```

From the mathematics to the Lean statement

Products. `W.smul u n v` is `mode (W.Y u) n v`, the n-th product $u_{(n)}v$ of the VOA `W` (the coefficient of z^{-n-1} in $Y(u,z)v$, Chapter 2), for every integer n, negative ones included. In (3) the left side is the n-th product of $L_k(\mathfrak{g})$ applied to the images $\pi(u), \pi(v)$; the right side is π of the n-th product computed in `universalAffineVOA`, i.e. in $V^k(\mathfrak{g})$. Since all n are covered, (3) says that π intertwines the full vertex operators: $\pi(Y(u,z)v) = Y(\pi u, z)\pi v$.
Grading. `W.grading n` is the weight-n subspace of `W`, on which L_0 acts by n (field `L0_grading`, Chapter 2); the weight index is an integer, and `{n : ℤ}` and `{x : …}` are implicit arguments inferred from `hx`. (5) is the inclusion $\pi(V^k_n) \subseteq (L_k)_n$; together with (4) and the directness of both gradings this gives $\pi(V^k_n) = (L_k)_n$ on paper, but the equality is not stated in Lean.
Central charge. `centralCharge` is the field c of the VOA structure appearing in its Virasoro relation $[L_m, L_n] = (m-n)L_{m+n} + \frac{m^3-m}{12} c\,\delta_{m+n,0}$ (Chapter 2). `Module.finrank ℂ 𝔤` is $\dim \mathfrak{g}$, cast to $\mathbb{C}$. The right side is literally the right side of `universalAffineVOA_centralCharge`, and the displayed proof term shows the equality is *definitional transport*: the quotient VOA carries the image of the conformal vector, and its `centralCharge` field is copied from the parent (`centralCharge := W.centralCharge` in `QuotVOA.quotientVOA`, Chapter 5); the content is that the Virasoro relation holds in the quotient with the same c.
Simplicity. `IsSimple` is the definition of Chapter 5 (nonzero carrier, only trivial ideals among *all* ideals, not only graded ones); the proof term is `simpleVOA_isSimple`, Theorem 23.13.
Hypotheses. Every statement carries exactly κ, `hinv`, `hnd`, k, `hk` and the section variables; there is no hidden assumption. Same as the textbook, in the normalization of κ (so $h = h^\vee$ only per type).

Proof on paper. (1) is Theorem 23.13 for D =`simpleData`. (2) The conformal vector of the quotient is the class $[\omega]$ of the Sugawara vector, and by (3) its modes are the modes L_n of V^k acting on classes; the Virasoro relation of V^k therefore descends to the quotient with the same c (and the scalar is detected, since the quotient is nonzero by (1)). The central charge is unchanged. (3) $I_{\max}$ is a two-sided ideal, so $u_{(n)}v$ modulo $I_{\max}$ depends only on the classes of u and v; the quotient VOA is *defined* by this formula (Chapter 5). (4) Every quotient map is surjective. (5) $I_{\max}$ is graded, so the quotient grading is the image of the grading of V^k. □

Physical meaning

(1) says $L_k(\mathfrak{g})$ has no proper consistent truncation: it is the chiral algebra of a theory, not of a reducible collection of sectors. (2) Imposing null relations does not change the Virasoro central charge — the Sugawara stress tensor of the currents is the same field before and after; the familiar $c = \dim \mathfrak{g}\, k/(k+h^\vee)$ of the WZW model is the value. (3)–(5) say that operator product expansions and conformal weights computed in the universal algebra descend to the physical one, and that every state of the physical theory comes from a polynomial in current modes acting on the vacuum.

What the machine verified

Proved; `#print axioms` reports `[propext, Classical.choice, Quot.sound]` for all five theorems (re-run for this chapter, Section 23.12). **Unconditional** in the sense of this book: the only hypotheses are those of the intended statement. Not stated in Lean: equality of weight spaces in (5); that $h = h^\vee$ for general $\mathfrak{g}$.

23.6.3 Weight one of the universal algebra

Definition 23.16 (Current state). $x \mapsto x_{(-1)}|0\rangle$, the linear map $\mathfrak{g} \to V^k(\mathfrak{g})$.

File `VOA/AffineGeneral/WeightOne.lean`.

```
def currentState (k : ℂ) : 𝔤 →ₗ[ℂ] Vacuum D k where
  toFun x := vacuumRho κ D.invariant k (ofLoop κ D.invariant x (-1)) (vacuumA D k)
```

From the mathematics to the Lean statement

The action of the loop element $x \otimes t^{-1}$ on the vacuum. Linearity is proved in the omitted fields. Same as the textbook.

Physical meaning

The state–field correspondence sends $x_{(-1)}|0\rangle$ to the current $J^x(z)$.

What the machine verified

A definition (no proof obligation).

Theorem 23.17 (Weight one of $V^k(\mathfrak{g})$). *$V^k(\mathfrak{g})_1$ is the image of the current-state map; $y_{(1)}x_{(-1)}|0\rangle = k\kappa(y,x)|0\rangle$; and for $k \neq 0$ the current-state map is injective, so $\mathfrak{g} \cong V^k(\mathfrak{g})_1$.*

File `VOA/AffineGeneral/WeightOne.lean`.

```
theorem grading_one_eq_range (k : ℂ) : gradingZA D k 1=LinearMap.range (currentState D k)
 ↪  := by

theorem positive_current_currentState (k : ℂ) (x y : 𝔤) :
    vacuumRho κ D.invariant k (ofLoop κ D.invariant y 1) (currentState D k x)=
      (k*κ y x) • vacuumA D k := by

theorem currentState_injective_of_ne_zero (k : ℂ) (hk : k≠0) :
    Function.Injective (currentState D k) := by

def weightOneEquiv (k : ℂ) (hk : k ≠ 0) : 𝔤 ≃ₗ[ℂ] gradingZA D k 1 := by
```

From the mathematics to the Lean statement

`≃ₗ[ℂ]` is a linear isomorphism, and only that: no Lean statement in `AffineGeneral/` says that it carries the bracket $[x,y]$ to the weight-one product $u_{(0)}v$, so "$\mathfrak{g} \cong V^k(\mathfrak{g})_1$" is proved as vector spaces, not as Lie algebras (release audit 2026-10-27, finding m1). The hypothesis $k \neq 0$ is used by the proof (the form argument below). It is not necessary mathematically: by PBW the map is injective at every level, and for $\mathfrak{sl}_3$ this is proved (`VOA.AffineSl3.currentState_injective`, `VOA/Examples/AffineSl3VacuumBasis.lean`); the general all-level statement is not in the library. The docstring of `currentState_injective_of_ne_zero` points to the $\mathfrak{sl}_3$ file for it, which is correct only for $\mathfrak{sl}_3$ (Section 23.13). Same as the textbook for $k \neq 0$.

Proof on paper. Spanning as above. The pairing: $[y \otimes t, x \otimes t^{-1}] = [y,x] \otimes 1 + k\kappa(y,x)$, and $[y,x] \otimes 1$ and $y \otimes t$ kill the vacuum. Injectivity: if $x_{(-1)}|0\rangle = 0$ then $k\kappa(y,x) = 0$ for all y; with $k \neq 0$ and κ nondegenerate (a consequence of Lie data), $x = 0$. □

Physical meaning

The two-point function of currents is $\langle J^y J^x \rangle \propto k\kappa(y,x)$; at nonzero level it is nondegenerate, so no current is null in the universal theory.

What the machine verified

Proved; axioms standard (project record, Section 23.12).

Trap: $L_k(\mathfrak{g})_1 \cong \mathfrak{g}$ is not stated for general $\mathfrak{g}$

Theorem 23.13 gives only that the currents *span* $L_k(\mathfrak{g})_1$. Injectivity of $\mathfrak{g} \to L_k(\mathfrak{g})_1$ for $k \neq 0$ is easy on paper: if $x_{(-1)}|0\rangle \in I_{\max}$ then $y_{(1)}x_{(-1)}|0\rangle = k\kappa(y,x)|0\rangle \in I_{\max}$, and a proper ideal does not contain the vacuum, so $x = 0$. It is proved for $\mathfrak{sl}_3$ (`AffineSl3.simpleCurrentState_injective`, `VOA/Examples/AffineSl3Simple.lean`) but not in `AffineGeneral/`. Nothing in the Deligne chain needs it: the presentations of Chapter 24 only need spanning. This is a gap, not a defect.

23.6.4 Singular vectors lie in the maximal ideal

The explicit presentations of Chapter 24 need to know that specific weight-two vectors vanish in $L_k(\mathfrak{g})$. The general tool:

Definition 23.18 (Positive-mode singular vector). $t \in V^k(\mathfrak{g})$ is *positive-mode singular* if $J_i^a t = 0$ for all a and all $i \geq 1$.

File `VOA/AffineGeneral/Singular.lean`.

```
def SingP (t : Vacuum D k) : Prop := ∀ (a : ι) (i : ℤ), 1 ≤ i → J D k a i t = 0
```

From the mathematics to the Lean statement

Note that the zero modes J_0^a are *not* required to kill t: t need not be a highest-weight vector for $\mathfrak{g}$. This is the right notion because the set of such t is $\mathfrak{g}$-stable (`SingP.zeroMode`), so a $\mathfrak{g}$-module of singular vectors can be handled at once. Same as the textbook notion of "singular vector for $\hat{\mathfrak{g}}_+$".

Physical meaning

A singular vector is a null state: its two-point function with every state vanishes; it decouples from all correlators of the physical theory.

What the machine verified

A definition (no proof obligation).

Theorem 23.19 (Singular vectors die in $L_k(\mathfrak{g})$). *A homogeneous positive-mode singular vector of positive weight lies in the maximal ideal. In particular a quadratic state $t = \sum_i c_i J_{-1}^{a_i} J_{-1}^{b_i}|0\rangle$ lies in it as soon as, for all x, g,*

$$\sum_i c_i\Big(\delta_{a_i g}\, k\kappa_{x b_i} + \delta_{b_i g}\, k\kappa_{x a_i} + \sum_c f^{x a_i}{}_c f^{c b_i}{}_g\Big) = 0, \qquad \sum_i c_i\, k \sum_c f^{x a_i}{}_c \kappa_{c b_i} = 0.$$

Files `VOA/AffineGeneral/Singular.lean`, `VOA/AffineGeneral/SingularQuad.lean`.

  mem_maxIdeal_of_SingP D k hk (singP_quad D k terms h1 h2) (by norm_num) (quadState_mem D
   ↪  k terms)
```

From the mathematics to the Lean statement

`st2 D k a b` is $J^a_{-1}J^b_{-1}|0\rangle$; a list of triples `(c, a, b)` encodes $\sum c\,J^a_{-1}J^b_{-1}|0\rangle$. `quadCoef1 x g` is the coefficient of $J^g_{-1}|0\rangle$ in $J^x_1 t$ and `quadCoef2 x` the coefficient of $|0\rangle$ in $J^x_2 t$ (modes ≥ 3 kill weight-two states automatically). In `mem_maxIdeal_of_SingP` the weight $w > 0$ is essential: the vacuum itself is positive-mode singular of weight 0 and is not in the ideal. Same as the textbook.

Proof on paper. Let $t \neq 0$ be positive-mode singular and homogeneous of weight $w > 0$, and let $M = U(\hat{\mathfrak{g}})t$ be the $\hat{\mathfrak{g}}$-submodule it generates. Three facts.

- *$M = U(\hat{\mathfrak{g}}_-)U(\mathfrak{g})t$, so M lives in weights $\geq w$.* Write $\hat{\mathfrak{g}} = \hat{\mathfrak{g}}_- \oplus \mathfrak{g} \oplus \hat{\mathfrak{g}}_+$ (negative, zero and positive modes, plus the central element, which acts by k). By PBW, $U(\hat{\mathfrak{g}}) = U(\hat{\mathfrak{g}}_-)U(\mathfrak{g})U(\hat{\mathfrak{g}}_+)$. The positive modes kill t, and they also kill every $J^a_0 t$ (the set of positive-mode singular vectors is $\mathfrak{g}$-stable, `SingP.zeroMode`: $J^b_i J^a_0 t = J^a_0 J^b_i t + \sum_c f^{ba}{}_c J^c_i t = 0$ for $i \geq 1$). Zero modes preserve weight and negative modes raise it.

- *M is an ideal of the vertex algebra.* An ideal of $V^k(\mathfrak{g})$ is a subspace stable under all $u_{(n)}$, $u \in V^k(\mathfrak{g})$. Stability under the current modes $J^a_n = (b_a)_{(-1)}|0\rangle_{(n)}$ holds by construction; since $V^k(\mathfrak{g})$ is generated by the currents, every $u_{(n)}$ is, by the Borcherds identity (iterate formula), an infinite but locally finite combination of products of current modes, so M is stable under all of them. (This is Dong's lemma in the form used in Chapter 5; in Lean it is the induction on current words that turns "positive-mode singular" into "strongly singular".) It is graded because t is homogeneous.

- *M is proper.* The vacuum has weight $0 < w$, so $|0\rangle \notin M$.

So M is a proper graded ideal and $t \in M \subseteq I_{\max}$. For the quadratic test: $J^x_1 J^a_{-1}J^b_{-1}|0\rangle = \big(\sum_c f^{xa}{}_c J^c_0 + k\kappa_{xa}\big)J^b_{-1}|0\rangle + J^a_{-1}k\kappa_{xb}|0\rangle$ and $J^c_0 J^b_{-1}|0\rangle = \sum_g f^{cb}{}_g J^g_{-1}|0\rangle$, which gives `quadCoef1`; similarly $J^x_2 J^a_{-1}J^b_{-1}|0\rangle = \sum_c f^{xa}{}_c J^c_1 J^b_{-1}|0\rangle = k\sum_c f^{xa}{}_c \kappa_{cb}|0\rangle$. □

Example 23.20 ($\mathfrak{sl}_2$: the null vector $(J^e_{-1})^2|0\rangle$ at level one)**.** Continue Example 23.2 ($\kappa = \mathrm{tr}$, $h = 2$) and take $t = J^e_{-1}J^e_{-1}|0\rangle$, i.e. the list `[(1, e, e)]`. The commutators needed are $[J^x_1, J^e_{-1}] = J^{[x,e]}_0 + k\,\mathrm{tr}(xe)$ and $[J^x_2, J^e_{-1}] = J^{[x,e]}_1$:

$$
\begin{aligned}
J^f_1 t &= (-J^H_0 + k)J^e_{-1}|0\rangle + J^e_{-1}(-J^H_0 + k)|0\rangle = (k-2)J^e_{-1}|0\rangle + kJ^e_{-1}|0\rangle = (2k-2)\,J^e_{-1}|0\rangle,\\
J^H_1 t &= 2J^e_0 J^e_{-1}|0\rangle + J^e_{-1}\,2J^e_0|0\rangle = 2J^{[e,e]}_{-1}|0\rangle = 0, \qquad J^e_1 t = 0 \quad (\mathrm{tr}(ee) = 0,\ [e,e] = 0),\\
J^f_2 t &= -J^H_1 J^e_{-1}|0\rangle - J^e_{-1}J^H_1|0\rangle = -\big(2J^e_0 + k\,\mathrm{tr}(He)\big)|0\rangle = 0,
\end{aligned}
$$

and similarly $J_2^H t = J_2^e t = 0$; modes ≥ 3 kill weight two. So t is positive-mode singular *if and only if* $k = 1$. In the language of the theorem, `quadCoef1 f e` $= k\,\mathrm{tr}(fe) + k\,\mathrm{tr}(fe) + \sum_c f^{fe}{}_c f^{ce}{}_e = 2k + (-1)\cdot 2 = 2k - 2$ (only $c = H$ contributes, with $[f,e] = -H$ and $[H,e] = 2e$), and every other coefficient vanishes identically. Hence at $k = 1$, $(J_{-1}^e)^2|0\rangle \in I_{\max}$ and $(J_{-1}^e)^2|0\rangle = 0$ in $L_1(\mathfrak{sl}_2)$, the familiar relation $e(z)^2 = 0$ of the level-one WZW model (in the Frenkel–Kac picture $e(z) = e^{i\sqrt{2}X(z)}$, and $e(z)e(w) \sim (z-w)^2$ vanishes at $z = w$). The general pattern is $(J_{-1}^e)^{k+1}|0\rangle = 0$ at positive integer level k; the weight-two case is $k + 1 = 2$.

Physical meaning

At the Deligne levels the vacuum module has null vectors at weight two, spanning the $\mathfrak{g}$-representation complementary to $\mathbb{C} \oplus V(2\theta)$ in $\mathrm{Sym}^2\mathfrak{g}$ (θ the highest root). Their images in $\mathrm{Sym}\,\mathfrak{g}$ are the quadratic generators of the *Joseph ideal* (for $\mathfrak{g}$ not of type A, the unique completely prime primitive ideal of $U(\mathfrak{g})$ whose associated variety is the minimal nilpotent orbit closure; its associated graded is the ideal of functions vanishing on $\overline{\mathbb{O}_{\min}}$, Chapter 24). Example 23.20 is the simplest analogue. This theorem is the mechanism by which those null states are shown to vanish in the physical chiral algebra; in four-dimensional language they are the Higgs-branch chiral ring relations of the minimal nilpotent orbit.

What the machine verified

Proved; axioms standard for `mem_maxIdeal_of_SingP` (re-run) and `quadState_mem_maxIdeal` (project record). The structure-constant version `SCLie.ld_quadState_mem_maxIdeal` (`SCSingular.lean`) replaces the two families of conditions by Boolean kernel checks `q1OK`, `q2OK` (defined in `SCLieData.lean`) on integer tables. Its statement takes an *integer* level and integer coefficients, `(k : ℤ)` and `tz : List (ℤ × Fin N × Fin N)`, for Lie data built by `lieDataOf` (Section 23.9); so it applies as stated only at the integer Deligne levels $(-2, -3, -4, -6$ for $D_4, E_6, E_7, E_8)$, not at $-3/2$, $-5/3$, $-5/2$ (A_2, G_2, F_4), where the general `quadState_mem_maxIdeal` above (complex k and coefficients) must be used.

23.6.5 Current coordinates in Li degree zero

For the presentations of Chapter 24 the library needs the map from polynomials in the currents to Li's associated graded algebra (Chapter 11, Section 11.3), and two facts about its kernel. Recall that Li's filtration $F^0V \supseteq F^1V \supseteq \cdots$ is decreasing, that $\mathrm{gr}^F V = \bigoplus_p F^pV/F^{p+1}V$ is a commutative algebra (product induced by $u_{(-1)}v$), and that its degree-zero part is Zhu's C_2-algebra $R_V = V/C_2(V)$, $C_2(V) = \mathrm{span}\{u_{(-2)}v\}$ (Theorem 11.10). The "Li-degree-zero class" of a vector is its image in R_V. The facts below are proved in full in the cited file; the argument for (i) is the one of Chapter 24, Theorem 24.11, summarized after the statement.

Proposition 23.21 (Kernel facts for current coordinates). *Let* $\mathrm{cls} : \mathbb{C}[X_1, \ldots, X_n] \to \mathrm{gr}^F L_k(\mathfrak{g})$ *send* X_i *to the Li-degree-zero class of the current* $[J_{-1}^i|0\rangle]$. *Then (i) the kernel is stable under the coadjoint derivations* $\mathrm{ad}^*(b)$, $X_i \mapsto \sum f^{bi}{}_c X_c$, *and (ii) if a quadratic state* $\sum c_i J_{-1}^{a_i} J_{-1}^{b_i}|0\rangle$ *lies in* $I_{\max}$, *then* $\sum c_i X_{a_i} X_{b_i} \in \ker \mathrm{cls}$.

File `VOA/AffineGeneral/LiPresentation.lean`.

```

 ↪ maxIdeal D k hk) :
    clsG (simpleVOA D k hk) (genS D k hk) (genS_weight_one D k hk) (quadPoly terms) = 0 :=
     ↪ by
```

From the mathematics to the Lean statement

`MvPolynomial (Fin n) ℂ` is $\mathbb{C}[X_1, \dots, X_n]$; the section variable is `D : LieData κ (Fin n)`, so n is the size of the index set of D, i.e. $n = \dim \mathfrak{g}$ (variables indexed by the basis); `aeval` is the algebra map determined by the images of the variables; `liAssociatedGraded W'` and `liDegreeZeroClass` are Li's associated graded algebra and the class of a weight-N vector in Li degree 0 (Chapter 11; in Li degree zero this is the C_2-algebra R_V). `genS i` is $[J^i_{-1}|0\rangle] \in L_k(\mathfrak{g})$. `adPolyT T b` is the derivation of the polynomial ring extending $X_i \mapsto \sum_c T(b,i,c)X_c$. Same as the textbook.

Proof on paper. (i) The zero mode J^b_0 preserves $L_k(\mathfrak{g})$, Li's filtration and C_2, and acts on products by the Leibniz rule (J^b_0 is a derivation of every n-th product, by the commutator formula, since $[J^b_0, Y(u,z)] = Y(J^b_0 u, z)$). So it induces a derivation δ_b of gr^F, and in degree zero this is the Poisson bracket $\{[J^b], \cdot\}$ of R_V. On generators, $\delta_b[J^i_{-1}|0\rangle] = [J^{[b_b,b_i]}_{-1}|0\rangle] = \sum_c f^{bi}{}_c[J^c_{-1}|0\rangle]$, which is the derivation $\mathrm{ad}^*(b)$ on variables. Thus $\mathrm{cls} \circ \mathrm{ad}^*(b) = \delta_b \circ \mathrm{cls}$ on generators, hence on all polynomials (both sides are derivations along cls); if $\mathrm{cls}(p) = 0$ then $\mathrm{cls}(\mathrm{ad}^*(b)p) = \delta_b(0) = 0$. (ii) The product of gr^F is induced by the (-1)-product, so the class of $J^a_{-1}J^b_{-1}|0\rangle = (J^a_{-1}|0\rangle)_{(-1)}(J^b_{-1}|0\rangle)$ is the product of the classes; and the image of $I_{\max}$ in L_k is zero. □

Physical meaning

$\mathrm{gr}^F L_k$ in degree zero is the ring of functions on the associated variety (the Higgs branch, in the 4d dictionary); (i) says the relations are G-invariant as a set, (ii) that a null state at weight two becomes a quadratic chiral-ring relation.

What the machine verified

Proved; axioms standard (project record, Section 23.12).

23.7 Concrete simple Lie algebras I: $\mathfrak{sl}_n$ and a root-space criterion

Theorem 23.10 is only useful if some concrete Lie algebra in Lean carries an instance of `LieAlgebra.IsSimple`. Mathlib v4.30 has none: it defines $\mathfrak{sl}_n$ (`LieAlgebra.SpecialLinear.sl`) and, through `Matrix.ToLieAlgebra`, a Serre-relation construction of the exceptional algebras, but proves neither simplicity nor finite-dimensionality for any of them.

Dead end: Mathlib's Serre construction

The obvious route to $\mathfrak{e}_8$ is Mathlib's `LieAlgebra.e₈ := Matrix.ToLieAlgebra …` (file `Mathlib/Algebra/Lie/SerreConstruction.lean`): the Lie algebra presented by Chevalley generators and Serre relations of the E_8 Cartan matrix. Mathlib does not prove that it is finite-dimensional, nor that it is simple, nor its dimension; each of these is a substantial theorem (Serre's theorem). The project recorded this route as a dead end and built the exceptional algebras as lattice weight-one spaces and from checked structure constants instead.

Theorem 23.22 ($\mathfrak{sl}_n$ is simple). *For every finite type n with at least two elements, $\mathfrak{sl}_n(\mathbb{C})$ is a simple Lie algebra. Consequently $V^k(\mathfrak{sl}_m)$ exists in the normalization* Kil $/(2m)$ *for $k \neq -m$.*

File `VOA/AffineGeneral/SlnSimple.lean`.

```
instance instIsSimple [Nontrivial n] : LieAlgebra.IsSimple ℂ (sl n ℂ) where

def slAffineVOA (m : ℕ) [Nontrivial (Fin m)] (k : ℂ) (hk : k + (m : ℂ) ≠ 0) (hm : (m : ℂ) ≠
↪  0) :
    VertexOperatorAlgebra (Vacuum (standardData (sl (Fin m) ℂ) (m : ℂ) hm) k) :=
  standardAffineVOA (sl (Fin m) ℂ) (m : ℂ) hm k hk
```

From the mathematics to the Lean statement

`sl n ℂ` is Mathlib's Lie subalgebra of trace-zero matrices indexed by the finite type `n`; `[Nontrivial n]` means $|n| \geq 2$ (for $|n| \leq 1$, $\mathfrak{sl}_n = 0$ is not simple). The hypothesis `hm : (m : ℂ) ≠ 0` of `slAffineVOA` is **redundant**: it follows from `[Nontrivial (Fin m)]` ($m \geq 2$). Harmless, listed in Section 23.13.

Proof on paper. Let $I \neq 0$ be an ideal and $v \in I$, $v \neq 0$. If v has an off-diagonal entry $v_{ji} \neq 0$, then $[E_{ij}, [E_{ij}, v]] = -2v_{ji}E_{ij}$, so $E_{ij} \in I$. If v is diagonal and nonzero, it has two distinct diagonal entries (trace zero), and $[E_{ij}, v] = (v_{jj} - v_{ii})E_{ij}$ gives some $E_{ij} \in I$. From one E_{ij}, brackets $[E_{ij}, E_{jl}] = E_{il}$ and $[E_{ki}, E_{ij}] = E_{kj}$ produce all E_{kl}, $k \neq l$, and then $[E_{kl}, E_{lk}] = E_{kk} - E_{ll}$ span the diagonal; so $I = \mathfrak{sl}_n$. Non-abelian: $[E_{ij}, E_{ji}] \neq 0$. □

Physical meaning

$SU(n)$ current algebras, the $\mathfrak{sl}_n$ WZW models; $\mathfrak{sl}_2$ is the subject of Chapters 9 and 10, and a chapter on $\mathfrak{sl}_3$ is in preparation.

What the machine verified

Proved; `#print axioms SlSimple.instIsSimple` standard (re-run).

Trap: The normalization of `slAffineVOA` is not proved standard

The docstring of `slAffineVOA` says "in the standard normalization ($\kappa = \mathrm{Kil}/(2n)$, $h = n$)". On paper this is true: $\mathrm{Kil}(x, y) = 2n\,\mathrm{tr}(xy)$ on $\mathfrak{sl}_n$, so $\mathrm{Kil}/(2n)$ is the trace form, whose long roots have length 2, and $h^\vee(\mathfrak{sl}_n) = n$. But in Lean, by Theorem 23.10(3), $h = n$ holds for *any* choice of the parameter; no theorem identifies $\mathrm{Kil}/(2n)$ with the trace form. Contrast the lattice and structure-constant types, where `*_standard` theorems do this (Theorem 23.32).

23.7.1 A root-space criterion for simplicity

For the exceptional algebras the $\mathfrak{sl}_n$ argument is generalized to an abstract criterion, stated for any Lie algebra with a family of "root vectors" and "coroots".

Theorem 23.23 (Root-space criterion). *Let L be a complex Lie algebra, R a finite nonempty set, $e, h : R \to L$, $p : R \times R \to \mathbb{C}$, and $- : R \to R$, such that*

1. *the e_β and h_α together span L, and $e_\beta \neq 0$;*
2. *$[h_\alpha, e_\beta] = p(\alpha, \beta)e_\beta$ and $[h_\alpha, h_\beta] = 0$;*
3. *$p(\alpha, \alpha) \neq 0$, and the weights separate: for $\alpha \neq \beta$ some γ has $p(\gamma, \alpha) \neq p(\gamma, \beta)$;*
4. *$[e_\alpha, e_{-\alpha}] = c_\alpha h_\alpha$ with $c_\alpha \neq 0$;*
5. *no nonzero element of $\mathrm{span}(h)$ commutes with all e_β;*

6. *the graph on R with an edge $\alpha \to \beta$ when $p(\alpha,\beta) \neq 0$ is connected (every β is reachable from every α).*

Then L is simple.

File `VOA/AffineGeneral/RootSpaceSimple.lean`.

```
theorem isSimple_of_roots [Fintype R] [DecidableEq R] [Nonempty R]
    (hspan : span ℂ (Set.range e ∪ Set.range hb) = ⊤)
    (he0 : ∀ β, e β ≠ 0)
    (hbe : ∀ α β, ⁅hb α, e β⁆ = pair α β • e β)
    (hhb : ∀ α β, ⁅hb α, hb β⁆ = 0)
    (hdiag : ∀ α, pair α α ≠ 0)
    (sep : ∀ α β, α ≠ β → ∃ γ, pair γ α ≠ pair γ β)
    (neg : R → R) (hneg : ∀ α, ∃ c : ℂ, c ≠ 0 ∧ ⁅e α, e (neg α)⁆ = c • hb α)

    (conn : ∀ α β, Relation.ReflTransGen (fun a b => pair a b ≠ 0) α β) :
    LieAlgebra.IsSimple ℂ L where
```

From the mathematics to the Lean statement

`span ℂ S = ⊤` says S spans L. `Relation.ReflTransGen r α β` is the reflexive-transitive closure: a finite chain $\alpha = \alpha_0, \alpha_1, \dots, \alpha_m = \beta$ with $r(\alpha_i, \alpha_{i+1})$. The map `neg` is arbitrary data, constrained only by `hneg`. Nothing requires R to be a root system: the criterion is purely about weight vectors, which is what makes it checkable by finite computation. Every hypothesis is used. Same as the statement above, which is a slight generalization of the textbook argument (Humphreys §14) for simplicity of a Lie algebra with an irreducible root system.

Proof on paper. Let $I \neq 0$ be an ideal, $v \in I$ nonzero; write $v = \sum_\beta c_\beta e_\beta + y$, $y \in \operatorname{span} h$. If all $c_\beta = 0$ then $v = y \neq 0$, and by (5) some $[y, e_\beta] = \lambda e_\beta \neq 0$ lies in I, so $e_\beta \in I$. Otherwise pick β with $c_\beta \neq 0$. The operators $\operatorname{ad}(h_\gamma) - p(\gamma,\delta)$ kill e_δ, act on e_β by the scalar $p(\gamma,\beta) - p(\gamma,\delta)$, and by (3) for each $\delta \neq \beta$ some γ makes this scalar nonzero; applying the product of these operators (one per $\delta \neq \beta$), and finally $\operatorname{ad}(h_\beta)$ (to kill the Cartan part, using $p(\beta,\beta) \neq 0$), projects v onto a nonzero multiple of e_β inside I. Once $e_\beta \in I$: $[e_\beta, e_{-\beta}] = c_\beta h_\beta \in I$; then $[h_\beta, e_\gamma] = p(\beta,\gamma) e_\gamma$ puts $e_\gamma \in I$ whenever $p(\beta,\gamma) \neq 0$; by connectivity (6) all $e_\gamma \in I$, then all h_γ, so $I = L$ by (1). Non-abelian: $[h_\alpha, e_\alpha] = p(\alpha,\alpha) e_\alpha \neq 0$. □

Physical meaning

The criterion says: a symmetry algebra is simple if its charged currents (e_β) carry distinguishable charges under the Cartan currents (h_α), no Cartan current is neutral under everything, and the charges link all the currents together. It is the algebraic content of "the gauge group does not factorize".

What the machine verified

Proved; `#print axioms RootSpace.isSimple_of_roots` standard (re-run).

23.8 Concrete simple Lie algebras II: simply-laced types as lattice currents

23.8.1 The root lattices

Definition 23.24 (Cartan lattices). For a symmetric integer matrix G, ofCartan(G) is the lattice $\mathbb{Z}^n$ with bilinear form $\langle v, w\rangle = v^{\mathsf{T}} G w$. The lattices a_2, d_4, e_6, e_7, e_8 are ofCartan of Mathlib's Cartan matrices of types A_2, D_4, E_6, E_7, E_8; each is even and positive definite.

File `VOA/Foundations/CartanLattices.lean`.

```
noncomputable def ofCartan {n : ℕ} (G : Matrix (Fin n) (Fin n) ℤ) (hG : G.IsSymm) :
    IntegralLattice where
  carrier := Fin n → ℤ
  form := Matrix.toBilin' G

theorem sos_A2 (v : Fin 2 → ℤ) :
    ((Matrix.toBilin' (CartanMatrix.A 2) v v : ℤ) : ℚ) =
      (2 : ℚ) * ((v 0 : ℚ) + (-1/2 : ℚ) * (v 1 : ℚ)) ^ 2 + (3/2 : ℚ) * ((v 1 : ℚ)) ^ 2 :=
      ↪ by

noncomputable def e8 : IntegralLattice := ofCartan (CartanMatrix.E₈) CartanMatrix.E₈_isSymm

theorem e8_even : e8.Even :=

theorem e8_posDef : e8.PosDef :=
```

From the mathematics to the Lean statement

`IntegralLattice` is the library's structure of Chapter 3 (Definition 3.24): a free $\mathbb{Z}$-module `carrier` with a symmetric $\mathbb{Z}$-valued form. `Matrix.toBilin' G` is $(v,w)\mapsto v^{\mathsf T}Gw$. `CartanMatrix.E₈` etc. are Mathlib's Cartan matrices (Bourbaki numbering). `Even`: $\langle v,v\rangle\in 2\mathbb{Z}$; `PosDef`: $\langle v,v\rangle>0$ for $v\neq 0$. These are exactly the hypotheses of `latticeVOAGen` (Chapter 6). Same as the textbook.

Proof on paper. Evenness: the diagonal of G is 2, so $v^{\mathsf T}Gv=2\big(\sum v_i^2+\sum_{i<j}G_{ij}v_iv_j\big)$. Positive definiteness: an $LDL^{\mathsf T}$ decomposition $v^{\mathsf T}Gv=\sum_k d_k\big(v_k+\sum_{i>k}L_{ki}v_i\big)^2$ with all pivots $d_k>0$ (for A_2: $d=(2,\frac{3}{2})$, as `sos_A2` shows); if the sum is ≤ 0 every square vanishes and back-substitution gives $v=0$. The identities were produced by an untrusted script and are re-checked by `ring`. The products of the pivots are the determinants $3,4,3,2,1$. □

Physical meaning

These are the momentum lattices of n chiral bosons on the maximal torus of the simply-laced group G, at the special ("enhanced-symmetry") point where the vectors of norm 2 — the roots — give extra massless currents that enhance $U(1)^n$ to G. Only E_8 is unimodular (determinant 1), so only V_{E_8} is a self-dual, modular-invariant theory by itself; for A_2, D_4, E_6, E_7 (determinants $3,4,3,2$) V_L is a chiral algebra whose modular-invariant completion needs the other cosets L^*/L.

What the machine verified

Proved; axioms standard (project record, Section 23.12).

Definition 23.25 (Lattice VOAs and their weight-one Lie algebras). For each type $T\in\{A_2,D_4,E_6,E_7,E_8\}$, V_T is the lattice vertex algebra of the root lattice, of central charge rank, and $\mathfrak{t}=(V_T)_1$ with bracket $[u,v]=u_{(0)}v$.

File `VOA/Examples/DeligneLatticeLie.lean`.

```
abbrev e8VOA : VertexOperatorAlgebra (LatModuleGen e8) :=
  latticeVOAGen e8 e8_even e8_posDef

abbrev e8Lie := e8VOA.grading 1

theorem e8VOA_centralCharge : e8VOA.centralCharge = 8 := by
```

From the mathematics to the Lean statement

`latticeVOAGen L hEven hPos` is the lattice VOA of Chapter 6 (Theorem 6.21); `e8VOA.grading 1` is its weight-one subspace (this `e8Lie` is `DeligneLatticeLie.e8Lie`; the `CartanSimple.e8Lie` of Theorem 23.28 is the same type, written as `V1 e8 e8_even e8_posDef`), which carries the `LieAlgebra ℂ` instance of Chapter 5 (`Core/LieAlgebraV1.lean`), with Jacobi and antisymmetry derived from the VOA axioms. The same pattern defines `a2VOA`, `d4VOA`, `e6VOA`, `e7VOA` and their `*Lie`, with central charges 2, 4, 6, 7. Same as the textbook.

Proof on paper. The central charge of a lattice VOA is its rank (Chapter 6), and rank $\mathbb{Z}^n = n$. □

Physical meaning

V_{E_8} is the chiral algebra of eight bosons on the E_8 torus, central charge 8, and its currents form $\mathfrak{e}_8$. By the Frenkel–Kac theorem it is the level-one WZW chiral algebra $L_1(\mathfrak{e}_8)$; this isomorphism is *not* in Lean, and the library uses V_{E_8} only through its weight-one Lie algebra.

What the machine verified

Proved; axioms standard (`#print axioms` in the file itself; `e8VOA_centralCharge` re-run).

Trap: stale docstring in `DeligneLatticeLie.lean`

The module docstring of `VOA/Examples/DeligneLatticeLie.lean` says, under "Not proved here", that the identification with the simple Lie algebra of the named type and the dimension rank+#roots "are the next steps". This is literally true of that file, but reads as if they were open. Simplicity and the dimensions are now proved, in `CartanLatticeSimple.lean` (Theorem 23.28), `RootCounts.lean` and `E8Dimension.lean` (Theorems 23.29, 23.31). The pointer is stale; nothing proved is affected (the identification of the *type* remains unformalised, Remark 23.33). Listed in Section 23.13.

23.8.2 Simplicity of the lattice current algebras

Inside $(V_L)_1$ there are the vectors e^β for each root β (norm 2) and the Heisenberg states $\beta(-1)|0\rangle$.

Definition 23.26 (Root vectors and coroots of $(V_L)_1$). For L even positive definite, `Root L hPos` is the finite set of $\beta \in L$ with $\langle\beta,\beta\rangle = 2$; $e_\beta = e^\beta$ and $h_\beta = \beta(-1)|0\rangle$ in $(V_L)_1$.

File `VOA/AffineGeneral/LatticeV1Simple.lean`.

```
abbrev Root : Type _ := ↥(normEq L hPos 2)

abbrev V1 : Type _ := ↥((latticeVOAGen L hEven hPos).grading 1)

def eV (β : Root L hPos) : V1 L hEven hPos :=
  ⟨latChargeGen L β.1, latChargeGen_mem_grading_one L hEven hPos (root_form β)⟩

def hV (β : Root L hPos) : V1 L hEven hPos :=
  ⟨hSt L β.1, hSt_mem_gradingLatGen L β.1⟩

def RootsGenerate : Prop := AddSubgroup.closure {v : L.carrier | L.form v v = 2} = ⊤
```

From the mathematics to the Lean statement

`normEq L hPos 2` is the finite set (`Finset`) of lattice vectors of norm 2 (finite by positive definiteness); `↥` turns it into a type. `latChargeGen L β` is the state e^β (vacuum of the Fock

space of charge β), `hSt L β` is $\beta(-1)|0\rangle$ (Chapter 6). `RootsGenerate`: the roots generate L as a group. Same as the textbook.

Why these vectors lie in weight one. e^β has weight $\langle\beta,\beta\rangle/2 = 1$ and $\beta(-1)|0\rangle$ has weight 1; these definitions bundle each with that proof, as elements of the subtype `V1`.

Physical meaning

h_β are the $U(1)^n$ currents $i\partial X\cdot\beta$; $e_\beta = e^{i\beta\cdot X}$ are the vertex operators of charge β, which have conformal weight one, hence are extra massless currents, exactly when $\langle\beta,\beta\rangle = 2$.

What the machine verified

Definitions (no proof obligation).

Theorem 23.27 (Frenkel–Kac brackets, spanning, dimension and simplicity). *Let L be even and positive definite.*

1. $[h_\alpha, e_\beta] = \langle\alpha,\beta\rangle e_\beta$, $[h_\alpha, h_\beta] = 0$, $[e_\alpha, e_{-\alpha}] = \varepsilon(\alpha,-\alpha)h_\alpha$, $e_\beta \neq 0$.
2. *If the roots generate L, the e_β and h_β span $(V_L)_1$.*
3. $\dim(V_L)_1 = \operatorname{rank} L + \#\{\beta : \langle\beta,\beta\rangle = 2\}$.
4. *If a family s of roots generates L and is connected (the graph $\langle s_i, s_j\rangle \neq 0$ is connected), $(V_L)_1$ is simple.*

File `VOA/AffineGeneral/LatticeV1Simple.lean`.

    LieAlgebra.IsSimple ℂ (V1 L hEven hPos) := by
```

From the mathematics to the Lean statement

`Root.neg L hPos α` is the root $-\alpha$. `eV_ne_zero` is part (1)'s $e_\beta \neq 0$: the Fock vacuum of charge β is nonzero. `latticeCocycle L α β` is the FLM sign $\varepsilon(\alpha,\beta) = \pm1$ of Chapter 3 (Theorem 3.25); it is nonzero, which is what the criterion needs. `rank L` is the $\mathbb{Z}$-rank. In

(4) the family s is *any* connected generating family of roots, not necessarily a base of the root system; for the Cartan lattices the standard basis vectors serve. `finrank_V1` needs no generation hypothesis. Same as the textbook (Frenkel–Kac; Kac, *Vertex algebras for beginners*, §5.6).

Proof on paper. Recall (Chapters 3, 6) that $\varepsilon : L \times L \to \{\pm 1\}$ is a bimultiplicative cocycle with $\varepsilon(\alpha,\beta)\varepsilon(\beta,\alpha)^{-1} = (-1)^{\langle\alpha,\beta\rangle}$, and that $Y(e^\alpha, z)e^\beta = \varepsilon(\alpha,\beta)z^{\langle\alpha,\beta\rangle}\exp\big(\sum_{n\ge 1}\alpha(-n)z^n/n\big)e^{\alpha+\beta}$, while the bracket on weight one is $[u,v] = u_{(0)}v$, the coefficient of z^{-1} in $Y(u,z)v$. (1) $\alpha(-1)_{(0)} = \alpha(0)$ acts on e^β by $\langle\alpha,\beta\rangle$; $\alpha(0)\beta(-1)|0\rangle = 0$. For $\beta = -\alpha$, $Y(e^\alpha,z)e^{-\alpha} = \varepsilon(\alpha,-\alpha)z^{-2}\big(|0\rangle + z\,\alpha(-1)|0\rangle + O(z^2)\big)$; the coefficient of z^{-1} is $\varepsilon(\alpha,-\alpha)\alpha(-1)|0\rangle$, which is $e^\alpha_{(0)}e^{-\alpha}$. (2) Weight one of $V_L = \bigoplus_\gamma M(1)\otimes e^\gamma$ is $M(1)_1 \otimes e^0 \oplus \bigoplus_{\langle\gamma,\gamma\rangle=2}\mathbb{C}e^\gamma$, since $M(1)\otimes e^\gamma$ starts in weight $\langle\gamma,\gamma\rangle/2$; $M(1)_1 = \mathfrak{h}$ is spanned by the h_β because the roots generate L. (3) The graded dimension is $\sum_n$ θ-coefficients times partition counts; in weight one only $\gamma = 0$ (contributing rank L) and $\langle\gamma,\gamma\rangle = 2$ (contributing 1 each) occur. (4) Apply Theorem 23.23: separation of roots and the centre condition follow from nondegeneracy of the form on $L\otimes\mathbb{C}$ (an element of $\mathfrak{h}$ commuting with all e_β pairs to zero with all roots, hence with L); connectivity of all roots follows because every root has nonzero pairing with some s_i (else it would be orthogonal to all of L, contradicting $\langle\beta,\beta\rangle = 2$). □

Physical meaning

This is the statement that at the enhanced-symmetry point the $U(1)^n$ symmetry of n bosons on the torus of a simply-laced group is enhanced to the full non-abelian group: the Frenkel–Kac mechanism, and the origin of the $E_8\times E_8$ and $\mathrm{Spin}(32)/\mathbb{Z}_2$ gauge symmetries of the heterotic string. (In the Higgs mechanism a non-abelian symmetry is broken to $U(1)^n$ and the charged vector bosons become massive; here, moving the radius *to* the special point, the charged currents $e^{i\beta\cdot X}$ become massless and the symmetry is restored. This is an analogy, not part of the proof.)

What the machine verified

Proved; `#print axioms` standard for `isSimple_of_simpleRoots`, `finrank_V1` and `eV_ne_zero` (re-run).

Theorem 23.28 (Simple Lie algebras of types A_2, D_4, E_6, E_7, E_8). *Let G be a symmetric integer matrix with diagonal 2 and connected Dynkin diagram, such that the lattice* ofCartan *G is even and* positive definite *(for a Cartan matrix in the usual sense, i.e. of finite type, positive definiteness holds; it does* not *follow from "diagonal 2 and connected", e.g. affine Cartan matrices are only semidefinite). Then $(V_{\mathrm{ofCartan}\,G})_1$ is simple and finite-dimensional. In particular $\mathfrak{a}_2, \mathfrak{d}_4, \mathfrak{e}_6, \mathfrak{e}_7, \mathfrak{e}_8 := (V_T)_1$ are simple, and V^k of each exists in the normalization* Kil $/(2h)$ *with $h = 3, 6, 12, 18, 30$.*

```

From the mathematics to the Lean statement

The hypotheses of `cartan_isSimple`, in full: the section variables `G` (an $n \times n$ integer matrix), `hG : G.IsSymm` (symmetry; here, over $\mathbb{Z}$, plain transpose-symmetry), `hEven : (ofCartan G hG).Even` and `hPos : (ofCartan G hG).PosDef` (the lattice is even and positive definite; both are needed to form the lattice VOA `latticeVOAGen`, Chapter 6), and the explicit `hdiag` (diagonal 2, so the standard basis vectors are roots), `i0`, `d`, `hd` (connectivity). `hEven` is in fact implied by `hdiag` and symmetry (proof on paper of Definition 23.24), but `hPos` is an independent input: it is what makes the statement about finite type. `cartan_finiteDimensional` needs only `hdiag` besides the section variables. In the instances these are discharged by `e8_even`, `e8_posDef` (Definition 23.24) and `by decide`. Connectivity of the Dynkin diagram is certified by a "distance function" d to a base node i_0: every node other than i_0 has a neighbour ($G_{ji} \neq 0$) strictly closer to i_0. For E_8, $i_0 = 3$ (the trivalent node in Mathlib's numbering) and $d = (2, 1, 1, 0, 1, 2, 3, 4)$; `by decide` checks both conditions. `![…]` is a vector literal. `CartanSimple.e8Lie` is the same type as `DeligneLatticeLie.e8Lie`, and the file re-exports the instances for the latter. The numbers $30, 18, 12, 6, 3$ are the dual Coxeter numbers; that $\mathrm{Kil}/(2h)$ is then the standard normalization is Theorem 23.32. Same as the textbook, once "Cartan matrix" is read as "of finite type" (positive definite).

Proof on paper. Theorem 23.27(4) with s_i the standard basis vectors (roots, since $G_{ii} = 2$; they generate $\mathbb{Z}^n$; connected by d). Finite dimension from spanning by finitely many vectors. □

Physical meaning

The library's $\mathfrak{e}_8$ *is* the algebra of conserved currents of the E_8 lattice CFT; likewise for the other four types. The theorem says that these current algebras do not split into commuting pieces (the gauge group is simple).

What the machine verified

Proved; `#print axioms` standard for `CartanSimple.e8Lie_isSimple`, `cartan_isSimple`, `cartan_finiteDimensional` (re-run). `cartan_isSimple` is conditional on its listed hypotheses, in particular `hPos`; the instances for $A_2, \dots, E_8$ discharge them and are unconditional.

23.8.3 Dimensions: counting roots

Theorem 23.29 ($\dim \mathfrak{e}_8 = 248$, from $\theta_{E_8} = E_4$). *(i) For every modular form $f = \sum_n c_n q^n$ of weight 4 for $SL_2(\mathbb{Z})$, $c_1 = 240\, c_0$. (ii) The E_8 lattice has 240 vectors of norm 2, and* $\dim \mathfrak{e}_8 = 8 + 240 = 248$.

The input for (ii) is that E_8 is even and unimodular (here: an explicit inverse of the Cartan matrix), so that its theta series is a modular form of weight 4; that theorem is from the vendored lattice library (Chapter 30), and the modular forms are those of Chapter 14. Lean proves the coefficient relation (i) for an arbitrary weight-four form and applies it to θ_{E_8}; it does not state $\theta_{E_8} = E_4$ as an identity of series (true on paper, since $\dim M_4 = 1$). File `VOA/AffineGeneral/E8Dimension.lean`.

```
theorem coeff_one_of_weight_four (f : ModularForm 𝒮ℒ ((4 : ℕ) : ℤ)) :
    (qExpansion 1 (f : ℍ → ℂ)).coeff 1 = 240 * (qExpansion 1 (f : ℍ → ℂ)).coeff 0 := by

theorem e8Inv_mul : e8Inv * CartanMatrix.E₈ = 1 := by decide

theorem e8E_repCount_two : e8E.repCount 2 = 240 := by

theorem card_roots_e8 : (normEq e8 e8_posDef 2).card = 240 := by

theorem finrank_e8Lie : Module.finrank ℂ e8Lie = 248 := by
```

From the mathematics to the Lean statement

`ModularForm 𝒮ℒ 4` is Mathlib's space of level-one modular forms of weight 4; `qExpansion 1 f` its q-expansion $\sum c_n q^n$ (Chapter 14). `e8Inv` is an explicit integer matrix (printed in the file) and `e8Inv_mul` checks by `decide` that it inverts the Cartan matrix, so $\det = \pm 1$. `e8E` is the same lattice as `e8`, re-expressed in the vendored `LatticesAndCodes` library (Chapter 30), where `thetaModularForm` (the theta series of an even unimodular positive-definite lattice as a modular form of weight rank/2) and `repCount m` (the number of vectors of norm m) live. Same as the textbook.

Proof on paper. $M_4(SL_2(\mathbb{Z}))$ is spanned by $E_4 = 1 + 240q + \dots$ (Mathlib's basis of monomials $E_4^a E_6^b$; only $(a,b) = (1,0)$ has weight 4), so $c_1 = 240c_0$ for every $f \in M_4$. For $\theta_{E_8} = \sum_v q^{\langle v,v\rangle/2}$, $c_0 = 1$ (the zero vector) and $c_1 = \#\{\langle v,v\rangle = 2\}$. Then Theorem 23.27(3). □

Physical meaning

θ_{E_8}/η^8 is the partition function of the E_8 lattice CFT; modular invariance of the torus partition function forces $\theta_{E_8} = E_4$ (on paper; Lean uses only the coefficient relation), so the number of massless currents $(8 + 240)$ is fixed by modularity alone.

What the machine verified

Proved; axioms standard (re-run for `E8Dim.finrank_e8Lie`).

For D_4, E_6, E_7 no such modular shortcut is available (the lattices are not unimodular), so the roots are counted by a verified enumeration.

Definition 23.30 (Pruned short-vector enumeration). A *row* is a triple (d, ℓ, R): a pivot $d \in \mathbb{Q}$, coefficients ℓ on the later coordinates, and a radius $R \in \mathbb{N}$. For rows $r_1, \dots, r_n$ the tail sum of an integer vector v is $\sum_k d_k\big(v_k + \sum_{i>k} \ell_{ki} v_i\big)^2$. `enum N rows` lists integer vectors built from the last coordinate backwards, choosing each coordinate from the window of $2R + 2$ consecutive integers starting at $\lfloor c \rfloor - R$, where $c = -\sum_{i>k} \ell_{ki} v_i$ (so the window contains $[c - R, c + R]$, though it is not exactly centred), and keeping only partial vectors whose tail sum is $\le N$.

```

From the mathematics to the Lean statement

`dotQ a x` is $\sum_i a_i x_i$ over the common length; the list `r.l` of a row is ordered like the coordinates that *follow* it, so `term r (x :: rest)` is $d\,(x + \sum_i \ell_i \,\mathrm{rest}_i)^2$ and `cands r rest` is the window above. `List.flatMap` concatenates; `filter` keeps elements satisfying a Boolean test; `decide` turns a decidable proposition into a Boolean. The definitions are *computable*, which is the point: the kernel can evaluate `enum`. `Admissible`: pivots positive and $dR^2 \geq N$, so the window is wide enough. Same as the Fincke–Pohst algorithm.

Why this definition. A naive enumeration of all integer vectors in a coordinate box containing the norm-2 vectors is too slow for the kernel (Section 23.12); building vectors from the last coordinate backwards and discarding a partial vector as soon as its partial sum of squares exceeds N visits only branches that can still succeed. Completeness of this pruning is Theorem 23.31.

Physical meaning

The output of `enum 2 rows` is the list of charge vectors β with $\langle\beta,\beta\rangle = 2$, i.e. of the vertex operators $e^{i\beta\cdot X}$ of conformal weight one: the number of extra massless currents beyond the n Cartan currents.

What the machine verified

Definitions (no proof obligation); computable, so the kernel can evaluate them.

Theorem 23.31 (Completeness of the enumeration; root counts and dimensions). *If the rows are admissible for N, every integer vector with tail sum $\leq N$ appears in* `enum N rows`. *Consequently, for the LDL^{T} rows of D_4, E_6, E_7, E_8, the roots are counted as* $24, 72, 126, 240$, *and* $\dim \mathfrak{so}_8 = 28$, $\dim \mathfrak{e}_6 = 78$, $\dim \mathfrak{e}_7 = 133$, $\dim \mathfrak{e}_8 = 248$.

From the mathematics to the Lean statement

`rootList rows` filters `enum 2 rows` to tail sum exactly 2. Each `card_roots_*` is `card_normEq_eq` applied to that type's rows, followed by the kernel-checked list length (as `e7_length` for E_7). The names here are in the namespace `VOA.AffineGeneral.RootCounts`; the primes in `card_roots_e8'` and `finrank_e8Lie'` only avoid a clash with `E8Dim.card_roots_e8` and `E8Dim.finrank_e8Lie` of Theorem 23.29, which state the same facts proved via $\theta_{E_8} = E_4$; `RootCounts.finrank_e6Lie` is the lattice algebra, not `SCLie.finrank_e6Lie` of Theorem 23.37. The hypothesis `hid` says the rows are an exact LDL^{T} decomposition of the Cartan form; it is proved per type by rewriting with the `sos_*` identities of `CartanLattices.lean` and `ring`; `hadm` and `hnd` (no duplicates) and the lengths are checked by `decide +kernel`, i.e. by evaluation in Lean's kernel, which is part of the trusted base. The counts of the enumerated lists are therefore not trusted computation outside Lean. The dimension theorems are rank +#roots (Theorem 23.27(3)): $4 + 24$, $6 + 72$, $7 + 126$, $8 + 240$. For A_2 the list length 6 is checked (`a2_length`) but no theorem `finrank_a2Lie = 8` is stated. Same as the textbook.

Proof on paper. If the tail sum of v is $\le N$, so is each term, hence $d_k(v_k + c)^2 \le N \le d_k R^2$, i.e. $|v_k + c| \le R$, and v_k lies in the window; induction on the number of rows. The counts are then finite evaluations. □

Physical meaning

Counting the massless charged currents of the lattice CFT; the dimensions are the numbers of conserved currents, i.e. the dimensions of the gauge groups Spin(8), E_6, E_7, E_8.

What the machine verified

Proved; axioms standard for `mem_enum`, `finrank_e7Lie`, `finrank_e8Lie'` and the four `card_roots_*` (re-run).

23.8.4 The standard normalization

Theorem 23.32 (Kil $/(2h^\vee)$ is the standard normalization). *Let L be generated by $n = \operatorname{rank} L$ simple roots s. Then the root vectors together with the simple coroots form a basis of $(V_L)_1$, and $\mathrm{Kil}(h_\alpha, h_\beta) = \sum_\beta \langle \alpha, \beta \rangle^2$ (sum over roots). For A_2, D_4, E_6, E_7, E_8 this sum is $12, 24, 48, 72, 120 = 4h^\vee$ for every root α,*

so $\big(\mathrm{Kil}/(2h^\vee)\big)(h_\alpha, h_\alpha) = 2$.

Files `VOA/AffineGeneral/LatticeKilling.lean`, `VOA/AffineGeneral/LatticeNormalization.lean`.

```

From the mathematics to the Lean statement

`⊕` is the disjoint union of index sets; `Sum.elim` combines two families. `basisOfTopLeSpanOfCardEqFinrank` is Mathlib's "a spanning family with as many elements as the dimension is a basis". The variables `s` and `hsgen` (simple roots generating L) are hypotheses of both statements. The value $\sum_\beta \langle\alpha,\beta\rangle^2$ is computed per type by enumerating roots (`sum_sq_form`, `decide +kernel`). Why $\kappa(h_\alpha, h_\alpha) = 2$ is the standard normalization: h_α is the coroot ($\alpha(h_\alpha) = 2$), and for an invariant form $\kappa(h_\alpha, h_\alpha) = 4/(\alpha,\alpha)_\kappa$, so the condition says all roots (here all of the same length) have squared length 2. Same as the textbook.

Proof on paper. In the basis $\{e_\beta\} \cup \{h_{s_i}\}$, $\mathrm{ad}\, h_\alpha$ is diagonal with eigenvalue $\langle\alpha,\beta\rangle$ on e_β and 0 on the Cartan part, so $\mathrm{tr}(\mathrm{ad}\, h_\alpha)^2 = \sum_\beta \langle\alpha,\beta\rangle^2$. The identity $\sum_{\beta\in\Phi}\langle\alpha,\beta\rangle^2 = 4h^\vee$ for a root of length 2 in a simply-laced system is classical (it is equivalent to $\mathrm{Kil} = 2h^\vee \cdot \kappa_{\mathrm{std}}$); here it is simply evaluated. □

Physical meaning

In the normalization where long roots have length 2, integrable levels are integers and the level-one lattice theory is $L_1(\mathfrak{g})$; the Deligne levels $-h^\vee/6 - 1$ are meaningful only in this normalization. The theorem certifies that the $k = -6$ of $L_{-6}(\mathfrak{e}_8)$ is the physicists' $k = -6$.

What the machine verified

Proved; axioms standard for `killing_hV_hV`, `e8_standard` (re-run); for the other four `*_standard` theorems, project record. These theorems are the *only* place where the Casimir number h of the library is tied to the dual Coxeter number $h^\vee$; the identification is per type, never for general $\mathfrak{g}$.

Remark 23.33 (Why the names are justified: the classification is not formalised)**.** Lean proves that `e8Lie` is a simple Lie algebra of dimension 248; it does not prove that it is "the" $\mathfrak{e}_8$, because the Cartan–Killing classification is not in Mathlib. On paper the identification is immediate in two independent ways. (a) By Frenkel–Kac, $(V_L)_1$ for a simply-laced root lattice L is the simple Lie algebra with root system the roots of L. (b) By dimension alone, using the classification: the dimensions of simple Lie algebras are $n(n+2)$ (A_n), $n(2n+1)$ (B_n, C_n), $n(2n-1)$ (D_n, $n \geq 4$), 14, 52, 78, 133, 248. The classical

values near the exceptional ones are: A_n: …, 15, 24, 35, 48, 63, 80, …, 120, 143, …, 224, 255; B_n, C_n: 10, 21, 36, 55, 78, 105, 136, …, 210, 253; D_n: 28, 45, 66, 91, 120, 153, …, 231, 276. So 14, 52, 133 and 248 are not classical, and 28 occurs only for D_4; hence these dimensions determine G_2, F_4, E_7, E_8, D_4. **But** 78 **is ambiguous**: $\dim B_6 = \dim C_6 = \dim E_6 = 78$, and all three have rank 6 and 72 roots. For the lattice $\mathfrak{e}_6$, (a) settles it. For the structure-constant $\mathfrak{e}_6$ of Section 23.9 it is settled by the Killing value $\mathrm{Kil}(h,h) = 48$ on the chosen coroot together with simplicity: for B_6 ($h^\vee = 11$) the possible values are 44 and 88, for C_6 ($h^\vee = 7$) 28 and 56. This argument is on paper only. *In Lean no Cartan type is ever identified*: the machine-checked content is "concrete simple Lie algebras of dimensions 14, 52, 78, 133, 248, built as the exceptional ones", and the three Lean models of $\mathfrak{e}_6$ are not proved isomorphic (release audit 2026-10-27, finding M3).

23.9 Concrete simple Lie algebras III: $\mathfrak{g}_2$, $\mathfrak{f}_4$, $\mathfrak{e}_6$ from checked structure constants

The non-simply-laced algebras are not weight-one spaces of lattice VOAs of their own root lattices. The library builds them, and a second $\mathfrak{e}_6$, directly from integer tables of structure constants, generated by untrusted Python scripts and re-checked in Lean's kernel.

23.9.1 Lie algebras from sparse tables

Definition 23.34 (Structure-constant algebra)**.** A *table* T assigns to each pair (i, j) of indices $< N$ a finite list of pairs (k, c), meaning $[b_i, b_j] = \sum c\, b_k$ with $c \in \mathbb{Z}$. The *checks* are: all indices $k < N$; antisymmetry $[b_i, b_j] + [b_j, b_i] = 0$; and the cyclic Jacobi identity on basis triples, coefficientwise. Given the checks, $\mathbb{C}^N$ with the bilinear extension of T is a complex Lie algebra `Alg N T hc`.

File `VOA/AffineGeneral/SCLie.lean`.

```
abbrev Table : Type := List (List (List (ℕ × ℤ)))

def cycK (T : Table) (N : ℕ) (i j l n : Fin N) : ℂ :=

↪  Fin N) :
    cycK T N i j l n = 0 := by
```

From the mathematics to the Lean statement

`sc T i j k` is the integer $c^{ij}{}_k$ cast to $\mathbb{C}$; `cycK T N i j l n` is the n-th coordinate of $[b_i,[b_j,b_l]] + [b_j,[b_l,b_i]] + [b_l,[b_i,b_j]]$. `boundOK`, `antiOK` are Boolean functions evaluated by the kernel; `jac` is a *proposition*, established by `jac_of_sorted` from Boolean checks of sorted triples $i < j < l$ only (by antisymmetry the cyclic sum is alternating, so sorted triples suffice, and triples with a repeated index vanish). The antisymmetry is a hypothesis of `jac_of_sorted`

that the printed signature does not show: it is the section variable `ha : antiOK T N = true` (`include ha`); the output coordinate `n` is fixed throughout. `Alg` is a type synonym for $\mathbb{C}^N$, so that it does not inherit the pointwise bracket of functions; the instance `LieAlgebra ℂ (Alg N T hc)` uses the bilinear map `B hc`, and `leibniz` (from the basis case by trilinearity) is its Jacobi identity. The table is stored in a sign-magnitude flat encoding (`tableOf`, `decZ`) for elaboration speed. Same as the textbook.

Proof on paper. A bilinear antisymmetric bracket satisfying Jacobi on a basis satisfies it everywhere by trilinearity. □

Physical meaning

A symmetry algebra specified by the simple-pole coefficients $f^{ab}{}_c$ of the current OPE (23.1) alone. The checks are the consistency conditions of that OPE: antisymmetry is the symmetry of $J^a(z)J^b(w)$ under exchange, and Jacobi is associativity of the triple OPE $J^aJ^bJ^c$. A table that passes them is a consistent set of current-current OPEs.

What the machine verified

Proved; axioms standard.

Theorem 23.35 (Simplicity from root tables). *Let* `Alg N T hc` *be a structure-constant algebra and D root data: a list of root indices $\beta \mapsto b_{\mathrm{idx}(\beta)}$, a map − on root indices (no involution axiom is needed), an integer pairing table p, r simple roots, an integer matrix M expressing every coroot $h_\alpha = [e_\alpha, e_{-\alpha}]$ in the simple coroots, a rational right inverse Q of the simple pairing matrix, and a distance function on roots. If the finite checks* `RootChecks` *hold, the algebra is simple.*

Before the Lean statement, here is what each ingredient is, on the smallest example.

Example 23.36 ($\mathfrak{sl}_2$ as a structure-constant algebra, with its root data). Take $N = 3$, $b_0 = e$, $b_1 = H$, $b_2 = f$. The table lists, for each ordered pair (i, j), the nonzero coordinates (k, c) of $[b_i, b_j]$:

$[b_i, b_j]$	$j = 0\,(e)$	$j = 1\,(H)$	$j = 2\,(f)$
$i = 0\,(e)$	[ ]	$[(0,-2)]\,(= -2e)$	$[(1,1)]\,(= H)$
$i = 1\,(H)$	$[(0,2)]\,(= 2e)$	[ ]	$[(2,-2)]\,(= -2f)$
$i = 2\,(f)$	$[(1,-1)]\,(= -H)$	$[(2,2)]\,(= 2f)$	[ ]

In Lean this is the list of rows `[[[], [(0, -2)], [(1, 1)]], [[(0, 2)], [], [(2, -2)]], [[(1, -1)], [(2, 2)], []]]`; a sparse vector such as `[(1, 1)]` means $1 \cdot b_1$. The checks of Definition 23.34 hold: indices are < 3; the table is antisymmetric; and Jacobi holds on the one sorted triple $(0, 1, 2)$: $[e,[H,f]] + [H,[f,e]] + [f,[e,H]] = [e,-2f] + [H,-H] + [f,-2e] = -2H + 0 + 2H = 0$.

Root data. The roots are α and $-\alpha$, with root vectors $e = b_0$ and $f = b_2$: `nr = 2`, `rootIdx` $= (0 \mapsto 0,\ 1 \mapsto 2)$, and `neg` swaps them. The coroots are *computed*, not supplied: $h_\alpha = [e, f] = H$ (sparse `[(1, 1)]`) and $h_{-\alpha} = [f, e] = -H$ (sparse `[(1, -1)]`). The pairing table is read off from $[h_\gamma, e_\beta] = p(\gamma,\beta)e_\beta$: $[H,e] = 2e$, $[H,f] = -2f$, $[-H,e] = -2e$, $[-H,f] = 2f$, so `pairT` $= \begin{pmatrix} 2 & -2 \\ -2 & 2 \end{pmatrix}$. There is $r = 1$ simple root, `simple 0` $= \alpha$; `M` expresses each coroot in the simple coroot: $h_\alpha = 1 \cdot h_\alpha$, $h_{-\alpha} = -1 \cdot h_\alpha$; the simple pairing matrix is $P = (2)$ and `Q` $= (\frac{1}{2})$. Take `base` $= \alpha$, `dist` $= (0, 1)$.

The checks, one by one. `inRange_h`: $h_{\pm\alpha}$ have index $1 < 3$. `hbe`: e.g. $[h_\alpha, e_\alpha] - 2e_\alpha = 2e - 2e = 0$. `hhb`: $[H, \pm H] = 0$. `diag`: $p(\alpha,\alpha) = p(-\alpha,-\alpha) = 2 \neq 0$. `sep`: for $\alpha \neq -\alpha$, $\gamma = \alpha$ gives $p(\alpha,\alpha) = 2 \neq -2 = p(\alpha,-\alpha)$. `symm`: `pairT` is symmetric. `M`: $h_{-\alpha} - (-1)h_\alpha = -H + H = 0$. `Q`: $2 \cdot \frac{1}{2} = 1$. `conn`: $-\alpha$ has the neighbour α with smaller distance and $p(\alpha,-\alpha) \neq 0$. `span`: b_0, b_2 are root vectors, and $b_1 = H = h_\alpha$ (the disjunct "$h_{s_i} - b_k = 0$"). So Theorem 23.35 proves $\mathfrak{sl}_2$ simple. For $\mathfrak{e}_6$ the same data have 78 basis vectors, 72 roots and 6 simple roots, and the checks are kernel evaluations.

From the mathematics to the Lean statement

Sparse vectors are lists of (index, integer) pairs; `brL` is the sparse bracket, `zeroL l` tests that all coefficients of l vanish, `scale` multiplies, `++` concatenates (i.e. adds). Thus `hbe` is $[h_\alpha, e_\beta] - p(\alpha,\beta)e_\beta = 0$, `hhb` is $[h_\alpha, h_\beta] = 0$, `M` is $h_\alpha = \sum_i M_{\alpha i} h_{s_i}$, `Q` is $PQ = 1$ for the simple pairing matrix P, `conn` is connectivity by a distance function, and `span`: every basis vector is a root vector or $\pm$ a simple coroot. `eL D β` is the root vector $e_\beta = b_{\mathrm{idx}(\beta)}$ and `hL T D α` is $h_\alpha := [e_\alpha, e_{\mathrm{neg}\,\alpha}]$, so the hypothesis `hneg` of Theorem 23.23 holds by construction with $c_\alpha = 1$; that is why `neg` needs no axiom. How the fields feed the criterion: `hbe`, `hhb`, `diag`, `sep` are its hypotheses of the same names; `inRange_h` (the sparse vector h_α has all indices $< N$) is a well-formedness condition that lets the sparse computations be read as statements in $\mathbb{C}^N$; `span` gives the spanning hypothesis; `M` and `Q` give the centre condition (`RootSpace.center_of_simple`). Connectivity takes two fields: `conn` only gives a path *from* the base root `D.base` to every root, and `symm` (a nonzero pairing has nonzero transpose) reverses such paths, so that any two roots are joined through the base, which is the two-way `Relation.ReflTransGen` hypothesis `conn` of Theorem 23.23. Root vectors are basis vectors, hence nonzero. Same as the criterion.

Proof on paper. Theorem 23.23. For the centre: an element $y = \sum_i d_i h_{s_i}$ (by `M`) commuting with all e_{s_k} satisfies $\sum_i d_i P_{ik} = 0$, so $d = dPQ = 0$. □

Physical meaning

`pairT` is the table of charges of the charged currents e_β under the Cartan currents h_α (the eigenvalues of $h_{\alpha,(0)}$), i.e. the weights read off from the simple poles $h_\alpha(z)e_\beta(w) \sim p(\alpha,\beta)e_\beta(w)/(z-w)$. The checks say that these charges are those of an irreducible root system: distinct currents carry distinct charges, and the charges link all currents, so the symmetry algebra does not factorize.

What the machine verified

Proved; axioms standard (re-run for `SCLie.isSimple_of_tables`).

23.9.2 The three algebras

Theorem 23.37 ($\mathfrak{g}_2$, $\mathfrak{f}_4$, $\mathfrak{e}_6$)**.** *The tables* `g2T` *($N = 14$),* `f4T` *($N = 52$),* `e6T` *($N = 78$) pass all checks and root checks; the algebras are simple, of dimensions* $14, 52, 78$*. On a long coroot h the Killing form is* $16, 36, 48 = 4h^\vee$ *with* $h^\vee = 4, 9, 12$*, so* $\mathrm{Kil}/(2h^\vee)$ *gives* $\kappa(h,h) = 2$*.*

From the mathematics to the Lean statement

All names in this block live in the namespace `VOA.AffineGeneral.SCLie`; in particular this `finrank_e6Lie` is `SCLie.finrank_e6Lie` (the 78-dimensional table algebra), not `RootCounts.finrank_e6Lie` of Theorem 23.31 (the lattice algebra). `g2Data`, `f4Data`, `e6Data` here are `RootData N` (the root tables), *not* Lie data (see the warning box in Section 23.10). `hbV … g2Long` is the bracket $[e_\alpha, e_{-\alpha}]$ for the root with index 1, which the file names `g2Long`; likewise `f4Long`, `e6Long`. *Sign:* `g2_coroot` (and `f4_coroot`, `e6_coroot`, same form) says $[\,\mathtt{hbV}, e_\alpha] = -2\,e_\alpha$, so `hbV` is the *negative* of the standard coroot h_α (for which $\alpha(h_\alpha) = 2$). The Killing values are quadratic, hence insensitive to this sign. Nothing in Lean certifies that `g2Long` is long (Lean checks $[\,\mathtt{hbV}, e] = -2e$ and the Killing value, but does not compare the chosen root with the other roots), so the "standard normalization" conclusion rests partly on the following paper argument (release audit 2026-10-27, finding m2): the computed Killing value $16 = 4 \cdot 4$ is the long-root value for G_2 (the short-root value would be 48); similarly $36 = 4 \cdot 9$ and $48 = 4 \cdot 12$ are the long-root values for F_4 and E_6. Thus `f4_standard` and `e6_standard` certify that Kil /18 and Kil /24 give these coroots squared length 2. Where the tables come from: $\mathfrak{g}_2$ is the fixed subalgebra of $\mathfrak{so}_8$ under triality and $\mathfrak{f}_4$ the fixed subalgebra of $\mathfrak{e}_6$ under the diagram involution, written in orbit-sum bases (generator `aff_fold.py`); $\mathfrak{e}_6$ is the Chevalley basis of `casimir_cert/cert_E6.json` with Frenkel–Kac signs. The generators are untrusted; only the tables enter Lean, and every property used is re-checked there. The identification of type is Remark 23.33.

Proof on paper. Theorem 23.35 with the checked tables; $\dim \mathbb{C}^N = N$; the Killing form of a sparse vector is the finite sum $\sum_k \big[h, [h, b_k]\big]_k$ (`killing_vec`), evaluated by `decide +kernel`. □

Physical meaning

G_2 and F_4 are the non-simply-laced members of the Deligne series. $\mathfrak{g}_2$ is the subalgebra of $\mathfrak{so}_8$ fixed by the triality outer automorphism (the order-three symmetry of the D_4 Dynkin diagram), and $\mathfrak{f}_4$ the subalgebra of $\mathfrak{e}_6$ fixed by the diagram involution, which in physics is charge conjugation of the E_6 currents ($\mathbf{27} \leftrightarrow \overline{\mathbf{27}}$).

What the machine verified

Proved; axioms standard for `g2Lie_isSimple`, `f4Lie_isSimple`, `e6Lie_isSimple`, `g2_standard`, `g2_coroot`, `f4_killing`, `f4_standard`, `e6_killing`, `e6_standard` (re-run).

Trap: `hbV` is minus the standard coroot

In `SCSimple.lean` the docstring of `hL` calls $[e_\alpha, e_{\mathrm{neg}\,\alpha}]$ the "sparse coroot", and the module docstrings of `F4Lie.lean` and `E6Lie.lean` speak of the Killing value "on a long coroot". But `g2_coroot`, `f4_coroot`, `e6_coroot` prove $[\mathtt{hbV}, e_\alpha] = -2e_\alpha$: with the tables' sign conventions this vector is $-h_\alpha$. Nothing proved is affected (the Killing values and the `*_standard` theorems are quadratic in it), but a user who feeds `hbV` into a formula linear in the coroot gets the wrong sign. Listed in Section 23.13.

How the tables are checked. Each table check (index bounds, antisymmetry, the cyclic Jacobi identity on all sorted basis triples — $\binom{14}{3} = 364$, $\binom{52}{3} = 22100$ and $\binom{78}{3} = 76076$ triples, each against all N output coordinates — and the fields of `RootChecks`) is a statement "this Boolean function of the table evaluates to `true`", proved by `decide +kernel`. A single such declaration over a whole table exceeds the kernel's memory, so the checks are split into many small declarations in generated files (one row or block of rows per declaration), and a separate file assembles the propositional conclusions. This is the only reason for the large number of files; what is trusted is the kernel evaluation, not the scripts that generated the tables. The file map, the costs and the dead ends that forced this design are recorded in Section 23.12.

23.9.3 Lie data with an explicit invariant form

For the explicit presentations of Chapter 24 one wants Lie data whose basis *is* the table basis and whose form has integer entries.

Definition 23.38 (Lie data from sparse tables)**.** Given an integer form table G_m (a list of entries (i, j, c)), dual vectors $d_j = \frac{1}{D_j}\mathrm{vec}(\ell_j)$, an integer $L \neq 0$ and $c \in \mathbb{Z}$, and Boolean checks that G_m is symmetric, that every basis vector is κ-skew ($\kappa([a, y], z) + \kappa(y, [a, z]) = 0$), that $\kappa(b_i, d_j) = \delta_{ij}$, and that $\sum_i \frac{L}{D_i}[b_i, [\mathrm{vec}\,\ell_i, b_x]] = cL\, b_x$ for every x, one obtains Lie data with $h = c/2$.

Files `VOA/AffineGeneral/SCLieData.lean`, `VOA/AffineGeneral/E6LieData.lean`.

theorem e6LieData_h : e6LieData.h = 12 := by
```

From the mathematics to the Lean statement

`formG hc Gm` is the bilinear form with Gram entries from `Gm`. Skewness of all basis vectors is derived from skewness of the 12 Chevalley generators (`E6LieDataSkew*`) propagated along single-term brackets (`skew_of_entry`), since the generators generate. The Casimir check is `casOK … 3 24`: $L = 3$ clears denominators, $c = 24 = 2h$. The docstring says *e6Gm* is the form with long roots of length 2, i.e. Kil /24; no Lean theorem states formG *e6Gm* = Kil /24. On paper it follows: on a simple algebra every invariant form is λ Kil, the Casimir of λ Kil is $\lambda^{-1} \cdot 1$ (by `killing_h`), and the check gives $\lambda^{-1} = 24$. The same construction gives `G2Lie.g2CertData` (form Kil /8, $h = 4$) and `F4Lie.f4CertData` (Kil /18, $h = 9$) in `VOA/DeligneAudit/G2LieData.lean` and `F4LieData.lean`, with checks in `F4LieTab.lean` and `F4LieChecks*.lean`.

Proof on paper. Invariance of a symmetric form follows from skewness of $\mathrm{ad}(a)$ for all a; the pairing and Casimir checks are the fields of Definition 23.1 in coordinates. □

Physical meaning

This is the current algebra with a *chosen* integral normalization of the two-point function, the form in which the Deligne singular vectors and Joseph relations of Chapter 24 are written.

What the machine verified

Proved; axioms standard for `lieDataOf`, `e6LieData`, `G2Lie.g2CertData` (re-run).

23.10 The Deligne instances

The higher-rank capstone of Chapter 24 (`VOA/Examples/DeligneHigherRankConditionalCapstone.lean`) is stated for a Deligne case `case : HigherRankDeligneCase` (one of `A2`, `G2`, `D4`, `F4`, `E6`, `E7`, `E8`), a VOA W, and a *current C_2 presentation*: weight-one generators indexed by `Fin case.currentDimension` (8, 14, 28, 52, 78, 133, 248) and an ideal of polynomial relations that vanish in Li degree zero. This section is the interface between this chapter and Chapter 24, so we first explain, informally and in one place, the notions it uses; the precise definitions are in Chapter 11 (Section 11.4) and Chapter 24 (Definitions 24.2 and 24.4).

The notions, informally.

- *Li degree zero; the C_2-algebra.* For a VOA W, Li's filtration $F^0W \supseteq F^1W \supseteq \cdots$ measures "how many derivatives" a state contains; its associated graded $\mathrm{gr}^F W$ is a commutative algebra, and its degree-zero part is Zhu's C_2-algebra $R_W = W/C_2(W)$, $C_2(W) = \mathrm{span}\{u_{(-2)}v\}$ (Chapter 11, Theorem 11.10). In R_W only the "leading order" of a state survives: derivatives of fields are set to zero. Its spectrum (as a variety) is the *associated variety* of W; for $L_k(\mathfrak{g})$ the currents generate R_W, so $R_W = \mathbb{C}[X_1, \dots, X_n]/\ker$ with $X_i \mapsto [J^i_{-1}|0\rangle]$.
- *A presentation* lists generators of R_W (here: the n currents) and an ideal I of relations known to hold among them.
- *Jets and the arc space.* For a commutative algebra $R = \mathbb{C}[X]/I$, the *jet algebra* $J_\infty R$ is the polynomial ring in infinitely many variables $X_i^{(j)}$ ($j \geq 0$, "the j-th derivative of X_i") modulo all derivatives $\partial^m f$ of the relations $f \in I$, where $\partial X_i^{(j)} = X_i^{(j+1)}$. Geometrically, it is the coordinate ring of the *arc space* of $\mathrm{Spec}\, R$ (formal curves in the variety). There is a canonical map, the *jet map*, $J_\infty(\mathbb{C}[X]/I) \to \mathrm{gr}^F W$ sending $X_i^{(j)}$ to the class of the divided derivative $\frac{1}{j!}L_{-1}^j J^i_{-1}|0\rangle = J^i_{-1-j}|0\rangle$ of the current (Chapter 11, Definition 11.14).
- *Current-jet surjectivity* (`CurrentJetSurjectivity`) says the jet map is onto: every state is, to leading order, a normally ordered polynomial in the currents and their derivatives (the currents "strongly generate" W).
- *Classical freeness* (`CaseClassicallyFree`) says the jet map is moreover injective, hence an isomorphism $J_\infty(\mathbb{C}[X]/I) \cong \mathrm{gr}^F W$: the only relations in the whole VOA are those forced, by differentiation, from the relations I of the C_2-algebra.
- *The two remaining inputs* are a way to prove injectivity by counting. `GeometricCarrierEmbedding` (`hgeom`) gives, for every weight N and Li degree p, an injective map from the dual of the (p, N) piece of $J_\infty(\mathbb{C}[X]/I)$ into a finite-dimensional "carrier" space $\mathrm{Carrier}_{p,N}$, so that $\dim J_\infty(\mathbb{C}[X]/I)_N \leq \sum_p \dim \mathrm{Carrier}_{p,N}$. `OrdinaryCarrierCharacter` (`hchar`) says $\sum_{p \leq N} \dim \mathrm{Carrier}_{p,N} = \dim W_N$. Together with surjectivity, which gives $\dim W_N = \dim(\mathrm{gr}^F W)_N \leq \dim J_\infty(\mathbb{C}[X]/I)_N$, the inequalities are squeezed into equalities,

and a surjection between spaces of equal finite dimension is an isomorphism (Chapter 24, Theorem 24.5).

A toy case. For the universal algebra $V^k(\mathfrak{g})$ itself, take $I = 0$: by PBW, $\mathrm{gr}^F V^k(\mathfrak{g})$ is the polynomial ring in the symbols of all $J^a_{-1-j}|0\rangle$, which is exactly $J_\infty\mathbb{C}[X_1, \dots, X_n]$; so $V^k(\mathfrak{g})$ is classically free with no relations at all. For $L_k(\mathfrak{g})$ at the Deligne level, relations appear already in weight two (the null vectors of Theorem 23.19), and the question answered in Chapters 24–27 is whether the quadratic relations I_2^{ns} coming from them (the Joseph relations) generate everything.

Definition 23.39 (Current C_2 presentation)**.** Let W be a VOA on V and $n = \dim \mathfrak{g}$ for the case. A *current C_2 presentation* of W consists of vectors $g_1, \dots, g_n \in W_1$ and an ideal $I \subseteq \mathbb{C}[X_1, \dots, X_n]$ contained in the kernel of the algebra map $X_i \mapsto [g_i] \in \mathrm{gr}^F_0 W = R_W$ (the class of g_i in Li degree zero, i.e. in Zhu's C_2-algebra).

From the mathematics to the Lean statement

`case`, `W` (and the carrier `V`) are the section variables printed first. `case.currentDimension` is $\dim \mathfrak{g}$ for the case $(8, 14, 28, 52, 78, 133, 248)$. `W.grading (1 : ℤ)` is W_1. `MvPolynomial (Fin n) ℂ` is $\mathbb{C}[X_1, \dots, X_n]$, `MvPolynomial.aeval f` the algebra map sending X_i to $f(i)$, `.toRingHom` forgets $\mathbb{C}$-linearity, and `RingHom.ker` is its kernel. `liDegreeZeroClass W 1 ⟨v, hv⟩` is the class of a weight-one vector v in Li degree zero of Li's associated graded algebra (Chapter 11). The field `relations` is the containment $I \leq \ker$: a presentation is only required to list *some* relations. The predicates used below are Lean structures of Chapter 24 (Definition 24.4), explained informally at the start of this section: `CurrentJetSurjectivity` (the jet map $J_\infty(\mathbb{C}[X]/I) \to \mathrm{gr}^F W$ is surjective), `GeometricCarrierEmbedding` (an injective map from the dual of each bidegree piece of the presented jets into a carrier space), `OrdinaryCarrierCharacter` (the carrier dimensions add up to $\dim W_N$) and `CaseClassicallyFree` (the presented jet map is an isomorphism). `exact_kernel_of_caseClassicallyFree` (Chapter 24, Theorem 24.6) says: if the case is classically free for the presentation P, then I is the *whole* kernel. Same as the textbook notion of a presentation of R_W by generators, with exactness not assumed.

Proof on paper. Definition; for the theorem: classical freeness makes the presented jet map injective, and its degree-zero part is $\mathbb{C}[X]/I \to R_W$, so $\ker \subseteq I$; the field `relations` gives $I \subseteq \ker$. □

Physical meaning

The currents g_i generate the Higgs-branch chiral ring R_W (in four-dimensional language, the moment maps of the flavour symmetry), and I is a list of chiral-ring relations among them; an exact presentation is the statement "the Higgs branch is cut out by these equations".

What the machine verified

Definition; `exact_kernel_of_caseClassicallyFree` proved, `#print axioms` standard (re-run).

Here we record what `AffineGeneral/` supplies.

Theorem 23.40 (Two capstone inputs for every case). *For every Deligne case, Lie data D indexed by* `Fin case.currentDimension`, *and $k + h \neq 0$, on $W = L_k(\mathfrak{g})$: (1) the current states $[J^a_{-1}|0\rangle]$, together with the* full *kernel of $X_a \mapsto [J^a_{-1}|0\rangle] \in R_{L_k}$ as ideal, form a current C_2 presentation; (2) every step of Li's filtration of $V^k(\mathfrak{g})$ and of $L_k(\mathfrak{g})$ is spanned by words in current modes, hence the jet map is surjective (*`CurrentJetSurjectivity`*); (3)* if *one is given a family of finite-dimensional carrier spaces with an injective carrier embedding (*`hgeom`*) and the carrier character identity (*`hchar`*), then the jet map is an isomorphism, i.e. $L_k(\mathfrak{g})$ is classically free for this presentation.*

From the mathematics to the Lean statement

The namespace is `VOA.AffineGeneral.Deligne`; `case`, `D`, `k`, `hk` are the section variables printed at the top (with the instance `[FiniteDimensional ℂ 𝔤]`). `GeneratorWordsSpanLiFiltration W g w` (Chapter 11) says that each step of Li's filtration of W is spanned by words in the modes of the generators `g` of weights `w`; `ugen case D k a` is the current state $J^a_{-1}|0\rangle$ in $V^k(\mathfrak{g})$, so `universal_genWordsSpan` is claim (2) for $V^k(\mathfrak{g})$ and `genWordsSpan`, obtained from it by passing to the quotient by the maximal graded ideal, is claim (2) for $L_k(\mathfrak{g})$. `gen case D k hk a` is $[J^a_{-1}|0\rangle] \in L_k(\mathfrak{g})$. `RingHom.ker` is the kernel and `le_rfl` proves $I \le I$. `Carrier p N` is a family of finite-dimensional spaces (the "geometric carrier" of Chapter 24); `hgeom`, `hchar` are the two named inputs. Nothing ties D to the case except its index type: the theorem applies to *any* Lie algebra of dimension `case.currentDimension`; the per-type files choose the right one.

Trap: The general presentation uses the full kernel

`Deligne.presentation` takes as ideal the *entire* kernel of the current-coordinate map, so its `relations` field is `le_rfl`. This presentation therefore does not *display* which relations hold; it only fixes generators. The statement `CaseClassicallyFree case W (presentation …)` is not weak: by `exact_kernel_of_caseClassicallyFree` (Definition 23.39) classical freeness for *any* presentation forces its ideal to be the full kernel, so for this presentation it is exactly the full capstone statement. What the full-kernel choice prevents is *discharging* the two inputs `hgeom`, `hchar`: they cannot be checked without knowing the kernel explicitly. The mathematical content of classical freeness for an explicit ideal (the Joseph-type ideal I_2^{ns} generated by weight-two singular vectors) is in the explicit presentations of Chapter 24 (`E6.explicitPresentation` etc.), which use Theorem 23.19 and Proposition 23.21. The theorem `currentJetSurjectivity` is genuine content (jet surjectivity does not depend on the ideal beyond the generators).

Proof on paper. (2) Let C_q be the span of current words of Li level at least q (the level of a word counts its derivatives, i.e. $\sum(n_i - 1)$ for $J^{a_1}_{-n_1} \cdots J^{a_r}_{-n_r}|0\rangle$). The *tracked estimate* (`GeneratorModeTracked`, `VOA/Filtered/GeneratorCurrentLiSpanning.lean`) says that the m-th mode of a generator maps C_q into $C_{\max(q-m-1,0)}$; for currents it follows from the commutator (23.2) (`generatorModeTracked_of_current_comm`), since commuting J^a_m past a word produces only words with the same total mode. By the Borcherds iterate formula the estimate extends from generators to all states; as current words span $V^k(\mathfrak{g})$, this shows that the p-th step of Li's filtration is contained in C_p (the reverse inclusion is clear), i.e. it is spanned by current words; spanning of Li's filtration by generator words descends to quotients (`generatorWordsSpanLiFiltration_quotient`); a spanning statement implies jet surjectivity (Chapter 11). (1) is `le_rfl`: the kernel contains itself. (3) is the squeeze explained at the start of this section — the capstone of Chapter 24 (Theorem 24.7) with (2) plugged in as its surjectivity input. □

Physical meaning

Classical freeness says that the chiral algebra is, as a filtered object, the quantization of the arc space of its Higgs branch: no extra relations appear in the chiral algebra beyond those forced by the Higgs-branch chiral ring. In general this is *not* true (there are known counterexamples among chiral algebras), and for the Deligne series it is a conjecture-level statement in the physics literature; this chapter proves nothing towards it beyond the reduction to `hgeom`, `hchar`, and the status of those inputs is the subject of Chapters 24–27. Jet surjectivity — every state

is a normally ordered product of currents and their derivatives — is the "easy half"; it says the currents strongly generate the chiral algebra.

What the machine verified

Proved; `#print axioms` standard for `Deligne.currentJetSurjectivity`, `Deligne.classicallyFree_of_two_inputs`, `Deligne.universal_genWordsSpan`, `Deligne.genWordsSpan` (re-run). `classicallyFree_of_two_inputs` is **conditional** on `hgeom`, `hchar`.

The per-type instances. Each Deligne type has a file choosing Lie data and the Deligne level, and restating the two theorems. The "model" column says how the Lie algebra is realized: as matrices, as the weight-one space of a lattice VOA (Section 23.8), or as a structure-constant table (Section 23.9). A primed name such as `g2Data'` is the Lie data of a table algebra built by `standardData`; the unprimed `SCLie.g2Data` is the root table of Theorem 23.35 (see the warning box in Section 23.10).

type	model	Lie algebra	Lie data	$h^\vee$	k	c

(The A_2 instance lives in the file `VOA/AffineGeneral/A2General.lean`.) The levels are $k = -h^\vee/6 - 1$ and the central charges $c = \dim \mathfrak{g} \cdot k/(k + h^\vee) = -2h^\vee - 2$ (computed here on paper from `standardAffineVOA_centralCharge`; the simple quotient has the same conformal vector). The E_8 file is representative:

Theorem 23.41 (The Deligne case E_8 on $L_{-6}(\mathfrak{e}_8)$). *With $\kappa = \mathrm{Kil}/60$ on $\mathfrak{e}_8 = (V_{E_8})_1$, indexed by $\{0, \dots, 247\}$ via $\dim \mathfrak{e}_8 = 248$, $h = 30$, and on $L_{-6}(\mathfrak{e}_8)$ the conclusions of Theorem 23.40 hold.*

File `VOA/AffineGeneral/E8Deligne.lean`.

From the mathematics to the Lean statement

`finCongr finrank_e8Lie` is the bijection $\mathrm{Fin}(\dim) \simeq \mathrm{Fin}\,248$ given by Theorem 23.29; this is where the dimension count is used. Conclusion (1) of Theorem 23.40 is the presentation `Deligne.presentation .E8 e8Data (-6) e8_level_ne` appearing in both statements; (2) is `e8_currentJetSurjectivity`; (3) is `e8_classicallyFree_of_two_inputs`, whose proof term is the general theorem specialized, and which is conditional on `hgeom` and `hchar`. `e8_level_ne` is the proof that $-6 + 30 \neq 0$. That Kil /60 is the standard normalization is `Normalization.e8_standard` (Theorem 23.32); without it, "−6" would be a level in an unidentified normalization. Same as the textbook.

Proof on paper. Theorem 23.40. □

Physical meaning

$L_{-6}(\mathfrak{e}_8)$ is the chiral algebra of the rank-one Minahan–Nemeschansky theory with E_8 flavour symmetry, $c_{2d} = -62$, $c_{4d} = 31/6$.

What the machine verified

Proved; axioms standard for `e8_classicallyFree_of_two_inputs` (re-run). Conditional on the two packages, which Chapter 24 discharges for the *explicit* presentations, not for this full-kernel one.

Trap: Coexisting models and clashing names

Several Lie algebras exist in more than one Lean model, and short names clash across namespaces. **Always read the namespace.**

algebra	model	Lie data	simple affine VOA
$\mathfrak{e}_6$ (i)	lattice: `CartanSimple.e6Lie` $= (V_{E_6})_1$	`LatticeDeligne.e6Data` (Kil /24)	`LatticeDeligne.e6SimpleVOA`
$\mathfrak{e}_6$ (ii)	table: `SCLie.e6Lie`	`E6Deligne.e6Data'` (Kil /24, Mathlib basis)	`E6Deligne.e6SimpleVOA`
$\mathfrak{e}_6$ (ii)	table: `SCLie.e6Lie`	`SCLie.e6LieData` (integer form, table basis)	`W6`
$\mathfrak{e}_6$ (iii)	certificate basis `E6Lat.xs` inside (i)	none (brackets only)	—
$\mathfrak{g}_2$	table: `SCLie.g2Lie`	`G2Deligne.g2Data'`; `G2Lie.g2CertData`	`g2W` (for the latter)
$\mathfrak{f}_4$	table: `SCLie.f4Lie`	`F4Deligne.f4Data'`; `F4Lie.f4CertData`	`f4W` (for the latter)
$\mathfrak{sl}_3$	matrices; lattice `CartanSimple.a2Lie`	`sl3Data` (matrices)	$L_k(\mathfrak{g})$ for `sl3Data` (`A2General.lean`)

Here `W6` is `simpleVOA e6LieData (-3) _`. No Lean theorem states that the $\mathfrak{e}_6$ models (i) and (ii) are isomorphic; the docstring of `E6LatTable.lean` asserts that its table equals `SCLie.e6T`, which is not checked in Lean. By the project's decision, the E_6 sector data of Chapter 24 (`DeligneCarrier.E6.E6sector`, the integer tables of the divisor comparison) are built on `SCLie.e6LieData`, and the final E_6 theorems of Chapter 27 are about `W6`.

Name clashes. `e6Lie_isSimple` names two different instances (`CartanSimple.`, `SCLie.`); `e6SimpleVOA` names two different VOAs (`LatticeDeligne.`, `E6Deligne.`); `e6Data` is Lie data in `LatticeDeligne` but a *root table* (`RootData 78`) in `SCLie`, and likewise `SCLie.g2Data`, `SCLie.f4Data` are root tables while the Lie data are the primed `g2Data'`, `f4Data'` and `G2Lie.g2CertData`, `F4Lie.f4CertData`.

23.11 The certificate-basis models

Several steps of Chapter 24 rest on large integer certificates: linear-algebra computations (ranks, divisibilities, explicit relations among current modes in each weight "sector", i.e. each pair of a weight and a Li degree) that were carried out by Python in a fixed "certificate basis" (a Chevalley basis with Frenkel–Kac signs, files `casimir_cert/cert_X.json`) and are re-checked in Lean's kernel. A certificate is a statement about structure constants *in its basis*: if Lean's Lie data used a different basis, every certificate would have to be transformed and re-verified, which for $\mathfrak{e}_8$ means tables of size 248^3. So Lean needs Lie data whose structure constants and form are *literally* the certificate tables. For the simply-laced types D_4, E_7, E_8 (and E_6, brackets only) this is achieved by realizing the certificate basis inside the lattice Lie algebra; for G_2, F_4 by `lieDataOf` on the table algebra (above). We describe the mechanism once, with E_8 quoted; D_4 and E_7 are identical in structure.

The basis. With α_i the simple roots and, for each root index a, its weight $\mathrm{wt}(a)$ and an explicit sign $u_a = \pm 1$,

$$x_i = \alpha_i(-1)|0\rangle \ (i < \mathrm{rank}), \qquad x_a = u_a\, f(\mathrm{wt}\, a)\, e^{\mathrm{wt}\, a},$$

where f is a coboundary sign that converts the library's FLM cocycle ε (defined from a *chosen*, noncomputable $\mathbb{Z}$-basis, so its values cannot be evaluated) into the explicit cocycle $\varepsilon'(\alpha,\beta) = (-1)^{\sum_{i<j}\alpha_i\beta_j G_{ij} + \sum_i \alpha_i\beta_i}$.

Theorem 23.42 (Certificate basis of $\mathfrak{e}_8$). *(1) $\varepsilon(\alpha,\beta)f(\alpha)f(\beta) = \varepsilon'(\alpha,\beta)f(\alpha+\beta)$. (2) For every pair (a,b) the kernel check* `pairOK a b` *holds, hence $[x_a, x_b] = \sum_c s_{abc}x_c$ with s the certificate table. (3) The x_a form a basis, and $\mathrm{Kil}(x_a,x_c) = 60\,G_{ac}$ with G the certificate form. (4) Hence there is Lie data for* Kil $/60$ *with basis x, $h = 30$, whose structure constants and Gram matrix are the certificate tables.*

Files `VOA/DeligneAudit/E8LieCocycle.lean`, `E8LieBasis.lean`, `E8LieTable.lean`, `E8LieModel.lean`, `E8LieModel00.lean`, `E8LieKilling.lean`, `E8LieForm.lean`, `E8LieData.lean` (all in `VOA/DeligneAudit/`); `casimir_transfer` in `VOA/DeligneAudit/D4LieCasimirTransfer.lean` (split off from `D4LieData.lean`, which imports it).

```

From the mathematics to the Lean statement

`Lat` is $\mathbb{Z}^8$; `ep α β` is the exponent of ε'. `sL a b` is the certificate's sparse row, `modelL a b` the bracket of the rescaled lattice basis computed with ε'; `pairOK` checks that they agree and some side conditions on weights (the omitted lines: for two roots, $\langle \mathrm{wt}\, a, \mathrm{wt}\, b\rangle \geq -2$, $= -2$ only for opposite roots, $= -1$ only when the target index has weight $\mathrm{wt}\, a + \mathrm{wt}\, b$), which let `bracket_of_pairOK` evaluate $[x_a, x_b]$ in the VOA via Theorem 23.27(1) and the formula $e^{\alpha}_{(0)} e^{\beta} = \varepsilon(\alpha,\beta) e^{\alpha+\beta}$ for $\langle \alpha, \beta\rangle = -1$. `spL` turns a sparse list into a vector, `sZ` is the dense integer table. `K` is the Killing form of `e8Lie`. Claim (3) is `span_xs` (the 248 vectors span; `⊤ ≤ span` means the span is everything) together with `bB`, Mathlib's "spanning family of size dim is a basis", using `finrank_e8Lie` $= 248$, and `killing_xs`. Claim (4) is `e8CertData` with `structureConstant_eq`, `formTable_eq`. `irreducible_def` makes a definition opaque except through its defining equation (used for elaboration speed). `Gz` is the integer certificate form G (in `E8LieForm.lean`); `Gi2L b` is the sparse b-th row of the integer matrix Gi2, and the kernel check `pairRowOK` (all rows, in `E8LieFormChecks.lean`) says $\sum_c \mathrm{Gi2}_{bc} G_{ac} = 2\delta_{ab}$, i.e. $\mathrm{Gi2} = 2G^{-1}$. So `dualx b`$= \sum_c \frac{1}{2}\mathrm{Gi2}_{bc}\, x_c = \sum_c (G^{-1})_{bc}\, x_c$, the κ-dual of x_b for the form with Gram matrix G. The omitted last field of `e8CertData` is the Casimir proof. `e8CertData : LieData κ8 (Fin 248)` has form `κ8 = (2 * 30 : ℂ)⁻¹ • killingForm ℂ e8Lie` (the same as `e8Data`), basis `bB` (with `bB a = xs a`, by `bB_apply`), dual vectors `dualx`, and $h = 30$, its Casimir field supplied by `casimir_transfer` from `E8Deligne.e8Data`: the Casimir does not depend on the choice of dual pair. Same as the textbook.

Proof on paper. (1) Any two bimultiplicative cocycles with the same commutator $(-1)^{\langle\alpha,\beta\rangle}$ differ by a coboundary $f(\alpha)f(\beta)/f(\alpha+\beta)$ with $f = (-1)^q$, q a quadratic refinement of the difference

of exponents (computed bilinearly from the values on basis vectors). (2) Finite evaluation of each bracket of basis vectors. (3) Spanning: the x_a cover the Cartan part and every root (the root count of Theorem 23.31 shows the certificate weights are all the roots), 248 vectors in dimension 248; the Killing form is obtained without computing any trace, by invariance from the coroot values $\mathrm{Kil}(h_\beta, h_\beta) = 120$ (Theorem 23.32): $\mathrm{Kil}(E_i, F_i) = 60$, $\mathrm{Kil}(H_j, H_i) = 60A_{ji}$, pairs of nonzero total weight are orthogonal, and opposite root pairs are determined by $\lambda\,\mathrm{Kil}(x_a, x_{-a}) = \mathrm{Kil}(H, [x_a, x_{-a}])$. (4) assembles these. □

Physical meaning

The certificate basis is a choice of currents with integer OPE coefficients; this theorem identifies the integer OPE table used in the computer algebra with the actual current algebra of the E_8 lattice CFT, sign by sign.

What the machine verified

Proved; axioms standard for `E8Lie.e8CertData`, `E8Lie.structureConstant_eq`, `E8Lie.pairOK_all` (re-run), and `E6Lat.bracket_xs`. `span_xs` and `bB` were not re-run in the revision (that needs the heavy E_8 imports); `e8CertData`, which was re-run, uses `bB` as its basis, so its clean report covers `bB` and `span_xs`, and `E8LieData.lean` has its own `#print axioms bB`.

What is checked, collectively, and at what size.

- D_4 (`D4Lie{Basis,Cocycle,Data,Table}`): the table comparison `sZ_eq_model` (28^3 entries) is one `decide +kernel` in `D4LieTable.lean`, together with the weight facts and `killZ_eq` ($\mathrm{Kil} = 12G$); result `D4Lie.d4CertData : LieData ((2 * 6)⁻¹ • killingForm ℂ d4Lie) (Fin 28)`, $h = 6$.
- E_7 (`E7Lie{Basis,CasimirChecks,Cocycle,Data,Facts,Form,FormChecks,Killing,Table}` and 20 `E7LieModel*`): all $133^2 = 17689$ pairs checked by `pairOK`; the Killing form by invariance from `e7_killing` $= 72$; `E7LieCasimirChecks` checks that the certificate Casimir is the inverse-form quadric; result `e7CertData`, form $\mathrm{Kil}/36$, $h = 18$.
- E_8 (`E8Lie{Basis,Cocycle,Data,DataChecks,Facts,Form,FormChecks,Killing,Table}` and 32 `E8LieModel*`): all $248^2 = 61504$ pairs checked by `pairOK` (assembled in `E8LieModel.lean`); result `e8CertData`, $\mathrm{Kil}/60$, $h = 30$.
- E_6 (18 `E6Lat*` files, 13 of them `E6LatModel*`): $78^2 = 6084$ pairs; result only `E6Lat.bracket_xs` (the certificate structure constants realized in the lattice algebra), used by the lattice realizations of Chapter 26; no Lie data (the E_6 Lie data in the certificate basis is `SCLie.e6LieData`).
- G_2, F_4 (`G2LieData.lean`; `F4LieData`, `F4LieTab`, ten `F4LieChecks*`): the `lieDataOf` checks (symmetry, skewness in four chunks, pairing in two, Casimir in four for $\mathfrak{f}_4$); results `g2CertData` ($\mathrm{Kil}/8$, $h = 4$) and `f4CertData` ($\mathrm{Kil}/18$, $h = 9$), with `g2W`, `f4W` the simple quotients at $k = -5/3, -5/2$.

In every case the data were generated by untrusted scripts and every fact used is re-established in the kernel; no data file contains a `sorry` or `native_decide`. How the checks are split across files, and what they cost, is recorded in Section 23.12.

23.12 Verification record

This section collects, in one place, what the machine confirmed and where the record comes from. The rest of the chapter refers here.

Provenance. The chapter was written against an earlier state of the library (the Lean sources under `VOA/` did not change between the snapshot against which it was first written and the commit at which it was revised). All quotations are checked against the released sources by `scripts/textbook/sync.py`. Runs made before 28 October 2026 used the former names `simpleAffineVOA` and `simpleAffineVOA_centralCharge`; they are printed below under the current names `universalAffineVOA` and `universalAffineVOA_centralCharge`.

Builds (from the project record, not re-run for this chapter). The project's workstream log `Notes/deligne/campaign/WS-AFF.md` records `campaign_build.sh VOA.AffineGeneral.All` → "Build completed successfully (4329 jobs)", and a build with `VOA.DeligneAudit.E6CarrierData` of 9212 jobs. The project's internal build record of 27 October 2026 reports `campaign_build.sh VOA.Deligne` green at an earlier commit, 11099 jobs, no `sorryAx`, and the last aggregate `lake build VOA` (26 October 2026) green with 13868 jobs. This chapter did *not* run `lake build`.

What "project record" means in a status box. Where a status box says "axioms standard (project record)", the `#print axioms` check is the one recorded in the workstream log for that file, not re-run for this chapter; where it says "re-run", the declaration is in one of the lists below.

Axioms (re-run for this chapter). Two scratch files importing the relevant modules were checked with `lake env lean -DmaxSynthPendingDepth=3` against the existing build products; every declaration below reported `[propext, Classical.choice, Quot.sound]`:

```
affineVOA  universalAffineVOA  universalAffineVOA_centralCharge
 ↪  standardAffineVOA_centralCharge
killing_h  casimir_scalar  simpleVOA_isSimple  simple_grading_one_eq_range
mem_maxIdeal_of_SingP  SlSimple.instIsSimple  RootSpace.isSimple_of_roots
LatticeLie.isSimple_of_simpleRoots  LatticeLie.finrank_V1  LatticeLie.killing_hV_hV
CartanSimple.e8Lie_isSimple  RootCounts.finrank_e7Lie  RootCounts.finrank_e8Lie'
E8Dim.finrank_e8Lie  RootEnum.mem_enum  Normalization.e8_standard
SCLie.isSimple_of_tables  SCLie.{g2,f4,e6}Lie_isSimple  SCLie.g2_standard
SCLie.lieDataOf  SCLie.e6LieData  Deligne.currentJetSurjectivity
Deligne.classicallyFree_of_two_inputs  E8Deligne.e8_classicallyFree_of_two_inputs
DeligneAudit.E8Lie.{e8CertData, structureConstant_eq, pairOK_all}
DeligneAudit.E6Lat.bracket_xs  DeligneAudit.G2Lie.g2CertData
DeligneLatticeLie.e8VOA_centralCharge
```

In the revision after the fidelity report, a third scratch file (importing the `AffineGeneral` modules `RootCounts`, `G2Lie`, `F4Lie`, `E6Lie`, `CartanLatticeSimple`, `LatticeV1Simple`, `DeligneInstance` and the capstone file; no E_7/E_8 data modules) gave the same three axioms for:

```
CartanSimple.cartan_isSimple  CartanSimple.cartan_finiteDimensional  LatticeLie.eV_ne_zero
Deligne.universal_genWordsSpan  Deligne.genWordsSpan
CurrentC2Presentation.exact_kernel_of_caseClassicallyFree
RootCounts.card_roots_{d4,e6,e7,e8'}  SCLie.g2_coroot
SCLie.{f4,e6}_killing  SCLie.{f4,e6}_standard  SCLie.{f4,e6}Lie_isSimple
```

For the named simple quotient (Section 23.6.2, added 2026-10-28; not re-run for this edition), a fourth scratch file — a copy of `VOA/AffineGeneral/SimpleAffineQuotient.lean` followed by `#print axioms` commands — was elaborated with `lake env lean -DmaxSynthPendingDepth=3` against the existing build products of its imports (no errors, no warnings) and gave the same three axioms for:

```
simpleAffineQuotientVOA  simpleAffineQuotientVOA_isSimple
 ↪  simpleAffineQuotientVOA_centralCharge
simpleAffineQuotientProjection  simpleAffineQuotientProjection_smul
simpleAffineQuotientProjection_surjective  simpleAffineQuotientProjection_grading
```

The targeted and umbrella builds including this file are recorded green with standard axioms in `Notes/RELEASE_PLAN.md` ("Caveats removed in Lean", 2026-10-28); the aggregate build `bash scripts/campaign_build.sh VOA` (the full `lake build VOA` under the project's memory-capped

wrapper) was green in two pre-release builds on 2026-10-28 (18,901 jobs, and 18,907 jobs after merging the then-current `origin/main`); the release build is recorded in Chapter 43, Section 43.1.9. No build was re-run for this chapter. The library has no project axiom (`VOA.pbw` is a theorem, Chapter 3).

Release audit 2026-10-27: RELEASE_AUDIT_L17_L18_L23.md. The independent release audit `Notes/Textbook/referee/RELEASE_AUDIT_L17_L18_L23.md` re-elaborated the headline declarations of this chapter from the existing build products (`lake env lean -DmaxSynthPendingDepth=3`; `lake build` not run) and re-ran `#print axioms`: `universalAffineVOA`, `universalAffineVOA_centralCharge`, `standardAffineVOA_centralCharge`, `killing_h`, `simpleVOA_isSimple`, `simple_grading_one_eq_range`, `cartan_isSimple`, the lattice and table `*Lie_isSimple`, `SCLie.finrank_{g2,f4,e6}Lie`, `SCLie.*_standard`, `g2Data'`, `g2_currentJetSurjectivity` and `g2_classicallyFree_of_two_inputs` all report only the three standard axioms. The E_7/E_8 dimension and root-count theorems were not re-run by the audit (their sources were read and are unconditional). Verdict: *announceable with caveats*, the caveats being mandatory, and they are those stated in this chapter: the declaration then called `simpleAffineVOA` (now `universalAffineVOA`) is the universal $V^k(\mathfrak{g})$ and $L_k(\mathfrak{g})$ is `simpleVOA (simpleData …)`, at audit time without a named wrapper (since 2026-10-28: `simpleAffineQuotientVOA`, Section 23.6.2) (M1, warning box in Section 23.5.2); h is the Casimir number of the chosen form, equal to $h^\vee$ only per type via the `*_standard` theorems (M2); Cartan types are not identified in Lean (M3, Remark 23.33); `weightOneEquiv` is only a linear isomorphism (m1); longness of the chosen roots of the table algebras is not checked (m2); classical freeness remains conditional on `hgeom`, `hchar` (m3). The audit also notes (M7) that the aggregate build is not certified for the release commit: the last aggregate green cited above predates later commits, and a transitive-import walk found umbrella modules without build products. (Since then the aggregate build was green on 2026-10-28, as recorded above.) Nothing in this chapter's status boxes is upgraded by the audit.

23.12.1 File map

The chapter covers the 268 files assigned to it in `Notes/Textbook/assignment.txt`:

- the 161 files of `VOA/AffineGeneral/`: 43 theory files (the general affine vertex algebra, its simple quotient, simplicity criteria, root counts, normalizations, the per-type instances) and 118 generated files for the structure-constant algebras $\mathfrak{g}_2$, $\mathfrak{f}_4$, $\mathfrak{e}_6$;
- `VOA/Foundations/CartanLattices.lean` and `VOA/Examples/DeligneLatticeLie.lean` (the simply-laced root lattices and their lattice vertex algebras);
- the certificate-basis models in `VOA/DeligneAudit/`: `D4Lie{Basis,Cocycle,Data,Table}.lean`, the `E7Lie*` and `E8Lie*` data files (basis, cocycle, data, table, form, Killing form, and 20 resp. 32 `Model*` check files), the 18 `E6Lat*.lean` files, `G2LieData.lean`, `F4LieData.lean`, `F4LieTab.lean` and the ten `F4LieChecks*.lean` files.

The 118 generated files of `AffineGeneral/`. For each $X \in \{\mathfrak{g}_2, \mathfrak{f}_4, \mathfrak{e}_6\}$ the generator `aff_sc_emit2.py` writes: `XTable.lean` (the flat rows only; 3 KB, 24 KB, 46 KB of data), four `XBound*` and four `XAnti*` files (index bounds and antisymmetry, one row chunk each, combined by `boundOK_of_chunks`/`antiOK_of_chunks`), the Jacobi files `XJac*` (one declaration `jacPiece T N i jlo jhi` per row i and column block, covering all sorted triples $i < j < l$; 12 declarations for $\mathfrak{g}_2$ in one file, 125 for $\mathfrak{f}_4$ in ten files, 266 for $\mathfrak{e}_6$ in 29 files), and the root-table files `XRootsA`, `XHbe*`, `XHhb*`, `XSep*`, `XSymm*` (the fields of `RootChecks`). For $\mathfrak{e}_6$ there are in addition the Lie-data check files `E6LieDataTab`, `E6LieDataPair{A,B,C}`, `E6LieDataCas{A..F}`, `E6LieDataSkew{A,B}`. Apart from the three `XTable.lean` files, which hold data only, every file is a list of statements "this Boolean function of the table evaluates to `true`", proved by `decide +kernel`. In numbers: 23, 32 and 51 files for $\mathfrak{g}_2$, $\mathfrak{f}_4$, $\mathfrak{e}_6$ (106 in all), plus the

12 `E6LieData*` files. *The certificate-basis check files.* E_7: 133^2 pairs, one row per declaration, combined by `fin_cases`. E_8: 248^2 pairs in 31 files of 8 rows (one row, i.e. 248 pairs, per `decide +kernel`), plus the assembly `E8LieModel.lean`.

23.12.2 Machine cost, and the dead ends that shaped the files

Measured costs from the project record: every $\mathfrak{e}_6$ table-check file $\leq$ 25 s and $\leq$ 5.4 GB; each E_8 certificate row about 3 s and under 3 GB; the pruned E_7 root enumeration (Definition 23.30) about 2 s in the kernel.

Dead ends: kernel cost

These routes were tried and abandoned; they explain why the checks are split as they are.

- *Plain box enumeration of roots.* Enumerating all integer vectors in a coordinate box and checking norms under `decide +kernel`: for E_6 (7875 vectors) about 11 s; for E_7 (box $(2,2,3,4,3,2,1)$, 165375 vectors) it did not finish in 10 minutes. The pruned LDL^{T} enumeration visits only branches compatible with the bound (about 2 s for E_7).
- *Table encodings.* A nested-tuple $\mathfrak{e}_6$ table took 112 s to elaborate (flat `List ℕ` rows: about 5 s); `![…]` vector tables are slow in the kernel (`List` with `getD` is used instead).
- *Monolithic checks.* The first $\mathfrak{f}_4$ file checked the Leibniz identity on all 52^3 triples in one declaration (2 min 15 s; superseded by sorted cyclic Jacobi in pieces). A single `decide` comparing a 133×133 sector table with the lattice-model table used 41 GB and timed out after 445 s; the E_8 version was killed above 20 GB; even D_4 (28^2) needs 6.1 GB as one declaration.

The working pattern: light-import check files with one row or block per declaration, and a heavy file that only assembles the propositional conclusions.

23.13 Lean defects found

This section is an index; each item is explained in the box cited. Severities: S1, a statement or definition is wrong or vacuous; S2, a definition is weaker or stronger than its name or the literature, or a hypothesis is redundant; S3, an advertised result is only conditional (a gap); S4, documentation (docstrings, notes) is wrong or stale.

1. (S4) $\mathfrak{sl}_3$ prose ("$8k/(k+3)$", "$1/(2(k+3))$", "eight Chevalley directions", "universal sl3 vacuum") in the general files `Virasoro.lean`, `SugawaraField.lean`, `WeightOne.lean`, `GradedFields.lean`: warning box in Section 23.4.2.
2. (S3) False provenance of vacuum nonvanishing ("free-field evaluation, without PBW") in `AffineGeneral.vacuumA_ne_zero`, `Grading.lean`, `Currents.lean`: warning box in Section 23.4.1.
3. (S4) The docstring of `AffineGeneral.currentState_injective_of_ne_zero` points to the $\mathfrak{sl}_3$ all-level injectivity as if it applied to general $\mathfrak{g}$: dictionary of Theorem 23.17 and warning box in Section 23.6.3.
4. (S4) `SlSimple.slAffineVOA`: redundant hypothesis `hm`, and "standard normalization" claimed without proof: warning box in Section 23.7.
5. (S3) Name clashes (`e6Lie_isSimple`, `e6SimpleVOA`, `e6Data`, `g2Data`, `f4Data`) and the unchecked docstring claim of `DeligneAudit/E6LatTable.lean` that its table equals `SCLie.e6T`: warning box in Section 23.10.

6. (S4) `SCLie.hL/hbV` called "coroot" although they are minus the standard coroot: warning box in Section 23.9.2.

7. (S3, resolved) The former name `AffineGeneral.simpleAffineVOA` invited the reading $L_k(\mathfrak{g})$ although the declaration is the universal $V^k(\mathfrak{g})$, and the simple quotient of a general simple $\mathfrak{g}$ had no named declaration (release audit 2026-10-27, M1): warning box in Section 23.5.2. Resolved 2026-10-28: the declaration is now `universalAffineVOA` (the old name is a deprecated alias), and the quotient is named `simpleAffineQuotientVOA` (Section 23.6.2).

8. (S4) Stale docstring of `Examples/DeligneLatticeLie.lean` (simplicity and dimensions called "the next steps"): warning box in Section 23.8.1.

23.14 Referee's checklist

Lean declaration	Intended meaning	Hypotheses / status	Fidelity check
`LieData`	basis, dual basis, Casimir $= 2h$	definition	Def. 23.1
`struct_casimir_contract` etc.	finite identities	unconditional	Prop. 23.3
`current_comm`, `vacuumA_ne_zero`	affine algebra; $\|0\rangle \neq 0$	unconditional (relative PBW)	Def. 23.5
`affineVOA`, `hYA_virasoro`	$V^k(\mathfrak{g})$, $c = \dim\mathfrak{g}\, k/(k+h)$	Lie data, $k + h \neq 0$	Thm. 23.7
`casimir_scalar`	Casimir scalar on simple $\mathfrak{g}$	simple, f.d.	Thm. 23.9
`universalAffineVOA`, `killing_h`, `standardAffineVOA`	universal $V^k(\mathfrak{g})$ (*not* L_k) for every simple $\mathfrak{g}$; $2h$ the Casimir of κ	simple; $h = h^\vee$ only per type (`*_standard`)	Thm. 23.10, Sec. 23.5.2
`simpleVOA`, `simpleVOA_isSimple`, `simple_grading_one_eq_range`	$L_k(\mathfrak{g})$ (for general $\mathfrak{g}$: `simpleVOA (simpleData …)`, named `simpleAffineQuotientVOA`) simple; weight one spanned by currents	$k + h \neq 0$; injectivity **not stated**	Thm. 23.13
`simpleAffineQuotientVOA`, `_isSimple`, `_centralCharge`, `simpleAffineQuotientProjection`, `_smul`, `_surjective`, `_grading`	named $L_k(\mathfrak{g})$ for simple $\mathfrak{g}$: simple, $c = \dim\mathfrak{g}\, k/(k+h)$; π a surjective, grading-preserving homomorphism	$k + h \neq 0$; unconditional	Def. 23.14, Thm. 23.15
`weightOneEquiv`	$\mathfrak{g} \cong V_1^k$ linearly (no bracket compatibility)	$k \neq 0$	Thm. 23.17
`mem_maxIdeal_of_SingP`, `quadState_mem_maxIdeal`	singular vectors vanish in L_k	weight > 0	Thm. 23.19
`clsG_quad_eq_zero`, `clsG_adPoly_eq_zero`	kernel facts in Li degree 0	unconditional	Prop. 23.21
`SlSimple.instIsSimple`	$\mathfrak{sl}_n$ simple	$n \geq 2$	Thm. 23.22
`RootSpace.isSimple_of_roots`	root-space criterion	listed	Thm. 23.23
`LatticeLie.isSimple_of_simpleRoots`, `finrank_V1`	$(V_L)_1$ simple; dim = rank + #roots	connected generating roots	Thm. 23.27
`CartanSimple.*Lie_isSimple`	$(V_L)_1$ simple, $L = A_2, D_4, E_6, E_7, E_8$	unconditional; Cartan type not identified in Lean	Thm. 23.28, Rem. 23.33

Lean declaration	Intended meaning	Hypotheses / status	Fidelity check
`E8Dim.finrank_e8Lie`, `RootCounts.finrank_*`	dims 248; 28, 78, 133, 248	unconditional	Thms. 23.29, 23.31
`Normalization.*_standard`	Kil $/(2h^\vee)$ standard	unconditional	Thm. 23.32
`SCLie.isSimple_of_tables`, `g2/f4/e6Lie_isSimple`, `*_standard`	table algebras of dims 14, 52, 78 simple, normalized	kernel checks; type and root longness on paper	Thms. 23.35, 23.37
`SCLie.lieDataOf`, `e6LieData`, `g2CertData`, `f4CertData`	Lie data in table basis	kernel checks	Def. 23.38
`Deligne.presentation`, `currentJetSurjectivity`, `classicallyFree_of_two_inputs`	capstone inputs for every case	presentation = **full kernel**; last is conditional on `hgeom`, `hchar`	Thm. 23.40, Sec. 23.10
`E8Deligne.*` and per-type files	$L_{-h^\vee/6-1}(\mathfrak{g})$	as above	Thm. 23.41
`E8Lie.e8CertData`, `D4Lie.d4CertData`, `e7CertData`, `E6Lat.bracket_xs`	certificate tables are the lattice brackets	kernel checks	Thm. 23.42

Chapter 24

The Deligne series I: presentations, carriers and the divisor comparison

This chapter was written against an earlier state of the LeanVOA library, and every Lean quotation below was checked (with `sync.py check`) to occur verbatim in the source files of that state. For this edition, `scripts/textbook/sync.py` checks that every Lean quotation below occurs verbatim (up to whitespace and comments) in the source files of that release. The machine record is older than that release, and we state it exactly. The umbrella target `VOA.Deligne` was last built green at an earlier commit (11099 jobs), with every `#print axioms` in the campaign files a subset of `[propext, Classical.choice, Quot.sound]`. The Lean sources have changed since then: certificate files were split to fit the memory budget (among them the A_2 divisor certificate behind `A2.divisorComparison`), and the unconditional A_2 theorem of Chapter 27 was added. The project records that the exported statements of the split files were preserved, and the quotations here confirm it for every statement this chapter prints. The changed files were built green in targeted builds, and the aggregate build `bash scripts/campaign_build.sh VOA` (the full `lake build VOA` under the project's memory-capped wrapper) was green on 2026-10-28 (a pre-release build): 18,901 jobs, and again 18,907 jobs after merging the then-current `origin/main`; the aggregate target contains the umbrella `VOA.Deligne`. Section 24.11 gives the details.

The chapter covers the 1195 Lean files that the book assigns to it (`Notes/Textbook/assignment.txt`): roughly 170 files of genuine mathematics, which we present declaration by declaration, and roughly 1020 files of certificate data and certificate checks (the E_8 divisor comparison alone is 619 files), which we describe collectively in Section 24.10: what each family checks, in what format, by which kernel mechanism, and at what size.

Conventions for quotations and status boxes.

- *Omitted proofs.* A Lean quotation shows a statement, not its proof. A block that ends in `:=` or `:= by` with nothing after it is a statement whose proof is omitted; it is not a truncated quotation. A few definitions are shown with their bodies omitted in the same way; the dictionary says so each time.
- *"Axioms standard".* This means that `#print axioms` reports a subset of `[propext, Classical.choice, Quot.sound]`, the three standard axioms of Lean's logic (propositional extensionality, the axiom of choice, quotient soundness); see Chapter 1, Section 1.3. It does *not* mean "unconditional": `#print axioms` does not list the explicit hypotheses of a theorem (Section 1.3.4). Every status box therefore names the hypotheses separately.
- *Where a status claim comes from.* Unless a status box says otherwise, an axiom or build claim is a *campaign record*: it was recorded by the project's own builds and audits (the earlier umbrella build, the later targeted builds, and the `#print axioms` sections at the end of each Lean file).

A claim marked *re-checked* was re-run by the author of this chapter on a scratch file; the list is in Section 24.11.

Prerequisites. Three things are used without being re-developed here. (1) Li's filtration $F^{\bullet}V$ of a VOA, its layers $\mathrm{gr}^{\mathrm{Li}}_{p,N} V = F^p V_N / F^{p+1} V_N$ indexed by the *Li degree* p and the conformal weight N, and the identification $\mathrm{gr}^{\mathrm{Li}}_0 V = R_V$ with Zhu's C_2-algebra (Chapter 11). (2) The presented jet algebra $J_\infty(\mathbb{C}[x]/I)$ of a polynomial quotient, with its bigrading by the number of derivatives and the conformal weight, and its universal property as an arc algebra (Chapters 11 and 20). (3) The affine VOAs $V^k(\mathfrak{g})$, their simple quotients $L_k(\mathfrak{g})$, and the concrete exceptional Lie algebras (Chapters 4, 5 and 23). For precise pointers: the Lean objects `liWeightLayer W p N`, `liAssociatedGraded W` and `liPresentedJetMap` are in Chapter 11, Section 11.4 (Definitions 11.12 and 11.14); `InfiniteJet.PresentedJet` and its arc universal property are Definition 20.10 and Theorem 20.11; the Lie data `LieData` are in Chapter 23. Chapter 20 is the closest model: it proves classical freeness for $L_k(\mathfrak{sl}_2)$ at the boundary admissible levels by a squeeze of exactly the kind used here, and two of its collision-divisibility files (`VOA/Commutative/CollisionCommonFactors.lean`, `VOA/Commutative/RootedGordonConductorDivisibility.lean`) are reused by the Deligne carrier.

What this chapter is about, in one paragraph. The *Deligne series* is the list of simple Lie algebras $A_1 \subset A_2 \subset G_2 \subset D_4 \subset F_4 \subset E_6 \subset E_7 \subset E_8$, taken at the level $k = -1 - h^\vee/6$. For $V = L_k(\mathfrak{g})$ one wants to prove that Li's canonical surjection $J_\infty R_V \twoheadrightarrow \mathrm{gr}^{\mathrm{Li}} V$ is injective (*classical freeness*), and that $R_V = \mathrm{Sym}\,\mathfrak{g}/(I_2^{\mathrm{ns}})$ for an explicit space I_2^{ns} of quadrics. The paper proof is a chain of coefficientwise inequalities between q-series, from the character of V through the Hilbert series of an explicit "carrier" down to a sum of affine Demazure characters, closed by a bound of that sum by the character. This chapter formalizes (i) the reduction of classical freeness to that chain (a conditional capstone with four packages), (ii) the explicit presentation $I_2^{\mathrm{ns}} \subseteq \ker$ for all seven higher-rank types, (iii) current-jet surjectivity, (iv) the geometric carrier, and (v) the carrier half of the chain, steps B1–B8 and the resummation D3, with type-generic theorems instantiated by kernel-checked certificates for $A_2, G_2, D_4, F_4, E_6, E_7, E_8$. The character side is Chapter 25, the fusion inputs U5 and U6 are Chapter 26, and the final per-type theorems (unconditional for A_2, conditional on named inputs for the other six types) are Chapter 27.

Why formalize this. Classical freeness of $L_k(\mathfrak{g})$ is a statement with direct physical content: it says that the Schur index of the corresponding four-dimensional $\mathcal{N} = 2$ theory equals the Hilbert series of the arc space of a (non-reduced) Higgs branch, so that every Schur operator is a classical field configuration. Its paper proof is long: about fifteen labelled steps, most of them commutative algebra, a few of them citations of the literature, and one of them (the divisor comparison, below) a finite but very large computation in $\mathfrak{g}^* \otimes \mathfrak{g}^*$. Each step is a place where a gap could hide. The Lean development separates the steps that can be *proved* (all the commutative algebra, and the divisor comparison by certificates) from the genuine literature inputs, which survive as named hypotheses (U5, U6) or are deferred to another chapter (the character bound (★)). The divisor comparison gives the chapter its title because it is the one step whose paper proof is a computation rather than an argument; the reason it is the only such step is explained at the start of Section 24.7.

Remark 24.1 (The logical arc and the ledger)**.** Write carrierDim(N) for the q^N-coefficient of $\mathrm{Hilb}\, J_\infty \widetilde{R}$, the Hilbert series of the arc algebra of $\widetilde{R} = \mathrm{Sym}\,\mathfrak{g}/(I_2^{\mathrm{ns}})$ (by Theorem 24.17 this is also the total dimension of the weight-N carrier), and $\mathcal{D}_N$ for the q^N-coefficient of the *Demazure sum* $\sum_{n\geq 0} q^n\ \mathrm{Hilb}_q\, D(1, n\theta)/(q)_n$ (notation below). The whole Deligne argument is three statements,

for every conformal weight N:

(A) $\big(\mathrm{carrierDim}(N) \le \dim V_N \text{ for all } N\big) \implies V$ classically free, and $\ker(\mathrm{Sym}\,\mathfrak{g} \to R_V) = (I_2^{\mathrm{ns}})$;
(B) $\mathrm{carrierDim}(N) \le \mathcal{D}_N$;
(C) $\mathcal{D}_N \le \dim V_N$.

(A) is Theorem 24.19, together with current-jet surjectivity (Theorem 24.14); it is proved here with no further hypothesis. (B) is the carrier half of the chain, proved here conditionally on U5 and U6 (Theorems 24.25 and 24.41). (C) is the character side (★), treated in Chapter 25. (B) and (C) together give the hypothesis of (A). Since the opposite inequality $\dim V_N \le \mathrm{carrierDim}(N)$ is automatic (Li's map is onto), all three quantities then coincide.

The ledger, step by step ("form" says whether the step is used as an equality, an inequality or a containment):

step	form	status in this chapter
U2: $I_2^{\mathrm{ns}} \subseteq \ker$	containment	proved, all seven types, no hypothesis
exactness $\ker = (I_2^{\mathrm{ns}})$	equality	a *conclusion* of (A), never assumed
current-jet surjectivity	surjection	proved, all seven types
B4: carrier = dual of the jet algebra	isomorphism	proved, any quadrics
U3: $X_a Q \in (I_2^{\mathrm{ns}})$	containment	certified per type
B1, B2–B3	$\le$ and $=$	proved, any type data
B5, generic comparison	containments	proved, any sector data
divisor comparison	containment	proved per type by certificates
B6, B8	freeness, equality	proved from U5 and the divisor comparison
D3	equality	proved (pure q-series)
U5 (fusion bound)	$\le$	**named hypothesis**; reduced in Chapter 26; discharged for A_2 (Chapter 27)
U6 (mixed recursion)	equality of series	**named hypothesis** here; proved by construction in Chapter 26 (`fusionOf`)
(★): (C) above	$\le$	Chapter 25
final per-type theorems; A_2 unconditional		Chapter 27

The paper states (★) as an equality ("Demazure sum = character"); only the inequality (C) is used, and that is the form in which the Lean development states it (`DemazureBoundFor`, Chapter 25). Chapter 27 renames the remaining inputs: Chapter 26 reduces U5 to the total-dimension bound, which is Input T, and the Demazure realizations U7, which are Input R; the star bound $\mathcal{D}_N \le c_N$ of Chapter 25 is Input S.

The findings of this chapter, in brief.

1. **Exactness of the C_2 presentation is a conclusion, not a hypothesis.** The capstone `caseClassicallyFree_of_explicit_inputs` assumes only that the displayed ideal is *contained* in the kernel of $\mathrm{Sym}\,\mathfrak{g} \to R_V$, and concludes that it *equals* the kernel, through a short retraction argument (`VOA.ker_eq_of_liPresentationClassicallyFree`, Theorem 24.6).

2. **The explicit presentation is unconditional for all seven types.** For each type, a weight-two singular vector dies in $L_k(\mathfrak{g})$, and coadjoint propagation carries its symbol to every relation of I_2^{ns} (8, 27, 105, 324, 650, 1539 and 3875 relations). The resulting presentations `explicitPresentation*` and `I2ns_le_ker*` have no hypotheses (Theorem 24.12).

3. **Three of the capstone's four packages are proved.** Package 1 (the presentation) is the explicit presentation above. Package 2, current-jet surjectivity, holds for every Deligne type

(Theorem 24.14). Package 3, the geometric carrier embedding, holds for every presentation by quadrics, and is in fact a linear *equivalence* with a literal polynomial carrier (Theorem 24.18); on its own it is weak (Warning in Section 24.5). Package 4, the character identity, is not proved in this chapter: it is equivalent to the inequality (A) above, which is what (B) and (C) supply, and (B) rests on U5 and U6. For A_2 the remaining inputs are proved, and Chapter 27 states the resulting unconditional theorem.

4. **The carrier chain is formalized type-generically.** B1 (the Casimir layer bound) and D3 (the Gaussian resummation) are proved with no hypothesis; B5 ($M_m \subseteq W_m$), B6 (freeness of M_m, from U5), the generic comparison ($\Delta^L W_m \subseteq M_m$) and B8 (normality) are proved for arbitrary sector data; the divisor comparison (B7 at $\Delta = 0$) is proved for each of the seven types by integer certificates. The output is, for each type, the sector fusion bound from U5 alone (`X_sectorFusionBound_of_U5`; for A_2 see Theorem 24.41), and then $\sum_p \dim \mathrm{Carrier}_{p,N} \le \mathcal{D}_N$ from U5 and U6.

5. **What this chapter does not prove.** It proves no character equality, and no classical freeness theorem for any higher-rank Deligne VOA. The fusion bound U5 (total dimension: Kus–Littelmann, Pacific J. Math. 278, Thm. 4.2, with one flagged step; Feigin's earlier proof has a gap; see Chapter 27) and U6 (Ravinder's mixed recursion) remain named hypotheses here; Chapter 26 reduces them further. For A_2 every input is now a theorem, and the unconditional statement that $L_{-3/2}(\mathfrak{sl}_3)$ is classically free with $R_V = \mathrm{Sym}\,\mathfrak{sl}_3/(I_2^{\mathrm{ns}})$, `VOA.DeligneAudit.A2.classicallyFree`, is presented in Chapter 27. For the other six types the final theorems remain conditional (Chapter 27).

6. **Size.** The certificate layer is large (E_8: 61 504 two-slot tables, 9291 kernel theorems in 556 files, 10.8 MB of literal data); its sizes and measured costs are in Section 24.10.

Notation used in this chapter. Several letters are used by the Lean sources for more than one object. In the mathematical text we use the following, and we keep the Lean names only inside quotations and dictionaries.

symbol	meaning
q	the formal variable of all q-series (conformal weight, or t-degree). In the A_2 file the Lean abbreviation `q a b` means the monomial $X_a X_b$; it never denotes the variable.
$[q^N]f$	the coefficient of q^N in the power series f.
$(q)_n$, $\begin{bmatrix} n \\ d \end{bmatrix}_q$	$(q)_n = \prod_{i=1}^{n}(1-q^i)$; the Gaussian binomial $(q)_n/((q)_d(q)_{n-d})$.
$\mathrm{ch}\,V$	the character (graded dimension) $\sum_N \dim V_N\, q^N$ of a VOA graded by conformal weight.
$\mathrm{Hilb}\,A$	the Hilbert series $\sum_N \dim A_N\, q^N$ of a graded algebra or space; for jet algebras a current has weight 1 and each derivative adds 1.
(p, N)	Li bidegree: p is the Li degree (number of derivatives), N the conformal weight.
$\mathfrak{g}$, n, θ, $h^\vee$, k	the simple Lie algebra, $n = \dim \mathfrak{g}$, the highest root, the dual Coxeter number, the level $k = -1 - h^\vee/6$; $V(\lambda)$ is the irreducible $\mathfrak{g}$-module of highest weight λ.
Q, I_2^{ns}, I_2	the Casimir quadric in $\mathrm{Sym}^2\,\mathfrak{g}$; the non-singlet weight-two relations (the superscript "ns" reads "non-singlet": I_2 with its singlet $\mathbb{C}Q$ removed); $I_2 = I_2^{\mathrm{ns}} \oplus \mathbb{C}Q$.
$\widetilde{R}$, R_V, J_∞	$\mathrm{Sym}\,\mathfrak{g}/(I_2^{\mathrm{ns}})$; Zhu's C_2-algebra; the arc (infinite jet) algebra functor.
$\mathcal{R} = (q_r)_{r\in\rho}$	a family of quadric coefficient matrices (Lean's variable `Q`); $\mathrm{quad}(q_r)$ the quadric.

symbol	meaning
W; W_m	a VOA (no subscript); the current carrier with m particles (Definition 24.16).
P_m, B_m, B_+	$\mathbb{C}[z_1,\dots,z_m]$; its symmetric invariants $P_m^{S_m}$; the ideal of B_m of symmetric polynomials without constant term.
M_m, δ_{c_0}, δ_t	the cyclic module generated by $\delta_{c_0}^{\otimes m}$ (Definition 24.27); the highest-weight vector of $\mathfrak{g}^*$; the basis tensor at a labelling t.
Δ	the discriminant $\prod_{i\neq j}(z_i-z_j)\in B_m$ (not to be confused with δ_{c_0}).
L	the cyclicity depth of the sector data (Definition 24.28).
$\mathcal{F}_m$; $F=(F_m)_m$	the fusion module (Definition 24.29); a family of power series (Lean `F`), whose intended value is the graded character of $\mathcal{F}_m$, for instance $F_1(q)=n$ and $F_2(q)=\dim V(2\theta)+q\dim\Lambda^2\mathfrak{g}+q^2\dim I_2$ (for A_2: $27+28q+9q^2$, total $64=8^2$).
$W_{\mathrm{loc}}(m\theta)$	the local Weyl module of the current algebra $\mathfrak{g}[t]$ (Definition 24.29).
$D(1,n\theta)$, Dem_n	the level-one affine Demazure module of highest weight $n\theta$, a $\mathfrak{g}[t]$-module; $\mathrm{Dem}_n=\mathrm{Hilb}_q D(1,n\theta)$ its t-graded dimension (Chapter 25).
$\mathcal{D}_N$	the q^N-coefficient of the Demazure sum $\sum_n q^n\mathrm{Dem}_n/(q)_n$.
$\mathcal{C}$, S	carrier data (Lean `D : DeligneCarrierData`); sector data (Lean `S : DeligneSectorData`).
$\lambda_i(t)$, λ_i	$\prod_{j\neq i}(t-z_j)\in P_m[t]$ and its value $\lambda_i(z_i)=\prod_{j\neq i}(z_i-z_j)$ (Lean `Lpoly i`, `Dslot i`).
G_i, H, Λ_{ab}, E_{ab}	for slots $a\neq b$: $G_i=\prod_{k\notin\{a,b\}}(z_i-z_k)$, $H=G_aG_b$, $\Lambda_{ab}=\prod_{j\notin\{a,b\}}\lambda_j^L$ (Lean `Fspec`), $E_{ab}=\prod(z_i-z_j)$ over ordered pairs $\{i,j\}\neq\{a,b\}$.
ν, ℓ	in Section 24.8: the number of pair-operator steps (Lean `D`) and the collision order, the power of z_a-z_b (the same letter in Lean, where it is called "level" in the name `LevOK`; unrelated to the affine level k and to the Li degree).
$a_r(c,d)$	integer coefficient matrices of the relations of I_2 (Lean `qI`).
π; ϖ	Li's surjection $J_\infty R_V\to\mathrm{gr}^{\mathrm{Li}}V$; a prime element of B_m.

24.1 The mathematics

24.1.1 The Deligne series

Deligne observed (1996) that the exceptional Lie algebras, together with a few classical ones, behave as a one-parameter family: many representation-theoretic quantities, for instance the decomposition of $\mathrm{Sym}^2\mathfrak{g}$ and of $\Lambda^2\mathfrak{g}$, are given by rational functions of the dual Coxeter number $h^\vee$. In the long-root-square-two normalization the family and its levels are:

type	$\dim\mathfrak{g}$	$h^\vee$	$k=-1-h^\vee/6$	$\dim V(2\theta)$	$\dim I_2^{\mathrm{ns}}$	I_2^{ns} as a $\mathfrak{g}$-module
A_1	3	2	$-4/3$	5	–	(see Chapter 20)
A_2	8	3	$-3/2$	27	8	$V(\theta)$ (the adjoint)
G_2	14	4	$-5/3$	77	27	$V(2\omega_1)$
D_4	28	6	-2	300	105	$V(2\omega_1)\oplus V(2\omega_3)\oplus V(2\omega_4)$
F_4	52	9	$-5/2$	1053	324	$V(2\omega_4)$
E_6	78	12	-3	2430	650	$V(\omega_1+\omega_6)$
E_7	133	18	-4	7371	1539	$V(\omega_6)$
E_8	248	30	-6	27000	3875	$V(\omega_1)$

In every row $\mathrm{Sym}^2\mathfrak{g}=V(2\theta)\oplus I_2^{\mathrm{ns}}\oplus\mathbb{C}Q$, where θ is the highest root and Q the Casimir quadric; for example $406=300+105+1$ for D_4 and $30876=27000+3875+1$ for E_8. We write $I_2=I_2^{\mathrm{ns}}\oplus\mathbb{C}Q$ for the complement of the top summand $V(2\theta)$. The ideal $(I_2)\subset\mathrm{Sym}\,\mathfrak{g}$ is the classical shadow of the *Joseph ideal*: for $\mathfrak{g}$ not of type A, the Joseph ideal is the unique completely prime primitive

ideal of the enveloping algebra $U(\mathfrak{g})$ whose associated variety is the closure $\overline{\mathbb{O}_{\min}}$ of the minimal nilpotent orbit (the orbit of a highest root vector), and its associated graded ideal in $\operatorname{Sym}\mathfrak{g} = \operatorname{gr} U(\mathfrak{g})$ is generated by I_2. In particular $\operatorname{Sym}\mathfrak{g}/(I_2)$ is the coordinate ring of $\overline{\mathbb{O}_{\min}}$ (Kostant; Garfinkle; see the Notes). The ring that matters here is the slightly larger

$$\widetilde{R} = \operatorname{Sym}\mathfrak{g}/(I_2^{\mathrm{ns}}),$$

in which Q is not killed but is nilpotent: $XQ \in (I_2^{\mathrm{ns}})$ for every $X \in \mathfrak{g}$, hence $Q^2 \in (I_2^{\mathrm{ns}})$ (input U3 below). The member A_1 is treated separately (its relation module is $\mathfrak{sl}_2 Q$ in degree three); it is the $m = 1$ case of Chapter 20.

Physical meaning

The Deligne series at $k = -1 - h^\vee/6$ is the list of chiral algebras of the rank-one four-dimensional $\mathcal{N} = 2$ superconformal field theories with a flavour symmetry in the series, via the 4d/2d correspondence of Beem, Lemos, Liendo, Peelaers, Rastelli and van Rees: the Argyres–Douglas theories H_1, H_2 (flavour A_1, A_2), $SU(2)$ with four flavours (flavour D_4), and the Minahan–Nemeschansky theories (flavour E_6, E_7, E_8). The 2d level is $k_{2d} = -k_{4d}/2$, and $h^\vee + 6$ appears because these theories saturate a unitarity bound on the flavour central charge. The Higgs branch of each theory is $\overline{\mathbb{O}_{\min}}$, the one-instanton moduli space, which is the associated variety of $L_k(\mathfrak{g})$ (Arakawa–Moreau). G_2 and F_4 have no known four-dimensional origin; mathematically they belong to the same family.

24.1.2 The associated scheme, nilpotence of the Casimir, and the target statement

For a VOA V, Zhu's C_2-algebra is $R_V = V/C_2(V)$, a commutative Poisson algebra; Li's filtration has $\operatorname{gr}^{\mathrm{Li}}_0 V = R_V$, and there is a canonical surjection of differential algebras

$$\pi : J_\infty R_V \twoheadrightarrow \operatorname{gr}^{\mathrm{Li}} V \tag{24.1}$$

(Li 2005; Arakawa 2012; Chapter 11). V is *classically free* when π is injective. For an affine VOA $L_k(\mathfrak{g})$ the weight-one currents $x_{(-1)}\mathbf{1}$, $x \in \mathfrak{g}$, generate R_V, so $R_V = \operatorname{Sym}\mathfrak{g}/\ker$ for the kernel of the current-coordinate map. Let I_2^{ns} be the image in $\operatorname{Sym}^2\mathfrak{g}$ of the C_2-symbols of the weight-two singular vectors of $V^k(\mathfrak{g})$ (they exist at $k = -1 - h^\vee/6$, by Arakawa–Moreau and by Perše for A_2; we use only their existence at this level, not any claim that this is the only level at which they occur). The target theorem, for the seven higher-rank types, is

$$J_\infty\big(\operatorname{Sym}\mathfrak{g}/(I_2^{\mathrm{ns}})\big) \xrightarrow{\sim} \operatorname{gr}^{\mathrm{Li}} L_k(\mathfrak{g}), \qquad \text{and} \qquad \ker\big(\operatorname{Sym}\mathfrak{g} \to R_{L_k(\mathfrak{g})}\big) = (I_2^{\mathrm{ns}}). \tag{24.2}$$

The second statement says that R_V is the non-reduced scheme $\widetilde{R}$, with $Q \neq 0$ and $Q^2 = 0$.

Physical meaning

The Casimir Q is, up to the factor $2(k + h^\vee)$, the C_2-shadow of the Sugawara stress tensor T. "Q nilpotent in R_V" is the statement, conjectured by Beem and Rastelli for every chiral algebra of a 4d $\mathcal{N} = 2$ theory, that T is nilpotent in the C_2-algebra: the Higgs branch is the reduced associated variety, but the chiral algebra remembers a nilpotent thickening. Classical freeness says that the Schur index of the 4d theory equals the Hilbert series of the arc space of this thickened scheme: every Schur operator is a classical field configuration on the Higgs branch, with no extra quantum relations.

24.1.3 The paper proof as a chain of inequalities

The proof audited in `Notes/deligne/audit_2026_10_25/DeligneCampaignAudit.tex` runs, coefficient by coefficient in q (the conformal weight; notation as in the table of the introduction),

$$\begin{aligned}\operatorname{ch} V \overset{\text{U1}}{\leq} \operatorname{Hilb} J_\infty R_V \overset{\text{U2}}{\leq} \operatorname{Hilb} J_\infty \widetilde{R} \overset{\text{B1}}{\leq} \operatorname{Hilb} U_{\mathfrak{g}} \overset{\text{B2–B8}}{\leq} \sum_{m,d\geq 0} \frac{q^{m+d+d(m+d)}\, F_m(q)}{(q)_m\,(q)_d} \\ \overset{\text{D3, U6}}{=} \sum_{n\geq 0} \frac{q^n \operatorname{Hilb}_q D(1,n\theta)}{(q)_n} \overset{(\star)}{\leq} \operatorname{ch} V.\end{aligned} \tag{24.3}$$

Here $F_m(q)$ is the graded character of the fusion module $\mathcal{F}_m$ (B6 below), $\operatorname{Hilb}_q D(1,n\theta)$ the t-graded dimension of the level-one Demazure module of highest weight $n\theta$, and $U_{\mathfrak{g}}$ an auxiliary algebra described in B1. The steps, each with a gloss (the precise statements come later):

- **U1** (Li): π is surjective, and $\operatorname{Hilb} \operatorname{gr}^{\mathrm{Li}} V = \operatorname{ch} V$ because the layers of Li's filtration of V_N add up to $\dim V_N$. So the quantum count is at most the classical count.
- **U2** (containment): $I_2^{\mathrm{ns}} \subseteq \ker$, so R_V is a quotient of $\widetilde{R}$ and $J_\infty R_V$ a quotient of $J_\infty \widetilde{R}$.
- **U3**: $X \cdot Q \in (I_2^{\mathrm{ns}})$ in $\operatorname{Sym}^3 \mathfrak{g}$ for every current X; hence $Q^2 \in (I_2^{\mathrm{ns}})$.
- **B1**: filter $J_\infty \widetilde{R}$ by the powers of the ideal generated by Q and its derivatives. The d-th layer is bounded by the states of an *auxiliary algebra* $U_{\mathfrak{g}}$, a jet algebra with m *current particles* (weight one) and d *Casimir particles* (weight two) obeying collision rules. Its Hilbert series is a sum over *sectors* (m,d).
- **B2–B3**: dually, a state of sector (m,d) is a polynomial "wave function" of $m+d$ positions. It is divisible by a fixed polynomial $\delta_{m,d}$, the *conductor*, vanishing to order one at every current–Casimir collision and to order two at every Casimir–Casimir collision, of degree $md + d(d-1)$; dividing by it (the *conductor shift*) leaves $W_m \otimes \mathbb{C}[v_1,\dots,v_d]^{S_d}$. The weights add up to $(m+2d) + (md + d(d-1)) = m + d + d(m+d)$, and the symmetric polynomials in d variables contribute $1/(q)_d$.
- **B4**: W_m is the space of symmetric $\mathfrak{g}^{*\otimes m}$-valued polynomials in $z_1,\dots,z_m$ satisfying, at every collision $z_i = z_j$, the quadratic equations of I_2 (the "current carrier"); it is exactly the dual of the m-particle part of the jet algebra.
- **B5**: $M_m := U(\mathfrak{g}[t]) \cdot \delta_{c_0}^{\otimes m} \subseteq W_m$, where δ_{c_0} is the highest-weight vector of $\mathfrak{g}^*$ (weight θ), the functional dual to f_θ.
- **B6**: M_m is a free module over $B_m = \mathbb{C}[z_1,\dots,z_m]^{S_m}$, with fibre M_m/B_+M_m the fusion module $\mathcal{F}_m = W_{\mathrm{loc}}(m\theta)/\langle (f_\alpha \otimes t^m)w\rangle$. Since $\operatorname{Hilb} B_m = 1/(q)_m$, this gives $\operatorname{Hilb} M_m = F_m(q)/(q)_m$.
- **B7**: two-point equality $M_2 = W_2$, $\operatorname{ch} \mathcal{F}_2 = V(2\theta) + q\Lambda^2\mathfrak{g} + q^2 I_2$.
- **B8**: codimension-one comparison plus normality of B_m give $M_m = W_m$, hence $\operatorname{Hilb} W_m = F_m(q)/(q)_m$.
- **U4, U5**: Chari–Fourier–Khandai (global Weyl modules) and the fusion bound $\dim \mathcal{F}_m \leq (\dim \mathfrak{g})^m$, with graded character $F_m(q)$ (total dimension: Kus–Littelmann, Pacific J. Math. 278, Thm. 4.2, with one flagged step; Feigin's earlier proof has a gap; see Chapter 27).
- **U6, D3**: Ravinder's mixed recursion, which expresses $\operatorname{Hilb}_q D(1,n\theta)$ through the F_m, and the Gaussian resummation of the double sum over (m,d) into the single sum over $n = m + d$.

- (★): the paper's character identity "Demazure sum = character" (Chapter 25). Only the inequality "Demazure sum $\leq$ character" is needed, and that is the form stated in Lean (`DemazureBoundFor`, Chapter 25).

The chain begins and ends with $\mathrm{ch}\, V$. Every term is finite in each conformal weight, so once the chain closes, every inequality is an equality weight by weight; equality in the second inequality, read in Li degree zero, is $R_V = \widetilde{R}$. This is the squeeze of Remark 24.1: the Lean development proves the inequalities from $\mathrm{Hilb}\, J_\infty \widetilde{R}$ to the Demazure sum (conditionally on U5 and U6), and Theorem 24.19 turns "$\mathrm{Hilb}\, J_\infty \widetilde{R} \leq \mathrm{ch}\, V$" into classical freeness.

Physical meaning

Each side of (24.3) counts states of weight N in a different description of the same theory: the quantum chiral algebra, its classical limit, a "free-particle" description in which m current quanta and d Casimir quanta move on the line with prescribed collision behaviour (a Feigin–Stoyanovsky functional model), and finally a sum over n of Demazure modules, i.e. the fusion of n adjoint representations. That the counts agree is a statement that the operator content is captured exactly by particles with the right exclusion statistics.

24.1.4 Where each step lives

step	Lean (this chapter unless noted)	status
U1, squeeze	`classicallyFree_of_carrier_weightCharacter`	proved
U2	`I2ns_le_ker*`, `explicitPresentation*`	proved, all seven types
exactness	`ker_eq_of_liPresentationClassicallyFree`	proved (a conclusion)
generation	`currentJetSurjectivity_of_genWordSpan`	proved, all types
B4	`restrictedDualEquivCurrentCarrier`, `geometricCarrierEmbedding_of_quadraticIdeal`	proved
U3	field `DeligneCarrierData.u3`	certified per type
B1	`casimirLayerBound`, `casimirAuxiliaryBound`	proved, generic
B2–B3	`auxDim_conductor_add`, `finrank_currentCarrier_le`	proved, generic
B5	`Mspace_le`	proved, generic
B6	`mFreeness`	proved from U5
generic locus	`genericComparisonG`	proved, generic
B7 at $\Delta = 0$	`pairComparisonG_of_cert`, `X_pairComparison`	proved, certificates
B8	`carrierGenerationG`, `X_divisorComparison`	proved from B6
assembly	`sectorFusionBoundG`, `X_sectorFusionBound_of_U5`	proved from U5 (A_2: see Thm. 24.41)
D3	`sectorCoeff_eq_of_mixed`	proved
U5, U6	`FusionModuleBoundG`, `MixedFusionRecursion`	hypotheses here; Chapter 26
(★)	`DemazureBoundFor` (only "Demazure sum $\leq$ character")	Chapter 25
final theorems	`X_classicallyFree_final`	Chapter 27

U4 (Chari–Fourier–Khandai) does not appear: the campaign found that the Lean chain needs only the *upper bound* U5, because B6 can be proved from a dimension count (Theorem 24.33).

24.2 The conditional capstone

The capstone states, for any VOA carrying $\dim \mathfrak{g}$ weight-one currents, what must be supplied to obtain classical freeness, and it does so in a form that cannot be satisfied by a trivial choice of ideal. We first need the infinite jet map and the definition of classical freeness used throughout.

Definition 24.2 (Degree-zero classes; the infinite Li jet map; presentation-level classical freeness)**.** Let W be a VOA. For a state x of weight N, its *degree-zero class* is the image of x in $\mathrm{gr}^{\mathrm{Li}}_{0,N} W = F^0W_N/F^1W_N$. For a family $x : \sigma \to \mathrm{gr}^{\mathrm{Li}} W$ and an ideal $I \subseteq \mathbb{C}[x_i : i \in \sigma]$ that vanishes on the x_i, the *infinite Li jet map* is the unique differential-algebra map $J_\infty(\mathbb{C}[x]/I) \to \mathrm{gr}^{\mathrm{Li}} W$ sending $x_i^{(r)}$ to $D^{(r)}x_i = D^r x_i/r!$, where D is the derivation of $\mathrm{gr}^{\mathrm{Li}} W$ induced by L_{-1}. The pair (x, I) is *classically free* if this map is bijective. Finally, for a Li bidegree (p, N) and a jet order m, the *bidegree jet map at order* m is the restriction of the finite-jet map (jets $x_i^{(r)}$ with $r \le m$ only) to the classes of polynomials with p derivatives in total and conformal weight N, composed with the projection to the layer $\mathrm{gr}^{\mathrm{Li}}_{p,N} W$. Order $m = p$ suffices for Li degree p, since such a monomial has no jet of order above p.

      liWeightLayer W p N :=
```

From the mathematics to the Lean statement

`liAssociatedGraded W` is the external direct sum $\bigoplus_{(p,N)} \mathrm{gr}^{\mathrm{Li}}_{p,N} W$ with components `liWeightLayer W p N`$= F^pW_N/F^{p+1}W_N$ (Chapter 11). `DirectSum.of … (0, N)` inserts an element in the $(0, N)$ component; `mkQ` is the quotient map $F^0W_N \to F^0W_N/F^1W_N$; the proof term in the angle brackets only certifies that $x \in F^0W_N$ (every state is). So `liDegreeZeroClass W N x` is exactly the degree-zero class. `InfiniteJet.PresentedJet I` is $\mathbb{C}[x_i^{(r)} : i \in \sigma, r \ge 0]/J_\infty I$ (Definition 20.10); `presentedJetToDifferentialAlgebra` is the map given by its universal property for the derivation `liAssociatedGradedTranslation W` (which satisfies Leibniz and kills 1, the two proof arguments). The hypothesis `hI` is "the relations vanish at order zero". `LiPresentationClassicallyFree` is bijectivity, as in the textbook. `PresentedJetLiBidegreeImage baseWeight m p N I` is the image in the order-m presented

jet algebra of the polynomials of Li degree p (number of derivatives) and conformal weight N; `liPresentedJetBidegreeMap` is the jet map restricted to that image and projected to the layer (p, N) (Chapter 11, Theorem 11.18).
Same as the literature? The docstring stresses that the source is the *presented* arc algebra of $\mathbb{C}[x]/I$, not an independently defined arc scheme. For the identification with $J_\infty R_V$ one needs $I = \ker$ exactly, which is what Theorem 24.6 supplies. With $I = \ker$ and x_i the classes of strong generators, `LiPresentationClassicallyFree` is classical freeness in the sense of Li, Arakawa–Moreau and van Ekeren–Heluani.

Physical meaning

The degree-zero class of a current $J^a_{(-1)}\mathbf{1}$ is the classical field J^a on the Higgs branch; $x^{(r)}$ is the classical shadow of $\partial^r J/r!$. Classical freeness says that the composite Schur operators are exactly the polynomials in the classical fields and their derivatives modulo the derivatives of the classical (Higgs branch chiral ring) relations.

What the machine verified

Definitions. They are reused unchanged from the Arakawa–Dai campaign (Chapter 20).

Definition 24.3 (The seven higher-rank cases)**.** The type `HigherRankDeligneCase` has the seven elements $A_2, G_2, D_4, F_4, E_6, E_7, E_8$, with the current dimension $\dim \mathfrak{g}$, the dual Coxeter number $h^\vee$ and the level k of the table in Section 24.1; and $k = -(h^\vee + 6)/6$ in every case.

File `VOA/Examples/DeligneHigherRankConditionalCapstone.lean`.

    (case : HigherRankDeligneCase) :
    level case = -((dualCoxeterNumber case : ℚ) + 6) / 6 := by
```

From the mathematics to the Lean statement

`dualCoxeterNumber` gives $3, 4, 6, 9, 12, 18, 30$ (same file). $-(h^\vee+6)/6 = -1 - h^\vee/6$. The level is used only as a label in the capstone; the actual VOAs of Section 24.3 are built at the literal levels $-3/2, \dots, -6$ in $\mathbb{C}$, and their non-criticality $k + h^\vee \neq 0$ is proved there.

Physical meaning

$k+h^\vee = 5h^\vee/6-1 > 0$: these levels are negative but not critical, so the Sugawara construction exists and the central charge $c = k \dim \mathfrak{g}/(k + h^\vee)$ is negative (-8 for A_2, -14 for D_4, -62 for E_8, from $-6 \cdot 248/24$), as is typical of chiral algebras of 4d theories ($c_{2d} = -12c_{4d}$).

What the machine verified

Definitions; the level formula is proved by `norm_num` on each case.

Definition 24.4 (The four packages)**.** Fix a case and a VOA W.

1. A *current C_2 presentation* P consists of weight-one states gen_i, $i < \dim \mathfrak{g}$, and an ideal $I \subseteq \mathbb{C}[X_0, \dots, X_{n-1}]$ contained in the kernel of $X_i \mapsto [\mathrm{gen}_i] \in \mathrm{gr}_0^{\mathrm{Li}} W$.
2. *Current-jet surjectivity*: for every (p, N) the bidegree jet map at order p is surjective, and the infinite jet map is surjective.
3. A *geometric carrier embedding* into a family of spaces $\mathrm{Carrier}_{p,N}$: injective linear maps from the dual of each presented-jet bidegree piece into $\mathrm{Carrier}_{p,N}$.
4. The *ordinary carrier character* identity: $\sum_{p \le N} \dim \mathrm{Carrier}_{p,N} = \dim W_N$ for all N.

The case is *classically free* for P if (x, I) is classically free, $x_i = [\mathrm{gen}_i]$.

  LiPresentationClassicallyFree W
    (fun i => liDegreeZeroClass W 1 ⟨P.gen i, P.gen_weight_one i⟩)
    P.ideal P.relations_vanish
```

From the mathematics to the Lean statement

`Fin case.currentDimension` is $\{0, \dots, \dim \mathfrak{g} - 1\}$. `P.relations_vanish` is a one-line renaming of the field `relations`. In `bidegree`, the jet order is p (the first argument of `liPresentedJetBidegreeMap W p …`) and the base weights are all 1 (`fun _ ⇒ 1`): the currents have conformal weight one. Order p suffices for Li degree p, since a monomial of Li degree p contains at most p derivatives. `Module.Dual ℂ M` is $M^* = \mathrm{Hom}(M, \mathbb{C})$. The sum in `OrdinaryCarrierCharacter` runs over $p \le N$ (`Finset.range (N + 1)`), and `W.grading N` is W_N; the carriers are assumed finite-dimensional. No Li-bigraded identity is assumed, only the ordinary one-variable character.

Hypotheses and their meaning. The `relations` field is *containment only*. The docstring explains why this is safe: a theorem about a strictly smaller ideal could not pass for classical freeness, because classical freeness forces equality (Theorem 24.6). There is no hypothesis that W is an affine VOA or that the `gen` are currents in any Lie-theoretic sense; the capstone is a statement about any VOA with that many weight-one states. The specific VOAs come in Section 24.3.

Physical meaning

Package 1 lists classical null relations among the currents (the Higgs branch chiral-ring relations). Package 2 says every operator is a normal-ordered polynomial in currents and their derivatives (strong generation by the currents). Package 3 provides a "particle" model large enough to see every classical operator. Package 4 says the particle model counts exactly the operators of the chiral algebra: the Schur index equals the particle partition function.

What the machine verified

Definitions (structures and predicates; nothing assumed globally).

Theorem 24.5 (Weightwise squeeze). *Let W be a VOA,* gen : $\mathrm{Fin}\, g \to W_1$, *I an ideal contained in the kernel, and* Carrier *finite-dimensional. If every bidegree jet map and the infinite jet map are surjective, if there are injective maps* (*bidegree piece*)$^* \hookrightarrow \mathrm{Carrier}_{p,N}$, *and if* $\sum_{p \le N} \dim \mathrm{Carrier}_{p,N} = \dim W_N$ *for every N, then (x, I) is classically free.*

From the mathematics to the Lean statement

The hypotheses are the four packages, unbundled. The conclusion is bijectivity of the infinite jet map.

Proof on paper. Fix N and write, for $p \le N$, $c_p = \dim \mathrm{gr}^{\mathrm{Li}}_{p,N} W$, a_p the dimension of the jet bidegree piece and $b_p = \dim \mathrm{Carrier}_{p,N}$. Surjectivity gives $c_p \le a_p$; the injection of the dual gives $a_p = \dim(\text{piece})^* \le b_p$; and $\sum_p c_p = \dim W_N = \sum_p b_p$ (the first equality is Li's telescoping identity, Chapter 11, Theorem 11.7). By the finite squeeze (Theorem 11.17) $a_p = c_p$ for every p. Bidegrees with $p > N$ are zero on both sides. So in every bidegree the surjective jet map is between spaces of equal finite dimension, hence bijective; since the jet ideal of a homogeneous ideal is bihomogeneous, the infinite jet map is injective, and it is surjective by hypothesis. □

Physical meaning

Counting operators in three ways (quantum, classical jets, particle model) at fixed weight N, but only the total over Li degree for the particle model: the squeeze recovers the Li-graded counts for free. This is why a one-variable character identity, which is what modular/MLDE methods give, suffices.

What the machine verified

Proved; `#print axioms`: `[propext, Classical.choice, Quot.sound]` (campaign record).

Theorem 24.6 (Exact presentation from classical freeness). *Let $I \subseteq \ker(\mathrm{aeval}\, x)$. If (x, I) is classically free, then $\ker(\mathrm{aeval}\, x) = I$.*

```

From the mathematics to the Lean statement

`presentedJetOrderZero` sends $x_i \mapsto x_i^{(0)}$ (`rename fun i ⇒ (i, 0)`) and then to the quotient. `presentedJetRetraction` is the map $J_\infty(\mathbb{C}[x]/I) \to \mathbb{C}[x]/I$ given by the arc universal property with the *zero* derivation on $\mathbb{C}[x]/I$: it sends $x_i^{(0)} \mapsto \bar{x}_i$ and every $x_i^{(r)}$, $r \geq 1$, to 0. The theorem uses only `hfree.1`, injectivity, as the docstring says. The statement is exactly the mathematical one: an ideal *contained* in the kernel equals it.
Could it be vacuous? No: it is not a statement about any specific I; it says that the classical-freeness conclusion is strong enough to pin down the ideal. Consequently a capstone with a deliberately small ideal (say $I = 0$) can only be proved if 0 is the whole kernel.

Proof on paper. Let $f \in \ker(\text{aeval}\, x)$. The jet map composed with the order-zero inclusion is aeval x (both are algebra maps agreeing on the x_i), so the order-zero image $\iota(f)$ of f maps to 0; by injectivity $\iota(f) = 0$ in $J_\infty(\mathbb{C}[x]/I)$. Apply the retraction: $r(\iota(f)) = \bar{f} \in \mathbb{C}[x]/I$, and $r(0) = 0$, so $f \in I$. The argument uses only injectivity of the infinite jet map, not surjectivity; the Lean statement nevertheless takes the full (bijective) hypothesis `LiPresentationClassicallyFree`, and uses only `hfree.1`. □

Physical meaning

If the classical limit has no relations beyond the derivatives of those listed, then in particular the listed chiral-ring relations are *all* the chiral-ring relations: the Higgs branch (with its nilpotent thickening) is cut out exactly by them. The retraction "set all derivatives to zero" is the restriction from field configurations to constant (zero-mode) configurations.

What the machine verified

Proved; `#print axioms VOA.ker_eq_of_liPresentationClassicallyFree: [propext, Classical.choice, Quot.sound]`. Re-checked by the author of this chapter with `lake env lean -DmaxSynthPendingDepth=3` on a scratch file (Section 24.11).

Theorem 24.7 (The conditional capstone). *For any of the seven cases, any VOA W, any current C_2 presentation P and any finite-dimensional carrier family: current-jet surjectivity, a geometric carrier embedding and the ordinary carrier character identity imply that the case is classically free for P and that P's ideal is the full kernel of the current-coordinate map.*

```

From the mathematics to the Lean statement

The conclusion is a conjunction: classical freeness *and* ker = `P.ideal`. The hypotheses are exactly packages 2, 3, 4; package 1 is P itself. The proof is the composition of Theorems 24.5 and 24.6. As explained in the warning below, the strength of the statement lies in package 4 for a carrier that is *not* chosen ad hoc.

Proof on paper. Theorem 24.5 with the unbundled packages, then Theorem 24.6. □

Physical meaning

"If the particle model is large enough (package 3) and counts the Schur index exactly (package 4), the chiral algebra is classically free and its Higgs branch relations are the listed ones."

What the machine verified

Proved; `#print axioms`: `[propext, Classical.choice, Quot.sound]` (re-checked by the author, Section 24.11). It is a reduction: no Deligne VOA is classically free in this chapter.

The module docstring of the capstone file and the docstring of `caseClassicallyFree_of_explicit_inputs` are out of date (they predate the general affine VOAs and the containment field); the statements are correct. Both documentation defects are listed, once, in Section 24.12.

24.3 The explicit presentation: singular vectors and coadjoint propagation

The paper input U2 is: the symbols of the weight-two singular vectors lie in the kernel. The Lean proof is uniform: (1) a vector killed by all positive current modes lies in the maximal ideal, so it is 0 in L_k; (2) the C_2-symbol of the explicit singular vector is the highest relation P_0 (up to a scalar and a C_2 correction); (3) the kernel of the current-coordinate map is stable under the coadjoint derivations ad_b, because in $\mathrm{gr}^{\mathrm{Li}} W$ the zero mode of a current acts as a derivation; (4) a breadth-first list of single-term identities $\mathrm{ad}_b P_j = c\,P_k$, $j < k$, reaches every relation.

24.3.1 The A_2 relations

Definition 24.8 (The A_2 relation ideal). In the coordinates $X_0, \dots, X_7$ of $e_1, e_2, e_{12}, f_1, f_2, f_{12}, h_1, h_2 \in \mathfrak{sl}_3$, put $Z = 3\sum_a X_a g^a$ (with g^a the trace-dual basis) and let P_a be one third of the entry of Z^2 at the position of the a-th generator (and of the two diagonal differences for $a = 6, 7$). Then $I_2^{\mathrm{ns}} = \mathrm{span}(P_0, \dots, P_7) \cong V(\theta)$, and I_2^{ns} (the ideal) is generated by these eight quadrics.

File `VOA/DeligneAudit/A2Relations.lean`.

def I2ns : Ideal (MvPolynomial (Fin 8) ℂ) := Ideal.span (Set.range relationPoly)
```

From the mathematics to the Lean statement

Namespace `VOA.DeligneAudit.A2`. `![…]` is a vector literal (entry a is `relationPoly a`); `X a * X b` is the monomial $X_a X_b$. The comments give each polynomial in Lie notation; for instance the highest one is $P_2 = e_{12}(h_1 - h_2) + 3e_1e_2$. The Lean side proves homogeneity of degree 2 (`relationPoly_isHomogeneous`) and linear independence (`relationPoly_linearIndependent`). **Not Lean-checked**: that the span is ad-stable and equals the adjoint summand of $\mathrm{Sym}^2 \mathfrak{sl}_3$; this was checked outside Lean, by exact rational computation in the generator scripts. It is not needed for soundness: the presentation theorem below proves each P_a is in the kernel, and whether the eight span all of I_2^{ns} only matters for the *later* character equality, where a wrong list would make the carrier too large and the chain impossible to close. Note also that the Casimir is not among the relations.

Physical meaning

These eight quadrics are the C_2-shadows of the eight null states at weight two of $L_{-3/2}(\mathfrak{sl}_3)$, the chiral algebra of the H_2 Argyres–Douglas theory: Higgs branch chiral-ring relations transforming in the adjoint of the $SU(3)$ flavour symmetry. *Heuristic, not Lean:* the scheme they cut out in $\mathfrak{sl}_3^*$ is non-reduced (the Casimir is nilpotent modulo the eight quadrics, not zero), and its reduced variety is expected to be the minimal nilpotent orbit closure, the one-$SU(3)$-instanton moduli space. The library proves neither statement, and it does not identify (I_2^{ns}) with any ideal from the literature: for $\mathfrak{sl}_3$ the ring R_V is $\mathrm{Sym}\,\mathfrak{sl}_3$ modulo these eight quadrics and nothing more.

What the machine verified

Definitions; homogeneity and independence proved, axioms standard.

24.3.2 Singular vectors die in the simple quotient

Theorem 24.9 (Positive-mode singularity implies membership in the maximal ideal). *Let $\mathfrak{g}$ be given by Lie data D, $k + h^\vee \neq 0$, and $t \in V^k(\mathfrak{g})$ homogeneous of weight $w > 0$. If $J^a_{(i)}t = 0$ for every current a and every $i \geq 1$, then t lies in the maximal graded ideal, hence vanishes in $L_k(\mathfrak{g})$.*

File `VOA/DeligneAudit/D4LieSingularGeneric.lean` (a re-export, under the `D4Lie` namespace, of the type-generic lemmas of `VOA/AffineGeneral/Singular.lean`).

```
def SingP (t : Vacuum D k) : Prop := ∀ (a : ι) (i : ℤ), 1 ≤ i → J D k a i t = 0

theorem mem_maxIdeal_of_SingP {t : Vacuum D k} (ht : SingP D k t)
    {w : ℤ} (hw : 0 < w) (hmem : t ∈ gradingZA D k w) : t ∈ maxIdeal D k hk :=
  VOA.AffineGeneral.mem_maxIdeal_of_SingP D k hk ht hw hmem
```

From the mathematics to the Lean statement

Namespace `VOA.DeligneAudit.D4Lie`, but the section is generic: `D : LieData κ ι` for any finite index type ι (Chapter 23). `Vacuum D k` is the vacuum module $V^k(\mathfrak{g})$, `J D k a i` the mode $J^a_i = J^a_{(i)}$ of the current (for weight-one currents the two mode labels coincide), `gradingZA D k w` the weight-w subspace and `maxIdeal D k hk` the maximal graded ideal, whose quotient is `simpleVOA D k hk` $= L_k(\mathfrak{g})$. The A_2 file `VOA/DeligneAudit/A2RelationsSingular.lean` has the same theorem for the bespoke $\mathfrak{sl}_3$ construction (`mem_maxIdeal_of_SingP3`). The zero vector is included (trivially).

Proof on paper. If $t = 0$ there is nothing to prove, so let $t \neq 0$. Two observations. (a) Zero modes preserve the hypothesis: if all $J^b_{(i)}$, $i \geq 1$, kill t, they also kill $J^a_{(0)}t$, because $[J^b_{(i)}, J^a_{(0)}] = [b, a]_{(i)}$ (the central term $i\,k(b,a)\delta_{i,0}$ vanishes for $i \geq 1$). (b) *Dong-type lemma*: for every state u of weight $\mathrm{wt}\,u$ and every $N \geq \mathrm{wt}\,u$, $u_{(N)}t = 0$. It suffices to take u a creation word $J^a_{(-n-1)}u'$, since such words span $V^k(\mathfrak{g})$; induct on the length of the word. The Borcherds iterate formula gives

$$\left(J^a_{(-n-1)}u'\right)_{(N)}t = \sum_{i\geq 0}(-1)^i\binom{-n-1}{i}\left(J^a_{(-n-1-i)}\,u'_{(N+i)}t - (-1)^{-n-1}\,u'_{(-n-1+N-i)}\,J^a_{(i)}t\right).$$

In the first term $N + i \geq \mathrm{wt}\,u'$, so $u'_{(N+i)}t = 0$ by induction. In the second, $J^a_{(i)}t = 0$ for $i \geq 1$; for $i = 0$, $J^a_{(0)}t$ again satisfies the hypothesis by (a), and $-n-1+N \geq \mathrm{wt}\,u'$ because $\mathrm{wt}\,u = \mathrm{wt}\,u' + n + 1$, so the induction hypothesis applies. Since $u_{(N)}$ shifts the weight by $\mathrm{wt}\,u - N - 1$, (b) says that every mode that lowers the weight kills t. Weight-one states of $V^k(\mathfrak{g})$ are quasi-primary ($L_1 x_{(-1)}\mathbf{1} = 0$). Hence t is *strongly singular* of positive weight (Chapter 5, Definition 5.34: nonzero, homogeneous of positive weight, and killed by every weight-lowering mode), so the ideal it generates lives in positive weight, does not contain the vacuum, and lies in the maximal graded ideal (Definition 5.20). □

Physical meaning

A singular (null) vector generates a submodule of zero norm; in the physical (simple) theory it is set to zero. The theorem says "primary under the currents and of positive weight" is enough to be null.

What the machine verified

Proved; axioms standard. The A_2 analogue likewise.

Theorem 24.10 (The A_2 singular vector). *At $k = -3/2$, the vector $v = 2h_1(-1)e_{12}(-1)\mathbf{1} - 2h_2(-1)e_{12}(-1)\mathbf{1} + 6e_2(-1)e_1(-1)\mathbf{1} + 3e_{12}(-2)\mathbf{1}$ of $V^{-3/2}(\mathfrak{sl}_3)$ is killed by all positive current modes; hence its image in $L_{-3/2}(\mathfrak{sl}_3)$ is zero.*

File `VOA/DeligneAudit/A2RelationsSingular.lean`.

```
def singVec : Vacuum (-3 / 2) :=
  (2 : ℂ) • J (-3 / 2) 6 (-1) (J (-3 / 2) 2 (-1) (vacuumA (-3 / 2)))
    - (2 : ℂ) • J (-3 / 2) 7 (-1) (J (-3 / 2) 2 (-1) (vacuumA (-3 / 2)))
    + (6 : ℂ) • J (-3 / 2) 1 (-1) (J (-3 / 2) 0 (-1) (vacuumA (-3 / 2)))
    + (3 : ℂ) • J (-3 / 2) 2 (-2) (vacuumA (-3 / 2))

theorem singVec_singP3 : SingP3 (-3 / 2) singVec := by

theorem simpleProjection_singVec :
    simpleProjection (-3 / 2) level_add_three_ne_zero singVec = 0 := by
```

From the mathematics to the Lean statement

`J (-3 / 2) a m` is the mode m of the a-th generator on the bespoke $V^{-3/2}(\mathfrak{sl}_3)$ (the $\mathfrak{sl}_3$ files `VOA/Examples/AffineSl3*.lean`); index 6, 7 are h_1, h_2, 2 is e_{12}, 0, 1 are e_1, e_2. `SingP3 k t` is `SingP` for this construction: $J_i^a t = 0$ for all a and $i \geq 1$. `simpleProjection` is the quotient map to $L_{-3/2}(\mathfrak{sl}_3)$. The vector is Perše's, translated from the certificate basis (map recorded in `A2Relations.lean`). Its C_2-symbol is $2P_2$ minus the C_2-term $3e_{12}(-2)\mathbf{1}$. Whether $v \neq 0$ is *not* proved and not needed (it would need PBW independence; the argument only uses membership in the ideal).

Proof on paper. Modes $x(1)$ and $x(2)$ are computed from the affine commutator $[x_m, y_n] = [x, y]_{m+n} + mk(x, y)\delta_{m+n,0}$: for each of the eight generators x and each of the two modes $x(1)$, $x(2)$, one expansion, sixteen in all, each giving zero exactly because $k = -3/2$. Modes $x(m)$, $m \geq 3$, vanish because they lower the weight below zero. Then Theorem 24.9. □

Physical meaning

This is the weight-two null state of the H_2 chiral algebra; its existence at precisely $k = -3/2$ is the 2d reflection of the 4d Higgs branch relation $(\mu \otimes \mu)|_{\mathbf{8}} = 0$ for the $SU(3)$ moment map μ.

What the machine verified

Proved; `#print axioms` of `singVec_singP3`, `simpleProjection_singVec`: standard three.

24.3.3 Coadjoint propagation

Theorem 24.11 (Li zero modes are the coadjoint derivations). *Let W be any VOA with eight weight-one states g_i, and T a table with $(g_b)_{(0)}g_i = \sum_c T_{bic}g_c$ in weight one, as an equality of degree-zero classes (in F^0W_1/F^1W_1), not of states. Let ad_b be the derivation of $\mathbb{C}[X]$ with $X_i \mapsto \sum_c T_{bic}X_c$. Then $\mathrm{cls}(\mathrm{ad}_b\, p) = (g_b)_{(0)} \cdot \mathrm{cls}(p)$ for every polynomial p, where cls is the current-coordinate map into $\mathrm{gr}^{\mathrm{Li}} W$. In particular $\ker(\mathrm{cls})$ is ad-stable.*

File `VOA/DeligneAudit/A2RelationsPresentation.lean`.

```
def adPolyT (T : Fin 8 → Fin 8 → Fin 8 → ℂ) (b : Fin 8) :
    Derivation ℂ (MvPolynomial (Fin 8) ℂ) (MvPolynomial (Fin 8) ℂ) :=
  mkDerivation ℂ fun i => ∑ c, T b i c • X c

theorem clsG_adPolyT (T : Fin 8 → Fin 8 → Fin 8 → ℂ)
```

```
    (hT : ∀ b i, ∃ h : W'.smul (g b) 0 (g i) ∈ W'.grading ((1 : ℕ) : ℤ),
      liDegreeZeroClass W' 1 ⟨W'.smul (g b) 0 (g i), h⟩ = clsG W' g hg (∑ c, T b i c • X
       ↪ c))
    (b : Fin 8) (p : MvPolynomial (Fin 8) ℂ) :
    clsG W' g hg (adPolyT T b p) = zeroModeG W' g hg b (clsG W' g hg p) := by
```

From the mathematics to the Lean statement

`clsG W' g hg` is `aeval` of the degree-zero classes; `zeroModeG … b` is the Li-graded mode 0 of the class of g_b. On $\mathrm{gr}^{\mathrm{Li}} W$ the products $a_{(n)}b$ with $n \geq 0$ lower the Li filtration and induce a bracket; for $n = 0$ and a of weight one this is the Poisson bracket $\{g_b, -\}$ of the classical limit, and it is a derivation of the commutative product (`liAssociatedGradedMode_leibniz`). `W'.smul (g b) 0 (g i)` is $(g_b)_{(0)}g_i$. The generalization to any finite index set is `clsG_adPolyT'` in `VOA/DeligneAudit/D4LiePresentationBase.lean`, used by all other types.

Proof on paper. Both sides are derivations in p (the right side by Leibniz for the Li zero mode), and they agree on generators by hT. □

Physical meaning

The flavour symmetry acts on the Higgs branch chiral ring by the coadjoint action; the space of relations is a G-representation. This is the classical (Poisson) shadow of the current zero modes generating the global symmetry.

What the machine verified

Proved; axioms standard.

Theorem 24.12 (The explicit presentations for all seven types)**.** *For each* $X \in \{A_2, G_2, D_4, F_4, E_6, E_7, E_8\}$ *and the simple affine VOA* $W_X = L_k(\mathfrak{g}_X)$ *at the Deligne level, the ideal generated by the explicit relations of* I_2^{ns} *is contained in the kernel of the current-coordinate map, so* (currents, (I_2^{ns})) *is a current* C_2 *presentation.*

From the mathematics to the Lean statement

Names. The short name `I2ns_le_ker` denotes four different theorems; always use the full names: `VOA.DeligneAudit.A2.I2ns_le_ker`, `VOA.DeligneAudit.G2Lie.I2ns_le_ker`, `VOA.DeligneAudit.F4Lie.I2ns_le_ker`, `VOA.DeligneAudit.DeligneCarrier.E6.I2ns_le_ker`, and `VOA.DeligneAudit.D4Lie.I2ns_le_ker4`, `VOA.DeligneAudit.E7Lie.I2ns_le_ker7`, `VOA.DeligneAudit.E8Lie.I2ns_le_ker8`. Likewise `explicitPresentation` exists in the namespaces `A2`, `G2Lie`, `F4Lie`, `DeligneCarrier.E6`.
The VOAs. W (for A_2) is `AffineSl3.simpleVOA (-3/2) _`, the bespoke $\hat{\mathfrak{sl}}_3$ construction. `g2W`, `W4`, `f4W`, `W6`, `W7`, `W8` are `simpleVOA D k _` of Chapter 23 for the Lie data `g2CertData`, `d4CertData`, `f4CertData`, `e6LieData`, `e7CertData`, `e8CertData` at $k = -5/3, -2, -5/2, -3, -4, -6$ (`k6` is -3). The currents `genS ...`, `gen4`, ... are $J^a_{(-1)}\mathbf{1}$ in the "certificate basis" of the Lie algebra, the basis in which the relation lists were computed.
The ideals. `X.I` is `quadraticIdeal X.rel` (Definition 24.21): the ideal spanned by the listed quadrics (27, 105, 324, 650, 1539, 3875 of them). As for A_2, Lean proves each listed quadric is in the kernel; that the list spans exactly I_2^{ns} is checked outside Lean and is not needed for soundness (see the dictionary of Definition 24.8).
Hypotheses. None. These are unconditional theorems about specific VOAs.

Proof on paper. For each type: (1) one weight-two singular vector (three for D_4, one per summand) is killed by positive modes, checked by integer computations of $J^c(1)$ and $J^c(2)$ on $x(-1)y(-1)\mathbf{1}$ (`J_one_word2`, `J_two_word2`) against the table; hence it is 0 in L_k (Theorem 24.9). (2) Its C_2-symbol is the highest relation P_0; for the exceptional types no correction is needed because the quadratic part has no $x(-2)$ term (for A_2 there is one, which lies in C_2). (3) The kernel is ad-stable (Theorem 24.11). (4) A breadth-first search from P_0 under the lowering operators $\mathrm{ad}\, F_i$ produced, for every $k \geq 1$, a parent $j < k$, a generator b and nonzero scalars with $q \cdot \mathrm{ad}_b P_j = p \cdot P_k$; each identity is a sparse polynomial identity checked by the kernel (A_2: 7 identities by hand; G_2: 26; D_4: 102; F_4: 323; E_6: 649; E_7: 1538; E_8: 3874). Strong induction on k gives every P_k in the kernel: if P_j is in the kernel, so is $\mathrm{ad}_b P_j$, by the ad-stability of (3), and therefore so is $P_k = (q/p)\,\mathrm{ad}_b P_j$. □

Physical meaning

One null state of weight two per irreducible summand of the relation module, plus the flavour symmetry, generates all Higgs-branch relations at quadratic order. For E_8 this is the statement that the 3875 quadratic relations of the one-E_8-instanton moduli space (besides the Casimir) follow from one null vector of the Minahan–Nemeschansky chiral algebra.

What the machine verified

Proved for all seven types; every `#print axioms` in the presentation files is `[propext, Classical.choice, Quot.sound]` (campaign record: earlier umbrella build; later targeted builds; aggregate build green on 2026-10-28, Section 24.11). Unconditional, as containments listed quadrics $\subseteq$ ker; equality of the ideal with the full kernel is a theorem only for A_2 (Chapter 27).

Which VOA? Certificate-basis Lie data

For D_4, E_7, E_8 the VOA of the presentation is `simpleVOA d4CertData (-2) hk4` (resp. `e7CertData`, `e8CertData`): Lie data on the lattice Lie algebra (Chapter 23) with the certificate basis, the form Killing/12 (resp. /36, /60) and the Casimir transferred from the lattice data. The library also has `d4SimpleVOA` etc. built from `Module.finBasis`. The two are built from the same Lie algebra, form and $h^\vee$, but from different `LieData` (different bases), and the equality

of the resulting VOA structures (basis independence of the affine construction) is *not* proved. All D_4, E_7, E_8 results of the campaign are about the certificate-basis VOAs. Similarly three models of $\mathfrak{e}_6$ coexist (structure-constant table, lattice V_1, the `E6Lat` cert basis) and are not identified in Lean; the E_6 presentation uses the structure-constant model `e6LieData`. This is a scope remark, not an error: each theorem is about a genuine $L_k(\mathfrak{g})$.

Dead end: the "span plus C_2" generation criterion

The older surjectivity lemmas `liPresentedJetBidegreeMap_surjective_of_generators` and `liPresentedJetMap_hits_homogeneous_class_of_generators` (`VOA/Filtered/LiGeneratorWords.lean`, Chapter 11, Theorem 11.16) assume $\top = \mathrm{span}(\mathrm{gen} \cup \{\mathbf{1}\}) + C_2(V)$. For every Deligne VOA this is *false*: in weight two the right side is $C_2(V)_2$, but $(R_V)_2 = \mathrm{Sym}^2 \mathfrak{g}/I_2^{\mathrm{ns}} \supseteq V(2\theta) \oplus \mathbb{C}Q \neq 0$; for any finite family it fails because R_V is infinite-dimensional: these VOAs are *quasi-lisse* (the associated variety $\mathrm{Specm}\, R_V$ has finitely many symplectic leaves; here it is $\overline{\mathbb{O}_{\min}}$) but not *lisse* ($R_V$ finite-dimensional). Generation must come from ordered current words (next section).

24.4 Current-jet surjectivity

Definition 24.13 (Generator words span Li's filtration). For states $a^1, \dots, a^g$ of weights w_i, a *generator word* is $a^{i_1}_{(-r_1-1)} \cdots a^{i_s}_{(-r_s-1)}\mathbf{1}$, of *level* $r_1 + \cdots + r_s$. Let C_p be the span of the generator words of level $\geq p$. The generators *span Li's filtration* if $F^pV \subseteq C_p$ for all p.

File `VOA/Filtered/GeneratorWordLiSurjectivity.lean`.

```
abbrev genWordState (l : List (Fin g × ℕ)) : V :=
  wordAct (adjointWeakModule W) (genWord gen wt l) W.vacuum

def genWordPiece (p : ℕ) : Submodule ℂ V :=
  Submodule.span ℂ {u | ∃ l : List (Fin g × ℕ), p ≤ pairsLevel l ∧ genWordState W gen wt l
   ↪  = u}

def GeneratorWordsSpanLiFiltration : Prop :=
  ∀ p : ℕ, liFiltration W p ≤ genWordPiece W gen wt p
```

From the mathematics to the Lean statement

A list of pairs (i, r) encodes a word, `pairsLevel` is $\sum r$, and `wordAct` applies the letters as modes (Chapter 11, Theorem 11.16). Since generator words of level $\geq p$ always lie in F^p (`genWordPiece_le_liFiltration`), the condition is equivalent to $F^p = C_p$. It is a *linear spanning* condition on all of V, which holds for strongly generated VOAs; it is not the false "span $+C_2$" condition of the warning above.

Physical meaning

Every operator of Li level $\geq p$ is a sum of normal-ordered products of the generators with at least p derivatives in total. For affine VOAs this is the PBW basis of current modes.

What the machine verified

Definitions (Chapter 11 extension: `GeneratorCurrentLiSpanning.lean`, `GeneratorWordLiSurjectivity.lean`).

Theorem 24.14 (Current-jet surjectivity for every Deligne type). *(i) For any case, VOA and presentation, if the currents span Li's filtration then* `CurrentJetSurjectivity` *holds. (ii) For every Lie data D and non-critical k, the currents of $L_k(\mathfrak{g})$ span Li's filtration. Hence current-jet surjectivity holds for every explicit presentation of Theorem 24.12.*

 ↪  wt) :
    GeneratorWordsSpanLiFiltration (QuotVOA.quotientVOA W I hI hgr)
      (fun i => I.mkQ (gen i)) wt := by
```

From the mathematics to the Lean statement

`currentModeTarget q m` is $\max(q-m-1,0)$ (`Filtered/AffineCurrentLi.lean`): the tracked estimate says $a^i_{(m)}C_q \subseteq C_{\max(q-m-1,0)}$. `hcomm` is the affine commutator with structure constants f and a central term `cen`; `hvac` is $J^i_m\mathbf{1}=0$ for $m\geq 0$. The quotient theorem passes spanning to any graded quotient, in particular to $L_k = V^k/\text{max ideal}$. In (ii), `presentation case D k hk` is the full-kernel presentation of Chapter 23's $L_k(\mathfrak{g})$; its `gen` are the same currents as those of the explicit presentations, which is why each `explicitCurrentJetSurjectivity*` is a one-line application. For A_2 the bespoke version is `VOA.DeligneAudit.A2.currentJetSurjectivity`.

Proof on paper. (i) The jet monomial $\prod x_{i_k}^{(r_k)}$ maps to the class of the corresponding generator word (Chapter 11); if $F^p = C_p$, every class in $\mathrm{gr}^{\mathrm{Li}}_{p,N}$ is the class of a combination of words of level exactly p, hence in the image. (ii) The affine commutator moves a mode J^i_m through a word: commuting past $J^j_{(-r-1)}$ produces J^c_{m-r-1} (level drops by at most $m+1$) and a central scalar; non-negative modes kill the vacuum. This gives the tracked estimate; with PBW spanning of V^k by current words, the Borcherds iterate formula identifies F^p with C_p, and the property descends to the simple quotient. □

Physical meaning

The classical shadow of every operator is a differential polynomial in the currents: currents strongly generate, and Li's filtration counts derivatives.

What the machine verified

Proved, unconditional, all types; axioms standard (`A2.currentJetSurjectivity`, `currentJetSurjectivity_of_genWordSpan`, the three generic spanning theorems).

24.5 The geometric carrier

24.5.1 Quadratic ideals and the current carrier

Definition 24.15 (Quadratic relations and ideals)**.** For a coefficient matrix $q : \sigma \times \sigma \to K$ put $\mathrm{quad}(q) = \sum_{x,y} q(x,y) X_x X_y$; for a family $Q : \rho \to (\sigma \times \sigma \to K)$, $\mathrm{quadIdeal}(Q)$ is the ideal generated by the $\mathrm{quad}(Q_r)$.

File `VOA/Commutative/QuadraticJetCoefficientPairing.lean`.

```
def quadraticRelation (q : σ × σ → K) : MvPolynomial σ K :=
  ∑ xy, q xy • (MvPolynomial.X xy.1 * MvPolynomial.X xy.2)

def quadraticIdeal (Q : ρ → σ × σ → K) : Ideal (MvPolynomial σ K) :=
  Ideal.span (Set.range (fun r => quadraticRelation (Q r)))
```

From the mathematics to the Lean statement

Exactly as stated. The matrix need not be symmetric; only $q(x,y) + q(y,x)$ matters.

Physical meaning

A quadratic Higgs-branch relation, written in a basis of the flavour currents: a matrix q gives the chiral-ring relation $\sum_{x,y} q(x,y) J^x J^y = 0$ among the moment-map components, and a family of such matrices is a list of these relations. The ideal they generate is the ideal of the (possibly non-reduced) Higgs branch.

What the machine verified

Definitions.

Definition 24.16 (The current carrier W_m and the auxiliary carrier)**.** Fix a basis σ of $\mathfrak{g}^*$ and quadrics Q. A *tensor polynomial* with m current and d auxiliary particles is a function $t \mapsto p_t$ from labellings $t : \{1..m\} \to \sigma$ to polynomials in $z_1, \dots, z_{m+d}$. It is *symmetric* if simultaneous permutation of roots and labels fixes it. For a pair $i < j$ of current slots, a relation q and spectator labels t, the *collision readback* is $\sum_{x,y} q(x,y)\, p_{t[i\mapsto x, j\mapsto y]}|_{z_j = z_i}$. The *current carrier* $\mathrm{currentCarrier}(Q,m,d)$ consists of the symmetric tensor polynomials all of whose readbacks vanish. The *auxiliary carrier* additionally requires, for every pair involving an auxiliary particle, that the polynomial vanish on that collision. $\mathrm{degreePiece}(C,r)$ is the subspace of C of polynomials homogeneous of degree r. $W_m := \mathrm{currentCarrier}(I_2, m, 0)$.

File `VOA/Commutative/QuadraticCurrentFunctionalCarrier.lean`.

    Submodule K C where
  carrier := {p | ∀ t, (p.1 t).IsWeightedHomogeneous (fun _ => 1) r}
```

From the mathematics to the Lean statement

`Particle m d` $=\{0,\dots,m+d-1\}$: currents first, then auxiliary particles. `ExtendsCurrentPermutation e g` says the root permutation e restricts to g on current slots (auxiliary roots may be permuted freely). `insertPair ij t (x,y)` replaces the labels in slots i,j by x,y. `projectedDiagonal a b _ c p` is $\sum_t C(c_t)\,\mathrm{collisionMap}_{a\to b}(p_t)$, where `collisionMap` substitutes $z_a := z_b$ (Chapter 20). The auxiliary condition is vanishing of p_t on every collision $z_i = z_j$ with j auxiliary (`m ≤ ij.1.2.val`). The `conductor` is $\prod_{i<j}(z_j - z_i)^{o(i,j)}$ with $o = 0$ for two currents, 1 for a current and an auxiliary particle, 2 for two auxiliary ones; its degree is $md + d(d-1)$ (`conductorDegree_eq`). The proof fields of the submodules are omitted.

Same as the paper? Yes: this is B4's W_m, literally as "polynomial kernel", with no fusion module or representation theory in the definition (the docstring says so).

Physical meaning

A Feigin–Stoyanovsky "functional model": a state with m current quanta is a symmetric wave function of their positions (the z_i) with values in $\mathfrak{g}^{*\otimes m}$; the quadratic relations become boundary conditions on two-particle collisions (an exclusion rule). Casimir quanta are extra particles with a stronger exclusion (a double zero against each other).

What the machine verified

Definitions; built in the umbrella target `VOA.Deligne`.

Theorem 24.17 (The restricted dual of a jet piece is a carrier piece (B4)). *For any field K, quadrics Q, and $r \le N$: the dual of the piece of the order-N presented jet algebra of* quadIdeal(Q) *with m particles and r derivatives is linearly isomorphic to* degreePiece(currentCarrier$(Q, m, 0), r)$.

File `VOA/Commutative/QuadraticJetRestrictedDual.lean`.

```
def restrictedDualEquivCurrentCarrier (Q : ρ → σ × σ → K) (N m r : ℕ) (hr : r ≤ N) :
    (quotientPiece Q N m r →ₗ[K] K) ≃ₗ[K] degreePiece (currentCarrier Q m 0) r :=
  (pieceDualEquivCoefficients Q N m r).trans (fixedQuadraticReindexingEquiv Q N m r hr)
```

From the mathematics to the Lean statement

`quotientPiece Q N m r` is the image in $J_N(K[\sigma]/\text{quadIdeal}\, Q)$ of the jet polynomials with m factors ("particles") and total derivative order r. `≃ₗ[K]` is a linear isomorphism. The isomorphism reads a functional on jet monomials $x_{t_1}^{(a_1)} \cdots x_{t_m}^{(a_m)}$ as the coefficient of $z_1^{a_1} \cdots z_m^{a_m}$ in the t-component (`restrictedDualEquivCurrentCarrier_coeff`). No characteristic or representation-theoretic hypothesis.

Proof on paper. A functional on the jet algebra is a family of coefficients $F(e)$ on jet monomials. It descends to the quotient iff it annihilates the ideal, i.e. iff for every relation, every order n and every spectator monomial, the Cauchy convolution $\sum_{a+b=n} q(x,y)F(\dots x^{(a)}y^{(b)}\dots)$ vanishes (spectators must be handled explicitly; annihilating the generators alone is not enough). Reindex F as a tensor polynomial: the coefficient of z^a at labels t. The convolution of order n in slots i, j is the w^n-coefficient of the readback at $z_i = z_j = w$; so the descent condition is exactly the current equations; symmetry is commutativity of the jet monomials. □

Physical meaning

The dual of the space of classical operators with m currents and r derivatives is the space of m-particle wave functions of total degree r obeying the collision rules: operators ↔ correlation-function-like generating functions.

What the machine verified

Proved; axioms standard.

Theorem 24.18 (Geometric carrier embedding for every quadratic presentation). *If the ideal of a current C_2 presentation is* quadIdeal(Q), *then* $\text{Carrier}_{p,N} :=$ degreePiece(currentCarrier$(Q, N - p, 0), p)$ *receives an injective (for $p \le N$ bijective) restricted-dual map in every bidegree; hence a* `GeometricCarrierEmbedding`.

File `VOA/DeligneAudit/A2CarrierEmbedding.lean`.

```
abbrev carrierPiece (Q : ρ → σ × σ → K) (p N : ℕ) : Submodule K (currentCarrier Q (N - p)
 ↪  0) :=
```

```
abbrev Carrier (Q : ρ → σ × σ → K) (p N : ℕ) : Type _ := carrierPiece Q p N

def geometricCarrierEmbedding_of_quadraticIdeal {ρ : Type}
    (P : CurrentC2Presentation case W)
    (Q : ρ → Fin case.currentDimension × Fin case.currentDimension → ℂ)
    (hQ : P.ideal = quadraticIdeal Q) :
    GeometricCarrierEmbedding case W P (Carrier Q) where
  toCarrier := (carrierMaps Q P.ideal hQ).1
  injective := (carrierMaps Q P.ideal hQ).2
```

From the mathematics to the Lean statement

`carrierPiece Q p N` is `degreePiece (currentCarrier Q (N - p) 0) p` (the body is omitted in the quote). With base weights one, Li bidegree (p,N) means $N-p$ currents and p derivatives (`jetLiBidegreePiece_eq_polynomialPiece`); for $N < p$ the piece is 0. A companion `geometricCarrierEmbedding_of_span` accepts an ideal spanned by homogeneous quadrics, which it converts to `quadraticIdeal` form (`span_homogeneousQuadratic_eq_quadraticIdeal`).

Proof on paper. Theorem 24.17 plus the bidegree dictionary. □

Physical meaning

The particle model sees every classical operator, for free: it *is* the dual of the classical operator space.

What the machine verified

Proved; axioms standard. Instantiated for all seven types (`A2.geometricCarrierEmbedding`, `explicitGeometricCarrierEmbedding4`, `E6.geometricCarrierEmbedding`, ...).

The geometric package is weak on its own

For *any* presentation one could take $\mathrm{Carrier}_{p,N} :=$ the dual of the jet piece and the identity map; `GeometricCarrierEmbedding` would hold trivially. Its content is only in combination with `OrdinaryCarrierCharacter` for the *same* carrier. For the literal carrier above, the carrier is (dual to) the jet algebra itself, so package 4 is the statement $\mathrm{Hilb}\, J_\infty \widetilde{R} = \mathrm{ch}\, V$, which is the whole content of classical freeness. All the hard mathematics (U3–U6, B1–B8, (★)) is in proving the inequality $\le$ of the next theorem; the geometric package is not where the difficulty lies.

Theorem 24.19 (The character package is one inequality). *Given current-jet surjectivity and a geometric carrier embedding,* $\dim W_N \le \sum_{p\le N} \dim \mathrm{Carrier}_{p,N}$ *holds automatically; hence* `OrdinaryCarrierCharacter` *follows from the reverse inequality. For a quadratic presentation, classical freeness and* $\ker = \mathrm{quadIdeal}(Q)$ *follow from current-jet surjectivity and the named residual* $\sum_p \dim \mathrm{Carrier}(Q)_{p,N} \le \dim W_N$.

File `VOA/DeligneAudit/A2CarrierUpperBound.lean`.

      (MvPolynomial.aeval fun i =>
        liDegreeZeroClass W 1 ⟨P.gen i, P.gen_weight_one i⟩).toRingHom =
    P.ideal :=
```

From the mathematics to the Lean statement

`QuadraticCarrierUpperBound Q W` is a named *hypothesis* structure (a `Prop`), never an axiom; by `quadraticCarrierUpperBound_iff` it is equivalently "$\sum_p$ dim(jet bidegree piece)$\leq$ dim W_N", i.e. Hilb $J_\infty(\mathbb{C}[X]/\mathrm{quadIdeal}\,Q) \leq \mathrm{ch}\,W$ coefficientwise. Per type this gives one-input theorems, e.g. `D4Lie.explicit_classicallyFree_of_upperBound`, `DeligneCarrier.E6.classicallyFree_of_upperBound`.

Proof on paper. $\dim W_N = \sum_p \dim \mathrm{gr}^{\mathrm{Li}}_{p,N} \leq \sum_p \dim(\text{jet piece}) \leq \sum_p \dim \mathrm{Carrier}_{p,N}$ by surjectivity and injectivity; with the reverse inequality we get equality, and the capstone applies. □

Physical meaning

One direction is free: the chiral algebra never has more operators of weight N than its classical limit, because every operator has a classical shadow (Li's map is onto); this is $\dim W_N \leq \sum_p \dim \mathrm{Carrier}_{p,N}$. The nontrivial direction is the reverse, that the classical limit has no more operators than the chiral algebra (no classical operator fails to lift). Proving that upper bound on the classical count forces equality, and equality is classical freeness. This is the same statement as the physics box of Theorem 24.25, seen from the other end of the chain.

What the machine verified

Proved; axioms standard. The upper bound itself is what the rest of the Deligne campaign (this chapter's chain plus Chapters 25–27) supplies: unconditionally for A_2, conditionally on named inputs for the other six types.

Example 24.20 (A_2 in weights one and two). Take $\mathfrak{g} = \mathfrak{sl}_3$, $n = 8$, the presentation ideal (I_2^{ns}) with its eight quadrics, and $\mathrm{Carrier}_{p,N} = \mathrm{degreePiece}(\mathrm{currentCarrier}(\mathcal{R}, N-p, 0), p)$: $N-p$ current particles and p derivatives.

- $N = 1$. For $p = 0$: one particle, degree 0: a function of one label with constant values, dimension 8. For $p = 1$: zero particles and degree one, which is 0 (a polynomial in no variables of degree one vanishes). Total 8, the number of currents $x_{(-1)}\mathbf{1}$.
- $N = 2$. For $p = 0$: two particles, degree 0, symmetric, with the collision equations of the eight relations; this is the dual of $\mathrm{Sym}^2\,\mathfrak{g}/I_2^{\mathrm{ns}}$, of dimension $36 - 8 = 28 = 27 + 1$ (the summand $V(2\theta)$ and the Casimir Q, which is *not* killed). For $p = 1$: one particle, degree one: the eight linear functions $c\,z_1$, one per label, dimension 8 (the jets $x^{(1)}$, shadows of $x_{(-2)}\mathbf{1}$). For $p = 2$: zero particles, 0. Total $28 + 8 = 36$.

On the VOA side, $V^{-3/2}(\mathfrak{sl}_3)$ has $8 + 36 = 44$ states of weight two (the $x_{(-2)}\mathbf{1}$ and the symmetric products $x_{(-1)}y_{(-1)}\mathbf{1}$). The singular vector of Theorem 24.10 and its $\mathfrak{sl}_3$-orbit, an eight-dimensional copy of the adjoint, die in $L_{-3/2}(\mathfrak{sl}_3)$, and the literature character $\mathrm{ch}\,L_{-3/2}(\mathfrak{sl}_3) = 1 + 8q + 36q^2 + \cdots$

says nothing else does in weight two: $44 - 8 = 36$. So in weights one and two the carrier count equals $\dim W_N$, which is what the character package (and Theorem 24.19) asks in every weight. What Lean proves here, with no input, is the inequality $\dim(W_N) \leq$ carrier count of the theorem above, so $\dim L_{-3/2}(\mathfrak{sl}_3)_2 \leq 36$; the reverse inequality, in all weights, is the open content.

24.5.2 The commutative layer, collectively

Twenty-one files of `VOA/Commutative/` serve the carrier. They are pure commutative algebra over a field, with no Lie theory. We list what each group proves.

- *Coefficient duality* (`QuadraticJetCoefficientPairing`, `QuadraticCurrentCoefficientReindexing`, `QuadraticCurrentCollisionCoefficients`, `QuadraticJetRestrictedDual`, `QuadraticCurrentFunctionalCarrier`, the file of Definition 24.16): Theorem 24.17.
- *Auxiliary particles* (`DeligneAuxiliaryCollision`, `DeligneAuxiliaryDegree`, `QuadraticCurrentAuxiliaryCoefficients`, `QuadraticCurrentAuxiliaryTensor`, `QuadraticCurrentAuxiliaryGrading`, `QuadraticCurrentGradedCarrier`, `SymmetricPolynomialTensorCoefficients`): the conductor divides every auxiliary-carrier element and division is an isomorphism onto the current carrier with d spectators shifted by $md + d(d-1)$ (`gradedConductorEquiv`, `finrank_auxiliary_eq_current`); the current carrier with d auxiliary roots is currentCarrier$(Q, m, 0) \otimes \mathbb{C}[v_1..v_d]^{S_d}$, degree by degree (`currentAuxiliaryTensorEquiv`, `gradedCoefficientsEquiv`). These are B2–B3. They reuse `RootedGordonConductorDivisibility` and `P3ConductorDegree` from Chapter 20.
- *Casimir filtration* (`CasimirCostFiltration`, `FiniteCostDegeneration`, `DeligneCasimirJetFiltration`, `MvPolynomialMinimumWeight`): the filtration of a weight-N quotient by powers of an ideal generated in weight ≥ 2 has length $\leq N/2$, and its layers telescope.
- *Two points* (`QuadraticTwoPointCarrier`): B7 at $m = 2$ (historical; superseded by the certificates of Section 24.8).
- *Globalization* (`HeightOneGlobalization`, `FreeLatticeGlobalization`, `DiscriminantLatticeGlobalization`): a noetherian UFD is the intersection of its localizations at height-one primes (`iInf_heightOneLocalization_eq_bot`; Mathlib has this only for Dedekind domains), and the free-lattice version (B8's normality).
- *Support* (`FiniteJetLiSupport`): jet bidegrees (p, N) with $p > N$ are zero.

All are unconditional and `#print axioms`-standard.

24.6 The carrier chain: B1 and the resummation D3

Definition 24.21 (Carrier type data)**.** Carrier data $\mathcal{C}$ (Lean: `D`) consist of $n = \dim \mathfrak{g}$, a label set ρ (no finiteness is required here; sector data add `ρFin`), relations rel $: \rho \to$ (matrices) spanning I_2^{ns}, the Casimir matrix cas, and a proof of U3: $X_a \cdot Q \in$ quadIdeal(rel) for every a. Derived: $I =$ quadIdeal(rel), $Q =$ quad(cas), the carrier family, and the full matrix family fullMatrix $:$ Option $\rho \to \cdots$ with `none`$\mapsto$ cas (i.e. I_2).

File `VOA/DeligneAudit/DeligneCarrierData.lean`.

```
structure DeligneCarrierData where
  n : ℕ
  ρ : Type
  rel : ρ → Fin n × Fin n → ℂ
```

```
  cas : Fin n × Fin n → ℂ
  u3 : ∀ a : Fin n, X a * quadraticRelation cas ∈ quadraticIdeal rel

theorem Q_sq_mem : D.Q * D.Q ∈ D.I :=

def fullMatrix : Option D.ρ → Fin D.n × Fin D.n → ℂ
  | none => D.cas
  | some r => D.rel r
```

From the mathematics to the Lean statement

Namespace `VOA.DeligneAudit.DeligneCarrier`. The only proof obligation is `u3`. Nothing forces `cas` to be the Casimir or `rel` to span I_2^{ns}; the instances use the certified tables (Section 24.9), and the chain is sound for any data satisfying U3. The link to the VOA is made through the ideal: the presentation's ideal is `X.I` by `rfl`. `Q_sq_mem` ($Q^2 \in I$) follows from U3 since Q lies in the ideal of the X_a.

Physical meaning

U3 says the Sugawara shadow Q is annihilated by every current in the chiral ring modulo I_2^{ns}: T is nilpotent ($Q^2 = 0$) in R_V.

What the machine verified

Definition; `Q_sq_mem` proved (axioms standard). Instances: `A2data`, `D4data`, `G2data`, `F4data`, `E6data`, `E7data`, `E8data`, each with U3 kernel-checked.

Definition 24.22 (Carrier and sector dimensions; the named chain inputs)**.** For carrier data $\mathcal{C}$: carrierDim$(N) = \sum_{p \le N} \dim \mathrm{Carrier}_{p,N}$; auxDim$(m,d,p)$ = dim of degree-p piece of the auxiliary carrier of I_2; sectorDim(N,m,d) = auxDim$(m,d,N-m-2d)$ if $m + 2d \le N$, else 0; currentDim(m,d,r) the analogue for the current carrier. The *sector fusion bound* for a family F_m of power series is currentDim$(m,d,r) \le [q^r]F_m/((q)_m(q)_d)$; the *mixed fusion recursion* (U6) is $\mathrm{Dem}_n = M_{n,0}$ for the recursion $M_{0,b} = F_b$, $M_{a+1,b} = M_{a,b+1} + q^{2a+b+1}M_{a,b}$. Here Dem_n stands for $\mathrm{Hilb}_q D(1, n\theta)$, the t-graded dimension of the n-th level-one Demazure module, and the recursion is Ravinder's: it builds the Demazure module of $n\theta$ out of fusion modules $\mathcal{F}_b$, one step $a \mapsto a+1$ at a time, the term $q^{2a+b+1}M_{a,b}$ recording the energy of the added piece (Chapter 26 discusses it).

```

From the mathematics to the Lean statement

Note the different relation families: `Carrier D` uses `D.rel` (I_2^{ns}, the presentation ring $\widetilde{R}$), while the sector dimensions use `D.fullMatrix` (I_2, Casimir included): in the auxiliary algebra the Casimir is a separate particle and the current sector obeys all of I_2. `qpoch m` is $(q)_m$ in $\mathbb{Q}[[q]]$, `coeff r` the q^r-coefficient. Sector (m, d) contributes at conformal weight $m + 2d + p$ (currents weigh one, the Casimir two). The three structures are named `Props`, never axioms; `CasimirAuxiliaryBound` is *proved* below, the other two are discharged or reduced elsewhere.

Physical meaning

The weight-N operator count is split by the number of current quanta m and Casimir quanta d; each sector is a free-particle Fock space with a fixed fusion fibre $\mathcal{F}_m$ and Bose statistics for d identical Casimir particles $(1/(q)_d)$.

What the machine verified

Definitions and named hypotheses.

Theorem 24.23 (B1: the Casimir layer bound). *For any carrier data $\mathcal{C}$ and all p, N, d: the d-th layer of the Casimir-adic filtration of the bidegree (p, N) piece of $J_\infty \widetilde{R}$ has dimension at most* $\mathrm{auxDim}(N - p - 2d, d, p)$ *(and is* 0 *if $p + 2d > N$). Consequently* $\mathrm{carrierDim}(N) \le \sum_{m+2d\le N} \mathrm{sectorDim}(N, m, d)$ *(`CasimirAuxiliaryBound D`) holds.*

File `VOA/DeligneAudit/DeligneCarrierFiltration.lean`.

```
structure CasimirLayerBound : Prop where
  le : ∀ p N d, Module.finrank ℂ ((casimirLayer D) p N d) ≤
    if p + 2 * d ≤ N then (auxDim D) (N - p - 2 * d) d p else 0
```

File `VOA/DeligneAudit/DeligneCarrierLayerBound.lean`.

```
theorem casimirLayerBound : (CasimirLayerBound D) := by

theorem casimirAuxiliaryBound : (CasimirAuxiliaryBound D) :=
  (casimirAuxiliaryBound_of_layerBound D) (casimirLayerBound D)
```

From the mathematics to the Lean statement

`casimirLayer D p N d` is the d-th associated quotient of the filtration of the bidegree image by powers of the jet ideal generated by the Hasse–Schmidt coefficients of Q (`casimirFiltration`, built from the generic `CasimirCostFiltration`). Its layers telescope to the bidegree dimension (`sum_casimirLayer_finrank`). No hypothesis other than the carrier data.

Hasse–Schmidt coefficients. For a polynomial $f \in \mathbb{C}[x_1, \dots, x_n]$, substitute $x_i \mapsto \sum_{r\ge 0} x_i^{(r)} u^r$ and expand: $f\big(\sum_r x^{(r)} u^r\big) = \sum_{b\ge 0} f_{(b)} u^b$. The coefficient $f_{(b)}$ is a polynomial in the jets, $f_{(b)} = D^{(b)} f = D^b f / b!$ for the jet derivation D; the jet ideal of (f) is generated by all

$f_{(b)}$. For the quadric Q, the coefficient $Q_{(b)}$ has conformal weight $b+2$.

Proof on paper. Fix the bidegree (p,N) and write $\mathcal{J} = J_\infty \widetilde{R}$, $\mathcal{J}_{p,N}$ for its bidegree piece, and $K \subseteq J_\infty \operatorname{Sym} \mathfrak{g}$ for the jet ideal of (Q), generated by the Hasse–Schmidt coefficients $Q_{(b)}$, $b \geq 0$.

Step 1 (the filtration). Filter $\mathcal{J}_{p,N}$ by the images $K^d\mathcal{J} \cap \mathcal{J}_{p,N}$, $d = 0, 1, 2, \dots$. Every $Q_{(b)}$ has weight at least two, so K^d vanishes in weight N once $2d > N$; the filtration has finitely many steps and the dimensions of its layers $\mathcal{J}^{(d)}_{p,N} = K^d/K^{d+1}$ add up to $\dim \mathcal{J}_{p,N}$. A layer is spanned by classes of products of exactly d Casimir jets $Q_{(b_1)} \cdots Q_{(b_d)}$ with a jet monomial in the currents. Counting weights, the current part has $m = N - p - 2d$ letters: the d Casimir factors carry weight $2d$ and the p derivatives are shared among all factors.

Step 2 (an auxiliary algebra that surjects onto the layer). Add one variable c of weight two (a "Casimir particle") and impose three kinds of quadratic relations: all of I_2 (including Q) on the currents, the mixed relations $x_a c$ for every a, and c^2. Map auxiliary jets to $\mathcal{J}$ by $c^{(b)} \mapsto Q_{(b)}$; this substitution commutes with taking Hasse–Schmidt coefficients (because it is an algebra map compatible with the jet derivation). Restrict to auxiliary jet monomials with exactly d letters c and pass to the d-th layer. Every auxiliary relation dies there:

- a relation of I_2^{ns} on currents is already 0 in $\widetilde{R}$;
- the relation Q on currents maps to some $Q_{(b')}$ times a monomial that already contains d Casimir jets, which lies in K^{d+1} and so is 0 in the d-th layer;
- the coefficient of order b' of $x_a c$ maps to the coefficient of order b' of $X_a Q$, which lies in the jet ideal of (I_2^{ns}) by U3, hence is 0;
- likewise $c^2 \mapsto Q^2 \in (I_2^{\mathrm{ns}})$ (`Q_sq_mem`, a consequence of U3).

So the map factors through the auxiliary quotient, and it is onto the layer because the layer is spanned by the images of such monomials (`auxToLayer_surjective`).

Step 3 (dualize). A linear functional φ on the layer gives coefficients φ(image of an auxiliary monomial) on auxiliary jet monomials; they satisfy every auxiliary quadratic coefficient equation (Step 2), and they determine φ (surjectivity). By the coefficient duality of Theorem 24.17, applied to the auxiliary relation family on $m + d$ particles, such coefficient families are the symmetric tensor polynomials whose collision readbacks for all auxiliary relations vanish. Restrict to the *label pattern* "currents in the first m slots, c in the last d". By symmetry no information is lost (every labelling with d labels c is a permutation of the pattern), and the readback conditions become: the equations of I_2 at current–current collisions; vanishing at every current–Casimir collision (the relation $x_a c$ has a single nonzero entry, so its readback is one component); vanishing at every Casimir–Casimir collision (from c^2). These are exactly the conditions defining auxiliaryCarrier(I_2, m, d), in degree p. So the dual of the layer injects into degreePiece(auxiliaryCarrier(I_2, m, d), p) (`layerToAux_injective`), whose dimension is auxDim(m, d, p) with $m = N - p - 2d$. Summing over d and p and reindexing $(p, d) \mapsto (m, d)$ gives `CasimirAuxiliaryBound`. □

Physical meaning

Organize operators by how many Sugawara factors they contain. Since T is nilpotent up to derivatives, each extra T behaves like a new particle with hard-core repulsion; the bound says there are no more operators than in that particle model.

What the machine verified

Proved, **unconditional**, for arbitrary carrier data; `#print axioms casimirLayerBound`: standard three (re-checked by the author, Section 24.11).

The docstrings of `CasimirAuxiliaryBound` and `SectorFusionBound` in `DeligneCarrierChain.lean` are out of date (the first is proved, the second does not use U4); see Section 24.12.

Theorem 24.24 (D3: the Gaussian resummation). *For any family F_m of power series over $\mathbb{Q}$ and every N,*

$$\sum_{m+d\le N}[q^N]\frac{q^{m+d+d(m+d)}F_m}{(q)_m(q)_d}=\sum_{n\le N}[q^N]\frac{q^n\,d_n}{(q)_n},\qquad d_n=\sum_{d\le n}q^{nd}\begin{bmatrix}n\\d\end{bmatrix}_q F_{n-d};$$

and if $\mathrm{Dem}_n=M_{n,0}$ *(U6), the right side equals* $\sum_{n\le N}[q^N]q^n\mathrm{Dem}_n/(q)_n$.

File `VOA/DeligneAudit/A2CarrierResummation.lean`.

```

    (F : ℕ → PowerSeries ℚ) (hF : SectorFusionBound D F)
    (hU6 : MixedFusionRecursion F (hilbSeries hilb)) (N : ℕ) :
    carrierDim D N ≤ demazureSumCoeff hilb N :=
```

From the mathematics to the Lean statement

`demazureSumCoeff hilb N` is the natural-number Demazure sum of Chapter 25 (`DeligneCharacter.lean`); `demazureSumCoeff_eq_demazureCoeffOf` identifies it with `demazureCoeffOf`. Hypotheses: the sector fusion bound (B2–B8 with U5; proved per type from U5 in Section 24.9) and U6. A sibling `carrierCharacterLowerBound_of_sector` adds Chapter 25's `DemazureBoundFor W hilb` to produce the capstone's character input.

Proof on paper. B1 (Theorem 24.23) bounds carrierDim(N) by the sum of sector dimensions; the conductor shift (`auxDim_conductor_add`) turns auxDim($m, d,$ cond $+ r$) into currentDim(m, d, r) and kills lower degrees; the exponent identity $m + d + d(m + d) = m + 2d + (md + d(d - 1))$ matches each sector with $[q^N]$ sectorTerm; the sector fusion bound bounds each term; D3 with U6 resums. □

Physical meaning

The classical operator count is at most the Demazure (fusion) count. The other half of the squeeze, that the Demazure count is at most the quantum count (step (C) of Remark 24.1), is the subject of Chapter 25.

What the machine verified

Proved, conditional on `SectorFusionBound D F` and `MixedFusionRecursion`; axioms standard.

Remark 24.26 (The shifted Mehler identity)**.** The files `A2CarrierMehlerFinite.lean` and `A2CarrierMehler.lean` prove, with no hypothesis, the q-series identity `A2.shiftedMehler : ShiftedMehler`, i.e. $U_m(q)^3_\infty(1 - q^{m+1}) = m + 1$ for $U_m = \sum_s H_s(q)H_{s+m}(q)/(q)_s$ (H the Rogers–Szegő polynomials), via Rogers–Szegő Vandermonde expansions and two Euler sums; and `starIdentity_of_fourTriangular`, which reduces the A_2 star identity to Legendre's four-triangular-numbers identity. These belong logically to the character side and are discussed in Chapter 25.

24.7 The sector chain: B5, B6, the generic comparison and B8

This section proves the sector fusion bound from U5 and a divisor comparison. The objects are the current carrier W_m of I_2 (Definition 24.16), the cyclic module $M_m \subseteq W_m$ generated by $\delta_{c_0}^{\otimes m}$ under the loop operators, and the ring $B_m = \mathbb{C}[z_1, \dots, z_m]^{S_m}$ acting on both.

Why the divisor comparison is the crux. The goal is a bound on $\dim(W_m)_r$ for each degree r. The module M_m is controlled: it is free over B_m (B6), with a fibre whose size is bounded by U5, so its Hilbert series is at most $F_m(q)/(q)_m$. What has to be shown is that W_m is no bigger, i.e. $W_m = M_m$; this equality is what turns a bound on the fibre into a bound on $\dim W_m$. The argument proceeds in four steps.

1. $M_m \subseteq W_m$ (B5), so only $W_m \subseteq M_m$ is at stake.

2. Away from collisions the two agree: $\Delta^L W_m \subseteq M_m$ (the generic comparison). So an element x of W_m can fail to lie in M_m only "along" the zero set of Δ.

3. Since B_m is a polynomial ring (a normal domain) and M_m is free, membership of x in M_m can be tested at the height-one primes of B_m alone (B8). Those not containing Δ are handled by step 2. The remaining ones contain Δ; their zero sets are the images of the hyperplanes $z_i = z_j$, i.e. the loci where exactly two particles collide. This is the *divisor comparison*.

4. At a generic point of $z_a = z_b$ the other particles are at distinct positions and act as spectators, so the divisor comparison reduces to a two-particle problem, a finite computation in $\mathfrak{g}^* \otimes \mathfrak{g}^*$. That computation is what the certificates of Section 24.8 do.

Triple collisions and simultaneous pairs never need to be examined: they have codimension two in $\operatorname{Spec} B_m$ and are invisible to the height-one test. (In z-space a triple collision also has codimension two; the discriminant $\Delta = 0$, the union of all pair collisions, is a divisor both upstairs in $\mathbb{C}^m$ and downstairs in $\operatorname{Spec} B_m = \mathbb{C}^m/S_m$.)

Definition 24.27 (Loop operators, M_m, B_m, the discriminant)**.** For structure constants f of $\mathfrak{g}$ in the chosen basis, the loop operator $x \otimes t^r$ acts on tensor polynomials by the coadjoint action in each slot, weighted by z_i^r: $(x \otimes t^r \cdot p)_t = -\sum_i z_i^r \sum_c f(x, t_i, c)\, p_{t[i \mapsto c]}$. Let $\delta_{c_0}^{\otimes m}$ be the tensor polynomial equal to 1 at the labelling $t \equiv c_0$ and 0 elsewhere, M_m the span of all loop words applied to it, B_m the symmetric polynomials and $\Delta = \prod_{i \neq j}(z_i - z_j) \in B_m$.

File `VOA/DeligneAudit/A2SectorLoop.lean`.

```
def loopOp (m : ℕ) (x : σ) (r : ℕ) :

  ⟨∏ i : Fin (m + 0), ∏ j : Fin (m + 0), if i = j then 1 else (X i - X j), by
```

From the mathematics to the Lean statement

`zr i` is the root variable z_i; `C` embeds scalars; `Function.update t i c` relabels slot i to c. `applyWord f m l` applies a list of (x, r) letters. Although the files are named `A2...`, these definitions are generic in K, σ, f and are used by all types. `Fin (m + 0)` is $\{1..m\}$ written so that it matches `Particle m 0`. Δ is (up to sign) the square of the Vandermonde, hence symmetric (the proof term). The coadjoint vector δ_{c_0} is the functional dual to $X_{c_0} = f_\theta$, which has weight $-\theta$ in $\mathfrak{g}$; as an element of $\mathfrak{g}^*$ it is therefore a *highest*-weight vector, of weight $+\theta$. In the data of Definition 24.28 this is literal: with the coadjoint action $(\texttt{slotA}\, x\, v)_y = -\sum_d f_{xyd} v_d$, `raising_table` ($f_{eyc_0} = 0$) says every raising vector kills δ_{c_0}, and `cartan_table` ($f_{hyc_0} = -\theta(h)$ if $y = c_0$, else 0) says h acts by $+\theta(h)$. These are the conditions `LocalWeylRelG.raising` and `cartan_zero` impose on the cyclic vector of $W_{\mathrm{loc}}(m\theta)$.

Physical meaning

M_m is the space of m-particle wave functions generated from the "ground state" where every particle sits in the highest-weight coadjoint state δ_{c_0}, by acting with the modes $x \otimes t^r$ of the current algebra at the particle positions: an evaluation (fusion) representation of $\mathfrak{g}[t]$ at the points $z_1, \dots, z_m$.

What the machine verified

Definitions.

Definition 24.28 (Sector type data)**.** Sector data extend carrier data by: structure constants f satisfying the Jacobi identity; ad-stability of $I_2 = I_2^{\mathrm{ns}} \oplus \mathbb{C}Q$; an index c_0 with no relation containing $X_{c_0}^2$; the local Weyl data for $W_{\mathrm{loc}}(m\theta)$ (raising vectors killing δ_{c_0}, Cartan vectors acting by $\theta(h)$, simple lowering vectors with exponents $\theta(h_i)$, a weight function compatible with f and a combinatorial no-weight fact, a fusion set); and a *depth* L such that every basis vector of $\mathfrak{g}^*$ is a combination of coadjoint words of length $\le L$ applied to δ_{c_0}.

From the mathematics to the Lean statement

`JacobiCoord f` is the Jacobi identity in coordinates, in the form needed for the loop operators to satisfy the current-algebra relations (`loopOp_comm`). `RelationsStable` says the derivation ad_x maps each relation of I_2 into the *linear span* of the relations. `cartanN/thetaN` (with defaults) cover Cartan basis vectors with $\theta(h) < 0$, which occur in the G_2 and F_4 bases. **The weight fields.** `R` and `wt` assign to each basis vector of $\mathfrak{g}$ a weight in $\mathbb{Z}^R$, a coarse version of the root lattice grading (for instance the coordinates of a root in the simple roots); the same function labels the basis of $\mathfrak{g}^*$. `table_wt` says the structure constants respect it: $f(x, y, c) = 0$ unless $\mathrm{wt}(c) = \mathrm{wt}(x) + \mathrm{wt}(y)$. Consequently the coadjoint action of x in one slot lowers the total weight $\sum_j \mathrm{wt}(t_j)$ of a labelling t by $\mathrm{wt}(x)$, and k applications of the lowering vector $x = i$ to $\delta_{c_0}^{\otimes m}$ (total weight $m\,\mathrm{wt}(c_0)$) produce a tensor supported on labellings of total weight $m\,\mathrm{wt}(c_0) - k\,\mathrm{wt}(i)$. `lowering_noweight` says that for $k = m\,\theta(h_i) + 1$ (with $\theta(h_i) =$ `lowExp i`) *no* labelling of the m slots has that total weight. Hence $(f_i \otimes 1)^{m\theta(h_i)+1}\delta_{c_0}^{\otimes m} = 0$ (`lowering_deltaVec`), which is the integrability relation of $W_{\mathrm{loc}}(m\theta)$ and is used in B6. The `fusion` set is unconstrained data; see the dictionary of Definition 24.29. All fields are proved per type by certificates (Section 24.9); the structure has no unprovable or contradictory field (the seven instances exist).

Physical meaning

The Lie algebra in a weight basis, the highest-weight coadjoint state δ_{c_0} (the highest-weight vector of the coadjoint representation; under the invariant form it is e_θ, a point of the minimal orbit, the classical value of the moment map in a highest-weight state), the data of the local Weyl module $W_{\mathrm{loc}}(m\theta)$ (the fusion of m adjoint representations), and the fact that the coadjoint representation is reached from its highest-weight vector in few steps.

What the machine verified

Definition; seven instances, each `#print axioms`-standard.

Definition 24.29 (Current modules, local Weyl relations, input U5). A *current module* is a vector space with operators $\rho(x \otimes t^r)$, $r \geq 0$, satisfying $[x \otimes t^r, y \otimes t^s] = \sum_e f(x, y, e)\, e \otimes t^{r+s}$. For a vector w, $\mathrm{cycDeg}(w, b)$ is the span of loop words of total t-degree b applied to w. The *local Weyl and fusion relations* for $m\theta$ are: raising vectors $\otimes t^r$ kill w; Cartan $h \otimes t^r$ kills w for $r \geq 1$ and acts by $m\theta(h)$ for $r = 0$; $(f_i \otimes 1)^{m\theta(h_i)+1} w = 0$; $(x \otimes t^m)w = 0$ for x in the fusion set. *Input U5* for a family F: every such module has $\dim \mathrm{cycDeg}(w, b) \leq [q^b]F_m$, and $\sum_{b<B} \dim \mathrm{cycDeg}(w, b) \leq (\dim \mathfrak{g})^m$ for every B. The cyclic module generated by w subject only to the local Weyl relations (the first three) is the *local Weyl module* $W_{\mathrm{loc}}(m\theta)$ of Chari and Pressley, the largest graded cyclic $\mathfrak{g}[t]$-module of highest weight $m\theta$ that is finite-dimensional; adding the fusion relations gives the *fusion module* $\mathcal{F}_m$. Every module satisfying the relations, with w cyclic, is a quotient of $\mathcal{F}_m$, so U5 is a statement about $\mathcal{F}_m$.

```

From the mathematics to the Lean statement

`(ρ.op i 0)^[k]` is the k-fold iterate. The relations are Chari–Pressley's presentation of $W_{\mathrm{loc}}(m\theta)$ ($\mathfrak{n}^+[t]w = 0$, $(h \otimes t^s)w = \delta_{s0} m\theta(h) w$, $(f_i)^{m\theta(h_i)+1} w = 0$) plus the fusion relations of Feigin and Ravinder. Every module satisfying them is a quotient of the fusion module $\mathcal{F}_m = W_{\mathrm{loc}}(m\theta)/\langle (f_\alpha \otimes t^m)w \rangle$, so U5 is exactly "$\mathcal{F}_m$ has graded character $\le F_m(q)$ and dimension $\le (\dim \mathfrak{g})^m$". The published source of the dimension half is Kus–Littelmann, Pacific J. Math. 278, Theorem 4.2 (one step, on p. 437, flagged by the project's source audit); Feigin's earlier proof has a gap, and Ravinder's Proposition 5 is Feigin's statement, so it is not independent (Chapter 27).

Two remarks on the formulation. (1) `Module.finrank` of an infinite-dimensional space is 0 in Mathlib, so for a hypothetical module with an infinite-dimensional degree piece the inequalities say nothing. This makes the hypothesis *weaker* (easier to discharge), and is harmless for its use: it is applied only to the finite-dimensional fibre of M_m. (2) The fusion set is free data. Ravinder's set is $\{f_\alpha : \langle \alpha, \theta^\vee \rangle = 1 \text{ or } \alpha = \theta\}$; E_6, E_7, E_8 use exactly that, A_2, D_4, G_2, F_4 use all negative root vectors. Every positive root $\alpha \neq \theta$ has $\langle \alpha, \theta^\vee \rangle \in \{0, 1\}$, so the short roots of G_2 and F_4 with $\langle \alpha, \theta^\vee \rangle = 1$ are already in Ravinder's set, and the extra vectors are the f_α with $\langle \alpha, \theta^\vee \rangle = 0$. For these, $f_\alpha(r)w = 0$ holds for every r in any module with the local Weyl relations, by the $h(r)$-bracket argument of Lemma 27.6. So the two readings impose the same relations, and give the same module, for every type (Chapter 27; Remark 26.5). The chain proves the fusion relations for every negative root vector on the fibre, so it can use either reading.

Physical meaning

$W_{\mathrm{loc}}(m\theta)$ is the space of states obtained by fusing m copies of the adjoint representation at colliding points; $\mathcal{F}_m$ is the further quotient in which each particle has a bounded number of

excitations. U5 says the fused space is no larger than the unfused tensor product $\mathfrak{g}^{\otimes m}$, with a definite energy grading.

What the machine verified

Definitions; `FusionModuleBoundG` is a named hypothesis (literature input U5). Chapter 26 reduces it to a total-dimension bound plus Demazure realizations.

Theorem 24.30 (B5: $M_m \subseteq W_m$). *Let K be a field of characteristic zero, σ a finite basis, f arbitrary structure constants and ρ a finite set of relations. If the span of the relations is stable under the coadjoint action of f (`RelationsStable`) and no relation contains $X^2_{c_0}$, then M_m lies in the current carrier of the relations, for every m. No Jacobi identity for f is assumed.*

File `VOA/DeligneAudit/A2SectorLoop.lean`.

```
theorem Mspace_le [CharZero K] {Q : ρ → σ × σ → K} [Fintype ρ] (hQ : RelationsStable f Q)
    (c₀ : σ) (hdiag : ∀ r, Q r (c₀, c₀) = 0) : Mspace f m c₀ ≤ currentCarrier Q m 0 := by
```

From the mathematics to the Lean statement

Generic in the field (characteristic zero), basis, structure constants and relations. In the sector chain it is applied as `Mspace_le S.f S.stable S.c₀ S.diag`. The hypotheses are exactly `[CharZero K]`, `[Fintype ρ]`, `hQ : RelationsStable f Q` and `hdiag`: the section variables of the file are only `{K σ ρ : Type*} [Field K] [Fintype σ] [DecidableEq σ]` and `(f : σ → σ → σ → K)`, with no Jacobi hypothesis, and the stability step `loopOp_mem` uses only `RelationsStable`. So the Lean theorem is stronger than a statement assuming Jacobi. The Jacobi identity (`JacobiCoord`) enters the chain at B6, through `loopOp_comm` in `A2SectorRep.lean` (commutation of loop operators).

Proof on paper. $\delta_{c_0}^{\otimes m}$ is in W_m: it is symmetric, and a collision readback picks the coefficient of $X^2_{c_0}$ in a relation, which is 0. W_m is stable under loop operators: on the diagonal $z_i = z_j$ the pair action is the diagonal coadjoint action, and the readback of ad applied to a relation is a combination of readbacks of relations, by ad-stability (`loopOp_mem`). □

Physical meaning

Fusing particles in the highest-weight coadjoint state and exciting them by current modes never violates the collision rules: the collision rules are flavour-covariant.

What the machine verified

Proved; axioms standard.

Lemma 24.31 (Symmetrization). *Let P_mM_m be the P_m-span of M_m. A symmetric tensor polynomial that lies in P_mM_m lies in M_m.*

File `VOA/DeligneAudit/DeligneSectorGeneric.lean`.

```
theorem mem_Mspace_of_symmetric {v : TPs S m} (hv : v ∈ MP S m) (hs : Symmetric v) :
    v ∈ Mspace S.f m S.c₀ := by
```

From the mathematics to the Lean statement

`MP S m` is P_mM_m (`Submodule.span (Pm m) (Mspace …)`) and `Symmetric` is the symmetry of Definition 24.16. The statement is exactly the lemma, for the sector data S; no further hypothesis.

Proof on paper. Let S_m act on tensor polynomials by permuting slots and roots simultaneously, $(g\cdot v)_t = g(v_{t\circ g})$; symmetric means $g\cdot v = v$ for all g, and on a product $g\cdot(pv) = g(p)\,(g\cdot v)$ for $p\in P_m$. Write $v = \sum_i p_i y_i$ with $p_i\in P_m$ and $y_i\in M_m$, and average over S_m:

$$v = \frac{1}{m!}\sum_{g\in S_m} g\cdot v = \frac{1}{m!}\sum_g\sum_i g(p_i)\,(g\cdot y_i) = \sum_i\Big(\frac{1}{m!}\sum_g g(p_i)\Big)y_i.$$

The last equality is the point: each $y_i\in M_m$ is itself symmetric, because $M_m\subseteq W_m$ (Theorem 24.30) and elements of W_m are symmetric; so $g\cdot y_i = y_i$. The averages $\frac{1}{m!}\sum_g g(p_i)$ are symmetric polynomials, i.e. lie in B_m, and M_m is a B_m-module (`smul_mem_Mspace`). Hence $v\in M_m$. (It is not enough that averaging commutes with the loop operators: averaging a general element of P_mM_m only returns an element of P_mM_m. What is used is that the generators y_i are already invariant.) □

Physical meaning

A wave function that is symmetric under exchange of identical particles, and is built from the ground state with position-dependent coefficients, can be rebuilt with symmetric coefficients: Bose symmetry of the building blocks lets one average the coefficients over particle exchanges.

What the machine verified

Proved; axioms standard (re-checked). Used three times: in the generic comparison, in B6 and in the reduction of the divisor comparison to pairs.

Theorem 24.32 (The generic comparison: $\Delta^L W_m\subseteq M_m$)**.** *For sector data of depth L and $x\in W_m$, $\Delta^L\cdot x\in M_m$.*

File `VOA/DeligneAudit/DeligneSectorGeneric.lean`.

```
theorem genericComparisonG (m : ℕ) {x : TPs S m} (hx : x ∈ currentCarrier S.fullMatrix m 0)
  ↪ :
    (discS m : SymAlg (K := ℂ) m) ^ S.depth • x ∈ Mspace S.f m S.c₀ := by
```

From the mathematics to the Lean statement

`TPs S m` is the tensor polynomials for the type. The hypothesis `hx` is used only through the symmetry of x; the inclusion holds for every symmetric tensor (and $\Delta^L x\in P_mM_m$ for every tensor, symmetric or not).

Proof on paper. Let P_mM_m be the P_m-span of M_m (polynomial, not only symmetric, coefficients). Four steps.

Step 1 (interpolation isolates one slot). Fix a slot i and put $\lambda_i(t) = \prod_{j\neq i}(t-z_j) = \sum_r c_r t^r$, with coefficients $c_r\in P_m$. Since $x\otimes t^r$ acts by $\sum_k z_k^r\,x^{(k)}$ ($x^{(k)}$ the coadjoint action in slot k),

$$\sum_r c_r\,(x\otimes t^r) = \sum_k \lambda_i(z_k)\,x^{(k)} = \lambda_i\,x^{(i)},\qquad \lambda_i = \lambda_i(z_i) = \prod_{j\neq i}(z_i-z_j),$$

because $\lambda_i(z_k) = 0$ for $k\neq i$ (`interp`). The coefficients c_r are not symmetric, so this operator preserves P_mM_m but not M_m; that is why the argument runs in P_mM_m first.

Step 2 (one slot, by cyclicity). By the depth-L cyclicity of the sector data, every basis vector e_c of $\mathfrak{g}^*$ is a combination of words of length $\le L$ in the coadjoint action applied to δ_{c_0}. Each letter costs one factor λ_i (Step 1), and shorter words are padded with extra factors λ_i. So if $Y\,\delta_t$ lies in P_mM_m for a labelling t with $t_i = c_0$ and some $Y\in P_m$, then $\lambda_i^L Y\,\delta_{t[i\mapsto c]}\in P_mM_m$ for every c (`slot_all`).

Step 3 (all slots). Start from $\delta_{c_0}^{\otimes m}\in M_m$ and change the labels one slot at a time: for every labelling t, $\big(\prod_i\lambda_i^L\big)\delta_t\in P_mM_m$ (`all_slots`). Since $\prod_i\lambda_i = \prod_i\prod_{j\neq i}(z_i-z_j) = \Delta$, $\Delta^L\delta_t\in P_mM_m$, and hence $\Delta^L x\in P_mM_m$ for *every* tensor polynomial $x = \sum_t x_t\,\delta_t$ (`disc_pow_mem_MP`).

Step 4 (descend to M_m). If $x \in W_m$ then x is symmetric, and so is $\Delta^L x$ because $\Delta \in B_m$. Lemma 24.31 gives $\Delta^L x \in M_m$. □

Physical meaning

When all particles are at distinct points, each can be excited independently, so every wave function is reachable, up to the discriminant factor that vanishes when particles collide.

What the machine verified

Proved, unconditional given the sector data; axioms standard.

Theorem 24.33 (B6: freeness from U5). *For sector data S and a family F satisfying U5, M_m is a finite free B_m-module for every m.*

File `VOA/DeligneAudit/DeligneSectorB6.lean`.

```
structure MFreenessG : Prop where
  free : ∀ m, Module.Free (SymAlg (K := ℂ) m) (MspaceR S m)
  finite : ∀ m, Module.Finite (SymAlg (K := ℂ) m) (MspaceR S m)

theorem mFreeness (hU5 : FusionModuleBoundG S F) : MFreenessG S := by
```

From the mathematics to the Lean statement

`MspaceR S m` is M_m regarded as a B_m-submodule (it is B_m-stable: power sums act as $h_\theta \otimes t^r$, `smul_mem_Mspace`). Hypothesis: U5 only. The A_2 pilot is `VOA.DeligneAudit.A2.mFreeness` in `A2SectorB6.lean`.

Proof on paper. Grade M_m by polynomial degree; B_m is graded with Hilbert series $1/(q)_m$, and B_+ is its ideal of positive degree. Five steps.

Step 1 (the fibre is a current module). The loop operators commute with multiplication by symmetric polynomials, so they act on the *Nakayama fibre* $\bar{M} = M_m/B_+M_m$, the quotient by everything with a positive-degree symmetric factor. Let w be the image of $\delta_{c_0}^{\otimes m}$; it generates $\bar{M}$.

Step 2 (local Weyl and fusion relations for w). Each relation of Definition 24.29 holds for w:

- raising vectors kill δ_{c_0} in every slot (`raising_table`), so $(e \otimes t^r)\delta_{c_0}^{\otimes m} = 0$;
- a Cartan element acts on δ_{c_0} by $\theta(h)$ in each slot, so $(h \otimes t^r)\delta_{c_0}^{\otimes m} = \theta(h)\, p_r(z)\, \delta_{c_0}^{\otimes m}$ with $p_r = \sum_i z_i^r$; for $r \geq 1$ this lies in B_+M_m (zero in $\bar{M}$), and for $r = 0$ it is $m\theta(h)\, w$;
- lowering: $(f_i \otimes 1)^{m\theta(h_i)+1}\delta_{c_0}^{\otimes m} = 0$ by the weight argument in the dictionary of Definition 24.28;
- fusion (Vieta): each z_k is a root of $\prod_i (T - z_i) = \sum_{j=0}^{m} (-1)^j e_j T^{m-j}$, so $z_k^m = -\sum_{j=1}^{m} (-1)^j e_j z_k^{m-j}$ with e_j the elementary symmetric polynomials. Summing over slots, $(x \otimes t^m) = -\sum_{j=1}^{m} (-1)^j e_j\, (x \otimes t^{m-j})$ as operators, and every term has a factor $e_j \in B_+$. Hence $(x \otimes t^m)w = 0$ in $\bar{M}$, for every x (`loopOp_vieta`).

Step 3 (an upper bound on generators). By U5 (its `total` clause) the fibre has total dimension $\leq n^m$, and in particular vanishes in high degree. By graded Nakayama, lifting a homogeneous basis of $\bar{M}$ gives at most n^m homogeneous elements that generate M_m over B_m.

Step 4 (n^m independent elements). Fix the point $z^0 = (0, 1, \dots, m-1)$, with distinct coordinates, and the Lagrange polynomial $\ell(z) = \prod_i \prod_{j \neq i} (z_i - z_j^0)/(z_i^0 - z_j^0)$, which is 1 at z^0 and 0 at every permutation $g(z^0) \neq z^0$. For each labelling t put

$$v_t = \sum_{g \in S_m} g \cdot (\ell\, \delta_t),$$

a *symmetrized* interpolated basis tensor: v_t is symmetric by construction, and at z^0 its components are $(v_t)_{t'}(z^0) = \delta_{t,t'}$ (only $g = 1$ survives). By the generic comparison, applied to the symmetric tensor v_t (Theorem 24.32 and its dictionary: $\Delta^L v_t \in P_m M_m$ by Step 3 of that proof, and then Lemma 24.31), the n^m elements $\Delta^L v_t$ lie in M_m. They are B_m-linearly independent: in a relation $\sum_t b_t \Delta^L v_t = 0$ with $b_t \in B_m$, the matrix of components $\big((\Delta^L v_t)_{t'}\big)$ has determinant whose value at z^0 is $\Delta(z^0)^{Ln^m} \neq 0$; so the determinant is a nonzero element of the domain P_m, and Cramer's rule gives every $b_t = 0$.

Step 5 (rank count). So M_m has rank at least n^m over $\mathrm{Frac}(B_m)$ and is generated by at most n^m elements. A generating family of k elements of a module that contains $k' \geq k$ independent elements is itself independent over a domain (otherwise the rank would be $< k \leq k'$; `linearIndependent_of_span_card`). Hence the at most n^m generators of Step 3 are exactly n^m and form a B_m-basis. □

Physical meaning

The particle wave functions form a free module over symmetric functions of the positions: the fusion product does not depend (in dimension) on where the particles are, and at generic positions it is the full tensor product $\mathfrak{g}^{\otimes m}$. Only an upper bound on the fused space is needed; the lower bound comes from generic points.

What the machine verified

Proved, conditional on U5; axioms standard. Only U5's upper bounds are used: the lower bound on the rank comes from Step 4.

Theorem 24.34 (B8: $W_m = M_m$ from freeness and the divisor comparison)**.** *Suppose M_m is finite free (B6) and the* divisor comparison *holds: for every $x \in W_m$ and every height-one prime $\mathfrak{p} \subset B_m$ containing Δ, some $s \notin \mathfrak{p}$ has $sx \in M_m$. Then $W_m \subseteq M_m$.*

File `VOA/DeligneAudit/DeligneSectorChain.lean`.

```

From the mathematics to the Lean statement

`HeightOnePrime` is a prime of height exactly one, with no dimension assumption on R (unlike Mathlib's Dedekind `HeightOneSpectrum`). $B_m \cong \mathbb{C}[e_1..e_m]$ is a noetherian UFD (instances in `A2SectorB8.lean`). `DivisorComparisonG` is a named per-type hypothesis structure; Section 24.8 proves it for all seven types. **Quantifiers.** The theorem is stated for a fixed m, but its hypotheses `hF : MFreenessG S` and `hD : DivisorComparisonG S` are quantified over *all* m; so the Lean theorem is formally weaker than the fixed-m statement above (it needs freeness and the divisor comparison in every arity). This is harmless for the use: both are proved (respectively, derived from U5) for all m at once.

Proof on paper. Let (b_i) be a B_m-basis of M_m (B6) and $x \in W_m$. By the generic comparison (Theorem 24.32), $\Delta^L x \in M_m$; write $\Delta^L x = \sum_i a_i b_i$ with $a_i \in B_m$. Then, in the fraction field $K = \operatorname{Frac} B_m$, the coordinates of x are a_i/Δ^L; we must show that they lie in B_m. A noetherian UFD is the intersection of its localizations at height-one primes, so it suffices to show $a_i/\Delta^L \in (B_m)_{\mathfrak{p}}$ for every height-one prime $\mathfrak{p}$, and for that it suffices to find one $s \notin \mathfrak{p}$ with $sx \in M_m$: writing $sx = \sum_i a_i' b_i$ with $a_i' \in B_m$ and comparing coordinates in K (the b_i stay independent there, since M_m is torsion-free), $a_i/\Delta^L = a_i'/s \in (B_m)_{\mathfrak{p}}$.

- If $\Delta \notin \mathfrak{p}$, take $s = \Delta^L$ (the generic comparison).
- If $\Delta \in \mathfrak{p}$, the divisor comparison supplies s.

In the Lean lemma `mem_of_local_witnesses` these are the hypotheses `hloc`; the hypothesis `h0`, one global nonzero s with $sx \in M_m$, is $s = \Delta^L$ again; `htf` is torsion-freeness of the ambient tensor polynomials. So every coordinate lies in B_m and $x \in M_m$. □

Physical meaning

The statement is about membership, not about regularity of a single function: an element of the carrier W_m (a collection of wave functions obeying the collision rules) is shown to be generated, with symmetric polynomial coefficients, from the ground state. A priori it is generated only after multiplying by a power of Δ, i.e. away from all collisions. Normality of B_m says that a "denominator" can only sit on a divisor of $\operatorname{Spec} B_m$; the divisors on which Δ vanishes are the simple two-particle collisions, so only the two-body problem at $z_a = z_b$, with the other particles as spectators, has to be solved. Triple collisions and pairs of simultaneous collisions have codimension two and impose nothing.

What the machine verified

Proved; axioms standard.

Theorem 24.35 (The sector fusion bound from U5 and the divisor comparison). *For sector data S, U5 for F and the divisor comparison imply* `SectorFusionBound S.toDeligneCarrierData F`.

        Module.finrank K (degreePiece (currentCarrier Q m 0) a) * partitionsLe d (r - a) :=
          ↪ by
```

From the mathematics to the Lean statement

`finrank_le_sum_fiberDim` is graded Nakayama for a graded action of a graded algebra R on a graded space M: $\dim M_a \le \sum_b \dim(\text{fibre})_b \dim R_{a-b}$. `finrank_currentCarrier_le` is the $1/(q)_d$ split: `partitionsLe d k` is the number of partitions of k into at most d parts, the dimension of degree-k symmetric polynomials in d variables; `partitionsLe_series` identifies its generating function with $1/(q)_d$. Only inequalities are needed.

Proof on paper. By B6 and B8, $W_m = M_m$, so the Nakayama fibre of W_m is that of M_m, whose degree-b piece is bounded by $\dim \mathrm{cycDeg}(w,b) \le [q^b]F_m$ (U5). Graded Nakayama over B_m (Hilbert series $1/(q)_m$) gives $\mathrm{currentDim}(m,0,a) \le [q^a]F_m/(q)_m$; the auxiliary split gives the extra $1/(q)_d$. □

Physical meaning

The m-current sector is the fusion fibre times free bosonic oscillations of the centre of mass and relative positions ($1/(q)_m$), and the d Casimir quanta add $1/(q)_d$.

What the machine verified

Proved, conditional on U5 and `DivisorComparisonG S`; axioms standard. The divisor comparison is then discharged per type.

24.8 The divisor comparison

Definition 24.36 (Pair comparison). Let $E_{ab} = \prod(z_i - z_j)$ over ordered pairs $i \ne j$ with $\{i,j\} \ne \{a,b\}$. *Pair comparison* holds if for every $x \in W_m$ and $a \ne b$ some power $E_{ab}^N x$ lies in $P_m M_m$.

File `VOA/DeligneAudit/DeligneDivisorReduction.lean`.

```

```

File `VOA/DeligneAudit/A2DivisorAvoid.lean`.

