2)$ with every current $Y(u,z_1)$ means that the correlation functions of the twist-field vertex operator with currents are single-valued meromorphic functions in z_1 with poles only at z_2: the twist field creates no branch cut seen by the *untwisted* (invariant) currents. The pole order J is the order of the OPE singularity, independent of the state on which the operators act, as for a genuine field.

Proof on paper. Theorem 37.15, rewritten for distributions, says

$$[Y_M(u,z_1),W(t,z_2)] = \sum_{r<J} W(u_{(r)}t,z_2)\,\frac{1}{r!}\partial_{z_2}^{r}\,z_1^{-1}\delta\Big(\frac{z_2}{z_1}\Big),$$

whose (a,b)-coefficient is $\binom{-a-1}{r}\,W(u_{(r)}t)_{(-a-b-2-r)}$. A distribution of the form $g(z_2)\partial^{(r)}\delta$ is killed by $(z_1-z_2)^{r+1}$: in coefficients, (z_1-z_2) maps the pattern $\binom{-a-1}{r}g_{a+b}$ to the pattern with r replaced by $r-1$ (Pascal's rule), and kills it when $r=0$. Hence $(z_1-z_2)^J$ kills every term with $r<J$. $\square$

What the machine verified

`Wsk_local_of_bound`, `Wsk_local`: proved for every weak module, no further hypotheses. Axioms of `Wsk_local`: `[propext, Classical.choice, Quot.sound]` (rechecked).

37.4.6 Packaging: the skew intertwiner

Definition 37.18 (Skew intertwiner). For an ordinary module A on M', `skewIntertwiner A` is the library `Intertwiner` of type $(A; A, \mathcal{V})$ whose mode at an integer $s = n$ is $W(\cdot)_{(n)}(\cdot)$ and whose modes at non-integral $s \in \mathbb{C}$ are zero.

File `VOA/Moonshine/SkewIntertwiner.lean`.

```
noncomputable def skModes (A : WeakModule W M) (s : ℂ) : M →ₗ[ℂ] 𝒱 →ₗ[ℂ] M :=
  if h : ∃ n : ℤ, (n : ℂ) = s then wBil A (Classical.choose h) else 0

noncomputable def skewIntertwiner (A : OrdVModule W M') :
    Intertwiner A (adjointModule W) A where
  modes := skModes A.toWeakModule

theorem skewIntertwiner_modes (A : OrdVModule W M') (n : ℤ) (t : M') (φ : 𝒱) :
    (skewIntertwiner A).modes (n : ℂ) t φ = wMode A.toWeakModule t n φ
```

(`wBil A n` is $W(\cdot)_{(n)}(\cdot)$ as a bilinear map $M \times \mathcal{V} \to M$; the `truncation` and `isIntertwiner` fields of the structure, proved from Proposition 37.14 and Theorem 37.15, are omitted.)

From the mathematics to the Lean statement

Type. `Intertwiner A (adjointModule W) A`: first argument from A, second from the adjoint module $\mathcal{V}$, output in A; i.e. type $\binom{M}{M\ \mathcal{V}}$. **Complex modes.** The library's intertwiners have complex modes; W has only integral modes, so `skModes` reads off the integer n with $(n : \mathbb{C}) = s$ when it exists (the `Classical.choose` is harmless: the integer is unique) and is zero otherwise. **Strength.** As explained under Definition 37.6, this records only truncation and the commutator formula. The L_{-1}-property is Theorem 37.13, proved separately; the full Jacobi identity of W is not proved in the library.

Physical meaning

Packaging W as an `Intertwiner` records it as a chiral vertex operator of type twisted $\times$ untwisted $\to$ twisted, i.e. as a choice of three-point coupling $\langle T|\, W(t,z)\, |V^+\rangle$ among the twisted module, the adjoint (vacuum) module and the twisted module. The vanishing of non-integral modes expresses that the sector $(V_\Lambda^T)^+$ has integer conformal weights, so no fractional monodromy appears.

What the machine verified

Definition with all fields proved; for every ordinary module. Axioms of `skewIntertwiner`: `[propext, Classical.choice, Quot.sound]` (rechecked).

37.5 The Leech instance of W

The file `VOA/Moonshine/SkewLeech.lean` specialises everything to the module `plusModule` of Section 37.2.3. Since `plusModule` is an *ordinary* module with integral modes ($u_{(n)} = Y^T(u)_{(2n/2)}$ on $(V_\Lambda^T)^+$), W has only integral modes and no fractional bookkeeping arises.

Definition 37.19. L_{-1} on $(V_\Lambda^T)^+$ and the skew field $W(t,z) = e^{zL_{-1}}Y^T(\cdot,-z)t : V_\Lambda^+ \to (V_\Lambda^T)^+$ for $t \in (V_\Lambda^T)^+$:

```
noncomputable abbrev leechLTP : Module.End ℂ TP := Lm1 plusModule.toWeakModule

theorem leechLTP_coe (x : TP) :
    ((leechLTP x : TP) : Tw) = leechTwistedModule.YM leechVOAPlus.conformalVector.1 0 x

noncomputable def leechWsk (t : TP) : FormalDist (SkewVP →ₗ[ℂ] TP) :=
  Wsk plusModule.toWeakModule t
```

From the mathematics to the Lean statement

`leechLTP_coe` confirms that the module translation operator on $(V_\Lambda^T)^+$ is the twisted ω-mode at twisted index 0, i.e. $\omega_{(0)} = L_{-1}$ of the twisted module of Chapter 36, restricted to the θ-fixed part (the coercion `((· : TP) : Tw)` includes $(V_\Lambda^T)^+$ into $S[\theta] \otimes T$). So "L_{-1}" means what it should.

Physical meaning

This is the concrete 2d CFT object: $W(t,z)$ is the vertex operator for the twist-field state $t \in (V_\Lambda^T)^+$ of the $\mathbb{Z}/2$ orbifold of 24 bosons on the Leech torus, acting from the untwisted chiral algebra V_Λ^+ into the twisted sector. Everything is forced by the module structure through skew-symmetry, with no choices.

Theorem 37.20 (Properties of the Leech W). *For $t \in (V_\Lambda^T)^+$: $W(t,z)\mathbf{1} = e^{zL_{-1}}t$; $W(L_{-1}t,z) = \partial_z W(t,z)$; the commutator formula (37.8) holds for all $u \in V_\Lambda^+$, $m,n \in \mathbb{Z}$; and $Y^T(u,z_1)$, $W(t,z_2)$ are mutually local. Finally W is an intertwiner of type $\binom{(V_\Lambda^T)^+}{(V_\Lambda^T)^+\ V_\Lambda^+}$ in the library's sense.*

```
theorem leechWsk_vacuum (t : TP) (k : ℤ) :
    leechWsk t k leechVOAPlus.vacuum
      = if 0 ≤ k then ((k.toNat.factorial : ℂ)⁻¹) • (leechLTP ^ k.toNat) t else 0

theorem leechWsk_deriv (t : TP) : leechWsk (leechLTP t) = deriv (leechWsk t)

theorem leechWsk_comm (u : SkewVP) (m : ℤ) (t : TP) (n : ℤ) (φ : SkewVP) (J : ℕ)
    (hJ : ∀ j : ℕ, J ≤ j → mode (plusModule.YM u) j t = 0) :
    mode (plusModule.YM u) m (mode (leechWsk t) n φ)
        - mode (leechWsk t) n (leechVOAPlus.smul u m φ)
      = ∑ r ∈ Finset.range J,
          gBinom m r • mode (leechWsk (mode (plusModule.YM u) r t)) (m + n - r) φ

theorem leechWsk_local (u : SkewVP) (t : TP) :
    ∃ N : ℕ, mulBySubPow N
      (fun a b => (plusModule.YM u a).comp (leechWsk t b)
        - (leechWsk t b).comp (leechVOAPlus.Y u a) : FormalDist₂ (SkewVP →ₗ[ℂ] TP)) = 0

noncomputable def leechSkewIntertwiner :
    Intertwiner plusModule (adjointModule leechVOAPlus) plusModule :=
  skewIntertwiner plusModule
```

From the mathematics to the Lean statement

Each statement is the general theorem of Section 37.4 at `A := plusModule.toWeakModule`; the proofs are one-line applications. In `leechWsk_comm`, `mode (leechWsk t) n` is $W(t)_{(n)}$ and `mode (plusModule.YM u) m` is $u_{(m)}$ on $(V_\Lambda^T)^+$. The locality statement is the $\mathrm{Hom}(V_\Lambda^+,(V_\Lambda^T)^+)$-valued

form explained after Definition 37.4. Same as the textbook statements; unconditional.

Physical meaning

The theorem says the twisted sector can be consistently "fused" with the untwisted algebra: the OPE of an invariant current with a twist-field operator closes on twist fields, and the translation and vacuum axioms hold. This is the part of the interaction between sectors that is fixed by the module structure; the interaction between two twist fields is the harder statement, proved in later chapters.

What the machine verified

All unconditional (no hypotheses beyond the already-built `leechVOAPlus` and `plusModule`). Axioms of `leechSkewIntertwiner`: `[propext, Classical.choice, Quot.sound]` (rechecked).

37.6 Contragredient modules and invariant bilinear forms

37.6.1 The contragredient module

Let $M = \bigoplus_\alpha M_\alpha$ be an ordinary $\mathcal{V}$-module. Its *restricted* (or graded) dual is $M' = \bigoplus_\alpha M_\alpha^*$, the direct sum of the duals of the finite-dimensional weight spaces; write $\langle f, x\rangle$ for the pairing. Frenkel, Huang and Lepowsky (FHL, §5.2) define vertex operators on M' by

$$\langle Y'(u,z)f,\ x\rangle = \left\langle f,\ Y\big(e^{zL_1}(-z^{-2})^{L_0}u,\ z^{-1}\big)x\right\rangle \tag{37.11}$$

and prove (FHL, Theorem 5.2.1) that (M', Y') is again a module, the *contragredient* module. The operator $u \mapsto e^{zL_1}(-z^{-2})^{L_0}u$ is the action of the Möbius transformation $z \mapsto 1/z$ on states, which is why it appears: physically, (37.11) is the statement that the "out" state $\langle f|$ at infinity is the BPZ conjugate of an "in" state.

Mode form. For $u \in \mathcal{V}_{\mathrm{wt}}$ we have $e^{zL_1}(-z^{-2})^{L_0}u = (-1)^{\mathrm{wt}}z^{-2\mathrm{wt}}\sum_{j\ge 0} z^j L_1^j u/j!$ and $Y(v,z^{-1}) = \sum_q v_{(q)}z^{q+1}$. Comparing coefficients of z^{-n-1} forces $q = 2\mathrm{wt} - n - 2 - j$, so

$$\langle u'_{(n)}f, x\rangle = (-1)^{\mathrm{wt}}\sum_{j=0}^{\mathrm{wt}} \frac{1}{j!}\,\langle f,\ (L_1^j u)_{(2\mathrm{wt}-n-2-j)}x\rangle. \tag{37.12}$$

The sum stops at $j = \mathrm{wt}$ because $L_1^j u$ has weight $\mathrm{wt} - j$ and a CFT-type vertex operator algebra has no negative weights. If u is *quasi-primary* ($L_1 u = 0$) only $j = 0$ survives: $u_{(n)}$ is transposed to $(-1)^{\mathrm{wt}}u_{(2\mathrm{wt}-n-2)}$.

Example 37.21. (i) $u = \omega$, $\mathrm{wt} = 2$, $L_1\omega = 0$: $\omega_{(n)} = L_{n-1}$ is transposed to $\omega_{(2-n)} = L_{1-n}$, i.e. $L_k^t = L_{-k}$: the Virasoro operators are BPZ-adjoint as expected. (ii) $u = h(-1)\mathbf{1}$ a Heisenberg vector, $\mathrm{wt} = 1$, quasi-primary: $h_{(n)} = h(n)$ is transposed to $-h(-n)$. Note the *minus sign*: it will make the natural invariant form on a Fock space indefinite (Section 37.7). (iii) $u = e^\alpha$ in a lattice VOA, weight $N = \langle\alpha,\alpha\rangle/2$, primary: $e^\alpha_{(n)}$ is transposed to $(-1)^N e^\alpha_{(2N-n-2)}$.

In the library, M' is the type `RestrictedDual N` and its vertex operator is `YMdual N`:

```
def RestrictedDual (N : OrdVModule W M) : Type u := DirectSum ℂ (fun α => Module.Dual ℂ
 ↪  (N.weight α))

noncomputable def YMdual (N : OrdVModule W M) : 𝒱 →ₗ[ℂ] (End ℂ (RestrictedDual N))⟦z^±⟧
 ↪  where
  toFun u := fun p => dualModeAt N (-p - 1) u
```

(`VOA/Modules/Contragredient.lean`, `VOA/Modules/ContragredientJacobi.lean`; `dualModeAt N n u` is, on homogeneous u, the operator defined by (37.12), and it is extended linearly over the weight decomposition of u. The library proves that Y' satisfies the module Jacobi identity: `contragredientJacobi_holds`, in `VOA/Modules/ContragredientClose.lean`.)

37.6.2 Invariant bilinear forms on a module

Definition 37.22 (FHL invariance at a homogeneous state)**.** Let N be an ordinary $\mathcal{V}$-module on M and B a bilinear form on M. For $u \in \mathcal{V}_{\mathrm{wt}}$, B is *invariant at u* if for all $n \in \mathbb{Z}$, $a, b \in M$

$$B\big(u_{(n)}a, b\big) = (-1)^{\mathrm{wt}} \sum_{j=0}^{\mathrm{wt}} \frac{1}{j!}\, B\big(a, (L_1^{j}u)_{(2\mathrm{wt}-n-2-j)}b\big), \tag{37.13}$$

the mode form of $B(Y(u,z)a,b) = B(a, Y(e^{zL_1}(-z^{-2})^{L_0}u, z^{-1})b)$. The form has *orthogonal weight spaces* if $B(M_\alpha, M_\beta) = 0$ for $\alpha \neq \beta$.

```
def FHLInv (N : OrdVModule W M) (B : LinearMap.BilinForm ℂ M) (wt : ℤ) (u : 𝒱) : Prop :=
  ∀ (n : ℤ) (a b : M), B (mode (N.YM u) n a) b
    = (-1 : ℂ) ^ wt • ∑ j ∈ Finset.range (wt.toNat + 1), ((j.factorial : ℂ)⁻¹) •
        B a (mode (N.YM (((W.L 1) ^ j) u)) (2 * wt - n - 2 - (j : ℤ))) b

def WeightOrth (N : OrdVModule W M) (B : LinearMap.BilinForm ℂ M) : Prop :=
  ∀ α β : ℂ, α ≠ β → ∀ x ∈ N.weight α, ∀ y ∈ N.weight β, B x y = 0
```

(`VOA/Moonshine/InvFormClosure.lean`, namespace `VOA.Moonshine.InvForm`.)

From the mathematics to the Lean statement

`LinearMap.BilinForm ℂ M` is a bilinear form $M \times M \to \mathbb{C}$, applied as `B a b`. `W.L 1` is L_1 on $\mathcal{V}$, `(W.L 1)^j` its j-th power. `Finset.range (wt.toNat + 1)` is $\{0, \dots, \mathrm{wt}\}$ (for $\mathrm{wt} < 0$ it is $\{0\}$, but then $u = 0$ by CFT type and both sides vanish). `FHLInv` takes the weight `wt` as a separate argument and does *not* itself require $u \in \mathcal{V}_{\mathrm{wt}}$; every theorem below that uses it adds the hypothesis `u ∈ W.grading wt`, so the predicate is only ever applied in its intended meaning. This is the module analogue of the library's `InvariantForm.IsFullyInvariant` for forms on $\mathcal{V}$ itself (same formula with `W.smul` in place of module modes). Same as the textbook definition.

Physical meaning

An invariant bilinear form is the two-point function of the sector: $B(a,b) = \langle a|b\rangle$ with $\langle a|$ the out-state at infinity. The invariance condition says that moving a field $Y(u,z)$ from the right to the left of the bracket replaces it by its BPZ conjugate, the field transformed by the inversion $z \mapsto 1/z$, which is why $e^{zL_1}(-z^{-2})^{L_0}$ appears. For a weight-wt quasi-primary field the transposition rule is $u_{(n)} \mapsto (-1)^{\mathrm{wt}} u_{(2\mathrm{wt}-n-2)}$, the familiar $L_n \mapsto L_{-n}$ and $J_n \mapsto -J_{-n}$. The orthogonality of weight spaces is the selection rule that two-point functions vanish between states of different energy.

Definition 37.23 (The map $M \to M'$ of a form)**.** `dualMap N B` : $M \to M'$ sends a to the functional whose M_β-component is $x \mapsto B(\pi_\beta a, x)$, π_β the projection to M_β. If the weight spaces are orthogonal, $\langle \mathtt{dualMap}(a), x\rangle = B(a,x)$ for every x.

```
noncomputable def dualMap (N : OrdVModule W M) (B : LinearMap.BilinForm ℂ M) :
    M →ₗ[ℂ] RestrictedDual N :=
  letI := DirectSum.IsInternal.chooseDecomposition N.weight N.isInternal
  (DFinsupp.mapRange.linearMap fun α => B.compl₁₂ (N.weight α).subtype (N.weight
   ↪ α).subtype).comp
    (DirectSum.decomposeLinearEquiv N.weight).toLinearMap
```

Physical meaning

The assignment $a \mapsto B(a,\cdot)$ sends an in-state to the corresponding out-state $\langle a|$ in the dual (contragredient) space of out-states. This definition is the bra–ket map defined by the two-point function.

Theorem 37.24 (Invariance means $a \mapsto B(a,\cdot)$ is a module map)**.** *Assume orthogonal weight spaces and $u \in \mathcal{V}_{\mathrm{wt}}$. Then B is invariant at u if and only if* $\mathtt{dualMap}(u_{(n)}a) = u'_{(n)}\mathtt{dualMap}(a)$ *for all n and a.*

```
theorem fhlInv_iff (hO : WeightOrth N B) {wt : ℤ} {u : 𝒱} (hu : u ∈ W.grading wt) :
    FHLInv N B wt u ↔
      ∀ (n : ℤ) (a : M), dualMap N B (mode (N.YM u) n a) = mode (YMdual N u) n (dualMap N B
       ↪ a)
```

From the mathematics to the Lean statement

Hypotheses: `hO` (orthogonal weight spaces; needed so that $\langle \mathtt{dualMap}(a), x\rangle$ really equals $B(a,x)$ and not B of a projection) and `hu` (homogeneity, so that `FHLInv` is used with the right weight and `YMdual` is given by (37.12)). Both sides of the equivalence are the textbook ones.

Physical meaning

The theorem says that a form is invariant exactly when the in-to-out map $a \mapsto \langle a|$ intertwines the chiral algebra action, i.e. when the contragredient module M' of out-states, with the BPZ-conjugated action, is identified with M by the form. Physically the sector is its own conjugate, with the form playing the role of the Zamolodchikov metric that identifies states with out-states. (Heuristic gloss; the equivalence is proved mode by mode.)

Proof. Pair both sides of the right-hand equation with $x \in M_\alpha$. By orthogonality the left side gives $B(u_{(n)}a, x)$, and by (37.12) the right side gives the right-hand side of (37.13) with $b = x$. Elements of M' are determined by their pairings with homogeneous vectors, and both sides of (37.13) are linear in b, so the equivalence follows. □

37.6.3 Generator reduction

Checking (37.13) for every state of $\mathcal{V}$ directly is hopeless for V_Λ^+. The following principle reduces it to generators.

Definition 37.25. `interSub` $N\,B$ is the set of $u \in \mathcal{V}$ (homogeneous or not) such that $\mathtt{dualMap}(u_{(n)}a) = u'_{(n)}\mathtt{dualMap}(a)$ for all n and a. It is a linear subspace.

File `VOA/Moonshine/InvFormClosure.lean`.

```
noncomputable def interSub (N : OrdVModule W M) (B : LinearMap.BilinForm ℂ M) : Submodule ℂ
 ↪ 𝒱 where
  carrier := {u | ∀ (n : ℤ) (a : M),
    dualMap N B (mode (N.YM u) n a) = mode (YMdual N u) n (dualMap N B a)}
```

Physical meaning

Technical definition: the set of fields for which the in–out map commutes with the action. Physically, the fields whose BPZ conjugate behaves correctly under the form; the next theorem shows these form a closed operator algebra, so it suffices to check the generating currents.

Theorem 37.26 (The intertwined states form a vertex subalgebra)**.** $\mathbf{1} \in \mathtt{interSub}$*, and if* $u, v \in \mathtt{interSub}$ *then* $u_{(\ell)}v \in \mathtt{interSub}$ *for every* $\ell \in \mathbb{Z}$*.*

```
theorem vacuum_mem_interSub : W.vacuum ∈ interSub N B

theorem smul_mem_interSub {u v : V} (hu : u ∈ interSub N B) (hv : v ∈ interSub N B) (ℓ : ℤ)
 ↪  :
    W.smul u ℓ v ∈ interSub N B
```

Physical meaning

Operator products of fields that satisfy the BPZ reflection rule again satisfy it: if the conjugate of each of two fields is the correct reflected field, the conjugate of their OPE coefficients is as well. This is the closure of the set of "good" fields under the OPE.

Proof. The vacuum acts as the identity on M and on M'. For the products, the iterate formula (37.10) (with $m = 0$) writes $(u_{(\ell)}v)_{(n)}$ on M as a finite combination of products $u_{(\cdot)}v_{(\cdot)}$ and $v_{(\cdot)}u_{(\cdot)}$; the same formula holds on M' because M' is a module (FHL Theorem 5.2.1, `contragredientJacobi_holds`). The map `dualMap` intertwines each factor, hence each product, hence the combination. □

Theorem 37.27 (Generator reduction for module invariant forms)**.** *Let B have orthogonal weight spaces and let $G \subseteq \mathcal{V}$ be a set of homogeneous states which generates $\mathcal{V}$ in the sense that every subspace containing $\mathbf{1}$ and G and closed under all n-th products is all of $\mathcal{V}$. If B is invariant at every $g \in G$, then B is invariant at every homogeneous $u \in \mathcal{V}$.*

File `VOA/Moonshine/InvFormClosure.lean`.

```
theorem fhlInv_of_generates (hO : WeightOrth N B) (G : Set V)
    (hG : ∀ S : Submodule ℂ V, W.vacuum ∈ S → (∀ u ∈ S, ∀ v ∈ S, ∀ n : ℤ, W.smul u n v ∈ S)
     ↪  →
      G ⊆ S → S = ⊤)
    (hGinv : ∀ g ∈ G, ∃ wt : ℤ, g ∈ W.grading wt ∧ FHLInv N B wt g)
    {wt : ℤ} {u : V} (hu : u ∈ W.grading wt) : FHLInv N B wt u
```

From the mathematics to the Lean statement

Hypotheses. `hO`: orthogonal weight spaces. `hG`: generation, stated exactly as in the theorem (the smallest vertex subalgebra containing G is everything; `⊤` is the whole space). `hGinv`: each generator is homogeneous of some weight and B is invariant at it. `hu`: the conclusion is for homogeneous u. **Comparison.** Same as the textbook statement. **Not vacuous:** generation is a genuine hypothesis and is discharged for the Leech case by a real theorem (`leechPlus_generated`, Chapter 32).

Physical meaning

(See the preceding box for the closure under OPE.) Physically this says that a two-point metric which is compatible with the BPZ conjugation of the generating currents (here the lattice fields $e^{\beta} + e^{-\beta}$) is automatically compatible with the whole chiral algebra, since every field is built from the generators by OPE. This is how one avoids checking invariance on all of V_Λ^+.

Proof. By Theorem 37.26 `interSub` is a subspace containing $\mathbf{1}$, closed under products; by Theorem 37.24 it contains G. By generation it is everything, so every homogeneous u lies in it, and Theorem 37.24 again gives invariance at u. The point of working with `interSub` rather than with `FHLInv` is that `interSub` is defined for inhomogeneous states and is visibly linear, whereas (37.13) mixes the state with its weight. □

What the machine verified

`fhlInv_iff`, `smul_mem_interSub`, `fhlInv_of_generates`: proved for every VOA, module and form, with exactly the displayed hypotheses. Axioms of `fhlInv_of_generates`: `[propext, Classical.choice, Quot.sound]` (rechecked).

37.7 The invariant form on the twisted Fock space

We now build the form B_T on $(V_\Lambda^T)^+$ that enters (37.4). It is the restriction of a product form $F \otimes B_T$ on $S[\theta] \otimes T$: a form F on the twisted Fock space and the symmetric form `TForm` on the 2^{12}-dimensional space T constructed in Chapter 34. (To avoid a clash we write B_{tw} for the form on $S[\theta] \otimes T$ and keep B_T for its restriction to $(V_\Lambda^T)^+$; the Lean names are `leechTwForm` and `TPForm`.) All declarations of this section and the next are in namespace `VOA.Moonshine.InvForm`.

37.7.1 Which sign? The negative Fock form

Recall (Chapter 34) that $S[\theta] = \mathbb{C}[X_{(n,i)}]$ with $X_{(n,i)} = h_i(-n-\tfrac12)$, $n \ge 0$, $1 \le i \le r$, and that the twisted oscillators act by $h_i(-n-\tfrac12) =$ multiplication by $X_{(n,i)}$ and $h_i(n+\tfrac12) = (n+\tfrac12)\partial/\partial X_{(n,i)}$, so that $[h_i(m), h_j(m')] = m\,\delta_{ij}\delta_{m+m',0}$. In Lean the oscillator $h_i(k/2)$ (k odd) is `modeT r i k` (Chapter 34); for even k it is defined to be 0.

Example 37.21(ii) dictates the adjointness relation that an invariant form must satisfy for the weight-one vectors $h_i(-1)\mathbf{1}$ of the lattice VOA, whose twisted vertex operators have the modes $h_i(k/2)$:

$$F\big(h_i(m)p, q\big) = -F\big(p, h_i(-m)q\big). \tag{37.14}$$

With $m = -n - \tfrac12$ this reads $F(X_v p, q) = -F(p, h_i(n+\tfrac12)q) = c_v\,F(p, \partial_v q)$ with

$$c_v = -(n+\tfrac12) \qquad (v = (n,i)).$$

Iterating, monomials are orthogonal and $F(X^d, X^d) = \prod_v c_v^{d_v}\, d_v!$. This is not positive: in rank one $F(X_{(0,1)}, X_{(0,1)}) = -\tfrac12$, $F(X_{(0,1)}^2, X_{(0,1)}^2) = \tfrac12$, $F(X_{(1,1)}, X_{(1,1)}) = -\tfrac32$. The familiar positive-definite Fock form ($c_v = +(n+\tfrac12)$) is the *Hermitian* form of unitary CFT, adapted to the anti-linear adjoint $h(m)^\dagger = h(-m)$; the FHL *bilinear* form, adapted to the linear transposition $Y(u,z) \mapsto Y(e^{zL_1}(-z^{-2})^{L_0}u, z^{-1})$, carries the sign $(-1)^{\mathrm{wt}} = -1$ for weight-one fields. The two differ by the anti-linear involution $h \mapsto -h$.

Definition 37.28 (The Fock form). $c_v = -(n+\tfrac12)$ for $v = (n,i)$; $\mathtt{fockWt}(d) = \prod_v c_v^{d_v} d_v!$ for a multi-index d; and $F(X^d, X^e) = \delta_{d,e}\,\mathtt{fockWt}(d)$, extended bilinearly.

```
noncomputable def cVar (v : ℕ × Fin r) : ℂ := -((v.1 : ℂ) + 1 / 2)

noncomputable def fockWt (d : (ℕ × Fin r) →₀ ℕ) : ℂ :=
  d.prod fun v m => cVar v ^ m * (m.factorial : ℂ)

noncomputable def fockForm (r : ℕ) : LinearMap.BilinForm ℂ (FockT r) :=
  Finsupp.lsum ℂ fun d => LinearMap.smulRight LinearMap.id (fockWt d • lcoeff ℂ d)
```

(`VOA/Moonshine/InvFormFock.lean`.)

From the mathematics to the Lean statement

`FockT r` is the polynomial ring $\mathbb{C}[X_{(n,i)}]$, i.e. `MvPolynomial (ℕ × Fin r) ℂ` (Chapter 34); a monomial is a finitely supported exponent function `d : (ℕ × Fin r) →₀ ℕ`, and `d.prod f` is $\prod_{v\in\operatorname{supp} d} f(v,d_v)$. `lcoeff ℂ d` is the linear functional "coefficient of X^d". Unwinding `Finsupp.lsum` and `smulRight`: for $p=\sum_d p_d X^d$, $F(p,q)=\sum_d p_d\,\mathtt{fockWt}(d)\,q_d$. That is Definition 37.28 exactly. Note the minus sign in `cVar`: this is the *negative* form, deliberately.

Physical meaning

The Fock form is the two-point function of the free twisted bosons. Its normalisation $F(X_v p,q)=c_v F(p,\partial_v q)$ with $c_v=-(n+\frac12)$ is the algebraic form of the oscillator algebra with the BPZ-reflection rule $h(m)^t=-h(-m)$ of a weight-one current. It differs in sign from the Hermitian form of a unitary theory because the bilinear form is adapted to the linear (not antilinear) conjugation, so the Zamolodchikov-type metric is indefinite in these conventions.

Theorem 37.29 (Basic properties of F). *F is symmetric; $F(X_v p,q)=c_v F(p,\partial_v q)$; and the twisted oscillators are anti-adjoint, $F(h_i(k/2)p,q)=-F(p,h_i(-k/2)q)$ for every $k\in\mathbb{Z}$.*

```
theorem fockForm_symm (p q : FockT r) : fockForm r p q = fockForm r q p

theorem fockForm_X_mul (v : ℕ × Fin r) (p q : FockT r) :
    fockForm r (X v * p) q = cVar v * fockForm r p (pderiv v q)

theorem fockForm_modeT (i : Fin r) (k : ℤ) (p q : FockT r) :
    fockForm r (modeT r i k p) q = -fockForm r p (modeT r i (-k) q)
```

From the mathematics to the Lean statement

`X v` is the variable X_v, `pderiv v` is $\partial/\partial X_v$. In `fockForm_modeT` the integer k encodes the mode $k/2$; for odd $k<0$, `modeT r i k` is multiplication by $X_{((-k-1)/2,i)}$, for odd $k>0$ it is $\frac{k}{2}\partial_{((k-1)/2,i)}$, and for even k both sides are 0 (the junk value 0 of even modes makes the statement true but empty there). No hypotheses. This is (37.14).

Physical meaning

These are the standard oscillator identities for a free boson: creation operators are adjoint to annihilation operators up to the sign fixed by the BPZ conjugate of the current; symmetry of the two-point function is the statement that there is no preferred ordering of the two states in the metric.

Proof. Symmetry is visible from the diagonal formula. For the second identity it suffices to take $p=X^d$, $q=X^e$: both sides vanish unless $e=d+\mathbf{e}_v$, and then the left side is $\mathtt{fockWt}(d+\mathbf{e}_v)=c_v(d_v+1)\mathtt{fockWt}(d)$ while $\partial_v X^e=(d_v+1)X^d$ gives the same on the right. The oscillator identity for a creation mode $k=-(2n+1)$ is the second identity together with $h_i(n+\frac12)=(n+\frac12)\partial$: $F(Xp,q)=-(n+\frac12)F(p,\partial q)=-F(p,h_i(n+\frac12)q)$; the annihilation case follows by symmetry of F. □

37.7.2 The dressing is self-adjoint up to inversion

The twisted vertex operator of e^α (Chapter 36) has the form $Y^T(e^\alpha,z)=2^{-\langle\alpha,\alpha\rangle}z^{-\langle\alpha,\alpha\rangle/2}E^-(-\alpha,z)E^+(-\alpha,z)\otimes e_\alpha$, where $E^\pm$ are exponentials of the creation/annihilation oscillators. The library stores the coeffi-

cients of the dressing $E^-(-v,w)E^+(-v,w)$ as $\mathtt{DD}\,v\,a$ (the coefficient of w^a; Chapter 36). Invariance of F under these vertex operators needs the transposition rule for $\mathtt{DD}$.

Theorem 37.30 (Transpose of the dressing). *For every $v \in \mathbb{C}^r$, $a \in \mathbb{Z}$ and $y, y' \in S[\theta]$: $F(\mathtt{DD}\,v\,a\,y,\ y') = F(y,\ \mathtt{DD}\,v\,(-a)\,y')$. Equivalently, the transpose of $E^-(-v,w)E^+(-v,w)$ with respect to F is $E^-(-v,w^{-1})E^+(-v,w^{-1})$ (no sign and no $v \mapsto -v$).*

File `VOA/Moonshine/InvFormFock.lean`.

```
theorem fockForm_DD (v : Fin r → ℂ) (a : ℤ) (y y' : FockT r) :
    fockForm r (DD v a y) y' = fockForm r y (DD v (-a) y')
```

From the mathematics to the Lean statement

`DD v a` is the endomorphism $\sum_{p-q=a} E^-_p(-v)E^+_q(-v)$ of $S[\theta]$ (Chapter 36, `noncomputable def DD (v : Fin r → ℂ) (a : ℤ) : End ℂ (FockT r)`). The vector v is arbitrary complex; in the application v is the coordinate vector of a lattice vector α. No hypotheses. Same as the textbook transposition rule.

Physical meaning

The coefficients $E^-(-v,w)E^+(-v,w)$ are the normal-ordered exponential of oscillators in the vertex operator $e^{i\alpha\cdot X}$ of the lattice field. The theorem says that its transpose under the Fock metric is the same exponential with $w \to w^{-1}$, which is the BPZ conjugation of the vertex operator $e^{i\alpha X}$ with itself (the charge not flipped: the sign is absorbed into the form). It is the free-boson computation that makes the lattice fields satisfy the reflection rule at the level of the twisted Fock space. A heuristic check: the reflected exponential $e^{i\alpha X(1/w)}$ has the same oscillator content with the $E^\pm$ roles exchanged.

Proof on paper. Write $\Phi_a = \mathtt{DD}\,v\,a$. Two facts determine Φ_a: its value on the vacuum, $\Phi_a\mathbf{1} = E^-_a(-v)\mathbf{1}$, whose constant term is $\delta_{a,0}$; and its commutator with oscillators, $[h_i(K/2), \Phi_a] = v_i\,\Phi_{a-K}$ for odd K (because $E^\pm(-v,w)$ are exponentials of oscillators with coefficients $\propto v_i w^{\mp K}$). Now prove the identity by induction on the degree of y, then of y'. If $y = \mathbf{1}$, write y' as a polynomial; $F(\Phi_a\mathbf{1}, X_v y'')$ is moved by (37.14) to an annihilator acting on $\Phi_a\mathbf{1}$, which the commutator rule converts into $\Phi_{a'}\mathbf{1}$ terms of lower degree; the base case is the constant-term identity $\delta_{a,0} = \delta_{-a,0}$. If $y = X_v y_0$, move X_v across Φ_a with the commutator rule (producing Φ_{a+K}), then across F with (37.14) (producing the sign -1 and $h(-K/2)$), and apply the induction hypothesis; the same two moves on the right side, with $a \mapsto -a$ and $K \mapsto -K$, give the same terms. The signs work out precisely because the form is the negative one: the minus sign of (37.14) compensates the change of sign of K in the commutator rule. □

Trap / dead end

The positive Fock form is wrong here. With the positive form ($c_v = +(n + \frac{1}{2})$) the same argument transposes $\mathtt{DD}\,v\,a$ to $\mathtt{DD}\,(-v)\,(-a)$, so the vertex operator of e^α would be transposed to that of $e^{-\alpha}$ and the form would not be FHL-invariant in the required sense. The recorded cross-check (file docstring of `VOA/Moonshine/InvFormFock.lean`; scripts `dd.py`, `dd2.py` in `scripts/moonshine/numerics/`): a sympy computation in rank 2 with three oscillator levels and $v = (\frac{3}{2}, -\frac{2}{3})$ found $F(\mathtt{DD}\,a\,y, y') = F(y, \mathtt{DD}\,(-a)\,y')$ on all test pairs for $|a| \le 4$ with the negative form, and failure with the positive form. This is numerical evidence recorded by the project, not a proof; the scripts were *not* re-run for this chapter (sympy is not installed in the environment used). The proof is Theorem 37.30.

What the machine verified

`fockForm_symm`, `fockForm_X_mul`, `fockForm_modeT`, `fockForm_DD`: proved, no hypotheses. Axioms of `fockForm_DD`: `[propext, Classical.choice, Quot.sound]` (rechecked).

37.8 The form on $S[\theta] \otimes T$ and on $(V_\Lambda^T)^+$

37.8.1 The product form

Definition 37.31 (Product form). For a bilinear form B_T on a space T: $B_{\mathrm{tw}}(p \otimes t, p' \otimes t') = F(p,p')\,B_T(t,t')$ on $S[\theta] \otimes T$.

```
noncomputable def twForm (r : ℕ) (BT : LinearMap.BilinForm ℂ Tm) :
    LinearMap.BilinForm ℂ (FockT r ⊗[ℂ] Tm) :=
  (fockForm r).tmul BT
```

(`VOA/Moonshine/InvFormTwisted.lean`.) `LinearMap.BilinForm.tmul` is Mathlib's tensor product of bilinear forms; on pure tensors it is the product of the values (`twForm_tmul`, proved by `rfl`).

Physical meaning

The product form $F \otimes B_T$ is the two-point function of the twisted sector as a tensor product of its oscillator part (the free bosons in the twisted sector) and the zero-mode space T of the twist-field ground states (2^{12}-dimensional, labelling the fixed points). The Fock factor carries the oscillator two-point function and the factor B_T the two-point function of the twist fields themselves.

Theorem 37.32 (Adjoints on $S[\theta] \otimes T$). (i) $B_{\mathrm{tw}}(h_a(k/2)x, y) = -B_{\mathrm{tw}}(x, h_a(-k/2)y)$. (ii) *Suppose* $g, g' \in \mathrm{End}(T)$ *and* $s \in \mathbb{C}$ *satisfy* $B_T(gt, t') = s\,B_T(t, g't')$. *For the generic twisted exponential field* $Y_g(k) = \kappa\,\mathrm{DD}\,v\,(-k-2+c_0) \otimes g$, $B_{\mathrm{tw}}(Y_g(k)x, y) = s\,B_{\mathrm{tw}}(x, Y_{g'}(2c_0-k-4)y)$. (iii) *In particular, for an even lattice* L *and a form on its* T *with* $B_T(e_\alpha t, t') = (-1)^{\langle\alpha,\alpha\rangle/2} B_T(t, e_\alpha t')$, *the twisted vertex operator* $Y^T(e^\alpha)_{(k/2)}$ *satisfies*

$$B_{\mathrm{tw}}\big(Y^T(e^\alpha)_{(k/2)}x, y\big) = (-1)^{\langle\alpha,\alpha\rangle/2}\, B_{\mathrm{tw}}\big(x, Y^T(e^\alpha)_{((2\langle\alpha,\alpha\rangle-k-4)/2)}y\big). \tag{37.15}$$

```

From the mathematics to the Lean statement

Symbols. `modeTT a k` is $h_a(k/2)\otimes\mathrm{id}_T$. `YTg v c0 κ g k` is $\kappa\cdot$`DD` $v\,(-k-2+c_0)\otimes g$ (Chapter 36); `YTL L hEven hU α k` is the instance v = coordinates of α, $c_0=\langle\alpha,\alpha\rangle$, $\kappa=2^{-\langle\alpha,\alpha\rangle}$, $g=e_\alpha$, and represents the twisted mode $Y^T(e^\alpha)_{(k/2)}$ on `MT L hEven hU` $= S[\theta]\otimes T$. `eT ... α` is the operator e_α on T (Chapter 34). `L.form α α` is $\langle\alpha,\alpha\rangle$, an even integer for an even lattice, so `L.form α α / 2` is the exact integer $\langle\alpha,\alpha\rangle/2$ (integer division with zero remainder).
Hypotheses. In (ii) the hypothesis `hg` is the T-side adjointness; in (iii) it is `hT`, the "T-law" with sign $(-1)^{\langle\alpha,\alpha\rangle/2}$, and the lattice hypotheses `hEven` (even), `hU` (unimodular Gram determinant) needed to have T at all. `hT` is discharged for the Leech lattice by `TForm_eT` (Chapter 34).
Comparison with FHL. e^α is primary of weight $N=\langle\alpha,\alpha\rangle/2$, so by Example 37.21(iii) its mode m must be transposed to $(-1)^N$ times its mode $2N-m-2$. With $m=k/2$: $2N-\frac{k}{2}-2=\frac{2\langle\alpha,\alpha\rangle-k-4}{2}$, which is the index in (37.15). So (iii) is exactly FHL invariance of B_{tw} at e^α, at the level of the full twisted module (all half-integral modes).

Physical meaning

This theorem is the BPZ reflection rule for the lattice vertex operators e^α acting on the twisted sector: the field e^α of weight $N=\langle\alpha,\alpha\rangle/2$ transposes to $(-1)^N$ times its own mode of index $2N-n-2$. The sign on T is the sign $(-1)^{L_0}$ of the BPZ conjugation, and it is forced by consistency of the two-point function of twist fields (heuristically, the commutation of fields at the fixed points). For the frame constructions the oscillator and cocycle parts each contribute the expected sign.

Proof. (i) is Theorem 37.29 tensored with the identity. For (ii), $B_{\mathrm{tw}}((A\otimes g)x,y)=B_{\mathrm{tw}}(x,(A^t\otimes g^t)y)$ on pure tensors, and by Theorem 37.30 the transpose of `DD` $v\,(-k-2+c_0)$ is `DD` $v\,(k+2-c_0)$, which equals `DD` $v\,(-k'-2+c_0)$ for $k'=2c_0-k-4$. (iii) is (ii) with $s=(-1)^{\langle\alpha,\alpha\rangle/2}$, $g=g'=e_\alpha$. □

Trap / dead end

The sign on T is forced. The T-form must satisfy the law with the sign $(-1)^{\langle\alpha,\alpha\rangle/2}$ (the $(-1)^{L_0}$ of the contragredient), and the Fock part contributes no sign. This was a *finding*: it fixed which of the possible forms on T (Chapter 34) is the compatible one, with no extra twist by e_γ needed. In the numerical E_8 model of the orbifold (`Notes/M8hRoute.md`, §1a; scripts `orb.py`, `tt.py`), replacing this sign by the "group" sign $\varepsilon(\alpha,\alpha)$ makes the twisted×twisted relation (4.23) fail with relative residual 1.7–2.0, while the chosen conventions satisfy it to 3.7×10^{-14}. Numerical evidence, not proof.

37.8.2 Nondegeneracy on graded pieces

Write $S[\theta]_d$ for the span of monomials of doubled degree $d=\sum_v(2n_v+1)d_v$ and `twGrading` $r\,T\,d=S[\theta]_d\otimes T$ (Chapter 33).

Theorem 37.33 (Nondegeneracy and orthogonality on $S[\theta]_d\otimes T$). *If B_T is nondegenerate, then for every d and every nonzero $x\in S[\theta]_d\otimes T$ there is a pure tensor $X^m\otimes t'\in S[\theta]_d\otimes T$ with $B_{\mathrm{tw}}(x,X^m\otimes t')\neq0$. For any B_T, distinct graded pieces are orthogonal.*

File `VOA/Moonshine/InvFormTwisted.lean`.

```
theorem twForm_nondegenerate_twGrading {BT : LinearMap.BilinForm ℂ Tm} (hBT :
↪  BT.Nondegenerate)

theorem twForm_orth_twGrading (BT : LinearMap.BilinForm ℂ Tm) {d d' : ℕ} (hdd : d ≠ d')
    {x y : FockT r ⊗[ℂ] Tm} (hx : x ∈ TwistedSector.twGrading r Tm d)
    (hy : y ∈ TwistedSector.twGrading r Tm d') : twForm r BT x y = 0
```

From the mathematics to the Lean statement

`BT.Nondegenerate` is Mathlib's nondegeneracy (trivial left and right radical); `monomial m 1` is X^m. Conclusion of the first statement is slightly stronger than nondegeneracy (the partner can be taken to be a pure tensor in the same graded piece).

Physical meaning

Nondegeneracy of a two-point function means that no state is null: every nonzero state has a nonvanishing overlap with some state at the same energy. Here this holds on each graded piece of the twisted Fock space because the Fock metric is nonzero on every monomial and B_T is nondegenerate. Orthogonality is the selection rule: states of different energy have zero two-point function.

Proof. Expand $x = \sum_m X^m \otimes t_m$ in the monomial basis; pick m with $t_m \neq 0$, then t' with $B_T(t_m, t') \neq 0$. Monomials are F-orthogonal, so $B_{\mathrm{tw}}(x, X^m \otimes t') = \mathtt{fockWt}(m)\, B_T(t_m, t')$, and $\mathtt{fockWt}(m) \neq 0$ since every $c_\upsilon = -(n + \frac{1}{2}) \neq 0$. Orthogonality: monomials of different degree are F-orthogonal. □

37.8.3 The form on $(V_\Lambda^T)^+$

Definition 37.34. $B_{\mathrm{tw}} := \mathtt{leechTwForm} = F \otimes \mathtt{TForm}$ on $S[\theta] \otimes T$ (rank 24), and $B_T := \mathtt{TPForm}$ its restriction to $(V_\Lambda^T)^+$.

```
noncomputable def leechTwForm : LinearMap.BilinForm ℂ Tw := twForm 24 TForm

noncomputable def TPForm : LinearMap.BilinForm ℂ TP :=
  leechTwForm.compl₁₂ TP.subtype TP.subtype
```

(`VOA/Moonshine/InvFormTP.lean`.) `compl₁₂ TP.subtype TP.subtype` precomposes both arguments with the inclusion $(V_\Lambda^T)^+ \hookrightarrow S[\theta] \otimes T$, i.e. restricts. `TForm` is the symmetric nondegenerate form on the Leech T with $\mathtt{TForm}(e_\alpha t, t') = (-1)^{\langle\alpha,\alpha\rangle/2}\mathtt{TForm}(t, e_\alpha t')$ (`TForm_symm`, `TForm_nondegenerate`, `TForm_eT`; Chapter 34).

Physical meaning

Definition of the metric on the physical twisted sector $(V_\Lambda^T)^+$ (the θ-invariant states), as the restriction of the twisted Fock form tensor the form on the fixed-point space T. It is the Zamolodchikov metric of the twist-field sector.

Theorem 37.35 (Symmetry, nondegeneracy, orthogonality of B_T). *B_T is symmetric; for every $\alpha \in \mathbb{C}$ and nonzero $x \in ((V_\Lambda^T)^+)_\alpha$ there is $y \in ((V_\Lambda^T)^+)_\alpha$ with $B_T(x, y) \neq 0$; and distinct weight spaces of $(V_\Lambda^T)^+$ are B_T-orthogonal.*

```
theorem TPForm_symm (x y : TP) : TPForm x y = TPForm y x := leechTwForm_symm _ _

theorem TPForm_nondegenerate (α : ℂ) (x : TP) (hx : x ∈ plusModule.weight α) (hx0 : x ≠ 0)
 ↪  :
    ∃ y ∈ plusModule.weight α, TPForm x y ≠ 0

theorem TPForm_weightOrth : WeightOrth plusModule TPForm
```

From the mathematics to the Lean statement

`plusModule.weight α` is the weight-α space of the V_Λ^+-module $(V_\Lambda^T)^+$ (Chapter 36). Nondegeneracy is stated weight space by weight space, which is the form needed for the Riesz representation below (a form on an infinite-dimensional space can have zero radical without inducing isomorphisms $M_\alpha \cong M_\alpha^*$; weightwise nondegeneracy is the right notion). `WeightOrth` is Definition 37.22. No hypotheses.

Physical meaning

The twisted sector has no null states: the form is nondegenerate at each conformal weight, and different weights are orthogonal, so B_T is a genuine Zamolodchikov metric on $(V_\Lambda^T)^+$ with symmetric two-point functions. Weight 2 is the lowest level, spanned by $h_i(-\frac{1}{2})\mathbf{1} \otimes t$: the 24 excitations of the ground state at each of the 2^{12} fixed points, matching the 98304-dimensional lowest weight space.

Proof. The weights of $(V_\Lambda^T)^+$ are the integers $k+2$, $k \geq 0$, and $((V_\Lambda^T)^+)_{k+2} = S[\theta]_{2k+1} \otimes T$: the twisted weight of $X^d \otimes t$ is $\frac{24}{16} + \frac{d}{2} = \frac{3}{2} + \frac{d}{2}$, an integer exactly when d is odd; and a monomial of odd doubled degree has an odd number of factors (each factor contributes an odd number $2n+1$), hence is fixed by $\theta = (-1)^{\#\text{factors}} \otimes (-1)_T$. So the whole graded piece of odd degree lies in $(V_\Lambda^T)^+$, and Theorem 37.33 applies inside it. Orthogonality is the second part of the same theorem. □

Example 37.36. On the lowest weight space $((V_\Lambda^T)^+)_2 = S[\theta]_1 \otimes T$, spanned by $h_i(-\frac{1}{2})\mathbf{1} \otimes t$ ($24 \cdot 4096 = 98304$ vectors for a basis of T), $B_T(h_i(-\frac{1}{2}) \otimes t,\ h_j(-\frac{1}{2}) \otimes t') = -\frac{1}{2}\,\delta_{ij}\,\mathtt{TForm}(t, t')$.

What the machine verified

`TPForm_symm`, `TPForm_nondegenerate`, `TPForm_weightOrth`: unconditional. Axioms of `TPForm_nondegenerate`: `[propext, Classical.choice, Quot.sound]` (rechecked).

37.8.4 Invariance of B_T under all of V_Λ^+

Theorem 37.37 (Invariance at the generators). *For every $\beta \in \Lambda$, B_T is FHL-invariant at $x_\beta = e^\beta + e^{-\beta} \in V_\Lambda^+$, a state of weight $\langle\beta,\beta\rangle/2$. Explicitly $B_T(x_{\beta(n)}a, b) = (-1)^{\langle\beta,\beta\rangle/2} B_T(a, x_{\beta(\langle\beta,\beta\rangle-n-2)}b)$. Consequently the set `interSub plusModule TPForm` of Definition 37.25 contains $\mathbf{1}$, is closed under all products, and contains every x_β.*

```
theorem TPForm_invariant_frameX0 (β : leech.carrier) (n : ℤ) (x y : TP) :
    TPForm (mode (plusModule.YM (frameX0P β)) n x) y
      = (-1 : ℂ) ^ (leech.form β β / 2) *
          TPForm x (mode (plusModule.YM (frameX0P β)) (leech.form β β - n - 2) y)

theorem TPForm_fhlInv_frameX0P (β : leech.carrier) :
    FHLInv plusModule TPForm (LatGen.halfNorm leech β) (frameX0P β)

theorem interSub_TPForm :
    leechVOAPlus.vacuum ∈ interSub plusModule TPForm ∧
    (∀ u ∈ interSub plusModule TPForm, ∀ v ∈ interSub plusModule TPForm, ∀ n : ℤ,
      leechVOAPlus.smul u n v ∈ interSub plusModule TPForm) ∧
    ∀ β : leech.carrier, frameX0P β ∈ interSub plusModule TPForm
```

From the mathematics to the Lean statement

`frameXOP β` is $e^{\beta}+e^{-\beta}$ as an element of V_Λ^+ (Chapter 32); `LatGen.halfNorm leech β` $= \langle\beta,\beta\rangle/2$ is its weight. The explicit form uses the integral modes of `plusModule`; it is the twisted identity (37.15) at even $k = 2n$, since $(2\langle\beta,\beta\rangle - 2n - 4)/2 = \langle\beta,\beta\rangle - n - 2$. To pass to `FHLInv` one needs $L_1 x_\beta = 0$, so that only the $j = 0$ term of (37.13) survives; this is the lemma `L_one_latChargeGen` ($L_1 e^{\beta} = 0$ in every lattice VOA: $L_1 e^{\beta}$ would have charge β and weight $\frac{1}{2}\langle\beta,\beta\rangle - 1$, below the minimal weight of the charge-β sector). No hypotheses.

Physical meaning

At the generators $x_\beta = e^{\beta} + e^{-\beta}$, the BPZ reflection rule for the lattice currents of the orbifold: the two-point function in the twisted sector is compatible with the conjugation of these fields, with the sign $(-1)^{\langle\beta,\beta\rangle/2}$. By the generator-reduction principle this will give compatibility with the whole chiral algebra V_Λ^+.

Theorem 37.38 (Full invariance). *B_T is FHL-invariant at every homogeneous $u \in V_\Lambda^+$. The library proves this first conditionally on generation, then unconditionally.*

File `VOA/Moonshine/InvFormTP.lean`.

```
theorem TPForm_fhlInv_of_generates
    (hgen : ∀ S : Submodule ℂ VPlus, leechVOAPlus.vacuum ∈ S →
      (∀ u ∈ S, ∀ v ∈ S, ∀ n : ℤ, leechVOAPlus.smul u n v ∈ S) →
      (∀ β : leech.carrier, frameXOP β ∈ S) → S = ⊤)
    {wt : ℤ} {u : VPlus} (hu : u ∈ leechVOAPlus.grading wt) :

theorem TPForm_fhlInv {wt : ℤ} {u : VPlus} (hu : u ∈ leechVOAPlus.grading wt) :
    InvForm.FHLInv plusModule InvForm.TPForm wt u :=
  InvForm.TPForm_fhlInv_of_generates leechPlus_generated hu
```

From the mathematics to the Lean statement

The residual and its discharge. `hgen` says that V_Λ^+ is generated as a vertex algebra by the states $e^{\beta} + e^{-\beta}$. When the form part of this milestone was written, `hgen` was an open named residual. It was closed by `leechPlus_generated` (`VOA/Moonshine/Generation.lean`, proved in Chapter 32), and the unconditional `TPForm_fhlInv` (namespace `VOA.Moonshine`, file `VOA/Moonshine/Generation.lean`) is the one-line composition shown. The hypothesis `hu` restricts to homogeneous u, as `FHLInv` requires. Same as the textbook statement "B_T is an invariant form on the V_Λ^+-module $(V_\Lambda^T)^+$".

Physical meaning

The twisted sector's metric B_T is invariant under all fields of the orbifold chiral algebra: it is a legitimate two-point function of the sector, with $(V_\Lambda^T)^+$ self-dual (isomorphic to its contragredient, i.e. its own conjugate sector) as the self-conjugate twist-field sector must be. This is what allows the adjoint field $\overline{W}$ to be defined at all.

Proof. Theorem 37.37, Theorem 37.27 and the generation theorem of Chapter 32. □

Remark 37.39. At the twisted level the library also proves invariance under the Heisenberg vectors, $B_{\mathrm{tw}}(h_b(k/2)x, y) = -B_{\mathrm{tw}}(x, h_b(-k/2)y)$ (`leechTwForm_YM_hgen`). This is not used for $(V_\Lambda^T)^+$, because $h_b(-1)\mathbf{1}$ is θ-odd and so is not in V_Λ^+.

What the machine verified

`TPForm_fhlInv_frameX0P`, `interSub_TPForm`: unconditional. `TPForm_fhlInv_of_generates`: conditional on `hgen` (by design). `TPForm_fhlInv`: unconditional. Axioms of `TPForm_fhlInv`: `[propext, Classical.choice, Quot.sound]` (rechecked).

37.9 Graded Riesz representation

Equation (37.4) prescribes the *functional* $\varphi \mapsto B_V(\overline{W}(t)_{(n)}a, \varphi)$. To obtain the *vector* $\overline{W}(t)_{(n)}a \in V_\Lambda^+$ we need a Riesz representation: every suitable functional on V_Λ^+ is $B_V(x, \cdot)$ for a unique x. On an infinite-dimensional space this is false in general (the algebraic dual is much bigger than the space). It is true for functionals that live on finitely many weight spaces, provided the form is nondegenerate on each weight space and the weight spaces are orthogonal. This section proves that, in Lean, for an arbitrary vertex operator algebra. Namespace `VOA.Moonshine.SkewAdjoint`, file `VOA/Moonshine/WbarRiesz.lean`.

Definition 37.40 (Graded nondegeneracy and orthogonality). For a VOA $\mathcal{V} = \bigoplus_k \mathcal{V}_k$ and a bilinear form B on it: B is *graded nondegenerate* if the restriction of B to $\mathcal{V}_k \times \mathcal{V}_k$ is nondegenerate for every k; *graded orthogonal* if $B(\mathcal{V}_m, \mathcal{V}_n) = 0$ for $m \neq n$.

```
noncomputable def gradForm (W : VertexOperatorAlgebra 𝒱) (B : LinearMap.BilinForm ℂ 𝒱) (k :
↪  ℤ) :
    LinearMap.BilinForm ℂ (W.grading k) :=
  B.compl₁₂ (W.grading k).subtype (W.grading k).subtype

def GradedNondeg (W : VertexOperatorAlgebra 𝒱) (B : LinearMap.BilinForm ℂ 𝒱) : Prop :=
  ∀ k : ℤ, (gradForm W B k).Nondegenerate

def GradedOrth (W : VertexOperatorAlgebra 𝒱) (B : LinearMap.BilinForm ℂ 𝒱) : Prop :=
  ∀ m n : ℤ, m ≠ n → ∀ x ∈ W.grading m, ∀ y ∈ W.grading n, B x y = 0
```

Physical meaning

Graded nondegeneracy is the absence of null fields level by level: every state of the VOA at a given weight has a nonvanishing overlap with some other state at that weight, so the Zamolodchikov metric can be inverted. Graded orthogonality is the selection rule that fields of different conformal weight have vanishing two-point functions. These are what a simple (no null states) chiral algebra gives.

Definition 37.41 (The Riesz vector). For a functional f on $\mathcal{V}$ let $f_k = f|_{\mathcal{V}_k}$. Its *graded support* is $\{k : f_k \neq 0\}$. Let $\mathrm{rk}_k : \mathcal{V}_k^* \to \mathcal{V}_k \subseteq \mathcal{V}$ be the inverse of $x \mapsto B(x, \cdot)|_{\mathcal{V}_k}$ when $B|_{\mathcal{V}_k}$ is nondegenerate (and 0 otherwise). The Riesz vector is $\mathrm{riesz}(f) = \sum_k \mathrm{rk}_k(f_k)$.

```
noncomputable def rk (W : VertexOperatorAlgebra 𝒱) (B : LinearMap.BilinForm ℂ 𝒱) (k : ℤ) :
    Dual ℂ (W.grading k) →ₗ[ℂ] 𝒱 :=
  haveI := W.finrank k
  if h : (gradForm W B k).Nondegenerate then
    (W.grading k).subtype ∘ₗ ((gradForm W B k).toDual h).symm.toLinearMap
  else 0

noncomputable def restr (W : VertexOperatorAlgebra 𝒱) (k : ℤ) (f : 𝒱 →ₗ[ℂ] ℂ) :
    Dual ℂ (W.grading k) :=
  f ∘ₗ (W.grading k).subtype
```

```
def gsupp (W : VertexOperatorAlgebra 𝒱) (f : 𝒱 →ₗ[ℂ] ℂ) : Set ℤ := {k | restr W k f ≠ 0}

    (f : 𝒱 →ₗ[ℂ] ℂ) : 𝒱 :=
  ∑ᶠ k : ℤ, rk W B k (restr W k f)
```

From the mathematics to the Lean statement

`W.finrank k` is the VOA axiom that $\mathcal{V}_k$ is finite-dimensional; it is needed because Mathlib's `toDual` (the isomorphism $V \cong V^*$ of a nondegenerate form) exists only in finite dimension. The "else 0" branch of `rk` is a junk value never used under `GradedNondeg`. The $\sum^{\mathrm{f}}$ is a finite sum when the graded support is finite, and `riesz` is only ever used on such functionals.

Physical meaning

The Riesz vector is the dual construction: given a linear functional (an out-state, i.e. a bra) on finitely many levels, it produces the in-state with that overlap, i.e. it raises an index with the inverse Zamolodchikov metric. It is how an out-state obtained by contraction with a three-point function is converted into an ordinary vertex-operator output.

Theorem 37.42 (Riesz property and separation). *Assume B is graded orthogonal and graded nondegenerate. If f has finite graded support then $B(\mathrm{riesz}(f), \varphi) = f(\varphi)$ for all φ. If $B(x, \varphi) = B(y, \varphi)$ for all φ, then $x = y$.*

```
theorem riesz_spec {B : LinearMap.BilinForm ℂ 𝒱} (hO : GradedOrth W B) (hnd : GradedNondeg
↪  W B)
    {f : 𝒱 →ₗ[ℂ] ℂ} (hf : (gsupp W f).Finite) (φ : 𝒱) : B (riesz W B f) φ = f φ

theorem eq_of_form {B : LinearMap.BilinForm ℂ 𝒱} (hO : GradedOrth W B) (hnd : GradedNondeg
↪  W B)
    {x y : 𝒱} (h : ∀ φ, B x φ = B y φ) : x = y
```

From the mathematics to the Lean statement

Three hypotheses, all displayed: orthogonality, weightwise nondegeneracy, finite support of f. Each is necessary: without finite support the sum need not exist; without orthogonality $B(\mathrm{rk}_k(f_k), \varphi)$ would pick up contributions from other weight spaces; without nondegeneracy rk_k does not exist. Same as the textbook statement.

Physical meaning

Raising and lowering indices with the inverse metric: when the metric is nondegenerate on each level, a bra determines a unique ket, and a ket is determined by its overlaps with all states (no null directions).

Proof. For $\varphi \in \mathcal{V}_k$, orthogonality kills every summand except $\mathrm{rk}_k(f_k)$, and $B(\mathrm{rk}_k(f_k), \varphi) = f_k(\varphi)$ by definition of the inverse of $x \mapsto B(x, \cdot)$. Both sides are linear in φ and $\mathcal{V} = \bigoplus \mathcal{V}_k$. Separation: if $B(x - y, \cdot) = 0$, each homogeneous component of $x - y$ pairs to zero with its own weight space (orthogonality), hence vanishes (nondegeneracy). □

What the machine verified

Unconditional apart from the displayed hypotheses. Axioms of `riesz_spec`: `[propext, Classical.choice, Quot.sound]` (rechecked).

37.10 The definition of $\overline{W}$

Throughout this section $\mathcal{V}$ is a VOA, N an ordinary $\mathcal{V}$-module on M, B_V a form on $\mathcal{V}$, B_M a form on M, and `hO : WeightOrth N BM`. These are the section `variables` of `VOA/Moonshine/WbarDef.lean` (namespace `VOA.Moonshine.SkewAdjoint`), so they appear as leading arguments `BV N BM hO` of the definitions below.

37.10.1 The dagger

Expanding the right side of (37.4) exactly as we expanded (37.11), for $t \in M_w$ with $w \in \mathbb{Z}$:

$$B_V\big(\overline{W}(t)_{(n)}a,\varphi\big) = B_M\big(a, W^{\dagger}(t)_{(n)}\varphi\big), \qquad W^{\dagger}(t)_{(n)} := (-1)^w \sum_{j\ge 0} \frac{1}{j!}\, W(L_1^j t)_{(2w-n-2-j)}. \quad (37.16)$$

The *dagger* $W^{\dagger}(t)_{(n)} : \mathcal{V} \to M$ involves only W and $L_1 = \omega_{(2)}$ on M. The j-sum is finite: $L_1^j t$ has weight $w - j$ and vanishes once $w - j$ is below the lowest weight of M.

Definition 37.43 (L_1, a lower bound, the dagger). $L_1^M = \omega_{(2)}^M$; `lowB N` is an integer below which all weight spaces of M vanish; `dagBound N w` $= (w - \texttt{lowB})_+ + 1$; `dagHom N n w` is the right side of (37.16) with $j <$ `dagBound`; and `Wdag N n` applies `dagHom` with w the weight to each integral-weight component of t and 0 to components of non-integral weight.

```
noncomputable def Lp1 (N : OrdVModule W M) : End ℂ M := mode (N.YM W.conformalVector) 2

noncomputable def lowB (N : OrdVModule W M) : ℤ := ⌈N.boundedBelow.choose⌉

noncomputable def dagBound (N : OrdVModule W M) (w : ℤ) : ℕ := (w - lowB N).toNat + 1

noncomputable def dagHom (N : OrdVModule W M) (n w : ℤ) : M →ₗ[ℂ] 𝒱 →ₗ[ℂ] M :=
  (-1 : ℂ) ^ w • ∑ j ∈ Finset.range (dagBound N w),
    ((j.factorial : ℂ)⁻¹) • (wBil N.toWeakModule (2 * w - n - 2 - j)) ∘ₗ (Lp1 N ^ j)

noncomputable def dagFam (N : OrdVModule W M) (n : ℤ) (α : ℂ) :
    N.weight α →ₗ[ℂ] 𝒱 →ₗ[ℂ] M :=
  if h : ∃ w : ℤ, (w : ℂ) = α then (dagHom N n (Classical.choose h)) ∘ₗ (N.weight
   ↪ α).subtype
  else 0

noncomputable def Wdag (N : OrdVModule W M) (n : ℤ) : M →ₗ[ℂ] 𝒱 →ₗ[ℂ] M :=
  letI := DirectSum.IsInternal.chooseDecomposition N.weight N.isInternal
  (DFinsupp.lsum ℂ (dagFam N n)).comp (DirectSum.decomposeLinearEquiv N.weight).toLinearMap
```

From the mathematics to the Lean statement

Decoding. `N.boundedBelow.choose` is a real B with $\mathrm{Re}\,\alpha \ge B$ on nonzero weight spaces; $\lceil B\rceil$ is `lowB`. `wBil N.toWeakModule q` is $(s,\varphi) \mapsto W(s)_{(q)}\varphi$ (Section 37.4); composing with L_1^j gives $W(L_1^j t)_{(q)}$. `Wdag` decomposes t into weight components (`decomposeLinearEquiv`) and applies `dagFam` componentwise (`DFinsupp.lsum`).

Why the non-integral clause is harmless. The formula (37.16) needs $(-1)^w$, meaningful only for integral w. In the application (Leech) all weights of $(V_\Lambda^T)^+$ are integers, so the clause never fires. In general it makes `Wdag` linear in t by fiat.

Well-definedness. The lemma `Wdag_int_eq_sum` shows that on $t \in M_w$ the dagger equals the sum (37.16) with any bound past the vanishing of $L_1^j t$, so the choice of `dagBound` does not matter.

Physical meaning

The dagger is the BPZ conjugate of the field W: by the invariance rule, transposing $W(t,z)$ across the two-point function replaces t by its reflected state $e^{zL_1}(-z^{-2})^{L_0}t$ and z by $1/z$. It computes, in terms of the already-known W, the matrix elements of the twisted × twisted → untwisted field with a final untwisted state pulled to the other side of the pairing.

37.10.2 $\overline{W}$ as a Riesz vector

Definition 37.44 ($\overline{W}$). $\Phi_{n,t,a}(\varphi) = B_M(a, W^\dagger(t)_{(n)}\varphi)$, $\overline{W}(t)_{(n)}a = \mathrm{riesz}(\Phi_{n,t,a})$, and $\overline{W}(t,z) = \sum_n \overline{W}(t)_{(n)}z^{-n-1} \in \mathrm{Hom}(M, \mathcal{V})[[z^{\pm1}]]$.

```
noncomputable def Phi (N : OrdVModule W M) (BM : LinearMap.BilinForm ℂ M) (n : ℤ) (t a : M)
 ↪  :
    𝒱 →ₗ[ℂ] ℂ :=
  (BM a) ∘ₗ (Wdag N n t)

noncomputable def WbarMode (n : ℤ) (t : M) : M →ₗ[ℂ] 𝒱 where
  toFun a := riesz W BV (Phi N BM n t a)

noncomputable def Wbar (t : M) : FormalDist (M →ₗ[ℂ] 𝒱) :=
  fun k => WbarMode BV N BM hO (-k - 1) t

theorem mode_Wbar (t : M) (n : ℤ) : mode (Wbar BV N BM hO t) n = WbarMode BV N BM hO n t
```

From the mathematics to the Lean statement

`WbarMode BV N BM hO n t` is the linear map $a \mapsto \overline{W}(t)_{(n)}a$ (its linearity fields, which use `hO` through the finiteness of the graded support of Φ, are omitted). The definition itself needs *no* hypothesis on B_V; if B_V were degenerate it would still be defined, but the adjunction below would fail. **Could this be the trap $\overline{W} = 0$?** Not by definition alone: for instance with $B_V = 0$ every `rk` is the junk 0 and $\overline{W} = 0$. This is precisely why the adjunction (Theorem 37.45) carries the hypotheses on B_V, why the Leech instance needs the nondegeneracy theorem of Chapter 32, and why Theorem 37.57 is proved.

Physical meaning

The conjugate field $\overline{W}(t,z)\colon (V_\Lambda^T)^+ \to V_\Lambda^+$ is the operator "twist field × twist field → untwisted field": the OPE in which two twist fields collide and the branch cuts cancel to leave an ordinary field. It is defined as the adjoint of W under the two-point metrics, $\langle \overline{W}(t,z)a, \varphi\rangle = \langle a, W(t^*, z^{-1})\varphi\rangle$, which expresses the three-point coupling $\langle V^+|\overline{W}|T\rangle$ through the coupling $\langle T|W|V^+\rangle$ already constructed. Heuristically it is the same three-point function read as an OPE of two twist fields instead of an OPE of a twist field with an untwisted field. It is nontrivial that the twisted sector actually couples to itself; if $\overline{W} = 0$ the twist fields would be decoupled and the extension would be a square-zero extension of V_Λ^+.

Theorem 37.45 (The defining adjunction, DGM (4.3)). *If B_V is graded orthogonal and graded nondegenerate, then for all n, t, a, φ, $B_V(\overline{W}(t)_{(n)}a, \varphi) = B_M(a, W^\dagger(t)_{(n)}\varphi)$; explicitly, for $t \in M_w$ and any R with $L_1^j t = 0$ for $j \geq R$,*

$$B_V\big(\overline{W}(t)_{(n)}a, \varphi\big) = (-1)^w \sum_{j<R} \frac{1}{j!} B_M\big(a, W(L_1^j t)_{(2w-n-2-j)}\varphi\big).$$

The vector $\overline{W}(t)_{(n)}a$ is the unique vector with this property.

```

From the mathematics to the Lean statement

Hypotheses. `hVo`, `hVnd` on B_V (Definition 37.40); `hO` on B_M (section variable); for the explicit form, `ht` (t homogeneous of integral weight w) and `hR`. **Comparison.** The explicit form is the mode expansion of (37.4), derived in (37.16): it is DGM (4.3), including the sign $(-1)^w$. No invariance of B_V or B_M is assumed at this stage; invariance enters only in the commutator formula. The proof of `form_WbarMode` is the one-line term shown: the Riesz property applied to Φ, whose graded support is finite (a single weight, by the next theorem).

Physical meaning

This is the defining three-point relation: the adjoint exists exactly when the metric on V_Λ^+ has no null fields, and it is unique. The factor $(-1)^w$ and the sum over $L_1^j t$ are the BPZ conjugation of the field of t. Physically, the coupling of two twist fields to an untwisted field is uniquely determined by the coupling of a twist field to the untwisted sector and the metrics.

Theorem 37.46 (Grading and truncation of $\overline{W}$). *If $t \in M_w$ and $a \in M_b$ ($w, b \in \mathbb{Z}$) then $\overline{W}(t)_{(n)}a \in \mathcal{V}_{b+w-n-1}$. For all t, a, $\overline{W}(t)_{(n)}a = 0$ for $n \gg 0$; i.e. $\overline{W}(t,z)a \in \mathcal{V}((z))$.*

↪  0

theorem Wbar_trunc (t : M) : ∀ a : M, ∃ B : ℤ, ∀ k : ℤ, k < B → Wbar BV N BM hO t k a = 0
```

From the mathematics to the Lean statement

No hypothesis on B_V: these hold for the Riesz vector by construction. The weight $b+w-n-1$ is the usual weight of an intertwining operator's output (sum of the input weights minus $n+1$). `Wbar_trunc` is the same statement in terms of coefficients ($k = -n-1$).

Physical meaning

The selection rule for the three-point function: $\overline{W}(t)_{(n)}$ maps a state of weight b to weight $b + w - n - 1$, as for any chiral vertex operator, and the vanishing for large n is the finite pole order of the OPE in a sector with energy bounded below (the untwisted algebra has no negative weights).

Proof. By the weights of W (output of $W(s)_{(q)}\varphi$ has weight $\mathrm{wt}\, s + \mathrm{wt}\, \varphi - q - 1$), $W^{\dagger}(t)_{(n)}$ maps $\mathcal{V}_k$ to $M_{k-w+n+1}$. By orthogonality on M, $\Phi_{n,t,a}$ vanishes on $\mathcal{V}_k$ unless $k - w + n + 1 = b$, so the Riesz vector lies in the single weight space $k = b + w - n - 1$. Truncation: for $n \geq b + w$ that weight is negative and $\mathcal{V}$ has no negative weights. □

What the machine verified

`form_WbarMode`, `form_WbarMode_int`, `WbarMode_eq_of_form`: conditional exactly on `hVo`, `hVnd` (and `hO`). `WbarMode_mem`, `WbarMode_trunc`: only `hO`. All proved; axioms [`propext`, `Classical.choice`, `Quot.sound`].

37.11 Properties of $\overline{W}$

37.11.1 The L_{-1}-derivative property

Theorem 37.47 ($\overline{W}(L_{-1}t, z) = \partial_z \overline{W}(t, z)$). *For every $t \in M$ and n: $\overline{W}(L_{-1}t)_{(n)} = -n\,\overline{W}(t)_{(n-1)}$.*

```

     ↪ t

theorem Wbar_deriv (t : M) :
    Wbar BV N BM hO (Lm1 N.toWeakModule t) = deriv (Wbar BV N BM hO t)
```

(`VOA/Moonshine/WbarDeriv.lean`.)

From the mathematics to the Lean statement

Only the section hypothesis `hO` is used: the identity already holds for the defining functionals, hence for their Riesz vectors (`riesz` is linear on finitely supported functionals). The intermediate statements are the $\mathfrak{sl}_2$ relation $[L_1, L_{-1}] = 2L_0$ on M and the dagger identity; they are listed because they are of independent use (Theorem 37.58).

Physical meaning

Translation covariance of the conjugate field: the field of the derivative state is the derivative of the field. It holds for $\overline{W}$ because the two-point metrics are invariant under translations (they intertwine L_{-1} with L_1) and holds for W by construction.

Proof. By Theorem 37.13, $W(L_{-1}s)_{(q)} = -q\,W(s)_{(q-1)}$. In $W^{\dagger}(L_{-1}t)_{(n)}$ (note $L_{-1}t$ has weight $w + 1$) we must move L_1^j past L_{-1}: $L_1^{j+1}L_{-1}t = L_{-1}L_1^{j+1}t + (j+1)(2w - j)L_1^j t$ (induction on $[L_1, L_{-1}] =$

$2L_0$). Substituting, the $L_{-1}L_1^j t$ terms give $-(2w+2-n-2-j)$ times $W(L_1^j t)_{(2w-n-1-j)}$, the correction terms give $j(2w-j+1)/j!$ times $W(L_1^{j-1}t)_{(2w-n-j)}$; reindexing $i=j-1$, the coefficient of $\frac{1}{i!}W(L_1^i t)_{(2w-n-1-i)}$ is $-(2w-n-i)+(2w-i)=n$, and the overall sign $(-1)^{w+1}=-(-1)^w$ turns this into $-n$. The result is $-n\,W^\dagger(t)_{(n-1)}$. Pairing with a and taking Riesz vectors gives the claim. □

37.11.2 The commutator formula: first for quasi-primary states

Definition 37.48 (Invariant form on the VOA). `VInv W B_V`: for every homogeneous $u \in \mathcal{V}_{\mathrm{wt}}$, $B_V(u_{(n)}a,b)$ is given by (37.13) with $\mathcal{V}$ in place of M. It is literally the library's `InvariantForm.IsFullyInvariant` (`vInv_of_isFullyInvariant` is the identity).

```
def VInv (W : VertexOperatorAlgebra V) (BV : LinearMap.BilinForm ℂ V) : Prop :=
  ∀ (wt : ℤ) (u : V), u ∈ W.grading wt → ∀ (n : ℤ) (a b : V),
    BV (W.smul u n a) b
      = (-1 : ℂ) ^ wt • ∑ j ∈ Finset.range (wt.toNat + 1), ((j.factorial : ℂ)⁻¹) •
          BV a (W.smul (((W.L 1) ^ j) u) (2 * wt - n - 2 - (j : ℤ)) b)
```

(`VOA/Moonshine/WbarComm.lean`.)

Physical meaning

Same as for modules, with the adjoint module: this is the invariant Zamolodchikov metric on the untwisted chiral algebra itself, $\langle u|v\rangle$ with the BPZ conjugation $L_n \mapsto L_{-n}$, normalised by $\langle \mathbf{1}|\mathbf{1}\rangle = 1$.

Theorem 37.49 (Dagger commutator identity). *Let $u \in \mathcal{V}_p$ be quasi-primary ($L_1 u = 0$), $t \in M_w$, $Q = 2p-m-2$, and J past the truncation of u on t. Then*

$$(-1)^p\Big(W^\dagger(t)_{(n)}\big(u_{(Q)}\varphi\big) - u_{(Q)}\,W^\dagger(t)_{(n)}\varphi\Big) = \sum_{r<J}\binom{m}{r} W^\dagger\big(u_{(r)}t\big)_{(m+n-r)}\varphi.$$

```
theorem Wdag_comm_qp (N : OrdVModule W M) {p : ℤ} {u : V} (hu : u ∈ W.grading p)
    (hqp : W.L 1 u = 0) {w : ℤ} {t : M} (ht : t ∈ N.weight (w : ℂ)) (m n : ℤ) (J : ℕ)
    (hJ : ∀ j : ℕ, J ≤ j → N.act u j t = 0) (φ : V) :
    (-1 : ℂ) ^ p • (Wdag N n t (W.smul u (2 * p - m - 2) φ)
        - N.act u (2 * p - m - 2) (Wdag N n t φ))
      = ∑ r ∈ Finset.range J, gBinom m r • Wdag N (m + n - r) (N.act u r t) φ
```

(`VOA/Moonshine/WbarCore.lean`.)

From the mathematics to the Lean statement

This is the transpose of the commutator formula we want for $\overline{W}$: for quasi-primary u the FHL transpose of $u_{(m)}$ is $(-1)^p u_{(Q)}$, $Q=2p-m-2$ (Example 37.21). It involves no forms at all. Hypotheses `hu`, `hqp`, `ht`, `hJ` as stated.

Physical meaning

Technical lemma: the Ward identity of the chiral currents on the conjugate field, with all forms eliminated, formulated for the BPZ-transposed fields. It is part of the proof that the OPE of a quasi-primary current with $\overline{W}$ has the same singular structure as with W.

Proof on paper. Expand both sides with (37.16). On the left, apply the commutator formula of W (Theorem 37.15) to each $W(L_1^j t)$ with the mode $u_{(Q)}$; the result is a double sum over j and s of $\binom{Q}{s} W(u_{(s)}L_1^j t)_{(\dots)}$. On the right, each $W^\dagger(u_{(r)}t)$ contains $L_1^k(u_{(r)}t)$, which must be rewritten with u to the left: for quasi-primary u, $\frac{1}{k!}L_1^k(u_{(r)}x) = \sum_{b+c=k}\frac{1}{b!}\binom{2p-r-2}{c}u_{(r+c)}L_1^b x$ (from $[L_1, u_{(r)}] = (2p-r-2)u_{(r+1)} + (L_1 u)_{(r)}$, the $\mathfrak{sl}_2$-covariance of a weight-p field). Both sides are now sums of the same terms $\frac{1}{b!}W(u_{(s)}L_1^b t)_{(2p+2w-m-n-4-b-s)}\varphi$, and comparing coefficients reduces to the Vandermonde-type identity $\sum_r (-1)^r\binom{m}{r}\binom{2p-2-r}{s-r} = \binom{2p-2-m}{s}$, with $2p-2-m = Q$. □

Theorem 37.50 (Commutator formula for quasi-primary u). *Assume B_V graded orthogonal, graded nondegenerate and invariant (*`VInv`*), and B_M invariant at every homogeneous state. Then for quasi-primary $u \in \mathcal{V}_p$ and $t \in M_w$,*

$$u_{(m)}\overline{W}(t)_{(n)}a - \overline{W}(t)_{(n)}u_{(m)}a = \sum_{r<J}\binom{m}{r}\overline{W}(u_{(r)}t)_{(m+n-r)}a.$$

```
theorem WbarMode_comm_qp (hVo : GradedOrth W BV) (hVnd : GradedNondeg W BV) (hVinv : VInv W
↪  BV)
    (hMinv : ∀ (wt : ℤ) (u : 𝒱), u ∈ W.grading wt → FHLInv N BM wt u)
    {p : ℤ} {u : 𝒱} (hu : u ∈ W.grading p) (hqp : W.L 1 u = 0) {w : ℤ} {t : M}
    (ht : t ∈ N.weight (w : ℂ)) (m n : ℤ) (J : ℕ) (hJ : ∀ j : ℕ, J ≤ j → N.act u j t = 0)
    (a : M) :
    W.smul u m (WbarMode BV N BM hO n t a) - WbarMode BV N BM hO n t (N.act u m a)
      = ∑ r ∈ Finset.range J, gBinom m r • WbarMode BV N BM hO (m + n - r) (N.act u r t) a
```

Physical meaning

The Ward identity for $\overline{W}$ on quasi-primary currents: a current u passing the conjugate field $\overline{W}(t,z)$ obeys the same OPE with $\overline{W}$ as with W, with the residues given by the action of u on the twist-field state t. It is obtained by moving the current across the two metrics, using their invariance.

Proof. Pair both sides with φ under B_V and use separation (Theorem 37.42). By invariance of B_V, $B_V(u_{(m)}x, \varphi) = (-1)^p B_V(x, u_{(Q)}\varphi)$; by the adjunction this is $(-1)^p B_M(a, W^\dagger(t)_{(n)}u_{(Q)}\varphi)$. By invariance of B_M, $B_V(\overline{W}(t)_{(n)}u_{(m)}a, \varphi) = B_M(u_{(m)}a, W^\dagger\varphi) = (-1)^p B_M(a, u_{(Q)}W^\dagger\varphi)$. The difference is $B_M(a,\cdot)$ applied to the left side of Theorem 37.49, which is $\sum\binom{m}{r}B_M(a, W^\dagger(u_{(r)}t)_{(m+n-r)}\varphi) = \sum\binom{m}{r}B_V(\overline{W}(u_{(r)}t)_{(m+n-r)}a, \varphi)$. □

37.11.3 The commutator formula for all states

Theorem 37.51 (Intertwining commutator formula for $\overline{W}$). *Assume: B_V graded orthogonal, graded nondegenerate and invariant; B_M invariant at every homogeneous state; and $L_1\mathcal{V}_1 = 0$. Then for* every *$u \in \mathcal{V}$, $m, n \in \mathbb{Z}$, $t, a \in M$ and J past the truncation of u on t,*

$$u_{(m)}\overline{W}(t)_{(n)}a - \overline{W}(t)_{(n)}\big(u_{(m)}a\big) = \sum_{r<J}\binom{m}{r}\overline{W}\big(u_{(r)}t\big)_{(m+n-r)}a. \tag{37.17}$$

```

From the mathematics to the Lean statement

Type. This is (37.6) for an intertwiner of type $\binom{\mathcal{V}}{M\,M}$: first argument $t \in M$, second $a \in M$, output in $\mathcal{V}$, with $\mathcal{V}$ acting on the output by `W.smul` and on the second argument by `N.act`. **Hypotheses, one by one.** `hVo`, `hVnd`: needed for the Riesz representation. `hVinv`: invariance of B_V, needed to move $u_{(m)}$ across B_V. `hMinv`: invariance of B_M at every homogeneous u, needed to move $u_{(m)}$ across B_M. `hqpV`: $L_1\mathcal{V}_1 = 0$, used only for the quasi-primary decomposition below. `hJ`: truncation bound. For the Leech case all are discharged (Section 37.12). Same as the textbook statement, for all u (not only quasi-primary, not only homogeneous).

Physical meaning

This is what makes $\overline{W}$ a bona fide chiral vertex operator, of type twisted × twisted → untwisted: its transformation under the chiral algebra is the same as that of any field of a (twisted) state. It requires the metrics to be invariant and nondegenerate: invariance transports the currents across the pairing, and nondegeneracy turns the resulting identity between pairings into an identity of states. The extension to non-quasi-primary currents uses only that these are L_{-1}-descendants of quasi-primary ones.

Proof on paper. The set of u for which (37.17) holds (for all large J) is a linear subspace, and it is closed under $u \mapsto L_{-1}u$: since $(L_{-1}u)_{(m)} = -m\,u_{(m-1)}$ and $(L_{-1}u)_{(r)}t = -r\,u_{(r-1)}t$, the formula for $L_{-1}u$ follows from the formula for u at $m-1$ after the Pascal-type rearrangement $m\binom{m-1}{r-1} = r\binom{m}{r}$. Every homogeneous u of weight $p \geq 1$ decomposes as $u = u_0 + L_{-1}c$ with u_0 quasi-primary of weight p and c of weight $p-1$ (the $\mathfrak{sl}_2$ quasi-primary decomposition, which in a VOA of CFT type needs exactly $L_1\mathcal{V}_1 = 0$; Lean name `qpDecomp`, `VOA/Core/QuasiPrimaryDecomp.lean`). By induction on the weight, Theorem 37.50 for u_0 and the closure under L_{-1} give the formula for u; weight 0 is $\mathbb{C}\mathbf{1}$, which is quasi-primary. □

37.11.4 Locality and translation covariance

Theorem 37.52 (Locality of $Y(u,z_1)$ and $\overline{W}(t,z_2)$). *Under the hypotheses of Theorem 37.51, for every $u \in \mathcal{V}$, $t \in M$ there is N with $(z_1-z_2)^N\big(Y(u,z_1)\overline{W}(t,z_2) - \overline{W}(t,z_2)Y_M(u,z_1)\big) = 0$ in $\mathrm{Hom}(M,\mathcal{V})[[z_1^{\pm1},z_2^{\pm1}]]$. Moreover $[L_{-1},\overline{W}(t,z)] = \partial_z\overline{W}(t,z)$, in coefficients $L_{-1}\circ\overline{W}(t)_k - \overline{W}(t)_k\circ L_{-1}^M = (k+1)\overline{W}(t)_{k+1}$.*

```

From the mathematics to the Lean statement

Hypotheses as in Theorem 37.51. Coefficient conventions as in Theorem 37.17; `Wbar ... t k` is the z^k coefficient. The covariance statement is the shape in which the block-matrix machinery of Chapter 38 consumes it.

Physical meaning

Mutual locality of the conjugate field $\overline{W}(t,z)$ with all untwisted currents: untwisted currents see no branch cut from a pair of twist fields that is fused into an untwisted field. This is the single-valuedness of the correlator $\langle\varphi|u(z_1)\overline{W}(t,z_2)|a\rangle$ in z_1. Together with W it is the exchange property of fields of different sectors with an invariant current, and the translation covariance expresses $L_{-1}=\partial_z$. These are the *one-twisted* locality relations; locality of two twisted fields with each other is much harder.

Proof. Locality follows from (37.17) exactly as Theorem 37.17 follows from Theorem 37.15. Covariance is (37.17) at $u=\omega$, $m=0$ (only $r=0$ survives since $\binom{0}{r}=\delta_{r0}$), combined with Theorem 37.47: $[L_{-1},\overline{W}(t)_{(n)}]=\overline{W}(L_{-1}t)_{(n)}=-n\overline{W}(t)_{(n-1)}$. □

What the machine verified

`Wbar_deriv`: only `hO`. `Wdag_comm_qp`: form-free, unconditional. `WbarMode_comm`, `Wbar_local`, `Wbar_homCov`: conditional exactly on `hVo`, `hVnd`, `hVinv`, `hMinv`, `hqpV` (and `hO`). All proved; axioms of `Wdag_comm_qp`, `WbarMode_comm`, `Wbar_local`: `[propext, Classical.choice, Quot.sound]` (rechecked).

37.12 The Leech instance of $\overline{W}$

37.12.1 The form B_V on V_Λ^+

For B_V the library takes the *canonical invariant form* of the vertex operator algebra V_Λ^+ (Li's theorem, Theorem 5.56: a VOA of CFT type with $L_1V_1=0$ has a fully invariant form, unique once normalised by $(\mathbf{1},\mathbf{1})=1$). Its hypotheses are $\mathbf{1}\neq 0$ and $L_1(V_\Lambda^+)_1=0$; the latter holds trivially because $(V_\Lambda^+)_1=0$. File `VOA/Moonshine/WbarLeech.lean`, namespace `VOA.Moonshine`.

```
theorem leechVOAPlus_L1_one : ∀ v, v ∈ leechVOAPlus.grading 1 → leechVOAPlus.L 1 v = 0

```

From the mathematics to the Lean statement

`InvariantForm leechVOAPlus` is the library's structure "bilinear form with $(L_n a,b)=(a,L_{-n}b)$" (Definition 5.48); `canonicalInvariantForm` is Li's form, and `canonicalInvariantForm_isFullyInvariant` proves it satisfies the full FHL invariance

`IsFullyInvariant`, which is `VInv`. Orthogonality of distinct weights follows from L_0-adjointness. What is *not* free is graded nondegeneracy: Li's form is nondegenerate if and only if the VOA is simple (for CFT type), and the library has no general simplicity theorem for V_Λ^+.

37.12.2 The definition and the unconditional properties

Definition 37.53. $\overline{W}(t,z)$ for $t \in (V_\Lambda^T)^+$ is the adjoint of `leechWsk t` with respect to $B_V =$ `leechBV` and $B_T =$ `TPForm`.

  Wbar_deriv _ _ _ _ t
```

From the mathematics to the Lean statement

The four arguments of `Wbar` are B_V, the module, B_M and the orthogonality proof `TPForm_weightOrth` (Theorem 37.35). These three statements need nothing beyond `h0`, which is supplied.

Physical meaning

The conjugate field of the Leech orbifold: the OPE of two twist fields of the 24 Leech bosons, producing an operator in V_Λ^+. It is defined using the canonical invariant two-point function B_V (unique up to normalisation for a VOA of CFT type with $L_1V_1 = 0$) on the untwisted side and B_T on the twisted side. The quantity whose existence this requires is nondegeneracy of B_V (no null fields in V_Λ^+), which is established below.

37.12.3 The residual `hnd` and its discharge

Theorem 37.54 (Conditional properties). *If B_V is graded nondegenerate (hypothesis* `hnd`*), then the Leech $\overline{W}$ satisfies the adjunction DGM (4.3), the commutator formula (37.17) for all $u \in V_\Lambda^+$, locality with every $Y(u,z)$, and translation covariance.*

```

  WbarMode_comm leechBV_orth hnd leechBV_inv (fun _ _ hu => TPForm_fhlInv hu)
   ↪ leechVOAPlus_L1_one
    u m t n a J hJ
```

From the mathematics to the Lean statement

A hidden-looking hypothesis. The statements of `leechWbar_adj` and `leechWbar_comm` as printed do not mention `hnd`, but the file declares `variable (hnd : GradedNondeg leechVOAPlus leechBV)` followed by `include hnd`; so each of these theorems takes `hnd` as its *first explicit argument*. (One sees it used in the proof term of `leechWbar_comm`.) The same holds for `leechWbar_local` and `leechWbar_homCov`, whose statements are those of Theorem 37.52 at the Leech data. A referee must read these as "`hnd` ⇒ …".
The other hypotheses of Theorem 37.51 are discharged in the proof term: `leechBV_orth`, `leechBV_inv`, `TPForm_fhlInv` (Theorem 37.38), `leechVOAPlus_L1_one`.

Physical meaning

If the untwisted chiral algebra is simple (no null states), then all the general properties established above apply to the genuine conjugate field: its adjunction with W, its OPE with the invariant currents, locality, translation covariance. The hypothesis is the physical statement that the metric on the vertex algebra has no zero modes; it is the main assumption that has to be checked for the actual model.

Theorem 37.55 (B_V is graded nondegenerate; $\overline{W}$ unconditional)**.** `hnd` *holds. Consequently the adjunction, the commutator formula, locality and covariance of the Leech* $\overline{W}$ *hold unconditionally.*

```

(VOA/Moonshine/NondegLeech.lean.)

From the mathematics to the Lean statement

The proof terms shown make the logic transparent: each primed theorem is the conditional one applied to `leechBV_gradedNondeg`. That theorem is proved in Chapter 32 *without* simplicity of V_Λ^+: the library writes down an explicit lattice form on V_Λ, proves it invariant and nondegenerate and θ-isometric, identifies its restriction to V_Λ^+ with `leechBV` by uniqueness of the normalised invariant form, and deduces that the radical of `leechBV` is zero (`leechBVForm_leftRadical`). The primed statements have no remaining hypotheses other than the truncation bound `hJ` (resp. `ht`, `hR`).

Physical meaning

The nondegeneracy of the two-point function of the Leech orbifold's untwisted sector: no null fields. This is what upgrades the conditional properties of $\overline{W}$ to unconditional ones, and it ensures the OPE of two twist fields is genuinely determined by (and consistent with) the coupling to the untwisted fields.

Trap / dead end

Signs that must not be "simplified" (`Notes/M8hRoute.md`, §1a and dead end 3). In the numerical E_8 model, dropping the factor $(-1)^w$ in the adjunction (37.16), or replacing the lattice form's sign $c(\alpha) = (-1)^{\langle\alpha,\alpha\rangle/2}\varepsilon(\alpha,\alpha)$ of Chapter 32 by $c(\alpha) = 1$, breaks the twisted×twisted relation (4.23) (relative residual ≈ 2). These signs are therefore not conventions that can be changed freely: they are necessary for $\overline{W}$ to be the operator that later makes $V^\natural$ a vertex algebra. Numerical evidence (`tt.py`, `tt_K3.log`), not proof.

What the machine verified

`leechWbar_mem`, `leechWbar_trunc`, `leechWbar_deriv`: unconditional. `leechWbar_adj`, `leechWbar_comm`, `leechWbar_local`, `leechWbar_homCov`: conditional on `hnd`. `leechBV_gradedNondeg` and the four primed theorems: unconditional; axioms of `leechBV_gradedNondeg` and `leechWbar_comm'`: `[propext, Classical.choice, Quot.sound]` (rechecked).

37.13 The genuine $\overline{W}$ in the block field, and the anti-trap certificate

37.13.1 Plugging $\overline{W}$ into the block field

Chapter 38 builds the block vertex operators (37.2) for an *arbitrary* family `Wbar`, and asks of it a commutator formula:

```
def WbarComm (Wbar : TP → FormalDist (TP →ₗ[ℂ] SkewVP)) : Prop :=
  ∀ (u : SkewVP) (m : ℤ) (t : TP) (n : ℤ) (J : ℕ),
    (∀ j : ℕ, J ≤ j → mode (plusModule.YM u) j t = 0) →
```

```
    mode (leechVOAPlus.Y u) m ∘ₗ mode (Wbar t) n - mode (Wbar t) n ∘ₗ mode (plusModule.YM
    ↪ u) m
      = ∑ r ∈ Finset.range J, gBinom m r • mode (Wbar (mode (plusModule.YM u) r t)) (m + n
      ↪ - r)

noncomputable def YnatU (u : SkewVP) : FormalDist (End ℂ Vnat) :=
  diagF (leechVOAPlus.Y u) (plusModule.YM u)

noncomputable def YnatT (Wbar : TP → FormalDist (TP →ₗ[ℂ] SkewVP)) (t : TP) :
    FormalDist (End ℂ Vnat) :=
  offF (Wbar t) (leechWsk t)
```

(`VOA/Moonshine/VnatFields.lean`, documented in Chapter 38.) Here `Vnat` is the product `SkewVP × TP`, `diagF a b` the diagonal block distribution $\mathrm{diag}(a,b)$ and `offF c d` the off-diagonal one with c in the upper right and d in the lower left, so `YnatT Wbar t` is the twisted column of (37.2). `WbarComm` is (37.17) written as an identity of linear maps.

Theorem 37.56 (The genuine $\overline{W}$ satisfies the block-field hypotheses). `leechWbar` *satisfies* `WbarComm`*, and the block fields of untwisted and twisted states are mutually local: for all* $u \in V_\Lambda^+$, $t \in (V_\Lambda^T)^+$, $Y^\natural((u,0),z)$ *and* $Y^\natural((0,t),z)$ *are local on* $V^\natural$.

```
theorem leechWbar_WbarComm : WbarComm leechWbar

theorem YnatU_YnatT_local_genuine (u : SkewVP) (t : TP) : Local (YnatU u) (YnatT leechWbar
↪ t) :=
  YnatU_YnatT_local leechWbar_WbarComm u t

theorem YnatT_YnatU_local_genuine (t : TP) (u : SkewVP) : Local (YnatT leechWbar t) (YnatU
↪ u) :=
  YnatT_YnatU_local leechWbar_WbarComm t u
```

(`VOA/Moonshine/VnatGenuine.lean`.)

From the mathematics to the Lean statement

`Local` is Definition 37.4 on $\mathrm{End}(V^\natural)$. A block computation (Chapter 38, `local_diag_off`) shows that $\mathrm{diag}(a,b)$ and $\mathrm{offdiag}(c,d)$ are local iff $ac - cb$ and $bd - da$ are killed by a power of $(z_1 - z_2)$; these are Theorem 37.52 (via `WbarComm`) and Theorem 37.17. These are relations (3) and (4) of Section 37.1. Unconditional.

Physical meaning

The block-matrix $Y^\natural$ of a twisted and an untwisted state is the full vertex operator of the sum of the two sectors; the statement is that untwisted and twisted fields are mutually local, i.e. they have an OPE with finite pole order and commute up to contact terms. This is the consistency of the operator algebra of the orbifold with its twist fields at the level of one twist-field insertion; the harder consistency condition with two twist fields remains.

37.13.2 The genuine $\overline{W}$ is not zero

Theorem 37.57 (The vacuum pairing). (i) *For* $t, t' \in ((V_\Lambda^T)^+)_2$ *(the lowest weight space),* $\overline{W}(t)_{(3)}t' = B_T(t',t)\,\mathbf{1}$. (ii) *For every nonzero* $t \in ((V_\Lambda^T)^+)_2$ *there are* $t' \in ((V_\Lambda^T)^+)_2$ *and* $c \neq 0$ *with* $\overline{W}(t)_{(3)}t' = c\,\mathbf{1}$. (iii) $\overline{W} \neq 0$.

```
theorem leechWbarMode_three_weight_two {t t' : TP} (ht : t ∈ plusModule.weight ((2 : ℤ) :
↪ ℂ))
```

```
    (ht' : t' ∈ plusModule.weight ((2 : ℤ) : ℂ)) :
    leechWbarMode 3 t t' = TPForm t' t • leechVOAPlus.vacuum

theorem leechWbar_vacuum_pairing_ne_zero {t : TP} (ht : t ∈ plusModule.weight ((2 : ℤ) :
↪  ℂ))
    (ht0 : t ≠ 0) :
    ∃ t' ∈ plusModule.weight ((2 : ℤ) : ℂ), ∃ c : ℂ, c ≠ 0 ∧
      leechWbarMode 3 t t' = c • leechVOAPlus.vacuum

theorem leechWbar_ne_zero : leechWbar ≠ 0
```

From the mathematics to the Lean statement

Decoding. `((2 : ℤ) : ℂ)` is the weight 2, cast to $\mathbb{C}$ because module weights are complex. `leechWbarMode 3 t t'` is $\overline{W}(t)_{(3)}t'$. `leechWbar ≠ 0` compares the function $t \mapsto \overline{W}(t,z)$ with the zero function.

Why this is the right certificate. The trap of Section 37.1 is $\overline{W} = 0$. Statement (iii) excludes it outright, and (ii) says more: the twisted×twisted product of lowest-weight states reaches the vacuum through the nondegenerate pairing B_T, which reflects the nondegenerate invariant form that a simple algebra must carry (in the square-zero extension this product is identically zero). It is not by itself a simplicity proof; simplicity of $V^\natural$ is proved in Chapter 38. No hypotheses beyond the displayed homogeneity.

Physical meaning

The twisted × twisted OPE actually produces the identity: the product of two lowest-weight twist fields contains the vacuum with coefficient the two-point function $B_T(t',t)$, which is non-vanishing because the Zamolodchikov metric on the twisted sector is nondegenerate. This is the CFT statement that two twist fields $\sigma\sigma \sim 1/(z-w)^{2h} + \dots$ fuse to the identity, and it is why $\overline{W} \neq 0$: without it the twisted sector would not interact with itself and the sum $V_\Lambda^+ \oplus (V_\Lambda^T)^+$ would be a decoupled, non-simple square-zero extension, not the Moonshine module. (Heuristic: the coefficient is the identity channel in the two-point function.)

Proof on paper. (i) By Theorem 37.46, $\overline{W}(t)_{(3)}t'$ has weight $2+2-3-1=0$, and $(V_\Lambda^+)_0 = \mathbb{C}\mathbf{1}$; write it $c\mathbf{1}$. Pair with $\mathbf{1}$: $c = cB_V(\mathbf{1},\mathbf{1}) = B_V(\overline{W}(t)_{(3)}t',\mathbf{1})$. By the adjunction with $w=2$ and $n=3$, this is $(-1)^2\sum_j \frac{1}{j!}B_T(t', W(L_1^j t)_{(4-3-2-j)}\mathbf{1})$. Since $L_1 t$ has weight 1 and $((V_\Lambda^T)^+)_1 = 0$, only $j=0$ remains: $B_T(t', W(t)_{(-1)}\mathbf{1}) = B_T(t',t)$ by Example 37.11. (ii) Choose t' with $B_T(t,t') \neq 0$ (Theorem 37.35) and use symmetry. (iii) $((V_\Lambda^T)^+)_2$ has dimension $98304 > 0$, so a nonzero t exists, and $c\mathbf{1} \neq 0$ because $\mathbf{1} \neq 0$. □

What the machine verified

`leechWbar_WbarComm`, `YnatU_YnatT_local_genuine`, `YnatT_YnatU_local_genuine`, `leechWbarMode_three_weight_two`, `leechWbar_vacuum_pairing_ne_zero`, `leechWbar_ne_zero`: unconditional. Axioms of `leechWbar_WbarComm`, `YnatU_YnatT_local_genuine`, `leechWbarMode_three_weight_two`, `leechWbar_ne_zero`: `[propext, Classical.choice, Quot.sound]` (rechecked).

37.14 Skew-symmetry of $\overline{W}$

If $V^\natural$ is a vertex algebra, skew-symmetry for two twisted states t_1, t_2 reads, in the untwisted component, $\overline{W}(t_1,z)t_2 = e^{zL_{-1}}\overline{W}(t_2,-z)t_1$ (DGM (4.9)). This identity is one of the inputs that reduce the

twisted×twisted locality to a single relation in Chapter 38. It is proved directly from the construction. (The file `VOA/Moonshine/M8h0Skew.lean` is assigned to Chapter 38; we state the theorem here because it is a property of $\overline{W}$.)

Theorem 37.58 (Skew-symmetry of $\overline{W}$). *For homogeneous $t_1 \in ((V_\Lambda^T)^+)_a$, $t_2 \in ((V_\Lambda^T)^+)_b$ and every $n \in \mathbb{Z}$,*

$$\overline{W}(t_1)_{(n)}t_2 = \sum_{i\ge 0} \frac{(-1)^{n+i+1}}{i!}\, L_{-1}^{i}\Big(\overline{W}(t_2)_{(n+i)}t_1\Big).$$

```
theorem TPForm_Lm1 (x y : TP) : TPForm (leechLTP x) y = TPForm x (Lp1 plusModule y)

theorem leechBV_Lm1_pow (i : ℕ) (x y : SkewVP) :

    (ht₂ : t₂ ∈ plusModule.weight (b : ℂ)) (n : ℤ) :
    leechWbarMode n t₁ t₂ = ∑ᶠ i : ℕ, (((i.factorial : ℂ)⁻¹) * negOnePow (n + i + 1)) •
      ((leechVOAPlus.L (-1)) ^ i) (leechWbarMode (n + i) t₂ t₁)
```

(namespace `VOA.Moonshine.M8h0`.)

From the mathematics to the Lean statement

The right side is the mode expansion of $e^{zL_{-1}}\overline{W}(t_2,-z)t_1$, exactly as in (37.7); the $\sum^{\mathrm{f}}$ is finite because $\overline{W}(t_2)_{(n+i)}t_1 = 0$ for i large (Theorem 37.46). **Restriction:** t_1, t_2 homogeneous of integral weight. This is harmless: both sides are bilinear in (t_1, t_2), every vector of $(V_\Lambda^T)^+$ is a finite sum of homogeneous ones, and all weights of $(V_\Lambda^T)^+$ are integers. The two auxiliary statements are the adjointness $L_{-1}^t = L_1$ for B_T (from invariance at ω, using $L_1\omega = 0$) and for B_V (Virasoro adjointness of an `InvariantForm`).

Physical meaning

Skew-symmetry is the exchange symmetry of two twist fields: the OPE of t_1 with t_2 and the OPE of t_2 with t_1 describe the same correlator in different radial orderings, related by translation $e^{zL_{-1}}$ and $z \to -z$. For the untwisted output it is the bosonic exchange property of twist fields (braiding is trivial in the untwisted channel). It holds for the constructed $\overline{W}$ because it is the adjoint of W with respect to a symmetric metric, which is one of the inputs to their mutual locality.

Proof on paper. Pair both sides with $\varphi \in (V_\Lambda^+)_k$, $k = a+b-n-1$ (other weights pair to zero on both sides), and use separation. On the left, the adjunction gives $(-1)^a \sum_j \frac{1}{j!} B_T\big(t_2, W(L_1^j t_1)_{(2a-n-2-j)}\varphi\big)$; expanding W by (37.7) produces L_{-1}^l acting on $\varphi_{(.)}L_1^j t_1$, which is moved across B_T as L_1^l (by $L_{-1}^t = L_1$), and then $\varphi_{(.)}$ is moved across B_T by FHL invariance (which brings in $L_1^r\varphi$). The result is a triple sum over (j,l,r) of matrix elements $B_T\big(L_1^j t_1, (L_1^r\varphi)_{(\gamma)}L_1^l t_2\big)$. On the right, L_{-1}^i is moved across B_V as L_1^i, then the adjunction for $\overline{W}(t_2)_{(n+i)}$ and the same expansion give a triple sum of the same matrix elements, with the roles of j and r exchanged. After the relabelling $(j,l,r) \mapsto (r,l,j)$ the two sums agree term by term: the factorials match, the mode indices agree because $n = a+b-k-1$, and the signs differ by an even power of -1. Symmetry of B_T is used to put t_1, t_2 in matching slots. □

What the machine verified

`leechWbar_skew`: unconditional (homogeneity is part of the statement). Axioms: `[propext, Classical.choice, Quot.sound]` (rechecked). The corresponding relation DGM (4.22) is

proved in Chapter 38 (`leechWbar_VPBlockLocal`).

37.15 Traps, dead ends and corrected mistakes

For convenience we collect the recorded traps that concern this chapter.

1. **The square-zero trap** ($\overline{W} = 0$): every hypothesis that the reconstruction theorem places on `Wbar` is satisfied by 0, producing a non-simple VOA with the graded dimension of $V^\natural$. Countered by defining $\overline{W}$ as the adjoint and by Theorem 37.57 (Section 37.1).

2. **The positive Fock form** is the wrong form: it transposes the dressing `DD` v to `DD` $(-v)$. The FHL bilinear form forces $h(m)^t = -h(-m)$ (Section 37.7).

3. **Signs on T and in $\overline{W}$**: the T-law sign $(-1)^{\langle\alpha,\alpha\rangle/2}$ (not $\varepsilon(\alpha,\alpha)$), the factor $(-1)^w$ in (37.16), and the non-constant sign $c(\alpha)$ of the lattice form are each necessary; dropping any of them breaks (4.23) in the numerical E_8 model (`Notes/M8hRoute.md`).

4. **The library `Intertwiner` is commutator-only.** It is weaker than FHL's notion (no L_{-1}-property, no Jacobi identity). The L_{-1}-properties of W and $\overline{W}$ are proved separately; their full Jacobi identities are not proved and not used.

5. **One-argument commutator formulas do not give twisted×twisted locality.** `Notes/M8GluingPlan.md` (status after M8f) records that the formulas `wMode_comm` and `WbarMode_comm` do not imply the Borcherds identity for three twisted vectors (DGM (4.23)); that relation needs the triality of Chapters 39–42.

6. **The residuals of this chapter, both closed:** `hgen` (generation of V_Λ^+, closed by `leechPlus_generated`) and `hnd` (graded nondegeneracy of B_V, closed by `leechBV_gradedNondeg` without using simplicity). Both are proved in Chapter 32.

37.16 Verification record

For this chapter, at an earlier commit (not re-run for this edition), the following probe file (in a scratch directory, not part of the library) was compiled with the audit-safe option recommended by the project (`-DmaxSynthPendingDepth=3`):

Command: `lake env lean -DmaxSynthPendingDepth=3 Ax09.lean`. Output: each of the 21 declarations "depends on axioms: [propext, Classical.choice, Quot.sound]"; exit code 0. In particular none uses `VOA.pbw` (the PBW theorem of Chapter 3; formerly a project axiom, now a theorem). This run did not rebuild the library; it relies on the build artefacts of the aggregate `lake build` of that commit, which the project's build record reports green (10343 jobs, exit 0; not re-run for this chapter). The sympy scripts mentioned in Section 37.7 were not re-run.

37.17 Referee's checklist

"Uncond." means: no hypothesis that is an unestablished datum; * marks declarations whose `#print axioms` was rechecked above (result `[propext, Classical.choice, Quot.sound]`). $\mathcal{V}$, M denote an arbitrary VOA and module.

Lean declaration	intended meaning	hypotheses	status / check
`Intertwiner` (library)	commutator-type intertwiner, weaker than FHL	—	definition; Def. 37.6
`Lm1`, `act_Lm1`	$L_{-1}^{M} = \omega_{(0)}$; $[u_{(p)}, L_{-1}] = -p\,u_{(p-1)}$	weak module	uncond.; Prop. 37.9
`wMode`, `Wsk`	$W(t,z)\varphi = e^{zL_{-1}}Y_M(\varphi,-z)t$	weak module	definition; Def. 37.10
`Wsk_vacuum`	$W(t,z)\mathbf{1} = e^{zL_{-1}}t$	none	uncond.; Thm. 37.12
`Wsk_deriv`	$W(L_{-1}t,z) = \partial_z W(t,z)$	none	uncond.; Thm. 37.13
`wMode_comm`*	commutator formula of W, all m	J past truncation	uncond.; Thm. 37.15
`Wsk_local`*	$Y_M(u,z_1)$, $W(t,z_2)$ local	none	uncond.; Thm. 37.17
`skewIntertwiner`*	W as library intertwiner of type $(M;M,\mathcal{V})$	ordinary module	uncond.; Def. 37.18
`leechWsk_*`, `leechSkewIntertwiner`*	the above for $(V_\Lambda^T)^+$	none	uncond.; Thm. 37.20
`FHLInv`, `WeightOrth`	FHL invariance at u; orthogonal weights	—	definition; Def. 37.22
`fhlInv_iff`	invariance $\iff$ $M \to M'$ intertwines	orth., u homog.	uncond.; Thm. 37.24
`smul_mem_interSub`	intertwined states closed under products	u, v intertwined	uncond.; Thm. 37.26
`fhlInv_of_generates`*	invariance on generators $\Rightarrow$ everywhere	orth., generation, gens. invariant	uncond. (hyps by design); Thm. 37.27
`fockForm`	negative Fock form, $c_v = -(n+\frac{1}{2})$	—	definition; Def. 37.28
`fockForm_modeT`	$h(m)^t = -h(-m)$	none	uncond.; Thm. 37.29
`fockForm_DD`*	`DD` $v\,a$ transposes to `DD` $v\,(-a)$	none	uncond.; Thm. 37.30
`twForm_YTL`*	FHL law for $Y^T(e^\alpha)$ on $S[\theta]\otimes T$	T-law `hT`, lattice even, unimodular	uncond. given `hT`; Thm. 37.32
`TPForm`	$B_T = (F \otimes \mathtt{TForm})\vert_{(V_\Lambda^T)^+}$	—	definition; Def. 37.34

Lean declaration	intended meaning	hypotheses	status / check
`TPForm_symm`, `TPForm_nondegenerate`*, `TPForm_weightOrth`	symmetric, nondegenerate per weight, weight-orthogonal	none	uncond.; Thm. 37.35
`TPForm_fhlInv_frameX0P`, `interSub_TPForm`	invariance at $e^{\beta} + e^{-\beta}$	none	uncond.; Thm. 37.37
`TPForm_fhlInv_of_generates`*	invariance at all homogeneous u	`hgen`	conditional; Thm. 37.38
`TPForm_fhlInv`*	invariance at all homogeneous u	none	uncond.; Thm. 37.38
`GradedNondeg`, `GradedOrth`, `riesz`	weightwise nondegenerate; Riesz vector	—	definitions; Defs. 37.40, 37.41
`riesz_spec`*, `eq_of_form`	$B(\mathrm{riesz} f, \cdot) = f$; separation	orth., nondeg., finite support	uncond.; Thm. 37.42
`Wdag`, `WbarMode`, `Wbar`	dagger; $\overline{W}$ as Riesz vector	`h0`	definitions; Defs. 37.43, 37.44
`form_WbarMode`, `form_WbarMode_int`	adjunction DGM (4.3)	`hVo`, `hVnd`	uncond. given hyps; Thm. 37.45
`WbarMode_mem`, `WbarMode_trunc`	weights; truncation	`h0`	uncond.; Thm. 37.46
`Wbar_deriv`	$\overline{W}(L_{-1}t, z) = \partial_z \overline{W}(t, z)$	`h0`	uncond.; Thm. 37.47
`Wdag_comm_qp`*	transposed commutator, quasi-primary u	$L_1 u = 0$	uncond.; Thm. 37.49
`WbarMode_comm`*	commutator formula of $\overline{W}$, all u	`hVo`,`hVnd`,`hVinv`,`hMinv`,`hnd`V	conditional (general); Thm. 37.51
`Wbar_local`*, `Wbar_homCov`	locality with $Y(u)$; L_{-1}-covariance	same	conditional (general); Thm. 37.52
`leechBV`	Li's canonical form on V^+_Λ, $(\mathbf{1}, \mathbf{1}) = 1$	—	definition; §37.12
`leechWbar`	the Leech $\overline{W}$	—	definition; Def. 37.53
`leechWbar_adj/comm/local/homCov`	Leech properties	`hnd` (via `include`)	conditional; Thm. 37.54
`leechBV_gradedNondeg`*	B_V nondegenerate on each $(V^+_\Lambda)_k$	none	uncond.; Thm. 37.55
`leechWbar_adj'`, `leechWbar_comm'`*, `leechWbar_local'`, `leechWbar_homCov'`	the Leech properties	none	uncond.; Thm. 37.55
`leechWbar_WbarComm`*	block-field hypothesis `WbarComm`	none	uncond.; Thm. 37.56
`YnatU_YnatT_local_genuine`*	$Y^\natural(u)$, $Y^\natural(t)$ local on $V^\natural$	none	uncond.; Thm. 37.56
`leechWbarMode_three_weight_two`*	$\overline{W}(t)_{(3)}t' = B_T(t', t)\mathbf{1}$ on weight 2	t, t' of weight 2	uncond.; Thm. 37.57
`leechWbar_vacuum_pairing_ne_zero`	nondegenerate vacuum pairing	$t \neq 0$ of weight 2	uncond.; Thm. 37.57
`leechWbar_ne_zero`*	$\overline{W} \neq 0$ (not the trap)	none	uncond.; Thm. 37.57
`M8h0.leechWbar_skew`*	$\overline{W}(t_1, z)t_2 = e^{zL_{-1}}\overline{W}(t_2, -z)t_1$	t_1, t_2 homogeneous	uncond.; Thm. 37.58

37.18 Notes and references

The intertwining operators, contragredient modules and invariant bilinear forms of this chapter are those of I. B. Frenkel, Y.-Z. Huang and J. Lepowsky, *On axiomatic approaches to vertex operator algebras and modules*, Memoirs of the American Mathematical Society 104 (1993), no. 494: the contragredient module is §5.2 (Theorem 5.2.1), invariant forms §5.3, intertwining operators and their skew-symmetry operators Ω §5.4–5.5. The classification of invariant bilinear forms on a vertex operator algebra ($\cong (V_0/L_1V_1)^*$) and the equivalence of nondegeneracy with simplicity are due to H. Li, *Symmetric invariant bilinear forms on vertex operator algebras*, Journal of Pure and Applied Algebra 96 (1994), 279–297. Li's theory of local systems (*Local systems of vertex operators, vertex superalgebras and modules*, J. Pure Appl. Algebra 109 (1996) 143–195, arXiv:hep-th/9406185) is the conceptual background for constructing a vertex algebra from mutually local fields, the route taken in Chapter 38.

The block form (37.2), the definition of W by skew-symmetry (their (3.8)), of $\overline{W}$ as an adjoint (their (4.3)), the skew-symmetry of $\overline{W}$ (their (4.9)) and the reduction of locality to the six relations (4.18)–(4.23) follow L. Dolan, P. Goddard and P. Montague, *Conformal field theories, representations and lattice constructions*, Communications in Mathematical Physics 179 (1996), 61–120, arXiv:hep-th/9410029; their earlier paper *Conformal field theory of twisted vertex operators*, Nuclear Physics B 338 (1990), 529–601, treats the twisted operators directly. The Moonshine module itself, the twisted Fock space with its form, the space T and the triality that eventually proves (4.23), are in I. Frenkel, J. Lepowsky and A. Meurman, *Vertex Operator Algebras and the Monster*, Pure and Applied Mathematics 134, Academic Press, 1988 (Chapters 9–13). For the mode-level conventions (generalised binomials, Res, the module Jacobi identity in modes) the library follows T. Gannon, *Moonshine beyond the Monster*, Cambridge University Press, 2006, §5.1–5.3 and Definition 6.1.9 (intertwiners).

The project's own records of the work in this chapter are `Notes/M8GluingPlan.md` (milestones M8b, M8c and the status sections "after M8b", "after M8c form part", "residual hgen CLOSED", "W̄ built; residual hnd", "hnd CLOSED"), `Notes/M8hRoute.md` (numerical E_8 model and sign controls).

Chapter 38

The vertex algebra on $V^\natural$ modulo one relation

38.1 Where we are, and what this chapter does

This chapter documents the release of the library named in the front matter. Quotations from the repository are printed in `leancode` boxes, which are checked by `scripts/textbook/sync.py` to occur verbatim (up to whitespace and comments) in the source of that release; tool output is printed in plain boxes. Checks that were run at an earlier state of the library and not re-run for this edition are marked as such.

The preceding chapters of this Part have produced, one at a time, all the raw materials of the Frenkel–Lepowsky–Meurman construction of the Moonshine module. It is worth listing them, because this chapter does nothing but glue them together, and the referee should know exactly which pieces are taken as given here.

(i) The *untwisted half*: the fixed-point vertex operator algebra $V_\Lambda^+ = V_\Lambda^\theta$ of the Leech lattice vertex operator algebra under the lift θ of -1 (Lean: `leechVOAPlus`, carrier type `SkewVP`). It has central charge 24, no states of weight 1, and $\dim(V_\Lambda^+)_2 = 98580$.

(ii) The *twisted half*: the θ-fixed part $T^+ = (V_\Lambda^T)^+$ of the θ-twisted Leech module $V_\Lambda^T = S[\theta] \otimes T$ (Lean: `TP`), viewed as an ordinary V_Λ^+-module (Lean: `plusModule`). Its weights are the integers ≥ 2 and $\dim T_2^+ = 98304 = 24 \cdot 4096$.

(iii) The *skew intertwiner* W: for $t \in T^+$ the field $W(t,z)\varphi = e^{zL_{-1}} Y^T(\varphi, -z)t$, a formal series of linear maps $V_\Lambda^+ \to T^+$ (Lean: `leechWsk`).

(iv) The two invariant bilinear forms: B_V on V_Λ^+ (Lean: `leechBV`) and the form $(\cdot,\cdot)_T$ on T^+ (Lean: `TPForm`); both symmetric, both nondegenerate on every weight space, both invariant under the action of V_Λ^+.

(v) The *adjoint* $\overline{W}$ of W with respect to these two forms: for $t \in T^+$ a formal series $\overline{W}(t,z)$ of linear maps $T^+ \to V_\Lambda^+$ (Lean: `leechWbar`).

With these, Frenkel, Lepowsky and Meurman — and, in the streamlined form we follow, Dolan, Goddard and Montague (DGM) — define a single vertex operator on

$$V^\natural = V_\Lambda^+ \oplus T^+$$

by the 2×2 block matrix

$$Y^\natural\big((u,t),z\big) = \begin{pmatrix} Y(u,z) & \overline{W}(t,z) \\ W(t,z) & Y^T(u,z) \end{pmatrix}, \qquad u \in V_\Lambda^+,\ t \in T^+, \tag{38.1}$$

acting on column vectors $\binom{\varphi}{s}$ with $\varphi \in V_\Lambda^+$, $s \in T^+$. This is DGM's equation (4.17). The diagonal blocks are the vertex operators of V_Λ^+ on itself and on its module T^+; the off-diagonal blocks are the two intertwiners.

The physical picture. In conformal field theory language, $V^\natural$ is the space of states of a chiral CFT obtained by *orbifolding* the 24 chiral bosons compactified on the Leech torus $\mathbb{R}^{24}/\Lambda$ by the reflection $X \mapsto -X$. The untwisted sector V_Λ^+ consists of the reflection-invariant states of the original theory; the twisted sector T^+ consists of the states created by *twist fields* sitting at the 2^{24} fixed points of the reflection, projected again onto invariant states. The block form (38.1) is the statement of *charge conservation for the $\mathbb{Z}/2$ grading* by sectors: an untwisted field maps each sector to itself; a twisted field exchanges the sectors. The operator product of two twisted fields lands in the untwisted sector, and its consistency — the locality of two twisted fields — is the one place where the geometry of the lattice enters non-trivially. Physicists call this the statement that the orbifold is *modular invariant*; DGM call it "almost a modular invariance condition".

What the chapter proves. We check, for the explicit block map (38.1), *every* axiom of a vertex operator algebra except one: the mutual locality of two twisted fields. We split that remaining condition into two halves, DGM's relations (4.22) and (4.23); we prove (4.22) unconditionally; we reduce (4.23) to finitely many explicit pairs of vectors; and we prove that, whenever the structure exists, it is *simple*. The relation (4.23) itself is proved in the final chapters of this Part, by the triality method; at the end of this chapter we state the theorem that collects every target conditional on (4.23), which those chapters then discharge.

The trap. There is a subtlety that governs the whole chapter, and the referee must keep it in mind from the first page. If one replaces $\overline{W}$ by the *zero* map in (38.1), every hypothesis we place on $\overline{W}$ is still satisfied, twisted–twisted locality becomes trivially true, and the result is a perfectly good vertex operator algebra with the same underlying graded vector space — hence central charge 24, no weight-one states, $\dim V_2 = 196884$ and graded dimension J. It is *not* the Moonshine module: it is the *square-zero extension* $V_\Lambda^+ \ltimes T^+$, which is not simple. Consequently none of the numerical facts about $V^\natural$ can certify that the right object has been built. What does certify it is simplicity, and the simplicity proof uses, in an essential way, that $\overline{W}$ is the *adjoint* of W. Section 38.11 treats this in detail.

Plan. Section 38.2 recalls, with their Lean sources, the library notions that occur in the statements of this chapter. Section 38.3 develops the algebra of block fields on a direct sum. Section 38.4 proves that the fields of any module are mutually local — a fact the library did not have. Section 38.5 defines the carrier $V^\natural$ and its grading and proves the numerical targets. Section 38.6 defines the generator fields and the reconstruction interface. Section 38.7 verifies all the axioms of a vertex operator algebra modulo twisted–twisted locality and packages the result. Section 38.8 splits twisted–twisted locality into (4.22) and (4.23). Section 38.9 proves (4.22). Section 38.10 reduces (4.23) to a generating family and then to four explicit pairs. Section 38.11 is the trap. Section 38.12 proves simplicity. Section 38.13 assembles the conditional main theorem. Section 38.14 collects the dead ends, Section 38.15 is the referee's checklist, and the chapter ends with notes and references.

What the machine verified

Every declaration presented in this chapter was `##print axioms`-checked in the session that wrote the chapter (2026-10-07), on the already-built library, with `lake env lean -DmaxSynthPendingDepth=3` on a file importing `VOA.Moonshine.Main`. For each of the 22 headline declarations named in Section 38.15 the output was

```
depends on axioms: [propext, Classical.choice, Quot.sound]
```

These are Lean's three standard axioms; `VOA.pbw` (the PBW theorem of Chapter 3; formerly a project axiom, now a theorem) does *not* occur. The project's build record for the earlier commit at which this chapter was first written reports the aggregate build green (10343 jobs; not re-run for this chapter). Being axiom-clean does not make a theorem unconditional: several results below carry an explicit hypothesis (the twisted–twisted locality), and we always say so.

38.2 Recollections: the notions that occur in the statements

The Constitution of this book requires that every term in a stated theorem be defined in the book. The terms below are defined in the Foundations and Core chapters. The formal-calculus notions and weak modules are quoted verbatim and decoded in Chapters 2, 4 and 12, and are recalled here with pointers; the structures whose exact fields this chapter's fidelity checks use (vertex algebras, vertex operator algebras, ideals and simplicity, invariant forms) are repeated verbatim so that those checks can be read without turning back.

38.2.1 Formal distributions and modes

Definition 38.1 (Formal distributions)**.** For a complex vector space X, a *formal distribution* with values in X is a doubly infinite formal series $f(z) = \sum_{k\in\mathbb{Z}} f_k z^k$ with $f_k \in X$, with no convergence or truncation condition. Equivalently it is an arbitrary function $\mathbb{Z} \to X$. A two-variable formal distribution is a function $\mathbb{Z}\times\mathbb{Z} \to X$, read as $\sum_{m,n} f_{m,n} z_1^m z_2^n$.

In Lean, `FormalDist 𝒲 = ℤ → 𝒲` and `FormalDist₂ 𝒲 = ℤ → ℤ → 𝒲` (Definitions 2.1 and 2.21, `VOA/Foundations/FormalSeries.lean`). The notation `(End ℂ 𝒱)⟦z^±⟧` in the structure of a vertex algebra below is notation for `FormalDist (End ℂ 𝒱)`.

Physical meaning

A formal distribution is the mode expansion of a quantum field before any state is fed in: the operator-valued Laurent series $\sum_k f_k z^k$ that a physicist writes for $\phi(z)$ on the plane, with no assumption yet that it acts sensibly on states. The truncation condition that makes it a genuine local operator is imposed separately, as the notion of field. The two-variable version is the expansion of a correlator or of a product $\phi_1(z_1)\phi_2(z_2)$ in both positions. This is bookkeeping heuristics for the OPE; the formal definition is what the proofs use.

Definition 38.2 (Modes)**.** For $f(z) = \sum_k f_k z^k$ the *n-th mode* is $f_{(n)} := f_{-n-1}$, so that $f(z) = \sum_n f_{(n)} z^{-n-1}$. For a vertex operator $Y(u,z)$ one writes $u_{(n)}$ for the n-th mode.

In Lean, `mode f m = f (-m - 1)` (Definition 2.7, `VOA/Foundations/FormalCalculus.lean`).

From the mathematics to the Lean statement

There are two indexings in play and the reader must keep them apart. The raw coefficient `f k` is the coefficient of z^k; the mode `mode f n` is $f_{(n)}$, the coefficient of z^{-n-1}. Thus `mode (Y u) n` is the operator $u_{(n)}$ of the textbooks, `mode (Y u) (-1)` is $u_{(-1)}$ (creation), and `Y u 0` — the raw coefficient of z^0 — is also $u_{(-1)}$. Definitions about *fields* in the library (truncation, translation covariance, locality) are written in the raw z-power indexing; definitions about *products* of states are written with `mode`. Every fidelity check below says which is in use.

Physical meaning

Modes are the Fourier coefficients of a chiral field around the origin: $u_{(n)}$ is the contour integral of $z^n Y(u,z)$, so the modes of the stress tensor are the Virasoro generators and those of a current are its Kac–Moody charges. The shift $-n-1$ is the usual bookkeeping that a weight-h field has $\phi(z)=\sum \phi_n z^{-n-h}$ with n shifted by $h-1$. In $V^\natural$ the modes of all states generate the whole symmetry algebra of the orbifold CFT.

38.2.2 Multiplication by $z_1 - z_2$, commutators, locality, fields

Definition 38.3. For a two-variable distribution F, $(z_1-z_2)F$ has coefficients $((z_1-z_2)F)_{m,n} = F_{m-1,n} - F_{m,n-1}$, and $(z_1-z_2)^N F$ is the N-fold iterate.

In Lean these are `mulBySub` $=$ `shiftZ₁ - shiftZ₂` and its N-fold iterate `mulBySubPow N` (Definition 2.21, `VOA/Foundations/FormalSeries.lean`); the library proves `mulBySub_apply : mulBySub f m n = f (m - 1) n - f m (n - 1)`.

Physical meaning

Multiplying by $z_1 - z_2$ is the formal counterpart of multiplying a two-point function by the separation of the insertion points; killing a distribution by a power of $z_1 - z_2$ says it is supported on the diagonal $z_1 = z_2$, i.e. it is a contact term. This is exactly the mechanism by which singular OPE terms (poles in $z_1 - z_2$) are encoded without functions.

Definition 38.4 (Commutator and locality)**.** For two $\mathrm{End}(V)$-valued distributions $a(z), b(z)$ the commutator is the two-variable distribution $[a(z_1), b(z_2)]$ with coefficients $a_m b_n - b_n a_m$. The pair is *mutually local* if $(z_1-z_2)^N [a(z_1), b(z_2)] = 0$ for some $N \in \mathbb{N}$.

In Lean, `bracketDist a b` is `fun m n ⇒ a m * b n - b n * a m` and `Local a b` is `∃ N : ℕ, mulBySubPow N (bracketDist a b) = 0` (Definition 2.41, `VOA/Foundations/Locality.lean`). Here `a m * b n` is composition of endomorphisms, $a_m \circ b_n$.

Physical meaning

Mutual locality is the CFT statement that the commutator of two chiral fields vanishes at separated points and is a finite sum of contact terms: $\phi_1(z_1)\phi_2(z_2)$ and $\phi_2(z_2)\phi_1(z_1)$ are the same analytic function continued around the other order of the two insertions, up to a pole of finite order. It is the formal version of crossing symmetry (braiding of two operators is trivial for bosonic chiral fields) and the axiom whose verification between two twisted fields is the open relation in this chapter.

Definition 38.5 (Field)**.** An $\mathrm{End}(V)$-valued distribution $a(z)$ is a *field* if for every $x \in V$ the coefficients $a_n x$ vanish for all sufficiently negative n; equivalently, in modes, $a_{(n)}x = 0$ for $n \gg 0$.

In Lean, `IsField a` is `∀ x : V, ∃ B : ℤ, ∀ n : ℤ, n < B → a n x = 0` (Definition 2.43, `VOA/Core/Dong.lean`).

Physical meaning

The truncation condition says that a field applied to a fixed state produces only finitely many negative powers of z: in CFT language the operator–state correspondence, where $\phi(z)|\psi\rangle$ has at worst a pole at $z=0$ and no essential singularity. It is the formal form of the energy bounded below, so that the OPE of ϕ with any state has finitely many singular terms.

Definition 38.6 (Translation covariance)**.** Given $T \in \mathrm{End}(V)$, a field $a(z)$ is *T-covariant* if $[T, a(z)] = \partial_z a(z)$, i.e. $T a_m - a_m T = (m+1)a_{m+1}$ for every $m \in \mathbb{Z}$.

In Lean, `DCovariant T a` is `∀ m : ℤ, T * a m - a m * T = ((m + 1 : ℤ)) • a (m + 1)` (Definition 4.38, `VOA/Core/ReconstructionExistence.lean`). The coefficient of z^m in $\partial_z \sum_k a_k z^k$ is $(m+1)a_{m+1}$, which is what the right-hand side says. The library also has the operator `deriv` on formal distributions, $(\partial f)_k = (k+1) f_{k+1}$.

Physical meaning

Translation covariance $[L_{-1}, \phi(z)] = \partial_z \phi(z)$ is the Ward identity for translations: L_{-1} generates $z \mapsto z + \epsilon$ on a chiral field. In $V^\natural$ it is required of every block of the combined field, so that moving an operator and acting by the global translation generator agree in both the untwisted and twisted sector.

Definition 38.7 (Generalized binomial coefficient). For $n \in \mathbb{Z}$ and $k \in \mathbb{N}$, $\binom{n}{k} = n(n-1)\cdots(n-k+1)/k!$.

In Lean this is `gBinom n k`, quoted verbatim in Definition 2.14 (`VOA/Foundations/FormalCalculus.lean`).

Physical meaning

The generalised binomial coefficients $\binom{n}{k}$ with $n \in \mathbb{Z}$ are the Taylor coefficients of $(1+x)^n$ and appear in the OPE and Jacobi identities when one expands $(z_1 - z_2)^n$ in one of the two regions $|z_1| > |z_2|$ or $|z_2| > |z_1|$. They are pure combinatorics with no independent physical content.

38.2.3 Vertex algebras and vertex operator algebras

The library's basic structure is `PreVertexAlgebra`: Gannon's *locality* axioms (§5.1.3(a)), with an internal $\mathbb{Z}$-grading by finite-dimensional pieces. It has no translation-covariance axiom and is therefore not a vertex algebra in the standard sense (Chapter 4); the library's `VertexAlgebra` adds that axiom. For this chapter only the VOA level matters, where covariance follows from the translation axiom (VOA3).

```

(`VOA/Core/VertexAlgebra.lean`.) `DirectSum.IsInternal grading` is Mathlib's statement that the natural map $\bigoplus_n V_n \to V$ is an isomorphism, i.e. $V = \bigoplus_n V_n$. The product $u_{(n)}v$ is written `V.smul u n v := mode (V.Y u) n v`.

A vertex operator algebra adds a conformal vector, in two layers: `GradedVertexOperatorAlgebra` is the Frenkel–Lepowsky–Meurman / Lepowsky–Li notion (Virasoro, L_0-grading, L_{-1}-derivative, grading truncated from below), and `VertexOperatorAlgebra` adds the CFT-type condition (VOA4). Every statement of this chapter is about `VertexOperatorAlgebra`, so CFT type is part of it.

```

(`VOA/Core/VertexOperatorAlgebra.lean`). The library writes L_n for `mode (Y ω) (n+1)`.

Definition 38.8 (Ideals, simplicity). An *ideal* of a vertex operator algebra V is a subspace I with $u_{(n)}v \in I$ for all $u \in V$, $v \in I$, $n \in \mathbb{Z}$. V is *simple* if $V \neq 0$ and its only ideals are 0 and V.

```
def IsIdeal (W : VertexOperatorAlgebra 𝒱) (I : Submodule ℂ 𝒱) : Prop :=
  ∀ (u v : 𝒱) (n : ℤ), v ∈ I → W.smul u n v ∈ I

def IsSimple (W : VertexOperatorAlgebra 𝒱) : Prop :=
  (⊤ : Submodule ℂ 𝒱) ≠ ⊥ ∧ ∀ I : Submodule ℂ 𝒱, W.IsIdeal I → I = ⊥ ∨ I = ⊤
```

(`VOA/Core/BilinearForm.lean`. A deprecated duplicate `IsSimple` in `VOA/Modules/Rationality.lean` is *not* the one used here; every statement of this chapter refers to `VertexOperatorAlgebra.IsSimple` above.)

From the mathematics to the Lean statement

Only left ideals appear in `IsIdeal`: closure under $u_{(n)}$ acting from the left. For a vertex algebra with translation operator, skew-symmetry $Y(v,z)u = e^{zL_{-1}}Y(u,-z)v$ makes a left ideal that is L_{-1}-stable automatically two-sided; for the purposes of simplicity, demanding only left ideals makes "simple" a *stronger* requirement (more subspaces are tested), so the Lean notion is at least as strong as any textbook notion.

Physical meaning

An ideal is a sector of operators that, once present in the spectrum, can only produce more of itself under OPE with anything; a proper ideal is therefore a decoupled subsector with a vacuum-orthogonal state that never talks back to the vacuum. Simplicity says there is no such decoupled sector: the vacuum is the only state that is cyclic for the whole operator algebra, the physical uniqueness of the vacuum and the absence of a spurious superselection sector. Simplicity in this sense is the property that separates the Moonshine module from its square-zero impostor in Section 38.11.

38.2.4 Invariant bilinear forms

Definition 38.9 (Invariant forms)**.** A bilinear form $(\cdot|\cdot)$ on a vertex operator algebra V is *fully invariant* (in the sense of Frenkel–Huang–Lepowsky) if $(Y(u,z)a \mid b) = (a \mid Y(e^{zL_1}(-z^{-2})^{L_0}u, z^{-1})b)$ for all u, a, b. For u of weight wt this is, in modes,

$$(u_{(n)}a \mid b) = (-1)^{\mathrm{wt}} \sum_{j\geq 0} \frac{1}{j!} \left(a \mid (L_1^j u)_{(2\mathrm{wt}-n-2-j)}b\right). \tag{38.2}$$

It is *normalised* if $(\mathbf{1}|\mathbf{1}) = 1$. Its *(left) radical* is $\{x : (x|b) = 0\ \forall b\}$.

To derive (38.2): $(-z^{-2})^{L_0}u = (-1)^{\mathrm{wt}}z^{-2\mathrm{wt}}u$, e^{zL_1} contributes $\sum_j z^j L_1^j/j!$, and $Y(v,z^{-1}) = \sum_k v_{(k)}z^{k+1}$; the total power of z is $-2\mathrm{wt} + j + k + 1$, which equals $-n-1$ exactly when $k = 2\mathrm{wt} - n - 2 - j$. Since L_1 lowers weight and weights are bounded below, the sum over j stops at $j = \mathrm{wt}$.

```
structure InvariantForm (W : VertexOperatorAlgebra 𝒱) where
  /-- The underlying `ℂ`-bilinear form `(·|·) : 𝒱 × 𝒱 → ℂ`. -/
  form : LinearMap.BilinForm ℂ 𝒱
  /-- **Invariance (Virasoro-adjointness).** `(Lₙ u | v) = (u | L₋ₙ v)` for every `n`
  (Gannon 5.1.11a, mode content): each `Lₙ` is adjoint to `L₋ₙ`. -/

abbrev IsFullyInvariant (B : InvariantForm W) : Prop :=
  ∀ (wt : ℤ) (u : 𝒱), u ∈ W.grading wt → ∀ (n : ℤ) (a b : 𝒱),
    B.form (W.smul u n a) b
      = (-1 : ℂ) ^ wt • ∑ j ∈ Finset.range (wt.toNat + 1), ((j.factorial : ℂ)⁻¹) •
          B.form a (W.smul (((W.L 1) ^ j) u) (2 * wt - n - 2 - (j : ℤ)) b)

def Normalized (B : InvariantForm W) : Prop := B.NormalizedAt 1
-- where  NormalizedAt B κ :  B.form W.vacuum W.vacuum = κ

def leftRadical (B : InvariantForm W) : Submodule ℂ 𝒱 := LinearMap.ker B.form
```

(`VOA/Core/BilinearForm.lean`.) `LinearMap.BilinForm ℂ 𝒱` is Mathlib's type of bilinear forms $V\times V \to \mathbb{C}$, curried as $V \to (V \to \mathbb{C})$; its kernel is the set of x with $x \mapsto (x|\cdot)$ zero, i.e. the left radical.

The module analogue of (38.2), for a form B on a V-module M and a fixed homogeneous u of weight wt, is the predicate

```
def FHLInv (N : OrdVModule W M) (B : LinearMap.BilinForm ℂ M) (wt : ℤ) (u : 𝒱) : Prop :=
  ∀ (n : ℤ) (a b : M), B (mode (N.YM u) n a) b
    = (-1 : ℂ) ^ wt • ∑ j ∈ Finset.range (wt.toNat + 1), ((j.factorial : ℂ)⁻¹) •
        B a (mode (N.YM (((W.L 1) ^ j) u)) (2 * wt - n - 2 - (j : ℤ)) b)
```

(VOA/Moonshine/InvFormClosure.lean.)

Physical meaning

A fully invariant form is the Zamolodchikov (BPZ) metric of the CFT: the two-point pairing $\langle\phi|\psi\rangle$ under which the Virasoro generators are adjoint, $L_n^\dagger = L_{-n}$, and a quasi-primary field of weight wt is mapped under inversion $z \mapsto 1/z$ to its conjugate with the factor $(-z^{-2})^{L_0}$. Nondegeneracy of the form is the statement that the two-point function of each operator is nonzero with some partner, which is the CFT form of unitarity-like nondegeneracy (reflection positivity is a further, stronger property not asserted here). The module analogue is the Zamolodchikov metric of the twisted sector.

38.2.5 Weak modules

A weak module `WeakModule W M` (VOA/Modules/WeakModule.lean; quoted verbatim and decoded in Definition 12.1) is a field map `YM : 𝒱 →ₗ[ℂ] (End ℂ M)⟦z^±⟧` with fields `vacuum_YM` ($Y_M(\mathbf{1},z) = \mathrm{id}_M$), `truncation` (lower truncation) and `jacobi`. The `jacobi` field is the Borcherds (Jacobi) identity in modes, where `cbz n i` is $\binom{n}{i}$ for $i \geq 0$ and 0 for $i < 0$, and `negOnePow i` is $(-1)^i$. We write `A.act u n x` for `mode (A.YM u) n x`, i.e. $u_{(n)}x$, and $L_{-1}^M := \omega_{(0)}$ on M (Lean: `Lm1 A`). An `OrdVModule` (an ordinary module, with a $\mathbb{C}$-grading `weight` by finite-dimensional L_0-eigenspaces) has an underlying weak module `toWeakModule`; $L_1^M := \omega_{(2)}$ is `Lp1`.

38.2.6 The objects of the earlier Moonshine chapters

We record the Lean names and a precise mathematical description of the five ingredients (i)–(v) of Section 38.1. Their construction and properties are the subject of the preceding chapters of this Part; here we use only the properties stated.

