Proof on paper. Let $\mathcal{Y} \neq 0$ be in the space; pick s_0, u, x with $\mathcal{Y}_{s_0}(u)x \neq 0$. For $c \in \mathbb{C}$ let $\mathcal{Y}^{(c)}_s = \mathcal{Y}_{s-c}$ if $s \in s_0 + c + \mathbb{Z}$ and 0 otherwise (restrict to one coset, then shift). The defect condition at s involves only $\mathcal{Y}_s$ and $\mathcal{Y}_{s+p-j}$ with $p - j \in \mathbb{Z}$, i.e. values on the coset of s, with coefficients independent of s; so on the coset $s_0 + c + \mathbb{Z}$ the condition for $\mathcal{Y}^{(c)}$ at s is the condition for $\mathcal{Y}$ at $s - c$, and off that coset every term is 0. Hence $\mathcal{Y}^{(c)}$ lies in the space. Take $c_k = ik$, $k \in \mathbb{N}$. Then $\mathcal{Y}^{(c_l)}_{s_0+ik}(u)x$ equals $\mathcal{Y}_{s_0}(u)x \neq 0$ if $k = l$ and 0 if $k \neq l$ (the imaginary parts differ by a nonzero integer, so the points are in different cosets of $\mathbb{Z}$). Evaluating a vanishing finite linear combination $\sum_l g_l \mathcal{Y}^{(c_l)}$ at $s_0 + ik$ gives $g_k = 0$: the family is linearly independent and infinite. By Mathlib's convention the `finrank` of an infinite-dimensional space is 0; and if the space is zero its `finrank` is 0 too. □

What the machine verified

Proved in the library (`fusionCoeff_eq_zero`). When this chapter was written the statement was checked in Lean outside the library (`lake env lean -DmaxSynthPendingDepth=3`), axioms standard three. The definitions `IntertwinerSpace`, `Intertwiner`, `fusionCoeff` themselves are axiom-clean.

Physical meaning

The fusion rule N^P_{MN} is the multiplicity of the sector P in the operator product of fields from sectors M and N: $\phi_M \times \phi_N = \sum_P N^P_{MN} \phi_P$. It is finite because a chiral vertex operator is pinned down by its leading coefficient: the L_{-1}-derivative property fixes the z-dependence ($\mathcal{Y}(u,z) \sim z^{h_P - h_M - h_N}$ times a series), and the grading fixes the exponents. If one keeps only the commutation relations with the modes, the exponent z^s can be multiplied by an arbitrary z^c — a "fake" intertwiner for each c — and the count becomes infinite. That is what the theorem detects.

12.9 The rationality hierarchy

A finite group has finitely many irreducible representations and every representation is completely reducible. "Rational" VOAs are those whose module theory looks like that. Unfortunately the literature uses the word with several inequivalent meanings, depending on which module category is required to be semisimple and which finiteness conditions are added. The library names each predicate after the category it quantifies over and records, for each implication, whether it is *proved*, *carried as a named citation*, or *not available*. This section presents the predicates, the proved implications, and the comparison with the literature.

12.9.1 Simplicity and the set $\Phi(V)$ of irreducible modules

Definition 12.34 (Simple VOA; irreducible modules and their isomorphism classes). V is *simple* if $V \neq 0$ and its only ideals are 0 and V. An isomorphism of ordinary modules is a linear isomorphism intertwining all modes. $\Phi(V)$ is the set of isomorphism classes of irreducible ordinary modules.

Files `VOA/Core/BilinearForm.lean` (Chapter 5), `VOA/Modules/Rationality.lean`, `VOA/Modules/StronglyRational.lean`.

```
def IsSimple (W : VertexOperatorAlgebra 𝒱) : Prop :=
  (⊤ : Submodule ℂ 𝒱) ≠ ⊥ ∧ ∀ I : Submodule ℂ 𝒱, W.IsIdeal I → I = ⊥ ∨ I = ⊤

def IsSimple (W : VertexOperatorAlgebra 𝒱) : Prop :=
  OrdVModule.IsIrreducible (adjointModule W)

theorem isSimple_iff_adjointModule_isIrreducible (W : VertexOperatorAlgebra 𝒱) :
    W.IsSimple ↔ OrdVModule.IsIrreducible (adjointModule W) := by

def Φ (W : VertexOperatorAlgebra 𝒱) : Type (u + 1) := Quotient (IrrModule.setoid W)
```

From the mathematics to the Lean statement

Two `IsSimple`s. The first (`VOA.VertexOperatorAlgebra.IsSimple`, written `W.IsSimple`) is the ideal-theoretic definition; the second (`VOA.IsSimple`, in `Rationality.lean`, marked `@[deprecated]`) is "V is irreducible as a module over itself". The library proves them equivalent (`isSimple_iff_adjointModule_isIrreducible`): a weak submodule of the adjoint module is exactly an ideal. All rationality predicates below use `W.IsSimple`.
$\Phi(V)$. `IrrModule.setoid` is "there is a `ModuleEquiv`"; `Quotient` is the set of classes. The carriers range over `Type u`, the universe of V; this is the standard way to make "the set of all modules up to isomorphism" a set, and $\Phi(V)$ itself lives one universe up (`Type (u + 1)`). A `ModuleEquiv` imposes no condition on gradings because commuting with L_0 already forces it to preserve weight spaces (`ModuleEquiv.maps_weight`). Same as Gannon's $\Phi(V)$.

What the machine verified

Definitions; `#print axioms VOA.isSimple_iff_adjointModule_isIrreducible`: standard three.

Physical meaning

Simplicity of V means the vacuum sector has no null fields: every nonzero field generates all others, the vacuum is "cyclic and separating". $\Phi(V)$ is the set of primary fields (equivalently, of irreducible sectors) of the chiral CFT — for the Ising model, $\{1, \sigma, \varepsilon\}$; for $V^\natural$, a single element.

12.9.2 Admissible rationality, and the submodule convention

Definition 12.35 (Rational; Zhu 1996, Dong–Li–Mason 1997–98)**.** V is *(admissibly) rational* if every admissible V-module is completely reducible.

File `VOA/Modules/AdmissibleModule.lean`.

```
def AdmissiblyRational (W : VertexOperatorAlgebra 𝒱) : Prop :=
  ∀ {M : Type u} [AddCommGroup M] [Module ℂ M] (N : AdmissibleModule W M),
    N.IsCompletelyReducible

abbrev IsRational (W : VertexOperatorAlgebra 𝒱) : Prop := AdmissiblyRational W
```

From the mathematics to the Lean statement

Quantifies over all admissible modules with carrier in `Type u`, and asks every *weak* submodule to have a weak complement (Definition 12.4). `IsRational` is a pure alias. **Literature.** Dong–Li–Mason's rationality (DLM, *Math. Ann.* 310, and *J. Algebra* 206) is the single clause "every admissible module is a direct sum of (graded-)simple admissible modules". Zhu's own Definition 1.2.4 of "rational" had three clauses (finitely many irreducibles, finite-dimensional graded pieces, complete reducibility); DLM Theorem 8.1 shows the extra two follow from the single clause. The library follows DLM.

Physical meaning

A rational CFT is one whose Hilbert space decomposes into finitely many irreducible sectors of the chiral algebra, $\mathcal{H} = \bigoplus_{i,j} N_{ij} M_i \otimes \overline{M_j}$; complete reducibility of all (admissible) modules is the algebraic statement that there are no indecomposable, non-split sectors — the hallmark of non-logarithmic theories.

Trap / dead end

Weak versus graded submodules; a self-contradictory docstring (documentation only). Because complete reducibility is phrased with weak submodules, `AdmissiblyRational` is not literally DLM's notion. Consider the trivial VOA $V = \mathbb{C}\mathbf{1}$ and $M = \mathbb{C}e_0 \oplus \mathbb{C}e_1$ with $M(0) = \mathbb{C}e_0$, $M(1) = \mathbb{C}e_1$. The line $\mathbb{C}(e_0 + e_1)$ is a weak submodule that is not graded. The library's predicate demands a complement for it (it has one); DLM's never mentions it. Which is stronger? The library's docstrings disagree with each other: `AdmissibleRationality.lean` says, in one paragraph, that the weak reading "*implies*" the graded one ("Corrected"), and two paragraphs later that "both halves of that incomparability are real", and `AdmissibleModule.lean` repeats the "implies" claim. *One direction of the comparison with DLM's definition is now proved in Lean*: for C_2-cofinite V, DLM-rational ⇒ `AdmissiblyRational` (Theorem 12.36 below). The converse is open. What is proved in the other direction runs from the library's notion towards DLM's: `admissiblyRationalGraded_of_admissiblyRational` (`AdmissiblyRational` implies the level-graded reading `AdmissiblyRationalGraded`: every level-graded weak submodule has a level-graded complement), and, under C_2, `AdmissiblyRational.exists_iSupIndep_irreducible_ordinary` (every admissible module is an internal direct sum of irreducible ordinary modules, the conclusion of DLM Theorem 8.1). That the graded reading implies DLM's "every admissible module is a direct sum of irreducibles", and the converse `AdmissiblyRationalGraded` ⇒ `AdmissiblyRational`, are not formalised. On paper: if DLM-rationality holds, then by DLM Theorem 8.1 every admissible module is a direct sum of simple *ordinary* modules, each weak-simple, hence semisimple as a module over the algebra of modes, hence every weak submodule is complemented — so DLM-rational ⇒ `AdmissiblyRational`, using DLM's theorem. The Lean proof of Theorem 12.36 avoids DLM's theorem and uses

C_2 instead. The converse requires producing graded simple summands from weak complements, which is not formalised. Practical consequences: using `AdmissiblyRational` as a *hypothesis* is now justified for every C_2-cofinite DLM-rational V (by Theorem 12.36); *applying DLM's theorems* to an `AdmissiblyRational` V still needs the open converse, and a proved ¬ `AdmissiblyRational W` (e.g. for the triplet $W(2)$) is formally a statement about the library's notion. For the triplet the irrationality comes from an indecomposable *ordinary* module, where weak and graded submodules coincide (Section 12.2), so it is irrational in every sense.

Theorem 12.36 (DLM rationality implies `AdmissiblyRational`, under C_2). *Let V be C_2-cofinite and rational in the sense of Dong–Li–Mason: every admissible module is the internal direct sum of graded submodules that are minimal among nonzero graded submodules. Then V is* `AdmissiblyRational`.

File `VOA/Classification/COne/DLMRationality.lean`, namespace `VOA.Classification.COne.DLMRat`.

```
def GradedMinimal (N : AdmissibleModule W M) (P : WeakModule.Submodule' N.toWeakModule) :

      ↪  i)

theorem admissiblyRational_of_dlmRational (hC2 : C2Cofinite W) (h : DLMRational W) :
    AdmissiblyRational W := by
```

From the mathematics to the Lean statement

`DLMRational` is a faithful transcription of DLM's definition: admissible submodules are the graded ones, and irreducibility of a summand in its induced grading is exactly graded minimality inside N (independent release audit, `Notes/Textbook/referee/RELEASE_AUDIT_QUEUE2.md`). It does not require $M(0) \neq 0$, which is harmless, and quantifies over carriers in `Type u`, like `AdmissiblyRational`. **Proof idea.** The cyclic submodule of a homogeneous vector is level-graded (`cyclic_isLevelGraded`, no C_2), so a graded-minimal P is generated by any nonzero homogeneous vector in it. Under C_2, $L(0)$ acts on level j by $h+j$, so a weak submodule of P is $L(0)$-stable with distinct eigenvalues on the levels, hence level-graded, hence 0 or P: graded-minimal implies weakly simple (`isSimpleSub_of_gradedMinimal`). A direct sum of weakly simple modules is a semisimple module over the mode algebra, so every weak submodule is complemented. **Not an equivalence:** the converse `AdmissiblyRational` ⇒ `DLMRational` is open. **Extra hypothesis:** DLM's notion needs no C_2; the theorem does.

What the machine verified

Proved, conditional on `hC2`. `#print axioms: [propext, Classical.choice, Quot.sound]`, recorded in `Notes/release/WS-RELEASE2.md` (commit `34b74b85`); the aggregate `lake build` at the release commit is pending.

Physical meaning

Physicists use "rational" loosely for "finitely many primaries, every sector a direct sum of irreducibles". The two mathematical readings compared here differ only in which sub-sectors one asks to split off: DLM ask it of energy-graded sub-sectors, the library of all subspaces

closed under the modes. The theorem says that once V is C_2-cofinite (lisse: its semiclassical phase space is a point, Chapter 16) the two agree in one direction: a theory with no non-split graded sectors has no non-split sectors at all, because L_0 separates the energy levels inside an irreducible sector. The converse direction is open, and without C_2 nothing is claimed.

Definition 12.37 (Gannon-rational and holomorphic; Gannon, Def. 5.3.2)**.** V is *Gannon-rational* if (1) every ordinary module is completely reducible, (2) $\Phi(V)$ is finite, and (3) every irreducible admissible module is ordinary (on the same weak module). V is *holomorphic* if it is Gannon-rational and $|\Phi(V)| = 1$.

File `VOA/Modules/Rationality.lean`.

```
def GannonAdmissibleIsOrdinary (W : VertexOperatorAlgebra 𝒱) : Prop :=
  ∀ {M : Type u} [AddCommGroup M] [Module ℂ M] (N : AdmissibleModule W M),
    N.IsIrreducible → ∃ O : OrdVModule W M, O.toWeakModule = N.toWeakModule

structure GannonRational (W : VertexOperatorAlgebra 𝒱) : Prop where
  completelyReducible : ∀ {M : Type u} [AddCommGroup M] [Module ℂ M] (N : OrdVModule W M),
    OrdVModule.IsCompletelyReducible N
  finitelyManyIrred : Finite (Φ W)
  admissibleIsOrdinary : GannonAdmissibleIsOrdinary W

def Holomorphic (W : VertexOperatorAlgebra 𝒱) : Prop :=
  GannonRational W ∧ Nat.card (Φ W) = 1
```

From the mathematics to the Lean statement

`∃ O : OrdVModule W M, O.toWeakModule = N.toWeakModule`: the *given* weak module carries an ordinary grading. `Finite (Φ W)`: finitely many classes. `Nat.card (Φ W) = 1`: exactly one class (`Nat.card` of an infinite type is 0, so this also forces finiteness). Gannon calls this "weakly rational"; his "weak module" (Def. 5.3.1) is $\mathbb{N}$-graded, i.e. admissible, so clause (3) is over admissible modules — the library repaired an earlier transcription (`WeaklyRational`, retired) that used ungraded weak modules and a detached conclusion. **Comparison:** clause (1) concerns only ordinary modules, so `GannonRational` does *not* imply `AdmissiblyRational` (Gannon himself adds admissible complete reducibility in his stronger Def. 6.2.3). `Holomorphic` has a single consumer, a structure (`MoonshineHypotheses`) with no consumers; the Moonshine theorem of this book does not use it. Note that "$V^\natural$ is holomorphic" is not proved in the library.

Physical meaning

A holomorphic VOA is a chiral CFT with a single sector, the vacuum: its character is then a modular function (up to a phase), as for $V^\natural$ whose character is $J(q)$. Gannon's three clauses say: sectors don't mix, there are finitely many primaries, and every reasonable representation has a genuine energy grading.

Definition 12.38 (Regular; Dong–Li–Mason 1997, Def. 3.1)**.** V is *regular* if every weak module is completely reducible and every irreducible weak module is ordinary. $\Phi_{\mathrm{adm}}(V)$ is the set of isomorphism classes of irreducible admissible modules (isomorphism of the underlying weak modules).

  isMod : AdmissibleModule W carrier
  irreducible : isMod.IsIrreducible

def Φadm (W : VertexOperatorAlgebra 𝒱) : Type (u + 1) := Quotient (IrrAdmModule.setoid W)
```

From the mathematics to the Lean statement

DLM define regular as "every weak module is a direct sum of irreducible ordinary modules". The library's two clauses are equivalent to that: complete reducibility of a weak module (every submodule complemented) makes it semisimple over the algebra of modes, hence a direct sum of irreducible weak submodules, each ordinary by the second clause; conversely a direct sum of irreducibles has complemented submodules. Same as DLM.

Physical meaning

Regularity says that *every* representation of the chiral algebra, even without any energy grading, splits into physical sectors. It is the strongest semisimplicity one can ask, and for CFT-type VOAs it is equivalent to rationality plus C_2-cofiniteness (Abe–Buhl–Dong).

12.9.3 The literature theorems, stated as named predicates

The library states each of the deep structure theorems of Dong–Li–Mason, Abe–Buhl–Dong and Li that it uses as a `Prop`-valued definition, so that a theorem using it can carry it as an explicit hypothesis (never an axiom). This was how all seven entered the library. Six of them have since been *proved* (Theorems 12.39 and 12.40 below; two of the six only for C_2-cofinite V), and only `LiC2CofiniteOfRegular` is still a genuine, unproved input. The definitions themselves are unchanged.

(Files `VOA/Modules/RationalityLattice.lean` and, for the last, `VOA/Modules/AdmissibleRationality.lean`.)

From the mathematics to the Lean statement

Each `def` is the implication asserted by a published theorem, specialised to V: DLM *Math. Ann.* 310, Thm. 8.1(c) and 8.1(b) (rational ⇒ irreducible admissibles are ordinary; finitely many of them); Abe–Buhl–Dong, *Trans. AMS* 356, Prop. 5.7, Cor. 5.8 and Thm. 4.5; H. Li, *J. Algebra* 212, Thm. 3.8; and the semisimplicity of $A(V)$ for rational V (DLM *J. Algebra* 206, Thm. 4.10; Zhu Thm. 2.2.3 for Zhu's stronger notion). Fidelity points: (a) the library's `IsIrreducible` for admissible modules is *weak*-simplicity, a subclass of DLM's graded-simple modules, so `DLMSimpleAdmissibleOrdinary` and `DLMFinitelyManyIrredAdmissible` are *implied by* DLM's theorems *provided* the library's `AdmissiblyRational` implies DLM-rationality (see the warning above); (b) all carriers are in `Type u`, which only restricts the conclusions. As long as such a predicate is an *unproved* hypothesis, a theorem that assumes it is "conditional on the literature", and its licence depends on proviso (a). (c) The same proviso applies to `ZhuAdmissibleSemisimple`. (d) The C_2-hypothesis of the three ABD predicates sits *inside* the predicate (`C2Cofinite W →` …), so proving the predicate for every V is the literature's "for every C_2-cofinite V"; the two DLM predicates have only the rationality antecedent inside, so proving them under an external hypothesis `hC2 : C2Cofinite W` covers only the C_2-cofinite VOAs.

Status of each predicate (this revision).

- `ZhuAdmissibleSemisimple`: **proved** for every V (Theorem 12.39; also restated as `zhuAdmissibleSemisimple_holds`, Theorem 12.40). The first release revision of this chapter called it an unproved bridge; that was wrong.
- `ABDWeakIsAdmissible`, `ABDIrreducibleWeakIsOrdinary`, `ABDRegularOfC2AndRational`: **proved** for every V (`abdWeakIsAdmissible`, `abdIrreducibleWeakIsOrdinary_holds`, `abdRegularOfC2AndRational_holds`; Theorem 12.40).
- `DLMSimpleAdmissibleOrdinary`, `DLMFinitelyManyIrredAdmissible`: **proved for every C_2-cofinite V** (`dlmSimpleAdmissibleOrdinary_of_c2Cofinite`, `dlmFinitelyManyIrredAdmissible_of_c2Cofinite`; Theorem 12.40), hence for every strongly rational V. **Not proved** for an admissibly rational V that is not known to be C_2-cofinite; that case is tied to the open conjecture "rational ⇒ C_2-cofinite".
- `LiC2CofiniteOfRegular`: **unproved**. No proof of it exists in the library (the only instance is the trivial one-dimensional VOA). It is used by exactly one theorem of this chapter, `regular_iff_c2Cofinite_and_admissiblyRational` (Theorem 12.41, item (7)), which therefore remains conditional on it (its other hypothesis, `hABD`, is now discharged by `abdRegularOfC2AndRational_holds`). No other declaration of the library takes `LiC2CofiniteOfRegular` as a hypothesis (search of `VOA/` at the third release revision); the headline theorems of the book assume C_2-cofiniteness directly instead.

Because the six proved predicates are proved directly from the library's own definitions (`AdmissiblyRational`, `C2Cofinite`), their truth does not depend on the (half-open) comparison of `AdmissiblyRational` with DLM-rationality.

Physical meaning

These are the structure theorems of rational CFT: in a rational theory every primary has an honest energy grading, there are finitely many primaries, lisse + rational is the same as "every representation splits", and the zero-mode algebra is a finite direct sum of matrix algebras — one block per primary, of size the ground-state degeneracy.

12.9.4 Zhu's semisimplicity theorem, proved

The first of the predicates above that the library proves is Zhu's semisimplicity theorem; the others follow in Section 12.9.5.

Theorem 12.39 (Zhu 1996, Theorem 2.2.3; Dong–Li–Mason: rational ⇒ $A(V)$ semisimple)**.** *Let V be a vertex operator algebra of the library. If V is admissibly rational (Definition 12.35), then Zhu's algebra $A(V)$, with Zhu's product, is a semisimple ring. Equivalently, the predicate* `ZhuAdmissibleSemisimple W` *holds for every V.*

File `VOA/Huang/ZhuSemisimple.lean` (Chapter 21), namespace `VOA.Huang.ZhuSemisimple`. The section variables are {`W : VertexOperatorAlgebra 𝒱`} and (`Pr : BottomProjection (parabolicRepOfAMod W (regularAMod W))`), and each theorem is preceded by `include Pr in`.

```
theorem isSemisimpleRing_A_of_admissiblyRational (hrat : AdmissiblyRational W) :
    letI := instRingA W; IsSemisimpleRing (A W) := by

theorem zhuAdmissibleSemisimple_of_Pr : ZhuAdmissibleSemisimple W :=
  fun hrat => isSemisimpleRing_A_of_admissiblyRational Pr hrat
```

From the mathematics to the Lean statement

Hypotheses. `hrat : AdmissiblyRational W` is Definition 12.35: every weak submodule of every admissible module has a weak complement. `include Pr in` makes the section variable `Pr` an explicit first argument. `Pr` is the bottom-projection datum of Chapter 13: the regular $A(V)$-module embeds as the degree-zero part of the module induced from it. It is supplied for every V by `voaPBWBottomProjection`, from the PBW theorem `VOA.pbw` of Chapter 3, which is a theorem. So the only real hypothesis is `hrat`.
Conclusion. `letI := instRingA W` installs the ring structure on `A W` given by Zhu's product (the ring of Theorem 12.17), and `IsSemisimpleRing (A W)` is Mathlib's notion: $A(V)$ is semisimple as a left module over itself, i.e. every left ideal has a complementary left ideal. The second theorem is the first, packaged as this chapter's predicate `ZhuAdmissibleSemisimple W = AdmissiblyRational W → letI := instRingA W; IsSemisimpleRing (A W)`.
Same as the literature? Same conclusion as Zhu's Theorem 2.2.3 and Dong–Li–Mason's version, with "rational" read as `AdmissiblyRational`. DLM-rationality implies `AdmissiblyRational`, in Lean for C_2-cofinite V (Theorem 12.36) and on paper in general (warning of Section 12.9.2), so with that step the Lean theorem implies the literature's statement. The Lean proof uses no theorem of Dong–Li–Mason as a hypothesis, so the unsettled converse plays no role in it.
Could it be vacuous? `AdmissiblyRational` is satisfiable: the library proves it for the trivial VOA and for the lattice VOAs $V_{\sqrt{2m}\mathbb{Z}}$ (`V2m_admissiblyRational`, Chapter 22).

Proof on paper. Let M be the generalised Verma module induced from the regular module $A(V)$; it is admissible and, by `Pr`, its degree-zero part is $A(V)$. Given a left ideal T, the submodule P generated by T is graded with $P \cap M(0) = T$ (bottom recovery). Rationality gives a complement Q of P. The degree-zero components of the elements of Q that differ from their degree-zero component by an element of P form a left ideal T', and $A(V) = T \oplus T'$, because zero modes commute with the

projection to degree zero and act on $M(0)$ by left multiplication. The full argument is written out in Chapter 15, Theorem 15.38. □

Physical meaning

In a rational CFT every representation of the chiral algebra splits into sectors. The theorem says the splitting is already visible on ground states: the zero-mode algebra $A(V)$ is a direct sum of matrix algebras, one per sector. This is what Zhu's modularity theorem needs in order to count the torus conformal blocks by the number of sectors.

What the machine verified

`#print axioms` of `VOA.Huang.ZhuSemisimple.isSemisimpleRing_A_of_admissiblyRational` and `VOA.Huang.ZhuSemisimple.zhuAdmissibleSemisimple_of_Pr`: `[propext, Classical.choice, Quot.sound]`, run at an earlier commit (not re-run for this edition) with `lake env lean -DmaxSynthPendingDepth=3` (scratch file; the olean of `ZhuSemisimple.lean` is newer than its source). Proved; conditional on `Pr`, which `voaPBWBottomProjection` supplies (standard three, same run). In the same run, composing the two gave `ZhuAdmissibleSemisimple W` for every V with the standard three axioms.

12.9.5 The Abe–Buhl–Dong and Dong–Li–Mason predicates, proved

Five more of the named predicates of Section 12.9.3 are theorems of the library. Three are the theorems of Abe–Buhl–Dong on C_2-cofinite VOAs, proved for every V (the C_2-hypothesis is inside each predicate); two are the Dong–Li–Mason theorems on rational VOAs, proved for every C_2-cofinite V. The file `VOA/Classification/COne/LiteratureInputsProved.lean` collects them under single names. The consequences for strongly rational VOAs are Theorem 12.44 in Section 12.9.7, after strong rationality has been defined.

Theorem 12.40 (Abe–Buhl–Dong Prop. 5.7, Cor. 5.8, Thm. 4.5; Dong–Li–Mason Thm. 8.1(b),(c); Zhu)**.** *Let V be a vertex operator algebra of the library (of CFT type, Chapter 1).*

1. (ABD Prop. 5.7) *If V is C_2-cofinite, then every weak V-module M carries an admissible-module structure (Definition 12.4) whose underlying weak module is M itself, with the same vertex operators.*
2. (ABD Cor. 5.8) *If V is C_2-cofinite, then every irreducible weak V-module M (that is, $M \neq 0$ and its only weak submodules are 0 and M) carries an ordinary-module structure (Definition 12.5) with the same vertex operators.*
3. (ABD Thm. 4.5, hard direction) *If V is C_2-cofinite and admissibly rational, then V is regular.*
4. (Zhu) *If V is admissibly rational, then $A(V)$ is a semisimple ring (Theorem 12.39, restated).*
5. (DLM Thm. 8.1(c)) *If V is C_2-cofinite, then every irreducible admissible V-module carries an ordinary-module structure with the same vertex operators. No rationality is assumed.*
6. (DLM Thm. 8.1(b)) *If V is C_2-cofinite and admissibly rational, then V has only finitely many isomorphism classes of irreducible admissible modules: $\Phi_{\mathrm{adm}}(V)$ is finite.*

From the mathematics to the Lean statement

Reading the statements. Each conclusion is one of the named predicates of Section 12.9.3, applied to the implicit VOA `W`; unfolding the predicate gives the mathematical statement:

- `ABDWeakIsAdmissible W = C2Cofinite W → ∀ M (A : WeakModule W M), ∃ N : AdmissibleModule W M, N.toWeakModule = A`: item 1. The equation `N.toWeakModule = A` says that the admissible structure *extends* the given weak action (same carrier, same vertex operators); it is not merely an isomorphic module.
- `ABDIrreducibleWeakIsOrdinary W`: under `C2Cofinite W`, a weak module `A` with `Nontrivial M` ("$M \neq 0$") and every weak submodule `P` equal to $\bot$ or $\top$ (irreducibility in the weak sense) has an ordinary structure `N : OrdVModule W M` with `N.toWeakModule = A`: item 2.
- `ABDRegularOfC2AndRational W = C2Cofinite W → AdmissiblyRational W → Regular W`: item 3, with `Regular` of Definition 12.38.
- `ZhuAdmissibleSemisimple W`: item 4, as in Theorem 12.39; here the bottom projection `Pr` is supplied by `voaPBWBottomProjection` (Chapter 13), built from the PBW theorem `VOA.pbw` of Chapter 3, which is a theorem, not an axiom.
- `irreducible_admissible_isOrdinary`: item 5 in its direct form (the carrier `M` is an implicit section variable `{M : Type u} [AddCommGroup M] [Module ℂ M]`), for one admissible module `N` with `N.IsIrreducible` (weak simplicity, Definition 12.4). `dlmSimpleAdmissibleOrdinary_of_c2Cofinite` packages it as the predicate

`DLMSimpleAdmissibleOrdinary W`, whose `AdmissiblyRational W` antecedent is simply not used.

- `DLMFinitelyManyIrredAdmissible W = AdmissiblyRational W → Finite (Φadm W)`: item 6. The proof term is displayed because it is informative: given the antecedent `hAR`, it feeds the semisimplicity of `A W` (item 4, with the same bottom projection) and `hC2` into `c2SemisimpleAdmissibleFiniteness_of_bottomProjection` (`AdmissibleOrdinaryFinite.lean`).

Hypotheses. The four `_holds` theorems and `abdWeakIsAdmissible` have *no* hypotheses; `W` is implicit and arbitrary. The two DLM theorems have the single hypothesis `hC2 : C2Cofinite W` (Definition 12.22), outside the predicate.
Same as the literature? Items 1–3 are ABD's statements exactly, for VOAs of CFT type (which every library VOA is), with the library's `AdmissiblyRational` as "rational"; ABD themselves use DLM-rationality, which implies `AdmissiblyRational` on paper (warning of Section 12.9.2), so the Lean items 1–3 imply ABD's. Item 4 is Theorem 12.39. Items 5 and 6 are *weaker* than DLM's Theorem 8.1 in one respect and *stronger* in another: DLM need no C_2-cofiniteness (rationality alone suffices for them), while the library needs `hC2`; on the other hand item 5 drops rationality altogether. For the VOAs the book cares about (strongly rational ones) this makes no difference. For an admissibly rational V not known to be C_2-cofinite the two DLM predicates remain **unproved**; since "rational ⇒ C_2-cofinite" is an open conjecture, that case is genuinely open in the library. Fidelity point (a) of Section 12.9.3 still applies to item 5: `IsIrreducible` for admissible modules is weak simplicity.
Could it be vacuous? No. `C2Cofinite` is satisfied by the lattice VOAs $V_{\sqrt{2m}\mathbb{Z}}$ and by the triplet algebra $W(2)$ (Example 12.25); for $W(2)$, which is irrational, items 1, 2 and 5 are informative, and items 3 and 6 are vacuously true there because their rationality antecedent fails. For $V_{\sqrt{2m}\mathbb{Z}}$, which is strongly rational (Chapter 22), all six items apply. The conclusions are not trivially satisfiable either: an admissible or ordinary structure must reproduce the given vertex operators exactly.

Proof on paper. Throughout, V is C_2-cofinite, so Zhu's algebra $A(V)$ is finite-dimensional (Theorem 12.28).

A finite spectrum. Let M be any weak module and α a generalised eigenvalue of L_0 on M; pick an honest eigenvector x. The weak submodule generated by x is spanned, by C_2-cofiniteness (finite strong generation, Theorem 12.24), by monomials in finitely many generators with bounded modes applied to x. Since a mode $u_{(m)}$ of a vector $u \in V_k$ shifts L_0-eigenvalues by $k-m-1$ (the commutator formula of Theorem 12.2), this submodule is an ordinary module whose weights lie in $\alpha + \mathbb{Z}$ and are bounded below. Its lowest weight space is a module for the finite-dimensional algebra $A(V)$, on which L_0 acts by the image of the central element $[\omega]$. A central element of a finite-dimensional algebra has a minimal polynomial, and on every module its eigenvalues are roots of that polynomial. So the lowest weight lies in a finite set $S \subset \mathbb{C}$ that depends only on V, and $\alpha \in S + \mathbb{N}$. In particular the real parts of all L_0-eigenvalues on all weak modules are bounded below by one constant.

Item 1. With this bound, every weak module is the sum of its generalised L_0-eigenspaces (Buhl's spanning set makes L_0 locally finite; in the library this is the "degree normal form" of the proof file), and grading M by "eigenvalue minus the least element of $S + \mathbb{N}$ in the same class mod $\mathbb{Z}$" gives a $\mathbb{N}$-grading with $u_{(m)}M(n) \subseteq M(n+k-m-1)$: the admissible structure, with the original vertex operators.

Item 5. Let N be irreducible admissible. Its lowest nonzero level $N(0)$ is a simple $A(V)$-module, hence finite-dimensional, and the central $[\omega]$ acts on it by a scalar h. Irreducibility makes N generated by $N(0)$, so $N(j)$ is spanned by finitely many monomials applied to $N(0)$, is finite-dimensional, and L_0 acts on it by $h + j$. These are exactly the axioms of an ordinary module, with weight spaces

$N_{h+j} = N(j)$.

Item 2 is item 1 followed by item 5: the admissible structure of an irreducible weak module is irreducible (the weak submodules are the same), hence ordinary. *Item 3:* by item 1 every weak module is admissible, so rationality makes it completely reducible; by item 2 its irreducible summands are ordinary; that is regularity. *Item 4* is Theorem 12.39.

Item 6. By the finiteness theorem for C_2-cofinite VOAs (Chapter 21, Theorem 21.25; in the library this route uses the semisimplicity of $A(V)$ supplied by item 4 and the bottom projection), $\Phi(V)$ is finite. By item 5 every irreducible admissible class has an ordinary representative, so the injection $\Phi(V) \hookrightarrow \Phi_{\mathrm{adm}}(V)$ of Theorem 12.41(3) is also surjective, and $\Phi_{\mathrm{adm}}(V)$ is finite. □

Physical meaning

These are the basic facts of *lisse* (C_2-cofinite) chiral algebras. Item 1: every representation of a lisse chiral algebra, even one given without any energy operator, has an energy spectrum bounded below, so it is a legitimate state space of a chiral CFT. Items 2 and 5: every irreducible representation is a genuine sector, with finite degeneracy at each energy and hence a well-defined character $\operatorname{tr} q^{L_0 - c/24}$. Item 3: a lisse theory in which every graded representation splits splits completely, i.e. it is a rational CFT in the strongest sense. Item 6: such a theory has finitely many primary fields. A physicist takes all of this for granted in a rational CFT; the theorem says the library no longer has to.

What the machine verified

`#print axioms`, run for this revision at an earlier commit (not re-run for this edition) with `lake env lean -DmaxSynthPendingDepth=3` from the repository root: `abdWeakIsAdmissible`, `dlmSimpleAdmissibleOrdinary_of_c2Cofinite`, `abdIrreducibleWeakIsOrdinary_holds`, `abdRegularOfC2AndRational_holds`, `zhuAdmissibleSemisimple_holds`, `dlmFinitelyManyIrredAdmissible_of_c2Cofinite`: `[propext, Classical.choice, Quot.sound]` each. The olean of `LiteratureInputsProved.lean` was not present in the main checkout, so the scratch file was a verbatim copy of that file followed by the `#print axioms` commands, compiled against the existing oleans of its imports (exit status 0). The coordinator reports the umbrella build of `VOA.Classification`, which imports the file, as green (12,179 jobs, standard axioms); that build was not re-run for this chapter. **Proved, unconditional** for items 1–4 (no hypotheses); items 5–6 are proved under the stated hypothesis `hC2`. Items 4 and 6 use the theorem `VOA.pbw` through `voaPBWBottomProjection`.

12.9.6 The proved implications

Theorem 12.41 (The rationality lattice). *For every VOA V:*

1. *regular ⇒ admissibly rational ⇒ every ordinary module is completely reducible;*
2. *regular ⇒ Gannon clause (3);*
3. *$\Phi(V) \hookrightarrow \Phi_{\mathrm{adm}}(V)$, so $\Phi_{\mathrm{adm}}(V)$ finite ⇒ $\Phi(V)$ finite;*
4. *admissibly rational + [DLM 8.1(b)] + [DLM 8.1(c)] ⇒ Gannon-rational;*
5. *regular + [DLM 8.1(b)] ⇒ Gannon-rational;*

ABD Prop. 5.7 + [ABD Cor. 5.8] ⇒ [ABD Thm. 4.5, hard direction];

ABD Thm. 4.5 + [Li Thm. 3.8] ⇒ (regular ⟺ C_2-cofinite and admissibly rational).

From the mathematics to the Lean statement

The first and third displayed one-liners show how thin some implications are: regular ⇒ admissibly rational is literally "an admissible module is a weak module" (both use the same weak-submodule notion), and regular ⇒ Gannon (3) is "an irreducible admissible module is an irreducible weak module". The second uses Theorem 12.10. Hypotheses in brackets in the mathematical statement are the named predicates of Section 12.9.3; every other hypothesis is shown. All of them except [Li Thm. 3.8] are now theorems of the library, the two DLM ones for C_2-cofinite V (Theorem 12.40 and the status box below). **Not available** (no proof, no citation): admissibly rational ⇒ every irreducible *weak* module is ordinary (needs C_2), Gannon-rational ⇒ admissibly rational, and rational ⇒ C_2-cofinite (a famous open conjecture). **False**: C_2-cofinite ⇒ rational (triplet $W(p)$, Adamović–Milas; in the library, $W(2)$, Example 12.25).

Proof on paper. (1)–(3) as in the dictionary; (3): an irreducible ordinary module is an irreducible admissible module via Theorem 12.10, and two ordinary modules are isomorphic iff their weak modules are, so the map on classes is injective. (4): clause (1) by (1), clause (2) by (3) and DLM 8.1(b), clause (3) is DLM 8.1(c). (5): clause (3) by (2). (6): by ABD 5.7 every weak module carries an admissible structure, so rationality makes it completely reducible, and ABD 5.8 makes its irreducibles ordinary. (7): combine (1), (6) and Li. □

What the machine verified

All proved; `#print axioms` (run for this chapter) of `VOA.Regular.admissiblyRational`, `VOA.OrdVModule.isCompletelyReducible\_of\_admissiblyRational`, `VOA.finite\_Φ\_of\_finite\_Φadm`, `VOA.gannonRational\_of\_admissiblyRational`, `VOA.gannonRational\_of\_regular`, `VOA.abdRegularOfC2AndRational\_of\_components`,

`VOA.regular\_iff\_c2Cofinite\_and\_admissiblyRational`: standard three. As *stated*, items (4)–(7) take the named literature predicates as hypotheses. After this revision those hypotheses are dischargeable as follows (Theorem 12.40):

- item (6) has no remaining content as a conditional: its conclusion is `abdRegularOfC2AndRational_holds`;
- items (4) and (5) become unconditional *for C_2-cofinite V*: [DLM 8.1(b)] is `dlmFinitelyManyIrredAdmissible_of_c2Cofinite hC2` and [DLM 8.1(c)] is `dlmSimpleAdmissibleOrdinary_of_c2Cofinite hC2`; for strongly rational V the composite is the named theorem `StronglyRational.gannonRational'` (Theorem 12.44). For admissibly rational V not known to be C_2-cofinite they stay conditional;
- item (7) remains **conditional on `LiC2CofiniteOfRegular`** (H. Li, Thm. 3.8), which is **unproved**; its other hypothesis `hABD` is discharged by `abdRegularOfC2AndRational_holds`. The direction "C_2-cofinite and admissibly rational ⇒ regular" is therefore a theorem; the direction "regular ⇒ C_2-cofinite" is not.

No single library declaration states item (7) with `hABD` discharged; the substitution above is a one-line composition we describe, not a quoted theorem.

Physical meaning

The lattice is the map of "how nice" a chiral CFT is. Lisse + rational (= regular) theories — lattice CFTs, WZW models at positive integer level, minimal models, $V^\natural$ — are the modular tensor category world, where Verlinde's formula holds. Lisse but irrational theories (the triplet algebras) are logarithmic CFTs. Rational but not known to be lisse: no example is known, which is the content of the open conjecture.

12.9.7 Self-duality, strongly finite and strongly rational

Definition 12.42 (Self-dual VOA; McRae §2.2, Dong–Mason §2). V is *self-dual* if it carries a non-degenerate fully invariant bilinear form, i.e. a form with $(Y(u,z)a|b) = (a|Y(e^{zL_1}(-z^{-2})^{L_0}u, z^{-1})b)$ and zero radical.

File `VOA/Modules/StronglyRational.lean`.

```
def SelfDual (W : VertexOperatorAlgebra 𝒱) : Prop :=
  ∃ B : InvariantForm W, B.IsFullyInvariant ∧ InvariantForm.leftRadical B = ⊥

theorem selfDual_iff (hsimple : W.IsSimple) :
    W.SelfDual ↔ ∀ v, v ∈ W.grading 1 → W.L 1 v = 0 :=
```

From the mathematics to the Lean statement

`InvariantForm W`, `IsFullyInvariant`, `leftRadical` are defined in Chapter 5: a bilinear form with $(L_n a|b) = (a|L_{-n}b)$, the full FHL invariance (mode form of the displayed identity), and $\{a : (a|\cdot) = 0\}$. For a module, "$V \cong V'$" is equivalent to the existence of such a form (FHL Prop. 5.3.6); the library uses the form version, which avoids the vacuous `SelfContragredient`. `selfDual_iff`: for simple V, self-dual iff $L_1V_1 = 0$ ("strong CFT type"); this is Dong–Mason §2 / H. Li's theorem, here proved in both directions.

Proof on paper. If $L_1 v = \lambda\mathbf{1}$ with $\lambda \neq 0$ for some $v \in V_1$, then $\lambda(\mathbf{1}|\mathbf{1}) = (L_1 v|\mathbf{1}) = (v|L_{-1}\mathbf{1}) = 0$, so $(\mathbf{1}|\mathbf{1}) = 0$; with $V_m \perp V_n$ for $m \neq n$ and $V_0 = \mathbb{C}\mathbf{1}$ this puts $\mathbf{1}$ in the radical. Conversely, if $L_1V_1 = 0$,

Li's canonical form (the coefficient of $\mathbf{1}$ in $Y(e^{zL_1}(-z^{-2})^{L_0}a, z^{-1})b$, suitably normalised) gives a fully invariant form whose radical is an ideal not containing $\mathbf{1}$, hence 0 by simplicity (Chapter 5). □

What the machine verified

Proved; `#print axioms VOA.VertexOperatorAlgebra.selfDual_iff`: standard three.

Physical meaning

A nondegenerate invariant form is the two-point function $\langle a(z)b(w)\rangle$ of the CFT on the sphere; self-duality is the statement that the vacuum sector is its own charge conjugate, i.e. that every field has a nonzero two-point function with some field. $L_1V_1 = 0$ says the currents are quasi-primary, which is what makes their two-point functions conformally covariant.

Definition 12.43 (Strongly finite, strongly rational; Creutzig–Gannon, Dong–Mason, McRae). V is *strongly finite* if it is simple, self-dual and C_2-cofinite (and of CFT type, which is automatic here); *strongly rational* if moreover it is admissibly rational.

File `VOA/Modules/StronglyRational.lean`.

From the mathematics to the Lean statement

Literature comparison. Creutzig–Gannon (2017, §2.2): strongly finite = simple, C_2-cofinite, CFT type, $V \cong V'$; strongly rational = strongly finite + *regular*. Dong–Mason (2004, §3): strongly rational = strong CFT type ($L_1V_1 = 0$), C_2-cofinite, rational. McRae (§2.2): CFT type, $V \cong V'$, C_2-cofinite, rational. The library: `StronglyFinite` = Creutzig–Gannon's (with $V \cong V'$ in the form version, and CFT type built in); `StronglyRational` = McRae's/Dong–Mason's definition with "rational" read as the library's `AdmissiblyRational` (DLM-rational ⇒ `AdmissiblyRational` is proved for C_2-cofinite V, Theorem 12.36, so every McRae/Dong–Mason strongly rational VOA satisfies the library's rationality; the converse is open), plus an explicit simplicity conjunct. By `selfDual_iff` and `stronglyFinite_iff`, given simplicity, self-duality is exactly $L_1V_1 = 0$, so the Dong–Mason and McRae versions agree; simplicity is implied in McRae's setting by CFT type + $V \cong V'$ (an argument the library does not formalise, hence the explicit conjunct). Creutzig–Gannon's strongly rational (with regular) implies the library's (`stronglyRational_of_regular`); the converse needs ABD Thm. 4.5 (`StronglyRational.regular_of_abd`), which is now a theorem, so the converse holds without hypothesis (`StronglyRational.regular`, Theorem 12.44). So: implied by McRae/Dong–

Mason (given simplicity), the same *modulo the open converse* `AdmissiblyRational` ⇒ *DLM-rational*, and *equivalent* to Creutzig–Gannon's (given `StronglyFinite`, admissible rationality and regularity are interchangeable in Lean).
Non-vacuity. `stronglyRational_of_span_vacuum`: any VOA spanned by a nonzero vacuum is strongly rational (instantiated at the trivial VOA in Chapter 15). More interesting, the lattice triplet algebra $W(2)$ is *strongly finite and irrational*: `VOA.LatGen.Wp.tripletWVOA_two_stronglyFinite_and_irrational` (Chapter 18; `#print axioms` run for this chapter: standard three). Nontrivial strongly rational VOAs now exist in the library: the rank-one lattice VOAs $V_{\sqrt{2m}\mathbb{Z}}$ (`V2m_stronglyRational`, Chapter 22). Strong rationality gives Zhu's modularity theorem for them, through Theorem 12.39: this is `zhuModularity_V2m`, and more generally `zhuModularity_canonical_of_stronglyRational` (Chapter 15). (The first release revision of this chapter said the opposite; that was wrong.) $V^\natural$ is not proved strongly rational in the library.

Proof on paper. `stronglyFinite_iff` is `selfDual_iff`. For $V = \mathbb{C}\mathbf{1}$: every subspace of every weak module is a weak submodule (the only modes are multiples of $\mathbf{1}_{(-1)} = \mathrm{id}$), so complements exist; V is simple, $L_1 = 0$, and $\dim V/C_2(V) \le 1$. □

What the machine verified

Proved; `#print axioms` of `VOA.stronglyFinite\_iff`, `VOA.stronglyRational\_of\_regular`, `VOA.stronglyRational\_of\_span\_vacuum`: standard three.

Physical meaning

Strongly rational VOAs are the chiral algebras of the "nicest" CFTs: finitely many sectors, all of them ordinary, semisimple fusion, a nondegenerate sphere two-point function and no negative-energy states. Huang's theorem (whose formalisation in the library, and its hypotheses, are the subject of Chapter 21) shows that their module categories are modular tensor categories, which is the mathematical form of the Moore–Seiberg axioms of rational CFT. Strongly finite but irrational theories are the logarithmic CFTs whose representation categories are only log-modular.

Theorem 12.44 (Strongly rational VOAs: regular, finitely many admissible irreducibles, Gannon-rational). *Let V be strongly rational (Definition 12.43). Then*

1. *V is regular (Definition 12.38);*
2. *V satisfies the predicate* `DLMFinitelyManyIrredAdmissible`*, and V has only finitely many isomorphism classes of irreducible admissible modules;*
3. *V is Gannon-rational (Definition 12.37).*

No named literature hypothesis is assumed.

File `VOA/Modules/StronglyRational.lean` (the older forms, which carry the literature predicates as hypotheses):

```

```

From the mathematics to the Lean statement

Names. `_root_.VOA.StronglyRational.regular` declares the theorem with the full name `VOA.StronglyRational.regular`, although the file's namespace is `VOA.Classification.COne.LiteratureInputs`; this places it in the namespace of the structure `StronglyRational`, so that for `h : StronglyRational W` one may write `h.regular` (dot notation). The same holds for the other three. The older `gannonRational` is likewise `VOA.StronglyRational.gannonRational` (it sits inside `namespace StronglyRational` in its file).

Hypotheses. Only `h : StronglyRational W`: simple, self-dual, C_2-cofinite (`h.c2Cofinite`) and admissibly rational (`h.rational`). The older forms carry, in addition, `hABD`, `hFin`, `hOrd`: exactly the literature predicates [ABD Thm. 4.5], [DLM 8.1(b)], [DLM 8.1(c)]. The new forms discharge them by `abdRegularOfC2AndRational_holds`, `dlmFinitelyManyIrredAdmissible_of_c2Cofinite h.c2Cofinite` and `dlmSimpleAdmissibleOrdinary_of_stronglyRational h` (the C_2-locus theorem of Theorem 12.40 item 5, applied to `h.c2Cofinite`); the one-line proof terms are shown because they are exactly these compositions.

Conclusions. `Regular W`, `Finite (Φadm W)` (with `Φadm` the set of isomorphism classes of irreducible admissible modules) and `GannonRational W` of Definitions 12.38 and 12.37. `StronglyRational.dlmFinitelyManyIrredAdmissible` is the predicate form (`AdmissiblyRational W → Finite (Φadm W)`); `finite_Φadm` applies it to `h.rational`.

Same as the literature? Yes, with "rational" read as `AdmissiblyRational`: for strongly rational VOAs in Dong–Mason's sense these are ABD Thm. 4.5 and DLM Thm. 8.1, and with `StronglyRational.regular` the library's strong rationality coincides with Creutzig–Gannon's (strongly finite + regular). **Vacuous?** No: `V2m_stronglyRational` (Chapter 22) supplies nontrivial instances.

Proof on paper. A strongly rational VOA is C_2-cofinite and admissibly rational; apply items 3, 5 and 6 of Theorem 12.40, and for (3) Theorem 12.41(4). □

Physical meaning

For the chiral algebra of a rational, lisse CFT with a nondegenerate two-point function, every structural property a physicist assumes — every representation splits into sectors, there are finitely many primaries, and all sectors have finite degeneracies — is now a theorem in Lean,

from the four defining properties alone. This is the input that Zhu's modular-invariance theorem (Chapter 15) and the modular tensor category of Chapter 21 rely on.

What the machine verified

Proved, **unconditional** given `h : StronglyRational W`. `#print axioms` of `VOA.StronglyRational.regular`, `.dlmFinitelyManyIrredAdmissible`, `.finite_Φadm`, `.gannonRational'`: `[propext, Classical.choice, Quot.sound]` (same scratch run as Theorem 12.40). The last three use the theorem `VOA.pbw` through `voaPBWBottomProjection`.

12.9.8 Summary table

Lean predicate	quantifies over / content	literature; same / weaker / stronger
`AdmissiblyRational`	admissible modules, weak complements	DLM "rational"; DLM ⇒ library proved under C_2 (`admissiblyRational_of_dlmRational`); converse open; library ⇒ graded reading proved
`GannonRational`	ordinary c.r. + $\lvert\Phi\rvert < \infty$ + adm. irreducibles ordinary	Gannon Def. 5.3.2 (his "weakly rational"); same
`Holomorphic`	Gannon-rational, $\lvert\Phi\rvert = 1$	Gannon; same
`Regular`	all weak modules c.r., irreducibles ordinary	DLM 1997 Def. 3.1; same
`C2Cofinite`	$\dim V/C_2(V) < \infty$	Zhu; same
`EtingofFinite`	$\dim \mathrm{HP}_0(R_V) < \infty$	weaker than AK quasi-lisse
`StronglyFinite`	simple, self-dual, C_2	Creutzig–Gannon; same
`StronglyRational`	strongly finite + adm. rational	McRae / Dong–Mason with `AdmissiblyRational` (see first row). Creutzig–Gannon's implies it
`SelfContragredient`	a linear iso $M \cong M'$	**vacuous**; not "$M \cong M'$ as modules"
`Unitary`	bilinear, non-isotropic, mode-symmetric form	**unsatisfiable** in dim ≥ 2; not unitarity

12.10 Recorded traps and dead ends

For the convenience of the referee we collect the traps of this chapter in one place, with their severity on a four-step scale: serious (a statement that is wrong or vacuous), moderate (weaker or stronger than advertised, or a redundant hypothesis), open gap (a conditional result whose hypothesis is not discharged, or a missing piece), and documentation only (docstrings and notes).

1. `fusionCoeff` $\equiv 0$ (serious; Theorem 12.33, proved in the library). No consumer.

2. `Unitary` unsatisfiable in dimension ≥ 2 and not the literature's unitarity (serious; Proposition 12.31, proved in the library). No consumer.

3. `SelfContragredient` holds for every module (serious, proved in the library by `selfContragredient_of_ordVModule`). No consumer.

4. `InducedAssignment` uninhabited; `forwardMap_invFun`, `forwardMap_comp_invFun`, `forwardMap_invFun_ofPointwise` vacuous (serious, proved in the library by `not_nonempty_inducedAssignment`); stale docstrings in `ZhuInduced.lean`, `ZhuBijection.lean` (documentation only).

5. `IsLowestWeight` allows $M_h = 0$ and requires a single coset (moderate; Section 12.3).

6. `On W n` omits DLM's generators $(L_{-1}+L_0)a$ for $n \geq 1$; `An` attributed to Frenkel–Zhu (moderate; documentation only; Section 12.6).

7. `A₂ W` is $V/C_2(V)$, not the second higher Zhu algebra (documentation only; Section 12.5).

8. `OrdVModule.boundedBelow` and `LogVModule.boundedBelow` are global bounds, stronger than FHL/HLZ per-coset truncation (moderate; Section 12.2).

9. `conformalWeight_char_periodicity` carries two unused hypotheses (moderate, marked by the library with underscores).

10. `isSimpleAMod_of_irreducible_of_semisimple` assumes semisimplicity of $A(V)$ and the PBW datum `Pr`, where Zhu's theorem needs neither (moderate; Theorem 12.20). The gap is closed elsewhere: the hypothesis-free `isSimpleAMod_toAMod_of_irreducible` (Chapter 13).

11. The docstrings of `AdmissibleRationality.lean` contradict each other on whether the weak-submodule reading of complete reducibility implies the graded one (documentation only; Section 12.9.2); DLM ⇒ `AdmissiblyRational` is now formalised under C_2 (Theorem 12.36), the converse is not.

12. `Fusion.lean` docstring: "built here faithfully" and "the Verlinde apex ...wires to `fusionCoeff`" (documentation only). `Contragredient.lean`: the closing section comment still calls the contragredient action a frontier (documentation only).

13. The module docstrings of `RationalityLattice.lean` and `Rationality.lean`, and the docstrings of `StronglyRational` and `StronglyRational.regular_of_abd`, still call the ABD and DLM predicates "cited" or "carried as a citation"; six of the seven are theorems (Theorem 12.40). Documentation only.

14. Open gap: `LiC2CofiniteOfRegular` is unproved, so `regular_iff_c2Cofinite_and_admissiblyRational` is conditional on it (Section 12.9.3).

Retired dead ends recorded by the library itself: the predicate `WeaklyRational` (wrong module category in its third clause, detached conclusion; replaced by `GannonRational` with no alias), and Gannon's conjecture "weakly rational $\iff$ C_2-cofinite" (false in the direction C_2 ⇒ rational, by the triplet algebras).

12.11 Referee's checklist

Lean declaration	intended meaning	hypotheses; status	check
`AdmissibleModule`, `LogVModule`	admissible / logarithmic modules	definitions	Defs. 12.4, 12.8
`WeakModule`, `WeakModule.act`	module Y_M with vacuum, truncation and Borcherds identity	definition; $\sum^{\mathrm{f}}$ finite	Def. 12.1
`mode_commutator` (module)	$[u^M_{(m)}, v^M_{(n)}] = \sum_i \binom{m}{i}(u_{(i)}v)^M_{(m+n-i)}$	weak module; unconditional	Thm. 12.2
`OrdVModule`, `OrdVModule.IsIrreducible`, `IsCompletelyReducible`	ordinary module; irreducible; completely reducible (weak submodules)	definitions; **global** lower bound on weights	Def. 12.5
`adjointWeakModule`, `adjointModule`	V as a module over itself	unconditional	Def. 12.6
`act_T_covariance`	$Y_M(L_{-1}a, z) = \partial_z Y_M(a, z)$	none; unconditional	Thm. 12.3

Lean declaration	intended meaning	hypotheses; status	check
`LogVModule.weight_eq_maxGenEigenspace`, `isL0Semisimple_iff_L0nil_eq_zero`	grading canonical; ordinary $\iff L_0^{\mathrm{nil}} = 0$	none; unconditional	Thm. 12.9
`OrdVModule.hasAdmissibleRefinement`	ordinary $\subseteq$ admissible	none; unconditional	Thm. 12.10
`ShortExact.gradedDim_eq_add`	characters additive	exactness; unconditional	Prop. 12.11
`restrictWeakModule`, `restrictOrdVModule`	restriction to a conformal subVOA	definitions	Def. 12.12
`IsLowestWeight`	weights in $h + \mathbb{N}$	M_h **may be** 0	Def. 12.14
`char_T_transform`	T-periodicity of χ_M	conformal weight h	Thm. 12.15
`zhuRingData_holds`, `instRingA`	$A(V)$ associative unital algebra	none; unconditional	Thm. 12.17
`oMod_zhuMul_lowest_all`, `rhoLW`, `O_le_ker_rhoLW`, `Pres_mem_O`	$o(u * v) = o(u)o(v)$ on M_h; $O(V)$ acts by 0; residues lie in $O(V)$	`IsLowestWeight` (M_h **may be** 0); unconditional	Thm. 12.16
`moduleMh`	M_h is an $A(V)$-module	`IsLowestWeight`; unconditional	Thm. 12.18
`forwardMap`	$[M] \mapsto [M_h]$	definition	Def. 12.19
`InducedAssignment.forwardMap_invFun`	round trip of Zhu's bijection	**vacuous** (hypothesis uninhabited)	§12.4
`isSimpleAMod_of_irreducible_of_semisimple`	bottoms of irreducibles simple	`Pr`, $A(V)$ semisimple; conditional (superseded by the unconditional Chapter 13 theorem)	Thm. 12.20
`DLMRational`, `admissiblyRational_of_dlmRational`	DLM rationality; DLM $\Rightarrow$ library rationality	`hC2`; proved; converse open	Thm. 12.36
`ZhuAdmissibleSemisimple`	rational $\Rightarrow$ $A(V)$ semisimple	named predicate; **proved** for every V (next row)	§12.9
`isSemisimpleRing_A_of_admissiblyRational`, `zhuAdmissibleSemisimple_of_Pr`	Zhu's semisimplicity theorem	`Pr` (from `VOA.pbw`), `AdmissiblyRational`; proved; used by the Zhu headline	Thm. 12.39
`isSimple_of_zhuPolynomial`	Zhu-polynomial simplicity test	$V \neq 0, V_1 = 0$, relation, roots	Thm. 12.21
`C2Cofinite`, `A₂CommRing`, `A₂LieRing`	C_2; Poisson algebra R_V	definitions; unconditional	Def. 12.22, Thm. 12.23
`iterProdSpan_eq_top`	finite strong generation	$V = \mathrm{span} S + C_2$	Thm. 12.24
`EtingofFinite_of_C2Cofinite`	$C_2 \Rightarrow$ Etingof-finite	C_2	Def. 12.26
`finiteDimensional_An_of_C2Cofinite` (+ `A`, `CGen`)	$C_2 \Rightarrow \dim A_n, \dim A, \dim V/C_m < \infty$	C_2; unconditional	Thm. 12.28
`contragredientModule`, `contragredientJacobi_holds`	M' is an ordinary module (FHL)	none; unconditional	Thm. 12.30
`onePoint_contragredient_holds`	$\chi_{M'}(v) = (-1)^n \chi_M(v)$	$v \in V_n, L_1 v = 0$	Thm. 12.30
`SelfContragredient`, `Unitary`	self-dual / unitary module	**vacuous / unsatisfiable**	§12.7
`fusionCoeff`	fusion rule	$\equiv 0$ (proved in the library)	Thm. 12.33

Lean declaration	intended meaning	hypotheses; status	check
`IntertwinerSpace`, `intertwiningDefect`, `Intertwiner`	kernel of the commutator-only defect; plus lower truncation	definitions; **weaker than FHL** (no iterate, no L_{-1} axiom)	Def. 12.32
`AdmissiblyRational`, `GannonRational`, `Regular`, `Holomorphic`	rationality notions	definitions	Defs. 12.35–12.38
`gannonRational_of_admissiblyRational` etc.	the lattice	named DLM/ABD/Li predicates as hypotheses; all dischargeable for C_2-cofinite V except Li's	Thm. 12.41
`abdWeakIsAdmissible`, `abdIrreducibleWeakIsOrdinary_holds`, `abdRegularOfC2AndRational_holds`, `zhuAdmissibleSemisimple_holds`	ABD 5.7, 5.8, 4.5; Zhu	none; **proved**, unconditional	Thm. 12.40
`dlmSimpleAdmissibleOrdinary_of_c2Cofinite`, `dlmFinitelyManyIrredAdmissible_of_c2Cofinite`	DLM 8.1(c), 8.1(b)	`hC2`; proved; open without C_2	Thm. 12.40
`LiC2CofiniteOfRegular`	regular $\Rightarrow$ C_2 (Li 3.8)	**unproved**; hypothesis of `regular_iff_c2Cofinite_and_admissiblyRational` only	§12.9.3
`selfDual_iff`	self-dual $\iff$ $L_1V_1 = 0$	simple; unconditional	Def. 12.42
`StronglyFinite`, `StronglyRational`	Creutzig–Gannon / McRae notions	definitions; satisfiable	Def. 12.43
`StronglyRational.regular`, `.finite_Φadm`, `.gannonRational'`	strongly rational $\Rightarrow$ regular, $\lvert\Phi_{\mathrm{adm}}\rvert < \infty$, Gannon-rational	`StronglyRational`; proved, no literature hypothesis	Thm. 12.44

The `#print axioms` results of the original revision of this chapter were obtained at an earlier commit (not re-run for this edition) by running a scratch file `import VOA` with `lake env lean -DmaxSynthPendingDepth=3` (never a bare `lake env lean`); later runs are dated where they occur below. No full `lake build` was run for this chapter. Every headline in this chapter reports exactly `[propext, Classical.choice, Quot.sound]`; `VOA.pbw` (now a theorem) is used by `zhuBijective_of_voaPBW` (Chapter 13) and, through `voaPBWBottomProjection`, by `zhuAdmissibleSemisimple_holds`, `dlmFinitelyManyIrredAdmissible_of_c2Cofinite` and the strongly-rational corollaries of Theorem 12.44.

Release audit 2026-10-27: RELEASE_AUDIT_ZHU.md. The release audit of the Zhu headlines (`Notes/Textbook/referee/RELEASE_AUDIT_ZHU.md`, finding F1) is the source of the corrections in this revision: the modularity theorem assumes semisimplicity of $A(V)$, not rationality, and the bridge `ZhuAdmissibleSemisimple` is unproved (this last statement was wrong; see the next paragraph). It also notes that the docstring of `StronglyRational.rational` (`StronglyRational.lean`: "Rational in the standard Zhu / Dong–Li–Mason sense") contradicts the "unsettled" note of `AdmissibleRationality.lean` (documentation only). The two `#print axioms` runs added in this revision (`VOA.Huang.LWBottomRecovery.isSimpleAMod_toAMod_of_irreducible`, `VOA.Huang.LWBottomRecovery.allBottomRecovers`) were made at an earlier commit (not re-run for this edition) with `lake env lean -DmaxSynthPendingDepth=3`: standard three. No `lake build` was

run.

Second release revision 2026-10-28: RELEASE_AUDIT_NEW_DECLS.md, finding F2. That audit found that the implication called unproved above, "rational $\Rightarrow$ $A(V)$ semisimple", is proved in the library (`VOA.Huang.ZhuSemisimple.isSemisimpleRing_A_of_admissiblyRational`). So the first release revision of this chapter, and the module docstrings that said the same, were wrong; the docstrings have been corrected in the library. This revision adds Theorem 12.39 and corrects the findings, the dictionary of the named literature predicates, the strong-rationality comparison and the checklist. A scratch file was run at an earlier commit (not re-run for this edition) with `lake env lean -DmaxSynthPendingDepth=3` from the repository root (the run is recorded in full in Chapter 15, end of Section 15.18). The lines relevant here:

```
'VOA.Huang.ZhuSemisimple.isSemisimpleRing_A_of_admissiblyRational' depends on axioms:
 ↪  [propext,
 Classical.choice,
 Quot.sound]
'VOA.Huang.ZhuSemisimple.zhuAdmissibleSemisimple_of_Pr' depends on axioms: [propext,
 ↪  Classical.choice, Quot.sound]
'VOA.Classification.COne.V2m_stronglyRational' depends on axioms: [propext,
 ↪  Classical.choice, Quot.sound]
'VOA.VHat.DLM3.voaPBWBottomProjection' depends on axioms: [propext, Classical.choice,
 ↪  Quot.sound]
```

No `lake build` was run. `Notes/RELEASE_PLAN.md` records the umbrella builds of `VOA.Modularity` and `VOA.Classification` as green (12,271 jobs, standard axioms) for the release follow-ups that use this theorem.

Third release revision 2026-10-28: the literature predicates. At that revision the file `LiteratureInputsProved.lean` records that six of the seven named literature predicates are theorems (Theorems 12.40 and 12.44); the investigation behind this revision is `Notes/Textbook/referee/LITERATURE_INPUTS_STATUS.md`. The olean of the new file was not present in the main checkout, so a scratch file consisting of a verbatim copy of it followed by `#print axioms` commands was compiled with `lake env lean -DmaxSynthPendingDepth=3` from the repository root (exit status 0). Output (line breaks of the long lines joined):

```
'VOA.Classification.COne.LiteratureInputs.abdIrreducibleWeakIsOrdinary_holds' depends on
 ↪  axioms: [propext, Classical.choice, Quot.sound]
'VOA.Classification.COne.LiteratureInputs.abdRegularOfC2AndRational_holds' depends on
 ↪  axioms: [propext, Classical.choice, Quot.sound]
'VOA.Classification.COne.LiteratureInputs.zhuAdmissibleSemisimple_holds' depends on axioms:
 ↪  [propext, Classical.choice, Quot.sound]
'VOA.Classification.COne.LiteratureInputs.dlmFinitelyManyIrredAdmissible_of_c2Cofinite'
 ↪  depends on axioms: [propext, Classical.choice, Quot.sound]
'VOA.StronglyRational.regular' depends on axioms: [propext, Classical.choice, Quot.sound]
'VOA.StronglyRational.dlmFinitelyManyIrredAdmissible' depends on axioms: [propext,
 ↪  Classical.choice, Quot.sound]
'VOA.StronglyRational.finite_Φadm' depends on axioms: [propext, Classical.choice,
 ↪  Quot.sound]
'VOA.StronglyRational.gannonRational'' depends on axioms: [propext, Classical.choice,
 ↪  Quot.sound]
'VOA.Classification.COne.ABDWeakAdmissible.abdWeakIsAdmissible' depends on axioms:
 ↪  [propext, Classical.choice, Quot.sound]
'VOA.Classification.COne.AdmissibleOrdinary.dlmSimpleAdmissibleOrdinary_of_c2Cofinite'
 ↪  depends on axioms: [propext, Classical.choice, Quot.sound]
'VOA.regular_iff_c2Cofinite_and_admissiblyRational' depends on axioms: [propext,
 ↪  Classical.choice, Quot.sound]
```

The last line is `#print axioms`-clean but *conditional* on its hypotheses `hABD` (now dischargeable) and `hLi : LiC2CofiniteOfRegular W` (**unproved**). The umbrella build of `VOA.Classification` including the new file is reported by the coordinator as green (12,179 jobs, standard axioms); it was not re-run for this chapter. The library docstrings of `RationalityLattice.lean` (module header) and `Rationality.lean` ("CITED" list), and those of `StronglyRational.regular_of_abd` and `StronglyRational` in `StronglyRational.lean` ("carried as a citation"), still describe the ABD/DLM predicates as citations (documentation only).

The open points of this chapter are now the converse comparison `AdmissiblyRational` ⇒ Dong–Li–Mason rationality (the forward direction is Theorem 12.36, under C_2), `LiC2CofiniteOfRegular`, and the two DLM predicates for admissibly rational VOAs not known to be C_2-cofinite.

Project records. The retirement of `WeaklyRational` and the rationality lattice are documented in the module docstrings of `Rationality.lean`, `AdmissibleModule.lean`, `AdmissibleRationality.lean` and `RationalityLattice.lean`; the refutation of `InducedAssignment` in `VOA/Modules/ZhuVermaAnArchZhu534.lean`; the defects of `fusionCoeff` and `Unitary` in `VOA/Modules/CoreFixFusion.lean` and `VOA/Modules/CoreFixUnitary.lean`.

Chapter 13

Zhu's bijection via the tower $A_n(V)$

This chapter documents the release of the LeanVOA library named in the front matter; it was first written against an earlier state of the library ("the snapshot" below), and checks that were run at an earlier state of the library and not re-run for this edition are marked as such. Every Lean quotation below is taken mechanically from the files of the release and is machine-checked by `scripts/textbook/sync.py` to occur verbatim (up to whitespace and comments) in the source. The chapter covers the 298 files `VOA/Modules/ZhuVerma*.lean` (about ninety thousand lines of Lean) assigned to it in `Notes/Textbook/assignment.txt`. They contain one headline: the *hard direction of Zhu's correspondence* between irreducible modules of a vertex operator algebra V and irreducible modules of its Zhu algebra $A(V)$. The easy direction, the algebra $A(V)$ itself, the bundled module types `AMod` and `LWModule`, and the definition of the library's higher Zhu spaces $A_n(V)$ were presented in Chapter 12; we use them freely and point back to them.

We do not tour 298 files. Instead we (i) state exactly what the headline theorem says, (ii) present every definition on which the statement and its proof depend, in the order in which the proof uses them, (iii) explain the proof on paper, and (iv) describe the remaining files by role in one short section (Section 13.7). The "critical path" was not taken from the library's own documentation: we computed it by a machine walk through the constants used by the proof term of the headline (Section 13.7); it touches 101 of the 298 files.

Release revision. The chapter was revised for the first public release, applying the release audit `Notes/Textbook/referee/RELEASE_AUDIT_ZHU.md` (2026-10-27). Two results proved outside this chapter's files since the snapshot change what can be said about the full correspondence, and are presented in Section 13.2.4: the bottom of every irreducible module is a simple $A(V)$-module, for every V (`VOA/Huang/LWBottomRecovery.lean`, Chapter 21); and the combined statement `zhuCorrespondence_of_C2Cofinite`, a genuine bijection between $\Phi(V)$ and isomorphism classes of simple $A(V)$-modules for C_2-cofinite V (`VOA/Modularity/ZhuModularityCanonical.lean`, Chapter 15). Their quotations were copied at that revision.

Second release revision (2026-10-28). At this revision one more consumer of this chapter's machinery is recorded (finding F2 of `Notes/Textbook/referee/RELEASE_AUDIT_NEW_DECLS.md`). The generalised Verma module induced from the regular $A(V)$-module, together with the datum `Pr` and bottom recovery, also proves Zhu's semisimplicity theorem "rational $\Rightarrow$ $A(V)$ semisimple" (`isSemisimpleRing_A_of_admissiblyRational`, `VOA/Huang/ZhuSemisimple.lean`; presented in Chapter 12, Theorem 12.39, and Chapter 15, Theorem 15.38). So for a C_2-cofinite rational V (rational in the library's sense `AdmissiblyRational`) the simple $A(V)$-modules of Theorem 13.8 are exactly the simple modules of a semisimple algebra, and Zhu's modularity theorem holds for V (Chapter 15). No statement or quotation of this chapter changed.

The findings of this chapter, in brief. The reader who only wants the verdict should read this paragraph and the warning boxes.

- **What is proved.** The headline `zhuBijective` states that a certain map $[M] \mapsto [M_h]$ is a bijection. Its domain is the set of isomorphism classes of *irreducible ordinary* V-modules (with their lowest weight); its codomain is the set of isomorphism classes of $A(V)$-modules *that are isomorphic to the bottom of some irreducible ordinary module*. Because the codomain is defined as the image, surjectivity is a tautology (the library says so itself). The genuine content is *injectivity*:

  > two irreducible ordinary V-modules whose lowest-weight spaces are isomorphic $A(V)$-modules are isomorphic.

  This is Zhu's uniqueness theorem, and it is proved for *every* vertex operator algebra of the library, with one explicit datum `Pr`. It is the *uniqueness half* of Zhu's correspondence, and must be announced as such, not as "Zhu's bijection". The equivalence "`zhuBijective` $\iff$ uniqueness" was checked in Lean against the library (the check is not part of this release).

- **The datum `Pr`.** `Pr : BottomProjection (parabolicRepOfAMod W (regularAMod W))` is a single linear-algebra statement attached to V: in the module induced from the *regular* $A(V)$-module along a parabolic subalgebra of the Frenkel–Zhu Lie algebra $\widehat{V}$, the canonical bottom copy of $A(V)$ is embedded. The library proves that a `BottomProjection` exists if and only if the bottom map is injective. It is a consequence of the Poincaré–Birkhoff–Witt theorem, hence true mathematics, and it is proved in the library for every V: `voaPBWBottomProjection` builds it from the theorem `VOA.pbw` (relative PBW, Chapter 3, Section 3.10.6). The wrapper `zhuBijective_of_voaPBW` uses it and is unconditional; its `#print axioms` is the standard three (at the snapshot, when `VOA.pbw` was an axiom, it contained `pbw`). So Zhu's bijection in its uniqueness form is now unconditional.

- **The genuine bijection, for C_2-cofinite V (new).** The two halves of Zhu's correspondence that the headline does not contain are now theorems: (1) the bottom of every irreducible module is a simple $A(V)$-module, for *every* V (`allBottomRecovers`, `isSimpleAMod_toAMod_of_irreducible`); (2) every simple $A(V)$-module is the bottom of an irreducible ordinary module, for C_2-cofinite V (`simpleAModsRealized_of_C2Cofinite`). Combined with the headline they give `zhuCorrespondence_of_C2Cofinite` (Theorem 13.8): for every C_2-cofinite V, $[M] \mapsto [M_h]$ is a bijection from $\Phi(V)$ onto the isomorphism classes of *simple* $A(V)$-modules, where "simple" is the intrinsic notion, not an image. C_2 is used only for existence (2); Zhu's own existence theorem does not need it, because it produces admissible rather than ordinary modules.

- **What is not proved.** Existence (2) without C_2, i.e. for V whose $L(U)$ might have infinite-dimensional weight spaces; there the bijection is stated only onto its image (Section 13.2.4).

- **A misnamed file.** The file `VOA/Modules/ZhuVermaAnArchCritPath.lean` ("the critical path of the Zhu bijection") is *not* on the critical path of `zhuBijective`, and its headline `zhuBijection_critpath` is vacuous: its hypothesis bundle cannot be inhabited (checked in Lean; the check is not part of this release).

- **The tower.** The library's circle-only $O_n(V)$ (`On`, which omits Dong–Li–Mason's $(L_{-1} + L_0)a$ for $n \geq 1$, Chapter 12) is used on the critical path only at $n = 0$, where it equals $O(V)$. The construction of the induced module uses the corrected `OnFull` and Dong–Jiang's full ideals `OnmFull`; so that defect does not touch the headline.

- **A redundant hypothesis, since removed.** `pHL0` used to carry the datum `Pr` without using it (checked in Lean; the check is not part of this release); the library has dropped it, and `zhuBijective` now applies the hypothesis-free `pHL0` directly.

13.1 Zhu's correspondence: the mathematics and the plan

13.1.1 The statement in the literature

Let V be a vertex operator algebra. Recall from Chapter 12 (Section 12.4) that Zhu's algebra is $A(V) = V/O(V)$ with product $[u][v] = [u * v]$, where for homogeneous u

$$u * v = \operatorname{Res}_z Y(u,z)v\,\frac{(1+z)^{\operatorname{wt} u}}{z}, \qquad u \circ v = \operatorname{Res}_z Y(u,z)v\,\frac{(1+z)^{\operatorname{wt} u}}{z^2}, \qquad O(V) = \operatorname{span}\{u \circ v\}.$$

If $M = \bigoplus_{n\geq 0} M_{h+n}$ is a V-module whose lowest weight h is attained ($M_h \neq 0$), then the zero modes $o(u) = u_{(\operatorname{wt} u - 1)}$ preserve M_h, and $[u] \mapsto o(u)|_{M_h}$ makes M_h an $A(V)$-module (Theorem 12.18). Zhu's theorem says much more.

Theorem 13.1 (Zhu 1996, Theorems 2.2.1 and 2.2.2)**.** *Let V be a vertex operator algebra.*

1. *If M is an irreducible $\mathbb{N}$-gradable (admissible) V-module with lowest piece $M(0)$, then $M(0)$ is a simple $A(V)$-module.*
2. *For every simple $A(V)$-module U there is an irreducible admissible V-module $L(U)$ with $L(U)(0) \cong U$.*
3. *The assignments $M \mapsto M(0)$ and $U \mapsto L(U)$ are mutually inverse bijections between isomorphism classes of irreducible admissible V-modules and isomorphism classes of simple $A(V)$-modules.*

Restricting to *ordinary* modules (finite-dimensional L_0-eigenspaces), one gets a bijection between irreducible ordinary modules and those simple $A(V)$-modules U for which $L(U)$ has finite-dimensional weight spaces; when V is C_2-cofinite these are all simple $A(V)$-modules (finite-dimensionality of $A(V)$ alone does not control the higher weight spaces of $L(U)$).

Part (3) contains two assertions of very different difficulty. *Well-definedness and surjectivity onto the simple modules* need the existence of $L(U)$, part (2). *Injectivity* — an irreducible module is determined by its bottom — needs a universal object: a "generalized Verma module" $M(U)$ generated by U that maps onto every module whose bottom contains U. Both directions therefore require the same construction: given an $A(V)$-module U, build a V-module $M(U)$ whose bottom is *exactly* U.

13.1.2 Why the construction is hard, and the tower

To build $M(U)$ one must know what the excited levels $M(U)(n)$, $n \geq 1$, are. The vectors of $M(U)(n)$ are formally $a_{(p)}w$ with $w \in U$ and $\operatorname{wt} a - p - 1 = n$, subject to every relation that holds in every V-module. Frenkel and Zhu found that these relations are encoded by quotients of V itself: Dong, Li and Mason introduced the associative algebras $A_n(V) = V/O_n(V)$ ("higher Zhu algebras") acting on the first n levels of any module, and Dong and Jiang introduced $A_{n,m}(V) = V/O_{n,m}(V)$, an $A_n(V)$–$A_m(V)$-bimodule which maps level m to level n. Their construction is

$$M(U) = \bigoplus_{n\geq 0} A_{n,0}(V) \otimes_{A(V)} U, \qquad M(U)(n) = A_{n,0}(V) \otimes_{A(V)} U, \tag{13.1}$$

with $a_{(p)}$ acting from level n to level $\operatorname{wt} a - p - 1 + n$ by a residue product. The irreducible module is then $L(U) = M(U)/J(U)$, $J(U)$ the largest graded submodule meeting the bottom trivially.

The delicate point is the bottom: one needs $M(U)(0) = A_{0,0}(V) \otimes_{A(V)} U \cong U$, i.e. $A_{0,0}(V) = A(V)$. Dong and Jiang prove this *representation-theoretically*: they realize the regular $A(V)$-module $A(V)$ as the bottom of some module (by the induced-module construction of Dong–Li–Mason, which uses the Poincaré–Birkhoff–Witt theorem) and read off $O_{0,0}(V) \subseteq O(V)$. This is precisely where the library's datum `Pr` enters.

13.1.3 The plan of the formal proof

The proof of `zhuBijective` in the library is the following chain; each arrow is a section of this chapter.

1. *The statement* (Section 13.2): the faithful forward map `forwardMapIrr`; its bijectivity is equivalent to *bottom rigidity* of irreducibles.

2. *The Lie algebra $\widehat{V}$ and induction* (Section 13.3): the Frenkel–Zhu Lie algebra $\widehat{V} = V \otimes \mathbb{C}[t,t^{-1}]/\operatorname{Im}(L_{-1}\otimes 1 + 1 \otimes \frac{d}{dt})$, its parabolic subalgebra P_0, the P_0-module structure on any $A(V)$-module, the induced module $\mathcal{U}(\widehat{V})\otimes_{\mathcal{U}(P_0)} U$, and the datum `BottomProjection`. `VOA.pbw` (an axiom at the snapshot, now a theorem) enters only here.

3. *The tower* (Section 13.4): circle products, O_n, A_n, and the Dong–Jiang ideals $O_{n,m}$ and spaces $A_{n,m}$.

4. *The induced module $M(U)$* (Section 13.5): the carrier (13.1), its V-action (a weak module, unconditionally), and the "gate" $A_{0,0}(V) = A(V)$, proved from `Pr` by realizing the regular module.

5. *$L(U)$ and the injectivity argument* (Section 13.6): $J(U)$, $L(U)$, the universal map $M(\Omega(P)) \to P$ for an irreducible P with bottom $\Omega(P)$, the isomorphism $P \cong L(\Omega(P))$, and functoriality $U_1 \cong U_2 \Rightarrow L(U_1) \cong L(U_2)$. Together: irreducibles are determined by their bottoms.

Physical meaning

In a two-dimensional chiral conformal field theory with chiral algebra V, an irreducible module is a *superselection sector*, and its lowest-weight space M_h is the space of *primary states* (ground states of the sector on the cylinder, all of energy $h - c/24$). The zero modes $o(u)$ of the fields are exactly the operators that preserve energy, so they act on the primaries; $A(V)$ is the algebra they generate, with all the relations imposed by the operator product expansion. Zhu's correspondence is the precise form of the physicist's slogan "a sector is determined by its primary multiplet": every sector is generated from its primaries by the negative modes (the descendants), and the only relations among descendants are those forced by the chiral algebra itself and by *null states*. The induced module $M(U)$ is the "Verma module" of all descendants of the primary multiplet U with no null states removed; $J(U)$ is the space of null descendants (states orthogonal to everything); $L(U)$ is the physical sector. The higher algebras $A_n(V)$ and $A_{n,m}(V)$ describe the fields as maps between *excited* levels: $A_{n,0}(V) \otimes U$ is the space of level-n descendants of U.

13.2 The statement that is proved

We begin at the top, with the theorem and the definitions that occur in its statement. The bundled types `AMod W` (an $A(V)$-module: a vector space U with a linear $\rho : A(V) \to \operatorname{End} U$, unital and multiplicative), `AModEquiv W U U'` (a linear isomorphism intertwining ρ), `LWModule W` (an ordinary module `isMod : OrdVModule W carrier` with a number `h` such that all weights lie in $h + \mathbb{N}$ and $M_h \neq 0$) and `LWModule.toAMod` (the bottom M_h with $[u] \mapsto o(u)$) are Definition 12.19 of Chapter 12; `OrdVModule` is the library's ordinary module (Chapter 1): a weak module with an internal direct-sum decomposition into L_0-eigenspaces M_α, $\alpha \in \mathbb{C}$, each finite-dimensional, with real parts bounded below.

13.2.1 Irreducibility and isomorphism

Definition 13.2 (Irreducible lowest-weight module; isomorphism of modules)**.** An ordinary module M is *irreducible* if $M \neq 0$ and its only subspaces stable under every mode $u_{(n)}$ are 0 and M. Two bundled lowest-weight modules are *isomorphic* if there is a linear isomorphism of carriers intertwining every mode: $e(u_{(n)}x) = u_{(n)}e(x)$ for all $u \in V$, $n \in \mathbb{Z}$.

Files `VOA/Modules/WeakModule.lean`, `VOA/Modules/ZhuVermaAnArchRigidity.lean`, `VOA/Modules/Rationality.lean` and `VOA/Modules/ZhuBijection.lean`.

```

```

From the mathematics to the Lean statement

`WeakModule.Submodule' N.toWeakModule` is a subspace of the carrier closed under every $u_{(n)}$ (no grading required); `P.carrier = ⊥ ∨ P.carrier = ⊤` says it is 0 or everything; `Nontrivial M` says $M \neq 0$. So `OrdVModule.IsIrreducible` is the textbook irreducibility of the underlying weak module. Note that the submodules are *not* required to be graded; for an ordinary module this makes no difference, because every mode-stable subspace is stable under $L_0 = \omega_{(1)}$ and hence is graded (L_0 acts semisimply with the weight spaces as eigenspaces; the library proves this in `ZhuVermaAnArchLUGraded.lean`, `submodule_isGraded`). `ModuleEquiv` bundles a $\mathbb{C}$-linear equivalence with the intertwining of all modes; it automatically maps M_α onto N_α because L_0 is a mode. `LWModule.Iso` is mere existence (`Nonempty`) of such an equivalence, a `Prop`, so that isomorphism classes can be formed as a quotient. All three are exactly the textbook notions.

Physical meaning

An irreducible module is a sector that cannot be split into smaller sectors: every state can be reached from every other by acting with modes of the chiral fields. An isomorphism of sectors is a relabelling of states that commutes with all fields, i.e. the two sectors are physically the same.

13.2.2 The faithful domain and codomain

Definition 13.3 ($\Phi(V)$ and the image-defined $\mathrm{Irr}A(V)$)**.** Let $\Phi(V)$ be the set of isomorphism classes of irreducible bundled lowest-weight modules. Call an $A(V)$-module U *a bottom of an irreducible* if there is an irreducible lowest-weight module P with $P_h \cong U$ as $A(V)$-modules, and let $\mathrm{Irr}A(V)$ denote the set of isomorphism classes of such U. The *faithful forward map* is

$$\mathrm{fwd} : \Phi(V) \to \mathrm{Irr}A(V), \qquad [P] \mapsto [P_h].$$

File `VOA/Modules/ZhuVermaAnArchFaithfulBijection.lean`.

    (fun _ _ ⟨e⟩ => Quotient.sound ⟨LWModule.isoToAModEquiv W e⟩)
```

From the mathematics to the Lean statement

Decoding. `{P : LWModule W // P.IsIrreducibleLW}` is a *subtype*: pairs $(P$, proof that P is irreducible); `P.1` is the module and `P.2` the proof. `IrrLWModule.setoid W` is the equivalence relation `IrrLWModule.Iso` (isomorphism of the underlying modules) and `Quotient` forms the set of classes; so `IrrLWModuleIsoClass W` is $\Phi(V)$. On the other side, `IsBottomOfIrr U` is literally "there exist an irreducible P and an $A(V)$-isomorphism $P_h \cong U$", and `IrrAModIsoClass W` is the set of $A(V)$-isomorphism classes of such U. `Quotient.lift f h` defines a function on classes from a function `f` on representatives, given a proof `h` that isomorphic inputs give equal outputs; here the proof is `LWModule.isoToAModEquiv`, the easy fact that an isomorphism of modules restricts to an $A(V)$-isomorphism of bottoms (Chapter 12). So `forwardMapIrr W` is $[P] \mapsto [P_h]$.

Universe bookkeeping. The carriers of modules live in the same universe `Type u` as V; the types of classes live one universe up. This is invisible mathematically: "all modules" means all modules whose carrier is a set of the same size class as V, which loses nothing (every irreducible module is a quotient of an object built from V and a vector space of the same size).

The crucial point: the codomain is the image. In Zhu's theorem the codomain is the set of *simple* $A(V)$-modules. Here it is, by definition, the set of $A(V)$-modules that already arise as bottoms of irreducibles. Every such module is simple, for every V (Theorem 13.6); the converse, that every simple module is such a bottom, is proved for C_2-cofinite V, and for those V the two sets are identified and the correspondence becomes a genuine bijection (Theorem 13.8). For general V the codomain remains the image; see Section 13.2.4.

Physical meaning

$\Phi(V)$ is the *spectrum of sectors* of the chiral theory; $\mathrm{Irr}A(V)$, as defined here, is the list of primary multiplets *that actually occur in some sector*. The forward map reads off the primary multiplet of each sector.

13.2.3 The headline

Theorem 13.4 (Zhu's correspondence, uniqueness form). *Let V be any vertex operator algebra of the library and assume the datum* `Pr` *of Definition 13.13 for the regular $A(V)$-module. Then* fwd $: \Phi(V) \to \mathrm{Irr}A(V)$ *is a bijection. Equivalently: if P, Q are irreducible bundled lowest-weight V-modules and $P_h \cong Q_{h'}$ as $A(V)$-modules, then $P \cong Q$. The datum* `Pr` *is supplied, for every V, by the theorem* `VOA.pbw` *(through* `voaPBWBottomProjection`*).*

Files `VOA/Modules/ZhuVermaAnArchLUBijection.lean` and `VOA/Modules/ZhuVermaAnArchLUBijectionPBW.lean`.

```
theorem zhuBijective (Pr : BottomProjection (parabolicRepOfAMod W (regularAMod W))) :

    Function.Surjective (forwardMapIrr W) := by
theorem forwardMapIrr_bijective_iff_rigidity :
    Function.Bijective (forwardMapIrr W) ↔ IrredBottomRigidity W :=
  ⟨fun hb => irredBottomRigidity_of_injective hb.1, forwardMapIrr_bijective_of_rigidity⟩
```

From the mathematics to the Lean statement

Hypotheses. The only explicit hypothesis of `zhuBijective` is `Pr`; the VOA `W` is implicit and arbitrary (any `VertexOperatorAlgebra 𝒱` on any complex vector space $\mathcal{V}$). There is no simplicity, rationality, C_2, or finiteness hypothesis on V. `Pr` is a structure (data, not a proposition) whose meaning is explained in Section 13.3; its type mentions `regularAMod W` ($A(V)$ as a module over itself) and `parabolicRepOfAMod` (Definition 13.10). `zhuBijective_of_voaPBW` has no hypothesis at all: it applies `zhuBijective` to the term `voaPBWBottomProjection ...`, which is built from `VOA.pbw`.
Conclusion. `Function.Bijective f` is Mathlib's "injective and surjective".
Exactly which bijection. Between $\Phi(V)$ = isomorphism classes of irreducible *ordinary* modules whose weights lie in one coset $h + \mathbb{N}$ with $M_h \neq 0$, and $\mathrm{Irr}A(V)$ = isomorphism classes of $A(V)$-modules occurring as such bottoms. Classes are taken up to isomorphism on both sides.
Same, weaker, or stronger than Zhu? Compared with Theorem 13.1(3) restricted to ordinary modules:

- *Surjectivity* is free: `forwardMapIrr_surjective_uncond` proves it with no hypothesis, by unpacking the definition of the codomain. It contains none of Zhu's existence theorem (2).
- *Injectivity* is exactly Zhu's uniqueness: by `forwardMapIrr_bijective_iff_rigidity`, bijectivity of `forwardMapIrr W` is *equivalent* to `IrredBottomRigidity W`, which reads: for irreducible P, Q, an $A(V)$-isomorphism $P_h \cong Q_{h'}$ implies $P \cong Q$. (The two lowest weights are then equal, because $[\omega]$ acts on the bottom by the lowest weight.)
- *Part (1)* of Zhu's theorem (bottoms of irreducibles are simple) is not asserted by this

theorem. It is a separate library theorem, valid for every V (Theorem 13.6), so the codomain consists of simple modules.

So the Lean theorem is *weaker* than Zhu's full theorem (3): it is precisely its uniqueness half. It is stated for a wider class of VOAs than many textbook versions (no CFT-type assumption is needed since every library VOA is of CFT type).

Could it be vacuous? The hypothesis `Pr` is satisfiable (it is a true consequence of PBW, Section 13.3), and for the conclusion there is no trick: `IrredBottomRigidity` is a non-trivial statement whenever V has irreducible modules (e.g. the adjoint module of any simple VOA). A check in Lean against the library (not part of this release) derives `IrredBottomRigidity`-shaped statements `zhu_rigidity` and `zhu_rigidity_voaPBW` directly from the two headlines, and conversely `bijective_of_rigidity_statement`.

Trap / dead end

The name oversells (moderate). The docstrings call `zhuBijective` "Zhu Theorem 5.3.4 (faithful form)". It is the *uniqueness* half of Zhu's correspondence only: its codomain `IrrAModIsoClass` is the image of the forward map by definition, so surjectivity is a tautology (as the library's own `forwardMapIrr_surjective_uncond` and its docstring state). A reader who sees "bijection $\Phi(V) \leftrightarrow \mathrm{Irr}A(V)$" must not conclude that every simple $A(V)$-module is realized; that is a separate theorem, proved only under C_2-cofiniteness (Section 13.2.4). For C_2-cofinite V the genuine bijection onto all simple $A(V)$-modules is `zhuCorrespondence_of_C2Cofinite` (Theorem 13.8); cite that, not `zhuBijective`, when announcing "Zhu's correspondence as a bijection". Checked in Lean against the library (the check is not part of this release): theorems `zhu_rigidity`, `bijective_of_rigidity_statement`, `forwardMapIrr_surjective_free`.

Proof on paper (overview). By `forwardMapIrr_bijective_iff_rigidity` it suffices to prove uniqueness. Let P be irreducible with bottom $\Omega(P) = P_h$. In Section 13.6 we construct, from the $A(V)$-module $\Omega(P)$ alone, the module $L(\Omega(P))$ and prove $P \cong L(\Omega(P))$. We also prove that $L(U)$ depends only on the isomorphism class of U. If $\Omega(P) \cong \Omega(Q)$ then $P \cong L(\Omega(P)) \cong L(\Omega(Q)) \cong Q$. □

What the machine verified

`zhuBijective`: proved, *conditional on* the explicit datum `Pr`; `#print axioms VOA.zhuBijective` = `[propext, Classical.choice, Quot.sound]`. `zhuBijective_of_voaPBW`: proved with no hypothesis; **unconditional**; `#print axioms` = `[propext, Classical.choice, Quot.sound]` in a later run, after `VOA.pbw` became a theorem, not re-run for this edition (at the snapshot the list also contained `pbw`, then an axiom). `forwardMapIrr_surjective_uncond`, `forwardMapIrr_bijective_iff_rigidity`: unconditional, standard three axioms. Except for the re-probe just stated, these results were obtained at the snapshot (not re-run for this edition) with `lake env lean -DmaxSynthPendingDepth=3` on a scratch file (output in Section 13.9).

Physical meaning

The theorem says: *a sector is determined by its primary multiplet.* Two sectors whose primaries carry isomorphic representations of the zero-mode algebra are the same sector. Physically this is the statement that all descendant states, their norms and their correlation functions are fixed by the chiral algebra once the primaries and the action of zero modes on them are fixed — the conformal bootstrap principle that "the spectrum of primaries plus the chiral algebra determines the representation". What the theorem does *not* say is which primary multiplets are allowed; that is the classification problem (for minimal models: the Kac table),

which is the content of the existence half.

13.2.4 What lies outside the headline: the scope of the codomain

We record where the two halves of Zhu's theorem that the headline does not contain stand, and how they combine with the headline. None of these results is in this chapter's files; we quote their statements so that the reader can see exactly what they assume. Since the snapshot, both halves have become theorems (the first for every V, the second for C_2-cofinite V), and the library now states their combination as one bijection.

Definition 13.5 (Simple $A(V)$-module; realizability)**.** An $A(V)$-module U is *simple* if $U \neq 0$ and its only $A(V)$-submodules are 0 and U. The predicate `SimpleAModsRealized W` says: every simple $A(V)$-module is the bottom of an irreducible graded module with finite-dimensional weight spaces (an `IrrRealization`).

Files `VOA/Modules/ZhuVermaAnArchLeaf3.lean`, `VOA/Modules/ZhuVermaAnArchZhu534.lean` and (Chapter 15) `VOA/Modularity/GNProp8Closure.lean`.

```
def IsSimpleAMod {W : VertexOperatorAlgebra 𝒱} (U : AMod W) : Prop :=
  Nontrivial U.carrier ∧ ∀ S : AModSubmodule U, S.carrier = ⊥ ∨ S.carrier = ⊤
def SimpleAModsRealized (W : VertexOperatorAlgebra 𝒱) : Prop :=
  ∀ U : AMod W, IsSimpleAMod U → Nonempty (IrrRealization W U)
theorem isBottomOfIrr_iff_isSimpleAMod (hrec : AllBottomRecovers W)
    (hreal : SimpleAModsRealized W) (U : AMod W) :
    IsBottomOfIrr U ↔ IsSimpleAMod U :=
theorem simpleAModsRealized_of_C2Cofinite {W : VertexOperatorAlgebra 𝒱}
    (hC2 : C2Cofinite W)
    (Pr : BottomProjection (parabolicRepOfAMod W (regularAMod W))) :
    SimpleAModsRealized W :=
```

From the mathematics to the Lean statement

`AModSubmodule U` is a subspace stable under every $\rho(a)$. `IrrRealization W U` packages an irreducible `GradedLWWeakModule` (Definition 13.24) with finite-dimensional weight spaces and an $A(V)$-isomorphism of its bottom with U; by `isBottomOfIrr_of_irrRealization` it puts U into the codomain `IrrAMod W`. `isBottomOfIrr_iff_isSimpleAMod` identifies the codomain with the simple $A(V)$-modules, under two hypotheses: `AllBottomRecovers W` (for the direction "bottoms are simple", Zhu's part (1)) and `SimpleAModsRealized W` (Zhu's part (2)). The second is proved in Chapter 15 from C_2-cofiniteness and `Pr`. The first is now a theorem for every V (`allBottomRecovers`, Theorem 13.6 below); at the snapshot it was an open hypothesis, and Chapter 12's Theorem 12.20 proved the irreducible case only under semisimplicity of $A(V)$ and `Pr`. A finiteness hypothesis is unavoidable for `SimpleAModsRealized` as typed: the library proves (`simpleAModsRealized_finiteDimensional`) that it forces every simple $A(V)$-module to be finite-dimensional, which fails e.g. for $A(V^k(\mathfrak{sl}_2)) \cong U(\mathfrak{sl}_2)$.

What the machine verified

`isBottomOfIrr_iff_isSimpleAMod`: conditional on `AllBottomRecovers` and `SimpleAModsRealized`; `#print axioms` = standard three (re-run at an earlier commit, not re-run for this edition). `simpleAModsRealized_of_C2Cofinite`: conditional on `C2Cofinite W` and `Pr` (both explicit; there is no `_voaPBW` wrapper); `#print axioms` = standard three. Since `AllBottomRecovers W` is now a theorem for every V (below), for a C_2-cofinite V both hypotheses of `isBottomOfIrr_iff_isSimpleAMod` hold, and the codomain of `forwardMapIrr` is exactly the simple $A(V)$-modules. (The earlier text of this box called "every element of the

codomain is simple" unproved; that is no longer so.)

Physical meaning

Existence ("every allowed primary multiplet generates a sector") is the half that physicists use to *classify* sectors: solve the zero-mode algebra's representation theory, then build the sector. In rational theories the zero-mode algebra is finite-dimensional and semisimple and the list of sectors is finite; in non-rational theories (e.g. the affine current algebra at generic level, whose zero modes generate $U(\mathfrak{g})$) there are infinite-dimensional primary multiplets that do not give ordinary sectors, which is why a finiteness hypothesis appears.

Theorem 13.6 (Bottoms of irreducible modules are simple; Zhu 1996, Theorem 2.2.1(1))**.** *For every vertex operator algebra V of the library and every irreducible bundled lowest-weight module P, the bottom P_h is a simple $A(V)$-module. More precisely, every lowest-weight module P has the* bottom-recovery property*: for every $A(V)$-submodule $S \subseteq P_h$, the V-submodule of P generated by S meets P_h in exactly S.*

The predicate is defined in `VOA/Modules/ZhuVermaAnArchLeaf3.lean` and `VOA/Modules/ZhuVermaAnArchAModScope.lean`:

```
def BottomRecovers : Prop :=
  ∀ S : AModSubmodule (P.toAMod),
    vSubmoduleBottomCarrier S.genVSubmodule ≤ S.carrier

def AllBottomRecovers (W : VertexOperatorAlgebra 𝒱) : Prop :=
  ∀ P : LWModule W, BottomRecovers P
```

and the theorems are in `VOA/Huang/LWBottomRecovery.lean` (Chapter 21), namespace `VOA.Huang.LWBottomRecovery`, with section variables {`W : VertexOperatorAlgebra 𝒱`} and (`P : LWModule W`):

```
theorem allBottomRecovers (W : VertexOperatorAlgebra 𝒱) : AllBottomRecovers W :=
  fun P => bottomRecovers P

theorem isSimpleAMod_toAMod_of_irreducible (hP : P.IsIrreducibleLW) : IsSimpleAMod P.toAMod
↪  :=
  isSimpleAMod_of_bottomRecovers P hP (bottomRecovers P)
```

From the mathematics to the Lean statement

`S.genVSubmodule` is the weak V-submodule of P generated by the subspace S of the bottom (all vectors $u^1_{(n_1)} \cdots u^k_{(n_k)} s$, $s \in S$); `vSubmoduleBottomCarrier` is its intersection with the bottom P_h. So `BottomRecovers P` says: *a mode word that carries a vector of S back to the bottom lands in S*; equivalently, the only way to return to the ground states is through the zero-mode algebra $A(V)$, which preserves S. The inclusion $\supseteq$ is trivial, so this is an equality. `allBottomRecovers` proves it for every lowest-weight module of every V, with no hypothesis: no C_2, no semisimplicity, no datum `Pr`. `isSimpleAMod_toAMod_of_irreducible` deduces simplicity of the bottom of an irreducible P: if $0 \neq S \subsetneq P_h$, the submodule generated by S is nonzero, hence all of P by irreducibility, and its bottom would be $S \neq P_h$, a contradiction. **Same as Zhu's part (1)**, for ordinary lowest-weight modules. It removes the extra hypotheses of Chapter 12's Theorem 12.20. The project had recorded `AllBottomRecovers` as unproved; that gap is now closed.

Proof on paper. View P as an admissible module with levels $P(k) = P_{h+k}$. A vector of the generated submodule lying in $P(0)$ is a sum of mode words $u^1_{(n_1)} \cdots u^k_{(n_k)} s$ of total degree 0. By the commutator and associativity formulas, any such word can be rewritten as a combination of words in which all degree-lowering modes stand to the right of all degree-raising ones; on the bottom the lowering

modes act by 0, and what remains are products of zero modes $o(u)$, i.e. the action of $A(V)$ (this is the standard argument of Dong–Li–Mason that $\Omega(M)$-generated submodules are controlled by $A(V)$, used by Zhu for part (1)). Since S is an $A(V)$-submodule, the result lies in S. The Lean proof applies the general bottom recovery of `VOA/Huang/BottomRecovery.lean`. □

Physical meaning

The ground states of a sector cannot be "re-entered" by a detour through excited states except through the zero modes: whatever a product of field modes does, if it starts and ends on ground states it acts as an element of the zero-mode algebra. Hence the ground-state multiplet of an irreducible sector is an irreducible multiplet: "one primary per sector, up to zero-mode symmetry".

What the machine verified

`VOA.Huang.LWBottomRecovery.allBottomRecovers`, `VOA.Huang.LWBottomRecovery.isSimpleAMod_toAMod_of_ir` `[propext, Classical.choice, Quot.sound]`, run at an earlier commit (not re-run for this edition) with `lake env lean -DmaxSynthPendingDepth=3`. **Unconditional.**

13.2.5 Zhu's correspondence as one bijection, for C_2-cofinite V

With both halves available, the library states Zhu's correspondence in the form one expects: a bijection between $\Phi(V)$ and isomorphism classes of simple $A(V)$-modules, where the codomain is defined intrinsically ("simple"), not as the image of the map.

Definition 13.7 (Simple $A(V)$-modules up to isomorphism; the bottom as a simple module)**.** Let Simple$A(V)$ be the collection of simple $A(V)$-modules (in the sense of Definition 13.5), and Simple$A(V)/\cong$ its set of isomorphism classes. For an irreducible lowest-weight module P, its bottom P_h is an element of Simple$A(V)$ by Theorem 13.6. The forgetful map forget : IrrLW$(V)/\cong \to \Phi(V)$ sends the class of a bundled lowest-weight module to the class of the underlying irreducible ordinary module; it is a bijection.

File `VOA/Modularity/ZhuModularityCanonical.lean`.

```

```
    IrrLWModuleIsoClass W ≃ Φ W where
  toFun := forgetClass W
  invFun := lowestWeightClass W
```

From the mathematics to the Lean statement

`{U : AMod W // IsSimpleAMod U}` is the subtype of bundled $A(V)$-modules that are simple (nonzero, with only the trivial $A(V)$-submodules): an *intrinsic* predicate on U, unlike `IsBottomOfIrr`, which asks for an irreducible V-module realising U. The setoid is $A(V)$-isomorphism (`AModEquiv`, Chapter 12); the displayed `where` clause shows the relation, and its three proof fields (reflexivity, symmetry, transitivity, borrowed from `AMod.setoid`) are omitted. `IrrLWModule.toSimpleAMod P` is the bottom `P.1.toAMod` together with the proof that it is simple, obtained from `IsBottomOfIrr.isSimpleAMod` and the theorem `allBottomRecovers`; no hypothesis on V. `forgetClass` forgets the lowest weight h (an irreducible bundled lowest-weight module *is* an irreducible ordinary module, `IrrLWModule.forget`); `irrLWModuleIsoClass_equiv_Φ` is the equivalence $\mathrm{IrrLW}(V)/\cong\ \simeq \Phi(V)$ whose forward map is `forgetClass` and whose inverse chooses the conformal weight (existence of a lowest weight for irreducible modules; we show its first two fields, the proofs of the two inverse laws are omitted). This identifies the domain `IrrLWModuleIsoClass` of the headline with Chapter 12's $\Phi(V)$.

Physical meaning

$\mathrm{Simple}A(V)/\cong$ is the list of *allowed* irreducible primary multiplets, computed from the zero-mode algebra alone, before asking whether each of them generates a sector.

What the machine verified

Definitions. `VOA.IrrLWModule.toSimpleAMod`: `[propext, Classical.choice, Quot.sound]` (run at an earlier commit, not re-run for this edition).

Theorem 13.8 (Zhu's correspondence as one bijection; Zhu 1996, Theorem 2.2.2 / Gannon, Theorem 5.3.4, for C_2-cofinite V). *Let V be C_2-cofinite. There is a bijection*

$$e : \Phi(V) \xrightarrow{\sim} \mathrm{Simple}A(V)/\cong$$

such that for every irreducible lowest-weight module P with bottom P_h, $e([P]) = [P_h]$.

File `VOA/Modularity/ZhuModularityCanonical.lean`.

```
theorem zhuCorrespondence_of_C2Cofinite (W : VertexOperatorAlgebra ℂ) (hC2 : C2Cofinite W)
↪  :
    ∃ e : Φ W ≃ SimpleAModIsoClass W, ∀ P : IrrLWModule W,
      e (forgetClass W (Quotient.mk (IrrLWModule.setoid W) P)) =
        Quotient.mk (SimpleAMod.setoid W) (IrrLWModule.toSimpleAMod P) := by
```

From the mathematics to the Lean statement

Decoding. `Φ W ≃ SimpleAModIsoClass W` is a Lean *equivalence*: a function with a two-sided inverse, i.e. a bijection. The second conjunct pins down *which* bijection: for every irreducible lowest-weight module `P`, the class of `P` in $\Phi(V)$ (obtained by forming its class `Quotient.mk (IrrLWModule.setoid W) P` and forgetting the lowest weight with `forgetClass`) is sent to the class of its bottom. Since every element of $\Phi(V)$ is of this form (`irrLWModuleIsoClass_equiv_Φ`), e is completely determined: it is $[M] \mapsto [M_h]$.
Hypotheses. Only `hC2 : C2Cofinite W`. The datum `Pr` is supplied inside the proof by

`voaPBWBottomProjection` (the theorem `VOA.pbw`).
Same, weaker, or stronger than Zhu? Compared with Theorem 13.1(3) restricted to ordinary modules:

- the codomain is the set of *all* simple $A(V)$-modules up to isomorphism, defined intrinsically, so this is no longer the image-defined statement of the headline: surjectivity is genuine content (existence of modules);
- injectivity is the headline's uniqueness, valid without C_2;
- well-definedness into simple modules is Theorem 13.6, valid without C_2;
- C_2-cofiniteness is used *only* for surjectivity, through `simpleAModsRealized_of_C2Cofinite`. Zhu's existence theorem needs no such hypothesis, but it yields an *admissible* module $L(U)$; to land in $\Phi(V)$, whose elements are *ordinary* modules, one needs the weight spaces of $L(U)$ to be finite-dimensional, which C_2 guarantees. For C_2-cofinite V every simple $A(V)$-module is finite-dimensional (since $A(V)$ is), as Zhu's ordinary-module version requires.

So, for C_2-cofinite V, this is exactly Zhu's correspondence between irreducible ordinary modules and simple $A(V)$-modules. For V that are not C_2-cofinite the library has only the uniqueness half (the headline).
Could it be vacuous? No: both sides are nonempty whenever V has an irreducible module (e.g. the adjoint module of a simple V), and the second conjunct ties e to the actual modules, so it is not an abstract cardinality statement.

Proof on paper. By Theorem 13.6, `AllBottomRecovers W` holds; by `simpleAModsRealized_of_C2Cofinite` (with `Pr` from `VOA.pbw`), `SimpleAModsRealized W` holds. So `isBottomOfIrr_iff_isSimpleAMod` identifies the image-defined codomain `IrrAModIsoClass W` of the headline with `SimpleAModIsoClass W`. Compose: $\Phi(V) \simeq$ `IrrLWModuleIsoClass W` (inverse of `irrLWModuleIsoClass_equiv_Φ`), then the headline's bijection `forwardMapIrr` (`zhuBijective_of_voaPBW`), then this identification. Each step sends $[P]$ to $[P_h]$. □

Physical meaning

For a C_2-cofinite chiral algebra, *sectors are in one-to-one correspondence with irreducible representations of the zero-mode algebra*: to classify the sectors, classify the simple modules of the finite-dimensional algebra $A(V)$. This is how the sectors of minimal models, WZW models and lattice theories are classified in practice.

What the machine verified

`VOA.zhuCorrespondence_of_C2Cofinite`: `[propext, Classical.choice, Quot.sound]`, run at an earlier commit (not re-run for this edition) with `lake env lean -DmaxSynthPendingDepth=3` on a scratch file containing the text of `ZhuModularityCanonical.lean` (which had no olean at that commit; its imports had). **`#print axioms`-clean, conditional on** `C2Cofinite W` only; uses the theorem `VOA.pbw`. This is the form to cite as "Zhu's correspondence (bijection)".

13.3 The Frenkel–Zhu Lie algebra, induction, and the datum Pr

This section explains the single input of the headline. We need a Lie algebra $\widehat{V}$ attached to V, a subalgebra P_0 of it, a way to make any $A(V)$-module a P_0-module, and induction from P_0 to $\widehat{V}$.

13.3.1 The Lie algebra $\widehat{V}$

Definition 13.9 (Frenkel–Zhu, Borcherds; Lie algebra of modes)**.** Let $V \otimes \mathbb{C}[t,t^{-1}]$ have basis-free elements $a(m) = a \otimes t^m$ ($a \in V$, $m \in \mathbb{Z}$), and let D be the subspace spanned by $(L_{-1}a)(m) + m\,a(m-1)$. Put $\widehat{V} = V \otimes \mathbb{C}[t,t^{-1}]/D$ with bracket

$$[a(m), b(k)] = \sum_{i \geq 0} \binom{m}{i} (a_{(i)}b)(m+k-i). \tag{13.2}$$

The sum is finite because $a_{(i)}b = 0$ for $i \gg 0$. Grade $\widehat{V}$ by $\deg a(m) = \operatorname{wt} a - m - 1$ for homogeneous a.

Files `VOA/Modules/ZhuVermaAnArchVhat.lean` and `VOA/Modules/ZhuVermaAnArchVhatJac3.lean`.

```

From the mathematics to the Lean statement

Decoding. `ℤ →₀ 𝒱` is Mathlib's type of finitely supported functions $\mathbb{Z} \to V$, i.e. $V \otimes \mathbb{C}[t,t^{-1}]$; `single m a` is $a \otimes t^m = a(m)$. `vloopBracket W` is the bilinear extension of (13.2); `vloopBracket_single` states its value on generators, with `gBinom m i` $= \binom{m}{i}$ for $m \in \mathbb{Z}$, $i \in \mathbb{N}$ and `W.smul a i b` $= a_{(i)}b$; $\sum^{\mathrm{f}}$ is a finitely supported sum, and its support is finite by the truncation axiom (the library proves this, `brLevel_support_finite'`). `W.L (-1)` is L_{-1}. `loopDerivSubmodule W` is D, `VHatCarrier W` is $\widehat{V}$, `gen W a m` is the class of $a(m)$, and `deg W d` is the span of the homogeneous generators of degree d.

The Lie structure is a theorem. `lieRing W` is assembled from three proved facts: the bracket descends to the quotient by D (`bracketDescends`: D is an ideal, because L_{-1} is a derivation of every product and $(L_{-1}a)_{(i)} = -i\,a_{(i-1)}$), antisymmetry (`vhatAntisymm`, from skew-symmetry $Y(a,z)b = e^{zL_{-1}}Y(b,-z)a$, valid only modulo D), and the Jacobi identity (`vhatLeibniz_holds`, from the Borcherds identity). There is no central extension: the conformal data already live in V. This is the Lie algebra of Frenkel–Zhu, Borcherds and Dong–Li–Mason. It is attached locally as an instance (`instLieRingVHat`) in the files that need it.

Same as the literature? Yes. In the literature the quotient is by the image of $L_{-1}\otimes 1 + 1 \otimes \frac{d}{dt}$;

on $a \otimes t^m$ this operator gives $(L_{-1}a) \otimes t^m + m\,a \otimes t^{m-1}$, exactly the generators of D.

Proof on paper (that $\widehat{V}$ is a Lie algebra). The commutator formula of a vertex algebra says that on any module $[a_{(m)}, b_{(k)}] = \sum_i \binom{m}{i} (a_{(i)}b)_{(m+k-i)}$, and the translation axiom says $(L_{-1}a)_{(m)} = -m\,a_{(m-1)}$. So (13.2) is the bracket of mode operators, and D lies in the kernel of $a(m) \mapsto a_{(m)}$ on every module. To prove the Lie axioms *abstractly* (without a faithful module) one checks them on generators: (i) D is an ideal because $L_{-1}(a_{(i)}b) = (L_{-1}a)_{(i)}b + a_{(i)}L_{-1}b$ and $(L_{-1}a)_{(i)}b = -i\,a_{(i-1)}b$, which turns $[D,\cdot]$ into combinations of generators of D; (ii) antisymmetry follows from skew-symmetry $b_{(k)}a = \sum_j (-1)^{k+j+1} \frac{1}{j!} L_{-1}^j (a_{(k+j)}b)$, the L_{-1}^j terms being absorbed by D; (iii) the Jacobi identity on three generators is the Borcherds identity with $\ell = 0$, after a Vandermonde-type rearrangement of binomial coefficients. □

What the machine verified

`VHat.lieRing`, `VHat.bracketDescends`, `VHat.vhatLeibniz_holds`: proved, unconditional; `#print axioms` = `[propext, Classical.choice, Quot.sound]`.

Physical meaning

$\widehat{V}$ is the Lie algebra of *all Laurent modes of all chiral fields*, with the commutators dictated by the singular part of the OPE — the "mode algebra" of the chiral algebra. For the free boson it contains the Heisenberg algebra $[J_m, J_k] = m\,\delta_{m+k,0}$ (from $J(z)J(w) \sim 1/(z-w)^2$), for an affine current algebra it contains the affine Kac–Moody algebra, and for the stress tensor the Virasoro algebra. Every sector of the chiral theory is a representation of $\widehat{V}$; the converse is false, because the OPE also contains *regular* terms (normal-ordered products) that a mere Lie-algebra representation need not respect. That defect is repaired below by a quotient.

13.3.2 The parabolic subalgebra and the $A(V)$-modules

Definition 13.10 (P_n; parabolic representation). For $n \in \mathbb{N}$ let $P_n \subseteq \widehat{V}$ be the span of the homogeneous generators of degree 0 or $\le -n-1$; its *deep part* is the span of those of degree $\le -n-1$. A *parabolic representation* of level n on a vector space U is a Lie-algebra homomorphism $P_n \to \operatorname{End} U$ which kills the deep part and sends $\mathbf{1}(-1)$ to the identity.

  vacuum_one : act ⟨gen W W.vacuum (-1), vacuumGen_mem_parabolic W n⟩ = 1
```

From the mathematics to the Lean statement

`LieSubalgebra ℂ (VHatCarrier W)` is a subspace closed under the bracket; closure is `degSpan_lie_mem` with the observation that the degree set $\{0\} \cup (-\infty, -n-1]$ is closed under addition. `Pn W n →ₗ[ℂ] End ℂ U` is a Lie-algebra homomorphism into the commutator Lie algebra of End U. The two fields are the two normalizations of Dong–Li–Mason's (4.1). Note the sign convention: `deg` is wt $a - m - 1$, so "degree $\le -n-1$" means the mode $a_{(m)}$ *lowers* weight by at least $n+1$; on level n of a module these modes act by zero.

Physical meaning

P_0 is spanned by the zero modes (degree 0) and all modes that lower the energy. On the ground states of a sector the lowering modes vanish and the zero modes act through $A(V)$: this is exactly a parabolic representation of level 0. The choice of P_0 is the chiral-algebra analogue of choosing a Borel-plus-Cartan subalgebra when constructing a Verma module: "annihilation operators kill the vacuum".

Definition 13.11 (The regular $A(V)$-module; the parabolic representation of an $A(V)$-module)**.** The *regular module* is $A(V)$ acting on itself by left multiplication. Every $A(V)$-module U becomes a level-0 parabolic representation by $a(m) \mapsto \rho([\pi_{m+1}a])$, where π_w is the projection onto V_w: a degree-0 generator $a(\mathrm{wt}\, a - 1)$ acts as $[a]$, every other homogeneous generator by 0.

From the mathematics to the Lean statement

`Amul (zhuRingData_holds W)` is left multiplication in the ring $A(V)$ (Chapter 12, Theorem 12.17); `regularAMod W` is the bundled $A(V)$-module $A(V)$. It is infinite-dimensional in general (for the Heisenberg VOA $A(V) \cong \mathbb{C}[x]$); this matters because an `OrdVModule` cannot have it as bottom, which is why the library works with weak modules in the construction. `zhuLoop W` is $a(m) \mapsto [\pi_{m+1}a]$ on $V \otimes \mathbb{C}[t, t^{-1}]$, where `gradeComp W w` is the projection π_w onto V_w along the grading, and `zhuDeg0 W` is the induced linear map $\widehat{V} \to A(V)$, $a(m) \mapsto [\pi_{m+1}a]$; it is well defined on the quotient by D because $(L_{-1} + L_0)w \in O(V)$ (`zhuLgen_mem_O`). `parabolicRepOfAMod W U` is the parabolic representation

$g \mapsto \rho(\mathrm{zhuDeg0}(g))$. Its three obligations are discharged by proofs: the Lie-homomorphism property (`zhuDeg0_bracket_parabolic`, which on the degree-0 part is Zhu's commutator formula $u * v - v * u \equiv \mathrm{Res}_z\, Y(u,z)v(1+z)^{\mathrm{wt}\,u-1} \pmod{O(V)}$, `zhu_comm_mod_0`), the vanishing on the deep part, and $\rho([\mathbf{1}]) = 1$. This is Dong–Li–Mason's Proposition 3.1 at $n = 0$: $a(\mathrm{wt}\,a - 1) \mapsto [a]$ is a surjective Lie homomorphism from the degree-0 part of $\widehat{V}$ to $A(V)$ with its commutator bracket.

What the machine verified

`regularAMod`, `zhuDeg0`, `parabolicRepOfAMod`: definitions whose obligations are proved, unconditional; `#print axioms` = standard three.

Physical meaning

The zero mode $o(a)$ of a field of weight $\mathrm{wt}\,a$ is its mode $a(\mathrm{wt}\,a - 1)$; "$a(\mathrm{wt}\,a - 1) \mapsto [a]$" is the statement that on ground states the zero modes multiply according to Zhu's product. The regular module is the "universal multiplet": any primary multiplet is a quotient of copies of it.

13.3.3 The induced module and the bottom map

Definition 13.12 (Induced module, bottom map, levels)**.** For a parabolic representation P of level n on U, let $\mathcal{U}(\widehat{V})$ be the universal enveloping algebra and

$$M_n(U) = \mathcal{U}(\widehat{V}) \otimes_{\mathcal{U}(P_n)} U = \big(\mathcal{U}(\widehat{V}) \otimes_{\mathbb{C}} U\big) \Big/ \mathrm{span}\{y\,g \otimes u - y \otimes g \cdot u \,:\, y \in \mathcal{U}(\widehat{V}),\ g \in P_n,\ u \in U\}.$$

The *bottom map* is $U \to M_n(U)$, $u \mapsto [1 \otimes u]$. The *level* k part $M_n(U)(k)$ is spanned by $[y \otimes u]$ with y of degree $k - n$ (degree extended multiplicatively from $\widehat{V}$ to $\mathcal{U}(\widehat{V})$).

Files `VOA/Modules/ZhuVermaAnArchMUVhat.lean`, `VOA/Modules/ZhuVermaAnArchDLM3Induced.lean`, `VOA/Modules/ZhuVermaAnArchDLM3Admissible.lean` and `VOA/Modules/ZhuVermaAnArchDLM3Level.lean`.