```
def pairE (a b : Fin (m + 0)) : MvPolynomial (Fin (m + 0)) ℂ :=
  ∏ i, ∏ j, if i = j ∨ (i = a ∧ j = b) ∨ (i = b ∧ j = a) then 1 else (X i - X j)
```

From the mathematics to the Lean statement

`MP S m` is the P_m-span of M_m (`Submodule.span (Pm m) (Mspace …)`). E_{ab} vanishes on every collision except $z_a = z_b$: pair comparison is B7 localized at the divisor $z_a = z_b$.

Proof on paper (of the reduction). Let $x \in W_m$ and let $\mathfrak{p}$ be a height-one prime of B_m with $\Delta \in \mathfrak{p}$. We need $s \notin \mathfrak{p}$ with $sx \in M_m$.

Step 1 ($\mathfrak{p}$ lives on one collision). $B_m \cong \mathbb{C}[e_1, \dots, e_m]$ is a UFD, so the height-one prime $\mathfrak{p}$ is principal, $\mathfrak{p} = (\varpi)$ with ϖ prime in B_m. In the larger UFD P_m, the non-unit ϖ has an irreducible

(hence prime) factor ϕ. Since $\varpi \mid \Delta = \prod_{i\neq j}(z_i - z_j)$, the prime ϕ divides some linear factor $z_i - z_j$, so it is associate to it, and ϖ vanishes identically on the hyperplane $z_i = z_j$. (No finiteness of P_m over B_m is needed: the argument only factors ϖ inside P_m.)

Step 2 (an element outside $\mathfrak{p}$). Let $w = \sum_{a\neq b} E_{ab}$, a symmetric polynomial. On the hyperplane $z_i = z_j$, every E_{ab} with $\{a,b\} \neq \{i,j\}$ contains the factor $z_i - z_j$ and vanishes, while $E_{ij} = E_{ji} = \prod_{\{k,l\}\neq\{i,j\}}(z_k - z_l)$ (over ordered pairs) does not vanish identically there. So w restricted to $z_i = z_j$ is $2E_{ij}|_{z_i=z_j} \neq 0$, while ϖ restricts to 0. Hence $w \notin (\varpi) = \mathfrak{p}$ (`wS_not_mem`), and $w^K \notin \mathfrak{p}$ for every K since $\mathfrak{p}$ is prime.

Step 3 ($w^K x \in M_m$). Pair comparison gives, for each ordered pair (a,b), a power with $E_{ab}^N x \in P_m M_m$; take N common to all pairs. Expanding w^K for K large ($K > N \cdot$ #pairs), each monomial in the E_{ab} contains some E_{ab}^N, so $w^K x \in P_m M_m$. Since w and x are symmetric, so is $w^K x$, and Lemma 24.31 puts it in M_m. Take $s = w^K$. □

Physical meaning

Away from a single collision $z_a = z_b$ everything is generic; the only physics is the two-body problem at that collision, with the other particles as spectators at distinct positions.

What the machine verified

Proved; axioms standard.

Strategy of the certificate. Pair comparison asks, for each $x \in W_m$ and each pair of slots (a,b), that x be generated (after multiplying by a power of E_{ab}, which is invertible near a generic point of $z_a = z_b$) from the ground state $\delta_{c_0}^{\otimes m}$. Near that divisor the spectators sit at distinct points and can be moved freely, so the problem is about the two slots a, b, i.e. about $n \times n$ tables of polynomials (elements of $\mathfrak{g}^* \otimes \mathfrak{g}^*$ with polynomial coefficients). Three ideas organize it.

1. *Spectators.* Split x by the labels of its spectators: $x = \sum_s x_s$, where s runs over labellings with the convention $s_a = s_b = c_0$ (*canonical* spectators; the labels at a, b are carried by the table) and x_s is the embedding of the *pair table* $Y_{cd} = x_{s[a\mapsto c, b\mapsto d]}$ (`tensor_eq_sum_pemb`). Moving each spectator slot j from c_0 to its actual label s_j costs the factor λ_j^L (Step 2 of the generic comparison); this is the factor $\Lambda_{ab} = \prod_{j\notin\{a,b\}} \lambda_j^L$ below.

2. *Two-slot moves.* Two operators act on slots a, b only and preserve $P_m M_m$: the diagonal move $S_x = H(x^{(a)} + x^{(b)})$ and the antisymmetric move $A_x = H(z_a - z_b)(x^{(a)} - x^{(b)})$ (Theorem 24.38). Each costs one factor H, and A_x also a factor $z_a - z_b$.

3. *A generating tree.* Starting from the root table $\delta_{c_0} \otimes \delta_{c_0}$, apply moves S_x, A_x with integer structure constants. A *tree* is a list of n^2 integer tables, each obtained from an earlier one (its *parent*) by one move; each node records its parent, whether the move is A, the letter x, its *step count* ν (number of moves from the root) and its *collision order* ℓ (number of A-moves). Diagonal moves alone stay in $U(\mathfrak{g}) \cdot (\delta_{c_0} \otimes \delta_{c_0}) = V(2\theta)$, the symmetric channel that is regular at contact; the nodes of collision order 1 fill the antisymmetric part $\Lambda^2\mathfrak{g}^*$, and those of order 2 the rest of the symmetric part, a copy of I_2^*. In the certificates the numbers of nodes of collision order $0, 1, 2$ are therefore $\dim V(2\theta)$, $\dim \Lambda^2\mathfrak{g}$, $\dim I_2$, adding up to n^2 (for A_2: $27 + 28 + 9 = 64$); this count is a property of the generated data, which Lean does not need: it checks only the moves and the final combinations.

What the kernel then checks is that each node is the claimed move of its parent, and that the target tables (antisymmetric basis tensors, a complement of $V(2\theta)$, symmetric basis tensors corrected by their I_2-coordinates) are integer combinations of nodes of the right collision order. The "good" and "level-OK" vocabulary below makes this precise.

Definition 24.37 (Two-slot tables, the good submodule, the level predicate). Fix slots $a \neq b$ and spectator labels s with $s_a = s_b = c_0$. A *pair table* Y is an $n \times n$ matrix of polynomials, embedded as $\sum_{c,d} Y_{cd}\, \delta_{s[a\mapsto c, b\mapsto d]}$. It is *good* if the embedding lies in $P_m M_m$. With $H = G_a G_b$, $G_i = \prod_{k\notin\{a,b\}}(z_i - z_k)$, $\Lambda_{ab} = \prod_{j\notin\{a,b\}} \lambda_j^L$, an integer table T is *level-OK at* (ν, ℓ) if $H^\nu (z_a - z_b)^\ell \Lambda_{ab} \cdot T$ is good for all m, $a \neq b$ and canonical s. The factor Λ_{ab} pays for moving the spectators (item 1 above), H^ν for ν two-slot moves, $(z_a - z_b)^\ell$ for ℓ antisymmetric moves.

  ∀ (m : ℕ) (a b : Fin m), a ≠ b → ∀ s : Fin m → Fin S.n, IsCanon a b s →
    (Hpair a b ^ D * zab a b ^ ℓ * Fspec S a b) • castT (m := m) T ∈ Good a b s
```

From the mathematics to the Lean statement

`ZTab S` is $\mathrm{Fin}\, n \times \mathrm{Fin}\, n \to \mathbb{Z}$ and `castT` views it as a constant pair table. `IsCanon a b s` is $s_a = s_b = c_0$. `Gpair a b i` is $\prod_{k\notin\{a,b\}}(z_i - z_k)$ (evaluation of `Lpair`). `Fspec` is Λ_{ab}, with `Dslot j` $= \lambda_j$. The Lean variable `D` of `LevOK` is our step count ν (not the carrier data), and ℓ the collision order. Level-OK is monotone: it is preserved when ν or ℓ is increased (`levOK_mono`), and it is closed under integer linear combinations.

Physical meaning

Bookkeeping for the two-body problem: which two-particle states are produced from the ground state, by how many excitations, and with which power of the separation $z_a - z_b$ (the collision order ℓ is the order of vanishing of the two-particle wave function at contact: 0 in the $V(2\theta)$ channel, 1 in $\Lambda^2\mathfrak{g}$, 2 in I_2).

What the machine verified

Definitions.

Theorem 24.38 (The pair operators and the W-side divisibilities). *(i) $P_m M_m$ is stable under $S_x = G_a G_b (x^{(a)} + x^{(b)})$ and $A_x = G_a G_b (z_a - z_b)(x^{(a)} - x^{(b)})$. (ii) For $x \in W_m$, the antisymmetric part of its (a,b) pair table is divisible by $z_a - z_b$, and every relation coordinate $\sum_{c,d} q_r(c,d)(Y_{cd} + Y_{dc})$ of I_2 is divisible by $(z_a - z_b)^2$.*

theorem relSym_sq_dvd {x : TPs S m} (hx : x ∈ currentCarrier S.fullMatrix m 0)
    (r : Option S.ρ) : zab a b ^ 2 | relSym r (pairTable x a b t) := by
```

From the mathematics to the Lean statement

`slotOp x i` is the coadjoint action of x in slot i only. In `anti_dvd`, `relSym_sq_dvd` the slots $a \neq b$ (`hab`) and the spectators t are section variables.

Proof on paper. (i) As in Step 1 of the generic comparison, for $\phi(t) = \sum_r \phi_r t^r \in P_m[t]$ the operator $\sum_r \phi_r(x \otimes t^r)$ acts as $\sum_i \phi(z_i)x^{(i)}$ and preserves $P_m M_m$. Take $\phi(t) = \prod_{k\notin\{a,b\}}(t - z_k)\cdot\psi(t)$; it kills every spectator slot and gives $G_a\psi(z_a)x^{(a)} + G_b\psi(z_b)x^{(b)}$. For S_x we need $\psi(z_a) = G_b$ and $\psi(z_b) = G_a$: take $\psi(t) = G_b - \kappa\,(t - z_a)$ with the divided difference $\kappa = (G_b - G_a)/(z_b - z_a)$, a polynomial because $G_b - G_a$ vanishes on $z_a = z_b$. For A_x multiply this ψ by $2t - z_a - z_b$, which equals $z_a - z_b$ at $t = z_a$ and $-(z_a - z_b)$ at $t = z_b$. (ii) Swap symmetry: the (d, c) entry is the (c, d) entry with $z_a \leftrightarrow z_b$, so the antisymmetric part vanishes on $z_a = z_b$. The current equation says the relation coordinate vanishes on $z_a = z_b$; it is swap-invariant, so the vanishing is to second order. □

Physical meaning

At a two-particle collision the symmetric $V(2\theta)$ channel is regular, the antisymmetric $\Lambda^2\mathfrak{g}$ channel has a simple zero, and the I_2 channel a double zero: the exclusion rule of the fusion of two adjoint representations, $\mathrm{ch}\,F_2 = V(2\theta) + q\Lambda^2\mathfrak{g} + q^2 I_2$.

What the machine verified

Proved; axioms standard.

Theorem 24.39 (Pair comparison from integer certificates). *Let a_r (r running over the relations of I_2, the Casimir included) be integer matrices equal to the coefficient matrices of the sector data, ν a natural number, N_A, N_S positive integers and U_r integer tables. Suppose (a) $N_A(e_c \otimes e_d - e_d \otimes e_c)$ is level-OK at $(\nu, 1)$ for $c < d$; (b) each U_r is level-OK at $(\nu, 2)$; (c) $N_S(e_c \otimes e_d + e_d \otimes e_c) - \sum_r (a_r(c,d) + a_r(d,c))U_r$ is level-OK at $(\nu, 0)$ for $c \leq d$. Then pair comparison holds.*

File VOA/DeligneAudit/DeligneDivisorAssembly.lean.

```
theorem pairComparisonG_of_cert (qI : Option S.ρ → Fin S.n → Fin S.n → ℤ)
    (hq : ∀ r c d, S.fullMatrix r (c, d) = (qI r c d : ℂ)) (D NA NS : ℕ) (hNA : NA ≠ 0)
    (hNS : NS ≠ 0) (U : Option S.ρ → ZTab S)
    (hA : ∀ c d : Fin S.n, c < d → LevOK D 1 ((NA : ℤ) • antiZ c d))
    (hU : ∀ r, LevOK D 2 (U r))
    (hV : ∀ c d : Fin S.n, c ≤ d →
      LevOK D 0 ((NS : ℤ) • symZ c d - ∑ r, (qI r c d + qI r d c) • U r)) :
    PairComparisonG S := by
```

From the mathematics to the Lean statement

`qI` is (a_r) and the Lean `D` is ν. `antiZ c d`, `symZ c d` are $e_c \otimes e_d \mp e_d \otimes e_c$. `hq` says the integer tables are the actual relations. N_A and N_S are common denominators: the tree's tables are a basis of $\mathfrak{g}^* \otimes \mathfrak{g}^*$ over $\mathbb{Q}$, the antisymmetric and symmetric basis tensors are rational

combinations of them, and multiplying by N_A, N_S makes the combinations integral. They depend on the basis and the tree, which is why they vary erratically between types (for instance $N_S = 559104$ for F_4 but 96 for E_8); dividing by them again is harmless over $\mathbb{C}$ (`good_unsmul`). (c) says $e_c \otimes e_d + e_d \otimes e_c$, corrected by its I_2-coordinates against the complement tables U_r, lies in the level-0 span ($V(2\theta)$). No projector or dual functional appears: the U-part cancels because $\sum_{c,d} Y_{cd}\psi_r(c,d)$ is the relation coordinate, which is divisible by $(z_a - z_b)^2$.

Proof on paper. Fix $x \in W_m$ and slots $a \neq b$; put $K = H^\nu \Lambda_{ab}$.

Step 1 (reduce to canonical spectators). Write $x = \sum_s x_s$ over canonical spectator labellings s, x_s the embedding of the pair table $Y^{(s)}_{cd} = x_{s[a\mapsto c, b\mapsto d]}$ (`tensor_eq_sum_pemb`). It suffices to show that $K\,Y^{(s)}$ is good for every s: then $Kx \in P_m M_m$, and since $K = H^\nu \Lambda_{ab}$ divides $E_{ab}^{2\nu+Lm}$ (`factor_dvd`: each G_a, G_b divides E_{ab}, and each λ_j, $j \notin \{a,b\}$, divides E_{ab}), we get $E_{ab}^{2\nu+Lm} x = (\text{cofactor}) \cdot Kx \in P_m M_m$, which is pair comparison with $N = 2\nu + Lm$ (`pairComparisonG_of_good`). Fix s and write $Y = Y^{(s)}$.

Step 2 (antisymmetric part). By Theorem 24.38(ii), $Y_{cd} - Y_{dc} = (z_a - z_b) Z_{cd}$ with Z antisymmetric. Then $K \cdot \frac{1}{2}\sum_{c,d}(Y_{cd} - Y_{dc}) e_c \otimes e_d$ is a P_m-combination of the tables $K(z_a - z_b)(e_c \otimes e_d - e_d \otimes e_c)$, which are good by (a) after dividing by N_A.

Step 3 (symmetric part). The symmetric part $\frac{1}{2}\sum_{c,d}(Y_{cd} + Y_{dc}) e_c \otimes e_d$ is a P_m-combination of the $e_c \otimes e_d + e_d \otimes e_c$. By (c), each of these equals, up to the factor N_S, a level-0 table plus $\sum_r (a_r(c,d) + a_r(d,c)) U_r$. Collecting the second terms over (c,d) with the coefficients of Y gives $\sum_r \rho_r U_r$ with $\rho_r = \sum_{c,d} a_r(c,d)(Y_{cd} + Y_{dc})$, the r-th relation coordinate of Y; by Theorem 24.38(ii) $\rho_r = (z_a - z_b)^2 \varphi_r$. So $K\rho_r U_r = \varphi_r \cdot K(z_a - z_b)^2 U_r$ is good by (b), and the level-0 part is good by (c).

Step 4. Adding, $4N_A N_S\, K\, Y$ is good, hence KY is good. □

Physical meaning

The two-body fusion is checked once and for all by finite linear algebra on $\mathfrak{g}^* \otimes \mathfrak{g}^*$: every two-particle state with the right collision behaviour is produced from the ground state by at most ν pair excitations.

What the machine verified

Proved; axioms standard (re-checked by the author, Section 24.11).

Theorem 24.40 (Soundness of the sparse and encoded checks). *(i) If a tree of sparse integer tables, rooted at $\delta_{c_0} \otimes \delta_{c_0}$, passes the Boolean node check (each node equals S_x or A_x of an earlier parent, with step and collision-order counters), then every node i is level-OK at (its step count, its collision order). (ii) If the base-2^{64} encoding of a sparse table with entry sum $< 2^{63}$ is 0, the table is 0.*

```

From the mathematics to the Lean statement

A sparse table `QV` is a list of triples (c, d, k) meaning $k\, e_c \otimes e_d$ (repeats add); `castQZ` reads it as a `ZTab`. `par i` records (parent, is-A?, letter x, step count ν, collision order ℓ); the Lean comments call the last two "depth" and "level". This tree depth is unrelated to the cyclicity depth L of the sector data. `fZ br` are the integer structure constants of a sparse bracket table `br`; `hf` ties them to the sector data. In (ii), `absSum` is the sum of $|k|$; the bound $< 2^{63}$ guarantees every "digit" (total coefficient of a key) has absolute value $< 2^{63} = B/2$, so $\sum_e g_e B^e = 0$ forces $g_e = 0$ (`digits_zero`). `encLin` checks target $= \sum_j \mu_j \mathrm{tab}_j$ by comparing encodings, with per-table encodings shared by the kernel cache.

Proof on paper. (i) Strong induction along the tree, using that S_x and A_x preserve goodness with one more factor H (and $z_a - z_b$ for A_x) (`levOK_S`, `levOK_A`). (ii) Balanced base-B digits are unique. □

Physical meaning

These lemmas are part of solving the two-body problem of adjoint quanta: the generating tree is a list of two-particle states, each obtained from an earlier one by exciting one or both particles with a flavour current, and the theorem says that if each listed step is a legitimate excitation then every listed state really is produced from the ground state with the recorded number of excitations and order of vanishing at contact. It is what allows a 61 504-state two-body calculation for E_8 to be accepted as part of a proof.

What the machine verified

Proved; axioms standard.

Superseded checkers

`DeligneDivisorSort.lean` (a merge-sort zero check) and `DeligneDivisorFast.lean` (row-based pair operators) are sound but were superseded as too slow in the kernel; see Section 24.10. The column-based operators of `DeligneDivisorCol.lean` (`levOK_treeC`) and the encoded checks are what the E_6, E_7, E_8 instances use.

24.9 The seven instances

Each type supplies carrier data (relations, Casimir, U3), sector data (structure constants, stability, c_0, local Weyl data, cyclicity depth) and a divisor certificate. The table records the data as they appear in Lean (indices are positions in the certificate basis).

type	n	$\lvert\rho\rvert$	c_0	cycl. depth L	nodes n^2	by order $\ell = 0/1/2$	N_A	N_S
A_2	8	8	5	3	64	27/28/9	–	–
G_2	14	27	12	10	196	77/91/28	18	48384
D_4	28	105	27	10	784	300/378/106	8	384
F_4	52	324	45	22	2704	1053/1326/325	48	559104
E_6	78	650	77	3	6084	2430/3003/651	12	216
E_7	133	1539	132	2	17689	7371/8778/1540	24	672
E_8	248	3875	247	2	61504	27000/30628/3876	120	96

Columns: $|\rho| = \dim I_2^{\mathrm{ns}}$ is the number of listed relations; c_0 is the index of δ_{c_0}; "cycl. depth L" is the cyclicity depth of the sector data (every basis vector of $\mathfrak{g}^*$ is reached from δ_{c_0} by at most L coadjoint steps; it depends on the basis, which is why it ranges from 2 to 22); "nodes" is the number of tables in the generating tree of the divisor certificate; the next column splits them by collision order (see the strategy paragraph of Section 24.8). A reader can check the arithmetic: in every row the three counts are $\dim V(2\theta)$, $\dim \Lambda^2\mathfrak{g} = n(n-1)/2$ and $\dim I_2 = |\rho| + 1$, and they add up to n^2 (for E_8: $27000 + 30628 + 3876 = 61504$). The step count of every tree node is at most 4 (a separate kernel check, e.g. `d4_dep`), so all certificates are used with $\nu = 4$. This is a different "depth" from L; that it is at most 4 for every type is a fact about the generated trees, checked by the kernel, not a theorem about Lie algebras. N_A, N_S are the denominators of Theorem 24.39. The A_2 certificate predates the generic assembly and uses a projector form (`A2DivisorPair*.lean`).

Theorem 24.41 (The divisor comparison and the sector fusion bound, all seven types)**.** *For each $X \in \{A_2, G_2, D_4, F_4, E_6, E_7, E_8\}$ the divisor comparison holds for the type's sector data, and therefore, for every family F, U5 for F implies the sector fusion bound* `SectorFusionBound Xdata F`*. For A_2, U5 is taken in the A_2-specific form* `SectorWeyl.FusionModuleBound F` *below, and the Lean theorem takes the divisor comparison as a second hypothesis, discharged by the proved theorem* `A2.divisorComparison`*.*

From the mathematics to the Lean statement

Full names. `VOA.DeligneAudit.DeligneDivisor.X.x_divisorComparison` for $X \in \{\mathrm{G2}, \mathrm{D4}, \mathrm{F4}, \mathrm{E6}, \mathrm{E7}, \mathrm{E8}\}$; for A_2, `VOA.DeligneAudit.A2.divisorComparison : A2.DivisorComparison` (the A_2-specific structure, same statement for A_2's data), bridged by `VOA.DeligneAudit.DeligneSector.divisorComparisonG_of` (there is no declaration named `a2_divisorComparison`). The sector data are `G2sector`, `D4sector`, `F4sector`, `E6sector`, `E7sector`, `E8sector`, `A2sector`, each with `Xsector.toDeligneCarrierData = Xdata` by `rfl`. In each certificate call, $D = 4$ and the two following numerals are N_A and N_S; `qI` are the integer relation tables, `hq*` their identification with the carrier data, `U*` the complement tables, `hA*`, `hU*`, `hV*` the three certificate families, obtained from the kernel checks by `levOK_tree`/`levOK_treeC` and `encLin`.

The A_2 hypotheses. `SectorWeyl.FusionModuleBound F` is U5 for $\mathfrak{sl}_3$ written in the bespoke A_2 indexing of `AffineSl3.bracketTable` (indices $0,1,2$ the raising vectors e_1, e_2, e_{12}; $3,4$ the simple lowering vectors; $5 = c_0$ the lowest root vector f_θ; $6,7$ the Cartan elements, with $\theta(h_1) = \theta(h_2) = 1$): `SectorWeyl.LocalWeylRel` is the local Weyl relations of $W_{\mathrm{loc}}(m\theta)$ plus fusion relations for the three negative root vectors, and the two clauses `le`, `total` are those of `FusionModuleBoundG` (Definition 24.29). `fusionModuleBoundG_of` shows `FusionModuleBound F` implies `FusionModuleBoundG A2sector F` (every module satisfying `LocalWeylRelG A2sector` satisfies `LocalWeylRel`, by `localWeylRel_of_G`); we do not claim the converse. `A2.DivisorComparison` is the divisor comparison of Theorem 24.34 for A_2's data (`fullMatrix`, `bracketTable`, $c_0 = 5$), and `divisorComparisonG_of` converts it to `DivisorComparisonG A2sector`. It is proved, with no hypothesis, by `A2.divisorComparison` (`A2DivisorFinal.lean`, printed above).
Hypotheses. The divisor comparisons are unconditional. For the six types $G_2, \dots, E_8$ the sector fusion bounds `X_sectorFusionBound_of_U5` assume exactly U5 (`FusionModuleBoundG Xsector F`) for F. For A_2 the printed theorem `A2_sectorFusionBound_generic` has two hypotheses, `hU5 : FusionModuleBound F` (A_2 form of U5) and `hD : A2.DivisorComparison`; the bound from U5 alone is the term `A2_sectorFusionBound_generic F hU5 A2.divisorComparison`. The library has no declaration of that statement under its own name (there is no `A2_sectorFusionBound_of_U5`). The D_4 corollary adds U6 and gives the carrier side of the chain against the Demazure sum.

Proof on paper. Theorems 24.39, 24.40 with the type's certificates, then the reduction of Definition 24.36 and Theorem 24.35. □

Physical meaning

For each flavour symmetry in the series, the two-body problem of adjoint quanta is solved exactly; together with the fusion bound U5 this bounds the number of operators of the chiral algebra in every sector by the fusion-product count.

What the machine verified

Proved; every name above is `#print axioms`-standard. `x_divisorComparison`: **unconditional**. `X_sectorFusionBound_of_U5` ($G_2, \dots, E_8$): `#print axioms`-clean, **conditional on U5** (`FusionModuleBoundG`). A_2: `A2_sectorFusionBound_generic` is `#print axioms`-clean, **conditional on the A_2 form of U5 and on** `A2.DivisorComparison`, which is discharged by the proved `A2.divisorComparison` (see the dictionary: the resulting "U5 alone" statement has no name of its own). Build evidence (campaign record): per-type builds of the divisor modules green (E_8 9919 jobs, E_7 9317, E_6 8927, F_4 9002, G_2 8835, D_4 8795), all within the earlier umbrella build (the A_2 divisor certificate was later split; its record is the targeted build of Section 24.11). The author re-ran `#print axioms` for `d4_divisorComparison` and `D4_sectorFusionBound_of_U5`.

24.10 The certificate library, described collectively

About 1020 of the chapter's 1195 files are certificate data or certificate checks. None contains mathematics beyond the soundness lemmas of the previous sections; each family exists to discharge one finite hypothesis.

24.10.1 Trust model: why a file of integers is a proof

A reader who has never used Lean will ask why 10.8 MB of integers should count as a proof, and what must be trusted. The answer has four parts.

1. **The generators are untrusted.** The certificates were produced by Python scripts (exact rational arithmetic, then integers). Nothing about those scripts is assumed: a wrong script produces a certificate that fails to check, not a false theorem.

2. **The predicates are defined in Lean and proved sound once.** Each family is checked by a Boolean function written in Lean (for instance `nodeCheck`, `encCheck`, `symP`), and a generic theorem says what a `true` value means mathematically (Theorems 24.39 and 24.40: "if every node passes the node check, every node is level-OK"). These soundness theorems are ordinary proofs, valid for all data.

3. **The kernel evaluates the predicates on the literal data, and that evaluation is a proof.** A statement `rangeAll pred lo hi = true` is proved by `decide +kernel`: Lean's kernel, the small trusted program that checks every proof, reduces the closed Boolean term to `true` by computation, and the equation then holds by definition (`rfl`). This is a proof in the same sense as any other: the kernel is the only arbiter. It differs from `native_decide`, which runs compiled code and adds the compiler to the trusted base; `native_decide` is forbidden in the library and used nowhere here. Likewise a theorem of the form `a = b := rfl` (the "bridges" below) is a proof that both sides compute to the same term, checked by the kernel.

4. **What a referee must audit.** Only the soundness theorems (Sections 24.8–24.9) and the identification of the literal tables with the Lie data, i.e. the hypotheses `hq*` (the integer relation tables are the relations of the sector data) and `hf` (the integer structure constants are those of the sector data), which are themselves kernel-checked equalities. The numbers in the data files need no inspection.

The three axioms that `#print axioms` reports for these theorems, `propext`, `Classical.choice` and `Quot.sound`, are the standard axioms of Lean's logic (Chapter 1, Section 1.3); no project axiom enters.

24.10.2 Families

family (files)	what the kernel checks	size
U3 certificates: `DeligneCarrierD4`, `E6CarrierU*`, `E7CarrierU*`, `E8CarrierU*`, F_4/G_2 in `*SectorTables`	$L_a X_a Q = \sum c X_x P_b$ in Sym^3 (a cubic identity per current)	D_4: 28 `ring` proofs (18–54 terms); E_7: 23 files; E_8: 62 files, 248 certificates (mean 590, max 993 terms; expansions up to 14 646 terms)
Presentation steps: `D4LiePresentationSteps`, `E6PresChecks`, `E7LieSteps*`, `F4LieSteps*`, `G2LieSteps` (E_8: the vacuum-step checks of Chapter 25)	$q\,\mathrm{ad}_b P_j = pP_k$, sparse quadratic identities	102 / 649 / 1538 (8 files of 193) / 323 / 26 steps
Singular-vector checks: `E6SingChecks`, `F4LieSing*`, `G2LieSing*`, `E8LieSingular*`, in-file for D_4, E_7	$J^c(1), J^c(2)$ of the highest-weight vector vanish (integer sums)	small; F_4 split into 9 files

family (files)	what the kernel checks	size

Divisor: `DeligneDivisorD4*`, `G2Divisor*`, `F4Divisor*`, `E6Divisor*`, `E7Divisor*`, `E8Divisor*`	tree nodes, column tables, depth ≤ 4, ψ completeness, complement tables U, antisymmetric and symmetric certificates	files: 3 / 12 / 83 / 7 / 77 / 619

24.10.3 Format and checking mechanism

- **Generation.** Python scripts compute certificates in exact rational arithmetic (E_8: mod-$(2^{61}-1)$ pivots per weight block, then exact verification over $\mathbb{Z}$) and emit Lean. The emitters reproduce the committed files byte for byte (campaign record). Constants (N_A, N_S, the U scale) are computed per type, not copied: the E_6 values failed for E_7.
- **Data.** Literal `List (List ℕ)` blocks, integers zig-zag encoded, stored two-level (rows of n) so that `getD` lookups stay shallow; each data file ≤ 200 KB of source, `set_option maxRecDepth 100000`. Data files import only `Mathlib.Data.Nat.Notation`.
- **Predicates.** Per-index Boolean predicates (`nodeP`, `colP`, `depthP`, `psiP`, `UCheck`, `antiP`, `symP`), with `rangeAll f lo hi` checking an index range.
- **Kernel checks.** Each chunk theorem is `rangeAll pred lo hi = true` proved by `decide +kernel`, sized by a calibrated cost model to about 1 s; chunks are glued by `rangeAll_split` (a balanced tree for E_8) and read back by `rangeAll_sound`. No `native_decide` anywhere.
- **Light imports bridged by `rfl`.** The E_8 chunk files import a file `E8DivisorLight.lean` containing verbatim copies of the Boolean checkers; `E8Divisor.lean` proves each copy equal to its original by `rfl` before applying the generic soundness theorems.

A typical chunk and the bridges: File `VOA/DeligneAudit/E8DivisorChk450.lean`.

```
theorem e8_sym_8144 : rangeAll symP 8144 8147 = true := by decide +kernel

theorem e8_sym_8147 : rangeAll symP 8147 8156 = true := by decide +kernel
```

File `VOA/DeligneAudit/E8DivisorDefs.lean`.

```
def rangeAll (f : ℕ → Bool) (lo hi : ℕ) : Bool := (List.range' lo (hi - lo)).all f

def symP (p : ℕ) : Bool := !decide (p / 248 ≤ p % 248) || symCheck (p / 248) (p % 248)
```

File `VOA/DeligneAudit/E8Divisor.lean`.

```
theorem nodeCheckCL_eq : @nodeCheckCL = @nodeCheckC := rfl
theorem colCheckL_eq : @colCheckL = @colCheck := rfl
theorem encLinL_eq : @encLinL = @encLin := rfl
theorem smulQL_eq : @smulQL = @smulQ := rfl
theorem qgetL_eq : @qgetL = @qget := rfl
```

From the mathematics to the Lean statement

The pair index $p = 248c+d$ encodes (c, d); `symP p` is vacuously true unless $c \le d$. As explained in Section 24.10.1, the data need no trust. The `rfl` bridges are checked by the kernel too, so the light copies cannot differ from the originals.

24.10.4 Sizes and measured costs

The table collects the size and measured peak memory of each certificate family. The campaign worked under a per-file memory rule of about 7 GB, tightened during the campaign; the last column says whether the measured files respect it.

family	files	measured peak, time	rule respected
E_8 divisor	619 (556 chunk files, 9291 theorems; 59 data files, 10.8 MB)	3.5–7.2 GB, 11–20 s (13 sampled chunks)	yes
E_7 divisor	77 (643 chunk theorems in 54 files)	7.0–8.0 GB, 23–53 s	no (earlier)
E_6 divisor	7	8.8–10.9 GB, 45–110 s	no (earlier)
F_4 divisor	83	$\le$ 6.9 GB	yes
G_2 divisor	12	$\le$ 6.4 GB, $\le$ 8 s	yes
D_4 divisor	3 (checks file: 33 theorems)	10.9 GB, 172 s	no (earlier)
E_8 U3 (carrier)	62	6.9 GB max; 6254 s CPU in total	yes
E_8 sector	37	5.1–6.6 GB, up to 94 s	yes

The figures come from the campaign's logs, measured with `/usr/bin/time -l lake env lean -DmaxSynthPendingDepth=3`; not every file was measured. They are evidence of feasibility, not part of any proof.

Dead ends in kernel checking (do not retry)

Only the lessons of architectural interest are kept here.

- **One small declaration per check.** The kernel's cache grows within a declaration and is released only between declarations, and memory is also retained across theorems of one file. Whole-family declarations reached 18–38 GB (an E_7 antisymmetric family, a depth check over all 17 689 E_7 nodes, a whole-range E_8 sector check). The fix is many theorems of a few thousand entries each, and per-file as well as per-theorem budgets.
- **Literal lists, not vector literals.** Kernel lookups in `![…]` tables are slow at high indices; literal `List` tables read with `getD` are about ten times faster.
- **Light imports.** Importing the sector and VOA stack costs about 6 GB before any work. Check files import verbatim copies of the checkers instead, bridged to the originals by `rfl` (floor about 2.2 GB).
- **No per-index re-walking, no kernel sorting.** Statements quantified over an index that re-walk a table entry for each index, kernel merge sorts, and dense zero checks are all too slow. What works: big-integer encodings of sparse tables (Theorem 24.40(ii)) whose per-table encodings are shared by the kernel cache, column tables, and bucketed checks of long identities.
- **Mathematical choices.** A kernel `decide` of the Jacobi identity for the E_8 bracket table (about $1.5 \cdot 10^7$ triples) is infeasible without `native_decide`; for E_7 and E_8, Jacobi is inherited from the lattice Lie algebra instead. Solving U3 current by current for E_7 did not finish; one solve at the highest weight plus propagation by lowering derivations

works. A breadth-first search of all coadjoint words is hopeless for E_8 (248^4 words at depth 4); extending only unit-vector states finds every basis vector at depth ≤ 2.

24.11 Verification record

What the machine confirmed (campaign records). The last complete umbrella build is at an earlier commit:

```
bash scripts/campaign_build.sh VOA.Deligne     # earlier: green, 11099 jobs, no sorryAx
#print axioms (all campaign files)             # subset of [propext, Classical.choice,
 ↪  Quot.sound]
lake build VOA (aggregate)                      # last green on 26 Oct (13868 jobs)
bash scripts/campaign_build.sh VOA              # 28 Oct (pre-release): green, 18901 jobs,
                                                #   then 18907 jobs after a merge
```

No `sorry`, `admit`, `native_decide` or `axiom` in the campaign files (campaign greps). The Lean sources changed after that build: between it and the state this chapter was written against, the diff of `VOA` touches 1390 files. The changes split certificate files to fit the per-file memory budget (the A_2 divisor certificate `A2DivisorPairCert` into tree identities, matrix-pair checks and fixed-row bridges; the D_4 divisor checks; the E_7 Lie steps), move declarations into lighter files (for example `SingP` into `VOA/DeligneAudit/D4LieSingularGeneric.lean`), and add the new A_2 files of Chapters 26 and 27. According to the project's internal build record of 27 October 2026 (not re-run for this chapter), the exported statements of the split files are unchanged and the repaired targets it lists were built green in targeted builds with standard axioms (some splits were still in progress when it was written); the targeted build of `VOA.DeligneAudit.A2Unconditional` (9755 jobs), whose import closure contains the A_2 certificates of this chapter, is green. On 2026-10-28 the aggregate build `bash scripts/campaign_build.sh VOA` (the full `lake build VOA` under the project's memory-capped wrapper) was green on 2026-10-28 (a pre-release build): 18,901 jobs, and again 18,907 jobs after merging the then-current `origin/main`; the aggregate target contains the umbrella `VOA.Deligne`. `scripts/check_repository.py` passed (10,431 library files, all reachable, 0 project axioms) and `scripts/audit/run_axiom_audits.py` passed (5,958 reports across 24 probes). "Axioms standard" in the status boxes remains the campaign record of the `#print axioms` sections and targeted builds, except where a claim is marked re-checked.

What this chapter's author checked. (1) Every `leancode` block occurs verbatim in the sources of the state this chapter was written against (`sync.py check`; one quotation was re-pointed to the file its declarations moved to). (2) On a scratch file importing the single module `VOA.DeligneAudit.DeligneDivisorD4`, with the checkout's oleans, at an earlier commit (not re-run for this edition):

```
lake env lean -DmaxSynthPendingDepth=3 AxCheck.lean     # 3.98 s, 5.6 GB peak RSS
'VOA.DeligneAudit.DeligneDivisor.D4.d4_divisorComparison' depends on axioms: [propext,
 ↪  Classical.choice, Quot.sound]
'VOA.DeligneAudit.DeligneDivisor.D4.D4_sectorFusionBound_of_U5' depends on axioms:
 ↪  [propext, Classical.choice, Quot.sound]
'VOA.DeligneAudit.DeligneDivisor.pairComparisonG_of_cert' depends on axioms: [propext,
 ↪  Classical.choice, Quot.sound]
'VOA.DeligneAudit.DeligneSector.sectorFusionBoundG' depends on axioms: [propext,
 ↪  Classical.choice, Quot.sound]
'VOA.DeligneAudit.DeligneCarrier.casimirLayerBound' depends on axioms: [propext,
 ↪  Classical.choice, Quot.sound]
'VOA.ker_eq_of_liPresentationClassicallyFree' depends on axioms: [propext,
 ↪  Classical.choice, Quot.sound]
'VOA.DeligneHigherRankConditionalCapstone.caseClassicallyFree_of_explicit_inputs' depends
 ↪  on axioms: [propext, Classical.choice, Quot.sound]
```

A second scratch file with the same single import, run during the revision of this chapter (4.6 s):

```
'VOA.DeligneAudit.DeligneSector.mem_Mspace_of_symmetric' depends on axioms: [propext,
 ↪  Classical.choice, Quot.sound]
'VOA.DeligneAudit.DeligneSector.genericComparisonG' depends on axioms: [propext,
 ↪  Classical.choice, Quot.sound]
'VOA.DeligneAudit.DeligneSector.mFreeness' depends on axioms: [propext, Classical.choice,
 ↪  Quot.sound]
'VOA.DeligneAudit.DeligneDivisor.divisorComparisonG_of_pair' depends on axioms: [propext,
 ↪  Classical.choice, Quot.sound]
'VOA.DeligneAudit.DeligneDivisor.pairComparisonG_of_cert' depends on axioms: [propext,
 ↪  Classical.choice, Quot.sound]
```

(3) No `#print axioms` was re-run at the state this chapter was written against: the checkout has no compiled objects for the new A_2 modules, and building them is outside the scope of a chapter revision. The author did not run `lake build`.

24.12 Findings, oddities and Lean defects

No statement-level defect was found: the headline statements say what the mathematics says, about genuine simple affine VOAs, with every hypothesis visible. The documentation defects and scope remarks are collected here, each once; the places in the chapter where they matter point back to this section.

Documentation defects (Lean docstrings and project notes)

Severity S4 means that documentation (a docstring or a note) is wrong or stale; no statement is affected.

1. **(Docstring, S4)** `DeligneHigherRankConditionalCapstone.lean`: the module docstring says "There is no universal affine VOA for a general simple Lie algebra yet, so this file does not pretend that the remaining higher-rank affine VOAs have been instantiated". This is false since `VOA/AffineGeneral` (Chapter 23); all seven cases are instantiated in Section 24.3. The docstring of `caseClassicallyFree_of_explicit_inputs` speaks of "the exact current C_2 presentation" as a hypothesis, while only containment is assumed.

2. **(Docstring, S4)** `DeligneCarrierChain.lean`: the docstring of `CasimirAuxiliaryBound` says "Not a literature input: a formalization target" and refers to Jet(Sym $\mathfrak{sl}_3/I_2^{ns}$) in a type-generic file; it is proved (`casimirAuxiliaryBound`, Theorem 24.23). The docstring of `SectorFusionBound` says it uses "U4 (Chari–Fourier–Khandai)"; the Lean derivation (`sectorFusionBoundG`, Theorem 24.35) uses U5 only.

3. **(Project notes, S4)** The project's internal records (entry of 27 October 2026) name `a2_divisorComparison`; no such declaration exists (the A_2 theorem is `VOA.DeligneAudit.A2.divisorComparison`, with the bridge `DeligneSector.divisorComparisonG_of`).

The statements themselves are correct in all three cases.

Further remarks for the referee (not defects):

1. **(Scope, S4)** D_4, E_7, E_8 results are about `simpleVOA` of the certificate-basis Lie data; their identification with the `Module.finBasis` constructions (and the three $\mathfrak{e}_6$ models) is not proved (Warning "Which VOA?" in Section 24.3).

2. **(Formulation)** `FusionModuleBoundG` uses `Module.finrank`, which is 0 on infinite-dimensional spaces; this weakens the named input harmlessly. The fusion set is free data; the two readings in use (Ravinder's set, all negative root vectors) impose the same relations for every type, short roots of G_2 and F_4 included: the extra vectors have $\langle \alpha, \theta^\vee \rangle = 0$ and are killed by the bracket step of Lemma 27.6 (dictionary of Definition 24.29).

3. **(Formulation)** The relation lists are not proved in Lean to span exactly I_2^{ns} (dictionary of Definition 24.8).

4. **(Naming)** Short names `I2ns_le_ker`, `explicitPresentation`, `mFreeness`, `divisorComparison`, `geometricCarrierEmbedding` denote different theorems in different namespaces; use the full names (dictionary of Theorem 24.12).

5. **(Design history)** An earlier version of `CurrentC2Presentation` had a field asserting that the ideal equals the kernel; it was replaced by the containment field `relations` and the theorem `exact_kernel_of_caseClassicallyFree`, so exactness is now a conclusion.

24.13 Referee's checklist

Lean declaration	Intended meaning	Hypotheses / status	Fidelity check
`LiPresentationClassicallyFree`, `liInfinitePresentedJetMap`	classical freeness of a presentation	definitions	Def. 24.2
`HigherRankDeligneCase`, `level`	the seven cases, $k = -1 - h^\vee/6$	definitions	Def. 24.3
`CurrentC2Presentation`, `CurrentJetSurjectivity`, `GeometricCarrierEmbedding`, `OrdinaryCarrierCharacter`, `CaseClassicallyFree`	the four packages	definitions; containment only	Def. 24.4
`classicallyFree_of_carrier_weightCharacter`	weightwise squeeze	packages; proved	Thm. 24.5
`VOA.ker_eq_of_liPresentationClassicallyFree`	exactness is a conclusion	unconditional	Thm. 24.6
`caseClassicallyFree_of_explicit_inputs`	capstone	three packages; reduction	Thm. 24.7
`D4Lie.mem_maxIdeal_of_SingP`	singular $\Rightarrow$ in max ideal	any Lie data; unconditional	Thm. 24.9
`A2.simpleProjection_singVec`	Perše's vector dies	unconditional	Thm. 24.10
`A2.clsG_adPolyT`	kernel is ad-stable	table hypothesis; proved	Thm. 24.11
`I2ns_le_ker*`, `explicitPresentation*` (seven types)	$I_2^{\mathrm{ns}} \subseteq \ker$	**unconditional**	Thm. 24.12
`currentJetSurjectivity_of_genWordSpan`, `Deligne.genWordsSpan`	currents generate	unconditional	Thm. 24.14
`currentCarrier`, `auxiliaryCarrier`, `degreePiece`, `conductor`	W_m, auxiliary carrier	definitions	Def. 24.16
`restrictedDual EquivCurrentCarrier`	B4: dual $\cong$ carrier	unconditional	Thm. 24.17
`geometricCarrierEmbedding_of_quadraticIdeal`	package 3 for quadrics	unconditional (weak alone)	Thm. 24.18
`caseClassicallyFree_of_quadraticCarrierUpperBound`	one-inequality capstone	`QuadraticCarrierUpperBound`	Thm. 24.19

Lean declaration	Intended meaning	Hypotheses / status	Fidelity check
`DeligneCarrierData`	type data with U3	U3 field	Def. 24.21
`casimirLayerBound`, `casimirAuxiliaryBound`	B1	**unconditional**	Thm. 24.23
`sectorCoeff_eq_of_mixed`	D3 resummation	U6 form; proved	Thm. 24.24
`carrierDim_le_demazureSum`	carrier $\leq$ Demazure sum	sector bound, U6	Thm. 24.25
`DeligneSectorData`, `LocalWeylRelG`, `FusionModuleBoundG`	sector data; U5	definitions; U5 named input	Defs. 24.28, 24.29
`Mspace_le`	B5	sector data	Thm. 24.30
`mem_Mspace_of_symmetric`	symmetrization	sector data	Lem. 24.31
`DeligneSector.mFreeness`	B6	U5	Thm. 24.33
`genericComparisonG`	$\Delta^L W_m \subseteq M_m$	sector data	Thm. 24.32
`carrierGenerationG`	B8	B6, divisor comparison	Thm. 24.34
`sectorFusionBoundG`	sector fusion bound	U5, divisor comparison	Thm. 24.35
`divisorComparisonG_of_pair`, `pairComparisonG_of_cert`	B7 at the divisor, from certificates	certificate hypotheses	Thms. 24.39, Def. 24.36
`levOK_tree`, `castQZ_eq_of_enc`	checker soundness	unconditional	Thm. 24.40
`x_divisorComparison` (G2, D4, F4, E6, E7, E8), `A2.divisorComparison`	divisor comparison per type	**unconditional**	Thm. 24.41
`X_sectorFusionBound_of_U5` (G2, D4, F4, E6, E7, E8)	sector bound per type	U5	Thm. 24.41
`A2_sectorFusionBound_generic`	A_2 sector bound	A_2-form U5 (`SectorWeyl.FusionModuleBound`) plus `hD`, discharged by the proved `A2.divisorComparison`	Thm. 24.41
`d4_carrierDim_le_demazureSum_of_U5_U6`	D_4 carrier $\leq$ Demazure sum	U5, U6	Thm. 24.41

Chapter 25

The Deligne series II: characters, the Arakawa–Kawasetsu MLDE and q-series identities

This chapter was written against an earlier state of the LeanVOA library. For this edition, `scripts/textbook/sync.py` checks that every Lean quotation below occurs verbatim (up to whitespace and comments) in the source files of that release. The machine record (builds and `#print axioms`) is older than that release; Section 25.1.7 states exactly what it covers. The list of files covered by the chapter is in Section 25.12.1.

25.1 Overview: the chain, its status, and how to read this chapter

25.1.1 What this chapter is about

The *Deligne exceptional series* is $A_1 \subset A_2 \subset G_2 \subset D_4 \subset F_4 \subset E_6 \subset E_7 \subset E_8$. For its seven higher-rank members, the level $k = -1 - h^\vee/6$ gives a simple affine vertex algebra $V = L_k(\mathfrak{g})$ of central charge $c = -2(h^\vee + 1)$. Physicists know these as the chiral algebras of the rank-one four-dimensional $\mathcal{N} = 2$ theories (for A_2, D_4, $E_{6,7,8}$). The project's main theorem (Chapter 27) is *classical freeness*. Its statement uses three objects, glossed in Section 25.1.4: the C_2-algebra $R_V = V/C_2(V)$, the arc space J_∞ of a scheme, and an explicit space I_2^{ns} of quadrics (the C_2-symbols of the weight-two singular vectors). It says that the graded algebra of V for Li's filtration is the coordinate ring of the arc space of $\operatorname{Spec}\operatorname{Sym}(\mathfrak{g})/(I_2^{\mathrm{ns}})$. For A_2 this is now a Lean theorem with no hypotheses (`VOA.DeligneAudit.A2.classicallyFree`, Chapter 27; aggregate build green on 2026-10-28, standard axioms); for the other six types it is proved conditionally on named inputs.

For counting purposes, classical freeness comes down to one equality of dimensions for each conformal weight N. On one side is $\dim V_N$, the number of quantum states of weight N. On the other is the number of classical states, $\sum_p \dim \mathrm{Carrier}_{p,N}$. Here the *carrier* is a combinatorial model of the arc space (Chapter 24), bigraded by Li degree p and weight N. One inequality, $\dim V_N \le \sum_p \dim \mathrm{Carrier}_{p,N}$, comes from the presentation (Chapter 24). The other, $\sum_p \dim \mathrm{Carrier}_{p,N} \le \dim V_N$, is a *lower bound on* $\dim V_N$, and this chapter supplies the part of it that is about V. That part has three layers.

1. **The VOA side** (Sections 25.3–25.6). For every type, $\dim V_N \ge c_N$, where c_N are the coefficients of the unique normalised solution of a second-order *modular linear differential equation* (MLDE; primer in Section 25.3). The proof is formal. One relation among states of weight four, the *vacuum quartic relation*, forces the MLDE, and the indicial equation then forces the equation's constant. These are the first MLDEs in the library proved for specific vertex algebras. They are identities of *formal* q-series (equivalently, recurrences for

the coefficients $\dim V_N$): nothing analytic is formalised, neither convergence nor modular invariance nor a second solution. The general Arakawa–Kawasetsu theorem of Chapter 16 (`IsSqPrimary.exists_monicMLDEOn_all_analyticBlocks_of_etingofFinite_uncond`) is conditional only on Etingof-finiteness (`EtingofFinite`, which holds for every C_2-cofinite VOA by `EtingofFinite_of_C2Cofinite`); its side inputs `AKWeightGrading` and `E46SerreClosed` are now theorems (`VOA.akWeightGrading`, `VOA.e46SerreClosed`). It gives, for abstract analytic genus-one blocks, a monic MLDE of *some* order with unspecified coefficients; it does not give the second-order equations proved here. The route here needs neither that theorem nor modularity (warning in Section 25.4).

2. **The q-series side** (Sections 25.7–25.8). A library of formal q-series identities, proved from scratch: the Jacobi triple product, Euler's pentagonal theorem, the sum side of the quintuple product, Legendre's four-triangular-numbers theorem, Ramanujan's three differential identities, and Lorenz's and Borwein's level-three identities. These give closed forms of c_N for A_2, G_2, D_4, E_6, E_7, E_8.

3. **The Demazure side** (Sections 25.9–25.10). Level-one affine Demazure characters, computed by an algorithm. The *star identity* "Demazure sum $= c_N$" is proved for A_2, proved for D_4 on the unclamped route (Chapter 27), and is a named input for the other five types, where it is a conjecture (Conjecture 27.10).

25.1.2 The chain of inequalities and its status

Write $\mathcal{C}_N = \sum_{p=0}^{N} \dim \mathrm{Carrier}_{p,N}$ (the classical count), D_N for the Demazure sum (Definition 25.3), and c_N =`DeligneCharacter.mldeCoeff h N` (Definition 25.7). The whole argument, at each weight N, is the chain

$$\mathcal{C}_N \overset{(a)}{\leq} D_N \overset{(b)}{\leq} c_N \overset{(c)}{\leq} \dim V_N \overset{(d)}{\leq} \mathcal{C}_N. \tag{25.1}$$

The chain starts and ends at $\mathcal{C}_N$. Once every link is proved, every link is an equality, and $\mathcal{C}_N = \dim V_N$ is the counting content of classical freeness. The links are as follows.

(a) *The carrier side*, $\mathcal{C}_N \leq D_N$: Chapters 24 and 26, conditional on the fusion inputs U5 and U6 (Section 25.1.4); for A_2 these inputs are proved, so (a) holds unconditionally there (Chapter 27). Not in this chapter.

(b) *The star bound*, $D_N \leq c_N$: Section 25.10. This is the one-sided form of the star identity $D_N = c_N$.

(c) *The target lower bound*, $c_N \leq \dim V_N$: Sections 25.3–25.6. It is proved for all seven types, with no hypothesis.

(d) *The upper bound*, $\dim V_N \leq \mathcal{C}_N$: current-jet surjectivity plus the geometric carrier embedding (Chapter 24; Theorem 25.2 below).

Links (b) and (c) together are the *Demazure bound* $D_N \leq \dim V_N$ (Definition 25.4), which is what Chapter 27 consumes. The table below records, for each type and each claim, what is a Lean theorem. The entries mean the following. *Theorem*: a Lean theorem with no hypotheses. *Derivable*: it follows by composing exported Lean theorems, but no single Lean statement says it. *Conditional*: a Lean theorem with the named hypothesis. *Open*: a named `Prop` that is not proved.

type	(c) $\dim V_N \geq c_N$	$\dim V_N = c_N$	(b) star: $D_N \leq c_N$ or $=$	closed form of c_N
A_2	theorem	theorem	theorem ($=$; Thm. 25.36)	theorem: $\prod_{r\geq 1}(1+q^r)^8$
G_2	theorem	derivable†	**open** (`G2StarBound`; Conj. 27.10)	theorem: $\theta_{A_2}(q)\frac{(q^3;q^3)_\infty^6}{(q;q)_\infty^8}$
D_4	theorem	derivable†	`d4SchurQ` $= c_N$ theorem; $D_N =$ `d4SchurQ` conditional on `D4DemazurePositivity`	theorem: $\frac{\delta_q E_4}{240\,(q)_\infty^{10}}$ (shifted)
F_4	theorem	derivable†	**open** (`F4StarBound`; Conj. 27.10)	none in the library
E_6	theorem	derivable‡	**open** (`E6StarBound`; Conj. 27.10)	theorem (Thm. 25.32)
E_7	theorem	derivable‡	**open** (`E7StarBound`; Conj. 27.10)	theorem (Thm. 25.32)
E_8	theorem	derivable‡	**open** (`E8StarBound`; Conj. 27.10)	theorem (Thm. 25.32)

†The composition was typechecked in a scratch file for this chapter. ‡The composition was not typechecked, because the $E_{6,7,8}$ modules are too heavy to import for a single check. For both marks see Caveat 1. The A_2 product entry has a further gap: the equality $\dim V_N = [q^N]\prod(1+q^r)^8$ is itself only derivable (Remark 25.23). Every "theorem" of the star column is a statement about the computed Demazure tables. Reading those tables as characters of Demazure modules is the input U7 (Caveat 2).

What Chapter 27 still needs from this chapter. Its final theorems for G_2, F_4, E_6, E_7, E_8 take the star bound `XStarBound` as an explicit hypothesis, the open entry of column (b). The A_2 final theorem takes no hypothesis at all: (b) and (c) are both proved here, and the carrier-side inputs are proved in Chapters 26 and 27. The D_4 final theorem takes no star hypothesis either, because it works with the unclamped Demazure series (see Chapter 27). Link (c) is used in full for all seven types.

25.1.3 Which sections are on the critical path

The **critical path**, needed for links (b) and (c) in Chapter 27, consists of these sections: Section 25.2 (the interface), Sections 25.3–25.6 (link (c)), Section 25.9 (the Demazure tables), Section 25.10 (link (b)), and those q-series results that feed the A_2 and D_4 star identities: the triple product, Legendre, Ramanujan's identities, the A_2 product, and the D_4 closed form.

The following are **side results**, off the critical path at this commit. They are marked as such where they occur.

- The G_2 target side (Lorenz, Borwein, Theorem 25.30). It becomes critical only if the open `G2DemazureEqKW` is proved.
- Euler's pentagonal theorem and the sum side of the quintuple product (Theorem 25.26), except as ingredients of Lorenz's formula.
- The E_6, E_7, E_8 closed forms (Theorem 25.32). The star bounds target c_N directly.
- The $q = 1$ counts and the energy bounds (Section 25.11). They serve Chapter 26 and the `energy` field of the D_4 positivity input.

25.1.4 Glossary of terms and named inputs

The terms below are used in this chapter but defined elsewhere. Each gets a one-line gloss here and a pointer to where it is developed.

- **C_2-algebra** $R_V = V/C_2(V)$, where $C_2(V)$ is spanned by the states $a_{(-2)}b$. It is a commutative Poisson algebra, the "classical limit" of V (Chapter 12). Its spectrum is the **associated scheme**; the reduced variety underneath is the **associated variety**.

- **Li filtration**: a decreasing filtration of V whose degree-0 graded piece is R_V. Its associated graded $\mathrm{gr}V$ is a quotient of the **arc space** (jet ring) $J_\infty R_V$, the ring of functions on formal curves $t \mapsto x(t)$ in $\operatorname{Spec} R_V$ (Chapters 11 and 24).

- **Quasi-lisse**: the associated variety has finitely many symplectic leaves. Arakawa and Kawasetsu prove that the characters of such VOAs satisfy an MLDE (the general theorem is in Chapter 16).

- **Higgs branch**: in the 4d $\mathcal{N} = 2$ theory, the moduli space on which the associated variety of the chiral algebra is realised. For the Deligne series it is the minimal nilpotent orbit closure.

- **Joseph relations, I_2, I_2^{ns}.** $\operatorname{Sym}^2 \mathfrak{g} = V(2\theta) \oplus I_2^{\mathrm{ns}} \oplus \mathbb{C}Q$, with Q the Casimir quadric. For $\mathfrak{g}$ not of type A, $I_2 = I_2^{\mathrm{ns}} \oplus \mathbb{C}Q$ generates the associated graded of the Joseph ideal (literature, not Lean); for A_2 there is no Joseph ideal, and in Lean I_2^{ns} is simply the ideal spanned by explicit lists of quadrics (Chapter 24). The superscript "ns" means *non-singlet*: I_2^{ns} is the part of I_2 without the $\mathfrak{g}$-invariant Q. These are the C_2-symbols of the weight-two singular vectors (Chapter 24, "The Deligne series").

- **U3**: $X_a\, Q \in (I_2^{\mathrm{ns}})$ in $\operatorname{Sym}^3 \mathfrak{g}$ for every current X_a, so Q^2 lies in the ideal too. It is certified per type, as the field `u3` of `DeligneCarrierData` (Chapter 24).

- **U5**: the fusion bound (Input T of Chapter 27). The fusion module $\mathcal{F}_m$ has dimension $\leq (\dim \mathfrak{g})^m$, with graded character F_m. Its published source for the total dimension is Kus–Littelmann, Pacific J. Math. 278, Theorem 4.2, with one flagged step (p. 437); Feigin's earlier proof has a gap (Chapter 27). It is a named hypothesis, reduced in Chapter 26.

- **U6**: Ravinder's mixed fusion recursion, which expresses $\mathrm{Hilb}_q D(1, n\theta)$ through the F_m. Named; Chapter 26.

- **U7**: the identification of a *computed* table with the graded character of the level-one Demazure module $D(1, n\theta)$. It rests on the Demazure character formula (Kumar, Mathieu) and on the identification of $D(1, n\theta)$ with a fusion product (Fourier–Littelmann, Chari–Venkatesh); for A_2, on Sanderson's and Ion's q-Whittaker formula. It is not formalised; in Chapters 26–27 it appears as the hypothesis `DemazureRealizationG` (Input R of Chapter 27). The star bound $D_N \leq c_N$ is Input S there.

- **Demazure module** $D(1, n\theta)$: the subspace of the level-one integrable module $L(\Lambda_0)$ of $\hat{\mathfrak{g}}$ generated by an extremal vector of weight $n\theta$ under the positive part. Its weight-0 part is the irreducible $V(n\theta)$, and $D(1, \theta) = \mathfrak{g} \oplus \mathbb{C}$.

- **Kirillov–Reshetikhin module** $\mathrm{KR}(\theta)$: $\mathfrak{g} \oplus \mathbb{C}$ as a module for the current algebra $\mathfrak{g}[t]$. Fusion products of copies of it give the $D(1, n\theta)$.

- **q-Whittaker polynomial** $P_\lambda(x; q, 0)$: the Macdonald polynomial at $t = 0$. **Gelfand–Tsetlin branching**: computing it by restricting $GL_3 \to GL_2 \to GL_1$ along interlacing patterns. At $t = 0$ each step contributes a product of q-binomials (dictionary of Theorem 25.36).

- **Rogers–Szegő polynomial** $H_M(x) = \sum_{r=0}^{M} \binom{M}{r}_q x^r$. We write $G_M = H_M(1)$.
- **HKOTY fermionic formula**: a sum over quasi-particle configurations, weighted by q-binomials. For graded fusion products of KR modules it is proved to give the character, for every $\mathfrak{g}$ (Ardonne–Kedem, Di Francesco–Kedem); the $X = M$ form, with one-dimensional sums, is a separate statement.
- **Plethystic (product) exponents** of a series $1+\sum_{n\geq 1} b_n q^n$: the integers a_n with $1+\sum b_n q^n = \prod_n (1-q^n)^{-a_n}$.

25.1.5 Notation

Several letters have more than one job in the sources. We fix them as follows; Lean names keep their Lean spelling.

symbol	meaning in this chapter	where
δ_q	the Euler operator $q\frac{d}{dq}$ on q-series (Lean `qDeriv`, `eulerOp`)	§25.3
θ	the highest root of $\mathfrak{g}$ (only); $\theta^\vee$ its coroot	§25.9
θ_{A_2}, θ_2, $\Theta(x)$	the A_2 lattice theta series; the Jacobi theta constant; the D_4 theta function in x	Thms. 25.30, 25.27, 25.37
Θ (with u)	the triple-product sum $\sum(-1)^j u^j q^{j(j-1)/2}$ in the heat-equation proof	Thm. 25.28
$\varkappa$	the constant of the vacuum quartic relation (Lean `ϰ` in `VacuumQuarticRelation W ϰ`); the bilinear form in `LieData ϰ …` is written $\varkappa_{\mathfrak{g}}$	Def. 25.13
h	the dual Coxeter number $h^\vee$ when it parametrises the MLDE; `D.h` is the same number read off a `LieData`	§25.3
hilb(n,N)	a table of Demazure coefficients $[q^N]\mathrm{Hilb}_q D(1,n\theta)$	Def. 25.3
c	the central charge; c_N the AK coefficients; c_0 (Lean `c₀`) the Casimir ratio of Thm. 25.21	
$z(k,m,m+p)$	Zhu's change-of-coordinate coefficients	Thm. 25.16
k	the level $-1-h/6$; elsewhere a modular weight (said explicitly)	
$(a;q)_n$, $(q)_n$	$\prod_{i=0}^{n-1}(1-aq^i)$; $(q)_n = (q;q)_n$; $n=\infty$ allowed. $(q)_\infty = (q;q)_\infty$ is the Euler product (Lean `euler`)	§25.7
p, r	p: Li degree; in the quintuple product, a nome. $r = q^{1/2}$ in the D_4 section; elsewhere r is a summation index	
P_λ, P_1, P_3, P	the q-Whittaker polynomial; the divisor series $\sum\sigma_1(n)q^n$, $\sum\sigma_3(n)q^n$ (Lean `P1`, `P3`); in the proof of Thm. 25.28 only, P is the triple-product side	
D_N; D_i	the Demazure sum; Demazure operators (with subscript)	
W	the VOA in a Lean statement (Lean `W`); the Lambert series of the D_4 proof is $\mathcal{W}_1$	
$S_M(v)$	the torus one-point function $\mathrm{tr}_M\, o(v)q^{L_0-c/24}$	§25.4

25.1.6 Reading the Lean in this chapter

Chapter 1, Section 1.2, is the general primer. The idioms that the printed code of this chapter needs are these.

- **Truncated blocks.** Proof bodies are omitted. A printed block therefore ends at `:=`, `:= by` or `where`, and the proof follows in the file. `theorem foo : S where` with nothing after it is such a block: the omitted body fills the fields of the structure `S` one by one. It is not a syntax error.
- **Binders.** `(x : T)` is an explicit argument, `{x : T}` an implicit one inferred by Lean, and `[Field K]` an instance argument (a structure found automatically). `(K := ℚ)` supplies the

named implicit argument `K`. `section` variables are arguments shared by all declarations of a section; we list them in the dictionaries.

- **`Prop`-valued structures.** `structure S : Prop where eq : …` is a bundled hypothesis. A proof `h : S` gives `h.eq`. A theorem that takes `(h : S)` is conditional on `S`, and `#print axioms` does not show this.

- **`abbrev` vs `def`**: both define, and `abbrev` unfolds automatically.

- **Finite sums.** `∑ i ∈ s, f i` is a sum over the finite set `s`. `Finset.range n` $= \{0, \dots, n-1\}$. `Finset.antidiagonal n` $= \{(i,j) : i+j = n\}$. `Finset.Icc a b` $= [a, b]$, and `Finset.Icc a b with e n = d` is its subset where $e(n) = d$.

- **Small notation.** `•` is scalar multiplication. `x⁻¹` is the inverse. `l.getD i 0` is entry i of a list (default 0). `f^[m]` is the m-fold iterate of `f`. `x.1.2` is the second component of the first component of a pair.

- **Algebra.** `(n : ℚ)` is a cast. `MvPolynomial ι ℂ` is $\mathbb{C}[X_i : i \in \iota]$. `Submodule.span ℂ s` is the span. `V ⧸ U` is the quotient space and `U.mkQ` the quotient map. `PowerSeries R` is $R[[q]]$ (Chapter 1).

- **Kernel checks.** `decide +kernel` proves a decidable statement by evaluating it in Lean's trusted kernel. `native_decide`, which would trust compiled code, is never used. `d4_precompute%` is a custom elaborator that only *proposes* literals; the kernel re-checks them.

25.1.7 What was machine-checked, and when

The quotations were re-verified against the state of the library this chapter was written against. The last complete build of the umbrella module `VOA.Deligne` is older: it was built green at an earlier commit. At that commit it imported, directly or transitively, all 239 files of this chapter, including the E_6, E_7, E_8 modules (we checked the import closure). The build took 11099 jobs and reported no `sorryAx`. The `#print axioms` commands in those files all reported a subset of `[propext, Classical.choice, Quot.sound]`. The *aggregate* `lake build VOA` was last run green on 26 October (13868 jobs), at an earlier commit. Neither has been re-run at the state this chapter was written against. Between that umbrella build and that state the Lean sources changed (the diff of `VOA` touches 1390 files): certificate files were split to fit the memory budget (among them the D_4 divisor and the A_2 divisor certificates), a few files of this chapter were edited (for example `VOA/DeligneAudit/DeligneMLDE.lean`, a docstring-only change), and the unconditional A_2 files were added. According to the project's internal build record of 27 October 2026 (not re-run for this chapter) the exported statements of the split files are unchanged and the repaired targets were built green in targeted builds with standard axioms; every statement this chapter quotes occurs verbatim in the state this chapter was written against. On 2026-10-28 the aggregate build `bash scripts/campaign_build.sh VOA` (the full `lake build VOA` under the project's memory-capped wrapper) was green on 2026-10-28 (a pre-release build): 18,901 jobs, and again 18,907 jobs after merging the then-current `origin/main`; the aggregate target contains the umbrella. The "standard axioms" of the status boxes are campaign records of the earlier umbrella build and of the later targeted builds. For this chapter we re-ran `#print axioms` on the generic lemmas named in the status boxes, plus the scratch checks reported in Caveat 1 and Example 25.11. We ran no build.

Axioms. Unless a status box says otherwise, every theorem of this chapter depends only on Lean's three standard axioms `propext`, `Classical.choice` and `Quot.sound`. The library has no project axiom (`VOA.pbw` is a theorem, Chapter 3), and nothing here uses it. The status boxes therefore say "standard axioms". They separately say whether we re-ran the check for this chapter.

25.1.8 Recurring caveats, stated once

1. **Equality is a Lean theorem only for A_2.** $\dim V_N = c_N$ is stated in Lean for A_2 only (`A2.finrank_eq_mldeCoeff'`). For the other six types only $\geq$ is stated. The equality is derivable (warning after Theorem 25.22).

2. **Demazure tables are algorithms.** `levelOneDemazureHilb` and the A_2 formula `demazureHilb` are computable tables. Reading them as characters of $D(1, n\theta)$ is input U7, which is not formalised.

3. **Named inputs are hypotheses, never axioms.** A star identity or bound is a `Prop`. A theorem that uses one takes it as an argument, and `#print axioms` does not show it.

4. **Stale documentation.** Several docstrings call proved statements "named" or "literature" inputs. They are listed once, in Section 25.13, and not repeated next to the theorems.

25.2 The character side of classical freeness

25.2.1 Where the characters enter

Let $V = L_k(\mathfrak{g})$ and let $R_V = V/C_2(V)$ be Zhu's C_2-algebra (Chapter 12). Classical freeness asserts that the Li filtration of V has associated graded equal to the coordinate ring of the arc space $J_\infty X$ of the scheme $X = \operatorname{Spec} R_V$, and that $R_V = \operatorname{Sym}(\mathfrak{g})/(I_2^{\mathrm{ns}})$ for an explicit ideal I_2^{ns} of quadrics. Chapter 24 reduces this to three *packages* for a presentation P of V and a "carrier" family of vector spaces $\mathrm{Carrier}_{p,N}$ (bigraded by Li degree p and conformal weight N): current-jet surjectivity, an injective geometric carrier embedding, and the *ordinary carrier character* identity $\sum_{p \leq N} \dim \mathrm{Carrier}_{p,N} = \dim V_N$. The first two give one inequality for free (link (d) of (25.1)); the third is the character side. Its lower half, links (b) and (c), is the subject of this chapter.

Definition 25.1 (Carrier character lower bound)**.** For a VOA V and a bigraded family $\mathrm{Carrier}_{p,N}$, the *carrier character lower bound* is the statement

$$\forall N \geq 0 : \qquad \sum_{p=0}^{N} \dim_{\mathbb{C}} \mathrm{Carrier}_{p,N} \;\leq\; \dim_{\mathbb{C}} V_N .$$

File `VOA/DeligneAudit/A2Character.lean`.

```
def CarrierCharacterLowerBound (W : VertexOperatorAlgebra V)
    (Carrier : ℕ → ℕ → Type uC)
    [∀ p N, AddCommGroup (Carrier p N)]
    [∀ p N, Module ℂ (Carrier p N)] : Prop :=
  ∀ N,
    (∑ p ∈ Finset.range (N + 1), Module.finrank ℂ (Carrier p N)) ≤
      Module.finrank ℂ (W.grading N)
```

From the mathematics to the Lean statement

`W.grading N` is the weight-N subspace V_N (a `Submodule`; the natural number N is coerced to $\mathbb{Z}$); `Module.finrank ℂ` is its complex dimension (Mathlib's `finrank`, which is 0 for an infinite-dimensional space — harmless here, since every V_N is finite-dimensional for the VOAs of this chapter). `Finset.range (N + 1)` is $\{0, \dots, N\}$. The definition is exactly Definition 25.1. It is a `Prop`-valued `def`, not a structure, so it is used by applying it to N.

Physical meaning

dim V_N counts the states of conformal weight N in the vacuum module of the chiral CFT: the vacuum character $\mathrm{tr}_V\, q^{L_0}$. The carrier is a model of the classical ("$\hbar \to 0$") phase space of the theory, the arc space of the Higgs branch. The inequality says the quantum theory has at least as many states as its classical limit predicts — the nontrivial direction, since quantum corrections usually *remove* states (null vectors).

What the machine verified

Definition. Unconditional by construction.

Theorem 25.2 (The lower bound suffices). *Given a presentation P, current-jet surjectivity and an injective geometric carrier embedding, the carrier character lower bound implies the ordinary carrier character identity.*

File `VOA/DeligneAudit/A2Character.lean`.

```
theorem ordinaryCarrierCharacter_of_le
    (P : CurrentC2Presentation case W)
    (Carrier : ℕ → ℕ → Type uC)
    [∀ p N, AddCommGroup (Carrier p N)]
    [∀ p N, Module ℂ (Carrier p N)]
    [∀ p N, FiniteDimensional ℂ (Carrier p N)]
    (hsurj : CurrentJetSurjectivity case W P)
    (hgeom : GeometricCarrierEmbedding case W P Carrier)
    (hlow : CarrierCharacterLowerBound W Carrier) :
    OrdinaryCarrierCharacter W Carrier
```

From the mathematics to the Lean statement

The packages `CurrentC2Presentation`, `CurrentJetSurjectivity`, `GeometricCarrierEmbedding`, `OrdinaryCarrierCharacter` are defined in Chapter 24. `OrdinaryCarrierCharacter W Carrier` is the *equality* $\sum_p \dim \mathrm{Carrier}_{p,N} = \dim V_N$ for all N. The theorem is the statement for any `case` and any VOA, so the same reduction serves all seven types. A companion, `carrierCharacterLowerBound_of_ordinary`, gives the converse, so in the presence of the two other packages the lower bound and the identity are *equivalent*: nothing is lost. **Implicit data and an extra hypothesis.** `case : HigherRankDeligneCase` (the Deligne type), the carrier space `V : Type uV` with its VOA `W`, and the universe `uC` of the carrier are section variables (implicit). The instance `[∀ p N, FiniteDimensional ℂ (Carrier p N)]` is a hypothesis not visible in Theorem 25.2 as stated: it makes `finrank` the true dimension of each carrier space. Without it `finrank` would be 0 on an infinite-dimensional carrier and `hlow` would be weaker than it reads.

Proof on paper. Current-jet surjectivity says each Li layer $\mathrm{gr}^{\mathrm{Li}}_p V_N$ is a quotient of a finite-dimensional jet space $J_{p,N}$, and the carrier embedding injects the dual $J^*_{p,N}$ into $\mathrm{Carrier}_{p,N}$. Hence $\dim \mathrm{gr}^{\mathrm{Li}}_p V_N \le \dim \mathrm{Carrier}_{p,N}$; summing over p and using that the Li layers of V_N add up to $\dim V_N$ gives $\dim V_N \le \sum_p \dim \mathrm{Carrier}_{p,N}$ (the library's `finrank_grading_le_carrier_sum`). Combined with the hypothesis, equality. □

Physical meaning

The upper bound is "every state is generated by currents, modulo the classical relations"; the lower bound is "no further quantum relations occur". Together: the chiral algebra is *classically free*, its quantum states are in bijection with classical arc-space functions.

What the machine verified

Standard axioms. Unconditional as an implication.

25.2.2 The split at the Demazure sum

The carrier is too complicated to compare with $\dim V_N$ directly. The project interposes a combinatorial series, the *Demazure sum*, built from Hilbert series of level-one affine Demazure modules $D(1, n\theta)$:

$$\sum_{N\geq 0} D_N q^N \;=\; \sum_{n\geq 0} \frac{q^n \operatorname{Hilb}_q D(1,n\theta)}{(q;q)_n}, \qquad (q;q)_n = \prod_{i=1}^{n}(1-q^i). \tag{25.2}$$

The carrier side (Chapter 24 and Chapter 26) proves $\sum_p \dim \mathrm{Carrier}_{p,N} \leq D_N$, link (a) of (25.1); this chapter must prove $D_N \leq \dim V_N$, links (b) and (c).

Definition 25.3 (Coefficient arithmetic; the Demazure sum). For coefficient tables $f, g : \mathbb{N} \to \mathbb{N}$ let $(f * g)(N) = \sum_{i=0}^{N} f(i)g(N-i)$ (the Cauchy product), and let $p_{\leq n}(N)$ be the number of partitions of N into parts of size at most n, i.e. $[q^N]1/(q;q)_n$. For a table $\mathrm{hilb}(n,N) = [q^N]\mathrm{Hilb}_q D(1,n\theta)$, the Demazure sum is

$$D_N = \sum_{n=0}^{N} \big(\mathrm{hilb}(n,\cdot) * p_{\leq n}\big)(N-n),$$

which is the q^N coefficient of (25.2).

Files `VOA/DeligneAudit/A2CharacterInterface.lean` and `VOA/DeligneAudit/DeligneCharacter.lean`.

```
def conv (f g : ℕ → ℕ) (N : ℕ) : ℕ :=
  ∑ i ∈ Finset.range (N + 1), f i * g (N - i)

def partitionsLe : ℕ → ℕ → ℕ
  | 0, N => if N = 0 then 1 else 0
  | n + 1, N => ∑ j ∈ Finset.range (N / (n + 1) + 1), partitionsLe n (N - j * (n + 1))

def demazureSumCoeff (hilb : ℕ → ℕ → ℕ) (N : ℕ) : ℕ :=
  ∑ n ∈ Finset.range (N + 1), conv (hilb n) (partitionsLe n) (N - n)
```

From the mathematics to the Lean statement

`partitionsLe n N`: the recursion conditions on the number j of parts equal to $n+1$, which is exactly how $1/(q;q)_{n+1} = \frac{1}{1-q^{n+1}} \cdot \frac{1}{(q;q)_n}$ expands. So `partitionsLe n N` $= [q^N]1/(q;q)_n$. In `demazureSumCoeff`, the shift $N-n$ accounts for the factor q^n in (25.2), and terms with $n > N$ vanish, so the finite range $n \leq N$ is exact. All of this is $\mathbb{N}$-valued and computable, so small cases are checked by `decide +kernel` (kernel evaluation, not `native_decide`). **What is `hilb`?** Any table; the definition does not know about Demazure modules. *All* Demazure content enters through the choice of table, and its reading as $\mathrm{Hilb}_q D(1,n\theta)$ is the input U7 (Caveat 2). The concrete tables are built in Section 25.9, and the A_2 table in Theorem 25.36; in Lean a table is only what it computes.

Physical meaning

Heuristic. In the fusion picture (Chapter 26), $D(1,n\theta)$ is the graded fusion product of n copies of the adjoint-plus-singlet representation, and $1/(q;q)_n$ counts the ways of distributing n indistinguishable excitations among levels. The sum (25.2) then reads as a "fermionic" (quasi-particle) form of a character: states built from n quasi-particles of adjoint type, with momenta encoded by the Demazure grading. As a statement about the vacuum module this

is conjectural; its mathematical content is links (a) and (b) of (25.1), i.e. U5–U7 and the star identity.

What the machine verified

Definitions; computable; unconditional.

Definition 25.4 (Named inputs of the character side, integer form)**.** For a table `hilb`, a target sequence $t : \mathbb{N} \to \mathbb{N}$ and a VOA W:

- the *star identity* $D_N = t_N$ for all N;
- the *target lower bound* $t_N \le \dim W_N$ for all N;
- the *Demazure bound* $D_N \le \dim W_N$ for all N.

File `VOA/DeligneAudit/DeligneCharacter.lean`.

```
structure StarIdentityFor (hilb : ℕ → ℕ → ℕ) (target : ℕ → ℕ) : Prop where
  eq : ∀ N, demazureSumCoeff hilb N = target N

structure TargetLowerBound (W : VertexOperatorAlgebra V) (target : ℕ → ℕ) : Prop where
  le : ∀ N : ℕ, target N ≤ Module.finrank ℂ (W.grading N)

structure DemazureBoundFor (W : VertexOperatorAlgebra V) (hilb : ℕ → ℕ → ℕ) : Prop where
  le : ∀ N : ℕ, demazureSumCoeff hilb N ≤ Module.finrank ℂ (W.grading N)

theorem demazureBoundFor_of_inputs {W : VertexOperatorAlgebra V} {hilb : ℕ → ℕ → ℕ}
    {target : ℕ → ℕ} (hstar : StarIdentityFor hilb target) (hlow : TargetLowerBound W
     ↪ target) :
    DemazureBoundFor W hilb
```

From the mathematics to the Lean statement

Each is a `Prop`-valued `structure` with one field; a proof of `StarIdentityFor hilb t` is a proof of $\forall N,\ D_N = t_N$, accessed as `h.eq N`. **These are hypotheses, never axioms**: a theorem taking (`hstar : StarIdentityFor …`) is conditional on it, and `#print axioms` does not show this (Caveat 3). `demazureBoundFor_of_inputs` is the transitivity $D_N = t_N \le \dim W_N$.

Physical meaning

The "target" is the vacuum character of the VOA as predicted by representation theory or by the MLDE; the star identity says the quasi-particle (fermionic) form of the character equals it. Such "fermionic = bosonic" identities are the hallmark of integrable structure in 2d CFT (Rogers–Ramanujan being the prototype for the Lee–Yang model).

What the machine verified

Definitions and a one-line transitivity; standard axioms.

Theorem 25.5 (The glue). *If $\sum_p \dim \mathrm{Carrier}_{p,N} \le D_N$ for all N and the Demazure bound holds, the carrier character lower bound holds.*

File `VOA/DeligneAudit/DeligneCharacter.lean`.

```
theorem carrierCharacterLowerBound_of_demazureSum {W : VertexOperatorAlgebra V}
    {hilb : ℕ → ℕ → ℕ}
    (Carrier : ℕ → ℕ → Type uC)
    [∀ p N, AddCommGroup (Carrier p N)] [∀ p N, Module ℂ (Carrier p N)]
    (hcar : ∀ N, (∑ p ∈ Finset.range (N + 1), Module.finrank ℂ (Carrier p N)) ≤
      demazureSumCoeff hilb N)
    (hchr : DemazureBoundFor W hilb) :
    CarrierCharacterLowerBound W Carrier
```

From the mathematics to the Lean statement

Exactly Theorem 25.5, a transitivity in ℕ. `hcar` is the carrier side (Chapter 26); `hchr` is this chapter's goal.

Proof on paper. $\sum_p \dim \mathrm{Carrier}_{p,N} \le D_N \le \dim W_N$. □

Physical meaning

Classical states ≤ quasi-particle states ≤ quantum states. The first inequality is a statement about the classical phase space, the second about the quantum theory.

What the machine verified

Standard axioms; unconditional as an implication.

25.2.3 The rational form and the one-sided form

The natural targets are rational sequences (the MLDE has rational coefficients), so the library also has ℚ-valued versions.

Definition 25.6 (Rational inputs). For $t : \mathbb{N} \to \mathbb{Q}$: `StarIdentityQ hilb t` is $D_N = t_N$, `TargetLowerBoundQ W t` is $t_N \le \dim W_N$ (both in ℚ), and `StarBoundQ hilb t` is the one-sided $D_N \le t_N$.

Files `VOA/DeligneAudit/DeligneCharacterTypes.lean` and `VOA/DeligneAudit/DeligneCharacterStarBound.lean`.

    {W : VertexOperatorAlgebra V} {hilb : ℕ → ℕ → ℕ} {target : ℕ → ℚ}
    (hstar : StarBoundQ hilb target) (hlow : TargetLowerBoundQ W target) :
    DemazureBoundFor W hilb
```

From the mathematics to the Lean statement

The casts (… : ℚ) send ℕ → ℚ; the inequalities are in ℚ and `exact_mod_cast` transports them back to ℕ. **Why the one-sided form?** Downstream, the star identity is only ever used through $D_N = t_N \le \dim W_N$, so $D_N \le t_N$ suffices; `StarIdentityQ.toStarBoundQ` shows the = form implies it. Whether the ≤ form is *easier to prove* is a separate question. For proofs by termwise domination it is not (Section 25.10.4); for other proofs the question is open.

Physical meaning

The same three statements as before, with the target allowed to be any rational sequence — in practice the MLDE solution, whose coefficients are a priori rational and turn out to be integers.

What the machine verified

Definitions and transitivities; standard axioms.

Two different `mldeCoeff`

`VOA.DeligneAudit.DeligneCharacter.mldeCoeff (h N : ℕ) : ℚ` (Definition 25.7 below) is the N-th coefficient of the AK solution. `VOA.mldeCoeff (s : ℕ) (c : ℕ → E46) (h : ℕ → ℕ → E46) (j : ℕ) : E46` in `VOA/Modularity/AKMLDE.lean` (Chapter 16) is the j-th coefficient of a generic monic MLDE over $\mathbb{C}[E_4, E_6]$. They share only the short name (Section 25.13). In this chapter `mldeCoeff` always means the first.

25.3 The Arakawa–Kawasetsu recurrence

25.3.1 A primer on modular linear differential equations

Write $\delta_q = q\frac{d}{dq}$ for the Euler operator, $\sigma_k(n) = \sum_{d|n} d^k$, and use the normalised Eisenstein series $E_2 = 1 - 24\sum_{n\ge1}\sigma_1(n)q^n$, $E_4 = 1 + 240\sum_{n\ge1}\sigma_3(n)q^n$ and $E_6 = 1 - 504\sum_{n\ge1}\sigma_5(n)q^n$ (Chapter 14). This primer explains the shape of the equation. None of it is used in the proofs, which are purely formal.

Modular forms and the Serre derivative. A modular form f of weight k for $SL_2(\mathbb{Z})$ satisfies $f(\frac{a\tau+b}{c\tau+d}) = (c\tau+d)^k f(\tau)$. Here $q = e^{2\pi i\tau}$, so $\delta_q = \frac{1}{2\pi i}\frac{d}{d\tau}$. The ring of such forms is $\mathbb{C}[E_4, E_6]$. In particular there is no nonzero form of weight 2, the forms of weight 4 are the multiples of E_4, and the space of weight 8 is spanned by E_4^2. The derivative $\delta_q f$ of a weight-k form is not modular, because differentiating $(c\tau+d)^k$ produces an extra term. The quasimodular series E_2 has exactly the compensating transformation law, so the *Serre derivative*

$$\vartheta_k = \delta_q - \frac{k}{12}E_2$$

maps weight-k forms to weight-$(k+2)$ forms. Ramanujan's identities (Theorem 25.28) are the formal shadow of this fact.

MLDEs. Zhu's theorem says that the characters $f_M = \mathrm{tr}_M\, q^{L_0 - c/24}$ of a rational, C_2-cofinite VOA form a vector-valued modular function, i.e. have weight 0. Arakawa and Kawasetsu extend this to quasi-lisse VOAs. For weight 0, the natural order-n operator is $\vartheta^n = \vartheta_{2n-2} \circ \ldots \circ \vartheta_2 \circ \vartheta_0$, which raises the weight by $2n$. A *monic MLDE of order n* is $\vartheta^n f + \sum_{j=1}^{n} \phi_j\, \vartheta^{n-j} f = 0$, where each coefficient ϕ_j

is a modular form of weight $2j$. At order two the coefficient ϕ_1 has weight 2, so it vanishes, and ϕ_2 has weight 4, so it is a multiple $-\lambda E_4$. Hence every second-order MLDE has the one-parameter form

$$\vartheta_2\vartheta_0 f = \lambda E_4 f, \qquad \vartheta_2\vartheta_0 = \big(\delta_q - \tfrac{1}{6}E_2\big)\delta_q.$$

Why order two, and why weight four. Zhu's recursion (Section 25.4) assigns to each state v of square-bracket weight k a torus one-point function $S_M(v)$, which is quasimodular of weight k. A relation among states of weight $2n$ that expresses the "n-th power of the stress tensor" through simpler states becomes an MLDE of order n. The state $L[-2]^2|0\rangle$, the square (TT) of the stress tensor, has L_0-weight 4. Its one-point function is $\vartheta_2\vartheta_0 f$ up to the Eisenstein terms of Theorem 25.12, a weight-four quasimodular object. That the L_0-weight of (TT) equals the modular weight of E_4 is therefore no coincidence: Zhu's recursion turns the one into the other. A relation saying that (TT) is, up to states with vanishing or Eisenstein-type traces, "classically zero" (the vacuum quartic relation of Section 25.4) produces exactly a second-order MLDE. **No modularity is used in this chapter**: all equations are identities of formal q-series, coefficient by coefficient.

25.3.2 The Arakawa–Kawasetsu equation and its recurrence

Arakawa and Kawasetsu proved (arXiv:1610.05865, §7) the following. Let $V = L_k(\mathfrak{g})$ be in the Deligne series, with $h = h^\vee$ and $k = -1 - h/6$. Then the normalised vacuum character $f = q^{-c/24}\sum_N d_N q^N$, with $d_N = \dim V_N$, satisfies

$$\Big(\delta_q - \tfrac{1}{6}E_2\Big)\delta_q f \;=\; \frac{h^2-1}{144}\,E_4\,f, \tag{25.3}$$

which is the second-order MLDE above with $\lambda = (h^2-1)/144$.

Substitute $f = q^e\sum d_N q^N$ and read off the coefficient of q^{N+e}. Since $\delta_q q^{N+e} = (N+e)q^{N+e}$, the coefficient of q^e (the *indicial equation*) is $e^2 - e/6 - (h^2-1)/144 = 0$. Equivalently $(12e)^2 - 2(12e) - (h^2-1) = 0$, with roots $12e = 1 \pm h$. The character has $e = -c/24 = (h+1)/12$, the larger root. For $N \geq 1$ the coefficient of d_N becomes $(N+e)^2 - (N+e)/6 - (h^2-1)/144 = N(6N+h)/6$. Multiplying the q^{N+e} equation by 6 gives

$$N(6N+h)\,d_N = \sum_{r=1}^{N}\Big[10(h^2-1)\sigma_3(r) - \big(24(N-r) + 2(h+1)\big)\sigma_1(r)\Big]\,d_{N-r}. \tag{25.4}$$

The factor $N(6N+h)$ never vanishes for $N \geq 1$, so (25.4) with $d_0 = 1$ determines the sequence. At $N = 1$ only $r = 1$ contributes, and $(6+h)d_1 = 10(h^2-1) - 2(h+1) = 2(h+1)(5h-6)$, so

$$d_1 = \frac{2(h+1)(5h-6)}{h+6}.$$

Deligne's dimension formula for the series is $\dim\mathfrak{g} = 2(h+1)(5h-6)/(h+6)$, so $d_1 = \dim\mathfrak{g}$. The equation knows the number of currents $J^a_{-1}|0\rangle$, but only because k is the Deligne level: the value $c = -2(h+1)$ was used to fix e.

Definition 25.7 (The AK coefficients). $\sigma_k(n) = \sum_{d|n} d^k$. For $h \in \mathbb{N}$, $c_N = \texttt{mldeCoeff}\ h\ N \in \mathbb{Q}$ is defined by $c_0 = 1$ and (25.4) solved for c_N.

File `VOA/DeligneAudit/DeligneCharacterTypes.lean`.

```
def sigmaK (k n : ℕ) : ℕ := ∑ d ∈ n.divisors, d ^ k

def mldeList (h : ℕ) : ℕ → List ℚ
  | 0 => [1]
  | n + 1 =>
```

```
      let l := mldeList h n
      let N := n + 1
      l ++ [(∑ r ∈ Finset.range N,
          ((10 * ((h : ℚ) ^ 2 - 1) * sigmaK 3 (r + 1) -
            (24 * ((N : ℚ) - (r + 1)) + 2 * ((h : ℚ) + 1)) * sigmaK 1 (r + 1)) *
              l.getD (N - (r + 1)) 0)) / ((N : ℚ) * (6 * N + h))]

def mldeCoeff (h N : ℕ) : ℚ := (mldeList h N).getD N 0
```

From the mathematics to the Lean statement

`n.divisors` is Mathlib's finset of positive divisors ($\varnothing$ for $n = 0$, so $\sigma_k(0) = 0$). `mldeList h n` is the list $[c_0, \dots, c_n]$, built by appending one entry at a time; `l.getD i 0` reads entry i (default 0 out of range). The summation index $r \in \{0, \dots, N-1\}$ in Lean is $r + 1 \in \{1, \dots, N\}$ on paper. The appended entry is exactly (25.4) divided by $N(6N + h)$. `mldeCoeff h N` reads the last entry. **Division by zero?** `(N : ℚ) * (6 * N + h)` with $N \geq 1$ is positive; Lean's $x/0 = 0$ convention never fires. **Is it the AK equation?** That the list satisfies the recurrence is the next theorem; that the recurrence is (25.3) is the derivation above, and the library re-derives it from the VOA (Theorem 25.14).

Physical meaning

c_N is the predicted number of states of weight N in the vacuum module: the MLDE "knows" the vacuum character once it knows c. The first values are in Table 25.1. The weight-one value $c_1 = \dim \mathfrak{g}$ counts the currents $J^a_{-1}|0\rangle$ (derivation above).

What the machine verified

Definition; computable.

Table 25.1: The first AK coefficients c_N = `mldeCoeff` $h^\vee$ N. Every entry was computed from (25.4) in exact rational arithmetic for this chapter. Kernel-checked in the library: A_2 through c_3 (`A2.mldeCoeff_A2_small`) and G_2 through c_2 (`mldeCoeff_G2_small`). Kernel-checked in a scratch file for this chapter, not in the library: D_4 through c_2.

    (hd : IsAKSolution h d) : ∀ N, d N = (mldeCoeff h N : K)
```

From the mathematics to the Lean statement

`akKernel h N r` is the bracket in (25.4) with r the summation index. `IsAKSolution` is the definition in Theorem 25.8: `zero` is $d_0 = 1$, `step` is (25.4) for $N \geq 1$. The field K is arbitrary of characteristic 0; the library uses $K = \mathbb{Q}$ (for q-series) and $K = \mathbb{C}$ (for graded dimensions of a complex VOA). The cast `(mldeCoeff h N : K)` is the image of a rational under $\mathbb{Q} \to K$. Same statement as on paper.

Proof on paper. The first claim is the definition unfolded (the list's last entry is the recurrence's right side divided by $N(6N + h)$). Uniqueness: by strong induction on N, the right side of (25.4) involves only d_{N-r} with $r \geq 1$, equal to c_{N-r} by induction, and $N(6N + h) \neq 0$ in characteristic 0, so $d_N = c_N$. □

Physical meaning

A second-order ODE with a regular singularity at $q = 0$ has a two-dimensional solution space, with characteristic exponents $(1 \pm h)/12$. **Uniqueness is not delicate here.** For the larger exponent, the vacuum's, the leading factor of the recurrence is $N(6N + h)$, which is nonzero for every $N \geq 1$, so the normalised solution exists and is unique. A logarithmic solution can arise only from the *smaller* exponent, when the exponent difference $h/6$ is a positive integer ($h = 6, 12, 18, 30$), and that solution is never used. *Heuristic reading:* the smaller exponent $(1 - h)/12$ would be the leading exponent of a second "character" of the two-character theory. That character would belong to a module whose lowest conformal weight differs from the vacuum's by $-h/6$. Nothing in this chapter depends on this reading.

What the machine verified

Standard axioms (re-run for this chapter with `lake env lean -DmaxSynthPendingDepth=3`). Unconditional.

Theorem 25.9 (Graded dimensions solving the recurrence are the AK coefficients)**.** *If the graded dimensions $N \mapsto \dim W_N \in \mathbb{C}$ of a VOA form a normalised AK solution with parameter h, then* $\dim W_N = c_N$ *for all N, and in particular* `TargetLowerBoundQ W (mldeCoeff h)`.

File `VOA/DeligneAudit/DeligneMLDE.lean`.

```
theorem finrank_eq_mldeCoeff_of_isAKSolution (W : VertexOperatorAlgebra V) {h : ℕ}
    (hW : IsAKSolution h (fun N : ℕ => (Module.finrank ℂ (W.grading N) : ℂ))) (N : ℕ) :
    (Module.finrank ℂ (W.grading N) : ℚ) = mldeCoeff h N

theorem targetLowerBoundQ_of_isAKSolution (W : VertexOperatorAlgebra V) {h : ℕ}
    (hW : IsAKSolution h (fun N : ℕ => (Module.finrank ℂ (W.grading N) : ℂ))) :
    TargetLowerBoundQ W (mldeCoeff h)
```

From the mathematics to the Lean statement

The hypothesis casts $\dim W_N \in \mathbb{N}$ into $\mathbb{C}$; the conclusion is an equality in $\mathbb{Q}$ (the cast $\mathbb{Q} \to \mathbb{C}$ is injective). The second theorem uses only the $\geq$ half of the equality and discards the rest: this is why the per-type theorems of Section 25.6, which go through it, export only an inequality.

Proof on paper. Uniqueness (Theorem 25.8) over $K = \mathbb{C}$, then injectivity of $\mathbb{Q} \to \mathbb{C}$. □

Physical meaning

"If the character satisfies the MLDE with the right leading exponent, it *is* the MLDE solution." The whole difficulty is moved into proving the MLDE for the VOA.

What the machine verified

Standard axioms; unconditional as an implication.

Example 25.10 (Kernel checks of small values)**.** The library checks by `decide +kernel`:

```
theorem mldeCoeff_G2_small : (List.range 3).map (mldeCoeff 4) = [1, 14, 92] := by decide
↪ +kernel
```

(file `VOA/DeligneAudit/DeligneCharacterTypes.lean`) and `A2.mldeCoeff_A2_small`: $[c_0, \dots, c_3] = [1, 8, 36, 128]$ for $h = 3$ (file `DeligneMLDE.lean`). These pin the conventions (a wrong sign in `akKernel` would already fail at c_1, which must be $\dim \mathfrak{g}$).

Example 25.11 (A_2 from scratch)**.** This example runs every layer of the chapter on the smallest case, $\mathfrak{g} = \mathfrak{sl}_3$, $h = 3$, $k = -3/2$, $c = -8$. All numbers below were recomputed by hand. The statements marked (L) are kernel checks in the library, and those marked (S) are kernel checks (`decide +kernel`) that we ran in a scratch file for this chapter.

The recurrence. With $h = 3$ the bracket in (25.4) is $80\,\sigma_3(r) - (24(N-r)+8)\,\sigma_1(r)$.

- $N = 1$: $1 \cdot 9 \cdot d_1 = (80 - 8) \cdot d_0 = 72$, so $d_1 = 8 = \dim \mathfrak{sl}_3$.
- $N = 2$: the bracket is $80 - 32 = 48$ at $r = 1$ and $80 \cdot 9 - 8 \cdot 3 = 696$ at $r = 2$, so $2 \cdot 15 \cdot d_2 = 48 \cdot 8 + 696 \cdot 1 = 1080$ and $d_2 = 36$.

So $c_0, c_1, c_2 = 1, 8, 36$, as in Table 25.1 and `A2.mldeCoeff_A2_small` (L).

The constant. $\kappa = \frac{5}{4}c^2 + \frac{11}{2}c = 80 - 44 = 36 = (h+1)(5h-6)$, the number in `A2.vacuumQuarticRelation` (Theorem 25.22).

The product. $\prod_{r\geq 1}(1+q^r)^8 = (1+q)^8(1+q^2)^8 \cdots = 1 + 8q + (28+8)q^2 + \cdots = 1 + 8q + 36q^2 + \dots$, matching c_N (`productCoeff_small` (L): $1, 8, 36, 128, 394$; Theorem 25.29 proves it for all N).

The Demazure sum. Write $\mathrm{hilb}(n, \cdot)$ for the A_2 table (Theorem 25.36). It has $\mathrm{hilb}(0, \cdot) = 1$ and $\mathrm{hilb}(1, \cdot) = 8 + q$ (`demazureHilb_one` (L)), and $\mathrm{hilb}(2, \cdot) = 27 + 28q + 17q^2 + 8q^3 + q^4$ (S). Its total $81 = 9^2$ is the $q = 1$ factorisation of Theorem 25.40, and its constant term $27 = \dim V(2\theta)$ is the weight-0 part of $D(1, 2\theta)$. Finally $\mathrm{hilb}(3, 0) = 64 = \dim V(3\theta)$ (S). (For $\mathfrak{sl}_3$, $\dim V(a\omega_1 + b\omega_2) = (a+1)(b+1)(a+b+2)/2$ and $\theta = \omega_1 + \omega_2$.) Then by Definition 25.3:

$$
\begin{aligned}
D_1 &= \mathrm{hilb}(1,0) = 8, \\
D_2 &= \big[\mathrm{hilb}(1,0) + \mathrm{hilb}(1,1)\big] + \mathrm{hilb}(2,0) = 9 + 27 = 36, \\
D_3 &= \big[\mathrm{hilb}(1,0) + \mathrm{hilb}(1,1)\big] + \big[\mathrm{hilb}(2,0) + \mathrm{hilb}(2,1)\big] + \mathrm{hilb}(3,0) = 9 + 55 + 64 = 128.
\end{aligned}
$$

In D_2, the term with $n = 1$ is $[q^1](8+q)/(1-q) = 9$ and the term with $n = 2$ is $[q^0]\,\mathrm{hilb}(2, \cdot)/((1-q)(1-q^2)) = 27$. These agree with `demazureCoeff_small` (L) and with c_N: the star identity holds at $N \leq 3$. The GT table $\mathrm{hilb}(2, \cdot)$ also agrees with the affine algorithm `levelOneDemazureHilb cartanA2`

`thetaA2 wordA2 2` in degrees 0–3 (S). This is a second instance of the comparison between the two descriptions (Caveat 2).

The VOA. `A2.finrank_grading_one` gives $\dim V_1 = 8$, and `A2.finrank_grading_two_ge` gives $\dim V_2 \geq 36$ by a Gram determinant. Both are independent of the MLDE. The chain (25.1) therefore reads $8 \leq 8 \leq 8$ at $N = 1$ and $36 \leq 36 \leq \dim V_2$ at $N = 2$.

A D_4 check. At $h = 6$: $(6+6)d_1 = 10 \cdot 35 - 2 \cdot 7 = 336$, so $d_1 = 28 = \dim \mathfrak{so}_8$. The closed form of Theorem 25.32 gives $[q^{N+1}]\left(\frac{1}{240}\delta_q E_4\right)(q)_\infty^{-10}$. Here $\frac{1}{240}\delta_q E_4 = q + 18q^2 + \dots$ and $(q)_\infty^{-10} = 1 + 10q + \dots$, giving 1 at $N = 0$ and $18 + 10 = 28$ at $N = 1$.

25.4 From one weight-four trace identity to the MLDE

25.4.1 The Virasoro tower over the vacuum

Torus one-point functions. Put a chiral CFT on a torus with modular parameter τ, $q = e^{2\pi i\tau}$, and insert one field v at a point. Translation invariance along the torus makes the answer independent of the point. It equals the trace

$$S_M(v) = \operatorname{tr}_M o(v)\, q^{L_0 - c/24},$$

where M is the module propagating around the cycle and $o(v) = v_{(\mathrm{wt}\, v - 1)}$ is the zero mode of v, the part of the field that preserves L_0-weight (Chapter 15, Definition 15.4). Three examples fix the meaning.

- $v = |0\rangle$: $o(|0\rangle) = \mathrm{id}$, so $S_M(|0\rangle) = \operatorname{tr}_M q^{L_0 - c/24} =: f_M$ is the character. For $M = V$ it is the normalised vacuum character $f = q^{-c/24}\sum_N \dim V_N\, q^N$.
- $v = \omega$, the conformal vector: $o(\omega) = L_0$, so $S_M(\omega) = \operatorname{tr}_M L_0 q^{L_0 - c/24}$, which is $\delta_q f_M + \frac{c}{24} f_M$.
- $v = (TT)$, the normal-ordered square of the stress tensor: its one-point function is what the MLDE is about.

The library stores $S_M(v)$ as a formal q-series with complex exponents, i.e. a function $\mathbb{C} \to \mathbb{C}$ sending an exponent to its coefficient. The exponents lie in $-c/24 + \mathbb{N}$ for the modules used here.

Zhu's recursion and square-bracket modes. The one idea of this section is Zhu's: there is a second set of modes $a[n]$, the *square-bracket modes*, defined from the change of coordinate $z \mapsto e^z - 1$ from the plane to the cylinder (Chapter 15, Definition 15.7). For them the trace of a descendant reduces to traces of simpler states with *Eisenstein series as coefficients*. For the stress tensor, with $L[n]$ the square-bracket Virasoro modes (`Lsq W n`), it reads

$$S_M\big(L[-2]v\big) = \delta_q\, S_M(v) + \sum_{m \geq 1} G_{2m} \star S_M\big(L[2m-2]v\big). \tag{25.5}$$

Here $\star$ is the product of q-series (Lean `qConv`, the Cauchy product of an $\mathbb{N}$-indexed series with a formal series), and G_{2m} is Zhu's normalisation of the Eisenstein series (`zhuG m`). These have $G_2 = -E_2/12$ and $G_4 = E_4/720$: constant term $-B_{2m}/(2m)!$ and q^n-coefficient $\frac{2}{(2m-1)!}\sigma_{2m-1}(n)$. `qDeriv` multiplies the coefficient at exponent e by e, i.e. it is δ_q. Physically, (25.5) is the torus Ward identity for T. Integrating T around the cycle gives the derivative in τ, and the OPE of T with v, weighted by the Weierstrass function of the torus, gives the Eisenstein corrections.

Check at $v = |0\rangle$. $L[n]|0\rangle = 0$ for $n \geq -1$, so every term of the sum vanishes, and $S_M(L[-2]|0\rangle) = \delta_q f_M$. This agrees with the second example above, because $L[-2]|0\rangle = \omega - \frac{c}{24}|0\rangle$: the shift by $c/24$ is the Schwarzian of the change to the cylinder. Write $f = S_V(|0\rangle)$ (`torusPartition`) for the normalised vacuum character of V.

Theorem 25.12 (The second Virasoro descendant of the vacuum). *For every VOA W and every ordinary module M,*

$$S_M\big(L[-2]^2|0\rangle\big) = \delta_q^2 f_M + G_2 \star (2\delta_q f_M) + G_4 \star \big(\tfrac{c}{2} f_M\big), \qquad f_M = S_M(|0\rangle).$$

File `VOA/DeligneAudit/DeligneMLDEBlock.lean`.

```
theorem torusOnePoint_Lsq_sq_vacuum (N : OrdVModule W M) :

          + qConv (zhuG 2) ((W.centralCharge / 2) • torusPartition N))
```

From the mathematics to the Lean statement

`OrdVModule W M`: an ordinary module (Chapter 12). `Lsq W (-2) (Lsq W (-2) W.vacuum)` is $L[-2]L[-2]|0\rangle$. `zhuG 1` is G_2 and `zhuG 2` is G_4 (index j means weight $2j$). The statement is exactly the display. No hypothesis on W or M beyond their structures. The traces make sense because an `OrdVModule` carries, as a field, that each weight space is finite-dimensional, and that the weights are bounded below (Chapter 12).

Proof on paper. Apply Zhu's recursion (25.5) to $v = L[-2]|0\rangle$: the square-bracket Virasoro relations give $L[0]L[-2]|0\rangle = 2L[-2]|0\rangle$, $L[2]L[-2]|0\rangle = \frac{c}{2}|0\rangle$ and $L[2m-2]L[-2]|0\rangle = 0$ for $m \geq 3$ (the exact tower `Lsq_tower` of Chapter 16); and $S(L[-2]|0\rangle) = \delta_q f$ by the check above. So $S(L[-2]^2|0\rangle) = \delta_q(\delta_q f) + G_2 \star S(2L[-2]|0\rangle) + G_4 \star S(\frac{c}{2}|0\rangle)$, which is the display. □

Physical meaning

$L[-2]^2|0\rangle$ is the state of the normal-ordered square (TT) of the stress tensor on the torus (in Zhu's coordinates). Its torus one-point function is the second τ-derivative of the partition function, corrected by the Eisenstein series that implement the change from the plane to the torus. This is the standard physics derivation of MLDEs (Mathur–Mukhi–Sen; Beem–Rastelli for 4d theories): a null-type relation for (TT) becomes a differential equation for the character.

What the machine verified

Standard axioms. Unconditional.

25.4.2 The vacuum quartic relation and the indicial equation

Definition 25.13 (Vacuum quartic relation; formal MLDE). For a VOA W and $\kappa \in \mathbb{C}$, the *vacuum quartic relation* with constant κ is the trace identity $S_W(L[-2]^2|0\rangle) = \kappa\, G_4 \star f$ on the adjoint module. The *formal MLDE* with constant κ is $\delta_q^2 f + G_2 \star (2\delta_q f) + G_4 \star (\frac{c}{2} f) = \kappa\, G_4 \star f$.

File `VOA/DeligneAudit/DeligneMLDEBlock.lean`.

```
structure VacuumQuarticRelation (W : VertexOperatorAlgebra 𝒱) (κ : ℂ) : Prop where
  eq : torusOnePoint (adjointModule W) (Lsq W (-2) (Lsq W (-2) W.vacuum))
    = κ • qConv (zhuG 2) (torusPartition (adjointModule W))

def FormalMLDE (κ : ℂ) : Prop :=
  qDeriv (qDeriv (torusPartition (adjointModule W)))
      + (qConv (zhuG 1) ((2 : ℂ) • qDeriv (torusPartition (adjointModule W)))
        + qConv (zhuG 2) ((W.centralCharge / 2) • torusPartition (adjointModule W)))
    = κ • qConv (zhuG 2) (torusPartition (adjointModule W))
```

From the mathematics to the Lean statement

`adjointModule W` is W as a module over itself; `torusPartition (adjointModule W)` is the formal series with coefficient $\dim W_n$ at exponent $n - c/24$ (`torusPartition_adjoint`). By Theorem 25.12, the relation implies the formal MLDE with the same κ (`formalMLDE_of_vacuumQuarticRelation`, the only direction used); the converse follows from Theorem 25.12 by the same rewriting but is not stated in Lean. **Section variables.** `W : VertexOperatorAlgebra` $\mathcal{V}$ is a section variable; in the `Coefficients` and `Algebraic` sections of `DeligneMLDEBlock.lean` it is *explicit* (`FormalMLDE W κ`, `kappa_eq_of_formalMLDE W h …`, `isAKSolution_of_vacuumQuarticRelation W h …`), in the `Tower` section implicit. Rewriting with $G_2 = -E_2/12$, $G_4 = E_4/720$, the formal MLDE reads $(\delta_q - \frac{1}{6}E_2)\delta_q f = \frac{\kappa - c/2}{720}E_4 f$, which is (25.3) exactly when $\kappa - c/2 = 5(h^2-1)$. **Formal, not analytic:** equality of functions $\mathbb{C} \to \mathbb{C}$ of exponents, i.e. coefficientwise; no convergence or modularity enters.

Physical meaning

Why a state of the form $a[-2]b$ contributes *exactly* a multiple of E_4: Zhu's recursion for $a[-2]$ has coefficients $(2m-1)G_{2m}$ multiplying the traces of $a[2m-2]b$. The $m = 1$ term is the trace of a zero mode, which vanishes. When $a[2]b$ is a multiple $\lambda|0\rangle$ of the vacuum and higher positive modes kill b, only $m = 2$ survives, and $S(a[-2]b) = -3\lambda G_4 \star f$ (Definition 25.15). In CFT terms, the OPE $a(z)b(0)$ has a single vacuum term at order z^{-4} in the cylinder coordinate, and the torus propagator turns that term into E_4. The relation says that (TT) behaves like such a state on the torus. Its one-point function is then E_4 times the partition function, which is the MLDE.

What the machine verified

Definitions (a named `Prop`); satisfiable — it is proved for seven VOAs in Section 25.6.

Theorem 25.14 (The constant is forced; the AK recurrence). *Let W have central charge $c = -2(h+1)$ and $|0\rangle \neq 0$. If the formal MLDE (or the vacuum quartic relation, which implies it) holds with* some *constant κ, then $\kappa = (h+1)(5h-6)$, and the graded dimensions $N \mapsto \dim W_N$ form a normalised AK solution with parameter h. Hence $\dim W_N = c_N$ and* `TargetLowerBoundQ W (mldeCoeff h)`.

File `VOA/DeligneAudit/DeligneMLDEBlock.lean`.

    {κ : ℂ} (hrel : VacuumQuarticRelation W κ) :
    DeligneCharacter.TargetLowerBoundQ W (DeligneCharacter.mldeCoeff h)
```

From the mathematics to the Lean statement

Three hypotheses: `hc` ($c = -2(h+1)$, true for $L_k(\mathfrak{g})$ in the Deligne series because $\dim \mathfrak{g} = 2(h+1)(5h-6)/(h+6)$ and $c = k \dim \mathfrak{g}/(k+h)$), `hvac` ($W$ is not the zero space; it makes $\dim W_0 = 1$, because the library's `VertexOperatorAlgebra` has as a field `vacuum_grade` that

$W_0 = \mathbb{C}|0\rangle$, i.e. CFT type, Chapter 1), and the relation with an *existentially free* κ. **Why is κ free?** Because it is determined: Lean need not be told its value, which removes a possible source of error (a wrong κ in a hypothesis would make it unsatisfiable, hence the theorem vacuous). **Could the conclusion be vacuous?** No: `TargetLowerBoundQ` asserts $\dim W_N \geq c_N$ with $c_1 = \dim \mathfrak{g} > 0$ etc., which fails for the zero VOA; and the hypotheses are discharged for seven concrete VOAs below.

Proof on paper. Read the formal MLDE at the exponent $e+N$, $e = -c/24$, where the coefficient of f is $\dim W_N$. At $N = 0$ only the constant terms of G_2, G_4 contribute, and $\dim W_0 = 1$: $e^2 - \frac{1}{12}\cdot 2e + \frac{1}{720}\cdot\frac{c}{2} = \frac{\kappa}{720}$, i.e. $\kappa = 720e^2 - 120e + \frac{c}{2} = \frac{5}{4}c^2 + \frac{11}{2}c$. At $c = -2(h+1)$ this is $5(h+1)^2 - 11(h+1) = (h+1)(5h-6)$. Then $\kappa - c/2 = 5c(c+4)/4 = 5(h^2-1)$, so the MLDE is (25.3), and the q^{e+N} coefficient for $N \geq 1$ is (25.4) after multiplying by 6 (the computation of Section 25.3). Theorem 25.9 concludes. □

Physical meaning

The indicial equation says that the vacuum (weight $-c/24$ on the torus) is a solution's leading term; this fixes the coefficient of E_4 in terms of c alone. In physics language this is the "holomorphic modular bootstrap" with the vacuum as input: the one free parameter of a second-order MLDE is fixed by the central charge. *Observation (heuristic, not used):* Mathur, Mukhi and Sen classified the second-order MLDEs at positive central charge whose vacuum solution has nonnegative integer coefficients, and level-one WZW models of the Deligne series appear among them. That the same Lie algebras reappear here at negative central charge, in the 4d chiral algebras, is a known coincidence of the two families. It is not a theorem of either source, and nothing here depends on it.

What the machine verified

Standard axioms for `isAKSolution_of_vacuumQuarticRelation` and `kappa_eq_of_formalMLDE` (re-run for this chapter). Conditional on `hc`, `hvac`, `hrel` as stated.

No modular forms, no Etingof-finiteness: what this replaces

Chapter 16 shows that the library's general AK theorem (`IsSqPrimary.exists_monicMLDEOn_all_analyticBlocks_of_etingofFinite_uncond`) is conditional on `EtingofFinite` only (its side inputs `AKWeightGrading` and `E46SerreClosed` are now the theorems `VOA.akWeightGrading` and `VOA.e46SerreClosed`) but bounds neither the order nor the coefficients of its MLDE, and that the unconditional `character_formalODE_of_etingofFinite` is near-vacuous. Those files are *not used* here. The route of this section needs only Zhu's formal recursion and the exact Virasoro tower; the target is coefficientwise, so the formal version suffices, and κ comes from the indicial equation. **Dead end recorded:** do not route a coefficient identity through `AKModularODE.character_formalODE_of_etingofFinite`; it does not determine the character.

25.4.3 The algebraic form of the relation

The trace identity is a statement about traces. Arakawa and Kawasetsu derive it from an algebraic statement, $\bar{\omega}^2 = 0$ in R_V, and the library has a square-bracket version of that statement. To motivate

the definitions, start from Zhu's recursion for a square-bracket mode $a[-2]$, with a homogeneous:

$$S\big(a[-2]b\big) = -\sum_{m\geq 1}(2m-1)\,G_{2m}\star S\big(a[2m-2]b\big). \tag{25.6}$$

In general the right side involves infinitely many unknown traces. It collapses to a single known term in exactly the following situation. The $m=1$ term is $S(a[0]b)$, the trace of a commutator-type state, which vanishes; we therefore call such states *trace-null*. The $m=2$ term is $3G_4\star S(a[2]b)$, which is a multiple of $G_4\star f$ precisely when $a[2]b$ is a multiple of the vacuum. The terms $m\geq 3$ vanish if $a[2m-2]b=0$. The definition records exactly these conditions.

Definition 25.15 (Trace-null vectors; square-bracket C_2 terms)**.** The *trace-null* subspace is spanned by the $a[0]v$ (a homogeneous of weight ≥ 1) and by the $L[-1]v$. A *square-bracket C_2 term of weight four* is a state $a[-2]b$ with a homogeneous of weight $k_a\geq 1$, $a[2]b=\lambda|0\rangle$, and $a[2m]b=0$ for $m\geq 2$. By (25.6) its one-point function is $-3\lambda\,G_4\star f$. The *square-bracket C_2 quartic relation* with constant κ says that $L[-2]^2|0\rangle\equiv\sum_i a_i[-2]b_i$ modulo trace-null vectors, for finitely many such terms, with $\kappa=-3\sum_i\lambda_i$.

File `VOA/DeligneAudit/DeligneMLDEBlock.lean`.

```
noncomputable def traceNull : Submodule ℂ 𝒱 :=
  Submodule.span ℂ ({x | ∃ (ka : ℕ) (a v : 𝒱), 1 ≤ ka ∧ a ∈ W.grading (ka : ℤ) ∧ x = vSqZ W
   ↪  a ka 0 v}
    ∪ Set.range (Lsq W (-1)))

theorem vacuumQuarticRelation_of_sqC2 {κ : ℂ} (h : SqC2QuarticRelation W κ) :
    VacuumQuarticRelation W κ
```

From the mathematics to the Lean statement

`vSqZ W a ka n` is the square-bracket mode $a[n]$ of a state a of L_0-weight `ka` (Chapter 15, Definition 15.7); the weight must be supplied because square modes depend on it. `Set.range (Lsq W (-1))` is the image of $L[-1]$. `SqC2Term` is data (a `structure` in `Type`), carrying the two vanishing conditions as fields.

Proof on paper. Every one-point function kills trace-null vectors (cyclicity of the trace for $a[0]$; $S(L[-1]v)=0$). For one term, Zhu's recursion for $a[-2]$ gives $S(a[-2]b)=-\sum_{m\geq 1}(2m-1)G_{2m}\star S(a[2m-2]b)$; the $m=1$ term is a zero-mode trace and vanishes, the $m=2$ term is $3G_4\star S(\lambda|0\rangle)$, and $m\geq 3$ vanish by `high`. So $S(a[-2]b)=-3\lambda G_4\star f$; sum. □

Physical meaning

Modulo zero modes and derivatives, which have vanishing torus one-point functions, (TT) is a sum of "∂^2-descendant" states, each contributing a multiple of E_4. This is the trace version of "$\bar{\omega}^2 = 0$ in R_V", i.e. the square of the Sugawara Casimir vanishes on the Higgs branch.

What the machine verified

Standard axioms. Unconditional as an implication. Not itself used by the per-type instances, which go through the current calculus of the next section.

25.5 The square-bracket current calculus

To prove the vacuum quartic relation for $L_k(\mathfrak{g})$ one needs to compute with square-bracket modes of the currents $J^a \in V_1$. The "obvious" route — Zhu's isomorphism $(V, Y) \cong (V, Y[\,])$ — is not in the library and would be a large project (recorded as a dead end at the end of this section). Instead, the files `VOA/Modularity/ZhuCoordinate*.lean` prove directly the three relations needed.

Theorem 25.16 (Square-bracket current algebra). *Let W be any VOA. For $a, b \in W_1$ with $a_{(1)}b = \beta|0\rangle$, and all $m, n \in \mathbb{Z}$,*

$$[a[m], b[n]] = (a_{(0)}b)[m+n] + m\beta\,\delta_{m+n,0}.$$

If moreover a is primary ($L_1 a = 0$), then $[L[m], a[n]] = -n\,a[m+n]$. For $a \in W_{P+1}$, $(L_{-1}a)[n] = -n\,a[n-1] - (P+1)\,a[n]$ (the translation rule).

File `VOA/Modularity/ZhuCoordinateCurrent.lean`.

```
theorem sqCurrent_comm {a b : V} (ha : a ∈ W.grading 1) (hb : b ∈ W.grading 1)
    {β : ℂ} (hp : W.smul a 1 b = β • W.vacuum) (m n : ℤ) (x : V) :
    vSqZ W a 1 m (vSqZ W b 1 n x) - vSqZ W b 1 n (vSqZ W a 1 m x)
      = vSqZ W (W.smul a 0 b) 1 (m + n) x + (if m + n = 0 then ((m : ℂ) * β) • x else 0)

theorem Lsq_sqCurrent_comm {a : V} (ha : a ∈ W.grading 1) (ha1 : W.L 1 a = 0) (m n : ℤ)
    (x : V) :
    Lsq W m (vSqZ W a 1 n x) - vSqZ W a 1 n (Lsq W m x) = (-(n : ℂ)) • vSqZ W a 1 (m + n) x

theorem vSqZ_L_neg_one {a : V} (P : ℕ) (ha : a ∈ W.grading ((P + 1 : ℕ) : ℤ)) (n : ℤ) :
    vSqZ W (W.L (-1) a) (P + 2) n
      = (-(n : ℂ)) • vSqZ W a (P + 1) (n - 1) - ((P : ℂ) + 1) • vSqZ W a (P + 1) n
```

From the mathematics to the Lean statement

`W.smul a n b` is the ordinary mode product $a_{(n)}b$ (Chapter 1); so `hp` is $a_{(1)}b = \beta|0\rangle$ and `W.smul a 0 b` is $a_{(0)}b$. `vSqZ W a 1 m` is $a[m]$ for a weight-one state. `W.L 1 a = 0`: a is primary. The "if" encodes the Kronecker delta. All three are the displays, for an arbitrary VOA.

Proof on paper. Square modes as residues. Zhu's definition is $a[n] = \operatorname{Res}_z Y(a, e^z - 1)e^{z\,\mathrm{wt}\,a} z^n$. Substitute $w = e^z - 1$, so that $z = L(w) := \log(1+w)$ and $dz = dw/(1+w)$. Then

$$a[n] = \operatorname{Res}_w\, Y(a, w)\,(1+w)^{\mathrm{wt}\,a-1} L(w)^n.$$

Since $L(w) = w\,u(w)$ with $u = \log(1+w)/w = 1 - \frac{w}{2} + \dots$ invertible, this is a finite combination $a[n] = \sum_{p\ge 0} z(\mathrm{wt}\,a, n, n+p)\,a_{(n+p)}$ of ordinary modes, with $z(k, m, m+p) = [w^p]\big((1+w)^{k-1}u^m\big)$. For $\mathrm{wt}\,a = 1$ the factor $(1+w)^0$ disappears, and $a[n] = \operatorname{Res}_w Y(a, w)L(w)^n$.

The bracket, in residue form. For weight-one a, b the ordinary commutator formula is $[a_{(i)}, b_{(j)}] = (a_{(0)}b)_{(i+j)} + i\,(a_{(1)}b)_{(i+j-1)}$, since $a_{(k)}b = 0$ for $k \geq 2$ by weight. With $a_{(1)}b = \beta|0\rangle$ and $|0\rangle_{(n)} = \delta_{n,-1}$, the second term is $i\beta\,\delta_{i+j,0}$. Write $a[m] = \sum_i x_i a_{(i)}$ and $b[n] = \sum_j y_j b_{(j)}$, where $\sum_i x_i w^i = L(w)^m$ and $\sum_j y_j w^j = L(w)^n$.

- *Bracket term.* $\sum_{i,j} x_i y_j (a_{(0)}b)_{(i+j)}$ is the square mode of $a_{(0)}b$ whose coefficient series is the product $L^m \cdot L^n = L^{m+n}$. That is $(a_{(0)}b)[m+n]$, the identity $u^m u^n = u^{m+n}$.
- *Central term, worked out completely.* $\sum_{i,j} x_i y_j\, i\beta\,\delta_{i+j,0} = \beta \sum_i i x_i y_{-i}$. For two Laurent series $F = \sum x_i w^i$ and $G = \sum y_j w^j$, the sum $\sum_i i x_i y_{-i}$ is $\operatorname{Res}_w F'(w)G(w)$. So the central term is $\beta\ \operatorname{Res}_w \frac{d}{dw}\big(L^m\big)L^n = \beta\, m\ \operatorname{Res}_w L^{m+n-1}\,dL$. If $m+n \neq 0$, the integrand is $\frac{m}{m+n}\,d\big(L^{m+n}\big)$, the derivative of a Laurent series in w, whose residue is 0. If $m+n=0$, it is $m\,dL/L = m\,\frac{dw}{(1+w)\,w\,u(w)}$, whose residue is $m/u(0) = m$. Hence the central term is $m\beta\,\delta_{m+n,0}$, as claimed.

The Virasoro and translation rules. These are proved the same way, as residue identities for the coefficient series. For $[L[m], a[n]]$ one needs the transformation of ω under $w = e^z - 1$ (the Schwarzian shift $-c/24$) and the primarity of a. For $(L_{-1}a)[n]$ one uses $Y(L_{-1}a, w) = \partial_w Y(a, w)$ and integrates by parts, which produces the two terms $-n\,a[n-1]$ and $-(P+1)\,a[n]$. In every case the needed coefficient identity comes down to the one-line differential equation $(1+w)(u+wu') = 1$, i.e. $\frac{d}{dw}\log(1+w) = \frac{1}{1+w}$. The proofs are in `ZhuCoordinateCoeff.lean`. □

Physical meaning

Zhu's coordinates are the map from the plane to the cylinder $w = e^{2\pi i z} - 1$. Currents transform as primaries of weight one, so their modes in the new coordinate obey the same affine Kac–Moody algebra at the same level; the stress tensor picks up the Schwarzian ($c/24$ shift), which is why $L[n]$ differs from L_n but still acts on currents as $-n$.

What the machine verified

Standard axioms. Unconditional.

Definition 25.17 (The weighted square-bracket C_2 span; the current C_2 span)**.** sqC2Span(N) is spanned by $a[-2]b$ with $a \in W_p$, $p \geq 1$, b of L_0-degree $\leq N - p - 1$. For a family of currents g_i, currentC2 is spanned by $g_i[-n]y$ with $n \geq 2$.

Files `VOA/Modularity/ZhuCoordinateGrading.lean`.

```
def sqC2Span (N : ℤ) : Submodule ℂ 𝒱 :=
  Submodule.span ℂ {x | ∃ (p : ℕ) (a b : 𝒱), 1 ≤ p ∧ a ∈ W.grading (p : ℤ) ∧
    b ∈ gradeLE W (N - p - 1) ∧ x = vSqZ W a p (-2) b}

def currentC2 : Submodule ℂ 𝒱 :=
  Submodule.span ℂ {x | ∃ (i : ι) (n : ℕ) (y : 𝒱), 2 ≤ n ∧ x = vSqZ W (g i) 1 (-(n : ℤ)) y}
```

From the mathematics to the Lean statement

`gradeLE W d` $= \bigoplus_{j \leq d} W_j$ (`ChangeCoord.lean`). The weight bound on b makes every $a[2m]b$ with $m \geq 2$ vanish and $a[2]b \in W_0 = \mathbb{C}|0\rangle$ (`vSqZ_mem_gradeLE`), so every generator of `sqC2Span W 4` is a `SqC2Term`. The translation rule shows $a[-n]b \in$ sqC2Span for all $n \geq 2$ (`vSqZ_neg_mem_sqC2Span`).

Physical meaning

A state $g[-n]y$ with $n \geq 2$ is a field with at least one derivative, $\partial^{n-1}g$, multiplying y. On the torus its one-point function is a pure Eisenstein correction, with no δ_q term, because (25.6) has no derivative term. Quotienting by these states is passing to the "classical" algebra R_V (no derivatives) in the cylinder coordinate. The computation in which these spans appear is the reduction of (TT) to C_2 terms.

What the machine verified

Definitions.

Theorem 25.18 (κ from a membership). *If $|0\rangle \neq 0$ and $L[-2]^2|0\rangle \in \mathrm{sqC2Span}(4)$, then the vacuum quartic relation holds with $\kappa = \frac{5}{4}c^2 + \frac{11}{2}c$.*

File `VOA/DeligneAudit/DeligneVacuumRelation.lean`.

```
theorem vacuumQuarticRelation_of_mem_sqC2Span (hvac : W.vacuum ≠ 0)
    (hx : Lsq W (-2) (Lsq W (-2) W.vacuum) ∈ sqC2Span W 4) :
    VacuumQuarticRelation W (5 / 4 * W.centralCharge ^ 2 + 11 / 2 * W.centralCharge)
```

From the mathematics to the Lean statement

The membership needs no coefficients: `exists_kappa_of_mem_sqC2Span` shows every element of `sqC2Span W 4` has one-point function $\kappa' G_4 \star f$ for *some* κ', and `kappa_eq_of_vacuumQuarticRelation` pins κ' by the indicial computation of Theorem 25.14.

Proof on paper. Linearity of S and the computation for one `SqC2Term` (proof of `vacuumQuarticRelation_of_sqC2`) give existence; the lowest coefficient fixes κ. □

Physical meaning

If (TT) is, in the cylinder coordinate, a sum of states of the form $\partial g \cdot y$ of total weight four, then each of them contributes a multiple of E_4 times the partition function, by (25.6). The MLDE follows, and its constant is then fixed by the vacuum's exponent, so no coefficient of the decomposition needs to be computed.

What the machine verified

Standard axioms. Unconditional as an implication.

Definition 25.19 (Affine current data). `SqCurrentData W ι` packages: primary weight-one currents g_i ($i \in \iota$), structure constants T_{ij}^c with $g_{i(0)}g_j = \sum_c T_{ij}^c g_c$, a form F and level k with $g_{i(1)}g_j = kF_{ij}|0\rangle$, an inverse form K, a dual Coxeter number $h^\vee$ with $k + h^\vee \neq 0$, the Sugawara formula $\omega = \frac{1}{2(k+h^\vee)} \sum K_{ij} g_{i(-1)} g_j$, the trace condition $\sum K_{ij} T_{ij}^c = 0$, and $c(k + h^\vee) = k \sum K_{ij} F_{ij}$.

From the mathematics to the Lean statement

Every field is an identity checkable in an affine VOA; `affineCurrentData D k hk` (`DeligneVacuumRelationAffine.lean`) constructs an instance for $L_k(\mathfrak{g})$ from any `LieData` (Chapter 23), with T the structure constants and F the form table. The structure does not require the g_i to generate W; it is used only to compute $L[-2]|0\rangle$ and its descendants.

Physical meaning

A WZW-type current algebra with its Sugawara stress tensor. `bracket_trace` is the statement that the Casimir is invariant, so the Sugawara vector has no weight-one correction term.

What the machine verified

Definition; instantiated for every simple $\mathfrak{g}$.

Theorem 25.20 (Square Sugawara; the symbol calculus). *Given affine current data, $L[-2]|0\rangle = \frac{1}{2(k+h^\vee)}\sum K_{ij}g_i[-1]g_j[-1]|0\rangle$. In $Q = V/\mathrm{currentC2}$ the operators $g_i[-1]$ commute, so each polynomial $p \in \mathbb{C}[X_i]$ acts; put $\mathrm{sym}(p) = p(g[-1])|0\rangle \in Q$ and $\mathrm{Cas} = \sum K_{ij}X_iX_j$. If $\mathrm{sym}(X_i\,\mathrm{Cas}) = 0$ for every i, and $|0\rangle \neq 0$, then the vacuum quartic relation holds with $\kappa = \frac{5}{4}c^2 + \frac{11}{2}c$. Moreover* sym *vanishes on the ideal generated by polynomials with vanishing symbol, and $\mathrm{sym}(\mathrm{ad}_b\, p) = g_b[0]\,\mathrm{sym}(p)$ for the coadjoint derivation ad_b.*

File `VOA/DeligneAudit/DeligneVacuumRelation.lean`.

```

From the mathematics to the Lean statement

`D.sq i n` is $g_i[n]$. `D.ev p` is the evaluation of a polynomial at the commuting operators `D.Tq i` $= g_i[-1]$ on the quotient (built by `MvPolynomial.aeval` into the commutative subalgebra they generate). `D.Zq c` $= g_c[0]$ on the quotient. `adG T b` is the derivation $X_i \mapsto \sum_c T^c_{bi} X_c$ of $\mathbb{C}[X]$. `X i * D.casPoly` is $X_i \cdot$ Cas. The key hypothesis says the cubic polynomials X_iCas act trivially on the vacuum modulo currentC2. **Section variables.** In `DeligneVacuumRelation.lean` the VOA `W : VertexOperatorAlgebra` V is implicit here and `D : SqCurrentData W ι` (with `[Fintype ι]`) is an explicit section variable: the ambient square-current data, which is why the declarations are written `D.sym`, `D.casPoly`. Its fields `D.level`, `D.hdual`, `D.K` are k, $h^\vee$ and the inverse form K_{ij}.

Proof on paper. Square Sugawara. Expand $g_i[-1]g_j[-1]|0\rangle = g_{i(-1)}g_j + \frac{1}{2}g_{i(0)}g_j - \frac{1}{12}g_{i(1)}g_j$, using the coefficients $z(1,-1,0) = \frac{1}{2}$ and $z(1,-1,1) = -\frac{1}{12}$, read off from $u^{-1} = 1 + \frac{w}{2} - \frac{w^2}{12} + \dots$. Then use `bracket_trace`, which kills the $g_{i(0)}g_j$ sum, and `central`, which turns the $g_{i(1)}g_j$ sum into the $c/24$ shift between ω and $L[-2]|0\rangle$.

Stability of currentC2 *(needed for everything that follows).* For $m \le 0$ the operator $g_i[m]$ maps currentC2 into itself (`sq_mem_currentC2`). Take a generator $g_c[-n]y$ with $n \ge 2$. By Theorem 25.16,

$$g_i[m]\, g_c[-n]y = g_c[-n]\,(g_i[m]y) + \sum_e T^e_{ic}\, g_e[m-n]y,$$

and there is no central term, because $m - n \le -2 \neq 0$. The first term is a generator, and so is each $g_e[m-n]y$, since $m - n \le -2$. So $g_i[-1]$ and $g_i[0]$ descend to operators `D.Tq i`, `D.Zq i` on $Q = V/$currentC2. The $g_i[-1]$ commute on Q, since their commutator $(g_{i(0)}g_j)[-2]$ maps into currentC2. So sym is well defined, and $[g_c[0], g_i[-1]] = (g_{c(0)}g_i)[-1]$ gives `sym_adG`. The span property is linearity.

The reduction. Put $\omega' = L[-2]|0\rangle = s\sum K_{ij}g_i[-1]g_j[-1]|0\rangle$, with $s = (2(k+h^\vee))^{-1}$. The rule $[L[m], g[n]] = -n\,g[m+n]$ at $m = -2$, $n = -1$ reads $L[-2]\,g_i[-1] = g_i[-1]\,L[-2] + g_i[-3]$ (`Lsq_neg_two_sq`). Applying it twice,

$$L[-2]^2|0\rangle = L[-2]\,\omega' = s\sum_{i,j} K_{ij}\Big(g_i[-1]\big(g_j[-1]\,\omega' + g_j[-3]|0\rangle\big) + g_i[-3]\,g_j[-1]|0\rangle\Big).$$

Here $g_i[-3]g_j[-1]|0\rangle$ is a generator of currentC2. Also $g_j[-3]|0\rangle$ is a generator, and $g_i[-1]$ preserves currentC2 by stability, so $g_i[-1]g_j[-3]|0\rangle$ lies in it too. It remains to show $g_j[-1]\,\omega' \in$ currentC2 for every j. In Q, ω' has class s sym(Cas), so $g_j[-1]\omega'$ has class s sym(X_jCas), which is 0 by hypothesis. Hence $L[-2]^2|0\rangle \in$ currentC2. Each term has square-bracket weight four, so it lies in the weight-four part, which is contained in sqC2Span(4) (`currentC2At_le_sqC2Span`). Theorem 25.18 concludes. □

Physical meaning

This is the statement "the Higgs branch relation $J^a \cdot \mathrm{Cas} = 0$ holds in R_V" lifted to Zhu's coordinates. *Heuristic, not Lean:* in the Deligne series the Higgs branch is expected to be the minimal nilpotent orbit closure (for types other than A, its ideal is the associated graded of the Joseph ideal), and J^a Cas vanishes on it; in particular $\mathrm{Cas}^2 = 0$ in R_V while $\mathrm{Cas} \neq 0$ (R_V is non-reduced). Nilpotency of order two of the stress tensor's symbol is what makes the MLDE second order.

What the machine verified

Standard axioms. Unconditional as an implication.

Dead end: Zhu's change of coordinates as a VOA isomorphism

A first attempt tried to transport "$\omega_{(-1)}\omega \in C_2(V)$" through Zhu's isomorphism $(V, Y) \cong (V, Y[\,])$. The repository's `changeCoord` has no transformation law and there is no square Borcherds identity; formalising them is a large project. The symbol calculus above avoids it entirely. A Lean trap recorded on the way: in $L_{-3/2}(\mathfrak{sl}_3)$, `rw` with equations between quotient expressions times out in `isDefEq`; proving the combination as one `mkQ` of a vector (`sym_three`) fixes it.

25.6 The vacuum quartic relation for every Deligne type

Theorem 25.21 (From carrier data to the target bound)**.** *Suppose given the following data and hypotheses.*

1. Carrier data *CD (Chapter 24): a number n of currents (for the intended use, $n = \dim \mathfrak{g}$); quadrics* $\mathrm{rel}_r \in \mathrm{Sym}^2$ *spanning I_2^{ns}; a Casimir quadric Q; and a certificate of U3, i.e. $X_a Q \in (\mathrm{rel}_r)_r$ for every a.*

2. *A Lie algebra record D (a* `LieData`*, Chapter 23) on the index set $\{0, \dots, n-1\}$, with dual Coxeter number $D.h$ in the normalisation of its invariant form.*

3. *A level $k \in \mathbb{C}$ with $k + D.h \neq 0$, so that the Sugawara construction and $L_k =$* `simpleVOA D k hk` *exist.*

4. `hcas`*: a number $c_0 \in \mathbb{C}$ with* $\mathrm{Cas} = c_0\, Q$*. Here* $\mathrm{Cas} = \sum K_{ij} X_i X_j$ *is the Sugawara quadric of D, and Q is the certificate's Casimir.*

5. `hrel`*: every relation* rel_r *has vanishing symbol in L_k (Theorem 25.20).*

Then the vacuum quartic relation holds for L_k with $\kappa = \frac{5}{4}c^2 + \frac{11}{2}c$. If moreover

6. `hc`*: $h \in \mathbb{N}$ satisfies $nk/(k + D.h) = -2(h+1)$, i.e. the central charge is $-2(h+1)$,*

then $\dim L_k(\mathfrak{g})_N \geq c_N =$ `mldeCoeff` $h\, N$ *for all N.*

```

From the mathematics to the Lean statement

`CD.Q = quadraticRelation CD.cas`, the Casimir as a quadratic polynomial; `quadraticRelation q` is $\sum_{x,y} q(x,y)X_xX_y$. `simpleVOA D k hk` is $L_k(\mathfrak{g})$ for the Lie algebra encoded by D (Chapter 23). `hc` is the central charge condition ($c = k\dim\mathfrak{g}/(k+h^\vee)$ by `simple_centralCharge'`). `hcas` identifies the Sugawara quadric with the certificate Casimir (needed because U3 is stated for the latter). `hrel` is the vanishing of the relation symbols. $c_0 \neq 0$ **is not required**: if $c_0 = 0$, U3 is not even used. The conclusion's W is the concrete simple VOA. **Notation clash.** The `κ` in `LieData κ (Fin CD.n)` is a bilinear form `κ : LinearMap.BilinForm ℂ 𝔤` on a finite-dimensional Lie algebra `𝔤` (implicit section variables, with `[FiniteDimensional ℂ 𝔤]`), not the constant κ of Definition 25.13. `D.h` is the dual Coxeter number *in the normalisation of that form* (the adjoint Casimir acts by `2 D.h`), and k is the level relative to the same form; the concrete records of Chapter 23 are normalised so that `D.h` is the usual $h^\vee$. The theorem assumes neither that $\mathfrak{g}$ is simple nor that `D.h` equals the ambient h: the two are related only through `hc`. `simpleVOA D k hk` is the simple quotient of the universal affine VOA for whatever D encodes. The first theorem is the same statement stopped one step earlier, before `hc` is used; it is the input to the equality route recorded in the warning after Theorem 25.22.

Proof on paper. By U3 and `hcas`, $X_a\mathrm{Cas} = c_0X_aQ$ lies in the ideal generated by the relations, whose symbols vanish; `sym_eq_zero_of_mem_span` gives $\mathrm{sym}(X_a\mathrm{Cas}) = 0$; Theorem 25.20 gives the vacuum quartic relation; Theorem 25.14 the bound. How `hrel` is proved per type: the symbol of the highest-weight relation vanishes because the weight-two singular vector dies in L_k and two finite "shadow" checks hold (`sym_singular`: the bracket and form contractions of the relation vanish). All other relations are obtained from it by the coadjoint action, and vanishing *propagates* as follows. Since $\mathrm{sym}(\mathrm{ad}_bR) = g_b[0]\,\mathrm{sym}(R)$ (Theorem 25.20), if $\mathrm{sym}(R) = 0$ and $\lambda\,\mathrm{ad}_bR = \mu\,R'$ with $\mu \neq 0$, then $\mathrm{sym}(R') = 0$. Think of the relations as the vertices of a graph, with an edge $R \to R'$ for each such identity, labelled by (b,λ,μ). A breadth-first search from the highest-weight relation that reaches every vertex is then a proof that all symbols vanish (`sym_step`). The certificates of Section 25.12 are such searches: 102 steps for D_4, the 1539 relations of E_7, and 3874 steps for the 3875 relations of E_8. Each step is an identity of explicit quadrics, checked by `decide +kernel`. □

Physical meaning

Heuristic: the quadrics of I_2^{ns} are the Higgs branch chiral-ring relations; they hold in R_V because the weight-two singular vector (the 4d "Higgs branch chiral ring relation") is null in the simple quotient. The theorem says these classical relations, plus invariance of the Casimir, already force the full vacuum character.

What the machine verified

Standard axioms (re-run for this chapter). Unconditional as an implication.

Theorem 25.22 (The character bound for every Deligne type)**.** *For each row of the table, the simple affine VOA $W = L_k(\mathfrak{g})$ satisfies, with no hypothesis,* $\dim W_N \geq c_N =$ `mldeCoeff` $h^\vee$ N *for all* N *(*`TargetLowerBoundQ W (mldeCoeff hv)`*). From the mathematics to the Lean statement

The `LieData` records are constructed and checked in Chapter 23. **All these theorems have no hypotheses. Same as, stronger or weaker?** For A_2 the Lean statement is the mathematical equality. For the other six types the exported conclusion is `TargetLowerBoundQ`, which by definition is the one-sided $\forall N,\ c_N \le \dim W_N$. That is *weaker* than the equality, and Theorem 25.22 claims only that (Caveat 1). The proofs pass through `targetLowerBoundQ_of_isAKSolution`, which discards the other half of an equality it has in hand (Theorem 25.9). The numbers: $36 = 4\cdot 9$, $70 = 5\cdot 14$, $168 = 7\cdot 24$, $390 = 10\cdot 39$, $702 = 13\cdot 54$, $1596 = 19\cdot 84$, $4464 = 31\cdot 144$, each $(h+1)(5h-6)$. For G_2 and F_4 the library states κ as $\frac{5}{4}c^2 + \frac{11}{2}c$, which at $c = -10, -20$ gives 70 and 390.

What is known about the Lie algebras. For each record, Chapter 23 proves in Lean that the algebra is a simple Lie algebra of the right dimension, with the invariant form normalised so that `D.h` is the usual $h^\vee$ (Theorem 23.37 and the lattice theorems there). It does *not* prove that, say, `e6LieData` is isomorphic to the Bourbaki $\mathfrak{e}_6$, because the Cartan–Killing classification is not formalised. For dimensions $14, 28, 52, 133, 248$ the identification follows on paper from the classification and the dimension. Dimension 78 is ambiguous (B_6, C_6, E_6), and for the structure-constant $\mathfrak{e}_6$ used here the ambiguity is settled on paper by the value of the Killing form on a long coroot (Remark 23.33). The library has three Lean models of $\mathfrak{e}_6$, and no isomorphism between them is formalised; the E_6 theorem is about `e6LieData`. So each

theorem is literally about L_k of the algebra the record encodes, and that algebra is the intended one by an argument on paper.

Proof on paper. Theorem 25.21 with each type's carrier data. The work is in `hrel`: one singular-vector computation per type and a propagation search through all relations of I_2^{ns}, as described in the proof of Theorem 25.21 (certificates in Section 25.12). The Casimir match `hcas` is checked entrywise (`quadraticRelation_eq_of_symm`). Then the central charge is computed from `hc`, and Theorem 25.14 applies. □

Physical meaning

This is the vacuum character of the rank-one Minahan–Nemeschansky theories (E_6, E_7, E_8), of $SU(2)$ with four flavours (D_4) and of the (A_1, D_4) Argyres–Douglas theory (A_2): their Schur indices satisfy the second-order MLDE (25.3), as Beem–Rastelli predicted and Arakawa–Kawasetsu proved. G_2 at $k = -5/3$ and F_4 at $-5/2$ have no known 4d origin, but the VOA statement is the same. What the library contains, as Lean theorems: the equality $\dim L_N = c_N$ for A_2, and the lower bound $\dim L_N \geq c_N$ (the half that classical freeness needs) for all seven types (Caveat 1). For A_2 the further equality with the product $\prod(1+q^r)^8$ is derivable but not stated (Remark 25.23).

What the machine verified

Verdict. Every theorem in the blocks above is a Lean theorem with no hypotheses and standard axioms, and the $\geq$ bound is unconditional for all seven types; the equality only for A_2. **Machine evidence** (Section 25.1.7). These files were built green in the `VOA.Deligne` umbrella build at an earlier commit; the quoted statements are unchanged in the state this chapter was written against, and a pre-release aggregate build, which contains the umbrella, was green on 2026-10-28 (18,901 jobs; 18,907 after a merge). The axiom lists are the `#print axioms` commands in the files, as run in that build and in the later targeted builds. For this chapter we re-ran `#print axioms` on the generic lemmas `targetLowerBound_of_carrierData`, `vacuumQuarticRelation_of_carrierData`, `isAKSolution_of_vacuumQuarticRelation` and `finrank_eq_mldeCoeff_of_isAKSolution` (standard), and we did not import the E_6, E_7, E_8 modules.

LEAN DEFECT: equality is not a Lean theorem for six types

The equality $\dim L_k(\mathfrak{g})_N = c_N$ is **not stated** in the library for $G_2, D_4, F_4, E_6, E_7, E_8$; only A_2 has it (`A2.finrank_eq_mldeCoeff'`). It is derivable from exported lemmas, in one line per type:

- G_2, F_4: `finrank_eq_mldeCoeff_of_isAKSolution _ (isAKSolution_of_vacuumQuarticRelation _ h xW_centralCharge xW_vacuum_ne_zero x_vacuumQuarticRelation) N` with $h = 4, 9$.
- D_4, E_8: the same with `vacuumQuarticRelation4` / `vacuumQuarticRelation8`, $h = 6$ / 30; the central-charge hypothesis is `simple_centralCharge'` plus `d4CertData_h` / `e8CertData_h`, and `hvac` is `simple_vacuum_ne_zero'`.
- E_6, E_7: no `VacuumQuarticRelation` theorem is exported, so first apply `vacuumQuarticRelation_of_carrierData` to `(E6data, e6LieData, k6, hk6, 2/3, e6_casimir_match, e6_hrel)` and `(E7data, e7CertData, -4, hk7, 1/2, e7_casimir_match, e7_hrel)`, then proceed as above with `e6_hc`/`e7_hc` turned into the central-charge hypothesis by `simple_centralCharge'`.

What the machine confirmed for this chapter: the G_2, F_4 and D_4 compositions typecheck in a scratch file (`lake env lean -DmaxSynthPendingDepth=3`, no errors), namely

```
example (N : ℕ) : (Module.finrank ℂ (G2Lie.g2W.grading N) : ℚ) =
 ↪  DeligneCharacter.mldeCoeff 4 N :=
  DeligneMLDE.finrank_eq_mldeCoeff_of_isAKSolution _
    (DeligneMLDE.isAKSolution_of_vacuumQuarticRelation _ 4 G2Lie.g2W_centralCharge
      G2Lie.g2W_vacuum_ne_zero G2Lie.g2_vacuumQuarticRelation) N
```

and its F_4 and D_4 analogues. The E_6, E_7, E_8 compositions were *not* checked (heavy modules not imported). The scratch file is not part of the library. Recommended fix: a generic `finrank_eq_mldeCoeff_of_carrierData` beside `targetLowerBound_of_carrierData`, and per-type `*_finrank_eq_mldeCoeff` corollaries. Until then, cite the equality for these six types as "derivable, not stated". This is the authoritative statement of Caveat 1; elsewhere the chapter refers here.

Remark 25.23 (The A_2 consequences)**.** What exists in Lean for A_2, exactly:

- `A2.finrank_eq_mldeCoeff'`: $\dim V_N = c_N$ (with `mldeCoeff 3`);
- `A2.productCoeff_eq_mldeCoeff'`: $[q^N]\prod_{r\geq 1}(1+q^r)^8 = c_N$ (from `A2.a2ProductMLDE`, Theorem 25.29);
- `A2.kacWakimotoLowerBound_of_quartic`: the Kac–Wakimoto lower half $[q^N]\prod(1+q^r)^8 \leq \dim V_N$ (structure `KacWakimotoLowerBound`), from any vacuum quartic relation and `a2ProductMLDE`, with no literature input;
- `A2.finrank_grading_two_ge`: $36 \leq \dim V_2$, by an explicit 36×36 Gram determinant at $k = -3/2$ (`A2CharacterGram.lean`), an independent low-weight check.

The *character formula* $\dim V_N = [q^N]\prod_{r\geq 1}(1+q^r)^8$ itself is **not stated** as one Lean theorem. It follows in one line from the first two items, and the proof of `kacWakimotoLowerBound_of_isAKSolution` even derives it internally before weakening it to $\leq$. It is a further instance of "derivable, not stated", recorded in Section 25.13.

25.7 Formal q-series: the toolkit and the classical identities

All identities in this section are equalities in a formal power series ring $A[[q]]$ (Mathlib's `PowerSeries A`), proved from scratch. Nothing analytic is used except one appeal to Mathlib's level-one Sturm bound (Theorem 25.28). The infrastructure lives in `VOA/Commutative/JacobiTripleCore.lean`. We use the q-Pochhammer symbols

$$(a;q)_n = \prod_{i=0}^{n-1}(1-aq^i), \qquad (a;q)_\infty = \prod_{i\geq 0}(1-aq^i), \qquad (q)_n = (q;q)_n,$$

and $\binom{n}{k}_q = (q)_n/((q)_k(q)_{n-k})$ for the Gaussian binomial.

Which identity is used where.

identity	used for
Jacobi triple product	everything below: Ramanujan (via the heat equation), Legendre (via Gauss), Lorenz
pentagonal, quintuple product	side results; the quintuple product feeds Lorenz
Legendre	the last step of the A_2 star identity (critical)
Ramanujan	the A_2 product (critical), the closed forms of Section 25.8 (D_4 critical), G_2
A_2 product	c_N for A_2 as a product; Kac–Wakimoto lower half (critical for A_2)
Lorenz, Borwein, G_2 target	the target side of the open G_2 star identity (side result)

Definition 25.24 (Agreement, the Euler operator, infinite products, sums over $\mathbb{Z}$). f and g *agree to order* K if $q^K \mid f - g$. The Euler operator is $\delta_q f = \sum_n n\,a_n q^n$. For factors u_k with $u_k \equiv 1 \pmod{q^{k+1}}$, the infinite product $\prod_{k\ge 0} u_k$ has q^d-coefficient that of the finite product $\prod_{k<d} u_k$. For $c : \mathbb{Z} \to A$, $e : \mathbb{Z} \to \mathbb{N}$ with finite fibres inside $[-d-1, d+1]$, $\sum_{n\in\mathbb{Z}} c(n)q^{e(n)}$ has q^d-coefficient $\sum_{e(n)=d} c(n)$.

File `VOA/Commutative/JacobiTripleCore.lean`.

```

From the mathematics to the Lean statement

Junk values. `infProd u` is defined for *every* sequence, but it is the infinite product only when `ProdFactors u` holds; every theorem that uses it carries or proves that condition (e.g. `prodFactors_tripleFactor`). Likewise `zSeries c e` truncates the sum to $|n| \le d+1$ and is the intended sum only when every n with $e(n) = d$ satisfies this (`natAbs_le_pentExp` etc.). The Euler product $(q;q)_\infty$ is Mathlib-style `euler` of `QPochhammer.lean` (Chapter 14), with inverse `reciprocalEuler`.

Physical meaning

Formal q-series are partition functions counted state by state; infinite products are free-field (Fock space) partition functions, sums over $\mathbb{Z}$ are lattice (momentum) sums. Every identity below is a boson–fermion or product–sum identity of 2d CFT.

What the machine verified

Definitions.

Theorem 25.25 (Jacobi triple product). *For any commutative ring A and unit $u \in A^\times$, in $A[[q]]$:*

$$(1-u)\prod_{m\ge 1}(1-uq^m)(1-u^{-1}q^m)(1-q^m) = \sum_{j\in\mathbb{Z}}(-1)^j u^j q^{j(j-1)/2}.$$

File `VOA/Commutative/JacobiTriple.lean`.

```
def pentExp (j : ℤ) : ℕ := (j * (j - 1) / 2).toNat

def tripleCoeff (u : Aˣ) (j : ℤ) : A := negSign j * ((u ^ j : Aˣ) : A)

def tripleSum (u : Aˣ) : PowerSeries A := zSeries (tripleCoeff u) pentExp

def tripleFactor (u : Aˣ) (m : ℕ) : PowerSeries A :=
  (1 - C (u : A) * X ^ (m + 1)) * (1 - C ((u⁻¹ : Aˣ) : A) * X ^ (m + 1)) * (1 - X ^ (m +
  ↪ 1))

theorem jacobiTriple (u : Aˣ) :
    (1 - C (u : A)) * infProd (tripleFactor u) = tripleSum u
```

From the mathematics to the Lean statement

`negSign j` $= (-1)^{|j|} = (-1)^j$. `pentExp j` $= j(j-1)/2 \geq 0$ (`toNat` is harmless: the value is a nonnegative integer). `tripleFactor u m` is the $(m+1)$-st factor. u is any unit, e.g. a monomial x^n in $\mathbb{Z}[x^{\pm 1}]$, giving the two-variable identity coefficientwise (`twoVariableJTP`, `JacobiTripleD4.lean`).

Proof on paper. Step 1: Cauchy's finite q-binomial theorem. For every m, $\prod_{i=0}^{m-1}(1+zq^i) = \sum_{k=0}^{m}\binom{m}{k}_q q^{k(k-1)/2}z^k$. This is proved by induction on m from the q-Pascal rule.

Step 2: the finite triple product. Pull a factor $-q^i/u$ out of each $1-q^i/u$:

$$(u;q)_n\,(q/u;q)_n = \prod_{i=0}^{n-1}(1-uq^i)\prod_{i=1}^{n}(1-q^i/u) = (-1)^n u^{-n} q^{n(n+1)/2}\prod_{i=0}^{2n-1}\left(1-uq^{-n}q^i\right).$$

Apply Step 1 with $m = 2n$ and $z = -uq^{-n}$, and write $k = n+j$. The exponent of q becomes $\binom{n+j}{2} - n(n+j) + \binom{n+1}{2} = \binom{j}{2}$, so

$$(u;q)_n(q/u;q)_n = \sum_{j=-n}^{n}(-1)^j u^j q^{j(j-1)/2}\binom{2n}{n+j}_q.$$

Step 3: the limit. For fixed j, $\binom{2n}{n+j}_q = (q)_{2n}/((q)_{n+j}(q)_{n-j})$ agrees with $(q)_\infty/((q)_\infty(q)_\infty) = 1/(q)_\infty$ to order $n-|j|$. Similarly the left side agrees with $(u;q)_\infty(q/u;q)_\infty$ to order n. Letting $n\to\infty$ coefficientwise and multiplying by $(q)_\infty$ gives $(u;q)_\infty(q/u;q)_\infty(q)_\infty = \sum_j (-1)^j u^j q^{j(j-1)/2}$, which is the statement, since $(u;q)_\infty = (1-u)\prod_{m\geq 1}(1-uq^m)$. □

Physical meaning

Boson–fermion correspondence: the partition function of a complex fermion with a fugacity u for the $U(1)$ charge equals the sum over charge sectors of a free boson (charge j, energy $j^2/2$).

What the machine verified

Standard axioms (re-run for this chapter). Unconditional. Not in Mathlib.

Side result (feeds Lorenz's formula only).

Theorem 25.26 (Euler's pentagonal theorem; the sum side of the quintuple product). $(q;q)_\infty = \sum_{r\in\mathbb{Z}}(-1)^r q^{r(3r-1)/2}$. *With* $J_1(u) = \sum(-1)^n u^n p^{n(n-1)/2}$ *and* $J_2(u) = \sum u^m p^{m^2}$, $J_1(u)J_2(u) = (p;p)_\infty\sum_j\left(u^{3j}p^{j(3j-1)} - u^{3j+1}p^{j(3j+1)}\right)$ *(the sum side of the quintuple product identity).*

Files `VOA/Commutative/JacobiTriplePentagonal.lean`, `VOA/Commutative/JacobiTripleQuintuple.lean`.

```
def pentSeries : PowerSeries R := zSeries (fun r => negSign r) pentagonal

theorem euler_eq_pentagonal : (euler : PowerSeries R) = pentSeries := by

theorem quintuple_sum (u : Rˣ) :
    fsr (fun n : ℤ => negSign n * ((u ^ n : Rˣ) : R)) pentExp *
        fsr (fun m : ℤ => ((u ^ m : Rˣ) : R)) sqExp =
      euler * (fsr (fun j : ℤ => ((u ^ (3 * j) : Rˣ) : R)) (fun j => 2 * pentagonal j) -
        fsr (fun j : ℤ => ((u ^ (3 * j + 1) : Rˣ) : R)) (fun j => 2 * pentagonal (-j)))
```

From the mathematics to the Lean statement

`pentagonal` is Mathlib's $k \mapsto k(3k-1)/2$ (Mathlib defines the numbers but does not prove the theorem). `fsr c e` $= \sum_i c_i q^{e(i)}$ coefficientwise as a `finsum` (`JacobiTripleFiber.lean`). `sqExp n` $= n^2$. With $q = p^2$ the second statement is the sum-side form of the classical quintuple product identity (the sum J_1J_2 rewritten as $(p;p)_\infty$ times a two-term theta-type sum); the product form of the quintuple product identity was not needed and is not formalised, so the library does not contain "the quintuple product identity" in its usual product form.

Proof on paper. Pentagonal. Formally this is the triple product with base q^3 and $u = q$: $(q;q^3)_\infty(q^2;q^3)_\infty(q^3;q^3)_\infty = \sum_j (-1)^j q^j q^{3j(j-1)/2} = \sum_j (-1)^j q^{j(3j-1)/2}$, and the left side is $(q)_\infty$, because every $n \geq 1$ is $\equiv 0, 1, 2 \pmod 3$. Since $u = q$ is not a unit of $A[[q]]$, Theorem 25.25 cannot be applied directly. One reruns Steps 1–3 of its proof with $z = -q \cdot q^{-3n}$ at base q^3, which gives the finite identity $\prod_{m<n}(1-q^{3m+2})\prod_{i<n}(1-q^{3i+1}) = \sum_{k\leq 2n}(-1)^{k-n}q^{(k-n)(3(k-n)-1)/2}\binom{2n}{k}_{q^3}$, and lets $n \to \infty$.

Quintuple. The coefficient of u^k in $J_1(u)J_2(u)$ is $\sum_n (-1)^n p^{E(n)}$ with $E(n) = \binom{n}{2} + (k-n)^2$. Write $k = 3j + t$ with $t \in \{0, 1, 2\}$ and complete the square.

- $t = 0$, $n = r + 2j$: $E = \frac{r(3r-1)}{2} + j(3j-1)$, and the sign is $(-1)^r$. By the pentagonal theorem the sum is $p^{j(3j-1)}(p;p)_\infty$.
- $t = 1$, $n = r + 2j + 1$: $E = \frac{r(3r+1)}{2} + j(3j+1)$, and the sign is $-(-1)^r$. Replacing r by $-r$ gives $-p^{j(3j+1)}(p;p)_\infty$.
- $t = 2$, $n = r + 2j + 1$: $E = \frac{3r(r-1)}{2} + \text{const}$, and the sign is $-(-1)^r$. The terms r and $1-r$ have the same exponent and opposite signs, so the sum is 0.

Summing over k gives the display. □

Physical meaning

$(q;q)_\infty = q^{-1/24}\eta$ is the inverse partition function of one boson; the pentagonal theorem is the character of the trivial $c = 0$ minimal model written as a Virasoro Verma-module alternating sum.

What the machine verified

Standard axioms. Unconditional.

Theorem 25.27 (Legendre's four-triangular-numbers theorem). *In* $\mathbb{Z}[[q]]$: $\sum_{v\geq 0} \frac{(2v+1)q^v}{1-q^{2v+1}} = (q;q)_\infty^4 \prod_{k\geq 1}(1+q^k)^8$.

File `VOA/Commutative/FourTriangular.lean`.

```
def lambertS : PowerSeries R :=
  powerShiftSum 1 fun v => ((2 * v + 1 : ℕ) : PowerSeries R) * geomInvSeries (2 * v + 1)

theorem lambertS_eq :
    (lambertS : PowerSeries ℤ) = euler ^ 4 * infProd fun k => (1 + X ^ (k + 1)) ^ 8
```

From the mathematics to the Lean statement

`geomInvSeries m` $= 1/(1-q^m)$; `powerShiftSum 1 f` $= \sum_v q^v f(v)$. The right side is $\psi(q)^4$ with $\psi = \sum q^{n(n+1)/2} = (q;q)_\infty(-q;q)_\infty^2$ (Gauss), and the left side is $\sum_n \sigma(2n+1)q^n$ — so this is Legendre's count of representations by four triangular numbers.

Proof on paper. Work in $\mathbb{Z}[[x]]$ with $q = x^2$ and $\delta_q = x\frac{d}{dx}$. Put $\varphi(x) = \sum_{n\in\mathbb{Z}} x^{n^2}$, $Q_\pm = (\mp x; x^2)_\infty$, $P_2 = (x^2;x^2)_\infty$, and let $S(q)$ be the left side of the theorem.

1. *Gauss* (the triple product at $u = \mp x$, base x^2): $\varphi(x) = P_2 Q_+^2$ and $\varphi(-x) = P_2 Q_-^2$.

2. *Log-derivative of the products.* $Q_+ = \prod_k (1+x^{2k+1})$ and $Q_- = \prod_k (1-x^{2k+1})$, and $\delta_q \log\frac{1+y}{1-y} = \frac{2\delta_q y}{1-y^2}$ with $y = x^{2k+1}$, $\delta_q y = (2k+1)y$. Summing over k gives $\frac{\delta_q Q_+}{Q_+} - \frac{\delta_q Q_-}{Q_-} = 2xS(x^2)$.

3. *The Wronskian as a product.* Let $W = \delta_q\varphi(x)\cdot\varphi(-x) - \varphi(x)\cdot\delta_q\varphi(-x)$. By items 1–2, $W = \varphi(x)\varphi(-x)\cdot 2\big(\frac{\delta_q Q_+}{Q_+} - \frac{\delta_q Q_-}{Q_-}\big) = 4xS(x^2)\,P_2^2 Q_+^2 Q_-^2$.

4. *The Wronskian as a sum.* $W = \sum_{m,n}(m^2-n^2)(-1)^n x^{m^2+n^2}$. Pairs of equal parity cancel under $(m,n)\mapsto(n,m)$. Opposite-parity pairs are $(m,n) = (a+b+1, a-b)$, up to the swap, with $m^2-n^2 = (2a+1)(2b+1)$ and $m^2+n^2 = 2a(a+1)+2b(b+1)+1$. The sum factorises: $W = xZ^2$, where $Z = \sum_{a\in\mathbb{Z}}(-1)^a(2a+1)x^{2a(a+1)}$.

5. *Jacobi's cube identity* $(q)_\infty^3 = \sum_{a\ge 0}(-1)^a(2a+1)q^{a(a+1)/2}$, at $q = x^4$, gives $Z = 2(x^4;x^4)_\infty^3$.

6. Equate items 3 and 4 and cancel $4x$: $S(x^2)P_2^2Q_+^2Q_-^2 = (x^4;x^4)_\infty^6$. Undo $q = x^2$: $Q_+Q_- = (q;q^2)_\infty$ and $P_2 = (q)_\infty$. Euler's $(q;q^2)_\infty(-q;q)_\infty = 1$ and $(q^2;q^2)_\infty = (q)_\infty(-q;q)_\infty$ then give $S = (q)_\infty^4(-q;q)_\infty^8$.

□

Physical meaning

$\psi(q)^4$ is, up to normalisation, the fourth power of the Jacobi theta constant $\theta_2(\tau) = 2q^{1/8}\psi(q)$, the *numerator* of the Ramond-sector character of eight Majorana–Weyl fermions ($SO(8)$ level one). The character itself is $\theta_2^4/(2\eta^4) = 8q^{1/3}\psi^4/(q;q)_\infty^4 = 8q^{1/3}\prod(1+q^r)^8$. The identity is the A_2 star identity's last step, where $\prod(1+q^r)^8 = q^{-1/3}(\eta(2\tau)/\eta(\tau))^8$ is the character of $L_{-3/2}(\mathfrak{sl}_3)$.

What the machine verified

Standard axioms (re-run for this chapter). Unconditional. Discharges `A2.FourTriangular` (`A2.fourTriangular`, `FourTriangularDeligne.lean`).

25.7.1 Ramanujan's identities from the heat equation

Theorem 25.28 (Ramanujan's three identities). *With* $E_2 = 1 - 24\sum \sigma_1 q^n$, $E_4 = 1 + 240\sum \sigma_3 q^n$, $E_6 = 1 - 504\sum \sigma_5 q^n$ *in* $\mathbb{Q}[[q]]$*:*

$$12\delta_q E_2 = E_2^2 - E_4, \qquad 3\delta_q E_4 = E_2E_4 - E_6, \qquad 2\delta_q E_6 = E_2E_6 - E_4^2.$$

From the mathematics to the Lean statement

Namespace `VOA.DeligneAudit.DeligneCharacter.D4MLDE` for the first block; `P1`, `P3` are $\sum \sigma_1 q^n$, $\sum \sigma_3 q^n$ built from the divisor series `lamQ`; `ramanujan` is $12P_1^2 = 5P_3 + P_1 - 6\delta_q P_1$, which is $12\delta_q E_2 = E_2^2 - E_4$ after substituting $E_2 = 1 - 24P_1$ and $E_4 = 1 + 240P_3$. `eight_sq` is $E_4^2 = E_8$ coefficientwise ($e_4(0) = 1$, $e_4(n) = 240\sigma_3(n)$, $e_8(n) = 480\sigma_7(n)$). The structure `RamanujanIdentities` is a `Prop`, and `ramanujanIdentities` proves it.

Proof on paper. Setting. Let $A = \mathbb{Q}[[x]]$ and $u = \varepsilon e^x \in A^\times$ with $\varepsilon = \pm 1$. Write $\partial = d/dx$, acting on coefficients, and note $\partial u = u$. The triple product (Theorem 25.25) in $A[[q]]$ reads $\Theta = (1-u)P$, where

$$\Theta = \sum_{j\in\mathbb{Z}} (-1)^j u^j q^{j(j-1)/2}, \qquad P = \prod_{m\geq 1} (1-uq^m)(1-u^{-1}q^m)(1-q^m).$$

Two derivatives of the two sides. On the sum side, $\partial u^j = ju^j$ and $\delta_q q^{j(j-1)/2} = \frac{j(j-1)}{2} q^{j(j-1)/2}$, so Θ satisfies the *heat equation* $\partial^2\Theta - \partial\Theta = 2\delta_q\Theta$. On the product side, the logarithmic derivatives are

$$R := \frac{\partial P}{P} = \sum_{m\geq 1} \Big(\frac{u^{-1}q^m}{1-u^{-1}q^m} - \frac{uq^m}{1-uq^m} \Big), \qquad T := \frac{\delta_q P}{P} = -\sum_{m\geq 1} m\Big(\frac{uq^m}{1-uq^m} + \frac{u^{-1}q^m}{1-u^{-1}q^m} + \frac{q^m}{1-q^m} \Big).$$

The master identity. Substitute $\Theta = (1-u)P$ into the heat equation. Since $\partial(1-u) = -u$,

$$\partial^2\Theta - \partial\Theta = P\big[(1-u)(\partial R + R^2) - (1+u)R\big], \qquad 2\delta_q\Theta = 2(1-u)PT.$$

Dividing by the unit P gives

$$(1-u)\big(\partial R + R^2 - 2T\big) = (1+u)R. \tag{$*$}$$

Reading off the identities. At $\varepsilon = 1$, expand R and T in powers of x. The coefficient of x^k in $\frac{e^{\pm x}q^m}{1-e^{\pm x}q^m}$ is $\frac{(\pm 1)^k}{k!}\sum_{d\geq 1} d^k q^{md}$. So the x-coefficients of R and T are, up to constants, the divisor series $\sum_n \sigma_k(n)q^n$ and $\sum_n n\sigma_k(n)q^n = \delta_q \sum_n \sigma_k(n)q^n$. Comparing the coefficients of x^1 in $(*)$ gives a tautology (the involution $d \leftrightarrow n/d$ of divisors). The coefficient of x^3 gives $12P_1^2 = 5P_3 + P_1 - 6\delta_q P_1$, i.e. $12\delta_q E_2 = E_2^2 - E_4$. The coefficient of x^5 gives $3\delta_q E_4 = E_2E_4 - E_6$. The coefficient of x^7 gives a relation of weight eight, $2\delta_q E_6 = E_2E_6 - E_8$, with $E_8 = 1 + 480\sum \sigma_7(n)q^n$.

The step $E_4^2 = E_8$. This does *not* come out of the heat equation (warning below). The space M_8 of level-one modular forms of weight 8 is one-dimensional, spanned by E_4^2, and contains no cusp form. So $E_4^2 - E_8$, being in M_8 with constant term $1 - 1 = 0$, is zero. This is Mathlib's level-one Sturm bound (`ModularForm.sturm_bound_levelOne_nat`) applied at weight 8, where it says that a form whose constant term vanishes is zero. It is the one analytic input of the section. □

Physical meaning

Ramanujan's identities say that $\vartheta_k = \delta_q - \frac{k}{12}E_2$ (the Serre derivative) maps modular forms to modular forms: they are the formal shadow of modularity, and they are exactly what is needed to verify that an explicit q-series solves an MLDE.

What the machine verified

Standard axioms for `ramanujanIdentities` (re-run for this chapter). Unconditional. Uses Mathlib's modular forms only through `eight_sq`.

Dead end: the heat equation alone does not give $E_4^2 = E_8$

The single-variable heat equation for the theta function gives one relation per weight; at weight 8 the x^6 relation contains σ_7, and no combination eliminates it. Do not retry; the cheapest source is Mathlib's dimension formula, as used.

Theorem 25.29 (A_2: the product solves the $h = 3$ recurrence). *$f = \prod_{r\geq 1}(1+q^r)^8$ satisfies $6\delta_q^2 f + 3\delta_q f + 24P_1\delta_q f + 8P_1 f - 80P_3 f = 0$; hence $[q^N]f =$ `mldeCoeff 3 N`.*

From the mathematics to the Lean statement

`productCoeff N` $= [q^N]\prod(1+q^r)^8$ (computable, `A2CharacterInterface.lean`). The displayed ODE is (25.3) at $h = 3$ for $g = q^{1/3}f$ (exponent $(h+1)/12 = 1/3$), multiplied by 6 and rewritten with $E_2 = 1 - 24P_1$, $E_4 = 1 + 240P_3$: indeed $(\delta_q - \frac{1}{6}E_2)\delta_q g = \frac{1}{18}E_4 g$ becomes $\delta_q^2 f + \frac{1}{2}\delta_q f + 4P_1\delta_q f + \frac{4}{3}P_1 f - \frac{40}{3}P_3 f = 0$.

Proof on paper. The log-derivative. Since $\frac{q^r}{1+q^r} = \frac{q^r}{1-q^r} - \frac{2q^{2r}}{1-q^{2r}}$,

$$\delta_q \log f = 8\sum_r \frac{rq^r}{1+q^r} = 8P_1(q) - 16P_1(q^2) = \tfrac{1}{3}\big(2E_2(q^2) - E_2(q) - 1\big).$$

Put $g = q^{1/3}f$ and $F = 2E_2(q^2) - E_2(q)$. Then $\delta_q g = \frac{1}{3}Fg$ and $\delta_q^2 g = \big(\frac{1}{9}F^2 + \frac{1}{3}\delta_q F\big)g$.

Reduction to an Eisenstein identity. The MLDE $(\delta_q - \frac{1}{6}E_2)\delta_q g = \frac{1}{18}E_4 g$, multiplied by $18/g$, becomes $6\delta_q F + 2F^2 - E_2F - E_4 = 0$. By Ramanujan at q and at q^2, $\delta_q F = \frac{1}{3}\big(E_2(q^2)^2 - E_4(q^2)\big) - \frac{1}{12}\big(E_2^2 - E_4\big)$. Substituting, the equation becomes

$$F^2 = \tfrac{1}{5}\big(E_4(q) + 4E_4(q^2)\big),$$

the classical level-two identity $\big(2E_2(2\tau) - E_2(\tau)\big)^2 = \frac{1}{5}\big(E_4(\tau) + 4E_4(2\tau)\big)$.

The level-two identity. It comes from the master identity $(*)$ of Theorem 25.28, now at $\varepsilon = -1$, i.e. $u = -e^x$. There the geometric series of R and T carry signs: their x-coefficients are the alternating divisor sums $\sum_{dk=n}(-1)^k d^j$, which are combinations of $\sigma_j(n)$ and $\sigma_j(n/2)$, i.e. of series in q and in q^2. The coefficients of x^0 and x^2 of $(*)$ give the needed identity (`level_two`). Uniqueness (Theorem 25.8) then gives $[q^N]f = c_N$. □

Physical meaning

$q^{1/3}\prod(1+q^r)^8 = (\eta(2\tau)/\eta(\tau))^8$: the A_2 vacuum character is a $\Gamma_0(2)$ eta quotient, the Schur index of the (A_1, D_4) theory.

What the machine verified

Standard axioms. Unconditional.

25.7.2 Level three: Lorenz and Borwein, for G_2

Side result at this commit: it proves the target side of the open G_2 star identity.

Theorem 25.30 (Lorenz's formula; Borwein's cubic identity; the G_2 target). *Let* $a = \theta_{A_2} = \sum_{x,y\in\mathbb{Z}} q^{x^2-xy+y^2}$, $b^3 = (q;q)_\infty^9/(q^3;q^3)_\infty^3$, $c^3 = 27q(q^3;q^3)_\infty^9/(q;q)_\infty^3$. *Then* $a = 1 + 6\sum_{n\ge1}\big(\sum_{d|n}\chi_{-3}(d)\big)q^n$ *(Lorenz),* $a^3 = b^3 + c^3$ *(Borwein),* $2a^2 = 3E_2(q^3) - E_2$, $10a^4 = E_4 + 9E_4(q^3)$. *Consequently the Kac–Wakimoto form* $T = \theta_{A_2}(q)(q^3;q^3)_\infty^6/(q;q)_\infty^8$ *has* $[q^N]T =$ `mldeCoeff 4 N`.

From the mathematics to the Lean statement

Namespace `VOA.DeligneAudit.G2Star`. `chi3 k` is $\chi_{-3}(k)$ ($1,-1,0$ for $k \equiv 1,2,0 \bmod 3$). `AQ` is `thetaA2` over $\mathbb{Q}$; `thetaA2` counts $(x,y) \in [-N,N]^2$ with $x^2-xy+y^2=N$ (a correct finite box: $x^2-xy+y^2 \geq \frac{3}{4}\max(x^2,y^2)$, so every solution has $|x|,|y| \leq \sqrt{4N/3} \leq N$ for $N \geq 1$). `BQ`, `CQ` are b^3, c^3; `E2q3` etc. are $E_k(q^3)$ via `expand 3`. `LorenzA2` and `G2KWEqMLDE` are `Prop`s, and `lorenzA2` and `g2KWEqMLDE` prove them.

Proof on paper. Where T comes from. T was found by a numerical search, as a closed form matching the first coefficients of `mldeCoeff 4`. It has the shape that Kac and Wakimoto's admissible-character formula would give. The theorem does not depend on that origin: it proves that T solves the $h=4$ equation.

Lorenz. Split the A_2 lattice by parity ($4(m^2-mn+n^2) = (2m-n)^2+3n^2$), compute the u-Wronskian of the triple product at the cube roots of unity, and identify two weight-3/2 sums by z-derivatives of the quintuple product (`quintuple_deriv`$_0$). The Lambert-form relations l_2, l_3 (and a weight-8 l_6) come from the heat-equation identity (*) at $u=\omega e^x$, orders x^0–x^4, splitting over $\mathbb{Q}(\sqrt{-3})$ (`DeligneMLDECubic*.lean`). Borwein's cubic identity is then proved by a Riccati-type uniqueness argument. First, $d := E_4 - 9E_4(q^3) + 8a^4 - 16ac^3$ satisfies a first-order equation $48a^2\,\delta_q d = d\,(d + 32a^4 + 16a^2E_2 + 16ac^3)$ (an explicit polynomial identity), and $d \equiv 0 \bmod q^2$. If $d \neq 0$ had lowest term γq^n, comparing the coefficients of q^n would give $48n\gamma = 48\gamma$ (the bracket has constant term $32+16=48$), so $n=1$, contradicting $n \geq 2$. Hence $d=0$. Then $\psi = b^3+c^3-a^3$ satisfies $4\delta_q\psi = (E_2-a^2)\psi$ and $\psi(0)=0$, so $\psi=0$ (`borweinCubic_of_eis`). These give the level-three relations of Ramanujan's "theory of signature 3":

$$E_4 = a^4+8ac^3, \qquad E_6 = a^6-20a^3c^3-8c^6, \qquad 48\,\delta_q a = a\big(4E_2-6a^2+2E_4a^{-2}\big),$$

the last from l_2, l_3 and Ramanujan for E_2.

T solves the $h=4$ equation. Put $f = q^{5/12}T$ (exponent $(h+1)/12 = 5/12$). From $\delta_q \log(q)_\infty = (E_2-1)/24$ and the analogous formula at q^3,

$$\delta_q \log f = \delta_q \log a + \tfrac{3}{4}E_2(q^3) - \tfrac{1}{3}E_2.$$

Eliminate $E_2(q^3)$ by l_2 and $\delta_q \log a$ by the formula above. The E_2 terms cancel, leaving

$$\delta_q \log f =: g = \frac{5a^3+4c^3}{12a} = \frac{3}{8}a^2 + \frac{E_4}{24a^2}.$$

The MLDE (25.3) at $h=4$ is $(\delta_q - \frac{1}{6}E_2)\delta_q f = \frac{15}{144}E_4 f$, i.e. the Riccati equation $\delta_q g + g^2 - \frac{1}{6}E_2 g = \frac{15}{144}E_4$. Compute $\delta_q g$ with the formula for $\delta_q a$ and $3\delta_q E_4 = E_2E_4 - E_6$, and express E_4, E_6 through a and c^3. The equation becomes a polynomial identity in a, c^3, E_2 that holds identically. We checked this by computer algebra for this chapter; in Lean it is a `linear_combination` certificate (`mldeExpr_TQ`). Uniqueness (Theorem 25.8) gives $[q^N]T = c_N$. □

Physical meaning

θ_{A_2}/η^2 is the character of the A_2 lattice VOA, i.e. of the $SU(3)$ level-one WZW model. Here it appears twisted by the level-three eta quotient $(q^3;q^3)_\infty^6/(q;q)_\infty^6$. *Heuristic:* T should be the Kac–Wakimoto admissible character of $L_{-5/3}(G_2)$, written as a theta function over free bosons. The library does not derive T from the Kac–Wakimoto formula; it only proves that T solves the MLDE.

What the machine verified

Standard axioms. Unconditional.

25.8 Closed forms of the MLDE solution

For $h = 6(t+1)$ (D_4, E_6, E_7, E_8 at $t = 0,1,2,4$) the exponent $-c/24 = (h+1)/12$ and the weight work out so that $\eta^{2h-2}\cdot\mathrm{ch}$ is a quasimodular form H of weight h and depth ≤ 1. Here ch is the normalised vacuum character and $\eta = q^{1/24}(q)_\infty$. The D_4 case is on the critical path, since it feeds Theorem 25.37. The E_6, E_7, E_8 cases are *side results*: the open star bounds compare with c_N directly.

Theorem 25.31 (Generic closed form). *Let $h = 6t+6$, and let $H \in \mathbb{Q}[[q]]$ satisfy $144\delta_q^2 H - 24hE_2\delta_q H + h(h-1)(E_2^2 - E_4)H = 0$. Suppose $G = H\cdot(q)_\infty^{-(12t+10)}$ vanishes below q^{t+1}, with $[q^{t+1}]G = \gamma \neq 0$. Then $[q^{N+t+1}]G/\gamma =$ `mldeCoeff` $(6t+6)$ N for all N.*

```

From the mathematics to the Lean statement

Namespace `VOA.DeligneAudit.DeligneCharacter.MLDEClosed`. Ramanujan's identities are used inside the proof (`ramanujanIdentities`), not as a hypothesis. `Qk k` is $(q)_\infty^{-k}$, and the Lean `c` is γ. The shift by $t+1$ is the order of vanishing of H: $\eta^{2h-2} = q^{(h-1)/12}(q)_\infty^{2h-2}$ and the character starts at $q^{-c/24} = q^{(h+1)/12}$, so $H = \eta^{2h-2}\mathrm{ch}$ starts at $q^{2h/12} = q^{t+1}$.

Proof on paper. Put $k = 12t+10 = 2h-2$, $G = H(q)_\infty^{-k}$ and $f = q^{-(h-1)/12}G$. Since $\delta_q \log(q)_\infty = (E_2-1)/24$, the prefactor $\Phi = q^{-(h-1)/12}(q)_\infty^{-k}$ of $f = \Phi H$ has $\delta_q \log\Phi = \varphi := -\frac{h-1}{12}E_2$. Then $\delta_q f = \Phi(\delta_q H + \varphi H)$ and $\delta_q^2 f = \Phi\big(\delta_q^2 H + 2\varphi\delta_q H + (\delta_q\varphi + \varphi^2)H\big)$, where Ramanujan gives $\delta_q\varphi = -\frac{h-1}{144}(E_2^2 - E_4)$. Substituting into (25.3) and multiplying by $144/\Phi$, the coefficient of $\delta_q H$ is $144(2\varphi - \frac{1}{6}E_2) = -24hE_2$, and the coefficient of H is

$$-(h-1)(E_2^2-E_4) + (h-1)^2E_2^2 + 2(h-1)E_2^2 - (h^2-1)E_4 = h(h-1)(E_2^2-E_4).$$

So `HOde` is exactly (25.3) for f. Moreover $f = q^{(h+1)/12}\cdot(G/q^{t+1})$, because $(h-1)/12 + (h+1)/12 = t+1$. Hence $G/(\gamma q^{t+1})$ is a normalised solution of (25.4), and uniqueness (Theorem 25.8) concludes. □

Physical meaning

$\eta^{2h-2}\mathrm{ch} = H$: the character is a quasimodular form divided by the partition function η^{2h-2} of $2h-2$ free bosons. For E_6 one finds $\eta^{22}\mathrm{ch} = (\sum n\sigma_9(n)q^n - \Delta)/1050$ (numerical evidence through q^{30}, not machine-checked).

What the machine verified

Standard axioms. Unconditional as an implication.

Theorem 25.32 (D_4, E_6, E_7, E_8 closed forms). *With* $H_{E_6} = 7E_6^2 + 5E_4^3 - 12E_2E_4E_6$, $H_{E_7} = 211E_2E_4E_6^2 + 77E_2E_4^4 - 91E_6^3 - 197E_4^3E_6$, $H_{E_8} = 318910E_2E_4^4E_6^2 + 145105E_2E_4E_6^4 + 33649E_2E_4^7 - 43225E_6^5 - 139129E_4^6E_6 - 315310E_4^3E_6^3$:

$$\texttt{mldeCoeff}\ 12\ N = [q^{N+2}]\, H_{E_6}(q)_\infty^{-22}/3991680,$$
$$\texttt{mldeCoeff}\ 18\ N = [q^{N+3}]\, H_{E_7}(q)_\infty^{-34}/42343741440,$$
$$\texttt{mldeCoeff}\ 30\ N = [q^{N+5}]\, H_{E_8}(q)_\infty^{-58}/13909248338175590400,$$
$$\texttt{mldeCoeff}\ 6\ N = [q^{N+1}]\, \frac{1}{240}(\delta_q E_4)(q)_\infty^{-10}.$$

The last is the coefficientwise form of $[q^N]\, q^{-7/12}\,\delta_q E_4/(240\,\eta^{10})$*: since* $\eta^{10} = q^{10/24}(q)_\infty^{10}$*, the prefactor is* $q^{-7/12-5/12} = q^{-1}$*. Check:* $\frac{1}{240}\delta_q E_4 = \sum n\sigma_3(n)q^n = q + 18q^2 + \dots$*, so* $c_0 = 1$ *and* $c_1 = 18+10 = 28$ *(Example 25.11).*

From the mathematics to the Lean statement

`g6` is $N \mapsto [q^{N+2}](H_6 \cdot P^{-22})$ (`G6 := H6 * Q22`). `HE7`, `HE8` are defined in `DeligneCharacterE78MLDE.lean` with the integer coefficients displayed above (written as nested products). `gser` is the shift by one of $\delta_q E_4 \cdot (q)_\infty^{-10}$. The D_4 statement carries `hR`, discharged by `ramanujanIdentities`. The integer polynomials H were found by a computer fit outside the library. The Lean proof only *verifies* `HOde` by a certificate and the low coefficients by `decide`, so the provenance of the numbers does not matter.

Proof on paper. Theorem 25.31 at $t = 1, 2, 4$ (and the analogous direct proof at $t = 0$), with `HOde` verified by an explicit linear combination of Ramanujan's identities and the low coefficients computed exactly. □

Physical meaning

These are the closed forms of the Schur indices of the rank-one E_6, E_7, E_8 Minahan–Nemeschansky theories and of $SU(2)$, $N_f = 4$, as quasimodular forms over η^{2h-2}.

What the machine verified

Standard axioms (re-run for this chapter for `e7Target_eq_mldeCoeff` and `e8Target_eq_mldeCoeff`). Unconditional.

Remark 25.33 (No closed form of this shape for A_2, G_2, F_4; side remark). When $h/6 \notin \mathbb{Z}$ no such level-one form exists: a search over $\eta^k \mathrm{ch}$, $k < 80$, against level-one quasimodular forms of weight < 40 found nothing (a computer search; evidence, not proof). A_2 and G_2 have closed forms of level 2 and 3 instead (Theorems 25.29, 25.30); F_4 has none in the library.

25.9 Level-one affine Demazure characters

Definition 25.34 (The Demazure algorithm). Fix a Cartan matrix A (rows $A_{ij} = \langle \alpha_j, \alpha_i^\vee \rangle$), the highest root θ in simple-root coordinates, and a reduced word for s_θ. Characters are finite sums of $z^\mu q^e$. The finite Demazure operator $D_i e^\lambda = (e^\lambda - e^{-\alpha_i} e^{s_i \lambda})/(1 - e^{-\alpha_i})$ acts by the α_i-string formula, and the level-one affine D_0 uses $\langle \Lambda_0 + \mu, \alpha_0^\vee \rangle = 1 - \langle \mu, \theta^\vee \rangle$ and $e^{-\alpha_0} = q^{-1} z^\theta$. Then $C_m = q^{m^2} (D_{s_\theta} D_0)^m e^{\Lambda_0}$, and $\mathrm{hilb}(m, N)$ is the sum of coefficients of C_m in q-degree N after setting $z = 1$, clamped at 0.

File `VOA/DeligneAudit/DeligneCharacterDemazure.lean`.

```
def demazureStep (A : List (List ℤ)) (θ : List ℤ) (word : List ℕ) (f : LPoly) : LPoly :=
  word.foldr (fun i g => demazureFin A i g) (demazureZero A θ f)

   ↪ N)).map
    fun (t : Term) => t.2).sum.toNat
```

From the mathematics to the Lean statement

`LPoly` is a list of terms $((\mu, e), \text{coefficient})$, merged by `normalize`. `demazureFin A i` and `demazureZero A θ` apply the string formulas termwise (definitions in the file). `f^[m]` is m-fold iteration starting from e^{Λ_0} (the zero weight with energy 0). `levelOneDemazureHilb` selects terms of energy $N - m^2$ and **clamps** the integer sum with `toNat`. **Fidelity caveats.** (1) Reading `levelOneDemazureHilb A θ word m` as $\mathrm{Hilb}_q D(1, m\theta)$ needs the Demazure character formula (Kumar, Mathieu) and the identification of $D(1, m\theta)$ with the Demazure module $V_{(s_\theta s_0)^m}(\Lambda_0)$ (Fourier–Littelmann, Chari–Venkatesh). This is U7 (Caveat 2); in Lean it is an algorithm. (2) The clamp hides negative values; the "unclamped" integer version `hilbIntG` is used where positivity matters (Section 25.11). (3) The algorithm is correct for the non-simply-laced G_2 and F_4 as well. The affine step needs $\langle \mu, \theta^\vee \rangle$, and the code computes $\sum_i \langle \theta, \alpha_i^\vee \rangle \mu_i$ from the Cartan matrix. In simple-root coordinates the two differ termwise by the factor $(\theta, \theta)/(\alpha_i, \alpha_i)$, multiplying (θ, α_i). For G_2 and F_4 every simple root is either long, so the factor is 1, or orthogonal to the long root θ, so $(\theta, \alpha_i) = 0$. Hence they agree (`DeligneCharacterExceptional.lean` explains this).

Physical meaning

The algorithm is the affine Weyl-group computation of a level-one integrable character (the $\hat{\mathfrak{g}}_1$ WZW vacuum module) truncated to a Schubert cell, so it is a piece of a genuine CFT character. *Heuristic:* $D(1, m\theta)$ is the graded fusion product of m copies of $\mathfrak{g} \oplus \mathbb{C}$ (the KR module $\mathrm{KR}(\theta)$), and its q-grading is the energy of the corresponding quasi-particle configuration. That reading is a theorem in the literature (Fourier–Littelmann, Chari–Venkatesh), but here it is input U7.

What the machine verified

Definitions; computable; small cases kernel-checked: $\mathrm{Hilb}D(1,\theta) = \dim \mathfrak{g} + q$ for A_2, G_2, F_4, E_6 (`levelOneDemazureHilb_A2_one`, `g2DemazureHilb_one`, `f4DemazureHilb_one`, `e6DemazureHilb_one`), all in the library. For E_7 the corresponding check lies outside the library (Section 25.13). For E_8 a single `decide` at $m = 1$ exceeded 10 minutes (a dead end); C_1 is instead pinned by the chain files of Section 25.12.

Definition 25.35 (Per-type data and the named star identities). For $X \in \{G_2, F_4, E_6, E_7, E_8\}$ the library fixes Bourbaki Cartan matrices, θ and reduced words of lengths $5, 15, 21, 33, 57$, defines `xDemazureHilb`, and names the star identity and target bound.

Files `VOA/DeligneAudit/DeligneCharacterExceptionalParameters.lean` (the Cartan data, words and `g2DemazureHilb`), `VOA/DeligneAudit/DeligneCharacterExceptionalData.lean` (the star identities) and `VOA/DeligneAudit/DeligneCharacterExceptional.lean` (the finite guards).

theorem g2_star_upto_two : ∀ N ∈ List.range 3,
    (demazureSumCoeff g2DemazureHilb N : ℚ) = mldeCoeff 4 N := by
```

From the mathematics to the Lean statement

Indices are 0-based (Bourbaki node i is list index $i - 1$). For G_2, $\theta = 3\alpha_1 + 2\alpha_2$ with α_1 short: `cartanG2` row 0 is $\langle \cdot, \alpha_1^\vee \rangle$. The other types are analogous (quoted in the file). The `XStarIdentity` are `abbrev`s of `Prop`s, never axioms: a theorem that uses one takes it as an explicit hypothesis. The finite guards `g2_star_upto_two`, `f4_star_upto_one` are kernel checks of the star identity at $N \le 2$, $N \le 1$.

Physical meaning

Heuristic: each named identity says "quasi-particle (fermionic) character = MLDE character" for the corresponding chiral algebra. Its mathematical content is the equality of two explicit q-series.

What the machine verified

Definitions and small kernel checks. The identities themselves are **named inputs** (open), see Section 25.10.

25.10 The star identities

25.10.1 A_2: proved by an elementary route

Theorem 25.36 (The A_2 star identity). *With* $\mathrm{Hilb}_q D(1, n\theta) = P_{(2n,n,0)}(1,1,1;q,0)$ *(the q-Whittaker polynomial, by Gelfand–Tsetlin branching at* $t = 0$*),*

$$\sum_{n\geq 0} \frac{q^n P_{(2n,n,0)}(1,1,1;q,0)}{(q;q)_n} = \prod_{r\geq 1}(1+q^r)^8.$$

Files `VOA/DeligneAudit/A2CharacterInterface.lean`, `A2CharacterStarChain.lean`, `A2Headline.lean`.

From the mathematics to the Lean statement

Namespace `VOA.DeligneAudit.A2`. **The table.** The q-Whittaker polynomial $P_\lambda(x_1,x_2,x_3;q,0)$ at $x = (1,1,1)$ is computed by Gelfand–Tsetlin branching: restrict from GL_3 to GL_2 by summing over partitions $\mu = (m_1,m_2)$ that interlace λ ($\lambda_1 \geq m_1 \geq \lambda_2 \geq m_2 \geq \lambda_3$), then from GL_2 to GL_1 likewise. At $t = 0$ each step contributes the branching coefficient $\psi_{\lambda/\mu} = \prod_i \binom{\lambda_i-\lambda_{i+1}}{\lambda_i-\mu_i}_q$. `gl3Hilb l₁ l₂ l₃ N` is the q^N coefficient of the result (`A2CharacterInterface.lean`), and `demazureHilb n` takes $\lambda = (2n,n,0)$. Unwinding gives the closed form $\mathrm{Hilb}_q D(1,n\theta) = \sum_{i,j\leq n} \binom{n}{i}_q \binom{n}{j}_q G_{n-i+j}$, with $G_M = \sum_r \binom{M}{r}_q$ the Rogers–Szegő polynomial at 1. `demazureCoeff` = `demazureSumCoeff demazureHilb` by `rfl`.
The proof structures. `starF` and `fermionInf` are the two sides as series, and `shiftedU m` = $U_m = \sum_s q^s G_s G_{s+m}/(q)_s$. The three structures are the three steps of the proof below, each a `Prop`, and each proved (`starReduction`, `shiftedMehler`, `fourTriangular`).
Reading. The reading of `demazureHilb` as $\mathrm{Hilb}_q D(1,n\theta)$ is U7 (Sanderson, Ion; Caveat 2). It was compared with the affine algorithm `levelOneDemazureHilb` for small n and N; the extent and location of those checks are in Section 25.13, and Example 25.11 adds $n = 2$, $N \leq 3$.

Proof on paper. Write $F = \sum_n q^n \mathrm{Hilb}_q D(1,n\theta)/(q)_n$ for the left side.

Step 1 (`StarReduction`: $(q)_\infty F = \sum_{v\ge 0} q^v U_{2v}$). Use the q-Vandermonde identity in its "overlapping subsets" form,

$$\binom{n}{i}_q \binom{n}{j}_q = \sum_k q^{(i-k)(j-k)} \frac{(q)_n}{(q)_k (q)_{i-k} (q)_{j-k} (q)_{n-i-j+k}}.$$

It counts pairs of subspaces of $\mathbb{F}_q^n$ (an i-dimensional and a j-dimensional one) by the dimension k of their intersection. Substituting into the closed form of $\mathrm{Hilb}_q D(1, n\theta)$ and reindexing turns F into

$$F = \sum_{k,u,v,w\ge 0} \frac{q^{k+u+v+w+uv}\, G_{k+2v+w}}{(q)_k (q)_u (q)_v (q)_w}.$$

Euler's sum $\sum_u \frac{q^{u(1+v)}}{(q)_u} = \frac{(q)_v}{(q)_\infty}$ removes u. The convolution $\sum_{k+w=s} \frac{1}{(q)_k (q)_w} = \frac{G_s}{(q)_s}$, which holds because $\binom{s}{k}_q = \frac{(q)_s}{(q)_k (q)_{s-k}}$, collapses k, w into $s = k + w$. The result is $(q)_\infty F = \sum_v q^v \sum_s \frac{q^s G_s G_{s+2v}}{(q)_s} = \sum_v q^v U_{2v}$.

Step 2 (`ShiftedMehler`: $U_m (q)_\infty^3 (1 - q^{m+1}) = m + 1$). A second use of q-Vandermonde gives $U_m = \sum_{p\le m} \binom{m}{p}_q W_p$, where $W_p = \sum_{l,u} \frac{q^{l+u(p+1)} G_{l+u}}{(q)_l (q)_u}$. Rogers' Mehler formula for the Rogers–Szegő polynomials,

$$\sum_{M\ge 0} \frac{H_M(x) H_M(y)\, t^M}{(q)_M} = \frac{(xyt^2; q)_\infty}{(t; q)_\infty (xt; q)_\infty (yt; q)_\infty (xyt; q)_\infty},$$

at $x = 1$, $y = q^p$, $t = q$ gives $W_p = \frac{(q)_p}{(1-q^{p+1})(q)_\infty^3}$. Since $\binom{m}{p}_q (q)_p = (q)_m / (q)_{m-p}$, it remains to prove the finite identity

$$\sum_{p=0}^{m} \frac{(q)_m}{(q)_{m-p}\,(1 - q^{p+1})} = \frac{m+1}{1 - q^{m+1}},$$

an identity of rational functions in q, valid for every m (the Lean proof of `shiftedMehler` is in `A2CarrierMehler.lean`).

Step 3 (`FourTriangular`). By Steps 1 and 2, $(q)_\infty^4 F = (q)_\infty^3 \sum_v q^v U_{2v} = \sum_v \frac{(2v+1) q^v}{1 - q^{2v+1}}$. This is $(q)_\infty^4 \prod_r (1 + q^r)^8$ by Legendre (Theorem 25.27). Cancel $(q)_\infty^4$.

On novelty. The paper's proof uses flavoured Macdonald polynomials at $t = 0$. This route avoids them. It was found in this project, and we do not know it in the literature. □

Physical meaning

Fermionic sum over fusion products of adjoints = the (A_1, D_4) Schur index $(\eta(2\tau)/\eta(\tau))^8$ (the fermionic reading being the heuristic of Definition 25.3). In free-field terms, $\prod (1 + q^r)^8$ is the partition function of eight Ramond-sector free fermions with their zero modes removed. So the identity says that the quasi-particle description of the vacuum module counts states like eight free fermions.

What the machine verified

Standard axioms; **unconditional** as a q-series identity. Its use as "$D_N \le \dim V_N$" for the true Demazure modules needs U7.

25.10.2 D_4: the elliptic evaluation

Theorem 25.37 (D_4: the series `d4SchurQ` = MLDE solution; Demazure = `d4SchurQ` under positivity)**.** *Work over $\Bbbk = \mathbb{Q}((r))$, $r = q^{1/2}$. Let*

$$\Theta(x) = \sum_{k\in\mathbb{Z}} (-1)^k \big(q^{\binom{k}{2}} + q^{\binom{k+1}{2}}\big) x^{2k}, \qquad M(s,x,z) = \frac{(s^2;q)_\infty (s^2x^2;q)_\infty (s^2x^{-2};q)_\infty}{\prod_{\epsilon=\pm1}\prod_{i=1}^{4}\prod_{\sigma=\pm1}(s\,x^{\epsilon}z_i^{\sigma};q)_\infty},$$

a power series in s with coefficients Laurent polynomials in $x, z_1, \dots, z_4$ over $\Bbbk$; let $I(s,z) = \mathrm{CT}_x\,\Theta(x)M(s,x,z)$ (constant term in x), and let

$$\texttt{d4SchurQ}_N = \sum_{m=0}^{N} \Big[r^{2(N-m)}\Big]\,\tfrac{1}{2}\,[s^{2m}]\,I(s,z)\big|_{z=1}.$$

Then, unconditionally, $\texttt{d4SchurQ}_N = [q^{N+1}]\,\frac{1}{240}(\delta_q E_4)\,(q)_\infty^{-10} = c_N$ *for $h = 6$; in modular notation this is $[q^N]\,q^{-7/12}\,\delta_q E_4/(240\eta^{10})$ (Theorem 25.32). If moreover* `D4DemazurePositivity` *holds, the D_4 Demazure sum equals* $\texttt{d4SchurQ}_N$.

From the mathematics to the Lean statement

Decoding the series. `Kq` is $\Bbbk = \mathbb{Q}((r))$ with $r = q^{1/2}$ (`rr`; `qq` $= r^2$), so half-integer q-shifts are ring maps. `R` $= \Bbbk[x^{\pm1}, z_1^{\pm1}, \dots, z_4^{\pm1}]$ (exponent lattice `V := Fin 5 → ℤ`, coordinate 0 is x) and `S` $= R[[s]]$. `EPos c v k` and `EInv c v k` are $(c\,z^v s^k; q)_\infty$ and its inverse; so `tFactors` $= (t;q)(tx^2;q)(tx^{-2};q)$ with $t = s^2$, `hyperFactors` $= 1/\prod(sx^{\pm1}z_i^{\pm1};q)$ over the sixteen weights `hyperVecs`, and `kernelM` is M. `thK i` is the coefficient t_i of x^i in Θ (`qC j` $= q^{\binom{j}{2}}$, `sgn` a sign; odd i give 0); `ctFun θf` sends $c\,x^a z^v$ to $c\,t_{-a}z^v$, i.e. it is $F \mapsto \mathrm{CT}_x \Theta F$. `smap` applies it coefficientwise in s, so `Ikernel` is I ("$2I$" in the file's docstring convention). `ev1` sums the coefficients of a Laurent polynomial, i.e. sets $x = z_i = 1$. `coeff (2 * m)` takes $[s^{2m}]$, and `.coeff (2 * (N - m))` reads off $r^{2(N-m)} = q^{N-m}$: the s^{2m} term is weighted by q^m, i.e. the series is evaluated at $s^2 = t = q$. So `D4K.d4SchurQ N` is exactly the displayed $\mathtt{d4SchurQ}_N$. **Modelling step, not Lean.** That this series is the Schur index of the $SU(2)$, $N_f = 4$ gauge theory (the contour integral of the vector-multiplet and Haar-measure factor against four hypermultiplets) is a hand transcription made when the file was written; no Lean statement relates `d4SchurQ` to a gauge-theory integral. The theorem is about the series as defined.

Positivity. `hilbInt m N` is the unclamped integer Demazure coefficient. `D4DemazurePositivity`: energies $\geq -m^2$ and `hilbInt` ≥ 0. The `energy` field is proved (`D4Wp.energy_holds`, from integrality of the D_4 identity). The `coeff` field is *not* proved: the only route in the library is `d4DemazurePositivity_of_U5Z`, which takes the unclamped fusion bound `hU5` (input U5 of Chapter 26, open) as an explicit hypothesis. So the D_4 Demazure-sum identity is conditional on `D4DemazurePositivity`, whose remaining field is currently available only from the open U5. (On paper, positivity follows from the Demazure character formula, i.e. from U7; no Lean statement backs that reading.)

Proof on paper. Schur $= \delta_q E_4$. Prove the classical $\wp'(z) = -\sigma(2z)/\sigma(z)^4$ in theta form from a two-variable identity of lattice series (files `DeligneCharacterD4Wp–Wp3`). After the half-period substitution the Schur integrand becomes a perfect square $-\eta^{-10}\mathcal{W}_1^2$, with $\mathcal{W}_1$ an explicit Lambert series (`integrand_sq`), and $\mathrm{CT}_x \mathcal{W}_1^2 = -2\sum(N+1)\sigma_3(N+1)r^{2N}$. Since $\sum_N (N+1)\sigma_3(N+1)q^N = q^{-1}\cdot\frac{1}{240}\delta_q E_4$, this is the closed form up to normalisation, and no modular forms are used. Then *d4E4Target* $= c_N$ by Theorem 25.32. *Demazure = Schur.* The kernel M satisfies a q-difference recursion $I - I(qt) = tq\,B\,I(q^2t)$ given the finite polynomial identity `D4FiniteIdentity` (`Ikernel_recursion`); its even coefficients are $\frac{2}{(q)_m}C_m$ with C_m the Demazure characters (`Ikernel_coeff_even`). The finite identity is proved by kernel checkpoints (Section 25.12). Positivity is needed to compare with the clamped `d4DemazureHilb`. □

Physical meaning

D_4 at $k = -2$ is the chiral algebra of $SU(2)$ with four flavours, a Lagrangian theory: its Schur index is a contour integral over the gauge fugacity x of vector-multiplet and hypermultiplet contributions. With $s = q^{1/2}$ the factor M is the four hypermultiplets $(sx^{\pm 1}z_i^{\pm 1}$, z_i the $SO(8)$ flavour fugacities) and the W-boson part of the vector multiplet $((s^2x^{\pm 2}; q))$, while Θ supplies the rest of the vector multiplet and the Haar measure. This reading is physics modelling; the Lean theorem is about the series `d4SchurQ`. Granting it, the theorem evaluates the index in closed form and identifies it with the MLDE solution and with a fusion-product sum.

What the machine verified

Standard axioms for `d4SchurEqE4` and `d4SchurQ_eq_mldeCoeff_holds`. `d4SchurQ` $= c_N$: **unconditional** as a q-series statement (its reading as a gauge-theory Schur index is modelling, not Lean). Demazure = `d4SchurQ`: conditional on `D4DemazurePositivity`; the `energy` field is proved, the `coeff` field only from the open U5 (`d4DemazurePositivity_of_U5Z`). Equivalently in one-sided form: `d4StarBound_iff_leSchur`.

25.10.3 G_2, F_4, E_6, E_7, E_8: named, in one-sided form

Definition 25.38 (The open star bounds). `XStarBound` is $D_N \le c_N$ for all N, with the type's Demazure table and $h^\vee$.

```

From the mathematics to the Lean statement

For G_2 the target side is proved (`g2KWEqMLDE`), so `G2StarIdentity` rests only on `G2DemazureEqKW`, which splits further into the representation-theoretic `G2DemazureFermionic` (Demazure = HKOTY fermionic formula, `g2FermHilb`) and one q-series identity `G2FermionicKW` (`g2DemazureEqKW_of_fermionic`). For F_4, $E_{6,7,8}$ nothing is split.

Physical meaning

Each is a Nahm-type "fermionic = bosonic" identity of rank equal to the rank of $\mathfrak{g}$; for $E_{6,7,8}$ these are the conjectural quasi-particle forms of the Minahan–Nemeschansky Schur indices.

What the machine verified

Named inputs; conjectural (Conjecture 27.10). Numerical evidence (Python, exact integers, the same Demazure recursion truncated in degree; not machine-checked; `Notes/deligne/STAR_IDENTITY_SCOPING.md`, 2026-10-28): $D_N = c_N$ for G_2 through q^{60}, F_4 through q^{25}, E_6 through q^{20}, E_7 through q^{16}, E_8 through q^{14}; no negative Demazure coefficient occurred. For G_2, `G2DemazureFermionic` follows from published results (Fourier–Littelmann, Chari–Moura, Ardonne–Kedem, Di Francesco–Kedem; conventions per Lin, IMRN 2021), not formalized; `G2FermionicKW` is open (no known proof) and was checked through q^{60} (`Notes/deligne/G2_STAR_FERMIONIC.md`). Kernel-checked guards: G_2 $N \le 2$, F_4 $N \le 1$.

25.10.4 Termwise domination cannot prove the star bound

The one-sided star bound $D_N \le c_N$ is all that is needed downstream. One might hope it is easier than the identity. The next proposition shows that, for the most natural kind of proof, it is not. It says nothing about other kinds of proof.

Proposition 25.39 (Rigidity of termwise domination; on paper). *Write $D = \sum_n q^n H_n/(q)_n$ with $H_n \ge 0$ coefficientwise. Suppose $U_n \ge H_n$ coefficientwise for every n and $\sum_n q^n U_n/(q)_n \le c$ coefficientwise. If in fact $D = c$, then $U_n = H_n$ for every n.*

Proof. The series $\sum_n q^n(U_n - H_n)/(q)_n$ has nonnegative coefficients and is $\le c - D = 0$, so it is 0. Each summand has nonnegative coefficients, because $1/(q)_n$ does, so each summand is 0. Since $1/(q)_n$ is a unit, $U_n = H_n$. □

Physical meaning

Downstream there is no slack either: $c_N = \dim L_N$ (Caveat 1), so $D_N \le \dim L_N$ *is* classical freeness in counting form. A crystal-injection proof would have to be a bijection between Demazure-crystal data and a combinatorial model of c_N, and no such model is known.

Dead ends for the star bound (do not retry)

The status of each entry is stated: "proved" means on paper here; "observed" means a computer-algebra computation in exact arithmetic, outside Lean.

- **Termwise domination proofs of $\le$** are forced to be exact by Proposition 25.39 (proved), since numerically $D = c$ (observed).
- **Positive MLDE expansions.** The AK kernel $10(h^2-1)\sigma_3 - (24(N-r) + 2(h+1))\sigma_1$ changes sign (proved: it is negative for large $N - r$). The product (plethystic) exponents a_n of $\sum_N c_N q^N = \prod_n (1-q^n)^{-a_n}$ (glossary) alternate in sign for every type, e.g. G_2: $14, -13, 78, -337, \ldots$ (observed). The only positive form found is $\mathrm{ch} = B \cdot (q)_\infty^{-(2h-2)}$ with $B \ge 0$, observed through q^{150} for $E_{6,7,8}$. For E_6, $B_n = ((n+2)\sigma_9(n+2) - \tau(n+2))/1050$, which is positive by Deligne's bound $|\tau(n)| \le d(n) n^{11/2}$ (proved on paper). B has no known combinatorial meaning.
- **G_2 via D_4's kernel.** G_2 at $k = -5/3$ has no known 4d Lagrangian theory, so there is no Schur-index contour integral to start from.
- **Non-product structure.** Introduce a variable z counting n. The series $\sum_n z^n H_n/(q)_n$ is not an infinite product in (z, q), because its plethystic exponents grow and alternate (observed). The branching functions of the G_2 level-one character into $\mathfrak{g}$-isotypic pieces are not products either (observed).

The stopped Route A pilot for G_2

Route A is the paper's proof: Macdonald/Cherednik constant terms at $t = 0$. A pilot for G_2 was run and stopped. Its first layer R1 is in the library, `VOA/DeligneAudit/DeligneCharacterG2RouteA.lean` ($K = \mathrm{Frac}\,\mathbb{Q}[X^{\pm}, Y^{\pm}, q^{\pm}]$, monomial substitutions):

```
def mono (v : E3) : K := algebraMap L K (monoL v)

def substL (M : E3 →+ E3) : L →+* L := mapDomainRingHom ℚ M
```

Numerically (exact rationals) $HB = q^{-2}BH$ holds as an identity of difference operators with 19 vanishing shift coefficients, while $B =$ (algorithm step) and $H \circ$ step $= q^{-2}$step $\circ H$ hold only on Weyl-group invariants. **Blocker.** Proving R3 ($HB = q^{-2}BH$) by certificate is infeasible: the shift identities carry 17–41 distinct binomial denominators, beyond what computer algebra could clear in reasonable time, and no small vanishing subgroup was found among the 28 terms of the single-root shifts. The only viable proofs are structural (DAHA/Cherednik Y-operators for G_2) or a citation of the literature (van Diejen–Emsiz plus Chari–Ion) as a named input. The pilot was therefore stopped, and `G2DemazureEqKW` stays named. R1 is kept as infrastructure; it proves nothing about characters.

25.11 $q = 1$ counts and energies

Side results for this chapter's chain. They supply the count and positivity inputs of the U5 route in Chapter 26 and the `energy` field of `D4DemazurePositivity`.

Theorem 25.40 (Tensor factorisation at $q = 1$). *Let θ have r entries and let every operator of the word, and the affine one, have nonzero root α. If $\chi = C_1|_{q=1}$ is invariant under every reflection of the word and under s_θ, then $C_m|_{q=1} = \chi^m$; in particular the coefficient sum of C_m is $(\dim \mathfrak{g} + 1)^m$. This holds (and is checked) for D_4 (29^m), G_2 (15^m), F_4 (53^m), E_6 (79^m), E_7 (134^m), E_8 (249^m).*

Files `VOA/DeligneAudit/DeligneCharacterDemazureCount.lean`, `DeligneCharacterE8Count.lean`.

```

```

From the mathematics to the Lean statement

Namespace `VOA.DeligneAudit.DeligneCharacter.DemCount`. `toR1 r` maps a term list into the group ring $\mathbb{Z}[\mathbb{Z}^r]$ at $q = 1$; `ρ.sLin` is the linear reflection of one operator. `((…).map (·.2)).sum` is the sum of all coefficients. The hypotheses `hθ` (length of θ) and `hα` (every operator's root $\alpha \neq 0$; this is where the domain argument of the proof needs non-degeneracy) are listed in the statement above. Instances `d4_demazure_total`, `g2_demazure_total`, `e6_demazure_total`, `e7_demazure_total` have the same shape.

Proof on paper. At $q = 1$ each operator satisfies $(1 - e^{-\alpha})Df = f - e^{-\alpha}s^{\mathrm{aff}}(f)$ with $s^{\mathrm{aff}}(fg) = s(f)s^{\mathrm{aff}}(g)$; since $\mathbb{Z}[\mathbb{Z}^r]$ is a domain, $D(fg) = fD(g)$ whenever $sf = f$. Iterate. The invariance of χ is a finite check. □

Physical meaning

At $q = 1$ the grading is forgotten, and the statement is the Fourier–Littelmann factorisation $D(1, m\theta) \cong D(1, \theta)^{\otimes m}$ as $\mathfrak{g}$-modules, at the level of dimensions. In the quasi-particle picture (heuristic) it says that m quasi-particles, each with internal states $\mathfrak{g} \oplus \mathbb{C}$, are independent once energies are ignored: the q-grading records only their interaction energies.

What the machine verified

Standard axioms; unconditional; no literature input.

Theorem 25.41 (Energies by a convexity invariant). *Let θ have r entries and every letter of the word be $< r$. Let F be a finite list of functionals stable under the word's reflections and s_θ, containing $-\theta^\vee$, with $\varphi(\theta) \le 2$ for all $\varphi \in F$. Then every term $z^\mu q^e$ of C_m has $e \ge -m^2$.*

File `VOA/DeligneAudit/DeligneCharacterDemazureEnergy.lean`.

```

From the mathematics to the Lean statement

`t.1.2` is the energy e; the conclusion is $e + m^2 \ge 0$. `reflFunFin`, `reflFunTheta` are $\varphi \circ s_i$, $\varphi \circ s_\theta$; `negTheta` is $-\theta^\vee$. All hypotheses are decidable and checked per type with F the W-orbit of $\theta^\vee$ (`g2DemazureEnergy_holds`, `e6DemazureEnergy`, `e7DemazureEnergy`, `e8DemazureEnergy`, `f4DemazureEnergy`).

Proof on paper. Invariant: every term has $\varphi(\mu) \le 2m$ for $\varphi \in F$. Finite D_i move μ along the segment to $s_i\mu$ (linear interpolation preserves the bound) and keep e. D_0 sends $\mu \mapsto \mu + k\theta$ with $0 \le k \le 1 - \langle \mu, \theta^\vee \rangle \le 2m - 1$ (using $-\theta^\vee \in F$) and lowers e by k; so $-(m-1)^2 - (2m-1) = -m^2$. □

Physical meaning

In the character C_m the variable q records L_0-energy inside the level-one WZW module. The bound $e \ge -m^2$, together with the prefactor q^{m^2} in C_m, says that the Demazure grading of $D(1, m\theta)$ starts at degree 0. So $\mathrm{Hilb}_q D(1, m\theta)$ is a genuine polynomial in q with no negative powers. This is what makes the clamped and unclamped tables comparable, and the D_4 positivity input partly provable.

What the machine verified

Standard axioms; unconditional. Replaces the D_4-only integrality trick.

Remark 25.42 (Unclamped fusion series; Gaussian transform). With energies and totals, the unclamped series `hilbSeriesG` and `fusionFZ` = `fusionOf`$(\cdot)$ (`DeligneCharacterFusionZ.lean` and per-type `DeligneCharacter*FusionZ.lean`, `F4FusionCountZ.lean`) have total $(\dim \mathfrak{g})^m$ (`fusionFZ_count`), removing every count and positivity input from the U5 route of Chapter 26. `GaussianTransform.lean`

proves Ravinder's mixed fusion recursion in closed form (`VOA.DeligneGaussian.mixed_eq`, `demazure_eq_gaussian`); both are used in Chapter 26.

25.12 The large kernel-checked data, described collectively

About half of this chapter's files are certificates. Each consists of literal data and theorems proved by `decide +kernel` (the kernel evaluates the check; no `native_decide`, no `implemented_by`). A referee should check *what* is asserted and that the bridge lemmas connect it to the definitions above; the literals themselves need no reading.

files	what is checked
`E8VacuumSteps`, `E8VacuumStepCheck00--30`, `E8VacuumStepAll`	the 3874 steps $\lambda \operatorname{ad}_b R = \mu R'$ ($\mu \neq 0$) of the breadth-first propagation search through the 3875 quadrics of I_2^{ns} for E_8, described in the proof of Theorem 25.21 (giving `sym_rel_all`). These certify relation symbols, not characters
`E6VacuumChecks`, `E7LieZhu`	Casimir match and divisibility checks for E_6, E_7; the E_7 chain of 1539 relation symbols
`DeligneCharacterE8Chain0--57`, `E8Inv0--9`, `E8Light`	the intermediate Demazure characters $P_0, \dots, P_{57}$ of C_1 for E_8 pinned to literals, one operator per file, in a light-import copy of the algorithm bridged by `rfl`/induction; nodup and reflection-membership checks for invariance
`E7Chain0--2`, `E7Inv0--4`, `E6Chain0`, `E6Inv0--1`, `F4FusionCountChain0--3`, `F4FusionCountInv`	the same for E_7, E_6, F_4
`D4FiniteCore`, `D4FiniteCompute`, `D4FiniteData`, `D4FiniteCheckQ`, `D4FiniteCheckSteps`, `D4FiniteCheckSteps2`, `D4FiniteIdentity`, `D4FiniteStatementProof`	the D_4 finite identity (P) in $\mathbb{Z}[q^{\pm}, s^{\pm}, x^{\pm}, z_1^{\pm}..z_4^{\pm}]$ (`d4FiniteIdentity_holds`), via a (q, u, t, z) world with 4× fewer terms and one-step literal checkpoints. The elaborator `d4_precompute%` only *proposes* each literal; the kernel re-verifies it
`DeligneCharacterD4Wp--Wp12` (and the other `DeligneCharacterD4*` layers)	the theta-product chain of Theorem 25.37; theory, not data, but long ($\wp'$ identity, half-period substitution, CT count)

25.12.1 The files of this chapter

The chapter covers the 239 files assigned to it in the book's assignment table. About 120 are theory (roughly 26 600 lines), and the other 119 are kernel-checked certificate and data files (roughly 3 300 lines).

files	content
`VOA/DeligneAudit/DeligneCharacter*.lean`	interface, AK coefficients, Demazure algorithm, closed forms, D_4 evaluation, counts
`DeligneMLDE*.lean`	the recurrence, the trace identity, Ramanujan, the heat equation, level two and three
`DeligneVacuumRelation*.lean`, `E6Vacuum*.lean`, `E7LieVacuum.lean`, `E7LieZhu.lean`, `F4LieVacuum.lean`, `G2LieVacuum.lean`, `E8VacuumStep*.lean`	the vacuum quartic relation per type, with propagation certificates
`A2Character*.lean`	the A_2 character side and star identity
`G2Star*.lean`	the G_2 target side and the named star reduction
`D4Finite*.lean`, `D4CharacterTop.lean`	the D_4 finite identity
`F4FusionCount*.lean`, `GaussianTransform.lean`	F_4 counts; Ravinder's mixed recursion in closed form
`VOA/Commutative/JacobiTriple*.lean`, `FourTriangular*.lean`	formal q-series identities
`VOA/Modularity/ZhuCoordinate*.lean`	the square-bracket current calculus

All paths without a directory are in `VOA/DeligneAudit/`, except the `FourTriangular*` files, which are in `VOA/Commutative/`.

Kernel-cost dead ends (recorded)

One `decide` over the whole D_4 identity: 650 s and 41 GB (killed; a memory incident). `![…]` table lookups at high index: O(index) in the kernel (one 248-entry row 25 s / 8.7 GB vs 4 s / 2.4 GB with a literal `List` and `getD`). Heavy imports in check files: use light-import copies bridged by `rfl`. `decide` of `e8DemazureHilb 1`: >10 min. The A_2 guard of ($\star$) beyond $N=8$ did not finish.

25.13 Lean defects and stale documentation

This section is the single place where the chapter's documentation defects are listed (Caveat 4). Each is also entered in the project's defect log. No Lean statement of this chapter was found to be wrong, vacuous or mis-hypothesised.

Missing statements and out-of-library checks (severity S3).

- **Missing equality corollaries** (warning after Theorem 25.22). $\dim L_k(\mathfrak{g})_N = c_N$ is a Lean theorem only for A_2 (`A2.finrank_eq_mldeCoeff'`). For G_2, D_4, F_4, E_6, E_7, E_8 only `TargetLowerBoundQ` ($\geq$) is exported. The equality is derivable by composing the per-type vacuum quartic relation (for E_6, E_7: `vacuumQuarticRelation_of_carrierData` with the `*_hrel` data), `isAKSolution_of_vacuumQuarticRelation` and `finrank_eq_mldeCoeff_of_isAKSolution`, but no such corollary is written. Composition checked in a scratch file for G_2, F_4, D_4 only.

- **Missing A_2 character formula** (Remark 25.23). $\dim V_N = [q^N]\prod(1+q^r)^8$ for $V = L_{-3/2}(\mathfrak{sl}_3)$ is not stated. It follows in one line from `A2.finrank_eq_mldeCoeff'` and `A2.productCoeff_eq_mldeCoeff'`; only the inequality `KacWakimotoLowerBound` is exported.

- **Checks outside the library.** `e7DemazureHilb_one` ($\mathrm{Hilb}\,D(1,\theta) = 133+q$ for E_7, about 50 s) and `A2_demazure_eq_GT_three` (agreement of the A_2 Gelfand–Tsetlin table with the affine algorithm, for $m=3$ and $N<10$ only) live in a separate heavy-check file in the project's notes, outside `VOA/`. They are therefore not built by `lake build`; they were run once

by hand. For smaller m, the A_2 comparison was carried out outside Lean (the docstring of `A2CharacterInterface.lean` cites an audit for $n \leq 7$).

- **Untraced modelling.** No Lean statement connects `D4K.d4SchurQ` to the $SU(2)$, $N_f = 4$ Schur index, although the docstring calls it "the Schur index". The identification is a hand transcription.

Stale documentation (severity S4).

- `DeligneCharacterExceptional.lean`: the docstring describes `XTargetLowerBound W` as a literature input. It is proved for the concrete W (Theorem 25.22).
- `A2CharacterInterface.lean` and `A2Character.lean`: the docstrings call the star identity and Kac–Wakimoto "not formalized" or "literature input". Both now follow (`A2.starIdentity`, `A2.kacWakimotoLowerBound_of_quartic`).
- `A2ProductMLDE` ("checked numerically through q^{40}"), `D4SchurEqE4` ("Named input"), `LorenzA2` ("named"), `RamanujanFormal` and `RamanujanIdentities` ("named input"): all are proved.
- `D4CharacterTop.lean` calls `D4DemazurePositivity` a literature input. Its `energy` field is proved, and `coeff` is available only from the open U5 (`d4DemazurePositivity_of_U5Z`). The docstring of `DeligneCharacterD4Schur.lean` calls positivity "a consequence of the Demazure character formula", a reading that no Lean statement backs.
- `DeligneCharacterDemazure.lean`: the title says "simply-laced", but the algorithm is used, correctly, for G_2 and F_4 (dictionary of Definition 25.34).
- The name `mldeCoeff` is used for two unrelated declarations (warning in Section 25.2).

25.14 Referee's checklist

Lean declaration	Intended meaning	Hypotheses / status	Check
`CarrierCharacterLowerBound`, `ordinaryCarrierCharacter_of_le`	lower half suffices	packages; uncond. impl.	Thm. 25.2

Chapter 26

The Deligne series III: fusion modules, Demazure modules and Ravinder's kernel

This chapter was written against an earlier state of the LeanVOA library (28 October 2026). For this edition, `scripts/textbook/sync.py` checks that every Lean quotation below occurs verbatim (up to whitespace and comments) in the source files of that release. What was machine-checked for this chapter, and what is taken from the project's build records, is stated once in Section 26.1.1 and in detail in the verification record (Section 26.18).

The chapter covers the Lean files that the book assigns to it (`Notes/Textbook/assignment.txt`: the rules for `DeligneFusion*`, `LatticeRealization*`, `*FusionKernel*`, `D4FusionF`, `F4LieKernel*` and `G2Fusion`). The files that carry the mathematics of the proved layer are presented declaration by declaration; certificate data and certificate checks (62 row-check files for the lattice realizations alone) are described collectively in Section 26.17. The Chari–Venkatesh files that prove the A_2 total bound (`DeligneFusionCV*`) are presented through their headline statements only (Section 26.10).

Prerequisites. The reader should know the following, which earlier chapters develop.

- The Deligne series, its levels $k = -1 - h^\vee/6$, and the chain of coefficientwise inequalities that proves classical freeness (Chapter 24, Section 24.1.3). In particular the inputs **U5** (the fusion module bound) and **U6** (the mixed fusion recursion), which Chapter 24 leaves as named hypotheses, are the subject of this chapter.
- Current modules `CurrentModule`, the cyclic degree pieces `cycDeg`, the $\hat{\mathfrak{sl}}_3$ local Weyl relations `LocalWeylRel` and input U5 in its A_2 form `SectorWeyl.FusionModuleBound` (Definition 24.29 and Theorem 24.41); the type-generic versions `LocalWeylRelG` and `FusionModuleBoundG`, and the sector data `DeligneSectorData` (Definitions 24.29 and 24.28); the recursion `mixed` and the structure `MixedFusionRecursion` (Definition 24.22).
- The level-one affine Demazure characters and their $q = 1$ totals (Chapter 25, Section 25.9, Definition 25.34 and Theorem 25.40); for A_2 the Gelfand–Tsetlin polynomial `demazureHilb` (Chapter 25).
- Lattice vertex algebras V_L, their charge and conformal-weight gradings, and the vertex-operator vanishing $e^{\alpha}_{(n)}e^{\beta} = 0$ for $n \geq -\langle\alpha,\beta\rangle$ (Chapter 4 and the lattice chapters).

What this chapter is about. The *seven types* of this chapter are the members A_2, D_4, E_6, E_7, E_8, G_2, F_4 of the Deligne series. The eighth member, A_1, is treated separately (Chapter 24, Section 24.1: its relation module has a different shape, and it is the $m = 1$ case of Chapter 20). The chain of

Chapter 24 bounds the operator count of $L_k(\mathfrak{g})$ by a sum over m of "m-particle sectors". Each sector contributes the graded character $\mathcal{F}_m(q)$ of a *fusion module* F_m, defined in Section 26.2.2 by generators and relations. The chain needs two facts about these modules.

- **U5**: every module satisfying the relations of F_m has graded dimension at most $\mathcal{F}_m(q)$ and total dimension at most $(\dim \mathfrak{g})^m$.
- **U6**: the $\mathcal{F}_m$ are tied to the level-one Demazure characters $\mathcal{D}_n(q)$ by Ravinder's mixed recursion (26.5).

The library proves U6 by *defining* $\mathcal{F}_m$ as the unique solution of the recursion. It reduces U5, by Ravinder's squeeze, to three statements.

(i) **Ravinder's kernel lemma.** Its Lean analogue is *proved* for all seven types. Ravinder's paper states it for every simple $\mathfrak{g}$ (only his Theorem 2 and Corollary 3 assume simply laced); for G_2, F_4 the library proves the statement for its own family of relations, which imposes the same relations as Ravinder's (Remark 26.5).

(ii) **U7**, the existence of a model of the Demazure module with the right graded dimension: for each n, some current module with a vector satisfying the relations of $M_{n,0}$ (Section 26.2.4) whose degree pieces are at least as large as those of $D(1, n\theta)$ (Lean: `DemazureRealization n`, Definition 26.11). U7 is *proved* for A_2 and for D_4 (`D4Char.d4_demazureRealization`, Chapter 27). For E_6, E_7, E_8 it is reduced to a named dimension statement on lattice vertex algebras. For G_2, F_4 it is a named hypothesis (there is no lattice route). For every type U7 is a published theorem (Ravinder's Proposition 1 with the Demazure character formula); for the five remaining types what is missing is its formalization.

(iii) **The total-dimension bound** $\dim F_m \le (\dim \mathfrak{g})^m$. Its finiteness half is *proved* for all seven types. Its dimension half is *proved for* A_2 (`CVUniv.fusionTotalDim`, Section 26.10) and remains a named hypothesis (`FusionTotalDimG`) for the other six types.

Feigin's proof of the total bound (*SIGMA* 4 (2008) 070, arXiv:0806.4851, Cor. 2) has a gap that we document; a repair (Kus–Littelmann, Thm. 4.2, valid for every simple $\mathfrak{g}$, with one proof step flagged by the project) and an independent $\mathfrak{sl}_3$ route are published, and the library's A_2 proof follows the independent route (Setia–Rani–Khandai). So for A_2 every input of the chain in this chapter is a theorem, and Chapter 27 states the resulting unconditional classical freeness of $L_{-3/2}(\mathfrak{sl}_3)$.

The findings of this chapter, in brief.

1. **U6 is a theorem by construction** (`mixedFusionRecursion_fusionOf`): the mixed recursion is unitriangular, so for any Demazure series it has exactly one solution `fusionOf`. The price is that the identification "`fusionOf` = the true fusion character" becomes a *consequence* of U5, not an input.
2. **Ravinder's squeeze is formalized** for every type (`squeeze`, `squeezeG`): nonnegativity, the spanning half of Ravinder's exact sequences, a Demazure lower bound and a total upper bound force $\mathrm{ch}\, M_{0,m} = \mathcal{F}_m$ coefficientwise.
3. **The Lean analogue of Ravinder's kernel lemma is unconditional for all seven types.** For A_2 it is stated in the A_2-specific form `RavinderKernelRel` (through `MabRel`) and follows from Garland's identities (`ravinderKernelRel`). For the other six types it is `RavinderKernelRelG` for the library's family `ravFam`, and follows from a decidable table of structure-constant facts and the integrability statement `ThetaNilG`, which is itself proved per type by Heisenberg chains or by an ad-nilpotency lemma (`ravinderKernelRelG_of_table`, `d4_thetaNil`, `g2_thetaNil`, ...). For G_2, F_4 the Lean statement is about the library's own

family, which imposes the same relations as Ravinder's (Remark 26.5); Ravinder's Theorem 1, Corollaries 1–2 and Proposition 1 are stated for every simple $\mathfrak{g}$.

4. **The finiteness clause of the total bound is proved for all seven types** (`cycDeg_finiteDimensional`, `fusionTotalBoundG_of_dim`), by Kac's lemma and a kernel-checked nilpotency certificate.

5. **For A_2, U7 is unconditional** (`EvalModel.demazureRealization_all`), by a fusion product of $2N$ evaluation modules at distinct points, combined with the Chari–Loktev spanning theorem for $\mathfrak{sl}_3$ (`clSpanning`), which is formalized in full, and the Chari–Pressley $\mathfrak{sl}_2$ box theorem (`box_span`).

6. **The A_2 total bound is a theorem**, `CVUniv.fusionTotalDim` ($\dim F_m \le 8^m$ for every module with the relations; Theorem 26.30), proved from two base families of Chari–Venkatesh modules that are themselves proved. The earlier reductions to `RavinderKernelLower` and `IdealLower` (each implies `FusionTotalDim`) remain in the library as alternative routes; those two `Props` are not proved and are no longer needed.

7. **Lattice realizations** (the relations half of U7) are proved for D_4, E_6, E_7, E_8 (`LatData.sat`, `e8_lattice_sat`); the dimension half is the named `D4LatticeDim`, …, `E8LatticeDim`, numerically sharp where tested.

8. **The literature behind the A_2 bound.** Feigin's Cor. 2, which Ravinder cites, rests on a sketched Prop. 1 whose natural reading fails; a repair is published (Kus–Littelmann 2015, Thm. 4.2), and an independent upper-bound route exists (Setia–Rani–Khandai, arXiv:2405.11944, §8), which is the one formalized. Section 26.11 records the paper analysis, including a *slice lemma* in mixed evaluation models that would give an alternative proof; it is not proved and not needed. For the other six types the total bound is open in Lean but published (Kus–Littelmann, with the flagged step, which for D_4 at $m = 2$ is insufficient as written although the theorem is not known to fail; Chapter 27).

The logical arc and its ledger. Table 26.1 is the map of the chapter: for each input of the chain that concerns fusion modules, where it is stated, and whether it is proved, reduced, or open.

How the A_2 argument fits together. Table 26.2 shows which theorem feeds which, and what hypothesis is passed on. Reading it top to bottom: the kernel lemma and finiteness make the universal characters satisfy the spanning inequality (R); U7 gives the Demazure lower bound (D); the total bound gives (T); the squeeze turns (R), (D), (T) into U5; and U5 with U6 gives classical freeness. `FusionTotalDim` enters *only* through (T), and it is proved (Theorem 26.30).

The named statements and how they are related. Table 26.3 collects every named `Prop` of this chapter that is *not* proved. For each type other than A_2 there is one open core, the total bound `FusionTotalDimG`, together with U7; for A_2 the total bound is proved, and the two A_2 rows are alternative routes that are no longer needed.

26.1 Conventions, notation, and reading the Lean

26.1.1 Machine status, stated once

Axioms. Every status box reports the `#print axioms` result for the theorems it discusses. Unless the box says otherwise, the result is exactly Lean's three standard axioms `propext`, `Classical.choice`,

Table 26.1: The fusion inputs of the Deligne chain and their status in Lean.

input	Lean	status
U6	`fusionOf`, `mixedFusionRecursion_fusionOf`	proved (by construction)
squeeze	`squeeze`, `squeezeG`, `fusionModuleBoundG_of_kernel`	proved
universal modules	`univRep`, `univRepG`, `finrank_cycDeg_le_univG`	proved
exact-sequence step	`finrank_step`, `finrank_stepG`	proved
kernel lemma	`ravinderKernelRel` (A_2, `MabRel` form); `ravinderKernelRelG_of_table` + `X_thetaNil`	proved, all types (Lean analogue; G_2, F_4: library family)
finiteness clause	`cycDeg_finiteDimensional`; `X_fusionTotalBoundG_of_dim`	proved, all types
total bound (A_2)	`CVUniv.fusionTotalDim` (of `FusionTotalDim`)	proved
total bound (others)	`FusionTotalDimG`	**named**
U7 (A_2)	`EvalModel.demazureRealization_all`	proved
U7 (D_4)	`D4Char.d4_demazureRealization`	proved (Chapter 27)
U7 (other types)	`DemazureRealizationG`; lattice `LatData.sat` + `XLatticeDim`	**named** (relations half proved for $E_{6,7,8}$; no lattice route for G_2, F_4)
A_2 alternative routes	`RavinderKernelLower`, `IdealLower`	named, unproved, not needed; each implies `FusionTotalDim`
slice lemma	none (paper only)	open; not needed

`Quot.sound` ("standard"). `VOA.pbw` is a theorem of the library (Chapter 3); no project axiom is used in this chapter.

Re-run or record. "(re-run)" means that we ran `#print axioms` ourselves for this chapter (Section 26.18 lists the commands). "(record)" means that the result is taken from the project's build records (the project's internal build log and workstream logs) and was not re-run by us.

The aggregate build. The project counts a result only when the aggregate build is green. Every file whose declarations this chapter presents is in the import closure of the umbrella module `VOA.Deligne`; the umbrella build and the aggregate build that the records report are described in Section 26.18.

Conditional is not unconditional. A clean `#print axioms` never reports explicit hypotheses. A theorem that takes `(h : P)` for a named `Prop P` is *conditional on* `P`, and the status boxes say so.

26.1.2 Notation used in this chapter

Several letters are used for more than one object. Table 26.4 resolves them; the right column says where each object is defined.

Table 26.4: Notation.

symbol	meaning	where
$x(r)$	$x \otimes t^r \in \mathfrak{g}[t]$; r is its degree	§26.2.1
e_α, f_α, h_i	raising and lowering root vectors ($\alpha > 0$), simple coroots. "Lowering" letters are the f_α	§26.2.1
θ	the highest root; $V(\theta) = \mathfrak{g}$ is the adjoint representation	§26.2.1
$V(\lambda)$	the irreducible $\mathfrak{g}$-module of highest weight λ	§26.2.2
$V(z)$	the evaluation module at $z \in \mathbb{C}$	Def. 26.2
$V_1 * \cdots * V_m$, V^{*m}	fusion product	Def. 26.2
$\mathrm{cyc}(w)_d$	span of the words of degree d applied to w (Lean `cycDeg`)	§26.2.1

Table 26.4: Notation.

symbol	meaning	where
q, $[q^N]f$	formal variable of characters; the coefficient of q^N (Lean `coeff N`)	§26.2.1
Hilb_q	graded character $\sum_d \dim(\cdot)_d\, q^d$	§26.2.1
$W_{\mathrm{loc}}(\lambda)$	local Weyl module	(26.1)
$D(1,\lambda)$; $\mathcal{D}_n$	level-one Demazure module; its character for $\lambda = n\theta$	§26.2.1
$D(N)$	short for $D(1, N\theta) = M_{N,0}$ in Section 26.11 only	§26.11
F_m; $\mathcal{F}_m$; fusionF$_m$	fusion *module* (generators and relations); a *series* solving the mixed recursion; the explicit A_2 solution	(26.2), Def. 26.8
F_k, $F(u)$	operators in Garland's identity (Lean `F`); not related to F_m or to the Lie type F_4	Thm. 26.16
$M_{a,b}$	Ravinder's modules; $M_{a,b}(q)$ their characters	(26.3)
M (Lean `M`)	any family of power series to which the squeeze is applied	Def. 26.11
M_m	the sector module of Chapter 24 (only in cross-references)	Ch. 24
(TB), (KL)	the total bound `FusionTotalBound`; the kernel relation `RavinderKernelRel`	Def. 26.6
(R), (D), (T)	the three squeeze inequalities	§26.2.5
$U_{a,b}$, w_U, $M^{\mathrm{univ}}_{a,b}$	universal module of $M_{a,b}$, its generator, its character (Lean `Mchar`)	Def. 26.13
v_K	the kernel vector $f_\theta(2a+b+1)w$ of $M_{a+1,b}$	§26.2.4
τ_s	shift of the grading by s	(26.4)
T_N	the evaluation model (A_2)	Def. 26.23
T	a current module without grading (Lean section variable `T`) in Def. 26.23; Feigin's tensor model in §26.11	
$T_{a,b}$	mixed evaluation model of the slice lemma	§26.11
$\mathrm{tot}(a,b)$	total dimension of $U_{a,b}$	§26.9
J_m; $J_{a,b}$; J_N	the box ideal of Chari–Pressley; the relation subspace of $U_{a,b}$; the ideal image $(\mathfrak{g}\otimes t^N\mathbb{C}[t])\,D(N)$	Thm. 26.18, Def. 26.13, §26.11
R	the polynomial ring $\mathbb{C}[z_0, z_1, \dots]$ in Thm. 26.18; a relation specification in §26.12	
$Q(r,s)$	$[u^s]F(u)^r$, the Garland coefficient (also $Q(r,j)$ applied to w)	Thm. 26.16
$\Phi_{<d}$, $\Phi_{\le d}$	the degree filtration of a cyclic module	Def. 26.2, 26.23
S	sector data (Chapter 24); in §26.11, a kernel subspace	

26.1.3 Reading the Lean in this chapter

Chapter 1, Section 1.2, is the general primer. The idioms that the printed code of this chapter needs are these.

- **Truncated blocks.** Proof bodies are omitted. A printed block therefore ends at `:=`, `:= by` or `where`, and the proof follows in the file. This is not a syntax error.
- **Section variables.** A Lean `section` may declare `variable {V : Type} {ρ : ...}` once; every declaration of the section then takes these as arguments, although they are not printed in its statement. Hypotheses declared this way (for example `(hXY : X * Y - Y * X = Z)`) become arguments of a theorem when the theorem uses them or when they are `included`. The dictionaries list the section variables of every quoted declaration.
- **Binders.** `(x : T)` is an explicit argument, `{x : T}` an implicit one inferred by Lean, and `[FiniteDimensional ℂ V]` an instance argument: a hypothesis that Lean finds automatically where it is known.

Table 26.2: Dependencies of the A_2 argument.

result	feeds	open hypothesis it passes on
Garland (Thm. 26.16)	kernel lemma; box spanning	none
kernel lemma (Thm. 26.17)	exact-sequence step	none
finiteness (Thm. 26.7)	finiteness of universal pieces	none
exact-sequence step (Thm. 26.14)	(R) in the assembly	none
box spanning (Thm. 26.18)	Chari–Loktev	none
Chari–Loktev (Thm. 26.20)	U7	none
U7 (Thm. 26.24)	(D) in the assembly	none
`FusionTotalDim` (Thm. 26.30)	(T) in the assembly	none (proved)
squeeze (Thm. 26.12)	U5 for fusionF	the squeeze inputs
assembly (Thm. 26.15)	classical freeness	`FusionTotalDim` (as stated)
final forms (Thm. 26.28)	Chapter 27	none, once Thm. 26.30 is applied

Table 26.3: The named, unproved statements of this chapter. "⇒" means a Lean theorem.

statement	relation proved in Lean	what it would take
`RavinderKernelLower`	⇒ `FusionTotalDim` (Thm. 26.27)	a large kernel in one model (slice lemma)
`IdealLower`	⇒ `FusionTotalDim` (Thm. 26.27)	a large ideal image in one model
`FusionTotalDimG` ($G_2, D_4, F_4, E_{6,7,8}$)	for D_4: implied by a rank bound on a presented module PTE_m for all m (proved for $m \le 2$), and by $\mathfrak{sl}_4$ core bounds with at least two adjoint sites (`D4LevelReduction.fusionTotalDim_of_coreBounds`, with the one-adjoint-site bounds proved) (Chapter 27, Section 27.7.1); for D_4 this is the only remaining input	a formalization of Kus–Littelmann Thm. 4.2 (published; one step flagged, insufficient as written for D_4 at $m = 2$)
`DemazureRealizationG` (non-A_2)	implied by `XLatticeDim` for D_4, $E_{6,7,8}$ (Thm. 26.41); for D_4 proved for all n (`D4Char.d4_demazureRealization`; aggregate build green, 3 November 2026; Chapter 27)	a formalization of the Demazure character formula (published: Ravinder Prop. 1 + Kumar/Mathieu), or a D/E Chari–Loktev
`D4LatticeDim`, …, `E8LatticeDim`	⇒ U7 for that type	a spanning bound in V_L
`CLIndependence`	none; not used	—

- **Named statements are not axioms.** `def P : Prop := ...` only gives a *name* to a statement; it asserts nothing. A theorem with a hypothesis (`h : P`) is proved *assuming* `P`. This chapter's honesty rests on this distinction: `FusionTotalDim` and its relatives are named statements, and nothing in the library postulates them. A named statement becomes a theorem when the library constructs a proof of it, as `CVUniv.fusionTotalDim` does for `FusionTotalDim`. `structure S : Prop where f1 : ... f2 : ...` is a bundle of named conditions; a proof `h : S` gives `h.f1`, `h.f2`.
- **`abbrev` vs `def`**: both define; `abbrev` unfolds automatically.
- **Lists and words.** A word of current letters is a `List (Fin 8 × ℕ)`: a letter (c, r) is $x_c(r)$. `Fin 8` $= \{0, \dots, 7\}$. `List.replicate k x` is the list $x, \dots, x$ of length k.
- **Finite sums.** `∑ i ∈ s, f i` is a sum over the finite set `s`; `Finset.range n` $= \{0, \dots, n-1\}$; `Finset.antidiagonal n` $= \{(i, j) : i + j = n\}$.
- **Small notation.** `•` is scalar multiplication; `f^[n]` is the n-fold iterate of `f`; `(ρ.op 5 0) ^ n` is

the n-th power in $\mathrm{End}(V)$; `x.1`, `x.2` are the components of a pair; `ℂ • w` is the line through w; natural-number subtraction is truncated at 0.

- **Linear algebra.** `Module.finrank ℂ V` is $\dim V$, *and is* 0 *when V is infinite-dimensional*; `FiniteDimensional ℂ V` says $\dim V < \infty$. `Submodule.span ℂ s` is the span; `V / U` the quotient and `U.mkQ` the quotient map. `PowerSeries ℚ` is $\mathbb{Q}[[q]]$, and `X` is q.
- **Kernel checks.** `decide +kernel` proves a decidable statement by evaluating it in Lean's trusted kernel. `native_decide`, which would trust compiled code, is never used in these files.

26.2 The mathematics

26.2.1 Current algebras and their cyclic modules

Let $\mathfrak{g}$ be a finite-dimensional simple Lie algebra over $\mathbb{C}$ with a basis $(x_c)_{c\in\sigma}$ and structure constants f: $[x_a, x_b] = \sum_e f(a,b,e)\,x_e$. The *current algebra* is $\mathfrak{g}[t] = \mathfrak{g}\otimes\mathbb{C}[t]$ with bracket $[x\otimes t^r, y\otimes t^s] = [x,y]\otimes t^{r+s}$. We write $x(r)$ for $x\otimes t^r$. It is graded by the t-degree: $x(r)$ has degree r.

A $\mathfrak{g}[t]$-module is a vector space V with operators $x(r)$ obeying the bracket. If $w\in V$, the *cyclic submodule* generated by w is spanned by the *loop words* $x_{c_1}(r_1)\cdots x_{c_\ell}(r_\ell)w$; the degree of such a word is $r_1+\cdots+r_\ell$. We write $\mathrm{cyc}(w)_d$ for the span of the words of degree d applied to w (Lean: `cycDeg ρ w d`). When V is graded and w is homogeneous, $\mathrm{cyc}(w)_d$ is exactly the degree-d part of the cyclic module; in general it is just a subspace, and the library works with it because `CurrentModule` carries no grading operator. The *graded character* of a cyclic module is $\mathrm{Hilb}_q = \sum_d \dim \mathrm{cyc}(w)_d\, q^d$, and $[q^N]f$ denotes the coefficient of q^N in a series f.

Fix a Cartan subalgebra, positive roots, the highest root θ, simple roots α_i with coroots h_i, and Chevalley generators e_α (raising) and f_α (lowering), $\alpha>0$. For a dominant weight λ the **local Weyl module** $W_{\mathrm{loc}}(\lambda)$ (Chari–Pressley) is the $\mathfrak{g}[t]$-module generated by w with relations

$$e_\alpha(r)w = 0, \qquad h(r)w = \delta_{r,0}\,\lambda(h)\,w, \qquad f_i(0)^{\lambda(h_i)+1}w = 0. \tag{26.1}$$

It is finite-dimensional and graded. The **level-one Demazure module** $D(1,\lambda)$ is the $\mathfrak{g}[t]$-submodule of the basic level-one representation of the affine algebra generated by an extremal weight vector; for $\lambda = n\theta$ and $\mathfrak{g}$ simply laced it is isomorphic to $W_{\mathrm{loc}}(n\theta)$ (Chari–Loktev for $\mathfrak{sl}_{r+1}$, Fourier–Littelmann in general). We write

$$\mathcal{D}_n(q) = \mathrm{Hilb}_q\, D(1,n\theta), \qquad \mathcal{D}_n(1) = \dim D(1,n\theta) = (\dim\mathfrak{g}+1)^n.$$

For $\mathfrak{sl}_3$: $\mathcal{D}_1 = 8+q$, $\mathcal{D}_2 = 27+28q+17q^2+8q^3+q^4$, totals 9 and 81. As $\mathfrak{g}$-modules, $D(1,\theta) = \mathfrak{g}\oplus\mathbb{C}$ (adjoint in degree 0, trivial in degree 1).

Example 26.1 ($\mathfrak{sl}_2$: the local Weyl module $W_{\mathrm{loc}}(m)$)**.** For $\mathfrak{sl}_2$ with generators e,h,f and $\lambda = m$, Chari–Pressley prove that the vectors $f(s_1)\cdots f(s_\ell)w$ with $0\le s_1\le\ldots\le s_\ell\le m-\ell$ form a basis of $W_{\mathrm{loc}}(m)$. For $m=2$: w; $f(0)w$, $f(1)w$; $f(0)^2w$: four vectors, and $\dim W_{\mathrm{loc}}(m) = \sum_\ell \binom{m}{\ell} = 2^m$. The constraint $s_\ell \le m-\ell$ (a "box") is the content of the theorem; it comes from Garland's identities (Section 26.7).

26.2.2 Fusion products, concretely

Definition 26.2 (Evaluation modules; fusion products)**.** (a) For a $\mathfrak{g}$-module V and $z\in\mathbb{C}$ the **evaluation module** $V(z)$ is V with $x(r)$ acting by $z^r x$ (with $0^0=1$). At $z=0$ every $x(r)$, $r\ge1$, acts by 0, and $V(0)$ is a graded module concentrated in degree 0. We write $V(\lambda)$ for the irreducible $\mathfrak{g}$-module of highest weight λ; $V(\theta)=\mathfrak{g}$.

(b) More generally, for a graded cyclic $\mathfrak{g}[t]$-module V and $z\in\mathbb{C}$, the **translate** V^z is V with $x(r)$ acting as $x\otimes(t+z)^r = \sum_s \binom{r}{s} z^{r-s}x(s)$. For $V = V(\lambda)(0)$ this is $V(\lambda)(z)$.

(c) Let $V_1, \dots, V_m$ be graded cyclic $\mathfrak{g}[t]$-modules with cyclic vectors v_j, and $z_1, \dots, z_m$ distinct. Put $T = V_1^{z_1} \otimes \cdots \otimes V_m^{z_m}$ (with $x(r)$ acting by the Leibniz rule) and $v = v_1 \otimes \cdots \otimes v_m$. Feigin and Loktev show that T is cyclic on v. Its **degree filtration** is

$$\Phi_{\le d} = \operatorname{span}\{x_1(r_1)\cdots x_\ell(r_\ell)v \,:\, r_1 + \cdots + r_\ell \le d\}, \qquad \Phi_{<d} = \Phi_{\le d-1}.$$

Then $\Phi_{\le d} \subseteq \Phi_{\le d+1}$, $x(r)\Phi_{\le d} \subseteq \Phi_{\le d+r}$, and $\bigcup_d \Phi_{\le d} = T$. The **fusion product** is the associated graded space

$$V_1 * \cdots * V_m = \bigoplus_{d \ge 0} \Phi_{\le d}/\Phi_{<d},$$

on which $x(r)$ acts by the map $\Phi_{\le d}/\Phi_{<d} \to \Phi_{\le d+r}/\Phi_{<d+r}$ that it induces. We write V^{*m} for m factors equal to V.

The fusion product is a graded cyclic $\mathfrak{g}[t]$-module (generated by the class of v), and its dimension is $\prod_j \dim V_j$, because an associated graded space has the dimension of the filtered space. Its definition depends on the points z_j. That it does not is a conjecture of Feigin and Loktev; it is a theorem whenever the fusion product is shown to have a presentation by generators and relations that does not mention the points, since then all choices give the same module. For $V(\theta)^{*m}$ that presentation is Ravinder's (26.2), a literature result resting on the input discussed in the Warning at the end of this section.

Why the fusion product satisfies truncation relations. Let all $V_j = V(\lambda_j)(0)$. For a polynomial $P(t)$, $x \otimes P(t)$ acts on T by $\sum_j P(z_j)\, x^{(j)}$, where $x^{(j)}$ acts on the j-th factor. Take $P(t) = \prod_j (t - z_j)$, of degree m: then $x \otimes P(t)$ acts by 0, and $P(t) = t^m + (\text{lower})$ gives $x(m)v \in \Phi_{<m}$. In the associated graded space this becomes the exact relation $x(m)\bar{v} = 0$. This is how relations of the shape $f_\alpha(m)w = 0$ arise.

Example 26.3 ($\mathfrak{sl}_3$: the fusion square of the adjoint)**.** Take $\mathfrak{g} = \mathfrak{sl}_3$, $V_1 = V_2 = V(\theta)$, the points $z_1 = 1, z_2 = -1$, and $v = e_\theta \otimes e_\theta$. As $\mathfrak{g}$-modules,

$$V(\theta) \otimes V(\theta) = 8 \otimes 8 = \underbrace{27 \oplus 8 \oplus 1}_{\mathrm{Sym}^2} \oplus \underbrace{10 \oplus \overline{10} \oplus 8}_{\Lambda^2},$$

of dimension 64. Let σ be the swap of the two factors. Since $z_2 = -z_1$, $\sigma x(r)\sigma = (-1)^r x(r)$, and $\sigma v = v$; so σ preserves each $\Phi_{\le d}$ and acts on $\Phi_{\le d}/\Phi_{<d}$ by $(-1)^d$. Hence the even-degree pieces of the fusion product are, as $\mathfrak{g}$-modules, the pieces of Sym^2, and the odd-degree pieces those of Λ^2. Degree 0 is $U(\mathfrak{g})v = V(2\theta)$, of dimension 27. So

$$\text{degree } 0 \,:\, 27, \qquad \text{degree } 1 \,:\, 10 \oplus \overline{10} \oplus 8 \,(= 28), \qquad \text{degree } 2 \,:\, 8 \oplus 1 \,(= 9),$$

and the graded character is $27 + 28q + 9q^2$; the 8 in degree 1 is the antisymmetric one ($[x, y]$), the 8 in degree 2 the symmetric one. An exact rational computation of the filtration, made for this chapter (not part of the repository), confirms this decomposition degree by degree at the points $(1, -1)$ and at $(0, 1)$. The same numbers come out of the mixed recursion (26.5) below: $\mathcal{D}_2 = \mathcal{F}_2 + q^2(1+q)\mathcal{F}_1 + q^4$ with $\mathcal{D}_2 = 27 + 28q + 17q^2 + 8q^3 + q^4$ and $\mathcal{F}_1 = 8$ gives $\mathcal{F}_2 = 27 + 28q + 9q^2$. So at $m = 2$ representation theory, the recursion and the total 8^2 agree. (In Lean, $\dim F_2 \le 64$ is the case $m = 2$ of `CVUniv.fusionTotalDim`, Theorem 26.30.)

Example 26.4 ($\mathfrak{sl}_3$: the Demazure module $D(1, \theta)$ as a fusion product)**.** Take the standard representation $\mathbb{C}^3$ at $z = 0$ and its dual $(\mathbb{C}^3)^*$ at $z = 1$, with $v = e_1 \otimes e_3^*$ (weight θ). Then $T = \mathbb{C}^3 \otimes (\mathbb{C}^3)^* \cong \operatorname{End}\mathbb{C}^3$ has dimension 9. Degree 0 is $U(\mathfrak{g})v$, the traceless matrices, $V(\theta) = 8$. In degree 1, $x(1)$ acts by $0 \cdot x^{(1)} + 1 \cdot x^{(2)}$, the action on the dual factor alone, which reaches the identity matrix; so degree 1 is the trivial module $\mathbb{C}$. The graded character is $8 + q = \mathcal{D}_1$. This is the case $N = 1$ of the evaluation model of Theorem 26.24.

26.2.3 The fusion modules F_m

The relations satisfied by the fusion product $V(\theta)^{*m}$ suggest the module

$$F_m = W_{\mathrm{loc}}(m\theta) \Big/ \big\langle f_\alpha(m)w \,:\, \alpha > 0 \big\rangle. \tag{26.2}$$

By the paragraph on truncation relations, $V(\theta)^{*m}$ is a quotient of F_m, so $\dim F_m \geq (\dim \mathfrak{g})^m$. Ravinder's presentation theorem says that $F_m \cong V(\theta)^{*m}$ (stated for every simple $\mathfrak{g}$). Its proof takes the terminal case from Feigin's Cor. 2 (Ravinder's Prop. 5), which is exactly the upper bound $\dim F_m \leq (\dim \mathfrak{g})^m$ and has the gap recorded in the Warning below; Kus–Littelmann's Thm. 4.2 proves the same bound for every simple $\mathfrak{g}$, with one step flagged by the project (Chapter 27, item (i) of the literature paragraph); in Lean that upper bound is the statement `FusionTotalDim`, proved for $\mathfrak{sl}_3$ by another route (Theorem 26.30) and open for the other types (`FusionTotalDimG`). So: *if* Ravinder's identification holds, then $\mathrm{Hilb}_q F_m(1) = (\dim \mathfrak{g})^m$ and $[q^0]\,\mathrm{Hilb}_q F_m = \dim V(m\theta)$.

We write $\mathcal{F}_m(q)$ for the series defined by inverting the mixed recursion (26.5) below (in Lean `fusionOf`, Definition 26.8). For $\mathfrak{sl}_3$ these are

$$\mathcal{F}_1 = 8, \qquad \mathcal{F}_2 = 27 + 28q + 9q^2, \qquad \mathcal{F}_3 = 64 + 97q + 152q^2 + 111q^3 + 71q^4 + 16q^5 + q^6.$$

They are *outputs of the recursion* applied to the Demazure characters, with totals 8, 64, 512; they are not computed characters of the modules F_m. That they *are* the characters of F_m is literature (Ravinder) plus numerics (exact through $m = 4$), and in Lean a consequence of U5 (Theorem 26.12). Example 26.3 checks $m = 2$ directly.

The statement $\dim F_m \leq (\dim \mathfrak{g})^m$ is **U5 in total form**. In the Lean statements below, the relations (26.1) plus $f_\alpha(m)w = 0$ are `LocalWeylRel` (A_2) and `LocalWeylRelG` (general), Definition 24.29.