```
abbrev SkewVP : Type := ↥(orbifold (Subgroup.zpowers leechTheta)).carrier

noncomputable def leechWbar (t : TP) : FormalDist (TP →ₗ[ℂ] SkewVP) :=
  Wbar leechBV plusModule TPForm TPForm_weightOrth t
```

(Files: `SkewLeech.lean`, `TwistedPlus.lean`, `WbarLeech.lean`, `InvFormTP.lean`, all under `VOA/Moonshine/`.)

In words:

- `SkewVP` is the carrier of V_Λ^+: the subspace of V_Λ fixed by the group generated by θ (the coercion `↥` turns a subspace into a type).
- `TP` is the subspace $T^+ \subseteq V_\Lambda^T = S[\theta] \otimes T$ (the type `Tw`) of fixed points of the lift of θ to the twisted module. It is used as a type through the same coercion.

- `plusModule` is T^+ as an ordinary V_Λ^+-module: $u_{(n)}x$ is the twisted vertex operator's mode at the integer n (for $u \in V_\Lambda^+$ only integral modes survive).
- `leechLTP` is L_{-1} on T^+.
- `leechWsk t` is the field $W(t,z)$ with coefficient of z^k equal to $W(t)_{(-k-1)}$, where

$$W(t)_{(n)}\varphi = \sum_{i\ge 0} \frac{(-1)^{n+i+1}}{i!}\, L_{-1}^{i}\big(\varphi_{(n+i)}t\big), \tag{38.3}$$

  the z^{-n-1} coefficient of $e^{zL_{-1}}Y^T(\varphi,-z)t$. On the vacuum, $W(t,z)\mathbf{1} = e^{zL_{-1}}t$; in Lean,

```
theorem leechWsk_vacuum (t : TP) (k : ℤ) :
    leechWsk t k leechVOAPlus.vacuum
      = if 0 ≤ k then ((k.toNat.factorial : ℂ)⁻¹) • (leechLTP ^ k.toNat) t else 0
```

- `leechBV` is the canonical invariant form B_V of V_Λ^+, normalised $B_V(\mathbf{1},\mathbf{1}) = 1$; it is symmetric, fully invariant, and nondegenerate on every weight space (`leechBV_gradedNondeg`).
- `TPForm` is the restriction to T^+ of an explicit form on V_Λ^T; it is symmetric (`TPForm_symm`), the weight spaces are mutually orthogonal (`TPForm_weightOrth`), it is nondegenerate on every weight space:

```
theorem TPForm_nondegenerate (α : ℂ) (x : TP) (hx : x ∈ plusModule.weight α) (hx0 : x
↪  ≠ 0) :
    ∃ y ∈ plusModule.weight α, TPForm x y ≠ 0
```

  and it is FHL-invariant for every homogeneous $u \in V_\Lambda^+$ (`TPForm_fhlInv`, with conclusion `InvForm.FHLInv plusModule InvForm.TPForm wt u`).
- `leechWbar t` is the field $\overline{W}(t,z)$ whose mode $\overline{W}(t)_{(n)}$ (`leechWbarMode n t`) is defined, by the Riesz representation on each weight space of V_Λ^+, as the unique linear map $T^+ \to V_\Lambda^+$ satisfying DGM's adjunction (4.3): for $t \in T_w^+$,

$$B_V\big(\overline{W}(t)_{(n)}a,\varphi\big) = (-1)^w \sum_{j\ge 0}\frac{1}{j!}\,\big(a,\ W(L_1^j t)_{(2w-n-2-j)}\varphi\big)_T. \tag{38.4}$$

  In Lean (`VOA/Moonshine/NondegLeech.lean`):

```
theorem leechWbar_adj' (n : ℤ) {w : ℤ} {t : TP} (ht : t ∈ plusModule.weight (w : ℂ))
↪  (R : ℕ)
    (hR : ∀ j : ℕ, R ≤ j → (Lp1 plusModule ^ j) t = 0) (a : TP) (φ : SkewVP) :
    leechBV (leechWbarMode n t a) φ = (-1 : ℂ) ^ w • ∑ j ∈ Finset.range R,
      ((j.factorial : ℂ)⁻¹) • TPForm a (mode (leechWsk ((Lp1 plusModule ^ j) t))
        (2 * w - n - 2 - j) φ)
```

  The bound R is any number past which $L_1^j t = 0$; the sum is then the full sum. Equation (38.4) is exactly (38.2) for the off-diagonal entries of the form $B_V \oplus (\cdot,\cdot)_T$ that we shall put on $V^\natural$: it says that $\overline{W}(t,z)$ is the "FHL adjoint" of $W(t,z)$.

Besides (38.4), the earlier chapters prove, unconditionally, three further properties of $\overline{W}$ that we shall use: it is graded, $\overline{W}(t)_{(n)}T_b^+ \subseteq (V_\Lambda^+)_{b+w-n-1}$ for $t \in T_w^+$ (`leechWbar_mem`); it is lower-truncated (`leechWbar_trunc`); it satisfies $\overline{W}(L_{-1}t,z) = \partial_z \overline{W}(t,z)$ (`leechWbar_deriv`); and it satisfies the intertwining commutator formula

$$u_{(m)}\overline{W}(t)_{(n)}a - \overline{W}(t)_{(n)}u_{(m)}a = \sum_{r\ge 0}\binom{m}{r}\overline{W}(u_{(r)}t)_{(m+n-r)}a \qquad (u \in V_\Lambda^+), \tag{38.5}$$

(`leechWbar_comm'`), the mirror image of the commutator formula for W.

Finally, the generating function of the final targets:

```
noncomputable def jShift : PowerSeries ℂ :=
  E4Series ^ 3 * ((deltaOverQUnit⁻¹ : (PowerSeries ℂ)ˣ) : PowerSeries ℂ)
noncomputable def JShift : PowerSeries ℂ := jShift - (744 : ℂ) • PowerSeries.X
```

(`VOA/Modularity/JFunction.lean`.) Here $E_4^3\cdot(\Delta/q)^{-1}$ is the power series $q\,j(q) = 1+744q+196884q^2+\cdots$, and subtracting $744q$ gives

$$\texttt{JShift} = q\,J(q) = q\big(j(q)-744\big) = 1 + 0\cdot q + 196884\,q^2 + 21493760\,q^3 + \cdots.$$

The coefficient of q^n in `JShift` is therefore the coefficient of q^{n-1} in J; with the usual $L_0-c/24 = L_0-1$ shift, it is the expected dimension of the weight-n space of $V^\natural$.

38.3 Block fields on a direct sum

Everything in this section is linear algebra on an arbitrary direct sum $V \oplus M$ of complex vector spaces; nothing about the Leech lattice is used. The point is to translate the four-block description (38.1) into the language of $\mathrm{End}(V\oplus M)$-valued fields that the definition of a vertex algebra uses, and to see which of the vertex-algebra conditions can be checked block by block.

38.3.1 Block operators

Definition 38.10 (Block operator). For linear maps $a : V \to V$, $c : M \to V$, $d : V \to M$, $b : M \to M$, the *block operator* $\left(\begin{smallmatrix} a & c \\ d & b \end{smallmatrix}\right) \in \mathrm{End}(V\oplus M)$ is $(x,y) \mapsto (ax+cy,\ dx+by)$.

```
def blockOp (a : End ℂ V) (c : M →ₗ[ℂ] V) (d : V →ₗ[ℂ] M) (b : End ℂ M) : End ℂ (V × M) :=
  (a.coprod c).prod (d.coprod b)

@[simp] theorem blockOp_apply (a : End ℂ V) (c : M →ₗ[ℂ] V) (d : V →ₗ[ℂ] M) (b : End ℂ M)
    (x : V × M) : blockOp a c d b x = (a x.1 + c x.2, d x.1 + b x.2) := rfl
```

(`VOA.Moonshine.VnatBlock.blockOp`, `VOA/Moonshine/VnatBlock.lean`.)

From the mathematics to the Lean statement

`V × M` is the product type; as a vector space it is the direct sum $V\oplus M$, with `x.1`, `x.2` the two components. `a.coprod c : V × M →ₗ V` is $(x,y)\mapsto ax+cy$, and `f.prod g` pairs two maps into a product. The argument order `a c d b` — top-left, top-right, bottom-left, bottom-right — is fixed throughout the chapter; note in particular that the off-diagonal block from M to V comes *second*. The `rfl` proof of `blockOp_apply` shows that the definition is literally the matrix action.

Physical meaning

A block operator is a 2×2 operator matrix on untwisted $\oplus$ twisted states: the diagonal entries are the sector-preserving parts of a vertex operator and the off-diagonal ones change sector. It is the formal expression of the $\mathbb{Z}/2$ charge grading of the orbifold, where an untwisted operator preserves twist and a twist field flips it.

Proposition 38.11 (Matrix multiplication). $\left(\begin{smallmatrix} a & c \\ d & b \end{smallmatrix}\right)\left(\begin{smallmatrix} a' & c' \\ d' & b' \end{smallmatrix}\right) = \left(\begin{smallmatrix} aa'+cd' & ac'+cb' \\ da'+bd' & dc'+bb' \end{smallmatrix}\right)$.

```
theorem blockOp_mul (a : End ℂ V) (c : M →ₗ[ℂ] V) (d : V →ₗ[ℂ] M) (b : End ℂ M)
    (a' : End ℂ V) (c' : M →ₗ[ℂ] V) (d' : V →ₗ[ℂ] M) (b' : End ℂ M) :
    blockOp a c d b * blockOp a' c' d' b'
      = blockOp (a * a' + c ∘ₗ d') (a ∘ₗ c' + c ∘ₗ b') (d ∘ₗ a' + b ∘ₗ d')
          (d ∘ₗ c' + b * b') := by
```

From the mathematics to the Lean statement

`*` on `End` is composition and `∘ₗ` is composition of linear maps between different spaces; so the statement is exactly the 2×2 matrix product. The library also proves additivity, scalar multiplication and `blockOp_zero` (the zero matrix is 0).

Physical meaning

Matrix multiplication of block operators is the rule for composing operators in the orbifold theory sector by sector: the untwisted→untwisted amplitude of a product is the untwisted-through-untwisted channel plus the channel with an intermediate twisted state. It is the origin of the sum over intermediate sectors in the orbifold OPE; it is linear algebra, with no physics input.

Proof. Apply both sides to (x, y) and expand. □

38.3.2 Block fields

Definition 38.12 (Block field; diagonal and off-diagonal fields)**.** Given distributions $a(z) \in \mathrm{End}(V)[[z^{\pm}]]$, $c(z) \in \mathrm{Hom}(M, V)[[z^{\pm}]]$, $d(z) \in \mathrm{Hom}(V, M)[[z^{\pm}]]$, $b(z) \in \mathrm{End}(M)[[z^{\pm}]]$, the *block field* is the $\mathrm{End}(V \oplus M)$-valued distribution whose z^k-coefficient is the block operator of the four z^k-coefficients. The *diagonal field* is $\mathrm{diag}(a, b)$ (with $c = d = 0$) and the *off-diagonal field* is $\mathrm{offdiag}(c, d)$ (with $a = b = 0$).

```
def blockF (a : FormalDist (End ℂ V)) (c : FormalDist (M →ₗ[ℂ] V)) (d : FormalDist (V →ₗ[ℂ]
↪  M))
    (b : FormalDist (End ℂ M)) : FormalDist (End ℂ (V × M)) :=
  fun n => blockOp (a n) (c n) (d n) (b n)

def diagF (a : FormalDist (End ℂ V)) (b : FormalDist (End ℂ M)) : FormalDist (End ℂ (V ×
↪  M)) :=
  blockF a 0 0 b

def offF (c : FormalDist (M →ₗ[ℂ] V)) (d : FormalDist (V →ₗ[ℂ] M)) :
    FormalDist (End ℂ (V × M)) :=
  blockF 0 c d 0
```

From the mathematics to the Lean statement

Since modes are just reindexed coefficients, the block field of the modes is the block operator of the modes: $(\text{block field})_{(n)} = \left(\begin{smallmatrix} a_{(n)} & c_{(n)} \\ d_{(n)} & b_{(n)} \end{smallmatrix}\right)$. In (38.1), an untwisted state u gives `diagF (Y u) (Y^T u)`, a twisted state t gives `offF (W̄ t) (W t)` — again with the $T^+ \to V_\Lambda^+$ block $\overline{W}$ first.

Physical meaning

A block field is the full chiral vertex operator of the orbifold theory: its diagonal part is the OPE of an untwisted operator with states of each sector (untwisted×untwisted→untwisted, untwisted×twisted→twisted) and its off-diagonal part is the OPE of a twist field (twisted×untwisted→twisted via W, twisted×twisted→untwisted via $\overline{W}$). Assembling all four channels into one field is what makes the two sectors into a single CFT with one vertex operator per state.

38.3.3 Truncation and translation covariance blockwise

For Hom-valued distributions the library uses the obvious generalisations of Definitions 38.5 and 38.6.

Definition 38.13. A distribution $f(z)$ with values in $\mathrm{Hom}(X, Y)$ is *lower-truncated* if for every $x \in X$ the coefficients $f_n x$ vanish for $n \ll 0$. Given $T_X \in \mathrm{End}\, X$, $T_Y \in \mathrm{End}\, Y$, it is (T_X, T_Y)*-covariant* if $T_Y f_m - f_m T_X = (m+1) f_{m+1}$ for all m, i.e. $T_Y f(z) - f(z) T_X = \partial_z f(z)$.

```
def Trunc {X : Type*} {Y : Type*} [AddCommGroup X] [Module ℂ X] [AddCommGroup Y] [Module ℂ
↪  Y]
    (f : FormalDist (X →ₗ[ℂ] Y)) : Prop :=
  ∀ x : X, ∃ B : ℤ, ∀ n : ℤ, n < B → f n x = 0

def HomCov {X : Type*} {Y : Type*} [AddCommGroup X] [Module ℂ X] [AddCommGroup Y] [Module ℂ
↪  Y]
    (TX : End ℂ X) (TY : End ℂ Y) (f : FormalDist (X →ₗ[ℂ] Y)) : Prop :=
  ∀ m : ℤ, TY ∘ₗ f m - f m ∘ₗ TX = (m + 1 : ℤ) • f (m + 1)
```

Physical meaning

Lower truncation of a Hom-valued distribution is the requirement that each channel of the OPE (e.g. twisted×untwisted→twisted) has a pole of bounded order at coincident points, and covariance is the Ward identity for translations with possibly different generators on source and target sector. Both are the standard consistency conditions on the OPE channels, imposed blockwise.

Proposition 38.14. *(a) If the four blocks are lower-truncated, the block field is a field.*

(b) If a is T_V-covariant, b is T_M-covariant, c is (T_M, T_V)-covariant and d is (T_V, T_M)-covariant, then the block field is covariant for $\mathrm{diag}(T_V, T_M)$.

    Reconstruction.DCovariant (blockOp TV 0 0 TM) (blockF a c d b) := by
```

From the mathematics to the Lean statement

Hypotheses in (a): the four truncations, one for each block; for c and d the relevant input vector lives in M resp. V. In (b) the order of the two translation operators in `HomCov` is (source, target): $c : M \to V$ is (T_M, T_V)-covariant, $d : V \to M$ is (T_V, T_M)-covariant. The conclusion uses the diagonal operator `blockOp TV 0 0 TM`. Both statements are the textbook ones; they are implications, so they cannot be vacuous unless their hypotheses are unsatisfiable, and the hypotheses are verified later for the actual blocks.

Physical meaning

Physically: if each of the four OPE channels has bounded-order singularities and obeys the translation Ward identity separately, the combined orbifold vertex operator does too. This is the statement that translation invariance and finiteness of the OPE are sector-by-sector conditions and need no cross-sector checking. It is bookkeeping, not dynamics.

Proof. (a) For (x, y) take the minimum of the four truncation bounds (for a, d at x, for c, b at y). (b) $[\mathrm{diag}(T_V, T_M), X]$ for a block matrix X is the block matrix with entries $T_V a - a T_V$, $T_V c - c T_M$, $T_M d - d T_V$, $T_M b - b T_M$; apply the four hypotheses. □

38.3.4 Locality blockwise

Here is the real content. Locality of two block fields is not, in general, a blockwise condition, because the product of two block matrices mixes the blocks. But in two important special cases it reduces to conditions on the blocks.

Theorem 38.15 (Diagonal–diagonal locality). *If $a \sim a'$ on V and $b \sim b'$ on M (mutually local), then* $\mathrm{diag}(a, b)$ *and* $\mathrm{diag}(a', b')$ *are mutually local.*

File `VOA/Moonshine/VnatBlock.lean`.

```
theorem local_diag_diag {a a' : FormalDist (End ℂ V)} {b b' : FormalDist (End ℂ M)}
    (ha : Local a a') (hb : Local b b') : Local (diagF a b) (diagF a' b') := by
```

Physical meaning

Two untwisted-type operators, acting on the untwisted and twisted sectors simultaneously, have trivial braiding on the orbifold space as soon as they do so on each sector. Here the untwisted×untwisted→untwisted locality is crossing symmetry in the parent CFT, and the module version is locality of the induced action on the twisted sector; both are established earlier in the book. The result is the easy half of the orbifold's mutual-locality consistency.

Theorem 38.16 (Diagonal–off-diagonal locality). $\mathrm{diag}(a(z_1), b(z_1))$ *and* $\mathrm{offdiag}(c'(z_2), d'(z_2))$ *are mutually local provided that, for some N,*

$$(z_1 - z_2)^N \big(a(z_1)c'(z_2) - c'(z_2)b(z_1)\big) = 0 \quad \text{and} \quad (z_1 - z_2)^N \big(b(z_1)d'(z_2) - d'(z_2)a(z_1)\big) = 0.$$

File `VOA/Moonshine/VnatBlock.lean`.

```
theorem local_diag_off {a : FormalDist (End ℂ V)} {b : FormalDist (End ℂ M)}
    {c' : FormalDist (M →ₗ[ℂ] V)} {d' : FormalDist (V →ₗ[ℂ] M)}
    (hc : ∃ N : ℕ, mulBySubPow N
      ((fun m n => a m ∘ₗ c' n - c' n ∘ₗ b m) : FormalDist₂ (M →ₗ[ℂ] V)) = 0)
    (hd : ∃ N : ℕ, mulBySubPow N
      ((fun m n => b m ∘ₗ d' n - d' n ∘ₗ a m) : FormalDist₂ (V →ₗ[ℂ] M)) = 0) :
    Local (diagF a b) (offF c' d') := by
```

From the mathematics to the Lean statement

The two hypotheses are Hom-valued: `fun m n ⇒ a m ∘ₗ c' n - c' n ∘ₗ b m` is the two-variable distribution with coefficients $a_m c'_n - c'_n b_m \in \mathrm{Hom}(M, V)$, the "intertwining commutator". For our application, $a = Y(u)$, $b = Y^T(u)$ and $c' = \overline{W}(t)$, $d' = W(t)$: the hypotheses say that $\overline{W}(t)$ intertwines $Y^T(u)$ with $Y(u)$ and that $W(t)$ intertwines $Y(u)$ with $Y^T(u)$, up to a power of $(z_1 - z_2)$ — the usual locality condition for an intertwining operator. The two `N`'s may differ (the proof takes the maximum), which matches the textbook. The theorem is an

implication, not an equivalence; only the direction needed is claimed.

Physical meaning

This is the crossing condition between an untwisted operator and a twist field: moving an untwisted operator around a twist field is controlled by the intertwining (fusion) relations of W and $\overline{W}$, and the theorem says that the two intertwining relations in the hypothesis suffice. Heuristically this is the statement that the twisted sector is a consistent representation of the untwisted chiral algebra. The hypotheses are verified for W in the earlier chapters and for $\overline{W}$ via the commutator formula.

Proof of both theorems. Write $X = \left(\begin{smallmatrix} a & c \\ d & b \end{smallmatrix}\right)$, $X' = \left(\begin{smallmatrix} a' & c' \\ d' & b' \end{smallmatrix}\right)$. By Proposition 38.11, the commutator $[X(z_1), X'(z_2)]$ is the block matrix

$$\begin{pmatrix} [a,a'] + cd' - c'd & ac' + cb' - a'c - c'b \\ da' + bd' - d'a - b'd & [b,b'] + dc' - d'c \end{pmatrix},$$

all entries evaluated at (z_1, z_2) in the obvious way. Since $(z_1 - z_2)^N$ acts entrywise, the commutator is killed by $(z_1 - z_2)^N$ iff each entry is. For two diagonal fields, $c = d = c' = d' = 0$, and the entries reduce to $[a,a']$, 0, 0, $[b,b']$. For a diagonal field against an off-diagonal one, $c = d = a' = b' = 0$, and the entries reduce to 0, $ac' - c'b$, $bd' - d'a$, 0. In both cases the hypotheses kill each entry for N the maximum of the given orders (a larger power of $(z_1 - z_2)$ still kills). □

Remark 38.17. For two off-diagonal fields ($a = b = a' = b' = 0$) the same computation gives a *diagonal* commutator, with entries $cd' - c'd$ on V and $dc' - d'c$ on M. This is the twisted–twisted case, treated in Section 38.8: there locality is *equivalent* to two End-valued relations, which for $V^\natural$ are DGM's (4.22) and (4.23).

What the machine verified

`blockOp`, `blockF`, `diagF`, `offF`, `isField_blockF`, `dCovariant_blockF`, `local_diag_diag`, `local_diag_off`: generic, unconditional, `##print axioms` = `[propext, Classical.choice, Quot.sound]` (checked for `local_diag_off`; the others are dependencies of checked theorems).

38.4 Locality of the fields of a module

For the diagonal blocks of (38.1) we need that the fields $Y^T(u,z)$, $Y^T(v,z)$ of the V_Λ^+-module T^+ are mutually local. For the vertex algebra itself locality is an axiom; for a module defined by the Jacobi identity it is a theorem — but one the library did not have when this part of the construction was written. It is proved here for an arbitrary weak module, and it is worth explaining because it shows the mechanism by which all localities in this chapter are proved: a *commutator formula* with finitely many terms.

Theorem 38.18 (Module commutator formula)**.** *Let M be a weak module over a vertex operator algebra W, $u, v \in W$, and suppose $J \in \mathbb{N}$ is such that $u_{(j)}v = 0$ for all $j \geq J$. Then for all $m, n \in \mathbb{Z}$ and $x \in M$,*

$$u_{(m)}v_{(n)}x - v_{(n)}u_{(m)}x = \sum_{r=0}^{J-1} \binom{m}{r} (u_{(r)}v)_{(m+n-r)}x.$$

File `VOA/Moonshine/VnatBlock.lean`.

```
theorem act_comm (A : WeakModule W M) (u v : 𝒱) (m n : ℤ) (x : M) (J : ℕ)
    (hJ : ∀ j : ℕ, J ≤ j → W.smul u j v = 0) :
    A.act u m (A.act v n x) - A.act v n (A.act u m x)
      = ∑ r ∈ Finset.range J, gBinom m r • A.act (W.smul u r v) (m + n - r) x := by
```

From the mathematics to the Lean statement

`A.act u m x` is $u_{(m)}x$ in M; `W.smul u r v` is $u_{(r)}v$ in W; `Finset.range J` is $\{0,\dots,J-1\}$; `gBinom m r` is $\binom{m}{r}$. The hypothesis `hJ` says J is past the truncation of $u_{(.)}v$; by VA5 such J exists. This is exactly the textbook commutator formula; since the sum is finite, no convergence issue arises.

Physical meaning

This is the operator-algebra form of the Jacobi identity: the commutator of two modes of a chiral algebra is a finite sum of modes of the OPE coefficients, $[u_{(m)},v_{(n)}] = \sum_r \binom{m}{r}(u_{(r)}v)_{(m+n-r)}$. Applied to modules it says that the commutator algebra of the vertex operators of any sector of the CFT closes in the way dictated by the OPE in the vacuum sector. It is the formal origin of the algebra of Noether charges and currents.

Proof. Take $\ell = 0$ in the module Jacobi identity (the `jacobi` field of `WeakModule`). On the left only $i = 0$ survives, because $\binom{0}{i} = 0$ for $i \neq 0$, leaving $u_{(m)}v_{(n)}x - v_{(n)}u_{(m)}x$. On the right, $\binom{m}{i}$ vanishes for $i < 0$ and $u_{(i)}v = 0$ for $i \geq J$, leaving the displayed finite sum. □

Theorem 38.19 (Locality of module fields). *For every weak module M of W and all $u, v \in W$, the fields $Y_M(u,z)$ and $Y_M(v,z)$ are mutually local.*

File `VOA/Moonshine/VnatBlock.lean`.

```
theorem local_YM (A : WeakModule W M) (u v : 𝒱) : Local (A.YM u) (A.YM v) := by
```

(`VOA.Moonshine.VnatBlock.local_YM`.)

From the mathematics to the Lean statement

No hypotheses beyond A being a weak module. `Local` is Definition 38.4 for the End(M)-valued fields `A.YM u`, `A.YM v`. Same as the textbook statement (e.g. Lepowsky–Li, Prop. 4.2.1 in the module setting). It could be vacuous only if `WeakModule` were unsatisfiable; the adjoint module of any VOA is a weak module, and the library's `plusModule` is one.

Physical meaning

Every sector of a chiral CFT (every module) carries mutually local fields: braiding of two untwisted operators acting on any representation is trivial up to contact terms, because the same OPE holds in every sector. This is why the twisted sector of the orbifold, viewed only as a representation of the untwisted algebra, causes no locality trouble; the difficulty sits entirely in twist×twist.

Proof. Let N be the truncation order of $u_{(.)}v$. By Theorem 38.18, rewritten as an identity of two-variable distributions,

$$[Y_M(u,z_1),Y_M(v,z_2)] = \sum_{r=0}^{N-1} Y_M(u_{(r)}v,z_2)\,\frac{1}{r!}\partial_{z_2}^{r}\delta(z_1-z_2),$$

where $\delta(z_1-z_2) = \sum_k z_1^{-k-1}z_2^{k}$ is the formal delta function (the coefficient pattern $\binom{-a-1}{r}$ of the r-th derivative is what the library calls a "jump distribution"). Since $(z_1-z_2)^{r+1}\partial_{z_2}^{r}\delta(z_1-z_2) = 0$, the power $(z_1-z_2)^N$ kills every term. □

Remark 38.20. The physical meaning: the operator product expansion $Y(u,z_1)Y(v,z_2) \sim \sum_r \frac{Y(u_{(r)}v,z_2)}{(z_1-z_2)^{r+1}}$ has a pole of finite order, and the same OPE governs the action on any module. Locality is the statement that the two orderings of the product are boundary values of one rational function with poles only on the diagonal.

Two consequences of the same commutator formula, used for translation covariance:

Proposition 38.21. *(a) The fields of a weak module are L_{-1}^M-covariant: $[L_{-1}^M, Y_M(u,z)] = \partial_z Y_M(u,z)$. (b) For a weak module M and $t \in M$, the skew field $W(t,z)\varphi = e^{zL_{-1}}Y_M(\varphi,-z)t$ is (L_{-1}, L_{-1}^M)-covariant.*

File `VOA/Moonshine/VnatBlock.lean`.

```
theorem dCovariant_YM (A : WeakModule W M) (u : 𝒱) :
    Reconstruction.DCovariant (Lm1 A) (A.YM u) := by

theorem homCov_Wsk (A : WeakModule W M) (t : M) : HomCov (W.L (-1)) (Lm1 A) (Wsk A t) := by
```

From the mathematics to the Lean statement

`Lm1 A` is $\omega_{(0)}$ on M; `W.L (-1)` is L_{-1} on W; `Wsk A t` is the field whose z^k-coefficient is the map $\varphi \mapsto W(t)_{(-k-1)}\varphi$ of (38.3). In `homCov_Wsk` the source of $W(t,z)$ is W (the VOA) and the target is M, so the order `(W.L (-1)) (Lm1 A)` is (source, target), as in Definition 38.13.

Physical meaning

Part (a) is the Ward identity for translations in every sector. Part (b) says that the skew field $W(t,z)$, i.e. the twisted operator t acting on untwisted states by reading the OPE backwards, $\phi_t(z)\varphi = e^{zL_{-1}}Y(\varphi,-z)t$, also translates correctly. This is the skew-symmetry of the OPE: exchanging two operators is the same as moving one by $e^{zL_{-1}}$ and flipping the sign of the coordinate.

Proof. (a) Apply Theorem 38.18 with u replaced by ω and $m = 0$: $[\omega_{(0)}, u_{(n)}] = (\omega_{(0)}u)_{(n)} = (L_{-1}u)_{(n)} = -n\,u_{(n-1)}$, the last step being the module translation property $Y_M(L_{-1}u,z) = \partial_z Y_M(u,z)$. Re-indexed by powers of z (the coefficient of z^m is $u_{(-m-1)}$), this is $[L_{-1}^M, Y_M(u)_m] = (m+1)Y_M(u)_{m+1}$. (b) The commutator formula for the skew operator W at $u = \omega$, $m = 0$ gives $L_{-1}^M W(t)_{(n)}\varphi - W(t)_{(n)}L_{-1}\varphi = W(L_{-1}^M t)_{(n)}\varphi$, and $W(L_{-1}^M t,z) = \partial_z W(t,z)$ (both proved for W in the chapter on intertwiners). □

What the machine verified

`act_comm`, `local_YM`, `dCovariant_YM`, `homCov_Wsk`: general (any VOA, any weak module), unconditional, axiom-clean (`local_YM` checked directly).

38.5 The carrier $V^\natural$ and its grading

Definition 38.22 (The carrier, its grading, vacuum and conformal vector). $V^\natural := V_\Lambda^+ \oplus T^+$, graded by $V^\natural{}_n := (V_\Lambda^+)_n \oplus T_n^+$ for $n \in \mathbb{Z}$, where T_n^+ is the L_0-eigenspace of eigenvalue n. The vacuum is $\mathbf{1}^\natural = (\mathbf{1}, 0)$ and the conformal vector is $\omega^\natural = (\omega, 0)$.

```
abbrev Vnat : Type := SkewVP × TP

noncomputable def gradingNat (n : ℤ) : Submodule ℂ Vnat :=
  (leechVOAPlus.grading n).prod (plusModule.weight (n : ℂ))

noncomputable def vacNat : Vnat := (leechVOAPlus.vacuum, 0)

noncomputable def omegaNat : Vnat := (leechVOAPlus.conformalVector, 0)
```

(`VOA/Moonshine/VnatCarrier.lean`.)

From the mathematics to the Lean statement

`p.prod q` for submodules $p \le V, q \le M$ is $p \oplus q \le V \oplus M$. The module T^+ carries a $\mathbb{C}$-indexed grading `plusModule.weight α` by L_0-eigenvalue; it is read here at the integer n (the cast `(n : ℂ)`). This loses nothing: the earlier chapter proves that every nonzero weight space of T^+ has an integral weight ≥ 2 (`plusModule_weight_ne_bot`). The conformal vector is $(\omega, 0)$, not ω plus a twisted correction: in the orbifold the Virasoro field is untwisted. **Important for the trap:** none of these four definitions involves W or $\overline{W}$. They describe a graded vector space, not a vertex algebra.

Physical meaning

The carrier $V^\natural$ is the state space of the orbifold CFT: untwisted sector (the reflection-invariant states of the Leech-torus theory) plus twisted sector (the invariant states of the twist-field Hilbert space at the 2^{24} fixed points). The vacuum is the untwisted vacuum and the conformal vector is the untwisted stress tensor $T(z)$, so the total theory has $c = 24$. Weight spaces are the L_0 eigenspaces, which is how the graded dimensions become the coefficients of the partition function.

Theorem 38.23 ($V^\natural = \bigoplus_n V^\natural{}_n$). *The subspaces $V^\natural{}_n$, $n \in \mathbb{Z}$, form an internal direct sum decomposition of $V^\natural$, and each $V^\natural{}_n$ is finite-dimensional with* $\dim V^\natural{}_n = \dim (V_\Lambda^+)_n + \dim T_n^+$.

```
theorem gradingNat_isInternal : DirectSum.IsInternal gradingNat :=

instance finiteDimensional_gradingNat (n : ℤ) : FiniteDimensional ℂ (gradingNat n) := by

theorem finrank_gradingNat (n : ℤ) :
    finrank ℂ (gradingNat n)
      = finrank ℂ (leechVOAPlus.grading n) + finrank ℂ (plusModule.weight (n : ℂ)) := by
```

From the mathematics to the Lean statement

`finrank ℂ X` is Mathlib's dimension of a $\mathbb{C}$-vector space X (as a natural number; it is 0 for infinite-dimensional X, which is why finite-dimensionality is stated separately, as an instance). The coercion turns the submodule `gradingNat n` into a vector space.

Physical meaning

The state space is a graded sum of finite-dimensional L_0-eigenspaces: the energy spectrum is discrete with finite degeneracies, so the partition function $\mathrm{Tr}\, q^{L_0 - c/24}$ exists as a formal power series. This is the minimal input needed to speak of a modular-invariant partition function.

Proof. Independence: if $x \in V^\natural{}_n$ also lies in the sum of the other $V^\natural{}_k$, project to the two components; the first lies in $(V_\Lambda^+)_n$ and in the sum of the other $(V_\Lambda^+)_k$, hence is 0; the second likewise, using the $\mathbb{C}$-grading of T^+ and that $k \ne n$ implies $(k : \mathbb{C}) \ne (n : \mathbb{C})$. Spanning: (V_Λ^+) is spanned by its graded pieces, and T^+ is spanned by its *integral* weight spaces because the others are zero. The dimension is that of a direct sum. □

Theorem 38.24 (Low weights). $V^\natural{}_n = 0$ *for* $n < 0$; $V^\natural{}_0 = \mathbb{C}\mathbf{1}^\natural$; $V^\natural{}_1 = 0$.

```
theorem gradingNat_neg {n : ℤ} (hn : n < 0) : gradingNat n = ⊥ := by

theorem gradingNat_zero : gradingNat 0 = ℂ • vacNat := by

theorem gradingNat_one : gradingNat 1 = ⊥ := by
```

From the mathematics to the Lean statement

`⊥` is the zero subspace; `ℂ • vacNat` is the line spanned by $\mathbf{1}^\natural$.

Physical meaning

No negative-energy states, a unique vacuum, and in particular no weight-one states: the theory has no conserved currents. In 2d CFT terms $V_1^\natural = 0$ means there is no continuous global symmetry, so the symmetry group is a finite group, which by FLM's theorem is the Monster (not formalized in the library). Such a theory has no free parameters in its Hilbert space and no marginal-looking Lie-algebra structure at weight one. The absence of a weight-one sector holds for the genuine theory and also for the impostor, so this does not distinguish them.

Proof. $T_n^+ = 0$ for $n < 2$ (its weights are ≥ 2), so in weights ≤ 1 only the untwisted part contributes. V_Λ^+ has CFT type ($V_0 = \mathbb{C}\mathbf{1}$, $V_n = 0$ for $n < 0$), and $(V_\Lambda^+)_1 = 0$: the weight-one space of V_Λ is $\mathfrak{h} = \mathbb{C} \otimes \Lambda$ (the Leech lattice has no roots), on which θ acts by -1. □

Theorem 38.25 (Griess dimension). $\dim {V^\natural}_2 = 196884$.

```
theorem finrank_gradingNat_two : finrank ℂ (gradingNat 2) = 196884 := by
```

Physical meaning

The first nontrivial energy level has $196884 = 196883 + 1$ states: the 196883-dimensional irreducible representation of the Monster plus the trivial one (the stress tensor); the Monster action is a fact of the literature, not formalized here. The weight-two space is the Griess algebra; in the orbifold it splits as 98580 untwisted states ($300 + 98280$: the symmetric square of the oscillators and the pairs $e^\alpha + e^{-\alpha}$, $\alpha^2 = 4$) plus $98304 = 24 \cdot 4096$ twist-field states. The total matches the first Moonshine coincidence $1 + 196883$ in the j-function.

Proof. $\dim(V_\Lambda^+)_2 = 98580$ and $\dim T_2^+ = 98304$, proved in the chapters on graded dimensions and on the twisted module; $98580 + 98304 = 196884$. For the reader's orientation: $(V_\Lambda)_2$ has dimension $\binom{24+1}{2} + 24 + 196560 = 300 + 24 + 196560 = 196884$ ($\mathrm{Sym}^2\mathfrak{h}$, $\mathfrak{h}(-2)$, and the e^α with $\alpha^2 = 4$); θ fixes $\mathrm{Sym}^2\mathfrak{h}$ (300), negates $\mathfrak{h}(-2)$, and fixes exactly one combination $e^\alpha + \theta e^\alpha$ per pair $\pm\alpha$ (98280), giving $300 + 98280 = 98580$; and $T_2^+ = \mathfrak{h}(-\frac{1}{2})\mathbf{1} \otimes T$ has dimension $24 \cdot 4096 = 98304$. □

Theorem 38.26 (Graded dimension = J). *For every $n \in \mathbb{N}$, $\dim {V^\natural}_n$ equals the coefficient of q^n in $qJ(q)$.*

File `VOA/Moonshine/VnatCarrier.lean`.

```
theorem finrank_gradingNat_eq_coeff_JShift (n : ℕ) :
    (finrank ℂ (gradingNat (n : ℤ)) : ℂ) = PowerSeries.coeff n JShift := by
```

From the mathematics to the Lean statement

The dimension is cast to $\mathbb{C}$ because `JShift` is a power series over $\mathbb{C}$; since the dimension is a natural number, equality in $\mathbb{C}$ is equality of integers. `PowerSeries.coeff n` extracts the coefficient of q^n. `JShift` $= qJ$ was defined in Section 38.2; it is the *pre-existing* library definition $E_4^3/(\Delta/q) - 744q$, not a series reverse-engineered from the dimensions. The statement covers every $n \geq 0$; for $n < 0$ both sides would be zero (Theorem 38.24).

Physical meaning

The partition function of the orbifold equals $J(\tau) = j(\tau) - 744$ (holomorphic, $c = 24$, modular invariant up to the usual q^{-1} prefactor). This is the analytic reading on paper; the Lean theorem is an identity of formal q-series, and neither modular invariance nor holomorphy of $V^\natural$ is formalized. This is the Moonshine statement: the graded dimension of $V^\natural$ is the unique modular function with the right pole and no constant term. It is the numerical check that the untwisted and twisted sectors together produce a modular-invariant theory; it does not detect whether the OPE is correct, as the trap section shows.

Proof. The weight-n dimension is a sum of two sector dimensions; the identity $\sum_n (\dim (V_\Lambda^+)_n + \dim T_n^+) q^n = qJ(q)$ is the main theorem of the chapter on graded dimensions (Leech theta series $\Theta_\Lambda = E_4^3 - 720\Delta$, Jacobi's product for Δ, and a level-two identity for the twisted sector). □

Trap / dead end

These four numerical theorems do not depend on any vertex operator. The grading `gradingNat` is defined from the two sectors alone. Therefore any vertex operator algebra structure on `Vnat` with grading `gradingNat` — the genuine one, or the square-zero extension of Section 38.11 — has $V_1 = 0$, $\dim V_2 = 196884$ and graded dimension J. The theorems of this section are necessary for the final result but cannot distinguish $V^\natural$ from an impostor.

What the machine verified

`Vnat`, `gradingNat`, `gradingNat_isInternal`, `gradingNat_zero`, `gradingNat_one`, `finrank_gradingNat_two`, `finrank_gradingNat_eq_coeff_JShift`: unconditional; `##print axioms` = `[propext, Classical.choice, Quot.sound]` for the last two (checked).

38.6 The generator fields and the reconstruction interface

38.6.1 Translation, and the untwisted fields

Definition 38.27. $T^\natural := \mathrm{diag}(L_{-1}, L_{-1}^T) \in \mathrm{End}\, V^\natural$, where L_{-1}^T is L_{-1} on T^+. For $u \in V_\Lambda^+$, $Y_U^\natural(u,z) := \mathrm{diag}(Y(u,z), Y^T(u,z))$.

```
noncomputable def Tnat : End ℂ Vnat := blockOp (leechVOAPlus.L (-1)) 0 0 leechLTP

noncomputable def YnatU (u : SkewVP) : FormalDist (End ℂ Vnat) :=
  diagF (leechVOAPlus.Y u) (plusModule.YM u)
```

(`VOA/Moonshine/VnatFields.lean`.)

Physical meaning

$T^\natural$ is the global translation generator L_{-1} acting simultaneously on both sectors, and $Y_U^\natural(u)$ is the vertex operator of an untwisted state, acting on both sectors by the parent vertex operator and its action on the twisted module: the diagonal part of the orbifold OPE. The twist field has no diagonal part.

Proposition 38.28. *For all $u, u' \in V_\Lambda^+$: (a) $Y_U^\natural(u,z)$ is a field; (b) its z^0-coefficient sends $\mathbf{1}^\natural$ to $(u,0)$ and its z^q-coefficients for $q < 0$ kill $\mathbf{1}^\natural$; (c) it is $T^\natural$-covariant; (d) $Y_U^\natural(u,z)$ and $Y_U^\natural(u',z)$ are mutually local.*

theorem YnatU_DCovariant (u : SkewVP) : DCovariant Tnat (YnatU u) :=
theorem YnatU_local (u u' : SkewVP) : Local (YnatU u) (YnatU u') :=
  local_diag_diag (leechVOAPlus.locality u u') (local_YM plusModule.toWeakModule u u')
```

From the mathematics to the Lean statement

(b) is stated in the raw indexing: `YnatU u 0` is the z^0-coefficient, i.e. the mode $u_{(-1)}$, and `q < 0` means modes $u_{(n)}$ with $n = -q - 1 \geq 0$. So (b) is the creation axiom VA3 for untwisted states. The proof term of (d), displayed, shows the logic: locality of the V_Λ^+-block is the VOA axiom, locality of the T^+-block is Theorem 38.19, and they combine by Theorem 38.15. These are DGM's relations (4.18)–(4.19).

Physical meaning

Untwisted operators, acting on the whole orbifold space, are bona fide quantum fields: finite OPE singularities, creation of u from the vacuum, the translation Ward identity, and mutual locality among themselves. These are the axioms of a chiral algebra restricted to the untwisted subalgebra V_Λ^+, which is a CFT in its own right.

Proof. (a) from VA5 for V_Λ^+ and module truncation, through Proposition 38.14(a); (b) from VA3 of V_Λ^+ (the T^+-component of $\mathbf{1}^\natural$ is 0); (c) from Proposition 38.21(a) and its VOA case, through Proposition 38.14(b); (d) as displayed. □

38.6.2 The twisted fields, with $\overline{W}$ as a parameter

To see clearly which properties of $\overline{W}$ are used where, the library first defines the twisted field with $\overline{W}$ an *arbitrary* parameter.

Definition 38.29. For any family $\overline{W}'$ assigning to each $t \in T^+$ a distribution $\overline{W}'(t,z) \in \mathrm{Hom}(T^+, V_\Lambda^+)[[z^{\pm}]]$, put $Y_T^\natural[\overline{W}'](t,z) := \mathrm{offdiag}(\overline{W}'(t,z), W(t,z))$.

```
noncomputable def YnatT (Wbar : TP → FormalDist (TP →ₗ[ℂ] SkewVP)) (t : TP) :
    FormalDist (End ℂ Vnat) :=
  offF (Wbar t) (leechWsk t)
```

Physical meaning

A twist-field operator acts on the orbifold space by the two intertwining channels: twisted→untwisted via $\overline{W}'$ and untwisted→twisted via W. Leaving $\overline{W}'$ as a parameter separates what holds for any choice of the twisted×twisted OPE from what depends on its actual value, which is the key to the trap: the choice $\overline{W}' = 0$ is the theory in which twist fields annihilate twisted states.

Proposition 38.30 (Creation for twisted states, for every $\overline{W}'$). *For every $\overline{W}'$ and $t \in T^+$: the z^0-coefficient of $Y_T^\natural[\overline{W}'](t,z)$ sends $\mathbf{1}^\natural$ to $(0,t)$, and the z^q-coefficients with $q < 0$ kill $\mathbf{1}^\natural$.*

```
theorem YnatT_vac_zero (Wbar : TP → FormalDist (TP →ₗ[ℂ] SkewVP)) (t : TP) :
    YnatT Wbar t 0 vacNat = (0, t) := by

theorem YnatT_vac_neg (Wbar : TP → FormalDist (TP →ₗ[ℂ] SkewVP)) (t : TP) (q : ℤ) (hq : q <
↪  0) :
    YnatT Wbar t q vacNat = 0 := by
```

Physical meaning

Acting on the vacuum, the operator of a twisted state creates that state, whatever the OPE twisted×twisted→untwisted is. This is the state–operator correspondence: it fixes only the W block, since the vacuum has no twisted component. Hence creation cannot detect whether $\overline{W}'$ is the correct OPE.

Proof. $\mathbf{1}^\natural = (\mathbf{1}, 0)$ has zero twisted component, so $\overline{W}'$ never acts on it; the untwisted component is fed to $W(t,z)$, and $W(t,z)\mathbf{1} = e^{zL_{-1}}t$, whose z^0-coefficient is t and which has no negative powers. □

Trap / dead end

Creation does not see $\overline{W}'$ at all. This is the first sign of the trap: anything proved from the vacuum alone cannot detect whether $\overline{W}'$ is the genuine $\overline{W}$ or zero.

The intertwining commutator formula for the parameter is singled out as a named property:

Definition 38.31 ($\overline{W}'$-commutator formula). $\overline{W}'$ satisfies *the commutator formula* if for all $u \in V_\Lambda^+$, $t \in T^+$, $m, n \in \mathbb{Z}$ and every J past the truncation of $u_{(.)}t$,

$$u_{(m)} \circ \overline{W}'(t)_{(n)} - \overline{W}'(t)_{(n)} \circ u_{(m)} = \sum_{r<J} \binom{m}{r} \overline{W}'(u_{(r)}t)_{(m+n-r)},$$

an equality of linear maps $T^+ \to V_\Lambda^+$ (on the left, the first $u_{(m)}$ acts on V_Λ^+, the second on T^+).

File `VOA/Moonshine/VnatFields.lean`.

```
def WbarComm (Wbar : TP → FormalDist (TP →ₗ[ℂ] SkewVP)) : Prop :=
  ∀ (u : SkewVP) (m : ℤ) (t : TP) (n : ℤ) (J : ℕ),
    (∀ j : ℕ, J ≤ j → mode (plusModule.YM u) j t = 0) →
    mode (leechVOAPlus.Y u) m ∘ₗ mode (Wbar t) n - mode (Wbar t) n ∘ₗ mode (plusModule.YM
     ↪ u) m
      = ∑ r ∈ Finset.range J, gBinom m r • mode (Wbar (mode (plusModule.YM u) r t)) (m + n
       ↪ - r)
```

Physical meaning

The commutator formula for $\overline{W}'$ is the Ward identity of the untwisted chiral algebra on the twisted→untwisted OPE channel: the algebra acts on twist fields by the same rule as on any intertwining operator, so that the charges of untwisted fields rotate $\overline{W}'$ into $\overline{W}'$ of the transformed twisted state. It is the property that makes $\overline{W}'$ an intertwiner rather than an arbitrary map.

Theorem 38.32 (Untwisted–twisted locality). *If $\overline{W}'$ satisfies the commutator formula, then for all $u \in V_\Lambda^+$, $t \in T^+$ the fields $Y_U^\natural(u,z)$ and $Y_T^\natural[\overline{W}'](t,z)$ are mutually local (in both orders).*

File `VOA/Moonshine/VnatFields.lean`.

```
theorem YnatU_YnatT_local {Wbar : TP → FormalDist (TP →ₗ[ℂ] SkewVP)} (hcomm : WbarComm
 ↪ Wbar)

  local_diag_off (local_Wbar_of_comm hcomm u t) (leechWsk_local u t)

theorem YnatT_YnatU_local {Wbar : TP → FormalDist (TP →ₗ[ℂ] SkewVP)} (hcomm : WbarComm
 ↪ Wbar)
    (t : TP) (u : SkewVP) : Local (YnatT Wbar t) (YnatU u) :=
```

From the mathematics to the Lean statement

The single hypothesis `hcomm` is Definition 38.31. The proof term shows the two inputs to Theorem 38.16: locality of $Y(u)$ with $\overline{W}'(t)$, which is derived from `hcomm` exactly as Theorem 38.19 is derived from the module commutator formula, and locality of $Y(u)$ with $W(t)$ (`leechWsk_local`), proved in the chapter on intertwiners from the commutator formula for W. These are DGM (4.20)–(4.21).

Physical meaning

Untwisted operators and twist fields are mutually local when $\overline{W}'$ is an intertwiner. This is the consistency of the orbifold with respect to moving an ordinary operator around a twist field: the monodromy is trivial up to the sector change, as is needed for the fields of one theory. It follows from the commutator formula for W (established) and for $\overline{W}'$ (a hypothesis here, true for the genuine $\overline{W}$).

Proposition 38.33. *If $\overline{W}'$ is lower-truncated, it yields fields; if it satisfies the commutator formula and $\overline{W}'(L_{-1}t,z) = \partial_z \overline{W}'(t,z)$, then $Y_T^\natural[\overline{W}'](t,z)$ is $T^\natural$-covariant.*

File `VOA/Moonshine/VnatFields.lean`.

```
theorem YnatT_isField {Wbar : TP → FormalDist (TP →ₗ[ℂ] SkewVP)} (hWbar : ∀ t, Trunc (Wbar
 ↪ t))
    (t : TP) : IsField (YnatT Wbar t) :=

theorem YnatT_DCovariant {Wbar : TP → FormalDist (TP →ₗ[ℂ] SkewVP)} (hcomm : WbarComm Wbar)
    (hderiv : ∀ t, Wbar (leechLTP t) = deriv (Wbar t)) (t : TP) :
    DCovariant Tnat (YnatT Wbar t) :=
```

Physical meaning

Twist-field operators obey the translation Ward identity and have finite OPE singularities provided the channel $\overline{W}'$ does. The derivative property $\overline{W}'(L_{-1}t,z) = \partial_z \overline{W}'(t,z)$ says that the field of the descendant $L_{-1}t$ is the derivative of the field of t, a basic property of any CFT.

Proof. Covariance of the W-block is Proposition 38.21(b). For the $\overline{W}'$-block, the commutator formula at $u=\omega$, $m=0$ gives $L_{-1}\overline{W}'(t)_{(n)} - \overline{W}'(t)_{(n)}L_{-1}^T = \overline{W}'(L_{-1}^T t)_{(n)}$, and `hderiv` converts the right side into $\partial_z \overline{W}'(t,z)$. □

38.6.3 The block vertex map and the reconstruction interface

Definition 38.34. For a *linear* $\overline{W}' : T^+ \to \mathrm{Hom}(T^+, V_\Lambda^+)[[z^{\pm}]]$, the *block vertex map* is $Y^\natural[\overline{W}'](u,t) = \begin{pmatrix} Y(u) & \overline{W}'(t) \\ W(t) & Y^T(u) \end{pmatrix}$.

File `VOA/Moonshine/VnatFields.lean`.

```
noncomputable def Ynat (Wbar : TP →ₗ[ℂ] FormalDist (TP →ₗ[ℂ] SkewVP)) :
    Vnat →ₗ[ℂ] FormalDist (End ℂ Vnat) where
  toFun x := blockF (leechVOAPlus.Y x.1) (Wbar x.2) (leechWskLin x.2) (plusModule.YM x.1)
```

(`leechWskLin` is $t \mapsto W(t,z)$ as a linear map; the omitted fields prove additivity and homogeneity.) One has $Y^\natural[\overline{W}'](u,0) = Y_U^\natural(u)$ and $Y^\natural[\overline{W}'](0,t) = Y_T^\natural[\overline{W}'](t)$ (`Ynat_inl`, `Ynat_inr`).

The library's general reconstruction theorem (proved in the Core chapters) says: given a vector space with a vacuum and a translation operator, and a family of pairwise local, translation covariant,

creating fields whose iterated products applied to the vacuum span the space, there is a unique linear state–field map extending them that satisfies VA3–VA5. Its specialisation:

Physical meaning

This is the vertex operator of the whole orbifold theory: a single operator $Y^\natural(u,t)$ whose four channels are untwisted×untwisted (Y), untwisted×twisted (Y^T), twisted×untwisted (W) and twisted×twisted ($\overline{W}'$). It is the OPE of the orbifold CFT as a 2×2 operator matrix, with the twisted×twisted channel left as a parameter.

Theorem 38.35 (Reconstruction interface for $V^\natural$). *Let $g : \kappa \to T^+$ be any family. Assume of $\overline{W}'$: lower truncation, the commutator formula, and the derivative property; assume twisted–twisted locality $Y_T^\natural[\overline{W}'](g_i) \sim Y_T^\natural[\overline{W}'](g_j)$ for all i, j; and assume the word states built from the fields $Y_U^\natural(u)$, $Y_T^\natural[\overline{W}'](g_i)$ span $V^\natural$. Then there is a linear map $Y_A : V^\natural \to \mathrm{End}(V^\natural)[[z^{\pm}]]$ whose values are fields, pairwise local, creating, $T^\natural$-covariant, and agreeing with $Y_U^\natural$ on $(u,0)$ and with $Y_T^\natural[\overline{W}']$ on $(0,g_i)$.*

File `VOA/Moonshine/VnatFields.lean`.

      (∀ u : SkewVP, YA (u, 0) = YnatU u) ∧
      (∀ i, YA (0, g i) = YnatT Wbar (g i)) := by
```

From the mathematics to the Lean statement

Hypotheses: `hWbar`, `hcomm`, `hderiv` are the three properties of the parameter; `htt` is the twisted–twisted locality on the chosen family (DGM (4.23) together with (4.22), see Section 38.8); `hspan` says that the vectors $a^1_{(n_1)}\cdots a^k_{(n_k)}\mathbf{1}^\natural$ obtained by applying modes of the generator fields `genNat Wbar g` (the family $\{Y_U^\natural(u)\}_u \cup \{Y_T^\natural(g_i)\}_i$) to the vacuum span $V^\natural$ (`wordSt` lists these word states, `Set.range` is the set of them, `Submodule.span ℂ` their linear span, `⊤` all of $V^\natural$). The conclusion lists VA3, VA4, VA5 in the raw indexing. The theorem is weaker than "$V^\natural$ is a VOA": it says nothing about grading or Virasoro, which are dealt with in Section 38.7.

Trap / dead end

The trap, first appearance. Take $\overline{W}' = 0$. Then `hWbar`, `hcomm`, `hderiv` hold trivially (every term is 0; $\partial_z 0 = 0$). And `htt` holds trivially: the product of two off-diagonal fields with zero top-right blocks is $\mathrm{diag}(0\cdot W,\ W\cdot 0) = 0$ (Remark 38.17), so the commutator is 0. With $g = \mathrm{id}$ the spanning hypothesis also holds (one-letter words already give every $(u,0)$ and $(0,t)$). Hence `reconstruct_nat` *does* produce a vertex algebra for $\overline{W}' = 0$: the square-zero extension. The theorem is correct and useful, but its hypotheses are consistent with the wrong answer. This observation was made by the agent writing this file, and is recorded as the TRAP in `Notes/MonsterRoadmap.md`.

Physical meaning

A chiral algebra is determined by the fields of a generating set: the OPE of the generators (untwisted fields and a few twist fields) fixes all other fields, and locality of the generators implies locality of the rest. This is the CFT statement that one needs to check crossing symmetry only for a generating set of operators, here reduced to twist×twist, the only pairs not already controlled.

What the machine verified

`YnatU_local`, `YnatU_YnatT_local`, `YnatT_DCovariant`, `reconstruct_nat`: unconditional as implications (their hypotheses are displayed); `reconstruct_nat ##print axioms`-checked: `[propext, Classical.choice, Quot.sound]`.

38.7 All vertex-operator-algebra axioms but one

From now on the parameter is the genuine adjoint, packaged as a linear map:

```
noncomputable def wbarL : TP →ₗ[ℂ] FormalDist (TP →ₗ[ℂ] SkewVP) where
  toFun := leechWbar

noncomputable def YN : Vnat →ₗ[ℂ] FormalDist (End ℂ Vnat) := Ynat wbarL

theorem mode_YN (x y : Vnat) (n : ℤ) :
    mode (YN x) n y = (mode (leechVOAPlus.Y x.1) n y.1 + mode (leechWbar x.2) n y.2,
      mode (leechWsk x.2) n y.1 + mode (plusModule.YM x.1) n y.2) := rfl
```

(`VOA/Moonshine/VnatAxioms.lean`.) So for $x = (u, t)$, $y = (\varphi, s)$,

$$x_{(n)}y = \big(u_{(n)}\varphi + \overline{W}(t)_{(n)}s,\ \ W(t)_{(n)}\varphi + u_{(n)}s\big), \tag{38.6}$$

which is (38.1) in modes, and the `rfl` proof confirms it is the definition. The genuine $\overline{W}$ satisfies the commutator formula of Definition 38.31 (`wbar_WbarComm`, a restatement of (38.5)).

38.7.1 The Virasoro algebra on any module

Proposition 38.36 (Conformal self-products). *In any vertex operator algebra of central charge c: $\omega_{(0)}\omega = L_{-1}\omega$, $\omega_{(1)}\omega = 2\omega$, $\omega_{(2)}\omega = 0$, $\omega_{(3)}\omega = \frac{c}{2}\mathbf{1}$, $\omega_{(j)}\omega = 0$ for $j \geq 4$.*

```
theorem omega_smul_three :
    W.smul W.conformalVector 3 W.conformalVector = (W.centralCharge / 2) • W.vacuum := by
theorem omega_smul_ge_four (j : ℤ) (hj : 4 ≤ j) :
    W.smul W.conformalVector j W.conformalVector = 0 := by
```

(`VOA/Moonshine/VnatAxiomsVir.lean`; the first three are analogous.)

Physical meaning

These are the standard OPE of the stress tensor with itself, $T(z)T(0) \sim \frac{c/2}{z^4} + \frac{2T}{z^2} + \frac{\partial T}{z}$: the central term $\frac{c}{2}\mathbf{1}$ in $\omega_{(3)}\omega$ is the Virasoro anomaly, with $c = 24$ for $V^\natural$. They hold in every vertex operator algebra and fix the conformal structure of the orbifold.

Proof. $\omega_{(j+1)}\omega = L_j\omega = L_jL_{-2}\mathbf{1}$. Use $[L_j, L_{-2}] = (j+2)L_{j-2} + \delta_{j,2}\frac{j^3-j}{12}c$ and $L_k\mathbf{1} = 0$ for $k \geq -1$: for $j = 1$ one gets $3L_{-1}\mathbf{1} = 0$, for $j = 2$ one gets $4L_0\mathbf{1} + \frac{c}{2}\mathbf{1} = \frac{c}{2}\mathbf{1}$; for $j \geq 3$ the weight $3 - j < 0$ is empty. $L_0\omega = 2\omega$ is VOA2. □

Theorem 38.37 (Virasoro relations on every weak module). *Let M be a weak module over a VOA W of central charge c, and $L_n^M := \omega_{(n+1)}$ on M. Then $[L_m^M, L_n^M] = (m-n)L_{m+n}^M + \delta_{m+n,0}\frac{m^3-m}{12}c$.*

```
theorem module_virasoro (A : WeakModule W M) (m n : ℤ) :
    ⁅mode (A.YM W.conformalVector) (m + 1), mode (A.YM W.conformalVector) (n + 1)⁆
      = ((m : ℂ) - n) • mode (A.YM W.conformalVector) (m + n + 1)
        + (if m + n = 0 then (((m : ℂ) ^ 3 - m) / 12 * W.centralCharge) • (1 : End ℂ M)
           else 0) := by
```

From the mathematics to the Lean statement

`⁅X, Y⁆` is the commutator $XY - YX$ of endomorphisms; the central charge on the right is `W.centralCharge`, the one of the *algebra*. This is the textbook statement; it is a genuine theorem because the library's `OrdVModule` does not carry the Virasoro relations as an axiom.

Physical meaning

Every representation of the chiral algebra, in particular the twisted sector, carries a Virasoro algebra with the same central charge c. For $V^\natural$ this is why both sectors have $c = 24$ and why the full theory is a single conformal field theory rather than a sum of two with different central charges.

Proof. The commutator formula (Theorem 38.18) with $u = v = \omega, J = 4$, and the self-products of Proposition 38.36: $[\omega_{(m+1)}, \omega_{(n+1)}] = (L_{-1}\omega)_{(m+n+2)} + (m+1)\,2\omega_{(m+n+1)} + \binom{m+1}{3}\frac{c}{2}\mathbf{1}_{(m+n-1)}$. Module translation gives $(L_{-1}\omega)_{(k)} = -k\,\omega_{(k-1)}$, and $\mathbf{1}_{(k)} = \delta_{k,-1}$. Collecting, $-(m+n+2)+2(m+1) = m-n$, and $\binom{m+1}{3}\frac{c}{2} = \frac{m^3-m}{12}c$ at $m+n=0$. □

Proposition 38.38. *$Y_M(L_{-1}a, z) = \partial_z Y_M(a, z)$ for every weak module.*

```
theorem module_YM_Lm1 (A : WeakModule W M) (a : 𝒱) :
    A.YM (W.L (-1) a) = deriv (A.YM a) := by
```

(The field form of the module translation property, which in turn is the $\ell = 0, v = \mathbf{1}$ case of the Jacobi identity combined with $L_{-1}a = a_{(-2)}\mathbf{1}$.)

Physical meaning

The field of $L_{-1}a$ is the derivative of the field of a in every sector: descendants under L_{-1} are space derivatives of the field, $\phi_{L_{-1}a} = \partial\phi_a$. This is the formal version of the state–operator map commuting with translation.

38.7.2 The axioms for the block map

Theorem 38.39. *For the block map $Y^\natural := Y^\natural[\overline{W}]$ on $V^\natural$, with no hypotheses:*

(1) (VA1) $x \in V^\natural{}_k$, $y \in V^\natural{}_l \Rightarrow x_{(n)}y \in V^\natural{}_{k+l-n-1}$;

(2) (VA2) $Y^\natural(\mathbf{1}^\natural, z) = \mathrm{id}$;

(3) (VA3) $x_{(-1)}\mathbf{1}^\natural = x$ and $x_{(n)}\mathbf{1}^\natural = 0$ for $n \geq 0$;

(4) (VA5) for all x, y there is N with $x_{(n)}y = 0$ for $n \geq N$;

(5) (VOA1) $L_n^\natural := \omega^\natural_{(n+1)}$ satisfy the Virasoro relations with $c = 24$;

(6) *(VOA2)* $L_0^\natural = n$ *on* $V^\natural{}_n$;

(7) *(VOA3)* $Y^\natural(L_{-1}^\natural v, z) = \partial_z Y^\natural(v, z)$ *for all* v.

File `VOA/Moonshine/VnatAxioms.lean`.

```

From the mathematics to the Lean statement

Each statement is literally the corresponding field of the structures of Section 38.2, with `Y := YN`, `grading := gradingNat`, `vacuum := vacNat`, `conformalVector := omegaNat`, `centralCharge := 24`; this is why they can be plugged into the structure below without change. In (5) the number 24 is written explicitly; it arises as the central charge of V_Λ^+. In (7), `mode (YN omegaNat) 0` is $\omega_{(0)}^\natural = L_{-1}^\natural = T^\natural$. The `1` in `YN_vacuum` is the identity field (z^0-coefficient id, all others 0).

Physical meaning

All axioms of a chiral CFT for the orbifold hold at once except the final crossing relation: grading by conformal weight, vacuum, creation, regularity (finite OPE), Virasoro with $c = 24$, L_0 giving the weight and translation covariance. The remaining axiom, mutual locality of two twist fields, is the hardest consistency condition in the orbifold construction. That the other axioms need no input from the twisted OPE channel $\overline{W}$ is exactly why they cannot detect the trap: the impostor satisfies them as well.

Proof. Each axiom is checked on the four blocks of (38.6).

(1) $u_{(n)}$ on V_Λ^+ and on T^+ respects weights by VA1 and by the module grading; $W(t)_{(n)}$ maps $(V_\Lambda^+)_l$ to $T^+_{k+l-n-1}$ for $t \in T_k^+$, read off (38.3) (L_{-1}^i raises by i, $\varphi_{(n+i)}$ shifts by $l - n - i - 1$); $\overline{W}(t)_{(n)}$ maps T_l^+ to $(V_\Lambda^+)_{l+k-n-1}$ (`leechWbar_mem`).

(2) $\mathbf{1}^\natural = (\mathbf{1}, 0)$: the twisted component is 0, so only $\mathrm{diag}(Y(\mathbf{1}), Y^T(\mathbf{1})) = \mathrm{diag}(\mathrm{id}, \mathrm{id})$ remains.

(3) $Y^\natural(x) = Y_U^\natural(x_1) + Y_T^\natural(x_2)$; apply Propositions 38.28(b) and 38.30.

(4) The block field is a field (Proposition 38.14(a)) since all four blocks are truncated.

(5) $\omega^\natural = (\omega, 0)$, so $Y^\natural(\omega^\natural) = \mathrm{diag}(Y(\omega), Y^T(\omega))$ and the commutator of two diagonal operators is diagonal. The V_Λ^+-block satisfies Virasoro with $c = 24$ (central charge of V_Λ^+), the T^+-block by Theorem 38.37 with the same c.

(6) L_0 acts by n on $(V_\Lambda^+)_n$ and on T_n^+ (the latter by definition of the weight spaces of an ordinary module).

(7) $L^\natural_{-1}(u,t) = (L_{-1}u, L^T_{-1}t)$; the four blocks of $Y^\natural(L^\natural_{-1}(u,t))$ are $Y(L_{-1}u) = \partial Y(u)$ (VOA3), $Y^T(L_{-1}u) = \partial Y^T(u)$ (Proposition 38.38), $W(L^T_{-1}t) = \partial W(t)$ and $\overline{W}(L^T_{-1}t) = \partial\overline{W}(t)$ (`leechWsk_deriv`, `leechWbar_deriv`). □

Theorem 38.40 (Locality modulo the twisted–twisted block). *If $Y^\natural_T(t)$ and $Y^\natural_T(t')$ are mutually local for all $t, t' \in T^+$, then $Y^\natural(x)$ and $Y^\natural(y)$ are mutually local for all $x, y \in V^\natural$. Moreover the hypothesis need only be checked on a family whose linear span is T^+.*

Physical meaning

Crossing symmetry of the full orbifold theory reduces to twist×twist crossing, since all other pairs of channels are already local. Physically, the consistency of the orbifold (the locality of all fields) is the single constraint on the four-point function of twist fields, the one that involves the geometry of the lattice and the fixed-point structure. It can be checked on a generating family of twist fields.

Proof. Write $Y^\natural(x) = Y^\natural_U(x_1) + Y^\natural_T(x_2)$. Locality is bilinear (a sum of local pairs is local, with the maximum order), and the three mixed cases are Propositions 38.28(d) and Theorem 38.32. For the span reduction, $t \mapsto Y^\natural_T(t)$ is linear, so locality extends from a spanning family to all pairs by bilinearity. □

38.7.3 The packaged structure

Theorem 38.41 (The VOA $V^\natural$, conditional on twisted–twisted locality). *Assume $Y^\natural_T(t) \sim Y^\natural_T(t')$ for all $t, t' \in T^+$. Then $(V^\natural, (V^\natural{}_n)_n, Y^\natural, \mathbf{1}^\natural, \omega^\natural, c = 24)$ is a vertex operator algebra in the sense of the library.*

From the mathematics to the Lean statement

The definition is printed in full because here the definition *is* the statement: every field of `VertexOperatorAlgebra` is filled by a theorem of this section, and the only input that is not a proved theorem is the argument `htt`, used in exactly one place, the `locality` field. `htt` is a proposition; `vnatVOA` is a family of structures indexed by proofs of it, but since any two proofs of a proposition are equal in Lean (proof irrelevance), `vnatVOA` does not depend on *which* proof is supplied. The theorem `vnat_VOA_of_htt` records that the vertex map of this VOA *is* the block map `Ynat wbarL` (with the genuine $\overline{W}$), and that its vacuum, conformal vector, central charge and grading are the intended ones. This matters: without `V.Y = Ynat wbarL`, the existence statement would be satisfied by any VOA structure on the same space, including the square-zero one.
Compared with the textbook: the textbook theorem is unconditional; this one is conditional on twisted–twisted locality, which is DGM's (4.22) together with (4.23). It is the only input.

Trap / dead end

`vnat_VOA_of_htt` *does not by itself identify* V with the Moonshine module. The same statement with `wbarL` replaced by 0 would be true (with a trivially satisfied hypothesis) and would give the square-zero extension with the same c, grading and graded dimension. What singles out $V^\natural$ is (a) that `wbarL` is the genuine, nondegenerate adjoint, certified by `leechWbar_ne_zero` (Section 38.11), and (b) the simplicity theorem of Section 38.12.

Physical meaning

Conditional on twist×twist locality, the assembled orbifold data form a bona fide chiral CFT with $c = 24$ and a finite-dimensional space of states at every energy: the Moonshine module as a vertex operator algebra. The conditional status is real: until that crossing relation is proved the object is not shown to be a CFT, and the numerical coincidences with J do not remedy that.

What the machine verified

All seven axioms of Theorem 38.39: unconditional. `vnatVOA`, `vnat_VOA_of_htt`: conditional on `htt` only; `##print axioms` = `[propext, Classical.choice, Quot.sound]` (checked). `module_virasoro`: general, unconditional, checked.

38.8 Twisted–twisted locality splits into DGM (4.22) and (4.23)

By Remark 38.17, the commutator of two off-diagonal fields is diagonal. For two twisted fields $Y_T^\natural(t_i) = \left(\begin{smallmatrix} 0 & \overline{W}(t_i) \\ W(t_i) & 0 \end{smallmatrix}\right)$ this reads

$$[Y_T^\natural(t_1,z_1), Y_T^\natural(t_2,z_2)] = \begin{pmatrix} \overline{W}(t_1,z_1)W(t_2,z_2) - \overline{W}(t_2,z_2)W(t_1,z_1) & 0 \\ 0 & W(t_1,z_1)\overline{W}(t_2,z_2) - W(t_2,z_2)\overline{W}(t_1,z_1) \end{pmatrix}. \tag{38.7}$$

The top-left entry is an operator on the untwisted sector built by passing through the twisted sector; the bottom-right entry is an operator on the twisted sector built by passing through the untwisted sector.

Theorem 38.42 (Off-diagonal locality is two diagonal relations). *For any $c, c' \in \mathrm{Hom}(M,V)[[z^{\pm}]]$, $d, d' \in \mathrm{Hom}(V,M)[[z^{\pm}]]$: $\mathrm{offdiag}(c,d) \sim \mathrm{offdiag}(c',d')$ if and only if $(z_1-z_2)^{N_1}\big(c(z_1)d'(z_2) - c'(z_2)d(z_1)\big) = 0$ on V for some N_1 and $(z_1-z_2)^{N_2}\big(d(z_1)c'(z_2) - d'(z_2)c(z_1)\big) = 0$ on M for some N_2.*

```
theorem local_off_off_iff (c c' : FormalDist (M →ₗ[ℂ] V)) (d d' : FormalDist (V →ₗ[ℂ] M)) :

      (∃ N : ℕ, mulBySubPow N
        ((fun m n => d m ∘ₗ c' n - d' n ∘ₗ c m) : FormalDist₂ (End ℂ M)) = 0) := by
```

(`VOA/Moonshine/TTBlock.lean`.)

Physical meaning

The OPE of two twist fields, which exchange sectors, is local if and only if two separate crossing relations hold: one for the amplitude untwisted→twisted→untwisted (relation (4.22)) and one for twisted→untwisted→twisted (relation (4.23)). Physically these are the two channels of four-point functions of twist fields on the plane, restricted to the untwisted or the twisted external states.

Proof. By (38.7) and the entrywise action of $(z_1-z_2)^N$; a block matrix is 0 iff each block is; for the converse take $N = \max(N_1, N_2)$. □

Definition 38.43 (DGM (4.22) and (4.23)). For $t_1, t_2 \in T^+$ and a parameter $\overline{W}'$:

- VP(t_1,t_2), DGM (4.22): for some N, $(z_1-z_2)^N\big(\overline{W}'(t_1,z_1)W(t_2,z_2) - \overline{W}'(t_2,z_2)W(t_1,z_1)\big) = 0$ in $\mathrm{End}(V_\Lambda^+)[[z_1^{\pm}, z_2^{\pm}]]$;
- TP(t_1,t_2), DGM (4.23): for some N, $(z_1-z_2)^N\big(W(t_1,z_1)\overline{W}'(t_2,z_2) - W(t_2,z_2)\overline{W}'(t_1,z_1)\big) = 0$ in $\mathrm{End}(T^+)[[z_1^{\pm}, z_2^{\pm}]]$.

```
def VPBlockLocal (Wbar : TP → FormalDist (TP →ₗ[ℂ] SkewVP)) (t₁ t₂ : TP) : Prop :=
  ∃ N : ℕ, mulBySubPow N
    ((fun m n => Wbar t₁ m ∘ₗ leechWsk t₂ n - Wbar t₂ n ∘ₗ leechWsk t₁ m) :
      FormalDist₂ (End ℂ SkewVP)) = 0

def TPBlockLocal (Wbar : TP → FormalDist (TP →ₗ[ℂ] SkewVP)) (t₁ t₂ : TP) : Prop :=
  ∃ N : ℕ, mulBySubPow N
    ((fun m n => leechWsk t₁ m ∘ₗ Wbar t₂ n - leechWsk t₂ n ∘ₗ Wbar t₁ m) :
      FormalDist₂ (End ℂ TP)) = 0
```

From the mathematics to the Lean statement

In `fun m n ⇒ Wbar t₁ m ∘ₗ leechWsk t₂ n - …`, the first index `m` belongs to z_1 and the second `n` to z_2, in the raw z-power indexing; so the first term is $\overline{W}(t_1)_m \circ W(t_2)_n$, coefficient of $z_1^m z_2^n$ in $\overline{W}(t_1,z_1)W(t_2,z_2)$, and the second is $\overline{W}(t_2)_n \circ W(t_1)_m$, coefficient of $z_1^m z_2^n$ in $\overline{W}(t_2,z_2)W(t_1,z_1)$ — exactly Definition 38.43. `SkewVP` and `TP` are V_Λ^+ and T^+. These are the relations (4.22) and (4.23) of Dolan–Goddard–Montague, Commun. Math. Phys. 179 (1996); the referee may compare: DGM write them as "$\overline{W}(t_1,z_1)W(t_2,z_2) \sim \overline{W}(t_2,z_2)W(t_1,z_1)$" with $\sim$ meaning equality after multiplication by a power of $(z_1 - z_2)$, which is what `mulBySubPow` encodes.

Physical meaning

The two relations are the two crossing conditions for twist fields: (4.22) is crossing with untwisted external states, (4.23) with twisted external states. The first is accessible from skew-symmetry and invariance of the form; the second needs real input about the twisted sector, the geometry of the 2^{24} fixed points, and is the hardest crossing condition in the orbifold. These are heuristic labels; the precise statements are the displayed equations.

Theorem 38.44. $Y_T^\natural[\overline{W}'](t_1) \sim Y_T^\natural[\overline{W}'](t_2)$ *if and only if* $\mathrm{VP}(t_1,t_2)$ *and* $\mathrm{TP}(t_1,t_2)$ *hold.*

```
theorem YnatT_local_iff (Wbar : TP → FormalDist (TP →ₗ[ℂ] SkewVP)) (t₁ t₂ : TP) :
    Local (YnatT Wbar t₁) (YnatT Wbar t₂) ↔
      VPBlockLocal Wbar t₁ t₂ ∧ TPBlockLocal Wbar t₁ t₂ :=
  local_off_off_iff _ _ _ _
```

From the mathematics to the Lean statement

An equivalence, valid for every parameter. The one-line proof term shows it is Theorem 38.42 with $c = \overline{W}'(t_1)$, $d = W(t_1)$, $c' = \overline{W}'(t_2)$, $d' = W(t_2)$. Combining with `reconstruct_nat`, the library also records `reconstruct_nat_of_blocks`, in which `htt` is replaced by the two block relations for the genuine $\overline{W}$ on a generating family.

Physical meaning

Locality of two twist fields is exactly the pair of crossing relations in the two channels: the four-point function of two twist fields and two external states is single-valued and symmetric in both the untwisted and twisted external sectors. There is no further condition.

Which half is hard. (4.22) is a statement about operators on the *untwisted* sector built from twisted intermediate states. On the vacuum it reduces, by the explicit vacuum behaviour of W, to a statement about $\overline{W}$ alone — its skew-symmetry — and this can be derived from the definition of $\overline{W}$ as an adjoint. So (4.22) is lattice-free; we prove it in the next section. (4.23) is a statement about operators on the *twisted* sector built from untwisted intermediate states; its matrix elements between twisted ground states are four-point functions of twist fields, given by sums over the whole Leech lattice (theta functions of cosets of 2Λ). Their consistency is "almost a modular invariance condition" (DGM §5.3) and genuinely uses the lattice: DGM show it holds only when $\sqrt{2}\Lambda^*$ is even. This is the relation the triality method of the following chapters is designed to prove.

What the machine verified

`local_off_off_iff`, `YnatT_local_iff`: unconditional, generic (any parameter); `YnatT_local_iff` `##print axioms`-checked clean.

38.9 DGM (4.22) holds unconditionally

38.9.1 Three tools

A two-variable Goddard lemma. Goddard's uniqueness lemma for vertex algebras says that a field that is local with all the fields and kills the vacuum is zero, because the states $a_{(n)}\mathbf{1}$ span. We need its analogue for a *two-variable* distribution $B(z_1, z_2)$, with locality in a third variable.

Theorem 38.45 (Two-variable Goddard lemma). *Let V be a vector space,* $\mathrm{vac} \in V$, $A(w) \in \mathrm{End}(V)[[w^{\pm}]]$ *with $A_p\,\mathrm{vac} = 0$ for $p < 0$ (raw indexing: no negative powers of w on the vacuum), and $B(z_1, z_2) \in \mathrm{End}(V)[[z_1^{\pm}, z_2^{\pm}]]$ with $B_{m,n}\mathrm{vac} = 0$ for all m, n. If $(w - z_1)^{M_1}(w - z_2)^{M_2}[A(w), B(z_1, z_2)] = 0$, then $B_{m,n}(A_p\,\mathrm{vac}) = 0$ for all p, m, n.*

```
theorem goddard₂ (vac : V) (A : FormalDist (End ℂ V)) (B : FormalDist₂ (End ℂ V)) (M₁ M₂ :
↪ ℕ)
    (hloc : mulBySub₁₂Pow M₁ (mulBySub₁₃Pow M₂ (brk3 A B)) = 0)
    (hneg : ∀ p : ℤ, p < 0 → A p vac = 0) (hvac : ∀ m n, B m n vac = 0) (p m n : ℤ) :
    B m n (A p vac) = 0 := by
```

(`VOA/Moonshine/M8h0Goddard.lean`.)

From the mathematics to the Lean statement

`brk3 A B` is the three-variable distribution $[A(w), B(z_1, z_2)]$ with coefficients $A_pB_{m,n} - B_{m,n}A_p$ (w first). `mulBySub₁₂Pow M` and `mulBySub₁₃Pow M` multiply by $(w - z_1)^M$ and $(w - z_2)^M$ respectively (the same shift formula as Definition 38.3 in the indicated pair of variables). The conclusion is coefficientwise. Same as the textbook argument; nothing hidden.

Physical meaning

This is the vertex-algebra form of the statement that a locality relation checked on the vacuum extends to all states: a field commuting (locally) with $A(w)$ and annihilating the vacuum vanishes on all states created by A. It is the formal version of the state–operator argument that a correlator is determined by its vacuum expectation value together with the Ward identities, and is the main tool of Goddard-type uniqueness theorems in CFT.

Proof. Apply the locality relation to vac. Since B kills vac, it becomes $(w-z_1)^{M_1}(w-z_2)^{M_2}G = 0$ for $G(w, z_1, z_2) := -B(z_1, z_2)A(w)\mathrm{vac}$. By the hypothesis on A, G has only non-negative powers of w. On such distributions, multiplication by $w - z$ is injective: if $(w - z)G = 0$ and p_0 is the lowest w-power present, the coefficient of w^{p_0} in $(w - z)G$ is $-z\,G_{p_0}$, forcing $G_{p_0} = 0$. So $G = 0$. □

The hypothesis of Theorem 38.45 holds for $B = (z_1 - z_2)^N[a(z_1), b(z_2)]$ whenever A is local with both a and b: by the Leibniz rule $[A, ab] = [A, a]b + a[A, b]$, each term is killed by the appropriate $(w - z_i)$-power (`loc3_mulBySubPow_bracketDist`).

The translation equation.

Definition 38.46. Given $L \in \mathrm{End}\,V$, a two-variable distribution D with values in V satisfies the *translation equation* if $LD = (\partial_{z_1} + \partial_{z_2})D$, i.e. $L\,D_{m,n} = (m + 1)D_{m+1,n} + (n + 1)D_{m,n+1}$.

```
def TEq (D : FormalDist₂ V) : Prop :=
  ∀ m n : ℤ, L (D m n) = ((m + 1 : ℤ) : ℂ) • D (m + 1) n + ((n + 1 : ℤ) : ℂ) • D m (n + 1)
```

Physical meaning

The translation equation is the Ward identity for a two-point object: translating both insertion points together gives $L_{-1}D = (\partial_{z_1} + \partial_{z_2})D$, so a two-variable correlation function depends on the difference $z_1 - z_2$ up to the action of the translation operator.

Theorem 38.47 (Closed form). *If D satisfies the translation equation, then for all $m, n \in \mathbb{N}$, $D_{m,n} = \sum_{s+r=n} \binom{m+r}{r} \frac{(-1)^r}{s!} L^s D_{m+r,0}$; that is, $D(z_1, z_2) = e^{z_2 L} D(z_1 - z_2, 0)$ on the quadrant $m, n \geq 0$.*

```
noncomputable def tcoef (m s r : ℕ) : ℂ :=
  ((m + r).choose r : ℂ) * (-1 : ℂ) ^ r * ((s.factorial : ℂ))⁻¹

theorem TEq.closed_form {D : FormalDist₂ V} (h : TEq L D) :
    ∀ n m : ℕ, D m n = ∑ p ∈ Finset.antidiagonal n,
      tcoef m p.1 p.2 • (L ^ p.1) (D ((m + p.2 : ℕ) : ℤ) 0) := by
```

(VOA/Moonshine/M8h0Translate.lean.)

From the mathematics to the Lean statement

`Finset.antidiagonal n` is the set of pairs (s, r) with $s + r = n$; `p.1`$= s$, `p.2`$= r$. The coefficient `tcoef m s r` is $\binom{m+r}{r}(-1)^r/s!$. The statement covers only $m, n \geq 0$ (natural numbers), which is exactly the quadrant where the closed form is meant. Note that no support hypothesis is needed for the identity itself.

Physical meaning

The solution of the translation equation is $D(z_1, z_2) = e^{z_2 L_{-1}} D(z_1 - z_2, 0)$: a two-point correlation is a function of the separation, dressed by the translation of the base point. It is the formal version of translation invariance of the vacuum correlators.

Proof. Induction on n: the equation solves for $(n+1)D_{m,n+1} = LD_{m,n} - (m+1)D_{m+1,n}$, and Pascal-type identities for the coefficients close the induction. Conceptually: $D(z_1, z_2)$ with $(\partial_1 + \partial_2 - L)D = 0$ is determined by its restriction to $z_2 = 0$, transported along $z_1 \mapsto z_1 - z_2$ and twisted by $e^{z_2 L}$. □

Skew-symmetry of $\overline{W}$.

Theorem 38.48 (DGM (4.9)). *For $t_1 \in T_a^+$, $t_2 \in T_b^+$ and every $n \in \mathbb{Z}$,*

$$\overline{W}(t_1)_{(n)}t_2 = \sum_{i \geq 0} \frac{(-1)^{n+i+1}}{i!} L_{-1}^i \, \overline{W}(t_2)_{(n+i)}t_1, \qquad \text{i.e.} \qquad \overline{W}(t_1, z)t_2 = e^{zL_{-1}} \overline{W}(t_2, -z)t_1.$$

```
theorem leechWbar_skew {a b : ℤ} {t₁ t₂ : TP} (ht₁ : t₁ ∈ plusModule.weight (a : ℂ))
    (ht₂ : t₂ ∈ plusModule.weight (b : ℂ)) (n : ℤ) :
    leechWbarMode n t₁ t₂ = ∑ᶠ i : ℕ, (((i.factorial : ℂ)⁻¹) * negOnePow (n + i + 1)) •
      ((leechVOAPlus.L (-1)) ^ i) (leechWbarMode (n + i) t₂ t₁) := by
```

(VOA/Moonshine/M8h0Skew.lean.)

From the mathematics to the Lean statement

`leechWbarMode n t₁ t₂` is $\overline{W}(t_1)_{(n)}t_2$ (mode indexing). $\sum^{\mathrm{f}}$ is a sum with finite support (only finitely many terms are nonzero because $\overline{W}(t_2)_{(n+i)}t_1 = 0$ for i large). `negOnePow k` is $(-1)^k$. The hypotheses `ht₁`, `ht₂` require homogeneity. This is *weaker* than the textbook statement for all t_1, t_2, but only formally: both sides are bilinear in (t_1, t_2) and T^+ is the direct sum of its

weight spaces, so the general case follows by linearity (and is not needed). The sign is the *even* skew-symmetry $Y(a,z)b = e^{zL_{-1}}Y(b,-z)a$, with no extra -1: the extension is a VOA, not a super VOA. (Numerical evidence on the E_8 model shows the super version of (4.23) fails; see Section 38.14.)

Physical meaning

Skew-symmetry of the twisted×twisted→untwisted OPE: exchanging two twist fields is the same as translating by $e^{zL_{-1}}$ and sending $z \to -z$, $\overline{W}(t_1,z)t_2 = e^{zL_{-1}}\overline{W}(t_2,-z)t_1$. This is the exchange symmetry of the OPE of two bosonic fields, and its proof uses nondegeneracy of the Zamolodchikov metric on the untwisted sector.

Proof. Since B_V is nondegenerate on each weight space, it suffices to pair both sides with an arbitrary $\varphi \in (V_\Lambda^+)_k$, $k = a+b-n-1$. The left side, by the adjunction (38.4), becomes $(-1)^a \sum_j \frac{1}{j!}(t_2, W(L_1^j t_1)_{(2a-n-2-j)}\varphi)_T$; expand W by (38.3). The right side: move L_{-1}^i across B_V as L_1^i (Virasoro adjointness of B_V), apply (38.4) to $\overline{W}(t_2)_{(n+i)}$, and expand W. Both sides become triple sums of the matrix elements $(L_1^j t_1, (L_1^r\varphi)_{(\gamma)}L_1^l t_2)_T$ — on the left after using $L_{-1} \dashv L_1$ and FHL-invariance of $(\cdot,\cdot)_T$ to move the L_{-1}'s and the φ-mode onto the other argument, together with symmetry of $(\cdot,\cdot)_T$. The two triple sums agree term by term after the relabelling $(j,l,r) \mapsto (r,l,j)$: the factorials match, the mode indices agree because $n = a+b-k-1$, and the signs differ by an even power of -1. □

Remark 38.49. Physically, skew-symmetry is the statement that the OPE of two twist fields is symmetric: $\sigma_{t_1}(z)\sigma_{t_2}(0)$ and $\sigma_{t_2}(-z)\sigma_{t_1}(0)$ differ by translation. Here it is a consequence of the *definition* of $\overline{W}$ as the adjoint of W and of the symmetry of the twisted form; for the fake $\overline{W}' = 0$ it holds trivially.

38.9.2 The theorem

Theorem 38.50 (DGM (4.22)). *For all $t_1, t_2 \in T^+$, $\mathrm{VP}(t_1,t_2)$ holds for the genuine $\overline{W}$. More precisely, for $t_1 \in T_a^+$, $t_2 \in T_b^+$ the order $N = a+b$ suffices.*

```
theorem leechWbar_VPBlockLocal (t₁ t₂ : TP) : VPBlockLocal leechWbar t₁ t₂ := by

theorem VPBlockLocal_homog {a b : ℤ} {t₁ t₂ : TP} (ht₁ : t₁ ∈ plusModule.weight (a : ℂ))
    (ht₂ : t₂ ∈ plusModule.weight (b : ℂ)) :
    mulBySubPow (a + b).toNat (VPfun t₁ t₂) = 0 := by
```

(`VOA/Moonshine/M8h0VPBlock.lean`; `VPfun t₁ t₂` is the two-variable distribution inside `VPBlockLocal leechWbar t₁ t₂`.)

From the mathematics to the Lean statement

No hypotheses: `t₁ t₂ : TP` are arbitrary. The parameter is the genuine `leechWbar`. Same as DGM's (4.22). Could it be vacuous? `VPBlockLocal` is an existential over N of an equation of distributions; it would be trivial if $\overline{W}$ were 0, but $\overline{W} \neq 0$ (Section 38.11), and the proof below uses the defining adjunction, not triviality.

Physical meaning

The untwisted-external crossing of two twist fields holds unconditionally, with pole order at most $a+b$, the sum of the weights. Physically the four-point function of two twist fields with two untwisted external states is consistent, a consequence of skew-symmetry and invariance

rather than of any lattice computation. It is the first half of twist×twist crossing.

Proof. Step 1 (vacuum). Let $t_1 \in T_a^+$, $t_2 \in T_b^+$ and $P \geq a+b$. Put $f(z_1,z_2) = \overline{W}(t_1,z_1)W(t_2,z_2)\mathbf{1}$ and $g(z_1,z_2) = \overline{W}(t_2,z_2)W(t_1,z_1)\mathbf{1}$, V_Λ^+-valued. Both satisfy the translation equation with $L = L_{-1}$, because $\overline{W}$ and W are translation covariant and $L_{-1}\mathbf{1} = 0$; so do $H = (z_1-z_2)^P f$ and $H' = (z_1-z_2)^P g$, since $\partial_1 + \partial_2$ kills $z_1 - z_2$. By $W(t,z)\mathbf{1} = e^{zL_{-1}}t$, f has only non-negative powers of z_2, and g only non-negative powers of z_1; the grading ($\overline{W}(t_1)_{(n)}t_2$ has weight $a+b-n-1$, which is negative for $n \geq a+b$) shows that the factor $(z_1-z_2)^P$ removes all negative powers, so H and H' are supported on the quadrant $m,n \geq 0$. Now compare the two on the edge $m = 0$, in the raw z-power indexing (so $\overline{W}(t)_k$ is the coefficient of z^k). Because f has only non-negative powers of z_2, the z_2^0-part of $H = (z_1-z_2)^P f$ is $z_1^P f(z_1,0)$, so $H_{r,0} = \overline{W}(t_1)_{r-P}\,t_2$ (using $W(t_2)_0\mathbf{1} = t_2$). The closed form (Theorem 38.47, $m = 0$) then gives

$$H_{0,n} = \sum_{s+r=n} \frac{(-1)^r}{s!}\, L_{-1}^s\, \overline{W}(t_1)_{r-P}\, t_2.$$

Because g has only non-negative powers of z_1, the z_1^0-part of $H' = (z_1-z_2)^P g$ is $(-z_2)^P g(0,z_2)$, so $H'_{0,n} = (-1)^P\,\overline{W}(t_2)_{n-P}\,t_1$. Skew-symmetry (Theorem 38.48) says precisely that these two edges coincide. Finally, a solution of the translation equation supported on the quadrant and vanishing on the edge $m = 0$ is identically zero (solve the equation for $D_{m+1,n}$ and induct on m). So $H - H'$ is a quadrant solution vanishing on $m = 0$, hence $H = H'$:

$$(z_1-z_2)^P\big(\overline{W}(t_1,z_1)W(t_2,z_2) - \overline{W}(t_2,z_2)W(t_1,z_1)\big)\mathbf{1} = 0.$$

Step 2 (Goddard). Let $B = (z_1-z_2)^P[Y_T^\natural(t_1,z_1), Y_T^\natural(t_2,z_2)]$ on $V^\natural$. By (38.7), B applied to $\mathbf{1}^\natural = (\mathbf{1},0)$ is (top-left entry applied to $\mathbf{1}$, 0), which vanishes by Step 1. Each $Y_U^\natural(u)$ is local with both twisted fields (Theorem 38.32), so B satisfies the three-variable locality with $A = Y_U^\natural(u)$. Theorem 38.45 with $p = 0$ gives $B_{m,n}(u,0) = 0$ for every $u \in V_\Lambda^+$ — this is (4.22) on u, for order P. *Step 3 (linearity).* (4.22) is bilinear in (t_1,t_2) and T^+ is spanned by its homogeneous vectors. □

Step 1 deserves a cleaner statement, since it is where the lattice-freeness lies:

Proposition 38.51 (Vacuum step). *For $t_1 \in T_a^+$, $t_2 \in T_b^+$ and $P \geq a+b$, $(z_1-z_2)^P\overline{W}(t_1,z_1)W(t_2,z_2)\mathbf{1} = (z_1-z_2)^P\overline{W}(t_2,z_2)W(t_1,z_1)\mathbf{1}$.*

```
theorem vac_step {a b : ℤ} {t₁ t₂ : TP} (ht₁ : t₁ ∈ plusModule.weight (a : ℂ))
    (ht₂ : t₂ ∈ plusModule.weight (b : ℂ)) (P : ℕ) (hP : a + b ≤ P) :
    mulBySubPow P (fF t₁ t₂) = mulBySubPow P (fun m n => fF t₂ t₁ n m) := by
```

From the mathematics to the Lean statement

`fF t s` is the V_Λ^+-valued distribution with coefficients $\overline{W}(t)_m\,W(s)_n\,\mathbf{1}$, i.e. $\overline{W}(t,z_1)W(s,z_2)\mathbf{1}$. The right side swaps the roles of the indices, giving $\overline{W}(t_2,z_2)W(t_1,z_1)\mathbf{1}$.

Physical meaning

This is the vacuum case of (4.22): the two orderings of two twist fields, evaluated on the vacuum, agree up to the pole of order $a+b$. In CFT terms the three-point amplitude of the vacuum with two twist fields is symmetric, which is the starting point of the Goddard argument to extend the relation to all untwisted states.

What the machine verified

`goddard₂`, `TEq.closed_form`: generic, unconditional. `leechWbar_skew`: unconditional (homogeneous arguments). `leechWbar_VPBlockLocal`: **unconditional**, all t_1, t_2. All four `##print axioms`-checked: `[propext, Classical.choice, Quot.sound]`.

38.10 Reducing (4.23) to a generating family and to four pairs

After Section 38.9, Theorem 38.41 needs only (4.23) for *all* pairs. The linear-span reduction (Theorem 38.40) would require checking a basis of T^+, which is infinite-dimensional. The point of this section is that (4.23) on a family which generates T^+ under the *modes* of V_Λ^+ suffices.

Definition 38.52 (Mode-generating family). A family $g : \kappa \to T^+$ is *mode-generating* if the vectors $u_{(n)}g_i$ ($u \in V_\Lambda^+$, $n \in \mathbb{Z}$, $i \in \kappa$) span T^+.

```
def ModeSpan : Prop :=
  Submodule.span ℂ {x : TP | ∃ (u : SkewVP) (n : ℤ) (i : κ), x = mode (plusModule.YM u) n
   ↪  (g i)} = ⊤
```

(`VOA/Moonshine/M8h0Gap.lean`.)

Physical meaning

A mode-generating family is a set of twisted states from which the whole twisted sector is built by acting with untwisted operators: the twisted sector is generated from a few twist fields (here two frame sectors, one for each parity) by the untwisted chiral algebra. This is the CFT notion of a set of primary states generating a representation.

Theorem 38.53 (Goddard identification of twisted fields). *Let g be mode-generating and $x \in T^+$. Let Ψ be a $T^\natural$-covariant field on $V^\natural$ with $\Psi_0\mathbf{1}^\natural = (0, x)$, $\Psi_q\mathbf{1}^\natural = 0$ for $q < 0$, local with every $Y_U^\natural(v)$ and with every $Y_T^\natural(g_j)$. Then $\Psi = Y_T^\natural(x)$.*

```
theorem YnatT_eq_of_creates (hspan : ModeSpan g) (x : TP) (Ψ : FormalDist (End ℂ Vnat))
    (hcov : DCovariant Tnat Ψ) (h0 : Ψ 0 vacNat = ((0 : SkewVP), x))
    (hneg : ∀ q : ℤ, q < 0 → Ψ q vacNat = 0) (hU : ∀ v : SkewVP, Local Ψ (YnatU v))
    (hT : ∀ j, Local Ψ (YnatT leechWbar (g j))) : YnatT leechWbar x = Ψ := by
```

From the mathematics to the Lean statement

Hypotheses, in order: the mode-span condition; covariance; creation of $(0, x)$ (raw z^0 coefficient, i.e. mode (-1)); no negative powers on the vacuum; locality with all untwisted fields; locality with the twisted generators. Note what is *not* assumed: that $Y_T^\natural(x)$ is local with $Y_T^\natural(g_j)$ — that would be circular.

Physical meaning

A field that creates a given twisted state from the vacuum, is translation covariant and is local with respect to the generators is the twist-field operator of that state. This is the uniqueness of the operator corresponding to a state, the Goddard identification: once crossing with a generating family is known, the operator–state map pins down the rest.

Proof. Let $F = Y_T^\natural(x) - \Psi$. Both are translation covariant and agree on the vacuum in degree 0; covariant fields with the same creation data agree on the vacuum in all degrees (the vacuum

vector $F(z)\mathbf{1}^\natural$ solves $T\,v(z) = \partial v(z)$ with $v(0) = 0$). So F kills $\mathbf{1}^\natural$. The set of vectors killed by all coefficients of F is stable under the modes of every field local with F (one-variable Goddard argument, as in the proof of Theorem 38.45); F is local with all $Y_U^\natural(v)$. So it suffices to show F kills each $(0, g_j)$ and then use the mode-span hypothesis and $V_\Lambda^+ \times 0$. Now $(0, g_j) = Y_T^\natural(g_j)_0\mathbf{1}^\natural$, and $(z-w)^M F(z)Y_T^\natural(g_j, w)\mathbf{1}^\natural = (z-w)^M[F(z), Y_T^\natural(g_j, w)]\mathbf{1}^\natural$. The Ψ-part of the commutator is killed by hypothesis. The $Y_T^\natural(x)$-part is killed on the vacuum because, on $(\mathbf{1}, 0)$, only the top-left entry of (38.7) acts — and that is *(4.22)*, proved unconditionally. So $(z-w)^M F(z)Y_T^\natural(g_j, w)\mathbf{1}^\natural = 0$, and injectivity of multiplication by $z - w$ on distributions with no negative powers of w gives $F(z)(0, g_j) = 0$. □

Theorem 38.54 ((4.23) for all pairs from a generating family). *If g is mode-generating and* $\mathrm{TP}(g_i, g_j)$ *holds for all i, j, then* $\mathrm{TP}(t, t')$ *holds for all $t, t' \in T^+$. Consequently $V^\natural$ carries the vertex operator algebra structure of Theorem 38.41.*

```

    (h423 : ∀ i j, TPBlockLocal leechWbar (g i) (g j)) (t t' : TP) :
    TPBlockLocal leechWbar t t' := by

theorem vnat_VOA_of_TPBlockLocal_gen {κ : Type*} (g : κ → TP) (hspan : ModeSpan g)
    (h423 : ∀ i j, TPBlockLocal leechWbar (g i) (g j)) :
    ∃ V : VertexOperatorAlgebra Vnat,
      V.Y = Ynat VnatAxioms.wbarL ∧ V.vacuum = vacNat ∧ V.conformalVector = omegaNat ∧
        V.centralCharge = 24 ∧ V.grading = gradingNat := by
```

From the mathematics to the Lean statement

Hypotheses: `hspan` (Definition 38.52) and `h423` ((4.23) on the pairs of g, for the genuine $\overline{W}$). (4.22) is not a hypothesis. The conclusion of the second theorem is that of `vnat_VOA_of_htt`, with the same five identifications, so the same warning about the trap applies.

Physical meaning

The twist×twist crossing with twisted external states, checked on pairs from a generating family of twist fields, extends to all pairs of twisted states by the structure of the chiral algebra. The reduction shrinks the infinite set of crossing conditions on twisted fields to finitely many four-point conditions.

Proof. From (4.22) and (4.23) on g, the fields $Y_T^\natural(g_i)$ are pairwise local (Theorem 38.44). For $u \in V_\Lambda^+$ and $k \geq 0$ the field $\Psi = Y_U^\natural(u)_{(k)}Y_T^\natural(g_i)$ (the k-th field product $\mathrm{Res}_{z_1}(z_1 - z_2)^k[\,\cdot, \cdot\,]$), and for $k = -1$ the normally ordered product $:Y_U^\natural(u)Y_T^\natural(g_i):$, are translation covariant, create $(0, u_{(k)}g_i)$, and by Dong's lemma are local with every $Y_U^\natural(v)$ and every $Y_T^\natural(g_j)$. By Theorem 38.53, $Y_T^\natural(u_{(k)}g_i) = \Psi$ (the *iterate formula*), and by Dong's lemma again these fields are pairwise local. Modes $u_{(-1-k)}$ with $k > 0$ reduce to $k = -1$ via $u_{(-1-k)}x = \frac{1}{k!}(L_{-1}^k u)_{(-1)}x$. So the twisted fields of the linearly spanning family $\{u_{(n)}g_i\}$ are pairwise local, and Theorem 38.40 extends to all pairs; Theorem 38.44 extracts (4.23). □

Theorem 38.55 (Four explicit pairs). *There exist $x_0 \in T_0^+$, $x_1 \in T_1^+$ (the two frame sectors of T^+) such that (4.23) on the four pairs (x_i, x_j) implies the conclusion of Theorem 38.41.*

File `VOA/Moonshine/M8h0Gap.lean`.

```
theorem vnat_VOA_of_TPBlockLocal_frame :

    V.centralCharge = 24 ∧ V.grading = gradingNat) := by
```

From the mathematics to the Lean statement

`TPframe s` for $s \in \mathbb{Z}/2$ is the frame sector $T_s^+ = T^+ \cap (S[\theta] \otimes T_s)$, where $T = T_0 \oplus T_1$ is the eigenspace decomposition of T under a central element of the extraspecial group attached to the Golay frame (defined in Chapter 39); the earlier chapter proves each T_s^+ is a cyclic module over the frame subalgebra V_0^+ with an explicit weight-two cyclic vector (`cyclic_TPframe`), and $T^+ = T_0^+ \oplus T_1^+$.

Quantifier order. The statement is $\exists x,\ (\dots) \wedge ((4.23) \text{ on } x \Rightarrow \text{VOA})$. The witness x is produced by a choice inside the proof; a user of this theorem does not get to pick it. Hence, to apply it, one must prove (4.23) for *whatever* cyclic vectors were chosen — in practice for all pairs, or at least for all vectors of the frame sectors. The consumers in Chapter 42 do exactly that: they prove (4.23) for all pairs from a different generating family and then specialise. So the theorem is a correct but slightly awkward interface; it is not vacuous (an x with the stated membership exists), and it is not weaker than intended because it is never used with a specific x in mind.

Physical meaning

The remaining crossing condition is reduced to four explicit pairs of twisted states, built from the two frame sectors of the twist-field Hilbert space. Physically the whole consistency of the Moonshine orbifold is encoded in four four-point functions of twist fields; the proof of these is the content of the later chapters on triality.

Proof. Take x_s the cyclic vector of T_s^+; then $\{x_0, x_1\}$ is mode-generating (modes of $V_0^+ \subseteq V_\Lambda^+$ already suffice, and the two sectors span T^+); apply Theorem 38.54. □

What the machine verified

`YnatT_eq_of_creates`, `TPBlockLocal_all_of_gen`: unconditional as implications; `vnat_VOA_of_TPBlockLocal_frame`: conditional on (4.23) on the four pairs (inside the statement). All `##print axioms`-checked clean.

38.11 The trap: the square-zero extension

This section is the heart of the referee's task for this Part. Its content was discovered during the project (it is recorded as "TRAP" in `Notes/MonsterRoadmap.md`, "Definition of done") and it changed what the project had to prove.

38.11.1 The construction

Definition 38.56 (Square-zero extension)**.** Let V be a vertex operator algebra and M an ordinary V-module with integral weights ≥ 1. On $V \oplus M$ put

$$Y^{\mathrm{sq}}\big((u,t),z\big) = \begin{pmatrix} Y(u,z) & 0 \\ W_M(t,z) & Y_M(u,z) \end{pmatrix}, \qquad W_M(t,z)\varphi = e^{zL_{-1}} Y_M(\varphi,-z)t.$$

That is, $(u,t)_{(n)}(\varphi,s) = \big(u_{(n)}\varphi,\ u_{(n)}s + W_M(t)_{(n)}\varphi\big)$: the product of two elements of M is zero.

For $V = V_\Lambda^+, M = T^+$ this is the block map $Y^\natural[0]$ of Definition 38.34, i.e. (38.1) with $\overline{W}$ replaced by 0.

Physical meaning

The square-zero extension is a theory in which the twisted sector does not interact: the OPE twisted×twisted→untwisted is zero, and the twist fields still act on untwisted states through W. It is a consistent chiral algebra, but the twisted sector is a decoupled module sitting inside it, like a free sector that never talks back to the vacuum.

Proposition 38.57 (The impostor is a VOA with the same numbers)**.** $(V_\Lambda^+ \oplus T^+,\ V^\natural_{\bullet},\ Y^\natural[0],\ \mathbf{1}^\natural,\ \omega^\natural)$ *is a vertex operator algebra of central charge* 24 *with* $V_1 = 0$, $\dim V_2 = 196884$ *and graded dimension* qJ.

Physical meaning

The impostor has the right central charge $c = 24$, no currents, 196884 states at weight two and partition function J: numerically indistinguishable from the Moonshine CFT. It satisfies the axioms because setting every twist×twist OPE to zero trivially makes the twisted–twisted crossing relation true. A partition function, or any count of states, cannot tell a genuine CFT from this degenerate theory.

Proof (on paper). Go through Theorem 38.39 and Theorem 38.40 with $\overline{W}' = 0$. Every block statement that involved $\overline{W}$ becomes $0 = 0$: grading (a zero map has any degree), truncation, translation ($\partial 0 = 0$), the commutator formula (both sides 0). The vacuum, creation and Virasoro statements never involved $\overline{W}$. Untwisted–untwisted and untwisted–twisted locality are Theorems 38.15 and 38.16 (the second hypothesis there for the 0 block is trivial). Twisted–twisted locality is trivial by (38.7): both entries are products with a zero factor. The numbers are those of Section 38.5, which depend only on the graded space. □

What the machine verified

Argued on paper only. The square-zero extension has *not* been constructed in Lean; no declaration named for it exists in the library (the phrase occurs only in docstrings of `VnatFields.lean`, `VnatAxioms.lean`, `VnatGenuine.lean`, `SimpleVnat.lean`, `Main.lean`). A Lean proof would be a line-by-line copy of `VnatAxioms.lean` with `leechWbar` replaced by 0; the point of this section is that such a copy *would* type-check, and hence that the final theorem must contain something it does not satisfy.

Proposition 38.58 (The impostor is not simple)**.** *In* $(V_\Lambda^+ \oplus T^+, Y^\natural[0])$ *the subspace* $0 \oplus T^+$ *is a nonzero proper ideal, with* $(0 \oplus T^+)_{(n)}(0 \oplus T^+) = 0$. *In particular it is not simple and not isomorphic to the genuine* $V^\natural$ *once the latter is known to be simple.*

Physical meaning

In the impostor the twisted sector is a decoupled subtheory: any correlator with only twisted insertions and no untwisted ones vanishes, the twisted two-point function in the vacuum channel is degenerate (the Zamolodchikov metric on twisted states cannot be reached from the vacuum) and the vacuum is not the unique cyclic state. This is not the unitary-looking, single-vacuum CFT of the Monster; it fails simplicity.

Proof. For $x = (u, t)$ and $(0, s)$: $x_{(n)}(0, s) = (0 \cdot s,\ u_{(n)}s + W(t)_{(n)}0) = (0, u_{(n)}s)$. It is proper because $\mathbf{1}^\natural \notin 0 \oplus T^+$, nonzero because $\dim T_2^+ = 98304$. Products of two twisted vectors vanish by definition. □

38.11.2 Why the numbers cannot see the difference

A vertex operator algebra and its square-zero deformation have the same graded vector space, the same Virasoro action, the same central charge, the same characters. More generally, for any module M the square-zero extension $V \ltimes M$ exists; it is the degenerate end of a one-parameter family. Conjugating the block form by $\mathrm{diag}(1, \lambda)$ leaves W unchanged and multiplies $\overline{W}$ by λ^{-2} (Chapter 37), and every locality relation is homogeneous in $\overline{W}$; so if $\overline{W}$ works, so does $c\overline{W}$ for every $c \in \mathbb{C}$, all $c \neq 0$ give isomorphic (simple) algebras, and $c = 0$ gives the impostor. Physically, the square-zero extension is a "theory" in which the operator product of two twist fields has no component in the untwisted sector — the two-point function of a twist field with itself vanishes — which is incompatible with a nondegenerate state space pairing.

Consequently:

- the five "numerical" targets (VOA structure, $c = 24$, $V_1 = 0$, $\dim V_2 = 196884$, $\chi = J$) are satisfied by the impostor and do *not* characterise $V^\natural$;
- every hypothesis of `reconstruct_nat` is satisfied by the impostor;
- the statement "$\exists V$, a VOA on `Vnat` with `V.grading = gradingNat` and $c = 24$" is satisfied by the impostor.

38.11.3 What excludes it

Two things, one cheap and one decisive.

The cheap certificate: $\overline{W} \neq 0$.

Theorem 38.59. *For $t, t' \in T_2^+$, $\overline{W}(t)_{(3)}t' = (t', t)_T \cdot \mathbf{1}$. Consequently, for every nonzero $t \in T_2^+$ there are $t' \in T_2^+$ and $c \neq 0$ with $\overline{W}(t)_{(3)}t' = c\mathbf{1}$; and $\overline{W} \neq 0$.*

```
theorem leechWbarMode_three_weight_two {t t' : TP} (ht : t ∈ plusModule.weight ((2 : ℤ) :

theorem leechWbar_ne_zero : leechWbar ≠ 0 := by
```

(`VOA/Moonshine/VnatGenuine.lean`, documented in Chapter 37.)

From the mathematics to the Lean statement

`leechWbar ≠ 0` is inequality of functions $T^+ \to \mathrm{Hom}(T^+, V_\Lambda^+)[[z^{\pm}]]$: some t and some coefficient give a nonzero map. The first theorem is the physically expected OPE $\sigma_t(z)\sigma_{t'}(0) \sim (t, t')_T\, z^{-4}\mathbf{1} + \cdots$ of two weight-two twisted fields: the mode (3) multiplies z^{-4}, and $2 + 2 - 3 - 1 = 0$ is the vacuum weight.

Physical meaning

For weight-two twist fields the twisted×twisted OPE contains the identity with coefficient equal to the Zamolodchikov two-point function, $\overline{W}(t)_{(3)}t' = (t',t)_T\mathbf{1}$ (the analogue of $\phi(z)\phi(0) \sim \langle\phi\phi\rangle/z^{2h}$ with $2h = 4$). Since the metric on twisted states is nondegenerate, the twist fields have nonzero two-point functions; so $\overline{W} \neq 0$ and the genuine orbifold is not the impostor. This is the nontrivial dynamical input that the numbers cannot supply.

Proof. $\overline{W}(t)_{(3)}t'$ has weight 0, so equals $c\mathbf{1}$; pair with $\mathbf{1}$ under B_V ($B_V(\mathbf{1},\mathbf{1}) = 1$) and use the adjunction (38.4) with $w = 2$, $n = 3$, $\varphi = \mathbf{1}$: $2w - n - 2 - j = -1 - j$, and $L_1 t = 0$ since $T_1^+ = 0$, so only $j = 0$ survives and $c = (t', W(t)_{(-1)}\mathbf{1})_T = (t',t)_T$. Nondegeneracy of $(\cdot,\cdot)_T$ on $T_2^+ \neq 0$ gives t' with $c \neq 0$. □

This certificate shows the library's $\overline{W}$ is not the impostor's zero map. It does not by itself prove that the resulting VOA is $V^\natural$: a nonzero $\overline{W}'$ that is not the adjoint could still give a non-simple algebra. The decisive argument is the next one.

The decisive argument: an invariant form that is nondegenerate. The genuine construction carries the block-diagonal form $B^\natural = B_V \oplus (\cdot,\cdot)_T$, which is FHL-invariant precisely because $\overline{W}$ is the adjoint of W, and is nondegenerate. Li's theorem (simple $\iff$ the radical of a normalised fully invariant form is zero) then gives simplicity. For the impostor, consider the same form. Invariance (38.2) for $x = (0,t)$ with $t \in T_2^+$, $n = 3$, $a = (0,t')$, $b = (\mathbf{1},0)$ reads

$$\underbrace{B_V\big(\overline{W}'(t)_{(3)}t', \mathbf{1}\big)}_{=0 \text{ for } \overline{W}'=0} = (-1)^2\big(t', W(t)_{(-1)}\mathbf{1}\big)_T = (t',t)_T,$$

(only $j = 0$ survives since $L_1 t = 0$). So invariance for the impostor would force $(t',t)_T = 0$ for all $t,t' \in T_2^+$, contradicting nondegeneracy of $(\cdot,\cdot)_T$ on the 98304-dimensional space T_2^+. Hence *the form $B^\natural$ is not invariant for the impostor*; and more strongly, by Li's theorem, every normalised fully invariant form on the impostor has the ideal $0 \oplus T^+$ in its radical, i.e. is degenerate. The simplicity proof of Section 38.12 therefore fails for the impostor at exactly one step: the invariance of $B^\natural$ in the off-diagonal blocks, which is the adjunction (38.4).

Trap / dead end

The rule that follows. A claim "$V^\natural$ constructed" must include simplicity (or an equivalent: nondegeneracy of the invariant form of the VOA, or that $\overline{W}$ is the nondegenerate adjoint of W *and* the form is invariant). The project's roadmap forbids marking the construction done without the simplicity theorem, and the final theorem of the Part, `VOA.Moonshine.moonshine`, contains `V.IsSimple` as a conjunct, together with `V.Y = Ynat VnatAxioms.wbarL`.

38.12 The invariant form of $V^\natural$ and simplicity

Throughout this section htt denotes the hypothesis of Theorem 38.41 (twisted–twisted locality for all pairs) and V = `vnatVOA`(htt). All results are therefore conditional on htt — the same hypothesis under which V exists at all.

38.12.1 The form

Definition 38.60. $B^\natural\big((u,t),(u',t')\big) = B_V(u,u') + (t,t')_T$.

theorem natForm_symm (x y : Vnat) : natForm x y = natForm y x := by
```

(`VOA/Moonshine/SimpleForm.lean`.) `B.compl₁₂ f g` is $(x,y)\mapsto B(fx,gy)$; `fst`, `snd` are the two projections. The `rfl` proof of `natForm_apply` confirms the formula.

Physical meaning

The form $B^\natural$ is the Zamolodchikov metric of the whole orbifold theory: the two-point pairing of untwisted states and of twisted states, with the two sectors orthogonal, as required by the $\mathbb{Z}/2$ charge conservation of the orbifold. Its invariance under the vertex operators is the statement that the two-point function is consistent with the OPE.

38.12.2 A combinatorial identity

Lemma 38.61. *(a)* $\sum_{i+j=k}\frac{(-1)^i}{i!\,j!}=\delta_{k,0}$. *(b) If* $f:\mathbb{N}\to\mathbb{C}$ *vanishes on* $[R,\infty)$, *then* $\sum_{j<R}\sum_{i<R}\frac{(-1)^j}{j!\,i!}f(i+j)=f(0)$.

```
theorem alt_antidiag (k : ℕ) :
    ∑ p ∈ Finset.antidiagonal k,
      (-1 : ℂ) ^ p.1 * (((p.1.factorial : ℂ))⁻¹ * ((p.2.factorial : ℂ))⁻¹)
      = if k = 0 then 1 else 0 := by

theorem double_sum_cancel (R : ℕ) (f : ℕ → ℂ) (hf : ∀ k, R ≤ k → f k = 0) :
    ∑ j ∈ Finset.range R, ∑ i ∈ Finset.range R,
      (-1 : ℂ) ^ j * (((j.factorial : ℂ))⁻¹ * ((i.factorial : ℂ))⁻¹) * f (j + i) = f 0 :=
       ↪  by
```

Physical meaning

A pure combinatorial identity (an alternating sum of inverse factorials) that implements the cancellation of the translation factors $e^{zL_{-1}}e^{-zL_{-1}}=1$ in the proof of invariance. No physics content.

Proof. (a) is $\frac{1}{k!}(1-1)^k$. (b) Group by $k=i+j$; terms with $k\ge R$ vanish, the others are (a) times $f(k)$. □

Meaning: the FHL transpose $u\mapsto e^{zL_1}(-z^{-2})^{L_0}u$, $z\mapsto z^{-1}$ is an involution; applying it twice produces exactly this alternating double sum, which collapses.

38.12.3 Invariance block by block

Lemma 38.62 (The W-block: the adjunction read backwards). *For* $t\in T^+_w$, $n\in\mathbb{Z}$, $a\in V^+_\Lambda$, $b\in T^+$:

$$\big(W(t)_{(n)}a,\,b\big)_T=(-1)^w\sum_{j=0}^{w}\frac{1}{j!}\,B_V\big(a,\,\overline{W}(L_1^j t)_{(2w-n-2-j)}b\big).$$

```
theorem pieceD {wt : ℤ} {t : TP} (ht : t ∈ plusModule.weight (wt : ℂ)) (n : ℤ) (a : SkewVP)
    (b : TP) :
    TPForm (mode (leechWsk t) n a) b = (-1 : ℂ) ^ wt • ∑ j ∈ Finset.range (wt.toNat + 1),
      ((j.factorial : ℂ)⁻¹) • leechBV a (leechWbarMode (2 * wt - n - 2 - j)
        ((Lp1 plusModule ^ j) t) b) := by
```

From the mathematics to the Lean statement

`Finset.range (wt.toNat + 1)` is $j = 0, \dots, w$ (`toNat` of a negative integer is 0; here $w \geq 2$ anyway). `Lp1 plusModule` is L_1 on T^+. This is (38.2) for the W-block of $B^\natural$; (38.4) is (38.2) for the $\overline{W}$-block. Note that (38.4) gives $B_V(\overline{W}(\cdot)\cdot,\cdot)$ in terms of $(\cdot, W(\cdot)\cdot)_T$; the lemma is the converse direction, which is not a restatement.

Physical meaning

This is the twisted-to-untwisted block of the invariance of the Zamolodchikov metric: the amplitude of the twist field $W(t)$ between an untwisted and a twisted state equals the amplitude of its conjugate $\overline{W}$ the other way, with the inversion $z \to 1/z$ factor. It says $\overline{W}$ is the BPZ conjugate of W, which is how $\overline{W}$ was defined.

Proof. Start from the right side. For each j, use symmetry of B_V and apply (38.4) to $\overline{W}(L_1^j t)_{(2w-n-2-j)}$ (weight $w-j$): it becomes $(-1)^{w-j}\sum_i \frac{1}{i!}(b, W(L_1^{i+j}t)_{(n-i-j)}a)_T$, since $2(w-j)-(2w-n-2-j)-2-i = n-i-j$. The signs combine to $(-1)^w(-1)^{w-j} = (-1)^j$, and with $f(k) = (b, W(L_1^k t)_{(n-k)}a)_T$ the right side is the double sum of Lemma 38.61(b), equal to $f(0) = (b, W(t)_{(n)}a)_T$; symmetry of $(\cdot,\cdot)_T$ finishes. □

Theorem 38.63 (Full FHL invariance of $B^\natural$). *Assume htt. For every* $\mathrm{wt} \in \mathbb{Z}$, $x \in V^\natural_{\mathrm{wt}}$, $n \in \mathbb{Z}$, $a, b \in V^\natural$,

$$B^\natural(x_{(n)}a, b) = (-1)^{\mathrm{wt}} \sum_{j=0}^{\mathrm{wt}} \frac{1}{j!} B^\natural\big(a, (L_1^j x)_{(2\mathrm{wt}-n-2-j)}b\big),$$

products and L_1 being those of $V =$ `vnatVOA`(htt).

File `VOA/Moonshine/SimpleForm.lean`.

```
theorem natForm_fhl (wt : ℤ) (x : Vnat) (hx : x ∈ gradingNat wt) (n : ℤ) (a b : Vnat) :
    natForm ((vnatVOA htt).smul x n a) b
      = (-1 : ℂ) ^ wt • ∑ j ∈ Finset.range (wt.toNat + 1), ((j.factorial : ℂ)⁻¹) •
          natForm a ((vnatVOA htt).smul ((((vnatVOA htt).L 1) ^ j) x) (2 * wt - n - 2 - (j
           ↪  : ℤ)) b) := by
```

From the mathematics to the Lean statement

`htt` is a section variable (the twisted–twisted locality hypothesis); it enters only to make `vnatVOA htt` a VOA. The products `(vnatVOA htt).smul x n a` are, by definition, the block products (38.6), and they do not depend on `htt`. So the identity is really a statement about the explicit block map, and its truth does not use htt at all; htt appears only because the statement is phrased with the VOA's own `smul` and `L`. The statement is literally the field `IsFullyInvariant` of Section 38.2 for the form `natForm`.

Physical meaning

Invariance of the Zamolodchikov metric under the full operator algebra, including twist fields: the two-point function of $\langle x_{(n)}a, b\rangle$ equals the inverted amplitude $\langle a, (\dots)b\rangle$. This is the BPZ conjugation property in the orbifold theory. It is conditional on twist×twist locality, because the proof uses the vertex algebra structure on the whole of $V^\natural$.

Proof. Write $x = (u, t)$, $a = (a_1, a_2)$, $b = (b_1, b_2)$. By (38.6) and Definition 38.60,

$$B^\natural(x_{(n)}a, b) = B_V(u_{(n)}a_1, b_1) + B_V(\overline{W}(t)_{(n)}a_2, b_1) + (W(t)_{(n)}a_1, b_2)_T + (u_{(n)}a_2, b_2)_T.$$

Since L_1 is block-diagonal, $L_1^j x = (L_1^j u, L_1^j t)$, and the right side of the claim splits into the same four blocks. The four identities are: FHL invariance of B_V on V_Λ^+; the adjunction (38.4); Lemma 38.62; FHL invariance of $(\cdot,\cdot)_T$ under V_Λ^+. Add them. □

Theorem 38.64 (The invariant form of V). *Assume htt. $B^\natural$ is an invariant form of V (Virasoro-adjoint: $B^\natural(L_n a, b) = B^\natural(a, L_{-n} b)$), fully invariant, normalised, and its left radical is zero.*

File `VOA/Moonshine/SimpleForm.lean`.

```
noncomputable def natInvForm : InvariantForm (vnatVOA htt) where
  form := natForm
  virasoro_adj := natForm_virasoro_adj htt

theorem natInvForm_isFullyInvariant : (natInvForm htt).IsFullyInvariant :=

theorem natInvForm_normalized : (natInvForm htt).Normalized := by

theorem natInvForm_leftRadical : InvariantForm.leftRadical (natInvForm htt) = ⊥ := by
```

Physical meaning

The orbifold has a nondegenerate invariant two-point function, normalised so that $\langle \mathbf{1}|\mathbf{1}\rangle = 1$ and with $L_n^\dagger = L_{-n}$. In CFT terms: a well-defined Zamolodchikov metric on the whole space of states, nondegenerate on every energy level. Nondegeneracy is what forces uniqueness of the vacuum and, by Li's theorem, simplicity.

Proof. Virasoro adjointness is the case $x = \omega^\natural$ (wt $= 2$) of Theorem 38.63: $L_1\omega = 0$ (as $V_1 = 0$), so only $j = 0$ survives and the index $2\cdot 2-(n+1)-2 = -n+1$ gives L_{-n}. Normalisation: $B_V(\mathbf{1},\mathbf{1}) = 1$ and the twisted part of $\mathbf{1}^\natural$ is 0. Radical: if $B^\natural(x,\cdot) = 0$, testing against $(y,0)$ gives $B_V(x_1,\cdot) = 0$, so $x_1 = 0$ by nondegeneracy of B_V; testing against $(0,y)$ gives $(x_2,\cdot)_T = 0$; since the weight spaces of T^+ are mutually orthogonal and $(\cdot,\cdot)_T$ is nondegenerate on each, every homogeneous component of x_2 is 0, so $x_2 = 0$. □

38.12.4 Simplicity

Theorem 38.65 (Li). *Let W be a VOA and B a normalised fully invariant form on W. Then W is simple if and only if the left radical of B is zero.*

```
theorem isSimple_iff_leftRadical_eq_bot {B : InvariantForm W} (hB : B.IsFullyInvariant)
    (hn : B.Normalized) :
    W.IsSimple ↔ InvariantForm.leftRadical B = ⊥ := by
```

(`VOA/Core/InvariantFormRadical.lean`; proved in the Core part of the book.) The idea: the radical of a normalised invariant form is an ideal (invariance moves modes across), it does not contain $\mathbf{1}$ (normalisation), and it equals the maximal proper graded ideal (every proper graded ideal pairs trivially with $\mathbf{1}$ in weight 0 and hence, by invariance, with everything).

Physical meaning

A vertex operator algebra is simple (the vacuum is the only cyclic state; no decoupled sector) if and only if its Zamolodchikov metric is nondegenerate: a state in the radical is orthogonal to everything, so it generates a proper ideal that cannot be reached from the vacuum, a decoupled sector. This is the algebraic form of the folk statement that a CFT with a nondegenerate two-point function has a unique vacuum.

Theorem 38.66 ($V^\natural$ is simple). *Assume htt. Then* `vnatVOA`(htt) *is simple, and the canonical invariant form of the library on it coincides with $B^\natural$ and is nondegenerate on every weight space.*

```
theorem vnatVOA_isSimple : (vnatVOA htt).IsSimple :=
  (LiRadical.isSimple_iff_leftRadical_eq_bot (natInvForm_isFullyInvariant htt)
    (natInvForm_normalized htt)).2 (natInvForm_leftRadical htt)

theorem vnatVOA_invariantForm_nondegenerate :
    (natInvForm htt).IsFullyInvariant ∧ (natInvForm htt).Normalized ∧
      InvariantForm.leftRadical (natInvForm htt) = ⊥ ∧
        GradedNondeg (vnatVOA htt) (natInvForm htt).form :=

theorem vnatVOA_canonicalForm_eq :
    (canonicalInvariantForm (vnatVOA_vacuum_ne_zero htt) (vnatVOA_L1_one htt)).form =
     ↪ natForm :=
```

(`VOA/Moonshine/SimpleVnat.lean`.)

From the mathematics to the Lean statement

`IsSimple` is Definition 38.8 (the `Core/BilinearForm` notion: $V \neq 0$ and every ideal is 0 or V). `GradedNondeg V B` says B is nondegenerate on each V_n. `canonicalInvariantForm` is the library's canonical (Li/FHL) normalised invariant form, which exists whenever $\mathbf{1} \neq 0$ and $L_1 V_1 = 0$; by uniqueness of fully invariant normalised forms it equals $B^\natural$. **Vacuity check.** The statement could have been weak in two ways, and is not. (i) It could have been about some VOA other than the block one; but `vnatVOA htt` has `Y := YN` by definition. (ii) `IsSimple` could have been a weak notion; it quantifies over all subspaces closed under left multiplication, which is at least as strong as the textbook notion. And the theorem is false for the impostor (Proposition 38.58), so it does distinguish.

Physical meaning

The Moonshine module has a unique vacuum and no decoupled sector: every state is reachable from the vacuum by the operator algebra. This is what separates the genuine orbifold CFT from the square-zero impostor, whose twisted sector is a decoupled ideal. It uses in an essential way that the twist×twist OPE $\overline{W}$ is the conjugate of W, because that is what makes the Zamolodchikov metric nondegenerate on the twisted sector as seen from the vacuum.

Proof. Theorem 38.65 applied to $B^\natural$ and Theorem 38.64. □

Theorem 38.67 (Simplicity through the four-pair hypothesis). *There are $x_s \in T_s^+$ ($s \in \mathbb{Z}/2$) such that (4.23) on the four pairs (x_i, x_j) yields a* simple *VOA structure on $V^\natural$ with vertex map $Y^\natural[\overline{W}]$, vacuum $\mathbf{1}^\natural$, conformal vector $\omega^\natural$, $c = 24$ and grading $V^\natural$.*.

```
theorem vnat_isSimple_of_TPBlockLocal_frame :
    ∃ x : ZMod 2 → TP, (∀ s, x s ∈ TPframe s) ∧
      ((∀ i j, TPBlockLocal leechWbar (x i) (x j)) →
        ∃ V : VertexOperatorAlgebra Vnat,
          V.Y = Ynat wbarL ∧ V.vacuum = vacNat ∧ V.conformalVector = omegaNat ∧
            V.centralCharge = 24 ∧ V.grading = gradingNat ∧ V.IsSimple) := by
```

Physical meaning

Conditional on four crossing relations for twist fields, the Moonshine orbifold is a CFT with $c = 24$, no currents and a unique vacuum. The statement packages the simple-VOA conclusion with the four-pair reduction; the physics content is that the only missing input is

four explicit four-point functions of twist fields.

Proof. Theorems 38.55 (with its proof, which produces htt) and 38.66. The quantifier caveat of Theorem 38.55 applies. □

What the machine verified

`natForm_fhl`, `natInvForm_leftRadical`, `vnatVOA_isSimple`, `vnatVOA_invariantForm_nondegenerate`: conditional on htt only. `vnat_isSimple_of_TPBlockLocal_frame`: conditional on (4.23) on four pairs (inside the statement). All `##print axioms`-checked: `[propext, Classical.choice, Quot.sound]`.

38.13 The assembled conditional theorem

Theorem 38.68 ($V^\natural$ modulo (4.23) on four pairs). *There exist $x_0 \in T_0^+$, $x_1 \in T_1^+$ such that, if DGM (4.23) holds on the four pairs (x_i, x_j), then there is a simple vertex operator algebra V on $V^\natural$ whose vertex map is the block map $Y^\natural[\overline{W}]$ of (38.1), with vacuum $(\mathbf{1}, 0)$, conformal vector $(\omega, 0)$, central charge 24, $V_1 = 0$, $\dim V_2 = 196884$, and $\dim V_n = [q^n]\, qJ(q)$ for all $n \geq 0$.*

```
theorem moonshine_of_frameLocality :
    ∃ x : ZMod 2 → TP, (∀ s, x s ∈ TPframe s) ∧
      ((∀ i j, TPBlockLocal leechWbar (x i) (x j)) →
        ∃ V : VertexOperatorAlgebra Vnat,
          V.Y = Ynat wbarL ∧ V.vacuum = vacNat ∧ V.conformalVector = omegaNat ∧
          V.centralCharge = 24 ∧
          V.grading 1 = ⊥ ∧
          finrank ℂ (V.grading 2) = 196884 ∧
          (∀ n : ℕ, (finrank ℂ (V.grading (n : ℤ)) : ℂ) = PowerSeries.coeff n JShift) ∧
          V.IsSimple) := by
```

(`VOA.Moonshine.moonshine_of_frameLocality`, `VOA/Moonshine/Main.lean`.)

From the mathematics to the Lean statement

Every conjunct, decoded: `V.Y = Ynat wbarL` — the vertex map is the genuine block map (Definition 38.34 with $\overline{W}$); `V.vacuum = vacNat`, `V.conformalVector = omegaNat` — Definition 38.22; `V.centralCharge = 24`; `V.grading 1 = ⊥` — $V_1 = 0$; `finrank ℂ (V.grading 2) = 196884`; the graded dimension identity with `JShift` $= qJ$; `V.IsSimple` (Definition 38.8). The grading of V is not mentioned as a separate conjunct, but the three dimension statements are about `V.grading`, the grading of the VOA itself, and the proof sets it to `gradingNat`.
Hypotheses: none outside the existential; inside, (4.23) on four pairs. Compared with the textbook theorem (FLM: $V^\natural$ is a simple VOA of central charge 24 with character J) this is *weaker*, being conditional on (4.23). Its vacuity analysis: without `V.IsSimple` the conclusion would be satisfied by the square-zero extension; without `V.Y = Ynat wbarL` it could be satisfied by any VOA on the same graded space; with both, the impostor is excluded (Section 38.11). The quantifier caveat of Theorem 38.55 applies: the four pairs are chosen by the proof.
The file `Main.lean` states in its docstring that this theorem is *superseded*: the unconditional theorem is `VOA.Moonshine.moonshine`, in which the hypothesis has been discharged.

Physical meaning

This is the assembled statement of the construction: modulo four twist-field four-point crossing conditions, $V^\natural$ is a simple chiral CFT with $c = 24$, no weight-one states (hence a

finite symmetry group, by FLM's theorem the Monster, which is not formalized), 196884 states at weight two and partition function J. Every physical feature of the Moonshine orbifold is present; what is not yet shown is the single twist×twist crossing condition, to be discharged by the triality method.

Proof. Theorem 38.67, together with Theorems 38.24, 38.25 and 38.26 transported along `V.grading = gradingNat`. □

What the machine verified

Conditional on (4.23) on four (chosen) pairs; `##print axioms = [propext, Classical.choice, Quot.sound]` (checked). The hypothesis is discharged in Chapters 39–42: the triality automorphism σ conjugates the untwisted locality into twisted locality (`tpBlockLocal_frame_of_sigma`, `moonshine_of_sigma` in `M8hKey.lean`), and the remaining finite identity is `topPairs_one`. The final, unconditional statement is

```
theorem moonshine :
    ∃ V : VertexOperatorAlgebra Vnat,
      V.Y = Ynat VnatAxioms.wbarL ∧ V.vacuum = vacNat ∧ V.conformalVector = omegaNat
       ↪ ∧
      V.centralCharge = 24 ∧
      V.grading 1 = ⊥ ∧
      Module.finrank ℂ (V.grading 2) = 196884 ∧
      (∀ n : ℕ, (Module.finrank ℂ (V.grading (n : ℤ)) : ℂ) = PowerSeries.coeff n
       ↪ JShift) ∧
      V.IsSimple :=
  moonshine_of_topPairs (by norm_num) topPairs_one
```

(`VOA/Moonshine/TopPairs.lean`, documented in Chapter 42); it has exactly the conclusion of Theorem 38.68, now with no hypothesis.

38.14 Dead ends and corrected mistakes

Trap / dead end

1. The square-zero extension. Recorded in `Notes/MonsterRoadmap.md` ("Definition of done", TRAP) and in Section 43.2.2. $\overline{W}' = 0$ satisfies every hypothesis of `reconstruct_nat` and gives a VOA with $c = 24$, $V_1 = 0$, $\dim V_2 = 196884$, character J, not simple. Remedy: simplicity is a conjunct of the final theorem. See Section 38.11.

Trap / dead end

2. The generator gap. An earlier version of `VnatAxioms.lean` could reduce htt only to a family whose *linear* span is T^+ (`htt_of_span`); a mode-generating family was not enough, because the iterate formula $Y^\natural(u_{(n)}t) = Y^\natural(u)_{(n)}Y^\natural(t)$ for the off-diagonal blocks was unavailable. It was closed by Theorem 38.53, whose key input is the unconditional (4.22). Recorded in `Notes/M8GluingPlan.md`, "M8h-0 DONE".

Trap / dead end

3. (4.23) is not a finite check. One might hope to verify (4.23) on finitely many matrix coefficients. This is impossible without a closed form or an a priori differential equation: the ground-state matrix element $\langle x_0', W(t_0,z_1)\overline{W}(t_0,z_2)x_0\rangle = z_2^a f(z_2/z_1)$ is an infinite power

series whose coefficients are sums over $(V_\Lambda^+)_k$, and locality is the statement that f is rational of a prescribed shape (`Notes/M8hRoute.md`, §5). This is why the triality route was chosen.

Trap / dead end

4. Sign conventions are each necessary. Numerical tests on an E_8 model of the library's construction (`Notes/M8hRoute.md`, §1a; evidence, not proof) confirmed (4.23) to relative residual $3.7 \cdot 10^{-14}$ on 64 identities, and showed that each of the following "simplifications" breaks it (residual 1.7–2.0): replacing the T-form sign $(-1)^{\langle\alpha,\alpha\rangle/2}$ by $\varepsilon(\alpha,\alpha)$; setting the charge sign $c(\alpha) = 1$ in the lattice form; dropping $(-1)^w$ in the definition of $\overline{W}$. The anticommutator (super) version fails (residual ≈ 2): the extension is a VOA, not a super VOA.

Trap / dead end

5. The library's Intertwiner is weaker than FHL's. The library notion `Intertwiner` (Chapter 37) consists of truncation and the intertwining commutator formula only, without the full Jacobi identity. Nothing in this chapter needs more: every locality is derived from commutator formulas (Theorem 38.18) and the Goddard lemmas.

38.15 Referee's checklist

All entries: `##print axioms` = `[propext, Classical.choice, Quot.sound]`, checked 2026-10-07 at an earlier commit (not re-run for this edition). "htt" = twisted–twisted locality for all pairs.

Square-zero extension (Proposition 38.57): **argued on paper only**, not formalised; its role is to show why `V.IsSimple` and `V.Y = Ynat wbarL` must appear in the final statement.

38.16 Notes and references

The block form (38.1), the reduction of locality to the six relations (4.18)–(4.23), the skew-symmetry (4.9) and the adjunction (4.3) defining $\overline{W}$ follow L. Dolan, P. Goddard and P. Montague, *Conformal field theory of twisted vertex operators*, Nuclear Phys. B 338 (1990) 529–601, and especially their *Conformal field theories, representations and lattice constructions*, Comm. Math. Phys. 179 (1996) 61–120, arXiv:hep-th/9410029, §§3–5 (the remark that (4.23) is "almost a modular invariance condition" is in §5.3; triality is in §§6–7).

The construction of the Moonshine module, including the triality used in the later chapters, is I. Frenkel, J. Lepowsky and A. Meurman, *Vertex Operator Algebras and the Monster*, Pure and Applied Mathematics 134, Academic Press, 1988 (chapters 9–12), announced in Proc. Natl. Acad. Sci. USA 81 (1984) 3256–3260.

Invariant bilinear forms on VOAs and modules, and the FHL transpose $e^{zL_1}(-z^{-2})^{L_0}$, are from I. Frenkel, Y.-Z. Huang and J. Lepowsky, *On axiomatic approaches to vertex operator algebras and modules*, Mem. Amer. Math. Soc. 104 (1993), no. 494. The equivalence between simplicity and nondegeneracy of the invariant form is H. Li, *Symmetric invariant bilinear forms on vertex operator algebras*, J. Pure Appl. Algebra 96 (1994) 279–297. Local systems of vertex operators and the reconstruction theorem in the locality formulation are H. Li, *Local systems of vertex operators, vertex superalgebras and modules*, J. Pure Appl. Algebra 109 (1996) 143–195, arXiv:hep-th/9406185, and

V. Kac, *Vertex Algebras for Beginners*, 2nd ed., University Lecture Series 10, AMS, 1998 (Dong's lemma, Goddard's uniqueness theorem, the existence theorem). The textbook treatment of modules, commutator formulas and skew-symmetry used throughout is J. Lepowsky and H. Li, *Introduction to Vertex Operator Algebras and Their Representations*, Progress in Mathematics 227, Birkhäuser, 2004. The library's conventions follow T. Gannon, *Moonshine beyond the Monster*, Cambridge University Press, 2006, §5.1.

The project-internal record — the TRAP, the generator gap, the numerical evidence and the route decision — is in `Notes/MonsterRoadmap.md`, `Notes/M8GluingPlan.md` ("Status" sections through "M8h-0 DONE") and `Notes/M8hRoute.md`.

Chapter 39

The Golay frame and the untwisted triality

At the end of Chapter 38 the space

$$V^\natural \;=\; V_\Lambda^+ \;\oplus\; (V_\Lambda^T)^+$$

carried a candidate vertex map $Y^\natural$, assembled in block form from the vertex operators of V_Λ^+ on itself, the twisted vertex operators Y^T of V_Λ^+ on the twisted sector, the skew intertwiner W and its adjoint $\overline{W}$. Every axiom of a vertex operator algebra had been verified for $Y^\natural$ except one family of locality relations: the locality of two operators $Y^\natural(t_1, z_1)$, $Y^\natural(t_2, z_2)$ whose *states* t_1, t_2 both lie in the twisted sector, evaluated on a twisted vector. In the numbering of Dolan, Goddard and Montague this is relation (4.23); in the library it is the predicate `TPBlockLocal`. This chapter begins the proof of that relation. It does so by the route of Frenkel, Lepowsky and Meurman: one finds a hidden symmetry σ of the would-be algebra $V^\natural$ — the *triality* — which exchanges part of the untwisted sector with part of the twisted sector, so that the unknown twisted×twisted products become conjugates of known untwisted products. The chapter documents the release of the library named in the front matter; every Lean quotation is checked by `scripts/textbook/sync.py` to occur verbatim (up to whitespace and comments) in the source files of that release. Checks that were run at an earlier state of the library and not re-run for this edition are marked as such.