```

From the mathematics to the Lean statement

`UniversalEnvelopingAlgebra ℂ (VHatCarrier W)` is Mathlib's $\mathcal{U}(\widehat{V})$, and `uι W` its canonical Lie map $\widehat{V} \to \mathcal{U}(\widehat{V})$. `⊗[ℂ]` and `⊗ₜ[ℂ]` are Mathlib's tensor product of vector spaces and its pure tensors. The balancing relations use only generators $g \in P_n$, not all of $\mathcal{U}(P_n)$; since $\mathcal{U}(P_n)$ is generated by P_n, the span is the same, so `IndMod P` is $\mathcal{U}(\widehat{V}) \otimes_{\mathcal{U}(P_n)} U$. `indMk P` is the quotient map, `indBottom P` is $u \mapsto [1 \otimes u]$, and `uenvDeg W d` is the span of products of homogeneous generators of total degree d. The $\widehat{V}$-action on `IndMod P` is left multiplication (`indRho`); it is a

representation of the Lie algebra for free.
Two facts proved without any PBW input. The levels span (`levCover_spanning`); $M_0(U)(d) = 0$ for $d < 0$ and $M_0(U)(0)$ is the image of the bottom map (`levCover_eq_bot_of_neg`, `levCover_zero_eq_range`); and the levels are linearly independent:

```
theorem levCover_iSupIndep (P : ParabolicRep W n U) : iSupIndep (levCover P) := by
```

(file `VOA/Modules/ZhuVermaAnArchDLM3PBWIndependence.lean`). **Proof on paper.** Let $\epsilon = \omega(1) \in \widehat{V}$ (the class of $\omega \otimes t$, i.e. the mode L_0; the library's `degreeElement`). By (13.2), $[\epsilon, a(m)] = (\mathrm{wt}\, a - m - 1)\, a(m)$ for homogeneous a: the adjoint action of ϵ is multiplication by the degree. Extend $\mathrm{ad}\,\epsilon$ to a derivation ∂ of $\mathcal{U}(\widehat{V})$; then $\partial y = d\, y$ for y of degree d. Define E on $\mathcal{U}(\widehat{V}) \otimes U$ by $E(y \otimes u) = \partial y \otimes u$. It preserves the balancing relations: $\partial(yg) \otimes u - \partial y \otimes gu = (\partial y\, g \otimes u - \partial y \otimes gu) + y[\epsilon, g] \otimes u$, and $[\epsilon, g]$ is a multiple of g that is 0 if $\deg g = 0$ and deep if g is deep, so it acts on U by zero and $y[\epsilon, g] \otimes u$ is itself a balancing relation. Hence E descends to $M_n(U)$, and level k lies in the eigenspace of eigenvalue $k - n$. Eigenspaces for distinct eigenvalues are independent. □

Physical meaning

$M_0(U)$ is the space of all formal descendants $a^1_{(m_1)} \cdots a^k_{(m_k)}|u\rangle$ of a primary multiplet, modulo only the commutation relations of the mode algebra and "lowering modes annihilate primaries". The level is the energy above the primaries. Independence of levels is the statement that energy is a good quantum number: it is measured by an operator.

13.3.4 The datum `BottomProjection` and its equivalents

Definition 13.13 (Bottom projection; DLM's PBW step)**.** A *bottom projection* for a level-n parabolic representation P on U is a linear map $\pi : M_n(U) \to U$ with $\pi([1 \otimes u]) = u$ for all u, and $\pi = 0$ on every level $M_n(U)(k)$, $k \neq n$. The *PBW freeness* of P is the conjunction of: the bottom map is injective, and the levels are independent.

Files `VOA/Modules/ZhuVermaAnArchDLM3Survival.lean` and `VOA/Modules/ZhuVermaAnArchDLM3PBWSplit.lean`.

```

The relations between them (files `VOA/Modules/ZhuVermaAnArchDLM3PBWIndependence.lean` and `VOA/Modules/ZhuVermaAnArchDLM3BottomProjectionBoundary.lean`):

```
theorem pbwFreeness_iff_bottom_injective (P : ParabolicRep W n U) :
    PBWFreeness P ↔ Function.Injective (indBottom P) :=
noncomputable def bottomProjectionOfInjective (Q : ParabolicRep W 0 U)
```

```
    (hinj : Function.Injective (indBottom Q)) : BottomProjection Q :=
theorem nonempty_bottomProjection_iff_bottom_injective (Q : ParabolicRep W 0 U) :
    Nonempty (BottomProjection Q) ↔ Function.Injective (indBottom Q) := by
```

From the mathematics to the Lean statement

`BottomProjection` is a structure carrying *data* (the map `proj`) and two equations. `{k}` are strict-implicit binders (inferred); `levCover P k` is $M_n(U)(k)$. Its use in the proof is Dong–Li–Mason's: to extend a linear functional u' on U to $M_n(U)$ by zero off level n, which defines the radical J below.

What it really asserts. By `nonempty_bottomProjection_iff_bottom_injective`, at level 0 a bottom projection exists *iff* the bottom map $u \mapsto [1 \otimes u]$ is injective. (Given injectivity, the projection is constructed from the independence of levels, which is a theorem.) Likewise `PBWFreeness P` is equivalent to injectivity. So the datum `Pr` in the headline is precisely:

> *in $\mathcal{U}(\widehat{V}) \otimes_{\mathcal{U}(P_0)} A(V)$, the canonical copy $1 \otimes A(V)$ of the regular $A(V)$-module is not collapsed.*

Note `Pr` is required *only for the regular module*, not for every U; the proof transports what it needs to arbitrary U through the Dong–Jiang construction (Section 13.5).

Is it a genuine open input? No longer. `voaPBWBottomProjection` produces `BottomProjection (parabolicRepOfAMod W (regularAMod W))` for every V from the theorem `VOA.pbw` (formerly a project axiom, now a theorem). At the snapshot it was open in Lean (supplied only by the then-axiom). The library also proves a bottom projection for a *different* $A(V)$-module, the weight-zero space of the adjoint module (`adjointBottomProjection`, below), which shows the structure is satisfiable but does not discharge `Pr`. Mathematically it is *true for every V*: it is a special case of the Poincaré–Birkhoff–Witt theorem (next theorem), and the library supplies it from `VOA.pbw`.

How could it be wrong? Two traps were checked. (a) A bottom projection could be vacuous if the levels were not independent (then "$\pi = 0$ on other levels" might force $\pi = 0$); independence is a theorem. (b) Requiring it for *all* U would be harmless too (PBW is true for all U), but the headline asks for less.

What the machine verified

`BottomProjection`, `PBWFreeness`: definitions. `levCover_iSupIndep`, `pbwFreeness_iff_bottom_injective`, `bottomProjectionOfInjective`, `nonempty_bottomProjection_iff_bottom_injective`: proved, unconditional, standard three axioms.

Physical meaning

The datum says that in the space of formal descendants of the universal primary multiplet, the primaries themselves are not accidentally identified with zero by the commutation relations. Physicists take this for granted ("the Verma module has a basis of ordered monomials"); mathematically it is the PBW theorem.

13.3.5 How `VOA.pbw` supplies the datum

Theorem 13.14 (Bottom injectivity from PBW). *For every Lie algebra $\mathfrak{g}$ over $\mathbb{C}$, every Lie subalgebra $\mathfrak{p}$ and every $\mathfrak{p}$-module U, the map $U \to \mathcal{U}(\mathfrak{g}) \otimes_{\mathcal{U}(\mathfrak{p})} U$, $u \mapsto 1 \otimes u$, is injective. Consequently every parabolic representation of $\widehat{V}$ has injective bottom map, is PBW-free, and (at level 0) has a bottom projection.*

Files `VOA/Foundations/AffineLie.lean` (the theorem `VOA.pbw`; Chapter 3, Section 3.10) and `VOA/Modules/ZhuVermaAnArchDLM3PBWAxiom.lean`.

```

noncomputable def voaPBWBottomProjection (Q : ParabolicRep W 0 U) : BottomProjection Q :=
  bottomProjectionOfInjective Q (voaPBWBottomInjective Q)
```

From the mathematics to the Lean statement

The PBW principle. `PBWPrinciple` has two fields (Chapter 3 identifies both with classical PBW consequences and presents their Lean proof). Only `inducedBottom` is used here: for any Lie algebra $\mathfrak{g}$, Lie subalgebra $\mathfrak{p}$ and Lie representation `rho : p →ₗ[ℂ] Module.End ℂ U`, the bottom map into `PBWInduction.Induced p rho` $= \mathcal{U}(\mathfrak{g}) \otimes_{\mathbb{C}} U/\operatorname{span}\{y\,x \otimes u - y \otimes \rho(x)u\}$ is injective. The library proves that, for `g = VHatCarrier W`, `p = Pn W n`, `rho = P.act`, this generic quotient and bottom map are *definitionally* the ones of Definition 13.12 (`pbwInduction_balancing_eq`, `pbwInduction_bottom_eq`, both `rfl`). So `voaPBWBottomInjective` is a literal specialization; no translation is hidden.
Universe. `VOA.PBWPrinciple.{u}` instantiates the theorem at the universe of V; the statement quantifies over Lie algebras in every universe, which is harmless.

Proof on paper (of the mathematics behind `VOA.pbw`). By PBW, if $\{x_i\}_{i\in I}$ is an ordered basis of $\mathfrak{g}$ extending a basis of $\mathfrak{p}$ (with the elements of the complement placed first), the ordered monomials form a basis of $\mathcal{U}(\mathfrak{g})$, and $\mathcal{U}(\mathfrak{g})$ is a free right $\mathcal{U}(\mathfrak{p})$-module on the ordered monomials in the complement. Hence $\mathcal{U}(\mathfrak{g}) \otimes_{\mathcal{U}(\mathfrak{p})} U \cong \bigoplus_{\text{monomials } m} m \otimes U$, and the summand of the empty monomial is $1 \otimes U \cong U$. For $\mathfrak{g} = \widehat{V}$, which is infinite-dimensional, one needs PBW for arbitrary Lie algebras over a field, which is classical (the symmetrization map is an isomorphism of coalgebras in characteristic 0; or Bergman's diamond lemma). Mathlib does not contain PBW; the library proves the needed relative form itself (`PBWTheorem.bottom_injective`, Chapter 3, Theorem 3.17), by Humphreys' relative construction rather than via the full PBW basis. □

What the machine verified

`voaPBWBottomInjective`, `voaPBWFreeness`, `voaPBWBottomProjection`: `#print axioms` = `[propext, Classical.choice, Quot.sound]` (re-probed at a later commit, after `VOA.pbw` became a theorem, not re-run for this edition; at the snapshot the list also contained `pbw`). Unconditional; they use the theorem `VOA.pbw` (field `inducedBottom`). Every other declaration of this chapter is free of `pbw`.

Physical meaning

PBW is the algebraic statement that a Fock-space-like basis exists: ordering creation operators to the left and annihilation operators to the right, every state of the induced module is uniquely a combination of ordered products of creation operators acting on the primaries. It is used tacitly whenever a physicist counts descendants (e.g. the character $q^h/\prod(1-q^n)$ of a Virasoro Verma module).

Theorem 13.15 (A satisfiability check: the adjoint bottom). *For the $A(V)$-module V_0 (the weight-zero space of the adjoint module, $=\mathbb{C}\mathbf{1}$), the bottom map is injective, without PBW, and hence a bottom projection exists.*

File `VOA/Modules/ZhuVermaAnArchDLM3AdjointBottom.lean`.

```
noncomputable abbrev adjointBottomAMod (W : VertexOperatorAlgebra 𝒱) : AMod W :=
  lowestAMod (adjointModule_isLowestWeight W)
noncomputable def adjointBottomProjection (W : VertexOperatorAlgebra 𝒱) :
    BottomProjection (parabolicRepOfAMod W (adjointBottomAMod W)) :=
  bottomProjectionOfInjective _ (adjoint_indBottom_injective W)
```

From the mathematics to the Lean statement

The proof uses the general principle `indBottom_injective_of_equivariant_embedding`: if U embeds P_0-equivariantly into *some* $\widehat{V}$-representation M, then the universal property of induction gives a left inverse of the bottom map. For $U = V_0 \subseteq V$ one takes $M = V$ with the action $a(m) \mapsto a_{(m)}$. This instance is *not* the regular module, as the file states; it is evidence that `BottomProjection` is satisfiable, nothing more.

Proof on paper. Given an equivariant injective $\varphi : U \to M$, the universal property of $M_0(U)$ gives a $\widehat{V}$-map $\Phi : M_0(U) \to M$ with $\Phi([1 \otimes u]) = \varphi(u)$; if $[1 \otimes u] = 0$ then $\varphi(u) = 0$ and $u = 0$. □

What the machine verified

`adjointBottomProjection`: proved, unconditional, standard three axioms, no `pbw`.

Physical meaning

The vacuum is a primary of every chiral algebra, and the vacuum sector exists; therefore the formal descendants of the vacuum cannot collapse the vacuum itself. The same argument would prove `Pr` if one already had a sector whose primaries contain a faithful copy of the regular module — but constructing such a sector is exactly what Zhu's theorem is for, so the argument would be circular.

Trap / dead end

Stale docstrings about the trust boundary (documentation only). Several module docstrings on the critical path still say that the project axiom does *not* cover the PBW step and "must not be cited here", or that the independence of levels is an unproved PBW input: `ZhuVermaAnArchDLM3Survival.lean` ("the project's sanctioned `pbw` axiom is about affine Lie algebras, not $\mathcal{U}(\widehat{V})$ over $\mathcal{U}(P_0)$; it must not be cited here"), and `ZhuVermaAnArchDLM3Zero.lean` ("independence of the levels is DLM3's PBW invocation …which the sanctioned `pbw` axiom does **not** cover"). Both are superseded: `PBWPrinciple.inducedBottom` covers exactly this step (`voaPBWBottomInjective`), and level independence is the theorem `levCover_iSupIndep`. The mathematics of the files is unaffected. (Both docstrings, and the word "axiom" in them, are further outdated since `VOA.pbw` became a theorem.)

13.4 The tower: circle products, O_n, A_n and the Dong–Jiang spaces $A_{n,m}$

All products in this section are residues of the form

$$\operatorname{Res}_z Y(a,z)b\,\frac{(1+z)^{\operatorname{wt}a+s}}{z^p}=\sum_{i\ge 0}\binom{\operatorname{wt}a+s}{i}a_{(i-p)}b\qquad(a\text{ homogeneous}),\tag{13.3}$$

for integers s and p, extended bilinearly to inhomogeneous a through the grading $V=\bigoplus_k V_k$. The sum is finite when $\operatorname{wt}a+s\ge 0$ (only $i\le \operatorname{wt}a+s$ contribute). The library has one generic implementation, `resHom W s p a b`, and expresses every product of the tower through it.

13.4.1 The generic residue and the circle products

Definition 13.16 (Generic residue; n-th circle product; O_n and A_n of the library)**.** `resHom W s p a b` is (13.3). The n-th circle product is $a\circ_n b=\operatorname{Res}_z Y(a,z)b\,(1+z)^{\operatorname{wt}a+n}/z^{2n+2}$, i.e. (13.3) with $s=n$, $p=2n+2$. The library's $O_n^{\mathrm{lib}}(V)$ is the span of all $a\circ_n b$ and $A_n^{\mathrm{lib}}(V)=V/O_n^{\mathrm{lib}}(V)$ (Definition 12.27 of Chapter 12).

Files `VOA/Modules/ZhuVermaAnBimodule.lean` and `VOA/Modules/ZhuVermaAn.lean`.

  Submodule.span ℂ {x | ∃ a b : 𝒱, x = circ W n a b}
abbrev An (W : VertexOperatorAlgebra 𝒱) (n : ℕ) : Type u := 𝒱 ⧸ On W n
```

From the mathematics to the Lean statement

`cbz m i` is $\binom{m}{i}$ for $m,i\in\mathbb{Z}$ (zero for $i<0$), `W.smul a j b` is $a_{(j)}b$. `resFamily W s p b k` is the formula on the weight-k slice V_k (the sum runs over $i=0,\dots,\max(k+s,0)$, beyond which the binomial vanishes when $k+s\ge 0$; when $k+s<0$ the range is just $i=0$, `(k + s).toNat = 0`). `DirectSum.decompose W.grading a` splits a into homogeneous components and `DFinsupp.lsum` sums the slice maps over them: this is "extend bilinearly over the grading". The truncation of the sum at $\max(k+s,0)$ when $k+s<0$ is a convention that never matters below, because every use has $s\ge 0$ and $k\ge 0$ (library VOAs have $V_k=0$ for $k<0$). `circ` is `resHom W n (2n+2)` written out separately (`circ_eq_resHom`).

Physical meaning

A residue $\operatorname{Res}_z Y(a,z)b\,(1+z)^{\operatorname{wt}a+s}/z^p$ is a weighted combination of OPE coefficients $a_{(j)}b$, i.e. of the fields appearing in the operator product $a(z)b(0)$. Such combinations arise when one computes how a mode of a acts on a state produced by b *at a fixed energy*: on the cylinder

$z = e^w - 1$, the factor $(1+z)^{\mathrm{wt}\,a}$ is the conformal transformation from the plane, and z^{-p} selects how many levels the mode moves. The circle products are the combinations that are guaranteed to act by zero on the lowest $n+1$ levels of every sector.

Theorem 13.17 ($O_0 = O$). *$O_0^{\mathrm{lib}}(V) = O(V)$; hence $A_0^{\mathrm{lib}}(V) = A(V)$.*

File `VOA/Modules/ZhuVermaAnDescent15.lean`.

```
theorem On_zero_eq_O (W : VertexOperatorAlgebra 𝒱) : On W 0 = O W := by
```

Proof on paper. Both are spans; $a \circ_0 b$ is exactly Zhu's generator $\mathrm{Res}_z\, Y(a,z)b(1+z)^{\mathrm{wt}\,a}/z^2$ of $O(V)$ (Chapter 12), so the generating sets agree. □

What the machine verified

Proved, unconditional; standard three axioms.

Physical meaning

$O(V)$ is the space of fields whose zero modes vanish on every primary; at level n, $O_n(V)$ is the space of fields whose zero modes vanish on the first n excited levels of every sector.

13.4.2 The corrected $O_n(V)$ and the product $*_n$

Definition 13.18 (Dong–Li–Mason's $O_n(V)$ and $*_n$). $O_n(V) = \mathrm{span}\{a \circ_n b\} + \mathrm{span}\{(L_{-1}+L_0)a\}$ and $A_n(V) = V/O_n(V)$. For homogeneous a,

$$a *_n b = \sum_{j=0}^{n} (-1)^j \binom{n+j}{n} \mathrm{Res}_z\, Y(a,z)b\, \frac{(1+z)^{\mathrm{wt}\,a+n}}{z^{n+j+1}}.$$

From the mathematics to the Lean statement

`⊔` is the sum of subspaces. `OnFull W n` is exactly Dong–Li–Mason's (2.1); `leftProd W n a b` is their $a *_n b$ with the external coefficients $(-1)^j\binom{j+n}{n}$ (`cbz ((j : ℤ) + n) (n : ℤ)`) and pole order $n+j+1$; at $n=0$ it is Zhu's product (`leftProd_zero : leftProd W 0 a b = zhuMul`

`W a b`). `AnIdeal W n` says $O_n(V)$ is a two-sided ideal for $*_n$, and `anIdeal_holds` proves it for every n (Dong–Li–Mason, Lemma 2.2). Associativity of $*_n$ modulo $O_n(V)$ for $n \geq 1$ is *not* proved (the library reduces it to a named target `AssocHom W n` and proves only $n = 0$); it is not needed for the headline.

Trap / dead end

Status of the O_n defect recorded in Chapter 12 (entry 49 of the project's defect list). The circle-only `On W n` omits Dong–Li–Mason's generators $(L_{-1}+L_0)a$ for $n \geq 1$. This chapter adds two facts. (i) The library also defines the correct ideal, `OnFull` $=$ `On` $\sqcup$ `OnL`, and it is `OnFull` (through the Dong–Jiang ideals below) that the construction of $M(U)$ uses; `On` enters the headline's proof only at $n = 0$, where `OnFull_zero_eq_On_zero` and `On_zero_eq_O` show all versions agree with $O(V)$. So the defect does not affect `zhuBijective`. (ii) The docstring of `OnFull` asserts that for $n \geq 1$ it is "strictly larger than the circle-only `On W n`"; no such strictness is proved in the library, and we do not know whether it holds for all V (documentation only, unverified claim).

What the machine verified

`anIdeal_holds`: proved, unconditional, standard three axioms. Associativity of $A_n(V)$, $n \geq 1$: open (named target), off the critical path.

Physical meaning

$A_n(V)$ is the algebra of "generalized zero modes" $o_{n,n}(a)$ acting on level n of every sector; $*_n$ is their composition law. That $O_n(V)$ is an ideal is the consistency of this composition with the null relations.

13.4.3 The Dong–Jiang bimodules $A_{n,m}(V)$

The induced module needs the maps from level m to level n, not only the algebras acting on one level. Dong and Jiang define, for homogeneous u,

$$u *^n_{m,p} v = \sum_{i=0}^{p} (-1)^i \binom{m+n-p+i}{i} \operatorname{Res}_z Y(u,z)v \, \frac{(1+z)^{\mathrm{wt}\,u+m}}{z^{m+n-p+i+1}}, \tag{13.4}$$

$$u \circ^n_m v = \operatorname{Res}_z Y(u,z)v \, \frac{(1+z)^{\mathrm{wt}\,u+m}}{z^{n+m+2}}, \qquad \text{grading generator } L_{-1}u + (L_0 + m - n)u.$$

The special case $u *^n_m v := u *^n_{m,m} v$ is the right $A_m(V)$-action and $u \bar{*}^n_m v := u *^n_{m,n} v$ the left $A_n(V)$-action; at $m = n$ both are $*_n$.

Definition 13.19 (Dong–Jiang ideals and spaces). $O'_{n,m}(V)$ is the span of all $u \circ^n_m v$ and all $L_{-1}u + (L_0 + m - n)u$. $O''_{n,m}(V)$ is the span of the *associator defects*

$$u *^n_{m,p_3} \big((a *^{p_3}_{p_1,p_2} b) *^{p_3}_{m,p_1} c - a *^{p_3}_{m,p_2} (b *^{p_2}_{m,p_1} c) \big), \qquad a,b,c,u \in V,\ p_i \in \mathbb{N}.$$

$O'''_{n,m}(V)$ is the span of $(a *^n_{p,p} g) *^n_{m,p} v$ with $g \in O'_{p,p}(V)$, $p \in \mathbb{N}$. The full ideal is $O_{n,m}(V) = O'_{n,m} + O''_{n,m} + O'''_{n,m}$ and $A_{n,m}(V) = V/O_{n,m}(V)$.

From the mathematics to the Lean statement

Line-by-line. `anmGen W n m p u v` is (13.4): the range `Finset.range (p + 1)` is $i = 0, \dots, p$; the coefficient is $(-1)^i\binom{m+n-p+i}{i}$; the residue has shift $s = m$ and pole $m + n - p + i + 1$. `anmRight W n m` is the special case $p = m$ (the library proves `anmGen_eq_anmRight`). `anmCirc` and `anmLgen` are $u \circ_m^n v$ and the shifted grading generator; note the shift $+(m-n)$, which at $m = n$ gives back $(L_{-1}+L_0)u$. `Onm` is $O'_{n,m}$, `OnmAssoc` is $O''_{n,m}$, `OnmLevel` is $O'''_{n,m}$ (with g ranging over $O'_{p,p}$ = `Onm W p p`), and `OnmFull` is their sum. Note that the indices p_i range over all of $\mathbb{N}$, as in Dong–Jiang: $O''_{n,m}$ and $O'''_{n,m}$ involve *all* levels of the tower at once.

Fidelity to Dong–Jiang. We compared each Lean definition with the formulas of Dong–Jiang (*Math. Z.* 259, §2) as transcribed, with line references to the arXiv text, in the docstring of `ZhuVermaAnArchAnmFull.lean`; they agree term by term. (We did not re-derive Dong–Jiang's formulas themselves.) The library also proves the expected diagonal identity `Onm_diag_eq_OnFull : Onm W n n = OnFull W n` ($O'_{n,n} = O_n$) and the $(0,0)$ anchor `Onm_zero_zero_eq_O : Onm W 0 0 = O W`.

Why the full ideal. Dong and Jiang note that they cannot prove $O_{n,m} = O'_{n,m}$ (their Remark 2.10); $V/O'_{n,m}$ is not known to be a bimodule. The library follows them and works with `OnmFull`; this is the conservative choice (a bigger ideal, a smaller quotient, more relations available).

Physical meaning

The products $*_{m,p}^n$ are the composition laws of transition operators between energy levels; the ideals $O_{n,m}(V)$ are the relations they satisfy in every sector. Writing them down explicitly is the algebraic counterpart of computing all three-point functions $\langle \text{level } n | u(z) | \text{level } m \rangle$ allowed

by the chiral algebra.

Definition 13.20 (The diagonal collapse, Dong–Jiang Proposition 4.6). `DJAnnEqAn W m` is the statement $O_{m,m}(V) \subseteq O_m(V)$, equivalently (since $O_m \subseteq O_{m,m}$ is proved) $A_{m,m}(V) = A_m(V)$.

File `VOA/Modules/ZhuVermaAnArchDJCarrier.lean`.

```
def DJAnnEqAn (W : VertexOperatorAlgebra 𝒱) (m : ℕ) : Prop :=
  OnmFull W m m ≤ OnFull W m
```

From the mathematics to the Lean statement

The reverse inclusion `onFull_le_OnmFull_diag` is a theorem, so `DJAnnEqAn W m` says exactly that the associator and level-mixing summands at (m, m) add nothing to $O_m(V)$. Only $m = 0$ is used: `DJAnnEqAn W 0` is $O_{0,0}(V) \subseteq O(V)$ (using `OnFull_zero_eq_On_zero` and `On_zero_eq_O`). It is derived from `Pr` in Theorem 13.25.

What the machine verified

All definitions above; no hypotheses. `#print axioms VOA.OnmFull` = standard three.

Physical meaning

$A_{n,m}(V)$ is the space of "transition operators": for a field u, the mode that maps level m of a sector to level n is $o_{n,m}(u) = u_{(\mathrm{wt}\,u-1+m-n)}$, and $O_{n,m}(V)$ is the space of fields all of whose level-m-to-level-n modes vanish in every sector. The three summands are, respectively: the analogue of Zhu's relation; the requirement that composing transition operators through intermediate levels is associative; and the requirement that the relations of intermediate levels are respected. $A_{n,0}(V) \otimes_{A(V)} U$ is then "the span of all level-n states $o_{n,0}(u)|w\rangle$ obtainable from the primary multiplet U".

13.5 The induced module $M(U)$ and the gate $A_{0,0}(V) = A(V)$

13.5.1 The carrier

Definition 13.21 (Level-m modules; the Dong–Jiang carrier). An $A_m(V)$-module (`AmMod W m`) is a vector space U with a linear $\rho : A_m(V) \to \mathrm{End}\, U$ such that $\rho[\mathbf{1}] = 1$ and $\rho[u *_m v] = \rho[u]\rho[v]$. For such U and $n \in \mathbb{N}$ put

$$M(U)(n) = A_{n,m}(V) \otimes_{A_m(V)} U := \big(A_{n,m}(V) \otimes_{\mathbb{C}} U\big) \Big/ \mathrm{span}\{[x *_m^n a] \otimes w - [x] \otimes \rho[a]w\},$$
$$M(U) = \bigoplus_{n \geq 0} M(U)(n).$$

Every $A(V)$-module is an $A_0(V)$-module via $A_0(V) = A(V)$ (`AMod.toAmModZero`).

From the mathematics to the Lean statement

The balanced tensor product. `AmMod` mirrors `AMod`, with `AnFull W m` $= A_m(V)$ and `leftProd W m` $= *_m$. Since associativity of $A_m(V)$ is not available for $m \geq 1$, the library cannot form Mathlib's `TensorProduct (AnFull W m)`; instead `DJPiece W U n` is the $\mathbb{C}$-tensor product divided by the span of the *representative-level* balancing relations $[x *_m^n a] \otimes w - [x] \otimes \rho[a]w$. This is the universal space in which Dong–Jiang's balancing holds; when $A_m(V)$ is a ring acting on the right of $A_{n,m}(V)$ it coincides with $A_{n,m}(V) \otimes_{A_m(V)} U$ (the relations generate the same subspace). On the critical path only $m = 0$ occurs, where $A_0(V) = A(V)$ *is* a ring and the right action of $A(V)$ on $A_{n,0}(V)$ descends unconditionally (`djRightSlot_zero`); so there the construction is literally $A_{n,0}(V) \otimes_{A(V)} U$.

The direct sum. `⊕ n : ℕ, DJPiece W U n` is Mathlib's external direct sum (finitely supported families); `DJCarrier.deg W U n` is the image of the n-th summand. It is an internal direct-sum decomposition (`DJCarrier.isInternal_deg`).

`toAmModZero`. Transports the $A(V)$-action along `anFullZeroEquiv : AnFull W 0 ≃ A W`; its multiplicativity is `leftProd_zero` ($*_0 = *$) and Zhu's ρ_{mul}. Nothing is lost.

Physical meaning

$M(U)(n)$ is the space of level-n descendants of the primary multiplet U, written as "(transition operator from level 0 to level n) applied to (a primary)". The balancing relation says that applying a zero mode to the primary first, or absorbing it into the transition operator, gives the same state.

13.5.2 The action of V

Definition 13.22 (Dong–Jiang's modes). For homogeneous u and $p \in \mathbb{Z}$, the mode $u_{(p)}$ maps $M(U)(n)$ to $M(U)(N)$, $N = \operatorname{wt} u - p - 1 + n$, by

$$u_{(p)}\big([v] \otimes w\big) = [u *^{N}_{m,n} v] \otimes w \quad (N \geq 0), \qquad u_{(p)} = 0 \text{ on } M(U)(n) \text{ if } N < 0,$$

and is extended linearly over the grading of u. For $m = 0$ this is `djModeZero W U p u`.

File `VOA/Modules/ZhuVermaAnArchDJAction.lean` (and `VOA/Modules/ZhuVermaAnArchMUFullMode.lean` for the target level).

From the mathematics to the Lean statement

`DJLeftSlot W N m n` is Dong–Jiang's Lemma 2.8 (left inclusion): $V *^{N}_{m,n} O_{n,m}(V) \subseteq O_{N,m}(V)$, which makes $[v] \mapsto [u *^{N}_{m,n} v]$ well defined $A_{n,m}(V) \to A_{N,m}(V)$ (`AnmFull.leftGen`). At base level $m = 0$ it is *proved* for all N, n (`djActionDescent_zero`); in general it is reduced to a named residual. `djCoverAct` applies this map on the first tensor factor; `djPieceAct` descends it to the balanced piece (the balancing relations are respected, `djBalancing_le_ker_coverAct`). `muTargetLevel k p n` is $k - p - 1 + n$; `djLevelIncl` is the case split of Definition 13.22 for $u \in V_k$; `djModeFamily`/`djMode` assemble the components over levels (by the universal property of $\oplus$) and over the grading of u. `djModeZero` is the hypothesis-free $m = 0$ instance. So `djModeZero W U p u` is the operator $u_{(p)}$ on $M(U)$; in particular `djModeZero W U 1 W.conformalVector` is $L_0 = \omega_{(1)}$.

Physical meaning

The mode $u_{(p)}$ of a field of weight $\operatorname{wt} u$ changes the energy by $\operatorname{wt} u - p - 1$; acting on a level-$n$ descendant it produces a level-$(\operatorname{wt} u - p - 1 + n)$ descendant, computed by composing transition operators. If the target level would be negative the state is annihilated — the statement that there are no states below the primaries.

Theorem 13.23 ($M(U)$ is a weak module; Dong–Jiang, Theorem 4.10)**.** *For every $A(V)$-module U (more precisely, every $A_0(V)$-module), the modes of Definition 13.22 make $M(U)$ a weak V-module. The decomposition $M(U) = \bigoplus_n M(U)(n)$ is a grading: $u_{(p)}M(U)(n) \subseteq M(U)(\operatorname{wt} u - p - 1 + n)$.*

File `VOA/Modules/ZhuVermaAnArchDJCarrierWeak.lean`.

```
noncomputable def djCarrierWeak (W : VertexOperatorAlgebra 𝒱) (U : AmMod W 0) :
    WeakModule W (DJCarrier W U) :=
  weakModuleOfRep (djRhoZero W U) (djActModeTruncated W U) (djVacuumCreation W U)
    (isModuleJacobi_djRhoZero W U)
```

From the mathematics to the Lean statement

`WeakModule W M` is the library's weak module (Chapter 1): a vertex operator Y_M satisfying truncation, vacuum creation $\mathbf{1}_{(m)} = \delta_{m,-1}$, and the Jacobi (Borcherds) identity. `weakModuleOfRep ρ htr hvac hjac` builds one from a representation ρ of $\widehat{V}$ (`VHatRep W M = VHatCarrier W →ₗ[ℂ] Module.End ℂ M`, with $u_{(p)} = \rho(u(p))$) satisfying truncation (`ActModeTruncated`), vacuum creation and the module Jacobi identity (`IsModuleJacobi`). Here ρ = `djRhoZero W U`, whose modes are `djModeZero`. All three obligations are *theorems* for every U; there is no hypothesis. The library records the action as `djCarrierWeak_act`: the weak-module mode $u_{(p)}$ is `djModeZero W U p u`.

Proof on paper. (i) ρ is a Lie-algebra representation of $\widehat{V}$: the translation relation $(L_{-1}u)_{(p)} = -p\,u_{(p-1)}$ holds because the grading generator $L_{-1}u+(L_0+m-n)u$ lies in $O_{N,m}$, and the commutator formula $[u_{(p)}, v_{(q)}] = \sum_i \binom{p}{i}(u_{(i)}v)_{(p+q-i)}$ is Dong–Jiang's Lemma 4.7, a binomial identity between the products $*^N_{m,n}$ modulo $O_{N,m}$. (ii) Truncation: $u_{(p)}$ lowers the level for p large and is zero once the target level is negative. (iii) Vacuum: $\mathbf{1} *^N_{m,n} v = v$ at $N = n$ and the other modes vanish. (iv) The Jacobi identity of a module follows from the commutator formula plus the *iterate* formula $(u_{(\ell)}v)_{(N)} = \sum_i (-1)^i\binom{\ell}{i}\big(u_{(\ell-i)}v_{(N+i)} - (-1)^\ell v_{(\ell+N-i)}u_{(i)}\big)$; for $\ell \geq 0$ it is a consequence of the commutator formula, and for $\ell < 0$ it is Dong–Jiang's Lemma 4.9, which holds on $M(U)$ because the associator defects (the summand O'') have been divided out. □

What the machine verified

`djCarrierWeak`: definition with all obligations proved, unconditional; `#print axioms` = standard three.

Physical meaning

The descendants of a primary multiplet, with the fields acting by the rules forced by the OPE, form a consistent representation of the full chiral algebra (including normal-ordered products) — *provided* the associativity of the OPE has been imposed, which is what quotienting by O'' does. This is the chiral-algebra version of "Verma modules are modules".

13.5.3 Graded lowest-weight weak modules

Definition 13.24 (Graded lowest-weight weak module)**.** A *graded lowest-weight weak module* of lowest weight $h \in \mathbb{C}$ is a weak module M with a decomposition $M = \bigoplus_{\alpha\in\mathbb{C}} M_\alpha$ such that $L_0 = \alpha$

on M_α, the real parts of the occurring α are bounded below, every occurring α lies in $h + \mathbb{N}$, and $M_h \neq 0$. It is *irreducible* if $M \neq 0$ and its only mode-stable subspaces are 0 and M.

From the mathematics to the Lean statement

`mode (YM W.conformalVector) 1 x` is $\omega_{(1)}x = L_0 x$ (recall `mode f n` is the coefficient f_{-n-1}, so `mode (YM u) n` is $u_{(n)}$). `GradedLWWeakModule` is *exactly* `OrdVModule` plus lowest weight `h` with all weights in $h + \mathbb{N}$ and $M_h \neq 0$, *minus* the requirement that weight spaces be finite-dimensional. The reason for the omission is substantive: the gate below needs $M(U)$ for the regular module $U = A(V)$, whose bottom is infinite-dimensional in general. `FiniteWeights` restores finiteness, and `toOrdVModule`/`toLWModule` convert back; these conversions change nothing else (every field is copied), so a `GradedLWWeakModule` with `FiniteWeights` is literally an `LWModule`. `IsIrreducible` is the same notion as `OrdVModule.IsIrreducible`, and `toLWModule_isIrreducibleLW` transports it (its proof is the identity).

Physical meaning

A graded lowest-weight weak module is a sector whose energy levels may be infinitely degenerate — harmless for building sectors, but not a "physical" sector with a well-defined character. The finiteness of L_0-eigenspaces is what makes the partition function $\operatorname{tr} q^{L_0 - c/24}$ meaningful.

13.5.4 The gate: $O_{0,0}(V) = O(V)$ from `Pr`

Theorem 13.25 (Survival of the bottom; the gate)**.** *Let* `Pr` *be a bottom projection for the parabolic representation of the regular $A(V)$-module. Then:*

1. *(Dong–Li–Mason, Theorem 4.1 at $n = 0$.) For every $A(V)$-module U with a bottom projection, U embeds into the weak module $\overline{M}_0(U) = M_0(U)/(\text{defects})$ as its bottom.*
2. *(Dong–Jiang, Proposition 4.6 at $(0,0)$.) $O_{0,0}(V) = O(V)$; hence $A_{0,0}(V) = A(V)$, and for every $A(V)$-module U the bottom level of $M(U)$ is $M(U)(0) \cong U$.*

Files `VOA/Modules/ZhuVermaAnArchDLM3Survive.lean` and `VOA/Modules/ZhuVermaAnArchDLM3Induced.lean`.

From the mathematics to the Lean statement

`IndBar`. `VHatRep.defectSubmodule (indRho P)` is the smallest $\widehat{V}$-stable subspace of $M_0(U)$ containing every *iterate defect* $(u_{(\ell)}v)_{(N)}x - \sum_i (-1)^i \binom{\ell}{i}\big(u_{(\ell-i)}v_{(N+i)}x - (-1)^\ell v_{(\ell+N-i)}u_{(i)}x\big)$, i.e. the failure of the module associativity law. The quotient is a weak V-module (`indBarWeakModule`, unconditional). `indBarBottom` is $u \mapsto$ class of $[1 \otimes u]$. The library's quotient imposes the defects for *all* vectors, which is a priori more than Dong–Li–Mason's (they impose them on the generating space); this only makes the survival statement (1) *stronger*.
Item (1) is `indBarBottom_injective_of_bottomProjection`: its hypothesis is a bottom projection *for that U*; we use it for U the regular module, which is what `Pr` is.
Item (2). `gate_of_pbwDatum` is literally $O_{0,0}(V) = O(V)$, `djAnnEqAn_zero_of_pbwDatum` is Definition 13.20 at $m = 0$, and `djCarrierDegZeroEquivOfPbwDatum Pr V` is a linear isomorphism $M(V)(0) \cong V$ for every $A_0(V)$-module V (here the bound variable `V` is the module, not the VOA). It is $A(V)$-equivariant (`djCarrierWeak_bottom_equiv_rho`). All three take `Pr` as the only hypothesis.

Proof on paper. *Step 1 (survival).* Let U have a bottom projection $\pi : M_0(U) \to U$. Following Dong–Li–Mason, define the radical $J = \{x \in M_0(U) : \pi(y \cdot x) = 0 \text{ for all } y \in \mathcal{U}(\widehat{V})\}$. It is $\widehat{V}$-stable by construction, and $J \cap (1 \otimes U) = 0$: if $[1 \otimes u] \in J$ then $u = \pi([1 \otimes u]) = 0$. The heart of the matter is that every iterate defect lies in J (`defectPairsToZero_of_bottomProjection`); then the defect submodule is contained in J, so it meets the bottom trivially, which is (1). To show that a defect δ lies in J one must show $\pi(y\delta) = 0$ for all y. Since π kills all levels except 0, only the level-0 component matters. Dong–Li–Mason's Proposition 4.3 shows that for $x = [1 \otimes u]$ the level-zero part of the defect is computed by Zhu's relation in $A(V)$ and vanishes; their Propositions 4.6–4.7 propagate this from the bottom to all of $M_0(U)$, using the commutator formula to move modes past the defect (the library proves the needed "mode-shift" identity for every truncated representation, `defectModeShift_of_truncated`). *Step 2 (annihilation, Dong–Jiang Lemma 4.1 and Proposition 4.5).* In any weak module with a non-negative level structure, the zero mode $o(x)$ of $x \in O_{0,0}(V)$ kills

the bottom level: for $x \in O'_{0,0}$ this is Zhu's argument; for the associator and level-mixing summands it is Dong–Jiang's composition law $o_{n,m}(a *^n_{m,p} b) = o_{n,p}(a)\, o_{p,m}(b)$ on level m (proved in the library as `djCompositionLev_holds`). *Step 3 (the regular module).* Apply Step 1 to the regular module $U = A(V)$: $A(V)$ embeds as the bottom of the weak module $\overline{M}_0(A(V))$, with $o(x)$ acting on the bottom as left multiplication by $[x]$. For $x \in O_{0,0}(V)$, Step 2 gives $0 = o(x)[\mathbf{1}] = [x * \mathbf{1}] = [x]$, i.e. $x \in O(V)$. The reverse inclusion is $O(V) = O'_{0,0}(V) \subseteq O_{0,0}(V)$. *Step 4.* With $A_{0,0}(V) = A(V)$, the balanced tensor $A_{0,0}(V) \otimes_{A(V)} U = A(V) \otimes_{A(V)} U \cong U$. □

What the machine verified

`indBarBottom_injective_of_bottomProjection`, `gate_of_pbwDatum`, `djAnnEqAn_zero_of_pbwDatum`, `djCarrierDegZeroEquivOfPbwDatum`: proved, *conditional on* the explicit `Pr`; `#print axioms` = standard three (the explicit hypothesis is not reported by `#print axioms`). Instantiated with `voaPBWBottomProjection` (built from the theorem `VOA.pbw`) they hold for every V; the `Pr` hypothesis is therefore always dischargeable.

Physical meaning

The gate is the statement "the primaries of the universal Verma-type module are exactly the primary multiplet we started with". Its proof is a beautiful piece of reasoning a physicist would recognize: to show that a relation among fields kills all primaries, exhibit one sector in which the primaries form the *regular representation* of the zero-mode algebra — the most faithful possible — and test the relation there. The PBW datum guarantees that this universal sector does not collapse.

Definition 13.26 ($M(U)$ as a graded lowest-weight weak module)**.** Let U be a nonzero $A(V)$-module and $h \in \mathbb{C}$ such that L_0 acts on $M(U)(n)$ by $h + n$ for all n. Then $M(U)$, with $M(U)_{h+n} = M(U)(n)$ and $M(U)_\alpha = 0$ for $\alpha \notin h + \mathbb{N}$, is a graded lowest-weight weak module of lowest weight h (the bottom is nonzero by the gate).

File `VOA/Modules/ZhuVermaAnArchDJCarrierWeak.lean`.

    GradedLWWeakModule W (DJCarrier W U) h :=
  djGradedLW W U h hL0 (djCarrier_deg_zero_ne_bot Pr U hU)
```

From the mathematics to the Lean statement

`⨆ (n : ℕ) (_ : h + n = α), DJCarrier.deg W U n` is the sum of the levels n with $h+n = \alpha$: the level-n piece is placed at weight $h + n$. The hypotheses are `Pr` (to know the bottom is U, hence nonzero), `hU : Nontrivial U.carrier` ($U \neq 0$), and `hL0`: $L_0 = h + n$ on level n. The last is a genuine condition on U: it holds iff $[\omega]$ acts on U by the scalar h (for a nonzero module); for the bottom $\Omega(P)$ of a lowest-weight module P it is a theorem (`pHL0`, Section 13.6).

What the machine verified

Definition; obligations proved given `Pr`, `hU`, `hL0`; standard three axioms.

Physical meaning

For $M(U)$ to be graded by energy, all primaries must have the same conformal weight h, i.e. L_0 must be a scalar on the multiplet. Then level n has energy $h+n$.

13.6 The irreducible quotient $L(U)$ and the uniqueness argument

13.6.1 The maximal bottom-trivial submodule

Definition 13.27 (J and $L = M/J$). Let M be a graded lowest-weight weak module of lowest weight h. A submodule Q (mode-stable subspace) is *graded* if $Q = \bigoplus_\alpha (Q \cap M_\alpha)$, and *bottom-trivial* if $Q \cap M_h = 0$. Let $J(M)$ be the sum of all graded bottom-trivial submodules and $L(M) = M/J(M)$. For $M = M(U)$ write $J(U)$ and $L(U)$.

  LU (djGradedLW_of_pbwDatum Pr U hU h hL0)
```

From the mathematics to the Lean statement

`IsGradedSub N Q` is the gradedness of Q; `⨆` of submodules is their sum. `maxJ N` is $J(M)$ (the library checks mode-stability of the sum). `maxJ_bottom_disjoint` is the key point: $J(M)$ *itself is bottom-trivial*. `LU N` is the quotient $M/J(M)$ with the induced grading, again a graded lowest-weight weak module of lowest weight h (its bottom is nonzero because J meets M_h trivially). `djJ`, `djLU` are the instances for $M = M(U)$ of Definition 13.26; the `variable` line shows the hypotheses they carry: `Pr`, `hU` ($U \neq 0$), a weight `h`, and `hL0` ($L_0 = h + n$ on level n).
Possible trap. In the literature $J(U)$ is usually defined as the *largest submodule meeting U trivially*, without the word "graded". For an ordinary module the two agree, because every submodule is graded (L_0-eigenspace decomposition). For a graded weak module the library proves the same thing, with no finiteness: every mode-stable subspace is graded (`submodule_isGraded`, by L_0-semisimplicity, using Lagrange interpolation polynomials in L_0). So nothing is lost.

Proof on paper (that J is bottom-trivial). Let $x \in J \cap M_h$. Then $x = q_1 + \cdots + q_r$ with $q_i \in Q_i$, Q_i graded and bottom-trivial. Take the weight-h component of both sides: since $x \in M_h$, the left side is x; since Q_i is graded, the weight-h component of q_i lies in $Q_i \cap M_h = 0$. So $x = 0$. □

What the machine verified

`maxJ`, `LU`: definitions; `maxJ_bottom_disjoint`: proved, unconditional (no finiteness). `djJ`, `djLU`: conditional on the displayed `Pr`, `hU`, `hL0`; standard three axioms.

Physical meaning

$J(U)$ is the space of *null descendants*: states that can never be brought back to the primaries by any field ("orthogonal to everything", in the presence of an inner product). Dividing them out produces the irreducible physical sector $L(U)$; e.g. for the Virasoro algebra at $c = 1/2$, $h = 1/16$, the null vector at level 2 generates part of J.

Theorem 13.28 ($L(U)$ is irreducible; its bottom is U; Dong–Jiang, Theorem 4.13)**.** *If U is a simple $A(V)$-module satisfying the hypotheses of Definition 13.26, then $L(U)$ is irreducible, and its bottom is isomorphic to U as an $A(V)$-module.*

theorem djLU_isBottomOfIrr (hsimple : IsSimpleAMod U) : IsBottomOfIrr U :=
  isBottomOfIrr_of_irrRealization (djIrrRealization Pr U hU hval hL0 hfin hsimple)
```

From the mathematics to the Lean statement

`GeneratedByBottom N`: a submodule containing M_h is everything. `BottomIrreducible N`: a nonzero subspace $S \subseteq M_h$ stable under every mode that keeps it in M_h is all of M_h. `LU_isIrreducible` derives irreducibility of M/J from these two; for $M(U)$ both are discharged (`djGeneratedByBottom`: Dong–Jiang's "$M(U)$ is generated by U"; `djBottomIrreducible`: from simplicity of U, `IsSimpleAmMod U`). `djLU_bottom_U` is the linear isomorphism $L(U)_h \cong U$ (it is $A(V)$-equivariant, `djLU_bottomAModEquiv`). `djLU_isBottomOfIrr` (with the section variables `Pr`, `hU`, `hval`, `hL0` and `hfin : FiniteWeights`) says: under these hypotheses, U lies in the codomain `IrrAMod W` of the headline. It is the existence half of Zhu's theorem for one U, *conditional on finiteness of the weight spaces of $L(U)$*; it is not used by the headline.

Warning on a literature shortcut. The library's docstring notes that Dong–Li–Mason's own Lemma 4.8 deduces irreducibility from complete reducibility, valid only for rational V; the argument here uses neither rationality nor finiteness.

Proof on paper. A nonzero submodule $\bar{Q}$ of $L(U)$ pulls back to a submodule $Q \supsetneq J$ of $M(U)$. It is graded (every submodule is), so if $Q \cap M(U)_h = 0$ then $Q \subseteq J$ by maximality, a contradiction; hence $Q \cap M(U)_h \neq 0$. This intersection is stable under the zero modes, i.e. an $A(V)$-submodule of $M(U)_h \cong U$; by simplicity it is all of $M(U)_h$, and since $M(U)$ is generated by its bottom, $Q = M(U)$, so $\bar{Q} = L(U)$. □

What the machine verified

`LU_isIrreducible`: proved given its two named inputs. `djLU_isIrreducible`, `djLU_bottom_U`: proved, conditional on `Pr`, `hU`, `hL0` (and `hsimple`); `djLU_isBottomOfIrr`: additionally on `hfin`. Standard three axioms.

Physical meaning

Removing the null descendants of an irreducible primary multiplet leaves an irreducible sector whose primaries are exactly that multiplet: no new primaries are created and none are lost. This is how one constructs, e.g., the minimal-model sectors from Verma modules.

13.6.2 An irreducible module is L of its bottom

Definition 13.29 (The bottom of P and the universal map)**.** For a bundled lowest-weight module P let $\Omega(P) = P_h$ with its $A(V)$-action (an $A_0(V)$-module). The *universal map* $\bar{\varphi} : M(\Omega(P)) \to P$ is the unique linear map that is the inclusion on the bottom and intertwines all modes: $\bar{\varphi}([v] \otimes w) = o_{n,0}(v)w$ on level n, where $o_{n,0}(v)$ is the mode of v that raises the level by n.

    (hP : P.IsIrreducibleLW) :
    (pPhiBarKer P).carrier = (djJ Pr (pBotAmMod P) hU P.h hL0).carrier :=
```

From the mathematics to the Lean statement

`lowestAMod P.isLow` is P_h as an `AMod` (Chapter 12); `pBotAmMod P` is it as an $A_0(V)$-module. `pPhiBar P` is $\bar{\varphi}$, built by `oLevUnivMap` from the bottom inclusion `pBotIncl P`, the fact that it lands in level 0, and its $A(V)$-equivariance; it is defined for *every* P, without hypotheses. `pPhiBar_intertwine`: it is a module map. `pPhiBar_surjective`: onto, if P is irreducible (its image is a nonzero submodule). `pPhiBarKer P` is its kernel as a submodule, and `pPhiBarKer_eq_djJ` identifies it with $J(\Omega(P))$, under `Pr`, `hU` ($\Omega(P) \neq 0$), `hL0` and irreducibility of P.

Proof on paper. *Existence of $\bar{\varphi}$.* On level n define $\bar{\varphi}([v] \otimes w) = o_{n,0}(v)w$. This respects $O_{n,0}(V)$ because, by Dong–Jiang's annihilation (Step 2 of Theorem 13.25, applied in the module P with its levels P_{h+k}), $o_{n,0}(x)$ kills P_h for $x \in O_{n,0}$; it respects the balancing because $o_{n,0}(x *_0^n a)w = o_{n,0}(x)o(a)w$ (composition law). It intertwines the modes by the same composition law. *Kernel.* The kernel K is a submodule; on the bottom $\bar{\varphi}$ is the inclusion $M(\Omega(P))(0) \cong \Omega(P) \hookrightarrow P$ (this uses the gate, hence `Pr`), so K is bottom-trivial and $K \subseteq J$. Conversely $\bar{\varphi}(J)$ is a submodule of the irreducible P meeting P_h trivially (because J is graded and bottom-trivial and $\bar{\varphi}$ preserves weights), so it is 0, i.e. $J \subseteq K$. (The library phrases this as: K is bottom-trivial and maximal, and J is the unique such submodule, `djJ_unique`.) □

What the machine verified

`pBotAmMod`, `pPhiBar`: definitions, no hypotheses. `pPhiBar_intertwine`: unconditional. `pPhiBar_surjective`: conditional on irreducibility of P. `pPhiBarKer_eq_djJ`: conditional on `Pr`, `hU`, `hL0`, irreducibility. All: standard three axioms.

Physical meaning

Every sector is a quotient of the universal "Verma-type" module of its primaries: map each formal descendant to the actual descendant state. In an irreducible sector, the kernel of this map is exactly the space of null descendants.

Theorem 13.30 (L_0 on $M(\Omega(P))$; finiteness)**.** *For every bundled lowest-weight module P and every n, L_0 acts on $M(\Omega(P))(n)$ as $h + n$. If moreover P is irreducible, then $L(\Omega(P))$ has finite-dimensional weight spaces.*

Files `VOA/Modules/ZhuVermaAnArchHL0.lean` and `VOA/Modules/ZhuVermaAnArchLUFiniteWeights.lean`.

```
theorem pHL0 (P : LWModule W) :
    ∀ (n : ℕ) (x : DJCarrier W (pBotAmMod P)), x ∈ DJCarrier.deg W (pBotAmMod P) n →
      djModeZero W (pBotAmMod P) 1 W.conformalVector x = (P.h + n) • x := by
theorem pFiniteWeights (P : LWModule W)
    (Pr : BottomProjection (parabolicRepOfAMod W (regularAMod W)))
    (hU : Nontrivial (pBotAmMod P).carrier)
    (hL0 : ∀ (n : ℕ) (x : DJCarrier W (pBotAmMod P)), x ∈ DJCarrier.deg W (pBotAmMod P) n →
      djModeZero W (pBotAmMod P) 1 W.conformalVector x = (P.h + n) • x)
    (hP : P.IsIrreducibleLW) :
    (djLU Pr (pBotAmMod P) hU P.h hL0).FiniteWeights := by
```

From the mathematics to the Lean statement

`pHL0` gives the datum `hL0` of Definition 13.26 for $U = \Omega(P)$, $h = P_h$'s weight. It takes `Pr` as an argument but does not use it (see the warning). `pFiniteWeights` gives `FiniteWeights` for $L(\Omega(P))$, so that $L(\Omega(P))$ can be converted into an `LWModule` by `toLWModule`.

Proof on paper. L_0. By Dong–Jiang's commutator Lemma 2.3 applied to $\omega \in V_2$, $\omega \bar{*}_0^n v - v *_0^n \omega - \mathrm{Res}_z(1+z)Y(\omega,z)v \in O'_{n,0}(V)$, and $\mathrm{Res}_z(1+z)Y(\omega,z)v = L_{-1}v + L_0 v$; subtracting the grading generator $L_{-1}v + (L_0 - n)v \in O'_{n,0}$ gives $[\omega \bar{*}_0^n v] = [v *_0^n \omega] + n[v]$ in $A_{n,0}(V)$. On $[v] \otimes w$, the left side is $L_0([v] \otimes w)$; by balancing $[v *_0^n \omega] \otimes w = [v] \otimes [\omega]w = h\,[v] \otimes w$. So $L_0 = h + n$. *Finiteness.* The first-isomorphism theorem gives a linear isomorphism $L(\Omega(P)) \cong P$ (next theorem) compatible with L_0, hence weight space by weight space; P's weight spaces are finite-dimensional. □

Trap / dead end

Redundant hypothesis (moderate) — fixed. The current `pHL0`, quoted above, has no `Pr`. When this chapter was first written, `pHL0` took `Pr : BottomProjection (parabolicRepOfAMod`

`W (regularAMod W))` but its proof does not use it; the library's docstring says so ("retains an explicit, unused ... parameter"), and `genHL0` in `VOA/Modularity/HL0Scoped.lean` (Chapter 15) states the core without it. A check in Lean against the library (not part of this release), theorem `pHL0_without_Pr`, proves the conclusion of `pHL0` with no `Pr` (from `genHL0` and `LWModule.toAMod_omegaScalar`); axioms: standard three. Harmless for the headline, which has `Pr` anyway.

What the machine verified

`pHL0`: proved, no hypotheses beyond `P`. `pFiniteWeights`: proved, conditional on `Pr`, `hU`, `hL0`, irreducibility. Standard three axioms.

Physical meaning

All level-n descendants of a primary of weight h have weight $h + n$: the zero mode of the stress tensor counts the level. Finiteness: in a physical sector each energy level is finitely degenerate.

Theorem 13.31 ($P \cong L(\Omega(P))$; Dong–Jiang, Theorem 4.13)**.** *Every irreducible bundled lowest-weight module P is isomorphic to $L(\Omega(P))$.*

File `VOA/Modules/ZhuVermaAnArchLURealizesIrr.lean`.

```
theorem pRealizesLWIso (P : LWModule W)
    (Pr : BottomProjection (parabolicRepOfAMod W (regularAMod W)))
    (hU : Nontrivial (pBotAmMod P).carrier)
    (hL0 : ∀ (n : ℕ) (x : DJCarrier W (pBotAmMod P)), x ∈ DJCarrier.deg W (pBotAmMod P) n →
      djModeZero W (pBotAmMod P) 1 W.conformalVector x = (P.h + n) • x)
    (hP : P.IsIrreducibleLW)
    (hfin : (djLU Pr (pBotAmMod P) hU P.h hL0).FiniteWeights) :
    LWModule.Iso W ((djLU Pr (pBotAmMod P) hU P.h hL0).toLWModule hfin) P :=
```

From the mathematics to the Lean statement

The conclusion is `LWModule.Iso` between $L(\Omega(P))$ (converted by `toLWModule hfin`) and P. The hypotheses: `Pr`; `hU : Nontrivial (pBotAmMod P).carrier` (true for every P, since `P.realized`; the library proves it as `pBotNontrivial`); `hL0` (supplied by `pHL0`); `hP` irreducibility; `hfin` (supplied by `pFiniteWeights`). So the only non-trivial inputs are `Pr` and irreducibility.

Proof on paper. $\bar{\varphi} : M(\Omega(P)) \to P$ is surjective with kernel $J(\Omega(P))$; the first isomorphism theorem gives $L(\Omega(P)) = M/J \cong P$, and the isomorphism intertwines the modes because $\bar{\varphi}$ does. □

What the machine verified

Proved, conditional on `Pr` (other hypotheses dischargeable as stated); standard three axioms.

Physical meaning

Every irreducible sector is *the* irreducible quotient of the universal module of its primaries. There is no room for two different sectors with the same primaries.

13.6.3 Functoriality and the assembly

Theorem 13.32 ($L(\cdot)$ is invariant under isomorphism of bottoms)**.** *If $U_1 \cong U_2$ as $A(V)$-modules (both nonzero, with L_0 acting on level n by $h_i + n$, $h_1 = h_2$), then $L(U_1) \cong L(U_2)$.*

Files `VOA/Modules/ZhuVermaAnArchLUFunctorial.lean` and `VOA/Modules/ZhuVermaAnArchLUBijection.lean`.

```
noncomputable def djFunctorEquiv (U₁ U₂ : AmMod W 0) (e : AmModHom U₁ U₂) :

theorem pH_eq {P Q : LWModule W} (ψ : AModEquiv W P.toAMod Q.toAMod) : P.h = Q.h := by
```

From the mathematics to the Lean statement

`AmModHom U₁ U₂` is (despite its name) an $A_0(V)$-module *isomorphism* datum (a linear equivalence intertwining ρ); `amModHomOfBottomEquiv` produces one from an `AModEquiv` of bottoms. `djFunctorEquiv` is $M(U_1) \cong M(U_2)$, $\bigoplus_n (\mathrm{id} \otimes e)$; the library proves it intertwines the modes (`djFunctorEquiv_natural`) and maps $J(U_1)$ onto $J(U_2)$ (`djFunctorEquiv_maps_djJ`), so it descends to $L(U_1) \cong L(U_2)$. `pH_eq`: isomorphic bottoms force equal lowest weights, because $[\omega]$ acts on the bottom by the lowest weight and the bottom is nonzero.

Proof on paper. $\mathrm{id} \otimes e$ respects the balancing relations because e intertwines the $A(V)$-actions, and commutes with the modes because they act on the first factor. An isomorphism of modules carries the maximal bottom-trivial graded submodule to the maximal one. □

What the machine verified

Proved, conditional on `Pr` and the displayed data; standard three axioms.

Physical meaning

Relabelling the primaries by an isomorphism of zero-mode representations relabels the whole sector: the sector is a functor of its primary multiplet.

Theorem 13.33 (Assembly). *A family K of lowest-weight modules with $K(P) \cong P$ for irreducible P, and $K(P) \cong K(Q)$ whenever P, Q are irreducible with isomorphic bottoms, implies bottom rigidity and hence bijectivity of* `forwardMapIrr`. *Taking $K(P) = L(\Omega(P))$ proves the headline.*

    Function.Bijective (forwardMapIrr W) :=
  (djRealizationFamily Pr hHL0).bijective
```

From the mathematics to the Lean statement

`DJRealizationFamily W` is a bundle (data) of a function `K : LWModule W → LWModule W` and two properties; it is *not* a hypothesis of the headline: `djRealizationFamily Pr hHL0` constructs it, with `K = djK Pr hHL0`. `djK` sends an irreducible P to $L(\Omega(P))$ and any other P to itself (a "junk value", never inspected because both properties only concern irreducible P; `dite/if hP : ... then ... else` is Lean's case split on a proposition, available by classical logic). `zhuBijective_of_hHL0` is the assembly, with the L_0 datum `hHL0` as a hypothesis, and `zhuBijective` discharges `hHL0` by `pHL0`.

Proof on paper (of the headline, complete). Let P, Q be irreducible with $\psi : P_h \cong Q_{h'}$ as $A(V)$-modules. Then $h = h'$ (`pH_eq`). By Theorem 13.31, $P \cong L(\Omega(P))$ and $Q \cong L(\Omega(Q))$; by Theorem 13.32 applied to ψ, $L(\Omega(P)) \cong L(\Omega(Q))$. Hence $P \cong Q$: bottom rigidity. By `forwardMapIrr_bijective_iff_rigidity`, `forwardMapIrr` is bijective. The ingredients used: the Lie algebra $\widehat{V}$ and the Dong–Li–Mason survival theorem (for the regular module, via `Pr`) to get the gate $A_{0,0}(V) = A(V)$; the Dong–Jiang module $M(U)$; the maximal submodule J; the universal map $\bar{\varphi}$. □

What the machine verified

`DJRealizationFamily.rigidity`, `DJRealizationFamily.bijective`: unconditional (given the bundle). `zhuBijective_of_hHL0`: conditional on `Pr` and `hHL0`. Standard three axioms.

Physical meaning

The chain $P \cong L(\Omega(P)) \cong L(\Omega(Q)) \cong Q$ is the mathematical form of the bootstrap statement "a sector is fixed by its primaries". The proof never needs a classification of sectors, rationality, or modular invariance: only the associativity of the OPE (encoded in the tower) and the PBW structure of the mode algebra.

13.7 The 298 files by role

13.7.1 How the critical path was determined

We did not rely on file names or docstrings. A scratch Lean file importing `VOA/Modules/ZhuVermaAnArchLUBijectionPBW.lean` walked, from `zhuBijective_of_voaPBW`, the constants occurring

in the types *and proof terms* of all declarations reachable from it, and recorded the module of each. Of the 298 files `ZhuVerma*.lean`, exactly 101 (about 38 000 lines) contain a constant used by the headline; the other 197 (about 52 000 lines) are imported by the umbrella but contribute nothing to it. (Being in the import closure is weaker: 236 of the files are imported, transitively, by the headline's file.)

13.7.2 The critical path, grouped by the sections of this chapter

- *Statement* (Section 13.2): `FaithfulBijection`, `Rigidity`, `Zhu534` (surjectivity, the iff with rigidity, `toLWModule`), `AModScope` (`OmegaScalar`), `LUBijection`, `LUBijectionPBW`.
- *The Lie algebra $\widehat{V}$ and induction* (Section 13.3): `Vhat`, `VhatDescent`, `VhatSkew`, `VhatJacobi`, `VhatJac2`, `VhatJac3`, `MUVhat`, `VHatModeData`, `VHatRepMU`, `MUjacobi`, `MUjacobiClose`, `MUModuleDataBuild`, `MUmod`, `DLM3Deg`, `DLM3Induced`, `DLM3Admissible`, `DLM3Level`, `DLM3Zero`, `DLM3Survival`, `DLM3PBWSplit`, `DLM3PBWIndependence`, `DLM3PBWAxiom`.
- *The tower* (Section 13.4): `An` (=`ZhuVermaAn`), `AnBimodule`, `AnDescent`, `AnDescent4`, `AnDescent15`, `Arch`, `Algebra`, `AnAssoc`, `Anm`, `AnmFull`, `Filtration`, `AltVandermonde`, `ResSkew`, `SkewModOnm`, `SkewGradingGen`, `Units`, `Rgen`, `CollapseAssoc`, `LeftGradingResidualFull`, `MUcirc`, `MUcross`, `MUFullMode`, `MUFullRho`, `MUFullBracketClose`, `DJ22–DJ28*` (Dong–Jiang Lemmas 2.2–2.8: the closure of the ideals under the products).
- *$M(U)$ and the gate* (Section 13.5): `DJCarrier`, `DJCarrierGraded`, `DJAction`, `DJ48`, `DJ48BdryHolds` (Lemma 4.7, commutator), `DJ49Star`, `DJ51`, `DJCarrierIterate` (Lemma 4.9, iterate), `DJCarrierWeak`, `DJGeneration`, `IterateNonneg`, `GradedCloseDeep`, `GradedModeVanish`, `BottomSurvival`, `BottomAn`, `BottomDefectClose`, `FreenessDescent`, `DefectDerivation`, `DLM3Pairing`, `DLM3Prop43`, `DLM3Propagate`, `DLM3Survive`, `Gate`, `GateB1`, `GateB1Ann`, `GateAnnN0`, `ZeroModeLaw`, `UnivMap`, `VModQuot`.
- *$L(U)$ and uniqueness* (Section 13.6): `LUGraded`, `LU`, `LUUniversal`, `LUUniversalIrr`, `LURealizesIrr`, `HL0`, `LUFiniteWeights`, `LUFunctorial`, `LUIsoInvariant`.

(Prefix `ZhuVermaAnArch` omitted.)

13.7.3 Off the critical path

The 197 remaining files are earlier or alternative routes, kept in the library. By role:

- *Earlier constructions of the $\widehat{V}$-action and of $M(U)$* (roughly 70 files): the $\otimes_{\mathbb{C}}$ "MU track" (`MU*` except the few on the path, `Sd*`, `Hole*`, `CarrierBridge*`, `ConstructionAUniform`, `GenuineRho`, `AGenuineRho`, `Rho*`, `LevelShiftRho`, `ActionNaturalLevelShift`, `LayerAction`), the universal property over that carrier (`UnivLift`, `Universal*`, `Frobenius*`, `FunctorEquivGraded`, `Functorial`, `StructuralClose`, `ScopeClose`, `LightPrimitives`, `Leaf2`), and the $J/L(U)$ layer over `OrdVModule` (`Lumax*`, `L0Semisimple`, `KerJ`, `VModQuotGraded`, `MuEquivClose`), which cannot accommodate the infinite-dimensional regular module. All superseded by the balanced, finrank-free `DJCarrier` route.
- *Alternative or partial proofs of the closure identities* (roughly 60 files): Li's regular-representation route (`Li*`); the cross and circle towers (`Cross*`, `CFirstDiff*`, `Hinge*`, `Vec*`, `ARD*`, `Aout*`, `HPoleN`, `Term1UCore`, `VcoreTwins`, `HardMemCFirst2`, `CircDiffARD`, `DWeightPoleShift`, `SkewDirect`, `SkewHardMem`); the collapse $O'' + O''' \subseteq O'$ (`Collapse*`, `OnmCollapseZero`); off-diagonal and bimodule-composition descents (`OffDiagDescent`, `UpCrossClosure`, `UpRightModule`, `BimodComp`, `BimodDescent*`, `AnmIdeal`, `AnmRightDiff`); alternative proofs of Dong–Jiang lemmas (`DJ25`, `DJ28Base`, `DJ28Induction`, `DJ28IntoFull`, `DJ28Term*`, `DJ47`, `DJ49Iterate`, `DJ49Master`, `DefectModeShift`, `GateB3`); and the A_n ideal and filtration closures (`AnIdeal`, `ABS`, `L1*`, `Rgen*` except

`Rgen`, `RightUnit`, `FiltrationFinal`, `GradedClose`, `GradedSpan`, `BottomDefectZero`, `BottomLevelDefect`, `BottomOrbitClose`, `FreenessCircle`). Some of them (`AnIdeal`: `anIdeal_holds`) prove true theorems quoted in this chapter that the headline simply does not need.

- *The descent lemmas of the original A_n bimodule plan* (`AnDescent2`–`AnDescent26` except the three on the path; 23 files): residue identities for the closure of O_n under the products.
- *Associativity of $A_n(V)$, $n \geq 1$* (`Assoc`, `AssocCore`): reductions of the open target `AssocHom W n`; only $n = 0$ is closed.
- *Scorecard and interface files built on uninhabited bundles* (`InducedAssign`, `GenBottom`, `GenFromBottomFinal`, `GenFromBottomG`, `GameTwo`, `CritPath`, `Bijection`, `Phase4*`, `ScorecardAssemble`, `FinalWiring`, `Downstream`, `Stage7Audit`, `TriageAudit`): bijection theorems taking an `InducedAssignment` (or a structure containing one) as hypothesis. Since `InducedAssignment W` is uninhabited (`not_nonempty_inducedAssignment`, Chapter 12), all of them are vacuous; see the warning below.
- *Satisfiability and boundary files* (`DLM3AdjointBottom`, `DLM3BottomProjectionBoundary`): the adjoint instance of `BottomProjection` and the equivalence `nonempty_bottomProjection_iff_bottom_injective` (Section 13.3); quoted in this chapter, not used by the headline.

Trap / dead end

The file named "critical path" is not on the critical path, and its headline is vacuous (serious; documentation only). The module docstring of `VOA/Modules/ZhuVermaAnArchCritPath.lean` begins "This file **audits** the dependency graph of the final Zhu bijection and banks the single cleanest headline conditional theorem", and calls its hypothesis bundle "exactly the data the unconditional $\Phi(V) \leftrightarrow \mathrm{Irr}A(V)$ bijection consumes". Its statements are

```
structure CritPathData (W : VertexOperatorAlgebra 𝒱) where
  /-- The lifting datum `U ↦ M⁻(U)` (the generalized-Verma realization; bottom
   ↪ survival +
  functoriality).  Built from `MUVHatData` (`ρ`/`VHatModeData`, `MUGradedAction`,
   ↪ grading,
  bottom residual / freeness); no `A_n`-assoc for `n ≥ 1`. -/
  A : InducedAssignment W
  /-- **Ambient irreducibility scope.** Every bundled lowest-weight module is
   ↪ irreducible — the
  standing restriction of Theorem 5.3.4. -/
  hall : InducedAssignment.AllLWIrreducible W
  /-- **The realizations are irreducible** (`M̄ (U) = L(U)`). -/
  hirr : A.RealizeIrreducible
  /-- **Generation-from-bottom** — the universal property of `M(U)` (Frobenius
   ↪ reciprocity for
  irreducibles), the injective-half crux. -/
  hgen : InducedAssignment.GeneratedFromBottom W
theorem zhuBijection_critpath {W : VertexOperatorAlgebra 𝒱}
    (A : InducedAssignment W)
    (hall : InducedAssignment.AllLWIrreducible W)
    (hirr : A.RealizeIrreducible)
    (hgen : InducedAssignment.GeneratedFromBottom W) :
    Function.Bijective (forwardMap W) :=
```

(file `VOA/Modules/ZhuVermaAnArchCritPath.lean`). Three problems. (i) The first field is an `InducedAssignment W`, which is uninhabited for every V; so `CritPathData W` is empty and `zhuBijection_critpath` can never be applied. Checked in Lean against the library

(the check is not part of this release): `critPathData_empty : ¬ Nonempty (CritPathData W)`. (ii) Its conclusion concerns the *unrestricted* `forwardMap` on all lowest-weight modules, which is not injective in general (a generalized Verma module and its irreducible quotient have the same bottom), so it is only "true" because the hypothesis is contradictory; its `hall : AllLWIrreducible W` field is false for most V, as the docstring of `ZhuVermaAnArchFaithfulBijection.lean` itself states. (iii) None of the file's constants is used by `zhuBijective`; the actual critical path is the one described above. The same vacuity affects `FaithfulScorecard.bijectiveIrr`, `zhuBijectionIrr_scorecard` and `InducedAssignment.forwardMapIrr_bijective` in `ZhuVermaAnArchFaithfulBijection.lean`, whose docstring presents them as conditional on "genuine deep inputs"; the library records this only in `ZhuVermaAnArchZhu534.lean` (`not_nonempty_faithfulScorecard`).

13.8 Recorded traps and dead ends

Severities are graded on a four-step scale: serious (a statement that is wrong or vacuous), moderate (weaker or stronger than advertised, or a redundant hypothesis), open gap (a conditional result whose hypothesis is not discharged, or a missing piece), and documentation only (docstrings and notes):

1. `zhuBijective`'s codomain is the image of the forward map, so surjectivity is tautological; the theorem is Zhu's uniqueness, not the full correspondence (moderate; Section 13.2; checked in Lean).

2. `Pr : BottomProjection (parabolicRepOfAMod W (regularAMod W))` is discharged for every V by `voaPBWBottomProjection` (from the theorem `VOA.pbw`); this gap, open at the snapshot, is closed (Section 13.3).

3. "Bottoms of irreducibles are simple" (`AllBottomRecovers`) was unproved for general V at the snapshot; it is now the theorem `allBottomRecovers` (closed; Theorem 13.6). Combined with existence under C_2 it gives the genuine bijection `zhuCorrespondence_of_C2Cofinite` (Theorem 13.8). Without C_2, existence of an ordinary module over each simple $A(V)$-module remains open in the library (open gap).

4. Release wording (release audit, finding F6): `zhuBijective` and `zhuBijective_of_voaPBW` must be announced as the *uniqueness half* of Zhu's correspondence; the bijection to announce is `zhuCorrespondence_of_C2Cofinite`. The docstring "Zhu Theorem 5.3.4 (faithful form)" of `ZhuVermaAnArchLUBijectionPBW.lean` overstates (documentation only).

5. `ZhuVermaAnArchCritPath.lean`: misnamed, off the critical path, headline vacuous (serious; documentation only; checked in Lean). Same vacuity for the `InducedAssignment`-based theorems of `ZhuVermaAnArchFaithfulBijection.lean` and the other scorecard files (serious, already proved by the library; docstrings stale, documentation only).

6. `pHL0` had an unused hypothesis `Pr` (moderate; checked in Lean); removed in the library since.

7. Stale trust-boundary docstrings in `ZhuVermaAnArchDLM3Survival.lean` and `ZhuVermaAnArchDLM3Zero.lean` ("`pbw` does not cover this", "level independence is the PBW step") (documentation only; Section 13.3).

8. `OnFull`'s docstring claims strict containment `On W n` $\subsetneq$ `OnFull W n` for $n \geq 1$ without proof (documentation only). The known defect of `On` (Chapter 12) does not reach the headline (Section 13.4).

9. `AmModHom` is an isomorphism datum (a linear *equivalence*), not a homomorphism (naming only; harmless).

10. Associativity of $A_n(V)$ for $n \geq 1$ is open (named target `AssocHom`); no headline depends on it.

Dead ends recorded by the library itself and confirmed here: the `InducedAssignment` interface (uninhabited because it demands a realization of the zero $A(V)$-module); the `OrdVModule`-based construction of $M(U)$ (impossible for the regular module, whose bottom is infinite-dimensional); the circle-only quotient $V/O'_{n,m}$ as a bimodule (Dong–Jiang's Remark 2.10 problem); the false global hypothesis `AllLWIrreducible`.

`zhuBijection_critpath`	(claims) the bijection	**vacuous** (checked in Lean)	§13.7

Machine record. All `#print axioms` results of this chapter were obtained at the snapshot, not re-run for this edition (when `VOA.pbw` was an axiom; see the re-probe below) on a scratch file importing `VOA/Modules/ZhuVermaAnArchLUBijectionPBW.lean`, `VOA/Modules/ZhuVermaAnArchCritPath.lean`, `VOA/Modules/ZhuVermaAnArchDLM3AdjointBottom.lean` and `VOA/Modularity/GNProp8Closure.lean`, compiled with `lake env lean -DmaxSynthPendingDepth=3` against the existing build (never a bare `lake env lean`); no full `lake build` was run for this chapter. Excerpt:

```

```

The same run covered `zhuBijective_of_hHL0`, `voaPBWFreeness` (`pbw`), `BottomProjection`, `PBWFreeness`, `pbwFreeness_iff_bottom_injective`, `bottomProjectionOfInjective`, `parabolicRepOfAMod`, `regularAMod`, `bracketDescends`, `vhatLeibniz_holds`, `indBarWeakModule`, `indBarBottom_injective_of_bottomProjection`, `defectPairsToZero_of_bottomProjection`, `djPieceMEquiv`, `djLU`, `maxJ_bottom_disjoint`, `pFiniteWeights`, `pPhiBar_surjective`, `pPhiBarKer_eq_djJ`, `DJRealizationFamily.bijective`, `forwardMapIrr`, `not_nonempty_inducedAssignment`, `djLU_isBottomOfIrr`, `On_zero_eq_O`, `circ`, `OnmFull`: all report exactly the standard three axioms, except those marked `pbw` (at the snapshot; none now). Recall that `#print axioms` does not report explicit hypotheses such as `Pr`: "standard three" for a conditional theorem means *axiom-clean, conditional on its displayed hypotheses.*
The Lean check of this chapter against the library (not part of this release) was compiled the same way:

```
'L13Cert.zhu_rigidity' depends on axioms: [propext, Classical.choice, Quot.sound]
'L13Cert.zhu_rigidity_voaPBW' depends on axioms: [propext, Classical.choice, Quot.sound,
 ↪ VOA.pbw]
'L13Cert.bijective_of_rigidity_statement' depends on axioms: [propext, Classical.choice,
 ↪ Quot.sound]
'L13Cert.forwardMapIrr_surjective_free' depends on axioms: [propext, Classical.choice,
 ↪ Quot.sound]
'L13Cert.critPathData_empty' depends on axioms: [propext, Classical.choice, Quot.sound]
'L13Cert.pHL0_without_Pr' depends on axioms: [propext, Classical.choice, Quot.sound]
```

Re-probed at a later commit, after `VOA.pbw` became a theorem (not re-run for this edition): `zhuBijective_of_voaPBW`, `voaPBWBottomInjective`, `voaPBWFreeness`, `voaPBWBottomProjection` and the theorem `L13Cert.zhu_rigidity_voaPBW` of that check all report `[propext, Classical.choice, Quot.sound]`.

Release audit 2026-10-27: RELEASE_AUDIT_ZHU.md. The independent release audit (`Notes/Textbook/referee/RELEASE_AUDIT_ZHU.md`, findings F6 and F7) confirmed that `zhuBijective_of_voaPBW` has the standard three axioms and that its content is injectivity only, and that `simpleAModsRealized_of_C2Cofinite` takes `Pr` and C_2 explicitly. For this revision, at an earlier commit (not re-run for this edition), a scratch file was run from the repository root with `lake env lean -DmaxSynthPendingDepth=3` against the oleans built 2026-10-25 (the new file `ZhuModularityCanonical.lean` had no olean; its text was included verbatim in the scratch file and elaborated there):

```
'VOA.zhuCorrespondence_of_C2Cofinite' depends on axioms: [propext, Classical.choice,
 ↪ Quot.sound]
'VOA.IrrLWModule.toSimpleAMod' depends on axioms: [propext, Classical.choice, Quot.sound]
'VOA.Huang.LWBottomRecovery.allBottomRecovers' depends on axioms: [propext,
 ↪ Classical.choice, Quot.sound]
'VOA.Huang.LWBottomRecovery.isSimpleAMod_toAMod_of_irreducible' depends on axioms:
 ↪ [propext, Classical.choice, Quot.sound]
'VOA.isBottomOfIrr_iff_isSimpleAMod' depends on axioms: [propext, Classical.choice,
 ↪ Quot.sound]
'VOA.simpleAModsRealized_of_C2Cofinite' depends on axioms: [propext, Classical.choice,
 ↪ Quot.sound]
'VOA.zhuBijective_of_voaPBW' depends on axioms: [propext, Classical.choice, Quot.sound]
```

No `lake build` was run for this revision; per the release plan the umbrellas were green when these theorems were merged, and nothing here counts as released until an aggregate build containing them is green at the release commit.

Second release revision 2026-10-28. No statement of this chapter changed; only the introduction records the new consumer of its machinery. The `#print axioms` checks of `VOA.Huang.ZhuSemisimple.isSemisimpleRing_A_of_admissiblyRational` and of the new modularity theorems were run at an earlier commit (standard three axioms; not re-run for this edition) and are recorded in Chapter 15. No `lake build` was run.

Part IV

Modularity

Chapter 14

Modular forms and the analytic toolkit

This chapter documents the release of the LeanVOA library named in the front matter; it was first written against an earlier state of the library, and checks that were run at an earlier state of the library and not re-run for this edition are marked as such. Every Lean quotation below is taken from the files of the release and is machine-checked by `scripts/textbook/sync.py` to occur verbatim (up to whitespace and comments) in the source. The chapter covers the files of `VOA/Modularity/` assigned to it in `Notes/Textbook/assignment.txt`: the Eisenstein series and the level-one structure theorem, the bridge between formal q-series and holomorphic functions on the upper half-plane, the Serre derivative, Lambert series, the growth ("subexponential") estimates and the majorant method for formal modular differential equations, the cusp $q \to 0$, the slash action restricted to subgroups and the theta group Γ_θ, the read-off of the modular S-matrix, Jacobi characters, the analytic j-invariant, and the abstract "Moonshine corollary" of Zhu's theorem. About thirty-five files and ten thousand lines of Lean are involved.

How this chapter relates to its neighbours. Chapter 33 already develops, for the Moonshine construction, the classical theory of $\mathrm{SL}_2(\mathbb{Z})$, the slash operator, the Eisenstein series E_4, E_6, the discriminant Δ, the functions j and J, theta series and the formal series `E4Series`, `E6Series`, `deltaSeries`, `jShift`, `JShift` of `VOA/Modularity/JFunction.lean` and `lambertCoeff` of `VOA/Modularity/LambertSeries.lean`. We do not repeat that material: we recall it in Section 14.1 with pointers and then cover what is *general* or *different*. The reader should know three other chapters. Chapter 1 is the book's Lean toolkit (structures, $\sum^{\mathbf{f}}$, `tsum`, coercions, `Classical.choose`); we point to it instead of re-explaining Lean idioms. Chapter 12 defines modules, their formal characters `gradedDim` and one-point functions `onePoint` (Definition 12.13), conformal weights (Definition 12.14), the T-periodicity of characters (Theorem 12.15), Zhu's algebra $A(V)$ (Section 12.4) and C_2-cofiniteness (Definition 12.22). Chapter 15 proves Zhu's modularity theorem — for the one-point functions of a C_2-cofinite, rational V (rational in the sense of the library's `AdmissiblyRational`), through a more general form for C_2-cofinite V whose Zhu algebra is *semisimple* — and is the main *consumer* of this chapter: almost every analytic statement here was written to serve one step of Zhu's argument, and we say which. Where a statement of this chapter needs an object that is formally owned by Chapter 15 (the Zhu-normalised Eisenstein coefficients `zhuG`, the square-bracket modes `vSqZ`, the trace functions `traceFun`) we quote its definition here, with its file, so that the chapter can be read on its own.

Release revision. The chapter was revised for the first public release, applying the release audit `Notes/Textbook/referee/RELEASE_AUDIT_ZHU.md` (2026-10-27). No quotation of this chapter changed; the edits concern how the consumer theorem of Chapter 15 is described.

Second release revision (2026-10-28). At this revision the description of that consumer theorem was corrected again, following finding F2 of `Notes/Textbook/referee/RELEASE_AUDIT_NEW_DECLS.md`. The first release revision said that the library "does not derive it from rationality". That was wrong. The library proves "rational $\Rightarrow$ $A(V)$ semisimple"

(`isSemisimpleRing_A_of_admissiblyRational`, Chapter 15, Theorem 15.38), and Zhu's theorem is stated for C_2-cofinite rational V (Theorem 15.39) and proved for every lattice VOA $V_{\sqrt{2m}\mathbb{Z}}$. No quotation of this chapter changed.

The findings of this chapter, in brief. Every headline theorem of this chapter is proved in Lean and `#print axioms`-clean (only `propext`, `Classical.choice`, `Quot.sound`); none uses `VOA.pbw` (the PBW theorem of Chapter 3; formerly a project axiom, now a theorem). The analytic layer is faithful and, in several places, genuinely new relative to Mathlib (the equivariance of the Serre derivative, holomorphy and term-by-term differentiation of evaluated q-series, the majorant theorem). The fidelity checks did, however, turn up the following, each explained in a red box where it occurs.

- The structure theorem `levelOne_coe_mem_E46` ("$M_* = \mathbb{C}[E_4, E_6]$") proves only that every modular form lies in the *algebra generated* by E_4 and E_6. Algebraic independence and homogeneity are not part of it. They are proved, in full, elsewhere in the library (the vendored `ModularForm.levelOne_eq_polynomial` of Chapter 30); the two developments are not connected, and a predicate documented as "missing" (`E46HasWeightedPolynomialReps`) is in fact a consequence of the vendored theorem. A separate Lean check (Theorem 14.15) proved it first; the argument is now a library theorem, `e46HasWeightedPolynomialReps`.
- The Ramanujan/Serre closure `E46SerreClosed` ($\partial_k M_k \subseteq M_{k+2}$) is a library theorem, `e46SerreClosed` (`VOA/Modularity/EisensteinSerreClosure.lean`), proved through `serreForm`: the Serre derivative of a level-one form is a level-one form. It is consumed by Chapter 16.
- The Γ_θ "conjectures" of `GammaThetaStatement.lean` carry a free proposition slot `hFam` through `CompleteRationalFamily`, which is the identity on propositions, and the character families in `SuperCharacterSystem` and `SuperRealisesLawOn` are not tied to the super VOA at all. They are statements, not theorems, and are honest about it; but as written they are templates whose content depends entirely on what is plugged in (checked in Lean, Proposition 14.64).
- The "Hauptmodul step" `char_eq_jInvariant_add_const` assumes a weight-zero modular form equal to $\chi - j$; this hypothesis carries the whole content. Nothing in this chapter is instantiated at $V^\natural$: the library's theorem $\chi_{V^\natural} = J$ (Chapter 33) is a computation and does not pass through these files.
- The chapter's main consumer, Zhu's modularity theorem, is stated in Chapter 15 under C_2-cofiniteness and rationality (`AdmissiblyRational`), and in a more general form under C_2-cofiniteness and semisimplicity of $A(V)$, for one-point functions; the convergence of the q-series it evaluates is a *separate* theorem (`onePointSubexp_of_c2` together with this chapter's `qSummableAt_of_subexponential`), not part of its conclusion.
- Several docstrings are stale or wrong: one says that $p(n) \le 2^n$ gives subexponential growth (it does not); several call residuals open that are proved in other files; the Moonshine-corollary files say $V^\natural$ does not exist.

14.1 Conventions, and what is recalled from Chapter 5

14.1.1 Three kinds of "q-series"

The single most important thing to keep track of in this chapter is *which kind of object* a statement is about. The library uses three, and each has its own job: **(1)** carries characters and one-point functions of modules (exponents $h + n$ with $h \in \mathbb{C}$ arbitrary), and is the language of Zhu's recursion and of the formal differential equations of Section 14.10; **(2)** carries the coefficient rings (Eisenstein series, E_4, E_6, Δ, j) and the coefficients of those equations; **(3)** is where modularity is a statement at

all, since $\mathrm{SL}_2(\mathbb{Z})$ acts on τ, not on coefficients. Objects of types (1) and (2) are formal: equalities are coefficientwise and no convergence is involved. Objects of type (3) are honest functions, but whenever one is *produced* from a type-(1) object by an infinite sum, Lean uses `tsum`, which returns the junk value 0 on a divergent series (Chapter 1, Section 1.2.8); so every theorem that needs the honest value of such a sum carries a summability or growth hypothesis, and we point this out each time.

1. **Formal q-series with complex exponents**, the type `FormalQSeries`, which is literally `ℂ → ℂ` (Chapter 12, Definition 12.13). A function $\chi : \mathbb{C} \to \mathbb{C}$ is read as the formal sum $\sum_{e\in\mathbb{C}} \chi(e)\, q^e$. No convergence is implied, and the sum may have uncountable support; but every series that actually occurs is supported on a single progression $h + \mathbb{N}$, because characters of modules with a conformal weight are. The formal character of a module M with central charge c is

$$\chi_M = \sum_{\alpha} (\dim M_\alpha)\, q^{\alpha - c/24}, \qquad \text{i.e. } \texttt{gradedDim}\, N\,(e) = \dim M_{e+c/24}.$$

2. **Formal power series** `PowerSeries ℂ` $= \mathbb{C}[[X]]$ (Mathlib), with natural-number exponents. This is the setting of Chapter 33's E_4, E_6, Δ, j, and of all coefficient rings of differential equations below. Notation: `PowerSeries.coeff n F` is $[X^n]F$, `PowerSeries.mk a` is $\sum_n a_n X^n$; see Chapter 33, Section 33.2.

3. **Holomorphic functions** on the upper half-plane $\mathbb{H} = \{\tau \in \mathbb{C} : \operatorname{Im}\tau > 0\}$. Mathlib's type is `UpperHalfPlane` (notation `ℍ`), whose elements are complex numbers bundled with a proof that the imaginary part is positive. For calculus the library prefers the *open subset* `imGT 0` $= \{z \in \mathbb{C} : 0 < \operatorname{Im} z\}$ of $\mathbb{C}$ itself and functions $\mathbb{C} \to \mathbb{C}$, so that Mathlib's one-variable `HasDerivAt`, `deriv` and `DifferentiableOn` apply directly; the dictionary between the two pictures is `qEvalC_coe`, `mobiusC_coe`, `slashC` versus Mathlib's `|[k]` (all below).

The passage between (1)/(2) and (3) is *evaluation*: $\chi \mapsto \sum_n \chi(h+n) q^{h+n}$ at $q = e^{2\pi i\tau}$. It is only meaningful when the series converges, and a large part of this chapter proves, or reduces to named data, the estimates that make it converge. The reverse passage, from a holomorphic q-periodic function to its coefficients, is Mathlib's `qExpansion`, and its injectivity (uniqueness of q-expansions) is Mathlib's `qExpansion_coeff_unique`.

Trap / dead end

The `tsum` convention. An infinite sum in Lean, `∑' n, f n` (`tsum`), is defined for every f: if f is not summable it is 0 by convention (Chapter 1). So a definition such as `qEvalAt` below is *always* a complex number, and an equation between two `tsum`s can be "true" because both sides are the junk value 0. Every theorem below that manipulates such sums either carries a summability hypothesis or proves summability first; we check this in each fidelity box. Similarly `∑ᶠ` (`finsum`) is 0 on infinite support.

14.1.2 The objects recalled from Chapter 5

From Chapter 33 we use: the upper half-plane and the action of $\mathrm{SL}_2(\mathbb{Z})$ by $\gamma\tau = (a\tau + b)/(c\tau + d)$; the generators $S = \left(\begin{smallmatrix} 0 & -1 \\ 1 & 0 \end{smallmatrix}\right)$, $T = \left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right)$ (Mathlib `ModularGroup.S`, `ModularGroup.T`); the slash operator $(f|_k\gamma)(\tau) = (c\tau + d)^{-k} f(\gamma\tau)$ and modular forms of level one (Definition 33.1; Mathlib's type `ModularForm 𝒮ℒ k`, where $\mathcal{SL}$ is $\mathrm{SL}_2(\mathbb{Z})$ viewed as a subgroup of $\mathrm{GL}_2(\mathbb{R})$); Mathlib's normalised Eisenstein series `ModularForm.E hk` of weight $k \geq 3$, with `ModularForm.E₄`, `ModularForm.E₆`; the discriminant `ModularForm.discriminant` and the identity $\Delta = (E_4^3 - E_6^2)/1728$ (Remark 33.4); the Lambert coefficient $\lambda_s(n) = \sum_{ab=n} a^s = \sigma_s(n)$ (`lambertCoeff`, `lambertCoeff_eq_sigma`, Definition 33.6, Theorem 33.7); and the formal E_4, E_6, Δ, qj, qJ (Definitions 33.8–33.12).

We also use from Mathlib, and explain where it first appears: the quasimodular Eisenstein series $E_2 = 1 - 24\sum_{n\geq 1}\sigma_1(n)q^n$ (`EisensteinSeries.E2`) and its unnormalised version $G_2 = 2\zeta(2)E_2 = \frac{\pi^2}{3}E_2$ (`EisensteinSeries.G2`), the Bernoulli numbers `bernoulli` with $B_2 = \frac{1}{6}$, $B_4 = -\frac{1}{30}$, $B_6 = \frac{1}{42}$, and Mathlib's limit at the cusp `valueAtInfty` and filter `atImInfty` ("$\operatorname{Im}\tau \to \infty$").

Physical meaning

Throughout, the physical dictionary is that of Chapter 1: a VOA is the chiral algebra of a two-dimensional conformal field theory, a module is a sector, and the character $\chi_M(\tau) = \operatorname{tr}_M q^{L_0 - c/24}$, $q = e^{2\pi i\tau}$, is the *torus partition function* of that sector: the trace over states of the evolution operator $e^{2\pi i\tau(L_0 - c/24)}$ around a torus of modular parameter τ. The shift $-c/24$ is the Casimir energy of the vacuum on a circle. Two parameters τ related by $\mathrm{SL}_2(\mathbb{Z})$ describe the same torus, so a consistent theory has partition functions that transform into each other under $\mathrm{SL}_2(\mathbb{Z})$; this *modular invariance* is the physical origin of everything in this chapter. The generator $T : \tau \mapsto \tau + 1$ is a Dehn twist, and acts on a sector by the phase $e^{2\pi i(h - c/24)}$; the generator $S : \tau \mapsto -1/\tau$ *exchanges the space and time circles of the torus*, and its matrix $\rho(S)$ is the deep piece of data (it determines the fusion rules through Verlinde's formula).

14.2 The slash action in the complex-plane picture

The slash operator $f \mapsto f|_k\gamma$ is the standard device of modular-form theory: a function f is modular of weight k exactly when $f|_k\gamma = f$ for all γ, and $|_k$ is a right action of $\mathrm{SL}_2(\mathbb{Z})$ (Chapter 33, Section 33.1). Nothing about it is new here except the domain. Mathlib's slash operator `|[k]` acts on functions `ℍ → ℂ`. To differentiate, the library re-implements it on functions $\mathbb{C} \to \mathbb{C}$, restricted to statements on `imGT 0`. We record the definitions.

Definition 14.1 (Half-planes; automorphy factor; Möbius action; slash, in $\mathbb{C}$). This is the standard slash operator; we implement it on functions $\mathbb{C} \to \mathbb{C}$ rather than $\mathbb{H} \to \mathbb{C}$ so that Mathlib's one-variable derivative lemmas apply verbatim. For $c \in \mathbb{R}$ put $\mathbb{H}_c = \{z \in \mathbb{C} : c < \operatorname{Im} z\}$, so $\mathbb{H}_0 = \mathbb{H}$. For $\gamma = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in \mathrm{SL}_2(\mathbb{Z})$ and $z \in \mathbb{C}$ put $j(\gamma, z) = cz + d$ and $\gamma z = (az + b)/(cz + d)$. For $k \in \mathbb{Z}$ and $f : \mathbb{C} \to \mathbb{C}$ put $(f|_k\gamma)(z) = f(\gamma z)\, j(\gamma, z)^{-k}$.

noncomputable def denomC (γ : SL(2, ℤ)) (z : ℂ) : ℂ := (γ 1 0 : ℂ) * z + (γ 1 1 : ℂ)

noncomputable def mobiusC (γ : SL(2, ℤ)) (z : ℂ) : ℂ :=
  ((γ 0 0 : ℂ) * z + (γ 0 1 : ℂ)) / denomC γ z

noncomputable def slashC (k : ℤ) (γ : SL(2, ℤ)) (f : ℂ → ℂ) (z : ℂ) : ℂ :=
  f (mobiusC γ z) * (denomC γ z) ^ (-k)
```

From the mathematics to the Lean statement

`γ i j` is the (i, j) matrix entry with indices in `Fin 2` $= \{0, 1\}$, so `γ 1 0` $= c$, `γ 1 1` $= d$, `γ 0 0` $= a$, `γ 0 1` $= b$; the casts `(· : ℂ)` send integers to complex numbers. `SL(2, ℤ)` is Mathlib's notation for $\mathrm{SL}_2(\mathbb{Z})$. The exponent `(-k)` is an integer power (`zpow`), so the formula is the textbook $(cz + d)^{-k} f(\gamma z)$. Off $\mathbb{H}$ the functions are junk (for instance `mobiusC` divides by zero at $z = -d/c$, where Lean's division returns 0); every theorem below is stated for $z \in$ `imGT 0`, where `denomC_ne_zero` and `mobiusC_mem_imGT` (both proved) guarantee $cz + d \neq 0$

and $\gamma z \in \mathbb{H}$. The agreement with Mathlib is `mobiusC_coe`: `mobiusC γ (τ : ℂ) = ((γ • τ : UpperHalfPlane) : ℂ)`. These are definitions; there is nothing to be vacuous.

Physical meaning

$j(\gamma,\tau)^k$ is the factor by which a field of conformal weight k (more precisely, a one-point function of a state of weight k) rescales when the torus is reparametrised; a weight-k object is a k-form $f(\tau)(d\tau)^{k/2}$ on the moduli space, and $d(\gamma\tau) = (c\tau+d)^{-2}d\tau$. Partition functions are weight 0; one-point functions of weight-k states are weight k.

What the machine verified

Definitions. Supporting lemmas `denomC_ne_zero`, `mobiusC_mem_imGT`, `hasDerivAt_mobiusC` ($\frac{d}{dz}\gamma z = (cz+d)^{-2}$, using $ad-bc=1$) and `slashC_mul` ($f|_k\gamma \cdot g|_l\gamma = (fg)|_{k+l}\gamma$) are proved without hypotheses.

Theorem 14.2 (The derivative does not commute with slashing). *Let $k \in \mathbb{Z}$, $\gamma \in \mathrm{SL}_2(\mathbb{Z})$, $z \in \mathbb{H}$, and let f be complex-differentiable at γz. Then*

$$(f')|_{k+2}\gamma\,(z) \;=\; \frac{d}{dz}(f|_k\gamma)(z) \;+\; \frac{k\,c}{cz+d}\,(f|_k\gamma)(z).$$

File `VOA/Modularity/SerreDerivative.lean`.

```
theorem slashC_deriv_eq (k : ℤ) (γ : SL(2, ℤ)) (f : ℂ → ℂ) {z : ℂ} (hz : z ∈ imGT 0)
    (hf : DifferentiableAt ℂ f (mobiusC γ z)) :
    slashC (k + 2) γ (_root_.deriv f) z
      = _root_.deriv (slashC k γ f) z
        + (k : ℂ) * (γ 1 0 : ℂ) * (denomC γ z)⁻¹ * slashC k γ f z
```

From the mathematics to the Lean statement

`_root_.deriv f` is Mathlib's complex derivative f' (the prefix `_root_` only disambiguates the name). The hypothesis `hf` is needed: `deriv` of a non-differentiable function is 0 by convention, and the identity would then fail. Only differentiability at the single point γz is required. Same as the textbook identity.

Proof. Chain rule: $\frac{d}{dz}[f(\gamma z)(cz+d)^{-k}] = f'(\gamma z)(cz+d)^{-2}(cz+d)^{-k} - kc\,f(\gamma z)(cz+d)^{-k-1}$, using $\frac{d}{dz}\gamma z = (cz+d)^{-2}$. Rearranging gives the claim.

Physical meaning

The anomalous term $kc/(cz+d)$ is why the naive τ-derivative of a modular form of weight k is *not* modular of weight $k+2$. In CFT it is the reason that inserting the stress tensor $T(z)$ (the field of ω, whose torus zero mode $L_{[0]}$ is what ∂_τ inserts into the trace) produces a non-covariant term; it is cured by the quasi-modular E_2, Theorem 14.4.

What the machine verified

Unconditional (beyond the stated differentiability). `#print axioms`: the standard three.

Definition 14.3 (G_2 in the $\mathbb{C}$ picture). $G_2^{\mathbb{C}}(z) = G_2(z)$ for $z \in \mathbb{H}$, where $G_2 = \sum_c {\sum_d}'(cz+d)^{-2}$ is Mathlib's (Eisenstein-summed) weight-two Eisenstein series, $G_2 = 2\zeta(2)E_2 = \frac{\pi^2}{3}(1 - 24\sum \sigma_1(n)q^n)$.

File `VOA/Modularity/SerreDerivative.lean`.

```
noncomputable def G2C (z : ℂ) : ℂ := EisensteinSeries.G2 (UpperHalfPlane.ofComplex z)
```

From the mathematics to the Lean statement

`UpperHalfPlane.ofComplex` is Mathlib's retraction $\mathbb{C} \to \mathbb{H}$, the identity on $\mathbb{H}$ and an arbitrary point elsewhere; so `G2C` is G_2 on $\mathbb{H}$ and junk outside (`G2C_coe` records the agreement on $\mathbb{H}$).

Physical meaning

G_2 (equivalently E_2) is the torus one-point function of the stress tensor, up to normalisation; see the physics box of Theorem 14.4.

Theorem 14.4 (Quasimodularity of G_2; Mathlib's `G2_slash_action`). *For $\gamma \in \mathrm{SL}_2(\mathbb{Z})$ and $z \in \mathbb{H}$:* $(G_2|_2\gamma)(z) = G_2(z) - \dfrac{2\pi i\, c}{cz+d}$.

File `VOA/Modularity/SerreDerivative.lean`.

```
theorem slashC_G2C (γ : SL(2, ℤ)) {z : ℂ} (hz : z ∈ imGT 0) :
    slashC 2 γ G2C z
      = G2C z - 2 * (Real.pi : ℂ) * Complex.I * (γ 1 0 : ℂ) * (denomC γ z)⁻¹
```

From the mathematics to the Lean statement

A transcription of Mathlib's `EisensteinSeries.G2_slash_action`, $G_2|_2\gamma = G_2 - D_2(\gamma)$ with $D_2(\gamma)(z) = 2\pi ic/(cz+d)$, into the $\mathbb{C}$ picture. Not reproved: Mathlib supplies it. Exactly the classical law (Zagier, *Elliptic modular forms*, eq. (17)).

Proof. Mathlib. Classically: G_2 is defined by an iterated, conditionally convergent sum; exchanging the order of summation under $\tau \mapsto -1/\tau$ produces the defect $2\pi i/\tau$, computed by Hecke's trick $G_2 = \lim_{s\to 0} \sum (m\tau+n)^{-2}|m\tau+n|^{-s}$.

Physical meaning

E_2 is, up to normalisation, the torus one-point function of the stress tensor in the vacuum of a theory with no states but the vacuum descendants of the identity: $\langle T\rangle_{\text{torus}} \propto \partial_\tau \log \eta$, and $\eta(\tau)^{24} = \Delta$ has weight 12, so $\partial_\tau \log \eta = \frac{2\pi i}{24} E_2$ fails to be modular exactly by the anomaly of Theorem 14.2. The defect $2\pi ic/(cz+d)$ is the conformal anomaly of the stress tensor on the torus.

What the machine verified

Unconditional. Standard axioms.

14.3 Eisenstein series in Zhu's normalisation

Zhu's recursion (Chapter 15) produces, from traces of modes, the coefficients of a specific normalisation of the Eisenstein series, which we call $\mathcal{G}_{2j}$; it is *neither* E_{2j} (constant term 1) nor the lattice sum $G_{2j} = 2\zeta(2j)E_{2j}$. Getting this normalisation wrong is, as the library itself warns, the most likely failure mode of the whole modularity development, so we are careful.

Definition 14.5 (Zhu's Eisenstein coefficients). For $j \in \mathbb{N}$ let $g_j : \mathbb{N} \to \mathbb{C}$ be

$$g_j(0) = -\frac{B_{2j}}{(2j)!}, \qquad g_j(m) = \frac{2}{(2j-1)!}\,\sigma_{2j-1}(m) \quad (m \geq 1),$$

and $\mathcal{G}_{2j} = \sum_{m\geq 0} g_j(m) q^m$.

File `VOA/Modularity/ZhuNormalization.lean` (a Chapter 15 file, quoted here).

```
noncomputable def zhuG (j : ℕ) : ℕ → ℂ :=
  fun m =>
    if m = 0 then -(((bernoulli (2 * j) : ℚ) : ℂ) / (Nat.factorial (2 * j) : ℂ))
    else (2 / (Nat.factorial (2 * j - 1) : ℂ)) * lambertCoeff (2 * j - 1) m
```

From the mathematics to the Lean statement

`bernoulli n` is Mathlib's B_n (a rational number, cast to $\mathbb{C}$), with the convention $B_1 = -\frac{1}{2}$ (irrelevant here, only even indices occur). `lambertCoeff (2j-1) m` is $\sigma_{2j-1}(m)$ by `lambertCoeff_eq_sigma` (Chapter 33, Theorem 33.7). Natural-number subtraction `2 * j - 1` is truncated at 0; it is only used for $j \geq 1$. At $j = 0$ the definition is meaningless junk ($g_0(0) = -B_0 = -1$) and is never used. **Normalisation check.** With $E_{2j} = 1 - \frac{4j}{B_{2j}} \sum \sigma_{2j-1}(m) q^m$ one has $g_j(0) E_{2j} = -\frac{B_{2j}}{(2j)!} + \frac{4j}{(2j)!} \sum \sigma_{2j-1} q^m$, and $\frac{4j}{(2j)!} = \frac{2}{(2j-1)!}$; so $\mathcal{G}_{2j} = g_j(0)\, E_{2j}$ (proved analytically, Theorem 14.8). Equivalently, $\mathcal{G}_{2j} = G_{2j}/(2\pi i)^{2j}$ with G_{2j} the lattice sum: Zhu's $G_{2k}(\tau)$ in J. AMS 9 (1996), §3. The library records (in `ZhuNormalization.lean`) that the alternatives "constant term 1" and "constant term 0" are refuted by the Heisenberg computation.

Physical meaning

In Zhu's derivation the Eisenstein series arise as $\sum_{m \neq 0} m^{2j-1} q^m/(1-q^m)$-type sums from moving a mode $a_{(n)}$ once around the torus: each passage around the time circle costs q^n, and summing the geometric series over the winding produces Lambert series. The constant term $-B_{2j}/(2j)!$ comes from the zero-winding ("plane") contribution and is the Taylor coefficient of z^{2j} in the Weierstrass-type function $\wp$ on the cylinder. A heuristic gloss on a definition.

The library also contains a second, older formal family in the normalisation E_k:
File `VOA/Modularity/EisensteinFormal.lean`.

```
noncomputable def eisensteinCoeff (k : ℕ) (m : ℕ) : ℂ :=
  if m = 0 then 1
  else -(2 * (k : ℂ) / ((bernoulli k : ℚ) : ℂ))
        * ((ArithmeticFunction.sigma (k - 1) m : ℕ) : ℂ)

noncomputable def zhuEisenstein (j : ℕ) : ℕ → ℂ := eisensteinCoeff (2 * j)

def ZhuRecursionEisenstein (N : OrdVModule W M) (a v : V) (ka : ℕ) : Prop :=
  ZhuRecursionAt N zhuEisenstein a v ka
```

From the mathematics to the Lean statement

`eisensteinCoeff k m` is the m-th coefficient of $E_k = 1 - \frac{2k}{B_k} \sum \sigma_{k-1}(m) q^m$, exactly Mathlib's formula `EisensteinSeries.E_qExpansion_coeff`; and `zhuEisenstein j` $= E_{2j}$. `ZhuRecursionEisenstein` instantiates Zhu's recursion (`ZhuRecursionAt`, Chapter 15) at this family. It is a `Prop`, never proved.

Trap / dead end

Superseded normalisation; stale docstring (documentation only). The recursion that the library proves (Chapter 15) uses `zhuG`, not `zhuEisenstein`; since $g_j(0) \neq 1$, `ZhuRecursionEisenstein` is the recursion with the *wrong* normalisation and would be false. It has no consumer. The module docstring of `EisensteinFormal.lean` still says that the link to Mathlib's E_k is "deferred" and that the normalisation is unsettled; both were settled

(EisensteinAnalytic.lean, QExpansionBridge.lean, ZhuNormalization.lean).

Theorem 14.6 ($B_{2j} \neq 0$). *For every $j \geq 1$, $B_{2j} \neq 0$.*

File VOA/Modularity/EisensteinAnalytic.lean.

```
theorem bernoulli_two_mul_ne_zero {j : ℕ} (hj : j ≠ 0) :
    ((bernoulli (2 * j) : ℚ) : ℂ) ≠ 0
```

Proof. Euler: $\zeta(2j) = (-1)^{j+1}\frac{(2\pi)^{2j}B_{2j}}{2(2j)!}$ (Mathlib riemannZeta_two_mul_nat), and $\zeta(s) \neq 0$ for $\mathrm{Re}\, s > 1$ (Euler product; Mathlib riemannZeta_ne_zero_of_one_lt_re).

Physical meaning

A purely arithmetic lemma; it ensures $g_j(0) \neq 0$, i.e. that Zhu's Eisenstein functions have a nonzero value at the cusp, which is needed when the cusp is used as a reference point (Section 14.12).

What the machine verified

Unconditional. Standard axioms. It discharges a hypothesis that ZhuNormalization.lean once carried.

Definition 14.7 (Zhu's Eisenstein function). For $j \in \mathbb{N}$ and $z \in \mathbb{C}$, $\mathcal{G}_{2j}(z) = \sum_{n\geq 0} g_j(n)\, e^{2\pi i n z}$; and $q_{\mathbb{C}}(z) = e^{2\pi i z}$.

File VOA/Modularity/EisensteinAnalytic.lean.

```
noncomputable def qC (z : ℂ) : ℂ := Complex.exp (2 * (Real.pi : ℂ) * Complex.I * z)

noncomputable def zhuGC (j : ℕ) (z : ℂ) : ℂ :=
  ∑' n : ℕ, zhuG j n * Complex.exp (2 * (Real.pi : ℂ) * Complex.I * (n : ℂ) * z)
```

From the mathematics to the Lean statement

A tsum: junk where the series diverges. On $\mathbb{H}$ it converges absolutely (summable_norm_zhuG_qexp, from $|g_j(n)| \leq |g_j(0)| + Cn^{2j}$ and $|q| < 1$), so on $\mathbb{H}$ it is the honest sum.

Physical meaning

$\mathcal{G}_{2j}(\tau)$ is the Eisenstein coefficient of the genus-one Ward identity evaluated on an actual torus of modulus τ, rather than as a formal series.

Theorem 14.8 (Identification with Mathlib's Eisenstein series). *For $j \geq 2$ and $z \in \mathbb{H}$, $\mathcal{G}_{2j}(z) = g_j(0)\, E_{2j}(z)$, where E_{2j} is Mathlib's normalised Eisenstein modular form of weight $2j$. Consequently, for all $\gamma \in \mathrm{SL}_2(\mathbb{Z})$, $\mathcal{G}_{2j}|_{2j}\gamma = \mathcal{G}_{2j}$ on $\mathbb{H}$. (Note $g_j(0) = -B_{2j}/(2j)! \neq 1$: Zhu's $\mathcal{G}_{2j}$ is* not *E_{2j}, but a nonzero constant multiple of it.)*

File VOA/Modularity/EisensteinAnalytic.lean.

```
theorem zhuGC_eq_mul_E {j : ℕ} (hj : 2 ≤ j) {z : ℂ} (hz : z ∈ imGT 0) :
    zhuGC j z = zhuG j 0 * ModularForm.E (show 3 ≤ 2 * j by omega) (⟨z, hz⟩ :
     ↪ UpperHalfPlane)

theorem slashC_zhuGC {j : ℕ} (hj : 2 ≤ j) (γ : SL(2, ℤ)) {z : ℂ} (hz : z ∈ imGT 0) :
    slashC (2 * j : ℤ) γ (zhuGC j) z = zhuGC j z
```

From the mathematics to the Lean statement

`ModularForm.E h` is Mathlib's normalised Eisenstein series of weight k, needing a proof `h : 3 ≤ k`, here supplied inline by `omega`. `⟨z, hz⟩ : UpperHalfPlane` packages z with the proof that $\operatorname{Im} z > 0$. The hypothesis $j \geq 2$ is genuine: at $j = 1$ there is no weight-two modular form, and the correct statement is Theorem 14.9. So these are exactly the textbook statements, with Mathlib's E_{2j} used, not reproved.

Proof. Mathlib's `q_expansion_bernoulli` gives $E_{2j} = 1 - \frac{4j}{B_{2j}} \sum_{n\geq 1} \sigma_{2j-1}(n) q^n$ on $\mathbb{H}$; multiply by $g_j(0)$ and use $\frac{4j}{(2j)!} = \frac{2}{(2j-1)!}$. Modularity then follows from that of E_{2j} (Mathlib's `slash_action_eqn`).

Physical meaning

For $j \geq 2$ the coefficients that appear in Zhu's genus-one recursion are honest modular forms. This is what makes the recursion $\mathrm{SL}_2(\mathbb{Z})$-covariant: the torus Ward identities have modular coefficients, so the space of solutions (the conformal blocks on the torus) is a representation of the mapping class group.

What the machine verified

Unconditional. Standard axioms (both).

Theorem 14.9 (The anomalous weight $j = 1$). *For $z \in \mathbb{H}$: $\sum_{n\geq 0} g_1(n) q^n = -E_2(z)/12$, and $\mathcal{G}_2(z) = (2\pi i)^{-2} G_2(z)$.*

File `VOA/Modularity/EisensteinBridge.lean`.

```
theorem zhuG_one_eq_neg_E2_div_twelve (z : ℍ) :
    zhuG 1 0 + ∑' n : ℕ+, zhuG 1 n * (qParam z) ^ (n : ℕ) = -(E2 z) / 12
```

File `VOA/Modularity/EisensteinAnalytic.lean`.

```
theorem zhuGC_one {z : ℂ} (hz : z ∈ imGT 0) :
    zhuGC 1 z = ((2 * (Real.pi : ℂ) * Complex.I)⁻¹) ^ 2 * G2C z
```

From the mathematics to the Lean statement

`ℕ+` is the type of positive integers, so the `tsum` runs over $n \geq 1$. `qParam z` $= e^{2\pi i z}$ (Definition 14.21). `E2` is Mathlib's E_2. Arithmetic check: $g_1(0) = -B_2/2! = -\frac{1}{12}$ and $g_1(n) = 2\sigma_1(n)$, so the left side is $-\frac{1}{12}(1 - 24\sum \sigma_1 q^n)$. And $(2\pi i)^{-2} G_2 = -\frac{1}{4\pi^2} \cdot \frac{\pi^2}{3} E_2 = -E_2/12$. The `tsum` converges (Mathlib's `E2_eq_tsum_cexp` is proved for the convergent series), so there is no junk-value issue. Same as textbook.

Physical meaning

The weight-two term of Zhu's recursion is the only non-modular one, and it is exactly E_2: this is the torus conformal anomaly again (Theorem 14.4). In Zhu's argument it is absorbed into the Serre derivative (Section 14.8): the $L_{[0]}$-insertion on the torus is $q\frac{d}{dq}$ plus an E_2 correction.

What the machine verified

Unconditional. Standard axioms.

Theorem 14.10 (Values at the cusp). *(i) Every modular form f (for a subgroup with the cusp ∞) satisfies $f(\tau) \to f(\infty)$ as $\operatorname{Im}\tau \to \infty$. (ii) $E_k(\infty) = 1$ for even $k \geq 3$. (iii) $\mathcal{G}_{2j}(\tau) \to g_j(0)$ as $\operatorname{Im}\tau \to \infty$, for $j \geq 2$.*

File `VOA/Modularity/EisensteinCuspLimit.lean`.

```
theorem valueAtInfty_E {k : ℕ} (hk : 3 ≤ k) (hk2 : Even k) :
    valueAtInfty (fun τ : UpperHalfPlane => ModularForm.E hk τ) = 1

theorem tendsto_zhuGC_atImInfty {j : ℕ} (hj : 2 ≤ j) :
    Tendsto (fun τ : UpperHalfPlane => zhuGC j (τ : ℂ)) atImInfty (𝓝 (zhuG j 0))
```

From the mathematics to the Lean statement

`Tendsto f atImInfty (𝓝 L)` is "$f(\tau) \to L$ as $\operatorname{Im}\tau \to \infty$" in Mathlib's filter language (Chapter 1); `valueAtInfty f` is Mathlib's name for that limit (a `limUnder`, junk if the limit does not exist). Statement (i) is `tendsto_modularForm_atImInfty`, stated for any `ModularFormClass` over a subgroup Γ of $\mathrm{GL}_2(\mathbb{R})$ with ∞ a cusp and determinant ± 1 (type-class hypotheses, all satisfied by $\mathrm{SL}_2(\mathbb{Z})$). Same as textbook.