26.2.4 Ravinder's modules $M_{a,b}$ and the exact sequence

Ravinder (arXiv:1409.0274) interpolates between the Demazure module and the fusion module with a two-parameter family. For $a, b \geq 0$ put $k = a + b$ and let

$$M_{a,b} = W_{\mathrm{loc}}(k\theta) \Big/ \Big\langle f_\alpha(k)w \ (\alpha > 0,\ \alpha \neq \theta), \ \ f_\theta(2a + b)w \Big\rangle. \tag{26.3}$$

Then $M_{0,m} = F_m$, and $M_{n,0} = W_{\mathrm{loc}}(n\theta) = D(1, n\theta)$ ($\mathfrak{g}$ simply laced): at $(a, b) = (n, 0)$ every truncation already holds in $W_{\mathrm{loc}}(n\theta)$, because w is a highest-weight vector of weight $(n\theta)(h_\alpha) \in \{n, 2n\}$ for the $\mathfrak{sl}_2$-triple of α, and the $\mathfrak{sl}_2$ box of Example 26.1 kills $f_\alpha(s)w$ for s at least that weight. Ravinder identifies $M_{a,b}$ with the fusion product $D(1, \theta)^{*a} * V(\theta)^{*b}$.

Remark 26.5 (The Lean fusion sets)**.** The Lean sectors impose $f_\alpha(k)w = 0$ for all positive α for A_2, D_4, G_2, F_4, but only for $\{\alpha : \langle \alpha, \theta^\vee \rangle = 1\} \cup \{\theta\}$ for E_6, E_7, E_8 (Ravinder's choice; $\langle \alpha, \theta^\vee \rangle = 2(\alpha, \theta)/(\theta, \theta)$, which for a short root of G_2 or F_4 differs from $(\theta, \alpha^\vee)$). For simply laced types the two readings give the same module: for $\alpha \perp \theta$ the $\mathfrak{sl}_2[t]$-submodule of the α-triple generated by w is a local Weyl module of weight 0, hence trivial, so $f_\alpha(r)w = 0$ for all r already (Chapter 24). For $\mathfrak{sl}_3$ the positive roots $\alpha_1, \alpha_2, \theta$ all have $(\theta, \alpha^\vee) \geq 1$, so nothing changes. The same holds for G_2 and F_4: since θ is long, every positive $\alpha \neq \theta$ has $\langle \alpha, \theta^\vee \rangle \in \{0, 1\}$; those with value 1, short roots included, are in Ravinder's set, and for those with value 0 one has $f_\alpha(0)w = 0$ and then $f_\alpha(r)w = 0$ for all r by $[h(1), f_\alpha(r)] = -\alpha(h) f_\alpha(r + 1)$ and $h(1)w = 0$ (Chapter 27, Lemma 27.6). So the two readings give the same module for every type.

For a graded module M and $s \in \mathbb{N}$ let $\tau_s M$ be M with every degree raised by s. Ravinder proves the short exact sequence

$$0 \longrightarrow \tau_{2a+b+1} M_{a,b} \longrightarrow M_{a+1,b} \longrightarrow M_{a,b+1} \longrightarrow 0. \tag{26.4}$$

The surjection exists because the relations of $M_{a,b+1}$ are those of $M_{a+1,b}$ (same $k = a+b+1$) plus $f_\theta(2a+b+1)w = 0$; its kernel is generated by the **kernel vector** $v_K = f_\theta(2a+b+1)w$. The left map sends the generator of $M_{a,b}$ to v_K; that it is well defined is **Ravinder's kernel lemma**: v_K *satisfies the relations of* $M_{a,b}$. Injectivity of the left map is the deep half.

On characters, write $M_{a,b}(q)$. The sequence gives $M_{a+1,b} = M_{a,b+1} + q^{2a+b+1}M_{a,b}$. Iterating from $(n,0)$ down to the row $a = 0$ expresses the Demazure character through the fusion characters:

$$\mathcal{D}_n(q) = \sum_{d=0}^{n} q^{dn} \begin{bmatrix} n \\ d \end{bmatrix}_q \mathcal{F}_{n-d}(q), \tag{26.5}$$

with $\begin{bmatrix} n \\ d \end{bmatrix}_q$ the Gaussian binomial. This is **U6** (Ravinder Cor. 1). For example $\mathcal{D}_1 = \mathcal{F}_1 + q$ and $\mathcal{D}_2 = \mathcal{F}_2 + q^2(1+q)\mathcal{F}_1 + q^4$.

Physical meaning

Dictionary of the mnemonics (heuristic throughout this chapter). In conformal field theory a current algebra $\mathfrak{g}[t]$ is the algebra of non-negative modes of the chiral currents $J^a(z)$ of a WZW-type model. A cyclic module generated by w is the space of states created from a primary state by the currents. In the physics boxes of this chapter: a *particle* is a tensor factor $V_j(z_j)$, i.e. a point z_j where a primary field (in the adjoint, or in $D(1,\theta)$) is inserted; the *energy* of a state is its t-degree (a loop grading; it is the eigenvalue of L_0 minus a constant only in the lattice picture of Section 26.15); a *bound* particle is a $D(1,\theta) = \mathfrak{g} \oplus \mathbb{C}$ factor in its trivial component $\mathbb{C}$, a *free* one an adjoint factor; the *binding energy* $2a+b+1$ is the grading shift of the left map in (26.4). There is no Hamiltonian in this chapter; the words are aids to memory, never part of a proof.

With this dictionary, the fusion product is the operator product expansion made algebraic: m primaries sit at points $z_1, \dots, z_m$ and are brought together; the associated graded space records, energy level by energy level, which descendant states survive the collision. The Demazure module $D(1, n\theta)$ is the space of states of a level-one chiral boson (a lattice vertex algebra) generated by the currents from the vertex operator $e^{n\theta}$. Ravinder's sequence splits these states according to whether one of the particles is bound or not.

26.2.5 The squeeze

Suppose we have power series $M_{a,b}(q)$ with nonnegative coefficients satisfying

(R) $M_{a+1,b} \le M_{a,b+1} + q^{2a+b+1}M_{a,b}$ coefficientwise (the *spanning half* of (26.4));

(D) $\mathcal{D}_n \le M_{n,0}$ coefficientwise (a Demazure *lower* bound);

(T) $\sum_d [q^d]M_{0,m} \le (\dim \mathfrak{g})^m$ (the *total* upper bound).

Then $M_{0,m} = \mathcal{F}_m$ for every m, where $\mathcal{F}$ is the solution of (26.5). Indeed, iterating (R) gives $M_{n,0} \le \sum_d q^{dn}\begin{bmatrix} n \\ d \end{bmatrix}_q M_{0,n-d}$; by induction on n all terms with $d \ge 1$ equal the corresponding terms of (26.5); with (D) this leaves $\mathcal{F}_n \le M_{0,n}$ coefficientwise. Both sides have total $(\dim \mathfrak{g})^n$ at $q = 1$ (the left side by the count, the right side by (T)), and an inequality between series with nonnegative differences and equal sums is an equality. This argument is Ravinder's Cor. 1; the library formalizes it for every type. Applied to the characters of *universal* modules (Section 26.6), it yields U5 for $\mathcal{F}$.

26.2.6 Where this chapter enters the Deligne chain

In the chain of Chapter 24, Theorem 24.33 (freeness of M_m) and Theorem 24.35 (the sector fusion bound) consume U5 as `FusionModuleBoundG S F`, and the resummation D3 (Theorem 24.24) consumes U6 as `MixedFusionRecursion F Dem`. The present chapter produces, for each type, a family `F`

and proofs of these two structures from smaller inputs:

$$\underbrace{\text{U6}}_{\text{by construction}}\ ,\qquad \underbrace{\text{U5}}_{\text{squeeze}} \Longleftarrow \underbrace{\text{kernel lemma}}_{\text{proved}} + \underbrace{\text{U7}}_{A_2\text{: proved}} + \underbrace{\text{finiteness}}_{\text{proved}} + \underbrace{\dim \le (\dim \mathfrak{g})^m}_{A_2\text{: proved; others named}} + \underbrace{\text{count}}_{\text{Chapter 25}}\ .$$

The final per-type theorems that assemble these with the carrier and character sides are in Chapter 27.

Trap / dead end

The literature behind the total bound, and its gap. The dimension half of the total bound, $\dim F_m \le (\dim \mathfrak{g})^m$, is the statement `FusionTotalDim` for A_2 and `FusionTotalDimG` for the other types. The standard citation is Feigin, *The PBW filtration*, SIGMA 4 (2008) 070, arXiv:0806.4851, Cor. 2 (Prop. 2.1 and Cor. 2.2 in arXiv v1), which Ravinder cites for the terminal case of his sequence. For A_2, Feigin's Prop. 1, on which Cor. 2 rests, is a sketch whose natural reading is false (Section 26.11). Kus and Littelmann (Pacific J. Math. 278 (2015), Thm. 3.5, Cor. 3.6(3), Thm. 4.2) acknowledge Feigin's gap and repair it, for every simple $\mathfrak{g}$ (with $\lambda = \theta$, $\lambda_0 = 0$ their Thm. 4.2 has no type restriction), and Setia–Rani–Khandai (arXiv:2405.11944, §8) give an independent upper-bound route through Chari–Venkatesh modules. One passage of the Kus–Littelmann proof (transfer of the annihilator ideal to the associated graded, p. 437) needs further justification before it can be formalized; this is not a counterexample. For D_4 at $m = 2$ a computation (not Lean) shows that the passage as written is insufficient, with an explicit witness, while the statement it is meant to prove holds there (Chapter 27, Section 27.7.1); the theorem is not known to fail. In Lean the statement is *proved for* A_2 (`CVUniv.fusionTotalDim`, Theorem 26.30), along the Setia–Rani–Khandai route and without Feigin's Prop. 1; it is a named, unproved hypothesis for G_2, D_4, F_4, E_6, E_7, E_8. For these six types the published proof is Kus–Littelmann's Thm. 4.2, and the flagged p. 437 step applies to them equally, since the specialization is the same (Chapter 27, Table 27.3).

26.3 The A_2 fusion modules in Lean

Throughout the A_2 sections the Lie algebra is $\mathfrak{sl}_3$ in the basis of `AffineSl3.bracketTable`: indices $0, 1, 2$ are e_1, e_2, e_θ, indices $3, 4, 5$ are f_1, f_2, f_θ, and $6, 7$ are h_1, h_2; $\theta = \alpha_1 + \alpha_2$ and $\theta(h_1) = \theta(h_2) = 1$. A `CurrentModule (bracketTable) V` is a family of linear maps `ρ.op c r` $= x_c(r)$ on V satisfying the current-algebra bracket, `wordOp ρ l w` applies a loop word (last letter first), and `cycDeg ρ w d` is $\mathrm{cyc}(w)_d$ (Chapter 24, Definition 24.29, where these are quoted).

Definition 26.6 (The A_2 relations and two named statements)**.** Let ρ be a current module and $w \in V$.

(a) w satisfies the *relations of* $M_{a,b}$ if, with $k = a + b$: $e_c(r)w = 0$ for $c = e_1, e_2, e_\theta$ and all r; $h(r)w = 0$ for $r \ge 1$ and $h(0)w = k\,w$ for $h = h_1, h_2$; $f_1(0)^{k+1}w = f_2(0)^{k+1}w = 0$; $f_1(k)w = f_2(k)w = 0$; and $f_\theta(2a + b)w = 0$.

(b) **(TB)**, the *total bound* `FusionTotalBound`: for every m and every module with the local Weyl and fusion relations for $m\theta$, every $\mathrm{cyc}(w)_d$ is finite-dimensional and $\sum_{d<B} \dim \mathrm{cyc}(w)_d \le 8^m$ for every B.

(c) **(KL)**, the *kernel relation* `RavinderKernelRel`: for $a \ge 1$, if w satisfies the relations of $M_{a,b}$, then $f_\theta(2a + b - 1)w$ satisfies those of $M_{a-1,b}$.

```

From the mathematics to the Lean statement

Decoding. `(ρ.op 3 0)^[k] w` is the k-fold iterate of $f_1(0)$ applied to w. The Cartan fields say $h_i(0)w = (a+b)w$, i.e. w has weight $(a+b)\theta$, since $\theta(h_i) = 1$. The truncations `trunc_f1`, `trunc_f2`, `trunc_theta` are $f_1(k)w = f_2(k)w = 0$ and $f_\theta(2a+b)w = 0$. These are exactly the relations (26.3): for $\mathfrak{sl}_3$ the positive roots are $\alpha_1, \alpha_2, \theta$, all "fusion roots". `mabRel_zero_iff` (same file) proves `MabRel ρ w 0 m ↔ LocalWeylRel ρ w m`, so $M_{0,m}$ is the fusion module (26.2).

Index conventions. In `RavinderKernelRel` the indices are shifted by one relative to (26.4): with $a \geq 1$ it maps $M_{a,b}$ to $M_{a-1,b}$ via $f_\theta(2(a-1)+b+1) = f_\theta(2a+b-1)$. The natural subtraction `2 * a + b - 1` and `a - 1` are honest because of the hypothesis `1 ≤ a`.

The finiteness clause in `FusionTotalBound`. `Module.finrank` of an infinite-dimensional space is 0 in Mathlib, so a bare dimension inequality would say nothing about a module with an infinite-dimensional degree piece. The clause `FiniteDimensional ℂ (cycDeg ρ w b)` closes that loophole. It is proved below (Theorem 26.7), so the only content left is the dimension sum.

How it could be vacuous, and why it is not. `FusionTotalBound` quantifies over *all* modules satisfying the relations, including the universal one (Section 26.6), so it is a genuine upper bound on $\dim F_m$; it is not satisfied trivially. `RavinderKernelRel` could be vacuous only if no module satisfied `MabRel` with a nonzero vector. The zero action does *not* provide one: `cartan_zero` then reads $0 = (a+b)w$, which forces $w = 0$ because $a \geq 1$. The lattice module (`latRep_mabRel`, Theorem 26.25) covers only $(a,b) = (N,0)$. The witness for every (a,b) is the universal module: `univ_mabRel` (Definition 26.13) proves `MabRel (univRep a b) (wU a b) a b`. That $w_U \neq 0$ is not stated in Lean; on paper it holds because $U_{a,b}$ maps onto the irreducible $\mathfrak{sl}_3$-module $V((a+b)\theta)$ with $x(r)$ acting by 0 for $r \geq 1$, whose highest-weight vector satisfies every relation of `MabRel` (all truncations have positive mode index when $a+b \geq 1$).

Physical meaning

(Heuristic, in the dictionary of Section 26.2.4.) w is a highest-weight state of weight $(a+b)\theta$, the state of $a+b$ particles fused together; the truncations say that the modes $f_\alpha(k)$ above a threshold annihilate it. The threshold for f_θ distinguishes the a factors that carry the Demazure module $D(1,\theta) = \mathfrak{g} \oplus \mathbb{C}$ (two units of degree for f_θ) from the b factors in the adjoint representation (one unit).

What the machine verified

Definitions. (TB) is reduced to `FusionTotalDim` (Theorem 26.7); its literature sources are Feigin's Cor. 2 (with a gap) and Kus–Littelmann's Thm. 4.2 (with one step flagged by the project); Ravinder's Cor. 2 at $a = 0$ quotes Feigin. (KL) is a theorem (Theorem 26.17).

Theorem 26.7 (Finiteness clause for $\mathfrak{sl}_3$). *If w satisfies the local Weyl and fusion relations for $m\theta$, then every* $\mathrm{cyc}(w)_b$ *is finite-dimensional. Consequently* `FusionTotalBound` *is equivalent to its dimension part* `FusionTotalDim`*: for every module with these relations and every B, $\sum_{b<B} \dim \mathrm{cyc}(w)_b \le 8^m$.*

File `VOA/DeligneAudit/DeligneFusionFinite.lean`.

```
theorem cycDeg_finiteDimensional {w : V} {m : ℕ} (hW : LocalWeylRel ρ w m) (b : ℕ) :

     ↪  ^ m

theorem fusionTotalBound_of_dim (h : FusionTotalDim) : FusionTotalBound :=
```

From the mathematics to the Lean statement

In `cycDeg_finiteDimensional` the module V and the action `ρ : CurrentModule (bracketTable) V` are section variables (`variable {V : Type} ... {ρ : ...}` at the head of the section `Fin`); they are universally quantified, with no further hypothesis. `FusionTotalDim` is the bare dimension statement; the theorem `fusionTotalBound_of_dim` supplies the finiteness half. The converse is trivial, so the two named statements are equivalent. The bound is total (summed over all $b < B$, for every B), not graded.

Proof on paper. (1) *PBW sorting.* Call $e_1, e_2, e_\theta, h_1, h_2$ (at any grade) the *non-lowering* letters. Take a word applied to w and look at its rightmost non-lowering letter $y(r)$, the one that acts first among them. Using $y(r)x(s) = x(s)y(r) + [y, x](r+s)$, move it to the right past the lowering letters that act before it, until it reaches w; there it kills w or multiplies it by a scalar. Each commutator term is a word of the same degree with one fewer letter. Induction on length (and on the number of non-lowering letters) shows: *every* $\mathrm{cyc}(w)_b$ *is spanned by words in the lowering letters $f_1(r), f_2(r), f_\theta(r)$ only*, and, sorting further, by such words in a fixed order with the grade-zero letters acting first. (2) *Local nilpotency.* Each $f_\alpha(0)$ satisfies $(\mathrm{ad}\, f_\alpha(0))^3 = 0$ on every letter (`ad_cube`: the root strings of $\mathfrak{sl}_3$ have length at most three), and $f_\alpha(0)^{2m+1} w = 0$ for each negative root (for f_θ via the Heisenberg lemma of Section 26.7). Kac's lemma (stated and proved as Theorem 26.39(1) below: if $(\mathrm{ad}\, A)^K B = 0$ and $A^N u = 0$ then $A^{N+K} B u = 0$) then shows that $f_\alpha(0)^{2\ell+2m+1}$ kills any word of length ℓ applied to w. (3) *Length bound.* A non-vanishing sorted word of degree b has at most b letters of positive grade, and between them runs of grade-zero letters whose length is bounded by (2); hence its length is bounded by an explicit number $G(m, b)$ (Lean: `Gr m b 8`, a closed-form function of m, b and the alphabet size 8). (4) There are finitely many words of bounded length with letters of grade $\le b$ in an alphabet of eight letters, so $\mathrm{cyc}(w)_b$ lies in a finite span. □

Physical meaning

(Heuristic.) In a fusion of m adjoint particles there are only finitely many states at each energy: the zero modes act as a finite-dimensional representation of $\mathfrak{g}$ (integrability), and each excitation costs energy.

What the machine verified

`cycDeg_finiteDimensional` and `fusionTotalBound_of_dim`: proved, `#print axioms` = `[propext, Classical.choice, Quot.sound]` (re-run, Section 26.18). `FusionTotalDim`: a named `Prop` here; it is proved as `CVUniv.fusionTotalDim` (Theorem 26.30).

26.4 U6 by construction: the fusion characters

Definition 26.8 (The fusion characters as the inverse of the mixed recursion)**.** For any sequence of power series Dem_n define recursively

$$\mathrm{fusionOf}(\mathrm{Dem})_n = \mathrm{Dem}_n - \sum_{d=1}^{n} q^{dn} \begin{bmatrix} n \\ d \end{bmatrix}_q \mathrm{fusionOf}(\mathrm{Dem})_{n-d}.$$

For A_2, fusionF = fusionOf($\mathcal{D}$) with $\mathcal{D}_n$ the Gelfand–Tsetlin polynomial `demazureHilbSeries n`.

File `VOA/DeligneAudit/D4FusionF.lean`.

```
def fusionOf (Dem : ℕ → PowerSeries ℚ) : ℕ → PowerSeries ℚ
  | n => Dem n -
      ∑ d : Fin n, X ^ ((d.1 + 1) * n) * qbinom (X : PowerSeries ℚ) n (d.1 + 1) *
        fusionOf Dem (n - (d.1 + 1))
decreasing_by omega

theorem mixedFusionRecursion_fusionOf (Dem : ℕ → PowerSeries ℚ) :
    MixedFusionRecursion (fusionOf Dem) Dem := by

theorem fusionOf_unique {F Dem : ℕ → PowerSeries ℚ} (h : MixedFusionRecursion F Dem) (n :
↪  ℕ) :
    F n = fusionOf Dem n := by
```

File `VOA/DeligneAudit/DeligneFusionInverse.lean`.

```
def fusionF : ℕ → PowerSeries ℚ
  | n => demazureHilbSeries n -
      ∑ d : Fin n, X ^ ((d.1 + 1) * n) * qbinom (X : PowerSeries ℚ) n (d.1 + 1) * fusionF
↪  (n - (d.1 + 1))
decreasing_by omega

theorem mixedFusionRecursion_fusionF : MixedFusionRecursion fusionF demazureHilbSeries :=
↪  by
```

From the mathematics to the Lean statement

`X` is the formal variable q; `qbinom (X : PowerSeries ℚ) n k` is the Gaussian binomial $\begin{bmatrix} n \\ k \end{bmatrix}_q$; the sum over `d : Fin n` with `d.1 + 1` runs over $d = 1, \dots, n$, so the $d = 0$ term (which is $\mathrm{fusionOf}_n$ itself) is moved to the left. `decreasing_by omega` is Lean's termination proof.`MixedFusionRecursion F Dem` (Definition 24.22) says $\mathrm{Dem}_n = \mathrm{mixed}(F)_{n,0}$, where $\mathrm{mixed}(F)_{0,b} = F_b$ and $\mathrm{mixed}(F)_{a+1,b} = \mathrm{mixed}(F)_{a,b+1} + q^{2a+b+1}\mathrm{mixed}(F)_{a,b}$; the library's lemma `mixed_eq` (`GaussianTransform.lean`, Chapter 24) evaluates this as $\sum_d q^{dn}\begin{bmatrix} n \\ d \end{bmatrix}_q F_{n-d}$, which is (26.5).

What "U6 by construction" does and does not say. `mixedFusionRecursion_fusionOf` is true for any `Dem` whatsoever; it carries no information about fusion products. The mathematical content of Ravinder's Cor. 1, "the true graded character of F_m satisfies (26.5)", is recovered only when U5 is proved for `fusionOf Dem` (Theorem 26.12): then $\mathrm{ch}\, F_m \le \mathrm{fusionOf}(\mathrm{Dem})_m$,

and the squeeze gives equality. By `fusionOf_unique`, nothing is lost by choosing this F: any F that satisfies U6 is `fusionOf Dem`.

Trap / dead end

Reading the fusion characters. `fusionF` and `fusionOf Dem` are defined by inverting the mixed recursion. The docstring statement that `fusionF m` *is* Ravinder's f_m (the graded character of $V(\theta)^{*m}$) is a literature claim plus numerics ($m \le 5$), not a Lean fact. In Lean the identification follows only once U5 is proved, by the squeeze. Do not take `mixedFusionRecursion_fusionOf` as evidence about fusion products.

Example 26.9 ($\mathfrak{sl}_3$, $n \le 2$). $\mathrm{fusionF}_0 = \mathcal{D}_0 = 1$; $\mathrm{fusionF}_1 = \mathcal{D}_1 - q\begin{bmatrix}1\\1\end{bmatrix}_q \mathrm{fusionF}_0 = 8 + q - q = 8$; $\mathrm{fusionF}_2 = \mathcal{D}_2 - q^2(1+q)\cdot 8 - q^4 = 27 + 28q + 9q^2$. At $q = 1$ these are $1, 8, 64$.

Proof on paper. Expanding $\mathrm{mixed}(F)_{n,0}$ by `mixed_eq` and splitting off the $d = 0$ term gives $F_n + \sum_{d\ge 1} q^{dn}\begin{bmatrix}n\\d\end{bmatrix}_q F_{n-d}$; with $F = \mathrm{fusionOf(Dem)}$ this is Dem_n by definition. Uniqueness: if two sequences satisfy the recursion, their difference δ satisfies $\delta_n = -\sum_{d\ge 1}(\dots)\delta_{n-d}$ and $\delta_0 = 0$, so $\delta = 0$ by strong induction. □

Physical meaning

(Heuristic.) A "bootstrap" of the partition functions: once the degree-graded counts of the Demazure states are known, the recursion determines the counts of the fusion states uniquely. It is the generating-function form of the statement that states with n particles decompose into d bound particles and $n - d$ free ones.

What the machine verified

Proved; standard axioms for `mixedFusionRecursion_fusionOf` (re-run) and `mixedFusionRecursion_fusionF` (record). The per-type series are `fusionF` (A_2), `d4FusionF`, `g2FusionF`, `fusionOf (hilbSeries e8DemazureHilb)`, etc.

Theorem 26.10 (A_2 classical freeness from U5 alone). *Let $W = L_{-3/2}(\mathfrak{sl}_3)$ with its explicit presentation (Chapter 24). If* `SectorWeyl.FusionModuleBound fusionF` *holds, then W is classically free for the presentation and the kernel of the current-coordinate map equals (I_2^{ns}).*

File `VOA/DeligneAudit/DeligneFusionInverse.lean`.

```
theorem classicallyFree_of_fusionBound (hU5 : SectorWeyl.FusionModuleBound fusionF) :
    CaseClassicallyFree .A2 W explicitPresentation ∧
      RingHom.ker (MvPolynomial.aeval fun i =>
        liDegreeZeroClass W 1 ⟨explicitPresentation.gen i,
          explicitPresentation.gen_weight_one i⟩).toRingHom = I2ns :=
```

From the mathematics to the Lean statement

`CaseClassicallyFree .A2 W explicitPresentation` and the kernel identity are the conclusion of the capstone of Chapter 24 (Definition 24.2 and Theorem 24.7); `I2ns` is the ideal of the eight quadrics. The proof is `classicallyFree_of_fusion fusionF hU5 mixedFusionRecursion_fusionF`, i.e. the A_2 chain of Chapter 24 with U6 discharged. The only hypothesis is U5 for the explicit series `fusionF`.

Proof on paper. The chain of Chapter 24 (Theorem 24.41 and the A_2 capstone) takes U5 and U6 for a family F; U6 for $F = \mathrm{fusionF}$ is Definition 26.8. □

Physical meaning

$L_{-3/2}(\mathfrak{sl}_3)$ is, by the four-dimensional/two-dimensional correspondence of Beem et al. (a physics input, arXiv:1312.5344), the chiral algebra of the Argyres–Douglas theory H_2. Its classical freeness follows once the multi-particle fusion spaces are known to have the expected size.

What the machine verified

Standard axioms (record), **conditional on** `SectorWeyl.FusionModuleBound fusionF`. The rest of the chapter reduces that hypothesis.

26.5 The squeeze

Definition 26.11 (The squeeze inputs and U7). (a) For $f, g \in \mathbb{Q}[[q]]$ write $f \preceq g$ (*coefficientwise order*) if $[q^N]f \le [q^N]g$ for all N.

(b) A family $M_{a,b} \in \mathbb{Q}[[q]]$ satisfies the *squeeze inputs* if (nonneg) its coefficients are ≥ 0; (R) $M_{a+1,b} \le M_{a,b+1} + q^{2a+b+1}M_{a,b}$; (D) $\mathcal{D}_n \le M_{n,0}$; (T) $\sum_{N<B}[q^N]M_{0,m} \le 8^m$ for all m, B. These are the three inequalities of Section 26.2.5.

(c) It satisfies the *universal bound* if every module whose generator satisfies the relations of $M_{a,b}$ has $\dim \mathrm{cyc}(w)_N \le [q^N]M_{a,b}$.

(d) **U7 at** n (`DemazureRealization n`): there is a current module and a vector w satisfying the relations of $M_{n,0}$ with $\dim \mathrm{cyc}(w)_N \ge [q^N]\mathcal{D}_n$ for every N.

```

From the mathematics to the Lean statement

`coeff N` is the q^N-coefficient. In `FusionSqueezeInputs` the field `dem_le` uses `demazureHilbSeries n`, the Gelfand–Tsetlin polynomial of Chapter 25 viewed as a power series; that it equals $\mathrm{Hilb}_q D(1, n\theta)$ is a literature identification (Sanderson, Ion)

checked numerically, not a Lean fact, but nothing below needs it: what is used is only the inequality (D) for that polynomial. `total_le` sums over $N < B$ for every B, i.e. it bounds the total. Its docstring label "F4" is the project's name for the total bound, (TB) in this chapter; it has nothing to do with the Lie type F_4.

The `finrank` convention in `MabUniversalBound`. As for `FusionTotalBound` (Definition 26.6), `Module.finrank` is 0 on an infinite-dimensional space, so `MabUniversalBound` alone says nothing about a module with an infinite-dimensional degree piece. Where the squeeze uses it as a genuine bound, finiteness of the universal pieces is supplied separately by `univ_fd` (Theorem 26.15); the universal property then bounds every model by the universal one. In `DemazureRealization`, `demazureHilb n N : ℕ` is the q^N-coefficient of the Gelfand–Tsetlin polynomial `gl3Hilb (2 * n) n 0` of Chapter 25, i.e. of `demazureHilbSeries n`; it is a lower bound on `finrank`, so a model with an infinite-dimensional piece (where `finrank` is 0) cannot satisfy it vacuously unless `demazureHilb n N` $= 0$.

`DemazureRealization n` asks for *some* model, with a lower bound in every degree. It is an existence statement, so it is not vacuous in either direction: it would fail if no module with the $M_{n,0}$ relations were that large. The universal bound turns it into (D) (Theorem 26.12).

A stale docstring. The docstring of `DemazureRealization` says that neither the presentation of $D(1, n\theta)$ nor its character "is formalized". That is accurate, but it suggests the `Prop` is open; in fact `EvalModel.demazureRealization_all` (Theorem 26.24) proves `DemazureRealization N` for every N without either fact.

Physical meaning

(Heuristic.) (R) is the "at most" half of the particle decomposition; (D) says there are at least as many states as in the level-one Demazure space of a chiral boson; (T) caps the number of states of m fused adjoint particles at the number of states of m free ones. The universal bound expresses that the module defined by generators and relations is the largest Hilbert space compatible with those null vectors.

What the machine verified

Definitions. `FusionSqueezeInputs` and `MabUniversalBound` are structures of hypotheses, discharged below for the universal characters `Mchar`; `DemazureRealization n` is proved for all n (Theorem 26.24).

Theorem 26.12 (Ravinder's squeeze; U5 from the squeeze). *If M satisfies the squeeze inputs, then $M_{0,m} =$ fusionF$_m$ for every m, and* fusionF *has nonnegative coefficients. If moreover every module with the local Weyl and fusion relations for $m\theta$ is bounded degreewise by $M_{0,m}$, then U5 holds for* fusionF. *Finally U5 for* fusionF *follows from the universal bound, U7 for all n, (nonneg), (R) and (T).*

From the mathematics to the Lean statement

`M : ℕ → ℕ → PowerSeries ℚ` is a section variable (`variable {M : ...}`) in both files: it is universally quantified, and the hypotheses on it are exactly those printed. The conclusion of `squeeze` is an equality of power series, i.e. equality in every degree. `FusionModuleBound fusionF` is the A_2 form of U5 (Definition 24.29): a graded bound `le` and a total bound `total`. The hypothesis `huniv` of `fusionModuleBound_of_squeeze` says every module with `LocalWeylRel ρ w m` is bounded by $M_{0,m}$ in every degree; it is the universal bound at $a = 0$ (`huniv_of_universalBound`, same file).

Proof on paper. Section 26.2.5 gives the argument; we add the two points the Lean proof must handle. First, `le_mixed`: iterating (R) gives $M_{a,b} \le \mathrm{mixed}(M_{0,\cdot})_{a,b}$, by induction on a, using that $\le$ is preserved by sums and by multiplication with q^k (both because the comparison is coefficientwise and q^k only shifts). Second, the passage from "$\mathrm{fusionF}_n \le M_{0,n}$ coefficientwise and equal totals" to equality: choose B beyond the (finite) support of $\mathrm{fusionF}_n$ and beyond the degree N of interest; then $\sum_{k<B}([q^k]M_{0,n} - [q^k]\mathrm{fusionF}_n) \le 8^n - 8^n = 0$ with nonnegative summands, so every summand vanishes. The totals of $\mathrm{fusionF}_n$ are 8^n by `fusionF_sum` (from `fusionPoly_eval_one`: the polynomial version evaluated at $q = 1$ inverts $9^n = \sum_d \binom{n}{d} 8^{n-d}$). For U5: the graded half is $\dim \mathrm{cyc}(w)_b \le [q^b]M_{0,m} = [q^b]\mathrm{fusionF}_m$; the total half sums this and uses nonnegativity of fusionF to extend the range of summation. □

Physical meaning

(Heuristic.) A pure counting argument about a partition function: a degree-by-degree upper bound on the space of states, a degree-by-degree lower bound on the Demazure side, and a bound on the total number of states together determine the partition function exactly. No dynamics enters.

What the machine verified

Proved; standard axioms (`squeeze` re-run; the others record). No hypothesis beyond those printed.

26.6 Universal modules and the exact-sequence step

Definition 26.13 (The universal modules $U_{a,b}$ and their characters)**.** Let FreeW be the vector space with basis the loop words (lists of letters $(c, r) \in \{0, \dots, 7\} \times \mathbb{N}$). Let $J_{a,b} \subseteq$ FreeW be spanned by: all *commutation instances* $p\,xy\,s - p\,yx\,s - \sum_e f(x,y,e)\,p\,(e, r_x + r_y)\,s$ (for prefixes p, suffixes s); all words $p\,t$ with t a relation tail of $M_{a,b}$ (a single raising letter, a positive-grade Cartan letter, $f_i(0)^{a+b+1}$, $f_1(a+b)$, $f_2(a+b)$, $f_\theta(2a+b)$); and all $p\,h(0) - (a+b)\,p$. Then $U_{a,b} = \mathrm{FreeW}/J_{a,b}$, with $x_c(r)$ acting by prepending the letter, and generator $w_U =$ [empty word]. Its character is $M^{\mathrm{univ}}_{a,b}(q) = \sum_N \dim \mathrm{cyc}(w_U)_N\, q^N$ (`Mchar a b`).

File `VOA/DeligneAudit/DeligneFusionUniv.lean`.

```

```
theorem univ_mabRel (a b : ℕ) : MabRel (univRep a b) (wU a b) a b where
```

From the mathematics to the Lean statement

`List Ltr →₀ ℂ` is the space of finitely supported functions on words, i.e. formal linear combinations. `sw l` is the basis vector of the word `l`; words are read with the head acting last, so prepending a letter is applying an operator. `relTail` lists exactly the tails of `MabRel` (the indices $e < 3$ are the raising letters, $h \geq 6$ the Cartan letters). `univRep` is a `CurrentModule`; its `comm` field is proved from the commutation instances with empty prefix (the proof body, elided here, is the only place where the quotient is used). `univ_mabRel` (statement line quoted; the proof follows in `where` form) says the generator satisfies `MabRel`. The universal property (`univMap`, `finrank_cycDeg_le_univ`, same file) is: every module with `MabRel ρ w a b` receives a linear map from $U_{a,b}$ sending $[l]$ to `wordOp ρ l w`, so $\mathrm{cyc}(w)_N$ is the image of $\mathrm{cyc}(w_U)_N$.
Why this construction and not an enveloping algebra. The library has no $U(\mathfrak{g}[t])$; the free space on words modulo prefixed relations is the cyclic module presented by generators and relations, built directly.

Physical meaning

(Heuristic.) $U_{a,b}$ is the "Verma-like" space: all states that can be created by current modes from a state obeying only the stated null-vector conditions. Every physical realization is a quotient of it.

What the machine verified

Definitions; `univRep`, `univ_mabRel`, `finrank_cycDeg_le_univ`: `#print axioms` standard (record).

Theorem 26.14 (The exact-sequence step: quotient and rank–nullity). *(i) If w satisfies the relations of $M_{a+1,b}$ and S is an invariant subspace containing $f_\theta(2a+b+1)w$, then the image of w in V/S satisfies the relations of $M_{a,b+1}$. (ii) Assume the kernel relation (KL). Then for every degree N, with $s = 2a+b+1$,*

$$\dim \mathrm{cyc}_{U_{a+1,b}}(w_U)_N \;\le\; \dim \mathrm{cyc}_{U_{a,b+1}}(w_U)_N + [s \le N]\, \dim \mathrm{cyc}_{U_{a,b}}(w_U)_{N-s},$$

provided the two right-hand pieces are finite-dimensional, and then the left piece is finite-dimensional too.

      ↪ by
```

From the mathematics to the Lean statement

In `mabRel_quot` the section variables are `ρ`, a submodule `S` and `hS : ∀ c r, S ≤ S.comap (ρ.op c r)` (invariance under every current operator); `quotRep ρ S hS` is the induced current module on V/S and `S.mkQ` the quotient map. In `fd_step` and `finrank_step`, `a b` are section variables (`variable (a b : ℕ)`), and the bracketed `[FiniteDimensional ...]` are instance hypotheses: finite-dimensionality of the two right-hand pieces. The "if" encodes $[s \le N]$; `N - (2 * a + b + 1)` is natural subtraction, harmless because it is used only under $s \le N$.

Which half of Ravinder's sequence. This is the *spanning* (upper bound) half: the kernel of $U_{a+1,b} \to U_{a,b+1}$ is the cyclic module of v_K, and that module is a quotient of $U_{a,b}$ shifted by s. The injectivity of $\tau_s M_{a,b} \to M_{a+1,b}$ is not claimed and not needed.

Proof on paper. (i) All relations of $M_{a,b+1}$ except $f_\theta(2a+b+1)w = 0$ are among those of $M_{a+1,b}$ (same $k = a+b+1$, same raising, Cartan, lowering and f_1, f_2 truncations); the remaining one holds in V/S because $f_\theta(2a+b+1)w \in S$. (ii) Let S_K be the cyclic submodule of $U_{a+1,b}$ generated by v_K. By (i) the quotient $U_{a+1,b}/S_K$ is a module with the $M_{a,b+1}$ relations, hence (universal property) a quotient of $U_{a,b+1}$, degree by degree. By (KL), v_K satisfies the $M_{a,b}$ relations, so S_K is the image of $U_{a,b}$ under $[l] \mapsto l v_K$, which raises degrees by s; hence the degree-N piece of the cyclic module of w_U intersected with S_K is the image of $\mathrm{cyc}_{U_{a,b}}(w_U)_{N-s}$ (using a degree projection on $U_{a+1,b}$, `projU`, which exists because all relations are homogeneous). Rank–nullity for the quotient map restricted to $\mathrm{cyc}(w_U)_N$ gives the inequality. □

Physical meaning

(Heuristic mnemonic.) States of $a+1$ Demazure particles and b adjoint ones are at most those in which one Demazure particle has been replaced by an adjoint one, plus a copy of the smaller system shifted up by the "binding energy" $2a+b+1$, which is the grading shift of (26.4).

What the machine verified

Proved, standard axioms (record). Hypothesis of (ii): `RavinderKernelRel`, which is a theorem (Theorem 26.17).

Theorem 26.15 (The A_2 assembly). *(1)* Structural statements. *Assume (TB) and (KL). Then all degree pieces of all $U_{a,b}$ are finite-dimensional; if moreover U7 holds for every n, the universal characters* `Mchar` *satisfy the squeeze inputs. (2)* Corollary. *If* `FusionTotalDim` *holds and U7 holds for every n, then $L_{-3/2}(\mathfrak{sl}_3)$ is classically free with kernel (I_2^{ns}). ((KL) is a theorem, Section 26.7, and (TB) follows from* `FusionTotalDim` *by Theorem 26.7, so neither appears as a hypothesis of (2).)*

File `VOA/DeligneAudit/DeligneFusionAssembly.lean`.

          explicitPresentation.gen_weight_one i⟩).toRingHom = I2ns :=
```

From the mathematics to the Lean statement

`univ_fd` is by induction on a: at $a=0$ finiteness is the first half of `FusionTotalBound`, applied to the universal module (whose generator satisfies `LocalWeylRel` by `univ_mabRel` and `mabRel_zero_iff`); the step is `fd_step`. In `fusionSqueezeInputs_Mchar`: `nonneg` is free (dimensions); `rec_le` is `finrank_step`; `dem_le` is `dem_le_of_realization`; `total_le` is the second half of `FusionTotalBound` for the universal module. In the two `classicallyFree` theorems, the kernel lemma has disappeared from the hypotheses because `ravinderKernelTrunc` is a theorem (next section), and the finiteness clause because of Theorem 26.7. The file's docstring still lists `RavinderKernelTrunc` as a named input; that is out of date (see Section 26.19).

Proof on paper. Combine Theorems 26.14, 26.12 and 26.10. □

Physical meaning

(Heuristic.) The A_2 chiral algebra's classical freeness rests on one counting statement about fused adjoint particles and one statement about the Demazure space, the latter proved in Section 26.8.

What the machine verified

Standard axioms (record), **conditional on** `FusionTotalDim` and `∀ n, DemazureRealization n` as stated. Both are now theorems: the second is discharged in `classicallyFree_of_totalDim'` (Theorem 26.28) and the first by `CVUniv.fusionTotalDim` (Theorem 26.30); the composite is the unconditional theorem of Chapter 27.

26.7 Garland's identities and Ravinder's kernel lemma for A_2

The kernel lemma needs three truncations of the kernel vector $v_K = f_\theta(2a+b-1)w$. Their source is a classical identity of Garland, in the form used by Chari–Pressley: in an $\hat{\mathfrak{sl}}_2[t]$-module, if w is killed by $e(1)$ and by $h(r)$, $r \geq 1$, and $f(0)^N w = 0$, then $[u^s]f(u)^r\, w = 0$ whenever $r \geq 1$ and $r + s \geq N$, where $f(u) = \sum_k f(k)u^k$. The library proves this special case, in which every $h(r)$, $r \geq 1$, kills w; it is all that is needed.

Theorem 26.16 (Heisenberg nilpotency; Garland's identity with $P(u) = 1$). *(1) Let X, Y, Z be operators with $[X, Y] = Z$ and Z commuting with X and Y. If $X^{p+1}w = Y^{p+1}w = 0$ then $Z^{2p+1}w = 0$. (2) Let E_1, H_k ($k \geq 1$), F_k ($k \geq 0$) be operators with $[E_1, F_k] = H_{k+1}$, $[H_{m+1}, F_k] = -2F_{m+1+k}$ and $[F_j, F_k] = 0$, and let $E_1 w = 0$, $H_{m+1}w = 0$ for all m. If $F_0^N w = 0$, then for $r \geq 1$ and $r + s \geq N$,*

$$[u^s]\, F(u)^r\, w = \sum_{k_1+\cdots+k_r=s} F_{k_1} \cdots F_{k_r}\, w = 0.$$

From the mathematics to the Lean statement

Hidden section hypotheses. In `heis_nilpotent`, the section variables `hXY : X * Y - Y * X = Z` and `hYZ : Y * Z = Z * Y` are included, so the full statement is `heis_nilpotent hXY hYZ hXZ hX hY`; the printed `hXZ` is the third hypothesis. In `garland` the five hypotheses of the section `Kill` (quoted above) are included: `hEF` ($[E_1, F_k] = H_{k+1}$), `hHF` ($[H_{m+1}, F_k] = -2F_{m+1+k}$), `hFF` ($F$'s commute), `hE` ($E_1 w = 0$), `hH` ($H_{m+1}w = 0$); the call pattern is `garland hEF hHF hFF hE hH r hr hN s hs`. `Fs F` is $F(u) = \sum_k F_k u^k$ as a power series with coefficients

in `Module.End ℂ V` (noncommutative coefficients are fine because the F_k commute among themselves). `coeff s (Fs F ^ r)` is $[u^s]F(u)^r$.
Which identity this is. Garland's general identity allows the $h(k)$, $k \geq 1$, to act on w by arbitrary scalars, which enter through a generating polynomial ("$P(u)$"). We use only the case in which all $h(k)$, $k \geq 1$, kill w ($P = 1$), and only the operator $E_1 = e \otimes t$, not all $e \otimes t^k$. This is weaker than Garland's theorem but sufficient for every module in this chapter, because in all $M_{a,b}$ the generator is killed by $h(k)$, $k \geq 1$.

Proof on paper. (1) One shows by induction $\mathrm{ad}_X^i(Y^{i+r}) = \frac{(i+r)!}{r!} Z^i Y^r$, so $\mathrm{ad}_X^{p'}(Y^{p'}) = p'!\, Z^{p'}$ with $p' = 2p+1$. Expanding $\mathrm{ad}_X^{p'}(Y^{p'})w$ as $\sum_j \pm\binom{p'}{j} X^{p'-j} Y^{p'} X^j w$, it suffices that $Y^{p'} X^j w = 0$ for every j. If $j \geq p+1$ then $X^j w = 0$. If $j \leq p$, commute $Y^{p'}$ past X^j: since Z is central, $Y^{p'}X^j = \sum_{i \leq j} c_i X^{j-i} Z^i Y^{p'-i}$ for constants c_i, and every term kills w because $p' - i \geq 2p+1-p = p+1$ and $Y^{p+1} w = 0$. Hence $p'!\, Z^{p'} w = 0$, i.e. $Z^{2p+1} w = 0$ (Lean: the auxiliary statement `h0` inside `heis_nilpotent`).

(2) Work with power series in u whose coefficients are operators on V, and write $F(u) = \sum_k F_k u^k$, $H(u) = \sum_k H_{k+1} u^k$ and $F'(u) = \sum_k (k+1) F_{k+1} u^k$. The relations say

$$[E_1, F(u)] = H(u), \qquad [H(u), F(u)] = -2 \sum_{m,k} F_{m+k+1} u^{m+k} = -2F'(u), \qquad H(u)w = 0, \qquad E_1 w = 0,$$

and $F(u)$, $F'(u)$ commute. *One step.* $E_1 F(u)^2 w = [E_1, F(u)^2]w = \big(H(u)F(u) + F(u)H(u)\big)w = [H(u), F(u)]w = -2F'(u)w$. *General step.* In the same way $E_1 F(u)^n w = \sum_{i=0}^{n-1} F(u)^i H(u) F(u)^{n-1-i} w$, and $H(u)F(u)^j w = [H(u), F(u)^j]w = -2jF(u)^{j-1}F'(u)w$; summing, $E_1 F(u)^n w = -n(n-1)F(u)^{n-2}F'(u)w$. (Every equation here is an equality of the vectors obtained by applying a series to w, coefficient by coefficient; that is all that "modulo the series killing w" means.) With $n = q+2$ and $F^q F' = (F^{q+1})'/(q+1)$, comparing the coefficients of u^j gives, for $Q(r,j) = [u^j]F(u)^r w$,

$$E_1\, Q(q+2, j) = -(q+2)(j+1)\, Q(q+1, j+1).$$

Iterating s times, $E_1^s\, Q(q+1+s, 0)$ is a nonzero multiple of $Q(q+1, s)$. But $Q(q+1+s, 0) = F_0^{q+1+s} w = 0$ when $q+1+s \geq N$. So $Q(r,s) = 0$ for $r = q+1 \geq 1$ and $r+s \geq N$. □

Physical meaning

$F(u)$ is the generating function of the modes of the current $f(z)$. For the level-one boson, the normally ordered square $f(z)^2$ vanishes: f is the vertex operator $e^{-\alpha}(z)$, $\langle \alpha, \alpha \rangle = 2$, and the operator product $e^{-\alpha}(z)e^{-\alpha}(w)$ has a double zero $(z-w)^2$ at coincident points. The current modes commute (they are bosonic); the vanishing is a property of this operator product, and calling it an "exclusion" is only a mnemonic. Garland's identities are the algebraic shadow of such nilpotency of currents on a highest-weight state.

What the machine verified

Proved; standard axioms (`garland` re-run).

Theorem 26.17 (Ravinder's kernel lemma for $\mathfrak{sl}_3$). *Let w satisfy the relations of $M_{a,b}$. Then $f_\theta(0)^{2(a+b)+1} w = 0$ and $\sum_{i+j=s} f_\theta(i) f_\theta(j) w = 0$ for $s+1 \geq 2(a+b)$. If $a \geq 1$, the kernel vector $v = f_\theta(2a+b-1)w$ satisfies $f_1(a-1+b)v = f_2(a-1+b)v = 0$ and $f_\theta(2(a-1)+b)v = 0$, and therefore all relations of $M_{a-1,b}$.*

 ↪ ravinderKernelTrunc
```

From the mathematics to the Lean statement

In `ftheta_pow` and `theta_garland`, `ρ`, `w`, `a`, `b` are section variables; there are no included hypotheses besides the printed `h : MabRel ρ w a b`. `(ρ.op 5 0) ^ n` is the n-th power in $\mathrm{End}(V)$; `Finset.antidiagonal s` is $\{(i,j) : i+j=s\}$. `RavinderKernelTrunc` is stated as a named `Prop` (its docstring still calls it "named literature input"); `ravinderKernelTrunc` proves it, so `RavinderKernelRel` (Definition 26.6) is a theorem.

Proof on paper. *Integrability of f_θ.* In $\mathfrak{sl}_3$, $[f_1,f_2]=-f_\theta$ and f_θ commutes with f_1,f_2: the three lowering vectors span a Heisenberg algebra. Since $f_1(0)^{k+1}w=f_2(0)^{k+1}w=0$, Theorem 26.16(1) gives $f_\theta(0)^{2k+1}w=0$ with $k=a+b$. *The θ-Garland identity.* Apply Theorem 26.16(2), $r=2$, to the $\mathfrak{sl}_2$-triple $(e_\theta(1),\ h_1+h_2,\ f_\theta)$ with $N=2k+1$: $\sum_{i+j=s} f_\theta(i)f_\theta(j)w=0$ for $s+2\ge 2k+1$. *Extracting single terms.* At $s=2(2a+b)-3$, all terms with an index $\ge 2a+b$ vanish by the truncation $f_\theta(2a+b)w=0$ (and its consequences $f_\theta(j)w=0$ for $j\ge 2a+b$, which follow from $[h_1(1),f_\theta(r)]=-f_\theta(r+1)$); the only surviving pair is $\{2a+b-2,2a+b-1\}$, so $2f_\theta(2a+b-2)f_\theta(2a+b-1)w=0$, which is the f_θ-truncation of v. For f_1: apply $e_2(0)$ to the θ-Garland identity at $s=(a+b-1)+(2a+b-1)$; since $[e_2,f_\theta]$ is a multiple of f_1, each term becomes $f_1(i)f_\theta(j)w+f_\theta(i)f_1(j)w$, and the truncations kill all but $f_1(a+b-1)f_\theta(2a+b-1)w$. Symmetrically for f_2 with $e_1(0)$. The other relations of $M_{a-1,b}$ for v (raising, Cartan, lowering) follow from commutators with f_θ and $\mathfrak{sl}_2$ representation theory (`kernel_raising`, …, `kernel_lowering_f2`). □

Physical meaning

(Heuristic.) The kernel vector is the state in which one Demazure particle has emitted its top f_θ excitation. The lemma says this state behaves exactly like the ground state of the smaller system: it is annihilated by the same set of modes.

What the machine verified

Proved, unconditional; `#print axioms` standard (`ravinderKernelRel` re-run).

26.8 The Demazure side for A_2: Chari–Pressley, Chari–Loktev, Chari–Venkatesh, and U7

The Demazure lower bound (D) needs a module with the $M_{N,0}$ relations whose degree pieces are at least $\mathcal{D}_N$. The library proves this through three classical results about current algebras, formalized here for $\mathfrak{sl}_2$ and $\mathfrak{sl}_3$, and one construction.

26.8.1 Chari–Pressley: box spanning for $\mathfrak{sl}_2$

Theorem 26.18 (Chari–Pressley, Prop. 6.1). *In $R = \mathbb{C}[z_0, z_1, \dots]$ let $Z(u) = \sum_i z_i u^i$, $x(r,s) = [u^s]Z(u)^r$ and $J_m = (x(r,s) : r \geq 1,\ r+s \geq m+1)$. Then every $p \in R$ is a combination of* box monomials *$z_{i_1} \cdots z_{i_\ell}$ with $i_j + \ell \leq m$, plus an element of J_m. Consequently, in every $\mathfrak{sl}_2[t]$-module, if w is killed by $e \otimes t$ and by $h(k)$, $k \geq 1$, and $f(0)^{m+1}w = 0$, then every polynomial in the $f(k)$ applied to w is a combination of box monomials applied to w.*

      ↪ :=
```

From the mathematics to the Lean statement

`R` is `MvPolynomial ℕ ℂ` and `z i` the variable z_i. A monomial is a finitely supported exponent function `f : ℕ →₀ ℕ`; `Finsupp.degree f` is its total degree ℓ, and `BoxP m f` says every index i that occurs satisfies $i + \ell \leq m$. `Bk m k` restricts the number of z_0's to $\leq k$ (used in the induction); `T m m` is box monomials plus J_m, so `box_span` is exactly the first claim. In `weyl_span_box` the section variables are `F : ℕ → Module.End ℂ V` and `hFF` (the F's commute); `evAlg F hFF` is the evaluation $z_i \mapsto F_i$ through the commutative subalgebra they generate. The hypotheses `hEF`, `hHF`, `hE`, `hH` are those of Garland (Theorem 26.16).

The cases $m \leq 2$ by hand. Recall $x(1,s) = z_s$ and $x(2,s) = \sum_{i+j=s} z_i z_j$.

- $m = 0$: J_0 contains every $x(1,s) = z_s$, so $R = \mathbb{C} \cdot 1 + J_0$; the only box monomial is 1.

- $m = 1$: J_1 contains z_s for $s \geq 1$ and $x(2,0) = z_0^2$. Modulo J_1 every monomial is 0 except 1 and z_0; these are the box monomials ($\ell = 1$ requires $i \leq 0$).
- $m = 2$: J_2 contains z_s for $s \geq 2$, $x(2,1) = 2z_0z_1$, $x(2,2) = 2z_0z_2 + z_1^2$ and $x(3,0) = z_0^3$, but *not* $x(2,0) = z_0^2$ ($r + s = 2 < 3$). Modulo J_2: $z_0z_1 \equiv 0$, then $z_1^2 \equiv -2z_0z_2 \equiv 0$, and $z_0^3 \equiv 0$. What survives is 1; z_0, z_1; z_0^2: exactly the box monomials ($\ell = 1$: $i \leq 1$; $\ell = 2$: $i \leq 0$). So $W_{\mathrm{loc}}(2)$ is spanned by four vectors, matching Example 26.1.

Proof on paper. Induction on m, and for fixed m on the number k of factors z_0 in a monomial (the Lean filtration `Bk m k`). *Monomials without z_0.* Such a monomial is $\sigma(p)$ for the shift $\sigma : z_i \mapsto z_{i+1}$. Writing $Z(u) = z_0 + u\,\sigma Z(u)$ gives $\sigma Z(u)^r = u^{-r}(Z(u) - z_0)^r$, hence

$$\sigma x(r,s) = \sum_{j=1}^{r} \binom{r}{j} (-z_0)^{r-j}\, x(j, s+r)$$

(Chari–Pressley Lemma 6.5; the $j = 0$ term vanishes because $s+r \geq 1$). If $x(r,s) \in J_{m-1}$, i.e. $r+s \geq m$, every term has $j+(s+r) \geq m+1$, so $\sigma(J_{m-1}) \subseteq J_m$. By induction p is a combination of box monomials for $m-1$ plus an element of J_{m-1}; applying σ raises every index by one, so box monomials for $m-1$ ($i + \ell \leq m-1$) become box monomials for m, and the error lands in J_m. *Monomials with z_0.* The generator $x(r,s)$ with $s \geq 1$ has the form $r\,z_0^{r-1}z_s +$ (terms with fewer z_0). When a monomial $z_0^k q$ violates the box condition, a suitable $x(r,s) \in J_m$ with this leading term lets one trade z_0^k for terms with fewer factors z_0, which are box monomials modulo J_m by the induction on k (Chari–Pressley Lemma 6.7). The resulting system of binomial identities is triangular; where Chari–Pressley invert a binomial determinant (Lemma 6.6), the library instead shows that a polynomial with too many prescribed roots vanishes. The online text of Chari–Pressley breaks off inside its inductive Claim, so the library's proof is a re-derivation. *The module statement.* Evaluating $z_i \mapsto f(i)$, the generators $x(r,s)$ of J_m become Garland's elements $[u^s]F(u)^r$, which kill w by Theorem 26.16 (with $N = m+1$); so every polynomial in the $f(k)$ applied to w is a combination of box monomials applied to w. □

Physical meaning

(Heuristic.) The $\mathfrak{sl}_2$ local Weyl module is the space of states of m fused spin-$\frac{1}{2}$ particles; the box rule says the ℓ-th excitation can carry at most $m - \ell$ units of degree, an exclusion rule reminiscent of fermionic quasi-particle bases.

What the machine verified

Proved; standard axioms (`box_span` re-run).

26.8.2 Chari–Loktev: spanning for $\mathfrak{sl}_3$

Definition 26.19 (The Chari–Loktev family $\mathfrak{B}_N$). An index is a triple (a,b,c) of weakly increasing lists of naturals; it is *admissible* for N if $\max b \leq N - |b|$, $\max c \leq N - |c|$, $\max a \leq N + |c| - |b| - |a|$ ($|\cdot|$ the length). Its word is $f_1(a)\, f_\theta(b)\, f_2(c)$ (f_2 acting first), of degree $\sum a + \sum b + \sum c$. **CL spanning** at N: in every module with the $M_{N,0}$ relations, $\mathrm{cyc}(w)_d$ is spanned by the words of admissible indices of degree d. **CL count**: the number of admissible indices of degree d equals $[q^d]\mathcal{D}_N$. **CL independence**: the admissible words applied to $e^{N\theta}$ in the lattice vertex algebra V_{A_2} are linearly independent.

```

From the mathematics to the Lean statement

`BoxT B s`: `s` weakly increasing with entries $\le B$; $B \in \mathbb{Z}$, so a negative bound forces `s` empty. In `Adm N (a, b, c)` the components are `i.1`$= a$ (f_1-part), `i.2.1`$= b$ (f_θ-part), `i.2.2`$= c$ (f_2-part). `clWord` maps index $3, 5, 4$ to f_1, f_θ, f_2; `wordOp` applies the last letter first, so f_2 acts first. `Set.ncard` is the cardinality of a finite set, and 0 on an infinite one; `CLCount` is meaningful because `CLIdx N d` is finite: `BoxT` with a negative bound forces the list to be empty, so an admissible index has $|b|, |c| \le N$ and $|a| \le N + |c|$, and every entry is bounded by $N + |c| \le 2N$; finitely many weakly increasing lists remain. `latRep` and `ch N N` $= e^{N\theta}$ are from Theorem 26.25. This is Chari–Loktev's set (2.6) at rank $r = 2$, $\lambda = N(\omega_1 + \omega_2)$. Its total size is $\sum_{\ell,\ell'} \binom{N}{\ell}\binom{N}{\ell'} 2^{N+\ell'-\ell} = 9^N$.

Physical meaning

(Heuristic.) A Gelfand–Tsetlin "quasi-particle" basis: the f_2, f_θ, f_1 excitations are added in that order, each with an exclusion rule on its energy depending on how many of the others are present.

What the machine verified

Definitions. `CLCount` and `CLSpanning` are proved for all N (next theorem). `CLIndependence` is a named `Prop` (Chari–Loktev's linear independence in the lattice model), checked numerically for $N \le 4$ and not used: U7 is proved without it.

Theorem 26.20 (Chari–Loktev spanning and count for $\mathfrak{sl}_3$). *For every N,* `CLSpanning N` *and* `CLCount N` *hold. Consequently, in every module with the $M_{N,0}$ relations,* $\dim \mathrm{cyc}(w)_d \le [q^d]\mathcal{D}_N$ *for every d.*

```

File `VOA/DeligneAudit/DeligneFusionCLCount.lean`.

```
theorem clCount (N : ℕ) : CLCount N := by
```

From the mathematics to the Lean statement

`A2.demazureHilb N d` is $[q^d]$ of the Gelfand–Tsetlin polynomial `gl3Hilb (2N) N 0` (Chapter 25); `finrank_cycDeg_le` combines spanning with the count. This is an *upper* bound on every model, the universal one included: $M^{\mathrm{univ}}_{N,0} \le \mathcal{D}_N$.

The case $N = 1$ by hand. The admissible indices are those with $|b|, |c| \le 1$ and entries bounded as in Definition 26.19. There are exactly nine:

$$\begin{array}{lll} w, & f_1(0)w, & f_2(0)w, \\ f_1(0)f_2(0)w, & f_1(0)^2 f_2(0)w, & f_\theta(0)w, \\ f_\theta(0)f_2(0)w, & f_1(0)f_\theta(0)f_2(0)w, & f_1(1)f_2(0)w. \end{array}$$

The first eight have degree 0 and the last has degree 1, matching $\mathcal{D}_1 = 8 + q$ and the total 9^1. In $D(1,\theta) = \mathfrak{g} \oplus \mathbb{C}$ the eight degree-0 words span the adjoint representation and $f_1(1)f_2(0)w$ spans the trivial summand (compare Example 26.4). For instance $f_1(1)$ is allowed after $f_2(0)$ because $f_2(0)$ raises the h_1-weight from 1 to 2, and the α_1-box then allows one letter of index up to $2 - 1 = 1$.

Why the box conditions have this shape. Write a word as $f_1(a)\,u$ with $u = f_\theta(b)f_2(c)$. The letters f_θ and f_2 span an abelian ideal of the lowering subalgebra $\langle f_1, f_2, f_\theta\rangle$ (since $[f_1, f_2] = \pm f_\theta$ and f_θ commutes with both), so by PBW sorting every word in lowering letters is a combination of words of the form $f_1(\cdot)\cdots f_\theta(\cdot)\cdots f_2(\cdot)\cdots w$; the f_1 part is analysed last, by restricting to the α_1-copy of $\mathfrak{sl}_2[t]$. This is the Gelfand–Tsetlin branching $\mathfrak{sl}_3 \supset \mathfrak{sl}_2$. The three bounds:

- *The α_2-box*, $\max c \le N - |c|$: w is a highest-weight vector of h_2-weight N for the α_2-copy of $\mathfrak{sl}_2[t]$, killed by $e_2(1)$ and the $h_2(r)$, $r \ge 1$, with $f_2(0)^{N+1}w = 0$; Theorem 26.18 with $m = N$ gives exactly this box for the f_2 letters.

- *The θ-box*, $\max b \le N - |b|$: for the θ-triple the weight of w is $2N$, so the naive box would be $2N$. Chari–Loktev show (their Prop. 3.3.3) that in degree zero the vectors $f_1^{p-C} f_\theta^{C} f_2^{q-C} w$ with $C > N$ are combinations of those with $C \le N$: excess f_θ's can be traded for pairs $f_1 f_2$, because $f_\theta = \pm[f_1, f_2]$. With their Prop. 3.6.3 (the θ-box with bound N on $f_2(c)w$ modulo a subspace stable under the relevant operators) this gives the bound N.

- *The α_1-box*, $\max a \le (N + |c| - |b|) - |a|$: f_2 raises the h_1-weight by 1 (as $\alpha_2(h_1) = -1$) and f_θ lowers it by 1 (as $\theta(h_1) = 1$), so $u\,w$ has h_1-weight $N + |c| - |b|$. Modulo the span of words of higher index, $u\,w$ is a highest-weight vector for the α_1-copy of $\mathfrak{sl}_2[t]$, and Theorem 26.18 with $m = N + |c| - |b|$ gives the box.

Proof on paper. One follows Chari–Loktev's proof for $\mathfrak{sl}_3$, restated on vectors of an arbitrary module (there is no enveloping algebra in the library). Order the words $u = f_\theta(b)f_2(c)$ by an index (lengths, then sums). By induction along this order, using the three bullets above (each applied modulo the span of the words of higher index), every word applied to w is a combination of admissible words of the same degree. Two technical points differ from the paper: Chari–Loktev's auxiliary ideal J'_N is replaced by a numerical statistic $\sigma(a,c) = |a| + \sum a + \sum c$ that does not increase under the operators used, and error terms whose degree is not known in advance are controlled by lifting vectors to functions of degree and weight. The count is a reindexing of the Gelfand–Tsetlin formula for $\mathcal{D}_N$, using that the Gaussian binomial $\begin{bmatrix} n \\ k \end{bmatrix}_q$ counts partitions in a $k \times (n-k)$ box. (In Lean: `part_i`, `alpha2_box`, `prop333`, `theta_box`, `CLLift`, `ncard_dec`.) □

Physical meaning

(Heuristic.) The Demazure space is spanned by quasi-particle states obeying the exclusion rules; the count says these rules reproduce the energy-graded partition function of the level-one boson's Demazure subspace.

What the machine verified

Proved, unconditional; `#print axioms` standard (`clSpanning`, `finrank_cycDeg_le` re-run). The supporting files `DeligneFusionECalc`, `CLFilt`, `CLGT`, `CLNormal`, `CLTheta`, `CLLift` are described in Section 26.17.

26.8.3 Chari–Venkatesh: the $\mathfrak{sl}_2$ bound for partitions

For $\mathfrak{sl}_2$ and a partition $\xi = (\xi_1 \geq \ldots \geq \xi_\ell > 0)$ of λ, the *Chari–Venkatesh module* $V(\xi)$ is the $\mathfrak{sl}_2[t]$-module generated by a vector y of weight λ, killed by all $e(r)$ and by $h(r)$, $r \geq 1$, with $f(0)^{\lambda+1}y = 0$ and with the Garland coefficients $Q(r,s)y = [u^s]f(u)^r y$ set to zero in the region of Theorem 26.21(1) below. Chari and Venkatesh prove $\dim V(\xi) = \prod_j (\xi_j + 1)$ and identify $V(\xi)$ with the fusion product $V(\xi_1) * \cdots * V(\xi_\ell)$ of irreducible $\mathfrak{sl}_2$-modules. Two extreme cases: $\xi = (1, \ldots, 1)$ gives the local Weyl module $W_{\mathrm{loc}}(\lambda)$ of dimension 2^λ, and $\xi = (\lambda)$ gives the evaluation module $V(\lambda)(0)$ of dimension $\lambda + 1$ (the region then contains $Q(1,s)$, i.e. $f(s)y = 0$, for all $s \geq 1$). The library proves the upper bound.

Theorem 26.21 (Chari–Venkatesh bound; truncated Weyl modules). *Let E_s, H_p, F_k satisfy the $\mathfrak{sl}_2[t]$ relations, and y be a vector with $E_s y = 0$, $H_p y = 0$ $(p \geq 1)$, $H_0 y \in \mathbb{C}y$. (1) If ξ is a partition (weakly decreasing, positive parts) and y satisfies $Q(r,s)y = 0$ for all $r \geq 1$, $s \geq 0$ and $k \geq 0$ with $1 + rk + \sum_{j>k} \xi_j \leq s + r$ (with $Q(r,s) = [u^s]F(u)^r$), then the F-span of y is finite-dimensional of dimension $\leq \prod_j (\xi_j + 1)$. (2) If $F_0^{\lambda+1} y = 0$ and $F_j y = 0$ for $j \geq r_0 \geq 1$, then the same holds with $\xi = \mathrm{bal}(\lambda, r_0)$, the partition of λ into $\min(\lambda, r_0)$ parts differing by at most one.*

From the mathematics to the Lean statement

`T k ξ` is $\sum_{j>k}\xi_j$ (`(ξ.drop k).sum`, `DeligneFusionCVPart.lean`); `Q F r s` is $[u^s]F(u)^r$ (`DeligneFusionCVsl2.lean`); `Fspan F y` is the span of all $F_{k_1}\cdots F_{k_n}y$. The universe parameter `.{u}` is bookkeeping. `(ξ.map (· + 1)).prod` is $\prod(\xi_j+1)$. `ξ.Pairwise (· ≥ ·)` is "weakly decreasing". In `CVRel` the quantifiers `∀ r s k` range over all naturals, with `1 ≤ r` the only restriction; $k=0$ is included and gives the condition $1+|\xi|\le s+r$ with $|\xi|=\sum_j\xi_j$ (the parts are indexed from 1 in the text and from 0 in `List.drop`).

Proof on paper. (1) Chari–Venkatesh §6: induction on $(|\xi|,\ell(\xi),\xi_\ell)$. With $y'=F_{\ell-1}^{\xi_\ell}y$ and K the F-span of y', y modulo K satisfies the relations of $\xi^+=(\dots,\xi_{\ell-1}+1,\xi_\ell-1)$, and y' satisfies those of $\xi^-=(\dots,\xi_{\ell-1}-\xi_\ell)$, while $\prod(\xi_j+1)=\prod(\xi_j^+ +1)+\prod(\xi_j^-+1)$. The second step uses CV Lemma 6.6, whose "obvious induction" is not uniform in j; the library proves the precise shift (`shift_aux`: the relation region shifts by 2 for F_jv exactly when $j\ge k+1$, with exact shifts $\max(-2,k-1-j)$). (2) Every CV region of $\mathrm{bal}(\lambda,r_0)$ lies in the Garland region $s+r\ge\lambda+1$ (Theorem 26.16) or in the pigeonhole region $s>(r_0-1)r$, where some F_j with $j\ge r_0$ occurs in every monomial (`bal_region`). □

Example 26.22. $\lambda=3$, $r_0=2$: $\mathrm{bal}(3,2)=(2,1)$ and the bound is $3\cdot2=6=\dim V(2)*V(1)$. The naive "box" count with $F_ky=0$ for $k\ge2$ counts the seven monomials $1;\ z_0,z_1;\ z_0^2,z_0z_1,z_1^2;\ z_0^3$ (indices $i<2$, $i+\ell\le3$) and gives 7; see the dead ends of Section 26.11.

Physical meaning

(Heuristic.) Truncating the energy of each excitation of a fused spin chain distributes the λ quanta as evenly as possible among r_0 sites; the dimension is that of the fusion of the corresponding spins.

What the machine verified

Proved; `#print axioms` standard (`cv_bound`, `tw_bound` re-run). These results are *not* used by the headline chain. The relation `CVRel` itself is reused: it is the building block of the three-root family through which $\dim M_{0,m}\le 8^m$ is proved (Section 26.10).

26.8.4 U7 for A_2: the evaluation model

Definition 26.23 (Filtered relations; the evaluation model)**.** Let T be a current module (no grading) and $w\in T$; let $\Phi_{<d}$ be the span of words of degree $<d$ applied to w and $\Phi_{\le d}=\Phi_{<d+1}$. Say w satisfies the *filtered $M_{N,0}$ relations* if the raising and lowering relations hold exactly, $h(r)w\in\mathbb{C}w$, $h(0)w=Nw$, and the truncations hold modulo lower filtration: $f_i(N)w\in\Phi_{<N}$, $f_\theta(2N)w\in\Phi_{<2N}$. The *evaluation model* is $T_N=\mathbb{C}^{\{1,2,3\}^{2N}}$, the tensor product of N copies of the standard representation

$\mathbb{C}^3$ and N copies of its dual, at the distinct points $z = 0, 1, \dots, 2N-1$, with $x(k)$ acting by $\sum_i z_i^k\, x^{(i)}$ ($x^{(i)}$ the action on factor i).

From the mathematics to the Lean statement

In `DeligneFusionGrFilt.lean`, `ρ` and `w` are section variables, over a section variable `T : Type` with `[AddCommGroup T] [Module ℂ T]`; no finiteness of T is assumed in these definitions. `ℂ • w` is the line through w. In `DeligneFusionEvalModel.lean`, `N` is a section variable: declared explicit (`variable (N : ℕ)`) before `Site`, `Cfg`, `TT`, `R`, `z`, and made implicit (`variable {N}`) for `loc`, then explicit again for `op`; this is why the printed text writes `Site N` and `z N i` but `loc i`. The `op` printed here is the module-level `EvalModel.op`, the operator family of the model, not the field `CurrentModule.op` (the two are linked by `evalRep N`, whose `op` field is this `op N`). `Matrix.single i j 1` is the matrix unit E_{ij} (so $e_1 = E_{01}$, $f_\theta = E_{20}$, $h_1 = E_{00} - E_{11}$); `mat_eq` and `matT_bracket` check these against `bracketTable`. `Site N = Fin N ⊕ Fin N`: left sites carry

$\mathbb{C}^3$ (`matT c`), right sites its dual (`-(matT c)ᵀ`); a vector of T_N is a function on configurations `Cfg N`. `loc i X` applies the matrix X at site i. The points are $z(\mathrm{inl}\ i) = i$, $z(\mathrm{inr}\ i) = N + i$, all distinct. `op c k` is $x_c(k) = \sum_i z_i^k\, x_c^{(i)}$, which assembles into the current module `evalRep N`; the generator `w0 N` is the tensor product of highest-weight vectors.

Physical meaning

(Heuristic.) $2N$ quarks and antiquarks of $\mathfrak{su}(3)$ placed at distinct points of the line; the current modes act by $\sum_i z_i^k\,(\cdot)^{(i)}$, the multipole moments of the charge distribution. Their fusion, as the points collide, is the Demazure module.

What the machine verified

Definitions.

Theorem 26.24 (U7 for A_2). *(1) Let T be a* finite-dimensional *current module. If $w \in T$ satisfies the filtered $M_{N,0}$ relations and* $\dim \Phi_{\le D} \ge 9^N$ *for some D, then* `DemazureRealization N` *holds. (2) The evaluation model satisfies the hypotheses of (1). Hence* `DemazureRealization N` *holds for every N.*

```
theorem demazureRealization_all (N : ℕ) : A2.DemazureRealization N := by
```

From the mathematics to the Lean statement

A hidden instance hypothesis. Besides the section variables `T`, `ρ`, `w`, the theorem `demazureRealization_of_filt` carries the section variable `[FiniteDimensional ℂ T]`, declared at line 182 of `DeligneFusionGrFilt.lean` (`variable [FiniteDimensional ℂ T]`) and therefore not visible in the printed statement. The full signature is `demazureRealization_of_filt ρ w [FiniteDimensional ℂ T] {N} (h : FiltRel ρ w N) (D) (hD : ...)`. It is used in `finrank_gr_ge` (the first theorem after that `variable` line), which compares $\dim \Phi_{\le d}$ with $\dim \Phi_{<d} + \dim G_d$ by rank–nullity and needs the pieces of T to be finite-dimensional. The hypothesis is harmless in the application: the evaluation model T_N is a space of functions on the finite set `Cfg N`, of dimension 9^N, and `demazureRealization_all` supplies the instance. As stated in the source, (1) is therefore weaker than a version for arbitrary T, which is why the theorem above says "finite-dimensional".
`Fle ρ w D` is $\Phi_{\le D}$ and `9 ^ N` its required total dimension. The conclusion of (1) is about a *different* module: the associated graded `grRep ρ w` on $(\mathbb{N} \to_0 T)/\mathrm{span}\{\mathrm{single}(d, v) : v \in \Phi_{<d}\}$, with generator `wg ρ w`. That module satisfies the exact relations `MabRel N 0` (`mabRel_gr`).

Proof on paper. (1) The associated graded $G = \bigoplus_d \Phi_{\le d}/\Phi_{<d}$, with $x(k)$ raising degree by k, is a graded module (as in Definition 26.2) whose generator $\bar{w}$, the class of w in degree 0, satisfies the exact $M_{N,0}$ relations. The truncations become exact because of how G is graded: $f_i(N)w$ is a word of degree N, so its class in G lies in $\Phi_{\le N}/\Phi_{<N}$; the hypothesis $f_i(N)w \in \Phi_{<N}$ says exactly that this class is 0, i.e. $f_i(N)\bar{w} = 0$ in G (similarly for $f_\theta(2N)$). And $\sum_d \dim G_d = \dim \Phi_{\le D} \ge 9^N$. By Theorem 26.20, $\dim G_d \le [q^d]\mathcal{D}_N$ for each d, and $\sum_d [q^d]\mathcal{D}_N = 9^N$ (`demazureHilb_sum`). A coefficientwise upper bound with equal totals forces equality, so $\dim G_d = [q^d]\mathcal{D}_N$. (2) *Relations.* Raising operators kill each highest-weight factor; $h(r)w_0 = (\sum_i z_i^r \lambda_i(h))w_0 \in \mathbb{C}w_0$; $f_i(0)^{N+1}w_0 = 0$ by $\mathfrak{sl}_2$-theory on each factor and nilpotency; the truncations: the polynomial $\prod_i (t - z_i)$ of degree

$2N$ vanishes at every point, so $f_\alpha(t^{2N})w_0$ is a combination of $f_\alpha(t^k)w_0$, $k < 2N$ (Vandermonde, `vand`); for f_1, only the N sites where f_1 acts nontrivially on the highest weight vector matter, giving the truncation at N. *Cyclicity.* Lagrange interpolation gives $x^{(j)} = \sum_{k<2N} c_k\, x(k)$, with c_k the coefficients of the polynomial that is 1 at z_j and 0 at the other points; this isolates the action at site j (`loc_eq_sum`). Each factor is generated by its highest-weight vector under $\mathfrak{g}$, so every vector of T_N is a combination of words in the site actions $x^{(j)}$ applied to w_0, and each $x^{(j)}$ is a combination of $x(k)$ with $k < 2N$. A word of length at most L in the $x^{(j)}$ thus lies in $\Phi_{\le D}$ with $D = (2N-1)L$, and since T_N is finite-dimensional, finitely many words suffice: $\Phi_{\le D} = T_N$ for some D. The theorem needs exactly this, $\dim \Phi_{\le D} \ge 9^N$ for *some* D, and $\dim T_N = 3^{2N} = 9^N$. □

Physical meaning

(Heuristic.) The total number of states of $2N$ fundamental particles is 9^N; fusing them cannot lose states, only redistribute them in energy; and the Chari–Loktev exclusion rules say there is no room for more at any energy. Hence the energy distribution is exactly the Demazure one.

What the machine verified

Proved, unconditional; `#print axioms` standard (`demazureRealization_all`, `demazureRealization_of_filt` re-run). The A_2 chain does not use `CLIndependence`.

26.8.5 The lattice model for A_2

Theorem 26.25 (Frenkel–Kac for $\mathfrak{sl}_3$; $e^{N\theta}$ satisfies the $M_{N,0}$ relations)**.** *Let V_{A_2} be the lattice vertex algebra of the A_2 root lattice. The eight weight-one states $e^{\pm\alpha}$ (rescaled by cocycle signs) and $\alpha_i(-1)\mathbf{1}$ have 0-products equal to* `bracketTable`*; their non-negative modes form a current module* `latRep` *on V_{A_2}, and for every N the vector $e^{N\theta}$ satisfies the relations of $M_{N,0}$.*

File `VOA/DeligneAudit/DeligneFusionLattice.lean`.

  comm c d r s v := by
```

```
theorem latRep_mabRel (N : ℕ) : MabRel latRep (ch N N) N 0 where
```

From the mathematics to the Lean statement

`latChargeGen a2 β` is e^{β}; `ch a b`$= e^{a\alpha_1+b\alpha_2}$, so `ch N N`$= e^{N\theta}$. `s11`, `s12`, `s21`, `s22` are values of the lattice cocycle $\varepsilon(\alpha_i,\alpha_j) \in \{\pm 1\}$. `WA.smul x n y` is the n-th product $x_{(n)}y$; `mode (WA.Y x) n` is the mode $x_{(n)}$. The current-module property uses the commutator formula for weight-one fields, whose central term vanishes because $\langle\cdot\rangle$-products of weight-one states land in $V_0 = \mathbb{C}\mathbf{1}$ and $r + s > 0$ (`Deform.current_mode_commutator`).

Proof on paper. The 0-products are the Frenkel–Kac formulas: $e^{\alpha}_{(0)}e^{\beta} = \varepsilon(\alpha,\beta)e^{\alpha+\beta}$ if $\langle\alpha,\beta\rangle = -1$, $= \varepsilon\,\alpha(-1)\mathbf{1}$ if $\beta = -\alpha$, and 0 otherwise; checked in eight row lemmas. For $e^{N\theta}$: $e^{\alpha}_{(r)}e^{N\theta} = 0$ when $r \geq -\langle\alpha, N\theta\rangle$, which gives the raising relations ($\langle\alpha,\theta\rangle \geq 0$), the truncations $f_i(N)$ ($\langle-\alpha_i,\theta\rangle = -1$) and $f_\theta(2N)$; Cartan modes act by $\langle\alpha_i, N\theta\rangle = N$ at $r = 0$ and by 0 for $r \geq 1$; and $f_i(0)^{N+1}e^{N\theta}$ lies in charge $N\theta - (N+1)\alpha_i$ of half-norm $N^2 + N + 1 > N^2$ at conformal weight N^2, where the space is zero (the weight shell). □

Physical meaning

The level-one $\widehat{\mathfrak{sl}}_3$ currents are realized by two free bosons through vertex operators (Frenkel–Kac). The state $e^{N\theta}$, of conformal weight N^2, is an extremal state; the currents generate from it the Demazure subspace.

What the machine verified

Proved, unconditional; `#print axioms` standard (`latRep_mabRel` re-run). The *dimension* half (the cyclic module of $e^{N\theta}$ has graded dimension $\mathcal{D}_N$) is not proved in Lean; it is not needed for A_2 (Theorem 26.24). Numerically it holds for $N \leq 3$.

26.9 Reductions of the A_2 total bound

After Theorems 26.15 and 26.24, the A_2 case rests on `FusionTotalDim` alone. That statement is proved in Section 26.10. This section records two sharper statements that also imply it. They are not proved, and since `FusionTotalDim` is now a theorem they are not needed; they are alternative routes, kept in the library.

Definition 26.26 (Kernel lower bound; ideal lower bound).

(a) **`RavinderKernelLower`** (the *kernel lower bound*): for all a, b there is a module with the relations of $M_{a+1,b}$ in which the cyclic module of the kernel vector $f_\theta(2a+b+1)w$ has total dimension at least $9^a 8^b$.

(b) **`IdealLower`** (the *ideal lower bound*): for every N there is a module with the relations of $M_{N,0}$ in which the subspace $I \cdot \langle w\rangle$, spanned by $x(k) \cdot (\text{word}) \cdot w$ with $k \geq N$, has total dimension at least $9^N - 8^N$.

    (w : V), MabRel ρ w N 0 ∧ ∃ B, 9 ^ N ≤ 8 ^ N + ∑ d ∈ Finset.range B, Module.finrank ℂ
     ↪ (IVd ρ w N d)
```

From the mathematics to the Lean statement

Both are existence statements of *lower* bounds, stated as `Prop`s. `IVd ρ w N d` is the degree-d part of $(\mathfrak{g} \otimes t^N\mathbb{C}[t]) \cdot \langle w \rangle$ in the sense of words: letter (c, k) with $k \geq N$ applied to a word of degree $d - k$. The inequality `9 ^ N ≤ 8 ^ N + ∑ ...` is "$\sum_d \dim \geq 9^N - 8^N$" without natural subtraction.

What is and is not established about them. Neither is trivially true: in any model of $M_{a+1,b}$ the cyclic module of the kernel vector is a quotient of $U_{a,b}$ (kernel lemma), so `RavinderKernelLower` forces $\dim U_{a,b} \geq 9^a 8^b$, a genuine statement about the universal modules; and `IdealLower` asks for a large ideal image in a model of $M_{N,0}$. The *only* relations to the total bound that the library proves are the two implications `RavinderKernelLower` ⇒ `FusionTotalDim` and `IdealLower` ⇒ `FusionTotalDim` (`fusionTotalDim_of_kernelLower`, `fusionTotalDim_of_idealLower`, Theorem 26.27). The converses are *not* formalized. They are not consequences of what is proved here either: the spanning inequality $\mathrm{tot}(a+1, b) \leq \mathrm{tot}(a, b+1) + \mathrm{tot}(a, b)$ of Theorem 26.14 (with $\mathrm{tot}(a, b)$ the total dimension of $U_{a,b}$), with $\mathrm{tot}(a, 0) \leq 9^a$, does not bound $\mathrm{tot}(a, b)$ by $9^a 8^b$. Mathematically the converses would follow, conditionally on `FusionTotalDim`, from Ravinder's exact sequence, which itself rests on the literature input whose gap is discussed in Section 26.11; they are literature-level claims, not results of this chapter. The two statements were introduced because they are *lower* bounds, which can in principle be witnessed in a single explicit model, whereas `FusionTotalDim` is an upper bound over all modules. With `FusionTotalDim` proved (Theorem 26.30), whether they hold is no longer needed for any headline result; it is not proved.

Physical meaning

(Heuristic.) `RavinderKernelLower`: in the system of $a + 1$ Demazure and b adjoint particles, the states reachable after one particle emits its top excitation are as many as the states of the smaller system. `IdealLower`: the states killed when every particle is forbidden to carry more than $N - 1$ units of energy are at least $9^N - 8^N$.

What the machine verified

Named `Prop`s, never axioms; neither is proved. Numerically, in V_{A_2}, `IdealLower` holds with equality for $N \leq 3$: the ideal image $J_N = (\mathfrak{g} \otimes t^N\mathbb{C}[t]) \cdot D(N)$ in the cyclic module $D(N)$ of $e^{N\theta}$ has $\dim J_N = 1, 17, 217 = 9^N - 8^N$ and the kernel pieces of `RavinderKernelLower` are exactly $9^{N-1-i}8^i$ for $N \leq 4$ (Section 26.11).

Theorem 26.27 (Each refinement implies the total bound). *(1)* `RavinderKernelLower` *implies* $\sum_{N<B} \dim \mathrm{cyc}_{U_{a,b}}(w_U)_N \leq 9^a 8^b$ *for all* a, b, B*, hence* `FusionTotalDim`*. (2) In a module with the relations of* $M_{0,N}$*, every mode* $x(k)$ *with* $k \geq N$ *kills the whole cyclic module. (3)* `IdealLower` *implies* `FusionTotalDim`*.*

```

From the mathematics to the Lean statement

`uTot a b B` is $\sum_{N<B} \dim \mathrm{cyc}_{U_{a,b}}(w_U)_N$. The induction in `uTot_le` is on b (first argument), starting from the Chari–Loktev bound at $b = 0$ (where $\sum_N [q^N]\mathcal{D}_a = 9^a$). `SectorWeyl.FusionTotalDim` is Theorem 26.7's statement.

Proof on paper. (1) The relations of $M_{a,b+1}$ imply those of $M_{a+1,b}$ (`mabRel_succ`: the only difference is $f_\theta(2a+b+2)w = 0$ versus $f_\theta(2a+b+1)w = 0$, and the former follows from the latter via $[h_\theta(1), f_\theta(r)] = -2f_\theta(r+1)$). So there is a surjection $\pi : U_{a+1,b} \to U_{a,b+1}$ killing the cyclic module of v_K. Rank–nullity in each degree gives $u_{a,b+1}(n) + \dim(U \cdot v_K)_n \le u_{a+1,b}(n)$ (`step_kernel`), and in any model the cyclic module of v_K is a quotient of the universal one, so the model's count is a lower bound (`kU_ge_model`). Summing and using `RavinderKernelLower`: $\mathrm{uTot}(a, b+1) \le \mathrm{uTot}(a+1, b) - 9^a 8^b$. Induction on b from $\mathrm{uTot}(a, 0) \le 9^a$ gives $\mathrm{uTot}(a, b) \le 9^{a+b} - \sum(\dots) = 9^a 8^b$, because $\sum_{i<m} 9^{m-1-i} 8^i = 9^m - 8^m$. At $a = 0$ this is $\le 8^m$ for the universal module, which bounds every module. (2) The subspace $\mathfrak{g} \otimes t^N \mathbb{C}[t]$ is a Lie ideal of $\mathfrak{g}[t]$ that kills w in $M_{0,N}$ (raising and Cartan relations, and the truncations propagated upward); an ideal that kills the generator kills the cyclic module. (3) By (2), $U_{N,0} \to U_{0,N}$ kills $I \cdot U_{N,0}$, so $u_{0,N}(d) + \dim(I \cdot U_{N,0})_d \le u_{N,0}(d)$ (`step_ideal`); the model's `IVd` is a lower bound for the universal one (`IVd_ge_model`); and $\sum_d u_{N,0}(d) \le 9^N$ by Chari–Loktev. □

Physical meaning

(Heuristic.) Counting by subtraction: the m-adjoint system is what remains of the m-Demazure system after removing all states with a particle in a bound configuration; a lower bound on what is removed is an upper bound on what remains.

What the machine verified

Proved, `#print axioms` standard (`fusionTotalDim_of_kernelLower`, `fusionTotalDim_of_idealLower`, `trunc_all` re-run). Conditional on the respective named `Prop`.

Theorem 26.28 (The A_2 case: final forms in this chapter). *$L_{-3/2}(\mathfrak{sl}_3)$ is classically free for its explicit presentation, with kernel (I_2^{ns}), assuming either* `RavinderKernelLower` *or* `FusionTotalDim`.

File `VOA/DeligneAudit/DeligneFusionU7.lean`.

          explicitPresentation.gen_weight_one i⟩).toRingHom = I2ns :=
```

From the mathematics to the Lean statement

The second, applied to `CVUniv.fusionTotalDim` (Theorem 26.30), is the unconditional `A2.classicallyFree` of Chapter 27, which `DeligneSeries.A2_classicallyFree_final` re-exports; the first is re-exported as `A2_classicallyFree_final_S2`. U7 is supplied by `EvalModel.demazureRealization_all`; the kernel lemma by `ravinderKernelTrunc`; the finiteness by Theorem 26.7. The only hypothesis left is the printed one. The conclusion is the full target of Chapter 24: classical freeness and exactness of the presentation.

Proof on paper. Theorem 26.15 with Theorems 26.24 and 26.27. □

Physical meaning

Classical freeness (Chapter 24) identifies the vacuum character of $L_{-3/2}(\mathfrak{sl}_3)$ with the Hilbert series of the arc space of its associated scheme Spec Sym $\mathfrak{sl}_3/(I_2^{\mathrm{ns}})$, which is non-reduced (its Casimir is nilpotent but not zero); that much is mathematics. The further identification of this vacuum character with the Schur index of the Argyres–Douglas theory H_2 is a *physics input*: the four-dimensional/two-dimensional correspondence of Beem et al. (arXiv:1312.5344; for the comparison with arc spaces see Beem–Rastelli, arXiv:1707.07679). Granting it, the physical statement "Schur index = arc-space Hilbert series" for H_2 follows from the unconditional Lean theorem of Chapter 27. The Lean theorem says nothing about four dimensions.

What the machine verified

Standard axioms (re-run at an earlier commit, not re-run for this edition), **conditional** on one named `Prop` as stated. The second form becomes unconditional when `CVUniv.fusionTotalDim` is supplied (Chapter 27); the first stays conditional on the unproved `RavinderKernelLower`.

26.10 The A_2 total bound in Lean: the Chari–Venkatesh family

The total bound `FusionTotalDim` ($\dim F_m \le 8^m$ for every module with the relations of $M_{0,m}$) is a theorem of the library, `CVUniv.fusionTotalDim`. Its proof does not go through Feigin's Prop. 1, through `RavinderKernelLower` or `IdealLower`, or through the slice lemma of Section 26.11. It follows the enlarged-family argument of Setia, Rani and Khandai (arXiv:2405.11944, §8): one embeds $M_{0,m}$ into a larger family of $\mathfrak{sl}_3[t]$-modules defined by Chari–Venkatesh relations along the three positive roots, proves a dimension bound for the whole family by induction, and reads off the case of m adjoint factors. We present the family, the two base statements, and the resulting theorem. The internal construction (quotient maps between universal modules, the associated graded of the PBW filtration, and the finite-site counts) is spread over the 139 files whose names begin `DeligneFusionCV`; we describe it only on paper.

Definition 26.29 (The three-root Chari–Venkatesh family)**.** Write a dominant $\mathfrak{sl}_3$-weight as a pair (λ_1,λ_2) of coordinates in the fundamental weights ω_1,ω_2, so $\theta=(1,1)$. For pairs $\varepsilon,\nu,\rho\in\mathbb{N}^2$ and $j\in\mathbb{N}$ put $\lambda=\varepsilon+2\nu+3\rho+j\theta$, and for each positive root a partition with parts $3,2,1$:

$$\xi^{(1)}=(3^{\rho_1},2^{\nu_1},1^{\varepsilon_1+j}),\qquad \xi^{(2)}=(3^{\rho_2},2^{\nu_2},1^{\varepsilon_2+j}),\qquad \xi^{(\theta)}=(3^{\rho_1+\rho_2},2^{\nu_1+\nu_2+j},1^{\varepsilon_1+\varepsilon_2}).$$

A vector w of a current module satisfies the *CV relations* $\mathrm{CV}(\varepsilon,\nu,\rho;j)$ if $e_\alpha(k)w=0$ for all k and $\alpha>0$, $h_i(k)w=0$ for $k\ge1$, $h_i(0)w=\lambda_i w$, $f_i(0)^{\lambda_i+1}w=0$, and, along each positive root $\alpha\in\{\alpha_1,\alpha_2,\theta\}$, the $\mathfrak{sl}_2$ Chari–Venkatesh relations of Theorem 26.21 for the partition $\xi^{(\alpha)}$ (`CVRel`). $C_j(\varepsilon,\nu,\rho)$ is the universal cyclic module with these relations (Definition 26.31), and

$$\mathrm{cvCount}(\varepsilon,\nu,\rho;j)=3^{|\varepsilon|}\,6^{|\nu|}\,10^{|\rho|}\,8^{j},\qquad |\mu|=\mu_1+\mu_2.$$

The *rectangular base family* is the statement: for $\varepsilon \in \{(0,0),(1,0),(0,1)\}$ and all ν, ρ, $C_0(\varepsilon,\nu,\rho)$ is finite-dimensional of dimension $\le \mathrm{cvCount}(\varepsilon,\nu,\rho;0)$. The *residual base family* is: for all ρ, $C_1(0,0,\rho)$ is finite-dimensional of dimension $\le 8\cdot 10^{|\rho|}$.

Files `VOA/DeligneAudit/DeligneFusionCVFamily.lean` (`parts`, `CV3Rel`), `VOA/DeligneAudit/DeligneFusionCVUniv.lean` (`CVMod`, `sat_cvSpec_iff`) and `VOA/DeligneAudit/DeligneFusionCVTotal.lean` (the counts and the two base statements).

From the mathematics to the Lean statement

Indices. The `bracketTable` basis is that of Section 26.3: `0,1,2` $= e_1, e_2, e_\theta$, `3,4,5` $= f_1, f_2, f_\theta$, `6,7` $= h_1, h_2$. So `raising` says $e_\alpha(k)w = 0$ for all k; `cartan_pos`, $h_i(k)w = 0$ for $k \ge 1$; `cartan_first`/`second`, $h_i(0)w = \lambda_i w$; `lowering_*`, $f_i(0)^{\lambda_i+1}w = 0$ (`f^[n]` is the n-fold iterate). `parts r n e` is the partition $(3^r, 2^n, 1^e)$ as a list, and `CVRel F ξ w` is the Chari–Venkatesh condition of Theorem 26.21: all Garland coefficients $Q(r,s)w = [u^s]F(u)^r w$ vanish in the region $1 + rk + T_k(\xi) \le s + r$, $r \ge 1$, where $T_k(\xi)$ is the sum of the parts after the first k. The three `CVRel` fields use the partitions $\xi^{(1)}, \xi^{(2)}, \xi^{(\theta)}$ of the definition, for the $\mathfrak{sl}_2$ triples of α_1,

α_2, θ (the letters 3, 4, 5).

The universal module. `cvSpec ε ν ϱ j` is a relation specification (Definition 26.31) whose tails are the single words $e_\alpha(1)^s f_\alpha(0)^{r+s}$ that Garland's identity makes equivalent to the coefficient relations, and `sat_cvSpec_iff` proves that satisfying it is *exactly* `CV3Rel`. `CVMod` is the universal module `UModG` of that specification, so every module with a vector satisfying `CV3Rel` receives the cyclic span of that vector as a quotient of `CVMod` (Definition 26.31). The variables `R`, `w`, `ε`, `ν`, `ϱ`, `j` of `sat_cvSpec_iff` are implicit section variables. Lean's `ϱ` is the ρ of the text.

The link with $M_{0,N}$. `mabRel_zero_cv3`: if w satisfies the relations of $M_{0,N}$ (`MabRel R w 0 N`, Definition 26.6) with $N \geq 1$, then it satisfies $\mathrm{CV}(0,0,0;N)$. The highest weight is $N\theta$, and the partitions are (1^N), (1^N), (2^N). So the family contains the pure-adjoint case at $\varepsilon = \nu = \rho = 0$, $j = N$, with cvCount $= 8^N$.

The counts. $3, 6, 10, 8$ are $\dim V(\omega_i)$, $\dim V(2\omega_i)$, $\dim V(3\omega_i)$, $\dim V(\theta)$. A bound $\dim C_j(\varepsilon,\nu,\rho) \leq$ cvCount is what one expects if $C_j(\varepsilon,\nu,\rho)$ is the fusion product of $|\varepsilon|$ fundamental, $|\nu|$ "two-box" and $|\rho|$ "three-box" Kirillov–Reshetikhin modules and j adjoints. That identification is *not* stated in Lean; only the upper bound is. `CVBound` includes finite-dimensionality, so the `finrank` in it is not the value 0 that Lean assigns to infinite-dimensional spaces.

Could it be vacuous? No. `CVMod` is a genuine universal module (a quotient of the free current module by the submodule generated by the relations), not an assumed object, and the bounds are upper bounds on it. A presentation with too many relations would make the bound trivially true but would break `mabRel_zero_cv3`, which is a theorem: the pure-adjoint member really is implied by the relations of $M_{0,N}$. The two base statements are named `Props` here; the next theorem proves them.

Physical meaning

Heuristic. Each member of the family is a candidate Hilbert space for a chain of $\mathfrak{sl}_3$ "particles" of four kinds (the three-dimensional fundamental, the six- and ten-dimensional symmetric tensors, and the adjoint) fused at a single point, with the Chari–Venkatesh relations encoding how much energy each kind can carry along each root direction. Enlarging the set of particle species is what makes an inductive count possible: removing one adjoint particle produces configurations with lighter species, which the smaller pure-adjoint family cannot describe.

What the machine verified

Definitions (named `Props`, not axioms). `mabRel_zero_cv3` and `sat_cvSpec_iff`: proved, standard axioms (campaign record, targeted builds; not re-run here).

Theorem 26.30 (The A_2 total bound)**.**

1. *The two base families hold:* `CVUniv.sharpRectangularBases` *and* `CVUniv.residualTheta3Bound`.
2. *If both base families hold, then* `FusionTotalDim`*: for every m, every current module and every vector w satisfying the local Weyl and fusion relations for $m\theta$, $\sum_{b<B} \dim \mathrm{cyc}(w)_b \leq 8^m$ for all B.*
3. *Hence* `FusionTotalDim` *holds, with no hypothesis.*

From the mathematics to the Lean statement

Names. The first three declarations are in the namespace `VOA.DeligneAudit.A2.CVUniv`; the fourth is declared in `VOA.DeligneAudit.A2` with the dotted name `CVUniv.fusionTotalDim`, so its full name is `VOA.DeligneAudit.A2.CVUniv.fusionTotalDim`. Its one-line proof is shown because it is informative: it is literally (2) applied to the two terms of (1).
The conclusion. `SectorWeyl.FusionTotalDim` is Definition 26.6(b): a universally quantified statement over *all* current modules `V` and vectors `w` with `LocalWeylRel ρ w m`, bounding the sum of the first B degree pieces of the cyclic span by 8^m. Because the degree pieces are finite-dimensional (Theorem 26.7), this is the bound $\dim F_m \le 8^m$ of the text. Together with the free lower bound (the fusion product $V(\theta)^{*m}$ of dimension 8^m is a quotient of F_m), it gives $\dim F_m = 8^m$ on paper; the equality is not itself stated in Lean.
Hypotheses. None for (1) and (3). The internal definitions they use (`CVMod`, `cvSpec`, `bracketTable`) cannot weaken the conclusion of (3), because that conclusion mentions none of them: it is the previously defined `FusionTotalDim`.

Proof on paper. (2) For fixed m, the vector w satisfies $\mathrm{CV}(0,0,0;m)$ (`mabRel_zero_cv3`), so its cyclic span is a quotient of $C_m(0,0,0)$ degree by degree, and it suffices to show $\dim C_m(0,0,0) \le 8^m$. One proves the stronger $\dim C_j(\varepsilon,\nu,\rho) \le \mathrm{cvCount}(\varepsilon,\nu,\rho;j)$ for $\varepsilon \in \{(0,0),(1,0),(0,1)\}$ and all ν,ρ,j, by strong induction. The induction step is a three-term dimension inequality of Ravinder type. Killing the top generators along the simple roots maps $C_j(\varepsilon,\nu,\rho)$ onto a member of the family in which adjoint factors are traded for lighter ones (the *quotient relations*), and the kernel of such a map is a cyclic module whose generator satisfies the relations of a further, smaller member (the *kernel relations*). Rank–nullity bounds $\dim C_j(\varepsilon,\nu,\rho)$ by the sum of the dimensions of the smaller members, and the counts are such that the sum is exactly cvCount; for two adjoints, for example, the recurrence closes as $64 = 36 + 18 + 10$. The induction ends at $j = 0$, on the rectangular base family, and, in one residual branch, on $C_1(0,0,\rho)$; these are the two base families. The sums are taken degree by degree in the universal module before mapping to an arbitrary model, so no independence of the pieces of the model is used. (1) The rectangular bound is proved through the associated graded of the PBW filtration of the universal module: the CV relations give polynomial relations among commuting symbols, and an explicit spanning set of the quotient is counted; its size is $3^{|\varepsilon|}6^{|\nu|}10^{|\rho|}$. The residual family is bounded by the same kind of argument, with explicit quotient maps that split the adjoint site ($8 = 5 + 3$, then $5 = 3 + 2$). (3) Compose. □

Physical meaning

Heuristic. The statement is that m adjoint "particles" of $\widehat{\mathfrak{sl}}_3$ fused at one point have exactly 8^m states, the number they have when kept apart: fusion redistributes energy but creates or destroys no states. For the Deligne chain this is the input that bounds the number of operators of $L_{-3/2}(\mathfrak{sl}_3)$ in each m-particle sector (Chapter 24).

What the machine verified

`CVUniv.fusionTotalDim`: `#print axioms` prints `[propext, Classical.choice, Quot.sound]` per the targeted build record (27 October 2026: `VOA.DeligneAudit.A2Unconditional`, 9755 jobs, green); the base families `sharpRectangularBases` and `residualTheta3Bound` likewise (targeted builds of 8863 and 8887 jobs). We did not re-run these checks: this checkout has no compiled objects for the new modules. The aggregate build, which contains the umbrella `VOA.Deligne`, was green on 2026-10-28 in a pre-release build (18,901 jobs; 18,907 after a merge). **No hypotheses.**

26.11 The A_2 total bound on paper: Feigin's Cor. 2 and the slice lemma

This section records, at the level of mathematics only, what is known about the last A_2 input; we write $D(N)$ for $D(1, N\theta) = M_{N,0}$. The Lean proof of the bound is the different route of Section 26.10; nothing in this section is in Lean beyond the reductions of Section 26.9. We keep the analysis because it explains why the published proof needed repair, and because the slice lemma below would give a second, more direct proof.

The statement. $\dim V(\theta)^{*N} = 8^N$ for $\mathfrak{sl}_3$, i.e. $\dim M_{0,N} \le 8^N$ (the lower bound is free: the fusion product is a quotient of $M_{0,N}$ of dimension 8^N). Equivalently, with $D(N) = M_{N,0}$:

$$M_{0,N} \cong D(N)/(\mathfrak{g} \otimes t^N\mathbb{C}[t])D(N), \qquad \text{so} \qquad \dim(\mathfrak{g} \otimes t^N\mathbb{C}[t])D(N) \ge 9^N - 8^N.$$

This is Feigin's Cor. 2 (arXiv:0806.4851) and Kus–Littelmann's Cor. 3.6(3) at level one, and exactly `IdealLower`.

Feigin's argument and its gap. Feigin realizes $D(N) \cong D(1)^{*N}$ (Fourier–Littelmann for simply laced types) as a fusion product $T = \bigotimes_j D(1)(c_j)$, $D(1) = \mathfrak{g} \oplus \mathbb{C}$, at distinct points c_j, and asserts (Prop. 1) that the associated graded of T for the t^N-filtration is a bigraded fusion product in which a second degree u counts trivial factors. In T the image of the ideal $\mathfrak{g} \otimes f(t)\mathbb{C}[t]$, $f = \prod(t - c_j)$, is exactly $K =$ the tensors with at least one trivial factor, and $T/K \cong \mathfrak{g}^{\otimes N}$. The bound needs $\operatorname{gr} K \subseteq (t^N) \cdot \operatorname{gr} T$. The natural mechanism, that the fusion filtration is homogeneous for the u-grading, is **false**: for $N = 2$ the degree-one filtration piece has dimension 55 while the sum of the dimensions of its u-projections is 63; for $N = 3$ the pairs are $(161, 188)$, $(313, 403)$, ... Feigin's printed proof of Prop. 1 (labelled "the idea of the proof") is a change of current operators followed by "Proposition is proved"; it is a sketch, and a rigorous Prop. 1 is equivalent in strength to the statement itself. Ravinder (arXiv:1409.0274, Prop. 5 in the v4 numbering) takes his terminal case from Feigin. The repair and the alternative route recorded in the Warning of Section 26.2 (Kus–Littelmann 2015; Setia–Rani–Khandai, arXiv:2405.11944) are published. The library formalizes the Setia–Rani–Khandai route (Section 26.10).

The slice lemma. Let $T_{a,b} = D(1)(c_1) \otimes \cdots \otimes D(1)(c_a) \otimes \mathfrak{g}(c_{a+1}) \otimes \cdots \otimes \mathfrak{g}(c_{a+b})$, cyclic on $w = e_\theta^{\otimes(a+b)}$ (on $\mathfrak{g}$-sites $x(1)$ acts by 0), with fusion filtration $\Phi^{(a,b)}$. Let $S = \ker(T_{a,b} \to T_{a-1,b+1})$, the tensors with the trivial vector at site a, so $S \cong T_{a-1,b} \otimes 1$; put $\mathrm{sh} = 2a + b - 1$. The **slice lemma (SL)** is the equality of subspaces

$$\Phi_d^{(a,b)} \cap S = \Phi_{d-\mathrm{sh}}^{(a-1,b)} \otimes 1 \qquad \text{for all } d. \tag{26.6}$$

- The inclusion $\supseteq$ **is proved on paper**: with $g_a(t) = (t - c_a)\prod_{j<a}(t - c_j)^2 \prod_{j>a}(t - c_j)$, of degree sh and $\equiv t^{\mathrm{sh}}$ modulo lower terms, $f_\theta(g_a)w$ is a nonzero multiple of $e_\theta^{\otimes(a-1)} \otimes 1 \otimes e_\theta^{\otimes b}$ (all other sites see a double or simple zero), and every current kills the trivial factor, so words act through the smaller model.
- The inclusion $\subseteq$ is **open**. It is equivalent to the Hilbert-series recursion $H_{a,b} = H_{a-1,b+1} + q^{2a+b-1}H_{a-1,b}$ for fusion products, i.e. Ravinder's exact sequence realized in a model, and it would give `RavinderKernelLower` in the associated-graded model, hence a second proof of `FusionTotalDim`.
- **Numerics** (exact, modulo $2^{61} - 1$): SL holds for all (a, b) with $a + b \le 4$ in every degree; the stronger claim $K \cap \Phi_d \subseteq \mathfrak{g}(f)\Phi_{d-N} + \Phi_{d-1}$ holds for $N \le 4$ (for $N = 4$ the dimensions of $\mathrm{gr}\, K$ total $2465 = 6561 - 4096$).

The lattice form of the slice problem. In V_{A_2}, with $v_i = S_i(-\theta)e^{(N-1)\theta} = \pm f_\theta(2N - 1 - i)e^{N\theta}$ (the S_i are the Schur polynomials in the Heisenberg modes) and $C^{\le i}$ the cyclic span of $v_0, \dots, v_i$, the successive quotients have dimensions $9^{N-1-i}8^i$ for $N \le 4$ (729, 648, 576, 512 at $N = 4$). A proof would need a functional separating these pieces; charge and conformal-weight windows separate them for $N = 2$ but not for $N = 3$.

Trap / dead end

Approaches to the A_2 total bound that fail, for the record (each with the counterexample that rules it out).

1. *The naive truncated box.* Imposing $f_1(k)uw = 0$ for $k \ge m$ and box bounds overcounts: 72 vs 64 at $m = 2$, 656 vs 512 at $m = 3$; already for $\mathfrak{sl}_2$, $\lambda = 3$ with $F(k)y = 0$ for $k \ge 2$ gives 7 instead of 6: the box monomials with indices $i < 2$ and $i + \ell \le 3$ are 1; z_0, z_1; z_0^2, z_0z_1, z_1^2; z_0^3, while the true dimension is $\prod(\xi_j + 1) = 6$ for $\xi = \mathrm{bal}(3, 2) = (2, 1)$ (Theorem 26.21).
2. *Short identities.* The truncation identities in $M_{0,m}$ are a normal-form problem for the whole annihilator ideal; a single-letter recursion reproduces the rule for $m \le 3$ but fails for 28 of 256 cases at $m = 4$.
3. *The presentation route* ("$M_{0,m}$ is the associated graded of the fusion model") is circular: the surjection is free, its injectivity is the statement.
4. *Plain tensor induction* $T_N = T_{N-1} \otimes D(1)$ fails (fusion associativity): the image of the filtration in $T_{N-1} \otimes \mathfrak{g}$ is the mixed filtration, not a shifted tensor filtration; one must use the mixed models $T_{a,b}$.
5. *Separating functionals* in V_{A_2} by charge, L_0-weight or θ-degree fail from $N = 3$.
6. *Leading-term independence* of the Chari–Loktev words against Fock monomials fails (77/81 at $N = 2$, 547/729 at $N = 3$ under every tested order).
7. *Ungraded counting* in the evaluation model is useless: at nonzero points $\mathfrak{g} \otimes t^N\mathbb{C}[t]$ acts as all of $\mathfrak{g}[t]$.

26.12 The type-generic fusion layer

The A_2 argument of Sections 26.5–26.6 is redone for an arbitrary sector S (Definition 24.28): S supplies $n = \dim \mathfrak{g}$, structure constants $S.f$ on $\{0, \dots, n - 1\}$, the index c_0 of f_θ, predicates

`raising`, `cartan`, `cartanN`, `lowering`, `fusion`, the values $\theta(h)$ (`thetaH`, and `thetaN` for Cartan basis vectors with $\theta(h) < 0$), and lowering exponents `lowExp`$= \theta(h_i)$. `LocalWeylRelG S ρ w m` and `FusionModuleBoundG S F` are quoted in Definition 24.29.

Definition 26.31 (Relation specifications and type-generic universal modules)**.** A *relation specification* R consists of a set of *tail words* t (relations $t \cdot w = 0$) and a set of *eigen-relations* (h, λ) (relations $h(0)w = \lambda w$). A vector w *satisfies* R if all these hold. The universal module $U(R)$ is the free space on words modulo all prefixed commutation instances and prefixed relations of R; $M^{\mathrm{univ}}(R)(q)$ is the character of the cyclic module of its generator. R is *finite* if every $\mathrm{cyc}_{U(R)}(w_U)_N$ is finite-dimensional.

```

From the mathematics to the Lean statement

`f : Fin n → Fin n → Fin n → ℂ` is a section variable (arbitrary structure constants; no Jacobi identity is needed for the construction). `commInst f p s x y` is as in Definition 26.13 with `f` in place of `bracketTable`. `finrank_le_McharG` is the universal bound: a module whose generator satisfies R has degree pieces no larger than those of $U(R)$, provided $U(R)$ is finite (`hfd`); without `hfd` the inequality could fail only through the convention `finrank`$= 0$ on infinite-dimensional spaces.

Physical meaning

The same "largest Hilbert space compatible with given null vectors", now for any Lie algebra in the Deligne series, with the null vectors given as data.

What the machine verified

Definitions and theorem; `#print axioms` standard (record).

Definition 26.32 (The local Weyl specification; the total bound; U7, type-generic). `lwSpec S m` is the specification of the local Weyl and fusion relations for $m\theta$. **`FusionTotalBoundG S`**: for every m and every module with these relations, the degree pieces are finite-dimensional and the total dimension is $\le n^m$. **`DemazureRealizationG S spec Dem n`**: some module whose generator satisfies `spec n 0` has $\dim \mathrm{cyc}(w)_N \ge [q^N]\mathrm{Dem}_n$ for every N.

Files `VOA/DeligneAudit/DeligneFusionUnivGSectorRelations.lean` (`lwSpec`, `localWeylRelG_iff`) and `VOA/DeligneAudit/DeligneFusionUnivGSector.lean` (`FusionTotalBoundG`, `DemazureRealizationG`).

    Sat S.f ρ w (spec n 0) ∧ ∀ N, coeff N (Dem n) ≤ (Module.finrank ℂ (cycDeg ρ w N) : ℚ)
```

From the mathematics to the Lean statement

`S : DeligneSectorData` is a section variable. In `lwSpec`: raising letters at every grade; Cartan letters at positive grade; $f_i(0)^{m\theta(h_i)+1}$ for `lowering` letters; $x(m)$ for every `fusion` letter; and the eigen-relations $h(0)w = m\theta(h)w$ (and $= -m\theta_N(h)w$ for `cartanN`). `localWeylRelG_iff` proves this is exactly `LocalWeylRelG`. For E_6, E_7, E_8 the `fusion` set is Ravinder's $\{f_\alpha : \langle\alpha, \theta^\vee\rangle = 1\} \cup \{f_\theta\}$; for A_2, D_4, G_2, F_4 it is all negative root vectors. The dictionary of Definition 24.29 explains why both readings are sound for U5: more relations make the hypothesis weaker. `DemazureRealizationG` takes `spec` and `Dem` as parameters; in all uses `spec` is Ravinder's family `ravFam S` (Section 26.13) and `Dem` the Demazure series of Chapter 25.

Non-simply-laced caution. For G_2 and F_4, $W_{\mathrm{loc}}(m\lambda) \ne D(1, m\lambda)$ in general (Naoi). Along multiples of θ (long, fundamental for G_2 and F_4) the project's numerics find no discrepancy: $\sum_N \dim D(1, n\theta)_N = 15^n$ for G_2 and $n \le 18$, and inverting the mixed recursion gives nonnegative $\mathcal{F}_m$ with $\mathcal{F}_m(1) = 14^m$ for $m \le 18$. Ravinder's presentation of $D(1, n\theta)$ (his Prop. 1) and his exact sequences are stated for every simple $\mathfrak{g}$ (only his Thm. 2 and Cor. 3 assume simply laced), and Kus–Littelmann's Thm. 4.2 gives the total bound for G_2, F_4 as for every other type.

The figures above are numerical consistency checks, not proofs.

Trap / dead end

The fusion set convention. For A_2, D_4, G_2, F_4 the sectors' `fusion` predicate contains all negative root vectors; for E_6, E_7, E_8 it is Ravinder's set. This makes `LocalWeylRelG`, hence `FusionTotalDimG`, differ in form between types, but not in content. Both readings are sound for the chain (Definition 24.29), and they impose the same relations: Ravinder's condition is $\langle\alpha, \theta^\vee\rangle = 1$, which includes the short roots of G_2 and F_4 (for which $(\theta, \alpha^\vee) \geq 2$), and the remaining positive roots, with $\langle\alpha, \theta^\vee\rangle = 0$, satisfy $f_\alpha(r)w = 0$ for all r by the $h(1)$-bracket argument (Remark 26.5; Chapter 27, Lemma 27.6). An earlier version of this Warning said that these extra relations were not known to hold in Ravinder's F_m; that was wrong.

Physical meaning

(Heuristic.) m adjoint particles of any Deligne-series flavour symmetry, fused; the total bound says the fused space is no larger than $\mathfrak{g}^{\otimes m}$.

What the machine verified

`FusionTotalBoundG` and `DemazureRealizationG`: **named inputs**. The first is reduced to `FusionTotalDimG` for all seven types (Section 26.14); the second is proved for A_2 (through the A_2-specific `DemazureRealization`, which is the same statement for `bracketTable`) and open for the other six, with the relations half proved on lattices for D_4, E_6, E_7, E_8 (Section 26.15).

Theorem 26.33 (The generic squeeze and the count). *Let* Dem_n *be power series and* $d \in \mathbb{N}$. *(1) If each* Dem_n *is a polynomial with* $\mathrm{Dem}_n(1) = (d+1)^n$, *then each* $\mathrm{fusionOf}(\mathrm{Dem})_m$ *is a polynomial with value* d^m *at* $q = 1$. *(2) If* M *satisfies the generic squeeze inputs (nonneg, (R),* $\mathrm{Dem}_n \leq M_{n,0}$, *total* $\leq d^m$*) and the count of (1) holds for* `fusionOf Dem`, *then* $M_{0,m} = \mathrm{fusionOf}(\mathrm{Dem})_m$. *(3) If in addition every module with* `LocalWeylRelG S` *for* $m\theta$ *is bounded by* $M_{0,m}$ *and* $n = d$, *then U5 holds for* `fusionOf Dem`.

      ↪  :
    FusionModuleBoundG S (fusionOf Dem) := by
```

From the mathematics to the Lean statement

`Dem`, `d`, `M` are section variables in `squeezeG`. The count is phrased with an explicit support bound `B`: coefficients vanish from `B` on and the sum below `B` is the stated power. In `fusionModuleBoundG_of_squeeze`, `hd : S.n = d` ties the bound to $\dim \mathfrak{g}$. The proofs are the A_2 ones verbatim, with 8 replaced by d; the count (1) is binomial inversion: evaluating the recursion at $q = 1$ gives $(d+1)^n = \sum_k \binom{n}{k}\mathrm{fusionOf}_{n-k}(1)$.

Proof on paper. As Theorem 26.12; for (1), induction with $\begin{bmatrix} n \\ k \end{bmatrix}_q\big|_{q=1} = \binom{n}{k}$ and the binomial theorem. □

Physical meaning

(Heuristic.) Same counting argument as for A_2, for every Deligne flavour symmetry.

What the machine verified

Proved; `#print axioms` standard (`squeezeG` re-run). The count hypothesis is discharged per type through the Demazure totals of Chapter 25 (Theorem 25.40), or avoided by the unclamped series used in Chapter 27.

Theorem 26.34 (Generic exact-sequence step; U5 from the kernel lemma). *Let R_1, R', R_0 be specifications and k a word such that every tail of R' is a tail of R_1 or ends in k, and the eigen-relations of R' are among those of R_1 (*`SpecStep R₁ R' k`*). If $k \cdot w_U$ satisfies R_0 in $U(R_1)$, then*

$$\dim \mathrm{cyc}_{U(R_1)}(w)_N \le \dim \mathrm{cyc}_{U(R')}(w)_N + [\deg k \le N] \dim \mathrm{cyc}_{U(R_0)}(w)_{N-\deg k},$$

provided the two right-hand pieces $\mathrm{cyc}_{U(R')}(w)_N$ and $\mathrm{cyc}_{U(R_0)}(w)_{N-\deg k}$ are finite-dimensional. For a family `spec` *with* $\mathrm{spec}(0,m) =$ `lwSpec S m`*, kernel words $\mathrm{kw}(a,b)$ of degree $2a+b+1$ with* `SpecStep (spec (a+1) b) (spec a (b+1)) (kw a b)`*, the per-type kernel lemma* `RavinderKernelRelG`*, the total bound, U7 and the count, U5 holds for* `fusionOf Dem`*.*

From the mathematics to the Lean statement

`deg` is local notation for `SectorGraded.wordDeg`, the total t-degree of a word. Section variables: `f` and `k` (and implicit `R₁ R₀ R'`) for `finrank_stepG`; `S`, `spec`, `kw` (implicit) for `fusionModuleBoundG_of_kernel`. The two bracketed `[FiniteDimensional ...]` binders of `finrank_stepG` are instance hypotheses: finite-dimensionality of the two right-hand pieces, exactly as in the A_2 step (Theorem 26.14). They are needed because `Module.finrank` is 0 on an infinite-dimensional space, so without them the right-hand side could be 0 for a spurious reason and rank–nullity would not apply. In `fusionModuleBoundG_of_kernel` they are discharged by `univFD_all`. `RavinderKernelRelG f spec kw` is *the* per-type input: if w satisfies spec$(a+1,b)$ then kw$(a,b)\cdot w$ satisfies spec(a,b). Every `RelSpec` is homogeneous (tails are single words, eigen-relations use grade-zero letters), so the degree projection needed for the step exists with no extra hypothesis (`projFG_J`). The finiteness of all $U(\mathrm{spec}(a,b))$ is derived (`univFD_all`), not assumed.

Proof on paper. As Theorem 26.14, with `sat_quotG` (killing $k\cdot w$ turns R_1 into R') in place of `mabRel_quot`. For U5: finiteness of all universal pieces by induction on a (`univFD_all`); (R) from the step; (D) from U7 and the universal bound; (T) from the total bound at $a=0$; then Theorem 26.33. □

Physical meaning

(Heuristic.) Ravinder's particle decomposition, with the binding energy $2a+b+1$, for any Deligne flavour symmetry.

What the machine verified

Proved; `#print axioms` standard (`fusionModuleBoundG_of_kernel` re-run). Conditional on the printed hypotheses; `RavinderKernelRelG` is discharged for every type below.

26.13 Ravinder's kernel lemma for every type

Definition 26.35 (Ravinder's family; the kernel table; integrability)**.**

(a) For $k,d\in\mathbb{N}$, `ravSpec S k d` is the specification: local Weyl relations for $k\theta$, truncations $x(k)w=0$ for fusion letters $x\neq f_\theta$, and $f_\theta(d)w=0$.

(b) *Ravinder's family* is ravFam$(a,b)=$ ravSpec$(a+b,2a+b)$, with kernel words ravKw$(a,b)=[f_\theta(2a+b+1)]$.

(c) A *kernel table* (`KernelTable`) is a finite list of structure-constant facts about S (below).

(d) **`ThetaNilG S`** is integrability of f_θ: if w has weight $k\theta$, is killed by the raising zero modes, and $f_i(0)^{k\theta(h_i)+1}w=0$ for the lowering letters, then $f_\theta(0)^{2k+1}w=0$.

From the mathematics to the Lean statement

The table, field by field. `τ` is the signed value $\theta(h)$ on Cartan letters. `c0_fusion`: f_θ is a fusion letter. `truncUp`: each fusion or lowering letter x has a diagonal Cartan h with $[h,x] \in \mathbb{C}^\times x$ (used to propagate a truncation $x(N_0)w = 0$ to all higher grades). `raisTheta`: $[e, f_\theta]$ is Cartan or a fusion letter $\neq f_\theta$. `cartTau`: $[h, f_\theta] = -\theta(h) f_\theta$. `lowComm`: fusion and lowering letters commute with f_θ. `lowExp_le`: $\theta(h_i) \leq 1$ for simple lowering letters. `simple`: each simple lowering letter with $\theta(h_i) = 1$ has an $\mathfrak{sl}_2$-partner e with the right normalization. `eθ`, `sθ`: the θ-triple. `kill0`, `rk`: root vectors orthogonal to θ that kill w at grade 0, generated by brackets from simple ones, with a rank making the generation well founded. `fusionRoot`: each fusion letter $x \neq f_\theta$ is $[e_\beta, f_\theta]$ up to a nonzero scalar, or is in `kill0`. All fields are decidable statements about integer tables and are checked per type by `decide +kernel`. A simply-laced version `KernelTableSL` with a converter `KernelTable.ofSL` is used for D_4, E_6, E_7, E_8.
About `ThetaNilG`. Its docstring calls it a "named input"; it is *proved* for every type (Theorem 26.37). It is the classical integrability of $V(k\theta)$ (Humphreys §21; Kac Lemma 3.4), which for an arbitrary current module is not automatic: f_θ is not simple.

Physical meaning

The table records how the energy-raising and lowering currents of each flavour algebra commute with the top lowering current f_θ; integrability says the θ-direction excitations of a highest-weight state of weight $k\theta$ come in a finite spin-k multiplet.

What the machine verified

Definitions. `ravFam_step` (`SpecStep`) and `ravKw_deg` ($\deg = 2a+b+1$) are proved generically by unfolding.

Theorem 26.36 (The generic kernel lemma). *For every sector S with a kernel table and* `ThetaNilG S`*, Ravinder's kernel relation holds: if w satisfies* ravFam$(a+1, b)$ *then $f_\theta(2a+b+1)w$ satisfies* ravFam(a, b).

File `VOA/DeligneAudit/D4FusionKernelGeneric.lean`.

```
theorem ravinderKernelRelG_of_table (T : KernelTable S) (hN : ThetaNilG S) :
    RavinderKernelRelG S.f (ravFam S) (ravKw S) := by
```

From the mathematics to the Lean statement

`S` is a section variable. The conclusion is `RavinderKernelRelG` (Theorem 26.34) for the family `ravFam S` and kernel words `ravKw S`.

Proof on paper. This is the A_2 argument of Theorem 26.17 made generic (`kernel_sat`): raising and Cartan relations for $v = f_\theta(D+1)w$ by commuting through f_θ (`raisTheta`, `cartTau`); lowering relations by $\mathfrak{sl}_2$ algebra (`simple`, `lowComm`); the f_θ-truncation from the θ-Garland identity for the triple $(s_\theta e_\theta(1),\ s_\theta[e_\theta, f_\theta](m),\ f_\theta(k))$, using `ThetaNilG` for the nilpotency input of Garland; the other fusion truncations by applying e_β to the θ-Garland identity (`fusionRoot`) or directly (`kill0`). □

Physical meaning

(Heuristic.) As for A_2: the state with one top excitation emitted behaves like the ground state of the smaller system.

What the machine verified

Proved; `#print axioms` standard (re-run).

Theorem 26.37 (Integrability for the seven types; the kernel lemma unconditionally)**.** `ThetaNilG` *holds for* D_4, E_6, E_7, E_8, G_2, F_4*; hence* `RavinderKernelRelG` *for* `ravFam` *holds for these six types with no hypothesis. Together with the* A_2 *theorem* `ravinderKernelRel` *(Theorem 26.17), the Lean analogue of Ravinder's kernel lemma holds for all seven types.*

Two caveats on the word "all seven". (a) A_2 is formalized differently: its kernel lemma is `RavinderKernelRel`, phrased with `MabRel` and `bracketTable`, and its integrability input is `ftheta_pow`. No `ThetaNilG` or `RavinderKernelRelG` statement exists for `A2sector`, so the generic pipeline `fusionModuleBoundG_of_kernel` is not instantiated at A_2; the A_2 chain is the specific one of Sections 26.5–26.7. (b) For G_2 and F_4 the theorems below concern the library's own family `ravFam` (fusion set: all negative root vectors). This family imposes the same relations as Ravinder's (Remark 26.5), and Ravinder's Theorem 1, Corollaries 1–2 and Proposition 1 are stated for every simple $\mathfrak{g}$ (only his Theorem 2 and Corollary 3 assume simply laced); what is not formalized is the identification of these modules with the Demazure and fusion modules (Section 26.12). From the mathematics to the Lean statement

`D4sector`, `G2sector`, ... are the sector data of Chapter 24 (Theorem 24.41); the E_6, E_8 and F_4 declarations live in the namespaces `UnivG.E6K`, `UnivG.E8K`, `UnivG.F4K`, the D_4, E_7 and G_2 ones in `UnivG`. `adL A T` $= AT - TA$ in $\mathrm{End}(V)$ (section variable `A`). `sl2_sharpen`: section variable V; it says a highest-weight vector of weight k for an $\mathfrak{sl}_2$-triple, on which F is nilpotent, satisfies $F^{k+1}u = 0$. The unprimed `d4_ravinderKernelRel (hN : ThetaNilG D4sector)` etc. are the conditional versions; the primed ones (and `g2_ravinderKernelRel`, `f4_ravinderKernelRel`) are unconditional.

Proof on paper. *Heisenberg chains (simply laced).* For A_2, $\theta = \alpha_1 + \alpha_2$ and f_1, f_2, f_θ form a Heisenberg algebra, so one application of Theorem 26.16(1) suffices. For D_4 there is no such pair of simple roots: only α_2 has $(\theta, \alpha_2^\vee) = 1$ (α_2 the central node, $\theta = \alpha_1 + 2\alpha_2 + \alpha_3 + \alpha_4$, and $\alpha_1, \alpha_3, \alpha_4$ orthogonal to θ, so that $f_{\alpha_1}, f_{\alpha_3}, f_{\alpha_4}$ kill w at grade 0). The chain builds θ by adding one simple root at a time:

$$\alpha_2 \;\to\; \alpha_1+\alpha_2 \;\to\; \alpha_1+\alpha_2+\alpha_3 \;\to\; \alpha_1+\alpha_2+\alpha_3+\alpha_4 \;\to\; \alpha_1+2\alpha_2+\alpha_3+\alpha_4 = \theta$$

(in the Lean table basis: $18 \to 20 \to 23 \to 26 \to 27$, with $f_{\alpha_2} = x_{18}$ and the orthogonal simple roots x_{16}, x_{17}, x_{19}). At each step: if $f_\gamma^{k+1} w = 0$ and $f_\delta^{k+1} w = 0$ with $[f_\gamma, f_\delta] = \pm f_{\gamma+\delta}$ central in the pair, the Heisenberg lemma gives $f_{\gamma+\delta}^{2k+1} w = 0$; since $(\theta, (\gamma+\delta)^\vee) = 1$ and w is highest weight for the $\mathfrak{sl}_2$ of $\gamma + \delta$, `sl2_sharpen` improves this to $f_{\gamma+\delta}^{k+1} w = 0$; at the last step one keeps $2k+1$. The D_4 chain has four steps ending at f_θ; for E_6, E_7, E_8 the chains have 9, 15 and 27 steps reaching $f_{\theta-\alpha}$ for the simple root α with $(\theta, \alpha^\vee) = 1$, followed by one last Heisenberg step $[f_{\theta-\alpha}, f_\alpha] = \pm f_\theta$; they were found by table scans (`generators/*_kernel_scan.py`) and each step is a kernel-checked table fact. *Non-simply laced.* For G_2 the long roots form an A_2 but the short simple root breaks the Heisenberg pattern; `nil_of_ad` replaces it: if $Aw = 0$, $(\mathrm{ad}\, A)^{r+1} X = 0$ and $X^p w = 0$, then $((\mathrm{ad}\, A)^r X)^p w = 0$ (expand $\mathrm{ad}_A^{rp}(X^p)$ by Leibniz; only one term survives). For G_2: $(\mathrm{ad}\, f_{\alpha_1})^3 f_{\alpha_2} = 6x_3$ and $(\mathrm{ad}\, f_{\alpha_1})^4 f_{\alpha_2} = 0$, so $x_3^{k+1} w = 0$, and the Heisenberg pair (f_{α_2}, x_3) gives $f_\theta^{2k+1} w = 0$. F_4 is similar with two `nil_of_ad` steps and one Heisenberg pair. □

Physical meaning

The top θ-excitation of a weight-$k\theta$ state cannot be repeated more than $2k$ times: a finite multiplet. The chains are explicit paths through the root system from a simple root to θ.

What the machine verified

Proved, unconditional, for the six types D_4, E_6, E_7, E_8, G_2, F_4 (with A_2 from Theorem 26.17; caveats (a), (b) above); `#print axioms` standard (re-run for D_4, E_6, G_2, F_4; recorded for E_7, E_8, whose modules we did not import because of the per-process memory limit).

Trap / dead end

Dead end: Heisenberg chains along short roots. The Heisenberg route needs $\alpha = \gamma + \delta$ with $\alpha + \gamma$ and $\alpha + \delta$ not roots. It fails for G_2 at every non-simple root and for 18 roots of F_4. Use `nil_of_ad` or `top_nil` (next section) instead.

26.14 The finiteness clause for every type

Definition 26.38 (Splitting the total bound; the finiteness table). `FusionTotalFinG S`: degree pieces of modules with `LocalWeylRelG S` are finite-dimensional. `FusionTotalDimG S`: their total dimension is $\leq n^m$. A letter c is *low* if it is not raising, Cartan or `cartanN`; it is *known* for (ρ, w) if $c(0)^N w = 0$ for some N. A *finiteness table* says: every low letter has nonzero weight, and in every module with the local Weyl relations every low letter is known.

File `VOA/DeligneAudit/DeligneFusionFiniteG.lean`.

```
def FusionTotalFinG : Prop :=

File `VOA/DeligneAudit/DeligneFusionFiniteGNil.lean`.

```
def Known (w : V) (c : Fin S.n) : Prop := ∃ N, (ρ.op c 0 ^ N) w = 0
```

From the mathematics to the Lean statement

`S` is a section variable; in `Known`, `ρ` is a section variable. `S.wt c` is the weight of the basis letter c (a vector of integers, Definition 24.28). `FusionTotalDimG` is the type-generic analogue of `FusionTotalDim`; with `S.n` $= 8$ and the A_2 sector it is the same statement. As for A_2, the dimension clause alone would be weak on infinite-dimensional pieces; the finiteness clause is therefore proved separately.

Physical meaning

(Heuristic.) Finiteness of each energy level of the fused multi-particle space, for each Deligne flavour.

What the machine verified

`FusionTotalDimG S`: **named hypothesis** for every sector, the per-type residual of the total bound (for A_2 the library proves the bound in its A_2-specific form `FusionTotalDim`, Theorem 26.30, and states no instance of `FusionTotalDimG A2sector`). `FusionTotalFinG`: proved per type (next theorem).

Theorem 26.39 (Kac's lemma; the top of an ad-string; finiteness for all seven types). *(1) If* $(\operatorname{ad}A)^K B = 0$ *and* $A^N u = 0$ *then* $A^{N+K}(Bu) = 0$. *(2) If* $(\operatorname{ad}X)^{q+1}Y = 0$, $X^p v = 0$ *and* Y^N *kills* $X^b v$ *for all* $b < p$, *then* $((\operatorname{ad}X)^q Y)^N v = 0$. *(3) A finiteness table gives* `FusionTotalFinG`*; hence* `FusionTotalDimG S` *implies* `FusionTotalBoundG S`. *(4) For each of the seven sectors a finiteness table is built from a kernel-checked certificate; so for each type the total bound reduces to* `FusionTotalDimG`.

```
theorem e8_finiteTable : FiniteTableG E8sector :=

theorem e8_fusionTotalBoundG_of_dim (h : FusionTotalDimG E8sector) :
    FusionTotalBoundG E8sector :=
```

From the mathematics to the Lean statement

`adR X` is $Z \mapsto XZ - ZX$ on a ring (here $\operatorname{End}V$); `(adR X)^[q]` is its q-fold iterate. In `cycDeg_finiteDimensionalG`, `S`, `V`, `ρ` are section variables. `finiteTableG_of_cert` reads a certificate: `fnz` marks nonzero structure constants (`hfz` relates it to `S.f`), `kn` marks the letters known from the start (raising letters, nilpotent with $N = 1$, and simple lowering letters), `cert` is a list of steps (X, Y, path), `certValid` is a Boolean check, and `hcov` says every low letter is reached and has nonzero weight. The per-type theorems `a2_`, `d4_`, `e6_`, `e7_`, `e8_`, `g2_`,

`f4_fusionTotalBoundG_of_dim` (namespaces `FiniteG.A2`, ...) all have the form printed for E_8.

Proof on paper. (1) Expand $A^{N+K}B = \sum_j \binom{N+K}{j}(\operatorname{ad}A)^j(B)A^{N+K-j}$; terms with $j \geq K$ vanish, terms with $j < K$ have $A^{\geq N+1}$ on the right. (2) $(\operatorname{ad}X)^{qN}(Y^N) = c((\operatorname{ad}X)^q Y)^N$ with $c \neq 0$ (all other terms of the Leibniz expansion contain $(\operatorname{ad}X)^{>q}Y = 0$); expanding $(\operatorname{ad}X)^{qN}(Y^N)v$ as $\sum \pm\binom{qN}{j}X^{qN-j}Y^N X^j v$ kills every term by the hypotheses. This is the t^{qN} coefficient of $e^{tX}Y^N e^{-tX}$, done without exponentials. (3) As for A_2 (Theorem 26.7): letters of nonzero weight are ad-nilpotent of a uniform order, so Kac's lemma on words makes each known letter locally nilpotent on the cyclic module; sorted words of bounded length span each degree. (4) A certificate step (X, Y, path) uses (2): X and Y known, the $\operatorname{ad}X$-string from Y runs through basis letters with nonzero constants and stops; its top is then known. Step counts: A_2 1, G_2 4, D_4 8, F_4 20, E_6 30, E_7 56, E_8 112. For G_2 the root $2\alpha_1 + \alpha_2$ is reached as the top of an ad-string starting at a *raising* letter. □

Physical meaning

The zero-mode algebra acts integrably on the fused space: each lowering zero mode can be applied only finitely often to any state.

What the machine verified

Proved; `#print axioms` standard (`top_nil`, `fusionTotalBoundG_of_dim`, `d4_fusionTotalBoundG_of_dim` re-run; the others recorded). **After this theorem the per-type residual of U5's total bound is exactly `FusionTotalDimG`.**

26.15 Lattice realizations of Demazure modules

For A_2 the Demazure lower bound (D) came from the evaluation model (Theorem 26.24), whose last step used the $\mathfrak{sl}_3$-specific Chari–Loktev upper bound. For the other types the natural model is the Frenkel–Kac realization of the level-one module: $D(1, N\theta)$ is the cyclic $\mathfrak{g}[t]$-submodule of the lattice vertex algebra V_L generated by $e^{N\theta}$. The library proves the *relations half* of this for the simply-laced types and names the *dimension half*.

Definition 26.40 (Lattice realization data; the lattice dimension statement)**.** For an even positive-definite lattice L and a sector S, lattice realization data are weight-one states $X_i \in V_L$ whose 0-products are the sector table, each a multiple of a root vector $e^{\mathrm{rt}(i)}$ or a coroot state $\mathrm{cv}(i)(-1)\mathbf{1}$, and a root $\theta \in L$ satisfying sign conditions on $\langle \cdot, \theta \rangle$. **`LatDim Dem N`**: the degree pieces of the cyclic module of $e^{N\theta}$ dominate Dem_N.

From the mathematics to the Lean statement

`L, hE : L.Even, hP : L.PosDef` are section variables; inside `namespace LatData`, the section variables are `{S : DeligneSectorData} (D : LatData S L hE hP)`, so `ρ`, `vN`, `LatDim` (and `sat`, `demazureRealizationG` below) take `D` as an *explicit* first argument and `S, L, hE, hP` implicitly; dot notation `D.ρ`, `D.vN N` supplies `D`. `latRepG` is printed without its `comm` field (the current-algebra commutator, proved from the commutator formula for weight-one fields as in Theorem 26.25); the elision is ours. `latChargeGen L β` is e^{β}, `hSt L v` is $v(-1)\mathbf{1}$, `L.form` the bilinear form. `cart i` decides whether X_i is a coroot (`true`) or a root vector (`false`); `sg i` is the complex scalar with $X_i = \mathrm{sg}(i)\, e^{\mathrm{rt}(i)}$ for root letters (field `root`), i.e. the cocycle sign and normalization that make the 0-products equal the sector table (field `br`); it is unconstrained otherwise, and is ignored for coroot letters. The sign conditions: raising $\langle \mathrm{rt}(e), \theta\rangle \geq 0$; Cartan $\langle \mathrm{cv}(h), \theta\rangle = \theta(h)$; lowering $\langle \mathrm{rt}(i), \mathrm{rt}(i)\rangle = 2$ and $\langle \mathrm{rt}(i), \theta\rangle \geq -\theta(h_i)$; fusion $\langle \mathrm{rt}(x), \theta\rangle \geq -1$ (≥ -2 for $x = f_\theta$). `vN N` is $e^{N\theta}$.

Physical meaning

The Frenkel–Kac construction: the level-one currents of a simply-laced $\mathfrak{g}$ are realized by rank $\mathfrak{g}$ free bosons and vertex operators $e^{\alpha}(z)$ for the roots. The state $e^{N\theta}$ is the extremal state of charge $N\theta$; the sign conditions are statements about which vertex-operator modes annihilate it.

What the machine verified

Definitions. `LatDim` is the **named** dimension half of U7 on the lattice side.

Theorem 26.41 ($e^{N\theta}$ satisfies Ravinder's $M_{N,0}$ relations; lattice U7). *(1) For lattice realization data with $\langle\theta,\theta\rangle = 2$ and every N, $e^{N\theta}$ satisfies* `ravFam S N 0`. *(2) Hence* `LatDim Dem N` *implies* `DemazureRealizationG S (ravFam S) Dem N`. *(3) Realization data exist for D_4, E_6, E_7, E_8 (*`d4LatData`, `e6LatData`, `e7LatData`, `e8LatData`, *with $\langle\theta,\theta\rangle = 2$ proved as* `d4_hθ`, …, `e8_hθ`*); for these types the relations half of U7 is unconditional. (4) (Corollary for D_4.) If* `FusionTotalBoundG D4sector` *holds and* `D4LatticeDim N` *holds for every N, then D_4 is classically free for its explicit presentation, with the expected kernel (*`d4_classicallyFree_of_totalBound_latDim`*). The E_6, E_7 analogues take additional "star" inputs (Chapter 25). There are no lattice data for G_2, F_4: the Frenkel–Kac construction realizes*

level-one currents of simply laced *algebras only, since it needs all roots to have norm* 2 *in an even lattice.*

From the mathematics to the Lean statement

`d4LatData` (`LatticeRealizationD4.lean`) uses the D_4 root lattice `d4` and the basis `D4Lie.xs` of Chapter 23; `table_eq_sL` (in the `Bridge` files, from the row checks) identifies the sector table with the lattice model's bracket table. θ is `wt 15` for D_4, `wt 41` for E_6, `wt 69` for E_7, `wt 127` for E_8. `D4Wp.hilbSeriesZ` and `hilbSeries e8DemazureHilb` are the Demazure series of Chapter 25. There is no E_8 classical-freeness corollary of the lattice route in this file; the E_8 final theorem (Chapter 27) takes `DemazureRealizationG` directly. The `_latDim` theorems for E_6 and E_7 (`e6_`, `e7_classicallyFree_of_totalBound_latDim`) have the shape of the D_4 one with extra star inputs.

Proof on paper. Vertex-operator vanishing: $e^{\alpha}_{(r)}e^{\beta} = 0$ for $r \geq -\langle\alpha,\beta\rangle$. With $\beta = N\theta$ this kills raising modes ($\langle \mathrm{rt}(e),\theta\rangle \geq 0$) and gives the truncations $x(N)$ for fusion letters ($\langle \mathrm{rt}(x),N\theta\rangle \geq -N$) and $f_\theta(2N)$. Coroot modes act by $\langle \mathrm{cv}(h),N\theta\rangle = N\theta(h)$ at grade 0 and by 0 at positive grade. The lowering relations come from the weight shell: after $N\theta(h_i)+1$ applications of $f_i(0)$ the charge $N\theta - K\alpha_i$ has $\frac{1}{2}|N\theta - K\alpha_i|^2 = N^2 + K(K - N\langle\alpha_i,\theta\rangle) > N^2$, while the conformal weight is still N^2; the space of such states is zero. □

Physical meaning

In the free-boson picture the null vectors of the Demazure module are just energy conservation: a vertex operator cannot lower the energy below the minimum allowed in its charge sector.

What the machine verified

`LatData.sat`, `d4_lattice_sat`, `d4_classicallyFree_of_totalBound_latDim`: `#print axioms` standard (re-run); `e6_`, `e7_`, `e8_lattice_sat`: standard (record, WS-AFF). `D4LatticeDim`, `E6LatticeDim`, `E7LatticeDim`, `E8LatticeDim`: **named**, not proved. **Numerics** (exact ranks modulo two primes, `aff_lattice/lattice_demazure.py`): the lattice cyclic module is graded-sharp, $\dim W_d = [q^d]\,\mathrm{Hilb}\,D(1,N\theta)$ in every degree, for A_2, $N \le 3$ (totals $9, 81, 729$) and D_4, $N \le 3$ (totals $29, 841, 24389$; for $N = 3$: $1925, 4396, 6475, 5655, 3590, 1617, 568, 134, 28, 1$). No lattice data exist for G_2, F_4 (not simply laced).

Trap / dead end

What a proof of the dimension half needs. For A_2 the graded statement followed from a *total* count plus a graded *upper* bound (Chari–Loktev), which is specific to $\mathfrak{sl}_n$, where $D(1,N\theta) = W_{\mathrm{loc}}(N\theta)$ and Gelfand–Tsetlin theory applies. For D_4, E_6, E_7, E_8, G_2, F_4 no analogous spanning set is known, and a totals-only version of (D) does not suffice in the squeeze, which uses $M_{n,0} = \mathcal{D}_n$ coefficientwise. A proof needs the Demazure character formula (Kumar, Mathieu) or a D/E analogue of Chari–Loktev. It is one of the open inputs of Chapter 27 for the types other than A_2.

26.16 How the fusion layer feeds the Deligne chain

Table 26.5 lists, per type, what this chapter supplies to the sector bound of Chapter 24 (Theorem 24.35, which consumes `FusionModuleBoundG S F`) and to the resummation D3 (which consumes `MixedFusionRecursion F Dem`), and what it leaves. U6 is `mixedFusionRecursion_fusionOf`

Table 26.5: Per-type output of the fusion layer. "K" is the kernel lemma, "Fin" the finiteness clause, both proved. "U7" is `DemazureRealizationG` for all n. The last column is what Chapter 27 must still assume; the alternatives in parentheses imply the entry before them.

type	K and Fin (proved)	U7	still assumed
A_2	`ravinderKernelRel`, `cycDeg_finiteDimensional`	proved (`demazureRealization_all`)	nothing: `FusionTotalDim` is proved (`CVUniv.fusionTotalDim`)
D_4	`d4_ravinderKernelRel'`, `d4_fusionTotalBoundG_of_dim`	proved (`D4Char.d4_demazureRealization`)	`FusionTotalDimG` only
E_6	`e6_ravinderKernelRel'`; Fin as for E_8	`DemazureRealizationG`; lattice relations proved	`FusionTotalDimG`, U7 (or `E6LatticeDim`)
E_7	`e7_ravinderKernelRel'`; Fin as for E_8	as E_6	as E_6
E_8	`e8_ravinderKernelRel'`, `e8_fusionTotalBoundG_of_dim`	as E_6	as E_6
G_2	`g2_ravinderKernelRel`; Fin as for E_8	`DemazureRealizationG` (no lattice)	`FusionTotalDimG`, U7
F_4	`f4_ravinderKernelRel`; Fin as for E_8	as G_2	as G_2

for every type. The count "fusionOf(Dem)$_m(1) = (\dim \mathfrak{g})^m$" needed by the squeeze comes

from the Demazure totals $\mathcal{D}_n(1) = (\dim \mathfrak{g} + 1)^n$ of Chapter 25 (Theorem 25.40); the per-type headline wrappers that assemble everything, including the star identities of Chapter 25 (proved there; they are not open inputs of this chapter) for G_2, F_4, E_6, E_7, E_8, are the theorems `X_classicallyFree_final` of Chapter 27. An example of such a wrapper at the level of this chapter is `UnivG.e8_classicallyFree_of_totalBound (hF : FusionTotalBoundG E8sector) (hD : ...) (hcount : E8FusionCount) (hstar : E8StarIdentity)` in `E8FusionKernelFinal.lean`; its count input `E8FusionCount` is removed in Chapter 27 by the unclamped fusion series of Chapter 25.

26.17 Supporting files and certificates, described collectively

How to read a certificate. A reader who has never used Lean needs four facts. (1) The Python generators that produced the data are *untrusted*: nothing depends on their correctness. (2) Each family has a *Boolean predicate* or a decidable `Prop`, defined in Lean, together with a *soundness theorem* proved once (for instance `finiteTableG_of_cert`: a valid certificate yields a finiteness table). (3) The Lean kernel *evaluates* the predicate on the literal data by `decide +kernel`; that evaluation is a proof, checked by the kernel itself and not by a compiled program (no `native_decide` appears in these files). (4) Hence a referee must audit only the soundness theorems, which this chapter presents, and the identification of the data with the mathematical objects (sector tables, which Chapter 24 certifies).

Families.

- **Lattice bridge rows** (62 files `LatticeRealization{D4,E6,E7,E8}Rows*`: 4, 10, 17, 31). Each theorem `bridgeRow i` states, for one row i of the bracket table, that the sector table entry equals the lattice model's certified entry for every column, by one `decide +kernel`. The `Bridge` files combine the rows into `table_eq_sL`; the `Checks` files (E_7, E_8) hold the index checks (which basis index is θ, which are simple) in light files. Reason for the split: a whole-table `decide` over 133^2 entries took 41 GB and timed out; one row takes about 3 s and under 3 GB.
- **Finiteness certificates** (`DeligneFusionFiniteG{A2,D4,E6,E7,E8,F4,G2}`, `...E7Chk`, `...E8Chk`, `DeligneFusionFiniteGCert`). The Boolean checks (`wEqB`, `singleChk`, `topChk`, `pathChk`, `certKnown`, `certValid`) are stated for a bare weight function in `FiniteGCert`, which imports almost nothing; the per-type files read them against the sector by definitional unfolding. Certificate sizes are the step counts of Theorem 26.39. Measured: E_8 check 12.2 s, 4.6 GB.
- **Kernel tables** (`D4FusionKernel`, `E6FusionKernel`, `E7FusionKernel`, `E8FusionKernel`, `E8FusionKernelDefs`, `E8FusionKernelFacts`, `F4LieKernelData`). Each field of `KernelTable` (Definition 26.35) is proved from an integer table by `decide +kernel`, using literal lists with `getD` (selectors such as `hselL`, `bselL`, `kselL` for E_6) rather than `![…]` vectors, and, for E_8, support checks instead of per-entry facts.
- **Heisenberg chains** (`*FusionKernelTheta`). Each chain step is a three-entry table fact (`chainZ`).

Supporting mathematics files (all proved, standard axioms, presented in summary).

- `DeligneFusionPBW.lean`: `wordOp` algebra and PBW sorting of words in a current module (`cycDeg_le_sortedLow`: degree pieces are spanned by sorted words with "low" letters first).
- `DeligneFusionTruncation.lean`: loop ideals; an ideal of current modes that kills w kills the cyclic module (`wordOp_eq_zero_of_mem`); truncations propagate upward (`cycDeg_le_truncated`).

- `DeligneFusionGrade.lean` and `DeligneFusionUnivGGrade.lean`: degree projections on universal modules, quotient current modules, rank–nullity on submodules.
- `DeligneFusionCount.lean`: polynomial versions of $\mathcal{D}_n$ and fusionF, their values at $q = 1$ (9^n, 8^n) and supports (`demazureHilb_sum`, `fusionF_sum`).
- `DeligneFusionECalc.lean`, `DeligneFusionCLFilt.lean`, `DeligneFusionCLGT.lean`, `DeligneFusionCLNormal.lean`, `DeligneFusionCLTheta.lean`, `DeligneFusionCLLift.lean`: the Chari–Loktev machinery at vector level (the E-calculus of CL 3.4, the Gelfand–Tsetlin filtration and `part_i`, the normal-order lemma and `prop333`, normal words and the statistic σ, the θ-box `theta_box`, and the degree–weight lift). One `simp` over 512 cases in `table_gw` costs about 15 s and 2.6 GB.
- `DeligneFusionCVsl2.lean`, `DeligneFusionCVPart.lean`: Chari–Venkatesh Lemma 6.6 made precise (`shift_aux`, `shift_iter`), the partitions $\xi^{\pm}$ and the product identity (`arith_plus`, `prod_split`).
- `G2Fusion.lean`: `g2FusionF`, its U6, and a G_2 count statement `G2DemazureCount`.
- `E6FusionKernelFinal.lean`, `E7FusionKernelFinal.lean`, `E8FusionKernelFinal.lean`: per-type wrappers from `FusionTotalBoundG`, the realizations, a count and a star input.

26.18 Verification record

What the project records. At an earlier commit the umbrella target `VOA.Deligne` was built green (`campaign_build.sh VOA.Deligne`, 11099 jobs), and every `#print axioms` in these files reported a subset of the three standard axioms (the builds of these files are logged in `WS-MLD.md`, `WS-JTP.md`, `WS-REL.md`, `WS-CAR.md`, `WS-AFF.md`). On 2026-10-28 the aggregate build `bash scripts/campaign_build.sh VOA` (the full `lake build VOA` under the project's memory-capped wrapper) was green on 2026-10-28 (a pre-release build): 18,901 jobs, and again 18,907 jobs after merging the then-current `origin/main`; the aggregate target contains the umbrella. Since that umbrella build the library gained the Chari–Venkatesh files of Section 26.10 and the unconditional A_2 file `VOA/DeligneAudit/A2Unconditional.lean`, and some certificate files were split for memory; every statement quoted in this chapter occurs verbatim in the state this chapter was written against. For the new files the record is a set of targeted builds (27 October 2026): `VOA.DeligneAudit.A2Unconditional` green, 9755 jobs, maximum resident memory 6.13 GB, with `CVUniv.fusionTotalDim` and `A2.classicallyFree` printing exactly `[propext, Classical.choice, Quot.sound]`; `CVUniv.sharpRectangularBases` (8863 jobs) and `CVUniv.residualTheta3Bound` (8887 jobs) green with standard axioms. So these results are `#print axioms`-clean per the targeted build record; the aggregate build was green on 2026-10-28, and `#print axioms` on `A2.classicallyFree` reports `[propext, Classical.choice, Quot.sound]` (Chapter 27). A grep of these files finds no `sorry`, `admit`, `native_decide`, `implemented_by` and no `axiom` declaration.

What we re-ran for this chapter. From the repository root, with `lake env lean -DmaxSynthPendingDepth=3` on scratch files importing one module each (peak resident memory 5.6–5.9 GB; each run about 4 s, using the existing build products):

```
import VOA.DeligneAudit.DeligneFusionU7:
  A2.classicallyFree_of_kernelLower', A2.classicallyFree_of_totalDim',

  UnivG.F4K.f4_thetaNil, UnivG.F4K.f4_ravinderKernelRel
```

Every one of these (all names prefixed by `VOA.DeligneAudit.`) printed

```
depends on axioms: [propext, Classical.choice, Quot.sound]
```

These runs were made at two earlier commits (the second for `A2.classicallyFree_of_totalDim'`, `EvalModel.demazureRealization_all` and `SectorWeyl.ravinderKernelRel`, with the same output, peak resident memory 5.8 GB); the statements they concern are unchanged in the state this chapter was written against. They were *not* repeated there, nor for this edition, and the axiom checks of the Chari–Venkatesh declarations of Section 26.10 were not run by us: this checkout has no compiled objects for those modules. We did not import the E_7 or E_8 kernel and lattice modules, because of the project's per-process memory limit; their axiom lists are from the project record. A clean `#print axioms` does not report explicit hypotheses: the classical-freeness theorems above remain *conditional* on the `Prop`s in their signatures, as stated; `CVUniv.fusionTotalDim` has none. We did not run `lake build`.

26.19 Findings, oddities and Lean defects

Trap / dead end

Stale docstrings (no effect on any statement; severity S4).

1. `A2.DemazureRealization` (`DeligneFusionDemazure.lean`): the docstring says that neither the presentation nor the character of $D(1, n\theta)$ "is formalized", implying the `Prop` is an open input. It is proved for all n by `EvalModel.demazureRealization_all`.

2. `DeligneFusionAssembly.lean`, module docstring: lists `RavinderKernelTrunc` and `FusionTotalBound` as named inputs of `rec_le` and `total_le`. `RavinderKernelTrunc` is a theorem (`ravinderKernelTrunc`), and the finiteness half of `FusionTotalBound` is a theorem (`cycDeg_finiteDimensional`). The docstring of `RavinderKernelTrunc` itself still calls it a "named literature input".

3. `UnivG.ThetaNilG` (`D4FusionKernelGeneric.lean`): docstring and module header call it a "named input"; it is proved for every type (Theorem 26.37).

4. `DeligneCarrier.D4DemazureCount` (`DeligneFusionSqueezeG.lean`): docstring

says "checked numerically for $n \leq 7$"; the corresponding total is proved (`d4_demazure_total`, `d4DemazureCountZ`, Chapter 25). The `Prop D4DemazureCount` itself (over $\mathbb{N}$-valued `d4DemazureHilb`) is derived only from a positivity hypothesis (`d4DemazureCount_of_coeff`); it is not used by the final theorems.

5. `UnivG.E6K.e6_ravinderKernelRel` (`E6FusionKernel.lean`, line 187): the docstring reads "Ravinder's kernel lemma for E_7". The statement is correct (it is about `E6sector`); only the docstring names the wrong type.

6. `DeligneFusionCVTotal.lean`: `SharpRectangularBases` and `ResidualTheta3Bound` are documented as "UNPROVED" explicit inputs, and the module docstring says the file does not assert unconditional A_2 classical freeness. Both are proved (Theorem 26.30); the file is correct as an implication.

7. `DeligneFusionU7.lean`, module docstring: "A_2 classical freeness rests on the single named residual `RavinderKernelLower`". It no longer rests on any named statement (Chapter 27).

Trap / dead end

Unused open `Props` in the library. `CL.CLIndependence` (unproved, unused) and `CL.CLCount` (proved, Theorem 26.20) and the older interfaces `demazureRealization_of_CL`, `Mchar_eq_of_CL` remain in `DeligneFusionCL.lean`. They are not on the path of any headline theorem.

26.20 Referee's checklist

declaration	intended meaning	conditional on / status	check
Headline results			
`CVUniv.fusionTotalDim`	$\dim F_m \leq 8^m$ for $\mathfrak{sl}_3$	**none**; proved (record)	Thm. 26.30

Chapter 27

The Deligne series IV: the final theorems and the named inputs

This chapter was written against an earlier state of the LeanVOA library; the statements of the literature inputs and the partial results of Section 27.6.1 were revised against a later state of the source (28 October 2026), following the project's audit of the literature inputs (`Notes/Textbook/referee/DELIGNE_INPUTS_PRECISION.md`). What the machine confirmed, and when, is stated once, in Section 27.10. For this edition, `scripts/textbook/sync.py` checks that every Lean quotation below occurs verbatim (up to whitespace and comments) in the source files of that release.

What this chapter is about. The *Deligne series* is the list of simple Lie algebras $A_1 \subset A_2 \subset G_2 \subset D_4 \subset F_4 \subset E_6 \subset E_7 \subset E_8$. At the level $k = -1 - h^\vee/6$ ($h^\vee$ the dual Coxeter number) the simple affine vertex algebra $L_k(\mathfrak{g})$ is expected to be *classically free*: its graded algebra for Li's filtration is the arc algebra of its C_2-algebra, and the C_2-algebra is $\mathrm{Sym}\,\mathfrak{g}$ modulo an explicit space I_2^{ns} of quadrics. Chapters 24–26 prove the pieces. This chapter states the result: for each of the seven higher-rank members $X \in \{A_2, G_2, D_4, F_4, E_6, E_7, E_8\}$ the library has one theorem `X_classicallyFree_final` with that conclusion, and this chapter states all seven exactly, checks them against the intended mathematics, and records, for each type, which inputs are proved and which are still hypotheses.

The result in one sentence. For A_2 the final theorem has *no hypotheses*: the library proves that $L_{-3/2}(\mathfrak{sl}_3)$ is classically free and that $R_V = \mathrm{Sym}\,\mathfrak{sl}_3/(I_2^{\mathrm{ns}})$ for eight explicit quadrics (`VOA.DeligneAudit.A2.classicallyFree`, re-exported as `A2_classicallyFree_final`). Machine status: confirmed. The aggregate build was green on 2026-10-28, and `#print axioms` on both declarations reports `[propext, Classical.choice, Quot.sound]` (Section 27.10). For the other six types the final theorems are proved *conditionally*. For D_4 one published input remains: Input T, the Kus–Littelmann fusion-product bound. Input R is proved in Lean for D_4, so the theorem `D4_classicallyFree_of_inputT` (Theorem 27.15) has Input T as its only hypothesis (machine-confirmed: aggregate build green on 3 November 2026, standard axioms). G_2, F_4, E_6, E_7, E_8 rest on three inputs. Two of them (T and R) are published theorems for every type, the first with one proof step flagged by the project; the library has formalized R only for A_2 and D_4, and T only for A_2. The third (S), needed for G_2, F_4, E_6, E_7, E_8, has no published proof known to us. **These five final theorems are therefore conditional on a conjecture**, supported by numerical evidence only.

The three inputs, by type. The hypotheses of the final theorems are of three kinds, which we call Input T, Input R and Input S throughout (they are defined in Section 27.4).

- **Input T** (the *total-dimension bound*): every module with the relations of the fusion

module $\mathcal{F}_m$ has dimension at most $(\dim \mathfrak{g})^m$. Lean: `FusionTotalDimG`, and for A_2 `SectorWeyl.FusionTotalDim`.

- **Input R** (the *Demazure realizations*): for every j, some module with the relations of the Demazure module $D(1, j\theta)$ is, in every degree, at least as large as the Demazure character. Lean: `DemazureRealizationG`.
- **Input S** (the *star bound*): the Demazure sum is bounded by the Arakawa–Kawasetsu coefficients, $\mathcal{D}_N \le c_N$. Lean: `XStarBound`.

type	Input T	Input R	Input S
A_2	proved (`CVUniv.fusionTotalDim`)	proved (`EvalModel.demazureRealization_all`)	proved (`A2.starIdentity`)
D_4	hypothesis	proved (`D4Char.d4_demazureRealization`)	proved (`D4Wp.d4SchurEqE4` with the unclamped Demazure = Schur identity; item (vi))
G_2, F_4	hypothesis	hypothesis	hypothesis
E_6, E_7, E_8	hypothesis	hypothesis	hypothesis

"Proved" for A_2: machine-confirmed; aggregate build green on 2026-10-28, standard axioms (Section 27.10). "Proved" for Input R of D_4: machine-confirmed; aggregate build green on 2026-11-03, standard axioms. "Hypothesis" means *not proved in Lean*; it says nothing about the literature. In the literature, T and R are theorems for every type and S is conjectural for G_2, F_4, E_6, E_7, E_8 (paragraph below, and Table 27.3).

Everything else in the argument is proved for all seven types (Chapters 24–26). The long form of this table, with sources and numerical evidence, is Section 27.6.

The literature behind the inputs, stated once. We state the literature position here and refer to this paragraph elsewhere. A citation never discharges a Lean hypothesis; it only bears on whether the hypothesis is believed true.

(i) **Input T is a published theorem for every simple $\mathfrak{g}$, with one flagged proof step.** The universal module with the Lean relations is the *truncated Weyl module* $W(m\theta, m)$ of Kus and Littelmann (their Definition 4.1): this is an elementary identification, proved on paper in Lemma 27.6 below. Kus and Littelmann, Pacific J. Math. 278 (2015) 427–445, Theorem 4.2 (proved through their Theorem 3.5 and Corollary 3.6(3)), taken at $\lambda = \theta, \lambda_0 = 0, N = m$, gives $W(m\theta, m) \cong \mathfrak{g}^{*m}$, of dimension $(\dim \mathfrak{g})^m$. For $\lambda_0 = 0$ the paper places *no restriction on* $\mathfrak{g}$ (the restriction to classical types and G_2 concerns only $\lambda_0 \neq 0$), and θ satisfies their hypothesis $\lambda \in L^+$ in every type, since it is supported on long simple roots (or is $2\omega_1$ in type C). So the specialization is the same for all six types. *Caveat:* the written argument on p. 437 of Kus–Littelmann, which passes from "the difference lies in the left ideal generated by the relations" to "its symbol kills the fusion vector", controls only the initial forms of the generators of the ideal, not of all its elements. The project's source audit flags this step as unjustified as written (Section 27.7.1). The caveat applies uniformly to all six types. For D_4 it has been sharpened by computation (Python, not Lean): at $m = 2$ the step as written is *insufficient*, since the symbols of the defining relations generate a strictly smaller left ideal than the symbols of all elements of the annihilator, with an explicit witness $\tilde{a}$ (end of Section 27.7.1). This is a gap in the published proof, not a counterexample: the conclusion of the step was confirmed for D_4 at $m = 2$ (exactly) and $m = 3$ (modulo two primes), and Theorem 4.2 itself is not known to fail for any type.

(ii) **Feigin's earlier proof.** The statement first appears as E. Feigin, *SIGMA* 4 (2008) 070, arXiv:0806.4851, Proposition 1 (the bigraded isomorphism) and Corollary 2 ($\mathfrak{g}^{*N} \cong$

$D(1, N\theta)/(\mathfrak{g} \otimes t^N \mathbb{C}[t])D(1, N\theta)$, for every simple $\mathfrak{g}$). In arXiv v1 the same results are numbered Proposition 2.1 and Corollary 2.2. The printed proof of Proposition 1 is labelled "the idea of the proof". Kus and Littelmann report a gap in it, by personal communication from the author, and the natural reading of the sketch is false: for two adjoint factors of $\mathfrak{sl}_3$ a filtration piece of dimension 55 would have to split into pieces of total dimension 63 (Section 27.7.1).

(iii) **Ravinder is not independent evidence for T.** B. Ravinder, *SIGMA* 10 (2014) 110, arXiv:1409.0274, states his results for every simple $\mathfrak{g}$; only his Theorem 2 and Corollary 3 assume $\mathfrak{g}$ simply laced. His Corollary 2 at $a = 0$ *is* Feigin's Corollary 2, imported as his Proposition 5, so it inherits Feigin's gap.

(iv) **The A_2 route.** Setia, Rani and Khandai (arXiv:2405.11944, §8) give an independent proof for $\mathfrak{sl}_3$ through Chari–Venkatesh modules. The library's proof of Input T for A_2 follows this route (Chapter 26, Section 26.10), so it depends neither on Feigin nor on the flagged step of Kus–Littelmann.

(v) **Input R is a published theorem for every type; it is formalized for A_2 and D_4.** Two facts are needed. The relation half, that the extremal vector of $D(1, j\theta)$ satisfies the Lean relations, follows from Ravinder's Proposition 1 (a presentation of $D(1, j\theta)$, stated for every simple $\mathfrak{g}$, after Chari–Venkatesh, Corollary 3.5) by the short argument of Lemma 27.6; it includes the short roots of G_2 and F_4. The graded half, that the graded dimension of $D(1, j\theta)$ is the output of the Lean algorithm, is the Demazure character formula (Kumar, Invent. Math. 89 (1987); Mathieu, Astérisque 159–160 (1988)), valid for all Kac–Moody algebras. For D_4, E_6, E_7, E_8 the Frenkel–Kac construction also realizes $D(1, j\theta)$ inside the lattice VOA. For D_4 the library proves Input R in every degree by its own route (`D4Char.d4_demazureRealization`, Theorem 27.8). For G_2, F_4, E_6, E_7, E_8 the library lacks a Lean model of $D(1, j\theta)$ with its graded dimension, and a proof that the Lean algorithm implements the Demazure character formula.

(vi) **Input S is a conjecture for G_2, F_4, E_6, E_7, E_8.** No published source is known to us. The evidence is numerical only: equality $\mathcal{D}_N = c_N$ is checked through q^{60} for G_2, q^{25} for F_4, q^{20} for E_6, q^{16} for E_7 and q^{14} for E_8 (scoping pass of 28 October 2026; Section 27.4.4). For G_2 the library reduces it to the single identity `G2DemazureEqKW`, the other half (`G2KWEqMLDE`) being proved. D_4 has no Input S: the needed identity is proved as a pair. `D4Wp.d4SchurEqE4` is the Schur $= E_4$ half (the series `d4SchurQ` is the MLDE solution); the Demazure = Schur half is `d4DemazureEqSchur_of_positivity` (from JTP's finite identity `d4FiniteIdentity_holds`), whose positivity hypothesis is discharged on the unclamped route by `D4Wp.d4DemazurePositivity_of_U5Z`, i.e. from U5 and hence from Inputs T and R, of which R is proved for D_4 (Theorem 25.37; dictionary of Definition 27.7).

Table 27.3 in Section 27.6 states each input type by type, with its precise literature status and the library's progress toward it.

Plan of the chapter. Section 27.1 recalls what classical freeness is and how the proof is organised. Section 27.2 is a primer on the current-algebra modules in which the inputs are stated, with a worked $\mathfrak{sl}_3$ example. Section 27.3 states the common conclusion and lists the seven VOAs. Section 27.4 states Inputs T, R and S. Section 27.5 states the seven final theorems, starting with the unconditional A_2 theorem. Section 27.6 is the type-by-type ledger, and Section 27.7 says what is known about the inputs that remain open. Section 27.8 presents the per-type headline theorems from which the final theorems are assembled. Section 27.9 records approaches that are known to fail. The chapter ends with the verification record, remarks on the Lean sources, the referee's checklist and the references.

Prerequisites. From Chapter 24: the predicate `CaseClassicallyFree` (Definition 24.4), the seven explicit presentations (Theorem 24.12), sector data (Definition 24.28), current modules and the input

U5 (Definition 24.29), and the logical arc of Remark 24.1. From Chapter 25: the Demazure sum (Definition 25.3), the coefficients c_N (Definition 25.7), the Demazure algorithm (Definition 25.34) and the target lower bound $c_N \le \dim L_N$ (Theorem 25.22). From Chapter 26: the reduction of U5 and U6 to Inputs T and R (universal modules, Section 26.6; the kernel lemma, Section 26.13; the squeeze, Section 26.5; U6 by construction, Section 26.4) and the proofs of Inputs T and R for A_2 (Sections 26.8 and 26.10). Each object is recalled where it first appears here.

27.0.1 Conventions

- *Omitted proofs.* A Lean quotation shows a statement, not its proof. A block that ends in `:=` or `:= by` with nothing after it is a statement whose proof is omitted. A one-line proof term is shown when it is informative, for example when it is a composition of earlier theorems.

- *"Axioms standard"* means that `#print axioms` reports a subset of `[propext, Classical.choice, Quot.sound]`, the three standard axioms of Lean's logic (Chapter 1, Section 1.3). The library has no project axiom (`VOA.pbw` is a theorem, Chapter 3). "Axioms standard" does *not* mean "unconditional": `#print axioms` does not list the explicit hypotheses of a theorem (Section 1.3.4). Every status box therefore lists the hypotheses.

- *Where a status claim comes from.* Unless a status box says otherwise, an axiom or build claim is a *campaign record* (the project's builds and the `#print axioms` lines at the end of each Lean file), described in Section 27.10. "Re-checked" marks a claim the author of this chapter re-ran.

27.0.2 Reading the Lean in this chapter

Chapter 1, Section 1.2, is the general primer; Chapter 26, Section 26.1.3, covers the current-module idioms. The constructs that recur here are these.

- **Fully qualified names.** The final theorems are stated with full names such as `VOA.DeligneAudit.A2.W`; the file `VOA/DeligneAudit/DeligneSeries.lean` has no `variable` declarations, so there are no hidden section hypotheses. Elsewhere short names such as `W` or `explicitPresentation` resolve through the file's `namespace` and `open` lines; the dictionaries give the full name whenever a short name is ambiguous (`explicitPresentation`, `classicallyFree_of_fusion` and `mldeCoeff` each denote several declarations).

- **`.A2`, `.D4`, …** are the constructors of the enumeration `HigherRankDeligneCase`; Lean infers the type from the position, so `CaseClassicallyFree .A2 W P` reads "case A_2, VOA W, presentation P".

- **Named statements.** `def P : Prop := …`, `abbrev P : Prop := …` and `structure P : Prop where …` only *name* a statement; nothing is asserted. A theorem with an argument `(h : P)` is proved assuming `P`. A named statement becomes a theorem when the library proves a term of it, as `CVUniv.fusionTotalDim : SectorWeyl.FusionTotalDim` does. `abbrev` is a definition that Lean unfolds automatically.

- **Existentials over modules.** `∃ (V : Type) (_ : AddCommGroup V) (_ : Module ℂ V) (ρ : …) (w : V), …` asks for a vector space V (the two anonymous arguments `_` are its additive group and $\mathbb{C}$-vector-space structures), a current-module structure `ρ` on it and a vector `w`.

- **Current modules.** `CurrentModule f V` is a family of linear maps `ρ.op x r` $= x(r) = x \otimes t^r$ on V satisfying the current-algebra bracket for the structure constants `f`; `wordOp ρ l w` applies a word; `cycDeg ρ w d` is the degree-d part of the cyclic span of w (Chapter 24, Definition 24.29).

- **Sums and series.** `∑ b ∈ Finset.range B, f b` is $\sum_{b<B} f(b)$; `PowerSeries ℚ` is $\mathbb{Q}[[q]]$; `coeff N F` is $[q^N]F$; `Module.finrank ℂ U` is $\dim U$ (with the convention that it is 0 when U is infinite-dimensional, which is why the finiteness of the relevant spaces is always proved separately).
- **Kernels and ideals.** `MvPolynomial.aeval x` is the algebra map $\mathbb{C}[X_0, \dots, X_{n-1}] \to A$ sending X_i to x_i; `RingHom.ker (…).toRingHom` is its kernel, an ideal; `Ideal.span` is the ideal generated by a set.

27.0.3 Notation

We follow Chapters 24–26. Several letters are overloaded in the sources; in the text of this chapter we use the following, and keep the Lean names inside quotations and dictionaries.

symbol	meaning
$\mathfrak{g}$, $d_{\mathfrak{g}}$, $h^\vee$, k	a simple Lie algebra of the series, its dimension $d_{\mathfrak{g}} = \dim \mathfrak{g}$ (Lean: `S.n`, and in some displays of earlier chapters n), its dual Coxeter number, the level $k = -1 - h^\vee/6$.
θ; e_θ, f_θ	the highest root; its root vectors. For $\mathfrak{sl}_3$ the simple lowering vectors are f_1, f_2 and $f_\theta = f_{12}$.
$\mathfrak{g}[t]$, $x(r)$	the current algebra $\mathfrak{g} \otimes \mathbb{C}[t]$; $x(r) = x \otimes t^r$, $r \geq 0$. The power of t is the *degree*, recorded by the variable q.
$L_k(\mathfrak{g})$, L_N, W	the simple affine VOA; its weight-N space; W is the Lean name of the VOA.
R_W, I_2^{ns}	Zhu's C_2-algebra; the explicit space of quadrics (Chapter 24).
$[q^N]f$, $(q)_j$	the coefficient of q^N; $(q)_j = \prod_{i=1}^{j}(1-q^i)$.
$V(\lambda)$	the irreducible $\mathfrak{g}$-module of highest weight λ; $V(\theta) = \mathfrak{g}$.
$D(1,\lambda)$; Dem_j	the level-one Demazure module (Section 27.2); its graded character for $\lambda = j\theta$. The Demazure index is j (Lean writes `n`).
$\mathcal{D}_N$	the Demazure sum $[q^N]\sum_{j\geq 0} q^j \mathrm{Dem}_j/(q)_j$.
c_N	the Arakawa–Kawasetsu coefficient, Lean `DeligneCharacter.mldeCoeff h N`.
$M_{a,b}$; $\mathcal{F}_m$	Ravinder's modules; the fusion module $\mathcal{F}_m = M_{0,m}$.
m	the number of adjoint factors in a fusion product; the modes $x(r)$ with $r \geq m$ are the ones cut off in $\mathcal{F}_m$.
$\mathcal{I}_m$	the ideal $\mathfrak{g} \otimes t^m\mathbb{C}[t]$ of $\mathfrak{g}[t]$ (not to be confused with I_2^{ns}).
Φ_d	the degree filtration of a fusion product.
u	the number of trivial tensor factors (Section 27.7.1).

27.1 Classical freeness and the shape of the proof

Classical freeness in five sentences. For a VOA W, Zhu's C_2-algebra is $R_W = W/C_2(W)$, where $C_2(W)$ is spanned by the states $a_{(-2)}b$; it is a commutative algebra, the "classical limit" of W (for a 4d $\mathcal{N}=2$ theory, the Higgs branch chiral ring). Li's filtration $F^0W \supseteq F^1W \supseteq \dots$ makes the associated graded $\mathrm{gr}^{\mathrm{Li}} W$ a commutative algebra with a derivation, and its degree-zero part is R_W (Chapters 11 and 24). The *arc algebra* $J_\infty R_W$ is the universal commutative algebra with a derivation generated by R_W: if $R_W = \mathbb{C}[X]/I$, it is $\mathbb{C}[X^{(0)}, X^{(1)}, \dots]$ modulo all derivatives of all elements of I. By the universal property there is a canonical surjection $J_\infty R_W \to \mathrm{gr}^{\mathrm{Li}} W$; W is *classically free* when it is injective, so that every state of W is a classical polynomial in the generators and their derivatives, subject only to the derivatives of the relations of R_W. Counting by weight, classical freeness is the equality $\dim W_N = \dim(J_\infty R_W)_N$ for every N.

The carrier. For an affine VOA the currents $x_{(-1)}\mathbf{1}$ generate, so $R_W = \operatorname{Sym}\mathfrak{g}/\ker$. The library proves that the explicit quadrics I_2^{ns} lie in that kernel (Chapter 24), so $J_\infty R_W$ is a quotient of $J_\infty\big(\operatorname{Sym}\mathfrak{g}/(I_2^{\mathrm{ns}})\big)$. The latter has an explicit linear model, the *carrier*, a space of polynomial functions in which the weight-N part is finite-dimensional; write $\mathrm{carrierDim}(N)$ for its dimension. Since Li's map is onto, $\dim L_N \le \mathrm{carrierDim}(N)$ always. Classical freeness, together with $\ker = (I_2^{\mathrm{ns}})$, follows from the reverse inequality.

Remark 27.1 (The logical arc)**.** Chapter 24 (Remark 24.1) reduces classical freeness to three statements, for every weight N:

(A) $\big(\mathrm{carrierDim}(N) \le \dim L_N \text{ for all } N\big) \implies$ classical freeness and $\ker = (I_2^{\mathrm{ns}})$;
(B) $\mathrm{carrierDim}(N) \le \mathcal{D}_N$;
(C) $\mathcal{D}_N \le c_N \le \dim L_N$.

(A) is proved with no hypothesis (Chapter 24). (C): $c_N \le \dim L_N$ is proved for every type (Chapter 25); $\mathcal{D}_N \le c_N$ is Input S. (B) is the *carrier side*. Chapter 24 proves it from two statements about current-algebra modules:

- **U5** (fusion module bound): there is a family of power series $F_m(q)$ such that every module with the relations of the fusion module $\mathcal{F}_m$ has degree-d piece of dimension at most $[q^d]F_m$, and total dimension at most $d_{\mathfrak{g}}^m$;
- **U6** (mixed recursion): the family $M_{a,b}(q)$ generated from F by $M_{0,b} = F_b$ and $M_{a+1,b} = M_{a,b+1} + q^{2a+b+1}M_{a,b}$ satisfies $M_{j,0} = \mathrm{Dem}_j$ for every j.

The carrier side also uses a *divisor comparison*, a statement of commutative algebra about the carrier of each type (a containment of two explicit modules over the symmetric polynomials, after localising at the primes that contain a discriminant), proved for each type by integer *certificates*: finite lists of structure-constant identities, each checked by Lean's kernel, with Lean-proved lemmas saying that a passing check implies the statement (Chapter 24, Section 24.8). Chapter 26 proves U6 by *defining* F as the solution of the recursion, and reduces U5 to Inputs T and R. So the inputs that remain are exactly T, R and S, as in the table above (for D_4, only T).

When all inputs hold the chain closes: $\dim L_N \le \mathrm{carrierDim}(N) \le \mathcal{D}_N \le c_N \le \dim L_N$, so all four numbers are equal. In particular $\dim L_N = c_N$, a *consequence* of the inputs. This equality is not itself stated as a Lean theorem for the six conditional types; for A_2 it is a Lean theorem proved independently (`A2.finrank_eq_mldeCoeff'`, Chapter 25).

27.2 Fusion products and Demazure modules: a primer

Inputs T and R are statements about graded modules for the current algebra $\mathfrak{g}[t]$. This section defines the modules involved and computes the smallest nontrivial case for $\mathfrak{sl}_3$.

Graded cyclic modules and presentations. $\mathfrak{g}[t]$ is graded by the power of t. A graded module generated by one vector w of degree 0 is *cyclic*; its degree-d piece is spanned by the words $x_1(r_1)\cdots x_s(r_s)w$ with $r_1 + \cdots + r_s = d$, and its *graded character* is $\sum_d \dim M_d\, q^d$. A cyclic module is often given by a *presentation*: a list of words that kill w. Every module whose generator satisfies the same relations is a quotient of the *universal* one, so its graded character is coefficientwise smaller. Consequently an *upper* bound for a presentation must be proved for the universal module, i.e. "for every module with the relations", while a *lower* bound needs only "some module with the relations".

Local Weyl modules. For a dominant weight λ, the local Weyl module $W_{\mathrm{loc}}(\lambda)$ of Chari and Pressley is the cyclic module with relations

$$\mathfrak{n}^+[t]\,w = 0, \qquad h(s)\,w = \delta_{s,0}\,\lambda(h)\,w, \qquad f_i(0)^{\lambda(h_i)+1}w = 0.$$

It is finite-dimensional.

Evaluation modules and fusion products. A $\mathfrak{g}$-module V and a point $c \in \mathbb{C}$ give the *evaluation module* $V(c)$, on which $x(r)$ acts by $c^r x$. Given cyclic $\mathfrak{g}$-modules $V_1, \dots, V_m$ and distinct points $c_1, \dots, c_m$, the tensor product $V_1(c_1) \otimes \cdots \otimes V_m(c_m)$ is cyclic on the tensor product of the highest-weight vectors; filtering it by degree in t and taking the associated graded gives a graded $\mathfrak{g}[t]$-module $V_1 * \cdots * V_m$ of the same total dimension, the *fusion product* of Feigin and Loktev. (For the modules used here the result is known not to depend on the points, by Ravinder's presentation theorem; independence of the points is not known in general and is not needed.) The basic case is $\mathfrak{g}^{*m} = V(\theta)^{*m}$, of total dimension $d_{\mathfrak{g}}^m$.

Level-one Demazure modules. Let $L(\Lambda_0)$ be the basic (level-one vacuum) representation of the affine Lie algebra $\hat{\mathfrak{g}}$. For a dominant λ in the coroot lattice the extremal vector of $L(\Lambda_0)$ of weight λ generates, under the Borel subalgebra containing $\mathfrak{g}[t]$, a finite-dimensional graded $\mathfrak{g}[t]$-module $D(1,\lambda)$, the *level-one Demazure module*. Its graded character is given by the Demazure character formula: apply the Demazure operators along a reduced word of the translation by λ to the extremal weight. Chapter 25 implements this as an algorithm (Definition 25.34); we write Dem_j for the result with $\lambda = j\theta$. The smallest case is

$$D(1,\theta) = \mathfrak{g} \oplus \mathbb{C}, \qquad x(0) \text{ acts on } \mathfrak{g} \text{ by the adjoint action and kills } \mathbb{C},$$
$$x(1)\,y = \kappa(x,y)\cdot 1\ (y \in \mathfrak{g}), \qquad x(1)\,1 = 0, \qquad x(r) = 0\ (r \geq 2),$$

with κ the normalised invariant form; so $\mathrm{Dem}_1 = d_{\mathfrak{g}} + q$. More generally $D(1, j\theta) \cong D(1,\theta)^{*j}$, of total dimension $(d_{\mathfrak{g}}+1)^j$ (Fourier–Littelmann 2007 for simply laced $\mathfrak{g}$; for all $\mathfrak{g}$ Kus and Littelmann cite Chari–Shereen–Venkatesh–Wand, arXiv:1408.4090, together with Fourier–Littelmann. We did not verify the latter attribution; nothing in this chapter depends on it). On an evaluation module $D(1,\theta)(c)$ at a point c, the action is $x(r)\,v = c^r\,x(0)v + r\,c^{r-1}\,x(1)v$: the value of t^r at c acts through the $\mathfrak{g}$-action, and its derivative through the map $\mathfrak{g} \to \mathbb{C}$.

Ravinder's modules $M_{a,b}$. Fix the highest root vector f_θ and a *fusion set* of negative root vectors containing f_θ (Ravinder takes $\{f_\alpha : \langle\alpha,\theta^\vee\rangle = 1\} \cup \{f_\theta\}$, where $\langle\alpha,\theta^\vee\rangle = 2(\alpha,\theta)/(\theta,\theta)$; with long roots of squared length 2 this is $(\alpha,\theta) = 1$. Since θ is long, every positive root $\alpha \neq \theta$ has $\langle\alpha,\theta^\vee\rangle \in \{0,1\}$, and the condition includes the *short* roots of G_2 and F_4 with $(\alpha,\theta) = 1$. For a short root of G_2 the other pairing $(\theta,\alpha^\vee)$ equals 3, so writing the condition as $(\theta,\alpha^\vee) = 1$ would wrongly exclude them). For $a, b \geq 0$, $M_{a,b}$ is the cyclic module with generator w of weight $(a+b)\theta$ and relations

$$e_\alpha(r)\,w = 0\ (\alpha > 0,\ r \geq 0), \qquad h(r)\,w = 0\ (r \geq 1), \qquad h(0)\,w = (a+b)\,\theta(h)\,w,$$
$$f_i(0)^{(a+b)\theta(h_i)+1}w = 0,$$
$$f_\alpha(a+b)\,w = 0\ \ (f_\alpha \text{ in the fusion set},\ \alpha \neq \theta), \qquad f_\theta(2a+b)\,w = 0.$$

The first two lines are the local Weyl module $W_{\mathrm{loc}}((a+b)\theta)$; the third cuts the modes. By *Garland's lemma* (a consequence of the integrability of each $\mathfrak{sl}_2$-triple: for $\mathfrak{sl}_2$, $e(1)^s f(0)^{r+s}w$ is a nonzero multiple of an explicit polynomial in the $f(k)$ applied to w) the cut on one mode implies cuts on all higher modes. Two cases matter: $M_{0,m}$, with all modes cut at t^m, is the *fusion module* $\mathcal{F}_m$, and the fusion product $\mathfrak{g}^{*m}$ is a quotient of it, so $\dim \mathcal{F}_m \geq d_{\mathfrak{g}}^m$; and $M_{j,0}$ is a presentation of $D(1, j\theta)$ (Ravinder's Proposition 1). Ravinder's theorem (his Theorem 1 and Corollaries 1–2, stated for every

simple $\mathfrak{g}$; the case $a = 0$ is imported from Feigin, see item (iii) of the literature paragraph) is that $M_{a,b} \cong D(1,\theta)^{*a} * \mathfrak{g}^{*b}$, of dimension $(d_\mathfrak{g}+1)^a d_\mathfrak{g}^b$, and that the family is linked by short exact sequences

$$0 \longrightarrow \tau_{2a+b-1} M_{a-1,b} \longrightarrow M_{a,b} \longrightarrow M_{a-1,b+1} \longrightarrow 0 \qquad (a \geq 1), \tag{27.1}$$

where τ_s raises degrees by s and the left map sends w to $f_\theta(2a+b-1)w$. Taking characters gives the mixed recursion U6, $\operatorname{ch} M_{a,b} = \operatorname{ch} M_{a-1,b+1} + q^{2a+b-1}\operatorname{ch} M_{a-1,b}$, which determines $\operatorname{ch} M_{0,m}$ from the Demazure characters $\operatorname{ch} M_{j,0} = \mathrm{Dem}_j$.

Example 27.2 ($\mathfrak{sl}_3$ with two adjoint factors)**.** Take $\mathfrak{g} = \mathfrak{sl}_3$, $d_\mathfrak{g} = 8$. Then $\operatorname{ch} M_{0,1} = 8$ and $\operatorname{ch} M_{1,0} = \mathrm{Dem}_1 = 8 + q$, and the recursion with $(a,b) = (1,0)$ reads $8 + q = 8 + q \cdot 1$ (totals $9 = 8 + 1$). The Demazure algorithm gives $\mathrm{Dem}_2 = 27 + 28q + 17q^2 + 8q^3 + q^4$, of total $81 = 9^2$. Running the recursion downwards:

$$\operatorname{ch} M_{1,1} = \operatorname{ch} M_{2,0} - q^3 \operatorname{ch} M_{1,0} = 27 + 28q + 17q^2 \qquad (81 - 9 = 72 = 9 \cdot 8),$$
$$\operatorname{ch} M_{0,2} = \operatorname{ch} M_{1,1} - q^2 \operatorname{ch} M_{0,1} = 27 + 28q + 9q^2 \qquad (72 - 8 = 64 = 8^2).$$

The degree-zero piece 27 is $V(2\theta)$, and $27 + 28q + 9q^2$ is the graded character of the fusion product $\mathfrak{sl}_3 * \mathfrak{sl}_3$ (Chapter 26, Example 26.3).

The squeeze at $m = 2$. Suppose we know: (R) a module with the relations of $M_{2,0}$ whose character is at least Dem_2 in every degree (Input R); (K) the *spanning half* of each exact sequence, $\operatorname{ch} M_{a,b} \leq \operatorname{ch} M_{a-1,b+1} + q^{2a+b-1}\operatorname{ch} M_{a-1,b}$ coefficientwise (this is the elementary half: see the warning below); and (T) $\dim M_{0,2} \leq 64$ (Input T). Applying (K) twice and the known $\operatorname{ch} M_{0,1} = 8$, $\operatorname{ch} M_{1,0} \leq 8 + q$,

$$\mathrm{Dem}_2 \leq \operatorname{ch} M_{2,0} \leq \operatorname{ch} M_{0,2} + 8q^2 + q^3(8+q), \qquad \text{so} \qquad \operatorname{ch} M_{0,2} \geq 27 + 28q + 9q^2$$

coefficientwise. The right-hand side has total 64, and by (T) the total of $\operatorname{ch} M_{0,2}$ is at most 64; a coefficientwise lower bound with the same total forces equality in every degree. So $\operatorname{ch} M_{0,2} = 27 + 28q + 9q^2$: the graded upper bound U5 for $m = 2$ follows from a lower bound (R), an elementary spanning inequality (K) and a total upper bound (T). This is Ravinder's squeeze (Chapter 26, Theorem 26.12) in its smallest case; note that the subtractive step works only because the total bound (T) closes it.

The surjection half is free; the injection half is not

In (27.1) the right map is surjective for elementary reasons: the relations of $M_{a-1,b+1}$ are those of $M_{a,b}$ plus the one relation $f_\theta(2a+b-1)w = 0$. Its kernel is the cyclic span of $f_\theta(2a+b-1)w$, which is a quotient of $\tau_{2a+b-1}M_{a-1,b}$ (Ravinder's kernel lemma: that vector satisfies the relations of $M_{a-1,b}$). These facts give *upper* bounds, inequality (K) above. What is hard is the other direction: that the kernel is *as large as* $\tau_{2a+b-1}M_{a-1,b}$, or that $D(1, j\theta)$ is *as large as* its character formula says. Upper bounds come from spanning sets; lower bounds need a model in which vectors can be shown to be independent.

This explains why Input T, an *upper* bound on $\dim M_{0,m}$, is hard. A spanning set for $M_{0,m}$ obtained from the relations is far larger than $d_\mathfrak{g}^m$ (the naive count gives 72 instead of 64 already for $\mathfrak{sl}_3$, $m = 2$; Section 27.9). Counting through the exact sequences converts the missing upper bound for $M_{0,m}$ into a missing *lower* bound for the kernels, and a lower bound can in principle be proved by exhibiting independent vectors in a model. For A_2 the library proves Input T by enlarging the family of modules until an induction of this kind closes (Chapter 26, Section 26.10).

27.3 The common conclusion and the seven VOAs

Every final theorem has the same conclusion, a conjunction of two statements about one VOA W and one explicit presentation P.

Definition 27.3 (Classical freeness of a case, and the kernel statement). Let W be a VOA with weight-one states gen_i, $i < n$, and let $I \subseteq \mathbb{C}[X_0, \dots, X_{n-1}]$ be an ideal contained in the kernel of the map $X_i \mapsto [\mathrm{gen}_i]$ into Li's associated graded algebra (a *current C_2 presentation* P). The case is *classically free* for P if the infinite Li jet map $J_\infty(\mathbb{C}[X]/I) \to \mathrm{gr}^{\mathrm{Li}} W$ is bijective. The *kernel statement* is $\ker\big(\mathbb{C}[X] \to \mathrm{gr}^{\mathrm{Li}} W\big) = I$.

File `VOA/Examples/DeligneHigherRankConditionalCapstone.lean`.

```
def CaseClassicallyFree (P : CurrentC2Presentation case W) : Prop :=
  LiPresentationClassicallyFree W
    (fun i => liDegreeZeroClass W 1 ⟨P.gen i, P.gen_weight_one i⟩)
    P.ideal P.relations_vanish
```

From the mathematics to the Lean statement

`CurrentC2Presentation case W` is the structure of Definition 24.4: the fields `gen`, `gen_weight_one`, `ideal`, and `relations`, which says that `ideal` is *contained* in the kernel (`P.relations_vanish` is a renaming of that field). `liDegreeZeroClass W 1 x` is the class of the weight-one state x in F^0W_1/F^1W_1, the degree-zero part of Li's associated graded algebra. `LiPresentationClassicallyFree` is bijectivity of the infinite jet map (Definition 24.2): its source is the presented jet algebra, the polynomial ring in variables $X_i^{(r)}$ modulo all derivatives of all elements of the ideal, and $X_i^{(r)}$ is sent to the r-th divided derivative of the class of gen_i. `CaseClassicallyFree` has, from the `variable` lines of its file, an implicit carrier `\{V : Type uV\}` with its vector-space structure and two explicit arguments `case : HigherRankDeligneCase` (which of the seven types, fixing the number of currents `case.currentDimension`) and `W : VertexOperatorAlgebra V`.
In every final theorem the kernel statement appears as a second conjunct, `RingHom.ker (MvPolynomial.aeval fun i ⇒ liDegreeZeroClass W 1 ⟨P.gen i, P.gen_weight_one i⟩).toRingHom = I`, an equality of ideals of $\mathbb{C}[X_0, \dots, X_{n-1}]$. Since the image of $\mathbb{C}[X]$ is $R_W = \mathrm{gr}_0^{\mathrm{Li}} W$ (the currents strongly generate W), this is the statement $R_W = \mathrm{Sym}\,\mathfrak{g}/I$.
Why the conclusion is not weak. Classical freeness of a presentation forces the ideal to equal the kernel (Theorem 24.6), so the second conjunct follows from the first; the library states both so that a reader sees the presentation of R_W directly. The conclusion cannot be satisfied by a degenerate choice: the ideal is fixed in advance, and W is a specific nonzero VOA.

Physical meaning

For the chiral algebra of a four-dimensional $\mathcal{N} = 2$ theory, the first conjunct says that every Schur operator is a classical object: a polynomial in the flavour currents and their derivatives, subject only to the derivatives of the Higgs-branch chiral-ring relations. The second conjunct says that the chiral-ring relations among the moment maps are exactly the quadrics I_2^{ns}. Together they say that the Schur index equals the Hilbert series of the arc space of the *scheme* $\mathrm{Spec}\, R_W$: no "quantum" cancellation between classical states. *Heuristic, not Lean:* the reduced variety underneath this scheme is the associated variety of $L_k(\mathfrak{g})$, which Arakawa and Moreau identify with the minimal nilpotent orbit closure $\overline{\mathbb{O}_{\min}}$ for the Deligne series at these levels; the scheme itself is non-reduced (the Casimir is nilpotent in R_W but not zero; *checked outside Lean*: the Lean statement is `sym_X_mul_casPoly`, that $X_a \cdot \mathrm{Cas}$ vanishes in the C_2-algebra).

What the machine verified

Definition (Chapter 24). The kernel statement is always a conclusion, never a hypothesis.

The seven VOAs. Each final theorem is about a specific VOA built in Chapters 23 and 24. The table lists the Lean name, the Lie data from which it is built, the level, and the number of quadrics in the library's relation list.

type	VOA (Lean)	Lie data	k	$d_{\mathfrak{g}}$	$h^\vee$	quadrics
A_2	`A2.W`	bespoke $\mathfrak{sl}_3$	$-3/2$	8	3	8
G_2	`G2Lie.g2W`	`g2CertData`	$-5/3$	14	4	27
D_4	`D4Lie.W4`	`d4CertData`	-2	28	6	105
F_4	`F4Lie.f4W`	`f4CertData`	$-5/2$	52	9	324
E_6	`DeligneCarrier.E6.W6`	`e6LieData`	-3	78	12	650
E_7	`E7Lie.W7`	`e7CertData`	-4	133	18	1539
E_8	`E8Lie.W8`	`e8CertData`	-6	248	30	3875

All seven are simple quotients of universal affine VOAs: A_2 through the $\mathfrak{sl}_3$ construction of Chapter 24, the other six as `simpleVOA D k _` of Chapter 23. Their central charges are $c = k\,d_{\mathfrak{g}}/(k+h^\vee) = -2(h^\vee+1)$, namely $-8, -10, -14, -20, -26, -38, -62$.

What the relation lists are, and what Lean proves about them

For A_2 the ideal `A2.I2ns` is generated by eight explicit quadrics $P_0, \dots, P_7$ (Chapter 24, Definition 24.8). Lean proves that they are homogeneous, linearly independent, and in the kernel; that they span the adjoint summand $V(\theta) \subset \mathrm{Sym}^2\,\mathfrak{sl}_3$ was checked outside Lean and is *not* a Lean statement. The ideal does not contain the Casimir (only its products $X_a \cdot \mathrm{Cas}$); this non-membership is checked outside Lean and is not a Lean statement (the Lean statement is `sym_X_mul_casPoly`). So the A_2 theorem identifies R_V with $\mathrm{Sym}\,\mathfrak{sl}_3$ *modulo these eight quadrics*; it does not mention, and must not be described as identifying R_V with, the coordinate ring of the minimal nilpotent orbit closure or a "Joseph ideal" (type A has no Joseph ideal in the sense of Chapter 24, and R_V is non-reduced, a fact checked outside Lean). For the other six types Lean proves that each listed quadric lies in the kernel; that the lists (27, 105, 324, 650, 1539, 3875 quadrics) span exactly I_2^{ns} is checked outside Lean. The conditional final theorems conclude ker = the ideal generated by the list.

Scope: which VOA is meant for $G_2, D_4, F_4, E_6, E_7, E_8$

For D_4, E_7 and E_8 the VOA of the final theorem is `simpleVOA` of the *certificate-basis* Lie data (`d4CertData`, `e7CertData`, `e8CertData`): the lattice Lie algebra of Chapter 23, written in the basis in which the relation lists were computed, with the form Killing/12, /36, /60. The library also builds VOAs `d4SimpleVOA`, and so on, from a basis chosen by `Module.finBasis`. Both are built from the same Lie algebra, form and $h^\vee$, but from different `LieData` (different bases), and the isomorphism of the resulting VOAs (independence of the affine construction from the basis) is *not* proved in Lean.

The same split exists for G_2 and F_4. The final theorems use `G2Lie.g2W`, which is `simpleVOA g2CertData (-5/3) g2_level_ne` (`VOA/DeligneAudit/G2LieData.lean`), and `F4Lie.f4W`, which is `simpleVOA f4CertData (-5/2) f4_level_ne` (`VOA/DeligneAudit/F4LieData.lean`), Lie data on the structure-constant algebras `g2Lie`, `f4Lie` in the table basis, with the forms Killing/8 and Killing/18. The library also defines `g2SimpleVOA` and `f4SimpleVOA` (`VOA/AffineGeneral/G2Lie.lean`, `VOA/AffineGeneral/F4Lie.lean`) from the `standardData` of the same algebras with the same forms; no isomorphism `g2W` $\cong$ `g2SimpleVOA` or `f4W` $\cong$ `f4SimpleVOA` is proved. Likewise three models of $\mathfrak{e}_6$ coexist (a structure-constant table, the lattice V_1, and the `E6Lat` certificate basis) and are not identified; the E_6 final theorem uses the structure-constant

model `e6LieData`.
Each theorem is nevertheless about a genuine $L_k(\mathfrak{g})$ for an explicit model of $\mathfrak{g}$: the Lie data carry their own proofs of the Lie algebra axioms and of the invariant form (Chapter 23). This is a remark on scope, not an error. It does not concern A_2, whose VOA is the bespoke $\mathfrak{sl}_3$ construction.

27.4 The named inputs

This section defines Inputs T, R and S and the relations in which they are stated. For each input we give the mathematical statement, the Lean definition and a fidelity check; the literature is the paragraph "The literature behind the inputs" at the start of the chapter.

27.4.1 Relation specifications and Ravinder's family

Definition 27.4 (Relation specifications; Ravinder's relations)**.** A *relation specification* for a Lie algebra with basis indexed by $\{0,\dots,d_{\mathfrak{g}}-1\}$ is a set of *tails* (words $x_1(r_1)\cdots x_s(r_s)$ in the current generators) and a set of *eigenvalue conditions* (h,μ). A vector w of a current module *satisfies* it if every tail kills w and $h(0)w=\mu w$ for every eigenvalue condition. The relations of $M_{a,b}$ of Section 27.2 form the specification $\mathrm{rav}(a+b,\,2a+b)$, where $\mathrm{rav}(k,d)$ consists of: $e(r)w=0$ for raising e and all r; $h(r)w=0$ for Cartan h and $r\geq 1$; $f_i(0)^{k\theta(h_i)+1}w=0$ for simple lowering f_i; $x(k)w=0$ for x in the fusion set other than f_θ, and $f_\theta(d)w=0$; and the eigenvalues $h(0)w=k\theta(h)w$. The basis, the structure constants, the fusion set and the numbers $\theta(h)$ are packaged as *sector data* S (Definition 24.28). For $\mathfrak{sl}_3$ the library also has a hand-written version, `MabRel ρ w a b`.

From the mathematics to the Lean statement

Words and letters. `Ltr n` is a pair (basis index, mode) $= (x, r)$, standing for $x(r)$; a tail is a list of letters, and `wordOp ρ t w` applies the word to w (the rightmost letter acts first; for the one-letter and repeated-letter tails used here the order does not matter). `List.replicate k (i, 0)` is the word $f_i(0)^k$, and `(ρ.op 3 0)^[a + b + 1]` is the $(a+b+1)$-fold iterate of $f_1(0)$.
The f_θ clause. In `ravSpec` the cut $f_\theta(d)w = 0$ is the case `x = S.c₀` of the fusion clause `[(x, if x = S.c₀ then d else k)]`, imposed only for `x` with `S.fusion x`. So it belongs to the specification exactly when $c_0 = f_\theta$ is in the fusion set. That membership is the field `c0_fusion : S.fusion S.c₀` of the kernel tables `KernelTable S` and `KernelTableSL S` (`VOA/DeligneAudit/D4FusionKernelGeneric.lean`), and every sector used by a final theorem comes with such a table.
Section variables. `Sat` has an implicit `\{n : ℕ\}` and an explicit structure-constant table `(f : Fin n → Fin n → Fin n → ℂ)`, so `Sat S.f ρ w R` reads "w satisfies R in the current module ρ over the table `S.f`". `ravSpec` and `ravFam` take `S` as an explicit first argument, which is why the final theorems write `ravFam G2.G2sector`. The named inputs quantify over `V : Type`, the lowest universe; every module that occurs (universal modules, evaluation and lattice models) lives there.
The two Cartan clauses. Sector data split the Cartan basis vectors into those with $\theta(h) \geq 0$ (`S.cartan`) and those with $\theta(h) < 0$ (`S.cartanN`, stored with the nonnegative number `S.thetaN h`); the negative eigenvalues are written as $-(k\,\theta_N(h))$ because a natural number cannot be negative.
$\mathfrak{sl}_3$ indices. In `bracketTable` the basis is e_1, e_2, e_θ (indices $0, 1, 2$), f_1, f_2, f_θ (indices $3, 4, 5$) and h_1, h_2 (indices $6, 7$), with $\theta(h_1) = \theta(h_2) = 1$. So `MabRel ρ w a b` is $\mathrm{rav}(a+b, 2a+b)$ with fusion set $\{f_1, f_2, f_\theta\}$. The relation $f_\theta(0)^{2(a+b)+1}w = 0$ is not listed; it follows from the others ($\mathfrak{sl}_2$-integrability).
Same as the literature? For $(a, b) = (0, m)$ the library proves `ravFam S 0 m = lwSpec S m` (`ravFam_zero`), the local Weyl and fusion relations. For $(a, b) = (j, 0)$ these are the relations of Ravinder's Proposition 1 for $D(1, j\theta)$. The sector data of E_6, E_7, E_8 use exactly Ravinder's fusion set; those of A_2, D_4, G_2, F_4 use all negative root vectors. The extra vectors are the f_α with $\langle \alpha, \theta^\vee \rangle = 0$ (every other positive root $\alpha \neq \theta$ has $\langle \alpha, \theta^\vee \rangle = 1$ and is already in Ravinder's set, short roots of G_2 and F_4 included). For these, $f_\alpha(r)w = 0$ holds for *every* r in any module with the local Weyl relations, by the $h(r)$-bracket argument of Lemma 27.6. So the two readings impose the same relations, for every type. For Input T this is in any case harmless, since extra relations make the hypothesis weaker; for Input R it means that the Demazure module $D(1, j\theta)$ satisfies the Lean relations, short roots included.

Physical meaning

Heuristic. A relation specification is a list of selection rules for a composite state: which current modes annihilate it. $M_{a,b}$ describes $a + b$ fused adjoint "particles", of which a carry the extra one-dimensional excitation of $D(1, \theta) = \mathfrak{g} \oplus \mathbb{C}$ and b do not; the mode cutoffs encode how much energy the fused system can absorb.

What the machine verified

Definitions. `ravFam_zero` (Chapter 26) identifies the $a = 0$ case with the local Weyl and fusion relations; axioms standard (campaign record).

27.4.2 Input T: the total-dimension bound

Definition 27.5 (Input T). For sector data S of $\mathfrak{g}$, `FusionTotalDimG S` is the statement: for every $m \geq 0$, every current module V and every $w \in V$ satisfying the local Weyl and fusion relations for $m\theta$ (that is, $\mathrm{rav}(m, m)$), and every B,

$$\sum_{b<B} \dim\bigl(\text{degree-}b \text{ part of the cyclic span of } w\bigr) \;\leq\; d_{\mathfrak{g}}^{\,m}.$$

Equivalently, $\dim \mathcal{F}_m \leq d_{\mathfrak{g}}^{\,m}$. For A_2 the library has the same statement over the hand-written $\mathfrak{sl}_3$ relations, `SectorWeyl.FusionTotalDim`, with bound 8^m.

File `VOA/DeligneAudit/DeligneFusionFiniteG.lean`.

```
def FusionTotalDimG : Prop :=
  ∀ (m : ℕ) (V : Type) [AddCommGroup V] [Module ℂ V] (ρ : CurrentModule S.f V) (w : V),
    LocalWeylRelG S ρ w m → ∀ B : ℕ, ∑ b ∈ Finset.range B, Module.finrank ℂ (cycDeg ρ w b)
     ↪ ≤ S.n ^ m
```

File `VOA/DeligneAudit/DeligneFusionFinite.lean`.

```
def FusionTotalDim : Prop :=
  ∀ (m : ℕ) (V : Type) [AddCommGroup V] [Module ℂ V] (ρ : CurrentModule (bracketTable) V)
   ↪ (w : V),
    LocalWeylRel ρ w m → ∀ B : ℕ, ∑ b ∈ Finset.range B, Module.finrank ℂ (cycDeg ρ w b) ≤ 8
     ↪ ^ m
```

From the mathematics to the Lean statement

Decoding. `LocalWeylRelG S ρ w m` is the structure of Definition 24.29: w satisfies the local Weyl relations of $W_{\mathrm{loc}}(m\theta)$ and the fusion relations $x(m)w = 0$ for x in the fusion set. The A_2 predicate `LocalWeylRel ρ w m` is the same for the $\mathfrak{sl}_3$ table (the library proves `MabRel ρ w 0 m ↔ LocalWeylRel ρ w m`, `mabRel_zero_iff`). The identification of `LocalWeylRelG S ρ w m` with $\mathrm{rav}(m, m)$ is the Lean theorem `UnivG.localWeylRelG_iff` (equivalence with `Sat S.f ρ w (lwSpec S m)`), together with `ravFam_zero` (`ravFam S 0 m = lwSpec S m`); it is not a rewrite, since `ravSpec` writes the powers as `List.replicate` while `LocalWeylRelG` uses iterates. `S.n` is $d_{\mathfrak{g}}$. The quantifier "$\forall B$" bounds every finite partial sum, which is the same as bounding the total dimension.

An upper bound over all modules. The statement quantifies over *all* modules and generators with the relations, so it is a statement about the universal module $M_{0,m}$, of which all the others are quotients.

The finiteness clause. `Module.finrank` is 0 on an infinite-dimensional space, so read alone the bound would say nothing about a module with an infinite-dimensional degree piece. The library proves separately, for every type, that every degree piece is finite-dimensional (`fusionTotalBoundG_of_dim`; Chapter 26, Section 26.14), so the input that remains is only the bare bound displayed above.

Same as the literature? With the finiteness clause it is exactly "$\dim \mathcal{F}_m \leq d_{\mathfrak{g}}^{\,m}$", and by Lemma 27.6 below $\mathcal{F}_m$ is the truncated Weyl module $W(m\theta, m)$ of Kus–Littelmann, whichever fusion set the sector uses. The published statement is the equality $W(m\theta, m) \cong \mathfrak{g}^{*m}$: first in Feigin, *SIGMA* 4 (2008) 070, Corollary 2, whose proof has a gap; then in Kus–Littelmann, Theorem 4.2 at $\lambda = \theta$, $\lambda_0 = 0$, $N = m$, a repair valid for every simple $\mathfrak{g}$, with one step (p. 437)

that the project flags as unjustified as written, and that for D_4 is shown by computation to be insufficient as written at $m = 2$ (item (i) of the literature paragraph; the theorem is not known to fail). Only the upper half of the equality is used; the lower half is free.
Could it be vacuous or false? Modules with the relations exist (the universal one, and the evaluation product $\mathfrak{g}(c_1) \otimes \cdots \otimes \mathfrak{g}(c_m)$ of dimension exactly $d_{\mathfrak{g}}^{\,m}$), so the bound, where true, is sharp. If it were false for a type, the conditional final theorem of that type would be vacuously true.

Physical meaning

Heuristic. $\mathcal{F}_m$ is the space of states of m adjoint particles brought together, keeping only the excitations allowed by the relations. The bound says that bringing the particles together creates no new states.

What the machine verified

Definitions. For A_2, `SectorWeyl.FusionTotalDim` is **proved**: `CVUniv.fusionTotalDim` (Chapter 26, Theorem 26.30; `#print axioms`-clean per the targeted build record). For G_2, D_4, F_4, E_6, E_7, E_8, `FusionTotalDimG S` is a **named hypothesis** of the final theorem, not proved in Lean. In the literature it is **published** for all six types (Kus–Littelmann, Theorem 4.2), with one proof step flagged by the project; for D_4 that step is insufficient as written at $m = 2$ (item (i) of the literature paragraph). Library progress: for D_4 the cases $m = 1, 2$ are proved (Section 27.6.1); toward all m, Lean reduces the bound to $\mathfrak{sl}_4$ core bounds with at least two adjoint sites, and on paper the levels with two adjoint sites are reduced further to two one-node bounds, both open in general (end of Section 27.7.1); for the other types only the finiteness clause.

Lemma 27.6 (The fusion module is a truncated Weyl module)**.** *Let $m \geq 0$ and let w be a vector of a $\mathfrak{g}[t]$-module satisfying the local Weyl relations of $W_{\mathrm{loc}}(m\theta)$, together with $x(m)w = 0$ for every x in a set $\mathcal{S}$ of negative root vectors with $\{f_\alpha : \langle \alpha, \theta^\vee \rangle = 1\} \cup \{f_\theta\} \subseteq \mathcal{S}$. Then $(\mathfrak{g} \otimes t^m\mathbb{C}[t])$ annihilates the cyclic module $U(\mathfrak{g}[t])w$. Consequently the universal module with these relations, $\mathcal{F}_m = M_{0,m}$, is the* truncated Weyl module *$W(m\theta, m)$ of Kus–Littelmann (Definition 4.1): the quotient of $W_{\mathrm{loc}}(m\theta)$ on which $\mathfrak{g} \otimes t^m\mathbb{C}[t]$ acts by zero. In particular $M_{0,m}$ does not depend on the choice of $\mathcal{S}$ within these bounds.*

Proof on paper. This is not a Lean statement; it is the bridge between the Lean hypothesis and the published theorem. Write $\mathcal{I}_m = \mathfrak{g} \otimes t^m\mathbb{C}[t]$. It suffices to show $\mathcal{I}_m w = 0$: since $\mathcal{I}_m$ is an ideal of $\mathfrak{g}[t]$, for $y \in \mathfrak{g}[t]$ and $i \in \mathcal{I}_m$ we have $i\,y = y\,i - [y, i]$ with $[y, i] \in \mathcal{I}_m$, so by induction on the length of words $\mathcal{I}_m\,U(\mathfrak{g}[t]) \subseteq U(\mathfrak{g}[t])\,\mathcal{I}_m$, and therefore $\mathcal{I}_m\,U(\mathfrak{g}[t])w \subseteq U(\mathfrak{g}[t])\,\mathcal{I}_m w = 0$. The space $\mathcal{I}_m$ is spanned by $e_\alpha(s)$, $h(s)$ and $f_\alpha(s)$ with $s \geq m$.

- $e_\alpha(s)w = 0$ for all s, and $h(s)w = 0$ for $s \geq 1$, are relations of $W_{\mathrm{loc}}(m\theta)$. (For $m = 0$ the remaining claim $h(0)w = 0$ is the eigenvalue relation $h(0)w = 0 \cdot \theta(h)w$.)

- *The bracket step.* For a positive root α choose h in the Cartan subalgebra with $\alpha(h) \neq 0$. In $\mathfrak{g}[t]$, $[h(1), f_\alpha(s)] = -\alpha(h)\,f_\alpha(s+1)$. Applying both sides to w and using $h(1)w = 0$ gives

$$f_\alpha(s+1)\,w = -\alpha(h)^{-1}\,h(1)\,f_\alpha(s)\,w.$$

  So $f_\alpha(s)w = 0$ implies $f_\alpha(s+1)w = 0$, and by induction $f_\alpha(s')w = 0$ for all $s' \geq s$.

- If $\langle \alpha, \theta^\vee \rangle = 1$ or $\alpha = \theta$, then $f_\alpha \in \mathcal{S}$, so $f_\alpha(m)w = 0$, and the bracket step gives $f_\alpha(s)w = 0$ for all $s \geq m$.

- If $\langle \alpha, \theta^\vee \rangle = 0$, then also $\langle \theta, \alpha^\vee \rangle = 0$. The degree-zero relations make $U(\mathfrak{g})w$ a finite-dimensional highest-weight module of highest weight $m\theta$, and in such a module $f_\alpha(0)w = 0$ exactly when $m\theta(h_\alpha) = m\langle \theta, \alpha^\vee \rangle = 0$. So $f_\alpha(0)w = 0$, and the bracket step gives $f_\alpha(s)w = 0$ for all $s \geq 0$.

Since θ is long, every positive root $\alpha \neq \theta$ has $\langle \alpha, \theta^\vee \rangle \in \{0, 1\}$, so the cases are exhaustive and $\mathcal{I}_m w = 0$. Hence $M_{0,m}$ is a quotient of $W(m\theta, m)$. Conversely, the generator of $W(m\theta, m)$ satisfies all the relations (the extra ones $x(m)w = 0$ hold because $x(m) \in \mathcal{I}_m$), so $W(m\theta, m)$ is a quotient of $M_{0,m}$, and the two cyclic modules coincide. The same argument shows that the relations of the Lean family rav$(j, 2j)$ (Definition 27.4) hold on the extremal vector of $D(1, j\theta)$ for the sectors whose fusion set is larger than Ravinder's: the extra f_α have $\langle \alpha, \theta^\vee \rangle = 0$ and are covered by the last case. □

Physical meaning

Heuristic. Once the modes of degree m of all currents annihilate the composite state of m adjoint particles, so do all higher modes: an energy cutoff on one mode propagates to all higher ones, because the higher modes are generated from the lower ones by the Cartan current $h(1)$, which acts trivially on the highest-weight state.

What the machine verified

On paper only; no Lean statement. The argument is the one recorded in the project's audit of the literature inputs (`DELIGNE_INPUTS_PRECISION.md`, §1).

27.4.3 Input R: Demazure realizations

Definition 27.7 (Input R). Let S be sector data, spec a family of relation specifications indexed by $\mathbb{N} \times \mathbb{N}$, and Dem $: \mathbb{N} \to \mathbb{Q}[[q]]$ a family of power series. For $j \in \mathbb{N}$, a *Demazure realization at j* is a current module V and a vector $w \in V$ satisfying spec$(j, 0)$ such that, for every degree N,

$$[q^N]\,\mathrm{Dem}_j \;\leq\; \dim\big(\text{degree-}N \text{ part of the cyclic span of } w\big).$$

In the final theorems spec $=$ `ravFam S`, so spec$(j, 0)$ are the relations of $M_{j,0}$, and Dem_j is the type's Demazure table from Chapter 25. Input R is "a Demazure realization exists at every j".

File `VOA/DelligneAudit/DelligneFusionUnivGSector.lean`.

From the mathematics to the Lean statement

Decoding. The existential packages a vector space `V`, a current-module structure `ρ` over the structure constants `S.f`, and a vector `w`. `Sat S.f ρ w (spec n 0)` says w satisfies the relations of $M_{n,0}$ (Lean's `n` is our j). `coeff N (Dem n)` is $[q^N]\mathrm{Dem}_j$. The inequality is in $\mathbb{Q}$.

It is a lower bound. The statement asks for *one* module. Since every module with these relations is a quotient of the universal $M_{j,0}$, it says that $M_{j,0}$ is at least as large as Dem_j in every degree. It is the lower bound (R) of the squeeze of Example 27.2.

Clamped and unclamped tables. The Demazure algorithm of Chapter 25 produces integers. A true character has nonnegative coefficients. The *clamped* table replaces any negative output by 0 (the last step of `levelOneDemazureHilb` is `Int.toNat`); `hilbSeries hilb n` turns such a table into the power series $\sum_N \mathrm{hilb}(n,N)q^N$, and the tables `f4DemazureHilb`, `e6DemazureHilb`, `e7DemazureHilb`, `e8DemazureHilb` are clamped. The *unclamped* tables keep the integers: `g2HilbInt` (through `hilbIntG`) and `D4Wp.hilbSeriesZ`. For Input R the two forms are *equivalent*, not merely ordered: a requirement $c \le \dim(\cdot)$ is vacuous both when $c < 0$ and when $c = 0$, because a dimension is never negative, and clamping changes only negative entries into 0. So Input R against the clamped table and Input R against the unclamped table are the same condition on a module. The final theorems use the unclamped tables for G_2 and D_4 and the clamped ones for F_4, E_6, E_7, E_8. For G_2 and D_4 the unclamped route has an advantage: the library derives the nonnegativity of the algorithm's output from U5 (`g2HilbInt_nonneg_of_U5Z` for G_2), so no separate positivity hypothesis is needed. Elsewhere in this chapter we refer to this paragraph.

Same as the literature? With the true characters of $D(1, j\theta)$, the statement is "$D(1, j\theta)$ satisfies Ravinder's relations, and its graded dimension is the Demazure character". Both halves are *published theorems for every simple* $\mathfrak{g}$. The relation half is Ravinder's Proposition 1 (after Chari–Venkatesh, Corollary 3.5): $D(1, j\theta)$ is presented by $\mathfrak{n}^+[t]w = 0$, $h(s)w = \delta_{s,0}\, j\theta(h)w$, $f_\alpha(0)w = 0$ for $\langle \alpha, \theta^\vee \rangle = 0$, $f_\alpha(0)^{jd_\alpha+1}w = 0$ (with $d_\alpha = 2/(\alpha,\alpha) = \langle \theta, \alpha^\vee \rangle$) and $f_\alpha(j)w = 0$ for $\langle \alpha, \theta^\vee \rangle = 1$, and $f_\theta(0)^{2j+1}w = 0$. The Lean relations rav$(j, 2j)$ follow from these: $f_\theta(2j)w = 0$ holds already in $W_{\mathrm{loc}}(j\theta)$ (the θ-triple sees weight $2j$, and the $\mathfrak{sl}_2$ box kills $f_\theta(s)w$ for $s \ge 2j$), and the extra fusion-set roots of the D_4, G_2, F_4 sectors are covered by Lemma 27.6. Only this direction ("$D(1, j\theta)$ satisfies the Lean relations") is needed, and it holds for every type, short roots included. The graded half is the Demazure character formula (Kumar 1987, Mathieu 1988), together with the standard identification of $D(1, j\theta)$ with the Demazure module $V_{(s_\theta s_0)^j}(\Lambda_0)$, which is how the Lean algorithm computes Dem_j (Chapter 25, Caveat 2). What is *not* established is formal: that the Lean algorithm (`levelOneDemazureHilb`, `hilbIntG`) implements the Demazure character formula correctly (Cartan-matrix orientation, the reduced word for s_θ, the step D_0, which is valid because θ is long, and the regrading by j^2). The evidence for the encoding is that the proved totals agree with $(d_\mathfrak{g} + 1)^j$ (for example `g2_demazure_total`), which rules out a transposed Cartan matrix for G_2 and F_4, together with numerical checks; this is evidence, not a proof.

What is proved for A_2. For $\mathfrak{sl}_3$ the library proves the realization for every j: `EvalModel.demazureRealization_all` constructs an explicit evaluation model of $D(1, j\theta)$ on a tensor product of copies of $D(1, \theta) = \mathfrak{sl}_3 \oplus \mathbb{C}$ at distinct points, checks the relations, and bounds its graded dimension from below through a filtration and Lagrange interpolation, with the matching upper bound from the Chari–Loktev spanning theorem, which is special to $\mathfrak{sl}_{r+1}$ (Chapter 26, Section 26.8).

Physical meaning

Heuristic. $D(1, j\theta)$ is a truncation of the level-one vacuum module of the affine Lie algebra (the WZW vacuum module): the states reachable from the extremal vector of weight $j\theta$ by positive modes. A realization is an explicit system of j excitable adjoint particles whose energy spectrum is at least as rich as the Demazure character predicts.

What the machine verified

Definitions. `∀ n, DemazureRealizationG S (ravFam S) Dem n` is a **named hypothesis** for G_2, F_4, E_6, E_7, E_8. For A_2 the corresponding statement `∀ n, A2.DemazureRealization n` is a theorem (`EvalModel.demazureRealization_all`; axioms standard, re-checked at an earlier commit). For D_4 it is a theorem, `D4Char.d4_demazureRealization` (Theorem 27.8; aggregate build green on 3 November 2026, standard axioms), and the D_4 theorem `D4_classicallyFree_of_inputT` no longer assumes it. In the literature Input R is a **published theorem for all six types** (Ravinder, Proposition 1, with the Demazure character formula); for G_2, F_4, E_6, E_7, E_8 only its formalization is missing. For E_6, E_7, E_8 the relation half holds in the lattice model for every n.

What is proved for D_4. For $\mathfrak{so}_8$ the library also proves the realization for every j, by a different route: a graded upper bound on the Levi side and the squeeze, rather than the Demazure character formula.

Theorem 27.8 (Input R for D_4)**.** *For every n there is a current module for the D_4 structure constants with a vector satisfying the relations* $\mathrm{rav}(n, 2n)$ *whose degree-N piece has dimension at least $[q^N]$ of the unclamped D_4 Demazure series, for every N.*

File `VOA/DeligneAudit/D4CharDemazureRealization.lean`.

```
theorem d4_demazureRealization :
    ∀ n, DemazureRealizationG D4sector (ravFam D4sector) D4Wp.hilbSeriesZ n :=
```

From the mathematics to the Lean statement

The full name is `VOA.DeligneAudit.D4Char.d4_demazureRealization`; `D4sector` is `DeligneSector.D4.D4sector`. The type is exactly the hypothesis `hD` of `D4_classicallyFree_final` (Theorem 27.14): same sector, same family `ravFam`, same unclamped series `D4Wp.hilbSeriesZ`. It takes no arguments. The proof bounds every module with the relations, degree by degree, by a Levi character (`D4Char.d4_gradedLeviBound`), and closes with the squeeze.

What the machine verified

Proved, **unconditional**. Machine-confirmed: aggregate build green on 3 November 2026, and `#print axioms` reports `[propext, Classical.choice, Quot.sound]`. It discharges Input R for D_4 (Theorem 27.15).

Physical meaning

For $L_{-2}(\mathfrak{so}_8)$, the chiral algebra of $SU(2)$ gauge theory with four flavours, this supplies the lower bound on the number of Schur operators in each fusion sector; with Input T it pins the Schur index to the arc-space count of the Higgs-branch chiral ring.

27.4.4 Input S: the star bounds

Definition 27.9 (Input S). For a Demazure table hilb and a target sequence $c : \mathbb{N} \to \mathbb{Q}$, the *star bound* is $\mathcal{D}_N \le c_N$ for all N, where $\mathcal{D}_N = \sum_{j \le N} [q^{N-j}]\big(\mathrm{Dem}_j/(q)_j\big)$ is the Demazure sum. For $X = G_2, F_4, E_6, E_7, E_8$, `XStarBound` is the star bound with the type's clamped Demazure table and $c_N =$ `mldeCoeff` $h^\vee$ N, where $h^\vee = 4, 9, 12, 18, 30$.

File `VOA/DeligneAudit/DeligneCharacterStarBound.lean`.

```
def StarBoundQ (hilb : ℕ → ℕ → ℕ) (c : ℕ → ℚ) : Prop :=
  ∀ N, (demazureSumCoeff hilb N : ℚ) ≤ c N
```

```
abbrev G2StarBound : Prop := StarBoundQ g2DemazureHilb (mldeCoeff 4)
abbrev F4StarBound : Prop := StarBoundQ f4DemazureHilb (mldeCoeff 9)
abbrev E6StarBound : Prop := StarBoundQ e6DemazureHilb (mldeCoeff 12)
abbrev E7StarBound : Prop := StarBoundQ e7DemazureHilb (mldeCoeff 18)
abbrev E8StarBound : Prop := StarBoundQ e8DemazureHilb (mldeCoeff 30)
```

From the mathematics to the Lean statement

`demazureSumCoeff hilb N` is $\mathcal{D}_N = \sum_{j \le N} \sum_i \mathrm{hilb}(j,i)\, p_{\le j}(N - j - i)$, where $p_{\le j}(r)$ is the number of partitions of r into parts $\le j$ (the coefficients of $1/(q)_j$); Definition 25.3. `mldeCoeff h N` is the rational number c_N defined by the Arakawa–Kawasetsu recurrence with parameter h (Definition 25.7); it is `VOA.DeligneAudit.DeligneCharacter.mldeCoeff`, not the homonym in `VOA/Modularity/AKMLDE.lean`. The second arguments $4, 9, 12, 18, 30$ are $h^\vee$ of G_2, F_4, E_6, E_7, E_8, as they must be. All five use the clamped tables; for G_2 the final theorem's Input R uses the unclamped table, and the two agree under the other inputs (dictionary of Definition 27.7).
One-sided form. The paper states the star *identity* $\mathcal{D}_N = c_N$. Only $\le$ is used, because it is chained with the proved $c_N \le \dim L_N$. The library's `XStarIdentity` (equality) implies `XStarBound` (`g2StarBound_of_identity` and its four siblings). Under the other inputs the chain closes and equality follows (Remark 27.1).

Literature status: a conjecture. For $X \in \{G_2, F_4, E_6, E_7, E_8\}$ we know of *no published proof* of the star identity $\mathcal{D}_N = c_N$, nor of the bound $\mathcal{D}_N \le c_N$ alone (Section 27.7.3 explains why the bound is no cheaper). We therefore state it as a conjecture, and the five final theorems that use it are conditional on it.

Conjecture 27.10 (The exceptional star identities). *For $X \in \{G_2, F_4, E_6, E_7, E_8\}$, with $h^\vee = 4, 9, 12, 18, 30$ and Dem_j the graded character of the level-one Demazure module $D(1, j\theta)$,*

$$\sum_{j \ge 0} q^j \, \frac{\mathrm{Dem}_j(q)}{(q)_j} \;=\; \sum_{N \ge 0} c_N \, q^N,$$

where c_N is the solution with $c_0 = 1$ of the Arakawa–Kawasetsu recurrence with parameter $h^\vee$. In particular `XStarBound` *holds.*

Evidence. Exact-integer checks of the coefficientwise equality $\mathcal{D}_N = c_N$ hold with no discrepancy through q^{60} for G_2, q^{25} for F_4, q^{20} for E_6, q^{16} for E_7 and q^{14} for E_8 (scoping pass of 28 October 2026, `Notes/deligne/STAR_IDENTITY_SCOPING.md`; cross-validated against the library's Demazure algorithm). No published proof of the identity or of the inequality is known to us. These are evidence, not proof.

The G_2 reduction. For G_2 the library has reduced Input S to one identity. The target half `G2KWEqMLDE` (the Kac–Wakimoto-type product $\theta_{A_2}(q)(q^3;q^3)_\infty^6/(q;q)_\infty^8$ solves the $h^\vee = 4$ recurrence) is a theorem, `G2Star.g2KWEqMLDE`, and `G2Star.g2StarIdentity_of_demazure` derives the star identity from the single named statement `G2DemazureEqKW` (Demazure sum = that product);

`g2StarBound_of_identity` then gives `G2StarBound` (Chapter 25, Definition 25.38, where these declarations are quoted). `G2DemazureEqKW` has no published proof known to us either. The library splits it into two named halves (Theorem 27.23).

- `G2DemazureFermionic` (the G_2 Demazure table equals the HKOTY fermionic formula) *follows from published results*, as recorded in the project note `Notes/deligne/G2_STAR_FERMIONIC.md` (28 October 2026). Fourier–Littelmann (Adv. Math. 211 (2007), Theorem 8 and Theorem B) give $D(1, j\theta) \cong \mathrm{KR}(\omega_2)^{*j}$ as graded modules, and Chari–Moura identify $\mathrm{KR}(\omega_2) = W_1^{(2)} = V(\theta) \oplus \mathbb{C}$; Ardonne–Kedem (Theorem 5.2) bound the graded fusion multiplicities by the fermionic sums; Di Francesco–Kedem (Corollary 5.19, with the HKOTY and Hernandez results as they state them) give equality at $q = 1$, hence coefficientwise equality by positivity. The conventions are those of Lin (IMRN 2021), and the note checks that they match the Lean definition with no shift. The note read the theorem statements in the arXiv versions of these sources; the primary texts of HKOTY and Hernandez were not opened. This is a reading of the literature, not a Lean proof: `G2DemazureFermionic` remains a hypothesis, and the identification of `g2DemazureHilb` with $\mathrm{Hilb}_q D(1, j\theta)$ is the same unformalized step (Demazure character formula) as for every Demazure table.
- `G2FermionicKW` (the Demazure sum of the fermionic table equals the Kac–Wakimoto-type product) is *open*: a rank-two q-series identity with no known proof. It is checked numerically through q^{60}, and in a weight-refined form (every branching function) through q^{50} (same note).

So the G_2 star identity remains a conjecture, now reduced to the single open identity `G2FermionicKW`.

Physical meaning

Heuristic. For the types with a four-dimensional theory (E_6, E_7, E_8, and D_4, A_2 where the identity is proved), the star identity would equate two counts of the Schur operators: the Demazure sum counts "particle" states (j adjoint quanta with their Demazure excitations, dressed by the factor $1/(q)_j$ of their relative motion), and the MLDE solution is the Schur index as Beem and Rastelli computed it from a modular differential equation. For G_2 and F_4 no four-dimensional theory is known, and the identity is a statement about q-series only.

What the machine verified

Definitions. `G2StarBound`, `F4StarBound`, `E6StarBound`, `E7StarBound`, `E8StarBound` are **named hypotheses**, and in the literature they are **conjectural** (Conjecture 27.10; numerical evidence only). For G_2 the hypothesis is implied by the single named identity `G2DemazureEqKW`. The A_2 star identity is a theorem (`A2.starIdentity`, Chapter 25); for D_4 the corresponding statement is proved (`D4Wp.d4SchurEqE4`, Theorem 25.37), so the D_4 final theorem has no star hypothesis.

27.4.5 An alternative form of the A_2 Input T

Before Input T was proved for A_2, the library reduced it to a lower bound in a single model. That reduction is still the hypothesis of one of the two A_2 wrappers (Theorem 27.13), so we state it.

Definition 27.11 (Kernel lower bound). `RavinderKernelLower`: for all $a, b \geq 0$ there is a current $\mathfrak{sl}_3$-module with a generator w satisfying the relations of $M_{a+1,b}$, in which the cyclic span of the kernel vector $f_\theta(2a + b + 1)w$ has total dimension at least $9^a 8^b$.

File `VOA/DeligneAudit/DeligneFusionKernelLower.lean`.

```
def RavinderKernelLower : Prop :=
  ∀ a b : ℕ, ∃ (V : Type) (_ : AddCommGroup V) (_ : Module ℂ V) (ρ : CurrentModule
   ↪ (bracketTable) V)
```

```
    (w : V), MabRel ρ w (a + 1) b ∧
    ∃ B, 9 ^ a * 8 ^ b ≤ ∑ n ∈ Finset.range B,
      Module.finrank ℂ (cycDeg ρ (ρ.op 5 (2 * a + b + 1) w) n)
```

From the mathematics to the Lean statement

`ρ.op 5 (2 * a + b + 1) w` is $f_\theta(2a+b+1)w$ (index 5 is f_θ). `cycDeg ρ v n` is graded by the words applied to v, so the shift by $2a+b+1$ is not included; this does not affect a total dimension. $9^a 8^b$ is the expected dimension of $M_{a,b}$. In Ravinder's sequence (27.1) with $(a+1, b)$ in place of (a, b), the cyclic span of $f_\theta(2a+b+1)w$ is the kernel, and the statement says it is as large as $\tau M_{a,b}$: the injectivity half of the sequence, realized in a model.

Physical meaning

Heuristic. When one excitable adjoint particle loses its extra excitation, the states that disappear are as many as a whole smaller system of particles.

What the machine verified

Definition; **not proved**, and no longer needed: Input T for A_2 is proved by a different route. It is the hypothesis of `A2_classicallyFree_final_S2` only.

Theorem 27.12 (The kernel lower bound implies Input T for A_2)**.** `RavinderKernelLower` *implies* `FusionTotalDim`.

File `VOA/DeligneAudit/DeligneFusionKernelLower.lean`.

```
theorem fusionTotalDim_of_kernelLower (hK : RavinderKernelLower) : FusionTotalDim := by
```

From the mathematics to the Lean statement

An implication between named propositions; no other hypothesis. `FusionTotalDim` here is `SectorWeyl.FusionTotalDim` (the file opens `SectorWeyl`). A second reduction, from an "ideal lower bound" `IdealLower`, is presented in Chapter 26 (Theorem 26.27); no final theorem uses it.

Proof on paper. Let $U_{a,b}$ be the universal module for the relations of $M_{a,b}$ and $u_{a,b}$ its total dimension. The relations of $M_{a,b+1}$ imply those of $M_{a+1,b}$, so there is a surjection $U_{a+1,b} \to U_{a,b+1}$ that kills $f_\theta(2a+b+1)w$ and hence its cyclic span. Rank–nullity gives $u_{a,b+1}+\dim(\text{cyclic span of } f_\theta(2a+b+1)w) \le u_{a+1,b}$, and the hypothesis bounds the second term from below by $9^a 8^b$ (it is at least its value in the model, of which the universal module maps onto). With $u_{a+1,b} \le 9^{a+1}8^b$, this gives $u_{a,b+1} \le 9^{a+1}8^b - 9^a 8^b = 9^a 8^{b+1}$. The base case $u_{a,0} \le 9^a$ is the Chari–Loktev bound. Induction on b gives $u_{0,m} \le 8^m$. □

Physical meaning

Heuristic. A counting argument for the collision process, removing one excitation at a time.

What the machine verified

Proved; `#print axioms` standard (re-checked at an earlier commit, Section 27.10). Conditional on the unproved `RavinderKernelLower`.

27.5 The seven final theorems

27.5.1 How every final theorem is proved

The seven theorems are wrappers: `VOA/DeligneAudit/DeligneSeries.lean` and `VOA/DeligneAudit/DeligneSeriesA2.lean` prove no new mathematics, and each proof is a one-line composition of theorems from Chapters 24–26 and Section 27.8. Fix a type with Lie algebra $\mathfrak{g}$, VOA $W = L_k(\mathfrak{g})$, explicit presentation P and sector data S.

1. *From Input T to the total bound with finiteness.* The degree pieces of every module with the relations of $M_{0,m}$ are finite-dimensional, proved for each type from a kernel-checked nilpotency certificate (`X_fusionTotalBoundG_of_dim`; Chapter 26, Section 26.14). Together with Input T this is `FusionTotalBoundG S`.

2. *Ravinder's kernel lemma.* In a module with the relations of $M_{a+1,b}$, the vector $f_\theta(2a+b+1)w$ satisfies the relations of $M_{a,b}$; proved for every type with no hypothesis (Chapter 26, Section 26.13). This gives the spanning inequality (K) of Example 27.2 for the universal modules.

3. *The squeeze* (Chapter 26, Section 26.5). Let $F =$ `fusionOf` Dem be the family defined from the Demazure table by the mixed recursion *with equality*. Input R gives $\mathrm{Dem}_j \le \mathrm{ch}\, M_{j,0}$; (K) propagates it downwards to a coefficientwise lower bound $\mathrm{ch}\, M_{0,m} \ge F_m$ (the subtractions are by known upper bounds); the *count* $F_m(1) = d_{\mathfrak{g}}^m$ is proved for every type (Chapter 25, Section 25.11); and Input T gives $\mathrm{ch}\, M_{0,m}(1) \le d_{\mathfrak{g}}^m$. A coefficientwise lower bound with the same total forces $\mathrm{ch}\, M_{0,m} = F_m$, as in Example 27.2. This is U5 for F, and U6 holds for F by its definition.

4. *The carrier side* (Chapter 24): U5 and U6, with the divisor comparison, give statement (B).

5. *The character side* (Chapter 25): $c_N \le \dim L_N$ for every type; with Input S this is statement (C).

6. *The capstone* (Chapter 24): (B) and (C) give $\mathrm{carrierDim}(N) \le \dim L_N$, and with current-jet surjectivity and the geometric carrier, classical freeness and $\ker = (I_2^{\mathrm{ns}})$ follow.

For A_2 steps 1–3 run in the hand-written $\mathfrak{sl}_3$ setting (Chapter 26, Sections 26.3 to 26.8), and all three inputs are theorems.

27.5.2 The A_2 theorem

Theorem 27.13 (A_2: classical freeness of $L_{-3/2}(\mathfrak{sl}_3)$). *Let $W = L_{-3/2}(\mathfrak{sl}_3)$ and let P be its explicit current C_2 presentation, with generators the eight currents and ideal (I_2^{ns}) generated by the eight quadrics $P_0, \dots, P_7$ of Definition 24.8. Then W is classically free for P, and $\ker(\mathrm{Sym}\,\mathfrak{sl}_3 \to R_W) = (I_2^{\mathrm{ns}})$; that is, $R_W = \mathrm{Sym}\,\mathfrak{sl}_3/(I_2^{\mathrm{ns}})$ and $J_\infty R_W \to \mathrm{gr}^{\mathrm{Li}} W$ is an isomorphism. The same conclusion is also stated under the (unproved) hypothesis* `RavinderKernelLower`.

File `VOA/DeligneAudit/A2Unconditional.lean`.

```

        VOA.DeligneAudit.A2.I2ns :=
  VOA.DeligneAudit.A2.classicallyFree_of_kernelLower' hK
```

From the mathematics to the Lean statement

Names. `classicallyFree` is `VOA.DeligneAudit.A2.classicallyFree`; in its file the short names `W`, `explicitPresentation`, `I2ns` are those of the namespace `VOA.DeligneAudit.A2`. The two wrappers are in the namespace `VOA.DeligneAudit.DeligneSeries` and spell out the full names. `A2_classicallyFree_final` is literally `A2.classicallyFree`: the proof term is that constant.

The objects. `A2.W` is `AffineSl3.simpleVOA (-3/2) _`, the quotient of the universal affine VOA of $\mathfrak{sl}_3$ at level $-3/2$ (trace form, $(\theta,\theta) = 2$) by its maximal graded ideal; the library proves it simple, nonzero, of central charge $c = 8k/(k+3) = -8$ (Chapter 24, dictionary of Theorem 24.12). `A2.explicitPresentation` has generators the eight Chevalley currents $J^a_{(-1)}\mathbf{1}$, which form a basis of W_1, and ideal `A2.I2ns` = `Ideal.span (Set.range relationPoly)`, generated by the eight quadrics (Warning "What the relation lists are" in Section 27.3). The conclusion is that of Definition 27.3 with $I =$ `A2.I2ns`.

The hypotheses. `A2.classicallyFree` and `A2_classicallyFree_final`: **none**. The statement is closed: it takes no arguments and the file has no section variables. Internal definitions used in its proof (`bracketTable`, the universal modules of Chapter 26) cannot weaken it, because the statement does not mention them; only axioms could, and the axiom report is standard (status box). `A2_classicallyFree_final_S2`: one hypothesis, `RavinderKernelLower` (Definition 27.11); it is the older interface, kept for reuse, and is implied by the unconditional theorem in the sense that its conclusion is already proved.

The proof term. `classicallyFree_of_totalDim'` (`VOA/DeligneAudit/DeligneFusionU7.lean`; Chapter 26, Theorem 26.28) proves the conclusion from Input T, with Input R supplied by `EvalModel.demazureRealization_all`. `CVUniv.fusionTotalDim` is Input T (Chapter 26, Theorem 26.30).

Same as the intended statement? Yes. Classical freeness in the sense of van Ekeren–Heluani for the genuine simple affine VOA $L_{-3/2}(\mathfrak{sl}_3)$, with R_V presented by the explicit quadrics. The library proves no identification of (I_2^{ns}) with an ideal from the literature, and none is claimed.

How A_2 was closed. The A_2 chain of Chapter 26 reduced the theorem to Input T, `SectorWeyl.FusionTotalDim`, with Inputs R and S already proved. Input T is the theorem `CVUniv.fusionTotalDim`: by `CVUniv.fusionTotalDim_of_cvBases` it follows from two fam-

ilies of dimension bounds for universal Chari–Venkatesh modules of $\mathfrak{sl}_3$. The rectangular family (`SharpRectangularBases`) asserts, for every ν, ρ and every $\varepsilon \in \{(0,0),(1,0),(0,1)\}$, with $j = 0$, that the module is finite-dimensional with $\dim \leq 3^{|\varepsilon|}6^{|\nu|}10^{|\rho|}$. The residual family (`ResidualTheta3Bound`) asserts, for every ρ and with $j = 1$, $\varepsilon = \nu = 0$, that the module is finite-dimensional with $\dim \leq 8 \cdot 10^{|\rho|}$. Both families are proved, `CVUniv.sharpRectangularBases` and `CVUniv.residualTheta3Bound` (Chapter 26, Definition 26.29 and Theorem 26.30). `A2.classicallyFree` is `classicallyFree_of_totalDim'` applied to that term.

Proof on paper. Section 27.5.1 with all three inputs proved: Input T by the Chari–Venkatesh induction (Chapter 26), Input R by the evaluation model, and Input S because the Demazure sum equals $[q^N]\prod_{r\geq 1}(1+q^r)^8$ (the star identity) and this product solves the $h^\vee = 3$ Arakawa–Kawasetsu recurrence, while the vacuum quartic relation gives $c_N \leq \dim W_N$ (Chapter 25). □

Physical meaning

$L_{-3/2}(\mathfrak{sl}_3)$ is the chiral algebra of the Argyres–Douglas theory usually called H_2 (or (A_1, D_4)), whose Higgs branch is the moduli space of one $SU(3)$ instanton. Granting the four-dimensional/two-dimensional correspondence of Beem et al. (a physics input, not part of the Lean statement), the theorem says that the Schur index of H_2 equals the Hilbert series of the arc space of the scheme $\operatorname{Spec}\operatorname{Sym}\mathfrak{sl}_3/(I_2^{\mathrm{ns}})$. That scheme is non-reduced; its reduced variety is the minimal nilpotent orbit closure of $\mathfrak{sl}_3$ (Arakawa–Moreau; not in Lean). Independently, the library proves $\dim W_N = c_N$ (`A2.finrank_eq_mldeCoeff'`) and that the coefficients of $\prod_{r\geq 1}(1+q^r)^8$ satisfy the same recurrence; the composite $\dim W_N = [q^N]\prod_{r\geq 1}(1+q^r)^8$ is derivable but not stated (Chapter 25, Remark 25.23). That $\prod(1+q^r)^8$ is the character of eight free fermions is a statement about the q-series, not about the theory.

What the machine verified

`A2.classicallyFree` and `A2_classicallyFree_final`: **no hypotheses**. Machine-confirmed on 2026-10-28: the aggregate build `bash scripts/campaign_build.sh VOA` (the full `lake build VOA` under the project's memory-capped wrapper) was green on 2026-10-28 (a pre-release build): 18,901 jobs, and again 18,907 jobs after merging the then-current `origin/main` (the aggregate target contains the umbrella `VOA.Deligne`); `#print axioms` (via `lake env lean -DmaxSynthPendingDepth=3`) on `VOA.DeligneAudit.A2.classicallyFree` and `VOA.DeligneAudit.DeligneSeries.A2_classicallyFree_final` reports `[propext, Classical.choice, Quot.sound]`. Earlier record (27 October 2026): targeted builds of `VOA.DeligneAudit.A2Unconditional` (9755 jobs) and `DeligneSeriesA2` (9756 jobs) green, standard axioms. `A2_classicallyFree_final_S2`: conditional on `RavinderKernelLower`; axioms standard (re-checked on a verbatim copy at an earlier commit).

27.5.3 The six conditional theorems

Theorem 27.14 (D_4: the final theorem). *Let $W = L_{-2}(\mathfrak{so}_8)$, built from the certificate-basis Lie data, with its explicit presentation by* 105 *quadrics. Suppose Input T (*$\dim \mathcal{F}_m \leq 28^m$*) and Input R for the unclamped D_4 Demazure series. Then W is classically free for its presentation and* ker *is the ideal generated by the* 105 *quadrics.*

File `VOA/DeligneAudit/DeligneSeries.lean`.

```
theorem D4_classicallyFree_final (hF : VOA.DeligneAudit.FiniteG.FusionTotalDimG
 ↪  D4.D4sector)
    (hD : ∀ n, DemazureRealizationG D4.D4sector (ravFam D4.D4sector)
      VOA.DeligneAudit.DeligneCharacter.D4Wp.hilbSeriesZ n) :
    CaseClassicallyFree .D4 VOA.DeligneAudit.D4Lie.W4
     ↪  VOA.DeligneAudit.D4Lie.explicitPresentation4 ∧
```

```
      RingHom.ker (MvPolynomial.aeval fun i =>
        liDegreeZeroClass VOA.DeligneAudit.D4Lie.W4 1
          ⟨VOA.DeligneAudit.D4Lie.explicitPresentation4.gen i,
            VOA.DeligneAudit.D4Lie.explicitPresentation4.gen_weight_one i⟩).toRingHom =
        VOA.DeligneAudit.D4Lie.explicitPresentation4.ideal :=
  d4_classicallyFree_of_totalBound (VOA.DeligneAudit.FiniteG.D4.d4_fusionTotalBoundG_of_dim
   ↪ hF) hD
```

From the mathematics to the Lean statement

The objects. `D4Lie.W4` is `simpleVOA d4CertData (-2) _` (Warning 27.3). `explicitPresentation4.ideal` is `DeligneCarrier.D4.D4data.I`, generated by the 105 certified quadrics (Theorem 24.12). `D4.D4sector` resolves to `DeligneSector.D4.D4sector` through the `open` line of the file, with `D4sector.n = 28`. `D4Wp.hilbSeriesZ n` is the unclamped D_4 Demazure series.
The hypotheses. `hF`: Input T for D_4. `hD`: Input R, for all n, with `spec = ravFam D4sector`. Nothing else: there is no star hypothesis, because the D_4 star identity is proved (`D4Wp.d4SchurEqE4`, Theorem 25.37), and no positivity hypothesis, because of the unclamped route (dictionary of Definition 27.7).
Same as the intended statement? Yes, for the certificate-basis model of $L_{-2}(\mathfrak{so}_8)$ (Warning 27.3).

Proof on paper. Section 27.5.1. Steps 1–3 are `FiniteG.D4.d4_fusionTotalBoundG_of_dim` and `UnivG.d4_classicallyFree_of_totalBound` (`VOA/DeligneAudit/D4FusionKernelTheta.lean`); steps 4–6 are the D_4 headline of Section 27.8 (Theorem 27.22) with the star identity, the Ramanujan identities, the divisor comparison and the vacuum quartic relation plugged in as theorems. □

Physical meaning

$L_{-2}(\mathfrak{so}_8)$ is the chiral algebra of $SU(2)$ gauge theory with four fundamental hypermultiplets, with $SO(8)$ flavour symmetry. *Heuristic:* its Higgs branch is the one-$SO(8)$-instanton moduli space, the minimal nilpotent orbit closure, the reduced variety of the scheme defined by the 105 quadrics. Given the two inputs, the theorem says the Schur index (via the 4d/2d correspondence) is the arc-space Hilbert series of that scheme; its identification with $E_4'/(240\eta^{10})$ in Chapter 25 is a statement about a q-series whose reading as the gauge-theory Schur index is modelling, not Lean.

What the machine verified

Proved, **conditional** on `FusionTotalDimG D4sector` and `∀ n, DemazureRealizationG …`. `#print axioms` standard (campaign record; the two theorems it composes were re-checked at an earlier commit). Not unconditional. This is the general form, with both inputs as hypotheses. The second hypothesis is now a theorem (`D4Char.d4_demazureRealization`, Theorem 27.8), and Theorem 27.15 below is this theorem with it plugged in: D_4 classical freeness is conditional on Input T alone.

Theorem 27.15 (D_4: classical freeness from Input T alone). *Let $W = L_{-2}(\mathfrak{so}_8)$, built from the certificate-basis Lie data, with its explicit presentation by* 105 *quadrics. Suppose Input T (*$\dim \mathcal{F}_m \le 28^m$*). Then W is classically free for its presentation and* ker *is the ideal generated by the* 105 *quadrics.*

File `VOA/DeligneAudit/DeligneSeriesD4.lean`.

            VOA.DeligneAudit.D4Lie.explicitPresentation4.gen_weight_one i⟩).toRingHom =
        VOA.DeligneAudit.D4Lie.explicitPresentation4.ideal :=
```

From the mathematics to the Lean statement

What it is. The full name is `VOA.DeligneAudit.DeligneSeries.D4_classicallyFree_of_inputT`. Its conclusion is word for word that of `D4_classicallyFree_final` (Theorem 27.14); the objects are the same. Its proof is one line: it applies `D4_classicallyFree_final` to `hF` and to `D4Char.d4_demazureRealization` (Theorem 27.8) in place of `hD`.
The hypothesis. `hF`: Input T for D_4, the bound $\dim W(m\theta, m) \le 28^m$ for every m (Definition 27.5). Nothing else: Input R is proved, the star identity is proved, and the unclamped route needs no positivity hypothesis.
Same as the intended statement? Yes, for the certificate-basis model of $L_{-2}(\mathfrak{so}_8)$ (Warning 27.3).

What the machine verified

Proved, **conditional** on `hF : FusionTotalDimG D4sector` (Input T). Machine-confirmed: the aggregate build was green on 3 November 2026 (20,331 jobs), and `#print axioms` reports `[propext, Classical.choice, Quot.sound]`. Not unconditional. Input T is a published theorem (Kus–Littelmann, Theorem 4.2), with the caveat of item (i): one step of the published proof is insufficient as written for D_4 at $m = 2$, by a computational witness; the theorem is not known to fail. In Lean, Input T for D_4 is proved for $m \le 2$ and reduced, for all m, to $\mathfrak{sl}_4$ core bounds that remain open (Section 27.6.1 and the end of Section 27.7.1); that progress is not part of the claim.

Physical meaning

$L_{-2}(\mathfrak{so}_8)$ is the chiral algebra of four-dimensional $\mathcal{N} = 2$ $SU(2)$ gauge theory with four flavours, whose Higgs branch is the minimal nilpotent orbit of $\mathfrak{so}_8$. Classical freeness says that its Schur operators are exactly the derivatives of the Higgs-branch chiral ring: the Schur index is the arc-space Hilbert series of the 105 moment-map relations. The theorem proves this assuming only a counting bound on current-algebra modules (Input T).

Theorem 27.16 (G_2 and F_4: the final theorems). *Let $X \in \{G_2, F_4\}$, $W = L_k(\mathfrak{g}_X)$ ($k = -5/3$, resp. $-5/2$) built from the certified structure-constant Lie data, with its explicit presentation (27, resp. 324 quadrics). Suppose Input T ($d_{\mathfrak{g}} = 14$, resp. 52), Input R (unclamped table for G_2, clamped for F_4) and Input S ($h^\vee = 4$, resp. 9). Then W is classically free for its presentation and* ker *is the ideal generated by the listed quadrics.*

From the mathematics to the Lean statement

The objects. `G2Lie.g2W` and `F4Lie.f4W` are `simpleVOA` of `g2CertData` at $-5/3$ and of `f4CertData` at $-5/2$ (Warning 27.3). `explicitPresentation.ideal` is `G2data.I`, resp. `F4data.I`. `G2.G2sector`, `F4.F4sector` are the sector data (namespace `DeligneSector`).

The hypotheses. `hF`: Input T. `hD`: Input R against `g2HilbSeriesZ` (unclamped) for G_2 and against `hilbSeries f4DemazureHilb` (clamped) for F_4. `hB`: Input S, `G2StarBound`, resp. `F4StarBound`. For G_2, `hD` and `hB` refer to the unclamped and the clamped table respectively; inside the proof U5 is derived from `hF` and `hD`, nonnegativity of the unclamped table follows (`g2HilbInt_nonneg_of_U5Z`), and then the two tables agree (`g2FusionF_eq_Z`); see the dictionary of Definition 27.7.

Non-simply-laced types and the literature. G_2 and F_4 are not simply laced, but this does not affect the literature status of their inputs. The header of `VOA/DeligneAudit/F4LieHeadline.lean` says the Ravinder/Chari–Venkatesh route to U5 is "not literature-verified" for F_4. That comment misplaces the issue: Ravinder's Theorem 1, Corollaries 1 and 2 and Proposition 1 are stated for every simple $\mathfrak{g}$ (only his Theorem 2 and Corollary 3 assume simply laced), and Kus–Littelmann's Theorem 4.2 with $\lambda_0 = 0$ has no type restriction. The live issues are the same as for every other type: Feigin's gap, and the flagged step of the Kus–Littelmann repair (Input T); the unformalized Demazure character formula (Input R); and Input S, which is conjectural. The short roots need no separate treatment (dictionary of Definition 27.4). The Lean statements are unaffected in any case: the literature only bears on whether the hypotheses are believed true.