The chapter has three parts.

(I) *The Golay frame* (Sections 39.2–39.5). An index-two sublattice $\Lambda_0 \subset \Lambda$ splits each of the two halves of $V^\natural$ into two pieces, so that $V^\natural$ becomes a sum of four modules over the subalgebra $V_0^+ = V_{\Lambda_0}^+$:

$$V^\natural \;=\; V_0^+ \;\oplus\; V_3^+ \;\oplus\; T_0^+ \;\oplus\; T_3^+.$$

We compute the weight-two dimensions of all four pieces.

(II) *Cyclicity* (Sections 39.6–39.7). Each of the four pieces is generated, as a V_0^+-module, by a single explicit vector. This is what later lets one *define* a V_0^+-equivariant map out of a piece by prescribing the image of one vector.

(III) *The untwisted triality* (Sections 39.8–39.10). On the lattice vertex algebra of the Niemeier lattice $N = N(A_1^{24})$ we construct an explicit involution σ out of exponentials of $\mathfrak{sl}_2$ zero modes, restrict it to the subalgebra $V_N^{\langle \chi, \Theta \rangle}$, and transport it, along an isomorphism of vertex operator algebras $V_N^{\langle \chi, \Theta \rangle} \cong V_0^+$ built from the functoriality of lattice VOAs (Chapter 31), to a nontrivial involutive automorphism `v0Sigma` of V_0^+.

The extension of σ to the remaining sectors, and the identity that makes it useful, are the subjects of Chapters 40–42.

Standing conventions. We use the conventions of the earlier chapters without change. For a vertex algebra V (in Lean, a term `V : VertexOperatorAlgebra` $\mathcal{V}$ on a complex vector space $\mathcal{V}$) and states u, v, the *n-th product* is $u_{(n)}v$, the coefficient of z^{-n-1} in $Y(u,z)v$. In Lean it is written `V.smul u n v`; by definition (`PreVertexAlgebra.smul_def`) this is `mode (V.Y u) n v`, where the library's `mode` is `mode f m = f (-m - 1)` (Definition 2.7, `VOA/Foundations/FormalCalculus.lean`): a formal distribution $f(z) = \sum_k f_k z^k$ is stored as the function $k \mapsto f_k$, and its m-th mode is the coefficient of z^{-m-1}. For a twisted module of order two the library writes `T.YM u k` for the operator $u_{(k/2)}$, half-integer modes being indexed by integers k (Chapter 34). An *automorphism* of a vertex operator algebra W is a term of the structure `Aut W` (Definition 5.9, `VOA/Core/Automorphism.lean`, where it is quoted verbatim): a linear bijection α (`toLinearEquiv`) with $\alpha(u_{(n)}v) = (\alpha u)_{(n)}(\alpha v)$ for *all* $n \in \mathbb{Z}$ (`map_smul'`), $\alpha\mathbf{1} = \mathbf{1}$ (`map_vacuum`), $\alpha\omega = \omega$ (`map_omega`). This is exactly the textbook notion of a VOA automorphism; requiring the product identity for all n is equivalent to $\alpha Y(u,z)\alpha^{-1} = Y(\alpha u, z)$. For a subgroup $G \le \mathrm{Aut}\, W$ the *orbifold* (fixed-point subalgebra) is

```
def orbifold (G : Subgroup (Aut W)) : VOASubalgebra W where
  carrier :=
    { carrier := {v | ∀ g ∈ G, g v = v}
      ...
```

(`VOA/Modularity/Twisted.lean`; the omitted lines are the closure proofs), and `orbifoldVOA G` is W^G regarded as a vertex operator algebra with the same vacuum and conformal vector. A *VOA homomorphism* is a linear map φ preserving vacua and all products, `IsVOAHom V T φ`, with fields `map_vacuum` ($\varphi\mathbf{1}_V = \mathbf{1}_T$) and `map_smul` ($\varphi(u_{(n)}v) = (\varphi u)_{(n)}(\varphi v)$) (Definition 5.22, `VOA/Core/SimpleImage.lean`, where it is quoted verbatim). Note that `IsVOAHom` does not mention the conformal vector; wherever an isomorphism of VOAs (rather than of vertex algebras) is claimed below, the statement $\varphi(\omega) = \omega$ is proved separately and recorded.

Finally, the lattice vertex algebra V_L of an even positive-definite lattice L is, as in Chapter 31, the space File `VOA/Examples/LatticeGenModule.lean`.

```
noncomputable abbrev LatModuleGen : Type :=
  HeisenbergN.FockN (rank L) ⊗[ℂ] (L.carrier →₀ ℂ)
```

— the bosonic Fock space $S(\hat{\mathfrak{h}}^-)$ tensored with the group algebra $\mathbb{C}\{L\}$, whose basis vector at α we write e^α (`eGen L α`). A pure tensor $p \otimes e^\alpha$ is `latStateGen L p α`; the *charged vacuum* $\mathbf{1} \otimes e^\alpha$ is `latChargeGen L α`; the *momentum-γ component* of a state x is the Fock vector `coordEα L γ x` ("the coefficient of e^γ"); and the *momentum sector* $F_\gamma = S(\hat{\mathfrak{h}}^-) \otimes e^\gamma$ is `chargeSec L γ`. The vertex operator algebra structure is `latticeVOAGen L hEven hPos`, the hypotheses being evenness and positive definiteness of L. The cocycle $\varepsilon(\alpha,\beta) = \pm 1$ of the vertex operators $Y(e^\alpha,z)e^\beta = \varepsilon(\alpha,\beta)z^{\langle\alpha,\beta\rangle}\cdots$ is `latticeCocycle L α β`; it is bimultiplicative and satisfies $\varepsilon(\alpha,\beta)\varepsilon(\beta,\alpha)^{-1} = (-1)^{\langle\alpha,\beta\rangle}$.

39.1 Why a triality is needed

39.1.1 The one relation that resists

Recall the shape of the problem. Write $V = V_\Lambda^+$ and $\mathcal{T} = (V_\Lambda^T)^+$, so that $V^\natural = V \oplus \mathcal{T}$. For $u \in V$ the operator $Y^\natural(u,z)$ is block diagonal, $Y^\natural(u,z) = \mathrm{diag}(Y(u,z), Y^T(u,z))$; for $t \in \mathcal{T}$ it is block off-diagonal, with $W(t,z) : V \to \mathcal{T}$ and $\overline{W}(t,z) : \mathcal{T} \to V$. The locality axiom for $Y^\natural$ splits into six relations according to which blocks are involved. Five of them are statements about a single module over a single vertex algebra:

- $u, u' \in V$ on V: locality in the vertex algebra V (Chapter 32);
- $u, u' \in V$ on $\mathcal{T}$: locality of the twisted module (Chapters 34–36);

- $u \in V$, $t \in \mathcal{T}$, in either order and on either sector: the fact that W and $\overline{W}$ are intertwining operators (Chapter 37).

The remaining relations have *two* twisted states. On the untwisted sector, the composite $\overline{W}(t_1,z_1)W(t_2,z_2) : V \to V$ must be local with its swap; DGM call this (4.22) and the library proves it unconditionally (Chapter 38) from the skew symmetry of $\overline{W}$. On the twisted sector the composite $W(t_1,z_1)\overline{W}(t_2,z_2) : \mathcal{T} \to \mathcal{T}$ must satisfy

$$(z_1-z_2)^N\Big(W(t_1,z_1)\overline{W}(t_2,z_2) - W(t_2,z_2)\overline{W}(t_1,z_1)\Big) = 0 \qquad (N \gg 0). \tag{39.1}$$

This is DGM (4.23). Its physical meaning is clear: it is the statement that the four-point function of four twist fields of the $\mathbb{Z}/2$-orbifold of the Leech CFT is single valued. Concretely, the matrix element of (39.1) between ground states is a theta series of Λ divided by η^{24}, evaluated at the modular parameter $q(x)$ of the double cover of the sphere branched over the four insertion points; single-valuedness in x is a statement about the behaviour of Θ_Λ under the full modular group, and DGM describe the condition as "almost a modular invariance condition", true precisely because $\sqrt{2}\Lambda^*$ is even. A direct proof along these lines requires analytic continuation of four-point functions, which the formal-variable framework of the library does not support.

39.1.2 The idea of triality

FLM avoid any computation of twisted×twisted products. Their idea can be explained in three sentences.

1. If $V^\natural$ were already known to be a vertex operator algebra and σ were an automorphism of it, then $\sigma Y^\natural(a,z)\sigma^{-1} = Y^\natural(\sigma a, z)$ for all states a.

2. If moreover σ mapped some untwisted subspace $X \subseteq V$ onto some twisted subspace $\sigma(X) \subseteq \mathcal{T}$, then for $t, t' \in \sigma(X)$,

$$Y^\natural(t,z_1)Y^\natural(t',z_2) \;=\; \sigma\, Y^\natural(\sigma^{-1}t,z_1)\, Y^\natural(\sigma^{-1}t',z_2)\,\sigma^{-1},$$

   and the right side involves only operators of *untwisted* states, whose locality is already known.

3. One therefore constructs σ *before* knowing that $V^\natural$ is a VOA, proves the conjugation identity in the one case that is not automatic, and *deduces* the missing locality.

The difficulty is concentrated in the conjugation identity of step 3; that is the content of Chapters 40–42. What makes step 2 possible at all is a decomposition of $V^\natural$ into pieces fine enough that σ can map an untwisted piece to a twisted piece. This is the Golay frame.

39.1.3 The frame and its four sectors

The Leech lattice contains an index-two sublattice Λ_0 which is simultaneously an index-two sublattice of the Niemeier lattice $N = N(A_1^{24})$. The discriminant group Λ_0^*/Λ_0 has order 4 (because $[\Lambda : \Lambda_0] = 2$ and Λ is unimodular), and it contains two different subgroups of order two, namely Λ/Λ_0 and N/Λ_0; a cyclic group of order four has only one, so $\Lambda_0^*/\Lambda_0 \cong (\mathbb{Z}/2)^2$. Following DGM we label the four cosets $\Lambda_0, \Lambda_1, \Lambda_2, \Lambda_3$ so that

$$N = \Lambda_0 \sqcup \Lambda_1, \qquad \Lambda = \Lambda_0 \sqcup \Lambda_3.$$

This is the origin of the subscript "3" below; in the library the two cosets of Λ_0 in Λ are indexed by $0, 1 \in \mathbb{Z}/2$, and V_3^+ is `frameSector 1`.

On the untwisted side, a state of V_Λ^+ splits according to whether its momenta lie in Λ_0 or in Λ_3:

$$V_\Lambda^+ = V_0^+ \oplus V_3^+, \qquad V_0^+ = V_{\Lambda_0}^+, \quad V_3^+ = \big(\theta\text{-fixed states with momenta in } \Lambda_3\big).$$

On the twisted side, the 4096-dimensional module T of the extraspecial group splits into two 2048-dimensional halves T_0, T_3 under a central element of the preimage of Λ_0, and

$$(V_\Lambda^T)^+ = T_0^+ \oplus T_3^+, \qquad T_s^+ = (S[\theta] \otimes T_s)^+.$$

FLM (and DGM, Proposition 7.1) show that the four pieces are irreducible V_0^+-modules. The triality is an involution of $V^\natural$ with

$$\sigma(V_0^+) = V_0^+, \qquad \sigma(V_3^+) = T_0^+, \qquad \sigma(T_3^+) = T_3^+. \tag{39.2}$$

At weight two the dimensions are (all proved below except the twisted ones, which come from Chapter 36 together with the 2048 + 2048 split proved here):

	V_0^+	V_3^+	T_0^+	T_3^+	total
weight 2	49428	49152	49152	49152	196884

The equality $\dim(V_3^+)_2 = \dim(T_0^+)_2$ is the first visible sign of the triality. The coincidence $49152 = 24 \cdot 2048$ on the twisted side (24 oscillators $h_a(-\frac{1}{2})$ of weight $\frac{1}{2}$ on the 2048-dimensional ground space of weight $\frac{3}{2}$) and $49152 = \frac{1}{2} \cdot 24 \cdot 2^{12}$ on the untwisted side (pairs $\pm\alpha$ of norm-four vectors outside Λ_0) is not an accident: both sides are "24 copies of a 2^{11}-dimensional representation".

39.1.4 What the untwisted triality is, physically

The Niemeier lattice N has 48 roots $\pm\alpha_j$, $j = 0, \dots, 23$, mutually orthogonal, so V_N contains the affine algebra $\widehat{\mathfrak{sl}}_2^{\,24}$ at level one; each $\widehat{\mathfrak{sl}}_2$ factor is the $SU(2)_1$ WZW model, the theory of a free boson at the self-dual radius. The global symmetry group contains $SU(2)^{24}$, acting on the j-th triple of currents (J^{j1}, J^{j2}, J^{j3}) by rotations. Two involutions of V_N are rotations by π in every factor: χ, about the "Cartan" axis $J^{j1} = \frac{1}{2}h_j$, and Θ, about the axis $J^{j2} \propto e_j + f_j$. In the bosonic language χ is a momentum sign, while Θ is a lift of -1 on the lattice (it negates the boson). The rotation by π about the *bisector* of these two axes swaps them; conjugation by it swaps χ and Θ. That rotation is the untwisted triality. Restricted to the fixed points of both χ and Θ it is an automorphism of $V_N^{\langle\chi,\Theta\rangle}$, and this algebra is $V_{\Lambda_0}^+ = V_0^+$ — the common part of V_N and of $V^\natural$. On V_N the triality exchanges the χ-odd part $V_{\Lambda_0}^-$ with the Θ-odd part $V_{\Lambda_1}^+$; the analogous statement in $V^\natural$, where the roles are played by the θ-twisted sector, is (39.2).

Trap / dead end

DGM's Section 7 is circular for this project. Dolan, Goddard and Montague construct σ on $V^\natural$ by combining the explicit triality on V_N with their Proposition 7.3, an isomorphism of twisted and untwisted realisations whose proof uses their earlier (analytic) theorem that the twisted construction defines a conformal field theory — i.e. it uses the locality (39.1) that we are trying to prove. Only the untwisted part of their Section 7 (the formula for σ on V_N) is used in this chapter; the extension to the twisted sectors is done non-circularly in Chapters 40–41. (Source: Notes/M8GluingPlan.md, route (A), "Caution".)

39.2 The frame lattice Λ_0

39.2.1 The model of the Leech lattice

The library uses Ebeling's model of the Leech lattice (Chapter 30), vendored in the file `VOA/LatticesAndCodes/Leech/Defs.lean`. Let $C \subset \mathbb{F}_2^{24}$ be the extended binary Golay code, $\rho : \mathbb{Z}^{24} \to \mathbb{F}_2^{24}$ reduction mod two, and

$$A = \left\{ a \in \mathbb{Z}^{24} \ : \ \rho(a) \in C,\ 4 \,\middle|\, \sum_i a_i \right\} \quad \text{(Lean: } \texttt{Leech.subA}\text{)}, \qquad u = (5, 1, 1, \dots, 1).$$

Then $\Lambda = 2A \sqcup (u + 2A) \subset \mathbb{Z}^{24}$ with bilinear form $\langle x, y \rangle = x \cdot y/8$. The Niemeier lattice is $N = \rho^{-1}(C)$ with form $x \cdot y/2$ (`Leech.golayLattice`); its roots (vectors of norm 2) are exactly $\pm 2e_j$. The *frame character* is

$$\beta : \Lambda \to \mathbb{Z}/2, \qquad \beta(x) = x_0 \bmod 2,$$

which is a homomorphism (`Leech.beta`). Since every vector of $2A$ has even coordinates and every vector of $u + 2A$ has odd coordinates, $\ker \beta = 2A$.

Definition 39.1 (The frame lattice). $\Lambda_0 := \ker \beta = 2A \subset \Lambda$, and $\Lambda_3 := \Lambda \setminus \Lambda_0 = u + 2A$.

```
/-- The Golay-frame character `β : Λ → ℤ/2`, `x ↦ x₀ mod 2`. -/
noncomputable def frameChar : leech.carrier →+ ZMod 2 := Leech.beta.toAddMonoidHom

/-- **`Λ₀`**, the index-`2` sublattice `ker β = 2A` of the Leech lattice. -/
noncomputable def lambda0 : Submodule ℤ leech.carrier := LinearMap.ker Leech.beta

theorem mem_lambda0 (α : leech.carrier) : α ∈ lambda0 ↔ frameChar α = 0 :=
 ↪  LinearMap.mem_ker
```

(`VOA/Moonshine/FrameSectors.lean`, `VOA.Moonshine.frameChar`, `VOA.Moonshine.lambda0`.)

From the mathematics to the Lean statement

Fidelity check. `leech` is the Leech lattice as a `VOA.IntegralLattice` (transported from the vendored Ebeling model, Chapter 30); `leech.carrier` is its underlying $\mathbb{Z}$-module, whose elements are vectors $x \in \mathbb{Z}^{24}$ in $2A \cup (u + 2A)$. `→+ ZMod 2` is "additive group homomorphism to $\mathbb{Z}/2$". `Submodule ℤ` of a $\mathbb{Z}$-module is a subgroup. `LinearMap.ker` is the kernel. So `lambda0` is literally $\ker \beta$. No hypotheses. The definition could only be "wrong" if `Leech.beta` were not the map $x \mapsto x_0 \bmod 2$; its source (displayed in Chapter 30) is `toFun x := (((x : Fin 24 → ℤ) 0 : ℤ)) : ZMod 2`, i.e. exactly that. The next two results show Λ_0 is neither Λ nor trivially small.

Physical meaning

The sublattice $\Lambda_0 = \ker \beta$ is the set of momenta whose first coordinate is even; it is the momentum lattice of the "frame" sub-theory V_{Λ_0}, a rank-24 lattice CFT sitting inside the Leech CFT. Heuristically, the Golay code organises the 24 chiral bosons into a frame of commuting Ising-like pieces (a code CFT / frame VOA in the sense of Dong–Griess–Miyamoto), and $\Lambda_0 = \Lambda \cap N$ is the part of the Leech charge lattice that this frame sees in the same way as the Niemeier lattice $N(A_1^{24})$. Charges in Λ_0 are the ones that the Leech theory and the A_1^{24} theory share; the remaining Leech charges Λ_3 are the ones only Leech has. This shared subtheory is what lets the triality of the A_1^{24} theory be transported to the moonshine theory. The identification with a frame is a heuristic guide; the definition is just a kernel of a map to $\mathbb{Z}/2$.

Proposition 39.2 (Index two). $[\Lambda : \Lambda_0] = 2$.

```
/-- `[Λ : Λ₀] = 2`. -/
theorem card_quotient_lambda0 : Nat.card (leech.carrier / lambda0) = 2
```

From the mathematics to the Lean statement

Fidelity check. `leech.carrier / lambda0` is the quotient group Λ/Λ_0 and `Nat.card` its cardinality (with the convention that an infinite set has `Nat.card` 0; since the value is 2, the quotient is finite of order exactly two). Same as the textbook statement. Not vacuous: a statement `Nat.card` $= 2$ cannot hold for the trivial quotient.

Physical meaning

In charge-lattice language, Λ_0 has index two: there are only two "frame charge" classes, even and odd, and every Leech charge falls in exactly one. This is what makes the frame a $\mathbb{Z}/2$-grading of the Leech theory, the simplest possible charge decomposition, and later forces exactly two sectors V_0^+ and V_3^+. It is a counting statement about the charge lattice, with no dynamical content beyond that.

Proof. β is surjective because $\beta(u) = 5 \bmod 2 = 1$, so $\Lambda/\ker\beta \cong \mathbb{Z}/2$. (The library proves the equivalent statement $[\Lambda : \mathrm{im}(a \mapsto 2a)] = 2$ for the model, and $\Lambda_0 = \mathrm{im}(a \mapsto 2a)$.) □

What the machine verified

Unconditional; `##print axioms card_quotient_lambda0` = [`propext`, `Classical.choice`, `Quot.sound`] (re-run for this chapter, see Section 39.12).

Proposition 39.3 ($\Lambda_0 \cong A$ isometrically)**.** *The doubling map $a \mapsto 2a$ is an isomorphism of groups $A \to \Lambda_0$, and if A carries the form $a \cdot b/2$ (the restriction of the form of N), it is an isometry: $\langle 2a, 2b\rangle_\Lambda = a \cdot b/2$.*

```
/-- `a ↦ 2a` identifies `A` with `Λ₀`. -/
noncomputable def lambda0Equiv : ↥Leech.subA ≃ₗ[ℤ] ↥lambda0 :=
  (LinearEquiv.ofInjective Leech.inclL Leech.inclL_injective).trans
    (LinearEquiv.ofEq _ _ lambda0_eq_range_inclL.symm)

/-- `A ≃ Λ₀` is an isometry: the Leech form on `Λ₀` is the halved Golay form on `A`. -/
theorem lambda0Equiv_form (a b : ↥Leech.subA) :
    leech.form (lambda0Equiv a : leech.carrier) (lambda0Equiv b : leech.carrier)
      = Leech.subALattice.bilin a b
```

From the mathematics to the Lean statement

Fidelity check. `↥Leech.subA` is the subtype of vectors in A; `≃ₗ[ℤ]` is a $\mathbb{Z}$-linear bijection. The map is built from `Leech.inclL`, whose source is `toFun a := ⟨(2 : ℤ) • (a : Fin 24 → ℤ), …⟩`, i.e. $a \mapsto 2a$; `ofInjective` makes it a bijection onto its range and `ofEq` identifies the range with `lambda0`. `Leech.subALattice` is A with the form `dotLattice 2 subA …`, i.e. $a \cdot b/2$. The statement is exactly the proposition.

Physical meaning

Physically this says that the frame sub-theory is the lattice CFT of A with the halved Golay form: the charge lattice Λ_0 of the Leech theory is, as a Euclidean lattice, the same object that appears inside the Niemeier theory V_N. Isometric charge lattices give isomorphic lattice CFTs, so this identification is the first step in comparing the Leech-side and Niemeier-side descriptions of the same subtheory, which the bridges of Section 39.10 make precise.

Proof. $(2a)\cdot(2b)/8 = 4(a\cdot b)/8 = a\cdot b/2$. □

What the machine verified

Unconditional; `##print axioms-clean`.

Trap / dead end

Λ_0 is not $\sqrt{2}\,\Gamma_{\text{Golay}}$. An early version of the project's gluing plan (`Notes/M8GluingPlan.md`) described Λ_0 as a rescaled Golay lattice. That lattice has minimum $2\cdot 4 = 8$, whereas Λ_0 contains norm-four vectors: for $a = (2,2,0,\dots,0) \in A$, $2a = (4,4,0,\dots,0)$ has $\langle 2a, 2a\rangle = 32/8 = 4$. The correct description is $\Lambda_0 = \Lambda \cap N$ up to the isometry above (Notes/M8GluingPlan.md, "Status and corrections after M8e", item 2).

Example 39.4 (Norm-four vectors)**.** The Leech lattice has 196560 vectors of norm 4. Those in $\Lambda_0 = 2A$ are $2a$ with $a \in A$, $a\cdot a = 8$: either $a = \pm 2e_i \pm 2e_j$ ($i<j$; these have $\sum a_i \in \{0,\pm 4\}$, all divisible by 4), giving $4\binom{24}{2} = 1104$ vectors, or $a = (\pm 1)^8$ supported on an octad with an even number of minus signs (so that $4 \mid \sum a_i$), giving $759\cdot 2^7 = 97152$ vectors. Thus $|\Lambda_0 \cap \{\text{norm } 4\}| = 98256$ and $|\Lambda_3 \cap \{\text{norm } 4\}| = 196560 - 98256 = 98304$. The second number is proved in Lean below (Theorem 39.10); the first was checked numerically (the Python count recorded in `FrameSectors.lean`) and follows from the second.

39.3 Momentum signs and the untwisted sectors

39.3.1 The automorphism attached to a character (recalled)

The device that splits V_Λ by cosets of Λ_0 was introduced in Section 31.11. For an even positive-definite lattice L and a homomorphism $\chi : L \to \mathbb{Z}/2$ one has the *sign automorphism*

$$g_\chi(p \otimes e^\alpha) = (-1)^{\chi(\alpha)}\, p \otimes e^\alpha \qquad \text{(Lean: } \texttt{VOA.LatGen.chiLat L χ}\text{, Definition 31.31)}, \tag{39.3}$$

where $(-1)^{\chi(\alpha)}$ is written `chiSign L χ α = Extraspecial.sgn (χ α)`, the function $\mathbb{Z}/2 \to \mathbb{C}$ sending $0 \mapsto 1$, $1 \mapsto -1$. Chapter 31 proves (Theorem 31.32) that g_χ is an automorphism of the vertex operator algebra V_L (`chiAut L χ hEven hPos : Aut (latticeVOAGen L hEven hPos)`), that $g_\chi^2 = 1$ (`chiAut_sq`) and that g_χ commutes with the standard lift θ of -1 (`chiAut_mul_thetaAut`); and (Theorem 31.33) that

$$g_\chi x = x \iff x_\alpha = 0 \text{ whenever } \chi(\alpha) \neq 0, \qquad g_\chi x = -x \iff x_\alpha = 0 \text{ whenever } \chi(\alpha) = 0, \tag{39.4}$$

where x_α (`coordEα L α x`) is the momentum-α Fock component of x (see `chiLat_eq_self_iff` and `chiLat_eq_neg_iff`). The physical picture: g_χ is the operator $(-1)^{\chi(\hat p)}$ of the momentum $\hat p$, a symmetry because momentum is conserved in every operator product. We use g_χ twice: with $L = \Lambda$, $\chi = \beta$ (this section), and with $L = N$, $\chi =$ parity (Section 39.9).

39.3.2 The sectors V_0^+ and V_3^+

Specialise to $L = \Lambda$, $\chi = \beta$. The resulting automorphism is the *frame automorphism* $g := g_\beta$ (`frameAut : Aut leechVOA`); it commutes with θ (`frameAut_comm_leechTheta`), hence preserves V_Λ^+ and restricts to an automorphism `plusFrameAut : Aut leechVOAPlus`. The carrier type of V_Λ^+ is

```
abbrev VPlus : Type := ↥(orbifold (Subgroup.zpowers leechTheta)).carrier
```

i.e. the vectors of V_Λ fixed by the cyclic group $\langle\theta\rangle$ (here `leechVOAPlus := orbifoldVOA (Subgroup.zpowers leechTheta)`, Chapter 32).

Definition 39.5 (Frame sectors). For $i \in \mathbb{Z}/2$, $V_{(i)} := \{v \in V_\Lambda^+ : gv = (-1)^i v\}$. We write $V_0^+ = V_{(0)}$ and $V_3^+ = V_{(1)}$.

```
/-- **The frame sectors** `V_i := {v ∈ V_Λ⁺ | g v = (-1)^i v}`; `V₀⁺ = frameSector 0`,
`V₃⁺ = frameSector 1`. -/
noncomputable def frameSector (i : ZMod 2) : Submodule ℂ VPlus :=
  Module.End.eigenspace (plusFrameAut.toLinearEquiv : Module.End ℂ VPlus)

theorem mem_frameSector_one_iff (v : VPlus) :
    v ∈ frameSector 1 ↔ ∀ α, α ∈ lambda0 → coordEα leech α v = 0
```

From the mathematics to the Lean statement

Fidelity check. `Module.End.eigenspace f c` is $\ker(f - c)$, a subspace of `VPlus`. `plusFrameAut.toLinearEquiv` is g restricted to V_Λ^+. The two characterisation theorems say that V_0^+ is the set of θ-fixed states with all momenta in Λ_0 and V_3^+ the set of θ-fixed states with all momenta in Λ_3 (the coercion `v : VPlus` to V_Λ is implicit in `coordEα leech α v`). This is the intended meaning of $V_{\Lambda_0}^+$ and of "$V_{\Lambda_3}^+$".

Physical meaning

The frame automorphism $g = (-1)^{\beta(\hat{p})}$ is a $\mathbb{Z}/2$ charge symmetry of the Leech theory: it is the parity of the first momentum coordinate, and is a symmetry because momentum is conserved in every operator product. Its two eigenspaces on V_Λ^+ are the charge sectors: V_0^+ (neutral under g, momenta in Λ_0) and V_3^+ (odd, momenta in Λ_3). In orbifold language one is projecting onto the g-even states to get the subtheory V_0^+, while V_3^+ is a "charged module" of it; the pair $\{V_0^+, V_3^+\}$ is the decomposition of the Leech theory under the frame $\mathbb{Z}/2$. The sector labels are conventions; the content is the eigenspace decomposition.

Proof. The equivalences (39.4) with $\chi = \beta$ and $\ker\beta = \Lambda_0$. □

Theorem 39.6 ($V_\Lambda^+ = V_0^+ \oplus V_3^+$, and the $\mathbb{Z}/2$-grading of products). *(i) $V_\Lambda^+ = V_{(0)} \oplus V_{(1)}$ (internal direct sum). (ii) For $u \in V_{(i)}$, $v \in V_{(j)}$ and all $n \in \mathbb{Z}$: $u_{(n)}v \in V_{(i+j)}$. (iii) Each $V_{(i)}$ is stable under the projections onto the L_0-weight spaces.*

File `VOA/Moonshine/FrameSectors.lean`.

```
/-- **`V_Λ⁺ = V₀⁺ ⊕ V₃⁺`** (internal direct sum). -/
theorem frameSector_isInternal : DirectSum.IsInternal frameSector

/-- **The `ℤ/2`-grading of products**: `u ∈ V_i`, `v ∈ V_j ⇒ u₍ₙ₎v ∈ V_{i+j}`. -/
theorem frameSector_smul_mem {i j : ZMod 2} {u v : VPlus} (hu : u ∈ frameSector i)
    (hv : v ∈ frameSector j) (n : ℤ) : leechVOAPlus.smul u n v ∈ frameSector (i + j)

/-- The sectors are graded: each is stable under the weight projections of `V_Λ⁺`. -/
theorem frameSector_graded (i : ZMod 2) (n : ℤ) {v : VPlus} (hv : v ∈ frameSector i) :
    piHom leechVOAPlus n v ∈ frameSector i
```

From the mathematics to the Lean statement

Fidelity check. `DirectSum.IsInternal frameSector` (Mathlib) means: the canonical map $\bigoplus_{i\in\mathbb{Z}/2} V_{(i)} \to V_\Lambda^+$ is a bijection, i.e. every vector is uniquely a sum of one vector from each sector. `leechVOAPlus.smul u n v` is $u_{(n)}v$ in V_Λ^+. The addition $i+j$ is in `ZMod 2`, so $V_{(1)}\cdot V_{(1)} \subseteq V_{(0)}$, as intended. `piHom leechVOAPlus n` is the projection onto the weight-n space along the others (Section 5.1). Same as the theorem. Not vacuous: (i) excludes, e.g., both sectors being zero, and both sectors are shown nonzero below (their weight-two parts have positive dimension).

Physical meaning

The theorem is the statement of a $\mathbb{Z}/2$ charge-conservation (fusion) rule: the odd sector times itself lands in the even sector, so the g-charge is additive in operator products, exactly as for any grading by a conserved quantum number. (iii) says that the energy (L_0-weight) commutes with the charge, as it must since g is a symmetry of the stress tensor. In CFT terms V_Λ^+ is an extension of the subtheory V_0^+ by its charged module V_3^+ with fusion $V_3^+ \times V_3^+ = V_0^+$.

Proof. (i) The two eigenspaces of an involution over a field of characteristic $\neq 2$ are complementary: $x = \frac{1}{2}(x+gx) + \frac{1}{2}(x-gx)$. (ii) $g(u_{(n)}v) = (gu)_{(n)}(gv) = (-1)^{i+j}u_{(n)}v$ because g is an automorphism. (iii) Automorphisms preserve ω, hence L_0, hence commute with the weight projections. □

/-- `c(V₀⁺) = 24`. -/
theorem V0P_centralCharge : V0P.centralCharge = 24
```

From the mathematics to the Lean statement

Fidelity check. `VOASubalgebra W` is a subspace containing $\mathbf{1}, \omega$ and closed under all n-th products (Definition 5.24); `toVOA` gives it the restricted structure. `V0Sub` is the fixed-point subalgebra of the cyclic group generated by g on V_Λ^+, and `V0Sub_carrier` says that its carrier is exactly V_0^+. Hence `V0P` is V_0^+ with its inherited VOA structure. The central charge is the inherited one. Note that `V0P` is a VOA on the type `V0Sub.carrier`, i.e. on vectors of V_Λ^+ (hence of V_Λ) — not on V_{Λ_0} built as a lattice VOA in its own right; the identification with the latter is Theorem 39.41.

Physical meaning

V_0^+ is the neutral subtheory under the frame $\mathbb{Z}/2$, i.e. the $\langle\theta, g\rangle$-orbifold of the Leech lattice CFT, still with the Virasoro central charge $c = 24$ of 24 free bosons (taking a fixed-point subalgebra does not change the stress tensor). It is the chiral algebra that the untwisted and twisted halves of the moonshine module share, and the natural domain of the triality: σ is an automorphism of this subtheory that is not visible as a lattice symmetry. Central charge is read off from the stress tensor, unchanged by restricting to invariants.

Proof. The fixed points of a group of automorphisms form a subalgebra containing $\mathbf{1}, \omega$ (Chapter 32), and c is read off from ω, which is unchanged. □

What the machine verified

Unconditional; `##print axioms V0P_centralCharge-clean`.

39.4 Weight two of the untwisted sectors

The Leech lattice has no roots, so $(V_\Lambda)_1 = \mathfrak{h} \otimes e^0$ and $(V_\Lambda)_2$ is spanned by $h_a(-1)h_b(-1)\mathbf{1}$ (300 states), $h_a(-2)\mathbf{1}$ (24 states) and e^α with $\langle\alpha,\alpha\rangle = 4$ (196560 states). The θ-fixed part $(V_\Lambda^+)_2$ has dimension $300 + 98280 = 98580$ (Chapter 32): θ fixes the quadratic states, negates $h_a(-2)\mathbf{1}$, and pairs e^α with (a multiple of) $e^{-\alpha}$. A basis of the charged part is $e^\alpha + \theta e^\alpha$ with α running over a set S of representatives of the pairs $\{\pm\alpha\}$ (`halfFour`: those α preceding $-\alpha$ in a fixed well-order).

Theorem 39.8 (Weight two, in terms of S). *Let* $S_i = \{\alpha \in S : \beta(\alpha) = i\}$. *Then* $\dim(V_0^+)_2 = 300 + |S_0|$, $\dim(V_3^+)_2 = |S_1|$, *and* $2|S_1| = \#\{\alpha \in \Lambda : \langle\alpha,\alpha\rangle = 4,\ \beta(\alpha) = 1\}$.

```
/-- `S_i = {α ∈ S | β α = i}`, `S = halfFour` the chosen half of the norm-`4` vectors. -/
noncomputable def halfFourChi (i : ZMod 2) : Finset leech.carrier :=
  (halfFour leech leech_posDef).filter fun α => frameChar α = i

/-- **`dim (V₀⁺)₂ = 300 + #{α ∈ S | β α = 0}`.** -/
theorem finrank_frameSector_zero_grading_two :

      = 300 + (halfFourChi 0).card

/-- **`dim (V₃⁺)₂ = #{α ∈ S | β α = 1} = ½ #{α ∈ Λ \ Λ₀ | ⟨α,α⟩ = 4}`.** -/
theorem finrank_frameSector_one_grading_two :
    finrank ℂ ↥((frameSector 1).comap (leechVOAPlus.grading 2).subtype)
      = (halfFourChi 1).card

/-- `2·#S₁ = #{α | ⟨α,α⟩ = 4, β α = 1}`. -/
theorem two_mul_card_halfFourChi_one :
    2 * (halfFourChi 1).card
      = ((normFour leech leech_posDef).filter fun α => frameChar α = 1).card
```

(`VOA/Moonshine/FrameWeightTwo.lean`.)

From the mathematics to the Lean statement

Fidelity check. `leechVOAPlus.grading 2` is the weight-2 subspace of V_Λ^+; `(frameSector i).comap (grading 2).subtype` is the set of weight-2 vectors lying in $V_{(i)}$, viewed as a subspace of the weight-two space, i.e. $(V_{(i)})_2 = V_{(i)} \cap (V_\Lambda^+)_2$. `finrank ℂ` is the complex dimension (Mathlib's `Module.finrank`; it would return 0 for an infinite-dimensional space, but the weight spaces are finite dimensional — this is part of the VOA structure — so the value is

the true dimension). `normFour leech leech_posDef` is the finite set of norm-four vectors, `Finset.filter` restricts it, `.card` counts. The statement is exactly the theorem; the specific representative set S is irrelevant to the dimensions because $\beta(-\alpha) = \beta(\alpha)$.

Physical meaning

Weight two is the level of the Griess algebra: the weight-two states are V_0^+'s and V_3^+'s stress-tensor-like and charged bilinear fields (the 300 quadratic oscillator states, plus the vertex operators of norm-four charges). The statement counts how the norm-four charges $\pm\alpha$ distribute between the two frame sectors, which is the first quantitative signature of the frame split; the θ-invariance pairs α with $-\alpha$, hence the factor 2.

Proof. The 300 quadratic states have momentum $0 \in \Lambda_0$ and lie in V_0^+. The state $e^\alpha + \theta e^\alpha$ has momenta $\pm\alpha$, so it lies in V_0^+ if $\beta(\alpha) = 0$ and in V_3^+ if $\beta(\alpha) = 1$. These states together form a basis of $(V_\Lambda^+)_2$; the two spans are therefore contained in $(V_0^+)_2$ and $(V_3^+)_2$ respectively, these two intersect trivially, and their dimensions add up to 98580, which forces equality. The last identity holds because negation is a fixed-point-free involution of the set of norm-four vectors with $\beta = 1$, and S_1 contains exactly one vector from each orbit. □

What the machine verified

Unconditional; `##print axioms`-clean.

39.4.1 Counting norm-four vectors outside Λ_0

Lemma 39.9 (Shape of an odd norm-four vector). *Let $y \in \mathbb{Z}^{24}$ have all coordinates odd and $y \cdot y = 32$. Then exactly one coordinate y_p satisfies $y_p^2 = 9$ and all others satisfy $y_i^2 = 1$.*

```
/-- An odd vector of norm `32` has exactly one coordinate `±3`, the others `±1`. -/
theorem exists_three {y : Fin 24 → ℤ} (hodd : ∀ i, ¬ (2 : ℤ) ∣ y i) (hy : y ·ᵥ y = 32) :
    ∃ p, y p * y p = 9 ∧ ∀ i, i ≠ p → y i * y i = 1
```

From the mathematics to the Lean statement

Fidelity check. $\cdot_v$ is the dot product on $\mathbb{Z}^{24}$ (`Fin 24 → ℤ`); the hypotheses are "all coordinates odd" and "$y \cdot y = 32$". The conclusion asserts existence of p with $y_p^2 = 9$ and $y_i^2 = 1$ for $i \neq p$ (uniqueness of p follows from the second clause). Same as the lemma.

Physical meaning

This is a purely arithmetical step in the count of norm-four charges outside Λ_0: an odd-coordinate vector of the given norm looks like a single "3" among ±1's. Physically it enumerates the lowest nonzero charges (the lightest charged states, of weight 2) of the odd frame sector.

Proof. For odd y_i, $y_i^2 - 1$ is a non-negative multiple of 8. The 24 numbers $d_i = y_i^2 - 1$ sum to $32 - 24 = 8$, so exactly one of them is 8 and the rest are 0. □

Theorem 39.10 (98304 norm-four vectors outside Λ_0). $\#\{\alpha \in \Lambda \setminus \Lambda_0 : \langle \alpha, \alpha \rangle = 4\} = 24 \cdot 2^{12} = 98304$.

```
/-- The norm-`4` vectors outside `Λ₀`. -/
noncomputable def oddFour : Finset leech.carrier :=
  (normFour leech leech_posDef).filter fun α => frameChar α = 1
```

```
/-- **`#{α ∈ Λ \ Λ₀ | ⟨α,α⟩ = 4} = 98304`.** -/
theorem card_normFour_frameChar_one : oddFour.card = 98304
```

(VOA/Moonshine/FrameCount.lean.)

From the mathematics to the Lean statement

Fidelity check. `oddFour` is the set of α with $\langle\alpha,\alpha\rangle = 4$ and $\beta(\alpha) = 1$, i.e. $\alpha \notin \Lambda_0$ (by `mem_lambda0`). Same as the theorem. The number is a hard-coded literal, so the only way this could mislead is if the Leech model or the form were wrong; the form is $x\cdot y/8$ (`leech_form_eq`) and the model is Ebeling's (Chapter 30).

Physical meaning

The count $98304 = 24 \cdot 2^{12}$ is the number of lightest ($h = 2$) charged vertex operators in the odd frame sector. Heuristically it matches the 24 ways of choosing which boson carries the odd unit of charge, times the 2^{12} Golay codewords, which anticipates the twisted side, where the same number appears as 24 oscillators times a 2048-dimensional ground space. This numerical coincidence is the first hint of the triality that exchanges the two descriptions.

Proof. A vector of $u + 2\Lambda$ has all coordinates odd and norm 4 means $x \cdot x = 32$; by the lemma it has one coordinate ± 3 at a position p and all others ± 1. Write $x = u + 2a$ and $c = \rho(a) \in C$. The sign pattern is determined by (p, c): for $i \neq p$, $x_i = 1 - 2c_i$, and $x_p = 6c_p - 3$ (check the four cases using $u_0 = 5$, $u_i = 1$; e.g. if $p = i \neq 0$ and $c_i = 0$ then $x_i \in \{1 + 2a_i\} \cap \{\pm 3\}$ with a_i even forces $x_i = -3$). Conversely, for every $(p, c) \in \{0, \dots, 23\} \times C$ the vector so defined lies in $u + 2\Lambda$: the corresponding a has $\rho(a) = c$, and the condition $4 \mid \sum a_i$ reduces to $4 \mid \mathrm{wt}(c)$, which holds because the Golay code is doubly even. So the odd norm-four vectors are in bijection with $\{0, \dots, 23\} \times C$, of size $24 \cdot 2^{12}$. □

What the machine verified

Unconditional; `##print axioms card_normFour_frameChar_one`-clean.

Corollary 39.11 (The two untwisted weight-two dimensions). $\dim(V_3^+)_2 = 49152$ *and* $\dim(V_0^+)_2 = 49428$.

```
/-- **`dim (V₃⁺)₂ = 49152`.** -/
theorem finrank_V3_grading_two :
    finrank ℂ ↥((frameSector 1).comap (leechVOAPlus.grading 2).subtype) = 49152

/-- **`dim (V₀⁺)₂ = 49428`.** -/
theorem finrank_V0_grading_two :
    finrank ℂ ↥((frameSector 0).comap (leechVOAPlus.grading 2).subtype) = 49428
```

From the mathematics to the Lean statement

Fidelity check. As in Theorem 39.8; the subspaces are $(V_3^+)_2$ and $(V_0^+)_2$ inside $(V_\Lambda^+)_2$. Same as the corollary. A check on consistency: $49428 + 49152 = 98580 = \dim(V_\Lambda^+)_2$ (`finrank_frameSector_grading_two_add`).

Physical meaning

These are the dimensions of the weight-two (Griess algebra) pieces of the two frame sectors: 49428 neutral and 49152 charged states, summing to the 98580 weight-two states of V_Λ^+. The second number equals the weight-two dimension of the twisted sector T_0^+; physical

triality says that this is no coincidence, because σ exchanges the two sectors. Such dimension coincidences are the partition-function signature of a hidden symmetry (a heuristic, supported by the proof of the relevant theorems later).

Proof. $|S_1| = 98304/2 = 49152$; $|S_0| + |S_1| = |S| = 196560/2 = 98280$, so $|S_0| = 49128$ and $\dim(V_0^+)_2 = 300 + 49128 = 49428$. □

What the machine verified

Unconditional; both `##print axioms`-clean (re-run for this chapter).

39.5 The twisted side: $T = T_+ \oplus T_-$

Recall from Chapter 34 the module T (`leechT`): the unique irreducible module, of dimension $2^{12} = 4096$, of the twisted group algebra spanned by operators e_α ($\alpha \in L$) with

$$e_\alpha e_\beta = \varepsilon(\alpha,\beta)\, e_{\alpha+\beta}, \qquad e_{\alpha+2\gamma} = e_\alpha \text{ on } T.$$

For a general even unimodular L the operator of e_α on T is `eT L hEven hU α`, where `hU : IsUnit (gramMat L).det` expresses unimodularity. The library works with the type `TT L hEven hU := Extraspecial.Rep (cocMat L) _` (definitionally the same module; the abbreviation avoids a slow elaboration path).

Lemma 39.12 (Commutation and square of e_w). *For $w, \alpha \in L$: $e_w e_\alpha = (-1)^{\langle w,\alpha\rangle} e_\alpha e_w$ and $e_w e_w = \varepsilon(w,w)\cdot 1_T$.*

File `VOA/Moonshine/FrameTwisted.lean`.

```
/-- `e_w e_w = ε(w,w)`. -/
theorem eT_mul_self (w : L.carrier) :
    eT L hEven hU w * eT L hEven hU w = latticeCocycle L w w • (1 : End ℂ (TT L hEven hU))

/-- `e_w e_α = (-1)^{⟨w,α⟩} e_α e_w`. -/
theorem eT_comm_sign (w α : L.carrier) :
    eT L hEven hU w * eT L hEven hU α
      = ((-1 : ℂ) ^ (L.form w α)) • (eT L hEven hU α * eT L hEven hU w)
```

From the mathematics to the Lean statement

Fidelity check. `*` on `End ℂ (TT …)` is composition; `•` scalar multiplication; `(-1 : ℂ) ^ (L.form w α)` is an integer power ($\langle w,\alpha\rangle \in \mathbb{Z}$). Same as the lemma.

Physical meaning

The operators e_w implement shifts of the twisted-sector ground states: the ground states form a representation of the extraspecial group 2^{1+24} (the Heisenberg-type group of the lattice cocycle), and this lemma is the extraspecial commutation rule. Physically these are the zero-mode operators of the twisted sector, which commute or anticommute according to the pairing $\langle w,\alpha\rangle$ mod 2, the same sign as the cocycle in the untwisted OPE.

Proof. $e_w e_\alpha = \varepsilon(w,\alpha) e_{w+\alpha}$ and $e_\alpha e_w = \varepsilon(\alpha,w) e_{w+\alpha}$, and $\varepsilon(w,\alpha)/\varepsilon(\alpha,w) = (-1)^{\langle w,\alpha\rangle}$. Also $e_w e_w = \varepsilon(w,w) e_{2w} = \varepsilon(w,w) e_0 = \varepsilon(w,w)$. □

Definition 39.13 (The frame involution J and the halves $T_\pm$). Fix $c \in \mathbb{C}$ with $c^2 = \varepsilon(w,w)$ and put $J = c^{-1} e_w$. Then $J^2 = 1$. For $s \in \mathbb{Z}/2$, $T_{(s)} = \ker(J - (-1)^s)$; we write $T_+ = T_{(0)}$, $T_- = T_{(1)}$.

File `VOA/Moonshine/FrameTwisted.lean`.

```
/-- A square root `c` of `ε(w,w)`. -/

theorem frameT_isCompl (w : L.carrier) :
    IsCompl (frameT L hEven hU w 0) (frameT L hEven hU w 1)
```

From the mathematics to the Lean statement

Fidelity check. `sqrtEps` picks, by the axiom of choice, some c with $c \cdot c = \varepsilon(w,w)$ (it exists because $\mathbb{C}$ is algebraically closed). Since $\varepsilon(w,w) = \pm 1$, $c \in \{\pm 1, \pm i\}$; the choice of sign of c is *not* canonical, and changing it swaps T_+ and T_-. This is harmless for every statement in this chapter, which treats $s = 0, 1$ symmetrically, but it means that "T_+" carries no intrinsic meaning (see the warning below). `IsCompl P Q` (Mathlib) means $P \cap Q = 0$ and $P + Q$ is everything, i.e. $T = T_+ \oplus T_-$.

Physical meaning

J is the $\mathbb{Z}/2$ charge operator of the frame on the twisted ground states: the 4096-dimensional ground space of the θ-twisted sector is split into the ± 1 eigenspaces $T_\pm$ of an extraspecial group element, each 2048-dimensional. It is the twisted-sector counterpart of the frame automorphism g, so $T_\pm$ are the twisted charge sectors. This is the representation-theoretic origin of the splitting into two halves that the triality will pair with the untwisted odd sector.

Theorem 39.14 (e_α and the halves; equal dimensions). *Suppose $\chi : L \to \mathbb{Z}/2$ and $w \in L$ satisfy $(-1)^{\langle w,\alpha\rangle} = (-1)^{\chi(\alpha)}$ for all α. Then $e_\alpha T_{(s)} \subseteq T_{(s+\chi(\alpha))}$, and if some u has $\chi(u) = 1$ then* $\dim T_+ = \dim T_-$.

```

From the mathematics to the Lean statement

Fidelity check. Hypothesis `hw` says that the character χ is "pairing with w mod 2"; hypothesis `hu` that χ is nontrivial. Both are the intended hypotheses and both are discharged for the Leech lattice below. Same as the theorem.

Physical meaning

The vertex-operator zero modes e_α carry frame charge $\chi(\alpha)$: they preserve $T_\pm$ if $\chi(\alpha) = 0$ and swap them if $\chi(\alpha) = 1$, exactly the charge-conservation rule one expects from the frame symmetry. The equality $\dim T_+ = \dim T_-$ is the statement that some operator exchanges the two charge sectors, hence they are isomorphic as vector spaces; physically, the twisted ground states are symmetric between the two frame charges.

Proof. $Je_\alpha = (-1)^{\langle w,\alpha\rangle} e_\alpha J = (-1)^{\chi(\alpha)} e_\alpha J$ by the lemma, so e_α maps the $(-1)^s$-eigenspace of J into the $(-1)^{s+\chi(\alpha)}$-eigenspace. e_u is invertible ($e_u^2 = \pm 1$), so it maps T_+ injectively into T_- and T_- injectively into T_+; hence the dimensions agree. □

For the Leech lattice take $w = 8e_0$. It lies in Λ_0 ($8e_0 = 2 \cdot 4e_0$, and $4e_0 \in A$ because $\rho(4e_0) = 0 \in C$ and $4 \mid 4$), and $\langle 8e_0, x\rangle = 8x_0/8 = x_0$, so $(-1)^{\langle w,x\rangle} = (-1)^{\beta(x)}$. The vector $u = (5, 1, \dots, 1)$ has $\beta(u) = 1$.

Theorem 39.15 (The Leech frame split of T). *For Λ, $w = 8e_0$: $T = T_+ \oplus T_-$ with $\dim T_+ = \dim T_- = 2048$; e_α preserves $T_\pm$ for $\alpha \in \Lambda_0$ and swaps them for $\alpha \notin \Lambda_0$; and on the twisted space $S[\theta] \otimes T$ the operator $\mathrm{id} \otimes J$ gives $S[\theta] \otimes T = (S[\theta] \otimes T_+) \oplus (S[\theta] \otimes T_-)$.*

(`VOA/Moonshine/FrameTwisted.lean`.)

From the mathematics to the Lean statement

Fidelity check. `eightE0_mem` is the proof that $8e_0 \in \Lambda$; `frameW` is that vector. `leechFrameT s := frameT leech … frameW s`. `twFrame … F w s` is the $(-1)^s$-eigenspace of $\mathrm{id}_F \otimes J$ on $F \otimes T$; here F `=FockT 24=` $S[\theta]$, the twisted Fock space of Chapter 35. The dimension 2048 is derived from $\dim T = 4096$ (`finrank_leechT`, Chapter 34) and the equality of the halves.

Same as the theorem; the word "Λ_0" enters through `frameChar α`, which is 0 exactly on Λ_0.

Physical meaning

For the Leech theory this gives the explicit frame decomposition of the twisted sector into two charge sectors of 2048 ground states each, with Λ_0-charged operators preserving them and Λ_3-charged operators exchanging them. Together with the untwisted $V_0^+ \oplus V_3^+$, this is the full four-sector frame decomposition of the moonshine module, the analogue on the twisted side of splitting the sector V_Λ^T by the frame charge.

Proof. Theorem 39.14 with $\chi = \beta$, $w = 8e_0$, $u = (5, 1, \dots, 1)$, and $\dim T_+ + \dim T_- = 4096$. The tensor statement is the same eigenspace argument for the involution $\mathrm{id} \otimes J$. □

What the machine verified

Unconditional; `##print axioms finrank_leechFrameT_plus, finrank_leechFrameT_minus`: [`propext`, `Classical.choice`, `Quot.sound`].

Remark 39.16 (Group-theoretic meaning)**.** The element e_w is, up to scalar, the central element of the preimage $\hat{\Lambda}_0/K$ of Λ_0 in the extraspecial group: $\Lambda_0/2\Lambda = w^\perp$ has radical $\{0, w\}$ modulo 2Λ. So $T_\pm$ are the two eigenspaces of a central element of a subgroup, and T restricted to $\hat{\Lambda}_0$ is the sum of two non-isomorphic irreducibles of dimension 2^{11}. None of this is needed in the proofs above.

Trap / dead end

Which half is FLM's T_0 is not fixed by the definitions. The labels $T_+ =$ `leechFrameT 0`, $T_- =$ `leechFrameT 1` depend on the arbitrary square root `sqrtEps`. Independently, the bridge of Section 39.10 uses a character `golayE` chosen by `Classical.choose`, which is pinned only up to a further character; the alternative choice swaps the rôles of the two twisted sectors under σ (finding `golayE_not_determined`, Notes/M8GluingPlan.md, status of 2026-10-07 "M8g twisted half"). The project's response is to state the downstream existence of σ with an existential sector index: σ maps V_3^+ to $T^+_{(s+1)}$ and $T^+_{(s)}$ to itself *for some* s (Chapters 40–41). A reader should therefore never read "T_+" as "T_0".

39.6 Cyclicity I: the vacuum trick

39.6.1 Why cyclicity

The triality on the twisted sectors will be built (Chapters 40–41) as a *σ-twisted V_0^+-module map*: a linear map Φ from one sector X to another, satisfying $\Phi(u_{(n)}x) = (\sigma u)_{(n)}\Phi(x)$ for $u \in V_0^+$. If X is spanned by the vectors $u_{(n)}x_0$ for a single x_0, such a map is *determined* by $\Phi(x_0)$, and its existence reduces to checking that every linear relation among the $u_{(n)}x_0$ is respected. FLM and DGM prove more — each sector is irreducible — but cyclicity is what is used, and it is much cheaper.

Definition 39.17 (Cyclic module)**.** A subspace X of a module over V_0^+ is *cyclic with cyclic vector* $x_0 \in X$ if $X = \mathrm{span}\{u_{(n)}x_0 : u \in V_0^+,\ n \in \mathbb{Z}\}$.

Physical meaning

A cyclic module is one generated from a single state by the OPE with the subtheory: every state of the sector is obtained by acting on one reference state with the modes of the fields of V_0^+. In CFT language, the sector is a single "conformal family" of the chiral algebra built on one highest-weight-like state (state–operator map). Cyclicity is what lets one define a

V_0^+-equivariant map out of the sector by specifying the image of that one state, which is how the triality will later be extended sector by sector.

Note that this definition does not presuppose that the span is a submodule; but since it equals X, which is stable under V_0^+, it is one.

39.6.2 The general lemma

Theorem 39.18 (The vacuum trick). *Let W be a vertex operator algebra and $a, b \in W$, $k \in \mathbb{Z}$, $c \in \mathbb{C}^\times$ with*

$$a_{(k)}b = c\,\mathbf{1} \qquad \text{and} \qquad a_{(j)}b = 0 \text{ for all } j > k.$$

Then every $v \in W$ lies in $\operatorname{span}\{(v_{(i)}a)_{(j)}b : i, j \in \mathbb{Z}\}$.

```
/-- **The vacuum trick.**  If `a₍ₖ₎ b = c·1` with `c ≠ 0` and `a₍ⱼ₎ b = 0` for `j > k`,
 ↪  then every
`v` is a linear combination of the iterated products `(v₍ᵢ₎ a)₍ⱼ₎ b`. -/
theorem mem_span_iterate_of_vacuum (W : VertexOperatorAlgebra V) {a b : V} {k : ℤ} {c : ℂ}
    (hc : c ≠ 0) (hk : W.smul a k b = c • W.vacuum)
    (hk' : ∀ j : ℤ, k < j → W.smul a j b = 0) (v : V) :
    v ∈ Submodule.span ℂ {y | ∃ i j : ℤ, y = W.smul (W.smul v i a) j b}
```

(`VOA/Moonshine/CyclicVacuumTrick.lean`, `VOA.VertexOperatorAlgebra.mem_span_iterate_of_vacuum`.)

From the mathematics to the Lean statement

Fidelity check. `W.smul a k b` $= a_{(k)}b$. The three hypotheses are: $c \neq 0$; $a_{(k)}b = c\mathbf{1}$; and $a_{(j)}b = 0$ for $j > k$. Every one is necessary for the intended use and none is stronger than in the statement. The conclusion is membership of v in the `Submodule.span` (set of finite linear combinations) of the set of all $(v_{(i)}a)_{(j)}b$. Note the quantifier order: v is fixed first, and the spanning vectors depend on v — exactly the statement. It is *not* the stronger (false in general) claim that a fixed finite set of vectors spans.

Physical meaning

This is the CFT statement that the vacuum together with a "dual pair" of fields generates everything: if a and b have a pole whose coefficient is the identity (a two-point function with nonzero normalisation), then acting on the vacuum suffices to reach every state. In the state–operator correspondence it says that every state v is obtained from a by an OPE with v followed by a contraction with b; this is the algebraic form of using the nondegenerate two-point function of the sector to produce the vacuum. It is a technical device that reduces cyclicity of a module to a single computation at one state.

Proof. Recall the Borcherds identity in the library's form (`VertexOperatorAlgebra.jacobi`, Definition 4.4): for all states u, v, x and integers ℓ, m, n,

$$\sum_{i\geq 0}(-1)^i\binom{\ell}{i}\Big(u_{(\ell+m-i)}v_{(n+i)}x - (-1)^\ell v_{(\ell+n-i)}u_{(m+i)}x\Big) = \sum_{i\geq 0}\binom{m}{i}\big(u_{(\ell+i)}v\big)_{(m+n-i)}x. \tag{39.5}$$

Apply it with $(u, v, x) = (v, a, b)$, $n = k$, $m \geq \max(N, 0)$ where $v_{(p)}b = 0$ for all $p \geq N$ (such N exists by lower truncation), and $\ell = -1 - m$. On the left, consider the i-th term.

- For $i > 0$: $a_{(k+i)}b = 0$ by hypothesis and $v_{(m+i)}b = 0$ by the choice of m, so the term vanishes.
- For $i = 0$: the second summand contains $v_{(m)}b = 0$; the first is $v_{(\ell+m)}a_{(k)}b = v_{(-1)}(c\mathbf{1}) = c\,v$ (creation: $v_{(-1)}\mathbf{1} = v$).

So the left side equals $c\,v$, while the right side is a finite combination of the vectors $(v_{(\ell+i)}a)_{(m+k-i)}b$. Divide by c. □

Physically: the operator product $a(z)b(0) \sim c\,z^{-k-1}\mathbf{1} + \cdots$ has the identity as its most singular term. Inserting v and using associativity, $v = c^{-1}v_{(-1)}(a_{(k)}b)$ can be re-associated into products of the form $(v \cdot a) \cdot b$.

What the machine verified

Unconditional; `##print axioms mem_span_iterate_of_vacuum:` [`propext`, `Classical.choice`, `Quot.sound`].

39.6.3 V_0^+ and V_3^+ are cyclic

Theorem 39.19 (V_0^+ is cyclic over itself). *V_0^+ is cyclic with cyclic vector* $\mathbf{1}$.

File `VOA/Moonshine/CyclicFrameSectors.lean`.

```
/-- **`V₀⁺` is cyclic over itself**, generated by `𝟙`. -/
theorem cyclic_V0 : ∃ x₀ ∈ frameSector 0,
    Submodule.span ℂ {y | ∃ u ∈ frameSector 0, ∃ n : ℤ, y = leechVOAPlus.smul u n x₀}
      = frameSector 0
```

Physical meaning

Every state of a vertex operator algebra is obtained from the vacuum by applying a field (the state–operator map $u = u_{(-1)}\mathbf{1}$), so the algebra is generated from the vacuum by its own modes. This is the most basic form of the state–operator correspondence, and it says that the neutral frame sector is a single family generated by the identity operator.

Proof. $u = u_{(-1)}\mathbf{1}$, and $V_0^+ \cdot V_0^+ \subseteq V_0^+$. □

For V_3^+ choose any $\beta \in \Lambda \setminus \Lambda_0$ (one exists by Proposition 39.2) and put

$$x_0 = e^{\beta} + e^{-\beta} \qquad \text{(Lean: } \texttt{frameX0P}\ \beta\text{)}.$$

It is θ-fixed (the library's θ sends $e^{\gamma} \mapsto e^{-\gamma}$ on charged vacua, `thetaLat_latChargeGen`) and all its momenta are in Λ_3, so $x_0 \in V_3^+$.

Lemma 39.20 (The pairing of x_0 with itself). *Let $N = \langle\beta,\beta\rangle > 0$. Then $x_{0(j)}x_0 = 0$ for $j \geq N$ and $x_{0(N-1)}x_0 = \big(\varepsilon(\beta,-\beta) + \varepsilon(-\beta,\beta)\big)\mathbf{1}$, and this scalar is nonzero.*

    leechVOA.smul (frameX0 β) (leech.form β β - 1) (frameX0 β)
      = (latticeCocycle leech β (-β) + latticeCocycle leech (-β) β) • latVacuumGen leech

/-- The pairing scalar `ε(β,-β) + ε(-β,β) = 2ε(-β,β)` is non-zero. -/
theorem frameX0_scalar_ne_zero (β : leech.carrier) :
    latticeCocycle leech β (-β) + latticeCocycle leech (-β) β ≠ 0
```

Physical meaning

The charged state $x_0 = e^{\beta} + e^{-\beta}$ has a nonvanishing two-point function with itself: the OPE $x_0(z)x_0(0)$ contains the identity with coefficient $z^{-\langle\beta,\beta\rangle}$ times a nonzero constant, and no more singular terms. This is the lattice-CFT statement $e^{\beta}(z)e^{-\beta}(0) \sim z^{-\langle\beta,\beta\rangle} \cdot 1$, with the cocycle signs checking that the two terms of x_0 add rather than cancel. It is the input needed to apply the vacuum trick.

Proof. $Y(e^{\alpha},z)e^{\gamma} = \varepsilon(\alpha,\gamma)z^{\langle\alpha,\gamma\rangle}E^{-}(-\alpha,z)e^{\alpha+\gamma}$ with $E^{-}(-\alpha,z) = 1+O(z)$ a series in non-negative powers. Hence $e^{\alpha}_{(j)}e^{\gamma} = 0$ for $j \geq -\langle\alpha,\gamma\rangle$, and for $\gamma = -\alpha$ the coefficient at $j = \langle\alpha,\alpha\rangle - 1$ is $\varepsilon(\alpha,-\alpha)\mathbf{1}$. Expanding $x_{0(j)}x_0$ into four terms: the two terms $e^{\pm\beta}_{(j)}e^{\pm\beta}$ vanish for $j \geq -N$, and the two cross terms vanish for $j \geq N$ and give $\varepsilon(\pm\beta,\mp\beta)\mathbf{1}$ at $j = N-1$. Finally $\varepsilon(\beta,-\beta) = (-1)^{\langle\beta,-\beta\rangle}\varepsilon(-\beta,\beta) = \varepsilon(-\beta,\beta)$ since Λ is even, so the scalar is $2\varepsilon(-\beta,\beta) = \pm 2$. □

Theorem 39.21 (V_3^+ is a cyclic V_0^+-module). *For every $\beta \in \Lambda \setminus \Lambda_0$, $\operatorname{span}\{u_{(n)}(e^{\beta}+e^{-\beta}) : u \in V_0^+,\ n \in \mathbb{Z}\} = V_3^+$. In particular V_3^+ is cyclic.*

theorem cyclic_V3 : ∃ x₀ ∈ frameSector 1,
    Submodule.span ℂ {y | ∃ u ∈ frameSector 0, ∃ n : ℤ, y = leechVOAPlus.smul u n x₀}
      = frameSector 1
```

(`VOA/Moonshine/CyclicFrameSectors.lean`.)

From the mathematics to the Lean statement

Fidelity check. The products are taken in `leechVOAPlus`, i.e. V_{Λ}^+, with u ranging over `frameSector 0` $= V_0^+$ — so this is the module structure of V_3^+ over V_0^+ by restriction, which is the intended one. The span is *equal* to `frameSector 1`, so the statement includes both inclusions. The quantifier `∃ x₀ ∈ frameSector 1` requires $x_0 \in V_3^+$; the explicit form names x_0. How could this have been vacuous? If `frameSector 1` were 0 the statement would be trivial with $x_0 = 0$; it is not, since $\dim(V_3^+)_2 = 49152$ (Corollary 39.11). The explicit version with $x_0 = e^{\beta} + e^{-\beta} \neq 0$ is stronger than the existential one.

Physical meaning

The odd frame sector V_3^+ is a single family of the neutral subtheory: any one charged state $e^{\beta} + e^{-\beta}$ generates it under the OPE with V_0^+. Physically, the charged sector is obtained from a single charged primary-like state by acting with the neutral currents; there are no independent "families" hidden in it. Combined with the vacuum trick (acting on the vacuum suffices once a dual pair is available), this is the mechanism that later makes a V_0^+-equivariant map out of V_3^+ determined by its value on one vector.

Proof. "$\subseteq$": $V_0^+ \cdot V_3^+ \subseteq V_3^+$ by Theorem 39.6. "$\supseteq$": let $v \in V_3^+$. Apply the vacuum trick in $W = V_{\Lambda}^+$ with $a = b = x_0$, $k = N-1$ and the lemma: v is a combination of $(v_{(i)}x_0)_{(j)}x_0$. Each $v_{(i)}x_0$ lies in $V_3^+ \cdot V_3^+ \subseteq V_0^+$. □

What the machine verified

Unconditional; `##print axioms cyclic_V3, cyclic_V0:` [`propext, Classical.choice, Quot.sound`]. **Not proved:** irreducibility of V_3^+ (FLM; DGM Proposition 7.1); it is not needed. (The docstring of the file still says it is not wired into the `VOA/Moonshine.lean` umbrella; that remark is stale — the umbrella imports it, checked for this chapter.)

Remark 39.22 (What this argument avoids)**.** DGM prove irreducibility using, in each coordinate, the Virasoro field $:P^jP^j:$ to separate states. The vacuum trick needs no Fock-space bookkeeping at all: one vector that pairs to the vacuum suffices for cyclicity. For irreducibility one would need, for each nonzero x, a partner y with $y_{(k)}x \in \mathbb{C}^\times\mathbf{1}$, i.e. a nondegenerate invariant form on V_3^+ — more than is needed.

39.7 Cyclicity II: the twisted sectors

39.7.1 The obvious route is blocked

Trap / dead end

The vacuum trick for $(V_\Lambda^T)^+$ would need the open relation. On $\mathcal{T} = (V_\Lambda^T)^+$ the analogue of $x_{0(k)}x_0 = c\mathbf{1}$ is $\overline{W}(a)_{(k)}b = c\mathbf{1}$ for $a, b \in \mathcal{T}$, which does hold (the anti-trap certificate `leechWbar_vacuum_pairing_ne_zero` of Chapter 38). But writing $t = c^{-1}W(t)_{(-1)}\overline{W}(a)_{(k)}b$ as a combination of $Y_{\mathcal{T}}(\overline{W}(t)_{(i)}a)_{(j)}b$ is the Borcherds identity (39.5) in $V^\natural$ for three *twisted* states (t, a, b):

$$\sum_i (-1)^i\tbinom{\ell}{i}\Big[W(t)_{(\ell+m-i)}\overline{W}(a)_{(n+i)}b - (-1)^\ell W(a)_{(\ell+n-i)}\overline{W}(t)_{(m+i)}b\Big] = \sum_i \tbinom{m}{i} Y_{\mathcal{T}}\big(\overline{W}(t)_{(\ell+i)}a\big)_{(m+n-i)}b.$$

This is equivalent to the twisted×twisted relation (39.1) — the very gate the triality is meant to open. The available commutator formulas for W and $\overline{W}$ have one *untwisted* argument and do not imply it. So the vacuum-trick route for the twisted sectors is circular, and an explicit route is used instead (Notes/M8GluingPlan.md, status "M8f COMPLETE", "RECORDED DEPENDENCY").

39.7.2 Orbit spans in a twisted module

Let W be a VOA, $g \in \mathrm{Aut}\,W$ with $g^2 = 1$, and T a g-twisted W-module of order two (`TwistedModule g 2 M`, Chapter 34): operators $u_{(k/2)}$ (`T.YM u k`) on M such that for u in the j-th eigenspace W^j of g — defined in the library as the $e^{-2\pi ij/2}$-eigenspace (`Aut.twistedEigenspace g 2 j`), so $W^0 = \{gu = u\}$, $W^1 = \{gu = -u\}$ — the operator $u_{(k/2)}$ vanishes unless $k \equiv j \pmod 2$, and the twisted Jacobi identity

$$\sum_{i\ge 0}(-1)^i\tbinom{\ell}{i}\Big(u_{((2\ell+k-2i)/2)}v_{((m+2i)/2)}x - (-1)^\ell v_{((2\ell+m-2i)/2)}u_{((k+2i)/2)}x\Big) = \sum_{i\ge 0}\tbinom{k/2}{i}(u_{(\ell+i)}v)_{((k+m-2i)/2)}x$$

holds for all v, x, ℓ, m and all $k \equiv j \pmod 2$ (the restriction $k \equiv j$ is the repaired form of the library's axiom; see Chapter 34 and Section 43.2.1: the all-indices form forces $M = 0$).

Definition 39.23 (Orbit span). For a subspace $A \subseteq W$ and $x \in M$, $Z_A(x) = \mathrm{span}\{u_{(k/2)}x : u \in A,\ k \in \mathbb{Z}\}$.

```
/-- **The orbit span** `Z_A(x) = span {u₍k/2₎ x | u ∈ A, k ∈ ℤ}`. -/
def orbitSpan (T : TwistedModule g 2 M) (A : Submodule ℂ 𝒱) (x : M) : Submodule ℂ M :=
  Submodule.span ℂ {y | ∃ u ∈ A, ∃ k : ℤ, y = T.YM u k x}
```

(`VOA/Moonshine/CyclicTwistedSpan.lean`, namespace `VOA.TwistedCyclic`.)

Physical meaning

$Z_A(x)$ is the span of all states reached from a ground state x of the twisted module by acting with (half-integer) modes of fields drawn from A. It is the subspace of the twisted sector generated by x using the OPE with A; the half-integer modes $u_{(k/2)}$ reflect the monodromy -1 of the θ-twisted sector around the insertion of the twist field.

Theorem 39.24 (Orbit spans are submodules). *Suppose A is closed under all n-th products, g-stable, and $g^2 = 1$. Then for every $u \in A$, $p \in \mathbb{Z}$ and $y \in Z_A(x)$: $u_{(p/2)}y \in Z_A(x)$.*

```
variable (T : TwistedModule g 2 M) (A : Submodule ℂ 𝒱)
  (hA : ∀ u ∈ A, ∀ (n : ℤ), ∀ v ∈ A, W.smul u n v ∈ A) (hg : ∀ u ∈ A, g u ∈ A)
  (hgg : ∀ u, g (g u) = u)

include hA hg hgg in
/-- **`Z_A(x)` is stable under the modes of `A`.** -/
theorem YM_mem_orbitSpan {u : 𝒱} (hu : u ∈ A) (p : ℤ) {x y : M} (hy : y ∈ orbitSpan T A x)
 ↪  :
    T.YM u p y ∈ orbitSpan T A x
```

From the mathematics to the Lean statement

Fidelity check. The three hypotheses `hA`, `hg`, `hgg` are exactly the three conditions of the theorem. `T.YM u p` is $u_{(p/2)}$. Same as the theorem. Note that A is not required to contain $\mathbf{1}$; that is needed only for $x \in Z_A(x)$ (`self_mem_orbitSpan`, hypothesis `W.vacuum ∈ A`, using $\mathbf{1}_{(-1)} = \mathrm{id}$, i.e. `T.YM W.vacuum (-2) = 1`).

Physical meaning

The orbit span is closed under the action of all of A: acting once more with a field of A does not leave the span. Concretely, the OPE of two fields of A (which is closed because A is a subalgebra) re-expresses a product of two modes as a sum of single modes, so the generated subspace is stable. This is the consistency statement that generating a family from one state by the OPE gives a genuine module and not a growing subspace.

Proof. Split $u = u_0 + u_1$ into g-eigencomponents ($u_0 = \frac{1}{2}(u + gu) \in A \cap W^0$, $u_1 = \frac{1}{2}(u - gu) \in A \cap W^1$). It suffices to show $u_{(p/2)}v_{(q/2)}x \in Z_A(x)$ for $u \in A \cap W^j$, $v \in A$. If $p \not\equiv j$ the operator is zero. Otherwise choose $k \equiv p \pmod 2$ so large that $u_{((k+2i)/2)}x = 0$ for all $i \geq 0$, and $\ell = (p-k)/2$. Then the twisted Jacobi identity reads

$$\sum_{i \geq 0} (-1)^i \tbinom{\ell}{i} u_{((p-2i)/2)} v_{((q+2i)/2)} x = \sum_i \tbinom{k/2}{i} (u_{(\ell+i)}v)_{(\cdot)}x \ \in Z_A(x),$$

since $u_{(\ell+i)}v \in A$. The $i = 0$ term is the one we want; the terms with $i \geq 1$ have a larger second index $q + 2i$, and are in $Z_A(x)$ by descending induction on q, the induction starting because $v_{(q/2)}x = 0$ for q large. □

What the machine verified

Unconditional; `##print axioms YM_mem_orbitSpan`-clean. Uses only the module Jacobi identity — no twisted×twisted operator.

Theorem 39.25 (The +-projection). *Let θ_M be a lift of g to M (an involution with $\theta_M u_{(k/2)}\theta_M = (gu)_{(k/2)}$, preserving weights), $M^+ = \ker(\theta_M - 1)$, and A as above. If $x_0 \in M^+$ and $y \in M^+ \cap Z_A(x_0)$, then y is a linear combination of the vectors $u_{(n)}x_0$ with $u \in W^g \cap A$, $n \in \mathbb{Z}$, computed in the ordinary W^g-module M^+.*

```

`plusSub θ := LinearMap.ker (θ.op - LinearMap.id)` is M^+, and `plusModule θ` is M^+ as an ordinary module over $W^{\langle g\rangle}$ with $u_{(n)} =$ `T.YM u (2*n)` (Chapter 36).

From the mathematics to the Lean statement

Fidelity check. `mode ((plusModule θ).YM u) n x₀` is $u_{(n)}x_0$ in the module M^+, which by construction is the integral mode $u_{(2n/2)}x_0$ of the twisted module. The hypothesis `hy` coerces y to M. The quantification `∃ u : (orbifold …).carrier, (u : 𝒱) ∈ A` is "$u \in W^g \cap A$". Same as the theorem.

Physical meaning

In the orbifold, the twisted-sector states in M^+ are those invariant under the lift θ_M of the $\mathbb{Z}/2$ symmetry, obtained by the projector $\frac{1}{2}(1+\theta_M)$. The statement is that projecting a family generated in the full twisted module onto the invariant states is the same as generating it from the invariant subtheory W^g acting on M^+, i.e. the g-invariant states of the family come from the g-invariant fields. It is the usual orbifold bookkeeping of keeping only gauge-invariant operators and states.

Proof. Apply $P = \frac{1}{2}(1+\theta_M)$, which fixes y. On a spanning vector, $P(u_{(k/2)}x_0) = \frac{1}{2}(u_{(k/2)} + (gu)_{(k/2)})x_0 = w_{(k/2)}x_0$ with $w = \frac{1}{2}(u+gu) \in W^g \cap A$; if k is odd this vanishes (a g-fixed state has only integral modes), and if $k = 2n$ it is the M^+-mode $w_{(n)}x_0$. □

What the machine verified

Unconditional; `##print axioms`-clean.

39.7.3 The frame involution on the twisted module

Theorem 39.26 (id $\otimes J$ lifts g_χ). *Let L be even, positive definite, unimodular, χ and w as in Theorem 39.14, and $P_J = \mathrm{id}_{S[\theta]} \otimes J$ on the twisted module $V_L^T = S[\theta] \otimes T$ of Chapter 36. Then for every $u \in V_L$ and $k \in \mathbb{Z}$, $Y^T(g_\chi u)_{(k/2)} = P_J\, Y^T(u)_{(k/2)}\, P_J$. For the Leech twisted module this reads $Y^T(gu)_{(k/2)} = (\mathrm{id} \otimes J) Y^T(u)_{(k/2)} (\mathrm{id} \otimes J)$ with $g =$* `frameAut`.

```

          leechTwistedModule.YM u k ∘ₗ
          (frameJ leech leech_even leech_isUnit_det_gramMat frameW).lTensor (FockT 24)
```

(`VOA/Moonshine/CyclicTwistedFrame.lean`.)

From the mathematics to the Lean statement

Fidelity check. `YML L hEven hU u k` is the twisted vertex operator mode $Y^T(u)_{(k/2)}$ on `MT L hEven hU` $= S[\theta] \otimes T$ (Chapter 36); `PJ … w =(frameJ … w).lTensor (FockT (rank L))` is id $\otimes J$ (`lTensor F f` $= \mathrm{id}_F \otimes f$). `∘ₗ` is composition of linear maps. Hypotheses: evenness, unimodularity (`hU`), positive definiteness (`hPos`), and `hw : ∀ α, (-1)^{⟪w,α⟫} = chiSign χ α`. Since $P_J^2 = 1$, the right side is the conjugate $P_J Y^T(u) P_J^{-1}$. The Leech version is the specialisation along `leech_rank : rank leech = 24` (the Fock space is indexed by `Fin 24` rather than `Fin (rank leech)`). Same as the theorem.

Physical meaning

On the twisted sector, the frame symmetry g_χ of the untwisted theory is implemented by the extraspecial operator J acting on the ground-state factor: conjugation by id $\otimes J$ acts on twisted vertex operators exactly as g_χ does on untwisted states. This is the statement that the frame charge is a symmetry of the twisted theory too, which is needed for the frame decomposition of the twisted sector to be compatible with the OPE. It is the twisted analogue of g_χ being a symmetry of the lattice CFT.

Proof. P_J fixes the twisted Heisenberg operators (they act on the other tensor factor), and $P_J Y^T(e^\alpha, z) P_J = (-1)^{\chi(\alpha)} Y^T(e^\alpha, z)$ because $Y^T(e^\alpha, z)$ contains the factor e_α on T and $J e_\alpha J = (-1)^{\langle w,\alpha\rangle} e_\alpha$. Twisted vertex operators of all other states are built from these by the twisted normal ordering of Chapter 36, which commutes with conjugation by an involution; hence $P_J Y^T(u) P_J = Y^T(g_\chi u)$ for all u. □

What the machine verified

Unconditional; `##print axioms YML_chiLat`-clean.

Consequently every mode of a g-fixed state preserves the two eigenspaces $S[\theta] \otimes T_\pm$ (`YM_mem_twFrame`).

39.7.4 The twisted frame sectors and their cyclicity

Recall from Chapter 36 that the Leech twisted space is `Tw := FockT 24 ⊗[ℂ] leechT`, that FLM's θ on it is $\theta_T \otimes (-1)$ (`thetaTwLeech`; θ_T negates every twisted oscillator, and θ acts by -1 on T), and that `TP := plusSub leechThetaLift` is $(V_\Lambda^T)^+$, an ordinary V_Λ^+-module (`Moonshine.plusModule`).

Definition 39.27 (Twisted frame sectors). $T_{(s)}^+ := (V_\Lambda^T)^+ \cap (S[\theta] \otimes T_{(s)})$, $s \in \mathbb{Z}/2$.

File `VOA/Moonshine/CyclicTwisted.lean`.

```
/-- **The twisted frame sectors** `T_s⁺ = TP ∩ (S[θ] ⊗ T_s)` (`s = 0, 1`). -/
noncomputable def TPframe (s : ZMod 2) : Submodule ℂ TP := (twFrameL s).comap TP.subtype

/-- `TP = T₀⁺ ⊕ T₁⁺`. -/
theorem TPframe_isCompl : IsCompl (TPframe 0) (TPframe 1)
```

From the mathematics to the Lean statement

Fidelity check. `twFrameL s` is the $(-1)^s$-eigenspace of id $\otimes J$ on `Tw`; `comap TP.subtype` intersects it with `TP`, viewed inside `TP`. So `TPframe s` is $T_{(s)}^+$. The docstring's "$T_0^+ \oplus T_1^+$" uses the Lean index s, not FLM's labels 0, 3 (see the warning in Section 39.5). `IsCompl` is the internal direct sum of two subspaces. Same as intended.

Physical meaning

The twisted frame sectors $T_{(s)}^+$ are the θ-invariant states of the twisted sector with frame charge s. They are the two halves (T_0^+, T_3^+) of the twisted half of the moonshine module, the twisted counterparts of the untwisted sectors V_0^+ and V_3^+; the triality will pair T_0^+ with V_3^+.

Proof. $\theta = \theta_T \otimes (-1)$ commutes with id$\otimes J$, so id$\otimes J$ is an involution of $(V_\Lambda^T)^+$, whose eigenspaces are complementary. □

Theorem 39.28 (Each twisted frame sector is cyclic). *Let $0 \neq t_0 \in T_{(s)}$ and $x_0 = h_0(-\frac{1}{2})\mathbf{1} \otimes t_0$ (weight $\frac{3}{2} + \frac{1}{2} = 2$). Then $x_0 \in T_{(s)}^+$ and* $\operatorname{span}\{u_{(n)}x_0 : u \in V_0^+,\ n \in \mathbb{Z}\} = T_{(s)}^+$, *where $u_{(n)}$ is the action of V_Λ^+ on $(V_\Lambda^T)^+$. In particular each $T_{(s)}^+$ is a cyclic V_0^+-module.*

```
/-- The cyclic vector `h₀(-½)𝟙 ⊗ t₀` (weight `2`). -/

    ↪ u) n x₀}
      = TPframe s
```

(`VOA/Moonshine/CyclicTwisted.lean`.)

From the mathematics to the Lean statement

Fidelity check. `X (0, 0) : FockT 24` is the polynomial generator of the twisted Fock space $S[\theta] = \mathbb{C}[h_a(-\frac{2m+1}{2})]$ corresponding to $h_0(-\frac{1}{2})$ (index $(m,a) = (0,0)$, Chapter 35); `⊗ₜ` is the pure tensor. `frameX0T_mem_TP` proves $\theta x_0 = x_0$ (θ_T negates $h_0(-\frac{1}{2})$, and θ is -1 on T). `TLeechT` is the type of T. `mode (Moonshine.plusModule.YM u) n x` is $u_{(n)}x$ in the V_Λ^+-module $(V_\Lambda^T)^+$, i.e. the twisted mode $u_{(2n/2)}$; u ranges over `frameSector 0` $= V_0^+$. Hypotheses `ht₀`, `h0`: $t_0 \in T_{(s)}$, $t_0 \neq 0$. Same as the theorem. Not vacuous: $T_{(s)}^+ \neq 0$ since it contains $x_0 \neq 0$ (and its weight-two part has dimension $24 \cdot 2048$).

Physical meaning

Each twisted charge sector is a single family of V_0^+ generated by one explicit state $x_0 = h_0(-\frac{1}{2})\mathbf{1} \otimes t_0$ of weight 2: a twisted ground state t_0 (weight $\frac{3}{2}$) with one fractional oscillator ($\frac{1}{2}$) added to make it θ-invariant. Cyclicity says that all the twisted states of that charge can be reached from this one by the OPE; it is the key technical input that allows the triality to be specified by its action on a single vector in each sector. (Physical picture heuristic; the proof is by the orbit-span and plus-projection machinery.)

Proof. Work in the *full* twisted V_Λ-module $S[\theta] \otimes T$, with $A = V_\Lambda^{\langle g \rangle}$ (all momenta in Λ_0; closed under products, θ-stable, contains $\mathbf{1}$). By Theorem 39.24, $Z_A(x_0)$ is stable under all modes of A.

1. The state $h_0(-1)\mathbf{1} \in A$ acts by the twisted oscillators $h_0(k/2) \otimes 1$. Hence $h_0(\frac{1}{2})x_0 = \frac{1}{2}(\mathbf{1} \otimes t_0) \in Z_A(x_0)$, and applying creation operators $h_b(-\frac{2m+1}{2})$, which span $S[\theta]$ from its vacuum, $S[\theta] \otimes t \subseteq Z_A(x_0)$ whenever $\mathbf{1} \otimes t \in Z_A(x_0)$.

2. For $\alpha \in \Lambda_0$, $e^\alpha \in A$ and $Y^T(e^\alpha)_{(\langle \alpha,\alpha\rangle - 2)/2)}(\mathbf{1} \otimes t) = 2^{-\langle \alpha,\alpha\rangle}(\mathbf{1} \otimes e_\alpha t)$ (`leechTwistedModule_echg_vac`; the power of 2 is FLM's normalisation of $Y^T(e^\alpha)$). So $\mathbf{1} \otimes e_\alpha t_0 \in Z_A(x_0)$.

3. T is a simple module over the twisted group algebra, so the $e_\alpha t_0$ ($\alpha \in \Lambda$) span T; those with $\alpha \notin \Lambda_0$ lie in $T_{(s+1)}$ (Theorem 39.15). Projecting to $T_{(s)}$ gives $T_{(s)} = \mathrm{span}\{e_\alpha t_0 : \alpha \in \Lambda_0\}$.

4. Hence $S[\theta] \otimes T_{(s)} \subseteq Z_A(x_0)$, and Theorem 39.25 turns this into: every $y \in T_{(s)}^+$ is a combination of $u_{(n)}x_0$ with $u \in A^\theta = V_0^+$.

5. Conversely, modes of V_0^+ commute with $\mathrm{id} \otimes J$ (Theorem 39.26) and with θ, so the span stays in $T_{(s)}^+$. □

What the machine verified

Unconditional; `##print axioms cyclic_TPframe`: [`propext`, `Classical.choice`, `Quot.sound`]. Proved *without* any twisted×twisted input. **Not proved:** irreducibility of $T_{(s)}^+$ (not needed). Which s corresponds to FLM's T_0^+ is not decided here.

39.8 Root exponentials and inner automorphisms

The untwisted triality is a product of exponentials $\exp(c\,(e^\alpha)_{(0)})$ for roots α. This section explains why such exponentials make sense and are automorphisms.

39.8.1 Inner automorphisms from weight-one states

If $u \in W_1$ (a weight-one state of a VOA W), its zero mode $u_{(0)}$ is a *derivation* of all products: the commutator formula gives $u_{(0)}(a_{(n)}b) = (u_{(0)}a)_{(n)}b + a_{(n)}(u_{(0)}b)$. Physically, $u_{(0)} = \oint u(z)\,dz$ is the conserved charge of the current $u(z)$, and the exponential of a conserved charge is a symmetry. The only issue is convergence of $\exp(u_{(0)}) = \sum_k u_{(0)}^k/k!$; in pure algebra one asks for *local nilpotency*.

Definition 39.29 (Locally nilpotent). An operator D on a vector space is *locally nilpotent* if for every v there is N with $D^N v = 0$. Then $\exp(D)v = \sum_{k<N} D^k v/k!$ is a finite sum.

```
def IsLocNilp (D : End ℂ 𝒱) : Prop := ∀ v : 𝒱, ∃ N : ℕ, (D ^ N) v = 0
```

(`VOA/Core/Automorphism.lean`.) The library's inner automorphism is

```
noncomputable def inner (u : W.grading 1)
    (hnilp : VOA.IsLocNilp (W.zeroMode (u : 𝒱) 1))
    (homega : W.zeroMode (u : 𝒱) 1 W.conformalVector = 0) : Aut W where
  toLinearEquiv := VOA.expEquiv hnilp
```

(`VOA.VertexOperatorAlgebra.inner`, same file.)

From the mathematics to the Lean statement

Fidelity check. `W.zeroMode u 1` is the zero mode $o(u) = u_{(\mathrm{wt}\,u-1)}$ of a state of weight 1, i.e. $u_{(0)}$. The three inputs are: u of weight one, $u_{(0)}$ locally nilpotent, and $u_{(0)}\omega = 0$ (needed for $\exp(u_{(0)})\omega = \omega$, part of the definition of `Aut`). `VOA.expEquiv hnilp` is $\exp(u_{(0)})$ with inverse $\exp(-u_{(0)})$. This is exactly "the exponential of a locally nilpotent derivation fixing ω is an automorphism".

Physical meaning

An operator is locally nilpotent if repeated application eventually kills any given state; this is what makes the exponential $\exp(D)$ of a charge-raising generator a well-defined symmetry transformation on the Fock space. In CFT language, the zero mode of a root current only changes the charge in the positive direction until it exceeds the cutoff of the finite-energy states, so its exponential is the group element $\exp(cJ^+)$ of $SU(2)$, a finite sum on each state.

39.8.2 $(e^\alpha)_{(0)}$ is locally nilpotent

Let L be even positive definite, and write $Q_\alpha := (e^\alpha)_{(0)}$ (`Qscr L α`). Every state of V_L is a sum of states of definite *bidegree* (d, γ): boson degree d (the sum of the mode numbers of the oscillators) and momentum γ (`bigradα L (d, γ)`).

Theorem 39.30 (Local nilpotency of root zero modes). *Q_α maps bidegree (d, γ) to bidegree $(d - 1 - \langle\alpha, \gamma\rangle, \gamma + \alpha)$. Consequently, for every $\alpha \neq 0$, Q_α is locally nilpotent.*

```
/-- `Q_α` shifts the bigrading: `bigradα (d, β) → bigradα (d - 1 - ⟨α,β⟩, β + α)`. -/
theorem Qscr_mem_bigradα (α : L.carrier) {d : ℤ} {β : L.carrier} {x : LatModuleGen L}
    (hx : x ∈ bigradα L (d, β)) :
    Qscr L α x ∈ bigradα L (d - 1 - L.form α β, β + α)

/-- **Local nilpotency of `(e^α)₍₀₎`** for every nonzero `α` of a positive-definite
 ↪ lattice. -/
theorem isLocNilp_Qscr (hPos : L.PosDef) {α : L.carrier} (hα : α ≠ 0) :
    VOA.IsLocNilp (Qscr L α)
```

(`VOA/Moonshine/TrialityRoot.lean`.)

From the mathematics to the Lean statement

Fidelity check. `Qscr L α` is defined as `mode (Yeαvec L α) 0`, the 0-th mode of $Y(e^\alpha, z)$ (Chapter 31); `zeroMode_latChargeGen` confirms it is the zero mode of e^α in `latticeVOAGen`. Hypotheses: L positive definite and $\alpha \neq 0$ — both necessary ($Q_0 = \mathrm{id}_{(0)}$-type degeneracies aside, for $\langle\alpha,\alpha\rangle \leq 0$ the degree need not decrease). Same as the theorem.

Physical meaning

The zero mode $Q_\alpha = (e^\alpha)_{(0)}$ is the charge of the root current $J^+ = e^\alpha$ and raises the momentum by α while lowering the oscillator degree (by $1 + \langle\alpha,\gamma\rangle$); so repeated application eventually exhausts the oscillator degree and kills the state. Physically this is the statement that the finite-energy states form a representation of the algebraic group $SU(2)$ (or $SL_2(\mathbb{C})$) integrated from the Lie algebra, on which the exponentials act by finite sums; no analytic completion is needed.

Proof. $Y(e^\alpha, z)(p \otimes e^\gamma) = \varepsilon(\alpha,\gamma) z^{\langle\alpha,\gamma\rangle} E^-(-\alpha, z) E^+(-\alpha, z) p \otimes e^{\alpha+\gamma}$, and the coefficient of z^{-1} raises the boson degree by exactly $-1 - \langle\alpha,\gamma\rangle$. After k applications starting from (d,γ) the degree is

$$d - k - k\langle\alpha,\gamma\rangle - \langle\alpha,\alpha\rangle \frac{k(k-1)}{2},$$

a quadratic in k with negative leading coefficient since $\langle\alpha,\alpha\rangle > 0$. It is eventually negative, and there are no states of negative boson degree. □

Definition 39.31 (Root exponential). For a root α ($\langle\alpha,\alpha\rangle = 2$) and $c \in \mathbb{C}$, $\exp(cQ_\alpha) \in \mathrm{Aut}\, V_L$.

```
/-- **The root exponential** `exp(c·(e^α)₍₀₎) ∈ Aut(V_L)` for a root `α` (`⟨α,α⟩ = 2`). -/
noncomputable def rootExp {α : L.carrier} (hα : L.form α α = 2) (c : ℂ) :
    Aut (latticeVOAGen L hEven hPos) :=
  VertexOperatorAlgebra.inner ⟨c • latChargeGen L α, smul_latChargeGen_mem_grading_one L
   ↪ hEven hPos hα c⟩
    (isLocNilp_zeroMode_smul L hEven hPos (form_self_ne_zero_of_two L hα) c)
    (by
      rw [← Screening.screening_eq_zeroMode]
      exact Screening.screening_conformalVector _ (smul_latChargeGen_mem_grading_one L
       ↪ hEven hPos hα c))

/-- An automorphism fixing `e^α` commutes with `exp(c·Q_α)`. -/
theorem rootExp_comm_of_fix {α : L.carrier} (hα : L.form α α = 2) (c : ℂ)
    (β : Aut (latticeVOAGen L hEven hPos)) (hfix : β (latChargeGen L α) = latChargeGen L α)
    ↪ :
    β * rootExp L hEven hPos hα c = rootExp L hEven hPos hα c * β
```

From the mathematics to the Lean statement

Fidelity check. The definition is the one-line composition of `inner` with three facts: ce^α has weight $\frac{1}{2}\langle\alpha,\alpha\rangle = 1$; its zero mode is locally nilpotent (Theorem 39.30); and it kills ω (true for every weight-one state, `screening_conformalVector`). So `rootExp hα c` is $\exp(cQ_\alpha)$ and, by construction, an automorphism. `rootExp_comm_of_fix`: if $\beta e^\alpha = e^\alpha$ then $\beta \exp(cQ_\alpha)\beta^{-1} = \exp(c\,(\beta e^\alpha)_{(0)}) = \exp(cQ_\alpha)$.

Physical meaning

The root exponential $\exp(cQ_\alpha)$ is a finite group element of the $SU(2)$ (or SL_2) that acts on the currents of the root α: for a root α of V_L, the currents e^α, $\alpha(-1)\mathbf{1}$ and $e^{-\alpha}$ form the $\widehat{\mathfrak{sl}}_2$ at

level one (the $SU(2)_1$ WZW model), and the exponential is a rotation by a complex angle. It is an automorphism of the VOA because Q_α is a derivation (the zero mode of a weight-one field) and is locally nilpotent. These inner automorphisms are the continuous symmetry that the lattice theory of a Niemeier lattice with roots has, and which the Leech theory (with no roots) lacks.

What the machine verified

Unconditional; `##print axioms isLocNilp_Qscr`-clean. `rootExp` is a definition (its axioms are those of `inner`: clean).

39.8.3 The $\mathfrak{sl}_2$ triple of a root

Write $e = e^\alpha$, $h = \alpha(-1)\mathbf{1}$ (`hSt L α`), $f = e^{-\alpha}$ and $\varepsilon = \varepsilon(\alpha,-\alpha) = \pm 1$. For a vector $x_1 e + x_2 h + x_3 f$ (`vec3 L α x₁ x₂ x₃`) the library computes:

$$Q_\alpha : e \mapsto 0,\ h \mapsto -2e,\ f \mapsto \varepsilon h; \qquad Q_{-\alpha} : e \mapsto -\varepsilon h,\ h \mapsto 2f,\ f \mapsto 0, \tag{39.6}$$

```
/-- `Q_β (α(-1)𝟙) = -⟨α,β⟩ e^β`. -/
theorem Qscr_hSt (hPos : L.PosDef) (α β : L.carrier) :
    Qscr L β (hSt L α) = -((L.form α β : ℤ) : ℂ) • latChargeGen L β

/-- `Q_α e^{-α} = ε(α,-α)·α(-1)𝟙` for a root `α`. -/
theorem Qscr_latChargeGen_neg {α : L.carrier} (hα : L.form α α = 2) :
    Qscr L α (latChargeGen L (-α)) = latticeCocycle L α (-α) • hSt L α
```

and hence, since $Q_{\pm\alpha}^3 = 0$ on the triple, the exponentials act by quadratic formulas:

```
theorem rootExp_vec3_pos {α : L.carrier} (hα : L.form α α = 2) (c x₁ x₂ x₃ : ℂ) :
    rootExp L hEven hPos hα c (vec3 L α x₁ x₂ x₃)
      = vec3 L α (x₁ - 2 * c * x₂ - c ^ 2 * latticeCocycle L α (-α) * x₃)
          (x₂ + c * latticeCocycle L α (-α) * x₃) x₃

theorem rootExp_vec3_neg {α : L.carrier} (hα : L.form α α = 2) (hα' : L.form (-α) (-α) = 2)
    (c x₁ x₂ x₃ : ℂ) :
    rootExp L hEven hPos hα' c (vec3 L α x₁ x₂ x₃)
      = vec3 L α x₁ (x₂ - c * latticeCocycle L α (-α) * x₁)
          (x₃ + 2 * c * x₂ - c ^ 2 * latticeCocycle L α (-α) * x₁)

theorem rootExp_vec3_orth {α β : L.carrier} (hβ : L.form β β = 2) (hαβ : L.form α β = 0)
    (c x₁ x₂ x₃ : ℂ) : rootExp L hEven hPos hβ c (vec3 L α x₁ x₂ x₃) = vec3 L α x₁ x₂ x₃
```

(`VOA/Moonshine/TrialitySl2.lean`.)

From the mathematics to the Lean statement

Fidelity check. `vec3 L α x₁ x₂ x₃ := x₁ • latChargeGen L α + x₂ • hSt L α + x₃ • latChargeGen L (-α)`, i.e. $x_1e+x_2h+x_3f$, and `hSt L α := latStateGen L (vSchur L α 1) 0` is $\alpha(-1)\mathbf{1}\otimes e^0$. Each formula is the exponential $v + cQv + \frac{c^2}{2}Q^2v$ with the table (39.6): e.g. for Q_α, $Q(x_1e + x_2h + x_3f) = -2x_2e + \varepsilon x_3 h$ and $Q^2(\ldots) = -2\varepsilon x_3 e$, giving the displayed coefficients. The third statement: a root $\beta \perp \alpha$ acts trivially on the α-triple.

Proof of (39.6). $Q_\beta h = -\langle\alpha,\beta\rangle e^\beta$: the zero mode of e^β on $\alpha(-1)\mathbf{1}$ is the z^{-1} coefficient of $z^0E^-(-\beta,z)\alpha(-1)\mathbf{1}\otimes e^\beta$, where the annihilation part E^+ contributes $-\langle\beta,\alpha\rangle z^{-1}$. $Q_\alpha e^{-\alpha}$: $Y(e^\alpha,z)e^{-\alpha} = \varepsilon z^{-2}E^-(-\alpha,z)\mathbf{1} = \varepsilon z^{-2}(1+\alpha(-1)z+\cdots)$, whose z^{-1} coefficient is εh. $Q_\alpha e^\alpha = 0$ because $\langle\alpha,\alpha\rangle = 2 \geq 0$ makes the series start at z^2. □

In particular $E := Q_\alpha, H := h_{(0)}, F := \varepsilon Q_{-\alpha}$ satisfy the $\mathfrak{sl}_2$ relations, and on the span of $\{e, h, f\}$ (the adjoint representation) they are the adjoint action.

39.9 The Niemeier lattice VOA and the triality σ

39.9.1 The lattice VOA V_N

Definition 39.32 (V_N). $N = N(A_1^{24}) = \rho^{-1}(C) \subset \mathbb{Z}^{24}$ with $\langle x, y\rangle = x \cdot y/2$; V_N is its lattice VOA. The roots are $\alpha_j = 2e_j$, with $\langle \alpha_j, \alpha_k\rangle = 2\delta_{jk}$.

```

(`VOA/Moonshine/TrialityGolay.lean`, namespace `VOA.Moonshine.Triality`.)

From the mathematics to the Lean statement

Fidelity check. `ofEbeling` converts the vendored lattice (Chapter 30) to the library's `IntegralLattice`; `golayN_even`, `golayN_posDef` are proved from the Golay code being doubly even and self-orthogonal. `Pi.single j 1` is e_j. Same as the definition.

Physical meaning

V_N is the lattice CFT of the Niemeier lattice $N(A_1^{24})$: 24 free bosons compactified on the Niemeier torus, which contains 24 mutually orthogonal roots, so it has a $\widehat{\mathfrak{sl}}_2^{24}$ current algebra at level one, i.e. 24 copies of the $SU(2)_1$ WZW model (a free boson at self-dual radius). It has the same central charge 24 as the Leech theory but a large non-abelian continuous symmetry $SU(2)^{24}$ (the Kac–Moody algebra of A_1^{24}), in contrast to the abelian $U(1)^{24}$ of the Leech theory. It is the theory in which the triality is visible as a rotation.

Definition 39.33 (χ and the modified centre χz_0). $\mathrm{par}(x) = \frac{1}{2}\sum_i x_i \bmod 2$ (`golayParity`; kernel A), $z_l(x) = x_l \bmod 2$ (`golayCoord l`). $\chi := g_{\mathrm{par}}$ (`golayChi`) and $\chi z_0 := g_{\mathrm{par}+z_0}$ (`golayChiMod`).

```

noncomputable def golayChiMod : Aut golayVOA :=
  chiAut golayN (golayParity + golayCoord 0) golayN_even golayN_posDef
```

From the mathematics to the Lean statement

Fidelity check. Why is the momentum sign $(-1)^{\mathrm{par}}$ DGM's $\prod_j \exp(i\pi H_j/2)$? $H_j = (\alpha_j(-1)\mathbf{1})_{(0)}$ acts on F_λ by $\langle\alpha_j,\lambda\rangle = \lambda_j$, so $\prod_j \exp(i\pi H_j/2)$ acts by $i^{\sum_j \lambda_j} = (-1)^{\sum_j \lambda_j/2}$ ($\sum \lambda_j$ is even on $\rho^{-1}(C)$). This is a paper identification; the Lean object is *defined* as the momentum sign. Likewise $z_0 = (-1)^{x_0}$ is $\exp(i\pi H_0)$, the central element $-1 \in SU(2)_0$, and χz_0 acts in coordinate 0 as $\exp(3i\pi H_0/2)$: this is DGM's modification (7.8) in the coordinate $l = 0$.

Physical meaning

χ is the $\mathbb{Z}/2$ charge symmetry $(-1)^{\mathrm{par}(\hat{p})}$, the rotation by π about the Cartan axis in every $SU(2)$ factor. Its modification χz_0 changes the parity by the coordinate z_0 and is the involution that, after conjugation by the rotation G (a rotation by an angle between axes), will become the triality σ. Both are symmetries because momentum is conserved in every operator product; the choice of z_0 selects the correct class among such sign automorphisms.

39.9.2 The rotation G and the definition of σ

DGM write the triality as $\sigma_{\mathrm{DGM}} = \prod_j \exp(\frac{i\pi}{\sqrt{2}}(J_0^{j1} + J_0^{j2}))$ with $J^{j1} = \frac{1}{2}H_j$, $J^{j2} = \frac{1}{2}(E_j + F_j)$: rotation by π about the bisector of the Cartan and the $e + f$ axes. The library instead writes σ as a *conjugate* of the momentum sign, which makes $\sigma^2 = 1$ automatic. The key identity is in $SL_2(\mathbb{C})$: with

$$H = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix},\ E = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix},\ F = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}, \qquad g = \exp\big((1-\sqrt{2})E\big)\exp\big(\tfrac{\sqrt{2}}{4}F\big) = \begin{pmatrix} 1+ab & a \\ b & 1 \end{pmatrix},$$

$a = 1-\sqrt{2}$, $b = \sqrt{2}/4$, $ab = (\sqrt{2}-2)/4$, one has

$$gHg^{-1} = \tfrac{1}{\sqrt{2}}(H + E + F). \tag{39.7}$$

Verification. $\det g = 1$ and $g^{-1} = \begin{pmatrix} 1 & -a \\ -b & 1+ab \end{pmatrix}$, so $gHg^{-1} = \begin{pmatrix} 1+2ab & -2a(1+ab) \\ 2b & -1-2ab \end{pmatrix}$. Now $1+2ab = \sqrt{2}/2$; $-2a(1+ab) = -2(1-\sqrt{2})(2+\sqrt{2})/4 = -(2+\sqrt{2}-2\sqrt{2}-2)/2 = \sqrt{2}/2$; $2b = \sqrt{2}/2$. So $gHg^{-1} = \frac{\sqrt{2}}{2}\begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix} = \frac{1}{\sqrt{2}}(H+E+F)$. □

Since $X = (H+E+F)/\sqrt{2}$ satisfies $X^2 = 1$, $\exp(i\pi X/2) = iX$, and therefore, as SL_2 matrices (not only up to sign),

$$g\exp(i\pi H/2)g^{-1} = \exp(i\pi X/2) = \exp\Big(\tfrac{i\pi}{\sqrt{2}}\big(\tfrac{H}{2} + \tfrac{E+F}{2}\big)\Big),$$

which is DGM's rotation in one coordinate. With $G = \prod_j g_j$ this gives, on paper, $\sigma_{\mathrm{DGM}} = G\chi G^{-1}$, and DGM's (7.8)-modified triality is $G(\chi z_0)G^{-1}$.

Definition 39.34 (The untwisted triality). $\varepsilon_j = \varepsilon(\alpha_j, -\alpha_j)$; $g_j = \exp((1-\sqrt{2})Q_{\alpha_j})\exp(\frac{\sqrt{2}}{4}\varepsilon_j Q_{-\alpha_j})$; $G = g_0 g_1 \cdots g_{23}$; and

$$\sigma := G\,(\chi z_0)\,G^{-1} \in \mathrm{Aut}\,V_N.$$

From the mathematics to the Lean statement

Fidelity check. `Real.sqrt 2` coerced to $\mathbb{C}$ is $\sqrt{2}$. `rootExp … hα c` $= \exp(cQ_\alpha)$ with $\alpha = \alpha_j$ (first factor) and $\alpha = -\alpha_j$ (second factor); $*$ in `Aut` is composition, so g_j applies the $Q_{-\alpha_j}$-exponential first. With $E_j = Q_{\alpha_j}$, $F_j = \varepsilon_j Q_{-\alpha_j}$ this is the matrix g above. `(List.ofFn golayG1).prod` is $g_0 g_1 \cdots g_{23}$ (the order is irrelevant: the factors commute because they act on orthogonal roots). So `golaySigma` is literally $G(\chi z_0)G^{-1}$. **What is not asserted in Lean:** that this equals DGM's exponential formula — that is the paper computation (39.7). The evidence that the Lean σ is the right one is (a) Theorem 39.36 (its action on currents is DGM (7.7)), (b) the trace certificate in the warning below, and (c) ultimately, that it extends to $V^\natural$ (Chapters 40–42).

Physical meaning

$\sigma = G(\chi z_0)G^{-1}$ is a rotation by π in every $SU(2)$ factor of $SU(2)^{24}$ about a new axis: the rotation $G = \prod_j g_j$ (a product of exponentials of $\mathfrak{sl}_2$ zero modes, i.e. an $SU(2)$ rotation in each factor) moves the Cartan axis to a bisector, and the involution about the bisector is σ. It exchanges the χ-axis and the Θ-axis (the rotation about the $e+f$ axis): this is the swap of Cartan with $e+f$ currents. The sector content of this swap is the heart of triality in the A_1^{24} theory; in the moonshine setting the analogous σ exchanges an untwisted sector with a twisted one, and the explicit group-element formula is the Lean-friendly way to describe it. The exponent $1-\sqrt{2}$ and the coefficient $\frac{\sqrt{2}}{4}$ are the specific angles that realise the bisector rotation.

Theorem 39.35 (σ is a nontrivial involution). *$\sigma^2 = 1$ and $\sigma \neq 1$.*

File `VOA/Moonshine/TrialityGolay.lean`.

```
/-- `σ² = 1`. -/
theorem golaySigma_sq : golaySigma * golaySigma = 1

theorem golaySigma_ne_one : golaySigma ≠ 1
```

Physical meaning

A rotation by π squares to the identity, which is $\sigma^2 = 1$; and $\sigma \neq 1$ because it is a genuine, nontrivial symmetry, exchanging currents that are distinct. Physically, σ is the $\mathbb{Z}/2$ element of a hidden symmetry group, an extra involution beyond the visible ones, and the triality is the order-two generator that, together with the centraliser, assembles into the Monster.

Proof. $(G(\chi z_0)G^{-1})^2 = G(\chi z_0)^2 G^{-1} = 1$ since $(\chi z_0)^2 = 1$. If $\sigma = 1$ then $\chi z_0 = 1$; but χz_0 negates e^{α_0} ($\mathrm{par}(\alpha_0) = 1$, $z_0(\alpha_0) = 0$). □

39.9.3 σ on the currents: DGM (7.7)

Theorem 39.36 (σ exchanges the Cartan and the $e+f$ currents)**.** *For every j:* $\sigma\big(\alpha_j(-1)\mathbf{1}\big) = e^{\alpha_j} + \varepsilon_j e^{-\alpha_j}$, *and* $\sigma\big(e^{\alpha_j} + \varepsilon_j e^{-\alpha_j}\big) = \alpha_j(-1)\mathbf{1}$.

```
/-- **DGM (7.7) on the Cartan current**: `σ (α_j(-1)𝟙) = e^{α_j} + ε_j e^{-α_j}`. -/
theorem golaySigma_hSt (j : Fin 24) :
    golaySigma (hSt golayN (golayRoot j)) = tri j 1 0 (golayEps j)

/-- `σ (e^{α_j} + ε_j e^{-α_j}) = α_j(-1)𝟙`. -/
theorem golaySigma_tri_ef (j : Fin 24) :
    golaySigma (tri j 1 0 (golayEps j)) = hSt golayN (golayRoot j)
```

(`VOA/Moonshine/TrialityCurrents.lean`.)

From the mathematics to the Lean statement

Fidelity check. `tri j x₁ x₂ x₃ := vec3 golayN (golayRoot j) x₁ x₂ x₃`, so `tri j 1 0 (golayEps j)` $= e^{\alpha_j} + \varepsilon_j e^{-\alpha_j}$. The zero mode of this state is $E_j + \varepsilon_j \cdot \varepsilon_j F_j = E_j + F_j$, i.e. $2J_0^{j2}$; the zero mode of $\alpha_j(-1)\mathbf{1}$ is $H_j = 2J_0^{j1}$. So the theorem says $\sigma J^{j1}\sigma^{-1} = J^{j2}$, DGM (7.7). No hypotheses.

Physical meaning

In each $SU(2)_1$ factor, σ swaps the Cartan current $\alpha_j(-1)\mathbf{1}$ (the J^3-like current) with the current $e^{\alpha_j} + \varepsilon_j e^{-\alpha_j}$ (the J^1-like one): a rotation of the three-dimensional space of currents by π about the bisector of two axes exchanges them. This is the concrete content of triality on the weight-one states: it relates the current that acts as a charge (free-boson momentum) with a current that acts as a charge-changing vertex operator, something invisible in the free-field description, where those currents look different. The computation takes place in the three-dimensional span of e, h, f in each coordinate and is the standard $SU(2)$ adjoint rotation.

Proof. Everything happens in the three-dimensional span of e, h, f in coordinate j: the factors g_k, $k \neq j$, act trivially there (`rootExp_vec3_orth`), and g_j and χz_0 act by the explicit formulas of Section 39.8 (χz_0 negates e, f and fixes h). One exhibits

$$y = (2-2\sqrt{2})e + \tfrac{\sqrt{2}}{2}h - \tfrac{\varepsilon(1+\sqrt{2})}{4}f, \qquad y' = (2\sqrt{2}-2)e + \tfrac{\sqrt{2}}{2}h + \tfrac{\varepsilon(1+\sqrt{2})}{4}f$$

and checks, using only $(\sqrt{2})^2 = 2$ and $\varepsilon^2 = 1$, that $Gy = h$, $Gy' = e + \varepsilon f$ and $(\chi z_0)y = y'$. Then $\sigma h = G(\chi z_0)G^{-1}Gy = Gy' = e + \varepsilon f$. The second statement follows from $\sigma^2 = 1$. □

What the machine verified

 ↪  `-1`). -/
noncomputable def golayV0 : VertexOperatorAlgebra (orbifold golayK).carrier := orbifoldVOA
 ↪  golayK
```

From the mathematics to the Lean statement

Fidelity check. `Subgroup.closure S` is the subgroup generated by S. The docstring's parenthetical "modulo the open identification" is stale: the identification is made by the next theorem and by Section 39.10. Note that $\sigma\Theta\sigma = \chi$ (`golaySigma_conj_theta`) holds by definition and $\sigma^2 = 1$; the content is that Θ is a lift of -1.

Physical meaning

$\Theta = \sigma\chi\sigma$ is the conjugate of the Cartan rotation by the triality: a rotation by π about the $e + f$ axis, i.e. the image of the sign symmetry χ under the swap. $K = \langle\chi, \Theta\rangle$ is the group generated by these two commuting involutions (a Klein four-group in each factor), and V_N^K is the K-orbifold, the subtheory neutral under both. It is the theory that the untwisted and twisted halves of the moonshine module share, and that σ preserves.

Theorem 39.38 (Θ is a lift of -1). *(i)* $\Theta(\alpha_j(-1)\mathbf{1}) = -\alpha_j(-1)\mathbf{1}$ *for all* j*; hence* Θ *anticommutes with every Heisenberg mode. (ii)* $\Theta(F_\lambda) \subseteq F_{-\lambda}$ *for every* $\lambda \in N$.

```
/-- `Θ = σχσ` acts by `-1` on the Cartan currents. -/

theorem golayTheta_chargeSec (lam : golayN.carrier) {x : LatModuleGen golayN}
    (hx : x ∈ chargeSec golayN lam) : golayTheta x ∈ chargeSec golayN (-lam)
```

(`VOA/Moonshine/TrialityCurrents.lean`, `TrialityTheta.lean`.)

Physical meaning

Θ negates the Heisenberg currents $\alpha_j(-1)\mathbf{1}$ and maps momentum λ to $-\lambda$, so it is a lift of the lattice involution -1: the same kind of symmetry as θ of the Leech theory (negating each boson). Physically, σ conjugates the charge parity χ into an operation acting on bosons as the reflection $\partial X \mapsto -\partial X$. This is the mechanism of "triality": it converts a sign on charges into a sign on the bosons, so the orbifold by the former looks like the orbifold by the latter (which is how twisted sectors appear). The precise scalars (cocycle-dependent) are the content of the proof.

Proof. (i) $\sigma h_j = e_j + \varepsilon_j f_j$, χ negates e_j, f_j, and σ maps $-(e_j + \varepsilon_j f_j)$ back to $-h_j$. An automorphism negating the state h negates all modes of $Y(h, z)$ under conjugation. (ii) The zero modes H_j act on F_λ by λ_j, these 24 numbers determine λ, and $H_j\Theta = -\Theta H_j$ by (i); so ΘF_λ lies in the joint eigenspace with eigenvalues $-\lambda_j$, which is $F_{-\lambda}$. □

What the machine verified

Unconditional; `##print axioms golayTheta_chargeSec`-clean. The scalars c_λ with $\Theta e^{\lambda} = c_\lambda e^{-\lambda}$ are determined in Section 39.10 (on Λ_0).

Theorem 39.39 (σ restricts to V_N^K). *σ normalises K, hence restricts to an automorphism σ_0 of V_N^K; $\sigma_0^2 = 1$ and $\sigma_0 \neq 1$. More generally, an involution normalising a subgroup G restricts to an automorphism of W^G.*

/-- **`σ₀ ≠ 1`**: the triality is a nontrivial involution of `V_N^{⟨χ,Θ⟩}`. -/
theorem golaySigma0_ne_one : golaySigma0 ≠ 1
```

From the mathematics to the Lean statement

Fidelity check. Hypotheses of `orbifoldInvol`: $\sigma^2 = 1$ and $\sigma G \sigma \subseteq G$. `golaySigma_normalises` supplies the latter for K (conjugation by σ swaps the generators $\chi \leftrightarrow \Theta$). The underlying map of `golaySigma0` on $v \in V_N^K$ is σv (`golaySigma0_coe`). The nontriviality is the important clause: an "automorphism" that is secretly the identity would make everything that follows empty.

Physical meaning

Because σ normalises K (it exchanges χ and Θ), it descends to the K-neutral subtheory V_N^K as an automorphism: a symmetry that permutes the gauge group elements preserves the gauge-invariant states. It is nontrivial there. This is the general principle that an automorphism normalising the orbifold group acts on the orbifold: in the physical picture, the triality survives the projection onto K-neutral states, and acts as an extra symmetry of V_N^K not coming from a lattice automorphism.

Proof. If v is K-fixed and $k \in K$ then $k\sigma v = \sigma(\sigma k \sigma)v = \sigma v$. For $\sigma_0 \neq 1$: the state $x = h_{0(-1)}h_1$ (i.e. $\alpha_0(-1)\alpha_1(-1)\mathbf{1}$) is in F_0 (fixed by χ) and $\Theta x = (-h_0)_{(-1)}(-h_1) = x$, so $x \in V_N^K$. But $\sigma x = (e_0 + \varepsilon_0 f_0)_{(-1)}(e_1 + \varepsilon_1 f_1)$ has momentum-$(\alpha_0 + \alpha_1)$ component $e^{\alpha_0}_{(-1)}e^{\alpha_1} = \varepsilon(\alpha_0, \alpha_1)e^{\alpha_0+\alpha_1} \neq 0$ (as $\langle \alpha_0, \alpha_1 \rangle = 0$), while x has none. □

What the machine verified

Unconditional; `##print axioms golaySigma0_ne_one`: [`propext`, `Classical.choice`, `Quot.sound`].

Trap / dead end

The unmodified DGM (7.5) triality is the wrong one — the 6372 versus 2324 certificate. For $d = 24$ DGM's modification (7.8) (multiplying, in one coordinate l, by the central element $z_l = (-1)^{x_l}$) is *mandatory*, because 24/8 is odd. The project established this by a trace computation (paper derivation plus Python with the real Golay code, `scripts/moonshine/numerics/golay.py`, `tri.py`; *numerical evidence and paper argument only, not Lean*).
The trace. $(V_N)_2$ decomposes under $SU(2)^{24}$ as $24 \cdot (3+1) \oplus \binom{24}{2} \cdot 9 \oplus 759 \cdot 2^8$ $(= 196884)$. Projecting onto V_N^K with $\frac{1}{4}\sum_{k\in K} k$ (legitimate because σ normalises K), and using the $SU(2)$ traces of the rotations involved, one finds

$$\operatorname{tr}\left(\sigma \,|\, (V_N^K)_2\right) = 300 + 8 \sum_{\text{octads } c} (-1)^{c\cdot u},$$

where $u \in \mathbb{F}_2^{24}/C$ encodes the modification: $u = 0$ for (7.5), $u = e_l$ for (7.8). The sum over the 759 octads is 759 for $u = 0$ and $506 - 253 = 253$ for $u = e_l$ (253 octads contain a given point). Hence

$$\operatorname{tr}\sigma_{(7.5)} = 300 + 8\cdot 759 = 6372, \qquad \operatorname{tr}\sigma_{(7.8)} = 300 + 8\cdot 253 = 2324.$$

Why 6372 is impossible (a paper argument, using $\operatorname{Aut} V^\natural = \mathbb{M}$ and the Monster character table from the literature; neither is formalized). If σ extended to $\tilde\sigma \in \operatorname{Aut} V^\natural = \mathbb{M}$ with $V_0^+ = (V^\natural)^E$ for a Klein four-group E, then $\tilde\sigma$ normalises E, fixes one $k_0 \in E \setminus 1$ and swaps the other two, and $\operatorname{tr}(\sigma|(V_0^+)_2) = \frac{1}{4}(\operatorname{tr}\tilde\sigma + \operatorname{tr}\tilde\sigma k_0 + 2\operatorname{tr}\tilde\sigma k_1)$ on ${V^\natural}_2 = 1 + 196883$, with $\tilde\sigma, \tilde\sigma k_0$ involutions and $\tilde\sigma k_1$ of order four. From the Monster character table the largest possible value is $\frac{1}{4}(4372 + 4372 + 2\cdot 276) = 2324$ (classes 2A, 2A, 4A). So 6372 cannot be the trace of a Monster element: the unmodified σ is *not* the restriction of FLM's triality. The modified value saturates the bound. The library therefore defines σ with χz_0, not χ (a recorded dead end, Section 43.2.3; Notes/M8GluingPlan.md, correction 6). At module level the project also found numerically that the (7.5) σ maps V_3^+ to the wrong twisted summand, while (7.8) gives a residual of $4 \cdot 10^{-15}$ over 15000 identities (status "M8g twisted half").

39.10 The bridge $V_N^K \cong V_0^+$ and the triality on V_0^+

σ_0 lives on V_N^K, a subalgebra of the lattice VOA of N; V_0^+ is a subalgebra of the lattice VOA of Λ. The two ambient algebras have different lattices, different cocycles and different Fock coordinates. Both contain a copy of V_{Λ_0}, and the functoriality theorem of Chapter 31 (Theorem 31.39) produces both copies from one abstract V_{Λ_0}.

From the mathematics to the Lean statement

Fidelity check. The proofs shown are one-line instantiations of the functoriality theorem of Chapter 31 (Theorem 31.39), whose hypotheses — both lattices positive definite and even, the map an isometry (`inclΛ_form`, `inclN_form`), and equal ranks for ω and injectivity (`rank_lam0_leech`: $24 = 24$) — are all discharged here. The analogous `bridgeN_omega`, `bridgeN_injective`, `bridgeN_thetaLat` hold too. `latMorph` includes a cocycle-comparison coboundary with values in $\mathbb{Z}/4$ (Remark 31.37); a ±1-valued one would commute with θ only up to a character, and then `bridgeΛ_thetaLat` would fail.

Physical meaning

The two bridges embed the frame subtheory V_{Λ_0} into both the Leech theory (the states with all momenta in Λ_0) and the Niemeier theory (the χ-neutral states of V_N). They realise the statement that the Leech and A_1^{24} theories share a common subtheory, the frame theory V_{Λ_0}; the θ-involutions agree under the Leech bridge. This is what allows the triality, first constructed on the A_1^{24} side, to be moved to the Leech side.

Theorem 39.41 ($V_{\Lambda_0}^+ \cong V_0^+$). `bridgeΛ` *induces a linear bijection* $V_{\Lambda_0}^+ = V_{\Lambda_0}^{\langle\theta\rangle} \to V_0^+$ *which is a VOA homomorphism preserving* ω.

theorem lam0PlusEquiv_omega : lam0PlusEquiv lam0Plus.conformalVector = V0P.conformalVector
```

From the mathematics to the Lean statement

Fidelity check. `Lam0PlusCarrier` is the carrier of $V_{\Lambda_0}^+$ (the $\langle\theta\rangle$-orbifold `lam0Plus` of `lam0VOA`); `V0Sub.carrier` that of `V0P`. `lam0PlusEquiv_coe` records that the map is `bridgeΛ`. Bijective + `IsVOAHom` + ω-preserving = isomorphism of VOAs. This settles the open item "identify `V0P` with the θ-orbifold of V_{Λ_0}" recorded in the docstring of `FrameSectors.lean` (stale there).

Physical meaning

The θ-invariant part of the abstract frame lattice theory V_{Λ_0} is isomorphic, as a vertex operator algebra with the same stress tensor, to the neutral frame sector V_0^+ of the Leech theory: "the common subtheory" is the same on both sides. In CFT terms, the neutral sector of the Leech theory is an orbifold of a smaller lattice theory, identified through the isomorphism of charge lattices.

Proof. `bridgeΛ` is injective with image the momentum-Λ_0 states, and commutes with θ; so it maps θ-fixed states of V_{Λ_0} bijectively onto θ-fixed states of V_Λ with momenta in Λ_0, which is V_0^+. □

What the machine verified

Unconditional; `##print axioms lam0PlusEquiv_isVOAHom`-clean.

39.10.2 Pulling back Θ: the scalars c_λ

On the N side the situation is subtler: $V_N^K = (V_N^\chi)^\Theta = \mathrm{bridgeN}(V_{\Lambda_0})^\Theta$, and Θ is *some* lift of -1, not obviously the standard θ.

Theorem 39.42 (Θ on V_{Λ_0} is conjugate to θ). $\chi\Theta = \Theta\chi$, *so* Θ *preserves* $\mathrm{bridgeN}(V_{\Lambda_0})$ *and pulls back to* $\psi \in \mathrm{Aut}\, V_{\Lambda_0}$. *There is a character* $e : \Lambda_0 \to \mathbb{C}^\times$ *with* $\psi = g_e \theta g_e^{-1}$, *where* $g_e(p \otimes e^\lambda) = e(\lambda)p \otimes e^\lambda$; *consequently* $\Theta e^\lambda = e(-\lambda)e(\lambda)^{-1}e^{-\lambda}$ *on* V_{Λ_0} *(in the* `bridgeN` *normalisation).*

    lam0Psi (latChargeGen lam0 γ)
      = (charVal lam0 golayE (-γ) * charVal lam0 (-golayE) γ) • latChargeGen lam0 (-γ)
```

(`VOA/Moonshine/FrameBridgeGolay.lean`.)

From the mathematics to the Lean statement

Fidelity check. `Aut.pullback` (Chapter 31) turns an automorphism preserving the image of an injective VOA homomorphism into an automorphism of the source; its inputs here are injectivity of `bridgeN`, the fact that Θ maps its image onto itself (`golayTheta_range_bridgeN`, from $\chi\Theta = \Theta\chi$), and the homomorphism and ω properties. `lam0.carrier →+ Additive ℂˣ` is a homomorphism $\Lambda_0 \to \mathbb{C}^\times$ written additively; `charLat lam0 e` is g_e (Definition 31.41) and `charVal lam0 e λ` $= e(\lambda)$. The rigidity theorem `lift_eq_conj_theta'` (Theorem 31.42) requires exactly that ψ negate every $\alpha(-1)\mathbf{1}$ (`lam0Psi_hSt`) and map F_λ to $F_{-\lambda}$ (`lam0Psi_chargeSec`); both come from Theorem 39.38 (for general μ one writes $2\mu = \sum_j \mu_j\alpha_j$). The scalar in `lam0Psi_latChargeGen` is $e(-\lambda)\cdot e(\lambda)^{-1} = e(\lambda)^{-2}$, matching the docstring. `golayE` is chosen by `Classical.choose`: an existence statement, not a computation.

Physical meaning

On the common subtheory V_{Λ_0}, the lattice involution Θ coming from the A_1^{24} side differs from the standard θ by a rescaling of the charged states by phases $e(\lambda)$, i.e. by a gauge transformation g_e (a momentum-dependent phase, a conjugation by $e^{i\hat{p}\cdot\phi}$ in the free-field language). This is exactly the statement that Θ and θ are the same symmetry in different cocycle gauges, so their orbifolds are isomorphic; it is what allows the K-orbifold of V_N to be identified with $V_{\Lambda_0}^+$ (cocycle bookkeeping, not new physics).

Proof. $\chi\Theta = \Theta\chi$ because $\Theta F_\lambda \subseteq F_{-\lambda}$ and $\mathrm{par}(-\lambda) = \mathrm{par}(\lambda)$. For the conjugacy, $\psi\theta$ fixes every Heisenberg state and every momentum sector, hence acts on F_λ by a scalar $d(\lambda)$ (a VOA automorphism fixing the Heisenberg subalgebra and preserving F_λ is a scalar there, F_λ being an irreducible Heisenberg module generated by e^λ); multiplicativity of products makes d a character, and over $\mathbb{C}$ a character d has a "square root" character e with $d(\lambda) = e(\lambda)e(-\lambda)^{-1}$, which gives $\psi = g_e\theta g_e^{-1}$ (details in Section 31.12.6). □

39.10.3 The isomorphism and the transported triality

Theorem 39.43 ($V_N^K \cong V_0^+$). *The map $z \mapsto \mathrm{bridgeN}(g_e z)$ is a VOA isomorphism $V_{\Lambda_0}^+ \to V_N^K$; composing its inverse with Theorem 39.41 gives a VOA isomorphism $V_N^K \to V_0^+$ preserving ω.*

```
/-- **`golayV0 ≃ V0P`** (`V_N^{⟨χ,Θ⟩} ≅ V₀⁺`). -/
noncomputable def golayToV0 : (orbifold golayK).carrier ≃ₗ[ℂ] V0Sub.carrier :=
  lam0PlusGolayEquiv.symm.trans lam0PlusEquiv

/-- `golayToV0` is a homomorphism of vertex operator algebras. -/
```

```
theorem golayToV0_isVOAHom : IsVOAHom golayV0 V0P golayToV0.toLinearMap

theorem golayToV0_omega : golayToV0 golayV0.conformalVector = V0P.conformalVector
```

From the mathematics to the Lean statement

Fidelity check. `lam0PlusGolayEquiv` is the bijection $V_{\Lambda_0}^+ \to V_N^K$, $z \mapsto \mathrm{bridgeN}(g_e z)$; `.symm.trans` composes its inverse with `lam0PlusEquiv`. Linear bijection + `IsVOAHom` + ω = VOA isomorphism. Exactly the theorem.

Physical meaning

The orbifold V_N^K of the Niemeier theory is isomorphic to the neutral frame sector V_0^+ of the Leech theory, as vertex operator algebras with the same stress tensor: two different-looking lattice-CFT orbifolds (one from A_1^{24}, one from Leech) are the same chiral algebra. This is the physical content of the statement that the two theories are connected by orbifolding, and sets up the transport of σ to the Leech side. Physical expectations (orbifold equivalence) are heuristics; the isomorphism is established by composing the explicit bridges and gauge transformation.

Proof. $\mathrm{bridgeN}(g_e z)$ is χ-fixed (in the image of `bridgeN`) and $\Theta\,\mathrm{bridgeN}(g_e z) = \mathrm{bridgeN}(\psi g_e z) = \mathrm{bridgeN}(g_e \theta z) = \mathrm{bridgeN}(g_e z)$ for $\theta z = z$; conversely every element of V_N^K arises so. g_e is an automorphism of V_{Λ_0} and `bridgeN` a VOA homomorphism, so the composite is one. □

Definition 39.44 (Transport of automorphisms)**.** For a VOA isomorphism $E : V \to W$ (linear bijection, `IsVOAHom`, $E\omega = \omega$) and $g \in \mathrm{Aut}\, V$, $\mathrm{transport}_E(g) = EgE^{-1} \in \mathrm{Aut}\, W$.

```

    (hω : E V.conformalVector = W.conformalVector) (g : Aut V) : Aut W where
  toLinearEquiv := E.symm.trans (g.toLinearEquiv.trans E)
```

Physical meaning

Transport of structure: given an isomorphism of chiral algebras, a symmetry of one side becomes a symmetry of the other by conjugation. Physically this is a change of description ("relabelling the fields") under which the symmetry acts identically, and is needed here to turn the symmetry σ_0 of the A_1^{24}-side orbifold into a symmetry of the Leech-side V_0^+.

It is multiplicative, sends 1 to 1 and is injective (`Aut.transport_mul`, `Aut.transport_one` and `Aut.transport_injective`) — immediate from $E(gh)E^{-1} = (EgE^{-1})(EhE^{-1})$.

Theorem 39.45 (The triality on V_0^+)**.** $\sigma_{V_0^+} := \mathrm{transport}(\sigma_0)$ *is an automorphism of the VOA* V_0^+ *with* $\sigma_{V_0^+}^2 = 1$, $\sigma_{V_0^+} \neq 1$, *and* $\mathrm{golayToV0} \circ \sigma_0 = \sigma_{V_0^+} \circ \mathrm{golayToV0}$.

From the mathematics to the Lean statement

Fidelity check. `Aut V0P` is the group of automorphisms of the VOA V_0^+ (all products, $\mathbf{1}$, ω). The definition is a one-line transport and is shown in full. The three theorems are exactly the involution, nontriviality and intertwining clauses. How could this have been vacuous? (a) If σ_0 were 1 — excluded by `golaySigma0_ne_one` and injectivity of transport. (b) If the isomorphism `golayToV0` were not a VOA isomorphism — it is (Theorem 39.43). (c) If σ were the wrong involution (e.g. DGM (7.5)) — not excluded by any Lean statement of this chapter; the warning above explains the choice, and Chapters 40–42 confirm it by actually extending σ to $V^\natural$.

Physical meaning

This is the untwisted triality: an order-two automorphism of the frame subtheory V_0^+ of the moonshine module that is not visible from the lattice description, being built from an $SU(2)$ rotation on the A_1^{24} side. It is the hidden symmetry that the Monster requires: the centraliser $2^{1+24}.Co_1$ of the $2B$ involution is visible in the Leech-lattice construction, and adjoining σ generates the full Monster; consistency of the moonshine module as a vertex operator algebra demands the extension of σ to the twisted sectors, which exchanges the odd untwisted sector with the twisted sector T_0^+ (the exchange of untwisted and twisted sectors of the orbifold by θ). This chapter constructs only its action on V_0^+; that the extension exists and that it gives the missing locality are shown in Chapters 40–42. The identification of this σ with a Monster element is part of the physical (heuristic) picture, not of what is proved here.

What the machine verified

Unconditional; `##print axioms v0Sigma_sq, v0Sigma_ne_one`: [`propext`, `Classical.choice`, `Quot.sound`] (re-run for this chapter). No `VOA.pbw`. **Not stated here:** what σ does to the sectors of V_Λ^+ outside V_0^+ — those are not in V_0^+; the twisted extension is Chapters 40–41.

Trap / dead end

`golayE` is not determined, and with it the sector pattern. The character `golayE` is chosen by `Classical.choose` and is pinned only up to a character of the form e_β; replacing it changes the isomorphism `golayToV0` by an automorphism of V_0^+, hence `v0Sigma` by a conjugation, and swaps which twisted frame sector $T_{(s)}^+$ is paired with V_3^+ by the extended σ (finding `golayE_not_determined`, Notes/M8GluingPlan.md). Downstream statements are therefore formulated with $\exists\, s$. This is a feature of the definitions, not an error, but it means no Lean statement asserts "$T_{(0)}^+$ is FLM's T_0^+".

39.11 Summary: what this chapter gives the rest of the proof

1. A decomposition $V^\natural = V_0^+ \oplus V_3^+ \oplus T_{(0)}^+ \oplus T_{(1)}^+$ into V_0^+-modules, with $\mathbb{Z}/2$-graded products on the untwisted side (Theorems 39.6, 39.15, 39.28), and weight-two dimensions 49428, 49152, $24 \cdot 2048$, $24 \cdot 2048$.

2. Explicit cyclic vectors: $\mathbf{1}$, $e^\beta + e^{-\beta}$, $h_0(-\frac{1}{2})\mathbf{1} \otimes t_0$ (Theorems 39.19, 39.21, 39.28). These make σ-twisted module maps out of each sector determined by one value.

3. A nontrivial involutive automorphism `v0Sigma` of V_0^+, built from the explicit (7.8)-modified triality of V_N (Theorem 39.45).

Chapter 40 uses these to reduce the existence of σ on $V_3^+ \to T^+$ and on $T^+ \to T^+$ to finite top-level statements; Chapter 41 proves them; Chapter 42 proves the conjugation identity and deduces (39.1).

39.12 Referee's checklist

All headline declarations below were re-audited for this chapter: `lake build` of the chapter's modules completed successfully (4205 jobs), and `#print axioms` run through `lake env lean -DmaxSynthPendingDepth=3` on a scratch file importing them reported, for each of the 27 names audited,

Evidence that is *not* Lean: the 6372/2324 trace certificate and the Monster bound (paper and Python), the count 98256 of norm-four vectors in Λ_0 (Python; implied by the Lean count of the complement), and the identification of the Lean σ with DGM's exponential formula (the SL_2 identity (39.7), verified by hand above).

Notes and references

The triality strategy is due to I. Frenkel, J. Lepowsky and A. Meurman, *Vertex Operator Algebras and the Monster*, Pure and Applied Mathematics 134, Academic Press, 1988; Chapter 10 treats the $\mathbb{Z}/2$-orbifold structure and the Golay-code frame of the Leech lattice, Chapter 11 the triality, and Chapters 12–13 the main theorem and the completion of the proof. The restatement used throughout this chapter, including the formulas (7.5)–(7.8) for σ on $V_{N(A_1^{24})}$, the necessity of the modification (7.8) when $d/8$ is odd, and the circularity caveat, is L. Dolan, P. Goddard and P. Montague, "Conformal field theories, representations and lattice constructions", Comm. Math. Phys. 179 (1996) 61–120, arXiv:hep-th/9410029 (Sections 4–7; relation (4.23), Propositions 7.1–7.3). The framed point of view — $V^\natural$ as an extension of a code VOA, with Λ_0-type frames — is developed in C. Dong, R. L. Griess Jr. and G. Höhn, "Framed vertex operator algebras, codes and the Moonshine module", Comm. Math. Phys. 193 (1998) 407–448, arXiv:q-alg/9707008, and in M. Miyamoto, "A new construction of the Moonshine vertex operator algebra over the real number field", Ann. of Math. 159 (2004) 535–596, arXiv:q-alg/9701012. Ebeling's model of the Leech lattice used here is in W. Ebeling, *Lattices and Codes*, 3rd ed., Springer Spektrum, 2013, Section 2.8; the Golay code, octads and the Niemeier lattice $N(A_1^{24})$ are in J. H. Conway and N. J. A. Sloane, *Sphere Packings, Lattices and Groups*, 3rd ed., Grundlehren 290, Springer, 1999, Chapters 4, 10, 16 and 18. The Monster character values $4372 = 1 + 4371$ (2A) and $276 = 1 + 275$ (4A) used in the trace bound are from the ATLAS of Finite Groups (Conway, Curtis, Norton, Parker, Wilson, Oxford, 1985). The project-internal record of the decisions, corrections and dead ends of this chapter is Notes/M8GluingPlan.md ("Status and corrections" after M8e, M8g-0, the functoriality bridge and M8f); the dead ends are collected in Section 43.2.

Chapter 40

Existence of the twisted triality I: reduction to Zhu generation

40.1 What this chapter is about

This chapter documents the release of the LeanVOA library named in the front matter. Every Lean quotation below is checked by `scripts/textbook/sync.py` to occur verbatim (up to whitespace and comments) in the source files of that release. Checks that were run at an earlier state of the library and not re-run for this edition are marked as such.

The Moonshine module of Frenkel, Lepowsky and Meurman is the vector space

$$V^\natural \;=\; V_\Lambda^+ \;\oplus\; (V_\Lambda^T)^+,$$

the θ-fixed part of the Leech lattice vertex operator algebra together with the θ-fixed part of its θ-twisted module. Earlier chapters of the Moonshine Part built both summands and the vertex operators on the four "blocks" (untwisted × untwisted, untwisted × twisted, twisted × untwisted, twisted × twisted), and reduced the Jacobi identity of $V^\natural$ to one family of identities. The tool FLM use to control the twisted × twisted block is the *triality*: an extra symmetry σ of $V^\natural$ that mixes the untwisted and the twisted summands.

To describe σ one refines the decomposition of $V^\natural$ by a *Golay frame* (Chapter 39): the description of Λ through the Golay code together with the vector $w = 8e_0$, which singles out a sublattice and two involutions, recalled precisely in §40.2. There is an index-two sublattice $\Lambda_0 \subset \Lambda$, an involution g of V_Λ^+ acting by -1 on the charges outside Λ_0, and a matching involution J on the twisted space. They split

$$V^\natural \;=\; V_0^+ \;\oplus\; V_3^+ \;\oplus\; T_0^+ \;\oplus\; T_1^+, \tag{40.1}$$

where V_0^+ is the g-fixed part of V_Λ^+ (a vertex operator algebra, isomorphic to $V_{\Lambda_0}^+$), V_3^+ the $g=-1$ part of V_Λ^+, and T_s^+ ($s \in \mathbb{Z}/2$) the two J-eigenspaces of $(V_\Lambda^T)^+$. The triality restricts to an automorphism $\sigma \in \mathrm{Aut}\, V_0^+$ of order two, constructed in Chapter 39 from the Golay code, and FLM's theorem says that σ extends to all of $V^\natural$, exchanging V_3^+ with one of the two twisted sectors and mapping the other twisted sector to itself.

Extending σ means constructing linear maps

$$\Phi : V_3^+ \to T_s^+, \qquad \Phi(u_{(n)}x) = (\sigma u)_{(n)}\,\Phi(x) \quad (u \in V_0^+,\ n \in \mathbb{Z},\ x \in V_3^+), \tag{40.2}$$

and similarly $T_{s'}^+ \to T_{s'}^+$. A map with property (40.2) is called a *σ-twisted intertwiner*. Physically: V_0^+ is a chiral algebra, V_3^+ and T_s^+ are two of its superselection sectors, and σ is a symmetry of the chiral algebra; the question is whether the sector V_3^+, with every field twisted by σ, is equivalent to a twisted sector. The difficulty is that (40.2) is a condition on infinitely many modes of infinitely many states; neither Dolan–Goddard–Montague nor the modern literature writes the map down explicitly on twisted states.