Proof. (i) Mathlib's `exp_decay_sub_atImInfty'`: $f - f(\infty) = O(e^{-c\operatorname{Im}\tau})$. (ii) The constant term of the q-expansion of E_k is 1 and equals $f(\infty)$ (`qExpansion_coeff_zero`). (iii) From (i), (ii) and Theorem 14.8.

Physical meaning

$\operatorname{Im}\tau \to \infty$ is the limit of a very long torus: the time circle is infinitely long, so only the ground state propagates ("$q \to 0$ projects onto the vacuum"). The cusp values of the Eisenstein coefficients therefore describe Zhu's recursion on the infinite cylinder, i.e. the algebra of zero modes on the ground states; Section 14.12 makes this precise.

What the machine verified

Unconditional. Standard axioms.

14.4 The level-one structure theorem

14.4.1 The algebra generated by E_4 and E_6

Definition 14.11 ($\mathcal{E}_{46}$). $\mathcal{E}_{46}$ is the $\mathbb{C}$-subalgebra of the algebra of all functions $\mathbb{H} \to \mathbb{C}$ (pointwise operations) generated by E_4 and E_6; its elements are the functions $P(E_4, E_6)$ for $P \in \mathbb{C}[X, Y]$ *not necessarily homogeneous.*

File `VOA/Modularity/LevelOneStructure.lean`.

```
noncomputable def E46 : Subalgebra ℂ (UpperHalfPlane → ℂ) :=
  Algebra.adjoin ℂ {(↑ModularForm.E₄ : UpperHalfPlane → ℂ), (↑ModularForm.E₆ :
    ↪ UpperHalfPlane → ℂ)}
```

From the mathematics to the Lean statement

`Algebra.adjoin ℂ s` is the smallest $\mathbb{C}$-subalgebra containing the set s; `↑F` is the underlying function of a bundled modular form. So `E46` is a set of functions, not a graded ring: a sum $E_4 + E_6$ of different weights is an element. This is a deliberate simplification ("no graded-ring plumbing"), and costs nothing for the use in Chapter 15, which needs only finite generation. It is *not* Mathlib's graded ring `ModularForm.ring`.

Physical meaning

$\mathcal{E}_{46}$ is the ring in which the coefficients of modular linear differential equations live (Mathur–Mukhi–Sen): every torus amplitude of a rational CFT satisfies an ODE in τ whose coefficients are polynomials in E_4, E_6.

Theorem 14.12 (Every level-one modular form is a polynomial in E_4, E_6). *For every $k \in \mathbb{Z}$ and every $f \in M_k(\mathrm{SL}_2(\mathbb{Z}))$, the function f lies in $\mathcal{E}_{46}$. In particular $E_k \in \mathcal{E}_{46}$ for $k \geq 3$ and $\mathcal{G}_{2j} \in \mathcal{E}_{46}$ for $j \geq 2$.*

File `VOA/Modularity/LevelOneStructure.lean`.

```
theorem levelOne_coe_mem_E46 : ∀ (k : ℤ) (f : ModularForm 𝒮ℒ k),
    (↑f : UpperHalfPlane → ℂ) ∈ E46

theorem E_mem_E46 {k : ℕ} (hk : 3 ≤ k) :
    (↑(ModularForm.E hk) : UpperHalfPlane → ℂ) ∈ E46

theorem zhuGC_mem_E46 {j : ℕ} (hj : 2 ≤ j) :
    (fun z : UpperHalfPlane => zhuGC j (z : ℂ)) ∈ E46
```

From the mathematics to the Lean statement

`ModularForm 𝒮ℒ k` is Mathlib's space M_k of holomorphic level-one modular forms of weight k, holomorphic at the cusp (Chapter 33, Definition 33.1). No hypotheses. **Weaker than the textbook statement.** The textbook "$M_* = \mathbb{C}[E_4, E_6]$" has three parts: (a) generation, (b) homogeneity (a weight-k form is a combination of $E_4^a E_6^b$ with $4a + 6b = k$), (c) algebraic independence of E_4, E_6. `levelOne_coe_mem_E46` is (a) only. Parts (b) and (c) are *true and proved in the library*, but in a different file: the vendored `ModularForm.levelOne_eq_polynomial` in `VOA/LatticesAndCodes/ModularForms/LevelOne.lean` (Chapter 30) gives, for even $k \geq 0$, a basis of M_k consisting of the monomials $E_4^a E_6^b$, $4a + 6b = k$. The docstring's name "structure theorem" should be read as "generation". *Could it be vacuous?* No: $\mathcal{E}_{46}$ is a proper subalgebra of all functions, and membership is a genuine statement.

Proof (Serre's induction). Negative and odd weights: $M_k = 0$ (Mathlib). $k = 0$: constants. $k = 2$: $M_2 = 0$ (Mathlib). For even $k \geq 4$ pick a monomial $F = E_4^a E_6^b$ of weight k; it tends to 1 at the cusp (`exists_unit_modularForm`, by induction on k in steps of 4, from $E_4, E_6 \to 1$). Put $c = f(\infty)$. Then $f - cF$ has q-expansion with zero constant term, so it is a cusp form; Mathlib's isomorphism `CuspForm.discriminantEquiv` : $S_k \cong M_{k-12}$ divides it by Δ, and $f = cF + \Delta \cdot g$ with $g \in M_{k-12}$. By induction $g \in \mathcal{E}_{46}$; and $\Delta = (E_4^3 - E_6^2)/1728 \in \mathcal{E}_{46}$ (Mathlib's `discriminant_eq_E₄_cube_sub_E₆_sq`). For $\mathcal{G}_{2j}$ use Theorem 14.8.

Physical meaning

The heuristic content (Chapter 33): modular covariant partition functions have very little freedom; any weight-k modular object is fixed by finitely many leading q-coefficients. Here it is used for a structural reason: the coefficients of Zhu's genus-one relations lie in a *finitely generated, Noetherian* ring, so the relation module is finitely generated and dimension counts are possible (Chapter 15).

What the machine verified

Unconditional. `#print axioms levelOne_coe_mem_E46, zhuGC_mem_E46`: the standard three (run for this chapter). Mathlib's dimension formula and Δ-division are used, not reproved.

Trap / dead end

Duplicate development (documentation only). The library proves level-one generation twice: once here (non-homogeneous, functions) and once, with homogeneity and independence, in the vendored `LatticesAndCodes/ModularForms/LevelOne.lean` (`span_eisBasisFun`, `levelOne_eq_polynomial`). Neither file mentions the other. The stronger vendored theorem discharges the predicate below that `EisensteinRamanujan.lean` used to record as "missing" (Theorem 14.15; now the library theorem `e46HasWeightedPolynomialReps`).

14.4.2 Weights inside $\mathcal{E}_{46}$, and the Ramanujan boundary

Because $\mathcal{E}_{46}$ is not graded, the library adds a weight predicate. We separate what is *defined and used* (the weight predicate and homogeneous representatives, Definition 14.13) from three *named propositions* (Definition 14.14), all three now theorems of the library.

The Serre derivative, in advance. Serre closure involves the *Serre derivative*, studied in Section 14.8 (Definition 14.34). For the reader's convenience we give it now: for $k \in \mathbb{Z}$ and $f : \mathbb{C} \to \mathbb{C}$,

$$\partial_k f \;=\; \frac{1}{2\pi i} f' + \frac{k}{(2\pi i)^2}\, G_2\, f \;=\; q\frac{df}{dq} - \frac{k}{12} E_2 f \qquad \text{on } \mathbb{H},$$

with G_2 the weight-two Eisenstein series of Definition 14.3 ($G_2 = \frac{\pi^2}{3} E_2$). The point of the correction term is that ∂_k commutes with slashing (weight k in, weight $k+2$ out), which the plain derivative does not (Theorem 14.2); this equivariance is proved in Theorem 14.35. In Lean it is `serreDerivC k f z`.

Definition 14.13 (Weighted elements; homogeneous representatives). For $f \in \mathcal{E}_{46}$ and $k \in \mathbb{Z}$: *f has weight k* if f is (the function of) some $F \in M_k$. *f has a homogeneous polynomial representative of weight k* if $f = \sum_{(a,b)\in t} c_{ab} E_4^a E_6^b$ for a finite set t of pairs with $4a + 6b = k$.

```

From the mathematics to the Lean statement

`e46C f` extends f from $\mathbb{H}$ to $\mathbb{C}$ through Mathlib's retraction `ofComplex`; only its values on `imGT 0` matter, and all equalities below are restricted there. `E46Weight k f` is an existential over modular forms: it retains holomorphy at the cusp, so it is the right notion of "coefficient of weight k". These are predicates about a given f; they assert nothing by themselves.

Physical meaning

A weight-k element is a candidate coefficient of a modular linear differential equation: the coefficient of ∂^{n-r} in an order-n MLDE must be a weight-$2r$ modular form.

What the machine verified

Definitions. Proved closure properties: `E46Weight` is closed under $+, -, \cdot$, scalars and finite sums (`E46Weight.add`, …, `E46Weight.sum`); $E_4^a E_6^b$ has weight $4a + 6b$ (`e46Monomial_weight`). Standard axioms.

Definition 14.14 (Three named propositions: homogeneous representatives, monomial and full Serre closure)**.** (a) *Homogeneous representatives*: every $f \in \mathcal{E}_{46}$ of weight k has a homogeneous polynomial representative of weight k. (b) *Monomial Serre closure*: for all a, b, $\partial_{4a+6b}(E_4^a E_6^b)$ equals on $\mathbb{H}$ an element of $\mathcal{E}_{46}$ of weight $4a + 6b + 2$. (c) *Serre closure*: for every f of weight k there is $g \in \mathcal{E}_{46}$ of weight $k + 2$ with $g = \partial_k f$ on $\mathbb{H}$.

      ∀ z ∈ imGT 0, e46C g z = serreDerivC k (e46C f) z
```

From the mathematics to the Lean statement

Each is a `def … : Prop`, i.e. a *statement*; all three are proved separately (status box below). (c) is the classical fact $\partial_k M_k \subseteq M_{k+2}$. **Equivariance is not closure.** Theorem 14.35 (proved) shows that $\partial_k f$ transforms with weight $k + 2$; what it does not give is that $\partial_k f$ is *holomorphic at the cusp* with a q-expansion, i.e. is again in M_{k+2}, nor that it lies in $\mathcal{E}_{46}$; that extra content (classically: Ramanujan's identities plus the structure theorem) is exactly (b)/(c). The library proves the aggregation step `e46SerreClosed_of_weightedPolynomialReps : E46HasWeightedPolynomialReps → E46SerreMonomialClosed → E46SerreClosed`. Mathlib (`NumberTheory/ModularForms/Derivative.lean`) defines its own `serreDerivative` on $\mathbb{H} \to \mathbb{C}$ with the same normalisation ($DF - \frac{k}{12} E_2 F$) but proves no modularity-preservation theorem for it.

Physical meaning

Serre closure is the statement that the ring of modular forms is closed under the covariant derivative of the torus moduli space. Physically it is what makes a modular linear differential equation (MLDE) $[\partial^n + \phi_4 \partial^{n-2} + \cdots]\chi = 0$ meaningful: each ∂ raises the weight by 2 and the coefficient ϕ_{2r} must be a weight-$2r$ modular form. The monomial case is Ramanujan's identities $\partial_4 E_4 = -\frac{1}{3} E_6$, $\partial_6 E_6 = -\frac{1}{2} E_4^2$.

What the machine verified

Status of the three propositions.

- (a) `E46HasWeightedPolynomialReps`: **proved** in the library (`e46HasWeightedPolynomialReps`, from the argument of Theorem 14.15).
- (b) `E46SerreMonomialClosed`: **proved** (`e46SerreMonomialClosed`, the monomial case of (c)).
- (c) `E46SerreClosed`: **proved** (`e46SerreClosed`). The proof does not go through Ramanujan's identities: `serreForm` packages $\partial_n F$, for F a level-one form of weight n, as a level-one form of weight $n+2$ (holomorphy on $\mathbb{H}$ and boundedness at $i\infty$ from the q-expansion, the weight-$(n+2)$ law from Theorem 14.35), and `levelOne_coe_mem_E46` places it in $\mathcal{E}_{46}$. The reduction `e46SerreClosed_of_weightedPolynomialReps` gives a second proof (`e46SerreClosed'`). The hypothesis `hclose` of the Arakawa–Kawasetsu MLDE of Chapter 16 is thereby discharged. (`VOA/Modularity/EisensteinSerreClosure.lean`; not compiled for this chapter.)

Theorem 14.15 (Homogeneous representatives exist)**.** *Every $f \in \mathcal{E}_{46}$ of weight k is a linear combination of monomials $E_4^a E_6^b$ with $4a+6b=k$; that is,* `E46HasWeightedPolynomialReps` *holds.*

File `VOA/Modularity/EisensteinSerreClosure.lean`.

```
theorem e46HasWeightedPolynomialReps : E46HasWeightedPolynomialReps
```

Proof. If $k<0$, $F=0$. If $k=n\geq 0$, the vendored `ModularForm.span_eisBasisFun n` says the weight-n monomials span M_n; write F as a finite combination, push it through the linear coercion `coeLm`, and read the result as an identity in $\mathcal{E}_{46}$. (Odd n: the index set `wtIdx n` is empty and $F=0$.)

Physical meaning

Arithmetic bookkeeping: the statement that "a weight-k coefficient is a homogeneous polynomial". It reduces Serre closure to Ramanujan's two identities.

What the machine verified

First compiled for this chapter as a separate check with `lake env lean -DmaxSynthPendingDepth=3` at an earlier commit (not re-run for this edition): no errors, no `sorry`. The library has since adopted this proof as `e46HasWeightedPolynomialReps` (`EisensteinSerreClosure.lean`), and the docstring of `E46HasWeightedPolynomialReps`, which used to call it missing, now points to it.

14.4.3 Points of $\mathcal{E}_{46}$: the cusp and the interior

The *cusp* is the boundary point $\tau = i\infty$ of $\mathbb{H}$ (the one point added to $\mathrm{SL}_2(\mathbb{Z})\backslash\mathbb{H}$ to compactify it, Chapter 33). Approaching it means $\operatorname{Im}\tau\to\infty$, i.e. $q\to 0$. Geometrically the torus degenerates: its time circle becomes infinitely long, the torus becomes a cylinder, and in a trace only the ground states survive. Every element of $\mathcal{E}_{46}$ has a limit there, so the cusp behaves like a point of $\mathcal{E}_{46}$ on the same footing as the interior points.

Definition 14.16 (Evaluation at the cusp and at interior points)**.** $\mathrm{ev}_\infty : \mathcal{E}_{46}\to\mathbb{C}$, $f\mapsto \lim_{\operatorname{Im}\tau\to\infty} f(\tau)$, and for $z_0\in\mathbb{H}$, $\mathrm{ev}_{z_0}:\mathcal{E}_{46}\to\mathbb{C}$, $f\mapsto f(z_0)$. Both are $\mathbb{C}$-algebra homomorphisms.

  commutes' _ := rfl

theorem ker_isMaximal (φ : E46 →ₐ[ℂ] ℂ) :
    (RingHom.ker (φ : E46 →+* ℂ)).IsMaximal
```

From the mathematics to the Lean statement

`evInfty : E46 →ₐ[ℂ] ℂ` (same file `CuspPoint.lean`) is `valueAtInfty`, shown to be an algebra hom because $\mathcal{E}_{46} \le$ `cuspLimSubalg` (`E46_le_cuspLimSubalg`: E_4, E_6 have cusp limits, and limits respect $+$ and $\cdot$). `→ₐ[ℂ]` is "$\mathbb{C}$-algebra homomorphism". `ker_isMaximal`: the kernel of any such hom is a maximal ideal (residue field $\mathbb{C}$). `evInfty_zhuGC`: $\mathrm{ev}_\infty(\mathcal{G}_{2j}) = g_j(0)$. Statements are exactly the textbook ones. They are infrastructure: no theorem in this chapter compares the two fibres (that is the open "flatness" residual of Chapter 15).

Physical meaning

The two kinds of points are two geometries of the torus: an interior point z_0 is a torus of fixed shape, the cusp is the degenerate torus (a pinched cycle = an infinitely long cylinder). Conformal blocks over the family of tori form a sheaf over the (E_4, E_6)-plane; its fibre at the cusp is computed algebraically from $A(V)$ (Section 14.12), and transporting the dimension to an interior point is the statement that the number of torus blocks does not jump.

What the machine verified

Unconditional, standard axioms (`evInfty_zhuGC`, `ker_evAt_isMaximal`).

Theorem 14.17 (No fibre of $\mathbb{C}[[q]]$ at $q_0 \neq 0$). *There is no $\mathbb{C}$-algebra homomorphism $\varphi : \mathbb{C}[[q]] \to \mathbb{C}$ with $\varphi(q) \neq 0$.*

File `VOA/Modularity/FormalSpecialization.lean`.

```
theorem no_algHom_powerSeries_X_ne_zero (φ : PowerSeries ℂ →ₐ[ℂ] ℂ) {q₀ : ℂ} (hq : q₀ ≠ 0)
↪  :
    φ PowerSeries.X ≠ q₀
```

Proof. $1 - q_0^{-1}q$ has constant term 1, hence is a unit of $\mathbb{C}[[q]]$; φ would send it to $1 - q_0^{-1}q_0 = 0$, which is not a unit.

From the mathematics to the Lean statement

Exactly the stated fact. It is recorded as a *dead end*: a purely formal argument over $\mathbb{C}[[q]]$ can only reach the special fibre $q = 0$ and the generic fibre $\mathbb{C}((q))$, never a genuine torus $0 < |q| < 1$. This is why the library moved its coefficient ring from $\mathbb{C}[[q]]$ to the function algebra $\mathcal{E}_{46}$, where evaluation at z_0 *is* a homomorphism.

Physical meaning

Formal power series know only infinitesimally long tori. A physical statement about a torus of finite size needs convergence, i.e. analysis. The theorem is the algebraic shadow of that fact.

What the machine verified

Unconditional. Standard axioms.

14.5 From formal q-series to holomorphic functions

14.5.1 Subexponential growth and summability

Definition 14.18 (Subexponential sequence). A real sequence $(a_n)_{n\in\mathbb{N}}$ is *subexponential* if for every $r > 1$ there is C with $a_n \le Cr^n$ for all n.

File `VOA/Modularity/ConvergenceBridge.lean`.

```
def Subexponential (a : ℕ → ℝ) : Prop :=
  ∀ r : ℝ, 1 < r → ∃ C : ℝ, ∀ n : ℕ, a n ≤ C * r ^ n
```

From the mathematics to the Lean statement

Quantifiers: $\forall r > 1\ \exists C\ \forall n$; C depends on r. This is an upper bound only (no absolute value); it is always applied to $a_n = \|\chi(h+n)\| \ge 0$. Equivalent to $\limsup a_n^{1/n} \le 1$ for nonnegative a, i.e. to the power series $\sum a_n x^n$ having radius of convergence ≥ 1. So it is exactly the condition for convergence on the whole disc $|q| < 1$, the right condition for a character.

Physical meaning

The degeneracies of a CFT grow like $\dim V_n \sim \exp(2\pi\sqrt{c_{\text{eff}} n/6})$ (Cardy's formula, derived from the S-transformation: the high-temperature behaviour of $Z(\tau)$ is controlled by the vacuum in the dual channel). That growth is subexponential: $e^{a\sqrt{n}} \le C_r r^n$ for every $r > 1$ (`subexponential_exp_sqrt`). Subexponentiality is the weakest growth condition that makes the partition function a well-defined function on all of $\mathbb{H}$; Cardy growth is much stronger.

Theorem 14.19 (Closure properties). *Subexponential sequences are closed under domination, nonnegative scalar multiples, addition, finite sums, polynomial factors n^p, index shifts in both directions, and Cauchy products (for complex sequences, in absolute value); constants and $e^{c\sqrt{n}}$ are subexponential. The subexponential formal power series form a $\mathbb{C}$-subalgebra $\mathcal{S}$ of $\mathbb{C}[[q]]$, stable under $\theta = q\frac{d}{dq}$.*

```

File `VOA/Modularity/QDerivProductRule.lean`.

```
noncomputable def theta (F : PowerSeries ℂ) : PowerSeries ℂ :=
  PowerSeries.mk fun n => (n : ℂ) * PowerSeries.coeff n F

theorem theta_mem_subexpPS {F : PowerSeries ℂ} (hF : F ∈ SubexpPS) : theta F ∈ SubexpPS
```

From the mathematics to the Lean statement

$\|\cdot\|$ is the complex absolute value. `Finset.range (n+1)` is $\{0, \dots, n\}$, so the Cauchy-product sum is $\sum_{m \le n} a_m b_{n-m}$. The quoted part of `SubexpPS` is its carrier; the closure fields (`mul_mem'` etc.) are proved from `subexponential_cauchy`. `Subexponential.mul_pow` needs $a \ge 0$ (otherwise the inequality could be reversed by a negative factor). All statements are the textbook ones. `theta F` is $qF'(q)$: $[q^n]\theta F = n[q^n]F$; `theta_mul` proves it is a derivation.

Proof sketch. $e^{c\sqrt{n}-n\log r} \le e^{c^2/(4\log r)}$ by completing the square. $n^p \le C_1(\sqrt{r})^n$ and $a_n \le C_2(\sqrt{r})^n$ give $n^p a_n \le C_1 C_2 r^n$. Cauchy: choose $1 < s < r$; then $\sum_{m \le n} Ds^m \cdot Cr^{n-m} \le CD(1-s/r)^{-1} r^n$. Shifts absorb finitely many terms into the constant.

Physical meaning

These are the bookkeeping rules of state counting: tensoring theories (Cauchy product of characters), multiplying by a polynomial in the energy (inserting L_0^p, which is what θ^p does), and shifting the vacuum energy all preserve the property "the partition function converges for every $\tau \in \mathbb{H}$".

What the machine verified

All unconditional; standard axioms (`subexponential_exp_sqrt`, `theta_mem_subexpPS` checked for this chapter).

Theorem 14.20 (Subexponential coefficients converge on the open disc). *If $a_n \ge 0$ is subexponential and $0 \le t < 1$, then $\sum_n a_n t^n$ converges.*

File `VOA/Modularity/ConvergenceBridge.lean`.

```

```

Proof. Choose $1 < r < t^{-1}$; compare with $C\sum(rt)^n$.

Physical meaning

The partition function at inverse temperature β ($t = e^{-2\pi\beta}$) is finite.

What the machine verified

Unconditional; standard axioms.

14.5.2 Evaluation

Definition 14.21 (The q-parameter; summability at τ; evaluation). For $\tau \in \mathbb{H}$ put $q = e^{2\pi i\tau}$. For χ a formal q-series and a base point $h \in \mathbb{C}$, χ is *summable at τ along h* if $\sum_{n\geq 0} \chi(h+n)q^n$ converges, and its *evaluation* is $\chi_h(\tau) = e^{2\pi i\tau h} \sum_{n\geq 0} \chi(h+n)q^n$, the formal $\sum_n \chi(h+n)q^{h+n}$ with $q^h := e^{2\pi i\tau h}$. In the $\mathbb{C}$ picture, $\chi_h^{\mathbb{C}}(z) = e^{2\pi izh} \sum_n \chi(h+n)e^{2\pi inz}$. (The function $q_{\mathbb{C}}(z) = e^{2\pi iz}$ of Definition 14.7 is the same q in the $\mathbb{C}$ picture.) The base point h is the lowest exponent of the series: for the character of a module of conformal weight h_M it is the ground-state energy $h = h_M - c/24$, so that the evaluation is $\operatorname{tr} q^{L_0 - c/24}$ (Chapter 12, Definition 12.13).

File `VOA/Modularity/ConvergenceBridge.lean`.

```

  χ (h + (n : ℂ)) * Complex.exp (2 * (Real.pi : ℂ) * Complex.I * (n : ℂ) * z)

noncomputable def qSeriesC (χ : FormalQSeries) (h : ℂ) (z : ℂ) : ℂ := ∑' n : ℕ, qTerm χ h n
 ↪  z

noncomputable def qEvalC (χ : FormalQSeries) (h : ℂ) (z : ℂ) : ℂ :=
  Complex.exp (2 * (Real.pi : ℂ) * Complex.I * z * h) * qSeriesC χ h z
```

From the mathematics to the Lean statement

Decoding. The prefactor `exp(2πi τ h)` is q^h with the principal choice $q^h = e^{2\pi i\tau h}$ (no branch ambiguity, because it is defined through τ, not through q). `qEvalAt` reads χ only along $h + \mathbb{N}$; values of χ off that progression are ignored, so `qEvalAt χ h` depends on the choice of h, and the caller must choose h to be the lowest exponent (for a character of a module of conformal weight h_M, $h = h_M - c/24$). `qEvalC_coe` proves `qEvalC χ h (τ : ℂ) = qEvalAt χ h τ`. **Junk value.** If the series diverges, `qEvalAt` is 0. Theorems that need the honest value carry `QSummableAt` or a `Subexponential` hypothesis. **Not Mathlib's `qExpansion`.** Mathlib goes from functions to coefficients; this goes from coefficients to functions.

Physical meaning

$\chi_h(\tau) = \operatorname{tr}_M q^{L_0 - c/24}$ is the torus partition function of the sector M; the choice $h = h_M - c/24$ is the ground-state energy on the cylinder.

Theorem 14.22 (The convergence bridge). *If $\|\chi(h+n)\|$ is subexponential then χ is summable at every $\tau \in \mathbb{H}$ along h. In particular, if the graded dimensions of a module N along $h + \mathbb{N}$ are subexponential, its character converges on $\mathbb{H}$.*

File `VOA/Modularity/ConvergenceBridge.lean`.

```
theorem qSummableAt_of_subexponential (χ : FormalQSeries) (h : ℂ)
    (hsub : Subexponential (fun n : ℕ => ‖χ (h + n)‖)) (τ : UpperHalfPlane) :
    QSummableAt χ h τ

def SubexponentialCoeffs (N : OrdVModule W M) (h : ℂ) : Prop :=
  Subexponential (fun n : ℕ => ‖gradedDim N (h + n)‖)
```

From the mathematics to the Lean statement

`OrdVModule W M` is an ordinary V-module on M (Chapter 12, Definition 12.5); `gradedDim N (h+n)` $= \dim M_{h+n+c/24}$ (cast to $\mathbb{C}$). `SubexponentialCoeffs` is the named "growth datum". The docstring of `ConvergenceBridge.lean` says its supply from C_2-cofiniteness is "not built"; that is stale: it is proved for the adjoint module (`subexponentialCoeffs_adjoint_of_C2Cofinite`, Chapter 15) and for modules with a finite lowest-weight generating family (`subexponentialCoeffs_of_C2Cofinite`).

Proof. Fix $\tau \in \mathbb{H}$ and put $t = |q| = e^{-2\pi \operatorname{Im}\tau}$; then $0 \le t < 1$ (`norm_qParam_lt_one`). Choose any r with $1 < r < t^{-1}$ (if $t = 0$ there is nothing to prove), for instance $r = (1+t^{-1})/2$. By subexponentiality, applied at this r, there is C with $\|\chi(h+n)\| \le Cr^n$ for all n. Hence

$$\sum_{n\ge 0} \|\chi(h+n)q^n\| = \sum_{n\ge 0} \|\chi(h+n)\|\, t^n \le C \sum_{n\ge 0} (rt)^n = \frac{C}{1-rt} < \infty,$$

since $0 \le rt < 1$. This is Theorem 14.20 with $a_n = \|\chi(h+n)\|$. An absolutely convergent series of complex numbers converges, which is `QSummableAt`.

Physical meaning

Growth bound on degeneracies ⇒ finite partition function at every temperature and every twist.

What the machine verified

Unconditional; standard axioms.

Trap / dead end

A wrong docstring claim (documentation only). The "Residual" section of `ConvergenceBridge.lean` says that only "that $p(n)$ is subexponential" is needed, "which follows from $p(n) \le 2^n$-type bounds". It does not: 2^n is not subexponential ($2^n \le C(3/2)^n$ fails for large n). The library's actual partition bound (Theorem 14.38) is the correct generating-function estimate $p_g(n)t^n \le \exp(gt/(1-t)^2)$ for all $t \in (0,1)$, which does give subexponential growth. No theorem is affected.

Theorem 14.23 (Holomorphy and term-by-term differentiation). *Let χ be a formal q-series with $\|\chi(h+n)\|$ subexponential. Then $z \mapsto \chi_h^{\mathbb{C}}(z)$ is holomorphic on $\mathbb{H}$, and for $z \in \mathbb{H}$*

$$\frac{d}{dz}\chi_h^{\mathbb{C}}(z) = 2\pi i\,(D\chi)_h^{\mathbb{C}}(z), \qquad (D\chi)(e) := e\,\chi(e).$$

In particular the character of a C_2-cofinite VOA (with $\mathbf{1} \ne 0$) is holomorphic on $\mathbb{H}$.

```

From the mathematics to the Lean statement

`qDeriv` is the formal Euler operator $q\frac{d}{dq}$ on series with complex exponents: $q\frac{d}{dq}q^e = eq^e$. `DifferentiableOn ℂ f U` is complex differentiability at every point of U, i.e. holomorphy on the open set U. The formula is exactly $\frac{d}{d\tau} = 2\pi i\, q\frac{d}{dq}$ applied termwise. `adjointModule W` is V as a module over itself (Definition 12.6); its conformal weight is 0, whence the base point $0 - c/24$. The hypothesis `hne` excludes the zero VOA. The derivative statement uses $\mathbb{H}$ only (`hz`); the growth hypothesis is the only analytic input. Same as textbook.

Proof. On $\mathbb{H}_c$ ($c > 0$), $|q^n| \le r^n$ with $r = e^{-2\pi c} < 1$; subexponentiality at $s = (1 + r^{-1})/2$ (so $s > 1$ and $sr < 1$) gives $|\chi(h+n)\, 2\pi n\, q^n| \le C\, 2\pi n (sr)^n$, a summable dominant independent of z. Mathlib's `hasDerivAt_tsum_of_isPreconnected` differentiates the series termwise on the convex (hence preconnected) open set $\mathbb{H}_c$. The prefactor $e^{2\pi i z h}$ is entire; product rule. For the adjoint module, Chapter 15 supplies the growth datum from C_2-cofiniteness.

Physical meaning

$\frac{1}{2\pi i}\frac{d}{d\tau}\chi = \mathrm{tr}(L_0 - c/24)q^{L_0 - c/24}$: differentiating in the modular parameter inserts the Hamiltonian, i.e. the zero mode of the stress tensor on the cylinder. This is the bridge between Zhu's recursion (stated with the formal operator D) and differential equations in τ.

What the machine verified

`differentiableOn_qEvalC`, `deriv_qEvalC`: unconditional beyond the growth hypothesis. `differentiableOn_char_adjoint`: unconditional for C_2-cofinite V with $\mathbf{1} \neq 0$. All `#print axioms`-clean (standard three); no `VOA.pbw`.

14.5.3 Algebra of evaluation

Definition 14.24 (Convolution with an $\mathbb{N}$-indexed series). For $f : \mathbb{N} \to \mathbb{C}$ and a formal q-series g: $(f \star g)(e) = \sum_{n\in\mathbb{N}} f(n)\, g(e-n)$ (a `finsum`: 0 if the support is infinite).

File `VOA/Modularity/ZhuRecursion.lean` (a Chapter 15 file).

```
noncomputable def qConv (f : ℕ → ℂ) (g : FormalQSeries) : FormalQSeries :=
  fun e => ∑ᶠ n : ℕ, f n * g (e - (n : ℂ))
```

Physical meaning

On coefficients, multiplying a torus amplitude by a q-series (an Eisenstein coefficient of a Ward identity) convolves the state counts level by level.

Theorem 14.25 (Convolution becomes multiplication). *If $\chi(h+i)=0$ for all integers $i<0$, and both $\sum|f(n)q^n|$ and $\sum|\chi(h+n)q^n|$ converge at z, then $(f\star\chi)_h^{\mathbb{C}}(z)=\left(\sum_n f(n)e^{2\pi inz}\right)\cdot\chi_h^{\mathbb{C}}(z)$.*

File `VOA/Modularity/QEvalConv.lean`.

```
theorem qEvalC_qConv (f : ℕ → ℂ) (χ : FormalQSeries) (h : ℂ) {z : ℂ}
    (hsupp : ∀ i : ℤ, i < 0 → χ (h + (i : ℂ)) = 0)
    (hf : Summable fun n : ℕ => ‖f n * Complex.exp (2 * (Real.pi : ℂ) * Complex.I * (n : ℂ)
    ↪  * z)‖)
    (hχ : Summable fun n : ℕ =>
      ‖χ (h + (n : ℂ)) * Complex.exp (2 * (Real.pi : ℂ) * Complex.I * (n : ℂ) * z)‖) :
    qEvalC (qConv f χ) h z
      = (∑' n : ℕ, f n * Complex.exp (2 * (Real.pi : ℂ) * Complex.I * (n : ℂ) * z))
          * qEvalC χ h z
```

From the mathematics to the Lean statement

`hsupp` makes $(f\star\chi)(h+m)=\sum_{n\le m}f(n)\chi(h+m-n)$ a genuine finite sum (`qConv_apply_of_support`); without it the `finsum` could have infinite support and be junk. The two absolute-summability hypotheses are what Mertens' theorem on Cauchy products needs (Mathlib `tsum_mul_tsum_eq_tsum_sum_range_of_summable_norm`). Same as textbook.

Proof. Cauchy product of two absolutely convergent series.

Physical meaning

Multiplying a torus amplitude by an Eisenstein series (as Zhu's recursion does) is, on coefficients, a convolution of state counts.

What the machine verified

Unconditional beyond hypotheses; standard axioms.

Theorem 14.26 (Linearity, rebasing, leading coefficient). *(i) Evaluation is additive and commutes with finite sums where the series converge, and is homogeneous unconditionally. (ii) $(D\chi)_h^{\mathbb{C}}=(2\pi i)^{-1}\frac{d}{dz}\chi_h^{\mathbb{C}}$ under the growth hypothesis. (iii) If $\chi(d+s)=0$ for $s<k$ and χ is summable at τ along d, then $\chi_d(\tau)=\chi_{d+k}(\tau)$. (iv) If $\|\chi(e_0+n)\|$ is subexponential and $\chi_{e_0}(it)=0$ for all $t>0$, then $\chi(e_0)=0$.*

```
noncomputable def imAxis (t : ℝ) (ht : 0 < t) : UpperHalfPlane :=
  ⟨Complex.I * (t : ℂ), by simp [ht]⟩
```

From the mathematics to the Lean statement

(i) `qEvalC_finsum`: `(Function.support g).Finite` says only finitely many g_i are nonzero, so both `finsums` are honest finite sums; summability of each term series is required because `tsum` is additive only on summable families. `qEvalAt_finsetSum` (`QEvalLinearity.lean`) is the same for `qEvalAt` and a `Finset`. (iii) `qEvalAt_shift`: the summability hypothesis is needed to split off finitely many terms. Because the library's progressions are rigid, rebasing is what allows comparison of characters of modules whose weights differ by integers. (iv) `imAxis t` is $\tau = it$, where $q = e^{-2\pi t} \in (0,1)$. The conclusion is only about the *leading* coefficient; iterating it (with (iii)) gives uniqueness of all coefficients. The hypothesis `hzero` quantifies over the whole imaginary axis, which is strictly more than needed (a sequence $t \to \infty$ suffices), so the theorem is slightly weaker than it could be but adequate.

Proof of (iv). On the imaginary axis $q = \rho \in (0,1)$ is real; $0 = \chi(e_0) + \sum_{n\geq 1} \chi(e_0+n)\rho^n$ and the tail is $\leq \rho\, C$ for $\rho \leq \frac{1}{2}$, with $C = \sum_n |\chi(e_0+n+1)|2^{-n} < \infty$. Let $\rho \to 0$. No identity theorem is needed.

Physical meaning

(iv) is the elementary form of "the low-temperature limit of the partition function sees the ground state": as $t \to \infty$ only the lowest level survives. It is used to prove linear independence of characters of inequivalent sectors (Zhu's Theorem 5.3.3, Chapter 15).

What the machine verified

All four unconditional beyond hypotheses; standard axioms.

14.5.4 The T-transformation, analytically

Definition 14.27 (Modular data; T-entries)**.** For a finite family $(M_i)_{i\in\iota}$ of irreducible V-modules with conformal weights h_i, a *modular datum* is a group homomorphism $\rho : \mathrm{SL}_2(\mathbb{Z}) \to \mathrm{Mat}_\iota(\mathbb{C})$ (multiplicative) together with a matrix ρ_S such that $\rho(S) = \rho_S$ and $\rho(T) = \mathrm{diag}\big(e^{2\pi i(h_i - c/24)}\big)$.

File `VOA/Modularity/ZhuTheorem.lean` (a Chapter 15 file).

    (h : ι → ℂ) : ι → ι → ℂ :=
  fun i j => if i = j then modularTEntry W (h i) else 0
```

```
structure ModularData (W : VertexOperatorAlgebra 𝒱) (ι : Type*) [Fintype ι] [DecidableEq ι]
 ↪  where
  Mfam : ι → IrrModule W
  h : ι → ℂ
  hasWeight : ∀ i, HasConformalWeight (Mfam i).isMod (h i)
  rep : Matrix.SpecialLinearGroup (Fin 2) ℤ →* Matrix ι ι ℂ
  repS : ι → ι → ℂ
  rep_S : rep ModularGroup.S = Matrix.of repS
  rep_T : rep ModularGroup.T = Matrix.of (modularRepT W h)
```

From the mathematics to the Lean statement

`IrrModule W` bundles an irreducible ordinary module (carrier, structure, irreducibility; `VOA/Modules/Rationality.lean`); `HasConformalWeight` is Definition 12.14 ($M_h \neq 0$ and all weights in $h+\mathbb{N}$). `→*` is a monoid homomorphism, i.e. a representation of $\mathrm{SL}_2(\mathbb{Z})$ on $\mathbb{C}^\iota$. `ModularData` contains *no* link between ρ and the characters; that link is the proposition `ZhuModularityAnalytic` (Chapter 15). Note that $\rho(T)$ is pinned but ρ_S is free data. A `ModularData` need not exist for an arbitrary weight vector: ρ must be a homomorphism, so $\rho(T)$ must be compatible with the relations of $\mathrm{SL}_2(\mathbb{Z})$ for some $\rho(S)$. The interesting objects are those produced by Zhu's theorem.

Physical meaning

A modular datum is the data of a rational CFT's modular tensor category at the level of the torus: the T-matrix (spins and central charge) and the S-matrix (exchange of space and time), forming a representation of the mapping class group $\mathrm{SL}_2(\mathbb{Z})$ of the torus.

Theorem 14.28 (Zhu's law on the translation subgroup, analytically). *For every modular datum D, every i, every $k \in \mathbb{N}$ and $\tau' = \tau + k$: $\chi_{M_i}(\tau') = \sum_j \rho(T^k)_{ij}\chi_{M_j}(\tau)$, where χ_{M_i} is the evaluated character based at $h_i - c/24$. No convergence hypothesis is needed.*

File `VOA/Modularity/ConvergenceBridge.lean`.

```
theorem zhu_modularity_T_pow_analytic {ι : Type*} [Fintype ι] [DecidableEq ι]
    {W : VertexOperatorAlgebra 𝒱} (D : ModularData W ι) (i : ι) (k : ℕ)
    {τ τ' : UpperHalfPlane} (hτ : (τ' : ℂ) = (τ : ℂ) + k) :
    qEvalAt (gradedDim (D.Mfam i).isMod) (D.h i - W.centralCharge / 24) τ'
      = ∑ j : ι, D.rep (ModularGroup.T ^ k) i j
          * qEvalAt (gradedDim (D.Mfam j).isMod) (D.h i - W.centralCharge / 24) τ
```

From the mathematics to the Lean statement

The right side evaluates *every* χ_{M_j} at the base point of M_i; this is harmless because $\rho(T^k)$ is diagonal and only $j = i$ survives. **Why no summability is needed:** $\tau \mapsto \tau + k$ multiplies each term $\chi(h+n)q^{h+n}$ by the same phase $e^{2\pi ikh}$, so the identity holds termwise, and `tsum` commutes with constant multiples even for non-summable families (both sides junk-0 together). Hence this is a true statement also when the character diverges; it is fully meaningful when it converges. The companion `zhu_modularity_T_analytic` (same file, $k = 1$) is stated with an arbitrary base point h for all j, which is also true by the same termwise argument.

Proof. `qEvalAt_translate` identifies $\tau \mapsto \tau + 1$ with the formal q-shift $q^e \mapsto e^{2\pi ie}q^e$; the character's T-periodicity (Theorem 12.15) says this is multiplication by $e^{2\pi i(h_i - c/24)}$; and $\rho(T)^k$ is diagonal (`Matrix.diagonal_pow`).

Physical meaning

The Dehn twist T acts on each sector by its spin phase $e^{2\pi i(h-c/24)}$; this is the trivially true half of modular invariance, valid for any theory with a well-defined L_0.

What the machine verified

Unconditional. Standard axioms.

14.6 Formal q-series as a module over $\mathbb{C}[[q]]$

The convolution $\star$ of Definition 14.24 is the only multiplication on `FormalQSeries`. For it to make "the R-span of the block values" a meaningful object, it must be an *action* of a ring.

Definition 14.29 (Series based at h; the $\mathbb{C}[[q]]$-action)**.** $\mathcal{Q}_h$ is the subspace of formal q-series supported on $h+\mathbb{N}$ (i.e. $\chi(e)=0$ unless $e=h+n$, $n\in\mathbb{N}$). For $F=\sum F_n q^n\in\mathbb{C}[[q]]$ and $\chi\in\mathcal{Q}_h$, $F\cdot\chi := (n\mapsto F_n)\star\chi$.

File `VOA/Modularity/QConvModule.lean`.

```
def QSeriesAt (h : ℂ) : Submodule ℂ FormalQSeries where
  carrier := {χ : FormalQSeries | ∀ e : ℂ, (∀ n : ℕ, e ≠ h + (n : ℂ)) → χ e = 0}

noncomputable def psSMul (F : PowerSeries ℂ) (χ : FormalQSeries) : FormalQSeries :=
  qConv (fun n => PowerSeries.coeff n F) χ

theorem psSMul_mul (F G : PowerSeries ℂ) {h : ℂ} {χ : FormalQSeries} (hχ : χ ∈ QSeriesAt h)
 ↪  :
    psSMul (F * G) χ = psSMul F (psSMul G χ)

noncomputable instance instModulePowerSeriesQSeriesAt (h : ℂ) :
    Module (PowerSeries ℂ) ↥(QSeriesAt h) where
```

From the mathematics to the Lean statement

Only the carrier of `QSeriesAt` is quoted; closure under $+$, 0, scalars is proved in the omitted fields. `↥(QSeriesAt h)` is the subspace regarded as a type. The `instance` line is quoted without its six proof fields (`one_smul`, `mul_smul`, ...), which are discharged by `psSMul_one`, `psSMul_mul`, etc. **Why the support condition is on all of $\mathbb{C}$.** The library notes (and we confirm) that requiring vanishing only at $h+i$, $i<0$, is *not* enough: it constrains χ only on the coset $h+\mathbb{Z}$, and at $e\notin h+\mathbb{Z}$ the `finsum` $\sum_n F_n\chi(e-n)$ may have infinite support (junk value 0), destroying associativity. With the support on $h+\mathbb{N}$ every convolution is a finite sum $\sum_{n\le N} F_n\chi(h+N-n)$. Faithful.

Proof. Unitality is immediate; associativity is the re-indexing of $\sum_{n+k\le N}$ by rows versus antidiagonals (`sum_triangle_swap`), i.e. associativity of the Cauchy product.

Physical meaning

$\mathcal{Q}_h$ is the space of formal "partition functions" of sectors with ground-state energy h, and $\mathbb{C}[[q]]$ acts by multiplication with q-series (e.g. Eisenstein series), exactly as in the coefficient form of a Ward identity.

What the machine verified

Unconditional. `#print axioms psSMul_mul`: standard three.

Theorem 14.30 (The Euler operator is a derivation over the action). *For $\chi \in \mathcal{Q}_h$ and $F \in \mathbb{C}[[q]]$: $D(F \cdot \chi) = F \cdot D\chi + (\theta F) \cdot \chi$.*

File `VOA/Modularity/QDerivProductRule.lean`.

```
theorem qDeriv_psSMul (F : PowerSeries ℂ) {h : ℂ} {χ : FormalQSeries} (hχ : χ ∈ QSeriesAt
↪  h) :
    qDeriv (psSMul F χ) = psSMul F (qDeriv χ) + psSMul (theta F) χ
```

Proof. At $h+N$: $(h+N)F_n\chi(h+N-n) = F_n(h+N-n)\chi(h+N-n) + nF_n\chi(h+N-n)$.

From the mathematics to the Lean statement

Exactly the Leibniz rule for $q\frac{d}{dq}$. The docstring's point: the coefficient ring of Zhu's formal ODE need not be closed under θ (which would require Ramanujan's identities, e.g. $\theta E_2 = (E_2^2 - E_4)/12$), because the downstream consumer only needs *subexponential* coefficients, and $\mathcal{S}$ is θ-stable (Theorem 14.19). This is a genuine simplification, correctly argued.

Physical meaning

Differentiating a product of an Eisenstein coefficient and an amplitude: the E_2-type terms that appear are the non-covariant pieces that the Serre derivative reorganises; for the growth estimate they are harmless.

What the machine verified

Unconditional; standard axioms.

14.7 The q-expansion bridge and the Noetherian coefficient ring

Definition 14.31 (Functions with analytic cusp function; the q-expansion map). A 1-periodic $f : \mathbb{H} \to \mathbb{C}$ has a *cusp function* $\tilde{f}$ with $f(\tau) = \tilde{f}(e^{2\pi i\tau})$ (Mathlib `cuspFunction 1 f`, defined on the punctured disc and extended to 0 by its limit). Let $\mathcal{C}$ be the set of f whose cusp function is analytic at 0; its *q-expansion* is the Taylor series of $\tilde{f}$ at 0 (Mathlib `qExpansion 1 f`).

File `VOA/Modularity/QExpansionBridge.lean`.

```
noncomputable def CuspAnalytic : Subalgebra ℂ (UpperHalfPlane → ℂ) where
  carrier := {f : UpperHalfPlane → ℂ | AnalyticAt ℂ (cuspFunction 1 f) 0}

noncomputable def qExpansionAlgHom : CuspAnalytic →ₐ[ℂ] PowerSeries ℂ where
  toFun f := qExpansion 1 (f : UpperHalfPlane → ℂ)
  map_one' := qExpansion_one 1
  map_mul' f g := qExpansion_mul f.2 g.2
  map_zero' := qExpansion_zero 1
  map_add' f g := qExpansion_add f.2 g.2
```

From the mathematics to the Lean statement

`AnalyticAt ℂ g 0`: g is given by a convergent power series near 0. Mathlib's `qExpansion` is defined for any function; it is a ring homomorphism only where the cusp functions are analytic (`qExpansion_mul` needs both), which is why the domain is restricted to $\mathcal{C}$. The quoted

carrier omits closure proofs; `qExpansionAlgHom` is quoted without its `commutes'` field. This is the statement "q-expansion turns pointwise products into Cauchy products".

Physical meaning

The partition function as a function of the torus versus its list of state counts: multiplication of partition functions (stacking decoupled theories) corresponds to convolution of degeneracies.

Theorem 14.32 (Formal and analytic Eisenstein coefficients agree). *For $j \geq 2$: the q-expansion of $\tau \mapsto \mathcal{G}_{2j}(\tau)$ is $\sum_m g_j(m)q^m$; the q-expansion coefficients of E_{2j} are $g_j(m)/g_j(0)$; and $\sum g_j(m)q^m$ lies in the subalgebra $\mathbb{C}[\widehat{E}_4, \widehat{E}_6] \subseteq \mathbb{C}[[q]]$ generated by the q-expansions of E_4, E_6.*

File `VOA/Modularity/QExpansionBridge.lean`.

```
theorem qExpansion_zhuGC {j : ℕ} (hj : 2 ≤ j) :
    qExpansion 1 (fun z : UpperHalfPlane => zhuGC j (z : ℂ)) = PowerSeries.mk (zhuG j)

noncomputable def E46Series : Subalgebra ℂ (PowerSeries ℂ) :=
  Algebra.adjoin ℂ ({qExpansion 1 (↑ModularForm.E₄ : UpperHalfPlane → ℂ),
    qExpansion 1 (↑ModularForm.E₆ : UpperHalfPlane → ℂ)} : Set (PowerSeries ℂ))

theorem mk_zhuG_mem_E46Series {j : ℕ} (hj : 2 ≤ j) :
    PowerSeries.mk (zhuG j) ∈ E46Series
```

From the mathematics to the Lean statement

This is the honest formal ↔ analytic dictionary for the Eisenstein coefficients: the *formal* sequence `zhuG j` (a definition) is proved to be the Fourier coefficient sequence of the *holomorphic* function `zhuGC j`, by Mathlib's uniqueness of q-expansions (`ModularFormClass.qExpansion_coeff_unique`). Then generation (Theorem 14.12) is transported to $\mathbb{C}[[q]]$ along `qExpansionAlgHom`. Faithful.

Proof. $\mathcal{G}_{2j}$ has the convergent expansion $\sum g_j(m)q^m$ on $\mathbb{H}$ (`hasSum_zhuG`); a function with a convergent q-expansion has that expansion as its `qExpansion`. For membership: $\mathcal{G}_{2j} \in \mathcal{E}_{46} \subseteq \mathcal{C}$ and `qExpansionAlgHom` maps $\mathcal{E}_{46}$ into `E46Series`.

Physical meaning

The Eisenstein coefficients of Zhu's recursion are, as formal series, polynomials in the q-expansions of E_4, E_6: the formal recursion lives over a finitely generated ring.

What the machine verified

Unconditional; standard axioms.

Definition 14.33 (Zhu's quasimodular coefficient ring). $\mathcal{G} = \mathbb{C}[\mathcal{G}_2, \mathcal{G}_4, \mathcal{G}_6] \subseteq \mathbb{C}[[q]]$, the subalgebra generated by the three formal series $\sum_m g_j(m)q^m$, $j = 1, 2, 3$.

File `VOA/Modularity/QExpansionBridge.lean`.

```
noncomputable def GSeries : Subalgebra ℂ (PowerSeries ℂ) :=
  Algebra.adjoin ℂ ({PowerSeries.mk (zhuG 1), PowerSeries.mk (zhuG 2),
    PowerSeries.mk (zhuG 3)} : Set (PowerSeries ℂ))

theorem mk_zhuG_mem_GSeries {j : ℕ} (hj : 1 ≤ j) :
    PowerSeries.mk (zhuG j) ∈ GSeries

theorem isNoetherianRing_GSeries : IsNoetherianRing GSeries
```

File `VOA/Modularity/SubexpSeriesRing.lean`.

```
theorem subexponential_coeff_of_mem_GSeries {F : PowerSeries ℂ} (hF : F ∈ GSeries) :
    Subexponential fun n : ℕ => ‖PowerSeries.coeff n F‖
```

From the mathematics to the Lean statement

`IsNoetherianRing`: every ideal finitely generated (Hilbert's basis theorem, via `Algebra.FiniteType`). The *formal* $\mathcal{G}_2$ is included as a generator because $\mathcal{G}_2$ is not a polynomial in E_4, E_6. All $\mathcal{G}_{2j}$, $j \geq 1$, lie in $\mathcal{G}$, every element of $\mathcal{G}$ has subexponential coefficients ($\mathcal{G} \leq \mathcal{S}$ because $|g_j(n)| \leq C + Cn^{2j}$). Faithful; these are exactly the properties used in Chapter 15.

Physical meaning

$\mathbb{C}[E_2, E_4, E_6]$ is the ring of quasimodular forms, the natural home of torus amplitudes with stress-tensor insertions (Kaneko–Zagier). Its Noetherianity is what ensures that Zhu's infinitely many relations reduce to finitely many, i.e. that torus characters satisfy a differential equation of finite order.

What the machine verified

Unconditional; standard axioms (`mk_zhuG_mem_GSeries`, `isNoetherianRing_GSeries`, `subexponential_coeff_of_mem_GSeries`).

14.8 The Serre derivative

Definition 14.34 (Serre derivative). For $k \in \mathbb{Z}$ and $f : \mathbb{C} \to \mathbb{C}$: $\partial_k f = \frac{1}{2\pi i} f' + \frac{k}{(2\pi i)^2} G_2 f$. On $\mathbb{H}$, with $G_2 = \frac{\pi^2}{3} E_2$, this is $\partial_k f = q\frac{df}{dq} - \frac{k}{12} E_2 f$.

File `VOA/Modularity/SerreDerivative.lean`.

```
noncomputable def serreDerivC (k : ℤ) (f : ℂ → ℂ) (z : ℂ) : ℂ :=
  (2 * (Real.pi : ℂ) * Complex.I)⁻¹ * _root_.deriv f z
    + (k : ℂ) * ((2 * (Real.pi : ℂ) * Complex.I)⁻¹) ^ 2 * (G2C z * f z)
```

From the mathematics to the Lean statement

$(2\pi i)^{-1}\frac{d}{dz} = q\frac{d}{dq}$. $(2\pi i)^{-2} = -\frac{1}{4\pi^2}$, so $\frac{k}{(2\pi i)^2} G_2 = -\frac{k}{4\pi^2} \cdot \frac{\pi^2}{3} E_2 = -\frac{k}{12} E_2$: the classical $\vartheta_k = D - \frac{k}{12} E_2$ (Zagier; Kaneko–Zagier), and the same as Mathlib's `serreDerivative` (which is defined on `ℍ → ℂ`). The docstring's claim that the coefficient $k(2\pi i)^{-2}$ is *forced* by equivariance is correct: by Theorems 14.2 and 14.4 the anomalies cancel for exactly this coefficient.

Physical meaning

The Serre derivative is the covariant derivative on the moduli space of tori; E_2 is the connection. It is the operation of inserting the zero mode $L_{[0]}$ of the *torus* stress tensor (Zhu's square-bracket $\tilde{\omega} = \omega - \frac{c}{24}\mathbf{1}$): this is the content of Zhu's ω-block condition, where the E_2 term is precisely the $j = 1$ Eisenstein coefficient (Theorem 14.9). In Mathur–Mukhi–Sen's classification of rational CFTs, characters satisfy MLDEs $\left[\partial^n + \sum_r \phi_{2r}\partial^{n-r}\right]\chi = 0$ with $\partial^n = \partial_{2n-2} \circ \cdots \circ \partial_0$ and $\phi_{2r} \in M_{2r}$; the second-order case with $\phi_4 = \mu E_4$ produces the famous list $c = -\frac{22}{5}, 1, 2, \frac{14}{5}, 4, \frac{26}{5}, 6, 7, \frac{38}{5}, 8$ (Lee–Yang and the Deligne series of WZW models; quoted

from the literature, not formalised).

Theorem 14.35 (Equivariance of the Serre derivative). *For $k \in \mathbb{Z}$, $\gamma \in \mathrm{SL}_2(\mathbb{Z})$, $z \in \mathbb{H}$, and f differentiable at γz: $(\partial_k f)|_{k+2}\gamma\,(z) = \partial_k(f|_k\gamma)(z)$. (No modularity of f is required. This is equivariance only: it does* not *show that ∂_k maps M_k into M_{k+2}, which also needs holomorphy at the cusp; that is Serre closure, Definition 14.14, proved separately in* `EisensteinSerreClosure.lean`*.)*

File `VOA/Modularity/SerreDerivative.lean`.

```
theorem serreDerivC_slashC (k : ℤ) (γ : SL(2, ℤ)) (f : ℂ → ℂ) {z : ℂ} (hz : z ∈ imGT 0)
    (hf : DifferentiableAt ℂ f (mobiusC γ z)) :
    slashC (k + 2) γ (serreDerivC k f) z = serreDerivC k (slashC k γ f) z
```

From the mathematics to the Lean statement

Pointwise in γ and z; differentiability at one point. No modularity of f is assumed: the statement is an identity of operators, and it implies at once that ∂_k maps weight-k slash-invariant functions to weight-$(k+2)$ ones. **Not in Mathlib**, which defines `serreDerivative` but proves no equivariance; this is the library's own theorem. It does *not* prove holomorphy at the cusp of $\partial_k f$, which is why Serre closure (`E46SerreClosed`) is a separate statement, proved separately in `EisensteinSerreClosure.lean` (`e46SerreClosed`). Same as the textbook (Zagier, Prop. 5 for the case of modular f).

Proof. Split $\partial_k f$ into its two terms. The derivative term picks up the anomaly $\frac{k}{2\pi i}\frac{c}{cz+d}(f|_k\gamma)$ (Theorem 14.2); the G_2 term picks up $\frac{k}{(2\pi i)^2}(-\frac{2\pi i c}{cz+d})(f|_k\gamma)$ (Theorem 14.4); they cancel.

Physical meaning

This one computation is "the only genuine computation in Zhu's S-law" (library docstring), and the physical statement is that the trace of the torus stress-tensor zero mode is a modular-covariant insertion: the conformal anomaly of ∂_τ and the anomaly of E_2 cancel exactly. It is what makes MLDEs $\mathrm{SL}_2(\mathbb{Z})$-covariant and hence what forces the solution space (the characters of a RCFT) to carry a representation of $\mathrm{SL}_2(\mathbb{Z})$.

What the machine verified

Unconditional; `#print axioms serreDerivC_slashC`: standard three. Every declaration in this section is pointwise in γ, so it restricts verbatim to any subgroup (Section 14.14).

Proposition 14.36 (Leibniz rule). *$\partial_{k+l}(fg) = (\partial_k f)g + f(\partial_l g)$ at points where f, g are differentiable (*`serreDerivC_mul`, `EisensteinRamanujan.lean`*); ∂_k is additive and $\mathbb{C}$-linear (*`serreDerivC_add`, `serreDerivC_smul`*).*

Proof. The product rule; the G_2 terms add up because $(k+l) = k+l$. Unconditional, standard axioms.

Physical meaning

Inserting the covariant torus derivative into a product of amplitudes obeys the Leibniz rule, with weights adding; this is what makes the coefficient algebra of MLDEs a differential ring.

14.9 Growth of degeneracies from ordered spanning sets

Why growth estimates. A character or one-point function is first constructed as a formal series. To speak of its modular transformation one must evaluate it at every $\tau \in \mathbb{H}$, and by Theorems 14.20 and 14.22 this is possible exactly when the coefficients (the degeneracies $\dim M_{h+n}$, or the traces $\mathrm{tr}_{M_{h+n}} o(v)$) are subexponential: for every $r > 1$, bounded by Cr^n. Holomorphy and term-by-term differentiation (Theorem 14.23) then come for free. Nothing in the VOA axioms gives such a bound directly; the library has two routes to it, and this section and the next develop them. *Route 1* (this section): a finite ordered spanning set, available under C_2-cofiniteness, bounds $\dim M_{h+n}$ by the number of states of finitely many free bosons, which grows like $e^{c\sqrt{n}}$, a subexponential rate. *Route 2* (Section 14.10): if the one-point functions satisfy a formal modular differential equation with subexponential coefficients, a majorant induction transfers the bound from the coefficients to the solution. Route 2 is needed for the traces $\mathrm{tr}\, o(v)$ with $v \neq \mathbf{1}$, which are not dimensions.

Definition 14.37 (Coloured partition count)**.** For $g, n \in \mathbb{N}$, $p_g(\leq n)$ is the number of functions $\mu : \{1..g\} \times \{1..n\} \to \{0..n\}$ with $\sum_{(i,m)} \mu(i,m)\, m \leq n$: the number of g-coloured partitions of integers $\leq n$.

File `VOA/Modularity/GrowthBound.lean`.

```
def partMultsLe (g n : ℕ) : Finset (Fin g × Fin n → Fin (n + 1)) :=
  Finset.univ.filter (fun μ => ∑ p, (μ p : ℕ) * (p.2 + 1) ≤ n)

def pcountLe (g n : ℕ) : ℕ := (partMultsLe g n).card
```

From the mathematics to the Lean statement

`Fin n` $= \{0, \dots, n-1\}$; the part size is `p.2 + 1` $\in \{1, \dots, n\}$, the multiplicity `μ p` $\in \{0, \dots, n\}$ (enough, since a multiplicity exceeding n is impossible when the total is $\leq n$). So the cardinality is exactly the number of g-coloured partitions of size $\leq n$.

Physical meaning

$p_g(\leq n)$ counts the states of g free chiral bosons up to level n; it is the reference count against which degeneracies of any finitely strongly generated theory are bounded.

Theorem 14.38 (The generating-function bound)**.** *For $0 < t < 1$: $p_g(\leq n)\, t^n \leq \exp\big(g\, t/(1-t)^2\big)$. Hence $n \mapsto p_g(\leq n)$ is subexponential.*

File `VOA/Modularity/GrowthBound.lean`.

```
theorem pcountLe_mul_pow_le (g n : ℕ) {t : ℝ} (ht0 : 0 < t) (ht1 : t < 1) :
    (pcountLe g n : ℝ) * t ^ n ≤ Real.exp (g * (t / (1 - t) ^ 2))

theorem pcountLe_subexponential (g : ℕ) : Subexponential (fun n => (pcountLe g n : ℝ))
```

Proof. $p_g(\leq n)t^n \leq \sum_\mu t^{|\mu|} \leq \prod_{k=1}^{n}(1-t^k)^{-g} \leq \exp\big(g \sum_k \frac{t^k}{1-t^k}\big) \leq \exp(gt/(1-t)^2)$, using $(1-x)^{-1} \leq e^{x/(1-x)}$. A uniform bound $a_n t^n \leq K(t)$ for every $t \in (0,1)$ is equivalent to subexponentiality (`Subexponential.of_mul_pow_le`, with $t = r^{-1}$).

Physical meaning

$\prod(1-q^k)^{-g}$ is the partition function of g free chiral bosons (up to $q^{-g/24}$), and this is the elementary (non-modular) half of Cardy's estimate. The true asymptotic $e^{\pi\sqrt{2gn/3}}$ needs the S-transformation of η; here only subexponentiality is needed and the crude bound suffices.

What the machine verified

Unconditional; standard axioms.

Definition 14.39 (PBW and ordered spanning data). For a module N with base weight h: *PBW spanning data* are finitely many generator weights $w_1, \dots, w_g \geq 1$, finitely many bottom weights $b_1, \dots, b_B \in \mathbb{N}$, and vectors $x_{\mu,j}$, indexed by multiplicity functions $\mu : \{1..g\} \times \mathbb{N} \to \mathbb{N}$ of finite support and $j \leq B$, with $x_{\mu,j} \in M_{h+b_j+\sum \mu(i,m)(w_i+m)}$, which span M. *Ordered spanning data* supply the $x_{\mu,j}$ as ordered monomials $\prod_{(i,m)} (s_i)^{\mu(i,m)}_{(-m-1)} u_j$ in homogeneous generators $s_i \in V_{w_i}$ applied to bottom vectors u_j.

File `VOA/Modularity/GrowthBound.lean`.

```
structure PBWSpanningData (N : OrdVModule W M) (h : ℂ) where
  g : ℕ

  wt_pos : ∀ i, 1 ≤ wt i
  b : ℕ
  botWt : Fin b → ℕ
  mono : (Fin g × ℕ →₀ ℕ) → Fin b → M
  mono_mem : ∀ μ j, mono μ j ∈ N.weight (h + (botWt j : ℂ) + (multWDeg wt μ : ℂ))
  spans : (⊤ : Submodule ℂ M) = Submodule.span ℂ {x | ∃ μ j, x = mono μ j}

def BuhlSpanning (W : VertexOperatorAlgebra 𝒱) : Prop :=
  ∀ (M : Type u) [AddCommGroup M] [Module ℂ M] (N : OrdVModule W M) (h : ℂ),
    HasConformalWeight N h → Nonempty (OrderedSpanningData N h)
```

From the mathematics to the Lean statement

`Fin g × ℕ →₀ ℕ` is a finitely supported function μ; `multWDeg wt μ` $= \sum \mu(i,m)(w_i + m)$. `N.weight α` is the weight space M_α. `OrderedSpanningData` (same file) has the same shape with `mono μ j` replaced by `orderedMonomial N gen μ (bot j)`, factors applied in lexicographic order of (i,m); `OrderedSpanningData.toPBW` converts. **Weaker than Buhl / Gaberdiel–Neitzke.** No strict decrease of mode indices is required: repetitions are allowed. This suffices for growth (coloured partitions allow repeats) but not for C_m-cofiniteness, as the library itself warns. **Stronger than Buhl's theorem as a hypothesis.** `BuhlSpanning W` asks for ordered spanning data for *every* module with a conformal weight, with a *finite* bottom family; Buhl's theorem concerns modules generated by one vector. Chapter 15 proves the adjoint case unconditionally and the module case under an explicit finite lowest-weight generation hypothesis (`BuhlSpanningC2.lean`); the "Residual" section of `GrowthBound.lean` is partly stale on this point (documentation only).

Physical meaning

An ordered (PBW) spanning set realises the module as a quotient of a Fock space of g generalised oscillators built on finitely many primaries; state counting is then bounded by that of g free bosons.

Theorem 14.40 (PBW spanning data give the growth datum). *Given PBW spanning data for N at h:* $\dim M_{h+n} \leq B \cdot p_g(\leq n)$ *for all n, hence the graded dimensions are subexponential along $h - c/24$. Under* `BuhlSpanning`*, every module with a conformal weight has subexponential graded dimensions.*

File `VOA/Modularity/GrowthBound.lean`.

 ↪  :
    SubexponentialCoeffs N (h - W.centralCharge / 24)

theorem subexponentialCoeffs_of_buhl {W : VertexOperatorAlgebra 𝒱} (hB : BuhlSpanning W)
    {M : Type u} [AddCommGroup M] [Module ℂ M] (N : OrdVModule W M) (h : ℂ)
    (hw : HasConformalWeight N h) : SubexponentialCoeffs N (h - W.centralCharge / 24)
```

From the mathematics to the Lean statement

The base point shifts from the L_0-weight h to $h - c/24$ because `gradedDim` indexes by $L_0 - c/24$. Since `Module.finrank` of an infinite-dimensional space is 0 (Mathlib), the dimension bound could be vacuous only if weight spaces were infinite-dimensional; they are finite-dimensional for every `OrdVModule` (field `finrank`). Faithful.

Proof. A spanning vector of weight exactly $h+n$ has $b_j + \sum \mu(i,m)(w_i+m) = n$, hence $\sum \mu(i,m)(m+1) \le n$ (as $w_i \ge 1$); restrict μ to the box $\{1..g\} \times \{0..n-1\}$, injective on such μ. Then the weight space is spanned by at most $B \cdot p_g(\le n)$ vectors. Theorem 14.38.

Physical meaning

Cardy-type growth of degeneracies, in the crude form "at most free-boson growth", from a finite set of strong generators.

What the machine verified

Unconditional (beyond the data); standard axioms (`subexponentialCoeffs_of_buhl` checked).

14.10 Formal modular differential equations and the indicial equation

Classically, Zhu proves convergence of one-point functions by showing that they satisfy a linear ODE in q with a regular singular point at $q = 0$ and then invoking the Frobenius–Fuchs theory. The library replaces the whole theory by its *coefficient-estimate half*, which is elementary and is all that is needed for subexponential growth. Mathlib has no regular-singular-point theory.

Theorem 14.41 (The majorant theorem). *Let $\chi_n, a_n, b_n \ge 0$ with a, b subexponential, let $p_n \to +\infty$, and suppose that for some N_0 and all $n \ge N_0$*

$$p_n\,\chi_n \;\le\; \sum_{m<n} a_{n-m}\,\chi_m + b_n.$$

Then χ is subexponential.

File `VOA/Modularity/Majorant.lean`.

```
theorem subexponential_of_majorant_recursion {χ a b p : ℕ → ℝ}
    (hχ0 : ∀ n, 0 ≤ χ n) (ha0 : ∀ n, 0 ≤ a n) (hb0 : ∀ n, 0 ≤ b n)
    (ha : Subexponential a) (hb : Subexponential b)
    (hp : Tendsto p atTop atTop) (N₀ : ℕ)
    (hrec : ∀ n, N₀ ≤ n → p n * χ n ≤ (∑ m ∈ Finset.range n, a (n - m) * χ m) + b n) :
    Subexponential χ
```

From the mathematics to the Lean statement

`Tendsto p atTop atTop`: $p_n \to +\infty$. All hypotheses are visible and are the intended ones. **Why $p_n \to \infty$ and not merely $p_n \geq c > 0$** (the library's warning, which we verify): to prove $\chi_n \leq Kr^n$ for a given r one bounds the right side by $(D\theta+1)Kr^n$ with $\theta = \frac{\sigma/r}{1-\sigma/r}$ and $D = D(\sigma)$ from $a_n \leq D\sigma^n$ $(1 < \sigma < r)$; one needs $p_n \geq D\theta + 1$, and since $D(\sigma)$ may blow up as $\sigma \to 1$ (equivalently as $r \to 1$), a fixed lower bound on p does not serve every r. With $p_n \to \infty$ it suffices to start the induction late enough. The finitely many initial values $n < N_0$ (where the recursion may fail, e.g. at resonances) are absorbed into K.

Proof. Fix $r > 1$, $\sigma = (1+r)/2$, $t = \sigma/r$. Choose $N \geq N_0$ with $p_n \geq D\theta + 1$ for $n \geq N$, and $K \geq E$ (the constant of b at r) with $\chi_n \leq Kr^n$ for $n < N$. Strong induction: for $n \geq N$, $p_n\chi_n \leq \sum_{m<n} D\sigma^{n-m}Kr^m + Er^n \leq (D\theta+1)Kr^n \leq p_nKr^n$.

Physical meaning

The majorant method is the elementary core of the statement "a solution of a Fuchsian ODE in q around a regular singular point converges in the largest disc free of other singularities". For characters the ODE is the MLDE of the theory, and the conclusion is that the partition function converges on $|q| < 1$: the theory has a finite free energy at every temperature.

What the machine verified

Unconditional; standard axioms. The docstring's "not yet connected to a VOA" is stale: it is connected through Theorem 14.45 (documentation only).

Definition 14.42 (Indicial polynomial, kernel and divisor). For a monic order-s equation $D^sF + \sum_{i<s} g_i(q)D^iF = 0$ with $g_i = \sum_k g_{i,k}q^k$, and an exponent λ: $P(\lambda+n) = (\lambda+n)^s + \sum_{i<s} g_{i,0}(\lambda+n)^i$ (indicial polynomial along $\lambda+\mathbb{N}$), $a_k = \sum_{i<s} |g_{i,k}|$ (kernel), and $p_n = |P(\lambda+n)|/(\max(|\lambda|,1)+n)^{s-1}$ (divisor).

File `VOA/Modularity/IndicialRecursion.lean`.

```
noncomputable def indicialP (lam : ℂ) (s : ℕ) (g : ℕ → ℕ → ℂ) (n : ℕ) : ℂ :=
  (lam + (n : ℂ)) ^ s + ∑ i ∈ Finset.range s, g i 0 * (lam + (n : ℂ)) ^ i

noncomputable def indicialKernel (s : ℕ) (g : ℕ → ℕ → ℂ) (k : ℕ) : ℝ :=
  ∑ i ∈ Finset.range s, ‖g i k‖

noncomputable def indicialDivisor (lam : ℂ) (s : ℕ) (g : ℕ → ℕ → ℂ) (n : ℕ) : ℝ :=
  ‖indicialP lam s g n‖ / (max ‖lam‖ 1 + (n : ℝ)) ^ (s - 1)
```

From the mathematics to the Lean statement

`g i k` is $g_{i,k}$, the k-th coefficient of the i-th ODE coefficient. `indicialP` is the classical indicial polynomial evaluated at $\lambda+n$; its roots are the Frobenius exponents. The divisor normalisation by $(B+n)^{s-1}$ is the device that turns the m-dependent weights $(\lambda+m)^i$ into a single factor (see below).

Physical meaning

The roots of the indicial polynomial at $q = 0$ are the possible leading exponents $h_i - c/24$ of the characters: in Mathur–Mukhi–Sen, the indicial equation of the MLDE determines the central charge and the conformal weights of the RCFT from the order n and the number ℓ of zeros of the Wronskian, via $\sum_i (h_i - c/24) = \frac{n(n-1)}{12} - \frac{\ell}{6}$.

Theorem 14.43 (Indicial recursion ⇒ subexponential; the divisor grows). *(i) If $s \geq 1$, all $\|g_{i,\cdot}\|$ are subexponential, $p_n \to \infty$, and $P(\lambda+n)\chi_n = -\sum_{m<n}\sum_{i<s} g_{i,n-m}(\lambda+m)^i\chi_m$ for all n, then $|\chi_n|$ is subexponential. (ii) For $s \geq 1$, $p_n \to \infty$ always (monicity).*

Files `VOA/Modularity/IndicialRecursion.lean` and `IndicialGrowth.lean`. File `VOA/Modularity/IndicialRecursion.lean`.

```
theorem subexponential_of_indicial_recursion {χ : ℕ → ℂ} (lam : ℂ) {s : ℕ} (hs : 1 ≤ s)

      = - ∑ m ∈ Finset.range n, ∑ i ∈ Finset.range s,
          g i (n - m) * (lam + (m : ℂ)) ^ i * χ m) :
    Subexponential (fun n => ‖χ n‖)
```

File `VOA/Modularity/IndicialGrowth.lean`.

```
theorem tendsto_indicialDivisor_atTop (lam : ℂ) {s : ℕ} (hs : 1 ≤ s) (g : ℕ → ℕ → ℂ) :
    Tendsto (indicialDivisor lam s g) atTop atTop
```

From the mathematics to the Lean statement

In (i) the hypothesis `hp` is redundant given (ii); it is kept separate for modularity of the proof. **Resonances are harmless.** If $P(\lambda+n) = 0$ for some n (a second Frobenius exponent at integer distance, the logarithmic case), the recursion at that n says $0 = \cdots$ and gives no information on χ_n; the majorant inequality $p_n|\chi_n| \leq \cdots$ then holds trivially because $p_n = 0$, and since $p_n \to \infty$ such n are finitely many. So the theorem is correct in the resonant case, where classical Frobenius theory needs logarithms. The docstring of `IndicialRecursion.lean` cites the growth lemma as `tendsto_indicial_quotient`; its actual name is `tendsto_indicialDivisor_atTop` (documentation only, trivial).

Proof. (i) For $m < n$, $i < s$: $|\lambda+m|^i \leq (B+n)^{s-1}$ with $B = \max(|\lambda|, 1)$; divide the norm of the recursion by $(B+n)^{s-1}$ and apply Theorem 14.41 with $b = 0$. (ii) With $u = |\lambda+n|$ and $C = \sum|g_{i,0}|$: $|P| \geq u^{s-1}(u-C)$ for $u \geq 1$; for $n \geq 2B+4C+4$, $u/(B+n) \geq \frac{1}{4}$ and $u \geq n/2$, so $p_n \geq 4^{-(s-1)}(n/4)$.

Physical meaning

The exponents of a Fuchsian equation are finitely many; beyond them each coefficient of the solution is determined from the lower ones with a "large denominator" $P(\lambda+n) \sim n^s$, which is what keeps the degeneracies from growing exponentially.

What the machine verified

Both unconditional; standard axioms.

Definition 14.44 (One-point functions on the torus; support and growth data). For a module N and $v \in V$, $Z_N(v)$ is the formal one-point function $\sum_\alpha \mathrm{tr}_{M_\alpha} o(v)\, q^{\alpha - c/24}$ (Chapter 12, Definition 12.13). The *support datum* at base h says $Z_N(v)(h+i) = 0$ for integers $i < 0$, for all v; the *growth datum* says $n \mapsto |Z_N(v)(h+n)|$ is subexponential for all v.

File `VOA/Modularity/OnePointFunctions.lean` (a Chapter 15 file).

```
noncomputable def torusOnePoint (N : OrdVModule W M) (v : V) : FormalQSeries := onePoint N
↪ v
```

File `VOA/Modularity/AnalyticBlock.lean` (a Chapter 15 file).

```
def OnePointSupported (N : OrdVModule W M) (h : ℂ) : Prop :=
  ∀ (v : 𝒱) (i : ℤ), i < 0 → torusOnePoint N v (h + (i : ℂ)) = 0

def OnePointSubexp (N : OrdVModule W M) (h : ℂ) : Prop :=
  ∀ v : 𝒱, Subexponential (fun n : ℕ => ‖torusOnePoint N v (h + (n : ℂ))‖)
```

From the mathematics to the Lean statement

`onePoint N v e` $= \mathrm{tr}_{M_{e+c/24}} o(v)$ with $o(v)$ the zero mode (Chapter 12). At $v = \mathbf{1}$, $o(\mathbf{1}) = \mathrm{id}$ and `OnePointSubexp` specialises to `SubexponentialCoeffs`. The support datum follows from a conformal weight (`onePointSupported_of_hasConformalWeight`).

Physical meaning

$Z_N(v)$ is the torus one-point function of the field v in the sector N; the support datum says the sector has no states below its ground-state energy, the growth datum that its twisted partition functions converge.

Theorem 14.45 (A formal ODE gives the growth datum)**.** *Let N have the support datum at h. Suppose that for every v there are $s \geq 1$ and sequences g_i $(i < s)$ with $|g_{i,\cdot}|$ subexponential such that, as formal q-series,*

$$D^s Z_N(v) + \sum_{i<s} g_i \star D^i Z_N(v) = 0.$$

Then N has the growth datum at h. The same conclusion holds if the coefficients g_i are elements of $\mathcal{G} = \mathbb{C}[\mathcal{G}_2, \mathcal{G}_4, \mathcal{G}_6]$.

File `VOA/Modularity/FormalODE.lean`.

          ↪ 0) :
    OnePointSubexp N hbase
```

From the mathematics to the Lean statement

`qDeriv^[i]` is the i-th iterate D^i; since D is diagonal, $D^i\chi(e) = e^i\chi(e)$ (`qDeriv_iterate_apply`). The equation is stated at *every* $e \in \mathbb{C}$, monic of order $s \geq 1$, with s and g allowed to depend on v (as in Zhu). The ODE is a **hypothesis**: producing it for a C_2-cofinite VOA is Zhu's Lemma 4.4.4, done (or not) in Chapter 15. These theorems are exactly "ODE ⇒ convergence". They are formal-power-series statements: no holomorphy is assumed or concluded; holomorphy then follows from Theorem 14.23.

Proof. Evaluating the equation at $\lambda + n$ and splitting off the $m = n$ term gives the indicial recursion (`indicialP_recursion_of_formalODE`); apply Theorem 14.43. For $\mathcal{G}$ use `subexponential_coeff_of_mem_GSeries` (Section 14.7).

Physical meaning

"Characters satisfying a modular linear differential equation converge", in its formal form: the MMS equation for the one-point functions forces Cardy-compatible (subexponential) growth.

What the machine verified

Unconditional given the ODE hypothesis; standard axioms (both).

Theorem 14.46 (First-order systems). *Let $z_1, \dots, z_g$ be sequences and a_{kl} subexponential sequences with $(h+N)z_k(N) = \sum_l \sum_{j \le N} a_{kl}(j) z_l(N-j)$ for all k, N. Then every $|z_k|$ is subexponential.*

File `VOA/Modularity/SystemGrowth.lean`.

theorem subexponential_of_system {g : ℕ} {hbase : ℂ}
    (z : Fin g → ℕ → ℂ) (a : Fin g → Fin g → ℕ → ℂ)
    (ha : ∀ k l, Subexponential (fun j => ‖a k l j‖))
    (hrec : ∀ (k : Fin g) (N : ℕ),
      (hbase + (N : ℂ)) * z k N
        = ∑ l, ∑ j ∈ Finset.range (N + 1), a k l j * z l (N - j)) :
    ∀ k, Subexponential (fun N => ‖z k N‖)
```

From the mathematics to the Lean statement

This is the coefficient form of $q\frac{d}{dq}\vec{z} = A(q)\vec{z}$ (a first-order system) for a vector of series based at `hbase`. Note that the $j = 0$ term of the right side involves $z_l(N)$ itself, which is why the proof moves it to the left with $K = \sum |a_{kl}(0)|$. No eigenvalue or matrix-inverse condition is needed. Faithful.

Proof. Sum the norms over k: $Z_N = \sum_k |z_k(N)|$ satisfies $(|h+N| - K)Z_N \le \sum_{m<N} B_{N-m} Z_m$; apply Theorem 14.41 with $p_N = |h+N| - K \to \infty$.

Physical meaning

A vector-valued modular form (the vector of characters of all sectors) satisfying a first-order modular system $D\vec{\chi} = A\vec{\chi}$; the system form is how block conditions in Zhu's argument are naturally organised.

What the machine verified

Unconditional; standard axioms.

14.11 The cylinder-to-torus coordinate: formal identities

Zhu's theorem rests on the change of coordinate $w = e^z - 1$ from the plane to the cylinder (and thence the torus). The library does all of its consequences as identities in $\mathbb{C}[[w]]$, without Laurent series or analysis. We collect the statements.

14.11.1 The square-bracket modes

Definition 14.47 (Square-bracket coefficients and modes). In $\mathbb{C}[[w]]$ let $\log(1+w) = \sum_{i\ge1}(-1)^{i+1}w^i/i$ and $u = \log(1+w)/w = \sum_i (-1)^i w^i/(i+1)$, a unit. For $k \in \mathbb{N}$, $m, i \in \mathbb{Z}$ put

$$c(k,m,i) = [w^{i-m}]\big((1+w)^{k-1}u^m\big) \quad (i \ge m), \qquad c(k,m,i) = 0 \quad (i < m).$$

For $a \in V$ and $m \in \mathbb{Z}$, $a[m]_k = \sum_{i\in\mathbb{Z}} c(k,m,i)\, a_{(i)}$ (a finite sum on each vector), and the torus Virasoro modes are $L_{[n]} = \omega[n+1]_2 - \frac{c}{24}\mathbf{1}[n+1]_0$.

File `VOA/Modularity/OnePointFunctions.lean` (a Chapter 15 file).

```
noncomputable def logOnePlusXSeries : PowerSeries ℂ :=

  if 0 ≤ i - m then
    PowerSeries.coeff (R := ℂ) (i - m).toNat
      ((↑(onePlusXUnit ^ ((k : ℤ) - 1)) : PowerSeries ℂ) * (↑(uUnit ^ m) : PowerSeries ℂ))
  else 0

noncomputable def vSqZ (v : V) (k : ℕ) (m : ℤ) : V →ₗ[ℂ] V where
  toFun x := ∑ᶠ i : ℤ, sqBracketCoeffZ k m i • mode (W.Y v) i x

noncomputable def Lsq (n : ℤ) : Module.End ℂ V :=
  vSqZ W W.conformalVector 2 (n + 1)
    - (W.centralCharge / 24) • vSqZ W W.vacuum 0 (n + 1)
```

From the mathematics to the Lean statement

`mode (W.Y v) i` is $v_{(i)}$ (Chapter 1). `onePlusXUnit` is $1+w$ as a unit, so that $(1+w)^{k-1}$ makes sense for $k = 0$ ($= (1+w)^{-1}$); `uUnit` is u as a unit, so u^m makes sense for negative m. The `finsum` is finite on each x (`sqModeZ_support_finite`: $c(k,m,i) = 0$ for $i < m$, and $v_{(i)}x = 0$ for $i \gg 0$). In Lean `vSqZ W v k m` takes the explicit VOA argument `W` (a section variable). **Agreement with Zhu.** Zhu defines $Y[a,z] = Y(a, e^z-1)e^{z\,\mathrm{wt}\,a}$ and $a[m] = \mathrm{Res}_z\, z^m Y[a,z]$ for $a \in V_k$. Substituting $w = e^z-1$: $z = \log(1+w)$, $dz = dw/(1+w)$, $e^{kz} = (1+w)^k$, so $a[m] = \mathrm{Res}_w\, Y(a,w)(1+w)^{k-1}\log(1+w)^m = \sum_i a_{(i)}[w^i]\big((1+w)^{k-1}w^m u^m\big) = \sum_i c(k,m,i)a_{(i)}$. So `vSqZ W a k m` is Zhu's $a[m]$ *provided* $k = \mathrm{wt}\,a$; the library passes the weight as a separate argument and imposes $a \in V_k$ where needed. $L_{[n]} = \tilde\omega[n+1]$ with $\tilde\omega = \omega - \frac{c}{24}\mathbf{1}$, as in Zhu.

Physical meaning

$a[m]$ are the modes of the field a on the cylinder $z \in \mathbb{C}/2\pi i\mathbb{Z}$ (equivalently on the torus before imposing periodicity in τ); $L_{[0]}$ is the cylinder Hamiltonian. The shift $\tilde\omega = \omega - \frac{c}{24}$ is the Schwarzian transformation of the stress tensor under $w = e^z - 1$, which produces the Casimir energy $-c/24$ (next theorem).

Theorem 14.48 (The Schwarzian of e^z-1). *In $\mathbb{C}[[z]]$, with $\{f;z\} = f'''/f' - \frac{3}{2}(f''/f')^2$: $\{e^z-1;z\} = -\frac{1}{2}$, and $\{z;z\} = 0$.*

File `VOA/Modularity/Schwarzian.lean`.

```
noncomputable def schwarzian (f : PowerSeries ℂ) : PowerSeries ℂ :=
  derivativeFun (derivativeFun (derivativeFun f)) * (derivativeFun f)⁻¹
    - (3 / 2 : ℂ) • ((derivativeFun (derivativeFun f) * (derivativeFun f)⁻¹) ^ 2)

noncomputable def expMinusOne : PowerSeries ℂ := PowerSeries.exp ℂ - 1

theorem schwarzian_expMinusOne :
    schwarzian expMinusOne = (-(1 / 2) : ℂ) • (1 : PowerSeries ℂ)
```

From the mathematics to the Lean statement

`derivativeFun` is the formal derivative; `⁻¹` on `PowerSeries ℂ` is the inverse when the constant term is nonzero (here $f' = e^z$, a unit), junk otherwise. So the definition is meaningful exactly for f with $f'(0) \neq 0$. Faithful.

Proof. All derivatives of $e^z - 1$ are e^z; $1 - \frac{3}{2} = -\frac{1}{2}$.

Physical meaning

The stress tensor transforms as $T(z) = f'(z)^2 T(f(z)) + \frac{c}{12}\{f; z\}$. For the cylinder map the Schwarzian is the constant $-\frac{1}{2}$, so $T_{\text{cyl}} = \cdots - \frac{c}{24}$: the vacuum on a circle has energy $-c/24$. This is the origin of the $q^{-c/24}$ in every character.

What the machine verified

Unconditional; standard axioms. The docstring's "Residual" calls the operator T_f of (C2) unbuilt; it is built in `ChangeCoord.lean` (documentation only). The two files also contradict each other on whether (C3) is a prerequisite of Zhu's theorem (documentation only).

Theorem 14.49 (exp ∘ log and the weight-matching identities). *In $\mathbb{C}[[w]]$: $\exp(\log(1+w)) = 1 + w$; $\exp(n \log(1+w)) = \sum_r \binom{n}{r} w^r$ for $n \in \mathbb{Z}$. Consequently, for $k \geq 1$, $d \in \mathbb{Z}$, $r \in \mathbb{N}$:*

$$\text{(I1)} \quad \sum_{m=0}^{r} \frac{d^m}{m!} c(k, m, r) = \binom{k-1+d}{r},$$

$$\text{(I3)} \quad \sum_{m \geq 0} \frac{2d^{2m+1}}{(2m+1)!} c(k, 2m+1, r) = \binom{k-1+d}{r} - \binom{k-1-d}{r},$$

$$\text{(I2)} \quad c(k, -1, r) - \binom{k-1}{r+1} - \frac{1}{2}\binom{k-1}{r} = \sum_{m \geq 0} g_{m+1}(0)\, c(k, 2m+1, r).$$

File `VOA/Modularity/ExpLogBinomial.lean`.

    ↪ 1) r
      = ∑ᶠ m : ℕ, zhuG (m + 1) 0 * sqBracketCoeff k (2 * m + 1) r
```

From the mathematics to the Lean statement

`log ℂ` is Mathlib's $\log(1+X)$ series, `exp ℂ` the exponential series, `.subst` formal substitution (meaningful as the substituted series has zero constant term). `expLog c` $= \exp(c\log(1+X))$ and `binomSeries n` $= \sum_r \binom{n}{r}X^r$ (same file). `cbz n r` is the generalised binomial $\binom{n}{r}$, 0 for $r<0$ (Chapter 1). `sqBracketCoeff k m r` is the natural-index version $[w^r]((1+w)^{k-1}\log(1+w)^m)$, equal to $c(k,m,r)$. The `finsums` are finite (terms vanish for $2m+1>r$). In (I2), $g_{m+1}(0) = -B_{2m+2}/(2m+2)!$, the cusp values of Zhu's Eisenstein coefficients. Faithful.

Proof. Both $\exp(c\log(1+X))$ and $\sum\binom{c}{r}X^r$ solve $(1+X)F' = cF$, $F(0)=1$, whose solution is unique coefficientwise (`onePlusX_ode_unique`). (I1) is $[w^r]$ of $(1+w)^{k-1}e^{d\log(1+w)} = (1+w)^{k-1+d}$; (I3) is its odd part; (I2) is $u = B(\log(1+w))$ with $B(z) = z/(e^z-1) = \sum B_n z^n/n!$, read through $\exp\circ\log = \mathrm{id}$.

Physical meaning

These identities match the weights of the plane and cylinder mode expansions: they are the combinatorics behind Zhu's recursion formula for torus one-point functions (Prop. 4.3.2), in which Bernoulli numbers enter as the cusp values of the Eisenstein series.

What the machine verified

Unconditional; standard axioms (all five).

Theorem 14.50 (Torus Virasoro relations with the same central charge)**.** *For all $m,n\in\mathbb{Z}$:* $[L_{[m]},L_{[n]}] = (m-n)L_{[m+n]} + \delta_{m+n,0}\frac{m^3-m}{12}c$.

File `VOA/Modularity/GelfandFuks.lean`.

```
theorem Lsq_virasoro (W : VertexOperatorAlgebra 𝒱) (m n : ℤ) :
    ⁅Lsq W m, Lsq W n⁆
      = ((m : ℂ) - (n : ℂ)) • Lsq W (m + n)
        + (if m + n = 0 then (((m : ℂ) ^ 3 - (m : ℂ)) / 12 * W.centralCharge)
            • (1 : Module.End ℂ 𝒱) else 0)
```

From the mathematics to the Lean statement

`⁅A, B⁆` is the commutator $AB-BA$ of endomorphisms. No hypotheses: true for every library VOA. Faithful (Zhu, Theorem 4.2.1; Gannon (5.3.15)).

Proof. The commutator of $\omega[m+1]$ and $\omega[n+1]$ is computed from the plane Virasoro relations; the central term is the moment $S(m,n) = \sum_a d[m,a]d[n,-a](a^3-a)$ of the change-of-basis coefficients, which equals $(m^3-m)\delta_{m+n,0} - \frac{m-n}{2}\delta_{m+n,-2}$ (`centralMomentClosed_holds`, proved by three formal Euler-operator ODE computations). The anomalous $\delta_{m+n,-2}$ term is exactly cancelled by the $-\frac{c}{24}\mathbf{1}[n+1]$ correction, which is nonzero only at $n=-2$.

Physical meaning

The Virasoro algebra on the cylinder has the same central charge as on the plane; the Schwarzian only shifts L_0 by $-c/24$. The $\delta_{m+n,-2}$ cocycle is a coboundary, removed by redefining ω to $\tilde{\omega}$.

What the machine verified

Unconditional; standard axioms.

Definition 14.51 (The coordinate-change operator). For coefficients $(a_k)_{k\geq 1}$, $A_f = \sum_{k\geq 1} a_k L_k$ is locally nilpotent on V, and $T_f = \exp(A_f)$ is a linear automorphism of V.

File `VOA/Modularity/ChangeCoord.lean`.

```
noncomputable def coordGen (W : VertexOperatorAlgebra 𝒱) (a : ℕ → ℂ) : 𝒱 →ₗ[ℂ] 𝒱 where
  toFun x := ∑ᶠ k : ℕ, a k • W.L ((k : ℤ) + 1) x

noncomputable def changeCoord (W : VertexOperatorAlgebra 𝒱) (a : ℕ → ℂ) : 𝒱 ≃ₗ[ℂ] 𝒱 :=
  expEquiv (coordGen_isLocNilp W a)
```

From the mathematics to the Lean statement

`a k` plays a_{k+1}. Each L_k, $k \geq 1$, lowers the L_0-grade by k, and the grading is bounded below, so A_f is locally nilpotent and the exponential is a finite sum (Chapter 5's `expEquiv`). `≃ₗ[ℂ]` is a linear equivalence. Only the operator is built; the transformation law $T_f Y(v,z) T_f^{-1} = \cdots$ (Huang's change of variables) is **not** formalised (named residual (C3) in the docstring).

Physical meaning

T_f implements a holomorphic reparametrisation $f(z) = z + a_1 z^2 + \cdots$ of the local coordinate at a puncture; on states it acts through the positive Virasoro modes.

What the machine verified

Definitions; standard axioms (`changeCoord`). No theorem uses the transformation law.

14.12 The cusp: Zhu's relations at $q = 0$

At $q = 0$ the Eisenstein series become their constant terms, and Zhu's genus-one relations degenerate into the defining relations of Zhu's algebra. This is the bridge from torus blocks to $A(V)$.

Theorem 14.52 (A Bernoulli identity). *With $B(z) = z/(e^z - 1)$: $B(z)^2 e^z = B(z) - zB'(z)$, hence $[z^n](B^2 e^z) = (1-n)B_n/n!$.*

File `VOA/Modularity/CuspDegeneration.lean`.

```
theorem bernoulliSq_mul_exp :
    (bernoulliPowerSeries ℂ) ^ 2 * exp ℂ
      = bernoulliPowerSeries ℂ - X * derivative ℂ (bernoulliPowerSeries ℂ)
```

Proof. Differentiate $B(e^z - 1) = z$: $Be^z + (e^z - 1)B' = 1$; multiply by B and use $B(e^z - 1) = z$ again.

From the mathematics to the Lean statement

`bernoulliPowerSeries ℂ` is Mathlib's $\sum B_n z^n/n!$. Equivalent to the expansion $e^z/(e^z-1)^2 = z^{-2} + \sum_{n\geq 1}(2n-1)g_n(0)z^{2n-2}$, i.e. the Laurent expansion of $\wp$ on the cylinder.

Physical meaning

$e^z/(e^z-1)^2$ is the cylinder propagator (the two-point function of a free boson current); its Laurent coefficients are the cusp values of the Eisenstein series.

What the machine verified

Unconditional; standard axioms.

Theorem 14.53 (DLM Lemma 9.2(c): the $q \to 0$ limit of the $[-2]$-family). *For $k \geq 1$ and $a, v \in V$:*

$$a[-2]v + \sum_{n\geq 2}(2n-1)g_n(0)\,a[2n-2]v \;=\; a \circ v + \frac{1}{12}a[0]v,$$

where all square-bracket modes are taken with weight parameter k and $a \circ v = \sum_{i=0}^{k}\binom{k}{i}a_{(i-2)}v = \operatorname{Res}_z \frac{(1+z)^k}{z^2}Y(a,z)v$ is Zhu's circle product.

File `VOA/Modules/ZhuModule.lean` (a Chapter 12 file).

```
noncomputable def Pres (W : VertexOperatorAlgebra V) (M : ℕ) (a b : V) (n : ℕ) : V :=
  ∑ i ∈ Finset.range (M + n + 1), cbz ((M : ℤ) + n) (i : ℤ) • W.smul a ((i : ℤ) - 2 - n) b
```

File `VOA/Modularity/CuspDegeneration.lean`.

```
theorem negTwoFamily_cusp {k : ℕ} (hk : 1 ≤ k) (a v : V) :
    vSqZ W a k (-2) v
        + ∑ᶠ m : ℕ, (((2 * (m + 2) - 1 : ℕ) : ℂ) * zhuG (m + 2) 0)
            • vSqZ W a k (2 * ((m : ℤ) + 2) - 2) v
      = Pres W k a v 0 + (1 / 12 : ℂ) • vSqZ W a k 0 v
```

From the mathematics to the Lean statement

`W.smul a j b` is $a_{(j)}b$; `Pres W k a v 0` $= \sum_{i\leq k}\binom{k}{i}a_{(i-2)}v$, Zhu's $a \circ v$ for $a \in V_k$. The `finsum` index m is $n-2$. The $\frac{1}{12}$ is the missing $n=1$ term ($(2\cdot 1-1)g_1(0) = -\frac{1}{12}$), i.e. the E_2 anomaly. **Stronger than DLM:** no hypothesis $a \in V_k$; the identity holds for any a once all modes use the same weight parameter k (it is a scalar identity of coefficients). Faithful.

Proof. All modes are finite combinations of $a_{(i)}v$ over a common window; coefficientwise, the identity is $[w^r]$ of $(1+w)^{k-1}u^{-2}\cdot(B^2e^z)|_{z=\log(1+w)} = (1+w)^k$, i.e. Theorem 14.52 pushed through $z = \log(1+w)$ (`sqBracketCoeffZ_neg_two_cusp`).

Physical meaning

On a degenerate (infinitely long) torus, the torus Ward identity for an insertion of a next to v becomes the operator-product relation defining $A(V)$: $a \circ v$ acts by zero on ground states. This is why Zhu's algebra controls the characters: it is the $q \to 0$ fibre of the sheaf of torus conformal blocks.

What the machine verified

Unconditional; standard axioms.

Definition 14.54 (Cusp relation spaces). $R_\infty = O(V) + \operatorname{span}\{a[0]v : a \in V_k, k \geq 1\}$; and R'_∞ is the span of the two Zhu relation families with the Eisenstein values replaced by their constant terms: all $a[0]v$, and all $a[-2]v + \sum_{m<K}(2m+3)g_{m+2}(0)a[2m+2]v$ with K beyond the support.

File `VOA/Modularity/CuspFunctionalCount.lean`.

```
def cuspRelSpan : Submodule ℂ V :=
  O W ⊔ Submodule.span ℂ
    {x : V | ∃ (ka : ℕ) (a v : V), 1 ≤ ka ∧ a ∈ W.grading (ka : ℤ) ∧ x = vSqZ W a ka 0 v}
```

File `VOA/Modularity/CuspLimit.lean`.

```
def blockRelSpanAtCusp : Submodule ℂ 𝒱 :=
  Submodule.span ℂ
    ({x : 𝒱 | ∃ (ka : ℕ) (a v : 𝒱), 1 ≤ ka ∧ a ∈ W.grading (ka : ℤ) ∧ x = vSqZ W a ka 0 v}
     ↪ ∪
     {x : 𝒱 | ∃ (ka K : ℕ) (a v : 𝒱), 1 ≤ ka ∧ a ∈ W.grading (ka : ℤ) ∧
        (∀ m : ℕ, K ≤ m → vSqZ W a ka (2 * (m + 1) - 2 : ℤ) v = 0) ∧
        x = vSqZ W a ka (-2) v + ∑ m ∈ Finset.range K,
              (((2 * (m + 2) - 1 : ℕ) : ℂ) * zhuG (m + 2) 0)
                • vSqZ W a ka (2 * (m + 2) - 2 : ℤ) v})
```

From the mathematics to the Lean statement

`O W` is Zhu's $O(V)$ (Chapter 12, Section 12.4); $\sqcup$ is the sum of subspaces. Only homogeneous a of positive weight k enter (weight-0 elements are multiples of $\mathbf{1}$ under `VacuumGradeZero`). The truncation K in `blockRelSpanAtCusp` is a witness that the tail vanishes, so the finite sum is the full sum. These are the definitions used in DLM §9.

Physical meaning

These are the torus Ward identities on the infinitely long torus: the relations that ground-state traces must satisfy.

Theorem 14.55 (The cusp fibre is $A(V)/[A(V),A(V)]$). *Assume $V_0 \subseteq \mathbb{C}\mathbf{1}$. Then $R'_\infty = R_\infty$, and $V/R_\infty \cong A(V)/[A(V),A(V)]$; in particular $\dim V/R'_\infty = \dim A(V)/[A(V),A(V)]$, which equals the number n of Wedderburn factors when $A(V) \cong \prod_{i\le n} \mathrm{Mat}_{d_i}(\mathbb{C})$.*

```
def commSpan : Submodule K A := Submodule.span K {x : A | ∃ a b : A, x = a * b - b * a}
```

From the mathematics to the Lean statement

`letI := instRingA W` installs the ring structure on Zhu's algebra `A W` (Theorem 12.17); `commSpan ℂ (A W)` is $[A,A]$, the span of commutators; `/` is the quotient space. `Module.finrank` is 0 on infinite-dimensional spaces, so the equality of `finrank`s is informative only when $A(V)$

is finite-dimensional (true under C_2, Chapter 12); the theorem is nonetheless correct as stated since the underlying linear equivalence `cuspRelSpanQuotEquiv` holds unconditionally. The Wedderburn form needs an algebra isomorphism `e` with a product of full matrix algebras. **Scope:** this is the $q = 0$ fibre only; the analogous statement at $z_0 \in \mathbb{H}$ is *false* as an identity of relation spaces (`blockRelSpan W z₀` moves with z_0, as the docstring notes), and the dimension transfer is a residual of Chapter 15.

Trap / dead end

Redundant hypothesis (moderate) — removed from the cusp theorems. The statements quoted above no longer carry `hzero`; the library dropped it after this finding. (Some other theorems of Chapter 15 still carry it.) `VacuumGradeZero W` holds for *every* library VOA: it is the structure field `vacuum_grade : grading 0 = ℂ • vacuum` weakened to $\leq$, and the library itself proves this as `vacuumGradeZero_of_vacuum_grade` (in `AKSl2Payoff.lean`, Chapter 16). So every theorem of this section carrying `hzero` is in fact unconditional. Harmless, but a referee should not count it as an assumption.

Proof. $\subseteq$: Theorem 14.53 turns each $[-2]$-relation into $a \circ v + \frac{1}{12}a[0]v$ with $a \circ v \in O(V)$. $\supseteq$: $O(V)$ is spanned by $(L_{-1} + L_0)u \circ v$-type elements which are Zhu circle products (`zhuMul_L_base`); weight-0 u contributes $\mathbf{1}_{(-2)} = 0$. The quotient: in $A(V)$, $a[0]v$ maps to $a * v - v * a$ (Zhu), so $V/R_\infty = A(V)/[A,A]$. For $\prod \mathrm{Mat}_{d_i}$, $[A,A]$ is the sum of trace-zero parts, of codimension n.

Physical meaning

At the cusp the torus conformal blocks are the symmetric (trace-like) linear functionals on $A(V)$; for a rational theory with $A(V) = \bigoplus \mathrm{End}(M_{i,h})$ there is one for each sector, the trace over its ground states. This is the infinite-cylinder version of "number of torus blocks = number of primaries".

What the machine verified

No hypothesis on V; the Wedderburn form is conditional on the decomposition `e`. Standard axioms (all three). The companions `exists_finset_span_sup_blockRelSpanAtCusp` (`CuspPoint.lean`: a spanning family of size $\dim A/[A,A]$ modulo R'_∞) and `exists_finrank_cuspFunctionals_le` (functionals killing the relations; at most n independent) are proved likewise.

14.13 Zhu's transformation law, the read-off of $\rho(S)$, and characters

This section states, in the language built above, what "the trace functions transform under $\mathrm{SL}_2(\mathbb{Z})$" means in the library, and proves the parts that are pure modular-group theory. The deep inputs (that the trace functions span the torus blocks) are Chapter 15's.

Definition 14.56 (Trace functions; the law at A; trace spanning)**.** For a family (M_i) of irreducible modules with weights h_i, $v \in V$ and $\tau \in \mathbb{H}$, the *trace function* is $S_i(v,\tau) = Z_{M_i}(v)$ evaluated at τ along $h_i - c/24$. With $j(A,\tau) = c\tau + d$, a matrix ρ_A *realises the law at* A if for every $n \in \mathbb{N}$, every v of square-bracket weight n ($L_{[0]}v = nv$), every i and τ:

$$S_i(v, A\tau) = j(A,\tau)^n \sum_j (\rho_A)_{ij} S_j(v,\tau).$$

Trace spanning means that every $A \in \mathrm{SL}_2(\mathbb{Z})$ has such a ρ_A. The law *on* Γ asks this only for $A \in \Gamma$.

  LinearMap.ker (Lsq W 0 - k • (LinearMap.id : 𝒱 →ₗ[ℂ] 𝒱))
```

From the mathematics to the Lean statement

`A • τ` is Mathlib's Möbius action; `autFactor A τ` is $c\tau + d$. The law is Zhu's Theorem 5.3.2 / Gannon (5.3.18a) with weights in the *square-bracket* grading, which is correct: Zhu's one-point functions are modular of weight n for $v \in V_{[n]}$, not for $v \in V_n$. `traceFun` is a `qEvalAt`, i.e. junk 0 where the series diverges; in all theorems below the growth datum `OnePointSubexp` is a hypothesis, so the values are honest. A family of trace functions that are all identically 0 would satisfy every law with any ρ; this is excluded where it matters by `TraceNonvanishing` / `TraceIndependent`, which make ρ_A unique (`rho_unique`).

Physical meaning

$S_i(v,\tau)$ is the torus one-point function $\mathrm{tr}_{M_i}\, o(v) q^{L_0 - c/24}$: the expectation value of the field v inserted on the torus, summed over states of the sector M_i running around the time circle. The law says these amplitudes form a finite-dimensional representation of the mapping class group of the torus, with v contributing its conformal weight.

Theorem 14.57 ($\rho(S)$ from the S-slash spanning statement)**.** *Assume that the M_i have conformal weights h_i and the growth datum, and that the S-slash of each trace block is a linear combination of the trace blocks (`SlashSpannedAtS`). Then trace spanning holds for every $A \in \mathrm{SL}_2(\mathbb{Z})$. If moreover the weights h_i are pairwise incongruent mod $\mathbb{Z}$ (equivalently T-eigenvalues distinct) and the trace functions do not all vanish, Zhu's law holds with a genuine representation ρ. (Of these hypotheses, the S-spanning statement is the deep one, Zhu's Theorem 5.3.3; the growth datum is supplied under C_2 in Chapter 15; nonvanishing follows from the growth datum; distinctness of weights mod $\mathbb{Z}$ is a genuine restriction.)*

File `VOA/Modularity/RhoS.lean`.

        (traceIndependent_of_tEigen_injective Mfam h hcw hinj hnv) hcw)
```

From the mathematics to the Lean statement

`traceBlock Mfam h i` is the trace function in the $\mathbb{C}$ picture (`traceBlock_coe`: it agrees with `traceFun` on $\mathbb{H}$); `blockSlash W γ F v = slashC (sqWtOf W v) γ (F v)`, slashing each v by its own square-bracket weight (`GradedBlock.lean`, Chapter 15). `tEigen W h i` $= e^{2\pi i(h_i - c/24)}$; `TraceNonvanishing` asks that each S_i be nonzero somewhere. `modularDataOf` assembles a `ModularData` (Definition 14.27) from the matrices, and `ZhuModularityAnalytic D` is the law of Definition 14.56 for every A with $\rho = D$.`rep`. **Hypotheses.** `hS` is the deep input (the spanning half of Zhu's Theorem 5.3.3, at S only); `hsub` the growth datum; `hinj` an honest restriction (false for tensor products and many lattice VOAs, as `TEigenInjective.lean` records; Chapter 15 removes it via fibre independence). The conclusion is the textbook law. Conditional, and the conditions are visible.

Proof. The law at S follows from `hS` by reading off coefficients (`realisesLaw_of_slashSpanned`). The law at T is T-periodicity (Theorem 14.28). The set of A admitting a law is closed under products (the cocycle $j(AB,\tau) = j(A,B\tau)j(B,\tau)$, `autFactor_mul`) and contains 1; and $\mathrm{SL}_2(\mathbb{Z})$ is generated by S, T *as a monoid*, because $S^{-1} = S^3$ and $T^{-1} = (ST)^5 S$ (`submonoid_closure_S_T_eq_top`, `TraceSpanningS.lean`). Independence (from distinct T-eigenvalues) makes the ρ_A unique, so $A \mapsto \rho_A$ is multiplicative.

Physical meaning

Modular invariance of a rational CFT is fixed by two pieces of data: the diagonal T (spins) and the matrix S (exchange of space and time). Once one knows that the S-transformed amplitudes lie in the span of the old ones, the full $\mathrm{SL}_2(\mathbb{Z})$-representation follows from group theory. $\rho(S)$ is the CFT's modular S-matrix, input to the Verlinde formula.

What the machine verified

Conditional on the named hypotheses. `#print axioms` of both: standard three; no `VOA.pbw`. The library's S-matrix is `rhoS_of_blockSpanned` (same file), conditional likewise.

Theorem 14.58 (T-eigenvalues are distinct iff the weights are distinct mod $\mathbb{Z}$). $e^{2\pi i(h_i - c/24)} = e^{2\pi i(h_j - c/24)}$ *iff* $h_i - h_j \in \mathbb{Z}$*; hence* `tEigen W h` *is injective iff the* h_i *are pairwise incongruent mod* $\mathbb{Z}$.

File `VOA/Modularity/TEigenInjective.lean`.

```
theorem tEigen_injective_iff (h : ι → ℂ) :
    Function.Injective (tEigen W h) ↔ ∀ i j : ι, (∃ n : ℤ, h i - h j = (n : ℂ)) → i = j
```

Proof. $e^x = e^y$ iff $x - y \in 2\pi i\mathbb{Z}$ (Mathlib `exp_eq_exp_iff_exists_int`).

Physical meaning

Sectors with spins differing by an integer cannot be told apart by the Dehn twist; then independence of characters needs the finer ground-state analysis of Theorem 14.26(iv).

What the machine verified

Unconditional; standard axioms. Used by `traceIndependent_of_weights_distinct_mod_int` (same file), which is conditional on ordered spanning data and the distinctness.

Definition 14.59 (Jacobi characters; Gannon §5.3.5). For $u, v \in V_1$ and a bilinear form β on V: $Z_M(\tau,u,v) = \sum_n \operatorname{tr}_{M_{h+n}}\big(e^{2\pi i(o(v)-\beta(u,v)/2)}e^{2\pi i\tau o(u)}\big)e^{2\pi i\tau(h+n-(c+12\beta(u,u))/24)}$, operator exponentials taken blockwise on the finite-dimensional weight spaces; $\chi^J_M(\tau,v,w) = e^{2\pi i w}Z_M(\tau,0,v)$.

File `VOA/Modularity/JacobiCharacter.lean`.

       ↪  24) τ
```

From the mathematics to the Lean statement

`Zfun` (same file) is the displayed Z_M, a `tsum` (junk if divergent); `twoPiI` $= 2\pi i$. `β` is an arbitrary bilinear form; the intended instance is an invariant form, but invariance is *not* required by the statement. `JacobiTransformation` is the Jacobi-form law $\chi^J_i(A\tau, \frac{v}{c\tau+d}, w - \frac{c\beta(v,v)}{2(c\tau+d)}) = \sum \rho(A)_{ij}\chi^J_j(\tau,v,w)$ (Gannon (5.3.20); Miyamoto; Krauel–Mason), a named `Prop`, **never proved**. `jacobiTransformation_zero` only checks that its $v = 0$, $w = 0$ instance is Zhu's law for characters (at $v = 0$ the Jacobi character is the character, `jacobiChar_zero_zero`).

Physical meaning

$Z_M(\tau,u,v)$ is the partition function twisted by the flavour (current) charges of the conserved currents in V_1: a torus with background gauge field. Its transformation as a Jacobi form encodes the anomaly (level) of the current algebra.

What the machine verified

`JacobiTransformation`: statement only (open). `jacobiTransformation_zero`: proved, standard axioms, but it is a consistency check, not a step toward the law.

14.14 Subgroups and the theta group

Definition 14.60 (Slash relations on a subgroup; the theta group). For a family $F : V \to (\mathbb{C} \to \mathbb{C})$ and γ: G is the *slash of F by γ* if $G(v) = F(v)|_n\gamma$ on $\mathbb{H}$ for every integer n and $v \in V_{[n]}$. F is *modular on* Γ if F is its own slash by every $\gamma \in \Gamma$. The *theta group* is $\Gamma_\theta = \langle S, T^2 \rangle \leq \mathrm{SL}_2(\mathbb{Z})$.

File `VOA/Modularity/BlockSlash.lean` (a Chapter 15 file).

```
def IsSlashOf (W : VertexOperatorAlgebra 𝒱) (γ : SL(2, ℤ)) (F G : 𝒱 → ℂ → ℂ) : Prop :=
  ∀ (n : ℤ) (v : 𝒱), v ∈ sqWeightSpace W (n : ℂ) → ∀ z ∈ imGT 0, G v z = slashC n γ (F v) z
```

File `VOA/Modularity/SlashSubgroup.lean`.

```

def RealisesLawOn (Γ : Subgroup SL(2, ℤ)) : Prop :=
  ∀ A ∈ Γ, ∃ ρA : ι → ι → ℂ, RealisesLaw Mfam h A ρA

def thetaGroup : Subgroup SL(2, ℤ) :=
  Subgroup.closure ({ModularGroup.S, ModularGroup.T ^ 2} : Set SL(2, ℤ))

def ThetaGroupProper : Prop := ModularGroup.T ∉ thetaGroup
```

From the mathematics to the Lean statement

All in namespace `VOA.SlashSub`. `Subgroup.closure s` is the subgroup generated by s. The classical theta group is $\{\gamma \equiv I \text{ or } S \bmod 2\}$, of index 3; `thetaGroup` is *defined* by generators. The identification with the congruence description, properness ($T \notin \Gamma_\theta$) and index 3 are proved in `ThetaGroup.lean` (Chapter 17) and imported into `GammaThetaStatement.lean` as `thetaGroup_eq`, `thetaGroupProper`, `thetaGroup_index`, `gamma_two_le_thetaGroup`. So `ThetaGroupProper`, stated "deliberately not proved" in `SlashSubgroup.lean`, is a theorem of the library (that file's comment is stale, documentation only). `IsSlashOf` only constrains G on *integer* square-bracket weights; for a bosonic VOA every $V_{[n]}$ with $n \notin \mathbb{N}$ is 0 (`sqWeightSpace_eq_bot_of_not_natCast`), so nothing is lost there, but the layer cannot express half-integral weights (the library proves this limitation explicitly: `isSlashOf_of_eqOn_int`, `blockSlash_apply_of_notInt`).

Physical meaning

Γ_θ is the stabiliser of the Neveu–Schwarz spin structure on the torus (antiperiodic fermions in both directions): T changes the time-direction boundary condition of fermions (NS $\to \widetilde{\text{NS}}$) and is therefore not a symmetry of the NS partition function, while T^2 and S are. Fermionic theories, and bosonic theories with half-integral weights, have characters modular only for Γ_θ.

Theorem 14.61 (Γ_θ as a monoid, and bosonic Γ_θ-modularity). *(i) Γ_θ is contained in the submonoid generated by S, T^2, T^{-2}. (ii) For any family with conformal weights, the law at S implies the law on Γ_θ. (iii)* $[\mathrm{SL}_2(\mathbb{Z}) : \Gamma_\theta] = 3$.

```

File `VOA/Modularity/GammaThetaStatement.lean`.

```
theorem thetaGroup_index : SlashSub.thetaGroup.index = 3 :=
  ThetaGroup.genSTsq_index_eq_three
```

From the mathematics to the Lean statement

(i) uses $S^{-1} = S^3$; T^{-2} must be adjoined because $\Gamma_\theta/\{\pm 1\} \cong \mathbb{Z}/2 * \mathbb{Z}$ is free on $\bar{S}$, $\bar{T}^2$ (as the docstring says; not proved, and not needed). (ii) the laws at $T^{\pm 2}$ come free from T-periodicity, since $\rho(T)$ is diagonal and invertible; so for a *bosonic* VOA Γ_θ-modularity costs exactly the S-law, i.e. restriction buys nothing (correctly stated). (iii) a one-line import from Chapter 17.

Proof. (i) Every element of the subgroup closure is a word in $S^{\pm 1}$, $T^{\pm 2}$. (ii) Realising matrices form a submonoid (Theorem 14.57's proof). (iii) Chapter 17.

Physical meaning

For a bosonic theory the NS-sector subtlety is absent, so modularity for Γ_θ is weaker than, and implied by, modularity for $\mathrm{SL}_2(\mathbb{Z})$.

What the machine verified

Unconditional ((i), (iii)); conditional on the S-law ((ii)). Standard axioms (all three).

Theorem 14.62 (The mechanism: the T-phase of half-integral weights). *For $m \in \mathbb{Z}$: $e^{2\pi i\, m/2} = (-1)^m$, which is -1 for odd m; and $e^{2\pi i \cdot 2 \cdot m/2} = 1$.*

File `VOA/Modularity/GammaThetaStatement.lean`.

```
theorem tPhase_half (m : ℤ) :
    Complex.exp (2 * (Real.pi : ℂ) * Complex.I * ((m : ℂ) / 2)) = (-1 : ℂ) ^ m

theorem tSqPhase_half (m : ℤ) :
    Complex.exp (2 * (Real.pi : ℂ) * Complex.I * (2 * ((m : ℂ) / 2))) = 1
```

Physical meaning

A state of weight $m/2$ picks up a sign under the Dehn twist T when m is odd, and nothing under T^2. This is the entire reason the symmetry group drops to $\langle S, T^2\rangle$. The library's docstring stresses, correctly, that it is the half-integral *weight*, not the fermion parity, that matters: a $\mathbb{Z}$-graded super VOA has supertraces modular for all of $\mathrm{SL}_2(\mathbb{Z})$ (Dong–Zhao), while its plain traces are modular for $\Gamma_0(2)$-type subgroups (the other spin structures).

What the machine verified

Unconditional arithmetic; standard axioms.

Definition 14.63 (Half-integral automorphy factors; the super law; character systems)**.** A *half-integral automorphy factor* is a consistent choice of square root of $c\tau + d$, needed to give meaning to $(c\tau+d)^{m/2}$; since a square root cannot be chosen multiplicatively, a multiplier μ records the failure of the cocycle law (for the theta group it is a root of unity, the theta multiplier). Precisely, a half-integral automorphy factor on Γ is a function $\sqrt{j}(A,\tau)$ with $\sqrt{j}(A,\tau)^2 = c\tau + d$, nowhere zero, $\sqrt{j}(1,\tau) = 1$, and a τ-independent multiplier $\mu(A,B)$ with $\sqrt{j}(AB,\tau) = \mu(A,B)\sqrt{j}(A,B\tau)\sqrt{j}(B,\tau)$ for $A, B \in \Gamma$. A *super character system* for a super VOA W is a grading sqWt of V supported on $\frac{1}{2}\mathbb{Z}$ with $\mathbf{1}$ in weight 0, and a family $\chi_i(v,\tau)$ with $\chi_i(0,\tau) = 0$. The *law on* Γ asks $\chi_i(v, A\tau) = \sqrt{j}(A,\tau)^m \sum_j \rho(A)_{ij}\chi_j(v,\tau)$ for v of weight $m/2$.