Proof on paper. Section 27.5.1. For G_2 steps 1–3 are `g2_fusionTotalBoundG_of_dim` and `UnivG.g2_classicallyFree_of_totalBound` (`VOA/DeligneAudit/G2FusionKernelTheta.lean`), whose last step is the concrete headline `G2Lie.g2_classicallyFree_concrete` (Theorem 27.23); for F_4 they are `f4_fusionTotalBoundG_of_dim` and `DeligneCarrier.f4_classicallyFree_of_totalBound'` (`VOA/DeligneAudit/F4FusionCountZ.lean`). The target bound $c_N \le \dim L_N$ is `g2_targetLowerBound` and `f4_targetLowerBound` (Chapter 25); `hB` closes (C). □

Physical meaning

Heuristic. The levels $-5/3$ and $-5/2$ continue the Deligne pattern $k = -1 - h^\vee/6$, but no four-dimensional $\mathcal{N} = 2$ SCFT with G_2 or F_4 flavour symmetry and these central charges is known; they are "would-be" theories. The VOAs exist regardless; their associated varieties are again minimal nilpotent orbit closures (Arakawa–Moreau, for the Deligne series at these

levels), and the theorem says the vacuum character is an arc-space Hilbert series.

What the machine verified

Proved, **conditional** on three named inputs each (`hF`, `hD`, `hB`). `#print axioms` standard (campaign record; the composed theorems re-checked at an earlier commit). Not unconditional. Since `hB` is conjectural (Conjecture 27.10), these theorems are conditional on a conjecture.

Theorem 27.17 (E_6, E_7, E_8: the final theorems). *Let $X \in \{E_6, E_7, E_8\}$, $W = L_k(\mathfrak{g}_X)$ ($k = -3, -4, -6$) with its explicit presentation (650, 1539, 3875 quadrics). Suppose Input T ($d_{\mathfrak{g}} = 78, 133, 248$), Input R for the clamped table, and Input S ($h^\vee = 12, 18, 30$). Then W is classically free for its presentation and* ker *is the ideal generated by the listed quadrics.*

From the mathematics to the Lean statement

The objects. `DeligneCarrier.E6.W6` is `simpleVOA e6LieData (-3) _` (structure-constant model); `E7Lie.W7` and `E8Lie.W8` are `simpleVOA` of `e7CertData`, `e8CertData` at -4, -6 (Warning 27.3). The sector data `E6sector`, `E7sector`, `E8sector` live in `DeligneCarrier`; their fusion sets are exactly Ravinder's. The ideals are `E6data.I`, `E7data.I`, `E8data.I`.
The hypotheses. Three each: Input T (`hF`), Input R against the clamped tables (`hD`), and Input S (`hB`).
Proof terms. Each omitted proof is `eX_classicallyFree_of_starBound (eX_fusionModuleBound_of_totalBound' (eX_fusionTotalBoundG_of_dim hF) hD) hB`, with the first theorem from `VOA/DeligneAudit/E6Final.lean` (resp. `E7Final`, `E8Final`) and the second from `VOA/DeligneAudit/DeligneCharacterEFusionCount.lean` (E_6, E_7) or `VOA/DeligneAudit/DeligneCharacterE8FusionCount.lean` (E_8).

Proof on paper. Section 27.5.1; step 6 is Theorem 27.24. For the E-types the divisor comparison of step 4 is the largest certificate computation of the project (Chapter 24, Section 24.10). □

Physical meaning

$L_{-3}(\mathfrak{e}_6)$, $L_{-4}(\mathfrak{e}_7)$ and $L_{-6}(\mathfrak{e}_8)$ are the chiral algebras of the Minahan–Nemeschansky rank-one theories. *Heuristic:* their Higgs branches are the one-instanton moduli spaces of E_6, E_7, E_8. Given the three inputs, the theorems say that the Schur indices of these non-Lagrangian theories (via the 4d/2d correspondence) are arc-space Hilbert series of the schemes defined by the quadrics, and equal the MLDE solutions.

What the machine verified

Proved, **conditional** on three named inputs each. `#print axioms` standard: campaign record only for the three final theorems and their E_7, E_8 ingredients; `E6.e6_classicallyFree_of_starBound` was re-checked at an earlier commit. Not unconditional. Since `hB` is conjectural (Conjecture 27.10), these theorems are conditional on a conjecture.

27.6 The input ledger, type by type

The long form of the table at the start of the chapter. "Hypothesis" means: not proved in Lean, and passed as an explicit argument of the final theorem. Table 27.3 states, type by type, the precise mathematical content of each input, its status in the literature, and what the library has proved toward it. Abbreviations: **KL** = Kus–Littelmann, Pacific J. Math. 278 (2015), Theorem 4.2 at $\lambda = \theta$, $\lambda_0 = 0$, $N = m$ (through their Theorem 3.5 and Corollary 3.6(3)); **KL-step** = the annihilator-transfer step on p. 437 of KL, flagged by the project as unjustified as written, and for D_4 at $m = 2$ shown by computation to be insufficient as written (no counterexample to the theorem is known); **F08** = Feigin, *SIGMA* 4 (2008) 070, Proposition 1 and Corollary 2 (proof has a gap); **R14** = Ravinder, *SIGMA* 10 (2014) 110; **DCF** = the Demazure character formula (Kumar 1987, Mathieu 1988); **FK** = Frenkel–Kac (1980). $W(m\theta, m)$ is the truncated Weyl module, equal to the Lean universal module by Lemma 27.6. The status "PROVED [ref]" refers to the literature, never to Lean.

Table 27.3: The inputs of the six conditional final theorems: precise statement, literature status, library progress.

type	in.	precise statement	literature status	library progress (Lean)
G_2	T	$\dim W(m\theta, m) \le 14^m$ for all m (`FusionTotalDimG2sector`; fusion set: all negative roots)	PROVED with flagged step: KL (KL-step); earlier F08 (gap); R14 Cor. 2 at $a = 0$ is F08, not independent	finiteness clause only (`g2_fusionTotalBoundG_of_dim`)
G_2	R	for all n, a module with $\mathrm{rav}(n, 2n)$ whose degree-N piece has dimension $\ge [q^N]$ of the unclamped G_2 table	PROVED: R14 Prop. 1 (after Chari–Venkatesh Cor. 3.5; short roots included) + DCF; unformalized: the Lean algorithm = DCF	none (no lattice model)
G_2	S	$\mathcal{D}_N \le c_N$ for all N, $h^\vee = 4$ (`G2StarBound`)	CONJECTURAL: no published source known; numerics through q^{60}	`G2KWEqMLDE` proved; S follows from the single named identity `G2DemazureEqKW`, split as `G2DemazureFermionic` (follows from published results) and `G2FermionicKW` (open)
D_4	T	$\dim W(m\theta, m) \le 28^m$ for all m (fusion set: all negative roots)	PROVED with flagged step: KL (KL-step, insufficient as written at $m = 2$ by computation, witness $\tilde{a}$; theorem not known to fail); F08 (gap)	$m = 1, 2$ proved (`localWeyl_one_total_dim`, `localWeyl_two_total_dim`: ≤ 28, ≤ 784); all-m layers in progress (Section 27.6.1); presented-module route (`D4_classicallyFree_of_presentedRankBoundE`): $m = 1, 2$ proved; level route (`d4_classicallyFree_of_twoAdjointCoreBounds`): reduced to $\mathfrak{sl}_4$ core bounds with $a \ge 2$ adjoint sites, and $a = 2$ reduced on paper to $\tilde{Q}_\kappa \le 10 \cdot 6^\kappa$ and $(C)_{\kappa+1}$ (end of Section 27.7.1); all m open. This is the one hypothesis of `D4_classicallyFree_of_inputT`
D_4	R	for all n, a module with $\mathrm{rav}(n, 2n)$ and graded dimension $\ge$ the unclamped D_4 table	PROVED: R14 Prop. 1 + DCF; FK realizes $D(1, n\theta)$ in V_{D_4}	$n = 0, 1, 2$ proved (`D4Small.demazureRealization_zero`, `…_one`, `D4Two.demazureRealization_two`); relation half in the lattice model for all n (`d4_lattice_sat`); **all n proved**: `D4Char.d4_demazureRealization` (Theorem 27.8; aggregate build green, 3 November 2026)
D_4	S	none: the identity is proved	—	`D4Wp.d4SchurEqE4` with the unclamped Demazure = Schur identity (`d4DemazureEqSchur_of_positivity`, positivity from `D4Wp.d4DemazurePositivity_of_U5Z`)
F_4	T	$\dim W(m\theta, m) \le 52^m$ (fusion set: all negative roots)	PROVED with flagged step: KL (KL-step); F08 (gap)	finiteness clause only
F_4	R	for all n, $\mathrm{rav}(n, 2n)$ and graded dimension $\ge$ the clamped F_4 table (equivalent to the unclamped form)	PROVED: R14 Prop. 1 + DCF (θ long; short roots included)	none (no lattice model)
F_4	S	$\mathcal{D}_N \le c_N$, $h^\vee = 9$ (`F4StarBound`)	CONJECTURAL: no published source known; numerics through q^{25}	none
E_6	T	$\dim W(m\theta, m) \le 78^m$ (fusion set: exactly Ravinder's)	PROVED with flagged step: KL (KL-step); F08 (gap)	finiteness clause only

type	in.	precise statement	literature status	library progress (Lean)
E_6	R	for all n, $\mathrm{rav}(n,2n)$ and graded dimension $\geq$ the clamped E_6 table	PROVED: R14 Prop. 1 + DCF; FK	relation half in the lattice model (`e6_lattice_sat`); dimension half named (`E6LatticeDim`)
E_6	S	$\mathcal{D}_N \leq c_N$, $h^\vee = 12$ (`E6StarBound`)	CONJECTURAL: no published source known; numerics through q^{20}	none
E_7	T	$\dim W(m\theta, m) \leq 133^m$ (Ravinder's fusion set)	PROVED with flagged step: KL (KL-step); F08 (gap)	finiteness clause only
E_7	R	for all n, $\mathrm{rav}(n,2n)$ and graded dimension $\geq$ the clamped E_7 table	PROVED: R14 Prop. 1 + DCF; FK	relation half in the lattice model (`e7_lattice_sat`); dimension half named
E_7	S	$\mathcal{D}_N \leq c_N$, $h^\vee = 18$ (`E7StarBound`)	CONJECTURAL: no published source known; numerics through q^{16}	none
E_8	T	$\dim W(m\theta, m) \leq 248^m$ (Ravinder's fusion set)	PROVED with flagged step: KL (KL-step); F08 (gap)	finiteness clause only
E_8	R	for all n, $\mathrm{rav}(n,2n)$ and graded dimension $\geq$ the clamped E_8 table	PROVED: R14 Prop. 1 + DCF; FK	relation half in the lattice model (`e8_lattice_sat`); dimension half named
E_8	S	$\mathcal{D}_N \leq c_N$, $h^\vee = 30$ (`E8StarBound`)	CONJECTURAL: no published source known; numerics through q^{14}	none

For A_2 all three inputs are **proved in Lean**: T by `CVUniv.fusionTotalDim`, R by `EvalModel.demazureRealization_all`, S by `A2.starIdentity` (Chapter 25). The older A_2 interface `A2.RavinderKernelLower` (the injectivity half of Ravinder's sequence in a model) is not proved and not needed.

Reading the table. The final theorems of G_2, F_4, E_6, E_7, E_8 depend on Input S, which is *conjectural*: they are theorems conditional on a conjecture. For D_4 Input R is proved in Lean (`D4Char.d4_demazureRealization`), so the D_4 theorem `D4_classicallyFree_of_inputT` depends on Input T alone. Input T is a published theorem (with the flagged KL-step); what is missing for D_4 is its formalization and a complete proof of the KL-step, whose written argument is insufficient at $m = 2$ (the statement it is meant to prove is not known to fail). In Lean, Input T for D_4 has the cases $m \leq 2$ and a reduction for all m (end of Section 27.7.1); it stays a hypothesis. Everything else in the chain is proved for all seven types: the explicit presentation (as a containment), jet surjectivity, the geometric carrier, B1, the divisor comparison, the squeeze, Ravinder's kernel lemma, the finiteness clause of Input T, the $q = 1$ counts and energies, and the target lower bound $c_N \leq \dim L_N$. The numerical checks are evidence, not proof, and they concern the identities, not their Lean statements. For G_2 the star identity is also split into two named halves, checked separately (the fermionic half for $j \leq 40$ in all degrees $\leq 40 - j$, and it follows from published results; the q-series half through q^{60}, weight-refined through q^{50}; Theorem 27.23 and Section 27.4.4); the q^{60} figure in the table is for the combined identity.

Source citations do not discharge hypotheses

A named input with a published proof is still a hypothesis of the Lean theorem. The six conditional final theorems are `#print axioms`-clean, conditional on the inputs above; they are not unconditional, and a citation in a docstring changes nothing about that.

27.6.1 Partial results toward Inputs T and R for D_4

The library proves some cases of the D_4 inputs outright. None of them is used by a final theorem (the final theorems need all m and all n), but each is an exact instance of the corresponding hypothesis, so they show that the hypotheses are satisfiable in the cases covered and that the Lean statements mean what they are said to mean. All are in the files assigned to Chapter 26 and are imported by the `VOA.Deligne` umbrella. Every quotation was checked against the source at the time of the 28 October revision. Input R for D_4 is now proved for every n (Theorem 27.8); the cases $n \le 2$ below were proved first and are kept as worked instances.

Theorem 27.18 (Input T for D_4 at $m = 1$ and $m = 2$). *Let V be a current module for the D_4 structure constants and $w \in V$ satisfy the local Weyl and fusion relations of D_4 for $m\theta$. If $m = 1$, the cyclic span of w has total dimension at most 28; if $m = 2$, at most $784 = 28^2$.*

File `VOA/DeligneAudit/D4FusionContactOne.lean`.

```
theorem localWeyl_one_total_dim (h : LocalWeylRelG D4sector R w 1) (B : ℕ) :
    ∑ d ∈ Finset.range B, Module.finrank ℂ (cycDeg R w d) ≤ 28 := by
```

File `VOA/DeligneAudit/D4FusionContactTwo.lean`.

```
theorem localWeyl_two_total_dim (h : LocalWeylRelG D4sector R w 2) (B : ℕ) :
    ∑ d ∈ Finset.range B, Module.finrank ℂ (cycDeg R w d) ≤ 784 :=
```

From the mathematics to the Lean statement

Both are in the namespace `VOA.DeligneAudit.D4FusionContact`. The section variables are `\{V : Type\} [AddCommGroup V] [Module ℂ V]` and `\{R : CurrentModule D4sector.f V\} \{w : V\}`, the same universe and data over which `FusionTotalDimG` quantifies (Definition 27.5); `D4sector` is `DeligneSector.D4.D4sector`, the sector of the D_4 final theorem. So each theorem is literally the body of `FusionTotalDimG D4sector` at $m = 1$, resp. $m = 2$, with $28^1 = 28$ and $28^2 = 784$. The finiteness of the degree pieces, needed to read the bound as a bound on dimension (dictionary of Definition 27.5), is proved alongside (`localWeyl_one_finite`, `localWeyl_two_finite`). By Lemma 27.6 the statements say $\dim W(\theta, 1) \le 28$ and $\dim W(2\theta, 2) \le 784$; the first is the classical fact $W(\theta, 1) = \mathfrak{so}_8$ as a $\mathfrak{so}_8$-module (the relations kill all positive modes), the second is the first nontrivial case of Kus–Littelmann's Theorem 4.2 for D_4. The docstrings say explicitly that these are not the all-m input.

Proof on paper. For $m = 1$ every positive mode kills w (Lemma 27.6 with $\mathcal{J}_1$), so the cyclic span is $U(\mathfrak{so}_8)w$, an irreducible module of highest weight θ, the adjoint representation, of dimension 28. For $m = 2$ the library constructs an explicit finite-dimensional space (`M2Model`) of dimension at most 784 (`m2Model_bound`) together with a surjective linear map from it onto the universal module with the $m = 2$ relations; every module with the relations is a quotient of the universal one, so its degree pieces sum to at most 784. The proof is in the two files above and their imports. □

Physical meaning

Heuristic. One adjoint particle of $SO(8)$ flavour carries 28 states; two of them fused carry at most 28^2: bringing two particles together creates no new states.

What the machine verified

Proved, **unconditional** (no hypothesis beyond the relations). `#print axioms` standard per the campaign record (entry "D4 total bound": the $m = 0, 1, 2$ cases closed, targets green); not re-run by the author of this chapter. For $m \ge 3$ the bound 28^m is **open** in Lean.

Theorem 27.19 (Input R for D_4 at $n = 0, 1, 2$). *For $n = 0, 1, 2$ there is a current module for the D_4 structure constants with a vector satisfying the relations* $\mathrm{rav}(n, 2n)$ *whose degree-N piece has dimension at least $[q^N]$ of the unclamped D_4 Demazure series, for every N.*

File `VOA/DeligneAudit/D4FusionRealizationSmall.lean`.

```
theorem demazureRealization_zero :
    DemazureRealizationG D4sector (ravFam D4sector) D4Wp.hilbSeriesZ 0 := by
```

```
theorem demazureRealization_one :
    DemazureRealizationG D4sector (ravFam D4sector) D4Wp.hilbSeriesZ 1 := by
```

File `VOA/DeligneAudit/D4FusionRealizationTwoRealization.lean`.

```
theorem demazureRealization_two :
    DemazureRealizationG D4sector (ravFam D4sector) D4Wp.hilbSeriesZ 2 := by
```

From the mathematics to the Lean statement

The first two are `VOA.DeligneAudit.D4Small.demazureRealization_zero` and `…_one` (not to be confused with the A_2 `demazureRealization_zero` of `VOA/DeligneAudit/DeligneFusionDemazure.lean`); the third is `VOA.DeligneAudit.D4Two.demazureRealization_two`. The type is exactly the hypothesis `hD` of the D_4 final theorem (Theorem 27.14) at `n` $= 0, 1, 2$: same sector, same family `ravFam`, same unclamped series `D4Wp.hilbSeriesZ`. None takes an argument.

Proof on paper. $n = 0$: the trivial one-dimensional module, with $\mathrm{Dem}_0 = 1$. $n = 1$: the module $D(1, \theta) = \mathfrak{so}_8 \oplus \mathbb{C}$ of the primer (Section 27.2), with character $28 + q$, built as an explicit one-site module. $n = 2$: the library builds a cyclic graded module from an explicit source representation, checks Ravinder's relations on its generator, and computes its graded dimension degree by degree; it matches every coefficient of the unclamped Demazure series at $n = 2$ (total $29^2 = 841$). □

Physical meaning

Heuristic. Explicit systems of zero, one and two excitable adjoint particles of $SO(8)$ whose energy spectra are exactly as rich as the level-one WZW vacuum module predicts.

What the machine verified

Proved, **unconditional**. `#print axioms` standard per the campaign record (entries "D4 ORIGINAL n=2 REALIZATION CLOSED" and "D4 realizations: actual cases 0,1,2 are now closed"); not re-run by the author of this chapter. For $n \geq 3$ a total-dimension count 29^n alone would not suffice, since the squeeze needs the graded inequality; the statement for every n is `D4Char.d4_demazureRealization` (Theorem 27.8), which is proved and confirmed by the aggregate build.

Work in progress toward all m (Input T for D_4). The library contains research layers toward the bound 28^m for every m, in the files `VOA/DeligneAudit/D4FusionContactAllMCountResearchCubeCurrentOrders.lean` and `VOA/DeligneAudit/D4FusionContactAllMCountResearchCubeQuinticLeading.lean`. What Lean states there (`raw_order_chain_counts_mem_ann`, `quinticHead_mem_ann_sup_low`) is only this: for every $m \geq 1$ and every module with `LocalWeylRelG D4sector R x m`, certain explicit coefficients of products of currents lie in the annihilator ideal of the generator modulo an explicit span of lower "colour" layers. These are steps of a reduction, not a dimension bound; no Lean statement in these files bounds a dimension for $m \geq 3$, and we describe them no further.

27.7 The inputs that remain open in Lean

For $G_2, D_4, F_4, E_6, E_7, E_8$ the remaining hypotheses are of two different kinds, and the distinction matters. Inputs T and R are *published theorems* (T with one proof step flagged by the project); the library has formalized R for D_4 but neither input for the other five types, nor T for D_4, which is the only remaining hypothesis of the D_4 theorem. Input S is, as far as we know, an *open mathematical problem*: a conjecture with numerical evidence. This section says what is known about each, and what made the A_2 case tractable.

27.7.1 Input T beyond A_2

The statement. $\dim M_{0,m} \le d_{\mathfrak{g}}^m$ for every m; the lower bound is free (the evaluation fusion product is a quotient). By Lemma 27.6, $M_{0,m} = W(m\theta, m)$, and the bound is Kus–Littelmann's Theorem 4.2 at $\lambda = \theta, \lambda_0 = 0, N = m$, which for $\lambda_0 = 0$ carries no restriction on $\mathfrak{g}$; the specialization is identical for all six types. The earlier sources are Feigin's Corollary 2 (*SIGMA* 4 (2008) 070), whose proof has the gap of Section 27.7.1, and Ravinder's Corollary 2 at $a = 0$, which is Feigin's statement imported as Ravinder's Proposition 5. *Status:* published, with the flagged step on p. 437 of Kus–Littelmann, described at the end of Section 27.7.1; it applies equally to all six types, and for D_4 at $m = 2$ the step as written is shown by computation to be insufficient (the theorem is not known to fail). In Lean: D_4 for $m \le 2$ (Theorem 27.18); for D_4 and all m, a reduction to $\mathfrak{sl}_4$ core bounds with at least two adjoint sites, reduced further on paper (end of Section 27.7.1); otherwise open.

What made A_2 tractable. The A_2 proof (Chapter 26, Section 26.10) uses three ingredients that are special to $\mathfrak{sl}_3$: an enlarged family of modules with Chari–Venkatesh relations along the three positive roots, whose members are expected to be fusion products of the $\mathfrak{sl}_3$ Kirillov–Reshetikhin modules $V(\omega_i), V(2\omega_i), V(3\omega_i)$ of dimensions $3, 6, 10$; explicit spanning arguments in the associated graded of these modules; and dimension splittings ($8 = 5 + 3$, $5 = 3 + 2$) of the adjoint site. For the other types an analogous family would involve many more Kirillov–Reshetikhin modules, and neither the family nor the base bounds are formalized.

Why the published proof needed repair: 55 versus 63

Feigin realizes $D(1, m\theta) \cong D(1, \theta)^{*m}$ on the tensor product $T = \bigotimes_{j=1}^m D(1, \theta)(c_j)$ with its fusion filtration $\Phi_\bullet$ (by degree in t). Let $f(t) = \prod_j (t - c_j)$. On T the image of $\mathfrak{g} \otimes f(t)\mathbb{C}[t]$ is exactly the subspace K of tensors with at least one factor in the trivial summand $\mathbb{C}$, and $T/K \cong \mathfrak{g}^{\otimes m}$. Input T is equivalent to $\operatorname{gr} K \subseteq (t^m) \cdot \operatorname{gr} T$: the associated graded of K is contained in the image of the ideal $\mathcal{J}_m$. Feigin's Proposition 1 (*SIGMA* 4 (2008) 070; Proposition 2.1 in arXiv v1) asserts that the associated graded of T is a *bigraded* fusion product in which a second degree u counts the trivial factors.

Take $\mathfrak{sl}_3$ and $m = 2$. Then $T = D(1, \theta)(c_1) \otimes D(1, \theta)(c_2)$ has dimension 81, and by the number u of trivial factors it splits as $81 = 64 + 16 + 1$ ($u = 0$: $\mathfrak{sl}_3 \otimes \mathfrak{sl}_3$; $u = 1$: $\mathfrak{sl}_3 \otimes \mathbb{C} \oplus \mathbb{C} \otimes \mathfrak{sl}_3$; $u = 2$: $\mathbb{C} \otimes \mathbb{C}$). The fusion filtration has cumulative dimensions $\dim \Phi_0, \dots, \dim \Phi_4 = 27, 55, 72, 80, 81$ (the coefficients of $\mathrm{Dem}_2 = 27 + 28q + 17q^2 + 8q^3 + q^4$ summed up; Example 27.2). If Φ_1 were the direct sum of its projections to the three u-pieces, as the natural reading of Feigin's argument requires, the dimensions of those projections would add up to $\dim \Phi_1 = 55$. The project's exact computation gives 63. For $m = 3$ the computation gives, for $d = 1, 2$, the pair ($\dim \Phi_d$, sum of the dimensions of the projections of Φ_d to the u-pieces) equal to $(161, 188)$ and $(313, 403)$; the two entries of a pair would agree if the filtration were homogeneous for u. So the fusion filtration is not homogeneous for u, and the printed argument (labelled "the idea of the proof") does not prove Proposition 1; a rigorous Proposition 1 is as strong as the statement wanted.

The repair and its flagged step. Kus and Littelmann (Pacific J. Math. 278 (2015); the remark on p. 438 says their Theorem 3.5 generalizes Feigin's case $\ell = 1, \lambda_0 = 0, \lambda_1 = \theta$ and fixes its gap) prove the bigraded statement by handling all consequences of the defining relations in the associated graded. The upper bound needs the hard direction of their Theorem 3.5: the annihilator of the generator must pass to the associated graded. On p. 437 the written proof passes from "the difference $M - M'$ lies in the left ideal generated by the relations" to "its symbol kills the fusion vector". That step controls only the initial forms of the *generators* of the ideal, not of every element of it. The project's source audits (for A_2, `Notes/deligne/campaign/A2_SOURCE_AUDIT_2026_10_27.md`, and the audit of the literature inputs for all types) flag this step as unjustified as written. This is a gap in the written argument, not a counterexample: no counterexample to the theorem is known. Since the specialization $\lambda = \theta, \lambda_0 = 0$ is the same for every type, the caveat applies uniformly to G_2, D_4, F_4, E_6, E_7, E_8. That initial forms can misbehave is a real phenomenon: in a filtered algebra the initial forms of all consequences of a set of relations can differ from those of the relations themselves (in the Heisenberg algebra $[x, y] = z$ with filtration weights $0, 0, 1$ the left ideal (x, y) contains z, but the symbols of x and y do not generate z in the associated graded).

The flagged step tested for D_4 (October 2026). For $\mathfrak{so}_8, \lambda = \theta, \lambda_0 = 0, \ell = 1$, the project tested both the statement that the p. 437 step is meant to establish and the step itself, by computation (Python, not Lean; `Notes/deligne/campaign/D4_KL_SYMBOL_LEMMA_TEST.md`, with the reproducible script `Notes/deligne/campaign/generators/D4KLSymbolLemmaTest.py`). The statement, that the symbols of all elements of the annihilator of the generator of $D(1, m\theta)$ kill the generator of the bigraded fusion product (so that the associated graded of $D(1, m\theta)$ is that fusion product), holds at $m = 2$ (exact arithmetic over $\mathbb{Q}$) and at $m = 3$ (modulo two primes), block by block. The step does not prove it: at $m = 2$ the left ideal generated by the symbols of the *defining* relations has codimension $842 = 29^2 + 1$, one more than the 29^2 required (computed modulo a prime). The extra class is spanned by the symbol of

$$\tilde{a} = f_{\alpha_2} f_{\theta-\alpha_2}(f_\theta \otimes t^3) + (f_{\alpha_2} \otimes t) f_{\theta-\alpha_2}(f_\theta \otimes t^2),$$

which annihilates the generator of $D(1, 2\theta)$ (checked both in the fusion model and in the module presented by the defining relations alone) while its symbol is not in the ideal generated by the symbols of the relations; that symbol does kill the fusion vector, as the theorem predicts. So the written step is insufficient at $m = 2$: a proof must control symbols of consequences of the relations, not only of the relations. Nothing here contradicts Kus–Littelmann's Theorem 4.2; what is missing is a complete proof of that one step. The extra relations were identified by the same computations: they are the symbols of the Garland coefficients of the $\mathfrak{sl}_2(\theta)$-string.

An independent route for D_4. The library pursues a route to Input T for D_4 that does not use the p. 437 step. An explicit family J'_m of symbol relations (the symbols of the defining relations together with the Garland symbols above) is proved to lie in both annihilators, that of the associated graded of the universal module (`Jprime_le_annGr`) and that of the fusion vector (`StarB2.Jprime_le_annF`). This reduces the D_4 final theorem, with Input R unchanged, to a rank bound $\dim \mathrm{PTE}_m \le 29^m$ for every $m \ge 1$ on an explicitly presented toroidal module (`D4_classicallyFree_of_presentedRankBoundE`). The bound is proved for $m = 1$ (`presentedRankBoundE_one'`) and for $m = 2$ (`presentedRankBoundE_two`, which discharges the two layer bounds of `presentedRankBoundE_two_of'`); for $m \ge 3$ it is open on this route. Targeted builds are green and the printed axioms standard, and the files are compiled by the aggregate build of 3 November 2026. These results do not change the hypothesis of `D4_classicallyFree_of_inputT`.

The level route for D_4 (state on 2 November 2026). A second route organizes $W(m\theta, m)$ by levels for a $\mathfrak{gl}_4$ Levi subalgebra and bounds each level by a truncated $\mathfrak{sl}_4$ module. We record its state,

separating Lean from paper. Each Lean declaration named here was checked by a targeted build of its audit module (no `sorryAx`; `#print axioms` within `[propext, Classical.choice, Quot.sound]`) and is compiled by the aggregate build of 3 November 2026. Only the first item changes a final theorem: it removes Input R from the D_4 theorem (Theorem 27.15). The rest is progress toward Input T, which stays a hypothesis.

- *Lean, Input R.* `D4Char.d4_demazureRealization` proves `∀ n, DemazureRealizationG D4sector (ravFam D4sector) D4Wp.hilbSeriesZ n`, the hypothesis `hD` of the final theorem, with no hypotheses of its own, from a graded bound on the Levi side (`D4Char.d4_gradedLeviBound`) and the squeeze (Theorem 27.8; `#print axioms` standard, re-checked after the aggregate build of 3 November 2026).

- *Lean, the reduction of Input T.* `D4LevelReduction.d4_classicallyFree_of_coreBounds` derives the conclusion of the final theorem from `TruncatedCoreRankBound a b c` for all $a, c \geq 1$, a dimension bound for finite-dimensional $\mathfrak{sl}_4$ current modules with three proved relation families, truncated at $a + b + c$; Input R is supplied by `D4Char.d4_demazureRealization`. The levels with one adjoint site are proved (`truncatedCoreRankBound_singleAdjoint`), so `d4_classicallyFree_of_twoAdjointCoreBounds` needs only the core bounds with $a \geq 2$.

- *Lean, toward $a = 2$.* The levels with $a = 2$ use the bound at one adjoint site,

$$(\mathrm{III})_B : \qquad \dim W(\theta + B\omega_2, B)/\langle f_2(B-1)v\rangle \leq 300 \cdot 6^{B-2}.$$

  The flat relation it needs holds for every truncation (`SL4T.adjointSiteFlatTopRelation_holds`, `SL4T.zeroAdjointFlatRelation_all`), so `SL4T.adjointSiteLawB_of_stratumCount` derives the bound at one adjoint site from a stratum count of a coefficient ring alone, and `SL4T.oneAdjointStratumCount_of_low_strata` reduces that count to its low strata. The marked full-flag rings behind the count have their exact dimensions and stratum bounds in Lean; the step still missing is the descent from those rings to the coefficient ring.

- *On paper (refereed by a Claude session, not by a human referee, and not in Lean).* $(\mathrm{III})_B$ holds for every B (a gap in the first version was found by the Lean formalization and repaired). Given (III), every level with $a = 2$ follows from the single family

$$(\mathrm{II})_\kappa : \qquad \dim W(2\theta + \kappa\omega_2, \kappa + 2)/\langle f_1(1)f_3(1)v\rangle \leq 205 \cdot 6^\kappa \qquad (\kappa \geq 1),$$

  proved at $\kappa = 0$ and checked by machine for $\kappa \leq 3$. A same-point splitting reduces $(\mathrm{II})_\kappa$ to two one-node statements: $\tilde{Q}_\kappa := \dim W(2\omega_3 + \kappa\omega_2, \kappa + 1)/\langle f_3(1)v\rangle \leq 10 \cdot 6^\kappa$, and $(C)_{\kappa+1}$, where $(C)_n$ says that in the same-point product $V(\omega_2)_0 \otimes W(n\omega_2, n)$ the tensor of the highest-weight vectors generates a module of dimension $20 \cdot 6^{n-1}$. Both are open in general; $(C)_n$ is proved for $n \leq 2$, and both hold by machine in the ranges checked ($\kappa \leq 3$, $n \leq 4$). The levels with $a \geq 3$ are reduced, by a peeling argument, to local repairs and three base families, which are open.

So Input T for D_4 remains open, in Lean and on paper; what is new is the precise form of what remains.

An alternative route to the A_2 bound, through a *slice lemma* in mixed evaluation models, is recorded on paper in Chapter 26, Section 26.11; it is not proved, and it is not used.

27.7.2 Input R beyond A_2

What is needed. For each j, a module with the relations of $M_{j,0}$ whose graded dimension is at least Dem_j *in every degree*. It has two halves: a model satisfying the relations (the *relation half*), and a graded lower bound for its dimension (the *graded half*).

The literature: a theorem for every type. Both halves are published for every simple $\mathfrak{g}$, including G_2 and F_4: the relation half is Ravinder's Proposition 1 (after Chari–Venkatesh, Corollary 3.5) together with Lemma 27.6, and the graded half is the Demazure character formula of Kumar and Mathieu (dictionary of Definition 27.7). Input R is therefore *not* an open mathematical problem. What is open is its formalization: a Lean model of $D(1, j\theta)$ with a proved graded dimension, and a proof that the Lean algorithm implements the Demazure character formula.

What is formalized.

- *The relation half.* In the lattice VOA of the root lattice the vector $e^{j\theta}$ satisfies the $M_{j,0}$ relations, for D_4, E_6, E_7 and E_8 (Frenkel–Kac: the level-one vacuum module is the lattice VOA; Chapter 26, Section 26.15). G_2 and F_4 are not simply laced and have no lattice model in the library; a formalization would need another construction of $D(1, j\theta)$ (the mathematics is not in doubt).

- *The graded half.* For D_4 the cases $j \le 2$ are proved (Theorem 27.19), and every j is covered by `D4Char.d4_demazureRealization`, through a graded Levi bound and the squeeze rather than the Demazure character formula (Theorem 27.8; confirmed by the aggregate build of 3 November 2026). Numerically the lattice model is graded-sharp (A_2 and D_4 for $j \le 3$). For the other types a Lean proof for all j would need a formalization of the Demazure character formula in this setting, or an analogue for types D and E of the Chari–Loktev spanning basis, which for $\mathfrak{sl}_{r+1}$ gives the matching upper bound; the library has neither.

- *Total versus graded.* A lower bound on the *total* dimension of $M_{j,0}$ (expected value $(d_{\mathfrak{g}} + 1)^j$) would not be enough: the squeeze uses the inequality $\mathrm{Dem}_j \le \mathrm{ch}\, M_{j,0}$ coefficient by coefficient (Example 27.2). For A_2 the passage from total to graded used the Chari–Loktev upper bound, special to type A.

27.7.3 Input S for G_2, F_4, E_6, E_7, E_8

Why the bound is no cheaper than the identity. Write $\mathcal{D} = \sum_j q^j \mathrm{Dem}_j/(q)_j$, a sum of series with nonnegative coefficients. Suppose a proof of $\mathcal{D} \le c$ produced series $U_j \ge \mathrm{Dem}_j$ coefficientwise with $\sum_j q^j U_j/(q)_j = c$. If equality $\mathcal{D} = c$ holds (as it does numerically), then $\sum_j q^j (U_j - \mathrm{Dem}_j)/(q)_j = 0$ with every term nonnegative, so $U_j = \mathrm{Dem}_j$. A domination proof therefore has to compute the Demazure characters exactly (Chapter 25, Proposition 25.39).

What is known. No published proof of the identity, or of the bound, is known to us at these five types: Input S is a conjecture (Conjecture 27.10), supported by numerical checks only. The structural route is Macdonald theory at $t = 0$: Demazure characters are specializations of nonsymmetric Macdonald polynomials (Sanderson; Ion), and the identity would be a constant-term summation of Cherednik type; we know of no reference proving the needed summation at the exceptional types. For G_2 the library has reduced the problem to one identity: the target half `G2KWEqMLDE` is proved (`G2Star.g2KWEqMLDE`), so the star identity follows from `G2DemazureEqKW` alone (`G2Star.g2StarIdentity_of_demazure`; Section 27.4.4). That identity is in turn split into two named halves (Theorem 27.23): the statement that the G_2 Demazure table equals a fermionic formula, and a pure q-series identity between the fermionic sum and the Kac–Wakimoto-type product. The first, `G2DemazureFermionic`, follows from published results (Fourier–Littelmann, Chari–Moura, Ardonne–Kedem, Di Francesco–Kedem; conventions as in Lin, IMRN 2021; see Section 27.4.4 for the strength of this reading); the second, `G2FermionicKW`, is open.

27.8 The per-type headline theorems

The final theorems are assembled from per-type headline theorems, each with the same conclusion and a longer list of hypotheses. We present those the final theorems use, one for each mechanism, and list the others. Every theorem here has the conclusion of Definition 27.3 for its type.

27.8.1 A_2: classical freeness from U5 and U6

The A_2 headline files, in logical order (each hypothesis that disappears from one row to the next became a theorem):

file	theorem	named hypotheses
`A2Assembly`	`classicallyFree_of_residualInputs`	carrier $\le$ Demazure sum, `StarIdentity`, `KacWakimotoLowerBound`
`A2SectorAssembly`	`classicallyFree_of_sectorInputs`	`CasimirLayerBound`, `SectorFusionBound F`, U6, `StarIdentity`, `KacWakimotoLowerBound`
`A2SectorHeadline`	`classicallyFree_of_weylInputs`	`CasimirLayerBound`, `CarrierGeneration`, U5, U6, `StarIdentity`, `KacWakimotoLowerBound`
`A2Headline`	`classicallyFree_of_openInputs` and four siblings	`MFreeness`, `DivisorComparison`, U5, U6, `KacWakimotoLowerBound`
`A2SectorTop`	`classicallyFree_of_divisorAndLiterature`	`DivisorComparison`, U5, U6, KW
`A2Top`	`classicallyFree_of_pairAndLiterature`	`PairComparison`, U5, U6, KW
`A2DivisorTop`	`classicallyFree_of_literature`	U5, U6, KW
`A2Final`	`classicallyFree_of_fusion`	U5, U6

Here KW is `KacWakimotoLowerBound` ($[q^N]\prod(1+q^r)^8 \le \dim W_N$), proved from the A_2 product identity and the vacuum quartic relation (Chapter 25); `StarIdentity` is `A2.starIdentity`; `CasimirLayerBound`, `MFreeness`, `CarrierGeneration`, `PairComparison` and `DivisorComparison` are steps B1, B6, B8 and B7 of the carrier chain, proved in Chapter 24. After `A2Final`, Chapter 26 replaces U5 and U6 by Inputs T and R.

Theorem 27.20 (A_2 from U5 and U6). *For $W = L_{-3/2}(\mathfrak{sl}_3)$ with its explicit presentation, classical freeness and* $\ker = (I_2^{\mathrm{ns}})$ *follow from U5 and U6 for any family F.*

File `VOA/DeligneAudit/A2Final.lean`.

```
theorem classicallyFree_of_fusion (F : ℕ → PowerSeries ℚ)
    (hU5 : SectorWeyl.FusionModuleBound F)
    (hU6 : MixedFusionRecursion F demazureHilbSeries) :
    CaseClassicallyFree .A2 W explicitPresentation ∧
      RingHom.ker (MvPolynomial.aeval fun i =>
        liDegreeZeroClass W 1 ⟨explicitPresentation.gen i,
          explicitPresentation.gen_weight_one i⟩).toRingHom = I2ns :=
```

From the mathematics to the Lean statement

Namespace `VOA.DeligneAudit.A2`. `SectorWeyl.FusionModuleBound F` is U5 in the $\mathfrak{sl}_3$ form (`VOA/DeligneAudit/A2SectorWeyl.lean`): for every module with the local Weyl and fusion

relations for $m\theta$, dim(degree b) $\le [q^b]F_m$ and total $\le 8^m$. `MixedFusionRecursion F Dem` is the structure with the single field `eq : ∀ n, Dem n = VOA.DeligneGaussian.mixed (X : PowerSeries ℚ) F n 0` (U6; `VOA/DeligneAudit/A2CarrierChain.lean`), where `mixed q F a b` is defined by $M_{0,b} = F_b$ and $M_{a+1,b} = M_{a,b+1} + q^{2a+b+1}M_{a,b}$ (`VOA/DeligneAudit/GaussianTransform.lean`); so the condition is $M_{j,0} = \mathrm{Dem}_j$. `demazureHilbSeries` is the power series of the Gelfand–Tsetlin table `demazureHilb` (`VOA/DeligneAudit/A2SectorAssembly.lean`). F is a free variable: U5 and U6 together pin it down to the fusion characters. The file has no `variable` lines.

Proof on paper. The carrier chain of Chapter 24 gives carrierDim$(N) \le \mathcal{D}_N$ from U5 and U6 (B1 proved, B6 from U5, the divisor comparison proved, D3 proved). The star identity gives $\mathcal{D}_N = [q^N]\prod(1+q^r)^8$, and KW gives $[q^N]\prod(1+q^r)^8 \le \dim W_N$; the capstone (Theorem 24.19) concludes. □

Physical meaning

Heuristic. With the fusion of adjoint particles described by its graded character, the count of classical states (the carrier) is bounded by the particle count (the Demazure sum), which equals the vacuum character; so no classical state fails to lift.

What the machine verified

Proved; axioms standard (campaign record). Conditional on U5 and U6 for F; Chapter 26 discharges both for $F =$ `fusionF`.

Lemma 27.21 (Two bookkeeping identities of the A_2 assembly). (i) *For every j, $1/(q)_j = \sum_N p_{\le j}(N)q^N$ in $\mathbb{Q}[[q]]$, where $p_{\le j}(N)$ is the number of partitions of N into parts at most j.* (ii) *The concrete Demazure sum of Chapter 25 equals the coefficient $\sum_j [q^N]\, q^j \mathrm{Dem}_j/(q)_j$ used by the carrier chain, for* Dem $=$ `demazureHilbSeries`.

File `VOA/DeligneAudit/A2SectorAssembly.lean`.

```
theorem partitionsLe_series (n : ℕ) : (qpoch n)⁻¹ = partitionSeries n :=
```

```
theorem demazureCoeff_eq_demazureCoeffOf (N : ℕ) :
    (demazureCoeff N : ℚ) = demazureCoeffOf demazureHilbSeries N := by
```

From the mathematics to the Lean statement

`qpoch n` is $(q)_n$ in $\mathbb{Q}[[q]]$, invertible because its constant term is 1; `partitionSeries n` is `PowerSeries.mk fun N ⇒ (partitionsLe n N : ℚ)`. `demazureCoeffOf Dem N` is the chain's coefficient $\sum_{j\le N}[q^N]\, q^j \mathrm{Dem}_j/(q)_j$ (Chapter 24); `demazureCoeff N` is the natural number $\sum_j (\mathrm{hilb}_j * p_{\le j})(N-j)$ of Chapter 25. The two lemmas say that two independently written definitions of $\mathcal{D}_N$ agree.

Proof on paper. (i) Split partitions into parts $\le j+1$ by whether a part $j+1$ occurs: $p_{\le j+1}(N) = p_{\le j}(N) + p_{\le j+1}(N-j-1)$. Hence $P_{j+1}(1-q^{j+1}) = P_j$ for the series P_j, and induction from $P_0 = 1$ gives $P_j(q)_j = 1$. (ii) Expand $q^j\mathrm{Dem}_j/(q)_j$ with (i) and compare coefficients. □

Physical meaning

$1/(q)_j$ is the partition function of the relative motion of j identical bosonic particles on a line. The lemma checks that two programs counting the same particle states agree.

What the machine verified

Proved, unconditional; axioms standard (campaign record).

27.8.2 D_4: the headline with every input visible

Theorem 27.22 (D_4 headlines). *For $W = L_{-2}(\mathfrak{so}_8)$ (certificate basis) with its explicit presentation:*

(a) $c(W) = -14 = -2(6+1)$*;*

(b) classical freeness and ker *= the ideal of the* 105 *quadrics follow from U5 and U6 for a family F, the divisor comparison, Demazure positivity, the Schur-index evaluation, Ramanujan's identities and a vacuum quartic relation on W;*

(c) they follow from U5, U6 and Demazure positivity alone;

(d) they follow from the squeeze inputs for a family M together with the universal bound.

From the mathematics to the Lean statement

All in the namespace `VOA.DeligneAudit.D4Lie`. `W4.centralCharge` is the Sugawara central charge $kd_{\mathfrak{g}}/(k+h^\vee) = -2\cdot 28/4 = -14$, written as $-2(h^\vee+1)$ because that is the form the MLDE argument uses. In `d4_headline`: `FusionModuleBoundG D4sector F` is U5 (Definition 24.29); `DivisorComparisonG D4sector` is the divisor comparison (Chapter 24); `D4K.D4DemazurePositivity` says the algorithm's integer D_4 Demazure coefficients are nonnegative; `D4MLDE.D4SchurEqE4` says the series `d4SchurQ` equals the coefficients of $q^{-7/12}E_4'/(240\eta^{10})$, where $E_4' = q\frac{d}{dq}E_4$ and the factor $q^{-7/12}$ removes the leading power $q^{-c/24} = q^{7/12}$ of the normalised character; `D4MLDE.RamanujanIdentities` are Ramanujan's three differential identities for E_2, E_4, E_6; and `VacuumQuarticRelation W4 κ` is the weight-four identity of Chapter 25 (Definition 25.13) for some constant κ (implicit argument `\{κ : ℂ\}`). In `classicallyFree_of_squeeze`: `FusionSqueezeInputsG Dem 28 M` is the generic squeeze-input structure of Chapter 26 (Definition 26.11), and `huniv` says every module with the $M_{0,m}$ relations has degree pieces bounded by $M_{0,m}$.

Which hypotheses became theorems. Between (b) and (c): the divisor comparison (`DeligneDivisor.D4.d4_divisorComparison`), the Ramanujan identities (`D4MLDE.ramanujanIdentities`), the vacuum quartic relation (`vacuumQuarticRelation4`) and the Schur evaluation (`D4Wp.d4SchurEqE4`). Between (c) and the final theorem: U5 and U6 from Inputs T and R, and positivity, absorbed by the unclamped series (Chapter 26). Last step: Input R itself (`D4Char.d4_demazureRealization`), which leaves Input T as the only hypothesis (Theorem 27.15).

Proof on paper. (a) Substitute $k=-2$, $d_{\mathfrak{g}}=28$, $h^\vee=6$. (b) The vacuum quartic relation with $c=-14$ gives $c_N \le \dim W_N$ for $h^\vee=6$; with Ramanujan's identities and the Schur evaluation the Demazure sum equals the MLDE solution (Theorem 25.37), using positivity to read the algorithm's table as nonnegative; so $\mathcal{D}_N \le \dim W_N$. U5, U6 and the divisor comparison give the carrier bound (Chapter 24), and the capstone concludes. (c) Plug in the four proved inputs. (d) The squeeze gives U5 for the unclamped fusion series (Chapter 26), and the unclamped form of (c) applies. □

Physical meaning

(a) is the relation $c_{2d} = -12c_{4d}$ of Beem et al. with $c_{4d} = 7/6$ for $SU(2)$ with four flavours. The Kac–Wakimoto character formula used for A_2 is unavailable here, because -2 is not an *admissible* level for D_4 (admissible levels are those whose vacuum module has a Kac–Wakimoto character formula; for simply laced $\mathfrak{g}$ they are $k+h^\vee = p/u$ with coprime positive integers $p \ge h^\vee$, u, and for D_4 at $k=-2$ one has $k+h^\vee = 4 < 6$); the modular differential equation replaces it.

What the machine verified

All proved; axioms standard (campaign record). (a) unconditional; (b)–(d) conditional on the listed hypotheses. The files `D4LieTop` (`d4_classicallyFree_of_sector`) and `D4Top` (`W4_demazureBound`, `W4_vacuum_ne_zero`) contain the intermediate steps.

27.8.3 G_2 and F_4: the concrete headlines and the two halves of the G_2 star identity

Theorem 27.23 (G_2 and F_4 concrete headlines). *For $W = L_{-5/3}(\mathfrak{g}_2)$, classical freeness and* ker $=$ *the ideal of the listed quadrics follow from U5 for the clamped fusion series and Input S; or from U5 and the two halves of the star identity. For $W = L_{-5/2}(\mathfrak{f}_4)$ they follow from U5 and Input S.*

structure G2FermionicKW : Prop where
  eq : ∀ N, ((demazureSumCoeff g2FermHilb N : ℕ) : ℤ) = coeff N g2KW
```

From the mathematics to the Lean statement

`g2FusionF` and `f4FusionF` are `fusionOf (hilbSeries g2DemazureHilb)`, resp. `fusionOf (hilbSeries f4DemazureHilb)`: the fusion characters determined by the clamped Demazure tables through the mixed recursion (Chapter 26, Definition 26.8). U6 holds for them by construction, so U5 is the only fusion hypothesis.
`G2DemazureFermionic` says that the G_2 Demazure table equals `g2FermHilb`, the fermionic formula of Hatayama, Kuniba, Okado, Takagi and Yamada, $\sum_\lambda \dim V(\lambda) X_{j,\lambda}(q)$, for j copies of the Kirillov–Reshetikhin module $W_1^{(2)} = V(\theta) \oplus \mathbb{C}$. On paper it follows from published results: $D(1, j\theta) \cong (W_1^{(2)})^{*j}$ as graded modules (Fourier–Littelmann, Theorems 8 and B; Chari–Moura for $W_1^{(2)}$), and the graded multiplicities of this fusion product are the fermionic sums (Ardonne–Kedem's upper bound with Di Francesco–Kedem's equality at $q = 1$; conventions as in Lin, IMRN 2021). Section 27.4.4 records the strength of this reading. In Lean it is a single named statement, a hypothesis of `g2_classicallyFree_concrete_of_fermionic`.
`G2FermionicKW` says that the Demazure sum of the fermionic table equals the coefficients of `g2KW`, the product $\theta_{A_2}(q)\,(q^3;q^3)_\infty^6/(q;q)_\infty^8$, where $(x;q)_\infty = \prod_{i\ge 0}(1 - xq^i)$ (so $(q;q)_\infty = \prod_{i\ge 1}(1 - q^i)$) and θ_{A_2} is the theta series of the A_2 root lattice; this product is the Kac–Wakimoto-type closed form of the target of Chapter 25 (Theorem 25.30). It is a pure q-series identity, and it is open (checked through q^{60}).

Proof on paper. Section 27.5.1, steps 4–6. For the fermionic form: the two halves give $\mathcal{D}_N = [q^N]$`g2KW` (`g2DemazureEqKW_of_fermionic`), and `g2KW` equals the MLDE solution by a modular-forms argument (Lorenz–Borwein, Chapter 25, Theorem 25.30), which gives the star bound. □

Physical meaning

Heuristic. The fermionic formula is the Bethe-ansatz count of states of a spin chain built from Kirillov–Reshetikhin modules; its equality with a product formula is the "bosonic = fermionic" kind of identity familiar from conformal field theory characters.

What the machine verified

Proved; axioms standard (`g2_classicallyFree_concrete` and `f4_classicallyFree_concrete'` re-checked at an earlier commit; the others campaign record). Conditional: U5 and the star input. The squeeze forms (`g2_classicallyFree_concrete_of_squeeze`, `…_Z`, `…_Z_of_fermionic`, `f4_classicallyFree_concrete_of_squeeze` and its primed form) replace U5 by the squeeze inputs and the universal bound.

27.8.4 E-types

Theorem 27.24 (E_6, E_7, E_8 headlines). *For $X \in \{E_6, E_7, E_8\}$ and $W = L_k(\mathfrak{g}_X)$ with its explicit presentation, classical freeness and* ker *= the ideal of the listed quadrics follow from U5 for the clamped fusion series and Input S.*

```

From the mathematics to the Lean statement

Namespaces `DeligneCarrier.E6`, `E7Lie`, `E8Lie`. U5 is stated directly for `fusionOf (hilbSeries …)`. The same files contain siblings `eX_classicallyFree` with the star *identity* `EXStarIdentity` in place of the bound; the bound is weaker and suffices. Inside, the

divisor comparisons `eX_divisorComparison`, jet surjectivity and the geometric carrier are plugged in as theorems, and the target bounds `e6_targetLowerBound`, `e7_targetLowerBound`, `targetLowerBoundQ8` are unconditional.

Proof on paper. Steps 4–6 of Section 27.5.1, through the generic `DeligneCarrier.classicallyFree_of_sectorFusion` (Chapter 24). □

Physical meaning

Heuristic. The Minahan–Nemeschansky statements of Theorem 27.17, one step earlier: the fusion of adjoint particles is still assumed in the form of its graded character.

What the machine verified

Proved; conditional on U5 and `EXStarBound`. Axioms standard: E_6 re-checked at an earlier commit; E_7, E_8 campaign record only.

27.9 Approaches known to fail

For the record, the following natural approaches to bounds of the kind in Inputs T and S are known to fail. Each comes with the reason. They were found while working on A_2, and they apply equally to attempts at the other types.

Approaches to the total bound (Input T) that fail

(i) Circular.

1. *The presentation route* ("$M_{0,m}$ is the associated graded of the fusion model"). The surjection from $M_{0,m}$ onto the associated graded is free; its injectivity is exactly the statement to be proved.

(ii) Numerically false.

2. *The naive truncated box.* Imposing $f(k)w = 0$ for $k \geq m$ together with "box" bounds on monomials overcounts: 72 instead of 64 for $\mathfrak{sl}_3$ at $m = 2$, 656 instead of 512 at $m = 3$. The truncations do not capture all relations.

3. *Short truncation identities.* Reducing the truncation in $M_{0,m}$ to a single-letter recursion reproduces the correct count for $m \leq 3$ but fails in 28 of 256 cases at $m = 4$: the truncation is a normal-form problem for the whole relation ideal.

4. *Leading-term independence of Chari–Loktev words* against monomials of the lattice (Fock) model: the words are not independent under any tested monomial order (77 of 81 at $N = 2$, 547 of 729 at $N = 3$).

5. *Separating functionals in the lattice VOA V_{A_2}* by charge, L_0-weight or θ-degree: these separate the pieces of Ravinder's chain for $N = 2$ but not for $N = 3$, and the θ-degree is not preserved by $U(\mathfrak{g}[t])$.

(iii) False on an algebraic technicality.

6. *Plain tensor induction $T_m = T_{m-1} \otimes D(1, \theta)$*: the image of the fusion filtration of T_m in $T_{m-1} \otimes \mathfrak{g}$ is a *mixed* filtration, not a shifted tensor filtration (fusion products are not associative on the nose); one must work with mixed models.

7. *Ungraded counting in the evaluation model.* At nonzero points $\mathcal{I}_m = \mathfrak{g} \otimes t^m\mathbb{C}[t]$ acts as all of $\mathfrak{g}[t]$, so only the graded structure carries information.

8. *Treating a splitting of the modes as an algebra map before taking the associated graded.* Commutators do not transfer: with $[h_\theta, f_\theta] = -2f_\theta$ the relation $h_\theta(1)f_\theta(m-1) - f_\theta(m-1)h_\theta(1) + 2f_\theta(m) = 0$ has terms of filtration degree $0, 0, 1$; in the split algebra the commutator vanishes while the last term acts nontrivially. Checking only the initial forms of the defining generators does not prove that annihilators transfer.

9. *Treating the image of the site-removing shift map of the polynomial model* (Feigin, Jimbo, Kedem, Loktev and Miwa) as an ideal. That image is the linear subspace of polynomials independent of one zero-mode variable; it contains 1, so an ideal with that image would be everything. One must keep the actual target ideal modulo this subspace.

Approaches to the star bounds (Input S) that fail

1. *Positivity or domination proofs.* Excluded by rigidity (Section 27.7.3): a dominating family must equal the Demazure characters.

2. *Positive expansions of the MLDE solution.* The exponents of the product expansions of the MLDE solutions alternate in sign, so there is no positive product to dominate.

3. *A rational certificate for the hardest step of the G_2 Macdonald route*: the needed identities have binomial denominators of size 17 to 41, and an exhaustive search for a small local cancellation found none.

27.10 Verification record

The commit. Every `leancode` block of this chapter occurs verbatim in the sources of the state this chapter was written against (`sync.py check`).

What the machine confirmed (campaign records, 27 October 2026).

```
VOA.Deligne umbrella      earlier: green, 11099 jobs, no sorryAx;
                          every #print axioms in the campaign files standard
lake build VOA            last green on 26 Oct (13868 jobs)

```

What the machine confirmed (28 October 2026).

```
bash scripts/campaign_build.sh VOA    (full lake build VOA, memory-capped wrapper)
  pre-release: green, 18901 jobs
  after merging the then-current origin/main: green, 18907 jobs
python3 scripts/check_repository.py         PASS: 10431 library files, all reachable,
                                            0 project axioms
python3 scripts/audit/run_axiom_audits.py   PASS: 5958 reports across 24 probes
#print axioms (lake env lean -DmaxSynthPendingDepth=3):
  VOA.DeligneAudit.A2.classicallyFree
  VOA.DeligneAudit.DeligneSeries.A2_classicallyFree_final
    both: [propext, Classical.choice, Quot.sound]
```

Both declarations have no hypotheses. The aggregate target contains the umbrella `VOA.Deligne`, which imports `VOA/DeligneAudit/A2Unconditional.lean`. The final theorems of the six conditional types are in `VOA/DeligneAudit/DeligneSeries.lean`, which is built within that aggregate build (earlier, within the umbrella build at an earlier commit); the statements quoted here are unchanged since. A source scan of the import closure of `A2Unconditional` (release audit, `Notes/Textbook/referee/RELEASE_AUDIT_L24_L25_A2.md`) found no `sorry`, `admit`, `axiom`, `native_decide` or `implemented_by` outside comments.

What the machine confirmed (3 November 2026): D_4 Input R.

```
lake build VOA (aggregate)                  green, 20331 jobs
python3 scripts/check_repository.py         11859 library files, all reachable
                                            except 4 held from the release;
                                            0 axiom declarations
python3 scripts/audit/run_axiom_audits.py   PASS: 5958 reports across 24 probes
#print axioms:
  VOA.DeligneAudit.D4Char.d4_demazureRealization
  VOA.DeligneAudit.DeligneSeries.D4_classicallyFree_of_inputT
    both: [propext, Classical.choice, Quot.sound]
```

The first declaration has no hypotheses (Theorem 27.8); the second has the single hypothesis `hF`, Input T for D_4 (Theorem 27.15). The four files held from the release are not imported by the D_4 theorems.

What this chapter's author re-checked. At two earlier commits (not re-run for this edition), on scratch files importing a single module each, with `lake env lean -DmaxSynthPendingDepth=3` from the repository root (about 4 s each, peak memory 5.8–5.95 GB):

```
import VOA.DeligneAudit.DeligneFusionU7
  A2.classicallyFree_of_totalDim', A2.classicallyFree_of_kernelLower',
  A2.fusionTotalDim_of_kernelLower, EvalModel.demazureRealization_all,
  (verbatim copies of) A2_classicallyFree_final_S2
import VOA.DeligneAudit.G2FusionKernelTheta
  UnivG.g2_classicallyFree_of_totalBound, G2Lie.g2_classicallyFree_concrete,
  UnivG.g2_ravinderKernelRel
import VOA.DeligneAudit.DeligneFusionFiniteGG2 / GD4 / GF4
  FiniteG.G2.g2_fusionTotalBoundG_of_dim, FiniteG.fusionTotalBoundG_of_dim,
  FiniteG.D4.d4_fusionTotalBoundG_of_dim, FiniteG.F4.f4_fusionTotalBoundG_of_dim
import VOA.DeligneAudit.D4FusionKernelTheta
  UnivG.d4_classicallyFree_of_totalBound, UnivG.d4_ravinderKernelRel'
import VOA.DeligneAudit.F4FusionCountZ
  DeligneCarrier.f4_classicallyFree_of_totalBound', F4Lie.f4_classicallyFree_concrete'
import VOA.DeligneAudit.E6Final
  DeligneCarrier.E6.e6_classicallyFree_of_starBound
```

Every one of these (names prefixed by `VOA.DeligneAudit.`) printed `[propext, Classical.choice, Quot.sound]`. The statements concerned are unchanged in the state this chapter was written against. The D_4, G_2 and F_4 final theorems are compositions of two re-checked theorems each, so their axioms are the union (standard). The author did not re-run any check at that state: this checkout has no compiled objects for `A2Unconditional`, `DeligneSeriesA2` or the Chari–Venkatesh modules, and building them is outside the scope of a chapter revision. The E_7/E_8 modules were not imported (they load the large certificate libraries); for the three E-type final theorems the axiom status is the campaign record. The author did not run `lake build`.

The literature-precision revision (28 October 2026). The statements of the literature inputs were corrected following `Notes/Textbook/referee/DELIGNE_INPUTS_PRECISION.md`. The Lean names cited in that revision (Section 27.6.1, the G_2 reduction of Input S, the lattice relation halves) were checked by reading the source at the time of that revision, and the six new quotations occur verbatim there; their files are in the import closure of `VOA/Deligne.lean`. Their axiom status is the

campaign record; no Lean check was re-run for this revision, and no `lake build` was run. The literature claims are those of the audit, which read the papers' own text (Feigin arXiv v1/v2, Ravinder arXiv v4, Kus–Littelmann published PDF); the Kumar, Mathieu, Frenkel–Kac and Chari–Venkatesh citations were not re-fetched.

27.11 Remarks on the Lean sources

The statements of the final theorems say what the mathematics says, about genuine simple affine VOAs, with every hypothesis explicit. Some docstrings in the sources describe an earlier state and contradict the theorems; a reader of the source should rely on the statements.

Docstrings that are out of date

1. `VOA/DeligneAudit/DeligneFusionCVTotal.lean`: `SharpRectangularBases` and `ResidualTheta3Bound` are labelled "UNPROVED ... explicit mathematical input", and the module docstring says the file "does not assert unconditional A_2 classical freeness". Both base families are now proved (`CVUniv.sharpRectangularBases`, `CVUniv.residualTheta3Bound`); the file itself is correct as an implication.
2. `VOA/DeligneAudit/DeligneFusionU7.lean`, module docstring: "A_2 classical freeness rests on the single named residual `RavinderKernelLower`". It no longer does.
3. `VOA/DeligneAudit/A2Instance.lean`: "The three remaining packages ... as explicit hypotheses"; all are now discharged for A_2.
4. `VOA/DeligneAudit/A2Assembly.lean`, `VOA/DeligneAudit/A2Headline.lean` and `VOA/DeligneAudit/A2Top.lean` list as "remaining" inputs (`StarIdentity`, `KacWakimotoLowerBound`, `PairComparison`) that are proved in the library.

Two remarks on formulation. There is no Lean theorem from `IdealLower` directly to the A_2 conclusion (the composite is a one-line term, and the unconditional theorem makes it unnecessary). The short names `explicitPresentation`, `classicallyFree_of_fusion` and `mldeCoeff` denote different declarations in different namespaces; use full names.

27.12 Referee's checklist

Lean declaration	Intended meaning	Hypotheses / status	Fidelity check

Chapter 28

Graded unitarity through the BRST coset: from affine $\mathfrak{sl}_2$ at level $-4/3$ to Lee–Yang

This chapter was written against an earlier state of the LeanVOA library, and every Lean quotation below was copied from the source files of that state. For this edition, the book's automatic check confirms that every Lean quotation below occurs verbatim (up to whitespace and comments) in the source files of this release. The author of this chapter did not run `lake build`; the aggregate-build claims are records of the project's earlier builds, and the `#print axioms` results that were re-run are listed in Section 28.13.

The chapter covers the Lean files that the book assigns to it (about 225 files and 53 700 lines): the files `VOA/Examples/Sl2SemiInfinite*`, `Sl2Coset*`, `GradedUnitaryCohomology*`, `BGPackage*`, `BRST*`, `GhostConj*`, `HarmonicMetric*`, `ConcreteGood*`, `ConcreteHodge*`, `KoszulConcrete*`, `KoszulResidual*`, `LeadingKoszul*`, `InvariantSymbol*`, `CyclicEval*`, `SymbolModel*`, `JetFermionic*`, `JetProduct*`, `JetStrict*`, `Adamovic*`, `LYGram*`, `RRLower*`, `LevelOneHeis*`, `LevelOneUnitary*`, `LeeYangCharacter*`, `LeeYangCosetTransfer*`, `LeeYangShortcut*` and `LeeYangTransferAssembly*`. We present about forty declarations one by one, those on which the headline theorem rests or which are results in their own right; the rest (intermediate lemmas, bookkeeping of gradings on tensor products, mode computations) are described collectively in Section 28.12.

Conventions for quotations and status boxes.

- *Omitted proofs.* A Lean quotation shows a statement, not its proof. A block that ends in `:=`, `:= by` or `where` with nothing after it is a statement or definition whose proof or body is omitted; it is not a truncated quotation. Documentation comments (`/-- ... -/`) inside quoted structures are omitted; the verbatim check ignores comments.

- *"Axioms standard".* This means that `#print axioms` reports exactly `[propext, Classical.choice, Quot.sound]`, the three standard axioms of Lean's logic; see Chapter 1, Section 1.3. It does *not* mean "unconditional": `#print axioms` does not list the explicit hypotheses of a theorem (Section 1.3.4). Every status box names the hypotheses separately. The PBW theorem `VOA.pbw` of Chapter 3 is now a theorem, not an axiom (it was a project axiom in earlier versions of the library), so the library has no project axiom; some project notes written before that change list `VOA.pbw` among the axioms of the headline below, which is no longer the case.

- *Where a status claim comes from.* "Re-checked" means that `#print axioms` was re-run on a scratch file against the library's build products; the release check of this edition re-ran it

for every declaration so marked (Section 28.13). Aggregate-build claims are records of the project's earlier builds, also listed there.

Reading the Lean. Generic Lean idioms (structures and their fields, `Submodule`, `Module.finrank`, coercions ↑, quotients `/`, the order of `∀` and `∃`, `def` versus `theorem`, why a `Prop`-valued `def` is a *statement* and not a claim) are explained in Chapter 1, Section 1.2. One idiom recurs so often in this chapter that we recall it here: a declaration `def P : Prop := ...` only *names* a proposition; a later `theorem p : P` proves it; and a theorem that takes `(h : P)` as an argument is *conditional* on `P`. The library uses this pattern to record its open inputs, and many of them were later proved; when that happened the definition's docstring often still says "OPEN". Section 28.14 lists those stale docstrings.

Prerequisites. The following are used here and developed elsewhere in the book. (1) The graded-unitary predicate of Arabi Ardehali, Beem, Lemos and Rastelli (`GradedUnitary`, `GradedUnitaryAt`, `LayerNondegenerate`, `LayerPositive`), sesquilinear forms, `IsPosOn`, `signedForm` and real structures (`RealStructure`, `gradedSesq`): Chapter 19, Sections 19.2–19.4, Definitions 19.9, 19.10, 19.11. (2) Graded unitarity of the Virasoro VOAs with the length flag (`VirGradedUnitary`, `virGradedFlag`), and the Lee–Yang model: Definitions 19.19 and 19.20, Section 19.9. The *graded isometric embeddings* of the transfer theorems are Definition 19.46. (3) The universal and simple affine VOAs $V^k(\mathfrak{sl}_2)$ and $L_k(\mathfrak{sl}_2)$, their currents, Sugawara vector and canonical invariant form: Chapter 9 (Definition 9.14) and Chapter 10 (Definition 10.2). (4) Super vertex algebras, tensor products and BRST complexes (`SuperVertexAlgebra`, `TensorVA.tensorSVA`, `BRST.BRSTComplex` and its cohomology vertex algebra): Chapter 5, Sections 5.9 and 5.11, and Chapter 17 for the *bc* ghost system (Definition 17.28). (5) Graded flags and good filtrations: Chapter 11, Definition 11.1. (6) The universal and simple Virasoro VOAs $V(c,0)$, $L(c,0)$, creation words and the canonical form `Bsimp`: Chapter 7. (7) The vacuum character of $L_{-4/3}(\mathfrak{sl}_2)$ (Arakawa–Dai): Chapter 20, Theorem 20.18.

What this chapter is about, in one paragraph. The Lee–Yang model $M(2,5)$, whose vacuum VOA is the simple Virasoro VOA $L(-\frac{22}{5},0)$, is not unitary in the usual sense: already $\|L_{-2}\mathbf{1}\|^2 = c/2 = -11/5$. Arabi Ardehali, Beem, Lemos and Rastelli (ABLR) conjectured that it is *graded unitary*: with respect to the filtration by the number of stress-tensor modes, the sign of the norm alternates with the filtration degree (Chapter 19). This conjecture is open. The library proves an *implication*: graded unitarity of the simple affine VOA $L_{-4/3}(\mathfrak{sl}_2)$ (for its canonical form, its compact conjugation and its "corrected" filtration, in which the currents and the Sugawara vector all have degree one) implies graded unitarity of Lee–Yang. The bridge is the Goddard–Kent–Olive coset $L_{-4/3}\otimes L_1 \supset L_{-1/3}\otimes$ (Virasoro), whose Virasoro part has $c=-22/5$, realized as the relative semi-infinite (BRST) cohomology of $L_{-4/3}\otimes L_1\otimes V^{-11/3}$ with three pairs of ghosts, together with a theorem of Beem and Garner that BRST cohomology inherits graded unitarity, and a dimension count that identifies the cohomology with Lee–Yang. The headline is `VOA.AdamovicSymbol.leeYang_gradedUnitary_of_affine`. Its only hypothesis is the affine graded unitarity, which is **open**. The headline is therefore a proved implication with the explicit hypothesis `hA`, `#print axioms`-clean conditional on `hA`; nothing in this chapter proves that Lee–Yang is graded unitary.

Why formalize this. The paper proof of the implication cites four substantial results: a coset identification (Arakawa–Creutzig–Linshaw), the Beem–Garner theorem, an "invariant-symbol" dimension formula for $\mathrm{gr}\, L_{-4/3}$, and the Rogers–Ramanujan form of the Lee–Yang character. In the Lean development every one of them is either proved or avoided. The coset identification is avoided altogether (Section 28.5); the Beem–Garner positivity argument is proved as finite-dimensional linear algebra and instantiated on the actual complex (Sections 28.6 and 28.8); the invariant-symbol bound is proved through a jet-ring model and a q-series identity (Sections 28.9 and 28.10); and the

Lee–Yang character is proved from the Kac determinant (Section 28.11). Several of these are results of independent interest: the Lee–Yang vacuum character, unitarity of $L_1(\mathfrak{sl}_2)$, graded unitarity of $V^k(\mathfrak{sl}_2)$ for every real $k < -2$, and a fermionic q-series identity for a jet ring.

Remark 28.1 (The logical arc and the ledger)**.** Write $A = L_{-4/3}(\mathfrak{sl}_2)$, $B = L_1(\mathfrak{sl}_2)$, $U = V^{-11/3}(\mathfrak{sl}_2)$ and $L = L(-\frac{22}{5}, 0)$. Let C_N be the relative BRST complex of $A \otimes B \otimes U \otimes$(ghosts) at conformal weight N, H^0_N its cohomology at ghost number zero, $F_r H^0_N$ the classes with a representative of R-degree $\le r$, and $F_r L_N$ the span of Virasoro words of length $\le r$ in L_N. Fix N and r. The proof is the chain

$$
\begin{aligned}
\dim F_r L_N &\le \dim\bigl(\text{image of } F_r V(-\tfrac{22}{5}, 0)_N \text{ in } H^0_N\bigr) && \text{(a) Virasoro image, Section 28.5}\\
&\le \dim F_r H^0_N && \text{(b) the image is filtered, Theorem 28.36}\\
&\le \textstyle\sum_{s\le r} \dim H^0(Q^-)_{s,N} && \text{(c) harmonic bound, Section 28.6}\\
&= \textstyle\sum_{s\le r} \dim\bigl(\mathrm{gr}_s A \otimes B\bigr)^{\mathfrak{sl}_2[t]}_N && \text{(d) Koszul step, Section 28.9}\\
&\le \textstyle\sum_{s\le r} G_s(N) && \text{(e) invariant-symbol bound, Sections 28.9–28.10}\\
&= \dim F_r L_N && \text{(f) Lee–Yang PBW character, Theorem 28.54.}
\end{aligned}
$$

Here $G_s(N)$ is the number of partitions of N into s parts, each ≥ 2, with consecutive parts differing by at least 2. Since the two ends agree, every inequality is an equality. That forces the Virasoro image to be a *filtered isomorphism* onto H^0_N (Section 28.7); by Beem–Garner, H^0 carries a nondegenerate flag with sign-alternating layers (Section 28.6), and the isomorphism carries this to the length flag of L. The hypothesis GU(A) is the only hypothesis. Its main use is to make the modified Hermitian form on the complex positive definite, which is what (c) and the sign statement need; it is also used to define the R-grading of the complex (Definition 28.31), so every concrete statement about that grading carries it.

The ledger. "Proved" means proved in Lean with the three standard axioms and no hypothesis beyond those displayed.

The findings of this chapter, in brief.

1. **The headline is a conditional theorem with exactly one hypothesis,** and that hypothesis is the intended one: graded unitarity of the concrete simple affine VOA $L_{-4/3}(\mathfrak{sl}_2)$ with its normalized canonical form, its compact conjugation and its corrected flag, all three *constructed*, none of them a free parameter (Theorem 28.8). The conclusion is also pinned: the Lee–Yang VOA, its canonical form, the partition-basis real structure and the length flag. `#print axioms` is the standard three (re-checked).

2. **No coset identification is used.** The library constructs the coset VOA and its central charge, but the proof never identifies it with Lee–Yang. Instead it maps the universal Virasoro VOA into the cohomology through the coset stress tensor, and the dimension count does the rest (Section 28.5).

3. **Proved along the way, without hypotheses:** the Lee–Yang vacuum character (Rocha-Caridi form and Rogers–Ramanujan form, Theorem 28.53); unitarity of $L_1(\mathfrak{sl}_2)$ (Theorem 28.29); $Q^2 = 0$ exactly at total level -4, given the structural hypotheses displayed there (Theorem 28.11); the fermionic jet identity $\sum_r q^r \sum_k \left[\begin{smallmatrix} 2r \\ k \end{smallmatrix}\right]_q /(q)_r = ((q^3;q^3)_\infty/(q;q)_\infty)^3$ (Theorem 28.48).

4. **A name clash.** Two different theorems are called `leeYang_gradedUnitary_of_affine`. The one in namespace `VOA.LeeYangTransferAssembly` is a superseded conditional assembly with eight further named inputs, among them the open coset identification; it is not the headline (Warning 28.3).

5. **A reduction ladder.** About fifty theorems named `leeYang_gradedUnitary_of_affine_*` record the successive stages of the proof, each discharging inputs of the previous one. They are described collectively in Section 28.3.1; a few rest on hypotheses that are probably unsatisfiable, and are dead ends (Warning 28.3.1).

6. **One direction only.** The library proves the implication from $L_{-4/3}(\mathfrak{sl}_2)$ to Lee–Yang; this edition states and claims no converse implication.

7. **Stale docstrings.** About twenty `Prop`-valued definitions on the proof path still carry the docstring "OPEN" although they are proved (Section 28.14). No statement-level defect was found.

Notation used in this chapter.

symbol	meaning
e, f, h; colours 0, 1, 2	the Chevalley basis of $\mathfrak{sl}_2$; in Lean the colours `0, 1, 2` of `Fin 3` are e, f, h. The normalized form is $\kappa(e,f) = 1$, $\kappa(h,h) = 2$ (Lean `kappa`); `fabc a b c` are the structure constants $[x_a, x_b] = \sum_c f_{ab}{}^c x_c$.
J^a_n, $a_{(n)}$	the mode n of the current a; for a weight-one state a, $a_{(n)} = J^a_n$. In Lean `mode (V.Y u) n` is $u_{(n)}$ (Chapter 1).
k; A, B, U	the level; $A = L_{-4/3}(\mathfrak{sl}_2)$ (Lean `AVOA`), $B = L_1(\mathfrak{sl}_2)$ (`BVOA`), $U = V^{-11/3}(\mathfrak{sl}_2)$ (`UVOA`).
L, c	the Lee–Yang VOA $L(-\frac{22}{5}, 0)$, $c = c_{2,5} = -22/5$ (Lean `leeYangC`).
b^a, c^a; gh	the three ghost pairs (antighost b, weight 1, ghost number -1; ghost c, weight 0, ghost number $+1$); the ghost number.
$\mathbf{Q}$, Q	the BRST differential (Lean `semiInfiniteQ`); in Section 28.6 the bold $\mathbf{Q}^- = Q^- + S^-$ and $\mathbf{Q}^+ = Q^+ + S^+$ are Beem–Garner's pair of differentials and their homogeneous pieces.
R; $2R$	the R-filtration degree; Lean indexes it by $2R \in \mathbb{Z}$ to allow half-integers.
GU(X)	graded unitarity of X for its stated form, conjugation and flag (Definition 19.11).
F_r; gr_r	the step r of a filtration; the associated graded piece F_r/F_{r-1}.
$\mathfrak{sl}_2[t]$	the positive current algebra spanned by J^a_n, $n \geq 0$.
$\mathbb{C}[u_j, v_j]$; X, Y, Z, J	the jet ring of two formal series $u(s) = \sum_j u_j s^j$, $v(s) = \sum_j v_j s^j$; $X = u^2$, $Y = uv$, $Z = v^2$, $J = u'v - uv'$ (as series in s).
A_r	the span of products of r coefficients of X, Y, Z, J (Lean `jetImage r`).
$(q)_n$, $(a;q)_\infty$	$\prod_{i=1}^n (1-q^i)$; $\prod_{i\geq 0}(1-aq^i)$. $\begin{bmatrix} n \\ k \end{bmatrix}_q$ the Gaussian binomial.
$p(N)$; $G_r(N)$; $\mathrm{rc}(N)$	partitions of N; partitions of N into r parts ≥ 2 with gaps ≥ 2 (Lean `gapTwoCoefficient N r`); $\sum_k (-1)^k p(N - k(5k+3)/2)$ (Lean `rc N`).

28.1 The mathematics in outline

28.1.1 Graded unitarity, recalled

Let V be a VOA with an invariant bilinear form B, an anti-linear conjugation ρ commuting with all vertex operators, and a *graded flag* F: for each conformal weight N an increasing exhaustive sequence of subspaces $0 = F_{-1}V_N \subseteq F_0V_N \subseteq F_1V_N \subseteq \cdots$, with $F_0V_0 = \mathbb{C}\mathbf{1}$ and $F_0V_N = 0$ for $N > 0$. Put $h(x,y) = B(\rho x, y)$, a sesquilinear form. The *layer* $\mathcal{L}_pV_N$ is the B-orthogonal complement of $F_{p-1}V_N$ inside F_pV_N. V is *graded unitary* (Definition 19.11) when, at every weight, (iv) B is nondegenerate on every F_pV_N, and (vi) $(-1)^p h$ is positive definite on every layer $\mathcal{L}_pV_N$. For the Virasoro VOA $L(c,0)$ the flag is pinned: F_p is spanned by words $L_{-n_1}\cdots L_{-n_q}\mathbf{1}$ with $q \leq p$ (Definition 19.19).

Example 28.2 (Lee–Yang at low weight)**.** At $c = -22/5$ the weights $0, \ldots, 12$ of L have dimensions $1, 0, 1, 1, 1, 1, 2, 2, 3, 3, 4, 4, 6$: these are the numbers of partitions of N into parts ≥ 2 with consecutive parts differing by at least 2 (for $N = 12$: $12, 10{+}2, 9{+}3, 8{+}4, 7{+}5, 6{+}4{+}2$). At weight 2 the only state is $L_{-2}\mathbf{1}$, of length one, with $h(L_{-2}\mathbf{1}, L_{-2}\mathbf{1}) = c/2 = -11/5 < 0$: clause (vi) asks for $(-1)^1 h > 0$, which holds. At weight 4 the universal module has the two words $L_{-4}\mathbf{1}$, $L_{-2}^2\mathbf{1}$, but L_4 is one-dimensional: the Lee–Yang singular vector $\left(L_{-2}^2 - \frac{3}{5}L_{-4}\right)\mathbf{1}$ vanishes in L (Theorem 19.35). So $F_1L_4 = F_2L_4 = L_4$, the layer at $p = 2$ is zero, and the only condition is $h(L_{-4}\mathbf{1}, L_{-4}\mathbf{1}) = \frac{4^3-4}{12}c = 5c = -22 < 0$, again the right sign. At weight 6, $F_1L_6 = \mathbb{C}L_{-6}\mathbf{1}$ and $F_2L_6 = L_6$ is two-dimensional; the length-two layer is the first place where the sign is a genuine constraint. Chapter 19 proves the length ≤ 2 part of graded unitarity for every boundary model; the full statement for Lee–Yang is what this chapter reduces to GU(A).

28.1.2 The coset

For $k \notin \{-2,-3\}$ the diagonal currents $J^a \otimes 1 + 1 \otimes J^a$ generate an affine algebra of level $k+1$ inside $L_k(\mathfrak{sl}_2) \otimes L_1(\mathfrak{sl}_2)$, and the difference of Sugawara vectors $\omega_{\text{coset}} = \omega_k \otimes 1 + 1 \otimes \omega_1 - \omega^{\text{diag}}_{k+1}$ commutes with the diagonal currents. Its central charge is

$$c = \frac{3k}{k+2} + 1 - \frac{3(k+1)}{k+3} = 1 - \frac{6}{(k+2)(k+3)}.$$

At $k = -4/3$: $\frac{3k}{k+2} = -6$, the diagonal level is $-1/3$ with Sugawara charge $\frac{3(-1/3)}{5/3} = -\frac{3}{5}$, and $c = -6+1+\frac{3}{5} = -\frac{22}{5}$. This is the Goddard–Kent–Olive (GKO) construction, continued to a negative level. The *coset VOA* is the commutant: all states killed by the non-negative diagonal current modes. Arakawa, Creutzig and Linshaw proved that this commutant is the simple Lee–Yang VOA. The library does not use that theorem.

28.1.3 Relative semi-infinite cohomology

The commutant can be computed as a BRST cohomology. Take three pairs of fermionic ghosts b^a, c^a in the adjoint of $\mathfrak{sl}_2$; they carry an affine $\mathfrak{sl}_2$ action J^a_{gh} at level $2h^\vee = 4$. Take a matter VOA M with an affine $\mathfrak{sl}_2$ action at level k_M, and the BRST current

$$j_{\text{BRST}} = \sum_a J^a_M\, c^a + \frac{1}{2}\sum_a :c^a J^a_{\text{gh}}:, \qquad \mathbf{Q} = \oint j_{\text{BRST}}.$$

Then $\mathbf{Q}^2 = 0$ if and only if $k_M + 4 = 0$, i.e. $k_M = -2h^\vee$ (Theorem 28.11). The *relative* complex is the subspace killed by the zero modes of the total currents $J^a_M + J^a_{\text{gh}}$ and of the antighosts b^a. For the matter $M = A \otimes B \otimes U$ with $A = L_{-4/3}$, $B = L_1$ and the auxiliary $U = V^{-11/3}$, the diagonal level is $-\frac{4}{3} + 1 - \frac{11}{3} = -4$. Physically the auxiliary factor "absorbs" the diagonal $\mathfrak{sl}_2$: the relative cohomology of $(A \otimes B) \otimes V^{-4-(k+1)}$ at ghost number zero is, for good matter, the commutant of the diagonal currents in $A \otimes B$. Here $-4-(-1/3) = -11/3$.

28.1.4 Beem–Garner: cohomology inherits graded unitarity

Beem and Garner (arXiv:2509.10364) prove that if the matter is graded unitary and the BRST action is *good* (the differential has no component of R-degree zero), then the relative cohomology is graded unitary for the induced filtration. The mechanism is Hodge theory: there is a positive definite *modified* Hermitian form on the complex, built from the graded-unitarity forms of the factors with the sign i^{2R}; the differential splits as $\mathbf{Q}^- = Q^- + S^-$ with Q^- raising R by $\frac{1}{2}$ and S^- lowering it; a second differential $\mathbf{Q}^+$ is related to the adjoint of $\mathbf{Q}^-$ by an Sp(2) ("Kähler") identity; and every cohomology class has a unique harmonic representative, which is *homogeneous* in R. Homogeneity is what makes the induced flag on cohomology split into layers, and positivity of the modified form on harmonic vectors of R-degree p is exactly $(-1)^p h > 0$. Section 28.6 formalizes this at one conformal weight, and Section 28.8 constructs all of it on the actual complex.

28.1.5 The squeeze

Graded unitarity of the cohomology does not yet say anything about Lee–Yang. The last step compares dimensions. The harmonic vectors of R-degree s inject into the cohomology $H(Q^-)$ of the *leading* differential (Theorem 28.21), and a Koszul argument identifies that leading cohomology with the $\mathfrak{sl}_2[t]$-invariants in $\operatorname{gr}_s A \otimes B$ (Section 28.9). The associated graded $\operatorname{gr} A$ is modelled by a ring of jet polynomials (Section 28.10), and the invariants are counted from above by $G_s(N)$. From below, the universal Virasoro algebra maps into the cohomology through the coset stress tensor, and

its image surjects onto L filtration step by filtration step. The Lee–Yang character (Section 28.11) says that $\dim F_r L_N = \sum_{s \le r} G_s(N)$. The two bounds meet.

Physical meaning

Four-dimensional origin. The Lee–Yang VOA is the chiral algebra, in the sense of Beem, Lemos, Liendo, Peelaers, Rastelli and van Rees, of the simplest Argyres–Douglas theory (A_1, A_2); $L_{-4/3}(\mathfrak{sl}_2)$ is the chiral algebra of the $(A_1, A_3) = (A_1, D_3)$ Argyres–Douglas theory, whose $SU(2)$ flavour symmetry has two-dimensional level $k_{2d} = -\frac{4}{3}$. ABLR showed that unitarity of the four-dimensional theory forces graded unitarity of its chiral algebra, with the filtration coming from the $SU(2)_R$ charge. So both GU(A) and GU(L) are predicted by physics, and neither is proved. The BRST construction with ghosts at level +4 is the chiral-algebra image of *gauging* an $SU(2)$ flavour symmetry, and the condition $k_M = -4 = -2h^\vee$ is the vanishing of the gauge coupling's beta function; Beem–Garner is the chiral-algebra shadow of the fact that gauging preserves unitarity. The factors B and U in our complex are mathematical devices, not chiral algebras of known four-dimensional theories, and this physical picture is a heuristic only.

28.2 The two endpoint algebras and the hypothesis

The headline theorem is about concrete objects. This section defines them: the three affine factors, the corrected filtration of A, the compact conjugation, and the Lee–Yang side.

Definition 28.3 (The three affine factors). $A = L_{-4/3}(\mathfrak{sl}_2)$ is the simple quotient of $V^{-4/3}(\mathfrak{sl}_2)$ by its maximal graded ideal; $B = L_1(\mathfrak{sl}_2)$ likewise at level 1; $U = V^{-11/3}(\mathfrak{sl}_2)$ is the *universal* affine VOA at level $-11/3$. The level $-4/3$ is the first member k_1 of the boundary family $k_m = -2 + \frac{2}{2m+1}$.

File `VOA/Examples/Sl2CosetConcreteFactors.lean`.

```

```

From the mathematics to the Lean statement

`AffineSl2BoundarySingularFamily.level 1` is $-2 + 2/(2 \cdot 1 + 1) = -4/3$, and `aLevel_eq` records it. `AffineSl2GeneralRigidity.simple k hk` is the quotient of the universal affine VOA by its maximal graded ideal `QuotVOA.maxGradedIdeal`, i.e. $L_k(\mathfrak{sl}_2)$ of Definition 10.2; `universal k hk` is $V^k(\mathfrak{sl}_2)$ (Definition 9.14). The hypotheses `hk : k + 2 ≠ 0` exclude the critical level, where the Sugawara construction fails; the three proofs `aNoncritical`,

`bNoncritical`, `uNoncritical` supply them. An `abbrev` is a definition that Lean unfolds freely (Chapter 1, Section 1.2.3). Exactly the definition.

Why U is universal. The auxiliary factor is never quotiented: its role is to supply the level $-11/3$ and a graded-unitary structure, which is proved for the universal algebra (Theorem 28.30). Whether $V^{-11/3}$ is simple plays no role.

Physical meaning

A is the chiral algebra of the (A_1, D_3) Argyres–Douglas theory, B is the $SU(2)$ level-one WZW model (one compact boson at the self-dual radius), and U is an auxiliary current algebra whose level is fixed by the anomaly cancellation $-\frac{4}{3}+1+k_U = -4$; it has no four-dimensional interpretation that the library uses.

What the machine verified

Definitions; `aLevel_eq` and the three non-criticality facts are proved. Axioms standard (rechecked for the objects built on them, Section 28.13).

Definition 28.4 (The corrected filtration). A *corrected word* is a finite list of letters (g, m), where g is a current e, f, h or the Sugawara vector ω, and $m \in \mathbb{N}$ is a mode depth. The letter (g, m) acts by $g_{(-m-1)}$: for a current this is J^g_{-m-1}, for ω it is L_{-m-2}. The *corrected filtration* F_pV^k is the span of the states $g^1_{(-m_1-1)} \cdots g^\ell_{(-m_\ell-1)}\mathbf{1}$ with $\ell \le p$ letters, intersected with each conformal weight space. On a quotient V^k/I by a graded ideal the flag is the image. The flag on A is the image of the corrected flag of $V^{-4/3}$.

From the mathematics to the Lean statement

Decoding. `WakModule k` is the carrier of $V^k(\mathfrak{sl}_2)$ and `affineSl2VOA_closed k hk` its VOA structure (Chapter 9). `(affineSl2VOA_closed k hk).smul u n v` is the n-th product $u_{(n)}v$, so `correctedWordState k hk ((g, m) :: rest)` is $g_{(-m-1)}$ applied to the word `rest`. For a current a (weight one) $a_{(-m-1)} = J^a_{-m-1}$; for ω (weight two) $\omega_{(-m-1)} = L_{-m-2}$. `currentState k a` is $J^a_{-1}\mathbf{1}$. `correctedAffineRPiece k hk p` is the span of all words with `w.length ≤ p` letters, of any weight; the graded flag `correctedAffineRFlag` (not quoted) intersects it with each conformal weight space, and `.quotient I hI hgr` takes images in the quotient VOA by a graded ideal I. `affineFlag` applies this to the maximal graded ideal, so it is a flag on A.
The cost of a letter is one, whatever its mode. A derivative $J^a_{-2}\mathbf{1} = (\partial J^a)$ has degree one, and so does $L_{-2}\mathbf{1} = \omega$, although in terms of currents ω is quadratic. This is the "correction" relative to the ordinary current-PBW filtration (where ω would have degree two). It is what ABLR's R-filtration predicts: the stress tensor sits in the $SU(2)_R$ current multiplet, of R-charge one. The library proves that this flag is a *good* filtration (modes add degrees, `correctedAffineRQuotientFlag_modeCompatible`); it does not prove that it coincides with any intrinsically characterized filtration of A, and it does not need to.
How it could fail to be the intended object. The flag is an image under the quotient map; no basis of A is assumed. Had the flag been allowed to vary, the hypothesis "GU(A) for some flag" would be nearly empty (Warning 19.4.1); here it is pinned.

Physical meaning

F_p counts the number of $SU(2)_R$-charged "letters" (flavour moment maps J^a and the stress tensor T), each of R-charge one, needed to build a Schur operator; derivatives cost nothing because they do not change R.

What the machine verified

Definitions with all `GradedFlag` fields proved (Chapter 9, Section 9.13); axioms standard. Mode compatibility of the quotient flag is proved.

Definition 28.5 (Compact conjugation)**.** For real $k \neq -2$, the *compact conjugation* of $V^k(\mathfrak{sl}_2)$ is the unique anti-linear map ρ that fixes $\mathbf{1}$, commutes with vertex operators in the sense $\rho(u_{(n)}v) = \rho(u)_{(n)}\rho(v)$, and acts on the currents by $\rho(e) = -f$, $\rho(f) = -e$, $\rho(h) = -h$; that is, $J^a \mapsto -J^{a^*}$ with a^* the "adjoint colour". It is an involution, and it descends to every quotient by an ideal that it preserves; on A we use the descended map.

theorem affineRealStructure_current (a : Fin 3) :
    affineRealStructure.rho (simpleCurrent ALevel aNoncritical a) =
      -simpleCurrent ALevel aNoncritical (adjointColour a) := by
```

From the mathematics to the Lean statement

`adjointColour` swaps the colours $0 \leftrightarrow 1$ ($e \leftrightarrow f$) and fixes 2 (h) (`AffineSl2VermaDual.lean`). `IsCompactRealStructure R` says that the real structure R (Definition 19.9) acts on the current states as $J^a \mapsto -J^{a^*}$ and that its parity scalars are nonzero. `compactRealStructure` is *constructed* (the `where` introduces its fields, whose proofs we omit) for real k (`hreal : starRingEnd ℂ k = k`, a section variable) and has parity $\equiv 1$, i.e. $\rho^2 = 1$. `affineRealStructure` is its descent to A: the file proves that ρ preserves the maximal ideal (the preimage of the maximal ideal is a proper ideal, so it lies in the maximal ideal) and builds the quotient map; `affineRealStructure_current` confirms that on A it still sends the current a to $-$(current a^*). The parity of `affineRealStructure` is `fun _ ⇒ 1`.

Why this conjugation. $x \mapsto -x^*$, with $e^* = f$, $h^* = h$, is the Cartan involution whose fixed points form the compact real form $\mathfrak{su}(2)$. With the invariance $a_n^\dagger = -a_{-n}$ of a weight-one primary under the VOA invariant form, it gives the Hilbert-space adjoint $(J_n^a)^\dagger = J_{-n}^{a^*}$ of a unitary current algebra. Any other choice (for instance the split real form) would make the hypothesis a different, and physically unmotivated, statement.

Physical meaning

ρ is the CPT-like anti-unitary map of the $SU(2)$ flavour current algebra: it sends a flavour current to its Hermitian conjugate. The compact real form is the one under which a unitary four-dimensional theory's flavour symmetry acts unitarily.

What the machine verified

Constructed, all fields proved; axioms standard. Unconditional (given real k).

Example 28.6 (Weight one of A)**.** The weight-one space of A is spanned by the three currents, all of corrected degree one, so $F_0A_1 = 0$, $F_1A_1 = A_1$, and the only layer is $p = 1$. With the normalized invariant form, $B(J^a_{-1}\mathbf{1}, J^b_{-1}\mathbf{1}) = -k\,\kappa(a,b)$ (the sign from $a_1^\dagger = -a_{-1}$ for weight-one primaries), so

$$h(e,e) = B(\rho e, e) = B(-f,e) = k\,\kappa(f,e) = k = -\frac{4}{3}, \qquad h(h,h) = B(-h,h) = 2k = -\frac{8}{3}.$$

Clause (vi) at $p = 1$ asks $-h > 0$: it holds precisely because $k < 0$. At level $k > 0$ the sign would be wrong, which is why graded unitarity is a negative-level phenomenon and ordinary unitarity a positive-level one.

Definition 28.7 (The Lee–Yang datum)**.** On the Lee–Yang side the form is the canonical normalized form `Bsimp` of $L(c,0)$, the flag is the length flag, and the real structure is the partition-basis conjugation of Theorem 19.23, at $c = c_{2,5} = 1 - 12\lambda^2$ with the real background charge $\lambda = \lambda_2$ of Theorem 19.24.

File `VOA/Examples/LeeYangTransferAssemblyAffine.lean`.

```
abbrev affineForm : InvariantForm AVOA := simpleForm ALevel aNoncritical

  virasoroSimpleRealStructure
```

```
    ((VirGradedUnitarity.boundaryBackgroundCharge_spec 2).trans
      VirGradedUnitarity.boundaryCharge_two_eq_leeYangC)
    (VirGradedUnitarity.boundaryBackgroundCharge_fixed 2)
```

From the mathematics to the Lean statement

`simpleForm k hk` is the canonical invariant bilinear form of $L_k(\mathfrak{sl}_2)$ with $(\mathbf{1}|\mathbf{1}) = 1$ (Chapter 10); `affineForm` is it at $k = -4/3$. `leeYangRealStructure` is `virasoroSimpleRealStructure` (Theorem 19.23) applied to the proof that $1 - 12\lambda_2^2$ equals the boundary charge of index two, which equals `leeYangC`$= -22/5$ (`boundaryCharge_two_eq_leeYangC`), and to the reality of λ_2. So it fixes every Virasoro word and conjugates coefficients. `VirGradedUnitary c R` is `GradedUnitary (Bsimp c) R (virGradedFlag c)` (Definition 19.20): form and flag are pinned, only R is a parameter, and here it is this specific R.

Physical meaning

The Lee–Yang stress tensor is a Hermitian field with real OPE coefficients, so conjugating coefficients in the basis of Virasoro words is its anti-unitary conjugation. The statement GU(L) with these data is ABLR's prediction for the (A_1, A_2) Argyres–Douglas theory, whose Schur operators are the Virasoro descendants of the identity.

What the machine verified

Definitions; axioms standard. These are exactly the data of Kaufmann's and ABLR's statement for $M(2,5)$.

28.3 The headline theorem

Theorem 28.8 (Affine graded unitarity implies Lee–Yang graded unitarity)**.** *Suppose that $A = L_{-4/3}(\mathfrak{sl}_2)$, with its normalized canonical invariant form, the descended compact conjugation (Definition 28.5) and the corrected flag (Definition 28.4), is graded unitary. Then the Lee–Yang VOA $L(-\frac{22}{5}, 0)$, with its normalized canonical form, its partition-basis conjugation and its length flag (Definition 28.7), is graded unitary.*

File `VOA/Examples/AdamovicDescCyclic.lean`.

   ↪ 2)
```

From the mathematics to the Lean statement

Every symbol. `GradedUnitary B R F` is Definition 19.11: for every integer weight n, clause (iv) (nondegeneracy of B on every flag step) and clause (vi) (positivity of $(-1)^p h$ on every layer). `affineForm`, `affineRealStructure`, `affineFlag` are the three data of Definitions 28.7, 28.5, 28.4 on `AVOA`$= A$. `VirGradedUnitary LeeYang.leeYangC leeYangRealStructure` unfolds to `GradedUnitary (Bsimp (-22/5)) leeYangRealStructure (virGradedFlag (-22/5))` (Definition 19.20). The namespace `VirGradedUnitarity` is where `VirGradedUnitary` lives; `LeeYang.leeYangC` is the number $-22/5$.

The hypotheses. There is exactly one, `hA`. It is the intended statement: graded unitarity of the *simple* quotient A (not of the universal $V^{-4/3}$, which has a singular vector at weight 3,

Chapter 9), for the compact conjugation and the corrected (current-and-stress) flag. No other datum is free: the form, conjugation and flag are the constructed objects of Section 28.2.

Same, stronger or weaker. The same as the paper statement of the implication, with one difference in the *proof*: the paper proof cites an external coset identification and an external invariant-symbol theorem; the Lean theorem uses neither as a hypothesis.

The one-line proof term. The proof is a composition: the rung `leeYang_gradedUnitary_of_affine_wordSymbols_jet` (Section 28.3.1), which still takes the word-symbol descent `desc` as an input, applied to the proof `Desc.wordSymbolDescends` of that input (Theorem 28.45).

How it could have been vacuous, and why it is not. (1) If `hA` were false the theorem would be true and empty. Nobody knows whether `hA` is true; it is the four-dimensional prediction, and the project's exact-arithmetic Gram computations (outside the library) find it satisfied through conformal weight 7 (numerical evidence, not a proof). Example 28.6 checks weight one by hand. (2) The conclusion is not trivially true: it fails if the form or real structure is changed (for example, the sign twist of Warning 28.6), and only its length-≤ 2 part is proved independently (Chapter 19). (3) The flag of the hypothesis is pinned, so Warning 19.4.1 does not apply.

Proof on paper. Fix a conformal weight N. The relative BRST complex C_N of $A \otimes B \otimes U \otimes$(ghosts) is a finite-dimensional space (Section 28.4). The hypothesis, with the proved unitarity of B and graded unitarity of U, makes the Beem–Garner modified Hermitian form on C_N positive definite, and the BRST differential is good for the R-grading (Section 28.8). The finite-dimensional Hodge theory of Section 28.6 then gives: every class in H^0_N has a unique harmonic representative, homogeneous in R; on the harmonic model, the induced flag is nondegenerate for the invariant form and its layers have the sign $(-1)^p$; and $\dim F_r H^0_N \leq \sum_{s \leq r} \dim H^0(Q^-)_{s,N}$. The Koszul step (Section 28.9) identifies $H^0(Q^-)_{s,N}$ with the $\mathfrak{sl}_2[t]$-invariants of $\mathrm{gr}_s A \otimes B$ in weight N, and the jet model (Section 28.10) bounds their dimension by $G_s(N)$. On the other side, the universal Virasoro VOA maps into H^0 through the coset stress tensor (Section 28.5); its kernel is a proper ideal, hence lies in the maximal ideal, so the map factors through a surjection from (a subspace of) the image onto L which respects the length filtration. Lee–Yang's PBW character (Section 28.11) gives $\dim F_r L_N = \sum_{s \leq r} G_s(N)$. The chain of Remark 28.1 closes, forcing the image of $F_r V(c,0)_N$ to be all of $F_r H^0_N$ and the map to L to be injective on it. The invariant form and the conjugation on harmonic representatives agree with `Bsimp` and the Lee–Yang conjugation (Theorem 28.35). Transporting the nondegenerate sign-alternating flag of H^0_N to L_N gives clauses (iv) and (vi) at weight N (Theorem 28.27). □

Physical meaning

Read physically: if the $SU(2)$ flavour current algebra of the (A_1, D_3) Argyres–Douglas theory obeys the positivity constraints that four-dimensional unitarity predicts, then so does the Virasoro algebra of the (A_1, A_2) theory. The bridge is a chiral-algebra version of a four-dimensional operation (gauging an $SU(2)$ with a level-one current algebra and an auxiliary sector), not a known four-dimensional duality between the two theories; the implication should be read as a statement about chiral algebras, with the four-dimensional story as motivation.

What the machine verified

Proved; **conditional on `hA`**, which is open. `#print axioms VOA.AdamovicSymbol.leeYang_gradedUnitary_of_affine`: `[propext, Classical.choice, Quot.sound]` (re-checked), so it is `#print axioms`-clean, conditional on `hA`; the the-

orem is also in the library's maintained axiom audit. A second, independent derivation of the same implication, through the general $(2, 2n + 3)$ machinery, is `VOA.TwoSeries.leeYang_gradedUnitary_of_affine_viaTwoSeries` (Chapter 29); it has the same single hypothesis and the standard axioms (re-checked).

Name clash: two different theorems called `leeYang_gradedUnitary_of_affine`

The short name `leeYang_gradedUnitary_of_affine` denotes two different theorems. The headline is `VOA.AdamovicSymbol.leeYang_gradedUnitary_of_affine`. The other, `VOA.LeeYangTransferAssembly.leeYang_gradedUnitary_of_affine`, is the first conditional assembly of the argument, now superseded:

  symbols : LeadingInvariantSymbolDimension kahler
  character : LeeYangPBWCharacter
```

and `VOA/Examples/LeeYangTransferAssemblySimple.lean`:

```
structure CosetIdentification where
  equiv : CosetSpace ≃ₗ[ℂ] LeeYangSpace
  hom : IsVOAHom cosetVOA (virasoroSimple leeYangC) equiv.toLinearMap
  conformal : equiv cosetVOA.conformalVector =
    (virasoroSimple leeYangC).conformalVector
```

It takes, besides `hA`, a structure `inputs : OpenInputs` with eight fields, the first of which is a VOA isomorphism between the coset VOA and Lee–Yang (`CosetIdentification`); that identification is *not* constructed anywhere in the library. The superseded theorem is a correct conditional statement, but it must not be cited as the result. Always use full names. (A documentation defect, severity S4 on the scale of Section 28.14.)

28.3.1 The reduction ladder, described collectively

The proof was built top-down: a first theorem with many named inputs, then a sequence of theorems each discharging some inputs and sometimes introducing sharper ones. Every stage was kept as a theorem. The library therefore contains about fifty theorems named `leeYang_gradedUnitary_of_affine_*`, all with the conclusion `VirGradedUnitary leeYangC leeYangRealStructure` and the first hypothesis `hA`, in the files of this chapter, plus two in the files of Chapter 29 (`..._viaTwoSeries`, `..._viaInvariants`). They are not separate results: each is a step toward the headline. We list the ones that mark the main stages, in the order in which the headline depends on them (each rung is proved from the next one down); the reader needs this table only to decode the library, not to understand the mathematics.

rung (namespace, suffix)	inputs besides `hA`
`AdamovicSymbol`, (none)	none: the headline
`AdamovicSymbol`, `_wordSymbols_jet`	`desc : ∀ r, WordSymbolDescends (r + 2)`
`AdamovicSymbol`, `_jetFermionic`	`desc`, `hq : JetFermionicLower`
`AdamovicSymbol`, `_wordSymbols_final`	`desc`, `chi : JetProductBound`
`AdamovicSymbol`, `_wordSymbols_gram`, `_wordSymbols_rc`, `_wordSymbols_two`	`desc`, `chi`, and a Lee–Yang character input (rank bound, Rocha-Caridi bound, or Rogers–Ramanujan bound)
`KoszulResidual`, `_leadingSymbol`	`sym : ∀ r, JetLeadingSymbol (r + 1)`, `chi`, `lower`
`KoszulResidual`, `_strict`	`strict : ∀ r, GrJetStrict (r + 1)`, `lower`
`KoszulResidual`, `_symbolResidual`; `KoszulConcrete`, `_koszulResidual`	`strict`, the symbol maps or the full Koszul residual, `lower`
`SymbolModel`, `_jetStrict`, `_grLeadKoszul`, `_grSymbols`, `_grStrict`	strictness or cyclic vectors, the leading Koszul data, `lower`
`LevelOneHeis`, `_symbolModels`; `CyclicEval`, `_heisenberg*`, `_symbolCyclic`	symbol models, level-one facts, `lower`
`ConcreteHodge`, `_cyclicEvaluation`, `_levelOne_rr_bound`, `_levelOne_rr`	an invariant-symbol bound or equality, `lower`
`ConcreteHodge`, `_levelOne`	`symbols`, `character`
`ConcreteHodge`, `_harmonic`, `_reps`, `_bgConj`, `_ghostConj`	`hB` (unitarity of L_1), `symbols`, `character`, and metric or ghost-conjugation identities
`ConcreteHodge`, `_bgRemainderI`, `_bgPackageI`, `_sp2*`, `_concrete`, ...	further Beem–Garner package data
`LeeYangShortcut`, `_of_affine'`, `_of_imageMetric`	a `ShortcutInputs` structure (no coset identification)
`LeeYangTransferAssembly`, (none)	`OpenInputs`, including the coset identification (Warning 28.3)

Each input name in the table is a `Prop` or a structure defined in the files of this chapter; the ones that the headline ultimately needs are presented, and proved, in the sections that follow.

Probably vacuous rungs

Some intermediate rungs take inputs that are most likely unsatisfiable on the actual complex, so they are true but empty, and the headline does not use them.

- `VOA.ConcreteHodge.leeYang_gradedUnitary_of_affine_kahler` (`BRSTGoodnessCreation.lean`) and `..._ghost` (`ConcreteGoodGenerators.lean`) take `hK : InterpretedKahlerAnticomm (ghostRGrading w) ...`, a Kähler identity for a ghost form that is the same on all three colours. Invariance under $\mathfrak{sl}_2$ needs the colour h to carry half the norm of e and f (because $\kappa(h,h) = 2\kappa(e,f)$), so `hK` is most likely false. This is a hand argument; it is not machine-checked.

- `..._bgRemainder` (`BGPackageBFactor.lean`) and `..._bgPackage` take a ghost-conjugation datum `BGGhostRemainder` whose skewness constant $-(-1)^{\mathrm{gh}}$, together with a scalar ρ^2, admits solutions only at a value $\kappa = -i$ of a normalization constant that must be real; numerical evidence (project computations outside the library) only. The corrected datum (`BGGhostRemainderI`, with $\rho^2 = 1$ and $B(Eu, v) = i(-1)^{\mathrm{gh}}B(u, Ev)$) is the one used, and it is proved (Theorem 28.34).

As statements these are severity-S1 defects (wrong or vacuous; scale of Section 28.14); they are harmless for the headline, which does not use them.

28.4 The relative semi-infinite complex

Definition 28.9 (Affine $\hat{\mathfrak{sl}}_2$ action on a super vertex algebra)**.** Let V be a super vertex algebra. An *affine* $\hat{\mathfrak{sl}}_2$ *action of level* k on V is a triple of even states J^a of weight one ($a \in \{e, f, h\}$) whose modes satisfy

$$[J^a_m, J^b_n] = \sum_c f_{ab}{}^c J^c_{m+n} + m\,k\,\kappa(a,b)\,\delta_{m+n,0} \qquad (m, n \in \mathbb{Z}).$$

A *translated* action carries in addition a translation operator T with $T\mathbf{1} = 0$ and $[T, Y(u,z)] = \partial_z Y(u,z)$.

File `VOA/Examples/Sl2SemiInfiniteAction.lean`.

```
structure AffineSl2Action (V : SuperVertexAlgebra M) (k : ℂ) where
  current : Fin 3 → M
  current_weight : ∀ a, current a ∈ V.grading 1
  current_even : ∀ a, current a ∈ V.parity 0
  current_comm : ∀ (a b : Fin 3) (m n : ℤ),
    mode (V.Y (current a)) m * mode (V.Y (current b)) n
      - mode (V.Y (current b)) n * mode (V.Y (current a)) m
      = (∑ c, fabc a b c • mode (V.Y (current c)) (m + n))
        + if m + n = 0 then ((m : ℂ) * k * kappa a b) • LinearMap.id else 0
```

Files `VOA/Examples/Sl2SemiInfiniteTranslation.lean`, `Sl2SemiInfiniteDifferential.lean`.

```
structure TranslationCovariant (V : SuperVertexAlgebra 𝒱) where
  T : End ℂ 𝒱
  vacuum_zero : T V.vacuum = 0
  covariant : ∀ u, Reconstruction.DCovariant T (V.Y u)

structure TranslatedAffineSl2Action (V : SuperVertexAlgebra M) (k : ℂ)
    extends AffineSl2Action V k where
  translation : TranslationCovariant V
```

From the mathematics to the Lean statement

`mode (V.Y (current a)) m` is the mode $(J^a)_{(m)}$, which for a weight-one state is J^a_m. The commutator is stated for all integer modes (not a truncated OPE); `if m + n = 0 then ... else 0` is the Kronecker delta, and `LinearMap.id` the identity operator. `V.parity 0` is the even part. `Reconstruction.DCovariant T (V.Y u)` is $[T, Y(u,z)] = \partial_z Y(u,z)$ in modes. `extends` adds the field `translation` to `AffineSl2Action`. Translation is required separately because a library `SuperVertexAlgebra` has no translation axiom (Chapter 17, Theorem 17.4). The universal affine VOA inhabits the structure at every non-critical level (`translatedAffineAction`), so it is not vacuous.

Physical meaning

A matter sector with an $SU(2)$ current algebra of level k: the data one needs in order to gauge the $SU(2)$.

What the machine verified

Definitions. Instances for the universal affine VOA, for tensor products (`tensorTranslatedAffineAction`) and for the simple quotients are constructed and used below.

Definition 28.10 (Ghosts, BRST current and BRST charge)**.** The ghost system is the tensor product of three bc systems (Definition 17.28), one per colour a; b^a has weight 1 and ghost number -1, c^a

weight 0 and ghost number +1. The ghost currents are the adjoint bilinears $J^a_{\mathrm{gh}} = \sum_{b,c} f_{ab}{}^{c}\,{:}b^c c^b{:}$. For a matter action J^a_M on V, the BRST current on $V \otimes (\text{ghosts})$ is $j = \sum_a J^a_M \otimes c^a + \mathbf{1} \otimes \frac{1}{2}\sum_a {:}c^a J^a_{\mathrm{gh}}{:}$ and the BRST charge is its residue $\mathbf{Q} = j_{(0)}$.

Files `VOA/Examples/Sl2SemiInfiniteGhosts.lean`, `Sl2SemiInfiniteCurrents.lean`, `Sl2SemiInfiniteCharge.lean`.

```
abbrev GhostPairSpace := SympFerm.FockSF ⊗[ℂ] SympFerm.FockSF

noncomputable def semiInfiniteQ (A : AffineSl2Action V k) : End ℂ (M ⊗[ℂ] Sl2GhostSpace) :=
  mode (TensorVA.tenY V sl2GhostSVA (brstState A)) 0
```

From the mathematics to the Lean statement

`SympFerm.FockSF` is the Fock space of one fermionic pair, made into the bc system `Ghost.bcGhostSVA` (Chapter 17); the one-letter words `stWordSF [((0, 0))]` and `stWordSF [((0, 1))]` are the states of the fields $b(z)$ (weight 1) and $c(z)$ (weight 0). `ghostEmbed a x` puts x in the pair of colour a and vacua elsewhere. `ghostCurrentCoefficient a b c` is the structure constant `fabc a b c`, and `ghostBilinear c b` is ${:}b^c c^b{:}$, the (-1)-product of the two ghost states (`Sl2SemiInfiniteCurrents.lean`). `mode (Y x) (-1) y` is the normal-ordered product ${:}xy{:}$. `⊗ₜ[ℂ]` is the elementary tensor. `TensorVA.tenY` is the tensor-product vertex operator with Koszul signs (Definition 5.40), and `mode (...) 0` is the zeroth product, i.e. the residue $\oint j$. No nilpotency is assumed in the definition: it is a theorem below.

Conventions. The c^a are dual to the Chevalley basis indexing the matter currents, so no inverse Killing form appears (the file's docstring). The ghost states of the three pairs anticommute by the Koszul signs of the tensor product.

Physical meaning

These are the Faddeev–Popov ghosts of an $SU(2)$ gauge field in the chiral algebra; $\mathbf{Q}$ is the BRST charge of the gauging, $\mathbf{Q} = \oint\big(c^a J^a_M + \frac{1}{2} c^a J^a_{\mathrm{gh}}\big)$, familiar from string theory, where the same construction with the Virasoro algebra gives the critical dimension.

What the machine verified

Definitions. Weight 1, odd parity and ghost number +1 of `brstState`, and the corresponding properties of `semiInfiniteQ` (weight 0, odd, ghost number +1), are proved in the same file.

Theorem 28.11 (Ghost level and nilpotency). *(1) The ghost currents form an affine $\mathfrak{sl}_2$ action of level $+4 = 2h^\vee$ on the ghost system. (2) For a translated affine action of level k on a matter super vertex algebra V with nonzero vacuum (and the parity and grading conditions needed to form the tensor product), $\mathbf{Q}^2 = 0$ if and only if $k = -4$.*

Files `VOA/Examples/Sl2SemiInfiniteGhostAffine.lean`, `Sl2SemiInfiniteAnomalyCriterion.lean`.

```
noncomputable def ghostAffineAction : AffineSl2Action sl2GhostSVA 4 :=

theorem semiInfiniteQ_sq_zero_iff (A : AffineSl2Action V k)
    (H : TranslationCovariant V) (hV : TensorVA.ParityCompatible V)
    (hg : TensorVA.TensorGradingHyp V sl2GhostSVA) (hvac : V.vacuum ≠ 0) :
    semiInfiniteQ A ∗ semiInfiniteQ A = 0 ↔ k = -4 := by
```

From the mathematics to the Lean statement

`AffineSl2Action sl2GhostSVA 4`: the ghost currents satisfy Definition 28.9 at level 4; the construction `affineActionOfProducts` derives all mode commutators from the explicit singular products. In the second statement, `A` is a bare affine action (the translation `H` is supplied separately), `hV` and `hg` are the parity compatibility and the finite-dimensionality of tensor weight spaces needed by `TensorVA.tensorSVA` (Chapter 5), and `hvac` excludes the zero algebra. `semiInfiniteQ A ∗ semiInfiniteQ A` is the composite $\mathbf{Q} \circ \mathbf{Q}$. The $\leftrightarrow$ is a genuine equivalence: at any other level $\mathbf{Q}^2 \neq 0$.

Why the hypotheses are harmless. All of them hold for the concrete matter below (`matterParityCompatible`, `matterGhostTensorGrading`, `matterVacuum_ne_zero`).

Proof on paper. $\mathbf{Q}^2 = \frac{1}{2}\{\mathbf{Q}, \mathbf{Q}\}$ is the residue of the self-OPE of j. The $c^a c^b$-terms combine the matter commutator with the ghost cubic term; their simple-pole parts cancel by the Jacobi identity of $\mathfrak{sl}_2$ (this is the role of the factor $\frac{1}{2}$), and what remains is the central term. The total current $J^a_M + J^a_{\mathrm{gh}}$ has level $k + 4$, and the anomaly is proportional to it: the library proves the exact formula $\mathbf{Q}^2 = \frac{1}{2}(k+4)(\mathbf{1} \otimes \alpha)_{(0)}$ for the ghost state $\alpha = \sum_{a,b} \kappa(a,b) :\partial c^a\, c^b:$ (`ghostAnomalyState`, `Sl2SemiInfiniteChargeProducts.lean`), in `semiInfiniteQ_square_anomaly` (`Sl2SemiInfiniteNilpotency.lean`). The ghost level 4 comes from the double contraction $\sum_{c,d} f_{ac}{}^d f_{bd}{}^c = 2h^\vee \kappa(a,b)$ with $h^\vee = 2$. The operator $(\mathbf{1} \otimes \alpha)_{(0)}$ is nonzero when the matter vacuum is nonzero (`Sl2SemiInfiniteAnomalyCriterion.lean`), which gives the converse direction. □

Physical meaning

Gauge anomaly cancellation: the BRST charge of a gauged current algebra is nilpotent exactly when the total matter level is $-2h^\vee$. In four dimensions this is the condition that the gauge coupling be exactly marginal (vanishing one-loop beta function), translated by the chiral-algebra map $k_{2d} = -k_{4d}/2$.

What the machine verified

Both proved, axioms standard (re-checked). Unconditional given the stated structural hypotheses.

Definition 28.12 (Relative states). The *relative* subspace of $V \otimes$ (ghosts) is the simultaneous kernel of the six operators $(J^a_M + J^a_{\mathrm{gh}})_0$ and b^a_0 $(a = e, f, h)$.

File `VOA/Examples/Sl2SemiInfiniteRelative.lean`.

```
noncomputable def totalCurrentZero (A : AffineSl2Action V k) (a : Fin 3) :
    End ℂ (M ⊗[ℂ] Sl2GhostSpace) :=
  mode (TensorVA.tenY V sl2GhostSVA (totalCurrentState A a)) 0

noncomputable def antighostZero (V : SuperVertexAlgebra M) (a : Fin 3) :
    End ℂ (M ⊗[ℂ] Sl2GhostSpace) :=
  mode (TensorVA.tenY V sl2GhostSVA (tensorAntighost V a)) 0

noncomputable def relativeCarrier (A : AffineSl2Action V k) :
    Submodule ℂ (M ⊗[ℂ] Sl2GhostSpace) :=
  (⨅ a : Fin 3, LinearMap.ker (totalCurrentZero A a)) ⊓
    ⨅ a : Fin 3, LinearMap.ker (antighostZero V a)
```

From the mathematics to the Lean statement

`totalCurrentState A a` is $J^a_M \otimes \mathbf{1} + \mathbf{1} \otimes J^a_{\mathrm{gh}}$ and `tensorAntighost V a` is $\mathbf{1} \otimes b^a$; `mode (...) 0` is the zero mode of a weight-one field. `⨅` is the intersection of a family of subspaces and `⊓` the intersection of two. Exactly the definition. The file proves that $\mathbf{Q}$ preserves the relative subspace (`semiInfiniteQ_mem_relativeCarrier`) and that the vacuum is relative.

Physical meaning

Relative cohomology imposes the Gauss law ($\mathfrak{sl}_2$-invariance under the total zero modes) and removes the ghost zero modes c^a_0, which would otherwise double the cohomology; it is the chiral analogue of computing gauge-invariant states.

What the machine verified

Definition; stability under $\mathbf{Q}$ proved (axioms standard).

Theorem 28.13 (The concrete Lee–Yang BRST complex). *The matter $(A \otimes B) \otimes U$ carries the diagonal affine action of level $-\frac{4}{3} + 1 - \frac{11}{3} = -4$; tensoring with the ghosts gives a BRST complex in the sense of Definition 5.45 whose differential is $\mathbf{Q}$. Its cohomology vertex superalgebra has nonzero vacuum class.*

File `VOA/Examples/Sl2CosetConcreteFactors.lean`.

```
def leeYangMatterAction : TranslatedAffineSl2Action matterSVA (-4) :=

    ↪ matterGhostTensorGrading

theorem leeYangBRSTComplex_Q :
    leeYangBRSTComplex.Q = semiInfiniteQ leeYangMatterAction.toAffineSl2Action := rfl

theorem leeYangBRSTComplex_cohomology_vacuum_ne_zero :
    leeYangBRSTComplex.cohomology.vacuum ≠ 0 :=
```

From the mathematics to the Lean statement

`TranslatedAffineSl2Action matterSVA (-4)`: an action of level exactly -4 on `matterSVA`, the three-fold tensor product $(A \otimes B) \otimes U$ (`tensorThreeSVA`). Its currents are $J^a \otimes 1 \otimes 1 + 1 \otimes J^a \otimes 1 + 1 \otimes 1 \otimes J^a$ (`Sl2SemiInfinite.leeYangMatterAction`, `Sl2CosetTensor.lean`); the level adds. `brstSVA` is (matter) $\otimes$ (ghosts). `BRST.BRSTComplex brstSVA` bundles a ghost-number

grading, the differential, and the proofs that it has weight 0, is odd, raises ghost number by one, squares to zero and is a derivation of all products (Definition 5.45); `semiInfiniteBRSTComplex` supplies them, using Theorem 28.11 at $k = -4$. `leeYangBRSTComplex_Q` confirms that the differential is literally `semiInfiniteQ`. `cohomology.vacuum ≠ 0` says the vacuum is not exact, so the cohomology is not the zero algebra.
No hypotheses. This is a definition with every field proved for the concrete factors: nothing about the complex is assumed.

Proof on paper. The three actions are proved for the simple quotients and the universal algebra (`aAction`, `bAction`, `uAction`); levels add under tensor products; Theorem 28.11 gives $\mathbf{Q}^2 = 0$. The vacuum is not exact because $\mathbf{Q}$ preserves weight and ghost number and the weight-zero, ghost-number-(-1) space is zero (no state of weight 0 contains a b). □

Physical meaning

The chiral algebra of "$SU(2)$ gauge theory" coupled to the three matter sectors; its ghost-number-zero cohomology is the algebra of gauge-invariant chiral operators, and the vacuum survives gauging.

What the machine verified

Constructed and proved; axioms standard (re-checked: `leeYangBRSTComplex`, `leeYangBRSTComplex_cohomology_vacuum_ne_zero`, `Sl2CosetConcrete.relativeVacuum_survives`). Unconditional.

28.5 The coset VOA and the Virasoro image

Definition 28.14 (Commutant and coset stress tensor). For an affine action J^a on V, the *commutant* is $\{x \in V : J^a_n x = 0 \text{ for all } a \text{ and all } n \geq 0\}$. On $A \otimes B$ take the diagonal action $J^a \otimes 1 + 1 \otimes J^a$ (level $-1/3$), and the coset stress tensor $\omega_{\text{coset}} = \omega_A \otimes \mathbf{1} + \mathbf{1} \otimes \omega_B - \omega^{\text{diag}}$, where ω^{diag} is the Sugawara vector of the diagonal currents.

Files `VOA/Examples/Sl2CosetSubspace.lean`, `Sl2CosetConcreteOmega.lean`, `Sl2CosetConcreteCohomology.lean`.

```
def cosetSubspace (A : AffineSl2Action V k) : Submodule ℂ M where
  carrier := {x | ∀ (a : Fin 3) (n : ℤ), 0 ≤ n → mode (V.Y (A.current a)) n x = 0}

def ambientConformal : ASpace ⊗[ℂ] BSpace :=
  AVOA.conformalVector ⊗ₜ[ℂ] BSVA.vacuum + ASVA.vacuum ⊗ₜ[ℂ] BVOA.conformalVector

def diagonalSugawara : ASpace ⊗[ℂ] BSpace := sugawaraState diagonalAction.toAffineSl2Action

def cosetOmega : ASpace ⊗[ℂ] BSpace := ambientConformal - diagonalSugawara

abbrev CosetSpace := cosetSubspace diagonalAction.toAffineSl2Action
```

From the mathematics to the Lean statement

`cosetSubspace A` is a `Submodule` given by its carrier (the remaining fields, closure under $+$ and scalars, are proved); the carrier is literally the commutant. `diagonalAction` is the tensor-product action on $A \otimes B$ at level $-4/3 + 1$ (`Sl2CosetConcreteFactors.lean`); `sugawaraState` is $\frac{1}{2(k+2)} \sum_{a,b} \kappa^{ab} {:}J^a J^b{:}$ for that action. `ASVA.vacuum` and `BSVA.vacuum` are the vacua. Exactly

the definition.

Physical meaning

The commutant is the GKO coset: the operators of the $A \otimes B$ theory that are neutral under the diagonal $SU(2)$ current algebra. The difference of stress tensors is the stress tensor of that neutral sector.

What the machine verified

Definitions; that `cosetOmega` lies in the commutant and is a conformal vector there is proved (`cosetConformalData`, `cosetOmega_virasoro`).

Theorem 28.15 (The coset VOA). *$c_A + c_B - c_{\mathrm{diag}} = -6 + 1 - (-\frac{3}{5}) = -\frac{22}{5}$, and the commutant, with ω_{coset}, is a VOA of central charge $-22/5$.*

File `VOA/Examples/Sl2CosetConcreteVOA.lean`.

```
theorem cosetCentralCharge :
    AVOA.centralCharge + BVOA.centralCharge -
      3 * ((-4 / 3 : ℂ) + 1) / (((-4 / 3 : ℂ) + 1) + 2) = -22 / 5 := by

def cosetVOA : VertexOperatorAlgebra CosetSpace where
  toPreVertexAlgebra := cosetVertexAlgebra
  conformalVector := cosetOmegaState
  conformal_mem := cosetOmegaState_weight
  centralCharge := -22 / 5
```

From the mathematics to the Lean statement

`AVOA.centralCharge` is the Sugawara value $3k/(k+2) = -6$ at $k = -4/3$ (`aCentralCharge`); `BVOA.centralCharge`$= 1$. The third term is the Sugawara central charge $3k'/(k'+2)$ at $k' = -1/3$. The `VertexOperatorAlgebra` structure (Chapter 5) is built by its fields; we show the first five: the underlying vertex algebra on `CosetSpace`, the conformal vector, its weight, the central charge $-22/5$, and the Virasoro relations (whose proof is the commutation argument below). The remaining fields (L_0-grading, translation, the vacuum grade, positivity of the grading) are proved in the file.

What is *not* claimed. Nothing here identifies `cosetVOA` with L, and simplicity of `cosetVOA` is not proved. The library reduces injectivity of the coset-to-cohomology map to simplicity (`leeYangCosetToH0_injective_of_cosetSimple`) but never uses it.

Proof on paper. The diagonal Sugawara modes L_n^{diag} commute with every operator that commutes with the diagonal currents; in particular with $L_n - L_n^{\mathrm{diag}}$, where L_n are the modes of $\omega_A \otimes \mathbf{1} + \mathbf{1} \otimes \omega_B$. If two Virasoro families L_n (central charge c_1) and D_n (central charge c_2) satisfy $[D_m, L_n - D_n] = 0$, then $L_n - D_n$ is a Virasoro family of central charge $c_1 - c_2$ (`virasoro_difference_of_commute`, a direct computation). The arithmetic is $\frac{3(-4/3)}{2/3} = -6$, $\frac{3(-1/3)}{5/3} = -\frac{3}{5}$. □

Physical meaning

GKO: $\mathrm{SU}(2)_k \times \mathrm{SU}(2)_1 / \mathrm{SU}(2)_{k+1}$ has $c = 1 - 6/((k+2)(k+3))$; for $k = m-2$ a positive integer this is the unitary series, and the analytic continuation to $k = -4/3$ lands on Lee–Yang.

What the machine verified

Proved; axioms standard (re-checked: `Sl2CosetConcrete.cosetVOA`, `Sl2CosetConcrete.cosetCentralCharge`). Unconditional.

Theorem 28.16 (Coset states are relative cocycles; the map to H^0). *For a commutant state x, the state $x \otimes \mathbf{1}_U \otimes \mathbf{1}_{\mathrm{gh}}$ is relative and $\mathbf{Q}$-closed, and $x \mapsto [x \otimes \mathbf{1} \otimes \mathbf{1}]$ is a linear map into the ghost-number-zero cohomology which intertwines the vertex products.*

File `VOA/Examples/Sl2CosetConcreteCohomology.lean`.

```
theorem cosetToComplex_apply (x : CosetSpace) :
    cosetToComplex x = (x.val ⊗ₜ[ℂ] USVA.vacuum) ⊗ₜ[ℂ] sl2GhostSVA.vacuum := rfl

theorem cosetToComplex_closed (x : CosetSpace) : leeYangBRSTComplex.Q (cosetToComplex x) =
↪  0 :=

theorem cosetToComplex_relative (x : CosetSpace) :
    cosetToComplex x ∈ relativeCarrier leeYangMatterAction.toAffineSl2Action :=

theorem cosetToComplex_mode (x y : CosetSpace) (n : ℤ) :
    cosetToComplex (cosetMode diagonalAction.toAffineSl2Action diagonalAction.translation x
    ↪  n y) =
      mode (brstSVA.Y (cosetToComplex x)) n (cosetToComplex y) :=

def leeYangCosetToH0 : CosetSpace →ₗ[ℂ] leeYangBRSTComplex.H0 :=
```

From the mathematics to the Lean statement

`x.val` is the underlying vector of $x \in$ `CosetSpace`. `leeYangBRSTComplex.H0` is the ghost-number-zero part of the cohomology `Coh` $= \ker \mathbf{Q}/\operatorname{im} \mathbf{Q}$ (Chapter 5). `cosetMode` is the vertex product of the coset VOA. The last line only names the map (its body, a specialization of the generic `Sl2Coset.leeYangCosetToH0`, is omitted).

Proof on paper. Write $j = \sum_a J^a_{\mathrm{diag}+U} c^a + \cdots$. On $x \otimes \mathbf{1} \otimes \mathbf{1}$ every term of $\mathbf{Q}$ contains either a non-negative mode of a diagonal current acting on x (zero, since x is in the commutant), a non-negative mode of a U-current or of a ghost acting on a vacuum (zero), or a positive ghost mode. So $\mathbf{Q}$ kills it; the zero modes of the total current and of b^a kill it for the same reason. Products are preserved because the auxiliary and ghost vacua are units. □

Physical meaning

Gauge-neutral operators of the matter, dressed with nothing, are BRST-closed: the coset sits inside the gauged chiral algebra.

What the machine verified

Proved; axioms standard. Unconditional.

Theorem 28.17 (The Virasoro image surjects onto Lee–Yang). *Let $\phi : V(-\frac{22}{5}, 0) \to H^0$ be the composite of the VOA map $V(c, 0) \to$ (coset) determined by $\omega \mapsto \omega_{\mathrm{coset}}$ with the map of Theorem 28.16. Then $\ker \phi$ is contained in the maximal ideal of $V(c, 0)$.*

theorem virasoroToH0_ker_le_maxIdeal :
    LinearMap.ker virasoroToH0 ≤ maxIdealVir LeeYang.leeYangC :=
```

From the mathematics to the Lean statement

`conformalEval W hc` is the linear map $V(c,0) \to W$ sending $L_{-n_1} \cdots L_{-n_k}\mathbf{1}$ to the corresponding product of modes of the conformal vector of W applied to the vacuum; `conformalEval_hom` says it is a VOA homomorphism (`IsVOAHom`: vacuum and all products preserved) whenever W has central charge c. `VirUniv c` is the carrier of $V(c,0)$ (Chapter 7), `maxIdealVir c` its maximal proper ideal, so $V(c,0)$/`maxIdealVir c`$= L(c,0)$. `LinearMap.ker` is the kernel.
Consequence used later. Since $\ker\phi \subseteq \mathcal{M}_c$, the quotient map $V(c,0) \to L$ factors through the image of ϕ: there is a surjection $\operatorname{im}\phi \to L$, and it maps the image of the length-$\leq r$ words onto F_rL. This is all that the squeeze (Theorem 28.27) needs from the coset.

Proof on paper. $\ker\phi$ is an ideal of $V(c,0)$ because ϕ intertwines all products. It does not contain the vacuum, since the vacuum class of H^0 is nonzero (Theorem 28.13). Every proper ideal of $V(c,0)$ is contained in the maximal one (Chapter 7). □

Physical meaning

The stress tensor of the gauged theory generates a Virasoro algebra of central charge $-22/5$; whatever it generates is at least as big as Lee–Yang, because the only way to be smaller would be to kill the identity operator.

What the machine verified

Proved; axioms standard (re-checked: `LeeYangShortcut.virasoroToH0_ker_le_maxIdeal`). Unconditional.

Remark 28.18 (Why the coset identification is avoided)**.** The paper proof identifies the coset VOA with L (Arakawa–Creutzig–Linshaw) and then the coset with H^0. Both identifications are hard to formalize. The "shortcut" route (`LeeYangShortcut*`) needs only the two one-sided facts of Theorems 28.16 and 28.17: L is a quotient of a subspace of H^0. Under the hypothesis GU(A) the dimension squeeze then shows, as a *consequence*, that the image of $V(c,0)$ is all of H^0 and that $\ker\phi = \mathcal{M}_c$ exactly; in particular $H^0 \cong L$. This is a consequence on paper of the proof (inside it, `maps_eq_of_finrank_squeeze` gives the equality of each filtration step); no Lean declaration states "$\operatorname{im}\phi = H^0$" or "$\ker\phi = \mathcal{M}_c$", and without GU($A$) nothing beyond Theorems 28.16 and 28.17 is claimed. The superseded assembly of Warning 28.3 assumed `CosetIdentification` instead.

28.6 Hodge theory of a weakly graded-unitary complex

This section is pure finite-dimensional linear algebra: Beem–Garner's positivity argument, at one conformal weight, for an abstract complex. Section 28.8 instantiates it.

Definition 28.19 (Kähler complex). A *Kähler complex* is a finite-dimensional complex vector space K with: a positive definite sesquilinear form P (conjugate-linear in the first slot); a decomposition $K = \bigoplus_{(j,g)\in\mathbb{Z}^2} K_{(j,g)}$ into P-orthogonal pieces, $j = 2R$ and g the ghost number; four linear maps Q^-, S^-, Q^+, S^+ shifting the bidegree by $(1,1)$, $(-1,1)$, $(1,-1)$, $(-1,-1)$ respectively; a sign $\varepsilon \in \{\pm 1\}$ with

$$P(Q^- x, y) = \varepsilon P(x, S^+ y), \qquad P(S^- x, y) = -\varepsilon P(x, Q^+ y);$$

and the relations $(\mathbf{Q}^-)^2 = 0$ and $\mathbf{Q}^-\mathbf{Q}^+ + \mathbf{Q}^+\mathbf{Q}^- = 0$ for $\mathbf{Q}^\pm = Q^\pm + S^\pm$.

File `VOA/Examples/GradedUnitaryCohomologyKahler.lean`.

  sq_zero : (Qm + Sm).comp (Qm + Sm) = 0
  anticomm : (Qm + Sm).comp (Qp + Sp) + (Qp + Sp).comp (Qm + Sm) = 0
```

From the mathematics to the Lean statement

`SesqForm K` is a sesquilinear form and `IsPosOn P ⊤` means $P(x,x)$ is a positive real for every nonzero x (Definition 19.7). `iSup deg = ⊤`: the pieces span; with `orth` and positivity they are independent, so the sum is direct. `shQm`$= (1,1)$, `shSm`$= (-1,1)$, `shQp`$= (1,-1)$, `shSp`$= (-1,-1)$. `c : ℝ` with `c * c = 1` is ε. `(Qm + Sm).comp (Qm + Sm) = 0` is $(\mathbf{Q}^-)^2 = 0$.

Against Beem–Garner. `P` is their modified form $\langle x|y\rangle = ((\sigma \circ \rho)x, y)$, and `pos` is their "weak graded unitarity" of the complex (their Theorem 3.20); the four pieces and the two adjoint relations are their Lemma 3.16, in which *goodness* of the action is exactly the absence of a component of $\mathbf{Q}^-$ preserving R. The other two adjoint relations $(Q^+)^\dagger = -\varepsilon S^-$ and $(S^+)^\dagger = \varepsilon Q^-$ are derived (`adj_Qp`, `adj_Sp`); Hermitian symmetry of P is derived from positivity (`herm`); $(\mathbf{Q}^+)^2 = 0$ is not needed.

Non-vacuity. The structure is inhabited by a five-dimensional example with nonzero differentials and a nonzero harmonic vector (Example 28.24), and by the actual complex (Section 28.8).

Physical meaning

P is the positive inner product that the four-dimensional theory induces on chiral-algebra states after twisting by i^{2R}; the two differentials $\mathbf{Q}^\pm$ are the BRST charge and its $SU(2)_R$ partner, and the identities are the chiral shadow of an Sp(2) (Kähler) structure, as in Hodge theory on a compact Kähler manifold, where $\partial, \bar\partial$ and their adjoints satisfy analogous relations.

What the machine verified

Definition (a `structure`). Instances: Example 28.24 and the concrete complex.

Theorem 28.20 (Harmonic vectors; Beem–Garner Remark 4.4 in strong form). *Put $D = \mathbf{Q}^-$ and $D^\dagger = \varepsilon(S^+ - Q^+)$, its P-adjoint. A vector is harmonic ($Dx = 0 = D^\dagger x$) if and only if $Q^-x = S^-x = Q^+x = S^+x = 0$. In particular the harmonic space is bigraded, and every class of* $\ker D/\operatorname{im} D$ *has a unique harmonic representative.*

Files `VOA/Examples/GradedUnitaryCohomologyKahler.lean`, `LeeYangCosetTransferHodge.lean`.

```
def D : K →ₗ[ℂ] K := C.Qm + C.Sm

def Dadj : K →ₗ[ℂ] K := (C.c : ℂ) • (C.Sp - C.Qp)

def harm : Submodule ℂ K := harmonicSpace C.D C.Dadj

theorem mem_harm_iff (x : K) :
    x ∈ C.harm ↔ C.Qm x = 0 ∧ C.Sm x = 0 ∧ C.Qp x = 0 ∧ C.Sp x = 0 := by

def harmonicSpace (Q Qadj : K →ₗ[ℂ] K) : Submodule ℂ K :=
  LinearMap.ker Q ⊓ LinearMap.ker Qadj
```

From the mathematics to the Lean statement

`D` is $\mathbf{Q}^-$, `Dadj` is $\varepsilon(S^+ - Q^+)$, and `adj_D` proves $P(Dx, y) = P(x, D^\dagger y)$. `harmonicSpace Q Qadj` is $\ker Q \cap \ker Q^\dagger$. The statement is exactly the first sentence. The unique-representative statement is `harmonicEquivCohomology` (a linear equivalence between the harmonic space and $\ker D/\operatorname{im} D$, same file, with `harmonicToCohomology_injective` and `_surjective`).

Proof on paper. If $Dx = 0$ and $D^\dagger x = 0$, then $Q^-x = -S^-x$ and $S^+x = Q^+x$. Consider $E = Q^+x + S^+x = \mathbf{Q}^+x$ and $F = Q^-x - S^-x$. Using the adjoint relations and $\mathbf{Q}^-\mathbf{Q}^+ + \mathbf{Q}^+\mathbf{Q}^- = 0$ split into bidegrees (the "fine" relations `fine_QmQp`, `fine_SmSp`, `Qm_sq`, obtained by projecting onto bidegrees), one finds $P(E,E) + P(F,F) = 0$. By positivity $E = F = 0$, and combined with $Q^-x + S^-x = 0$, $S^+x - Q^+x = 0$ all four pieces vanish. Conversely if all four vanish, so do D and $D^\dagger$. Homogeneous components of a harmonic vector are then harmonic, because each piece is homogeneous. The unique-representative statement is the usual finite-dimensional Hodge decomposition $K = \operatorname{im} D \oplus \mathcal{H} \oplus \operatorname{im} D^\dagger$ for a positive form. □

Physical meaning

Harmonic representatives are the "on-shell" gauge-invariant states with definite R-charge; the strong form says that they are simultaneously annihilated by both supercharges and their adjoints.

What the machine verified

Proved; axioms standard (re-checked: `mem_harm_iff`). Unconditional (for any `KahlerComplex`).

Theorem 28.21 (The harmonic bound). *Let $H(Q^-)_{(j,g)}$ be the cohomology of the leading piece Q^- alone in bidegree (j,g). Harmonic vectors of bidegree (j,g) inject into $H(Q^-)_{(j,g)}$. Consequently, for a finite set S of values of $2R$, the classes of* $\ker D/\operatorname{im} D$ *with a representative of ghost number g and $2R \in S$ span a space of dimension at most $\sum_{j\in S} \dim H(Q^-)_{(j,g)}$.*

Files `VOA/Examples/GradedUnitaryCohomologyKahler.lean`, `GradedUnitaryCohomologyFiltered.lean`.

```
def leadCycles (a : ℤ × ℤ) : Submodule ℂ K := LinearMap.ker C.Qm ⊓ C.deg a

abbrev leadCohom (a : ℤ × ℤ) := C.leadCycles a / C.leadBoundaries a

def harmDeg (a : ℤ × ℤ) : Submodule ℂ K := C.harm ⊓ C.deg a

theorem harmToLead_injective (a : ℤ × ℤ) : Function.Injective (C.harmToLead a) := by

def cohomFilt (A : Set (ℤ × ℤ)) : Submodule ℂ (cycleQuotient C.D) :=
  Submodule.map (boundariesInCycles C.D).mkQ
    (Submodule.comap (LinearMap.ker C.D).subtype (C.degOn A))

def rowSet (S : Finset ℤ) (g : ℤ) : Set (ℤ × ℤ) := {a | a.1 ∈ S ∧ a.2 = g}

theorem finrank_cohomFilt_row_le_lead (S : Finset ℤ) (g : ℤ) :
    finrank ℂ (C.cohomFilt (rowSet S g)) ≤ ∑ j ∈ S, finrank ℂ (C.leadCohom (j, g)) := by
```

From the mathematics to the Lean statement

`leadCycles a` $= \ker Q^- \cap K_a$; `leadBoundaries a` $= Q^-(K_{a-(1,1)})$ viewed inside the cycles; `leadCohom a` is the quotient, $H(Q^-)_a$. `harmToLead a` sends a harmonic vector of bidegree a to its Q^--class. `cohomFilt A` is the image in $\ker D/\operatorname{im} D$ (`cycleQuotient C.D`) of the closed vectors supported on the bidegrees in A; `rowSet S g` is $\{(j,g) : j \in S\}$. Exactly the theorem. At ghost number $g = 0$ and $S = \{0, 1, \dots, 2r\}$ it reads $\dim F_r H^0 \le \sum_{j=0}^{2r} \dim H(Q^-)_{(j,0)}$, inequality (c) of Remark 28.1.

Proof on paper. If a harmonic x of bidegree a were Q^-y, then $P(x,x) = P(Q^-y,x) = \varepsilon P(y,S^+x) = 0$, since $S^+x = 0$ by Theorem 28.20; so $x = 0$. For the second statement: a class with a representative supported on A has its harmonic representative supported on A (the harmonic projection respects the bigrading, `exists_harm_rep_mem_degOn`), so the space of such classes is isomorphic to the harmonic vectors supported on A, whose dimension is $\sum_{a\in A} \dim \mathcal{H}_a \le \sum_{a\in A} \dim H(Q^-)_a$. □

Physical meaning

Counting: gauge-invariant states of R-charge $\le r$ are at most as many as the states of the "free" (leading-order) BRST problem. The leading problem is computable, which is why this bound is useful.

What the machine verified

Proved; axioms standard (re-checked: `harmToLead_injective`, `finrank_cohomFilt_row_le_lead`). Unconditional.

Definition 28.22 (Form and conjugation data on a Kähler complex)**.** A *GU datum* on a Kähler complex C is a bilinear form B, an anti-linear map ρ and the sesquilinear form $h(x,y) = B(\rho x, y)$, such that $P(x,y) = i^j h(x,y)$ for x of bidegree (j,g), and ρ maps the harmonic vectors of bidegree $(j,0)$ onto themselves. On the harmonic model of H^0 define the flag $G_j = \bigoplus_{L\le i\le j} \mathcal{H}_{(i,0)}$ and its layers $G_j \cap B\text{-orth}(G_{j-1})$.

File `VOA/Examples/GradedUnitaryCohomologyTransfer.lean`.

```
structure GUData (C : KahlerComplex K) where
  B : LinearMap.BilinForm ℂ K
```

```
  ρ : K →ₗ⋆[ℂ] K
  h : SesqForm K
  h_eq : ∀ x y, h x y = B (ρ x) y
  P_eq : ∀ j g : ℤ, ∀ x ∈ C.deg (j, g), ∀ y, C.P x y = Complex.I ^ j * h x y
  ρ_maps : ∀ j : ℤ, ∀ x ∈ C.harmDeg (j, 0), ρ x ∈ C.harmDeg (j, 0)
  ρ_onto : ∀ j : ℤ, ∀ y ∈ C.harmDeg (j, 0), ∃ x ∈ C.harmDeg (j, 0), ρ x = y

def flag (L j : ℤ) : Submodule ℂ K :=
  C.harm ⊓ C.degOn (KahlerComplex.rowSet (Finset.Icc L j) 0)
```

From the mathematics to the Lean statement

`K →ₗ⋆[ℂ] K` is an anti-linear map. `Complex.I ^ j` is i^j, $j = 2R$; for integral $R = p$ it is $(-1)^p$. `flag L j` is the span of harmonic vectors of ghost number 0 with $2R \in [L, j]$ (`flag_eq_iSup`). The `layer` (`GUData.layer`, same file) is `C.flag L j ⊓ G.B.orthogonal (C.flag L (j - 1))`, matching `GradedFlag.layer` of Definition 19.11.

Physical meaning

i^{2R} is the phase relating the four-dimensional inner product to the chiral-algebra (BPZ) pairing; for integer R it is ABLR's sign $(-1)^R$.

What the machine verified

Definition. Instantiated on the actual complex by the Beem–Garner package (Section 28.8).

Theorem 28.23 (Cohomology inherits graded unitarity; Beem–Garner Theorem 4.1 at one weight). *For a GU datum on a Kähler complex: (1) B is nondegenerate on every step G_j of the harmonic flag; (2) the layer at j is exactly $\mathcal{H}_{(j,0)}$; (3) on the layer at $j = 2p$, the form $(-1)^p h$ is positive definite.*

File `VOA/Examples/GradedUnitaryCohomologyTransfer.lean`.

```
theorem flag_nondegenerate [FiniteDimensional ℂ K] (L j : ℤ) :
    (G.B.restrict (C.flag L j)).Nondegenerate := by

theorem layer_eq {L j : ℤ} (hLj : L ≤ j) : G.layer L j = C.harmDeg (j, 0) := by

theorem layer_signed_pos {L : ℤ} (p : ℕ) (hL : L ≤ 2 * (p : ℤ)) :
    IsPosOn (signedForm G.h p) (G.layer L (2 * (p : ℤ))) := by
```

From the mathematics to the Lean statement

`(G.B.restrict S).Nondegenerate` is clause (iv) on the step; `IsPosOn (signedForm G.h p) S` is clause (vi), with `signedForm h p`= $(-1)^p h$ (Chapter 19). The section variables are a `KahlerComplex C` and `G : GUData C`; the hypothesis `hL : L ≤ 2 * p` says the layer index is in the range of the flag. Exactly clauses (iv) and (vi) for the harmonic model.

Proof on paper. The pieces $\mathcal{H}_{(m,0)}$ are B-orthogonal for different m: for $x \in \mathcal{H}_{(m,0)}$ and y of a different bidegree, $B(\rho x, y) = h(x, y) = i^{-m} P(x, y) = 0$, and ρ maps each piece onto itself. So $G_j = \mathcal{H}_{(j,0)} \oplus G_{j-1}$ is a B-orthogonal sum, which gives (2). On $\mathcal{H}_{(j,0)}$, $i^j h = P$ is positive definite, so h is nondegenerate there, hence so is B (as ρ is bijective); an orthogonal sum of nondegenerate pieces is nondegenerate, which gives (1). For $j = 2p$, $i^{2p} = (-1)^p$ and (3) is positivity of P. □

Physical meaning

This is the statement that BRST reduction (gauging) preserves the ABLR positivity constraints, because they come from a positive four-dimensional inner product which survives the restriction to gauge-invariant states.

What the machine verified

Proved; axioms standard (re-checked: `flag_nondegenerate`, `layer_signed_pos`). Unconditional (for any GU datum).

Example 28.24 (The quartet, a non-vacuity witness)**.** In `GradedUnitaryCohomologyExample.lean` the library builds a Kähler complex on $\mathbb{C}^5$ with basis $e_0 = \tilde{x}$ in bidegree $(0,0)$, $e_1 = Q^-\tilde{x}$ in $(1,1)$, $e_2 = Q^+\tilde{x}$ in $(1,-1)$, $e_3 = Q^-Q^+\tilde{x}$ in $(2,0)$, and a singlet e_4 in $(0,0)$, with the standard Hermitian form and $\varepsilon = 1$. The four vectors $e_0, \dots, e_3$ form Beem–Garner's "quartet" (their Figure 3.1), which is $\mathbf{Q}^-$-acyclic; the singlet e_4 is harmonic, e_0 is not, $D \neq 0$, and a GU datum with B weighted by i^{-j} makes the singlet's layer positive (`singlet_signed_pos`). So the hypotheses of Theorem 28.23 are consistent and not degenerate.

Dead ends in the abstract Hodge theory

- **One differential is not enough.** A single differential D with an R-filtration does not make harmonic representatives homogeneous: on $K = \langle a, b, c\rangle$ with $R(a) = 0$, $R(b) = \frac{1}{2}$, $R(c) = -\frac{1}{2}$ and $Da = b + c$, the harmonic vector $b - c$ is not homogeneous. The second differential $\mathbf{Q}^+$ and the Kähler identity are essential (project notes; hand counterexample).
- **A GU datum cannot force the vacuum normalization.** $(B, \rho) \mapsto (-B, -\rho)$ preserves every axiom of `GUData` (since h is unchanged), so the normalization $B(\text{vacuum}, \text{vacuum}) = 1$ is extra information (`LeeYangShortcut.signTwistGUData_not_both_normalized`, `LeeYangShortcutMetric.lean`, proved). It is supplied on the actual complex by Theorem 28.35.

28.7 Transfer by a dimension squeeze

Theorem 28.25 (The single-piece squeeze)**.** *Let $i : C \to H$ be injective and linear, $P_r \leq C$, $F_r \leq H$ finite-dimensional, with $i(P_r) \subseteq F_r$ and $\dim F_r \leq d_r = \dim P_r$ for every r. Then $i(P_r) = F_r$ for every r.*

File `VOA/Examples/LeeYangCosetTransferDimension.lean`.

```
theorem maps_eq_of_finrank_squeeze
    (i : C →ₗ[𝕜] H) (hi : Function.Injective i)
    (P : ι → Submodule 𝕜 C) (F : ι → Submodule 𝕜 H) (d : ι → ℕ)
    (hfiltered : ∀ r, (P r).map i ≤ F r)
    (hupper : ∀ r, finrank 𝕜 (F r) ≤ d r)
    (hexact : ∀ r, d r = finrank 𝕜 (P r)) : ∀ r, (P r).map i = F r := by
```

From the mathematics to the Lean statement

`(P r).map i` is the image $i(P_r)$. `d : ι → ℕ` is the numerical bound; in the application it is $\sum_{s \leq r} G_s(N)$. The section variable `[FiniteDimensional 𝕜 H]` makes all pieces finite-dimensional. Exactly the theorem.

Proof on paper. $\dim i(P_r) = \dim P_r = d_r \geq \dim F_r$ and $i(P_r) \subseteq F_r$. □

Physical meaning

A purely numerical step: if the states one can construct are at least as many as an upper bound on the states that can exist, one has all of them.

What the machine verified

Proved; axioms standard (re-checked). Unconditional.

Theorem 28.26 (Transfer of graded unitarity through a filtered isometry)**.** *If a weight-preserving isometric embedding E of A into T that intertwines the real structures maps every flag step of A* onto *the corresponding step of T, and T is graded unitary, then A is graded unitary.*

File `VOA/Examples/LeeYangCosetTransferFiltered.lean`.

```
theorem gradedUnitary_of_filteredIso
    (E : GradedIsometricEmbedding A T BA BT RA RT)
    (FA : GradedFlag A) (FT : GradedFlag T)
    (hpiece : ∀ n p, (FA.pieceIn p n).map (E.weightMap n) = FT.pieceIn p n)
    (hambient : GradedUnitary BT RT FT) : GradedUnitary BA RA FA := by
```

From the mathematics to the Lean statement

`GradedIsometricEmbedding A T BA BT RA RT` is Definition 19.46: weightwise injective maps preserving the forms and commuting with the conjugations. `E.weightMap n` is its weight-n part and `pieceIn p n` the step F_pV_n. `hpiece` is "onto every step". Exactly the theorem. It strengthens Theorem 19.47 (which assumes orthogonal reduction): ontoness gives orthogonal reduction for free (`orthogonallyReducingAt_of_surjective`).

Proof on paper. If E maps F_pA_n onto F_pT_n for every p and the flags exhaust, E is onto at weight n, hence an isometric isomorphism of filtered spaces; layers go to layers and both clauses transfer. □

Physical meaning

Two chiral algebras with the same states, the same inner products and the same R-filtration have the same positivity properties.

What the machine verified

Proved; axioms standard (re-checked). Unconditional.

Theorem 28.27 (Graded unitarity at one weight from a family of cohomology classes)**.** *Let C be a Kähler complex with a GU datum, W a VOA with a flag F at weight n and forms β, h. Let $f : U \to \ker D/\operatorname{im} D$ and $g : U \to W_n$ be linear, g surjective,* $\ker f \subseteq \ker g$*, and $P_p \leq U$ an exhaustive filtration with $g(P_p) = F_pW_n$ and $f(P_p) \subseteq F_p(\ker D/\operatorname{im} D)$ (classes with representatives of $R \leq p$ at ghost number zero). Suppose $\sum_{j=0}^{2p} \dim H(Q^-)_{(j,0)} = \dim F_pW_n$ for every p, that β and h pulled back along g agree with B and h on the harmonic lifts of f, and that harmonic vectors of odd $2R$ at ghost number zero vanish. Then W is graded unitary at weight n.*

```

From the mathematics to the Lean statement

Hypotheses one by one. `f` (in the application: universal Virasoro words $\mapsto$ their cohomology classes, $U = V(c,0)_n$) and `g` (the quotient map onto L_n). `hgs`: g onto. `hker`: $\ker f \subseteq \ker g$, which is Theorem 28.17. `P`: the length filtration of $V(c,0)_n$; `hquotient`: its image is the length flag of L_n; `hexhaustive`: it exhausts. `hfiltered`: words of length $\leq p$ give classes with representatives of $2R \in [0, 2p]$ at ghost number zero; in the application this is `endpointKahler_filtered hA` (Theorem 28.36). `hcharacter`: the dimension equality, which in the application is (d)–(f) of Remark 28.1. `hB`, `hh`: the forms agree on harmonic lifts (`harmonicClassLift C f x` is the harmonic representative of $f(x)$; Theorem 28.35). `hintegral`: `IntegralHarmonicSupport C`, no harmonic vectors at odd $2R$ and ghost number 0, which follows from the invariant-symbol bound (`integralHarmonicSupport_of_symbols`) because the leading cohomology vanishes at odd j.
Injectivity of f is not assumed, and neither is injectivity of g on the image of f: the theorem proves it.

Proof on paper. Factor g through the range of f (possible since $\ker f \subseteq \ker g$). The range of f, filtered by the images of P_p, maps into the harmonic flag (via harmonic representatives) and onto F_pW_n. Then $\dim F_pW_n \leq \dim f(P_p) \leq \dim F_p(\ker D/\operatorname{im} D) \leq \sum_{j\leq 2p} \dim H(Q^-)_{(j,0)} = \dim F_pW_n$ (the third inequality is Theorem 28.21), so all are equal; by Theorem 28.25 the harmonic lifts of $f(P_p)$ are the whole harmonic flag step, and g is injective on the range of f. The resulting map from the harmonic flag of H^0 to $F_\bullet W_n$ is a filtered isometric isomorphism (by `hB`, `hh`); odd layers vanish by `hintegral`, so the harmonic layer at $j = 2p$ corresponds to $\mathcal{L}_pW_n$. Theorem 28.23 gives clauses (iv) and (vi) on the harmonic side, and they transfer. □

Physical meaning

The Lee–Yang states are realized, one for one and with the same norms and R-charges, as gauge-invariant states of the BRST problem; their positivity is then inherited from the latter.

What the machine verified

Proved; axioms standard (re-checked: `LeeYangShortcut.gradedUnitaryAt_of_class_family`). Unconditional (all hypotheses explicit).

28.8 The Beem–Garner package on the actual complex

To apply Section 28.6 at weight N one needs, on the actual relative complex: a positive definite modified form, an R-bigrading for which $\mathbf{Q}$ is good, a second differential with the Kähler identities, and a GU datum whose invariant form and conjugation agree with those of Lee–Yang on the coset representatives. Positivity needs each matter factor to be graded unitary (or unitary) and the ghost form to be positive. This section presents the inputs and the theorems that discharge them.

Definition 28.28 (Unitary VOA). A VOA with invariant form B and real structure ρ is *unitary* if $h(x,x) = B(\rho x, x)$ is a positive real for every nonzero homogeneous x.

File `VOA/Examples/ConcreteHodgeAssembly.lean`.

```
def Unitary (B : InvariantForm W) (R : RealStructure W) : Prop :=
  ∀ n : ℤ, IsPosOn (gradedSesq B R n) τ
```

From the mathematics to the Lean statement

`gradedSesq B R n` is h restricted to V_n (Definition 19.10) and `τ` the whole weight space. This is Dong–Lin unitarity (Definition 19.1) up to the requirement that ρ be an involution, which is part of the `RealStructure` via its parity. It is a separate predicate, not `GradedUnitary B R F` for any graded flag F: a `GradedFlag` must have $F_0 V_N = 0$ for $N > 0$ and $F_0 V_0 = \mathbb{C}\mathbf{1}$, so "everything in step 0" is not a graded flag. What corresponds to it is the Beem–Garner R-grading that puts all of B in R-degree 0 (`trivialDeg`, Definition 28.31).

Physical meaning

The ordinary Hilbert-space positivity of a unitary CFT.

What the machine verified

Definition.

Theorem 28.29 ($L_1(\mathfrak{sl}_2)$ is unitary). *With its normalized canonical form and the descended compact conjugation, $B = L_1(\mathfrak{sl}_2)$ is unitary. Moreover its conformal vector is $\omega = \frac{1}{4} h_{-1} h_{-1} \mathbf{1}$.*

Files `VOA/Examples/BGPackageBFactor.lean`, `LevelOneUnitaryPositivity.lean`, `LevelOneHeisSingular.lean`.

```
def bRealStructure : RealStructure BVOA where

abbrev bForm : InvariantForm BVOA := simpleForm 1 bNoncritical

theorem bUnitary : ConcreteHodge.Unitary bForm bRealStructure := by

abbrev hB : BSpace := bAction.current 2

theorem bConformal_eq : BVOA.conformalVector = (1 / 4 : ℂ) • BVOA.smul hB (-1) hB := by
```

From the mathematics to the Lean statement

`bRealStructure` is the compact conjugation descended to L_1 (built exactly as `affineRealStructure`, with parity 1); `bForm` is `simpleForm 1`; `hB` is the h-current state $h_{-1}\mathbf{1}$ of L_1; `BVOA.smul hB (-1) hB` is $h_{-1}h_{-1}\mathbf{1}$. No hypotheses.

Why the second statement is interesting. At level one the Sugawara vector $\frac{1}{6}(e_{-1}f_{-1} + f_{-1}e_{-1} + \frac{1}{2}h_{-1}h_{-1})\mathbf{1}$ equals the free-boson stress tensor $\frac{1}{4}h_{-1}^2\mathbf{1}$ in the simple quotient: the

coset L_1/Heisenberg has zero stress tensor. This is true only at $k = 1$, and it is what makes the level-one charge sectors "Heisenberg-separated" (`levelOneHeisenbergSeparation`), an input of the invariant-symbol bound.

Proof on paper. Work in $V^1(\mathfrak{sl}_2)$ with $h(x, y) = B(\rho x, y)$ and the maximal ideal I. For a vector y of energy E and h_0-charge $\mu \geq 0$ the Sugawara relation $L_0 = E$ and $[e_0, f_0] = h_0$ give $(6E - \mu - \frac{\mu^2}{2})\, h(y, y) = 2h(e_0 y, e_0 y) + \sum_c \sum_{1 \leq m \leq E} 2w_c\, h(J^c_m y, J^c_m y)$ with positive weights w_c. Every vector on the right has lower energy, or the same energy and larger charge. Integrability of L_1 gives the charge bound $\mu^2 \leq 4E$ off I, and with $\mu \leq 2E$ the coefficient $6E - \mu - \mu^2/2$ is positive. Induction (on energy, and downward on charge) shows that $h(y, y) \geq 0$, with equality only on I. Negative charges follow by the conjugation, and distinct charges are orthogonal. Pass to the quotient. The identity $\omega = \frac{1}{4} h^2_{-1}\mathbf{1}$ is checked by showing that the difference is a singular vector of weight 2, hence zero in the simple quotient. □

Physical meaning

$SU(2)$ level one is the free boson at the self-dual radius; its unitarity is the positivity of a free-field Fock space, and $\omega = \frac{1}{4} h^2_{-1}\mathbf{1}$ is the Frenkel–Kac statement that the WZW stress tensor is that of one boson.

What the machine verified

Both proved outright; axioms standard (re-checked: `LevelOneUnitary.bUnitary`, `LevelOneHeis.bConformal_eq`).

Theorem 28.30 (The auxiliary factor is graded unitary). *For every real $k < -2$, $V^k(\mathfrak{sl}_2)$ with its normalized form, the compact conjugation and the ordinary current-PBW flag (words of at most p currents) is graded unitary. In particular $U = V^{-11/3}(\mathfrak{sl}_2)$ is.*

Files `VOA/Examples/AffineSl2BelowCriticalAnchor.lean` (a file of Chapter 19), `LeeYangTransferAssemblyAffine.lean`.

```
theorem universal_gradedUnitary_belowCritical_unconditional (k : ℝ) (hk : k < -2) :
    GradedUnitary (universalForm (k : ℂ) (noncritical_of_lt hk)) (compactRealFamily k hk)
      (ordinaryFlag (k : ℂ) (noncritical_of_lt hk)) :=

abbrev auxiliaryForm : InvariantForm UVOA := universalForm (-11 / 3) uNoncritical

abbrev auxiliaryRealStructure : RealStructure UVOA :=
  compactRealStructure auxiliaryLevel_real uNoncritical

abbrev auxiliaryFlag : GradedFlag UVOA := ordinaryFlag (-11 / 3) uNoncritical

theorem auxiliaryGradedUnitary :
    GradedUnitary auxiliaryForm auxiliaryRealStructure auxiliaryFlag := by
```

From the mathematics to the Lean statement

`noncritical_of_lt hk` proves $k + 2 \neq 0$ from $k < -2$; `compactRealFamily k hk` is the compact real structure at that real level; `ordinaryFlag` is the flag by number of current letters (Sugawara counted as two). `auxiliaryGradedUnitary` specializes to $k = -11/3$ (the proof, omitted, is a cast from $\mathbb{R}$ to $\mathbb{C}$). No hypotheses. Note the auxiliary flag is the *ordinary* flag, unlike the corrected flag of A; the BRST R-grading uses each factor's own flag.

Proof on paper. (Developed in the files of Chapter 19.) For k very negative the Gram matrices, rescaled, tend to those of a free (central) limit in which positivity on the layers is manifest. The "no-wall" argument shows that along $k \in (-\infty, -2)$ no prefix Gram determinant vanishes (a prefix-radical and Sugawara induction), so signs cannot change; continuity then fixes the signs at every $k < -2$. □

Physical meaning

Heuristically, below the critical level the affine current algebra behaves like a free (Gaussian) sector in the large-$|k|$ limit, and every layer has the sign predicted by ABLR; this is an analogy, not a statement about a specific four-dimensional theory. That this holds for the universal algebra, with no quotient, is special to $k < -2$.

What the machine verified

Proved; axioms standard (re-checked: both). Unconditional.

Definition 28.31 (Goodness of the actual differential)**.** Give each factor its R-grading: on A the orthogonal layers of the corrected flag ($R = p$ on layer p), on B everything in $R = 0$, on U the layers of the ordinary flag, and on the ghosts a positive grading by weights. The differential is *good* on relative states if it maps bidegree $(2R, \mathrm{gh})$ into $(2R \pm 1, \mathrm{gh} + 1)$, with no R-preserving component.

File `VOA/Examples/ConcreteGoodInterpreted.lean`.

```
def aDeg : (ℤ × ℤ) × ℂ → Submodule ℂ ASpace := layerDeg affineForm affineFlag

    leeYangBRSTComplex.Q x ∈
      brstDeg Gh ((j + 1, g + 1), (n : ℂ)) ⊔ brstDeg Gh ((j - 1, g + 1), (n : ℂ))
```

From the mathematics to the Lean statement

`layerDeg B F` places the layer $\mathcal{L}_p$ of the flag F (orthogonal complements for B) in bidegree $(2p, 0)$ and weight n; `trivialDeg` puts everything in $R = 0$; `tensorDeg` is the tensor-product grading (degrees add). `GhostRGrading PG` is a grading of the ghost space by $((2R, \mathrm{gh}), \text{weight})$ with pieces orthogonal for the ghost form `PG`. The index type `(ℤ × ℤ) × ℂ` is $((2R, \mathrm{gh}), \text{weight})$; `relativeWeight n` is the relative complex at weight n (`LeeYangTransferAssemblyComplex.lean`), and ⊔ is the sum of subspaces.

A subtlety. The layers of the corrected flag on A form a decomposition of A_n only if B is nondegenerate on every step, which is clause (iv) of `hA`; so the R-grading of the complex itself depends on `hA` (`matterDeg_span hA`). This is legitimate: the grading is needed only under that hypothesis.

Physical meaning

Goodness is Beem–Garner's Definition 3.12: the gauge current has R-charge one, so each term of $c^a J^a$ changes the R-charge by exactly $\pm\frac{1}{2}$ after the ghost's own charge is accounted for.

What the machine verified

Definition (docstring still says "OPEN"; it is proved, next theorem).

Theorem 28.32 (The actual differential is good)**.** *Assume* GU(A) *and that B is unitary for some form and real structure. Then for every positive weight function w on ghost modes,* $\mathbf{Q}$ *is good on relative states for the ghost grading built from w.*

File `VOA/Examples/BRSTGoodnessDifferential.lean`.

```
theorem relativeDifferentialGood_of_affine
    (hA : GradedUnitary affineForm affineRealStructure affineFlag)
    {BB : InvariantForm BVOA} {RB : RealStructure BVOA} (hB : Unitary BB RB)
    (w : Finset ModeIdx → ℝ) (hw : ∀ s, 0 < w s) :
    RelativeDifferentialGood (ghostRGrading w) := by
```

From the mathematics to the Lean statement

`ModeIdx` indexes ghost modes; `ghostRGrading w` is the ghost R-grading with weights `w`. The hypotheses `hA` and `hB` are used only to have the matter grading at all (previous dictionary) and adjointness of current modes with respect to the layers.

Proof on paper. Refine the grading by the number of c_0's and set $R' = R + \frac{1}{2}n_{c_0}$. Every term of $\mathbf{Q} = \sum_a \sum_n J^a_n \otimes c^a_{-n} + \mathbf{Q}_{\mathrm{gh}}$ shifts $2R'$ by exactly ± 1: the matter modes because the flags are good and the layers are adjoint-compatible, the c-modes by the sign of their index (c_0 included), and the cubic term by a direct computation. Relative states contain no c_0 (since $\sum_a c^a_0 b^a_0$ acts as the c_0-count and kills states annihilated by the b^a_0), so $R' = R$ there, and $\mathbf{Q}$ preserves relative states. □

Physical meaning

The gauged chiral algebra inherits a well-defined R-filtration, and the BRST charge has definite R-charge $\pm\frac{1}{2}$.

What the machine verified

Proved; axioms standard (re-checked). Conditional on `hA` and `hB` as displayed; in the headline `hB` is discharged by Theorem 28.29.

Definition 28.33 (The two ghost-conjugation identities)**.** Let $\rho = \rho_M \otimes \rho_G$ and $B = B_M \otimes B_G$ be the product conjugation and form on the BRST space, Λ Beem–Garner's operator (a weighted sum of ghost bilinears) and $E = [\Lambda, \mathbf{Q}]$. The identities are: $\rho\,\mathbf{Q} = (-1)^{\mathrm{gh}} E\,\rho$ and $B(Eu, v) = i(-1)^{\mathrm{gh}(u)} B(u, Ev)$ on relative states.

File `VOA/Examples/GhostConjEndpoint.lean`.

```

def GhostConjBE : Prop :=
  ∀ (n j g : ℤ), ∀ u ∈ relativeWeight n, u ∈ brstDeg bgGh ((j, g), (n : ℂ)) →
    ∀ v ∈ relativeWeight n,
      ghBBRST (brstE n u) v = Complex.I * (-1 : ℂ) ^ g * ghBBRST u (brstE n v)
```

From the mathematics to the Lean statement

`matterRho bRealStructure` and `matterB bForm` are the product conjugation and form of the three matter factors; `ghostConj`, `ghostB` those of the ghosts. `brstQ` is $\mathbf{Q}$ and `brstE n` $= \Lambda\mathbf{Q} - \mathbf{Q}\Lambda$ (`BGPackageReduced.lean`); `bgGh` is the standard ghost R-grading. Both are statements about the BRST operator only: `hA` does not occur.

Physical meaning

E is (up to normalization) the second supercharge $\mathbf{Q}^+$, the $SU(2)_R$ partner of the BRST charge. The identities say that the anti-unitary conjugation exchanges the two supercharges, and that E is skew for the bilinear pairing with the phase i; together they make $\mathbf{Q}^+$ the adjoint partner required by Definition 28.19.

What the machine verified

Definitions (docstrings: “OPEN (numerically verified)”; both are proved, next theorem).

Theorem 28.34 (The ghost-conjugation identities hold). *Both identities of Definition 28.33 hold.*

Files `VOA/Examples/BRSTConjIdentityProved.lean`, `BRSTConjIdentityBE.lean`.

```
theorem ghostConjRhoD_proved : GhostConjRhoD := ghostConjRhoD_of_cubic
↪  ghostCubicConj_proved

theorem ghostConjBE_proved : GhostConjBE := by
```

From the mathematics to the Lean statement

Exactly the two identities, with no hypotheses. The first is the composition of a cubic-term identity (`ghostCubicConj_proved`) with the reduction `ghostConjRhoD_of_cubic`.

Proof on paper. Both sides are computed on the explicit ghost Fock basis tensored with matter: the matter part uses $\rho_M J_n^a \rho_M^{-1} = -J_n^{a*}$ and the adjointness of current modes, the ghost part the explicit action of ρ_G and Λ on b- and c-modes. The cubic ghost term needs a separate computation (`BRSTConjIdentityCubic*.lean`). The identities were first checked numerically to 10^{-12} at relative weights 2, 3, 4 (project computations outside the library); the Lean proof is independent of that. □

Physical meaning

The gauged theory is $SU(2)_R$-covariant: CPT conjugation maps the BRST charge to its R-partner.

What the machine verified

Proved outright; axioms standard (re-checked: `ConcreteHodge.ghostConjRhoD_proved`, `ConcreteHodge.ghostConjBE_proved`).

Theorem 28.35 (The metric on the coset representatives). *Let* $\mathrm{rep}(x) = \phi_{\mathrm{coset}}(x) \otimes \mathbf{1}_U \otimes \mathbf{1}_{\mathrm{gh}}$ *be the explicit representative of a universal Virasoro state* $x \in V(-\frac{22}{5}, 0)$. *With* $B = B_M \otimes B_G$ *and* $\rho = \rho_M \otimes \rho_G$*: the vacuum representative has norm one;* L_{-i-2} *and* L_{i+2} *are adjoint on representatives; and* ρ *fixes the representative of every Virasoro word.*

```
def repVec (x : VirUniv leeYangC) : BRSTSpace := cosetToComplex (virasoroToCoset x)

def RepVacuumNormalized : Prop := ghBBRST (repVec (vacVec leeYangC)) (repVec (vacVec
 ↪  leeYangC)) = 1

def RepCreationAdjoint : Prop :=
  ∀ (i : ℕ) (u v : VirUniv leeYangC),
    ghBBRST (repVec (Lop leeYangC (-(i : ℤ) - 2) u)) (repVec v) =
      ghBBRST (repVec u) (repVec (Lop leeYangC ((i : ℤ) + 2) v))

def RepWordsReal : Prop :=
  ∀ w : List ℕ, ghConjBRST (repVec (negWordVir leeYangC w)) = repVec (negWordVir leeYangC
   ↪  w)

theorem repVacuumNormalized_proved : RepVacuumNormalized := by

theorem repCreationAdjoint_proved : RepCreationAdjoint := by

theorem repWordsReal_proved : RepWordsReal := by
```

From the mathematics to the Lean statement

`repVec x` is `cosetToComplex (virasoroToCoset x)`, i.e. $\mathrm{rep}(x)$. `vacVec leeYangC` is the vacuum of $V(c, 0)$, `Lop c m` the Virasoro mode L_m on $V(c, 0)$, `negWordVir c w` the creation word of the list w. Exactly the three statements.

Why these three suffice. The harmonic representative of a class differs from $\mathrm{rep}(x)$ by a boundary, and the form pairs harmonic vectors trivially with boundaries (`HarmonicMetricGeneric.lean`), so the three statements hold for harmonic representatives too (`harmonicVacuumNormalized_of_rep` and companions). A bilinear form on the weight spaces of $V(c, 0)$ that is normalized on the vacuum and for which L_{-m} is adjoint to L_m is the canonical form (`LeeYangShortcut.weightForm_eq_Bsimp`, re-checked); and a conjugation fixing all words is the partition-basis conjugation. These are hypotheses `hB`, `hh` of Theorem 28.27.

Proof on paper. The representative is a matter state tensored with vacua, so all three are statements about the form and conjugation of $A \otimes B \otimes U$ on states of the form $x \otimes \mathbf{1}$. The vacuum norm is the product of the normalized vacuum norms. The coset Virasoro modes are built from the modes of ω_A, ω_B and the diagonal currents, whose adjoints are again of the same type (invariance of each factor form), and the coset projection commutes with them. The conjugation fixes ω_{coset} (it fixes each Sugawara vector) and commutes with all modes, so it fixes every word. □

Physical meaning

The inner product of Lee–Yang states computed in the gauged theory equals the intrinsic Lee–Yang (BPZ) inner product: the stress tensor's Hermiticity survives gauging.

What the machine verified

All proved outright; axioms standard (re-checked: the three `rep*_proved`). The rung `ConcreteHodge.leeYang_gradedUnitary_of_affine_levelOne` assembles everything of this section; its remaining inputs are the invariant-symbol and character statements, treated next (re-checked: standard axioms).

Theorem 28.36 (The Virasoro classes are filtered). *Assume* GU(A). *On the actual complex, at every conformal weight n and for every p, the cohomology class of a universal Virasoro word of length $\le p$ (through the coset stress tensor, Theorem 28.16) has a representative of $2R \in [0, 2p]$ at ghost number zero. This is step (b) of Remark 28.1.*

Files `VOA/Examples/LeeYangShortcutAssembly.lean`, `InvariantSymbolBridge.lean`.

```
def UniversalClassFiltered (S : ConcreteKahlerGeometry) : Prop :=
  ∀ n (hp : IsPosOn (S.geometry n).P τ) p,

      (S.model n hp).cohomFilt (KahlerComplex.rowSet (Finset.Icc 0 (2 * (p : ℤ))) 0)

abbrev endpointKahler (hA : GradedUnitary affineForm affineRealStructure affineFlag) :
    ConcreteKahlerGeometry :=
  sp2Kahler hA LevelOneUnitary.bUnitary bgPG_pos bgGh bgGh_isStd
    ((bgGhostRemainderI hA ghostConjRhoD_proved ghostConjBE_proved).pkg
      LevelOneUnitary.bUnitary).sp2

theorem endpointKahler_filtered (hA : GradedUnitary affineForm affineRealStructure
↪  affineFlag) :
    UniversalClassFiltered (endpointKahler hA) :=
```

From the mathematics to the Lean statement

`ConcreteKahlerGeometry` is a weightwise Kähler geometry on the relative complex (Definition 28.39); `S.model n hp` is the Kähler complex at weight n once the positivity `hp` of the modified form is supplied. `universalPrefix p n` is the span of the universal Virasoro words of length $\le p$ in $V(c,0)_n$ (`LeeYangShortcutRelative.lean`), `modelUniversalClass S n hp` sends a word to its cohomology class, and `cohomFilt (rowSet (Icc 0 (2p)) 0)` is the span of the classes with a representative in bidegrees $(j, 0)$, $0 \le j \le 2p$. `endpointKahler hA` is the Kähler geometry actually used by the headline: the Beem–Garner package of this section with the standard ghost grading `bgGh`, the proved unitarity of B and the proved ghost-conjugation identities. So `endpointKahler_filtered hA` is exactly the hypothesis `hfiltered` of Theorem 28.27 in the application. It is conditional on `hA` only because the complex's R-grading is built from `hA` (Definition 28.31).

Proof on paper. The proof (`universalClassFiltered_of_generators`, with the two generator tests of `interpretedGenerators_std`) is an induction on word length. The vacuum class is represented by the vacuum of the BRST space, which sits in bidegree $(0, 0)$ for the standard ghost grading. If the class of a word x of length $\le p$ has a representative in $2R \le 2p$, then the class of $L_{-i-2}x$ has one in $2R \le 2p + 2$: the coset Virasoro mode is built from the Sugawara vectors of A and B and the diagonal currents, each of corrected degree at most one (Definition 28.4), so it raises R by at most one. This is where the convention that ω costs one letter, not two, is used. Positivity of the modified form

at every weight, needed to speak of the Kähler complex at all, is `concreteKahler_weakGU` applied to `hA`, the unitarity of B and `auxiliaryGradedUnitary`. □

Physical meaning

The coset stress tensor has R-charge one, like the four-dimensional stress tensor it models, so a product of p of its modes has R-charge at most p.

What the machine verified

Proved; axioms standard (re-checked: `ConcreteHodge.endpointKahler_filtered`). Conditional on `hA`, as displayed.

Dead ends in the concrete package

- c_0 **breaks goodness off relative states.** With c_0 placed at $R = 0$, the cubic terms $c_0 c_{-j} b_j$, $c_{-i} c_i b_0$ preserve R; the fix is the shifted $R' = R + \frac{1}{2} n_{c_0}$ and the restriction to relative states (Theorem 28.32).
- **No global transposes of b_0 (conditional on `hA`).** `antighostZero_transpose_inconsistent` (`BGPackageReduced.lean`) takes `hA`, a unitarity datum `hB : Unitary BB RB` for B, a positive ghost form with a standard ghost grading, and then a bilinear form on the BRST space for which the antighost zero modes have a global transpose of the expected sign and which is compatible with the positive form at weight zero; from all of these it concludes `False` (it forces the vacuum to have norm zero). So the theorem proves "GU(A) implies that no such form exists"; if GU(A) failed it would say nothing. Under the standing hypothesis of the headline, the package must therefore be built on c_0-free (relative) states.
- **The full ghost current is not skew.** Once c_0 is present, the full ghost current is not skew for the ghost form (a pairing sum equals 4 instead of 0); the skewness lemma is proved on the projection to relative states instead.
- **Colour-uniform ghost forms and the old remainder.** See Warning 28.3.1.

28.9 The Koszul step: leading cohomology is a space of invariants

At ghost number zero the leading differential Q^- has two parts: a Koszul differential d_K that contracts the auxiliary creation modes of U against the antighosts b^a_{-n}, and a Chevalley–Eilenberg part d_{CE} that inserts a ghost c^a_n ($n \geq 0$) together with the positive mode J^a_n of $\mathrm{gr}\, A \otimes B$. Since the auxiliary U is freely generated (PBW), d_K is exact in positive antighost number, and the spectral sequence of the c-count collapses onto one row: $H^0(Q^-)$ is the kernel of the positive-mode action on $\mathrm{gr}\, A \otimes B$.

Theorem 28.37 (Leading cohomology equals invariants). *Let C be a Kähler complex whose pieces of bidegrees $a-(1,1)$, a, $a+(1,1)$ are modelled by the diagonals of a Koszul–CE bicomplex, with Koszul exactness in positive antighost degree, and suppose the zeroth Koszul homologies of the two lowest rows are identified with N and N^κ so that the induced CE map is $v \mapsto (\rho_k v)_k$. Then $H(Q^-)_a \cong \bigcap_k \ker \rho_k$, and harmonic vectors of bidegree a have dimension at most $\dim \bigcap_k \ker \rho_k$.*

From the mathematics to the Lean statement

`B : LeadingBicomplex ℂ X Y Z G` is the bicomplex: `X p`$= T^{p,p}$ (ghost number 0), `Y p`$= T^{p+1,p}$ (-1), `Z p`$= T^{p,p+1}$ $(+1)$, `G p`$= T^{p,p+2}$, where $T^{p,q}$ has p antighosts and q ghosts; its fields are the six components of d_K, d_{CE}, the used components of $(d_K+d_{CE})^2=0$, and Koszul exactness at two positions (`LeadingKoszulBicomplex.lean`). `B.D0`, `B.Dm` are the total differentials out of and into ghost number 0 (on the *product* totalization `∀ p, X p`). `LeadModel` identifies the three bidegrees of the Kähler complex with these totalizations, intertwining Q^-. `B.KH0`, `B.KH1` are the zeroth Koszul homologies of rows 0 and 1; `B.dbar` the map induced by d_{CE}. `invariants ρ` is $\bigcap_k \ker \rho_k$. The `finrank` statement additionally takes `M : LeadModel C B a`.

Proof on paper. (`LeadingBicomplex.equivKer`.) A ghost-number-zero cocycle $(x_p)_p$ with $x_p \in T^{p,p}$ has leading component x_0 whose class in H_0^K(row 0) is killed by $\bar d_{CE}$; conversely, given such a class, Koszul exactness lets one solve for $x_1, x_2, \dots$ in turn (a zigzag), and two solutions differ by a coboundary, again by exactness. So $H^0 \cong \ker \bar d_{CE}$. With the identifications, $\ker \bar d_{CE} = \{v \in N : \rho_k v = 0\ \forall k\}$. The dimension bound combines this with Theorem 28.21. □

Physical meaning

The "Gauss law" at leading order: after the auxiliary sector and the antighosts cancel in pairs (Koszul), the surviving gauge-invariant states are those annihilated by the positive gauge-current modes.

What the machine verified

Proved; axioms standard (re-checked: `LeadingKoszul.LeadingBicomplex.equivKer`). Unconditional for the abstract datum.

Theorem 28.38 (Koszul exactness and the symbol maps on the actual complex)**.** *On the actual relative complex at every weight N at which the modified Hermitian form is positive definite (hypothesis* `hp`*; under* GU(A) *this holds at every weight), the blocks of Q^- by antighost number satisfy Koszul exactness in positive antighost degree, and the two symbol maps from the antighost-free blocks onto* $\mathrm{gr}_r A \otimes B$ *exist, with kernels the d_K-boundaries and intertwining d_{CE} with the positive-mode action.*

Files `VOA/Examples/KoszulResidualExact.lean`, `KoszulResidualSymbolMaps.lean`.

```
theorem kExact_endpoint {n : ℤ} (hp : IsPosOn ((endpointKahler hA).geometry n).P τ)
    (a : ℤ × ℤ) : (endpointBlocks hA n hp).KExact a :=

def koszulResidual_endpoint : EndpointKoszulResidual hA :=
  koszulResidual_of_symbols hA (symbolResidual_endpoint hA)
```

From the mathematics to the Lean statement

`endpointKahler hA` is the actual Kähler geometry (assembled from the package of Section 28.8), `endpointBlocks hA n hp` its block decomposition by antighost number, and `KExact a` the two exactness statements of the bicomplex at bidegree a (`KoszulConcreteBlocks.lean`). `EndpointKoszulResidual hA` bundles, for every weight and degree, Koszul exactness and the two symbol maps π_0, π_1 (`KoszulConcreteEndpoint.lean`); `hA` is a section variable. **Hypotheses.** `kExact_endpoint` takes `hA` and, explicitly, `hp : IsPosOn ((endpointKahler hA).geometry n).P τ`, positivity of the modified form at weight n (the Kähler complex at weight n is only defined once `hp` is given). `hp` is not an extra assumption in the headline: it is discharged at every weight from `hA`, the unitarity of B and `auxiliaryGradedUnitary` by `concreteKahler_weakGU` (as in the proof of Theorem 28.36). `koszulResidual_endpoint` is a `def` whose type is a structure of proofs (`EndpointKoszulResidual hA`), not a `theorem`; constructing it is the proof. `hA` itself is needed only because the complex's grading is built from it.

Proof on paper. The auxiliary factor U is the universal affine VOA, whose PBW basis (Chapter 3, now a theorem) makes it a free polynomial algebra in the creation modes; d_K is the Koszul differential of the regular sequence of these modes against the antighosts, hence exact in positive degree, uniformly at each weight (`KoszulResidualPBW.lean`, `KoszulResidualHomotopy.lean`). The symbol maps send a b-free state to its U-vacuum component's class in $\mathrm{gr}\,A$. □

Physical meaning

The auxiliary current algebra is "pure gauge": its oscillators cancel against the antighosts, leaving the gauge-invariant content of $A \otimes B$.

What the machine verified

Proved, conditional on `hA` and (for `kExact_endpoint`) on the weightwise positivity `hp`, which itself follows from `hA`; axioms standard (re-checked: `KoszulResidual.kExact_endpoint`, `KoszulResidual.koszulResidual_endpoint`).

Definition 28.39 (The gap-two coefficient and the invariant-symbol statements). $G_r(n)$ is the coefficient of z^n in $z^{r(r+1)}/\prod_{j=1}^{r}(1-z^j)$, i.e. the number of partitions of n into exactly r parts, all ≥ 2, with consecutive parts differing by at least 2. In the Kähler coordinate $j = 2R$ put $\mathrm{lc}(n, j) = G_{j/2}(n)$ for even $j \geq 0$ and 0 otherwise. The *invariant-symbol bound* for a concrete Kähler geometry says $\dim H(Q^-)_{(j,0)} \leq \mathrm{lc}(n, j)$ at every weight n; the *dimension* statement says equality. The *Lee–Yang PBW character* says $\dim F_p L_n = \sum_{j=0}^{2p} \mathrm{lc}(n, j)$.

  ∀ n (hp : IsPosOn (S.geometry n).P ⊤) j,
    Module.finrank ℂ ((S.model n hp).leadCohom (j, 0)) ≤ leadingCoefficient n j
```

From the mathematics to the Lean statement

`gapTwoCoefficient n r` counts tuples $(a_1, \dots, a_r)$ with $r(r+1) + \sum_j j\,a_j = n$: a_j is the multiplicity of the part j in a partition into parts $\le r$, and adding $r(r+1) = 2 + 4 + \cdots + 2r$ turns it into a gap-two partition with r parts (the standard bijection). The bound `Fin (n.toNat + 1)` on multiplicities is harmless because $j\,a_j \le n$. `ConcreteKahlerGeometry` is a weightwise Kähler geometry on `relativeWeight n` whose differential is the actual BRST differential and whose ghost coordinate is the actual ghost number (`LeeYangTransferAssemblyInputs.lean`); `S.model n hp` is the Kähler complex once positivity `hp` is supplied. In the headline the geometry is the concrete `endpointKahler hA`; nothing is free. The docstrings still say "OPEN"; see Section 28.14.

Physical meaning

$\sum_r G_r(n) z^n$ is the generating function $\sum_r z^{r(r+1)}/(z)_r$ of the second Rogers–Ramanujan identity, $= \prod_{n\ge 0}(1 - z^{5n+2})^{-1}(1 - z^{5n+3})^{-1}$, the Lee–Yang vacuum character; G_r refines it by the number of stress-tensor modes, i.e. by R-charge.

What the machine verified

Definitions. `gapTwoCoefficient_vacuum`: $G_0(0) = 1$. `LeeYangPBWCharacter` is proved (Theorem 28.54); the symbol bound is proved for the actual geometry inside the headline's proof (Remark 28.41).

Theorem 28.40 (The cyclic-evaluation bound). *Let V be a vector space with an injective linear map $\mathrm{ev} : V \to \mathbb{C}[a_1, a_2, \dots]$ (oscillators, a_m of weight m) landing in weighted degree $n - r(r+1)$, whose image is annihilated, under the pairing $\langle F, P\rangle = F(2\partial_{a_1}, 4\partial_{a_2}, \dots)P$, by every element of matching degree of the Cartan ideal $I_r = \ker\big(\mathbb{C}[H_1, H_2, \dots] \to \mathbb{C}[s_1, \dots, s_r]^{S_r},\ H_m \mapsto 2\sum_i s_i^m\big)$. Then $\dim V \le G_r(n)$.*

File `VOA/Examples/InvariantSymbolCyclic.lean`.

```
theorem finrank_le_gapTwoCoefficient_of_cyclicEvaluation
    {V : Type*} [AddCommGroup V] [Module ℂ V] (N : ℤ) (r : ℕ)

      IsWeightedHomogeneous modeWeightZ F (N - r * (r + 1)) → modePairing F (ev x) = 0) :
    finrank ℂ V ≤ LeeYangTransferAssembly.gapTwoCoefficient N r := by
```

From the mathematics to the Lean statement

`MvPolynomial ℕ ℂ` with variable m of weight $m+1$ (`modeWeightZ`) models both $\mathbb{C}[H_1, H_2, \dots]$ and $\mathbb{C}[a_1, a_2, \dots]$. `IsWeightedHomogeneous modeWeightZ P d` says P has weighted degree d. `cartanIdeal r` is I_r and `modePairing` the pairing. Exactly the theorem.

Proof on paper. The pairing is perfect in each weighted degree, so the annihilator of $(I_r)_d$ has dimension $\dim(\mathbb{C}[H]/I_r)_d$. The quotient $\mathbb{C}[H]/I_r$ is the image of $H_m \mapsto 2\sum_i s_i^m$, which is the whole ring of symmetric polynomials in r variables (power sums generate it over $\mathbb{C}$); its degree-d part has dimension the number of partitions of d into at most r parts, equivalently into parts $\le r$. With $d = n - r(r+1)$ this is $G_r(n)$. An injective map into that annihilator bounds $\dim V$. □

Physical meaning

In the level-one lattice picture, a charge-r invariant symbol is detected by its overlap with the r-fermion (charge r) Fock sector; the Cartan relations express that r fermions have only symmetric functions of their r positions as degrees of freedom.

What the machine verified

Proved outright; axioms standard (re-checked). Unconditional.

Remark 28.41 (How inequality (e) is assembled)**.** To apply Theorem 28.40 to $V = H(Q^-)_{(2r,0)} \cong (\mathrm{gr}_r A \otimes B)_n^{\mathfrak{sl}_2[t]}$ (Theorem 28.37) the library builds ev as follows. (i) A *cyclic dual vector* on $\mathrm{gr}_r A$: a functional β such that $x \neq 0$ implies $\beta(J_{m_1}^{a_1} \cdots J_{m_\ell}^{a_\ell} x) \neq 0$ for some word of non-negative modes. It is obtained from strictness of the Adamović symbol map (Section 28.10), `GrJetStrict`, and the proved cyclicity of the jet ring (Theorem 28.44). (ii) Heisenberg separation of the charge sectors of $B = L_1$ (`levelOneHeisenbergSeparation`), proved from two facts: in charge $2r$ the bottom energy r^2 is one-dimensional (`levelOneBottomDetected`), and Heisenberg-singular vectors of charge $2r$ sit at energy r^2 (`levelOneHeisenbergSingular`), the latter using $\omega = \frac{1}{4}h_{-1}^2\mathbf{1}$. (iii) Combining, an invariant $\sum_i x_i \otimes y_i$ is evaluated by pairing with the cyclic vector on the A side and the Cartan monomials on the B side, and invariance under $\mathfrak{sl}_2[t]$ forces the Cartan relations (`CyclicEval*.lean`). All three are proved; the assembled result is that `LeadingInvariantSymbolBound (endpointKahler hA)` holds, inside the proof of the rung `SymbolModel.leeYang_gradedUnitary_of_affine_jetStrict`.

28.10 The jet ring and the Adamović symbol

The invariant-symbol bound needs a concrete model of $\mathrm{gr}_r A$, the associated graded of the corrected filtration, together with its $\mathfrak{sl}_2[t]$-action. Adamović's free-field realization of $L_{-4/3}(\mathfrak{sl}_2)$ suggests the model: $e \mapsto u^2$, $f \mapsto -v^2$, $h \mapsto -2uv$, and the Sugawara field $\mapsto -(u'v - uv')$, for two commuting formal series $u(s), v(s)$. The library does not use a free-field realization; it proves directly that this assignment defines an isomorphism on associated graded pieces.

Definition 28.42 (The jet ring and its image A_r)**.** Let $\mathbb{C}[u_j, v_j]_{j\ge 0}$ be the polynomial ring in two sequences of variables and $u(s) = \sum_j u_j s^j$, $v(s) = \sum_j v_j s^j$. Put $X = u^2, Y = uv, Z = v^2, J = u'v - uv'$ (power series in s with polynomial coefficients), and let A_r be the span of all products of r coefficients of X, Y, Z, J. The conformal grading of A_r puts u_j, v_j in degree j and adds r. The loop algebra $\mathfrak{sl}_2[s]$ acts by derivations: $e_m : v \mapsto s^m u$, $f_m : u \mapsto s^m v$, $h_m : u \mapsto s^m u,\ v \mapsto -s^m v$ (and $e_m u = f_m v = 0$).

Files `VOA/Examples/SymbolModelJet.lean`, `SymbolModelJetImage.lean`, `SymbolModelJetCyclic.lean`.

```

From the mathematics to the Lean statement

`MvPolynomial (Fin 2 × ℕ) ℂ`: variables u_j =`X (0, j)`, v_j =`X (1, j)`. `JetSer` is power series in s with coefficients in the jet ring, `dS` is d/ds. `genCoeff g a` is the s^a-coefficient of X, Y, Z, J for $g = 0, 1, 2, 3$. `genSpan ^ r` is the r-th power of a subspace in the algebra (the span of r-fold products). `jetDer k` is the derivation of $\mathbb{C}[u_j, v_j]$ determined by its values on variables (`jetDerVal`, which encodes the formulas above with `k = (a, m)`). `jetDeg r d` is the subspace of A_r of jet weight $d - r$, i.e. conformal weight d.

Physical meaning

u, v are the two components of an $\mathfrak{sl}_2$ doublet of commuting fields (a "$\beta\gamma$-type" pair seen classically); X, Y, Z are the classical (arc-space) images of the currents and J is the image of the stress tensor. A_r is the classical phase space of r letters.

What the machine verified

Definitions.

Definition 28.43 (Word symbols; descent; strictness)**.** The *symbol* of a corrected letter (g, m) (Definition 28.4) is the s^m-coefficient of X, $-Z$, $-2Y$ for $g = e, f, h$ and of $-J$ for $g = \omega$; the symbol of a word is the product. The *descent* statement in degree r asks for a linear map σ on F_rA vanishing on $F_{r-1}A$ and sending the class of each length-r word to its symbol. *Strictness* in degree r asks for an injective, degree-preserving map $\mathrm{gr}_r A \to A_r$ intertwining the non-negative modes J_m^a with the derivations of Definition 28.42; a *leading-symbol map* is the same with "surjective" in place of "injective".

abbrev GrA (r : ℕ) : Type := aFil r ⧸ grKer r
```

From the mathematics to the Lean statement

`aFil p` is $F_pA = \sum_n F_pA_n$ (all weights at once), `aFilLT r` is $F_{r-1}A$, `GrA r` is $F_rA/F_{r-1}A = \mathrm{gr}_r A$. `grRho r k` is the induced action of J^a_m, $m \geq 0$, on $\mathrm{gr}_r A$ (well defined because the flag is good), `jetImgRho r k` the derivation restricted to A_r, and `grDeg r d` the weight-d part of $\mathrm{gr}_r A$. `wordClass w hw` is the class in F_rA of the corrected word w; `∘ₗ` is composition of linear maps. A `structure` with data fields (`σ`, `f`, `g`) is a `Type`, not a `Prop`: having an element means having the map with its properties.

Why "descent" is the hard part. The words of length r span F_rA modulo $F_{r-1}A$ but satisfy relations in A (the maximal ideal is nonzero: there is a singular vector at weight 3). Descent says that every relation among words, modulo shorter words, is a relation among their symbols. This is the content of a free-field realization, and it is where the paper proof cites Adamović.

Physical meaning

Descent is the classical limit of the free-field realization: it says that the Schur operators of (A_1, D_3), at leading order in the R-filtration, are polynomials in two classical fields u, v, and that every null relation of the chiral algebra holds classically.

What the machine verified

Definitions (the docstrings say "OPEN"; all three are realized below for every r).

Theorem 28.44 (Cyclicity of the jet ring). *Let* ev *be evaluation at the base point* $(u, v) = (0, 1)$, *i.e.* $u_j \mapsto 0$, $v_0 \mapsto 1$, $v_j \mapsto 0$ $(j \geq 1)$. *If a jet polynomial* Q *satisfies* $\mathrm{ev}(D_{k_1} \cdots D_{k_\ell} Q) = 0$ *for every word* $D_{k_1} \cdots D_{k_\ell}$ *in the non-negative-mode derivations, then* $Q = 0$.

File `VOA/Examples/SymbolModelJet.lean`.

```
theorem jet_cyclic (Q : JetPoly)
    (hQ : ∀ l : List (Fin 3 × ℕ), evalBase (word jetRho l Q) = 0) : Q = 0 := by
```

From the mathematics to the Lean statement

`word jetRho l` is the composite of the operators `jetRho k`, $k \in l$ (`CyclicEvalCore.lean`); `evalBase` is evaluation at `baseVal`, which is 1 at v_0 and 0 elsewhere. Exactly the theorem.

Proof on paper. Shift $v_0 \mapsto v_0 + 1$, so that the base point becomes the origin. The derivations become derivations whose action on the variables has a "Taylor" form: from $f_0 u = v = 1 + \cdots$, words of derivations can produce any monomial's dual, so a polynomial with all iterated derivatives vanishing at the origin has all coefficients zero (`exists_taylor`). The library's proof is an algebraic Taylor argument replacing the orbit-and-density argument of the source note. □

Physical meaning

The orbit of the point $(u, v) = (0, 1)$ under the loop group $SL_2[[s]]$ is dense in the space of jets: a classical observable that vanishes along the whole orbit vanishes identically.

What the machine verified

Proved outright; axioms standard (re-checked). The base point is $(0, 1)$, not the $(1, 0)$ of the source note; this matches the charge convention of the dual vectors used later (file docstring).

Theorem 28.45 (The Adamović symbols descend, in every degree). *For every noncritical $k \notin \mathbb{N}$ and every VOA ideal I of $V^k(\mathfrak{sl}_2)$ that avoids conformal weight 0: if $y \in I$ and (y, Q) is in the span of the pairs (word, symbol) of length-r corrected words, modulo $F_{r-1}V^k \times 0$, then $Q = 0$. Consequently, at $k = -4/3$ the word symbols descend to $\mathrm{gr}_r A$ for every r.*

Files `VOA/Examples/AdamovicSymbolWords.lean`, `AdamovicDescCyclic.lean`.

```
def symMod (q : ℕ) : Submodule ℂ (WakModule k × JetPoly) :=
  symPairs k hk q ⊔ (lowerP k hk q).prod ⊥

theorem symbol_eq_zero_of_mem (hkN : ∀ i : ℕ, k ≠ i)
    (hI : (affineSl2VOA_closed k hk).IsIdeal I) (hIN : I ≤ offZero k hk) (r : ℕ)
    {y : WakModule k} {Q : JetPoly} (hyQ : (y, Q) ∈ symMod k hk r) (hy : y ∈ I) : Q = 0 :=

def wordSymbolDescends (r : ℕ) : WordSymbolDescends r where
```

From the mathematics to the Lean statement

`symPairs k hk q` is the span of the pairs (state of w, symbol of w) over words of length q, and `lowerP k hk q` is $F_{q-1}V^k$; `symMod` is their sum ($\sqcup$) in $V^k \times \mathbb{C}[u_j, v_j]$, with `.prod ⊥` meaning "paired with 0". In `symbol_eq_zero_of_mem` the section variables are `k`, `hk : k + 2 ≠ 0` and an ideal `I`; `hkN : ∀ i : ℕ, k ≠ i` says $k \notin \mathbb{N}$; `hI` says I is a VOA ideal; `hIN : I ≤ offZero k hk` says I is contained in $\bigoplus_{n \neq 0} V_n^k$. The conclusion `Q = 0` is the single-valuedness of the symbol modulo I. `wordSymbolDescends r` *constructs* the descent datum of Definition 28.43 in every degree r, at $k = -4/3$ and I the maximal ideal: the map σ is the graph of the relation (fields proved; we show only the header).

Proof on paper. (1) *A detecting functional.* Put $E = e_1$. For (y, Q) in the span, $E^r y \equiv (-1)^r c_r \,\mathrm{ev}(Q)\mathbf{1}$ modulo $\bigoplus_{n \neq 0} V_n$, with $c_r = \prod_{i<r}(i+1)(k-i)$. On a word, ev(symbol) is $(-1)^r$ for $f_{-1}^r\mathbf{1}$ and 0 otherwise, and $E^r f_{-1}^r \mathbf{1} = c_r \mathbf{1}$ by the $\mathfrak{sl}_2$-triple $(e_1, h_0 + k, f_{-1})$; every other word is sent

off weight 0 or into weight 0 with nonzero h_0-charge, where it vanishes since $V_0 = \mathbb{C}\mathbf{1}$. (2) *Detection on the ideal.* If $y \in I$ then $E^r y \in I \subseteq \bigoplus_{n\neq 0} V_n$, so $\mathrm{ev}(Q) = 0$; $c_r \neq 0$ because $k \notin \mathbb{N}$. (3) *Cyclicity.* The span is stable under the pairs of operators $(J^a_\mu, D_{(a,\mu)})$ (a mode on the state, the derivation on the symbol), and I is stable under J^a_μ; so $\mathrm{ev}(D_{k_1}\cdots D_{k_\ell} Q) = 0$ for every word, and Theorem 28.44 gives $Q = 0$. (4) *Descent.* The image of the span in $(V/I) \times \mathbb{C}[u_j, v_j]$ is therefore the graph of a linear map on $F_r A$, which is the descent datum. □

Physical meaning

The vacuum expectation value of e^r_1 against a state detects its "all-f" component; invariance under the current algebra then propagates this single measurement to all of the state's classical shadow. This replaces the free-field realization that the physics literature (Adamović) uses.

What the machine verified

Proved outright; axioms standard (re-checked: `AdamovicSymbol.Desc.symbol_eq_zero_of_mem`, `AdamovicSymbol.Desc.wordSymbolDescends`). This is the last input discharged before the headline.

Example 28.46 (The singular vector has vanishing degree-two symbol). At $k = -4/3$, V^k has the weight-3 singular vector $20e_{-3} - 12e_{-2}h_{-1} - 6h_{-2}e_{-1} + 36e_{-1}e_{-1}f_{-1} + 9e_{-1}h_{-1}h_{-1}$ (on $\mathbf{1}$; Chapter 9, Theorem 9.28). Rewriting $2e_{-1}f_{-1} - h_{-2} + \frac{1}{2}h^2_{-1} = \frac{4}{3}L_{-2}$ (the Sugawara relation at $k = -4/3$; a hand computation, not formalized) gives the corrected form $20e_{-3} - 12e_{-2}h_{-1} - 6h_{-2}e_{-1} + 24e_{-1}L_{-2} + 18e_{-1}h_{-2}$, whose length-two part must have zero symbol if descent holds. It does:
File `VOA/Examples/AdamovicSymbolDescent.lean`.

```
theorem singular_symbol_vanishes :
    -12 • wordSym [(.current 0, 1), (.current 2, 0)]
      - 6 • wordSym [(.current 2, 1), (.current 0, 0)]
      + 24 • wordSym [(.current 0, 0), (.sugawara, 0)]
      + 18 • wordSym [(.current 0, 0), (.current 2, 1)] = (0 : JetPoly) := by
```

In jet terms this is the identity $XJ = X'Y - XY'$ at $s = 0$. A sanity check, proved by computation.

Definition 28.47 (The jet character bound and the fermionic series). The *jet character bound* asks, for every N, that $[q^N]\big((q^3;q^3)_\infty/(q;q)_\infty\big)^3 \le \sum_{r\le N} \dim A_{r,N}$. The *fermionic jet series* is $\sum_{r\ge 0} q^r \big(\sum_{k=0}^{2r} \begin{bmatrix} 2r \\ k \end{bmatrix}_q\big)/(q)_r$, and the *fermionic identity* says it equals $\big((q^3;q^3)_\infty/(q;q)_\infty\big)^3$.

Files `VOA/Examples/JetStrictEndpoint.lean`, `JetProductCount.lean`, `JetProductEndpoint.lean`, `AffineSl2BoundaryVacuumCharacter.lean`.

```
def JetProductBound : Prop :=
  ∀ N : ℕ, PowerSeries.coeff N (AffineSl2BoundaryCharacter.product 1) ≤
    ∑ r ∈ Finset.range (N + 1), (Module.finrank ℂ (jetDeg r (N : ℤ)) : ℚ)

def jetTerm (r : ℕ) : PowerSeries ℚ :=
  PowerSeries.X ^ r * (∑ k ∈ Finset.range (2 * r + 1), gaussian PowerSeries.X (2 * r) k) *
    reciprocalQFactorial r

def jetSeries : PowerSeries ℚ := VOA.LocallyFinitePowerSeriesSum.sum jetTerm

def JetFermionicIdentity : Prop := jetSeries = AffineSl2BoundaryCharacter.product 1

def product (m : ℕ) : PowerSeries ℚ :=
  (PowerSeries.expand (denominator m) (by dsimp [denominator]; omega) euler) ^ 3 *
    reciprocalEuler ^ 3
```

From the mathematics to the Lean statement

`PowerSeries.coeff N` is $[q^N]$. `product m` is $(\mathrm{expand}_{2m+1}\,\phi)^3\cdot\phi^{-3}$ with $\phi=(q;q)_\infty$ (`euler`) and `reciprocalEuler`$=\phi^{-1}$; for $m=1$ (`denominator 1= 3`) it is $((q^3;q^3)_\infty/(q;q)_\infty)^3$. `gaussian PowerSeries.X n k` is the Gaussian binomial, `reciprocalQFactorial r` is $1/(q)_r$, and `LocallyFinitePowerSeriesSum.sum` is the sum of a family of power series of which only finitely many contribute to each coefficient. The coefficients are in $\mathbb{Q}$ (exact rationals).

Physical meaning

$((q^3;q^3)_\infty/(q;q)_\infty)^3$ is the vacuum character of $L_{-4/3}(\mathfrak{sl}_2)$ (Chapter 20), i.e. the Schur index of the (A_1,D_3) theory. The fermionic series counts the same states by number of letters: a fermionic (quasi-particle) formula.

What the machine verified

Definitions (docstring of `JetProductBound`: "OPEN"; it is proved, next theorem).

Theorem 28.48 (The fermionic jet identity, and strictness). *(1)* $\sum_{r\ge0}q^r\sum_{k=0}^{2r}\begin{bmatrix}2r\\k\end{bmatrix}_q/(q)_r=\big((q^3;q^3)_\infty/(q;q)_\infty\big)^3$. *(2)* $[q^N]$ *of the fermionic series is at most* $\sum_{r\le N}\dim A_{r,N}$*; hence the jet character bound holds. (3) Given leading-symbol maps in every degree* $r\ge1$ *and the jet character bound, strictness holds in every degree* $r\ge1$*; with Theorem 28.45 this gives strictness outright.*

Files `VOA/Examples/JetFermionicIdentity.lean`, `JetProductCount.lean`, `JetStrictEndpoint.lean`.

```
theorem jetFermionicIdentity : JetFermionicIdentity := by

theorem coeff_jetSeries_le (N : ℕ) :
    PowerSeries.coeff N jetSeries ≤
      ∑ r ∈ Finset.range (N + 1), (Module.finrank ℂ (jetDeg r (N : ℤ)) : ℚ) := by

def grJetStrict_of_leadingSymbol_product (sym : ∀ r, JetLeadingSymbol (r + 1))
    (chi : JetProductBound) (r : ℕ) : GrJetStrict (r + 1) :=
  grJetStrict_succ_of_leadingSymbol sym (jetCharacterBound_of_product chi) r
```

From the mathematics to the Lean statement

Exactly (1), (2) and (3). `grJetStrict_of_leadingSymbol_product` produces `GrJetStrict (r + 1)` for every r from `sym` and `chi`; it goes through `jetCharacterBound_of_product`, which uses the Arakawa–Dai character theorem `AffineSl2BoundaryCharacter.character_eq_product 1` (Chapter 20, Theorem 20.18): $\dim A_N=[q^N]((q^3;q^3)_\infty/(q;q)_\infty)^3$. The leading-symbol maps come from the descent data by `WordSymbolDescends.toJetLeadingSymbol` (surjective because word symbols span A_r), with degrees 0 and 1 done by hand (`jetLeadingSymbol_one`).

Proof on paper. (1) Multiply both sides by $(q;q)_\infty^3$. The left side becomes a double sum which a Wilf–Zeilberger certificate (`wzSum_eq`) and a moment identity (`euler_cube_mul_pairSum`) reduce to Jacobi's identity for $(q;q)_\infty^3$ (`jacobi_cube`); the right side is $(q^3;q^3)_\infty^3$. It is the case $k=1$, $t=q$, $z=1$ of a theorem of Chern, Tran and Wakhare combined with the Jacobi cube; the Lean proof uses no Bailey pairs. (2) A_r is a free module over a ring of symmetric functions with fibre of dimension 4^r (`block_indep`, `local_indep`), which gives a lower bound for $\dim A_{r,N}$ by the r-th term of the series. (3) The squeeze: a leading-symbol map $g_r:\mathrm{gr}_r A_N\twoheadrightarrow A_{r,N}$ gives $\sum_r\dim A_{r,N}\le\sum_r\dim\mathrm{gr}_r A_N=\dim A_N=[q^N]((q^3;q^3)/(q;q))^3\le\sum_r\dim A_{r,N}$, so each g_r is bijective. □

Physical meaning

The number of Schur operators of (A_1, D_3) built from r letters equals the number of classical jet polynomials of degree r: the R-filtered Schur index is computed by the classical theory, with no quantum corrections to the counting.

What the machine verified

(1) and (2) proved outright; (3) proved from its hypotheses, and those are discharged in the headline. Axioms standard (re-checked: `JetFermionic.jetFermionicIdentity`).

Dead ends for strictness

Recorded in the project notes, with counterexamples: (i) the subalgebra generated by X, Y, Z alone is too small (dimension 8 against 9 at weight 2), so the arc-space or Li-filtration route cannot give strictness and the generator J (the stress tensor) is essential; (ii) a leading-monomial basis of A_r overcounts (78 against 81 at weight 5); (iii) A_r is not free over $\mathbb{C}[X_a, Z_a]$; (iv) there is no naive multiplicity-≤ 2 monomial basis, because $X_0 Z_0 = Y_0^2$. These are hand or numerical findings, not machine-checked statements.

28.11 The Lee–Yang vacuum character

Definition 28.49 (The two sides of the character identity). The *Rogers–Ramanujan lower bound* for Lee–Yang says $\sum_r G_r(N) \leq \dim L_N$ for every N. The *Rocha-Caridi* number is $\mathrm{rc}(N) = \sum_{k\in\mathbb{Z}} (-1)^k p\big(N - \frac{k(5k+3)}{2}\big)$; the *Rocha-Caridi lower bound* says $\mathrm{rc}(N) \leq \dim L_N$, and the *Rocha-Caridi character* says equality. The *Gram-rank bound* says $\mathrm{rc}(N) \leq \operatorname{rank} G_N$, where G_N is the $p(N) \times p(N)$ Shapovalov matrix of the Verma module $M(-\frac{22}{5}, 0)$ at level N.

Files `VOA/Examples/LeeYangCharacterReduction.lean`, `RRLowerLimit.lean`, `RRLowerAndrews.lean`, `RRLowerReduction.lean`, `RRLowerGram.lean`.

```
def LeeYangRRLowerBound : Prop :=
  ∀ N : ℕ, (∑ r ∈ Finset.range (N + 1), gapTwoCoefficient (N : ℤ) r) ≤
    Module.finrank ℂ ((virasoroSimple leeYangC).grading (N : ℤ))

def rc (N : ℕ) : ℤ := ∑ k ∈ Ico (-(N : ℤ) - 1) ((N : ℤ) + 1), sgn k * pp ((N : ℤ) - ee k)

def ee (k : ℤ) : ℤ := k * (5 * k + 3) / 2

def sgn (k : ℤ) : ℤ := if k % 2 = 0 then 1 else -1

def LeeYangRochaCaridiLowerBound : Prop :=
  ∀ N : ℕ, rc N ≤ (Module.finrank ℂ ((virasoroSimple leeYangC).grading (N : ℤ)) : ℤ)

def LeeYangRochaCaridiCharacter : Prop :=
  ∀ N : ℕ, (Module.finrank ℂ ((virasoroSimple leeYangC).grading (N : ℤ)) : ℤ) = rc N

def LeeYangGramRankBound : Prop :=
  ∀ N : ℕ, rc N ≤ ((vermaGramMatrix leeYangC 0 N).rank : ℤ)
```

From the mathematics to the Lean statement

`Ico (-N - 1) (N + 1)` is the integer interval $[-N-1, N+1)$; terms outside it vanish. `sgn k`$=(-1)^k$, `ee k`$= k(5k+3)/2$ (an integer), `pp M`$= p(M)$, zero for $M < 0$ (`RRLowerQBinomial.lean`). `vermaGramMatrix c h N` (namespace `InverseDS.VirasoroVerma`) is the explicit Shapovalov

matrix of $M(c,h)$ in the PBW basis at level N; Gram matrices of Verma modules are introduced in Chapter 7, Definition 7.27. `virasoroSimple leeYangC` is L. Exactly the definitions; the casts (`... : ℤ`) are only there to compare naturals with integers.
Sanity check. $\mathrm{rc}(N) = p(N) - p(N-1) - p(N-4) + p(N-7) + p(N-13) - \cdots$; at $N=6$: $11-7-2=2$, at $N=8$: $22-15-5+1=3$, matching Example 28.2.

Physical meaning

$\mathrm{rc}(N)$ is the Rocha-Caridi character of the $(2,5)$ vacuum module: the Verma character minus the two embedded singular submodules at levels 1 and 4, plus the next ones, and so on (the Feigin–Fuchs resolution). $\sum_r G_r(N)$ is the fermionic (Rogers–Ramanujan) form of the same character.

What the machine verified

Definitions (all docstrings: "OPEN"; all are proved, Theorem 28.53).

Theorem 28.50 (Gap-two spanning and the upper bound). *In L, the length-$\le p$ step of the PBW flag at weight N is spanned by the gap-two words of length $\le p$ (words $L_{-n_1}\cdots L_{-n_q}\mathbf{1}$ with $n_1 \ge n_2+2 \ge \dots$ and $n_q \ge 2$). Hence* $\dim F_p L_N \le \sum_{j=0}^{2p} \mathrm{lc}(N,j)$.

Files `VOA/Examples/LeeYangCharacterSpanning.lean`, `LeeYangCharacterReduction.lean`.

```
def GapTwo (w : List ℕ) : Prop := w.IsChain (fun a b => b + 2 ≤ a)

noncomputable def gapSpan (ℓ N : ℕ) : Submodule ℂ (VirUniv leeYangC) :=
  Submodule.span ℂ
    {x | ∃ u : List ℕ, GapTwo u ∧ energyVir u = N ∧ u.length ≤ ℓ ∧ negWordVir leeYangC u =
     ↪ x}

theorem goodFil_leeYang_eq_gapSpan (p N : ℕ) :
    goodFil leeYangC p (N : ℤ) = (gapSpan p N).map (maxIdealVir leeYangC).mkQ := by

theorem finrank_pieceIn_le (n : ℤ) (p : ℕ) :
    Module.finrank ℂ ((virGradedFlag leeYangC).pieceIn p n) ≤
      ∑ j ∈ Finset.Icc 0 (2 * (p : ℤ)), leadingCoefficient n j := by
```

From the mathematics to the Lean statement

A word is a list $w = [i_1,\dots,i_q]$ standing for $L_{-(i_1+2)}\cdots L_{-(i_q+2)}\mathbf{1}$ (`negWordVir`, Chapter 7); `GapTwo w` says consecutive entries drop by at least 2 (`List.IsChain`). `goodFil leeYangC p N` is the image of the length-$\le p$ words in L_N (Definition 19.19); `(maxIdealVir leeYangC).mkQ` the quotient map. Exactly the theorem.

Proof on paper. Straightening: modulo the maximal ideal, which contains the level-4 singular vector and hence the relation $L_{-2}^2 \equiv \frac{3}{5}L_{-4}$ and all its descendants, any product $L_{-a}L_{-b}$ with $a-b \in \{0,1\}$ inside a word can be rewritten as a combination of words that are smaller in a suitable order (the sum of squares of the parts strictly increases, `sq_spread`), without increasing the length. Induction on that order. The count of gap-two words of length $\le p$ is $\sum_{r\le p} G_r(N)$. □

Physical meaning

The Lee–Yang null vector $(L_{-2}^2 - \frac{3}{5}L_{-4})\mathbf{1}$ is the "exclusion rule" of a quasi-particle description: two stress-tensor modes cannot be closer than distance two.

What the machine verified

Proved outright; axioms standard (re-checked: `LeeYangCharacter.goodFil_leeYang_eq_gapSpan`, `LeeYangCharacter.finrank_pieceIn_le`).

Theorem 28.51 (Rogers–Ramanujan in Rocha-Caridi form). *For every N, $\sum_{r\le N} G_r(N) = \mathrm{rc}(N)$. Hence $\dim L_N \le \mathrm{rc}(N)$.*

File `VOA/Examples/RRLowerReduction.lean`.

```
theorem sum_gapTwoCoefficient_eq_rc (N : ℕ) :
    ((∑ r ∈ Finset.range (N + 1), gapTwoCoefficient (N : ℤ) r : ℕ) : ℤ) = rc N := by

theorem finrank_le_rc (N : ℕ) :
    (Module.finrank ℂ ((virasoroSimple leeYangC).grading (N : ℤ)) : ℤ) ≤ rc N := by
```

From the mathematics to the Lean statement

Exactly the theorem; the left side is cast to $\mathbb{Z}$. The second statement is the case $p = N$ of Theorem 28.50 rewritten with the first.

Proof on paper. Andrews' polynomial identity: for each n, a finite sum of Gaussian binomials over j (the gap-two side, truncated) equals an alternating sum of Gaussian binomials (the Rocha-Caridi side, truncated). Let $n \to \infty$ coefficientwise: for $n = 7N + 7$ every Gaussian coefficient that contributes to q^N has stabilized, giving $\sum_j p_{\le j}(N - j(j+1)) = \sum_k (-1)^k p(N - k(5k+3)/2)$, which is the claim. No Jacobi triple product and no infinite product are needed. □

Physical meaning

The second Rogers–Ramanujan identity, in the form "fermionic sum = bosonic alternating sum": the two standard ways of writing the Lee–Yang vacuum character agree.

What the machine verified

Proved outright; axioms standard (re-checked).

Lemma 28.52 (Corank is at most the order of vanishing). *Let $P(c)$ be a square matrix of polynomials whose value at c_0 is symmetric. Then $(c - c_0)^{\dim \ker P(c_0)}$ divides $\det P(c)$.*

File `VOA/Examples/LYGramRank.lean`.

```
theorem pow_dvd_det_of_ker {ρ : Type} [Fintype ρ] (P : Matrix ρ ρ ℂ[X]) (c0 : ℂ)
    (hsym : (P.map (Polynomial.eval c0)).transpose = P.map (Polynomial.eval c0)) :
    ∃ Q : ℂ[X], P.det =
      (X - Polynomial.C c0) ^ Module.finrank ℂ (LinearMap.ker (P.map (Polynomial.eval
        ↪ c0)).mulVecLin) * Q := by
```

From the mathematics to the Lean statement

`ℂ[X]` is the polynomial ring in one variable (here the variable is called `X`); `P.map (Polynomial.eval c0)` is $P(c_0)$; `.mulVecLin` the associated linear map; `∃ Q, ... = (X - C c0)^k * Q` is divisibility. Exactly the lemma.

Proof on paper. Choose a basis whose first k vectors span $\ker P(c_0)$. In that basis (a constant change of basis, which changes det by a nonzero constant) the first k columns of $P(c)$ vanish at c_0, so each is divisible by $c - c_0$; pull out $(c - c_0)^k$. □

Physical meaning

The Jantzen-type principle: along a one-parameter deformation of the central charge, null states can only appear where the Kac determinant vanishes, and at least to the order of the number of null states.

What the machine verified

Proved; axioms standard (re-checked as part of `leeYangGramRankBound_holds`).

Theorem 28.53 (The Lee–Yang vacuum character). $\mathrm{rc}(N) \le \operatorname{rank} G_N \le \dim L_N$ *for every* N*; hence* $\dim L_N = \mathrm{rc}(N) = \sum_r G_r(N)$*, and the Rogers–Ramanujan lower bound holds.*

Files `VOA/Examples/RRLowerGram.lean`, `LYGramRank.lean`. File `VOA/Examples/LYGramRankCharacter.lean`.

```
theorem gramRank_le_finrank (N : ℕ) :
    (vermaGramMatrix leeYangC 0 N).rank ≤
      Module.finrank ℂ ((virasoroSimple leeYangC).grading (N : ℤ)) := by

theorem leeYangGramRankBound_holds : LeeYangGramRankBound := by

theorem leeYangRochaCaridiCharacter_holds : LeeYangRochaCaridiCharacter :=

theorem leeYangRRLowerBound_holds : LeeYangCharacter.LeeYangRRLowerBound :=
```

From the mathematics to the Lean statement

No hypotheses. `gramRank_le_finrank`: the irreducible quotient $L(c,0)$ of the Verma module has dimension $\operatorname{rank} G_N$ at level N (Theorem 7.18), and it is a composition factor of the simple VOA's weight space with multiplicity one, via the local composition series (`virLocalCompositionSeries`). The three `_holds` theorems are the definitions of Definition 28.49 (and of `LeeYangRRLowerBound`).

Proof on paper. Deform along the curve $c(t) = 13 - 6t - 6/t$, $h = 0$, which passes through $c = -22/5$ at $t_0 = 2/5$; on the whole curve $L_{-1}\mathbf{1}$ is singular. Choose, at t_0, a complement f of the descendants $L_{-\lambda}L_{-1}\mathbf{1}$ at level $1+m$, and let $D(c)$ be the Gram matrix of f. A factorization identity of the Kac determinant along the curve (`FFLower.curve_identity`) expresses $\det D(c(t))$ through Kac factors whose orders of vanishing at t_0 are computed exactly (`LYGramOrders.lean`: `aLY m`, `bLY m`). Lemma 28.52 bounds $\dim\ker D(c_0)$ by that order, so $\operatorname{rank} G_{1+m} \ge \operatorname{rank} D(c_0) \ge |f| - \mathrm{ord} = p(1+m) - p(m) - \mathrm{aLY}(m) + \mathrm{bLY}(m)$, and the exact count `rc_eq_orders` identifies the right side with $\mathrm{rc}(1+m)$. Combined with Theorem 28.51 this gives equality. □

Physical meaning

This is Feigin–Fuchs/Rocha-Caridi for the simplest non-unitary minimal model, proved from the Kac determinant alone: the vacuum module of Lee–Yang has exactly the null states that the Kac determinant predicts along a generic deformation, and no accidental ones.

What the machine verified

Proved outright; axioms standard (re-checked: `RRLower.leeYangGramRankBound_holds`, `leeYangRochaCaridiCharacter_holds`, `leeYangRRLowerBound_holds`). This is a result of independent interest: the vacuum character of $M(2,5)$.

Theorem 28.54 (The Lee–Yang PBW character, filtration level by filtration level). *For every weight N and every p,* $\dim F_pL_N = \sum_{s\le p} G_s(N)$*; that is, the statement* `LeeYangPBWCharacter` *of Definition 28.39 holds. It is equivalent to the Rogers–Ramanujan lower bound.*

File `VOA/Examples/LeeYangCharacterReduction.lean`.

```
theorem leeYangPBWCharacter_iff_lowerBound : LeeYangPBWCharacter ↔ LeeYangRRLowerBound :=
```

From the mathematics to the Lean statement

Both sides are the `Prop`s of Definitions 28.39 and 28.49; the equivalence has no hypotheses. Since `leeYangRRLowerBound_holds` proves the right side (Theorem 28.53), `leeYangPBWCharacter_iff_lowerBound.mpr leeYangRRLowerBound_holds` proves `LeeYangPBWCharacter`; this is the input `hcharacter` of Theorem 28.27 at the level of L, i.e. step (f) of Remark 28.1. The statements use `Module.finrank`, which is 0 on an infinite-dimensional space; here every weight space of L is finite-dimensional because the finitely many gap-two words span it (Theorem 28.50), so `finrank` is the true dimension.

Proof on paper. ($\Rightarrow$) Take $p = N$: $F_NL_N = L_N$, so $\dim L_N = \sum_{s\le N} G_s(N)$. ($\Leftarrow$) By Theorem 28.50 the gap-two words of weight N span L_N, and there are $\sum_s G_s(N)$ of them; the lower bound says $\dim L_N$ is at least that number, so they are linearly independent, hence a basis. Then the gap-two words of length $\le p$ are linearly independent, and they span F_pL_N (Theorem 28.50 again), so $\dim F_pL_N$ is their number $\sum_{s\le p} G_s(N)$. □

Physical meaning

The gap-two words are a quasi-particle basis of the Lee–Yang vacuum module, and the length of a word is its R-charge: the refined character counts Lee–Yang states by R-charge.

What the machine verified

Proved outright; axioms standard (re-checked: `LeeYangCharacter.leeYangPBWCharacter_iff_lowerBound`). With Theorem 28.53, `LeeYangPBWCharacter` is proved, unconditionally.

Dead ends for the Lee–Yang character

(i) Maps *out of* $V(c,0)$ (including into Fock spaces) only bound $\dim L$ from above. (ii) A single Jantzen deformation or the Kac determinant along a generic line is too weak: a generic line overshoots by $\dim(M(7)+M(13))$; the special curve $h = h_{1,1}$, on which $L_{-1}\mathbf{1}$ stays singular, is essential. (iii) A 5-adic leading-order argument fails at $N = 10$, and a modular-ODE route was not completed. (Project records; not machine-checked.)

28.12 The files of this chapter, described collectively

The table lists the file families of this chapter with their role. "Infrastructure" means: gradings on tensor products, mode computations, bookkeeping of weights, restrictions of operators to subspaces, and the intermediate rungs of the ladder. Every family is in the import closure of the umbrella `VOA` (checked by parsing the import graph of the state this chapter was written against).

family	files	role
`Sl2SemiInfinite*`	34	ghosts, ghost currents at level 4, BRST current and charge, $\mathbf{Q}^2 = 0 \iff k = -4$, relative subcomplex, gradings (Section 28.4)
`Sl2Coset*`	22	the three factors, diagonal action, coset subspace and VOA, coset-to-cohomology map, vacuum class (Sections 28.4, 28.5)
`GradedUnitaryCohomology*`	4	abstract Kähler complex, harmonic bound, GU data, the quartet example (Section 28.6)
`LeeYangCosetTransfer*`	4	Hodge isomorphism, dimension squeeze, filtered-isomorphism transfer (Sections 28.6, 28.7)
`LeeYangTransferAssembly*`	9	the concrete affine and auxiliary data, the relative weight complex, the superseded assembly (Sections 28.2, 28.3)
`LeeYangShortcut*`	12	Virasoro image, uniqueness of the normalized form, class-family theorem, shortcut assembly (Sections 28.5, 28.7)
`ConcreteGood*`, `BRSTGoodness*`	8+8	interpreted R-grading of the actual complex and its goodness (Section 28.8)
`ConcreteHodge*`, `BRSTKahler*`, `BGPackage*`	6+5+6	product form, Kähler identities, Λ, the Beem–Garner package and its earlier variants (Section 28.8)
`GhostConj*`, `BRSTConjIdentity*`	5+11	ghost conjugation and the two conjugation identities (Section 28.8)
`HarmonicMetric*`	6	metric on harmonic and explicit representatives (Section 28.8)
`LevelOneUnitary*`, `LevelOneHeis*`	4+3	unitarity of L_1; Heisenberg separation of its charge sectors (Sections 28.8, 28.9)
`LeadingKoszul*`, `KoszulConcrete*`, `KoszulResidual*`	7+3+18	abstract Koszul–CE collapse; block decomposition of the actual complex; Koszul exactness and symbol maps (Section 28.9)
`InvariantSymbol*`, `CyclicEval*`	3+6	cyclic-evaluation bound and its assembly with the level-one facts (Section 28.9)
`SymbolModel*`, `JetStrict*`, `JetProduct*`, `JetFermionic*`, `Adamovic*`	8+2+7+3+5	jet ring, cyclicity, strictness squeeze, jet-image lower bound, fermionic identity, Adamović symbols and their descent (Section 28.10)
`LeeYangCharacter*`, `RRLower*`, `LYGram*`	5+7+4	gap-two spanning, Andrews' identity, Rocha-Caridi, Kac-determinant order count (Section 28.11)

No file of this chapter contains `sorry`, `admit` or `native_decide` (a text search finds these words only in two docstrings, as ordinary English).

28.13 Verification record

Records of earlier builds. When the headline first compiled, the library still had the project axiom `VOA.pbw`, and `#print axioms` of the headline was `[propext, Classical.choice, Quot.sound, VOA.pbw]`; `VOA.pbw` entered through `Desc.wordSymbolDescends`. The aggregate `lake build` was green then and in later aggregate builds that include these files (13 543, 13 672 and 13 868 jobs); these are records of the project's builds, not re-run for this edition. The headline is in the library's maintained axiom audit. Since `VOA.pbw` became a theorem, the axiom list is the standard three.

What was re-run for this edition. One scratch file importing `VOA.Examples.AdamovicDescCyclic`, `LeeYangTransferAssembly`, `LeeYangShortcutAssembly`, `InvariantSymbolBridge`, `LeeYangCharacterReduction`, `LYGramRank`, `Sl2SemiInfiniteAnomalyCriterion`, `Sl2SemiInfiniteGhostAffine`, `LeeYangCosetTransferFiltered`, `AffineSl2BoundaryVacuumCharacter` and the Chapter 29 modules `TwoSeriesLeeYang`, `TwoSeriesKoszulLeeYang` and `TwoSeriesGenIncl`, run as `lake env lean -DmaxSynthPendingDepth=3` from the repository root against the build products already in the

checkout (no `lake build` was run). For each of the following 55 declarations it printed `depends on axioms: [propext, Classical.choice, Quot.sound]`, with no error and no `sorryAx`:

```

```

(The namespace `VOA.InverseDS.GradedIsometricEmbedding` of `gradedUnitary_of_filteredIso` is

a historical name; the file `LeeYangCosetTransferFiltered.lean` belongs to this chapter.) The same run printed the type of the headline as

```
VOA.AdamovicSymbol.leeYang_gradedUnitary_of_affine : VOA.GradedUnitary
 ↪  VOA.LeeYangTransferAssembly.affineForm
    VOA.LeeYangTransferAssembly.affineRealStructure VOA.LeeYangTransferAssembly.affineFlag
     ↪  →
  VOA.VirGradedUnitarity.VirGradedUnitary VOA.LeeYang.leeYangC
   ↪  VOA.LeeYangTransferAssembly.leeYangRealStructure
```

so the hypothesis `hA` is its only argument. The build products used are those already in the checkout; they were not rebuilt for this edition, so the result rests on the project's last aggregate build.

Quotations. Every `leancode` block of this chapter was compared, piece by piece with comments and whitespace normalized, with the current Lean sources; all occur verbatim.

28.14 Findings, oddities and Lean defects

No statement-level defect was found: the headline says what the mathematics says, about the intended concrete objects, with its one hypothesis visible. The defects are documentation defects, collected here once. Severities: S1, a statement or definition is wrong or vacuous; S2, a definition is weaker or stronger than its name or the literature, or a hypothesis is redundant; S3, an advertised result is only conditional (a gap); S4, documentation (docstrings, notes) is wrong or stale.

Documentation defects (Lean docstrings and project notes)

1. **(Docstrings, S4) "OPEN" on proved propositions.** The docstrings of the following `Prop`s or structures call them open, although each is proved for the objects used by the headline: `LeeYangRRLowerBound` (`LeeYangCharacterReduction.lean`, "OPEN (classical, not formalized)"); `LeeYangRochaCaridiLowerBound` (`RRLowerReduction.lean`); `LeeYangGramRankBound` and the module docstring of `RRLowerGram.lean`; `LeeYangPBWCharacter` (`LeeYangTransferAssemblyCharacter.lean`); `LeadingInvariantSymbolDimension` and several `OpenInputs` fields (`LeeYangTransferAssemblyInputs.lean`); `RelativeDifferentialGood` (`ConcreteGoodInterpreted.lean`); `GhostConjRhoD`, `GhostConjBE` (`GhostConjEndpoint.lean`); `RepVacuumNormalized`, `RepCreationAdjoint`, `RepWordsReal` (`HarmonicMetricBridge.lean`); `HarmonicVacuumNormalized`, `HarmonicCreationAdjoint`, `HarmonicWordsReal` (`LeeYangShortcutAssembly.lean`); `JetProductBound` and the module docstring (`JetStrictEndpoint.lean`); `JetLeadingSymbol`, `JetCharacterBound` (`JetStrictSqueeze.lean`); `GrJetStrict` (`SymbolModelJetCyclic.lean`); `WordSymbolDescends` and the module docstring (`AdamovicSymbolDescent.lean`); `LevelOneBottomDetected`, `LevelOneHeisenbergSingular` (`CyclicEvalHeisenberg.lean`).

2. **(Docstrings, S4) rung docstrings list proved inputs as open.** `..._wordSymbols_two` (`AdamovicSymbolDegreeOne.lean`), `..._wordSymbols` (`AdamovicSymbolDescent.lean`), `..._wordSymbols_final` (`LYGramEndpoint.lean`) and `..._wordSymbols_rc` (`RRLowerEndpoint.lean`) mark `desc`, `chi`, `lowerRC` "OPEN"; all are proved. The module docstrings of `LeadingKoszulKahler.lean` ("remain to be supplied by a concrete instantiation", with a final `OPEN` comment) and of `InvariantSymbolCyclic.lean` (the physical inputs "are not formalized here") are superseded by `KoszulConcrete*`, `KoszulResidual*` and `CyclicEval*`.

3. **(Name clash, S4)** Warning 28.3.

4. **(Project notes, S4)** Project records written before `VOA.pbw` became a theorem give the headline's axioms as including `VOA.pbw`; that was correct then and is obsolete now (Section 28.13).

Chapter 29

The $(2, 2n+3)$ series: coset transfer of graded unitarity at every boundary level

This chapter was written against an earlier state of the LeanVOA library. It covers the files `VOA/Examples/TwoSeries*.lean` (128 files in this release). Every Lean quotation below was copied from the source of that state, and for this edition the book's automatic check confirms that every one occurs verbatim (up to whitespace and comments) in the source files of this release. What the machine confirmed is collected in one place, Section 29.13.

Conventions for quotations and status boxes.

- *Omitted proofs and docstrings.* A Lean quotation shows a statement, not its proof. A block that ends in `:=` or `:= by` with nothing after it is a statement whose proof is omitted; it is not a truncated quotation. Documentation comments (`/-- ... -/`) are usually omitted; they are not part of the statement.
- *"Axioms standard".* This means that `#print axioms` reports exactly `[propext, Classical.choice, Quot.sound]`, the three standard axioms of Lean's logic (Chapter 1, Section 1.3). Since `VOA.pbw` became a theorem the library has no project axiom at all. A clean axiom list does *not* mean "unconditional": `#print axioms` does not list the explicit hypotheses of a theorem (Section 1.3.4). Every status box below therefore names the hypotheses separately, and the word **unconditional** is reserved for a statement with no hypothesis beyond the natural-number parameters.
- *Re-checked.* Every axiom claim in this chapter was re-run on a scratch file against the library's build products for this edition; the list is in Section 29.13.

Prerequisites. This chapter is the level-generic sequel of Chapter 28, which treats the first member of the series, the Lee–Yang model, in full. We do not re-derive the Lee–Yang chain; we explain what changes when the level moves, and we present in detail the parts that are new. We use without re-development: (1) the graded-unitarity predicate of Arabi Ardehali, Beem, Lemos and Rastelli, its layers and the Virasoro length flag (Chapter 19, Definitions 19.11 and 19.20), the boundary central charges $c_{2,2m+1}$ and their real structures (Definition 19.26, Theorem 19.24); (2) the boundary admissible levels $k_n = -2 + 2/(2n+1)$ of $\mathfrak{sl}_2$, the universal and simple affine VOAs $V^k(\mathfrak{sl}_2)$, $L_k(\mathfrak{sl}_2)$ and their vacuum characters (Chapter 20, Definitions 20.3, 20.4 and 20.5); (3) the Lee–Yang coset chain of Chapter 28: the BRST complex at total level -4, the Beem–Garner Hodge package, the Koszul step, the dimension squeeze, and the Rogers–Ramanujan character. Mathlib

notions (`Submodule`, `Module.finrank`, `Module.rank`, `MvPolynomial`, `PowerSeries`, `Ideal.span`) are explained in plain words the first time they appear. **Reading the Lean.** A reader who has never read Lean should first read the primer of Chapter 1, Section 1.2; the dictionaries below assume it.

What this chapter is about, in one paragraph. For every $n \geq 1$ let $k_n = -2 + \frac{2}{2n+1}$. The *coset* $(L_{k_n}(\mathfrak{sl}_2) \otimes L_1(\mathfrak{sl}_2))/L_{k_n+1}(\mathfrak{sl}_2)$ contains a Virasoro algebra of central charge

$$c_{2,2n+3} \;=\; \frac{3k_n}{k_n+2} + 1 - \frac{3(k_n+1)}{k_n+3} \;=\; 1 - \frac{3(2n+1)^2}{2n+3}, \tag{29.1}$$

the central charge of the non-unitary minimal model $M(2, 2n+3)$. Chapter 28 proved, at $n = 1$ ($k = -4/3$, $c = -22/5$), that *graded unitarity* of the affine VOA implies graded unitarity of the Lee–Yang model. This chapter proves the same implication for every n:

$$\mathrm{GU}\big(L_{k_n}(\mathfrak{sl}_2)\big) \implies \mathrm{GU}\big(M(2, 2n+3)\big) \qquad (n \geq 1), \tag{29.2}$$

as the Lean theorem `VOA.TwoSeries.JetPoincareTwo.twoSeries_gradedUnitary_of_affine_final` (Theorem 29.59). Its only hypothesis is graded unitarity of the affine VOA, which is **open**; the theorem is a *transfer*, not a proof that either side is graded unitary.

Why formalize this. Graded unitarity is the shadow, on a chiral algebra, of unitarity of a four-dimensional $\mathcal{N} = 2$ superconformal field theory. The level-k_n affine VOA is the chiral algebra of the Argyres–Douglas theory (A_1, D_{2n+1}), and $M(2, 2n+3)$ is the chiral algebra of (A_1, A_{2n}); so (29.2) says that a positivity property passes from one family of four-dimensional theories to the other, along the coset. The proof at $n = 1$ (Chapter 28) used one explicit model of the associated graded of $L_{-4/3}$ and one cyclic dual vector. Neither generalizes (warning on p. 1578). The general proof needed four new ingredients, each of independent interest, and each formalized here with no hypothesis: the vacuum characters of all $M(2, 2n+3)$ via the Andrews–Gordon identity; a jet model of the associated graded of L_{k_n} with the Chern–Tran–Wakhare fermionic character; a Drinfeld–Sokolov "slice map" with the descending half of Arakawa's theorem; and an ideal-membership theorem for the n-equal arrangement (block generators span the relevant ideal).

Remark 29.1 (The logical arc and the ledger)**.** Write $\mathrm{GU}(A)$ for graded unitarity of the affine factor $A = L_{k_n}(\mathfrak{sl}_2)$ (with its canonical form, compact conjugation and corrected flag, Definition 29.6) and $\mathrm{GU}(T)$ for that of the target $T = L(c_{2,2n+3}, 0)$ (partition-basis real structure, length flag). The Lean proof of (29.2) is the chain

(1) $\mathrm{GU}(A) \wedge \mathrm{Hodge} \wedge \mathrm{Squeeze(coeff)} \implies \mathrm{GU}(T)$;
(2) $\big(\dim \mathcal{J}_{r,N} \leq \mathrm{coeff}(N,r)\big) \wedge \big(\sum_{r\leq p} \mathrm{coeff}(N,r) \leq \dim F_pT_N\big) \implies \mathrm{Squeeze(coeff)}$;
(3) $\sum_{r\leq p} g_n(N,r) \leq \dim F_pT_N$ (take coeff $= g_n$);
(4) strict model maps $\wedge$ model socle data $\implies$ socle data of $\mathrm{gr}_r A \implies \dim \mathcal{J}_{r,N} \leq g_n(N,r)$;
(5) $\mathrm{Detect}_n \wedge \mathrm{ModelChar}_n \implies$ strict model maps;
(6) slice map $\wedge$ SliceArakawa $\wedge$ VirSymbol $\implies \mathrm{Detect}_n$;
(7) n-equal arrangement inclusion $\implies$ jet-ideal Poincaré lemma $\implies$ model socle data. (29.3)

Step (1) is Theorem 29.11, with the Hodge package supplied by Theorem 29.12; (2) is Theorem 29.15; (3) is Theorem 29.27; (4) is Section 29.6 (Theorems 29.33 and 29.31); (5) is Theorem 29.39, with $\mathrm{ModelChar}_n$ proved in Theorem 29.41; (6) is Section 29.7, all three inputs proved; (7) is Sections 29.6.5 and 29.8, the arrangement inclusion proved in Theorem 29.58. Here $\mathcal{J}_{r,N}$ is the space of $\mathfrak{sl}_2[t]$-invariant tensors of weight N in $\mathrm{gr}_r A \otimes L_1(\mathfrak{sl}_2)$ (Definition 29.13), F_pT_N is the length-$\leq p$

part of T_N, and $g_n(N,r)$ is the number of partitions of N into r parts ≥ 2 with $f_m + f_{m+1} \leq n$ (Definition 29.16).

The ledger:

step	form	status
level data, coset charge (29.1)	equality	proved, every n
GU of the auxiliary factor V^{k_U}	predicate	proved, every n ($k_U < -2$)
Hodge package (Beem–Garner)	construction	proved from GU(A), every n
Koszul embedding $H \hookrightarrow \mathcal{J}$	injection	proved from GU(A), every n
vacuum character of $M(2, 2n+3)$	equality	proved, every n (Andrews–Gordon)
refined PBW lower bound	$\leq$	proved, every n
socle-word count = Gordon count	equality	proved, every n
model character bound	$\leq$	proved, every $n \geq 1$ (Bailey chain)
detection (slice map + Arakawa half)	vanishing	proved, every $n \geq 1$
model socle data (transversality; box count)	$\leq$, disjoint	proved, every $n \geq 1$
jet-ideal Poincaré lemma, arrangement inclusion	containment	proved, every $n \geq 1$
GU(A)	predicate	**the one hypothesis; open**

So the headline is `#print axioms`-clean (standard axioms), *conditional on* GU(A) *alone*.

The findings of this chapter, in brief.

1. **The transfer holds at every boundary level.** `twoSeries_gradedUnitary_of_affine_final` (Theorem 29.59) concludes graded unitarity of $M(2, 2m+5)$ from graded unitarity of $L_{-2+2/(2m+3)}(\mathfrak{sl}_2)$, for every $m \in \mathbb{N}$, with no other hypothesis. At $m = 0$ it is the Lee–Yang theorem of Chapter 28 again, by a different route.

2. **Several standalone theorems, all unconditional:** the vacuum character of every $M(2, 2n+3)$ (Theorem 29.26); the model character bound (Theorem 29.41); the descending half of Arakawa's theorem for the Drinfeld–Sokolov slice map, at every level datum whose affine level is not a natural number, hence at every k_n (Theorem 29.51); the generation of $L_N \cap$ (vanishing ideal of the n-equal arrangement) by explicit block generators (Theorem 29.58).

3. **Two declarations share the short name** `twoSeries_gradedUnitary_of_affine`, in different namespaces and with different hypotheses (warning on p. 1567). Neither is the headline. Always read the fully qualified name.

4. **Several docstrings are stale**: they still call "open" inputs that later files prove (warning on p. 1604). The Lean statements are correct; only the prose lags.

5. **What this chapter does not prove**: graded unitarity of any affine VOA, or of any $M(2, 2n+3)$ with $n \geq 1$. Both remain open (Kaufmann's conjecture for the minimal models, Chapter 19).

Notation used in this chapter. The sources use three different indices for the same family; we fix them here.

symbol	meaning
$n \geq 1$	the member index of the series: level $k_n = -2 + \frac{2}{2n+1}$, target $M(2, 2n+3)$. Lean `twoSeriesLevels n`.
$m \geq 0$, $n = m+1$	the index of the headline theorem: level $-2 + \frac{2}{2m+3}$, target $M(2, 2m+5)$. Lean `twoSeriesLevels (m + 1)`. Used to exclude $n = 0$.

symbol	meaning
$c_{2,2j+1}$	$1-\frac{3(2j-1)^2}{2j+1}$, Lean `boundaryCharge j`; so the target is $c_{2,2n+3}$ = `boundaryCharge (n + 1)`, and the field `CosetLevels.m` equals $n+1$.
$q=2n+1$	the denominator of the level; also the formal variable of q-series when no confusion is possible. In Sections 29.5 and 29.6.4 q is the formal variable of power series.
$k=k_n$, k_U	the boundary level and the auxiliary level $k_U=-5-k_n=-3-\frac{2}{2n+1}<-2$.
A, B, U	$A=L_k(\mathfrak{sl}_2)$ (simple), $B=L_1(\mathfrak{sl}_2)$, $U=V^{k_U}(\mathfrak{sl}_2)$ (universal).
T	the target $L(c_{2,2n+3},0)$, the simple Virasoro VOA.
F_pT_N	the span of Virasoro words $L_{-j_1-2}\cdots L_{-j_\ell-2}\lvert 0\rangle$ with $\ell\le p$ and weight N (the length flag, Definition 19.19).
$\mathrm{gr}_r A$	the r-th layer of the corrected PBW filtration of A (Chapter 28).
$\mathcal{J}_{r,N}$	the $\mathfrak{sl}_2[t]$-invariant tensors of weight N in $\mathrm{gr}_r A\otimes B$ (Definition 29.13).
$g_n(N,r)$	the Andrews–Gordon count (Definition 29.16).
R_n	$\mathbb{C}[T_0,T_1,\dots]/(\text{jets of } T^n)$, the arc algebra of $M(2,2n+1)$ (Definition 29.34). Note the shift: R_n belongs to $M(2,2n+1)$, the Drinfeld–Sokolov image of A, not to the target $M(2,2n+3)$.
$S_{n,r}$	the model: products of r model letters in $R_n[u_j,v_j]$ (Definition 29.36).
$e,f,h;J^a_m$	the basis of $\mathfrak{sl}_2$ and the current modes; in Lean the letters are indexed by `Fin 3` with $0=e$, $1=f$, $2=h$, and `J k a m` is the mode J^a_m on V^k.
J_∞	the arc (infinite jet) functor.

29.1 The mathematics

29.1.1 The boundary levels and the $(2,2n+3)$ series

An affine level k of $\mathfrak{sl}_2$ is *admissible* when $k+2=p/p'$ with coprime integers $p\ge 2$, $p'\ge 1$. The admissible levels with the smallest possible numerator, $p=2$, are the *boundary* levels $k=-2+2/p'$; for p' odd we write $p'=2n+1$ and $k_n=-2+2/(2n+1)$. These are the levels of Chapter 20, where the vacuum character of $L_{k_n}(\mathfrak{sl}_2)$ was computed and the VOA was shown to be classically free. Two other levels attach to k_n in this chapter:

- the level k_n+1 of the diagonal $\mathfrak{sl}_2$ inside $L_{k_n}\otimes L_1$, and
- the auxiliary level $k_U=-5-k_n$, chosen so that $(k_n+1)+k_U=-4=-2h^\vee$: the total level at which the semi-infinite BRST charge of $\mathfrak{sl}_2$ squares to zero.

Example 29.2 (Level data for $n=1,2,3$)**.** With $c(k)=3k/(k+2)$ the Sugawara central charge of $\mathfrak{sl}_2$ at level k:

n	k_n	k_n+1	k_U	$c(k_n)$	$c(k_n+1)$	$c_{2,2n+3}$	DS image of A
1	$-4/3$	$-1/3$	$-11/3$	-6	$-3/5$	$-22/5$	$M(2,3)$, $c=0$
2	$-8/5$	$-3/5$	$-17/5$	-12	$-9/7$	$-68/7$	$M(2,5)$, $c=-22/5$
3	$-12/7$	$-5/7$	$-23/7$	-18	$-5/3$	$-46/3$	$M(2,7)$, $c=-68/7$

For $n=2$: $c(-8/5)=3(-8/5)/(2/5)=-12$, $c(-3/5)=3(-3/5)/(7/5)=-9/7$, and $-12+1+9/7=-68/7=1-3\cdot 25/7$. Also $(k_2+1)+k_U=-3/5-17/5=-4$. In general $k_n=-4n/(2n+1)$ and $k_n+2=2/(2n+1)$, so $c(k_n)=3k_n(2n+1)/2=-6n$, and $c(k_n)+1-c(k_n+1)=1-\frac{3(2n+1)^2}{2n+3}$ (Theorem 29.4). The last column is the Drinfeld–Sokolov reduction of A: $H_{DS}(L_{k_n}(\mathfrak{sl}_2))=L(c_{2,2n+1},0)$ (Arakawa), with $c_{\mathrm{DS}}(k)=1-6(k+1)^2/(k+2)$; it reappears in Section 29.7.

Physical meaning

Four-dimensional $\mathcal{N}=2$ superconformal theories have chiral algebras (Beem, Lemos, Liendo, Peelaers, Rastelli and van Rees). The Argyres–Douglas theory (A_1, D_{2n+1}) has flavour symmetry $SU(2)$ and chiral algebra $L_{k_n}(\mathfrak{sl}_2)$; the Argyres–Douglas theory (A_1, A_{2n}) has no flavour symmetry and chiral algebra $M(2, 2n+3)$. Their central charges are $c_{2d} = -12c_{4d}$. The coset of this chapter relates the two families, and the level $-4 = -2h^\vee$ of the BRST step is the level of a gauged $SU(2)$: the coset is, physically, the gauging of the diagonal flavour symmetry with a compensating auxiliary sector.

29.1.2 The coset and its BRST form

The GKO construction says that the commutant of the diagonal $\mathfrak{sl}_2$ in $L_k \otimes L_1$ contains the difference of Sugawara stress tensors $T_{\text{coset}} = T_{(k)} + T_{(1)} - T_{(k+1)}$, a Virasoro field of central charge $c(k) + 1 - c(k+1)$. At admissible $k = -2 + p/p'$ this coset is the minimal model $M(p, p+p')$; at $p = 2$, $p' = 2n+1$ it is $M(2, 2n+3)$. The Lean development never identifies the coset VOA with the minimal model. It works with the *relative semi-infinite BRST complex*

$$C \;=\; \big(A \otimes B \otimes U\big) \otimes \mathcal{G}, \qquad \text{total level } (k+1) + k_U = -4, \tag{29.4}$$

where $\mathcal{G}$ is the bc-ghost system of $\mathfrak{sl}_2$ and $U = V^{k_U}(\mathfrak{sl}_2)$ is universal. The Virasoro algebra maps into $H^0(C)$ through T_{coset}, and its kernel lies in the maximal ideal because the vacuum class survives; so the *simple* quotient $T = L(c, 0)$ is what is reached, with no simplicity statement about the coset needed. This is exactly the architecture of Chapter 28; the level-generic files reproduce it with the numbers $-4/3$, $-11/3$, $-22/5$ replaced by the fields of a structure (Definition 29.3).

29.1.3 What is transferred, and how

Graded unitarity of a VOA W with invariant form B, real structure ρ and filtration F (Chapter 19, Definition 19.11) asks, weight by weight, that the layers $F_p \cap F_{p-1}^{\perp}$ be nondegenerate and that the sign-corrected Hermitian form be positive definite on each layer. The transfer argument of Chapter 28, which this chapter re-runs at every level, has three parts.

1. **Hodge theory.** Positivity of the three factors A, B, U gives a positive Hermitian form on each finite piece of the relative complex C; with the Beem–Garner Kähler package (a BRST adjoint and an $\mathfrak{sp}_2$-type Lefschetz structure) every cohomology class has a unique harmonic representative and the form restricted to harmonic classes is positive in the graded sense. The positivity of A is the hypothesis; the positivity of $B = L_1$ (genuine unitarity) and of U (below the critical level) are theorems.

2. **Squeeze.** The images of Virasoro words of length $\le p$ in H^0 have harmonic representatives of "Kähler degree" $\le 2p$. If one knows that the leading cohomology in Kähler degree $2r$ has dimension at most $\mathrm{coeff}(N, r)$, and that T has at least $\sum_{r \le p} \mathrm{coeff}(N, r)$ independent words of length $\le p$ at weight N, then the two filtrations (length on T, Kähler degree on H^0) coincide dimensionally, and the positivity of harmonic classes is exactly clause (vi) of graded unitarity for the length flag.

3. **The dimension inputs.** (I) the leading cohomology is bounded by an *affine* invariant count (Koszul step); (II) the PBW lower bound is a statement about T alone.

At $n = 1$ both dimension inputs were proved with $\mathrm{coeff}(N, r)$ = the number of partitions of N into r parts differing by at least 2 (Rogers–Ramanujan). For general n the coefficient is the Andrews–Gordon count $g_n(N, r)$, (II) follows from the vacuum character of $M(2, 2n+3)$, and (I) is the hard new input.

29.1.4 What changes with n

ingredient	Lee–Yang ($n = 1$, Chapter 28)	general n (this chapter)
levels	literal $-4/3, -11/3, -22/5$	fields of `CosetLevels`
BRST complex, coset, Hodge, Koszul	concrete files	level-generic ports, same proofs
coefficient coeff(N, r)	parts differing by ≥ 2	Andrews–Gordon count $g_n(N, r)$
character of the target	Rogers–Ramanujan	Andrews–Gordon identity (Sec. 29.5)
model of $\mathrm{gr}_r A$	jet ring of $u^2, uv, v^2, u'v - uv'$	same letters over $R_n = \mathbb{C}[T_j]/(T^n)_\infty$
dual generators	one cyclic vector w_r	a family indexed by socle words
detection	level-one vacuum functional	Drinfeld–Sokolov slice map
commutative algebra	none needed	jet-ideal Poincaré lemma, n-equal arrangement

The new coefficient ring R_n deserves a word. At $n = 1$, $R_1 = \mathbb{C}$ (the jets of T^1 are all the T_j), and the model is the jet ring of the Lee–Yang chapter. For $n \geq 2$ the stress-tensor letter of the model carries a nilpotent "tail" $T_j \in R_n$: the model knows that A reduces, under Drinfeld–Sokolov, to $M(2, 2n + 1)$, whose arc algebra is R_n (classical freeness, Chapter 20).

29.2 The level data

The whole level-generic development is parametrized by one structure that bundles the four levels and every arithmetic fact about them that any later proof uses. This is a design decision worth understanding: the Lee–Yang files of Chapter 28 were written with literal numbers ($-4/3$, $-11/3$, $-22/5$), and every place where a proof used arithmetic ("$-4/3 + 1 + (-11/3) = -4$") is now a field of the structure.

Definition 29.3 (Coset level data)**.** A *coset level datum* consists of complex numbers k_A (the level of the boundary factor), k_{act} (the index of its current action), k_U (the auxiliary level), a real number $k_U^{\mathbb{R}}$, a target central charge c, and a natural number m, such that: $k_{\mathrm{act}} = k_A$; $k_A + 2 \neq 0$; $\overline{k_A} = k_A$; $k_U = k_U^{\mathbb{R}}$ and $k_U^{\mathbb{R}} < -2$; $k_U + 2 \neq 0$; $k_{\mathrm{act}} + 3 \neq 0$; $k_{\mathrm{act}} + 1 + k_U = -4$; $\frac{3k_A}{k_A+2} + 1 - \frac{3(k_{\mathrm{act}}+1)}{k_{\mathrm{act}}+3} = c$; and $c_{2,2m+1} = c$.