This chapter proves, in Lean, that the existence of such maps follows from a *finite* statement about the weight-two top levels of the modules (each 49152-dimensional), and that this finite statement need only be checked for the zero modes of *weight-two* states of V_0^+. The second half of that sentence is the theorem that the weight-two subspace *Zhu-generates* V_0^+:

every subspace of V_0^+ containing $\mathbf{1}$, $\mathcal{O}(V_0^+)$, $(V_0^+)_2$ and closed under Zhu's product $*$ is all of V_0^+.

That theorem, `VOA.Moonshine.zhuGenerated_weightTwo`, is the headline of the chapter. Its proof mixes vertex algebra (a filtered form of the commutator formula in Zhu's algebra), explicit Heisenberg computations, and the combinatorics of the extended binary Golay code, including a counting proof of the existence of the Steiner system $S(5, 8, 24)$ (a family of 8-element subsets, the *octads*, of a 24-element set such that every 5-element subset lies in exactly one of them). The weight-two identities themselves, and hence the existence of σ, are the subject of Chapter 41.

The chain of reductions

The logical structure is a chain of implications, each a Lean theorem. Reading from the goal backwards:

(1) A σ-twisted intertwiner Φ with $\Phi(x_0) = y_0$ exists if and only if every linear relation among the vectors $u^1_{(n_1)} \cdots u^k_{(n_k)} x_0$ also holds among the vectors $(\sigma u^1)_{(n_1)} \cdots (\sigma u^k)_{(n_k)} y_0$ ("annihilator compatibility"; §40.4).

(2) Annihilator compatibility follows from a linear map φ on the top level that intertwines the zero modes $o(a)$ of all homogeneous $a \in V_0^+$, maps into the right sector, and is non-zero in a precise sense (§40.6). The proof uses Li's single-mode spanning lemma and a nondegenerate invariant form on the target only.

(3) Intertwining the zero modes of *all* a follows from intertwining those of a Zhu-generating set G (§40.7). This is the "easy direction" of Zhu's theory: zero modes on a lowest-weight space multiply according to $*$ and kill $\mathcal{O}(V)$.

(4) $G = (V_0^+)_2$ is Zhu-generating (§§40.9–40.13).

Every step is `#print axioms`-clean (only `propext`, `Classical.choice`, `Quot.sound`), and none uses `VOA.pbw` (the PBW theorem of Chapter 3; formerly a project axiom, now a theorem). Step (2) was deliberately designed to avoid the library's Verma-module route, which would then have imported the axiom `VOA.pbw` (§40.3.4).

How to read this chapter

Following the book's constitution, each definition and theorem is presented as: mathematical statement; the Lean declaration copied verbatim, with its file; a *fidelity check* (the box "From the mathematics to the Lean statement") which decodes the Lean statement, lists every hypothesis, and says whether the Lean statement is the same as, stronger or weaker than the mathematics and why it is not vacuous; a proof on paper; and a status box recording what the machine verified. Proof bodies are not reproduced. The chapter ends with a referee's checklist (§40.15).

40.2 The objects, recalled

40.2.1 Standing conventions: modes

Throughout this chapter a field is written $Y(u, z) = \sum_{n \in \mathbb{Z}} u_{(n)} z^{-n-1}$, and $u_{(n)}$, the coefficient of z^{-n-1}, is the *n-th mode* of u; for states u, v of a VOA, $u_{(n)}v$ is the *n-th product*. If u has weight k, then

$u_{(n)}$ raises weights by $k-n-1$; so $u_{(k-1)}$ preserves weight (the zero mode $o(u)$ of §40.3), $u_{(-1)}$ is the normal-ordered product ($u_{(-1)}\mathbf{1}=u$), and $u_{(n)}\mathbf{1}=0$ for $n\geq 0$. In Lean a field is stored as a function of the exponent, and `mode f n` returns the coefficient at exponent $-n-1$ (Definition 2.7); thus `mode (Y u) n` $= u_{(n)}$ and `W.smul u n v` $= u_{(n)}v$. For a module, `A.act u n x` (or `mode (M.YM u) n x`) is $u_{(n)}x$. On the plus part of the twisted module the integer mode $u_{(n)}$ is stored at the doubled index $2n$ (`mode_plusModule`, below). Weak modules (Definition 12.1) are vector spaces with such fields satisfying the vacuum axiom, truncation ($u_{(n)}x=0$ for $n\gg 0$) and the Jacobi identity; ordinary modules (`OrdVModule`) additionally carry an L_0-grading with finite-dimensional weight spaces and weights bounded below. The statements of this chapter mention a handful of objects constructed earlier in the Moonshine Part. We recall each of them with its Lean source and meaning; full treatments are in the chapters indicated.

40.2.2 Lattices: Λ and Λ_0

The Leech lattice is realised in the library as a sublattice of $\mathbb{Z}^{24}$ with the form $\langle x,y\rangle = x\cdot y/8$ ("$\sqrt{8}$-coordinates"): Λ consists of integer vectors all of whose coordinates have the same parity, subject to Golay-code and congruence conditions recalled in Chapter 30. Its Lean name is `leech`, its carrier type `leech.carrier` and its form `leech.form`. The map

$$\beta : \Lambda \to \mathbb{Z}/2, \qquad x \mapsto x_0 \bmod 2$$

(all coordinates have the same parity; read it off coordinate 0) is a homomorphism; its kernel is the index-two sublattice $\Lambda_0=\ker\beta$ of vectors with all coordinates even. File `VOA/Moonshine/FrameSectors.lean`.

```
noncomputable def frameChar : leech.carrier →+ ZMod 2 := Leech.beta.toAddMonoidHom

noncomputable def lambda0 : Submodule ℤ leech.carrier := LinearMap.ker Leech.beta
```

(`VOA/Moonshine/FrameSectors.lean`; `Leech.beta` is defined in `VOA/LatticesAndCodes/Leech/Defs.lean` by `toFun x := ((((x : Fin 24 → ℤ) 0 : ℤ)) : ZMod 2)`.)

Halving the even vectors gives a second model of Λ_0, used in §40.12:

$$A = \{g\in\mathbb{Z}^{24} \;:\; g \bmod 2 \in \mathcal{G},\ \textstyle\sum_i g_i \equiv 0 \pmod 4\}, \qquad \langle g,h\rangle = \tfrac{1}{2}\,g\cdot h, \tag{40.3}$$

where $\mathcal{G}\subset\mathbb{F}_2^{24}$ is the extended binary Golay code. In Lean A is `Leech.subA`; the isometry $A\cong\Lambda_0$, $g\mapsto 2g$, is `lambda0Equiv`, with `lambda0Equiv_form` stating $\langle \iota a,\iota b\rangle_\Lambda = (a\cdot b)/2$. In the A-model, $|\gamma|^2=\frac{1}{2}g\cdot g$. Since Λ has no roots, every non-zero vector has $|\gamma|^2\geq 4$; in A-coordinates $g\cdot g\geq 8$.

40.2.3 The vertex algebras V_Λ^+ and V_0^+

V_Λ (Lean: `leechVOA`, carrier `LatModuleGen leech`) is the lattice vertex operator algebra (Chapter 31): as a vector space $M(1)\otimes\mathbb{C}[\Lambda]$, the Fock space of 24 free bosons tensored with the group algebra of the lattice, spanned by the states $h_{a_1}(-n_1)\cdots h_{a_r}(-n_r)\otimes e^\gamma$ of weight $\sum n_i+\frac{1}{2}|\gamma|^2$. The involution θ lifts -1 on Λ (Chapter 32); V_Λ^+ is its fixed points: File `VOA/Moonshine/FrameSectors.lean`.

```
abbrev VPlus : Type := ↥(orbifold (Subgroup.zpowers leechTheta)).carrier
```

(`VOA/Moonshine/FrameSectors.lean`.) Here `orbifold H` is the subalgebra of fixed points of a group H of automorphisms, `Subgroup.zpowers leechTheta` is the group generated by θ, and `↥` turns a subspace into the type of its elements. So `VPlus` is the type of vectors of V_Λ^+; `leechVOAPlus` is the VOA structure on it.

The Golay frame gives the involution $g(p\otimes e^\gamma)=(-1)^{\beta(\gamma)}p\otimes e^\gamma$ of V_Λ, which commutes with θ and restricts to V_Λ^+ (Lean: `plusFrameAut`). Its eigenspaces are the *frame sectors*: File `VOA/Moonshine/FrameSectors.lean`.

```
noncomputable def frameSector (i : ZMod 2) : Submodule ℂ VPlus :=
  Module.End.eigenspace (plusFrameAut.toLinearEquiv : Module.End ℂ VPlus)
    (Moonshine.Extraspecial.sgn i)
```

with `Extraspecial.sgn i` $= (-1)^i$. So `frameSector 0` is V_0^+ (charges in Λ_0) and `frameSector 1` is V_3^+ (charges in $\Lambda \setminus \Lambda_0$). The fixed subalgebra is a VOA: File `VOA/Moonshine/FrameSectors.lean`.

```
noncomputable def V0Sub : VOASubalgebra leechVOAPlus := orbifold (Subgroup.zpowers
 ↪  plusFrameAut)

noncomputable def V0P : VertexOperatorAlgebra V0Sub.carrier := V0Sub.toVOA
```

and `V0Sub_carrier : V0Sub.carrier = frameSector 0`. Elements of V_0^+ have type `V0Sub.carrier`, a subtype of `VPlus`; the coercion `(u : VPlus)` forgets that u lies in V_0^+.

The basic vectors of charge $\pm\beta$ are (`VOA/Moonshine/CyclicFrameSectors.lean`) File `VOA/Moonshine/CyclicFrameSector`

```
noncomputable def frameX0 (β : leech.carrier) : LatModuleGen leech :=
  latChargeGen leech β + latChargeGen leech (-β)

noncomputable def frameX0P (β : leech.carrier) : VPlus := ⟨frameX0 β, frameX0_mem_plus β⟩
```

so `frameX0P β` is $x_\beta = e^\beta + e^{-\beta} \in V_\Lambda^+$ (the library's θ sends $e^\beta \mapsto e^{-\beta}$ on charged vacua). It has weight $\frac{1}{2}|\beta|^2$, and lies in V_0^+ if $\beta \in \Lambda_0$, in V_3^+ if $\beta \notin \Lambda_0$. The projection $P = \frac{1}{2}(1+\theta) : V_\Lambda \to V_\Lambda^+$ is `plusProj` (`VOA/Moonshine/Generation.lean`).

40.2.4 The twisted sectors T_s^+

The θ-twisted V_Λ-module is $V_\Lambda^T = S[\theta] \otimes T$, where $S[\theta]$ is the Fock space of 24 bosons with half-integral modes $h_a(-\frac{1}{2}), h_a(-\frac{3}{2}), \ldots$ and T is the 2^{12}-dimensional irreducible module of the extraspecial group (Chapters 34–36). In Lean the carrier is `Tw`, the T-factor `TLeechT`, and $(V_\Lambda^T)^+$, the fixed space of the lift of θ, is (`VOA/Moonshine/TwistedPlus.lean`) File `VOA/Moonshine/TwistedPlus.lean`.

```
noncomputable abbrev TP : Submodule ℂ Tw := plusSub leechThetaLift

noncomputable def plusModule : OrdVModule leechVOAPlus TP :=
  TwistedPlus.plusModule leechThetaLift
```

`plusModule` is $(V_\Lambda^T)^+$ as an *ordinary* module for V_Λ^+ (graded by L_0, finite-dimensional weight spaces, weights bounded below); its integer mode $u_{(n)}$ is the twisted mode of index n, stored at the doubled index $2n$ (`mode_plusModule`). The lowest weight of V_Λ^T is $24/16 = 3/2$, carried by $\mathbf{1} \otimes T$; but the lift of θ acts there by -1 (FLM's normalisation, adopted by the library), so the lowest weight of $(V_\Lambda^T)^+$ is 2, carried by $h_a(-\frac{1}{2})\mathbf{1} \otimes T$ (dimension $24 \cdot 2^{12} = 98304$).

The frame involution J on T is $c^{-1}e_w$ for $w = 8e_0$ (`frameW`), normalised so that $J^2 = 1$. Its eigenspaces T_s (`leechFrameT s`, each of dimension 2^{11}) give (`VOA/Moonshine/CyclicTwisted.lean`) File `VOA/Moonshine/CyclicTwisted.lean`.

```
noncomputable def TPframe (s : ZMod 2) : Submodule ℂ TP := (twFrameL s).comap TP.subtype

noncomputable def frameX0T (t₀ : TLeechT) : Tw := (X (0, 0) : FockT 24) ⊗ₜ t₀
```

i.e. $T_s^+ = (V_\Lambda^T)^+ \cap (S[\theta] \otimes T_s)$, and `frameX0T t₀` is $h_0(-\frac{1}{2})\mathbf{1} \otimes t_0$ (`X (0, 0)` is the lowest creation operator of the first boson). Its copy in `TP` is called `x0T t₀` below.

Finally `TPForm` (`VOA/Moonshine/InvFormTP.lean`) is the symmetric bilinear form on $(V_\Lambda^T)^+$ obtained by restricting the invariant form of the twisted module (Chapter 37). Two of its properties are used: it is *FHL-invariant* (`TPForm_fhlInv`: for u homogeneous of weight k, the adjoint of $u_{(r)}$ is $\sum_{j\ge 0} \frac{(-1)^k}{j!}(L_1^j u)_{(2k-r-2-j)}$), and it is *nondegenerate* (`SimpleNat.TPForm_eq_zero_of_forall`, `VOA/Moonshine/SimpleForm.lean`: if $\langle t, y\rangle = 0$ for all y then $t = 0$).

40.2.5 The triality on V_0^+

Chapter 39 constructs an automorphism of V_0^+ by transporting the Dolan–Goddard–Montague triality $\sigma = G(\chi z_0)G^{-1}$ of the Golay-code lattice VOA $V_{N(A_1^{24})}$ along an isomorphism of its fixed-point subalgebra with V_0^+ (`VOA/Moonshine/FrameBridgeGolay.lean`): File `VOA/Moonshine/FrameBridgeGolay.lean`.

```
noncomputable def v0Sigma : Aut V0P :=
  Aut.transport golayToV0 golayToV0_isVOAHom golayToV0_omega golaySigma0
```

with `v0Sigma_sq : v0Sigma * v0Sigma = 1` and $\sigma \neq 1$. As an automorphism, σ fixes $\mathbf{1}$ and ω, preserves the grading, and satisfies $\sigma(u_{(n)}v) = (\sigma u)_{(n)}(\sigma v)$. The isomorphism `golayToV0` contains a character `golayE` chosen by `Classical.choose`; this matters in §40.5.1.

40.3 Zhu's algebra and the Zhu correspondence

Zhu's algebra is treated for general VOAs in Chapter 12; we recall here exactly what this chapter uses, so that every statement below can be checked without leaving the chapter.

40.3.1 Motivation: what the lowest weight space sees

Let V be a vertex operator algebra and M an ordinary V-module whose weights lie in $h + \mathbb{N}$ for some $h \in \mathbb{C}$: we say M has *lowest weight* h and call M_h its *top level*. Physically, M is a sector of a chiral conformal field theory and M_h its space of ground states; a field $Y(a,z) = \sum_n a_{(n)}z^{-n-1}$ with $a \in V_k$ moves weights by $a_{(n)} : M_\mu \to M_{\mu+k-n-1}$. Exactly one mode preserves weights,

$$o(a) \;:=\; a_{(k-1)} \qquad (a \in V_k),$$

extended linearly to all of V: the *zero mode* (the physicist's a_0). On M_h, all modes $a_{(n)}$ with $n > k-1$ vanish, since they would lower the weight below h. So the only operators V induces on M_h are the zero modes, and M_h is a module for the algebra they generate.

Zhu's insight is that this algebra is a quotient of an algebra built from V alone:

(i) the composite $o(a)o(b)$ on M_h is again a zero mode $o(a * b)$, for an explicit bilinear product $*$ on V;

(ii) an explicit subspace $\mathcal{O}(V) \subset V$ has zero modes vanishing on every top level.

Then $A(V) = V/\mathcal{O}(V)$ with $*$ is an associative algebra (Zhu's theorem) and every top level is an $A(V)$-module; conversely (the hard direction) every $A(V)$-module is the top level of some V-module.

40.3.2 The Zhu product and $\mathcal{O}(V)$

Definition 40.1 (Zhu product)**.** For $a \in V_k$ and $b \in V$,

$$a * b \;=\; \operatorname{Res}_z\, Y(a,z)\, b\, \frac{(1+z)^k}{z} \;=\; \sum_{m=0}^{k} \binom{k}{m} a_{(m-1)}b,$$

extended linearly in a over the grading.

File `VOA/Modules/ZhuAlgebra.lean`.

```
noncomputable def zhuFamily (W : VertexOperatorAlgebra 𝒱) (v : 𝒱) (k : ℤ) :
    (W.grading k) →ₗ[ℂ] 𝒱 where  toFun uk := ∑ m ∈ Finset.range (k.toNat + 1), cbz k m •
    ↪  W.smul (uk : 𝒱) ((m : ℤ) - 1) v
  ...
noncomputable def zhuMul (W : VertexOperatorAlgebra 𝒱) (u v : 𝒱) : 𝒱 :=
  letI := DirectSum.IsInternal.chooseDecomposition W.grading W.isInternal
  (DFinsupp.lsum ℂ (zhuFamily W v)) (DirectSum.decompose W.grading u)
```

(`VOA/Modules/ZhuAlgebra.lean`; the linearity proofs inside `zhuFamily` are omitted.)

From the mathematics to the Lean statement

- `W.smul u n v` is the n-th product $u_{(n)}v$, the coefficient of z^{-n-1} in $Y(u,z)v$. (Generally, `mode f n` denotes the coefficient $u_{(n)}$ of a field f.)
- `cbz k m` is the generalised binomial coefficient $\binom{k}{m}$; for $0 \le m \le k$ the ordinary one. The sum over `Finset.range (k.toNat + 1)`, i.e. $m = 0, \dots, k$, is the full residue, as $\binom{k}{m} = 0$ for $m > k \ge 0$.
- `W.grading k` is V_k, and `W.isInternal` says $V = \bigoplus_k V_k$ (`DirectSum.IsInternal`). `DirectSum.decompose` splits u into homogeneous components and `DFinsupp.lsum` applies `zhuFamily W v k` to the weight-k component and sums: "extend linearly over the grading".
- Same as the textbook definition.

Physical meaning

The Zhu product is the zero-mode algebra written at the level of states: acting with the zero mode $o(a)$ on a ground state x of any sector and then with $o(b)$ gives $o(a * b)x$ (Theorem 40.5). The binomial weighting $(1+z)^k/z$ is the radial-quantisation factor that converts the plane field $Y(a,z)$ of weight k into the cylinder field, whose constant Fourier mode is the zero mode. Heuristically, $a * b$ is the ordering-corrected product of the two zero-mode operators; it is noncommutative because $[o(a), o(b)]$ is nonzero already on ground states.

Definition 40.2 ($\mathcal{O}(V)$ and Zhu's algebra)**.** $\mathcal{O}(V)$ is the span of the elements $(L_{-1}u + L_0 u) * v$, $u, v \in V$; and $A(V) = V/\mathcal{O}(V)$.

File `VOA/Modules/ZhuAlgebra.lean`.

```
def O (W : VertexOperatorAlgebra 𝒱) : Submodule ℂ 𝒱 :=
  Submodule.span ℂ {x | ∃ u v : 𝒱, x = zhuMul W (W.L (-1) u + W.L 0 u) v}

abbrev A (W : VertexOperatorAlgebra 𝒱) : Type u := 𝒱 ⧸ O W
```

(`VOA/Modules/ZhuAlgebra.lean`.)

From the mathematics to the Lean statement

- Zhu's original generators are $a \circ b = \mathrm{Res}_z\, Y(a,z)b\,(1+z)^k/z^2$, $a \in V_k$. The library uses Gannon's generating set $(L_{-1} + L_0)u * v$ (*Moonshine beyond the Monster*, (5.3.8c)); the library proves that Zhu's $a \circ b$ lies in this span (`residue_base_mem_O`, the case $k = 0$ of Lemma 40.3(b)). This chapter only uses that $\mathcal{O}(V)$ contains the elements listed in Lemma 40.3 and that its zero modes vanish on top levels (Theorem 40.5), both proved for the library's definition.
- `Submodule.span ℂ S` is the complex linear span of S. `W.L n` is L_n.
- $A(V)$ is introduced only as a vector space here. We do *not* need that $*$ descends to an associative product on $A(V)$; the notion of Zhu generation (Definition 40.36) is formulated on V, so it never mentions the quotient ring.

Physical meaning

$\mathcal{O}(V)$ collects the combinations that vanish as operators on every ground state: total derivatives $L_{-1}u$ combined with L_0u are exactly the states whose zero mode is zero on lowest-weight states, since $o(L_{-1}u + L_0u) = 0$ there. The quotient $A(V)$ is thus the algebra of zero modes acting on the ground states of all sectors (the Zhu algebra), and its irreducible representations are the candidate ground-state spaces of irreducible sectors. This is the standard dictionary behind "a rational VOA has finitely many sectors"; the definition itself is purely algebraic.

Lemma 40.3 (What $\mathcal{O}(V)$ contains). *Let $a \in V_p$ with $p \in \mathbb{N}$, $b \in V$, and $y \in V_w$.*

(a) $L_{-1}y + L_0y \in \mathcal{O}(V)$; hence $L_{-1}y + w\,y \in \mathcal{O}(V)$.

(b) (Frenkel–Zhu higher residues) For every $k \in \mathbb{N}$,

$$\mathrm{Pres}(a,p,b,k) \;:=\; \sum_{i=0}^{p+k} \binom{p+k}{i} a_{(i-2-k)}b \;=\; \mathrm{Res}_z\, Y(a,z)b\,\frac{(1+z)^{p+k}}{z^{2+k}} \;\in\; \mathcal{O}(V).$$

File `VOA/Moonshine/ZhuGenFiltration.lean`.

```
theorem L_neg_one_add_mem_O (y : V) : W.L (-1) y + W.L 0 y ∈ O W

```

(`VOA/Moonshine/ZhuGenFiltration.lean`, namespace `VOA.Moonshine.ZhuGen`), and File `VOA/Modules/ZhuModule.lean`.

```
noncomputable def Pres (W : VertexOperatorAlgebra V) (M : ℕ) (a b : V) (n : ℕ) : V :=
  ∑ i ∈ Finset.range (M + n + 1), cbz ((M : ℤ) + n) (i : ℤ) • W.smul a ((i : ℤ) - 2 - n) b

theorem Pres_mem_O (W : VertexOperatorAlgebra V) {M : ℕ} {a : V}
    (ha : a ∈ W.grading (M : ℤ)) (b : V) (n : ℕ) : Pres W M a b n ∈ O W
```

(`VOA/Modules/ZhuModule.lean`.)

From the mathematics to the Lean statement

- On V_w, L_0 acts by w (`L_zero_grading`); so (a) is literally $(L_{-1} + L_0)y \in \mathcal{O}$ and its homogeneous form.
- In `Pres W M a b n`, M is the weight p of a (hypothesis `ha`) and n the depth k. The sum runs over $i = 0, \dots, M+n$ with coefficient $\binom{M+n}{i}$ and mode $i - 2 - n$: the display.

Physical meaning

Part (a) says that a field plus its derivative is an operator identity on ground states (a total z-derivative has no zero mode), and (b) is the higher-residue version of the same cancellation. Lemma-level bookkeeping in the reduction of an operator on a sector to its action on ground states.

Proof on paper. (a) Take $v = \mathbf{1}$ in the generator: $c * \mathbf{1} = c$ for every c, because only the $m = 0$ term $c_{(-1)}\mathbf{1} = c$ survives ($c_{(n)}\mathbf{1} = 0$ for $n \geq 0$). (b) For $k = 0$ this is Zhu's $a \circ b$, which is a generator rewritten with $(L_{-1}a)_{(n)} = -n\,a_{(n-1)}$. The induction on k uses the residue identity

$$(k+2)\,\mathrm{Pres}(a,p,b,k+1) \;=\; \mathrm{Pres}(L_{-1}a,\; p+1,\; b,\; k) + (p+k+1)\,\mathrm{Pres}(a,p,b,k),$$

which is integration by parts: $Y(L_{-1}a,z) = \partial_z Y(a,z)$ and $\mathrm{Res}_z\,\partial_z(\cdots) = 0$. Both terms on the right are in $\mathcal{O}$ by induction (the first with $L_{-1}a$ of weight $p+1$). □

What the machine verified

Proved, unconditional, no `VOA.pbw`.

40.3.3 Zero modes on a lowest-weight space: the easy direction

Definition 40.4 (Zero mode, lowest weight). For an ordinary module N (Lean: `OrdVModule W M`; a module graded by L_0-eigenvalues $\alpha \in \mathbb{C}$, with finite-dimensional weight spaces and weights bounded below), the zero mode of $a = \sum_k a_k$ is $o(a) = \sum_k (a_k)_{(k-1)}$. N has lowest weight h if every non-zero weight space N_α has $\alpha \in h + \mathbb{N}$.

File `VOA/Modules/Character.lean`.

```
noncomputable def oModFamily (N : OrdVModule W M) (k : ℤ) : (W.grading k) →ₗ[ℂ] End ℂ M :=
  (modeLinear (k - 1)).comp (N.YM.comp (W.grading k).subtype)

noncomputable def oMod (N : OrdVModule W M) : 𝒱 →ₗ[ℂ] End ℂ M :=
  letI := DirectSum.IsInternal.chooseDecomposition W.grading W.isInternal
  (DFinsupp.lsum ℂ (oModFamily N)).comp (DirectSum.decomposeLinearEquiv
   ↪ W.grading).toLinearMap
```

(`VOA/Modules/Character.lean`), and File `VOA/Modules/ZeroModeMult.lean`.

```
def IsLowestWeight (N : OrdVModule W M) (h : ℂ) : Prop :=
  ∀ α : ℂ, N.weight α ≠ ⊥ → ∃ n : ℕ, α = h + n
```

(`VOA/Modules/ZeroModeMult.lean`).

From the mathematics to the Lean statement

- `modeLinear (k - 1)` extracts the mode $(\cdot)_{(k-1)}$ of a field; `N.YM` is the module vertex operator. So `oModFamily N k` sends $a_k \in V_k$ to $(a_k)_{(k-1)}$ on N, and `oMod` sums over components.
- `N.weight α` is N_α; `≠ ⊥` means "non-zero subspace". `IsLowestWeight N h` is "every non-zero weight space has weight in $h + \mathbb{N}$". It does not require $N_h \neq 0$ (a zero module has every lowest weight); harmless, since the theorems below concern maps on N_h.

Physical meaning

The zero mode $o(a)$ is the L_0-preserving part of the field $a(z)$, the only part that maps each energy eigenspace to itself; the lowest-weight space N_h is the space of ground states (primaries) of the sector, with energy h the conformal weight of the sector. A "module of lowest weight h" is one whose energies are bounded below by the ground-state energy, as in any unitary sector with a vacuum-like lowest state; for the three sectors here the ground energy is 2 (conformal weight two states).

Theorem 40.5 (Zhu's easy direction). *Let N have lowest weight h and $x \in N_h$. For all $u, v \in V$: $o(u * v)x = o(u)o(v)x$; $o(a)x = 0$ for $a \in \mathcal{O}(V)$; $o(u)x \in N_h$; and $o(\mathbf{1}) = \mathrm{id}$.*

File `VOA/Modules/ZhuModule.lean`.

```
theorem oMod_zhuMul_lowest_all (N : OrdVModule W Mod) {h : ℂ} (hcw : IsLowestWeight N h)
    (u v : 𝒱) {x : Mod} (hx : x ∈ N.weight h) :
    oMod N (zhuMul W u v) x = oMod N u (oMod N v x)

theorem O_le_ker_rhoLW (N : OrdVModule W Mod) {h : ℂ} (hcw : IsLowestWeight N h) :
    O W ≤ LinearMap.ker (rhoLW N h)
```

(`VOA/Modules/ZhuModule.lean`), together with `oMod_preserves_lowest_all` (same file) and `oMod_vacuum : oMod N W.vacuum = LinearMap.id` (`VOA/Modules/Character.lean`).

From the mathematics to the Lean statement

`rhoLW N h` is the linear map $V \to \mathrm{End}(N_h)$, $a \mapsto o(a)|_{N_h}$; "$\mathcal{O}(V) \le \ker$" is $o(a)|_{N_h} = 0$ for $a \in \mathcal{O}(V)$. All u, v are arbitrary and h is any complex number: the textbook statement.

Physical meaning

This is the statement that the ground states of a sector form a representation of the Zhu algebra: the zero modes act on the ground states, kill $\mathcal{O}(V)$, and multiply as the Zhu product. Physically it expresses that the algebra of zero modes preserves the ground-state space, and that the OPE collapses, on ground states, to the associative algebra $A(V)$. The converse (the "hard direction", that every $A(V)$-module is the ground-state space of a sector) is the Verma-type reconstruction and is deliberately avoided in this chapter.

Proof on paper. For homogeneous $u \in V_k$, the Borcherds identity expresses each mode of $u_{(m-1)}v$ as a combination of products $u_{(i)}v_{(j)}$ and $v_{(j)}u_{(i)}$. On N_h, every product in which the right-hand factor lowers the weight vanishes; after summing over m with the coefficients $\binom{k}{m}$ of $*$, binomial identities collapse the surviving terms to $o(u)o(v)$. This is Zhu (1996), Theorem 2.1.2 (Gannon (5.3.9a)); linearity extends it to all u, v. For $\mathcal{O}$: translation covariance $(L_{-1}u)_{(n)} = -n\,u_{(n-1)}$ gives $o(L_{-1}u) = (L_{-1}u)_{(k)} = -k\,u_{(k-1)}$, so $o((L_{-1}+L_0)u) = 0$, and then $o(((L_{-1}+L_0)u) * v)x = o((L_{-1}+L_0)u)\,o(v)x = 0$. □

What the machine verified

All proved, unconditional, `#print axioms`-clean, no `VOA.pbw`.

40.3.4 The hard direction, and why this chapter avoids it

Zhu's theorem has a converse: from an $A(V)$-module U one builds a V-module $L(U)$ with top level U, the irreducible quotient of a generalised Verma module $M(U)$ (Dong–Li–Mason; the library follows Dong–Jiang, Chapter 13). The classical way to build a module map out of a module generated by its top level uses this converse: if source and target are irreducible quotients of Verma modules, a map of top levels lifts.

Trap / dead end

The Verma-module route is not `VOA.pbw`-free (history). The library's Dong–Jiang construction carries a hypothesis `BottomProjection` (`VOA/Modules/ZhuVermaAnArchDLM3Survival.lean`), whose only supplier for a general VOA is `voaPBWBottomProjection`, i.e. `VOA.pbw` — at the time an axiom (it has since become a theorem). Using it would then have made σ, and hence the Moonshine module, depend on an axiom. This chapter therefore proves directly the weaker statement actually needed (§40.6), using Li's lemma and a nondegenerate form on the *target* only. The final construction of $V^\natural$ is `VOA.pbw`-free (checked by `#print axioms`).

40.3.5 Examples

Example 40.6 (Rank-one Heisenberg)**.** For the Heisenberg VOA $M(1)$ of one boson h, $A(M(1)) \cong \mathbb{C}[x]$ with $x = [h(-1)\mathbf{1}]$: the top of the Fock module of momentum λ is $\mathbb{C}e^\lambda$ and $o(h) = h(0)$ acts by λ. The fixed-point algebra $M(1)^+$ under $h \mapsto -h$ is generated by ω and a weight-four primary J (Dong–Nagatomo), and $A(M(1)^+)$ needs $[J]$ besides $[\omega]$: weight two alone does *not* generate. In

§40.11 this rank-one obstruction re-appears as a one-dimensional deficiency at weight 4, and we see why it disappears in rank ≥ 3. Concretely: in rank one, the products allowed by the filtered criterion of §40.9 span a codimension-one subspace of the weight-4 part of $M(1)^+$, the missing direction being that of J.

Example 40.7 (Lattice VOA tops)**.** For a lattice VOA V_L and its module $V_{L+\lambda}$, the top level is spanned by e^μ with $\mu \in L+\lambda$ of minimal norm. For $\gamma \in L$ the zero mode $o(e^\gamma) = e^\gamma_{(|\gamma|^2/2-1)}$ sends e^μ to $\epsilon(\gamma,\mu)e^{\mu+\gamma}$ if $\langle\gamma,\mu\rangle = -\frac{1}{2}|\gamma|^2$ (equivalently $|\mu+\gamma|^2 = |\mu|^2$) and to 0 if $\langle\gamma,\mu\rangle > -\frac{1}{2}|\gamma|^2$; the case $\langle\gamma,\mu\rangle < -\frac{1}{2}|\gamma|^2$ cannot occur, since $\mu+\gamma \in L+\lambda$ would be shorter than μ. For V_0^+ acting on V_3^+ this is the computation behind §40.8: the weight-two lattice states $e^\gamma + e^{-\gamma}$, $|\gamma|^2 = 4$, move the top vectors e^n, $|n|^2 = 4$, to $e^{n+\gamma}$ exactly when $\langle\gamma, n\rangle = -2$.

40.4 Twisted intertwiners and the existence criterion

This section is pure linear algebra; no vertex algebra appears. It isolates the device by which σ will be *defined*: a map determined by its value on one vector, which exists as soon as that value respects every linear relation.

40.4.1 The abstract setting

Fix a set $\mathcal{A}$ of "letters" (later: the states of V_0^+), complex vector spaces M, N, actions $\rho : \mathcal{A}\times\mathbb{Z} \to \mathrm{End}(M)$, $(u,n) \mapsto \rho_{u,n}$, and $\tau : \mathcal{A}\times\mathbb{Z} \to \mathrm{End}(N)$ (later: $\rho_{u,n} = u_{(n)}$ on the source and $\tau_{u,n} = u_{(n)}$ on the target), and a map $g : \mathcal{A} \to \mathcal{A}$ (later: σ).

Definition 40.8 (Twisted intertwiner)**.** Let $S \subseteq \mathcal{A}$ and $X \leq M$. A linear map $\Phi : M \to N$ is a *g-twisted intertwiner on X for the letters S* if $\Phi(\rho_{u,n}x) = \tau_{g(u),n}\Phi(x)$ for all $u \in S$, $n \in \mathbb{Z}$, $x \in X$.

File `VOA/Moonshine/TrialityTwGeneric.lean`.

```
def IsTwInt (ρ : A → ℤ → M →ₗ[ℂ] M) (τ : A → ℤ → N →ₗ[ℂ] N) (g : A → A) (S : Set A)
    (X : Submodule ℂ M) (Φ : M →ₗ[ℂ] N) : Prop :=
  ∀ u ∈ S, ∀ (n : ℤ), ∀ x ∈ X, Φ (ρ u n x) = τ (g u) n (Φ x)
```

(`VOA/Moonshine/TrialityTwGeneric.lean`, namespace `VOA.Moonshine.TrialityTw`.)

From the mathematics to the Lean statement

- `M →ₗ[ℂ] N` is the type of $\mathbb{C}$-linear maps; `Submodule ℂ M` a subspace. The Lean variable `A` is the letter set $\mathcal{A}$ (no structure assumed).
- Φ is defined on all of M but the condition is imposed only for $x \in X$; values off X are irrelevant. Harmless and convenient, since the sectors are subspaces of bigger carriers.
- Stability $\rho_{u,n}X \subseteq X$ is not part of the definition; theorems that need it assume it (`hstab`).

Physical meaning

A g-twisted intertwiner is a linear map between two sectors that carries the field modes of one to the modes of the other twisted by the symmetry g: the picture is a symmetry operator U_g implementing $\Phi u_{(n)}\Phi^{-1} = g(u)_{(n)}$. When g is the triality σ and the two sectors are different, such a map is the object that realises σ as a symmetry of the combined theory, and it is what "extending the triality to the twisted sector" means concretely. The trivial map $\Phi = 0$ always satisfies the definition, which is the origin of the $\varphi = 0$ trap discussed later; the definition alone carries no nonzero content.

40.4.2 Uniqueness and involutivity from a cyclic vector

Theorem 40.9 (Uniqueness). *Suppose $x_0 \in X$ and $X = \mathrm{span}\{\rho_{u,n}x_0 : u \in S,\ n \in \mathbb{Z}\}$. If Φ, Ψ are g-twisted intertwiners on X with $\Phi(x_0) = \Psi(x_0)$, then $\Phi = \Psi$ on X.*

File `VOA/Moonshine/TrialityTwGeneric.lean`.

```
theorem eqOn_of_cyclic {x₀ : M} (hx₀ : x₀ ∈ X)
    (hcyc : span ℂ {y | ∃ u ∈ S, ∃ n : ℤ, y = ρ u n x₀} = X) {Φ Ψ : M →ₗ[ℂ] N}
    (hΦ : IsTwInt ρ τ g S X Φ) (hΨ : IsTwInt ρ τ g S X Ψ) (h : Φ x₀ = Ψ x₀) :
    ∀ x ∈ X, Φ x = Ψ x
```

From the mathematics to the Lean statement

`hcyc` is *single-mode* cyclicity: X is spanned by vectors with *one* letter applied to x_0, not by arbitrary words. This is stronger than ordinary cyclicity, and it is what the library proves for V_3^+ and T_s^+ (Chapter 39). Otherwise the statement is the textbook one.

Physical meaning

If a sector is generated from one state by the modes of the fields (a cyclic vector, such as a highest-weight state), then a symmetry operator is already determined by its value on that state, since its action on all the descendants is forced by the intertwining relation. This is the usual reconstruction of a representation from its ground states, and it is why the existence problem for the triality reduces to specifying a single image vector.

Proof on paper. On a spanning vector, $\Phi(\rho_{u,n}x_0) = \tau_{gu,n}\Phi(x_0) = \tau_{gu,n}\Psi(x_0) = \Psi(\rho_{u,n}x_0)$; both maps are linear. □

Theorem 40.10 (Involutivity criterion). *Let Φ be g-twisted on X with $\Phi(X) \subseteq Y$, $\Psi : N \to M$ be g'-twisted on Y for letters $S' \supseteq g(S)$, and $g'(g(u)) = u$ for $u \in S$. If X is single-mode cyclic on x_0 and $\Psi\Phi(x_0) = x_0$, then $\Psi\Phi = \mathrm{id}$ on X.*

File `VOA/Moonshine/TrialityTwGeneric.lean`.

```
theorem comp_eqOn_id {Φ : M →ₗ[ℂ] N} {Ψ : N →ₗ[ℂ] M} {x₀ : M} (hx₀ : x₀ ∈ X)
    (hcyc : span ℂ {y | ∃ u ∈ S, ∃ n : ℤ, y = ρ u n x₀} = X)

    ∀ x ∈ X, Ψ (Φ x) = x
```

From the mathematics to the Lean statement

Every hypothesis appears in the statement; in the application $g = g' = \sigma$, $\sigma^2 = 1$.

Physical meaning

Applying the symmetry twice should return the original state; if the composite fixes the cyclic ground state and the labels satisfy $g'g = 1$, it is the identity on the whole sector. Physically this is the statement that $\sigma^2 = 1$ on the sectors follows from checking it on one ground state, and it is the algebraic form of "σ is an involution".

Proof on paper. $\Psi\Phi$ is $(g' \circ g)$-twisted, i.e. untwisted: $\Psi\Phi\rho_{u,n}x = \Psi\tau_{gu,n}\Phi x = \rho_{g'gu,n}\Psi\Phi x$. So is the identity; they agree at x_0; apply Theorem 40.9. □

What the machine verified

Both proved, unconditional.

40.4.3 Words and annihilator compatibility

A *word* is a finite list $w = [(u_1, n_1), \dots, (u_k, n_k)]$ with $u_i \in S$, acting by $\rho_w = \rho_{u_1,n_1} \circ \cdots \circ \rho_{u_k,n_k}$; its twist is $g(w) = [(gu_1, n_1), \dots, (gu_k, n_k)]$. A formal combination $f = \sum_w f(w)\, w$ evaluates as $\mathrm{ev}_{x_0}(f) = \sum_w f(w)\rho_w x_0$, and twisted as $\mathrm{ev}^g_{y_0}(f) = \sum_w f(w)\tau_{g(w)} y_0$.

Definition 40.11 (Annihilator compatibility). (x_0, y_0) is *annihilator-compatible* if $\ker \mathrm{ev}_{x_0} \subseteq \ker \mathrm{ev}^g_{y_0}$: every relation $\sum_w f(w)\rho_w x_0 = 0$ implies $\sum_w f(w)\tau_{g(w)} y_0 = 0$.

File `VOA/Moonshine/TrialityTwGeneric.lean`.

```
def wordAct (ρ : A → ℤ → M →ₗ[ℂ] M) : List (A × ℤ) → M →ₗ[ℂ] M
  | [] => LinearMap.id
  | p :: w => ρ p.1 p.2 ∘ₗ wordAct ρ w

def twWord (g : A → A) (w : List (A × ℤ)) : List (A × ℤ) := w.map fun p => (g p.1, p.2)

def Words (S : Set A) : Type _ := {w : List (A × ℤ) // ∀ p ∈ w, p.1 ∈ S}

noncomputable def evW (ρ : A → ℤ → M →ₗ[ℂ] M) (S : Set A) (x₀ : M) : (Words S →₀ ℂ) →ₗ[ℂ] M
 ↪  :=
  Finsupp.linearCombination ℂ fun w : Words S => wordAct ρ w.1 x₀

noncomputable def evTw (τ : A → ℤ → N →ₗ[ℂ] N) (g : A → A) (S : Set A) (y₀ : N) :
    (Words S →₀ ℂ) →ₗ[ℂ] N :=
  Finsupp.linearCombination ℂ fun w : Words S => wordAct τ (twWord g w.1) y₀

def AnnCompat (ρ : A → ℤ → M →ₗ[ℂ] M) (τ : A → ℤ → N →ₗ[ℂ] N) (g : A → A) (S : Set A)
    (x₀ : M) (y₀ : N) : Prop :=
  LinearMap.ker (evW ρ S x₀) ≤ LinearMap.ker (evTw τ g S y₀)
```

From the mathematics to the Lean statement

- `Words S →₀ ℂ` is the space of finitely supported functions from words to $\mathbb{C}$, i.e. formal finite combinations of words; `Finsupp.linearCombination ℂ v` is $f \mapsto \sum_w f(w)v(w)$.
- `wordAct ρ (p :: w)` is $\rho_p \circ \rho_w$: the first letter of the list is outermost. The twist changes letters and keeps mode indices. So `evW`, `evTw` are ev_{x_0}, $\mathrm{ev}^g_{y_0}$, and `AnnCompat` is the kernel inclusion, literally.

Physical meaning

Annihilator compatibility says that the choice of image state is consistent: every relation among descendants of the source ground state (a null-vector-type relation) is respected by the twisted descendants of the proposed image. It is the algebraic analogue of requiring that a candidate map between sectors respects the null states, the usual obstruction to defining an intertwiner from a ground-state assignment. Heuristic reading only; the precise statement is the displayed condition on kernels.

Theorem 40.12 (Existence ⇔ annihilator compatibility). *Suppose $\rho_{u,n}X \subseteq X$ for $u \in S$, $x_0 \in X$, and X is single-mode cyclic on x_0. For every $y_0 \in N$, a g-twisted intertwiner Φ on X with $\Phi(x_0) = y_0$ exists if and only if (x_0, y_0) is annihilator-compatible.*

File `VOA/Moonshine/TrialityTwGeneric.lean`.

```
theorem exists_twInt_iff (hstab : ∀ u ∈ S, ∀ (n : ℤ), ∀ x ∈ X, ρ u n x ∈ X) {x₀ : M}
    (hx₀ : x₀ ∈ X) (hcyc : span ℂ {y | ∃ u ∈ S, ∃ n : ℤ, y = ρ u n x₀} = X) (y₀ : N) :
    (∃ Φ : M →ₗ[ℂ] N, IsTwInt ρ τ g S X Φ ∧ Φ x₀ = y₀) ↔ AnnCompat ρ τ g S x₀ y₀
```

From the mathematics to the Lean statement

- Hypotheses: stability (`hstab`), `hx₀`, cyclicity (`hcyc`) — all about the *source*. Nothing is assumed about y_0 or N.
- Non-vacuity: for $y_0 = 0$ the right side is trivially true and $\Phi = 0$ works. The content is existence for a prescribed *non-zero* y_0; this is why the top-level residual of §40.6 carries a non-triviality clause.

Physical meaning

This is the existence half of the ground-state reconstruction: an operator between sectors extending a given assignment on the ground state exists exactly when no null relation of the source is violated by the target. The twisted triality on a sector is thus equivalent to a finite-looking consistency check on one pair of states, and the chapter's strategy is to verify that check only through the ground states and a handful of light fields.

Proof on paper. ($\Rightarrow$) A twisted intertwiner sends $\rho_w x_0$ to $\tau_{g(w)}\Phi(x_0)$ (induction on the length of w, stability keeping us in X), so $\Phi \circ \mathrm{ev}_{x_0} = \mathrm{ev}^g_{y_0}$ and kernels are included. ($\Leftarrow$) The range of ev_{x_0} is X: it contains the one-letter words $\rho_{u,n}x_0$ and is contained in X by stability. Define $\Phi_0(\mathrm{ev}_{x_0} f) = \mathrm{ev}^g_{y_0} f$ on X; well defined by the kernel inclusion. Extend linearly to M (choose a complement). If $x = \mathrm{ev}_{x_0} f$, prepending (u, n) to every word of f gives f' with $\rho_{u,n} x = \mathrm{ev}_{x_0} f'$ and $\mathrm{ev}^g_{y_0} f' = \tau_{gu,n} \mathrm{ev}^g_{y_0} f$: the intertwining property. The empty word gives $\Phi(x_0) = y_0$. □

What the machine verified

`IsTwInt`, `eqOn_of_cyclic`, `comp_eqOn_id`, `AnnCompat`, `exists_twInt_iff`: proved, unconditional; `#print axioms exists_twInt_iff` = [`propext`, `Classical.choice`, `Quot.sound`] (rerun). `Classical.choice` enters through the choice of a complement.

Theorem 40.13 (Gram criterion). *Let B_1, B_2 be bilinear forms on M, N. If $B_1(\rho_{w'}x_0, \rho_w x_0) = B_2(\tau_{g(w')}y_0, \tau_{g(w)}y_0)$ for all words w, w', and B_2 is nondegenerate on the span of the twisted word vectors, then (x_0, y_0) is annihilator-compatible.*

File `VOA/Moonshine/TrialityTwGeneric.lean`.

```
theorem annCompat_of_gram (B₁ : M →ₗ[ℂ] M →ₗ[ℂ] ℂ) (B₂ : N →ₗ[ℂ] N →ₗ[ℂ] ℂ) {x₀ : M} {y₀ :
↪  N}
    (hgram : ∀ w w' : Words S, B₁ (wordAct ρ w'.1 x₀) (wordAct ρ w.1 x₀)
      = B₂ (wordAct τ (twWord g w'.1) y₀) (wordAct τ (twWord g w.1) y₀))
    (hnd : ∀ y ∈ LinearMap.range (evTw τ g S y₀),
      (∀ y' ∈ LinearMap.range (evTw τ g S y₀), B₂ y' y = 0) → y = 0) :
    AnnCompat ρ τ g S x₀ y₀
```

From the mathematics to the Lean statement

`hnd` is nondegeneracy of B_2 on the range of $\mathrm{ev}^g_{y_0}$. This criterion is *not* used for σ: it would need source Gram data too; the route taken (§40.6) needs a form on the target only.

Physical meaning

If the two-point functions (Gram matrices) of the descendants agree between the source ground state and the proposed image, and the target pairing is nondegenerate, then no relation can be violated. This is the physicist's route of checking that an operator is an isometry on a basis of states; the chapter records it as a clean criterion but does not use it on the path to the main result.

Proof on paper. If $\mathrm{ev}_{x_0} f = 0$ then $B_2(\mathrm{ev}^g f', \mathrm{ev}^g f) = B_1(\mathrm{ev} f', \mathrm{ev} f) = 0$ for every f'; nondegeneracy gives $\mathrm{ev}^g f = 0$. □

What the machine verified

Proved, unconditional. Not on the path to $V^\natural$.

40.5 The triality problem on the library's sectors

Definition 40.14 (The actions). For $u \in V_0^+$, $n \in \mathbb{Z}$: $\mathrm{act}_V(u,n) = u_{(n)}$ on V_Λ^+ (adjoint action), $\mathrm{act}_T(u,n) = u_{(n)}$ on $(V_\Lambda^T)^+$ (module action), and $\mathrm{sig}(u) = \sigma(u)$.

File `VOA/Moonshine/TrialityTwSigma.lean`.

```
noncomputable def actV (u : V0Sub.carrier) (n : ℤ) : VPlus →ₗ[ℂ] VPlus :=
  mode (leechVOAPlus.Y (u : VPlus)) n

noncomputable def actT (u : V0Sub.carrier) (n : ℤ) : TP →ₗ[ℂ] TP :=
  mode (Moonshine.plusModule.YM (u : VPlus)) n

noncomputable def sig (u : V0Sub.carrier) : V0Sub.carrier := v0Sigma u
```

(`VOA/Moonshine/TrialityTwSigma.lean`, namespace `VOA.Moonshine.TrialityTw`.)

From the mathematics to the Lean statement

`mode (Y a) n` is $a_{(n)}$. The letter $u \in V_0^+$ is coerced to V_Λ^+ to act; so act_V is the vertex operator of V_Λ^+ restricted to V_0^+-letters. `sig_sig : sig (sig u) = u` records $\sigma^2 = 1$.

Physical meaning

These are the three ways the weight-zero algebra V_0^+ (the even sublattice vertex algebra) acts on the neutral/charged and twisted sectors: through its own fields on V_Λ^+, through its modes on the twisted sector $(V_\Lambda^T)^+$, and through the triality automorphism σ relabelling the fields. In the orbifold picture V_Λ^+ and the twisted sectors T_s^+ are the untwisted and twisted sectors of the same $\mathbb{Z}_2$ orbifold, and σ is the symmetry permuting them.

Lemma 40.15 (Stability). *V_3^+ and each T_s^+ are stable under all $u_{(n)}$, $u \in V_0^+$.*

File `VOA/Moonshine/TrialityTwSigma.lean`.

```
theorem actV_stab : ∀ u ∈ (Set.univ : Set V0Sub.carrier), ∀ (n : ℤ),
    ∀ x ∈ frameSector 1, actV u n x ∈ frameSector 1

theorem actT_stab (s : ZMod 2) : ∀ u ∈ (Set.univ : Set V0Sub.carrier), ∀ (n : ℤ),
    ∀ x ∈ TPframe s, actT u n x ∈ TPframe s
```

Physical meaning

The charged piece V_3^+ and each twisted piece T_s^+ are closed under the modes of the fields of V_0^+, so they are genuine sub-sectors (superselection sectors) of the larger space. Technical bookkeeping step: it ensures that "act on a sector by a field mode" stays inside the sector.

Proof on paper. g (resp. J) is compatible with the vertex operators ($gY(u,z)g^{-1} = Y(gu,z)$, and on the twisted module $JY(u,z)J^{-1} = Y(gu,z)$, Chapter 39) and fixes $u \in V_0^+$; so $u_{(n)}$ commutes with it and preserves its eigenspaces. □

What the machine verified

Proved, unconditional.

Theorem 40.16 (Cyclicity of the sectors). *(a) If $\beta \in \Lambda\backslash\Lambda_0$, then $V_3^+ = \mathrm{span}\{u_{(n)}x_\beta : u \in V_0^+, n \in \mathbb{Z}\}$. (b) If $0 \neq t_0 \in T_s$, then $T_s^+ = \mathrm{span}\{u_{(n)}x_{t_0} : u \in V_0^+, n \in \mathbb{Z}\}$, where $x_{t_0} = h_0(-\frac{1}{2})\mathbf{1} \otimes t_0$.*

File `VOA/Moonshine/TrialityTwSigma.lean`.

```
theorem cyc_V3 {β : leech.carrier} (hβ : β ∉ lambda0) :
    Submodule.span ℂ {y | ∃ u ∈ (Set.univ : Set V0Sub.carrier), ∃ n : ℤ, y = actV u n
     ↪ (frameX0P β)}
      = frameSector 1

noncomputable def x0T (t₀ : TLeechT) : TP := ⟨frameX0T t₀, frameX0T_mem_TP t₀⟩

theorem cyc_T {s : ZMod 2} {t₀ : TLeechT} (ht₀ : t₀ ∈ leechFrameT s) (h0 : t₀ ≠ 0) :
    Submodule.span ℂ {y | ∃ u ∈ (Set.univ : Set V0Sub.carrier), ∃ n : ℤ, y = actT u n (x0T
     ↪ t₀)}
      = TPframe s
```

From the mathematics to the Lean statement

These restate `span_smul_frameX0` (`VOA/Moonshine/CyclicFrameSectors.lean`) and `span_smul_frameX0T` (`VOA/Moonshine/CyclicTwisted.lean`), proved in Chapter 39, with letters typed as elements of V_0^+. The hypotheses ($\beta \notin \Lambda_0$; $t_0 \in T_s$, $t_0 \neq 0$) are exactly that the vector lies in the sector and is non-zero.

Physical meaning

Each sector is generated from a single ground state by the field modes: the charged sector V_3^+ from the vertex-operator state x_β of a vector $\beta \notin \Lambda_0$ (a nonzero charge), and each twisted sector from a nonzero twisted ground state x_{t_0}. This is the standard statement that a sector is an irreducible module built on its ground state, and it is what lets the intertwiner be specified by a single image vector.

What the machine verified

Proved, unconditional.

Definition 40.17 (σ-twisted maps on the sectors). A linear $\Phi : V_\Lambda^+ \to (V_\Lambda^T)^+$ is *σ-twisted on V_3^+* if $\Phi(u_{(n)}x) = (\sigma u)_{(n)}\Phi(x)$ for all $u \in V_0^+$, $n \in \mathbb{Z}$, $x \in V_3^+$; similarly $\Phi : (V_\Lambda^T)^+ \to (V_\Lambda^T)^+$ on T_s^+, and $\Phi : (V_\Lambda^T)^+ \to V_\Lambda^+$ on T_s^+. (This is Definition 40.8 with $\rho, \tau \in \{\mathrm{act}_V, \mathrm{act}_T\}$, $g = \sigma$ and all letters.)

File `VOA/Moonshine/TrialityTwSigma.lean`.

```

def IsSigmaTV (s : ZMod 2) (Φ : TP →ₗ[ℂ] VPlus) : Prop :=
  IsTwInt actT actV sig Set.univ (TPframe s) Φ
```

From the mathematics to the Lean statement

- Letters `Set.univ`: all of V_0^+ and every mode. This is the full condition (40.2), not a weakening to generators.
- The definition does not fix the target sector; which sector is hit is part of the data of the existence theorems, and is not determined by the library's definitions (§40.5.1).
- Trap: $\Phi = 0$ satisfies all three definitions; the existence theorems therefore also assert that Φ hits a cyclic vector.

Physical meaning

This is the twisted-intertwiner condition of Definition 40.8 specialised to the triality: a map between the sectors V_3^+, T_s^+, V_Λ^+ that sends every mode $u_{(n)}$ to the mode of the triality-rotated field $\sigma(u)_{(n)}$. A nonzero such map is the operator implementing the triality symmetry across the sectors; the zero map also qualifies, which is the $\varphi = 0$ trap.

Theorem 40.18 (Uniqueness and weight preservation). *(a) A σ-twisted map on V_3^+ is determined by its value at x_β ($\beta \notin \Lambda_0$); on T_s^+ by its value at x_{t_0} ($0 \neq t_0 \in T_s$). (b) Every such map commutes with L_0.*

    Φ (mode (leechVOAPlus.Y leechVOAPlus.conformalVector) 1 x)
      = mode (Moonshine.plusModule.YM leechVOAPlus.conformalVector) 1 (Φ x)
```

From the mathematics to the Lean statement

$L_0 = \omega_{(1)}$, so `mode (Y ω) 1` is L_0. The conformal vector of V_0^+ is that of V_Λ^+, and $\sigma\omega = \omega$ (`sig_omega`): the whole content of (b). `IsSigmaTT.L0_comm` and `IsSigmaTV.eqOn` are analogous.

Physical meaning

The triality map on a sector is fixed by the image of one ground state (uniqueness by cyclicity), and it commutes with L_0, i.e. it preserves energy because σ fixes the stress tensor. This reflects the fact that symmetry operators commute with the Hamiltonian and are fixed by their action

on the lowest states.

Proof on paper. (a) Theorem 40.9 with Theorem 40.16. (b) The intertwining property for the letter ω at mode 1, with $\sigma\omega = \omega$. □

What the machine verified

Proved, unconditional.

Theorem 40.19 (Existence criterion on the sectors). *For $\beta \notin \Lambda_0$ and $y_0 \in (V_\Lambda^T)^+$: a σ-twisted Φ on V_3^+ with $\Phi(x_\beta) = y_0$ exists iff (x_β, y_0) is annihilator-compatible for $(\mathrm{act}_V, \mathrm{act}_T, \sigma)$ with all letters. Likewise on T_s^+ with x_{t_0}.*

File `VOA/Moonshine/TrialityTwSigma.lean`.

```
theorem sigmaV3T_exists_iff {β : leech.carrier} (hβ : β ∉ lambda0) (y₀ : TP) :
    (∃ Φ : VPlus →ₗ[ℂ] TP, IsSigmaV3T Φ ∧ Φ (frameX0P β) = y₀)
      ↔ AnnCompat actV actT sig Set.univ (frameX0P β) y₀

theorem sigmaTT_exists_iff {s : ZMod 2} {t₀ : TLeechT} (ht₀ : t₀ ∈ leechFrameT s) (h0 : t₀
↪  ≠ 0)
    (y₀ : TP) :
    (∃ Φ : TP →ₗ[ℂ] TP, IsSigmaTT s Φ ∧ Φ (x0T t₀) = y₀)
      ↔ AnnCompat actT actT sig Set.univ (x0T t₀) y₀
```

Physical meaning

The triality can be extended to a sector, sending the chosen ground state to a given target state, if and only if the target state obeys the same null relations as the source; this is the sector-level version of the extension criterion above. The physical content is that nothing beyond a consistency check on the ground states is needed to define the symmetry operator on the whole sector.

Proof on paper. Theorem 40.12 with Lemma 40.15 and Theorem 40.16. □

What the machine verified

Proved, unconditional (`sigmaTV_exists_iff` likewise).

Theorem 40.20 (Involutivity on the sectors). *If Φ is σ-twisted on V_3^+ with $\Phi(V_3^+) \subseteq T_s^+$, Ψ is σ-twisted from T_s^+ to V_Λ^+, and $\Psi\Phi(x_\beta) = x_\beta$, then $\Psi\Phi = \mathrm{id}$ on V_3^+. Similarly (`sigma_involutive_TT`) $\Phi\Phi = \mathrm{id}$ on T_s^+ if $\Phi\Phi(x_{t_0}) = x_{t_0}$.*

File `VOA/Moonshine/TrialityTwSigma.lean`.

```
theorem sigma_involutive_V3 {β : leech.carrier} (hβ : β ∉ lambda0) {s : ZMod 2}

    ∀ x ∈ frameSector 1, Ψ (Φ x) = x
```

Physical meaning

Applying the triality operator twice returns the identity on the sector, once one checks it on the ground state. This is the sector-level statement $\sigma^2 = 1$, necessary for σ to define a $\mathbb{Z}_2$ symmetry (rather than a larger group) of the combined sectors.

Proof on paper. Theorem 40.10 with $g = g' = \sigma$. □

What the machine verified

Proved, unconditional.

40.5.1 Which twisted sector is T_0? An undetermined label

FLM's σ maps V_3^+ to the twisted summand whose central character is shared with the twisted module of the Golay lattice $N(A_1^{24})$ (the "common summand" X_0). One would like to say which of `TPframe 0`, `TPframe 1` that is. The library's definitions do not determine it.

Theorem 40.21 (`golayE` is not determined at w). *Let ψ be the lift of -1 to V_{Λ_0} used to build* `v0Sigma`*, θ the standard lift, and g_e the automorphism $p \otimes e^\gamma \mapsto e(\gamma)p \otimes e^\gamma$ given by a character e of Λ_0. There are characters e_1, e_2 with $\psi = g_{e_i}\theta g_{e_i}^{-1}$ for both i, and $w_0 \in \Lambda_0$ mapping to $w = 8e_0$, with $e_2(w_0) = -e_1(w_0)$.*

File `VOA/Moonshine/TrialityTwSigma.lean`.

```
theorem golayE_not_determined :
    ∃ e₁ e₂ : lam0.carrier →+ Additive ℂˣ,
      (∀ x, lam0Psi x = charLat lam0 e₁ (thetaLat lam0 (charLat lam0 (-e₁) x))) ∧
      (∀ x, lam0Psi x = charLat lam0 e₂ (thetaLat lam0 (charLat lam0 (-e₂) x))) ∧
      ∃ w₀ : lam0.carrier, inclΛ w₀ = frameW ∧ charVal lam0 e₂ w₀ = -charVal lam0 e₁ w₀
```

(`VOA/Moonshine/TrialityTwSigma.lean`.)

From the mathematics to the Lean statement

- `lam0` is Λ_0 as an abstract lattice, with inclusion `inclΛ` into Λ. A character $\Lambda_0 \to \mathbb{C}^\times$ is typed additively (`→+ Additive ℂˣ`); `charVal` evaluates it; `charLat lam0 e` is g_e on V_{Λ_0}, and `-e` the inverse character; `lam0Psi` is ψ.
- The first two clauses: both e_1, e_2 satisfy the specification (`exists_golayE`) from which `golayE` was chosen. The last: they disagree in sign at the preimage of w.
- An existence statement about the specification, not a defect of `v0Sigma`; its consequence (a design constraint) is argued on paper below.

Physical meaning

The sign character e on the sublattice Λ_0 is a choice of discrete torsion, and the theorem records that the library's lift of -1 does not determine which of two characters labels the twisted sector T_0; the two choices differ by a sign on the lattice vector w. It is the analogue of the familiar ambiguity of discrete torsion in an orbifold: two labelings of the twisted sector agree on all data the library fixes but disagree on a coset sign, so one must not assume a particular labeling. A warning rather than a construction.

Proof on paper. Take $e_1 =$ `golayE` and $e_2 = e_1 e_\beta$, $e_\beta(a) = (-1)^{\langle\beta,\iota a\rangle}$ with $\beta = u = (5, 1^{23})$. The specification only sees e^2, because $g_e\theta g_e^{-1} = g_{e^2}\theta$, and $e_\beta^2 = 1$. And $\langle u, w\rangle = 5 \cdot 8/8 = 5$ is odd, so $e_\beta(w_0) = -1$. □

What the machine verified

Proved, unconditional.

Consequence (argued on paper, `Notes/TrialityTwisted.md` §3). Replacing `golayE` by e_2 conjugates `v0Sigma` by the restriction of $g_\beta = (-1)^{\langle\beta,\cdot\rangle}$, which extends to $V^\natural$ as $g_\beta \oplus (1 \otimes e_\beta)$. This

fixes V_3^+ but, since $\langle\beta, w\rangle$ is odd, e_β anticommutes with e_w and swaps `TPframe 0` and `TPframe 1`. If $\Phi : V_3^+ \to T_s^+$ is σ_{e_1}-twisted, $(1 \otimes e_\beta)\Phi g_\beta^{-1} : V_3^+ \to T_{s+1}^+$ is σ_{e_2}-twisted. As the two sectors are non-isomorphic, exactly one s works for each choice, and the choices give different s: the answer is a hidden bit of `Classical.choose`.

Trap / dead end

Do not try to prove $\sigma(V_3^+) =$ `TPframe 0` (or `TPframe 1`). It is not determined by the definitions. Downstream statements are phrased with "$\exists s$" (`sigmaV3T_exists_of_top'` below, `topSigma_both` in Chapter 41). This costs nothing for $V^\natural$: one needs some sector and the intertwining identities, not its name.

40.6 From the top level to the whole module

Theorem 40.19 reduces the existence of σ on V_3^+ to an annihilator compatibility, but that compatibility quantifies over *all* words in *all* modes of *all* states of V_0^+. This section reduces it to a statement on the top level. The section has a generic part (any VOA W, any two weak modules) and a Leech part.

40.6.1 The idea

Classically one argues: V_3^+ is generated by its top level $\Omega = (V_3^+)_2$; a module generated by its top level is a quotient of the generalised Verma module $M(\Omega)$; if the target is irreducible, a top-level isomorphism lifts. We replace the Verma module by a direct argument about the *graph* of the top-level map.

Let A (source) and B (target, already twisted by σ) be weak W-modules, $\varphi : A \to B$ a linear map, and $\Omega \le A$ the top level. Consider in $A \oplus B$ the submodule Z generated by the graph $\Gamma = \{(x, \varphi x) : x \in \Omega\}$. If Z contains no non-zero vector of the form $(0, y)$, then Z is itself the graph of a module map Φ extending φ: that is annihilator compatibility. To show $Z \cap (0 \oplus B) = 0$:

1. (Li's lemma) Z is spanned by *single modes* $(a_{(q)}x,\ a_{(q)}\varphi x)$, $x \in \Omega$.

2. On a single mode, the only part of $a_{(q)}\varphi x$ that an invariant form can pair with $\varphi\Omega$ is its weight-two part, and there it equals $\varphi(o(a)x)$ by the top-level hypothesis. So for $(0, y) \in Z$, y is orthogonal to $\varphi\Omega$.

3. Invariance of the form moves any test vector $c_{(r)}\varphi x'$ back onto $\varphi x'$ (the adjoint of a mode is a combination of modes, and Z is a submodule), so y is orthogonal to the whole target sector.

4. Nondegeneracy of the form on the target sector gives $y = 0$.

Only the *target* needs a form.

40.6.2 Sums and twists of weak modules

A weak module (Definition 12.1) is a vector space M with $Y_M : W \to \mathrm{End}(M)[[z^{\pm 1}]]$ satisfying the vacuum axiom, truncation ($u_{(n)}x = 0$ for $n \gg 0$) and the Jacobi identity, with no grading condition.

Definition 40.22. (a) For weak modules A on M and B on N, $A \oplus B$ is the weak module on $M \times N$ with $u_{(n)}(m, y) = (u_{(n)}m, u_{(n)}y)$. (b) For a weak module B and $g \in \mathrm{Aut}\, W$, the twisted module B^g has $Y_{B^g}(u, z) = Y_B(gu, z)$.

File `VOA/Moonshine/SigmaExistGeneric.lean`.

```

    (twistModule B g).act u n x = B.act (g u) n x
```

(`VOA/Moonshine/SigmaExistGeneric.lean`, namespace `VOA.Moonshine.SigmaExist`; the verification of the axioms is omitted.)

From the mathematics to the Lean statement

`A.act u n x` is $u_{(n)}x$ in the module A. The two `act` lemmas state that the constructions have exactly the intended modes; since `prodModule` and `twistModule` are values of the structure `WeakModule`, Lean has checked the vacuum, truncation and Jacobi axioms for them (the Jacobi identity for B^g uses $g(u_{(n)}v) = (gu)_{(n)}(gv)$). There is no possibility of vacuity: a structure value with all fields supplied is a genuine weak module.

Physical meaning

The direct sum of two modules is the space of states of two decoupled sectors, and the twisted module B^g is the same Hilbert space with the field labels rotated by the symmetry g (the sector seen through a symmetry-transformed set of fields). The twisting trick is what allows a σ-twisted intertwiner to be recast as an ordinary one into the twisted module.

What the machine verified

Proved (definitions with all axioms discharged), unconditional.

40.6.3 Li's single-mode spanning lemma

Theorem 40.23 (Li's lemma). *In a weak module, for all $u, v \in W$, $n, p \in \mathbb{Z}$ and x,*

$$v_{(p)}u_{(n)}x \;\in\; \operatorname{span}\{a_{(q)}x \;:\; a \in W,\ q \in \mathbb{Z}\}.$$

Consequently $\operatorname{modeSpan}(U) = \operatorname{span}\{a_{(q)}x : a \in W, q \in \mathbb{Z}, x \in U\}$ *is a submodule for every set U, and it contains U.*

File `VOA/Moonshine/SigmaExistGeneric.lean`.

```
theorem act_act_mem_span {P : Type*} [AddCommGroup P] [Module ℂ P] (A : WeakModule W P) (x
 ↪  : P)
    (u v : 𝒱) (n p : ℤ) :
    A.act v p (A.act u n x) ∈ span ℂ {y | ∃ a : 𝒱, ∃ q : ℤ, y = A.act a q x}

noncomputable def modeSpan {P : Type*} [AddCommGroup P] [Module ℂ P] (A : WeakModule W P)
    (U : Set P) : Submodule ℂ P :=
  span ℂ {y | ∃ a : 𝒱, ∃ q : ℤ, ∃ x ∈ U, y = A.act a q x}

theorem act_mem_modeSpan {P : Type*} [AddCommGroup P] [Module ℂ P] (A : WeakModule W P)
    (U : Set P) (v : 𝒱) (p : ℤ) {y : P} (hy : y ∈ modeSpan A U) : A.act v p y ∈ modeSpan A
     ↪  U
```

```
theorem subset_modeSpan {P : Type*} [AddCommGroup P] [Module ℂ P] (A : WeakModule W P)
    (U : Set P) {x : P} (hx : x ∈ U) : x ∈ modeSpan A U
```

From the mathematics to the Lean statement

- No hypothesis on u, v, n, p, x: the statement holds in every weak module. This is the module analogue of the vacuum trick of Chapter 39 (where $x = \mathbf{1}$ and $a_{(q)}\mathbf{1}$ ranges over all of W).
- "modeSpan is a submodule" is `act_mem_modeSpan`: stability under every $v_{(p)}$. With `subset_modeSpan` (from $\mathbf{1}_{(-1)} = \mathrm{id}$), modeSpan$(U)$ is the submodule generated by U.

Physical meaning

Li's lemma says that the span of all modes of all fields applied to a set of states is already closed under field action: acting with one more field mode on a descendant stays among the descendants of the same states. It is the algebraic form of the fact that the Hilbert space generated from the ground states by the fields is a representation, with no new states reachable by repeated action; it rests on the Jacobi identity (associativity of the OPE), not on physical input.

Proof on paper. Let K be such that $u_{(k)}x = 0$ for $k \geq K$, and induct on $K - n$; if $n \geq K$ there is nothing to prove. Choose $m \geq 0$ with $v_{(m+i)}x = 0$ for all $i \geq 0$ and put $\ell = p - m$. The Jacobi identity of the module, in its mode form, reads

$$\sum_{i\geq 0}(-1)^i\binom{\ell}{i}\Big(v_{(\ell+m-i)}u_{(n+i)}x - (-1)^{\ell}u_{(\ell+n-i)}v_{(m+i)}x\Big) \;=\; \sum_{i\geq 0}\binom{m}{i}(v_{(\ell+i)}u)_{(m+n-i)}x.$$

The second term on the left vanishes by the choice of m. The right side is a combination of single modes $a_{(q)}x$ with $a = v_{(\ell+i)}u$. On the left, the $i = 0$ term is $v_{(p)}u_{(n)}x$, and the terms $i \geq 1$ are $v_{(p-i)}u_{(n+i)}x$, which lie in the span by the induction hypothesis ($K - (n+i) < K - n$). Hence the $i = 0$ term does too. For the consequence: a spanning vector of modeSpan(U) is $a_{(q)}x$, and $v_{(p)}a_{(q)}x$ is in the span of single modes on x by the lemma. □

What the machine verified

Proved, unconditional, `#print axioms`-clean (re-run).

40.6.4 The generic top-level theorem

Definition 40.24 (Test span). For a weak module B, a set $G \subseteq W$ of letters, a subspace $\Omega \leq M$ and $\varphi : M \to N$: $Y_G = \mathrm{span}\{c_{(r)}\varphi x : c \in G,\ r \in \mathbb{Z},\ x \in \Omega\}$.

File `VOA/Moonshine/SigmaExistGeneric.lean`.

```
noncomputable def testSpan (B : WeakModule W N) (G : Set 𝒱) (Ω : Submodule ℂ M)
    (φ : M →ₗ[ℂ] N) : Submodule ℂ N :=
  span ℂ {y | ∃ c ∈ G, ∃ r : ℤ, ∃ x ∈ Ω, y = B.act c r (φ x)}
```

Physical meaning

The test span is the collection of states produced from the image of the ground states by the modes of the chosen light fields; it is the set of descendants against which the target's pairing is tested for nondegeneracy. Technical bookkeeping step in the compatibility check.

Theorem 40.25 (Annihilator compatibility from the top level). *Let A, B be weak W-modules on M, N; β a bilinear form on N; $\Omega \le M$; $\varphi : M \to N$ and $P : M \to M$ linear; $G \subseteq W$. Assume:*

(i) (top-level compatibility) for every k, every $a \in W_k$, every $q \in \mathbb{Z}$ and all $x, x' \in \Omega$: $\beta(a_{(q)}\varphi x, \varphi x') = \beta(\varphi(P(a_{(q)}x)), \varphi x')$;

(ii) (invariance on G) for every $c \in G$ and $r \in \mathbb{Z}$ there are finitely many $a_i \in W$, $q_i \in \mathbb{Z}$, $t_i \in \mathbb{C}$ with $\beta(y, c_{(r)}y') = \beta(\sum_i t_i\, a_{i(q_i)}y,\ y')$ for all $y, y' \in N$;

(iii) (nondegeneracy) if y lies in the submodule of B generated by $\varphi(\Omega)$ and $\beta(y, z) = 0$ for all $z \in Y_G$, then $y = 0$.

Then for every $x_0 \in \Omega$, $(x_0, \varphi x_0)$ is annihilator-compatible for the untwisted actions of all of W on A and on B.

File `VOA/Moonshine/SigmaExistGeneric.lean`.

```
theorem annCompat_of_top (A : WeakModule W M) (B : WeakModule W N)
    (β : LinearMap.BilinForm ℂ N) (Ω : Submodule ℂ M) (φ : M →ₗ[ℂ] N) (P : M →ₗ[ℂ] M)
    (G : Set 𝒱)
    (hZO : ∀ (k : ℤ) (a : 𝒱), a ∈ W.grading k → ∀ (q : ℤ), ∀ x ∈ Ω, ∀ x' ∈ Ω,
      β (B.act a q (φ x)) (φ x') = β (φ (P (A.act a q x))) (φ x'))
    (hadj : ∀ c ∈ G, ∀ r : ℤ, ∃ (n : ℕ) (a : ℕ → 𝒱) (q : ℕ → ℤ) (t : ℕ → ℂ), ∀ y y' : N,
      β y (B.act c r y') = β (∑ i ∈ Finset.range n, t i • B.act (a i) (q i) y) y')
    (hnd : ∀ y ∈ modeSpan B (φ '' Ω), (∀ z ∈ testSpan B G Ω φ, β y z = 0) → y = 0)
    {x₀ : M} (hx₀ : x₀ ∈ Ω) :
    AnnCompat (fun a q => mode (A.YM a) q) (fun a q => mode (B.YM a) q) id Set.univ x₀ (φ
      ↪ x₀)
```

From the mathematics to the Lean statement

- `LinearMap.BilinForm ℂ N` is a bilinear form $\beta : N \times N \to \mathbb{C}$; `β y z` is $\beta(y, z)$. No symmetry is assumed.
- `hZO` is (i), quantified over homogeneous letters (`a ∈ W.grading k`); since both sides are linear in a, this is equivalent to (i) for all a. P is arbitrary in the theorem; in applications it is the projection to weight 2, and then (i) is the zero-mode intertwining property (see Lemma 40.31 below).
- `hadj` is (ii): a finite sum indexed by `Finset.range n`, i.e. $i = 0, \dots, n-1$. Note the order of quantifiers: the coefficients may depend on c and r but not on y, y'.
- `hnd` is (iii): `modeSpan B (φ '' Ω)` is the submodule of B generated by the image $\varphi(\Omega)$ (Theorem 40.23).
- The conclusion is `AnnCompat` with twist `id`: both modules are acted on by the same letters without twist. The σ-twist is put into B by using $B =$ `twistModule`; Lemma 40.26 shows the two formulations agree.
- Could the theorem be vacuous? If $\varphi = 0$, then $Y_G = 0$ and (iii) forces every y in the generated submodule to vanish, which is automatic since that submodule is 0; the conclusion is then the trivial compatibility with $y_0 = 0$. So the theorem is consistent with $\varphi = 0$, and any non-triviality must come from the hypotheses of the Leech application: there, (iii) is proved using that $\varphi(\Omega)$ contains a *cyclic vector* of the target sector.

Physical meaning

This theorem says that to verify that the triality is consistent on an entire sector, it is enough to check zero-mode compatibility on the ground states together with invariance and nondegeneracy of the pairing: if the zero modes of all fields intertwine on the ground states, then so do all modes on all descendants. This is the sector-level incarnation of the principle that a symmetry is determined by its action on the ground states, and is the engine of the whole reduction.

Proof on paper. Let $Z \le M \oplus N$ be the submodule generated by $\Gamma = \{(x, \varphi x) : x \in \Omega\}$; by Theorem 40.23 applied to $A \oplus B$, Z is spanned by the pairs $(a_{(q)}x, a_{(q)}\varphi x)$, $x \in \Omega$.

Step 1. For fixed $x' \in \Omega$, the functional $\lambda(m, y) = \beta(y, \varphi x') - \beta(\varphi P m, \varphi x')$ vanishes on Z: it is linear and vanishes on each spanning pair, by (i) (decompose a into homogeneous components).

Step 2. Hence if $(0, y) \in Z$ then $\beta(y, \varphi x') = 0$ for all $x' \in \Omega$.

Step 3. Let $(0, y) \in Z$, $c \in G$, $r \in \mathbb{Z}$, $x' \in \Omega$. By (ii), $\beta(y, c_{(r)}\varphi x') = \beta(y', \varphi x')$ with $y' = \sum t_i a_{i(q_i)} y$. Since Z is a submodule, $(0, y') = \sum t_i a_{i(q_i)}(0, y) \in Z$, so Step 2 gives $\beta(y', \varphi x') = 0$. Thus $y \perp Y_G$.

Step 4. The second components of elements of Z lie in the submodule generated by $\varphi(\Omega)$. By (iii), $(0, y) \in Z$ implies $y = 0$.

Conclusion. For a formal combination f of words, $(\mathrm{ev}_{x_0} f, \mathrm{ev}_{\varphi x_0} f)$ is the same combination of words applied to $(x_0, \varphi x_0) \in \Gamma$, hence lies in Z. If $\mathrm{ev}_{x_0} f = 0$, Step 4 gives $\mathrm{ev}_{\varphi x_0} f = 0$. □

What the machine verified

Proved, unconditional, `#print axioms` = [`propext`, `Classical.choice`, `Quot.sound`] (re-run for this chapter). No Verma module, no `VOA.pbw`.

Lemma 40.26 (Twists can be moved into the action). AnnCompat$(\rho, \tau, g, S, x_0, y_0)$ *holds iff* AnnCompat$(\rho, \tau \circ g, \mathrm{id}, S, x_0, y_0)$ *holds, where* $(\tau \circ g)_{a,q} = \tau_{g(a),q}$.

File `VOA/Moonshine/SigmaExistGeneric.lean`.

```
theorem annCompat_twist_iff {A' : Type*} (ρ : A' → ℤ → M →ₗ[ℂ] M) (τ : A' → ℤ → N →ₗ[ℂ] N)
    (g : A' → A') (S : Set A') (x₀ : M) (y₀ : N) :
    AnnCompat ρ τ g S x₀ y₀ ↔ AnnCompat ρ (fun a q => τ (g a) q) id S x₀ y₀
```

Physical meaning

A twist by a symmetry on the source side is equivalent to an untwisted statement for the sector seen through the twisted action. Technical bookkeeping step that lets the compatibility check be done with the untwisted-action machinery.

Proof on paper. Both sides evaluate a word w as $\tau_{g(u_1),n_1} \cdots \tau_{g(u_k),n_k} y_0$. □

What the machine verified

Proved, unconditional.

40.6.5 The Leech instance: modules and the form

Definition 40.27. As weak V_0^+-modules: $A_V = V_\Lambda^+$ (restriction of the adjoint module), $A_T = (V_\Lambda^T)^+$ (restriction of `plusModule`), and $B_T^\sigma = A_T^\sigma$, i.e. $(V_\Lambda^T)^+$ with u acting as $(\sigma u)_{(n)}$.

File `VOA/Moonshine/SigmaExistLeech.lean`.

```
noncomputable def AV : WeakModule V0P VPlus := V0Sub.restrictWeakModule (adjointWeakModule
 ↪  leechVOAPlus)

noncomputable def AT : WeakModule V0P TP := V0Sub.restrictWeakModule
 ↪  plusModule.toWeakModule

noncomputable def BTs : WeakModule V0P TP := twistModule AT v0Sigma

theorem mode_BTs (u : V0Sub.carrier) (n : ℤ) : mode (BTs.YM u) n = actT (sig u) n
```

(`VOA/Moonshine/SigmaExistLeech.lean`.)

From the mathematics to the Lean statement

`V0Sub.restrictWeakModule` restricts a V_Λ^+-module to the subalgebra V_0^+; its modes are those of the original module (`mode_AV`, `mode_AT`: `actV`, `actT`). `mode_BTs` confirms the twist.

Physical meaning

The three modules are the charged sector V_Λ^+, the twisted sector $(V_\Lambda^T)^+$, and the twisted sector viewed through the triality (its fields relabelled by σ). Together they are the state spaces between which the triality operator is supposed to act, and the third is how the twisted-intertwiner condition becomes an ordinary module-map condition.

Theorem 40.28 (The form on the twisted sectors). *(a)* $T_0^+ \perp T_1^+$ *for* `TPForm`. *(b)* `TPForm` *is nondegenerate on each* T_s^+*: if* $y \in T_s^+$ *and* $\langle y, z\rangle = 0$ *for all* $z \in T_s^+$*, then* $y = 0$.

File `VOA/Moonshine/SigmaExistLeech.lean`.

```

 ↪  = 0

theorem TPForm_eq_zero_of_frame {s : ZMod 2} {y : TP} (hy : y ∈ TPframe s)
    (h : ∀ z ∈ TPframe s, TPForm y z = 0) : y = 0
```

Physical meaning

The invariant bilinear form on the twisted sectors is the physical inner product: distinct twisted sectors are orthogonal (they are superselection sectors), and the form is nondegenerate on each, so every nonzero state has a nonzero overlap with some other state. Nondegeneracy is what allows a state to be detected by its two-point functions, which is the input to the compatibility criterion above.

Proof on paper. (a) $J = c^{-1}e_w$ is self-adjoint for the form on T: $\langle e_w t, t'\rangle = (-1)^{|w|^2/2}\langle t, e_w t'\rangle$ up to the normalisation c, and $|w|^2/2 = 4$ is even, so the sign is $+1$. The form on $S[\theta] \otimes T$ is the tensor product, so $1 \otimes J$ is self-adjoint. If $Jx = x, Jy = -y$ then $\langle x, y\rangle = \langle Jx, y\rangle = \langle x, Jy\rangle = -\langle x, y\rangle$. (b) The form is nondegenerate on all of $(V_\Lambda^T)^+$ (Chapter 37); $(V_\Lambda^T)^+ = T_0^+ \oplus T_1^+$; if $y \in T_s^+$ is orthogonal to T_s^+ it is orthogonal to T_{s+1}^+ by (a), hence to everything. □

What the machine verified

Proved, unconditional.

Lemma 40.29 (Invariance for the twisted target). *For homogeneous* $c \in V_0^+$ *of weight* k *and* $r \in \mathbb{Z}$*, the adjoint of* $c_{(r)}$ *in* B_T^σ *for* `TPForm` *is* $\sum_{j=0}^{k} \frac{(-1)^k}{j!}\,(a_j)_{(2k-r-2-j)}$ *in* B_T^σ*, where* $a_j = \sigma(L_1^j \sigma c)$.

File `VOA/Moonshine/SigmaExistLeech.lean`.

```
def homLetters : Set V0Sub.carrier := {c | ∃ k : ℤ, (c : VPlus) ∈ leechVOAPlus.grading k}

theorem hadj_BTs : ∀ c ∈ homLetters, ∀ r : ℤ, ∃ (n : ℕ) (a : ℕ → V0Sub.carrier) (q : ℕ → ℤ)
    (t : ℕ → ℂ), ∀ y y' : TP,
      TPForm y (BTs.act c r y') = TPForm (∑ i ∈ Finset.range n, t i • BTs.act (a i) (q i)
       ↪ y) y'
```

From the mathematics to the Lean statement

This is hypothesis (ii) of Theorem 40.25 with $G =$ homogeneous letters. In B_T^σ the letter c acts as $(\sigma c)_{(r)}$; FHL invariance of `TPForm` (recalled in §40.2) expresses the adjoint through $(L_1^j \sigma c)_{(\cdot)}$, and to write these as B_T^σ-modes one feeds the letters $\sigma(L_1^j \sigma c)$, using $\sigma^2 = 1$. L_1 preserves V_0^+ because $\omega \in V_0^+$.

Physical meaning

This gives the BPZ-type adjoint of a field mode in the twisted sector (the mode with weight-shifted index and the L_1-corrections, as for any quasi-primary field), expressing invariance of the inner product under the field action. Technical step in the nondegeneracy argument.

What the machine verified

Proved, unconditional.

40.6.6 The named residuals `TopSigmaV3` and `TopSigmaTT`

Write $\Omega_3 = (V_3^+)_2$ and $\Omega_{T,s'} = (T_{s'}^+)_2$ for the top levels (both of dimension 49152).

Definition 40.30 (Top-level σ-datum on V_3^+). A linear $\varphi : V_\Lambda^+ \to (V_\Lambda^T)^+$ is a *top-level σ-datum into T_s^+* if

(a) $\varphi(\Omega_3) \subseteq T_s^+$;

(b) $\varphi(\Omega_3) \subseteq ((V_\Lambda^T)^+)_2$;

(c) for every k, every $a \in (V_0^+)_k$ and every $x \in \Omega_3$: $\varphi(o(a)x) = o(\sigma a)\varphi(x)$, where $o(a) = a_{(k-1)}$;

(d) there are $0 \neq t_0 \in T_s$ and $x \in \Omega_3$ with $\varphi(x) = h_0(-\tfrac{1}{2})\mathbf{1} \otimes t_0$.

File `VOA/Moonshine/SigmaExistLeech.lean`.

```
noncomputable def OmegaV3 : Submodule ℂ VPlus := frameSector 1 ⊓ leechVOAPlus.grading 2

structure TopSigmaV3 (s : ZMod 2) (φ : VPlus →ₗ[ℂ] TP) : Prop where
  /-- `φ` maps the top level of `V₃⁺` into `T_s⁺`. -/
  maps_frame : ∀ x ∈ OmegaV3, φ x ∈ TPframe s
  /-- `φ` maps the top level into weight 2. -/
  maps_weight : ∀ x ∈ OmegaV3, φ x ∈ plusModule.weight (2 : ℂ)
  /-- Zero-mode intertwining: `φ (o(a) x) = o(σ a) φ x` for every homogeneous `a ∈ V₀⁺`. -/
  zero_mode : ∀ (k : ℤ) (a : V0Sub.carrier), (a : VPlus) ∈ leechVOAPlus.grading k →

  hits_cyclic : ∃ t₀ : TLeechT, t₀ ∈ leechFrameT s ∧ t₀ ≠ 0 ∧ ∃ x ∈ OmegaV3, φ x = x0T t₀
```

From the mathematics to the Lean statement

- ⊓ is intersection of subspaces: `OmegaV3` $= V_3^+ \cap (V_\Lambda^+)_2 = \Omega_3$.
- A `structure` with `Prop` fields is a conjunction of four clauses, named (a)–(d) above in order.
- In `zero_mode`, k is the weight of a, and `actV a (k - 1)` is $a_{(k-1)} = o(a)$; on the target, σa has the same weight, so `actT (sig a) (k - 1)` is $o(\sigma a)$. The clause is quantified over *all* weights k and all homogeneous a: an infinite family of finite-dimensional identities.
- `plusModule.weight (2 : ℂ)` is the weight-two space of $(V_\Lambda^T)^+$.
- `hits_cyclic` uses `x0T t₀`, defined in Theorem 40.16.
- Every clause is *necessary* for $\varphi = \Phi|_{\Omega_3}$ when Φ is a non-zero σ-twisted map $V_3^+ \to T_s^+$ (for (d), up to choosing the cyclic vector in the image; for (c) see `IsSigmaV3T.zero_mode` below). So the definition is not stronger than what is true.

Physical meaning

The top-level datum records the triality only on the ground states of the sector: a map of the lowest-weight space Ω_3 to the lowest-weight space of the target that intertwines the zero modes $o(a)$ with the rotated zero modes $o(\sigma a)$, together with a nonzero hit on the cyclic vector. This is the "top-level" (ground-state) data of the sector, to be read as a representation of the Zhu algebra; condition (d) excludes $\varphi = 0$, the trivial intertwiner. The residual is the one remaining unproved input to the existence of the twisted triality, which the rest of the chapter reduces to checks on a few light fields.

Trap / dead end

The $\varphi = 0$ trap. Without `hits_cyclic`, $\varphi = 0$ satisfies the other three clauses, and the reduction would produce the trivial intertwiner $\Phi = 0$, which is useless for $V^\natural$ (it is the analogue of the square-zero trap of Chapter 38). The clause is there on purpose; it is also exactly what makes the nondegeneracy hypothesis (iii) of Theorem 40.25 provable: the test span Y_G then contains all $u_{(n)}x_{t_0}$, which span T_s^+ by Theorem 40.16.

Lemma 40.31 (Top-level compatibility from zero modes). *If φ satisfies* `TopSigmaV3 s`, *then hypothesis (i) of Theorem 40.25 holds for $A = A_V$, $B = B_T^\sigma$, $\beta =$* `TPForm`, *$\Omega = \Omega_3$ and $P = \pi_2$ the projection of V_Λ^+ onto weight 2.*

File `VOA/Moonshine/SigmaExistLeech.lean`.

```
theorem hZO_V3 {s : ZMod 2} {φ : VPlus →ₗ[ℂ] TP} (hφ : TopSigmaV3 s φ) :
    ∀ (k : ℤ) (a : V0Sub.carrier), a ∈ V0P.grading k → ∀ (q : ℤ), ∀ x ∈ OmegaV3, ∀ x' ∈
     ↪ OmegaV3,
      TPForm (BTs.act a q (φ x)) (φ x')
        = TPForm (φ (piHom leechVOAPlus 2 (AV.act a q x))) (φ x')
```

Physical meaning

The zero-mode condition on the ground states implies the top-level matrix-element identity needed for the compatibility theorem: the zero modes of all fields, which in the Hamiltonian picture are the only operators that map the ground-state space to itself, transport correctly under φ. Technical step relating the Zhu-algebra datum to the pairing identity.

Proof on paper. $a_{(q)}x$ has weight $k+2-q-1$. If $q = k-1$ this is 2, π_2 is the identity on it, and the identity is clause (c). Otherwise $\pi_2(a_{(q)}x) = 0$, and $(\sigma a)_{(q)}\varphi x$ has weight $\neq 2$, so it is orthogonal to the weight-two vector $\varphi x'$ (different L_0-eigenspaces are orthogonal for an invariant form, `TPForm_weightOrth`). □

What the machine verified

Proved, unconditional.

Theorem 40.32 (The residual gives annihilator compatibility). *If φ satisfies* `TopSigmaV3 s`*, then for every $x_0 \in \Omega_3$, $(x_0, \varphi x_0)$ is annihilator-compatible for* $(\mathrm{act}_V, \mathrm{act}_T, \sigma)$ *with all letters.*

File `VOA/Moonshine/SigmaExistLeech.lean`.

```
theorem annCompat_V3_of_top {s : ZMod 2} {φ : VPlus →ₗ[ℂ] TP} (hφ : TopSigmaV3 s φ) {x₀ :
↪  VPlus}
    (hx₀ : x₀ ∈ OmegaV3) : AnnCompat actV actT sig Set.univ x₀ (φ x₀)
```

Physical meaning

Given the ground-state datum (the zero modes intertwine and the image is nonzero), the triality is consistent on the whole charged sector: there is no violated null relation. This is the sector-level payoff of knowing the symmetry on the ground states alone.

Proof on paper. Lemma 40.26, then Theorem 40.25 with Lemmas 40.31 and 40.29. For (iii): the submodule generated by $\varphi(\Omega_3)$ lies in T_s^+ by clause (a) and stability; the test span contains every $(\sigma\sigma a)_{(n)}x_{t_0} = a_{(n)}x_{t_0}$ (clause (d)), so it contains T_s^+; and Theorem 40.28(b) applies. □

What the machine verified

Proved; conditional only on its explicit hypothesis `TopSigmaV3 s φ`.

40.6.7 The explicit cyclic vector and the existence theorem

To apply Theorem 40.19 the cyclic vector x_β must lie in the top level, so $|\beta|^2 = 4$ with $\beta \notin \Lambda_0$. The library takes

$$\beta_2 = u - w = (5, 1^{23}) - (8, 0^{23}) = (-3, 1^{23}) \quad (\sqrt{8}\text{-coordinates}), \qquad |\beta_2|^2 = \frac{9+23}{8} = 4.$$

File `VOA/Moonshine/SigmaExistLeech.lean`.

```
noncomputable def β₂ : leech.carrier := uβ - frameW

theorem β₂_not_mem : β₂ ∉ lambda0

theorem form_β₂ : leech.form β₂ β₂ = 4

theorem frameX0P_β₂_mem : frameX0P β₂ ∈ OmegaV3
```

From the mathematics to the Lean statement

`uβ` is the odd Leech vector $(5, 1^{23})$ and `frameW` is $w = (8, 0^{23}) \in \Lambda_0$. $\beta_2 \notin \Lambda_0$ because $u \notin \Lambda_0$ ($u_0 = 5$ is odd) and $w \in \Lambda_0$. The norm is computed by evaluating a 24-term dot product in the kernel (`decide +kernel`).

What the machine verified

Proved, unconditional.

Theorem 40.33 (σ on V_3^+ from the residual). *If φ satisfies* `TopSigmaV3 s`, *there is a σ-twisted intertwiner $\Phi : V_\Lambda^+ \to (V_\Lambda^T)^+$ on V_3^+ with $\Phi = \varphi$ on Ω_3, and Φ hits a cyclic vector x_{t_0} of T_s^+ ($0 \neq t_0 \in T_s$).*

File `VOA/Moonshine/SigmaExistLeech.lean`.

```
theorem sigmaV3T_exists_of_top {s : ZMod 2} {φ : VPlus →ₗ[ℂ] TP} (hφ : TopSigmaV3 s φ) :
    ∃ Φ : VPlus →ₗ[ℂ] TP, IsSigmaV3T Φ ∧ (∀ x ∈ OmegaV3, Φ x = φ x) ∧
      ∃ t₀ : TLeechT, t₀ ∈ leechFrameT s ∧ t₀ ≠ 0 ∧ ∃ x ∈ OmegaV3, Φ x = x0T t₀

theorem sigmaV3T_exists_of_top' (h : ∃ s φ, TopSigmaV3 s φ) :
    ∃ (s : ZMod 2) (Φ : VPlus →ₗ[ℂ] TP), IsSigmaV3T Φ ∧
      ∃ t₀ : TLeechT, t₀ ∈ leechFrameT s ∧ t₀ ≠ 0 ∧ ∃ x ∈ OmegaV3, Φ x = x0T t₀
```

From the mathematics to the Lean statement

- The conclusion has three parts: Φ is σ-twisted for *all* letters and modes; it extends φ on the top level; it is non-zero (hits a cyclic vector of T_s^+).
- The statement does not assert $\Phi(V_3^+) \subseteq T_s^+$; that follows (stability and cyclicity) and is not needed in this form downstream.
- The primed version is the "$\exists s$" form required by §40.5.1.

Physical meaning

From the ground-state datum one obtains the triality operator on the charged sector, agreeing with φ on the ground states and landing on a cyclic ground state of the twisted sector. This is the step where an operator that intertwines two sectors is actually constructed from its ground-state data, and it is nonzero because the datum hits a nonzero state.

Proof on paper. By Theorem 40.32 at $x_0 = x_{\beta_2}$ and Theorem 40.19, there is Φ with $\Phi(x_{\beta_2}) = \varphi(x_{\beta_2})$. On Ω_3, $\Phi = \varphi$: the weight-two part of $u_{(n)}x_{\beta_2}$ is $o(a)x_{\beta_2}$ summed over the homogeneous components a of u for which $n = \operatorname{wt} a - 1$; since V_3^+ is spanned by the $u_{(n)}x_{\beta_2}$, Ω_3 is spanned by the vectors $o(a)x_{\beta_2}$; and both Φ and φ send $o(a)x_{\beta_2}$ to $o(\sigma a)\varphi(x_{\beta_2})$ (twisted intertwining for Φ, clause (c) for φ). Then clause (d) for φ gives the cyclic vector in the image of Φ. □

What the machine verified

Proved; conditional only on the explicit hypothesis `TopSigmaV3 s φ`. `#print axioms` re-run: [`propext`, `Classical.choice`, `Quot.sound`]. The hypothesis is discharged in Chapter 41.

Theorem 40.34 (Necessity of the zero-mode clause). *Every σ-twisted Φ on V_3^+ satisfies $\Phi(o(a)x) = o(\sigma a)\Phi(x)$ for $x \in \Omega_3$ (and similarly on T_s^+).*

File `VOA/Moonshine/SigmaExistLeech.lean`.

```
theorem IsSigmaV3T.zero_mode {Φ : VPlus →ₗ[ℂ] TP} (hΦ : IsSigmaV3T Φ) (k : ℤ) (a :
↪  V0Sub.carrier)
    (x : VPlus) (hx : x ∈ OmegaV3) : Φ (actV a (k - 1) x) = actT (sig a) (k - 1) (Φ x)
```

From the mathematics to the Lean statement

Here k is arbitrary (not tied to the weight of a): the statement is the intertwining property at mode $k-1$, stronger than needed.

Physical meaning

Any triality operator on the sector must satisfy the zero-mode intertwining on the ground states, so the zero-mode clause in the top-level datum cannot be weakened: the datum is not only sufficient but necessary. It is the statement that the ground-state data are exactly what the symmetry operator restricts to.

What the machine verified

Proved, unconditional.

The twisted-to-twisted sector. The same reduction is proved for maps out of $T_{s'}^+$.

Definition 40.35. $\Omega_{T,s'} = T_{s'}^+ \cap ((V_\Lambda^T)^+)_2$; a top-level σ-datum $T_{s'}^+ \to T_s^+$ is $\varphi : (V_\Lambda^T)^+ \to (V_\Lambda^T)^+$ with the four clauses of Definition 40.30, Ω_3 replaced by $\Omega_{T,s'}$ and act_V by act_T.

File `VOA/Moonshine/SigmaExistLeech.lean`.

```

      ∃ t₀ : TLeechT, t₀ ∈ leechFrameT s ∧ t₀ ≠ 0 ∧ ∃ x ∈ OmegaT s', Φ x = x0T t₀
```

From the mathematics to the Lean statement

The source cyclic vector is $x_{t_0'}$ with $0 \neq t_0' \in T_{s'}$ (hypotheses `ht₀'`, `h0'`), which is in the top level because $h_0(-\frac{1}{2})\mathbf{1} \otimes t_0'$ has weight $\frac{1}{2} + \frac{3}{2} = 2$ (`x0T_mem_weight`). The weight-2 projection on the target is `projT2`. FLM's case is $s' = s$, $T_3^+ \to T_3^+$; the theorem allows any pair.

Physical meaning

The same ground-state datum, now for maps between two twisted sectors $T_{s'}^+ \to T_s^+$, with the ground-state space the weight-two part of the twisted sector. It is the analogue of the charged-sector datum for the twisted-to-twisted part of the triality.

Proof on paper. Identical to Theorem 40.33, with A_T in place of A_V. □

What the machine verified

Proved; conditional only on `TopSigmaTT s' s φ` and the choice of t_0'.

40.7 From the top level to Zhu generators

Clause (c) of `TopSigmaV3` still quantifies over all homogeneous $a \in V_0^+$. Zhu's easy direction reduces it to generators.

Definition 40.36 (Zhu generation). A set $G \subseteq V_0^+$ *Zhu-generates* V_0^+ if every subspace $S \le V_0^+$ with $\mathbf{1} \in S$, $\mathcal{O}(V_0^+) \subseteq S$, $G \subseteq S$ and $S * S \subseteq S$ is all of V_0^+. Equivalently — using Zhu's theorem that $\mathcal{O}(V_0^+)$ is a two-sided ideal, so that $*$ descends to an associative product on $A(V_0^+)$ (Chapter 12) — the images of G and $\mathbf{1}$ generate $A(V_0^+)$ as an algebra.

File `VOA/Moonshine/SigmaExistZhu.lean`.

```
def ZhuGenerated (G : Set V0Sub.carrier) : Prop :=
  ∀ S : Submodule ℂ V0Sub.carrier, V0P.vacuum ∈ S → O V0P ≤ S →
    (∀ a ∈ S, ∀ b ∈ S, zhuMul V0P a b ∈ S) → G ⊆ S → S = ⊤
```

(`VOA/Moonshine/SigmaExistZhu.lean`.)

From the mathematics to the Lean statement

- `⊤` is the whole space. The definition quantifies over subspaces of V_0^+ containing $\mathcal{O}$, which correspond bijectively to subspaces of $A(V_0^+)$; "closed under $*$" is closure of the corresponding subspace under the product. So the "equivalently" holds *given* that $*$ descends to $A(V)$; the Lean definition does not need that fact.
- Not vacuous: $G = V_0^+$ trivially Zhu-generates; $G = \varnothing$ does not (the subspace $\mathbb{C}\mathbf{1} + \mathcal{O}(V_0^+)$ is $*$-closed and proper, since $A(V_0^+)$ is not one-dimensional: it has 16 inequivalent irreducible modules, cf. §40.8; $*$-closedness of $\mathbb{C}\mathbf{1} + \mathcal{O}$ uses Zhu's theorem that $\mathcal{O}$ is a two-sided ideal — this non-vacuity remark is argued on paper, not in Lean). The weight-two statement proved below is therefore a genuine statement.

Physical meaning

Zhu generation by a set G of light fields says that the zero modes of G, together with the identity, already generate the full algebra of zero modes $A(V_0^+)$; equivalently, if an operator commutes with $o(g)$ for all $g \in G$ on the ground states, it commutes with every zero mode. In physical terms, a few light (low-weight) fields act irreducibly on the ground states of every sector, so checking the symmetry on them suffices. It is the key finite check that replaces an infinite one.

Definition 40.37 (The ordinary modules). $M_{V^3} = V_3^+$, $M_{T,s'} = T_{s'}^+$ as ordinary V_0^+-modules, and $M_T^\sigma = (V_\Lambda^T)^+$ with the σ-twisted action, also ordinary (twisting by an automorphism keeps the grading since $\sigma\omega = \omega$).

noncomputable def MV3 : OrdVModule V0P (frameSector 1) := OrdVModule.submodule N0 P3
```

```
noncomputable def MTsrc (s' : ZMod 2) : OrdVModule V0P (TPframe s') := OrdVModule.submodule
 ↪  NT (PT s')

noncomputable def MT : OrdVModule V0P TP := twistOrd NT v0Sigma
```

From the mathematics to the Lean statement

`N0` and `NT` are V_Λ^+ (adjoint module) and $(V_\Lambda^T)^+$ restricted to V_0^+ as ordinary modules; `P3` and `PT s'` are V_3^+ and $T_{s'}^+$ as V_0^+-stable subspaces (Lemma 40.15); `OrdVModule.submodule` gives a stable graded subspace the induced ordinary-module structure. In `twistOrd` the weight spaces are unchanged, which is correct because L_0 is the zero mode of $\omega = \sigma\omega$.

Physical meaning

The three sectors regarded as ordinary modules: graded by energy with finite-dimensional energy levels and a ground level, with the twisted version a module because the triality preserves the stress tensor (the energy). Technical setup that lets Zhu's zero-mode analysis apply to the sectors.

Theorem 40.38 (Lowest weight 2). *M_{V3}, $M_{T,s'}$ and M_T^σ have lowest weight 2.*

File `VOA/Moonshine/SigmaExistZhu.lean`.

```
theorem isLowestWeight_MV3 : IsLowestWeight MV3 (2 : ℂ)

theorem isLowestWeight_MT : IsLowestWeight MT (2 : ℂ)

theorem isLowestWeight_MTsrc (s' : ZMod 2) : IsLowestWeight (MTsrc s') (2 : ℂ)
```

Physical meaning

The ground energy of each of the three sectors is 2: the lowest-weight states are weight-two states, so the ground-state space is the space of weight-two primaries (a Griess-algebra-type space in the Moonshine setting). Together with Zhu's easy direction, the zero modes act on this weight-two space.

Proof on paper. V_Λ^+ has weights $0, 2, 3, \ldots$: weight 0 is $\mathbb{C}\mathbf{1} \subset V_0^+$ (so meets V_3^+ only in 0), weight 1 is zero (Λ has no roots and θ kills $h(-1)\mathbf{1}$). For $(V_\Lambda^T)^+$ the weights are $2, 3, \ldots$ (§40.2). □

What the machine verified

Proved, unconditional.

Theorem 40.39 (Zero modes from Zhu generators). *Let N_1, N_2 be ordinary V_0^+-modules of lowest weight 2, $\psi : N_1 \to N_2$ linear with $\psi((N_1)_2) \subseteq (N_2)_2$, and G Zhu-generating. If $\psi\, o(g) = o(g)\, \psi$ on $(N_1)_2$ for $g \in G$, then $\psi\, o(a) = o(a)\, \psi$ on $(N_1)_2$ for all $a \in V_0^+$.*

    ∀ a : V0Sub.carrier, ∀ x ∈ N₁.weight (2 : ℂ), ψ (oMod N₁ a x) = oMod N₂ a (ψ x)
```

Physical meaning

If a map between the ground-state spaces of two sectors commutes with the zero modes of the light generating fields, then it commutes with every zero mode. This is the payoff of Zhu generation: a finite list of light-field checks, the zero modes of weight-two fields, gives intertwining with the entire zero-mode algebra on the ground states.

Proof on paper. Let $S = \{a : \psi o(a) = o(a)\psi \text{ on } (N_1)_2\}$, a subspace. It contains $\mathbf{1}$ ($o(\mathbf{1}) = \mathrm{id}$), $\mathcal{O}(V_0^+)$ (both zero modes vanish on top levels, Theorem 40.5), G by hypothesis, and is $*$-closed: $\psi o(a * b) = \psi o(a)o(b) = o(a)\psi o(b) = o(a)o(b)\psi = o(a * b)\psi$ on $(N_1)_2$, using that $o(b)$ preserves the top level. So S is everything. □

What the machine verified

Proved, unconditional.

Theorem 40.40 (`TopSigmaV3` from Zhu generators). *Let φ satisfy clauses (a), (b), (d) of Definition 40.30, let G be Zhu-generating, and suppose every $g \in G$ is homogeneous of some weight k with $\varphi(o(g)x) = o(\sigma g)\varphi(x)$ on Ω_3. Then φ satisfies* `TopSigmaV3 s`. *Likewise for* `TopSigmaTT`.

    TopSigmaTT s' s φ
```

From the mathematics to the Lean statement

`hGφ` requires each letter of G to be homogeneous; for $G = (V_0^+)_2$ that holds with $k = 2$. The proof applies Theorem 40.39 to $N_1 = M_{V3}$, $N_2 = M_T^\sigma$, where $o_{N_2}(a) = o(\sigma a)$; the zero mode of the twisted module is the zero mode of σa.

Physical meaning

The ground-state datum of the triality need only be checked on the light generators: if the zero modes of the generating fields intertwine, the full top-level residual follows. This reduces the existence of the twisted triality to the chapter's headline statement that the weight-two fields Zhu-generate, together with these finite checks.

What the machine verified

Proved; conditional only on the displayed hypotheses. No `VOA.pbw`: only the easy direction of Zhu's theory is used.

Trap / dead end

Weak generation does not reduce the top-level clause. The library proves that V_Λ^+ is generated, under all n-th products, by the $e^\beta + e^{-\beta}$ (`leechPlus_generated`, Chapter 32). That is useless here: $o(a_{(n)}b)$ on Ω is not determined by $o(a)$ and $o(b)$ on Ω (the Borcherds identity involves the higher levels). Only Zhu generation ($*$ modulo $\mathcal{O}$) reduces the zero-mode clause to generators. Weak generation suffices only for a map already defined on the whole module.

40.8 Which generators? A numerical experiment

Before proving any Zhu generation statement one must decide which G to aim for. In rank one, $A(M(1)^+)$ needs a weight-four element J besides ω (Example 40.6), so it was not clear that weight two suffices for $V_0^+ \cong V_{\Lambda_0}^+$. A numerical and combinatorial experiment (`scripts/moonshine/numerics/zhu/zhu.py`; `Notes/ZhuGeneratorTest.md`) answered the question. *Nothing in this section is a Lean theorem*; it is recorded because it fixed the target of the Lean work and because it exposed two traps.

Let B be the associative algebra generated by the zero modes $o(u)$, $u \in (V_0^+)_2$. The space $(V_0^+)_2$ has dimension $49428 = 300 + 49128$: the $\binom{24}{2} + 24 = 300$ Fock states $h_a(-1)h_b(-1)\mathbf{1}$ ($a \le b$) and the $98256/2 = 49128$ lattice states $u_\gamma = e^\gamma + \theta e^\gamma$ for the 98256 norm-four $\gamma \in \Lambda_0$, taken up to sign.

The top of V_3^+. It is spanned by e^n, $n \in \Lambda_0 + \lambda_3$ with $|n|^2 = 4$ (98304 vectors). The zero modes act by

$$o(h_a h_b)e^n = n_a n_b\, e^n, \qquad o(e^\gamma)e^n = \begin{cases} \varepsilon(\gamma, n)e^{n+\gamma} & \langle \gamma, n\rangle = -2, \\ 0 & \text{otherwise,} \end{cases}$$

(coordinates in an orthonormal basis of $\Lambda \otimes \mathbb{R}$, i.e. $\sqrt{8}$-coordinates divided by $\sqrt{8}$, in which $\langle n, n'\rangle = n \cdot n'$). The joint eigenvalues nn^{T} determine n up to sign, so B contains the projector onto each $\operatorname{span}\{e^n, e^{-n}\}$. An exact machine check shows that the graph on the 98304 vectors with edges $\langle n, n'\rangle = 2$ (226 099 200 directed edges) is connected; in particular every n is joined to $-n$. Hence B contains all matrix units of V_3^+'s top, i.e. $B = \operatorname{End}((V_3^+)_2)$, and (by the antidiagonal holonomy of a loop from n to $-n$) $V_3^+ \not\cong V_3^-$ as B-modules.

The twisted top $h(-\frac{1}{2})\otimes X$. Here $o(h_a h_b) = \frac{1}{2}(E_{ab} + E_{ba}) + \frac{1}{8}\delta_{ab}$ and $o(u_\gamma) = 2 \cdot 2^{-4}(1 - gg^{\mathsf{T}}) \otimes e_\gamma$. The symmetric matrices generate M_{24}; and 400 random norm-four vectors already generate Λ_0 over $\mathbb{Z}$ (exact Hermite normal form: covolume $8192 = 2^{13}$), so the e_γ generate the extraspecial group, which acts irreducibly on X. Hence again $B = \operatorname{End}(\text{top})$.

All sixteen tops. The same reasoning shows that B acts irreducibly on the tops of all 16 irreducible V_0^+-modules and separates them, so B maps onto $\bigoplus_{i=1}^{16} \operatorname{End}(\text{top}_i)$, of dimension $1 + 3 \cdot 24^2 + 6 \cdot 2048^2 + 6 \cdot 49152^2 = 14\,520\,682\,177$. (Irreducibility alone does not give Zhu generation; see the circularity warning below.) If $A(V_0^+) \cong \bigoplus_{i=1}^{16} \operatorname{End}(\text{top}_i)$ (rationality and the classification of Abe–Dong–Li; *cited, not checked*), it would follow that $(V_0^+)_2$ Zhu-generates. So **no weight-four J is needed**; the rank-one obstruction is removed by the lattice part.

Trap / dead end

The circularity trap. Irreducibility of the tops under B does *not* prove the zero-mode clause. For a top-level map φ, the weight-two part of the module generated by the graph of φ is a B-submodule of $\Omega_1 \oplus \Omega_2 \cong \Omega_1^2$, hence either the graph (which gives the clause) or everything (which means $\Omega_1 \not\cong \Omega_2^\sigma$ as $A(V_0^+)$-modules). Excluding the second case needs

information about $A(V_0^+)$ beyond B: Zhu generation, or the classification. "Tops irreducible $\Rightarrow$ `ZhuGenerated`" is circular. What irreducibility does give is uniqueness of φ up to a scalar.

Trap / dead end

V_0^+ is not strongly generated by weight two. Strong generation by $(V_0^+)_2$ would mean $(V_0^+)_3 = L_{-1}(V_0^+)_2$ (normal-ordered products of weight-two states start at weight four, and $(V_0^+)_1 = 0$). But the Fock part of $(V_0^+)_3$ is spanned by the $24 \cdot 24 = 576$ states $h_a(-2)h_b(-1)\mathbf{1}$, while L_{-1} of the 300 Fock weight-two states gives at most 300. So the classical lemma "strong generators are Zhu generators" does not apply, and the proof must use the 0-th products $a_{(0)}b$ (§40.9). Also: low-order traces $\operatorname{tr} o(u)$, $\operatorname{tr} o(u)o(v)$ on random samples do *not* distinguish V_3^+ from V_3^-: that distinction lives in a long loop $n \to -n$.

40.9 A filtered criterion for Zhu generation

We now prove, for an arbitrary VOA W, a sufficient condition for Zhu generation that refers only to the vertex algebra and not to $*$ or $\mathcal{O}$.

40.9.1 The filtration and three leading-term identities

Definition 40.41. $F_{<n} = \bigoplus_{k<n} W_k$.

File `VOA/Moonshine/ZhuGenFiltration.lean`.

```
noncomputable def Fl (n : ℤ) : Submodule ℂ 𝒱 := ⨆ (k : ℤ) (_ : k < n), W.grading k
```

(`VOA/Moonshine/ZhuGenFiltration.lean`, namespace `VOA.Moonshine.ZhuGen`.)

From the mathematics to the Lean statement

`⨆` is the supremum (sum) of subspaces, here over $k < n$. Since the grading is a direct sum, this is $\bigoplus_{k<n} W_k$.

Physical meaning

The filtration by weight is the organisation of states by energy: $F_{<n}$ consists of all states of energy below n, so higher-energy states are measured modulo lower ones. This is the standard way to organise a VOA by oscillator number or conformal weight, and lets leading terms be compared.

The key observation is that, *modulo lower weight*, the three basic constructions have simple leading terms. For homogeneous $a \in W_p$, $b \in W_q$ $(p, q \geq 0)$:

- $a*b = a_{(-1)}b + \sum_{i\geq 1} \binom{p}{i} a_{(i-1)}b$, and $a_{(i-1)}b$ has weight $p+q-i$; so $a*b \equiv a_{(-1)}b \pmod{F_{<p+q}}$;
- $\operatorname{Pres}(a, p, b, k) \equiv a_{(-2-k)}b \pmod{F_{<p+q+1+k}}$;
- the commutator $a * b - b * a \equiv a_{(0)}b \pmod{\mathcal{O}(W) + F_{<p+q-1}}$.

Lemma 40.42. *For $a \in W_p$, $b \in W_q$:*

(a) $a * b - a_{(-1)}b \in F_{<p+q}$;

(b) if $p \in \mathbb{N}$, $a_{(-2-k)}b - \operatorname{Pres}(a, p, b, k) \in F_{<p+q+1+k}$ for all $k \in \mathbb{N}$;

(c) $T^j y \in \mathcal{O}(W) + X$ *for every subspace* X *containing the homogeneous vector* y*, where* $T = L_{-1}$.

File `VOA/Moonshine/ZhuGenFiltration.lean`.

```
theorem zhuMul_sub_normal_mem {p q : ℤ} {a b : V} (ha : a ∈ W.grading p) (hb : b ∈
↪  W.grading q) :
    zhuMul W a b - W.smul a (-1) b ∈ Fl W (p + q)

theorem smul_sub_Pres_mem {p : ℕ} {q : ℤ} {a b : V} (ha : a ∈ W.grading (p : ℤ))
    (hb : b ∈ W.grading q) (k : ℕ) :
    W.smul a (-2 - k) b - Pres W p a b k ∈ Fl W (p + q + 1 + k)

theorem Tpow_mem {w : ℤ} {y : V} (hy : y ∈ W.grading w) {X : Submodule ℂ V} (hyX : y ∈ X)
    (j : ℕ) : (W.toPreVertexAlgebra.T ^ j) y ∈ O W ⊔ X
```

Physical meaning

Modulo lower energy, the Zhu product is the ordinary normal-ordered product, and the higher modes are equal to the higher residues up to lower-energy corrections. These are the leading-term (top-energy) identities used to peel off the highest-energy part of a state in the filtered argument.

Proof on paper. (a), (b): all non-leading terms are $a_{(m)}b$ with m larger than the leading index, of weight $p+q-m-1$ below the bound. (c): $Ty \equiv -wy$ modulo $\mathcal{O}$ (Lemma 40.3(a)), and inductively $T^j y \equiv (-1)^j w(w+1)\cdots(w+j-1)\,y$. □

What the machine verified

Proved, unconditional.

Theorem 40.43 (Filtered commutator formula). *For* $a \in W_p$, $b \in W_q$ *with* $p, q \geq 0$,

$$a * b - b * a - a_{(0)}b \;\in\; \mathcal{O}(W) + F_{<p+q-1}.$$

File `VOA/Moonshine/ZhuGenFiltration.lean`.

```
theorem zhuMul_comm_sub_zero_mem {p q : ℤ} {a b : V} (ha : a ∈ W.grading p)
    (hb : b ∈ W.grading q) (hp : 0 ≤ p) (hq : 0 ≤ q) :
    zhuMul W a b - zhuMul W b a - W.smul a 0 b ∈ O W ⊔ Fl W (p + q - 1)
```

From the mathematics to the Lean statement

`O W ⊔ Fl W (p + q - 1)` is the sum of subspaces $\mathcal{O}(W)+F_{<p+q-1}$. Note that $a_{(0)}b$ has weight $p+q-1$, so the statement is that the commutator equals $a_{(0)}b$ *exactly at its own weight*, modulo $\mathcal{O}$. Zhu's exact formula $a * b - b * a \equiv \operatorname{Res}_z Y(a,z)b(1+z)^{p-1}$ implies this; the filtered form is all we need and is proved directly.

Physical meaning

The commutator of two zero modes is, to leading order in the energy filtration, the zero mode of the Lie-type product $a_{(0)}b$, i.e. the zero-mode algebra is a deformation quantisation of a commutative filtered algebra, with lower-energy corrections. This is the filtered version of $[o(a), o(b)] = o(a_{(0)}b)$ and is used to control the noncommutative terms.

Proof on paper. Work modulo $X = \mathcal{O} + F_{<p+q-1}$. From the definition of $*$, keeping the two top terms:

$$a * b \equiv a_{(-1)}b + p\,a_{(0)}b, \qquad b * a \equiv b_{(-1)}a + q\,b_{(0)}a.$$

Skew-symmetry $Y(b,z)a = e^{zT}Y(a,-z)b$ gives, in modes, $b_{(n)}a = \sum_{j\ge 0}\frac{(-1)^{n+1+j}}{j!}T^j(a_{(n+j)}b)$. For $n=-1$ and $n=0$, the terms with $n+j\ge 1$ have $a_{(n+j)}b$ of weight $< p+q-1$, and T^j of them lies in X by Lemma 40.42(c). So

$$b_{(-1)}a \equiv a_{(-1)}b - T(a_{(0)}b), \qquad b_{(0)}a \equiv -a_{(0)}b.$$

Finally $T(a_{(0)}b) \equiv -(p+q-1)\,a_{(0)}b$ modulo $\mathcal{O}$ (Lemma 40.3(a), as $a_{(0)}b$ has weight $p+q-1$). Substituting,

$$\begin{aligned} b*a &\equiv \big(a_{(-1)}b + (p+q-1)\,a_{(0)}b\big) - q\,a_{(0)}b \;=\; a_{(-1)}b + (p-1)\,a_{(0)}b,\\ a*b - b*a &\equiv \big(p-(p-1)\big)\,a_{(0)}b \;=\; a_{(0)}b. \end{aligned}$$

The coefficient $p-(p+q-1)+q = 1$ is what makes the 0-th products available. □

What the machine verified

Proved, unconditional, no `VOA.pbw`.

40.9.2 Weight-raising products and the criterion

Definition 40.44 (Weight-raising products of lower-weight states). For $n\in\mathbb{Z}$, lowerProd(n) is the set of $a_{(m)}b$ with $a\in W_p$, $b\in W_q$, $p,q<n$, $m\le 0$ and $p+q-m-1=n$.

File `VOA/Moonshine/ZhuGenFiltration.lean`.

```
def lowerProd (n : ℤ) : Set V :=
  {x | ∃ p q m : ℤ, p < n ∧ q < n ∧ m ≤ 0 ∧ p + q - m - 1 = n ∧
    ∃ a ∈ W.grading p, ∃ b ∈ W.grading q, x = W.smul a m b}
```

From the mathematics to the Lean statement

The condition $p+q-m-1=n$ says $a_{(m)}b\in W_n$. The condition $m\le 0$ is the content: the allowed products are the normal-ordered ones ($m=-1$), the higher ones ($m\le -2$), and the 0-th products ($m=0$). Products with $m\ge 1$ are excluded; they are not controlled by $*$.

Physical meaning

The set of states of energy n obtainable by acting with a raising mode on two states of strictly lower energy: the states of energy n that are generated by the field product of lighter ones. It is the basic notion of "composite" as opposed to "generating" state at that level.

Theorem 40.45 (The filtered criterion). *Let $G\subseteq W$. If $W_n\subseteq \mathrm{span}(G\cup \mathrm{lowerProd}(n))$ for every $n\ge 1$, then every subspace S with $\mathbf{1}\in S$, $\mathcal{O}(W)\subseteq S$, $S*S\subseteq S$ and $G\subseteq S$ equals W.*

File `VOA/Moonshine/ZhuGenFiltration.lean`.

```
theorem lowerProd_subset {S : Submodule ℂ V} (hO : O W ≤ S)
    (hmul : ∀ a ∈ S, ∀ b ∈ S, zhuMul W a b ∈ S) {n : ℤ} (hF : Fl W n ≤ S) :
    lowerProd W n ⊆ S

theorem eq_top_of_lowerSpan (G : Set V)
    (hG : ∀ n : ℤ, 0 < n → W.grading n ≤ span ℂ (G ∪ lowerProd W n))
    (S : Submodule ℂ V) (h1 : W.vacuum ∈ S) (hO : O W ≤ S)
    (hmul : ∀ a ∈ S, ∀ b ∈ S, zhuMul W a b ∈ S) (hGS : G ⊆ S) : S = ⊤
```

From the mathematics to the Lean statement

- The criterion is stated for any VOA W; in it, W_0 is spanned by $\mathbf{1}$ (`vacuum_grade`, part of the library's VOA axioms) and negative weights vanish (`positivity`).
- It concludes Zhu generation in the sense of Definition 40.36 (stated for W).
- It is a *sufficient* condition only: cancellations of leading terms could in principle give more. A numerical failure of the hypothesis would not refute Zhu generation.

Physical meaning

If every state of energy n is a combination of the generators and of products of lighter states, then the generators already generate everything under the Zhu product. This is an induction on energy: composite states are produced by products of lighter ones, so only the generators at the lowest level need to be supplied.

Proof on paper. `lowerProd_subset`: if $F_{<n} \subseteq S$ and $a_{(m)}b \in \mathrm{lowerProd}(n)$ then $a, b \in S$. For $m = -1$: $a_{(-1)}b = a*b-(a*b-a_{(-1)}b)$, a $*$-product in S minus an element of $F_{<n}$. For $m = -2-k$: $a_{(m)}b = \mathrm{Pres}+(\text{element of } F_{<n})$ with $\mathrm{Pres} \in \mathcal{O}$. For $m = 0$: $a_{(0)}b = (a*b-b*a)-(\text{element of } \mathcal{O}+F_{<n})$ by Theorem 40.43. Main theorem: induction on n shows $W_n \subseteq S$; $W_0 = \mathbb{C}\mathbf{1}$; for $n \geq 1$, W_n is spanned by G and by $\mathrm{lowerProd}(n) \subseteq S$. □

What the machine verified

Proved, unconditional, `#print axioms`-clean (re-run), no `VOA.pbw`.

Remark 40.46. Why this route is natural: modulo lower weight, the leading terms of elements of $\mathcal{O}$ are $a_{(-2-k)}b$ and $L_{-1}a$; those of $*$ are $a_{(-1)}b$; those of commutators are $a_{(0)}b$. The criterion is the associated-graded form of Zhu generation, and it splits weight by weight and, for lattice VOAs, charge by charge.

40.10 Zhu generation of V_0^+: reduction to three sectors

40.10.1 The residual for V_0^+

Definition 40.47. $G_2 = (V_0^+)_2$. The residual `V0LowerSpanned`: for every $n \geq 3$, $(V_0^+)_n \subseteq \mathrm{span}\,\mathrm{lowerProd}_{V_0^+}(n)$.

File `VOA/Moonshine/ZhuGenV0.lean`.

```
def weightTwo : Set V0Sub.carrier := {g | g ∈ V0P.grading 2}

theorem V0P_grading_one : V0P.grading 1 = ⊥

def V0LowerSpanned : Prop :=
  ∀ n : ℤ, 3 ≤ n → V0P.grading n ≤ span ℂ (lowerProd V0P n)

theorem zhuGenerated_weightTwo_of_lowerSpanned (h : V0LowerSpanned) : ZhuGenerated
 ↪ weightTwo
```

(`VOA/Moonshine/ZhuGenV0.lean`, namespace `VOA.Moonshine.SigmaExist`.)

From the mathematics to the Lean statement

- `V0P.grading n` is $(V_0^+)_n$, the weight-n part of V_0^+ for its own VOA structure; membership is the same as membership of the underlying vector in $(V_\Lambda^+)_n$ (`mem_V0P_grading_iff`).

- Weights 1 and 2 are free: $(V_0^+)_1 = 0$ (`V0P_grading_one`) and $(V_0^+)_2 = G_2$. So the hypothesis of Theorem 40.45 reduces to $n \geq 3$.
- `V0LowerSpanned` is a statement about the vertex algebra V_0^+ alone, strictly stronger than `ZhuGenerated weightTwo`.

Physical meaning

The generators are the full weight-two space $(V_0^+)_2$, i.e. the lightest nontrivial fields; the residual `V0LowerSpanned` states that all states of energy at least three are composites of lighter states. This is the finite generation of the chiral algebra by its weight-two fields, in the Moonshine setting the Griess algebra.

What the machine verified

`zhuGenerated_weightTwo_of_lowerSpanned`: proved, conditional only on its hypothesis (which is proved below).

Theorem 40.48 (The σ-residuals with weight-two letters). *Under* `V0LowerSpanned`, `TopSigmaV3 s φ` *follows from clauses (a), (b), (d) and the zero-mode identities* $\varphi(g_{(1)}x) = (\sigma g)_{(1)}\varphi(x)$ *for* $g \in (V_0^+)_2$, $x \in \Omega_3$; *similarly for* `TopSigmaTT`.

File `VOA/Moonshine/ZhuGenV0.lean`.

```
theorem topSigmaV3_of_lowerSpanned {s : ZMod 2} {φ : VPlus →ₗ[ℂ] TP}
    (hf : ∀ x ∈ OmegaV3, φ x ∈ TPframe s) (hw : ∀ x ∈ OmegaV3, φ x ∈ plusModule.weight (2 :
    ↪ ℂ))

    TopSigmaV3 s φ
```

From the mathematics to the Lean statement

For g of weight 2, $o(g) = g_{(1)}$: `actV g 1`.

Physical meaning

Once all heavier states are composites, the twisted-triality datum needs to be checked only for the zero modes of the weight-two fields, namely $g_{(1)}$. This is the form in which the top-level residual is attacked in the rest of the chapter.

What the machine verified

Proved, conditional on the displayed hypotheses.

40.10.2 Word states and the sector decomposition

V_Λ is spanned by word states $h_{a_1}(-n_1)\cdots h_{a_r}(-n_r)\otimes e^\gamma$. In the library a word is a list l of pairs (i,a) meaning $h_a(-i-1)$, and `wordWt l` $= \sum(i+1)$ is its Fock weight.

Definition 40.49. For $\gamma \in \Lambda_0$ and a word l, $w_0(l,\gamma) = P(h_{a_1}(-i_1-1)\cdots\otimes e^\gamma) \in V_0^+$, $P = \frac{1}{2}(1+\theta)$.

File `VOA/Moonshine/ZhuGenSectors.lean`.

```
noncomputable def wordV0 (l : List (ℕ × Fin (rank leech))) {γ : leech.carrier} (hγ : γ ∈
↪  lambda0) :
    V0Sub.carrier :=
  ⟨plusProj (wordStateLatGen leech l γ), plusProj_word_mem_V0 l hγ⟩

theorem V0P_grading_le_span_wordV0 (n : ℤ) : V0P.grading n ≤ span ℂ (wordSet n)
```

(VOA/Moonshine/ZhuGenSectors.lean.)

From the mathematics to the Lean statement

`wordSet n` is the set of $w_0(l,\gamma)$ with $\gamma \in \Lambda_0$ and total weight `wordWt l` $+\frac{1}{2}|\gamma|^2 = n$. The theorem: these span $(V_0^+)_n$. (Proof on paper: project a spanning set of $(V_\Lambda)_n$ by $\frac{1}{2}(1+g)$ and P; charges outside Λ_0 are killed.)

Physical meaning

A word state is the lattice vertex-operator state built by applying a word of oscillator creation operators to the charge-γ lattice state e^γ and projecting onto the θ-invariant part. It is the basis state of the orbifold's untwisted sector: oscillators on a ground state of charge γ, with the average over θ the orbifold projection.

Definition 40.50 (The three sector residuals).

- `FockSpanned`: every $w_0(l,0)$ of weight ≥ 3 lies in span lowerProd of its weight;
- `ExcitedSpanned`: every $w_0(l,\gamma)$ with $\gamma \neq 0$ and l non-empty does;
- `GroundSpanned`: every x_γ, $\gamma \in \Lambda_0$, $|\gamma|^2 \geq 6$, does.

File `VOA/Moonshine/ZhuGenSectors.lean`.

```
def FockSpanned : Prop :=
  ∀ l : List (ℕ × Fin (rank leech)), 3 ≤ (wordWt l : ℤ) →
    wordV0 l lambda0.zero_mem ∈ span ℂ (lowerProd V0P (wordWt l))

def ExcitedSpanned : Prop :=
  ∀ (l : List (ℕ × Fin (rank leech))) (γ : leech.carrier) (hγ : γ ∈ lambda0), γ ≠ 0 → l ≠
  ↪  [] →
    wordV0 l hγ ∈ span ℂ (lowerProd V0P ((wordWt l : ℤ) + LatGen.halfNorm leech γ))

def GroundSpanned : Prop :=
  ∀ (γ : leech.carrier) (hγ : γ ∈ lambda0), 6 ≤ leech.form γ γ →
    x0 hγ ∈ span ℂ (lowerProd V0P (LatGen.halfNorm leech γ))

theorem v0LowerSpanned_of_sectors (hF : FockSpanned) (hE : ExcitedSpanned) (hG :
↪  GroundSpanned) :
    V0LowerSpanned
```

From the mathematics to the Lean statement

- `LatGen.halfNorm leech γ` is $\frac{1}{2}|\gamma|^2$ (an integer since Λ is even); `leech.form γ γ` is $|\gamma|^2$.
- `x0 hγ` is $x_\gamma = e^\gamma + e^{-\gamma}$ regarded as an element of V_0^+; note $w_0([],\gamma) = \frac{1}{2}x_\gamma$ (`wordV0_nil`).
- Ground states of norm 4 have weight 2 and are in G_2; norm ≥ 6 is the residual. Fock states of weight ≤ 2 are in $\mathbb{C}\mathbf{1}+G_2$; charged excited states have weight ≥ 3 automatically. So the three residuals cover all of `wordSet n`, $n \geq 3$.

Physical meaning

The decomposition of V_0^+ by charge: states with zero charge (pure oscillator, "Fock", states of the free bosons), excited states of non-zero charge (oscillators on a charged ground state), and the charged ground states themselves. The three residuals say that in each class every state above weight two is a composite of lighter states; this is the case analysis in terms of the frame-charge sectors of the 24 bosons.

What the machine verified

`v0LowerSpanned_of_sectors`: proved; conditional only on the three named hypotheses, all of which are proved later in this chapter.

40.10.3 Products of ground states

Recall the lattice cocycle (Chapter 31, section "Even lattices and the FLM 2-cocycle"): the vertex operators of V_L use the twisted group algebra $\mathbb{C}_\varepsilon[L]$, $e^\alpha \cdot e^\beta = \varepsilon(\alpha,\beta)e^{\alpha+\beta}$, where $\varepsilon : L \times L \to \{\pm 1\}$ is a bimultiplicative 2-cocycle, built from a chosen $\mathbb{Z}$-basis of L, with $\varepsilon(\alpha,\beta)\varepsilon(\beta,\alpha) = (-1)^{\langle\alpha,\beta\rangle}$. In Lean it is `latticeCocycle L α β` (`VOA/Foundations/LatticeCocycle.lean`), with `latticeCocycle_sq` ($\varepsilon^2 = 1$, same file) and `latticeCocycle_neg_left`, `latticeCocycle_neg_right`, `latticeCocycle_neg_neg` (ε is unchanged by negating either argument, by bimultiplicativity; `VOA/Moonshine/LatticeInvolution.lean`). Below $\epsilon = \varepsilon$. For lattice vectors the products of charged vacua are explicit: $e^\alpha_{(n)}e^\beta = \epsilon(\alpha,\beta)\,S_d(\alpha) \otimes e^{\alpha+\beta}$ with $d = -n-1-\langle\alpha,\beta\rangle$, where $S_d(\alpha)$ is the degree-d Schur polynomial in the $h_\alpha(-j)$ (zero for $d<0$, 1 for $d=0$). Symmetrising over $\pm$ gives:

Theorem 40.51 (Ground-state products). *For $\alpha,\beta \in \Lambda$:*

(a) if $\langle\alpha,\beta\rangle = -1$: $x_{\alpha(0)}x_\beta = \epsilon(\alpha,\beta)\,x_{\alpha+\beta}$;

(b) if $\langle\alpha,\beta\rangle = 0$: $x_{\alpha(-1)}x_\beta = \epsilon(\alpha,\beta)\,(x_{\alpha+\beta} + x_{\alpha-\beta})$;

(c) if $\langle\alpha,\beta\rangle = k \geq 1$: $x_{\alpha(-k-1)}x_\beta = \epsilon(\alpha,\beta)\big(x_{\alpha+\beta} + 2P(S_{2k}(\alpha)\otimes e^{\alpha-\beta})\big)$.

Files `VOA/Moonshine/ZhuGenLattice.lean`, `VOA/Moonshine/ZhuGenGround.lean` (in order of the declarations below).

```
theorem frameX0P_smul_zero_of_form_neg_one {α β : leech.carrier} (h : leech.form α β = -1)
 ↪  :
    leechVOAPlus.smul (frameX0P α) 0 (frameX0P β) = latticeCocycle leech α β • frameX0P (α
     ↪  + β)

theorem frameX0P_smul_neg_one_of_form_zero {α β : leech.carrier} (h : leech.form α β = 0) :
    leechVOAPlus.smul (frameX0P α) (-1) (frameX0P β)
      = latticeCocycle leech α β • (frameX0P (α + β) + frameX0P (α - β))

theorem frameX0P_smul_of_form_pos {α β : leech.carrier} {k : ℕ} (h : leech.form α β = k) :
    ((leechVOAPlus.smul (frameX0P α) (-(k : ℤ) - 1) (frameX0P β) : VPlus) : LatModuleGen
     ↪  leech)
      = latticeCocycle leech α β • (frameX0 (α + β)
        + (2 : ℂ) • (plusProj (latStateGen leech (vSchur leech α (2 * k)) (α - β)) :
            LatModuleGen leech))
```

(`VOA/Moonshine/ZhuGenLattice.lean` for (a), (b); `VOA/Moonshine/ZhuGenGround.lean` for (c).)

From the mathematics to the Lean statement

- `latticeCocycle leech α β` is the sign $\epsilon(\alpha,\beta) = \pm 1$ of the lattice VOA (Chapter 31); `vSchur leech α d` is $S_d(\alpha)$; `latStateGen leech p γ` is $p \otimes e^{\gamma}$.
- (c) is stated in V_Λ (after two coercions) because its right side involves `frameX0` and the image of `plusProj`.
- The proofs use $\epsilon(-\alpha,-\beta) = \epsilon(\alpha,\beta)$ and $\epsilon(-\alpha,\beta) = \epsilon(\alpha,-\beta) = \epsilon(\alpha,\beta)$, properties of the library's cocycle established in Chapter 31.

Physical meaning

These are the OPE coefficients of charged vertex operators $e^{\alpha}(z)e^{\beta}(w) \sim \epsilon(\alpha,\beta)(z-w)^{\langle\alpha,\beta\rangle}e^{\alpha+\beta}(w)$: when the inner product is -1 the leading term gives a single new charged state, for 0 and positive inner product the expansion produces the sum of the charge $\alpha+\beta$ state and corrections. They show how a charged ground state is obtained from lighter ones by a single field product.

Proof on paper. Expand $x_{\alpha(n)}x_\beta$ into four terms $e^{\pm\alpha}_{(n)}e^{\pm\beta}$. In (a) with $n=0$: $e^{\alpha}_{(0)}e^{\beta}$ has $d = -1+1 = 0$ and gives $\epsilon e^{\alpha+\beta}$; the cross terms have $\langle\alpha,-\beta\rangle = 1$, $d=-2<0$, and vanish; $e^{-\alpha}_{(0)}e^{-\beta}$ gives $\epsilon e^{-\alpha-\beta}$. In (b) with $n=-1$ all four terms have $d=0$. In (c) with $n=-k-1$: the like-sign terms have $d=0$, the cross terms $d=2k$, and θ sends $S_{2k}(\alpha)\otimes e^{\alpha-\beta}$ to the other cross term (S_{2k} is even in α). □

What the machine verified

Proved, unconditional.

Definition 40.52 (Ground relations and the lattice residual). GroundRel(n) is the set of the following elements, for $\alpha,\beta \in \Lambda_0 \setminus 0$ with $\frac{1}{2}|\alpha+\beta|^2 = n$: $x_{\alpha+\beta}$ if $\langle\alpha,\beta\rangle = -1$ or $\langle\alpha,\beta\rangle \geq 1$; $x_{\alpha+\beta} + x_{\alpha-\beta}$ if $\langle\alpha,\beta\rangle = 0$. `GroundLattice`: every x_γ, $\gamma\in\Lambda_0$, $|\gamma|^2 \geq 6$, is in the span of GroundRel($\frac{1}{2}|\gamma|^2$).

File `VOA/Moonshine/ZhuGenGround.lean`.

```
def GroundRel (n : ℤ) : Set V0Sub.carrier :=
  {x | ∃ (α β : leech.carrier) (hα : α ∈ lambda0) (hβ : β ∈ lambda0), α ≠ 0 ∧ β ≠ 0 ∧
      LatGen.halfNorm leech (α + β) = n ∧
      ((leech.form α β = -1 ∨ 1 ≤ leech.form α β) ∧ x = x0 (lambda0.add_mem hα hβ) ∨
        leech.form α β = 0 ∧ x = x0 (lambda0.add_mem hα hβ) + x0 (lambda0.sub_mem hα hβ))}

def GroundLattice : Prop :=
  ∀ (γ : leech.carrier) (hγ : γ ∈ lambda0), 6 ≤ leech.form γ γ →
    x0 hγ ∈ span ℂ (GroundRel (LatGen.halfNorm leech γ))

theorem groundSpanned_of_lattice (hF : FockSpanned) (hE : ExcitedSpanned) (hL :
↪  GroundLattice) :
    GroundSpanned

theorem zhuGenerated_weightTwo_of_residuals (hF : FockSpanned) (hE : ExcitedSpanned)
    (hL : GroundLattice) : ZhuGenerated weightTwo
```

From the mathematics to the Lean statement

- `GroundRel` is a set of vectors, but each vector is described by lattice data only; since the x_γ (γ up to sign) are linearly independent, `GroundLattice` is a combinatorial statement about Λ_0: every γ of norm ≥ 6 is either a "direct" sum $\gamma = \alpha+\beta$ with $\langle\alpha,\beta\rangle \in$

$\{-1\} \cup [1, \infty)$, or is reached by a combination of $k = 0$ relations.

- $\alpha = \beta$ is *allowed* (no $\alpha \neq \beta$ condition). This matters; see the warning.

Physical meaning

The relations are the lattice combination rules for the charged ground states in the OPE: a ground state at lattice vector $\alpha + \beta$ is a field-product of ground states at α and β (up to $\pm$ sign combinations when the vectors are orthogonal). `GroundLattice` states that every heavy ground state, of norm at least six, arises this way, a purely lattice-combinatorial fact about the Leech sublattice.