    CharacterIndependent S → CompleteRationalFamily S hFam → GammaThetaModularityHolds S
```

From the mathematics to the Lean statement

`SuperVertexOperatorAlgebra` is Chapter 17's notion; `W.grading` its L_0-grading (complex weights). `GammaThetaModularityHolds S` = $\exists J\, \exists \rho$, law of `ModularLawOn` (the same shape as `SuperRealisesLawOn` but with `S.sqWt` in place of `W.grading`) on `thetaGroup`. `CharacterIndependent` is linear independence of the `chi i`; `SuperC2Cofinite`, `IsHalfIntegerGraded`, `HasStrictHalfWeight` are the evident predicates (super C_2; weights in $\frac{1}{2}\mathbb{Z}$; some weight in $\frac{1}{2} + \mathbb{Z}$ nonzero). **What is and is not tied to W.** Nothing in `SuperCharacterSystem` relates `chi` to traces over W-modules, and `sqWt` need not be W's square-bracket grading; these are explicitly abstracted because the library has no super module theory (the docstring says so). `SuperRealisesLawOn` uses L_0-weights rather than $L_{[0]}$-weights (also documented, and repaired by `ModularLawOn`). `HalfAutFactor` is satisfiable: on $\langle T^2 \rangle$ by `translationHalfAutFactor`, and on all of Γ_θ by

`thetaHalfAutFactorExists` (`ThetaHalfAutFactor.lean`, Chapter 17, principal square root); the docstring of `ThetaHalfAutFactorExists` in `GammaThetaStatement.lean` calling it "OPEN (task T5)" (an internal project task label) is stale (documentation only).

Trap / dead end

Template statements (moderate). `CompleteRationalFamily S P` is *definitionally* P, so `Conjecture_HalfWeight S hFam` takes an arbitrary proposition as its last hypothesis. With `hFam := False` it is trivially true; with `hFam := True` it asserts Γ_θ-modularity of an *arbitrary* independent family `chi` (unrelated to W), which is false in general. So the "conjecture" has content only after the caller supplies, in `hFam` and `chi`, the module theory the library lacks. Likewise `SuperRealisesLawOn` (and `IsGammaThetaModular`) is satisfied by the zero family for every Γ, J, ρ. The library is candid that these are `def`s, not theorems, and no theorem depends on them, but the names suggest more. Checked in Lean against the library (the check is not part of this release): `completeRationalFamily_iff`, `conjecture_halfWeight_false`, `superRealisesLawOn_zero`; compiled for this chapter.

Physical meaning

The intended statement (Höhn; Dong–Zhao; van Ekeren) is that the NS-sector characters of a C_2-cofinite, $\frac{1}{2}\mathbb{Z}$-graded theory form a representation of the theta group, with the half-integral factor $(c\tau + d)^{m/2}$ coming from the η-function multiplier (the theta multiplier $\theta(A\tau)/\theta(\tau)$).

Proposition 14.64 (Check for the template warning). *For every super character system S:* `CompleteRationalFamily` $S\,P \iff P$; `Conjecture_HalfWeight` S False *holds; and the zero family satisfies* `SuperRealisesLawOn` *for every Γ, J, ρ.*

Proof. Definitional unfolding; and $0 = J^m \cdot \sum \rho \cdot 0$.

What the machine verified

Checked in Lean against the library, compiled with `lake env lean -DmaxSynthPendingDepth=3`: no errors. The check is not part of this release.

Physical meaning

None: this is a logical check that the template statements have no physical content until the missing module theory is supplied.

Theorem 14.65 (Consistency: bosonic VOAs satisfy the Γ_θ statements). *(i) If D is a modular datum satisfying Zhu's law, then the character system of D (genuine square-bracket grading, genuine trace functions) satisfies the half-integral law on Γ_θ for every half-integral factor J. (ii) For a C_2-cofinite VOA with semisimple $A(V)$, a finite irreducible family of the right cardinality with simple, pairwise non-isomorphic bottoms, and the datum* `Pr`*, the characters are Γ_θ-modular.*

From the mathematics to the Lean statement

(i) is a pure restriction: on even doubled weight $m = 2n$, $J^{2n} = (c\tau + d)^n$ (`HalfAutFactor.zpow_even`); on odd m the bosonic weight space is 0. (ii) chains (i)'s character form off Chapter 15's headline `zhuModularity_pinned_of_C2Cofinite`; `Φ W` is the set of iso-classes of irreducibles, `Pr : BottomProjection …` is the datum discussed in Chapter 13 (supplied for every V by `voaPBWBottomProjection`, from the theorem `VOA.pbw`; MISTAKES entry 61, now resolved), the former redundant hypotheses `hzero` and `hsimp` have been removed from the current statement. `CharacterModularOn Γ χ ρ` is $\chi_i(A\tau) = \sum_j \rho(A)_{ij}\chi_j(\tau)$ for $A \in \Gamma$. As the library says, these buy nothing mathematically over $\mathrm{SL}_2(\mathbb{Z})$-modularity; they are type-checks of the statements. The hypotheses `[Finite (Φ W)]`, `hcard`, `hcw`, `hsep` and `Pr` of (ii) are all dischargeable: finiteness is the theorem `finite_Φ_of_C2Cofinite_pbw` from C_2 alone, and the canonical family of Chapter 15 (Theorem 15.37) satisfies the family hypotheses. The hypothesis `hss` is semisimplicity of $A(V)$, not rationality; for a rational V (`AdmissiblyRational`) it is supplied by the theorem `isSemisimpleRing_A_of_admissiblyRational` (Chapter 15, Theorem 15.38).

Physical meaning

A bosonic theory trivially passes the NS-sector test.

What the machine verified

(i) conditional on `hD`; (ii) conditional on C_2, semisimplicity, the family hypotheses and `Pr`. Both `#print axioms`-clean (standard three), **not** using `VOA.pbw`; the datum `Pr` is supplied for every V by `voaPBWBottomProjection` (from the theorem `VOA.pbw`; Chapter 15's `_voaPBW` variants).

14.15 The analytic j-invariant and the abstract Moonshine corollary

Definition 14.66 (Analytic j). $j(\tau) = E_4(\tau)^3/\Delta(\tau)$ on $\mathbb{H}$. It is $\mathrm{SL}_2(\mathbb{Z})$-invariant (`jInvariant_smul`). The "Hauptmodul step" `eq_jInvariant_add_const` states: **if one is given** a weight-0 modular form F (holomorphic, also at the cusp) with $F = \chi - j$, then $\chi = j + c$. **The hypothesis is the Hauptmodul content**: it is assumed, not proved.

File `VOA/Modularity/JInvariantAnalytic.lean`.

```
noncomputable def jInvariant (z : ℍ) : ℂ :=
  (ModularForm.E₄ z) ^ 3 / ModularForm.discriminant z

theorem jInvariant_smul (γ : SL(2, ℤ)) (z : ℍ) : jInvariant (γ • z) = jInvariant z

theorem eq_jInvariant_add_const (F : ModularForm 𝒮ℒ 0) (χ : ℍ → ℂ)
    (hF : ∀ z, F z = χ z - jInvariant z) : ∃ c : ℂ, ∀ z, χ z = jInvariant z + c
```

From the mathematics to the Lean statement

Division is honest because Δ has no zeros on $\mathbb{H}$ (Mathlib `discriminant_ne_zero`; `jInvariant_eq_iff`). Mathlib has E_4 and Δ but not j (true at this Mathlib version), so this is new, though elementary. `discriminant_slash` first upgrades Mathlib's S- and T-invariance of Δ to all of $\mathrm{SL}_2(\mathbb{Z})$ (the invariance set is a subgroup containing the generators). `eq_jInvariant_add_const`: **the hypothesis carries the whole content.** It *assumes* a holomorphic weight-0 form F, holomorphic at the cusp, with $F = \chi - j$; then F is constant (Mathlib `levelOne_weight_zero_const`). Proving that $\chi - j$ is such a form (holomorphy of χ and cancellation of the cusp poles) is exactly the Hauptmodul step, and it is **not** done anywhere in the library. The textbook Hauptmodul theorem (Chapter 33, Theorem 33.5) is not formalised.

Physical meaning

j is the unique (up to constant) modular-invariant function with a simple pole q^{-1}: the partition function of a holomorphic $c = 24$ CFT is $j +$ const, the constant being $\dim V_1 - 744$.

What the machine verified

`jInvariant_smul`, `eq_jInvariant_add_const`: unconditional, standard axioms. The second is nearly a restatement of Mathlib's lemma.

Definition 14.67 (Formal character of a VOA; the Moonshine hypotheses and identity). $\mathrm{ch}(V) = \sum_n (\dim V_n) q^n \in \mathbb{C}[[q]]$. The *Moonshine hypotheses* are $c = 24$, $V_1 = 0$, V holomorphic and C_2-cofinite; the *Moonshine character identity* is $\mathrm{ch}(V) = qJ$.

File `VOA/Modularity/MoonshineCorollary.lean`.

```
noncomputable def charSeries (W : VertexOperatorAlgebra 𝒱) : PowerSeries ℂ :=
  PowerSeries.mk (fun n => (Module.finrank ℂ (W.grading n) : ℂ))

structure MoonshineHypotheses (W : VertexOperatorAlgebra 𝒱) : Prop where
  centralCharge_eq : W.centralCharge = 24
  grading_one_eq_bot : W.grading 1 = ⊥
  holomorphic : Holomorphic W
  c2 : C2Cofinite W

def MoonshineCharacter (W : VertexOperatorAlgebra 𝒱) : Prop := charSeries W = JShift
```

From the mathematics to the Lean statement

`JShift` $= qJ$ (Chapter 33, Definition 33.12); `Holomorphic` is Chapter 12's Definition 12.37. `MoonshineCharacter` is a `Prop`; **the library never proves it for any** V, and `MoonshineHypotheses` is not used by any theorem. The library's actual $\chi_{V^\natural} = J$ (Chapter 33) is stated for the concrete $V^\natural$ and does not mention these definitions.

Physical meaning

$\mathrm{ch}(V)$ is $q \cdot Z(\tau)$, the torus partition function with the Casimir factor q^{-1} removed (Chapter 33).

What the machine verified

Definitions. The small lemmas `moonshineCharacter_coeff_zero_iff` ($\Rightarrow \dim V_0 = 1$) and `coeff_one_charSeries_of_grading_one_eq_bot` are proved, standard axioms.

Theorem 14.68 (Zhu's theorem forces invariance of a $c = 24$ weight-0 character)**.** *Let V have $c = 24$ and an irreducible module M of conformal weight 0 (for instance $M = V$). If trace spanning and trace independence hold for the one-element family $\{M\}$ and the character of M is not identically zero, then ρ is trivial and the character is $\mathrm{SL}_2(\mathbb{Z})$-invariant. Under C_2-cofiniteness, the growth datum and* $\dim(\textit{analytic S-slash ambient}) \le 1$*, the same conclusion holds without the spanning/independence hypotheses. (For a one-element family, independence is automatic once the character is nonzero; spanning is the real hypothesis of the first form, and the rank bound replaces it in the second.) Finally,* ***if one is given*** *a weight-0 modular form equal to $\chi_M - j$, then $\chi_M = j + \mathrm{const}$;* ***this last hypothesis is the Hauptmodul content and is assumed, not proved****, anywhere in the library.*

    ∃ c : ℂ, ∀ τ : UpperHalfPlane,
      traceFun (singleFam V) (fun _ => (0 : ℂ)) () W.vacuum τ = jInvariant τ + c
```

From the mathematics to the Lean statement

`singleFam V : Unit → IrrModule W` is the one-element family; `()` its index. `traceFun … () W.vacuum` is the character $\chi_M(\tau) = \mathrm{tr}_M\, q^{L_0 - 1}$ (base point $0 - 24/24$, $o(\mathbf{1}) = \mathrm{id}$). **Holomorphy of V is not assumed**: the theorem is about one module of weight 0, and uses $c = 24$ only to make $\rho(T) = e^{2\pi i(0-1)} = 1$. Then $\rho(-1) = 1$ (law at -1 on $\mathbf{1}$, using `hne`), $\rho(S)^2 = \rho(-1) = 1$ and $\rho(S)^3 = \rho((ST)^3)\rho(T)^{-3} = 1$, so $\rho(S) = 1$ and ρ is trivial (`modularRepOf_eq_one_of_holomorphic`). In `char_SL2Z_invariant_of_analyticRank`, `analyticSlashAmbient` is Chapter 15's finite-dimensional space of analytic blocks containing the trace block and its S-slash; its finite-dimensionality is a theorem there, and the bound ≤ 1 is the honest hypothesis ("$\#\Phi = 1$"). `char_eq_jInvariant_add_const` inherits the vacuous-looking hypothesis of `eq_jInvariant_add_const`: it assumes the conclusion's analytic content.

Proof. As in the dictionary, plus Theorem 14.57's machinery for the second statement (independence is free for one module once the character is nonzero, and nonvanishing is free from the growth

datum: on the imaginary axis the character is a convergent series with nonnegative coefficients and positive leading coefficient, `traceFun_vacuum_ne_zero`, Chapter 15).

Physical meaning

A $c = 24$ theory with a single sector (holomorphic) has a modular-invariant partition function; with $V_1 = 0$ it is J. These theorems get the first half from the torus Ward identities alone; the second half (Hauptmodul) is assumed.

What the machine verified

Conditional on the visible hypotheses; standard axioms, no `VOA.pbw` (all three).

Trap / dead end

Not instantiated at $V^\natural$; formerly stale docstrings (documentation only). No theorem of this section is applied to the library's $V^\natural$. The library's $\chi_{V^\natural} = J$ (Chapter 33) is proved by computing both sides (theta series, $\dim M_{12} = 2$, the level-two identity) and uses none of the modularity machinery of this chapter. When this chapter was first written, the docstrings of `MoonshineCorollary.lean`, `MoonshineFromBlocks.lean`, `MoonshineHauptmodul.lean` said that $V^\natural$ did not exist in the repository ("Phase-3 project"), although the library already constructed $V^\natural$, and the "Residual" of `MoonshineCorollary.lean` listed $[q^2]$`jShift` $= 196884$ as open, although it is `coeff_two_jShift` (Chapter 33). At a pre-release build commit these docstrings have been corrected: they name `Moonshine.moonshine` as the construction of $V^\natural$ and record `coeff_two_jShift` as proved.

14.16 Recorded traps, dead ends and defects

Severities are graded on a four-step scale: serious (a statement that is wrong or vacuous), moderate (weaker or stronger than advertised, or a redundant hypothesis), open gap (a conditional result whose hypothesis is not discharged, or a missing piece), and documentation only (docstrings and notes).

1. `levelOne_coe_mem_E46` is generation only; homogeneity and independence are elsewhere (vendored `levelOne_eq_polynomial`); the two developments are disconnected (documentation only; Theorem 14.12).

2. `E46HasWeightedPolynomialReps` was documented as missing but follows from the vendored `span_eisBasisFun` (Theorem 14.15). **Closed**: now the library theorem `e46HasWeightedPolynomialReps`.

3. `E46SerreClosed` / `E46SerreMonomialClosed` (Ramanujan identities, Serre closure) were open named predicates. **Closed**: `e46SerreClosed`, `e46SerreMonomialClosed` (Section 14.4.2).

4. `ZhuRecursionEisenstein` uses the superseded E_{2j} normalisation and would be false; no consumer; docstring of `EisensteinFormal.lean` stale (documentation only).

5. `VacuumGradeZero` was a redundant hypothesis of the cusp theorems (it holds for every VOA, `vacuumGradeZero_of_vacuum_grade`) (moderate; Section 14.12); fixed in the library since.

6. `CompleteRationalFamily` is the identity; `Conjecture_HalfWeight`/`Conjecture_ZGradedSuper` have a free proposition slot; `SuperCharacterSystem`, `SuperRealisesLawOn` are not tied to W (moderate; checked in Lean, Proposition 14.64).

7. `eq_jInvariant_add_const` and `char_eq_jInvariant_add_const` assume the Hauptmodul content (moderate; open gap).

8. `JacobiTransformation` (Gannon Thm 5.3.9), `MoonshineCharacter`: statements only (open gap).

9. `BuhlSpanning` is stronger than Buhl's theorem (all modules, finite bottom); its ordered monomials are weaker than GN/Buhl (no strict decrease) (moderate, documented by the library).

10. Docstrings: "$p(n) \leq 2^n$ gives subexponential" (false) in `ConvergenceBridge.lean`; "growth datum not built" (`ConvergenceBridge.lean`, `GrowthBound.lean`); "not connected to a VOA" (`Majorant.lean`); `tendsto_indicial_quotient` misnamed (`IndicialRecursion.lean`); (C2) unbuilt and (C3) prerequisite contradiction (`Schwarzian.lean` vs `ChangeCoord.lean`); `ThetaGroupProper` "not proved" (`SlashSubgroup.lean`); `ThetaHalfAutFactorExists` "OPEN" (`GammaThetaStatement.lean`); $V^\natural$ "does not exist" and $[q^2]j$ "open" (`MoonshineCorollary.lean` and siblings) (all documentation only).

11. Dead end, recorded by the library: the purely formal $\mathbb{C}[[q]]$ route cannot reach a point of $\mathbb{H}$ (Theorem 14.17). Dead end: a fixed positive lower bound on the indicial divisor does not close the majorant induction; $p_n \to \infty$ is needed (Theorem 14.41).

14.17 Referee's checklist

Lean declaration	intended meaning	hypotheses; status	check
`slashC_deriv_eq`, `slashC_G2C`	slash vs. derivative; G_2 quasi-modular	differentiability; unconditional	Thms. 14.2, 14.4

`MoonshineCharacter`	$\operatorname{ch} V = qJ$	**statement only**; not instantiated	Def. 14.67

All `#print axioms` results quoted in this chapter were obtained at an earlier commit (not re-run for this edition) by running a scratch file importing the relevant modules with `lake env lean -DmaxSynthPendingDepth=3` (never a bare `lake env lean`); 69 headline declarations were checked, and every one reports exactly

```
[propext, Classical.choice, Quot.sound]
```

No headline of this chapter uses `VOA.pbw`. No full `lake build` was run for this chapter. The separate Lean checks of this chapter (not part of this release) compiled with no errors.

Release audit 2026-10-27: RELEASE_AUDIT_ZHU.md. The release audit (`Notes/Textbook/referee/RELEASE_AUDIT_ZHU.md`) found this chapter's two headlines that it examined faithful as stated: `levelOne_coe_mem_E46` (generation of the level-one modular forms by E_4, E_6 only, as Section 14.4 says) and `subexponential_of_majorant_recursion` (an abstract lemma about nonnegative real sequences). Checked again later, at a commit before this edition (not re-run for this edition), with `lake env lean -DmaxSynthPendingDepth=3`: `VOA.qSummableAt_of_subexponential`, standard three axioms. No other entry was re-run.

Second release revision 2026-10-28. Only the description of the consumer theorem of Chapter 15 changed (finding F2 of `RELEASE_AUDIT_NEW_DECLS.md`: "rational ⇒ $A(V)$ semisimple" is proved in the library, so Zhu's theorem holds for C_2-cofinite `AdmissiblyRational` V). No statement of this chapter changed and no `#print axioms` of this chapter was re-run; the axiom checks of the new Chapter 15 theorems are recorded there (standard three axioms, at an earlier commit, not re-run for this edition). No `lake build` was run.

Chapter 15

Zhu's modularity theorem

This chapter documents the release of the LeanVOA library named in the front matter; it was first written against an earlier state of the library ("the snapshot" below), and checks that were run at an earlier state of the library and not re-run for this edition are marked as such. Every Lean quotation below is taken from the files of the release and is machine-checked by `scripts/textbook/sync.py` to occur verbatim (up to whitespace and comments) in the source. The chapter covers the files assigned to it in `Notes/Textbook/assignment.txt`: essentially all of `VOA/Modularity/` except the modular-forms toolkit (Eisenstein series, the ring $\mathbb{C}[E_4, E_6]$, the Serre derivative, the slash operator, evaluation of q-series; Chapter 14), the Arakawa–Kawasetsu files (Chapter 16), the super files (Chapter 17) and the logarithmic files (Chapter 18); plus four example files about the trivial vertex operator algebra $\mathbb{C}\mathbf{1}$. That was 122 files at the snapshot (two more were added for the release), roughly one and a half megabytes of Lean. We do not tour them. We state exactly what the headline theorem says, present every definition on which its statement depends, explain Zhu's proof on paper in the form in which the library actually carries it out, and describe the remaining files by role at the end (Section 15.17).

Release revision. The chapter was revised for the first public release, applying the release audit `Notes/Textbook/referee/RELEASE_AUDIT_ZHU.md` (2026-10-27). The quotations added in this revision — the canonical-family headline (Section 15.12.2), the closed trivial instance (Section 15.13) and the first nontrivial instances (Section 15.14) — were copied from the files of that release; the older quotations were re-verified there by `sync.py`. The two new source files are `VOA/Modularity/ZhuModularityCanonical.lean` (this chapter) and `VOA/Classification/COne/ZhuModularityV2mPlus.lean` (also assigned to this chapter, although it lives in the $c = 1$ classification directory of Chapter 22, because its theorems are instances of this chapter's headline).

Second release revision (2026-10-28). The chapter was revised again, applying finding F2 of `Notes/Textbook/referee/RELEASE_AUDIT_NEW_DECLS.md` and the entry "Zhu for rational VOAs" of `Notes/RELEASE_PLAN.md`. The first release revision said that the implication "rational $\Rightarrow$ $A(V)$ semisimple" was not formalised and that the lattice VOAs $V_{\sqrt{2m}\mathbb{Z}}$ were not covered. Both statements were false: the library already proved the implication (`VOA.Huang.ZhuSemisimple.isSemisimpleRing_A_of_admissiblyRational`, in `VOA/Huang/ZhuSemisimple.lean`, Chapter 21). It now also states Zhu's theorem in Zhu's own form, "C_2-cofinite and rational" (`zhuModularity_canonical_of_C2Cofinite_admissiblyRational` and `zhuModularity_canonical_of_stronglyRational`, Section 15.12.3), and it proves the instances `zhuModularity_V2m` (every $V_{\sqrt{2m}\mathbb{Z}}$, $m \geq 1$) and `zhuModularity_of_nice` (every nice VOA; Section 15.14). The quotations added in this revision were copied from the files at that revision. The one open point left at that revision was the relation between the library's rationality predicate `AdmissiblyRational` and Dong–Li–Mason rationality (Remark 15.2); since then the direction DLM $\Rightarrow$ `AdmissiblyRational` is proved under C_2 (`admissiblyRational_of_dlmRational`), and only the converse is open.

Third release revision (2026-10-28). At this revision the library proves, in `VOA/Classification/COne/LiteratureInputsProved.lean` (Chapter 12, Theorems 12.40 and 12.44), the Dong–Li–Mason finiteness predicate `DLMFinitelyManyIrredAdmissible` for every C_2-cofinite V

(`dlmFinitelyManyIrredAdmissible_of_c2Cofinite`), hence for every strongly rational V (`StronglyRational.dlmFinitelyManyIrredAdmissible`), and restates Zhu's semisimplicity predicate as the hypothesis-free `zhuAdmissibleSemisimple_holds`. So both literature hypotheses `hFin` and `hZhu` of the older packaging `zhuModularity_stronglyRational_voaPBW` (Theorem 15.40) are now theorems for every strongly rational V; that section was corrected (it previously called `hFin` "unproved"). No quotation changed.

Throughout we use, without repeating them, the following material from earlier chapters: vertex operator algebras, modes $a_{(n)}$ and the library's mode convention (Chapter 1); ordinary modules `OrdVModule`, their weight spaces, the zero mode $o(v)$, graded traces and formal q-series, the predicates `HasConformalWeight`, `IrrModule`, $\Phi(V)$, Zhu's algebra $A(V)$, C_2-cofiniteness, and the rationality predicates (Chapter 12); the datum `BottomProjection`, the PBW theorem `VOA.pbw`, the predicates `IsSimpleAMod` and `SimpleAModsRealized`, and Zhu's bijection (Chapter 13); Eisenstein series, slash operators and the analytic evaluation of q-series (Chapter 14).

The findings of this chapter, in brief. The reader who only wants the verdict should read this paragraph, Section 15.12, and the warning boxes.

- **The headline, in Zhu's form.** The two theorems `zhuModularity_canonical_of_C2Cofinite_admissiblyRational` and `zhuModularity_canonical_of_stronglyRational` (Theorem 15.39) say: let V be a *rational, C_2-cofinite* vertex operator algebra (of CFT type, which every vertex operator algebra of the library is), where "rational" is the library's `AdmissiblyRational` (every admissible module completely reducible); or let V be strongly rational, which contains these two conditions. Then the conclusion displayed in the next item holds. These are `#print axioms`-clean (the standard three axioms) and use the theorem `VOA.pbw`. The step "rational $\Rightarrow$ $A(V)$ semisimple" is the library theorem `isSemisimpleRing_A_of_admissiblyRational` (Zhu's Theorem 2.2.3; Dong–Li–Mason).

- **The engine: the semisimple form.** `zhuModularity_canonical_of_C2Cofinite_semisimple` (Theorem 15.37) is the more general form behind the headline. It says: let V be a C_2-cofinite vertex operator algebra whose Zhu algebra $A(V)$ is a *semisimple ring*. Then $\Phi(V)$, the set of isomorphism classes of irreducible ordinary V-modules, is finite, say with r elements, and for the canonical representatives $M_1, \dots, M_r$ of these classes, with their conformal weights $h_1, \dots, h_r$, there is a group homomorphism $\rho : SL_2(\mathbb{Z}) \to \mathrm{Mat}_r(\mathbb{C})$ with $\rho(T)$ the diagonal matrix of $e^{2\pi i(h_j - c/24)}$ such that, for *every* $\gamma = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in SL_2(\mathbb{Z})$, every $n \in \mathbb{N}$, every v of square-bracket weight n and every τ in the upper half-plane,

$$\mathcal{Z}_{M_i}\Big(v, \tfrac{a\tau+b}{c\tau+d}\Big) = (c\tau+d)^n \sum_{j=1}^{r} \rho(\gamma)_{ij}\, \mathcal{Z}_{M_j}(v,\tau), \qquad \mathcal{Z}_M(v,\tau) = \mathrm{tr}_M\; o(v)\, q^{L_0 - c/24}.$$

  The only hypotheses are C_2-cofiniteness and semisimplicity of $A(V)$. Finiteness of $\Phi(V)$ is a theorem (`finite_Φ_of_C2Cofinite_pbw`), and the family is the canonical one, so no family data are assumed. The theorem is `#print axioms`-clean (the standard three axioms) and uses the PBW theorem `VOA.pbw`, which is a theorem. It covers *one-point functions* only, not the n-point functions on the torus. This is Zhu's modular-invariance theorem for one-point functions (Zhu 1996, Theorem 5.3.3; Gannon's Theorem 5.3.8), with ρ attached to the actual modules ("pinned").

- **The one remaining caveat: what "rational" means.** Zhu assumes V rational and C_2-cofinite, and the headline assumes exactly that, with "rational" read as `AdmissiblyRational`. That predicate asks every *weak* submodule of an admissible module to have a weak complement. Dong–Li–Mason's rationality speaks of graded submodules. For C_2-cofinite V, DLM-rational implies `AdmissiblyRational` *in Lean*

(`VOA.Classification.COne.DLMRat.admissiblyRational_of_dlmRational`, Chapter 12, Theorem 12.36; `#print axioms`-clean, recorded by WS-RELEASE2; aggregate build at the release commit pending). Since the headline assumes C_2 anyway, it applies to every C_2-cofinite V that is rational in Dong–Li–Mason's sense, with no paper step. The converse (`AdmissiblyRational` ⇒ DLM-rational) is open.

- **Nontrivial instances.** `zhuModularity_V2m` (Theorem 15.44) proves Zhu's theorem for every rank-one lattice VOA $V_{\sqrt{2m}\mathbb{Z}}$, $m \geq 1$, from the library's `V2m_stronglyRational`; `zhuModularity_of_nice` proves it for every *nice* VOA (strongly rational and pseudo-unitary), so for every VOA that the library proves nice. `zhuModularity_V2mPlus` and `zhuModularity_cubicModel` (Theorem 15.43) discharge the hypotheses of the engine for the $c = 1$ orbifolds $V^+_{\sqrt{2m}\mathbb{Z}}$, $m \geq 2$, and for the tetrahedral orbifold, through a direct proof that $A(V)$ is semisimple. All four instances except `zhuModularity_of_nice` have no hypotheses beyond the range of m, and all four use only the standard three axioms. These are vertex operator algebras with nonconstant characters at which the library's Zhu theorem says something. The trivial VOA $\mathbb{C}\mathbf{1}$ is covered with no hypotheses (`trivialVOA_zhuModularity_closed`). *Correction:* the first release revision of this chapter said that $V_{\sqrt{2m}\mathbb{Z}}$ was not covered and that "rational ⇒ $A(V)$ semisimple" was unproved. Both claims were wrong, and so were the matching module docstrings (`RELEASE_AUDIT_NEW_DECLS.md`, F2). The docstrings have since been corrected.

- **The form for a given family.** `zhuModularity_pinned_of_C2Cofinite` (Theorem 15.34) is the same law for any list $M_1, \ldots, M_r$ of irreducible modules of length $r = \#\Phi(V)$, with conformal weights, whose bottoms are pairwise non-isomorphic when the weights agree; the headline is its specialisation to the canonical family. It is `#print axioms`-clean, *conditional on* the datum `Pr : BottomProjection (parabolicRepOfAMod W (regularAMod W))`; the variant `zhuModularity_pinned_of_C2Cofinite_voaPBW` supplies `Pr` from the theorem `VOA.pbw`.

- **Convergence and holomorphy are proved, not assumed, but by a separate theorem.** The growth theorem `onePointSubexp_of_c2` (from C_2-cofiniteness alone) says the coefficients of every one-point function grow subexponentially; the corollary `qSummableAt_of_subexponential` turns that into convergence on $\mathbb{H}$. Neither is part of the conclusion of the headline: the predicate `ZhuModularityAnalytic` evaluates q-series with a `tsum`, which returns 0 on a divergent series. A separate Lean check against the library (`headline_traces_are_genuine`) combines them and proves, from the headline's hypotheses, that the functions in the conclusion are genuinely convergent, holomorphic and not identically zero. That check is not part of the library or of this release.

- **The block count is an upper bound.** Zhu proves that the space of genus-one blocks has dimension exactly $\#\Phi(V)$. The library proves finite-dimensionality and dim $\leq \#\Phi(V)$ (`finiteDimensional_and_finrank_analyticBlocks_le_card_Φ`); the equality is a consequence of the chapter's results on paper but is not a Lean theorem.

- **Two redundant hypotheses, since removed from the headline** (checked in Lean; the check is not part of this release): `hzero : VacuumGradeZero W` holds for every vertex operator algebra of the library (it is a weakening of an axiom), and `hsimp` follows from `hss` and `Pr`. After this finding the library dropped both from `zhuModularity_pinned_of_C2Cofinite` and its `_voaPBW` wrapper (the quoted statements are the current ones); some auxiliary theorems still carry `hzero`.

- **What is not proved:** anything about the S-matrix beyond its existence (no unitarity, symmetry, $S^2 = C$, Verlinde formula) for this chapter's ρ (Chapter 21 proves Huang's Verlinde formula and the modular tensor category for nice VOAs); a modular linear differential equation with

modular-form coefficients for C_2-cofinite V; Zhu's theorem for n-point functions; and the orbifold (twisted) version, which appears only as the *statement* `Conjecture_5_3_10` — and that statement is mis-normalised (Section 15.15).

15.1 The theorem on paper, and the plan of the proof

15.1.1 Why characters should be modular

Let V be a vertex operator algebra of central charge c and M a module with conformal weight h, meaning that $M = \bigoplus_{n\geq 0} M_{h+n}$ with $L_0 = h + n$ on M_{h+n}, $M_h \neq 0$ and every M_{h+n} finite-dimensional. Its *character*, or graded dimension, is the formal series

$$\chi_M(q) = \operatorname{tr}_M q^{L_0 - c/24} = \sum_{n\geq 0} \dim M_{h+n}\, q^{h+n-c/24}.$$

For the Moonshine module $V^\natural$ one has $\chi_{V^\natural}(q) = J(q) = q^{-1} + 196884q + \cdots$, the normalised modular invariant; for the lattice VOA V_L of an even unimodular lattice one has $\chi_{V_L} = \Theta_L/\eta^{\mathrm{rk}L}$; for the Virasoro minimal models the characters are Rocha-Caridi's theta quotients. In every known rational example the characters, viewed as functions of τ in the upper half-plane $\mathbb{H}$ through $q = e^{2\pi i\tau}$, span a space that is mapped to itself by $\tau \mapsto \gamma\tau = (a\tau + b)/(c\tau + d)$, $\gamma \in SL_2(\mathbb{Z})$. Zhu's theorem explains this. More generally it treats the *one-point functions*

$$Z_M(v,\tau) = \operatorname{tr}_M o(v)\, q^{L_0 - c/24} = \sum_{n\geq 0} \operatorname{tr}\big(o(v)|_{M_{h+n}}\big)\, q^{h+n-c/24},$$

where $o(v)$ is the zero mode of v (for $v \in V_k$, $o(v) = v_{(k-1)}$, the mode that preserves each weight space; Chapter 12). For $v = \mathbf{1}$, $o(\mathbf{1}) = \mathrm{id}$ and $Z_M(\mathbf{1},\tau) = \chi_M$.

Theorem 15.1 (Zhu 1996, Theorem 5.3.3; Dong–Li–Mason 2000)**.** *Let V be rational and C_2-cofinite, with irreducible modules $M_1, \dots, M_r$. Then:*

1. *each $Z_{M_i}(v,\tau)$ converges to a holomorphic function on $\mathbb{H}$;*
2. *there is a representation $\rho : SL_2(\mathbb{Z}) \to GL_r(\mathbb{C})$ such that for every v in the square-bracket weight space $V_{[n]}$ (Section 15.3)*

$$Z_{M_i}(v,\gamma\tau) = (c\tau + d)^n \sum_j \rho(\gamma)_{ij} Z_{M_j}(v,\tau);$$

3. *the functions $Z_{M_1}(\cdot,\tau), \dots, Z_{M_r}(\cdot,\tau)$ are linearly independent, so ρ is unique.*

Physical meaning

This is the mathematical form of *modular invariance of the torus* in two-dimensional conformal field theory. A chiral CFT placed on a torus $\mathbb{C}/(\mathbb{Z} + \mathbb{Z}\tau)$ has a space of conformal blocks; the torus partition function of the full (left-right) theory is $Z(\tau,\bar\tau) = \sum_{i,j} N_{ij}\chi_i(\tau)\overline{\chi_j(\tau)}$, and it must not depend on how the torus was presented, i.e. it must be invariant under the mapping class group $SL_2(\mathbb{Z})$ of the torus. That is only possible if the χ_i span a representation of $SL_2(\mathbb{Z})$ — which is what Zhu proves. The one-point function $Z_M(v,\tau)$ is the torus expectation value $\langle v\rangle_\tau$ of the field v inserted at one point of the torus with the M-sector propagating around the cycle; inserting a field of conformal weight n (in the torus coordinate) turns the partition function into a modular form of weight n, which is the factor $(c\tau + d)^n$. The matrix $\rho(S)$, $S = \left(\begin{smallmatrix} 0 & -1 \\ 1 & 0 \end{smallmatrix}\right)$, is the *modular S-matrix*: it exchanges the space and time cycles of the torus, and through the Verlinde formula it determines the fusion rules.

Remark 15.2 (How the library uses rationality)**.** Theorem 15.1 is the statement in the literature, with the literature's hypothesis "rational". Zhu uses rationality in exactly two places: to know that $\Phi(V)$ is finite and that $A(V)$ is a semisimple algebra (his Theorem 2.2.3; Dong–Li–Mason for the version with their definition of rationality). The library proves the first from C_2-cofiniteness alone (`finite_Φ_of_C2Cofinite_pbw`, Section 15.12.2). It proves the second from its rationality predicate (`isSemisimpleRing_A_of_admissiblyRational`, Theorem 15.38). The theorem is stated in two layers. The *engine* (Theorem 15.37) has the two hypotheses

$$\text{(a) } V \text{ is } C_2\text{-cofinite}, \qquad \text{(b) } A(V) \text{ is a semisimple ring.}$$

Rationality implies (b), on paper and (for `AdmissiblyRational`) in Lean, so the engine implies Zhu's theorem. The converse is not claimed: Dong and Jiang characterise rationality by semisimplicity of *all* the higher Zhu algebras $A_n(V)$, so (b) alone is not known to imply rationality, and the library's form may be more general. The *headline* (Theorem 15.39) has Zhu's hypotheses,

$$\text{(a) } V \text{ is } C_2\text{-cofinite}, \qquad \text{(r) } V \text{ is rational (`AdmissiblyRational`)},$$

and the step (r) $\Rightarrow$ (b) is the Lean theorem `isSemisimpleRing_A_of_admissiblyRational`. (An earlier revision of this remark said that this step was missing and existed only as the named hypothesis `ZhuAdmissibleSemisimple` of Chapter 12. That was wrong: the library proves the step, and `zhuAdmissibleSemisimple_of_Pr` proves the named predicate itself.)

What remains open is the meaning of "rational". The library's `AdmissiblyRational` asks for complements of weak submodules; Dong–Li–Mason ask for complements of graded submodules. The library's own notes record that the relation is not settled (`VOA/Modules/AdmissibleRationality.lean`; Chapter 12, Section 12.9.2); one direction is now a theorem: for C_2-cofinite V, DLM-rationality implies `AdmissiblyRational` (`admissiblyRational_of_dlmRational`, Theorem 12.36). So for a C_2-cofinite V that is rational in the paper's sense the headline applies, through that Lean theorem; only the converse is open. For a V that the library proves `AdmissiblyRational`, such as the lattice VOAs $V_{\sqrt{2m}\mathbb{Z}}$ (Section 15.14), it applies with nothing on paper. Throughout this chapter "the library proves Zhu's theorem for rational C_2-cofinite V" therefore means rational in the sense of `AdmissiblyRational`.

15.1.2 Zhu's proof in seven steps

We describe the proof as the library carries it out. Each step is a section of this chapter.

1. **The second VOA structure.** Zhu changes coordinates from the plane to the cylinder, $z \mapsto e^z - 1$, obtaining new vertex operators $Y[v, z] = Y(e^{zL_0}v, e^z - 1)$, new modes $v[n]$ and a new Virasoro algebra $L[n]$ with the same central charge (Section 15.3).

2. **The recursion.** By a direct computation with traces and the Jacobi identity, the one-point functions of every module satisfy three identities, Zhu's *genus-one block conditions*: $\mathcal{Z}(a[0]v) = 0$; a recursion expressing $\mathcal{Z}(a[-2]v)$ through Eisenstein series times $\mathcal{Z}(a[2k-2]v)$; and an identity expressing $\frac{1}{2\pi i}\frac{d}{d\tau}\mathcal{Z}(v)$ through $\mathcal{Z}(L[-2]v)$ and Eisenstein series (Section 15.4). No finiteness hypothesis is needed for this.

3. **Convergence.** Under C_2-cofiniteness the formal q-series converge on all of $\mathbb{H}$ (Section 15.5).

4. **The block space.** Call a *genus-one block* any family $F(v, \tau)$, linear in v and holomorphic in τ, satisfying the three block conditions. They form a vector space $\mathfrak{B}$; the trace functions are in it (Section 15.6).

5. **Finiteness and the count.** $\dim \mathfrak{B} < \infty$ (Zhu's 5.3.2) and $\dim \mathfrak{B} \le \#\Phi(V)$ (Zhu's 5.3.3); the latter uses semisimplicity of $A(V)$ and the existence half of Zhu's correspondence, which itself rests on the Gaberdiel–Neitzke spanning theorem (Sections 15.7–15.8).

6. **The action.** The block conditions are covariant under $SL_2(\mathbb{Z})$, because Eisenstein series G_{2k}, $k \geq 2$, are modular and the defect of G_2 is compensated by the derivative term (Section 15.9).
7. **Reading off ρ.** The $r = \#\Phi(V)$ trace functions are linearly independent (Section 15.10); they lie in a space of dimension $\leq r$, so they are a basis; the slash of a trace function is again a block, hence a combination of traces; this defines ρ, and uniqueness makes it a homomorphism (Section 15.11). The headline is assembled in Section 15.12.

Remark 15.3 (What is different from Zhu)**.** Two steps are carried out differently from Zhu's paper, and the reader comparing with the literature should know where. (a) Convergence (step 3): Zhu derives a linear differential equation in $q\frac{d}{dq}$ with modular-form coefficients and uses the theory of regular singular points. The library does not; it proves that the span of the values of a formal block over a ring of "subexponential" power series is finitely generated and stable under $q\frac{d}{dq}$, and deduces subexponential growth of the coefficients from the resulting *first-order system* (Section 15.5). (b) Finite-dimensionality (step 5): Zhu proves $\dim \mathfrak{B} < \infty$ by the same differential equation. The library proves it with the identity theorem: condition (iii) expresses the derivative of a block through values of the block, so a block vanishing at one point on finitely many vectors vanishes identically (Section 15.7). Both are legitimate proofs; neither uses a modular linear differential equation.

15.2 One-point functions on the torus

15.2.1 Formal one-point functions

Recall from Chapter 12 (Definition 12.13) that a `FormalQSeries` is a function $\chi : \mathbb{C} \to \mathbb{C}$, read as the formal sum $\sum_e \chi(e)q^e$ over complex exponents; that `oMod N v` is the zero mode $o(v)$ on the module `N`; and that `onePoint N v` is the formal series whose coefficient at q^e is the trace of $o(v)$ on the weight space $M_{e+c/24}$. The modularity files re-export it under a torus name.

A note on two gradings. Two gradings of V occur in this chapter. V_n is the usual L_0-grading. $V_{[n]}$ (Lean: `sqWeightSpace W n`) is the eigenspace with eigenvalue n of $L[0]$, the zero mode of a *different* Virasoro algebra $L[m]$, the "square-bracket" or torus Virasoro algebra constructed in Section 15.3 (Definition 15.7, Theorem 15.8). $L[0] = L_0 +$ (operators lowering the L_0-degree), so $V_{[n]} \neq V_n$ in general, although they have the same dimensions. The modular weight in Zhu's law is the square-bracket weight n of $v \in V_{[n]}$; the zero mode $o(v)$ is always computed in the usual grading.

Definition 15.4 (Torus one-point function)**.** For an ordinary module M and $v \in V$, the *torus one-point function* is the formal series $Z_M(v;q) = \sum_{e\in\mathbb{C}} \operatorname{tr}\big(o(v)|_{M_{e+c/24}}\big)q^e$, i.e. $\operatorname{tr}_M o(v)q^{L_0-c/24}$; the *partition function* is $Z_M(\mathbf{1};q) = \chi_M(q)$. The map $v \mapsto Z_M(v;q)$ is linear.

From the mathematics to the Lean statement

Decoding. $\mathcal{V}$ is the underlying space of V and `W : VertexOperatorAlgebra` $\mathcal{V}$ the VOA structure. `OrdVModule W M` is an ordinary module structure on the space `M` (graded by L_0-eigenvalues $\alpha \in \mathbb{C}$ with finite-dimensional weight spaces, Definition 12.5). $\mathcal{V}$ `→ₗ[ℂ]` `FormalQSeries` is the type of $\mathbb{C}$-linear maps; `torusOnePointHom N` is $v \mapsto \mathcal{Z}_M(v;q)$ packaged as such a map, the linearity being the two proved lemmas named in the fields.
Exponent convention. The coefficient of `torusOnePoint N v` at the complex number e is the trace on the weight space of L_0-eigenvalue $e + c/24$. So for a module of conformal weight h the series is supported on $\{h - c/24 + n : n \in \mathbb{N}\}$, as in $\mathrm{tr}_M\, o(v) q^{L_0 - c/24}$. We shall check this convention at every place where a q-series is evaluated.
Fidelity. Same as the textbook definition. No grading hypothesis on v is needed: $o(v)$ is defined for every v by decomposing v into homogeneous components (Chapter 12).

Physical meaning

$\mathcal{Z}_M(v;q)$ is the torus one-point function $\langle v \rangle_{M,\tau}$: the path integral on a torus of modulus τ with one insertion of the field v and the states of the sector M running around the time cycle, weighted by $e^{2\pi i \tau (L_0 - c/24)}$. The shift $-c/24$ is the Casimir energy of the cylinder: mapping the plane to the cylinder shifts L_0 by $-c/24$ (Section 15.3). For $v = \mathbf{1}$ one gets the chiral partition function of the sector M.

What the machine verified

Definitions. `#print axioms VOA.torusOnePointHom_isFormalBlock` (which uses them): `propext, Classical.choice, Quot.sound`.

15.2.2 From formal series to functions on the upper half-plane

Definition 15.5 (Evaluation at τ; the trace functions). For $\tau \in \mathbb{H}$ put $q = e^{2\pi i \tau}$, so $|q| < 1$. For a formal series χ and an exponent offset $h_0 \in \mathbb{C}$ define

$$\mathrm{ev}_{h_0}(\chi)(\tau) = e^{2\pi i \tau h_0} \sum_{n \geq 0} \chi(h_0 + n)\, q^n,$$

the sum being the (unconditional) sum of the series when it converges, and 0 by convention otherwise. For a family $(M_i)_{i \in \iota}$ of irreducible modules with conformal weights h_i, the *trace function* is

$$S_i(v,\tau) = \mathrm{ev}_{h_i - c/24}\big(\mathcal{Z}_{M_i}(v;q)\big)(\tau) = \sum_{n \geq 0} \mathrm{tr}\big(o(v)|_{(M_i)_{h_i+n}}\big) e^{2\pi i \tau (h_i + n - c/24)}.$$

    (τ : UpperHalfPlane) : ℂ :=
  qEvalAt (torusOnePoint (Mfam i).isMod v) (h i - W.centralCharge / 24) τ
```

From the mathematics to the Lean statement

Decoding. `UpperHalfPlane` is Mathlib's $\mathbb{H} = \{\tau : \operatorname{Im}\tau > 0\}$; `(τ : ℂ)` its coercion to $\mathbb{C}$. `∑' n : ℕ, f n` is Mathlib's `tsum`: the sum of f if f is summable, and 0 otherwise. `Summable` is unconditional convergence (for $\mathbb{C}$-valued sequences: absolute convergence of the series). `Mfam : ι → IrrModule W` is a family of bundled irreducible modules (Definition 12.34) indexed by an arbitrary type `ι`; `(Mfam i).isMod` is the module structure. `h : ι → ℂ` is a separately supplied list of numbers, which the theorems below tie to the modules by the hypothesis `hcw : ∀ i, HasConformalWeight (Mfam i).isMod (h i)`.
Exponents. `traceFun` evaluates along the offset $h_i - c/24$, so the n-th term reads the coefficient $\chi(h_i - c/24 + n)$, which by the convention of Definition 15.4 is the trace on $(M_i)_{h_i+n}$, and multiplies by $e^{2\pi i\tau(h_i-c/24)}q^n$. That is exactly $\operatorname{tr}_{M_i} o(v)q^{L_0-c/24}$ with the standard branch $q^s := e^{2\pi i\tau s}$ for the complex power. The convention is consistent; compare the twisted case in Section 15.15, where it is not.
The junk value. Because `tsum` returns 0 on a divergent series, `traceFun` is a total function whether or not the trace series converges. Every theorem below that is *about* convergence says so with `QSummableAt` or with the growth predicate `OnePointSubexp` (Definition 15.14); the headline's conclusion does not, and we return to this in the fidelity check of the headline.

Physical meaning

$S_i(v,\tau)$ is the torus one-point function as an honest function of the modulus τ. Physically the convergence of the sum is the statement that the sector M_i has a finite partition function at every positive temperature $\operatorname{Im}\tau > 0$, i.e. that the number of states grows slower than exponentially in the energy. For a rational CFT the growth is $e^{2\pi\sqrt{c_{\text{eff}}n/6}}$ (Cardy's formula), far below any exponential.

What the machine verified

Definitions; no axioms beyond Mathlib's. The analytic facts about `qEvalAt` (holomorphy, termwise derivative, behaviour under $\tau \mapsto \tau + 1$) are in Chapter 14.

15.2.3 The T-transformation: proved for every module

The first and easiest part of modularity needs no hypothesis on V at all.

Theorem 15.6 (Zhu's law at T). *Let M have conformal weight h and let $v \in V$ be arbitrary. Then $\mathcal{Z}_M(v,\tau+1) = e^{2\pi i(h-c/24)}\mathcal{Z}_M(v,\tau)$, as formal q-series (where "$\tau \mapsto \tau+1$" acts on q^e by $e^{2\pi ie}$). Consequently, for a finite family (M_i,h_i) the law of Theorem 15.1(2) at $\gamma = T = \left(\begin{smallmatrix}1&1\\0&1\end{smallmatrix}\right)$ holds with $\rho(T) = \operatorname{diag}\big(e^{2\pi i(h_i-c/24)}\big)$.*

    qShift (torusOnePoint (D.Mfam i).isMod v)
      = ∑ j : ι, D.rep ModularGroup.T i j • torusOnePoint (D.Mfam j).isMod v := by
```

From the mathematics to the Lean statement

`qShift χ` is the formal series $e \mapsto e^{2\pi i e}\chi(e)$ (Chapter 12, Theorem 12.15), i.e. the effect of $\tau \mapsto \tau + 1$ on q^e. • is scalar multiplication. `ModularData` is defined in Section 15.11; its field `rep_T` forces `D.rep ModularGroup.T` to be `modularRepT`, so the second theorem is the first one read through that field. The analytic version (functions on $\mathbb{H}$ rather than formal series) is `zhu_modularity_T_analytic` in `ConvergenceBridge.lean`, also unconditional. Same as the textbook statement; no hypothesis on V.

Proof on paper. If $M_{e+c/24} \neq 0$ then $e + c/24 = h + n$ with $n \in \mathbb{N}$ (this is the second half of `HasConformalWeight`), so $e^{2\pi i e} = e^{2\pi i(h-c/24)}e^{2\pi i n} = e^{2\pi i(h-c/24)}$; if $M_{e+c/24} = 0$ both sides have coefficient 0. □

Physical meaning

T is the Dehn twist of the torus. Its eigenvalue on the sector M is $e^{2\pi i(h-c/24)}$: the twist rotates every state of energy $h + n - c/24$ by a phase, and the integer part n drops out. The T-matrix of a rational CFT is therefore diagonal with entries $e^{2\pi i(h_i-c/24)}$, the "topological spins" (up to the central-charge phase).

What the machine verified

`VOA.char_T_modularity`, `VOA.zhu_modularity_T_onePoint`: `propext`, `Classical.choice`, `Quot.sound`. Unconditional apart from `HasConformalWeight`.

15.3 The square-bracket vertex operator algebra

15.3.1 The change of coordinates

The torus is the quotient of the cylinder $\mathbb{C}/\mathbb{Z}$ (coordinate z) by $z \sim z+\tau$; the cylinder is the punctured plane (coordinate w) through $w = e^{2\pi i z}$. Zhu works with $w = e^z - 1$ (so that $z = 0$ goes to $w = 0$; the $2\pi i$ is put back at the end). Vertex operators transform under a change of coordinates, and for the map $z \mapsto e^z - 1$ Zhu proves that

$$Y[v,z] := Y\big(e^{zL_0}v,\ e^z - 1\big) = \sum_{n\in\mathbb{Z}} v[n]z^{-n-1}$$

defines a *second* vertex operator algebra structure on the same space V, with the same vacuum and the conformal vector $\tilde{\omega} = \omega - \frac{c}{24}\mathbf{1}$. For $v \in V_k$ the change of variable $w = e^z - 1$ in a residue gives

$$v[m] = \operatorname{Res}_z Y[v,z]z^m = \operatorname{Res}_w Y(v,w)(1+w)^{k-1}\big(\log(1+w)\big)^m = \sum_{i\geq m} c(k,m,i)\, v_{(i)}, \qquad (15.1)$$

where $c(k,m,i)$ is the coefficient of w^i in $(1+w)^{k-1}(\log(1+w))^m$. For $m < 0$, $(\log(1+w))^m$ is understood as $w^m u(w)^m$ with $u(w) = \log(1+w)/w = 1 - w/2 + \cdots$, a unit of $\mathbb{C}[[w]]$; for $k = 0$, $(1+w)^{-1}$ is the inverse unit. The sum in (15.1) is finite on each vector, because $v_{(i)}x = 0$ for i large.

Definition 15.7 (Square-bracket modes). For $k \in \mathbb{N}$, $m, i \in \mathbb{Z}$ let $c(k,m,i) = [w^{i-m}]\big((1+w)^{k-1}u(w)^m\big)$ if $i \geq m$ and 0 otherwise. For $v \in V$ and a declared weight k, the operator $v[m]_k = \sum_i c(k,m,i)v_{(i)}$. The torus Virasoro modes are $L[n] = \omega[n+1]_2 - \frac{c}{24}\mathbf{1}[n+1]_0$.

theorem Lsq_neg_one : Lsq W (-1) = W.L (-1) + W.L 0 := by
```

From the mathematics to the Lean statement

Decoding. `onePlusXUnit` is $1+w$ as a unit of $\mathbb{C}[[w]]$ and `uUnit` is $u(w) = \log(1+w)/w$ (`uSeries`, coefficients $(-1)^i/(i+1)$) as a unit, so `↑(onePlusXUnit ^ ((k : ℤ) - 1))` is $(1+w)^{k-1}$ for all $k \in \mathbb{N}$, including $k = 0$, and `↑(uUnit ^ m)` is u^m for all $m \in \mathbb{Z}$. `PowerSeries.coeff j` is the coefficient of w^j. So `sqBracketCoeffZ k m i` is $c(k,m,i)$. `mode (W.Y v) i` is $v_{(i)}$ (Chapter 1). $\sum^{\mathbf{f}}$ is a sum over a set of finite support (`finsum`); the support is finite because $c(k,m,i) = 0$ for $i < m$ and $v_{(i)}x = 0$ for large i (`sqModeZ_support_finite`). `vSqZ W v k m` is the operator $v[m]_k$.

The declared weight k. The square-bracket mode depends on a natural number k supplied separately; it is the genuine $v[m]$ of (15.1) only when $v \in V_k$. Every theorem below that uses `vSqZ W a ka m` carries the hypothesis `a ∈ W.grading (ka : ℤ)`, so this is harmless: the library defines $v[m]$ on homogeneous vectors and extends linearly where needed (`sqMode` in `SqGradedBlock.lean`).

$L[n]$. `Lsq W n` is $\omega[n+1] - \frac{c}{24}\mathbf{1}[n+1]$, i.e. $\tilde{\omega}[n+1]$, Zhu's $L[n]$. The vacuum term matters: $\mathbb{1}$`[n+1]` is the identity for $n = -2$ and 0 otherwise, so $L[-2] = \omega[-1] - \frac{c}{24}$. The file's docstring explains that without it the $\omega[n+1]$ satisfy a Virasoro algebra with a spurious extra cocycle. `Lsq_neg_one` is Zhu's $L[-1] = L_{-1} + L_0$ (Gannon writes $2\pi i(L_{-1} + L_0)$ because he uses $w = e^{2\pi i z} - 1$).

Fidelity. These are Zhu's definitions verbatim in the $w = e^z - 1$ normalisation (Zhu 1996, §4.2). The Bernoulli numbers in Zhu's recursion are, by `subst_expMinusOne_uSeries` (`SquareBracketSubst.lean`), the coefficients of u read in the variable z: $u(e^z - 1) = z/(e^z - 1)$. This is a proof that the coefficients are the right ones, not a numerical check.

Physical meaning

Mapping the plane to the cylinder is radial quantisation in reverse: the cylinder $\mathbb{R} \times S^1$ is the natural space-time of a closed string, and $L[0]$ is the Hamiltonian that generates translations along the cylinder. The Schwarzian derivative of $e^z - 1$ produces the constant $-\frac{c}{24}$ in the stress tensor: that is the Casimir energy of the cylinder, and it is the origin of $q^{-c/24}$ in every

character. $L[-1] = L_{-1} + L_0$ is the cylinder translation operator.

What the machine verified

`VOA.Lsq_neg_one: propext, Classical.choice, Quot.sound.` The coefficients were also checked by the project against Mathematica tables; that check is evidence, the Lean definitions and theorems are the proof.

15.3.2 The torus Virasoro algebra and the square-bracket grading

Theorem 15.8 (Zhu; Gannon 5.3.16). *The operators $L[n]$ satisfy the Virasoro relations with the same central charge: $[L[m], L[n]] = (m-n)L[m+n] + \frac{m^3-m}{12}\delta_{m+n,0}\,c$. The operator $L[0]$ is diagonalisable on V: V is the internal direct sum of the eigenspaces $V_{[k]} = \ker(L[0]-k)$, and only $k \in \mathbb{N}$ occur.*

Files `VOA/Modularity/GelfandFuks.lean` (a file of Chapter 14), `VOA/Modularity/SquareBracketGrading.lean`, `VOA/Modularity/SqWeightSpanning.lean`, `VOA/Modularity/SqWeightNat.lean`.

```

theorem sqWeightSpace_nat_spans_top (W : VertexOperatorAlgebra 𝒱) :
    (⨆ m : ℕ, sqWeightSpace W ((m : ℕ) : ℂ)) = ⊤ := by
```

From the mathematics to the Lean statement

`LinearMap.ker (Lsq W 0 - k • id)` is $\ker(L[0]-k)$. `DirectSum.IsInternal (sqWeightSpace W)` says that the natural map $\bigoplus_{k\in\mathbb{C}} V_{[k]} \to V$ is a linear isomorphism, i.e. V is the direct sum of the $L[0]$-eigenspaces. `⨆ m : ℕ, …` is the sum of submodules, so the last statement says that the eigenspaces with $k \in \mathbb{N}$ already span. `Lsq_virasoro_apply'` is the Virasoro relation applied to a vector `x`; the central term is $\frac{m^3-m}{12}c\,\delta_{m+n,0}$. All as in Zhu.

Proof on paper. Write $L[n] = \sum_a d(n,a)L_a$ (finite on each vector) with $d(n,a) = c(2, n+1, a+1)$, plus the vacuum term. The commutator $[L[m], L[n]]$ is a double sum of Virasoro commutators $[L_a, L_b] = (a-b)L_{a+b} + \frac{a^3-a}{12}\delta_{a+b,0}c$, so the relation reduces to two identities among the coefficients d: a "Witt" identity $\sum_a d(m,a)d(n,j-a)(2a-j) = (m-n)d(m+n,j)$ and a "central" identity for $\sum_a d(m,a)d(n,-a)(a^3-a)$. Both are identities of formal power series: they express that $z \mapsto e^z - 1$ is a coordinate change, under which vector fields transform as vector fields and the central term transforms with the Schwarzian derivative (Gelfand–Fuks cocycle). The second identity produces an extra term $-\frac{m-n}{2}\delta_{m+n,-2}$ which is exactly cancelled by the vacuum term $-\frac{c}{24}\mathbf{1}[n+1]$. For the grading: $L[0] = L_0 + \sum_{a\geq 1} d(0,a)L_a$ is L_0 plus operators that strictly lower the L_0-degree. On the finite-dimensional space $V_{\leq N} = \bigoplus_{k\leq N} V_k$, $L[0]$ is therefore triangular with diagonal L_0, hence diagonalisable with eigenvalues in $\{0, \dots, N\}$ (triangular with distinct diagonal blocks that are scalar). Eigenvectors for distinct eigenvalues are independent, and every vector lies in some $V_{\leq N}$. □

Physical meaning

The torus has its own conformal symmetry algebra, generated by $L[n]$; $L[0]$ is the energy measured on the cylinder, and its eigenvalue n on v is the modular weight with which v enters the torus one-point function. That the central charge is unchanged is the statement that c is an intrinsic property of the theory, independent of the surface.

What the machine verified

`VOA.Lsq_virasoro_apply'` and `VOA.sqWeightSpace_isInternal`: `propext`, `Classical.choice`, `Quot.sound`; unconditional, for every VOA of the library. (`Lsq_virasoro_apply` takes a hypothesis `CentralMomentClosed`, discharged by `centralMomentClosed_holds`.)

Remark 15.9 (What of the second VOA structure is formalised)**.** The library does *not* construct $(V, Y[\cdot,z], \mathbf{1}, \tilde{\omega})$ as a `VertexOperatorAlgebra`. It has the modes $v[m]$, the Virasoro relation for $L[n]$, the $L[0]$-grading, and the specific commutator facts that the block conditions need. The general statement "$a[m]$ shifts the $L[0]$-weight by $\mathrm{wt}[a]-m-1$" appeared as a carried datum `SqModeWeighted` in an earlier route; the route of the headline avoids it (Section 15.9). This is a legitimate economy, not a gap in the headline.

15.4 Zhu's recursion and the genus-one block conditions

15.4.1 Eisenstein series in Zhu's normalisation, and convolution

Definition 15.10 (Zhu's Eisenstein series; convolution)**.** For $j \geq 1$ let

$$G_{2j}(q) = -\frac{B_{2j}}{(2j)!} + \frac{2}{(2j-1)!}\sum_{n\geq 1}\sigma_{2j-1}(n)q^n,$$

with B_{2j} the Bernoulli numbers and $\sigma_s(n) = \sum_{d|n} d^s$. Equivalently $G_{2j} = \frac{2\zeta(2j)}{(2\pi i)^{2j}}E_{2j}$ with $E_{2j} = 1 + O(q)$ the normalised Eisenstein series; $G_2 = -\frac{1}{12}E_2$. For a sequence $f : \mathbb{N} \to \mathbb{C}$ (a power series $\sum_m f(m)q^m$) and a formal series χ, the *convolution* is $(f \star \chi)(e) = \sum_{m\geq 0} f(m)\chi(e-m)$, the coefficient of q^e in the product of the two series.

Files `VOA/Modularity/ZhuNormalization.lean`, `VOA/Modularity/ZhuRecursion.lean`, `VOA/Modularity/EisensteinAnalytic.lean` (Chapter 14).

```
noncomputable def zhuG (j : ℕ) : ℕ → ℂ :=
  fun m =>
    if m = 0 then -(((bernoulli (2 * j) : ℚ) : ℂ) / (Nat.factorial (2 * j) : ℂ))
    else (2 / (Nat.factorial (2 * j - 1) : ℂ)) * lambertCoeff (2 * j - 1) m

noncomputable def qConv (f : ℕ → ℂ) (g : FormalQSeries) : FormalQSeries :=
  fun e => ∑ᶠ n : ℕ, f n * g (e - (n : ℂ))

noncomputable def zhuGC (j : ℕ) (z : ℂ) : ℂ :=
  ∑' n : ℕ, zhuG j n * Complex.exp (2 * (Real.pi : ℂ) * Complex.I * (n : ℂ) * z)
```

From the mathematics to the Lean statement

`bernoulli` is Mathlib's Bernoulli number (with $B_1 = -\frac{1}{2}$; only even indices occur here, where conventions agree). `lambertCoeff (2 * j - 1) m` is $\sigma_{2j-1}(m)$ (`lambertCoeff_eq_sigma`). So

`zhuG j` is the coefficient sequence of G_{2j}, and `zhuGC j z` is the function $G_{2j}(e^{2\pi i z})$. `qConv f g` is the convolution (a `finsum`: it is finite on the series that occur, which are supported on a coset $h_0 + \mathbb{N}$). **Fidelity.** This is Zhu's normalisation (Zhu 1996, §3; Gannon §5.3.5): $\frac{2\zeta(2j)}{(2\pi i)^{2j}} = -\frac{B_{2j}}{(2j)!}$. The project first settled the constant by exact rational computations on the Heisenberg VOA, where other normalisations were falsified; but that is not what certifies it here: the recursion below is *proved* with this family.

Physical meaning

G_{2k} are the lattice sums $\sum_{(m,n)\neq 0}(m\tau+n)^{-2k}$ up to normalisation; they arise as the torus propagator: the Weierstrass functions $\wp$ and ζ expanded at the origin have the G_{2k} as Laurent coefficients. Zhu's recursion is the torus version of the operator product expansion: moving the field a around the torus and collecting the singular part of its OPE with v produces exactly these coefficients. G_2 is not modular; physically this is the holomorphic anomaly of the torus propagator.

What the machine verified

Definitions. `zhuG_eq_smul_zhuEisenstein` relates `zhuG` to the E-normalised series under the hypothesis $B_{2j} \neq 0$ (true, carried there because Mathlib lacks it); nothing downstream uses that comparison.

15.4.2 The recursion

Theorem 15.11 (Zhu's recursion; Zhu 1996, Prop. 4.3.2)**.** *Let M be any ordinary module, $a \in V_k$ with $k \geq 1$, and $v \in V$ arbitrary. Then, as formal q-series,*

$$Z_M(a[-1]v;q) = \operatorname{tr}_M o(a)o(v)q^{L_0-c/24} + \sum_{j\geq 1} G_{2j}(q)\, Z_M(a[2j-1]v;q),$$

the sum being finite.

Files `VOA/Modularity/OnePointFunctions.lean`, `VOA/Modularity/ZhuRecursion.lean`, `VOA/Modularity/ZhuNormalization.lean`, `VOA/Modularity/ZhuRecursionClose.lean`.

```
noncomputable def torusTwoPoint (N : OrdVModule W M) (a v : 𝒱) : FormalQSeries :=

theorem zhuRecursionPinned_holds {ka : ℕ} (hk : 1 ≤ ka) {a : 𝒱} (ha : a ∈ W.grading (ka :
↪  ℤ))
    (v : 𝒱) : ZhuRecursionPinned N a v ka := by
```

From the mathematics to the Lean statement

`weightBlock N A α` is the block of the operator A on the weight space M_α and `LinearMap.trace` its trace (Chapter 12); `(oMod N a).comp (oMod N v)` is $o(a)o(v)$. So `torusTwoPoint N a v` is $\mathrm{tr}_M\, o(a)o(v)q^{L_0-c/24}$ with the exponent convention of Definition 15.4. In `ZhuRecursionAt`, `G (k + 1)` stands for $G_{2(k+1)}$ and `vSqZ W a ka (2 * (k + 1) - 1 : ℤ) v` for $a[2k+1]v$; reindexing $j = k+1$ gives the displayed sum. The theorem quantifies over every module `N` (a section variable), every a of weight $k_a \geq 1$, and every v — there is no homogeneity hypothesis on v and no hypothesis on V. Same as Zhu's Proposition 4.3.2 (whose statement is for homogeneous v; the extension to all v is by linearity). The case $a = \mathbf{1}$, $k_a = 0$ is the trivial `zhuRecursionAt_vacuum_left`.

Trap / dead end

A wrong, unused interface (documentation only). The file `VOA/Modularity/OnePointFunctions.lean` still contains the earlier

```
def ZhuRecursion (N : OrdVModule W M) (G : ℕ → FormalQSeries) (a v : 𝒱) (ka : ℕ) :
 ↪  Prop :=
  torusOnePoint N (vSqZ W a ka (-1) v)
    = torusTwoPoint N a v
      + ∑ᶠ k : ℕ, G (k + 1) * torusOnePoint N (vSqZ W a ka (2 * (k + 1) - 1 : ℤ) v)
```

in which `G (k + 1) * torusOnePoint …` is the *pointwise* product of two functions $\mathbb{C} \to \mathbb{C}$, not the product of q-series. As a statement about q-series it is meaningless (the docstring of `qConv` says so itself). It is used nowhere (a repository-wide search finds no consumer), so no theorem is affected; but a reader must not take it for Zhu's recursion. Also stale: the docstring of `ZhuNormalization.lean` says that "`ZhuRecursionAt N zhuG` actually holds remains the open theorem", and its final "Residual" section repeats it; `zhuRecursionPinned_holds` proves it.

Proof on paper. Take $a \in V_k$, $v \in V_l$ homogeneous. By (15.1), $a[-1]v = \sum_{i\geq -1} c(k,-1,i)a_{(i)}v$, with $c(k,-1,-1) = 1$. So the left side is $\mathcal{Z}(a_{(-1)}v) + \sum_{i\geq 0} c(k,-1,i)\mathcal{Z}(a_{(i)}v)$. The heart of the matter is the computation of $\mathcal{Z}(a_{(i)}v) = \mathrm{tr}\, o(a_{(i)}v)q^{L_0-c/24}$. The Jacobi identity at $m = 0$ (the "iterate formula") writes $o(a_{(i)}v)$ as a finite combination of products $a_{(p)}v_{(k+l-p-2)}$ and $v_{(k+l-p-2)}a_{(p)}$ of modes, each of total degree zero. For such a "compensated pair" one uses cyclicity of the trace together with $q^{L_0}a_{(p)} = q^{p-k+1}a_{(p)}q^{L_0}$:

$$\mathrm{tr}\; a_{(p)}v_{(r)}q^{L_0} = \mathrm{tr}\; v_{(r)}q^{L_0}a_{(p)} = q^{k-1-p}\;\mathrm{tr}\; v_{(r)}a_{(p)}q^{L_0},$$

and the commutator $[a_{(p)}, v_{(r)}] = \sum_j \binom{p}{j}(a_{(j)}v)_{(p+r-j)}$. Solving the resulting geometric relation gives, for $p \neq k-1$, $\mathrm{tr}\, a_{(p)}v_{(r)}q^{L_0} = \frac{1}{1-q^{k-1-p}}\sum_j \binom{p}{j}\mathrm{tr}\, o(a_{(j)}v)q^{L_0}$, an expansion in q whose coefficients are the divisor-type sums $\sum_n n^s q^{nm}$. Collecting these geometric series over all p and all i is a purely combinatorial identity, and the result is exactly the Lambert series $\frac{2}{(2j-1)!}\sum_n \sigma_{2j-1}(n)q^n$ multiplying $\mathcal{Z}(a[2j-1]v)$; the constant terms collect into $-B_{2j}/(2j)!$ because the coefficients of $u(w)$ in the variable z are the Bernoulli generating function. The only term not of this form is $p = k-1$, which gives $\mathrm{tr}\, o(a)o(v)q^{L_0-c/24}$ with coefficient exactly 1. The library's proof is this computation, organised as an "abstract assembly" identity for the coefficient bookkeeping (`ZhuCoefficientIdentity.lean`) and the trace computation (`ZhuRecursionClose.lean`). □

Physical meaning

Zhu's recursion is the torus Ward identity: the one-point function of the descendant $a[-1]v$ (the normal-ordered product of the fields a and v on the cylinder) equals the two-point function of the zero modes plus a sum of torus propagator coefficients times one-point functions of the OPE coefficients $a[2j-1]v$. It is the higher-genus analogue of the statement that a correlation function on the sphere is determined by its OPE singularities.

What the machine verified

`VOA.zhuRecursionPinned_holds`: `propext, Classical.choice, Quot.sound`. Unconditional: every VOA, every module, every homogeneous a of positive weight, every v.

15.4.3 The three block conditions

Definition 15.12 (Formal genus-one block; Zhu 1996, Def. 4.3, 5.1)**.** A linear map $S : V \to \{\text{formal } q\text{-series}\}$ is a *formal genus-one block* if for every $k \geq 1$, every $a \in V_k$ and every $v \in V$:

(i) $S(a[0]v) = 0$;

(ii) $S(a[-2]v) + \sum_{j\geq 1}(2j-1)\,G_{2j} \star S(a[2j-2]v) = 0$;

(iii) and for every v: $S(L[-2]v) = q\frac{d}{dq}S(v) + \sum_{j\geq 1} G_{2j} \star S(L[2j-2]v)$.

Here $q\frac{d}{dq}$ acts on q^e by multiplication by e.

File `VOA/Modularity/ZhuBlockConditions.lean`.

```

Physical meaning

A formal genus-one block is a candidate assignment of torus one-point functions to all fields, written as power series in q (the torus seen from the degeneration limit of a long thin cylinder), and required to obey the torus Ward identities term by term. It is the algebraic shadow of a conformal block before any question of convergence is asked.

Theorem 15.13 (The trace functions are formal blocks; Zhu 1996, Prop. 4.3.5–4.3.6)**.** *For every ordinary module M of every VOA, $v \mapsto Z_M(v;q)$ is a formal genus-one block.*

File `VOA/Modularity/ZhuBlockConditions.lean`.

```
theorem torusOnePointHom_isFormalBlock (N : OrdVModule W M) : IsFormalBlock W
 ↪  (torusOnePointHom N) where
```

From the mathematics to the Lean statement

The three fields are the three conditions with $j = m+1$: `(2 * (m + 1) - 1 : ℕ)` is $2j-1$ and `2 * (m + 1) - 2` is $2j-2$. `qDeriv` is $q\frac{d}{dq}$ in the exponent convention $(e \cdot \chi(e))$. The quantifier "$a \in V_k$, $k \geq 1$" excludes only $V_0 = \mathbb{C}\mathbf{1}$, for which (i) and (ii) are trivial. The $j = 1$ term of (ii) involves $G_2 \star S(a[0]v)$, which vanishes by (i); the library keeps it, Zhu drops it — equivalent. Same as Zhu's definition.

Proof on paper. (i): for $a \in V_k$, $a[0] = \sum_i \binom{k-1}{i} a_{(i)}$, and the commutator formula gives $[o(a), o(v)] = \sum_i \binom{k-1}{i} o(a_{(i)}v) = o(a[0]v)$ (the "$\ell = 0$" case of the Jacobi identity). Since $o(a)$ and $o(v)$ preserve each finite-dimensional weight space M_{h+n}, the trace of their commutator there is 0. (ii) is the recursion (Theorem 15.11) applied to $L[-1]a$ in place of a: in the square-bracket structure $(L[-1]a)[m] = -m\,a[m-1]$, so $(L[-1]a)[-1] = a[-2]$ and $(L[-1]a)[2j-1] = -(2j-1)a[2j-2]$, which produces the factor $2j-1$; and the two-point term vanishes because $o(L[-1]a) = o(L_{-1}a) + o(L_0 a) = -k\,o(a) + k\,o(a) = 0$ (apply the recursion separately to the homogeneous pieces $L_{-1}a \in V_{k+1}$ and $L_0 a \in V_k$). (iii) is the recursion with $a = \omega$: $o(\omega) = L_0$, so $\operatorname{tr} o(\omega)o(v)q^{L_0 - c/24} = q\frac{d}{dq}Z(v) + \frac{c}{24}Z(v)$, and the $\frac{c}{24}$ is exactly absorbed by the vacuum term in $L[-2] = \omega[-1] - \frac{c}{24}$. □

Physical meaning

Conditions (i)–(iii) are the Ward identities of the chiral algebra on the torus. (i) says that zero modes of currents act by commutators, which are invisible in a trace (charge conservation around the cycle). (ii) is the OPE identity for the descendant $a[-2]v$. (iii) is the Ward identity of the stress tensor: inserting T on the torus is the same as differentiating with respect to the modulus τ (the torus has a one-dimensional moduli space, and T is its tangent vector) plus OPE terms. Condition (iii) is the seed of every differential equation for characters.

What the machine verified

`VOA.torusOnePointHom_isFormalBlock`: `propext`, `Classical.choice`, `Quot.sound`. Unconditional.

15.5 Convergence from C_2-cofiniteness

15.5.1 Subexponential growth

A power series $\sum a_n q^n$ converges on the whole unit disc $|q| < 1$ exactly when $\limsup |a_n|^{1/n} \leq 1$, i.e. when the coefficients grow slower than every exponential r^n, $r > 1$.

Definition 15.14 (Subexponential sequences; the growth and support data)**.** A sequence $a : \mathbb{N} \to \mathbb{R}$ is *subexponential* if for every $r > 1$ there is C with $a_n \leq Cr^n$ for all n. A module M with exponent offset h_0 has *subexponential one-point functions* if for every $v \in V$ the sequence $n \mapsto |Z_M(v;q)[q^{h_0+n}]|$ is subexponential, and *supported one-point functions* if $Z_M(v;q)[q^{h_0+i}] = 0$ for all v and all negative integers i.

Files `VOA/Modularity/ConvergenceBridge.lean`, `VOA/Modularity/AnalyticBlock.lean`.

```
def Subexponential (a : ℕ → ℝ) : Prop :=
  ∀ r : ℝ, 1 < r → ∃ C : ℝ, ∀ n : ℕ, a n ≤ C * r ^ n

theorem qSummableAt_of_subexponential (χ : FormalQSeries) (h : ℂ)
    (hsub : Subexponential (fun n : ℕ => ‖χ (h + n)‖)) (τ : UpperHalfPlane) :
```

```
    QSummableAt χ h τ := by

def OnePointSupported (N : OrdVModule W M) (h : ℂ) : Prop :=
  ∀ (v : V) (i : ℤ), i < 0 → torusOnePoint N v (h + (i : ℂ)) = 0

def OnePointSubexp (N : OrdVModule W M) (h : ℂ) : Prop :=
  ∀ v : V, Subexponential (fun n : ℕ => ‖torusOnePoint N v (h + (n : ℂ))‖)
```

From the mathematics to the Lean statement

`‖χ (h + n)‖` is the complex absolute value of the coefficient. The quantifier order in `Subexponential` is the right one (C may depend on r); with $\exists C\,\forall r$ the notion would be bounded growth, which is false for characters. `qSummableAt_of_subexponential` is the elementary comparison with a geometric series of ratio $r|q| < 1$. The offset h in `OnePointSubexp N h` is an *exponent*; the theorems below always use $h = h_M - c/24$, matching `traceFun`.

Physical meaning

Subexponential growth of $\dim M_{h+n}$ is the statement that the density of states grows slower than $e^{\beta E}$ for every inverse temperature $\beta > 0$: the theory has no Hagedorn temperature. Rational CFTs (and, more generally, all C_2-cofinite theories) have Cardy growth $e^{2\pi\sqrt{c_{\text{eff}}E/6}}$.

What the machine verified

Definitions and an elementary lemma: `propext, Classical.choice, Quot.sound`.

15.5.2 The vacuum hypothesis

Definition 15.15 (Vacuum spans the degree-zero space). $V_0 \subseteq \mathbb{C}\mathbf{1}$.

File `VOA/Modularity/BlockZeroMode.lean`.

```
def VacuumGradeZero : Prop := W.grading 0 ≤ Submodule.span ℂ ({W.vacuum} : Set V)
```

From the mathematics to the Lean statement

`W.grading 0` is V_0 and `Submodule.span ℂ {W.vacuum}` is $\mathbb{C}\mathbf{1}$; `≤` is inclusion of subspaces. Its docstring calls it "the only part of 'CFT type' that is not already a VOA axiom".

Trap / dead end

`VacuumGradeZero` is automatic (a redundant hypothesis, and a stale docstring). The library's `VertexOperatorAlgebra` has the axiom `vacuum_grade : W.grading 0 = Submodule.span ℂ {W.vacuum}` (Chapter 1), so `VacuumGradeZero W` holds for every V: it is `le_of_eq W.vacuum_grade`. The library knows this (`QuasiLisseSl2.vacuumGradeZero_of_vacuum_grade` in `AKSl2Payoff.lean`, and the strongly rational wrapper of Section 15.12 discharges it that way), but the hypothesis `hzero` is still carried by `onePointSubexp_of_c2`, by Zhu's 5.3.3 and by both headlines. Checked in Lean against the library: `VOA.L15Cert.vacuumGradeZero_always` (compiled with `-DmaxSynthPendingDepth=3`; standard three axioms; the check is not part of this release). It costs nothing and hides nothing, but a reader counting hypotheses should strike it.

Physical meaning

"CFT type": the vacuum is the unique state of zero energy. Physically this is uniqueness of the ground state of the chiral theory on the circle.

15.5.3 The growth theorem

Theorem 15.16 (Convergence of one-point functions; Zhu 1996 §4.4, Dong–Li–Mason 2000 §§6–7)**.** *Let V be C_2-cofinite and M an ordinary module with conformal weight h. Then for every $v \in V$ the coefficients of $\mathcal{Z}_M(v;q)$ along $h - c/24 + \mathbb{N}$ grow subexponentially. Consequently every trace function $S_i(v,\tau)$ is given by an absolutely convergent series on $\mathbb{H}$.*

File `VOA/Modularity/BlockGrowth.lean`.

```
theorem onePointSubexp_of_c2 {M : Type u} [AddCommGroup M] [Module ℂ M]
    (N : OrdVModule W M) {hw : ℂ} (hcw : HasConformalWeight N hw)
    (hzero : VacuumGradeZero W) (hC2 : C2Cofinite W) :
    OnePointSubexp N (hw - W.centralCharge / 24) := by
```

From the mathematics to the Lean statement

`C2Cofinite W` is $\dim V/C_2(V) < \infty$ (Definition 12.22). `HasConformalWeight N hw`: $M_{hw} \neq 0$ and every weight of M lies in $hw + \mathbb{N}$ (Chapter 12). `hzero` is redundant (warning above). The conclusion is for every v, not only $v = \mathbf{1}$. The "consequently" is `qSummableAt_of_subexponential`; it is assembled in a separate Lean check, `headline_traces_are_genuine`. Exactly the textbook statement, with no rationality hypothesis — as in Miyamoto and Dong–Li–Mason, convergence needs only C_2.

Proof on paper. Let R be the ring of power series $\sum f_m q^m$ whose coefficients grow subexponentially; it contains every G_{2j} (coefficients $O(m^{2j})$) and is closed under products and under $q\frac{d}{dq}$. Fix a formal block S (here $S = \mathcal{Z}_M$) whose values lie in $q^{h_0}\mathbb{C}[[q]]$, and let $\mathcal{S} = R \cdot S(V)$ be the R-span of its values. *Finite generation.* C_2-cofiniteness gives finitely many homogeneous $x_1, \dots, x_g$ spanning V modulo $C_2(V)$ (`exists_homog_gen_of_C2Cofinite`). Condition (ii) of the block expresses $S(a[-2]v)$, and therefore S of every element of $C_2(V)$ up to strictly lower degree, as an R-combination of values of S on vectors of lower degree. By induction on the degree, $\mathcal{S}$ is generated over R by $S(x_1), \dots, S(x_g), S(\mathbf{1})$. (Finiteness over the Noetherian ring $\mathbb{C}[G_2, G_4, G_6]$ is used to make this work uniformly.) *Stability under $q\frac{d}{dq}$.* By condition (iii), $q\frac{d}{dq}S(v) = S(L[-2]v) - \sum_j G_{2j} \star S(L[2j-2]v) \in \mathcal{S}$. So there is a $g' \times g'$ matrix A over R with $q\frac{d}{dq}Y = AY$ for the vector Y of generators. *Growth.* Writing $Y = \sum_n y_n q^{h_0+n}$, the system reads $(h_0+n)y_n = \sum_{j \le n} A_j y_{n-j}$; since $|h_0 + n| \sim n$, a majorant argument shows that if the A_j grow subexponentially then so do the y_n (`SystemGrowth.lean`). Finally every $S(v)$ is an R-combination of the generators, and convolution with a subexponential series preserves subexponential growth (`subexponential_qConv`). □

Physical meaning

The first-order system $q\frac{d}{dq}Y = AY$ is the torus version of the Knizhnik–Zamolodchikov-type equations: the genus-one conformal blocks form a flat vector bundle over the moduli space of tori, and A is its connection in the coordinate q. Convergence of the characters is then a statement about solutions of an ODE with a regular singularity at the cusp $q = 0$, which is how physicists usually think of it (Mathur–Mukhi–Sen).

What the machine verified

`VOA.onePointSubexp_of_c2`: `propext`, `Classical.choice`, `Quot.sound`. Conditional only on `C2Cofinite` (and the redundant `hzero`) and `HasConformalWeight`. Read exactly, it is a *growth* statement: the coefficients of $\mathcal{Z}_M(v;q)$ are subexponential. Convergence on $\mathbb{H}$ is the separate corollary `VOA.qSummableAt_of_subexponential` (standard three axioms, re-checked at an earlier commit (not re-run for this edition)); the two together give the "consequently" of Theorem 15.16. Neither appears in the conclusion of the headline (Section 15.12).

Trap / dead end

A refuted route to convergence (dead end, recorded in the library). Zhu's Lemma 4.4.4 converts the tower $S(L[-2]^i v)$ into the tower $(q\frac{d}{dq})^j S(v)$ unitriangularly. Read naively, *for every* v — the hypothesis `huni` of `onePointSubexp_of_unitriangular` and `onePointSubexp_of_unitriangular_cw` (`ZhuODEAssembly.lean`) — it is *false*: at $i=1$ and $v=L[-1]x$ the right side is built from $\mathcal{Z}(L[-1]x)=0$, while the left side is $\mathcal{Z}(L[-2]L[-1]x) = -\mathcal{Z}(L[-3]x)$ by the Virasoro relation, so it would force $\mathcal{Z}(L[-n]x)=0$ for all $n\geq 3$. Certificate in the library: `torusOnePoint_Lsq_neg_three_eq_zero_of_uniStep` in `VOA/Modularity/UniCollapse.lean`:

```
theorem torusOnePoint_Lsq_neg_three_eq_zero_of_uniStep
    (huni1 : ∀ v : 𝒱, ∃ hc : ℕ → PowerSeries ℂ,
      torusOnePoint N ((↟(Lsq W (-2)))^[1] v)
        = ∑ j ∈ Finset.range 2, psSMul (hc j) (qDeriv^[j] (torusOnePoint N v)))
    (x : 𝒱) : torusOnePoint N (Lsq W (-3) x) = 0 := by
```

Consequently the two theorems named above have an unsatisfiable hypothesis for any module with a nonzero $\mathcal{Z}(L[-3]x)$; they are "dead" (the library's own word) but still present. The correct statement holds for square-bracket *primary* v only (Arakawa–Kawasetsu, Lemma 5.5; Chapter 16). The headline uses neither: it uses the first-order system above.

Trap / dead end

Stale documentation (documentation only). The header of `ConvergenceBridge.lean` says that "`SubexponentialCoeffs` is carried as a named `Prop`" because "the ordering and the count are not built"; the header of `OnePointGrowth.lean` says the repository's growth theorem "only covers $v=\mathbf{1}$"; the docstring of `ZhuModularityWeightedAt` (`ZhuTheorem.lean`) says the convergence input is "present in neither this repo nor Mathlib"; and the header of `OnePointODE.lean` says `hode` "is not claimed to be discharged". All four predate `onePointSubexp_of_c2`, which proves the growth datum for every v from C_2-cofiniteness.

15.5.4 What about the modular differential equation?

Physicists know Zhu's convergence argument as the existence of a *modular linear differential equation* (MLDE): the characters of a rational VOA satisfy

$$\Big(D^s + \sum_{i<s} \phi_i(\tau) D^i\Big)\chi = 0, \qquad D = q\frac{d}{dq} - \frac{k}{12}E_2 \text{ (Serre derivative on weight } k),$$

with ϕ_i holomorphic modular forms of weight $2(s-i)$ (Mathur–Mukhi–Sen 1988; Zhu §4.4; Kaneko–Zagier for $s=2$). The library does *not* prove this for C_2-cofinite V. What exists:

- `exists_monic_Lsq_relation` (`FormalBlockFinite.lean`): Zhu's Lemma 4.4.2, a monic relation among $S(L[-2]^i v)$ with coefficients in $\mathbb{C}[G_2, G_4, G_6]$;

- `character_formalODE_of_etingofFinite` (Chapter 16): for the *character* ($v = \mathbf{1}$), a monic linear ODE in $q\frac{d}{dq}$ with *subexponential* (not modular) coefficients, under `EtingofFinite` (finite-dimensional zeroth Poisson homology; that quasi-lisse implies Etingof-finite is Etingof–Schedler and is not formalised); since C_2-cofinite implies `EtingofFinite` (`EtingofFinite_of_C2Cofinite`), this covers C_2-cofinite V too. By Chapter 16, Proposition 16.24, this equation is near-vacuous: every convergent q-series of the relevant kind satisfies one.

Neither is the MLDE with modular-form coefficients. The headline does not need it.

15.6 The space of genus-one blocks

Definition 15.17 (Analytic genus-one block; the block space $\mathfrak{B}$)**.** An *analytic genus-one block* is a map $F : V \times \mathbb{H} \to \mathbb{C}$, $F(v, z)$, linear in v and holomorphic in z, such that for every $k \geq 1$, $a \in V_k$, $v \in V$ and $z \in \mathbb{H}$:

(i) $F(a[0]v, z) = 0$;

(ii) $F(a[-2]v, z) + \sum_{j\geq 1}(2j-1)\,G_{2j}(z)F(a[2j-2]v, z) = 0$;

(iii) $F(L[-2]v, z) = \frac{1}{2\pi i}\frac{\partial}{\partial z}F(v, z) + \sum_{j\geq 1} G_{2j}(z)F(L[2j-2]v, z)$.

The *block space* $\mathfrak{B}$ is the vector space of such F, regarded as functions on $V \times \mathbb{H}$.

noncomputable def restrictImGT : (𝒱 → ℂ → ℂ) →ₗ[ℂ] (𝒱 → ℂ → ℂ) where
  toFun F := fun v => Set.indicator (imGT 0) (F v)
```

From the mathematics to the Lean statement

Decoding. A block is a function `F : 𝒱 → ℂ → ℂ`, defined on all of $\mathbb{C}$ in the second variable; `imGT 0` is $\mathbb{H}$ as a subset of $\mathbb{C}$. `DifferentiableOn ℂ (F v) (imGT 0)` is holomorphy on $\mathbb{H}$. `_root_.deriv` is the complex derivative ∂_z; since $\mathbb{H}$ is open, it only sees values on $\mathbb{H}$. Fields (ii) and (iii) are imposed only at $z \in \mathbb{H}$. Field (i) is stated as equality of functions on all of $\mathbb{C}$, i.e. also off $\mathbb{H}$; this is harmless (the trace blocks are extended by 0 off $\mathbb{H}$). `Set.indicator (imGT 0) f` is f on $\mathbb{H}$ and 0 elsewhere.

The block space is restrictImGT($\mathfrak{B}$)**, not $\mathfrak{B}$.** Since nothing constrains a block off $\mathbb{H}$ except linearity and (i), the submodule `analyticBlocks W` is infinite-dimensional for a trivial reason (arbitrary junk values off the half-plane). All dimension statements are therefore about its image under `restrictImGT`, which identifies blocks agreeing on $\mathbb{H}$. That image is Zhu's space $\mathfrak{B}$.

Fidelity with Zhu. Zhu's Definition 5.1.1 imposes the conditions on the $\mathbb{C}$-span of the functions, uses $q\frac{d}{dq} = \frac{1}{2\pi i}\partial_\tau$ in (iii), and requires holomorphy; all three are matched. Some later formulations (Dong–Li–Mason) also prescribe the shape of the q-expansion at the cusp; the library's $\mathfrak{B}$ imposes no condition at the cusp, which can only make $\mathfrak{B}$ larger, so the upper bound $\dim \mathfrak{B} \le \#\Phi(V)$ proved below is at least as strong as the literature's.

Physical meaning

$\mathfrak{B}$ is the space of torus one-point conformal blocks of the chiral algebra: all consistent assignments of a "one-point function" to fields, compatible with the torus Ward identities. In a rational CFT it is spanned by the characters of the sectors (with insertions), and its dimension is the number of primaries. The statement $\dim \mathfrak{B} = \#\Phi$ is the genus-one case of the Verlinde dimension formula.

What the machine verified

Definitions; the closure of `IsAnalyticBlock` under sums and scalars is proved (`IsAnalyticBlock.add`, `IsAnalyticBlock.smul`).

Theorem 15.18 (The trace functions are blocks; Zhu 1996, Thm. 5.3.1). *Let M have conformal weight h and subexponential one-point functions. Then $(v,z) \mapsto S_M(v,z)$ (the trace function, extended by 0 off $\mathbb{H}$) is an analytic genus-one block. In particular this holds for every ordinary module with a conformal weight over a C_2-cofinite V.*

theorem traceBlock_isAnalyticBlock
    (hcw : ∀ i, HasConformalWeight (Mfam i).isMod (h i))
    (hgr : ∀ i, OnePointSubexp (Mfam i).isMod (h i - W.centralCharge / 24)) (i : ι) :
    IsAnalyticBlock W (traceBlock Mfam h i) :=
```

From the mathematics to the Lean statement

`qEvalC χ h z` is `qEvalAt` in the plain complex variable z (Chapter 14). `traceBlock_coe` says that on $\mathbb{H}$ the block *is* the trace function `traceFun` of Definition 15.5. The support hypothesis is free from `HasConformalWeight` (`onePointSupported_of_hasConformalWeight`), and the

growth hypothesis from C_2 (Theorem 15.16). Same as Zhu's 5.3.1.

Proof on paper. The formal identities of Theorem 15.13 are transported to functions: under subexponential growth the evaluation map sends $q\frac{d}{dq}$ to $\frac{1}{2\pi i}\partial_z$ (termwise differentiation of a locally uniformly convergent series), sends the convolution $G_{2j} \star \chi$ to the product $G_{2j}(z)\cdot\chi(z)$ (Cauchy product of two absolutely convergent series), and is linear. Holomorphy is locally uniform convergence. □

Physical meaning

The characters with insertions solve the torus Ward identities: they are genuine conformal blocks. This is the "easy" inclusion span{characters} $\subseteq \mathfrak{B}$.

What the machine verified

`VOA.torusOnePoint_isAnalyticBlock`: `propext`, `Classical.choice`, `Quot.sound`; conditional on the displayed support and growth data, both of which are theorems under `HasConformalWeight` and `C2Cofinite`.

15.7 Finiteness of the block space and Zhu's count

15.7.1 Zhu's Theorem 5.3.2: $\dim \mathfrak{B} < \infty$

Theorem 15.19 (Zhu 1996, Thm. 5.3.2 in the form proved). *Let V be C_2-cofinite and let $x_1, \dots, x_g$ be homogeneous vectors spanning V modulo $C_2(V) + \mathbb{C}\mathbf{1}$. Then for any $z_0 \in \mathbb{H}$ the map $F \mapsto (F(x_1, z_0), \dots, F(x_g, z_0), F(\mathbf{1}, z_0))$ is injective on $\mathfrak{B}$. Hence $\dim \mathfrak{B} \le g + 1 < \infty$.*

Files `VOA/Modularity/C2Extraction.lean`, `VOA/Modularity/BlockFiniteDim.lean`.

```
theorem exists_homog_gen_of_C2Cofinite {V : Type u} [AddCommGroup V] [Module ℂ V]

    ∃ (g : ℕ) (gen : Fin g → V) (wt : Fin g → ℕ),
      (∀ i, 1 ≤ wt i) ∧ (∀ i, gen i ∈ W.grading (wt i : ℤ)) ∧
      (⊤ : Submodule ℂ V) = Submodule.span ℂ (Set.range gen ∪ {W.vacuum}) ⊔ O₂ W := by

theorem exists_finrank_analyticBlocks_le (hC2 : C2Cofinite W) {z₀ : ℂ} (hz₀ : z₀ ∈ imGT 0)
 ↪  :
    ∃ g : ℕ, FiniteDimensional ℂ (Submodule.map restrictImGT (analyticBlocks W)) ∧
      Module.finrank ℂ (Submodule.map restrictImGT (analyticBlocks W)) ≤ g + 1 := by
```

From the mathematics to the Lean statement

`O₂ W` is $C_2(V) = \mathrm{span}\{a_{(-2)}b\}$ (Definition 12.22); ⊔ is the sum of subspaces; `(⊤ : Submodule ℂ V) = …` says the right side is all of V. `Module.finrank` is the dimension. Since `finrank` is 0 on infinite-dimensional spaces, a bound on `finrank` alone would say nothing; the conjunct `FiniteDimensional` is what makes the bound meaningful, and it is present. The pointwise injectivity is the internal lemma `IsAnalyticBlock.eq_zero_of_vanish_at`.

Proof on paper. Suppose $F \in \mathfrak{B}$ vanishes at z_0 on $x_1, \dots, x_g, \mathbf{1}$. *Step 1: $F(\cdot, z_0) = 0$ on all of V.* By induction on the degree: modulo $C_2(V)$, V_n is spanned by the x_i, $\mathbf{1}$, and elements $a_{(-2)}b$; by (15.1), $a[-2]b = a_{(-2)}b +$ (lower degree), and condition (ii) at the single point z_0 gives $F(a[-2]b, z_0) = -\sum_j (2j-1)G_{2j}(z_0)F(a[2j-2]b, z_0)$, where all vectors on the right have lower degree. *Step 2: all derivatives vanish at z_0.* Condition (iii) gives $\partial_z F(v, z) = 2\pi i\big(F(L[-2]v, z) - \sum_j G_{2j}(z)F(L[2j-2]v, z)\big)$: the derivative of $F(v, \cdot)$ is a finite combination, with holomorphic coefficients, of the

functions $F(w,\cdot)$. Since $F(w,z_0)=0$ for all w by step 1, $\partial_z F(v,z_0)=0$ for all v; differentiating the same identity, by induction all $\partial_z^k F(v,z_0)=0$. *Step 3.* $F(v,\cdot)$ is holomorphic on the connected open set $\mathbb{H}$ with all derivatives zero at z_0, hence identically zero (identity theorem). □

Physical meaning

A torus conformal block is determined by finitely many numbers: its values on the finitely many "generating fields" at one value of the modulus. Equivalently, the genus-one blocks form a vector bundle of finite rank over the moduli space, with a flat connection given by the stress-tensor Ward identity (iii). Finite rank is the hallmark of a rational (or at least C_2-cofinite) theory.

What the machine verified

`VOA.exists_finrank_analyticBlocks_le`: `propext`, `Classical.choice`, `Quot.sound`; conditional only on `C2Cofinite`.

15.7.2 $A(V)$ is finite-dimensional

Theorem 15.20 (Zhu; Abe–Buhl–Dong). *If V is C_2-cofinite then* $\dim A(V)<\infty$.

File `VOA/Modularity/ZhuAlgebraFinite.lean`.

```
theorem finiteDimensional_A_of_C2Cofinite (hC2 : C2Cofinite W) :
    FiniteDimensional ℂ (A W) := by
```

From the mathematics to the Lean statement

`A W` is Zhu's algebra $V/O(V)$ (Chapter 12, Section 12.4). Textbook statement.

Proof on paper. For homogeneous $a\in V_m$, $a\circ b=\sum_{i=0}^{m}\binom{m}{i}a_{(i-2)}b\in O(V)$. Its $i=0$ term is $a_{(-2)}b$ and the others have strictly lower degree. So modulo $O(V)$ every element of $C_2(V)$ is congruent to an element of lower degree, and by induction the C_2-generators and $\mathbf{1}$ span V modulo $O(V)$. □

Physical meaning

$A(V)$ is the algebra of zero modes acting on ground states (primary states). Finite-dimensionality means finitely many species of primary states, the first sign of rationality.

What the machine verified

`propext`, `Classical.choice`, `Quot.sound`; conditional only on `C2Cofinite`.

15.7.3 Zhu's Theorem 5.3.3: $\dim \mathfrak{B}\le \#\Phi(V)$

The idea of Zhu's count is to look at a block at the cusp $q=0$. Expanding $F(v,\tau)=q^{\lambda}\sum_n F_n(v)q^n$, the leading coefficient F_0 is a linear functional on V which, by (i)–(iii) at $q=0$, factors through $A(V)$ and is *symmetric*: $F_0(a*b)=F_0(b*a)$. Symmetric functionals on a finite-dimensional semisimple algebra $A\cong\bigoplus_{i=1}^{m}\mathrm{Mat}_{n_i}(\mathbb{C})$ form a space of dimension m (the codimension of $[A,A]$), and each simple $A(V)$-module is the bottom of an irreducible V-module, distinct for distinct simple modules. So $m\le\#\Phi(V)$. The library carries this out with a "relation space" at the cusp and transports it to an interior point.

Definition 15.21 (Relation spaces). For $z_0\in\mathbb{C}$, $R(z_0)\subseteq V$ is the span of all $a[0]v$ and of all $a[-2]v+\sum_{j\ge2}(2j-1)G_{2j}(z_0)a[2j-2]v$ ($a\in V_k$, $k\ge1$). $R(\infty)$ is the same with $G_{2j}(z_0)$ replaced by the constant term $-B_{2j}/(2j)!$ of G_{2j}, i.e. its value at the cusp. $[A,A]$ is the span of commutators.

Files `VOA/Modularity/BlockFiniteDim.lean`, `VOA/Modularity/CuspLimit.lean`, `VOA/Modularity/SemisimpleTrace.lean`.

```
def blockRelSpan (z₀ : ℂ) : Submodule ℂ 𝒱 :=

def commSpan : Submodule K A := Submodule.span K {x : A | ∃ a b : A, x = a * b - b * a}
```

From the mathematics to the Lean statement

In both relation spaces the second family is condition (ii) with the sum started at $j = m+2 \geq 2$ (the $j = 1$ term is $G_2 \cdot a[0]v$, already in the first family), truncated at a K beyond which $a[2j-2]v = 0$. `zhuGC (m + 2) z₀` is $G_{2(m+2)}(z_0)$ and `zhuG (m + 2) 0` is its constant term. Every block kills $R(z_0)$ at z_0 (`IsAnalyticBlock.blockRelSpan_le_kerAt`).

Physical meaning

$V/R(z_0)$ is the space of "fields modulo torus Ward identities at modulus z_0"; its dual contains the space of blocks evaluated at z_0. At the cusp ($q \to 0$, the torus degenerating to a long cylinder) only the ground states propagate, and the Ward identities reduce to the zero-mode algebra $A(V)$ modulo commutators: a block becomes a trace over ground states.

What the machine verified

      Module.finrank ℂ (Submodule.map restrictImGT (analyticBlocks W)) ≤ Nat.card (Φ W) :=
      ↪ by
```

From the mathematics to the Lean statement

Hypotheses. `[Finite (Φ W)]`: finitely many irreducible ordinary modules up to isomorphism. `letI := instRingA W` installs the ring structure of $A(V)$ (Zhu's product) so that `IsSemisimpleRing (A W)` (Mathlib: every module is semisimple, equivalently Artin–Wedderburn) can be stated. `hreal : SimpleAModsRealized W`: every simple $A(V)$-module is the bottom of an irreducible module (Chapter 13, Definition 13.5); it is *discharged* in the headline from C_2 and `Pr` (Section 15.8). `Pr` is the datum of Chapter 13 (Definition 13.13); it is used through Zhu's bijection `zhuBijective Pr` to make distinct simple $A(V)$-modules give non-isomorphic V-modules. `Nat.card (Φ W)` is the number of elements of the finite type $\Phi(V)$.

Conclusion. `Submodule.map restrictImGT (analyticBlocks W)` is $\mathfrak{B}$ (dictionary of Definition 15.17). Both finite-dimensionality and the bound are stated, so the `finrank` trap does not apply. The name `finrank_analyticBlocks_le_card_Φ` denotes the bound alone; read alone it would be vacuous on an infinite-dimensional space, which is why we quote the conjunction.

Fidelity. Zhu proves $\dim \mathfrak{B} = \#\Phi(V)$ (with the traces as a basis) for rational C_2-cofinite V. Here only the *upper bound* $\leq$ is proved, together with finite-dimensionality. The reverse inequality follows on paper from the linear independence of $\#\Phi(V)$ trace functions (Section 15.10), so the equality is a consequence of the chapter's results under the headline's hypotheses; but it is *not* a Lean theorem, and the release must not announce "$\dim \mathfrak{B} = \#\Phi(V)$". When this result is cited, cite the conjunction `finiteDimensional_and_finrank_analyticBlocks_le_card_Φ`, not `finrank_analyticBlocks_le_card_Φ`.

The five displayed hypotheses are all dischargeable. `hzero` holds for every VOA of the library (Section 15.5); `hreal` is `simpleAModsRealized_of_C2Cofinite` (Theorem 15.25); `Pr` is `voaPBWBottomProjection`; `[Finite (Φ W)]` is `finite_Φ_of_C2Cofinite_pbw` (Theorem 15.35). So in substance the bound holds under C_2 and `hss` alone; the theorem as stated still displays all five.

Proof on paper. (1) A careful computation at $q = 0$ shows that $V/R(\infty) \cong A(V)/[A(V), A(V)]$: modulo $R(\infty)$, $O(V)$ dies (this uses condition (ii) at the cusp, whose constants $-B_{2j}/(2j)!$ reproduce the binomial coefficients of $a \circ b$), and $a[0]b \equiv a * b - b * a$ (Zhu's commutator lemma). For a finite-dimensional semisimple $\mathbb{C}$-algebra $A \cong \bigoplus_{i=1}^{m} \mathrm{Mat}_{n_i}(\mathbb{C})$, $[A, A] = \bigoplus \mathfrak{sl}_{n_i}$ has codimension m, the number of simple modules (Mathlib's Artin–Wedderburn over an algebraically closed field). Each simple module is realised as a bottom (`hreal`) and by the uniqueness half of Zhu's correspondence (`zhuBijective Pr`) non-isomorphic simple modules give non-isomorphic V-modules; so $m \leq \#\Phi(V)$.

(2) From (1), finitely many vectors T, $\#T \le \#\Phi(V)$, span V modulo $R(\infty)$. *Transport to the interior.* The relation module over the ring $\mathbb{C}[E_4, E_6]$ of modular forms (all G_{2j}, $j \ge 2$, lie in it) is finitely generated (Zhu's Lemma 4.4.1); evaluation at the cusp is a ring homomorphism $\mathbb{C}[E_4, E_6] \to \mathbb{C}$, and Nakayama's lemma at its kernel lifts the spanning family T from the cusp to a neighbourhood, hence to some interior point $z_0 \in \mathbb{H}$: $V = \operatorname{span}(T) + R(z_0)$. *Dual descent.* A block F kills $R(z_0)$ at z_0, so $F(\cdot, z_0)$ is determined by its values on T; by steps 1–3 of Theorem 15.19 (run with T in place of the generators) the evaluation $F \mapsto (F(t, z_0))_{t \in T}$ is injective on $\mathfrak{B}$. So $\dim \mathfrak{B} \le \#T \le \#\Phi(V)$. □

Physical meaning

"The number of independent torus blocks is at most the number of sectors." At the cusp each block becomes a trace functional on the primary states; a semisimple zero-mode algebra has exactly one trace per irreducible representation; each irreducible representation of $A(V)$ is the ground-state multiplet of exactly one sector.

What the machine verified

`VOA.finrank_quot_blockRelSpanAtCusp_le_card_Φ_of_C2`, `VOA.finiteDimensional_and_finrank_analyticBlocks_le_card_Φ`: `propext`, `Classical.choice`, `Quot.sound` (the conjunction, and the bound alone, re-checked at an earlier commit (not re-run for this edition)). Conditional on `C2Cofinite`, `IsSemisimpleRing (A W)`, `Finite (Φ W)`, `SimpleAModsRealized`, `Pr` (and the redundant `hzero`); all but the first two are dischargeable (dictionary). No `VOA.pbw`. An upper bound only.

15.8 Existence of modules: Gaberdiel–Neitzke and the realisation of simple $A(V)$-modules

Zhu's count needs every simple $A(V)$-module to occur as the bottom of an irreducible ordinary V-module. Chapter 13 constructs, for a simple $A(V)$-module U, Zhu's (Dong–Jiang's) irreducible module $L(U)$ with bottom U; what it does not supply is that the weight spaces of $L(U)$ are *finite-dimensional*, which is needed for $L(U)$ to be an ordinary module. That finiteness comes from a spanning theorem of Gaberdiel and Neitzke.

15.8.1 Strictly decreasing spanning

Definition 15.23 (Mode words; strict spanning; $C_m(V)$)**.** Fix homogeneous generators $x_1, \dots, x_g$ of positive weights. A *mode word* is $x^{i_1}_{(-p_1)} x^{i_2}_{(-p_2)} \cdots x^{i_k}_{(-p_k)}\mathbf{1}$ (outermost mode first), with $p_j \ge 1$; it is *strictly decreasing* if $p_1 > p_2 > \cdots > p_k \ge 1$. V has *strict spanning* if for some such generators the strictly decreasing words span V. $C_m(V) = \operatorname{span}\{u_{(-m)}v : u, v \in V\}$.

Files `VOA/Modularity/StrictSpanning.lean`, `VOA/Modularity/AnFiniteDim.lean`.

```
noncomputable def modeWord (W : VertexOperatorAlgebra ℱ) {g : ℕ} (gen : Fin g → ℱ) :

  spans : (τ : Submodule ℂ V) = Submodule.span ℂ
    {x | ∃ l : List (Fin g × ℕ), StrictDec l ∧ x = modeWord W gen l W.vacuum}

def CGen (W : VertexOperatorAlgebra V) (M : ℤ) : Submodule ℂ V :=
  Submodule.span ℂ {x | ∃ u v : V, x = W.smul u M v}
```

From the mathematics to the Lean statement

`W.smul u n v` is the product $u_{(n)}v$ (Chapter 1). A word is a list of pairs (generator index, p), head outermost, so `modeWord W gen l 𝟙` is the displayed word. `List.Pairwise (fun a b ⇒ b.2 < a.2) l` says that every later index is smaller than every earlier one: strict decrease. `StrictSpanning W` is a structure in `Type` (data, not a proposition): it records the generators. `CGen W (-m)` is $C_m(V)$; `CGen W (-2)` is `O₂ W`.

Convention. The library's words use *vertex-algebra* modes $x_{(-p)}$, $p \geq 1$, and require the index p to decrease strictly across *all* generators. Whether Gaberdiel–Neitzke's Proposition 8 is stated in these modes or in *weight* modes $x_{-n} = x_{(-n+\mathrm{wt}\,x-1)}$ ordered by n has **not been checked against the paper** (the release audit flags this as open). If GN use weight modes, the two statements differ whenever the generators have different weights, and neither implies the other. This is a question of labelling, not of correctness: the library *proves* its own form from C_2-cofiniteness (below), and uses it only through the consequence `cofinite_of_strictSpanning`, which is the content of GN's Theorem 11. When citing, say "strict-decrease spanning in vertex-algebra mode indices $x_{(-p)}$, $p \geq 1$", not "GN Proposition 8" without qualification.

Physical meaning

A PBW-type basis of the vacuum sector built from finitely many generating fields, with each mode used at most once: an "exclusion principle" for the modes. For the free fermion (not a VOA in this library's sense, but the paradigm) this is literally the Pauli principle; for C_2-cofinite theories it is a consequence of the null vectors that make $V/C_2(V)$ finite, and it is the algebraic reason for Cardy-type growth of the spectrum.

What the machine verified

Definitions.

Theorem 15.24 (Strict spanning; after Gaberdiel–Neitzke 2003, Prop. 8 and Thm. 11)**.** *Let V be C_2-cofinite and $x_1, \ldots, x_g$ homogeneous of positive weight spanning V modulo $C_2(V) + \mathbb{C}\mathbf{1}$. Then the mode words in the x_i whose vertex-algebra mode indices p (modes $x_{(-p)}$, $p \geq 1$) strictly decrease span V. Consequently, for every $m \geq 1$, $V/C_m(V)$ is finite-dimensional, spanned by the finitely many strictly decreasing words with all $p_j < m$.*

      (τ : Submodule ℂ 𝒱) = Submodule.span ℂ (S : Set 𝒱) ⊔ CGen W (-(m : ℤ)) := by
```

From the mathematics to the Lean statement

`GNReach W gen wt G N` is the induction statement of GN's proof: the part of V of total generator weight $\le G$ is spanned by ordered words with no repeated mode index at or below N; Proposition 8 is its limit, packaged into a `StrictSpanning` by `strictSpanning_of_GNReachBounded`. `strictSpanning_of_C2Cofinite` is a `def` (it produces data) defined by `Classical.choice` from the proposition `nonempty_strictSpanning_of_C2Cofinite`; this is the standard way to extract data from an existence proof and adds no assumption. `IsHomog W s`: s is homogeneous. The conclusion of `cofinite_of_strictSpanning` is "$V = \mathrm{span}(S) + C_m(V)$ with S finite", i.e. $\dim V/C_m(V) < \infty$.

Proof on paper. Prop. 8. Start from words with weakly ordered modes (Li's filtration gives spanning by such words modulo lower filtration). A word with a repeated index p contains $x_{(-p)}y_{(-p)}$; using the commutator formula, the iterate formula, and the fact that $x_{(-1)}y$ is a combination of generators modulo $C_2(V)$, one rewrites $x_{(-p)}y_{(-p)}w$ as a combination of words of lower total weight or with fewer repetitions (GN's Lemma 7). A lexicographic induction on (total weight, repetition bound) concludes. *Thm. 11.* In a strictly decreasing word the outermost index is the largest. If it is $\ge m$, the word is $x_{(-p)}w$ with $p \ge m$, which lies in $C_p(V) \subseteq C_m(V)$ (because $u_{(-p-1)}v = \frac{1}{p}(L_{-1}u)_{(-p)}v$). Otherwise all indices are $< m$; strictly decreasing lists of positive integers $< m$ have length $< m$, so there are finitely many such words. □

Physical meaning

C_2-cofiniteness ("finitely many fields modulo derivatives and normal-ordered products") propagates to all C_m-cofiniteness: the higher-level "zero-mode algebras" $A_n(V)$ that control excited states are all finite-dimensional.

What the machine verified

`VOA.gnProp8_GNReach`, `VOA.nonempty_strictSpanning_of_C2Cofinite`, `VOA.cofinite_of_strictSpanning`: `propext`, `Classical.choice`, `Quot.sound` (`nonempty_strictSpanning_of_C2Cofinite` re-checked at an earlier commit (not re-run for this edition)). Conditional only on `C2Cofinite`. The Prop-level results are `nonempty_strictSpanning_of_C2Cofinite` and `gnProp8_GNReach`; `strictSpanning_of_C2Cofinite` is a `def` producing data from them. The match of the mode convention with Gaberdiel–Neitzke's paper is unverified (dictionary).

15.8.2 Every simple $A(V)$-module is realised

Theorem 15.25 (Zhu's existence theorem under C_2; Zhu 1996, Thm. 2.2.1, with Dong–Li–Mason). *Let V be C_2-cofinite and assume the datum* `Pr`. *Then every simple $A(V)$-module is the bottom of an irreducible ordinary V-module.*

Files `VOA/Modularity/ZhuModularityGN.lean`, `VOA/Modularity/GNProp8Closure.lean`.

theorem simpleAModsRealized_of_C2Cofinite {W : VertexOperatorAlgebra 𝒱}
    (hC2 : C2Cofinite W)
    (Pr : BottomProjection (parabolicRepOfAMod W (regularAMod W))) :
    SimpleAModsRealized W :=
```

From the mathematics to the Lean statement

`SimpleAModsRealized W` (Chapter 13, Definition 13.5): for every $A(V)$-module U with `IsSimpleAMod U`, there is an `IrrRealization W U`: an irreducible graded module with finite-dimensional weight spaces and an $A(V)$-isomorphism of its bottom with U. Both hypotheses are explicit: `hC2` and `Pr` (there is no `_voaPBW` wrapper for this theorem; one instantiates `Pr` with `voaPBWBottomProjection`, as Chapter 13, Theorem 13.8 does). **Comparison with Zhu.** Zhu's existence theorem (part (2) of Theorem 13.1) needs *no* C_2 hypothesis: it produces an irreducible *admissible* module $L(U)$ for every simple U. The library's statement asks for more in the conclusion (finite-dimensional weight spaces, i.e. an ordinary module) and pays for it with C_2-cofiniteness, which is what makes the weight spaces finite-dimensional. Read correctly: "every simple $A(V)$-module is the bottom of an irreducible *ordinary* module, for C_2-cofinite V".

Proof on paper. Let U be simple. $A(V)$ is finite-dimensional (Theorem 15.20), so U is finite-dimensional and $[\omega]$ acts on it by a scalar h (it is central). Chapter 13 builds the irreducible module $L(U) = \bigoplus_n L(U)_{h+n}$ with $L(U)_h \cong U$; each $L(U)_{h+n}$ is a quotient of $A_{n,0}(V) \otimes_{A(V)} U$, where $A_{n,0}(V)$ is a Dong–Jiang bimodule, and $\dim A_{n,0}(V) < \infty$ as soon as $\dim V/C_{n+2}(V) < \infty$ (`finiteDimensional_AnmFull_of_cofinite`, `Anm0FiniteDim.lean`). By Theorem 15.24 the latter holds for every n, so $L(U)$ has finite-dimensional weight spaces and is an ordinary module. □

Physical meaning

Every primary multiplet allowed by the zero-mode algebra generates a sector with finitely many states at each energy level. In a C_2-cofinite theory there are no "infinite-multiplicity" sectors.

What the machine verified

`VOA.simpleAModsRealized_of_C2Cofinite`: `propext, Classical.choice, Quot.sound`; conditional on `C2Cofinite` and `Pr`. With `Pr` supplied by `voaPBWBottomProjection` it is conditional on C_2 alone, with the standard three axioms. At the snapshot `Pr` was available only through the then-axiom `VOA.pbw` (Chapter 13); that dependence was recorded as a library defect at the time and is now resolved, since `VOA.pbw` is a theorem.

Trap / dead end

Stale docstring (documentation only). The header of `RealizationCofinite.lean` lists "C_{n+2}-cofinite $\Leftarrow$ C_2-cofinite" as "Gaberdiel–Neitzke Prop. 8 — NOT BUILT". It is built (`GNProp8Closure.lean`).

15.9 The action of $SL_2(\mathbb{Z})$ on blocks

15.9.1 The slash operator

For $\gamma = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in SL_2(\mathbb{Z})$ and $k \in \mathbb{Z}$, the weight-k slash of a function f on $\mathbb{H}$ is $(f|_k\gamma)(z) = (cz+d)^{-k} f(\gamma z)$. Zhu's $SL_2(\mathbb{Z})$-action on $\mathfrak{B}$ is

$$(F|\gamma)(v,z) = (cz+d)^{-n} F(v, \gamma z) \qquad (v \in V_{[n]}),$$

extended linearly in v using the decomposition $V = \bigoplus_n V_{[n]}$ of Theorem 15.8.

Definition 15.26 (Slash; the pointwise slash of a family). $\mathrm{denom}_\gamma(z) = cz+d$, $\gamma z = (az+b)/(cz+d)$, $(f|_k\gamma)(z) = f(\gamma z)\,\mathrm{denom}_\gamma(z)^{-k}$. For a family F, the *pointwise slash* is $(F|\gamma)(v,\cdot) = F(v,\cdot)|_{\mathrm{wt}[v]}\gamma$, where $\mathrm{wt}[v]$ is the $L[0]$-weight of v if v is a nonzero $L[0]$-eigenvector and 0 otherwise.

Files `VOA/Modularity/SerreDerivative.lean` (Chapter 14), `VOA/Modularity/GradedBlock.lean`.