```

From the mathematics to the Lean statement

`structure ... where` declares a record type; each line `name : type` is a field. Fields whose type is a proposition (`kAct_eq`, `aNoncritical`, ...) are *proofs* that the record must carry, so an inhabitant of `CosetLevels` is a tuple of numbers *together with* proofs of the listed identities. `starRingEnd ℂ` is complex conjugation, so `aReal` says $k_A \in \mathbb{R}$. `(kUr : ℂ)` is the coercion $\mathbb{R} \hookrightarrow \mathbb{C}$. `boundaryCharge m` is $c_{2,2m+1} = 1-3(2m-1)^2/(2m+1)$ (Chapter 19, Definition 19.26).
Why two copies of the level. `kA` is the level at which the carrier L_{k_A} is built, `kAct` the number that indexes its current action in the diagonal sum. They are provably equal (`kAct_eq`). The duplication exists only to make the Lee–Yang instance reproduce the existing concrete objects *definitionally*: there the carrier was built at `level 1` (an expression equal to $-4/3$) and the action at the literal `-4 / 3`. Mathematically it is one level.
Each hypothesis. $k_A + 2 \neq 0$, $k_U + 2 \neq 0$, $k_{\text{act}} + 3 \neq 0$: the three Sugawara constructions (levels k_A, k_U, $k_A + 1$) are non-critical. $k_A \in \mathbb{R}$: needed for the compact real structure on A. $k_U < -2$ real: needed for the auxiliary positivity (Theorem 29.7). The sum $= -4$: nilpotency of the BRST charge. `charge`: the coset central charge is c. `boundary`: c is a boundary minimal-model charge, which is what selects the real structure on the target. Nothing in the record is a hidden assumption about any VOA; it is pure arithmetic, and it is inhabited for every n (Definition 29.5), so it is not vacuous.
Index. The field `m` is the index of c in the family $c_{2,2m+1}$; for the n-th member of the series it is $n + 1$ (Notation table).

Physical meaning

A coset level datum is the list of numbers that make a gauging consistent: the gauged diagonal $SU(2)$ current algebra sits at level $k + 1$, the auxiliary sector at k_U, and their sum must cancel the ghost contribution -4 (the level-matching, or anomaly-cancellation, condition of a G/G-type BRST reduction). The charge field is the GKO central-charge bookkeeping $c_{\text{coset}} = c_{\text{UV}} - c_{\text{gauged}}$.

What the machine verified

Definition. Inhabited for every n (below), so no theorem quantifying over it is vacuous.

Theorem 29.4 (The coset central charge). *For every $n \in \mathbb{N}$, with $k = k_n = -2 + \frac{2}{2n+1}$,*

$$\frac{3k}{k+2} + 1 - \frac{3(k+1)}{k+3} \;=\; c_{2,2n+3} \;=\; 1 - \frac{3(2n+1)^2}{2n+3}.$$

File `VOA/Examples/TwoSeriesLevels.lean`.

```
theorem twoSeries_charge (n : ℕ) :
    3 * level n / (level n + 2) + 1 - 3 * (level n + 1) / (level n + 1 + 2) =
      boundaryCharge (n + 1) := by
```

From the mathematics to the Lean statement

`level n` is $k_n = -2 + 2/(2n+1)$ as a complex number (Chapter 20, Definition 20.3; `level_eq` restates it with the denominator written out). `boundaryCharge (n + 1)` is $c_{2,2(n+1)+1} = c_{2,2n+3} = 1 - 3(2n+1)^2/(2n+3)$. Division in $\mathbb{C}$ is total (with $x/0 = 0$), so one must check that no denominator vanishes: $k_n + 2 = 2/(2n+1) \neq 0$ and $k_n + 3 = (2n+3)/(2n+1) \neq 0$ (`diag_noncritical`); hence the identity is the genuine rational identity. Same as the textbook statement, for every $n \in \mathbb{N}$ including $n = 0$ ($k_0 = 0$, $c_{2,3} = 0$: the trivial coset $L_0 \otimes L_1/L_1$).

Proof on paper. Put $q = 2n+1$. Then $k+2 = 2/q$, $k = -2(q-1)/q$, $k+1 = (2-q)/q$, $k+3 = (q+2)/q$. So $3k/(k+2) = -3(q-1)$ and $3(k+1)/(k+3) = 3(2-q)/(q+2)$. Hence the left side is $-3q + 3 + 1 - \frac{3(2-q)}{q+2} = \frac{(4-3q)(q+2)-6+3q}{q+2} = \frac{-3q^2+q+2}{q+2}$, and $1 - \frac{3q^2}{q+2} = \frac{q+2-3q^2}{q+2}$, the same. □

Physical meaning

The GKO formula for the central charge of $(\widehat{\mathfrak{su}}(2)_k \times \widehat{\mathfrak{su}}(2)_1)/\widehat{\mathfrak{su}}(2)_{k+1}$, here continued to the negative fractional levels of the Argyres–Douglas chiral algebras. At $n = 1$ it is the familiar $-6 + 1 + 3/5 = -22/5$ of the Lee–Yang edge singularity.

What the machine verified

Proved, unconditional. Axioms standard (re-checked).

Definition 29.5 (The level data of the series). For $n \in \mathbb{N}$, `boundaryFamilyLevels n` is the datum $k_A = k_{\mathrm{act}} = k_n$, $k_U = -5 - k_n$, $k_U^{\mathbb{R}} = -3 - 2/(2n+1)$, $c = c_{2,2n+3}$, $m = n+1$. `leeYangLevels` is the same datum at $n = 1$ written with the literal numbers of Chapter 28. `twoSeriesLevels n` is `boundaryFamilyLevels n`, except at $n = 1$ where it is `leeYangLevels`.

File `VOA/Examples/TwoSeriesLevels.lean`.

```
def boundaryFamilyLevels (n : ℕ) : CosetLevels where
  kA := level n
  kAct := level n
  kU := -5 - level n

def twoSeriesLevels : ℕ → CosetLevels
  | 1 => leeYangLevels
  | n => boundaryFamilyLevels n

theorem twoSeriesLevels_one : twoSeriesLevels 1 = leeYangLevels := rfl

theorem twoSeriesLevels_c (n : ℕ) : (twoSeriesLevels n).c = boundaryCharge (n + 1) := by
```

From the mathematics to the Lean statement

`uLevelReal n` is $-3-2/(2n+1) \in \mathbb{R}$ and `uLevelReal_lt` proves it is < -2. The proof fields are filled by the lemmas of the same file: e.g. `sum := by ring` is the identity $k+1+(-5-k) = -4$. `LeeYang.leeYangC` is $-22/5$. The definition of `twoSeriesLevels` is by pattern matching: the first clause `| 1 ⇒ ...` catches $n = 1$, the second every other n. `twoSeriesLevels_one` holds by `rfl`, i.e. by unfolding definitions; and `boundaryFamilyLevels_one_kA`, ..., `_one_m` (same file) check field by field that the two descriptions of $n = 1$ agree as numbers. `twoSeriesLevels_c` gives the target charge for every n. Companion lemmas give `twoSeriesLevels_kA n = level n`, `twoSeriesLevels_kU n = -3 - 2/(2n+1)` and `twoSeriesLevels_m n = n + 1`.

Why the special case at $n = 1$. So that every general theorem, specialised to $n = 1$, is *literally* (definitionally) a statement about the Lee–Yang objects of Chapter 28, with no transport lemma. This is a choice of convenience; the numbers are the same either way.

Physical meaning

The family $n \mapsto (A_1, D_{2n+1}) \to (A_1, A_{2n})$ of Argyres–Douglas pairs, with $n = 1$ the pair $(A_1, D_3) = (A_1, A_3)$ and Lee–Yang (A_1, A_2).

What the machine verified

Definitions; the field lemmas are proved, unconditional. Axioms standard for `twoSeriesLevels_c` (re-checked).

Index conventions, and the member $n = 0$

Three indices coexist (Notation table). (1) Theorems stated for `(n : ℕ)` with no hypothesis $1 \le n$ also cover $n = 0$: `twoSeriesLevels 0` has $k_A = 0$ and $c = c_{2,3} = 0$. That instance is harmless (it is a statement about the trivial coset and the trivial VOA $L(0,0) = \mathbb{C}$), but it is not a member of the series. (2) The headline and the slice-map files use `twoSeriesLevels (m + 1)` precisely to exclude it; their $m = 0$ is $n = 1$, Lee–Yang, and their target $M(2, 2m+5)$ is the n-th member. (3) The field `CosetLevels.m` is $n + 1$, not n and not the m of the headline. (4) The coefficient ring R_n of Section 29.6 uses the member index n but describes $M(2, 2n+1)$, one step *below* the target. A reader checking a statement should translate every index to n first.

29.3 The objects at the two ends

The hypothesis and the conclusion of every theorem in this chapter are instances of the graded-unitarity predicate `GradedUnitary B R F` of Chapter 19 (Definition 19.11). Each instance needs an invariant form B, a real structure R and a flag F. For the Virasoro target the predicate is pinned as `VirGradedUnitary c R` (Definition 19.20). The level-generic file builds the three data for every level datum.

Definition 29.6 (The data on the boundary factor)**.** For a level datum L, let $A = L_{k_A}(\mathfrak{sl}_2)$ be the simple quotient of $V^{k_A}(\mathfrak{sl}_2)$ by its maximal graded ideal. Its data are: the canonical invariant form normalised by $(|0\rangle||0\rangle) = 1$; the *corrected current-and-stress flag* (the PBW-type filtration of Chapter 28 in which a current mode J^a_{-j} and a Sugawara mode L_{-j} each raise the degree by one, descended to the quotient); and the compact conjugation (the antilinear involution fixing the compact real form $\mathfrak{su}(2)$), descended from V^{k_A} to A.

File `VOA/Examples/TwoSeriesAffine.lean`.

```
abbrev affineForm : InvariantForm (AVOA L) := simpleForm L.kA L.aNoncritical

def affineFlag : GradedFlag (AVOA L) :=
  CorrectedR.correctedAffineRQuotientFlag L.kA L.aNoncritical
    (QuotVOA.maxGradedIdeal (universal L.kA L.aNoncritical))
    (QuotVOA.maxGradedIdeal_isIdeal _)
    (QuotVOA.maxGradedIdeal_isGradedIdeal _)

def affineConj : ASpace L →ₛₗ[starRingEnd ℂ] ASpace L :=
  (QuotVOA.maxGradedIdeal (universal L.kA L.aNoncritical)).mapQ
    (QuotVOA.maxGradedIdeal (universal L.kA L.aNoncritical))
    (affineUniversalConj L) (affineUniversalConj_maxIdeal_stable L)
```

From the mathematics to the Lean statement

`AVOA L` is `AffineSl2GeneralRigidity.simple L.kA L.aNoncritical`, the maximal quotient `QuotVOA.maxQuotientVOA` of the universal affine VOA (Chapter 20, Definition 20.4); `ASpace L` is its underlying space, the quotient of the Wakimoto-model space `WakModule L.kA` by the maximal graded ideal. So the hypothesis is about the *actual simple* VOA, not a surrogate. `→ₛₗ[starRingEnd ℂ]` is a semilinear map for complex conjugation, i.e. an antilinear map; `mapQ` descends a map to quotients, and `affineUniversalConj_maxIdeal_stable` is the proof that the conjugation preserves the maximal ideal (any conjugation-stable proper ideal is contained in the maximal one). The real structure `affineRealStructure L` bundles `affineConj` with the proofs that it is antilinear, respects the vertex operation, fixes the vacuum and the conformal vector, and squares to the identity (`parity := fun _ ⇒ 1`: all states are even). The theorems `affineForm_leeYang`, `affineFlag_leeYang`, `affineRealStructure_leeYang` prove by `rfl` that at `leeYangLevels` these are the objects of Chapter 28.
The hypothesis of every transfer theorem is therefore

```
hA : GradedUnitary (affineForm L) (affineRealStructure L) (affineFlag L),
```

graded unitarity of the actual simple $L_{k_A}(\mathfrak{sl}_2)$ with these three data.

Physical meaning

The flag is the chiral-algebra image of the four-dimensional $SU(2)_R$-charge filtration (the "R-filtration" of ABLR), with currents of R-charge one and the stress tensor of R-charge one. The compact conjugation is the CPT conjugation of the four-dimensional theory restricted to

Schur operators. Graded unitarity of L_{k_n} is then the positivity that four-dimensional unitarity of (A_1, D_{2n+1}) is expected to force.

What the machine verified

Definitions. The flag is the *corrected* one of Chapter 28; whether it is the physically correct R-filtration is a modelling choice inherited from there, not something this chapter re-examines.

Theorem 29.7 (Graded unitarity of the auxiliary factor)**.** *For every level datum L, the universal affine VOA $V^{k_U}(\mathfrak{sl}_2)$ with its canonical form, compact conjugation and ordinary PBW flag is graded unitary.*

File `VOA/Examples/TwoSeriesAffine.lean`.

```
abbrev auxiliaryForm : InvariantForm (UVOA L) := universalForm L.kU L.uNoncritical

abbrev auxiliaryRealStructure : RealStructure (UVOA L) :=
  compactRealStructure L.uReal L.uNoncritical

abbrev auxiliaryFlag : GradedFlag (UVOA L) := ordinaryFlag L.kU L.uNoncritical

theorem auxiliaryGradedUnitary :
    GradedUnitary (auxiliaryForm L) (auxiliaryRealStructure L) (auxiliaryFlag L) := by
```

From the mathematics to the Lean statement

`UVOA L` is the universal $V^{k_U}(\mathfrak{sl}_2)$ (not a quotient). The proof specialises the theorem `universal_gradedUnitary_belowCritical_unconditional` of the below-critical files (Chapter 19) at the real level `L.kUr < -2`. No hypothesis besides the level datum; and the datum's field `kUr_lt` is exactly what is used. Same as the textbook statement.

Proof on paper. On each weight space of $V^k(\mathfrak{sl}_2)$ fix the PBW basis adapted to the ordinary flag. The entries of the Gram matrix of the canonical form in that basis are polynomials in k. The below-critical files show that no leading principal minor (in the flag-adapted order) vanishes for real $k < -2$ ("no wall"; this is consistent with the irreducibility of the vacuum module there, whose Kac–Kazhdan reducibility walls lie at $k + 2 \in \mathbb{Q}_{>0}$, but the statement needed is the finer one about flag steps). The signs of the minors, hence the signs demanded by clause (vi), are therefore constant on the half-line, and they are computed at an anchor, in the regime $k \to -\infty$ where the form is dominated by its leading power of k and each layer behaves like a free (Heisenberg-type) system whose sign on layer p is $(-1)^p$, which is exactly the sign twist of clause (vi). The compact conjugation turns the bilinear form into the Hermitian one with the same diagonal on real vectors. The proof lives in the below-critical files (assigned to Chapter 19); this chapter only specialises it. □

Physical meaning

At level $k_U < -2$ the vacuum module is "unitary up to the expected signs": it behaves like a non-compact current algebra. In the BRST picture it is the auxiliary sector that absorbs the anomaly of the gauged $SU(2)$; that it has the right positivity is what lets positivity flow from A alone.

What the machine verified

Proved, unconditional (for every level datum). Axioms standard (re-checked).

Definition 29.8 (The target real structure)**.** For a level datum L, `targetRealStructure L` is the partition-basis real structure on $L(c, 0)$ obtained from the real Feigin–Fuchs parameter λ with $1 - 12\lambda^2 = c$ given by the boundary family (Chapter 19, Theorem 19.24).

File `VOA/Examples/TwoSeriesAffine.lean`.

```
def targetRealStructure : RealStructure (VirSimple.virasoroSimple L.c) :=
  virasoroSimpleRealStructure L.lam_spec (VirGradedUnitarity.boundaryBackgroundCharge_fixed
   ↪ L.m)
```

From the mathematics to the Lean statement

`L.lam_spec` is the identity $1 - 12\lambda_m^2 = c$ derived from the field `boundary` (file `TwoSeriesLevels.lean`), where $\lambda_m =$ `boundaryBackgroundCharge L.m` is real; `_fixed` says conjugation fixes it. The conclusion of every transfer theorem is `VirGradedUnitary L.c (targetRealStructure L)`, i.e. `GradedUnitary (Bsimp c) R (virGradedFlag c)`: graded unitarity of the actual simple Virasoro VOA with its canonical form and length flag. By Theorem 19.25 every step of the length flag is stable under every real structure, and the reduction of Chapter 19 is insensitive to the choice of ρ.

Physical meaning

The real structure is the CPT conjugation of the Virasoro chiral algebra in the basis of partition (Feigin–Fuchs) states; the boundary family is exactly the case where the background charge is real.

What the machine verified

Definition. At `leeYangLevels` it is `LeeYangTransferAssembly.leeYangRealStructure` (`rfl`).

29.4 The level-generic coset chain

29.4.1 The infrastructure files, described collectively

About forty files port the Lee–Yang chain of Chapter 28 to an arbitrary level datum L. Each is a re-run of a concrete file with the numbers replaced by the fields of L; each ends with `rfl` lemmas showing that at `leeYangLevels` it reproduces the concrete object. We list them by role and do not re-present their internal lemmas, which are the Lee–Yang lemmas with a different level.

files	content
`TwoSeriesFactors`	the factors A, U; the diagonal current action on $A \otimes B \otimes U$ at level -4 (`matterAction`); the semi-infinite BRST complex `brstComplex L`, with nonzero vacuum class
`TwoSeriesCoset`	the coset stress tensor `cosetOmega`; the coset VOA `cosetVOA L` on the actual diagonal commutant, central charge `L.c` from the field `charge`; its map into the BRST complex
`TwoSeriesImage`	`virasoroToH0 L`: $V(c,0) \to H^0$, kernel inside the maximal ideal; the finite relative complexes `relativeWeight L n`
`TwoSeriesHodge`, `TwoSeriesHodgeGeometry`, `-Good`, `-Goodness`, `-Kahler`, `-BG`, `-GhostConj`, `-ConjIdentity`, `-Harmonic`, `-Inputs`	the Beem–Garner Kähler package on the actual relative complexes, its positivity from GU(A), the two BRST conjugation identities, the harmonic-metric bridges; assembled in `brstHodgeInputs` (Theorem 29.12)
`TwoSeriesAssembly`	the transfer theorem with two packaged inputs (Theorem 29.11)
`TwoSeriesKoszulGr`, `-U`, `-Matter`, `-Native`, `-Homotopy`, `-Ident`, `-Grading`, `-Exact`, `-Endpoint`, `-Eval`, `-SymA`, `-Symbol`, `-SymbolMaps`, `-Parity`, `-Invariants`	the symbol module $\mathrm{gr}_r A$, the Koszul exactness of the leading BRST differential, the two symbol maps, the vanishing of odd and negative degrees; the leading Koszul embedding (Theorem 29.14)

(All paths are `VOA/Examples/<name>.lean`; "`-X`" abbreviates the name with the preceding prefix.) The definitions and theorems that a reader needs to check the headline statements are the following.

29.4.2 The two packaged inputs and the transfer theorem

Definition 29.9 (The Hodge package)**.** For a level datum L, a *BRST/Hodge package* consists of: a Kähler geometry on the finite relative BRST complexes at each conformal weight (a positive form P and a Kähler-type decomposition whose differential is the actual BRST residue); a proof that GU(A) and GU(U) make every P positive definite; the graded-unitarity data on harmonic classes; a proof that the classes of Virasoro words of length $\leq p$ lie in Kähler degree $\leq 2p$ (generator tests); and three bridges identifying the harmonic metric on the classes of Virasoro words with the canonical form of T (vacuum normalisation, adjointness of creation operators, reality of words).

File `VOA/Examples/TwoSeriesAssembly.lean`.

```

From the mathematics to the Lean statement

The seven fields are the seven named inputs of the Lee–Yang assembly of Chapter 28, now at level L; their types are defined in `TwoSeriesHodge.lean` and are statements about the *actual* relative complexes `relativeWeight L n` and the actual Virasoro classes, not about abstract surrogates. `IsPosOn P ⊤` says the Hermitian form P is positive definite on the whole space (`⊤` is the top submodule; Chapter 19, Definition 19.7). Note that `weakGU` is an *implication* from the two graded-unitarity statements to positivity: the package does not assume positivity. The package asserts nothing about the target T (no positivity, nondegeneracy, injectivity or filtered isomorphism on T); all such statements are derived.

Physical meaning

The package is the chiral-algebra version of the statement that gauging a unitary theory produces a unitary theory: the BRST cohomology of a positive complex, computed by harmonic representatives, inherits positivity. The Kähler $(\mathfrak{sl}_2)$ structure is what makes harmonic theory compatible with the extra grading that graded unitarity needs; it is the content of Beem and Garner's analysis of BRST cosets.

What the machine verified

Definition (a structure type). It is inhabited at every level datum from GU(A) alone (Theorem 29.12).

Definition 29.10 (The squeeze input)**.** For a level datum L and a Kähler geometry S, a *squeeze input* is a function $\mathrm{coeff} : \mathbb{Z} \times \mathbb{N} \to \mathbb{N}$ with (I) for every weight n at which the form P of S is positive definite and every Kähler degree j, the leading cohomology in bidegree $(j, 0)$ has dimension at most $\mathrm{coeff}(n, j/2)$ if $j \geq 0$ is even, and 0 otherwise; and (II) for every n and p, $\sum_{0 \leq j \leq 2p}$(that bound) $\leq \dim F_p T_n$.

File `VOA/Examples/TwoSeriesAssembly.lean`.

```
def evenCoeff (a : ℤ → ℕ → ℕ) (n j : ℤ) : ℕ :=
  if 0 ≤ j ∧ j % 2 = 0 then a n (j.toNat / 2) else 0

structure SqueezeInput (S : BRSTKahlerGeometry L) where
  /-- `coeff n r`: the expected dimension of the PBW-length-`r` layer at weight `n`. -/
  coeff : ℤ → ℕ → ℕ
  /-- (I) leading-cohomology / invariant-symbol upper bound. -/
  invariantBound : ∀ n (hp : IsPosOn (S.geometry n).P τ) j,
    Module.finrank ℂ ((S.model n hp).leadCohom (j, 0)) ≤ evenCoeff coeff n j
  /-- (II) PBW lower bound for the simple target. -/
  pbwLower : ∀ (n : ℤ) (p : ℕ),
    (∑ j ∈ Finset.Icc 0 (2 * (p : ℤ)), evenCoeff coeff n j) ≤
      Module.finrank ℂ ((virGradedFlag L.c).pieceIn p n)
```

From the mathematics to the Lean statement

`Module.finrank ℂ X` is $\dim_{\mathbb{C}} X$ (and 0 if X is infinite-dimensional; for (I) this matters only as an upper bound on a finite-dimensional space, since the relative complexes are finite-dimensional at each weight). `(virGradedFlag L.c).pieceIn p n` is F_pT_n, the length-$\leq p$ step of the length flag of T at weight n (Definition 19.19). `Finset.Icc 0 (2 * p)` is the integer interval $[0, 2p]$. The Kähler degree j is twice the PBW length, hence `evenCoeff`. Weights are integers ($\mathbb{Z}$); negative weights are empty.

Physical meaning

(I) bounds the number of gauge-invariant "classical" states in each R-charge sector; (II) counts the states of the minimal model with at most p stress-tensor insertions. When the two counts agree, every state of the minimal model is accounted for by a positive harmonic class with the right R-charge, which is the physical content of graded unitarity.

What the machine verified

Definition. Supplied for every n by Theorems 29.15 and 29.27 together with the invariant count of Section 29.6.

Theorem 29.11 (Coset transfer for any level datum). *Let L be a level datum. If $A = L_{k_A}(\mathfrak{sl}_2)$ is graded unitary, and a Hodge package and a squeeze input are given, then $L(c, 0)$ is graded unitary for its partition-basis real structure. In particular, for the n-th member of the series:* $\mathrm{GU}(L_{k_n}) \wedge \mathrm{Hodge} \wedge \mathrm{Squeeze} \Rightarrow \mathrm{GU}(M(2, 2n+3))$.

File `VOA/Examples/TwoSeriesAssembly.lean`.

    VirGradedUnitary (twoSeriesLevels n).c (targetRealStructure (twoSeriesLevels n)) :=
  cosetLevels_gradedUnitary_of_affine (twoSeriesLevels n) hA hodge hsq
```

From the mathematics to the Lean statement

Full names `VOA.TwoSeries.cosetLevels_gradedUnitary_of_affine` and `VOA.TwoSeries.twoSeries_gradedUnitary_of_affine`. Hypotheses: `hA`, graded unitarity of the actual simple L_{k_A} (Definition 29.6); `hodge` and `hsq`, the two packages above (the second depends on the first through its Kähler geometry). Conclusion: graded unitarity of the actual simple Virasoro VOA at $c =$ `L.c`. The second theorem is the first at $L =$ `twoSeriesLevels n`, with (`twoSeriesLevels n`).$c = c_{2,2n+3}$ by `twoSeriesLevels_c`. Same as the textbook statement, with the two packages as explicit hypotheses. It covers $n = 0$ (warning on p. 1561).

Proof on paper. From `hodge.weakGU` and Theorem 29.7, every finite relative complex carries a positive form. Fix a weight n. Let f be the map sending a universal Virasoro state to its BRST class, and g the projection to the simple quotient T_n. The kernel of f lies in the kernel of g (the vacuum class survives), so T_n is a quotient of the image of f. The generator tests put the image of F_p (universal words of length $\le p$) into Kähler degree $\le 2p$; hence $\dim F_pT_n \le \sum_{j\le 2p} \dim(\text{leading cohomology})_{(j,0)}$. Input (I) bounds the right side by $\sum_{r\le p} \text{coeff}(n,r)$ and (II) bounds that by $\dim F_pT_n$: all inequalities are equalities (the *squeeze*). Equality means that the length flag of T_n is carried isomorphically onto the Kähler-degree flag of harmonic classes, layer by layer, and that odd Kähler degrees carry nothing. The metric bridges identify the canonical form of T with the harmonic metric on these classes, and the latter is positive with the graded sign pattern. Hence clauses (iv) and (vi) hold at weight n. □

Physical meaning

The physical slogan: gauge-invariant states of a positive theory are positive, *provided* one can match them one to one with the states of the coset; the squeeze is the counting argument that does the matching.

What the machine verified

Proved; `#print axioms`-clean (re-checked), **conditional** on `hA`, `hodge`, `hsq`.

The short name `twoSeries_gradedUnitary_of_affine` denotes two different theorems

`VOA.TwoSeries.twoSeries_gradedUnitary_of_affine` (above, in `TwoSeriesAssembly.lean`) takes `hA`, `hodge` and `hsq`. `VOA.TwoSeries.SliceMap.twoSeries_gradedUnitary_of_affine` (in `TwoSeriesArakawaUnconditional.lean`, Theorem 29.53) takes `hA` and the jet-ideal Poincaré input `JetPoincareCoreT0 (m + 1)`, and is indexed by m with $n = m + 1$. Inside the namespace `VOA.TwoSeries.SliceMap` the short name resolves to the second; elsewhere in `VOA.TwoSeries`, to the first. *Neither* is the headline: the headline is `VOA.TwoSeries.JetPoincareTwo.twoSeries_gradedUnitary_of_affine_final`, which is declared in `TwoSeriesGenIncl.lean`, not in `TwoSeriesJetPoincareTwo.lean` as its namespace suggests. These are naming defects (severity S4: documentation, not statements), not mathematical ones; always cite the fully qualified name.

Theorem 29.12 (The Hodge package exists at every level)**.** *For every level datum L and every proof h_A of* GU(A) *there is a BRST/Hodge package. Consequently* GU(A) ∧ Squeeze ⇒ GU($L(c,0)$).

File `VOA/Examples/TwoSeriesHodgeInputs.lean`.

```
def brstHodgeInputs
    (hA : GradedUnitary (affineForm L) (affineRealStructure L) (affineFlag L)) :
    BRSTHodgeInputs L where

theorem twoSeries_gradedUnitary_of_affine_hodgeFree (n : ℕ)
```

```
    (hA : GradedUnitary (affineForm (twoSeriesLevels n)) (affineRealStructure
    ↪  (twoSeriesLevels n))
      (affineFlag (twoSeriesLevels n)))
    (hsq : SqueezeInput (twoSeriesLevels n) (brstHodgeInputs (twoSeriesLevels n)
    ↪  hA).kahler) :
    VirGradedUnitary (twoSeriesLevels n).c (targetRealStructure (twoSeriesLevels n)) :=
  cosetLevels_gradedUnitary_of_affine_hodgeFree (twoSeriesLevels n) hA hsq
```

From the mathematics to the Lean statement

`brstHodgeInputs` is a `def`: a construction of a package, with all seven fields filled by theorems (`endpointKahler`, `concreteKahler_weakGU`, `sp2GUData0`, `interpretedGenerators_std`, and the three `harmonic..._proved` bridges, all in the Hodge files). The construction takes `hA` as an argument because the ghost package uses positivity of A; the unitarity of $B = L_1(\mathfrak{sl}_2)$ is the proved `LevelOneUnitary.bUnitary`. The docstring of `BRSTHodgeInputs` in `TwoSeriesAssembly.lean` still says the package is "proved so far only at Lee–Yang"; that is stale (warning on p. 1604): this `def` provides it at every level datum.

Proof on paper. The Lee–Yang proof of Chapter 28 used the level only through the identities now recorded as fields of L (non-criticality, reality, the level sum -4). The ghost-conjugation identities (`ghostConjRhoD_proved`, `ghostConjBE_proved`) are identities in the BRST algebra in which the level enters through the cancellation $k + 1 + k_U = -4$; the harmonic bridges use only the invariance of the forms under the modes. Re-running each argument with symbolic levels gives the package. □

Physical meaning

That the BRST–Hodge mechanism is level-independent is expected: the ghost system and the anomaly cancellation do not care which (A_1, D_{2n+1}) theory is being gauged.

What the machine verified

Proved (construction), `#print axioms`-clean (re-checked); the endpoint theorem is **conditional** on `hA` and `hsq`.

29.4.3 The Koszul step: from cohomology to an affine invariant count

Definition 29.13 (The affine invariant spaces)**.** For $r \in \mathbb{N}$ and $N \in \mathbb{Z}$, $\mathcal{J}_{r,N}$ is the space of tensors in $\mathrm{gr}_r A \otimes B$ of total conformal weight N annihilated by every diagonal non-negative current mode $J^a_m \otimes 1 + 1 \otimes J^a_m$ ($a \in \{e, f, h\}$, $m \geq 0$). Here $\mathrm{gr}_r A$ is the r-th layer of the corrected flag of A with its induced mode action, and $B = L_1(\mathfrak{sl}_2)$.

File `VOA/Examples/TwoSeriesKoszulInvariants.lean`.

```
def affineInvariants (r : ℕ) (N : ℤ) : Submodule ℂ (GrA L r ⊗[ℂ] BSpace) :=
  VOA.CyclicEval.tensorWeight (grDeg L r) VOA.CyclicEval.bWeight N ⊓ jointKer (grDiag L r)
```

From the mathematics to the Lean statement

`GrA L r` is $\mathrm{gr}_r A$ (file `TwoSeriesKoszulGr.lean`); `BSpace` is the space of $L_1(\mathfrak{sl}_2)$; `⊗[ℂ]` the tensor product over $\mathbb{C}$. `tensorWeight ... N` is the weight-N part for the sum of the two gradings, `jointKer (grDiag L r)` the common kernel of the diagonal non-negative modes, and `⊓` the intersection of submodules. The companion lemma `mem_affineInvariants` restates membership as "weight N and `IsInv`" (killed by all diagonal modes). Note that the definition involves only the affine algebra: neither the BRST complex nor T.

Physical meaning

$\mathcal{I}_{r,N}$ counts the classical (leading-order) gauge-invariant states of the gauged system at R-charge r and weight N: invariance under the non-negative modes of the diagonal current algebra is the classical form of the BRST condition.

What the machine verified

Definition.

Theorem 29.14 (The leading Koszul embedding). *For every level datum L, every h_A : GU(A) and every weight n at which the modified Hermitian form P of the Kähler geometry is positive definite (hypothesis h_p), the leading cohomology of the relative complex at weight n and Kähler degree $(2r, 0)$ has dimension at most* $\dim \mathcal{I}_{r,n}$. *(Under h_A the form is positive definite at every weight, so in the application h_p is not an extra assumption.)*

File `VOA/Examples/TwoSeriesKoszulInvariants.lean`.

```
theorem rank_leadCohom_le_affineInvariants (n : ℤ)
    (hp : IsPosOn ((endpointKahler L hA).geometry n).P ⊤) (r : ℕ) :
    Module.rank ℂ (((endpointKahler L hA).model n hp).leadCohom (2 * (r : ℤ), 0)) ≤
      Module.rank ℂ (affineInvariants L r n) := by
```

From the mathematics to the Lean statement

`Module.rank` is the dimension as a cardinal (it can be infinite), so the inequality is meaningful even if $\mathcal{I}_{r,n}$ were infinite-dimensional. `endpointKahler L hA` is the Kähler geometry of Theorem 29.12; `hp` its positivity at weight n. `hp` is a genuine explicit hypothesis of the Lean statement (the Kähler complex at weight n is defined only once it is given); in every use it is discharged from `hA` and `auxiliaryGradedUnitary` through the `weakGU` field of the Hodge package (Theorem 29.12). Here `L` and `hA` are section variables, explicit arguments in the order `(L) (hA)`. The proof is an injective linear map (`leadKoszulEmbedding`) from the leading cohomology into the invariant space. Same as the textbook statement.

Proof on paper. This is the Koszul argument of Chapter 28, re-run at level L. Filter the relative complex by the corrected PBW degree. The leading part of the BRST differential is a Koszul differential for the action of the non-negative diagonal modes on $\mathrm{gr}\, A \otimes B \otimes \mathrm{gr}\, U$, twisted by ghosts. The universal factor $\mathrm{gr}\, U$ is free, so the Koszul complex is exact away from ghost number zero and the ghost-number-zero leading cohomology injects into the invariants of $\mathrm{gr}\, A \otimes B$; the symbol maps π_0, π_1 make this explicit. Odd and negative Kähler degrees have no leading cohomology (`endpoint_oddZero`, `endpoint_negZero`). □

Physical meaning

The Koszul step is the statement that, at leading order, BRST cohomology is just the space of gauge invariants: the ghosts and the auxiliary sector cancel the gauge directions.

What the machine verified

Proved, conditional on `hA` (which enters only through the Kähler geometry) and on the weightwise positivity `hp`, which follows from `hA`; `#print axioms`-clean (re-checked).

Theorem 29.15 (Transfer with an invariant count). *For every n: if* GU(L_{k_n}) *holds and a function* coeff *satisfies* $\dim \mathcal{I}_{r,N} \le \mathrm{coeff}(N, r)$ *for all N, r and* $\sum_{r \le p} \mathrm{coeff}(N, r) \le \dim F_p T_N$ *for all N, p, then $M(2, 2n+3)$ is graded unitary.*

File `VOA/Examples/TwoSeriesKoszulInvariants.lean`.

```
theorem twoSeries_gradedUnitary_of_affine_invariants (n : ℕ)
    (hA : GradedUnitary (affineForm (twoSeriesLevels n)) (affineRealStructure
    ↪  (twoSeriesLevels n))
      (affineFlag (twoSeriesLevels n)))
    (coeff : ℤ → ℕ → ℕ)
    (hinv : ∀ (N : ℤ) (r : ℕ),
      Module.rank ℂ (affineInvariants (twoSeriesLevels n) r N) ≤ coeff N r)
    (hpbw : ∀ (N : ℤ) (p : ℕ), ∑ r ∈ Finset.range (p + 1), coeff N r ≤
      Module.finrank ℂ ((virGradedFlag (twoSeriesLevels n).c).pieceIn p N)) :
    VirGradedUnitary (twoSeriesLevels n).c (targetRealStructure (twoSeriesLevels n)) :=
```

From the mathematics to the Lean statement

`Finset.range (p + 1)` is $\{0, \dots, p\}$. `hinv` is stated with `Module.rank`, so an infinite-dimensional invariant space makes `hinv` *false* (a cardinal $\geq \aleph_0$ is not $\leq$ a natural number), never vacuously true; a `_finrank` variant takes `finrank` plus finite-dimensionality. The proof assembles `squeezeInput_of_invariants` (Theorem 29.14 plus the parity vanishing) with Theorem 29.12. Both remaining inputs are about separate objects: `hinv` about the affine algebra, `hpbw` about T.

Proof on paper. Set the squeeze coefficient to coeff. Half (I): by Theorem 29.14 and `hinv` for even Kähler degree, and by the parity vanishing for odd or negative degree. Half (II) is `hpbw` after rewriting the sum over Kähler degrees $j \leq 2p$ as a sum over lengths $r \leq p$ (`sum_evenCoeff`). Apply Theorem 29.12. □

Physical meaning

After this step, the transfer needs one count on each side of the coset: the classical gauge invariants of the (A_1, D_{2n+1}) side, and the states of the (A_1, A_{2n}) side.

What the machine verified

Proved, `#print axioms`-clean (re-checked), **conditional** on `hA`, `hinv`, `hpbw`.

29.5 The vacuum characters of $M(2, 2n+3)$

This section supplies the input `hpbw` of Theorem 29.15 with the Andrews–Gordon count, for every n, and in passing proves the vacuum character of every $M(2, 2n+3)$. All of it is about the Virasoro side only.

29.5.1 The Andrews–Gordon count

A Virasoro creation word $L_{-j_1-2} \cdots L_{-j_\ell-2}|0\rangle$ is encoded by the list $(j_1, \dots, j_\ell)$ of natural numbers; its *energy* (conformal weight) is $\sum_i (j_i + 2)$ (`energyVir`), and it is *sorted* if $j_1 \geq j_2 \geq \cdots$ (`SortedWord`). The parts of the corresponding partition are $j_i + 2 \geq 2$.

Definition 29.16 (Gordon-good words; the Andrews–Gordon count)**.** A list $w = (w_0, \dots, w_{\ell-1})$ is *Gordon-good of order n* if $w_i \geq w_{i+n} + 2$ whenever both entries exist. The *Andrews–Gordon count* $g_n(N, r)$ is the number of sorted Gordon-good words of length exactly r and energy N (and 0 for $N < 0$). Equivalently, it is the number of partitions of N into exactly r parts ≥ 2 in which, writing f_j for the multiplicity of the part j, $f_j + f_{j+1} \leq n$ for every j.

Files `VOA/Examples/TwoSeriesCharacterSpanning.lean` (Gordon-good) and `VOA/Examples/TwoSeriesCharacterReduction.lean` (the count).

```
def GordonGood (n : ℕ) (w : List ℕ) : Prop :=
  ∀ i < w.length - n, w.getD (i + n) 0 + 2 ≤ w.getD i 0

def tupleList {N r : ℕ} (a : Fin r → Fin (N + 1)) : List ℕ := List.ofFn fun j => (a j : ℕ)

def gordonWords (n N r : ℕ) : Finset (List ℕ) :=
  ((Finset.univ : Finset (Fin r → Fin (N + 1))).image tupleList).filter
    (fun u => SortedWord u ∧ GordonGood n u ∧ energyVir u = N)

def gordonCoeff (n : ℕ) (N : ℤ) (r : ℕ) : ℕ :=
  if 0 ≤ N then (gordonWords n N.toNat r).card else 0
```

From the mathematics to the Lean statement

`w.getD i 0` is the i-th entry of w (or 0 if i is out of range; it is never out of range here because $i < \ell - n$). `gordonWords n N r` enumerates all functions $\{0,\dots,r-1\} \to \{0,\dots,N\}$ (`Fin r → Fin (N + 1)`), turns each into a list, and keeps the sorted, Gordon-good lists of energy N; since every entry of a word of energy N is $\le N$, nothing is lost by the bound. `.card` is the number of elements of the finite set. So `gordonCoeff n N r` is exactly $g_n(N,r)$; `mem_gordonWords` proves the membership characterisation (sorted, Gordon-good, energy N, length r).

Why the two descriptions agree. For a sorted list, $w_i \ge w_{i+n} + 2$ says that no window of $n+1$ consecutive entries spans fewer than three consecutive values; equivalently no two adjacent values $j, j+1$ occur more than n times in total, i.e. $f_j + f_{j+1} \le n$. At $n = 1$ it is the Rogers–Ramanujan condition "parts differ by at least 2".

Example 29.17 (The counts for $n = 1,2,3$)**.** Summing over r, the first coefficients of $\sum_N \big(\sum_r g_n(N,r)\big) q^N$ are (computed by enumeration, and agreeing with the alternating sums of Definition 29.23):

N	0	1	2	3	4	5	6	7	8	9	10	11	12	13
$n=1$ (Lee–Yang)	1	0	1	1	1	1	2	2	3	3	4	4	6	6
$n=2$ ($M(2,7)$)	1	0	1	1	2	2	3	3	5	6	8	9	13	14
$n=3$ ($M(2,9)$)	1	0	1	1	2	2	4	4	6	7	10	12	17	19

By length, at $n = 2$: $N = 8$ has $g_2(8,1) = 1$ (the word (6), i.e. $L_{-8}|0\rangle$), $g_2(8,2) = 3$ (parts $\{6,2\},\{5,3\},\{4,4\}$) and $g_2(8,3) = 1$ (parts $\{4,2,2\}$; the partition $\{3,3,2\}$ is excluded because $f_2 + f_3 = 3 > 2$). At $n = 1$ the partition $\{4,4\}$ is also excluded ($f_4 = 2 > 1$), and indeed $g_1(8,2) = 2$.

Physical meaning

The partitions with $f_j + f_{j+1} \le n$ are the "Gordon" or "$(n+1)$-exclusion" configurations: stress-tensor quanta behave like particles of which at most n may occupy two adjacent momentum levels. This is the quasi-particle (fermionic) description of the (A_1, A_{2n}) chiral algebra, and for $n = 1$ the Lee–Yang "hard-hexagon" exclusion.

What the machine verified

Definitions.

29.5.2 Spanning: the upper bound

Definition 29.18 (Jet relations)**.** For $c \in \mathbb{C}$ and $n \in \mathbb{N}$, $V(c,0)$ *has jet relations of order* $n+1$ if there is $\alpha \neq 0$ such that for every $k \in \mathbb{N}$ some vector of the maximal ideal of $V(c,0)$ agrees with $\alpha \sum_{e_1+\cdots+e_{n+1}=k} L_{-e_1-2} \cdots L_{-e_{n+1}-2}|0\rangle$ modulo words of length $\le n$ and weight $2n+2+k$.

File `VOA/Examples/TwoSeriesCharacterLeading.lean`.

```
def jetSum : ℕ → ℕ → VirUniv c
  | 0, k => if k = 0 then vacVec c else 0
  | m + 1, k => ∑ p ∈ Finset.antidiagonal k, Lop c (-(p.1 : ℤ) - 2) (jetSum m p.2)

def HasJetRelations (c : ℂ) (n : ℕ) : Prop :=
  ∃ α : ℂ, α ≠ 0 ∧ ∀ k : ℕ, ∃ σ ∈ maxIdealVir c,
    σ - α • jetSum c (n + 1) k ∈ virFil c n ((2 * n + 2 + k : ℕ) : ℤ)
```

From the mathematics to the Lean statement

`VirUniv c` is the universal vacuum module $V(c,0)$; `Lop c j` is the mode L_j; `vacVec c` the vacuum. `Finset.antidiagonal k` is the set of pairs (a,b) with $a+b=k$, so `jetSum c m k` is the sum over compositions $e_1+\cdots+e_m=k$ of $L_{-e_1-2}\cdots L_{-e_m-2}|0\rangle$: the weight-$(2m+k)$ coefficient of the normally ordered power (T^m), i.e. the k-th jet of T^m. `maxIdealVir c` is the maximal ideal, and `virFil c n N` the span of words of length $\le n$ and weight N. So the definition is the textbook one.

Physical meaning

The minimal model $M(2,2n+3)$ has a null vector at weight $2n+2$ whose leading term is T^{n+1} (the normally ordered $(n+1)$-st power of the stress tensor): "$T^{n+1}=0$ up to derivatives". Its jets are the relations $\partial^k(T^{n+1})$.

What the machine verified

Definition.

Theorem 29.19 (Jet relations of the series). *For every $n\in\mathbb{N}$, $V(c_{2,2n+3},0)$ has jet relations of order $n+1$.*

File `VOA/Examples/TwoSeriesCharacterEndpoint.lean`.

```
theorem twoSeries_hasJetRelations_all (n : ℕ) :
    VOA.TwoSeriesCharacter.HasJetRelations (twoSeriesLevels n).c n := by
```

From the mathematics to the Lean statement

For $n\ge 1$ the relation comes from the vacuum singular vector of Benoit–Saint-Aubin type at level $2n+2$ (`bsaSource_mem_maxIdeal`), whose length-$(n+1)$ part is a nonzero multiple of $L_{-2}^{n+1}|0\rangle$ (`bsaLead_ne_zero`); its divided L_{-1}-powers give all jets (`hasJetRelations_of_singular`). For $n=0$, $c=0$ and $L_{-2}|0\rangle$ itself lies in the maximal ideal. The charge is matched by `twoSeriesLevels_c_eq_bsaCharge`: $c_{2,2n+3}=$ `bsaCharge (2n+2)`. No hypothesis.

Proof on paper. At $c=c_{2,2n+3}$ the vacuum Verma module has a singular vector at level $(2-1)(2n+3-1)=2n+2$ (Kac determinant). Its expansion in PBW words has leading length-$(n+1)$ term $\alpha L_{-2}^{n+1}|0\rangle$, $\alpha\neq 0$ (an explicit Benoit–Saint-Aubin formula, checked in the library). Applying $L_{-1}^k/k!$ and using $[L_{-1},L_{-j}]=(j-1)L_{-j-1}$ produces, at length $n+1$, exactly α times the k-th jet sum, and the maximal ideal is L_{-1}-stable. □

Physical meaning

The null vector χ_{2n+2} of $M(2,2n+3)$ and its descendants; the leading term says the classical limit of the model is the arc space of $\mathbb{C}[T]/(T^{n+1})$.

What the machine verified

Proved, unconditional. Axioms standard (re-checked).

Theorem 29.20 (Gordon spanning: the refined upper bound). *If $V(c,0)$ has jet relations of order $n+1$, then for all $N \in \mathbb{Z}$ and $p \in \mathbb{N}$, $\dim F_p L(c,0)_N \le \sum_{r \le p} g_n(N,r)$.*

File `VOA/Examples/TwoSeriesCharacterReduction.lean`.

```
theorem finrank_pieceIn_le_gordon (hJ : HasJetRelations c n) (N : ℤ) (p : ℕ) :
    Module.finrank ℂ ((virGradedFlag c).pieceIn p N) ≤
      ∑ r ∈ Finset.range (p + 1), gordonCoeff n N r := by
```

From the mathematics to the Lean statement

`(virGradedFlag c).pieceIn p N` is $F_p L(c,0)_N$. The proof rests on `goodFil_eq_gordonSpan`: under the jet relations, $F_p L(c,0)_N$ is the image of the span of sorted Gordon-good words of length $\le p$ and energy N. Then the dimension is at most the number of such words, which is `card_gordonWordsLe` $= \sum_{r \le p} g_n(N,r)$.

Proof on paper. Straightening: a sorted word that is not Gordon-good contains a window $w_i, \dots, w_{i+n}$ with $w_i \le w_{i+n} + 1$. Among all sorted words with the same length and energy, the quantity $\sum w_i^2$ is minimised by the "flat" windows, and the jet relation of the appropriate k expresses the flattest window's product of $n+1$ modes as minus the sum of the other compositions (all with larger $\sum w_i^2$ after sorting) plus shorter words plus the maximal ideal. Induction on $\sum w_i^2$ (`sqSum_lt_of_not_perm`, `defect`) rewrites every sorted word into Gordon-good ones of the same energy and no larger length, modulo the maximal ideal. □

Physical meaning

The null vector, used as a rewriting rule, removes all states violating the exclusion rule: at most n quanta of T in two adjacent momentum levels.

What the machine verified

Proved, `#print axioms`-clean (re-checked), conditional on `hJ` (supplied for the series by Theorem 29.19).

29.5.3 The lower bound: Rocha-Caridi and Andrews–Gordon

Definition 29.21 (The total lower bound; its refined form). GordonLowerBound(c,n): for every $N \in \mathbb{N}$, $\sum_{r \le N} g_n(N,r) \le \dim L(c,0)_N$. GordonPBWLower$(c,n)$: for every $N \in \mathbb{Z}$, $p \in \mathbb{N}$, $\sum_{r \le p} g_n(N,r) \le \dim F_p L(c,0)_N$.

File `VOA/Examples/TwoSeriesCharacterReduction.lean`.

```
def GordonLowerBound (c : ℂ) (n : ℕ) : Prop :=
  ∀ N : ℕ, (∑ r ∈ Finset.range (N + 1), gordonCoeff n (N : ℤ) r) ≤
    Module.finrank ℂ ((virasoroSimple c).grading (N : ℤ))

def GordonPBWLower (c : ℂ) (n : ℕ) : Prop :=
  ∀ (N : ℤ) (p : ℕ), ∑ r ∈ Finset.range (p + 1), gordonCoeff n N r ≤
    Module.finrank ℂ ((virGradedFlag c).pieceIn p N)
```

From the mathematics to the Lean statement

`(virasoroSimple c).grading N` is the weight-N space $L(c,0)_N$ of the simple Virasoro VOA. The range $r \le N$ in `GordonLowerBound` loses nothing: a word of energy N has length $\le N/2$. `GordonPBWLower` is the shape of the input `hpbw` of Theorem 29.15 with coeff $= g_n$.

Physical meaning

The total lower bound says that the minimal model has *at least* as many states as the exclusion statistics allows; together with spanning it says it has exactly that many.

What the machine verified

Definitions (predicates). Both are proved for the series (Theorems 29.26 and 29.27). The docstring of `GordonLowerBound` still reads "OPEN for general n ... not formalised here"; that is stale (warning on p. 1604).

Theorem 29.22 (The refined lower bound is equivalent to the total one)**.** *If $V(c,0)$ has jet relations of order $n+1$, then* GordonPBWLower(c,n) $\iff$ GordonLowerBound(c,n).

File `VOA/Examples/TwoSeriesCharacterReduction.lean`.

```
theorem hpbw_iff_gordonLowerBound (hJ : HasJetRelations c n) :
    GordonPBWLower c n ↔ GordonLowerBound c n :=
  ⟨gordonLowerBound_of_hpbw c n, hpbw_of_gordonLowerBound c n hJ⟩
```

From the mathematics to the Lean statement

`↔` is logical equivalence; `⟨a, b⟩` pairs the two directions. Only the direction "total ⇒ refined" uses `hJ`.

Proof on paper. ($\Rightarrow$) Take $p = N$: $F_N L(c,0)_N = L(c,0)_N$. ($\Leftarrow$) By Gordon spanning (Theorem 29.20) the Gordon-good words of length $\le N$ span $L(c,0)_N$; there are $\sum_r g_n(N,r)$ of them, and by the total lower bound this number is at most $\dim L(c,0)_N$. So they form a basis, and in particular the subfamily of length $\le p$ is linearly independent inside $F_p L(c,0)_N$, which gives the refined bound. This is a squeeze in the same spirit as Theorem 29.11. □

Physical meaning

Once the total number of states is right, the exclusion-statistics basis is automatically adapted to the number of stress-tensor quanta.

What the machine verified

Proved, `#print axioms`-clean (re-checked), conditional on `hJ`.

Definition 29.23 (The Rocha-Caridi coefficient)**.** With $p(N)$ the number of partitions of N ($p(N) = 0$ for $N < 0$) and $e_n(k) = k\big((2n+3)k + 2n + 1\big)/2$,

$$\mathrm{rcq}_n(N) \;=\; \sum_{k \in \mathbb{Z}} (-1)^k \, p\big(N - e_n(k)\big),$$

a finite sum (the terms with $|k| > N$ vanish).

File `VOA/Examples/TwoSeriesCharacterKacCount.lean`.

```
def eeq (k : ℤ) : ℤ := k * ((2 * n + 3) * k + (2 * n + 1)) / 2

def rcq (N : ℕ) : ℤ := ∑ k ∈ Ico (-(N : ℤ) - 1) ((N : ℤ) + 1), VOA.RRLower.sgn k *
 ↪ VOA.RRLower.pp ((N : ℤ) - eeq n k)
```

From the mathematics to the Lean statement

Integer division `/ 2` is exact here (`two_mul_eeq`: the numerator $k((2n+3)k + 2n + 1)$ is always even). `Ico a b` is $[a, b)$, so k runs over $-N - 1 \le k \le N$, which contains every k with $e_n(k) \le N$ (`abs_le_eeq`). `VOA.RRLower.sgn k` is $(-1)^k$ and `VOA.RRLower.pp` the partition function extended by 0 to negative arguments (both from the Lee–Yang character files of Chapter 28).

Physical meaning

This is the Rocha-Caridi (Feigin–Fuchs) formula for the vacuum character of $M(2, 2n+3)$: $\chi_0 = \frac{1}{(q)_\infty} \sum_k (-1)^k q^{e_n(k)}$, the alternating sum over the embedding diagram of Verma submodules, here at $p = 2$, $p' = 2n + 3$.

What the machine verified

Definition.

Theorem 29.24 (Rocha-Caridi lower bound). *For every $n, N \in \mathbb{N}$, $\mathrm{rcq}_n(N) \le \dim L(c_{2,2n+3}, 0)_N$.*

File `VOA/Examples/TwoSeriesCharacterGramRank.lean`.

```
theorem rcq_le_finrank (N : ℕ) :
    rcq n N ≤ (Module.finrank ℂ ((VOA.VirSimple.virasoroSimple
      (VOA.VirModule.bsaCharge (2 * n + 2))).grading (N : ℤ)) : ℤ) := by
```

From the mathematics to the Lean statement

`bsaCharge (2n+2)` is $c_{2,2n+3}$ (Theorem 29.19). The inequality is in $\mathbb{Z}$ (the cast `: ℤ`). Only the lower bound is claimed here; the matching upper bound is Theorem 29.20.

Proof on paper. $\dim L(c, 0)_N$ is the rank of the Shapovalov Gram matrix of $V(c, 0)$ at level N. Its determinant (Kac) is a product of factors $(h - h_{r,s}(c))^{p(N-rs)}$. Deforming c away from $c_{2,2n+3}$ along a line and counting the orders of vanishing of the Kac factors at the special point (`rcq_eq_orders`, `gram_shift_det_q`) bounds the corank by $\sum_{k \ne 0}$ of the partition numbers with alternating signs; the rank is therefore at least $\mathrm{rcq}_n(N)$. □

Physical meaning

The rank of the Gram matrix is the number of physical (non-null) states; the Kac determinant counts the nulls.

What the machine verified

Proved, unconditional. `#print axioms`-clean as part of Theorem 29.26 (re-checked there).

Theorem 29.25 (The Andrews–Gordon identity, coefficientwise). *For all $n, N \in \mathbb{N}$, $\sum_{r \le N} g_n(N, r) = \mathrm{rcq}_n(N)$. Equivalently,*

$$\sum_{\substack{\lambda \vdash N,\ \text{parts} \ge 2 \\ f_j + f_{j+1} \le n}} 1 \;=\; \sum_{k \in \mathbb{Z}} (-1)^k \, p\big(N - e_n(k)\big).$$

File `VOA/Examples/TwoSeriesCharacterAGIdentity.lean`.

```
theorem gordon_sum_eq_rcq (N : ℕ) :
    ((∑ r ∈ Finset.range (N + 1), gordonCoeff n (N : ℤ) r : ℕ) : ℤ) = KacGram.rcq n N := by
```

From the mathematics to the Lean statement

Full name `VOA.TwoSeriesCharacter.AG.gordon_sum_eq_rcq`. The left side is cast from $\mathbb{N}$ to $\mathbb{Z}$. This is the identity for one coefficient N at a time, for every N and n; it is equivalent to the identity of power series $\sum_N(\cdots)q^N = \prod_{j\not\equiv 0,\pm 1 \pmod{2n+3}}(1-q^j)^{-1}$ by Jacobi's triple product, but the library states and uses only the coefficientwise form against the alternating sum.

Proof on paper. Andrews' proof. Let $G_i(x;q) = \sum_{m,N} \#\{\text{partitions with } m \text{ parts, weight } N,\ f_j + f_{j+1} \le n,\ f_1 \le i-1\}\, x^m q^N$ (the shift by one between "parts ≥ 1 with $f_1 \le i-1$" and "parts ≥ 2" is the bookkeeping of `gC`). Removing the smallest parts gives Andrews' recursion $G_{a+1} - G_a = x^a q^a G_{n+1-a}(xq)$ (`GG_rec`). On the other side, Andrews' explicit series $H_i = F \cdot A_i$, with A_i an alternating sum of the Rocha-Caridi shape and $F = 1/(xq)_\infty$, satisfies the same recursion and boundary values (`HH_rec`). The recursion determines the series uniquely (induction on the q-degree, `GG_eq_HH`). Setting $x = 1$, $i = 1$ and reading off the q^N coefficient gives the identity; the evaluation at $x = 1$ is done on a ring of "admissible" two-variable series where it is a ring homomorphism (`Adm`, `ev`). □

Physical meaning

The Andrews–Gordon identity is the statement that the quasi-particle (fermionic) and the Feigin–Fuchs (bosonic) descriptions of the (A_1, A_{2n}) vacuum character agree. For $n = 1$ it is the first Rogers–Ramanujan identity.

What the machine verified

Proved, unconditional. Axioms standard (re-checked).

Theorem 29.26 (The vacuum character of $M(2, 2n+3)$). *For all $n, N \in \mathbb{N}$,*

$$\dim L(c_{2,2n+3}, 0)_N \;=\; \sum_{r \le N} g_n(N, r) \;=\; \mathrm{rcq}_n(N).$$

In particular the total lower bound GordonLowerBound$(c_{2,2n+3}, n)$ *holds.*

File `VOA/Examples/TwoSeriesCharacterAGIdentity.lean`.

```
theorem gordonLowerBound_twoSeries (n : ℕ) :
    VOA.TwoSeriesCharacter.GordonLowerBound (twoSeriesLevels n).c n := by

theorem twoSeries_character (n N : ℕ) :
    Module.finrank ℂ ((VOA.VirSimple.virasoroSimple (twoSeriesLevels n).c).grading (N : ℤ))
     ↪ =
      ∑ r ∈ Finset.range (N + 1), VOA.TwoSeriesCharacter.gordonCoeff n (N : ℤ) r ∧
    ((∑ r ∈ Finset.range (N + 1), VOA.TwoSeriesCharacter.gordonCoeff n (N : ℤ) r : ℕ) : ℤ)
     ↪ =
      VOA.TwoSeriesCharacter.KacGram.rcq n N :=
```

From the mathematics to the Lean statement

$\wedge$ is "and". The first conjunct is an equality of natural numbers, the second of integers. Both are about the *actual simple* Virasoro VOA at $c = c_{2,2n+3}$, for every n including $n = 0$ (where $c = 0$, every count vanishes for $N > 0$ and $L(0,0) = \mathbb{C}$). No hypothesis.

Proof on paper. $\le$: Gordon spanning (Theorem 29.20) with $p = N$ and the jet relations (Theorem 29.19). $\ge$: the Andrews–Gordon identity (Theorem 29.25) turns the count into $\mathrm{rcq}_n(N)$, which is at most $\dim L(c,0)_N$ by Theorem 29.24. The second conjunct is Theorem 29.25. □

Physical meaning

The Schur index of the (A_1, A_{2n}) Argyres–Douglas theory, $\prod_{j\neq 0,\pm 1\,(2n+3)}(1-q^j)^{-1}$, is the vacuum character of $M(2, 2n+3)$: this theorem proves its coefficients one by one from the definition of the simple Virasoro VOA.

What the machine verified

Proved, **unconditional**. Axioms standard (re-checked, both declarations).

Theorem 29.27 (The refined PBW character of $M(2, 2n+3)$). *For every $n \in \mathbb{N}$, $N \in \mathbb{Z}$, $p \in \mathbb{N}$: $\sum_{r\le p} g_n(N, r) \le \dim F_p L(c_{2,2n+3}, 0)_N$. Combined with Theorem 29.20, the inequality is an equality.*

File `VOA/Examples/TwoSeriesCharacterAGIdentity.lean`.

```
theorem twoSeries_hpbw (n : ℕ) :
    ∀ (N : ℤ) (p : ℕ), ∑ r ∈ Finset.range (p + 1), VOA.TwoSeriesCharacter.gordonCoeff n N r
     ↪  ≤
      Module.finrank ℂ ((virGradedFlag (twoSeriesLevels n).c).pieceIn p N) :=
```

From the mathematics to the Lean statement

Exactly the hypothesis `hpbw` of Theorem 29.15 at coeff $= g_n$ (`gordonCoeff n`, read as a function of (N, r)). Proved from Theorems 29.22, 29.19 and 29.26.

Physical meaning

The number of states of $M(2, 2n+3)$ with at most p stress-tensor insertions is exactly the number of exclusion configurations with at most p quanta.

What the machine verified

Proved, unconditional. Axioms standard (re-checked).

Theorem 29.28 (Transfer with the PBW input discharged). *For every n: if $L_{k_n}(\mathfrak{sl}_2)$ is graded unitary and $\dim \mathcal{J}_{r,N} \le g_n(N, r)$ for all N, r, then $M(2, 2n+3)$ is graded unitary.*

File `VOA/Examples/TwoSeriesCharacterAGIdentity.lean`. File `VOA/Examples/TwoSeriesCharacterGU.lean`.

```

    (hA : GradedUnitary (affineForm (twoSeriesLevels n)) (affineRealStructure
     ↪  (twoSeriesLevels n))
      (affineFlag (twoSeriesLevels n)))
    (hinv : ∀ (N : ℤ) (r : ℕ), Module.rank ℂ (affineInvariants (twoSeriesLevels n) r N) ≤
      VOA.TwoSeriesCharacter.gordonCoeff n N r) :
    VirGradedUnitary (twoSeriesLevels n).c (targetRealStructure (twoSeriesLevels n)) :=
```

From the mathematics to the Lean statement

Theorem 29.15 with coeff $= g_n$ and `hpbw` discharged by Theorem 29.27. The remaining hypothesis `hinv` is the *affine invariant count*: it compares a space built from $L_{k_n}(\mathfrak{sl}_2)$ and $L_1(\mathfrak{sl}_2)$ with a count of partitions attached to $M(2, 2n+3)$. At $n = 1$ it was proved in Chapter 28; for $n \ge 2$ it is discharged in Section 29.6.

Physical meaning

"The classical gauge invariants of $(A_1, D_{2n+1}) \otimes$ (free $SU(2)_1$) are no more numerous than the states of (A_1, A_{2n})."

What the machine verified

Proved, `#print axioms`-clean (re-checked), **conditional** on `hA` and `hinv`.

29.6 The affine invariant count: socle words and the jet model

The remaining input is the affine invariant count

$$\dim \mathcal{J}_{r,N} \;\le\; g_n(N,r) \qquad \text{for all } N \in \mathbb{Z},\ r \in \mathbb{N}. \tag{29.5}$$

This section explains how it is reduced, with proofs, to statements about one commutative algebra; the last two of those statements are proved in Sections 29.7 and 29.8.

29.6.1 Why the Lee–Yang argument does not generalize

Dead end: one cyclic dual vector

At $n = 1$ (Chapter 28) the bound (29.5) was proved by evaluating an invariant tensor $\Phi \in (\mathrm{gr}_r A \otimes B)^{\mathfrak{sl}_2[t]}$ against *one* cyclic dual vector w_r of $\mathrm{gr}_r A$, landing in a sector of $B = L_1$ of charge $2r$ whose dimension is the Rogers–Ramanujan count. For $n \ge 2$ this cannot work. At $n = 2$, $r = 2$, $N = 4$ there is a nonzero invariant tensor (the count is $g_2(4,2) = 1$; exact linear algebra over $\mathbb{F}_p$ confirms the invariant), but its evaluation against w_2 would land in the L_1 sector of charge 4 and energy $N - r = 2$, which is zero because that sector starts at energy 4. So the restricted dual of $\mathrm{gr}_r A$ is *not* cyclic over $\mathfrak{sl}_2[t]$ for $n \ge 2$: several dual generators are needed, one for each $\mathfrak{sl}_2[t]$-singular vector (the *socle*). (Source: the docstring of `TwoSeriesInvariantsSocle.lean` and the project's numerical records; the computation is numerical evidence, not a proof, and it is not used by any theorem.)

29.6.2 Socle words

Definition 29.29 (Socle words, their degree, and the socle-word count)**.** A *socle word* of size r is a word $x = (x_1, \dots, x_{N_1})$ in the letters $\{0, \dots, n-1\}$ with $\sum_j (x_j + 1) = r$ (a letter t is a cluster of size $t + 1$). With $c_t(x) = \#\{j : x_j \ge t\}$ and $\mathrm{inv}(x)$ the number of inversions, its degree is $\deg x = N_1 + \sum_{t=1}^{n-1} (c_t^2 + c_t) + \mathrm{inv}(x)$. The *socle-word count* is

$$\mathrm{swc}_n(N,r) = \sum_x \#\{\text{partitions of } N - N_1^2 - \deg x \text{ into at most } N_1 \text{ parts}\},$$

the sum over socle words of size r (of any length $N_1 \le r$).

File `VOA/Examples/TwoSeriesInvariantsSocle.lean`.

```
def SocleWord (n r N₁ : ℕ) : Type := {x : Fin N₁ → Fin n // ∑ j, ((x j : ℕ) + 1) = r}

def clusterAtLeast {n N₁ : ℕ} (x : Fin N₁ → Fin n) (t : ℕ) : ℕ :=
  (Finset.univ.filter fun j => t ≤ (x j : ℕ)).card

def inversions {n N₁ : ℕ} (x : Fin N₁ → Fin n) : ℕ :=
  (Finset.univ.filter fun p : Fin N₁ × Fin N₁ => p.1 < p.2 ∧ x p.2 < x p.1).card
```

```
def socleDegree {n N₁ : ℕ} (x : Fin N₁ → Fin n) : ℕ :=
  N₁ + ∑ t ∈ Finset.Ico 1 n, (clusterAtLeast x t ^ 2 + clusterAtLeast x t) + inversions x

abbrev SocleIndex (n r : ℕ) : Type := Σ N₁ : Fin (r + 1), SocleWord n r N₁

def socleWordCount (n : ℕ) (N : ℤ) (r : ℕ) : ℕ :=
  ∑ i : SocleIndex n r, LeeYangTransferAssembly.gapTwoCoefficient
    (N - (socleDegree i.2.1 : ℤ) + ((i.1 : ℕ) : ℤ)) (i.1 : ℕ)
```

From the mathematics to the Lean statement

`{x : X // P x}` is the subtype of elements satisfying P. `Σ N₁ : Fin (r + 1), ...` is a dependent pair: a length $N_1 \le r$ together with a word of that length. `gapTwoCoefficient M s` is the Lee–Yang coefficient of Chapter 28, the number of partitions of $M - s(s+1)$ into at most s parts (equivalently the coefficient of q^M in $q^{s(s+1)}/(q)_s$); with $M = N - \deg x + N_1$ and $s = N_1$ this is the number of partitions of $N - \deg x - N_1^2$ into at most N_1 parts. The definitions match the textbook ones.

Example 29.30 ($n = 2, r = 2$). The socle words of size 2 in the letters $\{0, 1\}$ are $(0, 0)$ (two clusters of size one: $N_1 = 2, c_1 = 0$, no inversion, degree 2) and (1) (one cluster of size two: $N_1 = 1, c_1 = 1$, degree $1 + 2 = 3$). So $\mathrm{swc}_2(N, 2) = \#\{\lambda \vdash N - 6,\ \le 2 \text{ parts}\} + \#\{\lambda \vdash N - 4,\ \le 1 \text{ part}\}$. At $N = 4$: $0 + 1 = 1$; at $N = 6$: $1 + 1 = 2$; at $N = 8$: $2 + 1 = 3$. These are $g_2(N, 2)$ from Example 29.17.

Physical meaning

A socle word labels a lowest-weight $\mathfrak{sl}_2[t]$-singular state of the classical limit of L_{k_n}: N_1 clusters of currents, a cluster of size $t + 1$ being a bound state of $t + 1$ current quanta. The degree is the energy of the bound-state configuration; the partitions count its descendants. This is the bound-state ("fermionic") picture of the (A_1, D_{2n+1}) chiral algebra.

What the machine verified

Definitions.

Theorem 29.31 (The socle-word count is the Andrews–Gordon count). *For all $n, N, r \in \mathbb{N}$, $\mathrm{swc}_n(N, r) = g_n(N, r)$.*

File `VOA/Examples/TwoSeriesSocleCountGordon.lean`.

```
theorem socleWordCount_eq (n N r : ℕ) :
    socleWordCount n (N : ℤ) r = gordonCoeff n (N : ℤ) r := by
```

From the mathematics to the Lean statement

Full name `VOA.SocleCount.socleWordCount_eq`. An equality of natural numbers for all n, N, r. The corollary `socleWordGordon n` is the inequality form $\mathrm{swc}_n \le g_n$ (for all integer N), which the docstring of `SocleWordGordon` in `TwoSeriesInvariantsSocle.lean` still calls "OPEN" (warning on p. 1604).

Proof on paper. $\#\{\text{partitions of } M \text{ into } \le s \text{ parts}\}$ is the q^M coefficient of $1/(q)_s$. For a fixed content (the multiset of letters, i.e. the cluster profile), MacMahon's theorem says that the inversion generating function of the words with that content is the q-multinomial coefficient. Summing, the socle-word count becomes the fixed-r coefficient of the Andrews (fermionic) multisum $\sum q^{N_1^2+\cdots+N_{n-1}^2+N_1+\cdots+N_{n-1}} / \prod (q)_{N_i - N_{i+1}}$ with an extra variable marking r (`sum_words_eq`, `coeff_F_one_eq`). That multisum satisfies Andrews' recursion and therefore equals the Gordon series of Theorem 29.25 (`F_eq_GG`). □

Physical meaning

The bound-state count of the affine side equals the exclusion-statistics count of the Virasoro side: the two quasi-particle descriptions of the coset agree.

What the machine verified

Proved, unconditional. Axioms standard (re-checked).

Definition 29.32 (Socle data of a mode module). Let M be a $\mathbb{C}$-vector space with operators $\rho(a, j)$ ($a \in \{e, f, h\}$, $j \geq 0$) and a grading $M = \bigoplus_d M_d$. The *lowest-weight singular vectors* of degree d and charge c are the $s \in M_d$ with $\rho(a, j+1)s = 0$ for all a, j, $f_0 s = 0$ and $h_0 s = cs$. Given labels i with degrees $\deg i$ and cluster numbers $\mathrm{cl}(i)$, and a "Cartan image" $\mathrm{Cart}(N) \subseteq M$, *socle data* means: (rank) the singular space of degree d and charge c has dimension at most the number of labels with $\deg i = d$ and $c = -2\,\mathrm{cl}(i)$; (transversality) a singular vector of charge $-2N$ and degree d that lies in $\mathrm{Cart}(N) + \sum_{d' \neq d} M_{d'} + \mathrm{im}(h_0 + 2N)$ is zero.

File `VOA/Examples/TwoSeriesSocleDualCore.lean`.

```
def sing (d : ℤ) (c : ℂ) : Submodule ℂ M where
  carrier := {s | s ∈ Mdeg d ∧ (∀ a j, ρ (a, j + 1) s = 0) ∧ ρ (1, 0) s = 0 ∧
    ρ (2, 0) s = c • s}

def avoid (d : ℤ) (N : ℕ) : Submodule ℂ M :=
  Cart N ⊔ (⨆ (d' : ℤ) (_ : d' ≠ d), Mdeg d') ⊔
    LinearMap.range (ρ (2, 0) + (2 * (N : ℂ)) • (1 : Module.End ℂ M))

structure SocleSpectrum : Prop where
  rank_le : ∀ (d : ℤ) (c : ℂ), finrank ℂ (sing ρ Mdeg d c) ≤
    Nat.card {i : ι // (deg i : ℤ) = d ∧ c = -(2 * (cl i : ℂ))}
  transverse : ∀ (d : ℤ) (N : ℕ),
    Disjoint (sing ρ Mdeg d (-(2 * (N : ℂ)))) (avoid ρ Mdeg Cart d N)
```

From the mathematics to the Lean statement

`ρ (a, j)` with `a : Fin 3` ($0 = e, 1 = f, 2 = h$) is the mode J^a_j; so `ρ (1, 0)` is f_0 and `ρ (2, 0)` is h_0. `⊔` is the sum of submodules and `⨆` an indexed sum; `LinearMap.range` the image. `Disjoint U W` for submodules means $U \cap W = 0$. `Nat.card` of the subtype of labels is the number of labels with the stated degree and charge. The proof fields of the omitted part of the definition (closure under addition and scalars) are routine. Same as the textbook definition. (The source writes `sing` with its proof fields; the quotation omits them, which is why the block stops at `carrier`.)

Physical meaning

The socle is the space of "primary" classical states for the current algebra: those annihilated by all positive modes and by f_0. The rank clause says the bound-state labels exhaust them; transversality says they are detected by their charge and energy.

What the machine verified

Definitions.

Theorem 29.33 (Transfer from the socle data of $\mathrm{gr}_r A$). *For every n: if $L_{k_n}(\mathfrak{sl}_2)$ is graded unitary and $\mathrm{gr}_r A$ (for every r, with the socle words of size r as labels and the Cartan image $I_N \cdot \mathrm{gr}_r A$) has socle data, then $M(2, 2n+3)$ is graded unitary.*

File `VOA/Examples/TwoSeriesSocleDual.lean`.

```

    VirGradedUnitary (twoSeriesLevels n).c (targetRealStructure (twoSeriesLevels n)) :=
  twoSeries_gradedUnitary_of_socleInput n hA S.toSocleInput
```

From the mathematics to the Lean statement

`grRho L r` and `grDeg L r` are the induced mode action and the conformal grading on $\mathrm{gr}_r A$; `grCart L r N` is the image of the Cartan ideal I_N (polynomials in the Cartan modes h_{i+1} acting through $H_{i+1} \mapsto -J^h_{i+1}$). `TwoSeriesSocleSpectrum n` is socle data (Definition 29.32) of the actual $\mathrm{gr}_r A$ for every r. Its docstring still calls it "OPEN"; it is now derivable for every $n \geq 1$ from the results of this and the next two sections, though no declaration states it as a standalone theorem (warning on p. 1604).

Proof on paper. From the socle data one constructs, by duality, a family of functionals on $\mathrm{gr}_r A$, one per socle word, that is *jointly cyclic*: their translates by mode words separate points (`exists_socleDuals`). Each is supported in one degree, has charge $2N_1$ and is killed by the Cartan ideal I_{N_1}. Evaluating an invariant tensor against them maps $\mathcal{I}_{r,N}$ injectively into a sum of L_1 sectors; each sector's Cartan-annihilated dual is bounded by the Heisenberg separation of L_1 (`levelOneHeisenbergSeparation`), giving $\dim \mathcal{I}_{r,N} \leq \mathrm{swc}_n(N, r)$ (`twoSeries_affineInvariants_rank_le_socleWordCount`). By Theorem 29.31 this is $g_n(N, r)$, and Theorem 29.28 applies. □

Physical meaning

Each bound-state primary of the (A_1, D_{2n+1}) classical limit pairs with a lattice sector of the free $SU(2)_1$ boson; the invariant states are counted sector by sector.

What the machine verified

Proved, `#print axioms`-clean, **conditional** on `hA` and `S`. (The intermediate `twoSeries_gradedUnitary_of_socleInput`, re-checked: axioms standard.)

29.6.3 The jet model

The socle data of $\mathrm{gr}_r A$ are hard to compute directly. The route taken embeds $\mathrm{gr}_r A$ into an explicit commutative model, proves the socle data for the model, and pulls them back along the injective intertwiner (`SocleSpectrum.comap`).

Definition 29.34 (The coefficient ring R_n)**.** Let $\mathbb{C}[T] = \mathbb{C}[T_0, T_1, \dots]$ and $T(s) = \sum_j T_j s^j$. The *jet ideal* of T^n is the ideal generated by the coefficients of $T(s)^n$, and $R_n = \mathbb{C}[T]/(\text{jet ideal of } T^n)$, with t_j the image of T_j.

File `VOA/Examples/TwoSeriesStrictEndpoint.lean`. File `VOA/Examples/TwoSeriesJetRing.lean`.

```
abbrev TPoly : Type := MvPolynomial ℕ ℂ

def tSer : PowerSeries TPoly := PowerSeries.mk X

def jetIdealT (n : ℕ) : Ideal TPoly :=
  Ideal.span (Set.range fun j => PowerSeries.coeff j (tSer ^ n))

abbrev Rn (n : ℕ) : Type := TPoly ⧸ jetIdealT n

def tn (n : ℕ) (j : ℕ) : Rn n := Ideal.Quotient.mk (jetIdealT n) (X j)
```

From the mathematics to the Lean statement

`MvPolynomial ℕ ℂ` is the polynomial ring in countably many variables $X_0, X_1, \dots$; `PowerSeries.mk X` is the series $\sum_j X_j s^j$ with coefficients in that ring; `PowerSeries.coeff j` extracts the coefficient of s^j. `Ideal.span (Set.range f)` is the ideal generated by the values of f; `⧸` is the quotient ring. At $n = 1$ the jet ideal contains every T_j, so $R_1 = \mathbb{C}$ (`jetIdealT_one`).

Example 29.35 ($n = 2$). The jet ideal of T^2 is generated by $T_0^2, 2T_0T_1, 2T_0T_2 + T_1^2, 2T_0T_3 + 2T_1T_2, \dots$. So in R_2: $t_0^2 = 0$, $t_0t_1 = 0$, $t_1^2 = -2t_0t_2$, and so on. R_2 is the arc algebra of the double point $\mathbb{C}[T]/(T^2)$, which by classical freeness (Chapter 20) is $\mathrm{gr}^{\mathrm{Li}}$ of $M(2,5)$, the Lee–Yang model.

Physical meaning

R_n is the ring of classical (arc-space) configurations of the stress tensor of $M(2, 2n+1)$: $T^n = 0$ with all its derivatives. It enters because L_{k_n} reduces, under Drinfeld–Sokolov, to $M(2, 2n+1)$, and the model remembers the stress tensor of the reduction.

What the machine verified

Definitions.

Definition 29.36 (The model $S_{n,r}$). Let $R_n[u_j, v_j]$ be the polynomial ring in two sequences of jet variables over R_n. Each generator letter of the corrected PBW basis of $V^k(\mathfrak{sl}_2)$ gets a *model symbol*: a current letter (J^a, j) gets the j-th jet of u^2, uv or v^2 (the Adamović symbols of Chapter 28); the Sugawara letter (L, j) gets the j-th jet of $-(u'v - uv')$ plus t_j. A word's symbol is the product of its letters' symbols. The model $S_{n,r}$ is the span of the symbols of words of length r; its degree-d piece is the span of symbols of words of length r and weight d.

Files `VOA/Examples/TwoSeriesStrictRing.lean` and `VOA/Examples/TwoSeriesStrictWords.lean`.

```
abbrev MPoly : Type := MvPolynomial (Fin 2 × ℕ) R

def mletter : Generator × ℕ → MPoly R
  | (.current a, n) => ι R (letterSym (.current a, n))
  | (.sugawara, n) => ι R (letterSym (.sugawara, n)) + MvPolynomial.C (t n)

def mword (w : List (Generator × ℕ)) : MPoly R := (w.map (mletter R t)).prod

def modelImage (r : ℕ) : Submodule ℂ (MPoly R) :=
  Submodule.span ℂ {Q | ∃ w : List (Generator × ℕ), w.length = r ∧ mword R t w = Q}

def modelDeg (r : ℕ) (d : ℤ) : Submodule ℂ (MPoly R) :=
  Submodule.span ℂ
    {Q | ∃ w : List (Generator × ℕ), w.length = r ∧ wordWt w = d ∧ mword R t w = Q}
```

From the mathematics to the Lean statement

The variables of `MPoly R` are indexed by `Fin 2 × ℕ`: $(0,j) \mapsto u_j$, $(1,j) \mapsto v_j$. `ι R` includes $\mathbb{C}[u_j, v_j]$ into $R[u_j, v_j]$; `letterSym` is the Adamović letter symbol (Chapter 28); `MvPolynomial.C (t n)` is the constant $t_n \in R$. `Generator` has the constructors `.current a` (a in `Fin 3`) and `.sugawara`. `wordWt w` is the conformal weight of the word. The ring R and $t : \mathbb{N} \to R$ are parameters; the model of the series is $R = R_n$, $t = t_\bullet$. So $S_{n,r} =$ `modelImage (Rn n) (tn n) r`.

Physical meaning

This is a free-field (Wakimoto-type) realisation of the classical limit of L_{k_n}: the currents are bilinears in a pair of symplectic bosons (u, v), and the stress tensor is the bilinear $-(u'v - uv')$ corrected by the stress tensor T of the Drinfeld–Sokolov reduction. The nilpotency $T^n = 0$ is what distinguishes level k_n.

What the machine verified

Definitions.

Definition 29.37 (Detection and the model character bound). *Detection* at member n: for every r, if a pair (state y, symbol Q) lies in the span of the pairs (state of a length-r word, its model symbol), modulo (lower PBW length)$\times 0$, and y lies in the maximal ideal of $V^{k_n}(\mathfrak{sl}_2)$, then Q evaluated at the base point $(u, v) = (0, 1)$ vanishes in R_n. *Model character bound*: for every N, the q^N coefficient of the Arakawa–Dai product $\left((q^{2n+1}; q^{2n+1})_\infty/(q;q)_\infty\right)^3$ is at most $\sum_{r \le N} \dim(S_{n,r})_N$.

Files `VOA/Examples/TwoSeriesStrictWords.lean`, `VOA/Examples/TwoSeriesStrictDescent.lean` and `VOA/Examples/TwoSeriesStrictEndpoint.lean`.

```
def symModM (r : ℕ) : Submodule ℂ (WakModule k × MPoly R) :=

def TwoSeriesModelCharacter (n : ℕ) : Prop :=
  ∀ N : ℕ, PowerSeries.coeff N (AffineSl2BoundaryCharacter.product n) ≤
    ∑ r ∈ Finset.range (N + 1), (Module.finrank ℂ (modelDeg (Rn n) (tn n) r (N : ℤ)) : ℚ)
```

From the mathematics to the Lean statement

`symPairsM` is the span of the pairs (`correctedWordState` of a length-r word, `mword` of it), and `(lowerP k hk r).prod ⊥` is $F_{r-1} \times 0$ (lower PBW length, zero symbol). `ImaxL L` is the maximal ideal of V^{k_A}. `evR R` is evaluation at $(u_j, v_j) =$ the base point $(0, 1)$ (only $v_0 = 1$, all other variables 0), with values in R. `AffineSl2BoundaryCharacter.product n` is the Arakawa–Dai product of Chapter 20, Definition 20.5, which equals the vacuum character of L_{k_n} for $n \ge 1$ (`character_eq_product`). The inequality is in $\mathbb{Q}$.

Why detection is the right condition. Detection is equivalent to the model symbol map being well defined on the simple quotient A (`symbol_eq_zero_of_detect`; conversely trivially). The base-point evaluation suffices because the model is cyclic under the modes (`m_cyclic`).

Physical meaning

Detection says that every null state of L_{k_n} has zero classical symbol after restriction to the Kostant slice $f + \mathbb{C}e$; i.e. the nulls of the affine theory are invisible on the slice where the Drinfeld–Sokolov reduction lives. The character bound says that the model has at least as many states as L_{k_n}.

What the machine verified

Definitions (predicates). Detection is proved for every $n \geq 1$ in Section 29.7 (Theorem 29.52); its T-free part was proved earlier at every non-integral level (`evR_aug_eq_zero`); at $n = 1$ it is `twoSeriesModelDetects_one` (re-checked). The character bound is Theorem 29.41.

Definition 29.38 (Strict model maps; model socle data). A *strict model map* at (n, r) is an injective linear map $\mathrm{gr}_r A \to S_{n,r}$ that intertwines the mode actions and preserves the conformal degree. *Model socle data* at (n, r) are socle data (Definition 29.32) for $S_{n,r}$ with its own mode action and Cartan image, labelled by the socle words of size r.

File `VOA/Examples/TwoSeriesStrictEndpoint.lean`.

```
structure StrictModelMap (n r : ℕ) where
  f : GrA (twoSeriesLevels n) r →ₗ[ℂ] modelImage (Rn n) (tn n) r
  injective : Function.Injective f
  intertwine : ∀ k, f ∘ₗ grRho (twoSeriesLevels n) r k = mImgRho (Rn n) (tn n) r k ∘ₗ f
  degree : ∀ d, ∀ m ∈ grDeg (twoSeriesLevels n) r d, f m ∈ mImgDeg (Rn n) (tn n) r d

def ModelSocleSpectrum (n r : ℕ) : Prop :=
  SocleSpectrum (mImgRho (Rn n) (tn n) r) (mImgDeg (Rn n) (tn n) r)
    (fun i : SocleIndex n r => socleDegree i.2.1) (fun i => (i.1 : ℕ))
    (modelCart (mImgRho (Rn n) (tn n) r) (mImg_cartanCommute (Rn n) (tn n) r))
```

From the mathematics to the Lean statement

`→ₗ[ℂ]` is a $\mathbb{C}$-linear map, `∘ₗ` composition of linear maps. `mImgRho` is the mode action on the model (the jet derivations of u, v together with the derivation of R_n), `mImgDeg` the degree pieces, `modelCart` the image of the Cartan ideal on the model. The labels are the socle words of Definition 29.29: degree `socleDegree`, cluster number N_1.

Physical meaning

A strict model map is a faithful free-field realisation of the classical limit, compatible with the current algebra and with energy. Model socle data are the bound-state spectrum computed in the free-field model.

What the machine verified

Definitions.

Theorem 29.39 (Transfer from the strict model). *For every $n \geq 1$: graded unitarity of L_{k_n}, detection, the model character bound and model socle data for every r imply graded unitarity of $M(2, 2n + 3)$.*

File `VOA/Examples/TwoSeriesStrictEndpoint.lean`.

```
theorem twoSeries_gradedUnitary_of_strictModel (n : ℕ) (hn : 1 ≤ n)
    (hA : GradedUnitary (affineForm (twoSeriesLevels n)) (affineRealStructure
     ↪  (twoSeriesLevels n))
      (affineFlag (twoSeriesLevels n)))
```

```
    (det : TwoSeriesModelDetects n) (chi : TwoSeriesModelCharacter n)
    (spec : ∀ r, ModelSocleSpectrum n r) :
    VirGradedUnitary (twoSeriesLevels n).c (targetRealStructure (twoSeriesLevels n)) :=
  twoSeries_gradedUnitary_of_socleModels n hA
    fun r => twoSeriesSocleModel_of_strict hn det chi r (spec r)
```

From the mathematics to the Lean statement

Full name `VOA.TwoSeries.StrictModel.twoSeries_gradedUnitary_of_strictModel`. The hypothesis $1 \le n$ is needed because the equality of the Arakawa–Dai product with the character is proved only for $n \ge 1$ (`character_eq_product`; at $n = 0$ both sides are 1, but no declaration states it). The strict maps are `twoSeriesStrictModel hn det chi r`: the model symbol is well defined on A by detection, and injective by a dimension squeeze against the character bound (`ModelSymbol.injective_of_bound`).

Proof on paper. Detection makes the symbol map $\sigma : \mathrm{gr}_r A \to S_{n,r}$ well defined; it is surjective onto $S_{n,r}$ by construction (both are spanned by words). Summed over r, $\dim A_N = \sum_r \dim \mathrm{gr}_r A_N$ (`sum_finrank_grDegL`) is the character of A, which by the model character bound is at most $\sum_r \dim(S_{n,r})_N$; a surjection between spaces whose dimensions go the other way is an isomorphism, so each σ is injective. Socle data pull back along injective intertwiners (`SocleSpectrum.comap`); apply Theorem 29.33. □

Physical meaning

If the free-field model is faithful (no affine null state survives in it) and big enough (at least as many states), it is exact, and its bound-state spectrum is that of L_{k_n}.

What the machine verified

Proved, `#print axioms`-clean (re-checked), **conditional** on `hA`, `det`, `chi`, `spec`.

29.6.4 The model character: the Bailey chain

Definition 29.40 (The Chern–Tran–Wakhare fermionic series)**.** Let $\beta_N^{(0)} = \delta_{N,0}$ and $\beta_N^{(n+1)} = \sum_{k \le N} q^{k^2+k} \beta_k^{(n)} / (q)_{N-k}$ (the Bailey chain started at the unit sequence). The *fermionic series* is

$$\mathrm{ferm}_n(q) \;=\; \sum_{N \ge 0} q^N \Big(\sum_{k \le 2N} \begin{bmatrix} 2N \\ k \end{bmatrix}_q \Big) \beta_N^{(n)}.$$

File `VOA/Examples/TwoSeriesModelCharFermionic.lean`.

```
def bet : ℕ → ℕ → PowerSeries ℚ
  | 0, N => if N = 0 then 1 else 0
  | n + 1, N => ∑ k ∈ Finset.range (N + 1),
      PowerSeries.X ^ (k * k + k) * reciprocalQFactorial (N - k) * bet n k

def fermTerm (n N : ℕ) : PowerSeries ℚ :=
  PowerSeries.X ^ N * (∑ k ∈ Finset.range (2 * N + 1), gaussian PowerSeries.X (2 * N) k) *
    bet n N

def fermSeries (n : ℕ) : PowerSeries ℚ := VOA.LocallyFinitePowerSeriesSum.sum (fermTerm n)
```

From the mathematics to the Lean statement

`PowerSeries.X` is q; `reciprocalQFactorial m` is $1/(q)_m$; `gaussian PowerSeries.X M k` the Gaussian binomial $\begin{bmatrix} M \\ k \end{bmatrix}_q$. `LocallyFinitePowerSeriesSum.sum` is the sum of a sequence of power series in which each coefficient receives finitely many contributions (here `fermTerm n N` starts at q^N), Chapter 20, Definition 20.7. Unwinding the recursion, $\beta_N^{(n)} = \sum_{N\ge N_1\ge\cdots\ge N_{n-1}\ge 0} q^{\sum_s (N_s^2+N_s)} / \prod_s (q)_{N_s-N_{s+1}}$ (with the conventions $N_0 = N$, $N_n = 0$, the sums and products over $1 \le s \le n-1$ and $0 \le s \le n-1$ respectively), a Gordon colour-profile sum.

Physical meaning

A quasi-particle formula for the vacuum character of $L_{k_n}(\mathfrak{sl}_2)$: N counts current quasi-particles, $\sum_k [2N,k]_q$ their $\mathfrak{sl}_2$ weights, and $\beta^{(n)}$ the clustering into bound states of size $\le n$.

What the machine verified

Definition. At $n = 1$ it is the level-one jet series of Chapter 28 (`fermSeries_one`).

Theorem 29.41 (The fermionic series is the product; the model character bound). *For every $n \in \mathbb{N}$, $\mathrm{ferm}_n = \big((q^{2n+1};q^{2n+1})_\infty/(q;q)_\infty\big)^3$. For every $n \ge 1$ the model character bound holds.*

Files `VOA/Examples/TwoSeriesModelCharFermionic.lean` and `VOA/Examples/TwoSeriesModelCharEndpoint.lean`.

```
theorem fermSeries_eq_product (n : ℕ) :
    fermSeries n = AffineSl2BoundaryCharacter.product n := by

theorem twoSeriesModelCharacter_all (n : ℕ) (hn : 1 ≤ n) : TwoSeriesModelCharacter n := by
  intro N
  rw [← fermSeries_eq_product n]
  exact fermSeries_le_model hn N
```

From the mathematics to the Lean statement

Full names `VOA.TwoSeries.ModelChar.fermSeries_eq_product` and `VOA.TwoSeries.ModelChar.twoSeriesModelCharacter_all`. The first is an equality of power series over $\mathbb{Q}$ (all coefficients), for every n. The second rewrites the product as the fermionic series and applies the lower bound `fermSeries_le_model`: the q^N coefficient of the fermionic series is at most $\sum_{r\le N} \dim(S_{n,r})_N$. No hypothesis beyond $n \ge 1$.

Proof on paper. Product. Multiply by $(q;q)_\infty^3$. A terminating q-binomial identity $\sum_m [M,m]_q (-1)^m q^{\binom{M-m}{2}} (x;q)_m = q^{\binom{M}{2}} x^M$ (`newton_sum`) shows, by induction on n, that the Bailey transform of $\beta^{(n)}$ is a pure power $q^{nj(j+1)+\binom{j}{2}}$ (`cTr_eq`). Combined with a moment identity for $(q)_\infty^3 \sum_N q^N \sum_k [2N,k]_q(\cdots)$ and Jacobi's identity $(q)_\infty^3 = \sum_j (-1)^j (2j+1) q^{j(j+1)/2}$, this gives $(q;q)_\infty^3\,\mathrm{ferm}_n = (q^{2n+1};q^{2n+1})_\infty^3$ (`euler_cube_mul_fermSeries`). *Lower bound.* For each Gordon colour profile one writes down explicit elements of $S_{n,r}$ (block covariants $T^c G$ times symmetrised Feigin–Stoyanovsky functions) and functionals that are triangular against them (`fFS`, `gFS`, `LamG`); triangularity proves linear independence, and the number of these elements in weight N is the q^N coefficient of the fermionic series (`fermSeries_le_model`). □

Physical meaning

The vacuum character of the (A_1, D_{2n+1}) chiral algebra has the quasi-particle form of Chern, Tran and Wakhare and the product form of Kac–Wakimoto/Arakawa–Dai; the theorem identifies the two and shows the free-field model is big enough to carry all of it.

What the machine verified

Proved, **unconditional** (the second for $n \geq 1$). Axioms standard (re-checked, both).

Theorem 29.42 (Transfer with the character bound discharged). *For every $n \geq 1$:* $\mathrm{GU}(L_{k_n})$, *detection and model socle data imply* $\mathrm{GU}(M(2, 2n+3))$.

File `VOA/Examples/TwoSeriesModelCharEndpoint.lean`.

From the mathematics to the Lean statement

Theorem 29.39 with `chi` supplied by Theorem 29.41. Full name `VOA.TwoSeries.ModelChar.twoSeries_gradedUnitary_of_strictModel_det`.

Physical meaning

What is left: the nulls are invisible on the slice (detection), and the bound-state spectrum of the free-field model is the expected one (socle data).

What the machine verified

Proved, `#print axioms`-clean (re-checked), **conditional** on `hA`, `det`, `spec`.

29.6.5 The model socle data, and the jet-ideal Poincaré lemma

The model socle data have two halves. **Transversality** is proved outright for every coefficient ring with a scaling automorphism (`model_transverse`, re-checked: axioms standard): the functional "coefficient of v_0^{2N}" kills $\mathrm{im}(h_0 + 2N)$ and the Cartan image, separates degrees through the scaling $t_j \mapsto 2^{j+1} t_j$, and is injective on singular vectors of charge $-2N$, which all have the form $\tau\, v_0^{2N}$. The **rank** half is reduced, through a chain of files, to a statement about $\mathbb{C}[T]$ alone:

1. A singular vector of degree d and charge $-q$ in $S_{n,r}$ is $\tau\, v_0^q$ with τ in the *membership space* $\{\tau \in R_n : \tau v_0^q \in (S_{n,r})_d\}$, injectively; odd q give nothing (`TwoSeriesModelSocleEndpoint`).

2. The membership space for N clusters lies in the image of T-polynomials of degree $r - N$ and weight $d - r$, and the cases $N \geq r$ are immediate (`TwoSeriesMembershipLine`).

3. *Box count* (proved for every n, r: `boxCount_all`, re-checked): the polynomials in $T_0, \dots, T_{N-1}$ of degree $r - N$ and weight $d - r$ have image in R_n of dimension at most the socle-word count. The proof is a fusion-product recursion for symmetric polynomials (`TwoSeriesBoxFusion`).

4. *Box inclusion*: the membership space lies in the span of monomials in $T_0, \dots, T_{N-1}$ (the "box"). It is proved directly in the slots with $N \le 1$, with T-degree $\le n+1$, and with weight below $2N+k$; the remaining slots are exactly the jet-ideal Poincaré lemma below (`TwoSeriesHighReduce`, `TwoSeriesHighEndpoint`, `TwoSeriesHighDegSucc`, `TwoSeriesPoincareZero`).

Definition 29.43 (T-monomial spans; the box). For a ring R with elements t_j: $\mathrm{tMon}(k,e)$ is the span of the products $t_{m_1}\cdots t_{m_k}$ with $\sum_i (m_i+1) = e$; $\mathrm{box}(N,k,e)$ is the span of those products with every $m_i < N$.

Files `VOA/Examples/TwoSeriesMembershipLine.lean` and `VOA/Examples/TwoSeriesMembershipEndpoint.lean`.

```
def tMonW (t : ℕ → R) (k : ℕ) (e : ℤ) : Submodule ℂ R :=
  Submodule.span ℂ
    {x | ∃ l : List ℕ, l.length = k ∧ (((l.map fun m => m + 1).sum : ℕ) : ℤ) = e ∧
      (l.map t).prod = x}

def boxW (t : ℕ → R) (N k : ℕ) (e : ℤ) : Submodule ℂ R :=
  Submodule.span ℂ {x | ∃ l : List ℕ, l.length = k ∧ (((l.map fun m => m + 1).sum : ℕ) : ℤ)
   ↪  = e ∧
    (∀ m ∈ l, m < N) ∧ (l.map t).prod = x}
```

From the mathematics to the Lean statement

A list $l = (m_1, \dots, m_k)$ encodes the monomial $t_{m_1}\cdots t_{m_k}$; its weight is $\sum(m_i+1)$ (the jet T_m has weight $m+1$ in these files). `R` is `TPoly` (with $t = X$) or `Rn n` (with $t = t_\bullet$).

Physical meaning

The box is the space of classical stress-tensor configurations that use only the first N Fourier modes; the Poincaré lemma says a configuration whose high-mode derivatives are null is, up to nulls, of this low-mode form.

What the machine verified

Definitions.

Definition 29.44 (The jet-ideal Poincaré lemma, and its core slots). $\mathrm{JP}_n(N,k,E)$: every $F \in \mathbb{C}[T]$ of degree k and weight E (a combination of monomials $T_{m_1}\cdots T_{m_k}$ with $\sum(m_i+1) = E$) such that $\partial F/\partial T_M$ lies in the jet ideal of T^n for every $M \ge N$ is, modulo the jet ideal, in $\mathrm{box}(N,k,E)$. The *core* JPCore_n is $\mathrm{JP}_n(N,k,E)$ for all $N \ge 2$, $k \ge n+2$, $2N+k \le E$ and $2N+2k < E+n+2$.

Files `VOA/Examples/TwoSeriesHighJet.lean` and `VOA/Examples/TwoSeriesPoincareZero.lean`.

```
def JetPoincare (n N k E : ℕ) : Prop :=
  ∀ F ∈ tMonW TPoly MvPolynomial.X k (E : ℤ), (∀ M, N ≤ M → pderiv M F ∈ jetIdealT n) →
    Ideal.Quotient.mk (jetIdealT n) F ∈ boxW (tn n) N k (E : ℤ)

def JetPoincareCoreT0 (n : ℕ) : Prop :=
  ∀ N k E : ℕ, 2 ≤ N → n + 2 ≤ k → 2 * N + k ≤ E → 2 * N + 2 * k < E + n + 2 →
    JetPoincare n N k E
```

From the mathematics to the Lean statement

`pderiv M F` is $\partial F/\partial T_M$; `Ideal.Quotient.mk` the projection $\mathbb{C}[T] \to R_n$. `JetPoincare` lives in the namespace `VOA.TwoSeries.StrictModel.HighJet`, `JetPoincareCoreT0` in `VOA.TwoSeries.StrictModel.PoincareZero`. Our JPCore_n is `JetPoincareCoreT0 n`; the library also has a pred-

icate `JetPoincareCore n` (`TwoSeriesHighDegSucc.lean`) without the last constraint, a different and stronger statement, converted by `jetPoincareCore_of_T0`. The slots outside the core are proved: $N = 0$ (Euler identity, `jetPoincare_zero`), $N = 1$ (`jetPoincare_one`), $E < 2N + k$ (`jetPoincare_of_wt_lt`: no monomial has two indices $\geq N$), $k = n+1$ (`jetPoincare_degSucc`, by an explicit primitive), and $E + n + 2 \leq 2N + 2k$ (`jetPoincare_of_T0`: every monomial with two high indices contains $T_0^n = (T^n)_0$). The box inclusions with T-degree $k \leq n$ never use the lemma; they are proved through a separate "test ring" (`boxInclusion_low`, `boxInclusion_degN`). This is why the core starts at $k \geq n + 2$ and $N \geq 2$.

Physical meaning

A "Poincaré lemma" for the arc space of the fat point $T^n = 0$: a classical configuration that is closed in the high directions is exact up to the constraints. It is the classical statement that the null-vector constraints of $M(2, 2n + 1)$ do not generate unexpected bound states.

What the machine verified

Definitions (predicates). JPCore_n is proved for every $n \geq 1$ (Theorem 29.55).

Theorem 29.45 (Transfer from detection and the Poincaré core). *For every $n \geq 1$:* $\mathrm{GU}(L_{k_n})$, *detection and* JPCore_n *imply* $\mathrm{GU}(M(2, 2n + 3))$.

File `VOA/Examples/TwoSeriesPoincareZero.lean`.

```
theorem twoSeries_gradedUnitary_of_strictModel_jetPoincareCoreT0 (n : ℕ) (hn : 1 ≤ n)
    (hA : GradedUnitary (affineForm (twoSeriesLevels n)) (affineRealStructure
    ↪  (twoSeriesLevels n))
      (affineFlag (twoSeriesLevels n)))
    (det : TwoSeriesModelDetects n) (h : JetPoincareCoreT0 n) :
    VirGradedUnitarity.VirGradedUnitary (twoSeriesLevels n).c
      (targetRealStructure (twoSeriesLevels n)) :=
  twoSeries_gradedUnitary_of_strictModel_jetPoincareCore n hn hA det (jetPoincareCore_of_T0
  ↪  h)
```

From the mathematics to the Lean statement

Full name `VOA.TwoSeries.StrictModel.twoSeries_gradedUnitary_of_strictModel_jetPoincareCoreT0`. The model socle data are assembled from transversality, box count, and box inclusion (proved slots plus `h`); the character bound from Theorem 29.41.

Proof on paper. Box inclusion in every slot follows from the proved slots and JPCore_n: given a membership element τ, lift it to $F \in \mathbb{C}[T]$; the model relations show that $\partial F/\partial T_M$ is in the jet ideal for $M \geq N$ (`TwoSeriesHighReduce`); the Poincaré lemma puts τ in the box. With the box count this bounds the membership spaces by the socle-word count, which is the rank half; transversality is proved. Apply Theorem 29.42. □

Physical meaning

Everything about the free-field model reduces to one classical fact about the arc space of $T^n = 0$, plus the statement that the affine nulls are invisible on the slice.

What the machine verified

Proved, `#print axioms`-clean (re-checked), **conditional** on `hA`, `det`, `h`.

29.7 Detection: the Drinfeld–Sokolov slice map

Detection (Definition 29.37) asks that the model symbol of every null vector of V^{k_n} vanish at the base point. At $n = 1$ ($R_1 = \mathbb{C}$) it followed from the level-one vacuum functional. For $n \geq 2$ the values lie in the non-reduced ring R_n, and the vacuum functional only sees their constant part (`evR_aug_eq_zero`). The idea that closes the gap is that evaluating at the base point $(u, v) = (0, 1)$ is the classical shadow of *Drinfeld–Sokolov reduction*: restricting to the Kostant slice $f + \mathbb{C}e$. So one builds a quantum map from V^k to the Virasoro vacuum module at the Drinfeld–Sokolov central charge, shows it sends nulls to nulls, and composes with the leading-symbol map of the Virasoro side, whose target is exactly R_n.

29.7.1 The Virasoro side: leading symbols into R_n

Definition 29.46 (The Virasoro symbol property). For $c \in \mathbb{C}$, a ring R and $t : \mathbb{N} \to R$: there are linear maps $\sigma_b : V(c, 0) \to R$ ($b \in \mathbb{N}$) that kill the maximal ideal, kill every creation word of length $< b$, and send every creation word $L_{-j_1-2} \cdots L_{-j_b-2}|0\rangle$ of length b (in any order) to $t_{j_1} \cdots t_{j_b}$.

File `VOA/Examples/TwoSeriesDSVirSymbol.lean`.

```
def vLen (b : ℕ) : Submodule ℂ (VirUniv c) :=
  Submodule.span ℂ {x | ∃ w : List ℕ, w.length ≤ b ∧ negWordVir c w = x}

def vBelow (b : ℕ) : Submodule ℂ (VirUniv c) :=
  Submodule.span ℂ {x | ∃ w : List ℕ, w.length < b ∧ negWordVir c w = x}

def VirSymbol : Prop :=
  ∃ σ : ℕ → (VirUniv c →ₗ[ℂ] R),
    (∀ b, ∀ v ∈ maxIdealVir c, σ b v = 0) ∧
    (∀ b, ∀ v ∈ vBelow c b, σ b v = 0) ∧
    (∀ w : List ℕ, σ w.length (negWordVir c w) = (w.map t).prod)
```

From the mathematics to the Lean statement

`negWordVir c w` is the creation word $L_{-w_1-2} \cdots L_{-w_\ell-2}|0\rangle$ for the list w (no ordering assumed). `(w.map t).prod` is $t_{w_1} \cdots t_{w_\ell}$. The words in `vLen`, `vBelow` have any weight and any order. Same as the textbook definition.

Physical meaning

A leading-symbol (classical-limit) map for the Virasoro chiral algebra with values in a ring where T^n's jets vanish: the quantum states of the minimal model project onto classical stress-tensor configurations.

What the machine verified

Definition.

Theorem 29.47 (Leading symbols of $M(2, 2m + 3)$). *For every $m \in \mathbb{N}$, the Virasoro symbol property holds for $c = c_{2,2m+3}$ with values in R_{m+1}.*

File `VOA/Examples/TwoSeriesDSVirSymbol.lean`.

```
theorem virSymbol_twoSeries (m : ℕ) :
    VirSymbol (twoSeriesLevels m).c (Rn (m + 1)) (tn (m + 1)) :=
  virSymbol_of _ _ _ m (twoSeries_hasJetRelations_all m) (gordonLowerBound_twoSeries m)
    (jet_rel_Rn m)
```

From the mathematics to the Lean statement

Full name `VOA.TwoSeries.DSSlice.virSymbol_twoSeries`. Note the indices: (`twoSeriesLevels m`).$c = c_{2,2m+3}$ and the ring is R_{m+1}, the arc algebra of $\mathbb{C}[T]/(T^{m+1})$. The proof uses the jet relations (Theorem 29.19), the total Gordon lower bound (Theorem 29.26) and the jet relations of R_{m+1} (`jet_rel_Rn`).
Scope. This is a PBW-length leading-symbol statement into the *presented* ring R_{m+1}; it does not mention Li's filtration or V/C_2V. Intrinsic classical freeness of $M(2, 2m+3)$ is a separate theorem (`VOA.VirasoroClassicalFreeness.classicallyFree`, Chapter 20) that uses this one as its injectivity input. The docstring of `TwoSeriesDSSlice.lean` still calls this input "classical freeness of $M(2, 2n+1)$" (warning on p. 1604).

Proof on paper. The Gordon-good sorted words form a basis of $L(c, 0)$ (spanning plus the character). Define σ_b on this basis: a Gordon-good word of length b goes to the product of its jets, every other basis word to 0. It remains to see that σ_b has the product property on *every* word. Straighten simultaneously: a pair (Virasoro word, its T-monomial) is rewritten, by the same jet relation applied on both sides (in $V(c, 0)$ the null vector of Theorem 29.19, in R_{m+1} the jets of T^{m+1}), into a combination of pairs of Gordon-good words of the same length, modulo (shorter words + maximal ideal)×0 (`pair_mem_pairGood`). Both sides of the product property are linear and compatible with this rewriting. □

Physical meaning

The null-vector relation of $M(2, 2m+3)$ and the classical constraint $T^{m+1} = 0$ have the same leading term, so the quantum straightening and the classical one run in parallel.

What the machine verified

Proved, **unconditional**. Axioms standard (re-checked).

29.7.2 The slice map and its Arakawa property

Definition 29.48 (A Drinfeld–Sokolov slice map; the slice Arakawa property)**.** For a central charge c and a level datum L, a *slice map* is a linear map $W : V^{k_A}(\mathfrak{sl}_2) \to \bigoplus_{a\in\mathbb{Z}} V(c, 0)$ (graded by the Rees parameter a) with: $W(|0\rangle) = |0\rangle$ in degree 0; the Whittaker relations $W \circ f_{-1} = -(\text{shift by one}) \circ W$ and $W \circ f_{-j-2} = 0$; the filtration property that a corrected PBW word of length ℓ has degree-a image of Virasoro length $\le \ell - a$, one less if it starts with an e- or h-letter; and the Sugawara letter acting as L_{-m-2} up to that lower piece. The *slice Arakawa property* of W: W maps the maximal ideal of V^{k_A} into the maximal ideal of $V(c, 0)$, in every degree.

File `VOA/Examples/TwoSeriesDSSlice.lean`.

```

def SliceArakawa (S : DSSliceMap c L) : Prop :=
  ∀ y ∈ ImaxL L, ∀ a : ℤ, S.W y a ∈ maxIdealVir c
```

From the mathematics to the Lean statement

`ℤ →₀ VirUniv c` is the space of finitely supported functions $\mathbb{Z} \to V(c,0)$, i.e. $\bigoplus_{a\in\mathbb{Z}} V(c,0)$; `W y a` is the degree-$a$ component, `Finsupp.single 0 v` the element v in degree 0. `J L.kA 1 (-1)` is f_{-1} (`Fin 3`: $1 = f$), `J L.kA 1 (-j-2)` is f_{-j-2}. `correctedWordState k hk w` is the corrected PBW word of V^k for the list of letters w (Chapter 28). `vLenZ c b` is the span of Virasoro words of length $\le b$ (and 0 for $b < 0$). `ImaxL L` is the maximal ideal of V^{k_A}. All the fields of `DSSliceMap` are statements about the *universal* objects; only `SliceArakawa` mentions the maximal ideals.

Physical meaning

W is the quantum Hamiltonian reduction $V^k(\mathfrak{sl}_2) \to \mathrm{Vir}^{c_{\mathrm{DS}}(k)}$ made concrete on the vacuum module: impose $f(z) = 1$ (the Whittaker character, $f_{-1} \mapsto -1$, higher f-modes $\mapsto 0$), and read the result in the Virasoro algebra generated by the improved Sugawara field. The slice Arakawa property says the reduction of the simple affine VOA is a quotient of the simple Virasoro VOA's universal cover by something containing its nulls: the "nulls go to nulls" half of Arakawa's theorem $H_{DS}(L_k(\mathfrak{sl}_2)) \cong L(c_{\mathrm{DS}}(k), 0)$.

What the machine verified

Definitions. Inhabited for every c and L (Definition 29.50); the Arakawa property is proved at every level datum whose affine level is not a natural number (Theorem 29.51).

Theorem 29.49 (Detection from a slice map). *For every m: a slice map $V^{k_{m+1}} \to \bigoplus_a V(c_{2,2m+3}, 0)$ with the slice Arakawa property gives detection at member $n = m + 1$.*

File `VOA/Examples/TwoSeriesDSSlice.lean`.

```
theorem twoSeriesModelDetects_of_dsSlice (m : ℕ)
    (S : DSSliceMap (twoSeriesLevels m).c (twoSeriesLevels (m + 1))) (hS : SliceArakawa S)
    ↪ :
    TwoSeriesModelDetects (m + 1) :=
  modelDetects_of_dsSlice S hS (virSymbol_twoSeries m)
```

From the mathematics to the Lean statement

The Virasoro charge is $c_{2,2m+3} = c_{\mathrm{DS}}(k_{m+1})$, one step below the target $c_{2,2m+5}$ of the member $n = m + 1$ (Example 29.2, last column). The Virasoro symbol input is Theorem 29.47.

Proof on paper. Put $\Lambda_r = \sum_a \sigma_{r-a} \circ W_a : V^k \to R_{m+1}$. It kills the maximal ideal (Arakawa property, then σ kills the Virasoro maximal ideal), kills corrected words of length $< r$ (filtration property), and on a word of length r equals the model symbol evaluated at the base point (Whittaker relations for the f-letters, which give $v_0 \mapsto 1$; the lower-term properties for e, h; the Sugawara property for the L-letters, whose symbol is t_j at the base point). Hence the base-point evaluation of the symbol of a null vector is Λ_r of it, which is 0. □

Physical meaning

Evaluating classical symbols on the Kostant slice is the classical limit of Drinfeld–Sokolov reduction; detection is the classical limit of "nulls reduce to nulls".

What the machine verified

Proved, `#print axioms`-clean (re-checked), conditional on `S` and `hS` (both supplied below).

Definition 29.50 (The constructed slice map). For every c and non-critical k: $W_0 : V^k \to \mathbb{C}[X_0, X_1, \dots]$ is the Whittaker coinvariant map (on the (f,h,e)-ordered PBW basis, $f^\lambda h^\nu e^\mu|0\rangle \mapsto \chi(f^\lambda)[\nu = 0]X^\mu$); ψ is the inverse of the isomorphism $V(c,0) \to \mathbb{C}[X]$ sending a Virasoro word to the corresponding word of descended Sugawara operators applied to 1; $W_1 = \psi \circ W_0$; and W places the image of a word of charge $\#f - \#e = a$ in degree a.

Files `VOA/Examples/TwoSeriesSliceMap.lean` and `VOA/Examples/TwoSeriesArakawaPositive.lean`.

```
def W1 : WakModule k →ₗ[ℂ] VirUniv c := (psi c k hk).toLinearMap.comp (W0 k hk)

    exact Submodule.zero_mem _

def cDS (k : ℂ) : ℂ := 1 - 6 * (k + 1) ^ 2 / (k + 2)
```

From the mathematics to the Lean statement

`psi c k hk` is a linear *equivalence* (`phi_injective`, `phi_surjective` in `TwoSeriesSliceMapVir.lean`); `.toLinearMap.comp` is composition. `chargeLift` implements the Rees grading. Every field of the structure is a proved lemma; the Sugawara property holds *exactly* (difference 0). `cDS k` is the Drinfeld–Sokolov central charge $1 - 6(k+1)^2/(k+2)$. The construction works for every c; only the Arakawa property needs $c = c_{\mathrm{DS}}(k)$.

Physical meaning

The Whittaker coinvariants of the vacuum module are a polynomial ring in the e-modes, and the improved Sugawara modes act on them triangularly, which identifies them with the Virasoro vacuum module: the vacuum-module version of Kostant's theorem on Whittaker vectors.

What the machine verified

Construction, proved; `#print axioms` of `dsSliceMap` standard (re-checked).

Theorem 29.51 (The slice form of Arakawa's theorem, unconditionally). *For every level datum L (Definition 29.3) whose affine level $k = k_A$ is not a natural number, the slice map at $c = c_{\mathrm{DS}}(k)$ sends the maximal ideal of $V^k(\mathfrak{sl}_2)$ into the maximal ideal of $V(c_{\mathrm{DS}}(k), 0)$, in every Rees degree. For an arbitrary non-critical $k \notin \mathbb{N}$ (no level datum) the same holds for the ungraded map W_1. In particular, for every m, the slice map of the member $n = m+1$ at $c = c_{2,2m+3}$ has the slice Arakawa property.*

File `VOA/Examples/TwoSeriesArakawaUnconditional.lean`.

```
theorem W1_maxIdeal (hkN : ∀ i : ℕ, k ≠ i) {y : WakModule k} (hy : y ∈ Imax k hk) :
    W1 (cDS k) k hk y ∈ maxIdealVir (cDS k) := by

theorem sliceArakawa_unconditional (L : CosetLevels) (hkN : ∀ i : ℕ, L.kA ≠ i) :
    SliceArakawa (dsSliceMap (cDS L.kA) L) := by

theorem twoSeries_kA_not_nat (m : ℕ) (i : ℕ) : (twoSeriesLevels (m + 1)).kA ≠ i := by

theorem twoSeries_sliceArakawa (m : ℕ) :
    SliceArakawa (dsSliceMap (twoSeriesLevels m).c (twoSeriesLevels (m + 1))) := by
```

From the mathematics to the Lean statement

`hkN : ∀ i : ℕ, k ≠ i` says $k \notin \{0, 1, 2, \dots\}$ (as complex numbers). `Imax k hk` is the maximal graded ideal of V^k. For generic k that ideal is 0 and the statement is trivial; it has content exactly at levels where V^k is reducible, such as k_n. `twoSeries_kA_not_nat`: $k_{m+1} = -2 + 2/(2m+3) \in (-2, 0)$ is not a natural number. `twoSeries_sliceArakawa` rewrites $c_{2,2m+3} = c_{\mathrm{DS}}(k_{m+1})$ (`twoSeries_c_eq_cDS`) and applies the general theorem. No other hypothesis.
Same, stronger or weaker than Arakawa? Weaker, deliberately: Arakawa's theorem identifies $H_{DS}(L_k)$ with $L(c_{\mathrm{DS}}(k), 0)$ (including non-vanishing and surjectivity statements about cohomology). Here only the "descends" half is proved, for this explicit map on the vacuum module, and only it is used. No result of Arakawa's is assumed.

Proof on paper. Let I be the maximal ideal of V^k and $S = W_1(I) \subseteq V(c, 0)$, $c = c_{\mathrm{DS}}(k)$. (1) S is stable under the Virasoro creation modes, because $W_1 \circ L_n^{\mathrm{sug}} = L_n \circ W_1$ for $n \leq -1$ and I is stable under the Sugawara modes. (2) S is stable under L_1, L_2, hence under all $L_{n \geq 1}$: there are explicit lifts $Q_1 = L_1 + h_1 + k f_0 + \frac{1}{2} f_0 h_0$ and Q_2 (a similar quadratic expression) with $W_1 \circ Q_i = L_i \circ W_1$, and $Q_i I \subseteq I$ since I is an ideal. (3) No vector of S has a vacuum component: the vacuum coefficient of $W_1(y)$ only sees the PBW words of Drinfeld–Sokolov weight zero, the powers $f_{-1}^N|0\rangle$; a polynomial projector in the commuting operators L_0, h_0 keeps y in I and isolates such a component, and $e_1^N f_{-1}^N|0\rangle = N!\, k(k-1)\cdots(k-N+1)|0\rangle \neq 0$ for $k \notin \mathbb{N}$, while $|0\rangle \notin I$; so that component is 0 (`eps_maxIdeal`). (4) A subspace stable under all modes with no vacuum component lies in the radical of the Shapovalov form, which is the maximal ideal of $V(c, 0)$ (Li). The graded components of $W =$ `chargeLift` W_1 are separated by a Lagrange projector in h_0. □

Physical meaning

"Under quantum Hamiltonian reduction, null states of $L_k(\mathfrak{sl}_2)$ go to null states of the Virasoro algebra." For k_n this is the statement that the reduction of the (A_1, D_{2n+1}) chiral algebra by its $SU(2)$ lands in $M(2, 2n+1)$, the chiral algebra of (A_1, A_{2n-2}).

What the machine verified

Proved, **unconditional** for `twoSeries_sliceArakawa`. The general `sliceArakawa_unconditional` is stated for a level datum L (a discrete set of levels, since $c(k)$ must be a boundary charge) with $k_A \notin \mathbb{N}$; only the ungraded `W1_maxIdeal` is stated for every non-critical $k \notin \mathbb{N}$. Axioms standard (re-checked: `sliceArakawa_unconditional`, `twoSeries_sliceArakawa`).

Theorem 29.52 (Detection holds for every member). *For every $n \geq 1$, detection holds at member n.*

This theorem is not a separate declaration of the library: it is the term `twoSeriesModelDetects_of_dsSlice m (dsSliceMap _ _) (twoSeries_sliceArakawa m)` with

$n = m + 1$. For this edition the composite was checked as a standalone statement in a scratch file importing `VOA.Examples.TwoSeriesGenIncl` (with the namespaces `VOA.TwoSeries`, `.DSSlice`, `.SliceMap`, `.StrictModel` opened):

```
theorem detect_check (m : ℕ) : TwoSeriesModelDetects (m + 1) :=
  twoSeriesModelDetects_of_dsSlice m (dsSliceMap _ _) (twoSeries_sliceArakawa m)

'detect_check' depends on axioms: [propext, Classical.choice, Quot.sound]
```

It is used in this form inside Theorem 29.53 (file `VOA/Examples/TwoSeriesDSSlice.lean`, through `twoSeries_gradedUnitary_of_dsSlice`). The quoted components are Theorems 29.49 and 29.51 and Definition 29.50.

Physical meaning

The free-field model of the classical limit of L_{k_n} is faithful on the null vectors.

What the machine verified

Proved as a composite term, not as a named declaration; unconditional; the composite and each component re-checked with standard axioms. The same holds for "model socle data for every $n \geq 1$" and for `TwoSeriesSocleSpectrum` at every $n \geq 1$: they are obtained inside the proof of the headline, not as standalone declarations.

Theorem 29.53 (Transfer conditional on the Poincaré core). *For every m:* $\mathrm{GU}(L_{-2+2/(2m+3)}) \wedge \mathrm{JPCore}_{m+1} \Rightarrow \mathrm{GU}(M(2, 2m+5))$.

File `VOA/Examples/TwoSeriesArakawaUnconditional.lean`.

```
theorem twoSeries_gradedUnitary_of_affine (m : ℕ)
    (hA : GradedUnitary (affineForm (twoSeriesLevels (m + 1)))
      (affineRealStructure (twoSeriesLevels (m + 1))) (affineFlag (twoSeriesLevels (m +
      ↪ 1))))
    (h : PoincareZero.JetPoincareCoreT0 (m + 1)) :
    VirGradedUnitary (twoSeriesLevels (m + 1)).c (targetRealStructure (twoSeriesLevels (m +
    ↪ 1))) :=
  twoSeries_gradedUnitary_of_sliceArakawa m hA (twoSeries_sliceArakawa m) h
```

From the mathematics to the Lean statement

Full name `VOA.TwoSeries.SliceMap.twoSeries_gradedUnitary_of_affine`: the *second* declaration with this short name (warning on p. 1567). Its hypotheses are `hA` and `h`; detection has been discharged.

Physical meaning

At this point the transfer depends on graded unitarity of the (A_1, D_{2n+1}) chiral algebra and one classical fact about the arc space of $T^n = 0$.

What the machine verified

Proved, `#print axioms`-clean (re-checked), **conditional** on `hA` and `h`.

29.8 The jet-ideal Poincaré lemma and the n-equal arrangement

The last input, JPCore_n, is pure commutative algebra. It is proved by duality: a linear functional on $\mathbb{C}[T]$ of weight E and degree k is the same as a symmetric polynomial $f(x_0, \dots, x_{k-1})$ ("polarisation":

$T_{m_1}\cdots T_{m_k}\leftrightarrow$ the symmetrised monomial x^m); a functional that kills the jet ideal of T^n corresponds to an f that vanishes whenever n of the variables coincide; and a functional that kills the box corresponds to an f in the ideal $(x_0^N,\dots,x_{k-1}^N)$. The Poincaré lemma then becomes an ideal-membership statement for the *n-equal arrangement*, the union of the diagonals $\{x_{s_1}=\cdots=x_{s_n}\}$.

29.8.1 The arrangement inclusion

Definition 29.54 (Diagonals and the arrangement inclusion). In $\mathbb{C}[x_0,\dots,x_{k-1}]$: for $S\subseteq\{0,\dots,k-1\}$, *$Y$ vanishes on the diagonal of S* if substituting $x_s\mapsto x_{s_0}$ for all $s\in S$ (any $s_0\in S$) gives 0. $L_N=(x_0^N,\dots,x_{k-1}^N)$. $W_{N,n}$ is the span of the products $x_l^N Y$ with Y vanishing on every n-element diagonal not containing l. The *arrangement inclusion* AI_n: every symmetric $f\in L_N$ vanishing on all n-element diagonals lies in $W_{N,n}$ (for all k,N). Its *narrowed* form SAI_n asks this only for f homogeneous of degree d in the window $N\ge 2$, $k\ge n+2$, $2N\le d$, $2N+k<d+n+2$.

Files `VOA/Examples/TwoSeriesJetPoincareVdm.lean`, `VOA/Examples/TwoSeriesJetPoincareArr.lean` and `VOA/Examples/TwoSeriesArrangementSym.lean`.

```
abbrev XP (k : ℕ) : Type := MvPolynomial (Fin k) ℂ

      f ∈ Lid k N → (∀ S : Finset (Fin k), #S = n → VanishOn S f) → f ∈ Wn k N n
```

From the mathematics to the Lean statement

`rename g Y` substitutes $x_i\mapsto x_{g(i)}$. So `rename (collapseTo s₀ S) Y = 0` is $Y|_{x_S=x_{s_0}}=0$; quantifying over $s_0\in S$ is harmless (all choices give the same substitution up to renaming). `##S = n` is $|S|=n$. `rename σ f = f` for all permutations σ says f is symmetric. `f.IsHomogeneous d`: all monomials of f have total degree d. `Wn k N n` is $W_{N,n}$; note $W_{N,n}\subseteq L_N$ and every element of $W_{N,n}$ vanishes on all n-element diagonals, so AI_n is the nontrivial inclusion "$L_N\cap$(vanishing)$\cap$(symmetric)$\subseteq W_{N,n}$". `symArrangementInclusion_of_arrangementInclusion` shows $\mathrm{AI}_n\Rightarrow\mathrm{SAI}_n$.

Physical meaning

The vanishing on n-fold diagonals is the functional (Feigin–Stoyanovsky) form of the exclusion rule "at most $n-1$ quanta at the same point", i.e. of $T^n=0$. The inclusion says that the exclusion rule and the mode cutoff x^N interact in the simplest possible way.

What the machine verified

Definitions (predicates). Both are proved for every $n \geq 1$ (Theorem 29.58).

Theorem 29.55 (The Poincaré core from the arrangement inclusion). *For every $n \geq 1$, $\mathrm{SAI}_n \Rightarrow \mathrm{JPCore}_n$.*

File `VOA/Examples/TwoSeriesArrangementSym.lean`.

```
theorem jetPoincareCoreT0_of_symArrangement {n : ℕ} (hn : 1 ≤ n)
    (hA : SymArrangementInclusion n) : PoincareZero.JetPoincareCoreT0 n :=
  fun _ _ _ hN hk hE hE' => jetPoincare_of_symArrangement hn hA hN hk hE hE'
```

From the mathematics to the Lean statement

Here `hA` is the arrangement hypothesis (not graded unitarity; the letter is reused). The window of SAI_n is exactly the image of the core window $2 \leq N$, $n+2 \leq k$, $2N+k \leq E$, $2N+2k < E+n+2$ under $d = E-k$.

Proof on paper. Suppose F of degree k, weight E has $\partial_M F \in J_n$ for $M \geq N$, and suppose its image in R_n is not in the box. Then some functional ψ on $\mathbb{C}[T]_{k,E}$ kills J_n and the box but not F. Its dual polynomial f (symmetric, homogeneous of degree $d = E-k$) vanishes on the n-fold diagonals (because ψ kills the jets of T^n; `dot_pol_jet_n`) and lies in L_N (because ψ kills the box). By SAI_n, $f = \sum_l x_l^N Y_l$ with Y_l vanishing on the diagonals avoiding l. Pairing F against $x_l^N Y_l$ is pairing ∂-derivatives of F in the high variables against Y_l, and Y_l's vanishing makes this a pairing of an element of J_n with a functional that kills J_n (`dot_pol_Wn`); so $\psi(F) = 0$, a contradiction. □

Physical meaning

The Poincaré lemma on the arc space and the exclusion statistics of the functional realisation are dual descriptions of the same fact.

What the machine verified

Proved, `#print axioms`-clean (re-checked), conditional on SAI_n (supplied below).

29.8.2 The Gröbner basis of the n-equal ideal

Definition 29.56 (Block generators; the generation input). For k variables, a *block labelling* is a map $c : \{0,\dots,k-1\} \to \{0,\dots,n-2\}$ (there are $n-1$ blocks). For a strictly increasing list of points $p_0 < \cdots < p_r$ inside one block and a power $m \geq N$, the *block generator* is

$$g = \prod_{\substack{a<b,\ c(a)=c(b)\\ \{a,b\}\not\subseteq\{p_0,\dots,p_r\}}} (x_b - x_a) \cdot \det\bigl(x_{p_i}^0, x_{p_i}^1, \dots, x_{p_i}^{r-1}, x_{p_i}^m\bigr)_{i=0}^{r}.$$

The *generation input* GI_n: every $f \in L_N$ vanishing on all n-element diagonals lies in the ideal generated by the block generators. The *vanishing ideal* is the ideal of polynomials vanishing on all n-fold diagonals.

Files `VOA/Examples/TwoSeriesJetPoincareVdm.lean`, `VOA/Examples/TwoSeriesArrangementGen.lean` and `VOA/Examples/TwoSeriesGenIncl.lean`.

```
def pprod (P : Finset (Fin k × Fin k)) : XP k := ∏ q ∈ P, (X q.2 - X q.1)

    f ∈ Ideal.span (genSet n k N)
```

From the mathematics to the Lean statement

`Matrix.of` builds the $(r+1)\times(r+1)$ matrix whose row p is $(x_{p_p}^0,\dots,x_{p_p}^{r-1},x_{p_p}^m)$ (`Fin.last r` is the last column); `.det` its determinant, an alternant. `StrictMono pt` says the points are strictly increasing; `c (pt p) = c (pt 0)` that they lie in one block. `univ.image pt` is the set of points. Note that GI_n does not ask f to be symmetric: it is a statement about the full ideal. `vanIdeal n k` (in `TwoSeriesGenIncl.lean`) is the vanishing ideal, and `span_genSet_le_vanIdeal` shows every block generator vanishes on the n-fold diagonals (by pigeonhole, n coinciding points among $n-1$ blocks put two of them in one block, killing a Vandermonde factor or the alternant).

Physical meaning

These are, up to normalisation, the generators of the ideal of the n-equal arrangement found by Li and Li; the alternant factor implements the cutoff x^N.

What the machine verified

Definitions.

Example 29.57 ($n=2$). At $n=2$ there is one block, the labelling is constant, and a block generator is the Vandermonde product over all pairs not both among the points, times an alternant in the points. With $r=k-1$ (all points) it is the single alternant $\det(x_i^0,\dots,x_i^{k-2},x_i^m)$, which is divisible by the Vandermonde $\Delta=\prod_{a<b}(x_b-x_a)$; the case $n=2$ of the inclusion is "$f\in L_N$ vanishing on all 2-fold diagonals (hence, being symmetric, divisible by Δ^2) lies in $\sum_l x_l^N Q_l$", proved in `TwoSeriesJetPoincareVdm.lean` by Vandermonde division (`arrangementInclusion_two`).

Theorem 29.58 (The generation input for every $n\ge 2$; the arrangement inclusions for every $n\ge 1$). *For every $n\ge 2$, GI_n holds; hence AI_n holds. For every $n\ge 1$, SAI_n holds.*

Files `VOA/Examples/TwoSeriesGenIncl.lean` (and `VOA/Examples/TwoSeriesArrangementGen.lean` for the passage GI ⇒ AI).

```
theorem genInclusion {n : ℕ} (hn : 2 ≤ n) : GenInclusion n := by

theorem arrangementInclusion {n : ℕ} (hn : 2 ≤ n) : ArrangementInclusion n :=
  arrangementInclusion_of_genInclusion hn (genInclusion hn)
```

```
theorem symArrangementInclusion {n : ℕ} (hn : 1 ≤ n) :
    ArrangementSym.SymArrangementInclusion n := by
```

From the mathematics to the Lean statement

Full names `VOA.TwoSeries.GenIncl.genInclusion`, `.arrangementInclusion`, `.symArrangementInclusion`. `arrangementInclusion_of_genInclusion` uses `span_genSet_le_Wn`: every block generator is in $W_{N,n}$ (expand the alternant along its last column: each term is x_p^m times a cofactor that, together with the block Vandermonde, vanishes on the diagonals avoiding p). At $n = 1$, SAI_1 is immediate: vanishing on all 1-element "diagonals" (the substitution $x_i \mapsto x_i$) means $f = 0$ (`symArrangementInclusion_one`). **What is not formalized.** The Lean statements are ideal *membership*: every $f \in L_N \cap$ (vanishing ideal) lies in the span of the block generators. The stronger statement that the block generators form a lexicographic Gröbner basis of $L_N \cap$ (vanishing ideal) (their leading monomials generate its initial ideal) can be read off the paper proof below, since the division remainder is 0 for every such f; it is a consequence on paper and is not a Lean declaration. Note also that the ideal is $L_N \cap$ (vanishing ideal), not the vanishing ideal of the n-equal arrangement itself.

Proof on paper. Divide f by the nonzero block generators in the lexicographic monomial order (`MonomialOrder.div_set`): $f = \sum a_b g_b + \rho$ with no monomial of the remainder ρ divisible by a leading monomial of a generator. The remainder still lies in L_N and in the vanishing ideal. Suppose $\rho \neq 0$ with leading exponent e. Since L_N is a monomial ideal, some $e_i \geq N$. Since ρ vanishes at every point with an n-fold repeated value (`eval_eq_zero_of_Q`), a combinatorial "point game" on e (`not_win_of_vanish`, `exists_blocks_of_not_win`) produces a block labelling c with $\#\{j > i' : c_j = c_{i'}\} \leq e_{i'}$ for every i'. From c, the suffix of the block of i starting at i, and the power $\max(N, r)$, one builds a nonzero block generator whose leading exponent is $\leq e$ componentwise (`exists_small_gen`); this contradicts the remainder property. So $\rho = 0$. □

Physical meaning

The functional realisation of the (A_1, A_{2n-2}) arc space has a clean, explicit basis of exclusion-rule constraints; nothing beyond the obvious Vandermonde-type relations is needed.

What the machine verified

Proved, **unconditional**. Axioms standard (re-checked: all three).

29.9 The headline theorem

Theorem 29.59 (Graded unitarity transfers along the coset, at every boundary level)**.** *For every $m \in \mathbb{N}$: if $L_{-2+2/(2m+3)}(\mathfrak{sl}_2)$, with its canonical form, compact conjugation and corrected current-and-stress flag, is graded unitary, then the minimal model $M(2, 2m+5) = L(c_{2,2m+5}, 0)$, with its canonical form, partition-basis real structure and length flag, is graded unitary.*

File `VOA/Examples/TwoSeriesGenIncl.lean`.

```
theorem twoSeries_gradedUnitary_of_affine_final (m : ℕ)
    (hA : GradedUnitary (affineForm (twoSeriesLevels (m + 1)))
      (affineRealStructure (twoSeriesLevels (m + 1))) (affineFlag (twoSeriesLevels (m +
      ↪ 1)))) :
    VirGradedUnitary (twoSeriesLevels (m + 1)).c (targetRealStructure (twoSeriesLevels (m +
    ↪ 1))) :=
  twoSeries_gradedUnitary_of_affine_symArrangement m hA
    (GenIncl.symArrangementInclusion (by omega))
```

From the mathematics to the Lean statement

Full name `VOA.TwoSeries.JetPoincareTwo.twoSeries_gradedUnitary_of_affine_final`, declared in `TwoSeriesGenIncl.lean` (the file reopens the namespace `VOA.TwoSeries.JetPoincareTwo` at its end).

- **Index.** $n = m + 1 \geq 1$: `(twoSeriesLevels (m + 1))`.$kA = k_{m+1} = -2 + 2/(2m + 3)$ and `(twoSeriesLevels (m + 1))`.$c = c_{2,2m+5}$ (Definition 29.5). At $m = 0$ the objects are definitionally those of the Lee–Yang chapter.
- **The one hypothesis** `hA`: graded unitarity (Chapter 19, Definition 19.11) of the actual simple VOA `AVOA` with the data of Definition 29.6. It is open for every m.
- **The conclusion**: `VirGradedUnitary c R` is `GradedUnitary (Bsimp c) R (virGradedFlag c)` (Definition 19.20) for the actual simple Virasoro VOA, with R the target real structure (Definition 29.8).
- **The proof term** composes: Theorem 29.58 → Theorem 29.55 → Theorem 29.53 (slice map, Arakawa property, Virasoro symbol) → Theorem 29.45 → strict model maps and model socle data → Theorem 29.33 (socle words, Theorem 29.31) → Theorem 29.28 (characters, Section 29.5) → Theorem 29.15 (Koszul) → Theorem 29.12 (Hodge package) → Theorem 29.11.

Could it be vacuous? Only if `hA` were unsatisfiable, i.e. if L_{k_n} provably failed graded unitarity; then the theorem would say nothing. That is not known either way. The predicate itself is not degenerate: its bilinear-positivity version, which *was* unsatisfiable, was repaired (Chapter 19, Theorem 19.4), and its weight-zero slice is checked to have the right sign (Theorem 19.14). Numerical evidence (not a proof; computed outside the library, not re-run here): $L_{-4/3}$, $L_{-8/5}$ and $L_{-12/7}$ pass the corrected-flag graded-unitarity test through weight 7. **Could the conclusion be weaker than intended?** No: the conclusion is about the simple quotient, with the pinned length flag, at every weight.

Proof on paper. The chain (29.3) of Remark 29.1, with every input other than GU(A) discharged: the Hodge package and the Koszul embedding from GU(A) (Section 29.4); the refined PBW character of $M(2, 2n + 3)$ (Section 29.5); the invariant count $\dim \mathcal{I}_{r,N} \leq g_n(N, r)$ from the socle data of $\mathrm{gr}_r A$, obtained by pulling back the socle data of the jet model along strict model maps (Section 29.6), with detection from the slice map (Section 29.7) and the model socle data from the jet-ideal Poincaré lemma (Section 29.8). □

Physical meaning

If the chiral algebra of the Argyres–Douglas theory (A_1, D_{2m+3}) satisfies the positivity constraints that four-dimensional unitarity imposes, so does the chiral algebra of (A_1, A_{2m+2}). Equivalently, a violation of graded unitarity in any $M(2, 2n + 3)$ would rule out graded unitarity of $L_{k_n}(\mathfrak{sl}_2)$. Since Kaufmann's conjecture (graded unitarity of the boundary minimal models) is open, the theorem reduces the whole $(2, 2n + 3)$ family to the affine side.

What the machine verified

Proved implication; `#print axioms = [propext, Classical.choice, Quot.sound]` (re-checked for this edition against the existing build products; the aggregate `lake build` was not re-run, Section 29.13); **conditional on `hA` only**. Not unconditional: `hA` is open for every m.

Corollary 29.60 (The first two members, and the arrangement form). $\mathrm{GU}(L_{-8/5}) \Rightarrow \mathrm{GU}(M(2,7))$ *and* $\mathrm{GU}(L_{-4/3}) \Rightarrow \mathrm{GU}(M(2,5))$*, each with no other hypothesis; and for every* m, $\mathrm{GU}(L_{k_{m+1}}) \wedge \mathrm{AI}_{m+1} \Rightarrow \mathrm{GU}(M(2, 2m+5))$.

File `VOA/Examples/TwoSeriesJetPoincareTwoEndpoint.lean`.

```

From the mathematics to the Lean statement

These predate the general theorem: they use the direct proofs of JPCore_2 (`jetPoincareCoreT0_two`, by the $n = 2$ Vandermonde argument) and JPCore_1. `twoSeriesLevels 2`: $k = -8/5$, $c = -68/7$. The arrangement form `twoSeries_gradedUnitary_of_affine_arrangement` (same file) takes AI_{m+1} as a hypothesis, now discharged by Theorem 29.58.

Physical meaning

$(A_1, D_5) \to (A_1, A_4)$ and $(A_1, D_3) \to (A_1, A_2)$.

What the machine verified

Proved, `#print axioms`-clean (re-checked), conditional on `hA` only (and `hArr` for the arrangement form).

29.10 Consistency at $n = 1$

Five files check that the general machinery reproduces the Lee–Yang results of Chapter 28: `TwoSeriesLeeYang` (the general Theorem 29.11 at $n = 1$, with the Hodge package and the squeeze input taken from the concrete Lee–Yang proofs), `TwoSeriesKoszulLeeYang` (the invariant count at $n = 1$ from one cyclic vector), `TwoSeriesSpectrumLeeYang` (the socle data of $\mathrm{gr}_r L_{-4/3}$, proved directly), `TwoSeriesModelSocleLevelOne` and `TwoSeriesStrictLevelOne` (the model at $n = 1$, where $R_1 = \mathbb{C}$, and its character bound). Each ends in a Lee–Yang theorem conditional only on graded unitarity of $L_{-4/3}$. We quote the first.

Theorem 29.61 (Lee–Yang from the general theorem). $\mathrm{GU}(L_{-4/3}(\mathfrak{sl}_2)) \Rightarrow \mathrm{GU}(M(2,5))$*, via Theorem 29.11 at* $n = 1$.

File `VOA/Examples/TwoSeriesLeeYang.lean`.

```
theorem leeYang_gradedUnitary_of_affine_viaTwoSeries
    (hA : GradedUnitary LeeYangTransferAssembly.affineForm
      LeeYangTransferAssembly.affineRealStructure LeeYangTransferAssembly.affineFlag) :
    VirGradedUnitarity.VirGradedUnitary LeeYang.leeYangC leeYangRealStructure :=
  twoSeries_gradedUnitary_of_affine 1 hA (leeYangHodgeInputs hA) (twoSeriesSqueezeInput_one
  ↪ hA)
```

From the mathematics to the Lean statement

The hypothesis and conclusion are stated with the *concrete* Lee–Yang objects of Chapter 28; the proof applies the general `VOA.TwoSeries.twoSeries_gradedUnitary_of_affine` at $n = 1$ (the short name resolves to the `TwoSeriesAssembly` declaration inside `VOA.TwoSeries`). That this typechecks is the content of the `rfl` lemmas: `twoSeriesLevels 1` *is* `leeYangLevels`, and every generic object at it is the concrete one. The squeeze coefficient at $n = 1$ is `gapTwoCoefficient` (Rogers–Ramanujan).

Physical meaning

The general machine, run at $(A_1, D_3) \to (A_1, A_2)$, reproduces the Lee–Yang result.

What the machine verified

Proved, `#print axioms`-clean (re-checked), conditional on `hA` only.

29.11 The other endpoints

The library keeps every intermediate endpoint of the reduction, each with its own extra hypotheses. They are all `#print axioms`-clean and all **conditional** on `hA` plus the listed inputs; none is needed once the headline is available, but each records an honest reduction and some are reused by others. Namespaces abbreviate `VOA.TwoSeries` as `TS`; $n \geq 1$ is assumed where marked.

declaration (file)	index	extra hypotheses
`TS.cosetLevels_gradedUnitary_of_affine` (Assembly)	any L	Hodge, squeeze
`TS.twoSeries_gradedUnitary_of_affine` (Assembly)	n	Hodge, squeeze
`TS.twoSeries_gradedUnitary_of_affine_hodgeFree` (HodgeInputs)	n	squeeze
`TS.twoSeries_gradedUnitary_of_affine_invariants` (KoszulInvariants)	n	coeff, `hinv`, `hpbw`
`TS.twoSeries_gradedUnitary_of_affine_invariants_gordon` (CharacterEndpoint)	n	`hinv`, `GordonLowerBound`
`TS.twoSeries_gradedUnitary_of_affine_invariants_gordon_final` (CharacterAGIdentity)	n	`hinv`
`TS.twoSeries_gradedUnitary_of_socle` (InvariantsSocle)	n	socle input, `SocleWordGordon`
`TS.twoSeries_gradedUnitary_of_socleInput` (SocleCountGordon)	n	socle input
`TS.twoSeries_gradedUnitary_of_socleSpectrum` (SocleDual)	n	socle data of gr A
`TS.twoSeries_gradedUnitary_of_socleModels` (SpectrumModel)	n	socle models
`TS.StrictModel.twoSeries_gradedUnitary_of_strictModel` (StrictEndpoint)	$n \geq 1$	det, chi, spec
`TS.ModelChar.twoSeries_gradedUnitary_of_strictModel_det`, `_of_fermionicLower`, `_two_of_strictModel` (ModelCharEndpoint)	$n \geq 1$; $n = 2$	det, spec (and ferm)

declaration (file)	index	extra hypotheses
`TS.StrictModel.twoSeries_gradedUnitary_of_evalFunctional`, `_of_coinv` (DetectFunctional)	$n \geq 1$	eval. functionals, spec

`..._of_strictModel_jetPoincare` (HighEndpoint); `_jetPoincare2`, `_jetPoincareCore` (HighDegSucc); `_jetPoincareCoreT0` (PoincareZero)	$n \geq 1$	det, a Poincaré input
`TS.DSSlice.twoSeries_gradedUnitary_of_dsSlice` (DSSlice)	$n = m + 1$	slice map, Arakawa, `JetPoincareCoreT0`
`TS.SliceMap.twoSeries_gradedUnitary_of_sliceArakawa` (SliceMap)	$n = m + 1$	Arakawa, `JetPoincareCoreT0`
`TS.SliceMap.twoSeries_gradedUnitary_of_maximalGeneration`, `_of_adamovicMilas` (ArakawaBottom); `_of_singularBottom`, `_of_singularBottomInput` (ArakawaEndpoint)	$n = m + 1$	generation of the maximal ideal / Adamović–Milas data / bottom input, `JetPoincareCoreT0`
`TS.SliceMap.twoSeries_gradedUnitary_of_affine` (ArakawaUnconditional)	$n = m + 1$	`JetPoincareCoreT0`
`TS.JetPoincareTwo.twoSeries_gradedUnitary_of_affine_arrangement` (JetPoincareTwoEndpoint)	$n = m + 1$	`ArrangementInclusion`
`TS.JetPoincareTwo.twoSeries_gradedUnitary_of_affine_symArrangement` (ArrangementSym)	$n = m + 1$	`SymArrangementInclusion`
`TS.JetPoincareTwo.twoSeries_gradedUnitary_M27_of_affine`, `_M25_of_affine`	$n = 2, 1$	none
`TS.JetPoincareTwo.twoSeries_gradedUnitary_of_affine_final` (GenIncl)	$n = m + 1$	**none**
`TS.leeYang_gradedUnitary_of_affine_viaTwoSeries`, `_viaInvariants`, `leeYang_gradedUnitary_viaSocleSpectrum`	$n = 1$	none

The `TwoSeriesArakawaBottom`/`TwoSeriesArakawaEndpoint` endpoints are an earlier route to the slice Arakawa property through a description of the maximal ideal by a singular vector (Adamović–Milas); the unconditional route of Theorem 29.51 made it unnecessary.

The remaining files not mentioned so far (`TwoSeriesSliceMapBasis`, `-Whittaker`, `-Sugawara`, `-Vir`; `TwoSeriesArakawaClosure`, `-Intertwine`, `-Positive`, `-Sugawara`, `-Transport`, `-Triplet`; `TwoSeriesModelChar*`; `TwoSeriesCharacter*`; `TwoSeriesSocleCount*`, `TwoSeriesSocleDualCore`, `TwoSeriesSpectrumCore`; `TwoSeriesBox*`, `TwoSeriesIncl*`, `TwoSeriesHigh*`, `TwoSeriesStrict*`, `TwoSeriesMembership*`, `TwoSeriesJetPoincare*`, `TwoSeriesArrangementGen`, `TwoSeriesGenInclLex`) are the internal lemmas of the proofs sketched above: PBW bases and Whittaker coinvariants for the slice map; the lifts Q_0, Q_1, Q_2 and the vacuum-row argument; the Bailey chain, the Feigin–Stoyanovsky functionals and the profile counting of the model character; Andrews' recursion and the Kac-determinant rank bound; MacMahon's theorem and the fusion recursion; the Vandermonde and alternant calculus and the point game.

29.12 Warnings: stale documentation and dead ends

Stale docstrings that call proved inputs "open"

The Lean statements are correct; the following documentation comments lag behind later files. A reader who trusts the docstring over the declaration will under-estimate what is proved.

1. `BRSTHodgeInputs` (`TwoSeriesAssembly.lean`): "in Lean proved so far only at Lee–Yang". It is provided at every level datum by `brstHodgeInputs` (Theorem 29.12).

2. `GordonLowerBound` and the header of `TwoSeriesCharacterReduction.lean`: "OPEN for general n ... not formalised here". Proved for the series (`gordonLowerBound_twoSeries`, Theorem 29.26).

3. `TwoSeriesInvariantsSocle.lean`: `SocleWordGordon` "OPEN as a Lean statement"; proved (`socleWordGordon`, Theorem 29.31). `TwoSeriesSocleInput` and `TwoSeriesSocleSpectrum` (`TwoSeriesSocleDual.lean`) are labelled "OPEN"; for every $n \geq 1$ they now follow from the chain of Sections 29.6–29.8, although no declaration states them as standalone theorems.

4. `TwoSeriesJetPoincareArr.lean` and `TwoSeriesArrangementSym.lean`: "`ArrangementInclusion n` (resp. `SymArrangementInclusion n`) for $n \geq 3$ is the named open input". Proved for every $n \geq 2$ (resp. ≥ 1) in `TwoSeriesGenIncl.lean` (Theorem 29.58).

5. `TwoSeriesDSSlice.lean` header: calls the Virasoro symbol input "classical freeness of $M(2, 2n+1)$". `virSymbol_twoSeries` is only a PBW-length leading-symbol theorem into the presented ring; intrinsic classical freeness is a separate theorem (Theorem 29.47, dictionary). The docstring of `virSymbol_twoSeries` itself was corrected in a later revision of that file.

6. `TwoSeriesSliceMap.lean` header: "the only universal-object input used is the sanctioned library PBW machinery". Since `VOA.pbw` is a theorem there is no sanctioned axiom; the phrase is historical, and `#print axioms` of `dsSliceMap` is standard.

These are documentation defects (severity S4: a docstring or note is wrong or stale; no statement is affected).

Dead ends

The following routes were tried for the invariant count and the detection input and failed; they are recorded so that they are not re-attempted. The evidence is the project's record (exact linear algebra modulo a large prime, computed outside the library); it was not re-run for this chapter.

1. *One cyclic dual vector* (warning on p. 1578): fails at $n = 2, r = 2, N = 4$.
2. *Test substitutions in the membership bound*: with the plain substitution $T \mapsto J$ (no correction term) the test space is strictly larger than the socle count at T-degree $\geq n$ ($n = 2$); with $T \mapsto J + \tilde{z}$ it is also too large; with $\tilde{x}$ or $\tilde{y}$ it is sharp (`TwoSeriesMembershipEndpoint.lean` docstring).
3. *Detection with the wrong ring*: the model symbols satisfy every relation of $\mathrm{gr}_r L_{k_n}$ modulo the jets of T^n, but *not* modulo the jets of T^{n+1} ($n = 2$, weight ≤ 8; $n = 3$, weight ≤ 7). So R_n, the arc algebra of $M(2, 2n+1)$, is forced.
4. *The slice map at the wrong central charge*: the inclusion of the image of the affine maximal ideal into the Virasoro maximal ideal holds at $c_{2,2n+1}$ and fails at $c_{2,2n+3}$ ($n = 2, 3$, weights ≤ 10).
5. *Other detection attempts*: a weight-zero Witt operator, single-ε specialisations at $k \geq n$, a test using only J, and Riccati-type maps. None gave detection; the slice map did.

The converse is not proved

Nothing in this chapter goes from $M(2, 2n+3)$ back to L_{k_n}. At $n = 1$ there is no coset route back: the coset partner $L_{-1/3}(\mathfrak{sl}_2)$ fails graded unitarity at weight 3 (a norm $-7/15$; the project's numerical record, not machine-checked), and BRST positivity only flows forward. No converse implication is stated or claimed in this edition.

29.13 Verification record

Files. The chapter was written against an earlier state of the library; the files it documents are `VOA/Examples/TwoSeries*.lean` (126 files at that state, 128 in this release). All are in the import closure of the umbrella `VOA/Examples.lean`.

Quotations. Every `leancode` block of this chapter was compared, piece by piece with comments and whitespace normalized, with the current Lean sources for this edition: all occur verbatim. Every Lean identifier and Lean file path cited in the chapter resolves to a declaration or file of the current library.

What was re-run for this edition. `#print axioms` on one scratch file importing `TwoSeriesGenIncl`, `TwoSeriesArakawaUnconditional`, `TwoSeriesCharacterAGIdentity`, `TwoSeriesModelCharEndpoint`, `TwoSeriesJetPoincareTwoEndpoint`, `TwoSeriesLeeYang`, `TwoSeriesSocleCountGordon`, `TwoSeriesBoxFusion`, `TwoSeriesHighDegSucc`, `TwoSeriesModelSocleCartan` and `TwoSeriesKoszulLeeYang` (all under `VOA.Examples`), run as `lake env lean -DmaxSynthPendingDepth=3` from the repository root against the build products already in the checkout (no `lake build` was run). Every declaration below, and the composite `detect_check` of Theorem 29.52, reported exactly `[propext, Classical.choice, Quot.sound]`, with no error and no `sorryAx`:

```
JetPoincareTwo.twoSeries_gradedUnitary_of_affine_final, GenIncl.genInclusion,
GenIncl.arrangementInclusion, GenIncl.symArrangementInclusion,

  (the names above relative to VOA.TwoSeries)
TwoSeriesCharacter.AG.gordon_sum_eq_rcq, TwoSeriesCharacter.finrank_pieceIn_le_gordon,
TwoSeriesCharacter.hpbw_iff_gordonLowerBound, TwoSeriesCharacter.KacGram.rcq_le_finrank,
SocleCount.socleWordCount_eq, SocleCount.socleWordGordon
  (these relative to VOA)
```

The same run printed the type of the headline as

```
VOA.TwoSeries.JetPoincareTwo.twoSeries_gradedUnitary_of_affine_final : ∀ (m : ℕ),
  VOA.GradedUnitary (VOA.TwoSeries.affineForm (VOA.TwoSeries.twoSeriesLevels (m + 1)))
      (VOA.TwoSeries.affineRealStructure (VOA.TwoSeries.twoSeriesLevels (m + 1)))
      (VOA.TwoSeries.affineFlag (VOA.TwoSeries.twoSeriesLevels (m + 1))) →
    VOA.VirGradedUnitarity.VirGradedUnitary (VOA.TwoSeries.twoSeriesLevels (m + 1)).c
      (VOA.TwoSeries.targetRealStructure (VOA.TwoSeries.twoSeriesLevels (m + 1)))
```

so, besides the natural number m, its only argument is the hypothesis `hA`. The build products used are those already in the checkout; they were not rebuilt for this edition.

Records of earlier builds (not re-run). The project's records give, for the state in which the headline was first obtained, an aggregate `lake build` green at 13 672 jobs and the maintained axiom audit passing, with the headline reporting the three standard axioms; and a later aggregate `lake build VOA` green at 13 868 jobs. The aggregate build was not re-run for this edition. The numerical evidence quoted in the warnings on pp. 1578 and 1605 and in the dictionary of Theorem 29.59 is the project's record (computations outside the library), not machine-checked here.

Forbidden constructs. A search of the `TwoSeries*` files for `sorry`, `admit`, `native_decide`, `implemented_by` (as words) and for lines beginning with `axiom` finds no occurrence; this is consistent with the axiom checks above.

29.14 Referee's checklist

declaration	intended meaning	hypotheses	where checked
`TS.JetPoincareTwo.twoSeries_gradedUnitary_of_affine_final`	$\mathrm{GU}(L_{k_{m+1}}) \Rightarrow \mathrm{GU}(M(2,2m+5))$	`hA` only; conditional	Thm. 29.59

The point that the jet-ideal Poincaré lemma reduces to this arrangement, via a fermionic realisation, is suggested by Ait El Manssour–Pogudin's work on arcs of fat points.

Part VII

The Moonshine module

Chapter 30

Lattices, codes and the Leech lattice

This chapter builds the combinatorial raw material of the Moonshine module: the extended binary Golay code $\mathcal{G}$, the Niemeier lattice $N(A_1^{24})$ obtained from it, and the Leech lattice Λ. Everything in the later chapters of the Moonshine Part rests on four facts about Λ, and the referee should keep them in view from the start:

(Λ1) Λ is an *even* lattice of rank 24 (so the lattice vertex operator algebra V_Λ of Chapter 31 exists and has central charge 24);

(Λ2) Λ is *positive definite* (so the weight spaces of V_Λ are finite-dimensional);

(Λ3) Λ is *unimodular* (so the extraspecial group of Chapter 34 has a unique irreducible faithful module T, of dimension 2^{12}, and the theta function of Λ is a modular form for the full modular group);

(Λ4) Λ has *no roots*, i.e. no vectors of norm 2 (so V_Λ has no weight-one states of the form e^α, which is the origin of $V^\natural{}_1 = 0$).

In addition the chapter proves the two counts $|\{x \in \Lambda : \langle x,x\rangle = 4\}| = 196560$ and $|\{x \in \Lambda : \langle x,x\rangle = 6\}| = 16773120$, which enter the graded dimension computations of Chapter 33 (for instance $\dim(V_\Lambda)_2 = 196884 = 300 + 24 + 196560$).

All results of this chapter are proved in Lean *unconditionally*: no hypotheses are left open, and every `##print axioms` report quoted below lists only Lean's three standard axioms `propext`, `Classical.choice`, `Quot.sound`. `VOA.pbw` (Chapter 3; formerly the library's only axiom, now a theorem) does not occur anywhere in this chapter.

30.1 Why lattices? The physical picture

Before any definitions, let us say why a conformal field theorist cares about even unimodular lattices. Consider d free chiral bosons $X^1, \dots, X^d$ in two dimensions, compactified on a torus $\mathbb{R}^d/L$ for some lattice $L \subset \mathbb{R}^d$. A state of the theory carries a momentum p, and single-valuedness of the wave function $e^{ip\cdot X}$ on the torus forces p to lie in a lattice (for a purely chiral theory, in L itself after suitable normalisation). The state $e^{ip\cdot X}$ has conformal weight $\frac{1}{2}p\cdot p$, and the operator product of two such vertex operators contains the factor $(z-w)^{p\cdot q}$. Three requirements on the lattice then appear naturally:

- **Integrality** $p\cdot q \in \mathbb{Z}$: the operator product expansion has integral powers, so the fields are *local* (Definition 2.41).
- **Evenness** $p\cdot p \in 2\mathbb{Z}$: the weights $\frac{1}{2}p\cdot p$ are integers, so the fields are *bosonic* (they commute, rather than anticommute, at separated points).

- **Unimodularity** $L = L^*$: the theory has a single sector; its partition function is then modular invariant by itself (a *holomorphic* conformal field theory).

Positive definiteness is the requirement that the energy $\frac{1}{2}p \cdot p$ is bounded below and that only finitely many momenta have a given energy. Finally, *rootlessness* — no p with $p \cdot p = 2$ — means that no momentum state has weight 1. Weight-one states generate a Lie algebra of symmetries (the currents of the theory), so a rootless lattice gives the smallest possible current algebra, namely the d abelian currents ∂X^i; the orbifold of Chapter 32 will remove even those. This is the mechanism behind $V^\natural{}_1 = 0$.

Even unimodular positive definite lattices exist only in ranks divisible by 8 (we prove this below, Theorem 30.42). In rank 8 there is one, E_8; in rank 16 two; in rank 24 there are exactly 24 (the *Niemeier lattices*), and exactly one of them has no roots: the Leech lattice. The uniqueness statements are classical and are *not* part of the Lean library (see Warning 30.3.1); the existence and properties of Λ are.

30.2 Integral lattices: the mathematics

Definition 30.1 (Integral lattice)**.** An *integral lattice* is a pair $(L, \langle\cdot,\cdot\rangle)$ where L is a free $\mathbb{Z}$-module of finite rank n (so $L \cong \mathbb{Z}^n$ as an abelian group) and $\langle\cdot,\cdot\rangle : L \times L \to \mathbb{Z}$ is a symmetric $\mathbb{Z}$-bilinear form. The number n is the *rank* of L. For $x \in L$ we call $\langle x, x\rangle$ the *norm* of x.

Physical meaning

A lattice $L \cong \mathbb{Z}^n$ with its bilinear form is the momentum lattice of n compactified chiral bosons: the chiral algebra of the free bosons ∂X^i has Fock modules labelled by a momentum $\alpha \in \mathbb{R}^n$, and the vertex operator $e^{i\alpha\cdot X}$ has conformal weight $h = \langle\alpha,\alpha\rangle/2$. Taking α to run over a lattice means the target is the torus $\mathbb{R}^n/L$ (up to normalisation). Integrality of $\langle\cdot,\cdot\rangle$ makes the operator product of two such vertex operators have integer-power (single-valued up to a sign) monodromy, so that the $e^{i\alpha\cdot X}$ can be local with respect to each other. The rank n becomes the central charge $c = n$ of the resulting chiral algebra.

Two remarks on terminology. First, the word "norm" here means the *square* of the Euclidean length, as is universal in lattice theory: in $\mathbb{Z}^n$ with the dot product the vector $(1, 1, 0, \dots, 0)$ has norm 2. Second, many books define a lattice as a discrete subgroup of a Euclidean space $\mathbb{R}^n$. The abstract definition used here is equivalent for positive definite forms (one can always realise a positive definite L inside $\mathbb{R}^n$, see Remark 30.8) and has the advantage that indefinite lattices and lattices with irrational embeddings need no special treatment.

Definition 30.2 (Gram matrix and determinant)**.** If $b_1, \dots, b_n$ is a $\mathbb{Z}$-basis of L, the *Gram matrix* is $G = (\langle b_i, b_j\rangle)_{i,j} \in M_n(\mathbb{Z})$. The *determinant* (or discriminant) of L is $\det L = \det G$.

Physical meaning

The Gram matrix is the matrix of inner products $\langle b_i, b_j\rangle$ of the basic momenta, that is, the metric on the compactification torus in the basis of the lattice. Its determinant measures the squared covolume of the lattice, hence the volume of the target torus $\mathbb{R}^n/L$. Basis independence is the statement that relabelling the momentum quantum numbers by $GL_n(\mathbb{Z})$ is a change of coordinates, not new physics.

The determinant does not depend on the basis: if $b'_j = \sum_i P_{ij} b_i$ is another basis, then $P \in GL_n(\mathbb{Z})$ has $\det P = \pm 1$ and $G' = P^{\mathsf{T}} G P$, so $\det G' = (\det P)^2 \det G = \det G$.

Definition 30.3 (Even, positive definite, unimodular, roots)**.** An integral lattice L is

- *even* if $\langle x, x\rangle \in 2\mathbb{Z}$ for every $x \in L$ (otherwise *odd*);
- *positive definite* if $\langle x, x\rangle > 0$ for every $x \neq 0$;
- *unimodular* if $\det L = \pm 1$.

A *root* of an even lattice is a vector of norm 2. The set of roots is denoted $R(L)$.

Physical meaning

Evenness, $\langle \alpha, \alpha\rangle \in 2\mathbb{Z}$, says that every vertex operator $e^{i\alpha\cdot X}$ has integer conformal weight $h = \langle \alpha, \alpha\rangle/2$ and is bosonic; odd lattices give half-integer weights and fermionic (spin-statistics-twisted) operators, as for the free fermion lattice $\mathbb{Z}^n$. Positive definiteness is unitarity: all weights are positive. Unimodularity is the condition that the theory has no other sectors, which is tied to modular invariance of the holomorphic partition function (see the dual lattice and Theorem 30.42). A root, a vector of norm 2, gives a weight-one field $e^{i\alpha\cdot X}$, hence a conserved current; the roots together with the Cartan currents ∂X^i generate a Kac–Moody (affine) algebra whose finite part is the simply laced Lie algebra with that root system.

Definition 30.4 (Dual lattice)**.** Let $L_{\mathbb{R}} = \mathbb{R} \otimes_{\mathbb{Z}} L$ with the $\mathbb{R}$-bilinear extension of the form. The *dual lattice* is $L^* = \{y \in L_{\mathbb{R}} : \langle y, x\rangle \in \mathbb{Z} \text{ for all } x \in L\}$. Integrality says precisely that $L \subseteq L^*$. L is called *self-dual* if $L = L^*$.

Physical meaning

The dual lattice L^* is the set of momenta that can be added to a state with trivial monodromy against all vertex operators $e^{i\alpha\cdot X}$ with $\alpha \in L$, that is, the set of labels of the (twisted) modules of the lattice chiral algebra: the module category is governed by the discriminant group L^*/L. The self-dual case $L = L^*$ means that the chiral algebra has exactly one irreducible module, itself, so the partition function is a single holomorphic character, invariant under $\tau \mapsto -1/\tau$ up to a possible phase. This is the sense in which the lattice gives a holomorphic CFT (Heuristic: the full proof of the module statement is in the VOA theory of later chapters, not here).

For a nondegenerate lattice, the dual basis $b_1^*, \dots, b_n^*$ (defined by $\langle b_i^*, b_j\rangle = \delta_{ij}$) is a $\mathbb{Z}$-basis of L^*, and $b_i^* = \sum_j (G^{-1})_{ij} b_j$. So L^*/L is a finite abelian group of order $|\det G|$, and

$$L \text{ is self-dual} \iff |\det L| = 1 \iff L \text{ is unimodular.} \tag{30.1}$$

Indeed, if $\det G = \pm 1$ then G^{-1} has integer entries, so each b_i^* lies in L. This one-line argument will reappear in the proof that the theta function of a unimodular lattice is modular (§30.8).

Example 30.5.

1. $\mathbb{Z}^n$ with the dot product: odd, positive definite, unimodular ($G = I$).
2. $A_1 = \mathbb{Z}$ with $\langle x, y\rangle = 2xy$: even, positive definite, $\det = 2$; its two roots are ± 1. Its dual is $\frac{1}{2}\mathbb{Z}$ and $A_1^*/A_1 \cong \mathbb{Z}/2$.
3. The hyperbolic plane $U = \mathbb{Z}^2$ with Gram matrix $\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$: even, unimodular ($\det = -1$), indefinite ($\langle (1,0), (1,0)\rangle = 0$). It shows that evenness and unimodularity do not force definiteness.
4. $\mathbb{Z}$ with $\langle x, y\rangle = xy$ is unimodular but odd, so unimodularity does not force evenness either.

Two elementary facts about positive definite lattices are used constantly.

Lemma 30.6 (Cauchy–Schwarz over $\mathbb{Z}$)**.** *If L is positive definite then $\langle x, y\rangle^2 \leq \langle x, x\rangle\langle y, y\rangle$ for all $x, y \in L$.*

Physical meaning

A technical lemma. It is the elementary bound $|\langle\alpha,\beta\rangle| \le |\alpha||\beta|$ on momenta, used to control the exponents $\langle\alpha,\beta\rangle$ in the operator product $e^{i\alpha\cdot X}(z)\,e^{i\beta\cdot X}(w) \sim (z-w)^{\langle\alpha,\beta\rangle}$ in terms of the conformal weights of the two operators.

Proof. If $x = 0$ there is nothing to show. Otherwise put $a = \langle x,x\rangle > 0$, $b = \langle x,y\rangle$, $c = \langle y,y\rangle$ and expand the norm of the lattice vector $ay - bx$: $\langle ay-bx, ay-bx\rangle = a(ac-b^2) \ge 0$. Dividing by $a > 0$ gives $b^2 \le ac$. Note that no real numbers were needed: the argument stays inside $\mathbb{Z}$. □

Lemma 30.7 (Finiteness)**.** *If L is positive definite then for every N the set $\{x \in L : \langle x,x\rangle \le N\}$ is finite.*

Physical meaning

A technical lemma with a direct physical meaning: each conformal-weight level of the lattice theory has finitely many momentum states. This is what makes the graded dimensions $\dim V_n$ finite and the partition function $\sum_\alpha q^{\langle\alpha,\alpha\rangle/2}/\eta^n$ a well-defined formal series, for positive definite (unitary) lattices.

Proof. Fix a basis $b_1,\dots,b_n$. The map $x \mapsto (\langle b_i,x\rangle)_i \in \mathbb{Z}^n$ is injective (if $\langle b_i,x\rangle = 0$ for all i then $\langle x,x\rangle = 0$, so $x = 0$). By Lemma 30.6, $|\langle b_i,x\rangle| \le \langle b_i,b_i\rangle N$ when $\langle x,x\rangle \le N$, so the image lies in a finite box. □

Lemma 30.7 makes the *representation numbers* $r_L(m) = |\{x \in L : \langle x,x\rangle = m\}|$ finite; their generating function is the theta series of §30.8.

Remark 30.8 (Euclidean realisation)**.** A positive definite L of rank n embeds isometrically in $\mathbb{R}^n$: the real Gram matrix G is positive definite, so $G = B^{\mathsf T}B$ for a real matrix B, and $x = \sum c_i b_i \mapsto Bc$ is the embedding. Its image is a discrete subgroup of full rank (a "$\mathbb{Z}$-lattice" in Mathlib's terminology) of covolume $\sqrt{\det L}$. This realisation is needed only for the analytic part of the chapter (Poisson summation). Note also that positivity on the integral points implies positivity on all of $L_{\mathbb{R}}$: by scaling it holds on $L_{\mathbb{Q}}$, by continuity the real form is positive semidefinite, and a positive semidefinite rational form with a real null vector has a rational null vector (its kernel is defined over $\mathbb{Q}$).

30.3 Two Lean encodings of an integral lattice

The library contains *two* structures called `IntegralLattice`. This is the single most confusing point of the chapter for a newcomer, so we explain it first.

- `VOA.IntegralLattice`, in `VOA/Foundations/Lattices.lean`, is the structure the VOA library uses: the lattice VOA V_L of Chapter 31 is built from it.
- `_root_.IntegralLattice`, in `VOA/LatticesAndCodes/Lattice/Defs.lean`, comes from a separate formalisation of Ebeling's book *Lattices and Codes*, written by the same authors and *vendored* (copied) into this repository. The Leech lattice is constructed and studied there.

Inside the Lean namespace `VOA` the bare name `IntegralLattice` refers to the first one; the second must be written `_root_.IntegralLattice`. A bridge `VOA.IntegralLattice.ofEbeling` (§30.9) transports a lattice from the second encoding to the first.

30.3.1 Why the companion library was vendored

The 25 files under `VOA/LatticesAndCodes/` are, according to the umbrella file `VOA/LatticesAndCodes.lean`, "copied verbatim from the companion formalization of Ebeling, *Lattices and Codes* (repository `Fedor-Popov/LatticeAndCodes`, commit `da62b9e2f44a04888abf6f797a429aa8ecc1d6dd`), so that this package depends on Mathlib alone. The ONLY edit is the module prefix `LatticesAndCodes.` → `VOA.LatticesAndCodes.` in `import` lines." The project's working records state that the copy was verified byte-for-byte with `cmp`; this verification is a claim of the source, not something the Lean kernel checks. The decision was that the package should have exactly one external dependency, Mathlib, so that a referee needs to trust only Lean, Mathlib and this repository. The 25 files are precisely the import closure of the three files the Moonshine construction needs: `Leech/Defs.lean` (the Leech lattice and its four properties), `Leech/RepCount.lean` (196560) and `Leech/RepCountHigher.lean` (16773120). They comprise:

directory	content
`Lattice/`	the structure, sublattices, index–determinant relation, Euclidean realisation
`Roots/`	roots, reflections, Weyl group, root lattices
`Codes/`	linear codes, weight enumerators, MacWilliams identity, the Golay code
`Construction/`	the lattice of a binary code (Construction A)
`Leech/`	the Leech lattice and its representation numbers
`Theta/`	theta functions, their modularity and q-expansions
`ModularForms/`	level-one modular forms, $M_* = \mathbb{C}[E_4, E_6]$
`ForMathlib/`	multivariable Poisson summation and Gaussian sums

Declaration names and namespaces were not changed (`_root_.IntegralLattice`, `Leech`, `Code`, `ModularForm`, `EuclideanTheta`, `ZLattice`, ...).

Trap: what was *not* vendored

The companion library also proves the uniqueness of the Leech lattice (`Leech.unique`) and related classification results. These are *not* in the import closure and were *not* copied (recorded in `Notes/MonsterRoadmap.md`, "Known traps"). Likewise no uniqueness theorem for the Golay code is present in the vendored files: the file `Codes/GolayEnumerator.lean` mentions that the octad count is "half of the input to the uniqueness of the Golay code", but the uniqueness itself is not there. Consequently nothing in this book's Lean development says that *the* Leech lattice has been constructed in the sense of "the unique rootless even unimodular lattice of rank 24"; what is proved is that a *specific, explicitly defined* lattice `Leech.lattice` has all the properties needed. For the construction of $V^\natural$ this is all that matters. (The roadmap's "Inputs" table says "unique" for both objects; read it as a statement about the upstream library, not about this repository.) Some docstrings of vendored files also refer to upstream files that were not copied (e.g. `ModularForms/ValenceFormula.lean`, `ModularForms/Eisenstein.lean`); nothing in this repository depends on them.

30.3.2 The VOA library's lattice

Definition 30.9 (`VOA.IntegralLattice`). `VOA/Foundations/Lattices.lean`. An integral lattice consists of a type L (the carrier) with an abelian group structure that is a free and finitely generated $\mathbb{Z}$-module, together with a symmetric $\mathbb{Z}$-bilinear form.

```
structure IntegralLattice where
  /-- The underlying `ℤ`-module. -/
  carrier : Type u
  [addCommGroup : AddCommGroup carrier]
  [free : Module.Free ℤ carrier]
```

```
  [finite : Module.Finite ℤ carrier]
  /-- The bilinear (Gram) form `⟨·,·⟩`. -/
  form : LinearMap.BilinForm ℤ carrier
  /-- The form is symmetric. -/
  isSymm : form.IsSymm
```

From the mathematics to the Lean statement

- A Lean `structure` is a record: an element `L : IntegralLattice` is a tuple of the listed fields. Fields in square brackets are *instances* that Lean will find automatically; here they say that `carrier` is an additive commutative group (`AddCommGroup`), that as a $\mathbb{Z}$-module it is free (`Module.Free ℤ`, i.e. has a basis) and finitely generated (`Module.Finite ℤ`). Free plus finitely generated is exactly "$\cong \mathbb{Z}^n$ for some n".
- `LinearMap.BilinForm ℤ carrier` is Mathlib's type of $\mathbb{Z}$-bilinear maps $L \times L \to \mathbb{Z}$, written in curried form: `L.form x y` is $\langle x, y\rangle$. `form.IsSymm` means $\langle x, y\rangle = \langle y, x\rangle$ for all x, y.
- `Type u` is a universe-polymorphic type; the universe level plays no mathematical role (the lattices used later live in the lowest universe, `Type = Type 0`).
- Fidelity: this is Definition 30.1 exactly. No definiteness or evenness is built in; those are separate predicates below. The structure is clearly satisfiable (the examples $\mathbb{Z}^n$ and $\sqrt{2}\mathbb{Z}$ below are terms of it), so it is not vacuous.

Physical meaning

This is the datum of the chiral boson CFT: the free abelian group of charges α (momenta) of the vertex operators together with the pairing that governs their operator product $e^{\alpha}(z)e^{\beta}(w) \sim (z-w)^{\langle\alpha,\beta\rangle}$. It is exactly the input from which the lattice vertex algebra V_L of Chapter 31 is built. No unitarity or locality is imposed yet; these correspond to the later predicates.

Definition 30.10 (Even and positive definite, VOA library). `VOA/Foundations/Lattices.lean`, namespace `VOA.IntegralLattice`.

```
def Even : Prop := ∀ v : L.carrier, 2 ∣ L.form v v

def PosDef : Prop := ∀ v : L.carrier, v ≠ 0 → 0 < L.form v v
```

From the mathematics to the Lean statement

`2 ∣ n` is divisibility in $\mathbb{Z}$: "there is an integer k with $n = 2k$". The symbol `∣` is Unicode U+2223 DIVIDES, typed differently from the ASCII bar `|`, which Lean uses for other purposes; in print they may look alike. So `L.Even` is "$\langle v, v\rangle \in 2\mathbb{Z}$ for all v" and `L.PosDef` is "$\langle v, v\rangle > 0$ for all $v \neq 0$", exactly Definition 30.3. Positivity is demanded only on lattice points; by Remark 30.8 this is equivalent to positive definiteness of the real form, so nothing is lost. (The library proves the consequence it actually needs — finiteness of the vectors of bounded norm — directly from `PosDef`, in `VOA/Foundations/LatticeFinite.lean`.)

Physical meaning

`Even` is locality with integer conformal weights for the vertex operators $e^{i\alpha\cdot X}$: $h = \langle\alpha,\alpha\rangle/2 \in \mathbb{Z}$. `PosDef` is unitarity (positive energies; the Hermitian form on V_L is positive). Together they are the conditions under which V_L is an honest unitary $\mathbb{Z}$-graded vertex operator algebra rather than a vertex operator superalgebra or a non-unitary theory.

Definition 30.11 (Rank, VOA library). `VOA/Foundations/LatticeCocycle.lean`, namespace `VOA.IntegralLattice`.

```
noncomputable def rank : ℕ := Module.finrank ℤ L.carrier
```

From the mathematics to the Lean statement

`Module.finrank ℤ M` is Mathlib's rank of a finite free module (the common cardinality of its bases; it is defined to be 0 for modules that are not finite free, which cannot happen here). The word `noncomputable` only means that Lean cannot evaluate this number by running a program; it has no mathematical content. The central charge of V_L will be `rank L`.

Physical meaning

The rank is the number of free bosons and therefore the Virasoro central charge $c = \operatorname{rank} L$ of the lattice theory (Sugawara stress tensor $T = \frac{1}{2}\sum_i (\partial X^i)^2$). It is also the dimension of the Cartan subalgebra of currents, the dimension of the target torus, and the number of left-moving gauge $U(1)$'s.

Definition 30.12 (Dual lattice and self-duality, VOA library). With $L_{\mathbb{R}} = \mathbb{R} \otimes_{\mathbb{Z}} L$, the real form `formℝ` is the base change of `form`, `toReal` is $v \mapsto 1 \otimes v$, and:

```
noncomputable def formℝ : LinearMap.BilinForm ℝ (ℝ ⊗[ℤ] L.carrier) := L.form.baseChange ℝ

noncomputable def toReal : L.carrier →ₗ[ℤ] ℝ ⊗[ℤ] L.carrier :=
  (TensorProduct.mk ℤ ℝ L.carrier) 1

noncomputable def dual : AddSubgroup (ℝ ⊗[ℤ] L.carrier) where
  carrier := {x | ∀ v : L.carrier, ∃ k : ℤ, L.formℝ x (L.toReal v) = (k : ℝ)}

theorem le_dual (v : L.carrier) : L.toReal v ∈ L.dual

def SelfDual : Prop := ∀ x : ℝ ⊗[ℤ] L.carrier, x ∈ L.dual ↔ ∃ v : L.carrier, L.toReal v = x
```

(The three closure proofs in the definition of `dual`, and the proof of `le_dual`, are omitted.)

From the mathematics to the Lean statement

`ℝ ⊗[ℤ] L.carrier` is the tensor product $\mathbb{R} \otimes_{\mathbb{Z}} L = L_{\mathbb{R}}$; `→ₗ[ℤ]` denotes a $\mathbb{Z}$-linear map; `baseChange ℝ` extends a $\mathbb{Z}$-bilinear form $\mathbb{R}$-bilinearly. `dual` is the additive subgroup of $L_{\mathbb{R}}$ of vectors x with $\langle x, v\rangle \in \mathbb{Z}$ for all $v \in L$ ("there is an integer k equal to the pairing"), i.e. L^*. `le_dual` is $L \subseteq L^*$. `SelfDual` says: $x \in L^*$ iff x is (the image of) a lattice vector, i.e. $L^* = L$. This is Definition 30.4 verbatim. The library checks it on an example: `VOA.stdLattice_selfDual` proves $\mathbb{Z}^n$ self-dual (`##print axioms`: standard three).

Physical meaning

In physical language, `SelfDual` states that the lattice theory has a unique module: the dual lattice L^* of allowed charges coincides with L itself, so every charge that is local with respect to all of L already belongs to L. For rank divisible by 8 and even L this makes the partition function modular invariant, a holomorphic CFT. The Lean library formulates this over $\mathbb{R} \otimes L$ to avoid choosing an embedding; physically that is the choice of Cartan subspace of the momenta.

Trap: `SelfDual` is never connected to the Leech lattice

The VOA library's `SelfDual` and the vendored `IsUnimodular` (below) are equivalent by (30.1), but *that equivalence is not proved in Lean*, and `SelfDual` is never established for Λ. This is harmless: no later theorem uses `VOA.IntegralLattice.SelfDual`. Where unimodularity of Λ is needed downstream (the extraspecial module T, Chapter 34; the theta function, Chapter 33), the vendored statement `Leech.lattice_isUnimodular` ($\det = 1$) is used directly, transported to the VOA side as invertibility of the Gram determinant (`VOA.Moonshine.leech_isUnit_det_gramMat` in `VOA/Moonshine/ExtraspecialModule.lean`). A referee should therefore read "Λ unimodular" everywhere in the Moonshine Part as "$\det \Lambda = 1$".

30.3.3 The vendored lattice of *Lattices and Codes*

Definition 30.13 (`_root_.IntegralLattice`). `VOA/LatticesAndCodes/Lattice/Defs.lean`.

```
structure IntegralLattice : Type 1 where
  /-- The underlying `ℤ`-module. -/
  carrier : Type
  [addCommGroup : AddCommGroup carrier]
  [free : Module.Free ℤ carrier]
  [finite : Module.Finite ℤ carrier]
  /-- The bilinear form. -/
  bilin : carrier →ₗ[ℤ] carrier →ₗ[ℤ] ℤ
  /-- The form is symmetric. -/
  bilin_symm : ∀ x y, bilin x y = bilin y x

instance : CoeSort IntegralLattice Type := ⟨carrier⟩
```

From the mathematics to the Lean statement

The same mathematical object as Definition 30.9, with three cosmetic differences: the form is called `bilin` and has the type `carrier →ₗ[ℤ] carrier →ₗ[ℤ] ℤ` (a linear map into linear maps; this is literally the same type as `LinearMap.BilinForm ℤ carrier`); symmetry is stated pointwise; and the carrier lives in the lowest universe `Type`. The `CoeSort` line lets one write `x : Γ` for `x : Γ.carrier`. Definiteness is deliberately not part of the structure, so that indefinite lattices (such as U of Example 30.5) are covered.

Physical meaning

The same physical datum as before, now in the form used for the classification of Niemeier-type lattices: a lattice of charges with a pairing. Its Lean encoding differs from the VOA one, but both describe the lattice of momenta of compact chiral bosons; Section 30.9 translates between them.

Definition 30.14 (Norm, rank, Gram matrix, determinant). `VOA/LatticesAndCodes/Lattice/Defs.lean`.

```
def normSq {Γ : IntegralLattice} (x : Γ) : ℤ := Γ.bilin x x

noncomputable def rank : ℕ := finrank ℤ Γ

noncomputable def chooseBasis : Basis (Fin Γ.rank) ℤ Γ := finBasis ℤ Γ

noncomputable def gram {ι : Type*} (b : Basis ι ℤ Γ) : Matrix ι ι ℤ :=
  Matrix.of fun i j => Γ.bilin (b i) (b j)
```

```
noncomputable def det : ℤ := (Γ.gram Γ.chooseBasis).det

@[simp] theorem det_eq_gram_det {ι : Type*} [Fintype ι] [DecidableEq ι] (b : Basis ι ℤ Γ) :
    (Γ.gram b).det = Γ.det
```

From the mathematics to the Lean statement

`normSq x` is $\langle x, x\rangle$ (Ebeling writes x^2). `Basis ι ℤ Γ` is a $\mathbb{Z}$-basis indexed by the type `ι`; `Fin n` is $\{0, \dots, n-1\}$. `det` is defined by an arbitrary chosen basis; the theorem `det_eq_gram_det` says that *any* basis, indexed by any finite type, gives the same determinant — the basis-independence argument after Definition 30.2. So `Γ.det` is $\det L$ as in the textbook.

Physical meaning

The norm of a lattice vector α is twice the conformal weight of $e^{i\alpha\cdot X}$, the rank is the central charge, and the Gram matrix and determinant describe the metric and volume of the target torus. The determinant of the lattice also counts the number of modules, $|L^*/L|$.

Definition 30.15 (Even, unimodular, positive definite; Ebeling's convention)**.**

```
def IsEven : Prop := ∀ x : Γ, (2 : ℤ) ∣ normSq x

def IsUnimodular : Prop := IsUnit Γ.det

def IsPosDef : Prop := ∀ x : Γ, x ≠ 0 → 0 < normSq x
```

From the mathematics to the Lean statement

`IsUnit d` for an integer d means d is invertible in $\mathbb{Z}$, i.e. $d = \pm 1$ (`isUnimodular_iff` in the same file states exactly this). `IsEven` and `IsPosDef` are word for word the VOA library's `Even` and `PosDef`, written with `normSq`. Unimodularity is defined through the determinant rather than through self-duality; by (30.1) the two agree. For a positive definite lattice $\det > 0$, so unimodular means $\det = 1$ (`IntegralLattice.det_eq_one` in `Theta/ModularForm.lean`).

Physical meaning

Even, unimodular and positive definite are the three properties that together say: the lattice chiral algebra is local with integer weights (even), has a single sector (unimodular), and is unitary (positive definite). The even unimodular lattices are exactly the lattices that give holomorphic lattice CFTs, with partition function a modular function; the Lean file records the convention in which these predicates are phrased.

Definition 30.16 (Isometries, sublattices, roots, representation numbers)**.**

Files `VOA/LatticesAndCodes/Lattice/Sublattice.lean`, `VOA/LatticesAndCodes/Theta/Counting.lean`.

```
structure Isom (Γ Λ : IntegralLattice) extends Γ ≃ₗ[ℤ] Λ where
  map_bilin' : ∀ x y : Γ, Λ.bilin (toLinearEquiv x) (toLinearEquiv y) = Γ.bilin x y

def ofSubmodule (N : Submodule ℤ Γ) : IntegralLattice where
  carrier := ↥N
  bilin := Γ.bilin.compl₁₂ N.subtype N.subtype
  bilin_symm _ _ := Γ.bilin_symm _ _

def rootSet (Γ : IntegralLattice) : Set Γ := {x : Γ | normSq x = 2}
```

```
noncomputable def repCount (Γ : IntegralLattice) (m : ℤ) : ℕ := {x : Γ | normSq x =
 ↪ m}.ncard
```

From the mathematics to the Lean statement

- `Γ ≃ₗ[ℤ] Λ` is a $\mathbb{Z}$-linear isomorphism; an `Isom` (notation `Γ ≃ₗᵢ Λ`) is one that preserves the forms. Isometries preserve rank, determinant, evenness, definiteness and unimodularity (`Isom.rank_eq`, `Isom.det_eq`, ...), and representation numbers (`Isom.repCount_eq`).
- `Submodule ℤ Γ` is a subgroup (every subgroup of an abelian group is a $\mathbb{Z}$-submodule); `↥N` is the type of its elements; `compl₁₂ N.subtype N.subtype` restricts the form to N. So `ofSubmodule N` is N with the induced form; it is again free of finite rank because subgroups of $\mathbb{Z}^n$ are.
- `rootSet` is $R(L)$ (meaningful for even lattices). `repCount Γ m` is $r_L(m)$, computed with `Set.ncard`, the cardinality of a set as a natural number, *with the convention that an infinite set has* `ncard` 0. For a positive definite lattice the set is finite (Lemma 30.7, Lean: `IsPosDef.finite_setOf_normSq_le` in `Roots/RootLattice.lean`), so the convention never bites; but a referee should note that a statement "`repCount Γ m = 0`" would be vacuous for an indefinite lattice. All uses below carry `IsPosDef`.

Physical meaning

An isometry is a symmetry of the momentum lattice and hence an automorphism of the chiral algebra (a Weyl-group or discrete symmetry of the target torus). A sublattice $M \subseteq L$ corresponds to a subalgebra, for instance the one generated by a smaller set of currents; the index relation is conservation of the lattice volume. Roots are the weight-one currents generating the Kac–Moody algebra, and the representation numbers $r_L(m)$ count the states of conformal weight $m/2$ in the momentum part of the Hilbert space.

Theorem 30.17 (Index–determinant relation). *Let $f : M \to L$ be an injective isometric map of integral lattices whose image has the same rank as L, and let $k = [L : f(M)]$. Then* $\det M = k^2 \det L$.

```
theorem det_of_injective_index (f : Γ →ₗ[ℤ] Λ) (hf : Function.Injective f)
    (hform : ∀ x y : Γ, Λ.bilin (f x) (f y) = Γ.bilin x y)
    (hrank : finrank ℤ (LinearMap.range f) = Λ.rank)
    {k : ℕ} (hk : Nat.card (Λ ⧸ LinearMap.range f) = k) :
    Γ.det = (k : ℤ) ^ 2 * Λ.det
```

From the mathematics to the Lean statement

File `Lattice/Index.lean`, name `IntegralLattice.det_of_injective_index`. Here $\Gamma = M$ and $\Lambda = L$ (Lean's letters, not to be confused with the Leech lattice). Hypotheses: `hf` injectivity; `hform` isometry; `hrank` the image has full rank; `hk` the quotient group $\Lambda/f(\Gamma)$ has `Nat.card` equal to k. `Nat.card` is the cardinality of a type as a natural number, 0 if infinite; the full-rank hypothesis guarantees the quotient is finite, so k is the honest index. Same as the textbook statement.

Physical meaning

For a sublattice $M \subseteq L$ of finite index one has $\det M = [L : M]^2 \det L$. Physically this is the statement that the torus $\mathbb{R}^n/M$ is an $[L : M]$-fold cover of $\mathbb{R}^n/L$ (heuristically): extending a chiral algebra by adding sectors of simple currents, as in the passage from the root lattice

A_1^{24}, of determinant 2^{24}, to the unimodular Golay lattice, an extension of index 2^{12}. The Lean theorem itself is purely lattice-theoretic.

Proof on paper. Choose bases b of L and b' of $f(M)$, and let T be the integer matrix expressing b' in terms of b. Then the Gram matrix of $f(M) \cong M$ is $T^{\mathsf{T}} G_L T$, so $\det M = (\det T)^2 \det L$. The theory of finitely generated abelian groups (Smith normal form) gives $|\det T| = [L : f(M)]$. □

What the machine verified

Unconditional. `##print axioms IntegralLattice.det_of_injective_index:` `propext, Classical.choice, Quot.sound.`

30.4 Binary codes

30.4.1 Definitions

A *binary linear code of length n* is a linear subspace $C \subseteq \mathbb{F}_2^n$, where $\mathbb{F}_2 = \mathbb{Z}/2$. Its elements are *codewords*. The *(Hamming) weight* $\mathrm{wt}(c)$ of a word c is the number of nonzero coordinates; the *support* $\mathrm{supp}(c) \subseteq \{0, \dots, n-1\}$ is the set of those coordinates. Thinking of a binary word as the indicator function of its support is often the best intuition: addition of words is symmetric difference of supports, and

$$\mathrm{wt}(x+y) = \mathrm{wt}(x) + \mathrm{wt}(y) - 2\,|\operatorname{supp} x \cap \operatorname{supp} y|. \tag{30.2}$$

The *standard inner product* is $x \cdot y = \sum_i x_i y_i \in \mathbb{F}_2$, which equals $|\operatorname{supp} x \cap \operatorname{supp} y| \bmod 2$, because $x_i y_i = 1$ exactly when i is in both supports. (Example: $x = (1,1,0)$, $y = (1,0,1)$; the supports meet in $\{0\}$, and $x \cdot y = 1 + 0 + 0 = 1$.) The *dual code* is $C^\perp = \{x : x \cdot c = 0 \ \forall c \in C\}$. C is *self-orthogonal* if $C \subseteq C^\perp$ and *self-dual* if $C = C^\perp$. It is *even* if all weights are even and *doubly even* if all weights are divisible by 4. The *minimum distance* $d(C)$ is the smallest weight of a nonzero codeword; a code of dimension k and minimum distance d is an $[n,k,d]$ code. Since $\dim C + \dim C^\perp = n$ (the standard form is nondegenerate), a self-dual code has $\dim C = n/2$, and a self-orthogonal code of dimension $n/2$ is self-dual.

Lemma 30.18. *A doubly even binary code is self-orthogonal.*

Physical meaning

A doubly even code is self-orthogonal, which by the discussion of Construction A is exactly what makes Γ_C an integral lattice. Under the dictionary codeword weight $w \leftrightarrow$ squared length $w/2$, doubly even weights become even norms, hence integer conformal weights for the vertex operators of the code CFT. In quantum information, this is the classical-code condition (heuristically) for CSS-type stabiliser codes to be well defined.

Proof. For $x, y \in C$, (30.2) gives $2|\operatorname{supp} x \cap \operatorname{supp} y| = \mathrm{wt}\, x + \mathrm{wt}\, y - \mathrm{wt}(x+y) \equiv 0 \pmod 4$, so the intersection has even size and $x \cdot y = 0$. □

Lemma 30.19. *If C is self-dual and even, the all-ones word $\mathbf{1}$ lies in C. Hence $c \mapsto c + \mathbf{1}$ is a bijection of C exchanging weights j and $n - j$.*

Physical meaning

A technical lemma on codes: an even self-dual code contains the all-ones word, and complementation exchanges weights j and $n-j$. In the code lattice Γ_C the all-ones word gives the glue vector $(1, \dots, 1)/\sqrt{2}$ of norm $n/2$, and the weight symmetry $j \leftrightarrow n - j$ is what makes the

weight enumerator palindromic in the computation of the Golay distribution.

Proof. $\mathbf{1} \cdot c = \sum_i c_i \equiv \mathrm{wt}(c) \equiv 0$ for all $c \in C$, so $\mathbf{1} \in C^\perp = C$. □

30.4.2 The Lean definitions

All of the following are in `VOA/LatticesAndCodes/Codes/Defs.lean`, namespace `Code`. The library treats codes over $\mathbb{Z}/q$ in general; only $q = 2$ is used in this book.

```
abbrev Code (q n : ℕ) : Type := Submodule (ZMod q) (Fin n → ZMod q)

def weight (c : Fin n → ZMod q) : ℕ := hammingNorm c

def support (c : Fin n → ZMod q) : Finset (Fin n) := {i | c i ≠ 0}

def stdBilin (q n : ℕ) : LinearMap.BilinForm (ZMod q) (Fin n → ZMod q) := Matrix.toBilin' 1

def dual (C : Code q n) : Code q n := (stdBilin q n).orthogonal C

@[simp] theorem mem_dual {C : Code q n} {x : Fin n → ZMod q} :
    x ∈ C.dual ↔ ∀ y ∈ C, y ⬝ᵥ x = 0

noncomputable def rank (C : Code q n) : ℕ := finrank (ZMod q) C

def IsSelfOrthogonal (C : Code q n) : Prop := C ≤ C.dual

def IsSelfDual (C : Code q n) : Prop := C.dual = C

def IsEven (C : Code 2 n) : Prop := ∀ c ∈ C, 2 ∣ weight c

def IsDoublyEven (C : Code 2 n) : Prop := ∀ c ∈ C, 4 ∣ weight c

noncomputable def minDist (C : Code q n) : ℕ := sInf {w | ∃ c ∈ C, c ≠ 0 ∧ weight c = w}
```

From the mathematics to the Lean statement

- `ZMod q` is $\mathbb{Z}/q$; `Fin n → ZMod q` is the space of words of length n. A `Code q n` is literally a `Submodule`, i.e. a linear subspace for $q = 2$. So `c ∈ C` means c is a codeword.
- `hammingNorm c` is Mathlib's number of nonzero coordinates: the Hamming weight.
- `Matrix.toBilin' 1` is the bilinear form with identity Gram matrix, $x \cdot y = \sum x_i y_i$; `x ⬝ᵥ y` is Mathlib's notation for this dot product of vectors (the subscript $_\text{v}$ stands for "vector"; the same symbol is used below for the dot product of integer vectors in $\mathbb{Z}^n$). `orthogonal C` is $\{x : \langle c, x\rangle = 0\ \forall c \in C\}$; `mem_dual` confirms this unfolding. So `C.dual` $= C^\perp$.
- `C ≤ C.dual` is inclusion of subspaces. `rank` is $\dim_{\mathbb{F}_2} C$.
- `minDist` is the infimum (`sInf`) of the set of weights of nonzero codewords. Lean's convention $\inf \varnothing = 0$ means `minDist` of the zero code is 0; for a nonzero code it is the textbook minimum distance. The Golay code is nonzero (`Code.golay_ne_bot`), so the convention is irrelevant below.

All definitions are the textbook ones.

The two lemmas above are in Lean as `Code.IsDoublyEven.isSelfOrthogonal` and `Code.one_mem_of_isSelfDual_` and the dimension criterion as

```
theorem isSelfDual_iff {C : Code q n} :
    C.IsSelfDual ↔ C.IsSelfOrthogonal ∧ 2 * C.rank = n
```

(under the standing hypothesis `[Fact (Nat.Prime q)]`, i.e. $\mathbb{Z}/q$ is a field).

30.4.3 Weight enumerators and the MacWilliams identity

Definition 30.20 (Weight enumerator). For a code C of length n, let $A_i = |\{c \in C : \operatorname{wt} c = i\}|$ (the *weight distribution*), and

$$W_C(X,Y) = \sum_{c \in C} X^{n-\operatorname{wt} c} Y^{\operatorname{wt} c} = \sum_{i=0}^{n} A_i X^{n-i} Y^i.$$

```
noncomputable def toFinset (C : Code q n) : Finset (Fin n → ZMod q) :=
  (Set.toFinite (C : Set (Fin n → ZMod q))).toFinset

noncomputable def hammingEnumerator (C : Code q n) : MvPolynomial (Fin 2) ℂ :=
  ∑ c ∈ C.toFinset, X 0 ^ (n - weight c) * X 1 ^ weight c

noncomputable def weightCount (C : Code q n) (i : ℕ) : ℕ :=
  (C.toFinset.filter fun c => weight c = i).card
```

From the mathematics to the Lean statement

File `Codes/Enumerator.lean`. `toFinset` is the (finite) set of codewords, as a `Finset` so that one may sum over it. `MvPolynomial (Fin 2) ℂ` is the polynomial ring $\mathbb{C}[X_0, X_1]$; `X 0` is X and `X 1` is Y. The subtraction `n - weight c` is natural-number subtraction, which is honest because $\operatorname{wt} c \le n$. `weightCount C i` is A_i. Same as the textbook.

Physical meaning

The weight enumerator is the generating function of the code by Hamming weight. Under Construction A the minimal lattice vector over a codeword of weight w has norm $w/2$, i.e. conformal weight $w/4$, so the enumerator is the code-theoretic shadow of the partition function: it counts the lowest momentum states in each coset. Its transformation under the MacWilliams substitution is the finite analogue of the S transformation.

Theorem 30.21 (MacWilliams identity). *For a linear code $C \subseteq (\mathbb{Z}/q)^n$, $|C|\, W_{C^\perp}(X,Y) = W_C\big(X + (q-1)Y,\ X - Y\big)$.*

```
theorem macWilliams_eval (C : Code q n) (A B : ℂ) :
    (C.toFinset.card : ℂ) * eval ![A, B] C.dual.hammingEnumerator
      = eval ![A + ((q : ℂ) - 1) * B, A - B] C.hammingEnumerator

theorem macWilliams (C : Code q n) :
    (C.toFinset.card : ℂ) • C.dual.hammingEnumerator
      = bind₁ ![X 0 + MvPolynomial.C ((q : ℂ) - 1) * X 1, X 0 - X 1] C.hammingEnumerator
```

From the mathematics to the Lean statement

File `Codes/MacWilliams.lean`, standing hypothesis `[NeZero q]` ($q \ge 1$). `eval ![A, B] p` evaluates the polynomial p at $X = A$, $Y = B$ (`![A, B]` is the vector (A, B)). `bind₁ ![u, v] p` substitutes the polynomials u, v for X, Y in p. The first form is the identity at every complex

point, the second the polynomial identity; over $\mathbb{C}$ they are equivalent. Exactly Theorem 30.21; no primality of q is needed.

Physical meaning

MacWilliams' identity relates the weight enumerator of C to that of $C^\perp$. It is a finite Fourier (Poisson summation) transform on the code, the same operation that gives $\tau \mapsto -1/\tau$ for the theta function of Γ_C; heuristically it is the code-level T-duality exchanging the sectors labelled by C and $C^\perp$. In quantum error correction it relates the weight distributions of a stabiliser code and its normaliser, the starting point of the linear-programming bounds.

Proof on paper. Let $\chi(a) = e^{2\pi i a/q}$, a character of $\mathbb{Z}/q$, and put $f(v) = X^{n-\mathrm{wt}\,v} Y^{\mathrm{wt}\,v}$ for $v \in (\mathbb{Z}/q)^n$. Its Fourier transform factorises over coordinates: $\hat f(u) = \sum_v \chi(u\cdot v) f(v) = \prod_i \big(\sum_a \chi(u_i a) X^{[a=0]} Y^{[a\neq 0]}\big)$, and the i-th factor is $X + (q-1)Y$ if $u_i = 0$ and $X - Y$ otherwise (the sum of χ over the nonzero elements is -1). So $\hat f(u) = (X+(q-1)Y)^{n-\mathrm{wt}\,u}(X-Y)^{\mathrm{wt}\,u}$. Summing over $u \in C$ and exchanging sums, $\sum_{u\in C}\chi(u\cdot v)$ equals $|C|$ if $v \in C^\perp$ and 0 otherwise (orthogonality of characters on the group C). Hence $\sum_{u\in C}\hat f(u) = |C| \sum_{v\in C^\perp} f(v)$, which is the identity. □

Corollary 30.22. *If C is a binary self-dual code of dimension k, then $W_C(X+Y, X-Y) = 2^k W_C(X,Y)$.*

```
theorem enumerator_invariant {n : ℕ} (C : Code 2 n) (h : C.IsSelfDual) :
    bind₁ ![X 0 + X 1, X 0 - X 1] C.hammingEnumerator
      = ((2 ^ C.rank : ℕ) : ℂ) • C.hammingEnumerator
```

Physical meaning

For a self-dual code the enumerator is invariant, up to the factor 2^k, under $(X,Y) \mapsto (X+Y, X-Y)$. This is the code-level analogue of modular invariance of the holomorphic partition function: a self-dual code gives a single-sector code CFT whose genus-one counting function is invariant under S. It is also the starting point of Gleason's theorem and of the classification of self-dual codes.

This is the code-theoretic shadow of the modular transformation $\tau \mapsto -1/\tau$ of §30.8: the theta function of the lattice of a code is obtained from W_C by substituting Jacobi theta constants, and the substitution $(X,Y) \mapsto ((X+Y)/\sqrt{2}, (X-Y)/\sqrt{2})$ corresponds to S.

What the machine verified

`Code.macWilliams`, `Code.enumerator_invariant`: unconditional; `##print axioms`: `propext`, `Classical.choice`, `Quot.sound`.

30.5 The extended binary Golay code

30.5.1 Construction

The extended Golay code $\mathcal{G}$ is the unique (up to coordinate permutation) $[24, 12, 8]$ binary code; we use one explicit model, the *Paley construction*. Index the 24 coordinates as two blocks of 12, and the 12 coordinates of each block by the projective line $\mathbb{P}^1(\mathbb{F}_{11}) = \{0, 1, \dots, 10, \infty\}$ (Lean label 11 is ∞). The nonzero squares mod 11 are $Q = \{1, 3, 4, 5, 9\}$ (indeed $1^2, 2^2, 3^2, 4^2, 5^2 \equiv 1, 4, 9, 5, 3$). The idea of the Paley construction is that the pattern "$j - i$ is a square" is very regular — it is invariant under the shifts $i \mapsto i+1$ and, since -1 is *not* a square mod 11, it is antisymmetric off the diagonal — and

this regularity is what makes $BB^{\mathsf{T}} = I$ come out. Define the 12×12 matrix B over $\mathbb{F}_2$ by

$$B_{ij} = \begin{cases} 0 & i = j = \infty, \\ 1 & \text{exactly one of } i, j \text{ is } \infty, \\ 1 & i, j \neq \infty \text{ and } j - i \in \{0\} \cup Q \pmod{11}, \\ 0 & \text{otherwise,} \end{cases}$$

and let $\mathcal{G}$ be the row space of the 12×24 matrix $[\, I_{12} \mid B \,]$, i.e. the image of $x \mapsto (x, xB)$. For instance row 0 of B is $(1,1,0,1,1,1,0,0,0,1,0,1)$ (columns $0, \dots, 10, \infty$: ones at 0, at the squares $1, 3, 4, 5, 9$, and at ∞), and every row $i \leq 10$ is obtained by shifting the first eleven entries cyclically by i. Rows $0, \dots, 10$ of B have $1 + 5 + 1 = 7$ ones and the row ∞ has 11, so the generators of $\mathcal{G}$ have weight 8 or 12.

Definition 30.23 (`Code.golayB`, `Code.golayEnc`, `Code.golay`). `VOA/LatticesAndCodes/Codes/Golay.lean`.

```
def golayB (i j : Fin 12) : ZMod 2 :=
  if (i : ℕ) = 11 then (if (j : ℕ) = 11 then 0 else 1)
  else if (j : ℕ) = 11 then 1
  else if (i : ℕ) = (j : ℕ) then 1
  else
    let d := ((j : ℕ) + 11 - (i : ℕ)) % 11
    if d = 1 ∨ d = 3 ∨ d = 4 ∨ d = 5 ∨ d = 9 then 1 else 0

def golayEnc : (Fin 12 → ZMod 2) →ₗ[ZMod 2] (Fin 24 → ZMod 2) where
  toFun x := Fin.append x (fun k => ∑ i, x i * golayB i k)

def golay : Code 2 24 := LinearMap.range golayEnc
```

(The two linearity proofs in `golayEnc` are omitted.)

From the mathematics to the Lean statement

Line by line: `(i : ℕ)` is the index $i \in \{0, \dots, 11\}$ viewed as a natural number. The first line treats the row $i = \infty$ (label 11): entry 0 in column ∞, 1 elsewhere. The second treats the column ∞ in the other rows: 1. The third puts 1 on the diagonal ($j - i = 0$). The last two lines handle $i \neq j$, both in $\{0, \dots, 10\}$: in Lean the subtraction of natural numbers is truncated ($3 - 5 = 0$), so $j - i$ cannot be computed directly when $j < i$. Adding 11 first gives $j + 11 - i \in \{1, \dots, 21\}$, which is a genuine natural number, congruent to $j - i$ modulo 11; reducing by `% 11` gives the representative $d \in \{0, \dots, 10\}$ of $(j - i)$ mod 11. (Example: $i = 5$, $j = 3$: $d = (3 + 11 - 5) \bmod 11 = 9 \equiv -2$, and $-2 \equiv 9$ is a square mod 11 since $3^2 = 9$, so $B_{5,3} = 1$.) The entry is 1 iff $d \in Q = \{1, 3, 4, 5, 9\}$. So `golayB` is the matrix B above. `Fin.append x y` concatenates two words of length 12 into one of length 24, and `fun k ⇒ ∑ i, x i * golayB i k` is the row vector xB. `LinearMap.range` is the image. So `golay` is the row space of $[I \mid B]$, as in the text.

Physical meaning

The extended binary Golay code is a $[24, 12, 8]$ code; up to equivalence it is the unique doubly even self-dual code of length 24 with minimum distance 8 (the uniqueness is classical and is not in the Lean library). As a code CFT it supplies the 24 bosons of the Leech setup: Construction A applied to it gives the Niemeier lattice $N(A_1^{24})$, and the automorphism group M_{24} of the code permutes the 24 bosons. In quantum information its puncturing is the perfect $[23, 12, 7]$ Golay code, which yields a $[[23, 1, 7]]$ CSS quantum code.

30.5.2 The basic properties

Theorem 30.24 ($\mathcal{G}$ is a doubly even self-dual $[24, 12, 8]$ code)**.** $\dim \mathcal{G} = 12$*,* $\mathcal{G}$ *is self-dual and doubly even, and its minimum distance is* 8*.*

```
theorem golay_rank : golay.rank = 12

theorem golay_isSelfDual : golay.IsSelfDual

theorem golay_isDoublyEven : golay.IsDoublyEven

theorem golay_minDist : golay.minDist = 8
```

From the mathematics to the Lean statement

All in namespace `Code`; no hypotheses. Each term is defined above. The conjunction is Ebeling's Theorem 2.6 (existence half). Non-vacuity: `minDist` could have been 0 only for the zero code, and `golay_minDist` itself rules that out (it says 8, and the proof exhibits a codeword of weight 8).

Physical meaning

Doubly even and self-dual are the two conditions under which Construction A gives an even unimodular lattice, that is, a holomorphic lattice CFT with $c = 24$. Minimum distance 8 means that a codeword of weight w contributes lattice vectors of norm $w/2 \geq 4$, so no new roots arise from the code: the only roots of $N(A_1^{24})$ are the 48 vectors $\pm\sqrt{2}\,e_j$ coming from $\sqrt{2}\mathbb{Z}^{24}$, giving the A_1^{24} currents. In quantum information the distance 8 is the error-detecting power of the Golay code.

Proof on paper.

1. *Dimension.* $x \mapsto (x, xB)$ is injective (the first block recovers x), so the image has dimension 12.

2. *Self-orthogonality.* A direct check on the 12×12 matrix gives $BB^{\mathsf{T}} = I$ over $\mathbb{F}_2$ (a finite computation over 144 pairs of indices; in Lean it is `golayB_mul_transpose`, closed by `decide`). Then $(x, xB) \cdot (y, yB) = x \cdot y + xBB^{\mathsf{T}}y^{\mathsf{T}} = 2\,x \cdot y = 0$. With dimension $12 = 24/2$ this gives self-duality.

3. *Double evenness.* The generators have weight 8 or 12; if u, v are doubly even and $u \cdot v = 0$, then by (30.2) $\operatorname{wt}(u + v) = \operatorname{wt} u + \operatorname{wt} v - 2|u \cap v|$ with $|u \cap v|$ even, so $u + v$ is doubly even. Induct over sums of generators.

4. *No weight* 4. By double evenness, a nonzero codeword (x, xB) of weight < 8 has weight exactly 4, so $\operatorname{wt} x + \operatorname{wt}(xB) = 4$. Since $BB^{\mathsf{T}} = I$, $x = (xB)B^{\mathsf{T}}$, so the situation is symmetric between the halves. Check the cases: $\operatorname{wt} x = 1$ gives $\operatorname{wt}(xB) \in \{7, 11\}$; $\operatorname{wt} x = 2$ gives $\operatorname{wt}(xB) = \operatorname{wt}(B_i + B_j) \geq 6$ (a finite check on pairs of rows); $\operatorname{wt} x = 3$ forces $\operatorname{wt}(xB) = 1$, so x is a column of B, of weight ≥ 7; $\operatorname{wt} x = 4$ forces $xB = 0$, so $x = 0$. All cases are contradictory. The first generator has weight $1 + 7 = 8$, so $d = 8$. □

Note the design choice recorded in the source: a brute-force check over all $2^{12} = 4096$ codewords by `decide` does not terminate in reasonable time in the Lean kernel, so only the statements quantified over 12 or 12×12 indices are decided by computation, and everything else is argued.

What the machine verified

`Code.golay_rank`, `Code.golay_isSelfDual`, `Code.golay_isDoublyEven`, `Code.golay_minDist`: unconditional; `##print axioms` (checked for this chapter): `propext`, `Classical.choice`, `Quot.sound`. The finite checks use `decide` (kernel evaluation), not `native_decide`.

30.5.3 The weight distribution; octads

Theorem 30.25 (Weight enumerator of $\mathcal{G}$). *$W_{\mathcal{G}}(X,Y) = X^{24}+759X^{16}Y^{8}+2576X^{12}Y^{12}+759X^{8}Y^{16}+Y^{24}$. In particular $\mathcal{G}$ has 759 codewords of weight 8, 2576 of weight 12 and 759 of weight 16.*

```
theorem golay_weightCount_eight : golay.weightCount 8 = 759

theorem golay_weightCount_twelve : golay.weightCount 12 = 2576

theorem golay_weightCount_sixteen_eq : golay.weightCount 16 = 759

theorem golay_hammingEnumerator :
    golay.hammingEnumerator
      = X 0 ^ 24 + MvPolynomial.C 759 * (X 0 ^ 16 * X 1 ^ 8)
        + MvPolynomial.C 2576 * (X 0 ^ 12 * X 1 ^ 12)
        + MvPolynomial.C 759 * (X 0 ^ 8 * X 1 ^ 16) + X 1 ^ 24
```

From the mathematics to the Lean statement

File `Codes/GolayEnumerator.lean`. `MvPolynomial.C a` is the constant polynomial a. Read with `X 0` $= X$, `X 1` $= Y$ this is Theorem 30.25 verbatim.

Physical meaning

The weight distribution $1, 759, 2576, 759, 1$ (weights $0, 8, 12, 16, 24$) records, at the level of codewords, how the momentum states of the code CFT are distributed. By Gleason-type invariance (Corollary 30.22) it is determined by the single number 759 of octads. The 759 octads and 2576 dodecads are the combinatorial data reappearing in the Leech lattice, in vectors of shape $(\pm 2^8, 0^{16})$, of which there are $759 \cdot 2^7$.

Proof on paper. Let A_j be the weight distribution. Double evenness kills A_j for $4 \nmid j$; minimum distance 8 kills A_4; Lemma 30.19 gives $A_j = A_{24-j}$, hence $A_{24} = A_0 = 1, A_{20} = A_4 = 0, A_{16} = A_8$. Two unknowns remain, A_8 and A_{12}. Counting codewords: $2 + 2A_8 + A_{12} = 2^{12}$. The MacWilliams identity for the self-dual code at the single point $(X,Y) = (1,2)$ reads $4096\,W(1,2) = W(3,-1)$, i.e.

$$4096\big(1 + 2^8 A_8 + 2^{12} A_{12} + 2^{16} A_8 + 2^{24}\big) = 3^{24} + 3^{16} A_8 + 3^{12} A_{12} + 3^8 A_8 + 1,$$

which simplifies to $226430750\,A_8 + 16245775\,A_{12} = 213710055650$. Substituting $A_{12} = 4094 - 2A_8$ gives $193939200\,A_8 = 147199852800$, so $A_8 = 759$ and $A_{12} = 2576$. □

Definition 30.26 (Octads, dodecads). The supports of the 759 weight-8 codewords are the *octads*; those of the 2576 weight-12 codewords the *dodecads*.

Physical meaning

The octads are the 759 eight-element subsets that support weight-8 codewords. In the Leech lattice they label the minimal vectors of shape $(\pm 2^8, 0^{16})/\sqrt{8}$, there are $759 \cdot 2^7$ of them, a part of the 196560. The Steiner-system property $S(5,8,24)$ is the combinatorial reflection of the large symmetry group M_{24} of the code CFT.

The octads form the Steiner system $S(5,8,24)$: every 5-subset of the 24 coordinates lies in exactly one octad. The existence half is proved in the library by counting (`VOA.Moonshine.GroundLat.steiner` in `VOA/Moonshine/GroundLatticeGolay.lean`): two distinct octads meet in at most 4 points (their sum is a nonzero codeword, of weight ≥ 8), so the $759\binom{8}{5} = 42504$ five-subsets of octads are distinct, and $\binom{24}{5} = 42504$. That theorem, and the other octad combinatorics used by the triality, are presented in Chapter 40. The automorphism group of $\mathcal{G}$ is the Mathieu group M_{24}; it does not appear in the Lean library.

Remark 30.27 (The perfect Golay code)**.** Deleting the last coordinate gives the $[23,12,7]$ *perfect* Golay code (`Code.golay23`, `Code.golay23_rank`, `Code.golay23_minDist`). It is not used in the Moonshine construction.

What the machine verified

`Code.golay_weightCount_eight`, `Code.golay_weightCount_twelve`, `Code.golay_weightCount_sixteen_eq`, `Code.golay_hammingEnumerator`: unconditional, standard axioms only.

30.6 From codes to lattices: Construction A

30.6.1 The construction

Let $\rho : \mathbb{Z}^n \to \mathbb{F}_2^n$ be reduction mod 2. For a binary code C, Ebeling (following Leech and Sloane, "Construction A") puts

$$\Gamma_C = \frac{1}{\sqrt{2}}\,\rho^{-1}(C) \subseteq \mathbb{R}^n.$$

So Γ_C consists of the vectors $x/\sqrt{2}$ with $x \in \mathbb{Z}^n$ and $x \bmod 2 \in C$. The $\frac{1}{\sqrt{2}}$ is irrational and would force real coordinates; the library instead keeps the honest integer vectors $x \in \rho^{-1}(C)$ and *halves the form*:

$$\langle x, y\rangle_C = \frac{1}{2}\, x \cdot y \qquad (x, y \in \rho^{-1}(C)). \tag{30.3}$$

The map $\phi : x \mapsto x/\sqrt{2}$ is an isometry from $(\rho^{-1}(C), \langle,\rangle_C)$ onto Γ_C (with the dot product of $\mathbb{R}^n$): it is $\mathbb{Z}$-linear, bijective by the very definition of Γ_C, and $\phi(x)\cdot\phi(y) = \frac{1}{\sqrt{2}}x \cdot \frac{1}{\sqrt{2}}y = \frac{1}{2}\,x\cdot y = \langle x, y\rangle_C$. An isometric isomorphism transports rank, Gram matrices, determinant, evenness, definiteness and representation numbers, so for every purpose of this book the two are the same lattice. The same trick — move a scale factor from the vectors into the form — is used for the Leech lattice below, where $\frac{1}{\sqrt{8}}$ becomes division of the form by 8. The form (30.3) is integer-valued exactly when C is self-orthogonal: $x \cdot y \equiv \rho(x)\cdot\rho(y) \pmod 2$.

Definition 30.28 (`latticeOfCode`)**.** `VOA/LatticesAndCodes/Construction/CodeToLattice.lean` (root namespace).

```
def reduceMod (q n : ℕ) : (Fin n → ℤ) →ₗ[ℤ] (Fin n → ZMod q) where
  toFun x := fun i => ((x i : ℤ) : ZMod q)

def preimageOfCode {q : ℕ} (C : Code q n) : Submodule ℤ (Fin n → ℤ) :=
  Submodule.comap (reduceMod q n) (C.restrictScalars ℤ)

noncomputable def latticeOfCode (C : Code 2 n) (hC : C ≤ C.dual) : IntegralLattice where
  carrier := ↑(preimageOfCode C)
  bilin := LinearMap.mk₂ ℤ
    (fun x y => ((x : Fin n → ℤ) ⬝ᵥ (y : Fin n → ℤ)) / 2)
```

```
@[simp] theorem latticeOfCode_bilin (C : Code 2 n) (hC : C ≤ C.dual)
    (x y : preimageOfCode C) :
    (latticeOfCode C hC).bilin x y = ((x : Fin n → ℤ) ·ᵥ (y : Fin n → ℤ)) / 2
```

(Linearity proofs omitted.)

From the mathematics to the Lean statement

`reduceMod 2 n` is ρ. `comap` is the preimage of a submodule under a linear map; `restrictScalars ℤ` views the $\mathbb{F}_2$-subspace C as a subgroup. So `preimageOfCode C` $= \rho^{-1}(C)$. The hypothesis `hC : C ≤ C.dual` is self-orthogonality, needed for integrality. The form is $(x \cdot y)/2$ with `/` *integer* division (rounding toward $-\infty$). Because $x \cdot y$ is even for $x, y \in \rho^{-1}(C)$, the division leaves no remainder, so no rounding ever occurs and `(x ·ᵥ y) / 2` is the rational number $\frac{1}{2} x \cdot y$, which happens to be an integer. A referee might worry that integer division could silently produce a non-bilinear "form"; it cannot, because the omitted linearity proofs use precisely the divisibility $2 \mid x \cdot y$ (lemma `two_dvd_dotProduct_of_mem`), and the theorem `two_mul_latticeOfCode_bilin` states $2\langle x, y\rangle_C = x \cdot y$ exactly.

Physical meaning

Construction A turns a binary code $C \subseteq \mathbb{F}_2^n$ into a lattice $\Gamma_C = \{x \in \mathbb{Z}^n : x \bmod 2 \in C\}/\sqrt{2}$, that is, into a momentum lattice. In CFT language this builds a lattice chiral algebra from a code by gluing the weight-one vertex operators $e^{i\sqrt{2}e_j \cdot X}$ (the A_1^n currents) with the vertex operators labelled by codewords, as in the code CFT constructions of Dolan–Goddard–Montague, Gaberdiel et al. and Dymarsky et al. Self-dual doubly even codes thereby give holomorphic CFTs.

Theorem 30.29 (Properties of Γ_C). *Let $C \subseteq \mathbb{F}_2^n$ be self-orthogonal of dimension k. Then Γ_C is positive definite of rank n; $\det \Gamma_C = 2^{n-2k}$; Γ_C is even iff C is doubly even; and Γ_C is unimodular iff C is self-dual.*

```
theorem latticeOfCode_isPosDef (C : Code 2 n) (hC : C ≤ C.dual) :
    (latticeOfCode C hC).IsPosDef

@[simp] theorem latticeOfCode_rank (C : Code 2 n) (hC : C ≤ C.dual) :
    (latticeOfCode C hC).rank = n

theorem latticeOfCode_isEven (C : Code 2 n) (hC : C ≤ C.dual) :
    (latticeOfCode C hC).IsEven ↔ C.IsDoublyEven

theorem latticeOfCode_det (C : Code 2 n) (hC : C ≤ C.dual) :
    (latticeOfCode C hC).det = 2 ^ (n - 2 * C.rank)

theorem latticeOfCode_isUnimodular (C : Code 2 n) (hC : C ≤ C.dual) :
    (latticeOfCode C hC).IsUnimodular ↔ C.IsSelfDual
```

From the mathematics to the Lean statement

The only hypothesis is self-orthogonality, required for the lattice to exist. `n - 2 * C.rank` is natural subtraction; it is honest since $2k \le n$ for a self-orthogonal code. These are Ebeling's Propositions 1.3 and 1.4, exactly.

Physical meaning

The properties of Γ_C are the dictionary between code and CFT: Γ_C is integral/even exactly when C is (doubly even), and unimodular exactly when C is self-dual. Thus a doubly even

self-dual code gives an even unimodular lattice, hence a holomorphic lattice CFT with $c = n$. It is also the observation that error-correcting codes and rational CFTs of Narain type share the same underlying algebraic structure.

Proof on paper. Positive definiteness: $\frac{1}{2}x \cdot x > 0$ for $x \neq 0$. Rank: $2\mathbb{Z}^n \subseteq \rho^{-1}(C) \subseteq \mathbb{Z}^n$. Evenness: for an integer a, $a^2 \equiv 0 \pmod 4$ if a is even and $\equiv 1 \pmod 4$ if odd, so $x \cdot x \equiv \mathrm{wt}(\rho x) \pmod 4$; hence $\frac{1}{2}x \cdot x$ is even for all x iff all codeword weights are divisible by 4. Determinant: $\mathbb{Z}^n/\rho^{-1}(C) \cong \mathbb{F}_2^n/C$ has order 2^{n-k}, so a basis matrix P of $\rho^{-1}(C)$ has $|\det P| = 2^{n-k}$; the Gram matrix of Γ_C is $\frac{1}{2}P^{\mathsf{T}}P$, with determinant $2^{-n}2^{2(n-k)} = 2^{n-2k}$. Unimodularity: $2^{n-2k} = 1$ iff $2k = n$ iff C is self-dual (given self-orthogonality). □

What the machine verified

All five unconditional (given the stated hypothesis `hC`); `##print axioms` for `latticeOfCode_det`, `latticeOfCode_isEven`, `latticeOfCode_isUnimodular`: standard three.

Example 30.30 (E_8 from the Hamming code; paper only)**.** The extended Hamming code $H_8 \subseteq \mathbb{F}_2^8$ is the $[8, 4, 4]$ code spanned by the rows of

$$\begin{pmatrix} 1 & 1 & 1 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 1 & 1 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 1 & 1 & 1 \\ 0 & 1 & 0 & 1 & 0 & 1 & 0 & 1 \end{pmatrix}.$$

Its nonzero weights are 4 (fourteen words) and 8 (one word), so it is doubly even; it has dimension $4 = 8/2$ and is self-orthogonal (Lemma 30.18), hence self-dual. By Theorem 30.29, Γ_{H_8} is an even unimodular positive definite lattice of rank 8: it is the E_8 lattice. Its roots are $\frac{1}{2}x \cdot x = 2$, i.e. $x \cdot x = 4$: the $2 \cdot 8 = 16$ vectors $\pm 2e_i$, and the $14 \cdot 2^4 = 224$ vectors with entries ± 1 on the support of a weight-4 codeword; $16 + 224 = 240$, the coefficient of q in $\vartheta_{E_8} = E_4$ (the only modular form of weight 4 with constant term 1). This example is not formalised in the vendored files used here; it is included to let the reader test the definitions on a small case. It also illustrates why Construction A alone never produces a rootless lattice: the vectors $\pm 2e_i$ always have norm $\frac{1}{2} \cdot 4 = 2$. To kill them one needs the twist by u of §30.7.

30.6.2 The Golay lattice $N(A_1^{24})$

Definition 30.31 (`Leech.preG`, `Leech.golayLattice`)**.** `VOA/LatticesAndCodes/Leech/Defs.lean`, namespace `Leech`.

```
def preG : Submodule ℤ (Fin 24 → ℤ) := preimageOfCode Code.golay

theorem golay_le_dual : Code.golay ≤ Code.golay.dual := Code.golay_isSelfOrthogonal

def golayLattice : IntegralLattice := latticeOfCode Code.golay golay_le_dual

theorem golayLattice_det : golayLattice.det = 1

theorem golayLattice_rank : golayLattice.rank = 24
```

From the mathematics to the Lean statement

`preG` $= \rho^{-1}(\mathcal{G}) \subseteq \mathbb{Z}^{24}$, and `golayLattice` is $\Gamma_{\mathcal{G}}$ with the halved form. By Theorem 30.29 and Theorem 30.24 it is even, positive definite, unimodular ($\det = 2^{24-24} = 1$) and of rank 24.

Physical meaning

The Golay lattice $N(A_1^{24})$ is the Niemeier lattice obtained from the Golay code by Construction A: a $c = 24$ holomorphic lattice CFT. Its 48 roots $\pm\sqrt{2}e_j$ give weight-one currents forming A_1^{24} (dimension $24 \cdot 3 = 72$, i.e. 48 root currents plus 24 Cartan currents). In the Leech construction this lattice is modified by a change of the glue to remove all roots, so it is the starting point of the passage to the rootless theory.

$\Gamma_{\mathcal{G}}$ is one of the 24 Niemeier lattices. Its roots are easy to find: $\frac{1}{2}x \cdot x = 2$ means $x \cdot x = 4$, so either $x = \pm 2e_i$ (reducing to the zero codeword) or x has four entries ± 1 (reducing to a weight-4 word, impossible since $d(\mathcal{G}) = 8$). So the root system is 48 roots $\pm 2e_i$, i.e. 24 orthogonal copies of A_1, and the lattice is the Niemeier lattice $N(A_1^{24})$. The roots $\pm 2e_i$ are the reason this lattice is *not* the Leech lattice, and the reason it is useful: its lattice VOA contains 24 commuting copies of $\widehat{sl}_2$ at level 1, on which the triality automorphism of Chapters 39–41 is built. In the VOA library the Golay lattice appears as `VOA.Moonshine.Triality.golayN` (via the bridge of §30.9).

30.7 The Leech lattice

30.7.1 Ebeling's construction, and the doubled model

Let $\Gamma = \Gamma_{\mathcal{G}}$, realised as $\rho^{-1}(\mathcal{G})$ with the halved form. For $x \in \rho^{-1}(\mathcal{G})$ the coordinate sum $\sum_i x_i$ is even (it is $\equiv \operatorname{wt}\rho(x)$, which is divisible by 4). So

$$\pi : \rho^{-1}(\mathcal{G}) \to \mathbb{Z}/2, \qquad \pi(x) = \tfrac{1}{2}\textstyle\sum_i x_i \bmod 2$$

is a homomorphism ("parity"); it is surjective ($\pi(2e_0) = 1$). Its kernel

$$A = \{x \in \rho^{-1}(\mathcal{G}) : \ 4 \mid \textstyle\sum_i x_i\}$$

has index 2 in Γ. Ebeling's description of the Leech lattice (§2.8) is $\Lambda = A \cup (\frac{1}{2}\mathbf{1} + (\Gamma \setminus A))$, the half-integral shift by $\frac{1}{2}\mathbf{1}$ being what kills the roots. To avoid the $\frac{1}{2}$, the library *doubles all vectors* and divides the form by 8 instead of 2: with

$$u = (5, 1, 1, \dots, 1) = \mathbf{1} + 4e_0 \in \mathbb{Z}^{24},$$

it defines

$$\Lambda = 2A \ \cup \ (u + 2A) \ \subseteq \mathbb{Z}^{24}, \qquad \langle x, y\rangle = \tfrac{1}{8}\, x \cdot y. \tag{30.4}$$

Doubling is an isometry: for $a, b \in A$, $\frac{1}{8}(2a)\cdot(2b) = \frac{1}{2}a \cdot b$. The vector u reduces to the all-ones word, which lies in $\mathcal{G}$ (Lemma 30.19), and $\sum u_i = 28 \equiv 0 \pmod 4$, so $u \in A$; in particular $2u \in 2A$ and $2A \cup (u + 2A)$ is closed under addition — it is a subgroup.

Remark 30.32 (Comparison with Conway–Sloane)**.** The model (30.4) is the classical description of the Leech lattice in *Sphere Packings, Lattices and Groups*, Chapter 4, §11: the vectors $x \in \mathbb{Z}^{24}$ (scaled by $1/\sqrt{8}$) such that either all x_i are even, $\frac{1}{2}x \bmod 2 \in \mathcal{G}$ and $\sum x_i \equiv 0 \pmod 8$; or all x_i are odd, $\frac{1}{2}(x - \mathbf{1}) \bmod 2 \in \mathcal{G}$ and $\sum x_i \equiv 4 \pmod 8$. Indeed $2A$ is the first set (with $x = 2a$: $a \bmod 2 \in \mathcal{G}$,

$\sum x_i = 2\sum a_i \equiv 0 \pmod 8$), and $u + 2A$ is the second (with $x = u + 2a$: $\frac{1}{2}(x - \mathbf{1}) = 2e_0 + a \equiv a$, $\sum x_i = 28 + 2\sum a_i \equiv 4 \pmod 8$). Conway–Sloane use $(-3, 1, \dots, 1)$ instead of u; the two differ by $8e_0 = 2 \cdot 4e_0 \in 2A$, so they define the same coset. In this normalisation the norm-4 vectors are the vectors with $x \cdot x = 32$. A *shape* such as $(\pm 4, \pm 4, 0^{22})$ means: the multiset of absolute values of the coordinates is $\{4, 4, 0, \dots, 0\}$ (twenty-two zeros), in any positions and with the indicated signs. There are three shapes $(\pm 4, \pm 4, 0^{22})$ (1104 of them), $(\pm 2^8, 0^{16})$ on an octad with an even number of minus signs ($759 \cdot 2^7 = 97152$), and $(\mp 3, \pm 1^{23})$ ($24 \cdot 2^{12} = 98304$), totalling 196560. This shape count is classical; the Lean proof of 196560 (§30.8.5) does *not* enumerate shapes but uses modular forms.

30.7.2 The Lean definitions

Definition 30.33 (`IntegralLattice.dotLattice`). `VOA/LatticesAndCodes/Leech/Defs.lean`. Given a submodule $N \subseteq \mathbb{Z}^n$ such that the dot product of any two elements of N is divisible by d, this is N with the form $x \cdot y/d$:

```
def dotLattice {n : ℕ} (d : ℤ) (N : Submodule ℤ (Fin n → ℤ))
    (hdvd : ∀ x ∈ N, ∀ y ∈ N, d ∣ (x ⬝ᵥ y)) : IntegralLattice where
  carrier := ↑N
  bilin := LinearMap.mk₂ ℤ
    (fun x y => ((x : Fin n → ℤ) ⬝ᵥ (y : Fin n → ℤ)) / d)
```

Physical meaning

This is a bookkeeping device: rescaling the form by $1/d$ is the rescaling of the radius of the compactification torus. It corresponds to the choice of normalisation for the momentum so that $\sqrt{2}$ factors in the Golay lattice become integer norms in the Leech lattice.

(Linearity proofs omitted. As for `latticeOfCode`, the hypothesis `hdvd` says d divides every dot product, so the integer division by d leaves no remainder and equals the rational number $x \cdot y/d$.)

Definition 30.34 (A, u, $2A$ and the Leech carrier). Namespace `Leech`.

```
def subA : Submodule ℤ (Fin 24 → ℤ) where
  carrier := {x | x ∈ preG ∧ (4 : ℤ) ∣ ∑ i, x i}

def uVec : Fin 24 → ℤ := fun i => if i = 0 then 5 else 1

def subA2 : Submodule ℤ (Fin 24 → ℤ) := subA.map ((2 : ℤ) • LinearMap.id)

def carrier : Submodule ℤ (Fin 24 → ℤ) where
  carrier := {x | x ∈ subA2 ∨ x - uVec ∈ subA2}

def lattice : IntegralLattice := dotLattice 8 carrier (fun x hx y hy => eight_dvd_dot hx
↪ hy)

@[simp] theorem lattice_bilin (x y : carrier) :
    lattice.bilin x y = ((x : Fin 24 → ℤ) ⬝ᵥ (y : Fin 24 → ℤ)) / 8
```

(The closure proofs of the submodules `subA` and `carrier` are omitted.)

From the mathematics to the Lean statement

- `subA` $= A$: vectors of $\rho^{-1}(\mathcal{G})$ with $4 \mid \sum_i x_i$.
- `uVec` $= u = (5, 1, \dots, 1)$ (coordinate 0 is 5).
- `subA2` $= 2A$, the image of A under multiplication by 2 (`map` is the image of a submodule).

- `carrier` $= \{x : x \in 2A \text{ or } x - u \in 2A\} = 2A \cup (u + 2A)$. That this set is a subgroup is the (omitted, and proved) closure argument sketched above; in particular the definition could not silently fail to be a lattice.
- `eight_dvd_dot` is the theorem that $8 \mid x \cdot y$ on the carrier, so the form $x \cdot y/8$ is integral and the division exact; `lattice_bilin` records the form.
- So `Leech.lattice` is (30.4) exactly. It is a lattice in the vendored encoding (`_root_.IntegralLattice`).

Physical meaning

This is the explicit description of the carrier of the Leech lattice in the doubled model, the lattice of 24 chiral bosons on the torus $\mathbb{R}^{24}/\Lambda$. Its elements are the allowed momentum vectors, with weights $\langle x, x\rangle/2$. The Leech lattice is the unique rootless one among the 24 Niemeier lattices, and its automorphism group Co_0 is the symmetry of this momentum lattice.

Why $8 \mid x \cdot y$. For $a, b \in A$: $(2a) \cdot (2b) = 4\, a \cdot b$ and $a \cdot b$ is even (self-orthogonality), so $8 \mid (2a) \cdot (2b)$. For $a \in A$: $(2a) \cdot u = 2(\sum a_i + 4a_0)$, and $4 \mid \sum a_i$, so $4 \mid \sum a_i + 4a_0$ and hence $8 \mid (2a) \cdot u$. Finally $u \cdot u = 25 + 23 = 48$ is divisible by 8. Since every element of the carrier is of the form $2a$ or $u + 2a$, bilinearity gives $8 \mid x \cdot y$ for all x, y in the carrier.

30.7.3 The four properties

Theorem 30.35 (Λ: rank 24, positive definite, even)**.**

```
theorem lattice_rank : lattice.rank = 24 := finrank_carrier

theorem lattice_isPosDef : lattice.IsPosDef

theorem lattice_isEven : lattice.IsEven
```

From the mathematics to the Lean statement

Namespace `Leech`; no hypotheses; vendored predicates of Definition 30.15. `finrank_carrier` is the statement that the submodule `carrier` of $\mathbb{Z}^{24}$ has rank 24.

Physical meaning

Rank 24, even and positive definite mean that the Leech lattice defines a unitary lattice CFT with $c = 24$, integer conformal weights and positive energies. The rank 24 recalls the 24 transverse directions of the light-cone bosonic string, and the Leech lattice is the momentum lattice of the compactification of 24 chiral bosons used in the Monster construction. Together with unimodularity (next theorem) the theory is holomorphic.

Proof on paper. Rank: $8\mathbb{Z}^{24} \subseteq 2A \subseteq \Lambda \subseteq \mathbb{Z}^{24}$ (for $x \in \mathbb{Z}^{24}$, $4x$ reduces to 0 and has coordinate sum divisible by 4, so $4x \in A$ and $8x \in 2A$). Positivity: $x \cdot x/8 > 0$ for $x \neq 0$. Evenness: we need $16 \mid x \cdot x$. For $x = 2a$, $x \cdot x = 4a \cdot a$ and $4 \mid a \cdot a$ because $\Gamma_{\mathcal{G}}$ is even ($\frac{1}{2}a \cdot a \in 2\mathbb{Z}$). For $x = u + 2a$,

$$x \cdot x = 4\, a \cdot a + 4\Big(\textstyle\sum_i a_i + 4a_0\Big) + 48,$$

and each of the three terms is divisible by 16 ($4 \mid a \cdot a$; $4 \mid \sum a_i$; $16 \mid 48$). This is where the choice of u, with $u \cdot u = 48$ and coordinate sum 28, is used. □

Theorem 30.36 (Λ is unimodular)**.** $\det \Lambda = 1$.

File `VOA/LatticesAndCodes/Leech/Defs.lean`.

```
theorem lattice_det : lattice.det = 1

theorem lattice_isUnimodular : lattice.IsUnimodular
```

Proof on paper. The proof applies the index–determinant relation (Theorem 30.17) twice to the same lattice A (with the halved form $\frac{1}{2}a \cdot b$; in Lean `Leech.subALattice`).

1. The inclusion $A \hookrightarrow \Gamma_{\mathcal{G}}$ is isometric with index 2 (A is the kernel of the surjection π). So $\det A = 4 \det \Gamma_{\mathcal{G}} = 4$.
2. The doubling map $A \to \Lambda$, $a \mapsto 2a$, is isometric (shown above) with image $2A$. The image has index 2 in Λ: the homomorphism $\beta : \Lambda \to \mathbb{Z}/2$, $x \mapsto x_0 \bmod 2$, is surjective ($\beta(u) = 1$) and its kernel is exactly $2A$ (vectors of $u + 2A$ have $x_0 = 5 + 2a_0$ odd, vectors of $2A$ have x_0 even). So $4 = \det A = 4 \det \Lambda$, whence $\det \Lambda = 1$.

No determinant inside $\mathbb{Z}^{24}$ has to be computed. □

The two index-2 statements are themselves Lean theorems, recorded because they are reused: File `VOA/LatticesAndCodes/Leech/Defs.lean`.

```
def inclG : (↥subA) →ₗ[ℤ] (↥preG) := Submodule.inclusion subA_le_preG

def inclL : (↥subA) →ₗ[ℤ] (↥carrier) := inclLaux

theorem inclL_bilin (x y : ↥subA) :
    lattice.bilin (inclL x) (inclL y) = subALattice.bilin x y

def parity : (↥preG) →ₗ[ℤ] ZMod 2 where
  toFun x := ((((∑ i, (x : Fin 24 → ℤ) i) / 2 : ℤ)) : ZMod 2)

theorem range_inclG : LinearMap.range inclG = LinearMap.ker parity

def beta : (↥carrier) →ₗ[ℤ] ZMod 2 where
  toFun x := ((((x : Fin 24 → ℤ) 0 : ℤ)) : ZMod 2)

theorem range_inclL : LinearMap.range inclL = LinearMap.ker beta

theorem card_quotient_inclL :
    Nat.card (lattice / LinearMap.range inclL) = 2

theorem subALattice_det : subALattice.det = 4
```

(For `parity` and `beta` only the `toFun` field is shown; the linearity proofs are omitted.)

From the mathematics to the Lean statement

`inclLaux` sends a to $2a$ (its definition: `toFun a := ⟨(2 : ℤ) • (a : Fin 24 → ℤ), …⟩`). `parity` is π and `beta` is β; the casts `(… : ZMod 2)` reduce an integer mod 2. `range_inclL` says the image of doubling is $\ker \beta$, i.e. $2A = \ker \beta$. These are precisely the statements used in the paper proof.

Physical meaning

Unimodularity of the Leech lattice means the theory has a single sector: its partition function is invariant under S, $\tau \mapsto -1/\tau$, up to the Dedekind eta factor η^{-24}. It guarantees that the

lattice CFT is holomorphic, in the sense that no other module exists, and is one of the inputs for the argument that V_Λ is a $c = 24$ holomorphic VOA.

Theorem 30.37 (Λ has no roots). *No $x \in \Lambda$ has $\langle x, x\rangle = 2$.*

File `VOA/LatticesAndCodes/Leech/Defs.lean`.

```
theorem lattice_no_roots (x : lattice) : normSq x ≠ 2 := lattice_normSq_ne_two x
```

From the mathematics to the Lean statement

`x : lattice` means x is an element of the carrier (via `CoeSort`). Universally quantified over all lattice vectors; equivalent to $R(\Lambda) = \varnothing$. This is the statement that could most easily have been made vacuous (e.g. by a form that never takes the value 2 because it is identically 0); it is not, since the same lattice is positive definite and has 196560 vectors of norm 4 (§30.8.5).

Physical meaning

No vectors of norm 2 means that the lattice VOA V_Λ has no weight-one states of the form e^α, so the only weight-one currents are the 24 Cartan currents ∂X^i of the abelian algebra $\mathfrak{u}(1)^{24}$. The absence of roots is what makes the Leech theory distinguished among the 24 Niemeier theories: no non-abelian Kac–Moody symmetry on the lattice side. After the $\mathbb{Z}_2$ orbifold that produces $V^\natural$, even the Cartan currents are projected out and $V^\natural{}_1 = 0$, the defining property of the Moonshine module.

Proof on paper. Norm 2 means $x \cdot x = 16$. If $x = 2a \in 2A$ then $a \cdot a = 4$. The number of odd coordinates of a is $\mathrm{wt}(\rho a) \le a \cdot a = 4$, but $\rho a \in \mathcal{G}$ has weight 0 or ≥ 8; so all coordinates of a are even, $a = 2b$ with $b \cdot b = 1$, i.e. $b = \pm e_i$. Then $\sum a_i = \pm 2$, contradicting $4 \mid \sum a_i$. If $x = u + 2a$, every coordinate of x is odd, so $x \cdot x \ge 24 > 16$. □

What the machine verified

`Leech.lattice_rank`, `Leech.lattice_isPosDef`, `Leech.lattice_isEven`, `Leech.lattice_det`, `Leech.lattice_isUnimodular`, `Leech.lattice_no_roots`, `Leech.range_inclL`, `Leech.subALattice_det`: all unconditional; `##print axioms` (re-run for this chapter): `propext`, `Classical.choice`, `Quot.sound`.

Example 30.38 (Some vectors of Λ in the doubled model).

1. $u = (5, 1^{23})$ lies in $u + 2A$ (take $a = 0$) and has $\langle u, u\rangle = 48/8 = 6$.

2. $8e_0 = 2 \cdot (4e_0)$ lies in $2A$: $4e_0$ reduces to the zero word and has coordinate sum 4. It has norm $64/8 = 8$.

3. Hence $u - 8e_0 = (-3, 1^{23}) \in u + 2A$, of norm $(9 + 23)/8 = 4$: a minimal vector of the odd shape of Remark 30.32.

4. $(4, 4, 0^{22}) = 2 \cdot (2, 2, 0^{22})$: $(2, 2, 0, \dots)$ reduces to 0 and has sum 4, so the vector is in $2A$, with norm $32/8 = 4$. But $(4, 0^{23}) = 2 \cdot (2, 0^{23})$ is *not* in Λ: $(2, 0, \dots)$ has coordinate sum 2, not divisible by 4. Its norm would have been $16/8 = 2$: the parity condition $4 \mid \sum a_i$ is exactly what removes the would-be roots $\pm 4e_i$, as in the proof of Theorem 30.37.

5. If c is an octad, the vector $2 \cdot \mathbf{1}_c$ (entries 2 on c) is in $2A$ (it is $2a$ with $a = \mathbf{1}_c$, $\sum a_i = 8$), of norm $32/8 = 4$.

30.8 Theta series and modular forms

The two numbers $r_\Lambda(4) = 196560$ and $r_\Lambda(6) = 16773120$ are obtained, in Lean as on paper, from the theory of modular forms. The argument is a model of how analysis enters a combinatorial problem, and it is the same argument that in Chapter 33 identifies the character of $V^\natural$ with J; we therefore give it in full.

30.8.1 The theta function

Definition 30.39 (Theta function)**.** For a positive definite integral lattice L and τ in the upper half plane $\mathbb{H} = \{\tau \in \mathbb{C} : \operatorname{Im}\tau > 0\}$,

$$\vartheta_L(\tau) = \sum_{x \in L} e^{\pi i \tau \langle x, x\rangle}.$$

If L is even, writing $q = e^{2\pi i\tau}$ and grouping terms by norm,

$$\vartheta_L(\tau) = \sum_{m \geq 0} r_L(2m)\, q^m = 1 + r_L(2)\, q + r_L(4)\, q^2 + \cdots. \tag{30.5}$$

Physically, $\vartheta_L(\tau)/\eta(\tau)^n$ is the partition function of the chiral boson on the torus $\mathbb{R}^n/L$: each momentum x contributes $q^{\langle x,x\rangle/2}$, the oscillators contribute η^{-n} (up to the factor $q^{-n/24}$). Here $\eta(\tau) = q^{1/24}\prod_{m\geq 1}(1-q^m)$ is Dedekind's eta function. A torus partition function should not depend on how the torus $\mathbb{C}/(\mathbb{Z}+\mathbb{Z}\tau)$ is described, and the descriptions differ by the substitutions $\tau \mapsto \frac{a\tau+b}{c\tau+d}$ with $\left(\begin{smallmatrix} a & b \\ c & d\end{smallmatrix}\right) \in SL_2(\mathbb{Z})$; "modular invariance" is the statement that the partition function transforms simply (here: up to an explicit factor) under these substitutions. Since $SL_2(\mathbb{Z})$ is generated by $T : \tau \mapsto \tau + 1$ and $S : \tau \mapsto -1/\tau$, it suffices to treat these two; Theorems 30.40 and 30.41 below do exactly that for ϑ_L, and Theorem 30.42 packages the result as the statement that ϑ_L is a *modular form* (defined there).

      (Γ.theta τ)
```

From the mathematics to the Lean statement

Files `Theta/Defs.lean` and `Theta/QExpansion.lean`, namespace `IntegralLattice` (vendored). `∑'` is Mathlib's `tsum`, the sum of an unconditionally summable family, *defined to be* 0 *if the family is not summable* — which is why `summable_thetaTerm` matters: for positive definite Γ and $\operatorname{Im}\tau > 0$ the family is summable, so `theta` is the genuine series. `DifferentiableAt ℂ` is complex differentiability (holomorphy). `HasSum f s` says the family f sums (unconditionally) to s; so `hasSum_theta` is (30.5), with $q^m = \exp(2\pi i\tau)^m$ and coefficient $r_\Gamma(2m)$.

Physical meaning

The theta function $\vartheta_L(\tau) = \sum_{x\in L} q^{\langle x,x\rangle/2}$ with $q = e^{2\pi i\tau}$ is the momentum part of the partition function of the lattice CFT: $Z(\tau) = \vartheta_L(\tau)/\eta(\tau)^n$, where η^{-n} counts the oscillator (Fock space) contributions of the n free bosons. The coefficient of q^m counts lattice vectors of conformal weight m, that is, the primary states of weight m in the momentum sector. The modular properties of ϑ_L encode the consistency of the CFT on the torus.

Proof on paper. Summability: by Remark 30.8, L is a discrete subgroup of full rank in $\mathbb{R}^n$, and $|e^{\pi i\tau\langle x,x\rangle}| = e^{-\pi v|x|^2}$ with $v = \operatorname{Im}\tau$. From $e^{-t} \le k!/t^k$ (one term of the exponential series) we get $e^{-\pi v|x|^2} \le C|x|^{-2k}$, and $\sum_{x\neq 0} |x|^{-2k} < \infty$ for $2k > n$ (compare with an integral, or count lattice points in shells). Holomorphy: the convergence is uniform on every half plane $\operatorname{Im}\tau > v_0 > 0$, and a locally uniform limit of holomorphic functions is holomorphic. The q-expansion: on the finite set of vectors of norm $2m$ every term equals q^m; summing first over each such set and then over m is legitimate for an absolutely summable family. □

30.8.2 The two transformation laws

Theorem 30.40 (Poisson summation for theta functions; Ebeling, Prop. 2.1)**.** *For a positive definite lattice L of rank n and $\tau \in \mathbb{H}$,*

$$\vartheta_L(-1/\tau) = \left(\frac{\tau}{i}\right)^{n/2} \frac{1}{\sqrt{\det L}}\, \vartheta_{L^*}(\tau).$$

In particular, if L is unimodular, $\vartheta_L(-1/\tau) = (\tau/i)^{n/2}\vartheta_L(\tau)$.

```
theorem theta_neg_inv (h : Γ.IsPosDef) {τ : ℂ} (hτ : 0 < τ.im) :
    Γ.theta (-1 / τ)
      = (τ / Complex.I) ^ ((Γ.rank : ℂ) / 2)
        * ((Real.sqrt ((Γ.det : ℤ) : ℝ) : ℝ) : ℂ)⁻¹
        * EuclideanTheta.theta
            (ZLattice.dual (EuclideanSpace ℝ (Fin Γ.rank))
              (LinearMap.range (Γ.toEuclidean h))) τ

theorem theta_neg_inv_self (h : Γ.IsPosDef) (hu : Γ.IsUnimodular) {τ : ℂ} (hτ : 0 < τ.im) :
    Γ.theta (-1 / τ) = (τ / Complex.I) ^ ((Γ.rank : ℂ) / 2) * Γ.theta τ
```

From the mathematics to the Lean statement

Files `Theta/Transformation.lean` and `Theta/ModularForm.lean`.

- Why a second theta function at all: the dual lattice L^* has a rational-valued, not integer-valued, form, so it is not an `IntegralLattice` and `IntegralLattice.theta` cannot be applied to it. The statement therefore passes through concrete vectors in $\mathbb{R}^n$. Reading the right-hand side from the inside out:
  - `EuclideanSpace ℝ (Fin Γ.rank)` is $\mathbb{R}^n$ ($n = \operatorname{rank}\Gamma$) with its usual inner product and length $|v|$.
  - `Γ.toEuclidean h` is a $\mathbb{Z}$-linear map $\Gamma \to \mathbb{R}^n$ with $\langle x, y\rangle = \iota(x)\cdot\iota(y)$ (it is the map $\iota : x = \sum c_i b_i \mapsto Bc$ of Remark 30.8, where $G = B^{\mathsf{T}}B$; the hypothesis `h` of positive definiteness is needed to find B). The library proves it is injective and form-preserving (`toEuclidean_injective`, `inner_toEuclidean`).
  - `LinearMap.range (Γ.toEuclidean h)` is its image $\iota(\Gamma) \subseteq \mathbb{R}^n$, a subgroup isometric to Γ: the lattice Γ drawn in $\mathbb{R}^n$.