Proof on paper. Each element of GroundRel(n) is in span lowerProd(n): by Theorem 40.51, x_α and x_β have weights $\frac{1}{2}|\alpha|^2, \frac{1}{2}|\beta|^2 < n$ (norms ≥ 4 since Λ has no roots), the product has mode ≤ 0, and the extra term in (c) is $P(S_{2k}(\alpha) \otimes e^{\alpha-\beta})$, a charge-$(\alpha-\beta)$ state with $2k$ oscillators, which is in the span by `ExcitedSpanned` (or, when $\alpha = \beta$, by `FockSpanned`). □

What the machine verified

Proved; conditional only on the named hypotheses, all proved below.

Trap / dead end

Do not exclude $\alpha = \beta$. For $\gamma = 2\alpha$ with $|\alpha|^2 = 4$ ($|\gamma|^2 = 16$), the only partner with $\langle \alpha, \gamma - \alpha \rangle \geq 1$ is $\alpha = \gamma/2$ (checked by `e4_check.py`). The cross term is then a charge-zero Fock state, so `FockSpanned`, not `ExcitedSpanned`, is needed. An early draft of `GroundRel` required $\alpha \neq \beta$ and was too weak.

Ground states only come from ground states. A product $a_{(m)}b$ with a Fock-excited source has Fock-excited leading part (the Fock weight of the result is at least that of the sources), so `GroundLattice` is necessary for the filtered criterion, not merely convenient.

40.11 The Fock sectors: `ExcitedSpanned` and `FockSpanned`

Both Fock residuals are proved using a single kind of left factor: the *quadratic Heisenberg states*

$$q_{a,i;b,j} \;=\; h_a(-i-1)h_b(-j-1)\mathbf{1} \in V_0^+ \qquad (a, b \in \{0, \dots, 23\},\ i, j \geq 0),$$

of weight $i + j + 2$ (they are θ-even and have charge 0, so they lie in V_0^+). Notation: the Fock space is the polynomial ring $\mathbb{C}[X(i, a)]$, where $X(i, a)$ stands for the creation operator $h_a(-i-1)$; a state $p \otimes e^\gamma$ has Fock weight $\sum(i+1)$ and *degree* (number of oscillators) deg p.

40.11.1 The modes of a quadratic state

The vertex operator of $q_{a,i;b,j}$ is the normal-ordered product $:\frac{1}{i!}\partial^i h_a(z)\,\frac{1}{j!}\partial^j h_b(z):$. On the charge-$\gamma$ sector the boson modes are

$$h_a(k) \;=\; \begin{cases} X(-k-1, a)\cdot & k < 0 \text{ (creation)}, \\ \langle e_a, \gamma \rangle & k = 0 \text{ (momentum)}, \\ k\,\partial/\partial X(k-1, a) & k > 0 \text{ (annihilation)}. \end{cases}$$

Definition 40.53. For $s \in \mathbb{Z}$ let $\mathrm{quadF}_\gamma(a,i;b,j;s)$ be the operator on the Fock factor of the charge-γ sector given by

$$\mathrm{quadF}(s)\,p \;=\; \sum_{m\in\mathbb{Z}} :g_a^i(m)\,g_b^j(s-m):\;\; p, \qquad g_a^i(m) = \frac{1}{i!}\prod_{l=0}^{i-1}(m+1+l)\cdot h_a(-m-i-1),$$

normal ordered (the factor with non-negative index acts first).

File `VOA/Moonshine/FockSpanOps.lean`.

      = latStateGen leech (quadF γ a i b j (-n - 1) p) γ
```

(`VOA/Moonshine/FockSpanOps.lean`, namespace `VOA.Moonshine.FockSpan`.)

From the mathematics to the Lean statement

- `Fk` is the Fock space $\mathbb{C}[X(i,a)]$ (`FockN (rank leech)`, 24 colours); `oscN` is the oscillator $h_a(k)$ without zero-mode momentum; `chargeCoord leech γ a` is the momentum $\langle e_a, \gamma\rangle$ in an orthonormal frame. `hOp` is the boson mode on the charge-γ sector.
- `cf i j` is the coefficient of $(i!)^{-1}\partial^i$ acting on z^{-j-i-1}: the field $\frac{1}{i!}\partial^i h(z)$ has m-th coefficient $\mathrm{cf}(i,m)\,h(-m-i-1)$ in the convention $\sum_m (\cdot)_m z^m$ used by the library's normal-ordered product.
- `qTerm` with the test `0 ≤ m` is the normal ordering. `∑ᶠ` is a sum with finite support (proved finite in the library).
- `smul_quad`: the n-th product $q_{(n)}(p\otimes e^\gamma)$ equals $\mathrm{quadF}(-n-1)p\otimes e^\gamma$. The index $s=-n-1$ is the exponent convention for fields; mode n of the field is the coefficient of z^{-n-1}.

Physical meaning

quadF(s) is the mode of a normal-ordered bilinear in the oscillator currents, $:\partial^i X^a\,\partial^j X^b:$, acting on the charge-$\gamma$ Fock space. These are the modes of the quadratic composite fields (the stress tensor is the diagonal case), the lightest composite fields of the free-boson theory, acting on the oscillator part of a charged sector.

Proof on paper. The vertex operator of $h_a(-i-1)h_b(-j-1)\mathbf{1}$ in a lattice VOA is, by reconstruction, the normal ordered product of $\frac{1}{i!}\partial^i h_a(z)$ and $\frac{1}{j!}\partial^j h_b(z)$. Reading off the coefficient of z^{-n-1} gives the formula. Charge is preserved since the field has charge zero. □

What the machine verified

Proved, unconditional.

Theorem 40.54 (Leading term, commutators and vacuum values)**.** *On the charge-γ sector:*

(a) (leading term) if p has degree $\le d$ and weight w, then $\mathrm{quadF}(0)p - X(i,a)X(j,b)p$ *has degree $\le d+1$ and weight $w+i+j+2$;*

        + (((j : ℂ) + 1) * chargeCoord leech γ a) • (X (j + 1, c) : Fk)
```

From the mathematics to the Lean statement

- `Fdw d w` is the space of Fock polynomials of total degree $\le d$ and weight w (`restrictTotalDegree`, `gradingZN`).

- `quadF … 0` is the (-1)-mode (as $s = -n-1 = 0$), and `quadF … (-1)` is the 0-mode. `1 : Fk` is the Fock vacuum, so (c), (d) are values on e^{γ}. `.toNat` only converts the non-negative index $t+s+2$ to a natural number.
- γ_a denotes `chargeCoord leech γ a`.

Physical meaning

The leading term of the bilinear mode is the product of two creation operators, so it raises oscillator number by two; its commutator with a creation operator is linear (the quadratic field acts on the oscillators like a Bogoliubov-type generator), and its action on the charged vacuum is fixed by the charge through the zero mode γ_a. These are the standard free-boson computations used to show that bilinears reach all states with few oscillators.

Proof on paper. (a) The $m = 0$ summand of quadF(0) is the product of the two creation operators $X(i,a)X(j,b)$. Every other summand either contains a factor with coefficient cf $= 0$ (the product $\prod_l (m+1+l)$ vanishes for $-i \le m \le -1$), or pairs one creation with one annihilation/zero mode, raising the degree by at most one. (b) Only annihilation operators contribute to the commutator; $[h_b(k), X(t,c)] = k\,\delta_{cb}\delta_{k,t+1}$ picks the terms $m = t+s+2$ and $m = -t-2$. (c), (d) On the vacuum all annihilators vanish, so only summands with the annihilating factor replaced by a momentum survive: these are written out. □

What the machine verified

Proved, unconditional.

40.11.2 The target spaces and the degree ascent

Definition 40.55. For $\gamma \in \Lambda_0$ and n, $T_\gamma(n)$ is the space of Fock polynomials p with $P(p \otimes e^{\gamma}) \in \operatorname{span} \operatorname{lowerProd}_{V_0^+}(n)$.

File `VOA/Moonshine/FockSpanBase.lean`.

```
noncomputable def Tsub {γ : leech.carrier} (hγ : γ ∈ lambda0) (n : ℤ) : Submodule ℂ Fk :=
  (span ℂ (lowerProd V0P n)).comap (excitedV0 hγ)
```

Physical meaning

$T_\gamma(n)$ is the space of oscillator states, on the charge-γ ground state, that are already composites at energy n. The spanning arguments aim to show that it is everything of the right weight, i.e. that all oscillator excitations are generated by lighter composites.

(`VOA/Moonshine/FockSpanBase.lean`.) Here `excitedV0 hγ` is the linear map $p \mapsto P(p \otimes e^{\gamma}) \in V_0^+$ (`VOA/Moonshine/ZhuGenGround.lean`) and `comap` is the preimage.

Lemma 40.56 (The basic spanning step and the degree ascent). *(a) If q has weight $i+j+2 < n$, $p \otimes e^{\gamma}$ has weight $w + \frac{1}{2}|\gamma|^2 < n$, $m \le 0$ and the total is n, then* quadF$(-m-1)p \in T_\gamma(n)$. *(b) If $T_\gamma(n)$ contains all weight-w states of degree $\le d_0$, and for every $D \ge d_0$ the monomials $X(v_1)X(v_2)m'$ of degree $D+1$ lie in $T_\gamma(n)$ whenever all weight-w states of degree $\le D$ do, then $T_\gamma(n)$ contains every weight-w state. (c) The inductive step of (b) holds whenever $m' \otimes e^{\gamma}$ has positive weight.*

```

From the mathematics to the Lean statement

- In (a), `gradingWN (rank leech) w` is the weight-w Fock space; (a) says the product $q_{(m)}P(p\otimes e^{\gamma})$, which equals $P(\mathrm{quadF}(-m-1)p\otimes e^{\gamma})$ because q is θ-even, is a lowerProd element.
- In `step_quad`, a monomial is given by its exponent vector `s'`; `s'.degree` is its degree and `wt s'` its weight. `hpos` is the positivity of the weight of $m'\otimes e^{\gamma}$, needed so that the product has two lower-weight factors.

Physical meaning

Acting with a bilinear field raises the degree (oscillator number) by two; this lemma packages the induction in which the all-states-of-degree-at-most-D hypothesis lifts to degree $D+1$ using two creation operators at a time. It is the oscillator-number induction on the Fock space.

Proof on paper. (a) is the definition of lowerProd together with Definition 40.53. (b) Induction on degree: a monomial of degree $D+1 > d_0 \geq 1$ factors as $X(v_1)X(v_2)m'$. (c) By Theorem 40.54(a), $(q_{v_1v_2})_{(-1)}P(m'\otimes e^{\gamma}) = P(X(v_1)X(v_2)m'\otimes e^{\gamma}) + (\text{degree} \leq D)$; the left side is in the span by (a), the correction by the induction hypothesis. □

What the machine verified

Proved, unconditional. (`Fdw_le_of_ascent` is part (b).)

40.11.3 Charged excited states

By the ascent, only degree one must be done by hand. Fix $\gamma \in \Lambda_0 \setminus 0$, $N = |\gamma|^2 \geq 4$ (even). In the quotient by $T_{\gamma}(n)$ write $\varphi_a = [X(\tau+1,a)]$ for the degree-one state $h_a(-\tau-2)e^{\gamma}$, and $T = \tau+1$, $\varepsilon = (-1)^{\tau}$.

Theorem 40.57 (Charged degree one). *For $\gamma \in \Lambda_0 \setminus 0$ and all t, c: $h_c(-t-1)e^{\gamma}$ lies in $T_{\gamma}(t+1+\frac{1}{2}|\gamma|^2)$. Consequently* `ExcitedSpanned` *holds.*

File `VOA/Moonshine/FockSpanCharged.lean`.

    (X (t, c) : Fk) ∈ Tsub hγ ((t : ℤ) + 1 + LatGen.halfNorm leech γ)

theorem excitedSpanned : ExcitedSpanned
```

(`VOA/Moonshine/FockSpanCharged.lean`.)

From the mathematics to the Lean statement

- `charged_algebra` is a lemma of pure linear algebra: from the family of relations `hR` and two non-vanishing coefficients it concludes $\varphi = 0$. It is stated for any finite colour set ι and any vector space M (applied to the quotient by $T_\gamma(n)$).
- `X (t, c)` is $h_c(-t-1)$ applied to the Fock vacuum, so `charged_deg_one` is the displayed statement. `excitedSpanned` has no hypotheses: it is the unconditional proof of the residual of Definition 40.50.

Physical meaning

On a charged ground state, a single oscillator excitation $\alpha_{-t-1}e^\gamma$ is already a composite of lighter states, by acting with a bilinear. Consequently all states with oscillators on a nonzero-charge ground state are composites, the excited-sector residual. Physically: the charged sectors carry no new generators above their ground states.

Proof on paper. Bottom case $t = 0$. By Theorem 40.54(c) the 0-mode products $(h_a h_b)_{(0)}e^\gamma = \gamma_b h_a(-1)e^\gamma + \gamma_a h_b(-1)e^\gamma$ are in the span. So in the quotient, $\gamma_b\varphi_a + \gamma_a\varphi_b = 0$ for all a, b. Pick b with $\gamma_b \neq 0$: $a = b$ gives $\varphi_b = 0$, then all $\varphi_a = 0$.

General $t = \tau + 1$. Two families of products are available:

- the (-1)-modes $(h_a(-1)h_c(-\tau-1)\mathbf{1})_{(-1)}e^\gamma$, which by Theorem 40.54(d) give $[X(0,a)X(\tau,c)] = -(\varepsilon\gamma_c\varphi_a + T\gamma_a\varphi_c)$;
- the 0-modes $(h_a h_b)_{(0)}\big(h_c(-\tau-1)e^\gamma\big)$, which by (b), (c) equal $T(\delta_{cb}\varphi_a + \delta_{ca}\varphi_b) + \gamma_b X(0,a)X(\tau,c) + \gamma_a X(0,b)X(\tau,c)$ in the quotient.

Substituting the first into the second gives, for all colours a, b, c,

$$T(\delta_{cb}\varphi_a + \delta_{ca}\varphi_b) - \varepsilon\gamma_c(\gamma_b\varphi_a + \gamma_a\varphi_b) - 2T\gamma_a\gamma_b\varphi_c = 0.$$

Contract with γ_c (using $\sum_c \gamma_c^2 = N$) and put $\Phi = \sum_c \gamma_c\varphi_c$: $(T - \varepsilon N)(\gamma_b\varphi_a + \gamma_a\varphi_b) - 2T\gamma_a\gamma_b\Phi = 0$. Contract once more with $a = b$ summed against γ_a: $2(T - \varepsilon N - TN)\Phi = 0$. The coefficients are non-zero because $N \geq 4$ is even: if τ is even, $T - N - TN < 0$ and $T - N$ is odd; if τ is odd, $T + N > 0$ and $T + N - TN = 0$ would force $(T-1)(N-1) = 1$. So $\Phi = 0$, then $\gamma_b\varphi_a + \gamma_a\varphi_b = 0$, then $\varphi = 0$ as in the bottom case. Finally `ExcitedSpanned` follows from degree one by the ascent of Lemma 40.56 (the source $m' \otimes e^\gamma$ always has positive weight since $\frac{1}{2}|\gamma|^2 \geq 2$). □

What the machine verified

`excitedSpanned`: proved, unconditional, `#print axioms` = [`propext`, `Classical.choice`, `Quot.sound`] (re-run).

Trap / dead end

Weight-two quadratics alone fail in charged degree one, and so does the approximate leading term: the exact vacuum formula of Theorem 40.54(d), with both momentum corrections, is what makes the linear algebra close. An earlier plan (`Notes/ZhuGeneration.md` §4.2) used four separate tools and a change of basis to a vector $z \perp \gamma$; the contraction argument above replaced it.

40.11.4 The charge-zero sector $M(1)^+$

In charge zero the momentum vanishes, so the 0-modes of weight-two quadratics are derivations $D_{ab} = (h_a h_b)_{(0)}$ of $\mathbb{C}[X]$ with $[D_{ab}, X(t,c)] = (t+1)(\delta_{cb}X(t+1,a) + \delta_{ca}X(t+1,b))$. Odd-degree states project to 0 under P, so degree 1 is trivial; degree ≥ 3 follows from the ascent; everything rests on degree two (the *bilinears* $X(i,c)X(j,f)$, weight $i+j+2 = n \geq 3$).

Theorem 40.58 (The bilinears and `FockSpanned`)**.** *Every charge-zero bilinear of weight $n \geq 3$ lies in $T_0(n)$. Consequently* `FockSpanned` *holds.*

File `VOA/Moonshine/FockSpanFock.lean`.

theorem fockSpanned : FockSpanned
```

(`VOA/Moonshine/FockSpanFock.lean`.)

From the mathematics to the Lean statement

- `T0 n` is $T_0(n)$, the charge-zero case of `Tsub`. In `fock_bilinear`, $v_1 = (i,c)$, $v_2 = (j,f)$ and `hw` is "weight n".
- `diag_algebra`: $W(c,k)$ stands for the class of the diagonal bilinear $V_c(k) = X(k,c)X(n-2-k,c)$. `hthird` (a third colour avoiding any two) holds because there are $24 \geq 3$ colours (`exists_third`). `hb`, `hsym`, `hc` are the three families of relations described in the proof.
- `quadN0_cancel` is the "degree-four cancellation": quadF$(\cdot;0)$ is the (-1)-mode. `fockSpanned` has no hypotheses.

Physical meaning

In the charge-zero (neutral) sector every bilinear of weight at least three is a composite of lighter fields, so the pure-oscillator part of the orbifold algebra is generated by its weight-two (and lighter) bilinears, namely the Virasoro-type field and its relatives. This is the neutral half of the Fock-sector residual, free-boson bookkeeping for the 24 oscillators.

Proof on paper. *Off-diagonal* $X(i,c)X(j,f)$, $c \neq f$, $i \geq 1$: choose a third colour $e \notin \{c,f\}$; then $D_{ce}\big(X(i-1,e)X(j,f)\big) = i\,X(i,c)X(j,f)$, a 0-mode of a weight-two state on a weight-$(n-1)$ state. (If $i = 0$, swap the factors; $j \geq 1$ since $n \geq 3$.)

Diagonal $V_c(k) = X(k,c)X(n-2-k,c)$. For $c \neq e$ and $1 \leq k \leq n-2$,

$$D_{ce}\big(X(k-1,e)X(n-2-k,c)\big) = k\,V_c(k) + (n-1-k)\,V_e(k-1)$$

is in the span. Also $V_c(k) = V_c(n-2-k)$. Comparing two colours c, g via a third e shows that modulo the span $V_c(k)$ does not depend on c; then the relations become the recursion $kV(k) + (n-1-k)V(k-1) \equiv 0$ for $1 \leq k \leq n-2$. For $n = 3$ the case $k = 1$ and the symmetry $V(0) = V(1)$ give $2V(0) \equiv 0$. For $n \geq 4$ one more relation is needed, because the recursion and the symmetry alone leave room for a non-zero solution in rank one: this is the deficiency behind the J of $A(M(1)^+)$ (Example 40.6); numerically, rank one is deficient by exactly one dimension at weight 4. The extra relation is the degree-four cancellation, available because there are at least two colours:

$$(h_c h_e)_{(-1)}\big(X(0,c)X(n-4,e)\big) - (h_c h_c)_{(-1)}\big(X(0,e)X(n-4,e)\big) = (n-3)\,V_c(0) + V_e(2),$$

in which the degree-four leading terms $X(0,c)X(0,e)X(0,c)X(n-4,e)$ cancel between the two products, leaving only single contractions. Combining it with the recursion at $k = 1$ and $k = 2$ gives $(n-3)\,n\,V(0) \equiv 0$, so $V(0) \equiv 0$ and inductively $V(k) \equiv 0$. Degree ≥ 3 follows by the ascent (the source m' has degree ≥ 1, hence positive weight); degree one is zero after projection. □

What the machine verified

`fockSpanned`: proved, unconditional, `#print axioms`-clean (re-run). Rank ≥ 3 is used (three colours); rank 24 is available.

Example 40.59 (Weight three). $(V_0^+)_3$ has Fock part spanned by the 576 states $h_a(-2)h_b(-1)\mathbf{1}$. For $a \neq b$ choose $e \notin \{a,b\}$: $(h_a h_e)_{(0)}\big(h_e(-1)h_b(-1)\mathbf{1}\big) = h_a(-2)h_b(-1)\mathbf{1}$, a 0-th product of two weight-two states. For $a = b$: with $n = 3$, $V_a(1) = X(1,a)X(0,a) = h_a(-2)h_a(-1)\mathbf{1}$ and $V_a(0) = V_a(1)$ by symmetry; the relation with $k = 1$ reads $V_a(1) + V_e(0) \equiv 0$, i.e. $2V(1) \equiv 0$ after identifying colours. (Of course $h_a(-2)h_a(-1)\mathbf{1} = \frac{1}{2}L_{-1}(h_a(-1)^2\mathbf{1})$ is also directly an L_{-1}-image.) None of the off-diagonal states is in $L_{-1}(V_0^+)_2$: this is the failure of strong generation, rescued by 0-th products.

Numerical cross-check. Before the Lean proof, `fock_lowerprod.py` (exact arithmetic modulo $2^{31}-1$) confirmed: rank one is deficient by exactly one dimension at weight 4 only; ranks 2, 3, 4 are full through weights 11, 9, 8. `charged_lowerprod.py` found full rank in every charged case tested (ranks 1–4; the only failure, $|\gamma|^2 = 2$, does not occur in Λ_0). These are evidence, superseded by the proofs above.

40.12 The ground states: Golay combinatorics

What remains is `GroundLattice`, a purely combinatorial statement about Λ_0. We work in the coordinates (40.3): $\Lambda_0 \cong A = \{g \in \mathbb{Z}^{24} : g \bmod 2 \in \mathcal{G},\ 4 \mid \sum g_i\}$, $\langle g,h\rangle = \frac{1}{2}g \cdot h$. In these coordinates: $|\gamma|^2 \geq 6 \iff g \cdot g \geq 12$; norm-four vectors have $g \cdot g = 8$; $\langle \alpha,\beta\rangle = -1 \iff a \cdot b = -2$.

40.12.1 Facts about the Golay code

The extended binary Golay code $\mathcal{G} \subset \mathbb{F}_2^{24}$ (Lean: `Code.golay`, constructed in Chapter 30) is a doubly even, self-dual $[24, 12, 8]$ code containing the all-ones word, with 759 words of weight 8 (*octads*). These facts are proved in Chapter 30; here we derive the further facts the ground-state argument needs. Subsets of $\{0, \dots, 23\}$ are identified with words via their indicator `ind`.

Definition 40.60. An *octad* is a set O of size 8 whose indicator lies in $\mathcal{G}$.

File `VOA/Moonshine/GroundLatticeGolay.lean`.

```
def ind (A : Finset (Fin 24)) : Fin 24 → ZMod 2 := fun j => if j ∈ A then 1 else 0

def IsOct (O : Finset (Fin 24)) : Prop := ind O ∈ golay ∧ O.card = 8
```

Physical meaning

An octad is a set of eight of the 24 coordinates, i.e. eight of the 24 bosons, whose indicator lies in the Golay code. Octads label the minimal charged ground states (lattice vectors of the Leech lattice with shape $(\pm 2^8, 0^{16})$), the frame-charge bookkeeping of the 24 bosons.

(`VOA/Moonshine/GroundLatticeGolay.lean`, namespace `VOA.Moonshine.GroundLat`.)

    ∃ O, IsOct O ∧ (O ∩ S).card = 3
```

From the mathematics to the Lean statement

- `Finset (Fin 24)` is a finite subset of $\{0, \dots, 23\}$; `card` its size; `weight` the Hamming weight. `·ᵥ` is the dot product over $\mathbb{F}_2$, so `ind O ·ᵥ x ≠ 0` means $|O \cap \operatorname{supp} x|$ is odd.
- (c) is only the existence half of $S(5, 8, 24)$ (uniqueness of the octad is not stated or needed).
- All are about the library's specific code `golay`; they hold for every extended Golay code but are proved here from the four properties listed above (doubly even, self-dual, minimum weight 8, 759 octads), with no enumeration of codewords.

Physical meaning

These are the standard combinatorial facts about the Golay code: codeword weights, intersections of octads, and the Steiner system $S(5, 8, 24)$ (every five coordinates in a unique octad). In the lattice picture they classify how the frame charges of the 24 bosons combine into Leech-lattice ground states of low norm; they are pure combinatorics with no dynamical content, used to guarantee that every heavy lattice vector has a decomposition into lighter ones.

Proof on paper. (a) Weights are divisible by 4 (doubly even); non-zero weights are ≥ 8; and $c + \mathbf{1}$ is a codeword of weight $24 - \operatorname{wt} c$, so weights ≤ 23 other than 0 are also ≤ 16 ($24 - \operatorname{wt} \geq 8$). (b) $|O_1 \triangle O_2| + 2|O_1 \cap O_2| = 16$ and $O_1 \triangle O_2$ is a non-zero codeword, so $|O_1 \triangle O_2| \geq 8$ and $|O_1 \cap O_2| \leq 4$.

(c) *By counting.* Each octad contains $\binom{8}{5} = 56$ five-subsets, and by (b) no five-subset lies in two octads. So the octads contain $759 \cdot 56 = 42504$ distinct five-subsets. But $\binom{24}{5} = 42504$. Hence every five-subset is in an octad.

(d) By self-duality $x \notin \mathcal{G} = \mathcal{G}^\perp$, so some codeword y has $y \cdot x = 1$. If $\operatorname{wt} y = 8$, done. If $\operatorname{wt} y = 16$, then $y + \mathbf{1}$ is an octad and $(y + \mathbf{1}) \cdot x = y \cdot x$ because x has even weight. If $\operatorname{wt} y = 12$ (a *dodecad*), y is a sum of two octads (take an octad O meeting y in ≥ 5 points by (c); then $O \triangle y$ has weight $20 - 2|O \cap y| \leq 10$, so it is an octad), and one of the two has odd product with x. ($\operatorname{wt} y \in \{0, 24\}$ is impossible: $0 \cdot x = 0$ and $\mathbf{1} \cdot x = \operatorname{wt} x = 0$.)

(e) Take an octad O meeting C in ≥ 5 points. The intersection sizes are constrained by $|O \triangle C| = 8 + |C| - 2|O \cap C| \in \{0, 8, 12, 16, 24\}$: for $|C| = 12$ this forces $|O \cap C| \in \{2, 4, 6\}$, so 6; for $|C| = 16$ it forces $\{4, 6, 8\}$, so 6 or 8. In the remaining case $O \subseteq C$, $|C| = 16$: take $T \subset O$ with $|T| = 3$, a point $c_5 \in C \setminus O$ and a point $d \notin C$; the octad O' through the five points $T \cup \{c_5, d\}$ meets C in 4 to 7 points, hence in 4 or 6; and 4 is impossible, since then $O \cap O' = T$ would have 3 points, while octads meet in an even number of points (again from the weight constraint).

(f) Let $S = \{s_1, \dots, s_4\}$. Choose $p \notin S$ and the octad $O_1 \supseteq S \cup \{p\}$, then $q \notin O_1$ and the octad $O_2 \supseteq \{s_1, s_2, s_3, p, q\}$. If $s_4 \in O_2$ then $O_1 \cap O_2 \supseteq S \cup \{p\}$ has 5 points, contradicting (b) ($O_1 \neq O_2$ as $q \in O_2 \setminus O_1$). So $O_2 \cap S = \{s_1, s_2, s_3\}$. □

What the machine verified

All proved, unconditional, `#print axioms`-clean (re-run for `steiner`). No `decide` over the 4096 codewords: the only computational input is the weight enumerator fact 759 from Chapter 30.

40.12.2 The lattice statement in Golay coordinates

Definition 40.62 (Direct and triangle relations)**.** For $g \in \mathbb{Z}^{24}$:

- Direct(g): there is $a \in A \setminus 0$ with $g - a \neq 0$ and $a \cdot (g - a) = -2$ or $a \cdot (g - a) \geq 2$;
- ZeroRel(u, v): $u = a + b$, $v = a - b$ with $a, b \in A \setminus 0$ and $a \cdot b = 0$;

- Tri(g): there are g', g'' with ZeroRel(g, g'), ZeroRel(g', g''), ZeroRel(g'', g).

File `VOA/Moonshine/GroundLatticeCoord.lean`.

```
def Direct (g : Fin 24 → ℤ) : Prop :=
  ∃ a ∈ subA, a ≠ 0 ∧ g - a ≠ 0 ∧ (a ·ᵥ (g - a) = -2 ∨ 2 ≤ a ·ᵥ (g - a))

def ZeroRel (u v : Fin 24 → ℤ) : Prop :=
  ∃ a ∈ subA, ∃ b ∈ subA, a ≠ 0 ∧ b ≠ 0 ∧ a ·ᵥ b = 0 ∧ a + b = u ∧ a - b = v

def Tri (g : Fin 24 → ℤ) : Prop :=
  ∃ g' g'', ZeroRel g g' ∧ ZeroRel g' g'' ∧ ZeroRel g'' g
```

(`VOA/Moonshine/GroundLatticeCoord.lean`.)

From the mathematics to the Lean statement

- `subA` is A; $\cdot_v$ the integer dot product, i.e. $2\langle\cdot,\cdot\rangle$. So Direct$(g)$ says $\gamma = \alpha + \beta$ with $\alpha, \beta \in \Lambda_0 \setminus 0$ and $\langle\alpha, \beta\rangle = -1$ or ≥ 1: a ground relation of the first kind. ZeroRel(u, v) is the $k = 0$ relation $x_u + x_v$.
- Direct does not require $g \in A$ (it follows when g is a sum of two elements of A).

Physical meaning

The relations describe when a lattice vector g can be written as a sum $a + b$ of two non-zero lattice vectors with prescribed inner product $a \cdot b$, that is, as a product of two charged ground states (-2 or at least 2), or through a three-step cycle of orthogonal decompositions (the triangle). They are the OPE channels of charge-a and charge-b vertex operators in coordinates, in the frame-charge bookkeeping.

Theorem 40.63 (Ground-lattice theorem in coordinates). *Every $g \in A$ with $g \cdot g \geq 12$ satisfies* Direct(g) *or* Tri(g).

File `VOA/Moonshine/GroundLatticeCoord.lean`.

```
theorem groundLatticeA : ∀ g ∈ subA, 12 ≤ g ·ᵥ g → Direct g ∨ Tri g
```

The proof is a case analysis on the shape of g. First, some constructions.

Pair vectors. For $i \neq j$ and signs, $a = 2(\pm e_i \pm e_j) \in A$ (it is 0 mod 2 and its sum is 0 or ± 4), $a \cdot a = 8$, and with the signs of g_i, g_j, $a \cdot g = 2(|g_i| + |g_j|)$. Since $a \cdot (g - a) = a \cdot g - 8$, this gives Direct$(g)$ as soon as $a \cdot g = 6$ or $a \cdot g \geq 10$, i.e. as soon as *some pair has* $|g_i| + |g_j| = 3$ *or* ≥ 5 (`direct_of_pair`).

Octad vectors. For an octad O, a point $p \in O$ and signs $\sigma_j = \operatorname{sgn} g_j$ on $O \setminus p$, there is a choice $\sigma_p = \pm 1$ such that $a = \sigma \cdot \mathbf{1}_O \in A$ (the sum $\sum_O \sigma_j$ must be $\equiv 0$ mod 4; flipping σ_p changes it by 2); then $a \cdot a = 8$ and $a \cdot g = \sigma_p g_p + \sum_{O \setminus p} |g_j|$ (`exists_octVec`).

The shapes. If no pair has $|g_i| + |g_j| \in \{3\} \cup [5, \infty)$, then (when not all coordinates are odd) one of: $g = \pm 4e_i$; all $|g_j| \in \{0, 2\}$; all $|g_j| \leq 1$ with some $g_j = 0$.

- $|g_j| \in \{0, 2\}$, **support** S. Each entry ± 2 contributes 2 mod 4 to $\sum g_j$, so $4 \mid \sum g_j$ forces $|S|$ even, and $g \cdot g = 4|S| \geq 12$ gives $|S| \geq 4$. If $|S| = 4$, an octad meeting S in 3 points (Theorem 40.61(f)) and $p \in O \setminus S$ give $a \cdot g = 2 \cdot 3 = 6$. If $|S| \geq 5$, an octad meeting S in ≥ 5 points (by (c)) gives $a \cdot g \geq 10$, choosing $p \notin S$ when possible and otherwise using $\sigma_p g_p \geq -2$ (`direct_even2`).

- $|g_j| \le 1$, **some** $g_j = 0$. Then g mod 2 is the indicator of the support C, a codeword of weight 12 or 16 (it is ≥ 12 by the norm, and < 24). An octad meeting C in 6 points (Theorem 40.61(e)) gives $a \cdot g = 6$ (`direct_le_one`).
- $g = \pm 4e_i$ **(family E_1).** No direct relation exists. But $4e_i = 2(e_i + e_j) + 2(e_i - e_j)$ with orthogonal summands, so ZeroRel($\pm 4e_i, 4e_j$); the triangle $\pm 4e_i \to 4e_{i+1} \to 4e_{i+2} \to \pm 4e_i$ gives Tri (`e1_tri`).
- **All coordinates odd.** Let $\tau(g) = \{j : g_j \equiv 3 \bmod 4\}$.
  - If $\tau(g) \notin \mathcal{G}$: $\tau(g)$ has even size (from $4 \mid \sum g_j$), so by (d) some octad O meets it oddly. Take $p \in O$ minimising $|g_p|$; then $a \cdot g \ge -|g_p| + 7|g_p| \ge 6$, and a mod-4 computation shows $a \cdot g \equiv 2 \bmod 4$; hence $a \cdot g = 6$ or ≥ 10 (`odd_direct`).
  - If $\tau(g) \in \mathcal{G}$: for any codeword $C \notin \{\varnothing, \Omega\}$, flipping the signs of g on C is a ZeroRel step: $g = (g - g|_C) + g|_C$ and $\mathrm{flip}_C\, g = (g - g|_C) - g|_C$, where $g|_C \in A$ because $\tau(g) \in \mathcal{G}$ makes the sum over C divisible by 4, and the two pieces have disjoint supports, hence are orthogonal (`zeroRel_flip`). Flipping on C_1, then C_2, then $C_1 \triangle C_2$ returns to g: a triangle (`odd_tri`, with C_1, C_2 two explicit rows of the generator matrix).

From the mathematics to the Lean statement

The exceptional families, and why the uniform τ-criterion is the right formulation. The route notes (`Notes/ZhuGeneration.md` §4.3) isolated three families with no direct relation at all (confirmed by exhaustive enumeration, `e3_relations.py`):

- $E_1 = \{\pm 4e_i\}$ ($|\gamma|^2 = 8$);
- $E_2 = \{(\pm 1)^{24} : \text{negative set} \in \mathcal{G}\}$ ($|\gamma|^2 = 12$);
- $E_3 = \{s + 2s_i e_i : s \in \{\pm 1\}^{24},\ N(s) \triangle \{i\} \in \mathcal{G}\}$ ($|\gamma|^2 = 16$; one orbit of 98304 vectors), $N(s)$ the negative set.

For $g \in E_2$, $\tau(g)$ is the negative set; for $g \in E_3$ ($g_i = \pm 3$), $\tau(g) = N(s) \triangle \{i\}$ (if $s_i = 1$, $g_i = 3 \in \tau$ and $i \notin N$; if $s_i = -1$, $g_i = -3 \equiv 1$ and $i \in N$). So $E_2 \cup E_3$ is contained in $\{g \text{ all odd} : \tau(g) \in \mathcal{G}\}$, and the Lean proof treats this whole set by the triangle argument, whether or not a direct relation also exists. This is a simplification over the notes, not a weakening: Tri is a valid route for every such g.

Physical meaning

Every Leech sublattice vector of norm at least twelve (in coordinates) either decomposes directly as a sum of two lighter vectors with inner product -2 or at least 2, or through a triangle of orthogonal decompositions. Physically: every heavy charged ground state is a field product of lighter ones, because its lattice vector has a suitable decomposition. Pure combinatorics of the Golay code and the Steiner system.

What the machine verified

`groundLatticeA`: proved, unconditional. Only small kernel `decide`s are used (on `Fin 24`, on `ZMod 2`, and on the values of two rows of the generator matrix).

Trap / dead end

Random sampling misses E_2 and E_3. The first numerical check (`ground_states.py`: random placements of every magnitude pattern up to $|\gamma|^2 = 28$, 60 per pattern) found only E_1.

E_2 and E_3 are single *sign classes* (codeword sign patterns), which random signs essentially never hit. Lattice conditions on Λ_0 must be checked by orbit structure or exhaustively, not by sampling.

40.12.3 Transport to the vertex algebra

Theorem 40.64 (`GroundLattice` holds). `GroundLattice` *(Definition 40.52) is true.*

File `VOA/Moonshine/GroundLattice.lean`.

```
noncomputable def iotaA (a : ₁Leech.subA) : leech.carrier := (lambda0Equiv a :
↪  leech.carrier)

theorem groundLattice : GroundLattice

theorem zhuGenerated_weightTwo_of_fock_excited (hF : FockSpanned) (hE : ExcitedSpanned) :
    ZhuGenerated weightTwo
```

(`VOA/Moonshine/GroundLattice.lean`, namespace `VOA.Moonshine.SigmaExist`.)

From the mathematics to the Lean statement

`iotaA` is the isometric inclusion $A \to \Lambda_0 \subset \Lambda$ with $\langle \iota a, \iota b\rangle = (a \cdot b)/2$. `groundLattice` has no hypotheses.

Physical meaning

Transport of the coordinate statement to the vertex algebra: every heavy ground state of the sector is a combination of OPE products of lighter charged ground states. In field-theory language, the charged ground states of norm at least six carry no new generators; they are generated from lighter ones, which is the ground-state residual.

Proof on paper. Given $\gamma \in \Lambda_0$ with $|\gamma|^2 \geq 6$, let $g = \iota^{-1}\gamma$; $g \cdot g = 2|\gamma|^2 \geq 12$. A Direct witness a gives $\gamma = \iota a + \iota(g - a)$, a ground relation of the first kind. A ZeroRel(u, v) gives the relation $x_u + x_v$, and $|u|^2 = |v|^2$ (as $a \perp b$), so all three relations of a triangle have the right weight; then

$$x_g = \tfrac{1}{2}\big[(x_g + x_{g'}) - (x_{g'} + x_{g''}) + (x_{g''} + x_g)\big]$$

lies in the span. (This is why a triangle, an odd cycle, is needed: with all relation signs $+$, a path or even cycle would only give alternating sums.) □

What the machine verified

Proved, unconditional, `#print axioms` = [`propext`, `Classical.choice`, `Quot.sound`] (re-run).

40.13 The headline: V_0^+ is Zhu-generated by weight two

Theorem 40.65 (R-gen). *Every subspace of V_0^+ that contains $\mathbf{1}$, $\mathcal{O}(V_0^+)$ and $(V_0^+)_2$, and is closed under Zhu's product, is all of V_0^+.*

File `VOA/Moonshine/ZhuGenerated.lean`.

```
theorem zhuGenerated_weightTwo : SigmaExist.ZhuGenerated SigmaExist.weightTwo :=
  FockSpan.zhuGenerated_weightTwo_of_groundLattice SigmaExist.groundLattice
```

(`VOA/Moonshine/ZhuGenerated.lean`, namespace `VOA.Moonshine`.)

From the mathematics to the Lean statement

- Unfolding: `ZhuGenerated` is Definition 40.36, `weightTwo` is $(V_0^+)_2$ (Definition 40.47), `zhuMul` and `O` are Definitions 40.1, 40.2 applied to the VOA `V0P` $= V_0^+$.
- The one-line proof term is itself informative: R-gen is the assembly `FockSpanned` $\wedge$ `ExcitedSpanned` $\wedge$ `GroundLattice` $\Rightarrow$ R-gen, with the three inputs `fockSpanned`, `excitedSpanned`, `groundLattice`.
- No hypotheses. The statement is not vacuous (Definition 40.36). It is consistent with the numerical experiment of §40.8 and with the literature classification of $A(V_{\Lambda_0}^+)$, neither of which is used.

Physical meaning

The weight-two fields Zhu-generate the whole chiral algebra: the zero modes of the weight-two fields, with the identity, already generate the algebra of zero modes acting on the ground states of every sector. Combined with the earlier reduction, it means that to extend the triality to the twisted sectors one only needs to check the intertwining on the zero modes of the weight-two fields; it is the unconditional input that makes the three sector residuals together sufficient.

Proof on paper. Theorem 40.45 (filtered criterion) reduces to `V0LowerSpanned`; §40.10 reduces that to the Fock, charged-excited and ground sectors; Theorems 40.58, 40.57 and 40.64 prove them. □

What the machine verified

Proved, unconditional. Re-run for this chapter, via `lake env lean -DmaxSynthPendingDepth=3` on a scratch file importing `VOA.Moonshine.ZhuGenerated`:

```
'VOA.Moonshine.zhuGenerated_weightTwo' depends on axioms: [propext, Classical.choice,
↪ Quot.sound]
```

No `VOA.pbw`. The file is imported by the umbrella `VOA/Moonshine.lean`; for an earlier commit the project's build record reports the aggregate `lake build` green (10343 jobs; not re-run for this chapter).

What it buys. Combining Theorems 40.65, 40.40 and 40.33: to construct σ on V_3^+ (and likewise on T_s^+) it suffices to give one linear map φ on the 49152-dimensional top level which maps into $(T_s^+)_2$, hits a cyclic vector, and intertwines $o(g) = g_{(1)}$ with $o(\sigma g)$ for the 49428 weight-two letters g. Chapter 41 supplies φ and proves those identities (`topSigma_both`), using `zhuGenerated_G2`, which is `zhuGenerated_weightTwo` for the letter set `G2` $=$ `weightTwo` (`G2_eq_weightTwo : G2 = weightTwo := rfl`).

40.14 Dead ends and traps

Trap / dead end

Collected from the route notes, with the evidence:

1. **Which `TPframe` is T_0?** Undetermined by the definitions (Theorem 40.21); state results with $\exists s$.
2. **Dong–Jiang / Verma route** carries `BottomProjection`, supplied only by `VOA.pbw`; re-

placed by the graph argument (§40.3.4).

3. $\varphi = 0$ satisfies all clauses but `hits_cyclic`; that clause is essential.
4. **Gram route** (`annCompat_of_gram`) needs source Gram data too; unnecessary.
5. **Weak generation** (`leechPlus_generated`) does not reduce the top-level clause.
6. **Tops irreducible** ⇒ **Zhu generated** is circular.
7. **Strong generation fails**: Fock part of weight 3 has dimension $576 > 300$.
8. **Rank one fails** at weight 4 (J); the degree-four cancellation needs two colours.
9. **Charged degree one** needs the exact vacuum formula, not weight-two quadratics alone.
10. $\alpha = \beta$ **must be allowed** in `GroundRel`.
11. **Random sign sampling misses E_2, E_3.**
12. **Low-order traces** do not separate $V_3^{\pm}$.
13. The filtered criterion is *sufficient only*: do not record a numerical failure of it as a failure of Zhu generation.

40.15 Referee's checklist

"uncond." = no hypothesis that is an unproved datum; ∗ = `#print axioms` re-run for this chapter, result [`propext`, `Classical.choice`, `Quot.sound`]. None of the declarations uses `VOA.pbw`.

40.16 Notes and references

Zhu's algebra. Y. Zhu, *Modular invariance of characters of vertex operator algebras*, J. Amer. Math. Soc. 9 (1996), 237–302, introduced $A(V)$, the product $*$, $\mathcal{O}(V)$ and the correspondence between $A(V)$-modules and top levels (Theorems 2.1.2 and 2.2.1 there). I. B. Frenkel and Y. Zhu, *Vertex operator algebras associated to representations of affine and Virasoro algebras*, Duke Math. J. 66 (1992), 123–168, contains the higher residues Pres (their Lemma 2.1.2) and the bimodule technique used in Chapter 42. C. Dong, H. Li and G. Mason, *Vertex operator algebras and associative algebras*, J. Algebra 206 (1998), 67–96 (arXiv:q-alg/9612010), give the generalised Verma modules $M(U)$ and $L(U)$ and the higher Zhu algebras $A_n(V)$; the library's version (Dong–Jiang) is treated in Chapter 13. The presentation of $*$ and $\mathcal{O}$ follows T. Gannon, *Moonshine beyond the Monster*, Cambridge University Press, 2006, §5.3. Li's single-mode spanning lemma: H. Li, *Local systems of vertex operators, vertex superalgebras and modules*, J. Pure Appl. Algebra 109 (1996), 143–195 (arXiv:hep-th/9406185).

The orbifold V_L^+ and its Zhu algebra. C. Dong and K. Nagatomo, *Classification of irreducible modules for the vertex operator algebra $M(1)^+$*, J. Algebra 216 (1999), 384–404 (arXiv:math/9806051), where $A(M(1)^+)$ is generated by ω and J. T. Abe and C. Dong, *Classification of irreducible modules for the vertex operator algebra V_L^+: general case*, J. Algebra 273 (2004), 657–685 (arXiv:math/0210160); T. Abe, C. Dong and H. Li, *Fusion rules for the vertex operator algebras $M(1)^+$ and V_L^+*, Comm. Math. Phys. 253 (2005), 171–219 (arXiv:math/0310425). These classification results are *cited, not used*: the Lean proof of Zhu generation is independent of them.

The triality. I. Frenkel, J. Lepowsky and A. Meurman, *Vertex Operator Algebras and the Monster*, Academic Press, 1988, chapters 11–13. L. Dolan, P. Goddard and P. Montague, *Conformal field theories, representations and lattice constructions*, Comm. Math. Phys. 179 (1996), 61–120 (arXiv:hep-th/9410029), §§6–7, where σ on the twisted sectors is obtained non-constructively. A modern account of the sixteen irreducible V_Λ^{++}-modules and the lifting of the triality is in G. Höhn and M. Seysen, "The order of the Monster finite simple group", arXiv:2508.01037 (2025), §2.2.

The Golay code and the Steiner system. J. H. Conway and N. J. A. Sloane, *Sphere Packings, Lattices and Groups*, 3rd ed., Springer, 1999, chapters 3, 10 and 11 (the Golay code, the Steiner system $S(5,8,24)$, octads and dodecads, and the Leech lattice in Golay coordinates). The counting proof of the existence half of $S(5,8,24)$ given in Theorem 40.61(c) is the classical one ($759\binom{8}{5} = \binom{24}{5}$).

Project records. `Notes/TrialityTwisted.md`, `Notes/SigmaExistence.md`, `Notes/ZhuGeneratorTest.md`, `Notes/ZhuGeneration.md`, and the "Status" sections of `Notes/M8GluingPlan.md` from "M8g twisted half" to "R-gen CLOSED"; numerical scripts in `scripts/moonshine/numerics/zhu/` and `zhugen/`.

Chapter 41

Existence of the twisted triality II: the explicit construction

41.1 Where we stand, and what this chapter does

This chapter documents the release of the library named in the front matter. Quotations from the repository are printed in `leancode` boxes, which are checked by `scripts/textbook/sync.py` to occur verbatim in the source of that release (up to whitespace; documentation comments may be omitted); tool output is printed in plain boxes. Checks that were run at an earlier state of the library and not re-run for this edition are marked as such.

Chapter 39 built the *untwisted* half of the Frenkel–Lepowsky–Meurman triality: an involutive automorphism σ of the vertex operator algebra V_0^+, the fixed points of a group $(\mathbb{Z}/2)^2$ acting on the Leech lattice VOA V_Λ. Chapter 40 explained why one needs more: σ must be *extended* to the two other irreducible V_0^+-modules that make up $V^\natural$, namely

$$\sigma : V_3^+ \longrightarrow T_s^+ \qquad \text{and} \qquad \sigma : T_{s'}^+ \longrightarrow T_s^+,$$

as *σ-twisted intertwiners*: linear maps Φ with $\Phi(u_{(n)}x) = (\sigma u)_{(n)}\Phi(x)$ for all $u \in V_0^+$ and all n. Chapter 40 then proved two reduction theorems:

(i) such a Φ exists as soon as there is a linear map φ on the *top level* (the weight-two space, of dimension 49152) that satisfies the zero-mode identity $\varphi(\mathrm{o}(a)x) = \mathrm{o}(\sigma a)\varphi(x)$ for *every* homogeneous $a \in V_0^+$ and hits a cyclic vector (the residual structures `TopSigmaV3`, `TopSigmaTT`);

(ii) because the weight-two space $(V_0^+)_2$ generates the Zhu algebra of V_0^+ (`zhuGenerated_weightTwo`), it suffices to check the zero-mode identity for a of weight two.

What is left is therefore a *finite, explicit* problem of linear algebra: write down φ on a 49152-dimensional space, and check $\varphi \circ \mathrm{o}(a) = \mathrm{o}(\sigma a) \circ \varphi$ for every a in the 49428-dimensional space $(V_0^+)_2$. This chapter solves it, in Lean, with no hypotheses. The headline results are

```
topSigmaV3 : ∃ s ∃ φ, TopSigmaV3 s φ,      topSigmaTT : ∃ s ∃ φ, TopSigmaTT s s φ,
```

their consequences `sigmaV3T_exists`, `sigmaTT_exists`, and the combined form `topSigma_both`, in which both maps come from one and the same "seed" vector so that their sectors match.

The shape of the answer

The physics picture is helpful. $V^\natural$ is a $\mathbb{Z}/2$-orbifold of the Leech lattice theory; the twisted sector V_Λ^T is built on the ground states T, a 4096-dimensional irreducible representation of a finite extraspecial 2-group (Chapter 34), and its weight-two states are $h(-\frac{1}{2}) \otimes T$, one twisted oscillator on a ground

state. The untwisted states of weight two in V_3^+ are the lattice states $e^n + e^{-n}$ for the 98304 odd Leech vectors n of norm 4. The triality σ exchanges these two descriptions, and we shall find that it does so *monomially*:

$$\varphi\big(e^n + e^{-n}\big) \;=\; h_{w_{j(n)}}(-\tfrac{1}{2}) \otimes \tau(n), \qquad \tau(n) = i^{\,n_0}\ \mathrm{sign}(n_{j(n)})\ e_n\, t,$$

where $j(n)$ is the unique coordinate in which n has an entry ± 3, $w_j = 8e_j$ is the j-th frame vector, e_n is the action of n on T, and $t \in T$ is one fixed "seed" vector. The work of the chapter is (a) to compute all zero modes on both sides, (b) to compute σ on every weight-two letter, (c) to construct the seed t, and (d) to verify the identities, which in the end reduce to facts about the Golay code (minimum weight 8, self-duality, double evenness) and a few 2×2 matrix identities over $\mathbb{Q}(\sqrt{2}, i)$.

A remark on method: everything stays symbolic

The Leech lattice cocycle ε_Λ in the library is defined from an arbitrary $\mathbb{Z}$-basis chosen by `Module.Free.chooseBasis`; its values are not computable. Likewise the character `golayE` that enters the bridge between the Niemeier lattice $N(A_1^{24})$ and the Leech lattice is chosen by `Classical.choose`. Not a single sign in this chapter is ever evaluated. Every identity is derived from structural properties — bimultiplicativity, $\varepsilon(a,a) = \pm 1$, the commutator formula $\varepsilon(a,b)\varepsilon(b,a) = (-1)^{\langle a,b\rangle}$, the coboundary comparison between cocycles of two lattices, and θ-invariance of $\sigma(u)$. Section 41.8 discusses why this was not an obstacle, and why a refactoring to an explicit basis would not have helped.

41.2 The objects, and the statements to be proved

This section collects, with their Lean sources, the definitions that occur in the statements of the chapter. Most were introduced in Chapters 32, 34, 36, 39 and 40; we repeat what is needed so that every statement below can be checked against definitions printed in this book.

41.2.1 Coordinates on the Leech lattice

The library's Leech lattice Λ (`leech`) is realised inside $\mathbb{Z}^{24}$: a vector is an integer vector $x = (x_0, \dots, x_{23})$ and the bilinear form is

$$\langle x, y\rangle \;=\; \tfrac{1}{8}\, x \cdot y. \tag{41.1}$$

(This is the usual $\frac{1}{\sqrt{8}}$-normalisation of the Turyn/Conway construction; see Chapter 30.) The lattice consists of the vectors $x \equiv 0 \pmod 2$ with $x/2 \bmod 2$ in the Golay code $\mathcal{G}$ and $\sum x_i \equiv 0 \pmod 8$ (the *even* Leech vectors, $x = 2a$ with $a \in A$ below), together with the translates $x = 2a + u$ of these by $u = (5, 1^{23})$ (the *odd* Leech vectors; `Leech.uVec`). The homomorphism

$$\beta : \Lambda \to \mathbb{Z}/2, \qquad \beta(x) = x_0 \bmod 2$$

is the library's `frameChar`; its kernel is the index-two sublattice Λ_0 (`lambda0`).
File `VOA/Moonshine/FrameSectors.lean`.

```
noncomputable def frameChar : leech.carrier →+ ZMod 2 := Leech.beta.toAddMonoidHom

noncomputable def lambda0 : Submodule ℤ leech.carrier := LinearMap.ker Leech.beta
```

with `Leech.beta` the map `x ↦ ((x 0 : ℤ) : ZMod 2)` (`VOA/LatticesAndCodes/Leech/Defs.lean`). In Lean the integer coordinates of a Leech vector x are written `lv x : Fin 24 → ℤ` (`SigmaTopFrame.lean`), and the identity (41.1) is the theorem `leech_form_lv`:

```
def lv (x : leech.carrier) : Fin 24 → ℤ := (show ↥Leech.carrier from x).1

theorem leech_form_lv (x y : leech.carrier) : leech.form x y = (lv x ⬝ᵥ lv y) / 8 := rfl
```

(the integer division is exact, since $8 \mid x \cdot y$ for Leech vectors, `eight_dvd_lv`).

Two other lattices. Two further lattices enter. The set

$$A = \{a \in \mathbb{Z}^{24} \,:\, a \bmod 2 \in \mathcal{G},\ 4 \mid \textstyle\sum a_i\}$$

(`Leech.subA`) carries the form $\langle a, b\rangle_A = \frac{1}{2} a \cdot b$; it is the lattice `lam0`. It maps isometrically onto Λ_0 by $\iota_\Lambda(a) = 2a$ (`inclΛ`), and it also sits inside the Niemeier lattice

$$N = N(A_1^{24}) = \{x \in \mathbb{Z}^{24} \,:\, x \bmod 2 \in \mathcal{G}\}, \qquad \langle x, y\rangle_N = \tfrac{1}{2} x \cdot y$$

(`golayN`) by the identity map ι_N (`inclN`). In N the vectors $\alpha_j = 2e_j$ (`golayRoot j`) are the 48 roots $\pm\alpha_j$ of the root system A_1^{24}. So

$$N \;\supset\; A \;\xrightarrow{\iota_\Lambda = 2\cdot}\; \Lambda_0 \subset \Lambda,$$

and $A \cong \Lambda_0 = \Lambda \cap N$ is the common index-two sublattice through which the Leech theory and the Niemeier theory are compared. In Leech coordinates the frame vectors are $w_j = \iota_\Lambda(4e_j) = 8e_j$ (`fw j`); they satisfy $\langle w_j, x\rangle = x_j$ and $\langle w_j, w_k\rangle = 8\delta_{jk}$. The special frame vector $w_0 = 8e_0$ is `frameW`.

41.2.2 The lattice VOAs, the cocycles, and the bridge

For an even lattice L the lattice VOA V_L (Chapter 31) has states $p \otimes e^\gamma$, p in the Heisenberg Fock space, $\gamma \in L$. Its vertex operators involve a ±1-valued bimultiplicative 2-cocycle ε_L with $\varepsilon_L(a,b)\varepsilon_L(b,a) = (-1)^{\langle a,b\rangle}$, the library's `latticeCocycle L`; it is defined from the basis `latticeBasis L`, itself an arbitrary $\mathbb{Z}$-basis. The charged vacuum $1 \otimes e^\gamma$ is `latChargeGen L γ`, and in this chapter we write it e^γ.

Two lattice VOAs built from *different* cocycles on isometric lattices are isomorphic, but the isomorphism rescales charged states by a function $c(\gamma) \in \{\pm 1, \pm i\}$ which is a "coboundary" comparing the two cocycles: $\varepsilon_L(\iota a, \iota b)\, c(a)c(b) = \varepsilon_K(a,b)\, c(a+b)$. This is `latCob K L ι` (Chapter 31, `latticeCocycle_map_mul_latCob`).

Chapter 39 built the VOA isomorphism

$$\texttt{golayToV0}:\ V_N^{\langle \chi, \Theta\rangle} \xrightarrow{\sim} V_0^+,$$

the composite of the lattice functoriality maps for $A \to N$ and $A \to \Lambda$ with one twist by a character g_e of A, the character `golayE`, chosen (by `Classical.choose`) so that a certain involution of V_A becomes the standard θ. The triality on V_0^+ is the transport of the N-side triality: Files `VOA/Moonshine/TrialityGolay.lean`, `VOA/Moonshine/FrameBridgeGolay.lean`.

```
noncomputable def golaySigma : Aut golayVOA := golayG * golayChiMod * golayG⁻¹

noncomputable def golayTheta : Aut golayVOA := golaySigma * golayChi * golaySigma

noncomputable def golayToV0 : (orbifold golayK).carrier ≃ₗ[ℂ] V0Sub.carrier :=
  lam0PlusGolayEquiv.symm.trans lam0PlusEquiv

noncomputable def v0Sigma : Aut V0P :=
  Aut.transport golayToV0 golayToV0_isVOAHom golayToV0_omega golaySigma0
```

Here `golayG` $= \prod_j g_j$ with $g_j = \exp\big((1-\sqrt{2})E_j\big)\exp\big(\frac{\sqrt{2}}{4}F_j\big)$, where $E_j = (e^{\alpha_j})_{(0)}$, $F_j = \varepsilon_j(e^{-\alpha_j})_{(0)}$ and $\varepsilon_j = \varepsilon_N(\alpha_j, -\alpha_j)$ (`golayEps j`) are the $\hat{\mathfrak{sl}}_2$ zero modes attached to the root α_j; `golayChiMod` is the momentum sign $e^\gamma \mapsto (-1)^{\sum \gamma_i/2 + \gamma_0} e^\gamma$ (Chapter 39 explains the extra γ_0, DGM's modification (7.8)); `golayChi` is $e^\gamma \mapsto (-1)^{\sum \gamma_i/2} e^\gamma$. `golaySigma0` is the restriction of σ to the orbifold $V_N^{\langle \chi, \Theta\rangle}$. In what follows σ always means `v0Sigma`, accessed through File `VOA/Moonshine/TrialityTwSigma.lean`.

```
noncomputable def sig (u : V0Sub.carrier) : V0Sub.carrier := v0Sigma u
```

41.2.3 The sectors

V_Λ^+ is `VPlus`, the θ-fixed subVOA (Chapter 32). The *frame automorphism* `plusFrameAut` acts on e^γ by $(-1)^{\beta(\gamma)}$; its eigenspaces are `frameSector 0` $= V_0^+$ (also `V0Sub`, with VOA structure `V0P`) and `frameSector 1` $= V_3^+$. File `VOA/Moonshine/FrameSectors.lean`.

```
noncomputable def frameSector (i : ZMod 2) : Submodule ℂ VPlus :=
  Module.End.eigenspace (plusFrameAut.toLinearEquiv : Module.End ℂ VPlus)
    (Moonshine.Extraspecial.sgn i)
```

(`Extraspecial.sgn i` is $(-1)^i$.) On the twisted side, `TLeechT` is the 4096-dimensional module T of the extraspecial group $\hat\Lambda/K$ (Chapter 34), with operators e_γ = `eT leech … γ`, $\gamma \in \Lambda$, satisfying

$$e_a e_b = \varepsilon_\Lambda(a,b)\, e_{a+b}, \qquad e_{a+2b} = e_a, \qquad e_{-a} = e_a, \qquad e_a e_b = (-1)^{\langle a,b\rangle} e_b e_a, \tag{41.2}$$

(`eT_mul`, `eT_add_two_nsmul`, `eT_neg`, `eT_comm_sign'`); in particular $e_a^2 = \varepsilon_\Lambda(a,a)$. The frame involution is $J = c^{-1} e_{w_0}$ with $c^2 = \varepsilon(w_0, w_0)$, and $T = T_0 \oplus T_1$ with $T_s = \{t : Jt = (-1)^s t\}$: File `VOA/Moonshine/FrameTwisted.lean`.

```
noncomputable def frameJ (w : L.carrier) : End ℂ (TT L hEven hU) :=
  (sqrtEps L w)⁻¹ • eT L hEven hU w

noncomputable def frameT (w : L.carrier) (s : ZMod 2) : Submodule ℂ (TT L hEven hU) :=
  Module.End.eigenspace (frameJ L hEven hU w) (Extraspecial.sgn s)

noncomputable abbrev leechFrameT (s : ZMod 2) : Submodule ℂ (TT leech leech_even
↪  leech_isUnit_det_gramMat) :=
  frameT leech leech_even leech_isUnit_det_gramMat frameW s
```

The θ-fixed twisted module $(V_\Lambda^T)^+$ is `TP`, a submodule of `Tw` $= S[\theta] \otimes T$, and `TPframe s` $= T_s^+$ is the part with $J = (-1)^s$. Its cyclic vector is $x_0^T(t_0) = h_0(-\frac{1}{2}) \otimes t_0$: Files `VOA/Moonshine/CyclicTwisted.lean`, `VOA/Moonshine/TrialityTwSigma.lean`.

```
noncomputable def frameX0T (t₀ : TLeechT) : Tw := (X (0, 0) : FockT 24) ⊗ₜ t₀
noncomputable def x0T (t₀ : TLeechT) : TP := ⟨frameX0T t₀, frameX0T_mem_TP t₀⟩
```

(`X (0, c)` is the Fock variable for the mode $h_c(-\frac{1}{2})$, $c \in \{0, \dots, 23\}$.)

41.2.4 The actions, the intertwiner predicates, the residuals

For $u \in V_0^+$ and $n \in \mathbb{Z}$ the operators $u_{(n)}$ on V_Λ^+ and on $(V_\Lambda^T)^+$ are File `VOA/Moonshine/TrialityTwSigma.lean`.

```
noncomputable def actV (u : V0Sub.carrier) (n : ℤ) : VPlus →ₗ[ℂ] VPlus :=
  mode (leechVOAPlus.Y (u : VPlus)) n

noncomputable def actT (u : V0Sub.carrier) (n : ℤ) : TP →ₗ[ℂ] TP :=
  mode (Moonshine.plusModule.YM (u : VPlus)) n
```

Recall (Definition 2.7) that `mode f n` is the coefficient $u_{(n)}$ of z^{-n-1} in $Y(u,z)$. For u of weight k the *zero mode* $\mathrm{o}(u)$, the operator that preserves weight, is $u_{(k-1)}$; for the weight-two letters of this chapter it is $u_{(1)}$, which is why the number `1` appears everywhere below. A twisted intertwiner is Files `VOA/Moonshine/TrialityTwGeneric.lean`, `VOA/Moonshine/TrialityTwSigma.lean`.

```
def IsTwInt (ρ : A → ℤ → M →ₗ[ℂ] M) (τ : A → ℤ → N →ₗ[ℂ] N) (g : A → A) (S : Set A)
    (X : Submodule ℂ M) (Φ : M →ₗ[ℂ] N) : Prop :=
  ∀ u ∈ S, ∀ (n : ℤ), ∀ x ∈ X, Φ (ρ u n x) = τ (g u) n (Φ x)

def IsSigmaV3T (Φ : VPlus →ₗ[ℂ] TP) : Prop :=
  IsTwInt actV actT sig Set.univ (frameSector 1) Φ

def IsSigmaTT (s : ZMod 2) (Φ : TP →ₗ[ℂ] TP) : Prop :=
  IsTwInt actT actT sig Set.univ (TPframe s) Φ
```

So `IsSigmaV3T Φ` says exactly: for all $u \in V_0^+$, all $n \in \mathbb{Z}$ and all $x \in V_3^+$, $\Phi(u_{(n)}x) = (\sigma u)_{(n)}\Phi(x)$. The top levels and the two residual structures of Chapter 40 are:

```
noncomputable def OmegaV3 : Submodule ℂ VPlus := frameSector 1 ⊓ leechVOAPlus.grading 2

structure TopSigmaV3 (s : ZMod 2) (φ : VPlus →ₗ[ℂ] TP) : Prop where
  /-- `φ` maps the top level of `V₃⁺` into `T_s⁺`. -/
  maps_frame : ∀ x ∈ OmegaV3, φ x ∈ TPframe s
  /-- `φ` maps the top level into weight 2. -/
  maps_weight : ∀ x ∈ OmegaV3, φ x ∈ plusModule.weight (2 : ℂ)
  /-- Zero-mode intertwining: `φ (o(a) x) = o(σ a) φ x` for every homogeneous `a ∈ V₀⁺`. -/
  zero_mode : ∀ (k : ℤ) (a : V0Sub.carrier), (a : VPlus) ∈ leechVOAPlus.grading k →
    ∀ x ∈ OmegaV3, φ (actV a (k - 1) x) = actT (sig a) (k - 1) (φ x)
  /-- `φ` hits a cyclic vector `h₀(-½)𝟙 ⊗ t₀` of `T_s⁺`. -/
  hits_cyclic : ∃ t₀ : TLeechT, t₀ ∈ leechFrameT s ∧ t₀ ≠ 0 ∧ ∃ x ∈ OmegaV3, φ x = x0T t₀

noncomputable def OmegaT (s' : ZMod 2) : Submodule ℂ TP := TPframe s' ⊓ plusModule.weight
↪ (2 : ℂ)

structure TopSigmaTT (s' s : ZMod 2) (φ : TP →ₗ[ℂ] TP) : Prop where
  maps_frame : ∀ x ∈ OmegaT s', φ x ∈ TPframe s
  maps_weight : ∀ x ∈ OmegaT s', φ x ∈ plusModule.weight (2 : ℂ)
  zero_mode : ∀ (k : ℤ) (a : V0Sub.carrier), (a : VPlus) ∈ leechVOAPlus.grading k →
    ∀ x ∈ OmegaT s', φ (actT a (k - 1) x) = actT (sig a) (k - 1) (φ x)
  hits_cyclic : ∃ t₀ : TLeechT, t₀ ∈ leechFrameT s ∧ t₀ ≠ 0 ∧ ∃ x ∈ OmegaT s', φ x = x0T t₀
```

(`SigmaExistLeech.lean`; the doc-strings of `TopSigmaTT` are omitted, they repeat those of `TopSigmaV3`.) The clause `hits_cyclic` is what excludes the trivial solution $\varphi = 0$, which satisfies every other clause: this was a recorded trap of Chapter 40.

Finally Zhu generation (Chapter 40): a set $G \subseteq V_0^+$ is *Zhu-generating* if every subspace containing the vacuum, $O(V_0^+)$ and G and closed under Zhu's product is everything. File `VOA/Moonshine/SigmaExistZhu.lean`.

```
def ZhuGenerated (G : Set V0Sub.carrier) : Prop :=
  ∀ S : Submodule ℂ V0Sub.carrier, V0P.vacuum ∈ S → O V0P ≤ S →
    (∀ a ∈ S, ∀ b ∈ S, zhuMul V0P a b ∈ S) → G ⊆ S → S = ⊤
```

The two reductions of Chapter 40 that this chapter feeds are `topSigmaV3_of_zhuGenerated` ("`TopSigmaV3 s φ` follows from `maps_frame`, `maps_weight`, `hits_cyclic`, a Zhu-generating set G, and the zero-mode identity for $g \in G$") and `sigmaV3T_exists_of_top` ("`TopSigmaV3 s φ` implies a genuine Φ with `IsSigmaV3T Φ` extending φ"), and their `TT` analogues.

Remark 41.1 (Why "$\exists s$")**.** Every final statement of this chapter has the form "there is a sector $s \in \mathbb{Z}/2$ such that…". This is forced. Chapter 40 proved `golayE_not_determined`: the specification of the chosen character `golayE` pins it only up to a character e_β with β odd, and the two admissible choices give versions of σ conjugate by an automorphism of $V^\natural$ that swaps T_0^+ and T_1^+. Which of the two T_s^+ is the image of V_3^+ is therefore not a property of the definitions; it depends on a bit hidden inside `Classical.choose`. The construction below produces the seed in whichever sector it lands (`seed_in_frame`) and reports that sector existentially.

41.3 The source side: zero modes on V_3^+ and the letters of $(V_0^+)_2$

41.3.1 The zero mode of a normally ordered product

The first computation is a VOA-generic one. A weight-two state of the form $u_{(-1)}v$ (normally ordered product of two weight-one states) acts on a vector x through its zero mode $(u_{(-1)}v)_{(1)}$. If u and v act on x "diagonally and only through their zero modes", the product acts by the product of eigenvalues — the familiar statement that $\frac{1}{2}h(-1)^2\mathbf{1}$ measures $\frac{1}{2}p^2$ on a momentum state.

Lemma 41.2 (`smul_neg_one_one`)**.** *Let W be a VOA, $u, v, x \in W$, $\mu, \nu \in \mathbb{C}$, and suppose $u_{(i)}x = \delta_{i0}\mu x$ and $v_{(i)}x = \delta_{i0}\nu x$ for all $i \geq 0$. Then $(u_{(-1)}v)_{(1)}x = \mu\nu\, x$.*

```
theorem smul_neg_one_one {V : Type*} [AddCommGroup V] [Module ℂ V] (W :
↪  VertexOperatorAlgebra V)
    (u v x : V) (μ ν : ℂ) (hu : ∀ i : ℕ, W.smul u i x = if i = 0 then μ • x else 0)
    (hv : ∀ i : ℕ, W.smul v i x = if i = 0 then ν • x else 0) :
    W.smul (W.smul u (-1) v) 1 x = (μ * ν) • x
```

From the mathematics to the Lean statement

`W.smul u n x` is the library's notation for $u_{(n)}x$ (Definition 4.2). The hypotheses `hu`, `hv` range over natural numbers `i`, i.e. over the non-negative modes only; nothing is assumed about negative modes. The conclusion is exactly $(u_{(-1)}v)_{(1)}x = \mu\nu x$. Same as the textbook statement. Non-vacuity: the hypotheses are met by $u = h_a(-1)\mathbf{1}$ on any charged vacuum e^γ of a lattice VOA (Lemma 41.3).

Physical meaning

A normally ordered product of two currents acts on a charged state through the product of their charges, as in the Sugawara-type statement that $\frac{1}{2}h(-1)^2\mathbf{1}$ measures $\frac{1}{2}p^2$ on a momentum eigenstate. Physically it is the statement that bilinears in the Cartan currents are diagonal on

momentum states. This is a technical computation used to read off the eigenvalues of the weight-two zero modes on the source ground states; it is an exact lemma, not a heuristic.

Proof. The iterate (Borcherds) formula gives $(u_{(-1)}v)_{(1)} = \sum_{i\geq 0}\big(u_{(-1-i)}v_{(1+i)} + v_{(-i)}u_{(i)}\big)$, with the second sum coming from $(-1)^{-1}$ times the reversed terms. Applied to x, every $v_{(1+i)}x$ vanishes $(1+i \geq 1)$, and in $v_{(-i)}u_{(i)}x$ only $i = 0$ survives, giving $v_{(0)}u_{(0)}x = \mu\nu x$. □

What the machine verified

Unconditional; `VOA/Moonshine/SigmaTopSource.lean`. Used only as a tool.

41.3.2 The letters

Fix the orthonormal coordinates $h_1, \dots, h_{24}$ of $\mathfrak{h} = \Lambda \otimes \mathbb{C}$ used by the library's Heisenberg algebra (an orthonormal basis obtained from the Gram matrix; not the Golay frame). Write γ_a for the a-th orthonormal coordinate of γ (`chargeCoord leech γ a`). The weight-two space of V_0^+ contains two kinds of states:

- the *Heisenberg letters* $q_{ab} = h_a(-1)h_b(-1)\mathbf{1}$ (`qV a b`), 300 linearly independent ones;
- the *lattice letters* $u_\gamma = e^{\gamma} + e^{-\gamma}$ (`lV γ hγ`) for $\gamma \in \Lambda_0$ of norm 4.

Both are θ-invariant and frame-even, i.e. lie in V_0^+. For the lattice letters the library uses one representative of each pair $\pm\gamma$: `halfFour` is the set of norm-four vectors γ with $\gamma \prec -\gamma$ for a fixed well-order $\prec$, and File `VOA/Moonshine/FrameWeightTwo.lean`.

```
noncomputable def halfFourChi (i : ZMod 2) : Finset leech.carrier :=
  (halfFour leech leech_posDef).filter fun α => frameChar α = i
```

S_0 =`halfFourChi 0` (49128 vectors, even) and S_1 =`halfFourChi 1` (49152 vectors, odd). The states

$$x_n = e^{n} + e^{-n} \in V_3^+ \qquad (n \in S_1)$$

(`frameX0P n`, with `frameX0 β = latChargeGen leech β + latChargeGen leech (-β)`) will be our basis of the top level of V_3^+.

Proposition 41.3 (source zero modes). *Let $n \in \Lambda$.*

(a) $\mathrm{o}(q_{ab})\,x_n = n_a n_b\, x_n$.

(b) If $\gamma \in \Lambda_0$, $n \notin \Lambda_0$ and both have norm 4, then $|\langle\gamma, n\rangle| \leq 2$ and

$$\mathrm{o}(u_\gamma)\,x_n = [\langle\gamma,n\rangle = -2]\,\varepsilon_\Lambda(\gamma,n)\,x_{\gamma+n} + [\langle\gamma,n\rangle = 2]\,\varepsilon_\Lambda(\gamma,-n)\,x_{\gamma-n}.$$

```
theorem actV_qV (a b : Fin (rank leech)) (n : leech.carrier) :
    actV (qV a b) 1 (frameX0P n)
      = (chargeCoord leech n a * chargeCoord leech n b) • frameX0P n

theorem form_bound {γ n : leech.carrier} (hγ : γ ∈ lambda0) (hn : n ∉ lambda0)
    (hγ4 : leech.form γ γ = 4) (hn4 : leech.form n n = 4) :
    -2 ≤ leech.form γ n ∧ leech.form γ n ≤ 2

theorem actV_lV {γ n : leech.carrier} (hγ : γ ∈ lambda0) (hn : n ∉ lambda0)
    (hγ4 : leech.form γ γ = 4) (hn4 : leech.form n n = 4) :
    actV (lV γ hγ) 1 (frameX0P n)
      = (if leech.form γ n = -2 then latticeCocycle leech γ n • frameX0P (γ + n) else 0)
        + (if leech.form γ n = 2 then latticeCocycle leech γ (-n) • frameX0P (γ - n) else
          ↪ 0)
```

From the mathematics to the Lean statement

Symbols. `actV g 1` is $g_{(1)}$, the zero mode of the weight-two letter g. `leech.form γ γ = 4` is "norm 4" in the convention $\langle\gamma,\gamma\rangle = 4$ (weight $\frac{1}{2}\langle\gamma,\gamma\rangle = 2$). Norm 4 is the minimal norm: Λ has no vectors of norm 2. **Hypotheses.** In (b), $\gamma \in \Lambda_0$ makes u_γ a letter of V_0^+, and $n \notin \Lambda_0$ makes x_n a state of V_3^+; the norms are those of weight-two states. In (a) no hypothesis on n is needed. **Fidelity.** The Lean statements are literally the textbook formulas; the Iverson brackets are `if … then … else 0`. **Could it be vacuous?** No: the hypotheses are satisfied by every pair (letter, basis vector) that occurs, e.g. $\gamma = 4e_0+4e_1$, $n = (-3,1^{23})$ up to the coordinate convention. The only caveat is that the cocycle signs are left symbolic (`latticeCocycle leech γ n`), which is also how the textbook formula is written.

Physical meaning

The states $x_n = e^n + e^{-n}$ are the lowest-weight (top-level) states of the untwisted sector, labelled by a norm-four momentum n of the Leech lattice. Part (a) says the Heisenberg bilinears $h_a(-1)h_b(-1)\mathbf{1}$ have zero modes that just measure the momentum components $n_a n_b$, i.e. they are diagonal charges. Part (b) says the lattice vertex operators $e^\gamma + e^{-\gamma}$ shift momentum by $\pm\gamma$ only when the inner product is ∓ 2, the standard momentum-conservation selection rule of a vertex-operator zero mode. These are the operators that σ must be made to intertwine, so this is the full list of what the source side does to ground states.

Proof. (a) On $e^{\pm n}$, $h_a(-1)\mathbf{1}$ acts only through its zero mode, with eigenvalue $\pm n_a$; Lemma 41.2 gives $(\pm n_a)(\pm n_b) = n_a n_b$ on both terms. (b) For lattice states the vertex operator gives $e^\gamma_{(m)}e^n = \varepsilon(\gamma,n)\,S_{-m-1-\langle\gamma,n\rangle}(\gamma)\,e^{\gamma+n}$, where S_k is the k-th elementary Schur polynomial in the modes $\gamma(-1),\gamma(-2),\dots$, and $S_k = 0$ for $k<0$. For $m=1$ the exponent is $-2-\langle\gamma,n\rangle$: the term vanishes if $\langle\gamma,n\rangle > -2$ and equals $\varepsilon(\gamma,n)e^{\gamma+n}$ if $\langle\gamma,n\rangle = -2$. The bound $|\langle\gamma,n\rangle| \le 2$ comes from $\|\gamma \pm n\|^2 = 8 \pm 2\langle\gamma,n\rangle \ge 4$ ($\gamma \pm n \neq 0$ because $\gamma \in \Lambda_0 \not\ni n$, and nonzero Leech vectors have norm ≥ 4). Expanding $(e^\gamma + e^{-\gamma})_{(1)}(e^n + e^{-n})$ into four terms and using $\varepsilon(-\gamma,-n) = \varepsilon(\gamma,n)$ and $\varepsilon(-\gamma,n) = \varepsilon(\gamma,-n)$ (bimultiplicativity and $\varepsilon = \pm 1$) gives the formula. □

What the machine verified

Unconditional; `SigmaTopSource.lean`; `##print axioms` = [propext, Classical.choice, Quot.sound] (stated in the file header; the headline results of the chapter, which depend on these, were re-checked in this writing, see §41.18).

So on V_3^+ the Heisenberg letters are *diagonal* and the lattice letters are *monomial* in the basis x_n. This is what makes the problem tractable.

41.3.3 Spanning

Proposition 41.4 (spanning sets). *(a)* $(V_3^+)_2 = \mathrm{span}\{x_n : n \in S_1\}$.

(b) $(V_0^+)_2 = \mathrm{span}\{q_{ab}\} + \mathrm{span}\{u_\gamma : \gamma \in S_0\}$.

```
theorem OmegaV3_le_span : OmegaV3 ≤ span ℂ (frameX0P '' (halfFourChi 1 : Set
↪  leech.carrier))

theorem grading_two_V0_le_span {g : VPlus} (hg : g ∈ frameSector 0) (h2 : g ∈
↪  leechVOAPlus.grading 2) :
    g ∈ span ℂ (Set.range (fun p : Fin (rank leech) × Fin (rank leech) => qP p.1 p.2)
      ∪ frameX0P '' (halfFourChi 0 : Set leech.carrier))

def G2 : Set V0Sub.carrier := {g | (g : VPlus) ∈ leechVOAPlus.grading 2}
```

From the mathematics to the Lean statement

`OmegaV3` is $(V_3^+)_2$ (frame sector 1 intersected with weight 2). `f '' S` is the image of a set; `span ℂ` the linear span; "$\leq$" between submodules is inclusion. Only the inclusion "$\subseteq$" is stated, which is the direction used; the reverse inclusion is `frameX0P_mem_OmegaV3` (each x_n lies in the top level). `qP a b` is q_{ab} viewed in V_Λ^+ (`qV` is the same state viewed in V_0^+). `G2` is the set of all weight-two elements of V_0^+ — the Zhu-generating set of Chapter 40.

Physical meaning

The weight-two layer of the untwisted sector is the space of the lowest-energy states of the odd part, and these two spanning sets say it is generated by the momentum states x_n over the odd norm-four vectors. On the other side, the weight-two fields are the quadratic currents plus the lattice vertex operators of the even norm-four vectors. This is the bookkeeping that lets us check a symmetry on a basis of states and a basis of fields; it is a purely technical completeness statement.

Proof. Weight two in V_Λ consists of the quadratic Fock states $p \otimes e^0$ (p of degree two: 300 states $h_a h_b$ and 24 states $h_a(-2)$), the states $h_a(-1) \otimes e^\gamma$ with $\|\gamma\|^2 = 2$ (none: no roots), and the 196560 charged vacua of norm 4. On the θ-fixed part the $h_a(-2)$ disappear (θ acts by -1) and the charged vacua pair up into $e^\gamma + e^{-\gamma}$. Splitting by β: frame-odd γ give $(V_3^+)_2$, frame-even γ and the Fock part give $(V_0^+)_2$. Both statements are then dimension counts against the dimensions 49152 and $300 + 49128 = 49428$ computed in Chapter 39 (`finrank_plusTwoChi`). □

What the machine verified

Unconditional; `SigmaTopSource.lean`.

41.3.4 Reduction of the zero-mode clause to letters and basis vectors

Definition 41.5 (`ZM`). For a linear map $\varphi : V_\Lambda^+ \to (V_\Lambda^T)^+$, a set X and a letter $g \in V_0^+$, `ZM φ X g` is the statement $\varphi(o(g)x) = o(\sigma g)\varphi(x)$ for all $x \in X$. `ZMT` is the same with source $(V_\Lambda^T)^+$.

File `VOA/Moonshine/SigmaTopTT.lean`.

```
def ZM (φ : VPlus →ₗ[ℂ] TP) (X : Set VPlus) (g : V0Sub.carrier) : Prop :=
  ∀ x ∈ X, φ (actV g 1 x) = actT (sig g) 1 (φ x)

def ZMT (φ : TP →ₗ[ℂ] TP) (X : Set TP) (g : V0Sub.carrier) : Prop :=
  ∀ x ∈ X, φ (actT g 1 x) = actT (sig g) 1 (φ x)
```

Physical meaning

This is the 2d CFT statement that a candidate map φ between two sectors is an intertwiner at one field: sending a state first and then acting with the light field g must agree with acting with the transformed field σg on the image state. In other words φ matches charges, the zero-mode eigenvalues of the field g on x and of σg on $\varphi(x)$. Requiring it for all weight-two fields is the discrete shadow of the Ward identity relating the two sectors. This is the basic compatibility condition that every later eigen-condition is a rewriting of.

Theorem 41.6 (basis reduction). *Let $\varphi : V_\Lambda^+ \to (V_\Lambda^T)^+$ be linear. Suppose $\varphi(o(g)x_n) = o(\sigma g)\varphi(x_n)$ for all $n \in S_1$ and all letters g of the form q_{ab} or u_γ ($\gamma \in S_0$). Then for every $g \in (V_0^+)_2$ there is k (namely $k = 2$) with g of weight k and $\varphi(g_{(k-1)}x) = (\sigma g)_{(k-1)}\varphi(x)$ for all $x \in (V_3^+)_2$.*

```
theorem hGφ_V3_of_basis (φ : VPlus →ₗ[ℂ] TP)
    (hQ : ∀ a b : Fin (rank leech), ∀ n ∈ halfFourChi 1,
      φ (actV (qV a b) 1 (frameX0P n)) = actT (sig (qV a b)) 1 (φ (frameX0P n)))
    (hL : ∀ γ ∈ halfFourChi 0, ∀ n ∈ halfFourChi 1,
      φ (actV (lV' γ) 1 (frameX0P n)) = actT (sig (lV' γ)) 1 (φ (frameX0P n))) :
    ∀ g ∈ G2, ∃ k : ℤ, (g : VPlus) ∈ leechVOAPlus.grading k ∧
      ∀ x ∈ OmegaV3, φ (actV g (k - 1) x) = actT (sig g) (k - 1) (φ x)
```

From the mathematics to the Lean statement

`lV' γ` is u_γ when $\gamma \in \Lambda_0$ and the junk value 0 otherwise (a total function is convenient; on $S_0 \subseteq \Lambda_0$ it is the genuine letter, `lV'_eq`). The conclusion has precisely the shape of the hypothesis `hGφ` of `topSigmaV3_of_zhuGenerated` with $G =$`G2`, which is why the existential $\exists k$ appears although $k = 2$. Same as the textbook statement.

Physical meaning

It is enough to test the intertwining property on a basis of ground states and a basis of light fields: the zero modes are linear in both the field and the state, so matching charges on the generators propagates to everything in the weight-two layer. Physically this is the familiar reduction of a symmetry check to checking the action on the generating currents and the lowest-energy states. It replaces an infinite family of conditions by finitely many (about 10^5) explicit ones; it is a technical reduction and carries no new physics.

Proof. The identity $\varphi\,\mathrm{o}(g) = \mathrm{o}(\sigma g)\varphi$ is linear in g (because σ and $g \mapsto g_{(1)}$ are linear) and linear in x. Proposition 41.4 gives spanning sets for both. □

What the machine verified

Unconditional; `SigmaTopSource.lean`. The analogous frame-form statements `hGφ_V3_of_frame`, `hGφ_TT_of_frame` (`SigmaTopTT.lean`) replace the abstract q_{ab} by the frame letters of §41.5.

41.4 The target side: zero modes on the twisted top level

The top level of $(V_\Lambda^T)^+$ is $h(-\frac{1}{2}) \otimes T$, of dimension $24 \cdot 4096$; the weight-two states $h_c(-\frac{1}{2}) \otimes t$ have conformal weight $\frac{24}{16} + \frac{1}{2} = 2$. On it we need the zero modes of q_{ab} and of e^α.

41.4.1 Twisted modes in Lean

The twisted module V_Λ^T is a θ-twisted module of period $N = 2$ (`TwistedModule leechTheta 2`, Chapter 34). Its vertex operator has half-integral modes, and the library stores the mode $u_{(k/2)}$ under the integer index k: `YM u k` is $u_{(k/2)}$. So the zero mode $u_{(1)}$ of a weight-two element is `YM u 2`, and on the θ-fixed part, which is an ordinary V_Λ^+-module, the ordinary mode $u_{(n)}$ is `YM u (2 * n)`; this is the theorem File `VOA/Moonshine/SigmaTopFrame.lean`.

```
theorem actT_coe (u : V0Sub.carrier) (n : ℤ) (y : TP) :
    ((actT u n y : TP) : Tw) = leechTwistedModule.YM ((u : VPlus) : LatModuleGen leech) (2
    ↪ * n) y
```

Proposition 41.7 (twisted zero modes). *On $h_c(-\frac{1}{2}) \otimes t$, $t \in T$:*

(a) $\mathrm{o}(h_a(-1)h_b(-1)\mathbf{1})\,(h_c \otimes t) = \big(\frac{1}{8}\delta_{ab}h_c + \frac{1}{2}\delta_{bc}h_a + \frac{1}{2}\delta_{ac}h_b\big) \otimes t$;

(b) for $\|\alpha\|^2 = 4$: $\mathrm{o}(e^\alpha)\,(h_c \otimes t) = 2^{-4}\big(h_c - 2\alpha_c\,\alpha(-\frac{1}{2})\big) \otimes e_\alpha t$;

(c) $\mathrm{o}(e^{-\alpha}) = \mathrm{o}(e^{\alpha})$ *on the twisted module (more generally on all even modes).*

File `VOA/Moonshine/SigmaTopTarget.lean`.

```
theorem YML_quadSt (a b c : Fin (rank L)) (t : Rep (cocMat L) (isUnit_det_cocMat L hEven
↪  hU)) :

          ⊗ₜ eT L hEven hU α t)

theorem YML_echg_neg_two (α : L.carrier) :
    YML L hEven hU (echg L (-α)) 2 = YML L hEven hU (echg L α) 2
```

From the mathematics to the Lean statement

These are stated for a general even unimodular positive-definite lattice L (`hEven`, `hU` = unimodularity, `hPos`); the Leech versions `leechYM_quad`, `leechYM_echg_X`, `leechYM_echg_neg_two` follow by transport along rank $\Lambda = 24$ (the casts `cc`, `chT` only renumber coordinates). `YML … u 2` is $u_{(1)}$, the zero mode, by the half-integer convention. `X (0, c)` is $h_c(-\frac{1}{2})$ and `vVarT v 0` is $v(-\frac{1}{2}) = \sum_a v_a h_a(-\frac{1}{2})$. `quadSt … a b` is $h_a(-1)h_b(-1)\mathbf{1}$ and `echg L α` is e^{α}. The factor $2^{-4} = 2^{-\|\alpha\|^2}$ is the normalisation $2^{-\langle\gamma,\gamma\rangle}$ of the twisted vertex operator $Y^T(e^{\gamma}, z)$ (Chapter 34, FLM's convention). The statements are exactly (a)–(c).

Physical meaning

This computes how the same light fields act on the twisted-sector ground states, the 2^{12}-dimensional space of twist fields T tensored with the weight-one-half oscillators $h_c(-\frac{1}{2})$ of the $\mathbb{Z}/2$-twisted bosons. The Heisenberg bilinears act with the characteristic twisted-sector shifts $\frac{1}{8}\delta_{ab}$ (the conformal weight 1/16 per boson from the twist field) plus mixing terms, and the lattice vertex operators act on the twist space through the Clifford-like operators e_{γ}. These are the target charges that σ must match against the source charges of the previous proposition.

Proof. (a) Use the twisted Jacobi identity for $u = h_a(-1)\mathbf{1}$ (a θ-eigenvector with eigenvalue -1) and $v = h_b(-1)\mathbf{1}$, at the indices that isolate $(u_{(-1)}v)$'s zero mode. The result is a finite sum: the normally ordered product $h_a(-\frac{1}{2})h_b(\frac{1}{2}) + h_b(-\frac{1}{2})h_a(\frac{1}{2})$ on $h_c(-\frac{1}{2})$ (giving the $\frac{1}{2}\delta_{bc}h_a + \frac{1}{2}\delta_{ac}h_b$, since $h_a(\frac{1}{2})h_c(-\frac{1}{2}) = \frac{1}{2}\delta_{ac}$), plus a correction coming from $u_{(1)}v = \delta_{ab}\mathbf{1}$ multiplied by the binomial coefficient $-\binom{1/2}{2} = \frac{1}{8}$. Physically: the twisted boson has a ground-state energy shift, and $\frac{1}{8}$ per coordinate is exactly what makes $\sum_a \frac{1}{2}h_a h_a$ measure $L_0 = \frac{24}{16} + \ldots$ ($24 \cdot \frac{1}{2} \cdot \frac{1}{8} = \frac{3}{2}$). (b) The twisted vertex operator is $Y^T(e^{\alpha}, z) = 2^{-\|\alpha\|^2} z^{-\|\alpha\|^2/2} E^-(-\alpha, z)E^+(-\alpha, z) \otimes e_{\alpha}$. For $\|\alpha\|^2 = 4$ the power of z is z^{-2}, so the zero mode $u_{(1)}$ (coefficient of z^{-2}) is 2^{-4} times the degree-zero coefficient of $E^-(-\alpha, z)E^+(-\alpha, z)$. On a one-oscillator state only two terms of that coefficient survive: the identity, and the product of the first annihilation term of E^+ (which contracts $\alpha(\frac{1}{2})$ with $h_c(-\frac{1}{2})$, producing α_c up to the factor 2 from $1/(k/2)$ at $k = 1$) with the first creation term of E^- (which creates $\alpha(-\frac{1}{2})$,

with the same factor). The result is $h_c - 2\alpha_c\,\alpha(-\frac{1}{2})$, as claimed. (c) $Y^T(e^{-\alpha}, z)$ is obtained from $Y^T(e^{\alpha}, z)$ by $z^{1/2} \mapsto -z^{1/2}$ and $e_{-\alpha} = e_\alpha$, which leaves integral (even-index) modes unchanged. □

What the machine verified

Unconditional; `SigmaTopTarget.lean`.

Remark 41.8. On the twisted top level every lattice letter $u_\gamma = e^\gamma + e^{-\gamma}$ thus acts by $h_v(-\frac{1}{2}) \otimes t \mapsto 2^{-3}\, h_{v-2\langle v,\gamma\rangle\gamma}(-\frac{1}{2}) \otimes e_\gamma t$ (the two terms are equal by (c), whence $2 \cdot 2^{-4} = 2^{-3}$). The linear map $v \mapsto v - 2\langle v,\gamma\rangle\gamma$ is *not* a reflection: it is the identity on $\gamma^\perp$ and multiplies γ by $1 - 2 \cdot 4 = -7$. On the source side, by contrast, u_γ simply moves x_n to $\pm x_{n\pm\gamma}$. The two descriptions look very different; they become equal only after σ has been applied to the letter, and that is the content of the rest of the chapter.

41.5 The Golay frame at weight two

The orthonormal coordinates h_a of §41.3 come from an arbitrary basis and have no relation to the Golay code. The right coordinates are those of the *frame*: the 24 mutually orthogonal vectors $w_j = 8e_j$ of norm 8. In this section we rewrite everything in the frame and discover the block structure of both top levels.

41.5.1 Blocks of $(V_3^+)_2$

Lemma 41.9 (one entry ±3). *Let $n \in \Lambda$ be odd ($n \notin \Lambda_0$) of norm 4. Then all coordinates of n are odd, and there is exactly one index $j = j(n)$ with $n_j^2 = 9$; all other coordinates satisfy $n_i^2 = 1$. The index $j(n)$ is the* block *of n, and $j(-n) = j(n)$.*

```
theorem exists_unique_three (f : Fin 24 → ℤ) (hodd : ∀ i, Odd (f i)) (hs : ∑ i, f i ^ 2 =
↪  32) :
    ∃ j, f j ^ 2 = 9 ∧ ∀ i, i ≠ j → f i ^ 2 = 1

noncomputable def blk (n : leech.carrier) : Fin 24 :=
  if h : ∃ j, lv n j ^ 2 = 9 then h.choose else 0

theorem lv_sq {n : leech.carrier} (hn : n ∉ lambda0) (h4 : leech.form n n = 4) (j : Fin 24)
↪  :
    lv n j ^ 2 = if j = blk n then 9 else 1

theorem blk_neg (n : leech.carrier) : blk (-n) = blk n
```

From the mathematics to the Lean statement

`blk` is defined by choice with a junk value 0; `lv_sq` shows that for the vectors that matter (odd, norm 4) the choice is forced, so the junk value is never seen. Norm 4 in the convention (41.1) means $\sum n_i^2 = 32$. Same as the textbook statement.

Physical meaning

The norm-four odd vectors of the Leech lattice have all coordinates odd, with a single coordinate of size 3 and the rest of size 1. This singles out one of the 24 frame directions for each ground state; physically this is the frame block, the one boson (out of 24) whose half-integer oscillator $h_{c_j}(-\frac{1}{2})$ carries the excitation in the image of x_n. It is a technical lemma underlying the construction of φ on the twisted top level.

Proof. Odd Leech vectors are $2a + u$ with $u = (5, 1^{23})$, so all entries are odd. An odd square is $8g + 1$ with $g \geq 0$ (a triangular number times 8), and $\sum(8g_i + 1) = 32$ forces $\sum g_i = 1$: exactly one $g_j = 1$ ($n_j^2 = 9$) and the rest vanish. □

What the machine verified

Unconditional; `SigmaTopFrame.lean`.

So $(V_3^+)_2$ splits into 24 blocks of 2048 basis vectors x_n (pairs $\pm n$ with a given block); a typical vector is $n = (\mp 3, \pm 1^{23})$ with the 3 in position j. In the same way $(T^+)_2 = \bigoplus_j h_{w_j}(-\frac{1}{2}) \otimes T$ has 24 blocks of 4096, and $(T_s^+)_2$ has 24 blocks of 2048. The first, numerically discovered, fact (§41.16) is that σ matches the blocks.

41.5.2 The twisted top level in frame coordinates

For $v \in \mathbb{C}^{24}$ (orthonormal coordinates) and $t \in T$ write $h_v(-\frac{1}{2}) \otimes t$ for $\sum_a v_a h_a(-\frac{1}{2}) \otimes t$ (`hP v t`). Let $c_j =$ `cw j` be the orthonormal coordinates of w_j; so $h_{c_j}(-\frac{1}{2})$ is the oscillator along the j-th frame direction.

Definition 41.10 (frame letters). For $\alpha, \beta \in \Lambda$ the *frame quadratic letter* is $d(\alpha, \beta) = \alpha(-1)\beta(-1)\mathbf{1} \in V_0^+$ (`dV α β`). The letters $d(w_j, w_k)$ are the frame versions of q_{ab}, and $q_{ab} = \frac{1}{64}\sum_{j,k}(c_j)_a(c_k)_b\, d(w_j, w_k)$ (`qV_eq_sum_dV`).

```
noncomputable def dV (α β : leech.carrier) : V0Sub.carrier :=
  ⟨⟨quadH leech leech_even leech_posDef α β, (mem_leechVOAPlus_iff _).mpr (quadH_theta α
   ↪ β)⟩, by
    rw [V0Sub_carrier, mem_frameSector, Extraspecial.sgn_zero, one_smul]
    exact quadH_frame α β⟩
```

Physical meaning

The frame letters $d(\alpha, \beta) = \alpha(-1)\beta(-1)\mathbf{1}$ are the Heisenberg bilinears written in the Golay frame instead of an orthonormal basis, i.e. the quadratic currents $J^\alpha J^\beta$ built from the frame vectors. The change of basis is a rotation of the 24 free bosons, which is a harmless relabelling of the same fields. The frame is the natural one because the twist fields and the triality action are expressed in terms of the Golay code and its frame vectors.

(`quadH L … α β` is $\alpha(-1)\beta(-1)\mathbf{1}$; the anonymous-constructor proofs record membership in V_Λ^+ and in frame sector 0. This one definition body is shown because it is short; it contains no choices.)

Proposition 41.11 (zero modes in the frame). *For $v \in \mathbb{C}^{24}$, $t \in T$, $\alpha, \beta \in \Lambda$, $\gamma \in \Lambda_0$ of norm 4:*

(a) $\mathrm{o}(d(\alpha, \beta))\, x_n = \langle \alpha, n\rangle\langle \beta, n\rangle\, x_n$;

(b) $\mathrm{o}(d(\alpha, \beta))\,(h_v \otimes t) = h_{\frac{\langle \alpha,\beta\rangle}{8} v + \frac{1}{2}\langle v,\beta\rangle\alpha + \frac{1}{2}\langle v,\alpha\rangle\beta} \otimes t$;

(c) $\mathrm{o}(u_\gamma)\,(h_v \otimes t) = 2^{-3}\, h_{v - 2\langle v,\gamma\rangle\gamma} \otimes e_\gamma t$;

(d) (diagonal letters) $\mathrm{o}(d(w_j, w_j))$ *acts by* 9 *on block* j *and by* 1 *on every other block, on* both $(V_3^+)_2$ *and* $(T^+)_2$: $\mathrm{o}(d(w_j, w_j))x_n = (9 \text{ if } j = j(n) \text{ else } 1)\, x_n$ *and* $\mathrm{o}(d(w_j, w_j))(h_{c_m} \otimes t) = (9 \text{ if } j = m \text{ else } 1)\, h_{c_m} \otimes t$.

```

    actV (dV (fw j) (fw j)) 1 (frameX0P n) = (if j = blk n then (9 : ℂ) else 1) • frameX0P
     ↪ n
```

From the mathematics to the Lean statement

`dL α β` is the linear map $v \mapsto \frac{\langle\alpha,\beta\rangle}{8}v + \frac{1}{2}\langle v,\beta\rangle\alpha + \frac{1}{2}\langle v,\alpha\rangle\beta$ on $\mathbb{C}^{24}$ and `latL γ` is $v \mapsto v - 2\langle v,\gamma\rangle\gamma$, both written in orthonormal coordinates; `quadL a b` (used in `actT_qV_hP`) is the special case $\alpha = h_a, \beta = h_b$. Note in (b) that the coefficient $\frac{\langle\alpha,\beta\rangle}{8}$ is the $\frac{1}{8}\delta_{ab}$ of Proposition 41.7 after bilinear expansion. In (d), on the source side the hypothesis "n odd of norm 4" is needed (to know $n_j^2 \in \{1,9\}$); on the target side no hypothesis on t. Same as the textbook statements.

Physical meaning

This restates the charges of the previous two propositions in frame letters. On the source, $d(\alpha,\beta)$ measures the product of momentum projections $\langle\alpha,n\rangle\langle\beta,n\rangle$; on the twisted ground states it acts as a rank-two operator on the oscillators plus a vertex-operator part acting on the twist space. These are the zero-mode charges of the light fields that σ must intertwine, in the basis where the Golay structure is visible.

Proof. (a)–(c) are bilinear expansions of Propositions 41.3 and 41.7, using $\alpha(-1) = \sum \alpha_a h_a(-1)$ and $\langle\alpha,\beta\rangle = \sum_a \alpha_a\beta_a$. (d) Source: $\langle w_j, n\rangle = n_j$ and $n_j^2 \in \{9,1\}$ by Lemma 41.9. Target: with $\alpha = \beta = w_j$, $v = c_m$, $\frac{\langle w_j,w_j\rangle}{8} = 1$ and $\langle c_m, w_j\rangle = 8\delta_{jm}$, so $c_m \mapsto c_m + 8\delta_{jm}c_m$. □

What the machine verified

Unconditional; `SigmaTopFrame.lean`.

The joint eigenspaces of the 24 commuting operators $o(d(w_j,w_j))$ are exactly the blocks, on both sides, with the same eigenvalue pattern. If these letters are σ-fixed, any intertwiner must preserve blocks — which is what we prove next.

41.5.3 σ fixes the diagonal frame letters

Lemma 41.12 (`root_square`). *Let L be an even lattice and α a root, $\|\alpha\|^2 = 2$, and $\varepsilon = \varepsilon_L(\alpha,-\alpha)$. Then $(e^\alpha + \varepsilon e^{-\alpha})_{(-1)}(e^\alpha + \varepsilon e^{-\alpha}) = \alpha(-1)^2\mathbf{1}$.*

File `VOA/Moonshine/SigmaTopSigma.lean`.

```
theorem root_square (α : L.carrier) (hα : L.form α α = 2) :
    (latticeVOAGen L hEven hPos).smul
```

```
      (latChargeGen L α + latticeCocycle L α (-α) • latChargeGen L (-α)) (-1)
      (latChargeGen L α + latticeCocycle L α (-α) • latChargeGen L (-α))
    = quadH L hEven hPos α α
```

From the mathematics to the Lean statement

`latticeVOAGen L …` is V_L; `.smul x (-1) y` is $x_{(-1)}y$. Exactly the lemma.

Physical meaning

For a root α, the combination $e^{\alpha} + \varepsilon e^{-\alpha}$ is the real vertex operator of the $su(2)$ at level one, and its normally ordered square is $\alpha(-1)^2\mathbf{1}$, the Cartan bilinear. This is the free-fermion-like statement $\psi^+\psi^- \sim J$, the usual bosonisation identity relating a charged pair to the square of the current. It is a technical computation used to identify σ on the diagonal frame letters.

Proof. $e^{\pm\alpha}_{(-1)}e^{\pm\alpha} = 0$ because $\langle\alpha,\alpha\rangle = 2$ forces the Schur index $-(-1) - 1 - 2 < 0$. The cross terms are $e^{\alpha}_{(-1)}e^{-\alpha} = \varepsilon(\alpha,-\alpha)S_2(\alpha)\mathbf{1}$ and $e^{-\alpha}_{(-1)}e^{\alpha} = \varepsilon(-\alpha,\alpha)S_2(-\alpha)\mathbf{1}$, where $S_2(\pm\alpha) = \frac{1}{2}(\alpha(-1)^2 \pm \alpha(-2))$. With $\varepsilon(-\alpha,\alpha) = \varepsilon(\alpha,-\alpha)$ (for a root the cocycle on $\pm\alpha$ is symmetric) and $\varepsilon^2 = 1$, the sum is $\alpha(-1)^2\mathbf{1}$: the $\alpha(-2)$ terms cancel. Physically: the level-one $\hat{\mathfrak{sl}}_2$ Sugawara vector $\frac{1}{4}\alpha(-1)^2\mathbf{1}$ can be written in any Cartan direction, and $e + \varepsilon f$ is another Cartan direction. □

Theorem 41.13 (σ fixes $w_j(-1)^2\mathbf{1}$). *$\sigma\big(d(w_j,w_j)\big) = d(w_j,w_j)$ for all j.*

```
theorem golayToV0_qN (a b : lam0.carrier) : golayToV0 (qN a b) = dV (inclΛ a) (inclΛ b)

theorem sig_dV_fw (j : Fin 24) : sig (dV (fw j) (fw j)) = dV (fw j) (fw j)
```

From the mathematics to the Lean statement

`qN a b` is $\iota_N(a)(-1)\iota_N(b)(-1)\mathbf{1} \in V_N^{\langle\chi,\Theta\rangle}$. `golayToV0_qN` says the bridge sends uncharged quadratic states to the corresponding uncharged quadratic states; this is *independent* of the choice of `golayE` and of the coboundaries, because these only rescale charged states. Hence `sig_dV_fw` is a statement with no hidden choice. Same as the textbook statement.

Physical meaning

The Cartan bilinears $w_j(-1)^2\mathbf{1}$ along the frame directions are fixed by the triality symmetry: the operator measuring the squared momentum in direction j is invariant. Physically these are the diagonal energy-like operators of the 24 bosons, and a symmetry that merely permutes lattice sectors should preserve them. This is the first and simplest check that σ is being built compatibly with the Heisenberg part of the algebra.

Proof. Under $A \to N$, $4e_j \mapsto 2\alpha_j$, and under $A \to \Lambda$, $4e_j \mapsto w_j$; so $d(w_j,w_j)$ corresponds to $4\,\alpha_j(-1)^2\mathbf{1}$ in V_N. On V_N, σ sends the Cartan current $\alpha_j(-1)\mathbf{1}$ to $e^{\alpha_j} + \varepsilon_j e^{-\alpha_j}$ (Chapter 39, `golaySigma_hSt`), and being a VOA automorphism it sends $\alpha_j(-1)^2\mathbf{1} = \alpha_j(-1)\mathbf{1}_{(-1)}\alpha_j(-1)\mathbf{1}$ to $(e^{\alpha_j} + \varepsilon_j e^{-\alpha_j})_{(-1)}(e^{\alpha_j} + \varepsilon_j e^{-\alpha_j})$, which is $\alpha_j(-1)^2\mathbf{1}$ by Lemma 41.12. Transport along `golayToV0`. □

What the machine verified

Unconditional; `SigmaTopSigma.lean`; the `golayE` choice drops out. `##print axioms sig_dV_fw` = [`propext`, `Classical.choice`, `Quot.sound`] (checked for this chapter).

41.6 The block maps and what the diagonal letters give for free

41.6.1 The map φ_τ on V_3^+

Guided by the block structure we look for φ of the form "block-monomial":

Definition 41.14 (phiV3). For an arbitrary function $\tau : \Lambda \to T$ let $\varphi_\tau : V_\Lambda^+ \to (V_\Lambda^T)^+$ be the linear map with $\varphi_\tau(x_n) = h_{c_{j(n)}}(-\frac{1}{2}) \otimes \tau(n)$ for $n \in S_1$, defined on all of V_Λ^+ by reading off the coefficient of e^n: $\varphi_\tau = \sum_{n \in S_1} \mathrm{coef}_n(\cdot)\, h_{c_{j(n)}} \otimes \tau(n)$.

File `VOA/Moonshine/SigmaTop.lean`.

```
noncomputable def coefN (n : leech.carrier) : VPlus →ₗ[ℂ] ℂ :=
  (MvPolynomial.lcoeff ℂ 0) ∘ₗ coordEα leech n ∘ₗ (orbifold (Subgroup.zpowers
  ↪ leechTheta)).carrier.subtype

noncomputable def phiV3 (τ : leech.carrier → TLeechT) : VPlus →ₗ[ℂ] TP :=
  ∑ n ∈ halfFourChi 1, (coefN n).smulRight (hP (cw (blk n)) (τ n))

theorem phiV3_frameX0P (τ : leech.carrier → TLeechT) {m : leech.carrier} (hm : m ∈
↪ halfFourChi 1) :
    phiV3 τ (frameX0P m) = hP (cw (blk m)) (τ m)
```

From the mathematics to the Lean statement

`coordEα leech n` extracts the Fock coefficient of e^n and `lcoeff ℂ 0` its constant term, so `coefN n` is the coefficient of the charged vacuum e^n. `f.smulRight y` is $x \mapsto f(x)y$. On the top level only the values on x_m matter, and `phiV3_frameX0P` confirms the intended values (for $m \in S_1$, e^{-m} has zero coefficient because $-m \notin S_1$). Off the top level φ_τ has some values that are irrelevant: every clause of `TopSigmaV3` quantifies only over `OmegaV3`.

Physical meaning

This is the explicit ansatz for the triality operator on the top level: each momentum ground state x_n of the untwisted sector is sent to a weight-one-half oscillator in the block direction $j(n)$ tensored with a twist-field state $\tau(n)$. The arbitrary function τ is the unknown, the choice of twist-space vector attached to each momentum. Heuristically this is the T-duality map between sectors, which trades a momentum label for a twist label; the whole difficulty is to choose τ so that charges match.

Proposition 41.15 (what holds for every τ). *(a) φ_τ lands in weight two; if all $\tau(n) \in T_s$ it lands in T_s^+.*

(b) If there is t_0 with $\tau(n_j) = t_0$ for one chosen $n_j \in S_1$ in each block j (the vector $\pm\big((1^{24}) - 4e_j\big)$, `nvec j`), then $x_0^T(t_0)$ is in the image of the top level.

(c) The diagonal letters intertwine: `ZM (phiV3 τ) OmegaV3 (dV (fw j) (fw j))`, *for every τ.*

```
theorem phiV3_hits {τ : leech.carrier → TLeechT} {t₀ : TLeechT} (hblk : ∀ j, τ (nvec j) =
↪ t₀) :
    ∃ x ∈ OmegaV3, phiV3 τ x = x0T t₀

theorem phiV3_ZM_diag (τ : leech.carrier → TLeechT) (j : Fin 24) :
    ZM (phiV3 τ) OmegaV3 (dV (fw j) (fw j))
```

Physical meaning

These are the properties of the ansatz that hold regardless of τ: it lands at the right conformal weight, in the right twisted sector T_s, and it can hit a prescribed twist-field state. The last point is the non-vanishing requirement, that φ is not the zero map; a zero map would satisfy every charge-matching condition trivially, so a genuine symmetry operator must reach a nonzero vector.

Proof. (a) Each $h_v \otimes t$ has weight two and lies in the $J = (-1)^s$ sector if t does. (b) The frame is complete: $\sum_j (c_j)_a (c_j)_b = 8\delta_{ab}$ (`cw_complete`, from $\langle w_j, w_k\rangle = 8\delta_{jk}$ and the fact that a square matrix with $MM^{\mathsf{T}} = 8$ also has $M^{\mathsf{T}}M = 8$). Hence $h_0(-\frac{1}{2}) = \frac{1}{8}\sum_j (c_j)_0 h_{c_j}(-\frac{1}{2})$, and $x = \frac{1}{8}\sum_j (c_j)_0 x_{n_j}$ maps to $x_0^T(t_0)$. (c) Both sides are eigenvectors with eigenvalue 9 or 1 by Proposition 41.11(d) and σ fixes the letter (Theorem 41.13). □

What the machine verified

Unconditional; `SigmaTop.lean`.

Theorem 41.16 (partial (R-top) on V_3^+). *For every s there is a linear φ satisfying* `maps_frame`, `maps_weight`, `hits_cyclic` *of* `TopSigmaV3 s`, *and the zero-mode identity for the* 24 *diagonal letters $d(w_j, w_j)$.*

```
theorem topSigmaV3_partial (s : ZMod 2) :
    ∃ φ : VPlus →ₗ[ℂ] TP, (∀ x ∈ OmegaV3, φ x ∈ TPframe s) ∧
      (∀ x ∈ OmegaV3, φ x ∈ plusModule.weight (2 : ℂ)) ∧
      (∃ t₀ : TLeechT, t₀ ∈ leechFrameT s ∧ t₀ ≠ 0 ∧ ∃ x ∈ OmegaV3, φ x = x0T t₀) ∧
      (∀ j : Fin 24, ∀ x ∈ OmegaV3,
        φ (actV (dV (fw j) (fw j)) 1 x) = actT (sig (dV (fw j) (fw j))) 1 (φ x))
```

From the mathematics to the Lean statement

The four conjuncts are the clauses of `TopSigmaV3 s` *except* `zero_mode`, which is replaced by its restriction to 24 letters. This is **much weaker** than `TopSigmaV3`; the witness is φ_τ with τ constant, which certainly does not satisfy the remaining identities.

Physical meaning

Already for an arbitrary choice of block value the diagonal Cartan letters intertwine and the image is nonzero. This is the statement that the easy part of charge matching, the diagonal currents, is automatically satisfied by the ansatz; the substantive conditions come from the off-diagonal letters and the lattice vertex operators. It is partial progress and is not enough to define σ.

Trap / dead end

`topSigmaV3_partial` and `topSigmaTT_partial` were milestones, not results about σ. A reader skimming the file headers of `SigmaTop.lean` could mistake them for (R-top); the files say explicitly "`TopSigmaV3` itself is NOT proved" there. Schur's lemma (the top levels are irreducible, Chapter 40) shows that at most one τ up to scalar satisfies all identities.

What the machine verified

Unconditional, but weak; `SigmaTop.lean`; superseded by Theorem 41.48.

Theorem 41.17 (`topSigmaV3_of_offdiag`). *Let τ take values in T_s, with $\tau(n_j) = t_0 \neq 0$ for all j, $t_0 \in T_s$. If* `ZhuGenerated G2`, *the off-diagonal frame letters $d(w_j, w_k)$ $(j \neq k)$ and the lattice letters u_γ $(\gamma \in S_0)$ intertwine for φ_τ on $(V_3^+)_2$, then* `TopSigmaV3 s` φ_τ.

```
theorem topSigmaV3_of_offdiag {s : ZMod 2} {τ : leech.carrier → TLeechT}
    (hτ : ∀ n ∈ halfFourChi 1, τ n ∈ leechFrameT s) {t₀ : TLeechT} (ht₀ : t₀ ∈ leechFrameT
     ↪ s)
    (h0 : t₀ ≠ 0) (hblk : ∀ j, τ (nvec j) = t₀) (hZhu : ZhuGenerated G2)
    (hoff : ∀ j k : Fin 24, j ≠ k → ZM (phiV3 τ) OmegaV3 (dV (fw j) (fw k)))
    (hlat : ∀ γ ∈ halfFourChi 0, ZM (phiV3 τ) OmegaV3 (lV' γ)) :
    TopSigmaV3 s (phiV3 τ)
```

Physical meaning

The map φ_τ is a genuine intertwiner as soon as the remaining field zero modes (the off-diagonal Heisenberg bilinears and the lattice vertex operators) match charges, together with Zhu generation, i.e. the fact that these fields generate the whole algebra of light fields. Physically the zero modes of a generating set of the algebra determine the action on the ground states, so intertwining them suffices. This reduces the problem to explicit eigen-conditions on τ.

Proof. Combine Theorem 41.6 (with q_{ab} expanded in the frame letters), Proposition 41.15, and `topSigmaV3_of_zhuGenerated`. □

What the machine verified

Conditional on `hZhu`, `hoff`, `hlat` (and the data hypotheses); `SigmaTop.lean`. All three inputs are later discharged.

41.6.2 The map φ_ψ on $T^+_{s'}$

For the twisted source the analogous ansatz uses a family of 24 linear maps $\psi_m : T \to T$:

Definition 41.18 (`phiTT`). $\varphi_\psi(h_{c_m}(-\tfrac{1}{2})\otimes t) = h_{c_m}(-\tfrac{1}{2})\otimes \psi_m t$, extended linearly; the h_{c_m} component of a vector of $(T^+)_2$ is extracted by `compW m` $= \frac{1}{8}\sum_a (c_m)_a \cdot$ (the h_a-component).

```
noncomputable def phiTT (ψ : Fin 24 → TLeechT →ₗ[ℂ] TLeechT) : TP →ₗ[ℂ] TP :=
  ∑ m, hPL m ∘ₗ ψ m ∘ₗ compW m

theorem phiTT_hP (ψ : Fin 24 → TLeechT →ₗ[ℂ] TLeechT) (m : Fin 24) (t : TLeechT) :
    phiTT ψ (hP (cw m) t) = hP (cw m) (ψ m t)

theorem OmegaT_le_span (s' : ZMod 2) :
    OmegaT s' ≤ span ℂ {y | ∃ (m : Fin 24) (t : TLeechT), t ∈ leechFrameT s' ∧ y = hP (cw
     ↪ m) t}
```

From the mathematics to the Lean statement

`hPL m` is $t \mapsto h_{c_m}\otimes t$. `OmegaT_le_span` is the spanning statement $(T^+_{s'})_2 = \mathrm{span}\{h_{c_m}\otimes t : t \in T_{s'}\}$ (proved by identifying the doubled degree-one part of $S[\theta]$ with $\{h_v(-\tfrac{1}{2})\}$ and projecting with $\frac{1}{2}(1 \pm J)$).

Physical meaning

This is the same ansatz for the twisted-to-twisted piece: σ maps the twisted ground states $h_{c_m}(-\tfrac{1}{2})\otimes t$ to the same oscillator tensored with $\psi_m t$, where each ψ_m is a linear map on the 2^{12}-dimensional twist space. Heuristically this is a Clifford-module intertwiner: σ acts on the spinor-like twist space by an operator to be determined. The extraction map `compW` just reads

off the coefficient of a given oscillator.

The analogues `phiTT_ZMT_diag`, `topSigmaTT_of_offdiag`, `topSigmaTT_partial` (`SigmaTopTT.lean`) are proved exactly as on V_3^+; the diagonal letters intertwine for every ψ.

What the machine verified

Unconditional (`topSigmaTT_partial`) resp. conditional on `ZhuGenerated G2`, off-diagonal and lattice letters (`topSigmaTT_of_offdiag`); `SigmaTopTT.lean`.

41.7 Off-diagonal letters and the eigen-conditions

41.7.1 Charged states through the bridge

Uncharged states cross the bridge `golayToV0` unchanged; charged states pick up constants.

Definition 41.19 (transport constant). For $a \in A$ let

$$t_c(a) = \frac{c_\Lambda(a)}{g_e(a)\, c_N(a)},$$

where $c_\Lambda =$`latCob lam0 leech inclΛ`, $c_N =$`latCob lam0 golayN inclN` are the comparison coboundaries and $g_e(a) =$`charVal lam0 golayE a` is the chosen character.

```
noncomputable def tc (a : lam0.carrier) : ℂ :=
  latCob lam0 leech inclΛ a / (charVal lam0 golayE a * latCob lam0 golayN inclN a)

theorem golayToV0_charged {ι : Type*} (s : Finset ι) (d : ι → ℂ) (a : ι → lam0.carrier)
    (y : (orbifold golayK).carrier)
    (hy : (y : LatModuleGen golayN) = ∑ i ∈ s, d i • latChargeGen golayN (inclN (a i))) :
    (((golayToV0 y : V0Sub.carrier) : VPlus) : LatModuleGen leech)
      = ∑ i ∈ s, (d i * tc (a i)) • latChargeGen leech (inclΛ (a i))
```

From the mathematics to the Lean statement

The statement: if $y \in V_N^{\langle\chi,\Theta\rangle}$ equals $\sum_i d_i e^{\iota_N a_i}$, then its image in $V_0^+ \subset V_\Lambda$ is $\sum_i d_i\, t_c(a_i)\, e^{\iota_\Lambda a_i}$. The triple coercion on the left views an element of V_0^+ as an element of V_Λ. $t_c(a)$ is a nonzero complex number whose value is *not* computable (it involves `golayE` and two basis-dependent coboundaries); it is always treated symbolically.

Physical meaning

The transport constant is the ratio of cocycle data, the comparison coboundaries of the Leech and Niemeier lattices divided by the chosen character, that records the phase picked up when a lattice vertex operator is transported through the triality identification. Physically these are the cocycle (sign and phase) factors in the vertex operators that must be carried along when the same momentum is relabelled between two lattice descriptions of the same theory. It is a bookkeeping device; the physical content is that the phases are fixed uniquely by consistency.

Proof. By construction, `golayToV0` is the inverse of (V_A-functoriality into V_N, after twisting by g_e) followed by V_A-functoriality into V_Λ; functoriality sends e^a to $c(a)e^{\iota a}$ and the twist multiplies e^a by $g_e(a)$. □

What the machine verified

Unconditional; `SigmaTopOffdiag.lean`.

41.7.2 σ on $w_j(-1)w_k(-1)\mathbf{1}$

For $j \neq k$ set $\gamma_\pm = \gamma_\pm(j,k) = 4e_j \pm 4e_k \in \Lambda_0$ (`gP j k`, `gM j k`); these are norm-four vectors of Λ_0, the images of $a_\pm = 2e_j \pm 2e_k = \alpha_j \pm \alpha_k \in A$ (`aP`, `aM`).

Proposition 41.20. *For $j \neq k$,*

$$\sigma\big(d(w_j,w_k)\big) = \sum_{i=0}^{3} 4\,c_i\,t_c(a_i)\,e^{\iota_\Lambda a_i}, \qquad (a_0,a_1,a_2,a_3) = (a_+,a_-,-a_-,-a_+),$$

with c_i the coefficients of $(e^{\alpha_j} + \varepsilon_j e^{-\alpha_j})_{(-1)}(e^{\alpha_k} + \varepsilon_k e^{-\alpha_k})$ on $e^{\pm\alpha_j \pm \alpha_k}$ in V_N. Consequently, on the twisted top level,

$$\mathrm{o}\big(\sigma d(w_j,w_k)\big)(h_v \otimes t) = \kappa_+\, h_{v-2\langle v,\gamma_+\rangle\gamma_+} \otimes e_{\gamma_+} t + \kappa_-\, h_{v-2\langle v,\gamma_-\rangle\gamma_-} \otimes e_{\gamma_-} t$$

for explicit symbolic constants $\kappa_\pm$ =`kP j k`, `kM j k`.

```
theorem sig_dV_offdiag_coe {j k : Fin 24} (hjk : j ≠ k) :
    (((sig (dV (fw j) (fw k)) : V0Sub.carrier) : VPlus) : LatModuleGen leech)
      = ∑ i : Fin 4, (4 * cQ j k i * tc (aQ j k i)) • latChargeGen leech (inclΛ (aQ j k i))

noncomputable def kP (j k : Fin 24) : ℂ :=
  (2 : ℂ) ^ (-(4 : ℤ)) * (4 * cQ j k 0 * tc (aQ j k 0) + 4 * cQ j k 3 * tc (aQ j k 3))

noncomputable def kM (j k : Fin 24) : ℂ :=
  (2 : ℂ) ^ (-(4 : ℤ)) * (4 * cQ j k 1 * tc (aQ j k 1) + 4 * cQ j k 2 * tc (aQ j k 2))

theorem actT_sig_dV_offdiag {j k : Fin 24} (hjk : j ≠ k) (v : Fin (rank leech) → ℂ) (t :
↪  TLeechT) :
    actT (sig (dV (fw j) (fw k))) 1 (hP v t)
      = kP j k • hP (latL (gP j k) v) (eT leech leech_even leech_isUnit_det_gramMat (gP j
      ↪  k) t)
        + kM j k • hP (latL (gM j k) v) (eT leech leech_even leech_isUnit_det_gramMat (gM j
        ↪  k) t)
```

From the mathematics to the Lean statement

`aQ j k` $= (a_+, a_-, -a_-, -a_+)$ and `cQ j k` $= (\varepsilon_N(\alpha_j,\alpha_k),\ \varepsilon_k\varepsilon_N(\alpha_j,-\alpha_k),\ \varepsilon_j\varepsilon_N(-\alpha_j,\alpha_k),\ \varepsilon_j\varepsilon_k\varepsilon_N(-\alpha_j,-\alpha_k))$. The factor 4 comes from $d(w_j,w_k) \leftrightarrow (2\alpha_j)(-1)(2\alpha_k)(-1)\mathbf{1}$. The definitions of $\kappa_\pm$ add the two terms $e^{\pm\gamma_+}$ (resp. $e^{\pm\gamma_-}$) because both act by the same zero mode on the twisted module (Proposition 41.7(c)). Exactly the proposition.

Physical meaning

This gives σ on an off-diagonal quadratic current explicitly: the image of $J^{w_j}J^{w_k}$ is a sum of four lattice vertex operators with momenta $\pm\alpha_j \pm \alpha_k$ in the Niemeier-type lattice, weighted by transport constants. This is the triality rotation of the Cartan bilinear into charged fields, the same mechanism by which an $SU(2)$ rotation turns a Cartan current into raising and lowering operators. It converts the abstract intertwining requirement into an explicit linear condition on the twist space.

Proof. In V_N, $\sigma(\alpha(-1)\mathbf{1}) = e^{\alpha} + \varepsilon e^{-\alpha}$ for each root, so $\sigma(\alpha_j(-1)\alpha_k(-1)\mathbf{1})$ is the (-1)-product of two such states; since $\langle \alpha_j, \alpha_k \rangle = 0$, each of the four products $e^{\pm\alpha_j}_{(-1)} e^{\pm\alpha_k}$ is just $\varepsilon(\pm\alpha_j, \pm\alpha_k) e^{\pm\alpha_j \pm \alpha_k}$ (`root_prod`). Transport with `golayToV0_charged`, then use Proposition 41.11(c) termwise. □

What the machine verified

Unconditional; `SigmaTopOffdiag.lean`.

41.7.3 The eigen-conditions

Now compare the two sides on the basis. On the source, $\mathrm{o}(d(w_j, w_k))x_n = n_j n_k\, x_n$. On the target, for $\varphi_\tau(x_n) = h_{c_b} \otimes \tau(n)$ with $b = j(n)$: if $\tau(n)$ is a common eigenvector of $\kappa_+ e_{\gamma_+}$ and $\kappa_- e_{\gamma_-}$ with the same eigenvalue λ, the right side is $\lambda\, h_{(\mathrm{latL}_{\gamma_+} + \mathrm{latL}_{\gamma_-})c_b} \otimes \tau(n)$, and a two-line computation gives

$$\left(\mathrm{latL}_{\gamma_+} + \mathrm{latL}_{\gamma_-}\right)c_m = \begin{cases} -6\, c_m, & m \in \{j, k\}, \\ 2\, c_m, & \text{otherwise} \end{cases}$$

(`latL_sum_cw`). Matching with $n_j n_k$ forces the eigenvalue

$$\lambda(j, k, n) = \begin{cases} -\dfrac{1}{6} n_j n_k, & j(n) \in \{j, k\}, \\ \dfrac{1}{2} n_j n_k, & \text{otherwise.} \end{cases}$$

Theorem 41.21 (off-diagonal letters ⇐ eigen-conditions). *(a) If for all $n \in S_1$, $\kappa_+ e_{\gamma_+}\tau(n) = \lambda(j,k,n)\tau(n)$ and $\kappa_- e_{\gamma_-}\tau(n) = \lambda(j,k,n)\tau(n)$, then $d(w_j, w_k)$ intertwines for φ_τ.*

(b) If on $T_{s'}$ the maps ψ_m satisfy $(\kappa_+ e_{\gamma_+} + \kappa_- e_{\gamma_-})\psi_m = 0$ and the block links *$\psi_k = 2\kappa_- e_{\gamma_-}\psi_j$, $\psi_j = 2\kappa_- e_{\gamma_-}\psi_k$, then $d(w_j, w_k)$ intertwines for φ_ψ on $(T^+_{s'})_2$.*

```
noncomputable def lam (j k : Fin 24) (n : leech.carrier) : ℂ :=

```

From the mathematics to the Lean statement

Hypotheses are exactly the eigen-conditions (a), resp. the vanishing and the two block links (b). In (b) the source letter $d(w_j, w_k)$ acts on $h_{c_m} \otimes t$ by moving block k to block j and vice

versa with factor 4 (`dL_fw_off`), which is why the links appear. Note: (a) is stated as sufficient; the file header records that, given $(\kappa_\pm e_{\gamma_\pm})^2 = \frac{1}{4}$ (proved later, Proposition 41.23), it is also necessary, but necessity is not a Lean statement.

Physical meaning

The matching of charges for an off-diagonal current is equivalent to eigenvalue conditions on the twist-space operators $e_{\gamma_\pm}$: the vertex-operator zero modes on the twist fields must act as multiples of the identity with the prescribed eigenvalue λ. In physical terms the twist-field state must be a joint eigenvector of the Clifford-type operators with definite charge, matching the momentum-space eigenvalue on the source. This is what turns the problem into finding a single common eigenvector.

Proof. The computation preceding the theorem, read in both directions on each basis vector, plus the linear reduction to basis vectors. □

Theorem 41.22 ((R-top) reduced to block data). `TopSigmaV3 s (phiV3 τ)` *follows from: τ valued in T_s, a common nonzero block value $t_0 \in T_s$,* `ZhuGenerated G2`*, the eigen-conditions of Theorem 41.21(a) for all $j \neq k$, and the lattice letters. Likewise* `TopSigmaTT s' s (phiTT ψ)` *from the conditions of (b) and the lattice letters.*

Physical meaning

The full requirement that σ be an intertwiner on the top level is reduced to a finite list of eigen-conditions, a nonzero block value and the remaining lattice letters. Physically one has found the exact charges that the twist ground states must carry; what remains is to show that such states exist. This is a reduction, conditional on the stated data, and does not itself construct σ.

What the machine verified

Conditional (as listed); `SigmaTopOffdiag.lean`; `##print axioms` clean. At the moment these were written, *none* of the eigen-conditions was known to be satisfiable: the values of $\kappa_\pm$ involve `golayE` and the coboundaries, and even the fact that $\kappa_\pm e_{\gamma_\pm}$ has eigenvalues $\pm\frac{1}{2}$ was unproved (recorded as "R-top partial" in the project's gluing plan, `Notes/M8GluingPlan.md`). The remaining sections discharge every hypothesis.

41.8 The cocycle design question

At this point the project faced a design decision, recorded in `Notes/M8GluingPlan.md` (status "R-top partial") as a question for both maintainers:

> *The Leech cocycle is* `latticeCocycle` *over* `Module.Free.chooseBasis` *and the oscillator frame is* $\sqrt{G}$*, not the Golay frame — no explicit sign is computable; every identity must stay symbolic. An explicit (Golay-frame) basis/cocycle model, transported via the functoriality machinery (*`latMorph`*), could drastically simplify R-top's remaining work.*

The alternatives were: (i) continue symbolically; (ii) introduce a second, explicit model of V_Λ (Golay-frame basis, explicit cocycle such as $\varepsilon(a,b) = (-1)^{a^\top U b}$ with U the strict upper triangle of a Gram matrix, as in the Python model of §41.16), prove an isomorphism, and compute signs by `decide`.

The project took route (i), and after the construction the agent's assessment, recorded in the status "σ EXISTS on both twisted sectors", was:

> *An explicit-basis refactor would NOT have materially reduced cost (all identities reduced to bimultiplicative-cocycle algebra / ξ / Golay facts; no concrete cocycle value on chooseBasis was ever needed). Keep the foundations as they are.*

It is worth understanding *why* this is true, because it is the conceptual heart of the construction. Three mechanisms replace explicit signs:

1. **θ-invariance pins products of unknown constants.** The state $\sigma(d(w_j, w_k))$ lies in V_Λ^+, so its coefficients of e^γ and $e^{-\gamma}$ agree. This one fact determines the square of the unknown character value $g_e(a_\pm)^2$ in terms of $\varepsilon_j\varepsilon_k$ (Proposition 41.23), which is all that is ever needed.

2. **The N-cocycle reappears on the Leech side.** The rescaled operators $W(a) = t_c(a)e_{\iota_\Lambda a}$ satisfy $W(a)W(b) = \varepsilon_N(a,b)W(a+b)$: the *Niemeier* cocycle, for which the root lattice $\bigoplus \mathbb{Z}\alpha_j$ admits an explicit quadratic refinement ξ (§41.10). So every Leech-side computation can be re-expressed in terms of ξ, whose values on the relevant vectors are known ($\xi(e_i) = i$) or follow from $\xi(x)\xi(y) = \varepsilon_N\xi(x+y)$.

3. **Eigenvalues instead of values.** The seed t is not computed; it is *characterised* as a joint eigenvector, and its existence is proved by a trace argument. All later identities only use the eigenvalues, never t itself.

An explicit model would have required an isomorphism between two lattice VOAs *and* between the corresponding twisted modules (the latter is not in the library), plus the transport of `golaySigma`; and the octad identities involve 2^8-term Hadamard sums that `decide` could not have handled at the scale of the Leech lattice anyway. The symbolic route proved shorter.

41.9 The constants $\kappa_\pm$ and the notion of a seed

41.9.1 A bridge that is a definitional identity

Chapter 40 proved Zhu generation for the set `SigmaExist.weightTwo` of weight-two elements of the VOA V_0^+, whereas the reductions of this chapter use `G2`, the set of elements of V_0^+ whose image in V_Λ^+ has weight two. The two agree by definition, since the grading of the subVOA is the restriction of the grading of the ambient VOA.

```
theorem G2_eq_weightTwo : G2 = weightTwo := rfl

theorem zhuGenerated_G2 : ZhuGenerated G2 := zhuGenerated_weightTwo
```

From the mathematics to the Lean statement

`rfl` means that Lean accepts the equality by unfolding definitions: no mathematics is hidden. `zhuGenerated_G2` is the Zhu-generation theorem of Chapter 40 restated for `G2`. It is unconditional (no `VOA.pbw`).

What the machine verified

Unconditional; `VOA/Moonshine/SigmaTop2Bridge.lean`; `##print axioms zhuGenerated_G2` clean (re-checked, §41.18). From now on the hypothesis `ZhuGenerated G2` is discharged everywhere.

41.9.2 θ-invariance and the squares of $\kappa_\pm$

Write $A_\pm = A_\pm(j,k) = \kappa_\pm e_{\gamma_\pm} \in \mathrm{End}\, T$ (`AP j k`, `AM j k`). The eigen-conditions ask that the vectors $\tau(n)$ be eigenvectors of $A_\pm$. The first thing to know is the spectrum of $A_\pm$.

Proposition 41.23. *For $j \neq k$:*

(a) (θ-invariance) the coefficients of e^{γ_+} and $e^{-\gamma_+}$ in $\sigma(d(w_j,w_k))$ are equal, and so are those of $e^{\pm\gamma_-}$; consequently $\kappa_+ = \frac{1}{2}\varepsilon_N(\alpha_j,\alpha_k)\,t_c(a_+)$, $\kappa_- = \frac{1}{2}\varepsilon_k\varepsilon_N(\alpha_j,\alpha_k)\,t_c(a_-)$, and $g_e(a_\pm)^2 = \varepsilon_j\varepsilon_k$;

(b) $\kappa_\pm^2\,\varepsilon_\Lambda(\gamma_\pm,\gamma_\pm) = \frac{1}{4}$;

(c) $A_\pm^2 = \frac{1}{4}\cdot \mathrm{id}_T$. In particular $A_\pm$ is diagonalisable with eigenvalues in $\{\pm\frac{1}{2}\}$.

File `VOA/Moonshine/SigmaTop2Eigen.lean`.

```
theorem dQ_symm {j k : Fin 24} (hjk : j ≠ k) : dQ j k 0 = dQ j k 3 ∧ dQ j k 1 = dQ j k 2

theorem kP_eq {j k : Fin 24} (hjk : j ≠ k) : kP j k = (1 / 2 : ℂ) * cQ j k 0 * tc (aP j k)

theorem eV_aP_sq {j k : Fin 24} (hjk : j ≠ k) : eV (aP j k) * eV (aP j k) = golayEps j *
↪ golayEps k

theorem kP_sq {j k : Fin 24} (hjk : j ≠ k) : kP j k * kP j k * εΛ (gP j k) (gP j k) = 1 / 4

theorem AP_mul_self {j k : Fin 24} (hjk : j ≠ k) : AP j k * AP j k = (1 / 4 : ℂ) • 1

theorem AM_mul_self {j k : Fin 24} (hjk : j ≠ k) : AM j k * AM j k = (1 / 4 : ℂ) • 1
```

From the mathematics to the Lean statement

`dQ j k i` $= 4c_i\, t_c(a_i)$ is the i-th coefficient of Proposition 41.20, so `dQ_symm` says: coefficient of e^{γ_+} = coefficient of $e^{-\gamma_+}$ (indices $0, 3$), and likewise for γ_- (indices $1, 2$). `eV a` is $g_e(a)$, `golayEps j` is $\varepsilon_j = \varepsilon_N(\alpha_j, -\alpha_j)$, `εΛ` is ε_Λ. `(1/4 : ℂ) • 1` is $\frac{1}{4}$ times the identity of End T, and `AP j k * AP j k` is composition. The analogues `kM_eq`, `eV_aM_sq`, `kM_sq` for γ_- are in the same file. **Non-vacuity:** the only hypothesis is $j \neq k$, which is necessary ($\gamma_\pm$ are only defined as norm-four vectors for $j \neq k$).

Physical meaning

This pins down the constants $\kappa_\pm$ that normalise the twist-space operators $e_{\gamma_\pm}$ by theta-invariance, i.e. invariance under the $\mathbb{Z}/2$ lattice reflection, and derives that they square to the right cocycle value. Physically it says the Clifford-type operators acting on the twist field space have eigenvalues fixed by the reflection symmetry up to a sign, so the matching charges are determined and not free parameters.

Proof. (a) σ maps V_0^+ to itself, and $V_0^+ \subset V_\Lambda^+$, on which θ acts trivially; $\theta e^\gamma = e^{-\gamma}$ on V_Λ (in the library's normalisation), so the coefficients of $e^{\pm\gamma}$ of any θ-invariant state agree. Since e^{γ_+} and $e^{-\gamma_+}$ have coefficients $4\varepsilon_N(\alpha_j,\alpha_k)t_c(a_+)$ and $4\varepsilon_j\varepsilon_k\varepsilon_N(-\alpha_j,-\alpha_k)t_c(-a_+)$, and $\varepsilon_N(-\alpha_j,-\alpha_k) = \varepsilon_N(\alpha_j,\alpha_k)$, $t_c(-a) = t_c(a)g_e(a)^2$, equality forces $\varepsilon_j\varepsilon_k g_e(a_+)^2 = 1$, i.e. $g_e(a_+)^2 = \varepsilon_j\varepsilon_k$. The formula for κ_+ follows by adding two equal terms: $2^{-4}\cdot 2\cdot 4\varepsilon_N(\alpha_j,\alpha_k)t_c(a_+) = \frac{1}{2}\varepsilon_N(\alpha_j,\alpha_k)t_c(a_+)$. (b) The coboundary relation $c(a)^2 = \varepsilon_A(a,a)\varepsilon_L(\iota a,\iota a)$ (from the comparison identity at $b = a$ and $c(2a) = 1$) for both lattices gives $t_c(a)^2 g_e(a)^2 = \varepsilon_\Lambda(\iota_\Lambda a,\iota_\Lambda a)\varepsilon_N(\iota_N a,\iota_N a)$; with $\varepsilon_N(\alpha_j+\alpha_k,\alpha_j+\alpha_k) = \varepsilon_j\varepsilon_k$ (cocycle law and the symmetry $\varepsilon_N(\alpha_j,\alpha_k) = \varepsilon_N(\alpha_k,\alpha_j)$, both because $\langle\alpha_j,\alpha_k\rangle = 0$) and (a) one gets $t_c(a_+)^2 = \varepsilon_\Lambda(\gamma_+,\gamma_+)$, hence $\kappa_+^2\varepsilon_\Lambda(\gamma_+,\gamma_+) = \frac{1}{4}\varepsilon_N(\alpha_j,\alpha_k)^2 = \frac{1}{4}$. (c) $e_\gamma^2 = \varepsilon_\Lambda(\gamma,\gamma)$ by (41.2). □

What the machine verified

Unconditional; `VOA/Moonshine/SigmaTop2Eigen.lean`. This settles the "eigenvalue $\pm\frac{1}{2}$" question that was open in the "R-top partial" status.

Remark 41.24 (Why this is surprising and why it works). Nothing in the definition of κ_+ looks like it should square to $\frac{1}{4}$: it is a product of an N-cocycle value, a Λ-coboundary, an N-coboundary and a value of a character chosen by `Classical.choose`. The point is that `golayE` was chosen precisely to make the transported Θ agree with the Leech θ (Chapter 39); θ-invariance of the image of σ is a consequence of that choice, and it encodes exactly the information about g_e that is needed.

41.9.3 The eigenvalue pattern is a character

Lemma 41.25 (`lam_eq`). *For $j \neq k$ and $n \in S_1$: $\lambda(j,k,n) = -\frac{1}{2}(-1)^{\langle\gamma_+,n\rangle} = \frac{1}{2}(-1)^{\langle\gamma_-,n\rangle}$.*

```
theorem lam_eq {j k : Fin 24} (hjk : j ≠ k) {n : leech.carrier} (hn : n ∈ halfFourChi 1) :
    lam j k n = -(1 / 2 : ℂ) * (-1 : ℂ) ^ (leech.form (gP j k) n) ∧
      lam j k n = (1 / 2 : ℂ) * (-1 : ℂ) ^ (leech.form (gM j k) n)
```

From the mathematics to the Lean statement

`(-1 : ℂ) ^ m` with $m = \langle\gamma_\pm, n\rangle \in \mathbb{Z}$ is an integer power (`zpow`). The statement is the lemma verbatim.

Physical meaning

The eigenvalue that the twist-space operators must have is the sign $(-1)^{\langle\gamma_\pm,n\rangle}$ times $\pm\frac{1}{2}$, a function of the momentum n through a mod-two inner product. This is the charge-matching phase: the Fourier dual of momentum on the twist side is a character of the lattice. It is a technical identity used to put the eigen-conditions in a uniform form.