```
noncomputable def denomC (γ : SL(2, ℤ)) (z : ℂ) : ℂ := (γ 1 0 : ℂ) * z + (γ 1 1 : ℂ)

noncomputable def slashC (k : ℤ) (γ : SL(2, ℤ)) (f : ℂ → ℂ) (z : ℂ) : ℂ :=
  f (mobiusC γ z) * (denomC γ z) ^ (-k)

noncomputable def sqWtOf (W : VertexOperatorAlgebra 𝒱) (v : 𝒱) : ℤ :=
  if h : ∃ n : ℤ, v ∈ sqWeightSpace W (n : ℂ) ∧ v ≠ 0 then h.choose else 0

noncomputable def blockSlash (W : VertexOperatorAlgebra 𝒱) (γ : SL(2, ℤ)) (F : 𝒱 → ℂ → ℂ) :
    𝒱 → ℂ → ℂ := fun v => slashC (sqWtOf W v) γ (F v)
```

From the mathematics to the Lean statement

`SL(2, ℤ)` is Mathlib's $SL_2(\mathbb{Z})$; `γ 1 0` is the entry c, `γ 1 1` is d (rows and columns indexed from 0). `sqWtOf W v` is the $L[0]$-weight of v when v is a nonzero eigenvector (`h.choose` picks it; it is unique since eigenspaces for distinct eigenvalues meet in 0) and the junk value 0 otherwise. So `blockSlash W γ F` agrees with Zhu's action on every $L[0]$-homogeneous v, but is *not* linear in v: on a sum $v+w$ of vectors of different weights it uses the junk weight 0.

Trap / dead end

The pointwise slash is not Zhu's action, and a theorem stated with it was vacuous (recorded in the library). Because `blockSlash W γ F` is not additive in v, it is not a block, and an earlier reduction of Zhu's theorem (`zhu_modularity_of_analytic_finrank_le`, `BlockFiniteDim.lean`, marked "do not use") assumed a rank bound on an ambient space containing it. The library proves that this rank hypothesis is contradictory as soon as V has nonzero vectors of two different $L[0]$-weights $n \neq 0$ and 0 and some trace function is nonzero at Sz (`not_rank_analyticSlashAmbient_le`, `VOA/Modularity/SlashAmbientObstruction.lean`):

```
theorem not_rank_analyticSlashAmbient_le
    (hcw : ∀ i, HasConformalWeight (Mfam i).isMod (h i))
    (hgr : ∀ i, OnePointSubexp (Mfam i).isMod (h i - W.centralCharge / 24))
    (hind : TraceIndependent Mfam h)
    {z : ℂ} (hz : z ∈ imGT 0) {n : ℤ} (hn : n ≠ 0) {v w : 𝒱}
    (hv : v ∈ sqWeightSpace W (n : ℂ)) (hv0 : v ≠ 0)
    (hw : w ∈ sqWeightSpace W ((0 : ℤ) : ℂ)) (hw0 : w ≠ 0)
    {i : ι} (hT : traceBlock Mfam h i v (mobiusC ModularGroup.S z) ≠ 0)
    (hD : denomC ModularGroup.S z ^ (-n) ≠ 1) :
```

```
¬ (Module.rank ℂ (analyticSlashAmbient Mfam h) ≤ (Fintype.card ι : Cardinal)) :=
 ↪ by
```

The repair, used by the headline, is to restrict all functions to $L[0]$-*homogeneous* vectors before comparing them (next definition), where the pointwise slash is additive, and to use the genuinely linear slash `sqBlockSlash` (`SqGradedBlockSlash.lean`) to show that the restricted slash is the restriction of a block.

Physical meaning

The modular group acts on the torus modulus; a field of conformal weight n on the torus transforms like a modular form of weight n. The pointwise slash attaches the weight to each field separately, which is correct for fields of definite weight; for a superposition of fields of different weights one must transform each component separately, which is what the linear extension does.

What the machine verified

Definitions; `VOA.not_rank_analyticSlashAmbient_le`: `propext, Classical.choice, Quot.sound`.

15.9.2 Homogeneous points and the slash of a trace function

Definition 15.27 (Restriction to homogeneous points). $\mathrm{Pt}(V) = \{(n, v) : n \in \mathbb{Z},\ v \in V_{[n]}\}$. For $F : V \times \mathbb{C} \to \mathbb{C}$, $\mathrm{res}(F)$ is the function on $\mathrm{Pt}(V) \times \mathbb{C}$ given by $(n, v, z) \mapsto F(v, z)$ for $z \in \mathbb{H}$ and 0 otherwise.

File `VOA/Modularity/SlashAmbientObstruction.lean`.

```
def SqPt (W : VertexOperatorAlgebra 𝒱) : Type u := Σ n : ℤ, (sqWeightSpace W (n : ℂ))

noncomputable def sqRestrict (W : VertexOperatorAlgebra 𝒱) :
    (𝒱 → ℂ → ℂ) →ₗ[ℂ] (SqPt W → ℂ → ℂ) where
  toFun F := fun p z => restrictImGT F (p.2 : 𝒱) z
```

From the mathematics to the Lean statement

`Σ n : ℤ, (sqWeightSpace W (n : ℂ))` is the type of pairs (n, v) with $v \in V_{[n]}$ (a dependent sum); it contains $(n, 0)$ for every n, harmlessly. `sqRestrict W` is linear. Only integer weights are recorded; by Theorem 15.8 the weights are in $\mathbb{N}$, so nothing is lost. Since Zhu's law (Theorem 15.1(2)) is only asserted for homogeneous v, comparing functions after `sqRestrict` loses nothing that the theorem needs.

Physical meaning

Only fields of definite torus weight have a definite modular transformation law; restricting to them is restricting to the fields for which "the one-point function is a modular form of weight n" makes sense.

What the machine verified

Definition.

Theorem 15.28 (The S-slash of a trace function is a block; Zhu 1996, Thm. 5.3.2(ii)/5.3.3 step). *Let V be C_2-cofinite and M_i have conformal weight h_i. Then the restriction to homogeneous points of the*

pointwise S-slash of the trace block of M_i equals the restriction of some analytic block. More generally, for every analytic block F and every γ, $\mathrm{res}(F|\gamma) \in \mathrm{res}(\mathfrak{B})$.

File `VOA/Modularity/SqSlashBridge.lean`.

```
theorem sqRestrict_blockSlash_mem_analyticBlocks {F : V → ℂ → ℂ}
    (hF : IsAnalyticBlock W F) (gamma : SL(2, ℤ)) :
    sqRestrict W (blockSlash W gamma F) ∈
      Submodule.map (sqRestrict W) (analyticBlocks W) := by

theorem traceBlock_S_sqRestrict_mem_analyticBlocks
    (hcw : ∀ i, HasConformalWeight (Mfam i).isMod (h i))
    (hzero : VacuumGradeZero W) (hC2 : C2Cofinite W) (i : iota) :
    sqRestrict W (blockSlash W ModularGroup.S (traceBlock Mfam h i)) ∈
      Submodule.map (sqRestrict W) (analyticBlocks W) := by
```

From the mathematics to the Lean statement

In this file the space is called `V` and the index type `iota`; they are the $\mathcal{V}$ and ι of the other files. `ModularGroup.S` is $S = \left(\begin{smallmatrix} 0 & -1 \\ 1 & 0 \end{smallmatrix}\right)$. `Submodule.map (sqRestrict W) (analyticBlocks W)` is $\mathrm{res}(\mathfrak{B})$. The first theorem holds for every VOA and every block; the second specialises it, using Theorems 15.16 and 15.18 to know that the trace function is a block. Textbook content: "$\mathfrak{B}$ is $SL_2(\mathbb{Z})$-stable" (Zhu's Theorem 5.3.2 includes this), read on homogeneous vectors.

Proof on paper. Define the linear slash $F\|\gamma$ by $(F\|\gamma)(v) = \sum_n F(v_n)|_n\gamma$, where $v = \sum_n v_n$, $v_n \in V_{[n]}$. On homogeneous v it agrees with the pointwise slash, so $\mathrm{res}(F|\gamma) = \mathrm{res}(F\|\gamma)$; it remains to show $F\|\gamma \in \mathfrak{B}$. Linearity and holomorphy are clear. For (i) and (ii) one decomposes into square-bracket weights, using that $a[m]$ shifts the $L[0]$-weight by $\mathrm{wt}[a] - m - 1$ (proved here for the needed modes); then (ii) for $F\|\gamma$ follows from (ii) for F and the modularity $G_{2j}|_{2j}\gamma = G_{2j}$ for $j \geq 2$ (the $j = 1$ term is absent because of (i)). For (iii) one uses the Serre derivative $\vartheta_k f = \frac{1}{2\pi i} f' + kG_2 f = \frac{1}{2\pi i} f' - \frac{k}{12} E_2 f$ (in Zhu's normalisation $G_2 = -E_2/12$), which satisfies $(\vartheta_k f)|_{k+2}\gamma = \vartheta_k(f|_k\gamma)$ (Chapter 14): the non-modular part of G_2 is exactly the defect of $\frac{1}{2\pi i}\frac{d}{dz}$ under slashing, and condition (iii) contains the term $G_2(z)F(L[0]v, z) = nG_2(z)F(v, z)$, which turns the derivative into a Serre derivative. So (iii) is equivalent to an $SL_2(\mathbb{Z})$-covariant identity. □

Physical meaning

The torus Ward identities are invariant under large diffeomorphisms of the torus. The derivative with respect to the modulus is not covariant by itself (the holomorphic anomaly of E_2), but the trace of the stress tensor supplies exactly the compensating term: the Serre derivative is the covariant derivative on the line bundle of weight-n modular forms.

What the machine verified

`VOA.traceBlock_S_sqRestrict_mem_analyticBlocks`: `propext`, `Classical.choice`, `Quot.sound`; conditional on `HasConformalWeight`, `C2Cofinite` (and the redundant `hzero`). This removed the last "residual (e1)" of the project's earlier reductions.

15.10 Linear independence of the trace functions

Definition 15.29 (Trace independence; fibre independence)**.** The trace functions of a family $(M_i, h_i)_{i\in\iota}$ are *independent* if $\sum_j c_j S_j(v, \tau) = 0$ for all $n \in \mathbb{N}$, $v \in V_{[n]}$, $\tau \in \mathbb{H}$ forces all $c_j = 0$. Write $t_i = e^{2\pi i(h_i - c/24)}$ for the T-eigenvalue. They are *fibre-independent* if the same holds for each class $\{j : t_j = t_i\}$ separately.

Files `VOA/Modularity/BlockSpanning.lean`, `VOA/Modularity/TraceIndependence.lean`.

```
def TraceIndependent (Mfam : ι → IrrModule W) (h : ι → ℂ) : Prop :=
  ∀ c : ι → ℂ, (∀ (n : ℕ) (v : 𝒱), v ∈ sqWeightSpace W (n : ℂ) → ∀ τ : UpperHalfPlane,
    ∑ j, c j * traceFun Mfam h j v τ = 0) → c = 0

def FibreIndependent (Mfam : ι → IrrModule W) (h : ι → ℂ) : Prop :=
  ∀ (i : ι) (c : ι → ℂ),
    (∀ (n : ℕ) (v : 𝒱), v ∈ sqWeightSpace W (n : ℂ) → ∀ τ : UpperHalfPlane,
      ∑ j ∈ Finset.univ.filter (fun j => tEigen W h j = tEigen W h i),
        c j * traceFun Mfam h j v τ = 0) →
    ∀ j ∈ Finset.univ.filter (fun j => tEigen W h j = tEigen W h i), c j = 0

theorem traceIndependent_of_fibreIndependent (hcw : ∀ i, HasConformalWeight (Mfam i).isMod
↪  (h i))
    (hfib : FibreIndependent Mfam h) : TraceIndependent Mfam h := by
```

From the mathematics to the Lean statement

`tEigen W h j` is $e^{2\pi i(h_j - c/24)}$ (`TEigenInjective.lean`). `Finset.univ.filter P` is the finite set of indices satisfying P. `TraceIndependent` quantifies over homogeneous v only, which is the form needed (and weaker than independence over all v, hence a weaker hypothesis to prove and a sufficient one to use). Textbook notions.

Physical meaning

Distinct sectors have distinguishable torus one-point functions: no linear combination of the characters-with-insertions of distinct sectors vanishes. The T-eigenvalue fibres are the sectors with the same spin $h - c/24$ mod 1.

What the machine verified

`VOA.traceIndependent_of_fibreIndependent`: standard three axioms; no hypothesis on V.

Theorem 15.30 (Zhu 1996, Thm. 5.3.3, independence). *Let $M_1, \dots, M_r$ have conformal weights h_i and subexponential one-point functions, with simple bottoms $(M_i)_{h_i}$, such that $(M_j)_{h_j} \not\cong (M_k)_{h_k}$ as $A(V)$-modules whenever $j \neq k$ and $h_j = h_k$. Then their trace functions are independent.*

File `VOA/Modularity/FibreIndependence.lean`.

```
theorem fibreIndependent_of_bottomSeparation (Mfam : ι → IrrModule W) (h : ι → ℂ)
    (hcw : ∀ i, HasConformalWeight (Mfam i).isMod (h i))
    (hgr : ∀ i, OnePointSubexp (Mfam i).isMod (h i - W.centralCharge / 24))
    (hsimp : ∀ j, IsSimpleAMod (lowestAMod (hcw j).2))
    (hsep : ∀ j k : ι, j ≠ k → h j = h k →
      IsEmpty (AModEquiv W (lowestAMod (hcw j).2) (lowestAMod (hcw k).2))) :
    FibreIndependent Mfam h := by
```

From the mathematics to the Lean statement

`(hcw j).2` is the `IsLowestWeight` half of `HasConformalWeight`, and `lowestAMod` of it is the bottom $(M_j)_{h_j}$ as an $A(V)$-module (Chapter 12). `AModEquiv W U U'` is the type of $A(V)$-module isomorphisms and `IsEmpty` says there are none. So `hsep` is "non-isomorphic bottoms at equal weight", `hsimp` is "simple bottoms". Same as Zhu's hypotheses (which follow from "pairwise non-isomorphic irreducible modules" for rational V).

Proof on paper. Reduction to fibres. If $\sum_j c_j S_j = 0$, apply $\tau \mapsto \tau + k$ for $k = 0, 1, 2, \dots$: S_j is multiplied by t_j^k, so $\sum_j t_j^k (c_j S_j) = 0$ for all k; a Vandermonde (Lagrange interpolation) argument

isolates each fibre $\{t_j = t\}$. *Within a fibre* the h_j differ by integers. Let h_0 be the smallest weight among the j with $c_j \neq 0$ and expand at the cusp: the combination is a single q-series vanishing on $\mathbb{H}$, so its lowest coefficient vanishes; that coefficient is $\sum_{j:h_j=h_0} c_j \operatorname{tr}_{(M_j)_{h_0}} o(v)$ for all v, i.e. a vanishing combination of the characters $v \mapsto \operatorname{tr}_{U_j} \rho_j([v])$ of the pairwise non-isomorphic simple finite-dimensional $A(V)$-modules $U_j = (M_j)_{h_0}$. By the Jacobson density theorem these characters are linearly independent (there is $x \in A(V)$ acting as an idempotent of trace $\neq 0$ on U_{j_0} and as 0 on the others), so some $c_j = 0$ with $h_j = h_0$, a contradiction. □

Physical meaning

At low temperature ($q \to 0$) each character is dominated by its ground states, and the zero-mode algebra distinguishes non-isomorphic ground-state multiplets by their traces; the T-twist separates sectors of different spin.

What the machine verified

`VOA.fibreIndependent_of_bottomSeparation`: `propext`, `Classical.choice`, `Quot.sound`; conditional on the displayed `hcw`, `hgr`, `hsimp`, `hsep`. No hypothesis on V itself.

15.11 Reading off the representation

15.11.1 Modular data and the analytic modularity law

Definition 15.31 (Modular data; Zhu's analytic law). For a finite index set ι, *modular data* for V consist of a family $(M_i)_{i\in\iota}$ of irreducible modules, numbers h_i which are their conformal weights, a monoid homomorphism $\rho : SL_2(\mathbb{Z}) \to \mathrm{Mat}_\iota(\mathbb{C})$, and a matrix S with $\rho\left(\begin{smallmatrix} 0 & -1 \\ 1 & 0 \end{smallmatrix}\right) = S$ and $\rho\left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right) = \operatorname{diag}(e^{2\pi i(h_i - c/24)})$. They satisfy *Zhu's analytic law* if for all $\gamma \in SL_2(\mathbb{Z})$, $n \in \mathbb{N}$, $v \in V_{[n]}$, $i \in \iota$, $\tau \in \mathbb{H}$: $S_i(v, \gamma\tau) = (c\tau + d)^n \sum_j \rho(\gamma)_{ij} S_j(v, \tau)$.

Files `VOA/Modularity/ZhuTheorem.lean`, `VOA/Modularity/BlockSpanning.lean`.

```

    traceFun D.Mfam D.h i v (A • τ)
      = autFactor A τ ^ n * ∑ j, D.rep A i j * traceFun D.Mfam D.h j v τ
```

From the mathematics to the Lean statement

Decoding. `[Fintype ι]`: ι is finite. `Matrix.SpecialLinearGroup (Fin 2) ℤ` $= \mathtt{SL(2,\ \mathbb{Z})} = SL_2(\mathbb{Z})$. `→*` is a monoid homomorphism: $\rho(1) = 1$ and $\rho(AB) = \rho(A)\rho(B)$; as $SL_2(\mathbb{Z})$ is a group, $\rho(A)$ is automatically invertible with inverse $\rho(A^{-1})$, so ρ is a representation $SL_2(\mathbb{Z}) \to GL_\iota(\mathbb{C})$. `Matrix.of f` is the matrix with entries $f\ i\ j$. `ModularGroup.S`, `ModularGroup.T` are S and T. `A • τ` is Mathlib's Möbius action $\gamma\tau$. `autFactor A τ` is $c\tau + d$. `traceFun D.Mfam D.h i v` is the trace function $S_i(v, \cdot)$ of Definition 15.5, built from the family and weights *stored in D*.
What is and is not constrained. The field `rep_T` pins $\rho(T)$ to the diagonal matrix proved in Theorem 15.6; `repS` is free data. Because S and T generate $SL_2(\mathbb{Z})$, ρ is determined by `repS` and h (`ModularData.rep_eq_of_repS_eq`, via `monoidHom_ext_SL2Z`). Nothing in `ModularData` requires $\rho(S)$ to be unitary or symmetric, or $\rho(S)^2$ to be a permutation matrix.
`ZhuModularityAnalytic` vs. Theorem 15.1(2). Same quantifiers, same automorphy factor $(c\tau + d)^n$ with n the $L[0]$-weight, same index placement $\rho(\gamma)_{ij}$. Two points to keep in mind: (a) the predicate reads its whole content off `D.Mfam` and `D.h`; a theorem concluding only $\exists D$, `ZhuModularityAnalytic` D says nothing about any given family (Section 15.12); (b) **the predicate does not assert convergence and is not self-contained.** `traceFun` uses `tsum`, which is 0 on a divergent series; read alone, `ZhuModularityAnalytic D` would be satisfied by junk-zero trace functions for any `rep` with the right $\rho(T)$. Convergence is a separate theorem (Theorem 15.16, `onePointSubexp_of_c2`), and a separate Lean check against the library, `headline_traces_are_genuine` (not part of this release), proves, under the headline's own hypotheses C_2 and `hcw`, that every series in the conclusion converges, every trace function is holomorphic on $\mathbb{H}$, and none is identically zero. A referee must read the headline together with that check.

Physical meaning

The modular data (h, S) of a rational CFT: the conformal weights (through T) and the modular S-matrix. The transformation law says that the vector $(\langle v\rangle_{M_i,\tau})_i$ of one-point functions is a vector-valued modular form of weight n for the representation ρ. For $v = \mathbf{1}$ ($n = 0$) it is the statement that the characters form a vector-valued modular function, which makes $\sum_{ij} N_{ij}\chi_i\bar{\chi}_j$ modular invariant whenever the matrix N commutes with ρ.

What the machine verified

Definitions; no axioms beyond Mathlib's.

15.11.2 From spanning and independence to modular data

Theorem 15.32 (ρ from spanning and independence). *Suppose (spanning) for every γ there is a matrix ρ_γ with $S_i(v, \gamma\tau) = (c\tau + d)^n \sum_j (\rho_\gamma)_{ij} S_j(v, \tau)$ for all homogeneous v of weight n, and (independence) the S_j are linearly independent. Then ρ_γ is unique, $\gamma \mapsto \rho_\gamma$ is a homomorphism, $\rho_T = \mathrm{diag}(e^{2\pi i(h_i - c/24)})$, and the resulting modular data, with the given family and weights, satisfy Zhu's analytic law. Moreover spanning at the single matrix S implies spanning at every γ.*

    (hS : ∃ ρS : ι → ι → ℂ, RealisesLaw Mfam h ModularGroup.S ρS) :
    TraceSpanning Mfam h := by
```

From the mathematics to the Lean statement

`hsp : TraceSpanning Mfam h` and `hind : TraceIndependent Mfam h` are section variables of `modularDataOf` and `zhu_modularity_of_spanning`. `RealisesLaw Mfam h A ρ` is the law at the single matrix A with matrix ρ. `modularDataOf` visibly stores the *given* `Mfam` and `h`; its `rep` is $\gamma \mapsto \rho_\gamma$ (`rhoOf` chooses ρ_γ from `hsp` with `Classical.choose`, and independence makes the choice irrelevant). Same as the textbook argument.

Proof on paper. Uniqueness: if ρ, ρ' both realise the law at γ, then $\sum_j (\rho_{ij} - \rho'_{ij}) S_j = 0$ (divide by $(c\tau + d)^n \neq 0$), so $\rho = \rho'$ by independence. Homomorphism: $j(\gamma\delta, \tau) = j(\gamma, \delta\tau) j(\delta, \tau)$ for $j(\gamma, \tau) = c\tau + d$ (the cocycle `autFactor_mul`), so $\rho_\gamma \rho_\delta$ realises the law at $\gamma\delta$, and by uniqueness equals $\rho_{\gamma\delta}$; likewise $\rho_1 = 1$. T: by Theorem 15.6 the diagonal matrix realises the law at T. From S to all γ: the set of γ at which the law is realisable is closed under products and contains S and T; since $S^{-1} = S^3$ and $T^{-1} = (ST)^5 S$, the *monoid* generated by S, T is all of $SL_2(\mathbb{Z})$. □

Physical meaning

Modular invariance need only be checked on the two generators: T (the Dehn twist, which is automatic) and S (the exchange of space and time, which is the real content). This is how physicists verify modular invariance of a proposed torus partition function.

What the machine verified

`VOA.zhu_modularity_of_spanning`: `propext, Classical.choice, Quot.sound`; conditional on the two named data. `VOA.traceSpanning_of_S`: same axioms; conditional on the S-law.

15.11.3 Spanning at S from the dimension count

Theorem 15.33 (S-spanning from a rank bound). *Let $\mathfrak{A}$ be any space of functions on homogeneous points containing* $\mathrm{res}(S_i)$ *and* $\mathrm{res}(S_i|S)$ *for all i, of dimension $\leq \#\iota$, and suppose the S_i are independent. Then each* $\mathrm{res}(S_i|S)$ *is a linear combination of the* $\mathrm{res}(S_j)$*. Under the hypotheses of Theorem 15.22 the space $\mathfrak{A} = \mathrm{res}(\mathfrak{B})$ has dimension $\leq \#\Phi(V)$.*

    Module.rank ℂ (Submodule.map (sqRestrict W) (analyticBlocks W))
      ≤ (Fintype.card ι : Cardinal) := by
```

From the mathematics to the Lean statement

`Module.rank` is the dimension as a cardinal (so no `finrank`-is-0 trap). `Fintype.card ι` is $\#\iota$; `hcard` says the family has exactly $\#\Phi(V)$ members (in the headline it forces one representative per isomorphism class; Section 15.12). `SlashSpannedAtS` uses the pointwise slash, but only on homogeneous v, where it is Zhu's action. `traceSpanning_of_slashSpannedAtS` converts the S-statement about blocks into the S-law for `traceFun` (using `traceBlock_coe` and that $\mathrm{denom}_S(\tau)^{-n}$ is $(c\tau+d)^{-n}$) and then applies `traceSpanning_of_S`. `rank_map_sqRestrict_analyticBlocks_le` is Theorem 15.22 pushed through the linear map res (dimension cannot increase).

Proof on paper. The $\#\iota$ functions $\mathrm{res}(S_i)$ are independent (independence of the S_i is already a statement on homogeneous vectors) and lie in $\mathfrak{A}$ of dimension $\leq \#\iota$; so they are a basis of $\mathfrak{A}$, and $\mathrm{res}(S_i|S) \in \mathfrak{A}$ is a combination of them. □

Physical meaning

Since there are as many characters as independent torus blocks, the characters *are* the blocks; the S-transform of a character is a block, hence a combination of characters: the coefficients are the S-matrix.

What the machine verified

All three theorems: `propext, Classical.choice, Quot.sound`. `rank_map_sqRestrict_analyticBlocks_le` is conditional on the hypotheses of Theorem 15.22 and `hcard`.

15.12 The modularity theorem

The section has four parts. First the general *pinned* form, for an arbitrary complete list of irreducible modules (Theorem 15.34); it is the theorem that does the work. Then its specialisation to the canonical list of representatives, which has only the two hypotheses C_2 and "$A(V)$ semisimple" (the engine, Section 15.12.2). Then the chapter's headline, in Zhu's own form "C_2-cofinite and rational", obtained from the engine through the Lean theorem "rational ⇒ $A(V)$ semisimple" (Section 15.12.3). Finally the older strongly rational packaging, now superseded.

15.12.1 The statement for a given family

Theorem 15.34 (Zhu's modularity theorem, pinned to a given family)**.** *Let V be a vertex operator algebra of the library such that*

(a) V is C_2-cofinite;

(b) Zhu's algebra $A(V)$ is semisimple;

(c) $\Phi(V)$, the set of isomorphism classes of irreducible ordinary modules, is finite;

(d) the datum `Pr : BottomProjection (parabolicRepOfAMod W (regularAMod W))` *is given (Chapter 13).*

Let ι be a finite set with $\#\iota = \#\Phi(V)$ (hypothesis `hcard`*: one index per isomorphism class), and $(M_i, h_i)_{i\in\iota}$ irreducible ordinary modules with conformal weights h_i, whose bottoms $(M_i)_{h_i}$ are simple $A(V)$-modules, pairwise non-isomorphic whenever $h_j = h_k$, $j \neq k$. Then there are modular data D with $D.\mathrm{Mfam} = (M_i)$ and $D.h = (h_i)$ satisfying Zhu's analytic law: there is a homomorphism $\rho : SL_2(\mathbb{Z}) \to \mathrm{Mat}_\iota(\mathbb{C})$ with $\rho(T) = \mathrm{diag}(e^{2\pi i(h_i - c/24)})$ such that for all $\gamma \in SL_2(\mathbb{Z})$, $n \in \mathbb{N}$, $v \in V_{[n]}$, $i \in \iota$, $\tau \in \mathbb{H}$,*

$$\mathrm{tr}_{M_i}\, o(v) q^{L_0 - c/24}\big|_{\gamma\tau} = (c\tau + d)^n \sum_{j\in\iota} \rho(\gamma)_{ij}\ \mathrm{tr}_{M_j}\, o(v) q^{L_0 - c/24}\big|_{\tau}.$$

Since (d) is supplied for every V by the theorem `VOA.pbw` *(through* `voaPBWBottomProjection`*), the conclusion holds under (a)–(c) (this is* `zhuModularity_pinned_of_C2Cofinite_voaPBW`*).*

Files `VOA/Modularity/GNProp8Closure.lean` and `VOA/Modularity/GNProp8PBW.lean`.

From the mathematics to the Lean statement

We go through the statement symbol by symbol; the section variables are `{𝒱 : Type u} [AddCommGroup 𝒱] [Module ℂ 𝒱] {W : VertexOperatorAlgebra 𝒱}` and `{ι : Type*} [Fintype ι] [DecidableEq ι]`.

Hypotheses, one by one.

- `[Finite (Φ W)]`: (c). An instance argument, i.e. a hypothesis found automatically when available.
- `Mfam`, `h`: the family and its weights; arbitrary data constrained only by the hypotheses below.
- `hzero : VacuumGradeZero W`: $V_0 \subseteq \mathbb{C}\mathbf{1}$. *Redundant*: true for every VOA of the library (Section 15.5).
- `hC2 : C2Cofinite W`: (a), Definition 12.22.
- `hss`: (b). `IsSemisimpleRing` is Mathlib's notion for the ring `A W` with Zhu's product.
- `Pr`: (d). In the `_voaPBW` form it is supplied by `voaPBWBottomProjection`, which uses the theorem `VOA.pbw`.
- `hcard : Fintype.card ι = Nat.card (Φ W)`: the index set has *exactly* $\#\Phi(V)$ elements. With `hcw` and `hsep` this forces the family to be one representative of each isomorphism class of irreducible modules, i.e. a complete irredundant list (argued in "The family is a complete list" below). It is the hypothesis that makes "the traces span the blocks" possible: $\#\iota$ independent traces in a space of dimension $\leq \#\Phi(V) = \#\iota$.
- `hcw`: each M_i has conformal weight h_i (nonzero bottom $(M_i)_{h_i}$, all weights in $h_i + \mathbb{N}$). It ties the free data `h` to the modules. For irreducible modules such an h_i always exists and is unique (`exists_hasConformalWeight_of_irreducible`, `LowestWeightExistence.lean`).
- (removed) `hsimp`: each bottom is a simple $A(V)$-module. It was *redundant given* `hss` *and* `Pr` and the current headline no longer carries it: it follows from Chapter 12's `isSimpleAMod_of_irreducible_of_semisimple` (Theorem 12.20).
- `hsep`: bottoms of distinct members with equal weight are non-isomorphic.

The family is a complete list. The hypotheses force (M_i) to be a system of representatives of $\Phi(V)$: if $M_j \cong M_k$ with $j \neq k$, then $h_j = h_k$ (the conformal weight of an irreducible module is an isomorphism invariant) and the bottoms are isomorphic, contradicting `hsep`; so $i \mapsto [M_i]$ is injective, and as $\#\iota = \#\Phi(V)$ is finite, bijective. (This is an argument on paper; the library does not state it as a lemma, and does not need to.) Thus the theorem is exactly about *all* irreducible modules, as Zhu's is.

The conclusion is pinned. `∃ D : ModularData W ι, D.Mfam = Mfam ∧ D.h = h ∧ ZhuModularityAnalytic D`: the modular data are those *of the given family*. Without the two equations the statement would be much weaker (see the warning below).

Same as, stronger or weaker than Zhu? Compared with Theorem 15.1:

- *Hypotheses on V*: "rational" is replaced by "$A(V)$ semisimple and $\Phi(V)$ finite"; and finiteness of $\Phi(V)$ is itself a theorem under C_2 (`finite_Φ_of_C2Cofinite_pbw`, Section 15.12.2). For rational V semisimplicity follows (Zhu; Dong–Li–Mason), and the library proves that implication for its predicate `AdmissiblyRational` (`isSemisimpleRing_A_of_admissiblyRational`, Theorem 15.38). Under C_2, Dong–Li–Mason rationality implies `AdmissiblyRational` in Lean (`admissiblyRational_of_dlmRational`); only the converse is open (Remark 15.2). In the other direction we make no claim that the library's hypotheses imply rationality (Dong and Jiang characterise rationality by semisimplicity of *all* the higher Zhu algebras $A_n(V)$, not of $A(V)$ alone), so as a theorem about V the library's form is at least as general as Zhu's.

- *Conclusion*: (2) and (3) of Theorem 15.1 for the one-point functions, with ρ a representation. Convergence (1) is proved by `onePointSubexp_of_c2` under the same hypotheses but is not part of the conclusion (next item). Zhu's theorem also covers n-point functions on the torus; the library does not.
- *Convergence*: `ZhuModularityAnalytic` uses `traceFun`, whose `tsum` would be 0 on a divergent series. Read alone, the conclusion would be compatible with all trace functions being junk zeros. It is not: under `hC2` and `hcw`, a separate Lean check, `headline_traces_are_genuine` (below), proves that every series in the conclusion converges, that every trace function is holomorphic on $\mathbb{H}$, and that each is not identically zero.

How it could have been vacuous, and why it is not. (1) If the hypotheses were jointly unsatisfiable: they are satisfied by $V = \mathbb{C}\mathbf{1}$ (Section 15.13). (2) If the conclusion could be met by an unrelated D: it is pinned. (3) If the trace functions were junk: they are not (checked in Lean; the check is not part of this release). (4) If ρ were unconstrained: by uniqueness (independence of the traces) ρ is determined by the family, and $\rho(T)$ is the correct diagonal matrix. What remains *weak* is the hypothesis bundle as displayed: `[Finite (Φ W)]` and the family data are dischargeable but are displayed; the canonical form of Section 15.12.2 discharges them. The hypotheses are now checked at nontrivial V: the lattice VOAs $V_{\sqrt{2m}\mathbb{Z}}$ and the $c = 1$ orbifolds of Section 15.14 (before this release, only at the trivial VOA); and `Pr`, which had no axiom-free witness while `VOA.pbw` was an axiom, is supplied for every V by `voaPBWBottomProjection`.

Trap / dead end

Two redundant hypotheses (moderate). A separate Lean check against the library (not part of this release) proves, with the standard three axioms only, that `VacuumGradeZero W` holds for every W (`vacuumGradeZero_always`, by `le_of_eq W.vacuum_grade`), that `hsimp` follows from `hss` and `Pr` (`hsimp_of_semisimple`), and that the `Pr`-form theorem holds without these two hypotheses (`zhuModularity_pinned_lean`). So the honest hypothesis list of the `Pr`-form theorem is: C_2, $A(V)$ semisimple, $\Phi(V)$ finite, `Pr`, and the family data `hcard`, `hcw`, `hsep`. *Correction (release audit).* An earlier version of this box said that `[Finite (Φ W)]` was "plausibly derivable ... not certified". That was stale: it is the library theorem `VOA.Huang.ZhuFiniteIrr.finite_Φ_of_C2Cofinite_pbw` (Theorem 15.35), which derives it from C_2 alone, without `hss`. The family data are discharged by the canonical family. Both discharges are carried out in the library's headline, Theorem 15.37, whose only hypotheses are C_2 and `hss`.

Trap / dead end

Unpinned variants: do not cite them as Zhu's theorem. Several theorems on the way conclude only `∃ D : ModularData W ι, ZhuModularityAnalytic D`: `exists_zhuModularity_of_c2`, `exists_zhuModularity_of_ode`, `exists_zhuModularity_of_strictSpanning`, `exists_zhuModularity_of_cofinite`, `exists_zhuModularity_of_c2_sqSlash`. Such a statement is *not* about the given family: `ZhuModularityAnalytic` reads everything off `D.Mfam` and `D.h`, so any single D whatsoever (e.g. for the trivial VOA) witnesses it. The library's own docstrings say so ("Conclusion-strength warning") and the README forbids advertising them as the result. The pinned forms are `zhuModularity_canonical_of_C2Cofinite_semisimple` (the headline), `zhuModularity_pinned_of_C2Cofinite`, `zhuModularity_pinned_of_C2Cofinite_voaPBW`, `zhuModularity_pinned_of_strictSpanning`, `zhuModularity_pinned_of_real`, `zhu_modularity_of_bottomSeparation`

and `zhuModularity_stronglyRational_voaPBW`.

Proof on paper (the assembly). Fix the family. (1) Growth: $\mathcal{Z}_{M_i}$ has subexponential coefficients (Theorem 15.16), so the trace functions S_i are analytic blocks (Theorem 15.18). (2) Existence of modules: V has strict spanning (Theorem 15.24), hence every simple $A(V)$-module is realised (Theorem 15.25). (3) Count: $\dim \mathrm{res}(\mathfrak{B}) \le \#\Phi(V) = \#\iota$ (Theorems 15.22 and 15.33). (4) Independence: the S_i are independent (Theorem 15.30, using `hsimp`, `hsep` and the growth). (5) Slash: each $\mathrm{res}(S_i|S)$ lies in $\mathrm{res}(\mathfrak{B})$ (Theorem 15.28). (6) By (3)–(5) and Theorem 15.33, each $S_i|S$ is a combination of the S_j on homogeneous vectors; by Theorem 15.32 this gives the law at every γ, a unique representation ρ with the correct $\rho(T)$, and modular data whose family and weights are the given ones. □

Physical meaning

This is the theorem behind every modular-invariant partition function of a rational CFT: the characters of the finitely many sectors span a representation of the modular group of the torus, and so does every family of torus one-point functions of a field of definite conformal weight. The matrix $\rho(S)$ is the modular S-matrix of the theory (the datum consumed by the Verlinde formula $N_{ij}^k = \sum_m S_{im}S_{jm}\overline{S_{km}}/S_{0m}$, proved by Huang for rational C_2-cofinite VOAs; not in this chapter, see Chapter 21); $\rho(T)$ encodes the spins of the primaries. The characters form a vector-valued modular form, which is the starting point of the modular bootstrap and of the classification of rational CFTs by the Mathur–Mukhi–Sen differential equation.

What the machine verified

Independent run on a scratch file, `lake env lean -DmaxSynthPendingDepth=3` (never a bare `lake env lean`):

```
'VOA.zhuModularity_pinned_of_C2Cofinite' depends on axioms: [propext,
 ↪ Classical.choice, Quot.sound]
'VOA.zhuModularity_pinned_of_C2Cofinite_voaPBW' depends on axioms: [propext,
 ↪ Classical.choice, Quot.sound]
```

So: `zhuModularity_pinned_of_C2Cofinite` is `#print axioms`-clean, *conditional on* `C2Cofinite`, `IsSemisimpleRing (A W)`, `Finite (Φ W)`, `Pr`, and the family data `hcard`, `hcw`, `hsep` (the formerly redundant `hzero`, `hsimp` have been removed). `zhuModularity_pinned_of_C2Cofinite_voaPBW` uses the theorem `VOA.pbw`; it is conditional on C_2, semisimplicity, finiteness of $\Phi(V)$ and the family data (no longer on `Pr`). Neither is unconditional. No full `lake build` was run for this chapter; the oleans of the snapshot were used (not re-run for this edition), and the `_voaPBW` line was re-probed in a later run, after `VOA.pbw` became a theorem (in the earlier run it also listed `VOA.pbw`, then an axiom).

15.12.2 The engine: the canonical family, from C_2 and semisimplicity alone

Theorem 15.34 asks the user to supply a finiteness instance and a family with three properties. All of them can be discharged once and for all. Finiteness of $\Phi(V)$ is a consequence of C_2-cofiniteness; and the family can be taken to be "one chosen representative of each isomorphism class, with its conformal weight". Doing both gives the form of Zhu's theorem from which the headline (Section 15.12.3) follows.

Theorem 15.35 (Finitely many irreducible modules; Dong–Li–Mason, Abe–Buhl–Dong). *If V is C_2-cofinite, then $\Phi(V)$ is finite.*

File `VOA/Classification/COne/McRaeO1FinitePhi.lean` (Chapter 22), in the namespace `VOA.Huang.ZhuFiniteIrr`, with section variable `{W : VertexOperatorAlgebra 𝒱}`.

```
theorem finite_Φ_of_C2Cofinite_pbw (hC2 : C2Cofinite W) : Finite (Φ W) :=
  finite_Φ_of_C2Cofinite' (voaPBWBottomProjection (parabolicRepOfAMod W (regularAMod W)))
   ↪ hC2
```

From the mathematics to the Lean statement

`Finite (Φ W)` is Mathlib's "the type $\Phi(V)$ has finitely many elements" (Chapter 12 for Φ). The one-line proof term is informative: the theorem is the general `finite_Φ_of_C2Cofinite'`, which takes the datum `Pr`, applied to `voaPBWBottomProjection`, i.e. to the theorem `VOA.pbw`. The only hypothesis is C_2; in particular no semisimplicity of $A(V)$ and no rationality is assumed. Same as the literature (for C_2-cofinite V, $A(V)$ is finite-dimensional, hence has finitely many simple modules, and each irreducible module is determined by its bottom). The docstring still calls `VOA.pbw` "the sanctioned axiom"; it is a theorem (documentation only). The analogue for *admissible* modules, Dong–Li–Mason's "finitely many irreducible admissible modules" (the predicate `DLMFinitelyManyIrredAdmissible`), follows for C_2-cofinite admissibly rational V, because there every irreducible admissible module is ordinary; it is the theorem `dlmFinitelyManyIrredAdmissible_of_c2Cofinite` of Chapter 12 (Theorem 12.40).

Proof on paper. $A(V)$ is finite-dimensional (Theorem 15.20). A finite-dimensional algebra has only finitely many simple modules up to isomorphism (each is a quotient of $A(V)$ by a maximal left ideal, and they are the simple modules of the semisimple quotient $A(V)/\mathrm{rad}A(V)$, of which there are finitely many by Artin–Wedderburn). The bottom of an irreducible module is a simple $A(V)$-module (Chapter 13, Theorem 13.6; the library's proof of this theorem instead goes through the datum `Pr`), and by the uniqueness half of Zhu's correspondence (Chapter 13) non-isomorphic irreducible modules have non-isomorphic bottoms. So $[M] \mapsto [M_h]$ is an injection of $\Phi(V)$ into a finite set. □

Physical meaning

A theory whose chiral algebra has finitely many independent fields modulo derivatives and normal ordering has only finitely many sectors. This is the algebraic shadow of "finitely many primaries".

What the machine verified

`VOA.Huang.ZhuFiniteIrr.finite_Φ_of_C2Cofinite_pbw`: `[propext, Classical.choice, Quot.sound]`, run at an earlier commit (not re-run for this edition) (scratch file, `lake env lean -DmaxSynthPendingDepth=3`). Conditional only on `C2Cofinite`; uses the theorem `VOA.pbw`.

Definition 15.36 (The canonical family)**.** For $c \in \Phi(V)$ let M_c be a chosen representative of the class c, and h_c its conformal weight (the unique h with $(M_c)_h \neq 0$ and all weights in $h + \mathbb{N}$; it exists for every irreducible ordinary module).

Files `VOA/Modularity/StronglyRationalFamily.lean` and `VOA/Modularity/ConformalWeightChoice.lean`.

```
noncomputable def canonicalIrrModule (c : Φ W) : IrrModule W := Quotient.out c

noncomputable def conformalWeightOf (V : IrrModule W) : ℂ :=
  (OrdVModule.exists_hasConformalWeight_of_irreducible V.isMod V.irreducible).choose
```

From the mathematics to the Lean statement

`Quotient.out c` picks a representative of the class `c` (by the axiom of choice). `conformalWeightOf` picks the h whose existence is `exists_hasConformalWeight_of_irreducible`; it is unique, so the choice is harmless.

Which representative is picked does not matter for the theorem below: the trace functions of isomorphic modules are equal.

Physical meaning

One primary field per sector, labelled by its conformal weight: the list of sectors of the theory.

What the machine verified

Definitions.

Theorem 15.37 (Zhu's modularity theorem for one-point functions, canonical family, semisimple form)**.** *Let V be a vertex operator algebra of the library (so of CFT type) such that*

(a) V is C_2-cofinite, and

(b) Zhu's algebra $A(V)$ is a semisimple ring.

Then $\Phi(V)$ is finite, and there are modular data D indexed by $\Phi(V)$, whose family is the canonical family $(M_c)_{c\in\Phi(V)}$ and whose weights are its conformal weights (h_c), satisfying Zhu's analytic law: there is a group homomorphism $\rho : SL_2(\mathbb{Z}) \to \mathrm{Mat}_{\Phi(V)}(\mathbb{C})$ with $\rho(T) = \mathrm{diag}(e^{2\pi i(h_c - c_V/24)})$ such that for all $\gamma = \left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in SL_2(\mathbb{Z})$, $n \in \mathbb{N}$, $v \in V_{[n]}$, $c' \in \Phi(V)$ and $\tau \in \mathbb{H}$,

$$\mathrm{tr}_{M_{c'}}\, o(v) q^{L_0 - c_V/24}\big|_{\gamma\tau} = (c\tau + d)^n \sum_{c''\in\Phi(V)} \rho(\gamma)_{c'c''}\ \mathrm{tr}_{M_{c''}}\, o(v) q^{L_0 - c_V/24}\big|_{\tau},$$

where c_V is the central charge.

File `VOA/Modularity/ZhuModularityCanonical.lean`.

From the mathematics to the Lean statement

Hypotheses. Exactly two, besides the ambient `{𝒱 : Type u} [AddCommGroup 𝒱] [Module ℂ 𝒱]`.

- `hC2 : C2Cofinite W`: $\dim V/C_2(V) < \infty$ (Definition 12.22). Standard.
- `hss`: `letI := instRingA W` installs Zhu's product on `A W` (Chapter 12, Section 12.4), and `IsSemisimpleRing (A W)` is Mathlib's "every module over this ring is semisimple" (equivalently, by Artin–Wedderburn, a finite product of matrix rings over division rings; over $\mathbb{C}$ and finite-dimensional, of matrix algebras $\mathrm{Mat}_{n_i}(\mathbb{C})$). In this form it stands in for Zhu's "rational"; the headline (Theorem 15.39) puts rationality back, and Remark 15.2 says exactly how the two compare.

CFT type is not a hypothesis because it is built into `VertexOperatorAlgebra` (the axioms `vacuum_grade` and `positivity`, Chapter 1); this is slightly narrower than Zhu's setting. No finiteness, family, cardinality or separation hypothesis is assumed, and `Pr` is supplied internally by `VOA.pbw`.

The three `letI` lines. They are not hypotheses; they *construct* instances that the statement needs in order to use $\Phi(V)$ as the index type of a `ModularData`, which requires `[Fintype ι] [DecidableEq ι]`. The first is the *proof* `finite_Φ_of_C2Cofinite_pbw hC2` (Theorem 15.35); the second turns finiteness into an enumeration (`Fintype.ofFinite`); the third is classical decidable equality. Because they appear in the statement, a user of the theorem sees exactly which instance is meant.
Conclusion. `∃ D : ModularData W (Φ W), D.Mfam = canonicalIrrModule ∧ D.h = … ∧ ZhuModularityAnalytic D`. The modular data (Definition 15.31) are indexed by $\Phi(V)$ itself; their family is *the* canonical family and their weights are *its* conformal weights (the two equations pin D, so the unpinned-variant trap of the warning above does not apply); and `ZhuModularityAnalytic D` is Zhu's law. By the structure `ModularData`, $\rho = $ `D.rep` is a monoid homomorphism, hence a representation, with `rep_T` the diagonal matrix of $e^{2\pi i(h_c - c_V/24)}$.
Same as, stronger or weaker than Zhu?

- *Hypotheses*: C_2 and semisimplicity of $A(V)$, in place of C_2 and rationality. As a theorem about V this is at least as general as Zhu's (Remark 15.2). For a V that is proved rational (`AdmissiblyRational`) the library applies it through `isSemisimpleRing_A_of_admissiblyRational`; that is the headline, Theorem 15.39. (The first release revision of this chapter said that this step was not formalised. That was wrong.)
- *Which functions*: one-point functions $\mathrm{tr}_M\, o(v)q^{L_0 - c/24}$ for all v of definite square-bracket weight, including the characters ($v = \mathbf{1}$). Not the n-point functions on the torus, which Zhu's theorem also treats.
- *Which modules*: all irreducible ordinary modules, one per isomorphism class, with no list to supply.
- *Convergence*: not in the conclusion; `traceFun` uses `tsum` (junk value 0 on divergence). It is supplied by the separate theorems `onePointSubexp_of_c2` and `qSummableAt_of_subexponential` (Theorem 15.16); a separate Lean check, `headline_traces_are_genuine`, assembles them (not part of this release).
- *What is said about ρ*: existence, the homomorphism property and $\rho(T)$. Linear independence of the trace functions, hence uniqueness of ρ, is proved internally (Section 15.10) but is not exported in this statement. Nothing is said about $\rho(S)$ beyond existence.

Could it be vacuous? The hypotheses are satisfied by nontrivial vertex operator algebras (Section 15.14) and by $\mathbb{C}\mathbf{1}$; the conclusion is pinned; the trace functions are genuine under the hypotheses (checked in Lean); $\rho(T)$ is fixed by `rep_T`.

Proof on paper. Apply Theorem 15.34 (in its `_voaPBW` form) to $\iota = \Phi(V)$, the canonical family and its conformal weights, with the finiteness instance of Theorem 15.35. Its remaining hypotheses hold: $\#\iota = \#\Phi(V)$ trivially (`canonicalIrrFamily_card`); each M_c has conformal weight h_c by the choice of h_c (`canonicalIrrFamily_hasConformalWeight`); and if $c \neq c'$ have $h_c = h_{c'}$, then the bottoms of M_c and $M_{c'}$ are not isomorphic, since otherwise the uniqueness half of Zhu's correspondence would give $M_c \cong M_{c'}$, i.e. $c = c'$ (`canonicalIrrFamily_bottomSeparated`). The Lean proof is this composition, in `ZhuModularityCanonical.lean`. □

Physical meaning

This is the form in which a physicist states the theorem: *the characters (and, more generally, the torus one-point functions) of all the sectors of a C_2-cofinite chiral CFT whose zero-mode algebra*

is semisimple form a vector-valued modular form for $SL_2(\mathbb{Z})$; the T-matrix is the diagonal of $e^{2\pi i(h-c/24)}$ (the spins and the Casimir energy) and the S-matrix exists. Semisimplicity of the zero-mode algebra on ground states is the algebraic statement that the primary multiplets do not form indecomposable, non-split "logarithmic" pairs at the level of ground states; without it (e.g. the triplet algebras) the characters alone are not closed under S, and one needs Miyamoto's pseudo-traces.

What the machine verified

`VOA.zhuModularity_canonical_of_C2Cofinite_semisimple`: `[propext, Classical.choice, Quot.sound]`, run at an earlier commit (not re-run for this edition) on a scratch file with `lake env lean -DmaxSynthPendingDepth=3`. The module `ZhuModularityCanonical.lean` had no olean at that commit; the scratch file therefore contained the file's text verbatim (its imports all had oleans, built 2026-10-25) followed by the `#print axioms` lines, so the theorem was elaborated and checked in that run. **`#print axioms`-clean, conditional on** `C2Cofinite W` and `IsSemisimpleRing (A W)`; uses the theorem `VOA.pbw`; one-point functions only. Per `Notes/RELEASE_PLAN.md` ("Caveats removed in Lean") the umbrellas containing it were built green when it was merged; that build was not re-run for this chapter.

15.12.3 The headline: Zhu's theorem for rational C_2-cofinite V

Zhu states his theorem for rational C_2-cofinite V. The engine of the previous subsection replaces "rational" by "$A(V)$ is semisimple". To return to Zhu's form one needs one more theorem, Zhu's semisimplicity theorem: rationality implies that $A(V)$ is semisimple. The library proves it. The theorem lives in the Huang directory (Chapter 21), because it was proved there as a stage of the modular-tensor-category track. Since this chapter consumes it, we present it in full here.

Theorem 15.38 (Zhu's semisimplicity theorem; Zhu 1996, Theorem 2.2.3; Dong–Li–Mason)**.** *Let V be a vertex operator algebra of the library, and let the datum* `Pr` *of Chapter 13 be given. If V is rational in the sense of* `AdmissiblyRational` *(every admissible V-module is completely reducible; Chapter 12, Definition 12.35), then Zhu's algebra $A(V)$ is a semisimple ring. Since* `Pr` *is supplied for every V by the theorem* `VOA.pbw`*, the implication holds for every V; in particular the named predicate* `ZhuAdmissibleSemisimple W` *of Chapter 12 holds for every V.*

File `VOA/Huang/ZhuSemisimple.lean` (Chapter 21), namespace `VOA.Huang.ZhuSemisimple`, with section variables `{𝒱 : Type u} [AddCommGroup 𝒱] [Module ℂ 𝒱] {W : VertexOperatorAlgebra 𝒱}` and `(Pr : BottomProjection (parabolicRepOfAMod W (regularAMod W)))`; each theorem is preceded by the line `include Pr in`.

```
theorem isSemisimpleRing_A_of_admissiblyRational (hrat : AdmissiblyRational W) :
    letI := instRingA W; IsSemisimpleRing (A W) := by

theorem zhuAdmissibleSemisimple_of_Pr : ZhuAdmissibleSemisimple W :=
  fun hrat => isSemisimpleRing_A_of_admissiblyRational Pr hrat
```

From the mathematics to the Lean statement

The arguments. The statement shows only `hrat`, but the line `include Pr in` makes the section variable `Pr` an explicit argument, placed first. So the full form is `isSemisimpleRing_A_of_admissiblyRational Pr hrat`, and this is how the headline below calls it, with `Pr` the term `voaPBWBottomProjection (parabolicRepOfAMod W (regularAMod W))`. `Pr` is the bottom-projection datum of Chapter 13: the regular $A(V)$-module embeds as the bottom of the module induced from it. It is a consequence of the Poincaré–Birkhoff–Witt theorem, which

is the library theorem `VOA.pbw`. So in effect the implication has no hypothesis besides `hrat`.
The hypothesis and the conclusion. `AdmissiblyRational W` is Definition 12.35 of Chapter 12: for every admissible module, every weak submodule has a weak complement. The conclusion `letI := instRingA W; IsSemisimpleRing (A W)` is literally the hypothesis `hss` of the engine (Theorem 15.37): the same ring structure (`instRingA W`, Zhu's product) and Mathlib's semisimplicity. So the two theorems compose with no conversion.
The named predicate. `ZhuAdmissibleSemisimple W` is the `Prop AdmissiblyRational W → letI := instRingA W; IsSemisimpleRing (A W)` of Chapter 12, Section 12.9. Earlier revisions of this book and of the library's docstrings called it an unproved bridge. `zhuAdmissibleSemisimple_of_Pr` proves it from `Pr`, and with `voaPBWBottomProjection` for every V. We checked this composition in the scratch run of the status box below:

```
example : ∀ {𝒱 : Type} [AddCommGroup 𝒱] [Module ℂ 𝒱] (W : VOA.VertexOperatorAlgebra
 ↪ 𝒱),
    VOA.ZhuAdmissibleSemisimple W :=
  fun W => VOA.Huang.ZhuSemisimple.zhuAdmissibleSemisimple_of_Pr
    (VOA.VHat.DLM3.voaPBWBottomProjection
      (VOA.VHat.DLM3.parabolicRepOfAMod W (VOA.regularAMod W)))
```

(This is a check, not a library declaration; the universe of $\mathcal{V}$ was fixed to `Type` for the check.)
Same as, stronger or weaker than the literature? Zhu (Theorem 2.2.3, for his three-clause rationality) and Dong–Li–Mason (for their one-clause rationality) prove: if V is rational, $A(V)$ is semisimple. (The library's docstring cites DLM, *Math. Ann.* 310, Theorem 4.10(a); Chapter 12 cites DLM, *J. Algebra* 206, Theorem 4.10. We have not resolved which numbering is meant; the statement is the same.) The Lean theorem has the same conclusion, with "rational" read as `AdmissiblyRational`. DLM-rationality implies `AdmissiblyRational`: in Lean for C_2-cofinite V (Theorem 12.36), on paper in general (Chapter 12, Section 12.9.2). So the Lean theorem implies the literature's (for C_2-cofinite V with no paper step): its hypothesis is *at most* as strong as DLM's. The Lean proof does not invoke any theorem of Dong–Li–Mason as a hypothesis, so the open question of whether `AdmissiblyRational` implies DLM-rationality does not affect it.
Could it be vacuous? Only if `AdmissiblyRational` were unsatisfiable. It is not: the library proves it for the trivial VOA and for every lattice VOA $V_{\sqrt{2m}\mathbb{Z}}$ (`V2m_admissiblyRational`, Chapter 22). And the conclusion is not automatic: the triplet algebra $W(2)$ is C_2-cofinite, and the library proves that it is not `AdmissiblyRational` (Chapter 12); on paper its Zhu algebra is not semisimple (Adamović–Milas), which is not a Lean theorem.

Proof on paper. Let $U = A(V)$, viewed as the regular left module, and let $M = M(U)$ be the generalised Verma module induced from U (Dong–Jiang). It is an admissible module whose degree-zero part is U; that the bottom is all of U, and not a quotient, is the datum `Pr`. Let $T \subseteq A(V)$ be a left ideal. Let $P \subseteq M$ be the submodule generated by $T \subseteq M(0)$. By bottom recovery (Chapter 21), P is graded and $P \cap M(0) = T$. By rationality, P has a complement Q with $M = P \oplus Q$. Let π_0 be the projection onto degree zero, and put

$$T' = \{u \in A(V) : \exists q \in Q,\ \pi_0(q) = u,\ q - u \in P\}.$$

Zero modes preserve degrees, so they commute with π_0. They act on $M(0) = U$ by left multiplication in $A(V)$. Hence T' is a left ideal. $T \cap T' = 0$: if $u \in T \cap T'$ with witness q, then $q = (q-u) + u \in P \cap Q = 0$, so $u = \pi_0(q) = 0$. $T + T' = A(V)$: write $u = p + q$ with $p \in P$, $q \in Q$. Then $u' := \pi_0(q)$ lies in T' with witness q (indeed $q - u' = \pi_0(p) - p \in P$, as P is graded), and $u - u' = \pi_0(p) \in P \cap M(0) = T$. So every left ideal has a complementary left ideal, i.e. $A(V)$ is a semisimple ring. The Lean proof is this argument, in `ZhuSemisimple.lean`. □

Physical meaning

$A(V)$ is the algebra of zero modes acting on the ground states of the sectors. Rationality says that every representation of the chiral algebra splits into irreducible sectors. The theorem says that this splitting is already visible on the ground states: the zero-mode algebra is a direct sum of matrix algebras, one block per sector, of size the ground-state degeneracy. A logarithmic theory, in which L_0 has Jordan blocks between sectors, fails both.

What the machine verified

`VOA.Huang.ZhuSemisimple.isSemisimpleRing_A_of_admissiblyRational` and `VOA.Huang.ZhuSemisimple.zhuAdmissibleSemisimple_of_Pr`: `[propext, Classical.choice, Quot.sound]`, run at an earlier commit (not re-run for this edition) (scratch file, `lake env lean -DmaxSynthPendingDepth=3`; the olean of `ZhuSemisimple.lean` is newer than its source). `#print axioms`-clean, *conditional on* `Pr` and `AdmissiblyRational W`; with `Pr` from `voaPBWBottomProjection` (also standard three in the same run), conditional only on `AdmissiblyRational W`.

Theorem 15.39 (Zhu's modularity theorem for rational C_2-cofinite V; the chapter's headline)**.** *Let V be a vertex operator algebra of the library (so of CFT type) such that*

(a) V is C_2-cofinite, and

(r) V is rational, in the sense of `AdmissiblyRational`.

Then the conclusion of Theorem 15.37 holds: $\Phi(V)$ is finite, and the one-point functions $\mathrm{tr}_{M_c}\, o(v)q^{L_0-c_V/24}$ of the canonical irreducible modules M_c, $c \in \Phi(V)$, with their conformal weights h_c, transform under $SL_2(\mathbb{Z})$ by a matrix representation ρ with $\rho(T) = \mathrm{diag}(e^{2\pi i(h_c-c_V/24)})$, with weight n for $v \in V_{[n]}$. In particular this holds for every strongly rational V.

```

From the mathematics to the Lean statement

Hypotheses. Besides the ambient {𝒱 : Type u} [AddCommGroup 𝒱] [Module ℂ 𝒱]:

- hC2 : C2Cofinite W: (a), Definition 12.22.
- hrat : AdmissiblyRational W: (r), Definition 12.35. This is Zhu's "rational", in the library's reading (weak complements). See the comparison below.
- In the second form, hSR : StronglyRational W (Definition 12.43) bundles simple, selfDual, c2Cofinite and rational : AdmissiblyRational W. The proof uses only hSR.c2Cofinite and hSR.rational. Simplicity and self-duality are not used, so this form is a special case of the first.

Nothing else is assumed: no finiteness of $\Phi(V)$, no family, no Pr, and no named literature hypothesis.
The proof terms are shown because they are the whole proof. The first is the engine zhuModularity_canonical_of_C2Cofinite_semisimple applied to hC2 and to the semisimplicity proof isSemisimpleRing_A_of_admissiblyRational Pr hrat of Theorem 15.38, with Pr the PBW datum. The second is the first applied to the two relevant fields of hSR.
The letI lines and the conclusion are those of the engine, word for word, except that in the second form the finiteness instance is built from hSR.c2Cofinite. The conclusion is pinned: the modular data have the canonical family and its conformal weights (Theorem 15.37, dictionary).
Same as, stronger or weaker than Zhu? Compare with Theorem 15.1.

- *Hypotheses*: Zhu's, "rational and C_2-cofinite", with rational read as AdmissiblyRational, and CFT type built into VertexOperatorAlgebra. Every C_2-cofinite DLM-rational V is AdmissiblyRational, by the Lean theorem admissiblyRational_of_dlmRational (Theorem 12.36), so the theorem covers every rational C_2-cofinite V of CFT type with no paper step. Whether AdmissiblyRational conversely implies DLM-rationality is open. That converse is not needed here, because the Lean proof uses no theorem of Dong–Li–Mason as a hypothesis.
- *Conclusion*: as for the engine: (2) and (3) of Theorem 15.1 for one-point functions, with ρ a representation and $\rho(T)$ the correct diagonal matrix. Convergence (1) is the separate growth theorem. n-point functions are not covered. Nothing is said about $\rho(S)$ beyond existence.

Could it be vacuous? No. The hypotheses hold for every lattice VOA $V_{\sqrt{2m}\mathbb{Z}}$ (Section 15.14, zhuModularity_V2m, which is literally the second form applied to V2m_stronglyRational) and for $\mathbb{C}\mathbf{1}$ (trivial_stronglyRational). The conclusion is pinned, and the trace functions are genuine (checked in Lean, headline_traces_are_genuine; the check is not part of this release).

Proof on paper. By Theorem 15.38 (with Pr from the PBW theorem), (r) gives (b): $A(V)$ is semisimple. Then (a) and (b) are the hypotheses of the engine, Theorem 15.37. For strongly rational V, (a) and (r) are two of the four clauses of the definition. □

Physical meaning

This is the theorem in the form a physicist quotes it: *for a rational chiral CFT whose chiral algebra is finitely generated in the C_2 sense (finitely many independent fields modulo derivatives and normal ordering), the characters of the finitely many sectors, and all torus one-point*

functions of fields of definite weight, form a vector-valued modular form for $SL_2(\mathbb{Z})$. The T-matrix is the diagonal of the phases $e^{2\pi i(h-c/24)}$, the spins of the primaries shifted by the Casimir energy, and the S-matrix exists. For the strongly rational case, which also asks for a unique vacuum and a nondegenerate two-point function, this is the starting point of the modular bootstrap and of Huang's modular tensor category (Chapter 21).

What the machine verified

`VOA.zhuModularity_canonical_of_C2Cofinite_admissiblyRational`, `VOA.zhuModularity_canonical_of_stronglyRational`: `[propext, Classical.choice, Quot.sound]`, run at an earlier commit (not re-run for this edition) on a scratch file with `lake env lean -DmaxSynthPendingDepth=3` from the repository root. The olean of `ZhuModularityCanonical.lean` predates the version of the file that contains these theorems, so the scratch file contained the file's text verbatim (after its imports, whose oleans were present), followed by the `#print axioms` lines. **`#print axioms`-clean, conditional on** `C2Cofinite W` and `AdmissiblyRational W` (respectively on `StronglyRational W`); uses the theorem `VOA.pbw`; one-point functions only. Per `Notes/RELEASE_PLAN.md` ("Zhu for rational VOAs", 2026-10-28) the umbrella builds of `VOA.Modularity` and `VOA.Classification` containing them were green (12,271 jobs) with standard axioms. That build was not re-run for this chapter, and no aggregate `lake build` was run.

15.12.4 The strongly rational packaging

Theorem 15.40 (Zhu's theorem for strongly rational V, the older packaging with two (now proved) literature hypotheses)**.** *Let V be strongly rational (simple, self-dual, C_2-cofinite, rational; Definition 12.43), and assume the Dong–Li–Mason finiteness theorem (rational ⇒ finitely many irreducible admissible modules) and Zhu's semisimplicity theorem (rational ⇒ $A(V)$ semisimple) for V. Then, with $\iota = \Phi(V)$ and the canonical family of representatives with their conformal weights, the pinned conclusion of Theorem 15.34 holds. The proof uses the theorem* `VOA.pbw`.

  (OrdVModule.exists_hasConformalWeight_of_irreducible V.isMod V.irreducible).choose

theorem zhuModularity_stronglyRational_voaPBW
    (hSR : StronglyRational W)
    (hFin : DLMFinitelyManyIrredAdmissible W)
    (hZhu : ZhuAdmissibleSemisimple W) :
    letI : Finite (Φ W) := finite_Φ_of_finite_Φadm W (hFin hSR.rational)
    letI : Fintype (Φ W) := Fintype.ofFinite (Φ W)
    letI : DecidableEq (Φ W) := Classical.decEq (Φ W)
    ∃ D : ModularData W (Φ W),
      D.Mfam = canonicalIrrModule ∧
      D.h = (fun c => conformalWeightOf (canonicalIrrModule c)) ∧
      ZhuModularityAnalytic D := by
```

From the mathematics to the Lean statement

`Quotient.out c` chooses a representative of the class $c \in \Phi(V)$. `conformalWeightOf` chooses the conformal weight (it exists for irreducible ordinary modules and is unique). `StronglyRational W` bundles `simple`, `selfDual`, `c2Cofinite`, `rational`

`: AdmissiblyRational W` (Chapter 12). `DLMFinitelyManyIrredAdmissible W` is `AdmissiblyRational W → Finite (Φadm W)` and `ZhuAdmissibleSemisimple W` is `AdmissiblyRational W → IsSemisimpleRing (A W)` (Chapter 12, Section 12.9): both are theorems of the literature for Dong–Li–Mason-rational V (DLM 1998, Thm. 8.1; DLM 1998 *J. Algebra*, Thm. 4.10, with Zhu 1996, Thm. 2.2.3 for Zhu's stronger notion), and in this declaration they are *carried as hypotheses*. They are, however, **theorems of the library** for every V to which the declaration applies:

- `hFin`: `StronglyRational.dlmFinitelyManyIrredAdmissible hSR` (more generally `dlmFinitelyManyIrredAdmissible_of_c2Cofinite` for any C_2-cofinite V; Chapter 12, Theorems 12.40 and 12.44). It is proved from C_2-cofiniteness, the semisimplicity of $A(V)$ and the bottom projection, and the predicate's own `AdmissiblyRational` antecedent. For an admissibly rational V that is not C_2-cofinite the predicate is not proved, but such a V is not strongly rational, so this declaration never needs that case.
- `hZhu`: `zhuAdmissibleSemisimple_holds` (equivalently `zhuAdmissibleSemisimple_of_Pr` applied to `voaPBWBottomProjection`) proves `ZhuAdmissibleSemisimple W` for every V (Theorem 15.38).

Since both are proved directly from the library's `AdmissiblyRational` and `C2Cofinite`, their truth does not depend on the comparison of `AdmissiblyRational` with Dong–Li–Mason rationality (Chapter 12, Section 12.9.2). The library contains no restatement of this declaration with the two hypotheses discharged; the discharge is the composition just described. **This packaging is superseded** anyway by the headline `zhuModularity_canonical_of_stronglyRational` (Theorem 15.39), which reaches the same conclusion from `hSR` alone, with finiteness of $\Phi(V)$ from Theorem 15.35. The `letI` lines construct the finiteness, enumeration and decidability instances needed to use $\Phi(V)$ as an index set. The other inputs of the headline are discharged: `hzero` by `le_of_eq W.vacuum_grade`, `hcard` tautologically, `hcw` by the choice of weights, `hsimp` from semisimplicity and `VOA.pbw`, `hsep` from the injectivity half of `zhuBijective_of_voaPBW`. Simplicity and self-duality of V are not used.

Proof on paper. Specialise Theorem 15.34 to the canonical family; the family inputs are discharged as described. □

Physical meaning

"Strongly rational" is the class of VOAs that are chiral algebras of the nicest rational CFTs: unique vacuum, nondegenerate two-point function, finitely many sectors, completely reducible representation theory. The theorem says that for these the vector of characters of all sectors is a vector-valued modular form. In this older form the two classical structure theorems (finitely many sectors; the zero-mode algebra is a sum of matrix blocks) are assumed as hypotheses, although the library now proves both for these theories; the headline (Theorem 15.39) does not take them.

What the machine verified

`VOA.zhuModularity_stronglyRational_voaPBW`: `[propext, Classical.choice, Quot.sound]` (re-probed at a later commit, after `VOA.pbw` became a theorem, not re-run for this edition; at the snapshot, when `VOA.pbw` was an axiom, the list also contained `VOA.pbw`). Conditional on `StronglyRational`, `DLMFinitelyManyIrredAdmissible`, `ZhuAdmissibleSemisimple`; uses the theorem `VOA.pbw`. Both literature hypotheses are now dischargeable for every strongly rational V: `ZhuAdmissibleSemisimple` by `zhuAdmissibleSemisimple_holds`

(or `zhuAdmissibleSemisimple_of_Pr`), and `DLMFinitelyManyIrredAdmissible` by `StronglyRational.dlmFinitelyManyIrredAdmissible` (proved for C_2-cofinite V; `#print axioms` of both: standard three, run at an earlier commit (not re-run for this edition), Chapter 12, Theorem 12.40). *Correction:* the previous revision called `DLMFinitelyManyIrredAdmissible` "unproved but unnecessary"; it is proved for every C_2-cofinite V, which covers every strongly rational V. So the declaration, with its hypotheses discharged, is unconditional given `StronglyRational W`; the discharged form is a composition, not a named declaration. It is still strictly worse than the headline `zhuModularity_canonical_of_stronglyRational` and should not be cited as the release form of Zhu's theorem.

15.13 Non-vacuity: the trivial vertex operator algebra

`#print axioms` cannot detect an unsatisfiable hypothesis bundle. The library therefore instantiates the headline at the simplest VOA, $V = \mathbb{C}\mathbf{1}$, realised as the lattice VOA of the rank-zero lattice.

Theorem 15.41 (Zhu's theorem at $\mathbb{C}\mathbf{1}$). *The trivial VOA $V = \mathbb{C}\mathbf{1}$ (central charge 0) satisfies all hypotheses of Theorem 15.34 with the one-element family $\{V\}$, $h = 0$; hence there are pinned modular data satisfying Zhu's law. V is also strongly rational, and the strongly rational packaging applies to it.*

From the mathematics to the Lean statement

`stdLattice 0` is the lattice $\mathbb{Z}^0 = \{0\}$, even and positive definite vacuously; `LatGen.latticeVOAGen` is the lattice VOA construction (Chapter 6), whose space is here one-dimensional. `adjointModule` is V as a module over itself. `Fin 1` is a one-element index set. The theorem `trivialVOA_zhuModularity` still carries `[Finite (Φ trivialVOA)]` and `hcard` (its docstring calls them "the classification $\#\Phi = 1$"), but `trivial_card_Φ` proves `hcard`, and finiteness follows from `trivial_subsingleton_Φ`. A separate Lean check against the library (not part of this release) composes them, in `trivialVOA_zhuModularity_uncond` (the pinned statement for $\mathbb{C}\mathbf{1}$ with the index set `Fin 1` and $h = 0$) and `stronglyRational_wrapper_fires` (`zhuModularity_stronglyRational_voaPBW` at `trivialVOA`). Both go through

the `_voaPBW` headline, i.e. through the theorem `VOA.pbw`. So the hypothesis bundle of the `Pr`-form headline is satisfiable (unconditionally since `VOA.pbw` became a theorem); `Pr` for $\mathbb{C}\mathbf{1}$ is supplied by `voaPBWBottomProjection`.

The closed form is now in the library. After the release audit the library states the closed instance itself (file `VOA/Modularity/ZhuModularityCanonical.lean`):

```
theorem trivialVOA_zhuModularity_closed :
    ∃ D : ModularData trivialVOA (Fin 1),
      D.Mfam = (fun _ => trivialAdjointIrr) ∧ D.h = (fun _ => 0) ∧
       ↪ ZhuModularityAnalytic D := by
```

It has no hypotheses: its proof supplies `[Finite (Φ trivialVOA)]` from `finite_Φ_of_C2Cofinite_pbw trivial_C2Cofinite` (Theorem 15.35) and `hcard` from `trivial_card_Φ`. It is the library counterpart of that check's `trivialVOA_zhuModularity_uncond`, with the same statement.

Trap / dead end

What the witness does and does not show. For $V = \mathbb{C}\mathbf{1}$ the theorem says $\chi_V(\tau) = 1$ is invariant under $SL_2(\mathbb{Z})$ with $\rho = 1$: true and trivial. It shows that the hypotheses are consistent and that the pinned conclusion is attainable; it exercises none of the hard steps (the block space is one-dimensional, Φ has one element, the slash is trivial). Nontrivial instances are the subject of the next section (Section 15.14); before this release there were none. The Lee–Yang model is proved C_2-cofinite (`leeYang_stronglyFinite`, Chapter 19), but semisimplicity of its Zhu algebra is not established, so it is not an instance. (Stale documentation: `trivialVOA_zhuModularity`'s docstring says it is "conditional only on the classification $\#\Phi = 1$"; that is now the theorem `trivial_card_Φ`, and the closed form is `trivialVOA_zhuModularity_closed`.)

Physical meaning

The trivial chiral algebra: a theory with one state, the vacuum. Its torus partition function is 1, trivially modular invariant. Its role is that of a consistency check, like verifying a formula on the empty set.

What the machine verified

`VOA.trivialVOA_zhuModularity`: `[propext, Classical.choice, Quot.sound]` (re-probed at a later commit, after `VOA.pbw` became a theorem, not re-run for this edition; at the snapshot, when `VOA.pbw` was an axiom, the list also contained `VOA.pbw`). Theorems of the separate Lean check (not part of this release) `VOA.L15Cert.trivialVOA_zhuModularity_uncond`, `VOA.L15Cert.stronglyRational_wrapper_fires`: the standard three (check re-run at that later commit). `VOA.trivial_stronglyRational`, `VOA.trivial_card_Φ`: standard three. `VOA.trivialVOA_zhuModularity_closed`: `[propext, Classical.choice, Quot.sound]`, run at an earlier commit (not re-run for this edition) (same scratch run as Theorem 15.37); no hypotheses.

15.14 Nontrivial instances: the $c = 1$ orbifolds and lattice VOAs

The release audit observed that, as long as the only vertex operator algebra satisfying the hypotheses was $\mathbb{C}\mathbf{1}$, the library's Zhu theorem had not been shown to say anything about a single nonconstant character. This section records instances with nontrivial content. They come from the $c = 1$

classification of Chapter 22. For two families of orbifolds of the compact boson, both hypotheses of the engine are proved directly, with no rationality (Theorem 15.43). For the rank-one lattice VOAs, and for every VOA proved *nice*, the headline applies through strong rationality (Theorem 15.44).

Definition 15.42 (The two vertex operator algebras). (i) For $m \geq 1$, V_{2m}^+ is the fixed-point subalgebra of the rank-one lattice VOA $V_{2m} = V_{\sqrt{2m}\mathbb{Z}}$ under the lift θ of -1 (Chapter 22, Definition 22.5). (ii) The *tetrahedral model* is the fixed-point subalgebra of V_8^+ (realised as the fixed points of the Klein four-group `klein` acting on V_2, with $V_2^{\mathtt{klein}} \cong V_8^+$, `klein_iso_plus_four`) under an explicit automorphism `kleinCubic` of order dividing three. It is a model of the orbifold $V_2^{A_4}$ by the tetrahedral group.

File `VOA/Classification/COne/OrbRat2Reduction.lean` (Chapter 22).

```
abbrev cubicModel := orbifoldVOA (Subgroup.zpowers kleinCubic)
```

From the mathematics to the Lean statement

`V2mPlus m hm` is quoted and decoded in Chapter 22 (`orbifoldVOA (Subgroup.zpowers (thetaV2m m hm))`); `orbifoldVOA G` is the fixed-point VOA W^G (Chapter 32); `Subgroup.zpowers g` is the cyclic group $\langle g \rangle$. `kleinCubic : Aut (orbifoldVOA klein)` (`OrbC2bKlein.lean`) is the restriction to $V_2^{\mathtt{klein}}$ of a rotation of V_2 of order three that normalises the Klein group; `kleinCubic_cube` proves $\mathtt{kleinCubic}^3 = 1$. The library's docstring describes `cubicModel` as "$(V_8^+)^{\mathbb{Z}/3}$". That it is isomorphic to $V_2^{A_4}$ is the content of the tetrahedral case of Chapter 22; we use only the definition.

Physical meaning

V_{2m}^+ is the chiral algebra of the $c = 1$ boson on the orbifold line $S^1/\mathbb{Z}_2$ at the radius where the momentum lattice is $\sqrt{2m}\mathbb{Z}$; it has $m + 7$ sectors (the untwisted sectors of the orbifold, plus the four θ-twisted ones). The tetrahedral model is one of the three exceptional isolated $c = 1$ theories, the gauging of the $SU(2)_1$ WZW model by the tetrahedral subgroup $A_4 \subset SO(3)$ of its symmetry.

What the machine verified

Definition.

Theorem 15.43 (Zhu's theorem for V_{2m}^+ and for the tetrahedral model, with no hypotheses). *(i) For every $m \geq 2$, the conclusion of Theorem 15.37 holds for $V = V_{2m}^+$: $\Phi(V_{2m}^+)$ is finite, and the one-point functions of its canonical irreducible modules, with their conformal weights, transform under $SL_2(\mathbb{Z})$ by a matrix representation with diagonal $\rho(T)$. (ii) The same holds for the tetrahedral model.*

File `VOA/Classification/COne/ZhuModularityV2mPlus.lean`, namespace `VOA.Classification.COne`.

```

  OrbRat2.isSemisimpleRing_of_charTable OrbA4.cubicModel_c2Cofinite_holds
    OrbSgl.cubicZhuDimensionBound_holds OrbRat6.cubicZhuCharacterTable_holds
```

From the mathematics to the Lean statement

Reading the statements. Each is Theorem 15.37 applied to a specific V; the proof terms (shown, since they are informative) are literally `zhuModularity_canonical_of_C2Cofinite_semisimple` applied to a proof of C_2-cofiniteness and a proof of semisimplicity of $A(V)$. The `letI` lines are the same instance constructions as in the headline. `VOA.ModularData`, `VOA.ZhuModularityAnalytic` are the objects of Definition 15.31 (the prefix `VOA.` only because the file lives in a sub-namespace).

Hypotheses. `zhuModularity_cubicModel` has none. `zhuModularity_V2mPlus` has only the parameters m and the bounds `hm : 1 ≤ m` (needed to form V_{2m}^+ at all, since the lattice $\sqrt{2m}\mathbb{Z}$ must be positive definite) and `hm2 : 2 ≤ m` (needed for the semisimplicity input; $V_2^+ \cong V_8$ is a lattice VOA, covered up to isomorphism by Theorem 15.44, although the modularity statement is not transported along that isomorphism). These are ranges of a parameter, not assumptions. As `hm2` implies `hm`, the latter is redundant; the library keeps it only because `V2mPlus m hm` takes it as an argument.

The inputs. `V2mPlus_c2Cofinite`: C_2-cofiniteness of V_{2m}^+ for all $m \geq 1$ (Yamskulna; Abe–Buhl–Dong; proved in Chapter 22 by an explicit strong-generation argument). `V2mPlus_zhuSemisimple`: semisimplicity of $A(V_{2m}^+)$ for $m \geq 2$ (Abe, Theorem 7.1(1)), proved

from the characters of $A(V_{2m}^+)$ on the tops of the four θ-twisted modules, which the library constructs from actual lattice modules (`V2mPlus_twistedOmegaECharacters`) and which complete the list needed for semisimplicity; the companion `V2mPlus_zhu_finrank` computes $\dim A(V_{2m}^+) = m + 7$. For the tetrahedral model, `cubicModel_zhuSemisimple` follows from a dimension bound $\dim A(V) \le 21$ and a table of 21 distinct characters of $A(V)$, which make the evaluation map $A(V) \to \mathbb{C}^{21}$ an algebra isomorphism; so $A(V) \cong \mathbb{C}^{21}$ is commutative and semisimple.

What is *not* used. Neither instance passes through rationality: the semisimplicity of $A(V)$ is proved directly. So these instances illustrate Remark 15.2: the hypothesis the library needs can be checked without first proving that V is rational.

(iii) The lattice VOAs V_{2m} go through rationality instead. $V_{2m} = V_{\sqrt{2m}\mathbb{Z}}$ is strongly rational in the library (`V2m_stronglyRational`, Chapter 22). So Zhu's theorem for it follows from the headline, with semisimplicity of $A(V_{2m})$ supplied by Theorem 15.38; this is Theorem 15.44 below. (The first release revision of this chapter said here that V_{2m} was not covered, because "rational $\Rightarrow$ $A(V)$ semisimple" was unproved. That was wrong; see the correction in the findings.) $V^\natural$ and the lattice VOAs of higher rank are still not covered: although every even positive-definite lattice VOA is proved C_2-cofinite (`latticeVOAGen_c2Cofinite`, Chapter 22), the library proves `AdmissiblyRational` (or semisimplicity of $A(V)$) only in rank one; for $V^\natural$ neither input is proved.

Could the instances be empty of content? No: unlike $\mathbb{C}\mathbf{1}$, V_{2m}^+ has $m + 7$ inequivalent irreducible modules, with conformal weights that include $r^2/4m$ ($1 \le r \le m$) and the twisted weights 1/16, 9/16, so the vector of characters is a genuinely multi-component vector-valued modular function, and $\rho(S)$ (which on paper mixes all the sectors) is not a permutation of a trivial representation.

Proof on paper. Immediate from Theorem 15.37 and the two inputs for each V. The inputs themselves are theorems of Chapter 22. □

Physical meaning

For the orbifold boson at radius $\sqrt{2m}$ the theorem says that the $m + 7$ characters — the two untwisted characters $(\chi_{V_{2m}} \pm \chi')/2$ of the vacuum and its partner, the $m-1$ charged sectors, the two sectors at the half-lattice point, and the four twisted characters built from $\eta(\tau)/\eta(\tau/2)$-type expressions — span a representation of $SL_2(\mathbb{Z})$, as they must for the orbifold partition function on the torus to be modular invariant. The theorem gives the representation's existence and its T-matrix; it does not compute the S-matrix (Dijkgraaf–Vafa–Verlinde–Verlinde did, by hand). The tetrahedral model is the analogous statement for an isolated exceptional $c = 1$ theory with 21 sectors.

What the machine verified

`VOA.Classification.COne.zhuModularity_V2mPlus`, `VOA.Classification.COne.zhuModularity_cubicModel`: both `[propext, Classical.choice, Quot.sound]`, run at an earlier commit (not re-run for this edition) (the file had no olean; its text was elaborated in the scratch run together with `ZhuModularityCanonical.lean`). Inputs `V2mPlus_c2Cofinite`, `V2mPlus_zhuSemisimple`, `V2mPlus_zhu_finrank`, `OrbA4.cubicModel_c2Cofinite_holds`, `OrbTop.cubicModel_zhuSemisimple`: the standard three, same run. **Unconditional** (no hypotheses beyond the range of m; the full hypothesis closure is the two proved inputs), using the theorem `VOA.pbw`. Content: one-point functions only; convergence by the separate growth theorem; $\rho(S)$ only shown to exist. (V_{2m} is covered by the next theorem; $V^\natural$ and the higher-rank lattice VOAs are not covered: the latter are C_2-cofinite (`latticeVOAGen_c2Cofinite`) but

not proved rational.)

Theorem 15.44 (Zhu's theorem for the lattice VOAs $V_{\sqrt{2m}\mathbb{Z}}$, and for every nice VOA). *(i) For every $m \geq 1$, the conclusion of Theorem 15.37 holds for the rank-one lattice VOA $V = V_{2m} = V_{\sqrt{2m}\mathbb{Z}}$, with no further hypotheses. (ii) It holds for every* nice *vertex operator algebra V, i.e. every V that is strongly rational and pseudo-unitary (Gannon–Rayhaun, Definition 2.6).*

File `VOA/Classification/COne/ZhuModularityV2mPlus.lean`, namespace `VOA.Classification.COne`.

The objects in these statements are, in `VOA/Classification/COne/Statement.lean` and `VOA/Classification/COne/LatticeStronglyRational.lean` (Chapter 22):

```
def Nice (V : VertexOperatorAlgebra 𝒱) : Prop :=
  StronglyRational V ∧ PseudoUnitary V

noncomputable def V2m (m : ℕ) (hm : 1 ≤ m) : VertexOperatorAlgebra (LatModuleGen (latP m))
 ↪ :=
  latticeVOAGen (latP m) (latP_even m) (latP_posDef m hm)

theorem V2m_stronglyRational (m : ℕ) (hm : 1 ≤ m) : StronglyRational (V2m m hm) :=
  { V2m_stronglyFinite m hm with rational := V2m_admissiblyRational hm }
```

From the mathematics to the Lean statement

The objects. `V2m m hm` is the lattice VOA (`latticeVOAGen`, Chapter 6) of the rank-one lattice `latP m` $= \sqrt{2m}\mathbb{Z}$, which is even (`latP_even`) and, for $m \geq 1$, positive definite (`latP_posDef m hm`); its central charge is 1. Chapter 22, Definition 22.5, decodes it. `Nice V` is the conjunction ($\wedge$) of `StronglyRational V` and `PseudoUnitary V`: every irreducible module not isomorphic to V has all its conformal weights of positive real part (Chapter 22, Definitions 22.2 and 22.3; Chapter 21). `hV.1` is the first component, the strong rationality. `V2m_stronglyRational` combines strong finiteness (simple, self-dual, C_2-cofinite; `V2m_stronglyFinite`) with `V2m_admissiblyRational`, the library's proof that every admissible V_{2m}-module is completely reducible (Dong's theorem for lattice VOAs, in the library's reading of rationality).

Reading the statements. The proof terms are shown because they are the whole proof:

each is the headline form `zhuModularity_canonical_of_stronglyRational` (Theorem 15.39) applied to a proof of strong rationality. The `letI` lines are the same instance constructions as in the headline, with the C_2-cofiniteness taken from the strong-rationality proof. The conclusion is pinned to the canonical family and its weights.

Hypotheses. `zhuModularity_V2m` has only the parameter m and the bound `hm : 1 ≤ m`, which is needed to form V_{2m} at all (positive definiteness). It is **unconditional**. `zhuModularity_of_nice` has the hypothesis `hV : Nice V`, of which only strong rationality is used; pseudo-unitarity is not. So it is the special case of Theorem 15.39 for nice V, stated because the classification and Huang chapters work with nice VOAs. Every VOA that the library proves nice is an unconditional instance, for example V_{2m} (`V2m_nice`) and V_{2m}^+ (`V2mPlus_nice`, every $m \geq 1$, which also covers $m = 1$, excluded from `zhuModularity_V2mPlus`).

What is used, and what is not. Unlike the orbifold instances of Theorem 15.43, these do not prove semisimplicity of $A(V)$ by a computation with the Zhu algebra. They go through rationality and `isSemisimpleRing_A_of_admissiblyRational`. So the two kinds of instance check the two layers of the theorem: the engine directly, and the headline through Zhu's semisimplicity theorem.

Could the instances be empty of content? No. $V_{\sqrt{2m}\mathbb{Z}}$ has $2m$ inequivalent irreducible modules $V_{\lambda+\sqrt{2m}\mathbb{Z}}$, $\lambda = r/\sqrt{2m}$, $r \in \mathbb{Z}/2m$, with conformal weights $\min(r, 2m-r)^2/4m$ for $0 \leq r < 2m$ (on paper; Dong's classification, not a Lean theorem here). Their characters $\theta_r(\tau)/\eta(\tau)$, $\theta_r = \sum_{n\in\mathbb{Z}} q^{(2mn+r)^2/4m}$, form a genuinely $2m$-dimensional vector-valued modular function, and $\rho(S)$ is, on paper and up to a sign convention, the discrete Fourier transform $e^{-2\pi irs/2m}/\sqrt{2m}$ on $\mathbb{Z}/2m$.

Proof on paper. (i) V_{2m} is strongly rational (`V2m_stronglyRational`); apply Theorem 15.39. (ii) A nice VOA is strongly rational by definition; apply Theorem 15.39. □

Physical meaning

$V_{\sqrt{2m}\mathbb{Z}}$ is the chiral algebra of the compact boson at the rational radius where the chiral momentum lattice is $\sqrt{2m}\mathbb{Z}$; $m = 1$ is the self-dual $SU(2)_1$ point. Its sectors are labelled by the momentum $r \in \mathbb{Z}/2m$, and the theorem says that the $2m$ characters θ_r/η span a representation of $SL_2(\mathbb{Z})$. This is the rational point of the $c = 1$ moduli space, where the chiral algebra is extended by the vertex operators $e^{\pm i\sqrt{2m}\phi}$ and the torus partition function becomes a finite sum of products of these characters. Pseudo-unitarity, which (ii) assumes but does not use, says that every non-vacuum sector has positive energy, as in a unitary CFT.

What the machine verified

`VOA.Classification.COne.zhuModularity_V2m`, `VOA.Classification.COne.zhuModularity_of_nice`: `[propext, Classical.choice, Quot.sound]`, run at an earlier commit (not re-run for this edition) in the same scratch run as Theorem 15.39 (the olean of `ZhuModularityV2mPlus.lean` also predates the theorems, so the file's text was elaborated in the scratch file). Inputs `V2m_stronglyRational`, `V2m_nice`, `V2mPlus_nice`: the standard three, same run. `zhuModularity_V2m`: **unconditional** (no hypotheses beyond the range of m), using the theorem `VOA.pbw`. `zhuModularity_of_nice`: `#print axioms`-clean, *conditional on* `Nice V`. One-point functions only. Per `Notes/RELEASE_PLAN.md` the umbrella build containing them was green (12,271 jobs); not re-run here.

15.15 Twisted modules and the orbifold conjecture: a statement only

Zhu's theorem has an orbifold generalisation (Dong–Li–Mason 2000): for a finite group G of automorphisms of a rational C_2-cofinite V, the twisted trace functions $Z(M,h;\tau)=\operatorname{tr}_M \varphi(h) q^{L_0-c/24}$ over g-twisted modules M ($g,h\in G$ commuting) span an $SL_2(\mathbb{Z})$-representation, and each is invariant under a congruence subgroup. The library states (part of) this as a proposition and never asserts it.

Definition 15.45 (Twisted trace; Conjecture 5.3.10 as a proposition). For a g-twisted module T (g of order N) with L_0-weights in $h_0+\frac{1}{N}\mathbb{N}$ and an operator φ commuting with the twisted action, the twisted trace is the formal series $\sum_e \operatorname{tr}(\varphi|_{T_{e+c/24}})q^e$. The proposition asserts that, evaluated along $h_0+\frac{1}{N}\mathbb{N}$, it is invariant under $\Gamma(N')$ for some $N'>0$, for all such g,T,h_0,φ.

        TwistedTraceModular T φ h₀
```

From the mathematics to the Lean statement

`TwistedModule g N M` is the twisted-module structure of `Twisted.lean` (fractional modes `YM u k` $= u_{(k/N)}$, with the repaired Jacobi identity restricted to the support coset; Chapter 34 explains the repair). `CongruenceSubgroup.Gamma N'` is Mathlib's $\Gamma(N')$. `T.weight α ≠ ⊥ → …` says the L_0-weights lie in $h_0+\frac{1}{N}\mathbb{N}$. The proposition takes no hypothesis on V (no C_2, no rationality); it is meant to be assumed for, or proved for, suitable V. It is used nowhere.

Trap / dead end

`Conjecture_5_3_10` reads the twisted trace along the wrong exponents (serious). The coefficient of `twistedTrace T φ` at e is the trace on the weight space $T_{e+c/24}$ (exponent convention of Definition 15.4). The hypothesis puts the weights in $h_0+\frac{1}{N}\mathbb{N}$, so the nonzero coefficients sit at $e=h_0-\frac{c}{24}+\frac{n}{N}$. But `qEvalAtFrac (twistedTrace T φ) h₀ N` reads the

coefficients at $e = h_0 + \frac{n}{N}$, i.e. the traces on $T_{h_0+n/N+c/24}$. (Compare `traceFun`, which correctly evaluates along $h_i - c/24$.) Consequences:

- If $\frac{c}{24} \notin \frac{1}{N}\mathbb{Z}$ (e.g. $c = \frac{1}{2}$, $N = 1$), every coefficient read is 0, the evaluated function is 0, and `TwistedTraceModular` holds trivially: the "conjecture" is vacuous for every twisted module of every such V. Checked in Lean against the library (the check is not part of this release): `VOA.L15Cert.twistedTraceModular_of_weight_bot` and `twistedTraceModular_of_c_off_lattice` (standard three axioms).
- If $\frac{c}{24} \in \frac{1}{N}\mathbb{Z}$, the function read is a truncated, shifted trace and is in general *not* modular. For example, for $V = V^\natural$, $g = 1$, $N = 1$, $T = V^\natural$, $\varphi = 1$, $h_0 = 0$ ($c = 24$) one reads $\sum_n \dim V^\natural_{n+1} q^n = J(\tau) - q^{-1}$, which is invariant under no $\Gamma(N')$ (on paper; the genuine statement, with $h_0 - c/24$, gives J, which is invariant).

So the proposition is not Dong–Li–Mason's conjecture/theorem. Fix: evaluate along $h_0 - \frac{c}{24}$, i.e. use `qEvalAtFrac (twistedTrace T φ) (h₀ - W.centralCharge / 24) N`. Two further, milder deviations: the proposition does not ask φ to come from $h \in C_G(g)$ (any commuting operator is allowed; harmless for irreducible T by Schur), and it omits the $SL_2(\mathbb{Z})$-covariance of the whole family (5.3.25), as its docstring says.

Physical meaning

Twisted sectors are the sectors of an orbifold theory: strings closed up to the symmetry g. The twisted trace with h inserted is the torus partition function with boundary conditions twisted by g along one cycle and h along the other, and modular transformations permute the pairs (g, h). This is how $V^\natural$ arises from the Leech lattice theory and how Monstrous Moonshine's McKay–Thompson series become modular functions. The library contains this only as a statement.

What the machine verified

`VOA.Conjecture_5_3_10`: a definition (`#print axioms`: standard three). Nothing proves or uses it. The theorems of the separate Lean check about it (not part of this release): standard three axioms.

15.16 What is not proved

For the reader comparing with textbook accounts of Zhu's theorem (Gannon §5.3; Dong–Li–Mason; Huang), the following standard companions are *not proved about the representation ρ of this chapter*. (Chapter 21 develops, for the class of VOAs it calls *nice* — strongly rational and pseudo-unitary — Huang's modular tensor category, a Verlinde theorem and congruence statements; their hypotheses and their relation to this chapter's ρ are discussed there, not here.)

- properties of $\rho(S)$: symmetry, unitarity, $S^2 = C$ (charge conjugation), $(ST)^3 = S^2$ beyond what ρ being a homomorphism implies; the *Verlinde formula* (Huang 2005), and indeed any nonzero fusion coefficient (the library's `fusionCoeff` is identically 0, a placeholder rather than the fusion rules; Chapter 12);
- the congruence property ($\ker\rho \supseteq \Gamma(N)$; Dong–Lin–Ng 2015) for general V: for nice V (strongly rational and pseudo-unitary) it is proved for Zhu's representation in the form of a Zhu datum (`Huang.CongruenceNamed.zhu_kernelContainsGamma_at_level`, Chapter 21; it uses only the kernel half of Ng–Schauenburg); and rationality of c and h_i;

- a modular linear differential equation with modular-form coefficients (Section 15.5.4);
- the theorem for torus n-point functions, and Miyamoto's extension to non-rational C_2-cofinite V via pseudo-traces (the logarithmic files are Chapter 18);
- the orbifold theorem (Section 15.15);
- the converse half of the comparison of the library's rationality `AdmissiblyRational` with Dong–Li–Mason rationality. (The direction DLM ⇒ `AdmissiblyRational`, needed to apply the headline to a V known only to be rational in the paper's sense, is now proved for C_2-cofinite V, `admissiblyRational_of_dlmRational`, Theorem 12.36, which is all the headline needs.) For the converse, Lean proves that `AdmissiblyRational` implies the level-graded reading (`admissiblyRationalGraded_of_admissiblyRational`) and, under C_2, DLM's decomposition into irreducible ordinary modules (`AdmissiblyRational.exists_iSupIndep_irreducible_ordinary`), but not DLM's definition itself (Remark 15.2);
- instances for $V^\natural$ and for lattice VOAs of rank > 1: the latter are proved C_2-cofinite (`latticeVOAGen_c2Cofinite`) but not rational, and for $V^\natural$ neither is proved (Section 15.14);
- the equality $\dim \mathfrak{B} = \#\Phi(V)$ (only $\leq$ is a Lean theorem; Theorem 15.22).

(Four items of earlier versions of this list are now proved, or were proved all along: nontrivial V satisfying the hypotheses, Section 15.14; an axiom-free `Pr`, supplied by the theorem `VOA.pbw`; the implication "rational ⇒ $A(V)$ semisimple", `isSemisimpleRing_A_of_admissiblyRational` (Theorem 15.38), which the first release revision wrongly listed here as unproved; and with it Zhu's theorem for the lattice VOAs $V_{\sqrt{2m}\mathbb{Z}}$, $m \geq 1$ (Theorem 15.44).) The corollary $\chi_{V^\natural} = J$ is treated in Chapter 14 and in the Moonshine part of the book (Chapter 33); it is not derived from the headline of this chapter.

15.17 The remaining files, by role

The 124 files (the 122 of the snapshot and the two release files) fall into the following groups. Files not named are helpers of the named ones.

- **Base objects:** `OnePointFunctions`, `GradedTrace`, `ZhuTheorem` (modular data, T-law), `ChiralBlock` (multilinear n-point block interface; not used by the headline), `Twisted`.
- **Square bracket:** `SquareBracketWitt`, `SquareBracketVirasoro`, `SquareBracketGrading`, `SquareBracketSubst`, `SquareBracketC2`, `SqWeightSpanning`, `SqWeightNat`, `SqModeLinear`, `SqModeWeight`.
- **Recursion and block conditions:** `ZhuRecursion`, `ZhuRecursionProof`, `ZhuRecursionClose`, `ZhuCoefficientIdentity`, `ZhuAssembly`, `ZhuNormalization`, `ZhuBlockConditions`, `JacobiZhu`, `BlockZeroMode`.
- **Convergence:** `BlockSystem`, `BlockGrowth`, `OnePointDescent`, `OnePointGrowth`, `OnePointODE`, `ZhuODEAssembly`, `FormalBlockFinite`, `UniCollapse` (dead-end certificate), `TraceGrowthReduction`, `C2Corollaries`; the Buhl/Li ordered-spanning route `LiFiltration`, `OrderedSpan`, `OrderedMonomialBridge`, `BuhlSpanning*` (an earlier route to the $v = \mathbf{1}$ growth, superseded).
- **Blocks and finiteness:** `AnalyticBlock`, `BlockSpace`, `BlockRank`, `BlockDeterminacy`, `BlockFiniteness`, `BlockFiniteDim`, `BlockRelSpanning`, `BlockRelSpanE`, `BlockRelSpanG`, `BlockRelSpanTransport`, `GradedBlock`, `SqGradedBlock`, `SqGradedBlockSlash`, `FormalBlockFinite`, `GNBlock`, `BlockFiniteEtingof` (Etingof-route variant).

- **Count:** `CuspLimit`, `CuspPoint`, `ZhuCount`, `ZhuCountC2`, `ZhuBlockCount`, `ZhuAlgebraFinite`, `SemisimpleTrace`, `SymmetricFunctionals`, `TraceSpace`, `WedderburnAMod`, `WedderburnSimples`, `SimpleAModFinite`, `AModBridge`.
- **Existence of modules:** `StrictSpanning`, the `GN*` files (Gaberdiel–Neitzke Prop. 8 in five "links"), `RealizationCofinite`, `RealizationAssembly`, `OmegaCentral`, `HL0Scoped`, `AnFiniteDim`, `Anm0FiniteDim`, `C2Extraction`, `C2GradedVanishing`, `LowestWeightExistence`.
- **Independence:** `TraceIndependence`, `FibreIndependence`, `CharIndependence`, `CharIndependenceAMod`, `BottomCharacter`, `TraceNonvanish`.
- **Assembly:** `BlockSpanning`, `SlashAmbientObstruction`, `SqAmbientRank`, `SqAmbientAssembly`, `SqSlashBridge`, `MinimalClosure`, `FamilyIndexing`, `ConformalWeightChoice`, `ZhuModularityFibre`, `ZhuModularityODE`, `ZhuModularityC2`, `ZhuModularitySurface`, `ZhuModularityGN`, `ZhuModularityPinned`, `GNProp8Closure`, `GNProp8PBW`, `StronglyRationalFamily`, `ZhuStronglyRational`, `ZhuModularityCanonical` (the engine, the rational and strongly rational headline forms, the closed trivial instance and the combined Zhu correspondence of Chapter 13). Zhu's semisimplicity theorem, which the headline uses, is in `VOA/Huang/ZhuSemisimple.lean` (Chapter 21). The instances `ZhuModularityV2mPlus` (for V_{2m}^+, the tetrahedral model, V_{2m} and nice VOAs; assigned to this chapter) live in `VOA/Classification/COne/`, next to their inputs (Chapter 22).
- **Examples:** `ZhuInstantiation`, `TrivialRationalityLattice`, `TrivialAdmissiblyRational`, `TrivialStronglyRational`.

15.18 Referee's checklist

Declaration	Intended meaning	Hypotheses	Check
`zhuModularity_canonical_of_C2Cofinite_admissiblyRational`	**headline**: Zhu's modularity theorem for one-point functions of rational C_2-cofinite V, all irreducibles (canonical family)	C_2; `AdmissiblyRational` (implied by DLM-rationality under C_2; converse open); conditional; via theorem `VOA.pbw`	Thm. 15.39
`zhuModularity_canonical_of_stronglyRational`	**headline**, strongly rational form	`StronglyRational`; conditional; via theorem `VOA.pbw`	Thm. 15.39
`isSemisimpleRing_A_of_admissiblyRational`, `zhuAdmissibleSemisimple_of_Pr`	rational ⇒ $A(V)$ semisimple (Zhu 2.2.3; DLM 4.10(a))	`Pr` (supplied by `VOA.pbw`), `AdmissiblyRational`; proved	Thm. 15.38
`zhuModularity_canonical_of_C2Cofinite_semisimple`	engine: the same conclusion from semisimplicity of $A(V)$	C_2; $A(V)$ semisimple; conditional; via theorem `VOA.pbw`	Thm. 15.37
`finite_Φ_of_C2Cofinite_pbw`	$\Phi(V)$ finite	C_2	Thm. 15.35
`zhuModularity_V2mPlus`, `zhuModularity_cubicModel`	first nontrivial instances (V_{2m}^+, $m \geq 2$; tetrahedral)	none; **unconditional**; via theorem `VOA.pbw`	Thm. 15.43
`zhuModularity_V2m`	Zhu's theorem for every lattice VOA $V_{\sqrt{2m}\mathbb{Z}}$, $m \geq 1$	none; **unconditional**; via theorem `VOA.pbw`	Thm. 15.44
`zhuModularity_of_nice`	Zhu's theorem for every nice VOA	`Nice V` (only strong rationality used); conditional	Thm. 15.44
`trivialVOA_zhuModularity_closed`	instance at $\mathbb{C}\mathbf{1}$	none; unconditional	Thm. 15.41

Declaration	Intended meaning	Hypotheses	Check
`zhuModularity_pinned_of_C2Cofinite`	Zhu's modularity theorem, pinned to the given family	C_2; $A(V)$ ss; Φ finite; `Pr`; `hcard`, `hcw`, `hsep`; conditional	Thm. 15.34
`zhuModularity_pinned_of_C2Cofinite_voaPBW`	same, `Pr` from the theorem `VOA.pbw`	as above minus `Pr`; via theorem `VOA.pbw`	Thm. 15.34
`zhuModularity_stronglyRational_voaPBW`	same for strongly rational V, canonical family	`StronglyRational`, DLM finiteness, Zhu semisimplicity (both carried, both now theorems for strongly rational V); via theorem `VOA.pbw`; superseded	Thm. 15.40
`trivialVOA_zhuModularity`	non-vacuity at $\mathbb{C}\mathbf{1}$	$\#\Phi = 1$ (a theorem); via theorem `VOA.pbw`	Thm. 15.41
`onePointSubexp_of_c2`	subexponential growth of all one-point coefficients	C_2, conformal weight	Thm. 15.16
`qSummableAt_of_subexponential`	growth ⇒ convergence on $\mathbb{H}$	subexponential	Thm. 15.16
`zhuRecursionPinned_holds`	Zhu's recursion	none	Thm. 15.11
`torusOnePointHom_isFormalBlock`	traces satisfy the block conditions	none	Thm. 15.13
`torusOnePoint_isAnalyticBlock`	traces are analytic blocks	support, growth	Thm. 15.18
`exists_finrank_analyticBlocks_le`	$\dim \mathfrak{B} < \infty$ (Zhu 5.3.2)	C_2	Thm. 15.19
`finiteDimensional_A_of_C2Cofinite`	$\dim A(V) < \infty$	C_2	Thm. 15.20
`finiteDimensional_and_finrank_analyticBlocks_le_card_Φ`	$\dim \mathfrak{B} < \infty$ and $\dim \mathfrak{B} \le \#\Phi$ (Zhu 5.3.3, **upper bound only**)	C_2, ss, Φ finite, `hreal`, `Pr`	Thm. 15.22
`gnProp8_GNReach`, `cofinite_of_strictSpanning`	strict spanning in VA modes (cf. GN Prop. 8; convention unverified), GN Thm. 11	C_2	Thm. 15.24
`simpleAModsRealized_of_C2Cofinite`	every simple $A(V)$-module is the bottom of an irreducible *ordinary* module	C_2, `Pr` (explicit)	Thm. 15.25
`traceBlock_S_sqRestrict_mem_analyticBlocks`	S-slash of a trace is a block	C_2, conformal weight	Thm. 15.28
`fibreIndependent_of_bottomSeparation`	traces independent	growth, simple separated bottoms	Thm. 15.30
`zhu_modularity_of_spanning`	ρ from spanning + independence	the two data	Thm. 15.32
`slashSpannedAtS_of_sqRank_le`	S-spanning from rank bound	rank, independence	Thm. 15.33
`char_T_modularity`, `zhu_modularity_T_onePoint`	law at T	conformal weight	Thm. 15.6
`Lsq_virasoro_apply'`, `sqWeightSpace_isInternal`	torus Virasoro, $L[0]$-grading	none	Thm. 15.8
`not_rank_analyticSlashAmbient_le`	legacy rank hypothesis is contradictory	displayed	Sec. 15.9
`Conjecture_5_3_10`	orbifold modularity (statement)	— ; **mis-normalised**	Sec. 15.15

All entries were checked with `#print axioms` under `lake env lean -DmaxSynthPendingDepth=3`: the standard three axioms for every entry (at the snapshot, `VOA.pbw` was added for the

three entries marked "via theorem VOA.pbw" and for the two wrappers of the separate Lean check below; re-run at a later commit, after VOA.pbw became a theorem (not re-run for this edition), for the changed entries, the _voaPBW items and those of the check: standard three; the unchanged entries were not re-run). The separate Lean check of this chapter against the library (not part of this release) compiled with the same flag; its theorems vacuumGradeZero_always, hsimp_of_semisimple, zhuModularity_pinned_lean, headline_traces_are_genuine, twistedTraceModular_of_weight_bot, twistedTraceModular_of_c_off_lattice use the standard three axioms; trivialVOA_zhuModularity_uncond and stronglyRational_wrapper_fires added VOA.pbw at the snapshot and report the standard three in that later run.

Release audit 2026-10-27: RELEASE_AUDIT_ZHU.md. The independent release audit (Notes/Textbook/referee/RELEASE_AUDIT_ZHU.md) re-ran #print axioms on the chapter's headlines (all standard) and required the corrections applied in this revision: the hypothesis is semisimplicity of $A(V)$, not rationality (Remark 15.2); one-point functions only; convergence is a separate theorem; the block count is an upper bound; [Finite (Φ W)] is a theorem; the mode convention of strict spanning is unverified against Gaberdiel–Neitzke; simpleAModsRealized_of_C2Cofinite takes Pr and C_2. The theorems it recommended were then added to the library and are presented here. For this revision a scratch file was run at an earlier commit (not re-run for this edition) with lake env lean -DmaxSynthPendingDepth=3 from the repository root, against the oleans built 2026-10-25 for the imported modules; the two new files had no oleans, so their text was included verbatim in the scratch file and elaborated there. Output:

No `lake build` was run for this revision. The release plan records that the umbrellas were green when these theorems were merged (2026-10-28 entry); the release audit's own caveat stands: nothing counts as released until an aggregate `lake build` containing the modularity umbrella is green at the release commit.

Second release revision 2026-10-28: RELEASE_AUDIT_NEW_DECLS.md, finding F2. The audit of the new declarations (`Notes/Textbook/referee/RELEASE_AUDIT_NEW_DECLS.md`) found that the module docstrings of `ZhuModularityCanonical.lean` and `ZhuModularityV2mPlus.lean` understated the library: the implication "rational $\Rightarrow$ $A(V)$ semisimple" was already proved (`VOA.Huang.ZhuSemisimple.isSemisimpleRing_A_of_admissiblyRational`), and the V_{2m} instance followed in two lines. The first release revision of this chapter repeated both errors. The library then added `zhuModularity_canonical_of_C2Cofinite_admissiblyRational`, `zhuModularity_canonical_of_stronglyRational`, `zhuModularity_V2m` and `zhuModularity_of_nice`, and corrected the two docstrings. This revision presents them (Sections 15.12.3 and 15.14) and corrects the chapter. For it, a scratch file was run at an earlier commit (not re-run for this edition) with `lake env lean -DmaxSynthPendingDepth=3` from the repository root. The oleans of `ZhuModularityCanonical.lean` and `ZhuModularityV2mPlus.lean` (2026-10-28 00:02) predate their current sources (04:27), so the scratch file imported the two files' imports and contained their text verbatim; all other modules were taken from existing oleans and nothing was built. Output (the run exited with status 0):

```

```

The same file also checked the `example` of Theorem 15.38 (`ZhuAdmissibleSemisimple W` for every V). No `lake build` was run for this revision. `Notes/RELEASE_PLAN.md` records that the umbrella builds of `VOA.Modularity` and `VOA.Classification` containing the new theorems were green (12,271 jobs) with standard axioms. The audit's process finding F1 stands: nothing counts as released until the aggregate `lake build` is green at the release commit.

15.19 Notes and references

The theorem is due to Yongchang Zhu, *Modular invariance of characters of vertex operator algebras*, J. Amer. Math. Soc. **9** (1996), 237–302; the square-bracket structure, the recursion (Prop. 4.3.2), the block space and Theorems 5.3.1–5.3.3 are from §§4–5 there. The orbifold and twisted generalisation, the systematic treatment of convergence and the symmetric-functional lemma (Lemma 10.7) are in C. Dong, H. Li, G. Mason, *Modular-invariance of trace functions in orbifold theory and generalized Moonshine*, Comm. Math. Phys. **214** (2000), 1–56 (arXiv:q-alg/9703016); finiteness of irreducible admissible modules is C. Dong, H. Li, G. Mason, *Twisted representations of vertex operator algebras*, Math. Ann. **310** (1998), 571–600. The extension to non-rational C_2-cofinite algebras by pseudo-traces is M. Miyamoto, *Modular invariance of vertex operator algebras satisfying C_2-cofiniteness*, Duke Math. J. **122** (2004), 51–91 (arXiv:math/0209101). The spanning theorem used for existence is M. R. Gaberdiel and A. Neitzke, *Rationality, quasirationality and finite W-algebras*, Comm. Math. Phys. **238** (2003), 305–331 (arXiv:hep-th/0009235), Prop. 8 and Thm. 11; related spanning sets are in G. Yamskulna, *C_2-cofiniteness of the vertex operator algebra V_L^+ when L is a rank one lattice*, Comm. Algebra **32** (2004), 927–954. The quasi-lisse extension (Chapter 16) is T. Arakawa and K. Kawasetsu, *Quasi-lisse vertex algebras and modular linear differential equations*, in *Lie groups, geometry, and representation theory*, Progr. Math. **326** (2018), 41–57 (arXiv:1610.05865).

Chapter 16

Quasi-lisse vertex algebras and the Arakawa–Kawasetsu theorem

This chapter documents the release of the LeanVOA library named in the front matter; it was first written against an earlier state of the library ("the snapshot" below), and checks that were run at an earlier state of the library and not re-run for this edition are marked as such. Every Lean quotation below is taken from the source files of the release and is machine-checked by `scripts/textbook/sync.py` to occur verbatim (up to whitespace and comments) in the source. The chapter covers the thirteen files assigned to it in `Notes/Textbook/assignment.txt`, about seven thousand three hundred lines of Lean:

- `VOA/Modules/PoissonTrace.lean`, `VOA/Modules/PoissonQuotient.lean`, `VOA/Modules/QuasiLisseFinite.lean` — the Poisson-trace side of the theory and the finiteness half of Arakawa–Kawasetsu;
- `VOA/Modularity/AKGrading.lean`, `AKModularODE.lean`, `AKUniformODE.lean`, `AKMLDE.lean`, `AKZhuModularity.lean`, `AKSl2Payoff.lean`, `AKSl2Instance.lean`, `AKGradingInstance.lean`, `AKGradingTotal.lean`, `AKMLDEUnconditional.lean` (all in `VOA/Modularity/`) — the differential-equation and modularity half;
- `VOA/Examples/AffineSl2QuasiLisse.lean`, `AffineSl2Presentation.lean`, `AffineSl2NonLisse.lean` (in `VOA/Examples/`) — the example $L_{-4/3}(\mathfrak{sl}_2)$.

We rely on earlier chapters for the following, and do not repeat them: Lean idioms (`Submodule`, quotients `/`, `FiniteDimensional`, `∃`/`∀`, coercions) in Chapter 1; the C_2-algebra $R_V = V/C_2(V)$ (the library's `A₂ W`), its Poisson structure, C_2-cofiniteness and finite strong generation in Chapter 12 (Section 12.5); filtrations, symbols and associated graded objects in Chapter 11; modules, characters and conformal weights in Chapter 12; the universal affine vertex algebra $V^k(\mathfrak{sl}_2)$, its singular vectors and symbols in Chapter 9; the simple quotient $L_{-4/3}(\mathfrak{sl}_2)$ and Li's invariant-form radical in Chapter 10; the modular-forms toolkit (formal q-series, Eisenstein series, the Serre derivative, the ring $\mathbb{C}[E_4, E_6]$) in Chapter 14; and Zhu's modularity theorem, square bracket modes, genus-one conformal blocks and the growth data in Chapter 15.

What this chapter is about, in one paragraph. Zhu's theorem says that if a vertex operator algebra V is C_2-cofinite ("lisse"), the characters of its modules are modular. Arakawa and Kawasetsu observed that Zhu's argument uses C_2-cofiniteness only to make a certain module over the ring of modular forms finitely generated, and that a much weaker hypothesis does the same job: *finiteness of the zeroth Poisson homology* $\mathrm{HP}_0(R_V) = R_V/\{R_V, R_V\}$. By a theorem of Etingof and Schedler this holds whenever the *associated variety* $X_V = \operatorname{Specm} R_V$ has finitely many symplectic leaves ("V is quasi-lisse"). Their conclusion is that the character of every ordinary module of a quasi-lisse V

satisfies a *modular linear differential equation* (MLDE). The motivating examples are admissible affine vertex algebras such as $L_{-4/3}(\mathfrak{sl}_2)$, and the chiral algebras of four-dimensional $\mathcal{N}=2$ superconformal field theories, whose vacuum characters are Schur indices. **The library does not prove this theorem for any vertex algebra** (finding 3 below): this chapter explains it, and then records exactly which parts of it are formalised, and under which hypotheses.

The findings of this chapter, in brief. Read these before anything else; each is explained where it occurs.

1. **Quasi-lisseness is not formalised.** No associated variety, no symplectic leaf and no part of Etingof–Schedler exists in the library. Every theorem is stated under the hypothesis `EtingofFinite W`, which *is* the finiteness of $\mathrm{HP}_0(R_V)$, i.e. the *conclusion* of Etingof–Schedler. So "quasi-lisse" in the file names means "Etingof-finite" in the statements. This is honest (every docstring says it) and mathematically it makes the theorems *stronger* (they assume less), but no theorem mentions symplectic leaves. **What is formalised instead** is the following, and nothing more: for $L_{-4/3}(\mathfrak{sl}_2)$, (a) it is not C_2-cofinite and its zeroth Poisson homology $\mathrm{HP}_0(R_V)$ is finite-dimensional ("Etingof-finite"); (b) its character q-series converges on the upper half plane; (c) its space of genus-one conformal blocks is finite-dimensional. And for every VOA, C_2-cofinite $\Rightarrow$ Etingof-finite. Wherever this chapter says "quasi-lisse" about a Lean statement it means "Etingof-finite"; that a quasi-lisse VOA is Etingof-finite is the Etingof–Schedler theorem, *known on paper, not formalised*.

2. **The hypothesis is discharged for a genuinely non-lisse example.** For $L_{-4/3}(\mathfrak{sl}_2)$, the simple affine vertex algebra at the admissible level $-4/3$, the library proves both `EtingofFinite` (`VOA.Sl2Pres.etingofFinite_simpleSl2QL'`) and `¬C2Cofinite` (`VOA.Sl2NonLisse.not_C2Cofinite_simpleSl2QL`), unconditionally (`#print axioms`: Lean's three standard axioms only). So the strictness of "C_2-cofinite $\Rightarrow$ Etingof-finite" is a theorem. **Namespace warning:** the unconditional non-lisseness theorem is `VOA.Sl2NonLisse.not_C2Cofinite_simpleSl2QL` (file `AffineSl2NonLisse.lean`). A second declaration with the same short name, `VOA.QuasiLisseSl2.not_C2Cofinite_simpleSl2QL` (file `AKSl2Payoff.lean`), *formerly* took a presentation `S` and an exactness hypothesis `hex`. After this chapter's finding, a later revision of the library restated it without hypotheses, as the one-line proof `:= Sl2NonLisse.not_C2Cofinite_simpleSl2QL`; the two twins now have *identical* types, and so do the twins `QuasiLisseSl2.etingofFinite_simpleSl2QL` and `Sl2Pres.etingofFinite_simpleSl2QL'`. The conditional forms survive only as `Sl2Pres.not_C2Cofinite_simpleSl2QL_of_exact` and `Sl2Pres.quasiLisseWitness_simpleSl2QL_of_exact`, whose hypothesis `hex : Sl2ExactSymbol` is unproved and redundant. Throughout this chapter we always write the namespace.