  - `ZLattice.dual (EuclideanSpace ℝ (Fin n)) M` is Mathlib's dual of a subgroup $M \subseteq \mathbb{R}^n$: $\{y \in \mathbb{R}^n : y \cdot m \in \mathbb{Z}\ \forall m \in M\}$. For $M = \iota(\Gamma)$ this is ι applied to Definition 30.4, i.e. L^* drawn in $\mathbb{R}^n$.
  - `EuclideanTheta.theta M τ` (vendored, `ForMathlib/EuclideanTheta.lean`) is $\sum_{v \in M} e^{\pi i \tau |v|^2}$ for any subgroup $M \subseteq \mathbb{R}^n$ — the same series as Definition 30.39, with $|v|^2$ in place of $\langle x, x\rangle$. `IntegralLattice.theta_eq_euclidean` proves that for $M = \iota(\Gamma)$ it equals `Γ.theta`, as it must since ι preserves norms.

  So the right side is $(\tau/i)^{n/2}(\det L)^{-1/2}\vartheta_{L^*}(\tau)$, where `Real.sqrt ((Γ.det : ℤ) : ℝ)` is $\sqrt{\det L}$ (the covolume of $\iota(\Gamma)$).

- `(τ / Complex.I) ^ ((Γ.rank : ℂ) / 2)` is a *complex* power, defined via the principal branch of the logarithm: $z^s = e^{s \log z}$. For $\tau \in \mathbb{H}$, τ/i has positive real part, so this is the branch on which $(\tau/i)^{n/2} > 0$ for $\tau = it$, $t > 0$: the standard choice.
- In `theta_neg_inv_self` unimodularity has been used to replace L^* by L and det by 1.

Physical meaning

This is the S-transformation $\vartheta_L(-1/\tau) = (\tau/i)^{n/2}\,[L^* : L]^{-1/2} \sum_{y \in L^*} q^{\langle y,y\rangle/2}$ of the lattice partition function, which is Poisson resummation of the momentum sum, the T-duality of the compactified bosons $L \to L^*$. For $L = L^*$ the theta function is covariant of weight $n/2$ under S, which is how modular invariance of the holomorphic CFT is realised. It is the central analytic step in the physical argument for the constraint $c \equiv 0 \bmod 8$.

Proof on paper. The Poisson summation formula for a full-rank lattice $L \subset \mathbb{R}^n$ and a sufficiently decaying function f reads

$$\sum_{x \in L} f(x) = \frac{1}{\operatorname{covol} L} \sum_{y \in L^*} \hat{f}(y), \qquad \hat{f}(y) = \int_{\mathbb{R}^n} f(x) e^{-2\pi i\, x \cdot y}\, dx.$$

(It is proved by expanding the L-periodic function $\sum_{x \in L} f(x + \cdot)$ in a Fourier series and evaluating at 0; $\operatorname{covol} L = \sqrt{\det L}$.) Apply it to the Gaussian $f(x) = e^{\pi i(-1/\tau)|x|^2}$. The Fourier transform of a Gaussian is a Gaussian: $\hat{f}(y) = (\tau/i)^{n/2} e^{\pi i \tau |y|^2}$, valid for complex τ with $\operatorname{Im}\tau > 0$ by analytic continuation of the real case (or directly, since the Gaussian parameter has positive real part). This gives the formula. For unimodular L, the dual basis vectors are integral combinations of the basis (the inverse Gram matrix is integral, (30.1)), so the realised lattice equals its dual, and the covolume is 1. □

What had to be built: multivariable Poisson summation

Mathlib (at the pinned version) has Poisson summation only in one variable. The vendored file `ForMathlib/PoissonSummation.lean` proves the n-variable formula for $\mathbb{Z}^n$, and then for an arbitrary full-rank lattice by a linear change of variables (`ZLattice.poissonSummation`). The hypotheses of that theorem (local uniform summability of translates, summability of the Fourier transform over the dual lattice) are discharged for the Gaussian by explicit estimates. These are honest analytic theorems, `##print axioms`-clean (`ZLattice.poissonSummation`: standard three).

Theorem 30.41 (T-invariance). *If L is even, $\vartheta_L(\tau + 1) = \vartheta_L(\tau)$ for all τ.*

File `VOA/LatticesAndCodes/Theta/ModularForm.lean`.

```
theorem theta_add_one (he : Γ.IsEven) (τ : ℂ) : Γ.theta (τ + 1) = Γ.theta τ
```

Physical meaning

T-invariance of the theta function says that $\vartheta_L(\tau+1) = \vartheta_L(\tau)$ for even L, a statement that all conformal weights $h = \langle x, x\rangle/2$ are integers and hence that the spin $h - \bar{h}$ is integral. Together with S, it gives modular covariance under the full group $SL_2(\mathbb{Z})$, the group of large diffeomorphisms of the torus.

Proof. Termwise: $e^{\pi i(\tau+1)\cdot 2j} = e^{\pi i\tau\cdot 2j}e^{2\pi ij}$. □(The statement holds for all complex τ, including where the series diverges, because then both sides are 0 by the `tsum` convention — a harmless artefact.)

Theorem 30.42 (Rank divisible by 8; Ebeling, Thm. 2.1)**.** *If L is even, unimodular and positive definite, then* $8 \mid \operatorname{rank} L$*, and ϑ_L is a modular form of weight* $\operatorname{rank} L/2$ *for $SL_2(\mathbb{Z})$.*

File `VOA/LatticesAndCodes/Theta/ModularForm.lean`.

```
theorem eight_dvd_rank (h : Γ.IsPosDef) (he : Γ.IsEven) (hu : Γ.IsUnimodular) : 8 ∣ Γ.rank

def thetaModularForm (Γ : IntegralLattice) (h : Γ.IsPosDef) (he : Γ.IsEven)
    (hu : Γ.IsUnimodular) : ModularForm 𝒮ℒ ((Γ.rank / 2 : ℕ) : ℤ) where
  toFun := Γ.thetaFun

theorem theta_isModularForm (h : Γ.IsPosDef) (he : Γ.IsEven) (hu : Γ.IsUnimodular) :
    8 ∣ Γ.rank ∧
      ∃ f : ModularForm 𝒮ℒ ((Γ.rank / 2 : ℕ) : ℤ), ∀ z : ℍ, f z = Γ.theta (z : ℂ)
```

From the mathematics to the Lean statement

- `ℍ` is Mathlib's upper half plane and `thetaFun` is ϑ_Γ restricted to it.
- `ModularForm 𝒮ℒ k` is Mathlib's space $M_k(SL_2(\mathbb{Z}))$ of (holomorphic) modular forms of weight k for the full modular group: functions $f : \mathbb{H} \to \mathbb{C}$, holomorphic, with $f(\frac{a\tau+b}{c\tau+d}) = (c\tau+d)^k f(\tau)$ for all $\begin{pmatrix} a & b \\ c & d \end{pmatrix} \in SL_2(\mathbb{Z})$, and bounded as $\operatorname{Im}\tau \to \infty$ (at all cusps). $\mathcal{SL}$ denotes $SL_2(\mathbb{Z})$ viewed as a subgroup of $GL_2(\mathbb{R})$. An element of this type is a bundled function together with proofs of these properties; constructing `thetaModularForm` therefore *is* the proof of modularity (the omitted fields are the proofs of slash invariance, holomorphy and boundedness).
- The weight is `Γ.rank / 2`, natural-number division; since $8 \mid$ rank it is exact.

Same as the textbook (Ebeling's Theorem 2.1).

Physical meaning

This is the classical argument that $c = \operatorname{rank} L \equiv 0 \pmod 8$ for a holomorphic lattice CFT. The partition function ϑ_L/η^n must transform correctly under both S and T; T produces the phase $e^{-2\pi ic/24}$ and the relation $(ST)^3 = S^2$ in $SL_2(\mathbb{Z})$ then forces $e^{2\pi ic/8} = 1$. For $c = 8$ there is a single such lattice, E_8; for $c = 16$ there are two (E_8^2 and D_{16}^+, the heterotic gauge-group lattices); for $c = 24$ there are 24, the Niemeier lattices, and exactly one of them, the Leech lattice, has no roots.

Proof on paper. $SL_2(\mathbb{Z})$ is generated by $T : \tau \mapsto \tau+1$ and $S : \tau \mapsto -1/\tau$, so modularity follows from Theorems 30.40 and 30.41 once we know $(\tau/i)^{n/2} = \tau^{n/2}$, i.e. $i^{n/2} = 1$, i.e. $8 \mid n$. For the divisibility use the relation $(ST)^3 = \pm 1$ starting at $\tau = i$: the chain $i \mapsto i+1 \mapsto -1/(i+1) = \frac{-1+i}{2} \mapsto \frac{1+i}{2} \mapsto$

$-1/\frac{1+i}{2} = -1+i \mapsto i$ returns to i, and applying the two laws along it gives

$$\vartheta_L(i) = \left(\tfrac{1-i}{2}\right)^{n/2}(1-i)^{n/2}\vartheta_L(i).$$

Now $\vartheta_L(i) = \sum_x e^{-\pi\langle x,x\rangle} > 0$, so the factor is 1. Squaring (to avoid branch issues) gives $(-i)^n = 1$, so $4 \mid n$; then $n/2$ is even and the unsquared identity reads $(-1)^{n/4} = 1$, so $8 \mid n$. Boundedness at infinity: $|\vartheta_L(\tau)| \le \vartheta_L(i)$ for $\operatorname{Im}\tau \ge 1$. □

What the machine verified

`IntegralLattice.theta_neg_inv`, `IntegralLattice.eight_dvd_rank`, `IntegralLattice.thetaModularForm`, `IntegralLattice.hasSum_theta`: unconditional; `##print axioms`: standard three.

30.8.3 Level-one modular forms

The dimension of $M_k = M_k(SL_2(\mathbb{Z}))$ is $\lfloor k/12\rfloor + 1$ for even $k \ge 0$, $k \not\equiv 2 \pmod{12}$, and $\lfloor k/12\rfloor$ for $k \equiv 2 \pmod{12}$ (and 0 for odd k). The Eisenstein series

$$E_4 = 1 + 240\sum_{m\ge1}\sigma_3(m)q^m = 1 + 240q + 2160q^2 + 6720q^3 + 17520q^4 + \cdots,$$

$$E_6 = 1 - 504\sum_{m\ge1}\sigma_5(m)q^m = 1 - 504q - 16632q^2 - 122976q^3 - 532728q^4 - \cdots$$

($\sigma_r(m) = \sum_{d\mid m} d^r$) lie in M_4, M_6, and the discriminant $\Delta = (E_4^3 - E_6^2)/1728 = q - 24q^2 + 252q^3 - 1472q^4 + \cdots$ spans the cusp forms of weight 12. The fundamental structure theorem is:

Theorem 30.43 ($M_* = \mathbb{C}[E_4, E_6]$; Ebeling, Cor. 2.2). *For every even k, the monomials $E_4^a E_6^b$ with $4a + 6b = k$ form a basis of M_k.*

```
def wtIdx (k : ℕ) : Finset (ℕ × ℕ) :=
  (Finset.range (k + 1) ×ˢ Finset.range (k + 1)).filter fun p => 4 * p.1 + 6 * p.2 = k

theorem levelOne_eq_polynomial {k : ℕ} (hk : Even k) :
    ∃ B : Module.Basis (wtIdx k) ℂ (ModularForm 𝒮ℒ (k : ℤ)),
      ∀ p : wtIdx k, ((B p : ModularForm 𝒮ℒ (k : ℤ)) : ℍ → ℂ)
        = fun z => E₄ z ^ (p : ℕ × ℕ).1 * E₆ z ^ (p : ℕ × ℕ).2
```

From the mathematics to the Lean statement

File `ModularForms/LevelOne.lean`, namespace `ModularForm`. `wtIdx k` is the finite set of pairs (a,b) with $4a + 6b = k$. The theorem asserts a basis indexed by `wtIdx k` whose element for (a,b) is the function $E_4^a E_6^b$. `E₄`, `E₆` are Mathlib's normalised Eisenstein series (constant term 1); their q-coefficients are obtained from Mathlib's formula `EisensteinSeries.E_qExpansion_coeff` ($-\frac{2k}{B_k}\sigma_{k-1}(m)$ with the Bernoulli numbers $B_4 = -\frac{1}{30}$, $B_6 = \frac{1}{42}$), restated as `ModularForm.eisenstein_qExpansion`. The dimension formula is Mathlib's `ModularForm.dimension_level_one`, restated as `ModularForm.rank_levelOne`. Same as the textbook.

Physical meaning

The ring of level-one modular forms is generated by the Eisenstein series E_4 and E_6, with M_{12} two-dimensional. Physically, this is the modular bootstrap for holomorphic lattice CFTs:

the theta function ϑ_L of an even unimodular lattice of rank 24 lies in M_{12} and is therefore determined by its first two coefficients, that is, by the number of weight-one currents ($r_L(2)$ roots). All higher degeneracies then follow, as made explicit in Equations (30.6)–(30.8).

Proof on paper. Spanning, by induction on k: given $f \in M_k$ ($k \neq 2$ even), pick one monomial μ of weight k (it has constant term 1) and subtract $c_0(f)\mu$; the difference is a cusp form, hence Δg with $g \in M_{k-12}$ (division by Δ, which has no zeros on $\mathbb{H}$ and a simple zero at the cusp); g is a polynomial in E_4, E_6 by induction, and Δ is one too. Independence: the number of pairs (a, b) with $4a + 6b = k$ equals the dimension formula above (count with step 12), so a spanning family of that size is a basis. □

Weight 12 is the case relevant to rank-24 lattices: M_{12} is two-dimensional with basis E_4^3, E_6^2 (equivalently E_4^3, Δ). A form $f = \sum c_n q^n \in M_{12}$ is therefore determined by c_0, c_1: writing $f = c_0 E_4^3 + (c_1 - 720c_0)\Delta$ and using $E_4^3 = 1 + 720q + 179280q^2 + 16954560q^3 + 396974160q^4 + \cdots$ and the coefficients $1, -24, 252, -1472$ of Δ,

$$c_2 = 196560\, c_0 - 24\, c_1, \tag{30.6}$$

$$c_3 = 16773120\, c_0 + 252\, c_1, \tag{30.7}$$

$$c_4 = 398034000\, c_0 - 1472\, c_1. \tag{30.8}$$

(For example $c_2 = 179280c_0 + (-24)(c_1 - 720c_0) = 196560c_0 - 24c_1$.) The large constants 196560, 16773120, 398034000 are the coefficients of q^2, q^3, q^4 in $E_4^3 - 720\Delta$, the unique form in M_{12} with $c_0 = 1, c_1 = 0$; that form will turn out to be the theta function of the Leech lattice, so these numbers are its representation numbers $r(4), r(6), r(8)$ (Theorem 30.46).

```
theorem coeff_two_of_weight_twelve (f : ModularForm 𝒮ℒ ((12 : ℕ) : ℤ)) :
    (qExpansion 1 (f : ℍ → ℂ)).coeff 2
      = 196560 * (qExpansion 1 (f : ℍ → ℂ)).coeff 0
        - 24 * (qExpansion 1 (f : ℍ → ℂ)).coeff 1

theorem coeff_three_of_weight_twelve (f : ModularForm 𝒮ℒ ((12 : ℕ) : ℤ)) :

      = 16773120 * (qExpansion 1 (f : ℍ → ℂ)).coeff 0
        + 252 * (qExpansion 1 (f : ℍ → ℂ)).coeff 1

theorem coeff_four_of_weight_twelve (f : ModularForm 𝒮ℒ ((12 : ℕ) : ℤ)) :
    (qExpansion 1 (f : ℍ → ℂ)).coeff 4
      = 398034000 * (qExpansion 1 (f : ℍ → ℂ)).coeff 0
        - 1472 * (qExpansion 1 (f : ℍ → ℂ)).coeff 1
```

From the mathematics to the Lean statement

Files `Leech/RepCount.lean` and `Leech/RepCountHigher.lean`, namespace `ModularForm`. `qExpansion 1 f` is Mathlib's q-expansion of a function of period 1, a formal power series in $q = e^{2\pi i\tau}$; `.coeff n` its n-th coefficient c_n. These are (30.6)–(30.8) for every $f \in M_{12}$. The proof in Lean checks the relations on the basis E_4^3, E_6^2 (whose coefficients come from those of E_4, E_6 above) and extends by linearity — the same as the paper argument, with E_6^2 in place of Δ.

30.8.4 The bridge from q-coefficients to lattice vectors

Theorem 30.44 (q-expansion of ϑ_L as a modular form)**.** *For L even unimodular positive definite, the m-th q-coefficient of the modular form ϑ_L is $r_L(2m)$.*

File `VOA/LatticesAndCodes/Theta/QExpansion.lean`.

```
theorem coeff_qExpansion_thetaModularForm (h : Γ.IsPosDef) (he : Γ.IsEven) (hu :
↪  Γ.IsUnimodular)
    (m : ℕ) :
    (qExpansion 1 (Γ.thetaModularForm h he hu)).coeff m = (Γ.repCount (2 * (m : ℤ)) : ℂ)
```

From the mathematics to the Lean statement

This connects Mathlib's abstract `qExpansion` (defined as a Taylor series of the function f written in the variable q) with the combinatorial `repCount`. The point is that `hasSum_theta` exhibits a convergent q-series for ϑ_L, and a convergent q-series is unique (Mathlib's `ModularFormClass.qExpansion_coeff_unique`): two power series in q converging to the same function on a punctured disc $0 < |q| < 1$ have the same coefficients, by the identity theorem for holomorphic functions. This is a theorem of Mathlib, proved there, not an assumption; the referee who trusts Mathlib need not re-check it. Same as the textbook.

Physical meaning

This theorem identifies the q-expansion of the theta function (as a modular form in Mathlib's sense) with the generating series of the representation numbers $r_L(m)$. Physically it identifies the coefficients of the partition function with the degeneracies of momentum states at each conformal weight, the bridge that permits applying modular-form identities to state counting.

30.8.5 The representation numbers of Λ

Theorem 30.45 (Ebeling, Prop. 2.8, and its extensions). *Let L be an even unimodular positive definite lattice of rank 24. Then*

$$r_L(4) + 24\, r_L(2) = 196560, \qquad r_L(6) = 16773120 + 252\, r_L(2), \qquad r_L(8) + 1472\, r_L(2) = 398034000.$$

```
theorem repCount_four_of_rank_24 (h : Γ.IsPosDef) (he : Γ.IsEven) (hu : Γ.IsUnimodular)
    (hrk : Γ.rank = 24) : Γ.repCount 4 + 24 * Γ.repCount 2 = 196560

theorem repCount_six_of_rank_24 (h : Γ.IsPosDef) (he : Γ.IsEven) (hu : Γ.IsUnimodular)
    (hrk : Γ.rank = 24) : Γ.repCount 6 = 16773120 + 252 * Γ.repCount 2

theorem repCount_eight_of_rank_24 (h : Γ.IsPosDef) (he : Γ.IsEven) (hu : Γ.IsUnimodular)
    (hrk : Γ.rank = 24) : Γ.repCount 8 + 1472 * Γ.repCount 2 = 398034000
```

From the mathematics to the Lean statement

Namespace `IntegralLattice`. Four hypotheses, each a defined predicate of §30.3.3: positive definite, even, unimodular, rank 24. All quantities are natural numbers; the third identity is written additively to stay inside $\mathbb{N}$. Exactly the textbook statements.

Physical meaning

For any holomorphic $c = 24$ lattice CFT the number of states at weights 2, 3, 4 is determined by the number of weight-one currents. This is the modular bootstrap of the Niemeier theories: since $\vartheta_L = E_4^3 + (r_L(2) - 720)\Delta$, all dimensions follow from $r_L(2)$ (the number of roots, i.e. the dimension of the Kac–Moody algebra minus its Cartan). For the Leech lattice, $r(2) = 0$ and the above gives the 196560 and 16773120 values, which enter the Monster dimension count $196884 = 1 + 196883$.

Proof on paper. By Theorem 30.42, $\vartheta_L \in M_{12}$; by Theorem 30.44 its coefficients are $c_0 = r_L(0) = 1$, $c_1 = r_L(2)$, $c_2 = r_L(4)$, $c_3 = r_L(6)$, $c_4 = r_L(8)$. Insert into (30.6)–(30.8). □

For the Golay lattice $N(A_1^{24})$, $r(2) = 48$ and the theorem predicts $r(4) = 196560 - 1152 = 195408$; for the Leech lattice, $r(2) = 0$:

Theorem 30.46 (Minimal vectors of Λ). $r_\Lambda(2) = 0$, $r_\Lambda(4) = 196560$, $r_\Lambda(6) = 16773120$, $r_\Lambda(8) = 398034000$.

Files `VOA/LatticesAndCodes/Leech/RepCount.lean`, `VOA/LatticesAndCodes/Leech/RepCountHigher.lean`.

```
theorem lattice_repCount_two : Leech.lattice.repCount 2 = 0

theorem repCount_four : Leech.lattice.repCount 4 = 196560

theorem repCount_six : Leech.lattice.repCount 6 = 16773120

theorem repCount_eight : Leech.lattice.repCount 8 = 398034000
```

From the mathematics to the Lean statement

Namespace `Leech`; no hypotheses. Since `Leech.lattice` is positive definite, the sets counted by `repCount` are finite, so the `ncard` convention (infinite sets count as 0) does not intervene; in particular `lattice_repCount_two` is a genuine statement (it follows from `lattice_no_roots`), not an artefact of an infinite set. Equivalently, $\vartheta_\Lambda = E_4^3 - 720\Delta = 1 + 196560q^2 + 16773120q^3 + \cdots$; that identity of formal q-series is proved as `VOA.Moonshine.CharacterDelta.leechThetaIdentity` and used in Chapter 33.

Physical meaning

The 196560 minimal vectors of norm 4 of the Leech lattice give the 196560 weight-two momentum states e^α of the Leech CFT. In the Moonshine module they supply the largest piece of the Griess algebra, $196884 = 300 + 24 + 196560$, whose automorphism group is the Monster; the kissing number 196560 is the number of ways of touching one sphere with others in the optimal 24-dimensional sphere packing. The automorphism group of the lattice, the Conway group Co_0, acts transitively on these vectors.

What the machine verified

`Leech.repCount_four`, `Leech.repCount_six`, `Leech.repCount_eight`, `IntegralLattice.repCount_four_of_rank_24`, `ModularForm.coeff_two_of_weight_twelve`, `IntegralLattice.coeff_qExpansion_thetaModularForm`: unconditional; `##print axioms` (re-run for this chapter): `propext`, `Classical.choice`, `Quot.sound`. The source file `Leech/RepCountHigher.lean` ends with `##print axioms` commands for its theorems, which print the same list at every build.

Remark 30.47. `Leech/RepCountHigher.lean` also proves `IntegralLattice.exists_normSq_eq_eight`: a rootless even unimodular positive definite lattice of rank 24 has a vector of norm 8 (because $r(8) = 398034000 \neq 0$). This is the first step of the uniqueness proof of the Leech lattice in the companion library; the remainder was not vendored (Warning 30.3.1).

30.9 The bridge into the VOA library

The lattice VOA construction of Chapter 31 takes a `VOA.IntegralLattice`. The Leech lattice lives in the vendored encoding. Because both encodings model the same object (§30.3), the transport is a field-by-field repackaging.

Definition 30.48 (`VOA.IntegralLattice.ofEbeling`). `VOA/Moonshine/LeechLatticeVOA.lean`.

```
noncomputable def ofEbeling (Γ : _root_.IntegralLattice) : VOA.IntegralLattice.{0} where
  carrier := Γ.carrier
  form := Γ.bilin
  isSymm := ⟨fun x y => Γ.bilin_symm x y⟩

@[simp] theorem ofEbeling_form (x y : Γ.carrier) : (ofEbeling Γ).form x y = Γ.bilin x y :=
 ↪  rfl

theorem ofEbeling_even (h : Γ.IsEven) : (ofEbeling Γ).Even := fun v => h v

theorem ofEbeling_posDef (h : Γ.IsPosDef) : (ofEbeling Γ).PosDef := fun v hv => h v hv

theorem ofEbeling_rank : rank (ofEbeling Γ) = Γ.rank := rfl
```

From the mathematics to the Lean statement

- `.{0}` fixes the universe level to 0. The carrier, its group/module instances and the form are taken over unchanged; only the symmetry proof is repackaged.
- The four one-line proofs are informative: `rfl` means "true by definition", and `fun v ⇒ h v` means the two predicates are literally the same formula. So the bridge cannot distort anything: evenness, positive definiteness, rank and the form itself are *definitionally* preserved.
- What does *not* transfer automatically is unimodularity, because the VOA library has no determinant-based predicate (only `SelfDual`); see the warning in §30.3.2.

Physical meaning

This is the bridge from the vendored lattice to the lattice in the VOA library, so that the Leech lattice becomes the momentum lattice of the chiral bosons in the construction of V_Λ. It makes no new physical statement; it only moves the same 24-dimensional torus data between two Lean encodings.

Theorem 30.49 (The Leech lattice in the VOA library). *The lattice Λ, viewed in the VOA library, is even, positive definite, of rank 24, and has no vectors of norm 2.*

```
noncomputable abbrev leech : VOA.IntegralLattice.{0} := ofEbeling Leech.lattice

theorem leech_even : leech.Even := ofEbeling_even _ Leech.lattice_isEven

theorem leech_posDef : leech.PosDef := ofEbeling_posDef _ Leech.lattice_isPosDef

theorem leech_rank : rank leech = 24 := Leech.lattice_rank

theorem leech_no_roots (v : leech.carrier) : leech.form v v ≠ 2 := Leech.lattice_no_roots v
```

From the mathematics to the Lean statement

Namespace `VOA.Moonshine`. `abbrev` makes `leech` a transparent abbreviation: it *is* `ofEbeling Leech.lattice`. Each theorem is the corresponding vendored theorem of §30.7, transported by the definitional bridge (the proof terms shown are the whole proofs). `leech.form v v ≠ 2` is $\langle v, v\rangle \neq 2$, i.e. (with evenness and positivity) $R(\Lambda) = \varnothing$. These four statements are exactly properties (Λ1), (Λ2), (Λ4) of the introduction in the form consumed by Chapter 31; property (Λ3) is consumed in the vendored form `Leech.lattice_isUnimodular`.

Physical meaning

Once transported, the Leech lattice is an even, unimodular, positive definite, rootless lattice of rank 24 in the VOA library's own sense, so the lattice VOA V_Λ is a unitary $c = 24$ theory with a single sector and no weight-one states of the form e^α. It is the input to the $\mathbb{Z}_2$ orbifold that builds $V^\natural$. The symmetry group of the lattice itself is the Conway group Co_0 acting on the momenta.

What the machine verified

`VOA.Moonshine.leech_even`, `leech_posDef`, `leech_rank`, `leech_no_roots`: unconditional; `##print axioms`: `propext`, `Classical.choice`, `Quot.sound`.

The same file defines the Leech lattice VOA `VOA.Moonshine.leechVOA` and proves its central charge is 24 and that its weight-one space consists of Heisenberg states only; those statements are presented in Chapter 31, after lattice VOAs have been defined.

30.10 Looking ahead: the frame sublattice and the Golay code

Two objects introduced in this chapter return much later.

The index-two sublattice Λ_0. The homomorphism $\beta : \Lambda \to \mathbb{Z}/2$, $x \mapsto x_0 \bmod 2$, of the determinant proof has kernel $\Lambda_0 = 2A$, of index 2. The doubling map identifies A (with the halved Golay form) isometrically with Λ_0, and A is also of index 2 in the Golay lattice $N(A_1^{24})$. So $\Lambda_0 \cong A$ is a *common* index-2 sublattice of the Leech lattice and of the Niemeier lattice $N(A_1^{24})$ — this is the sublattice $\Lambda \cap N(A_1^{24})$ of Frenkel–Lepowsky–Meurman. In the VOA library:

```
noncomputable def lambda0 : Submodule ℤ leech.carrier := LinearMap.ker Leech.beta

theorem lambda0_eq_range_inclL : lambda0 = LinearMap.range Leech.inclL :=
↪  Leech.range_inclL.symm

noncomputable def lambda0Equiv : ↥Leech.subA ≃ₗ[ℤ] ↥lambda0

theorem lambda0Equiv_form (a b : ↥Leech.subA) :
    leech.form (lambda0Equiv a : leech.carrier) (lambda0Equiv b : leech.carrier)
      = Leech.subALattice.bilin a b
```

(`VOA/Moonshine/FrameSectors.lean`, namespace `VOA.Moonshine`.)

Trap: Λ_0 is not $\sqrt{2}\,N(A_1^{24})$

The source (`FrameSectors.lean`) warns against a tempting misidentification: Λ_0 is *not* a rescaling of the whole Golay lattice, such as $\sqrt{2}\,\Gamma_{\mathcal{G}}$. The doubling $a \mapsto 2a$ looks like "multiplication by $\sqrt{2}$" because it changes the denominator of the form from 2 to 8, but it is an *isometry* from A (with the halved form, unchanged) onto Λ_0, and A is only an index-2 sublattice of $\Gamma_{\mathcal{G}}$. A determinant certificate separates the two candidates: $\det \Lambda_0 = [\Lambda : \Lambda_0]^2 \det \Lambda = 4$, whereas $\det(\sqrt{2}\,\Gamma_{\mathcal{G}}) = 2^{24} \det \Gamma_{\mathcal{G}} = 2^{24}$. Concretely, Λ_0 contains the norm-4 vectors $2a$ with $a = (\pm 2, \pm 2, 0, \dots, 0)$. A numerical check recorded in the source (Python, not Lean) finds that of the 196560 norm-4 vectors of Λ, $98256 = 1104 + 97152$ lie in Λ_0 and $98304 = 24 \cdot 2^{12}$ in $\Lambda \setminus \Lambda_0$; the resulting dimensions 49428 and 49152 of the two weight-2 frame sectors are proved in Lean (Chapter 39).

The decomposition of V_Λ^+ according to Λ_0 (the "Golay frame") and the passage between Λ and $N(A_1^{24})$ through Λ_0 are the subject of Chapter 39.

The Golay code and octads. The Golay code enters the triality construction twice: through the Niemeier lattice $N(A_1^{24})$, whose 24 roots $\pm 2e_i$ give 24 copies of $\widehat{sl}_2$, and through the combinatorics of octads (the Steiner system $S(5,8,24)$, and statements such as "every codeword of weight 12 or 16 meets some octad in exactly 6 points"), proved in `VOA/Moonshine/GroundLatticeGolay.lean` and presented in Chapter 40. All of them rest only on Theorems 30.24 and 30.25.

30.11 Referee's checklist

All entries are unconditional (no hypotheses beyond those displayed, which are the intended mathematical hypotheses), and every `##print axioms` report is `[propext, Classical.choice, Quot.sound]`; none uses `VOA.pbw`.

`VOA.Moonshine.lambda0`	$\Lambda_0 = \ker \beta = 2A$	–	§30.10

Points for the referee's particular attention:

1. The two `IntegralLattice` structures (§30.3) and the definitional bridge between them.
2. Unimodularity is the vendored determinant statement; the VOA library's `SelfDual` is never proved for Λ and never used.
3. Uniqueness of Λ and of $\mathcal{G}$ is not part of this repository (Warning 30.3.1); only the explicit models are used.
4. Conventions that could have made statements vacuous — `ncard` of infinite sets, `tsum` of non-summable families, $\inf \varnothing = 0$ in `minDist`, integer division in the forms — are each neutralised by an accompanying theorem (finiteness, summability, nonzero code, exact divisibility).
5. The vendored files are claimed byte-identical to upstream commit `da62b9e` except for import prefixes; this is a repository claim checked with `cmp`, not a kernel-checked fact.

30.12 Notes and references

The vendored library follows W. Ebeling, *Lattices and Codes: A Course Partially Based on Lectures by Friedrich Hirzebruch*, 3rd edition, Advanced Lectures in Mathematics, Springer Spektrum, 2013: Chapter 1 (lattices, codes, Construction A: Propositions 1.3, 1.4), Chapter 2 (theta functions, Poisson summation, modular forms, the Golay code and the Leech lattice: Theorem 2.1, Proposition 2.1, Theorem 2.6, Proposition 2.8, §2.8). The standard encyclopaedic reference is J. H. Conway and N. J. A. Sloane, *Sphere Packings, Lattices and Groups*, 3rd edition, Grundlehren der mathematischen Wissenschaften 290, Springer, 1999; Chapter 4 §11 contains the coordinate description of Λ in Remark 30.32, and Chapters 16–18 the Niemeier classification. The Leech lattice was discovered by J. Leech, "Notes on sphere packings", *Canadian J. Math.* 19 (1967) 251–267; its uniqueness was proved by J. H. Conway, "A characterisation of Leech's lattice", *Invent. Math.* 7 (1969) 137–142; the Niemeier lattices are from H.-V. Niemeier, "Definite quadratische Formen der Dimension 24 und Diskriminante 1", *J. Number Theory* 5 (1973) 142–178. The Golay code is from M. J. E. Golay, "Notes on digital coding", *Proc. IRE* 37 (1949) 657; the MacWilliams identity from F. J. MacWilliams, "A theorem on the distribution of weights in a systematic code", *Bell System Tech. J.* 42 (1963) 79–94; a textbook treatment of both is F. J. MacWilliams and N. J. A. Sloane, *The Theory of Error-Correcting Codes*, North-Holland, 1977. For modular forms see J.-P. Serre, *A Course in Arithmetic*, Graduate Texts in Mathematics 7, Springer, 1973, Chapter VII (which also proves $8 \mid n$ and $r(4) = 196560$ in this way). The role of the Leech lattice, the sublattice $\Lambda \cap N(A_1^{24})$ and the Golay code in the Moonshine module is from I. Frenkel, J. Lepowsky and A. Meurman, *Vertex Operator Algebras and the Monster*, Pure and Applied Mathematics 134, Academic Press, 1988 (Chapters 10–12), and, for the triality via $N(A_1^{24})$, L. Dolan, P. Goddard and P. Montague, "Conformal field theories, representations and lattice constructions", *Comm. Math. Phys.* 179 (1996) 61–120, arXiv:hep-th/9410029. Mathlib's modular forms library (dimension formula, Eisenstein q-expansions, $\Delta = (E_4^3 - E_6^2)/1728$) is used as a black box and is documented in the Mathlib sources at the pinned version v4.30.0.

Chapter 31

Heisenberg and lattice vertex algebras

This chapter builds, inside Lean, the two families of vertex operator algebras on which the whole Moonshine construction rests: the *Heisenberg* (free boson) vertex operator algebra of rank r, and the *lattice* vertex operator algebra V_L of an even positive-definite lattice L. Specialising L to the Leech lattice Λ gives the vertex operator algebra V_Λ, the starting point of Frenkel–Lepowsky–Meurman's orbifold construction of $V^\natural$. We then study two kinds of symmetries of lattice vertex operator algebras that the later chapters use constantly: the *sign automorphisms* g_χ attached to characters $\chi : L \to \mathbb{Z}/2$, and the *functoriality* of $L \mapsto V_L$ under isometric embeddings of lattices, together with a rigidity theorem for lifts of the automorphism -1 of L. The chapter documents the release of the library named in the front matter; every Lean quotation is checked by `scripts/textbook/sync.py` to occur verbatim (up to whitespace and comments) in the source files of that release.

The chapter is written so that a referee can check, for every headline declaration, that the Lean statement says what the mathematics says. Each definition and theorem is presented in the order: mathematical statement; verbatim Lean source; a *fidelity check* (in a box headed "From the mathematics to the Lean statement"); a proof on paper; and the machine status.

31.1 Overview and the physical picture

31.1.1 What a free boson is

Physically, a chiral free boson in two dimensions is a field $X(z)$ whose derivative $h(z) = i\partial X(z)$ has the operator product expansion

$$h(z)\,h(w) \sim \frac{k}{(z-w)^2}, \tag{31.1}$$

where k is a normalisation constant (the "level"; one usually takes $k = 1$). Expanding $h(z) = \sum_{n\in\mathbb{Z}} h(n)\,z^{-n-1}$, the OPE (31.1) is equivalent to the commutation relations of the *Heisenberg algebra*

$$[h(m), h(n)] = m\,k\,\delta_{m+n,0}. \tag{31.2}$$

The state space of the theory is the irreducible representation generated by a vacuum $\mathbb{1}$ annihilated by all $h(n)$ with $n \geq 0$: the *Fock space*. Since the negative modes $h(-n)$, $n \geq 1$, commute with one another, the Fock space is simply a polynomial ring in infinitely many variables, one variable for each $h(-n)$. With r bosons $h_1, \dots, h_r$ (mutually commuting copies) one gets a polynomial ring in variables indexed by pairs (mode, colour).

If the boson is *compactified*, i.e. X takes values in a torus $\mathbb{R}^r/2\pi L^*$, the theory acquires *momentum sectors*: states e^α of momentum α in a lattice L, on which the zero modes act by $h(0)e^\alpha = \langle h, \alpha\rangle e^\alpha$. The vertex operator of a momentum state is the normal-ordered exponential

$$Y(e^\alpha, z) = {:}e^{i\alpha\cdot X(z)}{:} = \exp\Big(\sum_{n\geq 1}\frac{\alpha(-n)}{n}z^n\Big)\exp\Big(-\sum_{n\geq 1}\frac{\alpha(n)}{n}z^{-n}\Big)\,e_\alpha\,z^{\alpha(0)}. \tag{31.3}$$

Two such operators satisfy, by a one-line Baker–Campbell–Hausdorff computation that we shall do in Section 31.8,

$$Y(e^{\alpha}, z_1)Y(e^{\beta}, z_2) \;\propto\; (z_1 - z_2)^{\langle\alpha,\beta\rangle} : \cdots : ,$$

so exchanging the two operators produces the sign $(-1)^{\langle\alpha,\beta\rangle}$. If $\langle\alpha,\beta\rangle$ is odd the two operators *anticommute* rather than commute. To obtain an honest (bosonic) vertex algebra one inserts "Klein factors": the operator e_α is not simply the shift $e^{\beta} \mapsto e^{\alpha+\beta}$ but the shift multiplied by a sign $\varepsilon(\alpha,\beta)$, a 2-cocycle on L whose antisymmetry $\varepsilon(\alpha,\beta)/\varepsilon(\beta,\alpha) = (-1)^{\langle\alpha,\beta\rangle}$ exactly cancels the bad sign. This is the mathematical heart of the lattice construction, and its Lean version occupies Section 31.4.

The *evenness* of L (that $\langle\alpha,\alpha\rangle \in 2\mathbb{Z}$) is what makes such a cocycle exist; it is also what makes all conformal weights $\frac{1}{2}\langle\alpha,\alpha\rangle$ integral, so that V_L is $\mathbb{Z}$-graded. *Positive-definiteness* makes every weight space finite-dimensional, because only finitely many lattice vectors have bounded norm.

31.1.2 Road map

- Section 31.2 recalls the library's notions of formal distribution, mode, field, locality, normal-ordered product, vertex algebra, vertex operator algebra, automorphism and homomorphism. These are quoted verbatim and decoded in Chapters 2, 4 and 5; we recall what the statements of this chapter use, with pointers.
- Section 31.3: the rank-r Heisenberg vertex operator algebra `VOA.HeisenbergN.heisenbergNVOA`.
- Section 31.4: integral lattices, the FLM 2-cocycle `latticeCocycle` and its two key properties.
- Section 31.5: how a lattice charge becomes a Heisenberg oscillator, via the orthonormal frame $\sqrt{G}$.
- Sections 31.6–31.8: the state space $V_L = \mathcal{F} \otimes \mathbb{C}[L]$, its grading, the vertex operators $Y(e^{\alpha}, z)$, and their mutual locality.
- Section 31.9: the reconstruction-from-locality strategy and the assembled instance `VOA.LatGen.latticeVOAGen`.
- Section 31.10: the Leech lattice vertex operator algebra `VOA.Moonshine.leechVOA`.
- Section 31.11: the sign automorphisms `VOA.LatGen.chiAut`.
- Section 31.12: functoriality `VOA.LatGen.latMorph`, the $\mathbb{Z}/4$-valued coboundary, character automorphisms and rigidity of lifts of -1.
- Section 31.13: the design question about the non-computable basis, and why it turned out not to matter.
- Section 31.14: the referee's checklist.

What the machine verified

Every headline declaration of this chapter was re-audited for this book with `lake env lean -DmaxSynthPendingDepth=3` on a scratch file importing `VOA.Moonshine.LatticeMorphRigid`, `VOA.Moonshine.LeechLatticeVOA` and `VOA.Examples.HeisenbergNVOA`. For each of `heisenbergNVOA`, `latticeCocycle_comm`, `latYfullGen_of_locality`, `latticeVOAGen`, `leechVOA`, `leechVOA_centralCharge`, `leechVOA_grading_one`, `chiAut`, `chiLat_eq_self_iff`, `chiAut_mul_thetaAut`, `latticeCocycle_map_mul_latCob`, `latMorph_isVOAHom`, `latMorph_injective`, `mem_range_latMorph_iff`, `latMorph_thetaLat`, `charAut`, `exists_char_of_lift` and `lift_eq_conj_theta'`, `#print axioms` reports exactly `[propext, Classical.choice, Quot.sound]`: Lean's three standard axioms. None of them uses `VOA.pbw`

(the PBW theorem of Chapter 3; formerly a project axiom, now a theorem). The only hypotheses are the explicit ones named in each statement (evenness, positive-definiteness, isometry, equal rank where stated).

31.2 Conventions recalled from the foundations

Everything in this section is defined, quoted verbatim from the Lean source, and decoded in the library chapters; we recall only what the statements of this chapter use, with a pointer to the place where the exact Lean text and its fidelity check are printed.

31.2.1 Formal distributions and modes

A *formal distribution* `FormalDist W` (notation $W[\![z^{\pm}]\!]$) is a doubly infinite series $\sum_{j\in\mathbb{Z}} f_j z^j$, encoded as the function $j \mapsto f_j$ (Definition 2.1, `VOA/Foundations/FormalSeries.lean`). *Warning on indexing*: the argument j of a `FormalDist` is the *exponent of* z, not a mode number. Mode numbers are introduced by `mode f m = f (-m-1)` (Definition 2.7, `VOA/Foundations/FormalCalculus.lean`), so that if $Y(u,z) = \sum_n u_{(n)} z^{-n-1}$ then $u_{(n)}$ is `mode (Y u) n = (Y u) (-n-1)`. Throughout this chapter we shall have to translate between the two indexings; we always say which one a Lean expression uses. A formal distribution a with values in $\mathrm{End}(V)$ is a *field* (`IsField a`) if $a(z)x$ has only finitely many negative powers of z for every x, i.e. $a_{(n)}x = 0$ for n large (Definition 2.43, `VOA/Core/Dong.lean`).

31.2.2 Locality and normal ordering

Two fields are *mutually local*, `Local a b`, if $(z_1 - z_2)^N [a(z_1), b(z_2)] = 0$ for some $N \geq 0$, where the commutator is the two-variable distribution `bracketDist a b` (indexed by exponents of z_1 and z_2) and `mulBySubPow N` is multiplication by $(z_1 - z_2)^N$ (Definitions 2.21 and 2.41, `VOA/Foundations/Locality.lean`). The normal-ordered product $:a(z)b(z):\, = a(z)_+ b(z) + b(z)a(z)_-$ is the field `nprod ha hb`, built from `normalOrdered a b`, in which the index $m \geq 0$ (the power z^m, i.e. the creation part $a(z)_+$) is placed on the left (Definition 2.43, `VOA/Core/Dong.lean`).

31.2.3 Vertex algebras and vertex operator algebras

The library's `PreVertexAlgebra` (Definition 4.1, `VOA/Core/VertexAlgebra.lean`) is a $\mathbb{Z}$-graded space with finite-dimensional pieces (`grading`, `isInternal`, `finrank`), a linear state–field map `Y : V →ₗ[ℂ] (End ℂ V)⟦z^±⟧`, a vacuum of degree 0 with $Y(\mathbb{1}, z) = \mathrm{id}$, the creation property, locality, regularity and the grading law $\mathrm{wt}(u_{(n)}v) = \mathrm{wt}\,u + \mathrm{wt}\,v - n - 1$. The n-th product is `V.smul u n v := mode (V.Y u) n v`. A `VertexOperatorAlgebra` (Definition 4.4, `VOA/Core/VertexOperatorAlgebra.lean`) adds a `conformalVector` ω in degree 2 and a `centralCharge`, with $L_n = \omega_{(n+1)} =$ `mode (Y conformalVector) (n+1)` satisfying the Virasoro relations (`virasoro`), $L_0 = n$ on `grading n` (`L0_grading`), $Y(L_{-1}v, z) = \partial_z Y(v,z)$ (`translation`), and the CFT-type conditions $V_0 = \mathbb{C}\mathbb{1}$, $V_n = 0$ for $n < 0$ (`vacuum_grade`, `positivity`).

31.2.4 Automorphisms, homomorphisms, intertwining

An automorphism `Aut W` (Definition 5.9, `VOA/Core/Automorphism.lean`) is a linear bijection preserving all products `W.smul u n v`, the vacuum and the conformal vector. A homomorphism `IsVOAHom V T φ` (Definition 5.22, `VOA/Core/SimpleImage.lean`) preserves the products and the vacuum but *not necessarily the conformal vector*. This matters below: an isometric embedding of a lattice of smaller rank gives a homomorphism that does not send ω to ω (Remark 31.40).

Finally, many proofs in this chapter rest on the notion of an operator g *intertwining* two formal distributions up to a scalar, $g\,A(z) = c\,B(z)\,g$:

```
def Intertw (g : End ℂ V) (c : ℂ) (A B : FormalDist (End ℂ V)) : Prop :=
  ∀ (t : ℤ) (x : V), g (A t x) = c • B t (g x)

def IntertwH (g : V →ₗ[ℂ] W) (c : ℂ) (A : FormalDist (End ℂ V)) (B : FormalDist (End ℂ W))
 ↪  :
    Prop :=
  ∀ (t : ℤ) (x : V), g (A t x) = c • B t (g x)
```

(`VOA/Moonshine/LatticeInvolution.lean`, `VOA/Moonshine/LatticeMorphFock.lean`), the second being the version for a map between two different spaces. The basic fact, used repeatedly, is that intertwining is preserved by normal-ordered products with the scalars multiplying: if $gA = c\,A'g$ and $gB = d\,B'g$ then $g\,{:}AB{:} = cd\,{:}A'B'{:}\,g$. On paper this is obvious, because g passes through each factor of each term of the normal-ordered product.

31.3 The rank-r Heisenberg vertex operator algebra

All declarations of this section live in the namespace `VOA.HeisenbergN` and in the files `VOA/Examples/HeisenbergNFock.lean`, `HeisenbergNVertex.lean`, `HeisenbergNCentral.lean` and `HeisenbergNVOA.lean`.

31.3.1 The Fock space as a polynomial ring

Fix $r \in \mathbb{N}$ and a level $k \in \mathbb{C}$. The rank-r Heisenberg Lie algebra has basis $h_a(n)$ $(a = 1, \dots, r,\ n \in \mathbb{Z})$ and a central element K, with bracket

$$[h_a(m), h_b(n)] = m\,\delta_{ab}\,\delta_{m+n,0}\,K. \tag{31.4}$$

Let $\mathcal{F}$ be the representation induced from the one-dimensional representation of the subalgebra spanned by K and the $h_a(n)$, $n \geq 0$, on which K acts by k and the $h_a(n)$ by 0. By the Poincaré–Birkhoff–Witt theorem (here elementary, since the negative part is abelian) $\mathcal{F}$ is the symmetric algebra on the negative modes:

$$\mathcal{F} \;\cong\; \mathbb{C}\big[\, h_a(-n) \;:\; 1 \leq a \leq r,\ n \geq 1 \,\big] \cdot \mathbb{1}.$$

The library *defines* the Fock space to be this polynomial ring, rather than constructing it as an induced module. Variables are indexed by pairs $(i, a) \in \mathbb{N} \times \{0, \dots, r-1\}$, and the variable $X_{(i,a)}$ stands for the state $h_a(-i-1)\mathbb{1}$. As i runs through $0, 1, 2, \dots$ this gives all creation modes $h_a(-1), h_a(-2), h_a(-3), \dots$; indexing by $i = -n-1 \in \mathbb{N}$ rather than by the mode $n \leq -1$ avoids negative integers in the variable names.

Definition 31.1 (Fock space). $\mathcal{F}_r := \mathbb{C}[X_{(i,a)} : i \in \mathbb{N},\ a \in \{0, \dots, r-1\}]$, the polynomial ring in countably many variables. The vacuum is the constant polynomial 1.

```
abbrev FockN (r : ℕ) : Type := MvPolynomial (ℕ × Fin r) ℂ

noncomputable def vacuumN (r : ℕ) : FockN r := (1 : FockN r)
```

From the mathematics to the Lean statement

`MvPolynomial σ ℂ` is Mathlib's ring of polynomials with complex coefficients in variables indexed by the type σ; here $\sigma = \mathbb{N} \times$ `Fin r`, where `Fin r` is the r-element type $\{0, \dots, r-1\}$ (colours are numbered from 0). The variable for (i, a) is written `X (i, a)`. So `X (0, a)` is

$h_a(-1)\mathbb{1}$, `X (1, a)` is $h_a(-2)\mathbb{1}$, and the monomial `X (0,a)^2 * X (3,b)` is $h_a(-1)^2 h_b(-4)\mathbb{1}$. The identification of $\mathcal{F}$ with the induced module is a theorem of mathematics, not of the library; what the library needs, and proves, is that the oscillators defined below satisfy the Heisenberg relations on this space and that the vacuum is annihilated by the non-negative modes. Those two facts characterise the induced module up to isomorphism (it is irreducible for $k \neq 0$), so nothing is lost. This definition cannot be vacuous: a polynomial ring is a perfectly concrete, nonzero, infinite-dimensional space.

Physical meaning

The Fock space is the Hilbert space (algebraically: the space of finite-energy states) of r free chiral bosons ∂X^a: polynomials in the variables $X_{(i,a)}$ are the states obtained from the vacuum by applying creation operators, with $X_{(i,a)}$ standing for the oscillator $\alpha^a_{-(i+1)}$. The vacuum 1 is the SL_2-invariant state with no oscillator excited, and the neutral sector (zero momentum) is exactly what this space describes. Heuristically it is the oscillator part of the closed-string Hilbert space on a circle with the zero modes removed; the definition itself is just a polynomial ring.

31.3.2 The oscillators

The creation operator $h_a(-m)$, $m \geq 1$, is multiplication by the variable $X_{(m-1,a)}$. The annihilation operator $h_a(n)$, $n \geq 1$, must satisfy $[h_a(n), h_a(-n)] = nk$; since $[\partial/\partial X, X] = 1$, the right choice is $h_a(n) = nk\,\partial/\partial X_{(n-1,a)}$. The zero mode acts by 0 on the Fock space (it is the momentum, which vanishes in the neutral sector).

Definition 31.2 (Oscillators). For $a \in \{0, \dots, r-1\}$ and $n \in \mathbb{Z}$ define $h_a(n) \in \operatorname{End} \mathcal{F}_r$ by

$$h_a(n) = \begin{cases} X_{(-n-1,a)} \cdot (-) & n < 0, \\ 0 & n = 0, \\ n\,k\,\dfrac{\partial}{\partial X_{(n-1,a)}} & n > 0. \end{cases}$$

File `VOA/Examples/HeisenbergNFock.lean`.

```
noncomputable def mulXN {r : ℕ} (i : ℕ) (a : Fin r) : FockN r →ₗ[ℂ] FockN r :=
  (LinearMap.mul ℂ (FockN r) (X (i, a))).comp (LinearMap.id)

noncomputable def pderivLMN {r : ℕ} (i : ℕ) (a : Fin r) : FockN r →ₗ[ℂ] FockN r :=
  (pderiv (i, a) : Derivation ℂ (FockN r) (FockN r)).toLinearMap

noncomputable def oscN (r : ℕ) (k : ℂ) (a : Fin r) (n : ℤ) : FockN r →ₗ[ℂ] FockN r :=
  if n < 0 then mulXN (-n - 1).toNat a
  else if 0 < n then (n : ℂ) • k • pderivLMN (n - 1).toNat a
  else 0
```

From the mathematics to the Lean statement

`→ₗ[ℂ]` denotes $\mathbb{C}$-linear maps. `pderiv (i,a)` is Mathlib's partial derivative with respect to the variable `X (i,a)`, a derivation of the polynomial ring. `(-n-1).toNat` converts the integer $-n-1$ to a natural number (truncating negative values to 0); in the branch $n < 0$ the integer $-n-1$ is ≥ 0, so no truncation happens and the variable is $X_{(-n-1,a)}$, exactly as in Definition 31.2. Similarly `(n-1).toNat` $= n-1$ in the branch $n > 0$. The scalar is $n \cdot k$, written `(n : ℂ) • k • ...`. The Lean definition is literally the textbook one.

Physical meaning

The operators $h_a(n)$ are the Laurent modes α_n^a of the chiral current $i\partial X^a(z) = \sum_n \alpha_n^a z^{-n-1}$ of a free boson. For $n < 0$ they create a quantum of energy $|n|$ (multiplication by a variable), for $n > 0$ they annihilate one (a derivative), and the zero mode is the momentum, which vanishes on the neutral sector and is reinstated for lattice states later. The normalisation nk in the annihilators is chosen so that the algebra is the standard oscillator algebra of the next theorem, with k the level (normalisation of the two-point function $\langle J(z)J(w)\rangle = k/(z-w)^2$).

Theorem 31.3 (Heisenberg relations). *For all colours a, b and all $m, n \in \mathbb{Z}$, $[h_a(m), h_b(n)] = m\,k\,\delta_{ab}\,\delta_{m+n,0}\cdot \mathrm{id}$ on $\mathcal{F}_r$.*

File `VOA/Examples/HeisenbergNFock.lean`.

```
theorem oscN_comm (r : ℕ) (k : ℂ) (a b : Fin r) (m n : ℤ) :
    oscN r k a m ∗ oscN r k b n - oscN r k b n ∗ oscN r k a m
      = (if a = b ∧ m + n = 0 then (m : ℂ) ∗ k else 0) • LinearMap.id
```

From the mathematics to the Lean statement

The product $*$ of two endomorphisms is composition. The right-hand side is the scalar mk if $a = b$ and $m + n = 0$, and 0 otherwise, times the identity map: this is $mk\,\delta_{ab}\delta_{m+n,0}$. No hypothesis is imposed on k (it may even be 0, in which case all annihilators vanish and the relation still holds). The statement is the textbook one, quantified over all integers m, n, including the zero modes.

Physical meaning

This is the canonical commutation relation of the free chiral boson, $[\alpha_m, \alpha_n] = m\delta_{m+n,0}$ (for $k = 1$): an infinite family of harmonic oscillators, one for each positive mode number. It is the algebraic form of the current–current OPE $J^a(z)J^b(w) \sim k\,\delta^{ab}/(z-w)^2$, whose double pole is the entire singular part. Since all the physics of the free boson is encoded in these relations, the Fock space is the unique irreducible module in which the $h_a(-m)$ act freely.

Proof on paper. Split according to the signs of m and n. Two creation operators are multiplications by variables, which commute; and $m + n \neq 0$, so the right side is 0. Two annihilation operators are multiples of partial derivatives, which commute; again $m+n \neq 0$. A zero mode is 0 and so commutes with everything, and $m \cdot \delta_{m+n,0}$ vanishes when $m = 0$, while if $n = 0 \neq m$ the delta vanishes. Finally take $m < 0 < n$: then $h_a(m)$ is multiplication by $X = X_{(-m-1,a)}$ and $h_b(n)$ is $nk\,\partial/\partial Y$ with $Y = X_{(n-1,b)}$. If $X \neq Y$ the two commute (different variables), and $X \neq Y$ happens exactly when $a \neq b$ or $m+n \neq 0$. If $X = Y$ the Leibniz rule gives $\partial_X(Xp) - X\partial_X p = p$, so $[X\cdot, nk\,\partial_X] = -nk = mk$ since $n = -m$. The case $m > 0 > n$ is symmetric. □

What the machine verified

Proved, unconditional, in `VOA/Examples/HeisenbergNFock.lean`; the file documents `#print axioms` = `[propext, Classical.choice, Quot.sound]`.

Proposition 31.4 (Vacuum). *$h_a(n)\mathbb{1} = 0$ for every colour a and every $n \geq 0$.*

```
theorem oscN_vacuum (r : ℕ) (k : ℂ) (a : Fin r) (n : ℤ) (hn : 0 ≤ n) :
    oscN r k a n (vacuumN r) = 0
```

Physical meaning

This says the Fock vacuum is the ground state: it is annihilated by every annihilation operator and by the momentum zero mode. In field language it is the statement that the current is regular at the origin acting on the vacuum, $J(z)\mathbb{1} = \sum_{n\le -1} h(n)\mathbb{1}\, z^{-n-1}$, i.e. the state–operator correspondence sends $\mathbb{1}$ to the identity operator. Technically it is the oscillator vacuum condition used in every normal-ordering argument.

Proof on paper. The derivative of a constant is 0, and the zero mode is 0. □

Example 31.5 (A small computation)**.** Take $r = 1$, $k = 1$ and write $x_i = X_{(i,0)}$. The state $h(-1)^2\mathbb{1}$ is x_0^2, and $h(1)x_0^2 = 1 \cdot \partial_{x_0}(x_0^2) = 2x_0 = 2h(-1)\mathbb{1}$, in agreement with the textbook computation $h(1)h(-1)^2\mathbb{1} = [h(1),h(-1)]h(-1)\mathbb{1} + h(-1)[h(1),h(-1)]\mathbb{1} = 2h(-1)\mathbb{1}$. Likewise $h(2)x_1 = 2\,\partial_{x_1} x_1 = 2$, i.e. $h(2)h(-2)\mathbb{1} = 2\mathbb{1}$.

31.3.3 Currents

The basic current of colour a is $h_a(z) = \sum_n h_a(n) z^{-n-1}$. As a `FormalDist` (indexed by exponents of z) its z^j-coefficient is $h_a(-j-1)$:

```
noncomputable def currentN (r : ℕ) (k : ℂ) (a : Fin r) :
    FormalDist (Module.End ℂ (FockN r)) := fun j => oscN r k a (-j - 1)

theorem currentN_mode (r : ℕ) (k : ℂ) (a : Fin r) (m : ℤ) :
    mode (currentN r k a) m = oscN r k a m

theorem currentN_local (r : ℕ) (k : ℂ) (a b : Fin r) :
    Local (currentN r k a) (currentN r k b)
```

`currentN_mode` confirms the dictionary: the m-th mode (in the sense of `mode`) of the current is the oscillator $h_a(m)$. `currentN_local` is the locality $(z_1 - z_2)^2[h_a(z_1), h_b(z_2)] = 0$; it is proved by computing the commutator as $k\delta_{ab}\,\partial_{z_2}\delta(z_1/z_2)$ (Theorem 31.3 in generating-function form) and using that $(z_1 - z_2)^2$ kills the derivative of the formal delta function.

A trap worth recording: in the definition of the currents the *Lean variable* `j` is a power of z, while in `oscN` the integer `n` is a mode. Mixing up the two produces off-by-one errors in every formula; the library's lemma `currentN_mode` pins the convention down once and for all.

31.3.4 The conformal grading

The conformal weight of $h_a(-i-1)\mathbb{1}$ is $i+1$, and weights add under multiplication.

Definition 31.6 (Weight spaces)**.** Give the variable $X_{(i,a)}$ weight $i+1$. For $w \in \mathbb{N}$ let $(\mathcal{F}_r)_w$ be the span of monomials of total weight w.

File `VOA/Examples/HeisenbergNVertex.lean`.

```
def weightFnN {r : ℕ} : ℕ × Fin r → ℕ := fun u => u.1 + 1

def gradingWN (r : ℕ) (w : ℕ) : Submodule ℂ (FockN r) :=
  weightedHomogeneousSubmodule ℂ weightFnN w

noncomputable def gradingZN (r : ℕ) (n : ℤ) : Submodule ℂ (FockN r) :=
  if 0 ≤ n then gradingWN r n.toNat else ⊥
```

From the mathematics to the Lean statement

`weightedHomogeneousSubmodule ℂ w d` is Mathlib's submodule of polynomials all of whose monomials have w-weighted degree d; with $w(i,a) = i+1$ (the field `u.1` is the first component i) this is exactly $(\mathcal{F}_r)_d$. The $\mathbb{Z}$-indexed version `gradingZN` is needed because a vertex algebra's grading is indexed by $\mathbb{Z}$: it is $(\mathcal{F}_r)_n$ for $n \geq 0$ and the zero submodule $\bot$ for $n < 0$.

Physical meaning

The weight of a state is its L_0 eigenvalue, the energy on the cylinder measured from the Casimir shift, and here it counts the total oscillator level: $X_{(i,a)}$ carries energy $i+1$. A weight-w state is a multi-particle state of r species of bosons with total energy w, so $\dim(\mathcal{F}_r)_w$ is the number of r-coloured partitions of w. Summing gives the oscillator partition function $\operatorname{Tr} q^{L_0} = \prod_n (1-q^n)^{-r}$, which is $q^{r/24}/\eta(\tau)^r$ once the Casimir energy is restored. That the weight-0 space is spanned by the vacuum and every weight space is finite is the finiteness of the spectrum (a gapped, discrete spectrum for each energy), a basic requirement of a unitary chiral CFT.

The weight-w space has a basis of monomials $\prod X_{(i,a)}^{e_{(i,a)}}$ with $\sum e_{(i,a)}(i+1) = w$, i.e. of r-coloured partitions of w. Hence

$$\sum_{w \geq 0} \dim(\mathcal{F}_r)_w \, q^w = \prod_{n \geq 1} (1-q^n)^{-r}. \tag{31.5}$$

Indeed, a monomial is a choice of an independent exponent $e \geq 0$ for each variable $X_{(i,a)}$, contributing weight $e(i+1)$, so the generating function factorises as $\prod_{(i,a)} \sum_{e \geq 0} q^{e(i+1)} = \prod_a \prod_{n \geq 1} (1-q^n)^{-1}$, one geometric series per variable. For $r = 1$ the dimensions are $1, 1, 2, 3, 5, 7, \ldots$ (the partition numbers). For $r = 24$ the first are 1, 24, $24 + \binom{25}{2} = 324$, 3200. Finite-dimensionality of each weight space is proved in the library (`gradingWN_finiteDimensional`, `gradingZN_finrank`), as is the fact that $(\mathcal{F}_r)_0 = \mathbb{C} \cdot 1$ (`gradingWN_zero_eq_span_one`). Creation modes $h_a(-m)$ raise weight by m and annihilation modes $h_a(m)$ lower it by m (`oscN_neg_weight`, `oscN_pos_weight`).

31.3.5 Vertex operators and the vertex algebra

The vertex operator of a monomial state is the normal-ordered product of derivatives of the currents:

$$Y\big(h_{a_1}(-i_1-1)\cdots h_{a_s}(-i_s-1)\mathbb{1}, z\big) = :\partial^{(i_1)}h_{a_1}(z)\cdots\partial^{(i_s)}h_{a_s}(z):, \qquad \partial^{(i)} := \frac{1}{i!}\partial_z^i. \tag{31.6}$$

The library implements (31.6) as follows: `genFieldN r k a i` is $\frac{1}{i!}\partial^i h_a(z)$; `YwordN r k l` is the iterated normal-ordered product $:g_1 : g_2 : \cdots : g_s\,\mathrm{id}: \cdots :$ over a list l of indices (nested to the right); `monoWordN` turns an exponent vector into such a list; and Y is extended linearly: File `VOA/Examples/HeisenbergNVertex.lean`.

```
noncomputable def genFieldN (r : ℕ) (k : ℂ) (a : Fin r) (i : ℕ) :
    FormalDist (End ℂ (FockN r)) :=
  (i.factorial : ℂ)⁻¹ • dcurrentN r k a i

noncomputable def monoWordN (a : (ℕ × Fin r) →₀ ℕ) : List (ℕ × Fin r) :=
  a.support.toList.flatMap (fun ia => List.replicate (a ia) ia)

noncomputable def YmonN (r : ℕ) (k : ℂ) (a : (ℕ × Fin r) →₀ ℕ) :
    FormalDist (End ℂ (FockN r)) := YwordN r k (monoWordN a)

noncomputable def YN (r : ℕ) (k : ℂ) : FockN r →ₗ[ℂ] FormalDist (End ℂ (FockN r)) :=
  Finsupp.linearCombination ℂ (YmonN r k)
```

From the mathematics to the Lean statement

`dcurrentN r k a j` is the j-th formal derivative $\partial_z^j h_a(z)$. An exponent vector `(ℕ × Fin r) →₀ ℕ` is a finitely supported function assigning to each variable its exponent; Mathlib represents the monomial with exponent vector e as `monomial e 1`, and a polynomial is a finitely supported function from exponent vectors to coefficients, so `Finsupp.linearCombination ℂ (YmonN r k)` is the linear map sending $\sum_e c_e\, x^e$ to $\sum_e c_e\, Y_{\mathrm{mon}}(e)$. The list `monoWordN` enumerates the support in an unspecified order (`Finset.toList`); this is harmless because the fields $\partial^{(i)} h_a$ are mutually local with commutators that are scalars, so the iterated normal-ordered products of the free-boson currents do not depend on the order of the factors. A referee may worry that such an arbitrary choice could make Y "wrong" on some monomial; it cannot, because the creation property proved below (`YN_creation`) pins $Y(u,z)\mathbb{1}$ to u, and Goddard's uniqueness theorem then pins $Y(u,z)$ itself among local fields.

The five vertex algebra axioms are then proved one by one (`YN_vacuum`, `YN_creation`, `YN_local`, `va5N_regularity`, `va1N_grading_mode`) and packaged: File `VOA/Examples/HeisenbergNVOA.lean`.

```
noncomputable def heisVAN (r : ℕ) (k : ℂ) (_hk : k ≠ 0) : PreVertexAlgebra (FockN r) where
  grading := gradingZN r
  isInternal := gradingZN_isInternal r
  finrank := gradingZN_finrank r
  Y := YN r k
  vacuum := vacuumN r
  ...
```

(the elided fields are the axiom proofs just named). Locality of arbitrary monomial fields is obtained from locality of the generating currents by *Dong's lemma*: if a, b, c are pairwise local, then $:ab:$ is local with c (Theorem 4.16).

31.3.6 The Sugawara conformal vector and the Virasoro relation

For $k \neq 0$, the conformal vector of the free boson is

$$\omega = \frac{1}{2k}\sum_a h_a(-1)^2\mathbb{1}, \qquad L_m = \frac{1}{2k}\sum_a \sum_{j\in\mathbb{Z}} :h_a(m-j)h_a(j):. \tag{31.7}$$

File `VOA/Examples/HeisenbergNCentral.lean`.

```
noncomputable def ωNa (r : ℕ) (k : ℂ) (a : Fin r) : FockN r :=
  (1 / (2 * k)) • oscN r k a (-1) (oscN r k a (-1) (vacuumN r))

noncomputable def ωN (r : ℕ) (k : ℂ) : FockN r := ∑ a : Fin r, ωNa r k a

noncomputable def LvirNa (r : ℕ) (k : ℂ) (a : Fin r) (m : ℤ) : End ℂ (FockN r) :=
  (1 / (2 * k)) • nprod (currentN_isField r k a) (currentN_isField r k a) (-m - 2)

noncomputable def LvirN (r : ℕ) (k : ℂ) (m : ℤ) : End ℂ (FockN r) :=
  ∑ a : Fin r, LvirNa r k a m
```

From the mathematics to the Lean statement

The field $:h_a(z)h_a(z):$ is `nprod ... ...`; its coefficient of z^{-m-2} is the mode $\sum_j :h_a(m-j)h_a(j):$ of a weight-2 field, i.e. $2k\,L_m^a$. So `LvirNa r k a m` is L_m^a as in (31.7). The library later proves $L_m = \omega_{(m+1)}$ (`LvirN_eq_mode_YN_omega`), connecting these explicit operators to the axioms of a vertex operator algebra, which are phrased in terms of $Y(\omega,z)$.

Theorem 31.7 (Virasoro relation, $c = r$). *For $k \neq 0$ and all $m, n \in \mathbb{Z}$,*

$$[L_m, L_n] = (m-n)L_{m+n} + \delta_{m+n,0}\,\frac{r(m^3-m)}{12}\,\mathrm{id}.$$

```
theorem L_virasoroN (r : ℕ) (k : ℂ) (hk : k ≠ 0) (m n : ℤ) :
    LvirN r k m * LvirN r k n - LvirN r k n * LvirN r k m
      = ((m : ℂ) - n) • LvirN r k (m + n)
        + (if m + n = 0 then (r : ℂ) * ((m : ℂ)^3 - m) / 12 else 0)
            • (LinearMap.id : End ℂ (FockN r))
```

Physical meaning

This is the statement that the Sugawara stress tensor $T = \frac{1}{2k}\sum_a :J^aJ^a:$ of r free bosons generates a Virasoro algebra with central charge $c = r$: each free boson contributes $c = 1$. It is the classical Sugawara construction in the abelian case and is verified by the same Wick-contraction computation that physicists use to derive the central term $\frac{c}{12}(m^3-m)$ from the double contraction of two currents. The result is independent of the level k, since T is quadratic in J and rescales accordingly.

Proof on paper. First, $[L^a_m, h_b(n)] = -n\,\delta_{ab}\,h_b(m+n)$: commute $h_b(n)$ through each normal-ordered quadratic term using (31.4). For $a \neq b$ the operators L^a_m and L^b_n commute, because they are built from mutually commuting oscillators. For $a = b$ one computes $[L^a_m, L^a_n]$ by applying $[L^a_m, \cdot\,]$ to the defining sum of L^a_n; the result is $(m-n)L^a_{m+n}$ plus a term that arises from re-normal-ordering, which is a finite "window" sum $\frac{1}{2}\sum_j(\dots)$ that evaluates to $\frac{m^3-m}{12}\delta_{m+n,0}$, the familiar $c = 1$ anomaly of one free boson. (The library computes this window by the explicit power sums $\sum i = N(N-1)/2$ and $\sum i^2 = N(N-1)(2N-1)/6$.) Summing over the r colours gives $c = r$. □

What the machine verified

Proved, conditional only on $k \neq 0$ (needed to divide by $2k$), in `VOA/Examples/HeisenbergNVOA.lean`.

31.3.7 The instance

Theorem 31.8 (Heisenberg vertex operator algebra). *For every $r \in \mathbb{N}$ and every $k \in \mathbb{C} \setminus \{0\}$, the Fock space $\mathcal{F}_r$ with the vertex operators (31.6), vacuum 1, conformal vector (31.7) and grading by weight is a vertex operator algebra of CFT type with central charge r.*

```
noncomputable def heisenbergNVOA (r : ℕ) (k : ℂ) (hk : k ≠ 0) :
    VertexOperatorAlgebra (FockN r) where
  toPreVertexAlgebra := heisVAN r k hk
  conformalVector := ωN r k
  conformal_mem := ωN_mem_gradingZN_two r k

  virasoro := fun m n => conf_virasoroN r k hk m n
  L0_grading := fun v hv => conf_L0_gradingN r k hk v hv
  translation := fun v => conf_translationN r k hk v
  vacuum_grade := gradingZN_zero_eq_span_vacuum r
  positivity := fun n hn => gradingZN_positivity r n hn

theorem heisenbergN_central_charge (r : ℕ) (k : ℂ) (hk : k ≠ 0) :
    (heisenbergNVOA r k hk).centralCharge = (r : ℂ) := rfl
```

From the mathematics to the Lean statement

A definition of a structure value is a theorem in disguise: to write down `heisenbergNVOA` Lean demands a proof of every axiom field, and these are the named lemmas. The only hypothesis is `hk : k ≠ 0`. The central charge lemma is proved by `rfl` (it just reads off the field `centralCharge`); this is *not* a vacuous statement, because the field `virasoro` forces the central charge to be what it is. Indeed $[L_2, L_{-2}] = 4L_0 + \frac{c}{2}\mathrm{id}$ applied to the vacuum gives $L_2\omega = \frac{c}{2}\mathbb{1}$, and $L_2\omega = \frac{r}{2}\mathbb{1}$ by direct computation; any wrong value of `centralCharge` would make the `virasoro` field unprovable. `translation` is proved via Goddard's uniqueness theorem and the covariance $[L_{-1}, Y(v,z)] = \partial_z Y(v,z)$ (`YN_DCovariant`).

Physical meaning

This theorem says that the free boson theory is a consistent chiral conformal field theory: the Fock space is the space of states, the normal-ordered products of derivatives of the current are the local fields, the vertex operator of $h_{-1}\mathbb{1}$ is the current $J(z)$, and the conformal vector gives the stress tensor with central charge $c = r$. Locality of the fields is the physical statement that correlators are single-valued up to meromorphic singularities, and CFT type that the spectrum is bounded below with a unique vacuum. The associated partition function is $q^{-r/24}\prod(1-q^n)^{-r} = 1/\eta^r$ up to the factor $q^{r/24}$. This is the model that the Moonshine construction then enlarges by adding momentum.

What the machine verified

Proved; `#print axioms VOA.HeisenbergN.heisenbergNVOA` = `[propext, Classical.choice, Quot.sound]` (re-checked for this book). Conditional only on $k \neq 0$. The lattice vertex operator algebra uses the level $k = 1$.

31.4 Even lattices and the FLM 2-cocycle

31.4.1 Integral lattices in the library

Lattices are treated in detail in Chapter 30. The vertex-algebra side of the library uses the following minimal notion.

Definition 31.9 (Integral lattice)**.** An *integral lattice* is a finitely generated free abelian group L together with a symmetric $\mathbb{Z}$-bilinear form $\langle\cdot,\cdot\rangle : L \times L \to \mathbb{Z}$. It is *even* if $\langle v, v\rangle \in 2\mathbb{Z}$ for all v, and *positive-definite* if $\langle v, v\rangle > 0$ for all $v \neq 0$. Its *rank* is the rank of L as a free $\mathbb{Z}$-module.

The Lean structure `VOA.IntegralLattice` and the predicates `Even`, `PosDef` and `rank` are quoted verbatim and decoded in Definitions 30.9, 30.10, 30.11 and 3.24 (`VOA/Foundations/Lattices.lean`, `VOA/Foundations/LatticeCocycle.lean`). We recall that the carrier is a free, finitely generated $\mathbb{Z}$-module but *no basis is part of the data*, and that `Even` and `PosDef` appear explicitly, as `hEven` and `hPos`, in every theorem that needs them.

From the mathematics to the Lean statement

Positivity is asked only on integer vectors; that it implies positivity of the real extension (and therefore finiteness of $\{v : \langle v, v\rangle \leq N\}$) is a theorem of the library, `IntegralLattice.boundedFinite` in `VOA/Foundations/LatticeFinite.lean`:

```
def BoundedFinite (L : IntegralLattice) : Prop :=
  ∀ N : ℤ, {α : L.carrier | L.form α α ≤ N}.Finite
```

```
theorem boundedFinite (hPos : L.PosDef) : BoundedFinite L
```

Note that `PosDef` on integer vectors is genuinely equivalent to real positive-definiteness: a rational positive quadratic form is positive on $\mathbb{Q}^n$, hence non-negative on $\mathbb{R}^n$ by density, and a non-degenerate non-negative form is positive; non-degeneracy over $\mathbb{Q}$ follows from positivity on $\mathbb{Q}^n$. So nothing is lost.

Physical meaning

An even positive-definite lattice L of rank r is the data of a compactification: the target space is the torus $\mathbb{R}^r/2\pi L^*$, and the vectors of L are the allowed (chiral) momenta. Evenness, $\langle\alpha,\alpha\rangle \in 2\mathbb{Z}$, says that the vertex operator $:e^{i\alpha\cdot X}:$ has integer conformal weight $\langle\alpha,\alpha\rangle/2$, so that it is a bosonic single-valued field; integrality of the pairing makes two such operators mutually local. Positive-definiteness is what makes the momentum $p \mapsto p^2/2$ energy bounded below. Heuristically this is the standard dictionary lattice $\leftrightarrow$ chiral algebra of a compact torus at a given background; the definition is the algebraic datum alone.

31.4.2 Why a cocycle is needed

Let L be even. As explained in Section 31.1, the naive vertex operators $Y(e^\alpha, z)$ built with the untwisted shift $e^\beta \mapsto e^{\alpha+\beta}$ satisfy $Y(e^\alpha,z_1)Y(e^\beta,z_2) = (-1)^{\langle\alpha,\beta\rangle}Y(e^\beta,z_2)Y(e^\alpha,z_1)$ "up to the $(z_1-z_2)^N$ ambiguity". The cure (Frenkel–Kac, Segal; FLM Chapter 5 and 8) is to replace the group algebra $\mathbb{C}[L]$ by a twisted group algebra $\mathbb{C}_\varepsilon[L]$, with product $e^\alpha \cdot e^\beta = \varepsilon(\alpha,\beta)e^{\alpha+\beta}$, where $\varepsilon : L\times L \to \{\pm 1\}$ satisfies

$$\varepsilon(\alpha,\beta)\varepsilon(\alpha+\beta,\gamma) = \varepsilon(\beta,\gamma)\varepsilon(\alpha,\beta+\gamma) \qquad \text{(2-cocycle law: associativity)}, \tag{31.8}$$

$$\varepsilon(\alpha,\beta)\varepsilon(\beta,\alpha) = (-1)^{\langle\alpha,\beta\rangle} \qquad \text{(commutator property)}. \tag{31.9}$$

A convenient way to produce such an ε is to make it *bimultiplicative*: $\varepsilon(\alpha,\beta) = (-1)^{B(\alpha,\beta)}$ for a $\mathbb{Z}$-bilinear form B. Then (31.8) is automatic, and (31.9) asks that $B(\alpha,\beta)+B(\beta,\alpha) \equiv \langle\alpha,\beta\rangle \pmod 2$. Choosing a basis $B_1,\dots,B_n$ of L one takes the strictly triangular part of the Gram matrix.

31.4.3 The cocycle in the library

Definition 31.10 (Cocycle exponent and cocycle)**.** Let $\mathcal{B} = (B_i)_{i<n}$ be a $\mathbb{Z}$-basis of L and write $\alpha = \sum_i \alpha_i B_i$. Put

$$\mathrm{coc}_{\mathcal{B}}(\alpha,\beta) = \sum_{j<i} \langle B_i, B_j\rangle\, \alpha_i\beta_j, \qquad \varepsilon_{\mathcal{B}}(\alpha,\beta) = (-1)^{\mathrm{coc}_{\mathcal{B}}(\alpha,\beta)} \in \mathbb{C}.$$

```
noncomputable def cocExp (α β : L.carrier) : ℤ :=
  ∑ i : Fin n, ∑ j : Fin n,
    (if j < i then L.form (B i) (B j) else 0) * B.repr α i * B.repr β j

noncomputable def cocycle (α β : L.carrier) : ℂ := (-1 : ℂ) ^ (cocExp L B α β)
```

(`VOA/Foundations/LatticeCocycle.lean`, with the section variable `(B : Basis (Fin n) ℤ L.carrier)`.)

From the mathematics to the Lean statement

`B.repr α i` is the i-th coordinate $\alpha_i \in \mathbb{Z}$ of α in the basis B. The sum over `i j : Fin n` with the guard `j < i` is the sum over pairs with $j<i$. The power `(-1 : ℂ) ^ (k : ℤ)` is an integer

power of -1 in $\mathbb{C}$; the cocycle takes values ± 1 viewed as complex numbers, because it will multiply complex vectors.

Physical meaning

The sign $\varepsilon(\alpha,\beta)$ is the Klein-factor (cocycle) correction in the product of vertex operators $:e^{i\alpha\cdot X}:$. Naively these exponentials commute up to the phase $(-1)^{\langle\alpha,\beta\rangle}$ coming from the OPE $(z-w)^{\langle\alpha,\beta\rangle}$, and for odd $\langle\alpha,\beta\rangle$ they would anticommute where bosons should commute. Multiplying the operators by momentum-shifting signs ε compensates, exactly as Klein factors in bosonisation convert statistics. The particular choice via the triangular part of the Gram matrix is a gauge: physical quantities are independent of it up to isomorphism, and the cocycle is the cohomology class in $H^2(L,\mathbb{Z}/2)$ fixed by the form.

Theorem 31.11 (Properties of $\varepsilon_{\mathcal{B}}$). *For every basis $\mathcal{B}$ and all $\alpha,\alpha',\beta,\beta',\gamma\in L$:*

(i) $\varepsilon(\alpha+\alpha',\beta)=\varepsilon(\alpha,\beta)\varepsilon(\alpha',\beta)$ *and* $\varepsilon(\alpha,\beta+\beta')=\varepsilon(\alpha,\beta)\varepsilon(\alpha,\beta')$;

(ii) $\varepsilon(0,\beta)=\varepsilon(\alpha,0)=1$ *and* $\varepsilon(\alpha,\beta)^2=1$;

(iii) *the 2-cocycle law* (31.8);

(iv) $\mathrm{coc}(\alpha,\beta)+\mathrm{coc}(\beta,\alpha)=\langle\alpha,\beta\rangle-\sum_i\langle B_i,B_i\rangle\alpha_i\beta_i$;

(v) *if L is even, the commutator property* (31.9).

```
theorem cocycle_add_left (α α' β : L.carrier) :
    cocycle L B (α + α') β = cocycle L B α β * cocycle L B α' β
theorem cocycle_add_right (α β β' : L.carrier) :
    cocycle L B α (β + β') = cocycle L B α β * cocycle L B α β'
theorem cocycle_zero_left (β : L.carrier) : cocycle L B 0 β = 1
theorem cocycle_zero_right (α : L.carrier) : cocycle L B α 0 = 1
theorem cocycle_sq (α β : L.carrier) : cocycle L B α β * cocycle L B α β = 1
theorem cocycle_cocycleLaw (α β γ : L.carrier) :
    cocycle L B α β * cocycle L B (α + β) γ = cocycle L B β γ * cocycle L B α (β + γ)
theorem cocExp_add_swap (α β : L.carrier) :
    cocExp L B α β + cocExp L B β α
      = L.form α β - ∑ i : Fin n, L.form (B i) (B i) * B.repr α i * B.repr β i
theorem cocycle_comm (hEven : L.Even) (α β : L.carrier) :
    cocycle L B α β * cocycle L B β α = (-1 : ℂ) ^ (L.form α β)
```

From the mathematics to the Lean statement

Every statement is universally quantified over an arbitrary basis `B`; the only hypothesis anywhere is `hEven` in the last one. Since $\varepsilon=\pm1$, the product form of (31.9) is equivalent to the quotient form $\varepsilon(\alpha,\beta)/\varepsilon(\beta,\alpha)=(-1)^{\langle\alpha,\beta\rangle}$. These are exactly the textbook properties.

Physical meaning

These identities say that the signs ε define an associative twisted product on the momentum lattice (the cocycle law) and that $\varepsilon(\alpha,\beta)\varepsilon(\beta,\alpha)=(-1)^{\langle\alpha,\beta\rangle}$: reordering two momentum shifts costs exactly the sign by which the naive vertex operators fail to commute. In CFT terms this is the condition for the Klein-factored vertex operators $:e^{i\alpha\cdot X}:$ to be mutually local with the correct (bosonic) statistics. The commutator property needs evenness, because otherwise the diagonal term $\sum_i\langle B_i,B_i\rangle\alpha_i\beta_i$ of (iv) does not vanish mod 2.

Proof on paper. coc is bilinear because coordinates are linear; (i)–(iii) follow by exponentiating. For (iv), write $\langle\alpha,\beta\rangle = \sum_{i,j}\langle B_i,B_j\rangle\alpha_i\beta_j$ and split the sum into $j<i$, $j>i$ and $j=i$; by symmetry of the form the $j>i$ part equals $\mathrm{coc}(\beta,\alpha)$. For (v), each $\langle B_i,B_i\rangle$ is even, so the diagonal correction in (iv) is even and disappears from $(-1)^{(\cdot)}$. □

Example 31.12 (A_1 and A_2)**.** For $A_1=\mathbb{Z}\alpha$ with $\langle\alpha,\alpha\rangle=2$, there is only one basis index, the sum is empty and $\varepsilon\equiv 1$; this is consistent with (31.9) because all pairings $2mn$ are even. For A_2 with basis B_0,B_1, $\langle B_i,B_i\rangle=2$ and $\langle B_0,B_1\rangle=-1$, the only pair with $j<i$ is $(i,j)=(1,0)$, so $\mathrm{coc}(\alpha,\beta)=-\alpha_1\beta_0$. Thus $\varepsilon(B_1,B_0)=-1$, $\varepsilon(B_0,B_1)=1$, and the product is $-1=(-1)^{\langle B_0,B_1\rangle}$. Exchanging the roles of B_0 and B_1 (another basis) gives a different but cohomologous cocycle; see Section 31.12.

31.4.4 The canonical cocycle of a lattice

Since an `IntegralLattice` carries no preferred basis, the library *chooses* one. File `VOA/Foundations/LatticeCocycle.lean`.

```
noncomputable def latticeBasis :
    Basis (Fin (Fintype.card (Module.Free.ChooseBasisIndex ℤ L.carrier))) ℤ L.carrier :=
  (Module.Free.chooseBasis ℤ L.carrier).reindex (Fintype.equivFin _)

noncomputable def latticeCocycle (α β : L.carrier) : ℂ := cocycle L (latticeBasis L) α β

theorem latticeCocycle_comm (hEven : L.Even) (α β : L.carrier) :
    latticeCocycle L α β * latticeCocycle L β α = (-1 : ℂ) ^ (L.form α β)
```

together with `latticeCocycle_cocycleLaw`, `latticeCocycle_zero_left`, `latticeCocycle_zero_right`, `latticeCocycle_add_left`, `latticeCocycle_add_right` and `latticeCocycle_sq`, which specialise Theorem 31.11.

From the mathematics to the Lean statement

`Module.Free.chooseBasis ℤ L.carrier` is *some* basis, extracted from the existence statement `Module.Free` by the axiom of choice. Lean's `Classical.choice` gives no way to compute which basis it is, and `reindex (Fintype.equivFin _)` renumbers it by `Fin n` through another non-constructive bijection. Consequently the value of `latticeCocycle L α β` for specific α,β is a well-defined complex number ±1, but it *cannot be computed*: no Lean proof can decide by evaluation whether $\varepsilon(\alpha,\beta)=1$. Every theorem must therefore use only properties valid for *every* basis. This is a design decision with consequences discussed in Section 31.13. It is not a fidelity defect: FLM's construction also depends on a choice (of central extension), and all choices give isomorphic vertex operator algebras.

Remark 31.13 (Further consequences of bimultiplicativity)**.** Because ε is bimultiplicative and ±1-valued, $\varepsilon(-\alpha,-\beta)=\varepsilon(\alpha,\beta)^{(-1)(-1)}=\varepsilon(\alpha,\beta)$ (`latticeCocycle_neg_neg`, `VOA/Moonshine/LatticeInvolution.lean`), and $\varepsilon(\alpha,\beta)=(-1)^{\langle\alpha,\beta\rangle}\varepsilon(\beta,\alpha)$ (`latticeCocycle_swap_sign`, `VOA/Examples/LatticeGenLocality.lean`):

```
theorem latticeCocycle_neg_neg (α β : L.carrier) :
    latticeCocycle L (-α) (-β) = latticeCocycle L α β
theorem latticeCocycle_swap_sign (hEven : L.Even) (α β : L.carrier) :
    latticeCocycle L α β = (-1 : ℂ) ^ (L.form α β) * latticeCocycle L β α
```

The first identity is why the lift θ of $-1\in O(L)$ (Chapter 32) needs *no* sign correction in this library: $\theta(p\otimes e^{\alpha})=\sigma(p)\otimes e^{-\alpha}$ exactly. For a general (non-bimultiplicative) cocycle, FLM must use $\theta e^{\alpha}=c(\alpha)e^{-\alpha}$ with a correcting function c.

The library also builds the twisted group algebra itself, with product `twMul` on `L.carrier →₀ ℂ` satisfying `twMul_e`: $e^{\alpha} \star e^{\beta} = \varepsilon(\alpha,\beta)e^{\alpha+\beta}$ and `twMul_assoc` (`VOA/Foundations/LatticeAlgebraTwisted.lean`). For the vertex algebra this product is never used as such: the cocycle is inserted directly into the vertex operators (Definition 31.21), and the state space uses the *vector space* $\mathbb{C}[L]$ =`L.carrier →₀ ℂ`.

What the machine verified

All of Theorem 31.11 and its `latticeCocycle` specialisations: proved, unconditional except for `hEven` in the commutator property; `#print axioms latticeCocycle_comm` = `[propext, Classical.choice, Quot.sound]` (`Classical.choice` enters, among other places, through `chooseBasis`).

31.5 Lattice charges as Heisenberg oscillators: the orthonormal frame

The lattice vertex algebra contains the Heisenberg algebra of $\mathfrak{h} = L \otimes_{\mathbb{Z}} \mathbb{C}$ with the *lattice* form: $[\alpha(m), \beta(n)] = \langle\alpha,\beta\rangle m\delta_{m+n,0}$. The library's Fock space $\mathcal{F}_r$ has *orthonormal* oscillators $h_a(n)$ (Theorem 31.3 with $k = 1$). To realise $\alpha(n)$ one needs real coordinates $\alpha^{\perp} \in \mathbb{R}^r$ with $\sum_a \alpha^{\perp}_a \beta^{\perp}_a = \langle\alpha,\beta\rangle$, and then $\alpha(n) := \sum_a \alpha^{\perp}_a h_a(n)$. The library obtains such coordinates from the symmetric positive square root of the Gram matrix.

Definition 31.14 (Frame and orthonormal coordinates). Let $G = (\langle B_i, B_j\rangle)_{ij}$ be the Gram matrix of the chosen basis `latticeBasis L`, viewed as a real matrix, and $C = \sqrt{G}$ its positive semidefinite square root. For $\alpha \in L$ with coordinate vector $\underline{\alpha} \in \mathbb{Z}^n$, put $\alpha^{\perp} = C\underline{\alpha} \in \mathbb{R}^n$.

```
noncomputable def latRank : ℕ := Fintype.card (Module.Free.ChooseBasisIndex ℤ L.carrier)

theorem orthCoord_inner (hPos : L.PosDef) (α β : L.carrier) :
    ∑ a, orthCoord L α a * orthCoord L β a = ((L.form α β : ℤ) : ℝ)
```

(`VOA/Foundations/LatticeFinite.lean`, `VOA/Foundations/LatticeOrthoFrame.lean`.)

From the mathematics to the Lean statement

`CFC.sqrt` is Mathlib's continuous-functional-calculus square root; on a positive semidefinite real symmetric matrix it is the unique positive semidefinite square root. `*ᵥ` is matrix–vector multiplication. `orthCoord_inner` is the identity $\alpha^{\perp}\cdot\beta^{\perp} = \underline{\alpha}^T C^T C\underline{\beta} = \underline{\alpha}^T G\underline{\beta} = \langle\alpha,\beta\rangle$, valid because C is symmetric and $C^2 = G$; it needs `hPos` only to know G is positive semidefinite so that the square root behaves. The integers `latRank L` and `rank L` are equal (`rank_eq_latRank`), and `rankEquiv : Fin (rank L) ≃ Fin (latRank L)` transports indices between the Fock colours and the frame coordinates.

Physical meaning

The frame $\alpha \mapsto \alpha^\perp$ realises the abstract lattice as a lattice of momentum vectors in the Euclidean space $\mathbb{R}^r$ with orthonormal coordinates: the a-th component $\alpha_a^\perp$ is the momentum carried by the a-th boson, and $\langle \alpha, \beta \rangle = \alpha^\perp \cdot \beta^\perp$. Choosing the frame is choosing Cartesian coordinates on the target torus, which is how one passes from r independent bosons to the vertex operator $:e^{i\alpha^\perp \cdot X}:$. It is pure bookkeeping (a change of basis), with no new physics, but all later formulas are written in these coordinates.

Definition 31.15 (Charge oscillators). $\alpha(m) := \sum_a \alpha_a^\perp \, h_a(m)$ on $\mathcal{F}_{\mathrm{rank}\, L}$ (level $k = 1$).

```
noncomputable def chargeOsc (α : L.carrier) (m : ℤ) :
    Module.End ℂ (HeisenbergN.FockN (rank L)) :=
  ∑ a : Fin (rank L), (orthCoord L α (rankEquiv L a) : ℂ) • HeisenbergN.oscN (rank L) 1 a m

noncomputable def chargeCoord (α : L.carrier) (b : Fin (rank L)) : ℂ :=
  (orthCoord L α (rankEquiv L b) : ℂ)

theorem chargeOsc_comm (hPos : L.PosDef) (α β : L.carrier) (m n : ℤ) :
    chargeOsc L α m * chargeOsc L β n - chargeOsc L β n * chargeOsc L α m
      = (if m + n = 0 then ((L.form α β : ℤ) : ℂ) * (m : ℂ) else 0) • LinearMap.id
```

(`VOA/Examples/LatticeGenCharge.lean`, `LatticeGenChargeFields.lean`.)

Physical meaning

The charge oscillator $\alpha(m) = \alpha^\perp \cdot h(m)$ is the mode of the current component $\alpha \cdot i\partial X(z)$ along the direction α in target space, and its zero mode $\alpha(0)$ measures the momentum of a state projected onto α. Its commutator $[\alpha(m), \beta(n)] = m\langle \alpha, \beta \rangle \delta_{m+n,0}$ is the OPE of two such projected currents with the lattice inner product as the two-point coefficient. It is the building block of the vertex operator $:e^{i\alpha \cdot X}:$, whose exponent is the integral of this current.

Proof on paper of `chargeOsc_comm`. Expand both oscillators in the h_a; by Theorem 31.3 only the diagonal $a = b$ terms survive and give $m\delta_{m+n,0} \sum_a \alpha_a^\perp \beta_a^\perp = m\delta_{m+n,0}\langle \alpha, \beta \rangle$. □

Remark 31.16 (Why $\sqrt{G}$, and what it costs). Any real matrix C with $C^T C = G$ would do; $\sqrt{G}$ is chosen because it exists canonically in Mathlib. The price is that the oscillator directions h_a of the library are *not* adapted to any interesting coordinate system. For the Leech lattice, for instance, the 24 Fock colours are not the coordinate directions of the Golay-code construction. A state such as $h_a(-1)\mathbb{1}$ (`heisSt`) is an orthonormal-frame state with no lattice meaning; the lattice-meaningful states are $\alpha(-1)\mathbb{1}$ (`hSt`). This is the second half of the design question of Section 31.13.

31.6 The state space of V_L and its grading

31.6.1 The underlying vector space

Definition 31.17. $V_L := \mathcal{F}_{\mathrm{rank}\, L} \otimes_{\mathbb{C}} \mathbb{C}[L]$, where $\mathbb{C}[L]$ is the vector space with basis $\{e^\alpha\}_{\alpha \in L}$. Write $p \otimes e^\alpha$ for basis-like states, $\mathbb{1} = 1 \otimes e^0$ for the vacuum and $e^\alpha = 1 \otimes e^\alpha$ for the charged vacua.

```
noncomputable abbrev LatModuleGen : Type :=
  HeisenbergN.FockN (rank L) ⊗[ℂ] (L.carrier →₀ ℂ)

noncomputable def eGen (α : L.carrier) : L.carrier →₀ ℂ := Finsupp.single α 1
```

```
noncomputable def latStateGen (p : HeisenbergN.FockN (rank L)) (α : L.carrier) :
↪  LatModuleGen L :=
  p ⊗ₜ[ℂ] eGen L α

noncomputable def latVacuumGen : LatModuleGen L :=
  latStateGen L (HeisenbergN.vacuumN (rank L)) 0

noncomputable def latChargeGen (α : L.carrier) : LatModuleGen L :=
  latStateGen L (HeisenbergN.vacuumN (rank L)) α
```

(`VOA/Examples/LatticeGenModule.lean`.)

From the mathematics to the Lean statement

`L.carrier →₀ ℂ` is the space of finitely supported functions $L \to \mathbb{C}$, i.e. the vector space with basis $e^\alpha =$ `Finsupp.single α 1`. `⊗[ℂ]` is the algebraic tensor product over $\mathbb{C}$ and `p ⊗ₜ[ℂ] x` a pure tensor. The cocycle is *not* part of the state space; it appears only in the vertex operators. The states $p \otimes e^\alpha$ span V_L (`latStateGen_span`).

Physical meaning

The space $V_L = \mathcal{F}_r \otimes \mathbb{C}[L]$ is the full space of states of r compactified chiral bosons: the Fock factor holds the oscillator excitations and the group algebra $\mathbb{C}[L]$ holds the discrete momentum $\alpha \in L$, with e^α the ground state of momentum α. The charged vacuum e^α is the state created from the vacuum by the vertex operator $:e^{i\alpha\cdot X}:$. Decomposing $V_L = \bigoplus_\gamma \mathcal{F} \otimes e^\gamma$ is the decomposition by $U(1)^r$ charge (the momentum sectors), and the chosen γ sector is the charge-γ module of the Heisenberg algebra.

We also need the inclusion of the charge-γ sector and the extraction of the charge-γ component: File `VOA/Examples/LatticeCharge.lean`.

noncomputable def chargeSec (γ : L.carrier) : Submodule ℂ (LatModuleGen L) :=
  LinearMap.range (mkEα L γ)
```

`mkEα L α p` $= p \otimes e^\alpha$; `coordEα L γ` sends $p \otimes e^\alpha$ to p if $\alpha = \gamma$ and to 0 otherwise (`coordEα_apply`), so that every $x \in V_L$ is $\sum_\gamma$ `coordEα`$_\gamma(x) \otimes e^\gamma$, a finite sum; and `chargeSec L γ` $= \mathcal{F} \otimes e^\gamma$ is the *momentum-γ sector*.

31.6.2 The conformal weight grading

The conformal weight of $p \otimes e^\alpha$, with p of Fock weight w, is $w + \frac{1}{2}\langle\alpha,\alpha\rangle$.

Definition 31.18 (Grading of V_L). For $\alpha \in L$ let $|\alpha|^2/2 := \langle\alpha,\alpha\rangle/2$ (an integer when L is even). For $(w,\alpha) \in \mathbb{Z} \times L$ let $V_{(w,\alpha)} = (\mathcal{F})_w \otimes e^\alpha$ (zero if $w < 0$), and for $n \in \mathbb{Z}$ let $(V_L)_n = \sum_\alpha V_{(n-|\alpha|^2/2,\alpha)}$.

```
noncomputable def halfNorm (α : L.carrier) : ℤ := L.form α α / 2

noncomputable def bigradα (wα : ℤ × L.carrier) : Submodule ℂ (LatModuleGen L) :=
```

```
  (HeisenbergN.gradingZN (rank L) wα.1).map (mkEα L wα.2)

noncomputable def gradingLatGen (k : ℤ) : Submodule ℂ (LatModuleGen L) :=
  ⨆ α : L.carrier, bigradα L (k - halfNorm L α, α)
```

(VOA/Examples/LatticeGenGrading.lean.)

From the mathematics to the Lean statement

`L.form α α / 2` is integer division; it equals $\langle\alpha,\alpha\rangle/2$ exactly when $\langle\alpha,\alpha\rangle$ is even, which is the content of

```
theorem two_halfNorm (hEven : L.Even) (α : L.carrier) : 2 * halfNorm L α = L.form α α
```

i.e. $2\cdot$`halfNorm L α` $=\langle\alpha,\alpha\rangle$. Without evenness `halfNorm` would silently round, but every theorem using it assumes `hEven`. `Submodule.map` is the image of a submodule under a linear map, and `⨆ α` is the supremum (sum) of a family of submodules. So `gradingLatGen L k` is literally $\sum_\alpha (\mathcal{F})_{k-|\alpha|^2/2}\otimes e^\alpha$.

Physical meaning

This is the conformal-weight formula for a state of momentum α and oscillator level w: $h=\frac{1}{2}\langle\alpha,\alpha\rangle+w$. The first term is the kinetic energy $p^2/2$ of the zero mode, the second the energy of the excited oscillators. The grading is the eigenvalue of L_0 on the cylinder (up to the $-c/24$ shift), and evenness makes it integral. The weight-one subspace $(V_L)_1$ is then the space of conserved currents: oscillators $h_a(-1)\mathbb{1}$ plus the momentum states of norm 2 (the roots).

Theorem 31.19 (The grading is a graded decomposition of CFT type). *Let L be even and positive-definite. Then $V_L=\bigoplus_n (V_L)_n$, each $(V_L)_n$ is finite-dimensional, $(V_L)_n=0$ for $n<0$ and $(V_L)_0=\mathbb{C}\mathbb{1}$.*

theorem gradingLatGen_zero_eq_span_vacuum (hEven : L.Even) (hPos : L.PosDef) :
    gradingLatGen L 0 = ℂ • latVacuumGen L
```

Physical meaning

This is the statement that the lattice theory has a well-defined, discrete energy spectrum with a unique vacuum: each energy level has finitely many states (because only finitely many lattice vectors have bounded norm, by positive-definiteness, and each Fock level is finite), no negative energies occur (unitarity-type positivity), and only the vacuum has $h=0$ (no zero-weight vertex operator other than the identity). These are the conditions for V_L to be of CFT type, the algebraic version of a unitary chiral CFT with a normalisable vacuum.

Proof on paper. The bigrading $V_L=\bigoplus_{(w,\alpha)}(\mathcal{F})_w\otimes e^\alpha$ is a direct sum because $\mathcal{F}=\bigoplus_w \mathcal{F}_w$ and $\mathbb{C}[L]=\bigoplus_\alpha \mathbb{C}e^\alpha$; collapsing along the fibres of $(w,\alpha)\mapsto w+|\alpha|^2/2$ preserves direct sums. If $n<0$ then $n-|\alpha|^2/2<0$ for every α (positivity of the norm), so $(V_L)_n=0$. The weight-0 space needs $w=0$ and $|\alpha|^2=0$, hence $\alpha=0$ and the state is a multiple of the vacuum. Finite-dimensionality: only the finitely many α with $|\alpha|^2\le 2n$ contribute (`boundedFinite`), and each contributes the finite-dimensional $\mathcal{F}_{n-|\alpha|^2/2}$. □

What the machine verified

Proved, conditional only on `hEven` and `hPos`. (The file's module docstring still calls the finiteness of bounded vectors an "isolated crux"; that crux has since been discharged by `boundedFinite`, and the `\_of\_posDef` versions above use it. The docstring is stale; the theorems are not.)

Consequently the graded dimension is

$$\sum_n \dim(V_L)_n\, q^n = \frac{\theta_L(q)}{\prod_{n\ge 1}(1-q^n)^r}, \qquad \theta_L(q) = \sum_{\alpha\in L} q^{\langle\alpha,\alpha\rangle/2}, \tag{31.10}$$

which for the Leech lattice is the subject of Chapter 33.

31.7 The vertex operators $Y(e^\alpha, z)$

31.7.1 The exponentials $E^\pm$

The two exponential factors in (31.3) are

$$E^-(\alpha,z) = \exp\Big(\sum_{n\ge1}\frac{\alpha(-n)}{n}z^n\Big) = \sum_{N\ge0} S_N(\alpha)z^N, \tag{31.11}$$
$$E^+(\alpha,z) = \exp\Big(-\sum_{n\ge1}\frac{\alpha(n)}{n}z^{-n}\Big) = \sum_{N\ge0} E^+_N(\alpha)z^{-N}.$$

Naming caution: these are FLM's $E^-(-\alpha,z)$ and $E^+(-\alpha,z)$; the library drops the minus sign from the name. The coefficients $S_N(\alpha)$ are the elementary Schur polynomials in the creation operators, and the library computes them, without any exponential, by the Newton-type recursion obtained by differentiating: if $E(z) = \exp(\sum_{n\ge1} a_n z^n/n) = \sum_N S_N z^N$ (the a_n commuting), then $E'(z) = (\sum_{n\ge1} a_n z^{n-1})E(z)$; comparing the coefficients of z^N on both sides gives $(N+1)S_{N+1} = \sum_{m=0}^{N} a_{m+1}S_{N-m}$, which determines all S_N from $S_0 = 1$. Conversely, the series defined by the recursion satisfies the same first-order differential equation with the same constant term, hence equals $E(z)$.

Definition 31.20 (Schur coefficients). $v_m(\alpha) := \sum_a \alpha_a^\perp X_{(m,a)}$ is the state $\alpha(-m-1)\mathbb{1}$. Define $S_0(\alpha) = 1$, $S_{N+1}(\alpha) = \frac{1}{N+1}\sum_{m=0}^{N} v_m(\alpha)S_{N-m}(\alpha)$, and the annihilation coefficients $E^+_0 = \mathrm{id}$, $E^+_{N+1} = \frac{1}{N+1}\sum_{m=0}^{N}(-\alpha(m+1))\circ E^+_{N-m}$.

```
noncomputable def vVar (α : L.carrier) (m : ℕ) : HeisenbergN.FockN (rank L) :=
  ∑ a : Fin (rank L), chargeCoord L α a • (MvPolynomial.X ((m, a)) : HeisenbergN.FockN
   ↪ (rank L))

noncomputable def vSchur (α : L.carrier) : ℕ → HeisenbergN.FockN (rank L)
  | 0 => 1
  | (N+1) => ((N+1 : ℂ))⁻¹ • ∑ m ∈ Finset.range (N+1), vVar L α m * vSchur α (N - m)

noncomputable def EminusVec (α : L.carrier) (N : ℕ) : End ℂ (HeisenbergN.FockN (rank L)) :=
  LinearMap.mulLeft ℂ (vSchur L α N)

noncomputable def aExpVec (α : L.carrier) : ℕ → End ℂ (HeisenbergN.FockN (rank L))
  | 0 => LinearMap.id
  | (N+1) => ((N+1 : ℂ))⁻¹ • ∑ m ∈ Finset.range (N+1),
      (-(chargeOsc L α (m+1 : ℤ))).comp (aExpVec α (N - m))
```

(`VOA/Examples/LatticeGenChargeFields.lean`.) Since creation operators are multiplications, E^- acts by multiplication by the polynomial $S_N(\alpha)$ (`LinearMap.mulLeft`). As formal distributions (indexed by exponents of z):

```
noncomputable def EminusVecField (α : L.carrier) : FormalDist (End ℂ (FockN (rank L))) :=
  fun t => if 0 ≤ t then EminusVec L α t.toNat else 0

noncomputable def EplusVecField (α : L.carrier) : FormalDist (End ℂ (FockN (rank L))) :=
  fun t => if t ≤ 0 then aExpVec L α (-t).toNat else 0

noncomputable def EEVec (α : L.carrier) : FormalDist (End ℂ (FockN (rank L))) :=
  nprod (EminusVecField_isField L α) (EplusVecField_isField L α)
```

(`VOA/Examples/LatticeGenVertex.lean`.)

From the mathematics to the Lean statement

`EminusVecField` has nonzero coefficients only at z^t, $t \geq 0$, and there it is $S_t(\alpha)$; `EplusVecField` only at z^t, $t \leq 0$, and there it is $E^+_{-t}(\alpha)$. `EEVec` is the normal-ordered product $:E^-(\alpha,z)E^+(\alpha,z):$; since all nonzero coefficients of E^- sit at non-negative powers, the normal ordering simply puts E^- on the left, so `EEVec` $= E^-(\alpha,z)E^+(\alpha,z)$, the boson dressing. It acts on the Fock factor only.

Physical meaning

The coefficients $S_N(\alpha)$ are the Schur polynomials in the creation modes and arise from expanding the exponential of the negative part of the current, $\exp\big(\sum_{m>0} \frac{\alpha(-m)}{m} z^m\big) = \sum_N S_N(\alpha) z^N$. They are the oscillator content of the vertex operator $:e^{i\alpha\cdot X}:$ in its factorised form (the creation part E^- and the annihilation part E^+), obtained by the standard normal-ordering of the exponential of a free field. This is technical infrastructure for writing $Y(e^{\alpha}, z)$ explicitly.

31.7.2 The charged vertex operator

Before the definition, one convention must be fixed: in $Y(e^{\alpha}, z) = E^-E^+ e_{\alpha} z^{\alpha(0)}$ the operator $z^{\alpha(0)}$ acts *first*, on the incoming momentum β, giving $z^{\langle\alpha,\beta\rangle}$, and then e_{α} shifts β to $\alpha+\beta$ with the sign $\varepsilon(\alpha,\beta)$. This is FLM's convention (8.4.1).

Definition 31.21 ($Y(e^{\alpha}, z)$)**.** For $\alpha \in L$, define $Y(e^{\alpha}, z)$ on $p \otimes e^{\beta}$ by

$$Y(e^{\alpha}, z)(p \otimes e^{\beta}) = \varepsilon(\alpha,\beta)\, z^{\langle\alpha,\beta\rangle} \big(E^-(\alpha,z)E^+(\alpha,z)p\big) \otimes e^{\alpha+\beta}. \tag{31.12}$$

Equivalently, its z^t-coefficient sends $p \otimes e^{\beta}$ to $\varepsilon(\alpha,\beta)\,[E^-E^+]_{t-\langle\alpha,\beta\rangle}\, p \otimes e^{\alpha+\beta}$.

```
noncomputable def YeαvecFam (α : L.carrier) (t : ℤ) (β : L.carrier) :

theorem Yeαvec_tmul (α β : L.carrier) (t : ℤ) (p : FockN (rank L)) :
    Yeαvec L α t (latStateGen L p β)
      = latticeCocycle L α β • latStateGen L (EEVec L α (t - L.form α β) p) (α + β)
```

From the mathematics to the Lean statement

The first two declarations are the bureaucracy of defining a linear map on a tensor product with a finitely supported factor; the third, `Yeαvec_tmul`, is the defining formula and is exactly the coefficient form of (31.12): the factor $z^{\alpha(0)}$ acts on the β-sector as $z^{\langle\alpha,\beta\rangle}$, which shifts the exponent t of the dressing by $\langle\alpha,\beta\rangle$; e_α shifts the momentum to $\alpha+\beta$ and contributes $\varepsilon(\alpha,\beta)$. Note the order convention $e_\alpha z^{\alpha(0)}$ with $z^{\alpha(0)}$ evaluated on the *incoming* momentum β; this is FLM's convention (8.4.1). With it, $Y(e^\alpha,z)\mathbb{1} = E^-(\alpha,z)e^\alpha$, so $(e^\alpha)_{(-1)}\mathbb{1} = e^\alpha$ (`Yeαvec_mode_neg_one_vacuum`), and

$$(e^\alpha)_{(-\langle\alpha,\beta\rangle-1)}e^\beta = \varepsilon(\alpha,\beta)e^{\alpha+\beta}$$

(`smul_latChargeGen`, used in Section 31.12.6).

Physical meaning

This is the vertex operator $:e^{i\alpha\cdot X(z)}: = E^-(\alpha,z)E^+(\alpha,z)\,e_\alpha\,z^{\alpha(0)}$ of the compactified boson: it shifts the momentum by α, the factor $z^{\alpha(0)}$ produces the OPE singularity $z^{\langle\alpha,\beta\rangle}$ with a state of momentum β, the exponentials $E^\mp$ are its oscillator dressing, and the sign $\varepsilon(\alpha,\beta)$ is the Klein factor. Its conformal weight is $\langle\alpha,\alpha\rangle/2$, and acting on the vacuum it creates the charged ground state e^α. This is the central formula of Frenkel–Kac and Segal (the construction of simply-laced affine algebras from lattices) and of FLM Chapter 8.

The boson currents on V_L are the *lifted* currents (the Fock currents acting on the first tensor factor only, $h_a(n)\otimes\mathrm{id}$) plus the momentum zero mode: $h_a(z) = \sum_n h_a(n)z^{-n-1}$ with $h_a(0)(p\otimes e^\beta) = \beta_a^\perp\, p\otimes e^\beta$.

```
noncomputable def zGradeOpGen (a : Fin (rank L)) : LatModuleGen L →ₗ[ℂ] LatModuleGen L :=

↪  (LatModuleGen L)) :=
  (i.factorial : ℂ)⁻¹ • (VOA.deriv^[i] (alphaLatGen L a))
```

(`VOA/Examples/LatticeGenBosonFields.lean`.) The coefficient of z^{-1} is the mode $h_a(0)$, which is why the zero-mode operator is added at `j = -1`. `rTensor f` is $f\otimes\mathrm{id}$, `lTensor g` is $\mathrm{id}\otimes g$, and `VOA.deriv^[i]` is the i-fold formal derivative.

31.8 Locality of the lattice vertex operators

Theorem 31.22 (Charge-pair locality). *Let L be even and positive-definite. For all $\alpha,\beta\in L$, $Y(e^\alpha,z)$ and $Y(e^\beta,z)$ are mutually local.*

```
theorem Yeαvec_local (hEven : L.Even) (hPos : L.PosDef) (α β : L.carrier) :
    Local (Yeαvec L α) (Yeαvec L β)
```

(`VOA/Examples/LatticeGenOppLocal.lean`.)

From the mathematics to the Lean statement

`Local` is Definition-level locality of Section 31.2: some power $(z_1 - z_2)^N$ annihilates the commutator. The hypothesis `hEven` is essential (it gives the commutator property of ε); `hPos` enters through the frame (`orthCoord_inner`), which needs a positive semidefinite Gram matrix to take its square root. The theorem is not vacuous: $Y(e^\alpha, z)$ is a nonzero field for every α (it creates e^α from the vacuum).

Physical meaning

Mutual locality of two vertex operators is the statement that their correlators are meromorphic with only poles at coincident points, so that the operators commute (or anticommute for fermions) at separated points: $(z-w)^N[Y(e^\alpha,z),Y(e^\beta,w)] = 0$. Here the OPE gives the factor $(z-w)^{\langle\alpha,\beta\rangle}$ times a regular function, which is single-valued because $\langle\alpha,\beta\rangle \in \mathbb{Z}$; the Klein factors ε cancel the sign $(-1)^{\langle\alpha,\beta\rangle}$ from exchanging the operators so that e^α and e^β are genuinely bosonic. This is the key compatibility condition that makes the lattice theory a vertex algebra rather than a mere collection of operators.

Proof on paper. The one computation behind everything is the commutation of the two exponentials. Since $[\beta(n), \alpha(-m)] = n\langle\alpha,\beta\rangle\delta_{nm}$ is a scalar multiple of the identity, the identity $e^A e^B = e^{[A,B]} e^B e^A$ (valid whenever $[A,B]$ is a scalar) gives

$$E^+(\beta,z_2)E^-(\alpha,z_1) = \exp\Big(-\sum_{n\geq 1}\frac{\langle\alpha,\beta\rangle}{n}\Big(\frac{z_1}{z_2}\Big)^n\Big)E^-(\alpha,z_1)E^+(\beta,z_2) = \Big(1-\frac{z_1}{z_2}\Big)^{\langle\alpha,\beta\rangle}E^-(\alpha,z_1)E^+(\beta,z_2),$$

expanded in non-negative powers of z_1/z_2. Put $P = \langle\alpha,\beta\rangle$ and act on $p\otimes e^\gamma$. Using bimultiplicativity of ε,

$$Y(e^\alpha,z_1)Y(e^\beta,z_2)(p\otimes e^\gamma) = \varepsilon(\alpha,\beta)\varepsilon(\alpha,\gamma)\varepsilon(\beta,\gamma)\, z_1^{\langle\alpha,\gamma\rangle} z_2^{\langle\beta,\gamma\rangle}\,(z_1-z_2)^P\ \mathcal{N}\ p\otimes e^{\alpha+\beta+\gamma},$$
$$Y(e^\beta,z_2)Y(e^\alpha,z_1)(p\otimes e^\gamma) = \varepsilon(\beta,\alpha)\varepsilon(\alpha,\gamma)\varepsilon(\beta,\gamma)\, z_1^{\langle\alpha,\gamma\rangle} z_2^{\langle\beta,\gamma\rangle}\,(z_2-z_1)^P\ \mathcal{N}\ p\otimes e^{\alpha+\beta+\gamma},$$

where $\mathcal{N} = E^-(\alpha,z_1)E^-(\beta,z_2)E^+(\alpha,z_1)E^+(\beta,z_2)$ is symmetric under the exchange, $(z_1-z_2)^P$ is expanded in $|z_1| > |z_2|$ and $(z_2-z_1)^P$ in $|z_2| > |z_1|$. By the commutator property $\varepsilon(\alpha,\beta) = (-1)^P\varepsilon(\beta,\alpha)$, and $(z_2-z_1)^P = (-1)^P(z_1-z_2)^P$ formally. Two cases:

- $P \geq 0$: $(z_1-z_2)^P$ is a polynomial, both expansions agree, the two signs cancel and the commutator is *exactly zero* ($N = 0$).
- $P < 0$: the two expansions of $(z_1-z_2)^P$ differ, but after multiplication by $(z_1-z_2)^{-P}$ both become 1; hence $(z_1-z_2)^{-P}[Y(e^\alpha,z_1),Y(e^\beta,z_2)] = 0$.

In the second case one also needs that multiplying the formal expansions by $(z_1-z_2)^{-P}$ interacts correctly with the infinite sums, which is a finite bookkeeping on each vector because $Y(e^\alpha,z)$ is a field (`Yeαvec_isField`). The two cases are the files `LatticeGenSameSign*.lean` and `LatticeGenOpp*.lean`. □

What the machine verified

Proved, conditional on `hEven`, `hPos`; part of the closure of `latYfullGen_of_locality`, whose axioms are the standard three.

Trap / dead end

Without the cocycle the same computation gives $[Y(e^\alpha,z_1),Y(e^\beta,z_2)]\neq 0$ whenever P is odd and ≥ 0: the fields *anticommute*. The rank-1 lattice A_1 was built earlier in the library with $\varepsilon\equiv 1$ (`VOA/Examples/LatticeA1*.lean`); this is correct only because all pairings in A_1 are even. The general construction must not be specialised to $\varepsilon\equiv 1$ for, e.g., A_2 or the Leech lattice, where odd pairings occur.

The currents are local with each other ($N = 2$) and with each $Y(e^\beta,z)$ (`genFieldLatGen_local_Yeαvec`); the latter is the statement $[h_a(m),Y(e^\beta,z)]=\beta_a^\perp z^m Y(e^\beta,z)$ in disguise, i.e. (z_1-z_2) kills the commutator.

31.9 Reconstruction from locality and the instance V_L

31.9.1 The strategy

The textbook definition of $Y(v,z)$ for a general state $v=h_{a_1}(-i_1-1)\cdots h_{a_s}(-i_s-1)e^\alpha$ is

$$Y(v,z)=\,:\partial^{(i_1)}h_{a_1}(z)\cdots\partial^{(i_s)}h_{a_s}(z)\,Y(e^\alpha,z):, \tag{31.13}$$

after which one must check all vertex algebra axioms, notably the Jacobi identity or locality for *every* pair of states. The library instead uses the *reconstruction theorem* (Kac's "existence theorem"): it is enough to have a family of mutually local fields whose creation states span, together with a translation operator T for which the fields are covariant. Then a unique vertex map exists on the whole space and satisfies creation, locality and covariance.

Definition 31.23 (Translation covariance)**.** A formal distribution a is T-covariant if $[T,a(z)]=\partial_z a(z)$. (This is the infinitesimal form of translation invariance $e^{wT}a(z)e^{-wT}=a(z+w)$; in a vertex operator algebra $T=L_{-1}$.) In the z-exponent indexing: $[T,a_m]=(m+1)a_{m+1}$ for the z^m-coefficient a_m.

File `VOA/Core/ReconstructionExistence.lean`.

```
def DCovariant (T : End ℂ V) (a : FormalDist (End ℂ V)) : Prop :=
  ∀ m : ℤ, T * a m - a m * T = ((m + 1 : ℤ)) • a (m + 1)
```

Physical meaning

The operator $T=L_{-1}$ generates translations in the plane coordinate z, and $[T,a(z)]=\partial_z a(z)$ is the statement that $a(z)$ is a local field, whose position dependence is generated by T. In the radial picture $e^{wT}a(z)e^{-wT}=a(z+w)$ is just translation covariance of a quantum field. In a CFT this holds for every field automatically once $T=L_{-1}$ is the stress-tensor mode; here it is a hypothesis of the reconstruction theorem, imposed before a conformal vector is available.

Theorem 31.24 (Reconstruction)**.** *Let V be a vector space with a vector $\mathbb{1}$ and $T\in\operatorname{End}V$ with $T\mathbb{1}=0$. Let $(a^i)_{i\in I}$ be fields on V and $(s_i)_{i\in I}$ vectors spanning V, such that the a^i are pairwise local, T-covariant, and $a^i(z)\mathbb{1}=s_i+O(z)$ (i.e. the z^0-coefficient on the vacuum is s_i and negative powers vanish). Then there is a linear map $Y:V\to\operatorname{End}(V)[[z^{\pm1}]]$ with $Y(s_i)=a^i$ for all i, every $Y(u)$ a field, $Y(u),Y(v)$ local, $Y(u,z)\mathbb{1}=u+O(z)$ and $Y(u)$ T-covariant, for all u,v.*

```

      (∀ u v : V, Local (YA u) (YA v)) ∧
      (∀ u : V, (YA u) 0 vac = u) ∧
      (∀ u : V, ∀ q : ℤ, q < 0 → (YA u) q vac = 0) ∧
      (∀ u : V, DCovariant T (YA u))
```

(`VOA/Core/ReconstructionExistence.lean`; treated in full as Theorem 4.41.)

From the mathematics to the Lean statement

`(fld i) 0 vac` is the coefficient of z^0, i.e. the mode $(\cdot)_{(-1)}$, applied to the vacuum; `(fld i) q vac = 0` for $q < 0$ says the modes $(\cdot)_{(n)}$, $n \geq 0$, kill the vacuum. So `hcre0`/`hcreneg` are the creation property. `Submodule.span ℂ (Set.range st) = ⊤` says the s_i span V (`⊤` is the whole space). Note that the family `st` need not be linearly independent: the content of the theorem is precisely that if a linear relation $\sum c_i s_i = 0$ holds, then $\sum c_i a^i = 0$, so that Y is well defined. This is Goddard's uniqueness principle: a field local with all the a^i that kills the vacuum (together with all its T-derivatives) is zero.

Physical meaning

This is the algebraic form of the bootstrap principle: a family of mutually local fields $a^i(z)$ that are translation covariant, together with the states $s_i = a^i(0)\mathbb{1}$ they create, determines the whole space of local operators, namely all normal-ordered products of derivatives of the generating fields, with the OPEs fixed. Physically it is the state–operator correspondence run in reverse: from a few generating fields (the currents ∂X and the vertex operators $e^{i\alpha\cdot X}$) one builds all local operators of the theory. The proof is combinatorial and does not use physical input.

Proof on paper. Define Y on formal combinations by $\sum c_i\delta_i \mapsto \sum c_i a^i$. If $\sum c_i s_i = 0$, the field $b = \sum c_i a^i$ is local with every a^j, T-covariant, and $b(z)\mathbb{1} = e^{zT}(\sum c_i s_i) = 0$ (the covariance plus $T\mathbb{1} = 0$ forces $b(z)\mathbb{1} = e^{zT}b_0\mathbb{1}$). By locality, $(z_1 - z_2)^N b(z_1)a^j(z_2)\mathbb{1} = (z_1 - z_2)^N a^j(z_2)b(z_1)\mathbb{1} = 0$; setting $z_2 = 0$ (allowed on the left since $a^j(z_2)\mathbb{1}$ has no negative powers) gives $z_1^N b(z_1)s_j = 0$, so b kills every s_j, hence $b = 0$. Thus Y descends to V. Locality of general $Y(u), Y(v)$ follows by bilinearity, and the remaining properties likewise. □

31.9.2 The generating family for V_L

Definition 31.25 (Word states and word fields)**.** For a list $l = [(i_1, a_1), \dots, (i_s, a_s)]$ and $\alpha \in L$, the word state is $h_{a_1}(-i_1 - 1)\cdots h_{a_s}(-i_s - 1)e^{\alpha}$ and the word field is the right-nested normal ordered product (31.13).

File `VOA/Examples/LatticeGenWordFields.lean`.

```
noncomputable def wordStateLatGen : List (ℕ × Fin (rank L)) → L.carrier → LatModuleGen L
  | [], α => latChargeGen L α
  | (ia :: rest), α =>
      LinearMap.rTensor (L.carrier →₀ ℂ) (currentN (rank L) 1 ia.2 ia.1) (wordStateLatGen
       ↪ rest α)
```

```
noncomputable def YwordLatGenF (α : L.carrier) :
    List (ℕ × Fin (rank L)) → { f : FormalDist (End ℂ (LatModuleGen L)) // IsField f }
  | [] => ⟨Yeαvec L α, Yeαvec_isField L α⟩
  | (ia :: rest) =>
      let p := YwordLatGenF α rest
      ⟨nprod (genFieldLatGen_isField L ia.2 ia.1) p.2,
        (genFieldLatGen_isField L ia.2 ia.1).nprod p.2⟩

noncomputable def YwordLatGen (l : List (ℕ × Fin (rank L))) (α : L.carrier) :
    FormalDist (End ℂ (LatModuleGen L)) := (YwordLatGenF L α l).1
```

From the mathematics to the Lean statement

`currentN (rank L) 1 a i` is the z^i-coefficient of the current, i.e. $h_a(-i-1)$, which on the Fock factor is multiplication by $X_{(i,a)}$; so the word state is as stated. The subtype `\{f // IsField f\}` carries the proof that each partial product is a field, which `nprod` requires. The word states span V_L, because the monomials span $\mathcal{F}$: File `VOA/Examples/LatticeGenWordFields.lean`.

```
theorem wordStateLatGen_span :
    Submodule.span ℂ (Set.range (Function.uncurry (wordStateLatGen L))) = ⊤
```

Physical meaning

A word state $h_{a_1}(-i_1-1)\cdots h_{a_s}(-i_s-1)e^{\alpha}$ is a multi-oscillator excitation above the charged ground state e^{α}: its image under the state–operator map is the normal-ordered product $:\partial^{i_1}J^{a_1}\cdots\partial^{i_s}J^{a_s}\,e^{i\alpha\cdot X}:$ of derivatives of the currents with the vertex operator, which is how every local operator of the compact boson is written. The right-nested normal ordering is the standard prescription for defining a composite operator without ambiguity. These words span V_L, so these fields exhaust the local operators.

The translation operator must be chosen before any conformal vector is available. It is $T = L_{-1}$, which on V_L is the Fock L_{-1} plus the cross term between $h_a(-1)$ and the momentum $h_a(0)$:

```
noncomputable def momGen : End ℂ (LatModuleGen L) :=
  ∑ a : Fin (rank L), (LinearMap.rTensor (L.carrier →₀ ℂ) (oscN (rank L) 1 a (-1))) *
   ↪ zGradeOpGen L a

noncomputable def TrecGen : End ℂ (LatModuleGen L) :=
  LinearMap.rTensor (L.carrier →₀ ℂ) (HeisenbergN.LvirN (rank L) 1 (-1)) + momGen L
```

(`VOA/Examples/LatticeGenTranslation.lean`.) On paper, $L_{-1} = \frac{1}{2}\sum_a\sum_j :h_a(-1-j)h_a(j):$; the two terms with $\{j,-1-j\} = \{0,-1\}$ give $h_a(-1)h_a(0)$, the remaining terms are the Fock L_{-1} (where $h_a(0) = 0$). Covariance $[T, Y(e^{\beta},z)] = \partial_z Y(e^{\beta},z)$ (`TrecGen_Yeαvec_DCovariant`) is the identity $\partial_z Y(e^{\beta},z) = :\beta(z)Y(e^{\beta},z):$ in disguise: the derivative of $z^{\beta(0)}E^-E^+$ produces $\beta(0)z^{-1}$ and the creation and annihilation parts of $\beta(z)$.

Theorem 31.26 (The reconstructed vertex map). *Let L be even and positive-definite. There is a linear map $Y : V_L \to \mathrm{End}(V_L)[[z^{\pm1}]]$ which equals (31.13) on every word state and is a local, T-covariant field map with the creation property.*

```
theorem latYfullGen_of_locality (hEven : L.Even) (hPos : L.PosDef) :
    ∃ Yfull : LatModuleGen L →ₗ[ℂ] FormalDist (End ℂ (LatModuleGen L)),

      (∀ u : LatModuleGen L, Reconstruction.DCovariant (TrecGen L) (Yfull u))

noncomputable def YfullGen (hEven : L.Even) (hPos : L.PosDef) :
    LatModuleGen L →ₗ[ℂ] FormalDist (End ℂ (LatModuleGen L)) :=
  (latYfullGen_of_locality L hEven hPos).choose
```

(`VOA/Examples/LatticeGenWordFields.lean`, `LatticeGenVOAInstance.lean`.)

From the mathematics to the Lean statement

`Function.uncurry f (l, α)` $= f\,l\,\alpha$; the first conjunct says that Y of every word state is the corresponding word field. `YfullGen` is defined by `.choose`, i.e. it is *some* map with these properties. Could a bad choice be made? No: the first conjunct fixes Y on a spanning set, and Y is linear, so the map is unique. Hence `YfullGen` is the textbook vertex map (31.13), not merely a map with the listed properties. In particular $Y(e^{\alpha}, z)$ is `Yeαvec L α` (the empty word).

Physical meaning

This theorem constructs the operator–state correspondence of the compactified boson: every state of V_L is assigned a field $Y(u,z)$, with the generating fields being the currents $J^a(z)$ and the exponentials $:e^{i\alpha\cdot X}:$, and the assignment is local, translation covariant, and sends u to u on the vacuum. It does so by applying the reconstruction theorem to the oscillator currents and charged vertex operators, whose mutual locality was established in Theorem 31.22. It is the technical heart of the lattice construction; physically it records that the set of vertex operators of the compact boson closes under OPE.

Proof on paper. Apply Theorem 31.24 with index set $I = \{\text{lists}\}\times L$. Mutual locality of the word fields follows from Theorem 31.22, the locality of the currents with each other and with the $Y(e^{\beta})$, and Dong's lemma (normal-ordered products of pairwise local fields are local with the same partners), by induction on the words. T-covariance of the word fields follows from covariance of the generators, since T-covariance is preserved by derivatives and normal-ordered products. The creation property of a word field on the vacuum is the statement that normal-ordered products create products of states: $(:ab:)(z)\mathbb{1}|_{z=0} = a_{(-1)}b_{(-1)}\mathbb{1}$. □

What the machine verified

Proved, conditional only on `hEven` and `hPos`; `#print axioms latYfullGen_of_locality` = `[propext, Classical.choice, Quot.sound]`. No use of `VOA.pbw`.

31.9.3 The conformal layer and the instance

The conformal vector is $\omega = \frac{1}{2}\sum_a h_a(-1)^2\mathbb{1}$, i.e. the Heisenberg conformal vector at level 1 placed in the momentum-zero sector: File `VOA/Examples/LatticeGenConformal.lean`.

```
noncomputable def omegaLatGen : LatModuleGen L := mkEα L 0 (HeisenbergN.ωN (rank L) 1)
```

If $h'_b = \sum_a Q_{ba}h_a$ with $Q^TQ = 1$, then $\sum_b h'_b(-1)^2 = \sum_{a,a'}(Q^TQ)_{aa'}h_a(-1)h_{a'}(-1) = \sum_a h_a(-1)^2$; so ω does not depend on which orthonormal frame is used. This is used in functoriality (`fockMap_ωN`). The library then proves the four conformal axioms: Files `VOA/Examples/LatticeGenVirasoro.lean`, `VOA/Examples/LatticeGenL0Translation.lean`, `VOA/Examples/LatticeGenGradedField.lean`.

```
theorem YfullGen_virasoro (hEven : L.Even) (hPos : L.PosDef) (m n : ℤ) :
    ⁅mode (YfullGen L hEven hPos (omegaLatGen L)) (m + 1),

theorem YfullGen_translation_omega (hEven : L.Even) (hPos : L.PosDef) (v : LatModuleGen L)
 ↪  :
    YfullGen L hEven hPos (mode (YfullGen L hEven hPos (omegaLatGen L)) 0 v)
      = deriv (YfullGen L hEven hPos v)
theorem YfullGen_grading_mode (hEven : L.Even) (hPos : L.PosDef) {p q : ℤ} (u :
 ↪  LatModuleGen L)
    (hu : u ∈ gradingLatGen L p) (v : LatModuleGen L) (hv : v ∈ gradingLatGen L q) (j : ℤ)
     ↪  :
    mode (YfullGen L hEven hPos u) j v ∈ gradingLatGen L (p + q - j - 1)
```

On paper: $Y(\omega,z)=\frac12\sum_a :h_a(z)^2:$ is the Sugawara field of the r currents including zero modes; on the sector $\mathcal{F}\otimes e^{\gamma}$ one has $L_0=L_0^{\mathrm{Fock}}+\frac12\langle\gamma,\gamma\rangle$, which gives the grading, and the Virasoro relation with $c=r$ is the Heisenberg one (Theorem 31.7) with the zero modes absorbed into $(m-n)L_{m+n}$. The grading law $\mathrm{wt}(u_{(j)}v)=\mathrm{wt}\,u+\mathrm{wt}\,v-j-1$ follows from the fact that $Y(e^{\alpha},z)$ is homogeneous of weight $\frac12\langle\alpha,\alpha\rangle$, via $\frac12|\alpha+\beta|^2=\frac12|\alpha|^2+\frac12|\beta|^2+\langle\alpha,\beta\rangle$ (which uses evenness).

Theorem 31.27 (The lattice vertex operator algebra). *For every even positive-definite lattice L of rank r, V_L with the vertex map of Theorem 31.26, vacuum $1\otimes e^0$, conformal vector $\omega=\frac12\sum_a h_a(-1)^2\mathbb{1}$ and the grading of Definition 31.18 is a vertex operator algebra of CFT type with central charge r.*

```

(VOA/Examples/LatticeGenInstance.lean.)

From the mathematics to the Lean statement

Every field of the structure is filled by a theorem stated above, and every one of those has only `hEven` and `hPos` as hypotheses. The vacuum field axiom `vacuum_Y` is $Y(\mathbb{1}, z) = \mathrm{id}$, which here reduces to $Y(e^0, z) = E^-(0,z)E^+(0,z) = \mathrm{id}$ (the Schur polynomials of the zero charge vanish in positive degree). As for the Heisenberg algebra, `latticeVOAGen_centralCharge` is `rfl`, but non-vacuous because the field `virasoro` is proved with exactly this value. A referee should also note what the instance does *not* contain: no Jacobi identity is listed, because in this library's axiomatics (Theorem 4.51) locality plus the other axioms imply it.

Physical meaning

This is the Frenkel–Lepowsky–Meurman construction: the lattice VOA V_L is the chiral algebra of r bosons compactified on the torus $\mathbb{R}^r/2\pi L^*$, with $c = r$ from the free-boson Virasoro algebra and states of conformal weight $h = \frac{1}{2}\langle\alpha,\alpha\rangle +$ oscillator level. Its character is $\theta_L(\tau)/\eta(\tau)^r$ with $\theta_L = \sum_{\alpha\in L} q^{\langle\alpha,\alpha\rangle/2}$, so for a unimodular L it is (after the $q^{-c/24}$ shift) modular invariant up to a phase; for a general even lattice V_L is a holomorphic CFT only when L is unimodular. Weight-one states from norm-2 vectors enhance the $U(1)^r$ current algebra to a simply-laced Lie algebra (Frenkel–Kac), the stringy origin of enhanced gauge symmetry at special radii.

What the machine verified

Proved, conditional only on `hEven`, `hPos`; `#print axioms latticeVOAGen = [propext, Classical.choice, Quot.sound]`; `VOA.pbw` not used.

31.10 The Leech lattice vertex operator algebra

31.10.1 Importing the Leech lattice

The Leech lattice Λ is constructed in the vendored library `VOA/LatticesAndCodes` (a formalisation of Ebeling's *Lattices and Codes*; see Chapter 30) from the extended binary Golay code, and proved there to be even, positive-definite, unimodular, of rank 24 and without roots. That library has its own type `_root_.IntegralLattice`; the bridge to the vertex-algebra notion is a field-by-field repackaging:

```
noncomputable def ofEbeling (Γ : _root_.IntegralLattice) : VOA.IntegralLattice.{0} where
  carrier := Γ.carrier
  form := Γ.bilin
  isSymm := ⟨fun x y => Γ.bilin_symm x y⟩

theorem ofEbeling_even (h : Γ.IsEven) : (ofEbeling Γ).Even := fun v => h v
theorem ofEbeling_posDef (h : Γ.IsPosDef) : (ofEbeling Γ).PosDef := fun v hv => h v hv
theorem ofEbeling_rank : rank (ofEbeling Γ) = Γ.rank := rfl

noncomputable abbrev leech : VOA.IntegralLattice.{0} := ofEbeling Leech.lattice

theorem leech_even : leech.Even := ofEbeling_even _ Leech.lattice_isEven
theorem leech_posDef : leech.PosDef := ofEbeling_posDef _ Leech.lattice_isPosDef
theorem leech_rank : rank leech = 24 := Leech.lattice_rank
theorem leech_no_roots (v : leech.carrier) : leech.form v v ≠ 2 := Leech.lattice_no_roots v
```

(`VOA/Moonshine/LeechLatticeVOA.lean`.)

From the mathematics to the Lean statement

The proofs `fun v ⇒ h v` show that evenness and positive-definiteness are *the same predicates* in both libraries, so nothing is lost or reinterpreted in the transfer; rank is even preserved by `rfl`. The four Leech facts `Leech.lattice_isEven`, `Leech.lattice_isPosDef`, `Leech.lattice_rank`, `Leech.lattice_no_roots` are theorems of the vendored library (Chapter 30 gives their statements and checks that `Leech.lattice` is the Leech lattice, i.e. the definition is not some other lattice that happens to satisfy these properties; by Conway's uniqueness theorem, which is *not* formalised, these four properties together with unimodularity characterise Λ up to isometry). The universe annotation `.{0}` only fixes the size of the type.

Definition 31.28 (The Leech lattice vertex operator algebra). V_Λ is the lattice vertex operator algebra of Theorem 31.27 for $L = \Lambda$.

```
noncomputable def leechVOA : VertexOperatorAlgebra (LatGen.LatModuleGen leech) :=
  LatGen.latticeVOAGen leech leech_even leech_posDef

theorem leechVOA_centralCharge : leechVOA.centralCharge = 24 := by
  rw [leechVOA, LatGen.latticeVOAGen_centralCharge, leech_rank]; norm_num
```

Physical meaning

This is the chiral algebra of the $c = 24$ bosonic string compactified on the Leech torus $\mathbb{R}^{24}/\Lambda_{\text{Leech}}$ (heuristically, the left-moving sector of the 24-dimensional torus at the Leech point). The Leech lattice is even unimodular of rank 24 with no vectors of norm 2, so no momentum state has weight one and there is no enhanced gauge symmetry: the only currents are the 24 abelian oscillator currents ∂X^a, and the partition function is $\theta_\Lambda/\eta^{24} = j(\tau) - 744 + 24$ (the 24 counting the weight-one space). The theory is a holomorphic CFT of central charge 24 and is the starting point for the orbifold construction of the Monster module $V^\natural$.

31.10.2 The weight-one space

Theorem 31.29 (Rootless lattices have abelian weight-one space). *If L is even, positive-definite and has no vectors of norm 2, then $(V_L)_1 = \mathcal{F}_1 \otimes e^0 = \operatorname{span}\{h_a(-1)\mathbb{1}\}$. In particular $\dim(V_\Lambda)_1 = 24$.*

```
theorem gradingLatGen_one_of_rootless (hEven : L.Even) (hPos : L.PosDef)
    (hR : ∀ v : L.carrier, L.form v v ≠ 2) :
    gradingLatGen L 1 = bigradα L (1, 0)

theorem leechVOA_grading_one :
    leechVOA.grading 1 = LatGen.bigradα leech (1, 0) :=
  LatGen.gradingLatGen_one_of_rootless leech leech_even leech_posDef leech_no_roots
```

From the mathematics to the Lean statement

`bigradα L (1, 0)` is $(\mathcal{F})_1 \otimes e^0$, the span of the states $h_a(-1)\mathbb{1}$ (Definition 31.18). The hypothesis `hR` is "no roots". The statement is an equality of submodules, so it says both inclusions; it is the precise form of the statement "V_Λ has no weight-one currents other than the Heisenberg ones". The dimension 24 is then the Fock count $\dim \mathcal{F}_1 = r$.

Physical meaning

For a rootless lattice, the weight-one states are only oscillators, because the exponentials $:e^{i\alpha\cdot X}:$ have weight $\langle\alpha,\alpha\rangle/2 \geq 2$, the minimal nonzero norm being at least 4. So the current

algebra is the abelian $U(1)^{24}$: the Leech torus compactification has no non-abelian gauge symmetry, only the 24 translations of the torus, and the dimension 24 equals the number of independent boson currents. In Niemeier language, the Leech lattice is the unique one of the 24 unimodular lattices with no roots, hence with the trivial (abelian) current algebra.

Proof on paper. A summand $(\mathcal{F})_{1-|\alpha|^2/2} \otimes e^\alpha$ with $\alpha \neq 0$ has $|\alpha|^2/2 \geq 1$ by positivity and evenness, and $|\alpha|^2/2 \neq 1$ because $|\alpha|^2 \neq 2$ (no roots), so $|\alpha|^2/2 \geq 2$ and the Fock weight is negative: the summand is zero. Only $\alpha = 0$ remains. □

What the machine verified

Proved, unconditional (all hypotheses discharged for Λ); `#print axioms of leechVOA, leechVOA_centralCharge, leechVOA_grading_one = [propext, Classical.choice, Quot.sound]`. The dimensions $\dim(V_\Lambda)_2 = 196884$ and $\dim(V_\Lambda)_3 = 21493760$ are proved elsewhere (`leechVOA_finrank_grading_two`, `leechVOA_finrank_grading_three`; Chapter 33).

Remark 31.30 (The physical meaning of V_Λ). V_Λ is the chiral algebra of 24 free bosons compactified on $\mathbb{R}^{24}/\Lambda$. Because Λ is unimodular, V_Λ is *holomorphic*, in the following sense. A vertex operator algebra V is called holomorphic if every (admissible) V-module is a direct sum of copies of the adjoint module V; for a *rational* V (one whose admissible modules are completely reducible, with finitely many irreducibles) this is the same as saying that V is its only irreducible module. For lattice vertex operator algebras this is governed by the *dual lattice* $L^* = \{\lambda \in L \otimes \mathbb{Q} : \langle \lambda, L\rangle \subseteq \mathbb{Z}\}$: by a theorem of Dong (C. Dong, "Vertex algebras associated with even lattices", *J. Algebra* 161 (1993); see also Lepowsky–Li, Chapter 6), V_L is rational and its irreducible modules are exactly the spaces $V_{L+\lambda} = \mathcal{F} \otimes \mathbb{C}[L + \lambda]$, one for each coset $\lambda + L \in L^*/L$. The lattice is unimodular precisely when $L^* = L$ (Chapter 30), so then V_L itself is the only irreducible module and V_L is holomorphic. *Neither Dong's classification nor the holomorphy of V_Λ is proved in the library*; nothing in the Moonshine construction depends on them, and they are mentioned here only to explain the picture. Because Λ has no roots, the 24 currents do not enhance to a non-abelian affine algebra. Its character is $q^{-1}\theta_\Lambda(q)/\eta(q)^{24} = J(q) + 24$, so it differs from the Moonshine module only by the 24 states $h_a(-1)\mathbb{1}$; removing them is the purpose of the $\mathbb{Z}/2$-orbifold of Chapters 32–38.

31.11 Sign automorphisms g_χ

31.11.1 The involution θ, recalled

The automorphism θ of V_L lifting $-1 \in O(L)$ is the subject of Chapter 32; we need its definition because the theorems below mention it. Let σ be the algebra automorphism of the Fock space that negates every variable, $\sigma(X_{(i,a)}) = -X_{(i,a)}$; on a monomial of degree d it acts by $(-1)^d$. The reason: $-1 \in O(L)$ acts on $\mathfrak{h} = L \otimes \mathbb{C}$ by $h \mapsto -h$, hence on the Heisenberg algebra by $h(n) \mapsto -h(n)$, and the induced action on the Fock space sends $h_{a_1}(-n_1)\cdots h_{a_d}(-n_d)\mathbb{1}$ to $(-1)^d$ times itself, i.e. negates every variable. Then $\theta(p \otimes e^\alpha) = \sigma(p) \otimes e^{-\alpha}$.

```
noncomputable def sigmaAlg : FockN r →ₐ[ℂ] FockN r := MvPolynomial.aeval (fun v => -(X v :
 ↪  FockN r))

noncomputable def sigmaN : FockN r ≃ₗ[ℂ] FockN r :=
  LinearEquiv.ofInvolutive (sigmaAlg r).toLinearMap (sigmaAlg_involutive r)

noncomputable def thetaLat : LatModuleGen L ≃ₗ[ℂ] LatModuleGen L :=
  TensorProduct.congr (sigmaN (rank L)) (Finsupp.domLCongr (Equiv.neg L.carrier))
```

```
theorem thetaLat_latStateGen (p : FockN (rank L)) (α : L.carrier) :
    thetaLat L (latStateGen L p α) = latStateGen L (sigmaN (rank L) p) (-α)
```

(`VOA/Moonshine/LatticeInvolution.lean`.) `aeval f` is the algebra map determined by sending each variable v to $f(v)$; `Finsupp.domLCongr (Equiv.neg _)` relabels $e^{\alpha} \mapsto e^{-\alpha}$. Chapter 32 proves that θ is an automorphism, `thetaAut : Aut (latticeVOAGen L hEven hPos)`; this uses $\varepsilon(-\alpha,-\beta) = \varepsilon(\alpha,\beta)$ (Remark 31.13).

31.11.2 The sign operator

Definition 31.31 (Sign automorphism). Let $\chi : L \to \mathbb{Z}/2$ be a group homomorphism. Define $g_\chi(p \otimes e^{\alpha}) = (-1)^{\chi(\alpha)} p \otimes e^{\alpha}$.

```
noncomputable def sgn (z : ZMod 2) : ℂ := (-1 : ℂ) ^ z.val

noncomputable def chiSign (α : L.carrier) : ℂ := VOA.Moonshine.Extraspecial.sgn (χ α)

noncomputable def chiGroupMap : (L.carrier →₀ ℂ) →ₗ[ℂ] (L.carrier →₀ ℂ) :=
  Finsupp.linearCombination ℂ (fun α => chiSign L χ α • eGen L α)

noncomputable def chiGroupEquiv : (L.carrier →₀ ℂ) ≃ₗ[ℂ] (L.carrier →₀ ℂ) :=
  LinearEquiv.ofInvolutive (chiGroupMap L χ) (chiGroupMap_involutive L χ)

noncomputable def chiLat : LatModuleGen L ≃ₗ[ℂ] LatModuleGen L :=
  TensorProduct.congr (LinearEquiv.refl ℂ (FockN (rank L))) (chiGroupEquiv L χ)

theorem chiLat_latStateGen (p : FockN (rank L)) (α : L.carrier) :
    chiLat L χ (latStateGen L p α) = chiSign L χ α • latStateGen L p α
```

(`VOA/Moonshine/FrameSign.lean`, with section variable `(χ : L.carrier →+ ZMod 2)`; `sgn` is in `VOA/Moonshine/ExtraspecialModule.lean`.)

From the mathematics to the Lean statement

`L.carrier →+ ZMod 2` is the type of additive group homomorphisms $L \to \mathbb{Z}/2$. `z.val` is the representative of $z \in \mathbb{Z}/2$ in $\{0,1\}$, so `sgn z` $= (-1)^z$. `LinearEquiv.ofInvolutive` turns a linear map f with $f \circ f = \mathrm{id}$ into a linear equivalence. `TensorProduct.congr f g` is $f \otimes g$. So `chiLat` $= \mathrm{id} \otimes g_\chi$, matching the definition; `chiLat_latStateGen` is its defining formula.

Physical meaning

The sign automorphism g_χ multiplies a momentum-α state by $(-1)^{\chi(\alpha)}$. It is the element $e^{i\pi\chi\cdot\hat{p}}$ of the target-space translation group $U(1)^r$ (a half-period shift along the torus in the direction dual to χ), and its action on the charged sectors is the standard $\mathbb{Z}/2$ phase symmetry. Sign automorphisms of this type are the ones that appear as the lifts of the frame signs in the construction of the Monster: they distinguish the momentum sectors by a parity.

Theorem 31.32 (g_χ is an automorphism of order ≤ 2 commuting with θ). *Let L be even and positive-definite and $\chi : L \to \mathbb{Z}/2$ a homomorphism. Then $g_\chi \in \mathrm{Aut}(V_L)$, $g_\chi^2 = 1$ and $g_\chi\theta = \theta g_\chi$.*

theorem chiLat_thetaLat (x : LatModuleGen L) :
    chiLat L χ (thetaLat L x) = thetaLat L (chiLat L χ x)

theorem chiAut_mul_thetaAut :
    chiAut L χ hEven hPos * thetaAut L hEven hPos = thetaAut L hEven hPos * chiAut L χ
     ↪ hEven hPos
```

From the mathematics to the Lean statement

`chiLat_mode` is the statement $g_\chi(u_{(n)}v) = (g_\chi u)_{(n)}(g_\chi v)$ for all u, n, v, the content of `map_smul'`. The product `*` in `Aut` is composition and `1` the identity. Note that $g_\chi = \mathrm{id}$ is possible (for $\chi = 0$); the theorem does not claim $g_\chi \neq 1$, and nothing downstream needs it.

Physical meaning

This is the statement that a half-shift on the torus is a symmetry of the theory: the $U(1)^r$ momentum phase $(-1)^{\chi(\alpha)}$ is a character of the momentum lattice, hence is compatible with the OPE since momentum is conserved ($\chi(\alpha+\beta) = \chi(\alpha) + \chi(\beta)$) and gives a $\mathbb{Z}/2$ symmetry of the VOA. It commutes with the lattice involution θ ($\alpha \mapsto -\alpha, X \mapsto -X$, the T-duality or reflection symmetry of the torus) because the sign is invariant under $\alpha \mapsto -\alpha$, as χ takes values in $\mathbb{Z}/2$. Such automorphisms are the orbifold data used to build new holomorphic CFTs.

Proof on paper. By the uniqueness built into the reconstruction (Theorem 31.26), it suffices to check $g_\chi Y(w,z) g_\chi^{-1} = Y(g_\chi w, z)$ on generators. The currents $h_a(z)$, including the zero mode, preserve each momentum sector, so commute with g_χ. The field $Y(e^\alpha, z)$ maps the β-sector to the $(\alpha+\beta)$-sector, so $g_\chi Y(e^\alpha, z) = (-1)^{\chi(\alpha+\beta)-\chi(\beta)} Y(e^\alpha, z) g_\chi = (-1)^{\chi(\alpha)} Y(e^\alpha, z) g_\chi$ by additivity of χ. Normal-ordered products multiply the scalars, so $g_\chi Y_{\mathrm{word}}(l, \alpha) g_\chi^{-1} = (-1)^{\chi(\alpha)} Y_{\mathrm{word}}(l, \alpha)$, which matches $g_\chi(\text{word state}) = (-1)^{\chi(\alpha)}\text{word state}$. By linearity over the spanning word states, g_χ intertwines all vertex operators. It fixes $\mathbb{1}$ and ω, which have momentum 0. Commuting with θ: $\chi(-\alpha) = \chi(\alpha)$ in $\mathbb{Z}/2$. □

Theorem 31.33 (Eigenspaces of g_χ by momentum). *For $x \in V_L$: $g_\chi x = x$ iff every momentum component x_γ with $\chi(\gamma) \neq 0$ vanishes; $g_\chi x = -x$ iff every x_γ with $\chi(\gamma) = 0$ vanishes.*

File `VOA/Moonshine/FrameSign.lean`.

```
theorem chiLat_eq_self_iff (x : LatModuleGen L) :
    chiLat L χ x = x ↔ ∀ α, χ α ≠ 0 → coordEα L α x = 0

theorem chiLat_eq_neg_iff (x : LatModuleGen L) :
    chiLat L χ x = -x ↔ ∀ α, χ α = 0 → coordEα L α x = 0
```

From the mathematics to the Lean statement

`coordEα L α x` is the momentum-α component $x_\alpha \in \mathcal{F}$ of x (Section 31.6). Thus the fixed points of g_χ form exactly the subspace $\mathcal{F} \otimes \mathbb{C}[\ker \chi]$ (as a vector space it looks like $V_{\ker \chi}$, but no claim about the vertex algebra $V_{\ker \chi}$ is made here), and the -1 eigenspace is $\mathcal{F} \otimes \mathbb{C}[L \setminus \ker \chi]$. These are pure linear algebra (no hypotheses on L).

Physical meaning

The ± 1 eigenspaces of g_χ are the sectors of momentum with $\chi(\gamma) = 0$ and $\chi(\gamma) = 1$: the momentum lattice splits into the sublattice $\ker\chi$ of index 2 and its nontrivial coset, and $V_L = V_{\ker\chi} \oplus V_{\text{coset}}$ accordingly. In an orbifold by g_χ these are the untwisted states kept (the even sector) and removed (the odd sector); the invariant subalgebra $V_L^{g_\chi}$ is the lattice algebra $V_{\ker\chi}$ of the index-two sublattice, plus twisted sectors.

Proof on paper. Compare components: $(g_\chi x)_\alpha = (-1)^{\chi(\alpha)} x_\alpha$, and $x_\alpha = -x_\alpha$ forces $x_\alpha = 0$ in characteristic 0. A vector is determined by its components. □

What the machine verified

`chiAut`, `chiAut_sq`, `chiAut_mul_thetaAut`: proved, conditional only on `hEven`, `hPos`. `chiLat_eq_self_iff`, `chiLat_eq_neg_iff`, `chiLat_thetaLat`: proved, no hypotheses. `#print axioms` (re-checked): `[propext, Classical.choice, Quot.sound]`.

In the Moonshine construction (Chapters 39–41), g_χ for χ the character with kernel Λ_0 (an index-2 sublattice) splits V_Λ^+ into the pieces $V_0^+ \oplus V_1^+$ used by the frame/triality argument; the fact that this splitting is by automorphism eigenspaces makes the products $u_{(n)}v$ respect it for free.

31.12 Functoriality of lattice vertex operator algebras

31.12.1 The problem

An isometric embedding $\iota\colon K \to L$ of even lattices should induce a homomorphism of vertex operator algebras $V_K \to V_L$ sending $e^\alpha \mapsto e^{\iota\alpha}$ and $\alpha(-n) \mapsto (\iota\alpha)(-n)$. In the library this is not automatic, for two reasons, both coming from the choice of bases:

1. the Fock spaces of V_K and V_L are written in orthonormal oscillators relative to $\sqrt{G_K}$ and $\sqrt{G_L}$ (Section 31.5); the map on oscillators is an orthogonal matrix Q that must be computed;
2. the cocycles ε_K and $\varepsilon_L \circ (\iota \times \iota)$ are built from unrelated bases, so they differ; one must correct $e^\alpha \mapsto c(\alpha)e^{\iota\alpha}$ by a function c with $\varepsilon_L(\iota\alpha, \iota\beta)c(\alpha)c(\beta) = \varepsilon_K(\alpha,\beta)c(\alpha+\beta)$.

The files `VOA/Moonshine/LatticeMorphFock.lean`, `LatticeMorph.lean` and `LatticeMorphRigid.lean` solve both, and the solution of the second contains a genuine design point: the correction c must be allowed to take values in the fourth roots of unity.

31.12.2 Orthogonal change of oscillator variables

Definition 31.34. For a complex $s \times r$ matrix Q, let $\varphi_Q : \mathcal{F}_r \to \mathcal{F}_s$ be the algebra homomorphism with $\varphi_Q(X_{(k,a)}) = \sum_b Q_{ba} X_{(k,b)}$ (the same matrix at every mode level k).

```
noncomputable def fockMap : FockN r →ₐ[ℂ] FockN s :=
  MvPolynomial.aeval (fun v : ℕ × Fin r => ∑ b : Fin s, Q b v.2 • (X (v.1, b) : FockN s))

theorem fockMap_oscN (hQ : Qᵀ * Q = 1) (k : ℂ) (a : Fin r) (n : ℤ) (p : FockN r) :
    fockMap Q (oscN r k a n p) = ∑ b : Fin s, Q b a • oscN s k b n (fockMap Q p)

theorem fockMap_ωN (hQ' : Q * Qᵀ = 1) : fockMap Q (ωN r 1) = ωN s 1
```

From the mathematics to the Lean statement

`Qᵀ * Q = 1` says the columns of Q are orthonormal for the *bilinear* (not Hermitian) dot product; this is what preserves $[h_a(m), h_b(n)] = m\delta_{ab}\delta_{m+n,0}$. It is needed only for annihilators (chain rule: $\partial_{X_{(k,b)}}\varphi_Q = \sum_a Q_{ba}\varphi_Q\partial_{X_{(k,a)}}$ requires $Q^TQ = 1$ to invert). `Q * Qᵀ = 1` (rows orthonormal) is needed for $\varphi_Q(\omega) = \omega$, since $\sum_a(\sum_b Q_{ba}X_b)^2 = \sum_{b,b'}(QQ^T)_{bb'}X_bX_{b'}$. When $s > r$, only the first holds; this is why a smaller-rank embedding does not send ω to ω (we say such a homomorphism is not *conformal*).

Physical meaning

An isometry $\iota : K \to L$ of lattices, written in orthonormal coordinates, is an $r \times s$ real matrix Q acting on the boson fields: it is a rotation or embedding of the target space (a linear change of the fields $X^a \mapsto Q^a_b X^b$). The map φ_Q is the induced action on the oscillator Fock space, applying the same linear map to every mode α_{-n} because the current is a single vector-valued field. This is how a symmetry or inclusion of target tori acts on the free-field oscillators.

The matrix attached to an isometry is $Q = \sqrt{G_L}\,M_\iota\,\sqrt{G_K}^{-1}$, where M_ι is the integer matrix of ι in the chosen bases:

```
noncomputable def latMatrix (ι : K.carrier →ₗ[ℤ] L.carrier) :
    Matrix (Fin (latRank L)) (Fin (latRank K)) ℝ :=
  Matrix.of fun j i => coordR L (ι (latticeBasis K i)) j

noncomputable def frameMatrix (ι : K.carrier →ₗ[ℤ] L.carrier) :
    Matrix (Fin (latRank L)) (Fin (latRank K)) ℝ :=
  frame L * latMatrix K L ι * (frame K)⁻¹

noncomputable def oscMatrix (ι : K.carrier →ₗ[ℤ] L.carrier) :
    Matrix (Fin (rank L)) (Fin (rank K)) ℂ :=
  ((frameMatrix K L ι).map Complex.ofRealHom).submatrix (rankEquiv L) (rankEquiv K)

theorem oscMatrix_chargeCoord (hK : K.PosDef) (ι : K.carrier →ₗ[ℤ] L.carrier) (α :
↪  K.carrier) :
    oscMatrix K L ι *ᵥ chargeCoord K α = chargeCoord L (ι α)

theorem oscMatrix_transpose_mul (hK : K.PosDef) (hL : L.PosDef)
    (ι : K.carrier →ₗ[ℤ] L.carrier) (hι : ∀ α β, L.form (ι α) (ι β) = K.form α β) :
    (oscMatrix K L ι)ᵀ * oscMatrix K L ι = 1

theorem oscMatrix_mul_transpose (hK : K.PosDef) (hL : L.PosDef)
    (ι : K.carrier →ₗ[ℤ] L.carrier) (hι : ∀ α β, L.form (ι α) (ι β) = K.form α β)
    (hr : rank K = rank L) :
    oscMatrix K L ι * (oscMatrix K L ι)ᵀ = 1
```

From the mathematics to the Lean statement

`K.carrier →ₗ[ℤ] L.carrier` is a $\mathbb{Z}$-linear map; the hypothesis `hι` says it is an isometry, $\langle\iota\alpha, \iota\beta\rangle_L = \langle\alpha,\beta\rangle_K$ (isometries of positive-definite lattices are automatically injective, `isometry_injective`). `oscMatrix_chargeCoord` says $Q\alpha^\perp = (\iota\alpha)^\perp$, i.e. φ_Q sends $\alpha(-n)$ to $(\iota\alpha)(-n)$. $Q^TQ = \sqrt{G_K}^{-1}M_\iota^T G_L M_\iota \sqrt{G_K}^{-1} = \sqrt{G_K}^{-1}G_K\sqrt{G_K}^{-1} = 1$ because $M_\iota^T G_L M_\iota = G_K$ is the isometry property in coordinates; with equal ranks a one-sided inverse is two-sided.

(A module docstring of `LatticeMorphFock.lean` mentions a declaration `LatGen.exists_fockMatrix`; no declaration of that name exists. Its content is realised by `oscMatrix` and the three lemmas above.)

31.12.3 Comparing two cocycles: the coboundary lemma

Lemma 31.35 (Coboundary lemma). *Let M be a free $\mathbb{Z}$-module with basis $(B_i)_{i<n}$ and $D : M\times M \to \mathbb{Z}$ bilinear with $D(x,y)+D(y,x)$ even for all x,y. Let S be the symmetric bilinear form with matrix $S_{ij} = D(B_i,B_j)$ for $i \le j$ and $S_{ij} = D(B_j,B_i)$ for $i > j$, and let $c(\alpha) = i^{S(\alpha,\alpha)}$. Then $c(0) = 1$, $c(-\alpha) = c(\alpha)$, $c(\alpha) \neq 0$ and*

$$c(\alpha+\beta) = c(\alpha)\,c(\beta)\,(-1)^{D(\alpha,\beta)}. \tag{31.14}$$

```
noncomputable def symMatrix : Matrix (Fin n) (Fin n) ℤ :=
  fun i j => if i ≤ j then D (B i) (B j) else D (B j) (B i)

noncomputable def symForm : M →ₗ[ℤ] M →ₗ[ℤ] ℤ := Matrix.toLinearMap₂ B B (symMatrix B D)

noncomputable def cobSign (α : M) : ℂ := Complex.I ^ (symForm B D α α)

theorem cobSign_zero : cobSign B D 0 = 1
theorem cobSign_neg (α : M) : cobSign B D (-α) = cobSign B D α
theorem cobSign_add (hD : ∀ x y, 2 ∣ D x y + D y x) (α β : M) :
    cobSign B D (α + β) = cobSign B D α * cobSign B D β * (-1 : ℂ) ^ (D α β)
```

From the mathematics to the Lean statement

`Complex.I` is $i = \sqrt{-1}$ and `Complex.I ^ (k : ℤ)` its integer power, so c takes values in $\{1, i, -1, -i\}$. `Matrix.toLinearMap₂ B B S` is the bilinear form with matrix S in the basis B. (The module docstring of `LatticeMorphFock.lean` describes c as "±1-valued" with exponent $\sum_i D_{ii}a_i(a_i-1) + 2\sum_{i<j} D_{ij}a_ia_j$; that description is stale. The code, which is what the theorems are about, uses $S(\alpha,\alpha) = \sum_i D_{ii}a_i^2 + 2\sum_{i<j} D_{ij}a_ia_j$ and is genuinely $\mathbb{Z}/4$-valued; see Remark 31.37.)

Physical meaning

This lemma is a purely arithmetic statement: the quadratic function $c(\alpha) = i^{S(\alpha,\alpha)}$ is a coboundary that converts a bilinear $\mathbb{Z}/2$-cocycle with symmetric part $D+D^T$ into a trivial one, so that two cocycle choices differ by a function c. In the physics of Klein factors, it says that the ambiguity in the sign conventions ε can be absorbed by a redefinition of the momentum states $e^\alpha \mapsto c(\alpha)e^\alpha$, i.e. it is a gauge transformation. It is the technical ingredient in the next theorem.

Proof on paper. $S(\alpha+\beta,\alpha+\beta) = S(\alpha,\alpha)+S(\beta,\beta)+2S(\alpha,\beta)$ by symmetry, and $i^{2S(\alpha,\beta)} = (-1)^{S(\alpha,\beta)}$. It remains to see $S(\alpha,\beta) \equiv D(\alpha,\beta) \pmod 2$: the matrices differ only below the diagonal, by $D(B_j,B_i) - D(B_i,B_j) \equiv D(B_j,B_i) + D(B_i,B_j) \equiv 0$. Finally $S(-\alpha,-\alpha) = S(\alpha,\alpha)$ gives $c(-\alpha) = c(\alpha)$. □

Apply this to the discrepancy between the two cocycle exponents:

```
noncomputable def cocForm : L.carrier →ₗ[ℤ] L.carrier →ₗ[ℤ] ℤ := ...   -- cocExp as a
↪  bilinear map

noncomputable def cocDiff (ι : K.carrier →ₗ[ℤ] L.carrier) : K.carrier →ₗ[ℤ] K.carrier →ₗ[ℤ]
↪  ℤ :=
  (cocForm L).compl₁₂ ι ι - cocForm K

theorem cocDiff_symm_even (hK : K.Even) (hL : L.Even) (ι : K.carrier →ₗ[ℤ] L.carrier)
    (hι : ∀ α β, L.form (ι α) (ι β) = K.form α β) (x y : K.carrier) :
    2 ∣ cocDiff K L ι x y + cocDiff K L ι y x

noncomputable def latCob (ι : K.carrier →ₗ[ℤ] L.carrier) (α : K.carrier) : ℂ :=
  cobSign (latticeBasis K) (cocDiff K L ι) α
```

(`cocForm` packages `cocExp L (latticeBasis L)` as a bilinear map; we have elided the bilinearity proofs, and `latticeCocycle_eq_zpow` records $\varepsilon_L(\alpha,\beta) = (-1)^{\mathtt{cocForm}(\alpha,\beta)}$.)

Theorem 31.36 (Cocycle comparison). *If K, L are even and ι is an isometry, then $c =$ `latCob` satisfies $\varepsilon_L(\iota\alpha,\iota\beta)\,c(\alpha)c(\beta) = \varepsilon_K(\alpha,\beta)\,c(\alpha+\beta)$, and $c(0) = 1$, $c \neq 0$, $c(-\alpha) = c(\alpha)$.*

```
theorem latticeCocycle_map_mul_latCob (hK : K.Even) (hL : L.Even) (ι : K.carrier →ₗ[ℤ]
 ↪ L.carrier)
    (hι : ∀ α β, L.form (ι α) (ι β) = K.form α β) (α β : K.carrier) :
    latticeCocycle L (ι α) (ι β) * (latCob K L ι α * latCob K L ι β)
      = latticeCocycle K α β * latCob K L ι (α + β)
theorem latCob_ne_zero (ι : K.carrier →ₗ[ℤ] L.carrier) (α : K.carrier) : latCob K L ι α ≠ 0
theorem latCob_zero (ι : K.carrier →ₗ[ℤ] L.carrier) : latCob K L ι 0 = 1
theorem latCob_neg (ι : K.carrier →ₗ[ℤ] L.carrier) (α : K.carrier) :
    latCob K L ι (-α) = latCob K L ι α
```

Physical meaning

This says that two different Klein-factor gauges, ε_K on the source lattice and $\varepsilon_L \circ (\iota\times\iota)$ on the target, differ by a coboundary c: a relabelling $e^{\alpha} \mapsto c(\alpha)e^{\alpha}$ of the momentum eigenstates. Since only cohomology classes of the cocycle are physically meaningful, this is the statement that an isometric embedding of lattices respects the Klein-factor structure up to the gauge freedom. The correction c is the phase needed so that the vertex operators $:e^{i\alpha\cdot X}:$ of V_K are carried to those of V_L.

Proof on paper. $D = \mathrm{coc}_L \circ(\iota\times\iota) - \mathrm{coc}_K$ is bilinear, and $D(x,y) + D(y,x) \equiv \langle \iota x, \iota y\rangle - \langle x, y\rangle = 0 \pmod 2$ by Theorem 31.11(iv)–(v) for both lattices and the isometry property. Lemma 31.35 gives $c(\alpha+\beta) = c(\alpha)c(\beta)(-1)^{D(\alpha,\beta)}$, i.e. $c(\alpha+\beta)\varepsilon_K(\alpha,\beta) = c(\alpha)c(\beta)\varepsilon_L(\iota\alpha,\iota\beta)$ using $(-1)^{-x} = (-1)^x$. □

Remark 31.37 (Why $\mathbb{Z}/4$ and not ±1: the design point). Any function c satisfying (31.14) obeys, at $\beta = -\alpha$, $1 = c(0) = c(\alpha)c(-\alpha)(-1)^{D(\alpha,\alpha)}$. If c were ±1-valued this would give

$$c(-\alpha) = c(\alpha)\,(-1)^{D(\alpha,\alpha)}.$$

The function $\alpha \mapsto (-1)^{D(\alpha,\alpha)}$ is a character of K (because $D(\alpha,\beta) + D(\beta,\alpha)$ is even), and it is in general *nontrivial*. The morphism $\Phi(p\otimes e^{\alpha}) = c(\alpha)\varphi(p)\otimes e^{\iota\alpha}$ then satisfies $\Phi\theta_K(p\otimes e^{\alpha}) = c(-\alpha)\,\sigma\varphi(p)\otimes e^{-\iota\alpha}$ and $\theta_L\Phi(p\otimes e^{\alpha}) = c(\alpha)\,\sigma\varphi(p)\otimes e^{-\iota\alpha}$, so $\Phi\theta_K = \theta_L\Phi\, g_\chi$, where g_χ is the sign automorphism of V_K (Section 31.11) for the character $\chi(\alpha) = D(\alpha,\alpha) \bmod 2$: Φ commutes with θ *only up to a character*. The orbifold argument needs $\Phi\theta_K = \theta_L\Phi$ on the nose, because it transports the fixed-point subalgebra V_K^+. Allowing $c(\alpha) \in \{\pm1, \pm i\}$ solves $c(\alpha)^2 = (-1)^{D(\alpha,\alpha)}$ with $c(-\alpha) = c(\alpha)$, which is exactly what $i^{S(\alpha,\alpha)}$ does.

A concrete example. Let $K = L = A_2$ with basis B_0, B_1 as in Example 31.12, so $\mathrm{coc}(\alpha,\beta) = -\alpha_1\beta_0$, and let ι be the reflection in B_1: $\iota B_0 = B_0+B_1$, $\iota B_1 = -B_1$. Then $D(B_0,B_0) = \mathrm{coc}(B_0+B_1, B_0+B_1) - 0 = -1$ is odd. So every ±1-valued solution c' has $c'(-B_0) = -c'(B_0)$, and the ±1 version of Φ fails to commute with θ. The library's c has $S_{00} = D_{00} = -1$, so $c(B_0) = i^{-1} = -i = c(-B_0)$. (Here we have used the basis order shown; for the library's `chooseBasis` the order is not known, but the phenomenon is basis-independent: whenever $D(\alpha,\alpha)$ is odd for some α, a ±1-valued coboundary cannot be even.)

Trap / dead end

Recorded in `Notes/M8GluingPlan.md` (Status 2026-10-06, "after the functoriality bridge"): the cocycle comparison *must* use the $\mathbb{Z}/4$-valued coboundary; a ±1-valued one would commute with θ only up to a character. A future refactor that "simplifies" `cobSign` to a sign would

silently break `latMorph_thetaLat` and everything downstream that identifies $V_{\Lambda_0}^+$ with a subalgebra of V_Λ^+.

31.12.4 The morphism Φ_ι

Definition 31.38. For a function $c\colon K \to \mathbb{C}$ let $\Phi^c(p \otimes e^\alpha) = c(\alpha)\varphi_Q(p) \otimes e^{\iota\alpha}$ with $Q =$ `oscMatrix K L ι`, and $\Phi_\iota := \Phi^{\mathrm{latCob}}$.

File `VOA/Moonshine/LatticeMorph.lean`.

```
noncomputable def momMap (c : K.carrier → ℂ) : (K.carrier →₀ ℂ) →ₗ[ℂ] (L.carrier →₀ ℂ) :=
  Finsupp.linearCombination ℂ (fun α => c α • eGen L (ι α))

noncomputable def latMorphC (c : K.carrier → ℂ) : LatModuleGen K →ₗ[ℂ] LatModuleGen L :=
  TensorProduct.map (fockMap (oscMatrix K L ι)).toLinearMap (momMap K L ι c)

noncomputable def latMorph : LatModuleGen K →ₗ[ℂ] LatModuleGen L := latMorphC K L ι (latCob
↪  K L ι)

theorem latMorph_latStateGen (p : FockN (rank K)) (α : K.carrier) :
    latMorph K L ι (latStateGen K p α)
      = latCob K L ι α • latStateGen L (fockMap (oscMatrix K L ι) p) (ι α)
```

Physical meaning

The map Φ_ι is the induced action on the chiral algebra of an isometric embedding $\iota\colon K \hookrightarrow L$ of the momentum lattices: it rotates the oscillators by φ_Q, relabels the momentum $\alpha \mapsto \iota\alpha$ (so $e^{i\alpha\cdot X}$ goes to $e^{i\iota\alpha\cdot X}$) and applies the gauge phase $c(\alpha)$ that compensates the change of Klein factors. For $K = L$ it is the lift of a lattice automorphism to an automorphism of the VOA, i.e. a target-space symmetry of the torus theory. For $K \subsetneq L$ it is the inclusion of the sublattice chiral algebra into the larger one.

Theorem 31.39 (Functoriality). *Let K, L be even positive-definite lattices and $\iota\colon K \to L$ an isometry. Then*

(i) *Φ_ι is a homomorphism of vertex algebras $V_K \to V_L$ (preserves $\mathbb{1}$ and all products $u_{(n)}v$);*

(ii) *if $\operatorname{rank} K = \operatorname{rank} L$, $\Phi_\iota(\omega_K) = \omega_L$ and Φ_ι is injective, with image the set of $x \in V_L$ all of whose momenta lie in $\iota(K)$;*

(iii) *$\Phi_\iota\theta_K = \theta_L\Phi_\iota$;*

(iv) *$\Phi_\iota g_{\chi\circ\iota} = g_\chi\Phi_\iota$ for every $\chi\colon L \to \mathbb{Z}/2$.*

(`VOA/Moonshine/LatticeMorph.lean`.)

From the mathematics to the Lean statement

The hypotheses are section variables, attached by `include` lines in the source:

- `latMorph_isVOAHom`, `latMorph_mode`: `hK : K.PosDef`, `hL : L.PosDef`, `hι` (isometry), `hKe : K.Even`, `hLe : L.Even`. *No equal-rank hypothesis.*
- `latMorph_omega`, `latMorph_injective`, `mem_range_latMorph_iff`: `hK`, `hL`, `hι` and `hr : rank K = rank L`.
- `latMorph_thetaLat`, `latMorph_chiLat`: no hypotheses at all (they are identities of linear maps on basis states; `latCob_neg` is unconditional).

`χ.comp ι.toAddMonoidHom` is $\chi \circ \iota$. `Set.range ι` is $\iota(K)$, and `LinearMap.range` the image of a linear map. Since `IsVOAHom` does not include ω (Section 31.2), statement (i) together with `latMorph_omega` is the full "conformal homomorphism" statement in the equal-rank case. The theorem could have been vacuous if `latMorph` were zero; it is not, since it sends $\mathbb{1}$ to $\mathbb{1}$ and is injective in equal rank.

Physical meaning

This theorem says that lattice isometries act functorially on lattice VOAs: a symmetry of the torus lattice becomes a symmetry of the chiral algebra, compatible with the conformal vector (so it commutes with L_n), with the lattice involution θ ($X \mapsto -X$) and with the sign automorphisms. In particular $\mathrm{Aut}(L)$, the target-space symmetry group of the torus (for the Leech lattice, Co_0), embeds in $\mathrm{Aut}(V_L)$ up to the central extension encoded by the cocycle comparison; a sublattice of equal rank gives the subalgebra of states with momenta in $\iota(K)$, which is the lattice algebra of the smaller (finite-index) lattice. This is what one needs to lift frame automorphisms and sign choices in the Monster construction, but the statement is only the algebraic fact.

Remark 31.40 (Unequal ranks). If $\mathrm{rank}\, K < \mathrm{rank}\, L$, Φ_ι is still a vertex algebra homomorphism, but $\Phi_\iota(\omega_K)$ is the Sugawara vector of the sub-Heisenberg algebra $\iota(K) \otimes \mathbb{C}$, not ω_L; $\omega_L - \Phi_\iota(\omega_K)$ is the conformal vector of the orthogonal complement. Injectivity also holds mathematically in that case, but the library proves it only under `hr` (its proof inverts φ_Q by φ_{Q^T}, which needs $QQ^T = 1$).

Proof on paper. (i) As for g_χ, check intertwining on generators. Because φ_Q is an algebra map with $Q\alpha^\perp = (\iota\alpha)^\perp$, it sends the Schur polynomials $S_N(\alpha)$ to $S_N(\iota\alpha)$, and (using $Q^TQ = 1$) intertwines $\alpha(n)$ with $(\iota\alpha)(n)$, hence $E^\pm(\alpha, z)$ with $E^\pm(\iota\alpha, z)$. Then, on $p \otimes e^\beta$,

$$\Phi\, Y(e^\alpha, z)(p \otimes e^\beta) = \varepsilon_K(\alpha,\beta)c(\alpha+\beta)z^{\langle\alpha,\beta\rangle}\varphi(E^-E^+p) \otimes e^{\iota(\alpha+\beta)} = c(\alpha)\, Y(e^{\iota\alpha}, z)\, \Phi(p \otimes e^\beta)$$

by Theorem 31.36 and $\langle\iota\alpha, \iota\beta\rangle = \langle\alpha,\beta\rangle$. So $\Phi Y(e^\alpha, z) = Y(\Phi e^\alpha, z)\Phi$, as $\Phi e^\alpha = c(\alpha)e^{\iota\alpha}$. For the currents, $\Phi h_a(z) = (\sum_b Q_{ba}h_b(z))\Phi$, including the zero mode (this is $Q^T(\iota\beta)^\perp = \beta^\perp$). On the L side, $Y(h_b(-i-1)v, z) = :\partial^{(i)}h_b(z)Y(v,z):$ for every v, and normal ordering is linear in the first factor. Induction over words gives $\Phi Y(w,z) = Y(\Phi w, z)\Phi$ on word states, hence everywhere. (ii) $\varphi_Q\omega = \omega$ needs $QQ^T = 1$. Injectivity: the momentum components of Φx are $c(\beta)\varphi(x_\beta)$ at $\iota\beta$ and 0 off $\iota(K)$; $c \neq 0$ and φ is invertible. Conversely a vector supported on $\iota(K)$ is the image of $\sum_\gamma c(\iota^{-1}\gamma)^{-1}\varphi_{Q^T}(x_\gamma) \otimes e^{\iota^{-1}\gamma}$. (iii) is the computation of Remark 31.37 with $c(-\alpha) = c(\alpha)$, plus $\varphi_Q\sigma = \sigma\varphi_Q$ (φ_Q is linear in the variables). (iv) is immediate. □

What the machine verified

All proved; `#print axioms` of `latMorph_isVOAHom`, `latMorph_injective`, `mem_range_latMorph_iff`, `latMorph_thetaLat`, `latticeCocycle_map_mul_latCob` = `[propext, Classical.choice, Quot.sound]` (re-checked). Conditional only on the hypotheses listed in the fidelity box. Every statement is in fact proved for the general `latMorphC ι c` under the minimal hypotheses on c ($c(0) = 1$, cocycle relation, $c \neq 0$, $c(-\alpha) = c(\alpha)$ for (iii)) and then specialised.

31.12.5 Character automorphisms

Taking $K = L$, $\iota = \mathrm{id}$ and $c = d$ a character gives automorphisms.

Definition 31.41. For a homomorphism $d : L \to \mathbb{C}^\times$, $g_d(p \otimes e^\alpha) = d(\alpha)\, p \otimes e^\alpha$.

File `VOA/Moonshine/LatticeMorph.lean`.

```
noncomputable def charVal (α : L.carrier) : ℂ := ((Additive.toMul (d α) : ℂˣ) : ℂ)

noncomputable def charLat : LatModuleGen L →ₗ[ℂ] LatModuleGen L :=
  latMorphC L L LinearMap.id (charVal L d)

theorem charLat_latStateGen (hL : L.PosDef) (p : FockN (rank L)) (α : L.carrier) :
    charLat L d (latStateGen L p α) = charVal L d α • latStateGen L p α

noncomputable def charAut : Aut (latticeVOAGen L hEven hPos) where ...

theorem charLat_thetaLat_conj (e : L.carrier →+ Additive ℂˣ) (x : LatModuleGen L) :
    charLat L e (thetaLat L (charLat L (-e) x)) = charLat L (2 • e) (thetaLat L x)

theorem exists_half_char : ∃ e : L.carrier →+ Additive ℂˣ, 2 • e = d
```

From the mathematics to the Lean statement

`L.carrier →+ Additive ℂˣ` is a homomorphism from L to the multiplicative group $\mathbb{C}^\times$ written additively (Lean's device for viewing a multiplicative group as an additive one); so `2 • e` is e^2 and `-e` is e^{-1}, and `charVal` extracts the complex number $d(\alpha)$. For $d = \mathrm{id}$, `oscMatrix L L id` $= 1$ (`oscMatrix_id`), so `charLat` indeed does not touch the Fock factor. `charLat_thetaLat_conj` is $g_e \theta g_e^{-1} = g_{e^2}\theta$, needing only `hPos` (to know $Q = 1$).

Physical meaning

A character $d : L \to \mathbb{C}^\times$ of the momentum lattice is an element of the dual torus, and g_d multiplies a state of momentum α by $d(\alpha) = e^{i\alpha\cdot\theta}$: it is a translation by θ on the target torus, i.e. an element of the $U(1)^r$ symmetry group generated by the zero modes of the currents. These are the continuous symmetries of the torus CFT present because the weight-one space contains the Cartan currents, and the sign automorphism g_χ is the special case $d = (-1)^\chi$.

Proof on paper. g_d is Φ^d_{id}, and d satisfies the cocycle relation with $\varepsilon_L = \varepsilon_K$ because d is multiplicative. The conjugation formula: on $p \otimes e^\alpha$, $g_e\theta g_e^{-1}$ multiplies by $e(\alpha)^{-1}e(-\alpha) = e(\alpha)^{-2}$, and $g_{e^2}\theta$ by $e(-\alpha)^2 = e(\alpha)^{-2}$. Square roots: L is free, so define e on a basis by choosing square roots of $d(B_i)$ in $\mathbb{C}$ (algebraically closed), and extend. □

31.12.6 Rigidity of lifts of -1

FLM show that lifts of $-1 \in O(L)$ to $\mathrm{Aut}(V_L)$ are unique up to the characters of L. The library proves the VOA-level statement needed in the Moonshine construction to identify an abstractly given involution with the standard θ (the "c_λ residual" of `Notes/M8GluingPlan.md`). File `VOA/Moonshine/LatticeMorphRigid.lean`.

```
noncomputable abbrev heisSt (a : Fin (rank L)) : LatModuleGen L := wordStateLatGen L [(0,
 ↪  a)] 0

noncomputable def hSt (α : L.carrier) : LatModuleGen L := latStateGen L (vSchur L α 1) 0
```

`heisSt L a` $= h_a(-1)\mathbb{1}$ (frame direction), and `hSt L α` $= \alpha(-1)\mathbb{1}$ since $S_1(\alpha) = v_0(\alpha) = \sum_a \alpha_a^\perp X_{(0,a)}$ (`hSt` lives in `VOA/Moonshine/TrialitySl2.lean`).

Theorem 31.42 (Rigidity). *Let L be even positive-definite and $\psi \in \mathrm{Aut}(V_L)$ such that $\psi(\alpha(-1)\mathbb{1}) = -\alpha(-1)\mathbb{1}$ for all $\alpha \in L$ (equivalently $\psi(h_a(-1)\mathbb{1}) = -h_a(-1)\mathbb{1}$ for all a) and $\psi(\mathcal{F} \otimes e^\gamma) \subseteq \mathcal{F} \otimes e^{-\gamma}$ for all γ. Then $\psi = g_d\theta$ for a character $d : L \to \mathbb{C}^\times$, and $\psi = g_e\theta g_e^{-1}$ for a character e; in particular ψ is conjugate to θ in $\mathrm{Aut}(V_L)$.*

```

theorem lift_eq_conj_theta' (ψ : Aut (latticeVOAGen L hEven hPos))
    (hh : ∀ α, ψ (hSt L α) = -hSt L α)
    (hsec : ∀ (γ : L.carrier) (x : LatModuleGen L), x ∈ chargeSec L γ → ψ x ∈ chargeSec L
     ↪  (-γ)) :
    ∃ e : L.carrier →+ Additive ℂˣ, ∀ x, ψ x = charLat L e (thetaLat L (charLat L (-e) x))
```

(`VOA/Moonshine/LatticeMorphRigid.lean`.)

From the mathematics to the Lean statement

`chargeSec L γ` is $\mathcal{F} \otimes e^\gamma$. The two hypotheses say that ψ acts as -1 on $\mathfrak{h} = (V_L)_1^{\mathrm{Heis}}$ and maps momentum γ to momentum $-\gamma$; this is what "ψ lifts $-1 \in O(L)$" means. The primed version states the first hypothesis on the lattice-meaningful states $\alpha(-1)\mathbb{1}$, which span the same space as the $h_a(-1)\mathbb{1}$: $\alpha(-1)\mathbb{1} = \sum_a \alpha_a^\perp h_a(-1)\mathbb{1}$, and the vectors $B_i^\perp = CB_i$ span $\mathbb{R}^r$ because $C = \sqrt{G}$ is invertible (the library proves the needed inclusion as `heisSt_mem_span_hSt`); it is the form used downstream. The conclusion is an equality of functions, quantified over all x. The sector hypothesis is an honest extra input: mathematically it follows from the first one (the momentum sectors are the joint eigenspaces of the zero modes $h_a(0)$, and ψ conjugates $h(0)$ to $-h(0)$), but the library does not prove that implication, so the theorem assumes it.

Physical meaning

This is a statement that every automorphism acting as -1 on the oscillator currents and swapping each momentum sector $\gamma \to -\gamma$ is conjugate to the reflection θ ($X \mapsto -X$) by a translation in the torus (a $U(1)^r$ symmetry). Physically, once the current algebra is fixed to be

acted on by -1, the only freedom left is a shift of the origin of the torus, so such reflection symmetries (the $\mathbb{Z}/2$ target-space inversion with fixed points) form a single conjugacy class. This is the rigidity input used to identify the lifted involution with the standard one in the orbifold construction.

Proof on paper. Let $\phi = \psi\theta$. It fixes every $h_a(-1)\mathbb{1}$ (two sign changes), preserves each sector $\mathcal{F} \otimes e^\gamma$, and, being an automorphism, preserves the L_0-grading. Hence $\phi(e^\gamma)$ lies in $(\mathcal{F} \otimes e^\gamma) \cap (V_L)_{|\gamma|^2/2} = \mathcal{F}_0 \otimes e^\gamma = \mathbb{C}e^\gamma$; write $\phi(e^\gamma) = d(\gamma)e^\gamma$. Since $(h_a(-1)\mathbb{1})_{(-i-1)} = h_a(-i-1)$ and ϕ fixes $h_a(-1)\mathbb{1}$, ϕ commutes with all creation oscillators, so $\phi = d(\gamma)$ on the whole sector. Applying ϕ to $(e^\alpha)_{(-\langle\alpha,\beta\rangle-1)}e^\beta = \varepsilon(\alpha,\beta)e^{\alpha+\beta} \neq 0$ gives $d(\alpha)d(\beta) = d(\alpha+\beta)$; $d(\gamma) \neq 0$ by injectivity. Thus $\psi = \phi\theta^{-1} = g_d\theta$. Writing $d = e^2$ (`exists_half_char`) and using $g_e\theta g_e^{-1} = g_{e^2}\theta$ gives the conjugacy. □

What the machine verified

Proved, conditional only on `hEven`, `hPos` and the two displayed hypotheses on ψ; `#print axioms exists_char_of_lift, lift_eq_conj_theta' = [propext, Classical.choice, Quot.sound]` (re-checked).

Finally, an automorphism of V_L preserving the image of an injective conformal homomorphism $\Phi : V \to W$ pulls back to an automorphism of V:

```
noncomputable def Aut.pullback (hΦ : IsVOAHom V W Φ)
    (hω : Φ V.conformalVector = W.conformalVector) : Aut V
theorem Aut.pullback_apply (hΦ : IsVOAHom V W Φ)
    (hω : Φ V.conformalVector = W.conformalVector) (x : 𝒱) :
    Φ (Aut.pullback Φ hinj g hg hΦ hω x) = g (Φ x)
```

with section variables `hinj : Function.Injective Φ`, `g : Aut W` and `hg : (LinearMap.range Φ).map g.toLinearEquiv.toLinearMap = LinearMap.range Φ`. Note the explicit hypothesis `hω`, needed precisely because `IsVOAHom` omits ω.

31.12.7 Where functoriality is used

The first application (`VOA/Moonshine/FrameBridge.lean`) takes $K = \Lambda_0 \cong A$, an index-2 sublattice common to the Leech lattice and the Niemeier lattice $N(A_1^{24})$ (the even unimodular lattice of rank 24 whose roots form 24 orthogonal copies of A_1, obtained from $\sqrt{2}\,\mathbb{Z}^{24}$ by gluing along the Golay code; Chapters 30 and 39), with the two isometric embeddings $\iota_\Lambda : a \mapsto 2a$ and $\iota_N : A \subseteq N$. The resulting `bridgeΛ := latMorph lam0 leech inclΛ` and `bridgeN := latMorph lam0 golayN inclN` are injective conformal homomorphisms commuting with θ, and give the vertex algebra isomorphism $V_{\Lambda_0}^+ \cong V_0^+$ (`lam0PlusEquiv`) through which the triality automorphism of V_N (Chapter 39) is transported to V_Λ. This is why both the exact θ-compatibility (Remark 31.37) and the rigidity theorem are needed.

31.13 The design question: a non-computable basis

The cocycle `latticeCocycle` is defined over `Module.Free.chooseBasis`, a basis selected by the axiom of choice, and the oscillator frame is $\sqrt{G}$ in that basis (Sections 31.4–31.5). Consequently *no explicit sign* $\varepsilon(\alpha,\beta)$ and no explicit frame coordinate can be computed in Lean: there is no way to evaluate, say, $\varepsilon_\Lambda(\alpha,\beta)$ for two given Leech vectors, nor to say which Fock colour corresponds to which Golay coordinate.

During the construction of the triality automorphism (the step called R-top in `Notes/M8GluingPlan.md`, Status 2026-10-07 "R-top partial"), this was recorded as a *design issue*: "the Leech cocycle is `latticeCocycle` over `Module.Free.chooseBasis` and the oscillator frame is $\sqrt{G}$, not the Golay frame — NO explicit sign is computable; every identity must stay symbolic. An explicit (Golay-frame) basis/cocycle model, transported via the functoriality machinery (`latMorph`), could drastically simplify R-top's remaining work; decision pending." The question was put to both maintainers.

The question was resolved without a refactor. The later status entry ("σ EXISTS on both twisted sectors — unconditional") records: *"DESIGN QUESTION RESOLVED: …an explicit-basis refactor would NOT have materially reduced cost (all identities reduced to bimultiplicative-cocycle algebra / ξ / Golay facts; no concrete cocycle value on* `chooseBasis` *was ever needed). Keep the foundations as they are."* The reasons, in mathematical terms:

1. Every identity that the Moonshine construction needs about ε follows from bimultiplicativity, $\varepsilon^2 = 1$ and the commutator property $\varepsilon(\alpha,\beta)\varepsilon(\beta,\alpha) = (-1)^{\langle\alpha,\beta\rangle}$. These determine ε up to coboundary, and the vertex operator algebra up to isomorphism; no specific value is ever required.

2. Where two different cocycles had to be compared (two lattices, two bases) the functoriality machinery of Section 31.12 does it once and for all, with the exactly θ-compatible $\mathbb{Z}/4$ coboundary.

3. Where an unknown scalar appeared (e.g. the c_λ in $\Theta e^\lambda = c_\lambda e^{-\lambda}$), rigidity (Theorem 31.42) shows it is a character and can be conjugated away; one never needs its value.

4. The frame directions only enter through the orthogonality relations $Q^TQ = QQ^T = 1$ and the identity $Q\alpha^\perp = (\iota\alpha)^\perp$, never through explicit coordinates.

Trap / dead end

For a referee the relevant lesson is the converse: a statement in this part of the library that *appears* to depend on a specific value of `latticeCocycle` (or of `orthCoord`) should be read with suspicion, because such a value cannot be computed and any proof of it must come from basis-independent properties. No such statement is used in the construction of $V^\natural$ (Chapter 42).

31.14 Referee's checklist

Abbreviations: E = `hEven` (evenness), P = `hPos` (positive-definiteness), I = isometry `hι`, R = equal rank `hr`. "Uncond." means no hypotheses beyond the displayed data; all entries have `#print axioms` ⊆ `[propext, Classical.choice, Quot.sound]` and none uses `VOA.pbw`. Namespaces are omitted in the table: `VOA.HeisenbergN` for the first three rows, `VOA.IntegralLattice` for the cocycle and frame rows, `VOA.Reconstruction` for `reconstruct`, `VOA.Moonshine` for the `leech...` rows, and `VOA.LatGen` otherwise.

Points a referee should specifically confirm:

1. *Indexing.* `FormalDist` is indexed by powers of z; modes via `mode f n = f (-n-1)`. The Fock variable `X (i,a)` is $h_a(-i-1)\mathbb{1}$.
2. *Naming.* The library's $E^{\mp}(\alpha,z)$ are FLM's $E^{\mp}(-\alpha,z)$.
3. *Choice.* `YfullGen` is defined by `.choose` but is unique; the cocycle is defined via `chooseBasis` and is non-computable but satisfies all needed identities.
4. *Homomorphisms.* `IsVOAHom` omits ω; conformality is `latMorph_omega`, under equal rank.
5. *The $\mathbb{Z}/4$ coboundary* is required for exact θ-compatibility (Remark 31.37); the ±1 description in one module docstring is stale.
6. *Stale docstrings* (no effect on statements): `LatticeGenGrading.lean` calls a discharged lemma a crux; `LatticeGenModule.lean` lists "remaining Goals" that are done; `LatticeMorphFock.lean` mentions a nonexistent `exists_fockMatrix`.

Notes and references

The free boson and its Fock space are classical; the vertex-algebraic treatment follows I. B. Frenkel, J. Lepowsky and A. Meurman, *Vertex Operator Algebras and the Monster*, Pure and Applied Mathematics 134, Academic Press, 1988, Chapters 1–4 (Heisenberg algebras and their Fock spaces)

and Chapters 5–8 (central extensions of lattices, the cocycle ε, the vertex operators $Y(e^{\alpha},z) = E^{-}(-\alpha,z)E^{+}(-\alpha,z)e_{\alpha}z^{\alpha}$, and the lattice vertex operator algebra V_L); our Definition 31.21 is their (8.4.1) up to the naming of $E^{\pm}$. The lifts of -1 and their uniqueness up to characters are in FLM Chapter 10 and Proposition 5.4.1 there.

The vertex operator realisation of affine Lie algebras by lattice vertex operators is due to I. B. Frenkel and V. G. Kac, "Basic representations of affine Lie algebras and dual resonance models", *Invent. Math.* 62 (1980), 23–66, and G. Segal, "Unitary representations of some infinite dimensional groups", *Comm. Math. Phys.* 80 (1981), 301–342. The first general definition of a vertex algebra, with lattice vertex algebras as the main example, is R. E. Borcherds, "Vertex algebras, Kac–Moody algebras, and the Monster", *Proc. Nat. Acad. Sci. USA* 83 (1986), 3068–3071.

The axiomatics by locality and the reconstruction ("existence") theorem used in Section 31.9 are from V. G. Ben-Zvi, *Vertex Algebras and Algebraic Curves*, 2nd ed., Mathematical Surveys and Monographs 88, AMS, 2004, Chapters 2 and 5 (free bosons, lattice vertex algebras, reconstruction), and J. Lepowsky and H. Li, *Introduction to Vertex Operator Algebras and Their Representations*, Progress in Mathematics 227, Birkhäuser, 2004, Chapter 6 (Heisenberg and lattice vertex operator algebras via the Jacobi identity), where the cocycle normalisation of Section 31.4 is also discussed. Dong's lemma is from C. Dong, "Vertex algebras associated with even lattices", *J. Algebra* 161 (1993), 245–265, and is presented in Kac's book (Lemma 3.2). Goddard's uniqueness theorem is from P. Goddard, "Meromorphic conformal field theory", in *Infinite-dimensional Lie algebras and groups* (Luminy–Marseille, 1988), Adv. Ser. Math. Phys. 7, World Scientific, 1989, 556–587. The library's own primary reference for the definitions is T. Gannon, *Moonshine beyond the Monster*, Cambridge University Press, 2006, §5.2.

The Leech lattice and its construction from the Golay code are in W. Ebeling, *Lattices and Codes*, 3rd ed., Springer Spektrum, 2013, and J. H. Conway and N. J. A. Sloane, *Sphere Packings, Lattices and Groups*, 3rd ed., Springer, 1999; uniqueness is J. H. Conway, "A characterisation of Leech's lattice", *Invent. Math.* 7 (1969), 137–142 (not formalised). The use of the sublattice Λ_0 and of the Niemeier lattice $N(A_1^{24})$ to construct the triality follows C. Dong, R. L. Griess Jr. and G. Höhn, "Framed vertex operator algebras, codes and the Moonshine module", *Comm. Math. Phys.* 193 (1998), 407–448 (arXiv:q-alg/9707008); see Chapters 39–41.

The design discussion of Section 31.13 and the $\mathbb{Z}/4$ coboundary are recorded in the repository files `Notes/M8GluingPlan.md` (Status sections of 2026-10-06 and 2026-10-07).

Chapter 32

The involution θ and the fixed-point algebra V_Λ^+

This chapter documents the release of the LeanVOA library named in the front matter; every Lean quotation below is checked by `scripts/textbook/sync.py` to occur verbatim (up to whitespace and comments) in the source files of that release. Checks that were run at an earlier state of the library and not re-run for this edition are marked as such. The Moonshine module of Frenkel, Lepowsky and Meurman is assembled from two halves,

$$V^\natural \;=\; V_\Lambda^+ \;\oplus\; (V_\Lambda^T)^+,$$

an *untwisted* half and a *twisted* half. This chapter is entirely about the first summand. Starting from the Leech lattice vertex operator algebra V_Λ (constructed in Chapter 31) we lift the isometry -1 of the lattice to an automorphism θ of V_Λ, form the subalgebra V_Λ^+ of θ-fixed vectors, and establish everything the later chapters need to know about it:

(i) θ is a genuine VOA automorphism of order exactly two (§32.3–§32.5);

(ii) V_Λ^+ is a vertex operator algebra of central charge 24 (§32.6);

(iii) $(V_\Lambda^+)_1 = 0$, $\dim(V_\Lambda^+)_2 = 98580$, $\dim(V_\Lambda^+)_3 = 10745856$, and more generally an exact formula for every $\dim(V_\Lambda^+)_k$ (§32.7–§32.9);

(iv) V_Λ^+ is generated, as a vertex algebra, by the vectors $e^{\beta} + e^{-\beta}$ (§32.10);

(v) the canonical invariant bilinear form of V_Λ^+ is nondegenerate on every weight space, proved by writing down an explicit form on all of V_Λ (§32.11).

Item (v) is the input that makes the twisted-by-twisted operator $\overline{W}$ of Chapter 37 nondegenerate, which in turn is what distinguishes $V^\natural$ from a degenerate "square-zero" impostor with the same graded dimension; we shall only point at that use here.

The physical picture. A rank-24 lattice VOA is the chiral half of the conformal field theory of 24 free bosons $X^a(z)$ compactified on the torus $\mathbb{R}^{24}/\Lambda$. Its states are oscillator excitations $h_a(-n)$ of the bosons, dressed by a momentum ("charge") $\alpha \in \Lambda$. The reflection $X \mapsto -X$ of the torus is a symmetry: it flips the sign of every oscillator and of every momentum. The quantum operator that implements this reflection is θ. Gauging the reflection ("orbifolding") has two effects on the space of states: one keeps only the reflection-invariant states of the original theory — this is V_Λ^+ — and one adds a *twisted sector* of strings closed only up to the reflection — that is $(V_\Lambda^T)^+$, the subject of Chapters 34–36. Seen this way, this chapter computes the *projected untwisted sector*: which states survive the projection, how many there are at each energy, how they are generated, and which inner product they carry.

How to read this chapter. Every definition and theorem is presented with the Fidelity Protocol of the book: the mathematical statement, then the Lean declaration copied verbatim from the repository, then a fidelity check (in a box titled "From the mathematics to the Lean statement") that decodes every symbol and hypothesis, then a proof on paper, then the machine status. The files of this chapter are, in `VOA/Moonshine/`, `LatticeInvolution.lean`, `PlusWeightOne.lean`, `PlusWeightTwo.lean`, `LatticeGradedDim.lean`, `GenerationFock.lean`, `Generation.lean`, `NondegFock.lean`, `NondegLattice.lean` and `NondegLeech.lean`.

What the machine verified

All statements quoted in this chapter are in files imported by the umbrella `VOA/Moonshine.lean` (checked at an earlier commit, when this chapter was first written, and again in the working tree of a pre-release build commit); the aggregate `lake build` recorded by the project for that earlier state was green (10343 jobs; not re-run for this chapter). While writing this chapter the command `lake env lean -DmaxSynthPendingDepth=3` was run on a scratch file importing `VOA.Moonshine.NondegLeech` and `VOA.Moonshine.LatticeGradedDim`, printing the axioms of nineteen headline declarations of the chapter (`thetaLat_mode`, `thetaAut_sq`, `thetaAut_ne_one`, `leechTheta_ne_one`, `mem_leechVOAPlus_iff`, `leechVOAPlus_centralCharge`, `leechVOAPlus_grading_one`, the four dimension theorems at weights 2 and 3, `hasProd_fockGenFun`, `hasProd_fockSignedGenFun`, `two_mul_finrank_plusK_eq_signed`, `leechPlus_generated`, `latForm_nondeg`, `latForm_Yeαvec`, `leechBV_eq_plusForm`, `leechBV_gradedNondeg`). Every one printed exactly `[propext, Classical.choice, Quot.sound]`: Lean's three standard axioms, and in particular *not* `VOA.pbw` (the PBW theorem of Chapter 3; a project axiom in earlier versions of the library, now a theorem). No theorem of the chapter has an unproved datum among its hypotheses; the only hypotheses anywhere are evenness and positive-definiteness of a lattice, which for the Leech lattice are themselves proved theorems.

32.1 What we take from the lattice VOA

The lattice VOA V_L is constructed in Chapter 31. To keep this chapter self-contained we recall every definition that appears in a statement below, with its Lean source. A reader who has just read Chapter 31 may skim this section.

32.1.1 Lattices

Definition 32.1 (Integral lattice)**.** An *integral lattice* is a free $\mathbb{Z}$-module L of finite rank together with a symmetric $\mathbb{Z}$-bilinear form $\langle\cdot,\cdot\rangle : L\times L \to \mathbb{Z}$. It is *even* if $\langle v, v\rangle \in 2\mathbb{Z}$ for all v, and *positive-definite* if $\langle v, v\rangle > 0$ for $v \neq 0$. The *half-norm* of α is $\frac{1}{2}\langle\alpha,\alpha\rangle$, an integer when L is even; it will be the conformal weight of e^{α}.

In Lean an integral lattice is the structure `VOA.IntegralLattice` (carrier a free, finitely generated $\mathbb{Z}$-module, symmetric form `L.form`), with the predicates `L.Even` and `L.PosDef` (`VOA/Foundations/Lattices.lean`); these are quoted verbatim and decoded in Definitions 30.9, 30.10 and 3.24. The half-norm is

```
-- VOA/Examples/LatticeGenGrading.lean
noncomputable def halfNorm (α : L.carrier) : ℤ := L.form α α / 2
```

From the mathematics to the Lean statement

`L.form α β` is $\langle\alpha,\beta\rangle$. `halfNorm` uses integer division `/ 2`; this equals $\frac{1}{2}\langle\alpha,\alpha\rangle$ exactly when $\langle\alpha,\alpha\rangle$ is even, which is why every theorem that uses `halfNorm` as a conformal weight carries

the hypothesis `hEven : L.Even` (the library records $2\cdot$`halfNorm L α` $= \langle\alpha,\alpha\rangle$ as `two_halfNorm`, under `hEven`). The *rank* `rank L` is `Module.finrank ℤ L.carrier`, the number of elements of a $\mathbb{Z}$-basis.

Physical meaning

An even lattice is the data of the momentum (charge) lattice of a chiral boson compactified on the torus $\mathbb{R}^r/L$: the evenness condition says the vertex operator $:e^{i\alpha\cdot X}:$ has integer conformal weight $\frac{1}{2}\langle\alpha,\alpha\rangle$ (so the fields are mutually local, with integer spin), and positive-definiteness says the energy is bounded below. The Leech lattice is special in having no vectors of norm 2, i.e. no extra weight-one currents, so the torus theory has only the 24 abelian $U(1)$ currents ∂X^a. Heuristic, not part of the proof.

The Leech lattice enters through the declaration `VOA.Moonshine.leech`. It is the Leech lattice of the vendored library in the directory `VOA/LatticesAndCodes/` (Chapter 30), transported into the structure above:

```
-- VOA/Moonshine/LeechLatticeVOA.lean
noncomputable abbrev leech : VOA.IntegralLattice.{0} := ofEbeling Leech.lattice
theorem leech_even : leech.Even := ofEbeling_even _ Leech.lattice_isEven
theorem leech_posDef : leech.PosDef := ofEbeling_posDef _ Leech.lattice_isPosDef
theorem leech_rank : rank leech = 24 := Leech.lattice_rank
theorem leech_no_roots (v : leech.carrier) : leech.form v v ≠ 2 := Leech.lattice_no_roots v
```

These facts — even, positive-definite, rank 24, no vectors of norm 2 — together with the counts $\#\{\alpha : \langle\alpha,\alpha\rangle = 4\} = 196560$ (`Leech.repCount_four`) and $\#\{\alpha : \langle\alpha,\alpha\rangle = 6\} = 16773120$ (`Leech.repCount_six`) are the only properties of Λ used in this chapter. All are proved theorems of the vendored library (Chapter 30).

32.1.2 The Fock space

Definition 32.2 (Rank-r Fock space)**.** Let $r \geq 0$. The Fock space of r free bosons is the polynomial ring

$$F_r = \mathbb{C}\big[\, x_{(m,a)} : m \in \mathbb{N},\ a \in \{0,\dots,r-1\}\,\big],$$

where the variable $x_{(m,a)}$ stands for the creation operator $h_a(-m-1)$ applied to the vacuum 1. The oscillators act by

$$h_a(-n) = \text{multiplication by } x_{(n-1,a)}\ (n \geq 1), \qquad h_a(n) = n\,\frac{\partial}{\partial x_{(n-1,a)}}\ (n \geq 1), \qquad h_a(0) = 0,$$

so that $[h_a(m), h_b(n)] = m\,\delta_{ab}\,\delta_{m+n,0}$. The *weight* of the monomial $x^d = \prod x_{(m,a)}^{d_{(m,a)}}$ is $\sum (m+1)\,d_{(m,a)}$, its *degree* is $\sum d_{(m,a)}$ (the number of oscillators), and $(F_r)_w$ is the span of the monomials of weight w.

```
-- VOA/Examples/HeisenbergNFock.lean
abbrev FockN (r : ℕ) : Type := MvPolynomial (ℕ × Fin r) ℂ

noncomputable def oscN (r : ℕ) (k : ℂ) (a : Fin r) (n : ℤ) : FockN r →ₗ[ℂ] FockN r :=
  if n < 0 then mulXN (-n - 1).toNat a
  else if 0 < n then (n : ℂ) • k • pderivLMN (n - 1).toNat a
  else 0

def weightFnN {r : ℕ} : ℕ × Fin r → ℕ := fun u => u.1 + 1
```

```
def gradingWN (r : ℕ) (w : ℕ) : Submodule ℂ (FockN r) :=
  weightedHomogeneousSubmodule ℂ weightFnN w

-- VOA/Examples/HeisenbergNVertex.lean
noncomputable def gradingZN (r : ℕ) (n : ℤ) : Submodule ℂ (FockN r) :=
  if 0 ≤ n then gradingWN r n.toNat else ⊥
```

From the mathematics to the Lean statement

`MvPolynomial (ℕ × Fin r) ℂ` is Mathlib's polynomial ring over $\mathbb{C}$ in variables indexed by pairs (m,a) with $m \in \mathbb{N}$ and $a \in \{0,\dots,r-1\}$ (`Fin r`). The variable `X (m,a)` is $x_{(m,a)} = h_a(-m-1)\mathbf{1}$: the index is shifted by one, $m=0$ being the first creation mode $h_a(-1)$. `oscN r k a n` is $h_a(n)$ at level k; every use in this chapter has $k=1$. `mulXN i a` multiplies by `X (i,a)` and `pderivLMN i a` is $\partial/\partial x_{(i,a)}$; `→ₗ[ℂ]` denotes a $\mathbb{C}$-linear map. A monomial is recorded by its exponent function d with finite support (Mathlib's `(ℕ × Fin r) →₀ ℕ`); its weight is `Finsupp.weight weightFnN d` $= \sum (m+1)d_{(m,a)}$ and its degree is `d.degree` $= \sum d_{(m,a)}$. `gradingWN r w` is the subspace (`Submodule`) of polynomials all of whose monomials have weight w (Mathlib's "weighted-homogeneous" submodule); `gradingZN` extends the index to $\mathbb{Z}$ by the zero subspace `⊥` in negative weight.

Physical meaning

The Fock space is the space of oscillator excitations of r free chiral bosons about the vacuum: a monomial is a state with $\deg d$ quanta, and its weight is the total energy $\sum(m+1)d_{(m,a)}$ in units where $h_a(-n)$ raises L_0 by n. The generating function of monomials by weight is the partition function of r free bosons, $\prod(1-q^n)^{-r}$, computed later in this chapter. The relation $[h_a(m), h_b(n)] = m\,\delta_{ab}\delta_{m+n,0}$ is the canonical commutation relation of the current $i\partial X^a$.

32.1.3 The lattice VOA as a vector space

Definition 32.3 (V_L as a graded vector space)**.** For an integral lattice L of rank r, put $\mathbb{C}\{L\} = \bigoplus_{\alpha\in L} \mathbb{C}e^{\alpha}$ (a vector space with basis e^{α}; no product is needed in this chapter) and

$$V_L = F_r \otimes_{\mathbb{C}} \mathbb{C}\{L\}.$$

The vector $p \otimes e^{\alpha}$ has *Fock weight* w if $p \in (F_r)_w$, *charge* α, and *conformal weight* $w + \frac{1}{2}\langle\alpha,\alpha\rangle$. The weight-$k$ space is

$$(V_L)_k = \bigoplus_{\alpha\in L} (F_r)_{k-\frac{1}{2}\langle\alpha,\alpha\rangle} \otimes e^{\alpha}.$$

We write e^{α} also for the "charged vacuum" $1 \otimes e^{\alpha}$; e^0 is the vacuum.

```
-- VOA/Examples/LatticeGenModule.lean
noncomputable abbrev LatModuleGen : Type :=
  HeisenbergN.FockN (rank L) ⊗[ℂ] (L.carrier →₀ ℂ)
noncomputable def eGen (α : L.carrier) : L.carrier →₀ ℂ := Finsupp.single α 1
noncomputable def latStateGen (p : HeisenbergN.FockN (rank L)) (α : L.carrier) :

-- VOA/Examples/LatticeGenGrading.lean
noncomputable def mkEα (α : L.carrier) : HeisenbergN.FockN (rank L) →ₗ[ℂ] LatModuleGen L :=
  (TensorProduct.mk ℂ (HeisenbergN.FockN (rank L)) (L.carrier →₀ ℂ)).flip (eGen L α)
```

```
noncomputable def bigradα (wα : ℤ × L.carrier) : Submodule ℂ (LatModuleGen L) :=
  (HeisenbergN.gradingZN (rank L) wα.1).map (mkEα L wα.2)
noncomputable def gradingLatGen (k : ℤ) : Submodule ℂ (LatModuleGen L) :=
  ⨆ α : L.carrier, bigradα L (k - halfNorm L α, α)
```

From the mathematics to the Lean statement

`L.carrier →₀ ℂ` (finitely supported functions $L \to \mathbb{C}$) is the vector space $\mathbb{C}\{L\}$, and `eGen L α` is the basis vector e^α. `⊗[ℂ]` is the algebraic tensor product over $\mathbb{C}$ and `p ⊗ₜ x` an elementary tensor. `latChargeGen L α` is $1 \otimes e^\alpha$. `mkEα L α` is the map $p \mapsto p \otimes e^\alpha$, and `bigradα L (w,α)` is its image of $(F_r)_w$, i.e. $(F_r)_w \otimes e^\alpha$. `gradingLatGen L k` is the sum (⨆, the supremum of subspaces) of these over all α with $w = k - \frac{1}{2}\langle\alpha,\alpha\rangle$. That this sum is direct and that the spaces exhaust V_L is proved in Chapter 31.

Physical meaning

$V_L = F_r \otimes \mathbb{C}\{L\}$ is the full chiral state space of the compact boson on $\mathbb{R}^r/L$: oscillators tensored with a momentum eigenstate $e^\alpha =: e^{i\alpha\cdot X} : (0)\,|0\rangle$. Under the state–operator correspondence, $p \otimes e^\alpha$ is the local operator obtained by dressing the vertex operator $: e^{i\alpha\cdot X} :$ with derivatives of X; its L_0 eigenvalue is the oscillator level plus the momentum energy $\frac{1}{2}\langle\alpha,\alpha\rangle = \frac{1}{2}p^2$. This is a statement about the Hilbert space only; the OPEs are defined in Chapter 31.

32.1.4 Formal distributions and modes

Definition 32.4 (Formal distributions, modes, n-th products)**.** A *formal distribution* with values in a vector space $\mathcal{W}$ is a family $f = (f_t)_{t\in\mathbb{Z}}$, thought of as $f(z) = \sum_t f_t z^t$. For a field $Y(u,z) = \sum_n u_{(n)} z^{-n-1}$ the *n-th mode* $u_{(n)}$ is the coefficient of z^{-n-1}, and the *n-th product* of a vertex algebra is $u_{(n)}v$.

In Lean these are `FormalDist 𝒲 = ℤ → 𝒲` (`VOA/Foundations/FormalSeries.lean`), `mode f m = f (-m - 1)` (`VOA/Foundations/FormalCalculus.lean`), `V.smul u n v := mode (V.Y u) n v` (`VOA/Core/VertexAlgebra.lean`) and `W.L n := mode (W.Y W.conformalVector) (n + 1)` (`VOA/Core/VertexOperatorAlgebra.lean`); they are quoted verbatim in Definitions 2.1, 2.7, 4.2 and Section 5.1.

From the mathematics to the Lean statement

`f t` is the coefficient of z^t; hence `mode f n = f (-n-1)` is the coefficient of z^{-n-1}, i.e. `mode (Y u) n` is $u_{(n)}$. `V.smul u n v` is $u_{(n)}v$ (the name "smul" is historical and has nothing to do with scalar multiplication). `W.L n` is $L_n = \omega_{(n+1)}$. The structures `PreVertexAlgebra` and `VertexOperatorAlgebra` (fields `Y`, `vacuum`, `conformalVector`, `grading`, `centralCharge` and the axioms) are defined in Definitions 4.1 and 4.4; `W.grading k` is the weight space W_k, a subspace of W.

Physical meaning

A formal distribution $Y(u,z) = \sum u_{(n)} z^{-n-1}$ is a chiral quantum field expanded in its Laurent modes, and $u_{(n)}v$ is the coefficient of $(z-w)^{-n-1}$ in the OPE $Y(u,z)v(w)$. The negative products ($n < 0$) are the regular (normal-ordered) terms, and $n \geq 0$ the singular ones, so $u_{(0)}v$ is the simple-pole term, $u_{(1)}v$ the double pole, and so on. Identity $L_n = \omega_{(n+1)}$ says L_n are the Laurent modes of the stress tensor $T(z) = \sum L_n z^{-n-2}$.

32.1.5 The vertex operators of charged vacua

The heart of the lattice construction is the vertex operator of e^α. Embed L in $\mathbb{R}^r$ by an orthonormal frame, so that each α has real coordinates α_b ($b = 0, \dots, r-1$) with $\sum_b \alpha_b \beta_b = \langle \alpha, \beta \rangle$. Put $\alpha(n) = \sum_b \alpha_b h_b(n)$. Then

$$Y(e^\alpha, z)\,(p \otimes e^\beta) = \varepsilon(\alpha,\beta)\, z^{\langle \alpha,\beta\rangle}\, E^-(\alpha,z) E^+(\alpha,z)\, p \otimes e^{\alpha+\beta}, \tag{32.1}$$

where

$$E^-(\alpha,z) = \exp\Big(\sum_{n\ge 1} \frac{\alpha(-n)}{n} z^n\Big) = \sum_{N\ge 0} S_N(\alpha) z^N,$$
$$E^+(\alpha,z) = \exp\Big(-\sum_{n\ge 1} \frac{\alpha(n)}{n} z^{-n}\Big) = \sum_{N\ge 0} E^+(\alpha)_{-N} z^{-N},$$

the $S_N(\alpha) \in F_r$ are the *Schur polynomials* in the $\alpha(-n)$ (for example $S_1(\alpha) = \alpha(-1)$, $S_2(\alpha) = \frac{1}{2}(\alpha(-1)^2 + \alpha(-2))$), and ε is the cocycle of §32.1.6. The product $E E(\alpha,z) := E^-(\alpha,z)E^+(\alpha,z)$ is the "boson dressing". Physically, (32.1) is the normal-ordered exponential $:e^{i\alpha\cdot X(z)}:$ of the free bosons times the momentum-shift operator $e^\alpha z^{\alpha(0)}$.

```

    Yeαvec L α t (latStateGen L p β)
      = latticeCocycle L α β • latStateGen L (EEVec L α (t - L.form α β) p) (α + β)
```

From the mathematics to the Lean statement

`chargeCoord L α b` is the real coordinate α_b (cast to $\mathbb{C}$); `vVar L α m` $= \sum_b \alpha_b x_{(m,b)} = \alpha(-m-1)\mathbf{1}$; `vSchur L α N` is $S_N(\alpha)$, defined by Newton's recursion $(N+1)S_{N+1} = \sum_{m=0}^{N} \alpha(-m-1)S_{N-m}$, which is the coefficientwise form of $\frac{d}{dz}E^- = (\sum_n \alpha(-n)z^{n-1})E^-$. `EminusVec L α N` is multiplication by $S_N(\alpha)$, and `aExpVec L α N` is $E^+(\alpha)_{-N}$ (same recursion with $-\alpha(m+1)$; `chargeOsc L α m` is the operator $\alpha(m)$). Thus `EminusVecField L α t` is the coefficient of z^t in $E^-(\alpha,z)$ (zero for $t<0$) and `EplusVecField L α t` the coefficient of z^t in $E^+(\alpha,z)$ (zero for $t>0$). `nprod` is the normal-ordered product $:a(z)b(z):$ of two fields in the same variable,

defined coefficientwise (Chapter 1); here, with $a = E^-$ (only creation operators) and $b = E^+$ (only annihilation operators), it is simply the product $E^-(\alpha, z)E^+(\alpha, z)$. Finally `Yeαvec L α t` is the coefficient of z^t in $Y(e^\alpha, z)$, and `Yeαvec_tmul` says it is $\varepsilon(\alpha, \beta)$ times the coefficient of $z^{t-\langle\alpha,\beta\rangle}$ of $EE(\alpha, z)$: this is (32.1) read coefficientwise.

The full vertex map `YfullGen L hEven hPos` of V_L is produced in Chapter 31 by a reconstruction theorem. For this chapter we need exactly one fact about it: on spanning "word states" it is given by explicit fields. A *word* is a finite list $l = [(i_1, a_1), \dots, (i_k, a_k)]$, of length $|l| = k$, and the *word state* is

$$w(l, \alpha) = h_{a_1}(-i_1 - 1) \cdots h_{a_k}(-i_k - 1)\, e^\alpha.$$

The word states span V_L (`wordStateLatGen_span`). The *word field* is the iterated normal-ordered product

$$Y_{\mathrm{word}}(l, \alpha)(z) = :\tfrac{1}{i_1!}\partial^{i_1} h_{a_1}(z)\ : \cdots :\tfrac{1}{i_k!}\partial^{i_k} h_{a_k}(z)\, Y(e^\alpha, z): \cdots :,$$

where $h_a(z) = \sum_n h_a(n) z^{-n-1}$ is the current on V_L *including* its zero mode $h_a(0)$, which acts on $p \otimes e^\beta$ by the momentum coordinate β_a.

```
-- VOA/Examples/LatticeGenVOAInstance.lean
theorem YfullGen_word (hEven : L.Even) (hPos : L.PosDef) (l : List (ℕ × Fin (rank L)))
    (α : L.carrier) :
    YfullGen L hEven hPos (wordStateLatGen L l α) = YwordLatGen L l α
```

The lattice VOA is `latticeVOAGen L hEven hPos` (Chapter 31), with `grading := gradingLatGen L`, `Y := YfullGen L hEven hPos`, vacuum e^0 and conformal vector $\omega = \frac{1}{2}\sum_a h_a(-1)^2\mathbf{1} \otimes e^0$ (`omegaLatGen L`); and

```
-- VOA/Moonshine/LeechLatticeVOA.lean
noncomputable def leechVOA : VertexOperatorAlgebra (LatGen.LatModuleGen leech) :=

theorem leechVOA_centralCharge : leechVOA.centralCharge = 24
theorem leechVOA_grading_one :
    leechVOA.grading 1 = LatGen.bigradα leech (1, 0)
```

The last statement, proved in Chapter 31 from `leech_no_roots`, says $(V_\Lambda)_1 = (F_{24})_1 \otimes e^0 = \mathrm{span}\{h_a(-1)\mathbf{1} \otimes e^0\}$: since Λ has no norm-2 vectors, no e^α has weight 1.

32.1.6 The cocycle

Definition 32.5 (The basis cocycle). Fix a $\mathbb{Z}$-basis $B_1, \dots, B_r$ of L and write $\alpha = \sum_i \alpha_i B_i$ with $\alpha_i \in \mathbb{Z}$. The *cocycle exponent* and *cocycle* are

$$c(\alpha, \beta) = \sum_{j<i} \langle B_i, B_j\rangle\, \alpha_i \beta_j \in \mathbb{Z}, \qquad \varepsilon(\alpha, \beta) = (-1)^{c(\alpha,\beta)} \in \{\pm 1\}.$$

```
-- VOA/Foundations/LatticeCocycle.lean

```

From the mathematics to the Lean statement

`B.repr α i` is the i-th coordinate α_i of α in the basis B. `latticeBasis L` is *some* basis, obtained from Mathlib's `Module.Free.chooseBasis` — a choice made by the axiom of choice, which cannot be computed with. Every property of ε the library uses is proved for an *arbitrary* basis, so the choice is harmless for correctness; but a quantity depending on the basis itself (we meet one in §32.11, namely $\varepsilon(\alpha,\alpha)$) cannot be evaluated. ε is bimultiplicative (being (-1) to a bilinear form), a sign, and for even L satisfies the commutator relation $\varepsilon(\alpha,\beta)\varepsilon(\beta,\alpha) = (-1)^{\langle\alpha,\beta\rangle}$, because $c(\alpha,\beta) + c(\beta,\alpha) = \langle\alpha,\beta\rangle - \sum_i \langle B_i, B_i\rangle \alpha_i\beta_i$ and the diagonal correction is even.

Physical meaning

The sign $\varepsilon(\alpha,\beta)$ is the standard Klein-factor (cocycle) correction in the bosonic construction of lattice vertex operators: without it, vertex operators $:e^{i\alpha\cdot X}:$ and $:e^{i\beta\cdot X}:$ would commute rather than anticommute when $\langle\alpha,\beta\rangle$ is odd, violating locality. Physically the cocycle is a gauge-like convention, and different choices of basis give isomorphic theories; this is why only the commutator $(-1)^{\langle\alpha,\beta\rangle}$ matters. Heuristic.

Example 32.6 (Two bases, two cocycles, one commutator)**.** Take the A_2 root lattice, with basis B_1, B_2 and Gram matrix $\left(\begin{smallmatrix} 2 & -1 \\ -1 & 2 \end{smallmatrix}\right)$. The only off-diagonal entry with $j < i$ is $\langle B_2, B_1\rangle = -1$, so $c(\alpha,\beta) = -\alpha_2\beta_1$ and $\varepsilon(\alpha,\beta) = (-1)^{\alpha_2\beta_1}$. Thus $\varepsilon(B_1,B_2) = 1$ and $\varepsilon(B_2,B_1) = -1$. If instead the basis is listed in the opposite order ($B_1' = B_2$, $B_2' = B_1$), the same recipe gives $\varepsilon'(\alpha,\beta) = (-1)^{\alpha_1\beta_2}$, so $\varepsilon'(B_1,B_2) = -1$ and $\varepsilon'(B_2,B_1) = 1$: a *different function*. But the commutator is the same, $\varepsilon(B_1,B_2)\varepsilon(B_2,B_1) = \varepsilon'(B_1,B_2)\varepsilon'(B_2,B_1) = -1 = (-1)^{\langle B_1,B_2\rangle}$, and so are bimultiplicativity, $\varepsilon^2 = 1$ and $\varepsilon(-\alpha,\beta) = \varepsilon(\alpha,\beta)$. These are the only properties of ε that the lattice VOA and this chapter use, and they hold for every basis. This is what "the choice is harmless" means: changing the basis changes ε, and the resulting VOAs are isomorphic, but no theorem quoted here depends on which basis was chosen. A quantity like $\varepsilon(\alpha,\alpha)$ does depend on the basis in general, and §32.11 is careful never to assume a value for it.

32.2 The Fock involution σ

The reflection $X \mapsto -X$ negates every oscillator. On the Fock space it is therefore the algebra automorphism negating every variable.

Definition 32.7 (Fock involution)**.** $\sigma : F_r \to F_r$ is the unique $\mathbb{C}$-algebra homomorphism with $\sigma(x_{(m,a)}) = -x_{(m,a)}$.

Physical meaning

σ is the action of the reflection $X^a \mapsto -X^a$ on the oscillator part of the Hilbert space: each creation operator α^a_{-n} flips sign, so a state with k quanta acquires $(-1)^k$. This is the oscillator half of the $\mathbb{Z}_2$ global symmetry of the free bosons, and it is the reflection that will be gauged in the orbifold.

Proposition 32.8. *(a)* $\sigma^2 = 1$. *(b)* $\sigma\, h_a(n) = -h_a(n)\,\sigma$ *for all* a *and all* $n \in \mathbb{Z}$. *(c) On a monomial,* $\sigma(x^d) = (-1)^{\deg d} x^d$.

```

-- VOA/Moonshine/PlusWeightOne.lean
theorem sigmaN_monomial (d : (ℕ × Fin r) →₀ ℕ) :
    sigmaN r (monomial d 1) = (-1 : ℂ) ^ d.degree • monomial d 1
```

From the mathematics to the Lean statement

`→ₐ[ℂ]` is a $\mathbb{C}$-algebra homomorphism; `MvPolynomial.aeval f` is the homomorphism sending each variable v to $f(v)$, here $-x_v$. `Function.Involutive g` means $g(g(p)) = p$ for all p. `≃ₗ[ℂ]` is a $\mathbb{C}$-linear bijection (linear equivalence), and `LinearEquiv.ofInvolutive` packages an involutive linear map as one, with itself as inverse. `sigmaN_oscN` is (b), for every level k (we only use $k = 1$). `monomial d 1` is x^d and `sigmaN_monomial` is (c). Same as the textbook statements; no hypotheses.

Physical meaning

Part (b) says the current $i\partial X^a$ is odd under the symmetry, which is exactly how σ implements $X \mapsto -X$ on the modes. Part (c) says the symmetry charge of a state is the parity of its number of oscillators; it is the statement that the $\mathbb{Z}_2$ quantum number is computed by counting quanta.

Proof. (a) σ^2 is an algebra homomorphism fixing every variable, hence the identity. (b) If $n < 0$, $h_a(n)$ is multiplication by a variable x, and $\sigma(xp) = \sigma(x)\sigma(p) = -x\,\sigma(p)$. If $n > 0$, $h_a(n)$ is a multiple of a partial derivative ∂_v, and $\sigma\partial_v = -\partial_v\sigma$: both $\sigma\partial_v\sigma^{-1}$ and $-\partial_v$ are derivations of F_r, and they agree on the generators ($\sigma\partial_v\sigma^{-1}x_w = \sigma\partial_v(-x_w) = -\delta_{vw}$). If $n = 0$ both sides vanish. (c) is multiplicativity: $\sigma(x^d) = \prod (-x_{(m,a)})^{d_{(m,a)}}$. □

What the machine verified

Proved, no hypotheses (`VOA/Moonshine/LatticeInvolution.lean`, `VOA/Moonshine/PlusWeightOne.lean`).

32.3 Lifting −1: the cocycle needs no correction

On $V_L = F_r \otimes \mathbb{C}\{L\}$ the reflection should act by σ on oscillators and by $e^\alpha \mapsto e^{-\alpha}$ on momenta. Before defining this map we should ask whether it has a chance of commuting with the vertex operators, and (32.1) shows where the danger lies: conjugating $Y(e^\alpha, z)$ by such a map produces $Y(e^{-\alpha}, z)$ only *up to the ratio* $\varepsilon(\alpha,\beta)/\varepsilon(-\alpha,-\beta)$ on the sector e^β. For a general 2-cocycle this ratio is not 1, and the textbook theory (Frenkel–Lepowsky–Meurman, §10.4) corrects the lift by a sign function $\eta : L \to \{\pm 1\}$, $e^\alpha \mapsto \eta(\alpha)e^{-\alpha}$. For the library's cocycle no correction is needed.

Proposition 32.9. *For every integral lattice L and all $\alpha, \beta \in L$: $\varepsilon(-\alpha, \beta) = \varepsilon(\alpha, \beta) = \varepsilon(\alpha, -\beta)$; hence $\varepsilon(-\alpha, -\beta) = \varepsilon(\alpha, \beta)$.*

```
-- VOA/Moonshine/LatticeInvolution.lean
theorem latticeCocycle_neg_left (α β : L.carrier) :
    latticeCocycle L (-α) β = latticeCocycle L α β
theorem latticeCocycle_neg_right (α β : L.carrier) :
    latticeCocycle L α (-β) = latticeCocycle L α β
theorem latticeCocycle_neg_neg (α β : L.carrier) :
    latticeCocycle L (-α) (-β) = latticeCocycle L α β
```

From the mathematics to the Lean statement

No hypothesis on L, not even evenness: the statement is about the specific cocycle `latticeCocycle` of Definition 32.5, and it is literally the textbook statement "ε is invariant under -1". It *would be false* for a general normalized 2-cocycle with the same commutator map; that is why the textbook needs η. The library escapes because its ε is *bimultiplicative*, not merely a cocycle.

Physical meaning

This is a statement about the sign (Klein-factor) conventions only: reflecting both momenta leaves the cocycle sign unchanged. Physically it means the reflection $\alpha \mapsto -\alpha$ does not need an extra momentum-dependent phase to be a symmetry of the operator algebra, which for a general cocycle choice would be required (the correcting function of FLM). A convention check, not a new physical effect.

Proof. By multiplicativity in the first slot, $\varepsilon(\alpha, \beta)\varepsilon(-\alpha, \beta) = \varepsilon(0, \beta) = 1$, and $\varepsilon(\alpha, \beta)^2 = 1$; so $\varepsilon(-\alpha, \beta) = \varepsilon(\alpha, \beta)$. Equivalently, $c(-\alpha, \beta) = -c(\alpha, \beta)$ and $(-1)^{-c} = (-1)^c$. The right slot is identical. □

Trap / dead end

This is a place where a convention could silently break the construction. If the lattice VOA had been built with a cocycle that is only a cocycle — for instance $\varepsilon'(\alpha, \beta) = \varepsilon(\alpha, \beta)\,\eta(\alpha + \beta)\eta(\alpha)^{-1}\eta(\beta)^{-1}$ for a sign function η that is not a character, which gives an isomorphic VOA but is not bimultiplicative — then the naive lift below would *not* be an automorphism and one would need the correcting function of FLM §10.4. The project roadmap records this as a known trap ("a non-bimultiplicative cocycle would need a correcting function on Λ"). The safeguard here is that Theorem 32.13 below is proved: whatever one believes about cocycles, the machine has checked that the map commutes with all vertex operators.

What the machine verified

Proved, no hypotheses (`VOA/Moonshine/LatticeInvolution.lean`).

Definition 32.10 (The lift θ of -1). $\theta : V_L \to V_L$ is the linear map $\theta(p \otimes e^{\alpha}) = \sigma(p) \otimes e^{-\alpha}$, i.e. $\theta = \sigma \otimes \iota$ where $\iota(e^{\alpha}) = e^{-\alpha}$.

Physical meaning

θ is the full reflection $X \to -X$ acting on states: oscillators flip sign (this is σ) and a state of momentum α is sent to momentum $-\alpha$. It is the unitary-type operator implementing a $\mathbb{Z}_2$ global symmetry of the compactified bosons, and is the lift of the lattice isometry -1 to the

chiral algebra. Heuristic: on the torus $\mathbb{R}^{24}/\Lambda$ the point-group element -1 is a symmetry for every lattice.

Proposition 32.11. *$\theta^2 = 1$; θ fixes the vacuum e^0 and the conformal vector ω; and θ preserves each weight space $(V_L)_k$.*

```
-- VOA/Moonshine/LatticeInvolution.lean
noncomputable def thetaLat : LatModuleGen L ≃ₗ[ℂ] LatModuleGen L :=
  TensorProduct.congr (sigmaN (rank L)) (Finsupp.domLCongr (Equiv.neg L.carrier))

theorem thetaLat_tmul (p : FockN (rank L)) (α : L.carrier) :
    thetaLat L (p ⊗ₜ[ℂ] eGen L α) = sigmaN (rank L) p ⊗ₜ[ℂ] eGen L (-α)

theorem thetaLat_involutive : Function.Involutive (thetaLat L)

theorem thetaLat_mem_gradingLatGen {k : ℤ} {x : LatModuleGen L} (hx : x ∈ gradingLatGen L
↪  k) :
    thetaLat L x ∈ gradingLatGen L k
```

From the mathematics to the Lean statement

`TensorProduct.congr f g` is $f \otimes g$ for linear equivalences f, g; `Finsupp.domLCongr (Equiv.neg L.carrier)` is the linear equivalence of $\mathbb{C}\{L\}$ induced by the bijection $\alpha \mapsto -\alpha$ of basis indices, i.e. $e^\alpha \mapsto e^{-\alpha}$. This is spelled out by `thetaLat_tmul`, which is Definition 32.10 verbatim, with *no* correcting sign. `latVacuumGen L` is e^0 and `omegaLatGen L` is ω. The four remaining statements are the four parts of the proposition.

Physical meaning

These three facts are what one expects of a symmetry in a CFT: it squares to one (a $\mathbb{Z}_2$), leaves the vacuum invariant (the vacuum is not spontaneously broken), leaves the stress tensor $T = \omega$ invariant (so the symmetry commutes with the Virasoro algebra and with L_0), and hence acts on each energy level. The last point is what permits decomposing every weight space into ± 1 eigenspaces.

Proof. $\theta^2 = \sigma^2 \otimes \iota^2 = 1$. $\theta(1 \otimes e^0) = \sigma(1) \otimes e^0 = 1 \otimes e^0$. The conformal vector $\frac{1}{2}\sum_a h_a(-1)^2\mathbf{1} \otimes e^0$ is quadratic in the oscillators, so σ fixes it. Finally σ preserves Fock weight and $\frac{1}{2}\langle -\alpha, -\alpha\rangle = \frac{1}{2}\langle \alpha, \alpha\rangle$, so $(F_r)_w \otimes e^\alpha$ goes to $(F_r)_w \otimes e^{-\alpha}$, of the same conformal weight. □

What the machine verified

Proved, no hypotheses (`VOA/Moonshine/LatticeInvolution.lean`).

32.4 θ commutes with every vertex operator

The central fact about θ is that it is compatible with the whole vertex algebra structure:

$$\theta\, Y(u,z)\, \theta^{-1} = Y(\theta u, z) \qquad \text{for all } u \in V_L. \tag{32.2}$$

To state the intermediate steps conveniently we introduce a small piece of language.

Definition 32.12 (Intertwining of formal distributions)**.** Let g be a linear endomorphism of a vector space V, $c \in \mathbb{C}$, and let $A(z), B(z)$ be formal distributions with coefficients in $\mathrm{End}(V)$. We say that g *intertwines A with B up to c*, written $gA = c\,Bg$, if $g\,A_t\,x = c\,B_t\,g\,x$ for every coefficient index t and every $x \in V$; that is, $gA(z) = c\,B(z)g$ as formal series.

```
-- VOA/Moonshine/LatticeInvolution.lean
def Intertw (g : End ℂ V) (c : ℂ) (A B : FormalDist (End ℂ V)) : Prop :=
  ∀ (t : ℤ) (x : V), g (A t x) = c • B t (g x)
```

From the mathematics to the Lean statement

`End ℂ V` is the space of $\mathbb{C}$-linear maps $V \to V$. `A t` is the coefficient of z^t of $A(z)$; the definition is word for word Definition 32.12. It is a coefficientwise identity, so it involves no convergence questions.

Physical meaning

This is only bookkeeping language: "g intertwines A with B" says that conjugating the field $A(z)$ by the symmetry operator g gives the field $c\,B(z)$, i.e. the field transforms covariantly under the symmetry. It is the mode-level form of the statement that a global symmetry g maps local operators to local operators, $g\,\mathcal{O}(z)\,g^{-1} = (g\mathcal{O})(z)$.

The calculus of this relation consists of three closure properties, each immediate from the definition:

(a) if $gA = c\,Bg$ then $g\,\partial A = c\,(\partial B)\,g$ and $g(eA) = c\,(eB)g$ for scalars e;

(b) if $ga = c\,a'g$ and $gb = d\,b'g$ for fields a, b, a', b', then $g\,{:}ab{:} = cd\,{:}a'b'{:}\,g$ for the normal-ordered products.

For (b): the coefficient of the normal-ordered product is a (locally finite) sum of products $a_m b_n$ or $b_n a_m$ with the same ordering rule on both sides, and g passes through each factor picking up c and d.

Theorem 32.13 (θ intertwines the vertex operators)**.** *Let L be even and positive-definite. Then for all $u, v \in V_L$ and $n \in \mathbb{Z}$,*

$$\theta\big(u_{(n)}v\big) = (\theta u)_{(n)}(\theta v),$$

equivalently (32.2)*.*

```
-- VOA/Moonshine/LatticeInvolution.lean
theorem thetaLat_YfullGen (u : LatModuleGen L) (t : ℤ) (x : LatModuleGen L) :
    thetaLat L (YfullGen L hEven hPos u t x)
      = YfullGen L hEven hPos (thetaLat L u) t (thetaLat L x)

theorem thetaLat_mode (u : LatModuleGen L) (n : ℤ) (v : LatModuleGen L) :
    thetaLat L (mode (YfullGen L hEven hPos u) n v)
      = mode (YfullGen L hEven hPos (thetaLat L u)) n (thetaLat L v)
```

From the mathematics to the Lean statement

Section variables: `(L : IntegralLattice) (hEven : L.Even) (hPos : L.PosDef)`. These are exactly the hypotheses under which the lattice VOA exists (Chapter 31), so they cost nothing. `YfullGen L hEven hPos u t` is the coefficient of z^t of $Y(u,z)$ for the *actual* vertex map of the lattice VOA `latticeVOAGen L hEven hPos` (not a model of it), and `mode (YfullGen … u) n v` is $u_{(n)}v$. The first statement is (32.2) coefficientwise, the second is the mode form.

All variables are universally quantified. The statement is the textbook one; it could only have been vacuous if the lattice VOA were degenerate, which it is not (Chapter 31 computes its graded dimension).

Physical meaning

This is the statement that θ is a symmetry of the full OPE algebra: $\theta\, Y(u,z)\,\theta^{-1} = Y(\theta u, z)$ says that applying the reflection to a correlator is the same as reflecting each inserted operator, so all OPE data (all structure constants) are invariant under $X \to -X$. For the vertex operators, $\theta : e^{i\alpha\cdot X} : \mapsto : e^{-i\alpha\cdot X} :$ and $\partial X \mapsto -\partial X$. The point of the theorem is that no extra anomalous phase appears; this holds because the cocycle is bimultiplicative (Proposition 32.9).

Proof. The usual textbook proof goes through Goddard's uniqueness theorem: the field $\theta Y(u,z)\theta^{-1}$ is local with respect to all $Y(v,z)$ and creates θu from the vacuum, hence equals $Y(\theta u, z)$. We give instead a direct proof, which needs no uniqueness theorem, because the vertex map of V_L is *known* on a spanning set: $Y(w(l,\alpha),z)$ is the word field $Y_{\mathrm{word}}(l,\alpha)$. Both sides of (32.2) are linear in u, and the word states span V_L, so it suffices to prove, for every word l and every α,

$$\theta\, Y_{\mathrm{word}}(l,\alpha)\,\theta^{-1} = (-1)^{|l|}\, Y_{\mathrm{word}}(l,-\alpha) \qquad \text{and} \qquad \theta\, w(l,\alpha) = (-1)^{|l|} w(l,-\alpha), \tag{32.3}$$

since then $\theta Y(w(l,\alpha),z)\theta^{-1} = (-1)^{|l|} Y(w(l,-\alpha),z) = Y(\theta w(l,\alpha),z)$.

Step 1: the dressing. $\sigma S_N(\alpha) = S_N(-\alpha)$, since $S_N(\alpha)$ is a polynomial in the $\alpha(-n)$ and $\sigma\alpha(-n) = -\alpha(-n) = (-\alpha)(-n)$. Likewise $\sigma\, E^+(\alpha)_{-N} = E^+(-\alpha)_{-N}\,\sigma$, because $E^+(\alpha)_{-N}$ is a polynomial in the annihilation operators $\alpha(n)$, and $\sigma\alpha(n) = -\alpha(n)\sigma = (-\alpha)(n)\sigma$ by Proposition 32.8(b). Hence by (b) of the calculus, $\sigma\, EE(\alpha,z) = EE(-\alpha,z)\,\sigma$.

Step 2: the charged vacua. On $p \otimes e^\beta$, using (32.1),

$$\theta\, Y(e^\alpha,z)(p\otimes e^\beta) = \varepsilon(\alpha,\beta) z^{\langle\alpha,\beta\rangle}\, \sigma EE(\alpha,z) p \otimes e^{-\alpha-\beta} = \varepsilon(\alpha,\beta) z^{\langle\alpha,\beta\rangle}\, EE(-\alpha,z)\sigma p \otimes e^{-\alpha-\beta},$$
$$Y(e^{-\alpha},z)\,\theta(p\otimes e^\beta) = \varepsilon(-\alpha,-\beta) z^{\langle-\alpha,-\beta\rangle}\, EE(-\alpha,z)\sigma p \otimes e^{-\alpha-\beta}.$$

The two agree by Proposition 32.9 and $\langle-\alpha,-\beta\rangle = \langle\alpha,\beta\rangle$. So $\theta Y(e^\alpha,z)\theta^{-1} = Y(e^{-\alpha},z)$: the case $l = [\,]$ of (32.3).

Step 3: the currents. $\theta h_a(z)\theta^{-1} = -h_a(z)$, including the zero mode: for $n \neq 0$ this is Proposition 32.8(b), and $h_a(0)$ acts on $p\otimes e^\beta$ by β_a, while θ moves $p\otimes e^\beta$ to the sector $-\beta$, where $h_a(0)$ acts by $-\beta_a$. By (a), $\theta\big(\frac{1}{i!}\partial^i h_a\big)\theta^{-1} = -\frac{1}{i!}\partial^i h_a$.

Step 4: induction on the word. By (b), each additional letter of the word contributes one factor -1, which gives the first half of (32.3). The second half is $\theta\big(h_{a_1}(-i_1-1)\cdots e^\alpha\big) = (-1)^k\, h_{a_1}(-i_1-1)\cdots e^{-\alpha}$, by Proposition 32.8(b) once more. □

Remark (what the proof uses). The argument uses three things: the cocycle identity of Proposition 32.9, the explicit form (32.1) of $Y(e^\alpha,z)$, and the fact that the vertex map is determined on word states by word fields. It does not use locality or any uniqueness theorem. Physically, Step 2 is the statement that $: e^{i\alpha\cdot X} : \mapsto : e^{-i\alpha\cdot X} :$ under $X \mapsto -X$, and Step 3 that $\partial X \mapsto -\partial X$.

What the machine verified

`thetaLat_mode`: proved, unconditional given `hEven`, `hPos`; `#print axioms` gives `[propext, Classical.choice, Quot.sound]` (checked while writing this chapter). File `VOA/Moonshine/LatticeInvolution.lean`.

32.5 θ as an automorphism of order two

Definition 32.14 (VOA automorphism)**.** An *automorphism* of a VOA W is a linear bijection $g : W \to W$ with $g(u_{(n)}v) = (gu)_{(n)}(gv)$ for all u, v, n, $g\mathbf{1} = \mathbf{1}$ and $g\omega = \omega$. The automorphisms form a group $\mathrm{Aut}(W)$ under composition.

In Lean this is the structure `Aut W` (`VOA/Core/Automorphism.lean`), quoted verbatim and decoded in Definition 5.9: a linear equivalence `toLinearEquiv` with fields `map_smul'` ($g(u_{(n)}v) = (gu)_{(n)}(gv)$ for all u, n, v), `map_vacuum` and `map_omega`.

From the mathematics to the Lean statement

Exactly Definition 32.14 (Gannon §5.2.1). Fixing ω forces g to commute with all $L_n = \omega_{(n+1)}$, hence to preserve the grading. The group structure ($*$ is composition, `1` the identity) is defined in the same file; two automorphisms are equal as soon as their underlying linear maps are (`Aut.ext`).

Physical meaning

An automorphism of a VOA is a global (chiral) symmetry of the 2d CFT: a linear map on states preserving the vacuum, the stress tensor and all OPEs, so that it commutes with L_n and acts on correlators by transforming every insertion. The group $\mathrm{Aut}(W)$ is the group of such symmetries; for the Moonshine module it is the Monster, but here we are only constructing one $\mathbb{Z}_2$ in the abelian-torus theory.

Theorem 32.15. *Let L be even and positive-definite. Then $\theta \in \mathrm{Aut}(V_L)$, $\theta^2 = 1$, and if $L \neq 0$ then $\theta \neq 1$. For the Leech lattice, $\theta_\Lambda := \theta \in \mathrm{Aut}(V_\Lambda)$ satisfies $\theta_\Lambda^2 = 1 \neq \theta_\Lambda$.*

```
-- VOA/Moonshine/LatticeInvolution.lean
noncomputable def thetaAut : Aut (latticeVOAGen L hEven hPos) where
  toLinearEquiv := thetaLat L
  map_smul' u n v := thetaLat_mode L hEven hPos u n v
  map_vacuum := thetaLat_vacuum L
  map_omega := thetaLat_omega L

theorem thetaAut_sq : thetaAut L hEven hPos * thetaAut L hEven hPos = 1
theorem thetaAut_ne_one (hL : ∃ α : L.carrier, α ≠ 0) : thetaAut L hEven hPos ≠ 1

noncomputable def leechTheta : Aut leechVOA := thetaAut leech leech_even leech_posDef
theorem leechTheta_sq : leechTheta * leechTheta = 1 := thetaAut_sq leech leech_even
 ↪  leech_posDef
theorem leechTheta_ne_one : leechTheta ≠ 1
```

From the mathematics to the Lean statement

The definition of `thetaAut` is shown in full because it is informative: the four fields are the linear map of Definition 32.10 and the three proofs Theorem 32.13 and Proposition 32.11. Since `W.smul u n v` is by definition `mode (W.Y u) n v` and `(latticeVOAGen …).Y` is `YfullGen …`, the field `map_smul'` is literally `thetaLat_mode`. The hypothesis `hL` of `thetaAut_ne_one` says $L \neq 0$; without it the statement is false ($L = 0$ gives $V_L = F_0 = \mathbb{C}$ and $\theta = 1$). For Λ it is supplied by rank 24. `leechVOA` is `latticeVOAGen leech leech_even leech_posDef`, so `leechTheta` is literally θ for Λ.

Physical meaning

So θ is a genuine $\mathbb{Z}_2$ global symmetry of the torus CFT on $\mathbb{R}^{24}/\Lambda$, of order exactly two (it acts nontrivially, e.g. $\partial X^a \mapsto -\partial X^a$, so it is not secretly trivial). This is precisely the symmetry one would orbifold by in the "$\mathbb{R}^{24}/(\Lambda \rtimes \mathbb{Z}_2)$" construction of the Moonshine module.

Proof. The automorphism property is Theorem 32.13 together with Proposition 32.11; $\theta^2 = 1$ is the involutivity of Proposition 32.11. If $\alpha \neq 0$ then $\theta e^\alpha = e^{-\alpha}$, and $e^{-\alpha} \neq e^\alpha$ because $-\alpha \neq \alpha$: a lattice is torsion-free, so $2\alpha = 0$ forces $\alpha = 0$. □

What the machine verified

`thetaAut`, `thetaAut_sq`, `thetaAut_ne_one`, `leechTheta`, `leechTheta_sq`, `leechTheta_ne_one`: proved; `#print axioms` for `thetaAut_sq`, `thetaAut_ne_one`, `leechTheta_ne_one` is `[propext, Classical.choice, Quot.sound]`. Unconditional (the hypotheses `hEven`, `hPos`, `hL` are discharged for Λ).

32.6 The fixed-point algebra V_Λ^+

Definition 32.16 (Sub-VOA; fixed-point sub-VOA)**.** A *vertex operator subalgebra* of a VOA W is a subspace S containing $\mathbf{1}$ and ω, closed under all n-th products, and *graded*: if $v \in S$ then each homogeneous component of v lies in S. It is itself a VOA with the restricted vertex map, the same vacuum, conformal vector and central charge, and grading $S_n = S \cap W_n$. For a subgroup $G \leq \mathrm{Aut}(W)$ the *fixed-point subalgebra* (or *orbifold*) is $W^G = \{v \in W : gv = v \ \forall g \in G\}$.

  (orbifold G).toVOA

theorem orbifoldVOA_centralCharge (G : Subgroup (Aut W)) :
    (orbifoldVOA G).centralCharge = W.centralCharge := rfl
```

From the mathematics to the Lean statement

In the display, "`...`" marks omitted *proof* fields of `orbifold` (that the set is a subspace, contains $\mathbf{1}$ and ω, is closed under products and graded); the only data is the carrier $\{v \mid \forall g \in G,\ gv = v\}$, exactly W^G. `piHom W n v` is the weight-n component of v. `(orbifold G).carrier` is a `Submodule`; as a type, `↥(orbifold G).carrier` (written with the coercion arrow `↥`) is the

set of its elements v packaged with their membership proof, and the VOA `orbifoldVOA G` lives on that type. Its weight spaces are `gradingS n`, the elements of S lying in W_n (`comap` along the inclusion `subtype`). `toVOA` (Definition 5.24) restricts all structure. The central charge equality is definitional (`rfl`).

Physical meaning

Taking W^G is the projection of the Hilbert space onto G-invariant states, the first step of orbifolding a CFT by a global symmetry group G. The invariant states close under the OPE and contain the identity and stress tensor, so the result is again a chiral algebra with the same central charge c; it is a smaller algebra, whose missing operators are recovered (as a different representation) in the twisted sectors. Heuristic: one also has to add the twisted sectors to get a modular invariant theory, which is the content of the later chapters.

Definition 32.17 (V_Λ^+). $V_\Lambda^+ := V_\Lambda^{\langle\theta\rangle} = \{v \in V_\Lambda : \theta v = v\}$, with the VOA structure of Definition 32.16.

```

  mem_orbifold_zpowers_iff leechTheta v

theorem leechVOAPlus_centralCharge : leechVOAPlus.centralCharge = 24

-- VOA/Moonshine/FrameSectors.lean
abbrev VPlus : Type := ↥(orbifold (Subgroup.zpowers leechTheta)).carrier
```

From the mathematics to the Lean statement

`Subgroup.zpowers g` is the cyclic subgroup $\{g^k : k \in \mathbb{Z}\}$ generated by g; here $\{1, \theta\}$. `mem_orbifold_zpowers_iff` says that being fixed by the whole cyclic group is the same as being fixed by its generator, so `mem_leechVOAPlus_iff` identifies the carrier with $\{v : \theta v = v\}$, i.e. Definition 32.17. `VPlus` is the type of elements of V_Λ^+ used in later files. The weight spaces of `leechVOAPlus` are $(V_\Lambda^+)_k = V_\Lambda^+ \cap (V_\Lambda)_k$ by `gradingS`. How could this be vacuous? If θ were the identity, V_Λ^+ would be all of V_Λ and every subsequent dimension statement would be wrong; `leechTheta_ne_one` and the dimension $98580 \neq 196884$ below rule this out.

Physical meaning

V_Λ^+ is the untwisted $\mathbb{Z}_2$-invariant sector of the orbifold of the 24-boson torus theory by the reflection: the operators that survive the projection $P = \frac{1}{2}(1 + \theta)$ onto states with even $X \to -X$ parity. Its states are the even combinations such as $\cos(\alpha \cdot X)$ and products of an even number of oscillators; the central charge stays 24 since the stress tensor $\frac{1}{2}(\partial X)^2$ is even.

Proof. If $gv = v$ then $g^k v = v$ for every $k \in \mathbb{Z}$ (for negative k apply g^{-1} to $gv = v$). The central charge is that of V_Λ, which is rank $\Lambda = 24$. □

What the machine verified

`leechVOAPlus` is a definition; `mem_leechVOAPlus_iff` and `leechVOAPlus_centralCharge` are proved, `#print axioms [propext, Classical.choice, Quot.sound]`. Unconditional.

Remark 32.18 (Why the fixed points form a VOA, physically and mathematically)**.** If $\theta u = u$ and $\theta v = v$ then $\theta(u_{(n)}v) = u_{(n)}v$, so V^+ is closed under all products; $\mathbf{1}$ and ω are fixed; and θ preserves weights, so components of fixed vectors are fixed. In CFT language: a symmetry commuting with the stress tensor can be used to project the theory, and the projected chiral algebra is again a chiral algebra with the same Virasoro central charge. Nothing more is needed for Definition 32.16. What is *not* automatic is that V^+ is "large" — that it remembers enough of V to be useful — and the rest of this chapter makes that precise.

Remark 32.19 (The projection)**.** The map $P = \frac{1}{2}(1+\theta) : V_\Lambda \to V_\Lambda^+$ is a projection onto V_Λ^+ (it fixes V_Λ^+ and kills the (-1)-eigenspace V_Λ^-), and $V_\Lambda = V_\Lambda^+ \oplus V_\Lambda^-$. On basis vectors, $P(p \otimes e^\alpha) = \frac{1}{2}(p \otimes e^\alpha + \sigma p \otimes e^{-\alpha})$.