Proof. $\langle\gamma_\pm,n\rangle=\frac{1}{2}(n_j\pm n_k)$. If neither j nor k is the block, $n_j,n_k\in\{\pm1\}$, $\lambda=\frac{1}{2}n_jn_k$; if $n_j=n_k$ then $\frac{1}{2}(n_j+n_k)=\pm1$ is odd and $\frac{1}{2}(n_j-n_k)=0$, giving $\frac{1}{2}=-\frac{1}{2}(-1)=\frac{1}{2}(+1)$; if $n_j=-n_k$ the roles swap and both sides are $-\frac{1}{2}$. If j is the block, $n_j=\pm3$, $n_k=\pm1$, $\lambda=-\frac{1}{6}n_jn_k=\mp\frac{1}{2}$, and $\frac{1}{2}(n_j\pm n_k)\in\{\pm1,\pm2\}$ is checked in the four sign cases. □

So the required eigenvalues of $A_\pm$ on $\tau(n)$ depend on n only through the characters $(-1)^{\langle\gamma_\pm,n\rangle}$. On T, the operator e_n satisfies $e_\gamma e_n=(-1)^{\langle\gamma,n\rangle}e_ne_\gamma$. Hence *if t is an eigenvector of A_+ with eigenvalue $-\frac{1}{2}$ and of A_- with eigenvalue $\frac{1}{2}$, then e_nt has exactly the eigenvalues $\lambda(j,k,n)$.* This motivates:

Definition 41.26 (seed). A vector $t\in T$ is a *seed* if $A_+(j,k)t=-\frac{1}{2}t$ and $A_-(j,k)t=\frac{1}{2}t$ for all $j\neq k$. `SeedExists` is the statement that a nonzero seed exists.

```
def IsSeed (t : TLeechT) : Prop :=
  ∀ j k : Fin 24, j ≠ k → AP j k t = -(1 / 2 : ℂ) • t ∧ AM j k t = (1 / 2 : ℂ) • t

def SeedExists : Prop := ∃ t : TLeechT, t ≠ 0 ∧ IsSeed t
```

From the mathematics to the Lean statement

The quantifier covers all 552 ordered pairs $j\neq k$, i.e. 1104 linear conditions on $t\in T$ ($\dim T=4096$). `t ≠ 0` excludes the trivial seed. Note that a seed satisfies infinitely many *a priori* incompatible conditions; that a nonzero one exists is a genuine theorem (Theorem 41.37).

Physical meaning

A seed is a twist-field state that carries the right eigenvalue $-\frac{1}{2}$ and $+\frac{1}{2}$ for the operators $A_\pm(j,k)$ for every pair of frame directions, a joint eigenvector of the Clifford-type operators. It is the image of one distinguished ground state: once it is known, all other images are obtained by acting with the operators e_n. The existence of a nonzero seed is exactly the existence of a state to which σ can send a given reference ground state.

Theorem 41.27 (eigen-conditions from a seed). *Let t be a seed and $c:\Lambda\to\mathbb{C}$ arbitrary. Then for $j\neq k$, $n\in S_1$, $A_\pm(c(n)e_nt)=\lambda(j,k,n)\,c(n)e_nt$. If moreover $t\neq0$, $t\in T_s$ and $c(n_j)=\mu_j$ for explicit nonzero constants μ_j (`mu`), the assignment $\tau(n)=c(n)e_nt$ (`tauOf c t`) satisfies all hypotheses of Theorem 41.22 except the lattice letters, with values in T_{s+1}.*

File `VOA/Moonshine/SigmaTop2Eigen.lean`.

```
theorem eig_of_seed {t : TLeechT} (ht : IsSeed t) (c : leech.carrier → ℂ) {j k : Fin 24}

    (hlat : ∀ γ ∈ halfFourChi 0, ZM (phiV3 (tauOf c t)) OmegaV3 (lV' γ)) :
    TopSigmaV3 (s + 1) (phiV3 (tauOf c t))
```

From the mathematics to the Lean statement

`eL γ` is e_γ on T. `mvec j` is the odd vector $m_j = (1^{24}) - 4e_j$, which has its -3 in position j; `nvec j` is $\pm m_j$, whichever lies in S_1. The constants μ_j make $\mu_j e_{n_j} t = e_{m_0} t$ for all j (`mu_nvec`), so the "common block value" required by `hits_cyclic` is $e_{m_0} t$. **The sector shift:** because n is odd, $\langle w_0, n\rangle = n_0$ is odd, so e_n anticommutes with e_{w_0} and swaps $T_0 \leftrightarrow T_1$; hence a seed in T_s yields `TopSigmaV3 (s + 1)`. The only remaining hypothesis `hlat` is the lattice letters.

Physical meaning

Given a seed, the images of all momentum ground states, obtained by acting with the Clifford-type operators e_n on the seed, automatically satisfy the eigen-conditions with the correct phases. This is the statement that the single seed state generates a whole covariant family of ground states under the lattice translation operators, the analogue of generating a representation from a highest-weight vector. A nonzero seed also guarantees the image is nonzero, excluding the trivial zero map.

Proof. $A_+ e_n t = \kappa_+ e_{\gamma_+} e_n t = (-1)^{\langle \gamma_+, n\rangle} e_n \kappa_+ e_{\gamma_+} t = -\frac{1}{2}(-1)^{\langle \gamma_+, n\rangle} e_n t = \lambda e_n t$ by Lemma 41.25; likewise for A_-. For the block value: $m_j = m_0 + \gamma_-(0, j)$, so $e_{m_j} = \varepsilon_\Lambda(m_0, \gamma_-)^{-1} e_{m_0} e_{\gamma_-}$ and $e_{\gamma_-} t = (2\kappa_-)^{-1} t$ (seed), whence $e_{m_0} t = \varepsilon(m_0, \gamma_-)(2\kappa_-) e_{m_j} t = \mu_j e_{m_j} t$. □

What the machine verified

Unconditional except for the displayed hypotheses; `SigmaTop2Eigen.lean`.

41.9.4 The transported operators $W(a)$ and the block links

Definition 41.28. For $a \in A$ put $W(a) = t_c(a)\, e_{\iota_\Lambda a} \in \mathrm{End}\, T$ (`Wop a`), and for $j \neq k$, $Z_{jk} = 2A_-(j,k) = 2\kappa_- e_{\gamma_-}$ (`ZZ j k`).

```
noncomputable def Wop (a : lam0.carrier) : End ℂ TLeechT := tc a • eL (inclΛ a)

theorem Wop_mul (a b : lam0.carrier) : Wop a * Wop b = εN (inclN a) (inclN b) • Wop (a + b)

noncomputable def ZZ (j k : Fin 24) : End ℂ TLeechT := (2 : ℂ) • AM j k

theorem ZZ_mul_self {j k : Fin 24} (hjk : j ≠ k) : ZZ j k * ZZ j k = 1

theorem ZZ_comp {i j k : Fin 24} (hij : i ≠ j) (hjk : j ≠ k) (hik : i ≠ k) :
    ZZ j k * ZZ i j = ZZ i k
```

From the mathematics to the Lean statement

`Wop_mul`: the rescaled operators multiply with the cocycle of N, not of Λ. Thus $a \mapsto W(a)$ is a projective representation of A on T whose 2-cocycle is ε_N. `ZZ_comp`: the Z's compose like

"transition functions" $Z_{jk} = V_j V_k^{-1}$ (the file's formal $\mathfrak{sl}_2$-doublet picture). $Z_{jk}^2 = 1$ follows from $A_-^2 = \frac{1}{4}$.

Physical meaning

The operators $W(a)$ are the transported vertex-operator zero modes acting on the twist space: for each Golay-type element a, $W(a)$ is the Clifford-type operator $e_{\iota a}$ times the transport phase. The operators Z_{jk} are rescaled versions of the eigenvalue operators A_- and are the commuting reflection-like symmetries whose joint eigenvalues label twist states. They are the discrete charges used to label the 2^{12} twist fields.

Proof. $W(a)W(b) = t_c(a)t_c(b)\varepsilon_\Lambda(\iota a, \iota b)e_{\iota(a+b)}$, and the two comparison identities for c_Λ and c_N together with $g_e(a+b) = g_e(a)g_e(b)$ give $t_c(a)t_c(b)\varepsilon_\Lambda(\iota a, \iota b) = \varepsilon_N(a,b)t_c(a+b)$: the ε_A's cancel. For `ZZ_comp`: Z_{jk} is a scalar multiple of $W(a_-(j,k))$ and $a_-(j,k) + a_-(i,j) = a_-(i,k)$; the scalar works out by the cocycle identities for the orthogonal roots. □

Theorem 41.29 (`topSigmaTT_of_seed`). *Let $B \in \mathrm{End}\, T$ map into T_s, satisfy $(A_+ + A_-)(Bt) = 0$ for $t \in T_{s'}$ and $j \neq k$, and send some $t_1 \in T_{s'}$ to a nonzero seed. Put $\psi_0 = B$ and $\psi_m = Z_{0m}B$ (`psiOf B`). If the lattice letters intertwine for φ_ψ, then `TopSigmaTT s' s` φ_ψ.*

    TopSigmaTT s' s (phiTT (psiOf B))
```

From the mathematics to the Lean statement

Hypotheses: `hBs` (B lands in T_s), `hBE` (the vanishing condition of Theorem 41.21(b) for ψ_0; for the other ψ_m it follows because Z_{0m} commutes with $A_\pm$, as all γ's involved have coordinates divisible by 4, so their pairings are even), `hseed`, `h0` (the block value Bt_1 is a nonzero seed, giving `hits_cyclic`), `hlat` (open at this stage). The block links hold by `ZZ_comp` and $Z^2 = 1$.

Physical meaning

This is the twisted-to-twisted analogue: if an operator B on the twist space produces a seed from some state and respects the eigenvalue relations, the family $\psi_m = Z_{0m}B$ gives an intertwiner for the diagonal and off-diagonal letters, provided the lattice letters also match charges. Physically the twisted sector is again determined by a single distinguished image state, the seed, and the other components are generated by the symmetry operators Z_{0m}. It is conditional on the lattice letters.

What the machine verified

Conditional on the displayed hypotheses; `SigmaTop2Eigen.lean`. Discharged in §41.15.

41.10 The quadratic refinement ξ and the spinor cube

41.10.1 ξ

On the root sublattice $R = \bigoplus_j \mathbb{Z}\alpha_j \subset N$ all inner products $\langle \alpha_i, \alpha_j \rangle = 2\delta_{ij}$ are even, so the commutator $\varepsilon_N(x,y)\varepsilon_N(y,x) = (-1)^{\langle x,y\rangle}$ is trivial: ε_N restricted to R is a *symmetric* 2-cocycle with values ± 1, hence a coboundary over $\mathbb{C}^\times$ (a symmetric cocycle on a free abelian group with values in a divisible group is a coboundary). We fix an explicit trivialisation.

Definition 41.30 (`xi`). Let $\phi_R : \mathbb{Z}^{24} \to N$, $x \mapsto \sum x_i\alpha_i = 2x$ (`phiR`). A function $\xi : \mathbb{Z}^{24} \to \mathbb{C}^\times$ with

$$\xi(x)\xi(y) = \varepsilon_N(\phi_R x, \phi_R y)\,\xi(x+y), \qquad \xi(e_i) = i$$

is constructed as $\xi = \xi_0 \cdot \chi$, where $\xi_0(x) = i^{S(x,x)}$ for the symmetrised exponent S of the cocycle (`xi0`, via `cobSign`), and $\chi(x) = \prod_i w_i^{x_i}$ is the character correcting $\xi(e_i)$ to i.

File `VOA/Moonshine/SigmaTop2Xi.lean`.

```

theorem xi_mul (x y : Fin 24 → ℤ) : xi x * xi y = εN (phiR x) (phiR y) * xi (x + y)

theorem xi_single (i : Fin 24) : xi (Pi.single i 1) = Complex.I
```

From the mathematics to the Lean statement

`phiR`'s body is shown (it contains no choices): $x \mapsto 2x$, which lies in N because $2x \equiv 0 \bmod 2$ and $0 \in \mathcal{G}$. `wXi i` $= i/\xi_0(e_i)$. `Pi.single i 1` is the unit vector e_i; `Complex.I` is i. The normalisation $\xi(e_i) = i$ is a *choice* — ξ is unique up to a character of $\mathbb{Z}^{24}$ — and the choice i is what makes the formulas of the cube (`nuC`) produce the standard $\mathfrak{sl}_2$ doublet matrices. Note $\xi(2e_i) = \xi(e_i)^2/\varepsilon_N(\alpha_i,\alpha_i) = -\varepsilon_i$, consistent with ξ being a refinement: $\xi(x)^2 = \varepsilon_N(\phi_R x, \phi_R x)\xi(2x)$.

Physical meaning

The function ξ is a refinement of the cocycle ε_N with value i on the generators: it plays the role of the choice of phases for the lattice vertex operators in a way compatible with the frame. Heuristically it is the discrete torus-phase, the square root of the cocycle that appears when the lattice is halved to the frame. It is a technical phase refinement whose only physical content is that such a consistent choice of vertex-operator phases exists.

Proof of `xi_mul`. Write $\varepsilon_N(\phi_R x, \phi_R y) = (-1)^{D(x,y)}$ with D the $\mathbb{Z}$-bilinear exponent of the library's cocycle (`cocForm`), pulled back along ϕ_R. Since ε_N is symmetric on R, $D(e_i,e_j) + D(e_j,e_i)$ is even for all i, j. Let S be the symmetric bilinear form with $S(e_i,e_j) = D(e_i,e_j)$ for $i \le j$ (`symForm`); then $S \equiv D \pmod 2$ entrywise (below the diagonal $S_{ij} - D_{ij} = D_{ji} - D_{ij}$, which is even). Put $\xi_0(x) = i^{S(x,x)}$. Then

$$\xi_0(x+y) = i^{S(x,x)}\, i^{S(y,y)}\, i^{2S(x,y)} = \xi_0(x)\xi_0(y)(-1)^{S(x,y)} = \xi_0(x)\xi_0(y)(-1)^{D(x,y)},$$

which, since $(-1)^D = (-1)^{-D}$, is the claimed identity. A character $\chi(x) = \prod_i w_i^{x_i}$ satisfies $\chi(x)\chi(y) = \chi(x+y)$, so $\xi = \xi_0\chi$ satisfies the same identity, and $w_i = i/\xi_0(e_i)$ gives $\xi(e_i) = i$. □

What the machine verified

Unconditional; `SigmaTop2Xi.lean`.

41.10.2 The spinor cube

Let $D \subseteq \{0,\dots,23\}$ with $4 \mid |D|$ and $\beta \in N$ with coordinates the indicator 1_D (so $\beta = \frac{1}{2}\sum_{i\in D}\alpha_i$, a "spinor" vector of N). The $2^{|D|}$ vectors $\beta - \delta_S$, $\delta_S = \sum_{i\in S}\alpha_i$, $S \subseteq D$, are obtained from β by flipping signs in S. Physically: each coordinate $i \in D$ carries an $\mathfrak{sl}_2$ doublet (momentum $\pm\frac{1}{2}\alpha_i$), and V_N restricted to these states is a tensor product of $|D|$ doublets. The cube basis is

$$b_S = \nu(S)\, e^{\beta-\delta_S}, \qquad \nu(S) = \varepsilon_N(\delta_S, \delta_S+\beta)\,\xi(1_S)\, i^{-|S|}$$

(`bp`, `nuC`). The normalisation ν is chosen so that the root operators act by the standard matrices: $E_i b_S = b_{S\setminus i}$ for $i \in S$, $F_i b_S = b_{S\cup i}$ for $i \notin S$ (and 0 otherwise). File `VOA/Moonshine/SigmaTop2Cube.lean`.

```
noncomputable def nuC (S : Finset (Fin 24)) : ℂ :=
  εN (dl S) (dl S + β) * xi (ind S) * (Complex.I ^ S.card)⁻¹

      gvec (chivec (ginv (chivec (gvec (chivec (ginv (φ m)))))))))

theorem theta_local :
    gvec (chivec (ginv (chivec (gvec (chivec (ginv ![1, 0])))))) = ![0, 1]

theorem golayTheta_codeword (hβ : gv β = ind D) (h4 : 4 ∣ D.card) :
    golayTheta (latChargeGen golayN β) = xi (ind D) • latChargeGen golayN (-β)
```

From the mathematics to the Lean statement

`gv β` is the coordinate vector of $\beta \in N$ in $\mathbb{Z}^{24}$; the hypothesis `gv β = ind D` says $\beta = 1_D$. `h4`: $4 \mid |D|$ (needed so that the momentum sign of the extreme states is a global sign; it holds for every Golay codeword). `gvec`, `ginv`, `chivec` are g, g^{-1}, χ applied to a vector of $\mathbb{C}^2$; `![1, 0]` is the column $(1,0)^{\mathsf{T}}$. `cD D` $= c_D$. The last statement is the one used later: the scalar by which Θ maps the codeword state e^{β} to $e^{-\beta}$ is $\xi(1_D)$. Nothing here is vacuous: $D =$ any octad, or $D = \varnothing$ ($\beta = 0$, where it says $\Theta\mathbf{1} = \mathbf{1}$).

Physical meaning

On the spinor cube, the 2^{12}-dimensional tensor product of two-dimensional factors, the triality operator σ acts as a tensor product of one-qubit matrices h, and the reflection Θ as another tensor product. This is the explicit Clifford-module picture: the twist-field space is a spinor of the frame, the group element acts on it by a Hadamard-like transform on each qubit, up to a scalar. The one-qubit Hadamard is precisely the discrete Fourier transform exchanging the two basis labels, here the momentum-like and twist-like labels.

Proof. The root operators act on the cube coordinatewise (by the normalisation ν): the recursion $\nu(S \cup i) = \nu(S)\varepsilon_i\varepsilon_N(\alpha_i, \beta - \delta_S)$ is exactly what makes $\varepsilon_i Q_{-\alpha_i}$ send $b_S \mapsto b_{S \cup i}$ and Q_{α_i} send $b_S \mapsto b_{S \setminus i}$, and $Q_{\pm\alpha_i}^2 = 0$ on the cube. Hence $g_i = \exp(aE_i)\exp(bF_i)$ acts by the 2×2 matrix g in the i-th factor, and g_k, $k \notin D$, acts trivially. The momentum signs: χ acts on $e^{\beta - \delta_S}$ by $(-1)^{\sum(\beta-\delta_S)_i/2}$, and $\sum(\beta - \delta_S) = |D| - 2|S|$; since $4 \mid |D|$ this is $(-1)^{|S|} = \prod_{i \in S}(-1)$, i.e. $\chi^{\otimes D}$. The extra γ_0-sign of `golayChiMod` is the constant c_D. Composing, $\Theta = \sigma\chi\sigma$ is the tensor power of $h\chi h$ (the two c_D cancel). Finally a 2×2 computation in $\mathbb{Q}(\sqrt{2})$ shows $h\chi h$ sends $(1,0) \mapsto (0,1)$, i.e. "all up" $\mapsto$ "all down": $\Theta e^{\beta} = \Theta b_{\varnothing} = b_D = \nu(D)e^{-\beta}$, and $\nu(D) = \varepsilon_N(2\beta, 3\beta)\xi(1_D)i^{-|D|} = \xi(1_D)$ (since $\varepsilon_N(\beta,\beta)^6 = 1$ and $4 \mid |D|$). □

What the machine verified

41.11 The seed exists

This is the single most important step of the chapter: a nonzero vector $t \in T$ satisfying the 1104 conditions of Definition 41.26. The construction has two parts: a projector argument produces a common fixed vector of 12 commuting involutions, and an algebraic "closure" argument shows that this fixed vector automatically satisfies all other conditions.

41.11.1 Common fixed vectors of a Lagrangian family

T is the unique irreducible representation of an extraspecial group of order 2^{1+24}, of dimension 2^{12}. A maximal commuting family of its "Pauli operators" has a one-dimensional joint eigenspace for each character — exactly as for n qubits, where $Z_1, \dots, Z_n$ have the computational basis as joint eigenbasis. The library encodes such a family as a *Lagrangian datum*.

Definition 41.32 (Lagrangian datum)**.** For an integral lattice L, a `Lagrangian L` consists of m with $2m = \operatorname{rank} L$, vectors $\gamma_0, \dots, \gamma_{m-1}$ with all $\langle \gamma_i, \gamma_j \rangle$ and $\frac{1}{2}\langle \gamma_i, \gamma_i \rangle$ even (so their images in $L/2L$ span a totally singular subspace for the quadratic form $q(x) = \frac{1}{2}\langle x, x \rangle \bmod 2$), and *partners* $g_0, \dots, g_{m-1}$ with $\langle g_i, \gamma_j \rangle$ even for $j < i$ and odd for $j = i$.

```
structure Lagrangian (L : VOA.IntegralLattice) where
  m : ℕ
  γ : ℕ → L.carrier
  g : ℕ → L.carrier
  form_even : ∀ i < m, ∀ j < m, _root_.Even (L.form (γ i) (γ j))
  halfNorm_even : ∀ i < m, _root_.Even (halfNorm L (γ i))
  partner_even : ∀ i < m, ∀ j < i, _root_.Even (L.form (g i) (γ j))
  partner_odd : ∀ i < m, Odd (L.form (g i) (γ i))
  two_mul_m : 2 * m = L.bRank
```

Physical meaning

A Lagrangian datum is a maximal isotropic (totally singular) subspace of the lattice modulo $2L$, the discrete analogue of choosing a polarisation or a maximal commuting set of observables. Physically one chooses half of the Clifford generators to be simultaneously diagonalised; the common eigenvectors form the lowest-energy states in the twisted sector. This is the standard stabiliser-code (Heisenberg group) construction of a state.

(`VOA/Moonshine/TFormLattice.lean`.) The Leech instance `leechLagrangian` (`TForm.lean`, Chapter 37) has $m = 12$, $\gamma_0 = 8e_0 = w_0$, $\gamma_i = 4e_0 + 4e_i$ $(1 \le i \le 11)$, and partners $g_0 = u$, $g_i = 2r_i$ with r_i the rows of the Golay generator matrix.

Theorem 41.33 (`exists_fixed_of_lagrangian`). *Let D be a Lagrangian datum for Λ and $\kappa_i \in \mathbb{C}$ with $\kappa_i^2 \varepsilon_\Lambda(\gamma_i, \gamma_i) = 1$ for $i < m$. Then there is $t \in T$, $t \neq 0$, with $\kappa_i e_{\gamma_i} t = t$ for all $i < m$.*

File `VOA/Moonshine/SigmaTop2Seed.lean`.

```
theorem exists_fixed_of_lagrangian (hκ : ∀ i < D.m, κ i * κ i * εΛ (D.γ i) (D.γ i) = 1) :
    ∃ t : TLeechT, t ≠ 0 ∧ ∀ i < D.m, κ i • eL (D.γ i) t = t
```

From the mathematics to the Lean statement

D and $\kappa : \mathbb{N} \to \mathbb{C}$ are section variables. The hypothesis makes each $F_i = \kappa_i e_{\gamma_i}$ an involution. No choice of κ_i beyond this normalisation is required — in particular the theorem applies to the uncomputable constants that occur below. Same as the textbook statement.

Physical meaning

Given a Lagrangian datum, the commuting Clifford-type operators have a common eigenvector with eigenvalue 1: the stabiliser state exists. Physically a maximal commuting set of observables on the twist space has a simultaneous eigenvector with the prescribed charges, which gives a nonzero twist field. This is the existence statement behind the seed, and it guarantees the vector is nonzero, so the resulting operator cannot be the zero map.

Proof. The F_i commute ($\langle \gamma_i, \gamma_j \rangle$ even) and square to 1. Let $P_k = \prod_{i<k} \frac{1}{2}(1 + F_i)$. Claim: $\operatorname{tr}(P_k) \cdot 2^k = \dim T$. Indeed $\operatorname{tr} P_{k+1} = \frac{1}{2} \operatorname{tr} P_k + \frac{1}{2} \operatorname{tr}(P_k F_k)$, and $\operatorname{tr}(P_k F_k) = 0$: the partner $G = e_{g_k}$ commutes with P_k (even pairings with γ_j, $j < k$) and anticommutes with F_k (odd pairing), and G^2 is a nonzero scalar, so $\operatorname{tr}(P_k F_k) = \operatorname{tr}(G^{-1} P_k F_k G) = -\operatorname{tr}(P_k F_k)$. With $k = m = 12$ and $\dim T = 2^{12}$, $\operatorname{tr} P_{12} = 1$; so the projector P_{12} is nonzero, and any nonzero vector in its image is fixed by all F_i (since $F_i P_{12} = P_{12}$). □

What the machine verified

Unconditional; `SigmaTop2Seed.lean`.

41.11.2 ξ-closure

Definition 41.34 (`chargesS`). For $t \in T$, $\mathrm{Ch}(t) = \{a \in A : \exists x \in \mathbb{Z}^{24},\ \iota_N a = \phi_R x \text{ and } W(a)t = \xi(x)t\}$. In words: a lies in the root lattice R (as a vector of N), and the transported operator $W(a)$ acts on t by the refinement value ξ.

```
noncomputable def chargesS (t : TLeechT) : AddSubgroup lam0.carrier where
  carrier := {a | ∃ x, inclN a = phiR x ∧ Wop a t = xi x • t}
  zero_mem' := ⟨0, by rw [map_zero, map_zero], by rw [Wop_zero, xi_zero, one_smul]; rfl⟩
```

From the mathematics to the Lean statement

Only the carrier and the first closure field are quoted; the remaining fields of the structure (`add_mem'`, `neg_mem'`) are proofs that the set is closed under addition and negation. That $\mathrm{Ch}(t)$ is a *subgroup* is the key point: it follows from $W(a)W(b) = \varepsilon_N(a,b)W(a+b)$ (Definition 41.28) and $\xi(x)\xi(y) = \varepsilon_N\xi(x+y)$ — the two projective representations W and $\xi \cdot \mathrm{id}$ have the same cocycle, so the set where they agree on t is closed. This is *why* ξ was introduced.

Physical meaning

The set $\mathrm{Ch}(t)$ collects the lattice directions along which the twist state t is an eigenvector of the transported vertex-operator zero mode with the prescribed phase ξ. It is the set of charges carried by the state, the stabiliser group of t in the stabiliser-state language. Demanding that this set be large is demanding that t has definite values of many commuting observables.

Proposition 41.35 (from charges to seeds). *(a) If $a_+(0,j) = \alpha_0 + \alpha_j \in \mathrm{Ch}(t)$ for all j (including $j = 0$, $a_+(0,0) = 2\alpha_0$), then t is a seed.*

(b) (codewords) If $b \in A$ has $\iota_N b = 1_D$ with $4 \mid |D|$, then $g_e(b)^{-2} = \xi(1_D)$, and $2b \in \mathrm{Ch}(t)$ for every t.

```
theorem isSeed_of_charges {t : TLeechT} (h : ∀ j, aP 0 j ∈ chargesS t) : IsSeed t

theorem eV_sq_codeword {b : lam0.carrier} {D : Finset (Fin 24)} (hb : gv (inclN b) = ind D)
    (h4 : 4 ∣ D.card) : (eV b * eV b)⁻¹ = xi (ind D)

theorem codeword_mem_chargesS (t : TLeechT) {b : lam0.carrier} {D : Finset (Fin 24)}
    (hb : gv (inclN b) = ind D) (h4 : 4 ∣ D.card) : b + b ∈ chargesS t
```

From the mathematics to the Lean statement

In (a) the hypothesis quantifies over all $j \in \{0, \dots, 23\}$. In (b), `gv (inclN b) = ind D` says that b, viewed in N, is the codeword vector 1_D. Note `codeword_mem_chargesS` holds for *every* t — because $W(2b)$ is a scalar.

Physical meaning

A state whose charge set contains the basic root combinations is a seed, and codewords of the Golay code automatically lie in the charge set of every state. Physically the Golay codewords act as charges that every twist field must carry, a selection rule coming from the code. The seed conditions thus reduce to checking finitely many charges on a lattice, which is a purely combinatorial statement about the stabiliser group.

Proof. (a) $\mathrm{Ch}(t)$ is a group, so $a_+(j,k) = a_+(0,j) + a_+(0,k) - a_+(0,0)$ and $a_-(j,k) = a_+(0,j) - a_+(0,k)$ lie in it. By Proposition 41.23(a), $A_+ = \frac{1}{2}\varepsilon_N(\alpha_j,\alpha_k)W(a_+)$ and $A_- = \frac{1}{2}\varepsilon_k\varepsilon_N(\alpha_j,\alpha_k)W(a_-)$. With

$\xi(e_j+e_k)=\xi(e_j)\xi(e_k)/\varepsilon_N(\alpha_j,\alpha_k)=-\varepsilon_N(\alpha_j,\alpha_k)$ and $\xi(e_j-e_k)=\varepsilon_k\varepsilon_N(\alpha_j,\alpha_k)$ one gets $A_+t=-\frac{1}{2}t$ and $A_-t=\frac{1}{2}t$. (b) Θ on the Leech side is $\theta\,(e^\gamma\mapsto e^{-\gamma})$; pulled back through the bridge it becomes, on $e^{\iota_N b}$, the map $e^{\iota_N b}\mapsto g_e(b)^{-2}e^{-\iota_N b}$ (this is what the specification of `golayE` says). Comparing with Theorem 41.31, $\Theta e^\beta=\xi(1_D)e^{-\beta}$, gives $g_e(b)^{-2}=\xi(1_D)$. Finally $W(2b)=t_c(2b)e_{2\iota b}=t_c(2b)$, and $t_c(2b)=g_e(b)^{-2}$ (coboundaries are 1 on doubles), $=\xi(1_D)$, where $\iota_N(2b)=2\cdot 1_D=\phi_R(1_D)$. □

41.11.3 The codeword relation and the seed

The Lagrangian gives $\alpha_0+\alpha_i\in\mathrm{Ch}(t)$ only for $i<12$ (and $2\alpha_0$). The other twelve come from codewords. Let D_k ($0\le k\le 11$) be the Golay codeword whose last twelve coordinates are e_k (so $D_k\cap\{12,\dots,23\}=\{12+k\}$); write d_l ($1\le l\le 11$) for its coordinates and $m=\frac{1}{2}(|D_k|-2[0\in D_k])$.

Lemma 41.36 (`colD_key`, kernel-checked). *For each $k<12$, in $\mathbb{Z}^{24}$: $\alpha_0+\alpha_{12+k}=2\cdot 1_{D_k}-\sum_{l=1}^{11}d_l(\alpha_0+\alpha_l)+m\cdot 2\alpha_0$ (with $\alpha_i=2e_i$).*

File `VOA/Moonshine/SigmaTop2Seed.lean`.

```
theorem colD_key : ∀ k : Fin 12, apv 0 (Fin.natAdd 12 k) =
    (2 : ℤ) • colD k - ∑ l, ccD k l • apv 0 l + mmD k • apv 0 0 := by decide +kernel
```

From the mathematics to the Lean statement

`apv j k` $=2(e_j+e_k)$, `colD k` $=1_{D_k}$ (computed from the library's Golay encoder), `ccD k l` $=d_l$ for $1\le l\le 11$ and 0 otherwise, `mmD k` $=m$. The proof `decide +kernel` is shown because it is informative: the twelve vector identities are checked by the Lean kernel's own evaluator on explicit integer vectors. This is *not* `native_decide`: it uses no compiled code and adds no axiom (confirmed: `##print axioms colD_key` is clean).

Physical meaning

This is a lattice identity expressing one frame sum in terms of earlier ones and codeword vectors. Physically it is the linear dependence among charges of the stabiliser group that guarantees consistency, i.e. that imposing a handful of charges forces the rest. It is a technical computation checked by the kernel.

Why it is true. Compare coordinates: at $12+k$ both sides have 2; at $l\in\{1,\dots,11\}$ the right side has $2d_l-2d_l=0$; at other positions ≥ 12 both vanish; at 0 the coefficient m is chosen to balance. □

Theorem 41.37 (the seed exists). *There is a nonzero $t\in T$ with $A_+(j,k)t=-\frac{1}{2}t$ and $A_-(j,k)t=\frac{1}{2}t$ for all $j\ne k$. Moreover one can take $t\in T_s$ for some s.*

File `VOA/Moonshine/SigmaTop2Eigen.lean`.

```
theorem seedExists : SeedExists

theorem seed_in_frame (h : SeedExists) :
    ∃ s : ZMod 2, ∃ t : TLeechT, t ∈ leechFrameT s ∧ t ≠ 0 ∧ IsSeed t
```

From the mathematics to the Lean statement

`SeedExists` unfolds to $\exists t,\ t\ne 0\wedge$`IsSeed t` (Definition 41.26). No hypotheses. The second statement is the projection to a frame sector; the sector s is not determined (Remark 41.1).

Physical meaning

A nonzero twist-field state with all the required charges exists. Physically this says the twisted-sector ground state, the image of the reference untwisted ground state under triality, exists in the 2^{12}-dimensional space and has the right quantum numbers. The nonzero condition is essential: it makes σ a genuine symmetry operator rather than the zero map. It is established in Lean, but the physical identification is heuristic.

Proof. Apply Theorem 41.33 to the Leech Lagrangian with $\kappa_i = -\varepsilon_N(\alpha_0, \alpha_i)t_c(a_+(0,i))$; the normalisation $\kappa_i^2\varepsilon_\Lambda(\gamma_i,\gamma_i) = 1$ is Proposition 41.23(b) (for $i = 0$ a separate but identical computation). The fixed vector t satisfies $W(a_+(0,i))t = -\varepsilon_N(\alpha_0,\alpha_i)t = \xi(e_0+e_i)t$, i.e. $a_+(0,i) \in \mathrm{Ch}(t)$ for $i < 12$. By Lemma 41.36 and Proposition 41.35(b), also $a_+(0,12+k) \in \mathrm{Ch}(t)$, since $\mathrm{Ch}(t)$ is a group. Proposition 41.35(a) concludes. For the sector: $A_\pm$ commute with J (all $\gamma_\pm \in \Lambda_0$ pair evenly with w_0), so $\frac{1}{2}(1 \pm J)t$ are seeds, not both zero. □

What the machine verified

Unconditional; `SigmaTop2Seed.lean`; `##print axioms seedExists` = [propext, `Classical.choice`, `Quot.sound`] (re-checked for this chapter). Two `decide +kernel` certificates (`colD_four`, `colD_key`) on explicit integer vectors.

Remark 41.38 (Physical reading). In the qubit picture, $T \cong (\mathbb{C}^2)^{\otimes 12}$ and the conditions on a seed are that t be a joint eigenvector of a maximal abelian "stabiliser group" with prescribed eigenvalues: t is a *stabiliser state*. The Lagrangian half is the standard construction of a stabiliser state; the content is that the ξ-twisted signs prescribed by σ are *consistent*, i.e. define a character of the stabiliser group. The codeword relation is where consistency could have failed, and the cube computation $\Theta e^\beta = \xi(1_D)e^{-\beta}$ is what guarantees it does not.

41.12 The root letters $(\pm4, \pm4, 0^{22})$

The lattice letters u_γ, $\gamma \in S_0$, are of two shapes (Theorem 41.47): the 1104 "root type" vectors $\pm\gamma_\pm(j,k)$, and the 97152 "octad type" vectors. This section treats the first.

41.12.1 σ on an $\mathfrak{sl}_2$ triple

For one root α_j of N, the weight-one space spanned by $e^{\alpha_j}, \alpha_j(-1)\mathbf{1}, e^{-\alpha_j}$ is a copy of $\mathfrak{sl}_2$; write $\mathrm{tri}_j(x_1,x_2,x_3) = x_1e^{\alpha_j} + x_2\alpha_j(-1)\mathbf{1} + x_3e^{-\alpha_j}$ (Chapter 39, `tri`).

Proposition 41.39 (`golaySigma_tri`). $\sigma\,\mathrm{tri}_j(x_1,x_2,x_3) = \mathrm{tri}_j\big(x_2 - \frac{x_1}{2} + \frac{\varepsilon_j x_3}{2},\ \frac{x_1}{2} + \frac{\varepsilon_j x_3}{2},\ \varepsilon_j x_2 + \frac{\varepsilon_j x_1}{2} - \frac{x_3}{2}\big)$.

File `VOA/Moonshine/SigmaTop2Root.lean`.

```
theorem golaySigma_tri (j : Fin 24) (x₁ x₂ x₃ : ℂ) :
    golaySigma (tri j x₁ x₂ x₃) =
      tri j (x₂ - x₁ / 2 + golayEps j * x₃ / 2) (x₁ / 2 + golayEps j * x₃ / 2)
        (golayEps j * x₂ + golayEps j * x₁ / 2 - x₃ / 2)
```

From the mathematics to the Lean statement

In the basis $H = \alpha_j(-1)\mathbf{1}$, $A = e + \varepsilon f$, $B = e - \varepsilon f$ (with $e = e^{\alpha_j}$, $f = e^{-\alpha_j}$), this says $\sigma H = A$, $\sigma A = H$, $\sigma B = -B$: σ is the rotation by π about the bisector of the H and A axes in $\mathfrak{so}_3 \cong \mathfrak{sl}_2$. A direct transcription.

Physical meaning

This gives the explicit action of σ on the three-dimensional blocks of the Golay frame as a 3×3 matrix with entries $\frac{1}{2}$, i.e. the triality rotation in the basis of frame blocks. It is the local form of the symmetry that permutes three isomorphic modules, and it is the finite-dimensional analogue of a Fourier-type rotation among the three sectors.

Proof. $\sigma H = A$ is Chapter 39's `golaySigma_hSt`; $\sigma^2 = 1$ gives $\sigma A = H$. For B: exhibit the preimage $y_B = \mathrm{tri}_j(4 - 2\sqrt{2}, 0, -\varepsilon_j(2+\sqrt{2})/4)$ with $g\, y_B = B$, observe $\chi z_0(y_B) = -y_B$, and conclude $\sigma B = g\chi z_0 g^{-1} B = -B$; the identity $g\, y_B = B$ is an identity in $\mathbb{Q}(\sqrt{2})$. □

41.12.2 $\sigma(u_{\gamma_\pm})$ and the root letter identities

For $j \neq k$ the products H_jH_k, A_jA_k, B_jB_k (normally ordered, (-1)-products) satisfy $\sigma(H_jH_k) = A_jA_k$, $\sigma(B_jB_k) = B_jB_k$. Now $A_jA_k \pm B_jB_k$ are combinations of $e^{\pm(\alpha_j+\alpha_k)}$ resp. $e^{\pm(\alpha_j-\alpha_k)}$, i.e. (after transport) of the letters $u_{\gamma_+}, u_{\gamma_-}$, while H_jH_k corresponds to $\frac{1}{4}d(w_j, w_k)$. Solving:

Theorem 41.40 (`sig_lV_gP`, `sig_lV_gM`). *For $j \neq k$,*

$$\sigma(u_{\gamma_+}) = (2\kappa_+)^{-1}\big(\tfrac{1}{8}d(w_j,w_k) + \kappa_+ u_{\gamma_+} - \kappa_- u_{\gamma_-}\big),$$
$$\sigma(u_{\gamma_-}) = (2\kappa_-)^{-1}\big(\tfrac{1}{8}d(w_j,w_k) - \kappa_+ u_{\gamma_+} + \kappa_- u_{\gamma_-}\big).$$

```
theorem sig_lV_gP {j k : Fin 24} (hjk : j ≠ k) :
    sig (lV (gP j k) (gP_mem j k)) = (2 * kP j k)⁻¹ • ((1 / 8 : ℂ) • dV (fw j) (fw k)
      + kP j k • lV (gP j k) (gP_mem j k) - kM j k • lV (gM j k) (gM_mem j k))

theorem sig_lV_gM {j k : Fin 24} (hjk : j ≠ k) :
    sig (lV (gM j k) (gM_mem j k)) = (2 * kM j k)⁻¹ • ((1 / 8 : ℂ) • dV (fw j) (fw k)
      - kP j k • lV (gP j k) (gP_mem j k) + kM j k • lV (gM j k) (gM_mem j k))
```

From the mathematics to the Lean statement

`gP_mem j k` is the proof that $\gamma_+ \in \Lambda_0$, needed to form the letter. Sanity check: applying σ to the first formula and using Proposition 41.20 for $\sigma(d(w_j,w_k))$ reproduces u_{γ_+} (since $\sigma^2 = 1$); the formulas are consistent with σ being an involution. They involve only the same symbolic constants $\kappa_\pm$ — no new unknowns.

Physical meaning

The images of the root-type lattice vertex operators $u_{\gamma_\pm}$ under σ are mixtures of a frame bilinear and the two charged operators with weights $\kappa_\pm$. Physically triality rotates charged and neutral currents into each other, the way a Weyl rotation mixes a Cartan current and its root vectors. This is the explicit formula needed to match zero modes on the twisted side.

What the machine verified

Unconditional; `SigmaTop2Root.lean`.

Theorem 41.41 (root letters intertwine). *Let τ be even ($\tau(-m) = \tau(m)$), satisfy the eigen-conditions, and the* transport rule *$\varepsilon_\Lambda(\gamma_+, n)\tau(\gamma_+ + n) = (2\kappa_+)^{-1}\tau(n)$ whenever n is odd of norm 4 with $\langle\gamma_+, n\rangle = -2$. Then u_{γ_+} intertwines for φ_τ; likewise for γ_-.*

```
theorem phiV3_ZM_gP {τ : leech.carrier → TLeechT} (hev : ∀ m, τ (-m) = τ m) {j k : Fin 24}
    (hjk : j ≠ k)
    (heig : ∀ n ∈ halfFourChi 1, kP j k • eL (gP j k) (τ n) = lam j k n • τ n ∧
      kM j k • eL (gM j k) (τ n) = lam j k n • τ n)
    (hrule : ∀ n : leech.carrier, n ∉ lambda0 → leech.form n n = 4 → leech.form (gP j k) n
     ↪  = -2 →
      εΛ (gP j k) n • τ (gP j k + n) = (2 * kP j k)⁻¹ • τ n) :
    ZM (phiV3 τ) OmegaV3 (lV (gP j k) (gP_mem j k))
```

From the mathematics to the Lean statement

`hev` lets one evaluate φ_τ on x_m for $m \notin S_1$ (then $-m \in S_1$ and $x_m = x_{-m}$). `heig` are the eigen-conditions (now known to follow from a seed). `hrule` is a genuinely new condition on τ: it ties together τ on the two endpoints of each move $n \mapsto n + \gamma_+$. `phiV3_ZM_gM` is identical with γ_-, κ_-.

Physical meaning

The root-type lattice letters intertwine once the twist images are even and obey transport rules, which say that translating the momentum by γ_+ translates the twist state by the corresponding operator with prescribed phase. This is the matching of charges for the vertex operators of norm-four roots, the lattice-translation covariance that a T-duality-type map must have.

Proof. Source: $\mathrm{o}(u_{\gamma_+})x_n = \varepsilon(\gamma_+, n)x_{\gamma_+ + n}$ or $\varepsilon(\gamma_+, -n)x_{\gamma_+ - n}$ or 0, according to $\langle\gamma_+, n\rangle = -2, 2$, else. The move $n \mapsto n + \gamma_+$ with $\langle\gamma_+, n\rangle = -2$ means $n_j + n_k = -4$, so $\{n_j, n_k\} = \{-3, -1\}$: it moves the block from j to k or back. Target: by Theorem 41.40, $\mathrm{o}(\sigma u_{\gamma_+})$ on $h_{c_m} \otimes \tau$, with τ an $A_\pm$-eigenvector with eigenvalue λ, is $(2\kappa_+)^{-1}(\frac{1}{2} - \lambda)$ times "swap $c_j \leftrightarrow c_k$" for $m \in \{j, k\}$ and 0 otherwise — the d-term contributes $4 \cdot \frac{1}{8} = \frac{1}{2}$ and the lattice terms contribute $-\lambda$ via the latL computation. Matching both sides on each basis vector in the three cases (block $\in \{j, k\}$ with $\langle\gamma_+, n\rangle = \mp 2$, block elsewhere where both sides are 0 because $\lambda = \frac{1}{2}$) gives exactly `hrule`. □

What the machine verified

Conditional on `hev`, `heig`, `hrule`; `SigmaTop2Root.lean`. Discharged for $\tau_\star$ below.

41.13 The explicit candidate $\tau_\star$

The transport rules determine the scalar $c(n)$ in $\tau(n) = c(n)e_n t$ along root moves. Solving them by hand (the root move γ_+ flips $\mathrm{sign}(n_{j(n)})$, γ_- keeps it; octad moves multiply by the χz_0-sign) leads to:

Definition 41.42 ($\tau_\star$). For $n \in \Lambda$ let $\mathrm{sgnBlk}(n) = n_{j(n)}/3$ and $c_\star(n) = i^{n_0}\,\mathrm{sgnBlk}(n)$ (an integer power of i; n_0 may be negative). Let $c_E(n) = \frac{1}{2}(c_\star(n) + c_\star(-n))$ and $\tau_\star(n) = c_E(n)\,e_n t$.

File `VOA/Moonshine/SigmaTop2Main.lean`.

```
noncomputable def sgnBlk (n : leech.carrier) : ℂ := ((lv n (blk n) : ℤ) : ℂ) / 3

noncomputable def cStar (n : leech.carrier) : ℂ := Complex.I ^ (lv n 0) * sgnBlk n

noncomputable def cE (n : leech.carrier) : ℂ := (cStar n + cStar (-n)) / 2

noncomputable def tauStar (t : TLeechT) (n : leech.carrier) : TLeechT := cE n • eL n t
```

From the mathematics to the Lean statement

On odd norm-four vectors $\mathrm{sgnBlk}(n) = \pm 1$ (Lemma 41.9), and $c_E = c_\star$ there (`cE_eq`): $c_\star(-n) = i^{-n_0}(-\mathrm{sgnBlk}\, n) = c_\star(n)$ because n_0 is odd and $i^{-n_0} = -i^{n_0}$. The symmetrisation c_E only serves to make $\tau_\star$ *literally* even on all of Λ (`tauStar_neg`), as required by `hev`. So on the relevant vectors this is the formula of the introduction, $\tau_\star(n) = i^{n_0}\,\mathrm{sign}(n_{j(n)})e_n t$.

Physical meaning

The explicit choice $\tau_\star$ is the candidate assignment of a twist state to each momentum: a phase i^{n_0} times the sign of the large coordinate, acting on the seed by e_n, symmetrised in $n \mapsto -n$. It is the physical image of the ground state of momentum n, the seed translated by the Clifford operator e_n with a specific phase. The choice is a trial that is verified by the intertwining theorems.

Theorem 41.43 (transport rules for $\tau_\star$). *If t is a seed, $\tau_\star$ satisfies the transport rules of Theorem 41.41 for γ_+ and γ_-, for all $j \neq k$.*

```
theorem tauStar_ruleP {t : TLeechT} (ht : IsSeed t) {j k : Fin 24} (hjk : j ≠ k) (n :
↪  leech.carrier)
    (hn0 : n ∉ lambda0) (h4 : leech.form n n = 4) (hf : leech.form (gP j k) n = -2) :
    εΛ (gP j k) n • tauStar t (gP j k + n) = (2 * kP j k)⁻¹ • tauStar t n

theorem tauStar_ruleM {t : TLeechT} (ht : IsSeed t) {j k : Fin 24} (hjk : j ≠ k) (n :
↪  leech.carrier)
    (hn0 : n ∉ lambda0) (h4 : leech.form n n = 4) (hf : leech.form (gM j k) n = -2) :
    εΛ (gM j k) n • tauStar t (gM j k + n) = (2 * kM j k)⁻¹ • tauStar t n
```

Physical meaning

The explicit candidate $\tau_\star$ satisfies the required transport rules for the root letters: the phase i^{n_0} sgnBlk is exactly the factor that makes translation covariance work. Physically this is the check that the candidate is compatible with the momentum-conservation rules of the vertex operators in the root sector.

Proof. Since $\langle \gamma_+, n\rangle = -2$ is even, $e_{\gamma_+ + n} = \varepsilon(\gamma_+, n)^{-1} e_n e_{\gamma_+}$, and on the seed $e_{\gamma_+} t = -(2\kappa_+)^{-1} t$. So the rule reduces to $c_E(\gamma_+ + n) = -c_E(n)$. The 0-th coordinate of γ_+ is divisible by 4 (it is 0, 4 or 8), so i^{n_0} is unchanged; and $\{n_j, n_k\} = \{-3, -1\}$ becomes $\{+1, +3\}$ or the reverse, so the ± 3 entry changes sign: sgnBlk flips. For γ_-: $n_j - n_k = -4$, so $(n_j, n_k) \in \{(-3, 1), (-1, 3)\}$ becomes $(1, -3)$ resp. $(3, -1)$; the sign of the ± 3 entry is preserved, and $e_{\gamma_-} t = +(2\kappa_-)^{-1} t$; consistent. □

What the machine verified

Unconditional given the seed; `SigmaTop2Main.lean`.

Theorem 41.44 ((R-top) on V_3^+ reduced to the octad letters). *For a nonzero seed $t \in T_s$, if every octad-type letter intertwines for $\varphi_{\tau_\star}$, then* `TopSigmaV3 (s+1)` $\varphi_{\tau_\star}$.

```

theorem topSigmaV3_of_octad {s : ZMod 2} {t : TLeechT} (hts : t ∈ leechFrameT s) (ht0 : t ≠
↪  0)
    (ht : IsSeed t) (hoct : OctadV3 (tauStar t)) :
```

```
    TopSigmaV3 (s + 1) (phiV3 (tauStar t))

def OctadResidualV3 : Prop :=
  ∀ (s : ZMod 2) (t : TLeechT), t ∈ leechFrameT s → t ≠ 0 → IsSeed t → OctadV3 (tauStar t)
```

From the mathematics to the Lean statement

`OctadV3 τ`: every letter u_γ, $\gamma \in S_0$, *not* of root type, intertwines. (Which these are is identified in Theorem 41.47; the definition avoids needing that classification by just excluding the root type.) `hits_cyclic` for $\varphi_{\tau_\star}$ uses the nonzero block constants $c_E(n_j)/\mu_j$, which is why `tauStar` need not literally equal `tauOf mu`.

Physical meaning

The only remaining charge conditions are those for the vertex operators of octad shape, namely the $(\pm 2)^8$ momenta supported on Golay octads. Once these also match charges, the candidate $\varphi_{\tau_\star}$ is a genuine intertwiner on the top level. This is a reduction, conditional on the octad letters, and points at the Golay-code part as the hard core of the construction.

Proof. Assemble: Zhu generation (`zhuGenerated_G2`), diagonal letters (any τ), off-diagonal letters (eigen-conditions from the seed, Theorem 41.27), root letters (Theorems 41.41 and 41.43), octad letters (hypothesis). □

What the machine verified

Conditional on `hoct`; `SigmaTop2Main.lean`.

41.14 The octad letters on V_3^+; classification; σ on V_3^+

41.14.1 The octad vectors

Let D be an octad (a Golay codeword of weight 8) and $S \subseteq D$ with $|S|$ even. In A-coordinates put $b_D = 1_D$ (`bAD hDA`), $\delta_S = 2 \cdot 1_S$ (`dSA S`), and

$$a_S = 1_D - 2 \cdot 1_S \in A \qquad (\texttt{aSA hDA S}),$$

the vector with entries $+1$ on $D \setminus S$, -1 on S, 0 off D (it lies in A: mod 2 it is the octad, and its coordinate sum $8 - 2|S|$ is divisible by 4 because $|S|$ is even). In Leech coordinates $\gamma_S = \iota_\Lambda a_S$ has entries ± 2 on D: the "octad type" norm-four vectors $(\pm 2^8, 0^{16})$ of Λ_0. In N, a_S is the spinor vector $1_D - \delta_S$ of the cube of §41.10. File `VOA/Moonshine/SigmaTop2Octad.lean`.

```
def bAD : lam0.carrier := (⟨ind D, hDA⟩ : ₁Leech.subA)

noncomputable def dSA (S : Finset (Fin 24)) : lam0.carrier :=
  if h : Even S.card then (⟨(2 : ℤ) • ind S, two_ind_mem S h⟩ : ₁Leech.subA) else 0

noncomputable def aSA (S : Finset (Fin 24)) : lam0.carrier := bAD hDA - dSA S
```

From the mathematics to the Lean statement

`hDA : ind D ∈ Leech.subA` is the hypothesis that $1_D \in A$, i.e. D is a codeword with $4 \mid |D|$; together with `hD8 : D.card = 8` it says D is an octad. `dSA` has a junk value 0 for odd $|S|$, never used (all statements assume `Even S.card`).

41.14.2 σ on the cube is a Hadamard transform

Theorem 41.45 (golaySigma_bp, sig_lV_aSA). *With $r = 1/\sqrt{2}$: $\sigma(b_T) = c_D \sum_{S\subseteq D} r^{|D|}(-1)^{|T\cap S|} b_S$ for $T \subseteq D$. Consequently, for an octad D and even $S \subseteq D$,*

$$\sigma(u_{\gamma_S}) = \sum_{S'\subseteq D,\ |S'|\ \text{even}} K(S,S')\, e^{\gamma_{S'}}$$

with explicit symbolic coefficients $K(S,S') = 2c_D r^8 X_S (-1)^{|S\cap S'|}\nu(S')t_c(a_{S'})$ (KS); in particular only even *S' occur.*

```

          KS hDA S S' • latChargeGen leech (inclΛ (aSA hDA S')) := by
```

From the mathematics to the Lean statement

rH $= \sqrt{2}/2 = r$. D.powerset.filter (… Even S'.card) is the set of even subsets of D. sig_lV_aSA carries the section hypotheses hDA, hD8. (The trailing := by belongs to the source line and is not part of the statement.)

Physical meaning

On the Golay frame, σ acts on the basis states indexed by subsets of an octad by the Hadamard matrix with entries $(-1)^{|T\cap S|}$ divided by $2^{|D|/2}$: a discrete Fourier transform over $\mathbb{F}_2^8$. This is a Fourier duality, in the spirit of T-duality, exchanging the two kinds of labels, the momentum-like subsets and the twist-like subsets. It gives the octad lattice letters u_{γ_S} an explicit image as a sum over even subsets with symbolic coefficients.

Proof. By Theorem 41.31, σ acts on each doublet by $h = g\chi g^{-1}$, and a 2×2 computation gives $h = r\left(\begin{smallmatrix}1 & 1\\ 1 & -1\end{smallmatrix}\right)$, the Hadamard matrix: so $\sigma b_T = c_D \bigotimes_i h$(basis vector), which expands to the stated sum. The letter u_{γ_S} is the image under the bridge of $y_S = t_c(a_S)^{-1}e^{a_S} + t_c(-a_S)^{-1}e^{-a_S} \in V_N^{\langle\chi,\Theta\rangle}$ (golayToV0_yA), and $e^{\pm a_S}$ are cube states ($-a_S$ corresponds to $D\setminus S$). So $\sigma(y_S)$ is a sum over all $S'\subseteq D$. The odd-$|S'|$ coefficients vanish *without computation*: $\sigma(y_S)$ lies in $V_N^{\langle\chi,\Theta\rangle}$, which contains only states e^x with $x\in A$, i.e. $\sum x_i \equiv 0 \pmod 4$, whereas $1_D - \delta_{S'}$ has coordinate sum $8-2|S'| \equiv 2 \pmod 4$ for $|S'|$ odd. The same parity argument forces the coefficients X_S, Y_S of b_S and $b_{D\setminus S}$ in y_S to be equal (XS_eq_YS), which simplifies the even coefficients. Transport back along the bridge. □

What the machine verified

Unconditional; SigmaTop2Octad.lean.

41.14.3 The octad identity

Theorem 41.46 (octad letters intertwine). *Let t be a seed, D an octad and $S\subseteq D$ even. Then u_{γ_S} intertwines for $\varphi_{\tau_\star}$: $\varphi_{\tau_\star}(o(u_{\gamma_S})x) = o(\sigma u_{\gamma_S})\varphi_{\tau_\star}(x)$ for all $x \in (V_3^+)_2$.*

```
theorem phiV3_ZM_aSA {t : TLeechT} (ht : IsSeed t) {S : Finset (Fin 24)} (h : _root_.Even
↪  S.card)
    (hS : S ⊆ D) : ZM (phiV3 (tauStar t)) OmegaV3 (lV (inclΛ (aSA hDA S)) (inclΛ_mem _))
```

From the mathematics to the Lean statement

Section hypotheses: `hDA : ind D ∈ Leech.subA`, `hD8 : D.card = 8`. Explicit: t is a seed, $|S|$ even, $S \subseteq D$. Note that no hypothesis "$t \in T_s$" or "$t \neq 0$" is needed here.

Physical meaning

The octad-type vertex operators intertwine for $\varphi_{\tau_\star}$: the Hadamard transform of the source side matches the Clifford-type action on the seed, so the charges agree. Physically this is the heart of the construction: the Fourier transform over each octad exchanges the momentum label with the twist label consistently. It completes the verification of charge matching for the top-level map.

Proof. Fix a basis vector x_n, $b = j(n)$, and write $p_i = \pm n_i$ with the sign $-$ on S, so $4\langle \gamma_S, n\rangle = \sum_{i\in D} p_i$.

Source. $\mathrm{o}(u_{\gamma_S})x_n \neq 0$ only if $\sum_D p_i = \mp 8$. If $b \notin D$, all $p_i = \pm 1$ and this means all eight p_i equal; if $b \in D$, $p_b = \pm 3$ and exactly one other $l_0 \in D$ has the opposite sign — the move $n \mapsto n \pm \gamma_S$ then carries the block from b to l_0.

Target. By Theorem 41.45 and Proposition 41.11(c), $\mathrm{o}(\sigma u_{\gamma_S})(h_{c_b}\otimes\tau_\star(n)) = 2^{-4}\sum_{S'} K(S,S')\, h_{\mathrm{latL}_{\gamma_{S'}}c_b}\otimes e_{\gamma_{S'}}\tau_\star(n)$. Two facts make the sum computable: (i) $\mathrm{latL}_{\gamma_{S'}}(c_b) = c_b - [b \in D]\sum_{l\in D} s'_b s'_l c_l$ with $s'_i = \pm 1$ the signs of $\gamma_{S'}$ (`latL_cw`); (ii) on the seed, $e_{\gamma_{S'}}e_n t = (-1)^{\langle \gamma_{S'}, n\rangle} e_n e_{\gamma_{S'}} t$ and $e_{\gamma_{S'}}t$ is, by ξ-closure ($\delta_{S'} \in \mathrm{Ch}(t)$), a known multiple of $W(b_D)t$ (`Wop_aSA_seed`). Each term becomes $C_0 \prod_{i\in S'} \zeta_i \cdot e_n W(b_D)t$ with explicit ± 1-valued ζ_i depending on n_i and $[i \in S]$ (`term_eval`). The sum over even S' of $\prod_{S'} f_i$ for a ± 1-pattern f is

$$\sum_{S'\subseteq D \text{ even}} \prod_{i\in S'} f_i = \tfrac{1}{2}\Big(\prod_D (1+f_i) + \prod_D (1-f_i)\Big) = 2^{|D|-1}\big([f \equiv 1] + [f \equiv -1]\big)$$

(`sum_even_pm`). So the target is nonzero exactly when the pattern ζ (or $\zeta\eta$, for the l-components) is constant — the same condition as on the source. In the block-outside case the surviving term reproduces $x_{n\pm\gamma_S}$'s image with the coefficient matching $c_E(n \pm \gamma_S) = c_D \cdot (\dots) c_E(n)$, where c_D (the χz_0-sign) is exactly the factor by which i^{n_0} changes when n_0 changes by $\pm 2 \cdot [0 \in D]$ (`cE_aSA_add`). In the block-inside case the l-sum picks out $l = l_0$, moving the oscillator to the new block. In both cases the remaining scalar identity is $2^{-4} \cdot 2c_D r^8 X_S \cdots = \dots$, with $r^8 = \frac{1}{16}$. □

41.14.4 Classification of S_0 and the theorem on V_3^+

Theorem 41.47 (`classify_S0`). *Every $\gamma \in S_0$ (norm 4, in Λ_0) is either $\pm\gamma_+(j,k)$ or $\pm\gamma_-(j,k)$ for some $j \neq k$ (shape $(\pm 4, \pm 4, 0^{22})$), or $\gamma = \gamma_S$ for an octad D and an even $S \subseteq D$ (shape $(\pm 2^8, 0^{16})$).*

```
theorem classify_S0 {γ : leech.carrier} (hγ : γ ∈ halfFourChi 0) :
    (∃ j k : Fin 24, j ≠ k ∧ (γ = gP j k ∨ γ = -gP j k ∨ γ = gM j k ∨ γ = -gM j k)) ∨
    (∃ (D : Finset (Fin 24)) (hDA : ind D ∈ Leech.subA), D.card = 8 ∧
      ∃ S : Finset (Fin 24), _root_.Even S.card ∧ S ⊆ D ∧ γ = inclΛ (aSA hDA S))
```

From the mathematics to the Lean statement

The second disjunct quantifies over a codeword D (`ind D ∈ Leech.subA`) of size 8 — an octad — and an even subset S. The statement is a disjunction, not a partition (the two cases are in fact disjoint, but that is not claimed). Same as the textbook statement.

Physical meaning

Every norm-four vector in the even part of the Leech lattice has one of two shapes, $(\pm 4, \pm 4, 0^{22})$ or $(\pm 2^8, 0^{16})$ on an octad. Physically this is the classification of the lowest vertex operators of the lattice by their momentum, which makes the check above exhaustive: no other type of lattice field has to be matched. It is a combinatorial fact about the Leech lattice, not a physical assumption.

Proof. Write $\gamma = 2a$, $a \in A$, $a \cdot a = 8$. Each $|a_i| \le 2$. With $O = \{i : |a_i| = 1\}$ and $F = \{i : |a_i| = 2\}$, $|O| + 4|F| = 8$. Since a mod 2 is a codeword with support O, and the Golay code has minimum weight 8, either $O = \varnothing$ (so $|F| = 2$: shape $(\pm 2, \pm 2, 0^{22})$ in A, i.e. $\pm\gamma_\pm$) or $|O| = 8$, $F = \varnothing$ (shape $(\pm 1^8)$ on an octad $D = O$, with S the set of -1 entries; $4 \mid \sum a_i = 8 - 2|S|$ forces $|S|$ even). The shape $(\pm 2, \pm 1^4)$ is excluded because no codeword has weight 4. □

What the machine verified

Unconditional; `SigmaTop2Class.lean`. Counting check (not a Lean statement): $4\binom{24}{2} + 759 \cdot 2^7 = 1104 + 97152 = 98256 = 2 \cdot 49128 = 2|S_0|$.

Theorem 41.48 (σ on V_3^+). *(a) There are s and φ with* `TopSigmaV3 s φ`.

(b) There are s and a σ-twisted intertwiner $\Phi : V_3^+ \to T_s^+$ of V_0^+-modules (`IsSigmaV3T Φ`) whose image contains a cyclic vector $x_0^T(t_0)$, $0 \ne t_0 \in T_s$.

```
theorem octadResidualV3 : OctadResidualV3

theorem topSigmaV3 : ∃ s φ, TopSigmaV3 s φ := topSigmaV3_exists octadResidualV3

theorem sigmaV3T_exists :
    ∃ (s : ZMod 2) (Φ : VPlus →ₗ[ℂ] TP), IsSigmaV3T Φ ∧
      ∃ t₀ : TLeechT, t₀ ∈ leechFrameT s ∧ t₀ ≠ 0 ∧ ∃ x ∈ OmegaV3, Φ x = x0T t₀ :=
  sigmaV3T_exists_of_octad octadResidualV3
```

From the mathematics to the Lean statement

No hypotheses. `IsSigmaV3T Φ` is the full intertwining property for all $u \in V_0^+$ and all modes $n \in \mathbb{Z}$, on all of V_3^+ (not just the top level). **Why it is not vacuous:** $\Phi = 0$ would satisfy `IsSigmaV3T`; the extra clause "$\Phi x = x_0^T(t_0)$ with $t_0 \ne 0$" rules it out. Also, `IsSigmaV3T` does not by itself say Φ maps V_3^+ into T_s^+; that follows from the cyclic-vector argument of Chapter 40 and is what `SigmaData` (Chapter 42) packages. **Compared with FLM:** FLM's σ is an isomorphism $V_3^+ \to V_0^+$; the Lean statement gives a nonzero intertwiner into the module generated by a cyclic vector, and bijectivity is proved downstream (Chapter 42, `Φ0_inj`, `Φ0_surj`). The one-line proof terms are shown because they are informative.

Physical meaning

There is a nonzero operator from the untwisted top level to a twisted sector, satisfying charge matching for every light field, i.e. an intertwiner twisted by σ, whose image contains a cyclic vector. This is the explicit existence of the triality operator on the lowest-energy states: the

twist-field space acts as the spinor on which triality is realised, and the matching of all zero modes is exactly the Ward identity of the symmetry. The cyclic vector shows it is nonzero and hence a genuine symmetry rather than the zero map.

Proof. `octadResidualV3`: a non-root letter of S_0 is of octad type by Theorem 41.47, so Theorem 41.46 applies. Then Theorem 41.44 with the seed of Theorem 41.37 gives (a), and `sigmaV3T_exists_of_top` (Chapter 40) gives (b). □

What the machine verified

Unconditional. `SigmaTop2Class.lean`. `##print axioms of topSigmaV3, sigmaV3T_exists`: [`propext`, `Classical.choice`, `Quot.sound`] — no `VOA.pbw` (re-checked, §41.18).

41.15 The twisted source: σ on T_s^+

41.15.1 $A_- = -A_+$ on the seed's sector

Lemma 41.49 (`AM_eq_neg_AP`). *Let $t \in T_s$ be a nonzero seed. Then $A_-(j,k)x = -A_+(j,k)x$ for every $x \in T_s$ and $j \neq k$.*

File `VOA/Moonshine/SigmaTop2TT.lean`.

```
theorem AM_eq_neg_AP {s : ZMod 2} {t : TLeechT} (hts : t ∈ leechFrameT s) (ht0 : t ≠ 0) (ht
 ↪  : IsSeed t)
    {j k : Fin 24} (hjk : j ≠ k) {x : TLeechT} (hx : x ∈ leechFrameT s) : AM j k x = -AP j
     ↪  k x
```

Physical meaning

On the twisted sector, once a nonzero seed exists, the two eigenvalue operators $A_\pm$ are opposite on the whole sector: the sector decomposes by a single sign. Physically this is a statement that the two commuting reflection-like charges are not independent, which reduces the number of conditions to check on twisted ground states.

Proof. $\gamma_+ + \gamma_- = w_j$ and $w_j \equiv w_0 \pmod{2\Lambda}$, so $e_{\gamma_+} e_{\gamma_-}$ is a scalar multiple of e_{w_0}, which acts on T_s by the frame scalar. Hence A_+A_- is a scalar c on T_s; on the seed, $A_+A_-t = -\frac{1}{4}t$, so $c = -\frac{1}{4}$ $(t \neq 0)$. With $A_+^2 = \frac{1}{4}$: $A_- = 4A_+(A_+A_-) = -A_+$ on T_s. □

So on T_s the vanishing condition $(A_+ + A_-)\psi_m = 0$ of Theorem 41.29 is automatic for any ψ_m with values in T_s. What is left is the choice of $B = \psi_0$.

41.15.2 The operator B

The Z_{0k} $(k \neq 0)$ are commuting involutions on T_s (`ZZ_mul_self`, and they commute because the γ_-'s have coordinates divisible by 4). Let $\omega = e^{i\pi/4} = (1+i)/\sqrt{2}$, $a = \frac{1+\omega}{2}$, $b = \frac{1-\omega}{2}$, so that $a + bu$ is 1 for $u = 1$ and ω for $u = -1$.

Definition 41.50 (`Bop`). $B_s = \left(\prod_{k\neq 0}(a + bZ_{0k})\right) \circ \pi_s$, with $\pi_s = \frac{1}{2}(1 + (-1)^s J)$ the projector onto T_s. On a joint eigenvector z of the Z_{0k} with eigenvalues u_k, $B_s z = \omega^{\#\{k : u_k = -1\}} z$.

↪  s • frameJL)
```

From the mathematics to the Lean statement

`rH` $= \sqrt{2}/2$, so `ωB` $= (1+i)/\sqrt{2} = e^{i\pi/4}$ (`ωB_sq : ωB ^ 2 = Complex.I`). The product over `List.finRange 24` is an ordered product, but the factors commute so the order is irrelevant. Only the factors $k \neq 0$ are nontrivial. The choice of B is *not* forced by the root letters; it is forced by the octad letters (§41.15.3) — this phase ω per flipped coordinate is the twisted-sector shadow of the factor i^{n_0} in $\tau_\star$.

Physical meaning

The operator B_s is a product of projectors that maps the twist space to the sector T_s while multiplying a joint eigenvector by a phase depending on how many of its signs are negative. Heuristically it is the twisted-to-twisted piece of the triality operator, a function of the discrete charges of the twist field; its eigenvalue phase $\omega^{\#}$ is the discrete Fourier-dual dependence on the twist label.

Proposition 41.51 (properties of B). *B_s maps into T_s; it commutes with every e_γ, $\gamma \in \Lambda_0$ with all coordinates divisible by 4; and it fixes every seed in T_s (on a seed, $Z_{0k}t = t$ for all k).*

File `VOA/Moonshine/SigmaTop2TT.lean`.

```
theorem Bop_mem (s : ZMod 2) (x : TLeechT) : Bop s x ∈ leechFrameT s

↪  (s : ZMod 2) :
    Commute (eL γ) (Bop s)
```

Physical meaning

B_s lands in the correct sector, commutes with the lattice-translation operators with 4-divisible coordinates, and fixes every seed. These are the properties of a symmetry operator on the twist space: it respects the sector, commutes with the relevant translation charges, and acts as the identity on the reference ground state; the last property also guarantees it is nonzero.

Proof. $Z_{0k} = 2A_(0,k)$ acts on a seed by $2 \cdot \frac{1}{2} = 1$, so each factor acts by $a + b = 1$. The rest is commutation of e-operators with even pairings. □

Theorem 41.52 (root letters on T_s^+). *For a nonzero seed $t \in T_s$, with $\psi = \psi(B_s)$ (Theorem 41.29), the letters $u_{\gamma_\pm(j,k)}$ intertwine for φ_ψ on $(T_s^+)_2$; and `TopSigmaTT s s` φ_ψ holds provided all lattice letters intertwine.*

    ↪  (lV' γ)) :
    TopSigmaTT s s (phiTT (psiOf (Bop s)))
```

From the mathematics to the Lean statement

Note the sectors: the source is T_s^+ and the target is T_s^+ for the *same* s as the seed, whereas V_3^+ went to T_{s+1}^+. This is the FLM pattern $\sigma\colon V_3^+ \to T_0^+$, $T_3^+ \to T_3^+$: the seed's sector is "T_3", the other one "T_0". (`phiTT_ZMT_gM` is the γ_- analogue.)

Physical meaning

The root-type vertex operators intertwine on the twisted-twisted top level when the operator B_s is built from a nonzero seed, so σ on the twisted sector is determined up to the remaining lattice letters. Physically the root fields matching charges is the twisted-sector analogue of the untwisted check, with the seed again serving as the image of the reference ground state.

Proof. As on V_3^+, using Theorem 41.40; on T_s, the sum $A_+ + A_- = 0$ makes the latL contributions cancel against the d-term in the right way, and the block links are `ZZ_comp`. □

What the machine verified

`phiTT_ZMT_gP`: unconditional; `topSigmaTT_of_seedB`: conditional on `hlat`; `SigmaTop2TT.lean`.

41.15.3 The octad letters on T_s^+

Here the structure of T_s under the abelian group generated by the Z_{0k} enters.

Definition 41.53 (joint eigenvectors). For $N \subseteq \{1, \dots, 23\}$ let $u_N(k) = -1$ if $k \in N$, $+1$ otherwise. z is a *joint eigenvector with character* N if $Z_{0k} z = u_N(k) z$ for all $k \neq 0$. Put $\beta(N) = \omega^{|N|}$.

File `VOA/Moonshine/SigmaTop2TTOct.lean`.

```
noncomputable def uN (N : Finset (Fin 24)) (k : Fin 24) : ℂ := if k ∈ N then -1 else 1

def IsEigN (N : Finset (Fin 24)) (z : TLeechT) : Prop := ∀ k, k ≠ 0 → ZZ 0 k z = uN N k • z

noncomputable def betaN (N : Finset (Fin 24)) : ℂ := ∏ i, if i ∈ N then ωB else 1

theorem eig_induct {s : ZMod 2} (P : TLeechT → Prop) (hadd : ∀ x y, P x → P y → P (x + y))
    (heig : ∀ z ∈ leechFrameT s, ∀ N : Finset (Fin 24), (0 : Fin 24) ∉ N → IsEigN N z → P
    ↪  z) :
    ∀ z ∈ leechFrameT s, P z
```

From the mathematics to the Lean statement

`eig_induct` is the spectral decomposition in induction form: an additive property holding on all joint eigenvectors in T_s holds on T_s (because the commuting involutions Z_{0k} are simultaneously diagonalisable). Hypothesis `(0 : Fin 24) ∉ N` is a normalisation ($k = 0$ is not among the operators). Then $B_s z = \beta(N) z$ and $\psi_m z = u_N(m)\beta(N) z$ (`Bop_eigN`, `psiOf_eigN`).

Physical meaning

A joint eigenvector with character N is a twist state whose reflection-like charges Z_{0k} have signs given by the subset N of frame directions, with phase $\omega^{|N|}$. These are the basis states of the twist space labelled by the discrete charges, the analogue of a computational basis for the spinor, in which the Hadamard transform will act.

Proposition 41.54 (how e_{γ_S} moves characters; twisted ξ-closure). *(a) If z has character N, then $e_{\gamma_S} z$ has character $\mathrm{flip}_D(N)$: u_k is flipped exactly for those k with $[k \in D] \neq [0 \in D]$.*

(b) For z with character N, the set $\mathrm{Ch}_N(z) = \{a : \iota_N a = \phi_R x,\ W(a)z = \xi(x)\chi_N(x)z\}$, $\chi_N(x) = (-1)^{\sum_{i\in N} x_i}$, is a subgroup.

File `VOA/Moonshine/SigmaTop2TTOct.lean`.

```

↪  where
  carrier := {a | ∃ x, inclN a = phiR x ∧ Wop a z = xiN N x • z}
  zero_mem' := ⟨0, by rw [map_zero, map_zero], by rw [Wop_zero, xiN_zero, one_smul]; rfl⟩
```

From the mathematics to the Lean statement

`flipN D N` written out: $k \neq 0$, and $k \in \mathrm{flip}_D(N) \iff (k \in N \iff (k \in D \iff 0 \in D))$; i.e. membership is kept when $[k \in D] = [0 \in D]$ and toggled otherwise. (a) is proved by $\langle \gamma_-(0,k), \gamma_S\rangle$ parity. For `chargesU` only the carrier and the zero field are quoted, as for `chargesS`. $\xi_N = \xi\chi_N$ still satisfies $\xi_N(x)\xi_N(y) = \varepsilon_N \xi_N(x+y)$ (`xiN_mul`), so the subgroup property holds for the same reason.

Physical meaning

Acting with the octad vertex operator on a state of character N flips the signs exactly on the positions inside the octad that differ from the base point, a bit-flip action on the labels of the basis. Physically this is the statement that the vertex operator of the octad shifts the discrete twist charge, so it is the analogue of a Pauli operator on the spinor. It also shows the set of charges is closed under this action.

Theorem 41.55 (Golay constraint). *Let $z \neq 0$ have character N and suppose $\delta_{S'} \in \mathrm{Ch}_N(z)$ for all even S'. Then $\prod_{i\in D'} u_N(i) = 1$ for every codeword D' (with $1_{D'} \in A$). Consequently (1_N is orthogonal mod 2 to every codeword, hence a codeword) $4 \mid |N|$.*

```
theorem golay_constraint {z : TLeechT} (hz0 : z ≠ 0) {N : Finset (Fin 24)}
    (hd : ∀ S' : Finset (Fin 24), _root_.Even S'.card → dSA S' ∈ chargesU z N)
    {D' : Finset (Fin 24)} (hD' : ind D' ∈ Leech.subA) : ∏ i ∈ D', uN N i = 1

theorem four_dvd_card_of_orth {N : Finset (Fin 24)}
    (h : ∀ D' : Finset (Fin 24), ind D' ∈ Leech.subA → ∏ i ∈ D', uN N i = 1) : 4 ∣ N.card
```

From the mathematics to the Lean statement

`ind D' ∈ Leech.subA` means D' is a Golay codeword (all codewords have $4 \mid |D'|$, so every codeword qualifies). In `four_dvd_card_of_orth`, N is an arbitrary subset; the hypothesis is "$|N \cap D'|$ is even for every codeword D'". Both are the textbook statements. The hypothesis `hd` is supplied on joint eigenvectors of the seed's sector by `dSA_mem_chargesU` (from $a_+(0,0)$, where W is the frame scalar read off at the seed, and $a_-(0,k)$, where W is Z_{0k} up to ξ).

Physical meaning

If a nonzero twist state is stabilised by all even octad charges, then its sign pattern N must be orthogonal to the Golay code and so is itself a codeword, with $4 \mid |N|$. This is a code-theoretic selection rule: the allowed discrete twist charges are dual to the Golay code, a Fourier-dual constraint relating the twist labels to the momentum lattice. It is a rigorous constraint, not a heuristic, and it is what makes the Hadamard sums below collapse.

Proof. For a codeword D', $2b_{D'} = \delta_{D'}$ and $W(2b_{D'}) = \xi(1_{D'})$ is a scalar (Proposition 41.35(b)). Membership in $\mathrm{Ch}_N(z)$ says $W(\delta_{D'})z = \xi(1_{D'})\chi_N(1_{D'})z$. As $z \neq 0$, $\chi_N(1_{D'}) = 1$, i.e. $\prod_{D'} u_N = (-1)^{|N\cap D'|} = 1$. For the consequence: 1_N mod 2 is orthogonal to the Golay code, which is self-dual, so 1_N is a codeword; Golay codewords have weight divisible by 4 (double evenness). □

What the machine verified

Unconditional; `SigmaTop2TTOct.lean`.

Lemma 41.56 (Hadamard sums with i). *Let $|D| = 8$ and $\epsilon : D \to \{\pm 1\}$ with $\prod_D \epsilon_i = 1$. Then $\sum_{S' \subseteq D \text{ even}} \prod_{i\in S'}(i\epsilon_i) = 16 \prod_{i\in D} g(\epsilon_i)$, where $g(1) = 1$, $g(-1) = i$.*

```
noncomputable def gI (e : ℂ) : ℂ := if e = 1 then 1 else Complex.I

theorem had_I (D : Finset (Fin 24)) (hD8 : D.card = 8) (ε : Fin 24 → ℂ)
    (hε : ∀ i ∈ D, ε i = 1 ∨ ε i = -1) (hp : ∏ i ∈ D, ε i = 1) :
    ∑ S' ∈ D.powerset.filter (fun S' : Finset (Fin 24) => _root_.Even S'.card),
        ∏ i ∈ S', (Complex.I * ε i) = 16 * ∏ i ∈ D, gI (ε i)
```

Physical meaning

A Hadamard-type sum over the even subsets of an octad with phases $i\epsilon_i$ evaluates to a product of single-site factors. This is the factorisation of a discrete Fourier transform over $\mathbb{F}_2^8$, the same factorisation that makes the cube action $h^{\otimes 8}$ a tensor product. It is a technical identity used to simplify the octad action on twist states.

Proof. The even sum is $\frac{1}{2}\big(\prod_D(1 + i\epsilon_i) + \prod_D(1 - i\epsilon_i)\big)$. If p coordinates have $\epsilon = -1$ (p even), $\prod(1 + i\epsilon) = (1 + i)^{8-p}(1 - i)^p = (1 + i)^8\big(\frac{1-i}{1+i}\big)^p = 16(-i)^p$ and $\prod(1 - i\epsilon) = 16\, i^p$; their average is $16\, i^p$ for p even ($(-i)^p = i^p$), and $\prod g(\epsilon_i) = i^p$. □

Lemma 41.57 (base identity). *Let $|D| = 8$, $S \subseteq D$, $0 \notin N$, $4 \mid |N|$ and $\prod_D u_N = 1$. Then*

$$i^{|S|}\Big(\prod_{i\in S} u_N(i)\Big)\beta(\mathrm{flip}_D N) = \beta(N) \prod_{i\in D} g\big(s_i u_N(i)\big), \qquad s_i = -1\ (i \in S),\ s_i = 1\ (i \notin S).$$

```
theorem base_identity {D S N : Finset (Fin 24)} (hD8 : D.card = 8) (hS : S ⊆ D)
    (hN0 : (0 : Fin 24) ∉ N) (hN4 : 4 ∣ N.card) (hND : ∏ i ∈ D, uN N i = 1) :
    (∏ _i ∈ S, Complex.I) * (∏ i ∈ S, uN N i) * betaN (flipN D N)
      = betaN N * ∏ i ∈ D, gI (sg S i * uN N i)
```

From the mathematics to the Lean statement

`sg S i` $= s_i$. The hypotheses $4 \mid |N|$ and $\prod_D u_N = 1$ are exactly the two outputs of the Golay constraint (Theorem 41.55); without them the identity is false in general, which is why the constraint is needed.

Physical meaning

This is the base identity showing that, for a joint eigenvector with Golay-constrained character, the phase produced by the octad operator agrees with the one produced by the Hadamard transform on the other side. It is the final charge-matching check for the octad letters on the twisted-twisted level; a technical lemma in the Hadamard/Golay computation.

Proof. Both sides are products of eighth roots of unity; compare them coordinate by coordinate. The ratio is a product of local correction factors ρ_i (`rhoF`) whose total product is $\omega^8 \prod_D u_N = 1$ when $0 \notin D$, or $\omega^{16}(-i)^{|N|} = 1$ when $0 \in D$ — the first case uses $\prod_D u_N = 1$, the second uses $4 \mid |N|$. □

Theorem 41.58 (octad letters on T_s^+; σ on T_s^+). *(a) For a nonzero seed $t \in T_s$, every octad letter u_{γ_S} intertwines for $\varphi_{\psi(B_S)}$ on $(T_s^+)_2$; first on joint eigenvectors (`octadTT_eig`), then on all of T_s by `eig_induct`.*

(b) There are s, φ with `TopSigmaTT s s φ`.

(c) There are s and a σ-twisted intertwiner $\Phi : T_s^+ \to T_s^+$ (`IsSigmaTT s Φ`) hitting a nonzero cyclic vector $x_0^T(t_0)$, $t_0 \in T_s$.

(d) For one and the same s: `TopSigmaV3 (s+1)` and `TopSigmaTT s s` both hold.

From the mathematics to the Lean statement

No hypotheses in (b)–(d); (a) carries the octad section hypotheses `hDA`, `hD8`. `IsSigmaTT s Φ`: $\Phi(u_{(n)}y) = (\sigma u)_{(n)}\Phi(y)$ for all $u \in V_0^+$, $n \in \mathbb{Z}$, $y \in T_s^+$. Non-vacuity as for V_3^+: the cyclic-vector clause excludes $\Phi = 0$. **Why (d) matters.** (b) and Theorem 41.48(a) separately each assert existence for *some* sector. For the assembly of σ on all of $V^\natural$ (Chapter 42, `SigmaData`) one needs $\sigma : V_3^+ \to T_{s+1}^+$ and $\sigma : T_s^+ \to T_s^+$ with the *same* s, i.e. the images of V_3^+ and of T_s^+ are the two different twisted summands. `topSigma_both` obtains both from a single seed and so guarantees the pattern. It is still stated with $\exists s$ (Remark 41.1).

Physical meaning

On the twisted top level the octad vertex operators also intertwine, first on joint eigenvectors using the Golay constraint and Hadamard sums, then on the whole 2^{12}-dimensional twist space by induction over the eigenbasis. Together with the root letters this gives a nonzero charge-matching operator on the twisted-to-twisted top level, hence the symmetry operator on

both pieces, which is combined in the final statement. Physically this completes the explicit construction of triality on the lowest-energy states of the twisted sectors as an operator that matches all light-field charges and is nonzero.

Proof. (a) On a joint eigenvector z with character N: the twisted ξ-closure gives $W(a_{S'})z = \varepsilon\,\xi_N(-1_{S'})W(b_D)z$, so each term of the Hadamard sum for $\mathrm{o}(\sigma u_{\gamma_S})$ is $C_1\prod_{S'}(i\,s_i u_N(i))\,W(b_D)z$; by Lemma 41.56 the sum is $16\,C_1\prod_D g(s_i u_N(i))$ (the hypothesis $\prod_D s_i u_N(i) = 1$ holds because $|S|$ is even and $\prod_D u_N = 1$). On the source side $\mathrm{o}(u_{\gamma_S})$ maps $h_{c_b}\otimes z$ to $2^{-3}h_{\mathrm{latL}\,c_b}\otimes e_{\gamma_S}z$, and φ_ψ multiplies by $u_{\mathrm{flip}N}(\cdot)\beta(\mathrm{flip}N)$ since $e_{\gamma_S}z$ has character $\mathrm{flip}_D N$. Equality of the two sides reduces, after the common factors, to the base identity (Lemma 41.57), whose hypotheses are supplied by the Golay constraint. (b) Combine (a), the root letters and Theorem 41.52 with `classify_S0`, for the seed of Theorem 41.37. (c) `sigmaTT_exists_of_top` (Chapter 40). (d) Use the same seed for Theorems 41.44 and (b). □

What the machine verified

Unconditional. `SigmaTop2TTOct.lean`. `##print axioms of topSigmaTT, sigmaTT_exists, topSigma_both`: [`propext`, `Classical.choice`, `Quot.sound`] (re-checked, §41.18). These are the results consumed by Chapter 42 (`SigmaAssemble.mkData`).

41.16 The numerical evidence that preceded the proof

Before any of the Lean work of this chapter was attempted, the existence of σ on the twisted sectors was tested numerically (`Notes/TrialityTwisted.md` §4; scripts in `scripts/moonshine/numerics/triality/`). This evidence is *not* part of the proof and is reported here only because it shaped the construction — and because it is honest to say what was known before the proof existed.

The model. A Python model of V_N, $N = N(A_1^{24})$, with an explicit basis cocycle $\varepsilon(a,b) = (-1)^{c(a)^{\mathsf{T}}Uc(b)}$ (U the strict upper triangle of a Gram matrix; Golay code from quadratic residues mod 23), the twisted vertex operator $Y^T(e^\gamma, z) = 2^{-\langle\gamma,\gamma\rangle}z^{-\langle\gamma,\gamma\rangle/2}E^-E^+\otimes e_\gamma$, and a T_N built as an induced module. All 196884 states of $(V_N)_2$ were constructed; the library's $\sigma = G(\chi z_0)G^{-1}$ was computed on the 1083 invariant blocks.

What was confirmed.

1. $\dim(V_0^+)_2 = 49428$ and $\mathrm{tr}(\sigma|(V_0^+)_2) = 2324$ (for the unmodified DGM (7.5) form $G\chi G^{-1}$ one gets 6372), reproducing the certificate of Chapter 39.
2. $\Theta e^\gamma = c_\gamma e^{-\gamma}$ with $c_\gamma = 1$ for all 98256 norm-four $\gamma\in\Lambda_0$ *in the model* — the numerical counterpart of the θ-invariance used in Proposition 41.23.
3. An explicit σ-twisted intertwiner $(V_3^c)_2 \to T(0,c)_2$ was built by breadth-first propagation from one seed along the monomial lattice letters; *every image vector had support* 2 in the $h_j\otimes t$ basis ("essentially monomial" — the origin of the block-monomial ansatz of Definition 41.14). 15000 identities $\Phi(\mathrm{o}(u)v) = \mathrm{o}(\sigma u)\Phi(v)$: maximal relative residual 4.2×10^{-15}; the wrong target sector: residual 2.0 (no intertwiner).
4. For DGM's unmodified (7.5) σ, the intertwiner goes to the *wrong* sector — an independent confirmation that the z_0-modification (7.8) is needed.
5. $T(1,+)\to T(1,+)$ on the full weight-two space: 3000 identities, residual 4.8×10^{-12} (the wrong sign: 2.0). This is the numerical form of $\sigma: T_3^+\to T_3^+$.

6. Block spectra (block $j = 5$, 33166 block-preserving letters): $V_3 \leftrightarrow T(0,\cdot)$ match to 2.5×10^{-14}, and $T(1,\cdot)$ is σ-stable (3.1×10^{-14}).

Caveats recorded at the time. Only zero modes of weight-two elements on weight-two spaces were tested; the model uses the cocycle of N, not the library's Leech cocycle; and the identification of the model's sectors with the library's T_s^+ used an unchecked normalisation step. The Lean theorems of this chapter have none of these caveats: they are about the library's own objects, and the reduction to weight two is the theorem of Chapter 40.

A related exact test. Notes/ZhuGeneratorTest.md (exact arithmetic, no floating point) showed that the weight-two zero modes generate all of End of both 49152-dimensional tops, so φ is unique up to a scalar once it exists; this justified looking for *one* explicit formula rather than a family.

41.17 Dead ends, traps and corrections

Trap / dead end: "Which T_s^+ is T_0^+" is not well posed

Do not try to prove $\sigma(V_3^+) = T_0^+$ (or T_1^+) from the library's definitions: the answer depends on the bit $g_e(w_0)$ hidden in `Classical.choose` (`golayE_not_determined`, Chapter 40). All results are stated with $\exists s$, and `topSigma_both` supplies the matching pair.

Trap / dead end: The partial theorems are not (R-top)

`topSigmaV3_partial`, `topSigmaTT_partial` (constant τ, ψ) satisfy only the frame, weight, cyclic-vector and 24 diagonal-letter clauses. A constant τ cannot satisfy the off-diagonal letters (Schur: the solution is unique up to scalar). They must not be cited as σ-existence.

Trap / dead end: Unknown constants: avoid evaluating them

The constants $\kappa_\pm$, $t_c(a)$, $g_e(a)$, and every value of ε_Λ are uncomputable in the library. An early plan ("R-top partial" status) considered a refactor to an explicit Golay-frame cocycle to compute them. This turned out unnecessary (§41.8); every needed fact is a consequence of θ-invariance, cocycle algebra, ξ and Golay-code facts.

Trap / dead end: The eigenvalue $\pm\frac{1}{2}$ was once an unproved assumption

`SigmaTopOffdiag.lean` states the off-diagonal identity as following from eigen-conditions and notes that necessity would need "$\kappa_\pm e_{\gamma_\pm}$ have eigenvalues $\pm\frac{1}{2}$ (not proved here)". This was later proved (Proposition 41.23); the file comment is historical.

Trap / dead end: Stale file headers

Several file headers of this chapter's files say "Not wired into the umbrella". Already when this chapter was first written, and still at a pre-release build commit, they *are* imported by the umbrella `VOA/Moonshine.lean` (which imports `SigmaTop2TTOct`) and are used by `VOA.Moonshine.moonshine`. The headers predate the wiring.

Trap / dead end: The choice of B on T_s^+ is forced by the octads

The root letters on T_s^+ are satisfied by $\psi_m = Z_{0m}B$ for *any* B into T_s sending some vector to a seed. A naive choice ($B = \pi_s$) fails the octad letters; the phase $\omega^{|N|}$ on the joint eigenspaces is what the base identity requires. The Golay constraint ($4 \mid |N|$, $\prod_D u_N = 1$) is used in an essential way: without it the base identity is false.

41.18 Referee's checklist

Machine check performed for this chapter. At an earlier commit (when the chapter was first written; not re-run for this edition), with the built library, the following file was compiled with `lake env lean -DmaxSynthPendingDepth=3` (the flag avoids the audit trap of Chapter 1):

```
import VOA.Moonshine.SigmaTop2TTOct
open VOA.Moonshine.SigmaTop
#print axioms topSigmaV3_partial
#print axioms topSigmaTT_partial
#print axioms topSigmaV3_of_eigen
#print axioms topSigmaTT_of_eigen
#print axioms sig_dV_fw
#print axioms zhuGenerated_G2
#print axioms golayTheta_codeword
#print axioms seedExists
#print axioms classify_S0
#print axioms topSigmaV3
#print axioms sigmaV3T_exists
#print axioms topSigmaTT
#print axioms sigmaTT_exists
#print axioms topSigma_both
#print axioms golay_constraint
#print axioms four_dvd_card_of_orth
#print axioms base_identity
#print axioms had_I
#print axioms colD_key
```

Every one of the 19 lines printed

```
'VOA.Moonshine.SigmaTop.<name>' depends on axioms: [propext, Classical.choice, Quot.sound]
```

In particular none uses `VOA.pbw` (the PBW theorem of Chapter 3; formerly a project axiom, now a theorem). (The aggregate `lake build` of that commit, 10343 jobs, is recorded in Chapter 43; it was not re-run for this chapter.)

What the referee should verify in particular. (1) That `TopSigmaV3`/`TopSigmaTT` contain the nontriviality clause `hits_cyclic` (they do), so that the headline theorems are not satisfied by $\varphi = 0$. (2) That `IsSigmaV3T`, `IsSigmaTT` quantify over *all* $u \in V_0^+$ and *all* modes $n \in \mathbb{Z}$ (`Set.univ`, `∀ n`). (3) That σ here is the library's `v0Sigma`, i.e. DGM's (7.8)-modified triality transported to V_0^+ (Chapter 39). (4) That the sector is existential and why (Remark 41.1).

Notes and references

The triality and its extension to the twisted sectors is the heart of the original construction: I. Frenkel, J. Lepowsky and A. Meurman, *Vertex Operator Algebras and the Monster*, Pure and Applied Mathematics 134, Academic Press, 1988, Chapters 11 ("Triality"), 12 and 13. FLM construct σ explicitly through the Golay code and rank-one $\hat{\mathfrak{sl}}_2$ isomorphisms between twisted and untwisted realisations; the book was not accessible to the project and its account was *not* checked against this chapter. The modern restatement used throughout is L. Dolan, P. Goddard and P. Montague, "Conformal field theories, representations and lattice constructions", Comm. Math. Phys. 179 (1996) 61–120, arXiv:hep-th/9410029, §§6–7: equations (7.1)–(7.8) define σ on V_N (the z_0-modified form (7.8) is the one in the library), and their Proposition 7.3 obtains the twisted extension *non-constructively* (via the uniqueness of the twisted module and a partition-function comparison). We have not compared the formula of this chapter for σ on twisted weight-two states with FLM's explicit construction (Chapter 11 of their book), which we could not consult.

The Golay code and Leech lattice facts used (minimum weight 8, self-duality, double evenness, the $(\pm 2^8, 0^{16})$ and $(\pm 4^2, 0^{22})$ shapes of norm-four vectors in Λ_0) are in J. H. Conway and N. J. A. Sloane, *Sphere Packings, Lattices and Groups*, 3rd ed., Grundlehren 290, Springer, 1999, Chapters 4 and 10. The Griess algebra and the 196884-dimensional weight-two space go back to R. L. Griess, "The friendly giant", Invent. Math. 69 (1982) 1–102; the extraspecial group and its 2^{12}-dimensional representation also appear there and in FLM Chapter 7. The modular-tensor-category picture of $V_\Lambda^{++} = V_0^+$ (16 irreducibles, the dihedral group of order 12 acting on them, the triality as an S_3) is in G. Höhn and M. Seysen, "The order of the Monster finite simple group", arXiv:2508.01037 (2025), §2.2 (the paper itself computes the order of the Monster), after H. Shimakura, "The automorphism group of the vertex operator algebra V_L^+ for an even lattice L without roots", J. Algebra 280 (2004) 29–57, and T. Abe, C. Dong and H. Li, "Fusion rules for the vertex operator algebras $M(1)^+$ and V_L^+", Comm. Math. Phys. 253 (2005) 171–219. Zhu's algebra and the top-level correspondence used in Chapter 40 are from Y. Zhu, "Modular invariance of characters of vertex operator algebras", J. Amer. Math. Soc. 9 (1996) 237–302. The stabiliser-state language of the remark in §41.11 is standard in quantum information (D. Gottesman, *Stabilizer Codes and Quantum Error Correction*, PhD thesis, Caltech, 1997, arXiv:quant-ph/9705052).

The project-internal record is `Notes/M8GluingPlan.md` (status sections "R-top partial" and "σ EXISTS on both twisted sectors"), `Notes/TrialityTwisted.md` and `Notes/ZhuGeneratorTest.md`.

Chapter 42

The key identity and the completion of the proof

This chapter documents the release of the library named in the front matter; every Lean quotation is checked by `scripts/textbook/sync.py` to occur verbatim (up to whitespace and comments) in the source files of that release. Checks that were run at an earlier state of the library and not re-run for this edition are marked as such. It is the last mathematical chapter of the Moonshine part of the book, and it is the one in which the construction of the Moonshine module is finished. When it ends, the reader will have seen every step of the proof of the Lean theorem

```
theorem moonshine :
    ∃ V : VertexOperatorAlgebra Vnat,
      V.Y = Ynat VnatAxioms.wbarL ∧ V.vacuum = vacNat ∧ V.conformalVector = omegaNat ∧
      V.centralCharge = 24 ∧
      V.grading 1 = ⊥ ∧
      Module.finrank ℂ (V.grading 2) = 196884 ∧
      (∀ n : ℕ, (Module.finrank ℂ (V.grading (n : ℤ)) : ℂ) = PowerSeries.coeff n JShift) ∧
      V.IsSimple
```

(`VOA/Moonshine/TopPairs.lean`, full name `VOA.Moonshine.moonshine`), which has *no hypotheses at all*, and whose `#print axioms` output is the three standard axioms of Lean's foundations, `propext`, `Classical.choice` and `Quot.sound`. The last section before the referee's checklist (§42.8) is a long, clause-by-clause fidelity check of this statement — the most careful one in the book, because it is the statement the whole library exists to prove. Everything before it explains, on paper, why it is true, and presents each intermediate statement with its own fidelity check.

The result in one sentence. In the wording recommended by the release audit of 2026-10-27 (`Notes/Textbook/referee/RELEASE_AUDIT_MOONSHINE.md`): *we have formalized in Lean 4 / Mathlib, with no hypotheses and only Lean's standard axioms, the Moonshine module $V^\natural$: a simple vertex operator algebra structure on the Frenkel–Lepowsky–Meurman space $V_\Lambda^+ \oplus (V_\Lambda^T)^+$ built from the Leech lattice, with central charge* 24, $V^\natural_1 = 0$, $\dim V^\natural_2 = 196884$, *and graded dimension equal, in every degree, to* $J(q) = j(q) - 744 = q^{-1} + 196884\,q + 21493760\,q^2 + \cdots$*; the Monster symmetry* $\mathrm{Aut}(V^\natural) = \mathbb{M}$ *is not part of the formalization.* Three readings of this sentence are fixed once and for all. (a) Although `moonshine` is written as an existential, it is a *construction*: the vertex map, vacuum, conformal vector and central charge are pinned to explicit definitions, the grading is then forced, and the witness is unique (§42.8). (b) J is the *formal* q-expansion `JShift` $= E_4^3/(\Delta/q) - 744q$; its identification with the analytic function $j(\tau) - 744$ on the upper half plane is classical but is not part of the Lean statement; it is proved separately in Lean (`qExpansion_qJ`, `hasSum_JShift`, in `VOA/Moonshine/JAnalyticQExpansion.lean`). (c) "The FLM space" refers to the carrier; the twisted×twisted block of the vertex operator is the form-adjoint of the skew intertwiner (the

Huang / Dolan–Goddard–Montague presentation), not FLM's own explicit formula, and the isomorphism with FLM's $V^\natural$ is a paper argument (uniqueness of simple-current extensions, Dong–Mason, Prop. 5.3), not a Lean theorem.

As everywhere in this book, our concern is the *meaning* of the Lean statements. Proofs are explained mathematically; we do not describe how the Lean proof scripts are organised.

42.1 Where we stand, and what remains

42.1.1 The state of the construction at the start of this chapter

Let us recall what the previous chapters have built. The carrier of the Moonshine module is

$$V^\natural \;=\; V_\Lambda^+ \,\oplus\, (V_\Lambda^T)^+,$$

where V_Λ^+ is the fixed-point subalgebra of the Leech lattice vertex operator algebra under the lift θ of -1 (Chapter 32) and $(V_\Lambda^T)^+$ is the θ-fixed part of the twisted module $V_\Lambda^T = S[\theta]\otimes T$ (Chapters 34–36). In Lean, V_Λ^+ is the type `SkewVP` (equivalently `VPlus`; both are abbreviations of the same subtype of the lattice VOA), $(V_\Lambda^T)^+$ is the submodule `TP` of `Tw := FockT 24 ⊗[ℂ] leechT`, and $V^\natural$ is the product type `Vnat := SkewVP × TP`.

Chapter 37 constructed the two "off-diagonal" fields: the skew intertwiner $W(t,z)$, which sends V_Λ^+ to $(V_\Lambda^T)^+$ and is defined by skew-symmetry,

$$W(t,z)\varphi \;=\; e^{zL_{-1}}\, Y^T(\varphi,-z)\, t,$$

and its adjoint $\overline{W}(t,z)$, which goes the other way and is defined by transposition through the two invariant bilinear forms B_V (`leechBV`) on V_Λ^+ and `TPForm` on $(V_\Lambda^T)^+$. Chapter 38 assembled the block vertex operator

$$Y^\natural\big((u,t),z\big) \;=\; \begin{pmatrix} Y(u,z) & \overline{W}(t,z) \\ W(t,z) & Y^T(u,z) \end{pmatrix} \tag{42.1}$$

(DGM (4.17); Lean `Ynat wbarL`) and proved that it defines a vertex operator algebra with central charge 24 *provided* one family of locality relations holds, the "twisted×twisted" relation that Dolan–Goddard–Montague call (4.23):

$$W(t_1,z_1)\,\overline{W}(t_2,z_2) \;\sim\; W(t_2,z_2)\,\overline{W}(t_1,z_1) \qquad \text{on } (V_\Lambda^T)^+, \tag{42.2}$$

where $\sim$ means equality after multiplication by a sufficiently high power of (z_1-z_2). In Lean this is the proposition `TPBlockLocal leechWbar t₁ t₂`. The companion relation (4.22), the analogous statement on V_Λ^+, was proved unconditionally (`leechWbar_VPBlockLocal`); simplicity was proved too, via nondegeneracy of an invariant form (`SimpleNat.vnatVOA_isSimple`). The result was `moonshine_of_frameLocality`: *all* targets, conditional on (4.23) for four explicit pairs of twisted vectors.

Chapters 39–41 then built the tool with which FLM prove (4.23): the *triality*. The Leech lattice contains a sublattice Λ_0 of index two (the Golay frame sublattice), and accordingly

$$V_\Lambda^+ = V_0^+ \oplus V_3^+, \qquad (V_\Lambda^T)^+ = T_0^+ \oplus T_1^+,$$

four V_0^+-modules (Lean: `frameSector 0`, `frameSector 1`, `TPframe 0`, `TPframe 1`). FLM's key insight is that there is an automorphism σ of the subalgebra V_0^+ that does not extend to V_Λ^+, but which permutes the three nontrivial sectors: twisting V_3^+ by σ gives one twisted sector, and the other twisted sector is σ-stable. Chapter 39 constructed σ on V_0^+ (`v0Sigma`); Chapters 40–41 constructed the twisted halves, the σ-twisted V_0^+-intertwiners

$$\Phi : V_3^+ \to T_s^+, \qquad \Theta : T_{s+1}^+ \to T_{s+1}^+,$$

unconditionally (`SigmaTop.topSigma_both`), using Zhu-algebra generation (`zhuGenerated_weightTwo`) to reduce their existence to finite top-level data.

42.1.2 What this chapter does

The idea of FLM is to *conjugate*. Assemble the sector maps into one linear involution $\sigma^\natural$ of $V^\natural$. If $\sigma^\natural$ were an automorphism of the (would-be) vertex algebra, then for $v \in V_3^+$,

$$\sigma^\natural\, Y^\natural(v,z)\,\sigma^\natural \;=\; Y^\natural(\sigma^\natural v, z),$$

and the right-hand side is a twisted field $Y^\natural((0,\Phi v),z)$. The left-hand side is local with itself because the untwisted field $Y^\natural(v,z)$ is (proved in Chapter 38). So the twisted field $Y^\natural((0,x),z)$, $x = \Phi v$, would be local with itself, which contains (4.23) for the pair (x,x); and one generating twisted vector suffices.

Of course, we cannot assume that $\sigma^\natural$ is an automorphism; that is what is to be proved. The honest content is an *identification of two fields*: the conjugated field $L_v = \sigma^\natural Y^\natural(v,z)\sigma^\natural$ and the block field $R_v = Y^\natural(\sigma^\natural v, z)$. The chapter proceeds as follows.

(1) §42.2: the conjugation set-up. Both L_v and R_v are local with all V_0^+-fields and create the same state from the vacuum, so their difference is determined by its values on the cyclic vectors of the four sectors. The remaining agreements are three "three-point identities" (`SigmaKey`); if they hold, then (4.23) holds for all pairs and $V^\natural$ is constructed (`moonshine_of_sigma`).

(2) §42.3: adjunction against the invariant forms reduces the three identities to two *isometry* statements and one *self-coupling* identity `KeySkew`; the isometries reduce further to finite top-level statements (`moonshine_of_top`).

(3) §42.4: the explicit triality data of Chapter 41 are assembled into `mkData c ε`, the isometries are proved (with the normalisation $\mu = +1$ *proved*), and the only remaining hypothesis is `KeySkew0 ε` for one sign ε (`moonshine_of_keySkew0`).

(4) §42.5: a lemma of Li type shows that `KeySkew` is controlled by the top-output components of a "block defect" (`keySkew_of_keyTopV`); that residual is still infinite.

(5) §42.6: Frenkel–Zhu bimodule theory makes it finite. The bimodule $A(V_3^+)$ is generated by its top level (`bimodGen_V3`), and the transposed top-level identities need only the commutator formula, so the intertwining Jacobi identity of W — which the library does not have — is never needed (`keySkew_of_FZ`).

(6) §42.7: the last finite identity, $\Theta\, o(v)\Phi b = o(b)\Phi v$ on the 49152-dimensional top level, is proved by an explicit sign computation in Leech coordinates (`topPairs_one`, with $\varepsilon = +1$). This yields `moonshine`.

(7) §42.8: the final theorem, read clause by clause; then the referee's checklist.

Remark 42.1 (The chain of reductions at a glance)**.** Each implication below is a Lean theorem presented in this chapter; the top line is the goal, the bottom lines are what is finally established by direct argument.

42.1.3 Notation used throughout the chapter

We fix the following abbreviations, which match the Lean files and the route notes `Notes/SigmaKey.md`, `Notes/KeySkew.md`.

- $A = V_0^+$ (Lean `V0Sub.carrier`, equal to `frameSector 0`); as a VOA in its own right it is `V0P`. $B = V_3^+$ (`frameSector 1`). $C = T_s^+$ and $D' = T_{s+1}^+$ (`TPframe s`, `TPframe (s+1)`), where $s \in \mathbb{Z}/2$ labels the twisted sector that the triality pairs with V_3^+. The label is part of the data because the library's definitions do not single out which of the two twisted frame sectors is FLM's T_0^+ (`golayE_not_determined`, Chapter 40).

- For $u \in A$ and $n \in \mathbb{Z}$, `actV u n` and `actT u n` are the modes $u_{(n)}$ of u acting on V_Λ^+ and on `TP`. Recall the library convention `mode f n = f (-n - 1)` (Definition 2.7): `mode (Y u) n` is the mathematician's $u_{(n)}$, whereas the raw coefficient `Y u k` is the coefficient of z^k in $Y(u,z) = \sum_n u_{(n)} z^{-n-1}$, i.e. $u_{(-k-1)}$. The library records this as `Y_eq_actV`: `leechVOAPlus.Y u k x = actV u (-k - 1) x`. *Every* statement of the form `∀ p, … Y v p …` below is therefore a statement about all coefficients of a series, and the reindexing $p \leftrightarrow -p-1$ never changes its content.

- $\sigma =$ `v0Sigma` $\in \mathrm{Aut}(V_0^+)$; `sig u` is its value on u.

- The cyclic vectors: $x_\beta = e^\beta + e^{-\beta} \in V_3^+$ for $\beta \in \Lambda \setminus \Lambda_0$ (`frameX0P β`); $x_0(t) = h_0(-\frac{1}{2})\mathbb{1} \otimes t \in T^+$ for $t \in T$ (`x0T t`), which lies in T_s^+ when $t \in T_s$ (`x0T_mem`) and has weight 2.

- $o(v)$ is the zero mode $v_{(\mathrm{wt}\, v - 1)}$ of a homogeneous v; it preserves weight.

- The weight-2 "tops": $\Omega_{V_3} = (V_3^+)_2$ (`OmegaV3`, of dimension 49152) and $\Omega_T(s) = (T_s^+)_2$ (`OmegaT s`). Both V_3^+ and T^+ have *no* states of weight below 2.

42.2 The would-be triality $\sigma^\natural$ and conjugation of fields

42.2.1 The physical picture

In the language of two-dimensional conformal field theory, $V^\natural$ is the chiral algebra of a $\mathbb{Z}/2$-orbifold of 24 free bosons compactified on the Leech torus. The untwisted sector V_Λ^+ contains the θ-invariant operators of the original theory; the twisted sector $(V_\Lambda^T)^+$ contains the θ-invariant *twist fields*, created by inserting a branch cut around which the bosons change sign. The operator product of two twist fields lands back in the untwisted sector, and the content of (4.23) is that these operator products are mutually local: the twist fields of $V^\natural$ behave like ordinary, single-valued local operators. In general an orbifold of a lattice theory by -1 produces a consistent chiral algebra only after a subtle sign analysis; FLM's triality makes this analysis unnecessary by exhibiting a *symmetry* of the would-be theory that turns twist fields into untwisted fields, for which locality is already known. The physicist's slogan is: "the twisted sector is not special; there is a hidden symmetry that rotates it into the untwisted sector." This section turns the slogan into a precise reduction.

42.2.2 One twisted vector generates the twisted sector

The first ingredient is a cyclicity statement: a single twisted vector of the simplest kind generates all of $(V_\Lambda^T)^+$ under the modes of V_Λ^+.

Definition 42.2 (Mode span). Let $g = (g_i)_{i \in \kappa}$ be a family of vectors of $T^+ = (V_\Lambda^T)^+$. We say that g *mode-spans* T^+ if

$$T^+ = \mathrm{span}_{\mathbb{C}}\{\, u_{(n)} g_i \;:\; u \in V_\Lambda^+,\ n \in \mathbb{Z},\ i \in \kappa \,\}.$$

```
def ModeSpan : Prop :=
  Submodule.span ℂ {x : TP | ∃ (u : SkewVP) (n : ℤ) (i : κ), x = mode (plusModule.YM u) n
   ↪ (g i)} = ⊤
```

(`VOA/Moonshine/M8h0Gap.lean`, `VOA.Moonshine.M8h0.ModeSpan`, with $g : \kappa \to \mathtt{TP}$ a section variable.)

From the mathematics to the Lean statement

Decoding. `plusModule` is the V_Λ^+-module structure on `TP` constructed in Chapter 36; `plusModule.YM u` is the formal series $Y^T(u,z)$ acting on `TP`, and `mode (plusModule.YM u) n` is its n-th mode $u_{(n)}$ by the convention `mode f n = f (-n-1)`. `Submodule.span ℂ S` is the smallest complex subspace containing S, and `= ⊤` says it is the whole space `TP`.
Same statement. The Lean set is exactly the set of vectors $u_{(n)}g_i$. No hypothesis.

Physical meaning

A family of twist fields generates the twisted sector if all twisted states arise from them by OPE with untwisted operators: the twisted sector is an irreducible "module" in the CFT sense, built over a few ground states.

Theorem 42.3 (One vector generates T^+). *For every nonzero $t_0 \in T$, the single vector $x_0(t_0) = h_0(-\frac{1}{2})\mathbb{1} \otimes t_0$ mode-spans $(V_\Lambda^T)^+$.*

```
theorem modeSpan_x0T {t₀ : TLeechT} (h0 : t₀ ≠ 0) : ModeSpan (fun _ : Unit => x0T t₀)
```

(`VOA/Moonshine/M8hKeySpan.lean`, `VOA.Moonshine.M8hKey.modeSpan_x0T`.)

From the mathematics to the Lean statement

Decoding. `TLeechT` is the 2^{12}-dimensional irreducible module T of the twisted group algebra of Λ (Chapter 36, `finrank_leechT = 4096`). `x0T t₀` is the vector $h_0(-\frac{1}{2})\mathbb{1} \otimes t_0$ regarded as an element of `TP`; here h_0 is the first orthonormal coordinate direction of $\mathbb{C} \otimes \Lambda$ and $h_0(-\frac{1}{2})$ the corresponding half-integral twisted Heisenberg creation operator. The family is indexed by the one-point type `Unit`, so "mode-spans" means: the $u_{(n)}x_0(t_0)$ span.
Hypothesis. Only $t_0 \neq 0$, which is obviously necessary. Note that t_0 is *not* required to lie in a frame sector T_s: the theorem uses all of V_Λ^+, not only V_0^+.
Same statement. Yes.
Could it be vacuous? No: $T \neq 0$, and the conclusion is a genuine spanning statement about a nonzero space.

Physical meaning

One twist field suffices: inserting untwisted operators (oscillators ∂X and vertex operators $e^{i\alpha\cdot X}$) next to a single ground-state twist field produces every twisted state. Physically the e^α act on the 2^{12} ground states as the Clifford-type algebra of the zero modes, which acts irreducibly.

Proof on paper. Let $Z \subseteq V_\Lambda^T$ be the span of all $Y^T(u)_{(k/2)}x_0$, with u running over the whole lattice VOA V_Λ (twisted modes are half-integral). Z is stable under every twisted mode. First, the annihilation operator $h_0(\frac{1}{2})$ removes the oscillator: $h_0(\frac{1}{2})x_0 = \frac{1}{2}\mathbb{1} \otimes t_0$, so $\mathbb{1} \otimes t_0 \in Z$. Next, the twisted vertex operator of e^α acts on $\mathbb{1} \otimes t$ with a lowest coefficient proportional to $\mathbb{1} \otimes e_\alpha t$, so $\mathbb{1} \otimes e_\alpha t_0 \in Z$ for all $\alpha \in \Lambda$. Since T is a *simple* module for the twisted group algebra (Chapter 36),

the $e_\alpha t_0$ span T; hence $\mathbb{1} \otimes T \subseteq Z$. The Heisenberg creation operators then produce $S[\theta] \otimes T$, so $Z = V_\Lambda^T$. Finally, project to the θ-invariant parts: the θ-fixed part of a mode $u_{(n)}x_0$ is the mode of the θ-fixed part of u applied to the θ-fixed x_0, so T^+ is spanned by modes of V_Λ^+ applied to x_0. □

What the machine verified

Unconditional. `#print axioms: [propext, Classical.choice, Quot.sound]` (the file is imported by `VOA.Moonshine.moonshine`, whose axiom list is this).

42.2.3 Conjugating a field by an involution

Definition 42.4 (Conjugate field). Let V be a complex vector space, $\sigma \in \mathrm{End}\, V$ and $A(z) = \sum_k A_k z^k$ a formal distribution with coefficients in $\mathrm{End}\, V$. The *conjugate* of A by σ is $(\sigma A \sigma)(z) = \sum_k \sigma A_k \sigma\, z^k$.

```
def conjF (σ : End ℂ V) (A : FormalDist (End ℂ V)) : FormalDist (End ℂ V) :=
  fun k => σ * A k * σ
```

(`VOA/Moonshine/M8hKeySigma.lean`, `VOA.Moonshine.M8hKey.conjF`.)

From the mathematics to the Lean statement

`FormalDist X` is the type of functions $\mathbb{Z} \to X$, read as formal series $\sum_{k\in\mathbb{Z}} A_k z^k$ (Definition 2.1); `A k` is the coefficient of z^k. The product `σ * A k * σ` is composition in the algebra `End ℂ V`. Exactly the textbook definition.

Physical meaning

Conjugating an operator by a symmetry, $\mathcal{O} \mapsto g\,\mathcal{O}\,g^{-1}$: the transformed field. For a genuine symmetry of the CFT, the transformed field of $\phi(z)$ is the field of the transformed state.

Proposition 42.5. *Let $\sigma^2 = 1$. (a) If A and B are mutually local, so are $\sigma A\sigma$ and $\sigma B\sigma$. (b) If σ commutes with an operator T and A is T-covariant, $[T, A(z)] = \partial_z A(z)$, then so is $\sigma A\sigma$.*

```
theorem local_conjF {σ : End ℂ V} (hσ : σ * σ = 1) {A B : FormalDist (End ℂ V)}
    (h : Local A B) : Local (conjF σ A) (conjF σ B)

theorem dCovariant_conjF {σ T : End ℂ V} (hT : σ * T = T * σ)
    {A : FormalDist (End ℂ V)} (h : DCovariant T A) : DCovariant T (conjF σ A)
```

(`VOA/Moonshine/M8hKeySigma.lean`.)

From the mathematics to the Lean statement

Decoding. `Local A B` (Definition 2.41) means: there is $N \in \mathbb{N}$ with $(z_1 - z_2)^N [A(z_1), B(z_2)] = 0$ coefficientwise. `DCovariant T A` means $[T, A_k]$ = the coefficient of z^k in $\partial_z A$, i.e. translation covariance with respect to T (which will be L_{-1}).
Hypotheses. $\sigma^2 = 1$ in (a); in (b), $\sigma T = T\sigma$. Note (b) does not need $\sigma^2 = 1$. Both are the textbook hypotheses.

Physical meaning

Locality and translation covariance are preserved by any operator that commutes with them in the obvious sense: a change of basis on the Hilbert space does not create new singularities in OPEs.

Proof on paper. (a) $[\sigma A_m\sigma, \sigma B_n\sigma] = \sigma[A_m, B_n]\sigma$ because $\sigma\sigma = 1$ in the middle; multiplying by $(z_1 - z_2)^N$ commutes with the linear map $X \mapsto \sigma X\sigma$. (b) $[T, \sigma A_k\sigma] = \sigma[T, A_k]\sigma$ since σ commutes with T. □

What the machine verified

Unconditional; standard axioms only.

42.2.4 The sector decomposition and the triality data

The splittings $V_\Lambda^+ = V_0^+ \oplus V_3^+$ and $T^+ = T_0^+ \oplus T_1^+$ were established in Chapter 39 (`frameSector_isCompl`, `TPframe_isCompl`). Consequently a linear map out of $V^\natural$ is determined by its four restrictions (`vnat_ext`); this "four-sector extensionality" is used constantly below.

Definition 42.6 (σ-twisted intertwiners)**.** Let M, N be V_0^+-modules (here: subspaces of V_Λ^+ or T^+ with the restricted mode action) and $X \subseteq M$ a subspace. A linear map $\Phi : M \to N$ is a *σ-twisted intertwiner on X* if

$$\Phi(u_{(n)}x) = (\sigma u)_{(n)}\Phi(x) \qquad \text{for all } u \in V_0^+,\ n \in \mathbb{Z},\ x \in X.$$

```
def IsTwInt (ρ : A → ℤ → M →ₗ[ℂ] M) (τ : A → ℤ → N →ₗ[ℂ] N) (g : A → A) (S : Set A)
    (X : Submodule ℂ M) (Φ : M →ₗ[ℂ] N) : Prop :=
  ∀ u ∈ S, ∀ (n : ℤ), ∀ x ∈ X, Φ (ρ u n x) = τ (g u) n (Φ x)

def IsSigmaV3T (Φ : VPlus →ₗ[ℂ] TP) : Prop :=
  IsTwInt actV actT sig Set.univ (frameSector 1) Φ
def IsSigmaTT (s : ZMod 2) (Φ : TP →ₗ[ℂ] TP) : Prop :=
  IsTwInt actT actT sig Set.univ (TPframe s) Φ
def IsSigmaTV (s : ZMod 2) (Φ : TP →ₗ[ℂ] VPlus) : Prop :=
  IsTwInt actT actV sig Set.univ (TPframe s) Φ
```

(`VOA/Moonshine/TrialityTwGeneric.lean`, `VOA/Moonshine/TrialityTwSigma.lean`.)

From the mathematics to the Lean statement

Decoding. `ρ u n`, `τ u n` are the n-th modes of u on source and target; `g = sig` is σ; `S = Set.univ` means "all $u \in V_0^+$". The map Φ is defined on the whole ambient space (V_Λ^+ or `TP`), but the intertwining condition is only imposed for x in the indicated sector X; this is harmless because only the restriction to X matters later. `M →ₗ[ℂ] N` is the type of $\mathbb{C}$-linear maps.
Same statement. Yes. Note the twist is on the *target* side: $\Phi \circ u_{(n)} = (\sigma u)_{(n)} \circ \Phi$; with $\sigma^2 = 1$ this is equivalent to the other convention.

Physical meaning

A map between sectors that commutes with the chiral algebra V_0^+ up to the outer automorphism σ: in CFT terms, Φ realises the action of a symmetry of the subtheory V_0^+ that permutes its superselection sectors.

Definition 42.7 (Triality data)**.** *Triality data* consist of a label $s \in \mathbb{Z}/2$ and three linear maps

$$\Phi : V_\Lambda^+ \to T^+, \qquad \Psi : T^+ \to V_\Lambda^+, \qquad \Theta : T^+ \to T^+$$

such that Φ is a σ-twisted intertwiner on V_3^+, Ψ on T_s^+, Θ on T_{s+1}^+; $\Phi(V_3^+) \subseteq T_s^+$, $\Psi(T_s^+) \subseteq V_3^+$, $\Theta(T_{s+1}^+) \subseteq T_{s+1}^+$; and $\Psi\Phi = \mathrm{id}$ on V_3^+, $\Phi\Psi = \mathrm{id}$ on T_s^+, $\Theta^2 = \mathrm{id}$ on T_{s+1}^+.

```

  ΘΘ : ∀ t ∈ TPframe (s + 1), Θ (Θ t) = t
```

(`VOA/Moonshine/M8hKeySigma.lean`, `VOA.Moonshine.M8hKey.SigmaData`.)

From the mathematics to the Lean statement

Decoding. A Lean `structure` is a record: a term of type `SigmaData` is a tuple of the data fields (s, Φ, Ψ, Θ) together with proofs of the listed properties. `ZMod 2` is $\mathbb{Z}/2$. Every field corresponds to one clause of Definition 42.7; nothing more is required.

What is *not* required. `SigmaData` does not ask that Φ, Θ preserve the invariant forms, nor any compatibility with the fields $W, \overline{W}$. It is thus a *weak* notion: the free normalisations $\Phi \mapsto c\Phi$, $\Psi \mapsto c^{-1}\Psi$ $(c \neq 0)$ and $\Theta \mapsto -\Theta$ preserve it. These freedoms are pinned later.

Could it be vacuous? A structure whose fields are contradictory would make every theorem "for all D: ..." empty. This one is inhabited: §42.4 constructs an explicit term `mkData c ε`.

Physical meaning

The candidate symmetry of the full orbifold theory, defined sector by sector: it is FLM's triality, which mixes the untwisted odd sector with a twisted sector. The physicist's expectation (to be proved) is that it is a symmetry of all OPEs, not only of those of V_0^+.

Definition 42.8 (The would-be triality $\sigma^\natural$). Given triality data D, let $\sigma^\natural = \sigma^\natural_D \in \operatorname{End} V^\natural$ be the operator acting by

sector	action of $\sigma^\natural$	lands in
V_0^+	σ	V_0^+
V_3^+	Φ	T_s^+
T_s^+	Ψ	V_3^+
T_{s+1}^+	Θ	T_{s+1}^+

extended linearly using the four-sector decomposition.

    (D.Θ ₒₗ (TPframe (D.s + 1)).projection (TPframe D.s) (TPframe_isCompl' D.s).symm)
```

(VOA/Moonshine/M8hKeySigma.lean, VOA.Moonshine.M8hKey.sigNat.)

From the mathematics to the Lean statement

Decoding. `blockOp a c d b` is the 2×2 block operator $\begin{pmatrix} a & c \\ d & b \end{pmatrix}$ on $V_\Lambda^+ \times T^+$ (Chapter 38). `sig0` projects onto V_0^+ along V_3^+, applies σ, and includes back; it is σ on V_0^+ and 0 on V_3^+. The top-right block is Ψ composed with the projection of T^+ onto T_s^+ along T_{s+1}^+; the bottom-left block is Φ after projecting V_Λ^+ onto V_3^+; the bottom-right is Θ after projecting onto T_{s+1}^+. The Lean theorems `sigNat_V0`, `sigNat_V3`, `sigNat_Ts`, `sigNat_Ts1` state exactly the four rows of the table. Same definition as the table.

Physical meaning

$\sigma^\natural$ is the would-be symmetry operator on the full Hilbert space $V^\natural$; in the Moonshine CFT it is the involution that, together with the obvious symmetries, generates the Monster (heuristic; not stated in Lean).

Theorem 42.9 ($\sigma^\natural$ is an involution compatible with V_0^+)**.** *For triality data D:*

(a) $(\sigma^\natural)^2 = 1$;

(b) for every $u \in V_0^+$ *and* $k \in \mathbb{Z}$: $\sigma^\natural\, Y^\natural(u)_k = Y^\natural(\sigma u)_k\, \sigma^\natural$, *where* $Y^\natural(u)$ *is the diagonal field* $\mathrm{diag}(Y(u,z), Y^T(u,z))$; *consequently* $\sigma^\natural Y^\natural(u)\sigma^\natural = Y^\natural(\sigma u)$;

(c) $\sigma^\natural$ *commutes with the translation operator* L_{-1} *of* $V^\natural$, *and fixes the vacuum.*

```
theorem sigNat_sq : sigNat D * sigNat D = 1

theorem sigNat_YnatU_V0 (u : V0Sub.carrier) (k : ℤ) :
    sigNat D * YnatU (u : VPlus) k = YnatU ((sig u : V0Sub.carrier) : VPlus) k * sigNat D

theorem conjF_YnatU_V0 (u : V0Sub.carrier) :
    conjF (sigNat D) (YnatU (u : VPlus)) = YnatU ((sig u : V0Sub.carrier) : VPlus)

theorem sigNat_Tnat : sigNat D * Tnat = Tnat * sigNat D

theorem sigNat_vac : sigNat D vacNat = vacNat
```

(VOA/Moonshine/M8hKeySigma.lean.)

From the mathematics to the Lean statement

Decoding. `YnatU u` is the field $Y^\natural((u,0),z)$, the diagonal block $\mathrm{diag}(Y(u,z), Y^T(u,z))$ (Chapter 38, `YnatU_apply`). `YnatU u k` is its coefficient of z^k. `Tnat` is the translation operator $L_{-1} \oplus L_{-1}^T$ of $V^\natural$; `vacNat` is $(\mathbb{1}, 0)$. The coercion `(u : VPlus)` views $u \in V_0^+$ as an element of V_Λ^+.
Hypotheses. Only the triality data D (a section variable). The statements are exactly (a)–(c).

Physical meaning

The candidate symmetry is an involution, preserves the vacuum and the stress tensor, and is a symmetry of the subalgebra V_0^+. What remains is to show it respects the OPEs involving the other three sectors.

Proof on paper. Check each identity on each of the four sectors. (a) On V_0^+, $\sigma^2 = 1$ (Chapter 39); on V_3^+, $\sigma^\natural$ goes to T_s^+ by Φ and back by Ψ, and $\Psi\Phi = \mathrm{id}$; on T_s^+, $\Phi\Psi = \mathrm{id}$; on T_{s+1}^+, $\Theta^2 = \mathrm{id}$. (b) The modes of $u \in V_0^+$ preserve each of the four sectors. On V_0^+ the identity is $\sigma(u_{(n)}a) = (\sigma u)_{(n)}\sigma a$, i.e. $\sigma \in \mathrm{Aut}\, V_0^+$; on the other three it is the twisted-intertwiner property of Φ, Ψ, Θ. The conjugation form follows from (a). (c) Take $u = \omega$: $\sigma\omega = \omega$, and L_{-1} is the coefficient of $Y^\natural(\omega)$ that gives $\omega_{(0)}$. The vacuum lies in V_0^+ and $\sigma\mathbb{1} = \mathbb{1}$. □

What the machine verified

Unconditional given D; standard axioms only.

42.2.5 Uniqueness using V_0^+-locality only

The heart of the conjugation argument is a uniqueness lemma. The library already had a "Goddard uniqueness" theorem from Chapter 38, which we now quote because it is the wrong tool here, and it is instructive to see why.

```
theorem YnatT_eq_of_creates (hspan : ModeSpan g) (x : TP) (Ψ : FormalDist (End ℂ Vnat))
    (hcov : DCovariant Tnat Ψ) (h0 : Ψ 0 vacNat = ((0 : SkewVP), x))
    (hneg : ∀ q : ℤ, q < 0 → Ψ q vacNat = 0) (hU : ∀ v : SkewVP, Local Ψ (YnatU v))
    (hT : ∀ j, Local Ψ (YnatT leechWbar (g j))) : YnatT leechWbar x = Ψ
```

(`VOA/Moonshine/M8h0Gap.lean`.) It says: a translation-covariant field Ψ that creates $(0, x)$ from the vacuum and is local with *every* untwisted field $Y^\natural(v)$, $v \in V_\Lambda^+$, and with the twisted generators, is the block field $Y^\natural((0, x))$.

Trap / dead end: The circularity of `YnatT_eq_of_creates` in this context

We want to identify $L_v = \sigma^\natural Y^\natural(v)\sigma^\natural$, for $v \in V_3^+$, with $Y^\natural(\sigma^\natural v)$. To apply `YnatT_eq_of_creates` with $\Psi = L_v$ we would need L_v to be local with $Y^\natural(b)$ for $b \in V_3^+$. Conjugating by $\sigma^\natural$, this is the statement that $Y^\natural(v)$ is local with $\sigma^\natural Y^\natural(b)\sigma^\natural = L_b$ — which is (part of) the very identity $L_b = Y^\natural(\sigma^\natural b)$ to be proved, now for b. Using the theorem would be circular. The same circularity reappears if one tries to use V_3^+-locality of the difference field (recorded in `Notes/SigmaKey.md` §7). The remedy is a uniqueness lemma that asks for locality with V_0^+-fields only, because $\sigma^\natural$ transports those for free (Theorem 42.9(b)).

Theorem 42.10 (Circularity-free uniqueness). *Let F be a formal distribution with coefficients in* $\mathrm{End}\, V^\natural$ *that is local with $Y^\natural(u)$ for every $u \in V_0^+$. Fix $\beta \in \Lambda \setminus \Lambda_0$ and nonzero $t_0 \in T_0$, $t_1 \in T_1$. If every coefficient of F kills the four vectors*

$$\mathbb{1}, \qquad (x_\beta, 0), \qquad (0, x_0(t_0)), \qquad (0, x_0(t_1)),$$

then $F = 0$.

```
theorem eq_zero_of_V0local (F : FormalDist (End ℂ Vnat))
    (hloc : ∀ u : V0Sub.carrier, Local F (YnatU (u : VPlus)))

```

(`VOA/Moonshine/M8hKeySigma.lean`, `VOA.Moonshine.M8hKey.eq_zero_of_V0local`.)

From the mathematics to the Lean statement

Decoding. `leech.carrier` is the Leech lattice Λ, `lambda0` its frame sublattice Λ_0 (Chapter 39); `leechFrameT s` is the frame eigenspace $T_s \subseteq T$; the two vectors t_0, t_1 are packaged as a function `t : ZMod 2 → TLeechT. F p v = 0` for all p says every coefficient of F kills v.
Hypotheses. (i) V_0^+-locality of F — only V_0^+, which is the point; (ii) $\beta \notin \Lambda_0$, so that x_β lies in V_3^+ and is V_0^+-cyclic there (Chapter 39, `cyc_V3`); (iii) $t_s \in T_s$ nonzero, so that $x_0(t_s)$ is V_0^+-cyclic in T_s^+ (`cyc_T`); (iv) the four annihilation hypotheses. No translation covariance is needed.
Same as textbook. This is the familiar "a field local with a generating set and annihilating the cyclic vectors is zero", in its four-sector form.

Physical meaning

A field that is local with a chiral algebra and annihilates the lowest state of each superselection sector vanishes: the Reeh–Schlieder-type principle that states generated by local operators from a cyclic vector exhaust the sector.

Proof on paper. Let $K = \bigcap_p \ker F_p$. Locality plus annihilation give the key fact: if F is local with $Y^\natural(u)$ and all F_p kill y, then all F_p kill every $u_{(q)}y$. (Write $(z_1 - z_2)^N[F(z_1), Y(u, z_2)] = 0$ and apply to y; since $F(z_1)y = 0$ one gets $(z_1 - z_2)^N F(z_1)Y(u, z_2)y = 0$; the series $Y(u, z_2)y$ has only finitely many negative powers of z_2, so the factor $(z_1 - z_2)^N$ can be cancelled, giving $F(z_1)Y(u, z_2)y = 0$.) Thus K is V_0^+-stable. It contains $\mathbb{1}$, hence $u_{(-1)}\mathbb{1} = u$ for all $u \in V_0^+$; it contains the V_0^+-cyclic vectors of the other three sectors, hence the three sectors. So $K = V^\natural$. □

What the machine verified

Unconditional; standard axioms only. Uses no form of (4.23).

42.2.6 The identification of L_v with R_v, and the key identities

Theorem 42.11 (Agreement on cyclic vectors suffices). *Let D be triality data, $v \in V_3^+$, and β, t as in Theorem 42.10. If $L_v = \sigma^\natural Y^\natural(v)\sigma^\natural$ and $R_v = Y^\natural((0, \Phi v))$ agree on $(x_\beta, 0)$ and on $(0, x_0(t_s))$ for both s, then $L_v = R_v$.*

```
theorem conjF_V3_eq {v : VPlus} (hv : v ∈ frameSector 1) {β : leech.carrier} (hβ : β ∉
 ↪ lambda0)
    (t : ZMod 2 → TLeechT) (ht : ∀ s, t s ∈ leechFrameT s) (ht0 : ∀ s, t s ≠ 0)

     ↪ (frameX0P β, 0))
    (hT : ∀ s p, conjF (sigNat D) (YnatU v) p (0, x0T (t s)) = YnatT leechWbar (D.Φ v) p
     ↪ (0, x0T (t s))) :
    conjF (sigNat D) (YnatU v) = YnatT leechWbar (D.Φ v)
```

(`VOA/Moonshine/M8hKey.lean`.)

From the mathematics to the Lean statement

Decoding. `YnatT leechWbar x` is the purely twisted block field $Y^\natural((0, x), z) = \begin{pmatrix} 0 & \overline{W}(x, z) \\ W(x, z) & 0 \end{pmatrix}$ built with the genuine adjoint `leechWbar` (Chapter 37). `YnatU v` for $v \in V_3^+$ is the untwisted block field of $(v, 0)$. Note that $R_v = Y^\natural(\sigma^\natural(v, 0))$ since $\sigma^\natural(v, 0) = (0, \Phi v)$.

Hypotheses. The two agreement hypotheses are for all coefficients p; there is no hypothesis on the vacuum — that agreement is *proved*.

Physical meaning

Two fields with the same OPEs with the even chiral algebra V_0^+ and the same action on the lowest state of every sector are the same field. This is how a physicist identifies the transform of an operator under a symmetry: compare its Ward identities and its matrix elements on primaries.

Proof on paper. Apply Theorem 42.10 to $F = L_v - R_v$. Locality with V_0^+: R_v is local with $Y^\natural(u)$ by the module/intertwiner relations (4.20)–(4.21) proved in Chapter 38; L_v is, because $Y^\natural(v)$ is local with $Y^\natural(\sigma u)$ (Chapter 38) and conjugation preserves locality and turns $Y^\natural(\sigma u)$ into $Y^\natural(u)$ (Theorem 42.9). The vacuum: both fields are L_{-1}-covariant (conjugation preserves covariance since $\sigma^\natural L_{-1} = L_{-1}\sigma^\natural$), both have vanishing coefficients of z^q, $q < 0$, on $\mathbb{1}$, and both create $(0, \Phi v)$ at z^0 (L_v because $\sigma^\natural$ fixes $\mathbb{1}$ and maps $(v, 0)$ to $(0, \Phi v)$). A covariant field is determined on $\mathbb{1}$ by these data: $F(z)\mathbb{1} = e^{zL_{-1}}F_0\mathbb{1}$. So F kills $\mathbb{1}$, and the remaining three vectors are the hypotheses. □

Definition 42.12 (The FLM three-point identities on cyclic vectors). Let D be triality data, $\beta \in \Lambda\backslash\Lambda_0$, and nonzero $t_s \in T_s$. Write $x = x_0(t_s) \in T_s^+$ (with $s = D.s$), $v = \Psi x \in V_3^+$, $x_3 = x_\beta$, $x' = x_0(t_{s+1})$. `SigmaKey D β t` is the conjunction of

$$\begin{aligned}
&\text{(key_V3)} && \Theta\big(Y^T(v,z)\,\Phi x_3\big) = W(x,z)\,x_3 && \text{in } T_{s+1}^+,\\
&\text{(key_Ts)} && \sigma\big(Y(v,z)\,v\big) = \overline{W}(x,z)\,x && \text{in } V_0^+,\\
&\text{(key_Ts1)} && \Psi\big(Y^T(v,z)\,\Theta x'\big) = \overline{W}(x,z)\,x' && \text{in } V_3^+,
\end{aligned}$$

coefficientwise, together with the side conditions on β and t.

```
structure SigmaKey (β : leech.carrier) (t : ZMod 2 → TLeechT) : Prop where
  hβ : β ∉ lambda0
  ht : ∀ s, t s ∈ leechFrameT s
  ht0 : ∀ s, t s ≠ 0

  key_Ts1 : ∀ p, D.Ψ (plusModule.YM (D.Ψ (x0T (t D.s))) p (D.Θ (x0T (t (D.s + 1)))))
    = leechWbar (x0T (t D.s)) p (x0T (t (D.s + 1)))
```

(`VOA/Moonshine/M8hKey.lean`, `VOA.Moonshine.M8hKey.SigmaKey`.)

From the mathematics to the Lean statement

Decoding. `leechWsk x p φ` is the coefficient of z^p in $W(x,z)\varphi$; `leechWbar x p y` that of $\overline{W}(x,z)y$. `sig0` is σ on V_0^+ (and 0 on V_3^+); the product $Y(v,z)v$ of two elements of V_3^+ lies in V_0^+ by the fusion rules of the frame grading, so `sig0` acts as σ there.

Why these three, and why they are the agreements. The Lean theorems

```
theorem key_V3_iff {v a : VPlus} (hv : v ∈ frameSector 1) (ha : a ∈ frameSector 1) (p
 ↪  : ℤ) :
    conjF (sigNat D) (YnatU v) p (a, 0) = YnatT leechWbar (D.Φ v) p (a, 0)
      ↔ D.Θ (plusModule.YM v p (D.Φ a)) = leechWsk (D.Φ v) p a
theorem key_Ts_iff {v : VPlus} (hv : v ∈ frameSector 1) {y : TP} (hy : y ∈ TPframe
 ↪  D.s) (p : ℤ) :
```

```
    conjF (sigNat D) (YnatU v) p (0, y) = YnatT leechWbar (D.Φ v) p (0, y)
      ↔ sig0 (leechVOAPlus.Y v p (D.Ψ y)) = leechWbar (D.Φ v) p y
theorem key_Ts1_iff {v : VPlus} (hv : v ∈ frameSector 1) {y : TP} (hy : y ∈ TPframe
 ↪ (D.s + 1)) (p : ℤ) :
    conjF (sigNat D) (YnatU v) p (0, y) = YnatT leechWbar (D.Φ v) p (0, y)
      ↔ D.Ψ (plusModule.YM v p (D.Θ y)) = leechWbar (D.Φ v) p y
```

show that, at $v = \Psi x$ (so $\Phi v = x$) and on the cyclic vectors, the three clauses are *exactly* the three agreement hypotheses of Theorem 42.11. To see it on paper: $\sigma^\natural$ sends $(a, 0)$, $a \in V_3^+$, to $(0, \Phi a)$; $Y^\natural(v)$ maps it to $(0, Y^T(v)\Phi a)$ with $Y^T(v)\Phi a \in T^+_{s+1}$; $\sigma^\natural$ applies Θ. The block field R_v sends $(a, 0)$ to $(0, W(\Phi v)a)$. The other two rows are similar.

Hypothesis status. `SigmaKey` is a *genuine open input* at this stage: each clause compares two different intertwining operators and does not follow from the intertwining property of Φ, Ψ, Θ alone. It also pins the normalisations that `SigmaData` leaves free.

Physical meaning

Three specific three-point functions (OPE coefficients) must agree in the original and the triality-rotated pictures. If $\sigma^\natural$ is a symmetry they do; these are FLM's "key identities".

Theorem 42.13 ((4.23) from the key identities)**.** *If* `SigmaKey D β t` *holds, then (i)* $\sigma^\natural Y^\natural(\Psi x)\sigma^\natural = Y^\natural((0, x))$ *for* $x = x_0(t_s)$*; (ii) (4.23) holds for* all *pairs* $t_1, t_2 \in T^+$*; (iii)* $V^\natural$ *carries all the structure listed in the final theorem.*

```

```

(`VOA/Moonshine/M8hKey.lean`.)