3. **What "modularity" means in the proved theorems. Arakawa–Kawasetsu Theorem 5.1 (an analytic MLDE for all characters of a quasi-lisse VOA) is proved in the form: for every Etingof-finite VOA, one monic MLDE of unbounded order for all abstract analytic genus-one blocks (Theorem 16.30); quasi-lisseness is not formalised.** Its one concrete instance is $L_{-4/3}(\mathfrak{sl}_2)$ at the vacuum, of unspecified order. The only MLDEs of *specified order* the library proves for specific VOAs are the formal, coefficientwise second-order equations for the *vacuum* characters of the seven Deligne-series VOAs, obtained by Zhu's recursion in Chapter 25. At $L_{-4/3}(\mathfrak{sl}_2)$ the library proves, unconditionally: (a) the character satisfies a monic linear ODE in $q\,d/dq$ whose coefficients are power series with subexponentially growing coefficients (`character_formalODE_simpleSl2QL_uncond`); (b) the character q-series converges on the upper half plane; (c) the space of genus-one conformal blocks is finite-dimensional (Zhu's Theorem 5.3.2). **Statement (a) is not an MLDE and is not AK Theorem 5.1, although the source calls it "AK equation (2), formal form": by**

Proposition 16.24 (on paper) every convergent q-series with nonzero leading term and zeros of bounded multiplicity in the unit disc satisfies such an equation, so (a) is near-vacuous — it carries almost no information beyond the convergence (b). A *genuine* MLDE (iterated Serre derivatives, coefficients modular forms of the forced weights, Theorem 16.29) is proved **conditionally only on** `EtingofFinite W`. Its two former side inputs are now theorems: the Arakawa–Kawasetsu weight grading `AKWeightGrading W` holds for every VOA of the library (CFT type), `akWeightGrading W` (Definition 16.26), and the Ramanujan/Serre closure `E46SerreClosed` is `e46SerreClosed` (Chapter 14). The resulting statement is `IsSqPrimary.exists_monicMLDEOn_all_analyticBlocks_of_etingofFinite_uncond` (conditional on `EtingofFinite` despite the suffix), and at $L_{-4/3}(\mathfrak{sl}_2)$ it gives the unconditional `exists_monicMLDEOn_all_analyticBlocks_simpleSl2QL`: one monic MLDE of some unspecified order $s \geq 1$ satisfied by the vacuum one-point function of every analytic genus-one block (AK's order 2 is not proved). Both are `#print axioms`-clean (recorded by WS-RELEASE2); the aggregate build at the release commit is pending. Zhu-style $SL_2(\mathbb{Z})$-invariance of the span of characters under `EtingofFinite` needs two more hypotheses (`hfib`, `hrank`), discharged only for the trivial VOA; and at the flagship $L_{-4/3}(\mathfrak{sl}_2)$ `hrank` is *expected to be false* for every family containing the adjoint module (a paper argument of the release audit, not machine-checked; Section 16.7). So the library contains *no* modularity theorem for any non-lisse VOA.

4. **Lean defects found** (listed in Section 16.12): the hypothesis `hex : Sl2ExactSymbol` of several theorems was redundant (now removed from the flagship ODE theorems); a dozen docstrings said that non-lisseness of $L_{-4/3}(\mathfrak{sl}_2)$ is unproved or that only the trivial VOA is Etingof-finite (the declaration docstrings have since been corrected); two theorems share the short name `not_C2Cofinite_simpleSl2QL` (namespaces `VOA.Sl2NonLisse` and `VOA.QuasiLisseSl2`; formerly with different hypotheses, now with identical types); the headline docstring of `Sl2Pres.character_formalODE_simpleSl2QL_uncond` (`AKSl2Instance.lean`, ll. 97–105 at the release audit) calls the near-vacuous formal equation "THE HEADLINE" and "the Arakawa–Kawasetsu character equation"; and the citation attached to `Sl2ExactSymbol` ("Arakawa's associated-variety theorem") names a strictly weaker result.

5. **What may be said about this chapter, in one sentence** (independent release audit, 2026-10-27, `Notes/Textbook/referee/RELEASE_AUDIT_L16.md`): *Lean proves that $L_{-4/3}(\mathfrak{sl}_2)$ is not C_2-cofinite but has finite-dimensional zeroth Poisson homology, and that for every VOA with this finiteness property characters of ordinary modules converge on the upper half plane and the space of genus-one conformal blocks is finite-dimensional; the Arakawa–Kawasetsu MLDE is formalised conditionally only on* `EtingofFinite` *(its grading and Serre-closure inputs are theorems), with an unbounded order, for Zhu's abstract analytic one-point blocks, and holds unconditionally for $L_{-4/3}(\mathfrak{sl}_2)$ at the vacuum, order unspecified.* (The audit's sentence, written before `akWeightGrading` landed, said the MLDE was instantiated for no VOA; that is superseded.) It would be false to say that "the Arakawa–Kawasetsu theorem for quasi-lisse VOAs" is formalised: quasi-lisseness is not formalised, and `EtingofFinite` stands in for it.

16.1 The mathematics: lisse, quasi-lisse, and the Arakawa–Kawasetsu theorem

16.1.1 The associated variety

Let V be a vertex operator algebra; in the library every VOA is of CFT type ($V = \bigoplus_{n\geq 0} V_n$, $V_0 = \mathbb{C}\mathbf{1}$, $\dim V_n < \infty$; Chapter 12, Section 12.1). Zhu's subspace $C_2(V)$ is the span of all $u_{(-2)}v$, and $R_V = V/C_2(V)$. Chapter 12 (Theorem 12.23) shows that R_V is a commutative, associative, unital algebra under $[u]\cdot[v] = [u_{(-1)}v]$, and a Poisson algebra under $\{[u],[v]\} = [u_{(0)}v]$: the bracket

is a Lie bracket and a derivation of the product in each argument. If V is strongly generated by fields $a^1, \dots, a^r$ (every state is a linear combination of monomials $a^{i_1}_{(-n_1)} \cdots a^{i_r}_{(-n_r)}\mathbf{1}$ with $n_j \geq 1$, i.e. normally ordered products of the fields a^i and their derivatives $\partial^{n-1}a^i \leftrightarrow a^i_{(-n)}\mathbf{1}$), then R_V is generated as a commutative algebra by the classes $[a^i]$, so it is a finitely generated commutative $\mathbb{C}$-algebra: the coordinate ring of an affine scheme. The *associated variety* of Arakawa is the reduced affine variety

$$X_V = \operatorname{Specm} R_V \subseteq \mathbb{C}^r,$$

the set of maximal ideals of R_V (equivalently, of points of the reduced affine scheme), i.e. the common zero set of the relations among the generators. It inherits a Poisson structure from R_V. *None of this geometry is formalised*: the library works with the algebra R_V and assumes finiteness of $\mathrm{HP}_0(R_V)$ directly (Definition 16.9).

Example 16.1 (Three associated varieties)**.**

1. If V is *lisse* (C_2-cofinite, $\dim R_V < \infty$), X_V is a finite set; since R_V is graded by conformal weight with $(R_V)_0 = \mathbb{C}$, the only point is the origin: $X_V = \{0\}$.

2. For the Heisenberg (free boson) VOA $M(1)$ generated by one field a of weight 1, $R_{M(1)} = \mathbb{C}[x]$, $x = [a]$, with zero bracket (since $a_{(0)}a = 0$). So $X_{M(1)} = \mathbb{C}$, a line.

3. For the universal affine vertex algebra $V^k(\mathfrak{g})$, PBW gives $R_{V^k(\mathfrak{g})} = \mathbb{C}[\mathfrak{g}^*]$ (symmetric algebra of $\mathfrak{g}$) with the Kirillov–Kostant bracket, so $X = \mathfrak{g}^*$. For the simple quotient $L_k(\mathfrak{sl}_2)$ at an admissible level k, Arakawa proved $X_{L_k} = \mathcal{N}$, the nilpotent cone $\{h^2 + 4ef = 0\} \subset \mathfrak{sl}_2^* \cong \mathbb{C}^3$, a two-dimensional cone isomorphic to $\mathbb{C}^2/\mathbb{Z}_2$.

16.1.2 Symplectic leaves, quasi-lisseness, Poisson homology

The Poisson bracket of R_V makes X_V a Poisson variety. Each function g generates a Hamiltonian vector field $\{g, \cdot\}$; following these vector fields partitions (the smooth locus of each stratum of) X_V into *symplectic leaves*, the maximal connected immersed submanifolds on which the Poisson structure is non-degenerate. For the nilpotent cone there are exactly two leaves: the origin and the regular nilpotent orbit $\mathcal{N} \setminus \{0\}$. For the line with zero bracket every point is its own leaf: infinitely many.

Definition 16.2 (Quasi-lisse; Arakawa–Kawasetsu 2018)**.** A finitely strongly generated VOA V is *quasi-lisse* if X_V has finitely many symplectic leaves.

Physical meaning

For the chiral algebra of a four-dimensional $\mathcal{N} = 2$ theory, X_V is (conjecturally) the Higgs branch, a hyperkähler cone stratified by finitely many symplectic leaves (the strata of partial Higgsing); quasi-lisse is the two-dimensional shadow of "the moduli space of vacua is a finite union of nice strata".

Lisse implies quasi-lisse (a point has one leaf). $M(1)$ is not quasi-lisse. Admissible $L_k(\mathfrak{sl}_2)$ is quasi-lisse but not lisse.

Definition 16.3 (Zeroth Poisson homology, Poisson traces)**.** For a Poisson algebra R, let $\{R, R\} \subseteq R$ be the *linear span* of all brackets $\{a, b\}$. The zeroth Poisson homology is the vector space $\mathrm{HP}_0(R) = R/\{R, R\}$. A *Poisson trace* is a linear functional $\varphi : R \to \mathbb{C}$ with $\varphi(\{a, b\}) = 0$ for all a, b; the Poisson traces form the dual space $\mathrm{HP}_0(R)^*$.

Physical meaning

A torus one-point function of a CFT is $\langle v\rangle_\tau = \operatorname{tr}_{\mathcal{H}} o(v)\, q^{L_0-c/24}$, the expectation value of the zero mode of the field v in the thermal ensemble at modular parameter τ. It is a linear functional of v which, by cyclicity of the trace, vanishes on commutators $[o(a), o(v)] = o(a_{(0)}v)$, i.e. on the symmetry variations of v (this is condition (i) of a genus-one block, Definition 16.19). In the semiclassical limit R_V replaces the operators, $u_{(0)}$ becomes the Hamiltonian vector field $\{u, \cdot\}$, and the trace becomes a functional on phase-space functions invariant under all Hamiltonian flows: a Poisson trace. So Poisson traces are the classical limits of torus one-point functions ("classical torus amplitudes").

Theorem 16.4 (Etingof–Schedler 2010). *If R is a finitely generated Poisson algebra whose variety* Specm R *has finitely many symplectic leaves, then* $\dim \mathrm{HP}_0(R) < \infty$.

Physical meaning

Heuristically: an invariant functional is determined by its behaviour on each leaf, where Hamiltonian flows act transitively, so finitely many leaves allow only finitely many independent invariant functionals. (This heuristic is not the proof, which is D-module theoretic.)

This is a deep theorem (its proof uses D-modules: the Poisson traces are the solutions of a holonomic D-module). It is *not* formalised in the library and is never used as a black box either; instead its conclusion is the hypothesis of every theorem. We shall call a VOA *Etingof-finite* if $\dim \mathrm{HP}_0(R_V) < \infty$.

16.1.3 The Arakawa–Kawasetsu theorem

Recall (Chapter 14) that the Serre derivative of weight k is $\vartheta_k f = \frac{1}{2\pi i} f' - \frac{k}{12} E_2 f$; it maps modular forms of weight k to modular forms of weight $k+2$. Its iterates are $\vartheta_{(k)}^0 f = f$ and $\vartheta_{(k)}^{i+1} f = \vartheta_{k+2i}\vartheta_{(k)}^i f$.

Theorem 16.5 (Arakawa–Kawasetsu 2018, Theorem 5.1 and its proof). *Let V be a quasi-lisse VOA (conformal, of CFT type). There are $s \geq 1$ and modular forms p_i of weight $2(s-i)$ for $SL_2(\mathbb{Z})$, i.e. $p_i \in \mathbb{C}[E_4, E_6]$ homogeneous, such that for every ordinary V-module M the normalised character $\chi_M(\tau) = \operatorname{tr}_M q^{L_0-c/24}$, $q = e^{2\pi i\tau}$, satisfies*

$$\vartheta_{(0)}^s \chi_M + \sum_{i=0}^{s-1} p_i(\tau)\, \vartheta_{(0)}^i \chi_M = 0. \tag{16.1}$$

Consequently V has finitely many ordinary irreducible modules, and the characters χ_M lie in the finite-dimensional, $SL_2(\mathbb{Z})$-invariant solution space of (16.1).

Arakawa and Kawasetsu's proof runs as follows. (i) Etingof–Schedler gives $\dim \mathrm{HP}_0(R_V) < \infty$ (their Theorem 2.2). (ii) Over the ring $\mathcal{A} = \mathbb{C}[G_4, G_6]$ (or $\mathbb{C}[G_2, G_4, G_6]$), the module $V_{\mathcal{A}}/O_q(V)$ of Zhu — $V_{\mathcal{A}} = \mathcal{A} \otimes V$ modulo the relations that all genus-one one-point functions satisfy — is finitely generated (their Proposition 5.2); in Zhu's proof this was where C_2-cofiniteness entered, and the new observation is that the relations $a[0]v$, which Zhu never used, have leading term $a_{(0)}v$, the Poisson bracket. (iii) Hence the tower $L[-2]^i\mathbf{1}$ satisfies a monic relation modulo $O_q(V)$ (Lemma 5.3). (iv) The ω-recursion of Zhu, $Z(L[-2]v) = q\frac{d}{dq}Z(v) + \sum_{m\geq 0} G_{2m+2} Z(L[2m]v)$ for every torus one-point function Z (condition (iii) of Definition 16.19), converts $L[-2]$ into a Serre derivative up to lower-order terms (Lemmas 5.4–5.6). (v) Substituting gives (16.1).

Physical meaning

Associated varieties are Higgs branches. Beem, Lemos, Liendo, Peelaers, Rastelli and van Rees (2015) showed that every four-dimensional $\mathcal{N} = 2$ superconformal field theory contains a protected sector, the *Schur operators*, whose operator product expansion on a plane is that of a two-dimensional chiral algebra (a VOA) V_{4d}, with central charge $c_{2d} = -12\,c_{4d}$. Its vacuum character is the *Schur limit of the superconformal index*. Beem and Rastelli (2018) conjectured, and verified in many examples, that the associated variety $X_{V_{4d}}$ is the *Higgs branch* of the four-dimensional theory — the moduli space of vacua on which the scalars of the hypermultiplets get expectation values. Higgs branches are hyperkähler cones with finitely many symplectic leaves, so these chiral algebras are quasi-lisse but (whenever the Higgs branch is not a point) not lisse. The Arakawa–Kawasetsu theorem then predicts that the Schur index satisfies a modular linear differential equation, which Beem and Rastelli found and used. The example of this chapter, $L_{-4/3}(\mathfrak{sl}_2)$ with $c = -6$, is the chiral algebra of the Argyres–Douglas theory $(A_1, D_3) \cong (A_1, A_3)$, whose $c_{4d} = 1/2$ and whose Higgs branch is $\mathbb{C}^2/\mathbb{Z}_2$, the nilpotent cone of $\mathfrak{sl}_2$. Such theories are non-rational in the two-dimensional sense (the chiral algebra has infinitely many non-ordinary modules) yet have finitely many ordinary modules, whose characters lie in the finite-dimensional, modular-invariant solution space of an MLDE. (The span of the ordinary characters alone need not be invariant; for $L_{-4/3}(\mathfrak{sl}_2)$ it is expected not to be, by the paper argument in the warning after Theorem 16.32.) Poisson traces are the classical shadow of torus one-point functions: a one-point function $v \mapsto \operatorname{tr}_M o(v) q^{L_0 - c/24}$ kills $a[0]v$, whose leading term is a Poisson bracket.

16.1.4 What the library formalises: a map

Mathematics	Library
associated variety, symplectic leaves, quasi-lisse	*not defined*
Etingof–Schedler (Thm. 16.4)	*not proved*; its conclusion is the hypothesis `EtingofFinite W`
C_2-cofinite ⇒ Etingof-finite	`EtingofFinite_of_C2Cofinite`, unconditional
AK Prop. 5.2 (finite generation)	`exists_finite_gen_sup_blockRelSpanG_of_etingofFinite` ($\mathbb{C}[G_2, G_4, G_6]$) and `exists_finite_gen_sup_blockRelSpanE_of_etingofFinite` ($\mathbb{C}[E_4, E_6]$), from `EtingofFinite`
AK Lemma 5.3, 5.5	proved, from `EtingofFinite`; Lemma 5.5 for square-bracket primary vectors
AK eq. (2) in formal q-series form (**near-vacuous**, Prop. 16.24)	`character_formalODE_of_etingofFinite`: $(q\frac{d}{dq})$-basis, subexponential coefficients; *not an MLDE*
AK weight grading	`akWeightGrading W : AKWeightGrading W`, for every VOA of the library (CFT type)
AK Thm. 5.1 (genuine MLDE)	`IsSqPrimary.exists_monicMLDEOn_all_analyticBlocks_of_etingofFinite_uncond`, conditional only on `EtingofFinite W` (grading and Serre closure discharged); order $s \geq 1$ existential, unbounded; for Zhu's abstract analytic blocks
AK example $L_{-4/3}(\mathfrak{sl}_2)$	`exists_monicMLDEOn_all_analyticBlocks_simpleSl2QL`, unconditional, vacuum insertion, order unspecified (AK's order 2 *not* proved)
Zhu modularity under Etingof-finiteness	`exists_zhuModularity_of_sqAnalyticRank_le_irr_etingofFinite`, conditional on `hfib`, `hrank`; discharged only for the trivial VOA, and `hrank` expected false at $L_{-4/3}(\mathfrak{sl}_2)$ (paper argument)
$L_{-4/3}(\mathfrak{sl}_2)$ Etingof-finite	`Sl2Pres.etingofFinite_simpleSl2QL'`, unconditional
$L_{-4/3}(\mathfrak{sl}_2)$ not lisse	`Sl2NonLisse.not_C2Cofinite_simpleSl2QL`, unconditional
$X_{L_{-4/3}} = \mathcal{N}$ (Arakawa)	*not proved*; a stronger scheme-theoretic form is the named `Sl2ExactSymbol`, now unneeded

16.2 The Poisson algebra as a $\mathbb{C}$-algebra, and quotients

Chapter 12 builds the commutative ring `A₂CommRing W` and the Lie ring `A₂LieRing W` on `A₂ W` $= R_V$, writes `mk₂ W : V →ₗ[ℂ] A₂ W` for the projection $u \mapsto [u]$, `A₂mul` and `A₂bracket` for the descended bilinear maps, and proves the Leibniz rule. Two small pieces of infrastructure are added in `VOA/Modules/PoissonQuotient.lean`.

Definition 16.6 (R_V as a $\mathbb{C}$-algebra). R_V is a $\mathbb{C}$-algebra with structure map $c \mapsto c[\mathbf{1}]$.

File `VOA/Modules/PoissonQuotient.lean`.

```

theorem A₂_algebraMap_apply (W : VertexOperatorAlgebra V) (c : ℂ) :
    algebraMap ℂ (A₂ W) c = c • (1 : A₂ W) := rfl
```

From the mathematics to the Lean statement

`c • p` is the scalar multiplication that `A₂ W` inherits as a quotient vector space; `p * q` is the product of `A₂CommRing`. `Algebra.ofModule` is Mathlib's constructor that turns a ring which is already a vector space, with the two interchange laws $(cp)q = c(pq) = p(cq)$, into a $\mathbb{C}$-algebra; it reuses the existing scalar multiplication, so there is no second, possibly different, $\mathbb{C}$-action (no "diamond"), and `A₂_algebraMap_apply` is true by `rfl` (by unfolding). Same as the textbook. Why it matters: with an `Algebra` instance, Mathlib's `MvPolynomial.aeval` defines algebra homomorphisms out of a polynomial ring by choosing images of the variables, which is how the symbol map $\mathbb{C}[e, h, f] \to R_V$ of Section 16.9 is built.

Proof on paper. The product is bilinear, hence $\mathbb{C}$-linear in each slot. □

Physical meaning

Scalars multiply states; the classical limit R_V of the chiral algebra is an algebra of functions on the classical phase space, and constants $c \cdot 1$ are the constant functions (multiples of the identity operator).

What the machine verified

Proved; `#print axioms` of the four declarations: `[propext, Classical.choice, Quot.sound]` (the file's own audit block, compiled in the aggregate build).

Theorem 16.7 (R is functorial for quotients). *Let $I \subseteq V$ be a graded ideal and V/I the quotient VOA. The map $[u] \mapsto [u + I]$ is a well-defined surjective homomorphism of $\mathbb{C}$-algebras $R_V \to R_{V/I}$ which also preserves the Poisson bracket.*

File `VOA/Modules/PoissonQuotient.lean`.

      = A₂bracket (quotientVOA W I hI hgr) (A₂quot hI hgr p) (A₂quot hI hgr q) :=
```

From the mathematics to the Lean statement

`→ₐ[ℂ]` is a homomorphism of $\mathbb{C}$-algebras. `quotientVOA W I hI hgr` is the quotient VOA of Chapter 5 (Section 5.4); its two arguments `hI` (I is a two-sided ideal) and `hgr` (I is the sum of its intersections with the weight spaces) are exactly what is needed for the quotient to be a VOA. `I.mkQ` is the quotient map $V \to V/I$. The four statements are: the map exists and is an algebra map (multiplicative, unital, linear); it sends $[u]$ to $[u + I]$; it is surjective; it is a Poisson map. Same as the textbook. Could it be vacuous? It is a construction, and the formula `A₂quot_mk₂` pins it down.

Proof on paper. Modes of the quotient are computed on representatives, $[u]_{(n)}[v] = [u_{(n)}v]$; so $C_2(V)$ maps into $C_2(V/I)$ and the composite $V \to V/I \to R_{V/I}$ factors through R_V. The same formula at $n = -1$ and $n = 0$ gives compatibility with product and bracket; surjectivity is inherited from $V \to V/I$. □

Physical meaning

Setting null states to zero (passing to a quotient) can only add relations among the classical fields: the classical phase space of the quotient is a closed Poisson subvariety, $X_{V/I} \subseteq X_V$. This is how the nilpotent cone appears inside $\mathfrak{sl}_2^*$ for $L_k(\mathfrak{sl}_2)$.

What the machine verified

Proved; axioms `[propext, Classical.choice, Quot.sound]` (re-run for this chapter on `VOA.QuotVOA.A₂quot` with `lake env lean -DmaxSynthPendingDepth=3`).

16.3 Poisson traces and the Etingof–Schedler hypothesis

Definition 16.8 (Bracket span, HP_0, Poisson traces). $\{R_V, R_V\}$ is the linear span of all $\{p, q\}$, $p, q \in R_V$; $\mathrm{HP}_0(R_V) = R_V/\{R_V, R_V\}$; the Poisson traces are the linear functionals on R_V vanishing on $\{R_V, R_V\}$.

File `VOA/Modules/PoissonTrace.lean`.

```
noncomputable def poissonSpan (W : VertexOperatorAlgebra 𝒱) : Submodule ℂ (A₂ W) :=
  bilinSpan (A₂bracket W)

theorem poissonSpan_def (W : VertexOperatorAlgebra 𝒱) :
    poissonSpan W = Submodule.span ℂ {x : A₂ W | ∃ p q : A₂ W, x = A₂bracket W p q} := rfl

noncomputable abbrev HP₀ (W : VertexOperatorAlgebra 𝒱) : Type u := A₂ W ⧸ poissonSpan W

noncomputable def poissonTraces (W : VertexOperatorAlgebra 𝒱) :
    Submodule ℂ (Module.Dual ℂ (A₂ W)) :=
  vanishingFunctionals ℂ (A₂ W) (poissonSpan W)

theorem mem_poissonTraces {W : VertexOperatorAlgebra 𝒱} {φ : Module.Dual ℂ (A₂ W)} :
    φ ∈ poissonTraces W ↔ ∀ p q : A₂ W, φ (A₂bracket W p q) = 0 :=
```

From the mathematics to the Lean statement

`bilinSpan B` (file `VOA/Modularity/TraceSpace.lean`, Chapter 15) is the span of the range of a bilinear map B; `poissonSpan_def` unfolds it to "the span of all $\{p, q\}$", by `rfl`. `Module.Dual ℂ X` is the space of linear functionals $X \to \mathbb{C}$; `vanishingFunctionals ℂ X S` is the subspace of those vanishing on S, so `poissonTraces` is literally $\{R_V, R_V\}^{\perp}$, and `mem_poissonTraces` says so. The library also proves `poissonTracesEquiv : poissonTraces W ≃ₗ[ℂ] Module.Dual ℂ (HP₀ W)` (traces = dual of HP_0) and `poissonSpan_eq_map` (the span downstairs is the image of the span of the representatives $u_{(0)}v$ upstairs). Note that HP_0 is defined as a *vector space*: $\{R, R\}$ is not an ideal, and no ring structure is claimed. All the same as Definition 16.3.

Physical meaning

A Poisson trace is a "classical torus one-point function": a linear functional on classical observables invariant under all Hamiltonian flows. On a symplectic leaf, invariance under all Hamiltonian flows forces a functional to be (up to the measure) constant along the leaf, which is the heuristic reason why finitely many leaves give finitely many independent traces.

What the machine verified

Definitions and membership lemmas; axioms `[propext, Classical.choice, Quot.sound]` (file docstring and aggregate audit).

Definition 16.9 (Etingof-finite). *V is Etingof-finite* if $\dim_{\mathbb{C}} \mathrm{HP}_0(R_V) < \infty$.

File `VOA/Modules/PoissonTrace.lean`.

```
def EtingofFinite (W : VertexOperatorAlgebra 𝒱) : Prop := FiniteDimensional ℂ (HP₀ W)
```

From the mathematics to the Lean statement

`FiniteDimensional ℂ (HP₀ W)`: the vector space $R_V/\{R_V, R_V\}$ is finite-dimensional. This is exactly Definition 16.9. **Is it quasi-lisseness?** No. Quasi-lisseness (Definition 16.2) implies it by Etingof–Schedler (Theorem 16.4); the converse is not claimed anywhere and we do not know it to be true in general. Every theorem of this chapter assumes `EtingofFinite`, not quasi-lisseness, so each is (mathematically) a *stronger* statement than the literature's version with "quasi-lisse" — provided its conclusion matches, which is the question for the later sections. The docstring of `EtingofFinite` states all of this in capitals; it is a deliberate choice that removes all algebraic geometry from the formalisation. **Could it be vacuous?** It holds for every C_2-cofinite VOA (next theorem) and for $L_{-4/3}(\mathfrak{sl}_2)$ (Theorem 16.38); it fails for the free boson on paper (Remark 16.11).

"Quasi-lisse" is a file name, not a definition

No declaration of the library defines quasi-lisseness, associated varieties or symplectic leaves (a search of `VOA/` for declarations whose names contain `QuasiLisse`, `AssociatedVariety`, `Leaf` or `Symplectic` finds none; the word "symplectic" occurs only in comments and in the unrelated symplectic-fermion files of Chapter 17). The files `QuasiLisseFinite.lean` and `AffineSl2QuasiLisse.lean` prove statements about `EtingofFinite`. A referee should read "quasi-lisse" in a Lean name as "Etingof-finite".

Physical meaning

Physically, $\dim \mathrm{HP}_0 < \infty$ says that the chiral algebra has finitely many independent "classical torus amplitudes". For a four-dimensional $\mathcal{N} = 2$ theory it is the statement that the Higgs branch chiral ring has finite-dimensional Poisson homology, true because the Higgs branch is a hyperkähler cone with finitely many leaves.

What the machine verified

Definition. Satisfiable (Theorems 16.10 and 16.38).

Theorem 16.10 (Lisse implies Etingof-finite; the trace space). *(i) If V is C_2-cofinite then V is Etingof-finite. (ii) If V is Etingof-finite, the space of Poisson traces on R_V is finite-dimensional. (iii) If the bracket of R_V vanishes identically, Etingof-finite is equivalent to C_2-cofinite.*

File `VOA/Modules/PoissonTrace.lean`.

```
theorem EtingofFinite_of_C2Cofinite (W : VertexOperatorAlgebra 𝒱) (h : C2Cofinite W) :
    EtingofFinite W := by

theorem finiteDimensional_poissonTraces (W : VertexOperatorAlgebra 𝒱) (h : EtingofFinite W)
 ↪  :
    FiniteDimensional ℂ (poissonTraces W) := by
```

```
theorem EtingofFinite_iff_C2Cofinite_of_poissonSpan_eq_bot (W : VertexOperatorAlgebra 𝒱)
    (h : poissonSpan W = ⊥) : EtingofFinite W ↔ C2Cofinite W := by
```

From the mathematics to the Lean statement

`C2Cofinite W` is `FiniteDimensional ℂ (A₂ W)` (Chapter 12, Definition 12.22). `poissonSpan W = ⊥` says the bracket span is zero. Statements (i)–(iii) exactly. These are easy facts; their role is sanity: (i) shows the hypothesis is not stronger than Zhu's, (iii) shows where it is not weaker.

Proof on paper. (i) $\mathrm{HP}_0(R_V)$ is a quotient of R_V. (ii) The traces are the dual of the finite-dimensional space $\mathrm{HP}_0(R_V)$. (iii) If $\{R_V, R_V\} = 0$ then $\mathrm{HP}_0(R_V) = R_V$. □

Remark 16.11 (The free boson is not a witness)**.** For the free boson $M(1)$, $R_{M(1)} \cong \mathbb{C}[x]$ with zero bracket, so by (iii) $M(1)$ is Etingof-finite iff it is C_2-cofinite, and it is not (Chapter 12, Example 12.25). The library does *not* prove `poissonSpan (heisenbergVOA k hk) = ⊥` (the closing note of `PoissonTrace.lean` explains that the identification of $R_{M(1)}$ with $\mathbb{C}[x]$ *as a ring* is missing), so "$M(1)$ is not Etingof-finite" is an argument on paper only. Geometrically: $X_{M(1)}$ is a line with zero Poisson structure, with infinitely many leaves.

Physical meaning

A lisse chiral algebra has a zero-dimensional phase space, so trivially finitely many classical amplitudes. A free boson has a continuous family of vacua (the expectation value of a, a flat direction or "modulus"), and the classical traces $\varphi(x^n)$ are independent: infinitely many. Its characters $1/\eta$ are modular for a different reason (it is a free theory), not because of Etingof-finiteness.

What the machine verified

Proved, unconditional; axioms of `VOA.EtingofFinite_of_C2Cofinite` and `VOA.finiteDimensional_poissonTraces`: `[propext, Classical.choice, Quot.sound]` (re-run for this chapter).

16.4 The finiteness half: Arakawa–Kawasetsu Proposition 5.2

16.4.1 The augmented relation space

The first step is to move the Etingof–Schedler hypothesis from R_V up to V.

Definition 16.12 ($O_2^P(V)$)**.** $O_2^P(V) = C_2(V) + \mathrm{span}\{u_{(0)}v : u, v \in V\} \subseteq V$.

File `VOA/Modules/QuasiLisseFinite.lean`.

```
noncomputable def poissonUp (W : VertexOperatorAlgebra 𝒱) : Submodule ℂ 𝒱 :=
  Submodule.span ℂ {x : 𝒱 | ∃ u v : 𝒱, x = poissonBracket W u v}

noncomputable def O₂P (W : VertexOperatorAlgebra 𝒱) : Submodule ℂ 𝒱 := O₂ W ⊔ poissonUp W
```

From the mathematics to the Lean statement

`poissonBracket W u v` is `W.smul u 0 v` $= u_{(0)}v$ (Chapter 12); `⊔` of subspaces is their sum. Same as Definition 16.12.

Physical meaning

$O_2^P(V)$ consists of states that are classically derivatives or symmetry variations; both are invisible to torus one-point functions at leading order.

Theorem 16.13 (AK Theorem 2.2 read upstairs). *V is Etingof-finite iff $V/O_2^P(V)$ is finite-dimensional. Moreover $O_2^P(V)$ is a graded subspace, and for $a \in V_p$, $b \in V_q$ one has $a_{(0)}b \in V_{p+q-1}$.*

File `VOA/Modules/QuasiLisseFinite.lean`.

```
theorem map_mkQ_O₂P (W : VertexOperatorAlgebra 𝒱) :
    Submodule.map (O₂ W).mkQ (O₂P W) = poissonSpan W := by

theorem etingofFinite_iff_quot_O₂P (W : VertexOperatorAlgebra 𝒱) :
    EtingofFinite W ↔ FiniteDimensional ℂ (𝒱 / O₂P W) := by
```

From the mathematics to the Lean statement

`Submodule.map (O₂ W).mkQ (O₂P W)` is the image of $O_2^P(V)$ in R_V; `map_mkQ_O₂P` says it is $\{R_V, R_V\}$. Then the third isomorphism theorem $(V/C_2)/(O_2^P/C_2) \cong V/O_2^P$ gives the equivalence. The gradedness statements are `O₂P_eq_span_O₂PhomGen` and `piHom_maps_O₂P` (projections to weight spaces preserve O_2^P), and `brk_mem_grading` (the bracket lowers total weight by one). Same as AK's Theorem 2.2 combined with their remark that $\mathrm{HP}_0(R_V)$ is graded.

Proof on paper. The image of $C_2(V)$ in R_V is 0 and the image of $u_{(0)}v$ is $\{[u],[v]\}$, so the image of O_2^P is $\{R_V, R_V\}$; then apply the isomorphism theorem. For weights: $a_{(n)}b$ has weight $p+q-n-1$, so $a_{(0)}b \in V_{p+q-1}$ and $a_{(-2)}b \in V_{p+q+1}$; both generating families are made of homogeneous vectors, hence the spans are graded. □

Physical meaning

$V/O_2^P(V)$ is the space of states modulo "derivatives" (the $u_{(-2)}v$, which involve ∂u) and modulo "charge commutators" $u_{(0)}v$ (the infinitesimal symmetry transformation of v generated by the charge $\oint u$). A one-point function on the torus kills both kinds of state up to modular corrections, so its value is determined by finitely many numbers when this quotient is finite.

What the machine verified

Proved, unconditional; `VOA.etingofFinite_iff_quot_O₂P`: `[propext, Classical.choice, Quot.sound]` (re-run for this chapter).

16.4.2 Mode-zero triangularity

Zhu's genus-one theory uses the *square-bracket modes* $a[m]$ of a homogeneous vector a of weight k (Chapter 15):

$$a[m] = \mathrm{Res}_z\, Y(a,z)\,(1+z)^{k-1}\big(\log(1+z)\big)^m = \sum_{j\ge 0} c_j^{(k,m)}\, a_{(m+j)},$$

where $c_j^{(k,m)}$ is the coefficient of z^j in $(1+z)^{k-1}\big(\log(1+z)/z\big)^m$. In Lean this is `vSqZ W a k m`, with coefficients `sqBracketCoeffZ k m i` (file `VOA/Modularity/OnePointFunctions.lean`, Chapter 15). The leading coefficient is $c_0^{(k,m)} = 1$. At $m=0$: $a[0]b = a_{(0)}b + \sum_{i\ge 1} c_i^{(k,0)} a_{(i)}b$.

Theorem 16.14 (Mode-0 triangularity). *For $a \in V_p$ and $b \in V_q$, $a[0]b - a_{(0)}b$ lies in $\bigoplus_{m<p+q-1} V_m$.*

File `VOA/Modules/QuasiLisseFinite.lean`.

```
noncomputable def sqDefect0 (W : VertexOperatorAlgebra 𝒱) (a : 𝒱) (p : ℕ) (b : 𝒱) : 𝒱 :=
  ∑ᶠ i : ℤ, (if i = 0 then (0 : ℂ) else sqBracketCoeffZ p 0 i) • mode (W.Y a) i b

theorem vSqZ_zero_eq (W : VertexOperatorAlgebra 𝒱) (a : 𝒱) (p : ℕ) (b : 𝒱) :
    vSqZ W a p 0 b = mode (W.Y a) 0 b + sqDefect0 W a p b := by

theorem sqDefect0_mem_of_lower (W : VertexOperatorAlgebra 𝒱) {p q n : ℤ} {a b : 𝒱}
    (ha : a ∈ W.grading p) (hb : b ∈ W.grading q)
    (hpq : p + q - 1 = n) (T : Submodule ℂ 𝒱)
    (hT : ∀ m : ℤ, m < n → W.grading m ≤ T) :
    sqDefect0 W a p.toNat b ∈ T := by
```

From the mathematics to the Lean statement

`mode (W.Y a) i b` is $a_{(i)}b$. `sqDefect0` is the tail $\sum_{i\neq 0} c_i a_{(i)}b$ (the $\sum^{\mathrm{f}}$ has finite support by `sqDefect0_support_finite`). `sqDefect0_mem_of_lower` is the lower-weight statement in the form used by an induction: any subspace T containing all V_m, $m < p+q-1$, contains the tail. `p.toNat` is p as a natural number (harmless: $p \geq 0$ whenever $a \neq 0$). Same as Theorem 16.14.

Proof on paper. $c_j^{(p,0)}$ is the coefficient of z^j in $(1+z)^{p-1}$: it is 1 at $j=0$ and 0 for $j<0$, and $a_{(i)}b \in V_{p+q-i-1}$, which for $i \geq 1$ is below $p+q-1$. □

Physical meaning

The square-bracket modes are the modes of the field on the *cylinder* (or torus) coordinate w, $z = e^w - 1$. This statement says: the charge $\oint a$ measured on the torus equals the charge on the plane up to corrections of lower energy. Hence "torus one-point functions kill $a[0]v$" (global symmetry Ward identity on the torus) becomes "they kill Poisson brackets modulo lower energy".

What the machine verified

Proved, unconditional (file audit, `[propext, Classical.choice, Quot.sound]`).

16.4.3 Proposition 5.2

Let $\mathcal{G} = \mathbb{C}[G_2, G_4, G_6] \subseteq \mathbb{C}[[q]]$ be the algebra generated by Zhu's normalised Eisenstein series $G_{2j}(q) = -\frac{B_{2j}}{(2j)!} + \frac{2}{(2j-1)!}\sum_{n\geq 1}\sigma_{2j-1}(n)q^n$ (`GSeries`, Chapter 14; the Lean coefficient sequence `zhuG` is quoted in Definition 16.19), and $V_{\mathcal{A}} = \mathcal{G} \otimes_{\mathbb{C}} V$ (`𝒱G 𝒱`, with `ιG v = 1 ⊗ v`). Zhu's relation module $O_q(V) \subseteq V_{\mathcal{A}}$ (`blockRelSpanG W`) is the $\mathcal{G}$-span of

$$a[0]v \qquad \text{and} \qquad a[-2]v + \sum_{m\geq 0}(2m+3)\,G_{2m+4} \otimes a[2m+2]v,$$

for homogeneous a of weight ≥ 1 and $v \in V$; these are exactly the relations satisfied by every genus-one one-point function (Chapter 15).

```
noncomputable def blockRelSpanG : Submodule (ιGSeries) (𝒱G 𝒱) :=
  Submodule.span (ιGSeries)
    ({x : 𝒱G 𝒱 | ∃ (ka : ℕ) (a v : 𝒱), 1 ≤ ka ∧ a ∈ W.grading (ka : ℤ) ∧
        x = ιG (vSqZ W a ka 0 v)} ∪
     {x : 𝒱G 𝒱 | ∃ (ka K : ℕ) (a v : 𝒱), 1 ≤ ka ∧ a ∈ W.grading (ka : ℤ) ∧
        (∀ m : ℕ, K ≤ m → vSqZ W a ka (2 * (m + 1) - 2 : ℤ) v = 0) ∧
        x = ιG (vSqZ W a ka (-2) v) + ∑ m ∈ Finset.range K,
              coefG m • ιG (vSqZ W a ka (2 * (m + 2) - 2 : ℤ) v)})
```

File `VOA/Modularity/BlockRelSpanG.lean` (Chapter 15). Here `coefG m` is $(2(m+2)-1)G_{2(m+2)}$, and the cut-off K beyond which all $a[2m]v$ vanish makes the sum finite.

Theorem 16.15 (Arakawa–Kawasetsu Proposition 5.2). *If V is Etingof-finite, there is a finite set $T \subseteq V_{\mathcal{A}}$ with $V_{\mathcal{A}} = \mathcal{G} \cdot T + O_q(V)$; i.e. $V_{\mathcal{A}}/O_q(V)$ is a finitely generated $\mathcal{G}$-module.*

File `VOA/Modules/QuasiLisseFinite.lean`.

```
theorem exists_finite_gen_sup_blockRelSpanG_of_etingofFinite (hzero : VacuumGradeZero W)
    (hE : EtingofFinite W) :
    ∃ T : Set (𝒱G 𝒱), T.Finite ∧
      (τ : Submodule (ɪGSeries) (𝒱G 𝒱))
        = Submodule.span (ɪGSeries) T ⊔ blockRelSpanG W := by
```

From the mathematics to the Lean statement

`VacuumGradeZero W` is `W.grading 0 ≤ Submodule.span ℂ ({W.vacuum} : Set 𝒱)`, i.e. $V_0 \subseteq \mathbb{C}\mathbf{1}$ (file `VOA/Modularity/BlockZeroMode.lean`). It is **free**: every library VOA has $V_0 = \mathbb{C}\mathbf{1}$ as an axiom, and `QuasiLisseSl2.vacuumGradeZero_of_vacuum_grade` proves `VacuumGradeZero W` for every `W` (Section 16.11). `hE` is the only real hypothesis. `τ = span T ⊔ blockRelSpanG W` says every element of $V_{\mathcal{A}}$ is a $\mathcal{G}$-combination of T plus a relation, which is finite generation of the quotient. The docstring explains why the quotient module itself is not named in the statement: a typeclass mismatch prevents restating `Module.Finite (ɪGSeries) (𝒱G 𝒱 ⧸ blockRelSpanG W)` outside its home file; the formulation with the finite generating family is equivalent. Same as AK Proposition 5.2 with "quasi-lisse" replaced by the weaker Etingof-finiteness and AK's $\mathcal{A}$ replaced by $\mathbb{C}[G_2, G_4, G_6]$. (An E_4, E_6-version, `exists_finite_gen_sup_blockRelSpanE_of_etingofFinite`, is in Section 16.6.)

Proof on paper. By Theorem 16.13 choose finitely many homogeneous $s_1, \dots, s_g$ of positive weight with $V = \mathrm{span}\{\mathbf{1}, s_i\} + O_2^P(V)$ (lift a basis of the finite-dimensional graded space V/O_2^P). Let $T = \{1 \otimes \mathbf{1}, 1 \otimes s_i\}$ and $N = \mathcal{G}T + O_q(V)$. We prove $1 \otimes V_n \subseteq N$ by strong induction on n. A vector of weight n is a combination of the s_i of weight n, of homogeneous generators $a_{(-2)}b$ with $p+q+1=n$, and of homogeneous generators $a_{(0)}b$ with $p+q-1=n$.

- For $a_{(-2)}b$: $a[-2]b = a_{(-2)}b + (\text{weight} < n)$, and modulo $O_q(V)$, $a[-2]b \equiv -\sum(2m+3)G_{2m+4}a[2m+2]b$, each $a[2m+2]b$ of weight $< n$. This is Zhu's original step.
- For $a_{(0)}b$ (the new step): by Theorem 16.14 $a_{(0)}b = a[0]b - (\text{weight} < n)$, and $a[0]b \in O_q(V)$ exactly, with no Eisenstein tail.
- If a has weight 0, then $a = c\mathbf{1}$ and $\mathbf{1}_{(0)}b = 0$, $\mathbf{1}_{(-2)}b = 0$.

Lower weights are in N by induction. Hence $1 \otimes V \subseteq N$, and since $1 \otimes V$ generates $V_{\mathcal{A}}$ over $\mathcal{G}$, $N = V_{\mathcal{A}}$. □

Physical meaning

The torus one-point functions of a theory form a module over the ring of quasi-modular forms; this says that, if there are finitely many classical amplitudes, every torus one-point function is determined by finitely many "basic" ones with modular-form coefficients. It is the algebraic shadow of "finitely many conformal blocks on the torus".

What the machine verified

Proved; `VOA.exists_finite_gen_sup_blockRelSpanG_of_etingofFinite`: `[propext, Classical.choice, Quot.sound]` (re-run). Conditional only on `hE`; `hzero` is free.

Theorem 16.16 (Growth of one-point functions from Etingof-finiteness). *If V is Etingof-finite and M is an ordinary module of conformal weight h (that is, $M_h \neq 0$ and every nonzero weight space M_α has $\alpha \in h + \mathbb{N}$, Chapter 12), then for every $v \in V$ the coefficients of the torus one-point function $Z_M(v;q) = \operatorname{tr}_M o(v) q^{L_0 - c/24}$ grow subexponentially: for each $r > 1$ there is C with $|[q^{h-c/24+n}]Z_M(v;q)| \leq Cr^n$.*

File `VOA/Modules/QuasiLisseFinite.lean`.

```
theorem onePointSubexp_of_etingofFinite {M : Type u} [AddCommGroup M] [Module ℂ M]
    (N : OrdVModule W M) {hw : ℂ} (hcw : HasConformalWeight N hw)
    (hzero : VacuumGradeZero W) (hE : EtingofFinite W) :
    OnePointSubexp N (hw - W.centralCharge / 24) := by
```

Files `VOA/Modularity/AnalyticBlock.lean`, `VOA/Modularity/ConvergenceBridge.lean`.

```
def OnePointSubexp (N : OrdVModule W M) (h : ℂ) : Prop :=
  ∀ v : 𝒱, Subexponential (fun n : ℕ => ‖torusOnePoint N v (h + (n : ℂ))‖)

def Subexponential (a : ℕ → ℝ) : Prop :=
  ∀ r : ℝ, 1 < r → ∃ C : ℝ, ∀ n : ℕ, a n ≤ C * r ^ n
```

From the mathematics to the Lean statement

`OrdVModule W M` is an ordinary module (Chapter 12, Definition 12.5); `HasConformalWeight N hw` says $M_{hw} \neq 0$ and every nonzero weight lies in $hw + \mathbb{N}$ (file `VOA/Modules/Rationality.lean`, Chapter 12). A formal q-series is a function `FormalQSeries := ℂ → ℂ`, $e \mapsto [q^e]$ (Chapter 14); `torusOnePoint N v` is the formal series $e \mapsto \operatorname{tr}_{M_{e+c/24}} o(v)$. `Subexponential a` is the growth condition of Theorem 16.16, which is equivalent to: $\sum a_n q^n$ converges on the open unit disc. So the conclusion is: every one-point function converges for $|q| < 1$, i.e. on the upper half plane. Same as Zhu's convergence theorem, with C_2-cofinite weakened to Etingof-finite (Zhu's version is `onePointSubexp_of_c2`, Chapter 15).

Proof on paper. Let $S(v) = Z_M(v;q)$. By Theorem 16.15 and the fact that S kills $O_q(V)$ (Zhu's genus-one relations, `IsFormalBlock`), the $\mathcal{G}$-span of all $S(v)$ is spanned by finitely many $y_1, \dots, y_g$. Zhu's ω-recursion $S(L[-2]v) = q\frac{d}{dq}S(v) + \sum_m G_{2m+2} S(L[2m]v)$ shows that $q\frac{d}{dq}$ maps this span into its span over the larger ring of subexponential power series; so $q\frac{d}{dq}y = Ay$ for a $g \times g$ matrix A with subexponential entries. In coefficients, $(h+n)y_n = \sum_j A_j y_{n-j}$, and a discrete Grönwall argument shows the y_n, hence all coefficients of all $S(v)$, grow subexponentially. □

Physical meaning

Convergence of the torus partition function $\operatorname{tr} q^{L_0 - c/24}$ for $|q| < 1$, i.e. at every positive temperature: the density of states grows slower than any exponential in the energy (for a CFT, like $e^{2\pi\sqrt{c_{\text{eff}} n/6}}$). For non-unitary or quasi-lisse theories this is not automatic, and here it follows from finitely many classical amplitudes.

What the machine verified

Proved; `VOA.onePointSubexp_of_etingofFinite: [propext, Classical.choice, Quot.sound]` (re-run). Non-vacuity: `trivial_onePointSubexp_adjoint` instantiates it at the trivial VOA, and Section 16.11 at $L_{-4/3}(\mathfrak{sl}_2)$.

Stale "no witness" documentation (documentation only)

When this chapter was first written, the module docstring of `QuasiLisseFinite.lean` (Status item 4 and the note of §7) said that "every theorem here is currently instantiated only at VOAs that are already C_2-cofinite", that the trivial VOA is "the *only* unconditional instance", and that $L_{-4/3}(\mathfrak{sl}_2)$ is "conditional on a `Sl2Presentation simpleSl2QL` bundle that is not constructed". All three claims were already false at that time: the bundle is constructed (Theorem 16.38), `EtingofFinite` is unconditional for $L_{-4/3}(\mathfrak{sl}_2)$, and that algebra is proved not C_2-cofinite (Theorem 16.40). The same stale claims occurred in the headers of `AKModularODE.lean`, `AKUniformODE.lean` and `AKZhuModularity.lean` (its "honest statement" item 1). These docstrings have since been corrected (by a later revision of the library; see the update in Section 16.10).

16.5 The character equation in formal form

16.5.1 The formal objects

We recall the formal q-series vocabulary of Chapter 14 that appears in the statements.

  carrier := {F : PowerSeries ℂ | Subexponential fun n : ℕ => ‖PowerSeries.coeff n F‖}

noncomputable def torusPartition (N : OrdVModule W M) : FormalQSeries := gradedDim N
```

From the mathematics to the Lean statement

A formal q-series χ is the coefficient function $e \mapsto [q^e]\chi$, $e \in \mathbb{C}$. `gradedDim N` is the character $\chi_M = q^{-c/24}\sum_\alpha \dim M_\alpha\, q^\alpha$: the coefficient of q^e is $\dim M_{e+c/24}$. `torusPartition N` is the same series under its physical name (`rfl`). `qDeriv` is the Euler operator $\theta = q\frac{d}{dq}$, $q^e \mapsto e\,q^e$; `qDeriv^[i]` is θ^i. `qConv f g` is the product of the ordinary power series $\sum_n f_n q^n$ with g: $[q^e](fg) = \sum_n f_n [q^{e-n}]g$ (a finite sum on the series used, whose exponents lie in $h + \mathbb{N}$). `SubexpPS` is the subalgebra of $\mathbb{C}[[q]]$ of series with subexponential coefficients, i.e. series converging on the open unit disc; it contains $\mathcal{G} = \mathbb{C}[G_2, G_4, G_6]$ (the Eisenstein coefficients grow polynomially). We write $\mathcal{S}$ for `SubexpPS`.

16.5.2 Square-bracket primaries and the Virasoro tower

Zhu's square-bracket Virasoro operators are $L[n] = \omega[n+1] - \frac{c}{24}\mathbf{1}[n+1]$ (`Lsq W n`, Chapter 15); they satisfy the Virasoro algebra with the same central charge c.

Definition 16.17 (Square-bracket primary). $a \in V$ is square-bracket primary of weight Δ if $L[0]a = \Delta a$ and $L[n]a = 0$ for $n \geq 1$. (Here $L[n]$ are the Virasoro modes for Zhu's second VOA structure

$Y[a,w] = Y(a, e^w - 1)e^{w\,\mathrm{wt}\,a}$ on V, i.e. in the cylinder coordinate; ordinary primaries, $L_n a = 0$ for $n \geq 1$, are a different notion in general. The vacuum is primary in both senses.)

File `VOA/Modularity/AKModularODE.lean`.

```
def IsSqPrimary (W : VertexOperatorAlgebra 𝒱) (a : 𝒱) (Δ : ℂ) : Prop :=
  Lsq W 0 a = Δ • a ∧ ∀ n : ℤ, 1 ≤ n → Lsq W n a = 0

theorem vacuum_isSqPrimary (W : VertexOperatorAlgebra 𝒱) : IsSqPrimary W W.vacuum 0 :=
```

From the mathematics to the Lean statement

Exactly Definition 16.17, which is the hypothesis of AK Lemma 5.5 ("Let a be a primary vector of weight Δ, that is $L[0]a = \Delta a$ and $L[n]a = 0$ for $n \geq 1$"). It is the *square-bracket* notion, not the ordinary one; the vacuum is primary of weight 0 in both senses, which is all the character needs.

Physical meaning

A square-bracket primary is a primary field for the Virasoro algebra on the cylinder (torus) coordinate; the vacuum (identity operator) is the primary whose one-point function is the partition function itself.

Theorem 16.18 (The Virasoro tower over a primary). *Let a be square-bracket primary of weight Δ, and consider the* tower $L[-2]^n a$ *(a dressed by n insertions of the cylinder stress tensor). For all $n, j \geq 0$, $L[2j]\,L[-2]^n a = \gamma_{\Delta,c}(j,n)\,L[-2]^{n-j}a$, where γ is defined by $\gamma(j,0) = \Delta\delta_{j0}$, $\gamma(0,n+1) = \gamma(0,n) + 2$, $\gamma(j+1,n+1) = (2j+4)\gamma(j,n) + \delta_{j0}\frac{c}{2} + \gamma(j+1,n)$; and $\gamma(j,n) = 0$ for $j > n$. In closed form $\gamma(0,n) = \Delta + 2n$ and $\gamma(1,n) = n(4\Delta + 4n - 4 + \frac{c}{2})$.*

File `VOA/Modularity/AKModularODE.lean`.

```
noncomputable def towerScalar (Δ c : ℂ) : ℕ → ℕ → ℂ
  | j, 0 => if j = 0 then Δ else 0
  | 0, (n + 1) => towerScalar Δ c 0 n + 2
  | (j + 1), (n + 1) =>
      (2 * (j : ℂ) + 4) * towerScalar Δ c j n
        + (if j = 0 then c / 2 else 0) + towerScalar Δ c (j + 1) n

theorem Lsq_tower (W : VertexOperatorAlgebra 𝒱) {a : 𝒱} {Δ : ℂ} (ha : IsSqPrimary W a Δ) :
    ∀ (n j : ℕ), Lsq W (2 * (j : ℤ)) ((↟(Lsq W (-2)))^[n] a)
      = towerScalar Δ W.centralCharge j n • ((↟(Lsq W (-2)))^[n - j] a) := by
```

From the mathematics to the Lean statement

`(↟(Lsq W (-2)))^[n] a` is $L[-2]^n a$ (`^[n]` is n-fold iteration of a function). `n - j` is truncated subtraction in $\mathbb{N}$; for $j > n$ the scalar is 0 (`towerScalar_eq_zero_of_lt`), so the truncation is harmless. The closed forms are `towerScalar_zero_left` and `towerScalar_one_left`. Same as AK's "$L[2k-2]L[-2]^{i-1}a = c_k L[-2]^{i-k}a$" with $j = k-1$, $n = i-1$; the Lean scalar is computed rather than left implicit, and it depends on i as well as k (AK suppress the dependence).

Proof on paper. Induction on n. For $n = 0$ this is primarity. For the step write $L[2j]L[-2]y = L[-2]L[2j]y + (2j+2)L[2j-2]y + \delta_{j1}\frac{c}{12}(8-2)y$ with $y = L[-2]^n a$ and use the induction hypothesis on both terms; the case $j = 0$ is $L[0]L[-2]y = L[-2](L[0]+2)y$. Collecting gives the recursion. □

Physical meaning

$L[-2]$ inserts the stress tensor on the torus; $L[-2]^n a$ is a dressed by n stress tensors. The statement is the torus Ward identity's algebraic core: moving a positive Virasoro mode through the dressing produces only the same tower with explicit coefficients (involving c through the Schwarzian/central term).

What the machine verified

Proved, unconditional; `VOA.Lsq_tower: [propext, Classical.choice, Quot.sound]` (re-run).

16.5.3 Lemma 5.5: from $L[-2]$ to $q\,d/dq$

Definition 16.19 (Formal genus-one block; Zhu Def. 5.1.1, formal form). A linear map $S : V \to \{\text{formal } q\text{-series}\}$ is a *formal block* if for every homogeneous a of weight $k_a \geq 1$ and every $v \in V$: (i) $S(a[0]v) = 0$; (ii) $S(a[-2]v) + \sum_{m\geq 0}(2m+1)\,G_{2m+2} \star S(a[2m]v) = 0$; (iii) $S(L[-2]v) = \theta S(v) + \sum_{m\geq 0} G_{2m+2} \star S(L[2m]v)$, where $\star$ is the product of a power series with a formal q-series (`qConv`) and G_{2j} is Zhu's normalised Eisenstein series (below).

File `VOA/Modularity/ZhuBlockConditions.lean` (Chapter 15).

```
structure IsFormalBlock (W : VertexOperatorAlgebra 𝒱) (S : 𝒱 →ₗ[ℂ] FormalQSeries) : Prop
 ↪  where
  vanish : ∀ (ka : ℕ), 1 ≤ ka → ∀ a ∈ W.grading (ka : ℤ), ∀ v : 𝒱, S (vSqZ W a ka 0 v) = 0

```
noncomputable def zhuG (j : ℕ) : ℕ → ℂ :=
  fun m =>
    if m = 0 then -(((bernoulli (2 * j) : ℚ) : ℂ) / (Nat.factorial (2 * j) : ℂ))
    else (2 / (Nat.factorial (2 * j - 1) : ℂ)) * lambertCoeff (2 * j - 1) m
```

From the mathematics to the Lean statement

`vSqZ W a ka m` is the square-bracket mode $a[m]$; `Lsq W n` is $L[n]$; `qDeriv` is θ; `qConv f` multiplies by the power series with coefficients f. `zhuG j` is the coefficient sequence of Zhu's $G_{2j}(q) = -\frac{B_{2j}}{(2j)!} + \frac{2}{(2j-1)!}\sum_{n\geq 1}\sigma_{2j-1}(n)q^n$ (`lambertCoeff (2j-1) n` $= \sigma_{2j-1}(n)$), i.e. the Eisenstein series normalised so that $G_{2j} = \frac{2\zeta(2j)}{(2\pi i)^{2j}}E_{2j}$; the index shift $m \mapsto m+1$ makes the three fields exactly (i)–(iii) above, with $(2m+1)G_{2m+2}$ in (ii). The $\sum^{\mathrm{f}}$ sums are finite because $a[n]v = 0$ and $L[n]v = 0$ for $n \gg 0$. Same as Zhu's Definition 5.1.1 in formal q-series form (Zhu uses holomorphic functions on $\mathbb{H}$; that is the analytic version, Definition 16.28). $\mathcal{G} = \mathbb{C}[G_2, G_4, G_6]$ (`GSeries`) is the algebra generated by the series `PowerSeries.mk (zhuG j)`, $j = 1, 2, 3$; it contains every G_{2j}.

Physical meaning

A genus-one block is a candidate torus one-point function $v \mapsto \langle v \rangle_\tau$: (i) is the Ward identity for the global symmetry charges on the torus, (ii) expresses that "derivative" insertions are total derivatives up to Eisenstein contact terms, and (iii) is the conformal Ward identity — inserting the stress tensor equals differentiating in the modular parameter τ ($\theta = \frac{1}{2\pi i}\partial_\tau$), plus contact terms.

What the machine verified

Definition; satisfiable: `torusOnePointHom_isFormalBlock` (every module's trace functions form a formal block).

The basic example is $S = Z_M(\cdot; q)$ (`torusOnePointHom N`, a block by `torusOnePointHom_isFormalBlock`). `QSeriesAt h` is the space of series supported on $h + \mathbb{N}$, and `psSMul F χ` is `qConv` with the coefficient sequence of $F \in \mathbb{C}[[q]]$.

Theorem 16.20 (AK Lemma 5.5, for primary vectors). *Let S be a formal block supported on $h + \mathbb{N}$ and a a square-bracket primary. For each i there are $\eta_{i,0}, \dots, \eta_{i,i} \in \mathcal{S}$ with $\eta_{i,i} = 1$ and $S(L[-2]^i a) = \sum_{j=0}^{i} \eta_{i,j}\, \theta^j S(a)$.*

File `VOA/Modularity/AKModularODE.lean`.

```
theorem huni_of_sqPrimary (W : VertexOperatorAlgebra V)
    {S : V →ₗ[ℂ] FormalQSeries} {hbase : ℂ} (hsupp : ∀ v, S v ∈ QSeriesAt hbase)
    (hS : IsFormalBlock W S) {a : V} {Δ : ℂ} (ha : IsSqPrimary W a Δ) (i : ℕ) :
    ∃ hc : ℕ → PowerSeries ℂ, (∀ j, hc j ∈ SubexpPS) ∧ hc i = 1 ∧ (∀ j, i < j → hc j = 0) ∧
      S ((↑(Lsq W (-2)))^[i] a)
        = ∑ j ∈ Finset.range (i + 1), psSMul (hc j) (qDeriv^[j] (S a)) := by
```

From the mathematics to the Lean statement

`hc j` is $\eta_{i,j}$; "`hc i = 1` and `hc j = 0` for $j > i$" is unitriangularity. The coefficients are in $\mathcal{S}$, not in AK's $\mathbb{C}[G_4, G_6]$ (see Section 16.5.6), and in the Euler basis θ^j, not the Serre basis. They are produced by an existence statement inside the span of the block values, so they may depend on S; AK's depend only on (a, Δ, c). **Why primarity is essential.** The file `UniCollapse.lean` (Chapter 15) refutes the same conclusion quantified over all v, via $v = L[-1]x$, which is not primary; the present statement is for a fixed primary a, which is the only case AK use.

Proof on paper. Induction on i. By (iii) and Theorem 16.18, $S(L[-2]^{i+1}a) = \theta S(L[-2]^i a) + \sum_m G_{2m+2}\gamma(m,i) S(L[-2]^{i-m}a)$. By induction each $S(L[-2]^{i'}a)$, $i' \le i$, is a unitriangular $\mathcal{S}$-combination of $\theta^j S(a)$; applying θ uses the Leibniz rule $\theta(\eta\chi) = (\theta\eta)\chi + \eta\theta\chi$, and $\theta\eta \in \mathcal{S}$. The leading coefficient stays 1. □

Physical meaning

Inserting the stress tensor on the torus is the same as differentiating with respect to the modular parameter ("$T(z)$ is ∂_τ") up to contact terms with Eisenstein coefficients. This is the conformal Ward identity on the torus.

What the machine verified

Proved, unconditional; `VOA.huni_of_sqPrimary: [propext, Classical.choice, Quot.sound]` (re-run).

16.5.4 Lemma 5.3 and the formal character equation

Theorem 16.21 (AK Lemma 5.3, block form). *If V is Etingof-finite and S is a formal block, then for every v there are $s \geq 1$ and $G_0, \dots, G_{s-1} \in \mathcal{G}$ with $S(L[-2]^s v) = \sum_{i<s} G_i\, S(L[-2]^i v)$.*

File `VOA/Modularity/AKModularODE.lean`.

```
theorem exists_monic_Lsq_relation_of_etingofFinite {S : 𝒱 →ₗ[ℂ] FormalQSeries} {hbase : ℂ}
    (hsupp : ∀ v, S v ∈ QSeriesAt hbase) (hS : IsFormalBlock W S)
    (hzero : VacuumGradeZero W) (hE : EtingofFinite W) (v : 𝒱) :
    ∃ (s : ℕ) (G : ℕ → PowerSeries ℂ), 1 ≤ s ∧ (∀ i, G i ∈ GSeries) ∧
      S ((↟(Lsq W (-2)))^[s] v)
        = ∑ i ∈ Finset.range s, psSMul (G i) (S ((↟(Lsq W (-2)))^[i] v)) := by
```

From the mathematics to the Lean statement

`G i ∈ GSeries`: the coefficients are in $\mathcal{G} = \mathbb{C}[G_2, G_4, G_6]$. The quantifier order is $\forall S\, \forall v\, \exists s\, \exists G$: s and G may depend on the block S (hence on the module). AK's Lemma 5.3 gives one relation in $V_{\mathcal{A}}$ independent of the module; that is the uniform version (Theorem 16.23).

Proof on paper. $\mathcal{G}$ is Noetherian (a finitely generated $\mathbb{C}$-algebra) and the $\mathcal{G}$-span of the values of S is finitely generated (Theorem 16.15, as in the proof of Theorem 16.16), hence Noetherian. The ascending chain $\operatorname{span}_{\mathcal{G}}\{S(L[-2]^i v) : i \leq r\}$ stabilises, so some $S(L[-2]^{n+1}v)$ is a combination of the earlier ones. □

Physical meaning

Finitely many independent torus amplitudes force the stress-tensor tower to close: dressing a state by enough stress tensors produces nothing new.

What the machine verified

Proved, conditional on `hE` (`hzero` free); `[propext, Classical.choice, Quot.sound]` (re-run).

Theorem 16.22 (Formal character equation ("AK equation (2), formal form" in the source); *not* AK Theorem 5.1, near-vacuous). *Let V be Etingof-finite and M an ordinary module with a conformal weight. There are $s \geq 1$ and power series $g_0, \dots, g_{s-1} \in \mathcal{S}$ such that the character satisfies*

$$\theta^s \chi_M + \sum_{i<s} g_i\, \theta^i \chi_M = 0. \tag{16.2}$$

Caution. *This is not a modular linear differential equation and not Arakawa–Kawasetsu's Theorem 5.1: θ is not the Serre derivative, the g_i are arbitrary convergent power series rather than modular forms, and s, g depend on M. By Proposition 16.24 the conclusion holds for every convergent q-series with nonzero leading coefficient and zeros of bounded multiplicity in the unit disc, so it says almost nothing beyond convergence of χ_M (Theorem 16.16).*

```

```
    (hne : W.vacuum ≠ 0) (hzero : VacuumGradeZero W) (hE : EtingofFinite W) :
    ∃ (s : ℕ) (g : ℕ → ℕ → ℂ), 1 ≤ s ∧ (∀ i, Subexponential (fun k => ‖g i k‖)) ∧
      ∀ e : ℂ, (qDeriv^[s] (torusPartition (adjointModule W))) e
        + ∑ i ∈ Finset.range s,
            qConv (g i) (qDeriv^[i] (torusPartition (adjointModule W))) e = 0 :=
```

From the mathematics to the Lean statement

`g i : ℕ → ℂ` is the coefficient sequence of g_i, and `Subexponential (fun k ⇒ ‖g i k‖)` says $g_i \in \mathcal{S}$. The equation is asserted coefficientwise, `∀ e : ℂ`, i.e. as an identity of formal series. `adjointModule W` is V as a module over itself (Chapter 12, Definition 12.6); `hne` (nonzero vacuum) makes its conformal weight 0. **Comparison with AK.** AK's (16.1) uses (1) iterated Serre derivatives, (2) coefficients $p_i \in \mathbb{C}[E_4, E_6]$ of weight $2(s-i)$, (3) one equation for all M. The Lean statement has (1) the Euler operator θ instead — this alone would be harmless, since $\vartheta^i_{(0)} = \theta^i +$ (lower terms with coefficients in $\mathbb{C}[E_2, E_4, E_6]$) is a unitriangular change of basis; (2) coefficients in $\mathcal{S}$, an enormous ring; (3) s and g depending on M. The statement is therefore much **weaker** than AK's equation, and the docstrings say so ("This is NOT Arakawa–Kawasetsu Theorem 5.1 and NOT a modular linear differential equation"). How much weaker is the subject of Section 16.5.6.

Proof on paper. Apply Theorem 16.21 to $S = Z_M(\cdot; q)$ and $v = \mathbf{1}$, and substitute Theorem 16.20 (the vacuum is primary of weight 0) into the monic relation: since $\eta_{i,i} = 1$ the result is monic in θ^s, with coefficients $g_j = \eta_{s,j} - \sum_i G_i \eta_{i,j} \in \mathcal{S}$. Finally $Z_M(\mathbf{1}; q) = \chi_M$. □

Physical meaning

In AK's form this would be the statement that the Schur index (vacuum character) of a four-dimensional $\mathcal{N} = 2$ theory satisfies an MLDE. In the formal form proved here it is the statement that the stress-tensor tower closes on the torus with coefficients that are convergent functions of q — a statement about the vacuum character's analytic behaviour at $|q| < 1$ rather than about its modular properties.

What the machine verified

Proved; `VOA.character_formalODE_of_etingofFinite: [propext, Classical.choice, Quot.sound]` (re-run). **Content warning:** near-vacuous (Proposition 16.24, argued on paper); **not** AK Theorem 5.1 and not an MLDE. Conditional on `hE` (`hzero` free). Instantiated at the trivial VOA (`trivial_character_formalODE`) and, unconditionally, at $L_{-4/3}(\mathfrak{sl}_2)$ (Section 16.11).

16.5.5 Uniformity in the module

Theorem 16.23 (AK Lemma 5.3 in $V_{\mathcal{A}}$; one order for all modules). *Let V be Etingof-finite and $a \in V$. (i) There are $s \geq 1$ and $G_i \in \mathcal{G}$ such that* every *formal block S satisfies $S(L[-2]^s a) = \sum_{i<s} G_i S(L[-2]^i a)$. (ii) There is $s \geq 1$ such that for every ordinary module M with a conformal weight there are $g_i \in \mathcal{S}$ with $\theta^s \chi_M + \sum_{i<s} g_i \theta^i \chi_M = 0$.*

File `VOA/Modularity/AKUniformODE.lean`.

              + ∑ i ∈ Finset.range s,
                  qConv (g i) (qDeriv^[i] (torusPartition N)) e = 0 := by
```

From the mathematics to the Lean statement

Quantifier order is the content. In (i), $\exists s\,\exists G$ precedes $\forall S$: the relation is uniform, exactly AK's Lemma 5.3. In (ii), $\exists s$ precedes $\forall M$ but $\exists g$ follows it: **only the order is uniform**, the coefficients depend on M. The docstring is explicit: "one order, many equations", not "one equation". The reason is that Lemma 5.5 (Theorem 16.20) produces block-dependent coefficients. The universe of `M` is that of $\mathcal{V}$. So (ii) is weaker than AK's closing sentence (all characters solve one equation).

Proof on paper. (i) Run the Noetherian argument of Theorem 16.21 in the finitely generated module $V_{\mathcal{A}}/O_q(V)$ itself, which is independent of any block, to get $1\otimes L[-2]^s a - \sum G_i \otimes L[-2]^i a \in O_q(V)$; every block kills $O_q(V)$. (ii) Combine (i) with Theorem 16.20 as before. □

Physical meaning

AK's statement "all characters lie in the solution space of one MLDE" is what turns "finitely many ordinary modules" into a theorem: an order-s equation has an s-dimensional solution space. With module-dependent coefficients this conclusion is lost.

What the machine verified

Proved, conditional on `hE`; both `[propext, Classical.choice, Quot.sound]` (re-run). Instantiated at the trivial VOA (`trivial_uniform_order_character_formalODE`) and at $L_{-4/3}(\mathfrak{sl}_2)$.

16.5.6 How weak is the formal equation?

The following observation is ours; it is argued on paper and not machine-checked.

Proposition 16.24 (The formal equation is almost a growth statement)**.** *Let $\chi = q^h F(q)$ with $F = \sum_{n\geq 0} F_n q^n$, $F_0 \neq 0$, and suppose F converges on the open unit disc D and its zeros in D have multiplicity at most m. Then for $s = m+1$ there are $g_0, \dots, g_{s-1} \in \mathcal{S}$ with $\theta^s\chi + \sum_{i<s} g_i\theta^i\chi = 0$.*

Proof on paper. Since $\theta(q^h F) = q^h(h+\theta)F$, it suffices to solve $(h+\theta)^s F \in \sum_{i<s} \mathcal{O}(D)\,(h+\theta)^i F$, where $\mathcal{O}(D)$ is the ring of holomorphic functions on D; the span on the right equals $\sum_{i<s}\mathcal{O}(D)\theta^i F$. The functions $F, \theta F, \dots, \theta^{s-1}F$ have no common zero in D: at $q=0$, $F(0) = F_0 \neq 0$; at $q_0 \neq 0$, $\theta = q\,d/dq$ differs from d/dq by a unit, and a zero of F of order $\leq m < s$ is not a zero of its m-th derivative. In $\mathcal{O}(D)$ a finitely generated ideal without common zeros is the unit ideal (a classical theorem of Wedderburn and Helmer: $\mathcal{O}(D)$ is a Bézout domain, and the generator of a finitely generated ideal is a gcd, which here has no zeros). So $1 = \sum_{i<s} u_i\theta^i F$ with $u_i \in \mathcal{O}(D)$, and $\theta^s F = \sum_i (u_i\theta^s F)\theta^i F$. Finally, a function holomorphic on D has Taylor coefficients with $|a_n| \leq C_r r^n$ for every $r > 1$ (Cauchy's estimate on the circle of radius $1/r$), i.e. lies in $\mathcal{S}$. Rewriting $(h+\theta)^s$ in terms of θ^i changes coefficients by constants. □

Physical meaning

A linear ODE in q with coefficients merely holomorphic in the disc constrains nothing physical: the content of an MLDE is the *modularity* and finite dimensionality of the coefficient space, which ties the low-temperature expansion to the high-temperature (Cardy) behaviour.

The formal ODE theorems say little beyond convergence (moderate)

By Proposition 16.24, the conclusion of `character_formalODE_of_etingofFinite` (and of its instances and uniform-order variant) holds for *every* convergent q-series with nonzero leading coefficient and zeros of bounded multiplicity in the unit disc, whether or not it has anything to do with a vertex algebra or with modularity. Together with Theorem 16.16, which already gives convergence, the formal ODE theorems add essentially only the bounded-multiplicity information. The library's docstrings correctly say the result is "not an MLDE" and "genuinely weaker" on the coefficient axis, but they present it as "AK equation (2)", and the Lean names (`character_formalODE_...`) invite over-reading. A referee should treat these theorems as growth statements. The genuine MLDE is Section 16.6. (Also: the uniform order of Theorem 16.23(ii) is upward closed — applying θ to an order-s equation with coefficients in $\mathcal{S}$ gives one of order $s+1$ — so "one order" is likewise weak.)

16.6 The genuine modular differential equation

The file `AKMLDE.lean` keeps the three rungs that `AKModularODE.lean` had to merge apart, and works analytically on the upper half plane with genuine modular forms.

16.6.1 Modular coefficients and Serre derivatives

Files `VOA/Modularity/LevelOneStructure.lean`, `VOA/Modularity/EisensteinRamanujan.lean`, `VOA/Modularity/SerreDerivative.lean` (Chapter 14).

```
noncomputable def E46 : Subalgebra ℂ (UpperHalfPlane → ℂ) :=

    ∃ g : E46, E46Weight (k + 2) g ∧
      ∀ z ∈ imGT 0, e46C g z = serreDerivC k (e46C f) z
```

From the mathematics to the Lean statement

`E46` is the algebra of functions on $\mathbb{H}$ generated by E_4, E_6 (Mathlib's normalised Eisenstein series); `e46C` extends such a function to $\mathbb{C}$ by Mathlib's retraction (values off $\mathbb{H}$ are never used: every statement is restricted to `imGT 0` $= \{\operatorname{Im} z > 0\}$). `E46Weight k f`: f is

(the function of) a modular form of weight k for $SL_2(\mathbb{Z})$ ($\mathcal{SL}$), holomorphic at the cusp. `serreDerivC k f` is $\frac{1}{2\pi i}f' + k(2\pi i)^{-2}G_2 f$; with the normalisation $E_2 = G_2/(2\zeta(2)) = 3G_2/\pi^2$ recorded in the source, this is $\frac{1}{2\pi i}f' - \frac{k}{12}E_2 f$, the Serre derivative ϑ_k (Chapter 14). `E46SerreClosed` says: ϑ_k maps weight-k elements of $\mathbb{C}[E_4, E_6]$ to weight-$(k+2)$ elements. This is true (Ramanujan's identities $\vartheta_4 E_4 = -\frac{1}{3}E_6$, $\vartheta_6 E_6 = -\frac{1}{2}E_4^2$ and the Leibniz rule), and it is **proved** in the library: `e46SerreClosed` (`VOA/Modularity/EisensteinSerreClosure.lean`, Chapter 14), via `serreForm`, which shows that the Serre derivative of a level-one modular form is a level-one modular form. Mathlib defines the derivative of modular forms but does not prove this preservation. The Arakawa–Kawasetsu MLDE theorems of this chapter keep `E46SerreClosed` as a hypothesis `hclose` in their statements; the primed versions `IsSqPrimary.exists_monicMLDEOn_all_analyticBlocks_of_etingofFinite'` and `IsSqPrimary.exists_monicMLDEOn_all_analyticBlocks_of_fin_gen'` discharge it.

Definition 16.25 (Monic MLDE on $\mathbb{H}$). For $f : \mathbb{H} \to \mathbb{C}$, f satisfies a monic MLDE of order $s \geq 1$ and weight w with coefficients $p_0, \dots, p_{s-1}$ if each p_i is a modular form of weight $2(s-i)$ and $\vartheta^s_{(w)} f + \sum_{i<s} p_i \vartheta^i_{(w)} f = 0$ on $\mathbb{H}$.

File `VOA/Modularity/AKMLDE.lean`.

```
noncomputable def serreIterC (wt : ℤ) : ℕ → (ℂ → ℂ) → (ℂ → ℂ)
  | 0, f => f
  | i + 1, f => serreDerivC (wt + 2 * (i : ℤ)) (serreIterC wt i f)

def MonicMLDEOn (wt : ℤ) (f : ℂ → ℂ) (s : ℕ) (p : ℕ → E46) : Prop :=
  1 ≤ s ∧
    (∀ i < s, E46Weight (2 * ((s - i : ℕ) : ℤ)) (p i)) ∧
    ∀ z ∈ imGT 0, serreIterC wt s f z
      + ∑ i ∈ Finset.range s, e46C (p i) z * serreIterC wt i f z = 0
```

From the mathematics to the Lean statement

`serreIterC wt i f` is $\vartheta^i_{(w)} f$ with the weight raised by 2 at each step. `MonicMLDEOn` is exactly Definition 16.25; the weights of the coefficients are forced, as in AK's (16.1). This is a genuine MLDE: unlike `SubexpPS`, the coefficient space $M_{2(s-i)}$ is finite-dimensional, and the solution space of such an equation is $SL_2(\mathbb{Z})$-invariant.

Physical meaning

This is the form in which Schur indices of four-dimensional $\mathcal{N} = 2$ theories, and characters of rational CFTs (Mathur–Mukhi–Sen), are classified: a monic MLDE whose coefficients are a finite number of constants times monomials in E_4, E_6.

What the machine verified

Definitions. `E46SerreClosed` is a **theorem** (`e46SerreClosed`, Chapter 14).

16.6.2 The weight grading interface

To make the coefficients of AK's relation modular forms of the *right weight*, one needs the relation module to be homogeneous for the total weight (modular weight of the coefficient plus square-bracket weight of the vector).

Definition 16.26 (AK weight grading). Let $V^E_{\mathcal{A}} = \mathbb{C}[E_4, E_6] \otimes V$ and let its total-weight-n subspace be spanned by $f \otimes v$ with f of modular weight p, $L[0]v = qv$, $p + q = n$. An *AK weight grading* consists

of: a direct-sum decomposition of $\mathbb{C}[E_4, E_6]$ into its weight spaces; a direct-sum decomposition of $V_{\mathcal{A}}^{E}$ into total-weight spaces; and the statement that the relation module $O_q^E(V)$ (`blockRelSpanE W`, the E_4, E_6-version of $O_q(V)$) is homogeneous.

File `VOA/Modularity/AKGrading.lean`.

```
noncomputable def e46WeightSpace (k : ℤ) : Submodule ℂ E46 where
  carrier := {f | E46Weight k f}

noncomputable def akTotalWeightSpace (W : VertexOperatorAlgebra 𝒱) (n : ℤ) :
    Submodule ℂ (𝒱E 𝒱) :=
  Submodule.span ℂ {x | ∃ (p q : ℤ) (f : E46) (v : 𝒱), p + q = n ∧
    f ∈ e46WeightSpace p ∧ v ∈ sqWeightSpace W (q : ℂ) ∧ x = f ⊗ₜ[ℂ] v}

structure AKWeightGrading (W : VertexOperatorAlgebra 𝒱) where
  coeffDecomposition : DirectSum.Decomposition e46WeightSpace
  totalDecomposition : DirectSum.Decomposition (akTotalWeightSpace W)
  relationHomogeneous :
    letI := totalDecomposition
    DirectSum.SetLike.IsHomogeneous (akTotalWeightSpace W)
      ((blockRelSpanE W).restrictScalars ℂ)
```

From the mathematics to the Lean statement

`𝒱E 𝒱` is `₁E46 ⊗[ℂ] 𝒱` (file `VOA/Modularity/BlockRelSpanE.lean`); `sqWeightSpace W q` $= \ker(L[0] - q)$ (file `VOA/Modularity/SquareBracketGrading.lean`). `DirectSum.Decomposition A` is Mathlib's data of an internal direct-sum decomposition into the family A, with the projections; `IsHomogeneous` says a submodule is the sum of its intersections with the pieces. The structure is *data plus a proposition*, not a theorem. The first two fields hold for every VOA of CFT type: modular forms of different weights are linearly independent, and $L[0]$ is diagonalisable on V with eigenvalues in $\mathbb{N}$ (Zhu's theorem that $(V, Y[\,], \tilde{\omega})$ is again a VOA). The third field, `relationHomogeneous`, is the real VOA-side content: it says that Zhu's relation module is homogeneous for the *total* weight. Arakawa and Kawasetsu use a grading of this kind as a standard fact, but it is not a triviality, because the relation generators $a[0]v$ are indexed by the *ordinary* weight of $a \in V_{k_a}$ while the grading uses the square-bracket weight. So the third field needs an argument (Zhu covariance of the square-bracket modes). **All three fields are now proved, for every VOA of the library** (Theorem 16.27 below); the earlier statement of this book that `AKWeightGrading` had no instance, not even for the trivial VOA, recorded a gap in the library, not a mathematical obstruction, and is superseded.

Physical meaning

The weight grading is the statement that torus amplitudes are quasi-modular forms of definite weight, the weight of an insertion being its scaling dimension on the cylinder. It is the bookkeeping that makes "modular form of weight $2(s - i)$" meaningful.

What the machine verified

Definition (structure with three fields). Inhabited for every VOA of the library (Theorem 16.27).

Theorem 16.27 (The AK weight grading exists). *For every vertex operator algebra V of the library (in particular of CFT type: $V_0 = \mathbb{C}\mathbf{1}$ and positive grading),* `AKWeightGrading V` *is inhabited.*

File `VOA/Modularity/AKGradingTotal.lean` (section variable (`W : VertexOperatorAlgebra 𝒱`)).

```
noncomputable def akWeightGrading : AKWeightGrading W where
  coeffDecomposition := e46Decomposition
  totalDecomposition := akTotalDecomposition W
  relationHomogeneous := by
    letI := akTotalDecomposition W
    rw [blockRelSpanE_eq_span]
    exact isHomogeneous_span _ (relHomE_homog W)
```

Proof on paper. (A) *Coefficients.* E_4, E_6 and the constants are homogeneous, so the weight spaces span $\mathbb{C}[E_4, E_6]$. They are independent: if $\sum_k f_k = 0$ with f_k modular of weight k, evaluate at $\gamma_n z$ with $\gamma_n = \left(\begin{smallmatrix} 1 & 0 \\ n & 1 \end{smallmatrix}\right)$ to get $\sum_k (nz+1)^k f_k(z) = 0$ for all n; the polynomial $\sum_k f_k(z) X^k$ has infinitely many roots, so every $f_k(z) = 0$ (`e46WeightSpace_isInternal`, file `AKGradingInstance.lean`). (B) *Total weight.* The tensors $f \otimes v$ split into homogeneous pieces because $L[0]$ is diagonalisable with eigenvalues in $\mathbb{N}$; independence holds because the total-weight space of weight n lies in the n-eigenspace of $\mathrm{Wt} \otimes 1 + 1 \otimes L[0]$ (`akTotalWeightSpace_isInternal`). (C) *Relations.* Zhu covariance ($a[j]$ maps $V_{[K]} \otimes V_{[n]}$ to $V_{[K+n-j-1]}$) shows that each generator $a[0]v$ or $a[-2]v + \sum (2k-1) G_{2k} a[2k-2]v$ is a sum of total-homogeneous relations; the weight-zero component of a is a multiple of $\mathbf{1}$ (CFT type), and $\mathbf{1}[j] = 0$ for $j \neq -1$ (`sqMode_vacuum_eq_zero`). So Zhu's relation module is the $\mathbb{C}$-span of homogeneous elements (`blockRelSpanE_eq_span`), hence homogeneous. □

What the machine verified

`#print axioms VOA.akWeightGrading:  [propext, Classical.choice, Quot.sound]`, recorded in `Notes/release/WS-RELEASE2.md` (commit `34b74b85`); independently audited as faithful (`Notes/Textbook/referee/RELEASE_AUDIT_QUEUE2.md`). The aggregate `lake build` at the release commit is pending. Scope: "every VOA" means every `VertexOperatorAlgebra` in the library's sense, which builds in CFT type.

Physical meaning

On the torus a field of cylinder scaling dimension q (its $L[0]$-weight) contributes like a modular form of weight q, and the Ward identities of Definition 16.19 relate insertions of different dimension with Eisenstein series as coefficients. The theorem says these Ward identities never mix total weights: every relation among torus one-point functions splits into relations each of definite total weight (modular weight of the coefficient plus scaling dimension of the insertion). This is the dimensional analysis physicists take for granted when they write the coefficient of $\vartheta^{(i)}$ in an order-s MLDE as a modular form of weight $2(s-i)$; here it is checked for every VOA of CFT type, with no finiteness assumption. By itself it produces no differential equation.

16.6.3 The conditional MLDE

Definition 16.28 (Analytic genus-one block; Zhu Def. 5.1.1)**.** A map $F : V \to \{\text{functions } \mathbb{C} \to \mathbb{C}\}$ is an *analytic block* if it is linear in v, each $F(v)$ is holomorphic on $\mathbb{H}$, and for homogeneous a of weight $k_a \geq 1$, all v and all $z \in \mathbb{H}$: (i) $F(a[0]v) = 0$; (ii) $F(a[-2]v)(z) + \sum_{m \geq 0} (2m+1) G_{2m+2}(z) F(a[2m]v)(z) = 0$; (iii) $F(L[-2]v)(z) = \frac{1}{2\pi i} F(v)'(z) + \sum_{m \geq 0} G_{2m+2}(z) F(L[2m]v)(z)$, with $G_{2j}(z)$ the Eisenstein *functions* (the sums of Definition 16.19 evaluated at $q = e^{2\pi i z}$).

File `VOA/Modularity/AnalyticBlock.lean` (Chapter 15).

```
structure IsAnalyticBlock (W : VertexOperatorAlgebra 𝒱) (F : 𝒱 → ℂ → ℂ) : Prop where
  holo : ∀ v : 𝒱, DifferentiableOn ℂ (F v) (imGT 0)
  addv : ∀ (v w : 𝒱) (z : ℂ), F (v + w) z = F v z + F w z
```

```
smulv : ∀ (c : ℂ) (v : V) (z : ℂ), F (c • v) z = c * F v z
vanish : ∀ (ka : ℕ), 1 ≤ ka → ∀ a ∈ W.grading (ka : ℤ), ∀ v : V, F (vSqZ W a ka 0 v) = 0
negTwo : ∀ (ka : ℕ), 1 ≤ ka → ∀ a ∈ W.grading (ka : ℤ), ∀ (v : V), ∀ z ∈ imGT 0,
  F (vSqZ W a ka (-2) v) z
    + ∑ᶠ m : ℕ, ((2 * (m + 1) - 1 : ℕ) : ℂ)
        * (zhuGC (m + 1) z * F (vSqZ W a ka (2 * (m + 1) - 2 : ℤ) v) z) = 0
omega : ∀ (v : V), ∀ z ∈ imGT 0,
  F (Lsq W (-2) v) z
    = (2 * (Real.pi : ℂ) * Complex.I)⁻¹ * _root_.deriv (F v) z
      + ∑ᶠ m : ℕ, zhuGC (m + 1) z * F (Lsq W (2 * (m + 1) - 2 : ℤ) v) z
```

From the mathematics to the Lean statement

`DifferentiableOn ℂ (F v) (imGT 0)`: holomorphic on $\mathbb{H}$. `zhuGC j z` is the function $G_{2j}(z)$ (Chapter 14); `_root_.deriv` is the complex derivative in z, so $(2\pi i)^{-1}F'$ is θF in the variable $q = e^{2\pi i z}$. Exactly Definition 16.28; the difference from Definition 16.19 is only that functions replace formal series. Note that `vanish` is required for all z (the function is identically 0), including off $\mathbb{H}$, which is harmless. The space of all analytic blocks is `analyticBlocks W`.

Physical meaning

The same Ward identities as Definition 16.19, now for honest functions of the modular parameter: these are the torus conformal blocks of the chiral algebra.

What the machine verified

Definition; trace functions of modules with subexponential growth are instances (`traceBlock_isAnalyticBlock`).

Theorem 16.29 (AK Theorem 5.1, conditional form). *Let V be Etingof-finite, $a \in V$ square-bracket primary of integer weight w, and assume an AK weight grading for V and* `E46SerreClosed`*. Then there are $s \geq 1$ and $p_0, \dots, p_{s-1}$ such that for* every *analytic genus-one block F the function $F(a)$ satisfies the monic MLDE of Definition 16.25 of weight w with these coefficients. Both side hypotheses are theorems:* `AKWeightGrading W` *is* `akWeightGrading W` *(Theorem 16.27) and* `E46SerreClosed` *is* `e46SerreClosed`*;* `IsSqPrimary.exists_monicMLDEOn_all_analyticBlocks_of_etingofFinite'` *discharges the second and Theorem 16.30 below discharges both.*

File `VOA/Modularity/AKMLDE.lean`.

```
theorem IsSqPrimary.exists_monicMLDEOn_all_analyticBlocks_of_etingofFinite
    {W : VertexOperatorAlgebra V} {a : V} {wt : ℤ}
    (ha : IsSqPrimary W a (wt : ℂ)) (hgrade : AKWeightGrading W)
    (hclose : E46SerreClosed) (hzero : VacuumGradeZero W) (hE : EtingofFinite W) :
    ∃ (s : ℕ) (p : ℕ → E46), 1 ≤ s ∧
      ∀ (F : V → ℂ → ℂ), IsAnalyticBlock W F → MonicMLDEOn wt (F a) s p := by
```

From the mathematics to the Lean statement

`IsAnalyticBlock W F` (file `VOA/Modularity/AnalyticBlock.lean`, Chapter 15) says $F : V \to (\mathbb{C} \to \mathbb{C})$ is linear in v, each $F(v)$ is holomorphic on $\mathbb{H}$, and Zhu's three conditions hold with the Eisenstein *functions*: $F(a[0]v) = 0$, the $[-2]$-identity, and $F(L[-2]v) = \frac{1}{2\pi i}F(v)' + \sum_m G_{2m+2}F(L[2m]v)$. The trace functions $v \mapsto Z_M(v;\tau)$ of irreducible modules with a conformal weight and subexponential one-point functions are analytic blocks (`traceBlock_isAnalyticBlock`, file `VOA/Modularity/SlashAmbientObstruction.lean`, Chapter 15), and the growth hypothesis is supplied by Theorem 16.16; so at $a = \mathbf{1}$ the theorem would give one MLDE for all such characters. (No library theorem composes the two; the composition

is immediate.) **Quantifier order:** $\exists s\,\exists p$ before $\forall F$ — one equation for all blocks, exactly AK's uniformity. **Hypotheses:** `hzero` free; `hE` the Etingof hypothesis; `hclose` is the classical Ramanujan closure of $\mathbb{C}[E_4, E_6]$ under the Serre derivative, **proved** (`e46SerreClosed`) and discharged in the primed form; `hgrade` is **proved** for every VOA (`akWeightGrading`, Theorem 16.27). Only `hE` remains. **Comparison with AK Theorem 5.1:** same conclusion (with "quasi-lisse" weakened to Etingof-finite and the character replaced by any analytic block evaluated at a primary insertion, which is more general). The conclusion is not vacuous in the sense of Section 16.5.6: the coefficient spaces are finite-dimensional.

Proof on paper. (1) Proposition 5.2 over $\mathbb{C}[E_4, E_6]$ (`exists_finite_gen_sup_blockRelSpanE_of_etingofFinite`): Zhu's G_2 never needs to appear, because the only relation in which G_2 would occur is $a[-2]v + 3G_4 a[2]v + \cdots + G_2(\ldots)a[0]v$, and the $a[0]v$ term is itself a relation. (2) Noetherianity of $\mathbb{C}[E_4, E_6]$ gives a uniform monic relation $L[-2]^s a - \sum c_i L[-2]^i a \in O_q^E(V)$ (`exists_uniform_monic_Lsq_relationE_mem_of_etingofFinite`); the weight grading lets one project it onto total weight $w + 2s$, which forces c_i to have modular weight $2(s-i)$. (3) Every analytic block evaluates this relation to $F(L[-2]^s a) = \sum c_i F(L[-2]^i a)$. (4) Using `E46SerreClosed` and the ω-recursion, in which the $G_2 L[0]$-term combines with the derivative into a Serre derivative, one shows by induction (`IsSqPrimary.exists_uniformSerreExpansionUpTo`) that $F(L[-2]^i a) = \vartheta^i_{(w)} F(a) + \sum_{j<i} h_{ij} \vartheta^j_{(w)} F(a)$ with h_{ij} modular of weight $2(i-j)$, independently of F. (5) Substitute. □

Physical meaning

This is the theorem physicists use: the Schur index, and more generally every torus one-point function of a primary, satisfies an MLDE whose order and coefficients are fixed by the chiral algebra alone. In the library it holds for every Etingof-finite chiral algebra (a stand-in for quasi-lisse; Etingof–Schedler is not formalised), for Zhu's abstract one-point blocks, with an order that is not bounded; at the (A_1, A_3) example $L_{-4/3}(\mathfrak{sl}_2)$ it is unconditional, but AK's order 2 is not proved.

What the machine verified

Proved; `#print axioms VOA.IsSqPrimary.exists_monicMLDEOn_all_analyticBlocks_of_etingofFinite: [propext, Classical.choice, Quot.sound]` (re-run). **Conditional** on `hE`, `hgrade`, `hclose`; `hclose` is discharged by `e46SerreClosed` in `IsSqPrimary.exists_monicMLDEOn_all_analyticBlocks_of_etingofFinite'` (`EisensteinSerreClosure.lean`); `hgrade` is discharged by `akWeightGrading` in Theorem 16.30, which leaves `hE` as the only hypothesis.

Theorem 16.30 (AK Theorem 5.1 under Etingof-finiteness; the $L_{-4/3}(\mathfrak{sl}_2)$ instance). *(i) Let V be Etingof-finite and $a \in V$ square-bracket primary of integer weight w. Then there are $s \geq 1$ and coefficients $p_i \in \mathbb{C}[E_4, E_6]$, modular of weight $2(s-i)$, such that for every analytic genus-one block F the function $F(a)$ satisfies $\vartheta^{(s)} F(a) + \sum_{i<s} p_i \vartheta^{(i)} F(a) = 0$ on $\mathbb{H}$ (iterated Serre derivatives). (ii) For $V = L_{-4/3}(\mathfrak{sl}_2)$ and $a = \mathbf{1}$ this holds with no hypothesis.*

File `VOA/Modularity/AKMLDEUnconditional.lean`.

```
theorem IsSqPrimary.exists_monicMLDEOn_all_analyticBlocks_of_etingofFinite_uncond

    (wt := 0) (by exact_mod_cast vacuum_isSqPrimary simpleSl2QL)
    ↪ VOA.Sl2Pres.etingofFinite_simpleSl2QL'
```

From the mathematics to the Lean statement

Read the name with care. Despite the suffix `_uncond`, (i) is *conditional on* `EtingofFinite W` (finite zeroth Poisson homology, the conclusion of Etingof–Schedler); quasi-lisseness is not formalised. The order s comes from Noetherianity and is *existential and unbounded*. "Analytic block" means Zhu's abstract one-point conditions (`IsAnalyticBlock`; the zero function is one). Module traces are blocks by a separate lemma, `torusOnePoint_isAnalyticBlock`, whose growth input `OnePointSubexp` is supplied under `EtingofFinite` by `onePointSubexp_of_etingofFinite` (`Modules/QuasiLisseFinite.lean`). (ii) is genuinely unconditional, with s unspecified: **AK's order 2 for $L_{-4/3}(\mathfrak{sl}_2)$ is not proved**. That the vacuum character of $L_{-4/3}(\mathfrak{sl}_2)$ is such a block follows from `torusOnePoint_isAnalyticBlock`, `onePointSubexp_adjoint_of_etingofFinite` and the support lemma, but no single library theorem states "the character satisfies a monic MLDE". Do not confuse (ii) with `Sl2Pres.character_formalODE_simpleSl2QL_uncond`, the near-vacuous formal $q\frac{d}{dq}$-equation of Section 16.5.6.

Physical meaning

For a quasi-lisse chiral algebra (in four-dimensional terms, a theory whose Higgs branch is a finite union of symplectic leaves) the characters of modules are expected to solve a modular linear differential equation fixed by the chiral algebra alone, as for rational theories. Part (i) proves this for every torus one-point function of a primary, with Etingof-finiteness standing in for quasi-lisseness; the order s is only shown to exist. Part (ii) is the first unconditional instance: $L_{-4/3}(\mathfrak{sl}_2)$ is the chiral algebra of the (A_1, A_3) Argyres–Douglas theory under the SCFT/VOA correspondence of Beem et al., so its vacuum character, the Schur index of that theory, lies in the solution space of one monic MLDE (once one composes with the trace-function lemmas listed above). The second-order equation of Arakawa–Kawasetsu and the identification of the remaining solutions with module characters are not proved.

What the machine verified

Proved, conditional on `EtingofFinite` for (i), unconditional for (ii). `#print axioms` of both: `[propext, Classical.choice, Quot.sound]`, recorded in `Notes/release/WS-RELEASE2.md` (commit `34b74b85`); audited as stated, with the caveats above, in `RELEASE_AUDIT_QUEUE2.md`. The aggregate `lake build` at the release commit is pending.

16.7 Zhu modularity and conformal blocks under Etingof-finiteness

Theorem 16.31 (Zhu's Theorem 5.3.2 under Etingof-finiteness). *If V is Etingof-finite, the space of analytic genus-one blocks (restricted to $\mathbb{H}$) is finite-dimensional.*

File `VOA/Modularity/AKZhuModularity.lean`.

```
theorem finiteDimensional_analyticBlocks_of_etingofFinite (hzero : VacuumGradeZero W)
```

```
    (hE : EtingofFinite W) :
    FiniteDimensional ℂ (Submodule.map restrictImGT (analyticBlocks W)) := by
```

From the mathematics to the Lean statement

`analyticBlocks W` is the subspace of all `F` with `IsAnalyticBlock W F` (`VOA/Modularity/BlockSpace.lean`); `restrictImGT` extends by zero off $\mathbb{H}$ (`VOA/Modularity/BlockRank.lean`), so two blocks agreeing on $\mathbb{H}$ are identified. Same as Zhu's Theorem 5.3.2 with C_2 weakened. The proof avoids the two places where the C_2-route needs C_2-cofiniteness (finite-dimensionality of Zhu's algebra $A(V)$ and finite generation of the E-relation module).

Proof on paper. At a fixed $z_0 \in \mathbb{H}$, evaluating the relations of $O_q(V)$ at z_0 gives numerical relations; the spanning argument of Theorem 16.15 with numbers in place of $\mathcal{G}$ shows that V is spanned by a finite set modulo these, so a block is determined at z_0 by finitely many values; by the ω-recursion and holomorphy, the block is determined on $\mathbb{H}$ by finitely many initial data. □

Physical meaning

Finitely many independent torus conformal blocks: a quasi-lisse chiral algebra on the torus has a finite-dimensional space of "partition functions with insertions", even though the theory may have infinitely many non-ordinary sectors.

What the machine verified

Proved, conditional on `hE`; `[propext, Classical.choice, Quot.sound]` (re-run).

Theorem 16.32 (Zhu modularity under Etingof-finiteness, conditional). *Let V be Etingof-finite and $(M_i)_{i\in\iota}$ a finite family of irreducible modules. If the trace functions are independent on each T-eigenvalue fibre (`hfib`) and the restricted analytic blocks together with the S-slashes of the traces span a space of dimension at most $|\iota|$ (`hrank`), then there is an $SL_2(\mathbb{Z})$-representation ρ with $Z_{M_i}(v;A\tau) = (c\tau+d)^n \sum_j \rho(A)_{ij} Z_{M_j}(v;\tau)$ for all v of $L[0]$-weight n.*

File `VOA/Modularity/AKZhuModularity.lean`.

```
theorem exists_zhuModularity_of_sqAnalyticRank_le_irr_etingofFinite
    (hE : EtingofFinite W)
    (hfib : FibreIndependent Mfam (fun i => conformalWeightOf (Mfam i)))
    (hrank : Module.rank ℂ
        (sqAnalyticSlashAmbient Mfam (fun i => conformalWeightOf (Mfam i)))
      ≤ (Fintype.card ι : Cardinal)) :
    ∃ D : ModularData W ι, ZhuModularityAnalytic D :=
```

From the mathematics to the Lean statement

`Mfam : ι → IrrModule W` is the family; `conformalWeightOf` picks its conformal weights; `ModularData`, `ZhuModularityAnalytic`, `FibreIndependent`, `sqAnalyticSlashAmbient` are the objects of Zhu's theorem in Chapter 15 (`ZhuModularityAnalytic D` is the displayed transformation law for every $A \in SL_2(\mathbb{Z})$). The statement is `exists_zhuModularity_of_sqAnalyticRank_le_irr_c2` of Chapter 15 with `C2Cofinite` replaced by `EtingofFinite`; a kernel-checked `example` in the same file shows that the C_2 theorem, re-proved through this one, has literally the same type. **Hypotheses:** `hfib`, `hrank` are open inputs, and for the motivating non-lisse examples `hrank` is expected to be *false* (warning below). The file's honesty block records that `hrank` is discharged only at the trivial VOA, and that Etingof-finiteness *cannot* supply it on this route (it bounds V/O_2^P, not Zhu's algebra $A(V) = V/O(V)$, since $a_{(0)}b \notin O(V)$ in general).

Proof on paper. Zhu's argument (Chapter 15) uses C_2-cofiniteness at exactly one place on this route, the growth of one-point functions; Theorem 16.16 supplies it. □

Physical meaning

The characters of the ordinary sectors transform into each other under the modular group — the statement that the torus partition function of the full CFT can be made modular invariant. For quasi-lisse theories AK only predict that characters lie in an invariant solution space; whether the span of characters itself is invariant is a separate question, and here it is reduced to `hfib` and `hrank`. For the Argyres–Douglas example the answer is expected to be no (warning below): the single ordinary character, with $c = -6$, cannot be modular invariant by itself.

What the machine verified

Proved; `[propext, Classical.choice, Quot.sound]` (re-run). Conditional on `hE`, `hfib`, `hrank`. Fully discharged only at the trivial VOA (`trivial_exists_zhuModularity_etingofFinite`), which is lisse. Expected *not* to be instantiable at $L_{-4/3}(\mathfrak{sl}_2)$ (warning below; paper argument). This is Zhu's theorem with `C2Cofinite` replaced by `EtingofFinite` in one step; it is not a modularity theorem for quasi-lisse VOAs. The file also gives the character-convergence corollary `qSummable_gradedDim_of_etingofFinite` and a holomorphic $c = 24$ corollary `char_SL2Z_invariant_of_sqAnalyticRank_of_etingofFinite` (conditional on a rank bound `hle`).

`hrank` is expected to fail at $L_{-4/3}(\mathfrak{sl}_2)$ (paper argument, release audit)

The following argument is due to the release audit (`Notes/Textbook/referee/RELEASE_AUDIT_L16.md`, finding 5). It is argued on paper and **not machine-checked**.

1. At $k = -4/3 = -2 + 2/3$ the admissible highest weights have $\lambda_1 \in \{0, -2/3, -4/3\}$, and only $\lambda_1 = 0$ gives a finite-dimensional top space. So (Adamović–Milas; Arakawa) $L = L_{-4/3}(\mathfrak{sl}_2)$ has exactly one ordinary irreducible module, L itself.

2. `FibreIndependent` forbids repeating a module, so a family containing the adjoint module is a singleton, and `ZhuModularityAnalytic` would make $\chi_L(\tau)$ a weight-0 modular function for a character ρ of $SL_2(\mathbb{Z})$.

3. $c = -6$, so the leading power of χ_L is $q^{-c/24} = q^{1/4}$, which forces $\rho(T) = i$; hence $\rho = \varepsilon^6$ with ε the multiplier of η. Then χ_L/η^6 would be a holomorphic modular form of level one and weight -3, nonzero at the cusp. No nonzero modular form of odd weight for $SL_2(\mathbb{Z})$ exists ($-I$ acts by $(-1)^k$).

Hence `hrank` must fail for every family containing the adjoint module of $L_{-4/3}(\mathfrak{sl}_2)$. This agrees with what Arakawa and Kawasetsu actually prove: the *solution space* of the MLDE is $SL_2(\mathbb{Z})$-stable, not the span of the ordinary characters. So for the motivating class of examples the hypotheses of Theorem 16.32 are not merely open but expected to be false, and the theorem must not be described as "modularity for quasi-lisse VOAs".

16.8 The example: the classical Poisson model of $L_{-4/3}(\mathfrak{sl}_2)$

A theorem with hypothesis `EtingofFinite W` is only interesting if the hypothesis holds for some V that is *not* C_2-cofinite (otherwise Zhu's theorem already applies). The canonical example is the simple affine vertex algebra $L_k(\mathfrak{sl}_2)$ at an admissible level. Recall (Chapter 10, where `AdmissibleLevel` is defined) that k is *admissible* for $\widehat{\mathfrak{sl}_2}$ if $k + 2 = p/q$ with p, q coprime positive integers and $p \geq 2$; for

$q \geq 2$ these levels are non-integral and L_k is not lisse. The library takes $(p, q) = (2, 3)$: $\gcd(2, 3) = 1$, $k = -2 + \frac{2}{3} = -\frac{4}{3}$, $k + 2 = \frac{2}{3} \neq 0$ (non-critical, which is what `hkQL` below records), and $c = 3k/(k+2) = 3(-\frac{4}{3})/\frac{2}{3} = -6$. The library's proof of admissibility is `Admissible.admissibleLevel_neg_four_thirds` (`AdmissibleLevel.lean`, Chapter 10). This section does the commutative algebra on the classical side, unconditionally; the next two transport it to the vertex algebra.

16.8.1 The symbol of the singular vector

By Chapter 9 (Theorem 9.28) $V^{-4/3}(\mathfrak{sl}_2)$ has the singular vector

$$s = 20\,e_{-3}\mathbf{1} - 12\,e_{-2}h_{-1}\mathbf{1} - 6\,h_{-2}e_{-1}\mathbf{1} + 36\,e_{-1}e_{-1}f_{-1}\mathbf{1} + 9\,e_{-1}h_{-1}h_{-1}\mathbf{1}$$

of weight 3, and (Theorem 9.30) its class $[s]$ in $R_{V^k} = V^k/C_2(V^k)$ (the image of s under the quotient map, called its *symbol*) is $9[e](4[e][f] + [h]^2) = 9\,e\,\mathrm{Cas}$. The reason: a current mode x_{-n} with $n \geq 2$ acting on a state w is $(x_{-1}\mathbf{1})_{(-n)}w$, and $u_{(-n)}w \in C_2(V)$ for $n \geq 2$ (for $n = 2$ by definition, for $n > 2$ by $u_{(-n)} = \frac{1}{n-1}(L_{-1}u)_{(-n+1)}$ and induction, Chapter 12, Theorem 12.23); so the first three terms of s have zero class, while $x_{-1}w = (x_{-1}\mathbf{1})_{(-1)}w$ has class $[x]\cdot[w]$, giving $[s] = 36[e]^2[f] + 9[e][h]^2$. Here $\mathrm{Cas} = h^2 + 4ef$ is the Casimir. In $\mathrm{Sym}(\mathfrak{sl}_2) = \mathbb{C}[e, h, f]$ with the Kirillov–Kostant bracket $\{e, f\} = h, \{h, e\} = 2e, \{h, f\} = -2f$, the Casimir is Poisson-central, so $\{x, e\mathrm{Cas}\} = \{x, e\}\mathrm{Cas}$, and the Poisson ideal generated by $e\mathrm{Cas}$ is

$$\mathrm{Cas}\cdot\mathfrak{m} = (\mathrm{Cas}\,e,\ \mathrm{Cas}\,h,\ \mathrm{Cas}\,f), \qquad \mathfrak{m} = (e, h, f).$$

Definition 16.33 (The classical model). $\mathrm{Sym}(\mathfrak{sl}_2) = \mathbb{C}[X_0, X_1, X_2]$ with $e = X_0$, $h = X_1$, $f = X_2$; $\mathrm{Cas} = h^2 + 4ef$; the three derivations $\mathrm{ad}_e = -2e\,\partial_h + h\,\partial_f$, $\mathrm{ad}_h = 2e\,\partial_e - 2f\,\partial_f$, $\mathrm{ad}_f = -h\,\partial_e + 2f\,\partial_h$ (the brackets $\{e,\cdot\}, \{h,\cdot\}, \{f,\cdot\}$); the ideal $\mathrm{Cas}\cdot\mathfrak{m}$; and the model algebra $R = \mathrm{Sym}(\mathfrak{sl}_2)/\mathrm{Cas}\cdot\mathfrak{m}$.

From the mathematics to the Lean statement

`MvPolynomial (Fin 3) ℂ` is $\mathbb{C}[X_0, X_1, X_2]$; `pderiv i` is $\partial/\partial X_i$; `adOf a i b j` is the first-order operator $p \mapsto a\,\partial_i p + b\,\partial_j p$. So `adE` $= -2e\partial_h + h\partial_f$, etc., exactly Definition 16.33; `adE_f`, `adE_h`,

`adH_e`, … (in `AffineSl2Presentation.lean`) check the nine values on generators against $\mathfrak{sl}_2$. **Index warning** (from the source): the polynomial variables are ordered (e, h, f), whereas the affine colours of Chapter 9 are $(e, f, h) = (0, 1, 2)$; the two `Fin 3`'s are different. `casIdeal` is the ideal generated by CasX_i, i.e. Cas $\cdot\, \mathfrak{m}$ — **not** the principal ideal (Cas), whose generator has degree 2. `casSub` is the same set viewed as a vector subspace, and `NilpAlg` is R as a vector space (no ring structure on the quotient is used). The library proves that `casIdeal` is a Poisson ideal (`adE_casIdeal`, `adH_casIdeal`, `adF_casIdeal`) and that the Casimir is central (`adE_cas`, …).

A retracted objection, recorded in the source

An earlier version of the source claimed that the hypothesis "the symbol ideal dies" was unsatisfiable because it would force R_V to be reduced; the error was to read `casIdeal` as (Cas). As the docstring of `Sl2Presentation` now explains, Cas $\notin$ Cas $\cdot\, \mathfrak{m}$, and indeed R_{L_k} is non-reduced: $[\mathrm{Cas}] \neq 0$ but $[\mathrm{Cas}]^2 = 0$, i.e. the Sugawara vector, which is proportional to the Casimir, is nilpotent in R_V. As a vector space $R = \mathbb{C}[\mathcal{N}] \oplus \mathbb{C}\mathrm{Cas}$, a one-dimensional thickening of the coordinate ring of the nilpotent cone (not formalised).

Physical meaning

e, h, f are the classical moment maps of the $SU(2)$ flavour symmetry. In the four-dimensional theory they are the Higgs-branch moment-map operators; Cas $= 0$ is the F-term (hyperkähler moment map) relation cutting out $\mathbb{C}^2/\mathbb{Z}_2$ as the nilpotent cone, $\{h^2 + 4ef = 0\}$. The nilpotence of [Cas] is the chiral-algebra statement that the stress tensor is, classically, a nilpotent element: the Sugawara construction identifies T with the Casimir of the currents, and in Beem–Rastelli's dictionary this is why the 2d stress tensor is not a Higgs-branch chiral ring element.

What the machine verified

Definitions, plus the Poisson-ideal lemmas, all `[propext, Classical.choice, Quot.sound]`.

Theorem 16.34 (The classical quasi-lisse phenomenon, unconditionally). *(i)* $\mathrm{Sym}(\mathfrak{sl}_2) = \mathrm{Cas} \cdot \mathfrak{m} + \{\mathfrak{sl}_2, \mathrm{Sym}(\mathfrak{sl}_2)\} + \mathrm{span}\{1, h^2, ef\}$, *where* $\{\mathfrak{sl}_2, \mathrm{Sym}\}$ *is the sum of the ranges of the three derivations. (ii)* R *is infinite-dimensional. (iii)* $\mathrm{Sym}(\mathfrak{sl}_2)/(\mathrm{Cas} \cdot \mathfrak{m} + \{\mathfrak{sl}_2, \mathrm{Sym}\})$ *is finite-dimensional; a fortiori* $\mathrm{HP}_0(R)$ *is.*

theorem not_finiteDimensional_NilpAlg : ¬ FiniteDimensional ℂ NilpAlg := by

theorem finiteDimensional_quot_adRange :
    FiniteDimensional ℂ (SymSl2 / (casSub ⊔ adRange)) := by
```

From the mathematics to the Lean statement

`LinearMap.range adE` is $\{e, \mathrm{Sym}\}$, etc.; `adRange` is contained in the full bracket span, so (iii) as stated (quotient by `casSub ⊔ adRange`) is *stronger* than finiteness of $\mathrm{HP}_0(R)$, which the library does not state separately for the model. Exactly Theorem 16.34. Note that (ii) and (iii) together are the whole point: an infinite-dimensional Poisson algebra with finite zeroth Poisson homology.

Proof on paper. (i) It suffices to treat monomials $e^a h^c f^b$; induct on $a+b$. Since ad_h acts on $e^a h^c f^b$ by $2(a-b)$, monomials with $a \neq b$ are brackets. If $a = b \geq 1$, write $u = e^{a-1}h^c f^{a-1}$, so $e^a h^c f^a = u \cdot ef$. Since $4ef = \mathrm{Cas} - h^2$,

$$e^a h^c f^a = \frac{1}{4}\, u\,\mathrm{Cas} - \frac{1}{4}\, u\, h^2 = \frac{1}{4}\,\mathrm{Cas}\cdot u - \frac{1}{4}\, e^{a-1}h^{c+2}f^{a-1}.$$

Unless $(a,c) = (1,0)$ (then $e^a h^c f^a = ef \in \mathrm{span}\{1, h^2, ef\}$), the monomial u has positive degree, i.e. $u \in \mathfrak{m}$, so $\mathrm{Cas}\cdot u \in \mathrm{Cas}\cdot\mathfrak{m}$, and therefore $e^a h^c f^a \equiv -\frac{1}{4}e^{a-1}h^{c+2}f^{a-1}$ modulo $\mathrm{Cas}\cdot\mathfrak{m}$, a monomial with smaller $a+b$, to which the induction hypothesis applies. Remain the powers h^c: $c = 0, 2$ are in the span; $h = \mathrm{ad}_e f$; for $c \geq 3$, $\mathrm{ad}_e(fh^{c-1}) = h\cdot h^{c-1} + f\cdot(c-1)h^{c-2}(-2e) = h^c - 2(c-1)efh^{c-2}$, and by the same computation with $u = h^{c-2} \in \mathfrak{m}$, $efh^{c-2} = \frac{1}{4}\mathrm{Cas}h^{c-2} - \frac{1}{4}h^c \equiv -\frac{1}{4}h^c$ modulo $\mathrm{Cas}\mathfrak{m}$, so $h^c - 2(c-1)(-\frac{1}{4})h^c = (1 + \frac{c-1}{2})h^c$ is in the sum, and the coefficient is nonzero. (ii) The algebra map $e \mapsto t$, $h, f \mapsto 0$ to $\mathbb{C}[t]$ kills Cas, hence $\mathrm{Cas}\mathfrak{m}$, and sends e^n to t^n; so the classes $[e^n]$ are linearly independent. (iii) By (i) the quotient is spanned by the images of $1, h^2, ef$. □

Physical meaning

(ii): the Higgs branch is not a point — the moment map e has arbitrarily high nonzero powers, the holomorphic functions μ^n on $\mathbb{C}^2/\mathbb{Z}_2$. (iii): yet only three classical torus amplitudes survive. The leaves of $\mathcal{N}$: the Poisson bivector of $\mathfrak{sl}_2^*$ at a point ξ has rank dim of the coadjoint orbit through ξ; it vanishes at $\xi = 0$ (the origin is a leaf by itself) and has rank 2 on $\mathcal{N}\setminus\{0\}$, which is a single coadjoint orbit (the regular nilpotent orbit, connected). So $\mathcal{N}$ has exactly two leaves, the situation of Theorem 16.4.

What the machine verified

Proved, unconditional; the three theorems: `[propext, Classical.choice, Quot.sound]` (re-run).

16.9 Transport to a vertex algebra: symbol presentations

Definition 16.35 (An $\mathfrak{sl}_2$ symbol presentation of R_V)**.** A presentation for V is a linear surjection $\sigma : \mathrm{Sym}(\mathfrak{sl}_2) \to R_V$ that kills $\mathrm{Cas}\cdot\mathfrak{m}$ and intertwines ad_x with $\{\sigma(x), \cdot\}$ for $x = e, h, f$. It is *exact* if $\ker\sigma \subseteq \mathrm{Cas}\cdot\mathfrak{m}$.

File `VOA/Examples/AffineSl2QuasiLisse.lean`.

```

  adF_compat : ∀ p, map (adF p) = A₂bracket W (map fSym) (map p)

def IsExact : Prop := ∀ p : SymSl2, S.map p = 0 → p ∈ casIdeal
```

From the mathematics to the Lean statement

Field by field, Definition 16.35; `IsExact` is defined inside `namespace Sl2Presentation` with `S : Sl2Presentation W`. **Is it a disguised finiteness assumption?** No: none of the fields mentions dimension, and the model R itself (with its own bracket) satisfies all of them while being infinite-dimensional. **Is it satisfiable for an interesting V?** Yes: it is constructed for $L_{-4/3}(\mathfrak{sl}_2)$ (Theorem 16.38). Note that `map` is only required to be linear, not multiplicative; the constructed one is an algebra map.

Physical meaning

A presentation identifies the classical phase space of the chiral algebra as (a thickening of) a subvariety of $\mathfrak{sl}_2^*$ cut out by the null vector's symbol; exactness says no further classical relations are imposed.

What the machine verified

Structure and predicate. Inhabited at $L_{-4/3}(\mathfrak{sl}_2)$; `IsExact` for that instance is not proved (but no longer needed, Section 16.10).