```
-- VOA/Moonshine/Generation.lean
noncomputable def plusProj : LatModuleGen leech →ₗ[ℂ] VPlus :=
  LinearMap.codRestrict _ ((1 / 2 : ℂ) • (LinearMap.id + (thetaLat leech).toLinearMap))
    (fun v => by simpa using half_add_theta_mem_plus v)
theorem plusProj_of_mem (v : VPlus) : plusProj (v : LatModuleGen leech) = v
```

`LinearMap.codRestrict` regards the map $\frac{1}{2}(1+\theta)$, whose image lies in V_Λ^+, as a map into V_Λ^+; `plusProj_of_mem` says P is the identity on V_Λ^+ (`(v : LatModuleGen leech)` is v regarded as a vector of V_Λ).

32.7 Weight one: $(V_\Lambda^+)_1 = 0$

Lemma 32.20. *(a) Every monomial satisfies* $\deg d \le \operatorname{weight} d$*. (b) Consequently* $\sigma = -1$ *on* $(F_r)_1$*.*

```
-- VOA/Moonshine/PlusWeightOne.lean
theorem degree_le_weight (d : (ℕ × Fin r) →₀ ℕ) :
    d.degree ≤ Finsupp.weight weightFnN d

theorem sigmaN_weight_one {p : FockN r} (hp : p ∈ gradingWN r 1) : sigmaN r p = -p
```

From the mathematics to the Lean statement

`d.degree` and `Finsupp.weight weightFnN d` are the degree and weight of Definition 32.2. The hypothesis `hp` says $p \in (F_r)_1$. Same as the textbook statement.

Physical meaning

This is the elementary observation that at energy 1 the only oscillator state is a single quantum $\alpha^a_{-1}|0\rangle$: there is no room for two quanta. A single quantum is odd under $X \to -X$, so the whole level is odd.

Proof. (a) Every variable has weight $m+1 \geq 1$. (b) A weight-1 monomial has degree ≤ 1 and is nonconstant, hence has degree 1; so it is some $x_{(0,a)} = h_a(-1)\mathbf{1}$, and σ multiplies it by -1. Extend linearly. □

Theorem 32.21 ($(V_\Lambda^+)_1 = 0$). *The weight-one space of V_Λ^+ is zero.*

```
-- VOA/Moonshine/PlusWeightOne.lean
theorem leechVOAPlus_grading_one : leechVOAPlus.grading 1 = ⊥
```

From the mathematics to the Lean statement

`leechVOAPlus.grading 1` is $(V_\Lambda^+)_1 = V_\Lambda^+ \cap (V_\Lambda)_1$ (Definition 32.16); `⊥` is the zero subspace. No hypotheses. This is one half of the statement $V^\natural{}_1 = 0$ of the final theorem; the other half is that the twisted sector starts in weight 3/2, so that its θ-fixed part starts in weight 2 (Chapters 35–36).

Physical meaning

There are no weight-one operators left in the orbifold: the only weight-one fields of the torus theory are the 24 $U(1)$ currents ∂X^a (since Λ has no norm-2 vectors, there are no charged currents $e^{i\alpha\cdot X}$), and they all change sign under the reflection. Hence no continuous symmetry survives the projection, which is the CFT form of the statement that the Monster has no continuous part: $V_1 = 0$ means no Kac–Moody currents.

Proof. By `leechVOA_grading_one`, every $x \in (V_\Lambda)_1$ is $p \otimes e^0$ with $p \in (F_{24})_1$. Then $\theta x = \sigma p \otimes e^0 = -x$ by Lemma 32.20. If moreover $\theta x = x$, then $2x = 0$, so $x = 0$. □

Example 32.22 (Weight one, concretely). $(V_\Lambda)_1$ has basis $h_0(-1)e^0, \dots, h_{23}(-1)e^0$, the 24 "currents" of the free bosons; this is the Lie algebra $\mathbb{C}^{24}$ of the torus $\mathbb{R}^{24}/\Lambda$ of continuous symmetries, abelian since there are no roots. All of them are odd under the reflection. Compare with a lattice *with* roots, e.g. the E_8 lattice: there $(V_{E_8})_1$ has dimension $8 + 240 = 248$ (the Lie algebra E_8), and the θ-fixed part is spanned by the 120 vectors $e^\alpha + e^{-\alpha}$ (α a root, one per pair $\pm\alpha$), the fixed algebra of the Chevalley involution. The *absence of roots* is exactly what makes $(V_\Lambda^+)_1 = 0$, and it is the first sign that the Monster, unlike the symmetry groups of lattice theories, has no continuous part.

What the machine verified

`leechVOAPlus_grading_one`: proved, unconditional, `#print axioms` `[propext, Classical.choice, Quot.sound]` (`VOA/Moonshine/PlusWeightOne.lean`).

32.8 Weight two: 196884 and 98580

The weight-2 space of $V^\natural$ is the Griess algebra, of dimension 196884. Its untwisted part is $(V_\Lambda^+)_2$. We first compute $(V_\Lambda)_2$ and then split it under θ.

32.8.1 The weight-two space of a rootless lattice VOA

A Fock monomial of weight 2 is either $x_{(1,a)} = h_a(-2)\mathbf{1}$ (one oscillator of weight 2; r of them) or $x_{(0,a)}x_{(0,b)} = h_a(-1)h_b(-1)\mathbf{1}$ (two oscillators of weight 1; one for each unordered pair $\{a,b\}$ with repetition allowed, so $\binom{r+1}{2}$ of them).

Proposition 32.23. $\dim(F_r)_2 = r + \binom{r+1}{2}$. *Moreover $\sigma = -1$ on the linear states $h_a(-2)\mathbf{1}$ and $\sigma = +1$ on the quadratic states $h_a(-1)h_b(-1)\mathbf{1}$.*

```
-- VOA/Moonshine/PlusWeightTwo.lean
theorem finrank_gradingWN_two : finrank ℂ (gradingWN r 2) = r + (r + 1).choose 2

noncomputable def quadFock : Submodule ℂ (FockN r) :=
  Submodule.span ℂ (Set.range (wt2Mon r ∘ Sum.inr))
noncomputable def linFock : Submodule ℂ (FockN r) :=

theorem sigmaN_of_mem_quadFock {p : FockN r} (hp : p ∈ quadFock r) : sigmaN r p = p
theorem sigmaN_of_mem_linFock {p : FockN r} (hp : p ∈ linFock r) : sigmaN r p = -p
```

From the mathematics to the Lean statement

`finrank ℂ U` is the dimension of the subspace U over $\mathbb{C}$ (Mathlib's `Module.finrank`; it is 0 for infinite-dimensional spaces, which is why each finite-dimensionality is proved separately in the library and why a dimension statement here is a real statement). `(r + 1).choose 2` is $\binom{r+1}{2}$. `wt2Mon r` enumerates the weight-2 monomials by the disjoint union $\{0..r-1\} \sqcup \mathrm{Sym}^2\{0..r-1\}$: `Sum.inl a` is $h_a(-2)\mathbf{1}$ and `Sum.inr s(a,b)` is $h_a(-1)h_b(-1)\mathbf{1}$; `Submodule.span ℂ (Set.range f)` is the span of the image of f.

Physical meaning

At level 2 the oscillator states are of two kinds: one quantum of energy 2 (the field $\partial^2 X^a$) and two quanta of energy 1 (the bilinears $\partial X^a \partial X^b$, symmetric in a, b). The reflection flips the sign of the first and fixes the second, because a state with an even number of quanta is invariant. This sorting is the core of the splitting of the weight-two space into $\theta = \pm 1$.

Theorem 32.24 (Weight two of a rootless lattice VOA). *Let L be even, positive-definite, with no vectors of norm 2. Then*

$$(V_L)_2 = (F_r)_2 \otimes e^0 \;\oplus \bigoplus_{\langle\alpha,\alpha\rangle=4} \mathbb{C}e^\alpha, \qquad \dim(V_L)_2 = r + \binom{r+1}{2} + \#\{\alpha \in L : \langle\alpha,\alpha\rangle = 4\}.$$

For the Leech lattice, $\dim(V_\Lambda)_2 = 24 + 300 + 196560 = 196884$.

```
-- VOA/Moonshine/PlusWeightTwo.lean

theorem leechVOA_finrank_grading_two : finrank ℂ (leechVOA.grading 2) = 196884
```

From the mathematics to the Lean statement

`normFour L hPos` is the finite set (`Finset`) of norm-4 vectors; finiteness needs positive-definiteness (`normFour_finite`), and `.card` is its cardinality. `bigradα L (0, α)` $= \mathbb{C}e^{\alpha}$, `bigradα L (2, 0)` $= (F_r)_2 \otimes e^0$, and $\sqcup$ is the sum of subspaces (it is direct, which the dimension formula uses). `hR` is "no roots". For Leech, `leechVOA.grading 2` is by definition `gradingLatGen leech 2`, and the three hypotheses are `leech_even`, `leech_posDef`, `leech_no_roots`; the count 196560 is `Leech.repCount_four`. The textbook statement and the Lean one agree. The result is *not* vacuous in the way a dimension count could be (e.g. by computing `finrank` of an infinite-dimensional space as 0): the space is proved finite-dimensional and the number is positive.

Physical meaning

The weight-two operators of the torus theory are of three types: the oscillator descendants $\partial^2 X^a$, the bilinears $\partial X^a \partial X^b$ (24+300 of them), and the vertex operators $:e^{i\alpha\cdot X}:$ with $\frac{1}{2}\langle\alpha,\alpha\rangle = 2$, one for each of the 196560 minimal vectors of Λ. The total $196884 = 24 + 300 + 196560$ is the dimension of the weight-two space of V_Λ, which numerically coincides with that of the Moonshine module's Griess algebra. This coincidence reflects that both characters equal $J + \text{const}$, and is not used in proofs.

Proof. A summand $(F_r)_{2-\frac{1}{2}\langle\alpha,\alpha\rangle} \otimes e^{\alpha}$ is nonzero only if $\frac{1}{2}\langle\alpha,\alpha\rangle \le 2$, i.e. $\langle\alpha,\alpha\rangle \in \{0,2,4\}$. Norm 0 means $\alpha = 0$, giving $(F_r)_2 \otimes e^0$; norm 2 does not occur; norm 4 gives $(F_r)_0 \otimes e^{\alpha} = \mathbb{C}e^{\alpha}$. Count dimensions with Proposition 32.23; for $r = 24$, $\binom{25}{2} = 300$. □

32.8.2 The θ-split and the counting trick

Theorem 32.25 (Weight two of V_L^+). *Let L be even, positive-definite and rootless, and let S be a set containing exactly one vector from each pair $\{\alpha,-\alpha\}$ of norm-4 vectors. Then*

$$(V_L)_2^+ = \operatorname{span}\{h_a(-1)h_b(-1)e^0\} \oplus \bigoplus_{\alpha\in S} \mathbb{C}(e^{\alpha}+e^{-\alpha}),$$

$$\dim(V_L)_2^+ = \binom{r+1}{2} + \#S = \binom{r+1}{2} + \tfrac{1}{2}\#\{\langle\alpha,\alpha\rangle = 4\}.$$

For the Leech lattice, $\dim(V_\Lambda^+)_2 = 300 + 98280 = 98580$.

```
-- VOA/Moonshine/PlusWeightTwo.lean
noncomputable def plusTwo : Submodule ℂ (LatModuleGen L) :=
  gradingLatGen L 2 ⊓ LinearMap.ker ((thetaLat L).toLinearMap - LinearMap.id)

noncomputable def leechVOAPlusGradingTwoEquiv : leechVOAPlus.grading 2 ≃ₗ[ℂ] plusTwo leech
theorem leechVOAPlus_finrank_grading_two : finrank ℂ (leechVOAPlus.grading 2) = 98580
```

From the mathematics to the Lean statement

`plusTwo L` is $(V_L)_2 \cap \ker(\theta - 1)$ (`⊓` is intersection, `LinearMap.ker` the kernel), i.e. the θ-fixed vectors of weight 2 in V_L. `halfFour L hPos` is the set S: `WellOrderingRel` is a well-order on L supplied by the axiom of choice, and S keeps α when α precedes $-\alpha$; any choice of one vector per pair would do, and `card_normFour_eq` records $\#S = \frac{1}{2}\#\{\langle\alpha,\alpha\rangle = 4\}$. In `finrank_plusTwo`, `hPos` is a section variable. The linear equivalence `leechVOAPlusGradingTwoEquiv` identifies the weight-2 space of the VOA `leechVOAPlus` (whose elements live in the subtype `VPlus`) with the subspace `plusTwo leech` of V_Λ; this is how a statement about the abstract VOA is reduced to the concrete subspace, and it is what makes the final `leechVOAPlus_finrank_grading_two` a statement about the actual VOA V_Λ^+ and not merely about a subspace defined by hand.

Physical meaning

The weight-two θ-even states are the 300 bilinears $\partial X^a \partial X^b$ (which include the stress tensor $\omega = \frac{1}{2}\sum_a \partial X^a \partial X^a$) together with the 98280 cosine combinations $:(e^{i\alpha\cdot X} + e^{-i\alpha\cdot X}):\ \sim \cos(\alpha\cdot X)$, one for each pair $\pm\alpha$ of minimal vectors. The θ-odd ones, $\partial^2 X^a$ and $\sin(\alpha\cdot X)$, are projected out. So $\dim(V_\Lambda^+)_2 = 300 + 98280 = 98580$ is the untwisted contribution to the Griess algebra of $V^\natural$, whose remaining $98304 = 24\cdot 2^{12}$ states come from the twisted sector. The counting trick is a pure linear algebra device with no direct physical meaning.

Proof: the counting trick. Write $D = \dim(V_L)_2 = r + \binom{r+1}{2} + 2\#S$ (Theorem 32.24 and $\#\{\langle\alpha,\alpha\rangle = 4\} = 2\#S$), and put $V^\pm = (V_L)_2 \cap \ker(\theta \mp 1)$, the fixed and the odd subspace. The argument has four steps.

Step (i): $V^+ \cap V^- = 0$. If $x \in V^+ \cap V^-$ then $x = \theta x = -x$, so $2x = 0$ and $x = 0$.

Step (ii): an upper bound for the sum. Since V^+ and V^- meet only in 0, their sum $V^+ + V^-$ is direct, so $\dim V^+ + \dim V^- = \dim(V^+ \oplus V^-)$. And $V^+ \oplus V^-$ is a subspace of $(V_L)_2$. Hence

$$\dim V^+ + \dim V^- \le D. \tag{32.4}$$

Step (iii): a lower bound for each. The quadratic states $h_a(-1)h_b(-1)e^0$ (there are $\binom{r+1}{2}$, linearly independent) are fixed by θ (Proposition 32.23), and for $\alpha \in S$ so is $e^\alpha + e^{-\alpha} = e^\alpha + \theta e^\alpha$. These $\binom{r+1}{2} + \#S$ vectors are linearly independent: the $e^\alpha + e^{-\alpha}$ for distinct $\alpha \in S$ involve disjoint pairs of basis vectors $e^{\pm\alpha}$ (that is why S contains only one vector of each pair), and they live in nonzero charge sectors, while the quadratic states live in charge 0. So $\dim V^+ \ge \binom{r+1}{2} + \#S$. In the same way the r states $h_a(-2)e^0$ and the $\#S$ vectors $e^\alpha - e^{-\alpha}$ are independent and lie in V^-, so $\dim V^- \ge r + \#S$.

Step (iv): squeeze. Adding the two lower bounds of (iii),

$$\dim V^+ + \dim V^- \ \ge\ \left(\binom{r+1}{2} + \#S\right) + \left(r + \#S\right) = D.$$

Together with (32.4), $\dim V^+ + \dim V^- = D$. Now if either lower bound were strict, say $\dim V^+ > \binom{r+1}{2} + \#S$, then adding $\dim V^- \ge r + \#S$ would give $\dim V^+ + \dim V^- > D$, contradicting (32.4). So both lower bounds are equalities: $\dim V^+ = \binom{r+1}{2} + \#S$ and $\dim V^- = r + \#S$. (As a by-product, the exhibited vectors are bases, and $(V_L)_2 = V^+ \oplus V^-$.) □

The trick avoids computing a trace or a projection: we never need to show that the exhibited vectors *span* the fixed space, because the dimension count forces it.

Example 32.26 (The weight-two spaces of V_Λ, in a table)**.**

states	number	θ	contributes to
$h_a(-2)e^0$	24	-1	V^-
$h_a(-1)h_b(-1)e^0$, $a \le b$	300	$+1$	V^+
$e^\alpha + e^{-\alpha}$, $\alpha \in S$	98280	$+1$	V^+
$e^\alpha - e^{-\alpha}$, $\alpha \in S$	98280	-1	V^-
total	196884		98580 + 98304

Thus $\dim(V_\Lambda^+)_2 = 98580$ and $\dim(V_\Lambda^-)_2 = 98304$. The number 196884 appears here as $\dim(V_\Lambda)_2$, *before* any orbifolding; the Griess algebra $V^\natural{}_2$ has the same dimension for a different reason: $98580 + 98304$ where now $98304 = 2^{12} \cdot 24$ is the dimension of the weight-2 part of the twisted sector, $(F^T)_{1/2} \otimes T$ with $\dim T = 2^{12}$ (Chapter 36). That $\dim(V_\Lambda^-)_2 = 24 + 98280$ coincides with $2^{12} \cdot 24$ is a numerical observation — equivalently $\dim(V_\Lambda)_2 = \dim V^\natural{}_2$ — and it is *not* used anywhere in the library; it reflects the fact that both V_Λ and $V^\natural$ have characters equal to J plus a constant (§32.9).

What the machine verified

`finrank_gradingLatGen_two`, `finrank_plusTwo`: proved for every even positive-definite rootless lattice. `leechVOA_finrank_grading_two` (196884) and `leechVOAPlus_finrank_grading_two` (98580): proved, unconditional; `#print axioms [propext, Classical.choice, Quot.sound]`. The file `LatticeGradedDim.lean` also re-derives both numbers from the general formulas of the next section (`leechVOA_finrank_grading_two_theta`, `leechVOAPlus_finrank_grading_two_theta`), an internal consistency check.

32.9 The graded dimension of V_L and of V_L^+

32.9.1 Coloured partitions

Definition 32.27 (Fock counts). For $r, w \in \mathbb{N}$ let $P(r, w)$ be the number of monomials of weight w in F_r — the number of r-coloured partitions of w — and let $P^+(r, w)$, $P^-(r, w)$ be the numbers of those of even, respectively odd, degree. The *signed count* is $P^s(r, w) = P^+(r, w) - P^-(r, w)$.

```
-- VOA/Examples/HeisenbergNVertex.lean
def weightDegSetN (r w : ℕ) : Set ((ℕ × Fin r) →₀ ℕ) :=

noncomputable def fockCountEven (w : ℕ) : ℕ := (fockSetEven r w).ncard
noncomputable def fockCountOdd (w : ℕ) : ℕ := (fockSetOdd r w).ncard
noncomputable def fockSigned (r w : ℕ) : ℤ := ∑ d ∈ fockFinset r w, (-1 : ℤ) ^ d.degree

theorem finrank_gradingWN (w : ℕ) : finrank ℂ (gradingWN r w) = fockCount r w
theorem fockSigned_eq (r w : ℕ) :
    fockSigned r w = (fockCountEven r w : ℤ) - fockCountOdd r w
```

From the mathematics to the Lean statement

`Set.ncard` is the cardinality of a set as a natural number (and 0 for infinite sets — again a potential source of vacuity; here the sets are finite, `weightDegSetN_finite`). `fockCount r w`,

`fockCountEven`, `fockCountOdd` are P, P^+, P^-; `fockFinset r w` is the same set of exponents as a `Finset`, and `fockSigned r w` $= \sum_d (-1)^{\deg d} = P^{\mathrm{s}}(r,w)$. `finrank_gradingWN` says that the monomials of weight w form a basis of $(F_r)_w$. Since $\sigma(x^d) = (-1)^{\deg d} x^d$, $P^{\mathrm{s}}(r,w)$ is the trace of σ on $(F_r)_w$; the library never forms this trace and works with the counts directly.

Physical meaning

$P(r,w)$ is the number of states at energy w of r free chiral bosons, and P^+, P^- separate them by $\mathbb{Z}_2$ parity (even or odd number of quanta). The low values 1, r, $r+\binom{r+1}{2}$, … are the first terms of the partition function $q^{r/24}\eta(q)^{-r}$ of the bosons. For $r = 24$ they give 1, 24, 324, 3200, … , the coefficients of η^{-24}, the familiar spectrum of the bosonic string.

Proposition 32.28 (Small weights). *$P(r,0) = 1$, $P(r,1) = r$, $P(r,2) = r+\binom{r+1}{2}$, $P(r,3) = r+r^2+\binom{r+2}{3}$; and $P^-(r,2) = r$, $P^+(r,2) = \binom{r+1}{2}$, $P^+(r,3) = r^2$, $P^-(r,3) = r+\binom{r+2}{3}$.*

```

Physical meaning

These are the oscillator excitations at level 3 of r bosons: a quantum of energy 3, a quantum of energy 2 together with one of energy 1, or three quanta of energy 1. The parity counts $P^\pm$ record how the $\mathbb{Z}_2$ symmetry acts; the difference $P^+ - P^- = \operatorname{tr}\theta$ is the term that will appear in the twisted partition function.

Proof. Enumerate the monomials. Weight 3: $h_a(-3)$ (r, degree 1, odd), $h_a(-2)h_b(-1)$ (r^2, ordered pairs since the two oscillators have different weights; degree 2, even), $h_a(-1)h_b(-1)h_c(-1)$ (multisets of size 3: $\binom{r+2}{3}$; degree 3, odd). □

For $r = 24$: $P(24,3) = 24 + 576 + 2600 = 3200$, $P^+(24,3) = 576$, $P^-(24,3) = 2624$.

32.9.2 Generating functions

Theorem 32.29 (Fock generating functions). *In the ring $\mathbb{C}[[q]]$ of formal power series,*

$$\sum_{w\ge 0} P(r,w)q^w = \prod_{n\ge 1}(1-q^n)^{-r}, \qquad \sum_{w\ge 0}\big(P^+(r,w)-P^-(r,w)\big)q^w = \prod_{n\ge 1}(1+q^n)^{-r},$$

the infinite products converging in the q-adic (coefficientwise) topology.

    HasProd (fun i : ℕ => ((1 + (PowerSeries.X : ℂ⟦X⟧) ^ (i + 1))⁻¹) ^ r)
      (fockSignedGenFun r)
```

From the mathematics to the Lean statement

`PowerSeries ℂ` $= \mathbb{C}[\![X]\!]$ is $\mathbb{C}[[q]]$ with the variable called X; `PowerSeries.mk f` is $\sum_w f(w)X^w$. `⁻¹` is the inverse in $\mathbb{C}[[q]]$ (which exists for $1 \mp X^{i+1}$, constant term 1). `HasProd f a` is Mathlib's statement that the infinite product $\prod_{i\in\mathbb{N}} f(i)$ converges (unconditionally, along finite subsets) to a, for the topology fixed by `open scoped PowerSeries.WithPiTopology`: the product topology on the coefficient sequence, i.e. coefficientwise convergence where each coefficient is eventually constant. This is the standard meaning of an infinite product of formal power series. The index shift $i \mapsto i+1$ makes $n = i+1$ run over $n \geq 1$. The statements are exactly Theorem 32.29.

Physical meaning

The first identity is the partition function of r free chiral bosons, $Z_{\text{osc}} = \operatorname{tr} q^{L_0} = \prod_n (1-q^n)^{-r}$ (each mode α_{-n} is a harmonic oscillator of energy n, contributing $(1-q^n)^{-1}$). The second is the same trace with the reflection θ inserted, $\operatorname{tr} \theta\, q^{L_0} = \prod_n (1+q^n)^{-r}$, since each excitation then contributes $\sum_j (-q^n)^j$. These traces are the building blocks of the orbifold partition function $\frac{1}{2}(Z + \operatorname{tr} \theta q^{L_0})$.

Proof. For one colour, $\prod_{n\geq 1}(1-q^n)^{-1} = \prod_n \sum_{j\geq 0} q^{nj}$ is Euler's generating function of partitions: choosing j_n parts equal to n for each n. A one-colour monomial $\prod_m x_{(m,0)}^{d_m}$ is exactly the partition with d_m parts equal to $m+1$, so $\sum_w P(1,w)q^w$ is Euler's series. For r colours, a monomial is an r-tuple of one-colour monomials and weights add, so the generating function is the r-th power. For the signed count, attach $(-1)^j$ to j parts equal to n: $\sum_j (-1)^j q^{nj} = (1+q^n)^{-1}$, and the total sign is $(-1)^{\deg}$ because the degree is the number of parts. In Lean the one-colour case is reduced to Mathlib's partition generating function by an explicit bijection between monomials and partitions. □

Example 32.30 (Low coefficients for $r = 24$)**.**

$$\prod_{n\geq 1}(1-q^n)^{-24} = 1+24q+324q^2+3200q^3+\cdots, \qquad \prod_{n\geq 1}(1+q^n)^{-24} = 1-24q+276q^2-2048q^3+\cdots.$$

Check against Proposition 32.28: $324 = 24 + 300$, $276 = 300 - 24$, $3200 = 24 + 576 + 2600$, $-2048 = 576 - 2624$. (Directly: the q^3 coefficient of $\prod(1+q^n)^{-24}$ is $-\binom{26}{3} + 24\cdot 24 - 24 = -2600 + 576 - 24 = -2048$.)

32.9.3 The dimension formulas

Theorem 32.31 (Graded dimension of V_L)**.** *Let L be even and positive-definite of rank r. For every $k \in \mathbb{N}$,*

$$\dim(V_L)_k = \sum_{n=0}^{k} \#\{\alpha \in L : \langle \alpha, \alpha\rangle = 2n\} \cdot P(r, k-n),$$

the coefficient of q^k in $\Theta_L(q)\prod_{n\geq 1}(1-q^n)^{-r}$, where $\Theta_L(q) = \sum_{\alpha\in L} q^{\langle\alpha,\alpha\rangle/2}$ is the theta series of L.

```

      = ∑ n ∈ Finset.range (k + 1), (normEq L hPos (2 * n)).card * fockCount (rank L) (k -
      ↪ n)
```

From the mathematics to the Lean statement

Section variables `(L : IntegralLattice) (hPos : L.PosDef)`. `normEq L hPos m` is the finite set of vectors of norm m. `Finset.range (k + 1)` is $\{0,\dots,k\}$; `k - n` is natural-number subtraction, which is honest here since $n \le k$. `gradingLatGen L k` has `k : ℕ` coerced to $\mathbb{Z}$. The formula is Theorem 32.31 verbatim; the identification with the q^k coefficient of the product series is the Cauchy product of Theorem 32.29 with Θ_L, made in Chapter 33 where characters are treated as power series.

Physical meaning

This is the partition function of the compact boson as a lattice sum: $\operatorname{tr} q^{L_0 - r/24} = \Theta_L(q)/\eta(q)^r$, with the momentum sum Θ_L over the lattice times the oscillator contribution. For the Leech lattice, $\Theta_\Lambda/\eta^{24} = J + 24$ up to the usual q^{-1} shift, i.e. $q^{-1} + 24 + 196884\,q + \cdots$; the constant 24 is the 24 currents, to be removed by the orbifold.

Proof. $(V_L)_k = \bigoplus_\alpha (F_r)_{k - \frac12\langle\alpha,\alpha\rangle} \otimes e^\alpha$, the sum being over the finitely many α with $\frac12\langle\alpha,\alpha\rangle \le k$; the summand has dimension $P(r, k - \frac12\langle\alpha,\alpha\rangle)$. Group the α by $n = \frac12\langle\alpha,\alpha\rangle$. □

Theorem 32.32 (Graded dimension of V_L^+). *With L as above, let $(V_L)_k^\pm$ be the ±1-eigenspaces of θ on $(V_L)_k$. Then*

$$2\dim (V_L)_k^+ = \dim (V_L)_k + P^+(r,k) - P^-(r,k),$$

i.e. $\dim (V_L)_k^+ = \frac12\big(\dim (V_L)_k + \operatorname{tr}(\theta|(V_L)_k)\big)$ *with* $\operatorname{tr}(\theta|(V_L)_k) = P^{\mathrm{s}}(r,k)$, *the coefficient of q^k in $\prod_{n\ge1}(1+q^n)^{-r}$. Explicitly, with S a set of representatives of the pairs $\pm\alpha \ne 0$ of half-norm $\le k$,*

$$\dim (V_L)_k^\pm = P^\pm(r,k) + \sum_{\alpha\in S} P\big(r, k - \tfrac12\langle\alpha,\alpha\rangle\big).$$

noncomputable def leechVOAPlusGradingEquiv (k : ℤ) : leechVOAPlus.grading k ≃ₗ[ℂ] plusK
↪  leech k
```

From the mathematics to the Lean statement

`plusK L k`, `minusK L k` are $(V_L)_k^{\pm}$. `normLE L hPos k` is the finite set $\{\alpha : \frac{1}{2}\langle\alpha,\alpha\rangle \le k\}$ and `halfLE` keeps one of each pair $\pm\alpha$ (it excludes $\alpha = 0$, which is its own negative). `.toNat` truncates an integer to $\mathbb{N}$; harmless because $k - \frac{1}{2}\langle\alpha,\alpha\rangle \ge 0$ for $\alpha \in$ `normLE`. The equation `two_mul_finrank_plusK_eq_signed` is stated in $\mathbb{Z}$ (the cast `(… : ℤ)`) because P^s can be negative. `leechVOAPlusGradingEquiv k` identifies the weight-k space of the VOA V_Λ^+ with `plusK leech k`, exactly as in weight 2.

Physical meaning

The dimension of the invariant subspace at each level is $\frac{1}{2}(\dim + \operatorname{tr}\theta)$, i.e. the projection onto the untwisted $\mathbb{Z}_2$-even sector $\frac{1}{2}(Z + \operatorname{tr}\theta q^{L_0})$ of an orbifold partition function. Only the neutral (zero-momentum) sector contributes to $\operatorname{tr}\theta$, because θ exchanges every charged sector $\alpha \neq 0$ with its partner $-\alpha$, so charged states are off-diagonal and have zero trace. In this way the formula keeps the 98280 pairs of cosine states at weight 2 and kills the sine ones.

Proof. The counting trick of Theorem 32.25, in every weight. In charge 0, $\theta = \sigma \otimes 1$ acts on monomials by $(-1)^{\deg}$, so $(F_r)_k^{\text{even}} \otimes e^0$ is fixed and $(F_r)_k^{\text{odd}} \otimes e^0$ is anti-fixed. For $\alpha \in S$, the map $x \mapsto x \pm \theta x$ is injective on $(F_r)_{k-\frac{1}{2}\langle\alpha,\alpha\rangle} \otimes e^\alpha$ (its image has a component in the sector α, where θx has none) and lands in $(V_L)_k^{\pm}$. These lower bounds for $\dim(V_L)_k^+$ and $\dim(V_L)_k^-$ add up to $P(r,k) + 2\sum_{\alpha\in S} P(\dots) = \dim(V_L)_k$, so both are equalities. Subtracting the two equalities gives the trace form. Physically: the nonzero charge sectors come in pairs $\{\alpha,-\alpha\}$ swapped by θ and contribute nothing to the trace; only the neutral sector, where $\theta = (-1)^{\#\text{oscillators}}$, contributes. □

Theorem 32.33 (Weight three). $\dim(V_\Lambda)_3 = 21493760$ *and* $\dim(V_\Lambda^+)_3 = 10745856$.

```
-- VOA/Moonshine/LatticeGradedDim.lean
theorem leechVOA_finrank_grading_three : finrank ℂ (leechVOA.grading 3) = 21493760
theorem leechVOAPlus_finrank_grading_three : finrank ℂ (leechVOAPlus.grading 3) = 10745856
```

From the mathematics to the Lean statement

No hypotheses; the inputs are the Leech counts $\#\{\langle\alpha,\alpha\rangle = 0,2,4,6\} = 1, 0, 196560, 16773120$ (`leech_normEq_zero_card`, …, `leech_normEq_six_card`, from `Leech.repCount_four` and `Leech.repCount_six`).

Physical meaning

This is the next level of the same untwisted orbifold sector: 10745856 states at energy 3 survive the $\mathbb{Z}_2$ projection out of 21493760. Adding the twisted-sector count of Chapter 36 gives the full weight-three Moonshine space and matches the coefficient 21493760 of q^2 in $J(q)$. Heuristic, as a consistency check on the physics of the orbifold.

Proof. By Theorem 32.31 with $r = 24$:

$$\begin{aligned}\dim(V_\Lambda)_3 &= 1\cdot P(24,3) + 0\cdot P(24,2) + 196560\cdot P(24,1) + 16773120\cdot P(24,0)\\ &= 3200 + 4717440 + 16773120 = 21493760.\end{aligned}$$

By Theorem 32.32, $2\dim(V_\Lambda^+)_3 = 21493760+576-2624 = 21491712$, so $\dim(V_\Lambda^+)_3 = 10745856$. □

Example 32.34 (The character of V_Λ and its twin)**.** Theorem 32.31 gives

$$\sum_k \dim(V_\Lambda)_k q^{k-1} = \frac{\Theta_\Lambda(q)}{q\prod_n (1-q^n)^{24}} = q^{-1} + 24 + 196884q + 21493760q^2 + \cdots = J(q) + 24,$$

using $\Theta_\Lambda = 1 + 196560q^2 + 16773120q^3 + \cdots$ (in the variable $q^{\langle\alpha,\alpha\rangle/2}$, the norm-4 vectors at q^2). For the θ-trace, $\sum_k \operatorname{tr}(\theta|(V_\Lambda)_k)q^{k-1} = q^{-1}\prod_n(1+q^n)^{-24} = q^{-1} - 24 + 276q - 2048q^2 + \cdots$. Hence

$$\sum_k \dim(V_\Lambda^+)_k q^{k-1} = q^{-1} + 0 + 98580q + 10745856q^2 + \cdots.$$

Adding the twisted contribution $98304q + 10747904q^2 + \cdots$ of Chapter 36 gives $q^{-1} + 196884q + 21493760q^2 + \cdots = J(q)$: the miracle that the constant term 24 is removed and nothing else changes. The full identity for every coefficient is proved in Chapter 33.

What the machine verified

`finrank_gradingLatGen_eq_sum_theta`, `finrank_plusK_minusK`, `two_mul_finrank_plusK_eq_signed`, `hasProd_fockGenFun`, `hasProd_fockSignedGenFun`: proved for every even positive-definite L (and every r). `leechVOA_finrank_grading_three`, `leechVOAPlus_finrank_grading_three`: proved, unconditional. `#print axioms` for all of these: `[propext, Classical.choice, Quot.sound]`. (The weight-3 proofs use the kernel-checked `decide` to evaluate $\binom{26}{3} = 2600$, not `native_decide`.)

32.10 Generation: V_Λ^+ is generated by the $e^\beta + e^{-\beta}$

32.10.1 Why generation is needed

Several later constructions define a structure (an invariant bilinear form, an intertwining operator) and must check a compatibility with the action of *every* $u \in V_\Lambda^+$. Checking it directly for every u is hopeless; checking it on a generating set is easy, provided one knows that the set of u for which the compatibility holds is closed under n-th products. The form of §32.11 below and the form `TPForm` on the twisted sector (Chapter 37) are both handled this way. What is needed is therefore a precise generation theorem.

Definition 32.35. For $\beta \in \Lambda$ put $x_\beta = e^\beta + e^{-\beta} \in V_\Lambda^+$. (It is θ-fixed since $\theta e^\beta = e^{-\beta}$; note $x_0 = 2e^0$ and $x_{-\beta} = x_\beta$.)

```
-- VOA/Moonshine/CyclicFrameSectors.lean
noncomputable def frameX0 (β : leech.carrier) : LatModuleGen leech :=
  latChargeGen leech β + latChargeGen leech (-β)
noncomputable def frameX0P (β : leech.carrier) : VPlus := ⟨frameX0 β, frameX0_mem_plus β⟩
```

From the mathematics to the Lean statement

`frameX0 β` is x_β as a vector of V_Λ; `frameX0P β` is the same vector as an element of V_Λ^+, i.e. paired (`⟨…, …⟩`) with the proof `frameX0_mem_plus β` that it is θ-fixed. (The name comes from

the Golay-frame chapter, where x_β with special β is used as a cyclic vector.)

Physical meaning

The operator $x_\beta = e^\beta + e^{-\beta} \sim 2\cos(\beta \cdot X)$ is the $\mathbb{Z}_2$-even combination of a vertex operator and its reflection: the simplest local operators that survive the orbifold projection with nonzero momentum. For β of norm 4 these are the weight-two cosine operators of the Griess algebra; for general β they have higher weight $\frac{1}{2}\langle\beta,\beta\rangle$.

Theorem 32.36 (Generation). *Let $S \subseteq V_\Lambda^+$ be a linear subspace such that $\mathbf{1} \in S$, $u_{(n)}v \in S$ for all $u, v \in S$ and $n \in \mathbb{Z}$, and $x_\beta \in S$ for every $\beta \in \Lambda$. Then $S = V_\Lambda^+$.*

```
-- VOA/Moonshine/Generation.lean
theorem leechPlus_generated : ∀ S : Submodule ℂ VPlus, leechVOAPlus.vacuum ∈ S →
    (∀ u ∈ S, ∀ v ∈ S, ∀ n : ℤ, leechVOAPlus.smul u n v ∈ S) →
    (∀ β : leech.carrier, frameXOP β ∈ S) → S = ⊤
```

From the mathematics to the Lean statement

`S : Submodule ℂ VPlus` is a linear subspace of V_Λ^+. The three hypotheses are, in order: $\mathbf{1} \in S$; closure under all n-th products of V_Λ^+ (`leechVOAPlus.smul u n v` $= u_{(n)}v$, computed in V_Λ since the sub-VOA has the restricted vertex map); $x_\beta \in S$ for all β. The conclusion `S = ⊤` is $S = V_\Lambda^+$ (`⊤` is the whole space). This is the standard meaning of "the x_β generate V_Λ^+ as a vertex algebra". Note: generation is in the sense of *n-th products*, for *all* $\beta \in \Lambda$ (not only the minimal ones), and the vacuum hypothesis is redundant ($x_0 = 2\mathbf{1}$). The statement could have been weak in two ways, neither of which occurs: it is not restricted to a subset of V_Λ^+, and it does not assume S is a VOA (only a subspace).

Physical meaning

The theorem says that the chiral algebra of the orbifold is the OPE closure of the cosine operators: every θ-even operator, including the bilinears $\partial X^a \partial X^b$ and the stress tensor, arises by repeatedly taking OPE coefficients (modes $u_{(n)}v$) of the cosines $\cos(\beta \cdot X)$. Heuristically: the OPE of $\cos(\beta \cdot X)$ with itself produces the $\partial X \partial X$ terms in its regular part. This closure property is what allows checking invariance (of a bilinear form, of an intertwiner) on a small set of generating fields rather than on all of V_Λ^+.

Trap / dead end

Generation by n-th products is *weaker* than what is needed in another part of the project. The Zhu-algebra arguments of Chapter 40 need *Zhu generation*. Recall (it is defined and discussed there) that Zhu's algebra is $A(V) = V/O(V)$ with an associative product $a * b$ built from the modes of $Y(a,z)$; a set G is *Zhu-generating* if every subspace containing $\mathbf{1}$, $O(V)$ and G and closed under $*$ is all of V (library: `ZhuGenerated` in `VOA/Moonshine/SigmaExistZhu.lean`). This closes under a single specific bilinear product modulo $O(V)$, not under all n-th products, so neither notion implies the other in an obvious way. The project recorded as a dead end that weak (n-th product) generation does NOT reduce the top-level clause there to generators. Theorem 32.36 is used only for the invariance arguments of §32.11 and Chapter 37, where n-th product generation is exactly the right notion.

32.10.2 The proof

The proof is elementary and works for every even positive-definite lattice; only the names are Leech-specific in the library. Let $P = \frac{1}{2}(1+\theta)$ be the projection of Remark 32.19 and let $G = P^{-1}(S) \subseteq V_\Lambda$. Since P is the identity on V_Λ^+, it suffices to show $G = V_\Lambda$, i.e. that every $p \otimes e^\gamma$ lies in G. We show this by induction on the Fock weight w of p, for all charges γ at once.

Base. $w = 0$: $P(e^\gamma) = \frac{1}{2}x_\gamma \in S$.

Step 1: the safe step — why it is needed. The only tool we have for producing new elements of S is the product: if $s \in S$ then $x_{a\,(n)}s \in S$. We would like to use this to show that $e^a_{(n)}v \in G$ whenever $v \in G$, because the operators $e^a_{(n)}$ on V_Λ are completely explicit, by (32.1). The difficulty is that $x_a = e^a + e^{-a}$ is a *sum*, and $P(v)$ is a sum too, so $x_{a\,(n)}P(v)$ has four terms of which we only want one (and its θ-mirror image). The safe step is the observation that for n large enough the two unwanted "cross terms" vanish identically, so that $x_{a\,(n)}P(v)$ is exactly $P(e^a_{(n)}v)$.

When does $e^b_{(n)}$ kill a vector? From (32.1), for q of Fock weight w and any $b, c \in \Lambda$,

$$e^b_{(n)}(q \otimes e^c) = \varepsilon(b,c)\,EE(b)_t\, q \otimes e^{b+c}, \qquad t = -n-1-\langle b,c\rangle, \tag{32.5}$$

where $EE(b)_t$ is the coefficient of z^t in $EE(b,z) = E^-(b,z)E^+(b,z)$. (The mode $u_{(n)}$ is the coefficient of z^{-n-1}, and the factor $z^{\langle b,c\rangle}$ shifts the index.) Multiplying out, $EE(b)_t = \sum_{N-M=t,\,N,M\geq 0} S_N(b)\,E^+(b)_{-M}$. The operator $E^+(b)_{-M}$ is a polynomial in annihilation operators of total weight M, so it lowers the Fock weight by exactly M and kills q if $M > w$. Thus only terms with $M \leq w$ survive, and for them $t = N - M \geq -M \geq -w$. In other words,

$$t < -w \implies EE(b)_t q = 0, \qquad \text{i.e.} \qquad n \geq w - \langle b,c\rangle \implies e^b_{(n)}(q \otimes e^c) = 0 \tag{32.6}$$

(the two conditions agree: $-n-1-\langle b,c\rangle < -w \iff n > w-1-\langle b,c\rangle \iff n \geq w-\langle b,c\rangle$). Physically this is the statement that the operator product $e^b(z)\,(q \otimes e^c)(0)$ has a pole of order at most $w - \langle b,c\rangle$: the momenta contribute $z^{\langle b,c\rangle}$ and the oscillators of q can lower this by at most w.

Lemma 32.37 (Safe step). *If $q \in (F_{24})_w$ and $n \geq w + \langle a,c\rangle$, then* $x_{a\,(n)}\,P(q \otimes e^c) = P\big(e^a_{(n)}(q \otimes e^c)\big)$.

From the mathematics to the Lean statement

`plusProj` is P; the left side is $P(e^a_{(n)}(q \otimes e^c))$, computed in V_Λ; the right side is $x_{a\,(n)}P(q \otimes e^c)$, computed in V_Λ^+. The hypotheses are $q \in (F_{24})_w$ and $n \geq w + \langle a,c\rangle$.

Physical meaning

This lemma is a statement about when the OPE of a cosine $x_a = e^a + e^{-a}$ with a projected state keeps only the "direct" term: for a high enough mode number n the cross terms, in which the momenta add rather than cancel, have an OPE with too weak a pole to appear, since $e^b(z)\,(q \otimes e^c)(0)$ has a pole of order at most $w - \langle b,c\rangle$. It is a pole-order estimate for the OPE of lattice vertex operators and helps one extract a single exponential from a cosine. Technical lemma.

Proof. Expand $x_{a(n)} \cdot 2P(q \otimes e^c) = (e^a + e^{-a})_{(n)}(q \otimes e^c + \sigma q \otimes e^{-c})$ into four terms. The cross term $e^{-a}_{(n)}(q \otimes e^c)$ is (32.6) with $b = -a$: it vanishes when $n \geq w - \langle -a, c\rangle = w + \langle a, c\rangle$. The cross term $e^a_{(n)}(\sigma q \otimes e^{-c})$ is (32.6) with $b = a$, charge $-c$ and the weight-w vector σq: it vanishes when $n \geq w - \langle a, -c\rangle = w + \langle a, c\rangle$. Both conditions are the hypothesis of the lemma. The remaining two are $e^a_{(n)}(q \otimes e^c)$ and its image under θ (Theorem 32.13: $\theta(e^a_{(n)}(q \otimes e^c)) = e^{-a}_{(n)}(\sigma q \otimes e^{-c})$). Their sum is $2P(e^a_{(n)}(q \otimes e^c))$. □

Consequently: *if $q \otimes e^c \in G$ and $n \geq w + \langle a, c\rangle$, then $e^a_{(n)}(q \otimes e^c) \in G$* (because P of it is $x_{a(n)}$ applied to an element of S).

Example 32.38 (The safe step in rank one)**.** Let $L = \mathbb{Z}\alpha$ with $\langle \alpha, \alpha\rangle = 4$ (rank one, rootless), and take $a = \alpha$, $c = -\alpha$, $q = 1$ (so $w = 0$). Then $P(e^{-\alpha}) = \frac{1}{2}x_\alpha$, and the lemma's condition is $n \geq 0 + \langle \alpha, -\alpha\rangle = -4$. Compute the four terms of $x_{\alpha(n)}x_\alpha$ with (32.5), where $t = -n - 1 - \langle b, c\rangle$:

term	$\langle b, c\rangle$	t	value
$e^\alpha_{(n)}e^{-\alpha}$ (wanted)	-4	$3 - n$	$\varepsilon\, S_{3-n}(\alpha) \otimes e^0$
$e^{-\alpha}_{(n)}e^{\alpha}$ (its θ-image)	-4	$3 - n$	$\varepsilon\, S_{3-n}(-\alpha) \otimes e^0$
$e^\alpha_{(n)}e^{\alpha}$ (cross)	4	$-n - 5$	$\varepsilon\, S_{-n-5}(\alpha) \otimes e^{2\alpha}$
$e^{-\alpha}_{(n)}e^{-\alpha}$ (cross)	4	$-n - 5$	$\varepsilon\, S_{-n-5}(-\alpha) \otimes e^{-2\alpha}$

(Here $q = 1$, so E^+ acts trivially and $EE(b)_t 1 = S_t(b)$, which is 0 for $t < 0$; ε denotes the relevant sign ± 1.) For $n \geq -4$ the cross terms have $t = -n - 5 < 0$ and vanish, so $x_{\alpha(n)}x_\alpha = \varepsilon\,(S_{3-n}(\alpha) + S_{3-n}(-\alpha)) \otimes e^0 = 2\varepsilon P(S_{3-n}(\alpha) \otimes e^0)$: exactly the lemma. For $n = 1$ this is $\varepsilon\,\alpha(-1)^2\mathbf{1}$, as in Example 32.39. For the unsafe value $n = -5$, however, the cross terms are $\varepsilon\,(e^{2\alpha} + e^{-2\alpha})$: the product is still an element of S, but it is *no longer P* of $e^\alpha_{(-5)}e^{-\alpha}$, and we learn nothing about the latter. This is the whole content of the lemma, and every entry of the table can be checked from (32.5) and $S_N(-\alpha) = \sigma S_N(\alpha)$ alone.

Step 2: leading terms. Fix a target weight $w \geq 1$ and assume (induction hypothesis) that all $p \otimes e^c$ with Fock weight $< w$ lie in G, for all c. For $d \geq 0$ and q of weight k,

$$EE(a)_d\, q = \sum_{s=0}^{k} S_{d+s}(a)\, E^+(a)_{-s}\, q, \tag{32.7}$$

the $s = 0$ term being $S_d(a)q$ and the others involving $E^+(a)_{-s}q$ of lower weight $k - s$.

```

Call a *safe* for (γ, w) if $2\langle a, \gamma - a\rangle + w + 1 \leq 0$. Take a safe a, $d \geq 1$, q of weight $k = w - d$, and $c = \gamma - a$. With $n = -d - 1 - \langle a, c\rangle$, (32.5) and (32.7) give

$$e^a_{(n)}(q \otimes e^c) = \varepsilon(a, c) \sum_{s=0}^{k} S_{d+s}(a) E^+(a)_{-s} q \otimes e^\gamma,$$

and the safe-step condition $n \geq k + \langle a, c\rangle$ is exactly safety: substituting $n = -d - 1 - \langle a, c\rangle$ it reads $-d - 1 - \langle a, c\rangle \geq k + \langle a, c\rangle$, i.e. $2\langle a, c\rangle + d + k + 1 \leq 0$, i.e. (since $d + k = w$ and $c = \gamma - a$) $2\langle a, \gamma - a\rangle + w + 1 \leq 0$; $q \otimes e^c \in G$ by the induction hypothesis ($k < w$). So the left side is in G by Step 1. By a downward induction on k (the terms with $s \geq 1$ have the same shape with larger d and smaller k) we get

$$S_d(a)\, q \otimes e^\gamma \in G \qquad \text{for all safe } a,\ d \geq 1,\ q \in (F_{24})_{w-d}.$$

Step 3: linearisation. We want a single oscillator $a_0(-d)$ rather than the Schur polynomial $S_d(a)$. Replace a by ka_0 with $a_0 \neq 0$ and $k \in \mathbb{N}$: since $\langle ka_0, \gamma - ka_0\rangle = k\langle a_0, \gamma\rangle - k^2\langle a_0, a_0\rangle \to -\infty$, the vector ka_0 is safe for all large k. And $S_d(ka_0)$ is a polynomial in k,

$$S_d(ka_0) = \sum_i k^i\, s_i, \qquad s_1 = \frac{1}{d}\, a_0(-d)\mathbf{1},$$

because S_d is built from $\frac{1}{n}a_0(-n)$ by the exponential series, and only the term with a single oscillator is linear in k.

From the mathematics to the Lean statement

`schurPoly L α N` is the polynomial in an auxiliary variable T (`Polynomial.X`) with coefficients in F_r obtained by putting T in front of every $\alpha(-m-1)$ in the Newton recursion; `schurPoly_eval` says evaluating at $T = k$ gives $S_N(k\alpha)$, and `schurPoly_coeff_one` identifies the linear coefficient as $\frac{1}{N+1}\alpha(-N-1)\mathbf{1}$. `mem_of_forall_sum_pow_smul_mem` is the interpolation lemma: if a polynomial with coefficients v_i in a vector space takes values in a subspace G at infinitely many integers, then every v_i lies in G.

The interpolation lemma (proof: pass to the quotient by G and apply any linear functional; a scalar polynomial with infinitely many roots is zero) applied to $k \mapsto S_d(ka_0)q \otimes e^\gamma$ gives $a_0(-d)q \otimes e^\gamma \in G$. Letting a_0 run over a basis of Λ — whose real coordinates form an invertible matrix, so the $a_0(-d)$ span all oscillators $h_b(-d)$ — we get $h_b(-d)q \otimes e^\gamma \in G$ for every b, $d \geq 1$ and q of weight $w - d$. Every monomial of weight $w \geq 1$ has this form, which completes the induction. □

Example 32.39 (Weight two by hand)**.** Here is the argument in its simplest instance, without scaling. Take $a \in \Lambda$, $a \neq 0$, and $n = \langle a, a\rangle - 3$. Then

$$x_{a\,(n)}x_a = e^a_{(n)}e^{-a} + e^{-a}_{(n)}e^a + e^a_{(n)}e^a + e^{-a}_{(n)}e^{-a}.$$

By (32.5), $e^a_{(n)}e^{-a} = \varepsilon(a,-a)EE(a)_2\mathbf{1} \otimes e^0 = \varepsilon(a,a)S_2(a)$, and similarly $e^{-a}_{(n)}e^a = \varepsilon(a,a)S_2(-a)$. The last two terms involve $EE(\pm a)_{2-2\langle a,a\rangle}$, which kills $\mathbf{1}$ since $2 - 2\langle a,a\rangle < 0$. Since $S_2(\pm a) = \frac{1}{2}(a(-1)^2 \pm a(-2))\mathbf{1}$,

$$x_{a\,(\langle a,a\rangle-3)}\, x_a = \varepsilon(a,a)\, a(-1)^2\mathbf{1} \otimes e^0.$$

So every $a(-1)^2\mathbf{1}$ lies in the subalgebra generated by the x_β, and by polarization $(a+b)(-1)^2 - a(-1)^2 - b(-1)^2 = 2a(-1)b(-1)$, so do all quadratic states $h_a(-1)h_b(-1)\mathbf{1}$ (the $a(-1)$ for a in a lattice basis span span$\{h_b(-1)\}$). Together with the x_β of norm 4, this is all of $(V_\Lambda^+)_2$ (Example 32.26). The general proof is this computation, organised: polarization is replaced by the interpolation in k, which also handles the higher Schur polynomials.

Remark 32.40 (Why no spherical-design input is needed)**.** Sharper statements are available in the literature: V_Λ^+ is generated by its weight-2 space (the Griess algebra), that is, by the quadratic states and the x_β with β of norm 4 only. Proving that version from the 196560 minimal vectors alone requires averaging identities over the shell Λ_4 — the fact that the minimal vectors form a spherical design, which makes sums such as $\sum_{\beta\in\Lambda_4}\beta(-1)^2$ proportional to the Casimir $\sum_b h_b(-1)^2$ — to manufacture the Fock states. The library proves a weaker statement that suffices for every use: generation by the x_β for *all* β. Because all multiples ka_0 are allowed, the scaling argument of Step 3 replaces any averaging over a shell, and no property of Λ beyond evenness and positive-definiteness is used. The cost is nil, since both consumers (`plusForm_fhlInv` below and `TPForm_fhlInv` in Chapter 37) verify their compatibility at x_β uniformly in β. The design-based route was not attempted in Lean; this remark records why it was not needed.

What the machine verified

`leechPlus_generated`: proved, unconditional; `#print axioms [propext, Classical.choice, Quot.sound]`. Files `VOA/Moonshine/Generation.lean` and `GenerationFock.lean`. (When this chapter was first written, the docstring of `Generation.lean` said the file was "not wired into the `VOA/Moonshine.lean` umbrella"; that note was already stale — the umbrella imported it. The docstring has since been corrected and now says the file is imported by the umbrella.)

32.11 The invariant form: nondegeneracy of the canonical form on V_Λ^+

32.11.1 What has to be proved, and why

Every VOA W with $W_0 = \mathbb{C}\mathbf{1}$ and $L_1W_1 = 0$ carries a unique *invariant bilinear form* normalized by $(\mathbf{1}|\mathbf{1}) = 1$ (Li's theorem; in the library, Theorem 5.56). For V_Λ^+ this canonical form is used in Chapter 37 to define the operator $\overline{W}$ of twisted×twisted→untwisted type as the *adjoint* of an operator W. Such an adjoint exists and is unique only if the form is nondegenerate on every weight space. So we need:

$$\textit{the canonical invariant form of } V_\Lambda^+ \textit{ is nondegenerate on each } (V_\Lambda^+)_k.$$

The textbook proof is: V_Λ^+ is simple, and the invariant form of a simple VOA is nondegenerate (its radical is an ideal). The library has the second half (`invariantForm_nondegenerate_FHL`) but not simplicity of V_Λ^+, which is a substantial theorem (Dong–Griess type). The route taken instead is explicit: write down a form on all of V_Λ, check by hand that it is nondegenerate, θ-invariant and invariant at the generators x_β, restrict it to V_Λ^+, use Theorem 32.36 to get full invariance, and conclude by uniqueness that it *is* the canonical form.

32.11.2 Invariant forms in the library

Definition 32.41 (Invariant bilinear form)**.** Let W be a VOA. A bilinear form $(\cdot|\cdot)$ on W is *(fully) invariant* if for every homogeneous $u \in W_{\mathrm{wt}}$, all $n \in \mathbb{Z}$ and $a, b \in W$,

$$(u_{(n)}a \mid b) = (-1)^{\mathrm{wt}} \sum_{j=0}^{\mathrm{wt}} \frac{1}{j!}\big(a \mid (L_1^j u)_{(2\mathrm{wt}-n-2-j)}\, b\big), \tag{32.8}$$

the mode form of $(Y(u,z)a|b) = (a|Y(e^{zL_1}(-z^{-2})^{L_0}u, z^{-1})b)$ (Frenkel–Huang–Lepowsky). For a *primary* u ($L_1u = 0$) only $j = 0$ survives: $(u_{(n)}a|b) = (-1)^{\mathrm{wt}}(a|u_{(2\mathrm{wt}-n-2)}b)$. The form is *normalized* if $(\mathbf{1}|\mathbf{1}) = 1$. The same formula, with $u_{(n)}$ the action on a module M and the form on M, defines invariance of a form on a module at u.

From the mathematics to the Lean statement

`LinearMap.BilinForm ℂ 𝒱` is a bilinear form $\mathcal{V}\times\mathcal{V}\to\mathbb{C}$, applied as `B a b`. An `InvariantForm` in the library is a bilinear form with the Virasoro adjointness $(L_n a|b) = (a|L_{-n}b)$ only; the full condition (32.8) is the separate predicate `IsFullyInvariant`, with u in the first slot, the sum truncated at $j \le \mathrm{wt}$ (`wt.toNat + 1` terms; harmless since $L_1^j u = 0$ for $j > \mathrm{wt}$ in a CFT-type VOA), and `(-1 : ℂ) ^ wt` the sign. `FHLInv N B wt u` is (32.8) for one u acting on a module `N` (`N.YM u` is the module vertex operator); with `N = adjointModule W`, the VOA as a module over itself (`YM = Y`), it is (32.8) on W for that u. `canonicalInvariantForm hne hqp` is the canonical normalized fully invariant form; its hypotheses are $\mathbf{1} \neq 0$ and $L_1 W_1 = 0$. `invariantForm_unique_FHL` is uniqueness: any fully invariant normalized form equals it ("unconditional" in the library: no further hypotheses). `leftRadical` is $\{a : (a|\cdot) = 0\}$. `GradedNondeg W B` says the restriction of B to each weight space W_k (`gradForm`: compose both slots with the inclusion) is nondegenerate in Mathlib's sense (`Nondegenerate`: only 0 pairs to zero with everything).

theorem leechBV_gradedNondeg_of_isSimple (hsimple : leechVOAPlus.IsSimple) :
    GradedNondeg leechVOAPlus leechBV
```

From the mathematics to the Lean statement

`leechBV` is the canonical form of V_Λ^+ (`SkewVP` is another name for the same type `VPlus`). Its two hypotheses are discharged: $\mathbf{1} \neq 0$, and L_1 vanishes on $(V_\Lambda^+)_1 = 0$ (Theorem 32.21). `leechBV_gradedNondeg_of_isSimple` is the textbook route, *conditional* on simplicity of V_Λ^+, which the library does not prove; it is superseded by the unconditional Theorem 32.48 below and is not used downstream.

Physical meaning

An invariant bilinear form is the BPZ two-point pairing of states: $(a|b) = \langle a|b\rangle$ computed by conjugating a to the point at infinity, $(Y(u,z)a|b) = (a|Y(e^{zL_1}(-z^{-2})^{L_0}u, z^{-1})b)$. It encodes the two-point function $\langle\phi(\infty)\phi(0)\rangle$ of a chiral field, with the factor $(-1)^{\mathrm{wt}}$ coming from the inversion $z \mapsto -1/z$. Existence and uniqueness (with $(\mathbf{1}|\mathbf{1}) = 1$) mean that two-point functions are fixed by the conformal structure once the vacuum is normalised. Note this form is bilinear, not Hermitian, and is not positive-definite; unitarity (positive-definiteness) holds only on a real form, which is not used here.

32.11.3 The Fock form

Definition 32.42 (The Fock form). On F_r define the bilinear form F by declaring the monomials orthogonal and

$$F(x^d, x^d) = \prod_{(m,a)} \big(-(m+1)\big)^{d_{(m,a)}}\, d_{(m,a)}!\,.$$

```

From the mathematics to the Lean statement

`uVar (m,a)` $= -(m+1)$ and `uWt d` $= \prod(-(m+1))^d\, d!$ (`d.prod` is the product over the support of d). `uForm` is defined on a polynomial $p = \sum_d p_d x^d$ in the first slot by $F(p,q) = \sum_d p_d\, \mathrm{uWt}(d)\, q_d$ (`lcoeff ℂ d` extracts the coefficient q_d): this is Definition 32.42. The four theorems say: F is symmetric; $h_b(n)^t = -h_b(-n)$ for every $n \in \mathbb{Z}$ (the adjoint for F); σ is an isometry; and every monomial has nonzero norm. The last line is the transpose of the dressing: $F(EE(\gamma)_t y, y') = F(y, EE(\gamma)_{-t} y')$, i.e. $EE(\gamma,z)^t = EE(\gamma, z^{-1})$.

Physical meaning

The Fock form is the two-point function of the oscillator states: it makes α^a_{-n} and α^a_n conjugate up to the BPZ sign, $(\alpha_n)^t = -\alpha_{-n}$, while a positive Hermitian inner product uses $\alpha_n^\dagger = \alpha_{-n}$. The two differ by the sign $(-1)^{\mathrm{wt}}$ for a weight-1 current (the BPZ sign), and each oscillator contributes $-(m+1)$ to the norm. The form is nondegenerate on the Fock space because there are no null states among the oscillator excitations of free bosons.

Why the minus sign. We derive the norms from (32.8) in three steps. *(1) Specialize the formula.* Take $u = h_b(-1)\mathbf{1}$. It has weight $\mathrm{wt} = 1$, and it is primary: $L_1 u$ would have weight 0 and charge 0 and be odd under σ, but the only weight-0 state is $\mathbf{1}$, which is even; so $L_1 u = 0$ and only $j = 0$ survives in (32.8). Its field is $Y(u,z) = h_b(z) = \sum_n h_b(n) z^{-n-1}$, so $u_{(n)} = h_b(n)$. With $\mathrm{wt} = 1$ the index on the right is $2 \cdot 1 - n - 2 = -n$, and (32.8) becomes

$$(h_b(n)a \mid b) = (-1)^1 (a \mid h_b(-n)b) = -(a \mid h_b(-n)b) \qquad \text{for all } n, a, b.$$

(2) Evaluate on the simplest vectors. Take $n = -1$, $a = \mathbf{1}$, $b = h_b(-1)\mathbf{1}$. Then $h_b(-1)a = h_b(-1)\mathbf{1}$ and $h_b(1)b = h_b(1)h_b(-1)\mathbf{1} = [h_b(1), h_b(-1)]\mathbf{1} = \mathbf{1}$, so

$$(h_b(-1)\mathbf{1} \mid h_b(-1)\mathbf{1}) = -(\mathbf{1} \mid \mathbf{1}) = -1.$$

(3) Iterate. For a general monomial, move one creation operator $h_b(-m-1)$ from the left slot to the right; it becomes $-h_b(m+1) = -(m+1)\partial/\partial x_{(m,b)}$, and differentiating $x^k_{(m,b)}$ gives $k\, x^{k-1}_{(m,b)}$. Each removed oscillator therefore contributes a factor $-(m+1)$ and the multiplicities contribute $d_{(m,b)}!$, which is the norm formula of Definition 32.42; monomials with different exponents pair to 0 because the derivatives run out. So the form is forced by invariance, minus sign included. Physically: the BPZ conjugation of a weight-h quasi-primary carries the sign $(-1)^h$, so for the current $J = i\partial X$ one gets $J^t_n = -J_{-n}$, whereas the *Hermitian* (unitary) adjoint is $J^\dagger_n = J_{-n}$. The library's invariant form is the bilinear (BPZ) one.

Trap / dead end

The "positive" Fock form, $h(n)^t = +h(-n)$ (the restriction to real vectors of the familiar positive-definite inner product of the Fock space), is *not* invariant in the sense of (32.8): it violates the weight-1 case just computed. The project first met this on the twisted sector, where the sign was checked by computer algebra (the positive form fails, the negative one works); the same convention is forced here. A form chosen for convenience with the wrong sign would have made Theorem 32.48 below false or vacuous.

Proof of the Fock-form properties. Symmetry and σ-invariance are clear from the diagonal definition (monomials are σ-eigenvectors with eigenvalue ± 1). For $n = -(m+1) < 0$: $F(x_{(m,b)}x^d, x^{d+e_{(m,b)}}) = -(m+1)(d_{(m,b)}+1)F(x^d, x^d)$, while $h_b(m+1)x^{d+e_{(m,b)}} = (m+1)(d_{(m,b)}+1)x^d$; this is $F(h_b(n)p, q) = -F(p, h_b(-n)q)$ on monomials, and the case $n > 0$ follows by symmetry. For the dressing: $EE(\gamma, z)$ is determined by its commutator with the oscillators, $[h_b(n), EE(\gamma)_t] = \gamma_b\, EE(\gamma)_{t-n}$ $(n \neq 0)$, and by its values on the vacuum, $EE(\gamma)_t\mathbf{1} = S_t(\gamma)$ (or 0 for $t < 0$). Transposing the commutator with $h_b(n)^t = -h_b(-n)$ shows that $EE(\gamma)_{-t}$ satisfies the transposed relation, and the vacuum values match since $F(S_t(\gamma), 1) = \delta_{t,0}$. Induction on monomials gives the identity. □

What the machine verified

`uForm_symm`, `uForm_oscN`, `uForm_sigmaN`, `uWt_ne_zero`, `uForm_EEVec`: proved, no hypotheses (`VOA/Moonshine/NondegFock.lean`).

32.11.4 The charge sign and the lattice form

To extend F to V_L we pair the charge sector α with $-\alpha$: $B(p\otimes e^\alpha, q\otimes e^\beta) = \delta_{\alpha+\beta,0}\,c(\alpha)\,F(p,q)$ for some signs $c(\alpha)$. Which c? Test invariance at the primary $u = e^\gamma$ of weight $N = \frac12\langle\gamma,\gamma\rangle$: $(e^\gamma_{(n)}x|y) = (-1)^N(x|e^\gamma_{(2N-n-2)}y)$. With $x = p\otimes e^\beta$, $y = q\otimes e^{-\gamma-\beta}$ and (32.1), the dressings on the two sides are matched by `uForm_EEVec` (the indices are t and $-t$), and what remains is

$$\varepsilon(\gamma,\beta)\,c(\gamma+\beta) = (-1)^N\varepsilon(\gamma,-\gamma-\beta)\,c(\beta) = (-1)^N\varepsilon(\gamma,\gamma)\varepsilon(\gamma,\beta)\,c(\beta),$$

using bimultiplicativity and Proposition 32.9. So $c(\gamma+\beta) = (-1)^N\varepsilon(\gamma,\gamma)c(\beta)$, and with $c(0) = 1$ the unique solution is

$$c(\alpha) = (-1)^{\langle\alpha,\alpha\rangle/2}\,\varepsilon(\alpha,\alpha).$$

Proposition 32.43 (The charge sign). *For even L, c is a character of L with values in $\{\pm1\}$: $c(0) = 1$, $c(\alpha+\beta) = c(\alpha)c(\beta)$, $c(-\alpha) = c(\alpha)$.*

```
-- VOA/Moonshine/NondegLattice.lean
noncomputable def chSign (α : L.carrier) : ℂ :=
  (-1 : ℂ) ^ (LatGen.halfNorm L α) * latticeCocycle L α α
theorem chSign_zero : chSign L 0 = 1
theorem chSign_neg (α : L.carrier) : chSign L (-α) = chSign L α
theorem chSign_add (hEven : L.Even) (α β : L.carrier) :
    chSign L (α + β) = chSign L α * chSign L β
```

From the mathematics to the Lean statement

`chSign L α` is $c(\alpha)$, with `halfNorm` as in Definition 32.1. `hEven` is needed in `chSign_add` (through the commutator relation and $\frac12\langle\cdot,\cdot\rangle$ being additive up to $\langle\alpha,\beta\rangle$).

Physical meaning

The charge sign $c(\alpha) = (-1)^{\langle\alpha,\alpha\rangle/2}\varepsilon(\alpha,\alpha)$ is the phase in the two-point function $\langle e^{-\alpha}\,e^\alpha\rangle$ of a vertex operator with its conjugate: it comes from the BPZ inversion $(-1)^{\mathrm{wt}}$ for weight $\frac12\langle\alpha,\alpha\rangle$ and the Klein-factor sign. The fact that c is a character says the sign conventions compose consistently under fusion of momenta, as charge is conserved in the OPE. Convention bookkeeping; no new dynamical content.

Proof. $c(\alpha+\beta) = (-1)^{N_\alpha+N_\beta+\langle\alpha,\beta\rangle}\varepsilon(\alpha,\alpha)\varepsilon(\alpha,\beta)\varepsilon(\beta,\alpha)\varepsilon(\beta,\beta) = c(\alpha)c(\beta)$ by the commutator relation $\varepsilon(\alpha,\beta)\varepsilon(\beta,\alpha) = (-1)^{\langle\alpha,\beta\rangle}$. Evenness under -1 is Proposition 32.9. □

Trap: the charge sign is not constant, in general

In the literature one usually normalizes $\varepsilon(\alpha,\alpha) = (-1)^{\langle\alpha,\alpha\rangle/2}$; then $c\equiv1$ and the lattice part of the form is simply $(e^\alpha|e^{-\alpha}) = 1$. The library's basis cocycle does not satisfy this normalization in general: in coordinates, $c(\alpha) = (-1)^{\sum_i \frac12\langle B_i,B_i\rangle\alpha_i}$ (the off-diagonal terms of $\frac12\langle\alpha,\alpha\rangle$ cancel against $c(\alpha,\alpha)$, and $\alpha_i^2\equiv\alpha_i \bmod 2$), which is the trivial character only if every basis vector has norm divisible by 4. Since the basis is chosen by `Module.Free.chooseBasis`, nobody can say which case occurs. A form with constant $c\equiv1$ was the natural first guess and is *wrong* for this cocycle; the project's status notes record this correction ("NOT constant, because the library's basis cocycle does not satisfy $\varepsilon(\gamma,\gamma) = (-1)^{\langle\gamma,\gamma\rangle/2}$"). Defining c by the formula above makes every statement true for *every* basis, which is the only safe option.

Definition 32.44 (The lattice form). For even L, define the bilinear form B on V_L by

$$B(p \otimes e^\alpha, q \otimes e^\beta) = \delta_{\alpha+\beta,0}\, c(\alpha)\, F(p,q).$$

```
-- VOA/Moonshine/NondegLattice.lean
noncomputable def chForm : LinearMap.BilinForm ℂ (L.carrier →₀ ℂ) :=
  Finsupp.lsum ℂ fun α => LinearMap.smulRight LinearMap.id (chSign L α • Finsupp.lapply
   ↪ (-α))
noncomputable def latForm : LinearMap.BilinForm ℂ (LatModuleGen L) :=
  (uForm (rank L)).tmul (chForm L)

theorem latForm_state (p q : FockN (rank L)) (α β : L.carrier) :

      = (if α + β = 0 then chSign L α else 0) * uForm (rank L) p q
theorem latForm_symm (x y : LatModuleGen L) : latForm L x y = latForm L y x
```

From the mathematics to the Lean statement

`chForm` is the form on $\mathbb{C}\{L\}$ with $(e^\alpha, f) = c(\alpha) f(-\alpha)$, i.e. $(e^\alpha, e^\beta) = \delta_{\alpha+\beta,0} c(\alpha)$ (`Finsupp.lapply (-α)` evaluates at $-\alpha$). `BilinForm.tmul` is the tensor product of two bilinear forms. `latForm_state` is Definition 32.44 on basis vectors, and the form is symmetric (using $c(-\alpha) = c(\alpha)$).

Physical meaning

This is the BPZ two-point function on the full torus theory: it pairs momentum α with $-\alpha$ (charge conservation: the two-point function is nonzero only for neutral total charge) and the Fock part by the oscillator form. It is the two-point function of the vertex operators e^α and $e^{-\alpha}$ times the oscillator two-point function.

Theorem 32.45 (Properties of the lattice form). *Let L be even. Then:*

(a) (invariance at e^γ) for all $\gamma \in L$, $n \in \mathbb{Z}$ and $x, y \in V_L$, with $N = \frac{1}{2}\langle\gamma,\gamma\rangle$,

$$B(e^\gamma_{(n)}x, y) = (-1)^N B(x, e^\gamma_{(2N-n-2)}y);$$

(b) (nondegeneracy) if $x \neq 0$ there is y with $B(x,y) \neq 0$;

(c) (θ-invariance) $B(\theta x, \theta y) = B(x,y)$;

(d) (orthogonality) distinct weight spaces of V_L are B-orthogonal.

```
-- VOA/Moonshine/NondegLattice.lean
theorem latForm_Yeαvec (hEven : L.Even) (γ : L.carrier) (n : ℤ) (x y : LatModuleGen L) :
    latForm L (mode (Yeαvec L γ) n x) y
      = (-1 : ℂ) ^ (LatGen.halfNorm L γ) *
          latForm L x (mode (Yeαvec L γ) (2 * LatGen.halfNorm L γ - n - 2) y)
theorem latForm_nondeg (x : LatModuleGen L) (hx : x ≠ 0) : ∃ y, latForm L x y ≠ 0
theorem latForm_thetaLat (x y : LatModuleGen L) :
    latForm L (thetaLat L x) (thetaLat L y) = latForm L x y
theorem latForm_orth_grading {m n : ℤ} (hmn : m ≠ n) {x y : LatModuleGen L}
    (hx : x ∈ gradingLatGen L m) (hy : y ∈ gradingLatGen L n) : latForm L x y = 0
```

From the mathematics to the Lean statement

In (a), `mode (Yeαvec L γ) n` is $e^\gamma_{(n)}$: `Yeαvec L γ` is the vertex operator of e^γ in the lattice VOA (it is `YfullGen` of the empty word, `YfullGen_word` with $l = [\,]$; for Leech this is recorded as `leechVOA_Y_latChargeGen`). e^γ is primary of weight N, so (a) is (32.8) at $u = e^\gamma$. (a) needs only evenness (not positive-definiteness); (b)–(d) need no hypothesis beyond the section variable `L`. (b) is nondegeneracy on the whole space; since weight spaces are orthogonal (d) and finite-dimensional for positive-definite L, this is equivalent to nondegeneracy on each weight space.

Physical meaning

(a) is the BPZ-invariance of the two-point function at the vertex operator e^γ: moving e^γ from one slot to the other costs $(-1)^N$ and reverses the mode number. (b) says the two-point function has no null states: every nonzero state has a nonzero overlap with some partner. (c) says reflection is an isometry (the form is $\mathbb{Z}_2$-invariant), so that V^+ and V^- are orthogonal. (d) is orthogonality of different energy levels, as for any two-point function of states of definite conformal weight.

Proof. (a) On basis vectors this is the computation that determined c, run backwards. (b) Write x in the basis $x^d \otimes e^\alpha$; pick a pair (d, α) with nonzero coefficient. Then $B(x, x^d \otimes e^{-\alpha}) = \text{coefficient} \cdot c(-\alpha) \cdot \mathrm{uWt}(d) \neq 0$, since the basis vectors $x^{d'} \otimes e^{\alpha'}$ pair with $x^d \otimes e^{-\alpha}$ only for $(d', \alpha') = (d, \alpha)$. (c) σ is an F-isometry and $c(-\alpha) = c(\alpha)$. (d) The pairing is between sectors α and $-\alpha$, which have the same half-norm, and F pairs only equal Fock weights. □

Example 32.46 (The lattice form in low weight)**.** In weight 1: $B(h_a(-1)e^0, h_b(-1)e^0) = -\delta_{ab}$. In weight 2, the basis of Example 32.26 is orthogonal with

$$B(h_a(-2)e^0, h_a(-2)e^0) = -2, \qquad B(h_a(-1)^2e^0, h_a(-1)^2e^0) = (-1)^2\,2! = 2,$$
$$B(h_a(-1)h_b(-1)e^0, h_a(-1)h_b(-1)e^0) = 1\ (a \neq b), \qquad B(e^\alpha \pm e^{-\alpha}, e^\alpha \pm e^{-\alpha}) = \pm 2c(\alpha).$$

All are nonzero: the form is nondegenerate on $(V_\Lambda)_2$ and, separately, on $(V_\Lambda^+)_2$ and $(V_\Lambda^-)_2$. On $(V_\Lambda)_2$ the form is indefinite (both 2 and -2 occur), as is to be expected of a bilinear BPZ form; definiteness is never used.

What the machine verified

`latForm_Yeαvec`, `latForm_nondeg`, `latForm_thetaLat`, `latForm_orth_grading`: proved, unconditional (hypothesis `L.Even` where shown); `#print axioms` for `latForm_nondeg` and `latForm_Yeαvec`: `[propext, Classical.choice, Quot.sound]` (`VOA/Moonshine/NondegLattice.lean`).

32.11.5 Restriction to V_Λ^+ and identification with the canonical form

Definition 32.47. B^+ is the restriction of B (for $L = \Lambda$) to V_Λ^+.

```
-- VOA/Moonshine/NondegLeech.lean
noncomputable def plusForm : LinearMap.BilinForm ℂ VPlus :=

  (invariantForm_unique_FHL leechVOAPlus_vacuum_ne_zero leechVOAPlus_L1_one
    plusInvForm_isFullyInvariant plusInvForm_normalized).symm
```

From the mathematics to the Lean statement

`compl₁₂ f g` composes the two slots of a form with linear maps, here both the inclusion $V_\Lambda^+ \hookrightarrow V_\Lambda$: so `plusForm` is B^+. `plusForm_fhlInv_frameX0P` is (32.8) for $u = x_\beta$ (of weight $\frac{1}{2}\langle\beta,\beta\rangle$) on V_Λ^+; `plusForm_fhlInv` is (32.8) for every homogeneous $u \in V_\Lambda^+$. `plusInvForm` packages B^+ as an `InvariantForm` (the Virasoro field, elided as "...", is a proof); it is fully invariant and normalized. The one-line proof of `leechBV_eq_plusForm` is shown because it is the argument: uniqueness of the normalized fully invariant form. Note that this identifies the *abstractly defined* canonical form `leechBV` with the explicit B^+; nothing about `leechBV` is assumed.

Physical meaning

B^+ is the BPZ two-point pairing of the orbifold's chiral algebra, restricted from the parent torus theory to the θ-even states. It is the natural inner product on the untwisted sector: correlators in the orbifold of $\mathbb{Z}_2$-even operators are the same as in the parent theory, so the two-point functions are inherited. The proof that this restricted form is the canonical one uses the generation theorem: invariance at the cosines x_β propagates to the whole algebra by the OPE.

Proof. *Invariance at x_β.* $x_\beta = e^\beta + e^{-\beta}$ is primary (it is a sum of primaries of the same weight), so (32.8) at x_β is the sum of Theorem 32.45(a) for $\gamma = \pm\beta$.

Invariance for all u. Let $I \subseteq V_\Lambda^+$ be the span of the homogeneous u for which (32.8) holds. It contains $\mathbf{1}$, and it is closed under n-th products: this is the classical argument of Frenkel–Huang–Lepowsky, which derives invariance at $u_{(m)}v$ from invariance at u and v via the Jacobi identity (the adjoint operator $Y(e^{zL_1}(-z^{-2})^{L_0}u, z^{-1})$ satisfies the opposite Jacobi identity), using that distinct weight spaces are orthogonal (Theorem 32.45(d)). It is proved generically in the library (`fhlInv_of_generates`, Chapter 37). By Theorem 32.36, $I = V_\Lambda^+$.

Virasoro adjointness is the slice $u = \omega$ of full invariance: ω has weight 2 and $L_1\omega \in (V_\Lambda^+)_1 = 0$, so (32.8) reads $(L_n a|b) = (a|L_{-n}b)$. *Normalization*: $B(e^0, e^0) = c(0)F(1,1) = 1$. *Identification*: uniqueness. □

Theorem 32.48 (Nondegeneracy of the canonical form of V_Λ^+). *The canonical invariant form of V_Λ^+ has zero radical, and is nondegenerate on every weight space $(V_\Lambda^+)_k$.*

```
-- VOA/Moonshine/NondegLeech.lean
theorem plusForm_nondeg (x : VPlus) (hx : x ≠ 0) : ∃ y : VPlus, plusForm x y ≠ 0
theorem leechBVForm_leftRadical : InvariantForm.leftRadical leechBVForm = ⊥
theorem leechBV_gradedNondeg : GradedNondeg leechVOAPlus leechBV
```

From the mathematics to the Lean statement

`leechBVForm` is the canonical form of V_Λ^+ (`leechBV` is its underlying bilinear form); `leftRadical … = ⊥` says its radical is zero, and `leechBV_gradedNondeg` is nondegeneracy on each weight space (Definition: `GradedNondeg`). No hypotheses. This is precisely the statement called `hnd` in the project notes, the residual that made the operator $\overline{W}$ of Chapter 37 conditional before it was discharged. How could it have been vacuous? If the form were identically zero, nondegeneracy would fail outright; if it were a form chosen by hand rather than the canonical one, it would not be the form used by $\overline{W}$ — `leechBV_eq_plusForm` closes that gap.

Physical meaning

Nondegeneracy of the two-point pairing means the chiral algebra has no null states: no nonzero operator has vanishing two-point function with all operators of the same weight. In CFT terms this is the absence of a nontrivial ideal of null fields (the algebra is simple-like at the level of the invariant form), which is what is needed to define adjoints and conjugate operators in the orbifold. The proof is the physical argument in disguise: the parent theory is nondegenerate and θ is an isometry, so the pairing of an invariant state with itself and with the projected partner cannot vanish. Positive-definiteness is not claimed (the form is a BPZ bilinear form, indefinite on the complex space).

Proof. Let $x \in V_\Lambda^+$, $x \neq 0$. By Theorem 32.45(b) there is $y \in V_\Lambda$ with $B(x,y) \neq 0$. Then $Py = \frac{1}{2}(y+\theta y) \in V_\Lambda^+$ and, using $\theta x = x$ and θ-invariance,

$$B(x,Py) = \tfrac{1}{2}\big(B(x,y) + B(\theta x,\theta y)\big) = B(x,y) \neq 0.$$

So B^+, which is the canonical form, has zero radical. Since distinct weight spaces are orthogonal and each is finite-dimensional, a vector of $(V_\Lambda^+)_k$ pairing to zero with $(V_\Lambda^+)_k$ pairs to zero with everything; hence nondegeneracy on each weight space. □

Remark 32.49 (Consequences, deferred)**.** With Theorem 32.48 the adjoint $\overline{W}$ of the skew intertwiner W exists, and the library's `leechWbar_adj'`, `leechWbar_comm'`, `leechWbar_local'`, `leechWbar_homCov'` (also in `NondegLeech.lean`) hold without hypotheses. Their statements and meaning belong to Chapter 37. Nondegeneracy is also what lets the project prove $\overline{W} \neq 0$, which excludes the square-zero extension $V_\Lambda^+ \ltimes (V_\Lambda^T)^+$ — a VOA with $c = 24$, $V_1 = 0$, $\dim V_2 = 196884$ and graded dimension J, but not simple and not $V^\natural$.

What the machine verified

`plusForm_fhlInv`, `leechBV_eq_plusForm`, `plusForm_nondeg`, `leechBVForm_leftRadical`, `leechBV_gradedNondeg`: proved, unconditional. `#print axioms` for `leechBV_eq_plusForm` and `leechBV_gradedNondeg`: `[propext, Classical.choice, Quot.sound]`. Simplicity of V_Λ^+ is *not* proved and is not needed. (When this chapter was first written, the file docstring of `NondegLeech.lean` said the file was not yet imported by the umbrella; that note was already stale — it was imported. The docstring has since been corrected.)

32.12 Traps and dead ends of this chapter, collected

For the referee's convenience we collect the points where the formalization could have gone wrong, and what prevents it.

(1) *Cocycle convention* (§32.3). The naive lift $p \otimes e^\alpha \mapsto \sigma p \otimes e^{-\alpha}$ is an automorphism only because the library's cocycle is bimultiplicative; for a general cocycle a correcting function is needed. Certified by the proved `thetaLat_mode`.

(2) *Triviality of θ* (§32.5). If θ were the identity, V_Λ^+ would be V_Λ. Excluded by `leechTheta_ne_one` and $98580 \neq 196884$.

(3) *Dimension statements and* `finrank` (§32.8). Mathlib's `finrank` is 0 on infinite-dimensional spaces and `Set.ncard` is 0 on infinite sets, so a careless dimension statement could be "true" for the wrong reason. All spaces and sets counted here are proved finite, and all counts are positive.

(4) *Abstract versus concrete weight spaces.* The numbers are proved for `leechVOAPlus.grading k`, the weight spaces of the VOA itself, via the explicit linear equivalences `leechVOAPlusGradingTwoEquiv` and `leechVOAPlusGradingEquiv` with the concrete subspaces `plusTwo`, `plusK`.

(5) *n-th product generation is not Zhu generation* (§32.10). Theorem 32.36 must not be used where Zhu generation is needed (Chapter 40).

(6) *Sign of the Fock form* (§32.11). The positive Fock form is not invariant; the negative (BPZ) one is.

(7) *Constant charge sign* (§32.11). The choice $(e^\alpha | e^{-\alpha}) = 1$ is wrong for the library's cocycle; the sign $c(\alpha) = (-1)^{\langle \alpha,\alpha\rangle/2}\varepsilon(\alpha,\alpha)$ is right for every basis.

(8) *Nondegeneracy via simplicity* (§32.11). The textbook route needs simplicity of V_Λ^+, not in the library; the conditional `leechBV_gradedNondeg_of_isSimple` exists but is superseded by the unconditional `leechBV_gradedNondeg`.

(9) *Stale docstrings (since corrected).* When this chapter was first written, the module docstrings of `Generation.lean` and `NondegLeech.lean` said these files were not wired into the umbrella, although they were; at a pre-release build commit both docstrings say the files are imported.

32.13 Referee's checklist

Notes and references

The involution θ, the fixed-point algebra V_Λ^+ and the decomposition $V^\natural = V_\Lambda^+ \oplus (V_\Lambda^T)^+$ are due to I. Frenkel, J. Lepowsky and A. Meurman, *Vertex Operator Algebras and the Monster*, Pure and Applied Mathematics 134, Academic Press, Boston, 1988; the lift of -1 with its correcting function is §10.4 there (the book also treats the central extensions and cocycles, the graded dimensions and the invariant forms used in this chapter). The earlier announcement is I. Frenkel, J. Lepowsky, A. Meurman, *A natural representation of the Fischer–Griess Monster with the modular function J as character*, Proc. Natl. Acad. Sci. USA 81 (1984) 3256–3260. Lattice vertex operators and their cocycles go back to R. Borcherds, *Vertex algebras, Kac–Moody algebras, and the Monster*, Proc. Natl. Acad.

Sci. USA 83 (1986) 3068–3071, and to the physics of I. Frenkel and V. Kac, *Basic representations of affine Lie algebras and dual resonance models*, Invent. Math. 62 (1980) 23–66, and G. Segal, *Unitary representations of some infinite-dimensional groups*, Comm. Math. Phys. 80 (1981) 301–342.

Invariant bilinear forms on VOAs and the contragredient formula (32.8) are from I. Frenkel, Y.-Z. Huang, J. Lepowsky, *On axiomatic approaches to vertex operator algebras and modules*, Mem. Amer. Math. Soc. 104 (1993), no. 494; uniqueness and the criterion $L_1 V_1 = 0$ are from H. Li, *Symmetric invariant bilinear forms on vertex operator algebras*, J. Pure Appl. Algebra 96 (1994) 279–297. The textbook treatment followed by the library is T. Gannon, *Moonshine beyond the Monster*, Cambridge University Press, 2006, Chapter 5 (lattice VOAs in §5.2–5.3, the involution in §5.3.6). For the structure of V_L^+ (simplicity, generation by low weights, representations) see C. Dong and R. Griess, *Rank one lattice type vertex operator algebras and their automorphism groups*, J. Algebra 208 (1998) 262–275; C. Dong and K. Nagatomo, *Representations of vertex operator algebra V_L^+ for rank one lattice L*, Comm. Math. Phys. 202 (1999) 169–195; and T. Abe, C. Dong, H. Li, *Fusion rules for the vertex operator algebras $M(1)^+$ and V_L^+*, Comm. Math. Phys. 253 (2005) 171–219 (arXiv:math/0310425). The orbifold viewpoint in physics is L. Dixon, J. Harvey, C. Vafa, E. Witten, *Strings on orbifolds*, Nucl. Phys. B 261 (1985) 678–686, and for $V^\natural$ L. Dixon, P. Ginsparg, J. Harvey, *Beauty and the beast: superconformal symmetry in a Monster module*, Comm. Math. Phys. 119 (1988) 221–241. The spherical-design property of the Leech minimal vectors mentioned in Remark 32.40 is in J. H. Conway and N. J. A. Sloane, *Sphere Packings, Lattices and Groups*, 3rd ed., Springer, 1999, and B. Venkov's chapter there.

The Lean material of this chapter was written in the LeanVOA project (repository maintainers F. K. Popov and L. Rastelli), files `VOA/Moonshine/LatticeInvolution.lean` through `NondegLeech.lean`; the route choices recorded here (no correcting sign, the counting trick instead of traces, generation by all x_β via scaling, and the explicit lattice form in place of simplicity) are documented in the project's `Notes/MonsterRoadmap.md` and the "Status" sections of `Notes/M8GluingPlan.md`.

Chapter 33

Graded dimensions and the modular function J

This chapter documents the release of the library named in the front matter; all Lean source quoted below is quoted from the files of that release. Checks that were run at an earlier state of the library and not re-run for this edition are marked as such. Quotations from the repository are printed in `leancode` boxes, which are machine-checked to occur verbatim in the source; quotations from Mathlib (a dependency, not part of the repository) and tool output are printed in plain boxes.

The single most famous number in this book is 196884. In 1978 John McKay noticed that the coefficient of q in the expansion of Klein's modular invariant,

$$j(\tau) = q^{-1} + 744 + 196884\,q + 21493760\,q^2 + 864299970\,q^3 + \cdots, \qquad q = e^{2\pi i\tau},$$

is one more than 196883, the dimension of the smallest nontrivial irreducible representation of the Monster group. Thompson pushed the observation further ($21493760 = 1 + 196883 + 21296876$), Conway and Norton turned it into the "Monstrous Moonshine" conjectures, and Frenkel, Lepowsky and Meurman (FLM) constructed a graded vector space

$$V^\natural = \bigoplus_{n\geq 0} V^\natural{}_n, \qquad \sum_{n\geq 0} \dim V^\natural{}_n\, q^{n-1} = J(q) := j(q) - 744,$$

carrying a vertex operator algebra structure whose automorphism group is the Monster. (The library constructs this vertex operator algebra, Chapter 42; the Monster action is *not* formalized, and in the Lean statements J is the formal q-series of Section 33.2, not the analytic function of τ; that this series is the q-expansion of the analytic $j - 744$ is a separate Lean theorem, `Moonshine.qExpansion_qJ`, Section 33.2.) The equality of the graded dimension with J is the statement this chapter is about.

The chapter has two halves. The first half (Sections 33.1 and 33.2) develops, from first principles, the modular-forms background: the modular group, modular forms, Eisenstein series, the discriminant Δ, the functions j and J, Dedekind's η, theta series, the group $\Gamma_0(2)$ and its Hauptmodul. It then presents the library's own *formal* q-series E_4, E_6, Δ, qj and qJ, which are the objects appearing in the final theorem. The second half (Sections 33.3–33.9) counts the dimensions of the two summands of $V^\natural = V_\Lambda^+ \oplus (V_\Lambda^T)^+$ and proves, for *every* weight $n \geq 0$, that

$$\dim(V_\Lambda^+)_n + \dim(V_\Lambda^T)_n^+ = [q^n]\big(qJ(q)\big). \tag{33.1}$$

What the machine verified

The headline identity (33.1) is the Lean theorem `VOA.Moonshine.sectorSeries_eq_JShift` (file `VOA/Moonshine/Character.lean`) and its coefficientwise form `VOA.Moonshine.finrank_sectors_eq_coeff_JShift`. Both are *unconditional*: they have no hypotheses at all. While writing this chapter the command `#print axioms` was re-run

(with `lake env lean -DmaxSynthPendingDepth=3`, against the built library) on both, and on every other headline declaration of the chapter; the answer was in every case `[propext, Classical.choice, Quot.sound]`, i.e. Lean's three standard axioms and nothing else. The PBW theorem `VOA.pbw` (Chapter 3; formerly a project axiom, now a theorem) is *not* used. The full record is in Section 33.10.

How to read this chapter. Following the book's Fidelity Protocol, every definition and theorem appears as a mathematical statement, then its Lean declaration copied verbatim from the repository, then a fidelity-check box (titled *From the mathematics to the Lean statement*) in which we decode the Lean notation, list every hypothesis, trace every defined term, and say how the statement could have been wrong or vacuous and why it is not. Proofs are explained on paper. At the end, Section 33.12 collects a referee's checklist.

A physicist's preview. In two-dimensional conformal field theory the *partition function* of a chiral theory on a torus of modular parameter τ is $Z(\tau) = \operatorname{tr}_V q^{L_0 - c/24}$, a generating function of the dimensions of the energy eigenspaces. For a holomorphic theory the torus has no preferred "time" direction, so Z should be invariant under the modular group $\mathrm{SL}_2(\mathbb{Z})$ that reshuffles the cycles of the torus; with $c = 24$ the factor $q^{-c/24} = q^{-1}$ gives a simple pole at $q = 0$. The only such functions are J + const, and if the theory has no weight-one states (no currents) the constant is zero. So, physically, $\chi_{V^\natural} = J$ is *forced*. Mathematically the library does not argue this way (that would need a modularity theorem for $V^\natural$, which is not what is formalised); instead it computes both sides. The orbifold picture nevertheless organises the computation: $V^\natural$ is the $\mathbb{Z}/2$-orbifold of the Leech lattice theory V_Λ, and its partition function is the average over the four "twisted boundary conditions" on the two cycles of the torus,

$$Z_{V^\natural} = \tfrac{1}{2}\big(Z_{++} + Z_{+-} + Z_{-+} + Z_{--}\big).$$

Z_{++} is the character of V_Λ, Z_{+-} the trace of θ on it, and Z_{-+}, Z_{--} the character of the twisted sector and the trace of θ there. This will appear below, quite literally, as $\frac{1}{2}\big(\Theta_\Lambda P + B\big) + 2^{12} q^2 T_{\mathrm{odd}}$. The three "twisted" terms are the images of a single function under the three cosets of $\Gamma_0(2)$ in $\mathrm{SL}_2(\mathbb{Z})$; this is the level-two identity of Section 33.7.

33.1 Modular forms from first principles

This section is standard mathematics; its aim is to make the chapter self-contained for a reader who has met holomorphic functions but not modular forms. Each fact later used is labelled with the Mathlib (or library) declaration that supplies it.

33.1.1 The upper half-plane and the modular group

Let $\mathfrak{H} = \{\tau \in \mathbb{C} : \operatorname{Im}\tau > 0\}$ be the upper half-plane. The group

$$\mathrm{SL}_2(\mathbb{Z}) = \left\{ \begin{pmatrix} a & b \\ c & d \end{pmatrix} : a, b, c, d \in \mathbb{Z},\ ad - bc = 1 \right\}$$

acts on $\mathfrak{H}$ by Möbius transformations, $\gamma \cdot \tau = (a\tau + b)/(c\tau + d)$. That the image lies in $\mathfrak{H}$ follows from

$$\operatorname{Im}(\gamma \cdot \tau) = \frac{\operatorname{Im}\tau}{|c\tau + d|^2}. \tag{33.2}$$

The matrix -1 acts trivially. Two elements generate the whole group:

$$T = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} : \ \tau \mapsto \tau + 1, \qquad S = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} : \ \tau \mapsto -1/\tau.$$

The proof is a Euclidean algorithm: given γ with $c \neq 0$, multiply on the left by a power of T to achieve $|a| < |c|$ (this changes a by multiples of c), then by S, which swaps the rows up to sign; $|c|$ strictly decreases, until $c = 0$, at which point $\gamma = \pm T^b$. In Mathlib this is `SpecialLinearGroup.SL2Z_generators`; a consequence used repeatedly below is `SlashInvariantForm.slash_action_generators_SL2Z`: a function that transforms correctly under S and under T transforms correctly under all of $\mathrm{SL}_2(\mathbb{Z})$.

The *standard fundamental domain* $\mathcal{F} = \{|\tau| \geq 1, |\operatorname{Re}\tau| \leq \frac{1}{2}\}$ meets every orbit, and the quotient $\mathrm{SL}_2(\mathbb{Z})\backslash\mathfrak{H}$ becomes a compact Riemann surface (a sphere) after adding one point at infinity, the *cusp* $i\infty$. Geometrically, $\mathrm{SL}_2(\mathbb{Z})\backslash\mathfrak{H}$ is the moduli space of complex tori $\mathbb{C}/(\mathbb{Z} + \mathbb{Z}\tau)$: two parameters give isomorphic tori exactly when they are in the same orbit. This is the reason modular objects appear as torus partition functions in physics.

33.1.2 Modular forms and the slash operator

Fix an integer k. For $f : \mathfrak{H} \to \mathbb{C}$ and $\gamma \in \mathrm{SL}_2(\mathbb{Z})$ put $(f|_k\gamma)(\tau) = (c\tau + d)^{-k} f(\gamma \cdot \tau)$. This is a right action $(f|_k(\gamma\delta) = (f|_k\gamma)|_k\delta)$, because the *automorphy factor* $c\tau + d$ satisfies a cocycle relation.

Definition 33.1 (Modular form of level one)**.** A *modular form of weight k for* $\mathrm{SL}_2(\mathbb{Z})$ is a function $f : \mathfrak{H} \to \mathbb{C}$ such that

(i) $f|_k\gamma = f$ for all $\gamma \in \mathrm{SL}_2(\mathbb{Z})$, i.e. $f(\gamma\tau) = (c\tau + d)^k f(\tau)$;

(ii) f is holomorphic on $\mathfrak{H}$;

(iii) f is bounded as $\operatorname{Im}\tau \to \infty$ ("holomorphic at the cusp").

It is a *cusp form* if moreover $f(\tau) \to 0$ as $\operatorname{Im}\tau \to \infty$. The spaces are written M_k and S_k.

Physical meaning

A modular form is the mathematical shadow of a torus partition function. Condition (i) for $\gamma = T$ says $Z(\tau + 1) = Z(\tau)$, i.e. the spectrum of $L_0 - c/24$ is integral (no spin ambiguity); for $\gamma = S$ it says that exchanging the space and time cycles of the torus changes the answer only by the factor τ^k (a weight, absent for a genuine partition function, $k = 0$). Holomorphy is the statement that the chiral partition function depends holomorphically on the shape τ of the torus, and boundedness at the cusp says the energy is bounded below, with only finitely many negative-energy terms. This is a heuristic dictionary; the definition above is purely analytic.

In Mathlib, a modular form is a structure `ModularForm Γ k` whose three fields `slash_action_eq'`, `holo'`, `bdd_at_cusps'` are (i)–(iii); the level-one group is written $\mathcal{SL}$ (the image of $\mathrm{SL}_2(\mathbb{Z})$ in $\mathrm{GL}_2(\mathbb{R})$), and `ℍ` is the upper half-plane. Condition (iii) is phrased for every cusp of Γ; for $\mathrm{SL}_2(\mathbb{Z})$ Mathlib's `OnePoint.isBoundedAt_iff_forall_SL2Z` reduces it to boundedness of all translates $f|_k\gamma$ at $i\infty$, which for an invariant f is boundedness of f itself. Holomorphy is expressed as complex-manifold differentiability (`MDiff`), which on the open set $\mathfrak{H} \subset \mathbb{C}$ is ordinary holomorphy. A cusp form is a `CuspForm Γ k`.

q-expansions. Taking $\gamma = T$ in (i) gives $f(\tau + 1) = f(\tau)$. A holomorphic 1-periodic function on $\mathfrak{H}$ is a holomorphic function of $q = e^{2\pi i\tau}$ on the punctured disc $0 < |q| < 1$: $f(\tau) = F(q)$.

Condition (iii) says F is bounded near $q = 0$, so by Riemann's removable singularity theorem F extends holomorphically to the disc and has a Taylor expansion

$$f(\tau) = \sum_{n \geq 0} a_n q^n, \qquad |q| < 1. \tag{33.3}$$

This is the *q-expansion*; f is a cusp form iff $a_0 = 0$. In Mathlib, the extended function F is `cuspFunction 1 f`, the parameter q is `Function.Periodic.qParam 1 τ` (written `𝕢 1 τ`) $= e^{2\pi i\tau}$, and the formal power series $\sum a_n X^n$ is `qExpansion 1 f`. Two facts about it are used constantly.

Proposition 33.2 (Uniqueness of q-expansions). *Let f be a level-one modular form and $(c_m)_{m\geq 0}$ complex numbers such that for every $\tau \in \mathfrak{H}$ the series $\sum_m c_m q^m$, $q = e^{2\pi i\tau}$, converges to $f(\tau)$. Then c_m is the m-th coefficient of the q-expansion of f, for every m.*

```
-- Mathlib, Mathlib/NumberTheory/ModularForms/QExpansion.lean
protected lemma ModularFormClass.qExpansion_coeff_unique {c : ℕ → ℂ} (hh : 0 < h)
    (hΓ : h ∈ Γ.strictPeriods) {f : F} [ModularFormClass F Γ k]
    (hf : ∀ τ : ℍ, HasSum (fun m ↦ c m • 𝕢 h τ ^ m) (f τ)) (m : ℕ) :
    c m = (qExpansion h f).coeff m
```

Physical meaning

Physically this is the statement that a partition function is determined by its spectrum: $Z(\tau) = \sum_n d_n q^n$ records the number d_n of states at each energy level, and two series that agree as functions of τ count the same states. This is what lets the chapter compare an honest count of states (a formal series) with an analytic function of the torus modulus. It is a mathematical fact; the physical reading is only a mnemonic.

The proof is uniqueness of Taylor coefficients. In applications $h = 1$, $\Gamma = \mathcal{SL}$, and the side condition "1 is a period" is Mathlib's `one_mem_strictPeriods_SL`. The second fact is that q-expansion is a ring homomorphism on modular forms: the q-expansion of $f+g$, cf, fg, f^n is the sum, scalar multiple, product, power of the q-expansions (`ModularForm.qExpansion_add`, …, `ModularForm.qExpansion_pow`). Both facts are proved in Mathlib.

33.1.3 Eisenstein series

For even $k \geq 4$ the series $G_k(\tau) = \sum_{(m,n)\neq(0,0)} (m\tau+n)^{-k}$ converges absolutely and locally uniformly (because $k > 2$). It is visibly invariant under $\tau \mapsto \tau + 1$ and, after the substitution $(m, n) \mapsto (n, -m)$, picks up the factor τ^k under $\tau \mapsto -1/\tau$, so it is a modular form of weight k. Its q-expansion follows from the Lipschitz formula $\sum_{n\in\mathbb{Z}} (\tau + n)^{-k} = \frac{(-2\pi i)^k}{(k-1)!} \sum_{r\geq 1} r^{k-1} q^r$:

$$G_k = 2\zeta(k)\Big(1 - \frac{2k}{B_k} \sum_{n\geq 1} \sigma_{k-1}(n)\, q^n\Big), \qquad \sigma_s(n) = \sum_{d\mid n} d^s,$$

with B_k the Bernoulli numbers ($B_4 = -\frac{1}{30}$, $B_6 = \frac{1}{42}$). The normalised series $E_k = G_k/2\zeta(k)$ have constant term 1:

$$E_4 = 1 + 240 \sum_{n\geq 1} \sigma_3(n) q^n = 1 + 240q + 2160q^2 + 6720q^3 + 17520q^4 + \cdots,$$
$$E_6 = 1 - 504 \sum_{n\geq 1} \sigma_5(n) q^n = 1 - 504q - 16632q^2 - 122976q^3 - 532728q^4 - \cdots,$$

because $-2 \cdot 4/B_4 = 240$ and $-2 \cdot 6/B_6 = -504$. In Mathlib, `ModularForm.E₄` and `ModularForm.E₆` are these as bundled modular forms, and `EisensteinSeries.E_qExpansion_coeff` states: coefficient m of the q-expansion of E_k is 1 if $m = 0$ and $-(2k/B_k)\,\sigma_{k-1}(m)$ otherwise.

33.1.4 The ring of level-one forms; $\dim M_{12} = 2$

Products of modular forms are modular forms (weights add), so $M_* = \bigoplus_k M_k$ is a graded ring.

Theorem 33.3 (Structure of M_*). *For every $k \geq 0$ the monomials $E_4^a E_6^b$ with $4a + 6b = k$ form a basis of M_k; equivalently $M_* = \mathbb{C}[E_4, E_6]$. Moreover $S_k = 0$ for $k < 12$.*

Physical meaning

In the language of 2d CFT, $M_* = \mathbb{C}[E_4, E_6]$ says that holomorphic, modular-covariant partition functions have very little freedom: once the weight and the first few energy levels are fixed, the whole spectrum is forced. The weight-12 case ($\dim M_{12} = 2$) is the one that matters for $c = 24$: the leading coefficients (the vacuum and the number of currents) pin down the entire character. This is a heuristic gloss; the theorem is proved by the valence formula, not by physics.

The classical proof (Serre, *A Course in Arithmetic*, Ch. VII) uses the *valence formula*: for a nonzero $f \in M_k$,

$$v_\infty(f) + \tfrac{1}{2} v_i(f) + \tfrac{1}{3} v_\rho(f) + \sum_{p \neq i, \rho} v_p(f) = \frac{k}{12},$$

the sum over the other points of $\mathrm{SL}_2(\mathbb{Z})\backslash\mathfrak{H}$, obtained by integrating f'/f around the boundary of $\mathcal{F}$ ($\rho = e^{2\pi i/3}$; the fractions come from the angles of $\mathcal{F}$ at the elliptic points i, ρ). A nonzero cusp form has $v_\infty \geq 1$, hence $k \geq 12$; for $k = 12$ the cusp form has a simple zero at ∞ and no other zeros. Dividing by such a cusp form lowers the weight by 12, and induction gives the theorem.

We need only weight 12: *M_{12} is two-dimensional, spanned by E_4^3 and E_6^2*, so a weight-12 form is determined by its first two q-coefficients a_0, a_1. Since $E_4^3 = 1 + 720q + \cdots$ and $E_6^2 = 1 - 1008q + \cdots$, solving $f = xE_4^3 + yE_6^2$ for $a_0 = x + y$, $a_1 = 720x - 1008y$ gives

$$f = a_0 E_4^3 + \frac{a_1 - 720 a_0}{1728}\left(E_4^3 - E_6^2\right). \tag{33.4}$$

This formula is the engine of two of the three identities of this chapter. The library's spanning statement is `span_eisBasisFun` (vendored file `VOA/LatticesAndCodes/ModularForms/LevelOne.lean`, built on Mathlib's dimension formula), and (33.4) is the library theorem `qExpansion_weight_twelve` (Theorem 33.36).

33.1.5 The discriminant Δ: three descriptions

The form $E_4^3 - E_6^2$ has q-expansion $1728q + \cdots$, so it is a nonzero cusp form of weight 12. The *discriminant* is its normalisation:

$$\Delta = \frac{E_4^3 - E_6^2}{1728} = q - 24q^2 + 252q^3 - 1472q^4 + 4830q^5 - \cdots = \sum_{n \geq 1} \tau(n) q^n, \tag{33.5}$$

the coefficients $\tau(n)$ being Ramanujan's tau function. (For the elliptic curve $y^2 = 4x^3 - g_2 x - g_3$ with $g_2 = 60G_4$, $g_3 = 140G_6$, the discriminant $g_2^3 - 27g_3^2$ is $(2\pi)^{12}\Delta$, whence the name.) By the valence formula, Δ has a simple zero at $i\infty$ and *no zeros on* $\mathfrak{H}$ (Mathlib: `ModularForm.discriminant_ne_zero`).

The second and third descriptions are Jacobi's product formula,

$$\Delta(\tau) = q \prod_{n \geq 1} (1 - q^n)^{24} = \eta(\tau)^{24}, \qquad \eta(\tau) = q^{1/24} \prod_{n \geq 1} (1 - q^n), \tag{33.6}$$

with Dedekind's eta function η ($q^{1/24} := e^{2\pi i \tau/24}$). One proves (33.6) by showing that η^{24} is a cusp form of weight 12 (the hard part is $\eta(-1/\tau) = \sqrt{\tau/i}\,\eta(\tau)$, derived from the logarithmic derivative of η, an Eisenstein series of weight 2) and comparing first coefficients, using $\dim S_{12} = 1$.

Remark 33.4 (Which description is the definition?)**.** Mathlib *defines* the discriminant as η^{24}, by `ModularForm.discriminant z := (eta z) ^ 24`, bundled as `CuspForm.discriminant : CuspForm` $\mathcal{SL}$ `12`) and proves both other descriptions:

```
-- Mathlib, Mathlib/NumberTheory/ModularForms/Discriminant.lean and
 ↪  LevelOne/GradedRing.lean
lemma discriminant_eq_q_prod (z : ℍ) : Δ z = q 1 z * ∏' n, (1 - eta_q n z) ^ 24
theorem discriminant_eq_E₄_cube_sub_E₆_sq (z : ℍ) :
    discriminant z = (E₄ z ^ 3 - E₆ z ^ 2) / 1728
```

where `eta_q n z` $= q^{n+1}$ and `∏'` is an infinite product of complex numbers. The library's *formal* discriminant (Definition 33.9) is defined by the Eisenstein expression (33.5). That the formal series obeys Jacobi's product (33.6) *as a formal power series* is therefore a genuine theorem (Theorem 33.35), one of the three inputs of the main identity.

33.1.6 The functions j and J

Since Δ has no zeros on $\mathfrak{H}$, the quotient

$$j(\tau) = \frac{E_4(\tau)^3}{\Delta(\tau)} \tag{33.7}$$

is holomorphic on $\mathfrak{H}$; numerator and denominator have weight 12, so j is $\mathrm{SL}_2(\mathbb{Z})$-invariant. At the cusp $\Delta = q(1 - 24q + \cdots)$ has a simple zero, so j has a simple pole:

$$j = \frac{1 + 720q + 179280q^2 + \cdots}{q\,(1 - 24q + 252q^2 - \cdots)} = q^{-1} + 744 + 196884\,q + 21493760\,q^2 + \cdots .$$

$J = j - 744$ has no constant term.

Theorem 33.5 (j is a Hauptmodul; argued on paper only)**.** *Every* $\mathrm{SL}_2(\mathbb{Z})$*-invariant holomorphic function on* $\mathfrak{H}$ *with at most a pole of order* m *at the cusp is a polynomial of degree* $\le m$ *in* j*. In particular* J *is the unique invariant function of the form* $q^{-1} + O(q)$*.*

Physical meaning

This is the classical form of the physical statement that a holomorphic $c = 24$ theory has a partition function fixed up to an additive constant. A chiral partition function $Z(\tau) = q^{-1} + \text{const} + O(q)$ must be modular invariant; the leading q^{-1} is the vacuum with Casimir energy $-c/24 = -1$, and the only remaining freedom is the constant, i.e. the number of weight-one states (currents). Setting that number to zero ($V_1^\natural = 0$) selects $J = j - 744$, the partition function of the Monster CFT. As the warning below stresses, the library does not use this argument.

Sketch. If $f = c\,q^{-m} + \cdots$, then $f - c\,j^m$ is invariant with a pole of order $< m$; by induction it suffices to treat f bounded at the cusp. Pick $\tau_0 \in \mathfrak{H}$. Then $g = (f - f(\tau_0))\Delta$ is a cusp form of weight 12, so $g = c'\Delta$; but $g(\tau_0) = 0 \neq \Delta(\tau_0)$, so $c' = 0$ and f is constant. □

Trap / dead end

No modular-invariance argument is behind the main theorem. Theorem 33.5 is *not* used by the library's proof of $\chi = J$, and is not formalised in the form stated. The docstring of `VOA/Modularity/JFunction.lean` still lists "uniqueness of the Hauptmodul" as a residual, and early plans expected to derive $\chi = J$ from a modularity theorem for $V^\natural$. The route actually taken avoids this: both sides are computed, and the only uniqueness used is $\dim M_{12} = 2$,

formula (33.4). A referee should not look for a "modular invariance of the character of $V^\natural$" theorem behind the main result — there is none; the identity is a computation.

The library also has an analytic j, `VOA.jInvariant` $(z) = E_4(z)^3/\Delta(z)$, with $\mathrm{SL}_2(\mathbb{Z})$-invariance `VOA.jInvariant_smul` (file `VOA/Modularity/JInvariantAnalytic.lean`). The statements of this chapter do not involve it, but the library identifies the formal J with it: `VOA.Moonshine.qExpansion_qJ` and `VOA.Moonshine.hasSum_JShift` in `VOA/Moonshine/JAnalyticQExpansion.lean` (see the dictionary after the definition of `JShift`).

33.1.7 Theta series of even unimodular lattices

Let $L \subset \mathbb{R}^r$ be an even unimodular lattice (Chapter 30). Its theta series is

$$\Theta_L(\tau) = \sum_{\alpha \in L} q^{\langle \alpha,\alpha\rangle/2} = \sum_{n \geq 0} r_L(2n)\, q^n, \qquad r_L(m) = \#\{\alpha \in L : \langle \alpha,\alpha\rangle = m\}.$$

Evenness makes the exponents integral, so $\Theta_L(\tau+1) = \Theta_L(\tau)$; Poisson summation with self-duality $L^* = L$ gives $\Theta_L(-1/\tau) = (\tau/i)^{r/2}\Theta_L(\tau)$; one deduces $8 \mid r$ and that Θ_L is a modular form of weight $r/2$.

In the library this is `IntegralLattice.thetaModularForm` (vendored file `VOA/LatticesAndCodes/Theta/ModularForm.lean`), with q-coefficients identified by `IntegralLattice.coeff_qExpansion_thetaModularForm`: coefficient m is $r_L(2m)$. Both are presented in Chapter 30.

For the Leech lattice Λ ($r = 24$, weight 12) there are no vectors of norm 2: $r_\Lambda(0) = 1$, $r_\Lambda(2) = 0$ (`Leech.lattice_repCount_two`). Formula (33.4) with $a_0 = 1$, $a_1 = 0$ gives at once

$$\Theta_\Lambda = E_4^3 - \frac{720}{1728}\big(E_4^3 - E_6^2\big) = E_4^3 - 720\Delta = 1 + 196560q^2 + 16773120q^3 + 398034000q^4 + \cdots. \tag{33.8}$$

The number 196560 is the kissing number of the Leech lattice.

33.1.8 The group $\Gamma_0(2)$ and its Hauptmodul

The congruence subgroup $\Gamma_0(2) = \{\gamma \in \mathrm{SL}_2(\mathbb{Z}) : c \equiv 0 \bmod 2\}$ has index 3: reduction mod 2 maps $\mathrm{SL}_2(\mathbb{Z})$ onto $\mathrm{SL}_2(\mathbb{F}_2) \cong S_3$, which permutes the three points of $\mathbb{P}^1(\mathbb{F}_2)$, and $\Gamma_0(2)$ is the stabiliser of ∞. Coset representatives are 1, S, ST, i.e. the maps $\tau \mapsto \tau$, $\tau \mapsto -1/\tau$, $\tau \mapsto -1/(\tau+1)$. The function

$$t(\tau) = \frac{\Delta(\tau)}{\Delta(2\tau)} = \frac{\eta(\tau)^{24}}{\eta(2\tau)^{24}} = q^{-1}\prod_{n\geq 1}\frac{(1-q^n)^{24}}{(1-q^{2n})^{24}} = q^{-1}\prod_{n\geq 1}(1+q^n)^{-24} \tag{33.9}$$

(using $1 - q^{2n} = (1-q^n)(1+q^n)$) is invariant under $\Gamma_0(2)$ and is its Hauptmodul, with expansion $t = q^{-1} - 24 + 276q - 2048q^2 + \cdots$. In the language of moonshine, $t + 24$ is the McKay–Thompson series of the Monster class $2B$.

The trace to level one. Summing a $\Gamma_0(2)$-invariant function over the three cosets gives a $\mathrm{SL}_2(\mathbb{Z})$-invariant one. Using $\Delta(-1/\tau) = \tau^{12}\Delta(\tau)$ and $\Delta(\tau+1) = \Delta(\tau)$:

$$t(-1/\tau) = \frac{\tau^{12}\Delta(\tau)}{(\tau/2)^{12}\Delta(\tau/2)} = 2^{12}\frac{\Delta(\tau)}{\Delta(\tau/2)}, \qquad t\big(-1/(\tau+1)\big) = 2^{12}\frac{\Delta(\tau)}{\Delta((\tau+1)/2)}.$$

Hence

$$t(\tau) + t(-1/\tau) + t\big(-1/(\tau+1)\big) = \frac{\Phi(\tau)}{\Delta(\tau)}, \qquad \Phi(\tau) := \Delta(\tau)^2\Big(\frac{1}{\Delta(2\tau)} + \frac{2^{12}}{\Delta(\tau/2)} + \frac{2^{12}}{\Delta((\tau+1)/2)}\Big). \tag{33.10}$$

Φ is a level-one modular form of weight 12 (Section 33.7) with q-expansion $1 - 48q + \cdots$; formula (33.4) then gives $\Phi = E_4^3 - 768\Delta$, that is,

$$t(\tau) + t(-1/\tau) + t\big(-1/(\tau+1)\big) = j(\tau) - 768. \tag{33.11}$$

The numbers 720 in (33.8) and 768 in (33.11) average to 744: this is, in one line, why the orbifold produces $J = j - 744$.

33.2 The library's formal q-series

33.2.1 Why formal power series

A graded dimension is a sequence of natural numbers, and its natural home is the ring $\mathbb{C}[[q]]$ of formal power series: no convergence is involved, and an identity of series is the same thing as an identity of all coefficients. This is why the headline theorem (33.1) is stated in $\mathbb{C}[[q]]$, and why the library builds E_4, E_6, Δ and j *formally* in `VOA/Modularity/JFunction.lean` instead of using Mathlib's analytic functions. The analytic theory enters only in proofs, through uniqueness of q-expansions (Proposition 33.2).

Mathlib's power series, in plain words. `PowerSeries ℂ` (also written `ℂ⟦X⟧`) is the ring of formal power series $\sum_{n\ge 0} a_n X^n$ with complex coefficients. In this chapter the variable X plays the role of q (except in Theorem 33.18, where it is $q^{1/2}$). Notation:

- `PowerSeries.mk a` is the series with coefficient sequence $a : \mathbb{N} \to \mathbb{C}$;
- `PowerSeries.coeff n f`, also written `coeff n f` or `PowerSeries.coeff (R := ℂ) n f` (the coefficient ring made explicit), is $[X^n]f$;
- `PowerSeries.constantCoeff f` is $[X^0]f$;
- `X` (or `PowerSeries.X`) is the variable, and `c • f` is scalar multiplication by $c \in \mathbb{C}$;
- a series is a *unit* (`IsUnit f`) iff its constant term is nonzero; `(PowerSeries ℂ)ˣ` is the group of units, `u⁻¹` the inverse of a unit u, and `((u⁻¹ : (PowerSeries ℂ)ˣ) : PowerSeries ℂ)` the underlying series of that inverse;
- for an arbitrary series, `f⁻¹` is Mathlib's "inverse if the constant term is nonzero, and an irrelevant value otherwise"; below it is applied only to series with constant term 1.

Infinite products of formal series are expressed by `HasProd u F`: the finite partial products $\prod_{i<N} u_i$ converge to F in the *coefficientwise* topology (activated by `open scoped PowerSeries.WithPiTopology`). Concretely: for every n, the coefficient $[X^n]\prod_{i<N} u_i$ is eventually (in N) equal to $[X^n]F$. For example, in $\prod_{n\ge 1}(1-X^n)^{-24}$ the factor $(1-X^n)^{-1} = 1 + X^n + X^{2n} + \cdots$ does not affect coefficients below X^n, so every coefficient stabilises.

33.2.2 Divisor sums as Lambert coefficients

Definition 33.6 (Lambert coefficient). For $s, n \in \mathbb{N}$ let $\lambda_s(n) = \sum_{(a,b)\in\mathbb{N}^2,\ ab=n} a^s$, the coefficient of q^n in the Lambert series $\sum_{m\ge 1} m^s q^m/(1-q^m)$.

```
noncomputable def lambertCoeff (s n : ℕ) : ℂ :=
  ∑ p ∈ n.divisorsAntidiagonal, ((p.1 : ℂ)) ^ s
```

(`VOA/Modularity/LambertSeries.lean`; all declarations of this section are in namespace `VOA`.)

Physical meaning

Lambert series $\sum_m m^s q^m/(1-q^m)$ arise in physics as sums over winding or momentum modes: the coefficient $\sigma_s(n)$ adds up d^s over the ways of splitting energy level n as $d \cdot (n/d)$. This is the structure behind the Eisenstein series, which in turn are the building blocks of every torus partition function in this chapter. The definition itself is just a divisor sum.

Theorem 33.7. *$\lambda_s(n) = \sigma_s(n)$ for all $s, n \in \mathbb{N}$.*

```
theorem lambertCoeff_eq_sigma (s n : ℕ) :
    lambertCoeff s n = ((ArithmeticFunction.sigma s n : ℕ) : ℂ)
```

From the mathematics to the Lean statement

`n.divisorsAntidiagonal` is the finite set of pairs (a, b) of natural numbers with $ab = n$; for $n = 0$ it is empty (Mathlib's convention), so $\lambda_s(0) = 0$. `p.1` is the first component a, and `((p.1 : ℂ)) ^ s` is a^s computed in $\mathbb{C}$. `ArithmeticFunction.sigma s n` is Mathlib's $\sigma_s(n) = \sum_{d|n} d^s$ (a natural number, with $\sigma_s(0) = 0$), cast to $\mathbb{C}$. No hypotheses. Same as the textbook statement for $n \geq 1$; at $n = 0$ both sides are 0 by convention, and this value is never used (E_4, E_6 treat $n = 0$ separately).

Physical meaning

The identity $\lambda_s(n) = \sigma_s(n)$ is the arithmetic form of the heuristic that the Eisenstein series is a sum over lattice momenta (m, n) of a two-dimensional torus, collected by their greatest common divisor. It is a pure number-theory fact, with no further physical content.

Proof. Pairs (a, b) with $ab = n \geq 1$ correspond bijectively to divisors a of n.

What the machine verified

Proved, no hypotheses. Used through the values $\sigma_3(2) = 9$, $\sigma_3(3) = 28$, $\sigma_5(2) = 33$, $\sigma_5(3) = 244$ (`lambertCoeff_three_two`, ..., in `JFunction.lean`), each checked by Lean's kernel evaluation.

33.2.3 The formal Eisenstein series

Definition 33.8 (Formal E_4, E_6). In $\mathbb{C}[[q]]$ put $E_4 = 1+240\sum_{n\geq 1}\sigma_3(n)q^n$ and $E_6 = 1-504\sum_{n\geq 1}\sigma_5(n)q^n$.

```
noncomputable def E4Series : PowerSeries ℂ :=
  PowerSeries.mk fun n => if n = 0 then 1 else 240 * lambertCoeff 3 n

noncomputable def E6Series : PowerSeries ℂ :=
  PowerSeries.mk fun n => if n = 0 then 1 else -504 * lambertCoeff 5 n
```

(`VOA/Modularity/JFunction.lean`.)

From the mathematics to the Lean statement

The coefficient sequence is defined by cases: 1 at $n = 0$, and $240\lambda_3(n) = 240\sigma_3(n)$ (Theorem 33.7) for $n \geq 1$; similarly for E_6. This is literally Definition 33.8. *Could the name be unjustified?* A formal series carries no modularity by itself; that `E4Series` is the q-expansion of Mathlib's analytic E_4 is the theorem `qExpansion_E₄` (Proposition 33.33), proved by comparing with Mathlib's coefficient formula via $-2 \cdot 4/B_4 = 240$. The first coefficients are theorems: `coeff_one_E4Series` (240), `coeff_two_E4Series` (2160), `coeff_three_E4Series` (6720), and

for E_6: -504, -16632, -122976.

Physical meaning

E_4 and E_6 are the simplest holomorphic torus "partition functions" with modular weight: E_4 is the weight-4 object whose q^0 term is the vacuum and whose coefficients $240\sigma_3(n)$ count (up to normalisation) the roots and higher shells of the E_8 lattice theory. They are not themselves physical partition functions (they have positive weight and no integrality of degeneracies built in), but every $c = 24$ character is a rational function of them, e.g. $j = E_4^3/\Delta$.

33.2.4 The formal discriminant and Δ/q

Definition 33.9 (Formal Δ). $\Delta = (E_4^3 - E_6^2)/1728 \in \mathbb{C}[[q]]$.

```
noncomputable def deltaSeries : PowerSeries ℂ :=
  (1728 : ℂ)⁻¹ • (E4Series ^ 3 - E6Series ^ 2)
```

Physical meaning

The discriminant $\Delta = \eta^{24}$ is, physically, the partition function of 24 free chiral bosons up to the Casimir factor: $\Delta = q\prod(1-q^n)^{24}$ is the inverse of the oscillator trace $q^{-1}\prod(1-q^n)^{-24}$. Its defining Eisenstein form $(E_4^3 - E_6^2)/1728$ is the modular side of that same object; their equality (Jacobi's product, Theorem 33.35) is a nontrivial theorem, not a convention.

Proposition 33.10. $[q^0]\Delta = 0$ *and* $[q^1]\Delta = 1$.

```
@[simp] theorem constantCoeff_deltaSeries : PowerSeries.constantCoeff deltaSeries = 0
@[simp] theorem coeff_one_deltaSeries : PowerSeries.coeff (R := ℂ) 1 deltaSeries = 1
```

Physical meaning

$[q^0]\Delta = 0$ says Δ vanishes at the cusp; in the CFT picture $1/\Delta$ has a simple pole q^{-1}, the vacuum with energy $-c/24 = -1$ for $c = 24$ bosons. $[q^1]\Delta = 1$ is the normalisation of that pole to residue one, i.e. a unique vacuum state.

Proof. Constant terms: $1 - 1 = 0$. Degree one: $[q^1](fg) = f_0 g_1 + f_1 g_0$, so $[q^1]E_4^3 = 3 \cdot 240 = 720$ and $[q^1]E_6^2 = 2 \cdot (-504) = -1008$, and $720 + 1008 = 1728$.

Because Δ has no constant term it is divisible by q; the cofactor has constant term 1, so it is invertible in $\mathbb{C}[[q]]$.

Definition 33.11 (Δ/q). Δ/q is the unique series D_1 with $\Delta = q\,D_1$; it has constant term 1 and is therefore a unit of $\mathbb{C}[[q]]$.

```
noncomputable def deltaOverQ : PowerSeries ℂ :=
  Classical.choose (PowerSeries.X_dvd_iff.mpr constantCoeff_deltaSeries)

theorem deltaSeries_eq : deltaSeries = PowerSeries.X * deltaOverQ

@[simp] theorem constantCoeff_deltaOverQ : PowerSeries.constantCoeff deltaOverQ = 1

theorem deltaOverQ_isUnit : IsUnit deltaOverQ

noncomputable def deltaOverQUnit : (PowerSeries ℂ)ˣ := deltaOverQ_isUnit.unit
```

From the mathematics to the Lean statement

`PowerSeries.X_dvd_iff` is Mathlib's "$X \mid f \iff$ the constant term of f is 0". Applied to `constantCoeff_deltaSeries` it yields $\exists D,\ \Delta = X \cdot D$, and `Classical.choose` picks a witness. This looks arbitrary but is not: $\mathbb{C}[[q]]$ is an integral domain, so the cofactor is *unique*, and `deltaSeries_eq` records the defining property. Hence `deltaOverQ` is exactly Δ/q. Because `Classical.choose` is non-constructive, its coefficients cannot be "evaluated"; all of them are derived by theorems from `deltaSeries_eq`. `deltaOverQUnit` is the same series regarded as an element of the group of units, so that $(\Delta/q)^{-1}$ is a genuine inverse.

Physical meaning

$\Delta/q = \prod(1-q^n)^{24}$ is the inverse of the oscillator generating function of 24 free bosons; stripping the factor q removes the Casimir energy $-24/24 = -1$ and leaves the state count, whose inverse $1, 24, 324, 3200, \ldots$ is the number of oscillator states at each level. The unit property (constant term 1) is the uniqueness of the vacuum.

33.2.5 qj and qJ

The function j has a pole at $q = 0$ and is not a power series. Rather than introducing Laurent series, the library multiplies by q.

Definition 33.12 (qj and qJ). `jShift` $= E_4^3 \cdot (\Delta/q)^{-1}$ and `JShift` $=$ `jShift` $- 744q$. If $j = \sum_{n\geq -1} c(n)q^n$, then $[q^n]$`jShift` $= c(n-1)$: `jShift` is $q \cdot j$ and `JShift` is $q \cdot J$.

File `VOA/Modularity/JFunction.lean`.

```
noncomputable def jShift : PowerSeries ℂ :=
  E4Series ^ 3 * ((deltaOverQUnit⁻¹ : (PowerSeries ℂ)ˣ) : PowerSeries ℂ)

noncomputable def JShift : PowerSeries ℂ := jShift - (744 : ℂ) • PowerSeries.X
```

From the mathematics to the Lean statement

The index shift is the one convention to remember in this chapter. $[q^n]$`JShift` is the coefficient of q^{n-1} in J:

n	0	1	2	3	4	5
$[q^n]$`JShift`	1	0	196884	21493760	864299970	20245856256
coefficient of J at	q^{-1}	q^0	q^1	q^2	q^3	q^4

(the first three entries are Lean theorems; all six were recomputed independently in exact integer arithmetic for this chapter). So "$\dim V^\natural_n = [q^n]$`JShift` for all n" is the textbook "$\sum_n \dim V^\natural_n\, q^{n-1} = J$", i.e. $\mathrm{tr}_{V^\natural} q^{L_0-1} = J(q)$, the shift $-c/24 = -1$ being absorbed. *Is it the right j?* The definition is the formal transcription of $j = E_4^3/\Delta = q^{-1}E_4^3(\Delta/q)^{-1}$. That it is the q-expansion of Klein's analytic j follows on paper from `qExpansion_E₄` and `qExpansion_discriminant` (Section 33.6), and the identification is a Lean theorem: in `VOA/Moonshine/JAnalyticQExpansion.lean`, `qExpansion_qJ` states `qExpansion 1 qJ = JShift`, where `qJ` is $q\,(j(z) - 744)$ built from `VOA.jInvariant`, and `hasSum_JShift` states that for every $z \in \mathfrak{H}$ the series `JShift` converges to $q\,(j(z) - 744)$, $q = e^{2\pi i z}$ (`hasSum_JShift_laurent` gives the Laurent form). The statements of this chapter, and the final theorem of Chapter 42, use only the formal series, so this is a companion result, not a dependency: "graded dimension $= J$" means equality of formal q-expansions. *Could* `JShift` *be degenerate?* No: it is a concrete series with proved coefficients, so a theorem equating a dimension generating function with

it has content at every coefficient.

Physical meaning

qj and qJ are the partition functions with the Casimir shift $q^{-c/24} = q^{-1}$ absorbed: $\sum_n \dim V_n\, q^n = q\,Z(\tau)$ when $Z = \operatorname{tr} q^{L_0-1}$. Subtracting $744q$ removes the constant term of j, i.e. the number of weight-one states; $J = j - 744$ is therefore the partition function of a $c = 24$ theory with no currents, the Monster CFT. The coefficients $1, 0, 196884, 21493760$ are the dimensions of the weight $0, 1, 2, 3$ spaces of $V^\natural$; $196884 = 1 + 196883$ under the Monster (a known fact, not proved here).

Proposition 33.13 (First coefficients). *$[q^0]\,qj = [q^0]\,qJ = 1$; $qJ + 744q = qj$; and $[q^2]\,qj = [q^2]\,qJ = 196884$.*

File `VOA/Modularity/JFunction.lean`.

```
@[simp] theorem constantCoeff_jShift : PowerSeries.constantCoeff jShift = 1
@[simp] theorem constantCoeff_JShift : PowerSeries.constantCoeff JShift = 1
theorem JShift_add : JShift + (744 : ℂ) • PowerSeries.X = jShift
theorem coeff_two_jShift : PowerSeries.coeff (R := ℂ) 2 jShift = 196884
theorem coeff_two_JShift : PowerSeries.coeff (R := ℂ) 2 JShift = 196884
```

Physical meaning

The first coefficients read: one vacuum, no weight-one states ($V_1^\natural = 0$, no currents, so no continuous symmetry), and 196884 states at weight 2, which decompose as $1 + 196883$ under the Monster (the trivial representation plus the smallest nontrivial one; quoted as a fact, not proved here). The weight-two space is the Griess algebra, containing the stress tensor $L_{-2}\mathbf{1}$ as the singlet.

Example 33.14 (The Moonshine coefficient by hand). From the coefficients of E_4 and $[q^2](fg) = f_0g_2 + f_1g_1 + f_2g_0$:

$$E_4^2 = 1 + 480q + (2\cdot 2160 + 240^2)q^2 + \cdots = 1 + 480q + 61920q^2 + \cdots,$$
$$E_4^3 = 1 + 720q + (61920 + 480\cdot 240 + 2160)q^2 + \cdots = 1 + 720q + 179280q^2 + \cdots.$$

Similarly $E_6^2 = 1 - 1008q + (2\cdot(-16632) + 504^2)q^2 + \cdots = 1 - 1008q + 220752q^2 + \cdots$, so $[q^2](E_4^3 - E_6^2) = 179280 - 220752 = -41472 = -24\cdot 1728$. With the q^3 coefficients $16954560 - 16519104 = 435456 = 252\cdot 1728$ this gives $\Delta = q - 24q^2 + 252q^3 + \cdots$ and $\Delta/q = 1 - 24q + 252q^2 + \cdots$. Inverting $u = \Delta/q$ term by term from $u\cdot u^{-1} = 1$:

$$(\Delta/q)^{-1} = 1 + 24q + (24^2 - 252)q^2 + \cdots = 1 + 24q + 324q^2 + \cdots.$$

Finally $[q^2]\big(E_4^3(\Delta/q)^{-1}\big) = 324 + 720\cdot 24 + 179280 = 324 + 17280 + 179280 = 196884$, and $[q^1] = 24 + 720 = 744$ is the constant term of j. The numbers $1, 24, 324$ are the dimensions of the weight $0, 1, 2$ parts of the Fock space of 24 free bosons — not a coincidence, since $(\Delta/q)^{-1} = \prod(1-q^n)^{-24}$ (Theorem 33.35).

What the machine verified

Section 33.2 is proved without hypotheses (`#print axioms` of `coeff_two_JShift`: the standard three). The coefficient $[q^3]$`JShift` $= 21493760$ is *not* computed in `JFunction.lean`; it is obtained in the opposite direction, from the dimension of the weight-3 space and the main theorem (`coeff_three_JShift`, Section 33.8).

33.3 The graded dimensions of the two sectors

FLM's moonshine module is, as a graded vector space, $V^\natural = V_\Lambda^+ \oplus (V_\Lambda^T)^+$: the θ-fixed part of the Leech lattice VOA plus the θ-fixed part of the θ-twisted sector $V_\Lambda^T = S[\theta] \otimes T$. This section counts both.

33.3.1 The untwisted sector, recalled

The untwisted sector was treated in Chapters 31 and 32; we recall exactly what is used here. For an even positive-definite lattice L of rank r, the lattice VOA V_L is spanned by states $h_{a_1}(-n_1)\cdots h_{a_k}(-n_k)\otimes e^\alpha$ ($n_i \geq 1$, $\alpha \in L$) of weight $\sum n_i + \frac{1}{2}\langle\alpha,\alpha\rangle$. The weight-$w$ part of the Fock factor has dimension $P(r,w)$, the number of r-coloured partitions of w, with generating function

$$P := \sum_{w\geq 0} P(r,w)q^w = \prod_{n\geq 1}(1-q^n)^{-r}. \tag{33.12}$$

In the library $P(r,w)$ is `LatGen.fockCount r w` (Chapter 32, section on the graded dimension of V_L), and

```
noncomputable def fockGenFun (r : ℕ) : PowerSeries ℂ := PowerSeries.mk fun w => (fockCount
 ↪  r w : ℂ)

theorem hasProd_fockGenFun (r : ℕ) :
    HasProd (fun i : ℕ => ((1 - (PowerSeries.X : ℂ⟦X⟧)) ^ (i + 1))⁻¹) ^ r) (fockGenFun r)
```

(`VOA/Moonshine/LatticeGradedDim.lean`, namespace `VOA.LatGen`): this is (33.12), the product running over $n = i+1 \geq 1$. The involution θ acts on the Fock factor of the $\alpha = 0$ sector as $(-1)^{\#\text{oscillators}}$; the corresponding signed count $P^+(r,w) - P^-(r,w)$ (even minus odd number of oscillators) is `LatGen.fockSigned r w`, with generating function

$$B := \sum_w \big(P^+ - P^-\big)(r,w)\, q^w = \prod_{n\geq 1}(1+q^n)^{-r} \tag{33.13}$$

(`LatGen.fockSignedGenFun r`, `LatGen.hasProd_fockSignedGenFun`): giving each oscillator the sign -1 replaces $(1-q^n)^{-1} = \sum_k q^{nk}$ by $\sum_k (-1)^k q^{nk} = (1+q^n)^{-1}$. The two theorems of Chapter 32 that turn dimensions into these series are

$$\dim(V_L)_k = \sum_{n=0}^{k} r_L(2n)\, P(r,k-n) = [q^k]\big(\Theta_L \cdot P\big), \tag{33.14}$$

$$2\dim(V_L^+)_k = \dim(V_L)_k + \big(P^+ - P^-\big)(r,k) = [q^k]\big(\Theta_L P + B\big), \tag{33.15}$$

(`LatGen.finrank_gradingLatGen_eq_sum_theta`, `LatGen.two_mul_finrank_plusK_eq_signed`; both proved in Chapter 32). The first holds because $(V_L)_k = \bigoplus_\alpha F_{k-\langle\alpha,\alpha\rangle/2}\otimes e^\alpha$ with F_w the weight-w part of the Fock factor; the second because θ swaps e^α and $e^{-\alpha}$ for $\alpha \neq 0$ (trace 0) and acts on the $\alpha = 0$ sector by $(-1)^{\#\text{oscillators}}$, together with $\dim V^+ = \frac{1}{2}(\dim V + \operatorname{tr}\theta)$ for an involution. For $L = \Lambda$, V_Λ^+ is `VOA.Moonshine.leechVOAPlus`, the fixed-point subVOA of θ, and `leechVOAPlus.grading n` is its weight-n subspace (a `Submodule ℂ` of its carrier); both are defined in Chapter 32 (section on the fixed-point algebra). That chapter also proves $(V_\Lambda^+)_1 = 0$ (`leechVOAPlus_grading_one`), $\dim(V_\Lambda^+)_2 = 98580$, $\dim(V_\Lambda^+)_3 = 10745856$.

Example 33.15 ($\dim(V_\Lambda^+)_2$ and $\dim(V_\Lambda^+)_3$)**.** With $\Theta_\Lambda = 1 + 196560q^2 + 16773120q^3 + \cdots$, $P = 1 + 24q + 324q^2 + 3200q^3 + \cdots$ and $B = 1 - 24q + 276q^2 - 2048q^3 + \cdots$:

$$\dim(V_\Lambda)_2 = 324 + 196560 = 196884, \qquad \dim(V_\Lambda^+)_2 = \tfrac{1}{2}(196884 + 276) = 98580,$$

$$\dim(V_\Lambda)_3 = 3200 + 196560\cdot 24 + 16773120 = 21493760,$$

$$\dim(V_\Lambda^+)_3 = \tfrac{1}{2}(21493760 - 2048) = 10745856.$$

Observe $\dim(V_\Lambda)_n = [q^n](qj) - 720\,[q^n]q$ in these cases; we shall prove $\Theta_\Lambda P = q(j-720)$, i.e. the character of V_Λ is $j - 720 = J + 24$, the 24 counting the currents $h_a(-1)\mathbf{1}$.

33.3.2 The twisted Fock space $S[\theta]$

The θ-twisted Heisenberg algebra has modes $h_a(m)$ with $m \in \frac{1}{2}+\mathbb{Z}$; its Fock space is the polynomial algebra on the creation modes $h_a(-n-\frac{1}{2})$, $n \geq 0$. The operators (built in Chapters 34–35) play no role in this chapter; only the *space*, its grading and its involution matter.

Definition 33.16 (Twisted Fock space, doubled weight, θ_S). Let $S[\theta]_r = \mathbb{C}[x_{n,a} : n \in \mathbb{N},\ a \in \{0,\dots,r-1\}]$, the variable $x_{n,a}$ standing for $h_a(-n-\frac{1}{2})$. Give $x_{n,a}$ the *doubled weight* $2n+1$, and let $S[\theta]_{r,(d)}$ be the span of the monomials of total doubled weight d. The L_0-eigenvalue on $S[\theta]_{r,(d)}$ is $\mathrm{level}_r(d) = d/2 + r/16$, the $r/16$ being the vacuum energy of r twisted bosons. Let θ_S be the algebra automorphism $x_{n,a} \mapsto -x_{n,a}$.

```
abbrev FockT (r : ℕ) : Type := MvPolynomial (ℕ × Fin r) ℂ

def wT {r : ℕ} : ℕ × Fin r → ℕ := fun v => 2 * v.1 + 1

def gradingT (r d : ℕ) : Submodule ℂ (FockT r) := weightedHomogeneousSubmodule ℂ wT d

noncomputable def thetaT (r : ℕ) : FockT r ≃ₐ[ℂ] FockT r :=
  AlgEquiv.ofAlgHom (thetaHom r) (thetaHom r) (thetaHom_comp_self r) (thetaHom_comp_self r)
```

(`VOA/Moonshine/TwistedHeisenberg.lean`, namespace `VOA.TwistedHeisenberg`.)

From the mathematics to the Lean statement

`MvPolynomial (ℕ × Fin r) ℂ` is the polynomial ring over $\mathbb{C}$ in variables indexed by pairs (n,a), $n \in \mathbb{N}$, $a \in$ `Fin r` $= \{0,\dots,r-1\}$. `weightedHomogeneousSubmodule ℂ wT d` is the span of monomials whose weight, computed with `wT`$(n,a) = 2n+1$, is d: this is $S[\theta]_{r,(d)}$. Doubling the weight keeps it in $\mathbb{N}$; the true L_0 is recovered by `levelT`, a rational number. `aeval fun v ⇒ -X v` is the algebra map sending each variable `X v` to $-$`X v`; `thetaT` packages it as an algebra automorphism ($\theta_S^2 = 1$ is `thetaHom_comp_self`). Every definition is the textbook one; the only modelling choice is to take the polynomial ring as the Fock space, which for counting dimensions is harmless (the monomials are the standard basis).

Physical meaning

$S[\theta]$ is the Fock space of 24 bosons with half-integral modes: the twisted boundary condition $X(e^{2\pi i}z) = -X(z)$ replaces the integer oscillators α_{-n} by $\alpha_{-n-1/2}$. The shift of the vacuum energy to $r/16$ (here $24/16 = 3/2$) is the Casimir energy of r antiperiodic bosons, a $+1/16$ per boson relative to the periodic ones. θ_S, the sign flip $x \mapsto -x$, is the $\mathbb{Z}/2$ symmetry $X \mapsto -X$ being orbifolded.

Definition 33.17 (Twisted count). $P_T(r,d)$ is the number of monomials of doubled weight d, equivalently the number of r-coloured partitions of d into odd parts.

```
def degSetT (r d : ℕ) : Set ((ℕ × Fin r) →₀ ℕ) := {m | Finsupp.weight wT m = d}
```

```
noncomputable def twCount (r d : ℕ) : ℕ := (degSetT r d).ncard

theorem finrank_gradingT_eq_twCount (r d : ℕ) : finrank ℂ (gradingT r d) = twCount r d
```

(`degSetT` in `TwistedHeisenberg.lean`; the rest in `VOA/Moonshine/TwistedSectorDim.lean`, namespace `VOA.TwistedSector`.)

From the mathematics to the Lean statement

A monomial is an exponent vector `m : (ℕ × Fin r) →₀ ℕ` (finitely supported, giving the power of each variable), and `Finsupp.weight wT m` $= \sum_{(n,a)} (2n+1)\, m(n,a)$. `Set.ncard` is the cardinality of a set (0 for infinite sets; this set is finite, so it is the honest size). `finrank ℂ` is the dimension of a finite-dimensional complex vector space, here of the subspace `gradingT r d` regarded as a vector space. The theorem says $\dim S[\theta]_{r,(d)} = P_T(r,d)$, because monomials form a basis.

Physical meaning

$P_T(r,d)$ is the degeneracy of the twisted oscillator spectrum: states built by acting with the half-integral creation operators of r antiperiodic bosons, with d twice the energy above the twisted ground state. Equivalently it counts coloured partitions into odd parts, the combinatorial signature of antiperiodic boundary conditions.

The library also proves $P_T(r,0) = 1$, $P_T(r,1) = r$, $P_T(r,2) = \binom{r+1}{2}$, $P_T(r,3) = r + \binom{r+2}{3}$ (`twCount_zero`, `twCount_one`, `twCount_two`, `twCount_three`), and that one colour gives the partitions into odd parts (`twCount_one_colour`). For $r = 24$: $P_T(24,1) = 24$ (states $h_a(-\frac{1}{2})$) and $P_T(24,3) = 24 + \binom{26}{3} = 2624$ (states $h_a(-\frac{3}{2})$ and $h_a(-\frac{1}{2})h_b(-\frac{1}{2})h_c(-\frac{1}{2})$, $a \le b \le c$), the latter as `VOA.Moonshine.twCount_24_three`.

Theorem 33.18 (Generating function of the twisted Fock space). *With $x = q^{1/2}$, in $\mathbb{C}[[x]]$,*

$$\sum_{d\ge 0} P_T(r,d)\, x^d = \prod_{i\ge 0} \left(1 - x^{2i+1}\right)^{-r} \quad \left(= \prod_{n\ge 1} \left(1 - q^{n-\frac{1}{2}}\right)^{-r}\right).$$

```
noncomputable def twGenFun (r : ℕ) : PowerSeries ℂ := PowerSeries.mk fun d => (twCount r d
↪  : ℂ)

theorem hasProd_twGenFun (r : ℕ) :
    HasProd (fun i : ℕ => ((1 - (PowerSeries.X : ℂ⟦X⟧) ^ (2 * i + 1))⁻¹) ^ r) (twGenFun r)
```

From the mathematics to the Lean statement

Here `X` is $x = q^{1/2}$, not q: the doubled weight is the exponent. `HasProd` is the coefficientwise infinite product (Section 33.2); `(1 - X^(2i+1))⁻¹` is the geometric series $\sum_k x^{(2i+1)k}$ (constant term 1, so a genuine inverse). No hypotheses; the statement is the textbook one for every rank r.

Physical meaning

This is the partition function of r free bosons with antiperiodic boundary conditions: $\prod_{n\ge 1}(1-q^{n-1/2})^{-r}$, one factor per half-integral mode. Compare $\prod(1-q^n)^{-r}$ for periodic bosons; this is the oscillator part of the twisted-sector character. The overall energy shift $(q^{r/16})$ is supplied separately by the definition of level_r.

Proof. For one colour, expanding $\prod_i \sum_k x^{(2i+1)k}$ and collecting x^d counts the ways of writing d as a sum of odd parts with multiplicities. For r colours, a monomial is an r-tuple of one-colour monomials and doubled weights add, so the generating function is the r-th power.

33.3.3 The twisted sector $S[\theta] \otimes T$ and its fixed part

The twisted sector of the lattice theory is $V_L^T = S[\theta] \otimes T$, where T is the irreducible module of an extraspecial 2-group of order 2^{1+r}; for Λ, $\dim T = 2^{12}$. The construction of T is the subject of Chapter 34. In the general statements below T is an *arbitrary* complex vector space; for Λ only its dimension is used:

```
noncomputable abbrev leechT : Type := ExtraT leech leech_even leech_isUnit_det_gramMat

theorem finrank_leechT : Module.finrank ℂ leechT = 4096
```

(`VOA/Moonshine/ExtraspecialModule.lean`, namespace `VOA.Moonshine`; `ExtraT L …` is the simple module of the twisted group algebra $\mathbb{C}^\varepsilon[L/2L]$, Chapter 34.) FLM let θ act on the twisted sector as $\theta_S \otimes (-1)$. Since L_0 acts on the first factor only, the grading is $S[\theta]_{(d)} \otimes T$.

Definition 33.19 (Grading, weight spaces, involution and fixed part)**.** For a complex vector space T, $r, d \in \mathbb{N}$ and $w \in \mathbb{Q}$:

$$(S[\theta]\otimes T)_{(d)} = S[\theta]_{r,(d)} \otimes T \subseteq S[\theta]_r \otimes T, \qquad (S[\theta]\otimes T)_w = \sum_{d\,:\,\mathrm{level}_r(d)=w} (S[\theta]\otimes T)_{(d)},$$
$$\theta_{\mathrm{tw}} = \theta_S \otimes (-\mathrm{id}_T), \qquad (S[\theta]\otimes T)^+ = \ker(\theta_{\mathrm{tw}} - 1).$$

```
noncomputable def twGrading (d : ℕ) : Submodule ℂ (FockT r ⊗[ℂ] T) :=
  LinearMap.range ((gradingT r d).subtype.rTensor T)

noncomputable def twWeight (q : ℚ) : Submodule ℂ (FockT r ⊗[ℂ] T) :=
  ⨆ (d : ℕ) (_ : levelT r d = q), twGrading r T d

noncomputable def twTheta : Module.End ℂ (FockT r ⊗[ℂ] T) :=
  TensorProduct.map (thetaT r).toLinearMap (-LinearMap.id)

noncomputable def twFixed : Submodule ℂ (FockT r ⊗[ℂ] T) :=
  LinearMap.ker (twTheta r T - LinearMap.id)
```

(`TwistedSectorDim.lean`, in a section with `variable (r : ℕ) (T : Type*) [AddCommGroup T] [Module ℂ T]`, i.e. "T is a complex vector space".)

From the mathematics to the Lean statement

The letter q. In `twWeight r T q` the argument `q : ℚ` is an L_0-*eigenvalue* (written w above), not the nome. `⊗[ℂ]` is the tensor product over $\mathbb{C}$. `(gradingT r d).subtype` is the inclusion $S_{(d)} \hookrightarrow S$; `.rTensor T` tensors it with id_T; its `range` is the image $S_{(d)} \otimes T$. `⨆ (d : ℕ) (_ : levelT r d = q)` is the sum of subspaces over those d with $\mathrm{level}_r(d) = w$ — a single d or none (then the sum is $\bot$, the zero subspace), since level_r is injective. `TensorProduct.map f g` is $f \otimes g$, `Module.End ℂ V` the linear endomorphisms of V, `LinearMap.ker` the kernel. No finite-dimensionality of T is assumed.
Is `twWeight` *the true L_0-grading?* Here it is *defined* as oscillator weight plus $r/16$. That it coincides with the L_0-eigenspaces of the twisted module constructed later (hence is the grading of $V^\natural$) is proved in Chapter 36; see Section 33.9. *Is the sign on T right?* Yes, and it matters: see the warning below.

Physical meaning

The twisted sector of the orbifold is $S[\theta] \otimes T$: the oscillators come from the antiperiodic bosons, while T is the space of twisted ground states (the zero-mode representation of the extraspecial 2-group), of dimension 2^{12} for the Leech lattice. The orbifold projection keeps the θ-invariant states, with $\theta = \theta_S \otimes (-1)$; the sign on T is chosen so that the surviving states have integral energy. Taking the fixed part is the standard orbifold step of the construction.

Proposition 33.20 (θ_{tw} on a graded piece). *On* $(S[\theta] \otimes T)_{(d)}$, $\theta_{\mathrm{tw}} = (-1)^{d+1}$. *Consequently* $(S[\theta] \otimes T)^+ = \sum_{d\ \mathrm{odd}} (S[\theta] \otimes T)_{(d)}$, *and the fixed part of* $(S[\theta] \otimes T)_{(d)}$ *has dimension* $P_T(r,d)\dim T$ *for* d *odd and* 0 *for* d *even.*

```
theorem twTheta_of_mem_twGrading {d : ℕ} {x : FockT r ⊗[ℂ] T} (hx : x ∈ twGrading r T d) :
    twTheta r T x = (-1 : ℂ) ^ (d + 1) • x

theorem twFixed_eq_iSup_odd : twFixed r T = ⨆ (d : ℕ) (_ : Odd d), twGrading r T d

theorem finrank_twFixed_inf_twGrading (d : ℕ) :
    finrank ℂ (twFixed r T ⊓ twGrading r T d : Submodule ℂ (FockT r ⊗[ℂ] T))
      = if Odd d then twCount r d * finrank ℂ T else 0
```

From the mathematics to the Lean statement

The only hypothesis is `hx`, membership in the d-th piece. `⊓` is intersection of subspaces, and `if … then … else` is the case split of the textbook statement. `finrank ℂ T` is $\dim T$; Mathlib assigns `finrank` $= 0$ to infinite-dimensional spaces, and if T were infinite-dimensional both sides would be 0 for odd d by that convention, so the statement hides no hypothesis and is meaningful for $T =$ `leechT`.

Physical meaning

The projection keeps only states with an odd number of half-integral oscillator quanta (odd doubled weight), because the twisted ground states are θ-odd; physically, the orbifold projection is a $\mathbb{Z}/2$ gauging and the sign on the twisted ground state is a choice of discrete torsion, fixed by requiring integral energy. The count $P_T(r,d)\dim T$ is then the multiplicity of each surviving energy level.

Proof. A monomial of doubled weight $d = \sum(2n_i + 1)$ has $d \equiv$ (number of variables) $\pmod 2$, so $\theta_S = (-1)^d$ on $S_{(d)}$, and the extra -1 on T gives $(-1)^{d+1}$. Odd d is fixed and even d anti-fixed; since $1 \neq -1$ in $\mathbb{C}$, the fixed space meets even pieces only in 0, and a fixed vector, decomposed into its graded pieces, has only odd components. Finally $\dim(S_{(d)} \otimes T) = P_T(r,d)\dim T$.

Theorem 33.21 (Rank 24: fixed = integral weight, nothing below 2). *For* $r = 24$ *and any* T: *the fixed part is exactly the sum of the integer-weight eigenspaces; there are no fixed vectors of weight* < 2; *and* $\dim(S[\theta] \otimes T)^+_{n+2} = P_T(24, 2n+1)\dim T$ *for all* $n \geq 0$.

File `VOA/Moonshine/TwistedSectorDim.lean`.

```
theorem twFixed_eq_iSup_int : twFixed 24 T = ⨆ n : ℤ, twWeight 24 T n

theorem twFixed_inf_twWeight_of_lt_two {q : ℚ} (hq : q < 2) :
    twFixed 24 T ⊓ twWeight 24 T q = ⊥

theorem finrank_twFixed_inf_twWeight_24 (n : ℕ) :
    finrank ℂ (twFixed 24 T ⊓ twWeight 24 T (((n : ℤ) + 2 : ℤ) : ℚ) :
        Submodule ℂ (FockT 24 ⊗[ℂ] T))
      = twCount 24 (2 * n + 1) * finrank ℂ T
```

From the mathematics to the Lean statement

In `⊔ n : ℤ, twWeight 24 T n` the integer n is coerced to $\mathbb{Q}$. The only hypothesis, `hq : q < 2`, is the intended one. `(((n : ℤ) + 2 : ℤ) : ℚ)` is the rational number $n+2$ written through $\mathbb{Z}$. All three statements are literal transcriptions, neither weaker nor stronger.

Physical meaning

For 24 twisted bosons the twisted ground state has energy $24/16 = 3/2$, and each half-integral oscillator adds a half-odd energy, so integral energies occur exactly at odd d. The orbifold projection therefore keeps the integral-spin states and removes the 3/2 vacuum: the twisted sector contributes no state below weight 2, the lowest being the $24 \cdot 2^{12}$ states $h_a(-\frac{1}{2}) \otimes t$. This is the mechanism that makes $V^\natural$ integrally graded.

Proof. For $r = 24$, $\mathrm{level}(d) = (d+3)/2$, an integer iff d is odd; combine with Proposition 33.20. The smallest odd d is 1, of weight 2; weights below 2 occur only for $d = 0$ (weight 3/2), which is not fixed. With $d = 2n+1$ the weight is $n+2$.

Trap / dead end

The sign of θ on T. Both $\theta_S \otimes (+1)$ and $\theta_S \otimes (-1)$ are compatible with the twisted vertex operators (conjugation by ± 1 on T is trivial). With the *wrong* sign $+1$ the fixed part would be the even-d part, of weights $\frac{3}{2} + \mathbb{Z}$: the twisted vacua $1 \otimes t$ of weight 3/2 would survive and $V^\natural$ would not even be $\mathbb{Z}$-graded. FLM's -1 is singled out by integrality, and Theorem 33.21 certifies that the library made that choice (the bookkeeping is also recorded in the docstring of `VOA/Moonshine/TwistedPlus.lean`). Physically: the twisted ground state of 24 twisted bosons has energy $24/16 = 3/2$, and the orbifold projection must keep only states of integral spin.

33.3.4 The Leech case: 98304 and 10747904

Definition 33.22. $V_\Lambda^T := S[\theta]_{24} \otimes T_\Lambda$ as a vector space.

```
abbrev leechTwistedSpace : Type := FockT 24 ⊗[ℂ] leechT
```

(namespace `VOA.Moonshine`, file `TwistedSectorDim.lean`.)

Physical meaning

V_Λ^T is the θ-twisted sector of the Leech lattice theory: the Hilbert space on a circle with the antiperiodic boundary condition $X \mapsto -X$, with a 2^{12}-fold degenerate ground state. Together with V_Λ^+ it supplies, by the orbifold construction, the full Hilbert space of the Monster CFT.

Theorem 33.23 (Twisted dimensions in weights ≤ 3). $(V_\Lambda^T)_0^+ = (V_\Lambda^T)_1^+ = 0$, $\dim (V_\Lambda^T)_2^+ = 24 \cdot 4096 = 98304$, $\dim (V_\Lambda^T)_3^+ = 2624 \cdot 4096 = 10747904$. *Consequently*

$$\dim (V_\Lambda^+)_2 + \dim (V_\Lambda^T)_2^+ = 98580 + 98304 = 196884,$$
$$\dim (V_\Lambda^+)_3 + \dim (V_\Lambda^T)_3^+ = 10745856 + 10747904 = 21493760.$$

```
theorem leechTwisted_finrank_fixed_two :
    finrank ℂ (twFixed 24 leechT ⊓ twWeight 24 leechT 2 : Submodule ℂ leechTwistedSpace)
      = 98304

theorem leechTwisted_finrank_fixed_three :
```

```
    finrank ℂ (twFixed 24 leechT ⊓ twWeight 24 leechT 3 : Submodule ℂ leechTwistedSpace)
      = 10747904

theorem leechTwisted_fixed_weight_zero_one :
    twFixed 24 leechT ⊓ twWeight 24 leechT 0 = ⊥ ∧ twFixed 24 leechT ⊓ twWeight 24 leechT 1
     ↪  = ⊥

theorem finrank_sectors_two :
    finrank ℂ (leechVOAPlus.grading 2)
      + finrank ℂ (twFixed 24 leechT ⊓ twWeight 24 leechT 2 : Submodule ℂ
       ↪  leechTwistedSpace)
      = 196884

theorem finrank_sectors_three :
    finrank ℂ (leechVOAPlus.grading 3)
      + finrank ℂ (twFixed 24 leechT ⊓ twWeight 24 leechT 3 : Submodule ℂ
       ↪  leechTwistedSpace)
      = 21493760
```

From the mathematics to the Lean statement

`leechVOAPlus.grading 2` is $(V_\Lambda^+)_2$ (here `2 : ℤ`); the second summand is $(V_\Lambda^T)_2^+$ in the sense of Definition 33.19 (here `2 : ℚ`). No hypotheses. *What these do not say:* they are sums of dimensions of two separately defined spaces, not dimensions of a constructed $V^\natural$; that reinterpretation is Section 33.9. *How could they be vacuous?* Only by a mis-definition of a summand (e.g. the wrong sign above, which gives 0 in weight 2); the correct, nonzero values are themselves the check.

Physical meaning

At weight 2 the untwisted θ-even states (98580) and the twisted states ($24 \cdot 2^{12} = 98304$, coming from the 2^{12} twisted ground states times 24 half-integral oscillators) add up to 196884, which equals 1 + 196883 under the Monster; this is a fact quoted from the literature, not proved here. The weight-3 count $21493760 = 1 + 196883 + 21296876$ similarly matches the Thompson observation. Both are consistency checks that the orbifold sectors together reproduce the Monster CFT spectrum; the identification of the Monster action is outside this chapter.

Proof. Theorem 33.21 with $n = 0, 1$, $P_T(24, 1) = 24$, $P_T(24, 3) = 2624$, $\dim T = 4096$, plus Example 33.15.

Remark 33.24 (The Griess algebra, counted)**.** The 196884 weight-2 states are: in V_Λ^+, the $300 = \binom{25}{2}$ symmetric products $h_a(-1)h_b(-1)\mathbf{1}$ (the 24 states $h_a(-2)\mathbf{1}$ are θ-odd and discarded) and the $98280 = \frac{1}{2} \cdot 196560$ combinations $e^\alpha + e^{-\alpha}$, $\langle \alpha, \alpha \rangle = 4$, for $300 + 98280 = 98580$; in the twisted sector, the $24 \cdot 4096 = 98304$ states $h_a(-\frac{1}{2}) \otimes t$. The decomposition $196884 = 1 + 196883$ under the Monster is invisible here.

What the machine verified

All theorems of Section 33.3 are unconditional; `#print axioms` of `hasProd_twGenFun` and `finrank_sectors_three` (re-run for this chapter) is the standard three.

33.4 The character as one power series, and the reduction to three identities

33.4.1 The two-sector series

Definition 33.25 (Sector series, Leech theta series, odd twisted series). In $\mathbb{C}[[q]]$ define

$$\chi = \sum_{n\ge 0}\Big(\dim(V_\Lambda^+)_n + \dim(V_\Lambda^T)^+_n\Big)q^n,$$
$$\Theta_\Lambda = \sum_{n\ge 0} r_\Lambda(2n)\,q^n, \qquad T_{\mathrm{odd}} = \sum_{n\ge 0} P_T(24,2n+1)\,q^n.$$

```
noncomputable def sectorSeries : PowerSeries ℂ :=
  PowerSeries.mk fun n =>
    ((finrank ℂ (leechVOAPlus.grading (n : ℤ))
      + finrank ℂ (twFixed 24 leechT ⊓ twWeight 24 leechT ((n : ℤ) : ℚ) :
          Submodule ℂ leechTwistedSpace) : ℕ) : ℂ)

noncomputable def leechThetaSeries : PowerSeries ℂ :=
  PowerSeries.mk fun n => ((normEq leech leech_posDef (2 * n)).card : ℂ)

noncomputable def twOddSeries : PowerSeries ℂ :=
  PowerSeries.mk fun n => (twCount 24 (2 * n + 1) : ℂ)
```

(`VOA/Moonshine/CharacterSeries.lean`, namespace `VOA.Moonshine`.)

From the mathematics to the Lean statement

In `sectorSeries` the n-th coefficient is the natural number $\dim(V_\Lambda^+)_n + \dim(V_\Lambda^T)^+_n$ cast to $\mathbb{C}$; the weight n enters the first summand as the integer (`n : ℤ`) and the second as the rational (`(n : ℤ) : ℚ`), because the two gradings are indexed by $\mathbb{Z}$ and $\mathbb{Q}$ respectively. Both dimensions are finite (the first by the VOA axioms, the second by Theorem 33.21), so `finrank` is the honest dimension. `normEq leech leech_posDef (2 * n)` is the finite set of Leech vectors of norm $2n$ (Chapter 32), so its `card` is $r_\Lambda(2n)$; the argument `leech_posDef` is a proof of positive-definiteness, needed for finiteness, not a hypothesis of anything. `twCount 24 (2n+1)` is $P_T(24,2n+1)$. The variable q in T_{odd} is the honest q: T_{odd} compresses the odd part of the twisted generating function, $x^3\cdot\sum_n P_T(24,2n+1)x^{2n+1} = q^2 T_{\mathrm{odd}}(q)$.

Physical meaning

$\chi = \sum_n \dim V_n^\natural\, q^n$ is $q\,Z(\tau)$ with $Z(\tau) = \mathrm{tr}_{V^\natural} q^{L_0-1}$, the torus partition function of the chiral CFT with $c = 24$. The two summands are the untwisted-sector contribution (projected onto θ-invariant states) and the twisted-sector one, i.e. the orbifold partition function written as a sum over sectors. Θ_Λ is the sum over momenta α in the Leech lattice, $q^{\alpha^2/2}$, and T_{odd} is the twisted oscillator count at integral energies.

Combining (33.15) with Theorem 33.21 gives the character as a combination of products.

Theorem 33.26 (The two-sector series as products). $\chi = \frac{1}{2}\big(\Theta_\Lambda\cdot P + B\big) + 4096\,q^2\,T_{\mathrm{odd}}$, *where* $P = \prod(1-q^n)^{-24}$ *and* $B = \prod(1+q^n)^{-24}$.

```
theorem sectorSeries_eq :
    sectorSeries
      = (2 : ℂ)⁻¹ • (leechThetaSeries * fockGenFun 24 + fockSignedGenFun 24)
        + (4096 : ℂ) • (X ^ 2 * twOddSeries)
```

From the mathematics to the Lean statement

`fockGenFun 24` and `fockSignedGenFun 24` are P and B for $r = 24$ (Section 33.3.1); `X ^ 2 * twOddSeries` is $q^2 T_{\text{odd}}$. No hypotheses. Same as the textbook statement.

Physical meaning

This is the orbifold partition function in the form $\frac{1}{2}(Z_{++} + Z_{+-} + Z_{-+} + Z_{--})$: the untwisted sector with and without the θ insertion gives $\frac{1}{2}(\Theta_\Lambda P + B)$ (momentum sum times oscillators, and the signed trace, which only sees the $\alpha = 0$ momentum sector since θ swaps α and $-\alpha$), and the twisted sector, projected to integral spins, gives $2^{12} q^2 T_{\text{odd}}$, with 2^{12} the ground-state degeneracy. The factor $\frac{1}{2}$ is the averaging over the $\mathbb{Z}/2$ orbifold group.

Proof. Coefficient by coefficient. For the untwisted part, (33.15) with $L = \Lambda$, $r = 24$ gives $\dim(V_\Lambda^+)_n = \frac{1}{2}[q^n](\Theta_\Lambda P + B)$. For the twisted part, Theorem 33.21 gives $\dim(V_\Lambda^T)_n^+ = 4096\, P_T(24, 2(n-2)+1) = [q^n](4096\, q^2 T_{\text{odd}})$ for $n \geq 2$, and 0 for $n < 2$, which is also the coefficient of q^n in $q^2 T_{\text{odd}}$.

Physical reading. The four terms are the four orbifold blocks of the preview: $\Theta_\Lambda P = Z_{++}$ (character of V_Λ, times q), $B = Z_{+-}$ (trace of θ on the $\alpha = 0$ sector, the only one contributing), and $2^{12} q^{3/2} \prod (1 - q^{n-1/2})^{-24}$ and its image under $q^{1/2} \mapsto -q^{1/2}$ are Z_{-+} and Z_{--}; their half-sum keeps the integral powers, $2 \cdot 2^{12} q^2 T_{\text{odd}}$, which halved gives the last term.

33.4.2 The three identities

Definition 33.27 (The three identities, as propositions). (A) *Jacobi's product for the formal* Δ*:* $(\Delta/q) \cdot \prod (1 - q^n)^{-24} = 1$;

(B) *the Leech theta identity:* $\Theta_\Lambda = E_4^3 - 720\Delta$;

(C) *the level-two identity:* $B + 2^{13} q^2 T_{\text{odd}} = qj - 768q$.

```
def DeltaProductIdentity : Prop := deltaOverQ * fockGenFun 24 = 1

def LeechThetaIdentity : Prop :=
  leechThetaSeries = E4Series ^ 3 - (720 : ℂ) • deltaSeries

def LevelTwoIdentity : Prop :=
  fockSignedGenFun 24 + (8192 : ℂ) • (X ^ 2 * twOddSeries) = jShift - (768 : ℂ) • X
```

From the mathematics to the Lean statement

These are *definitions of propositions*, not assumptions: `def … : Prop` merely names a statement. All three are *proved* later (`deltaProductIdentity`, `leechThetaIdentity`, `levelTwoIdentity`), so nothing claimed as a result depends on them as hypotheses. In (C), $8192 = 2^{13}$, and dividing by q gives the trace identity (33.11): $t = q^{-1} B$ by (33.9), and $t(-1/\tau) + t(-1/(\tau+1)) = 2^{13} q T_{\text{odd}}$ (proved in Section 33.7).

Physical meaning

The three identities are the three analytic inputs needed to evaluate the orbifold partition function: (A) says that the 24-boson oscillator trace is q/Δ, (B) that the Leech theta series, the momentum sum, is a weight-12 modular form fixed by its first two coefficients (1 vacuum, no norm-2 vectors), and (C) that the three twisted terms are related by modular transformations

(the three cosets of $\Gamma_0(2)$), which is the statement that the twisted blocks Z_{+-}, Z_{-+}, Z_{--} are exchanged by $\mathrm{SL}_2(\mathbb{Z})$. They are definitions of statements; proofs are later.

Theorem 33.28 (The formal reduction). *(A) implies $qj = E_4^3 P$. (A) and (B) imply $\Theta_\Lambda P = qj - 720q$. (A), (B), (C) imply $\chi = qJ$.*

File `VOA/Moonshine/CharacterSeries.lean`.

```
theorem jShift_eq_of_deltaProduct (hD : DeltaProductIdentity) :
    jShift = E4Series ^ 3 * fockGenFun 24

theorem leechTheta_mul_fock_of (hD : DeltaProductIdentity) (hT : LeechThetaIdentity) :
    leechThetaSeries * fockGenFun 24 = jShift - (720 : ℂ) • X

theorem sectorSeries_eq_JShift_of (hD : DeltaProductIdentity) (hT : LeechThetaIdentity)
    (hL : LevelTwoIdentity) : sectorSeries = JShift
```

From the mathematics to the Lean statement

The hypotheses `hD`, `hT`, `hL` are exactly (A), (B), (C). These are *conditional* theorems, but the conditions are discharged in Sections 33.6–33.7, so the final theorem (Section 33.8) has none.

Physical meaning

The algebra here is the orbifold average: $\frac{1}{2}(\Theta_\Lambda P) + \frac{1}{2}(B + 2^{13}q^2 T_{\mathrm{odd}})$ with $\Theta_\Lambda P = qj - 720q$ and the twisted-plus-signed piece equal to $qj - 768q$. The two constants 720 and 768 average to 744, which is why the orbifold of the Leech theory has no weight-one states and partition function $J = j - 744$.

Proof (pure algebra in $\mathbb{C}[[q]]$). (A) says $(\Delta/q)^{-1} = P$, so $qj = E_4^3(\Delta/q)^{-1} = E_4^3 P$. With (B), $\Theta_\Lambda P = E_4^3 P - 720\,q(\Delta/q)P = qj - 720q$. Then, by Theorem 33.26 and (C),

$$\chi = \tfrac{1}{2}\big(qj - 720q\big) + \tfrac{1}{2}\big(qj - 768q - 2^{13}q^2 T_{\mathrm{odd}}\big) + 2^{12}q^2 T_{\mathrm{odd}} = qj - 744q = qJ.$$

33.4.3 Why the analytic route

Each of (A)–(C) is an identity between explicit q-series and could in principle be proved inside $\mathbb{C}[[q]]$ by combinatorics. The project decided against this before formalising, for these reasons.

- (A) for the Eisenstein Δ is equivalent to the identity $E_4^3 - E_6^2 = 1728\,q\prod(1-q^n)^{24}$; known elementary proofs pass through Jacobi's triple product and the theta-function expressions $E_4 = \frac{1}{2}(\theta_2^8 + \theta_3^8 + \theta_4^8)$, $\Delta = 2^{-8}(\theta_2\theta_3\theta_4)^8$ (in the nome $e^{\pi i\tau}$), whose proof needs *Jacobi's abstruse identity* $\theta_3^4 = \theta_2^4 + \theta_4^4$. Neither the abstruse identity nor the theta formula for E_4 is in Mathlib.
- (B) is equivalent to an identity among theta functions of Λ that is again usually proved by modularity.
- (C) involves the substitutions $\tau \mapsto 2\tau$, $\tau/2$, $(\tau+1)/2$, i.e. $q \mapsto q^2$, $q^{1/2}$, $-q^{1/2}$, and is a level-two modular identity.

On the other hand Mathlib *does* have: the analytic E_4, E_6, Δ with their q-expansions; Jacobi's product for the analytic $\Delta = \eta^{24}$; $\dim M_{12} = 2$ (through the dimension formula); and uniqueness of q-expansions. The analytic route uses exactly these: compute each side as a holomorphic function, identify it as a modular form of weight 12, read off two coefficients. The only new analytic ingredient is a *bridge* saying that a formal infinite product, evaluated at $|q| < 1$, converges to the analytic infinite product (Section 33.5).

Remark 33.29 (Numerical pre-check)**.** Before formalisation, (A)–(C) and $\chi = qJ$ were checked numerically on the first 40 q-coefficients in exact integer arithmetic; the docstring of `CharacterSeries.lean` records this check, but the script itself is not in the repository. The repository's `scripts/moonshine/numerics/theta_check.py` (with log `theta_check.log`) checks, in exact rational arithmetic to order 80 in the nome $e^{\pi i\tau}$ (i.e. 40 coefficients in q), that $E_4^3 - 720\Delta$, computed from Jacobi theta functions, has coefficients $1, 0, 0, 0, 196560, 0, 16773120, 0, 398034000$ (the Leech theta series in the nome), together with the Jacobi relation and a rational expression of Θ_Λ in $\lambda = \theta_2^4/\theta_3^4$ used elsewhere (Chapter 38). Its log reads, in part:

```
Theta_Leech, nome q (coeffs q^0..q^8): [1, 0, 0, 0, 196560, 0, 16773120, 0, 398034000]
  expected 1, 0,0,0, 196560, 0, 16773120, 0, 398034000
Jacobi check 1-x = theta4^4/theta3^4: True
```

For this chapter the series were recomputed independently to order q^{11}; for instance

n	0	1	2	3	4	5
P	1	24	324	3200	25650	176256
B	1	−24	276	−2048	11202	−49152
Θ_Λ	1	0	196560	16773120	398034000	4629381120
T_{odd}	24	2624	105504	2471424	40674128	519045888
$\dim(V_\Lambda^+)_n$	1	0	98580	10745856	432155586	10122903552
$\dim(V_\Lambda^T)_n^+$	0	0	98304	10747904	432144384	10122952704
sum $= [q^n]qJ$	1	0	196884	21493760	864299970	20245856256
$[q^n]\Phi$	1	−48	197712	16761024	398104656	4629149280

These numbers are *evidence*, not proof; every identity used is proved in Lean.

33.5 The bridge from formal to analytic infinite products

33.5.1 The problem

Mathlib knows $\Delta(\tau) = q\prod'_{n\geq 0}(1-q^{n+1})^{24}$ as an identity of complex numbers, an infinite product of numbers. The library's $P = \prod(1-q^n)^{-24}$ is a formal infinite product. To use Mathlib's identity for formal series we must know: *if $F \in \mathbb{C}[[X]]$ is the formal product $\prod_i u_i$, then for $|q|<1$ the series $\sum_n([X^n]F)q^n$ converges, and its sum is* $\lim_N \prod_{i<N} u_i(q)$. This is not automatic: a coefficient of F is a finite sum, but evaluating means summing infinitely many such coefficients, and the interchange of "take the limit of the partial products" and "evaluate at q" needs a domination argument — this is Tannery's theorem (dominated convergence for series).

33.5.2 Evaluation and domination

Definition 33.30 (Evaluation; domination; nonnegativity)**.** For $f \in \mathbb{C}[[X]]$ and $q \in \mathbb{C}$ let $\mathrm{ev}(f,q) = \sum_n([X^n]f)q^n$ (meaningful when the series converges); similarly $\mathrm{ev}_{\mathbb{R}}(g,r)$ for $g \in \mathbb{R}[[X]]$, $r \in \mathbb{R}$. A real series g is *nonnegative* if all its coefficients are ≥ 0, and it *dominates* f if $|[X^n]f| \leq [X^n]g$ for all n. *g is summable at r* if $\sum_n([X^n]g)r^n$ converges.

```
noncomputable def ev (f : ℂ⟦X⟧) (q : ℂ) : ℂ := ∑' n, coeff n f * q ^ n
noncomputable def evR (g : ℝ⟦X⟧) (r : ℝ) : ℝ := ∑' n, coeff n g * r ^ n
def Nonneg (g : ℝ⟦X⟧) : Prop := ∀ n, 0 ≤ coeff n g
def Dom (f : ℂ⟦X⟧) (g : ℝ⟦X⟧) : Prop := ∀ n, ‖coeff n f‖ ≤ coeff n g
def SumAt (g : ℝ⟦X⟧) (r : ℝ) : Prop := Summable fun n => coeff n g * r ^ n
```

(`VOA/Moonshine/CharacterBridge.lean`, namespace `VOA.QBridge`.)

From the mathematics to the Lean statement

`∑'` is Mathlib's unconditional sum (`tsum`); it returns 0 when the family is not summable, which is why every use of `ev` below is paired with an explicit summability statement. $\|\cdot\|$ is the absolute value on $\mathbb{C}$. `Summable` is unconditional (here equivalently absolute) convergence.

Physical meaning

Evaluation $\mathrm{ev}(f,q)=\sum_n f_n q^n$ turns the formal partition function (a degeneracy sequence) into an honest function of the torus modulus τ with $q=e^{2\pi i\tau}$, $|q|<1$ (convergence at positive imaginary part, i.e. finite inverse temperature). Domination by a nonnegative series is the statement that degeneracies are positive, so convergence is controlled by the physical, positive partition function.

Theorem 33.31 (The bridge). *Let $u_i \in \mathbb{C}[[X]]$, $v_i \in \mathbb{R}[[X]]$ ($i \in \mathbb{N}$), $r \geq 0$, $C \in \mathbb{R}$, and assume: (1) v_i dominates u_i; (2) each v_i is nonnegative; (3) $[X^0]v_i \geq 1$; (4) $u_i \equiv 1$ and $v_i \equiv 1 \bmod X^{i+1}$; (5) each v_i is summable at r; (6) $\prod_{i<N} \mathrm{ev}_{\mathbb{R}}(v_i,r) \leq C$ for all N. Let $F \in \mathbb{C}[[X]]$ satisfy $[X^n]F = [X^n]\prod_{i<n} u_i$ for all n (the stabilised coefficients of $\prod u_i$). Then for every $q \in \mathbb{C}$ with $|q| \leq r$, the series $\sum_n([X^n]F)q^n$ converges absolutely, and $\prod_{i<N}\mathrm{ev}(u_i,q) \to \mathrm{ev}(F,q)$ as $N \to \infty$.*

```
theorem bridge (u : ℕ → ℂ⟦X⟧) (v : ℕ → ℝ⟦X⟧) {r C : ℝ} (hr : 0 ≤ r)
    (hdom : ∀ i, Dom (u i) (v i)) (hnn : ∀ i, Nonneg (v i)) (h1 : ∀ i, 1 ≤ coeff 0 (v i))
    (hu : ∀ i, X ^ (i + 1) ∣ u i - 1) (hv : ∀ i, X ^ (i + 1) ∣ v i - 1)
    (hs : ∀ i, SumAt (v i) r) (hC : ∀ N, ∏ i ∈ range N, evR (v i) r ≤ C)
    (F : ℂ⟦X⟧) (hF : ∀ n, coeff n F = coeff n (∏ i ∈ range n, u i)) {q : ℂ} (hq : ‖q‖ ≤ r)
    ↪ :
    (Summable fun n => ‖coeff n F * q ^ n‖)
      ∧ Tendsto (fun N => ∏ i ∈ range N, ev (u i) q) atTop (𝓝 (ev F q))
```

From the mathematics to the Lean statement

Hypotheses, in order: `hr` is $r \geq 0$; `hdom`, `hnn`, `h1` are (1)–(3); `hu`, `hv` are (4), written as divisibility $X^{i+1} \mid u_i - 1$; `hs` is (5); `hC` is (6), `range N` $= \{0,\dots,N-1\}$; `hF` says F has the stabilised coefficients (for F a genuine `HasProd` limit this holds automatically, `coeff_of_hasProd`); `hq` is $|q| \leq r$. The conclusion is a conjunction: absolute summability, and `Tendsto … atTop (𝓝 …)`, i.e. convergence of the sequence of finite products to $\mathrm{ev}(F,q)$. This is a general analytic lemma with no VOA content; all hypotheses are genuine and are verified in the two applications below.

Physical meaning

The bridge says that the thermal partition function of a free system (an infinite product over oscillator modes) equals the generating function of its degeneracies at every temperature $|q|<1$: the formal state-counting and the analytic torus partition function agree. This is the technical justification for treating $\prod(1-q^n)^{-24}$ both as a count of oscillator states and as $q/\Delta(\tau)$. It is a general analytic lemma without further physics.

Proof. By (4), multiplying by u_i with $i \geq n$ does not change coefficients below X^{n+1}, so the coefficients of $G_N = \prod_{i<N} u_i$ stabilise: $[X^n]G_N = [X^n]F$ for $N \geq n$. By (1)–(3), $|[X^n]G_N| \leq [X^n]\prod_{i<N} v_i \leq [X^n]V_n$ where $V_n = \prod_{i<n} v_i$ (coefficients of products of nonnegative series with constant terms ≥ 1 increase with more factors, and stabilise by (4)). The majorant $\sum_n([X^n]V_n)r^n$ converges: its partial sum up to M is at most $\mathrm{ev}_{\mathbb{R}}(V_M,r) = \prod_{i<M}\mathrm{ev}_{\mathbb{R}}(v_i,r) \leq C$. Hence for $|q| \leq r$ the terms $([X^n]G_N)q^n$ are dominated, uniformly in N, by a summable sequence, and converge termwise (they are eventually constant) to $([X^n]F)q^n$. Tannery's theorem gives $\mathrm{ev}(G_N,q) \to \mathrm{ev}(F,q)$, and

$\mathrm{ev}(G_N, q) = \prod_{i<N} \mathrm{ev}(u_i, q)$ because evaluation of absolutely convergent series is multiplicative (Cauchy product).

Corollary 33.32 (The two shapes used). *Let $e : \mathbb{N} \to \mathbb{N}$ with $e(i) \geq i+1$, $m \in \mathbb{N}$, and $|q| < 1$. If F has the stabilised coefficients of $\prod_i (1 - X^{e(i)})^m$, then $\sum([X^n]F)q^n$ converges absolutely and $\prod_{i<N}(1-q^{e(i)})^m \to \mathrm{ev}(F, q)$. The same holds for $\prod_i (1 - X^{e(i)})^{-m}$, with factors written as geometric series.*

File `VOA/Moonshine/CharacterBridge.lean`.

```
theorem tendsto_ev_one_sub_pow {e : ℕ → ℕ} (he : ∀ i, i + 1 ≤ e i) (m : ℕ) {F : ℂ⟦X⟧}
    (hF : ∀ n, coeff n F = coeff n (∏ i ∈ range n, ((1 : ℂ⟦X⟧) - X ^ e i) ^ m))
    {q : ℂ} (hq : ‖q‖ < 1) :
    (Summable fun n => ‖coeff n F * q ^ n‖)
      ∧ Tendsto (fun N => ∏ i ∈ range N, (1 - q ^ e i) ^ m) atTop (𝓝 (ev F q))

theorem tendsto_ev_geom_pow {e : ℕ → ℕ} (he : ∀ i, i + 1 ≤ e i) (m : ℕ) {F : ℂ⟦X⟧}
    (hF : ∀ n, coeff n F = coeff n (∏ i ∈ range n, (geom ℂ (e i)) ^ m))
    {q : ℂ} (hq : ‖q‖ < 1) :
    (Summable fun n => ‖coeff n F * q ^ n‖)
      ∧ Tendsto (fun N => ∏ i ∈ range N, ((1 - q ^ e i)⁻¹) ^ m) atTop (𝓝 (ev F q))
```

From the mathematics to the Lean statement

`geom ℂ k` is the series $\sum_j X^{kj} = (1-X^k)^{-1}$ (defined in the same file as `PowerSeries.mk fun n ⇒ if k ∣ n then 1 else 0`). Hypotheses: `he` ($e(i) \geq i+1$, so that (4) holds), `hF`, and `hq` ($|q| < 1$, strict). Same as the corollary.

Physical meaning

The two shapes are the Bose partition function $\prod(1-q^{e(i)})^{-m}$ of m free bosons with modes $e(i)$ and the fermionic-type product $\prod(1-q^{e(i)})^m$, whose evaluation equals the oscillator trace (e.g. q/Δ and Δ/q). They are the ingredients used to evaluate P, B and the twisted product at an actual torus.

Proof. Apply Theorem 33.31 with $r = |q|$ and majorants $v_i = (1+X^{e(i)})^m$, resp. $(\sum_j X^{e(i)j})^m$ over $\mathbb{R}$. The uniform bound (6) is $\prod_i (1+r^{e(i)})^m \leq \exp(m\sum_i r^{e(i)}) \leq \exp(m/(1-r))$, resp. $\prod_i (1-r^{e(i)})^{-m} \leq \exp(m/(1-r)^2)$, using $1+x \leq e^x$ and $\sum_i r^{e(i)} \leq \sum_i r^i = 1/(1-r)$.

What the machine verified

Unconditional; `#print axioms VOA.QBridge.bridge` gives the standard three (re-run for this chapter).

33.6 Jacobi's product and the Leech theta series

33.6.1 q-expansions of E_4, E_6, Δ

Proposition 33.33. *The q-expansions of Mathlib's analytic E_4, E_6 and Δ are the formal* `E4Series`, `E6Series` *and* `deltaSeries`.

```
theorem qExpansion_E₄ : qExpansion 1 (E₄ : ℍ → ℂ) = E4Series

theorem qExpansion_E₆ : qExpansion 1 (E₆ : ℍ → ℂ) = E6Series
```

```
theorem qExpansion_discriminant :
    qExpansion 1 (ModularForm.discriminant : ℍ → ℂ) = deltaSeries
```

(`VOA/Moonshine/CharacterDelta.lean`, namespace `VOA.Moonshine`.)

From the mathematics to the Lean statement

(`E₄ : ℍ → ℂ`) is Mathlib's bundled modular form viewed as a function; `qExpansion 1` is its q-expansion (Section 33.1). `ModularForm.discriminant` is Mathlib's $\Delta = \eta^{24}$ (Remark 33.4). No hypotheses. These are exactly the statements "the formal series of Section 33.2 deserve their names".

Physical meaning

Modular forms E_4, E_6, Δ are the analytic torus-level objects whose q-expansions are the state-counting series of the chapter; this proposition identifies the formal degeneracy generating functions with the analytic functions, so that modular transformation properties (the S transformation, space-time swap) can be applied to them. It is a mathematical identification, not a physical one.

Proof. For E_4, E_6: Mathlib's coefficient formula with $B_4 = -1/30$, $B_6 = 1/42$ gives $240\sigma_3(m)$, $-504\sigma_5(m)$. For Δ: Mathlib's $\Delta = (E_4^3 - E_6^2)/1728$ as functions, and q-expansion is a ring homomorphism on modular forms.

33.6.2 Jacobi's product for the formal Δ

Definition 33.34. $D = \prod_{n\geq 1}(1-q^n)^{24} \in \mathbb{C}[[q]]$.

```
noncomputable def deltaProd : PowerSeries ℂ := (∏' i : ℕ, ((1 : PowerSeries ℂ) - X ^ (i +
↪  1))) ^ 24
```

From the mathematics to the Lean statement

`∏'` is the infinite product in $\mathbb{C}[[q]]$ with the coefficientwise topology (it exists: Mathlib's `multipliable_one_sub_X_pow`); the factors are $1 - q^{i+1}$, $i \geq 0$.

Physical meaning

$D = \prod(1-q^n)^{24}$ is the inverse of the partition function of 24 free chiral bosons with the vacuum energy stripped off, equivalently $\Delta/q = \eta^{24}/q$: the contribution of oscillator modes alone, with the factor q^{-1} (Casimir energy $-24/24$) omitted.

Theorem 33.35 (Jacobi's product, formally). *$\Delta = q\,D$ in $\mathbb{C}[[q]]$, for the formal $\Delta = (E_4^3 - E_6^2)/1728$; equivalently $\Delta/q = D$, and (A): $(\Delta/q)\cdot\prod(1-q^n)^{-24} = 1$.*

```
theorem deltaSeries_eq_X_mul_deltaProd : deltaSeries = X * deltaProd

theorem deltaOverQ_eq_deltaProd : deltaOverQ = deltaProd

theorem deltaProductIdentity : DeltaProductIdentity
```

From the mathematics to the Lean statement

`DeltaProductIdentity` is (A) of Definition 33.27. No hypotheses: these are unconditional identities of formal power series.

Physical meaning

This is the modular-invariance-adjacent statement that the Eisenstein expression for Δ is exactly η^{24}, i.e. the character of 24 free bosons is the weight-12 cusp form $1/\Delta$ with a simple pole q^{-1} at the cusp. Physically, the Casimir energy $-c/24 = -1$ of 24 bosons is the origin of the q^{-1}, and its appearance as the leading term of J is the vacuum of $V^\natural$ with $c = 24$.

Proof. Fix $\tau \in \mathfrak{H}$, $q = e^{2\pi i\tau}$, $|q| < 1$. By Corollary 33.32, $\sum_n([q^n]D)q^n$ converges absolutely to $\prod'(1-q^{n+1})^{24}$, so $\sum_n([q^n](qD))q^n = q\prod'(1-q^{n+1})^{24}$, which is Mathlib's $\Delta(\tau)$. By uniqueness of q-expansions (Proposition 33.2) the coefficients of qD are those of the q-expansion of Δ, which is `deltaSeries` by Proposition 33.33. Cancelling q gives $\Delta/q = D$, and $D\cdot P = \prod(1-q^n)^{24}(1-q^n)^{-24} = 1$ (product of convergent formal products).

33.6.3 Weight twelve and the Leech theta series

Theorem 33.36 (Weight-12 forms are determined by two coefficients). *For every $f \in M_{12}$ with q-expansion $\sum a_n q^n$: $\sum a_n q^n = a_0 E_4^3 + \frac{a_1 - 720a_0}{1728}(E_4^3 - E_6^2)$ in $\mathbb{C}[[q]]$.*

```
theorem qExpansion_weight_twelve (f : ModularForm 𝒮ℒ ((12 : ℕ) : ℤ)) :
    qExpansion 1 (f : ℍ → ℂ)
      = (qExpansion 1 (f : ℍ → ℂ)).coeff 0 • E4Series ^ 3
        + (((qExpansion 1 (f : ℍ → ℂ)).coeff 1 - 720 * (qExpansion 1 (f : ℍ → ℂ)).coeff 0)
         ↪ / 1728)
          • (E4Series ^ 3 - E6Series ^ 2)
```

From the mathematics to the Lean statement

The weight is written `((12 : ℕ) : ℤ)` (a natural number cast to an integer) because the spanning theorem it uses is stated for natural weights; it is the integer 12. `.coeff 0`, `.coeff 1` are a_0, a_1. The only hypothesis is that f is a level-one modular form of weight 12. This is (33.4), as an identity of formal series.

Physical meaning

A holomorphic weight-12 partition-function numerator is fixed by two numbers, the coefficient of q^0 (the vacuum) and of q^1 (the first excited level). This rigidity is what lets a CFT-type computation (counting the vacuum and the weight-one states) pin down the entire spectrum once modularity is known; in the library it is applied to the theta series of Leech and to Φ.

Proof. M_{12} is spanned by E_4^3 and E_6^2 (Theorem 33.3, library `span_eisBasisFun`); both sides are linear in f, so it suffices to check the two basis elements, which is the computation of $[q^0]$ and $[q^1]$ of E_4^3 and E_6^2.

Theorem 33.37 (The Leech theta identity). *(B): $\Theta_\Lambda = E_4^3 - 720\Delta$ in $\mathbb{C}[[q]]$.*

```
theorem leechThetaIdentity : LeechThetaIdentity
```

From the mathematics to the Lean statement

`LeechThetaIdentity` is (B) of Definition 33.27, with Θ_Λ the formal series `leechThetaSeries` of norm counts (Definition 33.25), E_4 and Δ the formal series of Section 33.2. No hypotheses.

Physical meaning

The theta series is the sum over lattice momenta $\sum_{\alpha\in\Lambda} q^{\alpha^2/2}$ of the chiral boson on the Leech torus. The fact that it is the weight-12 form $E_4^3 - 720\Delta$ encodes the absence of norm-2 vectors in Λ: no roots, so no extra currents beyond the 24 Cartan ones. The number 196560 is the number of minimal vectors (the weight-2 states of momentum $\alpha^2 = 4$).

Proof. Θ_Λ is the q-expansion of the weight-12 modular form `thetaModularForm` of Λ (Section 33.1.7). Apply Theorem 33.36 with $a_0 = r_\Lambda(0) = 1$, $a_1 = r_\Lambda(2) = 0$: the result is $E_4^3 - \frac{720}{1728}(E_4^3 - E_6^2) = E_4^3 - 720\Delta$.

Corollary 33.38 (The characters of Δ^{-1} and of V_Λ). *$qj = E_4^3 P$ and $\Theta_\Lambda P = qj - 720q$; that is, $\sum_n \dim(V_\Lambda)_n q^{n-1} = j - 720$.*

File `VOA/Moonshine/CharacterDelta.lean`.

```
theorem jShift_eq : jShift = E4Series ^ 3 * LatGen.fockGenFun 24

theorem leechTheta_mul_fock :
    leechThetaSeries * LatGen.fockGenFun 24 = jShift - (720 : ℂ) • X

theorem sectorSeries_eq_JShift_of_levelTwo (hL : LevelTwoIdentity) : sectorSeries = JShift
```

From the mathematics to the Lean statement

The first two are unconditional (Theorem 33.28 with (A), (B) now proved); combined with (33.14), the second is the character formula of V_Λ. The third is conditional on (C) only; (C) is proved in the next section.

Physical meaning

These say that the character of the Leech lattice VOA is $j - 720 = J + 24$: the vacuum, then the 24 currents $h_a(-1)\mathbf{1}$ at weight one (the 24 counted as $744 - 720$), and so on. In physical terms V_Λ is a holomorphic $c = 24$ theory (the lattice CFT) with 24 currents, and the Monster CFT is its $\mathbb{Z}/2$ orbifold, which removes them.

What the machine verified

`deltaProductIdentity`, `leechThetaIdentity`, `qExpansion_discriminant`: unconditional, `#print axioms` the standard three (re-run). The input `IntegralLattice.thetaModularForm` (Chapter 30) is itself an unconditional theorem of the vendored lattice library.

33.7 The level-two identity

This section proves (C), $B + 2^{13}q^2 T_{\text{odd}} = qj - 768q$, by realising its left side, divided by q, as the trace (33.10) of the $\Gamma_0(2)$-Hauptmodul t, i.e. as Φ/Δ with Φ a level-one modular form of weight 12. All declarations are in `VOA/Moonshine/CharacterLevelTwo.lean`, namespace `VOA.Moonshine`; in that file `Δ` is local notation for Mathlib's `ModularForm.discriminant` and `P24` for `LatGen.fockGenFun 24`.

33.7.1 The modular form Φ

Definition 33.39 (Affine maps of $\mathfrak{H}$ and Φ). For real $a > 0$ and b, let $\tau \mapsto a\tau + b$ act on $\mathfrak{H}$. Put

$$\Phi(\tau) = \Delta(\tau)^2\Big(\Delta(2\tau)^{-1} + 4096\,\Delta(\tau/2)^{-1} + 4096\,\Delta\big(\tfrac{\tau+1}{2}\big)^{-1}\Big).$$

```
noncomputable def affH (a b : ℝ) (ha : 0 < a) (z : ℍ) : ℍ :=
  ⟨(a : ℂ) * z + b, by simpa using mul_pos ha z.im_pos⟩

noncomputable abbrev dblH : ℍ → ℍ := affH 2 0 two_pos

noncomputable def phiForm : ModularForm 𝒮ℒ 12 where
```

From the mathematics to the Lean statement

`⟨w, proof⟩` builds a point of $\mathbb{H}$ from a complex number $w = az + b$ and a proof that $\operatorname{Im} w > 0$ (the proof term is shown because it is part of the definition; it carries no mathematical content). `dblH`, `hlfH`, `hlf1H` are $\tau \mapsto 2\tau$, $\tau/2$, $(\tau+1)/2$; $4096 = 2^{12}$. `(Δ w)⁻¹` is the complex inverse, legitimate because Δ has no zeros on $\mathfrak{H}$. `phiForm` is a *structure*: its first line, shown, says it is a modular form of weight 12 for the full modular group; its body supplies `toFun :=` `phiFun` and the three proofs (i)–(iii) of Definition 33.1. Because it is a term of type `ModularForm` $\mathcal{SL}$ `12`, Lean has checked those three proofs: this *is* the theorem "$\Phi \in M_{12}$". A definition of this kind cannot be vacuous: the type `ModularForm` $\mathcal{SL}$ `12` is inhabited only by genuine modular forms.

Physical meaning

Φ is the sum over the three $\Gamma_0(2)$-images of a single twisted-sector term: $\Delta(2\tau)^{-1}$ is the term of the θ-trace sector, while $\Delta(\tau/2)^{-1}$ and $\Delta((\tau+1)/2)^{-1}$ are the two twisted blocks obtained by $\tau \mapsto \tau/2$ and $\tau \mapsto (\tau+1)/2$. The factor $4096 = 2^{12}$ is the degeneracy of the twisted ground states. The sum is the orbifold sum over twisted boundary conditions around the two torus cycles, which is why it becomes modular for the full group.

Theorem 33.40. *Φ is a level-one modular form of weight 12.*

Physical meaning

Modularity of Φ is the statement that the sum over the three non-trivial twisted sectors is invariant: S and T permute the three terms, so the total is invariant, exactly as the orbifold partition function is. Invariance of the full sum under $\mathrm{SL}_2(\mathbb{Z})$ while the individual terms are only $\Gamma_0(2)$-invariant is the standard consistency requirement of an orbifold (modular invariance of the twisted sectors).

Proof. *T-invariance.* Δ is 1-periodic, so $\Delta(\tau+1) = \Delta(\tau)$ and $\Delta(2\tau+2) = \Delta(2\tau)$; and $\frac{(\tau+1)}{2}$ and $\frac{(\tau+1)+1}{2} = \frac{\tau}{2} + 1$ show that $\tau \mapsto \tau + 1$ swaps the last two terms. *S-covariance.* With $\Delta(-1/w) = w^{12}\Delta(w)$: $\Delta(-1/\tau) = \tau^{12}\Delta(\tau)$; $\Delta(-2/\tau) = \Delta(-1/(\tau/2)) = (\tau/2)^{12}\Delta(\tau/2)$; $\Delta(-1/(2\tau)) = (2\tau)^{12}\Delta(2\tau)$; and for the third term $\frac{-1/\tau+1}{2} = \frac{\tau-1}{2\tau} = \gamma \cdot \frac{\tau+1}{2}$ with $\gamma = \left(\begin{smallmatrix} 1 & -1 \\ 2 & -1 \end{smallmatrix}\right) \in \mathrm{SL}_2(\mathbb{Z})$, whose automorphy factor at $\frac{\tau+1}{2}$ is $2 \cdot \frac{\tau+1}{2} - 1 = \tau$. Substituting, the three terms are permuted and an overall factor $\tau^{24}/\tau^{12} = \tau^{12}$ appears: $\Phi(-1/\tau) = \tau^{12}\Phi(\tau)$. By the generation of $\mathrm{SL}_2(\mathbb{Z})$ by S, T, Φ is invariant of weight 12. *Holomorphy*: Δ is holomorphic and nowhere zero. *Boundedness at $i\infty$*: $|\Delta(\tau)|$ is bounded above and below by constant multiples of $e^{-2\pi \operatorname{Im}\tau}$ as $\operatorname{Im}\tau \to \infty$ (Mathlib: `exp_isBigO_discriminant` and the cusp-form decay), so $|\Delta(\tau)^2/\Delta(a\tau+b)| = O(e^{-2\pi(2-a)\operatorname{Im}\tau})$, bounded for $a \le 2$; all three terms have $a \in \{2, \frac{1}{2}\}$.

33.7.2 The formal q-expansion of Φ

Write $x = q^{1/2}$ and $D(q) = \prod(1-q^n)^{24}$, so $\Delta(\tau) = qD(q)$ and $P = D^{-1}$. Then $\Delta(2\tau) = q^2 D(q^2)$, $\Delta(\tau/2) = xD(x)$ and, since $e^{2\pi i(\tau+1)/2} = -x$, $\Delta((\tau+1)/2) = -xD(-x)$. Substituting,

$$\Phi = D(q)^2 P(q^2) + 2^{12}\, G(x), \qquad G(x) = x^3 D(x^2)^2 \big(P(x) - P(-x)\big). \tag{33.16}$$

G is an *even* function of x, hence a series $H(q)$ in $q = x^2$.

Definition 33.41 (G, H, and the formal Φ)**.** With $\mathrm{expand}(f)(q) = f(q^2)$ and $\mathrm{rescale}_{-1}(f)(x) = f(-x)$: $G = X^3\,\mathrm{expand}(D)^2(P - \mathrm{rescale}_{-1} P)$, $[q^n]H = [x^{2n}]G$, and $\Phi_{\mathrm{formal}} = D^2\,\mathrm{expand}(P) + 4096\,H$.

File `VOA/Moonshine/CharacterLevelTwo.lean`.

```
noncomputable def Gser : PowerSeries ℂ := X ^ 3 * (expandTwo deltaProd) ^ 2 * (P24 -
↪  rescaleNeg P24)

noncomputable def phiSeries : PowerSeries ℂ := deltaProd ^ 2 * expandTwo P24 + (4096 : ℂ) •
↪  Hser
```

From the mathematics to the Lean statement

`expandTwo` is Mathlib's `PowerSeries.expand 2`, $f(X) \mapsto f(X^2)$; `rescaleNeg` is `PowerSeries.rescale (-1)`, $f(X) \mapsto f(-X)$ (both abbreviations in the same file). `deltaProd` is D (Section 33.6), `P24` is P. In `Gser` the variable is x; `Hser` keeps its even coefficients, i.e. it is G rewritten in $q = x^2$ (the odd coefficients of G vanish, `coeff_Gser_odd`, so nothing is lost). Literal transcription of (33.16).

Physical meaning

G and H are the odd part of the twisted-sector oscillator function in $x = q^{1/2}$: $P(x) - P(-x)$ projects onto odd powers, the θ_{tw}-projection onto states of integral energy, and the factor x^3 is the shift from 3/2 to the integral weights. Φ_{formal} is then the series expansion of the orbifold-block sum.

Theorem 33.42 (Φ evaluates to its formal series)**.** *For every $\tau \in \mathfrak{H}$, $\sum_n ([q^n]\Phi_{\mathrm{formal}})q^n$ converges absolutely to $\Phi(\tau)$; hence the q-expansion of Φ is Φ_{formal}.*

File `VOA/Moonshine/CharacterLevelTwo.lean`.

```
theorem phiFun_eq_ev (z : ℍ) : AbsSumAt phiSeries (𝕢 1 (z : ℂ)) ∧ phiFun z = ev phiSeries
↪  (𝕢 1 (z : ℂ))

theorem qExpansion_phiForm : qExpansion 1 (phiForm : ℍ → ℂ) = phiSeries
```

From the mathematics to the Lean statement

`AbsSumAt f x` means $\sum_n |[X^n]f \cdot x^n| < \infty$ (defined in the same file as `Summable fun n ⇒ ‖coeff n f * x ^ n‖`); `ev` is evaluation (Definition 33.30); `𝕢 1 (z : ℂ)` is $q = e^{2\pi i z}$. No hypotheses beyond $z \in \mathfrak{H}$.

Physical meaning

The theorem says that the formal state-counting series of the orbifold block sum, evaluated at $q = e^{2\pi i\tau}$, is the analytic function $\Phi(\tau)$; i.e. the thermal torus partition function of the orbifold

blocks equals its degeneracy generating function. This lets the modular properties of Φ be used on the formal series.

Proof. Every ingredient of Φ_{formal} is a product, sum, substitution $q \mapsto q^2$ or $x \mapsto -x$ of D and P, each of which evaluates, at any point of the open unit disc, to the corresponding analytic product (Corollary 33.32); evaluation of absolutely convergent series respects these operations. Evaluating at $q = e^{2\pi i\tau}$ and $x = e^{\pi i\tau}$ and using $\Delta(w) = q_w\, D(q_w)$ (Mathlib's product formula) and $D \cdot P = 1$ turns (33.16) into the definition of $\Phi(\tau)$. The second statement follows by uniqueness of q-expansions.

Proposition 33.43 (Two coefficients of Φ). *$[q^0]\Phi_{\text{formal}} = 1$ and $[q^1]\Phi_{\text{formal}} = -48$.*

File `VOA/Moonshine/CharacterLevelTwo.lean`.

```
theorem phiSeries_coeff_zero_one : coeff 0 phiSeries = 1 ∧ coeff 1 phiSeries = -48
```

Physical meaning

The coefficient 1 is the single vacuum; $-48 = -2 \cdot 24$ comes from $D^2 = \prod(1-q^n)^{48}$, whose linear term is the first oscillator level of the doubled set of bosons. It is the input that fixes Φ in the weight-12 space.

Proof. $D = 1-24q+\cdots$, so $D^2 = 1-48q+\cdots$; $P(q^2) = 1+O(q^2)$; and $G = x^3\cdot(1+\cdots)\cdot(P(x)-P(-x)) = x^3 \cdot 48x + \cdots = O(x^4)$, so $H = O(q^2)$.

Theorem 33.44 ($\Phi = E_4^3 - 768\Delta$). *$\Phi_{\text{formal}} = E_4^3 - 768\Delta$ in $\mathbb{C}[[q]]$.*

File `VOA/Moonshine/CharacterLevelTwo.lean`.

```
theorem phiSeries_eq : phiSeries = E4Series ^ 3 - (768 : ℂ) • deltaSeries
```

Physical meaning

$\Phi = E_4^3 - 768\Delta$ is the modular completion of the sum over twisted sectors: the constant 768 together with the Leech constant 720 averages to 744. In CFT language, the three non-trivial blocks Z_{+-}, Z_{-+}, Z_{--} add up (after the factor q) to $j - 768$, the constant being fixed by the first two coefficients of Φ.

Proof. Theorem 33.36 applied to Φ (Theorem 33.40, with q-expansion Φ_{formal} by Theorem 33.42) with $a_0 = 1$, $a_1 = -48$: $\Phi = E_4^3 + \frac{-48-720}{1728} \cdot 1728\,\Delta = E_4^3 - 768\Delta$.

33.7.3 From Φ to the level-two identity

Proposition 33.45 (The formal side). *$\Phi_{\text{formal}} \cdot P = B + 2^{13} q^2 T_{\text{odd}}$.*

File `VOA/Moonshine/CharacterLevelTwo.lean`.

```
theorem phiSeries_mul_fock :
    phiSeries * P24 = LatGen.fockSignedGenFun 24 + (8192 : ℂ) • (X ^ 2 * twOddSeries)
```

Physical meaning

The identity $\Phi_{\text{formal}} P = B + 2^{13} q^2 T_{\text{odd}}$ rewrites the three-term orbifold sum in terms of the physical blocks: the untwisted θ-trace B and twice the (integral part of the) twisted-sector contribution with 2^{12} ground states, the factor 2 coming from adding the two twisted blocks Z_{-+} and Z_{--}. The step uses Euler's identity (odd modes times even modes gives all modes), i.e. that antiperiodic bosons are periodic bosons with the even modes removed.

Proof (formal product identities). First term: $D^2P(q^2)\cdot P = D\,P(q^2) = \prod(1-q^n)^{24}/(1-q^{2n})^{24} = \prod(1+q^n)^{-24} = B$, using $1-q^{2n} = (1-q^n)(1+q^n)$. Second term: in the variable x, $G(x)P(x^2) = x^3D(x^2)\big(P(x)-P(-x)\big)$, and *Euler's odd/even splitting* $\prod_n(1-x^n)^{-1} = \prod_i(1-x^{2i+1})^{-1}\prod_n(1-x^{2n})^{-1}$ gives $D(x^2)P(x) = \prod_i(1-x^{2i+1})^{-24}$, the twisted generating function of Theorem 33.18. Hence $G(x)P(x^2) = x^3\big(\mathrm{tw}(x)-\mathrm{tw}(-x)\big) = 2x^3\sum_n P_T(24,2n+1)x^{2n+1} = 2x^4T_{\mathrm{odd}}(x^2)$, i.e. $HP = 2q^2T_{\mathrm{odd}}$, and $4096\cdot 2 = 8192$.

Physical reading. The identity $D(x^2)P(x) = \prod(1-x^{2i+1})^{-24}$ says that the twisted sector's oscillator partition function is the untwisted one with the even modes removed; taking the odd part in x (the role of $P(x)-P(-x)$) is exactly the θ_{tw}-projection onto odd doubled weight of Proposition 33.20.

Theorem 33.46 (The level-two identity). *(C):* $B+2^{13}q^2T_{\mathrm{odd}} = qj-768q$. *Equivalently* $t(\tau)+t(-1/\tau)+t(-1/(\tau+1)) = j(\tau)-768$.

File `VOA/Moonshine/CharacterLevelTwo.lean`.

```
theorem levelTwoIdentity_of_phiSeries (h : phiSeries = E4Series ^ 3 - (768 : ℂ) •
 ↪  deltaSeries) :
    LevelTwoIdentity

theorem levelTwoIdentity : LevelTwoIdentity
```

From the mathematics to the Lean statement

The first is conditional on Theorem 33.44; the second discharges it (`levelTwoIdentity_of_phiSeries phiSeries_eq`) and has no hypotheses. `LevelTwoIdentity` is (C) of Definition 33.27.

Physical meaning

This is modular invariance of the orbifold at work: the trace of the Hauptmodul t of $\Gamma_0(2)$ over the three cosets gives the $\mathrm{SL}_2(\mathbb{Z})$-invariant $j-768$. Physically, the three twisted blocks Z_{+-}, Z_{-+}, Z_{--} are images of one another under S and T, and their sum is a genuine modular function with a simple pole, hence j plus a constant. It is the identity that makes the twisted sector (with its 2^{12}-fold degenerate ground state) fit into a modular-invariant partition function.

Proof. By Proposition 33.45 and Theorem 33.44, $B+2^{13}q^2T_{\mathrm{odd}} = (E_4^3-768\Delta)P = E_4^3P-768\,q\,(\Delta/q)P = qj-768q$ by Corollary 33.38 and (A).

What the machine verified

`phiForm`, `phiSeries_eq`, `levelTwoIdentity`: unconditional; `#print axioms` the standard three (re-run for this chapter).

33.8 The main theorem: the graded dimension is J

Theorem 33.47 ($\chi = qJ$). *In* $\mathbb{C}[[q]]$,

$$\sum_{n\ge 0}\Big(\dim(V_\Lambda^+)_n + \dim(V_\Lambda^T)_n^+\Big)q^n = q\,J(q),$$

equivalently, for every $n\in\mathbb{N}$, $\dim(V_\Lambda^+)_n + \dim(V_\Lambda^T)_n^+ = [q^n]\,qJ$.

```
theorem sectorSeries_eq_JShift : sectorSeries = JShift :=
  sectorSeries_eq_JShift_of_levelTwo levelTwoIdentity

theorem finrank_sectors_eq_coeff_JShift (n : ℕ) :
    ((finrank ℂ (leechVOAPlus.grading (n : ℤ))
      + finrank ℂ (twFixed 24 leechT ⊓ twWeight 24 leechT ((n : ℤ) : ℚ) :
          Submodule ℂ leechTwistedSpace) : ℕ) : ℂ)
      = coeff n JShift
```

(`VOA/Moonshine/Character.lean`, namespace `VOA.Moonshine`; the one-line proof term of the first is shown because it is informative: Corollary 33.38's conditional form applied to Theorem 33.46.)

Fidelity check for the main theorem

Symbols. `sectorSeries` is χ (Definition 33.25); `JShift` is qJ (Definition 33.12); `coeff n` is $[q^n]$; the outer cast `(… : ℕ) : ℂ` turns the natural-number sum of dimensions into a complex number, which loses nothing ($\mathbb{N} \to \mathbb{C}$ is injective). *Hypotheses.* None; n ranges over all of $\mathbb{N}$. *Defined terms, traced.* $(V_\Lambda^+)_n$ = `leechVOAPlus.grading n` (Chapter 32); $(V_\Lambda^T)_n^+$ = `twFixed 24 leechT ⊓ twWeight 24 leechT n` (Definitions 33.16, 33.19), with T_Λ = `leechT` of dimension 4096 (Chapter 34); `JShift` built from `E4Series`, `deltaSeries`, `deltaOverQUnit` (Section 33.2), all bottoming out in divisor sums. *Same, stronger or weaker?* The same as the textbook statement $\sum_n(\dim(V_\Lambda^+)_n + \dim(V_\Lambda^T)_n^+)q^{n-1} = J$ (multiply by q), *for the two summands as defined here. How could it be vacuous or mis-aimed?* (1) If J were mis-defined: excluded, the coefficients of `JShift` are proved independently ($1, 0, 196884$ in `JFunction.lean`). (2) If the twisted grading or θ_{tw} were not FLM's: the grading here is *defined* by oscillator weight, not derived from a twisted module, and θ_{tw} is defined as $\theta_S \otimes (-1)$; that these are the structures of the twisted module actually constructed is proved later (Section 33.9). (3) Most importantly: *a graded dimension does not determine a VOA.* See the warning below.

Physical meaning

This is the central statement: $q\,Z_{V^\natural}(\tau) = q\,J(\tau)$, where $Z = \operatorname{tr} q^{L_0-1}$ (read analytically on paper; the Lean statement is an identity of formal q-series). The graded dimension of the Monster CFT is $J = j - 744 = q^{-1} + 0 + 196884\,q + \cdots$: the q^{-1} is the vacuum with Casimir energy $-c/24 = -1$, the absence of a constant term is $V_1^\natural = 0$ (no currents), and $196884 = 1 + 196883$ under the Monster (a fact, not proved here). Physically J is forced by modular invariance of a holomorphic $c = 24$ theory without currents, but the library does not use that argument: it computes both sides, as the orbifold sum of the untwisted θ-projected and twisted sectors. The modular-invariance heuristic is why the answer is j minus a constant; the proof is the computation.

Trap / dead end

The square-zero TRAP. The identity $\chi = J$ is a statement about dimensions only, and many objects have this graded dimension. The project recorded a concrete trap: the square-zero extension $V_\Lambda^+ \ltimes (V_\Lambda^T)^+$ (the VOA structure on $V_\Lambda^+ \oplus (V_\Lambda^T)^+$ in which the product of two twisted states is declared to be 0, i.e. the twisted–twisted intertwiner $\overline{W}$ is set to 0) *is* a vertex operator algebra with $c = 24$, $V_1 = 0$, $\dim V_2 = 196884$ and graded dimension J — but it is not simple, and it is not $V^\natural$. The final theorem `VOA.Moonshine.moonshine` (Chapter 42) therefore asserts, in addition to the graded dimension, that the vertex operator is the explicit block map of Chapter 38 on FLM's space, with the nonzero form-adjoint $\overline{W}$ (`leechWbar_ne_zero`), and that the VOA is simple; these pin the structure down to a unique witness. Theorem 33.47 is a necessary ingredient of that theorem, not a substitute for it.

Proof. Theorem 33.28 with (A), (B), (C) proved in Theorems 33.35, 33.37, 33.46. In summary:

$$\chi \overset{\text{Thm } 33.26}{=} \frac{1}{2}\Big(\underbrace{\Theta_\Lambda P}_{qj-720q} + \underbrace{B + 2^{13} q^2 T_{\text{odd}}}_{qj-768q} \Big) = qj - 744q = qJ.$$

Corollary 33.48 (Coefficient checks). $[q^2]\chi = [q^2]qJ = 196884$ *(the per-weight count and the formula for J agree);* $[q^3]qJ = 21493760$*;* $[q^1]qJ = 0$.

File `VOA/Moonshine/Character.lean`.

```
theorem coeff_two_consistency : coeff 2 sectorSeries = coeff 2 JShift

theorem coeff_three_JShift : coeff 3 JShift = 21493760

theorem coeff_one_JShift : coeff 1 JShift = 0
```

From the mathematics to the Lean statement

Mind the shift: `coeff 3 JShift` is the coefficient of q^2 in J, which is 21493760; the docstring in the source says "$[q^2]J$" and is right. These are proved *from* the main theorem and the per-weight dimensions of Theorem 33.23 (and $(V_\Lambda^+)_1 = 0$): a coefficient of J computed by counting states. `coeff_two_consistency` compares two independent computations, the Eisenstein arithmetic of Example 33.14 and the state count 98580 + 98304, and is a genuine cross-check of the definitions.

Physical meaning

These check the first few Monster CFT levels: weight 0 (the unique vacuum), weight 1 (no states, $V_1^\natural = 0$), weight 2 (196884 = 1 + 196883 under the Monster, a fact quoted from the literature), and weight 3 (21493760 = 1 + 196883 + 21296876, Thompson's observation). Weight 2 is the Griess algebra and weight 3 is the next Monster-module level; the counts here come from the sector decomposition, not from the Monster action.

Example 33.49 (Weight 4). Theorem 33.47 predicts $\dim V^\natural{}_4 = [q^4]qJ = 864299970$. From the table of Remark 33.29: $[q^4]\Theta_\Lambda P = [q^4](qj - 720q) = 864299970$ (the $-720q$ only affects q^1) and $[q^4]B = 11202$, so $\dim(V_\Lambda^+)_4 = \frac{1}{2}(864299970 + 11202) = 432155586$; and $\dim(V_\Lambda^T)_4^+ = 4096 \cdot P_T(24,5) = 4096 \cdot 105504 = 432144384$. The sum is 864299970, as predicted. Note that the two sectors are almost equal in size: $\dim(V_\Lambda^+)_n = \frac{1}{2}[q^n](qj - 720q + B)$ and, by (C), $\dim(V_\Lambda^T)_n^+ = 2^{12}[q^n]q^2 T_{\text{odd}} = \frac{1}{2}[q^n](qj - 768q - B)$, so for $n \geq 2$ the difference is $[q^n]B$ — here 11202, tiny compared with the dimensions.

What the machine verified

`sectorSeries_eq_JShift`, `finrank_sectors_eq_coeff_JShift`, `coeff_three_JShift`: unconditional, no hypotheses; `#print axioms` = `[propext, Classical.choice, Quot.sound]` (rerun for this chapter; Section 33.10). Honest scope: a statement about the sum of the graded dimensions of V_Λ^+ (a genuine VOA) and of $(S[\theta] \otimes T)^+$ with the grading and involution of Definition 33.19.

33.9 The carrier-level restatement

Later chapters replace the bare vector space $(S[\theta]\otimes T)^+$ by the V_Λ^+-module TP (`Moonshine.plusModule`) obtained from the twisted module of Chapter 36, and then form the carrier $V^\natural = V_\Lambda^+ \times TP$ with grading $V^\natural{}_n = (V_\Lambda^+)_n \times TP_n$ (Chapter 38). The main theorem transfers to both, because the module grading is proved to coincide with the grading of Definition 33.19:

```
theorem finrank_plusModule_weight (q : ℚ) :
    finrank ℂ (plusModule.weight (q : ℂ))
      = finrank ℂ (twFixed 24 leechT ⊓ twWeight 24 leechT q : Submodule ℂ Tw)
```

(`VOA/Moonshine/TwistedPlus.lean`; `Tw` abbreviates `FockT 24 ⊗[ℂ] leechT`; `plusModule.weight α` is the $L_0 = \alpha$ eigenspace of the module, $\alpha \in \mathbb{C}$; proved in Chapter 36.) Consequently:

Theorem 33.50 (Graded dimension of $V_\Lambda^+ \oplus TP$ and of the carrier $V^\natural$). *For every $n \in \mathbb{N}$:* $\dim(V_\Lambda^+)_n + \dim TP_n = [q^n]qJ$, *and* $\dim {V^\natural}_n = [q^n]qJ$.

```
theorem finrank_plusModule_eq_coeff_JShift (n : ℕ) :
    ((finrank ℂ (leechVOAPlus.grading (n : ℤ))
      + finrank ℂ (plusModule.weight ((n : ℤ) : ℂ)) : ℕ) : ℂ)
      = PowerSeries.coeff n JShift

theorem finrank_gradingNat_eq_coeff_JShift (n : ℕ) :
    (finrank ℂ (gradingNat (n : ℤ)) : ℂ) = PowerSeries.coeff n JShift
```

(`TwistedPlus.lean` and `VOA/Moonshine/VnatCarrier.lean`; `gradingNat n` is the submodule $(V_\Lambda^+)_n \times TP_n$ of the carrier `Vnat`, both defined in Chapter 38.)

From the mathematics to the Lean statement

No hypotheses. The weight n enters `plusModule.weight` as the complex number `((n : ℤ) : ℂ)`. These are Theorem 33.47 transported along the dimension equalities just quoted and $\dim(A \times B) = \dim A + \dim B$; they are the forms consumed by the final theorem `VOA.Moonshine.moonshine` (Chapter 42), whose clause `(∀ n : ℕ, (Module.finrank ℂ (V.grading (n : ℤ)) : ℂ) = PowerSeries.coeff n JShift)` is exactly the second statement for the VOA grading of $V^\natural$.

Physical meaning

The statement transfers the graded dimension from the pair of sectors to the actual carrier $V^\natural = V_\Lambda^+ \oplus TP$, with TP the θ-projected twisted module. In CFT terms, the torus partition function of the Monster CFT is the sum of the untwisted and twisted-sector characters, both read off from L_0-eigenspaces of the actual module rather than from the combinatorial model; the equality of gradings is the identification of the twisted sector of the orbifold with the space of twisted-module states.

What the machine verified

Both unconditional; `#print axioms` the standard three (re-run).

33.10 Verification record

For this chapter the following file was compiled against the built library at an earlier commit (when the chapter was first written; not re-run for this edition) with `lake env lean -DmaxSynthPendingDepth=3` (the flag matters: a bare `lake env lean` can silently change elaboration, see Chapter 1 and Section 43.1.6):

```
import VOA.Moonshine.VnatCarrier
#print axioms VOA.Moonshine.sectorSeries_eq_JShift
#print axioms VOA.Moonshine.finrank_sectors_eq_coeff_JShift
... (15 declarations, listed below)
```

Output, verbatim:

```
'VOA.Moonshine.sectorSeries_eq_JShift' depends on axioms: [propext, Classical.choice,
 ↪  Quot.sound]

```

This check used the existing build artefacts; the aggregate `lake build` (10343 jobs, green) was recorded by the project's build record for that commit and was not re-run for this chapter. None of these depends on `VOA.pbw`. As always, a clean axiom list says nothing about explicit hypotheses; the point of the fidelity checks above is that the headline theorems have none.

33.11 Dead ends, traps and corrected statements

- **The square-zero TRAP** (warning in Section 33.8): graded dimension J does not certify $V^\natural$.
- **The sign of θ on T** (warning after Theorem 33.21): with $+1$ the fixed sector would sit in weights $\frac{3}{2} + \mathbb{Z}$.
- **Formal-only routes** were rejected before formalisation because they need Jacobi's abstruse identity or the theta formula for E_4, absent from Mathlib (Section 33.4.3). This is a recorded decision, not a failure.
- **Hauptmodul uniqueness is not used** (warning after Theorem 33.5); the residual note in `JFunction.lean` describing it as needed is superseded.
- **Missing script.** The 40-coefficient pre-check of (A)–(C) mentioned in `CharacterSeries.lean` is not in `scripts/`; only `theta_check.py` is (Remark 33.29). Nothing in Lean depends on either.

33.12 Referee's checklist

All entries are unconditional (no hypothesis that is an unproved datum); $*$ marks a `#print axioms` run for this chapter with result `[propext, Classical.choice, Quot.sound]`. Namespaces: `VOA` (JFunction), `VOA.TwistedSector`, `VOA.QBridge`, else `VOA.Moonshine`.

What a referee should still keep in mind. (i) Graded dimension alone does not characterise $V^\natural$ (TRAP). (ii) The twisted grading and involution are defined here and identified with the module structure only in Chapter 36. (iii) The analytic inputs (Mathlib's E_k, η, Δ, dimension formula, q-expansion uniqueness) are Mathlib theorems, trusted to the same standard as the rest of Mathlib.

33.13 Notes and references

The modular-forms background follows J.-P. Serre, *A Course in Arithmetic*, Graduate Texts in Mathematics 7, Springer, 1973 (Chapter VII: the modular group, the valence formula, $M_* = \mathbb{C}[E_4, E_6]$, Δ, j, and the theta series of even unimodular lattices); F. Diamond and J. Shurman, *A First Course in Modular Forms*, Graduate Texts in Mathematics 228, Springer, 2005 (congruence subgroups such as $\Gamma_0(2)$, Dedekind η, q-expansions); and T. M. Apostol, *Modular Functions and Dirichlet Series in Number Theory*, 2nd ed., Graduate Texts in Mathematics 41, Springer, 1990 (Chapter 1 for j and its expansion; Chapter 3 for η and the product formula for Δ).

The moonshine module, the twisted sector $S[\theta] \otimes T$, the sign of θ on T and the character computation are from I. Frenkel, J. Lepowsky and A. Meurman, *Vertex Operator Algebras and the Monster*, Pure and Applied Mathematics 134, Academic Press, 1988 (Introduction; Sections 1.10, 9.1–9.3, 10.4). The moonshine conjectures are J. H. Conway and S. P. Norton, "Monstrous Moonshine", *Bull. London Math. Soc.* **11** (1979), 308–339, where the Hauptmodul t of $\Gamma_0(2)$ appears as the series of class $2B$; McKay's and Thompson's observations are recorded there and in J. G. Thompson, "Some numerology between the Fischer–Griess Monster and the elliptic modular function", *Bull. London Math. Soc.* **11** (1979), 352–353. For a survey connecting characters of VOAs to modular functions, see T. Gannon, *Moonshine beyond the Monster*, Cambridge University Press, 2006 (Sections 2.2 and 5.3), which the library's `JFunction.lean` cites. Tannery's theorem (dominated convergence for series), used in the bridge, is in Mathlib as `tendsto_tsum_of_dominated_convergence`. Jacobi's abstruse identity and the theta-function formulas mentioned in Section 33.4.3 can be found in Apostol (above) and in E. T. Whittaker and G. N. Watson, *A Course of Modern Analysis*, Chapter 21.

Chapter 34

Twisted modules, the twisted Fock space and the module T

The Moonshine module of Frenkel, Lepowsky and Meurman is built from two halves,

$$V^\natural \;=\; V_\Lambda^+ \;\oplus\; \left(V_\Lambda^T\right)^+,$$

where V_Λ is the vertex operator algebra of the Leech lattice (Chapter 31), θ is the lift of the lattice involution $\alpha \mapsto -\alpha$ to V_Λ, V_Λ^+ is its fixed-point subalgebra (the *untwisted sector*, Chapter 32), and V_Λ^T is a θ-*twisted module* for V_Λ (the *twisted sector*), of which one keeps again the θ-fixed part. This chapter lays the foundations for the twisted sector. It contains three independent pieces of mathematics, which are assembled into V_Λ^T in Chapters 35 and 36. The chapter documents the release of the library named in the front matter; every Lean quotation is checked by `scripts/textbook/sync.py` to occur verbatim (up to whitespace and comments) in the source files of that release. Checks that were run at an earlier state of the library and not re-run for this edition are marked as such.

(I) **The notion of a twisted module** (Dong–Li–Mason). We must say precisely what it means for a vector space M to carry a g-twisted action of a vertex operator algebra V for an automorphism g of finite order N. The library's answer is the structure `VOA.TwistedModule`. Its first version contained a defect: one axiom was quantified over too many indices and, as a consequence, *no nonzero vector space could carry a twisted module structure for* $N \geq 2$. We present the defect, the machine-checked certificate that exhibits it, the repair, and the argument that the repair loses nothing. A structurally identical defect remains, unrepaired, in the super version `VOA.SuperTwistedModule`.

(II) **The twisted Heisenberg algebra and its Fock space** $S[\theta]$**.** Twisting by θ turns the integer-moded free bosons $h(n)$ of the lattice theory into half-integer-moded bosons $h(n+\frac{1}{2})$. Their Fock space $S[\theta]$ is a polynomial ring in infinitely many variables; its lowest L_0-eigenvalue is $r/16$ (for the Leech lattice, $r = 24$, this is $3/2$).

(III) **The module** T**.** The lattice part of the twisted sector is not a group algebra of Λ, as in the untwisted case, but a finite-dimensional irreducible representation T of an *extraspecial* 2*-group* 2^{1+24}, of dimension $2^{12} = 4096$. We build T as the simple module of a twisted group algebra $\mathbb{C}^\varepsilon[\Lambda/2\Lambda]$, prove its dimension from Wedderburn–Artin, and construct on T a nondegenerate *symmetric* invariant bilinear form with the sign law $B(e_\alpha t, t') = (-1)^{\langle\alpha,\alpha\rangle/2} B(t, e_\alpha t')$. The sign was fixed after a numerical experiment with the E_8 lattice ruled out a plausible alternative.

The Lean sources are:

`VOA/Modularity/Twisted.lean`	`TwistedModule`, eigenspaces, `OrdVModule.toTwisted`
`VOA/Moonshine/HeisenbergTwistedModuleDefect.lean`	the defect certificate, `TwistedJacobi`
`VOA/Moonshine/TwistedHeisenberg.lean`	$S[\theta]$: `FockT`, `modeT`, grading, θ, L_0
`VOA/Moonshine/ExtraspecialModule.lean`	$\mathbb{C}^{\varepsilon}[L/2L]$, Wedderburn–Artin, T
`VOA/Moonshine/TFormAlg.lean`	anti-involutions and trace forms on T
`VOA/Moonshine/TFormLattice.lean`	the sign $(-1)^Q$, Lagrangian data
`VOA/Moonshine/TForm.lean`	the Leech Lagrangian and `TForm`

How to read this chapter. Following the book's protocol, each definition and theorem appears four times: as mathematics, as the verbatim Lean declaration, in a *fidelity check* (the box headed "From the mathematics to the Lean statement") in which every symbol and every hypothesis of the Lean text is decoded and compared with the mathematics, and in a *status* box saying what the machine verified. Proofs are explained on paper; we do not describe the Lean proof scripts. Where a Lean proof body is a one-line composition of earlier results we show it, because then the proof term is itself informative.

Trust model, recalled. The library contains no project axiom (`VOA.pbw`, formerly its only axiom, is now a theorem; Chapter 3). Nothing in this chapter uses it. When we say a declaration is "`#print axioms`-clean" we mean that Lean reports that it depends only on `propext`, `Classical.choice` and `Quot.sound`, the three standard axioms of Lean's logic. For this chapter we re-ran `#print axioms` on twenty-four headline declarations against the current build of the library, in the audit mode the project prescribes,

```
lake env lean -DmaxSynthPendingDepth=3 ax06.lean
```

and every one returned exactly

```
depends on axioms: [propext, Classical.choice, Quot.sound]
```

A clean axiom list does not make a theorem unconditional: hypotheses stated in the theorem are not "axioms". We therefore always list the hypotheses as well.

34.1 Why twisted modules

34.1.1 The physical picture: strings on an orbifold

A vertex operator algebra V is the algebra of chiral fields of a two-dimensional conformal field theory. A state $u \in V$ corresponds to a field $Y(u,z) = \sum_{n\in\mathbb{Z}} u_{(n)} z^{-n-1}$ on the punctured plane, and the fact that only integer powers of z occur says that $Y(u,z)$ is single-valued: transporting z once around the origin, $z \mapsto e^{2\pi i} z$, returns the same operator.

Suppose g is an automorphism of V of finite order N. Physically g is a symmetry of the theory, and one may form the *orbifold* theory in which only g-invariant states are kept. Consistency of the orbifold (modular invariance of its torus partition function) forces one to add new sectors: states created by "twist fields" around which the fields are *not* single-valued, but come back transformed by g:

$$Y_M(gu,z) \;=\; Y_M\big(u, e^{2\pi i} z\big) \qquad \text{(monodromy around a twist field).} \tag{34.1}$$

If $gu = e^{-2\pi i j/N} u$, then (34.1) says that $Y_M(u,z)$ picks up the phase $e^{-2\pi i j/N}$ around the origin, so the exponents of z in $Y_M(u,z)$ must lie in $\frac{j}{N} + \mathbb{Z}$ (because $z^a \mapsto e^{2\pi i a} z^a$; the sign conventions are such that the two phases agree). Writing $Y_M(u,z) = \sum_r u_{(r)} z^{-r-1}$, this means $r \in -\frac{j}{N} + \mathbb{Z}$. This is the defining feature of a twisted module: *fractional modes*. For the Moonshine module, $g = \theta$ has order $N = 2$; the Heisenberg fields $h(z)$ satisfy $\theta h = -h$ (so $j = 1$) and become half-integer moded

in the twisted sector. This is the "twisted boson" of string theory on the orbifold $\mathbb{R}^{24}/\Lambda$ divided by ± 1: the string is closed only up to the reflection $x \mapsto -x$, so its oscillators have half-integral frequencies.

34.1.2 The mathematical picture

Algebraically, a g-twisted module is to the automorphism g what an ordinary module is to the identity. The axioms (the Jacobi identity in particular) are those of an ordinary module, with the delta-function that encodes locality modified by a fractional power that absorbs the monodromy. They were formulated by Frenkel–Lepowsky–Meurman for the case at hand ($g = \theta$, $N = 2$) and in general by Dong, Li and Mason. We now develop them.

34.2 Fractional modes and the twisted Jacobi identity

34.2.1 Setting

Throughout, V is a vertex operator algebra over $\mathbb{C}$ in the sense of the library (the structure `VertexOperatorAlgebra`, Definition 4.4): V has a vacuum $\mathbf{1}$, a conformal vector ω with $\omega_{(1)} = L_0$, and products $u_{(n)}v$ for $n \in \mathbb{Z}$. In Lean the n-th product is written `W.smul u n v := mode (W.Y u) n v`, where `W : VertexOperatorAlgebra` V (Definition 4.2, `VOA/Core/VertexAlgebra.lean`), with `mode f n = f (-n - 1)` (Definition 2.7, `VOA/Foundations/FormalCalculus.lean`): the library stores a formal series $f(z) = \sum_k f_k z^k$ as the function $k \mapsto f_k$, and the mode $u_{(n)}$ is the coefficient of z^{-n-1}. One consequence of the vacuum axiom is used below: $\mathbf{1}_{(n)}v = \delta_{n,-1}v$ (Lean: `PreVertexAlgebra.smul_vacuum_left`).

Definition 34.1 (Automorphism). An *automorphism* of V is a linear bijection $g : V \to V$ with $g(u_{(n)}v) = (gu)_{(n)}(gv)$ for all u, v, n, $g\mathbf{1} = \mathbf{1}$ and $g\omega = \omega$.

In Lean this is the structure `VOA.Aut` (`VOA/Core/Automorphism.lean`), quoted verbatim and decoded in Definition 5.9: a $\mathbb{C}$-linear bijection `toLinearEquiv` (`≃ₗ[ℂ]`) with fields `map_smul'`, `map_vacuum`, `map_omega`; it is literally Definition 34.1.

Physical meaning

An automorphism of V is a symmetry of the chiral algebra: a transformation of the fields that preserves all operator product expansions, the identity operator, and the stress tensor ω, hence commutes with L_0 and the Virasoro algebra. It is the data one needs to gauge: the finite group $\langle g \rangle$ acts on the theory, and the orbifold keeps only the g-invariant states. The requirement $g\omega = \omega$ says the symmetry is internal (it does not move the worldsheet), which is why the twisted sectors below are again conformal theories.

34.2.2 Eigenspaces

Let g have order dividing $N \geq 1$ and put $\xi_N = e^{2\pi i/N}$. Since $g^N = 1$ and $\mathbb{C}$ contains the N-th roots of unity, g is diagonalisable and

$$V = \bigoplus_{j=0}^{N-1} V^j, \qquad V^j = \{v \in V : gv = \xi_N^{-j} v\}.$$

Definition 34.2 (Twisted eigenspace). For $g \in \mathrm{Aut}(V)$, $N \in \mathbb{N}$ and $j \in \mathbb{N}$, $V^j = \ker(g - e^{-2\pi i j/N})$.

File `VOA/Modularity/Twisted.lean`.

```
noncomputable def Aut.twistedEigenspace (g : Aut W) (N : ℕ) (j : ℕ) : Submodule ℂ 𝒱 :=
  Module.End.eigenspace (g.toLinearEquiv : Module.End ℂ 𝒱)
    (Complex.exp (-(2 * (Real.pi : ℂ) * Complex.I * j) / N))
```

From the mathematics to the Lean statement

`Module.End.eigenspace f μ` is Mathlib's $\ker(f-\mu)$, a subspace (`Submodule ℂ 𝒱`). The eigenvalue is $\exp(-2\pi ij/N) = \xi_N^{-j}$, exactly as in the definition. The index j is a natural number, not a residue mod N; $V^j = V^{j+N}$ automatically, since the eigenvalue depends only on j mod N. Nothing in the definition requires $g^N = 1$: if that fails, V need not be the sum of these eigenspaces, but every statement below only speaks about vectors that lie in some V^j, so this is harmless. In Lean, division by 0 returns 0, so at $N = 0$ the "eigenspace" is the fixed space $\ker(g-1)$; no result of this book applies the definition at $N = 0$. The vacuum lies in V^0 for every g (Lean: `Aut.vacuum_mem_twistedEigenspace_zero`), because $g\mathbf{1} = \mathbf{1}$.

Physical meaning

The space V^j is the set of fields carrying charge j under the $\mathbb{Z}_N$ symmetry g, in the convention that g acts by the phase $e^{-2\pi ij/N}$. Charge j is exactly the monodromy that a field of V^j picks up when transported around a twist field, so the decomposition $V = \bigoplus_j V^j$ sorts fields by how they behave in the twisted sector. The vacuum has charge 0, as it must: the identity operator is single-valued.

34.2.3 The generating form of the twisted Jacobi identity

Definition 34.3 (Twisted module, informal)**.** Let $g \in \mathrm{Aut}(V)$ with $g^N = 1$. A (weak) g-twisted V-module is a vector space M with a linear map

$$u \longmapsto Y_M(u,z) = \sum_{r \in \frac{1}{N}\mathbb{Z}} u_{(r)} z^{-r-1}, \qquad u_{(r)} \in \mathrm{End}(M),$$

such that: (a) $Y_M(\mathbf{1},z) = \mathrm{id}_M$; (b) for $u \in V$, $x \in M$, $u_{(r)}x = 0$ for r large (lower truncation); (c) for $u \in V^j$, $u_{(r)} = 0$ unless $r \in -\frac{j}{N} + \mathbb{Z}$ (the *support condition*); (d) for $u \in V^j$ and $v \in V$ the *twisted Jacobi identity*

$$z_0^{-1}\delta\!\left(\frac{z_1-z_2}{z_0}\right)Y_M(u,z_1)Y_M(v,z_2) - z_0^{-1}\delta\!\left(\frac{z_2-z_1}{-z_0}\right)Y_M(v,z_2)Y_M(u,z_1)$$
$$= z_2^{-1}\left(\frac{z_1-z_0}{z_2}\right)^{j/N}\delta\!\left(\frac{z_1-z_0}{z_2}\right)Y_M\big(Y(u,z_0)v,z_2\big) \quad (34.2)$$

holds, where $\delta(x) = \sum_{n\in\mathbb{Z}} x^n$ and binomials $(a-b)^c$ are expanded in nonnegative powers of the second variable.

Physical meaning

This is the definition of a twisted sector of the orbifold. A g-twisted module is the space of states on a circle around which every field $Y(u,z)$ returns to $Y(gu,z)$, i.e. $Y_M(gu,z) = Y_M(u,e^{2\pi i}z)$; such states are created by a twist field inserted at the origin. A field of charge j then has expansion exponents in $\frac{j}{N}+\mathbb{Z}$, so the modes are fractional (multiples of $1/N$), while the fusion identity acquires the factor $((z_1-z_0)/z_2)^{j/N}$ that records the branch cut running from the twist field. For $N = 1$ this reduces to the ordinary periodic (Neveu–Schwarz-type, untwisted) sector.

The factor $\left(\frac{z_1-z_0}{z_2}\right)^{j/N}$ is the only difference from an ordinary module. Its purpose is bookkeeping of exponents. On the left, the powers of z_1 that occur are the exponents $-r-1$ of $Y_M(u,z_1)$, which by (c) lie in $\frac{j}{N}+\mathbb{Z}$. On the right, the delta function contributes only integral powers of z_1; multiplying by $(z_1-z_0)^{j/N}$ shifts them into $\frac{j}{N}+\mathbb{Z}$, so that both sides live in the same space of formal series. This is the algebraic shadow of the monodromy (34.1). When $N=1$ the factor is 1 and (34.2) is the Jacobi identity of an ordinary module.

34.2.4 The mode form

Lean has no formal series in fractional powers, so the library states the Jacobi identity as an identity between *coefficients*. We now derive that coefficient identity from (34.2), carefully, because the derivation is what explains the hypothesis $N \mid k+j$ of the library. Write $a = j/N$ and fix $u \in V^j$, $v \in V$. By the support condition (c), $Y_M(u,z_1) = \sum_{p\in -a+\mathbb{Z}} u_{(p)} z_1^{-p-1}$, while $Y_M(v,z_2) = \sum_{q\in \frac{1}{N}\mathbb{Z}} v_{(q)} z_2^{-q-1}$ and $Y(u,z_0)v = \sum_{p\in\mathbb{Z}} (u_{(p)}v) z_0^{-p-1}$ (integral modes in V). Fix $\ell \in \mathbb{Z}$ and $r,s \in \frac{1}{N}\mathbb{Z}$, and compare the coefficients of $z_0^{-\ell-1} z_1^{-r-1} z_2^{-s-1}$ on the two sides.

Step 1: the first term on the left. Expanding the delta function and then the binomial in nonnegative powers of z_2,

$$z_0^{-1}\delta\Big(\frac{z_1-z_2}{z_0}\Big) = \sum_{n\in\mathbb{Z}} (z_1-z_2)^n z_0^{-n-1} = \sum_{n\in\mathbb{Z}}\sum_{i\ge 0} (-1)^i \binom{n}{i} z_1^{n-i} z_2^i z_0^{-n-1}.$$

The coefficient of $z_0^{-\ell-1}$ selects $n = \ell$. Multiplying by $Y_M(u,z_1)Y_M(v,z_2) = \sum_{p,q} u_{(p)}v_{(q)} z_1^{-p-1} z_2^{-q-1}$, the power of z_1 is $\ell - i - p - 1$ and that of z_2 is $i-q-1$; equating them with $-r-1$ and $-s-1$ gives $p = \ell + r - i$, $q = s+i$. So the coefficient is $\sum_{i\ge 0}(-1)^i\binom{\ell}{i} u_{(\ell+r-i)}v_{(s+i)}$.

Step 2: the second term on the left. Similarly $z_0^{-1}\delta(\frac{z_2-z_1}{-z_0}) = \sum_n (-1)^n (z_2-z_1)^n z_0^{-n-1}$, now expanded in powers of z_1: $(z_2-z_1)^\ell = \sum_{i\ge 0}(-1)^i\binom{\ell}{i} z_2^{\ell-i} z_1^i$. Against $Y_M(v,z_2)Y_M(u,z_1)$ this gives $p = r+i$, $q = \ell+s-i$, and with the overall minus sign the coefficient is $-\sum_{i\ge 0}(-1)^i\binom{\ell}{i}(-1)^\ell v_{(\ell+s-i)}u_{(r+i)}$.

Step 3: the right side. Here

$$z_2^{-1}\Big(\frac{z_1-z_0}{z_2}\Big)^a \delta\Big(\frac{z_1-z_0}{z_2}\Big) = \sum_{n\in\mathbb{Z}} (z_1-z_0)^{n+a} z_2^{-n-a-1}, \qquad (z_1-z_0)^{n+a} = \sum_{i\ge 0}(-1)^i\binom{n+a}{i} z_1^{n+a-i} z_0^i,$$

the binomial series in nonnegative powers of z_0 (convergent as a formal series, because the exponent of z_1 is merely shifted). Against $Y_M(Y(u,z_0)v,z_2) = \sum_{p\in\mathbb{Z}}\sum_t (u_{(p)}v)_{(t)} z_0^{-p-1} z_2^{-t-1}$: the power of z_0 is $i-p-1$, so $p = \ell + i$; the power of z_1 is $n+a-i$, so we need

$$n + a - i = -r - 1, \qquad \text{i.e.} \qquad n = i - 1 - r - a \in \mathbb{Z}. \tag{34.3}$$

This has an integer solution n if and only if $r \in -a+\mathbb{Z}$, i.e. $Nr \equiv -j \pmod N$. When it does, the power of z_2 gives $t = -n-a-1+s = r+s-i$, and the coefficient is $(-1)^i\binom{-r-1+i}{i} = \binom{r}{i}$ (the elementary identity $(-1)^i\binom{-x-1+i}{i} = \binom{x}{i}$, valid for every x). So the right side contributes $\sum_{i\ge 0}\binom{r}{i}(u_{(\ell+i)}v)_{(r+s-i)}$.

Conclusion. For r on the support coset $-\frac{j}{N}+\mathbb{Z}$, comparing coefficients gives the *mode form* (Dong–Li–Mason; FLM for $N=2$)

$$\sum_{i\geq 0}(-1)^i\binom{\ell}{i}\Big(u_{(\ell+r-i)}v_{(s+i)}-(-1)^{\ell}v_{(\ell+s-i)}u_{(r+i)}\Big)=\sum_{i\geq 0}\binom{r}{i}\big(u_{(\ell+i)}v\big)_{(r+s-i)}, \tag{34.4}$$

with the *generalised binomial coefficient* $\binom{r}{i}=r(r-1)\cdots(r-i+1)/i!$ for $r\in\mathbb{Q}$. Both sums are finite when applied to a vector $x\in M$: on the left, the factors $v_{(s+i)}x$ and $u_{(r+i)}x$ vanish for i large by truncation; on the right, $u_{(\ell+i)}v=0$ for i large because V itself is truncated. Conversely, the coefficients with r on the coset are *all* the coefficients of (34.2) that can be nonzero, so (34.4) for all such r (and all ℓ, s) is equivalent to (34.2).

What happens off the coset. For $r\notin -\frac{j}{N}+\mathbb{Z}$, the left side of the coefficient comparison is 0: in Steps 1 and 2 the operators $u_{(\ell+r-i)}$ and $u_{(r+i)}$ have indices off the coset and vanish by (c). The right side is also 0: by (34.3) no term of the expansion has the power z_1^{-r-1} at all. So the generating identity says only "$0=0$" there. But the *formula* on the right of (34.4), evaluated at such an r, is not this coefficient: it is the expression $\sum_i\binom{r}{i}(u_{(\ell+i)}v)_{(r+s-i)}$, which never occurred in the expansion and can be nonzero. Requiring (34.4) off the coset therefore adds new, unjustified relations; this is the whole story of §34.4. In the library's encoding $r=k/N$, "r on the coset" is exactly `(k + j) % N = 0`, i.e. $N\mid k+j$. **Honesty note:** this derivation, and the equivalence of the mode form with the generating form, are argued here on paper; the library has no fractional formal series and does not prove the equivalence in Lean. It takes the mode form as the definition.

Three special cases are worth keeping in mind.

- $\ell=0$: since $\binom{0}{i}=\delta_{i,0}$, only $i=0$ survives on the left, which becomes $u_{(r)}v_{(s)}-v_{(s)}u_{(r)}$; this is the *commutator formula* $[u_{(r)},v_{(s)}]=\sum_{i\geq 0}\binom{r}{i}(u_{(i)}v)_{(r+s-i)}$. This is what one uses in practice; for the twisted Heisenberg algebra (§34.5) it is the whole content. Take $u=h_a$, $v=h_b$, two of the weight-one Heisenberg states, with $\theta h_a=-h_a$, so $h_a\in V^1$ for $N=2$ and $r\in\frac{1}{2}+\mathbb{Z}$ is on the coset. In the Heisenberg VOA (Chapter 31) $h_{a(0)}h_b=0$, $h_{a(1)}h_b=\langle h_a,h_b\rangle\mathbf{1}=\delta_{ab}\mathbf{1}$, and $h_{a(i)}h_b=0$ for $i\geq 2$ (it would have weight $1-i<0$). So the right side has only the terms $i=0$ and $i=1$:

  $$[h_{a(r)},h_{b(s)}]=\binom{r}{0}(h_{a(0)}h_b)_{(r+s)}+\binom{r}{1}(h_{a(1)}h_b)_{(r+s-1)}=0+r\,\delta_{ab}\,\mathbf{1}_{(r+s-1)}=r\,\delta_{ab}\,\delta_{r+s,0}\,\mathrm{id}_M,$$

  using $\mathbf{1}_{(t)}=\delta_{t,-1}\mathrm{id}_M$. These are exactly the twisted Heisenberg relations (34.5), now with half-integral r, s.

- $N=1$: (34.4) is the Borcherds identity of an ordinary module.

- $u=\mathbf{1}$ (so $j=0$, $r\in\mathbb{Z}$): both sides collapse using $\mathbf{1}_{(n)}=\delta_{n,-1}$ and the identity is a tautology. We shall see that it is *not* a tautology if one allows $r\notin\mathbb{Z}$.

34.3 The library's `TwistedModule`

34.3.1 Auxiliary definitions

The Lean statement of (34.4) uses three small functions. We give them verbatim.

```
def negOnePow (n : ℤ) : ℂ := if Even n then 1 else -1
```

(`VOA/Foundations/Expansion.lean`): $(-1)^n$ for an integer n.

```
noncomputable def gBinom (n : ℤ) (k : ℕ) : ℂ :=
  (∏ i ∈ Finset.range k, ((n : ℂ) - (i : ℂ))) / (k.factorial : ℂ)

noncomputable def cbz (n k : ℤ) : ℂ := if 0 ≤ k then gBinom n k.toNat else 0
```

(VOA/Foundations/FormalCalculus.lean, VOA/Foundations/Substitution.lean): `gBinom n k` is $\binom{n}{k} = n(n-1)\cdots(n-k+1)/k!$ for $n \in \mathbb{Z}$, $k \in \mathbb{N}$ (negative upper indices allowed: $\binom{-1}{k} = (-1)^k$), and `cbz n k` extends it to $k \in \mathbb{Z}$ by 0 for $k < 0$ (`k.toNat` is k viewed as a natural number, used only when $k \geq 0$).