From the mathematics to the Lean statement

Decoding. `TPBlockLocal leechWbar t₁ t₂` is (4.23): File `VOA/Moonshine/TTBlock.lean`.

```
def TPBlockLocal (Wbar : TP → FormalDist (TP →ₗ[ℂ] SkewVP)) (t₁ t₂ : TP) : Prop :=
  ∃ N : ℕ, mulBySubPow N
    ((fun m n => leechWsk t₁ m ∘ₗ Wbar t₂ n - leechWsk t₂ n ∘ₗ Wbar t₁ m) :
      FormalDist₂ (End ℂ TP)) = 0
```

i.e. $(z_1 - z_2)^N \big(W(t_1, z_1)\overline{W}(t_2, z_2) - W(t_2, z_2)\overline{W}(t_1, z_1)\big) = 0$, with `mulBySubPow N` multiplication by $(z_1 - z_2)^N$ on two-variable formal series. The conclusion of `moonshine_of_sigma` is literally the conclusion of the final theorem, decoded in §42.8.

Hypotheses. Only D (implicit section variable) and h. Since `SigmaKey` contains the side conditions on β and t, nothing else is assumed.

Physical meaning

If the candidate symmetry maps one untwisted field to the corresponding twist field, mutual locality of twist fields (single-valuedness of their OPEs, the delicate point of any orbifold) is inherited from the untwisted sector. Once one twist field is local with itself, Dong's lemma propagates locality to all.

Proof on paper. (i) By Theorem 42.11 with $v = \Psi x$, whose hypotheses are the clauses of `SigmaKey` (by the three `iff` theorems), and $\Phi\Psi x = x$. (ii) The untwisted field $Y^{\natural}(\Psi x)$ is local with itself (Chapter 38); conjugating, by (i), $Y^{\natural}((0,x))$ is local with itself. Self-locality of a twisted block field is the conjunction of (4.22) and (4.23) for the pair (x,x) (`YnatT_local_iff`), so (4.23) holds for (x,x). By Theorem 42.3, x mode-spans T^{+}, and the propagation theorem of Chapter 38 (`TPBlockLocal_all_of_gen`: (4.23) on a mode-spanning family implies (4.23) for all pairs; its proof is Dong's lemma plus the Goddard uniqueness theorem, now used legitimately, because the twisted generator's locality is supplied) gives (4.23) for all pairs. (iii) Feed (ii) into `moonshine_of_frameLocality` (Chapter 38). □

What the machine verified

Conditional on `SigmaKey D β t` (and on the data D). `#print axioms VOA.Moonshine.M8hKey.moonshine_of_sigma`, re-run for this chapter with `lake env lean -DmaxSynthPendingDepth=3`: `[propext, Classical.choice, Quot.sound]`. No step assumes (4.23) for any pair.

42.3 Reducing the key identities: isometries and one self-coupling

The three clauses of `SigmaKey` are not independent. The difference field $F_v = L_v - R_v$ (for $v \in V_3^+$) has four off-diagonal blocks between the four sectors, and the invariant bilinear forms pair them up:

block of F_v	content	how it is handled
$A \to C$	creation	automatic (vacuum + V_0^+-locality)
$C \to A$	`key_Ts`	adjoint of $A \to C$, given that Φ is an isometry
$B \to D'$	`key_V3`	the genuine content: `KeySkew`
$D' \to B$	`key_Ts1`	adjoint of $B \to D'$, given that Φ, Θ are isometries

This section makes this table precise.

42.3.1 Automorphisms preserve invariant forms

Recall from Definition 5.48 that an *invariant bilinear form* on a VOA W is a bilinear form $(\cdot|\cdot)$ with $(L_n a|b) = (a|L_{-n}b)$, and that it is *fully invariant* if for every homogeneous u of weight k

$$(u_{(n)}a \,|\, b) = (-1)^k \sum_{j\ge 0} \frac{1}{j!} \left(a \,\middle|\, (L_1^j u)_{(2k-n-2-j)} b\right) \tag{42.3}$$

(FHL's invariance, the adjoint of $Y(u,z)$ being $Y(e^{zL_1}(-z^{-2})^{L_0}u, z^{-1})$). It is *normalised* if $(\mathbb{1}|\mathbb{1}) = 1$. For a VOA of CFT type with $L_1 V_1 = 0$ there is exactly one normalised fully invariant form (`invariantForm_unique_FHL`, Theorem 5.56).

Theorem 42.14 (Automorphisms are isometries). *Let W be a VOA with $\mathbb{1} \neq 0$ and $L_1 W_1 = 0$, B a fully invariant normalised form, and $\alpha \in \operatorname{Aut} W$. Then $B(\alpha a, \alpha b) = B(a,b)$ for all a, b.*

```
theorem aut_isometry {W : VertexOperatorAlgebra 𝒱} (hne : W.vacuum ≠ 0)
    (hqp : ∀ v, v ∈ W.grading 1 → W.L 1 v = 0) {B : InvariantForm W}
    (hB : B.IsFullyInvariant) (hn : B.Normalized) (α : Aut W) (a b : 𝒱) :
    B.form (α a) (α b) = B.form a b
```

(VOA/Moonshine/SigmaKeyForm.lean, VOA.Moonshine.SigmaKey.aut_isometry.)

From the mathematics to the Lean statement

Decoding. `InvariantForm W` bundles a bilinear form `B.form` with the Virasoro adjointness; `IsFullyInvariant` is (42.3); `Normalized` is $(\mathbb{1}|\mathbb{1}) = 1$. `Aut W` is the group of VOA automorphisms (linear bijections fixing $\mathbb{1}$, ω and intertwining all modes). Hypotheses `hne`, `hqp` are exactly those of the uniqueness theorem; `hqp` is "L_1 kills W_1". Note that CFT type is part of the library's definition of a VOA (Definition 4.4: $W_0 = \mathbb{C}\mathbb{1}$, $W_n = 0$ for $n < 0$). Same statement as the textbook one.

Physical meaning

A symmetry preserves the two-point function: $\langle ga|gb\rangle = \langle a|b\rangle$. Here this follows from uniqueness of the vacuum-normalised two-point function in a CFT with no currents annihilated by L_1.

Proof on paper. The pull-back $(a, b) \mapsto B(\alpha a, \alpha b)$ is again fully invariant (since α commutes with every L_n and every mode) and normalised (since $\alpha\mathbb{1} = \mathbb{1}$); by uniqueness it equals B. □

Corollary 42.15. *(a) For the canonical form B_V on V_Λ^+: $B_V(V_0^+, V_3^+) = 0$. (b) σ is an isometry of B_V restricted to V_0^+.*

```
theorem leechBV_frame_orth {a b : VPlus} (ha : a ∈ frameSector 0) (hb : b ∈ frameSector 1)
 ↪  :
    leechBV a b = 0

theorem leechBV_sig (a b : V0Sub.carrier) :
    leechBV ((sig a : V0Sub.carrier) : VPlus) (sig b : V0Sub.carrier) = leechBV (a : VPlus)
     ↪  b
```

(VOA/Moonshine/SigmaKeyForm.lean.)

From the mathematics to the Lean statement

`leechBV` is the canonical (Li/FHL) normalised invariant form of V_Λ^+ (Chapter 37, `leechBVForm`). The frame sectors are the ±1 eigenspaces of the frame automorphism π (`plusFrameAut`), which acts by $+1$ on V_0^+ and -1 on V_3^+. (b) is stated for elements of V_0^+, coerced into V_Λ^+. Both exactly the intended statements.

Physical meaning

States in different eigenspaces of a $\mathbb{Z}/2$ symmetry have vanishing two-point functions (charge conservation); and the triality restricted to V_0^+ is unitary for its two-point function.

Proof on paper. (a) Apply Theorem 42.14 to π: $B_V(a, b) = B_V(\pi a, \pi b) = -B_V(a, b)$. (b) Apply it to the VOA V_0^+, whose restricted form is fully invariant and normalised, and to σ. ($(V_0^+)_1 = 0$, so L_1 kills it trivially.) □

What the machine verified

Unconditional; standard axioms only.

42.3.2 The three named conditions

Definition 42.16 (Isometry conditions and the self-coupling identity)**.** For triality data D and t as before, with $x = x_0(t_s)$:

- `PhiIso D`: $\langle \Phi a, \Phi b\rangle_T = B_V(a,b)$ for all $a, b \in V_3^+$;
- `ThetaIso D`: $\langle \Theta y, \Theta y'\rangle_T = \langle y, y'\rangle_T$ for all $y, y' \in T_{s+1}^+$;
- `KeySkew D t`: $\Theta\big(Y^T(\Psi x, z)x\big) = W(x,z)\Psi x$, coefficientwise;

here $\langle\cdot,\cdot\rangle_T$ is `TPForm`.

```
def PhiIso : Prop :=
  ∀ a ∈ frameSector 1, ∀ b ∈ frameSector 1, TPForm (D.Φ a) (D.Φ b) = leechBV a b

def ThetaIso : Prop :=
  ∀ y ∈ TPframe (D.s + 1), ∀ y' ∈ TPframe (D.s + 1), TPForm (D.Θ y) (D.Θ y') = TPForm y y'

def KeySkew (t : ZMod 2 → TLeechT) : Prop :=
  ∀ p, D.Θ (plusModule.YM (D.Ψ (x0T (t D.s))) p (x0T (t D.s)))
    = leechWsk (x0T (t D.s)) p (D.Ψ (x0T (t D.s)))
```

(`VOA/Moonshine/SigmaKeyAdj.lean`.)

From the mathematics to the Lean statement

Decoding. `TPForm` is the symmetric nondegenerate invariant form on T^+ of Chapter 37. In `KeySkew`, $v = \Psi x$, the left side is $\Theta(Y^T(v,z)x)$ and the right side $W(x,z)v$; by the definition of W this is $e^{zL_{-1}}Y^T(v,-z)x$. So `KeySkew` says: the series $J(z) = Y^T(v,z)x$ is mapped by Θ to its "skew-symmetric partner" $e^{zL_{-1}}J(-z)$. It is a statement about one vector-valued series.
Status as hypotheses. These are *named Props*, i.e. statements to be proved; they are not assumed anywhere in the final theorem. Note `PhiIso` is not a normalisation that can always be arranged: it requires Φ to be a similitude in the first place.

Physical meaning

`PhiIso`, `ThetaIso`: the candidate symmetry preserves two-point functions between sectors. `KeySkew`: the OPE of one odd untwisted operator with one twist field is symmetric under exchange after applying the symmetry — a single crossing-type relation.

42.3.3 The creation block and the adjunction chains

Proposition 42.17 (Creation block)**.** *For triality data D, $v \in V_3^+$, $a \in V_0^+$ and $m \in \mathbb{Z}$:* $\Phi\big(v_{(m)}\sigma a\big) = W(\Phi v)_{(m)}a$.

```
theorem phi_create {v : VPlus} (hv : v ∈ frameSector 1) (a : V0Sub.carrier) (m : ℤ) :
    D.Φ (leechVOAPlus.smul v m ((sig a : V0Sub.carrier) : VPlus))
      = mode (leechWsk (D.Φ v)) m (a : VPlus)
```

(`VOA/Moonshine/SigmaKeyAdj.lean`.)

From the mathematics to the Lean statement

`leechVOAPlus.smul v m w` is the m-th product $v_{(m)}w$ in V_Λ^+ (Definition 4.2: `smul` is the mode action, already in mode indexing). `mode (leechWsk x) m` is $W(x)_{(m)}$. Unconditional given D; this is *not* an assumption.

Physical meaning

The state-operator map intertwines the rotated and unrotated pictures on the even sector: creating a state with the rotated odd operator equals creating it with the twist field. This is automatic because both are fixed by their action on the vacuum.

Proof on paper. The difference field F_v is local with all V_0^+-fields and kills the vacuum (proof of Theorem 42.11); by the locality argument in the proof of Theorem 42.10 it kills $u_{(-1)}\mathbb{1} = u$ for every $u \in V_0^+$. Now compute both fields on $(a, 0)$: $\sigma^\natural(a, 0) = (\sigma a, 0)$; the untwisted field of v maps it to $(v_{(m)}\sigma a, 0)$ with $v_{(m)}\sigma a \in V_3^+$ (frame grading: $B \cdot A \subseteq B$); the second $\sigma^\natural$ maps this to $(0, \Phi(v_{(m)}\sigma a))$. On the other side $R_v(a, 0) = (0, W(\Phi v)_{(m)}a)$. Equality of the second components is the claim. □

Theorem 42.18 (`key\_Ts` and `key\_Ts1` by adjunction). *Let D be triality data, $x \in T_s^+$ of weight 2, $v = \Psi x$.*

(a) If `PhiIso D`*, then $\sigma\big(v_{(n)}\Psi y\big) = \overline{W}(x)_{(n)}y$ for all $y \in T_s^+$, $n \in \mathbb{Z}$.*

(b) If `PhiIso D, ThetaIso D`*, and the whole block $B \to D'$ vanishes, i.e. $\Theta\big(v_{(m)}\Phi b\big) = W(x)_{(m)}b$ for all $b \in V_3^+$, m, then $\Psi\big(v_{(n)}\Theta y\big) = \overline{W}(x)_{(n)}y$ for all $y \in T_{s+1}^+$.*

```
theorem keyTs_gen (hΦ : PhiIso D) {x : TP} (hx : x ∈ TPframe D.s)

```

(`VOA/Moonshine/SigmaKeyAdj.lean`.)

From the mathematics to the Lean statement

Decoding. `plusModule.weight w` is the L_0-eigenspace of eigenvalue w in T^+ (weights of an ordinary module are complex numbers in the library, hence the cast `((2 : ℤ) : ℂ)`). `leechWbarMode n x` is $\overline{W}(x)_{(n)}$. The hypothesis `hV3` in (b) is exactly "the $B \to D'$ block vanishes for all b". Weight 2 for x is needed: it makes x and v quasi-primary, which collapses the FHL sum (42.3) to one term.

Physical meaning

Three-point functions $\langle a|\phi_1(z)|b\rangle$ can be read with any leg as the outgoing state; if the symmetry preserves two-point functions, OPE coefficients in one channel determine those in the adjoint channel.

Proof on paper. (a) Both sides lie in V_0^+, and B_V is nondegenerate on V_Λ^+ with $V_0^+ \perp V_3^+$; so it suffices to pair with $a \in V_0^+$:

$$\begin{aligned} B_V\big(\overline{W}(x)_{(n)}y,\, a\big) &= \langle y,\, W(x)_{(2-n)}a\rangle_T && \text{(definition of } \overline{W},\, L_1x = 0) \\ &= \langle y,\, \Phi(v_{(2-n)}\sigma a)\rangle_T && \text{(creation block)} \\ &= B_V\big(\Psi y,\, v_{(2-n)}\sigma a\big) && (\texttt{PhiIso},\, y = \Phi\Psi y) \\ &= B_V\big(v_{(n)}\Psi y,\, \sigma a\big) && \text{(invariance, } v \text{ quasi-primary of weight 2)} \\ &= B_V\big(\sigma(v_{(n)}\Psi y),\, a\big) && (\sigma \text{ isometry and involution of } V_0^+). \end{aligned}$$

(b) Similarly, pairing with $b \in V_3^+$ and using `ThetaIso`, invariance of `TPForm` and `PhiIso`: $B_V(\overline{W}(x)_{(n)}y, b) = \langle y, \Theta(v_{(2-n)}\Phi b)\rangle_T = \langle \Theta y, v_{(2-n)}\Phi b\rangle_T = \langle v_{(n)}\Theta y, \Phi b\rangle_T = B_V(\Psi(v_{(n)}\Theta y), b)$; pairing with V_0^+ gives zero on both sides by sector orthogonality. □

Theorem 42.19 (`SigmaKey` from the isometries and `KeySkew`). *If* `PhiIso D`, `ThetaIso D` *and* `KeySkew D t` *hold (with $\beta \notin \Lambda_0$, $t_s \in T_s$ nonzero), then* `SigmaKey D β t`*; consequently all targets of the final theorem hold.*

```
theorem sigmaKey_of_skew {β : leech.carrier} (hβ : β ∉ lambda0) {t : ZMod 2 → TLeechT}
    (ht : ∀ s, t s ∈ leechFrameT s) (ht0 : ∀ s, t s ≠ 0)
    (hΦ : PhiIso D) (hΘ : ThetaIso D) (hk : KeySkew D t) : SigmaKey D β t
```

(`VOA/Moonshine/SigmaKeyAdj.lean`; the corollary is `moonshine_of_skew`.)

From the mathematics to the Lean statement

All hypotheses are visible: the side conditions on β, t and the three named Props. The conclusion is the structure of Definition 42.12.

Physical meaning

All three key identities follow from unitarity of the symmetry on two sectors and one self-coupling OPE; this is the reduction a physicist would make by using conjugation and crossing.

Proof on paper. The key extra observation is that $v = \Psi x$ is itself a V_0^+-cyclic vector of V_3^+: Ψ is a bijection $T_s^+ \to V_3^+$ intertwining up to σ, and x is cyclic in T_s^+. `KeySkew` says precisely that F_v kills $(v, 0)$ (by `key_V3_iff` with $a = v$, $\Phi v = x$). By the locality argument, F_v then kills all of V_3^+: the block $B \to D'$ vanishes identically. This gives `key_V3` (at x_β), and through Theorem 42.18 also `key_Ts` and `key_Ts1`. □

42.3.4 The isometries are top-level statements

Theorem 42.20 (Top-level reduction of the isometry conditions). *Let $z_0 \in V_3^+$ be V_0^+-cyclic and homogeneous of weight w. If $\langle \Phi z_0, \Phi b\rangle_T = B_V(z_0, b)$ for all $b \in (V_3^+)_w$, then* `PhiIso D`*. Likewise, if $x' \in T_{s+1}^+$ is cyclic of weight w and $\langle \Theta x', \Theta y\rangle_T = \langle x', y\rangle_T$ for all $y \in (T_{s+1}^+)_w$, then* `ThetaIso D`*.*

```

      TPForm (D.Θ x') (D.Θ y) = TPForm x' y) : ThetaIso D
```

(VOA/Moonshine/SigmaKeyTop.lean.)

From the mathematics to the Lean statement

Decoding. `hcyc` says z_0 is V_0^+-cyclic: the modes of all $u \in V_0^+$ applied to z_0 span V_3^+. `leechVOAPlus.grading w` is the weight-w subspace. `htop` is one "row" of the Gram matrices, on a single finite-dimensional weight space. Same as the mathematical statement.

Physical meaning

A two-point function of a sector generated by its lowest state is determined by the two-point function of that lowest state with other lowest states (Ward identities move all modes to one side).

Proof on paper. The defect $F(a,b) = \langle \Phi a, \Phi b\rangle_T - B_V(a,b)$ is a symmetric bilinear form on V_3^+ satisfying the same FHL invariance (42.3) for $u \in V_0^+$ (both forms do; for the first one transports u through Φ as σu, and σ commutes with L_1). Invariance moves every mode from the left slot to the right, so by cyclicity $F = 0$ as soon as $F(z_0, \cdot) = 0$; by symmetry and cyclicity again it suffices that $F(z_0, c) = 0$ for homogeneous c; both forms vanish between different weights; so only c of weight w matter. □

Definition 42.21 (The finite isometry residuals). `PhiTop D t`: $\langle x, \Phi b\rangle_T = B_V(\Psi x, b)$ for all $b \in (V_3^+)_2$, with $x = x_0(t_s)$. `ThetaTop D t`: $\langle \Theta x', \Theta y\rangle_T = \langle x', y\rangle_T$ for all $y \in (T_{s+1}^+)_2$, with $x' = x_0(t_{s+1})$.

```

```

```
(∀ n : ℕ, (Module.finrank ℂ (V.grading (n : ℤ)) : ℂ) = PowerSeries.coeff n JShift) ∧
V.IsSimple
```

(VOA/Moonshine/SigmaKeyTop.lean.)

From the mathematics to the Lean statement

In PhiTop the cyclic vector is $z_0 = \Psi x$, which has weight 2 and satisfies $\Phi z_0 = x$; thus PhiTop is the htop of Theorem 42.20 for this z_0. PhiTop and ThetaTop are *finite*: they involve only the 49152-dimensional weight-2 spaces. The hypotheses of moonshine_of_top are listed in full; nothing else enters.

Physical meaning

The consistency of the orbifold now rests on finitely many normalisations and one OPE identity.

Proof on paper. Theorem 42.20 turns PhiTop, ThetaTop into PhiIso, ThetaIso; then Theorem 42.19 and Theorem 42.13. □

What the machine verified

Conditional on D, PhiTop D t, ThetaTop D t, KeySkew D t; standard axioms only.

42.3.5 Normalisation: what is forced and what is free

SigmaData leaves free $\Phi \mapsto c\Phi$, $\Psi \mapsto c^{-1}\Psi$ ($c \neq 0$) and $\Theta \mapsto -\Theta$. How do the residuals react?

- PhiTop scales as c on the left and c^{-1} on the right. If Φ is a *similitude*, $\langle \Phi a, \Phi b\rangle_T = \kappa_0 B_V(a,b)$, then PhiTop holds iff $c^2\kappa_0 = 1$: the scalar is determined up to sign. The remaining sign is a genuine symmetry: $(\Phi, \Psi, \Theta) \mapsto (-\Phi, -\Psi, \Theta)$ is $\sigma^\natural$ composed with the automorphism -1 on $V_3^+ \oplus T_s^+$, and changes none of the clauses.
- ThetaTop is insensitive to the sign of Θ. Since $\Theta^2 = 1$ and the invariant form on T_{s+1}^+ is unique up to a scalar, $\langle \Theta\cdot, \Theta\cdot\rangle_T = \mu\langle\cdot,\cdot\rangle_T$ with $\mu = \pm 1$. ThetaTop asserts $\mu = +1$, which is a *condition*, not a normalisation. If $\mu = -1$, both eigenspaces of Θ would be isotropic and SigmaKey unsatisfiable.
- KeySkew flips under $\Theta \mapsto -\Theta$; at most one sign can work.

Evidence: Numerical de-risking of the normalisation, and its limits

Before any of this was formalised, the project tested the conditions numerically in an independent model of the weight-2 spaces built from the Niemeier lattice $N(A_1^{24})$ (route notes Notes/SigmaKey.md §6, scripts in scripts/moonshine/numerics/sigmakey/). Findings, *evidence only*: (N1) $\Theta_J^2 \propto 1$, and after normalisation $\mu = 1.000000000000$ ($|\mu - 1| < 4 \cdot 10^{-12}$); independently $\operatorname{tr}\Theta_J = -112 \neq 0$ excludes $\mu = -1$. (N2) Φ is a similitude: the ratio $\langle \Phi v, \Phi v\rangle / B_V(v,v)$ is constant to spread $6.7 \cdot 10^{-12}$, off-diagonal entries $< 3.8 \cdot 10^{-12}$. (N3) The top level of key_V3, $\Theta\, o(v)\Phi b = \varepsilon\, o(b)\Phi v$, holds on 170 pairs with one global ε. *Caveat*: with Θ replaced by the identity the vectors were also proportional (they all lay in one eigenspace), so this test fixes the sign but discriminates weakly. The model's sector identifications and cocycle were not checked against the library's. In the Lean development, $\mu = +1$ was eventually *proved* (§42.4), and the sign was proved to be $\varepsilon = +1$ for the library's Θ_0 (§42.7).

Trap / dead end: Dead ends recorded at this stage

(1) "An intertwiner is determined by its top component" is false without the full $A(M)$-bimodule theory: the top-level part of `KeySkew` is necessary but *not* sufficient; the iterate formula moves descendants of the input into non-top outputs. Do not formalise "top-level `key_V3` ⇒ `key_V3`". (2) Using V_3^+-locality of L_v is circular (see the warning before Theorem 42.10). (3) (4.22) gives no new information: it constrains only products of already matched blocks or the $B \to D' \to B$ composite, which is symmetric under the unknown scalar. (4) Skew-symmetry alone does not decide `KeySkew`: it says that $J(v,z)b = \Theta Y^T(v,z)\Phi b$ is a fixed point of the involution $J \mapsto \Theta e^{zL_{-1}} J(\cdot,-z)$ (swapping v, b); without a one-dimensional space of intertwiners, J could have components in both eigenspaces.

42.4 The assembled triality data

We now produce a concrete term of type `SigmaData` and prove `PhiTop` and `ThetaTop` for it. The raw material is Chapter 41: a seed vector, explicit top-level maps, and their unique twisted extensions.

42.4.1 The seed and the explicit top maps

Recall (Chapter 41) the operators on T: for $j \neq k$ there are lattice vectors $\gamma_{jk}^{\pm} \in \Lambda_0$ of norm 4 (Lean `gP j k`, `gM j k`), with the corresponding normalised operators $A_{jk}^{\pm} = \kappa_{jk}^{\pm} e_{\gamma_{jk}^{\pm}}$ on T (`AP`, `AM`), and $Z_{0k} = 2A_{0k}^{-}$ (`ZZ 0 k`). These Z_{0k}, $k \neq 0$, commute and square to 1.

Definition 42.23 (Seed). A vector $t \in T$ is a *seed* if $A_{jk}^{+} t = -\frac{1}{2} t$ and $A_{jk}^{-} t = \frac{1}{2} t$ for all $j \neq k$.

```
def IsSeed (t : TLeechT) : Prop :=
  ∀ j k : Fin 24, j ≠ k → AP j k t = -(1 / 2 : ℂ) • t ∧ AM j k t = (1 / 2 : ℂ) • t
```

Physical meaning

A seed is a twisted ground state with prescribed eigenvalues under certain lattice-shift symmetries of the ground-state space: a "highest-weight" reference state for the finite Heisenberg group 2^{1+24} acting on the 2^{12} ground states.

(`VOA/Moonshine/SigmaTop2Eigen.lean`.) Chapter 41 proved that a nonzero seed exists, and lies in a frame sector (`seed_in_frame seedExists`). We fix one: $t_0 \in T_{s_0}$ (Lean `t0`, `s0`, chosen by `Classical.choice`; the theorems below hold for every such choice).

The two explicit weight-2 maps of Chapter 41 are:

- $\varphi_\star : (V_3^+)_2 \to (T^+)_2$, $\varphi_\star(x_n) = c_\star(n)\, h_{w_{j(n)}}(-\frac{1}{2}) \otimes e_n t_0$ on the basis $x_n = e^n + e^{-n}$, $n \in S_1$ (a fixed half of the norm-4 vectors of $\Lambda \setminus \Lambda_0$), where $j(n)$ is the coordinate of the entry ± 3 of n, w_j the j-th frame vector, and $c_\star(n) = i^{n_0} \cdot n_{j(n)}/3$, a fourth root of unity times ± 1; here $n_0, \dots, n_{23}$ are the integer coordinates of n in the scaling where $\langle \mu, \nu \rangle = \frac{1}{8} \sum_k \mu_k \nu_k$ (Lean `lv`), in which a norm-4 vector of $\Lambda \setminus \Lambda_0$ has shape $(\mp 3, (\pm 1)^{23})$ (Lean `phiV = phiV3 (tauStar t0)`, `cStar`);
- $\varphi_B : (T_{s_0}^+)_2 \to (T_{s_0}^+)_2$, $\varphi_B(h_{w_m}(-\frac{1}{2}) \otimes t) = h_{w_m}(-\frac{1}{2}) \otimes \psi_m t$, where $\psi_0 = B = \prod_{k \neq 0}(a + bZ_{0k})$ (restricted to T_{s_0}), $\psi_m = Z_{0m} B$, with $a = \frac{1}{2}(1+\omega)$, $b = \frac{1}{2}(1-\omega)$, $\omega = e^{i\pi/4}$ (Lean `phiB = phiTT (psiOf (Bop s0))`).

On a joint eigenvector z of the Z_{0k} with eigenvalues $u_k = \pm 1$, B acts by $\omega^{|N|}$ with $N = \{k : u_k = -1\}$, because $a + b = 1$ and $a - b = \omega$.

Definition 42.24 (The unnormalised intertwiners). $\Phi_0 : V_3^+ \to T^+_{s_0+1}$ and $\Theta_0 : T^+_{s_0} \to T^+_{s_0}$ are the unique σ-twisted intertwiners extending $\varphi_\star$ and φ_B (Chapter 41, `sigmaV3T_exists_of_top`, `sigmaTT_exists_of_top`).

```
noncomputable def Φ0 : VPlus →ₗ[ℂ] TP := (sigmaV3T_exists_of_top topV).choose
theorem Φ0_isSigma : IsSigmaV3T Φ0
theorem Φ0_top : ∀ x ∈ OmegaV3, Φ0 x = phiV x

noncomputable def Θ0 : TP →ₗ[ℂ] TP := (sigmaTT_exists_of_top topB t0_mem t0_ne).choose
theorem Θ0_isSigma : IsSigmaTT s0 Θ0
theorem Θ0_top : ∀ x ∈ OmegaT s0, Θ0 x = phiB x
```

(`VOA/Moonshine/SigmaAssemble.lean`.)

From the mathematics to the Lean statement

Decoding. `.choose` picks a witness of an existence theorem; the accompanying theorems record its properties. Because the extension is *unique* (an intertwiner is determined on a cyclic vector, `IsSigmaV3T.eqOn`), the choice is immaterial. `topV : TopSigmaV3 (s0 + 1) phiV` and `topB : TopSigmaTT s0 s0 phiB` are the top-level existence certificates of Chapter 41.
Sector bookkeeping. Φ_0 lands in $T^+_{s_0+1}$, so the triality label is $s = s_0 + 1$ and the Θ-sector is $T^+_{s+1} = T^+_{s_0}$, which is where Θ_0 acts (the Lean identity `s0_add_one_add_one : s0 + 1 + 1 = s0`).

Physical meaning

Φ_0, Θ_0 are the triality maps defined by their action on the lowest states and extended by the chiral algebra V_0^+ — exactly how one constructs a symmetry operator in CFT from its action on primaries.

42.4.2 Properties of Θ_0: involution and isometry, with no rescaling

Theorem 42.25. *(a) For a seed $t \in T_s$ and every m, $\psi_m^2 = 1$ on T_s, and ψ_m is an isometry of the invariant form $\langle\cdot,\cdot\rangle$ on T. (b) Hence φ_B is an isometric involution of $(T^+_{s_0})_2$, and (c) $\Theta_0^2 = 1$ on $T^+_{s_0}$ and Θ_0 preserves* `TPForm` *on the top.*

```
theorem psi_psi {s : ZMod 2} {t : TLeechT} (hts : t ∈ leechFrameT s) (ht0 : t ≠ 0) (ht :

    ↪  leechFrameT s) :
    TForm (psiOf (Bop s) m x) (psiOf (Bop s) m y) = TForm x y

theorem Θ0_Θ0 : ∀ y ∈ TPframe s0, Θ0 (Θ0 y) = y

theorem Θ0_isom {x y : TP} (hx : x ∈ OmegaT s0) (hy : y ∈ OmegaT s0) :
    TPForm (Θ0 x) (Θ0 y) = TPForm x y
```

(`VOA/Moonshine/SigmaAssembleTop.lean`, `VOA/Moonshine/SigmaAssemble.lean`.)

From the mathematics to the Lean statement

`TForm` is the symmetric invariant form on T of Chapter 36 (it satisfies $\langle e_\alpha t, t'\rangle = (-1)^{|\alpha|^2/2}\langle t, e_\alpha t'\rangle$, `TForm_eT`). `Fin 24` indexes the 24 coordinates. The seed hypothesis is genuinely needed in (a): it is what makes every joint eigenvector character satisfy the Golay constraint below. Statements identical to (a)–(c).

Physical meaning

The triality acts on twisted ground states by a discrete Fourier-type transform whose eigenvalues are eighth roots of unity; on the physical (Golay-constrained) states it squares to one and is unitary.

Proof on paper. Decompose T_s into joint eigenvectors z of the Z_{0k}. On z with character N, ψ_m acts by $u_m\omega^{|N|}$, so ψ_m^2 acts by $\omega^{2|N|}$. The Golay constraint of Chapter 41 (`golay_constraint`, `four_dvd_card_of_orth`) says that the characters that occur in T_s — given the seed — satisfy $4 \mid |N|$; then $\omega^{2|N|} = \omega^{8q} = 1$. Isometry: each Z_{0k} is symmetric for the form (since $|\gamma^-|^2 = 4$), joint eigenvectors of different characters are orthogonal, hence ψ_m is symmetric; symmetric and involutive means isometric. (b) The blocks $h_{w_m}(-\frac{1}{2}) \otimes T$ are mutually orthogonal for `TPForm` with form $-4\langle\cdot,\cdot\rangle$ on the diagonal, and φ_B acts blockwise by ψ_m. (c) Θ_0^2 is a $(\sigma^2 = 1)$-twisted, i.e. honest, intertwiner which is the identity on the cyclic vector $x_0(t_0)$, hence the identity. □

What the machine verified

Unconditional; standard axioms only. This *proves* $\mu = +1$ (cf. §42.3.5): no rescaling of Θ_0 was needed, consistent with the numerics.

42.4.3 Φ_0 is a nonzero similitude

Theorem 42.26 (Similitude). *Let $z_0 = x_{n_0}$ for a fixed $n_0 \in S_1$. Then $B_V(z_0, z_0) \neq 0$, and with $\kappa_0 = \langle \Phi_0 z_0, \Phi_0 z_0\rangle_T / B_V(z_0, z_0)$,*

$$\langle \Phi_0 a, \Phi_0 b\rangle_T = \kappa_0\, B_V(a, b) \qquad \text{for all } a, b \in V_3^+,$$

and $\kappa_0 \neq 0$. Consequently $\Phi_0 : V_3^+ \to T_{s_0+1}^+$ is bijective, and its inverse Ψ_0 (extended linearly to T^+) is a σ-twisted intertwiner on $T_{s_0+1}^+$.

```
noncomputable def κ0 : ℂ := TPForm (Φ0 z0) (Φ0 z0) / leechBV z0 z0

theorem Φ0_simil : ∀ a ∈ frameSector 1, ∀ b ∈ frameSector 1,

theorem Ψ0_isSigma : IsSigmaTV (s0 + 1) Ψ0
```

(`VOA/Moonshine/SigmaAssemble.lean`.)

From the mathematics to the Lean statement

Decoding. `z0 := frameX0P (nvec 0)`. Division in `κ0` is honest field division in $\mathbb{C}$; the theorem `bv_z0 : leechBV z0 z0 ≠ 0` guarantees the denominator is nonzero, so `κ0` is not a junk value (in Lean, $x/0 = 0$, which would have made `Φ0_simil` suspicious had the denominator vanished). `Ψ0` is obtained by extending the inverse of the linear bijection $V_3^+ \to T^+_{s_0+1}$ arbitrarily to a complement; only its values on $T^+_{s_0+1}$ ever matter.

Physical meaning

The triality map from odd untwisted states to twisted states preserves two-point functions up to one overall constant, which can be absorbed in the normalisation of the twisted sector.

Proof on paper. Both $(a,b) \mapsto \langle \Phi_0 a, \Phi_0 b\rangle_T$ and B_V are invariant symmetric forms on V_3^+ for which the zero mode $o(n(-1)^2\mathbb{1})$ ($n \in S_1$) is symmetric. On the top basis x_m this zero mode has eigenvalue $\langle n,m\rangle^2$, and $\langle n,n\rangle^2 = 16 \neq \langle n,m\rangle^2$ for $m \neq n$ in S_1 (since $\langle n,m\rangle = \pm 4$ would force $n \mp m$ to have norm 0). Hence the basis is orthogonal for both forms and each Gram matrix is determined by its row at z_0 restricted to the top; by the top-level reduction (Theorem 42.20, scaled by κ_0), proportionality on one row propagates to all of V_3^+. $B_V(z_0,z_0) \neq 0$ because otherwise z_0 would be in the radical of B_V (by the same propagation with $\Phi = 0$), contradicting nondegeneracy. If $\kappa_0 = 0$, then `TPForm` would vanish on $\Phi_0(V_3^+) = T^+_{s_0+1}$ (surjectivity: Φ_0 hits a cyclic vector), where it is nondegenerate. Injectivity follows from $\kappa_0 \neq 0$ and nondegeneracy of B_V. □

What the machine verified

Unconditional; standard axioms only.

42.4.4 The triality data $D(c,\varepsilon)$

Definition 42.27 ($D(c,\varepsilon)$)**.** For $c \in \mathbb{C}^\times$ and ε with $\varepsilon^2 = 1$, the triality data $D(c,\varepsilon)$ have $s = s_0 + 1$, $\Phi = c\Phi_0$, $\Psi = c^{-1}\Psi_0$, $\Theta = \varepsilon\Theta_0$.

```
noncomputable def mkData (c ε : ℂ) (hc : c ≠ 0) (hε : ε * ε = 1) : SigmaData where
  s := s0 + 1
  Φ := c • Φ0
  Ψ := c⁻¹ • Ψ0
  Θ := ε • Θ0
```

(`VOA/Moonshine/SigmaAssemble.lean`; the proof fields are omitted — they are the properties established above, rescaled.)

From the mathematics to the Lean statement

This is the whole normalisation freedom of §42.3.5 made explicit. The hypothesis $\varepsilon\varepsilon = 1$ allows exactly $\varepsilon = \pm 1$. Its existence shows that `SigmaData` is inhabited, so none of the earlier universally quantified results over D is vacuous.

Physical meaning

The ambiguity in normalising a symmetry operator on sectors: an overall rescaling of a sector and a sign on a self-paired sector.

Theorem 42.28 (Isometries for the normalised data)**.** *(a) There is c with $c^2\kappa_0 = 1$. (b) For such c and either ε,* `PhiIso` *holds for $D(c,\varepsilon)$. (c) For every $c \neq 0$ and ε,* `ThetaTop` *holds for $D(c,\varepsilon)$ with the frame vectors $t_{s_0} = t_0$, $t_{s_0+1} = e_{m_0}t_0$.*

```
theorem exists_norm : ∃ c : ℂ, c * c * κ0 = 1

theorem phiIso_mkData {c ε : ℂ} (hc : c * c * κ0 = 1) (hε : ε * ε = 1) :
    PhiIso (mkData c ε (c_ne_of_norm hc) hε)

noncomputable def tF (s' : ZMod 2) : TLeechT := if s' = s0 then t0 else eL (mvec 0) t0

theorem thetaTop_mkData (c ε : ℂ) (hc : c ≠ 0) (hε : ε * ε = 1) :
    ThetaTop (mkData c ε hc hε) tF
```

(VOA/Moonshine/SigmaAssemble.lean.)

From the mathematics to the Lean statement

`eL (mvec 0)` is the operator e_{m_0} for a fixed $m_0 \in \Lambda \setminus \Lambda_0$, which swaps the frame sectors of T (`tF_mem`); `tF_ne` records $t_s \neq 0$. The theorem `phiTop_of_phiIso` converts `PhiIso` into `PhiTop` for any D. These are exactly the needed residuals, now *proved*.

Physical meaning

With the right normalisation the triality is unitary on the relevant sectors; the possible obstruction $\mu = -1$ (an anti-unitary-like sign) does not occur.

Proof on paper. (a) $\mathbb{C}$ is algebraically closed and $\kappa_0 \neq 0$. (b) $\langle c\Phi_0 a, c\Phi_0 b\rangle = c^2\kappa_0 B_V(a,b)$. (c) The rescaling by ε squares away, and Θ_0 is an isometry on the top (Theorem 42.25). □

42.4.5 The one remaining hypothesis

Definition 42.29 (c-free self-coupling)**.** With $x_K = x_0(t_{s_0+1}) \in T^+_{s_0+1}$: `KeySkew0 ε` $:\iff \varepsilon\,\Theta_0\big(Y^T(\Psi_0 x_K, z)x_K\big) = W(x_K, z)\Psi_0 x_K$.

```
noncomputable def xK : TP := x0T (tF (s0 + 1))

def KeySkew0 (ε : ℂ) : Prop :=
  ∀ p, ε • Θ0 (plusModule.YM (Ψ0 xK) p xK) = leechWsk xK p (Ψ0 xK)

theorem keySkew_mkData_iff (c ε : ℂ) (hc : c ≠ 0) (hε : ε * ε = 1) :
    KeySkew (mkData c ε hc hε) tF ↔ KeySkew0 ε

theorem moonshine_of_keySkew0 (h : KeySkew0 1 ∨ KeySkew0 (-1)) :
    ∃ V : VertexOperatorAlgebra Vnat,
      V.Y = Ynat VnatAxioms.wbarL ∧ V.vacuum = vacNat ∧ V.conformalVector = omegaNat ∧
      V.centralCharge = 24 ∧
      V.grading 1 = ⊥ ∧
      Module.finrank ℂ (V.grading 2) = 196884 ∧
      (∀ n : ℕ, (Module.finrank ℂ (V.grading (n : ℤ)) : ℂ) = PowerSeries.coeff n JShift) ∧
      V.IsSimple
```

(VOA/Moonshine/SigmaAssemble.lean.)

From the mathematics to the Lean statement

Why c drops out. With $\Psi = c^{-1}\Psi_0$, both sides of `KeySkew` are linear in Ψx, hence scale by c^{-1}; `keySkew_mkData_iff` cancels it. The disjunction in `moonshine_of_keySkew0` is honest: at this stage the sign was not determined in Lean.
Hypotheses. Only `h`. The conclusion is the final theorem's.

Physical meaning

The single remaining OPE identity, now free of normalisation ambiguity except for one sign.

What the machine verified

`moonshine_of_keySkew0`: conditional on `KeySkew0 1 v KeySkew0 (-1)`; `#print axioms` (re-run): `[propext, Classical.choice, Quot.sound]`. `mkData`, `phiIso_mkData`, `thetaTop_mkData`: unconditional.

42.5 The self-coupling identity reduced to top-level output data

42.5.1 The block defect

`KeySkew` is one entry of a larger object. For $v, b \in V_3^+$ the two candidate $B \to D'$ blocks are $b \mapsto \Theta(Y^T(v,z)\Phi b)$ (from $\sigma^\natural Y^\natural(v)\sigma^\natural$) and $b \mapsto W(\Phi v, z)b$ (from $Y^\natural(\sigma^\natural v)$).

Definition 42.30 (Block defect)**.** For triality data D, $v, b \in V_\Lambda^+$ and $q \in \mathbb{Z}$,

$$D_q(v,b) = \Theta\big(v_{(q)}\Phi b\big) - W(\Phi v)_{(q)}b \in T^+, \qquad W(t)_{(q)}\varphi = \sum_{i\geq 0} \frac{(-1)^{q+i+1}}{i!} L_{-1}^i\big(\varphi_{(q+i)}t\big).$$

```
noncomputable def Dq (v b : VPlus) (q : ℤ) : TP :=
  D.Θ (mode (plusModule.YM v) q (D.Φ b)) - mode (leechWsk (D.Φ v)) q b
```

File `VOA/Moonshine/KeySkewBlock.lean`.

From the mathematics to the Lean statement

`mode (plusModule.YM v) q` is $v_{(q)}$ on T^+; `mode (leechWsk x) q` is $W(x)_{(q)}$, whose expansion in the display is the library theorem `mode_leechWsk` (Chapter 37). The definition is made for all $v, b \in V_\Lambda^+$ but used only for $v, b \in V_3^+$, where $D_q(v,b) \in T_{s+1}^+$ (`Dq_mem`). `KeySkew D t` is exactly $D_q(\Psi x, \Psi x) = 0$ for all q (since $\Phi\Psi x = x$).

Physical meaning

$D_q(v,b)$ measures the failure of the triality to be a symmetry of one particular operator product: the OPE of the untwisted operator v with the untwisted operator b, both in the "odd" frame sector V_3^+, *after* rotating by $\sigma^\natural$, compared with the OPE of the twist field Φv with b. In a genuine CFT with a symmetry $\sigma^\natural$ these OPE coefficients agree, so the defect is a quantity that a physicist expects to vanish identically; proving that it does is the content of the rest of the chapter.

Coefficient by coefficient, writing $v = \Psi x$, the output weight is $w = 3 - q$, and `KeySkew` reads

$$\begin{aligned} w = 2: &\quad \Theta(o(v)x) = o(v)x, \\ w = 3: &\quad \Theta(v_{(0)}x) = L_{-1}(v_{(1)}x) - v_{(0)}x, \\ w = 4: &\quad \Theta(v_{(-1)}x) = v_{(-1)}x - L_{-1}v_{(0)}x + \tfrac{1}{2}L_{-1}^2 v_{(1)}x. \end{aligned}$$

Equivalently, with $K(z) = e^{-zL_{-1}/2}Y^T(v,z)x$, `KeySkew` says $\Theta K_w = (-1)^w K_w$ on each weight component (an analysis remark from `Notes/KeySkew.md`, not formalised).

Evidence: Numerical evidence at weights 3 and 4

In the $N(A_1^{24})$ model (`Notes/KeySkew.md` §1, `scripts/moonshine/numerics/keyskew/`), the general block identity $\Theta Y^T(v,z)\Phi b = e^{zL_{-1}}Y^T(b,-z)\Phi v$ was tested through lowering modes: at weight 3 on about 5300 nonzero identities (residual $1.1\cdot 10^{-11}$) and at weight 4 on about 3300 ($1.1\cdot 10^{-11}$). Controls fail decisively: $-\Theta$ gives residual 2.0, $\Theta \to \mathrm{Id}$ at least 0.32, dropping L_{-1} at least 0.75. This is evidence, not proof; the tests see a 323-dimensional slice per fibre, not the whole weight space.

42.5.2 The commutator formula and Li's lemma

Proposition 42.31 (Commutator formula for the defect). *For $v, b \in V_3^+$, $u \in V_0^+$, $m, q \in \mathbb{Z}$ there is $J \in \mathbb{N}$ with*

$$u_{(m)}D_q(v,b) = D_q(v,u_{(m)}b) + \sum_{r<J}\binom{m}{r} D_{m+q-r}\big((\sigma u)_{(r)}v,\ b\big).$$

```
theorem Dq_comm {v b : VPlus} (hv : v ∈ frameSector 1) (hb : b ∈ frameSector 1)
    (u : V0Sub.carrier) (m q : ℤ) :
    ∃ J : ℕ, actT u m (Dq D v b q) = Dq D v (actV u m b) q
      + ∑ r ∈ Finset.range J, gBinom m r • Dq D (actV (sig u) r v) b (m + q - r)
```

File `VOA/Moonshine/KeySkewBlock.lean`.

From the mathematics to the Lean statement

`gBinom m r` is the generalised binomial coefficient $\binom{m}{r} = m(m-1)\cdots(m-r+1)/r!$, valid for negative m. The existential J is any bound beyond which $(\sigma u)_{(r)}v = 0$ (truncation). This is the textbook intertwining commutator formula, applied to both terms of the defect.

Physical meaning

This is the Ward identity for the V_0^+-symmetry: moving a mode of a symmetry current past an OPE coefficient produces the OPE coefficients of the transformed operators. Both candidate blocks satisfy the same Ward identity (one because Φ, Θ intertwine up to σ, the other because W is built from the module vertex operator), hence so does their difference.

Proof on paper. For the first term: $u_{(m)}\Theta = \Theta(\sigma u)_{(m)}$, then the module commutator formula $[(\sigma u)_{(m)}, v_{(q)}] = \sum_r \binom{m}{r}((\sigma u)_{(r)}v)_{(m+q-r)}$ on T^+, and $(\sigma u)_{(m)}\Phi b = \Phi(u_{(m)}b)$. For the second term: the commutator formula for the skew intertwiner W, proved in Chapter 37 (`leechWsk_comm`), together with $u_{(r)}\Phi v = \Phi((\sigma u)_{(r)}v)$. Subtract. □

Lemma 42.32 (Only the $i = 0$ term of W survives against weight 2). *For $y \in (T^+)_2$, $t \in T^+$, $\varphi \in V_\Lambda^+$: $\langle y, W(t)_{(q)}\varphi\rangle_T = (-1)^{q+1}\langle y, \varphi_{(q)}t\rangle_T$.*

```
theorem TPForm_W_top {y : TP} (hy : y ∈ plusModule.weight (2 : ℂ)) (t : TP) (q : ℤ) (φ :
↪  VPlus) :
    TPForm y (mode (leechWsk t) q φ) = negOnePow (q + 1) * TPForm y (mode (plusModule.YM φ)
    ↪  q t)
```

File `VOA/Moonshine/KeySkewBlock.lean`.

From the mathematics to the Lean statement

`negOnePow k` is $(-1)^k$ for $k \in \mathbb{Z}$. No hypothesis on t or φ.

Physical meaning

The terms $L^i_{-1}(\cdots)$, $i \geq 1$, are derivatives (descendants); they pair to zero with a primary state of lowest weight, since L_1 annihilates y. In CFT language: a two-point function with a lowest-weight state only sees the primary part of the OPE.

Proof. $\langle y, L^i_{-1}X\rangle = \langle L^i_1 y, X\rangle = 0$ for $i \geq 1$, since $L_1 y$ has weight 1 and T^+ has nothing below weight 2. □

Theorem 42.33 (Li's lemma for the block defect). *Let x' be a V_0^+-cyclic vector of T^+_{s+1}. If $\langle x', D_q(v,b)\rangle_T = 0$ for all $v, b \in V_3^+$ and all q, then $D_q(v,b) = 0$ for all $v, b \in V_3^+$, $q \in \mathbb{Z}$.*

```
theorem Dq_eq_zero_of_pair {x' : TP}
    (hcyc : Submodule.span ℂ {y | ∃ u ∈ (Set.univ : Set V0Sub.carrier), ∃ n : ℤ, y = actT u
    ↪  n x'}
      = TPframe (D.s + 1))
    (hpair : ∀ v ∈ frameSector 1, ∀ b ∈ frameSector 1, ∀ q : ℤ, TPForm x' (Dq D v b q) = 0)
    {v b : VPlus} (hv : v ∈ frameSector 1) (hb : b ∈ frameSector 1) (q : ℤ) : Dq D v b q =
    ↪  0
```

File `VOA/Moonshine/KeySkewBlock.lean`.

From the mathematics to the Lean statement

The conclusion is a vector equation; the hypothesis is a family of scalar equations against one vector. `hcyc` is cyclicity of x'. Same as stated.

Physical meaning

A correlation function $\langle x' | \mathcal{O} \rangle$ with all possible insertions of symmetry currents determines the state $\mathcal{O}$ when x' generates the sector: the "state–operator" principle that states are determined by their overlaps with a complete set of descendants of one cyclic state. This is the mechanism of Li's uniqueness theorem for intertwining operators.

Proof on paper. The set of $y \in T^+_{s+1}$ with $\langle y, D_q(v,b)\rangle = 0$ for all v, b, q contains x' and is stable under the modes of V_0^+: by FHL invariance (42.3), $\langle u_{(n)}x', D\rangle$ is a combination of $\langle x', (L_1^j u)_{(\cdot)}D\rangle$, and by Proposition 42.31 each $u'_{(m)}D_q(v,b)$ is a combination of defects, which pair to zero with x'. By cyclicity it is all of T^+_{s+1}. The defect also pairs to zero with T^+_s (the two frame sectors are orthogonal), so it lies in the radical of the nondegenerate `TPForm`. □

Theorem 42.34 (Input reduction). *Let $b_0 \in (V_3^+)_2$ be V_0^+-cyclic. If $\langle y, D_q(v,b_0)\rangle_T = 0$ for all $v \in V_3^+$, all q and all $y \in (T^+_{s+1})_2$, then the same holds with b_0 replaced by any $b \in V_3^+$.*

```
theorem pair_of_b0 {b₀ : VPlus} (hb₀ : b₀ ∈ frameSector 1) (hb₀2 : b₀ ∈
↪  leechVOAPlus.grading 2)
    (hcyc : Submodule.span ℂ {y | ∃ u ∈ (Set.univ : Set V0Sub.carrier), ∃ n : ℤ, y = actV u
    ↪  n b₀}
      = frameSector 1)
    (h0 : ∀ v ∈ frameSector 1, ∀ q : ℤ, ∀ y ∈ TPframe (D.s + 1), y ∈ plusModule.weight (2 :
    ↪  ℂ) →
      TPForm y (Dq D v b₀ q) = 0)
    {b : VPlus} (hb : b ∈ frameSector 1) :
    ∀ v ∈ frameSector 1, ∀ q : ℤ, ∀ y ∈ TPframe (D.s + 1), y ∈ plusModule.weight (2 : ℂ) →
      TPForm y (Dq D v b q) = 0
```

File `VOA/Moonshine/KeySkewBlock.lean`.

From the mathematics to the Lean statement

The only pairings tested are against *top* vectors y (weight 2). Hypotheses: cyclicity and weight 2 of b_0. Same as stated.

Physical meaning

Inputs can be moved off the primary b_0 by symmetry Ward identities: every state of V_3^+ is a descendant of b_0 under the V_0^+-algebra, and the top-level three-point functions of descendants are fixed by those of the primary.

Proof on paper. Write $b = u_{(n)}b_0$ for homogeneous u (cyclicity). By Proposition 42.31, $D_q(v, u_{(n)}b_0) = u_{(n)}D_q(v, b_0) - \sum_r \binom{n}{r} D_{n+q-r}((\sigma u)_{(r)}v, b_0)$; the sum pairs to zero with y by hypothesis (it is a defect with input b_0). For the first term, FHL invariance moves $u_{(n)}$ onto y, producing vectors of weight $n - \mathrm{wt}\, u + 3$: if this is 2, they are top vectors and the hypothesis applies; if it is below 2, they vanish. If $u_{(n)}b_0$ itself has weight below 2 it is zero. (The two lowest-weight facts used: V_3^+ and T^+ start in weight 2.) □

Definition 42.35 (Top-output residual). `KeyTopV D t`: for every k and every $v \in (V_3^+)_k$, $\Theta\big(o(v)x\big) = (-1)^k(\Psi x)_{(k-1)}\Phi(v)$ with $x = x_0(t_s)$. Its $k = 2$ slice `KeyTopTwo` is $\Theta(o(v)x) = o(\Psi x)\Phi(v)$.

```
def KeyTopV (t : ZMod 2 → TLeechT) : Prop :=
  ∀ (k : ℤ), ∀ v ∈ frameSector 1, v ∈ leechVOAPlus.grading k →
    D.Θ (mode (plusModule.YM v) (k - 1) (x0T (t D.s)))
      = negOnePow k • mode (plusModule.YM (D.Ψ (x0T (t D.s)))) (k - 1) (D.Φ v)

def KeyTopTwo (t : ZMod 2 → TLeechT) : Prop :=
  ∀ v ∈ frameSector 1, v ∈ leechVOAPlus.grading 2 →
    D.Θ (mode (plusModule.YM v) 1 (x0T (t D.s)))
      = mode (plusModule.YM (D.Ψ (x0T (t D.s)))) 1 (D.Φ v)
```

File `VOA/Moonshine/KeySkewBlock.lean`.

From the mathematics to the Lean statement

`mode (plusModule.YM v) (k - 1)` for v of weight k is the zero mode $o(v)$; applied to the weight-2 vector x it gives a weight-2 vector. The right side is the weight-2 output of $W(x)$ applied to v, rewritten via Lemma 42.32. `KeyTopV` is *not finite*: k is unbounded.

Physical meaning

`KeyTopV` compares, for every operator v of the sector V_3^+, the *primary-to-primary* three-point coefficient $\langle \mathrm{top}|\, v\, |x\rangle$ computed in the two pictures. It is the collection of all three-point functions with two legs on the lowest twisted states.

Theorem 42.36 (`KeySkew` from top-level output data). *If* `KeyTopV D t` *holds (with* $t_s \in T_s$ *nonzero), then* `KeySkew D t`*; consequently, together with* `PhiTop` *and* `ThetaTop`*, all targets of the final theorem hold.*

```
theorem keySkew_of_keyTopV {t : ZMod 2 → TLeechT} (ht : ∀ s, t s ∈ leechFrameT s)
    (ht0 : ∀ s, t s ≠ 0) (hk : KeyTopV D t) : KeySkew D t
```

File `VOA/Moonshine/KeySkewBlock.lean`; the corollary is `moonshine_of_keyTopV`.

From the mathematics to the Lean statement

Hypotheses: frame membership and non-vanishing of t_s (needed for cyclicity), and `KeyTopV`.

Physical meaning

A "bootstrap" statement: all OPE coefficients of the defect are determined by its primary three-point functions, so it vanishes once those do.

Proof on paper. `KeyTopV` gives, by linearity and a weight count, $\langle y, D_q(v, \Psi x)\rangle = 0$ for all top y, all v, q (only $q = \operatorname{wt} v - 1$ is nontrivial; the other components have the wrong weight). Theorem 42.34 with $b_0 = \Psi x$ extends this to all inputs b; in particular to $\langle x', D_q(v, b)\rangle = 0$ for the cyclic $x' = x_0(t_{s+1})$; Li's lemma gives $D \equiv 0$, and in particular $D_q(\Psi x, \Psi x) = 0$. □

What the machine verified

`Dq_comm`, `TPForm_W_top`, `Dq_eq_zero_of_pair`, `pair_of_b0`: unconditional given D. `keySkew_of_keyTopV`: conditional on `KeyTopV`. `#print axioms Dq_eq_zero_of_pair` (re-run): `[propext, Classical.choice, Quot.sound]`.

Trap / dead end: Dead ends on the way to finiteness

(1) Reducing the *state* slot v by the same trick would need the iterate (associativity) formula for both blocks; for W that is the intertwining Jacobi identity, which the library does not have, and even with it the recursion does not close on the top level. (2) Induction on total weight $\operatorname{wt} v + \operatorname{wt} b$ using skew-symmetry and `Dq_comm` does not close: zero-mode reductions raise the state weight. (3) `Modules.Fusion.Intertwiner` is commutator-only (no L_{-1} or associativity axiom), so its `fusionCoeff` is *not* the classical fusion rule; do not route uniqueness through it.

42.6 The Frenkel–Zhu bimodule route

42.6.1 Why bimodules

Zhu's algebra $A(V) = V/O(V)$ (Chapter 40) captures the action of zero modes on lowest-weight spaces. Frenkel and Zhu (1992) extended this to a V-module M: there is an $A(V)$-*bimodule* $A(M) = M/O(M)$, and an intertwining operator of type $\binom{M_3}{M\ M_1}$ induces, on lowest-weight spaces, a map $A(M) \otimes_{A(V)} M_1^{\mathrm{top}} \to M_3^{\mathrm{top}}$. Li showed that the intertwiner is *determined* by this top-level map. For us: `KeyTopV` compares two such top-level maps $\varphi_1, \varphi_2 : V_3^+ \to (T_{s+1}^+)_2$. If both factor through $A(V_3^+)$ and are compatible with the left and right $A(V_0^+)$-actions, and if $A(V_3^+)$ is generated as a bimodule by its top level $(V_3^+)_2$, then $\varphi_1 = \varphi_2$ follows from equality on the top: a *finite* statement.

42.6.2 The Frenkel–Zhu operations

Definition 42.37 (Frenkel–Zhu operations). Let W be a VOA, M a weak W-module, $a \in W_p$ homogeneous, $m \in M$.

$$a * m = \operatorname{Res}_z z^{-1}(1+z)^p Y(a,z)m = \sum_{i=0}^{p} \binom{p}{i} a_{(i-1)}m,$$

$$m * a = \operatorname{Res}_z z^{-1}(1+z)^{p-1} Y(a,z)m = \sum_{i=0}^{p} \binom{p-1}{i} a_{(i-1)}m,$$

$$\operatorname{Res}_k(a,m) = \operatorname{Res}_z z^{-2-k}(1+z)^{p+k} Y(a,z)m = \sum_{i=0}^{p+k} \binom{p+k}{i} a_{(i-2-k)}m \quad (k \geq 0),$$

and $O(M)$ is the span of all $\operatorname{Res}_k(a,m)$, a homogeneous.

```
noncomputable def fzLeft (N : WeakModule W M) (p : ℕ) (a : V) (m : M) : M :=
  ∑ i ∈ Finset.range (p + 1), cbz (p : ℤ) (i : ℤ) • mode (N.YM a) ((i : ℤ) - 1) m

noncomputable def fzRight (N : WeakModule W M) (p : ℕ) (a : V) (m : M) : M :=
  ∑ i ∈ Finset.range (p + 1), cbz ((p : ℤ) - 1) (i : ℤ) • mode (N.YM a) ((i : ℤ) - 1) m

noncomputable def fzRes (N : WeakModule W M) (p k : ℕ) (a : V) (m : M) : M :=
  ∑ i ∈ Finset.range (p + k + 1), cbz ((p : ℤ) + k) (i : ℤ) • mode (N.YM a) ((i : ℤ) - 2 -
  ↪ k) m

def fzOgen (N : WeakModule W M) : Set M :=
  {x | ∃ (p k : ℕ) (a : V), a ∈ W.grading (p : ℤ) ∧ ∃ m : M, x = fzRes N p k a m}

def fzO (N : WeakModule W M) : Submodule ℂ M := Submodule.span ℂ (fzOgen N)
```

File `VOA/Modules/FZBimodule.lean`.

From the mathematics to the Lean statement

Decoding. `cbz n i` is the binomial coefficient $\binom{n}{i}$ extended by 0 for $i < 0$ (`cbz_apply_neg`); `Finset.range (p+1)` is $\{0, \dots, p\}$. The weight p is passed as an explicit natural number, and the formulas are meant for $a \in W_p$; `fzOgen` imposes $a \in W_p$. For $p = 0$, `fzRight` truncates $(1+z)^{-1}$ at $i = 0$; since $W_0 = \mathbb{C}\mathbb{1}$ and $\mathbb{1}_{(i-1)} = \delta_{i0}$, this is the exact value.
Difference from Frenkel–Zhu. FZ's $O(M)$ is spanned by the $k = 0$ residues $a \circ m$ only. The library spans by all $k \geq 0$. FZ's Lemma 2.1.2 says the spans agree; this is *not* formalised in `FZBimodule.lean`, but the larger spanning set only makes the generation hypothesis below *weaker* (it quantifies over subspaces containing a *bigger* $O(M)$), and the module form of Lemma 2.1.2 is in fact proved in `FZGenFiltration.lean` (`PresM_mem`, below). The bimodule structure on $M/O(M)$ itself ($O(W) * M \subseteq O(M)$ etc.) is *not* formalised and *not needed*: only closure of subspaces under $a * \cdot$, $\cdot * a$ is used.

Physical meaning

$a * m$ and $m * a$ are the zero-mode actions "from the left and from the right": on a correlation function $\langle \mathrm{top}_3 | \, Y(m,z) \, | \mathrm{top}_1 \rangle$, inserting a near the outgoing state or near the incoming state. The bimodule $A(M)$ is the space of "primary fields up to descendants", the algebraic shadow of the fusion rule $M \times M_1 \to M_3$.

Proposition 42.38 (Exact commutator). $a*m - m*a = \sum_{i=0}^{p-1} \binom{p-1}{i} a_{(i)}m$ *exactly (no $O(M)$ correction).*

```

```

File `VOA/Modules/FZBimodule.lean`.

From the mathematics to the Lean statement

Holds for every a (the identity is pure Pascal arithmetic, $\binom{p}{i} - \binom{p-1}{i} = \binom{p-1}{i-1}$). For $a = \omega$ it is $\omega * m - m * \omega = (L_{-1} + L_0)m$.

Physical meaning

The left and right actions differ by the "non-negative modes" of a, i.e. by the singular part of the OPE of a with m; for the stress tensor this is translation plus scaling of the field m.

Definition 42.39 (Bimodule generation). An ordinary W-module M is *FZ-generated by its weight-h space* if every subspace $S \subseteq M$ that contains $O(M)$ and M_h, and is closed under $a * \cdot$ and $\cdot * a$ for all homogeneous $a \in W$, is all of M.

```
def FZGenerated (N : OrdVModule W M) (h : ℂ) : Prop :=
  ∀ S : Submodule ℂ M, fzO N.toWeakModule ≤ S → N.weight h ≤ S →
    (∀ (p : ℕ) (a : V), a ∈ W.grading (p : ℤ) → ∀ m ∈ S,
      fzLeft N.toWeakModule p a m ∈ S ∧ fzRight N.toWeakModule p a m ∈ S) → S = ⊤
```

File `VOA/Modules/FZBimodule.lean`.

From the mathematics to the Lean statement

`OrdVModule` is an ordinary (graded, L_0-semisimple) module (Definition 12.5); `N.weight h` is its weight-h space. The property says $A(M)$ is generated by the image of M_h as an $A(W)$-bimodule, phrased without forming the quotient. It is a property of the pair (W, M) only. It could be trivially true only if $M = M_h + O(M)$, which is not the case here (but nothing is lost if it were: it is a hypothesis to be *proved*).

Physical meaning

"Every field of the sector M is, modulo descendants, obtained from the lowest-weight fields by fusing with chiral-algebra fields on either side." This is what makes the fusion rule detectable on the lowest states.

42.6.3 Transposed top-level identities from the commutator formula alone

Definition 42.40 (Commutator data). Operators $A_1(r)$ on M_1, $A_3(r)$ on M_3, $B(n) : M_1 \to M_3$ and $C_j(n) : M_1 \to M_3$ form *commutator data with bound J* if $A_3(r)B(n) - B(n)A_1(r) = \sum_{j<J} \binom{r}{j} C_j(r + n - j)$ for all r, n.

```
def CommData : Prop :=
  ∀ (r n : ℤ) (m : M₁), A₃ r (B n m) - B n (A₁ r m)
    = ∑ j ∈ Finset.range J, gBinom r j • C j (r + n - j) m
```

File `VOA/Modules/FZBimodule.lean`.

From the mathematics to the Lean statement

Section variables: A_1, A_3, B, C, J. This is the commutator formula of an intertwining operator $B(n) = Y(b)_{(n)}$ with $C_j = Y(a_{(j)}b)$, with *no* associativity or L_{-1}-derivative axiom.

Physical meaning

Only the singular part of the OPE of a current with a field is assumed (the Borcherds commutator formula); the full OPE associativity is not.

Theorem 42.41 (Skew top-level identities). *Let the data satisfy* `CommData` *with bound $J = p$, and let $B(r)m = 0$ for $r > n$. Then*

$$\sum_{i=0}^{p}(-1)^{p-i}\tbinom{p}{i}\,B(n+p-i)A_1(i-1)m = A_3(p-1)B(n)m,$$

$$\sum_{i=0}^{p-1}(-1)^{p-1-i}\tbinom{p-1}{i}\,B(n+p-1-i)A_1(i)m = A_3(p-1)B(n)m - C_{p-1}(n)m \quad (p \geq 1),$$

$$\sum_{i=0}^{p+k}(-1)^{p+k-i}\tbinom{p+k}{i}\,B(n+1+p+k-i)A_1(i-2-k)m = 0.$$

```
theorem skew_left (p : ℕ) (hc : CommData A₁ A₃ B C p) (n : ℤ) (m : M₁)
    (hlow : ∀ r : ℤ, n < r → B r m = 0) :

      • B (n + 1 + (p + k : ℕ) - i) (A₁ ((i : ℤ) - 2 - k) m) = 0
```

File `VOA/Modules/FZBimodule.lean`.

From the mathematics to the Lean statement

`asgn N i` is the signed binomial $(-1)^{N-i}\binom{N}{i}$. `hlow` says $B(n)m$ is the top (highest-index nonzero) component. These are the FZ identities $o(a * m) = o(a)o(m)$, $o(m * a) = o(m)o(a)$, $o(O(M)) = 0$ for the *transposed* operator $m \mapsto e^{zL_{-1}}Y(\cdot, -z)m$, read on the top level.

Physical meaning

Skew-symmetry $Y(m,z)m_1 = e^{zL_{-1}}Y(m_1,-z)m$ exchanges the roles of the two inputs. These identities say that, at the level of primary three-point functions, the transposed operator still respects the bimodule structure — and this only needs Ward identities.

Proof on paper. Sum the commutator formula with the weights $(-1)^{N-i}\binom{N}{i}$; the C-terms combine by the finite-difference identity $\sum_i (-1)^{N-i}\binom{N}{i}\binom{s+i}{j} = \binom{s}{j-N}$, leaving one C-term or none according to the residue taken; the A_3B-terms collapse to the single top one by `hlow`. □

42.6.4 The reduction of `KeyTopV` to bimodule generation and top pairs

For a top input $y \in (T_s^+)_2$ define two maps $V_3^+ \to T^+$ on homogeneous $v \in (V_3^+)_k$:

$$\varphi_1^y(v) = \Theta\big(o(v)y\big), \qquad \varphi_2^y(v) = (-1)^k (\Psi y)_{(k-1)}\Phi(v), \qquad F_y = \varphi_1^y - \varphi_2^y.$$

Definition 42.42.

```
noncomputable def phi2Fam (y : TP) (k : ℤ) : VPlus →ₗ[ℂ] TP :=
  negOnePow k • ((mode (plusModule.YM (D.Ψ y)) (k - 1)) ∘ₗ D.Φ)

noncomputable def phi2 (y : TP) : VPlus →ₗ[ℂ] TP := gradedExt leechVOAPlus (phi2Fam D y)

noncomputable def phi1 (y : TP) : VPlus →ₗ[ℂ] TP := D.Θ ∘ₗ (oMod plusModule).flip y

noncomputable def Fy (y : TP) : VPlus →ₗ[ℂ] TP := phi1 D y - phi2 D y
```

File `VOA/Moonshine/FZBimoduleKey.lean`.

From the mathematics to the Lean statement

`oMod plusModule v y` is the zero mode $o(v)y$, extended linearly over the grading of v. `gradedExt` extends a family of maps, one per weight, linearly over the direct-sum decomposition of V_Λ^+ (`gradedExt_of_mem`: on V_k it is the k-th map). So these are exactly $\varphi_1^y, \varphi_2^y, F_y$.

Physical meaning

$\varphi_1^y(v)$ is the top-level matrix element of v between twisted lowest states, rotated by the triality; $\varphi_2^y(v)$ is the matrix element of the twist field Φv seen through skew-symmetry. F_y is their difference — the candidate violation of the triality symmetry at the level of primary three-point couplings.

Theorem 42.43 (Bimodule compatibility of F_y). *For $a \in (V_0^+)_p$, $y \in (T_s^+)_2$, $v \in (V_3^+)_k$:*

(a) $F_y(a * v) = o(\sigma a)F_y(v)$;

(b) for $p = q + 1$: $F_y\big(\sum_{i \le q} \binom{q}{i} a_{(i)}v\big) = (\sigma a)_{(q)}F_y(v) - F_{a_{(q)}y}(v)$, *hence* $F_y(v * a) = F_{o(a)y}(v)$;

(c) F_y *kills* $O(V_3^+)$.

```
theorem Fy_lV {p : ℕ} {a : V0Sub.carrier} (ha : (a : VPlus) ∈ leechVOAPlus.grading (p : ℤ))

    (hk : v ∈ leechVOAPlus.grading k) :
    Fy D y (lV p a v) = actT (sig a) ((p : ℤ) - 1) (Fy D y v)

theorem Fy_cV {q : ℕ} {a : V0Sub.carrier} (ha : (a : VPlus) ∈ leechVOAPlus.grading ((q + 1
 ↪  : ℕ) : ℤ))
    {y : TP} (hy : y ∈ OmegaT D.s) {v : VPlus} (hv : v ∈ frameSector 1) {k : ℤ}
    (hk : v ∈ leechVOAPlus.grading k) :
    Fy D y (cV (q + 1) a v) = actT (sig a) (q : ℤ) (Fy D y v) - Fy D (actT a (q : ℤ) y) v

theorem Fy_resV {p k' : ℕ} {a : V0Sub.carrier} (ha : (a : VPlus) ∈ leechVOAPlus.grading (p
 ↪  : ℤ))
    {y : TP} (hy : y ∈ OmegaT D.s) {v : VPlus} (hv : v ∈ frameSector 1) {k : ℤ}
    (hk : v ∈ leechVOAPlus.grading k) : Fy D y (resV p k' a v) = 0
```

File `VOA/Moonshine/FZBimoduleKey.lean`.

From the mathematics to the Lean statement

`lV p a`, `cV p a`, `resV p k a` are $v \mapsto a * v$, $v \mapsto \sum_{i<p} \binom{p-1}{i} a_{(i)}v$ and $v \mapsto \mathrm{Res}_k(a,v)$ computed inside V_Λ^+; they agree with `fzLeft`, `fzLeft - fzRight`, `fzRes` for the module `MV3` (V_3^+ as a V_0^+-module), by `coe_fzLeft` etc. `actT (sig a) (p - 1)` is $o(\sigma a)$ on T^+ (weight p). Note in (b) that $a_{(q)}y = o(a)y$ is again top.

Physical meaning

These are the Ward identities for the primary three-point couplings: inserting a chiral-algebra field on the left of v acts on the outgoing state, on the right acts on the incoming state.

Proof on paper. For φ_1: $a * v$, $\mathrm{Res}_k(a,v)$ are computed inside the VOA V_Λ^+, and on the lowest-weight space of the V_Λ^+-module T^+ Zhu's theorem gives $o(a*v) = o(a)o(v)$ and $o(O(V_\Lambda^+)) = 0$ (Chapter 40); then $\Theta o(a) = o(\sigma a)\Theta$. (b) is the module commutator formula. For φ_2: Φ turns $a_{(i)}v$ into $(\sigma a)_{(i)}\Phi v$, and then Theorem 42.41 applies to the operators $B(n) = (\Psi y)_{(n)}$ on T^+, with $A_1 = A_3 = (\sigma a)_{(\cdot)}$ and bound $J = p$: the commutator sum stops at p because $(\sigma a)_{(j)}\Psi y$ has weight $p + 2 - j - 1 < 2$ for $j \geq p$, and $(\Psi y)_{(r)}\Phi v = 0$ above the top mode for the same reason. The sign $(-1)^k$ in φ_2 matches the signs `asgn`. □

Definition 42.44 (The three named Props). `KeyTopAll D`: $F_y = 0$ for every $y \in (T_s^+)_2$ (i.e. `KeyTopV` for every top input). `BimodGenV3`: V_3^+ is FZ-generated by $(V_3^+)_2$ as a V_0^+-module. `TopPairs D`: $\Theta\big(o(v)\Phi b\big) = o(b)\Phi v$ for all $v, b \in (V_3^+)_2$.

```
def KeyTopAll : Prop :=
  ∀ y ∈ OmegaT D.s, ∀ (k : ℤ), ∀ v ∈ frameSector 1, v ∈ leechVOAPlus.grading k →
    D.Θ (mode (plusModule.YM v) (k - 1) y)
      = negOnePow k • mode (plusModule.YM (D.Ψ y)) (k - 1) (D.Φ v)

def BimodGenV3 : Prop := FZGenerated MV3 (2 : ℂ)

def TopPairs : Prop :=
  ∀ v ∈ OmegaV3, ∀ b ∈ OmegaV3,
    D.Θ (mode (plusModule.YM v) 1 (D.Φ b)) = mode (plusModule.YM b) 1 (D.Φ v)
```

File `VOA/Moonshine/FZBimoduleKey.lean`.

From the mathematics to the Lean statement

`MV3` is V_3^+ as an ordinary `V0P`-module (Chapter 40). `OmegaV3` $= (V_3^+)_2$. In `TopPairs`, `mode (plusModule.YM v) 1` is $o(v)$ for weight-2 v. `TopPairs` is a finite identity on a 49152-dimensional space (bilinear in v, b).

Physical meaning

`TopPairs` is the statement that the primary couplings of two weight-2 operators of V_3^+ to the lowest twisted states are symmetric under exchange of the two operators, once the triality is applied: a finite "crossing symmetry" of OPE coefficients.

Theorem 42.45 (The Frenkel–Zhu reduction and its converse). *(a)* `BimodGenV3` *and* `TopPairs D` *imply* `KeyTopAll D`.

(b) `KeyTopAll D` *implies* `TopPairs D` *(so* `TopPairs` *is also necessary).*

(c) Hence `BimodGenV3` *and* `TopPairs D` *imply* `KeySkew D t`*, and with* `PhiTop`, `ThetaTop`*, all targets.*

      V.IsSimple
```

File `VOA/Moonshine/FZBimoduleKey.lean`.

From the mathematics to the Lean statement

All hypotheses appear explicitly. (b) guarantees that the reduction did not replace the goal by a *stronger* unprovable statement: `TopPairs` is exactly what must be true.

Physical meaning

Fusion-rule logic: the space of intertwiners $V_3^+ \times T_s^+ \to T_{s+1}^+$ injects into top-level data, which is generated by the lowest states; so two intertwiners agree once their lowest couplings do. In CFT one would say the fusion coefficient $N = 1$ makes the coupling unique up to scale; here uniqueness is replaced by the more economical statement that the *difference* vanishes.

Proof on paper. (a) Let $S = \{v \in V_3^+ : F_y(v) = 0\ \forall y \in (T_s^+)_2\}$. By Theorem 42.43, S contains $O(V_3^+)$ and is closed under $a * \cdot$ and $\cdot * a$ (for the right action use $v * a = a * v - (a * v - v * a)$, and $F_y(v * a) = F_{o(a)y}(v)$ with $o(a)y$ top). On the top, $v \in (V_3^+)_2$: $F_y(v) = \Theta o(v)y - o(\Psi y)\Phi v$, which is `TopPairs` at $(v, \Psi y)$ since $\Phi\Psi y = y$. So S contains $(V_3^+)_2$, and `BimodGenV3` gives $S = V_3^+$. (b) Take $y = \Phi b$, $k = 2$. (c) Specialise $y = x$ and apply Theorem 42.36. □

Trap / dead end: How the intertwining Jacobi identity of W was avoided

The obvious route needed the three FZ top-level identities for the intertwiner W, i.e. its full intertwining Jacobi identity, which the library lacks (`Notes/KeySkew.md` §3; this was the recorded main risk). The trick: φ_2 is the top component of $W(\Phi v, z)\Psi y$, but it is *written* through the module modes $(\Psi y)_{(n)}$ acting on Φv, and Φ turns $a * v$ into an expression in modes of σa. The needed identities are then the transposed ones (Theorem 42.41), which require only the commutator formula of Y^T and the lowest weights. Neither the Jacobi identity of W, nor a transpose through `TPForm`, nor `Fusion.Intertwiner` is used.

What the machine verified

`Fy_lV`, `Fy_cV`, `Fy_resV`, `topPairs_of_keyTopAll`: unconditional given D. `keyTopAll_of_FZ`, `keySkew_of_FZ`: conditional on `BimodGenV3` and `TopPairs D`. `#print axioms VOA.Moonshine.FZKey.keySkew_of_FZ` (re-run): `[propext, Classical.choice, Quot.sound]`.

42.6.5 Bimodule generation of $A(V_3^+)$

Evidence: Numerical de-risking before formalisation

`BimodGenV3` was the recorded "real risk": the analogous strong-generation statement had *failed* for V_0^+ itself. It was first tested (`Notes/BimoduleGenTest.md`, `scripts/moonshine/numerics/bimodule/`) by the filtered criterion below at weights 3, 4, 5, exact arithmetic mod $2^{31}-1$: full rank in every excited sector; in the ground sector every coset vector v has a partner with $f=-1$ (counts at weight 3: 276; weight 4: 2048; weight 5: 11178); the pair lemma checked on 3937 patterns up to weight 30. *Control*: using only the left action (no 0-modes) gives rank 0 of 24 at weight 3 — the right action is essential. This is evidence; the Lean proof below is the proof.

Definition 42.46 (Weight-raising products). For an ordinary W-module M and $n\in\mathbb{Z}$, `lowerProdM N n` is the set of $a_{(j)}x$ with $a\in W_p$, $x\in M_q$, $q<n$, $j\le 0$, $p+q-j-1=n$.

```
def lowerProdM (N : OrdVModule W M) (n : ℤ) : Set M :=
  {y | ∃ p q j : ℤ, q < n ∧ j ≤ 0 ∧ p + q - j - 1 = n ∧
    ∃ a ∈ W.grading p, ∃ x ∈ N.weight (q : ℂ), y = N.act a j x}
```

File `VOA/Moonshine/FZGenFiltration.lean`.

From the mathematics to the Lean statement

`N.act a j x` is $a_{(j)}x$. $p+q-j-1$ is the weight of $a_{(j)}x$. So these are products landing in weight n built from strictly lower-weight module states using non-positive modes.

Physical meaning

States obtained by acting with creation-type modes ($j\le 0$) of chiral fields on lower states: "descendants and composites" of lower-weight fields.

Theorem 42.47 (Filtered generation criterion). *Let M be an ordinary W-module with integer weights bounded below by n_0, and $G\subseteq M$ with $M_n\subseteq \mathrm{span}(G\cup \texttt{lowerProdM}\,n)$ for all n. Then every subspace $S\supseteq G$ containing all $\mathrm{Res}_0(a,x)$ and closed under $a*\cdot$, $\cdot*a$ ($p\ge 1$) is M. Along the way: (module FZ Lemma 2.1.2) if a subspace contains all $\mathrm{Res}_0(a,x)$ for fixed x, it contains all $\mathrm{Res}_k(a,x)$.*

```
theorem PresM_mem (N : OrdVModule W M) (x : M) (X : Submodule ℂ M)
    (hbase : ∀ (p : ℕ) (a : V), a ∈ W.grading (p : ℤ) → fzCirc N p a x ∈ X) (k : ℕ) :
    ∀ (p : ℕ) (a : V), a ∈ W.grading (p : ℤ) → PresM N p a x k ∈ X

theorem eq_top_of_lowerSpanM (N : OrdVModule W M) (G : Set M) (n₀ : ℤ)
    (hint : ∀ α : ℂ, N.weight α ≠ ⊥ → ∃ k : ℤ, α = k)
    (hbot : ∀ k : ℤ, k < n₀ → N.weight (k : ℂ) = ⊥)
    (hG : ∀ n : ℤ, N.weight (n : ℂ) ≤ span ℂ (G ∪ lowerProdM N n))

    (hGS : G ⊆ S) : S = ⊤
```

File `VOA/Moonshine/FZGenFiltration.lean`.

From the mathematics to the Lean statement

`fzCirc N p a x` $= \mathrm{Res}_0(a,x) = a \circ x$ and `PresM N p a x k` $= \mathrm{Res}_k(a,x)$; here these are local copies in namespace `FZGen`, with `fzRight` summing $i < p$ (it agrees with `FZ.fzRight` for $p \geq 1$, `fzRight_eq`). `hint`: all weights are integers; `hbot`: nothing below n_0. Hypothesis `hO` uses only FZ's original $O(M)$ generators — strictly fewer than `fzO`.

Physical meaning

Induction on conformal weight: if every field of weight n is primary-generated or a composite of lower fields, and composites are reachable by left/right fusion and descendants, then everything is.

Proof on paper. Lemma 2.1.2 by induction on k, using $Y(L_{-1}a,z) = \partial_z Y(a,z)$ and a Pascal identity for the coefficients. Then induction on n: if $M_{<n} \subseteq S$, each $a_{(j)}x \in$ `lowerProdM n` lies in S — for $j = -1$ because $a * x - a_{(-1)}x$ has lower weight; for $j \leq -2$ because $a_{(j)}x - \mathrm{Res}_{-2-j}(a,x)$ has lower weight; for $j = 0$ because $a * x - x * a - a_{(0)}x$ has lower weight (the exact commutator). □

Theorem 42.48 (Charged excited spanning, generic form). *For $\gamma \in \Lambda \setminus \{0\}$ and any family $T(n)$ of subspaces of the Fock space with the closure property* `QuadClosed γ T`*, every Fock state of weight $w \geq 1$ lies in $T(w + \frac{1}{2}|\gamma|^2)$.*

```
def QuadClosed (γ : leech.carrier) (T : ℤ → Submodule ℂ Fk) : Prop :=
  ∀ (i j : ℕ) (a b : Fin (rank leech)) (n m : ℤ), m ≤ 0 → ∀ (w : ℕ) (p : Fk),
    p ∈ gradingWN (rank leech) w → (i : ℤ) + j + 2 < n → (w : ℤ) + LatGen.halfNorm leech γ
    ↪ < n →
    ((i : ℤ) + j + 2) + ((w : ℤ) + LatGen.halfNorm leech γ) - m - 1 = n →
    quadF γ a i b j (-m - 1) p ∈ T n

theorem gradingWN_le_of_quadClosed (hT : QuadClosed γ T) (hγ0 : γ ≠ 0) {w : ℕ} (hw : 1 ≤ w)
↪  :
    gradingWN (rank leech) w ≤ T ((w : ℤ) + LatGen.halfNorm leech γ)
```

File `VOA/Moonshine/FZGenExcited.lean`.

From the mathematics to the Lean statement

`Fk` is the 24-boson Fock space, `gradingWN _ w` its weight-w part; `halfNorm γ` is $\frac{1}{2}|\gamma|^2$; `quadF γ a i b j k p` is the Fock part of the action of the quadratic state $h_a(-i-1)h_b(-j-1)\mathbb{1}$ on $p \otimes e^{\gamma}$. `QuadClosed` says: weight-raising modes ($m \leq 0$) of quadratic Heisenberg states on lower charge-γ states lie in the target. The charge is arbitrary, in particular in the coset $\Lambda \setminus \Lambda_0$ of V_3^+.

Physical meaning

Every oscillator excitation of a charged state can be produced by bilinear currents $\partial X \partial X$ acting on lower excitations — the free-boson statement that the θ-even Heisenberg fields generate all excited states of a charged sector of nonzero momentum.

Proof on paper. The argument of Chapter 40 for V_0^+ (excited spanning), which used its target only through this closure and the charge only through $|\gamma|^2 \geq 4$ even: induction on the number of oscillators, with a degree-one base case solved by a small linear-algebra system in the charge coordinates. □

Theorem 42.49 (The pair lemma). *(a) If $x \in \mathbb{Z}^{24}$ has all entries odd, $x \cdot x \geq 48$ and $16 \mid x \cdot x$, there are $i \neq k$ with $|x_i| + |x_k| = 6$ or ≥ 10. (b) For $\nu \in \Lambda \setminus \Lambda_0$ with $|\nu|^2 \geq 6$ there is $\gamma \in \Lambda_0$ of norm 4 with $\langle \gamma, \nu \rangle = 3$ or ≥ 5.*

 ↪  :
    ∃ γ ∈ lambda0, leech.form γ γ = 4 ∧ (leech.form γ ν = 3 ∨ 5 ≤ leech.form γ ν)
```

File `VOA/Moonshine/FZGenV3.lean`.

From the mathematics to the Lean statement

`x ·ᵥ x` is the dot product; `leech.form` the Leech inner product. In (b), $x =$ `lν ν` (coordinates with $\langle \mu, \nu \rangle = \mu \cdot \nu/8$, all entries odd for $\nu \notin \Lambda_0$), and $\gamma = 4(\pm e_i \pm e_k)$; then $\langle \gamma, \nu \rangle = (|x_i| + |x_k|)/2$. Pure arithmetic; no Golay facts.

Physical meaning

A momentum-space statement: every high-momentum state of the odd sector can be split as the product of a norm-4 momentum of the even sector and a lower one, with an OPE singularity of the right order to produce it (the exponent $\langle \gamma, \nu - \gamma \rangle$ governs $e^{\gamma}(z)e^{\delta}(w) \sim (z-w)^{\langle \gamma, \delta \rangle}$).

Proof on paper. (a) Suppose every pair has $|x_i| + |x_k| \in \{2, 4, 8\}$. If two entries had magnitude ≥ 3, the pair sum $\in \{6, \geq 10\}$ unless they are $\{3, 5\}$, and no third value is then compatible; so at most one entry exceeds 1: $x = (m, (\pm 1)^{23})$ with m odd, $x \cdot x = m^2 + 23$. Now $m^2 + 23 \geq 48$ forces $|m| \geq 5$; $|m| = 5$ has the good pair $5 + 1 = 6$, and $|m| \geq 9$ has $|m| + 1 \geq 10$; the only remaining value $|m| = 7$ gives $x \cdot x = 72$, not divisible by 16. Contradiction. (b) Choose signs $s_i = \operatorname{sgn} x_i$. □

Theorem 42.50 ($A(V_3^+)$ is generated by its top). *(a) For $\nu \in \Lambda \setminus \Lambda_0$, $|\nu|^2 \geq 6$, the ground state $x_\nu = e^{\nu} + e^{-\nu}$ is in the span of weight-raising products of lower states. (b) For $n \geq 3$, $(V_3^+)_n \subseteq$ span `lowerProdM` n. (c) Every subspace of V_3^+ containing $O(V_3^+)$ and $(V_3^+)_2$ and closed under the left and right actions of homogeneous $a \in V_0^+$ is V_3^+; i.e.* `BimodGenV3` *holds.*

```

File `VOA/Moonshine/FZGenV3.lean`.

```
theorem fzGenerated_MV3 : FZ.FZGenerated MV3 (2 : ℂ)
```

File `VOA/Moonshine/FZGenBridge.lean`.

From the mathematics to the Lean statement

`Lv n` is `lowerProdM MV3 n` viewed inside V_Λ^+. `bimodGen_V3` is stated with the local operations; `fzGenerated_MV3` transfers it to the vocabulary of `FZBimodule.lean` (the operations agree on homogeneous a, and `fz0` contains the Res_0), so it is literally `BimodGenV3`. No hypotheses: unconditional.

Physical meaning

Every field of the odd frame sector V_3^+ is, modulo descendants, generated from its 49152 lowest-weight fields by fusion with the even chiral algebra V_0^+ from both sides.

Proof on paper. $(V_3^+)_n$ is spanned by projected word states $P(p \otimes e^\nu)$, $\nu \in \Lambda \setminus \Lambda_0$. Excited ones ($p$ of positive Fock weight) are handled by Theorem 42.48, with the target "Fock states whose projection is a combination of weight-raising products". Ground ones: pick γ by the pair lemma, $\delta = \nu - \gamma$, $f = \langle\gamma,\delta\rangle = \langle\gamma,\nu\rangle - 4$. If $f = -1$, $(x_\gamma)_{(0)}x_\delta = \pm x_\nu$. If $f = k \geq 1$, $(x_\gamma)_{(-k-1)}x_\delta = \pm(x_\nu + 2P(S_{2k}(\gamma)e^{\gamma-\delta}))$, the second term excited. Both are weight-raising products of lower states. Then the criterion (Theorem 42.47) with $G = (V_3^+)_2$, $n_0 = 2$. □

What the machine verified

`bimodGen_V3`, `fzGenerated_MV3`: unconditional. `#print axioms VOA.Moonshine.FZGen.fzGenerated_MV3` (re-run): `[propext, Classical.choice, Quot.sound]`.

42.7 The final finite identity

42.7.1 Everything reduced to `TopPairs`

Theorem 42.51 ($V^\natural$ from one finite identity). *For $\varepsilon^2 = 1$: if* `TopPairs` *holds for $D(c_\star, \varepsilon)$, where $c_\star^2\kappa_0 = 1$ is the fixed normalisation, then all targets of the final theorem hold.*

```
theorem moonshine_of_topPairs {ε : ℂ} (hε : ε * ε = 1)
    (htop : FZKey.TopPairs (mkData cStar0 ε (c_ne_of_norm cStar0_norm) hε)) :
    ∃ V : VertexOperatorAlgebra Vnat,
      V.Y = Ynat VnatAxioms.wbarL ∧ V.vacuum = vacNat ∧ V.conformalVector = omegaNat ∧

      Module.finrank ℂ (V.grading 2) = 196884 ∧
      (∀ n : ℕ, (Module.finrank ℂ (V.grading (n : ℤ)) : ℂ) = PowerSeries.coeff n JShift) ∧
      V.IsSimple
```

File `VOA/Moonshine/MainTopPairs.lean`.

From the mathematics to the Lean statement

`cStar0` is a fixed choice of c with `cStar0 * cStar0 * κ0 = 1` (`cStar0_norm`). The proof term is a one-line composition: `moonshine_of_keySkew cStar0_norm hε (FZKey.keySkew_of_FZ_tF_mem tF_ne FZGen.fzGenerated_MV3 htop)` — i.e. Theorems 42.28, 42.45, 42.50. The only hypotheses are `hε` and `htop`.

Physical meaning

The entire consistency of the Moonshine orbifold — that twist fields are mutually local — has been reduced to one finite table of OPE coefficients among the 49152 lowest states of the odd frame sector and the lowest twisted states. In the bootstrap language: crossing symmetry of the full theory follows from a finite set of primary couplings, given the symmetry structure.

What the machine verified

Conditional on `htop`; `#print axioms` (re-run): `[propext, Classical.choice, Quot.sound]`.

42.7.2 Sign arithmetic of two odd norm-4 Leech vectors

Work in the integer coordinates $n = (n_0, \dots, n_{23})$ (`lv n`) with $\langle \mu, \nu \rangle = \frac{1}{8}\mu \cdot \nu$. A norm-4 vector $n \in \Lambda \setminus \Lambda_0$ has one entry ± 3, at position $i = j(n)$ (`blk n`), and twenty-three entries ± 1. Define for odd x: $\chi(x) = 1$ if $x \equiv 1 \pmod 4$, else -1; and $s(x) = \operatorname{sgn} x$.

Definition 42.52 (Characters and the set N). For $n, m \in \Lambda$, $N(n,m) = \{k : \langle \gamma_{0k}^-, n\rangle + \langle \gamma_{0k}^-, m\rangle \text{ odd}\}$.

```
def chiZ (x : ℤ) : ℂ := if x % 4 = 1 then 1 else -1

def sgnZ (x : ℤ) : ℂ := if 0 < x then 1 else -1

noncomputable def NS (n m : leech.carrier) : Finset (Fin 24) :=
  Finset.univ.filter fun k => ¬ Even (leech.form (gM 0 k) n + leech.form (gM 0 k) m)
```

File `VOA/Moonshine/TopPairsArith.lean`.

From the mathematics to the Lean statement

`x % 4` is Lean's integer remainder, in $\{0,1,2,3\}$ for the modulus 4 (Euclidean for positive modulus), so for odd x it is 1 or 3; `chiZ` is χ. `sgnZ` is used only on nonzero arguments. `Finset.univ.filter` is $\{k \in \{0..23\} : \dots\}$. The theorem `uN_NS` identifies N as the character of the joint Z_{0k}-eigenvector $e_n e_m t_0$.

Physical meaning

N records which of the commuting $\mathbb{Z}/2$ "frame" symmetries Z_{0k} of the twisted ground states act by -1 on the state $e_n e_m t_0$: it is the charge vector of a ground state of the twisted sector under a maximal abelian subgroup of the extraspecial group 2^{1+24}.

Theorem 42.53 (The B-eigenvalue). *For $n, m \in \Lambda \setminus \Lambda_0$ of norm 4, with $i = j(n)$, $j = j(m)$,*

$$\omega^{|N(n,m)|} = (-1)^{\langle m,n\rangle}\, s(n_i m_i)\, s(n_j m_j).$$

```
theorem betaN_NS {n m : leech.carrier} (hn : n ∉ lambda0) (hn4 : leech.form n n = 4)
    (hm : m ∉ lambda0) (hm4 : leech.form m m = 4) :
    betaN (NS n m) = (-1 : ℂ) ^ (leech.form m n)
      * (sgnZ (lv n (blk n) * lv m (blk n)) * sgnZ (lv n (blk m) * lv m (blk m)))
```

File `VOA/Moonshine/TopPairsArith.lean`.

From the mathematics to the Lean statement

`betaN N` $= \prod_i(\omega$ if $i \in N$ else $1) = \omega^{|N|}$ (`betaN_eq`), $\omega = e^{i\pi/4}$ (`ωB`). `(-1 : ℂ) ^ (leech.form m n)` is an integer power. Hypotheses: odd coset and norm 4 for both vectors — exactly the top basis vectors.

Physical meaning

The operator B is the twisted-sector part of the triality, a "discrete Fourier transform" on the 2^{12} ground states; its eigenvalue on a ground state is an eighth root of unity determined by the charges. The theorem says this phase is in fact a sign, computable from the momenta n, m.

Proof on paper (counting $|N|$). Since $\langle \gamma_{0k}^-, n\rangle = (n_0 - n_k)/2$ and $(-1)^{(x-y)/2} = \chi(x)\chi(y)$ for odd x, y,

$$2|N| = \sum_k \big(1 - \chi(n_0)\chi(m_0)\,\chi(n_k)\chi(m_k)\big) = 24 - \chi(n_0)\chi(m_0)\sum_k \chi(n_k)\chi(m_k).$$

On the four possible values $\pm1, \pm3$ one has the polynomial identity $6\chi(x) = x(7 - x^2)$: $x = 1 \mapsto 6$, $x = -1 \mapsto -6$, $x = 3 \mapsto -6$, $x = -3 \mapsto 6$, matching $\chi(1) = 1, \chi(-1) = -1, \chi(3) = -1, \chi(-3) = 1$. Substituting and using $n_k^2, m_k^2 \in \{1, 9\}$,

$$36\sum_k \chi(n_k)\chi(m_k) = 36\,n \cdot m - 48(n_i m_i + n_j m_j) + 64[i = j]\,n_i m_i,$$

with $n \cdot m = 8\langle n, m\rangle$. Hence $|N| \equiv 0 \pmod 4$ and $|N|/4$ has the parity of $\langle m, n\rangle$ corrected by the block signs; $\omega^{|N|} = (-1)^{|N|/4}$. A finite case split over the signs finishes. No Golay-code fact is needed beyond $\langle n, m\rangle \in \mathbb{Z}$. □

Example 42.54. Take $n = m$. Then $N = \varnothing$ (each $\langle \gamma_{0k}^-, n\rangle$ is counted twice), $\omega^0 = 1$; on the right, $(-1)^4 s(9)s(9) = 1$. □

Theorem 42.55 (The coefficient identity). *For n, m as above and every l:*

$$c_\star(m)\Big(\delta_{jl} - \tfrac{n_j n_l}{4}\Big)u_l\,\omega^{|N|} = c_\star(n)(-1)^{\langle m,n\rangle}\Big(\delta_{il} - \tfrac{m_i m_l}{4}\Big),$$

where $u_l = (-1)^{[l\in N]}$.

```
theorem coef_identity {n m : leech.carrier} (hn : n ∉ lambda0) (hn4 : leech.form n n = 4)
    (hm : m ∉ lambda0) (hm4 : leech.form m m = 4) (l : Fin 24) :
    cStar m * ((if blk m = l then 1 else 0) - ((2 * lv n (blk m) * lv n l : ℤ) : ℂ) / 8)
        * (uN (NS n m) l * betaN (NS n m))
      = cStar n * (-1 : ℂ) ^ (leech.form m n)
        * ((if blk n = l then 1 else 0) - ((2 * lv m (blk n) * lv m l : ℤ) : ℂ) / 8)
```

File `VOA/Moonshine/TopPairsArith.lean`.

From the mathematics to the Lean statement

$\frac{2n_j n_l}{8} = \frac{n_j n_l}{4}$; `uN N l` $= -1$ if $l \in N$ else 1; `cStar n` $= i^{n_0} \cdot n_{j(n)}/3$. Note $\delta_{jl} - n_j n_l/4$ are the coordinates of $w_j - 2\langle w_j, n\rangle n$ in the frame basis.

Physical meaning

The equality of two explicit OPE coefficients: the coupling of (x_n, x_m) to the twisted state $h_{w_l}(-\frac{1}{2}) \otimes e_n e_m t_0$ in the two orders. It is the place where the phases of the cocycle, of the

triality on ground states, and of the oscillator part must conspire.

Proof on paper. Insert Theorem 42.53, $u_l = \chi(n_0)\chi(n_l)\chi(m_0)\chi(m_l)$, and $i^{m_0}\chi(n_0)\chi(m_0) = i^{n_0}$; what remains is a local identity in the coordinates i, j, l, checked by cases on $n_i, m_j \in \{\pm 3\}$ and the remaining entries ± 1. □

42.7.3 Both sides on the top basis

Theorem 42.56 (The top-pair identity). *(a) For $|n|^2 = 4$: $o(x_n)\big(h_v(-\frac{1}{2}) \otimes t\big) = 2^{-3} h_{v-2\langle v,n\rangle n}(-\frac{1}{2}) \otimes e_n t$. (b) $e_n e_m t_0$ is a joint Z_{0k}-eigenvector with character $N(n,m)$. (c) For all $v, b \in (V_3^+)_2$: $\Theta_0\big(o(v)\Phi_0 b\big) = o(b)\Phi_0 v$.*

```
theorem oX_hP {n : leech.carrier} (hn4 : leech.form n n = 4) (v : Fin (rank leech) → ℂ)
    (t : TLeechT) :
    mode (plusModule.YM (frameX0P n)) 1 (hP v t)
      = ((2 : ℂ) ^ (-(3 : ℤ))) • hP (latL n v) (eT leech leech_even
       ↪  leech_isUnit_det_gramMat n t)

theorem isEig_z (n m : leech.carrier) : IsEigN (NS n m) (zz n m)

theorem top_pairs0 {v b : VPlus} (hv : v ∈ OmegaV3) (hb : b ∈ OmegaV3) :
    Θ0 (mode (plusModule.YM v) 1 (Φ0 b)) = mode (plusModule.YM b) 1 (Φ0 v)
```

File `VOA/Moonshine/TopPairsCore.lean`.

From the mathematics to the Lean statement

`hP v t` is $h_v(-\frac{1}{2}) \otimes t$ for $v \in \mathbb{C}^{24}$ (orthonormal coordinates); `latL n v` is $v - 2\langle v, n\rangle n$; `eT …n` is e_n on T; `zz n m := eL n (eL m t0)`; `IsEigN N z` means $Z_{0k} z = u_k z$ for $k \neq 0$. (c) is for the *unnormalised* data.

Physical meaning

(a) is the twisted vertex operator of $e^n + e^{-n}$ acting on the lowest twisted states: it shifts the ground state by e_n and rotates the oscillator polarisation. (c) is the finite crossing symmetry of `TopPairs` for the explicit triality.

Proof on paper. (a) from the explicit twisted operator $Y^T(e^\alpha, z)$ of Chapter 36 at its top coefficient. (b) Z_{0k} commutes with e_n up to the sign $(-1)^{\langle \gamma_{0k}, n\rangle}$ and fixes t_0 (seed). (c) On the basis: $\Phi_0 x_m = c_\star(m) h_{w_j} \otimes e_m t_0$; by (a), $o(x_n)$ of it is $2^{-3} c_\star(m) \sum_l (\delta_{jl} - n_j n_l/4) h_{w_l} \otimes e_n e_m t_0$; Θ_0 acts on block l by ψ_l, i.e. by $u_l \omega^{|N|}$ (by (b)). The other side gives $2^{-3} c_\star(n) \sum_l (\delta_{il} - m_i m_l/4) h_{w_l} \otimes e_m e_n t_0$ and $e_m e_n = (-1)^{\langle m,n\rangle} e_n e_m$. Coefficients agree by Theorem 42.55. Extend bilinearly. □

Theorem 42.57 (`TopPairs`).

```
theorem TopPairs :
    FZKey.TopPairs (mkData cStar0 1 (c_ne_of_norm cStar0_norm) (by norm_num))
```

File `VOA/Moonshine/TopPairs.lean`.

From the mathematics to the Lean statement

`(by norm_num)` is the proof of $1 \cdot 1 = 1$. For $D(c_\star, 1)$ both sides of `TopPairs` are $c_\star$ times the two sides of Theorem 42.56(c). Unconditional.

Physical meaning

The correct "orientation" of the triality on the self-paired twisted sector is Θ_0 itself, with no extra sign.

Trap / dead end: The sign ε and the earlier numerics

For $\varepsilon = -1$, `TopPairs` would force $\Theta_0(o(x_n)\Phi_0 x_n) = 0$, which is false; this is *analysis only*, not machine-proved — and not needed. Before the proof, the identity was tested numerically with the library's own symbolic formulas on all 98304 odd norm-4 vectors (via the Golay code): 200,000 random pairs and 64 full rows, 0 failures. The earlier $N(A_1^{24})$ model had prescribed "$-\Theta_J$"; the relation of Θ_J to Θ_0 was never computed, and the Lean proof does not depend on it.

Theorem 42.58 (The Moonshine module). *There is a vertex operator algebra structure on $V^\natural$ whose vertex operator is the block operator (42.1), with vacuum $(\mathbb{1}, 0)$, conformal vector $(\omega, 0)$, central charge 24, $V^\natural_1 = 0$, $\dim V^\natural_n$ = the coefficient of q^n in the formal q-expansion $qJ(q)$ for all $n \geq 0$ (so $\dim V^\natural_2 = 196884$), and which is simple. These data determine the structure uniquely, so the theorem constructs a specific object. The Lean statement and its full fidelity check are in §42.8.*

```
theorem moonshine :
    ∃ V : VertexOperatorAlgebra Vnat,

      V.IsSimple :=
  moonshine_of_topPairs (by norm_num) topPairs_one
```

File `VOA/Moonshine/TopPairs.lean`.

Physical meaning

The chiral algebra of the $c = 24$ conformal field theory of Frenkel–Lepowsky–Meurman: a chiral CFT with a unique vacuum, no currents (no continuous symmetry), 196884 weight-two states (by FLM's theorem, the stress tensor plus 196883 primaries forming the smallest faithful representation of the Monster), and torus partition function $J(\tau)$. As a string compactification it is the internal CFT of the "Monster string". This is the physical picture, not the content of the Lean statement: the Monster symmetry, the holomorphy of the theory (a single irreducible module) and the analytic modular invariance of $J(\tau)$ are *not* part of this theorem.

42.8 The final theorem, read clause by clause

This section is the fidelity check of the headline result of the book. We restate the theorem, unfold *every* defined term that occurs in it down to standard mathematics, examine each conjunct, and ask how the statement could have been weaker than intended — vacuous, satisfied by an impostor, or silently using a different convention — and why it is not.

42.8.1 The statement and the objects it mentions

```
theorem moonshine :
    ∃ V : VertexOperatorAlgebra Vnat,
      V.Y = Ynat VnatAxioms.wbarL ∧ V.vacuum = vacNat ∧ V.conformalVector = omegaNat ∧

      (∀ n : ℕ, (Module.finrank ℂ (V.grading (n : ℤ)) : ℂ) = PowerSeries.coeff n JShift) ∧
      V.IsSimple
```

File `VOA/Moonshine/TopPairs.lean` (namespace `VOA.Moonshine`).

Shape. The statement is an existential: *there is* a term `V` of type `VertexOperatorAlgebra Vnat` — a VOA structure on the fixed vector space $V^\natural$ — satisfying eight conjuncts joined by ∧. There are no hypotheses, no section variables, no implicit arguments. The space $V^\natural$ is fixed in advance; what is asserted to exist is the *structure*, and the first four conjuncts then pin that structure down completely. So the existential is not a loophole: it is the standard way of saying "the following explicit data form a VOA".

A construction with a unique witness. Every datum of a `VertexOperatorAlgebra` on $V^\natural$ is fixed by the statement: `Y`, `vacuum` and `conformalVector` by conjuncts (1)–(3), `centralCharge` by (4); the `grading` is forced, because `isInternal` and `L0_grading` make `V.grading n` exactly the n-eigenspace of the pinned operator $L_0 = \omega_{(1)}$ (argued under (2)–(3) below); and all remaining fields are propositions (the field `finrank` is the `Prop` `FiniteDimensional`), so two witnesses with the same data are equal. Hence any two witnesses of the existential coincide: the theorem cannot be satisfied by "an unrelated VOA structure on the same space". It is a *construction* of one specific object, stated in the form "these explicit data satisfy the VOA axioms and the listed properties". (The release audit suggests, as a cosmetic improvement, exposing the witness as a named definition `Classical.choose moonshine`; the mathematical content is the same.) This uniqueness is also what excludes the recorded trap, the square-zero extension with $\overline{W} = 0$: it is not a witness, because conjunct (1) pins the twisted×twisted block to $\overline{W}$, which is proved nonzero (`leechWbar_ne_zero`), and independently because it is not simple (conjunct (8)); see the discussion under (8).

The type `VertexOperatorAlgebra`. This is the library's definition (Definitions 4.1 and 4.4), which we reproduce so that the referee need not turn back:

From the mathematics to the Lean statement

The definition is the textbook one, of CFT type (Frenkel–Lepowsky–Meurman, Gannon Def. 5.1.3): an internal $\mathbb{Z}$-graded space with finite-dimensional pieces (`DirectSum.IsInternal grading`: the canonical map $\bigoplus_n \mathcal{V}_n \to \mathcal{V}$ is an isomorphism), a linear state–field map $Y : \mathcal{V} \to \mathrm{End}(\mathcal{V})[[z^{\pm 1}]]$, a vacuum, grading compatibility, vacuum and creation axioms, locality, truncation, a conformal vector of weight 2 whose modes $L_n = \omega_{(n+1)}$ satisfy Virasoro with central charge c, L_0 acting by the grading, L_{-1}-translation, and CFT type ($\mathcal{V}_0 = \mathbb{C}\mathbb{1}$, $\mathcal{V}_{n<0} = 0$). The two blocks above are the library's two layers: `GradedVertexOperatorAlgebra` is the general FLM/Lepowsky–Li notion (grading truncated from below), and `VertexOperatorAlgebra` adds CFT type, its truncation field being filled automatically by $N = 0$; a `VertexOperatorAlgebra` is CFT type by definition. Locality plus the other axioms imply the Jacobi identity (Chapter 4). It is a demanding definition: the library has a recorded trap where an over-quantified axiom made a related structure (`TwistedModule`) unsatisfiable (Chapter 34); the *existence* of the concrete VOAs of Chapters 31–32, and here of $V^\natural$, shows this definition is satisfiable and non-degenerate. Note that CFT type and finite-dimensionality are *part of* the definition, so they are asserted for $V^\natural$ too.

Physical meaning

These are the axioms of the chiral algebra of a 2d CFT: states ↔ fields, a unique SL_2-invariant vacuum, mutually local fields, a stress tensor $T(z) = Y(\omega, z) = \sum L_n z^{-n-2}$ with central charge c, and L_0 = energy. CFT type means a unique vacuum and positive energies.

42.8.2 Conjunct by conjunct

(1) `V.Y = Ynat VnatAxioms.wbarL`: the vertex map is the genuine block operator.

```
abbrev Vnat : Type := SkewVP × TP
```

File `VOA/Moonshine/VnatCarrier.lean`.

```
noncomputable def Ynat (Wbar : TP →ₗ[ℂ] FormalDist (TP →ₗ[ℂ] SkewVP)) :
    Vnat →ₗ[ℂ] FormalDist (End ℂ Vnat) where
  toFun x := blockF (leechVOAPlus.Y x.1) (Wbar x.2) (leechWskLin x.2) (plusModule.YM x.1)
```

File `VOA/Moonshine/VnatFields.lean`.

```
noncomputable def wbarL : TP →ₗ[ℂ] FormalDist (TP →ₗ[ℂ] SkewVP) where
  toFun := leechWbar
```

File `VOA/Moonshine/VnatAxioms.lean`.

```
noncomputable def leechWbar (t : TP) : FormalDist (TP →ₗ[ℂ] SkewVP) :=
  Wbar leechBV plusModule TPForm TPForm_weightOrth t
```

File `VOA/Moonshine/WbarLeech.lean`.

```
noncomputable def leechWsk (t : TP) : FormalDist (SkewVP →ₗ[ℂ] TP) :=
  Wsk plusModule.toWeakModule t
```

File `VOA/Moonshine/SkewLeech.lean`.

From the mathematics to the Lean statement

Decoding. For $x = (u, t) \in V^\natural$, `Ynat wbarL x` is the 2×2 block field (42.1): top-left $Y(u, z)$, the vertex operator of the VOA V_Λ^+ (`leechVOAPlus`, Chapter 32); bottom-right $Y^T(u, z)$, the module vertex operator of V_Λ^+ on $(V_\Lambda^T)^+$ (`plusModule`, Chapter 36); bottom-left $W(t, z)$, the skew intertwiner $W(t, z)\varphi = e^{zL_{-1}} Y^T(\varphi, -z)t$ (`Wsk`, Chapter 37); top-right $\overline{W}(t, z)$, the adjoint of W through the canonical forms `leechBV` and `TPForm` (`Wbar`, Chapter 37). `wbarL` is merely `leechWbar` packaged as a linear map.

Why this conjunct is essential. Without it, the theorem would assert the existence of *some* VOA on the vector space $V^\natural$ with the listed numerical properties, and the space $V^\natural$ would be playing no role beyond its graded dimension. With it, the vertex operator is *the* FLM/DGM vertex operator on $V_\Lambda^+ \oplus (V_\Lambda^T)^+$: every field is the explicit untwisted, twisted, or intertwining field built in Chapters 31–37.

The adjoint is not zero. The theorem

```
theorem leechWbar_ne_zero : leechWbar ≠ 0
```

File `VOA/Moonshine/VnatGenuine.lean`. shows that the top-right block is genuinely present: for a nonzero weight-2 twisted t there is t' with $\overline{W}(t)_{(3)}t' = c\,\mathbb{1}$, $c \neq 0$.

Physical meaning

The OPE of two twist fields contains the identity operator: $\sigma_t(z)\sigma_{t'}(w) \sim \langle t, t'\rangle (z-w)^{-4}\mathbb{1} + \cdots$ for weight-2 twist fields. This is what $\overline{W} \neq 0$ expresses, and it is what makes the twisted sector part of one theory rather than a module glued on with no interaction.

(2)–(3) `V.vacuum = vacNat`, `V.conformalVector = omegaNat`.

```
noncomputable def vacNat : Vnat := (leechVOAPlus.vacuum, 0)

noncomputable def omegaNat : Vnat := (leechVOAPlus.conformalVector, 0)
```

File `VOA/Moonshine/VnatCarrier.lean`.

From the mathematics to the Lean statement

Vacuum and conformal vector are those of V_Λ^+, i.e. of the Leech lattice VOA: $\mathbb{1} = e^0$ and $\omega = \frac{1}{2}\sum_{a=1}^{24} h_a(-1)^2\mathbb{1}$ (Chapter 31).
The grading is determined by (1)–(3). The theorem does not say `V.grading = gradingNat`, but it need not: by `L0_grading` each `V.grading n` is contained in the n-eigenspace of $L_0 = \omega_{(1)}$, and because the grading is an internal direct sum, it *equals* that eigenspace (decompose an eigenvector into homogeneous components; each component is an eigenvector of its own weight, so only the weight-n component survives). Since Y and ω are pinned, L_0 is the explicit operator $L_0 \oplus L_0^T$, and `V.grading n` is the explicit space $(V_\Lambda^+)_n \times (T^+)_n$ (the library's `gradingNat n`). Thus the dimension statements (5)–(7) refer to the intended spaces, not to an arbitrary regrading. Likewise `V.L n` are the explicit Virasoro operators.

Physical meaning

The stress tensor of the orbifold is the stress tensor of the 24 free bosons, $T = -\frac{1}{2}\sum {:}\partial X^a \partial X^a{:}$, which is θ-invariant; the orbifold does not change the conformal structure.

(4) `V.centralCharge = 24`. With ω pinned, c is determined by $[L_2, L_{-2}] = 4L_0 + \frac{c}{2}$; a wrong value would be refutable. It is the rank of the Leech lattice.

Physical meaning

$c = 24$: 24 free bosons; the critical dimension of the bosonic string after light-cone gauge. Holomorphic $c = 24$ CFTs are exactly those whose characters are (essentially) modular functions, $Z(\tau) = J(\tau) + \text{const}$.

(5) `V.grading 1 = ⊥`. ${V^\natural}_1 = 0$: $\perp$ is the zero subspace. This holds because $(V_\Lambda^+)_1 = 0$ (θ kills the 24 currents $h_a(-1)\mathbb{1}$, and Λ has no roots) and T^+ starts in weight 2.

Physical meaning

No weight-one states means no conserved currents: the Moonshine CFT has no continuous symmetry — its symmetry group is finite (by FLM's theorem it is the Monster; Aut $V^\natural = \mathbb{M}$ is not formalized). This distinguishes it from the Leech lattice theory, whose 24 currents generate a $U(1)^{24}$.

(6) `Module.finrank ℂ (V.grading 2) = 196884`. `Module.finrank ℂ S` is the dimension of the subspace S (a natural number; it would be 0 for an infinite-dimensional space, but every `V.grading n` is finite-dimensional by the axiom `finrank`). $196884 = 98580 + 98304$ ($(V_\Lambda^+)_2$ plus $(T^+)_2 = 24 \cdot 4096$).

Physical meaning

$196884 = 1 + 196883$: the stress tensor and the smallest nontrivial representation of the Monster (a fact from the literature; no Monster action is formalized); McKay's observation that started Monstrous Moonshine. The weight-two space carries the commutative non-associative Griess algebra via $a \cdot b = a_{(1)}b$.

(7) the full graded dimension.

```
noncomputable def jShift : PowerSeries ℂ :=
  E4Series ^ 3 * ((deltaOverQUnit⁻¹ : (PowerSeries ℂ)ˣ) : PowerSeries ℂ)

noncomputable def JShift : PowerSeries ℂ := jShift - (744 : ℂ) • PowerSeries.X
```

File `VOA/Modularity/JFunction.lean`.

From the mathematics to the Lean statement

`E4Series` is the q-expansion $1 + 240\sum \sigma_3(n)q^n$ of E_4; `deltaOverQUnit` is $\Delta/q = \prod(1-q^n)^{24}$, invertible as a power series (constant term 1). So `jShift` $= E_4^3 q/\Delta$ is the formal q-expansion of $q\,j$, and `JShift` $= q(j - 744) = q\,J$ is the formal q-expansion of qJ:

$$\texttt{JShift} = 1 + 0 \cdot q + 196884\,q^2 + 21493760\,q^3 + \cdots .$$

`PowerSeries.coeff n` is the coefficient of q^n; the cast to $\mathbb{C}$ compares a natural-number dimension with a complex coefficient. The conjunct says $\sum_n \dim V^\natural{}_n\, q^n = qJ(q)$, i.e. $\mathrm{ch}\, V^\natural = q^{-1}\sum \dim V^\natural{}_n q^n = J$. It is *independent* of (5) and (6) in principle, consistent with them ($[q^1] = 0$, $[q^2] = 196884$), and was proved in Chapter 33 from $\Theta_\Lambda = E_4^3 - 720\Delta$ and the twisted-sector character. The quantifier is over all $n \in \mathbb{N}$; negative n are covered by `positivity`.

Formal, not analytic. `JShift` is a formal power series, defined from divisor sums; it is not a function on the upper half plane. That it is the q-expansion of Klein's analytic $j(\tau) - 744$ is classical (and follows on paper from Mathlib's q-expansions of E_4 and Δ, Chapter 33), but no Lean theorem identifies `JShift` with the analytic function, and no modular-invariance statement about the character of $V^\natural$ is formalized. The conjunct is therefore "graded dimension $= J$" in the standard sense of formal q-series, which is how the statement of FLM is usually read.

Physical meaning

The torus partition function of the chiral CFT, $Z(\tau) = \mathrm{tr}_{V^\natural}\, q^{L_0 - c/24}$, equals $J(\tau)$: it is modular invariant, as a holomorphic $c = 24$ theory must be, with no constant term (no currents). (Heuristic: the Lean conjunct equates formal q-series coefficients; neither the analytic modular invariance nor holomorphy of $V^\natural$ is formalized.)

(8) `V.IsSimple`.

```
def IsIdeal (W : VertexOperatorAlgebra V) (I : Submodule ℂ V) : Prop :=
  ∀ (u v : V) (n : ℤ), v ∈ I → W.smul u n v ∈ I
```

```
def IsSimple (W : VertexOperatorAlgebra 𝒱) : Prop :=
  (⊤ : Submodule ℂ 𝒱) ≠ ⊥ ∧ ∀ I : Submodule ℂ 𝒱, W.IsIdeal I → I = ⊥ ∨ I = ⊤
```

File `VOA/Core/BilinearForm.lean`.

From the mathematics to the Lean statement

An ideal is a subspace stable under all modes $u_{(n)}$ (a left ideal; for VOAs L_{-1}-stable left ideals are two-sided by skew-symmetry, and $L_{-1} = \omega_{(0)}$ is among the modes). Simple: nonzero (`⊤ ≠ ⊥`), and the only ideals are 0 and everything. Since *all* left ideals are excluded, not only two-sided ones, this notion is at least as strong as the textbook notion of a simple VOA.

Why this conjunct cannot be dropped — the square-zero impostor. Recorded trap (Section 43.2.2, Chapter 38): replacing $\overline{W}$ by 0 in (42.1) gives the square-zero extension $V_\Lambda^+ \ltimes (V_\Lambda^T)^+$. It *is* a VOA, with the same vacuum, conformal vector, $c = 24$, $V_1 = 0$, $\dim V_2 = 196884$ and graded dimension J — it satisfies conjuncts (2)–(7). It is *not* $V^\natural$, and it is excluded twice: (i) by conjunct (1), since `leechWbar ≠ 0`; (ii) by simplicity, since $0 \oplus (V_\Lambda^T)^+$ is a proper nonzero ideal there (untwisted fields preserve it, twisted fields send untwisted states into it and kill it). Either exclusion alone suffices; the theorem has both. In the library simplicity was proved via nondegeneracy of an invariant form on $V^\natural$ that pairs the twisted sector with itself through $\overline{W}$ — exactly what fails for the impostor.

Physical meaning

Simplicity is the algebraic form of "a unique vacuum and a non-degenerate two-point function": no decoupled sector, every state has a nonzero overlap with some other state. A unitary CFT with a unique vacuum has a simple chiral algebra.

42.8.3 How the constructed object relates to FLM's $V^\natural$

Conjuncts (1)–(4) fix the data $(V^\natural, Y, \mathbb{1}, \omega, c)$ completely: the carrier is FLM's space $V_\Lambda^+ \oplus (V_\Lambda^T)^+$, and the vertex operator is the explicit block operator (42.1). Given those, (5)–(8) are *properties* of a fixed object, not choices; they are what the literature states about $V^\natural$. What the Lean theorem does *not* contain is a comparison with FLM's own vertex operator algebra, and the reader should be clear about where the two presentations differ.

- The carrier, the untwisted block Y, the twisted-module block Y^T and the intertwiner block W are FLM's (up to the conventions recorded in Chapters 31–37).
- The twisted×twisted block $\overline{W}$ is *defined* as the adjoint of the skew intertwiner W through the invariant forms `leechBV` and `TPForm` (Chapter 37). This is the presentation of Huang and of Dolan–Goddard–Montague, *not* FLM's explicit formula for the twisted vertex operators on $T \times T$; likewise the locality relation (4.23) is proved here by the Frenkel–Zhu / triality reduction of this chapter, not by FLM's own route.
- No Lean theorem states that the constructed VOA is isomorphic to FLM's $V^\natural$. On paper the identification is standard: $(V_\Lambda^T)^+$ is a simple current of V_Λ^+, and a simple-current extension of V_Λ^+ by it carries at most one VOA structure up to isomorphism (Dong–Mason, Prop. 5.3; see the notes), so any two such structures — FLM's and the one constructed here — are isomorphic. That uniqueness theorem is not formalized.

One normalisation subtlety remains: the library's $\overline{W}$ is fixed by the canonical forms (`leechBV` normalised by $(\mathbb{1}|\mathbb{1}) = 1$, and `TPForm`). Rescaling the twisted sector by λ rescales the twisted×twisted block by a nonzero scalar and gives an isomorphic VOA, so normalisations of this kind do not affect the isomorphism class. It is therefore fair to call the constructed object "the Moonshine module $V^\natural$

(the FLM Leech-lattice orbifold)"; it is *not* fair to say that FLM's construction is formalized verbatim, or that the isomorphism with FLM's $V^\natural$ is proved.

42.8.4 What the theorem does not say

- **No uniqueness.** It does not say that $V^\natural$ is the unique holomorphic $c = 24$ VOA with $V_1 = 0$ (the FLM uniqueness conjecture; proved under additional hypotheses, e.g. by Dong–Griess–Lam, see the notes). It does not say any VOA with these numerical properties is isomorphic to $V^\natural$ — the square-zero impostor shows the numerical properties alone do not suffice.

- **No Monster.** It does not construct Aut $V^\natural$ or identify it with the Monster group; the Lean library contains no Monster group. The triality $\sigma^\natural$ used in the proof is *not* asserted to be an automorphism in the final statement (it is one, by the proof, but no Lean theorem states it).

- **No McKay–Thompson series**, no Borcherds' Monstrous Moonshine theorem, no modular invariance of trace functions (only the graded dimension), no rationality or C_2-cofiniteness of $V^\natural$.

- **No module category**: holomorphicity (that $V^\natural$ is its only irreducible module) is not stated.

- **No analytic j in the statement.** The headline's J is the formal q-series `JShift`; that it is the q-expansion of the analytic $j(\tau) - 744$ on the upper half plane is a separate Lean theorem (`Moonshine.qExpansion_qJ`, `Moonshine.hasSum_JShift`), not a clause of `moonshine`.

- **No isomorphism with FLM's explicit $V^\natural$.** See the previous subsection: the twisted×twisted block is the form-adjoint $\overline{W}$, and the identification with FLM's own vertex operators rests on the (unformalized) uniqueness of simple-current extensions.

Accordingly, none of the following may be said on the strength of this theorem: "$V^\natural$ is characterised / unique", "Aut$(V^\natural) = \mathbb{M}$", "$V^\natural$ is holomorphic", or "FLM's construction is formalized verbatim".

42.8.5 Axioms and the trust model

```
'VOA.Moonshine.moonshine' depends on axioms: [propext, Classical.choice, Quot.sound]
```

This was run for this chapter at an earlier commit (when the chapter was first written; not re-run for this edition) with `lake env lean -DmaxSynthPendingDepth=3` on a file importing `VOA.Moonshine.TopPairs` (the flag is required: a bare `lake env lean` can silently drop it). The three axioms are Lean's standard ones (propositional extensionality, choice, quotient soundness). `VOA.pbw` (the PBW theorem of Chapter 3; formerly the library's only project axiom, now a theorem) does *not* appear: the Moonshine construction does not use it. `#print axioms` does not report hypotheses — but `moonshine` has none. So the theorem is *unconditional*. The project's build record for that earlier commit reports an aggregate `lake build` of 10343 jobs with exit 0 and `scripts/check_repository.py` passing; the full build was not re-run for this chapter. One upstream definition was changed during the Moonshine work: the repair of `TwistedModule.jacobi` (Chapter 34); the core definitions of VOA, module, J used in this statement are otherwise unchanged in content. (For the release the vertex-algebra structures were renamed and layered — `PreVertexAlgebra`, and `VertexOperatorAlgebra` extending `GradedVertexOperatorAlgebra` — without changing the fields a VOA must supply; the truncation field of the new middle layer is filled automatically from `positivity`.)

Release audit 2026-10-27: `RELEASE_AUDIT_MOONSHINE.md`. An independent release audit (`Notes/Textbook/referee` at an earlier commit, not re-run for this edition) re-ran `#print axioms` for `VOA.Moonshine.moonshine` and `moonshine_of_topPairs` (result: the three standard axioms), confirmed `leechWbar_ne_zero` and two non-vacuity examples (the witness's grading pieces are L_0-eigenspaces of the pinned vertex map; the twisted×twisted block of the pinned map is nonzero), and scanned the 619 modules of the import closure for `axiom`, `sorry`, `native_decide` and similar escape hatches (none outside comments; the closure does not contain `VOA/Foundations/AffineLie.lean`, where `VOA.pbw` lives). Its verdict is "announceable with caveats": no mathematical or formal defect, and caveats on wording only — the unique-witness reading of the existential, J as a formal q-series, the informal identification with FLM's explicit $V^\natural$, and the absence of the Monster, holomorphy and uniqueness. This chapter has been worded accordingly. The audit did not re-run the aggregate `lake build`; the release commit still requires one.

42.8.6 The dependency chain through the book

ingredient	where
VOA axioms, locality, forms	Chapters 4–5
Leech lattice, Golay code	Chapter 30
V_Λ (`leechVOA`), $c = 24$	Chapter 31
θ, V_Λ^+, $(V_\Lambda^+)_1 = 0$, `leechBV`	Chapter 32
graded dimension $= J$	Chapter 33
twisted modules (repair), T	Chapters 34–35
V_Λ^T, $(V_\Lambda^T)^+$ (`plusModule`)	Chapter 36
W, $\overline{W}$, `TPForm`	Chapter 37
block VOA modulo (4.23); simplicity	Chapter 38
frame, σ on V_0^+	Chapter 39
twisted triality: Zhu generation, existence	Chapters 40–41
(4.23) via conjugation, FZ, `TopPairs`	this chapter

What the machine verified

`VOA.Moonshine.moonshine`: **unconditional** (no hypotheses); a construction with a unique witness; `#print axioms` = `[propext, Classical.choice, Quot.sound]` (re-run for this chapter, and again by the release audit of 2026-10-27). Not formalized: Aut $V^\natural = \mathbb{M}$, holomorphy, uniqueness of $V^\natural$, the analytic j, and the isomorphism with FLM's explicit $V^\natural$.

Part VIII

Verification

Chapter 43

Verification, dead ends, numerics and open problems

This chapter documents the release of the library named in the front matter; every Lean quotation is checked by `scripts/textbook/sync.py` to occur verbatim (up to whitespace and comments) in the source files of that release. Its body was first written against the commit "Construct the Moonshine module $V^\natural$ (FLM) unconditionally" (7 October 2026, then the head of the main branch; "the Moonshine commit" below); records tied to that snapshot, and other checks not re-run for this edition, are marked as such, and the update of October 2026 is described below. The preceding fourteen chapters presented the mathematics of the LeanVOA library and, as their culmination, the construction of the Moonshine module $V^\natural$. Each of them followed the same discipline: a mathematical statement, the Lean declaration copied verbatim from the repository, a fidelity check explaining why the one is the other, an argument on paper, and an honest status report. This last chapter turns the discipline on the library as a whole. It asks four questions that a referee-editor must be able to answer before signing off on the book.

(1) *What exactly has been checked, by what, and how would we know if it had not?* The answer is a verification protocol made of a compiler run, two scripts and a manual audit, each of which certifies something specific and nothing more (Section 43.1).

(2) *Which statements were wrong, vacuous or circular at some point, and how was that discovered?* The project kept a register of dead ends, traps and corrected mistakes, library-wide and for the Moonshine construction in particular. Section 43.2 consolidates it, each entry with its precise statement, the certificate of failure and the lesson.

(3) *What was computed numerically, and what is the status of those computations?* Section 43.3 describes every numerical experiment of the Moonshine construction, with its method, tolerance and controls, and says plainly that none of it is part of any proof.

(4) *Why was the construction done this way, can it be reproduced, and what is still open?* Sections 43.4, 43.5 and 43.6.

Throughout, four registers of claims are kept strictly apart, as the project's working agreements demand:

- **proved unconditionally** in Lean: the declaration has no hypothesis that is not itself established, and `#print axioms` lists only Lean's three standard axioms;
- **proved conditionally** in Lean: the declaration is accepted by the kernel, but its statement carries a hypothesis (a `Prop`-valued premise, or a structure that has to be supplied) which is not proved anywhere; the hypothesis is then named;

- **checked numerically**: a computer calculation outside Lean, in floating point or in exact arithmetic, agrees with the claim on a finite sample; this is evidence, never proof;
- **argued on paper only**, or **open**.

Earlier editions had a fifth register, **proved using the project axiom** `VOA.pbw`; since 19 October 2026 that axiom is a theorem, and the register is empty (Section 43.1.2; Chapter 3, Section 3.2). The Moonshine construction never used it.

The update of October 2026. The body of this chapter was written against the Moonshine commit. In October 2026 the book was brought up to date with the library on the branch `deligne-lean`: five chapters were added (Chapters 23–27: affine vertex algebras for every simple Lie algebra and the four chapters on the Deligne series; the chapter on affine $\hat{\mathfrak{sl}}_3$ is in preparation; the two chapters on graded unitarity through the BRST coset, Chapters 28 and 29, were added for the v1.0 release), Chapters 11, 19 and 20 were extended, and every chapter that described `VOA.pbw` as an axiom was corrected. The present chapter was extended, not rewritten, to cover that work. The additions are: the book's own verification record and the trust base at the manifest commit (Section 43.1.10); the independent release audits of 27–28 October 2026 (Section 43.1.11); the dead ends recorded in the new and extended chapters (Section 43.2.9); and the open problems that those chapters name (Section 43.6.3). Following the book's scope decision, work in progress in the library is not described; where a route is under development, we say so and nothing more.

Remark 43.1 (A note on the physics)**.** A physicist reading this chapter may wonder why so much effort goes into checking that a statement means what it says. In a conformal field theory one rarely writes down the axioms of the operator algebra completely; one computes correlation functions and trusts that locality, associativity and modular invariance hold because the theory "exists". A formalization cannot work that way. Every axiom is a line of code, and a mistyped quantifier produces a theory that either does not exist (no nonzero object satisfies the axioms) or exists for trivial reasons (the zero theory, or a degenerate extension). Both happened in this project. The checks of this chapter are the mathematical counterpart of a physicist's sanity checks: is the partition function right, is the vacuum unique, does the operator product expansion close, and is the theory non-trivial.

43.1 The verification protocol

43.1.1 What a Lean proof certifies, and what it does not

A Lean file is a sequence of declarations: definitions (`def`, `structure`, `abbrev`) and theorems (`theorem`). A theorem declaration has the shape

```
theorem name (hypotheses) : statement := proof
```

When the file is compiled, Lean's *kernel*, a small and carefully audited type checker, verifies that `proof` is a term of type `statement` in the context of the hypotheses. This is the only thing a successful compilation certifies, and it is a great deal: every step of every argument has been checked down to the rules of dependent type theory. It is not everything a reader wants, for three reasons.

(a) *Definitions are trusted, not verified.* If `statement` mentions a notion such as `VertexOperatorAlgebra`, `IsSimple` or `TwistedModule`, the kernel checks the proof against the definition as written. It cannot know whether the definition captures the intended mathematical notion. A definition with a mistyped quantifier is a perfectly good definition of something else. This is why the book prints every definition verbatim and checks its fidelity; it is also the most common source of the dead ends of Section 43.2.

(b) *Hypotheses are assumed, not proved.* A theorem with a hypothesis (`h : P`) proves "P implies the statement". If P is false, or unsatisfiable, the theorem is true and worthless.

(c) *Axioms are assumed.* A declaration introduced with `axiom` is accepted without proof, and every theorem whose proof term mentions it, directly or through a chain of lemmas, depends on it.

The verification protocol of the project addresses each of these. Point (c) is handled mechanically, by `#print axioms` and the axiom audit; point (b) by a rule of language ("unconditional" versus "conditional") and a manual trace of hypotheses; point (a) only by human reading, which is what the fidelity checks of this book are for.

43.1.2 The trust base: three standard axioms (and the former project axiom)

Lean's logic has three axioms that essentially all of Mathlib uses:

- `propext` (*propositional extensionality*): two propositions that imply each other are equal;
- `Quot.sound`: the quotient of a type by a relation identifies related elements; this is what makes quotient constructions (such as quotient modules, or the Zhu algebra $A(V) = V/O(V)$) behave as in ordinary mathematics; it also implies function extensionality;
- `Classical.choice`: from a proof that a type is nonempty one may extract an element; this gives the law of excluded middle and all of classical reasoning, including the choice of bases of vector spaces.

These three are the background logic of ordinary mathematics (Zermelo–Fraenkel set theory with choice proves corresponding statements), and a theorem whose axiom list is a subset of {`propext`, `Classical.choice`, `Quot.sound`} is called `#print axioms`-*clean*.

The library adds no axiom of its own. Until 19 October 2026 it added exactly one, in `VOA/Foundations/AffineLie.lea` the same declaration is now a theorem:

```
structure PBWPrinciple : Prop where
  /-- PBW nonvanishing for every affine vacuum module. -/
  affineVacuum : ∀ {𝔤 : Type u} [LieRing 𝔤] [LieAlgebra ℂ 𝔤]
      (κ : LinearMap.BilinForm ℂ 𝔤) (hκ : κ.IsInvariant) (k : ℂ),
    PBW κ hκ k
  /-- The canonical bottom embeds in every module induced from a Lie subalgebra. -/
  inducedBottom : ∀ {g U : Type u} [LieRing g] [LieAlgebra ℂ g]
      [AddCommGroup U] [Module ℂ U] (p : LieSubalgebra ℂ g)
      (rho : p →ₗ[ℂ] Module.End ℂ U),
    Function.Injective (PBWInduction.bottom p rho)

theorem pbw : PBWPrinciple :=
  ⟨fun κ hκ k => AffineLie.vacuumVector_ne_zero_of_induction κ hκ k,
    fun p rho => PBWTheorem.bottom_injective p rho⟩
```

where `PBW κ hκ k` is defined, in the same file, as `AffineLie.vacuumVector κ hκ k ≠ 0`.

From the mathematics to the Lean statement

What the principle says. The Poincaré–Birkhoff–Witt theorem says that the universal enveloping algebra $U(\mathfrak{g})$ of a Lie algebra has a basis of ordered monomials in a basis of $\mathfrak{g}$; consequently $U(\mathfrak{g})$ is free as a right module over $U(\mathfrak{p})$ for any subalgebra $\mathfrak{p}$. The principle bundles two consequences of PBW:

- `affineVacuum`: for every Lie algebra $\mathfrak{g}$ over $\mathbb{C}$ with an invariant bilinear form κ and every

level $k \in \mathbb{C}$, the vacuum vector of the affine vacuum module $V^k(\mathfrak{g}) = U(\hat{\mathfrak{g}}) \otimes_{U(\mathfrak{g}[t] \oplus \mathbb{C}K)} \mathbb{C}_k$ is nonzero. (Without PBW one cannot exclude that the induced module collapses to 0.)

- `inducedBottom`: for a Lie subalgebra $\mathfrak{p} \subseteq \mathfrak{g}$ and a representation ρ of $\mathfrak{p}$ on U, the canonical map $U \to U(\mathfrak{g}) \otimes_{U(\mathfrak{p})} U$, $u \mapsto 1 \otimes u$, is injective.

Both are classical theorems; Mathlib (v4.30.0) does not provide PBW, and the library now proves the needed relative form itself (Chapter 3, Section 3.10.6). The quantification over all universes `Type u` is the reason the statement is a `structure` of two fields rather than two separate declarations. **Could it be mis-stated?** Since it is proved, it cannot be inconsistent; the remaining risk is a mis-encoding of `PBWInduction.bottom` or `vacuumVector` that would make it weaker than intended, which is why those definitions are printed and checked in Section 3.10.

Physical meaning

PBW is the algebraic statement that a Verma-type module built by acting with creation operators on a highest-weight state is "as large as it looks": the states $J^{a_1}_{-n_1} \cdots J^{a_r}_{-n_r}|0\rangle$ with ordered modes are linearly independent before any null vectors are quotiented out. Every physicist uses this silently when counting the states of a current algebra (the Wess–Zumino–Witten vacuum module at level k) or when writing the character $\prod_n (1-q^n)^{-\dim \mathfrak{g}}$ of the universal affine algebra. `VOA.pbw` (with `pbwBasis_holds`) proves exactly that counting, nothing more.

Where `VOA.pbw` is used, and the twin pattern (history). While `VOA.pbw` was an axiom, the library followed a strict pattern (Chapter 3, Section 3.2): wherever a result needed PBW, it was proved twice. One version carries the needed consequence as an explicit hypothesis (a datum such as `Pr : BottomProjection ...`) and is `#print axioms`-clean; a companion wrapper, whose name ends in `_voaPBW` or `_of_voaPBW`, supplies that datum from `VOA.pbw`. Since `VOA.pbw` became a theorem the datum is supplied by a theorem, so each `_voaPBW` wrapper is the form of its twin with the PBW datum discharged. The two most important instances are Zhu's bijection and Zhu's modularity theorem. From `VOA/Modules/ZhuVermaAnArchLUBijection.lean` and `VOA/Modules/ZhuVermaAnArchLUBijectionPBW.lean`:

```
theorem zhuBijective (Pr : BottomProjection (parabolicRepOfAMod W (regularAMod W))) :
    Function.Bijective (forwardMapIrr W) :=

theorem zhuBijective_of_voaPBW (W : VertexOperatorAlgebra 𝒱) :
    Function.Bijective (forwardMapIrr W) :=
  zhuBijective
    (voaPBWBottomProjection (parabolicRepOfAMod W (regularAMod W)))
```

and from `VOA/Modularity/GNProp8Closure.lean` and `VOA/Modularity/GNProp8PBW.lean`:

```
theorem zhuModularity_pinned_of_C2Cofinite [Finite (Φ W)]
    (Mfam : ι → IrrModule W) (h : ι → ℂ)
    (hC2 : C2Cofinite W)
    (hss : letI := instRingA W; IsSemisimpleRing (A W))
    (Pr : BottomProjection (parabolicRepOfAMod W (regularAMod W)))
    (hcard : Fintype.card ι = Nat.card (Φ W))
    (hcw : ∀ i, HasConformalWeight (Mfam i).isMod (h i))
    (hsep : ∀ j k : ι, j ≠ k → h j = h k →
      IsEmpty (AModEquiv W (lowestAMod (hcw j).2) (lowestAMod (hcw k).2))) :
    ∃ D : ModularData W ι, D.Mfam = Mfam ∧ D.h = h ∧ ZhuModularityAnalytic D :=

theorem zhuModularity_pinned_of_C2Cofinite_voaPBW [Finite (Φ W)]
```

```
(Mfam : ι → IrrModule W) (h : ι → ℂ)
(hC2 : C2Cofinite W)
(hss : letI := instRingA W; IsSemisimpleRing (A W))
(hcard : Fintype.card ι = Nat.card (Φ W))
(hcw : ∀ i, HasConformalWeight (Mfam i).isMod (h i))
(hsep : ∀ j k : ι, j ≠ k → h j = h k →
  IsEmpty (AModEquiv W (lowestAMod (hcw j).2) (lowestAMod (hcw k).2))) :
∃ D : ModularData W ι, D.Mfam = Mfam ∧ D.h = h ∧ ZhuModularityAnalytic D :=
```

From the mathematics to the Lean statement

The pattern, decoded. The two modularity statements are identical except that the first has the extra binder (`Pr : BottomProjection ...`). A `BottomProjection` for the parabolic representation attached to the regular $A(W)$-module is a linear projection from the induced module onto its bottom piece, compatible with the structure; it exists if and only if the bottom embeds (the `inducedBottom` consequence of PBW). So the first theorem says "if such a projection exists, Zhu's modularity holds", the second says "Zhu's modularity holds", and the second is the first applied to the projection `voaPBWBottomProjection`, which is derived from `VOA.pbw`. For the referee this means: the content of Zhu's theorem is entirely in the `#print axioms`-clean version, and `VOA.pbw` enters only at one clearly marked seam. The remaining hypotheses (`hC2`: C_2-cofiniteness; `hss`: semisimplicity of $A(W)$, which follows from (admissible) rationality by `VOA.Huang.ZhuSemisimple.isSemisimpleRing_A_of_admissiblyRational`, `VOA/Huang/ZhuSemisimple.lean`; `hcard`, `hcw`, `hsep`: the family `Mfam` is a complete irredundant list of irreducible modules with conformal weights `h`) are the hypotheses of Zhu's theorem itself; Chapter 15 explains each. (Earlier versions also carried `hzero` and `hsimp`; both were redundant and have been removed.)

What the machine verified

Re-run for this chapter (`lake env lean -DmaxSynthPendingDepth=3` on a scratch file importing `VOA`, at the Moonshine commit; not re-run for this edition): `zhuModularity_pinned_of_C2Cofinite` and `zhuBijective`: `[propext, Classical.choice, Quot.sound]`. `zhuModularity_pinned_of_C2Cofinite_voaPBW`, `zhuBijective_of_voaPBW`, `AffineLie.vacuumVector_ne_zero` and `VHat.DLM3.voaPBWBottomInjective`: `[propext, Classical.choice, Quot.sound, VOA.pbw]` (at that commit, when `VOA.pbw` was an axiom). Re-probed at a later commit, after `VOA.pbw` became a theorem, all four reported `[propext, Classical.choice, Quot.sound]` (not re-run for this edition). The same probe reports `[propext, Classical.choice, Quot.sound]` for `heisenbergVOA`, `VirModule.virasoroVOA`, `AffineVOA.affineSl2VOA_closed`, `LatGen.latticeVOAGen`, `levelOne_coe_mem_E46`, `LQ43.L43_graded_rigidity`, `finiteDimensional_A_of_C2Cofinite`, `onePointSubexp_of_c2`, `strictSpanning_of_C2Cofinite`, `simpleAModsRealized_of_C2Cofinite`, `VertexOperatorAlgebra.borcherds`, `Moonshine.LatticeTwisted.leechTwistedModule`, `Moonshine.sectorSeries_eq_JShift` and `Moonshine.moonshine`. In particular, the affine $\mathfrak{sl}_2$ vertex operator algebra and the whole Moonshine chain do not depend on `VOA.pbw`.

Many files mention the string `pbw` (a word search finds it in several hundred files, mostly in documentation and in names such as `PBWFreeness`); this says nothing about dependence. Dependence is a property of proof terms and is decided only by `#print axioms`.

43.1.3 What `lake build` certifies: aggregate versus isolated

`lake` is Lean's build tool. The library is one Lean package, `VOA`, whose root module `VOA.lean` (the *umbrella*) imports the category umbrellas `VOA/Foundations.lean`, `VOA/Core.lean`, ..., `VOA/Moonshine.lean`, which in turn import every production file. Running `lake build` with no argument builds the

default target `VOA`, i.e. compiles the umbrella and, transitively, everything it imports, together with the needed part of Mathlib. The output ends with a line such as

```
Build completed successfully (10343 jobs).
```

where a *job* is one unit of work (compiling one module, or one of its artefacts). The job count is a useful fingerprint: if two runs on what should be the same tree give different counts, the trees differ.

Two kinds of build must be distinguished.

- An **isolated build**, `lake build VOA.Moonshine.TTBlock`, compiles one module and its imports. It certifies that this file, in the presence of exactly the files it imports, is correct.
- The **aggregate build**, `lake build` (equivalently `lake build VOA`), compiles the umbrella. It certifies that *all* production files compile *together*.

The difference matters. A file can compile in isolation and still break the aggregate: two files may declare the same name in the same namespace (the second import then fails), a file may add an instance or a `simp` lemma that changes the behaviour of proofs in another file that imports both, or a file may simply not be imported by the umbrella at all, in which case its theorems are not part of the library that the umbrella describes. During the Moonshine work many files were first built in isolation by background agents (for example the route notes record "`lake build VOA.Moonshine.TTBlock` is green (4243 jobs)" and "Build completed successfully (9039 jobs)" for three `SigmaExist` files) and only later wired into `VOA/Moonshine.lean`. The project rule is therefore:

> *A result counts only when the aggregate* `lake build` *is green.*

A second, subtler point was learned the hard way earlier in the library's history: a green build is a property of a *tree at an instant*, not of a session. Twice, a recorded "green at N jobs" failed to reproduce because a later, unrelated file had been added to the working copy, and once because a second session was editing files while the build ran. Hence the operational rules: re-run the aggregate build immediately before recording a result, record the job count actually seen, never run two builds concurrently in one working tree, and prefer separate `git worktrees` for concurrent work.

43.1.4 `scripts/check_repository.py`

The aggregate build cannot see files that nobody imports, and it cannot forbid tokens that Lean accepts. Both gaps are closed by a Python script, `scripts/check_repository.py`, which is also run in continuous integration before the Lean build. It does three things.

1. **Lexing.** It tokenizes every production file `VOA/**/*.lean` and the umbrella, correctly skipping line comments `--`, nested block comments `/- ... -/` and string literals, so that the word "sorry" in a docstring is not a false positive.
2. **Forbidden tokens and the sanctioned axiom.** Its policy is the constant

   ```
   ALLOWED_AXIOM_FILE = SOURCE_ROOT / "Foundations" / "AffineLie.lean"
   FORBIDDEN_TOKENS = frozenset(
       {"sorry", "admit", "native_decide", "stop", "implemented_by"}
   )
   ```

   Any code occurrence of these five tokens is an error. They are, respectively: the placeholder for a missing proof; its tactic synonym; a tactic that evaluates a decidable proposition by compiling it to machine code (thereby trusting the compiler, not only the kernel); the tactic that abandons the rest of a proof; and an attribute that replaces a definition's executable code

by other code. Since `VOA.pbw` became a theorem every occurrence of the keyword `axiom` is an error (the constant `ALLOWED_AXIOM_FILE` survives in the script but no axiom is accepted); the script still prints a count of "sanctioned axiom declarations", now 0. (At the Moonshine commit the one exception was `axiom pbw` in `VOA/Foundations/AffineLie.lean`.)

3. **Reachability.** Starting from `VOA.lean` it follows every local import (`import VOA...`) and reports (i) imports naming a non-existent file and (ii) production files not reachable from the umbrella.

Its success line, as run for the first edition of this chapter on the tree of the Moonshine commit, was

```
Repository check passed: 1867 library files scanned; 1867 reachable through 4676 local
↪  import edges; 1 sanctioned axiom declaration(s).
```

So, at that commit, every one of the 1867 files then in the library was part of the aggregate build, none contained a forbidden token, and there was exactly one axiom. At a later commit, after `VOA.pbw` became a theorem, the script reported "7107 library files scanned; 7105 reachable through 17543 local import edges; 0 sanctioned axiom declaration(s)", with verdict "failed" only because two draft files in `VOA/Huang/` are unreachable. The reachability check was the one that fired most often during the Moonshine work. Agents wrote new files that compiled in isolation; until a maintainer added the import line, the check listed them as unreachable, and on one occasion it caught an in-flight, unwired draft (`VOA/Moonshine/HeisenbergTwistedModuleFieldComm.lean`) that still contained `sorry`. That file was not committed in that state; it was later completed and wired.

43.1.5 `scripts/audit/run_axiom_audits.py` and its blind spot

The third mechanical check, `scripts/audit/run_axiom_audits.py`, enforces *exact* axiom sets for a maintained list of declarations. It runs 20 Lean "probe" files under `scripts/audit/` (for example `RigidityProgressAxiomAudit.lean`, `Phase5AxiomAudit.lean`, `SuperAxiomAudit.lean`), each of which consists of `#print axioms` commands; it parses Lean's answers and compares each with the expected set: by default {`propext`, `Classical.choice`, `Quot.sound`}; for the single declaration `VOA.zhuModularity_pinned_of_C2Cofinite_voaPBW` the default plus `pbw` (while `VOA.pbw` was an axiom; since it became a theorem the expected set `PBW_AXIOMS` equals the default, so any reappearance of `pbw` is a failure); and for a short explicit list of elementary lemmas a *smaller* set (some use only `propext`, or no axiom at all). It fails if a declaration is missing, reported twice, or has a different set, larger *or smaller*. Insisting on exactness in both directions is deliberate: a set that shrinks unexpectedly usually means that a declaration was replaced by a different one with the same name. The success line of the final run was

```
Axiom audit enforcement passed: 4876 reports across 20 probes.
```

Trap / dead end

The blind spot. The 20 probes were written before the Moonshine construction began, and none of them mentions a declaration under `VOA.Moonshine` or `VOA.LatticesAndCodes`. The report count 4876 is *identical* before and after the construction (it is the count recorded in the project's build records at each of the last four checkpoints of the Moonshine work). A green audit therefore says nothing whatsoever about $V^\natural$. The headline Moonshine theorems were audited individually instead: at each checkpoint a scratch file importing `VOA` and containing `#print axioms` for the milestone declarations was compiled with `-DmaxSynthPendingDepth=3` (Section 43.1.6), and the result was recorded in the project's internal records and in the route notes. Adding a Moonshine probe to the maintained list is an open housekeeping task (Section 43.6).

43.1.6 `#print axioms` and the audit trap

`#print axioms foo` makes Lean walk the proof term of `foo`, and of every declaration that term mentions, and list the axioms reached. It is the only reliable way to know whether a theorem depends on `sorryAx`, the axiom that a `sorry` silently introduces (or, while it was an axiom, on `VOA.pbw`).

There is a trap, recorded in the project's working rules and in `README.md`. The package's `lakefile.toml` sets an elaboration option,

```
[leanOptions]
pp.unicode.fun = true # pretty-prints `fun a ↦ b`
relaxedAutoImplicit = false
weak.linter.mathlibStandardSet = true
maxSynthPendingDepth = 3
```

which raises the depth to which type-class synthesis may postpone sub-problems. `lake build` passes this option to every file it compiles. A bare `lake env lean file.lean` does *not*: it runs Lean in the package's environment but with Lean's default options. With the default depth, some instance problems in the library fail; Lean then reports an elaboration error and, to continue, replaces the failed term by `sorryAx`. A `#print axioms` run in that mode can therefore report `sorryAx` for a theorem that is in fact complete, or, worse, a file of probes can appear to succeed while auditing something other than what the build produced. The rule is: audit only through `lake build`, or through

```
lake env lean -DmaxSynthPendingDepth=3 probe.lean
```

which supplies the option explicitly. The maintained audit script does the latter for its newer probes.

43.1.7 Unconditional versus conditional

`#print axioms` does not list hypotheses. The theorem

```
theorem moonshine_of_frameLocality :
    ∃ x : ZMod 2 → TP, (∀ s, x s ∈ TPframe s) ∧
      ((∀ i j, TPBlockLocal leechWbar (x i) (x j)) →
        ∃ V : VertexOperatorAlgebra Vnat,
          V.Y = Ynat wbarL ∧ V.vacuum = vacNat ∧ V.conformalVector = omegaNat ∧
          V.centralCharge = 24 ∧
          V.grading 1 = ⊥ ∧
          finrank ℂ (V.grading 2) = 196884 ∧
          (∀ n : ℕ, (finrank ℂ (V.grading (n : ℤ)) : ℂ) = PowerSeries.coeff n JShift) ∧
          V.IsSimple) := by
```

(`VOA/Moonshine/Main.lean`) has no binders at all, and its axiom list is clean; yet it is *conditional*: inside the statement, after the existential, sits an implication whose premise `∀ i j, TPBlockLocal leechWbar (x i) (x j)` (four instances of the twisted-sector locality relation (4.23) of Dolan–Goddard–Montague, Chapter 40) was, at the time, not proved. The project's rule of language, stated in `README.md` and in the project's working rules, is:

> Say "`#print axioms`-clean, conditional on …" for a declaration whose proof term uses only the standard axioms but whose statement carries a hypothesis. Reserve *unconditional* for a theorem whose full hypothesis closure contains no unestablished datum.

The *hypothesis closure* is found by tracing every hypothesis, including those hidden in a statement as premises of implications and those carried as fields of structures, down to its leaves. The `README.md` adds two further audit items for every headline result: *conclusion strength* (is the conclusion the intended one, or a weaker variant such as "there exists some datum with property P" where a pinned

datum was intended?) and *satisfiability of carried data* (can the hypotheses be met at all?). The Moonshine construction illustrates all three. Its final theorem is unconditional in the strict sense: no binder, no premise inside the statement. Its conclusion had to be strengthened once (simplicity was added to exclude the square-zero extension, Section 43.2.2). And several intermediate reductions had to be guarded against vacuous satisfaction by trivial data (the `hits_cyclic` clause, Section 43.2.2).

43.1.8 Independent re-verification of agent-produced work

Most of the roughly 155 files of `VOA/Moonshine/` were written by background agents (Lean sessions running in parallel, each assigned one milestone and allowed to write only new files), coordinated by a supervising session that followed the operating rules recorded in `Notes/MonsterRoadmap.md`. Those rules make agent output count only after an independent re-check by the supervisor:

1. read the roadmap and the working agreements at every iteration;
2. for every finished agent, build its *new* files in isolation (`lake build VOA.Moonshine.<File>`); grep them for `sorry`, `admit`, `native_decide` and `axiom`; run `#print axioms` on the headline declarations via `lake env lean -DmaxSynthPendingDepth=3`;
3. only then wire the files into `VOA/Moonshine.lean`;
4. update the status table with exact declaration names, and flip a status marker only after a green aggregate build;
5. never weaken a statement, never introduce `sorry` or an axiom, never commit or push (the maintainers' decision), never run two builds concurrently in one tree, never touch unrelated work (the parallel $\hat{\mathfrak{sl}}_3$ thread);
6. periodically run `scripts/check_repository.py` and an aggregate build, and at checkpoints write a dated hand-off record (commit, build state, open residuals, dead ends) for the next session.

The agents' own reports were treated as claims, not facts. Concretely, this caught: unwired drafts (listed by the reachability check); a draft with `sorry` (Section 43.1.4); agent notes that described their files as "not wired" long after wiring, or a residual as open after it had been closed (the route notes carry "Update" sections and the gluing plan carries dated "Status and corrections" sections for exactly this reason); and, most importantly, several mathematical errors in the plan itself, recorded as numbered "Corrections" in `Notes/M8GluingPlan.md` and catalogued below. A general lesson of the library's history, learned twice, applies with full force: *prose drifts behind theorems*. A docstring saying "open" or "not possible" was false when read at least seven times in earlier sessions; the remedy is to search for the declaration the prose claims is missing before believing it.

43.1.9 The final verification record

The release commit. This edition documents the release of the library named in the front matter, at commit (`recorded at release`). The protocol of this section — the aggregate `lake build`, `scripts/check_repository.py`, `scripts/audit/run_axiom_audits.py`, and `sync.py check` for the book's quotations — is run at that commit by the release procedure. The records below were made at earlier states of the library, are dated, and say what was run.

The release build (3 November 2026)

Run on the development tree at the feature freeze, the source of this release (the released tree omits the held material listed in Chapter 1):

- aggregate `lake build` of `VOA`: `Build completed successfully (20331 jobs)`, exit code 0;
- `scripts/check_repository.py`: 11,859 library files, 0 axiom declarations, no `sorry`, `admit`, `native_decide`, `stop` or `implemented_by`; all files reachable from the umbrella except four held files that the release does not contain;
- `scripts/audit/run_axiom_audits.py`: passed, 5,958 reports across 24 probes;
- `#print axioms` on the 28 headline declarations of the release (including `VOA.Moonshine.moonshine`, `A2_classicallyFree_final`, `D4_classicallyFree_of_inputT` and `twoSeries_gradedUnitary_of_affine_final`): every one reports exactly `[propext, Classical.choice, Quot.sound]`.

What the machine verified

Recorded at the end of the Moonshine construction (the project's checkpoint record of 7 October 2026), on the tree that became the Moonshine commit ("Construct the Moonshine module $V^\natural$ (FLM) unconditionally"), then the head of the main branch:

- aggregate `lake build`: `Build completed successfully (10343 jobs)`, exit code 0;
- `scripts/check_repository.py`: passed, 1867 library files, all reachable, one sanctioned axiom declaration (`VOA.pbw`, then an axiom; 0 since it became a theorem);
- `scripts/audit/run_axiom_audits.py`: passed, 4876 reports across 20 probes (which do not cover `VOA.Moonshine`);
- `#print axioms VOA.Moonshine.moonshine`, via `import VOA` with `-DmaxSynthPendingDepth=3`: `[propext, Classical.choice, Quot.sound]`; no `VOA.pbw`;
- the core definitions (`VOA/Core`, `VOA/Foundations`, `VOA/Modularity/JFunction.lean`, `VOA/Modules/Fusion.lean`) are unchanged since the parent of the Moonshine commit; the only change to a pre-existing definition is the nine-line repair of `TwistedModule.jacobi` in `VOA/Modularity/Twisted.lean` (Section 43.2.1).

Re-run for this chapter on the same tree: `scripts/check_repository.py` passed with "1867 library files scanned; 1867 reachable through 4676 local import edges; 1 sanctioned axiom declaration(s)"; `#print axioms` gave `[propext, Classical.choice, Quot.sound]` for `VOA.Moonshine.moonshine`, `VOA.Moonshine.topPairs_one`, `VOA.jacobiAllIndices_eq_zero` and `VOA.Moonshine.TrialityTw.golayE_not_determined`, plus the library-wide list of Section 43.1.2. `scripts/audit/run_axiom_audits.py` was re-run and printed twenty `PASS` lines (from "`PASS RigidityProgress: 3932 declarations match the trust boundary`" to "`PASS PairClosure: 54 declarations match the trust boundary`") and "Axiom audit enforcement passed: 4876 reports across 20 probes." (1 minute 34 seconds). The aggregate `lake build` was *not* re-run for this chapter; its figure of 10343 jobs is the one recorded at the time.

For the reader's convenience we reprint the headline statement once more (`VOA/Moonshine/TopPairs.lean`):

```
theorem moonshine :
    ∃ V : VertexOperatorAlgebra Vnat,
      V.Y = Ynat VnatAxioms.wbarL ∧ V.vacuum = vacNat ∧ V.conformalVector = omegaNat ∧
      V.centralCharge = 24 ∧
      V.grading 1 = ⊥ ∧
      Module.finrank ℂ (V.grading 2) = 196884 ∧
```

```
    (∀ n : ℕ, (Module.finrank ℂ (V.grading (n : ℤ)) : ℂ) = PowerSeries.coeff n JShift) ∧
    V.IsSimple :=
moonshine_of_topPairs (by norm_num) topPairs_one
```

From the mathematics to the Lean statement

Fidelity check of the headline, from the verification point of view. The full fidelity check, with every term traced to its definition, is in Chapter 42; here we record only the points that the protocol of this section is designed to protect.

- *No hypotheses.* The statement has no binders and no premise. Its proof is the composition of the conditional theorem `moonshine_of_topPairs` (whose premises are $\varepsilon^2 = 1$, discharged by `norm_num` at $\varepsilon = 1$, and the finite identity `TopPairs`) with `topPairs_one`, which proves that identity. So the hypothesis closure is empty.
- *The existential is pinned.* "$\exists V$" alone would be weak: some VOA structure on the vector space `Vnat`. The four equations `V.Y = Ynat VnatAxioms.wbarL`, `V.vacuum = vacNat`, `V.conformalVector = omegaNat` pin the vertex operator map to the explicit block map of Frenkel–Lepowsky–Meurman, built from the untwisted fields, the skew intertwiner W and its adjoint $\overline{W}$ (Chapters 37–38); the vacuum and conformal vector are pinned likewise.
- *The non-triviality clause.* `V.IsSimple` excludes the square-zero extension, which satisfies every other clause (Section 43.2.2). In addition `wbarL` is the genuine adjoint, proved nonzero by `leechWbar_ne_zero`.
- *Graded dimension.* `JShift` is the pre-existing series $E_4^3/(\Delta/q) - 744q = qJ(q)$ of `VOA/Modularity/JFunction.lean`, untouched by the construction, so the identity $\dim V_n = [q^n]\, qJ(q)$ is tested against an independent definition of J.
- *Axioms.* Standard only; no `VOA.pbw`.

What the statement does *not* say: nothing about $\mathrm{Aut}(V)$, the Monster, or uniqueness; see Section 43.6.

Physical meaning

The verified statement underwrites the physicist's description of the Moonshine conformal field theory: a chiral $c = 24$ CFT (holomorphy, i.e. a single sector, is the physical expectation and is not proved in Lean) obtained by orbifolding 24 chiral bosons compactified on the Leech torus by the reflection $X \mapsto -X$, keeping the invariant untwisted states and the invariant twisted states (twist fields of weight 3/2 dressed by oscillators). The clause $V_1 = 0$ says the theory has no conserved spin-one currents, hence no continuous symmetry; $\dim V_2 = 196884$ counts the stress tensor plus the 196883 primaries of the Griess algebra; the graded dimension is the torus partition function $Z(\tau) = J(\tau)$ up to the factor q; uniqueness of the vacuum (the only state of weight 0 up to scale) is CFT type, built into the library's definition of a vertex operator algebra; simplicity says that no consistent subsector decouples, i.e. the operator product expansion genuinely couples the twisted states back into the untwisted ones ($\overline{W} \neq 0$).

43.1.10 The book's own verification record (October 2026)

The protocol above certifies the *library*. The book needs a second, separate record: that what it prints is what the library says. By the book's rules (its constitution, Article 9), the book documents the library as of the commit stored in `Notes/Textbook/manifest.json`, which records, for every

`.lean` file, the chapter that documents it and the hash of its contents at that commit. The script `scripts/textbook/sync.py` then checks the chapters against the sources. Its `check` command reports, among other things, four kinds of failure that are treated as blocking:

- **STALE QUOTE**: a `leancode` block that no longer occurs verbatim in the source. This breaks the book's central promise, that the Lean text the referee reads is the Lean text the kernel checked.
- **MISSING PATH**: a quoted declaration with no nearby `\leanpath` citation of the file that defines it, so the reader cannot find the source.
- **NO PHYSICS**: a definition or theorem not followed by a physical-meaning box, which the constitution requires for every statement.
- **UNASSIGNED** files (reported by `sync.py coverage`): a library file that no chapter is responsible for.

These checks are textual. They confirm that the quotations are verbatim and attributed, not that the quoted files compile together; that is the job of the aggregate build of Section 43.1.3, and the two must not be confused.

What the machine verified

The book's record at the end of the October 2026 update, as recorded in `Notes/Textbook/BOOK_CAMPAIGN.md` ("Status") and in the commit messages of the book:

- **Manifest snapshot** at a pre-release commit, with `sync.py coverage` reporting 0 unassigned files. Every `.lean` file of the library is therefore assigned to exactly one chapter.
- **`sync.py check`** at that snapshot: 0 STALE QUOTE, 0 MISSING PATH, 0 NO PHYSICS.
- **Full book** at that snapshot: `book.pdf`, 2118 pages, 0 undefined references. (The release edition, `main_release.pdf`, then had 2201 pages.)
- **Brief**: `brief.pdf`, 199 pages; all 1199 of its 1199 Lean chunks verbatim against the sources at that snapshot.
- **Chapters in preparation.** The chapter on affine $\mathfrak{sl}_3$ is not part of this edition. The two chapters on graded unitarity through the BRST coset, then held, are part of the v1.0 release edition (Chapters 28 and 29); their verification records are in those chapters. Chapter 27, held at this snapshot, was rewritten around the A_2 theorem without hypotheses and is included.

Not done at that snapshot. The book was *not* checked against an aggregate `lake build` at that snapshot. The last aggregate build recorded green is that of 26 October 2026, at the A_2 milestone of the Deligne campaign: 13868 jobs, with the axiom audit passing (the project's build record; not re-run for the book). By the project's policy the aggregate build is run only before a merge to the main branch, and it is memory-heavy, so it was not re-run for the book. Since then, the aggregate build `bash scripts/campaign_build.sh VOA` (the full `lake build VOA` under the project's memory-capped wrapper) was green in two pre-release builds on 2026-10-28 (18,901 jobs, and 18,907 jobs after merging the then-current `origin/main`); `scripts/check_repository.py` passed (10,431 library files, all reachable, 0 project axioms) and `scripts/audit/run_axiom_audits.py` passed (5,958 reports across 24 probes). For the release commit see Section 43.1.9. The quotations are verbatim against the sources at the manifest commit; their compilation at that commit is inferred from the build of 26 October and from the targeted builds recorded in the project's internal build records, not re-confirmed.

The trust base at the manifest commit. The library has *no* project axiom. `VOA.pbw`, which until 19 October 2026 was the single sanctioned axiom (Section 43.1.2), is now the theorem `theorem pbw : PBWPrinciple` in `VOA/Foundations/AffineLie.lean`, proved through the files `VOA/Foundations/PBWTheorem/` (Chapter 3). `#print axioms VOA.pbw` lists only Lean's three standard axioms; this was re-run for Chapter 3 and again, independently, by the release audit of Chapter 22 (Section 43.1.11). Two of the release audits also searched `VOA/` for top-level `axiom` declarations and found none: every occurrence of the word is in a comment. Consequently the register "proved using the project axiom" of the introduction is empty, and "`#print axioms`-clean" now means, without exception, that the axiom list is a subset of `[propext, Classical.choice, Quot.sound]`. What it still does *not* mean is "unconditional" (Section 43.1.7): the new chapters contain many `#print axioms`-clean theorems that carry open named hypotheses, and they are listed in Section 43.6.3.

Two further facts of the record.

- **The repository check passes.** `scripts/check_repository.py` (Section 43.1.4) failed for a time on 27 October 2026 because of unwired files; after they were wired in or moved, the Foundations release audit recorded it passing (7,839 files, all reachable). Re-run on the working tree of the branch `deligne-lean` on 28 October 2026, it reported: "Repository check passed: 10353 library files scanned; 10353 reachable through 24571 local import edges; 0 sanctioned axiom declaration(s)". That working tree had uncommitted changes; for the release commit see Section 43.1.9.
- **Docstrings were edited after the last aggregate build.** A first batch of stale docstrings (45 files, comments only) was corrected on 27 October; a targeted build of those 45 modules was green (13,276 jobs). The release audits below found further edits of the same kind in the import closures they examined and inspected them as comment-only. A comment cannot change a theorem, but an edited file must still be rebuilt, which is one more reason why every audit asks for an aggregate build at the release commit.

Physical meaning

The physicist's analogue is the difference between a calculation and its write-up. The library is the calculation; the book is the paper that reports it. A paper can misquote its own calculation (a sign dropped in transcription, a hypothesis forgotten in the abstract), and the sync check is the systematic comparison of the two. It does not re-run the calculation; the aggregate build does that.

43.1.11 The independent release audits of 27–28 October 2026

Before a public release the project decided (`Notes/RELEASE_PLAN.md`, "Release tiers") that every headline theorem to be named in an announcement must pass one independent *release audit*: a fresh referee, who had not written the chapter, compares the statement with the source paper, traces every definition it depends on down to its leaves, lists every explicit hypothesis, and re-runs `#print axioms`. The chapter is used only as a map; every conclusion is checked against Lean. The project's record of over-claims caught late (three in the week before the audits alone) is the reason this step exists. Twelve such audits were run on 27 and 28 October 2026; their verdicts are recorded in `Notes/RELEASE_PLAN.md` ("Release audit results"). One line each:

- `RELEASE_AUDIT_L16.md` (Chapter 16, Arakawa–Kawasetsu), 27 October: the proposed announcement is not announceable as worded; 1 BLOCKING (the wording), 4 MAJOR, 6 MINOR. Discussed below.
- `RELEASE_AUDIT_L20.md` (Chapter 20, Arakawa–Dai), 27 October: no blocker; 0 BLOCKING, 1 MAJOR (the release build), 7 MINOR. Discussed below.

- `RELEASE_AUDIT_L21.md` (Chapter 21, Huang and related), 27 October: no blocker; 0 BLOCKING, 3 MAJOR, 8 MINOR. Discussed below.
- `RELEASE_AUDIT_L22.md` (Chapter 22, Gannon–Rayhaun), 27 October: announceable with caveats; 0 BLOCKING, 2 MAJOR, 5 MINOR. Discussed below.
- `RELEASE_AUDIT_MOONSHINE.md` (Chapters 30–42, $V^\natural$), 27 October: announceable with caveats, wording only; 0 BLOCKING, 0 MAJOR, 6 MINOR. `moonshine` takes no hypotheses, has standard axioms and a unique witness; J is a formal q-series; the isomorphism with FLM's explicit $V^\natural$ is on paper only; no Monster, holomorphy or uniqueness claim.
- `RELEASE_AUDIT_RIGIDITY.md` (Chapters 8 and 10), 27 October: announceable with caveats; 0 BLOCKING, 0 MAJOR, 3 MINOR (say "graded first-order"; non-vacuity argued on paper only).
- `RELEASE_AUDIT_ZHU.md` (Chapters 12–15), 27 October: no headline blocked, but "Zhu's modularity theorem is formalized" is misleading without qualification; 3 HIGH, 4 MEDIUM, 6 lower. Its finding that "rational ⇒ $A(V)$ semisimple" is unproved was superseded the next day (see the new-declarations audit).
- `RELEASE_AUDIT_FOUNDATIONS.md` (core definitions and constructions), 27 October: faithful with caveats; 0 BLOCKING, 2 MAJOR, 7 MINOR (every headline must say "of CFT type"; the structure now called `PreVertexAlgebra` lacks translation covariance, Section 43.2.8).
- `RELEASE_AUDIT_L17_L18_L23.md` (Chapters 17, 18, 23), 27 October: 0 BLOCKING, 7 MAJOR, 14 MINOR; includes the `SuperTwistedModule` defect of Section 43.2.1.
- `RELEASE_AUDIT_L24_L25_A2.md` (Chapters 24, 25 and the A_2 final theorem), 28 October: 1 HIGH, 5 MEDIUM, 8 LOW; the A_2 statement is faithful, its announcement blocked until green umbrella and aggregate builds exist at the release commit (condition met on 28 October: Chapter 27, Section 27.10).
- `RELEASE_AUDIT_NEW_DECLS.md` (the declarations added on 28 October), 28 October: all announceable with caveats; 0 BLOCKING, 4 MEDIUM, 7 LOW.
- `RELEASE_AUDIT_FOLLOWUPS.md` (the other account's follow-ups), 28 October: none wrong, none blocked; 2 announceable as stated, 4 with caveats.

A separate precision audit of the Deligne literature inputs (`DELIGNE_INPUTS_PRECISION.md`, 28 October) found the total-dimension bound and the Demazure realizations published for all six types and the star bound unpublished for G_2, F_4 and the E-types. The paragraphs below record the first four audits in detail, as reported on 27 October; where Lean results of 28 October have since removed a caveat, this is said in the paragraph. The corrections the audits asked of their chapters have been applied.

What the auditors of 27 October ran, and what they did not. No auditor ran `lake build`. Each wrote scratch files importing the headline modules and ran them with `lake env lean -DmaxSynthPendingDepth=3` (the safe form of Section 43.1.6) against the compiled `.olean` files already present, dated 25–26 October; the cost was 2.6–9.5 seconds and 3.4–8.1 GB per file. Each audit was made at a different pre-release commit of a working tree with uncommitted changes. Each auditor checked that the uncommitted changes in the relevant import closure were comment-only, or that the closure was unchanged. *Every one of the four reports therefore carries the same process caveat*: the aggregate build, the repository check and the axiom audit must be re-run, green, on the committed release commit before anything is announced. All three were green on 28 October 2026 (paragraph *Not done at that snapshot* above); for the release commit see Section 43.1.9.

Chapter 16 (Arakawa–Kawasetsu): the proposed announcement is not announceable as worded. Counts: 1 BLOCKING, 4 MAJOR, 6 MINOR. The BLOCKING finding concerns the wording of the proposed announcement, not the Lean code. That wording ("the Arakawa–Kawasetsu theorem, characters of quasi-lisse VOAs satisfy an MLDE, and an explicit non-lisse quasi-lisse example are formalized") is false on three counts. (1) *No Lean theorem proves the analytic Arakawa–Kawasetsu MLDE for any vertex algebra.* (The audit's wording, "no MLDE for any VOA", was slightly too broad: Chapter 25 proves formal, coefficientwise second-order MLDEs for the vacuum characters of the seven Deligne-series VOAs.) Within Chapter 16, the only theorem with a genuine MLDE conclusion, `VOA.IsSqPrimary.exists_monicMLDEOn_all_analyticBlocks_of_etingofFinite`, is `#print axioms`-clean but conditional on two hypotheses that were inhabited nowhere in the library, `AKWeightGrading W` and `E46SerreClosed` (Section 43.6.3). Since 28 October the second is a theorem, `VOA.e46SerreClosed` (`VOA/Modularity/EisensteinSerreClosure.lean`), and since 29 October the first is a theorem for every VOA of the library (CFT type), `VOA.akWeightGrading` (`VOA/Modularity/AKGradingTotal.lean`). The MLDE is therefore conditional only on Etingof-finiteness: `VOA.IsSqPrimary.exists_monicMLDEOn_all_analyticBloc` (despite the suffix, it keeps `EtingofFinite W`) gives one monic MLDE of some unbounded order $s \geq 1$, coefficients in $\mathbb{C}[E_4, E_6]$ of weight $2(s-i)$, satisfied by $F(a)$ for every abstract analytic genus-one block F; and `VOA.exists_monicMLDEOn_all_analyticBlocks_simpleSl2QL` is its unconditional instance at the vacuum of $L_{-4/3}(\mathfrak{sl}_2)$, of unspecified order (Arakawa–Kawasetsu's order 2 is not proved; that the vacuum character is such a block follows from library lemmas but is not packaged as one theorem). Both are `#print axioms`-clean (recorded in `Notes/release/WS-RELEASE2.md`); the aggregate build at the release commit is pending. (2) *Quasi-lisseness is not formalized*: there is no associated variety and no symplectic leaf; the theorems assume `EtingofFinite`, finite-dimensionality of the zeroth Poisson homology $R_V/\{R_V, R_V\}$, which is the *conclusion* of the Etingof–Schedler theorem (logically more general, but not "quasi-lisse"). (3) *The unconditional "character ODE" theorems* at $L_{-4/3}(\mathfrak{sl}_2)$ (`character_formalODE_simpleSl2QL_uncond` and siblings) have arbitrary subexponential power series as coefficients, chosen after the module; they are near-vacuous growth statements, not MLDEs, although a docstring still calls one of them "the Arakawa–Kawasetsu character equation" (Chapter 16, Section 16.5.6). A further MAJOR: the Zhu-modularity chain under Etingof-finiteness has its rank hypothesis discharged only for the trivial VOA, and it is expected to be false at $L_{-4/3}(\mathfrak{sl}_2)$ (a paper argument). *What is announceable*, with standard axioms only: $L_{-4/3}(\mathfrak{sl}_2)$ is not C_2-cofinite yet has finite-dimensional zeroth Poisson homology (`not_C2Cofinite_simpleSl2QL`, `etingofFinite_simpleSl2QL'`, `strictEtingofFinite_simpleSl2QL`); for such VOAs characters of ordinary modules converge on the upper half-plane and the genus-one conformal blocks form a finite-dimensional space; and C_2-cofinite implies Etingof-finite. The MLDE may be mentioned only as formalized conditionally on `EtingofFinite` (the stand-in for quasi-lisseness), with an unspecified order, and unconditionally at $L_{-4/3}(\mathfrak{sl}_2)$ in that form. Consequence recorded in the release plan: Chapter 16 is released, but it leaves the announcement's list of headlines.

Chapter 20 (Arakawa–Dai): no blocker. Counts: 0 BLOCKING, 1 MAJOR, 7 MINOR. All ten headline declarations of `VOA/Examples/AffineSl2BoundaryMainTheorems.lean` are `#print axioms`-clean, with the single hypothesis $1 \leq m$; the definitions trace to the genuine objects (the actual simple quotient, the real Li filtration, a genuine Poisson vertex algebra, the character computed from actual dimensions). The four character theorems (`coeff_product_le_character`, `character_eq_product`, `character_eq_chain`, `character_eq_fermionic_chain`, the last being the paper's Theorem 1.2 display) and `arcPoissonEquiv_conformal_iff` are announceable as stated. The caveats: `canonicalMap_bijective`, `boundary_classically_free` and `arcPoissonEquiv` are stated on the arc algebra of the *presented* algebra $\mathbb{C}[e, h, f]/(eQ^m, hQ^m, fQ^m)$, and no single Lean theorem has the paper's shape "the canonical map $J_\infty R_V \to \mathrm{gr}^F V$ is bijective"; the paper's Theorem 1.1 follows from two Lean theorems together (the presented isomorphism and `baseC2AlgEquiv`) and should be announced in that two-part form (audit verdict of 27 October; superseded on 28 October, see below and Chapter 20, Theorem 20.26; naturality proved). `actualC2ArcEquiv` is a bare bijection of hom-sets for each coefficient algebra, with no

naturality stated, so it must not be announced as a representability statement; and `baseC2AlgEquiv` is canonical by its definition, not by its type. The single MAJOR is the release build (above). Chapter 20, Section 20.15, records the same points. *Since 28 October* two of these caveats are removed in Lean, in the namespace `VOA.AffineSl2BoundaryClassicalFreeness`: `arakawaDai_theorem_1_1` (`VOA/Examples/AffineSl2BoundaryTheorem11.lean`) states the paper's Theorem 1.1 as one theorem, and `actualC2ArcEquiv_natural` (`VOA/Examples/AffineSl2BoundaryMainTheorems.lean`) states the naturality, so representability holds; the follow-ups audit rated both "as stated". What remains is that $J_\infty R_V$ is realized as `PresentedJet` with a universal arc, since the library has no J_∞ functor on abstract algebras.

Chapter 21 (Huang and related): no blocker. Counts: 0 BLOCKING, 3 MAJOR, 8 MINOR. Every headline is `#print axioms`-clean and instantiated at the lattice VOA V_2, so none is vacuous. Verdicts:

- the braided monoidal category of ordinary modules of a strongly rational VOA (a genuine Mathlib `BraidedCategory`, on the Huang–Lepowsky tensor product, with pentagon and hexagons proved), and the logarithmic braided tensor category of a C_2-cofinite VOA: *announceable as stated*;

- rigidity, Verlinde and the modular category: *with caveats*. (F1, MAJOR) They are proved for `Nice` VOAs, i.e. strongly rational *and pseudo-unitary*, although Huang's theorems do not need pseudo-unitarity; the hypothesis is genuinely used in the proofs. (Since 29 October its use for $V' \cong V$ is removed: `VOA.contra_vacuum_equiv_of_stronglyRational` and the `_of_stronglyRational` copies in `VOA/Huang/VerlindeVacuumFusionSR.lean` give the vacuum-fusion chain for strongly rational VOAs; the Cardy-positivity step `vacColumn_mem_K` keeps it, essentially, and the headline theorems still take `Nice`.) Rigidity was right rigidity only (`rightRigid_ordinary`); since 28 October the two-sided `RigidCategory` is a theorem, `VOA.Huang.HuangRigid.ri` (`VOA/Huang/RigidOrdinary.lean`), on the same monoidal instance as the braiding (checked by the new-declarations audit), still for `Nice` VOAs. Verlinde is proved in the form $S_{ax}S_{bx} = S_{0x}\sum_c N_{ab}^c S_{cx}$ with $S_{0x} \neq 0$;

- the congruence property: *not announceable until it has a named theorem* (F2, MAJOR). It is true in the library (it is discharged inside the proof of the Gannon–Rayhaun theorem, and the auditor's scratch declarations `audit_dln_congruence` and `audit_zhuCongruence` compile with standard axioms), but every library declaration that concluded it carried hypotheses. Since 28 October the named theorems exist, for `Nice` VOAs: `dlnCongruenceInput_holds`, `zhuCongruenceInput_holds` and `zhu_kernelContainsGamma_at_level`, in the namespace `VOA.Huang.Congruenc` (`VOA/Huang/CongruenceNamed.lean`). (F3, MAJOR, wording) Only the kernel half of Ng–Schauenburg's Theorem 6.8 is proved (`nsProjectiveKernelAll_holds`); the half saying that the level equals the Frobenius–Schur exponent is not. (The new-declarations audit adds a precision: at the minimal level the kernel statement is the full kernel claim of Dong–Lin–Ng; "kernel half" refers only to the Ng–Schauenburg input.)

- Deligne's theorem (`deligneTannakian_holds`): *with caveats*; it is the positive-dimension (Tannakian, bosonic) case for symmetric fusion categories, not the super version.

Chapter 22 (Gannon–Rayhaun): announceable with caveats. Counts: 0 BLOCKING, 2 MAJOR, 5 MINOR. The three headlines (`gannonRayhaun_forward`, `gannonRayhaunConverse_holds`, `gannonRayhaun_class` have no hypotheses, their axioms are standard, and the statement matches Gannon–Rayhaun's Theorem 3.1 and Proposition 3.2 (the same list, both directions, pairwise non-isomorphism). Non-vacuity is proved (`V2m_nice`, `exceptionalV2Group_exists`). The caveats: (M1, MAJOR, wording) "rational" is formalized as `AdmissiblyRational`: every weak (mode-stable, not necessarily

graded) submodule of an admissible module has a weak complement. The library's own note (`VOA/Modules/AdmissibleRationality.lean`) says that its relation to Dong–Li–Mason rationality is not settled and that neither implication is proved in Lean; the chapter overstated the match and has been corrected (Chapter 22, Remark 22.4). Since 29 October one direction is a theorem: for C_2-cofinite V, Dong–Li–Mason rationality (formalized faithfully as `DLMRational`) implies `AdmissiblyRational` (`VOA.Classification.COne.DLMRat.admissiblyRational_of_dlmRational`); the converse is open. (M2, MAJOR) the release build. The minor points: the combined statement and the converse are stated for carriers in `Type 0` only (disclosed in Remark 22.38); rationality and pseudo-unitarity quantify over modules in the VOA's own universe; and stale docstrings.

Physical meaning

In physical language the audits separate three things that a CFT paper often runs together. "The theory is consistent" (the braided tensor category exists) was confirmed as stated. "The theory is unitary in the weak sense needed for positivity arguments" (pseudo-unitarity, quantum dimensions equal to the ratios of S-matrix entries) turns out to be an extra input in the Lean proofs of rigidity and the Verlinde formula (now essentially only in the Cardy-positivity step), while Huang's proofs do without it. And "the characters obey a modular differential equation", the physicist's working definition of a theory with finitely many characters, is proved with a specified order for no theory analytically: formal coefficientwise second-order MLDEs are proved for the seven Deligne vacuum characters (Chapter 25); the analytic Arakawa–Kawasetsu MLDE, of unspecified order and for abstract genus-one blocks, is proved conditionally only on Etingof-finiteness, and unconditionally at the vacuum of $L_{-4/3}(\mathfrak{sl}_2)$. The audits' contribution is to say which of these sentences may be printed.

43.2 A catalogue of dead ends, traps and corrected mistakes

The working agreements of the project single out the record of dead ends as *the highest-value section* of every hand-off record between sessions: "the project's worst time sinks have all been re-attempts of routes already known to fail". This section consolidates that record. Each entry states (i) the claim, definition or route; (ii) why it fails, with the counterexample or certificate; (iii) the lesson. Entries backed by a Lean theorem are presented with the full fidelity protocol; entries backed by a numerical certificate or by a paper argument say so.

The entries fall into six kinds, and it helps to name them, because each kind is caught by a different check:

(A) *unsatisfiable definitions*: an axiom system no nonzero object satisfies (caught only by constructing an example, or by proving a certificate of emptiness);

(B) *conclusions satisfied by trivial objects*: the target theorem holds for a degenerate object as well as for the intended one (caught by asking "what else satisfies this?");

(C) *wrong formulas and conventions*: a sign, a normalisation or a modification that a source states differently or not at all (caught by numerical controls);

(D) *ambiguities*: a definition that does not determine what it was meant to determine (caught when a proof needs the missing information);

(E) *circular or insufficient reductions*: a reduction step that silently assumes its conclusion, or reduces to something no easier (caught by tracing what each step uses);

(F) *tooling and process traps*.

43.2.1 Unsatisfiable definitions

The twisted Jacobi identity over all indices

Recall from Chapter 34 that a g-twisted module, for an automorphism g of order N, has vertex operators $Y_M(u,z) = \sum_{r \in \frac{1}{N}\mathbb{Z}} u_{(r)} z^{-r-1}$, and that for u in the eigenspace $V^j = \{v : gv = e^{-2\pi i j/N} v\}$ only the modes $r \in -\frac{j}{N} + \mathbb{Z}$ occur. The library encodes the mode $u_{(k/N)}$ as `YM u k` with $k \in \mathbb{Z}$, so the support condition says `YM u k = 0` unless $k \equiv -j \pmod N$. The twisted Jacobi identity of Dong–Li–Mason is a family of identities indexed by $\ell \in \mathbb{Z}$ and by the fractional indices k, m; in the source it is asserted only for k in the support coset of u. Before 6 October 2026 the field `TwistedModule.jacobi` asserted it for *every* k. That predicate is preserved, under its own name, as the subject of a certificate. File `VOA/Moonshine/HeisenbergTwistedModuleDefect.lean`:

```
def JacobiAllIndices (g : Aut W) (N : ℕ) {M : Type*} [AddCommGroup M] [Module ℂ M]
    (YM : V →ₗ[ℂ] (ℤ → End ℂ M)) : Prop :=
  ∀ (j : ℕ) (u : V), u ∈ g.twistedEigenspace N j → ∀ (v : V) (x : M) (ℓ k m : ℤ),
    (∑ᶠ i : ℤ, (negOnePow i * cbz ℓ i) •
        (YM u (ℓ * N + k - i * N) (YM v (m + i * N) x)
          - negOnePow ℓ • YM v (ℓ * N + m - i * N) (YM u (k + i * N) x)))
      = ∑ᶠ i : ℕ, cbinom ((k : ℂ) / N) i • YM (W.smul u (ℓ + i) v) (k + m - i * N) x
```

Theorem 43.2 (The all-indices twisted Jacobi identity forces $M = 0$)**.** *Let V be a vertex operator algebra, $g \in \operatorname{Aut} V$, $N \geq 2$, and let Y_M be a linear map from V to fractional-mode families of endomorphisms of a vector space M such that $Y_M(\mathbf{1}, z) = \mathrm{id}$ (only the mode $\mathbf{1}_{(-1)}$, label $k = -N$, is nonzero, and it is the identity). If Y_M satisfies the twisted Jacobi identity for all $j, u \in V^j, v, x, \ell, k, m$ without restriction on k, then $M = 0$.*

File `VOA/Moonshine/HeisenbergTwistedModuleDefect.lean`:

```
theorem jacobiAllIndices_eq_zero {g : Aut W} {N : ℕ} (hN : 2 ≤ N) {M : Type*}
    [AddCommGroup M] [Module ℂ M] (YM : V →ₗ[ℂ] (ℤ → End ℂ M))
    (hvac : ∀ k : ℤ, YM W.vacuum k = if k = -(N : ℤ) then 1 else 0)
    (hJ : JacobiAllIndices g N YM) (x : M) : x = 0 := by
```

From the mathematics to the Lean statement

- `YM : V →ₗ[ℂ] (ℤ → End ℂ M)`: a $\mathbb{C}$-linear map assigning to each state u the family of its fractional modes, `YM u k` $= u_{(k/N)}$. `End ℂ M` is the algebra of linear endomorphisms of M.
- `hvac`: the vacuum acts by $\mathbf{1}_{(-1)} = \mathrm{id}$, which in the label convention $k/N = -1$ is $k = -N$; all other modes vanish. This is the twisted-module vacuum axiom `vacuum_YM`.
- `cbz ℓ i` is the integer binomial $\binom{\ell}{i}$ extended to $i \in \mathbb{Z}$ (zero for $i < 0$), `negOnePow i` is $(-1)^i$, and `cbinom x i` is the generalised binomial $x(x-1)\cdots(x-i+1)/i!$ with complex upper index; `W.smul u n v` is the n-th product $u_{(n)}v$ in the VOA; $\sum^{\mathrm{f}}$ is a sum of finitely many nonzero terms.
- The conclusion `x = 0` for an arbitrary `x : M` is $M = 0$.

The theorem is *stronger* than needed to condemn the old definition: it uses only the vacuum axiom, not the other fields of a twisted module.

Proof on paper. Take $u = v = \mathbf{1}$ (so $j = 0$), $\ell = -1$, $k = 1$, $m = -N - 1$. On the left every term contains a vacuum mode with label $-N + 1 - iN$ or $1 + iN$; neither equals $-N$ for any integer i when $N \geq 2$ (the first would need $iN = 1$, the second $(i+1)N = -1$). So the left side is 0. On the right the

term i involves $\mathbf{1}_{(-1+i)}\mathbf{1}$, which is $\mathbf{1}$ for $i = 0$ and 0 otherwise; the $i = 0$ term is $\binom{1/N}{0} Y_M(\mathbf{1})_{(-N)}x = x$. Hence $0 = x$. The point is that $k = 1$ lies outside the support coset of $u = \mathbf{1}$ (which is $k \equiv 0$), so the identity is being asserted for modes that do not exist. The repair adds exactly the hypothesis `(k + j) % (N : ℤ) = 0` to the field; Chapter 34 prints the repaired field and checks that it is the Dong–Li–Mason identity.

Physical meaning

In an orbifold CFT the twist field creates a branch cut: a field u of g-charge j picks up the phase $e^{2\pi i j/N}$ when carried around the twisted state, so its mode expansion only contains powers z^{-r-1} with $r \in -\frac{j}{N} + \mathbb{Z}$. The Jacobi identity is the statement that the operator product expansion is associative and local *for the modes that exist*. Demanding it for non-existent modes is like demanding that a fermion in the Ramond sector also have Neveu–Schwarz modes: the only Hilbert space compatible with both is empty.

What the machine verified

`VOA.jacobiAllIndices_eq_zero`: unconditional (its hypotheses are exactly the data being refuted); `#print axioms` re-run for this chapter: `[propext, Classical.choice, Quot.sound]`. The repair is the only change to a pre-existing definition made by the Moonshine work (diff of `VOA/Modularity/Twisted.lean` across the Moonshine commit: one hypothesis line, the docstring, and one binder in `OrdVModule.toTwisted`, which is the case $N = 1$ and is unaffected). Before the repair, every theorem with a hypothesis "`T : TwistedModule g N M`" with $N \geq 2$ and $M \neq 0$ was vacuous.

Trap / dead end

Lesson. A structure with no nontrivial instance can hide a modelling bug indefinitely (`README.md` calls the first instance of a definition its "correctness oracle"). The defect surfaced only when the first nonzero twisted module (the twisted Heisenberg module of Chapter 35) was attempted. Every new structure should be instantiated nontrivially as early as possible.

SuperTwistedModule: the same defect, not repaired

The library's super analogue, in `VOA/Modules/SuperTwistedModule.lean`, has the same shape. File `VOA/Modules/SuperTwistedModule.lean`:

```
support : ∀ (j : ℕ) (u : 𝒱), u ∈ g.twistedEigenspace N j →
  ∀ k : ℤ, (k - j) % (N : ℤ) ≠ 0 → YM u k = 0
/-- The full Koszul twisted Jacobi identity in fractional-mode form. -/
jacobi : ∀ {p q : ZMod 2} (j : ℕ) (u : 𝒱),
  u ∈ g.twistedEigenspace N j → u ∈ W.parity p →
  ∀ (w : 𝒱), w ∈ W.parity q → ∀ (x : M) (ℓ k m : ℤ),
  (∑ᶠ i : ℤ, (negOnePow i * cbz ℓ i) •
      (YM u (ℓ * N + k - i * N) (YM w (m + i * N) x)
        - (koszul p q * negOnePow ℓ) •
          YM w (ℓ * N + m - i * N) (YM u (k + i * N) x))) =
    ∑ᶠ i : ℕ, fractionalBinom ((k : ℂ) / N) i •
      YM (W.smul u (ℓ + i) w) (k + m - i * N) x
```

Trap / dead end

Open defect. The field `jacobi` carries no restriction of k to the support coset (here written $k \equiv j \pmod N$, a different sign convention from `TwistedModule`). The vacuum is even, so the certificate of Theorem 43.2 applies verbatim with

$p = q = 0$, `koszul 0 0 = 1`: for $N \geq 2$ every `SuperTwistedModule` is zero. The source file `VOA/Moonshine/HeisenbergTwistedModuleDefect.lean` records this in its docstring; the super certificate itself has *not* been formalised (argued on paper here). The structure is mentioned in twelve files (`VOA/Modules/SuperTwistedModule.lean`, `VOA/Modules/SuperTwistedZhu.lean`, `VOA/Modules/SuperRelativeEtingofFinite.lean`, seven files `VOA/Modularity/Super*.lean`, `VOA/Modularity/Twisted.lean`, and the certificate file). Any theorem among them whose hypotheses include a `SuperTwistedModule` with $N \geq 2$ is vacuous until the field is repaired. Repairing it is a decision left to the maintainers (Section 43.6). The Moonshine construction does not use `SuperTwistedModule`.

Bilinear positivity on a complex subspace

Theorem 43.3 (A $\mathbb{C}$-bilinear form is never positive on a nonzero $\mathbb{C}$-subspace)**.** *Let β be a $\mathbb{C}$-bilinear form on a complex vector space E and $S \leq E$ a subspace. If $\beta(x, x)$ is a positive real number for every nonzero $x \in S$, then $S = 0$.*

File `VOA/Core/GradedUnitarity.lean`:

```
theorem eq_bot_of_bilinear_pos (β : BilinForm ℂ E) (S : Submodule ℂ E)
    (hpos : ∀ x ∈ S, x ≠ 0 → ∃ r : ℝ, 0 < r ∧ β x x = (r : ℂ)) : S = ⊥ := by
```

From the mathematics to the Lean statement

`BilinForm ℂ E` is a $\mathbb{C}$-bilinear form, `Submodule ℂ E` a complex subspace, `(r : ℂ)` the real number r viewed as a complex number, and `S = ⊥` says S is the zero subspace. The statement is exactly Theorem 43.3.

Proof on paper. If $x \neq 0$ in S has $\beta(x, x) = r > 0$, then $ix \in S$ and $\beta(ix, ix) = i^2 r = -r < 0$, a contradiction.

Physical meaning

Unitarity of a CFT is positivity of a *Hermitian* inner product $\langle \cdot | \cdot \rangle$ (antilinear in one slot); the Zamolodchikov metric, the BPZ form with an antilinear involution, reflection positivity are all Hermitian. A bilinear form can only be "positive" on a real form of the space. An earlier encoding of clause (vi) of the graded-unitarity conjecture of Arabi Ardehali–Beem–Lemos–Rastelli (a positivity condition) used a bilinear form and was therefore false for every VOA with a nonzero weight space, while its documentation called the conjecture open. Fixed by stating clause (vi) for a sesquilinear form (`SesqForm`).

What the machine verified

Unconditional; standard axioms (it is part of the maintained audit). Recorded among the library's dead ends (`README.md`, "Known dead ends").

Other unsatisfiable or refutable predicates in the library

The library-wide register (`README.md` "Known dead ends", and the project's internal session records) contains several more entries of kind (A). We list them with their certificates; the full fidelity treatment of each is in the chapter covering the relevant area.

- **`GenFields` over the left ideal `MRbot` is empty** (generators-and-OPE presentation of the Virasoro VOA). File `VOA/Core/NonlinearVirasoro.lean`:

```
theorem not_nonempty_genFields_MRbot_virasoro (c : ℂ) :
    ¬ Nonempty (GenFields (MRbot (virasoroOPE c))) := by
```

The structure `GenFields` asks for local fields generating a quotient of the tensor algebra by an ideal of relations; with the *left* ideal `MRbot` the creation part of the generating field is forced to be left multiplication, and then the mode commutator modulo a left ideal cannot be a sum of delta functions. The certificate is an explicit linear functional on words of length three that kills `MRbot` but must equal $(-1)^N$ by locality of order N. A step documented as "precisely the open step" was thus false; the correct ideal is the two-sided `MRtwo`.

- **The formal $\mathbb{C}[[q]]$ route says nothing about the upper half-plane.** File `VOA/Modularity/FormalSpecializatio`

```
theorem no_algHom_powerSeries_X_ne_zero (φ : PowerSeries ℂ →ₐ[ℂ] ℂ) {q₀ : ℂ} (hq : q₀
↪  ≠ 0) :
    φ PowerSeries.X ≠ q₀ := by
```

A $\mathbb{C}$-algebra homomorphism $\mathbb{C}[[q]] \to \mathbb{C}$ must send q to 0 (if $q \mapsto q_0 \neq 0$, then $1 - q/q_0$, a unit of $\mathbb{C}[[q]]$, would map to 0). So "evaluation at $q_0 = e^{2\pi i\tau}$" does not exist on formal power series and no Nakayama argument over $\mathbb{C}[[q]]$ reaches a point of the upper half-plane.

- **`BlockFiniteDim.zhu_modularity_of_analytic_finrank_le` is vacuous**: its hypothesis `hle` is refuted by `not_finrank_analyticSlashAmbient_le` in `VOA/Modularity/SlashAmbientObstruction.lean`. (The underlying cause was a helper definition returning a junk value on inhomogeneous vectors.)
- **`qInjOnBottomResidual` is false** for $\dim A(V) > 1$ (free-boson counterexample, certificate `qInjOnBottom_false_of_balancing_ne_bot` in `VOA/Modules/ZhuVermaAnArchSdBalancedBottom.lean`).
- **`SimpleAModsRealized` as first typed was false**: it forced every simple $A(V)$-module to be finite-dimensional, false for $A(V^k(\mathfrak{sl}_2)) \cong U(\mathfrak{sl}_2)$; now scoped under finite-dimensionality of $A(V)$.
- **`FZModeDescent` is false** (free-boson counterexample: only the zero mode descends to the Frenkel–Zhu quotient).
- **Zhu's Lemma 4.4.4 in "unitriangular" form is false** (it would force $Z(L[-n]x) = 0$ for $n \geq 3$); Zhu carries a Virasoro-primary hypothesis for this reason.
- **General `DiagonalFHL` is not a theorem**: full invariance for an arbitrary bilinear form forces symmetry conditions on V_1; the canonical invariant form is obtained by a different route.

Trap / dead end

A mirror-image mistake. The register also contains a *retracted* dead end: an earlier note declared the structure `Sl2Presentation` unsatisfiable, judging from the *name* of an ideal (`casIdeal`) without reading its one-line definition; it was satisfiable, and the note retired live work. Lesson: before declaring a predicate unsatisfiable, read the definition, not the name; a false "do not attempt" is as harmful as a false "done".

43.2.2 Conclusions satisfied by trivial objects

The square-zero TRAP

The first "definition of done" for $V^\natural$ in `Notes/MonsterRoadmap.md` listed five targets: a VOA structure on $V^\natural = V_\Lambda^+ \oplus (V_\Lambda^T)^+$, central charge 24, $V_1 = 0$, $\dim V_2 = 196884$, and graded dimension J. While building the reconstruction interface (`reconstruct_nat`, Chapter 38), an agent noticed that all its hypotheses hold when the twisted×twisted→untwisted operator $\overline{W}$ is set to 0.

Proposition 43.4 (The square-zero extension). *Let U be a vertex operator algebra and M an ordinary U-module with integral weights. On $U \oplus M$ define $Y(u,z) = \mathrm{diag}(Y_U(u,z), Y_M(u,z))$ for $u \in U$ and, for $t \in M$, $Y(t,z)(u',t') = (0,\ e^{zL_{-1}} Y_M(u',-z)t)$. Then $U \ltimes M$ is a vertex operator algebra with the same vacuum, conformal vector and central charge as U, and graded dimension $\dim U_n + \dim M_n$. It is not simple when $M \neq 0$: $0 \oplus M$ is a proper ideal.*

Proof on paper. The products are $u \cdot u' \in U$, $u \cdot t \in M$, $t \cdot u \in M$ (by skew-symmetry) and $t \cdot t' = 0$. Locality of $Y(t)$ with $Y(t')$ holds because both map $U \oplus M$ into $0 \oplus M$ and kill $0 \oplus M$, so their products vanish; the remaining locality relations are module locality and the intertwining property of the skew map W. The other axioms reduce to those of U and M. The subspace $0 \oplus M$ is stable under all modes and does not contain the vacuum.

For $U = V_\Lambda^+$ and $M = (V_\Lambda^T)^+$ this object satisfies all five original targets, because the graded dimension depends only on the underlying graded vector space. It is not $V^\natural$. In Lean the statement is not formalised as a separate theorem; it is recorded in `Notes/MonsterRoadmap.md` and in `Notes/M8GluingPlan.md` ("Status, after M8d part 1"), and the defence against it is built into the final theorem in two ways: the vertex map is pinned to `Ynat VnatAxioms.wbarL` with the genuine adjoint $\overline{W}$, proved nonzero, and the conclusion contains `V.IsSimple`. File `VOA/Moonshine/VnatGenuine.lean`:

```
theorem leechWbar_ne_zero : leechWbar ≠ 0 := by
```

From the mathematics to the Lean statement

`leechWbar` is the family $t \mapsto \overline{W}(t,z)$ of operators $(V_\Lambda^T)^+ \to V_\Lambda^+$ defined as the adjoint of the skew intertwiner W with respect to the invariant forms (Chapter 37). The proof exhibits a nonzero coefficient: for weight-2 twisted states, $\overline{W}(t)_{(3)}t' = \mathrm{TPForm}(t',t)\,\mathbf{1}$, and the form `TPForm` is nondegenerate. Nonvanishing of $\overline{W}$ alone would not exclude every degenerate structure; it is `IsSimple` that does, via nondegeneracy of the invariant form $B^\natural = B_V \oplus \mathrm{TPForm}$ (`SimpleNat.vnatVOA_isSimple`, Chapter 38), which fails for the square-zero extension because the $\overline{W}$-block of invariance is exactly the adjunction $\overline{W} = W^\dagger$.

Physical meaning

The square-zero extension is a chiral algebra in which the twisted-sector states never fuse back into the untwisted sector: tw × tw → 0. It has the right partition function $J(\tau)$ but it is not a unitary CFT: its two-point functions of twisted states vanish ($\langle t|t'\rangle$ would be computed by $t \cdot t'$ landing on the vacuum), so the twisted states are null. A physicist's check that the theory is non-degenerate is exactly the nondegeneracy of the Zamolodchikov two-point function, which is what simplicity encodes here. The lesson is a classic one: the partition function does not determine the operator algebra.

What the machine verified

`leechWbar_ne_zero` and `SimpleNat.vnatVOA_isSimple` are proved; the latter was first conditional on `htt` (twisted×twisted locality), which is discharged in the final theorem: for the final structure, `V.IsSimple` is the last clause of `VOA.Moonshine.moonshine` itself (`VOA/Moonshine/TopPairs.lean`), which has no hypotheses. The square-zero proposition itself is argued on paper only.

Trap / dead end

Lesson. For every target ask what else satisfies it. Numerical invariants (dimensions, characters) do not determine algebraic structure. "Done" for $V^\natural$ requires simplicity, or equivalently a nondegenerate invariant form.

The $\varphi = 0$ trap and the hits_cyclic clause

The triality σ on the twisted sectors was reduced (Chapter 40) to top-level data: a linear map φ from the weight-2 space of V_3^+ to T_s^+ intertwining zero modes. File `VOA/Moonshine/SigmaExistLeech.lean`:

```
structure TopSigmaV3 (s : ZMod 2) (φ : VPlus →ₗ[ℂ] TP) : Prop where
  /-- `φ` maps the top level of `V₃⁺` into `T_s⁺`. -/
  maps_frame : ∀ x ∈ OmegaV3, φ x ∈ TPframe s
  /-- `φ` maps the top level into weight 2. -/
  maps_weight : ∀ x ∈ OmegaV3, φ x ∈ plusModule.weight (2 : ℂ)
  /-- Zero-mode intertwining: `φ (o(a) x) = o(σ a) φ x` for every homogeneous `a ∈ V₀⁺`. -/
  zero_mode : ∀ (k : ℤ) (a : V0Sub.carrier), (a : VPlus) ∈ leechVOAPlus.grading k →
    ∀ x ∈ OmegaV3, φ (actV a (k - 1) x) = actT (sig a) (k - 1) (φ x)
  /-- `φ` hits a cyclic vector `h₀(-½)𝟙 ⊗ t₀` of `T_s⁺`. -/
  hits_cyclic : ∃ t₀ : TLeechT, t₀ ∈ leechFrameT s ∧ t₀ ≠ 0 ∧ ∃ x ∈ OmegaV3, φ x = x0T t₀
```

Trap / dead end

Without the last clause, $\varphi = 0$ satisfies the first three, and the existence theorem `sigmaV3T_exists_of_top` would produce the zero intertwiner, from which nothing about σ follows. `hits_cyclic` (its image contains a nonzero cyclic vector $h_0(-\frac{1}{2})\mathbf{1} \otimes t_0$) excludes this. Lesson: every existence-by-reduction statement needs a non-degeneracy clause, and the referee should look for it.

A sign that is a condition, not a normalisation

The data of σ (`SigmaData`) leave free $\Phi \mapsto c\Phi$, $\Psi \mapsto c^{-1}\Psi$ and $\Theta \mapsto -\Theta$. One might think every scalar condition can be met by normalising. The condition `ThetaTop` says $\mathrm{TPForm}(\Theta\cdot, \Theta\cdot) = \mu\,\mathrm{TPForm}$ with $\mu = +1$; since $\Theta^2 = 1$ and the form is unique up to scalar, $\mu = \pm 1$, and μ is *invariant* under $\Theta \mapsto -\Theta$. If μ were -1, both eigenspaces of Θ would be isotropic, the trace of Θ on the top would be 0, and the key identity would be unsatisfiable. Numerically $\mu = 1$ to 4×10^{-12} and $\mathrm{tr}\,\Theta_J = -112 \neq 0$ (Section 43.3.7); in Lean $\mu = +1$ is proved (`thetaTop_mkData`). Similarly the final identity holds for $\varepsilon = +1$ (`topPairs_one`); that it fails for $\varepsilon = -1$ is argued on paper only (it would force $\Theta_0(o(x_n)\Phi_0 x_n) = 0$).

43.2.3 Wrong formulas and conventions

The unmodified triality of Dolan–Goddard–Montague: 6372 versus 2324

The triality σ on the Niemeier lattice VOA V_N, $N = N(A_1^{24})$, is built from the 24 copies of $\widehat{\mathfrak{sl}}_2$ at level one. Dolan, Goddard and Montague give it as $\sigma = \prod_j \exp\big(\frac{i\pi}{\sqrt{2}}(J_0^{j1} + J_0^{j2})\big)$ (their (7.5)) and, for $d/8$ odd, a modification inserting a sign $z_l = (-1)^{x_l}$ in one coordinate (their (7.8)). The docstring of `VOA/Moonshine/TrialityGolay.lean` records a trace computation that decides between them.

Proposition 43.5 (Trace certificate). *On* $(V_0^+)_2$, $\dim = 49428$, $\mathrm{tr}(\sigma|(V_0^+)_2) = 300 + 8\sum_{c\ octad}(-1)^{c\cdot u}$, *where* $u = 0$ *for (7.5) and* $u = e_l$ *for (7.8). Hence* $\mathrm{tr} = 6372$ *for (7.5) and* $\mathrm{tr} = 2324$ *for (7.8).*

Proof on paper. $(V_N)_2$ decomposes under $\mathfrak{sl}_2^{24}$ into Fock and root states and the $759 \cdot 2^8$ octad states e^n, $n = \pm 1$ on an octad. Projecting to the fixed points of $\langle \chi, \Theta \rangle$ with $\frac{1}{4}\sum_k$ (legitimate because σ normalises this group) and using the $SU(2)$ characters of σ_j on spin $\frac{1}{2}$ and spin 1, the non-octad contribution is 300 and each octad contributes $8(-1)^{c\cdot u}$. There are 759 octads, so $u = 0$ gives $300 + 8 \cdot 759 = 6372$. Each point lies in 253 octads, so for $u = e_l$ the sum is $(759 - 253) - 253 = 253$, giving $300 + 8 \cdot 253 = 2324$.

Now suppose σ were the restriction of an automorphism $\tilde{\sigma}$ of $V^\natural$, i.e. (by FLM) of an element of the Monster $\mathbb{M}$, with $V_0^+ = (V^\natural)^E$, $E \cong 2^2$. Then $\mathrm{tr}(\sigma|{V_0^+}_2) = \frac{1}{4}(\mathrm{tr}\,\tilde{\sigma} + \mathrm{tr}\,\tilde{\sigma}k_0 + 2\,\mathrm{tr}\,\tilde{\sigma}k_1)$ on ${V^\natural}_2 = 1 + 196883$, with $\tilde{\sigma}, \tilde{\sigma}k_0$ involutions and $\tilde{\sigma}k_1$ of order 4. The largest values of the Monster characters on 196883 for such elements are 4371 (class 2A) and 275 (class 4A), so the trace is at most $\frac{1}{4}(4372 + 4372 + 2 \cdot 276) = 2324$. Thus 6372 is impossible and 2324 saturates the bound.

Physical meaning

The trace of a symmetry on a weight space is a twined partition-function coefficient: it is what a physicist would compute to identify which symmetry of the Moonshine CFT an operator is. Here a character-table bound from the Monster acts as a consistency check on a formula copied from a paper: the unmodified rotation of the 24 $SU(2)$ currents is a symmetry of the Niemeier theory but not one that extends to the Moonshine theory.

What the machine verified

Argued on paper (in the file docstring) and checked numerically: with the real Golay code the weight-2 model (`scripts/moonshine/numerics/triality/`) reproduces $\dim(V_0^+)_2 = 49428$ and the traces 6372 and 2324, and at module level the unmodified σ maps V_3^+ to the wrong twisted summand (Section 43.3.4). The Monster bound uses the Monster character table, which is cited, not formalised. In Lean the library's `golaySigma` is defined in the (7.8) form; nothing in Lean depends on the bound.

Sign conventions that each turned out to be necessary

The numerical model of Section 43.3.2 tested the twisted×twisted locality relation (4.23) in the library's conventions and then broke one convention at a time. Each of the following "simplifications" makes (4.23) fail with relative residual 1.7–2.0, and each is therefore recorded as a dead end.

1. **The $\varepsilon(\alpha,\alpha)$ sign on T.** The invariant form on the 4096-dimensional module T must satisfy $B(e_\alpha t, t') = (-1)^{\langle\alpha,\alpha\rangle/2} B(t, e_\alpha t')$ (File `VOA/Moonshine/TForm.lean`, `TForm_eT`), the factor $(-1)^{L_0}$ of the contragredient. The "group" sign $\varepsilon(\alpha,\alpha)$ (transpose = inverse) differs from it by a basis-dependent character, and the corresponding form is symmetric or *alternating* according to an Arf invariant that depends on the chosen basis: for random bases of E_8 the count $\#\{x : x \cdot Mx = 0\}$ is 136 or 120 (`VOA/Moonshine/TFormLattice.lean`).

2. **The positive Fock form.** The invariant form on $S[\theta]$ must satisfy $h(m)^t = -h(-m)$ (`fockForm`, File `VOA/Moonshine/InvFormFock.lean`); the positive, Hermitian-looking form $h(m)^t = +h(-m)$ transposes the dressing $E^-E^+(v)$ to $E^-E^+(-v)$ and breaks invariance (sympy check recorded in the file).

3. **A constant charge sign.** On V_L the form is $B(p \otimes e^\alpha, q \otimes e^\beta) = \delta_{\alpha+\beta,0}\, c(\alpha) F(p,q)$ with $c(\alpha) = (-1)^{\langle\alpha,\alpha\rangle/2}\varepsilon(\alpha,\alpha)$, which is *not* constant because the library's cocycle does not satisfy $\varepsilon(\gamma,\gamma) = (-1)^{\langle\gamma,\gamma\rangle/2}$. File `VOA/Moonshine/NondegLattice.lean`:

   ```
   noncomputable def chSign (α : L.carrier) : ℂ :=
     (-1 : ℂ) ^ (LatGen.halfNorm L α) * latticeCocycle L α α
   ```

   Setting $c \equiv 1$ breaks (4.23).

4. **Dropping $(-1)^w$ in $\overline{W}$.** The adjoint formula carries a weight sign; dropping it breaks (4.23).

5. **The super sign.** The anticommutator version of the twisted×twisted relation fails (residual ≈ 2): with the library's signs the extension is a VOA, not a vertex superalgebra.

Physical meaning

These are the familiar sign headaches of lattice CFT: the cocycle ε that makes vertex operators $e^{i\alpha\cdot X}$ mutually local, the BPZ conjugation $(-1)^{L_0}$ and z^{-2L_0} of a primary field, and the reality condition $a_n^\dagger = a_{-n}$ versus the bilinear transpose $a_n^t = -a_{-n}$ for a chiral boson ∂X (the bilinear form differs from the Hermitian one by $X \mapsto -X$ on the antilinear side). Each sign controls whether the twisted-sector OPE is associative; getting one wrong gives a theory that is not local.

43.2.4 Ambiguities

The golayE ambiguity

The automorphism σ of V_0^+ (`v0Sigma`) is transported from V_N through an isomorphism that involves a character `golayE` chosen by `Classical.choose` from an existence statement. The specification determines only twice the character.

Theorem 43.6 (golayE is not determined). *There are two characters e_1, e_2 of Λ_0 with values in $\mathbb{C}^\times$, both satisfying the specification $\psi = g_e\,\theta\,g_e^{-1}$, whose values at the preimage w_0 of $8e_0$ differ by a sign.*

File `VOA/Moonshine/TrialityTwSigma.lean`:

```
theorem golayE_not_determined :
    ∃ e₁ e₂ : lam0.carrier →+ Additive ℂˣ,
      (∀ x, lam0Psi x = charLat lam0 e₁ (thetaLat lam0 (charLat lam0 (-e₁) x))) ∧
      (∀ x, lam0Psi x = charLat lam0 e₂ (thetaLat lam0 (charLat lam0 (-e₂) x))) ∧
      ∃ w₀ : lam0.carrier, inclΛ w₀ = frameW ∧ charVal lam0 e₂ w₀ = -charVal lam0 e₁ w₀ :=
       ↪ by
```

From the mathematics to the Lean statement

`lam0.carrier →+ Additive ℂˣ` is a group homomorphism from Λ_0 to the multiplicative group $\mathbb{C}^\times$ (written additively); `charLat lam0 e` is the induced automorphism g_e of V_{Λ_0} ($e^\alpha \mapsto e(\alpha)e^\alpha$); `thetaLat` is θ; `lam0Psi` is the target involution ψ; `inclΛ w₀ = frameW` says w_0 maps to $8e_0$ in the Leech lattice; `charVal` evaluates. The proof takes $e_2 = e_1 + e_\beta$ with $e_\beta = (-1)^{\langle\beta,\cdot\rangle}$, $\beta = (5, 1^{23})$, which has $2e_\beta = 0$ and $\langle\beta, 8e_0\rangle$ odd.

Physical meaning

Changing the choice conjugates σ by the symmetry $g_\beta \oplus (1 \otimes e_\beta)$ of the Moonshine CFT, which exchanges the two twisted subsectors T_0^+ and T_1^+. Physically the question "which twisted sector does triality map the untwisted sector V_3^+ to" has no convention-independent answer until a choice is made; both answers describe isomorphic theories.

What the machine verified

Unconditional; `#print axioms` re-run: standard axioms. Consequence: downstream statements are phrased with "$\exists s$" (e.g. `topSigma_both`); one must not try to prove that $\sigma(V_3^+)$ is `TPframe 0` (or `1`) from the definitions.

The non-computable cocycle, and why it did not matter

The Leech cocycle is `latticeCocycle` over a basis obtained from `Module.Free.chooseBasis`, a choice; and the oscillator frame is the $\sqrt{G}$ frame, not the Golay frame. So no explicit sign $\varepsilon(\alpha, \beta)$ is computable, and every identity must be proved symbolically. During the top-level work this was flagged

as a design issue: an explicit Golay-frame model transported via functoriality might simplify the remaining proofs. The agent who completed the triality reported, and the supervisor confirmed by inspection of the finished proofs, that no concrete cocycle value was ever needed: everything reduced to bimultiplicativity, the commutator $\varepsilon(\alpha,\beta)\varepsilon(\beta,\alpha) = (-1)^{\langle\alpha,\beta\rangle}$, and Golay-code facts. The refactor was not done. Related design point: comparing cocycles of a sublattice and of the ambient lattice needs a $\mathbb{Z}/4$-valued coboundary; a ±1-valued one would commute with θ only up to a character.

Two lattice types

There are two structures called `IntegralLattice`: the vendored `_root_.IntegralLattice` and `VOA.IntegralLattice`; inside `namespace VOA` the bare name means the latter. The bridge `IntegralLattice.ofEbeling` transports between them. A wrong resolution of a shadowed name typechecks and yields an unprovable goal; the same trap is recorded library-wide for `mode_iterate` and `mode_commutator`.

43.2.5 Circular and insufficient reductions

1. **The vacuum trick for $(V_\Lambda^T)^+$ is circular.** The untwisted sectors are cyclic by the "vacuum trick" (a Borcherds identity applied to $u_{(n)}\mathbf{1}$). The analogous route for the twisted sector needs the $V^\natural$ Borcherds identity for three twisted vectors, which is (4.23), the very relation being proved. Commutator formulas with one untwisted argument do not imply it. Twisted cyclicity (`cyclic_TPframe`) was proved by an explicit route inside the twisted module.

2. **`YnatT_eq_of_creates` is circular for the key identity.** File `VOA/Moonshine/M8h0Gap.lean`:

```
theorem YnatT_eq_of_creates (hspan : ModeSpan g) (x : TP) (Ψ : FormalDist (End ℂ
↪  Vnat))
    (hcov : DCovariant Tnat Ψ) (h0 : Ψ 0 vacNat = ((0 : SkewVP), x))
    (hneg : ∀ q : ℤ, q < 0 → Ψ q vacNat = 0) (hU : ∀ v : SkewVP, Local Ψ (YnatU v))
    (hT : ∀ j, Local Ψ (YnatT leechWbar (g j))) : YnatT leechWbar x = Ψ := by
```

   It identifies a field with $Y^\natural(0,x)$ if the field is local with *all* $Y^\natural(g_j)$, twisted generators included (`hT`). Applied to $\Psi = \sigma Y^\natural(v)\sigma^{-1}$, the hypothesis `hT` is twisted×twisted locality, i.e. the goal. The replacement uses locality with V_0^+ only. File `VOA/Moonshine/M8hKeySigma.lean`:

```
theorem eq_zero_of_V0local (F : FormalDist (End ℂ Vnat))
    (hloc : ∀ u : V0Sub.carrier, Local F (YnatU (u : VPlus)))
    {β : leech.carrier} (hβ : β ∉ lambda0) (t : ZMod 2 → TLeechT)
    (ht : ∀ s, t s ∈ leechFrameT s) (ht0 : ∀ s, t s ≠ 0)
    (hvac : ∀ p, F p vacNat = 0) (h3 : ∀ p, F p (frameX0P β, 0) = 0)
    (hT : ∀ s p, F p (0, x0T (t s)) = 0) : F = 0 := by
```

   Similarly, using V_3^+-locality of $L_v = \sigma Y^\natural(v)\sigma$ is circular: it is equivalent to the identity for $b \in V_3^+$.

3. **"Irreducible tops ⇒ Zhu generation" is circular.** The numerics showed that the weight-2 zero modes generate End(top) on every top (Section 43.3.5). This does not prove `ZhuGenerated`: the set $S = \{a : \varphi o(a) = o(\sigma a)\varphi\}$ being everything is exactly the conclusion; irreducibility gives only a dichotomy (the graph of φ, or everything), and excluding the second case needs information about $A(V_0^+)$ beyond its image. What irreducibility does give is uniqueness of φ up to scalar.

4. **V_0^+ is not strongly generated by its weight-2 space.** dim of the weight-3 Fock part is 576, while L_{-1} of weight 2 gives only 300. So the classical lemma "strong generators are Zhu generators" does not apply; the 0-mode products $a_{(0)}b$ are essential (filtered commutator $a * b - b * a \equiv a_{(0)}b$).

5. **Weak generation does not reduce the top clause.** V_Λ^+ is generated under n-th products by the $e^\beta + e^{-\beta}$ (`leechPlus_generated`), but $o(a_{(n)}b)$ on the top is not determined by $o(a)$, $o(b)$ on the top. Only Zhu generation (closure under $*$ modulo $O(V)$) reduces the zero-mode clause to generators.

6. **(4.23) is not decided by finitely many low-weight coefficients**: the top four-point function is $z_2^a f(z_2/z_1)$ with f an infinite series whose rationality is the content; no finite set of coefficients certifies it without a closed form or an ODE.

7. **Top-level vanishing does not imply that an intertwiner vanishes** without the Frenkel–Zhu bimodule $A(M)$: the top-level part of the key identity is necessary, not sufficient. Machine-checked replacement: top-level *output* vanishing for *all* states v suffices (`keySkew_of_keyTopV`); finiteness then comes from bimodule generation.

8. **Induction on** $\mathrm{wt}\, v + \mathrm{wt}\, b$ via the defect commutator and skew-symmetry does not close (zero-mode reductions raise the state weight); skew-symmetry alone does not decide `KeySkew` (it says J is a fixed point of an involution, which allows components in both eigenspaces); the relation (4.22) gives no new information about the key block.

9. **Weight-2 quadratic left factors alone fail in charged degree 1**: the exact charged-vacuum formula `quadF_lead_one` was needed (Fock spanning).

10. **Ground states cannot be reached from Fock-dressed sources** (weight count), so the lattice statement `GroundLattice` is necessary for the filtered criterion, not merely convenient.

11. **`Modules.Fusion.Intertwiner` is commutator-only.** File `VOA/Modules/Fusion.lean`:

```
structure Intertwiner (A : OrdVModule W M) (B : OrdVModule W N) (C : OrdVModule W P)
 ↪  where
  /-- The mode data `𝒴_s(u)x`. -/
  modes : IntertwinerModes M N P
  /-- Lower truncation: `𝒴_s(u)x = 0` for `Re s ≫ 0`. -/
  truncation : ∀ (u : M) (x : N), ∃ s₀ : ℝ, ∀ s : ℂ, s₀ ≤ s.re → modes s u x = 0
  /-- The defining intertwining commutator (membership in `IntertwinerSpace`). -/
  isIntertwiner : modes ∈ IntertwinerSpace A B C
```

It has truncation and the commutator formula but no L_{-1}-derivative property and no associativity, so it is weaker than an intertwining operator of Frenkel–Huang–Lepowsky. Do not route uniqueness arguments through it; the Moonshine proof avoids it entirely. Its fusion coefficient is discussed in Section 43.2.8.

Trap / dead end

Lesson for (E). For each reduction write down what each step *uses*, not only what it proves. Circularity in this project always entered through a hypothesis that looked general ("local with all generators", "a uniqueness lemma") but specialised to the goal.

43.2.6 Combinatorial and numerical pitfalls

- **Random sign sampling misses lattice exceptions.** In the ground-state step of Zhu generation the exceptional families $E_2 = \{(\pm 1)^{24} : \text{negative set} \in \mathcal{G}\}$ and $E_3 = \{s + 2s_i e_i : N(s)\Delta\{i\} \in \mathcal{G}\}$ are single sign classes indexed by Golay codewords; random sampling of signs found only $E_1 = \{\pm 4e_i\}$. E_2, E_3 were found by hand and confirmed by exhaustive enumeration. Use orbit structure or exhaustive enumeration.

- **Do not exclude** $\alpha = \beta$ in the ground product with $\langle \alpha, \beta \rangle \geq 1$: $\gamma = 2\alpha$ has $\gamma/2$ as its only partner, and an earlier `GroundRel` with $\alpha \neq \beta$ was too weak.
- **Low-order traces do not distinguish modules**: $\operatorname{tr} o(u)$ and $\operatorname{tr} o(u)o(v)$ agree on all six weight-2 V_0^+-modules; the V_3^+/V_3^- distinction lives in long loops $n \to -n$.
- **Ground-state rationality is not a unimodularity test**: D_8 also gives a rational four-point function.
- **Left action alone** (no 0-modes) gives rank 0/24 at weight 3 in the bimodule test.

43.2.7 Tooling and process traps

- **`abbrev ExtraT` times out.** File `VOA/Moonshine/ExtraspecialModule.lean`:

  ```
  noncomputable abbrev ExtraT : Type := Rep (cocMat L) (isUnit_det_cocMat L hEven hU)
  ```

  Instance search for the scalar action through the `abbrev` times out; downstream code uses `Rep (cocMat L) _` directly.
- **The audit trap** `-DmaxSynthPendingDepth=3` (Section 43.1.6).
- **`ring` inside `first`** silently "succeeds" (falls back to `ring_nf`); use `ring1`. **`ext` on a `FormalDist₂`** descends too far; use `FormalDist₂.ext`.
- **Disk and pickles in numerics.** The first triality pipeline wrote multi-GB pickled intermediates (one stage alone about 1 GB, about 2 GB in total); they were deleted, and the KeySkew numerics were rebuilt to compute σ block by block with a cache of about 68 MB. Scripts first lived in a temporary session scratchpad and had to be copied to `scripts/moonshine/numerics/` to survive; paths inside them may need adjusting.
- **A naive rename.** When the library was renamed from `MoonshineVOA` to `VOA`, a case-insensitive substitution would have destroyed the genuine monstrous-moonshine module names (`MoonshineHauptmodul`, `MoonshineModule`, ...); only the exact token was substituted.
- **Concurrent sessions in one tree** invalidated recorded builds (Section 43.1.3).
- **Stale prose** (Section 43.1.8, and Section 43.2.8).

43.2.8 Documentation debt and open library issues found while writing the book

The authors of the other chapters, reading every quoted declaration against its source, recorded discrepancies. Each item below was re-checked against the source for this chapter.

1. **The structure called "vertex algebra" was not one** (*resolved by renaming, 28 October 2026*). The library's transcription of Gannon's Definition 5.1.3(a), then named `VertexAlgebra` (and its ungraded companion `BareVA`), has no translation-covariance axiom, and VA1–VA5 imply neither covariance nor the Borcherds identity: a three-dimensional counterexample was machine-checked for Chapter 4 (Theorem 4.7) and is now in the library as `TranslationCovariantCounterexample`. No theorem was wrong — every Borcherds-type result is stated for `VertexOperatorAlgebra`, whose axiom (VOA3) supplies covariance — but the name and an old docstring were. The structures are now `PreVertexAlgebra` and `BarePreVA`; `VertexAlgebra` is the genuine notion (a `PreVertexAlgebra` with the field `translation_covariant`), and `VertexOperatorAlgebra.toVertexAlgebra` makes every VOA one. At the same time the VOA structure was layered: `GradedVertexOperatorAlgebra` (the FLM/Lepowsky–Li notion) and `VertexOperatorAlgebra` (that, of CFT type). Similarly the

universal affine VOA $V^k(\mathfrak{g})$, formerly `simpleAffineVOA`, is now `universalAffineVOA` (Chapter 23). The super analogue `SuperVertexAlgebra` has the same omission and keeps its name (Chapter 17).

2. **`VOA.fusionCoeff` is identically** 0 (argued on paper, not formalised). File `VOA/Modules/Fusion.lean`:

```
noncomputable def fusionCoeff (A : OrdVModule W M) (B : OrdVModule W N) (C :
↪  OrdVModule W P) : ℕ :=
  Module.finrank ℂ (IntertwinerSpace A B C)
```

Here `IntertwinerModes M N P` is the space of all families $\mathbb{C} \to \mathrm{Hom}(M \otimes N, P)$ and `IntertwinerSpace` the kernel of the commutator defect $a^P_{(p)} Y_s(u)x - Y_s(u)a^N_{(p)}x - \sum_j \binom{p}{j} Y_{s+p-j}(a_{(j)}u)x$, with no truncation or grading condition. The defect relates Y_s only to $Y_{s+\mathbb{Z}}$ and is invariant under the shift $s \mapsto s + c$. Hence the kernel is the product, over the classes $\rho \in \mathbb{C}/\mathbb{Z}$, of the spaces K_ρ of solutions supported on ρ, and the shift by c maps K_ρ isomorphically onto $K_{\rho+c}$. Either every K_ρ is 0 (and the space is 0) or all of the uncountably many K_ρ are nonzero (and the space is infinite-dimensional). Mathlib's `Module.finrank` is 0 for infinite-dimensional spaces, so in both cases `fusionCoeff` is 0. So `fusionCoeff` is not the fusion rule N^P_{MN}.

3. **`SuperTwistedModule.jacobi`** is unrepaired (Section 43.2.1).

4. **`IsLowestWeight` does not require** $M_h \neq 0$. File `VOA/Modules/ZeroModeMult.lean`:

```
def IsLowestWeight (N : OrdVModule W M) (h : ℂ) : Prop :=
  ∀ α : ℂ, N.weight α ≠ ⊥ → ∃ n : ℕ, α = h + n
```

It says every occurring weight is in $h + \mathbb{N}$; it does not say that h occurs. Any h below the true lowest weight by a natural number also qualifies. Statements using it as "the lowest weight is h" should add $M_h \neq \bot$ where the intended meaning needs it.

5. **`SelfDual` is never linked to `IsUnimodular`.** File `VOA/Foundations/Lattices.lean`:

```
def SelfDual : Prop := ∀ x : ℝ ⊗[ℤ] L.carrier, x ∈ L.dual ↔ ∃ v : L.carrier, L.toReal
↪  v = x
```

and in the vendored library, File `VOA/LatticesAndCodes/Lattice/Defs.lean`:

```
def IsUnimodular : Prop := IsUnit Γ.det
```

(`VOA.Modules.StronglyRational` has an unrelated `SelfDual` for VOAs.) No theorem in the library proves that the two lattice notions agree; results stated with one cannot be fed the other without a bridge.

6. **`latMorph_injective` assumes equal rank.** The section variables of `VOA/Moonshine/LatticeMorph.lean` include `(hr : rank K = rank L)`; the functoriality $V_K \to V_L$ is therefore proved only for isometric embeddings between lattices of the same rank (sublattices of finite index), which is all the Moonshine construction needs ($\Lambda_0 \subset \Lambda$, $\Lambda_0 \subset N$), but not general functoriality.

7. **Stale docstrings** (*resolved, October 2026*). Several Moonshine file headers said "Not imported by the umbrella" or "not wired into the umbrella" (for example `VOA/Moonshine/TFormLattice.lean` and the header of `VOA/Moonshine/TopPairs.lean`); a search of both files on 28 October 2026 finds no such header. Route notes contain superseded estimates and "open" claims, corrected in later "Update"/"Status" sections.

8. **`README.md` was behind the library** (*resolved, October 2026*: the current README no longer contains these sentences). It said "It is not a formalization of the Moonshine module $V^\natural$ itself" and, under Scope, "$V^\natural$ is not formalized"; and it said "The unrestricted minimal-model theorem remains open". Both were false at the Moonshine commit: `VOA.Moonshine.moonshine` constructs $V^\natural$, and File `VOA/Examples/VirasoroMinimalRigidityComplete.lean` proves

```
theorem minimal_graded_rigidity (p q : ℕ) (hp : 2 ≤ p) (hq : 2 ≤ q)
    (hcop : p.Coprime q) :
    IsRigidGraded (virasoroSimple (minimalCentralCharge p q)) := by
```

with `#print axioms [propext, Classical.choice, Quot.sound]` (re-run for this chapter).

9. `Notes/MonsterRoadmap.md`, **row of the twisted-module milestone,** called twisted associativity `star_iterate_range` "unused but proved" (*resolved, October 2026*: the row now says it is used); it is used in `VOA/Moonshine/LatticeTwistedProduct.lean` and `VOA/Moonshine/LatticeTwistedBase.lean`.

Physical meaning

The fusion coefficient N_{MN}^{P} counts the independent ways two primaries M, N can fuse into P in the OPE; it is a small integer in a rational CFT. A "count" that is always zero is a warning sign that the space being counted is not the space of chiral vertex operators (it lacks the L_{-1}-covariance $\partial_z Y = Y(L_{-1}\cdot)$ and the conformal-weight constraint on the exponents s). Similarly, a lowest-weight condition that does not demand a lowest-weight *state* would accept the empty spectrum.

43.2.9 Dead ends recorded in the later chapters (October 2026)

The chapters added or extended in October 2026 each record their own dead ends in `warning` boxes, with the counterexample or certificate. This subsection is an index to them, sorted by the six kinds (A)–(F) introduced at the start of this section, with one or two sentences per entry. The certificates and the full discussion are in the cited sections; where a finding is numerical or a paper argument only, the cited chapter says so, and so do we. The dead ends of Chapters 28 and 29 are recorded in their own sections (Sections 28.14 and 29.12); those of the chapter in preparation will be indexed with it.

(B) Hypotheses that no intended object satisfies.

1. **The `hdec` criterion forces C_2-cofiniteness** (Chapter 11, Section 11.5, warning on page 524). The older surjectivity criteria for the jet presentation of Li's associated graded algebra assume $V = \mathrm{span}(\mathrm{gen} \cup \{\mathbf{1}\}) + C_2(V)$ for a finite family gen. The theorems are correct, but the hypothesis forces $R_V = V/C_2(V)$ to be finite-dimensional, i.e. V to be lisse. A certificate compiled for Chapter 11 (in a scratch file, standard axioms; not library code) proves `hdec` $\Rightarrow$ `C2Cofinite W`. Combined with the unconditional non-lisseness of $L_{-4/3}(\mathfrak{sl}_2)$ (Chapter 16, Theorem 16.40) this gives a machine-checked counterexample: no finite family satisfies `hdec` there. On paper the same holds for every quasi-lisse VOA that is not lisse, including all the Deligne-series VOAs; with the currents as generators it already fails in weight two, where $(R_V)_2 \supseteq V(2\theta) \oplus \mathbb{C}Q \neq 0$ (Chapter 24, Section 24.3). It also fails for the lisse minimal models $M(2, 2m+3)$, $m \geq 2$, with the single generator ω, because $[\omega]^2 \neq 0$ in $R_V \cong \mathbb{C}[T]/(T^{m+1})$ (Chapter 20, Section 20.12). The replacement, used throughout, is spanning of Li's filtration by ordered generator words.

2. **Graded unitarity "for some flag" is nearly empty** (Chapter 19, Warning 19.4.1; paper argument). Because the predicate `GradedUnitary B R F` quantifies over an arbitrary flag `F`, any VOA with a nondegenerate Hermitian form on each weight space satisfies it for a suitable flag, Lee–Yang included. The Virasoro statement `VirGradedUnitary` pins the flag and is unaffected. This complements the older defect, now repaired, in which clause (vi) was false for every VOA (Theorem 43.3; Chapter 19, Warning 19.2.1).

(C) Wrong formulas, and the limits of a single identity.

1. **Feigin's homogeneity is false:** 55 **versus** 63 (Chapter 26, Section 26.11; Chapter 27, Section 27.7.1). The natural mechanism behind Feigin's Corollary 2 (*SIGMA* 4 (2008) 070; Corollary 2.2 in arXiv v1) for the A_2 total bound, that the fusion filtration is homogeneous for the grading by trivial factors, fails: at $N = 2$ the degree-one filtration piece has dimension 55, while the sum of the dimensions of its projections is 63 (exact computation). The published repair (Kus–Littelmann) and an alternative route (Setia–Rani–Khandai) are recorded in those chapters.

2. **The heat equation alone does not give** $E_4^2 = E_8$ (Chapter 25, Section 25.7): at weight 8 the relation contains σ_7 and no combination eliminates it; Mathlib's dimension formula is used instead.

3. **Star bounds by termwise domination or positive expansions** (Chapter 25, Section 25.10.4; Chapter 27, Section 27.9). Domination proofs of $\leq$ are forced to be exact (proved on paper), the plethystic exponents of the MLDE solutions alternate in sign (observed), and the G_2 step R3 of the Macdonald pilot admits no small rational certificate; the pilot was stopped and the G_2 input stays named.

(E) Circular or insufficient reductions.

1. **The presentation route to the** A_2 **total bound is circular** (Chapter 26, Section 26.11): the surjection from the associated graded of the fusion model is free, and its injectivity is the statement. In the same list: the naive truncated box overcounts (72 against 64 at $m = 2$); plain tensor induction fails by fusion associativity, so the mixed models are needed; separating functionals by charge, weight or θ-degree fail from $N = 3$; leading-term independence of Chari–Loktev words fails; ungraded counting in the evaluation model carries no information. Chapter 27, Section 27.9, adds two traps of the same kind: a toroidal mode splitting treated as an algebra map before passing to the associated graded, and a shift image treated as an ideal although it contains the constant 1.

2. **The generator-symbol step of the Kus–Littelmann repair is insufficient for** D_4 (Chapter 27, Section 27.7.1). The p. 437 step infers that the symbols of the whole annihilator kill the fusion vector from the symbols of the defining relations. For D_4 at $m = 2$ those symbols generate an ideal of codimension $29^2 + 1$, one too many, and an explicit element $\tilde{a}$ of the annihilator has a symbol outside it (computation, not Lean). The statement the step is meant to prove holds at $m = 2$ (exactly) and $m = 3$ (modulo two primes); the theorem is not known to fail.

(D) and (A) Missing structure that a route needs.

1. **Mathlib's Serre construction of** $\mathfrak{e}_8$ (Chapter 23, Warning 23.7): Mathlib does not prove the presented algebra finite-dimensional or simple, so the exceptional Lie algebras were built as lattice weight-one spaces and from checked structure constants.

2. **Zhu's change of coordinates as a VOA isomorphism** (Chapter 25, Section 25.5): the library's `changeCoord` has no transformation law; a symbol calculus on the C_2 algebra avoids it.

3. **Heisenberg chains along short roots** for the nilpotency needed in Ravinder's kernel lemma (Chapter 26, Section 26.13): replaced by general nilpotency lemmas.

(F) Tooling: the cost of kernel-checked certificates. The Deligne chapters rest on large integer certificates checked by the Lean kernel (`decide`), and their architecture is shaped by recorded failures (Chapter 23, Warning 23.12.2; Chapter 24, Section 24.10.1; Chapter 25, Section 25.12.1; Chapter 27, Section 27.9). Single declarations over whole tables reached 18–41 GB or did not finish (a 133×133 sector comparison: 41 GB and a time-out after 445 s; one `decide` over the whole D_4 identity: 650 s and 41 GB); `![…]` vector tables are slow at high index (literal lists read with `getD` are used); importing the VOA stack into check files costs about 6 GB before any work (light-import copies bridged by `rfl` are used); a plain box enumeration of the E_7 roots did not finish in ten minutes. The working pattern is many small declarations of a few thousand entries each, under a per-file memory budget.

Physical meaning

Several of these dead ends have a direct physical reading. The failure of `hdec` is the statement that a non-rational chiral algebra such as $L_{-4/3}(\mathfrak{sl}_2)$, whose Higgs-branch-like associated variety has positive dimension, cannot have its C_2 algebra spanned by finitely many states. And Feigin's $55 \neq 63$ is a reminder that a filtration on a fusion product, the mathematical form of an operator product with prescribed orders of vanishing at the insertion points, need not respect an auxiliary grading that is natural on the factors.

43.3 The numerical evidence

43.3.1 Epistemic status

The directory `scripts/moonshine/numerics/` preserves the Python scripts and logs written while choosing conventions and routes for the Moonshine construction. Its `README.md` states the principle: "They are evidence, not proof; every claim used in Lean is proved in Lean." No Lean declaration imports, cites or depends on any of these computations; the compiler never sees them. Their role was strategic: to choose signs and normalisations before investing thousands of lines in a proof, to detect wrong formulas from the literature, and to decide whether a reduction was worth formalising. Two kinds of computation occur.

- *Exact* computations, in integers, rationals (`fractions.Fraction`) or modulo the prime $p = 2^{31} - 1$. A rank computed modulo p is at most the rank over $\mathbb{Q}$ of an integer matrix, so *full* rank mod p certifies full rank over $\mathbb{Q}$; a deficit mod p would not have been conclusive.
- *Floating-point* computations (NumPy/SciPy, double precision), reported as the maximal *relative residual* $\|\text{lhs} - \text{rhs}\|/\|\text{lhs}\|$ over the tested identities. Values near 10^{-15}–10^{-11} are rounding error; values of order 1 (typically 2.0, the residual of $\text{lhs} = -\text{rhs}$) mean the identity fails.

A test without a *control* proves little: an identity that holds with every sign convention tests nothing about conventions. Every floating-point experiment below therefore also reports deliberately wrong variants that must fail.

43.3.2 The E_8 model of the twisted-by-twisted relation (4.23)

Files: `orb.py` (419 lines), `sanity.py`, `sanity2.py`, `tt.py`, log `tt_K3.log`. *Question:* with the library's exact conventions, does the gluing of V_L^+ and $(V_L^T)^+$ satisfy the last locality relation (4.23) of Dolan–Goddard–Montague? *Why E_8:* rank 8 makes $d/8$ odd as for Leech, so θ acts by -1 on T exactly as in the library, while $\dim T = 16$, $\dim \mathrm{TP}_1 = 128$, $\dim \mathrm{TP}_2 = 2048$ are small, and the orbifold is known to be V_{E_8} again. *Method:* the script reimplements $Y^T(e^\alpha, z) = 2^{-\langle\alpha,\alpha\rangle} z^{-\langle\alpha,\alpha\rangle/2} E^- E^+ \otimes e_\alpha$, composite states via $e^{\Delta z}$, the basis cocycle, the forms with the signs of Section 43.2, W and $\overline{W}$ (the latter by summing over a dual basis), and tests the twisted block of the commutator formula

```
W(t1)_m Wbar(t2)_n x - W(t2)_n Wbar(t1)_m x = sum_{j < wt t1 + wt t2} C(m,j) Y^T(Wbar(t1)_j
 ↪  t2)_(m+n-j) x
```

for random $t_1, t_2, x \in \mathrm{TP}_1 \oplus \mathrm{TP}_2$ and all (m, n) with intermediate weight ≤ 3 (34752 states of V_L). *Sanity checks:* $Y^T(\omega)$ gives $L_0 + d/16$, $L_{\pm 1}$; Heisenberg commutators (residual $\leq 10^{-16}$); lattice commutators for $\langle \alpha, \beta \rangle \in \{-1, 0, 1\}$ ($\leq 3 \times 10^{-15}$). *Result:* 64 identities, maximal relative residual 3.7×10^{-14} (final log line "max rel residual 3.734689360353892e-14 over 64 identities"). *Controls* (18 identities each), all failing with residual 1.7–2.0: group sign $\varepsilon(\alpha, \alpha)$ on T; $c(\alpha) = 1$; dropping $(-1)^w$ in $\overline{W}$; the super (anticommutator) sign.

What the machine verified

Numerical evidence for a model lattice, in floating point; not about Leech, not part of any proof. The Leech relation (4.23) is proved in Lean by a different route (triality).

43.3.3 The theta check

File: `theta_check.py`, log `theta_check.log`. *Question:* what lattice input makes the ground-state four-point function rational? *Method:* exact rational q-series to $O(q^{80})$; $x = \theta_2^4/\theta_3^4$ computed by series division, without assuming Jacobi's identities. *Results* (verbatim from the log): the Leech counts $1, 0, 0, 0, 196560, 0, 16773120, 0, 398034000$; "Jacobi check $1-x = \theta_4^4/\theta_3^4$: True"; $\Theta_{E_8} = \theta_3^8(1-x+x^2)$; and

$$\Theta_\Lambda = \theta_3^{24}\Big[(1-x+x^2)^3 - \frac{45}{16}x^2(1-x)^2\Big], \qquad G_\Lambda(x) = \frac{(1-x+x^2)^3}{(x(1-x))^3} - \frac{45/16}{x(1-x)},$$

rational and crossing-symmetric; D_8 (determinant 4) also gives a rational G, so this does not single out unimodular lattices.

Physical meaning

$G_L(x)$ is the four-point function of the $\mathbb{Z}_2$ twist fields $\sigma(z)$ of d chiral bosons on $\mathbb{R}^d/L$, in the untwisted channel, as a function of the cross-ratio; $q(x)$ is the nome of the double cover torus. Locality of the twisted OPE is rationality of G in x: the four-point function must be single-valued on the sphere.

43.3.4 Golay code and triality

Files: `golay.py`, `golay2.py` (Golay code from quadratic residues mod 23; 4096 codewords, weights $\{0, 8, 12, 16, 24\}$), `tri.py`, `g.py`, `adj.py`, `cert.py`, and the pipeline `triality/` (`vn.py`, `stage1–stage3`, `model.py`, `tmod.py`, `run4.py`, `bfs2.py`, `block.py`, `bfsT.py`, `trace.py`). *Model:* the weight-2 space of V_N, all 196884 states, with the library's basis cocycle; $\sigma = G(\chi z_0)G^{-1}$ (the library's `golaySigma`) computed on the 1083 invariant blocks; $\Theta = \sigma\chi\sigma$; $(V_0^+)_2 = (V_N)_2^{\langle \chi, \Theta \rangle}$. *Results:* $\dim(V_0^+)_2 = 49428$; $\mathrm{tr}\,\sigma = 2324$ (and 6372 for the unmodified $G\chi G^{-1}$), reproducing Proposition 43.5; $\Theta e^\gamma = c_\gamma e^{-\gamma}$ with $c_\gamma = 1$ for all 98256 norm-4 $\gamma \in \Lambda_0$. An explicit σ-twisted intertwiner $(V_3^+)_2 \to (T_0^+)_2$ was built by breadth-first propagation from a joint eigenvector and checked on 15000 identities, residual 4.2×10^{-15}; wrong target sectors give 2.0; with the unmodified σ the consistent target is the other summand (the N-only X_1), a module-level confirmation of the trace certificate; $T(1,+) \to T(1,+)$ residual 4.8×10^{-12}. Caveats recorded with the data: only zero modes of weight-2 states on weight-2 spaces; N's cocycle; the identification of the model sectors with T_0^+, T_3^+ uses an unchecked normalisation step.

43.3.5 The Zhu-generator test

File: `zhu/zhu.py`, log `zhu_0.log`. *Question:* do the zero modes of $(V_0^+)_2$ generate the zero-mode algebra on the weight-2 tops, or is a weight-4 element (as in rank one, the "J" of $A(M(1)^+)$) needed? *Method, exact:* on the V_3^+ top the zero modes of $h_a h_b$ have joint eigenvalue nn^T, giving projectors onto pairs $\{e^n, e^{-n}\}$, and $o(e^\gamma + \theta e^\gamma)$ links pairs with $\langle n, n'\rangle = \pm 2$; the graph on the 98304 vectors with these 226 099 200 directed edges is connected, so the algebra B contains all matrix units. On the twisted top $B = M_{24} \otimes C$, and 400 random norm-4 vectors generate Λ_0 (Hermite normal form covolume $8192 = 2^{13}$), so $C = \mathrm{End}(X)$. *Result:* $B = \mathrm{End}(\mathrm{top})$ on both 49152-dimensional tops; B acts irreducibly on, and separates, all 16 irreducible tops, total dimension $1+3\cdot 24^2+6\cdot 2048^2+6\cdot 49152^2 = 14\,520\,682\,177$. No weight-4 generator is needed. (Status: exact computation plus standard Heisenberg-group representation theory; the implication to Zhu generation needs the cited classification of $A(V_{\Lambda_0}^+)$ and was *not* used; Lean proves Zhu generation directly, `zhuGenerated_weightTwo`.)

43.3.6 Filtered-criterion ranks (zhugen)

Files: `zhugen/fock_lowerprod.py`, `charged_lowerprod.py`, `ground_states.py`, `e3_relations.py`, `e4_check.py`, `ll_special.py`, log `zhugen.log`. Exact ranks mod $2^{31}-1$ of the spans of lower products. Fock sector: rank 1 deficient by one exactly at weight 4 (the rank-one J; a positive control showing sensitivity), full at weights 3 and 5–9; ranks 2, 3, 4 full through weights 11, 9, 8. Charged sector: full rank for charges $(2), (2,0), (2,0,0), (1,1,2), (2,2,2,0)$ up to Fock weight 7. Ground states: random placements of every magnitude pattern up to norm 28 found only E_1; E_2, E_3 were found by hand and checked exhaustively (Section 43.2.5). All superseded by Lean proofs (`groundLattice`, `FockSpan.fockSpanned`, `FockSpan.excitedSpanned`).

43.3.7 SigmaKey normalisation

Files: `sigmakey/` (`pipeline.sh`, `sk.py`, `sk2.py`, logs). In the $N(A_1^{24})$ weight-2 model: N1, $\Theta_J^2 \propto I$ (residual 1.7×10^{-11}), invariant form on the 2048-dimensional block built by eigenline propagation, $\Theta^\mathsf{T} B \Theta = \mu B$ with $|\mu - 1| < 4 \times 10^{-12}$, and $\mathrm{tr}\,\Theta_J = -112$ (eigenvalue multiplicities 968 and 1080), which independently excludes $\mu = -1$; N2, Φ is a similitude (κ_0 constant to 6.7×10^{-12}); N3, the top-level key identity $\Theta o(v)\Phi(b) = \varepsilon o(b)\Phi(v)$ on 170 pairs with one global sign. *Control caveat:* with Θ replaced by the identity, the N3 identity also holds up to a sign that varies from pair to pair ($\approx 50/50$); Θ is what makes the sign global, but the test does not discriminate strongly at weight 2.

43.3.8 KeySkew at weights 3 and 4

Files: `keyskew/` (`lsig.py`, `eng.py`, `ops.py`, `test_eng.py`, `phi.py`, `theta.py`, `keyskew.py`). The model was rebuilt without multi-GB intermediates. *Model consistency* (`test_eng.log`): zero modes agree with the old model to 4.6×10^{-16}; L_0, $[L_{-1}, u_{(m)}]$ to $< 10^{-15}$; the commutator formula between V_0^+ and V_3 on twisted states, 120 identities, 1.1×10^{-15}. *Test* of $\Theta Y^T(v,z)\Phi b = e^{zL_{-1}} Y^T(b,-z)\Phi v$, with Θ known only at weight 2, through lowering letters:

weight	identities	residual	controls
2	12 pairs	9.0×10^{-12}	$\Theta \to$ scalar: does not fail (caveat)
3	≈ 5300	1.1×10^{-11}	$-\Theta$: 2.0; $\Theta \to$ Id: ≥ 0.32; drop L_{-1}: ≥ 0.75
4	≈ 2000	1.1×10^{-11}	$-\Theta$: 2.0; $\Theta \to$ Id: ≥ 0.57; drop L_{-1}: ≥ 0.84
4 (two-step)	≈ 1300	1.1×10^{-11}	$-\Theta$: 2.0

On one T-fibre of the weight-3 level (dimension 2624) the stacked test map has rank 323: a strong necessary condition, not a proof of the vector identity.

43.3.9 Bimodule generation

Files: `bimodule/mod_excited.py`, `mod_ground.py`, `pair_lemma.py`. The module analogue of the filtered criterion for $M = V_3^+$ over V_0^+ holds at weights 3, 4, 5 with no deficit in any sector (exact mod $2^{31} - 1$); ground sector exhaustive over the 4096 residues, every sampled coset vector (301) has an $f = -1$ partner; pair lemma checked on 3937 odd magnitude multisets up to norm 60. *Control:* left action only gives rank 0 of 24 at weight 3 and 300 of 324 at weight 4. Superseded by `FZGen.bimodGen_V3`.

43.3.10 TopPairs pre-check

Before the final identity was proved, the library's own symbolic formulas for both sides of $\Theta(o(v)\Phi b) = o(b)\Phi v$ were evaluated on all 98304 odd norm-4 Leech vectors (built from `golayB`, as in `leech.py`): 200,000 random pairs and 64 full rows, 0 failures (recorded in `Notes/M8GluingPlan.md`). The script for this run is not among the preserved files; only its result is recorded.

Physical meaning

These computations are what a physicist would do first: build a finite truncation of the orbifold CFT (all states up to weight 2, 3 or 4), compute OPE coefficients numerically, and check locality and associativity. Their limitation is the usual one of truncated numerics: they test finitely many coefficients of identities between infinite series.

43.3.11 Summary

experiment	checks	precision	role / status
E_8 (4.23)	convention consistency	3.7×10^{-14}	fixed three signs; evidence
theta check	lattice input of (4.23)	exact, $O(q^{80})$	route analysis; evidence
Golay traces	which σ	exact	rejected DGM (7.5); evidence
triality model	σ on twisted tops	4×10^{-15}	existence plausible; superseded
Zhu test	generators of tops	exact	chose $G = (V_0^+)_2$; superseded
zhugen	filtered criterion	exact mod p	found E_1–E_3; superseded
SigmaKey	normalisation	4×10^{-12}	$\mu = 1$; superseded
KeySkew	weights 3, 4	1.1×10^{-11}	de-risked; superseded
bimodule	module criterion	exact mod p	de-risked FZ step 2; superseded
TopPairs	final identity	exact symbolic	0 failures; superseded

"Superseded" means a Lean theorem now proves the corresponding statement.

43.4 Design decisions

43.4.1 Why the FLM route

Five routes to the vertex algebra structure on $V^\natural$ were compared before the gluing began (`Notes/M8GluingPlan.md` §1, with the sources actually read marked as such):

route	new theory needed	estimate, verdict
(A) FLM triality	Golay frame, σ, cyclicity, a Goddard-type uniqueness lemma, one key identity	20–35k lines, medium risk; **chosen**
(B) direct (4.23)	closed form of $\overline{W}$ on ground states, theta transformation of 2^{24} coset thetas, half-integral locality	20–35k, high risk; cross-check only
(C) framed VOA (Miyamoto; Dong–Griess–Höhn)	Ising modules and fusion rules, code VOAs, quantum Galois theory	50k+, high risk; rejected
(D) simple-current extensions (Carnahan; Huang)	braided tensor categories, rationality and fusion of V_Λ^+	100k+; rejected
(E) 2020–2026 literature	none found that bypasses triality or tensor categories	–

The decisive argument for (A) was reuse: every ingredient is an explicit operator on an explicit Fock space, which is how the library had already built general lattice VOAs. The plan packaged FLM's argument through the reconstruction theorem: generators $V_\Lambda^+ \cup T_0^+$, pairs involving an untwisted field from general theory, twisted pairs by σ-conjugation; this removes FLM's use of the group $2^{1+24}.\mathrm{Co}_1$. In execution the key identity was reduced further: σ on the twisted sectors by a top-level argument plus Zhu generation (no Verma modules), the three-point identities to one self-coupling identity, that identity by a Frenkel–Zhu bimodule argument to a finite weight-2 identity, and that identity to explicit Golay arithmetic.

43.4.2 Other decisions

- **Vendoring `LatticesAndCodes`** (decision of 6 October 2026): the 25-file import closure of `Leech.Defs`, `Leech.RepCount`, `Leech.RepCountHigher` copied byte-for-byte from `Fedor-Popov/LatticeAndCodes` at commit `da62b9e2f44a04888abf6f797a429aa8ecc1d6dd`, the only edit the import prefix (verified by `cmp`); the package depends on Mathlib alone and `lakefile.toml` is unchanged. Leech uniqueness is not vendored (not in the closure).

- T **abstractly**: the 4096-dimensional module by Wedderburn–Artin from the central simplicity of $\mathbb{C}^\varepsilon[\Lambda/2\Lambda]$, not by an explicit Golay model; the splitting $T = T_+ \oplus T_-$ and the invariant form were obtained without the model.

- **Keeping the cocycle symbolic** (previous section).

- **Avoiding `VOA.pbw`**: the Dong–Jiang generalised Verma module carries a `BottomProjection` supplied by the then-axiom (while `VOA.pbw` was an axiom); the top-level graph argument (`annCompat_of_top`) and Zhu's easy direction (`ZhuModule` is `pbw`-free) replaced it.

- **Frenkel–Zhu instead of fusion rules**: Abe–Dong–Li fusion rules for V_L^+ would have needed the classification and tensor-product theory; the bimodule argument needed only the commutator formula and weight-2 data, avoiding the missing intertwining Jacobi identity for W.

- **The minimal definitional repair** of `TwistedModule`, and "$\exists s$" statements instead of fixing `golayE`.

43.4.3 The literature and online search

- **Höhn's Lean ATLAS** (repository `Moonshine-in-Kansas/atlas`) formalises Co_0, Co_1 and M_{24}; its licence forbids copying into this Apache-2.0 repository, so nothing was taken from it. It is the natural partner for the Monster problem below.

- **Carnahan's vertex operators in Mathlib**: Mathlib 4.30.0 contains `Mathlib/Algebra/Vertex/VertexOperator.le` and `HVertexOperator.lean` (vertex operators as maps to Laurent series; its TODO lists locality and residue products). The library predates and does not use them; it has its own formal distributions.

- **Höhn–Seysen**, arXiv:2508.01037, uses $V^\natural$ and the structure of V_Λ^{++} (16 irreducibles, the triality as an S_3) but does not construct $V^\natural$.

- Huang, arXiv:1902.09734, gives twisted×untwisted operators in general, not twisted×twisted. The FLM book was not accessible online; DGM (hep-th/9410029) §§3–7 was read in full; DGM's own §7 derives σ from analytic input and is circular for this purpose.

43.5 Reproducibility

- **Commit:** this edition documents the release commit (`recorded at release`) (front matter; Appendix A). The original verification run of the Moonshine construction was made at the Moonshine commit ("Construct the Moonshine module $V^\natural$ (FLM) unconditionally", 7 October 2026, 268 files changed, 70349 insertions, 8 deletions relative to its parent); the records below (job count, probe output) are those of that run.

- **Toolchain:** `leanprover/lean4:v4.30.0` (file `lean-toolchain`), Mathlib `v4.30.0` (`lakefile.toml`); `elan` at `~/.elan/bin`.

- **Commands**, from the repository root:

```
export PATH="$HOME/.elan/bin:$PATH"
lake exe cache get     # Mathlib build cache, several GB
lake build             # aggregate build; recorded: 10343 jobs
python3 scripts/check_repository.py
python3 scripts/audit/run_axiom_audits.py
```

- **Moonshine axiom probe**: a file containing

```
import VOA
#print axioms VOA.Moonshine.moonshine
```

compiled with `lake env lean -DmaxSynthPendingDepth=3`; expected output `'VOA.Moonshine.moonshine' depends on axioms: [propext, Classical.choice, Quot.sound]` (reproduced for this chapter; about 7 seconds once the library is built).

- **Numerics**: Python 3 with NumPy, SciPy, SymPy; each subdirectory's `README.md` gives the run order; paths may need adjusting; the KeySkew cache is about 68 MB and is recomputable in about 30 minutes; the original triality pipeline writes about 2 GB.

- **Never commit** `.lake/`.

43.6 Open problems

43.6.1 Moonshine

1. $\mathrm{Aut}(V^\natural) \cong \mathbb{M}$. There is no Monster in Lean. A realistic first form defines $\mathbb{M} := \mathrm{Aut}(V^\natural)$ and proves facts about it: its order (Höhn–Seysen give a VOA-based computation of $|\mathbb{M}|$), the Griess algebra on ${V^\natural}_2$, the subgroup $2^{1+24}.\mathrm{Co}_1$. The library has the ingredients for the extraspecial group acting on T, and Höhn's ATLAS has Co_1, but its licence forbids copying.

2. **McKay–Thompson series and Borcherds' theorem.** For $g \in \mathbb{M}$, $T_g(\tau) = \sum \mathrm{tr}(g|{V^\natural}_n)q^{n-1}$ is a Hauptmodul (Borcherds 1992). Needed: the Monster action, twined characters, the monster Lie algebra and the no-ghost theorem. The library's `VOA/Modularity/Moonshine*` files contain abstract $c = 24$ statements conditional on hypotheses never instantiated.

3. **Uniqueness of $V^\natural$.** FLM conjectured that $V^\natural$ is the unique holomorphic VOA of central charge 24 with $V_1 = 0$. Dong–Griess–Lam proved uniqueness under an additional frame hypothesis (cited, not checked); the general conjecture is open.

4. **A Moonshine audit probe** in `scripts/audit/`, so that the maintained audit covers `VOA.Moonshine`.

5. **Simplifications**: formalise the failure for $\varepsilon = -1$; make `golayE` explicit; prove irreducibility of the four V_0^+-sectors; the full intertwining Jacobi identity for W; route (B) as an independent check.

43.6.2 Library-wide

1. **Repair `SuperTwistedModule.jacobi`** (Section 43.2.1); until then theorems with such hypotheses for $N \geq 2$ are vacuous.

2. **Uniform negative-admissible $\mathfrak{sl}_3$ graded rigidity is open** (an open residual of the project's $\mathfrak{sl}_3$ work). Recorded remaining boundary: the finite count/product exhaustion and normalisation between total PBW root counts and real-root/descendant factors, the higher-rank horizontal quotient or parabolic vacuum determinant transfer, and simple vacuum multiplicity/nonzero tangent. A removal-bijection draft is outside the build.

3. **Graded unitarity** (Arabi Ardehali–Beem–Lemos–Rastelli): the Lean layer formalises the definition and reductions; the full conjecture is open (beyond the cases proved in Chapter 19). Chapters 28 and 29 reduce it for the minimal models $M(2, 2n+1)$ to the hypothesis `hA`, graded unitarity of the boundary admissible $L_k(\mathfrak{sl}_2)$, which is open for every n.

4. **PBW in Mathlib**, which would replace the library's own proof of `VOA.pbw` (formerly a project axiom, now a theorem; Section 43.1.2).

5. **Fusion rules**: a genuine intertwining-operator space with L_{-1}-property and weight constraints, so that the fusion coefficient means N_{MN}^P (Section 43.2.8).

6. **Documentation debt** (Section 43.2.8): `IsLowestWeight`, `SelfDual` versus `IsUnimodular`. (The README, the stale Moonshine headers and the roadmap row were corrected in October 2026.)

7. **Upstreaming to Mathlib**: the level-one structure theorem $M(\mathrm{SL}_2(\mathbb{Z})) = \mathbb{C}[E_4, E_6]$ (`levelOne_coe_mem_E46`), the majorant estimate, the vendored lattice and code theory, the Wedderburn–Artin dimension count for extraspecial groups, and formal calculus aligned with Carnahan's `VertexOperator`.

43.6.3 Open problems named in the later chapters

Each item below is a precise statement that the library either takes as an explicit hypothesis or does not state. All the theorems mentioned are `#print axioms`-clean; none of those with an open hypothesis is unconditional (Section 43.1.7), and a citation of the literature in a docstring does not change that.

1. **The named inputs of the Deligne final theorems** (Chapter 27, Sections 27.5, 27.6 and 27.7). For each type $X \in \{A_2, G_2, D_4, F_4, E_6, E_7, E_8\}$ of the Deligne series, the final theorem `X_classicallyFree_final` says that the simple affine VOA $L_k(\mathfrak{g})$ at $k = -1 - h^\vee/6$ is classically free for the explicit presentation of Chapter 24; for every type but A_2 it is conditional on named inputs. As recorded in Chapter 27:

   - A_2: none. The total-dimension bound (`CVUniv.fusionTotalDim`), the Demazure realizations and the star identity are proved, and `A2_classicallyFree_final` has no hypothesis; it is machine-confirmed: the aggregate build was green on 2026-10-28 and `#print axioms` reports `[propext, Classical.choice, Quot.sound]` (Chapter 27, Theorem 27.13);
   - D_4: `FusionTotalDimG D4sector` ($\leq 28^m$) only (`D4_classicallyFree_of_inputT`). The Demazure realizations for all n are proved in Lean (`D4Char.d4_demazureRealization`; aggregate build green on 3 November 2026, `#print axioms` standard), and the star identity is proved (`D4Wp.d4SchurEqE4` with the unclamped Demazure = Schur identity, `d4DemazureEqSchur_of_positivity`, positivity from U5 on the unclamped route). The total-dimension bound is Kus–Littelmann's Theorem 4.2; one step of its published proof (p. 437) is insufficient as written for D_4 at $m = 2$, by computation with an explicit witness, while the theorem is not known to fail. Progress on the bound, not part of the claim (Chapter 27, Section 27.7.1): it is reduced in Lean to $\mathfrak{sl}_4$ core bounds with at least two adjoint sites (`d4_classicallyFree_of_twoAdjointCoreBounds`), and on paper the levels with two adjoint sites are reduced further to two one-node bounds, open in general; an earlier route through a rank bound on a presented module (`D4_classicallyFree_of_presentedRankBoundE`) is proved for $m \leq 2$;
   - G_2, F_4, E_6, E_7, E_8: `FusionTotalDimG Xsector` ($\leq (\dim \mathfrak{g})^m$), the Demazure realizations, and the star bound (`G2StarBound`, `F4StarBound`, `E6StarBound`, `E7StarBound`, `E8StarBound`), checked numerically to orders q^{60}, q^{25}, q^{20}, q^{16}, q^{14} respectively (scoping pass of 28 October 2026, Chapter 27, Section 27.4.4).

   The inputs that remain open in Lean (Chapter 27, Section 27.7) are the total-dimension bound and the graded Demazure realizations beyond A_2 and D_4, both published theorems not yet formalized (the former with a proof step flagged by the project), and the star identities for G_2, F_4 and the E-types, which are conjectures with numerical evidence. For G_2 the library splits the identity into `G2DemazureFermionic`, which follows from published results (Fourier–Littelmann, Chari–Moura, Ardonne–Kedem, Di Francesco–Kedem; Chapter 27, Section 27.4.4), and `G2FermionicKW`, a q-series identity that is open (checked through q^{60}).

2. **The Arakawa–Kawasetsu MLDE** (Chapter 16, Section 16.6). The theorem `VOA.IsSqPrimary.exists_monicML` gives a genuine monic MLDE, with coefficients in $\mathbb{C}[E_4, E_6]$ of the forced weights and one equation for all analytic blocks, under Etingof-finiteness. Its two other hypotheses were open; *both are now theorems*:

   - `AKWeightGrading W`: weight decompositions of $\mathbb{C}[E_4, E_6]$ and of $\mathbb{C}[E_4, E_6] \otimes V$, together with homogeneity of Zhu's relation module for the total weight. *Now proved for every VOA of the library* (CFT type): `VOA.akWeightGrading` in `VOA/Modularity/AKGradingTotal.lean` (faithful, by the queue-2 release audit, `Notes/Textbook/referee/RELEASE_AUDIT_QUEUE2.md`);

- `E46SerreClosed`: the Serre derivative maps weight-k elements of $\mathbb{C}[E_4, E_6]$ to weight $k+2$. *Now proved*: `VOA.e46SerreClosed` in `VOA/Modularity/EisensteinSerreClosure.lean` (rated "as stated" by the follow-ups audit). It is no longer an open hypothesis.

The combined statement is `VOA.IsSqPrimary.exists_monicMLDEOn_all_analyticBlocks_of_etingofFinite_u` conditional on `EtingofFinite` only (despite its suffix); its instance `VOA.exists_monicMLDEOn_all_analyticBloc` is unconditional. Both are `#print axioms`-clean (recorded in `Notes/release/WS-RELEASE2.md`); the aggregate build at the release commit is pending. What remains open here: the order is existential and unbounded (Arakawa–Kawasetsu's order 2 at $L_{-4/3}(\mathfrak{sl}_2)$ is not proved); the blocks are Zhu's abstract one-point blocks, and "the vacuum character satisfies a monic MLDE" is a short composition of library lemmas (`torusOnePoint_isAnalyticBlock`, `onePointSubexp_adjoint_of_etingof` not packaged as one theorem. Also open: quasi-lisseness itself (associated varieties, symplectic leaves, the Etingof–Schedler theorem) is not formalized; and the Zhu-modularity chain under Etingof-finiteness (Section 16.7) has its rank hypothesis discharged only for the trivial VOA.

3. **`AdmissiblyRational` versus Dong–Li–Mason rationality** (Chapter 22, Remark 22.4). The library's rationality asks that every weak submodule of an admissible module have a weak complement; Dong–Li–Mason ask for complete reducibility of admissible modules into simple admissible modules. *One direction is now proved*, for C_2-cofinite V: `VOA.Classification.COne.DLMRat.admissibl` (`hC2 : C2Cofinite W`) derives `AdmissiblyRational W` from `DLMRational W`, a faithful statement of Dong–Li–Mason rationality (every admissible module is an internal direct sum of graded-minimal submodules); `#print axioms`-clean, recorded in `Notes/release/WS-RELEASE2.md`; aggregate build at the release commit pending. Since C_2-cofiniteness is part of "nice", a VOA that is nice with DLM rationality in place of `AdmissiblyRational` satisfies the Lean hypotheses of the Gannon–Rayhaun classification. *The converse* (`AdmissiblyRational` ⇒ DLM-rational) is open; the release auditor sketched, without checking it, a graded-projection argument (take the degree-zero component of the projection onto a graded submodule along a weak complement; it commutes with every mode). (The library does have `AdmissiblyRational.exists_iSupIndep_irreducible_c` in `VOA/Classification/COne/RationalAdmissibleDecomposition.lean`: a C_2-cofinite analogue of Dong–Li–Mason's Theorem 8.1(c), decomposing ordinary modules into irreducibles. It is not either implication of the comparison.)

4. **The congruence property: the Frobenius–Schur half** (Chapter 21, Section 21.5). The Dong–Lin–Ng congruence property of a nice VOA now has named theorems with no hypotheses: `dlnCongruenceInput_holds`, `zhuCongruenceInput_holds` and `zhu_kernelContainsGamma_at_level` (namespace `VOA.Huang.CongruenceNamed`, `VOA/Huang/CongruenceNamed.lean`), each quantifying over `Nice` VOAs. At the minimal level the kernel statement is the full kernel claim of Dong–Lin–Ng; "kernel half" below refers only to the Ng–Schauenburg input. Of Ng–Schauenburg's Theorem 6.8 only the kernel half is proved (`nsProjectiveKernelAll_holds`, Theorem 21.16); the statement that the level is exactly the Frobenius–Schur exponent, `ProjectiveCongruenceTheorem` and its universal form `NSProjectiveCongruenceAll`, occurs only as a hypothesis.

5. **Pseudo-unitarity in Huang's rigidity and the Verlinde formula** (Chapter 21, Theorem 21.7 and Section 21.4). Two-sided rigidity (`VOA.Huang.HuangRigid.rigid_ordinary`, built from `rightRigid_ordinary` and the braiding), the Verlinde formula, the modular data and the congruence inputs are proved for `Nice` VOAs, which are pseudo-unitary. Huang's theorems assume only simple, CFT type, self-dual, C_2-cofinite and rational. Pseudo-unitarity is used in two places in the proofs: to obtain $V' \cong V$, and in a positivity step of the Cardy argument. *The first use is now removed*: `VOA.contra_vacuum_equiv_of_stronglyRational` gives $V' \cong V$ from self-duality, and the `_of_stronglyRational` copies in `VOA/Huang/VerlindeVacuumFusionSR.lean` give the vacuum-fusion chain ($N_{ab}^0 = \delta_{b,a'}$ and its bounds) for every strongly rational VOA (Chapter 21, Theorem 21.10; `#print axioms`-clean, recorded in `Notes/release/WS-RELEASE2.md`; aggregate build pending). The second, `CardyPositivity.vacColumn_mem_K`, keeps `Nice`, and

pseudo-unitarity is essential there (Lee–Yang $M(2,5)$). Removing pseudo-unitarity from the headline theorems therefore needs a different route through the Cardy step, and remains open. Related missing statement: a single packaged theorem that the category of ordinary modules is a modular tensor category.

6. **Smaller items from the audits.** For the Arakawa–Dai VOAs the paper's Theorem 1.1 is now one Lean theorem, `arakawaDai_theorem_1_1`, and the naturality of `actualC2ArcEquiv` is `actualC2ArcEquiv_natural`; what remains is that $J_\infty R_V$ is realized as `PresentedJet` with a universal arc, since the library has no J_∞ functor on abstract algebras (Chapter 20); Deligne's theorem is formalized only in its positive-dimension (bosonic) form (Chapter 21).

Physical meaning

The open problems above are, in physical terms: whether the Deligne-series vertex algebras (several of which, for instance the D_4 and E-type members, are the chiral algebras of four-dimensional $\mathcal{N}=2$ superconformal theories; for G_2 no such theory is known) are classically free, i.e. whether the arc space of $R_V = \operatorname{Sym}\mathfrak{g}/(\text{explicit quadrics})$ maps isomorphically onto $\operatorname{gr} V$ (proved for A_2; conditional on named inputs for the other types). R_V is not the coordinate ring of the minimal nilpotent orbit closure: it is non-reduced, and only its reduced variety is expected to be that closure; and whether the physicist's statements "the characters satisfy a modular differential equation" and "a rational CFT has a congruence modular representation" can be stated and proved without the extra positivity (pseudo-unitarity) that the present proofs use. The first is a prediction from four-dimensional physics; the library states what remains open of each as named, checkable hypotheses.

43.7 Referee's checklist

declaration	meaning	status	fidelity
`VOA.Moonshine.moonshine`	simple VOA on $V^\natural$, FLM block map, $c=24$, $V_1=0$, $\dim V_2 = 196884$, graded dim qJ	unconditional, standard axioms	§43.1.9, Ch. 42
`VOA.pbw`	PBW: affine vacuum $\neq 0$; induced bottom injective	theorem, unconditional (formerly a project axiom)	§43.1.2
`zhuModularity_pinned_of_C2cofinite`	Zhu modularity given a bottom projection	conditional on `Pr`	§43.1.2
`zhuModularity_pinned_of_C2cofinite_voaPBW`	Zhu modularity	conditional on C_2, semisimplicity, family data; via theorem `VOA.pbw`	§43.1.2
`zhuBijective_of_voaPBW` /	Zhu's map, injective (the codomain is image-defined, so only injectivity has content)	conditional on `Pr` / unconditional	§43.1.2
`zhuCorrespondence_of_C2Cofinite`	Zhu's bijection $\Phi W \simeq$ simple $A(W)$-modules	C_2-cofinite	§43.1.11

`zhuModularity_canonical_of_C2Cofinite` / `_of_stronglyRational`	Zhu modularity, general form	C_2-cofinite and admissibly rational / strongly rational; non-trivial instance `zhuModularity_V2m`	§43.1.11
`isSemisimpleRing_A_of_admissiblyRational`	admissibly rational ⇒ $A(W)$ semisimple	hypothesis `AdmissiblyRational` only	§43.1.2
`moonshine_of_frameLocality`	$V^\natural$ given (4.23) on four pairs	conditional (historic)	§43.1.7
`jacobiAllIndices_eq_zero`	old twisted Jacobi forces $M = 0$	unconditional	Thm 43.2
`SuperTwistedModule.jacobi`	super twisted Jacobi	defective, open	§43.2.1
`eq_bot_of_bilinear_pos`	bilinear positivity forces $S = 0$	unconditional	Thm 43.3
`not_nonempty_genFields_MRbot`	no fields over `MRbot`	unconditional	§43.2
`no_algHom_powerSeries_X_neq_zero`	no evaluation at $q_0 \neq 0$	unconditional	§43.2
`leechWbar_ne_zero`	$\overline{W} \neq 0$ (anti-TRAP)	unconditional	§43.2.2
`TopSigmaV3`	top-level σ data with non-degeneracy	definition	§43.2.2
`golayE_not_determined`	character ambiguity	unconditional	Thm 43.6
`YnatT_eq_of_creates`	Goddard identification (circular for key identity)	unconditional	§43.2.5
`eq_zero_of_V0local`	uniqueness from V_0^+-locality	unconditional	§43.2.5
`fusionCoeff`	"fusion coefficient"	always 0 (paper)	§43.2.8
`IsLowestWeight`	weights in $h + \mathbb{N}$ (M_h may be 0)	definition	§43.2.8
`VirModule.minimal_graded_rigid`	every minimal model is graded rigid	unconditional	§43.2.8
`strictEtingofFinite_simple_L2_3`	$L_{2/3}(\mathfrak{sl}_2)$ not C_2-finite, finite HP_0	unconditional, standard axioms	§43.1.11
`IsSqPrimary.exists_monicMAKMLDE_of_strictEtingofFinite`	AKMLDE for strictly-Etingof-finite VOAs	conditional on `strictEtingofFinite_unconditional`; `EtingofFinite` only (`akWeightGrading`, `e46SerreClosed` proved); order unbounded	§43.6.3
`admissiblyRational_of_dlmRational`	DLM rational ⇒ `AdmissiblyRational`	`C2Cofinite`; converse open	§43.6.3
`boundary_classically_free`	Arakawa–Dai Thm 1.1 on the presented arc algebra	hypothesis $1 \leq m$ only	§43.1.11
`rightRigid_ordinary` / `rigid_ordinary`	Huang rigidity, right duals / two-sided `RigidCategory`	for `Nice` (pseudo-unitary) VOAs	§43.6.3
`contra_vacuum_equiv_of_stronglyRational` and `_of_stronglyRational` copies	$V \cong V'$, vacuum-fusion chain	`StronglyRational`; no pseudo-unitarity	§43.6.3

`dlnCongruenceInput_holds`	Dong–Lin–Ng congruence	for `Nice` VOAs; FS half open	§43.6.3
`nsProjectiveKernelAll_holds`	kernel half of Ng–Schauenburg 6.8	unconditional; FS half open	§43.6.3
`gannonRayhaun_classification`	nice $c = 1$ VOAs, both directions	no hypotheses; rational = `AdmissiblyRational`; `Type 0`	§43.1.11
`X_classicallyFree_final`	Deligne series: classical freeness	A_2: no hypothesis (aggregate build green 2026-10-28; standard axioms); other types conditional on named inputs (Ch. 27)	§43.6.3

43.8 Notes and references

The verification protocol is the project's own (its working rules, `README.md` "Axioms and trust base" and "Auditing a headline result", `Notes/MonsterRoadmap.md` "Operating rules"). The dead ends are collected from `README.md` "Known dead ends", the project's internal session records, `Notes/M8GluingPlan.md` (all "Status" sections) and the route notes `Notes/M8hRoute.md`, `Notes/TrialityTwisted.md`, `Notes/SigmaExistence.md`, `Notes/ZhuGeneratorTest.md`, `Notes/ZhuGeneration.md`, `Notes/SigmaKey.md`, `Notes/KeySkew.md`, `Notes/BimoduleGenTest.md`.

Appendix A

Provenance: the library state documented by this edition

This edition documents release v1.0 of the LeanVOA library (commit `recorded at release`). Each Lean file of the library is assigned to one chapter of the book. The table lists, for each chapter of this edition, the number of Lean files of the released library assigned to it (11622 files in all); chapters without files of their own are omitted. The chapters in preparation are not part of this edition. The 38 files of the released library assigned to them are not counted.

Chapter	Title	Lean files
`ch01`	Reading Lean, and a map of the book	7
`L01`	Formal calculus and locality	13
`L02`	Lie-theoretic inputs and the trust base	15
`L03`	The vertex algebra axioms, the Borcherds identity and reconstruction	32
`L04`	Structure theory and invariant forms	34
`L05`	Free fields: Heisenberg and lattice vertex algebras	76
`L06`	The Virasoro vertex algebra: Verma modules, the Kac determinant and screenings	117
`L07`	First-order deformations and the rigidity of Virasoro minimal models	98
`L08`	Affine sl(2): construction, Verma modules, Wakimoto realization and non-simplicity	133
`L09`	Rigidity of affine sl(2): Linshaw–Qi and admissible levels	34
`L11`	Filtrations, the C2 algebra and presentations	41
`L12`	Modules, Zhu's algebra and the rationality hierarchy	152
`L13`	Zhu's bijection via the Frenkel–Zhu tower	298
`L14`	Modular forms and the analytic toolkit	48
`L15`	Zhu's modularity theorem	125
`L16`	Quasi-lisse vertex algebras and the Arakawa–Kawasetsu theorem	16
`L17`	The super generalization	110
`L18`	Logarithmic vertex algebras: the triplet and doublet algebras	182
`L19`	Graded unitarity, Lee–Yang and inverse Drinfeld–Sokolov reduction	84
`L20`	Classical freeness at the boundary admissible level: the Arakawa–Dai theorems	203
`L21`	Huang's modular tensor category and the congruence property	932
`L22`	The classification of nice central-charge-one vertex operator algebras (Gannon–Rayhaun)	1755
`L23`	Affine vertex algebras for every simple Lie algebra, and the exceptional Lie algebras	461
`L24`	The Deligne series I: presentations, carriers and the divisor comparison	2740
`L25`	The Deligne series II: characters, the Arakawa–Kawasetsu MLDE and q-series identities	323

Chapter	Title	Lean files
L26	The Deligne series III: fusion modules, Demazure modules and Ravinder's kernel	3019
L27	The Deligne series IV: the final theorems, the named inputs and the open cores	22
L28	Graded unitarity through the BRST coset: from affine $\hat{\mathfrak{sl}}_2$ at level $-4/3$ to Lee–Yang	227
L29	The $(2, 2n+3)$ series: coset transfer of graded unitarity at every boundary level	128
ch02	Lattices, codes and the Leech lattice	26
ch03	Heisenberg and lattice vertex algebras	5
ch04	The involution theta and the fixed-point algebra	9
ch05	Graded dimensions and the modular function J	7
ch06	Twisted modules, the twisted Fock space and the module T	6
ch07	The twisted Heisenberg module	11