Theorem 16.36 (Consequences of a presentation). *Let σ be a presentation for V. (i) V is Etingof-finite (without C_2-cofiniteness). (ii) If σ is exact, V is not C_2-cofinite, and σ induces a linear isomorphism $R \cong R_V$.*

File `VOA/Examples/AffineSl2QuasiLisse.lean`.

```
theorem etingofFinite (S : Sl2Presentation W) : EtingofFinite W := by

theorem not_C2Cofinite (hex : S.IsExact) : ¬ C2Cofinite W := by

def nilpEquiv (S : Sl2Presentation W) (hex : S.IsExact) : NilpAlg ≃ₗ[ℂ] A₂ W :=

theorem quasiLisseWitness (S : Sl2Presentation W) (hex : S.IsExact) :
    ¬ C2Cofinite W ∧ EtingofFinite W :=
```

From the mathematics to the Lean statement

All in `namespace VOA.QuasiLisseSl2.Sl2Presentation`. `≃ₗ[ℂ]` is a linear isomorphism. Exactly Theorem 16.36.

Proof on paper. (i) $R_V = \sigma(\mathrm{Sym}) = \sigma(\mathrm{Cas}\mathfrak{m} + \{\mathfrak{sl}_2, \mathrm{Sym}\} + \mathrm{span}\{1, h^2, ef\})$ by Theorem 16.34(i); the first summand maps to 0, the second into $\{R_V, R_V\}$ by the intertwining, the third onto a space of dimension ≤ 3. So $\dim \mathrm{HP}_0(R_V) \leq 3$. (ii) Exactness makes the induced map $R \to R_V$ injective; it is surjective; and R is infinite-dimensional by Theorem 16.34(ii). □

Physical meaning

Once the classical phase space is known to be (a thickening of) the nilpotent cone, both halves of "quasi-lisse but not lisse" follow: a two-dimensional Higgs branch (not lisse) with finitely many leaves (finitely many classical amplitudes).

What the machine verified

Proved; all `[propext, Classical.choice, Quot.sound]` (re-run for `etingofFinite`, `not_C2Cofinite`). (i) is conditional only on the presentation; (ii) also on exactness.

16.9.1 The flagship algebra

Definition 16.37 ($V^{-4/3}(\mathfrak{sl}_2)$ and $L_{-4/3}(\mathfrak{sl}_2)$). $V^{-4/3}(\mathfrak{sl}_2)$ is the universal affine vertex operator algebra of $\mathfrak{sl}_2$ at level $-4/3$, and $L_{-4/3}(\mathfrak{sl}_2)$ is its quotient by the maximal proper graded ideal.

File `VOA/Examples/AffineSl2QuasiLisse.lean`.

```
theorem hkQL : (-4 / 3 : ℂ) + 2 ≠ 0 :=

    VertexOperatorAlgebra (AffineVOA.WakModule (-4 / 3 : ℂ) / QuotVOA.maxGradedIdeal
     ↪ affineSl2QL) :=
  QuotVOA.maxQuotientVOA affineSl2QL
```

From the mathematics to the Lean statement

`affineSl2VOA_closed k hk` is the universal affine VOA $V^k(\mathfrak{sl}_2)$ on the vacuum module `WakModule k` (despite its name, not a Wakimoto module), Chapter 9, Definition 9.14; `hkQL` is the non-criticality $k+2 \neq 0$, obtained from admissibility of $-4/3$. `maxQuotientVOA` is the quotient by the maximal proper graded ideal (Chapter 5). So `simpleSl2QL` is $L_{-4/3}(\mathfrak{sl}_2)$. It is definitionally the algebra `LQ43.L43` of Chapter 10 (the two differ only in the proof of non-criticality, and proofs are irrelevant; `affineSl2QL_eq_voaSl2Adm` is `rfl`), which is proved simple, nonzero, and a proper quotient of $V^{-4/3}$, all without `VOA.pbw`. So the example is the intended object and is not the zero algebra.

Physical meaning

$L_{-4/3}(\mathfrak{sl}_2)$, $c=-6$: the chiral algebra of the $(A_1, D_3) \cong (A_1, A_3)$ Argyres–Douglas theory (Beem et al., Creutzig), with $c_{4d}=1/2$ and Higgs branch $\mathbb{C}^2/\mathbb{Z}_2$. It is non-unitary and non-rational: in category $\mathcal{O}$ it has three irreducible highest-weight modules (admissible weights $0, -2/3, -4/3$), of which only the vacuum module has finite-dimensional conformal-weight spaces (standard admissible-level representation theory, Adamović–Milas; not formalised).

What the machine verified

Definitions; `simpleSl2QL` nonzero by `Sl2Pres.vacuum_simpleSl2QL_ne_zero'` (pbw-free).

Theorem 16.38 (The presentation of $R_{L_{-4/3}}$ is constructed). *(i) For every non-critical k, the algebra map* $\mathrm{Sym}(\mathfrak{sl}_2) \to R_{V^k(\mathfrak{sl}_2)}$, $x \mapsto [x_{-1}\mathbf{1}]$, *is surjective. (ii) In* $R_{L_{-4/3}}$, $[e]\cdot \mathrm{Cas} = 0$, *and the whole ideal* $\mathrm{Cas}\cdot\mathfrak{m}$ *maps to* 0. *(iii) These maps form an $\mathfrak{sl}_2$ symbol presentation of $L_{-4/3}(\mathfrak{sl}_2)$. (iv) Hence $L_{-4/3}(\mathfrak{sl}_2)$ is Etingof-finite.*

def sl2PresentationSimpleSl2QL : Sl2Presentation simpleSl2QL where

theorem etingofFinite_simpleSl2QL' : EtingofFinite simpleSl2QL :=
  sl2PresentationSimpleSl2QL.etingofFinite
```

From the mathematics to the Lean statement

`eCl k hk`, `hCl`, `fCl` are the classes $[e_{-1}\mathbf{1}]$, $[h_{-1}\mathbf{1}]$, $[f_{-1}\mathbf{1}]$ in R_{V^k} (`AffineSl2Symbol.lean`, Chapter 9); `MvPolynomial.aeval ![x,y,z]` is the algebra map sending X_0, X_1, X_2 to x, y, z (note the order e, h, f). `eL`, `hL`, `fL` are their images in $R_{L_{-4/3}}$ under the map of Theorem 16.7, and `casL` $= 4\,eL\,fL + hL^2$. The structure `sl2PresentationSimpleSl2QL` has `map := symbolAlgL.toLinearMap`, `surjective := symbolAlgL_surjective`, `cas_vanishes := cas_vanishes_L` and the three compatibilities `adE_compat_L`, ... Exactly Theorem 16.38. (i) is only the surjective half of $R_{V^k} = \mathrm{Sym}(\mathfrak{sl}_2)$; injectivity is not used.

Proof on paper. (i) V^k is spanned by word states $J^{a_1}_{-n_1-1}\cdots J^{a_r}_{-n_r-1}\mathbf{1}$ (`wordStateA_span`, Chapter 9). If some mode is ≤ -2 the word lies in C_2; otherwise it is the iterated product $[J^{a_1}]\cdots[J^{a_r}]$ in R_{V^k}, because $x_{-1}v = (x_{-1}\mathbf{1})_{(-1)}v$. (ii) s lies in the maximal ideal of $V^{-4/3}$ (Chapter 10: `LQ43.mkQ_sl2Singular_eq_zero`, via Li's theorem that the maximal ideal is the radical of the invariant form), so $0 = [s] = 9[e]\mathrm{Cas}$ in R_L. Then, Cas being central, $[h]\mathrm{Cas} = -\{[f],[e]\mathrm{Cas}\} = 0$ and $2[f]\mathrm{Cas} = \{[f],[h]\mathrm{Cas}\} = 0$. (iii) The compatibilities hold on generators by the nine brackets of currents ($\{[x],[y]\} = [[x,y]]$) and propagate to all polynomials by the Leibniz rule. (iv) Theorem 16.36(i). □

Physical meaning

The null vector at level $-4/3$ imposes, classically, $e\cdot\mathrm{Cas} = 0$; the $SU(2)$ symmetry then forces $\mathrm{Cas}\cdot\mathfrak{m} = 0$. That is enough to leave only three classical torus amplitudes. In four-dimensional terms: the Higgs-branch relation is implied by the chiral algebra's null state.

What the machine verified

Proved, unconditional, pbw-free; `VOA.Sl2Pres.symbolAlg_surjective`, `VOA.Sl2Pres.eL_mul_casL`, `VOA.Sl2Pres.sl2PresentationSimpleSl2QL`, `VOA.Sl2Pres.etingofFinite_simpleSl2QL'`: `[propext, Classical.choice, Quot.sound]` (re-run).

Definition 16.39 (The exactness citation). `Sl2ExactSymbol` is the proposition that the constructed presentation of $R_{L_{-4/3}}$ is exact, i.e. that $\ker(\mathrm{Sym}(\mathfrak{sl}_2) \to R_{L_{-4/3}}) \subseteq \mathrm{Cas}\cdot\mathfrak{m}$.

File `VOA/Examples/AffineSl2Presentation.lean`.

```
def Sl2ExactSymbol : Prop := sl2PresentationSimpleSl2QL.IsExact

theorem not_C2Cofinite_simpleSl2QL_of_exact (hex : Sl2ExactSymbol) : ¬ C2Cofinite
↪  simpleSl2QL :=
  sl2PresentationSimpleSl2QL.not_C2Cofinite hex
```

From the mathematics to the Lean statement

`Sl2ExactSymbol` says that the kernel of the constructed symbol map is contained in $\mathrm{Cas}\cdot\mathfrak{m}$, i.e. $R_{L_{-4/3}} \cong \mathrm{Sym}(\mathfrak{sl}_2)/\mathrm{Cas}\cdot\mathfrak{m}$. It is a named, **unproved** proposition; the library never assumes it globally, only as an explicit hypothesis.

The citation attached to `Sl2ExactSymbol` names a weaker theorem (documentation only)

The docstring calls `Sl2ExactSymbol` "Arakawa's associated-variety theorem for $L_{-4/3}(\mathfrak{sl}_2)$, in the form this repository consumes" and says that it is "a lower bound on A_2" supplied by $X_{L_k(\mathfrak{sl}_2)} = \mathcal{N}$. Arakawa's theorem is a statement about the *reduced* variety: it gives $\sqrt{\ker\sigma} = (\mathrm{Cas})$, not $\ker\sigma = \mathrm{Cas}\cdot\mathfrak{m}$. The scheme-theoretic statement `Sl2ExactSymbol` is true, but its proof (on paper) uses different inputs: (a) the maximal ideal of $V^{-4/3}$ is generated by s (a standard fact of admissible-level $\widehat{\mathfrak{sl}_2}$ representation theory, going back to Kac–Wakimoto and Malikov–Feigin–Fuchs), so by PBW it equals $U(\hat{\mathfrak{g}}_{<0})\cdot\mathrm{span}\{s, f_0 s, f_0^2 s\}$; (b) in $R_{V^k} = \mathrm{Sym}(\mathfrak{sl}_2)$ (which needs PBW injectivity) the image of this space is the ideal generated by the $\mathfrak{sl}_2$-orbit of $e\mathrm{Cas}$, which is $\mathrm{Cas}\cdot\mathfrak{m}$. Since non-lisseness is now proved without it (Section 16.10), the hypothesis has become **redundant** wherever it occurs (checked in Lean against the library; the check is not part of this release).

Physical meaning

Exactness would say that the chiral algebra's classical phase space is *exactly* the thickened nilpotent cone, with no further nilpotent relations — a scheme-theoretic refinement of "associated variety = Higgs branch".

What the machine verified

`Sl2ExactSymbol`: unproved named proposition. `not_C2Cofinite_simpleSl2QL_of_exact`: proved from it, `[propext, Classical.choice, Quot.sound]`; superseded by Theorem 16.40.

16.10 $L_{-4/3}(\mathfrak{sl}_2)$ is not lisse

The file `AffineSl2NonLisse.lean` proves the lower bound on $R_{L_{-4/3}}$ that exactness was meant to give, by a direct and much weaker argument: only the tower $[e^r]$ is shown to survive.

Theorem 16.40 (Non-lisseness of $L_{-4/3}(\mathfrak{sl}_2)$). *Let $E_r = e_{-1}^r\mathbf{1}$ and $F_r = f_{-1}^r\mathbf{1}$ in $V = V^{-4/3}(\mathfrak{sl}_2)$, and $\langle\cdot,\cdot\rangle$ the canonical invariant bilinear form. (i) $\langle F_r, x\rangle = 0$ for all $x \in C_2(V)$. (ii) $\langle F_r, E_r\rangle = (-1)^r\, r!\prod_{j<r}(k-j) \neq 0$ at $k = -4/3$. (iii) The class of E_r in R_L, $L = L_{-4/3}(\mathfrak{sl}_2)$, is nonzero, and these classes are linearly independent. (iv) L is not C_2-cofinite. (v) L is not C_2-cofinite and is Etingof-finite.*

File `VOA/Examples/AffineSl2NonLisse.lean`.

```
theorem form_fHarmonic_O₂_zero (r : ℕ) {x : WakModule kk} (hx : x ∈ O₂ W43) :
    LQ43.formAdm.form (fHarmonic kk r) x = 0 := by

theorem strictEtingofFinite_simpleSl2QL :
    ¬ C2Cofinite L43 ∧ EtingofFinite L43 :=
  ⟨not_C2Cofinite_simpleSl2QL, Sl2Pres.etingofFinite_simpleSl2QL'⟩
```

From the mathematics to the Lean statement

`kk`, `W43`, `I43`, `L43` are *local notations* of the file for $-4/3$, `affineSl2QL`, `QuotVOA.maxGradedIdeal affineSl2QL` and `simpleSl2QL`; so `VOA.Sl2NonLisse.not_C2Cofinite_simpleSl2QL` is literally `¬ C2Cofinite simpleSl2QL`. `eHarmonic k r`, `fHarmonic k r` are E_r, F_r (`AffineSl2HarmonicNorm.lean`), and `eHarmonicL r` is the image of E_r in L. `LQ43.formAdm` is the canonical invariant form on $V^{-4/3}$ of Chapter 10. (ii) is `form_fHarmonic_eHarmonic` (`AffineSl2HarmonicNorm.lean`) evaluated at $k = -4/3$: $k - j \neq 0$ because k is not a non-negative integer. Exactly Theorem 16.40; (iv) is unconditional. **Name clash:** the full name is `VOA.Sl2NonLisse.not_C2Cofinite_simpleSl2QL`; the declaration `VOA.QuasiLisseSl2.not_C2Cofinite_simpleSl2QL` (`AKSl2Payoff.lean`) has the same short name. At the snapshot it took a presentation `S` and `hex : S.IsExact`; a Lean check (not part of this release) showed the two are equal as proofs, so the hypotheses were redundant, and the library has since restated it without hypotheses, as `¬ C2Cofinite simpleSl2QL` proved by `Sl2NonLisse.not_C2Cofinite_simpleSl2QL`. The two twins now have identical types.

Proof on paper. Write h_0-charge for the eigenvalue of h_0 (e has charge 2, f has -2, h has 0). (i) The form is invariant, so $\langle h_0 x, y\rangle = -\langle x, h_0 y\rangle$ and vectors of different charge γ, γ' with $\gamma \neq -\gamma'$ are orthogonal; also different conformal weights are orthogonal. F_r has weight r and charge $-2r$. A homogeneous generator $u_{(-2)}v$ of $C_2(V)$ of weight r has $\mathrm{wt}\, u + \mathrm{wt}\, v = r - 1$; writing u, v in the word basis, each current contributes charge ≤ 2 and weight ≥ 1, so the charge is $\leq 2(r-1) < 2r$. Hence $\langle F_r, u_{(-2)}v\rangle = 0$. (ii) Move f_{-1} across with invariance ($f_{-1}^{\dagger} \sim e_1$) and use $e_1 E_r =$ an explicit multiple of E_{r-1}: one gets the recursion $\langle F_{r+1}, E_{r+1}\rangle = -(r+1)(k-r)\langle F_r, E_r\rangle$. (iii) If $\bar{E}_r \in C_2(L)$, lift: $C_2(L)$ is the image of $C_2(V)$, so $E_r = x + n$ with $x \in C_2(V)$ and n in the maximal ideal, which is the (right) radical $\{y : \langle x, y\rangle = 0\ \forall x\}$ of the form (Li's theorem: for a VOA of CFT type with $L_1 V_1 = 0$ the maximal proper ideal equals the radical of the canonical invariant form; Chapter 10, `LiRadical.rightRadical_eq_maxGradedIdeal`). Pairing with F_r gives $\langle F_r, E_r\rangle = 0$, contradicting (ii). The classes have distinct weights, so are independent. (iv) An infinite independent family. (v) Add Theorem 16.38. □

Physical meaning

$E_r = (J_{-1}^{+})^r \mathbf{1}$ is the chiral-algebra image of the Higgs-branch operator μ^r, the r-th power of the moment map's highest component, of $SU(2)_R$-spin r; and F_r is its conjugate. Their two-point function is nonzero, so these states are not null; and they are not "derivatives" (in C_2) because an excited mode costs energy without supplying charge. The infinite tower of Higgs-branch chiral ring elements is what makes the chiral algebra non-lisse.

What the machine verified

Proved, unconditional, pbw-free: `#print axioms` of `VOA.Sl2NonLisse.eHarmonicL_not_mem_O₂`, `VOA.Sl2NonLisse.not_C2Cofinite_simpleSl2QL`, `VOA.Sl2NonLisse.strictEtingofFinite_simpleSl2QL`: `[propext, Classical.choice, Quot.sound]` (re-run for this chapter).

Stale "non-lisseness is not proved" documentation (documentation only)

The module docstrings of `AffineSl2QuasiLisse.lean` ("`¬ C2Cofinite (simpleSl2QL)` is still NOT proved"), `AffineSl2Presentation.lean` ("`L-4⁄3(𝔰𝔩₂)` may NOT be described as 'proved non-lisse'"), `AKSl2Payoff.lean` ("`¬ C2Cofinite (L_{-4/3}(𝔰𝔩₂))` is NOT proved"), `AKSl2Instance.lean` (item 1, "NOT a non-lisse instance"), and the docstrings of `VOA.Sl2Pres.not_C2Cofinite_simpleSl2QL_of_exact`, `VOA.QuasiLisseSl2.`

`not_C2Cofinite_simpleSl2QL`, `character_formalODE_of_non_lisse_simpleSl2QL` and `character_formalODE_adjoint_of_non_lisse_simpleSl2QL` all said that non-lisseness is conditional on `Sl2ExactSymbol`. Already at the snapshot it was the unconditional Theorem 16.40. *Update (release audit, 2026-10-27):* these declaration docstrings and module headers have been corrected (by a later revision of the library); what remains in `AffineSl2Presentation.lean` is the correct statement that `Sl2Presentation.IsExact` (and `Sl2ExactSymbol`) is not proved.

Theorem 16.41 ($R_{L_{-4/3}} \neq 0$, two proofs). *$R_{L_{-4/3}}$ is a nonzero vector space.*

Files `VOA/Examples/AffineSl2QuasiLisse.lean`, `VOA/Examples/AffineSl2Presentation.lean`.

```
theorem A₂_simpleSl2QL_nontrivial : Nontrivial (A₂ simpleSl2QL) :=
  A₂_nontrivial simpleSl2QL vacuum_simpleSl2QL_ne_zero

theorem A₂_simpleSl2QL_nontrivial' : Nontrivial (A₂ simpleSl2QL) :=
  A₂_nontrivial simpleSl2QL vacuum_simpleSl2QL_ne_zero'
```

From the mathematics to the Lean statement

`Nontrivial X`: X has two distinct elements. The two proofs differ only in how the nonzero vacuum is obtained: the first (namespace `QuasiLisseSl2`) uses `AffineVOA.vacuumA_ne_zero`, which goes through `VOA.pbw` (an axiom at the snapshot, a theorem now); the second (namespace `Sl2Pres`) uses the Wakimoto realisation and does not use `VOA.pbw`. Since `VOA.pbw` is now a theorem, the difference has no axiom significance: both report Lean's three standard axioms only. Both are now implied by Theorem 16.40 (an infinite-dimensional space is nonzero).

Proof on paper. $C_2(V) \subseteq \bigoplus_{n\neq 0} V_n$ since $a_{(-2)}b$ has weight $\mathrm{wt}\,a + \mathrm{wt}\,b + 1 \geq 1$; so $[\mathbf{1}] \neq 0$ when $\mathbf{1} \neq 0$. □

Physical meaning

The identity operator is not a derivative: the classical phase space is non-empty.

What the machine verified

`VOA.QuasiLisseSl2.A₂_simpleSl2QL_nontrivial`: `[propext, Classical.choice, Quot.sound, VOA.pbw]` at the snapshot; now `[propext, Classical.choice, Quot.sound]` (re-probed at a later commit, after `VOA.pbw` became a theorem, not re-run for this edition; confirmed by the release audit). Its proof passes through the theorem `VOA.pbw`, which is no longer an axiom, so this carries no axiom significance. `A₂_simpleSl2QL_nontrivial'`: standard three only.

16.11 The payoff at $L_{-4/3}(\mathfrak{sl}_2)$

Theorem 16.42 (`VacuumGradeZero` is free). *For every library VOA, $V_0 \subseteq \mathbb{C}\mathbf{1}$.*

File `VOA/Modularity/AKSl2Payoff.lean`.

```
theorem vacuumGradeZero_of_vacuum_grade (W : VertexOperatorAlgebra 𝒱) : VacuumGradeZero W
↪  :=
  le_of_eq W.vacuum_grade
```

From the mathematics to the Lean statement

`W.vacuum_grade : W.grading 0 = ℂ • W.vacuum` is a structure field of `VertexOperatorAlgebra` (CFT type); `le_of_eq` weakens $=$ to $\leq$. So the hypothesis `hzero` carried by every theorem of Sections 16.4–16.7 is redundant in the strict sense (always satisfied); it is harmless.

Physical meaning

The vacuum is the unique state of zero energy.

What the machine verified

Proved, unconditional.

Theorem 16.43 (Generic payoff from a presentation). *If V has an $\mathfrak{sl}_2$ symbol presentation, then the character of every ordinary module with a conformal weight satisfies a formal equation (16.2); if the presentation is exact, V is moreover not C_2-cofinite.*

File `VOA/Modularity/AKSl2Payoff.lean`.

```
theorem character_formalODE_of_sl2Presentation (W : VertexOperatorAlgebra 𝒱)
    (P : Sl2Presentation W) (N : OrdVModule W M) {hw : ℂ} (hcw : HasConformalWeight N hw) :

theorem finiteDimensional_analyticBlocks_simpleSl2QL :
    FiniteDimensional ℂ (Submodule.map restrictImGT (analyticBlocks simpleSl2QL)) :=
```

From the mathematics to the Lean statement

All in `namespace VOA.Sl2Pres`. No hypotheses at all. `QSummableAt χ h τ` is `Summable (fun n : ℕ ⇒ χ (h + n) * (qParam τ) ^ n)` (`VOA/Modularity/ConvergenceBridge.lean`), the convergence of $\sum_n \dim L_n\, q^n$ at $q = e^{2\pi i\tau}$; here $h = -c/24 = 1/4$. Module carriers `M : Type` live in universe 0, matching `simpleSl2QL`. (i)–(iii) are formal equations in the weak sense of Section 16.5.6, **not** MLDEs; the file header says so ("NOT AK Theorem 5.1, and NOT a modular linear differential equation"). (iv) is genuine convergence. (v) is genuine (Theorem 16.31). **What is not here:** an MLDE for the character of $L_{-4/3}$ packaged as a statement about the character (the genuine MLDE for abstract analytic blocks is Theorem 16.30(ii), of unspecified order), and Zhu-type modular invariance (Theorem 16.32 needs `hfib`, `hrank`).

Proof on paper. Theorem 16.38(iv) gives Etingof-finiteness; Theorem 16.42 gives `hzero`; the vacuum of L is nonzero (pbw-free); now apply Theorems 16.22, 16.23, 16.16 and 16.31. □

Physical meaning

For the (A_1, A_3) Argyres–Douglas theory: the Schur index converges for $|q| < 1$ (the protected spectrum has subexponential growth) and the torus conformal blocks of its chiral algebra form a finite-dimensional space. The MLDE that Beem–Rastelli observe for this Schur index has order 2; the library proves only that the vacuum insertion of every analytic block satisfies *some* monic MLDE (Theorem 16.30(ii)), not one of these formal equations, and not the order.

What the machine verified

Proved, unconditional, pbw-free: `VOA.Sl2Pres.character_formalODE_simpleSl2QL_uncond`, `uniform_order_character_formalODE_simpleSl2QL`, `qSummable_character_simpleSl2QL`,

`finiteDimensional_analyticBlocks_simpleSl2QL: [propext, Classical.choice, Quot.sound]` (re-run).

Theorem 16.45 (The "non-lisse" conjunctions, as stated in the library). *$L_{-4/3}(\mathfrak{sl}_2)$ is not C_2-cofinite and its character satisfies a formal equation* (16.2).

Files `VOA/Modularity/AKSl2Instance.lean`, `VOA/Modularity/AKSl2Payoff.lean`.

```

               ↪ :=
```

From the mathematics to the Lean statement

The first is `VOA.Sl2Pres.character_formalODE_of_non_lisse_simpleSl2QL` (`AKSl2Instance.lean`); the other two are in `namespace VOA.QuasiLisseSl2` (`AKSl2Payoff.lean`). The hypotheses `hex : Sl2ExactSymbol, P, hex : P.IsExact` were **all redundant**: the conclusions hold hypothesis-free (checked in Lean; the check is not part of this release). After this finding the library removed them from these three flagships, whose current, hypothesis-free statements are quoted above.

Proof on paper. Theorem 16.40(iv) and Theorem 16.44(i). □

Physical meaning

This is the configuration in which Arakawa–Kawasetsu say something Zhu cannot: a chiral algebra with a continuous Higgs branch whose characters are nonetheless controlled. In the form proved, the control is convergence and a closed recursion, not modularity.

What the machine verified

Library: `Sl2Pres.character_formalODE_of_non_lisse_simpleSl2QL` standard three; the two `QuasiLisseSl2` flagship statements `character_formalODE_simpleSl2QL` and `character_formalODE_adjoint_of_non_lisse_simpleSl2QL: [propext, Classical.choice, Quot.sound, VOA.pbw]` at the snapshot; now `[propext, Classical.choice, Quot.sound]` (re-probed at a later commit, after `VOA.pbw` became a theorem, not re-run for this edition; confirmed by the release audit, 2026-10-27). At the snapshot they used `VOA.pbw` via `vacuum_simpleSl2QL_ne_zero`; the current source routes `QuasiLisseSl2.character_formalODE_`

`simpleSl2QL` through the Wakimoto `Sl2Pres.vacuum_simpleSl2QL_ne_zero'` instead. Either way, since `VOA.pbw` is now a theorem, "`pbw`-free" is no longer a property that `#print axioms` can detect or that carries any weight. **Content:** these are the near-vacuous formal equations of Section 16.5.6, not MLDEs.

16.12 Traps, dead ends, and Lean defects

Primarity is essential in Lemma 5.5 (recorded dead end)

`VOA/Modularity/UniCollapse.lean` refutes the unitriangular conversion (Theorem 16.20) when quantified over *all* vectors, via $v = L[-1]x$. An earlier note in `QuasiLisseFinite.lean` wrongly identified that refutation with AK Lemmas 5.4–5.6; the corrected note (Status item 1) explains that only Lemma 5.5 needs primarity and that the refuted instance is not primary.

Etingof-finiteness cannot supply Zhu's rank bound

`EtingofFinite W` bounds $V/O_2^P(V)$, not Zhu's algebra $A(V)$, since $a_{(0)}b \notin O(V)$ in general. So the rank hypothesis `hrank` of Theorem 16.32 stays open on the Etingof route (`AKZhuModularity.lean`, honesty item 2). Its satisfiability is witnessed only at the trivial VOA, which (the file notes) cannot distinguish it from a refuted legacy hypothesis.

Lean defects found while writing this chapter.

1. **Moderate: redundant hypotheses.** `hex : Sl2ExactSymbol` in `VOA.Sl2Pres.character_formalODE_of_non_lisse_simpleSl2QL`, `not_C2Cofinite_simpleSl2QL_of_exact`, `quasiLisseWitness_simpleSl2QL_of_exact`, `nilpEquiv_simpleSl2QL_of_exact` (the first three; the fourth needs it genuinely), and `S, hex` in `VOA.QuasiLisseSl2.not_C2Cofinite_simpleSl2QL`, `quasiLisseWitness_simpleSl2QL`, `character_formalODE_adjoint_of_non_lisse_simpleSl2QL`, and `S` or `P` in `QuasiLisseSl2.etingofFinite_simpleSl2QL`, `finiteDimensional_poissonTraces_simpleSl2QL`, `character_formalODE_simpleSl2QL` (`AffineSl2Presentation.lean`, `AffineSl2QuasiLisse.lean`, `AKSl2Instance.lean`, `AKSl2Payoff.lean`). Evidence: a Lean check against the library (not part of this release). Fix: restate with `Sl2NonLisse.not_C2Cofinite_simpleSl2QL`.

2. **Moderate: near-vacuous conclusion.** The formal ODE theorems (`character_formalODE_of_etingofFinite`, `uniform_order_character_formalODE_of_etingofFinite` and their instances) hold for any convergent q-series with zeros of bounded multiplicity in the disc (Proposition 16.24, on paper). Fix: state them as growth results, or use the E_4, E_6 route.

3. **Closed gap (formerly open): the genuine MLDE's side inputs.** `AKWeightGrading` is now inhabited for every VOA (`akWeightGrading`) and `E46SerreClosed` is `e46SerreClosed`, so `IsSqPrimary.exists_monicMLDEOn_all_analyticBlocks_of_etingofFinite_uncond` is conditional only on `EtingofFinite` (Theorem 16.30). **Documentation only:** the suffix `_uncond` is misleading, since the theorem keeps `hE`.

4. **Documentation only: stale docstrings** saying $L_{-4/3}(\mathfrak{sl}_2)$ is not proved non-lisse / only the trivial VOA is Etingof-finite / the presentation is never constructed: `QuasiLisseFinite.lean` (Status item 4, §7), `AKModularODE.lean` (header and `trivial_character_formalODE`), `AKUniformODE.lean` (`trivial_uniform_order_character_formalODE`), `AKZhuModularity.lean` (honesty item 1, headline docstring), `AffineSl2QuasiLisse.lean`, `AffineSl2Presentation.lean`, `AKSl2Payoff.lean`, `AKSl2Instance.lean`.

5. **Documentation only: name clash** (*partly resolved*). `VOA.QuasiLisseSl2.not_C2Cofinite_simpleSl2QL` (needed `S`, `hex` at the snapshot) and `VOA.Sl2NonLisse.not_C2Cofinite_simpleSl2QL` (unconditional); similarly `QuasiLisseSl2.etingofFinite_simpleSl2QL` (needed `S`) versus `Sl2Pres.etingofFinite_simpleSl2QL'`. At the release audit (2026-10-27) the `QuasiLisseSl2` twins in `AKSl2Payoff.lean` are hypothesis-free and have the same types as their `Sl2NonLisse`/`Sl2Pres` counterparts; the duplicate names remain.

6. **Documentation only: imprecise citation.** `Sl2ExactSymbol` is described as Arakawa's associated-variety theorem, which only gives the radical of the kernel (Definition 16.39 and its warning).

7. **Documentation only: unnecessary `pbw`** (*moot*). At the snapshot `QuasiLisseSl2.A₂_simpleSl2QL_nontrivial`, `QuasiLisseSl2.character_formalODE_simpleSl2QL`, `character_formalODE_adjoint_of_non_lisse_simpleSl2QL` depended on the then-axiom `VOA.pbw` although `pbw`-free twins existed. The two formal-ODE statements are now routed through the Wakimoto vacuum, and `VOA.pbw` is a theorem (`VOA/Foundations/AffineLie.lean`), so every declaration of this chapter reports Lean's three standard axioms and "without `VOA.pbw`" is not a meaningful selling point.

8. **Documentation only: overclaiming headline docstring** (release audit, finding 3). The docstring of `Sl2Pres.character_formalODE_simpleSl2QL_uncond` (`AKSl2Instance.lean`) calls the near-vacuous formal equation "THE HEADLINE" and "the Arakawa–Kawasetsu character equation", contradicting the disclaimers elsewhere in the same files. It should say "formal growth equation".

9. **Minor: redundant `hzero : VacuumGradeZero W`** (release audit, finding 6). It holds for every VOA (`vacuumGradeZero_holds`, `VOA/Modularity/BlockZeroMode.lean`) but is still an argument of `IsSqPrimary.exists_monicMLDEOn_all_analyticBlocks_of_etingofFinite`, `character_formalODE_of_etingofFinite`, `onePointSubexp_of_etingofFinite` and `finiteDimensional_analyticBlocks_of_etingofFinite`. Harmless.

16.13 Referee's checklist

Lean declaration	Intended meaning	Hypotheses / status	Fidelity check
`A₂Algebra`, `QuotVOA.A₂quot`	R_V is a $\mathbb{C}$-algebra; $R_V \twoheadrightarrow R_{V/I}$ Poisson	graded ideal; unconditional	Def. 16.6, Thm. 16.7
`poissonSpan`, `HP₀`, `poissonTraces`	$\{R,R\}$, $\mathrm{HP}_0(R_V)$, Poisson traces	definitions; standard	Def. 16.8
`EtingofFinite`	$\dim \mathrm{HP}_0(R_V) < \infty$	definition; **not** quasi-lisseness (weaker, by Etingof–Schedler)	Def. 16.9
`EtingofFinite_of_C2Cofinite`, `finiteDimensional_poissonTraces`	lisse ⇒ Etingof-finite; finite trace space	unconditional	Thm. 16.10
`etingofFinite_iff_quot_O₂P`	AK Thm. 2.2 upstairs	unconditional	Thm. 16.13
`vSqZ_zero_eq`, `sqDefect0_mem_of_lower`	$a[0]b = a_{(0)}b$+lower	unconditional	Thm. 16.14
`exists_finite_gen_sup_blockRelSpanG_of_etingofFinite`	AK Prop. 5.2	`hE`; `hzero` free	Thm. 16.15
`onePointSubexp_of_etingofFinite`	one-point functions converge	`hcw`, `hE`	Thm. 16.16

Lean declaration	Intended meaning	Hypotheses / status	Fidelity check
`IsSqPrimary`, `Lsq_tower`	primaries; Virasoro tower	unconditional	Def. 16.17, Thm. 16.18
`huni_of_sqPrimary`	AK Lemma 5.5 (θ-basis, $\mathcal{S}$-coefficients, block-dependent)	primary a	Thm. 16.20
`exists_monic_Lsq_relation_of_etingofFinite`	AK Lemma 5.3 (block form)	`hE`	Thm. 16.21
`character_formalODE_of_etingofFinite`	"AK eq. (2)" formal; **not an MLDE, not AK Thm. 5.1; near-vacuous** (Prop. 16.24)	`hcw`, `hE`	Thm. 16.22, Prop. 16.24
`exists_uniform_monic_Lsq_relation_of_etingofFinite`, `uniform_order_character_formalODE_of_etingofFinite`	uniform Lemma 5.3; uniform order only	`hE`	Thm. 16.23
`MonicMLDEOn`, `AKWeightGrading`, `E46SerreClosed`	genuine MLDE; grading data; Ramanujan closure	definitions; `AKWeightGrading` inhabited for every VOA (`akWeightGrading`); `E46SerreClosed` proved (`e46SerreClosed`)	Defs. 16.25, 16.26, Thm. 16.27
`IsSqPrimary.exists_monicMLDEOn_all_analyticBlocks_of_etingofFinite`	AK Thm. 5.1 (one MLDE for all blocks)	`hE`, `hgrade`, `hclose`; `hclose` discharged in the primed form	Thm. 16.29
`IsSqPrimary.exists_monicMLDEOn_all_analyticBlocks_of_etingofFinite_uncond`	AK Thm. 5.1, side inputs discharged	`hE` only (despite the name); order unbounded	Thm. 16.30
`exists_monicMLDEOn_all_analyticBlocks_simpleSl2QL`	one monic MLDE for all blocks of $L_{-4/3}$ at the vacuum	unconditional; order unspecified (AK's order 2 not proved)	Thm. 16.30
`finiteDimensional_analyticBlocks_of_etingofFinite`	Zhu 5.3.2 under `hE`	`hE`	Thm. 16.31
`exists_zhuModularity_of_sqAnalyticRank_le_irr_etingofFinite`	Zhu modularity under `hE`	`hE`, `hfib`, `hrank` (discharged only for the trivial VOA; `hrank` expected **false** at $L_{-4/3}$, paper argument)	Thm. 16.32
`QuasiLisseSl2.bigSub_eq_top`, `not_finiteDimensional_NilpAlg`, `finiteDimensional_quot_adRange`	classical model: infinite R, finite HP_0	unconditional	Thm. 16.34
`Sl2Presentation`, `.etingofFinite`, `.not_C2Cofinite`	presentations and consequences	presentation (+ exactness)	Def. 16.35, Thm. 16.36
`affineSl2QL`, `simpleSl2QL`	$V^{-4/3}(\mathfrak{sl}_2)$, $L_{-4/3}(\mathfrak{sl}_2)$	definitions; = `L43` of L09	Def. 16.37
`Sl2Pres.sl2PresentationSimpleSl2QL`, `etingofFinite_simpleSl2QL'`	presentation constructed; $L_{-4/3}$ Etingof-finite	**unconditional**, `pbw`-free	Thm. 16.38
`Sl2ExactSymbol`	exactness of the presentation	**unproved**; now redundant; citation imprecise	Def. 16.39

Lean declaration	Intended meaning	Hypotheses / status	Fidelity check
`Sl2NonLisse.not_C2Cofinite_simpleSl2QL`, `strictEtingofFinite_simpleSl2QL`	$L_{-4/3}$ not lisse, and Etingof-finite	**unconditional**, `pbw`-free	Thm. 16.40
`A₂_simpleSl2QL_nontrivial` (and `'`)	$R_L \neq 0$	unconditional; standard axioms (unprimed passes through the theorem `VOA.pbw`)	Thm. 16.41
`Sl2Pres.character_formalODE_simpleSl2QL_uncond` and siblings	formal ODE, convergence, finite blocks at $L_{-4/3}$	unconditional; formal ODE **near-vacuous**, not an MLDE	Thm. 16.44
`character_formalODE_of_non_lisse_simpleSl2QL` and `QuasiLisseSl2` flagships	not lisse $\wedge$ formal ODE (**not an MLDE**)	none (`hex/P` removed); standard axioms	Thm. 16.45

Verification record. Statements re-checked against the source for this chapter at the earlier commits indicated in its status boxes (the snapshot and a later re-probe); they were not re-run for this edition. Release audit 2026-10-27: see Notes/Textbook/referee/RELEASE_AUDIT_L16.md.

Project records. The honesty blocks in the module docstrings of the thirteen files of this chapter; the axiom audit `scripts/audit/AKZhuModularityAxiomAudit.lean`.

Part V

Super, logarithmic and unitary theories

Chapter 17

The super generalization

This chapter documents the release of the LeanVOA library named in the front matter; it was first written against an earlier state of the library, and checks that were run there and not re-run for this edition are marked as such. Every Lean quotation below is taken from the files of the release (docstrings and comments inside a quotation are omitted; the remaining text is machine-checked by `scripts/textbook/sync.py` to occur verbatim, up to whitespace, in the source; a line `...` marks an elision). The chapter covers the files assigned to it in `Notes/Textbook/assignment.txt`: in `VOA/Core/` the files `Super*.lean` and `DongSuper*.lean`; in `VOA/Examples/` the files `FreeFermion.lean`, `GhostSystem.lean`, `BCGhosts.lean`, `BetaGamma*.lean`, `SymplecticFermion*.lean`, `SympFerm*.lean` and `LatticeSuperAmbient*.lean`; in `VOA/Modules/` the files `Super*.lean`; and in `VOA/Modularity/` the files `Super*.lean`, `TwistedSuperSymmetricFunctionals.lean`, `ThetaHalfAutFactor.lean`, `HalfIntegralGridFoundations.lean`, `QueerOddTrace.lean` and `ThetaGroup.lean`. Together these are about one hundred and ten files and forty-five thousand lines. They are not a single theory with a single headline; they are a foundation (super vertex algebras, their Borcherds identity, their modules), four model examples (free fermion, *bc* ghosts, $\beta\gamma$ symplectic bosons, symplectic fermions), a super Zhu theory, and a large, explicitly incomplete programme for super and half-integral modularity. The chapter presents all of these, at the level of the statements on which the headlines rest. (The release audit of 2026-10-27 re-elaborated the headline statements at a later pre-release commit on branch `deligne-lean`, and re-verified the quotations below against the source at that commit; see Section 17.12.)

Some results of this chapter were checked in Lean by short checks written against the library; these checks are not part of the library or of this release.

17.1 What this chapter is about, and what it found

Ordinary vertex operator algebras (Chapters 1, 4, 12) describe the chiral algebra of a two-dimensional conformal field theory whose fields all *commute* at space-like separation and whose states all have *integer* conformal weight. Physics needs two generalisations at once. Fermions anticommute, so the locality axiom must carry a sign; and the energy-momentum tensor of a theory with fermions typically has half-integer eigenvalues on some states. The library generalises the axioms along two *independent* axes:

- **Axis A (weights).** The conformal-weight grading is indexed by $\mathbb{C}$ instead of $\mathbb{Z}$, so that weights $\frac{1}{2}, \frac{3}{2}, \ldots$ (and, for the lattice examples, arbitrary rational weights) are allowed. The mode index is *not* changed: a field is still $Y(u,z) = \sum_{n\in\mathbb{Z}} u_{(n)} z^{-n-1}$.
- **Axis B (parity).** A second grading by $\mathbb{Z}/2$ (even/odd, bosonic/fermionic) enters the locality axiom through the Koszul sign $(-1)^{|u||v|}$.

The relation "integer weight ⇔ even" (spin–statistics) is deliberately *not* an axiom; it is a separate predicate. The four model examples are chosen to separate the axes: the $\beta\gamma$ system is half-integrally graded and purely even; the *bc* system is integrally graded and odd; symplectic fermions are integrally graded and odd; the free fermion is both half-integral and odd.

What is solidly proved. The Koszul-signed formal calculus, Dong's lemma and Goddard uniqueness (§17.4); the full super Borcherds (Jacobi) identity in all three indices for a super near-VOA, and from it super skew-symmetry (§17.5); the canonical parity automorphism and the even part as an ordinary VOA (§17.6); the adjoint super module; two super VOA instances: symplectic fermions ($c = -2$), the *only* instance with genuinely odd states (so the only one in which the Koszul sign rule is exercised), and $\beta\gamma$ ($c = -1$), which is half-integrally graded but *purely even* (its parity is `ParityGrading.even`, so it never exercises the sign rule); and a super vertex algebra for the *bc* system in the library's weak sense, without translation covariance (§17.8); super C_2-cofiniteness and a *non-semisimple* super Zhu algebra of dimension *at most* 4 (and at least 1; exact dimension not proved) for symplectic fermions; failure of super C_2-cofiniteness together with super Etingof-finiteness for $\beta\gamma$; the honest associative super Zhu ring of every integrally graded super VOA; finite-dimensionality of twisted super Zhu quotients under C_2 (§17.9); the theta group $\Gamma_\theta = \langle S, T^2\rangle$ of index 3, a half-integral automorphy factor on it, the theta-characteristic S-law, the $(+,+)$ spin-sector S-cells, and a super Arike–Nagatomo upper bound (§17.10).

What is not proved. The project organises super modularity as a "four-by-three grid" (defined precisely in §17.11): four *columns*, one for each combination of integral or half-integral weights with purely even or genuinely super parity, and three *rows*, one for each known route to modular invariance (Zhu's rational route, the Arike–Nagatomo C_2-cofinite route, and the Arakawa–Kawasetsu quasi-lisse route). A cell is *complete* when the modular-invariance theorem of that route is proved for that class and instantiated by a model. The first column (integral, purely even) is the bosonic theory of earlier chapters; the other three are "new". No modular-invariance theorem exists in any of the three new columns of the grid; the free fermion exists only as a pair of anticommuting operator families; the *bc* Virasoro relation is stated and unproved; "symplectic fermions are not super-rational" is proved only *from a hypothesis that is itself the missing module*. Neither the free fermion nor "symplectic fermions are not super-rational" may be announced as a result.

Findings of this chapter (each is detailed in a `warning` box where it arises):

(F1) **`SuperTwistedModule` is uninhabitable for $N \geq 2$** (confirmed by a Lean check, Theorem 17.24). Its `jacobi` field has the same over-quantification as the pre-repair `TwistedModule.jacobi` of Chapter 34. Hence every parity-twisted (Ramond) carrier, every denominator-two half-integral trace carrier, the sector-rationality realization and the relative Etingof layer for twisted modules are statements about the zero vector space. **When this chapter was first written, and still in the released source (the `jacobi` field is unchanged), the only `SuperTwistedModule` with $N \geq 2$ is the zero module $M = 0$** (checked in Lean against the library; the check is not part of this release). Throughout this chapter, no statement about a `SuperTwistedModule` with $N \geq 2$ is presented as having mathematical content; wherever such a statement is mentioned, it is marked "(F1)" and called vacuous.

(F2) **`SuperVertexAlgebra` has no translation-covariance axiom**, exactly like the bosonic `PreVertexAlgebra` of Chapter 4: a Lean check (not part of this release) exhibits a super vertex algebra in the library's sense violating the super Jacobi identity (Theorem 17.4). The library is consistent with this: `superJacobi` is stated for `SuperNearVOA`, which has the axiom.

(F3) **Orientation defect** in `FreeFermion.psi`, `BCGhosts.bfield`, `BCGhosts.cfield`, `BetaGamma.beta`, `BetaGamma.gamma`: these are indexed by mode number while `FormalDist` is indexed by z-exponent, so they are not fields (not lower-truncated). Certificate for ψ (Theorem 17.27). Their locality statements remain true. The later files `GhostSystem.lean` and `BetaGammaField.lean` redo *bc* and $\beta\gamma$ correctly; nothing redoes the free fermion.

(F4) **`SympFerm.sympFermSVOA_not_isSuperRational` is conditional on `NonSplitSuperModule sympFermSVOA`, which is never constructed** and is essentially the conclusion. The status docstring of `SympFermIrrational.lean` is stale (it says the library has no super Jacobi identity).

(F5) **Super skew-symmetry exists twice**: gated (`skew_modeε`, conditional on `WeakAssocLocε`) in `Core/SuperSkew.lean`, and unconditional (`superSmul_eq_skew_Lpow`) in `Modularity/SuperZhuCommutator.lean`. The "gated" remarks in `Core/SuperSkew.lean`, `Core/ScreeningKernel.lean`, `Modules/SuperAdjointModule.lean` are stale.

(F6) *bc* **system**: `IsGhostVirasoro` is a `Prop`, not a theorem; the string value $c = -26$ is the arithmetic identity `ghostCentralCharge_two`; the grading and the super vertex algebra exist only at $\lambda = 1$.

(F7) **Twist conventions differ** between the bosonic `TwistedModule` (support $k \equiv -j$) and `SuperTwistedModule` (support $k \equiv j$) for the same eigenvalue $e^{-2\pi i j/N}$; harmless but undocumented.

(F8) `IsSuperRational` quantifies over `SympFermSuperOrdVModule`, a second copy of `SuperOrdVModule` that *lacks* the mode-weight axiom `weight_mode`; the library itself flags the name as non-standard.

Read first: `SuperTwistedModule` can only be the zero module for $N \geq 2$

The library structure `SuperTwistedModule W g N M`, for every super VOA W, every even automorphism g and every twist order $N \geq 2$, is inhabited only by the zero space $M = 0$. The cause is the over-quantified `jacobi` field (finding (F1)); the proof takes the `jacobi` field at $u = w = \mathbf{1}$, $\ell = -1$, $k = 1$, $m = -N - 1$ and is checked by Lean (Theorem 17.24; the check is not part of this release). The release audit of 2026-10-27 re-ran the check at a later pre-release commit and confirmed that **the defect was still present there**; at that commit the docstrings of `VOA/Modules/SuperTwistedModule.lean` carried no warning. In the released source the `jacobi` field is still over-quantified, and the docstrings of the file and of the structure now flag the defect. Twelve library files use the structure. Consequently **every claim about twisted or Ramond super modules is vacuous**: every parity-twisted (Ramond) carrier `ParityTwistedModule`, every half-integral (denominator-two) trace or supertrace carrier, the sector-rationality realization, irreducible twisted modules (`SuperTwistedModule.IsIrreducible`), the twisted zero-mode bridge to the twisted Zhu quotient, and the relative Etingof statements for twisted super modules are statements about the zero vector space. Throughout this chapter such statements are marked "(F1)" and *vacuous*; none of them may be announced. Only the identity-twist case $N = 1$ carries content. Twisted *Zhu quotients* $A_g(W)$ (an algebra-level construction, Theorem 17.45) do not involve the structure and are unaffected; only their intended link to twisted modules is.

How to read the chapter. Section 17.2 recalls conventions. Sections 17.3–17.6 are the foundations. Section 17.7 treats modules, including the defect (F1). Section 17.8 treats the examples, Section 17.9 Zhu algebras, Section 17.10 the modular toolkit, and Section 17.11 states precisely what each cell of the grid contains.

17.2 Conventions recalled

Modes and z-exponents. As everywhere in the library (Chapter 1, Example 1.1; Chapter 2), a formal distribution f with values in W is a function $\mathbb{Z} \to W$, $f(k)$ being the coefficient of z^k; the mode is `mode f n = f (-n - 1)`. For a field $Y(u,z) = \sum_n u_{(n)} z^{-n-1}$ one has `mode (Y u) n` $= u_{(n)}$, while `Y u k` $= u_{(-k-1)}$. The n-th product is `V.smul u n v` $= u_{(n)}v$. A distribution is a *field*

(`IsField`, `Core/Dong.lean`) when for every vector x the coefficients $f(k)x$ vanish for $k \ll 0$; that is $f(z)x \in W((z))$. We shall see (F3) that getting the direction of this indexing wrong is the commonest mistake in the early free-field files.

Physics modes. A field of conformal weight h is written by physicists as $\phi(z) = \sum_r \phi_r z^{-r-h}$, so $\phi_r = \phi_{(r+h-1)}$. For $h = \frac{1}{2}$ the physics modes are $r \in \mathbb{Z} + \frac{1}{2}$ while the vertex-algebra modes $n = r - \frac{1}{2}$ are integers. This is why Axis A does not touch the mode index.

Parity, the Koszul sign and the parity involution. The file `Foundations/Parity.lean` (Chapter 2) defines the following.

Definition 17.1 (Parity sign, Koszul sign). For $p \in \mathbb{Z}/2$ let $\mathrm{parSign}(p) = (-1)^p$, and for $p, q \in \mathbb{Z}/2$ let $\mathrm{koszul}(p,q) = (-1)^{pq}$, which is -1 exactly when $p = q = 1$.

File `VOA/Foundations/Parity.lean`.

```
def parSign (p : ZMod 2) : ℂ := if p = 0 then 1 else -1
...
def koszul (p q : ZMod 2) : ℂ := parSign (p * q)
```

From the mathematics to the Lean statement

`ZMod 2` is $\mathbb{Z}/2$, with elements `0` (even) and `1` (odd); the product $p * q$ is computed in $\mathbb{Z}/2$, so $\mathrm{koszul}(1,1) = \mathrm{parSign}(1) = -1$ and all other values are 1 (`koszul_one_one`, `koszul_zero_left`). The sign is a complex number, so it can multiply operators. This is the standard Koszul rule of Kac, *Vertex algebras for beginners* §1.3, $p(a,b) = (-1)^{p(a)p(b)}$.

Physical meaning

Exchanging two fermionic operators costs a minus sign; exchanging a boson with anything costs nothing. The Koszul sign is that rule, and it is the only place statistics enters the axioms.

Where the Koszul sign is used. The Koszul sign enters every super axiom and identity of this chapter in one way only: whenever two homogeneous objects of parities p, q are exchanged, a factor $\mathrm{koszul}(p,q)$ appears. Concretely: in the locality axiom VA4 (Definition 17.3) it is the scalar ε of ε-locality (Definition 17.2 below); in the super Jacobi identity (Theorem 17.14) it multiplies the term in which v acts before u; in skew-symmetry (Theorem 17.15) it is the overall sign; and in the supertrace it is the sign of cyclicity, $\mathrm{str}(fg) = \mathrm{koszul}(p,q)\,\mathrm{str}(gf)$.

What the machine verified

Definitions; standard axioms only (they appear in every `#print axioms` below).

A `ParityGrading` on a complex vector space M is a pair of subspaces $M_{\bar 0}, M_{\bar 1}$ forming an internal direct sum (Mathlib's `DirectSum.IsInternal`: every vector is uniquely a sum of an even and an odd vector). From it the library builds, without choosing a basis, the *parity involution* $(-1)^F$ (`parityInvol`, $+1$ on $M_{\bar 0}$ and -1 on $M_{\bar 1}$, defined as $2\pi_0 - \mathrm{id}$ with π_0 the projection onto $M_{\bar 0}$ along $M_{\bar 1}$). In a formula: for a homogeneous vector $u \in M_{\bar p}$,

$$(-1)^F u = (-1)^p\, u = \mathrm{parSign}(p)\, u,$$

and a general vector $u = u_{\bar 0} + u_{\bar 1}$ is sent to $u_{\bar 0} - u_{\bar 1}$. The library also builds the Koszul operator `koszulOp P p` $= ((-1)^F)^p$. The purely even grading `ParityGrading.even M` has $M_{\bar 0} = M$ and $M_{\bar 1} = 0$.

Super-locality. Chapter 2, Definition 2.44, defines for a scalar ε the twisted commutator and ε-locality.

Definition 17.2 (ε-twisted commutator, ε-locality). For operator-valued distributions a, b and $\varepsilon \in \mathbb{C}$, $[a,b]_\varepsilon(z_1,z_2) = a(z_1)b(z_2) - \varepsilon\, b(z_2)a(z_1)$ (coefficientwise), and a, b are ε-local if $(z_1 - z_2)^N [a,b]_\varepsilon = 0$ for some $N \in \mathbb{N}$.

File `VOA/Foundations/Locality.lean`.

```
def bracketDistε (ε : ℂ) (a b : FormalDist (Module.End ℂ V)) : FormalDist₂ (Module.End ℂ V)
↪  :=
  fun m n => a m ∗ b n - ε • (b n ∗ a m)
...
def Localε (ε : ℂ) (a b : FormalDist (Module.End ℂ V)) : Prop :=
  ∃ N : ℕ, mulBySubPow N (bracketDistε ε a b) = 0
```

From the mathematics to the Lean statement

`a m ∗ b n` is composition of the z_1^m-coefficient of a with the z_2^n-coefficient of b (exponent indexing). `mulBySubPow N` is multiplication by $(z_1 - z_2)^N$. The sign ε is a bare scalar: $\varepsilon = 1$ is ordinary locality (`localε_one_iff`) and the super case uses $\varepsilon = \mathrm{koszul}(p, q)$. Chapter 2, Theorem 2.47, proves the free-field criterion: if $[a_m, b_n]_\varepsilon = \delta_{m+n+1,0} S$ then a, b are ε-local with $N = 1$ (`localε_of_car`, `localε_neg_one_of_anticomm`). Note that this criterion is symmetric under reindexing $m \mapsto -m - 1$ in both slots, which is why locality cannot detect an orientation error (F3).

Physical meaning

$(z - w)^N [a(z), b(w)]_\varepsilon = 0$ says that the (anti)commutator is supported at $z = w$: fields (anti)commute at space-like separation, and their operator product has a pole of order at most N. For two fermions $\psi(z)\psi(w) \sim 1/(z - w)$ the anticommutator is a delta function and $N = 1$.

What the machine verified

Definitions (Chapter 2).

17.3 Super vertex algebras

17.3.1 The axioms

The library's definition of a super vertex algebra was quoted verbatim, field by field, in Chapter 1, §1.2.14, from `VOA/Core/SuperVertexAlgebra.lean`. We restate it mathematically and compare it with the literature.

Definition 17.3 (Super vertex algebra, library sense)**.** A *super vertex algebra* (`SuperVertexAlgebra` $\mathcal{V}$) on a complex vector space $\mathcal{V}$ consists of

- a grading $\mathcal{V} = \bigoplus_{h \in \mathbb{C}} \mathcal{V}_h$ (internal direct sum) with every $\mathcal{V}_h$ finite-dimensional (`grading`, `isInternal`, `finrank`);
- a second grading $\mathcal{V} = \mathcal{V}_{\bar{0}} \oplus \mathcal{V}_{\bar{1}}$ (`parity`, `parity_isInternal`);
- a linear map $Y : \mathcal{V} \to \mathrm{End}(\mathcal{V})[[z^{\pm 1}]]$ and a vector $\mathbf{1}$;

such that: $\mathbf{1} \in \mathcal{V}_0 \cap \mathcal{V}_{\bar{0}}$; (VA1) $u \in \mathcal{V}_h$, $v \in \mathcal{V}_k$ imply $u_{(n)}v \in \mathcal{V}_{h+k-n-1}$; (VA1′) $u \in \mathcal{V}_{\bar{p}}$, $v \in \mathcal{V}_{\bar{q}}$ imply $u_{(n)}v \in \mathcal{V}_{\overline{p+q}}$; (VA2) $Y(\mathbf{1}, z) = \mathrm{id}$; (VA3) $u_{(-1)}\mathbf{1} = u$ and $u_{(n)}\mathbf{1} = 0$ for $n \geq 0$; (VA4) for parity-homogeneous u, v of parities p, q, $Y(u, z)$ and $Y(v, z)$ are koszul(p, q)-local; (VA5) for all u, v there is N with $u_{(n)}v = 0$ for $n \geq N$. There is *no* translation operator and *no* translation-covariance axiom; because of this the super Borcherds identity can fail for such an object (finding (F2), Theorem 17.4), so this is weaker than (and incomparable with) a vertex superalgebra in Kac's sense. Translation covariance is added in Definition 17.8.

From the mathematics to the Lean statement

Decoding. Each clause of the definition is one field of the structure quoted in §1.2.14; `finrank` is a proposition (finite-dimensionality), not a number. Locality is demanded only for homogeneous pairs, which is the standard formulation (it cannot be demanded for inhomogeneous pairs, since the sign would not be defined).
Comparison with Kac. Kac (*Vertex algebras for beginners*, Definition 1.3 and §4.1) defines a vertex superalgebra as $(V, \mathbf{1}, T, Y)$ with $V = V_{\bar{0}} \oplus V_{\bar{1}}$, $Y(a,z)$ a field of parity $p(a)$, $T\mathbf{1} = 0$, $[T, Y(a,z)] = \partial_z Y(a,z)$ (translation covariance), $Y(\mathbf{1},z) = \mathrm{id}$, $Y(a,z)\mathbf{1}|_{z=0} = a$, and super-locality. The library's definition differs in three ways. (i) It *adds* a $\mathbb{C}$-grading with finite-dimensional pieces compatible with the modes (VA1); Kac has no grading in a vertex superalgebra. (ii) It *adds* VA1′ ("$Y(a,z)$ has parity $p(a)$"), which in Kac is part of the data. (iii) It *omits* the translation operator and translation covariance. Exactly as for the bosonic `PreVertexAlgebra` (Chapter 4, §4.5), omission (iii) is not harmless: the Borcherds identity does not follow (Theorem 17.4). So the library's `SuperVertexAlgebra` is *incomparable* with Kac's vertex superalgebra. With the conformal layer added (`SuperNearVOA`, Definition 17.8), translation covariance comes back through VOA3, and the notion becomes Kac's vertex superalgebra with a compatible $\mathbb{C}$-grading and conformal vector.
No spin–statistics. Nothing relates the two gradings. This is intended (Definition 17.5).
How it could have been wrong. An unsatisfiable axiom system is excluded by the instances of §17.8 (symplectic fermions, $\beta\gamma$, bc are genuine inhabitants with nonzero odd or half-integral parts) and by `PreVertexAlgebra.toSuper` below.

Physical meaning

States ↔ fields: $Y(u,z)$ is the local field creating the state u from the vacuum. Odd states create fermionic fields; the super-locality axiom says their operator products are radially ordered with the fermionic sign. The $\mathbb{C}$-grading is the spectrum of the dilatation operator L_0 (once a conformal vector is present); allowing $h \in \frac{1}{2} + \mathbb{Z}$ is needed for any theory with free fermions in the Neveu–Schwarz sector.

What the machine verified

A definition. `#print axioms VOA.SuperVertexAlgebra: [propext, Classical.choice, Quot.sound]` (run for this chapter).

Theorem 17.4 (No translation covariance). *There is a three-dimensional super vertex algebra in the library's sense (purely even, weights* 0 *and* 2*) on which the super Jacobi identity fails at* $(u,v,x,\ell,m,n) = (x_1, \mathbf{1}, \mathbf{1}, -2, 0, -2)$ *and on which* $Y(Tu,z) \neq \partial_z Y(u,z)$.

From the mathematics to the Lean statement

The example is the counterexample of Chapter 4, Theorem 4.7: $V = \mathrm{span}\{\mathbf{1}, x_1, y\}$, $Y(u,z) =$ multiplication by $\varphi_z(u)$ with $\varphi_z(x_1) = x_1 + z^2 y$, read as a super vertex algebra (`PreVertexAlgebra.toSuper`, Proposition 17.6). The failing identity is *exactly* the conclusion of `superJacobi` (Theorem 17.14) at parities $p = q = 0$.

Physical meaning

A "vertex algebra" without a momentum operator is not a chiral algebra: nothing ties the z-dependence of a field to the action of translations on states, and operator product associativity fails. Physically every chiral algebra has L_{-1}; the library adds it in `SuperNearVOA`.

Proof on paper. Since $\varphi_z(x_1)\mathbf{1}$ has no z^1 term, $Tx_1 = x_{1(-2)}\mathbf{1} = 0$, but $\partial_z Y(x_1, z) = 2zy \neq 0$. In the Jacobi identity at the stated indices the right side is $(x_{1(-2)}\mathbf{1})_{(-2)}\mathbf{1} = 0$ while the left side is $2\,x_{1(-3)}\mathbf{1} = 2y \neq 0$ (Chapter 4). □

What the machine verified

Checked in Lean against the library (the check is not part of this release); not a library theorem. `#print axioms` of both statements: `[propext, Classical.choice, Quot.sound]`.

Finding (F2): the bare super vertex algebra has the L03 defect

`SuperVertexAlgebra` omits translation covariance, so a theorem about a bare `SuperVertexAlgebra` cannot use the Borcherds identity. The library is consistent: Goddard uniqueness and Dong's lemma (which do not need it) are stated for `SuperVertexAlgebra`; the Borcherds/Jacobi identity, skew-symmetry and everything downstream are stated for `SuperNearVOA` or `SuperVertexOperatorAlgebra`. The danger is only in the name. The bosonic structure with the same omission was renamed `VOA.PreVertexAlgebra` for exactly this reason, the name `VertexAlgebra` now denoting the translation-covariant structure (Chapter 4); the super structure still carries the name `SuperVertexAlgebra` in the released source. Severity: moderate (the remedy is the one applied on the bosonic side).

Definition 17.5 (Spin–statistics). A super vertex algebra satisfies *spin–statistics* if every nonzero homogeneous vector u of weight h and parity p satisfies: $h \in \mathbb{Z}$ if and only if $p = \bar{0}$.

File `VOA/Core/SuperVertexAlgebra.lean`.

```
def SpinStatistics {V : Type u} [AddCommGroup V] [Module ℂ V]
    (W : SuperVertexAlgebra V) : Prop :=
  ∀ (h : ℂ) (p : ZMod 2) (u : V), u ≠ 0 → u ∈ W.grading h → u ∈ W.parity p →
    ((∃ m : ℤ, (m : ℂ) = h) ↔ p = 0)
```

From the mathematics to the Lean statement

"$h \in \mathbb{Z}$" is written $\exists m : \mathbb{Z},\ (m : \mathbb{C}) = h$. The quantification is over homogeneous nonzero u (an inhomogeneous vector has no single weight). It is a predicate, never a field; theorems needing it must say so. Kac's §4.1 notion "$V_{\bar{0}} = \bigoplus_{n\in\mathbb{Z}} V_n$, $V_{\bar{1}} = \bigoplus_{n\in\frac{1}{2}+\mathbb{Z}} V_n$" is this predicate together with half-integrality of all weights.

Physical meaning

The spin–statistics theorem of relativistic quantum field theory: integer spin ⇔ Bose statistics. In a chiral algebra the spin of a field is its conformal weight. Ghost systems (bc, $\beta\gamma$) and symplectic fermions violate it, because they are not unitary theories; the library must admit them, hence the predicate.

What the machine verified

A definition; standard axioms. It is satisfiable (Theorem 17.7) and fails for $\beta\gamma$ (`bgSVA_not_spinStatistics`, §17.8.3). For symplectic fermions its failure is noted in a docstring but not formalised.

Proposition 17.6 (Every vertex algebra is a super vertex algebra). *Every ordinary vertex algebra V (Chapter 4, Definition 4.1) defines a super vertex algebra with the same Y and vacuum, the $\mathbb{Z}$-grading pushed forward along $\mathbb{Z} \hookrightarrow \mathbb{C}$ (zero off the integers), and purely even parity.*

File `VOA/Core/SuperVertexAlgebra.lean`.

```
noncomputable def toSuper (V : PreVertexAlgebra 𝒱) : SuperVertexAlgebra 𝒱 where
  grading := V.gradingC
...
  parity := (ParityGrading.even 𝒱).parity
  parity_isInternal := (ParityGrading.even 𝒱).isInternal
  Y := V.Y
  vacuum := V.vacuum
```

From the mathematics to the Lean statement

`V.gradingC` is `extendGrading (fun n : ℤ ⇒ (n : ℂ)) V.grading`: equal to V_n at $h = n \in \mathbb{Z}$ and 0 elsewhere. The remaining fields are proved: locality at Koszul sign $\mathrm{koszul}(0,0) = 1$ is ordinary locality; pairs with an odd member are zero. The analogous `VertexOperatorAlgebra.toSuper` exists in `Core/SuperVertexOperatorAlgebra.lean`. So the super theory is a generalisation, not a parallel hierarchy.

Physical meaning

A bosonic chiral algebra is a fermionic one with no fermions. This embedding is what lets the super modularity statements specialise to the ordinary ones (the "integral non-super" column of §17.11).

Proof on paper. Internality of the pushed-forward grading is `isInternal_extend` (an internal decomposition reindexed along an injection, with zero pieces added, is still internal). Every other axiom is the bosonic one, the Koszul signs being 1. □

What the machine verified

`#print axioms`: standard (checked for the dependent theorem below).

Theorem 17.7 (Spin–statistics is satisfiable). *For every ordinary VOA W, the super VOA* `W.toSuper` *satisfies spin–statistics.*

File `VOA/Core/SuperVertexOperatorAlgebra.lean`.

```
theorem toSuper_spinStatistics (W : VertexOperatorAlgebra 𝒱) :
    SpinStatistics W.toSuper.toSuperVertexAlgebra := by
```

From the mathematics to the Lean statement

Unconditional. Its role is a non-vacuity check: the predicate is not malformed.

Physical meaning

A purely bosonic theory with integer weights trivially obeys spin–statistics.

Proof on paper. Every nonzero vector is even and has integer weight, so both sides of the equivalence hold. □

What the machine verified

`#print axioms VOA.VertexOperatorAlgebra.toSuper_spinStatistics: [propext, Classical.choice, Quot.sound].`

17.3.2 The conformal layer

Definition 17.8 (Super near-VOA). A *super near-VOA* is a super vertex algebra with an even vector $\omega \in V_2$ and $c \in \mathbb{C}$ such that $L_n := \omega_{(n+1)}$ satisfy the Virasoro relations with central charge c (VOA1), $L_0 v = hv$ for $v \in V_h$ (VOA2), and $Y(L_{-1}v, z) = \partial_z Y(v, z)$ for all v (VOA3).

File `VOA/Core/SuperNearVOA.lean`.

```
structure SuperNearVOA (V : Type u) [AddCommGroup V] [Module ℂ V]
    extends SuperVertexAlgebra V where
  conformalVector : V
  conformal_mem : conformalVector ∈ grading 2
  conformal_parity : conformalVector ∈ parity 0
  centralCharge : ℂ
  virasoro : ∀ m n : ℤ,
      ⁅mode (Y conformalVector) (m + 1), mode (Y conformalVector) (n + 1)⁆
        = ((m : ℂ) - n) • mode (Y conformalVector) (m + n + 1)
          + (if m + n = 0 then (((m : ℂ) ^ 3 - m) / 12 * centralCharge) • (1 : End ℂ V)
             else 0)
  L0_grading : ∀ {h : ℂ} (v : V), v ∈ grading h → mode (Y conformalVector) 1 v = h • v
  translation : ∀ v : V, Y (mode (Y conformalVector) 0 v) = deriv (Y v)
```

From the mathematics to the Lean statement

`mode (Y conformalVector) (m + 1)` is $\omega_{(m+1)} = L_m$; `⁅·,·⁆` is the commutator of endomorphisms; VOA1 reads $[L_m, L_n] = (m-n)L_{m+n} + \delta_{m+n,0}\frac{m^3-m}{12}c$. VOA2 has no cast because the grading index is the eigenvalue itself. VOA3 uses `mode (Y ω) 0` $= L_{-1}$, and `deriv` is coefficientwise ∂_z. The evenness of ω is an axiom (it does not follow, since spin–statistics is not assumed). Missing, by design: $V_0 = \mathbb{C}\mathbf{1}$ and "no weights of negative real part" (the CFT-type conditions), because ambient lattice algebras with background charge (§17.8.5) violate positivity. The weaker `BoundedBelow` ($\exists B \in \mathbb{R}$, $V_h = 0$ whenever $\operatorname{Re} h < B$) is a separate predicate. This is the super analogue of the bosonic `NearVOA` of Chapter 4.

Physical meaning

ω is the stress tensor $T(z) = \sum L_n z^{-n-2}$; c the central charge (conformal anomaly); L_0 the energy; L_{-1} the momentum ∂_z. The stress tensor is a bosonic field even in a fermionic theory, hence even.

What the machine verified

A definition; standard axioms.

Definition 17.9 (Super VOA). A *super vertex operator algebra* (`SuperVertexOperatorAlgebra`) has the same data and axioms as a super near-VOA, plus (VOA4) $V_0 = \mathbb{C}\mathbf{1}$ and $V_h = 0$ whenever $\operatorname{Re} h < 0$.

File `VOA/Core/SuperVertexOperatorAlgebra.lean`.

```
structure SuperVertexOperatorAlgebra (V : Type u) [AddCommGroup V] [Module ℂ V]
    extends SuperVertexAlgebra V where
...
  vacuum_grade : grading 0 = ℂ • vacuum
  positivity : ∀ h : ℂ, h.re < 0 → grading h = ⊥
```

From the mathematics to the Lean statement

The elided fields are verbatim those of `SuperNearVOA` (`conformalVector` through `translation`). `ℂ • vacuum` is the line spanned by **1**; `⊥` the zero subspace. Conversions: `SuperVertexOperatorAlgebra.toSuperNearVOA` (forget VOA4) and `SuperNearVOA.toSVOA W hvac hpos` (supply VOA4). Compared with Kac §4.1 and with Dong–Zhao's "vertex operator superalgebra", the library allows complex weights (they require $\frac{1}{2}\mathbb{Z}$) and does not require $\dim \mathcal{V}_h < \infty$ to come from a $\frac{1}{2}\mathbb{Z}_{\geq 0}$-grading; these are generalisations, and every theorem below states the integrality it needs: `IntegralWeights` says $\mathcal{V}_h = 0$ unless $h \in \mathbb{Z}$, and `IsHalfIntegerGraded` says $\mathcal{V}_h = 0$ unless $h \in \frac{1}{2}\mathbb{Z}$ (both are predicates on the weight grading, defined in `Core/SuperEvenPart.lean` and `Modularity/GammaThetaStatement.lean` respectively, and recalled where they are used).

Physical meaning

CFT type: a unique vacuum and energy bounded below by zero, as in a unitary theory. Symplectic fermions and $\beta\gamma$ at $\lambda = \frac{1}{2}$ are CFT type though non-unitary.

What the machine verified

A definition; standard axioms.

Theorem 17.10 (Dong's lemma for super vertex algebras). *If u, v, w are homogeneous of parities p, q, r, then for every $k \geq 0$ the field $Y(u,z)_{(k)}Y(v,z)$ (the k-th OPE coefficient of the* koszul(p,q)*-twisted commutator) is* koszul$(p+q,r)$*-local with $Y(w,z)$.*

File `VOA/Core/SuperVertexAlgebra.lean`.

```
theorem dong_fields (V : SuperVertexAlgebra 𝒱) {p q r : ZMod 2} {u v w : 𝒱}
    (hu : u ∈ V.parity p) (hv : v ∈ V.parity q) (hw : w ∈ V.parity r) (k : ℕ) :
    Localε (koszul (p + q) r)
      (cCoeff k (bracketDistε (koszul p q) (V.Y u) (V.Y v))) (V.Y w)
```

From the mathematics to the Lean statement

`cCoeff k F` is $\mathrm{Res}_{z_1}(z_1-z_2)^k F(z_1,z_2)$, the k-th OPE coefficient (Chapter 4, §4.2); for $k \geq 0$ it is the field $Y(u_{(k)}v,z)$ once Borcherds is known. The sign of the product field is koszul$(p+q,r)$, exactly the Koszul sign of a state of parity $p+q$, as VA1′ predicts. The general ε-generic Dong lemma (`dong_nonnegε`, `Core/DongSuper.lean`) needs only $\varepsilon_{ab}^2 = 1$, which for Koszul signs is `koszul_mul_self`; negative products are in `Core/DongSuperNeg.lean` (`dong_negε`). Kac, Lemma 3.2 (super version).

Physical meaning

The OPE of two local fields produces local fields, with the statistics of the product: two fermions make a boson. This is what makes the operator algebra close.

Proof on paper. The bosonic proof (Chapter 4, Theorem 4.16) multiplies the three-variable Jacobi identity of commutators by a large power of $(z_1 - z_3)$ and $(z_2 - z_3)$. With signs, the twisted Jacobi identity $[[a,b]_{ab},c]_{ac\,bc} = [a,[b,c]_{bc}]_{ab\,ac} - \varepsilon_{ab}[b,[a,c]_{ac}]$ holds provided $\varepsilon_{ab}^2 = 1$ (the residual otherwise is $(1-\varepsilon_{ab}^2)$ times a nonzero expression), and the sign of the composite is $\varepsilon_{(ab)c} = \varepsilon_{ac}\varepsilon_{bc}$, i.e. `koszul_add_left`. □

What the machine verified

`#print axioms VOA.SuperVertexAlgebra.dong_fields:` `[propext, Classical.choice, Quot.sound]`. Unconditional.

17.4 Goddard uniqueness with signs

Theorem 17.11 (Goddard uniqueness, ε-generic core). *Let A be an operator-valued distribution, $a, b \in \mathcal{V}$ and $\varepsilon \in \mathbb{C}$ arbitrary. If A and $Y(a,z)$ are both ε-local with $Y(b,z)$, and $A(z)\mathbf{1} = Y(a,z)\mathbf{1}$ coefficientwise, then $A(z)b = Y(a,z)b$.*

File `VOA/Core/SuperGoddard.lean`.

```
theorem goddard_pointwiseε (V : SuperVertexAlgebra 𝒱) (A : FormalDist (End ℂ 𝒱)) (a : 𝒱)
    (ε : ℂ) (b : 𝒱) (hAloc : Localε ε A (V.Y b)) (hVloc : Localε ε (V.Y a) (V.Y b))
    (hAvac : ∀ m : ℤ, A m V.vacuum = (V.Y a) m V.vacuum) (m : ℤ) :
    A m b = (V.Y a) m b
```

From the mathematics to the Lean statement

`A m` is the z^m-coefficient. The conclusion is for every m, i.e. $A(z)b = Y(a,z)b$. No parity hypothesis: ε is any scalar, the *same* for both locality hypotheses. No translation operator is used, so the statement is correctly placed at the bare level.

Physical meaning

A local field is determined by the state it creates: there is one field per state. This is the uniqueness half of the state–field correspondence, and it does not care about statistics.

Proof on paper. Let $D(z,w) = A(z)Y(b,w)\mathbf{1} - Y(a,z)Y(b,w)\mathbf{1}$. Using the creation hypothesis, D is the difference of the two twisted brackets applied to $\mathbf{1}$ (the ε-terms $\varepsilon Y(b,w)A(z)\mathbf{1}$ and $\varepsilon Y(b,w)Y(a,z)\mathbf{1}$ coincide and cancel). Hence $(z-w)^N D = 0$ for large N. But D has no negative powers of w (VA3), and in $\mathcal{V}((z))[[w]]$ the element $z-w$ is not a zero divisor, so $D = 0$; setting $w = 0$ gives $A(z)b = Y(a,z)b$. □

What the machine verified

`#print axioms VOA.SuperVertexAlgebra.goddard_pointwiseε:` `[propext, Classical.choice, Quot.sound]`. Unconditional.

Theorem 17.12 (Goddard uniqueness for super vertex algebras). *Let $a \in \mathcal{V}_{\bar{p}}$ and let A be a distribution that is* koszul(p,q)*-local with $Y(b,z)$ for every q and every $b \in \mathcal{V}_{\bar{q}}$, and creates the same vacuum tower as $Y(a,z)$. Then $A = Y(a,z)$.*

File `VOA/Core/SuperGoddard.lean`.

```
theorem goddard_uniquenessε (V : SuperVertexAlgebra 𝒱) (A : FormalDist (End ℂ 𝒱)) (a : 𝒱)
    {p : ZMod 2} (_ha : a ∈ V.parity p)
    (hAloc : ∀ (q : ZMod 2) (b : 𝒱), b ∈ V.parity q → Localε (koszul p q) A (V.Y b))
    (hAvac : ∀ m : ℤ, A m V.vacuum = (V.Y a) m V.vacuum) :
    A = V.Y a
```

From the mathematics to the Lean statement

The hypothesis `_ha` is used (the underscore is only a naming style): it supplies `V.locality a _ha b₀ hb₀`. The conclusion is equality of distributions. Inhomogeneous b are handled

by splitting $b = b_0 + b_1$; the conclusion is linear in b although locality is not. Matches Kac, Theorem 4.4 (super case) and Frenkel–Ben-Zvi §3.1.

Physical meaning

Same as above: uniqueness of the field attached to a state, for bosons and fermions alike.

Proof on paper. Apply Theorem 17.11 to the even and odd parts of b, with $\varepsilon = \mathrm{koszul}(p,0)$ and $\mathrm{koszul}(p,1)$ respectively, using VA4 for $Y(a,z)$. □

What the machine verified

`#print axioms VOA.SuperVertexAlgebra.goddard_uniquenessε:` `[propext, Classical.choice, Quot.sound]`. Unconditional.

The super reconstruction theorem `reconstructε` (`Core/SuperReconstruction.lean`) is the existence counterpart: from a spanning family of states with T-covariant, mutually Koszul-local generating fields and the vacuum conditions, it produces a linear Y with the creation, locality and covariance properties. It is the super analogue of the operator-first reconstruction of Chapter 4, Theorem 4.41, and it is how every example of §17.8 obtains its vertex operator. Its proof uses Theorem 17.11 and the super Dong lemma; translation covariance of normal-ordered products is `DCovariant.nprodε` in `Core/SuperCovariant.lean`, whose key observation is that the twisted normal-ordered product differs from the bosonic one by a scalar depending only on the first mode index.

17.5 The super Borcherds identity and skew-symmetry

Definition 17.13 (The two sides of the super Borcherds identity)**.** For a super near-VOA V, vectors u, v, x, a scalar ε and $\ell, m, n \in \mathbb{Z}$ put

$$B_R(u,v,x;\ell,m,n) = \sum_{i\ge 0} \binom{m}{i} (u_{(\ell+i)}v)_{(m+n-i)}x,$$

$$B_L^{\varepsilon}(u,v,x;\ell,m,n) = \sum_{i\ge 0} (-1)^i \binom{\ell}{i} \Big(u_{(\ell+m-i)}v_{(n+i)}x - \varepsilon(-1)^{\ell}\, v_{(\ell+n-i)}u_{(m+i)}x \Big).$$

```

From the mathematics to the Lean statement

`cbz m i` is the generalised binomial coefficient $\binom{m}{i}$ for $m \in \mathbb{Z}$, $i \in \mathbb{Z}$, equal to 0 for $i < 0$ (Chapter 4, Definition 4.24); so the $\mathbb{Z}$-indexed `finsum` $\sum^{\mathrm{f}}$ is really over $i \ge 0$, and it has finite support by VA5 even when $m < 0$. `negOnePow i` is $(-1)^i$. The exchanged term carries the single scalar $\varepsilon(-1)^{\ell}$; all sign-free parts are literally the bosonic ones of Chapter 4.

Physical meaning

B_L is the contour-deformation side of the OPE (the difference of the two radial orderings of $u(z)v(w)$, with the fermionic sign on the reversed ordering); B_R is the OPE side (the fields appearing in $u \times v$). Their equality is operator-product associativity.

What the machine verified

Definitions; standard axioms.

Theorem 17.14 (Super Borcherds / Jacobi identity). *Let V be a super near-VOA, $u \in V_{\bar{p}}$, $v \in V_{\bar{q}}$, $x \in V$. For all $\ell, m, n \in \mathbb{Z}$,*

$$\sum_{i\geq 0}(-1)^i\binom{\ell}{i}\Big(u_{(\ell+m-i)}v_{(n+i)}x - (-1)^{pq}(-1)^{\ell}\, v_{(\ell+n-i)}u_{(m+i)}x\Big) = \sum_{i\geq 0}\binom{m}{i}(u_{(\ell+i)}v)_{(m+n-i)}x.$$

File `VOA/Core/SuperBorcherds.lean`.

```

From the mathematics to the Lean statement

Index dictionary with Kac. Kac's (4.8.3) (super case, *Vertex algebras for beginners*) reads $\sum_j \binom{m}{j}(a_{(n+j)}b)_{(m+k-j)}c = \sum_j (-1)^j\binom{n}{j}\big(a_{(m+n-j)}b_{(k+j)}c - p(a,b)(-1)^n b_{(n+k-j)}a_{(m+j)}c\big)$. Renaming Kac's (n, m, k) as the library's (ℓ, m, n) gives the library statement character for character, including the position of the sign. The quantifiers are "for all homogeneous u, v, all x, all $\ell, m, n \in \mathbb{Z}$": the full identity, not a slice. Inhomogeneous u, v are not covered, since the sign is undefined; by linearity nothing is lost.
Hypotheses. Only the structure `SuperNearVOA` (no CFT type, no spin–statistics, no integrality of weights) and parity homogeneity. The second form is the first unfolded (`BL_as_finsumε`).
Why it is not vacuous. It is consumed definitionally as the `jacobi` field of the adjoint super module (Proposition 17.21), and it is the input to the super Zhu ring (Theorem 17.43); at $p = 0$ it reduces to the bosonic Jacobi identity (`superJacobi_even_left`).

Physical meaning

This is the full OPE associativity of a fermionic chiral algebra: for every choice of three contour exponents, the reordered product of $u(z)$ and $v(w)$, with the minus sign for two fermions, equals the field of the OPE coefficients. All the usual consequences (the commutator formula $[u_{(m)}, v_{(n)}]_{\pm} = \sum\binom{m}{i}(u_{(i)}v)_{(m+n-i)}$, the associativity/normal-ordering formula) are special cases ($\ell = 0$, resp. $m = 0$).

Proof on paper. Exactly as in the bosonic case (Chapter 4, Theorem 4.26). Both sides satisfy the Pascal recursion $B(\ell, m+1, n) = B(\ell, m, n+1) + B(\ell+1, m, n)$; the sign $\varepsilon(-1)^{\ell}$ is constant in m, n and changes by -1 under $\ell \mapsto \ell + 1$, exactly as $(-1)^{\ell}$ does in the bosonic recursion. So it suffices to know two boundary lines. At $m = 0$ the identity is the iterate (associativity) formula

$(u_{(\ell)}v)_{(n)} = \sum_i (-1)^i \binom{\ell}{i}(u_{(\ell-i)}v_{(n+i)} - \varepsilon(-1)^\ell v_{(\ell+n-i)}u_{(i)})$ (`mode_iterateε`), proved for $\ell \geq 0$ from the n-th product theorem (Dong's lemma plus Goddard uniqueness plus translation covariance) and for $\ell < 0$ from the twisted normal-ordered product, where the Koszul factor sits precisely on the reordered branch. At $\ell = 0$ it is the commutator formula $[u_{(m)}, v_{(n)}]_\varepsilon = \sum_i \binom{m}{i}(u_{(i)}v)_{(m+n-i)}$ (`commBoundε`), which follows from the ε-generic OPE decomposition (Chapter 2, Theorem 2.46). Induction on m in both directions, with the anti-diagonal pin of Chapter 4, closes the argument. Translation covariance enters through the n-th product theorem, which is why the statement needs `SuperNearVOA`. □

What the machine verified

`#print axioms VOA.SuperNearVOA.superBorcherds` and `VOA.SuperNearVOA.superJacobi`: `[propext, Classical.choice, Quot.sound]`. Unconditional.

17.5.1 Skew-symmetry

Skew-symmetry $Y(u,z)v = (-1)^{|u||v|}e^{zT}Y(v,-z)u$ exists twice in the library.

Theorem 17.15 (Super skew-symmetry, unconditional). *Let V be a super near-VOA, $a \in V_{\tilde{p}}$, $b \in V_{\tilde{q}}$. For every $t \in \mathbb{Z}$,*

$$b_{(t)}a = (-1)^{pq} \sum_{j \geq 0} \frac{(-1)^{t+j+1}}{j!} L_{-1}^j (a_{(t+j)}b).$$

File `VOA/Modularity/SuperZhuCommutator.lean`.

```
theorem superSmul_eq_skew_Lpow {p q : ZMod 2} {a b : V}
    (ha : a ∈ V.parity p) (hb : b ∈ V.parity q) (t : ℤ) :
    V.smul b t a
      = koszul p q • ∑ᶠ j : ℕ, ((j.factorial : ℂ)⁻¹) •
          (sgn (-t - 1 - (j : ℤ))) •
            ((V.L (-1) ^ j) (V.smul a (t + (j : ℤ)) b))
```

From the mathematics to the Lean statement

`V` is a `SuperNearVOA` (file variable). `sgn k` $= (-1)^k$ (`Core/Skew.lean`), so `sgn (-t-1-j)` $= (-1)^{t+j+1}$. `V.L (-1) ^ j` is L_{-1}^j; the sum is finite by VA5. This is Kac's (4.2.1)/(4.8.6) in modes: $b_{(n)}a = p(a,b)\sum_j (-1)^{n+j+1} T^{(j)}(a_{(n+j)}b)$ with $T^{(j)} = T^j/j!$ and $T = L_{-1}$; it is the coefficient form of $Y(b,z)a = p(a,b)e^{zT}Y(a,-z)b$.

Physical meaning

Exchanging the two operators in an OPE: $b(z)a(0) = \pm e^{zL_{-1}}a(-z)b(0)$, the translation moving the insertion point from 0 to z. For two fermions the sign is -1; e.g. for a free fermion $\psi_{(0)}\psi = \mathbf{1}$ is symmetric under the exchange only because of the sign.

Proof on paper. Take the Jacobi identity with $x = \mathbf{1}$, $u = a$, $v = b$, $\ell = t$, $m = -1$, $n = 0$. On the left only the $i = 0$ term of the first sum survives and gives $a_{(t-1)}b_{(0)}\mathbf{1} = 0$, while the second sum gives $-\varepsilon(-1)^t \sum_i (-1)^i \binom{t}{i} b_{(t-i)}a_{(-1+i)}\mathbf{1}$, in which only $i = 0$ survives: $-\varepsilon(-1)^t b_{(t)}a$. The right side is $\sum_i \binom{-1}{i}(a_{(t+i)}b)_{(-1-i)}\mathbf{1} = \sum_i (-1)^i L_{-1}^i (a_{(t+i)}b)/i!$ by the creation formula $w_{(-1-i)}\mathbf{1} = L_{-1}^i w/i!$. Solve for $b_{(t)}a$. □

What the machine verified

`#print axioms VOA.SuperNearVOA.superSmul_eq_skew_Lpow`: `[propext, Classical.choice, Quot.sound]`. Unconditional.

Proposition 17.16 (Super skew-symmetry, gated version). *In a super VOA W, for $u \in W_{\bar{p}}$, $v \in W_{\bar{q}}$, if the skew candidate field $v \mapsto (-1)^{pq} e^{zT} Y(v,-z)u$ is Koszul-local with every $Y(b,z)$ (the "gate"* `WeakAssocLocε W u p`*), then the mode form of skew-symmetry holds.*

File `VOA/Core/SuperSkew.lean`.

```
def WeakAssocLocε (W : SuperVertexOperatorAlgebra 𝒱) (u : 𝒱) (p : ZMod 2) : Prop :=
  ∀ (q : ZMod 2) (b : 𝒱), b ∈ W.parity q → Localε (koszul p q) (skewDistε W u p) (W.Y b)
...
theorem skew_modeε (W : SuperVertexOperatorAlgebra 𝒱) (u v : 𝒱) {p q : ZMod 2}
    (hu : u ∈ W.parity p) (hv : v ∈ W.parity q) (hloc : WeakAssocLocε W u p) (n : ℤ) :
    W.smul u n v
      = koszul p q • ∑ᶠ j : ℕ, ((j.factorial : ℂ)⁻¹) • (sgn (-n - 1 - j)) •
          ((W.L (-1) ^ j) ((W.Y v) (-n - 1 - j) u))
```

From the mathematics to the Lean statement

`(W.Y v) (-n - 1 - j) u` is the z^{-n-1-j}-coefficient, i.e. $v_{(n+j)}u$; so this is Theorem 17.15 with the roles of the two vectors named differently. The gate `WeakAssocLocε` is never discharged in `Core/`: the file reduces it to the sign-free `SkewVacLocal₀` (`Core/SuperWeakAssoc.lean`, `skew_modeε_of_signFree`) and stops. The conclusion is nevertheless true for every super VOA, by Theorem 17.15 applied to `W.toSuperNearVOA`.

Physical meaning

Same content as Theorem 17.15; the gated route follows the bosonic history in which skew-symmetry was proved from Goddard uniqueness before Borcherds was available.

What the machine verified

`#print axioms VOA.SuperVertexOperatorAlgebra.skew_modeε:` `[propext, Classical.choice, Quot.sound]`; conditional on `hloc : WeakAssocLocε W u p`, which is never proved.

Finding (F5): a superseded gate and stale documentation

The conditional `skew_modeε` is superseded by the unconditional `superSmul_eq_skew_Lpow`, which is derived from `superJacobi`. The remarks "super skew-symmetry is still gated on `WeakAssocLocε`" in `Core/ScreeningKernel.lean`, `Examples/DSReductionSl2.lean` and `Modules/SuperAdjointModule.lean` ("the `conformal` hypothesis …still waits on the super skew gate") are stale. Severity: documentation only. Remedy: derive `WeakAssocLocε` (or delete the gated route) from `superSmul_eq_skew_Lpow`.

17.6 Automorphisms and the even part

Definition 17.17 (Even automorphism). An (even) automorphism of a super VOA W is a linear bijection g with $g(u_{(n)}v) = (gu)_{(n)}(gv)$ for all u, v, n, $g\mathbf{1} = \mathbf{1}$, $g\omega = \omega$, and $gW_{\bar{p}} = W_{\bar{p}}$.

File `VOA/Core/SuperAutomorphism.lean`.

```
structure SuperAut (W : SuperVertexOperatorAlgebra 𝒱) where
  toLinearEquiv : 𝒱 ≃ₗ[ℂ] 𝒱
  map_smul' : ∀ (u : 𝒱) (n : ℤ) (v : 𝒱),
    toLinearEquiv (W.smul u n v) = W.smul (toLinearEquiv u) n (toLinearEquiv v)
  map_vacuum : toLinearEquiv W.vacuum = W.vacuum
```

```
  map_omega : toLinearEquiv W.conformalVector = W.conformalVector
  map_parity' : ∀ (p : ZMod 2) (u : V),
    toLinearEquiv u ∈ W.parity p ↔ u ∈ W.parity p
```

From the mathematics to the Lean statement

$V \simeq_{\mathbb{C}[\mathbb{C}]} V$ is a $\mathbb{C}$-linear bijection. Preservation of the conformal weights is a theorem (`map_mem_grading`: g commutes with $L_0 = \omega_{(1)}$). Only parity-preserving automorphisms are considered; this is the standard notion for twisted modules of super VOAs (Dong–Zhao). The automorphisms form a group (`instance : Group (SuperAut W)`).

Physical meaning

Global internal symmetries of the chiral algebra that commute with the stress tensor and with fermion number. Twisting by such a symmetry gives the twisted sectors (orbifold theory). (In the library the twisted-sector structure `SuperTwistedModule` is, for every twist of order $N \geq 2$, inhabited only by the zero space; see the warning before Definition 17.23.)

What the machine verified

A definition; standard axioms.

Theorem 17.18 (The parity automorphism). *For every super VOA W the fermion-number involution $\sigma = (-1)^F$ is an even automorphism, $\sigma u = (-1)^p u$ on $W_{\bar{p}}$, $\sigma^2 = 1$, and σ has order exactly 2 when $W_{\bar{1}} \neq 0$ (and is the identity when $W_{\bar{1}} = 0$).*

File `VOA/Core/SuperAutomorphism.lean`.

```
noncomputable def parityAut (W : SuperVertexOperatorAlgebra V) : SuperAut W where
  toLinearEquiv := W.parityGrading.parityLinearEquiv
...
theorem parityAut_homog (W : SuperVertexOperatorAlgebra V) {p : ZMod 2} {v : V}
    (hv : v ∈ W.parity p) : W.parityAut v = parSign p • v :=
...
theorem orderOf_parityAut_eq_two (W : SuperVertexOperatorAlgebra V)
    (hodd : W.parity 1 ≠ ⊥) : orderOf W.parityAut = 2 :=
```

From the mathematics to the Lean statement

The hypothesis `hodd` is necessary (without odd vectors $\sigma = 1$, `parityAut_eq_one_of_odd_eq_bot`). The mode law $\sigma(u_{(n)}v) = (\sigma u)_{(n)}(\sigma v)$ is VA1′ plus $\mathrm{parSign}(p+q) = \mathrm{parSign}(p)\,\mathrm{parSign}(q)$.

Physical meaning

$(-1)^F$ is a symmetry of every fermionic theory. Twisting by it changes the boundary condition of fermions around the spatial circle from Neveu–Schwarz to Ramond; inserting it in a trace changes the temporal boundary condition (the supertrace). The four combinations are the four spin structures on the torus (§17.10). Caution: the automorphism σ itself is genuine, but the library's Ramond-sector carrier `W.ParityTwistedModule M`, i.e. `SuperTwistedModule W W.parityAut 2 M`, is inhabited only by $M = 0$ (F1, Theorem 17.24); so only the temporal (supertrace) half of this picture has content in Lean.

What the machine verified

`#print axioms VOA.SuperVertexOperatorAlgebra.orderOf_parityAut_eq_two:` `[propext, Classical.choice, Quot.sound]`. Unconditional.

Theorem 17.19 (The even part is an ordinary VOA). *Let W be a super VOA whose even part has only integer weights. Then $W_{\bar{0}}$, with the restricted vertex operators, vacuum and conformal vector, is a* `VertexOperatorAlgebra` *of the same central charge, with weight spaces $(W_{\bar{0}})_n = W_n \cap W_{\bar{0}}$.*

File `VOA/Core/SuperEvenPart.lean`.

```
noncomputable def evenPartVOA (W : SuperVertexOperatorAlgebra 𝒱)
    (hint : ∀ h : ℂ, (¬ ∃ n : ℤ, (n : ℂ) = h) → ∀ x ∈ W.parity 0, x ∈ W.grading h → x = 0)
    ↪ :
    VertexOperatorAlgebra (W.parity 0) :=
```

From the mathematics to the Lean statement

The carrier is the subtype `W.parity 0`. `hint` is the integrality of the even part, a genuine hypothesis (it fails for ambient algebras with weight-$\frac{5}{2}$ states). The identifications of Y, $\mathbf{1}$, ω, c and the grading with the ambient ones are `rfl`-lemmas (`evenPartVOA_Y_coe`, `evenPartVOA_grading`, …), so this is the even part and not some other VOA structure on the same space.

Physical meaning

The bosonic subalgebra of a fermionic theory is the $\mathbb{Z}/2$-orbifold by $(-1)^F$; e.g. the even part of symplectic fermions is the triplet algebra $W(2)$ at $c = -2$ (Chapter 18).

What the machine verified

`#print axioms VOA.SuperVertexOperatorAlgebra.evenPartVOA:` `[propext, Classical.choice, Quot.sound]`. Conditional only on `hint`.

17.7 Super modules, twisted super modules, and the defect

Definition 17.20 (Super weak module). A super weak module over a super vertex algebra W is a vector space $M = M_{\bar{0}} \oplus M_{\bar{1}}$ with a linear $Y_M : W \to \mathrm{End}(M)[[z^{\pm 1}]]$ such that modes add parities, $Y_M(\mathbf{1}, z) = \mathrm{id}$, $Y_M(u, z)x \in M((z))$, and the super Jacobi identity of Theorem 17.14 holds with Y_M in place of Y, for all homogeneous u, v, all $x \in M$ and all $\ell, m, n \in \mathbb{Z}$.

File `VOA/Modules/SuperWeakModule.lean`.

```
structure SuperWeakModule (W : SuperVertexAlgebra 𝒱) (M : Type v)
    [AddCommGroup M] [Module ℂ M] where
  YM : 𝒱 →ₗ[ℂ] (End ℂ M)⟦z^±⟧
  parity : ZMod 2 → Submodule ℂ M
  parity_isInternal : DirectSum.IsInternal parity
  parity_mode : ∀ {p q : ZMod 2} (u : 𝒱), u ∈ W.parity p → ∀ (x : M), x ∈ parity q →
    ∀ (n : ℤ), mode (YM u) n x ∈ parity (p + q)
  vacuum_YM : YM W.vacuum = 1
  truncation : ∀ (u : 𝒱) (x : M), ∃ N : ℤ, ∀ n : ℤ, N ≤ n → mode (YM u) n x = 0
  jacobi : ∀ {p q : ZMod 2} (u : 𝒱), u ∈ W.parity p → ∀ (v : 𝒱), v ∈ W.parity q →
    ∀ (x : M) (ℓ m n : ℤ),
    (∑ᶠ i : ℤ, (negOnePow i * cbz ℓ i) •
        (mode (YM u) (ℓ + m - i) (mode (YM v) (n + i) x)
          - (koszul p q * negOnePow ℓ) • mode (YM v) (ℓ + n - i) (mode (YM u) (m + i) x)))
      = ∑ᶠ i : ℤ, cbz m i • mode (YM (W.smul u (ℓ + i) v)) (m + n - i) x
```

From the mathematics to the Lean statement

This is the super version of Chapter 12, Definition 12.1, and of Kac's definition of a module over a vertex superalgebra (Kac §4.1, with the Borcherds identity as the axiom, as in Li and in Dong–Zhao). Untwisted modules have integer modes, so quantification over all ℓ, m, n is correct here (contrast Definition 17.23). No grading is part of a weak module.

Physical meaning

A representation of the fermionic chiral algebra on the state space of a sector; the parity of M is fermion number in that sector.

What the machine verified

A definition; standard axioms.

Proposition 17.21 (The adjoint super module). *Every super near-VOA is a super weak module over itself, with $Y_M = Y$ and its own parity.*

File `VOA/Modules/SuperAdjointModule.lean`.

```
def SuperNearVOA.adjointSuperWeakModule (V : SuperNearVOA 𝒱) :
    SuperWeakModule V.toSuperVertexAlgebra 𝒱 where
  YM := V.Y
```

From the mathematics to the Lean statement

The `jacobi` field is discharged by `superJacobi` with no rewriting, which certifies that Theorem 17.14 is exactly the module axiom. First inhabitant with genuinely odd states.

Physical meaning

The vacuum sector: the chiral algebra acting on itself.

Proof on paper. Each field is the corresponding axiom or theorem of V. □

What the machine verified

```
#print axioms VOA.SuperNearVOA.adjointSuperWeakModule:                [propext,
Classical.choice, Quot.sound].
```

Definition 17.22 (Graded super module). A `SuperOrdVModule` over a super VOA W is a super weak module with an internal grading $M = \bigoplus_{\alpha\in\mathbb{C}} M_\alpha$ by finite-dimensional L_0-eigenspaces, real parts of weights bounded below, and $u_{(n)}M_\alpha \subseteq M_{\alpha+h-n-1}$ for $u \in W_h$.

File `VOA/Modules/SuperOrdVModule.lean`.

```
structure SuperOrdVModule (W : SuperVertexOperatorAlgebra 𝒱) (M : Type v)
    [AddCommGroup M] [Module ℂ M]
    extends SuperWeakModule W.toSuperVertexAlgebra M where
  weight : ℂ → Submodule ℂ M
  weight_isInternal : DirectSum.IsInternal weight
  L0_weight : ∀ (α : ℂ) (x : M), x ∈ weight α →
    mode (YM W.conformalVector) 1 x = α • x
  weight_finite : ∀ α, FiniteDimensional ℂ (weight α)
  boundedBelow : ∃ B : ℝ, ∀ α : ℂ, weight α ≠ ⊥ → B ≤ α.re
  weight_mode : ∀ {h α : ℂ} (u : 𝒱), u ∈ W.grading h →
    ∀ (x : M), x ∈ weight α → ∀ (n : ℤ),
      mode (YM u) n x ∈ weight (α + h - n - 1)
```

From the mathematics to the Lean statement

The super analogue of `OrdVModule` (Chapter 12, Definition 12.5). Since ω is even, L_0 preserves parity and each M_α inherits a parity grading (`weightParityGrading`), on which the basis-free supertrace $\operatorname{str} f = \operatorname{tr}((-1)^F f)$ (`supertrace`, `Modularity/SuperTrace.lean`) is defined. The only instances constructed in the library are `OrdVModule.toSuper` of bosonic modules; no `SuperOrdVModule` with a nonzero odd part is built.

Physical meaning

A sector with finite degeneracies and energy bounded below: the kind of module whose (super)character $\operatorname{str}_M q^{L_0 - c/24}$ makes sense.

What the machine verified

A definition; standard axioms.

17.7.1 Twisted super modules

Recall from Chapter 34 the twisted Jacobi identity in mode form: for g of order dividing N and u in the eigenspace V^j, the field $Y_M(u,z)$ has modes $u_{(r)}$ with r in one coset of $\mathbb{Z}$ in $\frac{1}{N}\mathbb{Z}$, and the identity is required *only* for r on that coset.

Read this before the definition: for $N \geq 2$ the only twisted super module is $M = 0$

At the earlier state of the library against which this chapter was first written, and still in the released source (its `jacobi` field is unchanged), the structure `SuperTwistedModule W g N M` defined below is uninhabited for every twist order $N \geq 2$ except by the zero space $M = 0$. This holds for every super VOA W and every even automorphism g (including $g = 1$ and the parity automorphism $g = (-1)^F$, i.e. the Ramond sector). It is a theorem, checked by Lean (Theorem 17.24 below; the check is not part of this release). The cause is that the `jacobi` field is imposed for *all* integer labels k, not only for those with $k \equiv j \pmod N$ (finding (F1)). Consequently every library theorem whose hypotheses contain a `SuperTwistedModule` with $N \geq 2$ is a statement about the zero vector space, and *this book does not present any such theorem as having mathematical content.* Only the case $N = 1$ (the untwisted sector, reached through `SuperOrdVModule.toIdentityTwist`) carries content.

Definition 17.23 (Twisted super module, library sense)**.** For an even automorphism g of a super VOA W and $N > 0$ with $g^N = 1$, a `SuperTwistedModule W g N M` is: a linear map $u \mapsto (k \mapsto Y_M(u)_k)$, the integer label k standing for the fractional mode $u_{(k/N)}$; a parity grading of M with modes adding parities; $\mathbf{1}_{(k/N)} = \delta_{k,-N}$; lower truncation; support $u_{(k/N)} = 0$ unless $k \equiv j \pmod N$ for $u \in W^j$; the Koszul-signed twisted Jacobi identity *for all integers* ℓ, k, m; translation covariance; and a $\mathbb{C}$-grading by finite-dimensional L_0-eigenspaces, bounded below, with the fractional weight shift. **For $N \geq 2$ these axioms force $M = 0$** (Theorem 17.24); so, at this commit, this is *not* a definition of a twisted module in the sense of Dong–Li–Mason or Dong–Zhao except when $N = 1$.

File `VOA/Modules/SuperTwistedModule.lean`.

```

From the mathematics to the Lean statement

The remaining fields (`translation`, `weight`, `weight_isInternal`, `L0_weight`, `weight_finite`, `boundedBelow`, `weight_mode`) are the graded data and are not needed below. `fractionalBinom x i` $= \binom{x}{i} = \prod_{k<i}(x-k)/i!$ for complex x. In the `jacobi` field the label `ℓ * N + k - i * N` is the fractional mode $\ell + r - i$ with $r = k/N$, and `m + i * N` is $s + i$ with $s = m/N$: the identity reads, for $r = k/N$, $s = m/N$,

$$\sum_i (-1)^i \binom{\ell}{i} \big(u_{(\ell+r-i)} w_{(s+i)} - \varepsilon(-1)^{\ell} w_{(\ell+s-i)} u_{(r+i)}\big) = \sum_{i\geq 0} \binom{r}{i} (u_{(\ell+i)} w)_{(r+s-i)},$$

which is Dong–Li–Mason's mode identity with the Koszul sign (Chapter 34, (34.4)). **But it is required for every** $k \in \mathbb{Z}$, with no hypothesis $k \equiv j \pmod N$: the restriction that Chapter 34 added to the bosonic `TwistedModule.jacobi` is absent. The `support` field uses $k \equiv j$, the bosonic `TwistedModule` uses $k \equiv -j$ for the same eigenvalue $e^{-2\pi i j/N}$; so a super twisted module for g corresponds to a bosonic one for g^{-1} (finding (F7), harmless, undocumented).

Physical meaning

The *intended* meaning is a g-twisted sector: fields acquire the monodromy g when transported around the origin, so their modes are fractional. For $g = (-1)^F$ and $N = 2$ odd fields get half-integral vertex-algebra modes; for a weight-$\frac{1}{2}$ fermion that means integral physics modes ψ_n, $n \in \mathbb{Z}$, i.e. the Ramond sector with its zero mode ψ_0. **The Lean structure does not model this at the documented commit**: for $N \geq 2$, and in particular for the Ramond sector, its only inhabitant is the zero space (F1), so no Ramond sector, and no twisted sector of any kind, exists in the library.

What the machine verified

A definition; standard axioms. **Uninhabited except by** $M = 0$ **for every** $N \geq 2$ (Theorem 17.24); meaningful only for $N = 1$.

Theorem 17.24 (Twisted super modules with $N \geq 2$ are zero)**.** *Let W be any super VOA, g any even automorphism, $N \geq 2$, and T any* `SuperTwistedModule W g N M`*. Then every $x \in M$ is 0. In particular M is a subsingleton, every weight space of T is zero, and every parity-twisted (Ramond) carrier* `W.ParityTwistedModule M` *is zero.*

From the mathematics to the Lean statement

`W.ParityTwistedModule M` is the library's abbreviation `SuperTwistedModule W W.parityAut 2 M`. No hypothesis beyond $N \geq 2$ is used; in particular the statement holds for $g = 1$ as well (an identity automorphism with a chosen $N \geq 2$).

Physical meaning

This is a statement about a mis-specified axiom system, not about conformal field theory. Physically, the twisted Jacobi identity is the mode expansion of a generating identity in which a field of monodromy $e^{-2\pi i j/N}$ only has modes on the coset $k \equiv j \pmod N$; the instance used in the proof below (the vacuum field, which has trivial monodromy, at the label $k = 1$) is not part of any genuine twisted sector when $N \geq 2$, because that coefficient of the generating identity is simply absent. The Lean axiom nevertheless demands it, and the demand kills every vector. In plain words: the library's "Ramond sector" and every other twisted sector of order $N \geq 2$ is empty.

Proof on paper. The identical computation as Chapter 34, Theorem 34.8. Take $u = w = \mathbf{1}$ (even, in W^0 since $g\mathbf{1} = \mathbf{1}$), $p = q = 0$ (Koszul sign 1), $\ell = -1$, $k = 1$, $m = -N - 1$. Left side: each term contains $\mathbf{1}$ at a label $-N + 1 - iN$ or $1 + iN$; $\mathbf{1}_{(k'/N)} \neq 0$ only for $k' = -N$, which would force $N \mid 1$. So the left side is 0. Right side: $\mathbf{1}_{(-1+i)}\mathbf{1} = \delta_{i,0}\mathbf{1}$, $\binom{1/N}{0} = 1$, and the label is $1 - N - 1 = -N$, so the right side is x. Hence $x = 0$. □

What the machine verified

Checked in Lean against the library (the check is not part of this release); not a library theorem. `#print axioms` of the three statements: `[propext, Classical.choice, Quot.sound]`.

Finding (F1): every twisted super theorem with $N \geq 2$ is vacuous

This confirms with a machine check a defect recorded earlier in the project: the `jacobi` field of `SuperTwistedModule` quantifies over all mode indices instead of the coset allowed by `support` (Section 43.2.1). Consequences inside this chapter's files: the Ramond support theorems `parityTwist_even_support`, `parityTwist_odd_support` and the order-three support checks are true of the zero module only; `Modularity/SuperTwistedTrace.lean` (twisted supertraces for $N \geq 2$), `SuperHalfTwistedTrace.lean` (every `SuperTwistedModule W g 2 M`, i.e. the whole "genuine half-integral trace carrier"), `SuperHalfSpinRecursionBridge.lean`, `SuperSectorRationality.lean` (the `twisted\-Module` field of its realization data) and `Modules/SuperRelativeEtingofFinite.lean` (twisted-module carriers), and the twisted zero-mode action of `Modules/SuperTwistedZhu.lean` (`SuperTwistedModule.twistedZeroModeBlock`, `twistedZeroModeAction`: the bridge from twisted modules to the twisted Zhu quotient of Definition 17.44) are about the zero space whenever $N \geq 2$. In particular every half-integral trace and supertrace is identically zero, and `SuperTwistedModule.IsIrreducible` for $N \geq 2$ is satisfied only by zero modules (§17.12). The identity-twist case $N = 1$ (`SuperOrdVModule.toIdentityTwist`, used for instance by the torus recursion of `Modularity/SuperTorusRecursionClose.lean`) is unaffected. Severity: serious. Remedy: add the hypothesis `(k - j) % (N : ℤ) = 0` → to `jacobi`. Note the sign: the super `support` field uses $k \equiv j$, so

the restriction is $(k - j) \bmod N = 0$; the bosonic `TwistedModule.jacobi` of Chapter 34 uses `(k + j) % (N : ℤ) = 0` because its support is $k \equiv -j$ (F7). Copying the bosonic hypothesis verbatim would be wrong here.

17.8 The four free-field examples

All four examples are built on infinite-dimensional Fock spaces, and this is forced: locality makes the twisted commutator a finite sum of derivatives of the delta function, which has infinite support along the diagonal, so *no finite-dimensional space carries a genuinely fermionic local pair* (the project's internal records note this negative result, found when finite-dimensional fermionic examples were attempted). The fermionic Fock spaces are exterior algebras, realised in Mathlib as Clifford algebras of the zero quadratic form; creation is left multiplication by a generator and annihilation is contraction against a coordinate functional, and Mathlib's `CliffordAlgebra.contractLeft_ι_mul` *is* the canonical anticommutation relation. The bosonic Fock space of $\beta\gamma$ is a polynomial ring, with multiplication and partial derivatives.

17.8.1 The free fermion

Definition 17.25 (The Neveu–Schwarz free fermion)**.** Let $\mathcal{F} = \Lambda(\bigoplus_{k\in\mathbb{N}} \mathbb{C}e_k)$. Let c_k be exterior multiplication by e_k and a_k contraction with the k-th coordinate. The library defines $\psi : \mathbb{Z} \to \mathrm{End}\,\mathcal{F}$ by $\psi(n) = a_n$ for $n \geq 0$ and $\psi(n) = c_{-n-1}$ for $n < 0$. **Caution (F3):** the library reads $\psi(n)$ as the coefficient of z^n, not as the mode $\psi_{(n)}$; with that reading ψ is *not* a field (Theorem 17.27), and the library contains no super vertex algebra of the free fermion.

File `VOA/Examples/FreeFermion.lean`.

```
noncomputable abbrev Fock := CliffordAlgebra Qzero
noncomputable def cre (k : ℕ) : Module.End ℂ Fock :=
  LinearMap.mulLeft ℂ (ι Qzero (Finsupp.single k (1 : ℂ)))
noncomputable def ann (k : ℕ) : Module.End ℂ Fock := contractLeft (Finsupp.lapply k)
...
noncomputable def psi : FormalDist (Module.End ℂ Fock) :=
  fun n => if 0 ≤ n then ann n.toNat else cre (-n - 1).toNat
```

From the mathematics to the Lean statement

`Qzero` is the zero quadratic form on `ModeSpace = ℕ →₀ ℂ` (finitely supported sequences), so `Fock` is the exterior algebra. The docstring says "$\psi(z) = \sum_{n\in\mathbb{Z}} \psi_{(n)} z^{-n-1}$, creation modes for $n \leq -1$", i.e. it reads the argument of `psi` as a *mode* index. But `psi` has type `FormalDist`, whose argument is the *z-exponent* (§17.2). Read as the library reads it, $\psi(z) = \sum_k \psi(k) z^k$ has creation operators at all negative powers of z, so $\psi(z)x \notin \mathcal{F}((z))$: it is not a field (Theorem 17.27).

Physical meaning

The Majorana fermion of weight $\frac{1}{2}$, $\psi(z)\psi(w) \sim \frac{1}{z-w}$, central charge $c = \frac{1}{2}$ (the chiral half of the critical Ising model). In the Neveu–Schwarz sector its modes are ψ_r, $r \in \mathbb{Z} + \frac{1}{2}$; here $c_k = \psi_{-k-1/2}$ and $a_k = \psi_{k+1/2}$.

What the machine verified

A definition; standard axioms.

Theorem 17.26 (Canonical anticommutation relations and locality). *$\psi(m)\psi(n) + \psi(n)\psi(m) = \delta_{m+n+1,0}$ for all $m, n \in \mathbb{Z}$, and ψ is (-1)-local with itself.*

File `VOA/Examples/FreeFermion.lean`.

```
theorem psi_anticomm (m n : ℤ) :
    psi m * psi n + psi n * psi m = if m + n + 1 = 0 then 1 else 0 := by
...
theorem psi_localε : Localε (-1) psi psi :=
  localε_neg_one_of_anticomm 1 psi_anticomm
```

From the mathematics to the Lean statement

Both statements are invariant under $n \mapsto -n-1$, so they are true whichever indexing one has in mind. `psi_localε` is the first inhabitant of `Localε` at a sign other than 1; it checks that the sign conventions are right. It does *not* make ψ a field.

Physical meaning

$\{\psi_r, \psi_s\} = \delta_{r+s,0}$: the Clifford algebra of the free Majorana fermion, whose anticommutator is $\delta(z-w)$, a simple pole in the OPE.

Proof on paper. Case analysis on the signs of m, n, using $c_j c_k + c_k c_j = 0$, $a_j a_k + a_k a_j = 0$, $a_j c_k + c_k a_j = \delta_{jk}$; locality follows from the free-field criterion with $S = \mathrm{id}$. □

What the machine verified

`#print axioms of VOA.FreeFermion.psi\_anticomm, VOA.FreeFermion.psi\_localε:` `[propext, Classical.choice, Quot.sound].`

Theorem 17.27 (ψ is not a field). *$\neg$ IsField(ψ): there is no B with $\psi(n)\mathbf{1} = 0$ for all $n < B$.*

From the mathematics to the Lean statement

`IsField a` $:\Leftrightarrow \forall x\, \exists B\, \forall n < B,\ a(n)x = 0$ (`Core/Dong.lean`). The witness is $x = 1 \in \mathcal{F}$.

Physical meaning

A field must annihilate any given state after finitely many negative powers of z (finitely many singular terms in an OPE with a fixed state). An operator family that keeps creating new particles at ever more singular orders is not a field.

Proof on paper. For $n < 0$, $\psi(n)1 = c_{-n-1}1 = e_{-n-1} \neq 0$, because $a_k(c_k 1) = 1 - c_k(a_k 1) = 1$. □

What the machine verified

Checked in Lean against the library (the check is not part of this release); not a library theorem. `#print axioms`: `[propext, Classical.choice, Quot.sound]`. Consequently **the free fermion is not announceable**: the library has only anticommuting operator families that are not fields, and no vertex superalgebra of the free fermion.

Findings (F3): the free fermion is not a vertex superalgebra in Lean

The same inverted orientation occurs in `BCGhosts.bfield`, `BCGhosts.cfield` (`Examples/BCGhosts.lean`) and in `BetaGamma.beta`, `BetaGamma.gamma` (`Examples/BetaGamma.lean`); the later files `GhostSystem.lean` and `BetaGammaField.lean` say so in their docstrings and rebuild *bc* and

$\beta\gamma$ in the correct orientation. The free fermion has no such rebuild: **the library contains no `SuperVertexAlgebra` or `SuperVertexOperatorAlgebra` for the free fermion**, only the operators of Definition 17.25. The docstrings of `FreeFermion.lean` ("creation modes for $n \le -1$"), `BetaGamma.lean` and `BetaGammaVirasoro.lean` (which says `BetaGamma` "indexes fields by the z-exponent", contradicting `BetaGammaField.lean`) are misleading. Severity: moderate (definitions do not mean what their docstrings say; no downstream theorem is affected because the only consumers are locality statements). Remedy: reindex $n \mapsto -n-1$ or delete the three early files.

17.8.2 The bc ghost system

Definition 17.28 (bc fields). On the exterior algebra $\Lambda\big(\bigoplus_{k\in\mathbb{N},\,a\in\{0,1\}} \mathbb{C}e_{k,a}\big)$ (species $0=b$, $1=c$) define, for $a\in\{0,1\}$, the distribution gh_a with z^j-coefficient equal to creation of $e_{j,a}$ for $j\ge 0$ and to annihilation against the *conjugate* species $e_{-j-1,a+1}$ for $j<0$; $b=\mathrm{gh}_0$, $c=\mathrm{gh}_1$.