```
noncomputable def cbinom (x : ℂ) (i : ℕ) : ℂ :=
  (∏ k ∈ Finset.range i, (x - k)) / (i.factorial : ℂ)
```

(VOA/Modularity/Twisted.lean): $\binom{x}{i}$ for complex x, used at $x = r \in \frac{1}{N}\mathbb{Z}$.

Finally, $\sum^{\mathrm{f}}$ (Lean $\sum^{\mathtt{f}}$, Mathlib's `finsum`) is the sum of a family with finite support. *Convention:* if the support is infinite, Mathlib defines `finsum` to be 0. For the sums in the Jacobi identity the supports are finite whenever the truncation axioms hold (as explained after (34.4)), so the convention never bites in a genuine module: in the field `jacobi` below, the left sum has finite support because $v_{(s+i)}x = 0$ and $u_{(r+i)}x = 0$ for large i (truncation in M) and $\binom{\ell}{i} = 0$ for $i < 0$, and the right sum because $u_{(\ell+i)}v = 0$ for large i (truncation in V). We flag it because a referee must know that "$\sum^{\mathrm{f}} = \ldots$" is not automatically a statement about a convergent infinite sum.

34.3.2 The definition

The library encodes the fractional mode $u_{(k/N)}$ by its integer numerator k.

Definition 34.4 (g-twisted module, as in the library)**.** Let $g \in \mathrm{Aut}(V)$ and $N \in \mathbb{N}$. A g-twisted V-module structure on a complex vector space M consists of a linear map $u \mapsto (k \mapsto u_{(k/N)})$ from V to $\mathbb{Z}$-indexed families of endomorphisms of M and a family of subspaces $(M_\alpha)_{\alpha\in\mathbb{C}}$ such that

(i) $\mathbf{1}_{(k/N)} = \delta_{k,-N}\,\mathrm{id}_M$;

(ii) for all u, x there is K with $u_{(k/N)}x = 0$ for all $k \geq K$;

(iii) for $u \in V^j$: $u_{(k/N)} = 0$ whenever $N \nmid k + j$;

(iv) for $u \in V^j$, $v \in V$, $x \in M$, $\ell, k, m \in \mathbb{Z}$ **with** $N \mid k + j$, the identity (34.4) holds at $r = k/N$, $s = m/N$, applied to x;

(v) $M = \bigoplus_\alpha M_\alpha$ (internal direct sum), $L_0 = \omega_{(1)}$ acts on M_α as α, each M_α is finite-dimensional, and $\mathrm{Re}\,\alpha$ is bounded below on the α with $M_\alpha \neq 0$.

(`VOA.TwistedModule`, `VOA/Modularity/Twisted.lean`.)

From the mathematics to the Lean statement

The carrier of modes. `YM : V →ₗ[ℂ] (ℤ → Module.End ℂ M)` is a $\mathbb{C}$-linear map from V to functions $\mathbb{Z} \to \mathrm{End}_{\mathbb{C}}(M)$. The documented reading is `YM u k` $= u_{(k/N)}$. Note that this is the *mode itself*, not the coefficient of a power of z: unlike the untwisted `mode` convention there is no shift $-n-1$ here. The field is $\sum_k u_{(k/N)} z^{-k/N-1}$.

(i) `vacuum_YM`. $\mathbf{1}_{(k/N)} = 1$ if $k = -N$ (i.e. $r = -1$) and 0 otherwise: $Y_M(\mathbf{1}, z) = \mathbf{1}_{(-1)} z^0 = \mathrm{id}$. Same as (a).

(ii) `truncation`. Same as (b), quantifiers $\forall u\, \forall x\, \exists K\, \forall k \geq K$; K may depend on u and x, as it should.

(iii) `support`. `(k + j) % (N : ℤ) ≠ 0` says that the remainder of $k + j$ on division by N is nonzero, i.e. $N \nmid k + j$, i.e. $k/N \notin -\frac{j}{N} + \mathbb{Z}$; for such k the whole operator `YM u k` is 0. Same as (c).

(iv) `jacobi`. Substitute $r = k/N$, $s = m/N$. The u-index `ℓ * N + k - i * N` is $N(\ell + r - i)$, the v-index `m + i * N` is $N(s + i)$, the second term's indices `ℓ * N + m - i * N` and `k + i * N` are $N(\ell + s - i)$ and $N(r + i)$; the coefficient `negOnePow i * cbz ℓ i` is $(-1)^i \binom{\ell}{i}$ (zero for $i < 0$, so summing over $i \in \mathbb{Z}$ is summing over $i \geq 0$). On the right, `cbinom ((k : ℂ) / N) i` $= \binom{r}{i}$, `W.smul u (ℓ + i) v` $= u_{(\ell+i)} v$ (the product in V, integral index), and the index `k + m - i * N` is $N(r + s - i)$. So the Lean identity is (34.4) applied to x, term by term. Hypotheses: $u \in V^j$ (`u ∈ g.twistedEigenspace N j`); v *arbitrary* (it need not be an eigenvector; this is the intended generality, as the identity is linear in v); ℓ, m arbitrary; and `(k + j) % (N : ℤ) = 0`, i.e. r in the support coset. This last hypothesis is the 2026-10-06 repair (§34.4).

(v) the grading. `weight : ℂ → Submodule ℂ M` is the family (M_α); `DirectSum.IsInternal weight` is Mathlib's statement that the natural map $\bigoplus_\alpha M_\alpha \to M$ is an isomorphism. `L0_weight` uses the mode numerator $k = N$, i.e. $\omega_{(N/N)} = \omega_{(1)} = L_0$ (note $\omega \in V^0$, so this index is on the support coset). Together with `isInternal` this forces M_α to be the full L_0-eigenspace of eigenvalue α. `finrank` says each M_α is finite-dimensional, `boundedBelow` that $\{\mathrm{Re}\,\alpha : M_\alpha \neq 0\}$ is bounded below; $\bot$ is the zero subspace.

Same, stronger or weaker? The structure matches Definition 34.3 plus the grading conditions of an ordinary (not merely weak) twisted module in the sense of Dong–Li–Mason, with the Jacobi identity in its mode form. Three remarks. (1) The structure does not itself demand $g^N = 1$ or $N > 0$; those are hypotheses of the theorems that consume it (the proposition `Conjecture_5_3_10` in the same file adds `0 < N` and `g ^ N = 1`), and the Moonshine instances

have $N = 2$ and $\theta^2 = 1$. (2) The mode form is *taken as the definition*; the equivalence of (34.4) (on the support coset) with the generating identity (34.2) is the classical computation sketched above, argued on paper, not formalised. (3) No L_{-1}-derivative axiom is included; it is not part of the DLM definition either, where it is a consequence of the other axioms.
Could it be vacuous? It *was*: before the repair, (iv) was required for every k, and no nonzero M satisfied it for $N \geq 2$ (§34.4). After the repair it is satisfiable by genuine objects: the library constructs the twisted Heisenberg module `Moonshine.heisTwistedModule r : TwistedModule (sigma1 r) 2 (FockT r)` (Chapter 35) and the twisted Leech module `Moonshine.LatticeTwisted.leechTwistedModule`, of type `TwistedModule leechTheta 2 (FockT 24 ⊗[ℂ] Rep (cocMat leech) _)` (Chapter 36), on nonzero spaces; and every ordinary module is a twisted module for $g = 1$, $N = 1$ (Proposition 34.6).

Physical meaning

The repaired structure is the precise statement that a twisted sector is a state space on which the modes of a charge-j field are supported only on the coset $-\frac{j}{N} + \mathbb{Z}$: the support condition is the monodromy, and the coset hypothesis in `jacobi` says that only mode numbers compatible with that monodromy ever appear in the operator product expansion. The grading by L_0 with finite-dimensional, bounded-below eigenspaces is the usual physical requirement of a Hamiltonian with a gapped, discrete spectrum bounded from below on the twisted circle. The fractional L_0 eigenvalues (here multiples of $1/N$ up to a shift) are the scaling weights of twist-field excitations. This is a restatement of standard orbifold lore (Dong–Li–Mason, FLM); the physical picture motivates the axioms but certifies nothing.

What the machine verified

`TwistedModule` is a definition (a structure), so there is nothing to prove; its satisfiability is witnessed by the instances just named. The only change to an upstream definition made by the Moonshine work is the addition of the hypothesis `(k + j) % (N : ℤ) = 0` to the field `jacobi` (Section 34.4).

Remark 34.5 (Twisted traces)**.** The same file defines `TwistedModule.weightBlock` (the block of an operator on M_α) and `twistedTrace T φ`, the formal series $\sum_e \operatorname{tr}(\varphi|_{M_{e+c/24}})\, q^e$, i.e. $q^{-c/24} \operatorname{tr}_M \varphi\, q^{L_0}$; and the proposition `Conjecture_5_3_10` (modularity of twisted traces), which is *stated and never asserted*. None of these is used in the Moonshine construction.

34.3.3 Ordinary modules are twisted modules for the identity

Recall (Definition 12.5) that an ordinary module `OrdVModule W M` has a field map `YM : V →ₗ[ℂ] (End ℂ M)⟦z^±⟧` (formal series, read through `mode`) with the Borcherds identity in mode form

```
jacobi : ∀ (u v : V) (x : M) (ℓ m n : ℤ),
  (∑ᶠ i : ℤ, (negOnePow i * cbz ℓ i) •
      (mode (YM u) (ℓ + m - i) (mode (YM v) (n + i) x)
        - negOnePow ℓ • mode (YM v) (ℓ + n - i) (mode (YM u) (m + i) x)))
    = ∑ᶠ i : ℤ, cbz m i • mode (YM (W.smul u (ℓ + i) v)) (m + n - i) x
```

together with vacuum, truncation and grading fields of the same shape (`VOA/Modules/WeakModule.lean`).

Proposition 34.6. *Every ordinary V-module is a 1-twisted module with $N = 1$, with $u_{(k/1)} = u_{(k)}$ and the same grading.*

File `VOA/Modularity/Twisted.lean`.

```
noncomputable def OrdVModule.toTwisted {M : Type u} [AddCommGroup M] [Module ℂ M]
    (Nm : OrdVModule W M) : TwistedModule (1 : Aut W) 1 M where
```

From the mathematics to the Lean statement

This is a *construction* (`def`) whose type is the statement: from `Nm` it produces a `TwistedModule (1 : Aut W) 1 M`. Its modes are `fun u k ⇒ mode (Nm.YM u) k`, i.e. $u_{(k)}$; vacuum, truncation and grading are copied. For $N = 1$ the support condition is vacuous (every integer is $\equiv 0 \bmod 1$) and the coset hypothesis of `jacobi` is always true, so the twisted Jacobi identity must hold for all k; it is the module identity with $m := k$, $n := m$, after observing $\binom{k/1}{i} = \binom{k}{i}$ and that the sum over $i \in \mathbb{Z}$ weighted by `cbz` equals the sum over $i \in \mathbb{N}$. So the construction is exactly the proposition.

Physical meaning

For $g = 1$ there is no twist: the boundary condition around the circle is periodic and the twisted sector is the ordinary (untwisted) sector, all modes are integral, and the support condition is empty. The proposition says that the twisted-module formalism contains ordinary representation theory as its trivial-twist case, so it genuinely generalises the notion of a state space of the CFT.

Proof on paper. Identify $u_{(k/1)}$ with $u_{(k)}$; the twisted axioms with $N = 1$ are then literally the module axioms, the only bookkeeping being that $\binom{m}{i} = 0$ for $i < 0$. □

What the machine verified

`#print axioms VOA.OrdVModule.toTwisted:` `[propext, Classical.choice, Quot.sound]`. Unconditional.

34.4 The defect and its repair

34.4.1 What went wrong

Until 2026-10-06 the field `jacobi` read exactly as above *without* the line `(k + j) % (N : ℤ) = 0 →`. That is, the mode identity (34.4) was required for every $r = k/N \in \frac{1}{N}\mathbb{Z}$, including those off the support coset of u. As explained after (34.4), such instances are not coefficients of the generating identity. They are not merely redundant: they are false in every nonzero module.

To make this a theorem, the library isolates the old field as a predicate on a mode map.

Definition 34.7. For a linear map $Y_M : V \to (\mathbb{Z} \to \mathrm{End}\, M)$ write JacobiAllIndices(g, N, Y_M) for the statement: for all j, $u \in V^j$, $v \in V$, $x \in M$ and all $\ell, k, m \in \mathbb{Z}$, identity (34.4) holds at $r = k/N$, $s = m/N$, applied to x.

File `VOA/Moonshine/HeisenbergTwistedModuleDefect.lean`.

```
def JacobiAllIndices (g : Aut W) (N : ℕ) {M : Type*} [AddCommGroup M] [Module ℂ M]
    (YM : V →ₗ[ℂ] (ℤ → End ℂ M)) : Prop :=
  ∀ (j : ℕ) (u : V), u ∈ g.twistedEigenspace N j → ∀ (v : V) (x : M) (ℓ k m : ℤ),
    (∑ᶠ i : ℤ, (negOnePow i * cbz ℓ i) •
        (YM u (ℓ * N + k - i * N) (YM v (m + i * N) x)
          - negOnePow ℓ • YM v (ℓ * N + m - i * N) (YM u (k + i * N) x)))
      = ∑ᶠ i : ℕ, cbinom ((k : ℂ) / N) i • YM (W.smul u (ℓ + i) v) (k + m - i * N) x
```

From the mathematics to the Lean statement

Character for character this is the body of the current `TwistedModule.jacobi` with the coset hypothesis deleted (compare the two displays). It is a `Prop` about an arbitrary mode map `YM`, so it can be studied without the rest of the structure. (`End ℂ M` is `Module.End ℂ M`, the endomorphisms, with the namespace opened.)

Physical meaning

This predicate is the old, overly strong form of the fusion identity in which the OPE relation is demanded even for mode numbers that cannot occur in a twisted sector (those off the monodromy coset). Physically such mode numbers are simply absent from the field, so demanding a relation for them is demanding a constraint with no counterpart in the correlation functions; it is a bookkeeping error, not a different theory.

Theorem 34.8 (Dead-end certificate). *Let $N \geq 2$, and let $Y_M : V \to (\mathbb{Z} \to \mathrm{End}\, M)$ be linear with $\mathbf{1}_{(k/N)} = \delta_{k,-N}$. If* JacobiAllIndices$(g, N, Y_M)$ *holds, then $M = 0$: every $x \in M$ is zero.*

File `VOA/Moonshine/HeisenbergTwistedModuleDefect.lean`.

```
theorem jacobiAllIndices_eq_zero {g : Aut W} {N : ℕ} (hN : 2 ≤ N) {M : Type*}
    [AddCommGroup M] [Module ℂ M] (YM : 𝒱 →ₗ[ℂ] (ℤ → End ℂ M))
    (hvac : ∀ k : ℤ, YM W.vacuum k = if k = -(N : ℤ) then 1 else 0)
    (hJ : JacobiAllIndices g N YM) (x : M) : x = 0
```

From the mathematics to the Lean statement

Hypotheses: `hN` ($N \geq 2$); `hvac` (the vacuum axiom (i), verbatim the field `vacuum_YM`); `hJ` (the old Jacobi field). Conclusion: `x = 0` for the arbitrary `x : M`. No truncation, support or grading hypotheses are needed, so the theorem applies *a fortiori* to every structure of the old shape. Consequence: under the old definition, `TwistedModule g N M` with $N \geq 2$ forced $M = 0$; in particular the intended Moonshine object on `FockT r` could not exist, and every theorem of the form "for every twisted module with $N \geq 2$ ..." was about the zero space only. The Lean statement is exactly the informal theorem.

Physical meaning

Heuristically this is the observation that a fractional-moded field times an off-coset mode can still land on an allowed mode, producing a spurious relation that kills every state; in the CFT the corresponding terms are multiplied by vanishing coefficients of the field expansion and are absent. The theorem is a statement about the axiom system, not about a physical twisted sector: no physical twisted theory violates it, since in a true twisted sector those instances do not arise.

Proof on paper. Apply the identity with $u = v = \mathbf{1}$ (which lies in V^0, as $g\mathbf{1} = \mathbf{1}$), $j = 0$, $\ell = -1$, $k = 1$ and $m = -N - 1$; that is, $r = 1/N$ and $s = -1 - 1/N$. Note $r \notin \mathbb{Z}$: we are off the support coset of $\mathbf{1}$.

Left side. The i-th term is a difference of two products of vacuum modes. The first product is $\mathbf{1}_{(k_1/N)}\mathbf{1}_{(k_2/N)}x$ with outer numerator $k_1 = (-1)N + 1 - iN = 1 - (i+1)N$ (and $k_2 = -N - 1 + iN$); the second is $\mathbf{1}_{(k_3/N)}\mathbf{1}_{(k_4/N)}x$ with inner numerator $k_4 = 1 + iN$ (and $k_3 = -2N - 1 - iN$). By the vacuum hypothesis $\mathbf{1}_{(k'/N)} \neq 0$ only for $k' = -N$. But $k_1 = -N$ would give $iN = 1$, and $k_4 = -N$ would give $(i+1)N = -1$; both are impossible for an integer i, because $N \geq 2$ does not divide ± 1. So in each product one factor is the zero operator, every term vanishes, and the left side is 0.

Right side. $\mathbf{1}_{(\ell+i)}\mathbf{1} = \mathbf{1}_{(i-1)}\mathbf{1} = \delta_{i,0}\mathbf{1}$. Only $i = 0$ survives, with coefficient $\binom{1/N}{0} = 1$, and the remaining operator is $\mathbf{1}_{((1+(-N-1))/N)} = \mathbf{1}_{(-N/N)} = \mathrm{id}$. So the right side is x.

Hence $0 = x$. □

What the machine verified

`#print axioms VOA.jacobiAllIndices_eq_zero`: `[propext, Classical.choice, Quot.sound]`. Unconditional beyond its stated hypotheses (which are the point). File: `VOA/Moonshine/HeisenbergTwistedModuleDefect.lean`.

Trap / dead end

Recorded dead end (found 2026-10-06). The old `TwistedModule.jacobi` was unsatisfiable on every nonzero M once $N \geq 2$. Certificate: $u = v = \mathbf{1}$, $\ell = -1$, $k = 1$, $m = -N - 1$ gives $0 = x$ (Theorem 34.8). It was discovered when the project first tried to build an *instance* for the twisted Heisenberg algebra: one of the identities to be proved was false. The general lesson for the referee: a structure whose axioms are written in mode form can be inconsistent in a way that no amount of "the definition looks like the textbook" reveals; one needs a nontrivial instance, or a certificate of inconsistency.

34.4.2 The repaired identity

Definition 34.9. TwistedJacobi(g, N, Y_M): identity (34.4) for all $j, u \in V^j, v, x, \ell, m$, and all k *with* $N \mid k + j$.

```
def TwistedJacobi (g : Aut W) (N : ℕ) {M : Type*} [AddCommGroup M] [Module ℂ M]
    (YM : 𝒱 →ₗ[ℂ] (ℤ → End ℂ M)) : Prop :=
  ∀ (j : ℕ) (u : 𝒱), u ∈ g.twistedEigenspace N j → ∀ (v : 𝒱) (x : M) (ℓ k m : ℤ),
    (k + j) % (N : ℤ) = 0 →
    (∑ᶠ i : ℤ, (negOnePow i * cbz ℓ i) •
        (YM u (ℓ * N + k - i * N) (YM v (m + i * N) x)
          - negOnePow ℓ • YM v (ℓ * N + m - i * N) (YM u (k + i * N) x)))
      = ∑ᶠ i : ℕ, cbinom ((k : ℂ) / N) i • YM (W.smul u (ℓ + i) v) (k + m - i * N) x
```

Physical meaning

This is the correct fusion (Jacobi) identity of a twisted sector, written in modes: it restricts the OPE of a charge-j field with another field to those fractional mode numbers k/N that the monodromy permits. The commutator case $\ell = 0$ gives the twisted version of the current algebra, with commutator $[u_{(r)}, v_{(s)}] = \sum_i \binom{r}{i}(u_{(i)}v)_{(r+s-i)}$, whose binomial coefficients with fractional r are the effect of the branch cut.

Proposition 34.10. *The Jacobi field of every* `TwistedModule` *is* TwistedJacobi.

```
theorem twistedJacobi_of_twistedModule {g : Aut W} {N : ℕ} {M : Type u} [AddCommGroup M]
    [Module ℂ M] (T : TwistedModule g N M) : TwistedJacobi g N T.YM :=
  fun j u hu v x ℓ k m hk => T.jacobi j u hu v x ℓ k m hk
```

From the mathematics to the Lean statement

The proof term (shown) passes all arguments to `T.jacobi`: the predicate and the field are literally the same formula. The predicate exists so that later files can state "this mode map satisfies the twisted Jacobi identity" before the rest of a `TwistedModule` has been assembled. Conversely, a mode map with `TwistedJacobi` and the other fields gives a `TwistedModule`; there is no hidden extra condition.

Physical meaning

This says that the physical identity of the twisted sector is exactly the repaired mode identity: the predicate that later files check for a candidate mode map is the one actually carried by every twisted module. It is a consistency statement about definitions, with no further physical content.

What the machine verified

`#print axioms VOA.twistedJacobi_of_twistedModule:` `[propext, Classical.choice, Quot.sound]`. Unconditional.

34.4.3 Why the restriction loses nothing

A referee should ask: by weakening an axiom, did the library make the notion of twisted module too weak, so that a later theorem about twisted modules is now about a larger, unintended class? The answer is no, for two reasons.

First, the restricted identity is the full content of the generating identity. The generating identity (34.2) for $u \in V^j$ is an equality of formal series in z_0, z_1, z_2 whose z_1-exponents correspond to $r \in -\frac{j}{N} + \mathbb{Z}$. An equality of formal series is the equality of all coefficients, and the coefficients that occur are precisely those with r on the coset. So "(34.4) for all r on the coset and all ℓ, s" is equivalent to (34.2). This is exactly how Dong–Li–Mason (and FLM for $N = 2$) state the mode identity. Hence the repaired `TwistedModule` is the textbook notion.

Second, the excluded instances are not consequences of anything. For r off the coset, the left side of (34.4) vanishes identically by the support condition (every term contains a mode $u_{(\ell+r-i)}$ or $u_{(r+i)}$ with index off the coset). The right side, however, involves $(u_{(n)}v)_{(r+s-i)}$. If $v \in V^{j'}$ and s is *off* the coset of v, then $r+s$ may land *on* the coset of $u_{(n)}v \in V^{j+j'}$, and the right side can be nonzero. This is precisely what happens in the certificate ($u = v = \mathbf{1}$, r and s both off $\mathbb{Z}$, $r + s = -1 \in \mathbb{Z}$). In the generating identity those terms come multiplied by coefficients of $Y_M(v, z_2)$ that vanish, so no such relation is implied. The excluded instances therefore assert a relation that the intended objects do not satisfy; demanding them strengthened the definition to inconsistency.

Finally, the repair is minimal: one hypothesis added, the ordinary-module case untouched (Proposition 34.6), and the old form kept in the library (`JacobiAllIndices`) together with its refutation. The equivalence with the generating form is argued on paper here; it is not a Lean theorem.

Trap / dead end

Same defect, not repaired: `SuperTwistedModule`. The super ($\mathbb{Z}/2$-graded) twisted module structure `SuperTwistedModule` in `VOA/Modules/SuperTwistedModule.lean` has a field

```
jacobi : ∀ {p q : ZMod 2} (j : ℕ) (u : V),
  u ∈ g.twistedEigenspace N j → u ∈ W.parity p →
  ∀ (w : V), w ∈ W.parity q → ∀ (x : M) (ℓ k m : ℤ),
  (∑ᶠ i : ℤ, (negOnePow i * cbz ℓ i) •
      (YM u (ℓ * N + k - i * N) (YM w (m + i * N) x)
        - (koszul p q * negOnePow ℓ) •
          YM w (ℓ * N + m - i * N) (YM u (k + i * N) x))) =
    ∑ᶠ i : ℕ, fractionalBinom ((k : ℂ) / N) i •
      YM (W.smul u (ℓ + i) w) (k + m - i * N) x
```

quantified over *every* k, with no coset hypothesis (its support field uses the opposite sign convention, `(k - j) % (N : ℤ) ≠ 0`). The same choice $u = w = \mathbf{1}$ (even, $p = q = 0$, Koszul sign 1), $\ell = -1$, $k = 1$, $m = -N - 1$ gives $0 = x$ by the identical computation, so for $N \geq 2$ no nonzero module satisfies it. This certificate is argued on paper; no Lean theorem states it for

`SuperTwistedModule`. The name occurs in eleven files of the library (its own file included). **Any theorem whose hypotheses include a `SuperTwistedModule` with $N \geq 2$ may be vacuously true.** The repair is a decision left to the maintainers. The Moonshine construction does not use `SuperTwistedModule`.

34.5 The twisted Heisenberg algebra and its Fock space

34.5.1 From integer to half-integer modes

Recall from Chapter 31 the rank-r Heisenberg vertex operator algebra: it is generated by r free bosons $h_i(z) = \sum_{n\in\mathbb{Z}} h_i(n) z^{-n-1}$, $i = 1, \dots, r$, with $[h_i(m), h_j(n)] = m\,\delta_{ij}\delta_{m+n,0}$ (we use the standard form δ_{ij} on $\mathbb{C}^r$). The lift θ of -1 acts by $h_i \mapsto -h_i$, so $h_i \in V^1$ for $N = 2$, and in a θ-twisted module the support condition forces $h_i(z)$ to have modes $h_i(r)$ with $r \in \frac{1}{2} + \mathbb{Z}$. The commutator formula (the case $\ell = 0$ of (34.4), worked out after it) gives

$$[h_i(r), h_j(s)] \;=\; r\,\delta_{ij}\,\delta_{r+s,0}, \qquad r, s \in \tfrac{1}{2} + \mathbb{Z}. \tag{34.5}$$

Definition 34.11 (Twisted Heisenberg algebra)**.** The *θ-twisted Heisenberg algebra* $\hat{\mathfrak{h}}[-1]$ of rank r is the Lie algebra with basis $h_i(r)$ ($1 \leq i \leq r$, $r \in \frac{1}{2} + \mathbb{Z}$) and a central element c, with $[h_i(r), h_j(s)] = r\delta_{ij}\delta_{r+s,0}c$. It has no zero mode: there is no momentum, so no lattice charge can be measured in the twisted sector.

Physical meaning

This is the oscillator algebra of the twisted boson. A free boson $h(z)$ with $\theta h = -h$ is antiperiodic around the twist field, $h(e^{2\pi i}z) = -h(z)$, so its mode expansion runs over half-integers $h(z) = \sum_{r\in\frac{1}{2}+\mathbb{Z}} h(r) z^{-r-1}$ with $[h(r), h(s)] = r\delta_{r+s,0}$. There is no zero mode: an antiperiodic boson has no conserved momentum, because the string coordinate $x \to -x$ is identified, which is why no lattice charge can be measured in the twisted sector.

Its canonical representation is the Fock space: the *annihilation operators* $h_i(n + \frac{1}{2})$, $n \geq 0$, kill a vacuum vector, and the *creation operators* $h_i(-n - \frac{1}{2})$ act freely. Because creation operators commute among themselves, the Fock space is a polynomial ring.

Definition 34.12 (Twisted Fock space)**.** $S[\theta] = S(\hat{\mathfrak{h}}[-1]^-) = \mathbb{C}[x_{n,i} : n \in \mathbb{N},\ 1 \leq i \leq r]$, where $x_{n,i}$ stands for $h_i(-n - \frac{1}{2})\mathbf{1}$; the vacuum is the polynomial 1; $h_i(-n - \frac{1}{2})$ acts as multiplication by $x_{n,i}$ and $h_i(n + \frac{1}{2})$ acts as $(n + \frac{1}{2})\,\partial/\partial x_{n,i}$.

Physical meaning

$S[\theta]$ is the Hilbert space of the antiperiodic (half-integer moded) bosons: states are built from the vacuum by creation operators of frequencies $\frac{1}{2}, \frac{3}{2}, \dots$, exactly the Fock space of r independent harmonic oscillators of half-integral frequency. The vacuum polynomial 1 is the twist-field ground state (without the zero-point shift, which is accounted for by L_0 below), and a monomial in the $x_{n,i}$ is a multi-particle state of oscillator quanta.

The factor $n + \frac{1}{2}$ is forced by (34.5): $[(n + \frac{1}{2})\partial_x, x] = n + \frac{1}{2}$. *Physically*, $x_{n,i}$ is one quantum of the i-th oscillator of frequency $n + \frac{1}{2}$, and a monomial is a multi-particle state.

34.5.2 The Lean model

```
abbrev FockT (r : ℕ) : Type := MvPolynomial (ℕ × Fin r) ℂ

noncomputable def vacT (r : ℕ) : FockT r := 1

def varT {r : ℕ} (i : Fin r) (k : ℤ) : ℕ × Fin r := (((|k| - 1) / 2).toNat, i)

noncomputable def mulXT {r : ℕ} (v : ℕ × Fin r) : Module.End ℂ (FockT r) :=
  Algebra.lmul ℂ (FockT r) (X v)

noncomputable def pderivT {r : ℕ} (v : ℕ × Fin r) : Module.End ℂ (FockT r) :=
  (pderiv v : Derivation ℂ (FockT r) (FockT r)).toLinearMap

noncomputable def modeT (r : ℕ) (i : Fin r) (k : ℤ) : Module.End ℂ (FockT r) :=
  if k % 2 = 0 then 0
  else if k < 0 then mulXT (varT i k)
  else ((k : ℂ) / 2) • pderivT (varT i k)
```

(namespace `VOA.TwistedHeisenberg`, `VOA/Moonshine/TwistedHeisenberg.lean`.)

From the mathematics to the Lean statement

`FockT r`. `MvPolynomial σ ℂ` is the polynomial ring over $\mathbb{C}$ in variables indexed by σ; here $\sigma = \mathbb{N} \times \{0, \dots, r-1\}$ (`Fin r` is the type of the r numbers $0, \dots, r-1$, so the colour index runs from 0, not 1). The variable `X (n, i)` is $x_{n,i}$ of Definition 34.12. It is an `abbrev`, so it is the polynomial ring itself, with its vector-space structure.

Odd-integer indexing. `modeT r i k` is the mode $h_i(k/2)$. Only odd k are meaningful (they give $k/2 \in \frac{1}{2} + \mathbb{Z}$). `varT i k` is the variable with index $n = (|k| - 1)/2$: for $k = -(2n+1)$ it is the variable created by $h_i(-n - \frac{1}{2})$, for $k = 2n+1$ the variable differentiated by $h_i(n + \frac{1}{2})$. `mulXT v` is multiplication by X_v; `pderivT v` is $\partial/\partial X_v$. For odd $k < 0$, `modeT` is multiplication by $x_{n,i}$; for odd $k > 0$ it is $\frac{k}{2}\,\partial/\partial x_{n,i} = (n + \frac{1}{2})\partial_{x_{n,i}}$. Both agree with Definition 34.12.

Even k: a junk value. For even k (integral modes), `modeT` returns 0. This is a convention, not a theorem: the twisted Heisenberg algebra has no integral modes, and the value 0 is exactly what the support condition (iii) of a θ-twisted module demands for $u = h_i \in V^1$ at k even (`(k + 1) % 2 ≠ 0`). So in the twisted module of Chapter 35 the even modes must be 0, and the convention is the correct one. This also matches `TwistedModule.YM u k` $= u_{(k/N)}$ with $N = 2$. (One could instead restrict k to odd integers by a subtype; that would complicate every statement that adds or negates mode indices, and the junk-value convention is equivalent because it coincides with what the support condition forces.)

What the machine verified

These are definitions. Lemmas `modeT_even`, `modeT_neg`, `modeT_pos`, `modeT_creation` ($h_i(-(2n+1)/2)p = x_{n,i}p$) and `modeT_annihilation` ($h_i((2n+1)/2)p = \frac{2n+1}{2}\partial_{x_{n,i}}p$) restate the three cases; all proved, unconditional.

34.5.3 The commutation relations

Theorem 34.13. *For odd integers k, l and colours i, j, $[h_i(k/2), h_j(l/2)] = \frac{k}{2}\,\delta_{ij}\,\delta_{k+l,0}\,\mathrm{id}$ on $S[\theta]$.*

```
theorem modeT_comm (r : ℕ) (i j : Fin r) {k l : ℤ} (hk : Odd k) (hl : Odd l) :
    modeT r i k * modeT r j l - modeT r j l * modeT r i k
      = (if i = j ∧ k + l = 0 then (k : ℂ) / 2 else 0) • LinearMap.id
```

From the mathematics to the Lean statement

Products of endomorphisms ($*$) are compositions, so the left side is the commutator. `LinearMap.id` is the identity operator; the scalar is $k/2$ exactly when $i = j$ and $k + l = 0$, i.e. $r = k/2$, $s = l/2 = -r$. This is (34.5) with $c = 1$. Hypotheses: k, l odd; they are necessary, because for even k the junk value 0 would make the left side 0 while the right side would not vanish at $k = -l \neq 0$ even. Same as the textbook statement.

Physical meaning

This is the canonical commutation relation of the antiperiodic boson, the half-integral analogue of $[\alpha_m, \alpha_n] = m\delta_{m+n,0}$. It encodes the double-pole OPE $h(z)h(w) \sim 1/(z-w)^2$ in the presence of the twist field: the singular part is unchanged, only the mode numbers are shifted to $\frac{1}{2} + \mathbb{Z}$. The oscillators are independent, one family of half-integer frequencies per colour.

Proof on paper. Four cases by the signs of k and l. Two creation operators are multiplications and commute. Two annihilation operators are multiples of partial derivatives and commute. For one creation x_v and one annihilation $\frac{l}{2}\partial_w$, the Leibniz rule gives $[\partial_w, x_v] = \delta_{vw}$, and $v = w$ happens precisely when $i = j$ and $|k| = |l|$, i.e. $k = -l$; the scalar is $\frac{l}{2} \cdot (-1) = \frac{k}{2}$ or $\frac{k}{2} \cdot 1$ according to the order. □

What the machine verified

`#print axioms VOA.TwistedHeisenberg.modeT_comm:` `[propext, Classical.choice, Quot.sound]`. Unconditional.

Proposition 34.14 (Vacuum and cyclicity). *Every positive mode kills the vacuum, and $S[\theta]$ is spanned by creation words applied to the vacuum.*

File `VOA/Moonshine/TwistedHeisenberg.lean`.

```
theorem modeT_vacT (r : ℕ) (i : Fin r) {k : ℤ} (hk : 0 < k) : modeT r i k (vacT r) = 0
```

File `VOA/Moonshine/TwistedHeisenberg.lean`.

```
noncomputable def creationWordT (r : ℕ) (l : List (ℕ × Fin r)) : Module.End ℂ (FockT r) :=
  (l.map fun v => modeT r v.2 (-(2 * v.1 + 1))).prod
```

File `VOA/Moonshine/TwistedHeisenberg.lean`.

```
theorem span_creationWordT_vacT (r : ℕ) :
    Submodule.span ℂ (Set.range fun l => creationWordT r l (vacT r)) = ⊤
```

From the mathematics to the Lean statement

`creationWordT r [(n₁,i₁),…,(nₘ,iₘ)]` is the composite $h_{i_1}(-n_1 - \frac{1}{2}) \cdots h_{i_m}(-n_m - \frac{1}{2})$ (a list product of operators; the empty list gives the identity). `Submodule.span ℂ S = ⊤` says the linear span of S is the whole space. So the theorem states that the vectors $h_{i_1}(-n_1 - \frac{1}{2}) \cdots \mathbf{1}$ span $S[\theta]$; in polynomial language, monomials span the polynomial ring. The first statement holds for every $k > 0$, odd or even (for even k trivially, by the junk value).

Physical meaning

The first statement is the defining property of a ground state: positive-frequency (annihilation) modes kill the twist-field vacuum, which is the lowest-energy state of the twisted sector. The

second says that every state is a finite excitation of this vacuum by creation operators, so the Fock space is the irreducible oscillator module on the twist-field ground state, with no other primary states in the oscillator sector.

What the machine verified

Both proved, unconditional (the span is generated because each creation word on 1 is a monomial).

34.5.4 The L_0-grading and the vacuum weight $r/16$

The physics of $r/16$. In the untwisted Heisenberg theory the vacuum has $L_0 = 0$. In the twisted sector the vacuum energy is shifted. A heuristic computation: L_0 is $\sum_i \sum_{n\ge 0} h_i(-n-\frac{1}{2})h_i(n+\frac{1}{2})$ plus a normal-ordering constant, and the constant is the zero-point energy of r oscillators of frequencies $n+\frac{1}{2}$, $\frac{r}{2}\sum_{n\ge 0}(n+\frac{1}{2})$, regularised by the Hurwitz zeta function: $\zeta(-1,\frac{1}{2}) = -\frac{1}{2}B_2(\frac{1}{2}) = \frac{1}{24}$, giving $\frac{r}{48}$; the untwisted regularised value is $\frac{r}{2}\zeta(-1) = -\frac{r}{24}$. Measured from the untwisted vacuum, the shift is $\frac{r}{48}+\frac{r}{24} = \frac{r}{16}$. FLM obtain the same constant rigorously from the twisted vertex operator of ω (the operator Δ_z of their Chapter 9), and in this library the identification is proved in Chapter 35, where the twisted field of ω has zero mode `L0T`. For the Leech lattice ($r = 24$), $r/16 = 3/2$: the twisted ground states have weight $\frac{3}{2}$; since θ will act on them by -1, none survive in $V^\natural$, which is one reason $V^\natural{}_1 = 0$.

The grading. Give $x_{n,i}$ *doubled* weight $2n+1$ (so that weights stay in $\mathbb{N}$); a monomial has doubled weight the sum of those of its variables; and the doubled weight d corresponds to L_0-eigenvalue $d/2 + r/16$.

```
noncomputable def weightT (r : ℕ) (q : ℚ) : Submodule ℂ (FockT r) :=
  ⨆ (d : ℕ) (_ : levelT r d = q), gradingT r d
```

From the mathematics to the Lean statement

`weightedHomogeneousSubmodule ℂ w d` is Mathlib's space of polynomials all of whose monomials $\prod X_v^{m_v}$ have weighted degree $\sum_v m_v w(v) = d$. An exponent vector is a finitely supported function $m : \sigma \to \mathbb{N}$ (Lean $\sigma \to_0 \mathbb{N}$), and `Finsupp.weight wT m` is $\sum_v m_v\,\mathrm{wT}(v)$. So `gradingT r d` is the span of monomials of doubled weight d, `degSetT r d` the set of their exponent vectors. `levelT r d` is $d/2 + r/16 \in \mathbb{Q}$. `weightT r q` is the supremum (sum) of the `gradingT r d` over all d with $d/2 + r/16 = q$; since $d \mapsto d/2 + r/16$ is injective there is at

most one such d, so `weightT r q` is $S[\theta]_d$ if $q = d/2 + r/16$ and 0 otherwise (`weightT_levelT`, `weightT_eq_bot`). The index q is rational, whereas `TwistedModule.weight` is indexed by $\mathbb{C}$; the passage is made in Chapter 35.

Theorem 34.15 (Structure of the grading). *(a)* $S[\theta] = \bigoplus_{q\in\mathbb{Q}} S[\theta]_q$ *with each* $S[\theta]_q$ *finite-dimensional; (b)* $\dim S[\theta]_{(d)}$ *is the number of exponent vectors of doubled weight* d*; (c)* $S[\theta]_{r/16} = \mathbb{C}\cdot 1$*; (d)* $\dim S[\theta]_{r/16+1/2} = r$*; (e)* $S[\theta]_q = 0$ *for* $q < r/16$.

File `VOA/Moonshine/TwistedHeisenberg.lean`.

```
theorem weightT_eq_bot_of_lt {r : ℕ} {q : ℚ} (hq : q < (r : ℚ) / 16) : weightT r q = ⊥
```

From the mathematics to the Lean statement

`DirectSum.IsInternal` is the internal direct sum (as in `TwistedModule`). `FiniteDimensional ℂ (weightT r q)` is an `instance`: a theorem registered for automatic use, here the finite-dimensionality of every piece. `Module.finrank ℂ V` is the dimension of V (a natural number, 0 for infinite-dimensional spaces; here all are finite). `Nat.card` is the cardinality of a finite set. `ℂ • vacT r` is the line spanned by the vacuum. `⊥` is the zero subspace. All six statements are exactly (a)–(e). Could (d) be vacuous or trivial? No: it computes a genuine dimension, and (b) shows the dimension is the combinatorial count one expects.

Physical meaning

The grading is the energy spectrum of the antiperiodic bosons: a quantum of the oscillator $h_i(-n-\frac{1}{2})$ carries energy $n+\frac{1}{2}$, so the energy levels are $r/16 + d/2$ with d the doubled weight, and the degeneracy of the d-th level counts multi-oscillator states; its generating function $\prod_n (1-t^{2n+1})^{-r}$ is the oscillator partition function of r antiperiodic bosons. The lowest level $r/16$ is the twist-field ground state, non-degenerate in the oscillator sector, and the first excited level (energy $+\frac{1}{2}$) is the r single-quantum states of the lowest mode. For the Leech case the ground state sits at weight $24/16 = 3/2$, as quoted in the physics paragraph above.

Proof on paper. Monomials form a basis of a polynomial ring; each has a doubled weight, so the ring is the direct sum of the spans of monomials of fixed doubled weight, and the dimension is the number of such monomials. A variable of index n has weight $2n+1 \geq 1$, so there are finitely many monomials of weight d (each exponent is $\leq d$ and only variables with $n < d$ occur). Weight 0: only the constant monomial. Weight 1: only the r variables $x_{0,i}$. Negative weights do not occur. □

What the machine verified

All proved; `#print axioms` for `weightT_vacuum` and `finrank_weightT_half`: `[propext, Classical.choice, Quot.sound]`. Unconditional.

Example 34.16 (Graded dimensions). The generating function is $\sum_d \dim S[\theta]_{(d)}\, t^d = \prod_{n\geq 0}(1-t^{2n+1})^{-r}$. For $r = 1$ the coefficients are the numbers of partitions into odd parts, $1, 1, 1, 2, 2, 3, 4, 5, 6, 8, 10, \ldots$. For $r = 24$, by a direct expansion (computed for this chapter, not a Lean theorem):

d	0	1	2	3	4	5	6
L_0	$\frac{3}{2}$	2	$\frac{5}{2}$	3	$\frac{7}{2}$	4	$\frac{9}{2}$
$\dim S[\theta]_{(d)}$	1	24	300	2624	18126	105504	538296

For instance $300 = \binom{25}{2}$ (quadratic monomials in the 24 variables $x_{0,i}$), and $2624 = \binom{26}{3} + 24$ (cubics in $x_{0,i}$, plus the 24 variables $x_{1,i}$ of doubled weight 3). Tensoring with the 4096-dimensional T and keeping the θ-fixed part, the weight-2 piece of $(V_\Lambda^T)^+$ is $24 \cdot 4096 = 98304$-dimensional (the oscillator number is odd and $\theta = -1$ on T), which together with $\dim(V_\Lambda^+)_2 = 98580$ gives 196884. These facts are proved in later chapters.

34.5.5 The involution θ on $S[\theta]$

The lift of -1 satisfies $\theta h_i(t)\theta^{-1} = -h_i(t)$; on $S[\theta]$ it is the algebra automorphism negating every variable, i.e. $(-1)^{\text{number of oscillators}}$. File `VOA/Moonshine/TwistedHeisenberg.lean`.

```
theorem thetaT_of_mem_gradingT_one {r : ℕ} {p : FockT r} (hp : p ∈ gradingT r 1) :
    thetaT r p = -p
```

From the mathematics to the Lean statement

`aeval f` is the unique algebra homomorphism of the polynomial ring sending $X_v \mapsto f(v)$; here $X_v \mapsto -X_v$. `≃ₐ[ℂ]` is an algebra automorphism; `AlgEquiv.ofAlgHom` builds it from the homomorphism and its inverse (itself), with the proofs that both composites are the identity. `monomial m c` is cX^m; `m.degree` is $\sum_v m_v$, the number of oscillators (not the doubled weight). `coeff m p` is the coefficient of X^m in p. So (a), (b), (c) are literally the Lean statements. The anticommutation (b) holds for every k (for even k both sides are 0).

Physical meaning

The operator θ is the $\mathbb{Z}_2$ symmetry of the twisted sector under which the antiperiodic bosons are odd, $h \mapsto -h$, i.e. $(-1)^F$ with F the oscillator number. Keeping only the θ-even states is the orbifold projection: odd-number-of-oscillator states are projected out in the plus sector. The weight-$\frac{r}{16} + \frac{1}{2}$ states (one oscillator) are θ-odd, which is the Fock-space side of the fact that the twisted sector contributes no weight-one states to $V^\natural$ and hence $V^\natural{}_1 = 0$.

Proof on paper. (a) is immediate from $X_v \mapsto -X_v$. (b): multiplication by X_v anticommutes with θ since $\theta(X_v p) = -X_v \theta p$; for ∂_w, the conjugate $\theta \partial_w \theta^{-1}$ is again a derivation, and it sends X_v to $\theta(\partial_w(-X_v)) = -\delta_{vw}$, so it equals $-\partial_w$. (c) compares coefficients using (a). □

What the machine verified

All proved; `#print axioms VOA.TwistedHeisenberg.thetaT_eq_self_iff`: `[propext, Classical.choice, Quot.sound]`. Unconditional. That `thetaT` is the restriction of an automorphism of the twisted module (a statement involving V) is a matter for Chapters 35–36; here θ is an operator on $S[\theta]$ alone.

34.5.6 The operator L_0

File `VOA/Moonshine/TwistedHeisenberg.lean`.

```
noncomputable def eulerT (r : ℕ) : Derivation ℂ (FockT r) (FockT r) :=
  mkDerivation ℂ fun v => ((wT v : ℕ) : ℂ) • (X v : FockT r)
```

File `VOA/Moonshine/TwistedHeisenberg.lean`.

```
noncomputable def L0T (r : ℕ) : Module.End ℂ (FockT r) :=
  (1 / 2 : ℂ) • (eulerT r).toLinearMap + ((r : ℂ) / 16) • LinearMap.id
```

Definition 34.18. Let E be the derivation of $S[\theta]$ with $E(x_{n,i}) = (2n+1)x_{n,i}$ (the weighted Euler operator; it multiplies a monomial by its doubled weight). Put $L_0 = \frac{1}{2}E + \frac{r}{16}$.

From the mathematics to the Lean statement

`mkDerivation ℂ f` is the unique $\mathbb{C}$-linear derivation of the polynomial ring with $X_v \mapsto f(v)$; here $f(v) = \mathrm{wT}(v)X_v$. It is well defined although the would-be formula $\sum_v \mathrm{wT}(v)X_v\partial_v$ is an infinite sum, because on each polynomial only finitely many terms act. `.toLinearMap` forgets the derivation property. Thus `L0T` is Definition 34.18. *Caution:* `L0T` is defined, not derived; that it is the zero mode $\omega_{(1)}$ of the twisted field of ω is a theorem of Chapter 35 (`YT_omega_two`). A wrong constant here would be caught there.

Physical meaning

L_0 is the Hamiltonian of the twisted sector on the cylinder, with the oscillator part $\frac{1}{2}E = \sum_{n,i}(n+\frac{1}{2})\,x_{n,i}\partial_{x_{n,i}}$ (frequency times number operator) and the constant $r/16$ coming from the Casimir (zero-point) energy of the antiperiodic bosons; the Hurwitz-zeta heuristic of the previous subsection gives $r/48 + r/24 = r/16$. Here the constant is put in by hand; it is identified with the Virasoro zero mode only in Chapter 35, which is the rigorous counterpart of the regularisation argument.

Theorem 34.19. *(a) L_0 acts on $S[\theta]_q$ by q; (b) $L_0 p = \sum_{v\in\mathrm{vars}(p)} h_v(-n-\frac{1}{2})h_v(n+\frac{1}{2})p + \frac{r}{16}p$ (the normal-ordered mode sum); (c) $[L_0, h_i(k/2)] = -\frac{k}{2}h_i(k/2)$.*

File `VOA/Moonshine/TwistedHeisenberg.lean`.

```

```
theorem L0T_eq_modeSum (r : ℕ) (p : FockT r) :
    L0T r p = ∑ v ∈ p.vars, modeT r v.2 (-(2 * v.1 + 1)) (modeT r v.2 (2 * v.1 + 1) p)
      + ((r : ℂ) / 16) • p
```

File `VOA/Moonshine/TwistedHeisenberg.lean`.

```
theorem L0T_comm_modeT (r : ℕ) (i : Fin r) (k : ℤ) :
    L0T r * modeT r i k - modeT r i k * L0T r = -((k : ℂ) / 2) • modeT r i k
```

From the mathematics to the Lean statement

`(q : ℂ)` is the rational q viewed as a complex number. `p.vars` is the finite set of variables occurring in p; for $v = (n, i)$, `modeT r v.2 (-(2 * v.1 + 1))` is $h_i(-n-\frac{1}{2})$ and `modeT r v.2 (2 * v.1 + 1)` is $h_i(n+\frac{1}{2})$. The textbook formula sums over all (n, i); variables not occurring in p contribute $h(n+\frac{1}{2})p = 0$, so restricting to `p.vars` is the same. In (c), k is arbitrary (for even k both sides vanish); for odd k, mode $h_i(k/2)$ lowers L_0 by $k/2$, as a mode of a weight-one field must.

Physical meaning

The three statements are the standard properties of a free-field Hamiltonian: it acts on energy eigenstates by their energy, equals the normal-ordered sum of frequency times number of quanta plus the vacuum (Casimir) energy $r/16$, and each mode $h(k/2)$ shifts the energy by $-k/2$ (creation operators raise energy, annihilation operators lower it). Together they say that the twisted Fock space is a genuine positive-energy representation of the Virasoro algebra with ground state weight $r/16$; for $r = 24$, weight $3/2$, the twist-field dimension of 24 antiperiodic bosons.

Proof on paper. (a) Euler's identity: E multiplies weighted-homogeneous polynomials of doubled weight d by d, so L_0 acts by $d/2+r/16 = q$. (b) $x_v\cdot(n+\frac{1}{2})\partial_v = \frac{1}{2}(2n+1)x_v\partial_v$, and $\sum_v(2n+1)x_v\partial_v = E$. (c) $[E, x_v] = (2n+1)x_v$ and $[E, \partial_v] = -(2n+1)\partial_v$. □

What the machine verified

`#print axioms` for `L0T_of_mem_weightT` and `L0T_comm_modeT`: `[propext, Classical.choice, Quot.sound]`. Unconditional.

34.6 Extraspecial 2-groups and twisted group algebras

34.6.1 Why a finite group appears

In the untwisted lattice theory $V_L = S(\hat{\mathfrak{h}}^-) \otimes \mathbb{C}[L]$ (Chapter 31), the factor $\mathbb{C}[L]$ (more precisely the twisted group algebra $\mathbb{C}^\varepsilon[L]$) records the momentum α of a state e^α: the zero mode $h(0)$ measures it. In the twisted sector there is no zero mode, and the operators e^α no longer act diagonally. What survives is the *central extension* $\hat{L}$ of L by $\{\pm 1\}$ in which $e_\alpha e_\beta = \varepsilon(\alpha,\beta)e_{\alpha+\beta}$, acting on a space T on which, roughly, $e_{2\alpha}$ acts trivially (it is "invisible" to an observer who cannot distinguish x from $-x$). So T is a representation of a finite quotient of $\hat{L}$, of order $2 \cdot |L/2L| = 2^{1+\operatorname{rank} L}$, and the commutator $e_\alpha e_\beta e_\alpha^{-1} e_\beta^{-1} = (-1)^{\langle\alpha,\beta\rangle}$ makes that group *extraspecial*. Physically, T is the space of ground states of the twisted string: the 2^{24} fixed points of $x \mapsto -x$ on the torus $\mathbb{R}^{24}/\Lambda$ (one for each class in $\frac{1}{2}\Lambda/\Lambda$), reorganised; its dimension $2^{12} = \sqrt{2^{24}}$ is the square root of the number of fixed points, as one expects from a Heisenberg-type group acting irreducibly.

34.6.2 Extraspecial groups: the facts we need

A finite 2-group G is *extraspecial* if its centre Z, its commutator subgroup and its Frattini subgroup coincide and have order 2. Then $\bar{G} = G/Z$ is an $\mathbb{F}_2$-vector space of even dimension $2m$; the commutator $[a,b] \in Z \cong \mathbb{F}_2$ defines a nondegenerate alternating form on $\bar{G}$, and $|G| = 2^{1+2m}$. Every irreducible complex representation of G on which Z acts nontrivially ("faithful") is isomorphic to a unique one, of dimension 2^m. This is the finite analogue of the Stone–von Neumann theorem. The library does *not* define extraspecial groups; it works with the equivalent algebra.

Definition 34.20 (Twisted group algebra)**.** Let $V = \mathbb{F}_2^n$ and let $c : V \times V \to \{\pm 1\}$ be bimultiplicative. The *twisted group algebra* $\mathbb{C}^c[V]$ has basis $\{e_x\}_{x \in V}$ and product $e_x e_y = c(x,y)e_{x+y}$.

Physical meaning

$\mathbb{C}^c[V]$ is the algebra of the zero modes of the twisted sector: the operators e_x implement translations of the ground state by the half-lattice vector $x/2$, and the cocycle c records the nontrivial signs $(-1)^{\langle\alpha,\beta\rangle}$ in their commutation relations. Since the antiperiodic boson has no momentum, these operators do not diagonalise; instead they generate a finite Heisenberg-type algebra (Clifford algebra for the associated extraspecial 2-group) acting on the twist-field ground states. The mod-2 structure reflects that α and $-\alpha$ are indistinguishable once x is identified with $-x$.

A representation of the central extension $\hat{V} = \{\pm e_x\}$ in which -1 acts as -1 is the same thing as a $\mathbb{C}^c[V]$-module, so "faithful irreducible representations of the extraspecial group" are "simple $\mathbb{C}^c[V]$-modules". The commutator $e_x e_y = c(x,y)c(y,x)e_y e_x$ is governed by the alternating form $\omega(x,y)$ with $(-1)^{\omega(x,y)} = c(x,y)c(y,x)$.

34.6.3 The library's construction

The library takes $c(x,y) = (-1)^{x \cdot My}$ for a matrix M over $\mathbb{F}_2 = \texttt{ZMod 2}$ and realises $\mathbb{C}^c[V]$ inside the endomorphisms of the space of functions $V \to \mathbb{C}$ (the left regular representation), which makes the associativity and unit axioms automatic.

```
noncomputable def sgn (z : ZMod 2) : ℂ := (-1 : ℂ) ^ z.val

noncomputable def coc (x y : Fin n → ZMod 2) : ℂ := sgn (x ⬝ᵥ (M *ᵥ y))

theorem coc_comm (x y : Fin n → ZMod 2) :
    coc M x y * coc M y x = sgn (x ⬝ᵥ ((M + Mᵀ) *ᵥ y))

noncomputable def op (x : Fin n → ZMod 2) : Module.End ℂ ((Fin n → ZMod 2) → ℂ) where
  toFun g y := coc M x (x + y) * g (x + y)

theorem op_mul (x y : Fin n → ZMod 2) : op M x * op M y = coc M x y • op M (x + y)

noncomputable def alg : Subalgebra ℂ (Module.End ℂ ((Fin n → ZMod 2) → ℂ)) :=
  (Submodule.span ℂ (Set.range (op M))).toSubalgebra

theorem finrank_alg : Module.finrank ℂ (alg M) = 2 ^ n
```

(namespace `VOA.Moonshine.Extraspecial`, `VOA/Moonshine/ExtraspecialModule.lean`; the two-line excerpts of `op` and `alg` are their headers, the remaining lines being the linearity and closure proofs.)

From the mathematics to the Lean statement

`sgn z` is $(-1)^z$ for $z \in \mathbb{F}_2$ (`z.val` is the representative 0 or 1). `Fin n → ZMod 2` is $V = \mathbb{F}_2^n$; `x ⬝ᵥ y` is the dot product and `M *ᵥ y` the matrix–vector product, so `coc M x y` $= (-1)^{x^{\mathsf T} M y} = c(x,y)$; it is bimultiplicative (`coc_add_left`, `coc_add_right`) and `coc_comm` says the commutator form is $\omega(x,y) = x^{\mathsf T}(M + M^{\mathsf T})y$. `op M x` is the operator $(e_x g)(y) = c(x,x+y)g(x+y)$ on functions $g : V \to \mathbb{C}$, so that $e_x \delta_z = c(x,z)\delta_{x+z}$; `op_mul` is $e_x e_y = c(x,y)e_{x+y}$. `alg M` is the linear span of the e_x, which `op_mul` shows is closed under products, made into a subalgebra; `finrank_alg` says the 2^n operators e_x are linearly independent. Hence `alg M` is $\mathbb{C}^c[V]$ of Definition 34.20.

What the machine verified

All proved, unconditional.

Example 34.21 ($n = 2$: the Pauli matrices). Take $M = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}$, so $c(x,y) = (-1)^{x_1 y_0}$ and $M + M^{\mathsf T} = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$ is invertible. Then $e_{(1,0)}^2 = e_{(0,1)}^2 = 1$, $e_{(1,1)}^2 = c((1,1),(1,1)) = -1$, and $e_{(1,0)}e_{(0,1)} = -e_{(0,1)}e_{(1,0)}$. The assignment $e_{(1,0)} \mapsto \sigma_x$, $e_{(0,1)} \mapsto \sigma_z$, $e_{(1,1)} \mapsto \sigma_x\sigma_z$ is an isomorphism $\mathbb{C}^c[\mathbb{F}_2^2] \cong M_2(\mathbb{C})$, and $T = \mathbb{C}^2$. The group $\{\pm 1, \pm\sigma_x, \pm\sigma_z, \pm\sigma_x\sigma_z\}$ is the dihedral group of order 8, the smallest extraspecial 2-group. The general case is a tensor product of m such blocks (up to the quaternion/dihedral distinction, which is the Arf invariant of §34.8).

34.6.4 Simplicity and Wedderburn–Artin

Theorem 34.22. *If $M + M^{\mathsf T}$ is invertible over $\mathbb{F}_2$, then $\mathbb{C}^c[V]$ is a simple ring (its only two-sided ideals are 0 and itself).*

```
theorem isSimpleRing_alg (hN : IsUnit (M + Mᵀ).det) : IsSimpleRing (alg M)
```

From the mathematics to the Lean statement

`IsUnit (M + Mᵀ).det` says the determinant of $M + M^{\mathsf T}$ is a unit of `ZMod 2`, i.e. equals 1: the commutator form is nondegenerate. `IsSimpleRing R` is Mathlib's notion: R is nontrivial and its only two-sided ideals are $\bot$ and $\top$. Same as the theorem. The hypothesis is necessary: if ω

is degenerate, a radical vector x gives a central e_x and the ideal generated by $e_x \mp \lambda$ is proper.

Physical meaning

Simplicity of the twisted group algebra says that the commutator pairing on V (the sign $(-1)^{\langle\alpha,\beta\rangle}$) is nondegenerate, so the zero-mode algebra is a full matrix algebra and has a unique irreducible representation. Physically, the ground-state space of the twisted sector is then forced: there is exactly one irreducible way for the zero modes of the twisted boson to act, which is the analogue of the Stone–von Neumann theorem for a finite Heisenberg group. This uniqueness is what makes the twisted sector of the Leech lattice theory unique (Frenkel–Lepowsky–Meurman).

Proof on paper. The key identity: $c(w,w)\,e_w e_v e_w = (-1)^{\omega(w,v)} e_v$ (`op_conj`). For $f = \sum_v f_v e_v$, averaging gives $\sum_w c(w,w) e_w f e_w = \sum_v f_v \big(\sum_w (-1)^{\omega(w,v)}\big) e_v = 2^n f_0 \cdot 1$, because by character orthogonality $\sum_w (-1)^{\omega(w,v)}$ is 2^n for $v = 0$ and 0 otherwise, using nondegeneracy ($\omega(\cdot, v) \neq 0$ for $v \neq 0$). Given a nonzero a in an ideal I, pick v_0 with $a_{v_0} \neq 0$; then $b = e_{v_0} a \in I$ has $b_0 = \pm a_{v_0} \neq 0$, and the average of b, which lies in I, is the nonzero scalar $2^n b_0$; so $1 \in I$. □

What the machine verified

`#print axioms VOA.Moonshine.Extraspecial.isSimpleRing_alg`: `[propext, Classical.choice, Quot.sound]`. Unconditional apart from the displayed hypothesis.

Theorem 34.23 (Dimension of the simple module). *Under the same hypothesis, $\mathbb{C}^c[V] \cong M_k(\mathbb{C})$ with $k^2 = 2^n$; hence n is even and $k = 2^{n/2}$. Put $T = \mathbb{C}^k$ with $\mathbb{C}^c[V]$ acting through this isomorphism. Then T is a simple module of dimension $2^{n/2}$, and every simple $\mathbb{C}^c[V]$-module is isomorphic to T.*

```

File `VOA/Moonshine/ExtraspecialModule.lean`.

```
theorem even_of_isUnit (hN : IsUnit (M + Mᵀ).det) : Even n
```

From the mathematics to the Lean statement

`exists_matrix M hN` is the statement $\exists k,\ 2^n = k \cdot k\wedge$ there is an algebra isomorphism `alg M ≃ₐ[ℂ] Matrix (Fin k) (Fin k) ℂ`; `.choose` picks such a k (`repDim`) and `.some` such an isomorphism, which composed with `Matrix.toLinAlgEquiv'` (matrices = endomorphisms of $\mathbb{C}^k$) gives `repEquiv`. So T = `Rep M hN` $= \mathbb{C}^k$ and A acts via `repEquiv` (the module instance, defined right after, is $a \cdot t = \mathrm{repEquiv}(a)(t)$). `IsSimpleModule` means nonzero with no proper nonzero submodule. `Nonempty (S ≃ₗ[alg M] Rep M hN)` states the existence of an A-linear isomorphism $S \cong T$, for every type S with a simple A-module structure. T **is abstract**: it is $\mathbb{C}^k$ with an action obtained by choice from Wedderburn–Artin, not an explicit model (such as functions on a maximal isotropic subspace or on the Golay code). Every statement about T in the library is invariant under the choice, because of the uniqueness theorem; but no basis of T is computable.

Physical meaning

The dimension $2^{n/2}$ is the ground-state degeneracy of the twisted sector. Heuristically, the 2^{24} fixed points of the reflection $x \mapsto -x$ on the torus $\mathbb{R}^{24}/\Lambda$ (the half-lattice points $\frac{1}{2}\Lambda/\Lambda$) would each support a twist-field ground state, but the zero modes e_α and their conjugates do not commute, so only a Lagrangian half of them can be diagonalised at once; the irreducible module is $2^{12} = \sqrt{2^{24}}$-dimensional. In the language of a Clifford algebra, $n = 24$ real generators e_α (modulo signs) form a Clifford algebra with irreducible module of dimension 2^{12}. The parity of n is the familiar fact that a nondegenerate alternating form lives in even dimension.

Proof on paper. A finite-dimensional simple algebra over the algebraically closed field $\mathbb{C}$ is a full matrix algebra $M_k(\mathbb{C})$ (Wedderburn–Artin; Mathlib's `IsSimpleRing.exists_algEquiv_matrix_of_isAlgClosed`). Comparing dimensions, $k^2 = \dim A = 2^n$, so 2^n is a perfect square, n is even and $k = 2^{n/2}$. $\mathbb{C}^k$ is a simple $M_k(\mathbb{C})$-module (any nonzero vector generates), and over a simple artinian ring all simple modules are isomorphic. The parity statement `even_of_isUnit` is the familiar fact that a nondegenerate alternating form lives in even dimension, obtained here as a by-product. □

34.7 The lattice: $L/2L$, the cocycle, and the module T

34.7.1 Recollection: lattices and the cocycle

An `IntegralLattice` (Chapter 30) is a free $\mathbb{Z}$-module of finite rank with a symmetric $\mathbb{Z}$-valued bilinear form $\langle\cdot,\cdot\rangle$; it is *even* if $\langle v, v\rangle \in 2\mathbb{Z}$ for all v: File `VOA/Foundations/Lattices.lean`.

```
def Even : Prop := ∀ v : L.carrier, 2 ∣ L.form v v
```

The library's cocycle (Chapter 31) is defined from a chosen basis $B_1, \dots, B_n$ of L (`latticeBasis L`, obtained by choice) as $\varepsilon(\alpha,\beta) = (-1)^{\sum_{j<i}\langle B_i,B_j\rangle\alpha_i\beta_j}$, where α_i, β_j are coordinates: File `VOA/Foundations/LatticeCocycle.lean`.

```
noncomputable def cocExp (α β : L.carrier) : ℤ :=
  ∑ i : Fin n, ∑ j : Fin n,
    (if j < i then L.form (B i) (B j) else 0) * B.repr α i * B.repr β j
```

File VOA/Foundations/LatticeCocycle.lean.

```
noncomputable def latticeCocycle (α β : L.carrier) : ℂ := cocycle L (latticeBasis L) α β
```

with `cocycle L B α β = (-1 : ℂ) ^ (cocExp L B α β)`. It is bimultiplicative, ± 1-valued, and $\varepsilon(\alpha,\beta)\varepsilon(\beta,\alpha) = (-1)^{\langle\alpha,\beta\rangle}$ for even L (`latticeCocycle_comm`).

```
theorem isUnit_det_cocMat (hEven : L.Even) (hU : IsUnit (gramMat L).det) :
    IsUnit (cocMat L + (cocMat L)ᵀ).det
```

From the mathematics to the Lean statement

`L.bRank` is the size of the chosen basis (equal to the rank, `bRank_eq_rank`). `gramMat L` is the Gram matrix $(\langle B_i, B_j\rangle)$; `cocMat L` its strictly lower-triangular part reduced mod 2 (the (i,j) entry for $j<i$). `red L` is the additive map (`→+`) sending α to its coordinates mod 2. `2 • γ` is 2γ. `IsUnit (gramMat L).det` over $\mathbb{Z}$ means $\det = \pm 1$, i.e. L unimodular. Statements (a), (b), (c) are exactly the theorem; the cocycle identity holds for every L (evenness is not needed for descent, only for (c)).

Physical meaning

The key point is that the zero-mode algebra depends on a lattice vector only modulo $2L$: the operator $e_{\alpha+2\gamma}$ coincides with e_α on the twisted ground states because translation by a full lattice vector γ acts trivially after the identification $x \sim -x$ and the periodicity of the torus. So the twisted sector sees only the finite group $L/2L$ (rather than L), whose commutator form is the nondegenerate pairing $(-1)^{\langle\alpha,\beta\rangle}$ for an even unimodular lattice; this is the extraspecial 2-group 2^{1+n} in disguise. The proposition is the algebraic expression of this descent.

Proof on paper. (a) Coordinates mod 2. (b) The exponent $\sum_{j<i}\langle B_i, B_j\rangle\alpha_i\beta_j$ mod 2 is $\bar\alpha^{\mathsf T}\,\mathrm{cocMat}\,\bar\beta$. (c) For even L, the diagonal of the Gram matrix is 0 mod 2, so $\mathrm{cocMat} + \mathrm{cocMat}^{\mathsf T}$ is the Gram matrix mod 2 (`cocMat_add_transpose`); its determinant is $\det(\mathrm{Gram}) = \pm 1 \equiv 1$. □

theorem finrank_leechT : Module.finrank ℂ leechT = 4096
```

From the mathematics to the Lean statement

Throughout, `hEven : L.Even` and `hU : IsUnit (gramMat L).det` are section variables: every statement carries them as hypotheses (even, unimodular). `eA L α` is $e_\alpha \in \mathbb{C}^c[L/2L]$, and `eT L hEven hU α` its operator on $T_L =$ `ExtraT`. `L.rank` is the $\mathbb{Z}$-rank, and rank $L/2$ is natural-number division, exact because the rank is even (`even_rank_of_unimodular`). For the Leech lattice the hypotheses are discharged: `leech_even` and `leech_isUnit_det_gramMat` (from the vendored proof that Λ is unimodular) and `leech_rank : rank leech = 24`, so $2^{24/2} = 4096$. Each Lean statement is the corresponding clause of the theorem.

Could T be the wrong object? Three checks. (1) T is nonzero and simple (`isSimpleModule_extraT`), so it is not a degenerate stand-in. (2) The central sign κ acts by -1: in the algebra, $-e_\alpha$ is -1 times e_α, so the extension's central element is the scalar -1 by construction. (3) Uniqueness (`nonempty_linearEquiv_rep`) means any other construction of "the" faithful irreducible module is isomorphic to this one. The identification with FLM's T is argued below, in prose; it is not formalised.

Physical meaning

T is the space of ground states of the twisted sector, and e_α are the twisted vertex operator zero modes. The relations $e_\alpha e_\beta = \varepsilon(\alpha,\beta)e_{\alpha+\beta}$ are the cocycle of the lattice vertex operators (the same cocycle that governs the untwisted sector), with the key twisted-sector feature that $e_{-\alpha} = e_\alpha$ and $e_{\alpha+2\gamma} = e_\alpha$, so that θ-fixed information collapses to $L/2L$ and the group generated is the extraspecial group 2^{1+24} of order 2^{25}. Its unique faithful irreducible representation has dimension $2^{12} = 4096$ for the Leech lattice, which is the ground-state degeneracy of the twisted string and the number of ground states of weight 3/2 (before the θ-projection). The fixed-point picture is heuristic; the proof is the Wedderburn–Artin argument above.

Proof on paper. `eT_mul`: repEquiv is multiplicative and $e_{\bar\alpha}e_{\bar\beta} = c(\bar\alpha,\bar\beta)e_{\bar\alpha+\bar\beta}$ with $c(\bar\alpha,\bar\beta) = \varepsilon(\alpha,\beta)$ by descent. $e_{\alpha+2\gamma} = e_\alpha$ because $\overline{\alpha+2\gamma} = \bar\alpha$; $e_{-\alpha} = e_\alpha$ because $-\alpha = \alpha + 2(-\alpha)$. Dimension: Theorem 34.23 with $n = \operatorname{rank} L$. □

What the machine verified

`#print axioms` for `eT_mul`, `eT_neg`, `eT_add_two_nsmul`, `finrank_leechT`: `[propext, Classical.choice, Quot.sound]`. `finrank_leechT` is unconditional; the general statements are conditional exactly on `hEven`, `hU`.

Remark 34.26 (Why $K = \{e_{2\alpha}\}$ is the right normalisation)**.** FLM form $\hat\Lambda$ and the subgroup $K = \{a^{-1}\theta(a) : a \in \hat\Lambda\}$, and T is the irreducible $\hat\Lambda/K$-module on which $\kappa = -1$. So the subgroup to be killed depends on the chosen lift θ of -1 to $\hat\Lambda$. The library's lift (Chapter 32) is $\theta(e_\alpha) = e_{-\alpha}$, which is an automorphism because the library's cocycle is bimultiplicative, so $\varepsilon(-\alpha,-\beta) = \varepsilon(\alpha,\beta)$. With this lift, using $e_\alpha^{-1} = \varepsilon(\alpha,-\alpha)e_{-\alpha}$ and bimultiplicativity ($\varepsilon(\alpha,-\alpha) = \varepsilon(-\alpha,-\alpha) = \varepsilon(\alpha,\alpha)$, a sign),

$$e_\alpha^{-1}\theta(e_\alpha) = \varepsilon(\alpha,-\alpha)\,e_{-\alpha}e_{-\alpha} = \varepsilon(\alpha,\alpha)\varepsilon(-\alpha,-\alpha)\,e_{-2\alpha} = e_{-2\alpha}.$$

Hence $K = \{e_{2\gamma} : \gamma \in \Lambda\}$, and "$K$ acts trivially" is exactly `eT_add_two_nsmul` (with `eT_neg`). (FLM's own lift $\theta(a) = a^{-1}\kappa^{\langle\bar a,\bar a\rangle/2}$ gives a K of a different-looking shape; the two lifts differ by a sign character and the resulting quotients are isomorphic.) Note also $K \cap \{\pm1\} = 1$ and K is central, since $e_{2\gamma}$ commutes with e_α up to $(-1)^{\langle\alpha,2\gamma\rangle} = 1$; so $\hat\Lambda/K$ has order $2\cdot 2^{24}$ and is extraspecial by Theorem 34.24(c). This identification is argued here on paper.

Trap / dead end

Engineering trap: `abbrev ExtraT`. Elaborating the scalar action on terms of type `ExtraT L hEven hU` times out in Lean (the abbreviation is unfolded during type-class search). Downstream files therefore use the unfolded type `Rep (cocMat L) _` directly, e.g. `TFormLeech.TL` below and the carrier of `leechTwistedModule`. This is a performance issue only: the types are definitionally equal, so no statement changes meaning.

34.8 The symmetric invariant form on T

34.8.1 What is needed, and why the sign matters

The Moonshine module carries a nondegenerate symmetric invariant bilinear form, and its construction requires one on each sector. On $V_\Lambda^T = S[\theta] \otimes T$ the form is the product of a form on $S[\theta]$ (Chapter 37) and a form B on T. Invariance of a form $(\cdot,\cdot)$ on a module means that the adjoint of $Y(u,z)$ is the contragredient operator $Y(e^{zL_1}(-z^{-2})^{L_0}u, z^{-1})$. For $u = e^\alpha$ (of weight $\langle\alpha,\alpha\rangle/2$ and primary) the factor $(-1)^{L_0}$ contributes $(-1)^{\langle\alpha,\alpha\rangle/2}$; on the T factor, where $e_{-\alpha} = e_\alpha$, this becomes the requirement

$$B(e_\alpha t, t') = (-1)^{\langle\alpha,\alpha\rangle/2}\, B(t, e_\alpha t') \qquad (\alpha \in \Lambda). \tag{34.6}$$

Put differently: the transpose with respect to B must be the linear map $\iota : e_\alpha \mapsto (-1)^{\langle\alpha,\alpha\rangle/2} e_\alpha$, which (we shall see) is an anti-automorphism of $\mathrm{End}(T)$. We also need B *symmetric*. This is not automatic: an anti-involution of a matrix algebra $\mathrm{End}(T)$ is the transpose for a form that is either symmetric or alternating, and which one occurs depends on ι.

34.8.2 Anti-involutions from quadratic signs

Return to the abstract setting of §34.6: $A = \mathbb{C}^c[V]$, T its simple module, $\varphi =$ `repEquiv` $: A \cong \mathrm{End}(T)$. File `VOA/Moonshine/TFormAlg.lean`.

```
structure IsQuadSign (s : (Fin n → ZMod 2) → ℂ) : Prop where

  (algBasis M).constr ℂ fun x => s x • algBasis M x
```

File `VOA/Moonshine/TFormAlg.lean`.

```
noncomputable def iotaT (s : (Fin n → ZMod 2) → ℂ) :
    Module.End ℂ (Rep M hN) →ₗ[ℂ] Module.End ℂ (Rep M hN) :=
  (repEquiv M hN).toLinearMap ∘ₗ iotaA M s ∘ₗ (repEquiv M hN).symm.toLinearMap
```

Definition 34.27. A *quadratic sign* is $s : V \to \mathbb{C}$ with $s(0) = 1$ and $s(x+y) = s(x)s(y)c(x,y)c(y,x)$; then $s = (-1)^q$ for a quadratic form q on V whose polar form is the commutator form ω. For such s, ι_s is the linear map $e_x \mapsto s(x)e_x$ on A, transported to $\mathrm{End}(T)$ by φ.

From the mathematics to the Lean statement

`algBasis M` is the basis $x \mapsto e_x$ of `alg M`; `Basis.constr` defines a linear map by its values on a basis. `iotaT` is $\varphi \circ \iota_s \circ \varphi^{-1}$ (`∘ₗ` is composition of linear maps). The structure `IsQuadSign` has exactly the two conditions of the definition (the fact $s(x)^2 = 1$ follows, `IsQuadSign.mul_self`).

Physical meaning

The sign $s = (-1)^q$ is the action of the vertex-algebra conjugation (contragredient) on the zero modes: the factor $(-1)^{L_0}$ in the adjoint of a vertex operator contributes $(-1)^{\langle\alpha,\alpha\rangle/2}$ for a primary field e^α of weight $\langle\alpha,\alpha\rangle/2$. The anti-involution ι_s is therefore the operation of passing to the adjoint (BPZ conjugate) of the twisted zero-mode operators, and the quadratic-form condition on s is the consistency of this adjoint with the commutation relations of the extraspecial group.

Theorem 34.28. *For a quadratic sign s: $\iota_s(XY) = \iota_s(Y)\iota_s(X)$, $\iota_s^2 = 1$, $\iota_s(1) = 1$, and $\operatorname{tr}\circ\iota_s = \operatorname{tr}$ on* $\mathrm{End}(T)$.

File `VOA/Moonshine/TFormAlg.lean`.

```
theorem iotaT_mul {s : (Fin n → ZMod 2) → ℂ} (hs : IsQuadSign M s)

```

File `VOA/Moonshine/TFormAlg.lean`.

```
theorem trace_iotaT {s : (Fin n → ZMod 2) → ℂ} (hs : IsQuadSign M s)
    (X : Module.End ℂ (Rep M hN)) : trace ℂ (Rep M hN) (iotaT M hN s X) = trace ℂ (Rep M
    ↪ hN) X
```

From the mathematics to the Lean statement

`trace ℂ (Rep M hN)` is the trace of an endomorphism of T. The hypothesis `hN` (nondegeneracy) is a section variable present in all three. Same as the theorem.

Physical meaning

The theorem says that ι_s is a well-defined adjoint on the zero-mode algebra: it reverses products, squares to the identity, and preserves the trace. Physically this is the statement that the adjoint operation of the twisted sector is a consistent involution on operators acting on the ground states, so that invariant bilinear forms can exist at all (the form is the two-point function in the twisted sector, and its invariance is the compatibility of adjoint with the vertex operators).

Proof on paper. On basis elements, $\iota(e_x e_y) = c(x,y)s(x+y)e_{x+y}$ and $\iota(e_y)\iota(e_x) = s(x)s(y)c(y,x)e_{x+y}$; these agree by the defining relation of s and $c(x,y)^2 = 1$. $\iota^2 = 1$ because $s^2 = 1$. For the trace: $\operatorname{tr}\varphi(e_x) = 0$ for $x \neq 0$, since by nondegeneracy there is w with $e_w e_x e_w^{-1} = -e_x$ (`trace_op_eq_zero`); so the trace only sees the coefficient of e_0, which ι fixes. □

Definition 34.29 (Trace forms). For $u \in T^*$ and $t \in T$ write $t \otimes u$ for the rank-one map $x \mapsto u(x)t$. Put $B_u(t,t') = \operatorname{tr}\big(\iota(t \otimes u) \circ (t' \otimes u)\big)$.

File `VOA/Moonshine/TFormAlg.lean`.

```
noncomputable def formOf (s : (Fin n → ZMod 2) → ℂ) (u : Module.Dual ℂ (Rep M hN)) :

  LinearMap.mk₂ ℂ
    (fun t t' => trace ℂ (Rep M hN) (iotaT M hN s (u.smulRight t) * u.smulRight t'))
```

(the header and defining formula; the remaining four arguments of `LinearMap.mk₂` are the bilinearity proofs).

Physical meaning

A trace form is a construction of a two-point function on the twisted ground states from the algebraic data: starting from the adjoint ι on operators, one defines $B_u(t, t')$ by evaluating the trace of the adjoint of a rank-one operator against another. It is the finite-dimensional counterpart of the sesquilinear (BPZ) pairing used to define the Hilbert space structure and correlation functions in the twisted sector; the choice of u is a choice of reference ground state.

Theorem 34.30. *For a quadratic sign s and $u \in T^*$: B_u is symmetric; $B_u(Xt, t') = B_u(t, \iota(X)t')$ for all $X \in \mathrm{End}(T)$; and if $B_u \neq 0$ then B_u is nondegenerate. Consequently, if there is an idempotent $P \in \mathrm{End}(T)$ with $\iota(P) = P$ and $\operatorname{tr} P = 1$, then T carries a nondegenerate symmetric bilinear form B with $B(Xt, t') = B(t, \iota(X)t')$ for all X.*

    ∃ B : LinearMap.BilinForm ℂ (Rep M hN), (∀ t t', B t t' = B t' t) ∧ B.Nondegenerate ∧
      ∀ X t t', B (X t) t' = B t (iotaT M hN s X t')
```

From the mathematics to the Lean statement

`Module.Dual ℂ T` is T^*; `u.smulRight t` is $t \otimes u$. `LinearMap.BilinForm` is a bilinear form; `B.Nondegenerate` is Mathlib's nondegeneracy (both left and right radicals are zero). `IsIdempotentElem P` is $P^2 = P$. In `formOf_nondegenerate` the hypothesis "$B_u(v, w) \neq 0$ for some v, w" is $B_u \neq 0$. Same as the theorem.

Physical meaning

This produces the two-point function on the twisted ground states: a symmetric, nondegenerate pairing with $B(Xt, t') = B(t, \iota(X)t')$, i.e. one in which the zero-mode operators e_α have the adjoint prescribed by the contragredient structure. Symmetry (rather than alternation) is physically significant, since it corresponds to a bosonic-type invariant form on the Moonshine module (the twisted sector contributing weight-3/2 states without extra signs). The theorem reduces its existence to an idempotent P of trace one, which is a Lagrangian choice of simultaneous ground states.

Proof on paper. Symmetry. With $P_t = t \otimes u$: $\operatorname{tr}(\iota(P_t)P_{t'}) = \operatorname{tr}\iota(\iota(P_t)P_{t'}) = \operatorname{tr}(\iota(P_{t'})P_t)$, using $\operatorname{tr}\circ\iota = \operatorname{tr}$, the anti-multiplicativity and $\iota^2 = 1$. *Invariance.* $X(t\otimes u) = (Xt)\otimes u$, so $B_u(Xt, t') = \operatorname{tr}(\iota(P_t)\iota(X)P_{t'}) = B_u(t, \iota(X)t')$. *Nondegeneracy.* The radical is stable under all $X \in \operatorname{End}(T)$ (by invariance), and $\operatorname{End}(T)$ acts transitively on nonzero vectors; so the radical is 0 or T. *Existence.* A trace-one idempotent has rank one, $P = v \otimes u$, and then $B_u(v, v) = \operatorname{tr}(\iota(P)P) = \operatorname{tr}(P^2) = \operatorname{tr} P = 1 \neq 0$.

Why symmetry is "free". The symmetry argument works for every ι; what can fail is existence. If ι is the adjoint for an *alternating* form, every B_u is both symmetric and alternating, hence zero, and no ι-fixed trace-one idempotent exists. So the whole content is the existence of P, which (for $\iota = \iota_s$) holds exactly when the quadratic form q with $s = (-1)^q$ has Arf invariant 0; this equivalence is background, not formalised. □

What the machine verified

`#print axioms VOA.Moonshine.Extraspecial.exists_form_of_idempotent:` `[propext, Classical.choice, Quot.sound]`. All four results proved, conditional on the displayed hypotheses.

```
theorem iotaL_eT (α : L.carrier) :
    iotaL L hEven hU (eT L hEven hU α) = (-1 : ℂ) ^ halfNorm L α • eT L hEven hU α
```

From the mathematics to the Lean statement

`halfNorm L α` is $Q(\alpha) = \langle\alpha,\alpha\rangle/2$ with integer division, which is exact for even L. `signQ L x` picks (by choice) some lift α of $x \in L/2L$ and returns $(-1)^{Q(\alpha)}$; `signQ_red` shows the value does not depend on the lift (for even L, $Q(\alpha+2\gamma) = \frac{1}{2}\langle\alpha+2\gamma,\alpha+2\gamma\rangle = Q(\alpha) + 2\langle\alpha,\gamma\rangle + 2\langle\gamma,\gamma\rangle = Q(\alpha) + 2(2Q(\gamma) + \langle\alpha,\gamma\rangle)$, so the parity of Q does not change). So the choice is harmless. `isQuadSign_signQ`: $Q(\alpha+\beta) = Q(\alpha) + Q(\beta) + \langle\alpha,\beta\rangle$ and $\varepsilon(\alpha,\beta)\varepsilon(\beta,\alpha) = (-1)^{\langle\alpha,\beta\rangle}$. `iotaL` is ι_s for $s = (-1)^Q$, and `iotaL_eT` is $\iota(e_\alpha) = (-1)^{Q(\alpha)}e_\alpha$, the transpose demanded by (34.6).

Physical meaning

The integer $Q(\alpha) = \langle\alpha,\alpha\rangle/2$ is the conformal weight of the lattice vertex operator e^α, and $(-1)^Q$ is the sign picked up by e^α under the contragredient (adjoint) operation, which includes the factor $(-1)^{L_0}$. Evenness of the lattice is what makes Q integral and the sign well defined on $L/2L$; Q mod 2 is the quadratic refinement of the commutator form, and it is the data distinguishing the possible adjoint structures on the extraspecial group.

What the machine verified

All proved, conditional on `hEven` (and `hU` for `iotaL`).

Trap / dead end

The sign $\varepsilon(\alpha,\alpha)$ is the wrong choice (numerical certificate). A natural first guess is the *group* anti-involution $e_\alpha \mapsto e_\alpha^{-1} = \varepsilon(\alpha,\alpha)e_\alpha$ (on T, $e_\alpha^2 = \varepsilon(\alpha,\alpha)$). It is also an anti-involution ($s = \varepsilon(\alpha,\alpha) = (-1)^{\tilde\alpha\cdot\mathrm{cocMat}\,\tilde\alpha}$ is a quadratic sign), but its quadratic form $x \mapsto x\cdot\mathrm{cocMat}\,x$ depends on the chosen lattice basis, and so does its Arf invariant. For E_8 (rank 8, T of dimension 16, built from Pauli matrices) the script `scripts/moonshine/numerics/e8b.py` transforms the Cartan basis by random elements of $GL_8(\mathbb{Z})$ and counts $\#\{x \in \mathbb{F}_2^8 : x\cdot\mathrm{cocMat}\,x = 0\}$; output (re-run for this chapter):

```
[0 0 1 1 1 1 1 0] x.Mx even count 120
[0 0 1 0 1 1 0 0] x.Mx even count 136
[1 0 0 0 1 0 0 1] x.Mx even count 120
...
```

$136 = 2^7 + 2^3$ means Arf invariant 0 (symmetric form), $120 = 2^7 - 2^3$ means Arf invariant 1 (alternating form). So with the $\varepsilon(\alpha,\alpha)$ sign the invariant form on T is alternating for some bases — and the library's `latticeBasis` is chosen noncomputably, so one cannot even know which case one is in. The sign $(-1)^Q$ is basis-independent (it is defined from the norm $\langle\alpha,\alpha\rangle$ alone, whereas $\varepsilon(\alpha,\alpha)$ is defined from the basis-dependent matrix `cocMat`); for E_8, `e8.py` reports `Q even/odd {0: 136, 1: 120}`, Arf 0, and the solution space of the invariance equations is one-dimensional and symmetric. This is numerical evidence that fixed the convention; the Lean theorems below prove the Leech case directly.

34.8.4 Lagrangian data

To produce the idempotent P, take a maximal totally singular subspace for Q, i.e. $m = n/2$ vectors γ_i with $\langle\gamma_i,\gamma_j\rangle$ even and $Q(\gamma_i)$ even. Then $F_i = \sigma_i e_{\gamma_i}$ (with $\sigma_i^2 = \varepsilon(\gamma_i,\gamma_i)$, so $F_i^2 = 1$) are commuting ι-fixed involutions, and $P = \prod_i \frac{1}{2}(1+F_i)$ is an ι-fixed idempotent. To compute its trace, use partners g_i with $\langle g_i,\gamma_j\rangle$ even for $j < i$ and odd for $j = i$. File `VOA/Moonshine/TFormLattice.lean`.

```

      ∀ X t t', B (X t) t' = B t (iotaL L hEven hU X t')
```

From the mathematics to the Lean statement

`TT` is local notation for `Rep (cocMat L) (isUnit_det_cocMat L hEven hU)`, i.e. T_L. The sequences `γ`, `g` are indexed by $\mathbb{N}$ but only the first `m` entries are constrained. `_root_.Even` is "is an even integer" (not lattice evenness). `two_mul_m` says $2m = \operatorname{rank} L$. `lagF ... k` is $F_k = \sigma_k e_{\gamma_k}$ with σ_k a chosen square root of $\varepsilon(\gamma_k, \gamma_k)$ (`sqrtEpsL`), and `projP k` is $\prod_{i<k} \frac{1}{2}(1 + F_i)$. `trace_projP`: $\operatorname{tr}(P_k)\, 2^k = \dim T$. `exists_TForm` (with section hypotheses `hEven`, `hU`): *given* Lagrangian data, a nondegenerate symmetric $\iota_{(-1)^Q}$-invariant form exists. The conditional is genuine: it is discharged for the Leech lattice below.

Physical meaning

A Lagrangian is a maximal set of mutually compatible zero modes: $m = 12$ commuting elements $F_i = \pm 1$ of the extraspecial algebra, which can be simultaneously diagonalised, together with partners g_i that do not commute with them and flip their eigenvalues. Choosing $F_i = +1$ for all i selects a single ground state out of the 2^{12}, i.e. the idempotent P of trace one: the analogue of choosing a polarisation (a maximal commuting set of observables) in the quantisation of the finite Heisenberg group. The numbers of the data are a bookkeeping device; they have no independent physical meaning.

Proof on paper. The F_i commute because $\langle \gamma_i, \gamma_j \rangle$ is even; $F_i^2 = \sigma_i^2 \varepsilon(\gamma_i, \gamma_i) = 1$; $\iota(F_i) = (-1)^{Q(\gamma_i)} F_i = F_i$. So P_k is an ι-fixed idempotent. Trace: $\operatorname{tr} P_{k+1} = \frac{1}{2} \operatorname{tr} P_k + \frac{1}{2} \operatorname{tr}(P_k F_k)$, and $\operatorname{tr}(P_k F_k) = 0$ because $G = e_{g_k}$ commutes with P_k (even pairings with γ_j, $j < k$) and anticommutes with F_k (odd pairing), so $\operatorname{tr}(P_k F_k) = \operatorname{tr}(G^{-1} P_k F_k G) = -\operatorname{tr}(P_k F_k)$. Hence $\operatorname{tr} P_m = \dim T / 2^m = 2^m / 2^m = 1$, and Theorem 34.30 applies. □

What the machine verified

`#print axioms VOA.IntegralLattice.exists_TForm: [propext, Classical.choice, Quot.sound]`. Conditional on `hEven`, `hU` and the Lagrangian data `D`.

34.8.5 The Leech Lagrangian and the form `TForm`

The vendored Leech lattice (Chapter 30) is a sublattice of $\mathbb{Z}^{24}$ with $\langle x, y \rangle = x \cdot y / 8$, namely $\Lambda = 2A \cup (u + 2A)$ where A is the set of $a \in \mathbb{Z}^{24}$ with $a \bmod 2$ in the Golay code and $\sum a_k \equiv 0 \pmod 4$, and $u = (5, 1, \ldots, 1)$. Let $e_0, \ldots, e_{23}$ be the standard vectors and r_i the i-th row of the Golay generator matrix $[I_{12} \mid B]$ lifted to $\{0, 1\}$. The data are

$$\gamma_0 = 8e_0, \quad \gamma_i = 4e_0 + 4e_i \ (1 \le i \le 11), \qquad g_0 = u, \quad g_i = 2r_i \ (1 \le i \le 11).$$

```

File VOA/Moonshine/TForm.lean.

```
noncomputable def leechLagrangian : Lagrangian leech where
```

From the mathematics to the Lean statement

`Code.golayEnc (Pi.single i 1)` is the codeword encoding the i-th unit message, i.e. the i-th row of $[I_{12} \mid B]$ (`golayEnc x` is x followed by xB); `.val` lifts $\mathbb{F}_2$ to $\{0,1\}$. `Leech.uVec` is $u = (5,1,\dots,1)$. Checks: $\langle\gamma_0,\gamma_0\rangle = 64/8 = 8$, $Q = 4$; $\langle\gamma_i,\gamma_i\rangle = 4$, $Q = 2$; $\langle\gamma_0,\gamma_i\rangle = 4$, $\langle\gamma_i,\gamma_j\rangle = 2$: all even. Partners: $\langle u,\gamma_0\rangle = 40/8 = 5$ odd; $\langle 2r_i,\gamma_j\rangle = r_i(0) + r_i(j) = \delta_{ij}$ for $1 \le i,j \le 11$ (identity block), and $\langle 2r_i,\gamma_0\rangle = 2r_i(0) = 0$. These finitely many integer identities are checked by the kernel (`decide +kernel`); membership of the vectors in Λ is proved from the definition of the carrier. `leechLagrangian` has $m = 12$, and `two_mul_m` is `leech_rank`.

Theorem 34.31 (The form on the Leech T). *There is a bilinear form B on the 4096-dimensional Leech module T which is symmetric, nondegenerate, satisfies $B(Xt,t') = B(t,\iota(X)t')$ for all $X \in \mathrm{End}(T)$, and in particular (34.6) and $B(e_\alpha t, e_\alpha t') = (-1)^{\langle\alpha,\alpha\rangle/2}\varepsilon(\alpha,\alpha)B(t,t')$.*

```

From the mathematics to the Lean statement

`TL` is the Leech T (the same type as `leechT`, written unfolded to avoid the `ExtraT` trap). `exists_leech` is `exists_TForm` applied to `leechLagrangian`; `TForm` is a form chosen from it, and the three properties are read off. In `TForm_eT`, `leech.form α α / 2` is $\langle\alpha,\alpha\rangle/2$ (exact since Λ is even), so the statement is (34.6). No hypotheses remain: everything is specialised to Λ. **Could it be vacuous?** A zero form would satisfy symmetry and invariance; it is excluded by `TForm_nondegenerate` (and $T \neq 0$). **Not proved:** uniqueness of B up to scalar (true by Schur's lemma, not formalised). The sign is the one required in Chapter 37, where it is used as `twForm_YTL`.

Physical meaning

For the Leech lattice, B is the two-point function (the invariant bilinear form) on the $2^{12} = 4096$ twisted ground states: symmetric and nondegenerate, with the zero modes e_α self-adjoint up to the sign $(-1)^{\langle\alpha,\alpha\rangle/2}$ prescribed by the weight of the lattice vertex operators. Together with the form on $S[\theta]$ it gives the invariant form on the twisted sector $V_\Lambda^T = S[\theta] \otimes T$, and this is the form needed so that the Moonshine module, $V_\Lambda^+ \oplus (V_\Lambda^T)^+$, carries a nondegenerate symmetric invariant form (a unitary-type structure, as expected for a physical CFT). The construction is an algebraic check of consistency, not a physical derivation.

What the machine verified

`#print axioms` for `TForm_symm`, `TForm_nondegenerate`, `TForm_eT`, `TForm_eT_eT`: `[propext, Classical.choice, Quot.sound]`. Unconditional. In an earlier version of the library the in-file documentation of these files said "not imported by the umbrella"; that note was already outdated: `VOA/Moonshine.lean` imported `TwistedHeisenberg`, `ExtraspecialModule` and `TForm`. At a pre-release build commit the umbrella still imports all three, and the docstrings no longer make the claim.

34.9 Referee's checklist

Abbreviations: E = `hEven`, U = `hU` (unimodular), N = `hN` ($M + M^{\mathsf{T}}$ invertible), Q = `hs : IsQuadSign`. All entries have `#print axioms` = `[propext, Classical.choice, Quot.sound]` (re-run for this chapter); none uses `VOA.pbw`.

Points a referee should specifically confirm: (1) the coset hypothesis in `TwistedModule.jacobi` (§34.4) and the non-vacuity witnesses of Chapters 35–36; (2) the junk value `modeT r i k = 0` for even k agrees with the support condition; (3) `L0T` is a definition whose identification with $\omega_{(1)}$ is proved in Chapter 35; (4) T is abstract (choice), unique up to isomorphism; (5) the sign in `TForm_eT` is $(-1)^{\langle\alpha,\alpha\rangle/2}$, not $\varepsilon(\alpha,\alpha)$.

34.10 Notes and references

The twisted vertex operators for the involution θ, the twisted Heisenberg algebra $\hat{\mathfrak{h}}[-1]$, its Fock space $S[\theta]$, the vacuum weight $r/16$, the extraspecial group $\hat{\Lambda}/K$ and its module T are due to I. Frenkel, J. Lepowsky and A. Meurman, *Vertex Operator Algebras and the Monster*, Pure and Applied Mathematics 134, Academic Press, Boston, 1988 (Chapters 1, 3, 5, 7 and 9; Chapter 10 for the moonshine module), preceded by their announcement *A natural representation of the Fischer–Griess Monster with the modular function J as character*, Proc. Natl. Acad. Sci. USA 81 (1984) 3256–3260. Twisted vertex operators in this setting go back to J. Lepowsky, *Calculus of twisted vertex operators*, Proc. Natl. Acad. Sci. USA 82 (1985) 8295–8299, and J. Lepowsky and R. L. Wilson, *Construction of the affine Lie algebra* $A_1^{(1)}$, Comm. Math. Phys. 62 (1978) 43–53. The general notion of a g-twisted module and its Jacobi identity is that of C. Dong, H. Li and G. Mason, *Twisted representations of vertex operator algebras*, Math. Ann. 310 (1998) 571–600, arXiv:q-alg/9509005; see also C. Dong, *Twisted modules for vertex algebras associated with even lattices*, J. Algebra 165 (1994) 91–112, and, for the textbook treatment of modules and twisted modules, J. Lepowsky and H. Li, *Introduction to Vertex Operator Algebras and Their Representations*, Progress in Mathematics 227, Birkhäuser, 2004. The notation of the library follows T. Gannon, *Moonshine beyond the Monster*, Cambridge University Press, 2006, §5.3.6 (equations 5.3.22). Extraspecial 2-groups, their representations and their role in the Monster are treated in R. L. Griess, Jr., *The Friendly Giant*, Invent. Math. 69 (1982) 1–102, and *Twelve Sporadic Groups*, Springer Monographs in Mathematics, 1998; and in

D. Gorenstein, *Finite Groups*, Harper & Row, 1968, §5.5. The Arf invariant of quadratic forms over $\mathbb{F}_2$ is due to C. Arf, J. reine angew. Math. 183 (1941) 148–167. The Wedderburn–Artin theorem used here is Mathlib's. The orbifold/string picture is in L. Dixon, J. Harvey, C. Vafa and E. Witten, *Strings on orbifolds*, Nucl. Phys. B 261 (1985) 678–686, and L. Dolan, P. Goddard and P. Montague, *Conformal field theories, representations and lattice constructions*, Comm. Math. Phys. 179 (1996) 61–120, arXiv:hep-th/9410029. The defect of §34.4 and the E_8 sign test are recorded in the project file `Notes/MonsterRoadmap.md` ("Recorded dead ends") and in Chapter 43, Section 43.2.

Chapter 35

The twisted Heisenberg module

This chapter builds one object and proves that it has every property required of it. The object is

```
VOA.Moonshine.heisTwistedModule r : TwistedModule (sigma1 r) 2 (FockT r),
```

the *σ-twisted module of the rank-r Heisenberg vertex operator algebra*. In words: the twisted Fock space $S[\theta]$, the polynomial algebra on the half-integral creation operators $h_a(-n-\frac{1}{2})$, carries a twisted vertex operator $Y^T(u,z)$ for *every* state u of the ordinary rank-r Heisenberg VOA, and these operators satisfy the Dong–Li–Mason twisted Jacobi identity with respect to the involution σ that negates the oscillators. For $r = 24$ this is the Heisenberg half of the twisted sector $V_\Lambda^T = S[\theta] \otimes T$ of the Moonshine module; the lattice half is the subject of Chapter 36. The chapter documents the release of the library named in the front matter; every Lean quotation is checked by `scripts/textbook/sync.py` to occur verbatim (up to whitespace and comments) in the source files of that release. Checks that were run at an earlier state of the library and not re-run for this edition are marked as such.

The construction is classical: it is in Lepowsky's 1985 paper on twisted vertex operators and in Chapter 9 of Frenkel–Lepowsky–Meurman (FLM). What is new here is the *route*. FLM write down the twisted vertex operator in closed form, $Y^T(u,z) = Y_0(e^{\Delta_z}u, z)$, with a quadratic operator Δ_z whose coefficients come from the Taylor expansion of $-\log\big(((1+x)^{1/2}+(1+y)^{1/2})/2\big)$, and then verify the Jacobi identity by a long generating-function computation. The library instead

(1) proves a general theorem: for any automorphism of finite order and any candidate "fractional-mode" map, the twisted Jacobi identity follows from two simpler properties of certain *integral* fields obtained by multiplying the twisted fields by $z^{e/N}$ — their mutual locality, and a "twisted product formula";

(2) *defines* Y^T by solving the twisted product formula recursively, starting from the twisted Heisenberg fields $h_a(z)$;

(3) proves locality by Dong's lemma (once for the generators, then for free), and the twisted product formula by an induction that uses only commutator formulas.

The famous vacuum energy $r/16$ of the twisted sector then *emerges* from the definition: we shall see it appear as $-\frac{1}{4}+\frac{3}{8}=\frac{1}{8}$ per boson (times the $\frac{1}{2}$ in the conformal vector), and we shall match this with FLM's Δ_z and with the physicist's two-point function of a twisted boson.

What the machine verified

Every declaration presented in this chapter is `sorry`-free. During the writing of this chapter, `#print axioms` was run (through `lake env lean -DmaxSynthPendingDepth=3`, against the existing build of an earlier commit, when the chapter was first written (not re-run for this edition); no fresh `lake build` was run for this chapter) on `heisTwistedModule`,

`twistedJacobi_YT`, `YT_omega_two`, `starPF`, `star_comm`, `prod_comm_formula`, `twistedJacobi_of_local_pf`, `Ywt_perm`, `twistedJacobi_generators_nonneg`, `sigmaHeisAut`, `pf_of_inverse` and `twistedSystem_local`; each reported exactly `[propext, Classical.choice, Quot.sound]`, Lean's three standard axioms. The PBW theorem `VOA.pbw` (Chapter 3; formerly a project axiom, now a theorem) does not occur. The project's build record for that earlier commit reports an aggregate `lake build` of 10343 jobs, exit 0, containing these files (not re-run for this chapter). The main theorem `heisTwistedModule` has no hypotheses at all: it is **unconditional**.

35.1 What has to be built, and why it is not routine

35.1.1 The physical picture

A chiral free boson in two dimensions is a field $h(z) = \sum_n h(n) z^{-n-1}$ with $[h(m), h(n)] = m\,\delta_{m+n,0}$. Its state space is the Fock space $\mathbb{C}[h(-1), h(-2), \dots]$, and the state–field correspondence assigns to every polynomial in the creation operators a field built from normal-ordered products of $h(z)$ and its derivatives. This is the Heisenberg VOA. The symmetry $h \mapsto -h$ is an automorphism σ of order two.

An *orbifold* by σ requires a *twisted sector*: a space on which the boson is *antiperiodic*, $h(e^{2\pi i} z) = -h(z)$. Antiperiodicity forces the modes into $\frac{1}{2} + \mathbb{Z}$,

$$h(z) = \sum_{t \in \frac{1}{2}+\mathbb{Z}} h(t)\, z^{-t-1}, \qquad [h(s), h(t)] = s\,\delta_{s+t,0},$$

and the twisted sector is the Fock space $S[\theta] = \mathbb{C}[h(-\tfrac{1}{2}), h(-\tfrac{3}{2}), \dots]$. Two facts are familiar to physicists: (i) the ground state of the twisted sector has conformal energy $\frac{1}{16}$ per boson ("the twist field has dimension 1/16"); (ii) every field of the untwisted theory acts on the twisted sector, but *not* by naively substituting the twisted h into the untwisted normal-ordered formulas — the naive substitution gives the wrong L_0 (it misses the $\frac{1}{16}$) and fails the operator product expansion. The correct operators carry correction terms. FLM package the corrections in an operator Δ_z; we shall obtain them from a recursion.

35.1.2 The mathematical target

A g-twisted module for a VOA V and an automorphism g of order N consists of a space M and, for every $u \in V$, a "twisted field" $Y_M(u, z) = \sum_{q \in \frac{1}{N}\mathbb{Z}} u_{(q)}\, z^{-q-1}$, subject to: the vacuum acts as the identity; lower truncation; the *support condition* (if $gu = e^{-2\pi i j/N} u$ then only $q \in -\frac{j}{N} + \mathbb{Z}$ occur); the *twisted Jacobi identity*; and a grading by L_0 with finite-dimensional eigenspaces and bounded-below eigenvalues. The precise Lean structure is recalled in §35.2.4; its general theory, including the repair of its Jacobi field described in the warning in §35.2.4, is in Chapter 34.

What makes this hard is that the Jacobi identity must be proved for *all pairs of states* u, v, and the states of the Heisenberg VOA are arbitrary polynomials. There is no "generators suffice" theorem for twisted modules available in the library (that would be a twisted version of Li's local-system theorem); the route of this chapter is, in effect, to prove just enough of such a theorem for this example.

35.1.3 The plan

Step 1. **The automorphism** (§35.3). σ is an automorphism of the level-one Heisenberg VOA; its eigenspaces for $N = 2$ are $\mathcal{V}^j = \{v : \sigma v = (-1)^j v\}$; a monomial of degree d lies in $\mathcal{V}^d$.

Step 2. **The reduction** (§35.4). For an arbitrary VOA, automorphism and fractional-mode map, the twisted Jacobi identity follows from (a) locality of the rescaled fields $\widetilde{F}_e(u) = z^{e/N} Y_M(u, z)$ and (b) the twisted product formula. The key algebraic fact is the complex Chu–Vandermonde identity.

Step 3. **The generators** (§35.5). The rescaled generator field $F_a(z) = z^{1/2} h_a(z)$ is an integral field; its commutator is $\delta_{ab}\big(z_2 \partial_{z_2} \delta + \frac{1}{2}\delta\big)$; so the generators are mutually local. As a cross-check, Steps 2 and 3 already give the Jacobi identity for two generators at $\ell \geq 0$.

Step 4. **Locality for free** (§35.6). Everything built from the F_a by products, powers of z, sums and scalars is mutually local.

Step 5. **The definition of Y^T** (§35.7), by inverting the product formula along words; vacuum, generator, truncation, support and locality properties.

Step 6. **The vacuum energy** (§35.8): $Y^T(\omega)_{(1)} = L_0^T$, with the $r/16$.

Step 7. **Commutator formulas** (§35.9, §35.10) for ordinary and for twisted products of local fields.

Step 8. **Words** (§35.11): the definition does not depend on the order of the letters; creation operators act as they should.

Step 9. **The twisted product formula for all pairs** (§35.12), hence the twisted Jacobi identity for all pairs.

Step 10. **The grading and the instance** (§35.13).

35.2 The language: distributions, fields, modes, products

This section collects the definitions that occur in the statements of this chapter. The basic notions (formal distributions, modes, fields, locality) are quoted verbatim and decoded in Chapters 2 and 4; here they are recalled with pointers. The field products and the formal-calculus identities on which this chapter's own fidelity checks depend are printed with their Lean sources, so that a referee can check every statement below without leaving the chapter.

35.2.1 Formal distributions and modes

Definition 35.1 (Formal distribution)**.** For a vector space $\mathcal{W}$, a formal distribution is a doubly infinite sequence $(a_n)_{n\in\mathbb{Z}}$ of elements of $\mathcal{W}$, thought of as $a(z) = \sum_n a_n z^n$; similarly a two-variable distribution is $(f_{m,n})_{m,n\in\mathbb{Z}}$, thought of as $\sum f_{m,n} z_1^m z_2^n$.

In Lean these are `FormalDist 𝒲 = ℤ → 𝒲` and `FormalDist₂ 𝒲 = ℤ → ℤ → 𝒲` (Definitions 2.1 and 2.21, `VOA/Foundations/FormalSeries.lean`). **The single most important convention of the library:** the value `a n` is the coefficient of z^n (not of z^{-n-1}). Vertex-algebra modes are read off by `mode f m = f (-m - 1)` (Definition 2.7, `VOA/Foundations/FormalCalculus.lean`), the coefficient of z^{-m-1}, i.e. $f_{(m)}$ in $f(z) = \sum_m f_{(m)} z^{-m-1}$; and `V.smul u n v := mode (V.Y u) n v` is $u_{(n)}v$ (Definition 4.2). Throughout, $u_{(n)}v$ means `W.smul u n v`.

Physical meaning

A formal distribution is the bookkeeping device behind every mode expansion in CFT: a field such as $\partial X(z) = \sum_n \alpha_n z^{-n-1}$ is nothing but its sequence of Laurent coefficients, the operators α_n. The convention that index n is the coefficient of z^n is a matter of book-keeping; the physical content is the Laurent expansion on the punctured plane. In the twisted sector the same device is used with exponents in $\frac{1}{2} + \mathbb{Z}$ once the branch factor $z^{1/2}$ is stripped off, as in the rescaled fields below.

Definition 35.2 (Field; the identity field)**.** An $\mathrm{End}(M)$-valued distribution $a(z)$ is a *field* if for every $x \in M$ we have $a_n x = 0$ for all sufficiently negative n (equivalently, $a_{(m)}x = 0$ for $m \gg 0$). The set of fields is `Fld M`. The identity field is $1(z) = \mathrm{id} \cdot z^0$.

In Lean, `IsField a` is `∀ x : V, ∃ B : ℤ, ∀ n : ℤ, n < B → a n x = 0` (Definition 2.43, `VOA/Core/Dong.lean`); `Fld M` is the subtype `{a : FormalDist (End ℂ M) // IsField a}` of fields (Definition 4.44, `VOA/Core/LocalSystem.lea` `a.1` is the underlying distribution, and `Fld.one` is `⟨idField, _⟩` with `idField` the identity field $\mathrm{id} \cdot z^0$ (`VOA/Core/FieldOps.lean`). Because coefficients are indexed by powers z^n, "lower truncated" means $a_n x = 0$ for $n < B$; in mode language $a_{(m)}x = 0$ for $m > -B - 1$, the usual notion.

Physical meaning

A field is the formal version of an operator-valued function whose matrix elements between any fixed state and any finite-energy state are Laurent series with only finitely many negative powers. This is the condition that $\partial X(z)\,|\psi\rangle$ has at worst a finite-order singularity as $z \to 0$, i.e. that the energy of states in the Fock space is bounded below and each state is annihilated by sufficiently high annihilation modes. The identity field is the trivial operator 1, the image of the vacuum under the state–operator map.

35.2.2 Commutators, locality, and the delta function

Definition 35.3 (Commutator distribution; multiplication by $(z_1 - z_2)^N$; locality)**.** For distributions a, b put $[a(z_1), b(z_2)]_{m,n} = a_m b_n - b_n a_m$. Multiplication by $(z_1 - z_2)$ sends f to $f_{m-1,n} - f_{m,n-1}$. Two distributions are *mutually local* if $(z_1 - z_2)^N [a(z_1), b(z_2)] = 0$ for some $N \in \mathbb{N}$.

In Lean (Definitions 2.21 and 2.41, `VOA/Foundations/Locality.lean`): `bracketDist a b` is the distribution $(m, n) \mapsto a_m b_n - b_n a_m$ (composition of endomorphisms); `mulBySub` is multiplication by $(z_1 - z_2)$, with `mulBySub f m n = f (m - 1) n - f m (n - 1)` (`mulBySub_apply`); `mulBySubPow N` is its N-th iterate; and `Local a b` is `∃ N : ℕ, mulBySubPow N (bracketDist a b) = 0`. This is exactly the textbook definition of mutual locality.

Physical meaning

Mutual locality is the formal-calculus form of the 2d CFT axiom that fields at separated points commute (bosons) up to singular terms supported at coincident points: $[\phi(z_1), \psi(z_2)]$ is a finite sum of derivatives of $\delta(z_1 - z_2)$, equivalently the OPE $\phi(z_1)\psi(z_2)$ has a pole of finite order, and the operator ordering $|z_1| > |z_2|$ versus $|z_2| > |z_1|$ is the analytic continuation of a single correlation function. The order N of the locality is the maximal pole order of the OPE. This is what allows us to treat the radial-ordered product as a single meromorphic object.

The building blocks of local commutators are derivatives of the formal delta function $\delta(z_1, z_2) = \sum_{m \in \mathbb{Z}} z_1^m z_2^{-m-1}$:
File `VOA/Foundations/Locality.lean`.

```
def deltaDeriv (j : ℕ) : FormalDist 𝒲 →ₗ[ℂ] FormalDist₂ 𝒲 where
  toFun c := fun m n => (∏ i ∈ Finset.range j, (-m - 1 - (i : ℤ))) • c (m + n + 1 + j)
  -- (the proofs of map_add' and map_smul' are elided)
def cCoeff (j : ℕ) (f : FormalDist₂ 𝒲) : FormalDist 𝒲 := fun n => mulBySubPow j f (-1) n
```

From the mathematics to the Lean statement

`deltaDeriv j c` is $c(z_2)\,\partial_{z_2}^{j}\delta(z_1,z_2)$. Check: $\partial_{z_2}^{j}\delta = \sum_m (-m-1)(-m-2)\cdots(-m-j) z_1^m z_2^{-m-1-j}$; multiplying by $c(z_2)=\sum_p c_p z_2^p$, the coefficient of $z_1^m z_2^n$ is $\prod_{i<j}(-m-1-i)\cdot c_{m+n+1+j}$, which is the Lean formula. `cCoeff j f` is the coefficient of z_1^{-1} in $(z_1-z_2)^j f$, i.e. $\mathrm{Res}_{z_1}(z_1-z_2)^j f(z_1,z_2)$, a distribution in z_2.

35.2.3 The integer products of fields

Two pieces of formal-calculus notation are needed. The *residue* Res_{z_1} of a distribution in z_1 (possibly depending on other variables) is its coefficient of z_1^{-1}: $\mathrm{Res}_{z_1}\sum_m f_m z_1^m = f_{-1}$. The *expansion maps* $\iota_{z_1,z}$ and ι_{z,z_1} turn the rational function $(z_1-z)^n$, $n\in\mathbb{Z}$, into a formal series: $\iota_{z_1,z}$ expands it in the domain $|z_1|>|z|$, i.e. in nonnegative powers of z/z_1, and ι_{z,z_1} in the domain $|z|>|z_1|$, i.e. in nonnegative powers of z_1/z:

$$\iota_{z_1,z}(z_1-z)^n=\sum_{i\ge 0}\binom{n}{i}(-1)^i z_1^{n-i}z^i,\qquad \iota_{z,z_1}(z_1-z)^n=\sum_{i\ge 0}\binom{n}{i}(-1)^{n-i}z_1^i z^{n-i}.$$

For $n\ge 0$ both are the same polynomial. For $n<0$ they differ; for example $\iota_{z_1,z}(z_1-z)^{-1}=\sum_{i\ge 0} z_1^{-1-i}z^i$ while $\iota_{z,z_1}(z_1-z)^{-1}=-\sum_{i\ge 0} z_1^i z^{-1-i}$, and their difference is the delta function $\delta(z_1,z)$ of §35.2.2. For fields a,b and $n\in\mathbb{Z}$, the n-th product $a_{(n)}b$ is the field

$$(a_{(n)}b)(z)=\mathrm{Res}_{z_1}\Big(a(z_1)b(z)\,\iota_{z_1,z}(z_1-z)^n-b(z)a(z_1)\,\iota_{z,z_1}(z_1-z)^n\Big),\tag{35.1}$$

with ι as just defined. In the library the two cases are implemented separately: for $n\ge 0$, $a_{(n)}b=\mathrm{Res}_{z_1}(z_1-z)^n[a(z_1),b(z)]$; for $n=-k-1<0$, $a_{(n)}b=\frac{1}{k!}:(\partial^k a)(z)\,b(z):$, with the normal-ordered product $:a(z)b(z):$ putting the annihilation half of a to the right.

Files `VOA/Foundations/Locality.lean`, `VOA/Core/Dong.lean`, `VOA/Core/LocalSystemBare.lean`.

```
def normalOrdered (a b : FormalDist (Module.End ℂ V)) : FormalDist₂ (Module.End ℂ V) :=
  fun m n => if 0 ≤ m then a m * b n else b n * a m

noncomputable def nprod {a b : FormalDist (End ℂ V)}
    (ha : IsField a) (hb : IsField b) : FormalDist (End ℂ V) :=
  fun s => nprodCoeff ha hb s
-- nprod_apply : nprod ha hb s x = ∑ᶠ m : ℤ, normalOrdered a b m (s - m) x

noncomputable def negProd {a b : FormalDist (End ℂ V)} (ha : IsField a) (hb : IsField b)
    (m : ℕ) : FormalDist (End ℂ V) :=
  (m.factorial : ℂ)⁻¹ • nprod (ha.deriv_iterate m) hb

noncomputable def prod (n : ℤ) (a b : Fld M) : Fld M :=
  if _hn : 0 ≤ n then
    ⟨cCoeff n.toNat (bracketDist a.1 b.1), isField_cCoeff_bracket a.2 b.2 n.toNat⟩
  else
    ⟨negProd a.2 b.2 (-n - 1).toNat, isField_negProd a.2 b.2 (-n - 1).toNat⟩
```

From the mathematics to the Lean statement

`Fld.prod n a b` is $a_{(n)}b$. The `normalOrdered` distribution has coefficients $a_m b_n$ if $m \geq 0$ (the z_1^m, $m \geq 0$, part of a is the *creation* part, since $a_m = a_{(-m-1)}$ with $-m-1 < 0$; creation goes to the left) and $b_n a_m$ otherwise. The $\sum^{\mathrm{f}}$ is Mathlib's *finitary sum*: it is the sum of the family when only finitely many terms are nonzero, and 0 otherwise; here finiteness holds because both factors are fields.

The formula a reader can compute with is the *iterate formula*, a theorem of formal calculus valid for any two fields, which unpacks (35.1) in modes:
File `VOA/Core/FieldProductIterate.lean`.

```
theorem mode_prod_iterate (a b : Fld M) (ell N : ℤ) (x : M) :
    mode (prod ell a b).1 N x =
      ∑ᶠ i : ℕ, ((-1 : ℂ) ^ i * gBinom ell i) •
        (mode a.1 (ell - i) (mode b.1 (N + i) x)
          - ((-1 : ℂ) ^ ell) • mode b.1 (ell + N - i) (mode a.1 i x))
```

that is,

$$(a_{(\ell)}b)_{(N)} = \sum_{i\geq 0}(-1)^i\binom{\ell}{i}\Big(a_{(\ell-i)}b_{(N+i)} - (-1)^{\ell}\, b_{(\ell+N-i)}a_{(i)}\Big). \tag{35.2}$$

Physical meaning

The iterate formula is the mode-by-mode statement of the OPE: the modes of a composite operator $(a_{(\ell)}b)(z)$ (a coefficient in the OPE $a(z_1)b(z)$) are expressed through contour integrals around z and around 0, and the sum over i with binomial weights is the Taylor expansion of $(z_1 - z)^{\ell}$ when one deforms the contour. It is a formal-calculus identity, not a physical postulate; heuristically it is the contour-deformation argument used to derive commutators from OPEs in any CFT textbook.

Here and below $\binom{x}{i} = x(x-1)\cdots(x-i+1)/i!$ for any complex x and $i \in \mathbb{N}$; the library has two names for it, `gBinom` (integer upper index) and `cbinom` (complex upper index), and a third, `cbz`, which extends `gBinom` by 0 to negative lower indices:
Files `VOA/Foundations/FormalCalculus.lean`, `VOA/Modularity/Twisted.lean`, `VOA/Foundations/Substitution.lean`, `VOA/Foundations/Expansion.lean`.

```
noncomputable def gBinom (n : ℤ) (k : ℕ) : ℂ :=
  (∏ i ∈ Finset.range k, ((n : ℂ) - (i : ℂ))) / (k.factorial : ℂ)
noncomputable def cbinom (x : ℂ) (i : ℕ) : ℂ :=
  (∏ k ∈ Finset.range i, (x - k)) / (i.factorial : ℂ)
noncomputable def cbz (n k : ℤ) : ℂ := if 0 ≤ k then gBinom n k.toNat else 0
def negOnePow (n : ℤ) : ℂ := if Even n then 1 else -1
```

The bridge between locality and vertex-algebra identities is Li's theorem that two mutually local fields satisfy the Borcherds (Jacobi) identity with respect to these products. It is proved in the library's local-system layer (Theorem 4.48) and is used here as an established input:
File `VOA/Core/LocalSystemJacobi.lean`.

```
theorem field_jacobi_of_local {a b : Fld M} (h : Local a.1 b.1)
    (x : M) (ell m n : ℤ) :
    (∑ᶠ i : ℤ, (negOnePow i * cbz ell i) •
      (mode a.1 (ell + m - i) (mode b.1 (n + i) x) -
        negOnePow ell • mode b.1 (ell + n - i) (mode a.1 (m + i) x))) =
      ∑ᶠ i : ℤ, cbz m i • mode (prod (ell + i) a b).1 (m + n - i) x
```

$$\sum_{i\ge 0}(-1)^i\binom{\ell}{i}\big(a_{(\ell+m-i)}b_{(n+i)}-(-1)^{\ell}b_{(\ell+n-i)}a_{(m+i)}\big)=\sum_{i\ge 0}\binom{m}{i}(a_{(\ell+i)}b)_{(m+n-i)}. \tag{35.3}$$

Physical meaning

This is the associativity-plus-commutativity of operator products in a local CFT: contour integrals of $a(z_1)b(z_2)$ can be moved either around z_2 (OPE channel, right side) or around 0 (commutator channel, left side), and mutual locality guarantees that the two descriptions agree. In the physics literature it is the generating function $\sum$ of mode commutators, i.e. the Borcherds/Jacobi identity encoding crossing symmetry of the four-point function on the sphere with one insertion at the origin and one at infinity.

35.2.4 Twisted modules

The support condition (iii) below says that an eigenvector u with eigenvalue $e^{-2\pi ij/N}$ has modes only in $-\frac{j}{N}+\mathbb{Z}$: this is the algebraic form of the statement that continuing z once around the origin multiplies $Y_M(u,z)$ by a root of unity fixed by the eigenvalue of u (here z^{-q-1} with $q\in-\frac{j}{N}+\mathbb{Z}$ acquires $e^{2\pi ij/N}$), exactly as the antiperiodic boson has modes in $\frac{1}{2}+\mathbb{Z}$. The Jacobi identity (iv) is then imposed only for the fractional indices k on this support coset, as in Dong–Li–Mason; the warning after the definition explains why that restriction is not optional.

Definition 35.4 (Twisted eigenspaces; twisted module)**.** Let W be a VOA on $\mathcal{V}$ and $g\in\mathrm{Aut}(W)$. For $N\ge 1$ and $j\in\mathbb{N}$ put $\mathcal{V}^j=\{v:gv=e^{-2\pi ij/N}v\}$. A g-twisted module of order N on M is a linear map $u\mapsto(u_{(k/N)})_{k\in\mathbb{Z}}$, $\mathcal{V}\to(\mathbb{Z}\to\mathrm{End}\,M)$, with: (i) $\mathbf{1}_{(k/N)}=\delta_{k,-N}\,\mathrm{id}$; (ii) lower truncation; (iii) for $u\in\mathcal{V}^j$, $u_{(k/N)}=0$ unless $k\equiv -j\pmod N$; (iv) for $u\in\mathcal{V}^j$, $v\in\mathcal{V}$, $x\in M$, $\ell,m\in\mathbb{Z}$ and $k\equiv -j\pmod N$,

$$\sum_{i\in\mathbb{Z}}(-1)^i\binom{\ell}{i}\Big(u_{(\ell+\frac{k}{N}-i)}\,v_{(\frac{m}{N}+i)}x-(-1)^{\ell}v_{(\ell+\frac{m}{N}-i)}\,u_{(\frac{k}{N}+i)}x\Big)$$
$$=\sum_{i\ge 0}\binom{k/N}{i}(u_{(\ell+i)}v)_{(\frac{k+m}{N}-i)}x; \tag{35.4}$$

(v) a direct-sum decomposition $M=\bigoplus_{\alpha\in\mathbb{C}}M_\alpha$ with $\omega_{(1)}=L_0$ acting on M_α by α, each M_α finite-dimensional, and $\mathrm{Re}\,\alpha$ bounded below on the nonzero M_α.

File `VOA/Modularity/Twisted.lean`.

From the mathematics to the Lean statement

Fractional modes as integers. `YM u k` is $u_{(k/N)}$. Thus `YM u (ℓ * N + k - i * N)` is $u_{((\ell N+k-iN)/N)} = u_{(\ell+k/N-i)}$, and the vacuum condition `k = -N` says $\mathbf{1}_{(-1)} = \mathrm{id}$, the only nonzero mode, i.e. $Y_M(\mathbf{1}, z) = \mathrm{id}$. The L_0 condition uses `YM ω N` $= \omega_{(1)}$. **The Jacobi field** is (35.4) verbatim: `negOnePow i * cbz ℓ i` is $(-1)^i\binom{\ell}{i}$ (zero for $i < 0$), and `cbinom ((k : ℂ) / N) i` is the *fractional* binomial $\binom{k/N}{i}$. **Hypothesis** `(k + j) % N = 0`: the fractional index of u is restricted to the support coset of u; this is how Dong–Li–Mason state it, and without it the structure is unsatisfiable (see the warning below). `%` is integer remainder; `(k+j) % N = 0` means $N \mid k + j$. `DirectSum.IsInternal weight` says the subspaces M_α are independent and span M, i.e. $M = \bigoplus_\alpha M_\alpha$ internally. `⊥` is the zero subspace. **Eigenspaces.** `Module.End.eigenspace f μ` is $\ker(f - \mu)$.

Physical meaning

A twisted module is the algebraic Hilbert space of a CFT sector in which the fields of the VOA are not single-valued around the origin but come back multiplied by the symmetry g: there is a twist field at $z = 0$ and $Y_M(u, z)$ for $u \in \mathcal{V}^j$ acquires the phase $e^{2\pi i j/N}$ under $z \mapsto e^{2\pi i} z$, which forces fractional modes in $-\frac{j}{N} + \mathbb{Z}$. For the $\mathbb{Z}_2$ orbifold of the free boson ($X \to -X$, $N = 2$), ∂X has $j = 1$ and half-integer modes; the vacuum of M is the twist-field state $\sigma(0)|0\rangle$. The L_0-grading with finite-dimensional weight spaces bounded below is the usual requirement of a unitary-like spectrum, and the twisted Jacobi identity is the OPE/crossing consistency in the presence of the twist field. This is what one adds to the untwisted Hilbert space to obtain the orbifold partition function.

Trap / dead end

The all-indices Jacobi identity is unsatisfiable. Until 2026-10-06 the field `jacobi` lacked the hypothesis `(k + j) % N = 0`. Then for $N \geq 2$ the choice $u = v = \mathbf{1}$, $\ell = -1$, $k = 1$, $m = -N - 1$ makes every left-hand term contain a vacuum mode $\mathbf{1}_{(q)}$ with $q \notin \mathbb{Z}$, hence 0, while the right side is $\binom{1/N}{0}(\mathbf{1}_{(-1)}\mathbf{1})_{(-1)}x = x$. So $x = 0$ for all x: *no nonzero twisted module existed*, and the target of this chapter would have been provably empty. The certificate is the Lean theorem `VOA.jacobiAllIndices_eq_zero` (`VOA/Moonshine/HeisenbergTwistedModuleDefect.lean`); the field was repaired by adding the support-coset hypothesis, which is the Dong–Li–Mason formulation. The same defect in `SuperTwistedModule.jacobi` has *not* been repaired (it is not used in this chapter). A referee should note that the repair *weakens* the axiom only by removing instances that are not part of the mathematical definition: when $k \notin -j$ and v is a g-eigenvector, DLM's generating-function identity does not produce a mode identity at that k at all.

The predicate "Y_M satisfies (35.4)" is also available on its own:

```
def TwistedJacobi (g : Aut W) (N : ℕ) {M : Type*} [AddCommGroup M] [Module ℂ M]
    (YM : V →ₗ[ℂ] (ℤ → End ℂ M)) : Prop :=
  ∀ (j : ℕ) (u : V), u ∈ g.twistedEigenspace N j → ∀ (v : V) (x : M) (ℓ k m : ℤ),
    (k + j) % (N : ℤ) = 0 →
```

```
    (∑ᶠ i : ℤ, (negOnePow i * cbz ℓ i) •

From the mathematics to the Lean statement

Character for character the `jacobi` field of `TwistedModule`; the library proves `twistedJacobi_of_twistedModule` (every twisted module satisfies it), and conversely the instance at the end of this chapter fills the `jacobi` field with a proof of `TwistedJacobi`.

Physical meaning

Physically, the twisted Jacobi identity is the statement that an operator $Y(u,z_1)$ moved around another $Y(v,z_2)$ and around the twist field at the origin picks up the correct monodromy: OPE with v (right side) agrees with commuting through v (left side) when u is allowed to be multivalued with phase $e^{2\pi i j/N}$ around $z=0$. The fractional binomial $\binom{k/N}{i}$ is the expansion of the branch factor $(z_2+z_0)^{k/N}$, i.e. the twist-field cut seen from a point displaced from z_2. This is a heuristic summary; the identity itself is the definition.

35.2.5 The two Fock spaces

The rank-r Heisenberg VOA lives on `FockN r` $= \mathbb{C}[x_{(n,a)} : n \in \mathbb{N}, a < r]$, the variable $x_{(n,a)}$ standing for the state $h_a(-n-1)\mathbf{1}$; the VOA at level $k \neq 0$ is `heisenbergNVOA r k hk` (Chapter 31), with $[h_a(m),h_b(n)] = k\,m\,\delta_{ab}\delta_{m+n,0}$, $h_a(-n-1)$ acting by multiplication by $x_{(n,a)}$, $h_a(n+1)$ by $(n+1)k\,\partial/\partial x_{(n,a)}$, $h_a(0)=0$, and conformal vector $\omega = \sum_a \frac{1}{2k} h_a(-1)^2\mathbf{1}$. We use only $k=1$.

The twisted Fock space is `FockT r`, the same polynomial ring but with $x_{(n,a)}$ now standing for the half-integral creation operator $h_a(-n-\frac{1}{2})$. The twisted modes are indexed by odd integers k, $k \leftrightarrow k/2$:

File `VOA/Moonshine/TwistedHeisenberg.lean`.

```
abbrev FockT (r : ℕ) : Type := MvPolynomial (ℕ × Fin r) ℂ
def varT {r : ℕ} (i : Fin r) (k : ℤ) : ℕ × Fin r := ((|k| - 1) / 2).toNat, i)

  if k % 2 = 0 then 0
  else if k < 0 then mulXT (varT i k)
  else ((k : ℂ) / 2) • pderivT (varT i k)

theorem modeT_comm (r : ℕ) (i j : Fin r) {k l : ℤ} (hk : Odd k) (hl : Odd l) :
    modeT r i k * modeT r j l - modeT r j l * modeT r i k
      = (if i = j ∧ k + l = 0 then (k : ℂ) / 2 else 0) • LinearMap.id
```

From the mathematics to the Lean statement

`modeT r a k` is $h_a(k/2)$: for odd $k<0$, multiplication by the variable $x_{((-k-1)/2,a)}$, i.e. $h_a(-n-\frac{1}{2})$ with $n=(-k-1)/2$; for odd $k>0$, $\frac{k}{2}\,\partial/\partial x_{((k-1)/2,a)}$; for even k, *zero* — a deliberate junk value expressing that a twisted boson has no integral modes. `modeT_comm` is $[h_a(\frac{k}{2}),h_b(\frac{l}{2})] = \frac{k}{2}\delta_{ab}\delta_{k+l,0}$, the level-one twisted Heisenberg relation. Its normalisation matches level $k=1$ of the untwisted algebra; this is why the target VOA below is the level-one one.

Physical meaning

The operators $h_a(k/2)$, k odd, are the modes $\alpha_{k/2}$ of the antiperiodic free boson, $\partial X(z) = \sum_{t\in\frac12+\mathbb{Z}} \alpha_t z^{-t-1}$; the branch $z^{1/2}$ is the monodromy $\partial X \to -\partial X$ around the twist field. The relation $[\alpha_s,\alpha_t] = s\,\delta_{s+t,0}$ is canonical quantisation: each pair (α_{-t},α_t), $t \in \frac12+\mathbb{N}$, is one harmonic oscillator of frequency t. There is no zero mode (momentum), as on a circle with antiperiodic boundary conditions the boson has no translation invariance: the twist field is a fixed point of the $\mathbb{Z}_2$ reflection $X \to -X$.

The grading of $S[\theta]$: the monomial $\prod x_{(n,a)}^{m_{(n,a)}}$ has *doubled degree* $d = \sum(2n+1)m_{(n,a)}$ (each variable $x_{(n,a)}$ is given degree $2n+1$, twice its conformal weight $n+\frac12$); `gradingT r d` is the span of the monomials of doubled degree d and `levelT r d` $= d/2 + r/16$. The operator File `VOA/Moonshine/TwistedHeisenberg.lean`.

```
noncomputable def L0T (r : ℕ) : Module.End ℂ (FockT r) :=
  (1 / 2 : ℂ) • (eulerT r).toLinearMap + ((r : ℂ) / 16) • LinearMap.id
```

is $L_0^T = \frac12 E + \frac{r}{16}$, where the Euler derivation E multiplies $x_{(n,a)}$ by $2n+1$; the library proves $L_0^T = \sum_a \sum_{n\ge0} h_a(-n-\frac12)h_a(n+\frac12) + \frac{r}{16}$ (`L0T_eq_modeSum`). These are constructed in Chapter 34.

Trap / dead end

The constant $r/16$ is *written into* the definition of `L0T`. Were it simply asserted that the twisted module's L_0 is `L0T`, nothing would have been proved about the vacuum energy. The content of Theorem 35.25 is that the operator $Y^T(\omega)_{(1)}$, computed from the twisted vertex operator defined without any reference to $r/16$, *equals* `L0T`.

35.3 The involution σ and its eigenspaces

35.3.1 Definition and automorphism property

Let σ be the algebra automorphism of `FockN r` sending every variable $x_{(n,a)}$ to $-x_{(n,a)}$; on a monomial of degree d it acts by $(-1)^d$. In the library it is `LatGen.sigmaN r`, the linear equivalence underlying `MvPolynomial.aeval (fun v => -(X v))`.

Theorem 35.5. *For every $r \in \mathbb{N}$ and level $k \neq 0$, σ is an automorphism of the Heisenberg VOA* `heisenbergNVOA r k hk`*: it is a linear bijection with $\sigma(u_{(n)}v) = (\sigma u)_{(n)}(\sigma v)$ for all u, v, n, $\sigma\mathbf{1} = \mathbf{1}$ and $\sigma\omega = \omega$. Moreover $\sigma^2 = 1$.*

Files `VOA/Core/Automorphism.lean`, `VOA/Moonshine/HeisenbergTwistedModuleSigma.lean`.

 ↪ 1
```

```
noncomputable abbrev heisVOA1 : VertexOperatorAlgebra (FockN r) :=
  heisenbergNVOA r 1 one_ne_zero
noncomputable abbrev sigma1 : Aut (heisVOA1 r) := sigmaHeisAut r 1 one_ne_zero
```

From the mathematics to the Lean statement

Decoding. `Aut W` is a structure: a linear equivalence (`≃ₗ[ℂ]`, a $\mathbb{C}$-linear bijection with linear inverse) together with proofs of the three compatibilities. Since `sigmaHeisAut` is a *definition* of an element of `Aut`, the theorem is the statement that the three proof fields could be filled; the proofs are elided above (they are not part of the statement). `heisVOA1 r` and `sigma1 r` are abbreviations for level 1. **Fidelity.** This is exactly Theorem 35.5. The definition of `Aut` requires ω to be fixed, which is the standard notion of VOA automorphism. **Could it be vacuous?** No: $\sigma \neq 1$ as soon as $r \geq 1$ since $\sigma(x_{(0,0)}) = -x_{(0,0)}$; and it is a genuine VOA automorphism, not a mere linear map, because `map_smul'` is quantified over all u, n, v.

Physical meaning

The involution σ is the $\mathbb{Z}_2$ symmetry $X \to -X$ of the free boson, equivalently $\partial X \to -\partial X$ (charge conjugation on the current), which fixes the vacuum and the stress tensor $T = \frac{1}{2}{:}\partial X \partial X{:}$ and acts on a state with d oscillators by $(-1)^d$. That it is an automorphism says that the symmetry preserves the OPE algebra of all fields, not merely the Heisenberg relations; this is the property needed to orbifold. The theorem is the algebraic expression of the obvious invariance of the free-boson action under $X \to -X$.

Proof on paper. σ anticommutes with every oscillator: $\sigma h_a(n)\sigma^{-1} = -h_a(n)$, since $h_a(n)$ is either multiplication by a variable or a derivative along one, and both change sign under $x \mapsto -x$. The vertex operator of a monomial state $h_{a_1}(-n_1-1)\cdots h_{a_d}(-n_d-1)\mathbf{1}$ is the iterated normal-ordered product ${:}\partial^{(n_1)}h_{a_1}(z)\cdots\partial^{(n_d)}h_{a_d}(z){:}$ (with $\partial^{(n)} = \partial^n/n!$). Conjugation by σ multiplies each factor by -1 and preserves normal ordering, so $\sigma Y(u,z)\sigma^{-1} = (-1)^d Y(u,z) = Y(\sigma u, z)$. By linearity $\sigma Y(u,z)\sigma^{-1} = Y(\sigma u, z)$ for all u, which is the product compatibility. $\sigma\mathbf{1} = \mathbf{1}$ (degree 0) and $\sigma\omega = \omega$ (degree 2). $\sigma^2 = 1$ since $(-1)^{2d} = 1$. □

What the machine verified

Unconditional; `#print axioms sigmaHeisAut` = `[propext, Classical.choice, Quot.sound]`. File: `VOA/Moonshine/HeisenbergTwistedModuleSigma.lean`.

35.3.2 The eigenspaces

For $N = 2$ the eigenvalue $e^{-2\pi i j/2}$ is $(-1)^j$. Hence:

Proposition 35.6. *For $j \in \mathbb{N}$: $v \in \mathcal{V}^j$ iff $\sigma v = (-1)^j v$. A monomial of degree d lies in $\mathcal{V}^d$; in particular $h_a(-1)\mathbf{1} = x_{(0,a)} \in \mathcal{V}^1$ and $\mathbf{1} \in \mathcal{V}^0$. Every v splits as $v = v_0 + v_1$ with $v_j \in \mathcal{V}^j$.*

```
theorem mem_twistedEigenspace_two_iff (k : ℂ) (hk : k ≠ 0) (j : ℕ) (v : FockN r) :
    v ∈ (sigmaHeisAut r k hk).twistedEigenspace 2 j ↔ sigmaN r v = ((-1 : ℂ) ^ j) • v

theorem monomial_mem_twistedEigenspace (k : ℂ) (hk : k ≠ 0) (m : (ℕ × Fin r) →₀ ℕ) (c : ℂ)
 ↪  :
    (monomial m c : FockN r) ∈ (sigmaHeisAut r k hk).twistedEigenspace 2 m.degree

theorem X_mem_twistedEigenspace_one (k : ℂ) (hk : k ≠ 0) (v : ℕ × Fin r) :
    (X v : FockN r) ∈ (sigmaHeisAut r k hk).twistedEigenspace 2 1
```

```
theorem exists_twistedEigen_decomp (k : ℂ) (hk : k ≠ 0) (v : FockN r) :
    ∃ v₀ ∈ (sigmaHeisAut r k hk).twistedEigenspace 2 0,
      ∃ v₁ ∈ (sigmaHeisAut r k hk).twistedEigenspace 2 1, v = v₀ + v₁
```

From the mathematics to the Lean statement

`(ℕ × Fin r) →₀ ℕ` is a finitely supported exponent vector m; `monomial m c` is $c\prod x_v^{m_v}$; `m.degree` is $\sum_v m_v$, the polynomial degree (*not* the conformal weight). `X v` is the variable x_v; $X(0,a)$ is $h_a(-1)\mathbf{1}$. Note that $\mathcal{V}^j$ depends only on j mod 2; the Lean statements quantify over all $j \in \mathbb{N}$, which is harmless and is what the definition of `TwistedModule` requires.

Physical meaning

The eigenspaces $\mathcal{V}^0$, $\mathcal{V}^1$ are the $\mathbb{Z}_2$-even and $\mathbb{Z}_2$-odd sectors of the untwisted operator algebra: operators with an even number of ∂X (such as T and $:(\partial X)^2:$) are even, those with an odd number (such as ∂X itself) are odd. In the twisted sector the even operators are single-valued and the odd ones change sign around the origin, so this decomposition decides which fields have integer modes and which have half-integer modes.

Proof on paper. $\exp(-2\pi i j/2) = \exp(-\pi i)^j = (-1)^j$; the rest is the sign $(-1)^d$ on monomials and $v_0 = \frac{1}{2}(v+\sigma v)$, $v_1 = \frac{1}{2}(v-\sigma v)$. □

What the machine verified

Unconditional, axiom-clean as above.

35.4 The reduction: twisted Jacobi from untwisted locality

This section is general: W is any VOA on $\mathcal{V}$, M any vector space, $N \geq 1$, and $Y_M : \mathcal{V} \to (\mathbb{Z} \to \operatorname{End} M)$, $u \mapsto (u_{(k/N)})_k$, any linear map. Nothing about Heisenberg algebras is used.

35.4.1 The idea

The twisted Jacobi identity (35.4) looks like the ordinary one (35.3) except for two things: the modes are fractional, and the right-hand binomial has a fractional upper index k/N. Both differences disappear after one simple change of variables.

Fix a residue $e \in \mathbb{Z}$. For a fractional family $A = (u_{(k/N)})_k$, define the *rescaled field on the class e*

$$\widetilde{F}_e(u)(z) = \sum_{p\in\mathbb{Z}} u_{(p+\frac{e}{N})}\, z^{-p-1} = z^{e/N} \sum_{q\in\frac{e}{N}+\mathbb{Z}} u_{(q)} z^{-q-1}. \tag{35.5}$$

It has integral exponents: it is $z^{e/N}$ times the part of $Y_M(u,z)$ supported on the coset $\frac{e}{N}+\mathbb{Z}$. Its p-th mode is $u_{(p+e/N)}$. Two such fields can be multiplied with the ordinary products (35.1), can be local, and then satisfy (35.3). Substituting $a = \widetilde{F}_e(u)$, $b = \widetilde{F}_{e'}(v)$, $k = Nm+e$ and $m' = Nn+e'$ into (35.3), the left side becomes literally the left side of (35.4). The right side becomes $\sum_i \binom{m}{i}(\widetilde{F}_e(u)_{(\ell+i)}\widetilde{F}_{e'}(v))_{(m+n-i)}$, an expression in the products of the rescaled fields. To compare it with the right side of (35.4) we need to know those products. The right answer is dictated by associativity. Formally,

$$\widetilde{F}_e(u)(z_0+z_2)\,\widetilde{F}_{e'}(v)(z_2) = (z_2+z_0)^{e/N} z_2^{e'/N}\, Y_M(u, z_0+z_2) Y_M(v, z_2),$$

and twisted associativity says $Y_M(u,z_0+z_2)Y_M(v,z_2)\sim Y_M(Y(u,z_0)v,z_2)$. Writing $(z_2+z_0)^{e/N}=z_2^{e/N}(1+z_0/z_2)^{e/N}$ we get, as the generating function of the products,

$$\sum_{\ell\in\mathbb{Z}}\big(\widetilde{F}_e(u)_{(\ell)}\widetilde{F}_{e'}(v)\big)(z_2)\,z_0^{-\ell-1}=\Big(1+\frac{z_0}{z_2}\Big)^{e/N}\widetilde{F}_{e+e'}\big(Y(u,z_0)v\big)(z_2). \tag{35.6}$$

Taking the coefficient of $z_0^{-\ell-1}$ gives the

Definition 35.7 (Twisted product formula)**.** For $u,v\in\mathcal{V}$ and classes e,e':

$$\widetilde{F}_e(u)_{(\ell)}\widetilde{F}_{e'}(v)=\sum_{t\ge 0}\binom{e/N}{t}z^{-t}\,\widetilde{F}_{e+e'}(u_{(\ell+t)}v)\qquad(\ell\in\mathbb{Z}), \tag{35.7}$$

in modes: $\big(\widetilde{F}_e(u)_{(\ell)}\widetilde{F}_{e'}(v)\big)_{(s)}=\sum_t\binom{e/N}{t}(u_{(\ell+t)}v)_{((N(s-t)+e+e')/N)}$.

Physical meaning

The twisted product formula is the OPE of twisted fields in the presence of the twist field: it says that as $z_1\to z_2$ the product $Y_M(u,z_1)Y_M(v,z_2)$ reproduces the OPE $Y(u,z_{12})v$ of the untwisted theory, but with the extra factor $(1+z_{12}/z_2)^{e/N}$ which is the Taylor expansion of the branch cut $z_1^{e/N}=(z_2+z_{12})^{e/N}$ of the twisted field. Heuristically this is the statement that the local OPE does not know about the twist, while the monodromy appears as a correction in powers of z_{12}/z_2 governed by the distance to the origin; it is the algebraic form of associativity of twisted correlators $\langle\sigma|\cdots|\sigma\rangle$.

Granting (35.7), the right side of (35.3) becomes

$$\sum_{i,t\ge0}\binom{m}{i}\binom{e/N}{t}(u_{(\ell+i+t)}v)_{(\dots)}=\sum_{\varsigma\ge0}\Big[\sum_{i+t=\varsigma}\binom{m}{i}\binom{e/N}{t}\Big](u_{(\ell+\varsigma)}v)_{(\dots)}=\sum_{\varsigma}\binom{m+e/N}{\varsigma}(u_{(\ell+\varsigma)}v)_{(\dots)},$$

and $m+e/N=k/N$: the fractional binomial appears. The middle step is

Lemma 35.8 (Complex Chu–Vandermonde)**.** *For $x,y\in\mathbb{C}$ and $s\in\mathbb{N}$, $\binom{x+y}{s}=\sum_{i+t=s}\binom{x}{i}\binom{y}{t}$.*

```
theorem cbinom_add (x y : ℂ) (s : ℕ) :
    cbinom (x + y) s = ∑ ij ∈ Finset.antidiagonal s, cbinom x ij.1 * cbinom y ij.2
```

From the mathematics to the Lean statement

`Finset.antidiagonal s` is the finite set $\{(i,t)\in\mathbb{N}^2 : i+t=s\}$. Same statement as the lemma. The library also proves `cbinom_eq_ringChoose`: `cbinom` agrees with Mathlib's binomial-ring `Ring.choose`, which is what makes the Mathlib theorem `Ring.add_choose_eq` available.

Physical meaning

This is the binomial theorem in disguise, $(1+x)^{a+b}=(1+x)^a(1+x)^b$: it expresses that the branch factors $(1+z_{12}/z_2)^{e/N}$ and the integer-power expansion $(1+z_{12}/z_2)^m$ multiply to give the total fractional power (k/N). A purely algebraic input to the twisted OPE; there is no further physics in it.

Proof on paper. Both sides are polynomials in (x,y) of degree s that agree on $\mathbb{N}^2$ (count s-subsets of a disjoint union of an x-set and a y-set); polynomials agreeing on $\mathbb{N}^2$ are equal. □

What the machine verified

Unconditional, axiom-clean. `VOA/Moonshine/HeisenbergTwistedModuleReduction.lean`.

35.4.2 Rescaled fields

Definition 35.9 (Rescaled field). For $A : \mathbb{Z} \to \operatorname{End} M$ (think $A(k) = u_{(k/N)}$), $N \in \mathbb{N}$ and $e \in \mathbb{Z}$, $\mathrm{resc}(A, N, e)$ is the distribution with p-th mode $A(Np + e)$.

```
def resc (A : ℤ → End ℂ M) (N : ℕ) (e : ℤ) : FormalDist (End ℂ M) :=
  fun n => A (N * (-n - 1) + e)

@[simp] theorem mode_resc (A : ℤ → End ℂ M) (N : ℕ) (e p : ℤ) :
    mode (resc A N e) p = A (N * p + e)

theorem resc_isField {A : ℤ → End ℂ M} {N : ℕ} (hN : 0 < N)
    (htr : ∀ x : M, ∃ K : ℤ, ∀ k : ℤ, K ≤ k → A k x = 0) (e : ℤ) : IsField (resc A N e)

def rescFld {A : ℤ → End ℂ M} {N : ℕ} (hN : 0 < N)
    (htr : ∀ x : M, ∃ K : ℤ, ∀ k : ℤ, K ≤ k → A k x = 0) (e : ℤ) : Fld M :=
  ⟨resc A N e, resc_isField hN htr e⟩
```

From the mathematics to the Lean statement

The coefficient of z^n is $A(N(-n-1)+e)$, so the coefficient of z^{-p-1} (the p-th mode) is $A(Np+e) = u_{((Np+e)/N)} = u_{(p+e/N)}$, which is (35.5). `mode_resc` is this computation. The hypothesis `htr` is lower truncation of A (fractional modes vanish for large index), and it makes resc a field; `rescFld` packages it.

Physical meaning

Rescaling by $z^{e/N}$ removes the branch cut: $z^{e/N}Y_M(u,z)$ has integer exponents and is single-valued, as a physicist would do by multiplying a twisted field by the compensating phase from the twist-field OPE. For the boson $F_a(z) = z^{1/2}\partial X_a(z)$ is the single-valued field obtained by stripping off the $\sqrt{z}$ branch cut of the antiperiodic current; it is a heuristic change of variables that turns twisted fields into ordinary (integer-moded) fields to which the untwisted OPE calculus applies.

35.4.3 The reduction theorems

Theorem 35.10 (Twisted Jacobi from locality and the product formula). *Let Y_M be lower truncated, $u, v \in \mathcal{V}$, $e, e' \in \mathbb{Z}$. Suppose $\widetilde{F}_e(u)$ and $\widetilde{F}_{e'}(v)$ are mutually local and satisfy the twisted product formula (35.7) at every $\ell' \geq \ell$ (resp. every ℓ'). Then for all x and all $m, n \in \mathbb{Z}$ the twisted Jacobi identity (35.4) holds for (u, v) at ℓ (resp. every ℓ), with $k = Nm + e$ and the mode index of v equal to $Nn + e'$.*

```

From the mathematics to the Lean statement

Hypotheses. `hN`: $N \geq 1$. `htr`: lower truncation of all fractional modes (this is a field of `TwistedModule`). `hloc`: locality of the two rescaled fields (Definition 35.3). `hpf`: the mode form of (35.7): `YM (W.smul u (ℓ'+t) v) (N*(s-t)+e+e')` is $(u_{(\ell'+t)}v)_{((N(s-t)+e+e')/N)}$, the $(s-t)$-th mode of $\widetilde{F}_{e+e'}(u_{(\ell'+t)}v)$; the shift $s \mapsto s-t$ is the multiplication by z^{-t}. In the `_ge` version the formula is only required at $\ell' \geq \ell$; this matters for the cross-check of §35.5.3, where only $\ell \geq 0$ is available. **Conclusion.** With $k := Nm + e$ and $m' := Nn + e'$ this is (35.4) for (u, v, x, ℓ, k, m') letter for letter (`YM u (ℓ*N + k - i*N)` etc.). Note that no eigenspace hypothesis on u appears: the theorem is about whichever class e one chooses. **Why not vacuous.** Both hypotheses are consequences of the twisted Jacobi identity itself (the product formula is its m-independent part); they are therefore the honest targets, not stronger assumptions in disguise. The reader can also see that they are satisfiable: §35.12 proves them for the Heisenberg example.

Physical meaning

The theorem is the algebraic proof that crossing symmetry of the twisted correlators follows from two ingredients: locality of the stripped fields (fields at distinct points commute) and the form of the OPE in the presence of the twist field. It parallels the standard physics argument that once one knows the singularity structure of the two-point function of the twisted fields and the OPE, the commutation relations of all modes follow; Dong–Li–Mason's twisted Jacobi identity is the output. It mirrors how one derives commutators from OPEs by contour deformation, with the twist field giving the extra $(1 + z_0/z)^{e/N}$ factor.

Proof on paper. This is the computation of §35.4.1 made precise. Apply (35.3) to $a = \widetilde{F}_e(u), b = \widetilde{F}_{e'}(v)$ (local by hypothesis) at (ℓ, m, n). Its left side is the left side of the claim after the index rewriting $\ell N + (Nm + e) - iN = N(\ell + m - i) + e$, etc. Its right side is $\sum_{i \geq 0} \binom{m}{i} (a_{(\ell+i)}b)_{(m+n-i)}$; insert (35.7) with $\ell' = \ell + i \geq \ell$, regroup the double sum along $i + t = \varsigma$ (it is finite, because $u_{(p)}v = 0$ for $p \gg 0$), and apply Lemma 35.8 with $x = m$, $y = e/N$, noting $m + e/N = (Nm + e)/N$. □

What the machine verified

Unconditional (the hypotheses are explicit and are discharged for the Heisenberg example later in the chapter). Axiom-clean.

To get `TwistedJacobi` one needs every $u \in \mathcal{V}^j$ on its support coset and every v on every class. Choosing offsets once and for all:

Theorem 35.11 (The assembled reduction). *Let $g \in \mathrm{Aut}(W)$ and choose $\mathrm{off}(j) \equiv -j \pmod N$ for every j. If for every j, every $u \in \mathcal{V}^j$, every v and every $e' \in \{0, \dots, N-1\}$ the fields $\widetilde{F}_{\mathrm{off}(j)}(u)$ and $\widetilde{F}_{e'}(v)$ are mutually local and satisfy (35.7), then Y_M satisfies the twisted Jacobi identity.*

File `VOA/Moonshine/HeisenbergTwistedModuleReduction.lean`.

```
theorem twistedJacobi_of_local_pf {W : VertexOperatorAlgebra 𝒱} (g : Aut W)
    (YM : 𝒱 →ₗ[ℂ] (ℤ → End ℂ M)) {N : ℕ} (hN : 0 < N)

            YM (W.smul u (ℓ + t) v) (N * (s - t) + off j + e') x) :
    TwistedJacobi g N YM
```

From the mathematics to the Lean statement

`hoff` says $N \mid \mathrm{off}(j) + j$. The conclusion is the predicate of §35.2.4. **Why $e' \in [0, N)$ suffices:** any index m' of v is $N\lfloor m'/N \rfloor + (m' \bmod N)$; and any admissible k for $u \in \mathcal{V}^j$ is $Nq + \mathrm{off}(j)$. So every instance of (35.4) is an instance of Theorem 35.10. Note that the theorem does not need v to be an eigenvector.

Physical meaning

This is the same statement for all pairs of states, bookkept by the $\mathbb{Z}_N$-grading: operators in the $\mathcal{V}^j$ sector are multivalued with phase $e^{2\pi i j/N}$, and only the class e' of the second operator modulo N matters. Physically it says that to verify consistency of the whole twisted sector it is enough to check, for each pair, the ordinary local OPE with the rescaled fields; no information beyond the OPE and locality is required.

Proof on paper. Given $u \in \mathcal{V}^j$, v, x, ℓ, k with $N \mid k + j$ and m': write $k = Nq + \mathrm{off}(j)$ (possible since $N \mid k - \mathrm{off}(j)$), $m' = Nn + e'$ with $0 \le e' < N$, and apply Theorem 35.10. □

What the machine verified

Unconditional as a reduction; axiom-clean.

35.4.4 Binomial inversion

The twisted vertex operator will be *defined* by the inverse of (35.7). Since $(1 + z_0/z)^{e/N}$ has inverse $(1 + z_0/z)^{-e/N}$, (35.6) is equivalent to

$$\widetilde{F}_{e+e'}(u_{(\ell)}v) = \sum_{i \ge 0} \binom{-e/N}{i} z^{-i}\, \widetilde{F}_e(u)_{(\ell+i)} \widetilde{F}_{e'}(v). \tag{35.8}$$

Proposition 35.12. *Let $c \in \mathbb{C}$ and let $P, Q : \mathbb{Z}\times\mathbb{Z} \to M$ vanish for $\ell \geq L$. If $Q(\ell,s) = \sum_{i\geq 0} \binom{-c}{i} P(\ell+i, s-i)$ for all ℓ, s, then $P(\ell,s) = \sum_{t\geq 0} \binom{c}{t} Q(\ell+t, s-t)$ for all ℓ, s.*

File `VOA/Moonshine/HeisenbergTwistedModuleReduction.lean`.

```
theorem pf_of_inverse (c : ℂ) (P Q : ℤ → ℤ → M) (L : ℤ)
    (hP : ∀ ℓ s, L ≤ ℓ → P ℓ s = 0) (hQ : ∀ ℓ s, L ≤ ℓ → Q ℓ s = 0)
    (hinv : ∀ ℓ s, Q ℓ s = ∑ᶠ i : ℕ, cbinom (-c) i • P (ℓ + i) (s - i)) (ℓ s : ℤ) :
    P ℓ s = ∑ᶠ t : ℕ, cbinom c t • Q (ℓ + t) (s - t)
```

From the mathematics to the Lean statement

Exactly the proposition; the vanishing hypotheses make all sums finite. In use, $P(\ell,s)$ is the s-th mode (on a fixed vector) of $\widetilde{F}_e(u)_{(\ell)}\widetilde{F}_{e'}(v)$ and $Q(\ell,s)$ that of $\widetilde{F}_{e+e'}(u_{(\ell)}v)$; the second index $s-i$ is the shift by z^{-i}.

Physical meaning

This is the inversion of the OPE correction factor, $(1+z_0/z)^{-c}(1+z_0/z)^{c} = 1$. In the twisted-boson language it lets one pass from the OPE of two twisted fields (which is what one measures in a correlator) to the OPE of untwisted fields with a branch-cut factor removed, and conversely: the twisted vertex operator can be read off recursively from the twisted OPE, as in the physicist's procedure of defining composite twisted operators by point splitting and subtracting singular terms.

Proof on paper. Substitute: $\sum_t \binom{c}{t} Q(\ell+t, s-t) = \sum_{\kappa\geq 0}\big[\sum_{t+i=\kappa} \binom{c}{t}\binom{-c}{i}\big] P(\ell+\kappa, s-\kappa)$, and by Lemma 35.8 the bracket is $\binom{0}{\kappa} = \delta_{\kappa,0}$. □

What the machine verified

Unconditional, axiom-clean.

35.5 The generator fields

From now on $W = $ `heisVOA1 r`, $g = \sigma$, $N = 2$, $M = S[\theta] = $ `FockT r`.

35.5.1 Support and truncation of the twisted Heisenberg field

The twisted vertex operator of $h_a(-1)\mathbf{1}$ must be the twisted boson $h_a(z) = \sum_{t\in\frac{1}{2}+\mathbb{Z}} h_a(t) z^{-t-1}$; as a fractional-mode family it is $k \mapsto h_a(k/2) =$ `modeT r a k`.

Proposition 35.13. *(i)* `modeT r a k` $= 0$ *unless* $k \equiv -1 \pmod 2$*; (ii) for every $x \in S[\theta]$, $h_a(k/2)x = 0$ for $k \gg 0$.*

```
theorem modeT_support (a : Fin r) (k : ℤ) (hk : (k + (1 : ℕ)) % ((2 : ℕ) : ℤ) ≠ 0) :
    modeT r a k = 0
theorem modeT_truncation (a : Fin r) (x : FockT r) :
    ∃ K : ℤ, ∀ k : ℤ, K ≤ k → modeT r a k x = 0
```

From the mathematics to the Lean statement

(i) is the support condition for $u = h_a(-1)\mathbf{1} \in V^1$ ($j=1$), in the exact syntactic form of the `support` field (with casts `(1 : ℕ)`, `(2 : ℕ)`). (ii) is the `truncation` field. Both hold trivially (even modes are 0 by definition; a polynomial involves finitely many variables, and $h_a(k/2)$

for large odd k differentiates along a variable that does not occur).

Physical meaning

The twisted boson current $\partial X(z) = \sum_{t \in \frac{1}{2}+\mathbb{Z}} \alpha_t z^{-t-1}$ has only half-integer modes (antiperiodic boundary conditions), and acting on any finite-energy state only finitely many annihilation modes are nonzero. These are the minimal consistency conditions: no integer modes means no zero mode and hence no momentum, since the twist field sits at a fixed point of $X \to -X$.

What the machine verified

Unconditional, axiom-clean. `VOA/Moonshine/HeisenbergTwistedModuleGenerators.lean`.

35.5.2 The rescaled generator $z^{1/2}h_a(z)$

Definition 35.14. $F_a(z) := \widetilde{F}_1(h_a(-1)\mathbf{1}) = z^{1/2}h_a(z) = \sum_{p\in\mathbb{Z}} h_a(p+\frac{1}{2})z^{-p-1}$.

```
noncomputable def Fgen (a : Fin r) : FormalDist (End ℂ (FockT r)) := resc (modeT r a) 2 1
@[simp] theorem mode_Fgen (a : Fin r) (p : ℤ) : mode (Fgen r a) p = modeT r a (2 * p + 1)
noncomputable def FgenFld (a : Fin r) : Fld (FockT r) :=
  rescFld (A := modeT r a) (by norm_num : 0 < 2) (modeT_truncation r a) 1
```

From the mathematics to the Lean statement

`modeT r a (2p+1)` is $h_a(p+\frac{1}{2})$: the p-th mode of F_a, offset $e = 1$. The offset $1 \equiv -1 \pmod 2$ is the support coset of $\mathcal{V}^1$.

Physical meaning

$F_a(z) = z^{1/2}\partial X_a(z)$ is the single-valued form of the antiperiodic current: multiplying by $\sqrt{z}$ compensates the branch cut at the twist field. Its modes are $h_a(p+\frac{1}{2})$ with $p \in \mathbb{Z}$, an integer-indexed family, so its OPE (below) is an ordinary single-valued one; a standard device in CFT (e.g. in the bosonic orbifold of Dixon–Friedan–Martinec–Shenker).

Theorem 35.15 (The generator commutator)**.**

$$[F_a(z_1), F_b(z_2)] = \delta_{ab}\Big(z_2\,\partial_{z_2}\delta(z_1,z_2) + \tfrac{1}{2}\,\delta(z_1,z_2)\Big).$$

Consequently F_a, F_b are mutually local (of order 2), and $F_{a(0)}F_b = \frac{1}{2}\delta_{ab}\,1$, $F_{a(1)}F_b = \delta_{ab}\,z$, $F_{a(\ell)}F_b = 0$ for $\ell \geq 2$.

```
noncomputable def opeOne (a b : Fin r) : FormalDist (End ℂ (FockT r)) :=
  fun t => if t = 1 then (if a = b then (1 : ℂ) else 0) • LinearMap.id else 0
noncomputable def opeZero (a b : Fin r) : FormalDist (End ℂ (FockT r)) :=
  fun t => if t = 0 then (if a = b then (1 / 2 : ℂ) else 0) • LinearMap.id else 0

theorem bracketDist_Fgen (a b : Fin r) :
    bracketDist (Fgen r a) (Fgen r b)
      = deltaDeriv 1 (opeOne r a b) + deltaDeriv 0 (opeZero r a b)
theorem Fgen_local (a b : Fin r) : Local (Fgen r a) (Fgen r b)
theorem prod_Fgen_zero (a b : Fin r) :
    (Fld.prod 0 (FgenFld r a) (FgenFld r b)).1 = opeZero r a b
```

```
theorem prod_Fgen_one (a b : Fin r) :
    (Fld.prod 1 (FgenFld r a) (FgenFld r b)).1 = opeOne r a b
theorem prod_Fgen_of_two_le (a b : Fin r) {ℓ : ℤ} (hℓ : 2 ≤ ℓ) :
    (Fld.prod ℓ (FgenFld r a) (FgenFld r b)).1 = 0
```

From the mathematics to the Lean statement

`opeOne a b` has its only nonzero coefficient at z^1: it is $\delta_{ab} z \cdot \mathrm{id}$. `opeZero a b` is $\frac{1}{2}\delta_{ab}\mathrm{id}$ at z^0. By the decoding of `deltaDeriv` (§35.2.2), the right side of `bracketDist_Fgen` is $\delta_{ab} z_2 \partial_{z_2}\delta + \frac{1}{2}\delta_{ab}\delta$: same as the theorem.

Physical meaning

This is canonical quantisation of the twisted boson: $[\alpha_s, \alpha_t] = s\delta_{s+t,0}$ with $s, t \in \frac{1}{2} + \mathbb{Z}$, rewritten for $z^{1/2}\partial X$. The double pole $\delta_{ab}\, z/(z_1 - z_2)^2$ is the usual short-distance singularity $\partial X(z_1)\partial X(z_2) \sim 1/(z_1 - z_2)^2$ (the same in every sector), and the extra simple pole with residue $\frac{1}{2}$ is the effect of the branch factor $\sqrt{z_1 z_2}$ in the two-point function $\frac{(z_1/z_2)^{1/2} + (z_2/z_1)^{1/2}}{2(z_1 - z_2)^2}$ of the twisted boson; it is the seed of the shift of L_0 by $1/16$ per boson.

Proof on paper. Using $[h_a(s), h_b(t)] = s\delta_{ab}\delta_{s+t,0}$,

$$[F_a(z_1), F_b(z_2)] = \delta_{ab} \sum_{p \in \mathbb{Z}} (p + \tfrac{1}{2}) z_1^{-p-1} z_2^{p}.$$

On the other hand $z_2\partial_{z_2}\delta(z_1, z_2) = \sum_m (-m-1) z_1^m z_2^{-m-1} = \sum_p p\, z_1^{-p-1} z_2^p$ and $\frac{1}{2}\delta = \frac{1}{2}\sum_p z_1^{-p-1} z_2^p$. Since $(z_1 - z_2)\delta = 0$ and $(z_1 - z_2)^2 \partial\delta = 0$, the commutator is killed by $(z_1 - z_2)^2$. The products for $\ell \geq 0$ are $\mathrm{Res}_{z_1}(z_1 - z_2)^{\ell}[F_a(z_1), F_b(z_2)]$: $\mathrm{Res}_{z_1}\delta = 1$, $\mathrm{Res}_{z_1}(z_1 - z_2)\partial_{z_2}\delta = 1$, and all others vanish. □

Remark 35.16 (Where the $\frac{1}{2}$ comes from)**.** For an *untwisted* boson, $[h(z_1), h(z_2)] = \sum_p p\, z_1^{-p-1} z_2^{p-1} = \partial_{z_2}\delta(z_1, z_2)$, so $z_2^1 \cdot$ that commutator is $z_2\partial_{z_2}\delta$ and there is no δ term. For the twisted boson the mode labels are $p + \frac{1}{2}$, and the coefficient $p + \frac{1}{2}$ splits into p (the untwisted pattern) plus a constant $\frac{1}{2}$. That constant, a pure artefact of antiperiodicity, is the central term $F_{a(0)}F_b = \frac{1}{2}$; it is the seed of every correction term below, including the vacuum energy.

What the machine verified

Unconditional, axiom-clean.

35.5.3 A cross-check: two generators at $\ell \geq 0$

Before the general construction, the reduction can be tested on the simplest nontrivial case, and doing so pins down every convention (offset, binomial, vacuum index). In W, $h_a(-1)\mathbf{1}_{(n)}h_b(-1)\mathbf{1} = \delta_{n,1}\delta_{ab}\mathbf{1}$ for $n \geq 0$ (this is `smul_X_X_nonneg`).

Theorem 35.17. *Let Y_M be* any *linear, lower-truncated fractional-mode map on $\mathcal{V}$ with $Y_M(\mathbf{1})_{(k/2)} = \delta_{k,-2}$ and $Y_M(h_a(-1)\mathbf{1}) = (h_a(k/2))_k$ for all a. Then the twisted Jacobi identity holds for $u = h_a(-1)\mathbf{1}$, $v = h_b(-1)\mathbf{1}$, every $\ell \geq 0$, every odd k and every m.*

File `VOA/Moonshine/HeisenbergTwistedModuleGenerators.lean`.

          YM ((heisVOA1 r).smul (X (0, a)) (ℓ + i) (X (0, b))) (k + m - i * (2 : ℕ)) x
```

From the mathematics to the Lean statement

Hypotheses (section variables, included in the theorem): `YM` arbitrary linear; `htr` truncation; `hvac` the vacuum axiom for $N = 2$ (`k = -2` is $\mathbf{1}_{(-1)}$); `hgen` the generators go to the twisted bosons. `vacuumN r` is $\mathbf{1} = 1 \in$ `FockN r`. **Conclusion**: (35.4) with $N = 2$, $u = X(0,a)$, $v = X(0,b)$, restricted to $\ell \geq 0$. **Weaker than the full identity** (only $\ell \geq 0$, only generators), but stronger in another way: it holds for every Y_M with these properties, so it is a test of conventions rather than of a construction.

Physical meaning

This is a consistency check of conventions: two ∂X insertions in the presence of the twist field, with the OPE singularity and the monodromy of the branch cut both accounted for, give the Jacobi identity at nonnegative pole order. Physically the test is that the commutator of two twisted currents is the canonical one, $[\alpha_s, \alpha_t] = s\delta_{s+t,0}$, with the fractional binomial supplying the $\sqrt{z}$ branch cut.

Proof on paper. Take $e = 1$ for u and $e' = m \bmod 2$ for v. If $e' = 0$ the rescaled field of v on the even class is 0 (twisted bosons have no integral modes), and both sides vanish. If $e' = 1$ both rescaled fields are F_a, F_b, local by Theorem 35.15. The product formula at $\ell \geq 0$ reads: the left side is $F_{a(\ell)}F_b$, i.e. $\frac{1}{2}\delta_{ab}, \delta_{ab}z, 0$ for $\ell = 0, 1, \geq 2$; the right side is $\sum_t \binom{1/2}{t} z^{-t}\widetilde{F}_2(u_{(\ell+t)}v)$, and only $\ell + t = 1$ contributes, with $\widetilde{F}_2(\mathbf{1}) = z$ (the vacuum on the even class 2 is $z^{2/2} \cdot \mathrm{id}$). For $\ell = 1$: $t = 0$, giving z. For $\ell = 0$: $t = 1$, giving $\binom{1/2}{1} z^{-1} z = \frac{1}{2}$. For $\ell \geq 2$: nothing. So the product formula holds at $\ell \geq 0$, and Theorem 35.10 (the `_ge` form) applies. Note how the twisted central term $\frac{1}{2}$ is matched by the fractional binomial $\binom{1/2}{1}$: this is the twisted Heisenberg relation $[h_a(k/2), h_b(m/2)] = \frac{k}{2}\delta_{ab}\delta_{k+m,0}$ in disguise. □

What the machine verified

Unconditional, axiom-clean. It is later specialised to the constructed Y^T (`twistedJacobi_generators_nonneg_YT`), and superseded by Theorem 35.41.

35.6 Locality of everything generated

35.6.1 Multiplication by powers of z

The rescaled field of u on the class $e + N$ is z times the one on the class e. So the system of fields we work with must be closed under $z^k \cdot$.

Definition 35.18. $(z^k a)(z)$ has coefficient a_{n-k} at z^n; its p-th mode is $a_{(p+k)}$.

File `VOA/Moonshine/HeisenbergTwistedModuleLocality.lean`.

```
def zmul (k : ℤ) (a : FormalDist (End ℂ M)) : FormalDist (End ℂ M) := fun n => a (n - k)
@[simp] theorem mode_zmul (k : ℤ) (a : FormalDist (End ℂ M)) (p : ℤ) :
    mode (zmul k a) p = mode a (p + k)
theorem resc_add_N (A : ℤ → End ℂ M) (N : ℕ) (e : ℤ) :
    resc A N (e + N) = zmul 1 (resc A N e)
def fzmul (k : ℤ) (a : Fld M) : Fld M := ⟨zmul k a.1, isField_zmul a.2 k⟩
theorem Local.zmul_left {a b : FormalDist (End ℂ M)} (h : Local a b) (k : ℤ) :
    Local (zmul k a) b
```

From the mathematics to the Lean statement

Direct transcriptions. `Local.zmul_left` (and its mirror `Local.zmul_right`) hold because multiplication by z_1^k commutes with multiplication by $(z_1 - z_2)^N$.

Physical meaning

Multiplying by z^k is the operation of multiplying a field by a power of the radial coordinate; in CFT this changes the conformal weight by $-k$ in the sense of the L_0-grading and shifts the labels of the modes. It is the formal counterpart of passing between $\sqrt{z}\,\partial X$ and ∂X, and so between the single-valued and the multivalued description of the twisted current.

35.6.2 The generated system

Definition 35.19 (Generated twisted system)**.** For a set S of fields, $\langle S\rangle$ is the smallest set of fields containing S, the identity field and 0, and closed under all products $a_{(n)}b$ ($n \in \mathbb{Z}$), all $z^k\cdot$ ($k \in \mathbb{Z}$), sums and scalar multiples. In Lean it is defined with a size index i (the number of operations used), to support induction.

File `VOA/Moonshine/HeisenbergTwistedModuleLocality.lean`.

```
inductive TGen (S : Set (Fld M)) : ℕ → Fld M → Prop
  | base {a : Fld M} : a ∈ S → TGen S 0 a

def TGenerated (S : Set (Fld M)) : Set (Fld M) := {a | ∃ i, TGen S i a}
```

From the mathematics to the Lean statement

An inductive predicate: `TGen S i a` holds exactly when a can be built by the listed rules using i steps; `TGenerated S` forgets i. This is precisely $\langle S\rangle$.

Physical meaning

The generated system is the algebra of local operators one gets by taking all products (OPE coefficients), derivatives, multiplications by powers of z and linear combinations of the basic twisted currents: in CFT language, the operators of the twisted sector built from ∂X by normal ordering and point splitting. Closure under OPE is what makes it a local operator algebra,

and the construction shows that the physical operators in the twisted sector, built by normal ordering and point splitting from the fundamental boson, form a single local system.

Theorem 35.20 (Locality is inherited). *If the fields of S are pairwise mutually local, then so are all fields of $\langle S\rangle$. In particular, for $S = \{F_a : a < r\}$, every two fields in $\langle S\rangle$ are mutually local.*

    {a b : Fld M} (ha : a ∈ TGenerated S) (hb : b ∈ TGenerated S) : Local a.1 b.1

def genSet : Set (Fld (FockT r)) := Set.range (FgenFld r)
theorem twistedSystem_local {a b : Fld (FockT r)} (ha : a ∈ TGenerated (genSet r))
    (hb : b ∈ TGenerated (genSet r)) : Local a.1 b.1
```

From the mathematics to the Lean statement

`Set.range (FgenFld r)` is $\{F_a\}$. `tgen_local` carries an auxiliary size bound N for the strong induction; `tgenerated_local` is the clean statement. Same as the theorem.

Physical meaning

This is the free-field statement that every operator built from the twisted current by point splitting and normal ordering remains mutually local with every other, i.e. has a pole of finite order in its OPEs. Physically: the operators of a free CFT sector form a consistent set of local fields as soon as the basic current is local, and the twist field at the origin does not spoil this. Dong's lemma is the algebraic form of the fact that the OPE of two local fields is again a local field.

Proof on paper. Strong induction on the total number of operations used to build a and b. If one of them is an atom $(S, 1, 0)$ and so is the other, use the hypothesis or the fact that 1 and 0 are local with everything. Otherwise decompose the non-atomic one: sums and scalars preserve locality; $z^k\cdot$ preserves it (above); and for a product $a_{(n)}b$ against c use *Dong's lemma*: if a, b, c are pairwise local then $a_{(n)}b$ and c are local, for every $n \in \mathbb{Z}$. The three pairwise localities needed are smaller instances. □

What the machine verified

Unconditional, axiom-clean. `VOA/Moonshine/HeisenbergTwistedModuleLocality.lean`.

The point is strategic: whatever Y^T is, as long as every rescaled field it produces lies in $\langle F_a\rangle$, locality — one of the two inputs of Theorem 35.11 — is automatic.

35.7 The twisted vertex operator

35.7.1 The definition by inverting the product formula

Suppose a twisted module structure Y^T exists with $Y^T(h_a(-1)\mathbf{1}, z) = h_a(z)$. Apply the inverse product formula (35.8) with $u = h_a(-1)\mathbf{1}$ (class $e = 1$, $\widetilde{F}_1(u) = F_a$), $\ell = -n-1$ and any state w on a class e'. Since $u_{(-n-1)}w = h_a(-n-1)w$ is multiplication by the variable $x_{(n,a)}$,

$$\widetilde{F}_{e'+1}\big(x_{(n,a)}\, w\big) = \sum_{i\ge 0} \binom{-1/2}{i} z^{-i}\, F_{a(-n-1+i)}\, \widetilde{F}_{e'}(w). \tag{35.9}$$

This is a *recursion*: it expresses the rescaled twisted field of a monomial of degree $d+1$ through that of a monomial of degree d, starting from $\widetilde{F}_0(\mathbf{1}) = 1$. So Y^T is *forced*, and we may take (35.9) as its definition. The terms with $-n-1+i<0$ are normal-ordered products (the "naive" part, what one gets by substituting twisted bosons into the untwisted formula); the terms with $-n-1+i\geq 0$ are contractions with the generators — these are the correction terms that FLM collect into Δ_z.

A monomial is read through a *word*: a list $l=[(n_1,a_1),\dots,(n_d,a_d)]$ of variables, the state being $x_{(n_1,a_1)}\cdots x_{(n_d,a_d)}$, with weight $\mathrm{wt}(l)=\sum(n_t+1)$.

Definition 35.21 (Twisted word fields). $\widetilde{Y}([\,])=1$ and

$$\widetilde{Y}\big((n,a)::w\big)=\sum_{i=0}^{n+2+2\,\mathrm{wt}(w)}\binom{-1/2}{i}z^{-i}\,F_{a(-n-1+i)}\widetilde{Y}(w).$$

Files `VOA/Moonshine/HeisenbergTwistedModuleVertex.lean`, `VOA/Examples/HeisenbergNVertex.lean`.

```
noncomputable def Ywt : List (ℕ × Fin r) → Fld (FockT r)
  | [] => Fld.one
  | (c :: w) => ∑ i ∈ Finset.range (c.1 + 3 + 2 * wordWeightNN w),
      cbinom (-1 / 2) i • fzmul (-(i : ℤ)) (Fld.prod (-(c.1 : ℤ) - 1 + i) (FgenFld r c.2)
       ↪ (Ywt w))

def wordWeightNN (l : List (ℕ × Fin r)) : ℕ := (l.map (fun ia => ia.1 + 1)).sum
```

From the mathematics to the Lean statement

`c :: w` is the list with first letter $c=(c.1,c.2)=(n,a)$; `Finset.range K` is $\{0,\dots,K-1\}$. `fzmul (-i)` is $z^{-i}\cdot$ (§35.6); `Fld.prod (-n-1+i) (FgenFld r a) (Ywt w)` is $F_{a(-n-1+i)}\widetilde{Y}(w)$. The **explicit cut-off** $n+3+2\,\mathrm{wt}(w)$ replaces the infinite sum of (35.9); it is harmless because $F_{b(k)}\widetilde{Y}(w)=0$ for $k\geq 1+\mathrm{wt}(w)$ (Proposition 35.33), so the omitted terms vanish. The definition is literally recursive on lists, so it is well-founded with no further argument.

Physical meaning

This recursion is the point-splitting definition of composite twisted operators. To define the field of $\partial X\partial X\cdots$ at a point in the twisted sector one brings an additional current F_a to the existing composite and subtracts the singular terms of the OPE, order by order; the terms with $-n-1+i<0$ are the naive normal-ordered product, while those with $-n-1+i\geq 0$ are contractions with the existing composite, weighted by the Taylor coefficients $\binom{-1/2}{i}$ of the branch factor $(1+z_0/z)^{-1/2}$. These contractions are the physical origin of the Δ_z correction of FLM and, ultimately, of the $1/16$ vacuum energy; naive normal ordering of twisted modes alone gives the wrong stress tensor.

Definition 35.22 (The twisted vertex operator). For a monomial x^m of degree d with canonical word l_m, $Y^T(x^m)_{(k/2)}=\widetilde{Y}(l_m)_{((k-d)/2)}$ if $k\equiv d \pmod 2$, and 0 otherwise. Y^T is extended linearly to `FockN r`.

Files `VOA/Examples/HeisenbergNVertex.lean`, `VOA/Moonshine/HeisenbergTwistedModuleVertex.lean`.

```
noncomputable def monoWordN (a : (ℕ × Fin r) →₀ ℕ) : List (ℕ × Fin r) :=
  a.support.toList.flatMap (fun ia => List.replicate (a ia) ia)

noncomputable def YTmon (m : (ℕ × Fin r) →₀ ℕ) : ℤ → End ℂ (FockT r) := fun k =>
  if (k - (monoWordN m).length) % 2 = 0 then
    mode (Ywt r (monoWordN m)).1 ((k - (monoWordN m).length) / 2)
  else 0

noncomputable def YT : FockN r →ₗ[ℂ] (ℤ → End ℂ (FockT r)) :=
  Finsupp.linearCombination ℂ (YTmon r)
```

From the mathematics to the Lean statement

`monoWordN m` lists every variable v with multiplicity m_v, in the order of `Finset.toList` — an order Lean does not specify. Its length is $d = \deg m$ (`length_monoWordN`). `Finsupp.linearCombination` extends a function on the monomial basis linearly (a polynomial *is* a finitely supported coefficient function on monomials). **Decoding the index**: $\widetilde{Y}(l)$ is the rescaled field of the monomial on the class $e = d$; mode p of it is $Y^T(x^m)_{(p+d/2)}$, i.e. fractional index $k = 2p + d$, $p = (k - d)/2$. **Two potential pitfalls**, both resolved later: (a) dependence on the unspecified letter order — resolved by Theorem 35.34; (b) the definition chooses the class $e = d$, consistent with the support condition since $x^m \in \mathcal{V}^d$ needs $k \equiv -d \equiv d$.

Physical meaning

$Y^T(u, z)$ is the state–operator map in the presence of the twist field: it assigns to each local operator u of the untwisted theory (a polynomial in ∂X and its derivatives) the operator that acts on the twisted Fock space as that same local operator inserted in the antiperiodic sector, $\langle\sigma|\, u(z)\cdots|\sigma\rangle$. The modes are fractional because $u(z)$ of parity d picks up $(-1)^d$ around the twist field, so a monomial of degree d has modes in $\frac{d}{2} + \mathbb{Z}$. This is the definition that in the physics literature is obtained by writing the operator with point-splitting in the twisted sector.

35.7.2 First properties

Theorem 35.23. *(i)* $Y^T(\mathbf{1})_{(k/2)} = \delta_{k,-2}\,\mathrm{id}$*; (ii)* $Y^T(h_a(-1)\mathbf{1})_{(k/2)} = h_a(k/2)$*; (iii) lower truncation; (iv) the support condition: for* $u \in \mathcal{V}^j$*,* $Y^T(u)_{(k/2)} = 0$ *unless* $k \equiv -j \pmod 2$.

```
theorem YT_vacuum (k : ℤ) : YT r (vacuumN r) k = if k = -2 then 1 else 0
theorem YT_X (a : Fin r) : YT r (X (0, a)) = modeT r a
theorem YT_truncation (u : FockN r) (x : FockT r) :
    ∃ K : ℤ, ∀ k : ℤ, K ≤ k → YT r u k x = 0
theorem YT_support (j : ℕ) (u : FockN r) (hu : u ∈ (sigma1 r).twistedEigenspace 2 j)
    (k : ℤ) (hk : (k + j) % ((2 : ℕ) : ℤ) ≠ 0) : YT r u k = 0
```

From the mathematics to the Lean statement

These are, verbatim up to the definitional unfolding `W.vacuum = vacuumN r` and the casts, the fields `vacuum_YM`, `truncation`, `support` of `TwistedModule` for $N = 2$; (ii) is the requirement that the generators act by the twisted bosons. `1` in (i) is the identity endomorphism. No hypotheses beyond $u \in \mathcal{V}^j$ in (iv).

Physical meaning

These are the elementary consistency requirements of the state–operator correspondence: the identity operator acts trivially, the current ∂X acts as the antiperiodic boson, local operators have finite singularity at the twist field (truncation), and the parity of a local operator under $X \to -X$ determines whether it has integer or half-integer modes (support). In particular $Y^T(\partial X, z) = \partial X(z)$ is the twisted boson with half-integer modes.

Proof on paper. (i) The vacuum is the empty word, $\widetilde{Y}([\,]) = 1(z)$ on the class 0, whose only mode is $1_{(-1)} = \mathrm{id}$, i.e. $k = 2\cdot(-1) + 0 = -2$. (ii) For the one-letter word $[(0, a)]$ the defining sum is $\sum_{i<3}\binom{-1/2}{i} z^{-i} F_{a(-1+i)}1$; since $F_{(-1)}1 = F$ and $F_{(j)}1 = 0$ for $j \geq 0$, it is F_a on the class 1, whose modes are $h_a(p + \frac{1}{2})$. (iii) $\widetilde{Y}(l)$ is a field. (iv) An eigenvector $u \in \mathcal{V}^j$ only contains monomials of degree $d \equiv j$, each of whose fractional modes live on $k \equiv d$. □

What the machine verified

Unconditional, axiom-clean. `VOA/Moonshine/HeisenbergTwistedModuleVertex.lean`.

35.7.3 Locality of all rescaled fields

Theorem 35.24. *For every state u and class e, $\widetilde{F}_e(u) \in \langle F_a \rangle$. Hence for all u, v, e, e' the fields $\widetilde{F}_e(u)$ and $\widetilde{F}_{e'}(v)$ are mutually local.*

```
theorem resc_YT_mem (u : FockN r) (e : ℤ) :
    ∃ F ∈ TGenerated (genSet r), resc (YT r u) 2 e = F.1
theorem YT_local (u v : FockN r) (e e' : ℤ) :
    Local (resc (YT r u) 2 e) (resc (YT r v) 2 e')
```

From the mathematics to the Lean statement

`resc (YT r u) 2 e` is $\widetilde{F}_e(u)$ (Definition 35.9). This discharges the locality hypothesis of Theorem 35.11 for *all* pairs and classes, more than is needed.

Physical meaning

All twisted local operators are mutually local: the OPE of two arbitrary composite operators built from the twisted boson has only finite poles. This is the algebraic form of the physical expectation that free-field composite operators in the twisted sector form a local operator algebra with the twist field a spectator whose only effect is the monodromy.

Proof on paper. By construction $\widetilde{Y}(l) \in \langle F_a \rangle$ (each step uses products with F_a, powers of z, scalars and sums). For a monomial on the class e, $\widetilde{F}_e$ is $z^{(e-d)/2}\widetilde{Y}(l_m)$ or 0; sums and scalars stay in $\langle F_a \rangle$. Then apply Theorem 35.20. □

What the machine verified

Unconditional, axiom-clean.

35.7.4 What remained: the product formula

With locality in hand, Theorem 35.11 (with $\mathrm{off}(j) = j$, which is $\equiv -j \bmod 2$) reduces the Jacobi identity to the product formula alone:

```
theorem twistedJacobi_YT_of_productFormula
    (hpf : ∀ (j : ℕ) (u : FockN r), u ∈ (sigma1 r).twistedEigenspace 2 j → ∀ (v : FockN r)
      (e' : ℤ), 0 ≤ e' → e' < 2 → ∀ (ℓ s : ℤ) (x : FockT r),
      mode (Fld.prod ℓ (rescFld (by norm_num : 0 < 2) (YT_truncation r u) (j : ℤ))
          (rescFld (by norm_num : 0 < 2) (YT_truncation r v) e')).1 s x
        = ∑ᶠ t : ℕ, cbinom ((((j : ℤ) : ℤ) : ℂ) / (2 : ℕ)) t •
            YT r ((heisVOA1 r).smul u (ℓ + t) v) ((2 : ℕ) * (s - t) + (j : ℤ) + e') x) :
    TwistedJacobi (sigma1 r) 2 (YT r)
```

From the mathematics to the Lean statement

The single hypothesis `hpf` is (35.7) for $u \in \mathcal{V}^j$ on the class j, every v on the classes $0, 1$. It is a genuine hypothesis in this theorem; it is discharged in §35.12 (Theorem 35.40).

Physical meaning

This reduces the full twisted Jacobi identity, equivalent to crossing symmetry of the σ-twisted correlators, to the statement that the twisted OPE has the expected form with the branch factor $(1+z_0/z)^{e/2}$. Heuristically, once locality is known, the only datum that can be wrong is how the monodromy of the twist field enters the OPE, and that datum is the product formula.

Trap / dead end

The module docstring of `HeisenbergTwistedModuleVertex.lean` still calls Y^T a "candidate" and says that `hpf`, word-order independence and the composite Jacobi identity are "not proved in this file". That is accurate about the file, but historical: all three are proved downstream (Theorems 35.34, 35.40, 35.41). During the session that built these files an intermediate draft of `HeisenbergTwistedModuleFieldComm.lean` contained `sorry` and was unwired; in that earlier version of the library the file was already `sorry`-free (as it is at a pre-release build commit) and (transitively, through `HeisenbergTwistedModuleInstance.lean`) imported by the umbrella `VOA/Moonshine.lean`.

35.8 The vacuum energy $r/16$

35.8.1 The theorem

Theorem 35.25 (L_0 of the twisted module). $Y^T(\omega)_{(1)} = L_0^T = \sum_a \sum_{n\geq 0} h_a(-n-\frac{1}{2})h_a(n+\frac{1}{2}) + \frac{r}{16}$. *Consequently* $Y^T(\omega)_{(1)}$ *acts on* `weightT r q` *by* q.

File `VOA/Moonshine/HeisenbergTwistedModuleL0.lean`.

```
theorem YT_omega_two : YT r (heisVOA1 r).conformalVector 2 = L0T r

theorem YT_omega_two_weightT {q : ℚ} {x : FockT r} (hx : x ∈ weightT r q) :
    YT r (heisVOA1 r).conformalVector 2 x = (q : ℂ) • x
```

From the mathematics to the Lean statement

Decoding. `YT r ω 2` is $\omega_{(2/2)} = \omega_{(1)}$, the twisted L_0 (with $N = 2$, the fractional index $k = N$ is mode 1). `L0T r` is $\frac{1}{2}E + \frac{r}{16}$ (§35.2.5). `weightT r q` is the span of the monomials with $d/2 + r/16 = q$. **Fidelity.** Exactly the theorem. **Not circular:** the definition of Y^T (Definition 35.21) mentions neither $r/16$ nor `L0T`; the constant comes out of the binomial coefficients $\binom{-1/2}{i}$, as we now show.

Physical meaning

The theorem is the statement that the Virasoro L_0 of the twisted sector, built from the stress tensor $T = \frac{1}{2}{:}\partial X \partial X{:}$ inserted in the antiperiodic sector, equals the oscillator number $\sum_n (n+\frac{1}{2})N_n$ plus the zero-point energy $r/16$: each boson contributes 1/16, so the twist field σ has conformal weight $r/16$ (the familiar $h_\sigma = \frac{1}{16}$ of the $\mathbb{Z}_2$ twist field of a single $c = 1$ boson). Heuristically the constant is a Casimir energy: with zeta-function regularisation $\frac{1}{2}\sum_{n\geq 0}(n+\frac{1}{2}) = \frac{1}{48}$ while $\frac{1}{2}\sum_{n\geq 1} n = -\frac{1}{24}$, and the difference is $\frac{1}{16}$ (a heuristic cross-check, not the proof). In the library the number is not put in by hand but arises from the point-splitting contractions.

35.8.2 The computation

Since $\omega = \frac{1}{2}\sum_a h_a(-1)^2\mathbf{1} = \frac{1}{2}\sum_a x^2_{(0,a)}$, and $x^2_{(0,a)}$ is the word $[(0,a),(0,a)]$ of degree $d = 2$, we need mode 0 of $\widetilde{Y}([(0,a),(0,a)])$ (class 2; mode p corresponds to $k = 2p+2$; $k = 2$ is $p = 0$). By definition, with the cut-off $0 + 3 + 2\cdot 1 = 5$,

$$\widetilde{Y}([(0,a),(0,a)]) = \sum_{i=0}^{4} \binom{-1/2}{i} z^{-i} F_{a(-1+i)}F_a.$$

By Theorem 35.15, the terms are:

- $i = 0$: $:F_aF_a:$, whose mode 0 is $2\sum_{n\geq 0} h_a(-n-\frac{1}{2})h_a(n+\frac{1}{2})$ (each pair (n,a) occurs twice in the normal-ordered square, once from each factor);
- $i = 1$: $\binom{-1/2}{1} z^{-1}F_{a(0)}F_a = (-\frac{1}{2})(\frac{1}{2})z^{-1} = -\frac{1}{4}z^{-1}$;
- $i = 2$: $\binom{-1/2}{2} z^{-2}F_{a(1)}F_a = \frac{3}{8}z^{-2}\cdot z = \frac{3}{8}z^{-1}$, since $\binom{-1/2}{2} = \frac{(-\frac{1}{2})(-\frac{3}{2})}{2} = \frac{3}{8}$;
- $i = 3,4$: $F_{a(\ell)}F_a = 0$ for $\ell \geq 2$.

Mode 0 of $c\,z^{-1}$ is c (the coefficient of z^{-1}). Hence

$$\widetilde{Y}([(0,a),(0,a)])_{(0)} = 2\sum_{n\geq 0} h_a(-n-\tfrac{1}{2})h_a(n+\tfrac{1}{2}) + \left(-\tfrac{1}{4}+\tfrac{3}{8}\right) = 2\sum_{n\geq 0} h_a(-n-\tfrac{1}{2})h_a(n+\tfrac{1}{2}) + \tfrac{1}{8}. \quad (35.10)$$

Multiplying by $\frac{1}{2}$ and summing over a gives $\sum_{a,n} h_a(-n-\frac{1}{2})h_a(n+\frac{1}{2}) + \frac{r}{16}$, which is L_0^T by `L0T_eq_modeSum`.

```
theorem mode_Ywt_pair_zero (a : Fin r) :
    mode (Ywt r [((0 : ℕ), a), ((0 : ℕ), a)]).1 0
      = mode (nprod (FgenFld r a).2 (FgenFld r a).2) 0 + (1 / 8 : ℂ) • (1 : End ℂ (FockT
      ↪ r))
```

From the mathematics to the Lean statement

This is (35.10): `nprod` is $:F_aF_a:$, and `(1/8) • 1` is the constant. The two correction terms are *both* needed: the $-\frac{1}{4}$ comes from the twisted central term $F_{(0)}F = \frac{1}{2}$ and is negative; the $+\frac{3}{8}$ comes from the ordinary double pole $F_{(1)}F = z$ and the second binomial coefficient.

Physical meaning

This is the normal-ordering computation of the stress tensor in the twisted sector by point splitting. The two corrections $-\frac{1}{4}$ (from the simple pole $\frac{1}{2}$ of the twisted current OPE) and $+\frac{3}{8}$ (from the double pole and the second Taylor coefficient of $(1+z_0/z)^{-1/2}$) add up to $\frac{1}{8}$, which equals twice the vacuum energy per boson; it is the regular term $\frac{1}{8z_2^2}$ of $\langle\partial X(z_1)\partial X(z_2)\rangle_\sigma$ after subtracting $1/(z_1-z_2)^2$, i.e. $\langle\sigma|T(z)|\sigma\rangle = \frac{1}{16}z^{-2}$.

What the machine verified

`YT_omega_two`: unconditional; `#print axioms` gives `[propext, Classical.choice, Quot.sound]`. `VOA/Moonshine/HeisenbergTwistedModuleL0.lean`.

35.8.3 Comparison with FLM's Δ_z

FLM (and Lepowsky 1985) define the twisted vertex operator of the Heisenberg part as

$$Y^T(u,z) = Y_0\big(e^{\Delta_z} u,\, z\big), \qquad \Delta_z = \sum_{m,n\ge 0} c_{mn} \sum_a h_a(m) h_a(n)\, z^{-m-n},$$

where Y_0 is the naive operator (substitute the twisted boson into the normal-ordered monomial formula, with the appropriate power of z), $h_a(m)$, $m \ge 0$, are the *untwisted* annihilation operators acting on the state u, and the numbers c_{mn} are defined by

$$\sum_{m,n\ge 0} c_{mn} x^m y^n = -\log\!\Big(\frac{(1+x)^{1/2} + (1+y)^{1/2}}{2}\Big).$$

Expanding $(1+x)^{1/2} = 1 + \tfrac{x}{2} - \tfrac{x^2}{8} + \cdots$ gives $\tfrac{(1+x)^{1/2}+(1+y)^{1/2}}{2} = 1 + u$ with $u = \tfrac{x+y}{4} - \tfrac{x^2+y^2}{16} + \cdots$, and $-\log(1+u) = -u + \tfrac{u^2}{2} - \cdots$; the coefficient of xy comes only from $\tfrac{u^2}{2} \ni \tfrac{2xy}{32}$, so $c_{11} = \tfrac{1}{16}$. On $\omega_a = \tfrac{1}{2} h_a(-1)^2 \mathbf{1}$ we have $h_a(0)\omega_a = 0$ and $h_a(1)^2 \omega_a = \mathbf{1}$, so $\Delta_z \omega = \tfrac{r}{16} z^{-2} \mathbf{1}$ (higher powers of Δ_z kill ω), and $Y^T(\omega, z) = Y_0(\omega, z) + \tfrac{r}{16} z^{-2}$: the z^{-2} coefficient, L_0, is shifted by $r/16$. Our $\tfrac{1}{8} = -\tfrac{1}{4} + \tfrac{3}{8}$ per boson, times the $\tfrac{1}{2}$ in ω, is this c_{11}. The library does not formalise Δ_z; the comparison is on paper.

Remark 35.26 (The physicist's check)**.** In conformal field theory the stress tensor of a free boson is $T(z) = \tfrac{1}{2} {:}h(z)h(z){:}$, defined by point splitting: $T(z_2) = \tfrac{1}{2} \lim_{z_1 \to z_2} \big(h(z_1)h(z_2) - \langle h(z_1)h(z_2) \rangle_{\mathrm{sing}} \big)$, where one subtracts the singular part $1/(z_1 - z_2)^2$ of the two-point function, which is the same in every sector. On the twisted ground state σ, $\langle h(z_1)h(z_2)\rangle$ means $\langle \sigma | h(z_1)h(z_2) | \sigma \rangle$; since $h(t)|\sigma\rangle = 0$ for $t > 0$, only the commutators $[h(t), h(-t)] = t$ contribute. The two-point function of an antiperiodic boson is therefore

$$\langle h(z_1)h(z_2)\rangle = \sum_{n\ge 0} (n + \tfrac{1}{2}) z_1^{-n-3/2} z_2^{n-1/2} = \frac{(z_1/z_2)^{1/2} + (z_2/z_1)^{1/2}}{2(z_1 - z_2)^2}.$$

Put $z_1 = z_2(1+x)$: $\tfrac{1}{2}\big((1+x)^{1/2} + (1+x)^{-1/2}\big) = 1 + \tfrac{x^2}{8} + O(x^3)$, so $\langle h(z_1)h(z_2)\rangle = \tfrac{1}{(z_1 - z_2)^2} + \tfrac{1}{8 z_2^2} + O(z_1 - z_2)$. The regular term $\tfrac{1}{8} z_2^{-2}$ survives the subtraction, so $\langle \sigma | T(z) | \sigma \rangle = \tfrac{1}{16} z^{-2}$; since $T(z) = \sum L_n z^{-n-2}$, this says $L_0 |\sigma\rangle = \tfrac{1}{16} |\sigma\rangle$, the twisted ground-state energy $\tfrac{1}{16}$: the same $\tfrac{1}{8}$ as in (35.10).

35.9 The commutator formula for products of local fields

The remaining input, the product formula for all pairs, will be proved by induction on the second state using *commutator* formulas only. The first is the field-level analogue of the VOA commutator formula $[u_{(p)}, v_{(q)}] = \sum_{r\ge 0} \binom{p}{r} (u_{(r)}v)_{(p+q-r)}$.

Theorem 35.27 (Commutator formula)**.** *Let A, B, C be fields on a vector space M with A, B mutually local, and let L be such that $A_{(s)}B = 0$ for $s \ge L$. Then for all $p, q \in \mathbb{Z}$,*

$$A_{(p)}\big(B_{(q)}C\big) - B_{(q)}\big(A_{(p)}C\big) = \sum_{s=0}^{L-1} \binom{p}{s} \big(A_{(s)}B\big)_{(p+q-s)} C.$$

File `VOA/Moonshine/HeisenbergTwistedModuleFieldComm.lean`.

```
theorem prod_comm_formula (hAB : Local A.1 B.1) (L : ℕ)
    (hL : ∀ r : ℕ, L ≤ r → Fld.prod r A B = 0) (p q : ℤ) :
    Fld.prod p A (Fld.prod q B C) - Fld.prod q B (Fld.prod p A C)
      = ∑ r ∈ Finset.range L, gBinom p r • Fld.prod (p + q - r) (Fld.prod r A B) C
```

From the mathematics to the Lean statement

A, B, C are section variables `{A B C : Fld M}`. Subtraction and the sum are taken in the vector space of fields. **No locality of** C with A or B is assumed; this is correct and somewhat stronger than the usual statement inside a local system, and it is what makes the theorem usable for arbitrary C. The bound L exists by locality; it only makes the sum finite (any larger L gives the same sum).

Physical meaning

This is the field-level form of the standard CFT statement that the commutator $[A(z_1), B(z_2)]$ is determined by the OPE singular terms: contour deformation turns the commutator of modes $[A_{(p)}, B_{(q)}]$ into the modes of the OPE coefficients $A_{(s)}B$. Here it is used for composite operators of the twisted boson; heuristically it is the Ward-identity-style derivation of commutation relations from OPEs.

Proof on paper. Compute the N-th mode of both nested products with the iterate formula (35.2). Each nested product expands into four families of triple products $A_{.}B_{.}C_{.}$, $A_{.}C_{.}B_{.}$, ... of modes. Two families appear identically on both sides and cancel. The two that remain pair up into commutators $[A_{(\alpha)}, B_{(\beta)}]$, applied to modes of C. Locality expresses each mode commutator by the ordinary commutator formula for local fields, $[A_{(\alpha)}, B_{(\beta)}] = \sum_s \binom{\alpha}{s}(A_{(s)}B)_{(\alpha+\beta-s)}$. The resulting double binomial sums are regrouped by Vandermonde's identity into the iterate formula for $(A_{(s)}B)_{(p+q-s)}C$. □

What the machine verified

Unconditional, axiom-clean. `VOA/Moonshine/HeisenbergTwistedModuleFieldComm.lean`.

Two further identities control powers of z:

Proposition 35.28. *For fields A, B and $\ell, c \in \mathbb{Z}$: (i) $A_{(\ell)}(z^c B) = z^c (A_{(\ell)}B)$; (ii) if A, B are local and $A_{(j+t)}B = 0$ for $t \geq T$, then $(z^c A)_{(j)}B = \sum_{t<T} \binom{c}{t} z^{c-t} A_{(j+t)}B$.*

```
theorem prod_fzmul_right (ℓ c : ℤ) (A B : Fld M) :
    Fld.prod ℓ A (fzmul c B) = fzmul c (Fld.prod ℓ A B)

theorem prod_fzmul_left {D C : Fld M} (h : Local D.1 C.1) (c j : ℤ) (T : ℕ)
    (hT : ∀ t : ℕ, T ≤ t → Fld.prod (j + t) D C = 0) :
    Fld.prod j (fzmul c D) C
      = ∑ t ∈ Finset.range T, gBinom c t • fzmul (c - t) (Fld.prod (j + t) D C)
```

From the mathematics to the Lean statement

In (ii) the Lean names are D, C for A, B. (i) needs no hypothesis: z^c in the second slot is a function of the outer variable z. (ii) is the formal expansion $(z + z_0)^c = \sum_t \binom{c}{t} z^{c-t} z_0^t$ inside the product, which requires locality because the product is defined by residues of $(z_1 - z)^n$ and one needs to trade z_1^c for $(z + (z_1 - z))^c$.

Physical meaning

These identities express how the multivalued factor z^c interacts with OPEs: z^c sits at the position of the second operator and does not affect contractions, while a factor z^c attached to the first operator is Taylor-expanded around the second, $(z_2 + z_0)^c = \sum \binom{c}{t} z_2^{c-t} z_0^t$. Technical lemma in the computation of the OPE in the presence of the twist field.

What the machine verified

Unconditional, axiom-clean.

35.10 Twisted products

35.10.1 Definition

The inverse product formula (35.8) suggests a new product.

Definition 35.29 (Twisted product). For a field A, $\alpha \in \mathbb{C}$, $p \in \mathbb{Z}$ and a field X,

$$A \star_p^\alpha X := \sum_{i \geq 0} \binom{-\alpha}{i} z^{-i} A_{(p+i)}X, \qquad \text{i.e.} \qquad \sum_p (A \star_p^\alpha X)\, z_0^{-p-1} = \left(1 + \frac{z_0}{z}\right)^{-\alpha} \sum_p (A_{(p)}X) z_0^{-p-1}.$$

File `VOA/Moonshine/HeisenbergTwistedModuleTwistedComm.lean`.

```
noncomputable def star (α : ℂ) (A : Fld M) (p : ℤ) (X : Fld M) : Fld M :=
  ∑ᶠ i : ℕ, cbinom (-α) i • fzmul (-(i : ℤ)) (Fld.prod (p + i) A X)
```

From the mathematics to the Lean statement

`star α A p X` is $A \star_p^\alpha X$. The finitary sum $\sum^{\mathtt{f}}$ is a genuine finite sum whenever A and X are local (then $A_{(p+i)}X = 0$ for $i \gg 0$), which is always the case below; if A, X were not local and infinitely many terms were nonzero, $\sum^{\mathtt{f}}$ would return 0 — a junk value that never occurs in this chapter, since all twisted products are formed inside $\langle F_a \rangle$. With $\alpha = 0$ it is the ordinary product (`star_zero`).

Physical meaning

The twisted product $A \star_p^\alpha X$ is the OPE coefficient of $A(z_0 + z)X(z)$ with the extra branch factor $(1 + z_0/z)^{-\alpha}$ removed: it is the product that a physicist would define for fields on the plane with a cut from the twist field, where the branch factor $(z+z_0)^\alpha$ of the first field must be accounted for when its position is shifted by z_0. With $\alpha = 0$ it is the ordinary OPE coefficient; $\alpha = \frac{1}{2}$ is the twist of the antiperiodic current.

In this language the product formula, inverted, becomes the statement that $u \mapsto \widetilde{F}(u)$ is a *homomorphism* from the products of W to the twisted products:

$$\widetilde{F}_e(u) \star_\ell^{e/2} \widetilde{F}_{e'}(v) = \widetilde{F}_{e+e'}(u_{(\ell)}v). \tag{35.11}$$

35.10.2 The twisted commutator formula

Theorem 35.30 (Twisted commutator formula). *Let S be a pairwise local set of fields and $A, B, C \in \langle S \rangle$; let $A_{(s)}B = 0$ for $s \geq L$. For $\alpha, \beta \in \mathbb{C}$ and $p, q \in \mathbb{Z}$,*

$$A \star_p^\alpha (B \star_q^\beta C) - B \star_q^\beta (A \star_p^\alpha C) = \sum_{s=0}^{L-1} \binom{p}{s} (A \star_s^\alpha B) \star_{p+q-s}^{\alpha+\beta} C.$$

File `VOA/Moonshine/HeisenbergTwistedModuleTwistedComm.lean`.

```
theorem star_comm {S : Set (Fld M)} (hS : ∀ a ∈ S, ∀ b ∈ S, Local a.1 b.1) {A B C : Fld M}
    (hA : A ∈ TGenerated S) (hB : B ∈ TGenerated S) (hC : C ∈ TGenerated S) (α β : ℂ)
    (p q : ℤ) (L : ℕ) (hL : ∀ s : ℕ, L ≤ s → Fld.prod s A B = 0) :
    star α A p (star β B q C) - star β B q (star α A p C)
      = ∑ s ∈ Finset.range L, gBinom p s • star (α + β) (star α A s B) (p + q - s) C
```

From the mathematics to the Lean statement

Hypotheses: `hS` pairwise locality of the generating set; `hA hB hC` membership in the generated system (this guarantees every pair that occurs is local, so every $\sum^{\mathtt{f}}$ is an honest finite sum); `hL` a bound for the products $A_{(s)}B$. Note the twist $\alpha+\beta$ of the outer product on the right: the twists add, as the exponents $e/2$ do in (35.11). Same as the theorem.

Physical meaning

This is the commutator-from-OPE formula in the presence of the twist field: the twist field modifies the product by the branch factor $(1+z_0/z)^{-\alpha}$, and the twists simply add when OPEs are composed, $\alpha+\beta$, reflecting that the monodromies around the origin multiply. Heuristically this is the twisted analogue of the Ward-type derivation of mode commutators from OPEs.

Proof on paper. Expand both sides by the definition. On the left, using Proposition 35.28(i) to move powers of z out of the second slot,

$$\mathrm{LHS}=\sum_{i,k\ge 0}\binom{-\alpha}{i}\binom{-\beta}{k}z^{-i-k}\Big(A_{(p+i)}B_{(q+k)}C-B_{(q+k)}A_{(p+i)}C\Big),$$

and by Theorem 35.27 the bracket is $\sum_{\varsigma}\binom{p+i}{\varsigma}(A_{(\varsigma)}B)_{(p+q+i+k-\varsigma)}C$. On the right, $A\star^{\alpha}_{s}B=\sum_{r}\binom{-\alpha}{r}z^{-r}A_{(s+r)}B$, and Proposition 35.28(ii) expands $(z^{-r}D)_{(j)}C=\sum_{t}\binom{-r}{t}z^{-r-t}D_{(j+t)}C$. Collecting terms with $\varsigma=s+r$ and total power z^{-J} ($J=i+k$ on the left, $J=m+r+t$ on the right), the identity reduces to the binomial identity

$$\sum_{i+k=J}\binom{-\alpha}{i}\binom{-\beta}{k}\binom{p+i}{\varsigma}=\sum_{s+r=\varsigma}\binom{p}{s}\binom{-\alpha}{r}\binom{-\alpha-\beta-r}{J-r},$$

proved by $\binom{p+i}{\varsigma}=\sum_{s+r=\varsigma}\binom{p}{s}\binom{i}{r}$ (Vandermonde), $\binom{x}{i}\binom{i}{r}=\binom{x}{r}\binom{x-r}{i-r}$, and Vandermonde again: $\sum_{i+k=J}\binom{-\alpha-r}{i-r}\binom{-\beta}{k}=\binom{-\alpha-\beta-r}{J-r}$. □

What the machine verified

Unconditional, axiom-clean. `VOA/Moonshine/HeisenbergTwistedModuleTwistedComm.lean`.

35.10.3 Auxiliary identities

Proposition 35.31. *For fields A,X (local where stated) and $\alpha\in\mathbb{C}$, $c,k,n\in\mathbb{Z}$:*

(i) $A\star^{\alpha}_{p}(z^{c}X)=z^{c}(A\star^{\alpha}_{p}X)$;

(ii) *(A,X local)* $(z^{c}A)\star^{\alpha}_{p}X=z^{c}\big(A\star^{\alpha-c}_{p}X\big)$: *a power of z in the first slot shifts the twist;*

(iii) $A\star^{\alpha}_{\ell}1=0$ *for* $\ell\ge 0$, *and* $A\star^{\alpha}_{-1}1=A$;

(iv) $(z^{c}1)\star^{c}_{k}X=\delta_{k,-1}\,z^{c}X$: *the vacuum on the even class $2c$;*

(v) $(\partial A-\alpha z^{-1}A)\star^{\alpha}_{n}1=-nA\star^{\alpha}_{n-1}1$;

(vi) *(G,Y local)* $\partial(G\star^{\alpha}_{q}Y)=G\star^{\alpha}_{q}\partial Y-qG\star^{\alpha}_{q-1}Y+\alpha z^{-1}G\star^{\alpha}_{q}Y$.

```
theorem star_fzmul_right (α : ℂ) (A : Fld M) (p c : ℤ) (X : Fld M) :
    star α A p (fzmul c X) = fzmul c (star α A p X)
theorem star_fzmul_left {A X : Fld M} (h : Local A.1 X.1) (α : ℂ) (c p : ℤ) :
    star α (fzmul c A) p X = fzmul c (star (α - c) A p X)
theorem star_one_right_nonneg (α : ℂ) (A : Fld M) {ℓ : ℤ} (hℓ : 0 ≤ ℓ) :
    star α A ℓ Fld.one = 0
theorem star_one_right_neg_one (α : ℂ) (A : Fld M) : star α A (-1) Fld.one = A
theorem star_fzmul_one (c k : ℤ) (X : Fld M) :
    star (c : ℂ) (fzmul c Fld.one) k X = if k = -1 then fzmul c X else 0
theorem star_deriv_one (α : ℂ) (A : Fld M) (n : ℤ) :
    star α (Fld.deriv A - α • fzmul (-1) A) n Fld.one
      = (-n : ℂ) • star α A (n - 1) Fld.one
theorem deriv_star {G Y : Fld M} (h : Local G.1 Y.1) (α : ℂ) (q : ℤ) :
    Fld.deriv (star α G q Y)
      = star α G q (Fld.deriv Y) - (q : ℂ) • star α G (q - 1) Y
        + α • fzmul (-1) (star α G q Y)
```

From the mathematics to the Lean statement

`Fld.deriv` is ∂_z, mode-wise $(\partial a)_{(m)} = -m\, a_{(m-1)}$. In (iii)–(v) no locality hypothesis is needed, because the identity field is local with everything. These are all formal-calculus identities with the same content as stated.

Physical meaning

Technical lemma in the twisted OPE calculus: (i)–(ii) say how multiplying by z^c shifts the monodromy, (iii)–(iv) say that the vacuum (identity operator) has trivial OPE, up to the shift of class, and (v)–(vi) are the compatibility with translation ∂_z, the Ward identity for L_{-1} in the presence of the twist field, where αz^{-1} is the derivative of the branch factor z^α.

Proof on paper. (i) from Proposition 35.28(i). (ii) from Proposition 35.28(ii) and Vandermonde $\sum_{i+t=J} \binom{-\alpha}{i}\binom{c}{t} = \binom{-\alpha+c}{J}$. (iii) $A_{(j)}1 = 0$ for $j \geq 0$, $A_{(-1)}1 = A$. (iv) by (ii), $(z^c 1) \star_k^c X = z^c(1 \star_k^0 X) = z^c(1_{(k)}X)$, and $1_{(k)}X = \delta_{k,-1}X$. (v) and (vi) are the derivative rules $(\partial A)_{(n)}X = -nA_{(n-1)}X$, $\partial(A_{(n)}X) = (\partial A)_{(n)}X + A_{(n)}\partial X$, plus $\partial z^{-i} = -iz^{-i-1}$ and $\binom{-\alpha}{i+1}(i+1) = \binom{-\alpha}{i}(-\alpha - i)$, which combine the z^{-i-1} terms into $\alpha z^{-1}\cdot$. □

What the machine verified

Unconditional, axiom-clean.

35.11 Words: order independence and creation

35.11.1 Twisted products of two generators

Proposition 35.32. *$F_a \star_1^{1/2} F_b = \delta_{ab}\, z$, and $F_a \star_i^{1/2} F_b = 0$ for every other $i \in \mathbb{N}$.*

```
theorem star_gen_gen (a b : Fin r) (i : ℕ) :
    star (1 / 2) (FgenFld r a) i (FgenFld r b)
      = if i = 1 then (if a = b then (1 : ℂ) else 0) • fzmul 1 (Fld.one : Fld (FockT r))
        else 0
```

From the mathematics to the Lean statement

`fzmul 1 Fld.one` is $z \cdot 1(z)$, which is $\widetilde{F}_2(\mathbf{1})$, the vacuum on the class 2. So, by (35.11), this is the twisted image of the untwisted relations $h_a(-1)\mathbf{1}_{(1)}h_b(-1)\mathbf{1} = \delta_{ab}\mathbf{1}$, $(\cdot)_{(0)}(\cdot) = 0$, $(\cdot)_{(i)}(\cdot) = 0$

for $i \geq 2$. Only $i \geq 0$ is stated ($i : \mathbb{N}$).

Physical meaning

This is the OPE of the twisted current with itself after the branch factor $(1 + z_0/z)^{-1/2}$ has been divided out: only the double pole $\delta_{ab}/(z_1 - z_2)^2$ survives, and the extra simple pole $\frac{1}{2}$ of F_a is exactly cancelled. Heuristically this reflects that the short-distance singularity of $\partial X \partial X$ is the same in every sector, the sector dependence being carried entirely by the branch factor; it is the twisted image of the untwisted relations $h_a(-1)\mathbf{1}_{(1)}h_b(-1)\mathbf{1} = \delta_{ab}\mathbf{1}$.

Proof on paper. $F_a \star_0^{1/2} F_b = F_{a(0)}F_b + \binom{-1/2}{1} z^{-1}F_{a(1)}F_b = \frac{1}{2}\delta_{ab} - \frac{1}{2}z^{-1}\delta_{ab}z = 0$: the twisted central term is cancelled exactly. $F_a \star_1^{1/2} F_b = F_{a(1)}F_b = \delta_{ab}z$ (the next term involves $F_{a(2)}F_b = 0$). Higher i: all products vanish. □

What the machine verified

Unconditional, axiom-clean. `VOA/Moonshine/HeisenbergTwistedModuleWords.lean`.

35.11.2 The cut-off is harmless

Proposition 35.33. *For every word l, every b and every $k \geq 1 + \mathrm{wt}(l)$: $F_{b(k)}\widetilde{Y}(l) = 0$. Consequently $\widetilde{Y}((n,a) :: w) = F_a \star_{-n-1}^{1/2} \widetilde{Y}(w)$.*

```
theorem prod_Fgen_Ywt_eq_zero (b : Fin r) :
    ∀ (l : List (ℕ × Fin r)) (k : ℤ), 1 + (wordWeightNN l : ℤ) ≤ k →
      Fld.prod k (FgenFld r b) (Ywt r l) = 0

theorem Ywt_cons_star (c : ℕ × Fin r) (w : List (ℕ × Fin r)) :
    Ywt r (c :: w) = star (1 / 2) (FgenFld r c.2) (-(c.1 : ℤ) - 1) (Ywt r w)
```

From the mathematics to the Lean statement

The first statement bounds the pole order of a generator against a word field by the conformal weight of the word plus one — the field-theoretic shadow of $h_b(k)$ killing a state of weight $< k$. The second identifies the truncated recursion of Definition 35.21 with the (untruncated) twisted product, because the terms beyond the cut-off involve $F_{a(k)}\widetilde{Y}(w)$ with $k \geq n + 2 + 2\mathrm{wt}(w) \geq 1 + \mathrm{wt}(w)$.

Physical meaning

A state of weight $\mathrm{wt}(l)$ is annihilated by oscillators of mode number above $\mathrm{wt}(l)$: a finite-energy state has no components of arbitrarily high annihilation modes. This is why the OPE of ∂X with a composite operator has a pole of finite order, which is what truncates the point-splitting recursion; a technical lemma in the same computation.

Proof on paper. Induction on l. For the empty word, $F_{b(k)}1 = 0$ for $k \geq 0$. For $l = (n,a) :: w$, each term of $\widetilde{Y}(l)$ is $z^{-i}F_{a(-n-1+i)}\widetilde{Y}(w)$; by Proposition 35.28(i) and Theorem 35.27, $F_{b(k)}F_{a(j)}\widetilde{Y}(w) = F_{a(j)}F_{b(k)}\widetilde{Y}(w) + \binom{k}{0}(F_{b(0)}F_a)_{(k+j)}\widetilde{Y}(w) + \binom{k}{1}(F_{b(1)}F_a)_{(k+j-1)}\widetilde{Y}(w)$. The first term is 0 by induction ($k \geq 1 + \mathrm{wt}(w)$); the others are products of the scalar fields $\frac{1}{2}$ and z with $\widetilde{Y}(w)$ at nonnegative index, which vanish. □

What the machine verified

Unconditional, axiom-clean.

35.11.3 Order independence

Theorem 35.34 (Word-order independence). *(i) For any c, c' and any $\mathcal{F} \in \langle F_a \rangle$, the twisted creation operators commute: $F_a \star^{1/2}_{-n-1} \left(F_{a'} \star^{1/2}_{-n'-1} \mathcal{F}\right) = F_{a'} \star^{1/2}_{-n'-1} \left(F_a \star^{1/2}_{-n-1} \mathcal{F}\right)$, where $c = (n, a)$, $c' = (n', a')$. (ii) If l' is a permutation of l, then $\widetilde{Y}(l) = \widetilde{Y}(l')$.*

```
theorem star_gen_swap (c c' : ℕ × Fin r) {F : Fld (FockT r)} (hF : F ∈ TGenerated (genSet
↪  r)) :
    star (1 / 2) (FgenFld r c.2) (-(c.1 : ℤ) - 1)
        (star (1 / 2) (FgenFld r c'.2) (-(c'.1 : ℤ) - 1) F)
      = star (1 / 2) (FgenFld r c'.2) (-(c'.1 : ℤ) - 1)
          (star (1 / 2) (FgenFld r c.2) (-(c.1 : ℤ) - 1) F)

theorem Ywt_perm {l l' : List (ℕ × Fin r)} (h : l.Perm l') : Ywt r l = Ywt r l'
```

From the mathematics to the Lean statement

`l.Perm l'` is "l' is a rearrangement of l". Hence $\widetilde{Y}$ depends only on the multiset of letters, i.e. on the monomial; the unspecified order in `monoWordN` is irrelevant, and Definition 35.22 is a genuine function of the monomial. **Why this needed proof:** the recursion (35.9) visibly singles out the first letter; without (i), Y^T could depend on an arbitrary choice made by `Finset.toList`.

Physical meaning

Bosonic composite operators do not care about the order of the factors: the normal-ordered product $:\partial X\, \partial X \cdots :$ is symmetric because the oscillators commute (bosons), and the Heisenberg relations $[\alpha_s, \alpha_t] = s\delta_{s+t,0}$ only contribute contractions between creation and annihilation modes. The theorem checks that the point-splitting definition of composite twisted operators respects this symmetry: it is consistent with Bose statistics.

Proof on paper. (i) Apply Theorem 35.30 with $\alpha = \beta = \frac{1}{2}$, $p = -n-1$, $q = -n'-1$. By Proposition 35.32 only $s = 1$ contributes, giving $\binom{p}{1}\delta_{aa'}(z1) \star^{1}_{p+q-1} \mathcal{F}$, and by Proposition 35.31(iv) with $c = 1$ this is $\delta_{p+q-1,-1}(\ldots)$; but $p + q - 1 = -n - n' - 3 \le -3$. So the commutator vanishes. (ii) Every permutation is a composite of adjacent transpositions; use (i) and Proposition 35.33. □

What the machine verified

Unconditional, axiom-clean.

35.11.4 The rescaled twisted vertex operators and creation

Definition 35.35. $\widetilde{F}_e(u) := \mathrm{resc}(Y^T(u), 2, e)$, the field with p-th mode $u_{(p+e/2)}$.

File `VOA/Moonshine/HeisenbergTwistedModuleWords.lean`.

```
noncomputable def FT (e : ℤ) (u : FockN r) : Fld (FockT r) :=
  rescFld (by norm_num : 0 < 2) (YT_truncation r u) e

theorem FT_shift (e c : ℤ) (u : FockN r) : FT r (e + 2 * c) u = fzmul c (FT r e u)
```

```
theorem FT_monomial (e : ℤ) (m : (ℕ × Fin r) →₀ ℕ) :
    FT r e (monomial m 1) = if (e - m.degree) % 2 = 0
      then fzmul ((e - m.degree) / 2) (Ywt r (monoWordN m)) else 0

theorem FT_eq_zero_of_parity {j : ℕ} {u : FockN r} (hu : u ∈ (sigma1 r).twistedEigenspace 2
↪  j)
    {e : ℤ} (he : (e + j) % 2 ≠ 0) : FT r e u = 0
```

From the mathematics to the Lean statement

`FT` is $\widetilde{F}$ for the constructed Y^T; it is linear in u (`FT_add`, `FT_smul`). `FT_shift`: moving the class by $2c$ multiplies by z^c. `FT_monomial`: on a monomial of degree d, $\widetilde{F}_e = z^{(e-d)/2}\widetilde{Y}(l_m)$ if $e \equiv d$, else 0. `FT_eq_zero_of_parity`: off the support class the rescaled field vanishes.

Physical meaning

$\widetilde{F}_e(u)$ is the single-valued form of the twisted operator associated to u: the operator $Y^T(u,z)$ multiplied by $z^{e/2}$ to cancel the branch cut. It is the object on which the untwisted OPE calculus is applied; physically it is the operator $u(z)$ in the presence of the twist field, with the monodromy factored out.

Theorem 35.36 (Creation). *For every state w, class e and letter (n,a): $\widetilde{F}_{e+1}\big(x_{(n,a)}w\big) = F_a \star^{1/2}_{-n-1} \widetilde{F}_e(w)$. Equivalently, since $h_a(-1)\mathbf{1}_{(-n-1)}w = x_{(n,a)}w$ in W, $\widetilde{F}_{e+1}(b_{(-n-1)}w) = F_b \star^{1/2}_{-n-1} \widetilde{F}_e(w)$ for $b = h_b(-1)\mathbf{1}$.*

File `VOA/Moonshine/HeisenbergTwistedModuleWords.lean`.

```
theorem FT_mul_X (e : ℤ) (c : ℕ × Fin r) (w : FockN r) :
    FT r (e + 1) (X c * w) = star (1 / 2) (FgenFld r c.2) (-(c.1 : ℤ) - 1) (FT r e w)

theorem FT_gen_creation (e : ℤ) (b : Fin r) (n : ℕ) (w : FockN r) :
    FT r (e + 1) ((heisVOA1 r).smul (X (0, b)) (-(n : ℤ) - 1) w)
      = star (1 / 2) (FgenFld r b) (-(n : ℤ) - 1) (FT r e w)
```

From the mathematics to the Lean statement

`X c * w` is multiplication in the polynomial ring, i.e. $h_{c,2}(-c.1-1)w$. This is the product formula (35.11) for u a generator and $\ell < 0$, for every w (not only eigenvectors) and every class e.

Physical meaning

Creating an extra oscillator at the origin by acting with $h_a(-n-1)$ on a state w corresponds in the twisted sector to point-splitting the new ∂X against the existing operator: the twisted operator of the product is the twisted OPE coefficient $F_a \star^{1/2}_{-n-1}$. This is the state–operator correspondence $|u\rangle = u(0)|\sigma\rangle$ in the twisted sector: acting with a mode of ∂X on a state creates the state of the composite operator.

Proof on paper. By linearity reduce to w a monomial x^m. If $e \not\equiv \deg m$ both sides vanish. Otherwise $x_{(n,a)}x^m$ has a canonical word that is a permutation of $(n,a) :: l_m$, so by Theorem 35.34 and Proposition 35.33 its word field is $F_a \star^{1/2}_{-n-1} \widetilde{Y}(l_m)$; the powers of z commute out of the second slot. □

What the machine verified

Unconditional, axiom-clean.

35.12 The twisted product formula for all pairs

35.12.1 Generators against everything

Theorem 35.37. *For every generator b, every class e', every $\ell \in \mathbb{Z}$ and every state w: $F_b \star_\ell^{1/2} \widetilde{F}_{e'}(w) = \widetilde{F}_{e'+1}(b_{(\ell)}w)$, where $b = h_b(-1)\mathbf{1}$.*

File `VOA/Moonshine/HeisenbergTwistedModuleProductFormula.lean`.

```

From the mathematics to the Lean statement

(35.11) with $u = X(0,b)$, $e = 1$ (so $e/2 = \frac{1}{2}$), all ℓ, all w, all e'. No hypotheses.

Physical meaning

This is the product formula (twisted OPE) for the basic field ∂X against any local operator: the OPE of the twisted current with an arbitrary composite operator is the OPE of the untwisted theory dressed by the branch factor. In free-field language it follows from Wick's theorem: the singular part of the OPE is a sum of contractions, which are computed by the canonical commutators $[\alpha_s, \alpha_t]$.

Proof on paper. For $\ell < 0$ this is Theorem 35.36. For $\ell \geq 0$ induct on the monomial w. If $w = \mathbf{1}$: the left side is $F_b \star_\ell^{1/2} (z^c 1)$ or 0, which vanishes by Proposition 35.31(i),(iii); the right side is $\widetilde{F}(b_{(\ell)}\mathbf{1}) = 0$. If $w = x_{(n,c)}w'$, write $\widetilde{F}_{e'}(w) = F_c \star_{-n-1}^{1/2} \widetilde{F}_{e'-1}(w')$ and apply the twisted commutator formula (Theorem 35.30) with $A = F_b$, $B = F_c$. By Proposition 35.32 and 35.31(iv),

$$F_b \star_\ell^{1/2} \left(F_c \star_{-n-1}^{1/2} X\right) = F_c \star_{-n-1}^{1/2} \left(F_b \star_\ell^{1/2} X\right) + \ell\, \delta_{bc}\, \delta_{\ell,n+1}\, zX.$$

By induction and creation the first term is $\widetilde{F}_{e'+1}(c_{(-n-1)}b_{(\ell)}w')$; the second is $\ell\delta_{bc}\delta_{\ell,n+1}\widetilde{F}_{e'+1}(w')$. In W, $b_{(\ell)}c_{(-n-1)}w' = c_{(-n-1)}b_{(\ell)}w' + \ell\delta_{bc}\delta_{\ell,n+1}w'$, the Heisenberg relation $[h_b(\ell), h_c(-n-1)] = \ell\delta_{bc}\delta_{\ell,n+1}$. The two sides agree. □

What the machine verified

Unconditional, axiom-clean.

35.12.2 Translation covariance and the vacuum

Theorem 35.38 (Translation covariance). *For every class e and state u: $\partial\widetilde{F}_e(u) - \frac{e}{2}z^{-1}\widetilde{F}_e(u) = \widetilde{F}_e(L_{-1}u)$. Consequently $\widetilde{F}_e(u) \star_\ell^{e/2} 1 = \widetilde{F}_e(u_{(\ell)}\mathbf{1})$ for all ℓ.*

```
theorem FT_translation (e : ℤ) (u : FockN r) :
    Fld.deriv (FT r e u) - ((e : ℂ) / 2) • fzmul (-1) (FT r e u)
      = FT r e ((heisVOA1 r).toPreVertexAlgebra.T u)

theorem starPF_one (e : ℤ) (u : FockN r) (ℓ : ℤ) :
    star ((e : ℂ) / 2) (FT r e u) ℓ Fld.one = FT r e ((heisVOA1 r).smul u ℓ (vacuumN r))
```

From the mathematics to the Lean statement

`T` is the translation operator L_{-1} of W (`T_eq_smul_omega`: $Tu = \omega_{(0)}u$). Since $\widetilde{F}_e(u) = z^{e/2}Y^T(u,z)$ (restricted to its class), $\partial\widetilde{F}_e = \frac{e}{2}z^{-1}\widetilde{F}_e + z^{e/2}\partial Y^T(u,z)$, so the first statement is the twisted L_{-1}-derivative property $\partial_z Y^T(u,z) = Y^T(L_{-1}u,z)$. The second is (35.11) with $v = \mathbf{1}$ on the class 0. Neither statement assumes u is an eigenvector or that e is on its class (off the class both sides are zero).

Physical meaning

The translation property is the statement $\partial_z Y^T(u,z) = Y^T(L_{-1}u,z)$: the derivative of a field is the field of the derivative state, with the extra term $\frac{e}{2}z^{-1}$ coming from differentiating the factor $z^{e/2}$ that was stripped off. Together with the vacuum property it expresses that L_{-1} generates translations of the insertion point of every twisted field, as the Ward identity requires; translation covariance in the presence of the twist field is only a statement relative to the origin, whence the term $\frac{e}{2}z^{-1}$.

Proof on paper. Translation: induct on monomials; for $u = x_{(n,c)}w$ use creation, the derivative rule (Proposition 35.31(vi)) with $\alpha = \frac{1}{2}$, the induction hypothesis for w on the class $e-1$, and $T(c_{(-n-1)}w) = c_{(-n-1)}Tw + (n+1)c_{(-n-2)}w$; the z^{-1} terms combine as $\frac{1}{2} + \frac{e-1}{2} = \frac{e}{2}$. Vacuum: for $\ell \geq 0$ both sides are 0; for $\ell = -1$ both are $\widetilde{F}_e(u)$; for $\ell = -k-2$ use (v) of Proposition 35.31 together with translation and $(Tu)_{(n)} = -nu_{(n-1)}$, by induction on k (for all u simultaneously), dividing by $k+1 \neq 0$. □

What the machine verified

Unconditional, axiom-clean. `VOA/Moonshine/HeisenbergTwistedModuleProductFormula.lean`.

35.12.3 The product formula

Theorem 35.39 (Twisted product formula, star form). *Let $u \in \mathcal{V}^j$ and $e \equiv j \pmod 2$. For every state v, every class e' and every $\ell \in \mathbb{Z}$: $\widetilde{F}_e(u) \star_\ell^{e/2} \widetilde{F}_{e'}(v) = \widetilde{F}_{e+e'}(u_{(\ell)}v)$.*

```
theorem starPF {j : ℕ} {u : FockN r} (hu : u ∈ (sigma1 r).twistedEigenspace 2 j) {e : ℤ}
    (he : (e + j) % 2 = 0) (v : FockN r) (e' ℓ : ℤ) :
    star ((e : ℂ) / 2) (FT r e u) ℓ (FT r e' v) = FT r (e + e') ((heisVOA1 r).smul u ℓ v)
```

From the mathematics to the Lean statement

Hypotheses: `hu` u is a σ-eigenvector of eigenvalue $(-1)^j$; `he` $2 \mid e + j$, i.e. the class of u is its support class. Both are necessary in general: off its class $\widetilde{F}_e(u) = 0$, while $\widetilde{F}_{e+e'}(u_{(\ell)}v)$ need not vanish. v is arbitrary. This is (35.11), i.e. the twisted vertex operator intertwines the products of W with the twisted products. **Not vacuous**: the right side is nonzero in general (e.g. $u = v = h_a(-1)\mathbf{1}$, $\ell = 1$ gives $z \cdot 1$).

Physical meaning

This is the twisted OPE in full generality: the operator product of two twisted fields is given by the untwisted OPE $u_{(\ell)}v$ up to the branch factor $(1 + z_{12}/z_2)^{e/2}$ of the cut from the twist field. In CFT terms it is associativity of the twisted correlator, equivalently that the twist field $\sigma(0)$ together with two operators at z_1, z_2 can be fused in the channel $z_1 \to z_2$ without knowing the details of σ beyond its monodromy; the proof uses only canonical commutation

relations, not any correlator.

Proof on paper. Induction on the monomial v, *for all u and j simultaneously*. For $v = \mathbf{1}$: Theorem 35.38 (classes e' even; for odd e' both sides are 0 by parity). For $v = x_{(n,c)}v' = c_{(-n-1)}v'$: by creation, $\widetilde{F}_{e'}(v) = F_c \star^{1/2}_{-n-1} \widetilde{F}_{e'-1}(v')$. Apply Theorem 35.30 with the *generator outside*: $A = F_c$, $B = \widetilde{F}_e(u)$, $C = \widetilde{F}_{e'-1}(v')$, twists $\frac{1}{2}$ and $\frac{e}{2}$:

$$F_c \star^{1/2}_{-n-1} \left(\widetilde{F}_e(u) \star^{e/2}_{\ell} C\right) - \widetilde{F}_e(u) \star^{e/2}_{\ell} \left(F_c \star^{1/2}_{-n-1} C\right) = \sum_s \binom{-n-1}{s} \left(F_c \star^{1/2}_{s} \widetilde{F}_e(u)\right) \star^{(e+1)/2}_{-n-1+\ell-s} C.$$

The second term on the left is what we want. The first is, by induction (shorter v') and creation, $\widetilde{F}_{e+e'}(c_{(-n-1)}u_{(\ell)}v')$. In the sum, Theorem 35.37 gives $F_c \star^{1/2}_s \widetilde{F}_e(u) = \widetilde{F}_{e+1}(c_{(s)}u)$; now $c_{(s)}u \in \mathcal{V}^{j+1}$ and $e+1 \equiv j+1$, so the induction hypothesis (for the eigenvector $c_{(s)}u$ and the shorter v') turns each summand into $\widetilde{F}_{e+e'}((c_{(s)}u)_{(-n-1+\ell-s)}v')$. Finally the VOA commutator formula $c_{(-n-1)}u_{(\ell)}v' - u_{(\ell)}c_{(-n-1)}v' = \sum_s \binom{-n-1}{s}(c_{(s)}u)_{(-n-1+\ell-s)}v'$ matches the two sides. *No associativity* of either side is used — only commutator formulas, creation and translation. □

What the machine verified

Unconditional; `#print axioms starPF` = `[propext, Classical.choice, Quot.sound]`.

Theorem 35.40 (Twisted product formula, product form). *For $u \in \mathcal{V}^j$ and every v, class e', ℓ, s, x: the product formula (35.7) holds for $\widetilde{F}_j(u)$ and $\widetilde{F}_{e'}(v)$.*

```
theorem productFormula_YT (j : ℕ) (u : FockN r) (hu : u ∈ (sigma1 r).twistedEigenspace 2 j)
    (v : FockN r) (e' : ℤ) (ℓ s : ℤ) (x : FockT r) :
    mode (Fld.prod ℓ (rescFld (by norm_num : 0 < 2) (YT_truncation r u) (j : ℤ))
        (rescFld (by norm_num : 0 < 2) (YT_truncation r v) e')).1 s x
      = ∑ᶠ t : ℕ, cbinom ((((j : ℤ) : ℤ) : ℂ) / (2 : ℕ)) t •
          YT r ((heisVOA1 r).smul u (ℓ + t) v) ((2 : ℕ) * (s - t) + (j : ℤ) + e') x
```

From the mathematics to the Lean statement

Character for character the hypothesis `hpf` of `twistedJacobi_YT_of_productFormula` (§35.7), except that it holds for all e', not only $e' \in \{0, 1\}$.

Physical meaning

The product form is the twisted OPE written mode by mode: it says that the commutation relations of the twisted modes follow from the untwisted OPE and the monodromy $e/2$ around the twist field. Physically it is the same statement as the star form, the input to the Jacobi identity.

Proof on paper. Theorem 35.39 with $e = j$ is the inverse formula (35.8) in modes; Proposition 35.12 with $c = j/2$ inverts it (both families vanish for large ℓ, by locality and by $u_{(\ell)}v = 0$ for $\ell \gg 0$). □

What the machine verified

Unconditional, axiom-clean.

Theorem 35.41 (The twisted Jacobi identity). *Y^T satisfies the Dong–Li–Mason twisted Jacobi identity (35.4) for σ, $N = 2$, for all pairs of states.*

File `VOA/Moonshine/HeisenbergTwistedModuleProductFormula.lean`.

```
theorem twistedJacobi_YT : TwistedJacobi (sigma1 r) 2 (YT r) :=
  twistedJacobi_YT_of_productFormula r
    (fun j u hu v e' _ _ ℓ s x => productFormula_YT r j u hu v e' ℓ s x)
```

From the mathematics to the Lean statement

The one-line proof term is informative: it is literally "the reduction of §35.7, fed with Theorem 35.40", and locality was already built into that reduction (Theorem 35.24). `TwistedJacobi` is defined in §35.2.4.

Physical meaning

The twisted Jacobi identity is the complete algebraic form of the consistency of the free boson in the $\mathbb{Z}_2$-twisted sector: locality, OPE and monodromy around the twist field all hold simultaneously, so the twisted sector is a genuine module of the orbifold chiral algebra. It encodes crossing symmetry of all correlators $\langle\sigma|\, u(z_1)\, v(z_2)\,|\sigma\rangle$ (sphere with the twist field at 0 and the conjugate twist field at infinity).

What the machine verified

Unconditional; `#print axioms twistedJacobi_YT` = `[propext, Classical.choice, Quot.sound]`.

35.13 The grading and the instance

35.13.1 The complex weight decomposition

`TwistedModule` wants a grading indexed by $\mathbb{C}$; $S[\theta]$ comes with the grading `gradingT r d` by doubled degree $d \in \mathbb{N}$, with L_0-eigenvalue $d/2 + r/16$.

Definition 35.42. $M_\alpha := \sum\{\texttt{gradingT r d} : d \in \mathbb{N},\ d/2 + r/16 = \alpha\} \subseteq S[\theta]$, for $\alpha \in \mathbb{C}$.

```
noncomputable def weightC (α : ℂ) : Submodule ℂ (FockT r) :=
  ⨆ (d : ℕ) (_ : ((levelT r d : ℚ) : ℂ) = α), gradingT r d

theorem weightC_isInternal : DirectSum.IsInternal (weightC r)
theorem weightC_finiteDimensional (α : ℂ) : FiniteDimensional ℂ (weightC r α)
theorem YT_omega_two_weightC {α : ℂ} {x : FockT r} (hx : x ∈ weightC r α) :
    YT r (heisVOA1 r).conformalVector 2 x = α • x
theorem weightC_boundedBelow :
    ∃ B : ℝ, ∀ α : ℂ, weightC r α ≠ ⊥ → B ≤ α.re
```

From the mathematics to the Lean statement

`⨆` is the supremum (sum) of submodules over all d satisfying the condition; since $d \mapsto d/2 + r/16$ is injective, M_α is a single `gradingT r d` or 0 (`weightC_level`, `weightC_eq_bot`). The four theorems are exactly the fields `isInternal`, `finrank`, `L0_weight`, `boundedBelow` of `TwistedModule`; the bound is $B = r/16$. **Not vacuous**: the grading is the honest L_0-eigenspace decomposition (by `YT_omega_two_weightC`, L_0 really acts by α on M_α), and $M_{r/16} = \mathbb{C}\,\mathbf{1} \neq 0$.

Physical meaning

The grading is by L_0, the conformal weight: oscillator states $h_{a_1}(-t_1)\cdots h_{a_m}(-t_m)|\sigma\rangle$, $t_i \in \frac{1}{2}+\mathbb{N}$, have energy $\sum t_i + r/16$, with the twist-field ground state at $h_\sigma = r/16$. Finite-dimensionality of each level and the bound below are the standard properties of a unitary Fock space with positive-frequency oscillators (the partition function $\mathrm{Tr}\, q^{L_0-c/24}$ is then well defined).

Proof on paper. Monomials of each doubled degree d are finitely many (each variable has weight $2n+1 \geq 1$), the polynomial ring is the direct sum of its homogeneous pieces, and L_0^T acts on degree d by $d/2 + r/16$ (Theorem 35.25). Real parts are $\geq r/16$. □

What the machine verified

Unconditional, axiom-clean. `VOA/Moonshine/HeisenbergTwistedModuleInstance.lean`.

35.13.2 The main theorem

Theorem 35.43 (The twisted Heisenberg module)**.** *For every $r \in \mathbb{N}$, the twisted Fock space $S[\theta]$, with the twisted vertex operator Y^T of Definition 35.22 and the grading M_α, is a σ-twisted module of order 2 for the level-one rank-r Heisenberg VOA, in the sense of Definition 35.4. Its generators act by the twisted bosons, and its L_0 is $\sum h_a(-n-\frac{1}{2})h_a(n+\frac{1}{2}) + \frac{r}{16}$.*

```
noncomputable def heisTwistedModule : TwistedModule (sigma1 r) 2 (FockT r) where
  YM := YT r
  vacuum_YM k := by
    change YT r (vacuumN r) k = _
    rw [YT_vacuum]
    push_cast
    rfl
  truncation := YT_truncation r
  support := fun j u hu k hk => YT_support r j u hu k hk
  jacobi := twistedJacobi_YT r
  weight := weightC r
  isInternal := weightC_isInternal r
  L0_weight := fun α x hx => YT_omega_two_weightC r hx
  finrank := weightC_finiteDimensional r
  boundedBelow := weightC_boundedBelow r

@[simp] theorem heisTwistedModule_YM : (heisTwistedModule r).YM = YT r := rfl
```

From the mathematics to the Lean statement

What the declaration asserts. A `def` whose type is the structure `TwistedModule (sigma1 r) 2 (FockT r)`: Lean accepts it only if every field is supplied, so the existence of this term is the theorem. The field list is printed in full; each is a theorem of this chapter: `YM` (Definition 35.22), `vacuum_YM`, `truncation`, `support` (Theorem 35.23), `jacobi` (Theorem 35.41), and the grading fields (§35.13). **Hypotheses:** none, beyond $r \in \mathbb{N}$. **The additional content** of Theorem 35.43 (generators act by twisted bosons; the form of L_0) is not part of the type `TwistedModule`, but is recorded by `heisTwistedModule_YM` together with `YT_X` and `YT_omega_two`. A referee should insist on this: `TwistedModule` alone would also be satisfied by other structures (for instance, for $r = 0$ the space is $\mathbb{C}$), so it is the pair "instance + `YT_X` + `YT_omega_two`" that identifies *the* twisted Heisenberg module. **How it could have been vacuous:** before the 2026-10-06 repair, the type `TwistedModule (sigma1 r) 2 (FockT r)` was empty (§35.2.4); with the repaired,

DLM-faithful Jacobi field it is inhabited, and the inhabitant is nontrivial (`FockT r` is a nonzero space — the library records `Nontrivial (FockT r)` — with $Y^T(h_a(-1)\mathbf{1}) \neq 0$ for $r \geq 1$).

Physical meaning

This is the construction of the $\mathbb{Z}_2$-twisted sector of the rank-r free-boson CFT: the Hilbert space of r antiperiodic bosons, with twist field σ of weight $r/16$ (for $r = 24$ this is $24/16 = \frac{3}{2}$; this is the oscillator half of the twisted sector of the Leech lattice CFT by the lift of -1, which enters the Moonshine orbifold). The vertex operators Y^T are the untwisted fields acting in the presence of the twist field, the half-integer modes realise the antiperiodic boundary condition, and the twisted Jacobi identity is crossing symmetry. This sector is what must be added to the $\mathbb{Z}_2$-invariant part of the Leech lattice CFT to obtain a modular-invariant theory, the Moonshine module.

Proof on paper. Assemble: Theorems 35.23, 35.41 and §35.13. □

What the machine verified

Unconditional. `#print axioms VOA.Moonshine.heisTwistedModule` (run while writing this chapter):

```
'VOA.Moonshine.heisTwistedModule' depends on axioms: [propext, Classical.choice,
↪ Quot.sound]
```

No `VOA.pbw`. This is only the Heisenberg part of the project's twisted-module milestone (the construction of the θ-twisted module of the Leech lattice VOA): the lattice twisted module $S[\theta] \otimes T$ is constructed in Chapter 36.

35.14 Dead ends, traps and corrections

Trap / dead end

1. The over-quantified Jacobi field (§35.2.4): unsatisfiable for $N \geq 2$, certificate $u = v = \mathbf{1}$, $\ell = -1$, $k = 1$, $m = -N - 1$ gives $0 = x$ (`jacobiAllIndices_eq_zero`). Repaired in `VOA/Modularity/Twisted.lean`; the same defect remains in `SuperTwistedModule.jacobi` (unrepaired, unused here).
2. Naive substitution is wrong. Defining $Y^T(u)$ by the untwisted normal-ordered formula with h replaced by the twisted h (i.e. keeping only the i with $-n-1+i<0$ in (35.9)) gives $Y^T(\omega)_{(1)} = \sum h(-n-\frac{1}{2})h(n+\frac{1}{2})$, missing the $r/16$; it also violates the product formula. The contraction terms are essential (§35.8).
3. Word order. The canonical word of a monomial is produced by `Finset.toList`, whose order is unspecified; until Theorem 35.34 was proved the definition of Y^T on quadratic states was not known to be choice-independent.
4. Stale docstrings. `HeisenbergTwistedModuleVertex.lean` and `HeisenbergTwistedModuleGenerators.lean` describe the product formula and the $\ell < 0$ Jacobi identity as "not here"/"open"; they are proved in later files. A referee reading those docstrings should not conclude that the instance is conditional: its type has no hypotheses and its axioms are the standard three.

35.16 Notes and references

The twisted Heisenberg vertex operators, including the operator Δ_z and its coefficients c_{mn}, were introduced by J. Lepowsky, *Calculus of twisted vertex operators*, Proceedings of the National Academy of Sciences USA 82 (1985) 8295–8299, and are developed systematically in I. Frenkel, J. Lepowsky and A. Meurman, *Vertex Operator Algebras and the Monster*, Pure and Applied Mathematics 134, Academic Press, Boston, 1988: Chapter 3 for the untwisted and twisted Heisenberg algebras and their Fock spaces, Chapter 9 for twisted vertex operators and the twisted Jacobi identity. The ground-state energy 1/16 is also explained in J. Lepowsky, *Perspectives on vertex operators and the Monster*, Proc. Symp. Pure Math. 48 (1988).

The mode form of the twisted Jacobi identity used here, with the fractional binomial $\binom{k/N}{i}$ and the support-coset restriction, is from C. Dong, H. Li and G. Mason, *Modular-invariance of trace functions in orbifold theory and generalized Moonshine*, Communications in Mathematical Physics 214 (2000) 1–56, arXiv:q-alg/9703016; twisted modules for general automorphisms go back to C. Dong, *Twisted modules for vertex algebras associated with even lattices*, Journal of Algebra 165 (1994) 91–112, and C. Dong and J. Lepowsky, *Generalized Vertex Algebras and Relative Vertex Operators*, Progress in Mathematics 112, Birkhäuser, 1993.

The local-system method — fields, their integer products, Dong's lemma, and the theorem that a local system is a vertex algebra — is H.-S. Li, *Local systems of vertex operators, vertex superalgebras and modules*, Journal of Pure and Applied Algebra 109 (1996) 143–195, arXiv:hep-th/9406185; the twisted version (twisted products $Y^\star$ with the factor $(1+z_0/z)^{-\alpha}$) is H.-S. Li, *Local systems of twisted vertex operators, vertex operator superalgebras and twisted modules*, in: Moonshine, the Monster, and Related Topics, Contemporary Mathematics 193 (1996) 203–236, arXiv:q-alg/9504022. The present chapter's reduction (rescale by $z^{e/N}$, apply untwisted Jacobi, absorb $(1+z_0/z)^{e/N}$ by Vandermonde) is a hands-on special case of Li's twisted local systems; the library proves exactly the pieces needed for this example rather than Li's general theorem. For the physical picture (antiperiodic bosons, twist fields of dimension 1/16) see L. Dixon, D. Friedan, E. Martinec and S. Shenker, *The conformal field theory of orbifolds*, Nuclear Physics B 282 (1987) 13–73.

The history of the repair and the construction is recorded in the repository file `Notes/MonsterRoadmap.md` (the row of the twisted-module milestone and "Recorded dead ends").

Chapter 36

The twisted Leech lattice module and $(V_\Lambda^T)^+$

This chapter documents the release of the LeanVOA library named in the front matter. Every Lean quotation below is checked by `scripts/textbook/sync.py` to occur verbatim (up to whitespace and comments) in the source files of that release. Checks that were run at an earlier state of the library and not re-run for this edition are marked as such. It constructs the second half of the Moonshine module. In Chapter 31 we built the lattice vertex operator algebra V_L of an even lattice L, in Chapter 32 the lift θ of the lattice involution -1 to V_L and its fixed points V_L^+, in Chapter 34 the twisted Fock space $S[\theta]$, the finite-dimensional module $\mathcal{T}$ of the extraspecial group and the (repaired) notion of a twisted module, and in Chapter 35 the twisted Heisenberg module, i.e. the θ-twisted module structure on $S[\theta]$ for the Heisenberg sub-VOA. Here we put the lattice into it.

The two headline results are:

(A) **The twisted module.** For every even, positive-definite, unimodular lattice L the space $V_L^T = S[\theta] \otimes \mathcal{T}_L$ carries the structure of a θ-twisted V_L-module of order 2, with the twisted vertex operators of Frenkel, Lepowsky and Meurman (FLM). For $L = \Lambda$ the Leech lattice this is the declaration `VOA.Moonshine.LatticeTwisted.leechTwistedModule`.

(B) **The plus part.** The involution θ lifts to V_Λ^T (acting by -1 on $\mathcal{T}$), and its fixed space $(V_\Lambda^T)^+$ is an ordinary module for the fixed-point VOA V_Λ^+, whose weight spaces are integral, start at weight 2 with dimension 98304, and whose graded dimension added to that of V_Λ^+ is $qJ(q)$. This is `VOA.Moonshine.plusModule` together with `VOA.Moonshine.finrank_plusModule_eq_coeff_JShift`.

Both are proved *unconditionally*: the only hypotheses of the general construction are that L is even, positive definite, and has unimodular Gram matrix, and these are proved for the Leech lattice in Chapter 30.

How to read this chapter. Following the book's constitution, each definition and theorem is presented as: mathematical statement; the Lean declaration copied verbatim; a *fidelity check* (the box "From the mathematics to the Lean statement") which decodes the Lean statement, lists every hypothesis, and says whether the Lean statement is the same as, stronger, or weaker than the mathematics and why it is not vacuous; a proof on paper; and the machine status. Proofs are explained mathematically; we do not tour the Lean proof scripts.

36.1 The physical picture and the plan

36.1.1 Chiral bosons on a double cover

Physically, V_Λ is the chiral algebra of 24 free chiral bosons $X^i(z)$ compactified on the torus $\mathbb{R}^{24}/\Lambda$; the states e^α are the vertex operators $:e^{i\alpha\cdot X(z)}:$, and the Heisenberg fields $h_i(z) = i\partial X^i(z)$ are the currents. The involution θ is the reflection $X \mapsto -X$. The *θ-twisted sector* is the space of states of the bosons on which X is antiperiodic around the origin: $X(e^{2\pi i}z) = -X(z)$. The currents then have half-integral modes,

$$h_i(z) = \sum_{n\in\frac{1}{2}+\mathbb{Z}} h_i(n)\, z^{-n-1}, \qquad [h_i(m), h_j(n)] = m\,\delta_{ij}\,\delta_{m+n,0},$$

and the Fock space they generate from a ground state is $S[\theta] = \mathbb{C}[h_i(-\tfrac12), h_i(-\tfrac32), \dots]$ (Chapter 34). The ground state of 24 antiperiodic bosons has conformal weight $24/16 = 3/2$. Antiperiodic bosons have no zero modes, hence no momentum: the lattice cannot appear as a momentum label. Instead, the zero-mode part of the operator $:e^{i\alpha\cdot X}:$ survives only as a finite-dimensional "cocycle" operator e_α acting on a degenerate ground-state space $\mathcal{T}$ of dimension 2^{12} (for Λ): the e_α satisfy $e_\alpha e_\beta = (-1)^{\langle\alpha,\beta\rangle} e_\beta e_\alpha$, which is a representation of an extraspecial 2-group (Chapter 34). So

$$V_\Lambda^T = S[\theta]\otimes\mathcal{T}, \qquad \dim\mathcal{T} = 2^{12} = 4096.$$

36.1.2 The twisted vertex operator

On V_Λ^T the vertex operator of e^α is (FLM, Chapter 9)

$$Y^T(e^\alpha, z) = 2^{-\langle\alpha,\alpha\rangle}\, z^{-\langle\alpha,\alpha\rangle/2}\, E^-(-\alpha, z)\, E^+(-\alpha, z)\otimes e_\alpha, \tag{36.1}$$

$$E^\mp(-\alpha, z) = \exp\Big(\pm\sum_{n\in\frac12+\mathbb{N}} \frac{\alpha(\mp n)}{n} z^{\pm n}\Big), \tag{36.2}$$

where $\alpha(n) = \sum_i \alpha_i h_i(n)$ in orthonormal coordinates. The creation part E^- contains only $h(-n)$ with $n>0$ and the annihilation part E^+ only $h(n)$, $n>0$; both are well defined on $S[\theta]$ because on any given vector only finitely many terms of E^+ survive. The powers z^n with $n\in\frac12+\mathbb{Z}$ are the reason everything is written in the doubled variable $w = z^{1/2}$.

The heart of the theory of these operators is a single reordering identity (proved below as `EpC_sMz_mul`):

$$E^+(-\alpha,z_1)E^-(-\beta,z_2) = E^-(-\beta,z_2)E^+(-\alpha,z_1)\Big(\frac{1-z_2^{1/2}/z_1^{1/2}}{1+z_2^{1/2}/z_1^{1/2}}\Big)^{\langle\alpha,\beta\rangle}. \tag{36.3}$$

In the untwisted theory the corresponding factor is $(1-z_2/z_1)^{\langle\alpha,\beta\rangle}$; here it is a ratio. Near the diagonal, $w_1\approx w_2$, we have $1-w_2/w_1 \approx (z_1-z_2)/(2z_1)$ and $1+w_2/w_1\approx 2$, so the factor behaves like $\big((z_1-z_2)/(4z_1)\big)^{\langle\alpha,\beta\rangle}$. The stray $4^{-\langle\alpha,\beta\rangle}$ is exactly what the normalisation $2^{-\langle\alpha,\alpha\rangle}$ in (36.1) is designed to cancel, since

$$2^{-\langle\alpha,\alpha\rangle}\,2^{-\langle\beta,\beta\rangle}\,4^{-\langle\alpha,\beta\rangle} = 2^{-\langle\alpha+\beta,\alpha+\beta\rangle}. \tag{36.4}$$

This one line is the reason the product formula $e^\alpha_{(-\langle\alpha,\beta\rangle-1)}e^\beta = \varepsilon(\alpha,\beta)e^{\alpha+\beta}$ of V_L is reproduced on the twisted side (§36.10).

36.1.3 Plan of the construction

The construction follows the route "locality plus product formula implies the Jacobi identity" prepared in Chapter 35:

1. §36.3–§36.5: the algebra of $E^{\pm}$ on $S[\theta]$: Newton exponentials, the contraction factor $((1-x)/(1+x))^n$, the reordering (36.3), the two-point identity and the locality of the operators (36.1).
2. §36.6: the twisted vertex operators $Y^T(e^\alpha, z)$ and the locality of the whole generated system of fields.
3. §36.7: the extension of Y^T to every state of V_L, forced by the twisted iterate formula for the Heisenberg generators.
4. §36.8–§36.10: the *twisted product formula* for all pairs of states, reduced to the pair (e^α, e^β), which is proved by a descent in the mode index together with a uniqueness lemma and an explicit vacuum computation; here the normalisation $2^{-\langle\alpha,\alpha\rangle}$ enters.
5. §36.11: the twisted Jacobi identity, the grading, and the instance `latticeTwistedModule` / `leechTwistedModule`.
6. §36.12–§36.14: θ on the twisted sector, the general "plus part of an order-two twisted module" construction, and $(V_\Lambda^T)^+$ as a V_Λ^+-module, with its dimensions.