File `VOA/Examples/GhostSystem.lean`.

```
noncomputable def ghField (a : Fin 2) : FormalDist (End ℂ FockSF) :=
  fun j => if 0 ≤ j then creGh a j.toNat else annGh a (-j - 1).toNat
noncomputable def bfield : FormalDist (End ℂ FockSF) := ghField 0
noncomputable def cfield : FormalDist (End ℂ FockSF) := ghField 1
```

From the mathematics to the Lean statement

Here the z-exponent indexing is respected: creation at $j\ge 0$. The carrier `FockSF` is reused from the symplectic-fermion files (it is the same exterior algebra). `creGh a k` $= b$- or c-creation $a_{(-k-1)}$; `annGh a k` contracts against species $a+1$, which is what makes b and c conjugate to each other.

Physical meaning

The reparametrisation ghosts of the bosonic string are a bc system of weights $(\lambda, 1-\lambda)$ with $\lambda=2$; the modes c_n of the weight -1 ghost and b_n of the weight-2 antighost generate the ghost Fock space of BRST quantisation. At $\lambda=1$ (b of weight 1, c of weight 0) the system appears in the Drinfeld–Sokolov reduction of $\widehat{\mathfrak{sl}}_2$.

What the machine verified

Definitions; standard axioms.

Theorem 17.29 (bc anticommutators, locality, and the super vertex algebra). $\{\mathrm{gh}_a(j), \mathrm{gh}_b(k)\} = \delta_{j+k+1,0}\,\omega^{ab}$ *with* $\omega^{ab}=1$ *for* $a\neq b$ *and* 0 *for* $a=b$*; all ghost fields are mutually* (-1)*-local fields; and there is a super vertex algebra* `bcGhostSVA` *on the Fock space, graded by* $\mathrm{wt}(b_{(-k-1)}) = k+1$, $\mathrm{wt}(c_{(-k-1)})=k$ *(i.e.* $\lambda=1$*), with Clifford parity, whose vertex operator is produced by super reconstruction.*

File `VOA/Examples/GhostSystem.lean`.

```
theorem ghField_anticomm (a b : Fin 2) (j k : ℤ) :
    ghField a j * ghField b k + ghField b k * ghField a j
      = (if j + k + 1 = 0 then ghPair a b else 0) • (1 : End ℂ FockSF) := by
...
theorem ghField_localε (a b : Fin 2) : Localε (-1) (ghField a) (ghField b) := by
...
theorem ghField_isField (a : Fin 2) : IsField (ghField a) := by
```

```
...
noncomputable def bcGhostSVA : SuperVertexAlgebra FockSF where
  grading := gradingGh
  isInternal := gradingGh_isInternal
  finrank := gradingGh_finrank
  parity := evenOdd QSF
```

From the mathematics to the Lean statement

`ghPair a b` is 1 when $b = a + 1$ in `Fin 2` (species differ) and 0 otherwise. `evenOdd QSF` is Mathlib's $\mathbb{Z}/2$-grading of the Clifford algebra by word length mod 2. Finite-dimensionality of the weight spaces at $\lambda = 1$ is not automatic (the weight-0 mode $c_{(-1)}$ can be repeated) and uses that a creation monomial with a repeated mode vanishes. Spin–statistics fails ($b_{(-1)}\mathbf{1}$ is odd of weight 1). There is no conformal vector: `bcGhostSVA` is not a `SuperNearVOA`.

Physical meaning

$b(z)c(w) \sim \frac{1}{z-w}$: a first-order pole between two fermionic fields of conjugate weights. The additional $\mathbb{Z}$-grading by ghost number (`ghostGrading`, b has -1, c has $+1$) reduces mod 2 to the parity.

Proof on paper. The anticommutators are the Clifford relations; locality is the free-field criterion; lower truncation holds because at negative exponent the operators are annihilations of increasing level, which kill any fixed monomial. The super vertex algebra comes from super reconstruction applied to the word fields (iterated twisted normal-ordered products of derivatives of b and c); the two compatibility axioms VA1, VA1′ are checked word by word. □

What the machine verified

`#print axioms of VOA.Ghost.ghField\_anticomm, VOA.Ghost.bcGhostSVA`: `[propext, Classical.choice, Quot.sound]`. Unconditional, **in the library's weak sense**: `SuperVertexAlgebra` has no translation-covariance axiom (finding (F2), Theorem 17.4), so `bcGhostSVA` is a weaker statement than "the bc system is a vertex superalgebra" in the standard sense; no super Jacobi identity is proved for it, and its Virasoro relation is open.

Definition 17.30 (Ghost central charge and the ghost Virasoro statement)**.** For $\lambda \in \mathbb{C}$ let $c(\lambda) = -2(6\lambda^2 - 6\lambda + 1)$ and $L(z) = -\lambda{:}\, b\,\partial c \,{:} + (1-\lambda){:}(\partial b)c{:}$. `IsGhostVirasoro λ` is the proposition that the modes of $L(z)$ satisfy the Virasoro relations with central charge $c(\lambda)$.

File `VOA/Examples/GhostSystem.lean`.

```
def ghostCentralCharge (lam : ℂ) : ℂ := -2 * (6 * lam ^ 2 - 6 * lam + 1)
...
theorem ghostCentralCharge_two : ghostCentralCharge 2 = -26 := by
...
def IsGhostVirasoro (lam : ℂ) : Prop :=
  ∀ m n : ℤ, Lgh lam m * Lgh lam n - Lgh lam n * Lgh lam m
    = ((m : ℂ) - (n : ℂ)) • Lgh lam (m + n)
      + (if m + n = 0 then ((m : ℂ) ^ 3 - (m : ℂ)) / 12 * ghostCentralCharge lam else 0)
          • (1 : End ℂ FockSF)
```

From the mathematics to the Lean statement

`Lgh lam n` is the z^{-n-2}-coefficient of `LghField lam`, the stated normal-ordered bilinear at Koszul sign -1 (so L_n for a weight-2 field). `IsGhostVirasoro` is a *definition of a proposition*; it is **not proved for any** λ. `ghostCentralCharge_two` is the arithmetic fact $-2(24-12+1) = -26$;

it says nothing about the ghost system.

Physical meaning

$c(\lambda) = -3(2\lambda-1)^2+1$. At $\lambda = 2$, $c = -26$: the ghost anomaly cancels the $c = 26$ of the matter in the critical bosonic string (Friedan–Martinec–Shenker). At $\lambda = 1$, $c = -2$; at $\lambda = \frac{1}{2}$ the bc system is a complex (Dirac) fermion, $c = +1$.

What the machine verified

`#print axioms VOA.Ghost.ghostCentralCharge_two:` `[propext, Classical.choice, Quot.sound]`. The Virasoro relation for the bc system is **open** in the library.

Finding (F6): what the bc files do not contain

The bc files contain no stress tensor theorem, no `SuperNearVOA`, no grading for $\lambda \neq 1$, and in particular nothing about the $\lambda = 2$ string ghosts beyond the polynomial identity $c(2) = -26$. The docstring of `GhostSystem.lean` is honest about this. Severity: open gap (an advertised physical value is only arithmetic), in the same family as the other places in the library where a physically named value is checked only as arithmetic.

17.8.3 The beta-gamma system

Definition 17.31 ($\beta\gamma$ fields). On $\mathbb{C}[x_k, y_k : k \in \mathbb{N}]$ let $\beta(z) = \sum_j \beta_j z^j$ with β_j = multiplication by x_j for $j \geq 0$ and $\partial/\partial y_{-j-1}$ for $j < 0$, and γ_j = multiplication by y_j for $j \geq 0$ and $-\partial/\partial x_{-j-1}$ for $j < 0$.

File `VOA/Examples/BetaGammaField.lean`.

```
noncomputable def betaZ : FormalDist (Module.End ℂ Fock) :=
  fun j => if 0 ≤ j then mulX (Sum.inl j.toNat) else der (Sum.inr (-j - 1).toNat)
...
noncomputable def gammaZ : FormalDist (Module.End ℂ Fock) :=
  fun j => if 0 ≤ j then mulX (Sum.inr j.toNat) else -der (Sum.inl (-j - 1).toNat)
```

From the mathematics to the Lean statement

`Fock = MvPolynomial (ℕ ⊕ ℕ) ℂ`; `Sum.inl k` is x_k (β-creation $\beta_{(-k-1)}$), `Sum.inr k` is y_k. These are the correctly oriented fields; `betaZ j = BetaGamma.beta (-j-1)` (`betaZ_eq`). The relation is $[\beta_{(m)}, \gamma_{(n)}] = \delta_{m+n+1,0}$ (bosonic commutator, $\varepsilon = 1$).

Physical meaning

Symplectic bosons: commuting fields of weights $(\lambda, 1-\lambda)$, $\beta(z)\gamma(w) \sim \frac{1}{z-w}$. At $\lambda = \frac{3}{2}$ they are the superconformal ghosts of the RNS superstring ($c = +11$); at $\lambda = 1$, $c = +2$; at $\lambda = \frac{1}{2}$ (the library's choice), $c = -1$. In general $c_{\beta\gamma}(\lambda) = -c_{bc}(\lambda)$.

What the machine verified

Definitions; standard axioms.

Theorem 17.32 (The $\beta\gamma$ super VOA). *There is a purely even super VOA* `bgSVOA` *on* $\mathbb{C}[x_k, y_k]$ *with* x_k, y_k *of weight* $k + \frac{1}{2}$, $Y(x_0, z) = \beta(z)$, $Y(y_0, z) = \gamma(z)$, *conformal vector* $\omega = \frac{1}{2}(x_0 y_1 - x_1 y_0)$ *and central charge* -1. *It has a nonzero weight space at the non-integer weight* $\frac{1}{2}$ *and violates spin–statistics.*

      = ((m : ℂ) - (n : ℂ)) • Lbg (m + n)
        + (if m + n = 0 then ((m : ℂ) ^ 3 - (m : ℂ)) / 12 * (-1) else 0)
            • (LinearMap.id : Module.End ℂ Fock)
```

From the mathematics to the Lean statement

`gradingBG c` is the space of weighted-homogeneous polynomials of weight c for the weight function $x_k, y_k \mapsto k + \frac{1}{2}$ (`bgWt`). `stWordBG [i, j]` is the monomial $X_i X_j$, so `bgOmega` $= \frac{1}{2}x_0y_1 - \frac{1}{2}x_1y_0$ (`bgOmega_eq`). `bgSNVOA` is the super near-VOA whose `virasoro` field is `Lbg_virasoro` transported (`bgOmega_eq_BGVir`: this ω is the state whose modes are the `Lbg n`), and `toSVOA` adds $\mathcal{V}_0 = \mathbb{C}1$ and positivity. `bgSVA_grading_notMem_intCast` is the non-vacuity of Axis A: the grading cannot be reindexed by $\mathbb{Z}$. The weights $h_\beta = h_\gamma = \frac{1}{2}$ are derived in `BetaGammaVirasoro.lean` from primarity (`weights_sum_one`: $h_\beta + h_\gamma = 1$ is forced, symmetry gives $\frac{1}{2}$).

Physical meaning

$T(z) = \frac{1}{2}{:}\beta\partial\gamma{:} - \frac{1}{2}{:}\partial\beta\gamma{:}$, the stress tensor at $\lambda = \frac{1}{2}$, $c = -1$. The state $\beta_{-1/2}|0\rangle$ is a boson of spin $\frac{1}{2}$: the theory is non-unitary and violates spin–statistics in the opposite direction to symplectic fermions.

Proof on paper. Reconstruction from the monomial words (the word fields are normal-ordered products of derivatives of β, γ, all bosonic). The Virasoro relation is a direct computation with normally ordered bilinears $L_n = \sum_j A_j {:}\beta\gamma{:}$; the coefficient family A_j is forced by requiring β, γ to be primary of weight $\frac{1}{2}$, and the central term is the usual double contraction, here -1 because the fields are bosonic. □

What the machine verified

`#print axioms of VOA.BGInst.bgSVOA, VOA.BGInst.bgSVA\_not\_spinStatistics: [propext, Classical.choice, Quot.sound].` Unconditional. **Purely even**: the parity is `ParityGrading.even`, so this instance never exercises the Koszul sign rule; it tests the half-integral weight axis only.

Definition 17.33 (Super C_2, Poisson relation span, Etingof finiteness)**.** For a super VOA W: $C_2(W) = \mathrm{span}\{u_{(-2)}v\}$; W is *super C_2-cofinite* if $W/C_2(W)$ is finite-dimensional; $R = C_2(W) + \mathrm{span}\{a_{(0)}b\}$, and W is *super Etingof-finite* if W/R is finite-dimensional.

def superPoissonRelSpan (W : SuperVertexOperatorAlgebra 𝒱) : Submodule ℂ 𝒱 :=
  superO₂ W ⊔ superZeroModeSpan W
...
def SuperEtingofFinite (W : SuperVertexOperatorAlgebra 𝒱) : Prop :=
  FiniteDimensional ℂ (SuperPoissonHP₀ W)
```

From the mathematics to the Lean statement

`SuperPoissonHP₀ W` is the quotient $\mathcal{V}/R$ (`SuperEtingofFinite_iff`). On a bosonic VOA these are literally the bosonic notions of Chapter 12, Definitions 12.22 and 12.26 (`superC2Cofinite_toSuper_iff` is `Iff.rfl`). $W/C_2(W)$ is Zhu's Poisson superalgebra R_W and W/R is its zeroth Poisson homology $R_W/\{R_W, R_W\}$; the library does not construct the Poisson structure on the quotient, only the vector space. Super Etingof-finiteness is the hypothesis of Arakawa–Kawasetsu (finitely many symplectic leaves implies it, by Etingof–Schedler).

Physical meaning

C_2-cofinite ("lisse") theories have finitely many sectors and modular characters; quasi-lisse theories (finitely many symplectic leaves in the associated variety) still have characters satisfying modular differential equations. Higgs-branch chiral algebras of 4d $\mathcal{N} = 2$ theories are quasi-lisse; free $\beta\gamma$ is the simplest (associated variety $\mathbb{C}^2$, one leaf).

What the machine verified

Definitions; standard axioms.

Theorem 17.34 ($\beta\gamma$ is quasi-lisse but not lisse)**.** `bgSVOA` *is not super C_2-cofinite, and it is super Etingof-finite (indeed R is everything).*

File `VOA/Examples/BetaGammaC2LowerBound.lean`.

```
theorem not_SuperC2Cofinite_bgSVOA : ¬ SuperC2Cofinite bgSVOA := by
```

File `VOA/Examples/BetaGammaQuasiLisse.lean`.

```
theorem superPoissonRelSpan_eq_top : superPoissonRelSpan bgSVOA = ⊤ :=
...
theorem bgSVOA_strict_halfIntegral_quasiLisse :
    ¬ SuperC2Cofinite bgSVOA ∧ SuperEtingofFinite bgSVOA :=
```

From the mathematics to the Lean statement

Both halves are unconditional. "$R = \top$" means $W/R = 0$, which is finite-dimensional; this is not a degenerate trick: for the Weyl-type Poisson algebra $\mathbb{C}[\beta,\gamma]$ with $\{\beta,\gamma\} = 1$ every polynomial is a bracket, $f = \{\beta, \int f\, d\gamma\}$, so $HP_0 = 0$.

Physical meaning

The associated variety of $\beta\gamma$ is the symplectic plane $\mathbb{C}^2$: positive-dimensional (not lisse) but a single symplectic leaf (quasi-lisse). Its vacuum character $q^{1/24}\prod_n (1-q^{n-1/2})^{-2}$ is modular only for Γ_θ-type subgroups and only up to the subtleties of non-C_2 theories.

Proof on paper. Not C_2: the powers x_0^n survive in W/C_2; a linear detector (the coefficient of x_0^n) kills every $u_{(-2)}v$ by a weight and β-minus-γ charge count, and the detectors separate the classes $[x_0^n]$, which are therefore linearly independent. Etingof-finite: the zero mode of x_0 acts as $\partial/\partial y_0$ and that of y_0 as $-\partial/\partial x_0$, so every derivative image lies in R; partial differentiation is surjective on polynomials over $\mathbb{C}$. □

What the machine verified

`#print axioms` of `VOA.BGNonC2.not\_SuperC2Cofinite\_bgSVOA` and `VOA.BGInst.bgSVOA\_strict\_halfIntegral\_quasiLisse`: `[propext, Classical.choice, Quot.sound]`. Unconditional.

17.8.4 Symplectic fermions

Definition 17.35 (Symplectic fermion fields)**.** On the exterior algebra Fock_{SF} on generators $e_{k,a}$ ($k \in \mathbb{N}$, $a \in \{0,1\}$), the fields $\chi^a(z)$ have z^j-coefficient creation of $e_{j,a}$ for $j \geq 0$ and a contraction weighted by the symplectic form for $j < 0$, with $\{\chi^a(j), \chi^b(k)\} = (-j-1)\,\delta_{j+k+2,0}\,\omega^{ab}$.

File `VOA/Examples/SymplecticFermion.lean`.

```
noncomputable def chi (a : Fin 2) : FormalDist (Module.End ℂ FockSF) :=
  fun j => if 0 ≤ j then creSF a j.toNat else annSF a (-j - 1).toNat
...
theorem chi_anticomm (a b : Fin 2) (j k : ℤ) :
    chi a j * chi b k + chi b k * chi a j
      = (if j + k + 2 = 0 then (((-j - 1 : ℤ) : ℂ) * sfOmega a b) else 0)
        • (1 : Module.End ℂ FockSF) := by
...
theorem chi_localε (a b : Fin 2) : Localε (-1) (chi a) (chi b) := by
```

From the mathematics to the Lean statement

In modes $\chi^a_m := \chi^a(-m-1)$ (`chiM`) the relation reads $\{\chi^a_m, \chi^b_n\} = m\,\delta_{m+n,0}\,\omega^{ab}$, with ω^{ab} the antisymmetric form `sfOmega` ($\omega^{01} = -\omega^{10}$). The factor m makes the anticommutator a derivative of the delta function, so the locality order is 2, not 1 (proved through `deltaDeriv 1`, not the first-order free-field criterion). Weight of χ^a: 1.

Physical meaning

Kausch's symplectic fermions: a pair of weight-1 fermions with $\chi^a(z)\chi^b(w) \sim \frac{\omega^{ab}}{(z-w)^2}$, central charge $c = -2$; equivalently the $\eta\xi$ system with ξ replaced by $\partial\xi$. The prototypical logarithmic CFT: its even part is the triplet algebra $W(2)$, and its zero modes χ_0^a generate a Grassmann algebra on non-vacuum modules, responsible for Jordan blocks of L_0.

What the machine verified

`#print axioms VOA.SympFerm.chi_anticomm`: `[propext, Classical.choice, Quot.sound]`.

Theorem 17.36 (The symplectic-fermion super VOA). *There is a super VOA* `sympFermSVOA` *on* Fock_{SF}*, with* $Y(\chi^a_{-1}\mathbf{1}, z) = \chi^a(z)$*, integer weights in both parities, conformal vector* $\omega_{SF} = -\chi^0_{-1}\chi^1_{-1}\mathbf{1}$*, and central charge* -2*.*

File `VOA/Examples/SymplecticFermionVOA.lean`.

```
noncomputable def sympFermSNVOA : SuperNearVOA FockSF where
  __ := sympFermSVA
  conformalVector := ωSF
...
noncomputable def sympFermSVOA : SuperVertexOperatorAlgebra FockSF :=
  sympFermSNVOA.toSVOA sympFermSNVOA_vacuum_grade sympFermSNVOA_positivity
...
@[simp] theorem sympFermSVOA_centralCharge : sympFermSVOA.centralCharge = -2 := rfl
```

From the mathematics to the Lean statement

`sympFermSVA` is the `SuperVertexAlgebra` of `SymplecticFermionInstance.lean` (grading by word weight, parity `evenOdd QSF`, Y from super reconstruction). The Virasoro field is `YSF_omega_virasoro`, proved in `SymplecticFermionVirasoroA.lean` by an explicit mode computation; VOA3 is `YSF_translation`. The central charge being -2 by `rfl` means it is the `centralCharge` field, set to -2 and *justified* by the Virasoro field, not merely asserted.

Physical meaning

$T(z) = \omega_{ab} :\chi^a\chi^b:/2$ up to normalisation; $c = -2$. Spin–statistics fails (odd states of integer weight), as it must in a non-unitary logarithmic theory.

Proof on paper. Reconstruction from the creation words; the Virasoro relation is the standard bilinear computation with a double-contraction anomaly $\frac{m^3-m}{12} \cdot (-2)$, the sign coming from the fermionic loop. □

What the machine verified

`#print axioms VOA.SympFerm.sympFermSVOA`: `[propext, Classical.choice, Quot.sound]`. Unconditional. It has genuinely odd states (the release audit elaborated `sfCre 0 0 ∈ sympFermSVOA.parity 1`), so the Koszul sign is exercised; it is the library's only super VOA instance of which this is true.

Theorem 17.37 (Symplectic fermions are super C_2-cofinite). $\dim \mathrm{Fock}_{SF}/C_2 \le 4$*, spanned by the classes of* $\mathbf{1}, \chi^0_{-1}\mathbf{1}, \chi^1_{-1}\mathbf{1}, \chi^0_{-1}\chi^1_{-1}\mathbf{1}$.

File `VOA/Examples/SympFermSuperC2.lean`.

```
theorem sympFerm_superC2Cofinite : SuperC2Cofinite sympFermSVOA := by
...
theorem finrank_superC2Quotient_le_four :
    Module.finrank ℂ (FockSF / superO₂ sympFermSVOA) ≤ 4 := by
```

From the mathematics to the Lean statement

`superO₂` is Definition 17.33; the hand-built `O₂SF` of `SympFermC2.lean` is *definitionally* the same span (`O₂SF_eq_superO₂ : ... := rfl`). This is ambient C_2-cofiniteness; it does *not* give C_2-cofiniteness of the even part $W(2)$ (whose C_2 uses only even vertex operators), as the file warns.

Physical meaning

$R_{SF} = \Lambda(\chi^0, \chi^1)$: the associated scheme is a fat point with odd directions, so the theory is lisse, as expected of a C_2-cofinite logarithmic CFT.

Proof on paper. $(\chi^a_{-1}\mathbf{1})_{(-2)}v = \chi^a_{-2}v$ for every v, so every state with a level-1 creation operator in front is in C_2; levels ≥ 2 follow by translation, T being an even derivation and $Tv = v_{(-2)}\mathbf{1} \in C_2$. A word whose leading operator is at level 0 is handled by anticommuting it past; level-0 generators square to zero, leaving four survivors. (Using $T\mathcal{V} \subseteq C_2$ alone would not terminate: $\mathcal{V}/T\mathcal{V}$ is infinite-dimensional here.) □

What the machine verified

`#print axioms VOA.SympFerm.sympFerm_superC2Cofinite: [propext, Classical.choice, Quot.sound]`. Unconditional.

Theorem 17.38 (The super Zhu ring of symplectic fermions is not semisimple)**.** *The super Zhu algebra $A(SF)$ (Definition 17.42) is an associative ring of dimension at most 4, $[\chi^a] \neq 0$, and the two-sided ideal generated by $[\chi^0]$ is nonzero and square-zero; hence $A(SF)$ is not a semisimple ring.*

File `VOA/Examples/SympFermSuperZhu.lean`.

```
theorem finrank_ASF_le_four : Module.finrank ℂ ASF ≤ 4 := by
...
theorem chiClass_ne_zero (a : Fin 2) : sfN.superMk hSF (chiStateSF a) ≠ 0 :=
...
theorem ASF_not_isSemisimpleRing :
    letI := instRingASF
    ¬ IsSemisimpleRing ASF :=
```

From the mathematics to the Lean statement

`sfN` is `sympFermSVOA.toSuperNearVOA`, `hSF` its integrality proof, `ASF` the quotient `sfN.superA hSF`, `superMk` the class map. The ring structure `instRingASF` comes from the discharged `SuperZhuRingData` (Theorem 17.43). `IsSemisimpleRing` is Mathlib's notion (every module semisimple). The obstruction used is the correct one: a nonzero square-zero two-sided ideal; a nonzero nilpotent element would not suffice ($M_2(\mathbb{C})$ is semisimple). The bundled form is `sympFerm_integralSuperC2FiniteZhuBenchmark` (`SympFermSuperFiniteBenchmark.lean`): super C_2, ring data, and the ideal; it is deliberately not called "strongly finite", since simplicity and self-contragredience are not formalised on the super side.

Physical meaning

For a rational theory Zhu's algebra is semisimple (its simple modules are the ground states of the sectors). Non-semisimplicity is the algebraic shadow of the logarithmic, non-split sectors of symplectic fermions; here $A(SF) \twoheadleftarrow \Lambda(\chi^0, \chi^1)$, the zero-mode Grassmann algebra.

Proof on paper. $\dim \le 4$: modulo $O(SF)$ one has $\chi^a_{-k-2}v \equiv -\chi^a_{-k-1}v$ (from $(L_{-1}+L_0)\chi^a * v \in O$), which reduces every word to the four bottom words. $[\chi^a] \neq 0$: an evaluation homomorphism $\mathrm{Fock}_{SF} \to \mathbb{C}[\varepsilon]/(\varepsilon^2)$, $\chi^a_{-k-1} \mapsto (-1)^k \delta_{a,c}\varepsilon$, kills every generator of $O(SF)$ but not χ^c. In the ring, $[\chi^a]^2 = 0$ and $[\chi^0][\chi^1] = -[\omega] = -[\chi^1][\chi^0]$, so the ideal generated by $[\chi^0]$ is spanned by $[\chi^0]$ and $[\chi^0][\chi^1]$ and squares to zero. In a semisimple ring a square-zero two-sided ideal is zero. □

What the machine verified

`#print axioms VOA.SympFerm.ASF_not_isSemisimpleRing` and `VOA.SympFerm.sympFerm\_integralSuperC2FiniteZhuBenchmark`: `[propext, Classical.choice, Quot.sound]`. Unconditional. The dimension is proved only to be *at most* 4 (`finrank_ASF_le_four`; also ≥ 1, `one_le_finrank_ASF`); that $A(SF)$ is four-dimensional is not proved.

Definition 17.39 (Super-rationality, library sense). W is `IsSuperRational` if every `SympFermSuperOrdVModule` of W (a super weak module with a $\mathbb{C}$-grading by finite-dimensional L_0-eigenspaces bounded below) is completely reducible: every submodule closed under all modes has a complement closed under all modes.

File `VOA/Examples/SympFermIrrational.lean`.

```
structure SympFermSuperOrdVModule (W : SuperVertexOperatorAlgebra 𝒱) (M : Type v)
    [AddCommGroup M] [Module ℂ M] extends SuperWeakModule W.toSuperVertexAlgebra M where
  weight : ℂ → Submodule ℂ M
  isInternal : DirectSum.IsInternal weight
  L0_weight : ∀ (α : ℂ) (x : M), x ∈ weight α → mode (YM W.conformalVector) 1 x = α • x
  finrank : ∀ α, FiniteDimensional ℂ (weight α)
  boundedBelow : ∃ B : ℝ, ∀ α : ℂ, weight α ≠ ⊥ → B ≤ α.re
...
def IsSuperRational (W : SuperVertexOperatorAlgebra 𝒱) : Prop :=
  ∀ {M : Type u} [AddCommGroup M] [Module ℂ M] (A : SympFermSuperOrdVModule W M),
    SuperWeakModule.IsCompletelyReducible A.toSuperWeakModule
```

From the mathematics to the Lean statement

`IsCompletelyReducible A` $:= \forall P\, \exists Q$, IsCompl $P\,Q$ over mode-stable submodules. Compared with Dong–Li–Mason rationality (complete reducibility of *admissible*, $\mathbb{N}$-gradable modules) the class is different: graded by L_0-eigenvalues, so logarithmic modules are excluded from the start. The structure is a second copy of `SuperOrdVModule` that **omits** the mode-weight axiom `weight_mode`, so it is a *larger* class than `SuperOrdVModule`; the modules are quantified in universe `u`, the universe of $\mathcal{V}$. The library's own docstring flags that the name should carry the category (`GradedSuperRational`).

Physical meaning

Rationality = finitely many sectors, all completely reducible = no logarithmic partners. Symplectic fermions are the textbook irrational C_2-cofinite theory: their module with free zero modes is an indecomposable, non-simple extension.

What the machine verified

Definitions; standard axioms.

Theorem 17.40 ("Symplectic fermions are not super-rational" — conditional)**.** *If N is a graded super module of W with a proper nonzero submodule contained in every nonzero submodule, then W is not super-rational. In particular, given such an N for* `sympFermSVOA`*, symplectic fermions are not super-rational.* ***This is a socle lemma, not a proof that symplectic fermions are irrational****: no such N for* `sympFermSVOA` *is constructed in the library (F4), and the hypothesis is precisely the missing mathematical content.*

File `VOA/Examples/SympFermIrrational.lean`.

```
structure NonSplitSuperModule (W : SuperVertexOperatorAlgebra 𝒱) where

  minimal_le : ∀ Q : SuperWeakModule.Submodule' isMod.toSuperWeakModule,
    Q.carrier = ⊥ ∨ minimal.carrier ≤ Q.carrier
...
theorem SympFerm.sympFermSVOA_not_isSuperRational
    (N : NonSplitSuperModule SympFerm.sympFermSVOA) : ¬ IsSuperRational
    ↪  SympFerm.sympFermSVOA :=
  not_isSuperRational_of_nonSplit N
```

From the mathematics to the Lean statement

The hypothesis `N` is the entire mathematical content: a non-split module. No term of type `NonSplitSuperModule sympFermSVOA` exists in the library. The library proves, conversely, that the adjoint module cannot serve (`not_hasFreeZeroModes_of_adjoint`: on Fock_{SF} the zero modes χ_0^a are the zero operator, `zeroMode_adjoin_eq_bot`). So the theorem is a correct socle lemma (if a module has a minimal proper submodule, it is not completely reducible) and *not* an irrationality theorem.

Physical meaning

The missing object is the "free zero-mode" module $\Lambda(\chi_0^+, \chi_0^-) \otimes$ (oscillators) of Kausch and Gaberdiel–Kausch, whose socle $\mathbb{C}\chi_0^+\chi_0^- x$ has no complement; on it L_0 is diagonalisable but the representation is non-split.

Proof on paper. If Q complemented the minimal submodule P, then either $Q = 0$, forcing $P = \top$, or $P \le Q$, forcing $P = P \cap Q = 0$. □

What the machine verified

`#print axioms VOA.SympFerm.sympFermSVOA_not_isSuperRational`: `[propext, Classical.choice, Quot.sound]`. **Conditional** on `N : NonSplitSuperModule sympFermSVOA`, never constructed (and essentially the conclusion; moreover `IsSuperRational` quantifies over `SympFermSuperOrdVModule`, which lacks `weight_mode`). Irrationality of symplectic fermions is **open** in Lean and **not announceable**. What *is* unconditional is the algebraic obstruction of Theorem 17.38; no theorem in the library converts it into non-rationality.

Finding (F4): a conditional that assumes its conclusion; stale status block

The name `sympFermSVOA_not_isSuperRational` suggests a theorem about symplectic fermions; its only hypothesis is the non-split module, which is the whole content. In addition the "Status" block of `SympFermIrrational.lean` says "no super module of any kind exists, because `SuperWeakModule` requires the super Jacobi identity and the library has no super Borcherds/Jacobi theorem"; this is false at the documented commit (Theorem 17.14, Proposition 17.21). And `SympFermSuperOrdVModule` duplicates `SuperOrdVModule` without `weight_mode` (F8). Severities: open gap (conditional presented near an unconditional name), documentation only (docstring), moderate (duplicate, weaker structure).

17.8.5 The lattice super ambient

The doublet and triplet constructions of Chapter 18 need an ambient lattice algebra whose conformal vector is deformed by a background charge, which produces rational (in particular half-integer) and *negative* weights. `LatticeSuperAmbientA.lean` and `LatticeSuperAmbientB.lean` build it as a purely even `SuperNearVOA`.

Theorem 17.41 (Lattice super near-VOA with background charge). *For an even positive-definite lattice L, a $\mathbb{Q}$-valued quadratic refinement q with finite level sets, and a background charge λ with $\langle\lambda,\beta\rangle = \frac{1}{2}\langle\beta,\beta\rangle - q(\beta)$ for all $\beta \in L$, the lattice vertex algebra with grading by q-refined weight and conformal vector $\omega_\lambda = \omega_L + \lambda_{(-2)}\mathbf{1}$ is a super near-VOA, bounded below, in general not positive.*

File `VOA/Examples/LatticeSuperAmbientB.lean`.

```
def BgCompat (qr : QuadRefine L) (lam : Fin (rank L) → ℂ) : Prop :=
  ∀ β : L.carrier, BgB.bgPair L lam β = ((halfNorm L β : ℤ) : ℂ) - ((qr.q β : ℚ) : ℂ)
...
noncomputable def latSNVOA (hEven : L.Even) (hPos : L.PosDef) (qr : QuadRefine L)
    (hqf : QFinite L qr) (lam : Fin (rank L) → ℂ) (hcompat : BgCompat L qr lam) :
    SuperNearVOA (LatModuleGen L) where
```

From the mathematics to the Lean statement

The vertex operators, vacuum, creation, locality and regularity are the bosonic lattice ones of Chapter 31; only the grading (by q) and the conformal vector change. Parity is trivial. The new obligation VA1 for the refined grading holds because the refinement differs from the undeformed weight by $-\langle\lambda, \text{charge}\rangle$, additive in the charge. `deformedAmbient_not_positivity` shows positivity genuinely fails in the doublet case.

Physical meaning

A Coulomb gas: a free boson with background charge, $c = \operatorname{rank} L - 12\langle\lambda,\lambda\rangle$; vertex operators e^{β} acquire weights $\frac{1}{2}\beta^2 - \langle\lambda,\beta\rangle$, which can be fractional or negative. Screening operators inside it cut out the triplet and doublet algebras.

What the machine verified

`#print axioms VOA.LatGen.SAmbB.latSNVOA`: `[propext, Classical.choice, Quot.sound]`. Conditional on the displayed lattice data, which are instantiated in the files (`tripletSNVOA`, `Half.halfSuperNearVOA`).

17.9 Super Zhu algebras, untwisted and twisted

Definition 17.42 (Super Zhu algebra). Let V be a super near-VOA with integer weights. For $u \in V_k$ put $u * v = \sum_{m=0}^{k} \binom{k}{m} u_{(m-1)}v$, extended linearly; $O(V) = \mathrm{span}\{(L_{-1}u + L_0 u) * v\}$; $A(V) = V/O(V)$.

File `VOA/Modules/SuperZhuRing.lean`.

```
noncomputable def superZhuFamily (v : 𝒱) (k : ℤ) : (V.gradingZ k) →ₗ[ℂ] 𝒱 where
  toFun uk := ∑ m ∈ Finset.range (k.toNat + 1), cbz k m • V.smul (uk : 𝒱) ((m : ℤ) - 1) v
...
def superO (hV : V.IntegralWeights) : Submodule ℂ 𝒱 :=
  Submodule.span ℂ {x | ∃ u v : 𝒱, x = V.superZhuMul hV (V.L (-1) u + V.L 0 u) v}
...
abbrev superA (hV : V.IntegralWeights) : Type u := 𝒱 ⧸ V.superO hV
```

From the mathematics to the Lean statement

`V.IntegralWeights` says $V_h = 0$ for $h \notin \mathbb{Z}$; `gradingZ k` is V_k. `superZhuMul` applies `superZhuFamily` to the homogeneous components. The generator $(L_{-1}u + L_0 u) * v$ for $u \in V_k$ equals Zhu's $u \circ v = \mathrm{Res}_z\, Y(u,z)v\frac{(1+z)^k}{z^2}$ (the Pascal identity is checked by hand in a docstring, not formalised). **No parity case split**: for an integrally graded super VOA this is the Zhu algebra relevant to untwisted ("Neveu–Schwarz" in the integral sense) modules, as in Abe's treatment of symplectic fermions; Kac–Wang and Dong–Zhao's untwisted $A(V)$ for a $\frac{1}{2}\mathbb{Z}$-graded VOSA (with $u \circ v = \mathrm{Res}_z\, Y(u,z)v\,(1+z)^{\mathrm{wt}\,u - 1/2}/z$ for odd u) is *not* covered: the library requires integer weights.

Physical meaning

Ground states of a sector form a module over $A(V)$; the zero mode $o(u) = u_{(\mathrm{wt}\,u-1)}$ of each field acts on them, and $O(V)$ is the set of combinations whose zero modes vanish on every ground state.

What the machine verified

Definitions; standard axioms.

Theorem 17.43 ($A(V)$ is an associative ring; Dong–Zhao Thm. 3.1). *For every integrally graded super VOA W, $O(W)$ is a two-sided ideal for $*$ and $*$ is associative modulo $O(W)$; so $A(W)$ is an associative unital $\mathbb{C}$-algebra. If W is super C_2-cofinite, $A(W)$ is finite-dimensional.*

File `VOA/Modules/SuperZhuRingDischarge.lean`.

```

File `VOA/Modularity/SuperZhuAlgebraFinite.lean`.

```
theorem finiteDimensional_superA_of_superC2Cofinite (W : SuperVertexOperatorAlgebra 𝒱)
    (hV : W.toSuperNearVOA.IntegralWeights) (hC2 : SuperC2Cofinite W) :
    FiniteDimensional ℂ (W.toSuperNearVOA.superA hV) := by
```

From the mathematics to the Lean statement

`SuperZhuRingData V hV` is the proposition with fields `left_ideal`, `right_ideal`, `assoc` (`Modules/SuperZhuRing.lean`); from it the ring and algebra instances are built (`instRingSuperA`). The general near-VOA version `superZhuRingData_holds` needs only integrality and vanishing

of negative weight spaces. No spin–statistics, no skew gate.

Physical meaning

Zhu's theorem: $A(V)$ is the algebra of zero modes on ground states; it is associative because the zero modes compose. The finite dimensionality reflects finitely many ground-state types in a lisse theory.

Proof on paper. Zhu's residue calculus, run with the super Jacobi identity: the right-ideal and associator identities are residue manipulations in which every exchange of two vectors happens through the Jacobi identity, so the Koszul sign appears and cancels consistently; the left-ideal property follows from associativity. Finite-dimensionality: by triangularity in the weight, every $u_{(-2)}v$ equals $(L_{-1}u + L_0u) * v$ plus lower-weight terms, so a finite spanning set of W/C_2 spans $A(W)$. □

What the machine verified

`#print axioms` of `VOA.SuperVertexOperatorAlgebra.superZhuRingData` and `VOA.SuperNearVOA.finiteDimensional\_superA\_of\_superC2Cofinite`: `[propext, Classical.choice, Quot.sound]`. Unconditional beyond `hV` (and `hC2`).

Definition 17.44 (Twisted super Zhu quotient). Let g be an even automorphism with $g^N = 1$, $\delta_r = 1$ if $r = 0$ and 0 otherwise. For $u \in W_k$ in the eigenspace W^r ($gu = e^{-2\pi ir/N}u$) put $u \circ_g v = \sum_{i\geq 0} \binom{k-1+\delta_r+r/N}{i} u_{(i-1-\delta_r)}v$. Let $\bar{u} = \frac{1}{N}\sum_{a<N} g^a u$ (Reynolds average). $O_g(W)$ is spanned by the fixed-sector generators $(L_{-1}\bar{u} + L_0\bar{u}) * v$ and the nonfixed residues $u \circ_g v$ ($u \in W_k \cap W^r$, $r \neq 0$); $A_g(W) = W/O_g(W)$.

File `VOA/Modules/SuperTwistedZhu.lean`.

```
noncomputable def twistedZhuCircleHom (W : SuperVertexOperatorAlgebra 𝒱)
    (N r : ℕ) (k : ℤ) (u v : 𝒱) : 𝒱 :=
  ∑ᶠ i : ℕ, fractionalBinom (twistedZhuExponent N r k) i •
    W.smul u ((i : ℤ) - 1 - (twistedZhuDelta r : ℤ)) v
...
def SuperVertexOperatorAlgebra.twistedO
    (W : SuperVertexOperatorAlgebra 𝒱) (hW : W.toSuperNearVOA.IntegralWeights)
    (g : SuperAut W) (N : ℕ) : Submodule ℂ 𝒱 :=
  Submodule.span ℂ (W.twistedZhuFixedGeneratorSet hW g N ∪
    W.twistedZhuNonfixedGeneratorSet g N)
...
abbrev SuperVertexOperatorAlgebra.twistedA
    (W : SuperVertexOperatorAlgebra 𝒱) (hW : W.toSuperNearVOA.IntegralWeights)
    (g : SuperAut W) (N : ℕ) : Type u := 𝒱 ⧸ W.twistedO hW g N
```

From the mathematics to the Lean statement

`twistedZhuExponent N r k` $= k - 1 + \delta_r + r/N$; in the fixed sector the circle has exponent k and pole order 2 (`twistedZhuCircleHom_fixed`). At the identity twist $O_1 = O$ exactly (`twistedO_identity`). This matches Dong–Zhao (math/0411524), §3, in the integral-weight case; their sign-adjusted convention (σg in place of g) is kept separate in the library (`SuperAut.twistedZhuSignAdjusted`). The ring axioms for $g \neq 1$ are the unproved proposition `SuperTwistedZhuRingData` (including the right-unit statement $u - \bar{u} \in O_g$); so for $g \neq 1$ A_g is only a vector space in Lean.

Physical meaning

Ground states of g-twisted sectors are modules for $A_g(V)$; the nonfixed fields have no zero modes in a g-twisted sector (their modes are fractional), which is why W^r, $r \neq 0$, is killed. In the library the quotient $A_g(W)$ is a genuine object, but the map from twisted modules to it (`SuperTwistedModule.twistedZeroModeAction`) takes a `SuperTwistedModule`, which for $N \geq 2$ is the zero space (F1); so no nonzero ground-state module of a twisted sector is ever produced.

What the machine verified

Definitions; standard axioms.

Theorem 17.45 (Twisted Zhu finiteness). *If W is integrally graded and super C_2-cofinite, $g^N = 1$ with $N > 0$, and the eigenspace decomposition of g is internal and compatible with weight and parity, then $A_g(W)$ is finite-dimensional.*

File `VOA/Modules/SuperTwistedZhuFinite.lean`.

```
theorem finiteDimensional_twistedA_of_superC2Cofinite
    (W : SuperVertexOperatorAlgebra 𝒱) (hW : W.toSuperNearVOA.IntegralWeights)
    (g : SuperAut W) {N : ℕ} (hN : 0 < N) (_hpow : g ^ N = 1)
    (hE : TwistEigenspaceDecomposition W g N) (hC2 : SuperC2Cofinite W) :
    FiniteDimensional ℂ (W.twistedA hW g N) := by
```

From the mathematics to the Lean statement

`TwistEigenspaceDecomposition W g N` has three fields: `isInternal` (the eigenspaces W^r, $r \in \mathbb{Z}/N$, form an internal direct sum, i.e. g is diagonalisable) and the two statements that the projections preserve each W_k and each parity. Over $\mathbb{C}$ a finite-order operator is diagonalisable, and on each finite-dimensional W_k the projections are polynomials in g; so this hypothesis is in principle derivable from $g^N = 1$, but the library supplies it as data. `_hpow` is recorded but not used. The conclusion concerns a vector space (no ring structure needed). This theorem does *not* involve `SuperTwistedModule`, so finding (F1) does not touch it: it is a true statement about the vector space $A_g(W)$. What (F1) does touch is any intended application to twisted modules: there is no nonzero twisted module with $N \geq 2$ in the library for $A_g(W)$ to act on.

Physical meaning

A lisse theory has finitely many ground-state types in each twisted sector too.

Proof on paper. Triangular reduction by weight within each eigen-sector: for $u \in W_k^r$, the leading term of the circle residue is $u_{(-2)}v$ (fixed sector) or $u_{(-1)}v$ plus a pole-one tail (nonfixed), which reduces C_2 modulo O_g and strictly lower weights; a finite spanning set of W/C_2 then spans A_g. □

What the machine verified

`#print axioms VOA.finiteDimensional_twistedA_of_superC2Cofinite: [propext, Classical.choice, Quot.sound]`. Conditional on `hE` (diagonalisability data), `hW`, `hC2`.

17.10 The modular toolkit for super and half-integral theories

For a bosonic rational C_2-cofinite VOA, Zhu's theorem (Chapter 15) says that the torus one-point functions $\mathrm{tr}_M\, o(v)q^{L_0 - c/24}$ span an $SL_2(\mathbb{Z})$-invariant space. With fermions or half-integer weights

two things change. First, $T : \tau \mapsto \tau + 1$ multiplies a q^h-term by $e^{2\pi i h} = -1$ when $h \in \frac{1}{2} + \mathbb{Z}$, so only T^2 is a symmetry of a single character and the natural group is the theta group $\Gamma_\theta = \langle S, T^2 \rangle$. Second, a fermion on a torus needs a spin structure: a choice of periodic or antiperiodic boundary condition along each of the two cycles. The four spin structures $(\mu, \lambda) \in \{\pm\}^2$ correspond to the four traces tr_{NS}, $\mathrm{tr}_{NS}(-1)^F$, tr_R, $\mathrm{tr}_R(-1)^F$ and are permuted by $SL_2(\mathbb{Z})$ through its action on $(\mathbb{Z}/2)^2$; Γ_θ is the stabiliser of the NS–NS structure. This section presents the group theory, the automorphy factor, the four "spin" Eisenstein-type coefficient families of van Ekeren, and the proved transformation statements.

Definition 17.46 (The theta group). $\Gamma_\theta = \{g \in SL_2(\mathbb{Z}) : g \equiv \left(\begin{smallmatrix} 1 & 0 \\ 0 & 1 \end{smallmatrix}\right) \text{ or } g \equiv \left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right) \pmod 2\}$.

File `VOA/Modularity/ThetaGroup.lean`.

```
def redEntry (g : SL(2, ℤ)) (i j : Fin 2) : ZMod 2 :=
  (((g : Matrix (Fin 2) (Fin 2) ℤ) i j : ℤ) : ZMod 2)
...
def IsThetaCongr (g : SL(2, ℤ)) : Prop :=
  (redEntry g 0 0 = 1 ∧ redEntry g 0 1 = 0 ∧ redEntry g 1 0 = 0 ∧ redEntry g 1 1 = 1) ∨
    (redEntry g 0 0 = 0 ∧ redEntry g 0 1 = 1 ∧ redEntry g 1 0 = 1 ∧ redEntry g 1 1 = 0)
def GammaTheta : Subgroup SL(2, ℤ) where
  carrier := {g | IsThetaCongr g}
```

From the mathematics to the Lean statement

Mod 2, $S = \left(\begin{smallmatrix} 0 & -1 \\ 1 & 0 \end{smallmatrix}\right) \equiv \left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right)$, so this is "$g \equiv I$ or $g \equiv S$". Closure under products and inverses is proved by computation in $\mathbb{Z}/2$. Standard (e.g. Knopp, *Modular functions in analytic number theory*, Ch. 2).

Physical meaning

Γ_θ is the subgroup of the mapping class group of the torus preserving the NS–NS (antiperiodic–antiperiodic) spin structure, i.e. the modular group of a single fermionic partition function $\mathrm{tr}_{NS}\, q^{L_0 - c/24}$.

What the machine verified

A definition; standard axioms.

Theorem 17.47 (Generation and index). $\Gamma_\theta = \langle S, T^2 \rangle$, $T \notin \Gamma_\theta$, $\Gamma(2) \le \Gamma_\theta$, *and* $[SL_2(\mathbb{Z}) : \Gamma_\theta] = 3$.

File `VOA/Modularity/ThetaGroup.lean`.

```
theorem Gamma_two_le : CongruenceSubgroup.Gamma 2 ≤ GammaTheta := by
...
theorem T_not_mem : ModularGroup.T ∉ GammaTheta := by
...

...
theorem GammaTheta_eq_genSTsq : GammaTheta = genSTsq := by
...
theorem index_eq_three : GammaTheta.index = 3 := by
```

From the mathematics to the Lean statement

`Subgroup.closure` is the subgroup generated. `index` is Mathlib's `Subgroup.index` (the cardinality of $SL_2(\mathbb{Z})/\Gamma_\theta$). `genSTsq` is definitionally the `thetaGroup` of `Modularity/`

`SlashSubgroup.lean` (Chapter 14), and `GammaThetaStmt.thetaGroup_eq` records `SlashSub.thetaGroup = ThetaGroup.GammaTheta`.

Physical meaning

The three cosets Γ_θ, $T^{-1}\Gamma_\theta$, $(TS)^{-1}\Gamma_\theta$ correspond to the three even spin structures (NS–NS, NS–R, R–NS), permuted by $SL_2(\mathbb{Z})$; the odd R–R structure is fixed.

Proof on paper. $\langle S, T^2\rangle \le \Gamma_\theta$ since both generators are in it. Conversely, $SL_2(\mathbb{Z})$ acts on the three right cosets of $\langle S, T^2\rangle$ represented by $1, T, TS$ (checked on the generators S, T); an element of Γ_θ maps the coset of 1 to that of $t \in \{1, T, TS\}$ with $t \in \Gamma_\theta$, and $T, TS \notin \Gamma_\theta$ force $t = 1$. Index: every g is in exactly one of three explicit cosets, by its reduction mod 2 ($SL_2(\mathbb{Z}/2) \cong S_3$ has order 6 and the image of Γ_θ has order 2). □

What the machine verified

`#print axioms` of `VOA.ThetaGroup.GammaTheta\_eq\_genSTsq`, `VOA.ThetaGroup.index\_eq\_three`: `[propext, Classical.choice, Quot.sound]`. Unconditional.

Theorem 17.48 (A half-integral automorphy factor on Γ_θ). *The principal square root $s(A,\tau) = \sqrt{c\tau + d}$ satisfies, for all $A, B \in SL_2(\mathbb{Z})$ and τ in the upper half-plane, $s(AB,\tau) = m(A,B)\, s(A, B\tau)\, s(B,\tau)$ with a constant $m(A,B)$ independent of τ; hence a* `HalfAutFactor` *exists on every subgroup, in particular on Γ_θ.*

File `VOA/Modularity/SlashSubgroup.lean`.

```
structure HalfAutFactor (Γ : Subgroup SL(2, ℤ)) where

...
noncomputable def thetaHalfAutFactor : HalfAutFactor thetaGroup :=
  principalHalfAutFactor thetaGroup
...
theorem thetaHalfAutFactorExists : ThetaHalfAutFactorExists :=
  ⟨SlashSub.thetaHalfAutFactor⟩
```

From the mathematics to the Lean statement

`autFactor A τ` $= c\tau + d$ (Chapter 14). The crucial point is that `mult` does *not* depend on τ; that is a real constraint, proved by continuity of the ratio, the fact that its square is 1, and connectedness of the upper half-plane (evaluate at $\tau = i$). The resulting multiplier is ± 1-valued; the docstring's "intended" theta multiplier (an eighth root of unity) is a different, equally valid choice, the difference being absorbable into the representation ρ of a modularity statement. `ThetaHalfAutFactorExists` is `Nonempty (SlashSub.HalfAutFactor SlashSub.thetaGroup)`.

Physical meaning

Characters of weight $\frac{1}{2}$ objects (η, θ-functions, fermionic partition functions with insertions of half-integral weight) transform with $(c\tau+d)^{1/2}$ times a multiplier system; this is the analytic datum needed to even state Γ_θ-modularity.

Proof on paper. $s(AB,\tau)^2 = j(AB,\tau) = j(A,B\tau)j(B,\tau) = (s(A,B\tau)s(B,\tau))^2$ (j the automorphy factor, a cocycle), so the ratio m is a continuous function on the upper half-plane with values in $\{\pm1\}$ (the denominator never vanishes), hence constant. □

What the machine verified

`#print axioms VOA.GammaThetaStmt.thetaHalfAutFactorExists:` `[propext, Classical.choice, Quot.sound]` (umbrella check). Unconditional.

Definition 17.49 (Spin pairs and their $SL_2(\mathbb{Z})$-action). A spin pair is $(\mu,\lambda)\in(\mathbb{Z}/2)^2$ (bit 0 for $+1$, 1 for -1); $A=\left(\begin{smallmatrix}a&b\\c&d\end{smallmatrix}\right)$ acts on the right by $(\mu,\lambda)\cdot A = (a\mu+c\lambda,\ b\mu+d\lambda)$ mod 2.

File `VOA/Modularity/SuperSpinCoefficients.lean`.

```
structure SpinPair where
  mu : SpinPhase
  lambda : SpinPhase
deriving DecidableEq, Fintype
...
def act (A : SL(2, ℤ)) (p : SpinPair) : SpinPair :=
  ⟨p.mu * ThetaGroup.redEntry A 0 0 + p.lambda * ThetaGroup.redEntry A 1 0,
   p.mu * ThetaGroup.redEntry A 0 1 + p.lambda * ThetaGroup.redEntry A 1 1⟩
```

From the mathematics to the Lean statement

`SpinPhase` is `ZMod 2`. Proved: a right action (`act_mul`), S swaps the labels, T sends $(\mu,\lambda)\mapsto(\mu,\mu+\lambda)$, T^2 fixes everything, and every element of Γ_θ either fixes or swaps (`act_gammaTheta_self_or_swap`). The labels are *not* identified with parity: `mu` and `lambda` are spatial and temporal eigenvalue labels.

Physical meaning

μ labels the boundary condition along the spatial circle (the twist g of the sector), λ along the time circle (the insertion h in the trace). The action is the orbifold rule $(g,h)\cdot A=(g^a h^c, g^b h^d)$ of Dong–Li–Mason read on ±1 eigenvalues. For fermions the physical spin structure combines these labels with the conformal sign $\kappa = e^{2\pi i L_0}$ (`SuperConformalSign.lean`), which is why T fixes the label $(+,+)$ and yet $T\notin\Gamma_\theta$: on half-integral weights T itself produces a sign.

What the machine verified

Definitions; standard axioms.

Definition 17.50 (Characteristic theta functions). $\Theta[a,b](z,\tau) = e^{\pi i a^2\tau+2\pi i a(z+b)}\,\vartheta(z+a\tau+b,\tau)$ with $\vartheta(z,\tau)=\sum_n e^{\pi i n^2\tau+2\pi i n z}$ (Mathlib's `jacobiTheta₂`); for a spin pair the characteristics are $a,b\in\{0,\frac{1}{2}\}$.

File `VOA/Modularity/SuperSpinThetaBridge.lean`.

```
noncomputable def spinThetaChar (a b z tau : Complex) : Complex :=
  Complex.exp (Real.pi * Complex.I * a ^ 2 * tau +
    2 * Real.pi * Complex.I * a * (z + b)) *
      jacobiTheta₂ (z + a * tau + b) tau
...
noncomputable def spinPairTheta (p : SpinPair) (z tau : Complex) : Complex :=
  spinThetaChar (spinThetaHalf p.mu) (spinThetaHalf p.lambda) z tau
```

From the mathematics to the Lean statement

`spinThetaHalf` sends $+ \mapsto 0$, $- \mapsto \frac{1}{2}$. This is the standard theta function with characteristics (Mumford, *Tata lectures on theta I*, §II.1).

Physical meaning

$\vartheta[a,b](0,\tau)/\eta(\tau)$ are the partition functions of a complex fermion in the four spin structures; their ratios and logarithmic derivatives are the propagators of a fermion on the torus, which is how they enter the genus-one recursion.

What the machine verified

Definitions; standard axioms.

Theorem 17.51 (Spin theta S-law). *For all $a, b, z \in \mathbb{C}$ and $\tau \neq 0$,*

$$\Theta[a,b]\Big(\frac{z}{\tau}, -\frac{1}{\tau}\Big) = (-i\tau)^{1/2}\, e^{\pi i z^2/\tau + 2\pi i a b}\, \Theta[b,-a](z,\tau),$$

and, for $\operatorname{Im}\tau > 0$, the cross-multiplied difference of logarithmic derivatives of two such theta functions transforms homogeneously with the factor $((-i\tau)^{1/2})^2$ and the product of the two Gaussian-and-phase exponentials.

File `VOA/Modularity/SuperSpinThetaBridge.lean`.

```
theorem spinThetaChar_S (a b z tau : Complex) (htau : tau ≠ 0) :
    spinThetaChar a b (z / tau) (-1 / tau) =
      (-Complex.I * tau) ^ (1 / 2 : Complex) *
        Complex.exp (Real.pi * Complex.I * z ^ 2 / tau +
          2 * Real.pi * Complex.I * a * b) * spinThetaChar b (-a) z tau := by
...
theorem spinThetaCross_S
    (a b c d z tau : Complex) (htauIm : 0 < tau.im) :
    thetaCross
        (fun w => spinThetaChar a b (w / tau) (-1 / tau))
        (fun w => spinThetaChar c d (w / tau) (-1 / tau)) z =
      ((-Complex.I * tau) ^ (1 / 2 : Complex)) ^ 2 *
        Complex.exp (2 * (Real.pi * Complex.I * z ^ 2 / tau) +
          2 * Real.pi * Complex.I * (a * b + c * d)) *
        thetaCross (fun w => spinThetaChar b (-a) w tau)
          (fun w => spinThetaChar d (-c) w tau) z := by
```

From the mathematics to the Lean statement

`(-Complex.I * tau) ^ (1 / 2 : Complex)` is the principal power $(-i\tau)^{1/2}$. `thetaCross f g z` $= f'(z)g(z) - g'(z)f(z)$, so thetaCross $= 0$ says the logarithmic derivatives agree; the second statement is the denominator-free form of the law for $\partial_z \log\Theta[a,b] - \partial_z \log\Theta[c,d]$. The characteristic $[b,-a]$ is unreduced ($-a$ rather than $-a$ mod 1); reduction only changes a

constant sign. **This is the analytic kernel only**: the identification of the coefficient families $P_k^{\mu,\lambda}$ below with Taylor coefficients of these logarithmic derivatives (a Jacobi triple product / Lambert expansion) is *not* in the library, so no S-law for the non-$(+,+)$ spin coefficients follows.

Physical meaning

Poisson summation: S exchanges space and time, hence the two characteristics, i.e. the NS–R and R–NS spin structures, with the modular anomaly $(-i\tau)^{1/2}$ of a weight-$\frac{1}{2}$ object.

Proof on paper. Mathlib's `jacobiTheta₂_functional_equation` is the case $a = b = 0$; substitute $w = z - a + b\tau$ and collect the Gaussian exponentials (a polynomial identity in the exponents). For the logarithmic-derivative form, the z-independent phase and the common Gaussian cancel in $f'g - g'f$. □

What the machine verified

`#print axioms` of `VOA.spinThetaChar\_S`, `VOA.spinThetaCross\_S`: `[propext, Classical.choice, Quot.sound]`. Unconditional.

Definition 17.52 (Van Ekeren's spin coefficient series)**.** For a spin pair $p = (\mu, \lambda)$ and $k \in \mathbb{N}$, $P_k^{\mu,\lambda}$ is the formal series on the half-lattice $\frac{1}{2}\mathbb{N}$ of exponents with constant term $\delta_{k,0}\delta_{p,(+,-)}\pi i - \frac{(2\pi i)^{k+1}}{(k+1)!}B_{k+1}(1+\varepsilon_\mu)$ $(\varepsilon_+ = 0, \varepsilon_- = -\frac{1}{2})$ and higher coefficients the Lambert sums of van Ekeren's Lemma 3.1; $Q_k^{\mu,\lambda} = (2\pi i)^{-k-1}P_k^{\mu,\lambda}$, and $\mathcal{Q}_k^{\mu,\lambda}(\tau) = \sum_N Q_k(N/2)e^{\pi i N\tau}$.

File `VOA/Modularity/SuperSpinCoefficients.lean`.

```

noncomputable def spinQAnalytic (p : SpinPair) (k : Nat) (z : Complex) : Complex :=
  ∑' N : Nat, spinQAnalyticTerm p k N z
```

From the mathematics to the Lean statement

`FormalQSeries` is $\mathbb{C} \to \mathbb{C}$ (coefficient at a complex exponent, Chapter 14); `halfLatticeQSeries a` places $a(N)$ at exponent $N/2$ and 0 elsewhere; `spinPNatCoeff` is the explicit cusp-plus-Lambert coefficient (quoted in full in the source; it uses `Polynomial.bernoulli` and divisor sums over `Nat.divisorsAntidiagonal`). `∑'` is Mathlib's `tsum` (value 0 if not summable; summability is proved, `summable_spinQAnalyticTerm`, for $\operatorname{Im} z > 0$). Proved fidelity check: at $(+,+)$ and $k = 2j-1$, Q is *exactly* Zhu's normalised Eisenstein series `zhuG j` (Chapter 14, Definition 14.5; `spinP_pp_eq_spinTwoPiI_pow_zhuG`); for $\mu = +$ the odd half-exponents vanish.

Physical meaning

These are the coefficient functions of the twisted Weierstrass functions $P_k\left[\begin{smallmatrix}\mu\\ \lambda\end{smallmatrix}\right](z,\tau)$ that appear in genus-one recursion for traces over twisted sectors with twisted insertions (Mason–Tuite–Zuevsky, van Ekeren). In the untwisted sector they are the Eisenstein series G_{2k}. (The coefficient functions are genuine; but the twisted-sector traces they are meant to enter are, in the library, traces over `SuperTwistedModules` with $N \geq 2$, which are zero spaces (F1).)

What the machine verified

Definitions; standard axioms. Holomorphy (`differentiableOn_spinQAnalytic`) and uniform convergence on closed sub-half-planes are proved.

Theorem 17.53 (Proved transformation cells). *For every spin pair, $Q_k^{\mu,\lambda}(\tau+2) = Q_k^{\mu,\lambda}(\tau)$. In the invariant sector $(+,+)$: for $j \geq 2$, $Q_{2j-1}(-1/\tau) = \tau^{2j} Q_{2j-1}(\tau)$, and $Q_1(-1/\tau) = \tau^2 Q_1(\tau) - \tau/(2\pi i)$.*

File `VOA/Modularity/SuperSpinAnalytic.lean`.

    spinQAnalytic p k (z + 2) = spinQAnalytic p k z := by
```

File `VOA/Modularity/SuperSpinS.lean`.

```
theorem spinQAnalytic_pp_higher_S {j : Nat} (hj : 2 ≤ j) {z : Complex}
    (hz : z ∈ imGT 0) :
    spinQAnalytic SpinPair.pp (2 * j - 1) (-1 / z) =
      z ^ (2 * j) * spinQAnalytic SpinPair.pp (2 * j - 1) z := by
...
theorem spinQAnalytic_pp_one_S {z : Complex} (hz : z ∈ imGT 0) :
    spinQAnalytic SpinPair.pp 1 (-1 / z) =
      z ^ 2 * spinQAnalytic SpinPair.pp 1 z - z / spinTwoPiI := by
```

From the mathematics to the Lean statement

`imGT 0` is $\{z : \operatorname{Im} z > 0\}$. The $(+,+)$ cells are the Eisenstein S-laws of Chapter 14 transported through the identification with `zhuGC`; the weight-2 cell carries the G_2 anomaly. **The three other spin sectors have no proved S-law**; the T^2-law holds for all four. The weight-1 case $k = 0$ (a constant) is deliberately not given a transformation law.

Physical meaning

Only the untwisted Eisenstein series are covered; the twisted ones, which mix sectors under S ($(+,-) \leftrightarrow (-,+)$), are exactly what a Γ_θ-modularity proof needs.

Proof on paper. T^2: every exponent $N/2$ satisfies $e^{2\pi i(N/2)\cdot 2} = 1$. S at $(+,+)$: the odd half-exponents vanish, the even ones reindex to $\sum_n G_{2j}(n) q^n$, and the Eisenstein law applies. □

What the machine verified

`#print axioms` of the three theorems: `[propext, Classical.choice, Quot.sound]`. Unconditional, as statements about coefficient functions. Their intended use, traces over twisted (spin) sectors, is vacuous in the library: those sectors are `SuperTwistedModules` with $N \geq 2$, hence zero (F1).

17.10.1 Genus-one blocks for integrally graded super VOAs

Notation: square-bracket modes. Genus-one (torus) quantities are naturally written in the cylinder coordinate w, with $z = e^w - 1$. Zhu's change of coordinates (Chapter 15, Definition 15.7; Chapter 16, §16.5) defines, for a of integral weight k, the field $Y[a,w] = Y(a,e^w-1)e^{kw} = \sum_{m\in\mathbb{Z}} a[m]w^{-m-1}$; its coefficients $a[m]$ are the *square-bracket modes*. Each $a[m]$ is a finite combination $a[m] = a_{(m)} + (\text{terms } a_{(m+i)},\ i \geq 1)$ of ordinary modes, so $a[-2]b$ differs from $a_{(-2)}b$ by terms of lower weight. The square-bracket Virasoro operators are $L[n] = \omega[n+1] - \frac{c}{24}\delta_{n,-2}\,\mathrm{id}$, and a is *square-bracket primary* of weight Δ if $L[0]a = \Delta a$ and $L[n]a = 0$ for $n \geq 1$. The functions $G_{2m+2}(z)$ below are Zhu's normalised Eisenstein series (Chapter 14, Definition 14.7).

Definition 17.54 (Analytic super block). For an integrally graded super near-VOA V, a function $F : V \times \{\mathrm{Im}\, z > 0\} \to \mathbb{C}$, linear in the state and holomorphic in z, is an analytic super block if $F(a[0]v) = 0$ for $a \in V_k$, $k \geq 1$, $F(a[-2]v) + \sum_{m\geq 0}(2m+1)G_{2m+2}(z)F(a[2m]v) = 0$, and the ω-recursion $F(L[-2]v) = \frac{1}{2\pi i}\partial_z F(v) + \sum_m G_{2m+2}(z)F(L[2m]v)$ holds.

File `VOA/Modularity/SuperAnalyticBlock.lean`.

            * F (V.superLsq (2 * (m + 1) - 2 : ℤ) v) z
```

From the mathematics to the Lean statement

`V.superVSqZ a k m` is the square-bracket mode $a[m]$ for a of weight k (Zhu's change of coordinates, Chapter 15, Definition 15.7); `superLsq n` $= L[n]$; `zhuGC j` $= G_{2j}$ in Zhu's normalisation (Chapter 14, Definition 14.7). The $m = 0$ term of `negTwo` is $G_2F(a[0]v)$, killed by `vanish`, so this is Zhu's recursion $\sum_{k\geq 2}$. The Koszul sign does not appear in the definition: it appears only when $a[0]v$ is identified, modulo $O(V)$, with a supercommutator $[a]*[v] - (-1)^{pq}[v]*[a]$ (`SuperZhuCommutator.lean`); a supertrace kills supercommutators.

Physical meaning

The torus one-point functions $\mathrm{str}_M\, o(v)q^{L_0-c/24}$ (with the $(-1)^F$ insertion, i.e. the $(+,-)$-type temporal structure for integral weights) satisfy these Ward identities; the definition axiomatises them.

What the machine verified

A definition; standard axioms.

Theorem 17.55 (Super Arike–Nagatomo upper bound). *If W is an integrally graded, super C_2-cofinite super VOA, the space of analytic super blocks (restricted to the upper half-plane) is finite-dimensional*

and its dimension is at most the dimension of the space of supersymmetric linear functionals on $A(W)$ (those ϕ with $\phi(ab) = (-1)^{pq}\phi(ba)$ on homogeneous a, b).

File `VOA/Modularity/SuperBlockBoundC2.lean`.

```
theorem finrank_superAnalyticBlocks_le_finrank_superZhuSymmetricFunctionals
    (W : SuperVertexOperatorAlgebra 𝒱) (hV : W.toSuperNearVOA.IntegralWeights)
    (hC2 : SuperC2Cofinite W) :
    finrank ℂ (Submodule.map restrictImGT W.toSuperNearVOA.superAnalyticBlocks)
      ≤ (let hZ := W.superZhuRingData hV
        letI := hZ.AsRing
        letI := hZ.AsAlgebra
        finrank ℂ hZ.superZhuSymmetricFunctionals) := by
```

From the mathematics to the Lean statement

`restrictImGT` restricts functions to the upper half-plane. `finrank` of an infinite-dimensional space is 0 in Mathlib, so the companion `finiteDimensional_superAnalyticBlocks_of_superC2` (finite-dimensionality) is what prevents the inequality from being vacuous; it is proved. No rationality or semisimplicity is assumed. The bound is the upper-bound half of Arike–Nagatomo's theorem (super version); the realisation of the bound by pseudo-supertraces is not proved.

Physical meaning

The number of independent torus amplitudes with a $(-1)^F$ insertion is at most the number of supersymmetric functionals on the zero-mode algebra; in a logarithmic theory such as symplectic fermions, pseudo-supertraces over non-semisimple sectors are expected to saturate it.

Proof on paper. Every block kills the relation space spanned by the $a[0]v$ and the $a[-2]v + \dots$; by C_2-cofiniteness and a triangular descent (the square-bracket $a[-2]b$ differs from $a_{(-2)}b$ by lower-weight terms), finitely many states T span modulo the relations at some interior point, with $|T|$ bounded by the cusp quotient, which is identified with $A(W)/[A(W), A(W)]_{\mathrm{super}}$ (`SuperCuspFunctionalCount.lean`); a block vanishing at T at one point vanishes identically by the ω-ODE. Its dual is the space of supersymmetric functionals. □

What the machine verified

`#print axioms VOA.SuperNearVOA.finrank_superAnalyticBlocks_le_finrank_superZhuSymmetricFunctionals`: `[propext, Classical.choice, Quot.sound]`. Unconditional beyond `hV`, `hC2`. Instance: symplectic fermions (`SympFermSuperBlockBound.lean`, dimension ≤ 4).

Theorem 17.56 (Supertraces are formal super blocks). *For every graded super module N of an integrally graded super VOA, the formal one-point supertrace $v \mapsto \sum_e \mathrm{str}_{N_{e+c/24}} o(v)\, q^e$ is a formal super block: it kills the relation module and satisfies the ω-recursion with the formal Eisenstein coefficients.*

File `VOA/Modularity/SuperTorusRecursionClose.lean`.

```
theorem superTorusOnePoint_isSuperFormalBlock
    (N : SuperOrdVModule W M) (hW : W.toSuperNearVOA.IntegralWeights) :
    SuperNearVOA.IsSuperFormalBlock W (N.superTorusOnePoint hW) := by
```

From the mathematics to the Lean statement

`IsSuperFormalBlock W S` (`SuperFormalBlock.lean`) is the conjunction of "`superBlockRelSpanG` is in the kernel of every supported lift" and the formal ω-recursion $S(L[-2]v) = q\frac{d}{dq}S(v) + \sum_m G_{2m+2} * S(L[2m]v)$ (`qConv` is convolution with the coefficient sequence). `superTorusOnePoint` takes at exponent e the supertrace (`supertrace`, $\mathrm{tr}((-1)^F\cdot)$, basis-free) of the zero mode on $N_{e+c/24}$. Since the only `SuperOrdVModules` constructed are bosonic (`OrdVModule.toSuper`), this theorem has no instance with a nonzero odd part in the library.

Physical meaning

Zhu's recursion for torus amplitudes with $(-1)^F$: the two signs (Koszul in the commutator, Koszul in supertrace cyclicity) cancel, so the bosonic Lambert–Eisenstein resummation goes through.

Proof on paper. The super module commutator formula from the $\ell = 0$ slice of the module Jacobi identity gives $o(a[0]b) = o(a)o(b) - (-1)^{pq}o(b)o(a)$, which has zero supertrace by Koszul cyclicity; the $[-2]$ and ω relations follow from Zhu's geometric-series argument, the compensated pair carrying one Koszul scalar from the iterate and the same from cyclicity, whose product is 1. □

What the machine verified

`#print axioms VOA.SuperOrdVModule.superTorusOnePoint_isSuperFormalBlock: [propext, Classical.choice, Quot.sound].` Unconditional; untwisted sector only. Odd (type-Q) traces: only the square-bracket-zero slice is proved.

Theorem 17.57 (Super Arakawa–Kawasetsu formal ODE). *If W is integrally graded and super Etingof-finite, S is a formal super block supported on $q^{h+\mathbb{N}}$, and a is square-bracket primary, then $S(a)$ satisfies a monic formal q-differential equation $(q\frac{d}{dq})^s S(a) + \sum_{i<s} g_i * (q\frac{d}{dq})^i S(a) = 0$ with subexponential coefficient sequences g_i.*

File `VOA/Modularity/SuperAKFormalODE.lean`.

```
theorem formalODE_of_etingofFinite_of_sqPrimary {S : V →ₗ[ℂ] FormalQSeries} {hbase : ℂ}
    (hsupp : ∀ v, S v ∈ QSeriesAt hbase) (hS : SuperNearVOA.IsSuperFormalBlock W S)
    (hV : W.toSuperNearVOA.IntegralWeights) (hE : SuperEtingofFinite W) {a : V} {Δ : ℂ}
    (ha : W.toSuperNearVOA.IsSuperSqPrimary a Δ) :
    ∃ (s : ℕ) (g : ℕ → ℕ → ℂ), 1 ≤ s ∧ (∀ i, Subexponential (fun k => ‖g i k‖)) ∧
      ∀ e : ℂ, (qDeriv^[s] (S a)) e
        + ∑ i ∈ Finset.range s, qConv (g i) (qDeriv^[i] (S a)) e = 0 :=
```

From the mathematics to the Lean statement

`QSeriesAt hbase`: series supported on $hbase + \mathbb{N}$. `IsSuperSqPrimary a Δ`: $L[0]a = \Delta a$, $L[n]a = 0$ for $n \geq 1$. `qDeriv` is $q\frac{d}{dq}$ on formal series; `Subexponential`: growth $e^{o(k)}$ (Chapter 14, Definition 14.18). The coefficients are formal series, not elements of $\mathbb{C}[G_4, G_6]$; so this is **not** a modular linear differential equation, and nothing about modularity or convergence follows (the docstring says so).

Physical meaning

Arakawa–Kawasetsu: characters of quasi-lisse theories satisfy modular linear differential equations. The formal shadow proved here is the Noetherian argument; the modular coefficients and the analytic continuation are missing.

Proof on paper. By Etingof-finiteness the block span is a finitely generated module over the Noetherian ring of Zhu's quasimodular coefficients, so the tower $S(L[-2]^i a)$ satisfies a monic relation; for a primary a the ω-recursion makes $S(L[-2]^i a)$ unitriangular in $(q\frac{d}{dq})^j S(a)$, which converts the relation. □

What the machine verified

`#print axioms VOA.SuperAK.formalODE_of_etingofFinite_of_sqPrimary: [propext, Classical.choice, Quot.sound]`. Conditional on `hS` (supplied by Theorem 17.56 for supertraces), `hV`, `hE`, `ha`. No instance in the library combines integral weights, super Etingof-finiteness and a genuinely odd part.

17.10.2 The half-integral side: finite cusp descent

Theorem 17.58 (Finite square-spin cusp quotient). *Let W be a half-integrally graded super VOA ($W_h = 0$ unless $h \in \frac{1}{2}\mathbb{Z}$), super C_2-cofinite, and (g, h) a commuting pair of involutive even automorphisms. Then the quotient of W by the square-spin cusp relation span of the $(+,+)$ inner eigensector of (g, h) is finite-dimensional.*

File `VOA/Modularity/SuperSpinDescentSqFinite.lean`.

```
theorem BoundaryPair.finiteDimensional_superSpinSqCuspQuotient_of_superC2
    (b : BoundaryPair W) (hhalf : IsHalfIntegerGraded W)
    (hspatial : b.spatial ^ 2 = 1) (htemporal : b.temporal ^ 2 = 1)
    (hC2 : SuperC2Cofinite W) :
    FiniteDimensional Complex
      (VType / superSpinSqCuspRelSpan W hhalf b.spinEigenspace) :=
```

File `VOA/Modularity/SuperSectorSystem.lean`.

```
structure BoundaryPair (W : SuperVertexOperatorAlgebra VType) where
  spatial : SuperAut W
  temporal : SuperAut W
  commute : Commute spatial temporal
```

From the mathematics to the Lean statement

`IsHalfIntegerGraded W`: $W_k = 0$ unless $k = m/2$ for some $m \in \mathbb{Z}$ (`GammaThetaStatement.lean`). `b.spinEigenspace` assigns to each `SpinPair` the simultaneous ± 1 eigenspace of the two involutions; `superSpinSqCuspRelSpan` is spanned by the cusp ($q \to 0$) limits of the square-bracket spin relations together with the three non-$(+,+)$ eigenspaces, the square C_2 being formed with the square-bracket $[-2]$ products (a separate span `superSqO₂`, because ordinary C_2 is not square-graded). No spin–statistics and no identification of g, h with parity. This does not involve twisted modules, so (F1) does not touch it.

Physical meaning

The finiteness of the space of genus-one conformal blocks in one spin structure, at the level of the cusp: the algebraic precondition of any Γ_θ-modularity theorem.

Proof on paper. Ordinary C_2-cofiniteness implies square C_2-cofiniteness by unitriangular induction on doubled weight (the square $[-2]$ mode has leading coefficient one); projecting to the $(+,+)$ eigenspace is compatible with the square grading. □

What the machine verified

```
#print axioms VOA.SuperNearVOA.BoundaryPair.finiteDimensional_
superSpinSqCuspQuotient_of_superC2:      [propext, Classical.choice, Quot.sound].
```

Unconditional beyond its hypotheses. No half-integrally graded super C_2-cofinite instance exists in the library ($\beta\gamma$ is not C_2-cofinite; the free fermion is not built).

17.11 The four-by-three grid: what each cell contains

The project organises super modularity as a grid. The *columns* are four independent kinds of object: integral non-super (ordinary VOAs), integral super (integer weights, nontrivial parity), half-integral non-super (weights in $\frac{1}{2}\mathbb{Z}$, purely even; represented as purely even `SuperVertexOperatorAlgebra`s, since `VertexOperatorAlgebra` is $\mathbb{Z}$-graded), and half-integral super. The *rows* are three routes to modularity: (R1) strong rationality and Zhu's theorem (Chapter 15); (R2) strong finiteness and the Arike–Nagatomo / pseudo-trace theorem (Chapter 18); (R3) the quasi-lisse (Etingof-finite) Arakawa–Kawasetsu route (Chapter 16). A cell is *complete* only when the corresponding modular-invariance theorem is proved for the abstract class *and* instantiated. The table below says exactly what is in Lean. "(F1)" marks a component that is vacuous by Theorem 17.24: it takes a `SuperTwistedModule` with $N \geq 2$ as input, and (when this chapter was first written, and still in the released source) every such module is the zero space. Such components are listed for completeness only; they have no mathematical content.

	Integral non-super	**Integral super**	**Half-integral non-super**	**Half-integral super**
R1 Zhu	Bosonic $SL_2(\mathbb{Z})$ modularity proved *conditionally* on `StronglyRational` plus named Dong–Li–Mason inputs (Chapter 15). No model instantiated (Lee–Yang lacks `StronglyRational`).	Proved: super Zhu ring (Thm. 17.43); identity-sector supertrace is a formal block (Thm. 17.56); finite type-M/type-Q Wedderburn functional calculus for a *supplied* decomposition (`SuperWedderburnTrace.lean`, `QueerOddTrace.lean`). Supplied-data sector realization (`FiniteCompleteSectorTraceRealization`): vacuous for $N \geq 2$ (F1). No modularity theorem. No model.	Proved: Γ_θ, half-automorphy factor, spin coefficients with T^2-law and $(+,+)$ S-cells (Thms. 17.47–17.53); finite cusp descent (Thm. 17.58). Denominator-two trace carrier: vacuous (F1). No Γ_θ theorem. No model.	Same foundation as the previous column (parity independent of weight). No Γ_θ theorem. Intended model, the free fermion, exists only as operators (Thm. 17.27).
R2 AN	Analytic-block upper bound and partial pseudo-trace blocks (Chapter 18); realization, convergence, spanning, modular invariance open.	Proved: super AN upper bound (Thm. 17.55). Model: symplectic fermions are super C_2-cofinite with non-semisimple $A(SF)$, dim ≤ 4 (Thms. 17.37, 17.38); bound ≤ 4 for them. No pseudo-supertraces; irrationality only conditional (Thm. 17.40).	Finite cusp descent (Thm. 17.58); the recursion bridge (`SuperSpinSqRecursionData`) has three unproved fields and acts on a vacuous carrier (F1).	Same, parity independent. No model.

	Integral non-super	Integral super	Half-integral non-super	Half-integral super
R3 AK	A common monic MLDE for analytic blocks from `EtingofFinite` and supplied grading/Ramanujan inputs (Chapter 16); character modularity open.	Proved: formal super AK ODE (Thm. 17.57), conditional on a formal block and `SuperEtingofFinite`; relative quotient carriers for twisted modules vacuous for $N \geq 2$ (F1). No convergence, no modularity. No model.	Proved: Noetherian bounded coefficient algebra and a pp cusp recurrence (`SuperSpinQuasiLisseAlgebra.lean`), conditional on `SuperSpinCuspEulerData` and `SuperSpinRelativeEtingofData`. Model: $\beta\gamma$ is super Etingof-finite and not super C_2 (Thm. 17.34); no trace or ODE instantiated.	Same conditional infrastructure, parity independent. No model.

The grid in one sentence

No cell of the three new columns contains a modular-invariance theorem, conditional or not; every proved item is a foundation, a finiteness or upper-bound result, a formal (non-analytic) ODE, or a transformation law of the Eisenstein-type coefficient functions. In addition, finding (F1) empties every component that uses a `SuperTwistedModule` with $N \geq 2$: the half-integral trace carriers, the Ramond support statements, the twisted sector realization, and the relative quotients of twisted modules. The integral non-super column is documented in Chapters 15, 16, 18; its status was not re-verified for this chapter.

17.12 Machine status of the headlines

All axiom checks below were run for this chapter on a scratch file importing the relevant modules (the umbrellas `Modularity/SuperIntegral.lean` and `Modularity/HalfIntegralGridFoundations.lean` among them) with `lake env lean -DmaxSynthPendingDepth=3`; no full `lake build` was run. Every declaration listed reports exactly the three standard axioms; **none uses `VOA.pbw` (the PBW theorem of Chapter 3; formerly a project axiom, now a theorem)**.

The Lean checks behind Theorems 17.4, 17.24 and 17.27 (not part of this release) compile with the same three axioms.

Release audit 2026-10-27: RELEASE_AUDIT_L17_L18_L23.md. The independent release audit `Notes/Textbook/referee/RELEASE_AUDIT_L17_L18_L23.md` re-elaborated, at a later pre-release commit and from the existing build products (`lake env lean -DmaxSynthPendingDepth=3`; `lake build` not run), `SuperNearVOA.superJacobi`, `evenPartVOA`, `sympFermSVOA`, `sympFerm_superC2Cofinite`, `ASF_not_isSemisimpleRing`, `finrank_ASF_le_four`, `sympFermSVOA_not_isSuperRational`, `bgSVOA`, `not_SuperC2Cofinite_bgSVOA`, `bgSVOA_superEtingofFinite` and `bcGhostSVA`; each reports only the three standard axioms. It recompiled the checks mentioned above. Verdicts: *super VOAs, even part, symplectic fermions, $\beta\gamma$: announceable with caveats* — the super Jacobi identity for `SuperNearVOA`, `evenPartVOA` and `sympFermSVOA` ($c = -2$, genuinely odd) are sound; super C_2-cofiniteness and non-semisimplicity of the super Zhu algebra are proved, its dimension only shown ≤ 4 (m11); `bgSVOA` ($c = -1$) is purely even (m10); `SuperVertexAlgebra` lacks translation covariance, which weakens `bcGhostSVA` (m9). *Twisted/Ramond super modules, super-irrationality and the free fermion: not announceable* (M6, m10, m12): `SuperTwistedModule` is the zero module for $N \geq 2$, still at the audited commit and then unflagged in the library (the released source now flags it in docstrings) (warning box in Section 17.1); `NonSplitSuperModule sympFermSVOA` is never constructed; the free fermion is not a field. No modular-invariance theorem exists in any of the three new grid columns (m13). The audit also records (M7) that the aggregate build is not certified for the release commit.

Further minor finding: irreducible twisted modules may be zero

`SuperTwistedModule.IsIrreducible` (`Modularity/SuperSectorRationality.lean`) requires only that every graded invariant subspace be $\bot$ or $\top$; it does not require $M \neq 0$, so the zero module is "irreducible". Combined with (F1), for $N \geq 2$ the irreducible objects of

`PackagedIrreducibleSuperTwistedModule` are exactly zero modules. Severity: moderate (compare `IsLowestWeight`, which likewise does not require $M_h \neq 0$; Chapter 12).

17.13 Referee's checklist

Lean declaration	Intended meaning	Hypotheses; status	Fidelity
`SuperVertexAlgebra`	super vertex algebra with $\mathbb{C}$-grading	definition; lacks translation covariance (F2)	Def. 17.3, Thm. 17.4
`SpinStatistics`	integer weight iff even	predicate; satisfiable	Def. 17.5
`SuperNearVOA`, `SuperVertexOperatorAlgebra`	conformal super vertex algebra (of CFT type)	definitions	Defs. 17.8, 17.9
`dong_fields`	OPE of local fields is local, with product sign	homogeneity; unconditional	Thm. 17.10
`goddard_uniquenessε`	a field is determined by the state it creates	locality, vacuum tower; unconditional	Thm. 17.12
`superBorcherds`, `superJacobi`	full super Borcherds identity, all ℓ, m, n	`SuperNearVOA`, homogeneity; unconditional	Thm. 17.14

Within the library. Project notes written before `BetaGammaInstance.lean` and `GhostSystem.lean` describe the *bc* and $\beta\gamma$ systems as "not yet" super VOA instances; that is out of date for them (it remains true of the free fermion). The bosonic counterparts are Chapters 4 (axioms, Borcherds), 12 (modules, Zhu), 34 (twisted modules and the repaired `TwistedModule.jacobi`), 14 and 15 (modular forms and Zhu's theorem).

Chapter 18

Logarithmic vertex algebras: the triplet and doublet algebras

This chapter documents the release of the LeanVOA library named in the front matter. Checks that were run at an earlier state of the library and not re-run for this edition are marked as such. Every Lean quotation below is taken from the files of the release and is machine-checked by `scripts/textbook/sync.py` to occur verbatim (up to whitespace and comments) in the source; proof bodies are not reproduced, and a quotation that ends in `:=` or `:= by` is the statement only. The chapter covers the files assigned to it in `Notes/Textbook/assignment.txt`: in `VOA/Examples/` the files `TripletLattice.lean`, `TripletScreening.lean`, `TripletTTNull.lean`, `TripletIrrational.lean`, `TripletLogModular.lean`, `TripletW2*.lean`, `TripletWp*.lean`, `Doublet*.lean` and `ZhuTripletW2*.lean`; in `VOA/Modularity/` the files `LogarithmicPseudoTrace*.lean`, `LogarithmicQSeries.lean` and `PseudoTrace.lean`. That is 182 files and roughly thirty-three thousand lines, but about 140 of the files are the pieces of two large exact computations (a sparse polynomial identity in a Fock space and a sparse certificate in Zhu's algebra), each of which is consumed by a single theorem; we explain what those computations are, and quote their interfaces, but do not tour them. (The release audit of 2026-10-27 re-elaborated the headline statements on branch `deligne-lean` at an earlier commit, where the `VOA/` sources were unchanged since the audit's start; they still match the quotations below. The quotations were re-verified at that commit (not re-run for this edition); see Section 18.11.)

A few results of this chapter were checked in Lean by short checks written against the library. These checks are not part of the library or of this release; every theorem in them depends only on `[propext, Classical.choice, Quot.sound]`.

Chapter 1 is the Lean toolkit of the book; generic Lean idioms (`Submodule`, `finrank`, `↥`, `→ₗ[ℂ]`, structures and their fields, `Prop`-valued definitions used as named hypotheses) are explained there and are not explained again. We rely on the following accepted chapters and do not repeat them: Chapter 5 (subalgebras generated by a set, screening operators), Chapter 6 (lattice vertex algebras, background charge, quadratic refinements), Chapter 7 (the Virasoro algebra, Kac determinant, screenings), Chapter 11 (C_2, presentations), Chapter 12 (modules of all kinds, Zhu's algebra, C_2-cofiniteness, the rationality hierarchy), Chapter 13 (the Dong–Jiang induced module), Chapters 14 and 15 (the modular toolkit and Zhu's modularity theorem) and Chapter 17 (super vertex algebras, the even part, symplectic fermions).

18.1 What this chapter is about, and what it found

The rational vertex operator algebras — lattice VOAs, affine VOAs at positive integer level, the Virasoro minimal models, the Moonshine module — have a semisimple representation theory: a finite list of irreducible modules, every module a direct sum of them, and characters that span a

representation of $SL_2(\mathbb{Z})$ (Zhu's theorem, Chapter 15). The simplest vertex operator algebras that are *not* of this kind, yet are still "finite" in the sense of C_2-cofiniteness, are the *triplet algebras* $W(p)$, $p \geq 2$, of Kausch (1991). They are the chiral algebras of the logarithmic conformal field theories of central charge

$$c_{1,p} = 1 - \frac{6(p-1)^2}{p}, \qquad c_{1,2} = -2, \quad c_{1,3} = -7, \quad c_{1,4} = -\frac{25}{2}, \ \ldots \tag{18.1}$$

This chapter documents what the library proves about them, and about two neighbouring objects: the *doublet algebra* $\mathcal{A}(p)$, and the *pseudo-trace* construction which replaces traces in the modular theory of non-semisimple module categories.

Two different Lean objects called "$W(2)$". The single most important thing a reader must keep in mind is that the library contains *two* constructions of the $p = 2$ triplet algebra, on different carrier types, and *no isomorphism between them is proved*:

- `VOA.LatGen.Wp.tripletWVOA 2 hp` — the *lattice model*: the vertex operator subalgebra, generated by four explicit states, of the rank-one lattice VOA V_{L_2}, $L_2 = \mathbb{Z}\alpha$, $\langle\alpha,\alpha\rangle = 4$, deformed by a background charge. It exists for every $p \geq 1$ as `tripletWVOA p hp` (Section 18.4).
- `VOA.SympFerm.tripletW2` — the *Abe model*: the even part of the symplectic-fermion super vertex operator algebra of Chapter 17 (Section 18.7). The name "Abe model" refers to T. Abe's 2007 paper, which studies $W(2)$ in exactly this realization $\mathrm{SF}(1)^+$. Concretely: the symplectic-fermion algebra is generated by two fermionic fields of weight one; its *even part* is the span of the states containing an even number of fermion modes, and that even part, with its own vertex operator algebra structure, is the Abe model. The formal definition, with its Lean source, is Definition 18.22; until then, "Abe model" means exactly this sentence.

In the literature these are the same algebra (Kausch; Gaberdiel–Kausch; Abe; Adamović–Milas). In Lean they are unrelated, and *the theorems proved about them are different*. The only formal link is the equality of the two central charges, $-2 = -2$ (`tripletW_centralCharge_eq_tripletW2`, Theorem 18.6). Table 18.1 summarises what is proved about each.

Vocabulary used in the table and the headlines. The table and the list of headline results below use a number of notions whose home is an earlier chapter. So that this section can be read on its own, here is a one-sentence definition of each, with a pointer to the place where it is developed in full (with its Lean source and fidelity check). Throughout, V is a vertex operator algebra with conformal vector ω and $L_0 = \omega_{(1)}$.

- *Generalized L_0-eigenspace.* For a linear operator L_0 on a space M and $h \in \mathbb{C}$, the generalized eigenspace of eigenvalue h is $M_{[h]} = \{v \in M \mid (L_0 - h)^k v = 0 \text{ for some } k \geq 1\}$. It contains the ordinary eigenspace $\{v \mid L_0 v = hv\}$ and equals it exactly when L_0 is diagonalisable on $M_{[h]}$. On $M_{[h]}$ one splits $L_0 = h + L_0^{\mathrm{nil}}$ with $L_0^{\mathrm{nil}} = L_0 - h$ nilpotent.
- *Jordan block.* A Jordan block of size two at eigenvalue h is a pair of vectors ϕ, ψ on which L_0 acts by the matrix $\left(\begin{smallmatrix} h & 1 \\ 0 & h \end{smallmatrix}\right)$, i.e. $L_0\phi = h\phi$ and $L_0\psi = h\psi + \phi$; then ψ lies in the generalized eigenspace but is not an eigenvector. Any nilpotent operator on a finite-dimensional space is, in a suitable basis, a direct sum of such blocks (of various sizes); $L_0^{\mathrm{nil}} \neq 0$ means at least one block has size ≥ 2.
- *Ordinary module* (Chapter 12, Definition 12.5). A V-module on which L_0 is *diagonalisable*, with finite-dimensional eigenspaces and eigenvalues bounded below in real part. These are the modules of rational CFT.

- *Admissible module* (Chapter 12, Definition 12.4; also Chapter 10, Section 10.2 for the affine use of the word). A module graded by $\mathbb{N}$ ("by the mode degree") so that every mode $u_{(n)}$ of a homogeneous u shifts the degree by $\operatorname{wt} u - n - 1$; L_0 is *not* required to be diagonalisable. Every ordinary module carries such a grading (Chapter 12, Theorem 12.10).

- *Admissibly rational* (Chapter 12, Definition 12.35). V is admissibly rational if *every admissible module is completely reducible*, i.e. a direct sum of irreducible ones. A logarithmic module (below) is admissible but not a direct sum of irreducibles, so its existence is exactly the failure of this property.

- *Gannon-rational* (Chapter 12, Definition 12.37). The variant of rationality used in Gannon's book: every ordinary module is completely reducible, there are finitely many irreducible ordinary modules up to isomorphism, and every irreducible admissible module is ordinary.

- *C_2-cofinite* (Chapter 12, Definition 12.22). The quotient $R_V = V/C_2(V)$, where $C_2(V)$ is the span of all $u_{(-2)}v$, is finite-dimensional. This is the "finiteness" that replaces rationality in the logarithmic world.

- *Strongly generated* (made precise in Section 18.3). V is strongly generated by a set S if every state is a linear combination of "words" $s^1_{(-m_1)}\cdots s^k_{(-m_k)}\mathbf{1}$ with $s^j \in S$ and all $m_j \geq 1$; physically, every field is a normally ordered polynomial in the fields of S and their derivatives.

- *Strongly finite* (Chapter 12, Definition 12.43). V is simple, self-dual (isomorphic to its contragredient module) and C_2-cofinite (CFT type being automatic in the library's setting): the hypotheses under which the modern non-semisimple ("logarithmic") theory of Creutzig–Gannon and McRae works.

- *Logarithmic module* (Chapter 12, Definition 12.8). A module that is the direct sum of its generalized L_0-eigenspaces, each finite-dimensional, with weights bounded below. The definition allows $L_0^{\mathrm{nil}} = 0$ (then the module is ordinary); a module is *genuinely* logarithmic when $L_0^{\mathrm{nil}} \neq 0$, i.e. when it has at least one Jordan block of size ≥ 2, and that is what Theorem 18.29 produces.

- *Super vertex operator algebra* (Chapter 17, Definitions 17.3 and 17.9). A vertex algebra whose state space is $\mathbb{Z}/2$-graded into an even (bosonic) and an odd (fermionic) part, with locality and the Jacobi identity holding up to the Koszul sign $(-1)^{|u||v|}$ when two odd fields are exchanged. Its *even part* is an ordinary vertex (operator) algebra. Symplectic fermions (Section 18.2 below) are the example used here.

The headline results, stated honestly.

1. *The lattice triplet at $p = 2$ is C_2-cofinite, simple, strongly finite, and neither admissibly rational nor Gannon-rational* — all unconditionally, *for the lattice model* `tripletWVOA 2 hp` only (Theorems 18.17, 18.18, 18.20). The rationality notions are the library's (Chapter 12): `AdmissiblyRational` asks that every weak submodule of every admissible module have a weak complement, which is not literally the complete reducibility of Dong–Li–Mason; the witness used here (the ambient V_{L_2}, in which $W(2)$ has no complement even among weak submodules) refutes the DLM notion as well, on paper. This is the library's first non-rational, strongly finite vertex operator algebra; it is the benchmark that the logarithmic literature (Creutzig–Gannon, McRae) calls a "strongly finite but non-rational" VOA. The C_2 proof rests on an exact polynomial identity in the Fock space of weight ten (the $p = 2$ case of an identity of Adamović and Milas, with leading coefficient $B_2 = 1024/1575$), and the simplicity proof on an exact membership certificate in Zhu's algebra.

	lattice model `tripletWVOA 2 hp`	Abe model `tripletW2`
VOA structure, $c = -2$	proved	proved
no weight-one states	proved (needs strong generation)	proved (elementary)
strongly generated by ω, E, H, F	**proved**	open (named `Prop`)
C_2-cofinite	**proved**, $\dim A_2 \le 80$	conditional on one generation gate
nilpotency of generators in A_2	proved (ω via the Adamović–Milas identity)	proved ($\bar{\omega}^6 = 0$)
simple	**proved** (Zhu certificate)	not addressed
strongly finite	**proved**	not addressed
not admissibly rational	**proved**	conditional on `hC2`, `hfive` (plus the vacuously true `hblocks`); `hzhu` discharged
not Gannon-rational	**proved**	not proved
$A(V)$ not semisimple	not addressed	conditional on citations
logarithmic module exists	not addressed	conditional on *four* hypotheses, one of which (`OmegaJordanAt`) essentially assumes the Jordan block
formal link to the other column	only the equality of central charges $-2 = -2$; no map between the two models	

Table 18.1: What the library proves about its two realizations of $W(2)$. "Proved" means `#print axioms`-clean (standard three axioms only) with no hypothesis; "conditional" means a theorem with explicit named hypotheses. Neither column uses `VOA.pbw`. The unconditional results are theorems about the *lattice* model only; nothing transfers to the Abe model.

2. *For general p*, C_2-cofiniteness of `tripletWVOA p hp` is proved conditionally on two named finite computations: a generation statement (`AdjoinGenWp`, or the finite OPE table `LoweringPairsWp`) and the nilpotency of $\bar{\omega}$ in the form `OmegaPowMem p hp m` (or the identity `AMOmegaIdentity p hp (3p-1)`) (Theorem 18.12). A Lean check (not part of this release) shows these hypotheses are satisfiable (they hold at $p = 2$), but for $p \ge 3$ they are not discharged: "$W(p)$ is C_2-cofinite" for general p is a **conditional** reduction, not a theorem. In the course of this the library found that the printed argument of Adamović–Milas (2008, Theorem 3.1) for the nilpotency of $\bar{\omega}$ is a non-sequitur, and routes around it through their own Corollary 4.6 (Warning in Section 18.5).

3. *For the Abe model* (a separate Lean object, linked to the lattice model only by $c = -2$), C_2-cofiniteness is reduced to one named generation statement (`AbeQuotientGeneration`) and is **conditional**; all four generators are proved nilpotent in A_2; non-rationality and non-semisimplicity of Zhu's algebra are proved only **conditionally** on explicitly cited literature theorems (`C2Cofinite`, a Wedderburn block count, and $\dim \ge 5$ of a block space, or $\dim A(V) = 11$ in place of the C_2/block-space pair; the fourth input of the non-rationality theorem, the semisimplicity criterion `hzhu`, is discharged for every VOA by `zhuAdmissibleSemisimple_holds`, Chapter 12); and a logarithmic module (one on which L_0 has a nonzero nilpotent part) is constructed conditionally on **four** hypotheses, not one: two finiteness hypotheses on Zhu's algebras (`hAnm`, `hA`), the Dong–Jiang gate `DJAnnEqAn tripletW2 0`, and `OmegaJordanAt tripletW2 h`. The last literally asserts that $[\omega] - h$ is not semisimple in $A(V)$, so the Jordan block of the module is a formal transcription of that hypothesis, which is proved for no VOA and no h.

4. *Pseudo-traces* (Miyamoto 2004, in Arike's Hattori–Stallings form) are constructed for arbitrary finitely generated projective modules over arbitrary algebras and validated against the ordinary trace (Section 18.8); the logarithmic one-point q-series built from them is polynomial in τ, which is the precise source of the τ-linear terms in logarithmic modular transformations. No

VOA instance of the required "commutant data" is constructed, so the genus-one layer applies to no concrete VOA yet.

5. *The doublet* $\mathcal{A}(p)$ is constructed as a generated super subalgebra of a concrete half-lattice ambient (a super near-VOA with states of negative weight), for $4 \mid p$ only, and proved only bounded below; its identification with the literature's doublet and the relation $\mathcal{A}(p)^{\text{even}} = W(p)$ are not proved (Section 18.9). "The doublet algebra is formalized" would overclaim.

The findings of the fidelity checks, in brief. Each is explained in a red box where it occurs.

- The docstrings of `TripletWp.lean` and `TripletWpC2.lean` list "$E \neq 0$" and "$W(p) \neq V_{L_p}$" as unproved. At $p = 2$ both follow in a few lines from library theorems; we checked them in Lean (Theorem 18.7; the check is not part of this release). For $p \geq 3$ they remain unproved.
- The library calls $Q = (e^{\alpha})_{(0)}$ the "short screening" in `TripletScreening.lean` and `TripletWp.lean`, but the "long screening" in `TripletWpC2.lean`. The literature's name is the latter (α is the longer of the two screening momenta α and $-\alpha/p$).
- The name `tripletW p hp` is mathematically faithful (the subalgebra of V_{L_p} generated by ω, E, H, F is the triplet algebra), but the library never proves that it equals the kernel of the short screening $\widetilde{Q} = (e^{-\alpha/p})_{(0)}$, which is the definition most papers use.
- Several hypotheses of the Abe-model irrationality theorems are redundant or vacuously true (`hfin` beside `hdim`; `WedderburnBlockCount ℂ (A tripletW2) 4` is true for any non-semisimple algebra); none is harmful.
- `TripletWpPairClosure.lean` still says the three mixed coordinates (the three explicit products $F_{(0)}H, F_{(1)}E, F_{(3)}E$ of the lowering generator F with H and E, expressed as polynomials in the generators; they are the only entries of the generator OPE table not handled by a general argument, see Section 18.6.1 and Theorem 18.15) and the Adamović–Milas identity are "not claimed here"; they are now proved in later files (stale docstring).
- The logarithmic pseudo-trace layer (`LogPseudoTraceCommutantData`) has no instance in the library; it is not vacuous (an instance with auxiliary algebra $\mathbb{C}$ exists on paper, recovering ordinary traces), but no theorem of that layer is about a concrete VOA.

18.2 The physical picture: logarithmic conformal field theory

This section is motivation; nothing in it is a claim about the Lean library. The theorems that formalise pieces of it are pointed to.

18.2.1 Why logarithms

In a two-dimensional conformal field theory the dilatation operator on the plane is $L_0 + \bar{L}_0$. In unitary theories, and in rational theories generally, L_0 is diagonalisable on every module, so two-point functions of L_0-eigenstates of weight h are pure powers, $\langle \phi(z)\phi(0)\rangle \propto z^{-2h}$. Nothing forces diagonalisability in a non-unitary theory. If L_0 has a Jordan block,

$$L_0\,\phi = h\,\phi, \qquad L_0\,\psi = h\,\psi + \phi, \tag{18.2}$$

then L_0 acts on the span of ϕ, ψ by the 2×2 *Jordan block* $\left(\begin{smallmatrix} h & 1 \\ 0 & h \end{smallmatrix}\right)$ (in the basis ϕ, ψ, the columns being the images): ϕ is an honest eigenvector, while ψ is only a *generalized* eigenvector, $(L_0 - h)\psi = \phi \neq 0$ but $(L_0 - h)^2\psi = 0$. One calls ψ the *logarithmic partner* of ϕ: "partner" because ψ is tied to ϕ by

the off-diagonal entry and the two cannot be separated into independent eigenstates, "logarithmic" because of what this does to correlation functions. Indeed, the dilatation $z \mapsto \lambda z$ acts on a field by λ^{L_0}, and on the Jordan block $\lambda^{L_0} = \lambda^h(1 + \log\lambda\,(L_0 - h))$, so $\lambda^{L_0}\psi = \lambda^h(\psi + \log\lambda\,\phi)$: the logarithm of the scale enters the transformation law. Imposing global conformal covariance with this transformation law (together with the vanishing of $\langle\phi\phi\rangle$ which it implies) forces

$$\langle\phi(z)\phi(0)\rangle = 0, \qquad \langle\phi(z)\psi(0)\rangle = \frac{b}{z^{2h}}, \qquad \langle\psi(z)\psi(0)\rangle = \frac{\theta - 2b\log z}{z^{2h}}.$$

This is the origin of the name: correlators acquire logarithms, the term $-2b\log z$ in $\langle\psi\psi\rangle$, which never occurs in a theory where L_0 is diagonalisable. Such theories occur in statistical mechanics at the points where a model is non-unitary and non-generic: dense polymers and the two-dimensional sandpile ($c = -2$), critical percolation ($c = 0$), the spanning-tree and loop-erased random-walk models, and they occur in string theory as the bc and $\beta\gamma$ ghost sectors and as worldsheet theories on supergroups. The constant b is a genuine invariant (the "logarithmic coupling" of Gaberdiel, Mathieu, Ridout, Vasseur and others).

In vertex-algebra language, (18.2) says that a module M is a *logarithmic* (grading-restricted generalized) module in the sense of Huang–Lepowsky–Zhang: M is the direct sum of generalized L_0-eigenspaces, and the nilpotent part $L_0^{\mathrm{nil}} = L_0 - L_0^{ss}$ is nonzero. The library's notion is `LogVModule` (Chapter 12, Definition 12.8); Theorem 18.29 below constructs such a module for the Abe model, conditionally.

18.2.2 The triplet algebra

Take one free boson φ with background charge, so that the stress tensor is $T = \frac{1}{2}(\partial\varphi)^2 + \frac{\alpha_0}{2}\partial^2\varphi$ and $c = 1 - 3\alpha_0^2$. The vertex operators $V_\beta = e^{\beta\varphi}$ have weight $\frac{1}{2}\beta(\beta - \alpha_0)$. There are exactly two momenta $\alpha_\pm$ with weight one, $\alpha_+\alpha_- = -2$, $\alpha_+ + \alpha_- = \alpha_0$; their contour integrals $Q_\pm = \oint V_{\alpha_\pm}$ are the *screening charges*, which commute with the Virasoro algebra (Chapter 7, Section 7.11). For $\alpha_+ = \sqrt{2p}$, $\alpha_- = -\sqrt{2/p}$ one gets $c = c_{1,p}$ of (18.1). Normalise $\alpha := \alpha_+$, so that $\langle\alpha,\alpha\rangle = 2p$ and $\alpha_- = -\alpha/p$. The lattice $L_p = \mathbb{Z}\alpha$ is even, and the lattice vertex algebra V_{L_p} (Chapter 6) with the deformed stress tensor is a vertex operator algebra of central charge $c_{1,p}$; in it,

$$\mathrm{wt}\big(e^{m\alpha}\big) = pm^2 - (p-1)m, \qquad \mathrm{wt}\,e^{\alpha} = 1, \qquad \mathrm{wt}\,e^{-\alpha} = 2p - 1. \tag{18.3}$$

The *long screening* $Q = e^{\alpha}_{(0)}$ acts on V_{L_p}; the *short screening* $\widetilde{Q} = e^{-\alpha/p}_{(0)}$ maps V_{L_p} to the module $V_{L_p - \alpha/p}$. Following Kausch, Feigin–Gainutdinov–Semikhatov–Tipunin and Adamović–Milas, the triplet algebra is

$$W(p) = \ker_{V_{L_p}} \widetilde{Q}, \tag{18.4}$$

and it is strongly generated by ω and the three states

$$F = e^{-\alpha}, \qquad H = QF, \qquad E = Q^2F, \qquad Q^3F = 0, \tag{18.5}$$

of weight $2p - 1$, which transform as an $\mathfrak{sl}_2$-triplet under the screening algebra (hence the name). All three are *Virasoro primary*: $L_nE = L_nH = L_nF = 0$ for all $n \geq 1$ (Chapter 5, Definition 5.6; proved in Theorem 18.14), i.e. they are highest-weight vectors for the Virasoro algebra, the fields of a W-algebra beyond T. For $p = 2$ the three generators have weight 3.

The representation theory of $W(p)$ (Adamović–Milas 2008, Nagatomo–Tsuchiya) has $2p$ irreducible modules, with lowest weights among the entries of the extended Kac table

$$h_{r,s} = \frac{(pr - s)^2 - (p-1)^2}{4p}. \tag{18.6}$$

At $p=2$ these are $h=0,\ 1,\ -\tfrac{1}{8},\ \tfrac{3}{8}$ (the vacuum module; the odd part of the symplectic fermions, whose ground states $\chi^{\pm}_{-1}\mathbf{1}$ have weight 1; and two "twisted" modules). There are finitely many irreducibles, but the category is *not semisimple*: there are indecomposable projective modules on which L_0 has Jordan blocks of size two. Correspondingly Zhu's algebra $A(W(p))$ has dimension $6p-1$ but is not semisimple ($11=1+4+4+2$ at $p=2$, the last summand being $\mathbb{C}[\varepsilon]/(\varepsilon^2)$).

18.2.3 Symplectic fermions

At $p=2$ there is a second, fermionic, realization. A pair of weight-one fermions $\chi^{\pm}$ with $\chi^{+}(z)\chi^{-}(w)\sim(z-w)^{-2}$ generates the symplectic-fermion super VOA SF at $c=-2$ (Kausch 2000; Chapter 17, Section 17.8.4). It violates spin–statistics (fermions of integer weight), which is why it is a super VOA and not a VOA. Its even part SF^{+} (the $\mathbb{Z}/2$-orbifold by fermion number) is $W(2)$; the three triplet generators are the fermion bilinears $\chi^{a}_{-2}\chi^{b}_{-1}|0\rangle$, symmetrised. In statistical mechanics this is the theory of dense polymers and of the abelian sandpile. Free fields make $W(2)$ computable by hand, which is why Abe's 2007 analysis works in this model.

18.2.4 Characters, modular transformations and pseudo-traces

The vacuum character of $W(2)$ is

$$\chi_0(\tau)=q^{1/12}\cdot\frac{1}{2}\Big[\prod_{n\geq1}(1+q^n)^2+\prod_{n\geq1}(1-q^n)^2\Big]=q^{1/12}\big(1+q^2+4q^3+5q^4+8q^5+10q^6+\cdots\big),\tag{18.7}$$

and under $S:\tau\mapsto-1/\tau$ it transforms (Flohr; Fuchs–Hwang–Semikhatov–Tipunin; Flohr–Gaberdiel) as

$$\chi_0(-1/\tau)=\tfrac{1}{4}\big[\chi_{-1/8}(\tau)-\chi_{3/8}(\tau)\big]+\Big(-\frac{i\tau}{2}\Big)\big[\chi_0(\tau)-\chi_1(\tau)\big].\tag{18.8}$$

The term proportional to τ cannot be a combination of characters, since each character is q^h times a power series and so is an eigenfunction of $\tau\mapsto\tau+1$. The $SL_2(\mathbb{Z})$-closure of the characters therefore needs extra functions with explicit τ-dependence; Miyamoto (2004) showed that for any C_2-cofinite VOA these come from *pseudo-traces*: functionals φ on an auxiliary algebra P commuting with the action, such that $\mathrm{tr}^{\varphi}_{M}\,o(v)q^{L_0-c/24}$ makes sense even when L_0 is not diagonalisable. On a generalized eigenspace, $q^{L_0}=q^h e^{2\pi i\tau L_0^{\mathrm{nil}}}=q^h\sum_k\frac{(2\pi i\tau)^k}{k!}(L_0^{\mathrm{nil}})^k$ is a *polynomial in* τ times q^h. Section 18.8 formalises exactly this. Section 18.7.8 formalises the converse direction: a τ-linear term in $\chi_0(-1/\tau)$ is incompatible with rationality.

18.2.5 The doublet

Halving the lattice, $\frac{1}{2}L_p=\mathbb{Z}\frac{\alpha}{2}$, gives two states $a^{-}=e^{-\alpha/2}$ and $a^{+}=Qa^{-}$ of weight $\frac{3p-2}{4}$, which generate the *doublet* algebra $\mathcal{A}(p)$ (Adamović–Milas 2009). Its even part for the charge-parity automorphism is $W(p)$. For $p=2$ the doublet generators have weight 1 and $\mathcal{A}(2)$ is the symplectic-fermion algebra itself; for $4\mid p$ the weight is a half-integer and the half lattice is even, so $\mathcal{A}(p)$ is a vertex algebra with half-integral weights (another spin–statistics violation).

18.3 Conventions recalled

- **Modes.** `mode f n = f (-n-1)`: if $Y(u,z)=\sum_n u_{(n)}z^{-n-1}$ then `mode (W.Y u) n` is $u_{(n)}$, and `W.smul u n v` is $u_{(n)}v$. Virasoro modes are `W.L n` $=\omega_{(n+1)}$, so $L_{-2}=\omega_{(-1)}$, $L_{-1}=T=\omega_{(0)}$, $L_0=\omega_{(1)}$. A mode $u_{(n)}$ of a homogeneous $u\in V_k$ maps V_l to $V_{k+l-n-1}$.

- **C_2 and Zhu.** `O₂ W` is $C_2(V) = \mathrm{span}\{u_{(-2)}v\}$, `A₂ W` $= V/C_2(V)$ with its commutative product induced by $u_{(-1)}v$ (written `poissonMul`), `mk₂ W u` $= \bar{u}$ is the class of u, and `C2Cofinite W` means `FiniteDimensional ℂ (A₂ W)` (Chapter 12, Definition 12.22). `O W`, `A W` $= V/O(V)$, `zhuMul` and `mk W` are Zhu's subspace, algebra, product and quotient map (Section 12.4).

- **Strong generation.** `iterProdSpan W S` is the span of the words $s^1_{(-m_1)}\cdots s^k_{(-m_k)}\mathbf{1}$ with $s^j \in S$ and all $m_j \geq 1$ (Chapter 12, Theorem 12.24). V is *strongly generated* by S when this span is everything.

- **Generated subalgebras.** `VOASubalgebra.generated W S` is the smallest vertex operator subalgebra containing S: it contains $\mathbf{1}$ and ω, is closed under all products $u_{(n)}v$, $n \in \mathbb{Z}$, and under the homogeneous projections (Chapter 5, Definition 5.26; the defect that it always contains ω is harmless here since ω is one of our generators). `generatedVOA W S` is the VOA structure on its carrier.

- **Lattices.** `LatModuleGen L` is the state space $\mathcal{F}\otimes\mathbb{C}[L]$ of the lattice vertex algebra of an integral lattice L, `latChargeGen L β` is e^{β}, `latStateGen L q β` is $q\otimes e^{\beta}$ for a Fock polynomial q, `latVacuumGen L` is $\mathbf{1} = 1\otimes e^0$, and `latticeCocycle L β γ` $= \varepsilon(\beta,\gamma) \in \{\pm 1\}$ is the cocycle (Chapter 6, Section 6.7). `YfullGen` is the reconstructed vertex map.

- **Background charge.** For $\lambda \in \mathbb{C}^{\mathrm{rank}}$, `BgA.omegaBg L lam` $= \omega_\lambda = \omega + \lambda(-2)\mathbf{1}$ and `BgA.LBg L lam n` $= L^\lambda_n = L_n - (n+1)\lambda(n)$; `BgB.LBG` is the same operator in a second file's conventions, and `bgPair L lam β` $= \langle\lambda,\beta\rangle$ (Chapter 6, Definition 6.31). The weight of $q\otimes e^{\beta}$ for L^λ_0 is $\deg q + \frac{1}{2}\langle\beta,\beta\rangle - \langle\lambda,\beta\rangle$.

- **Hypotheses `hp : 1 ≤ p`.** Every lattice-model declaration carries `(p : ℕ) (hp : 1 ≤ p)`; at $p = 2$ the argument `(hp : 1 ≤ 2)` is a proof of a true numeral inequality and carries no information. The literature's range is $p \geq 2$; at $p = 1$ the construction still type-checks but describes $V_{L_1} = V_{A_1}$ (see Section 18.4).

18.4 The lattice model I: the ambient and the generators

18.4.1 The deformed rank-one lattice VOA

Definition 18.1 (The lattice L_p and its background charge)**.** For $p \in \mathbb{N}$ let $L_p = \mathbb{Z}\alpha$ be the rank-one lattice with $\langle m\alpha, n\alpha\rangle = 2pmn$. The *background charge* is $\lambda_p = c_p\,\alpha$ with $c_p = \frac{p-1}{2p}$, so that $\langle\lambda_p, m\alpha\rangle = (p-1)m$ and $\langle\lambda_p,\lambda_p\rangle = \frac{(p-1)^2}{2p}$. The *deformed weight* of $e^{m\alpha}$ is $q_p(m) = \frac{1}{2}\langle m\alpha, m\alpha\rangle - \langle\lambda_p, m\alpha\rangle = pm^2 - (p-1)m$.

```

From the mathematics to the Lean statement

`latP p` has carrier $\mathbb{Z}$ (the integer m stands for $m\alpha$, and `alphaP p = 1` is α) and Gram form $\langle m, n\rangle = 2pmn$ (`latP_form`). It is even for every p and positive definite for $p \geq 1$ (`latP_even`, `latP_posDef`); at $p = 1$ it is the A_1 lattice (`latP_one_form`). `BgA.latBg L c α` is the frame-coordinate vector of $c \cdot \alpha$ in the orthonormal frame used for background charges (Chapter 6, Definition 6.31); `bgPair_lamP` confirms $\langle \lambda_p, m\alpha\rangle = (p-1)m$ and `qZP_eq_halfNorm_sub_bgPair` confirms that the integer `qZP p m` is exactly $\frac{1}{2}\langle\beta,\beta\rangle - \langle\lambda_p,\beta\rangle$ at $\beta = m\alpha$. The integrality of q_p is what allows a $\mathbb{Z}$-grading (it is wrapped as a $\mathbb{Q}$-valued quadratic refinement `qrP p`, Definition 6.33). `centralCharge_latP` is $c = \mathrm{rank} - 12\langle\lambda,\lambda\rangle$ evaluated: $1 - 12\cdot\frac{(p-1)^2}{2p} = c_{1,p}$. The hypothesis `hp : 1 ≤ p` is needed only to divide by p and for positive definiteness. Everything matches (18.1)–(18.3); there is no hidden convention.

Physical meaning

L_p is the momentum lattice of a compact boson at the radius where the screening momentum $\alpha_+ = \sqrt{2p}$ is a lattice vector; λ_p is the background charge $\frac{\alpha_0}{2}$ of the Coulomb gas, and $q_p(m)$ is the Feigin–Fuchs conformal weight $\frac{1}{2}\beta(\beta-\alpha_0)$ at $\beta = m\alpha_+$. Positivity of q_p off $m = 0$ (`qZP_pos`) is the reason the deformed lattice theory is still of CFT type, although it is not unitary.

What the machine verified

All proved, no hypotheses beyond `hp`; `#print axioms` of the instance below is `[propext, Classical.choice, Quot.sound]`.

Theorem 18.2 (The deformed lattice VOA V_{L_p}). *For $p \geq 1$ the lattice vertex algebra V_{L_p}, graded by $L_0^{\lambda_p}$ and with conformal vector $\omega_{\lambda_p} = \omega_{L_p} + \lambda_p(-2)\mathbf{1}$, is a vertex operator algebra of central charge $c_{1,p}$, with weight spaces $(V_{L_p})_k = \bigoplus_m \mathcal{F}_{k-q_p(m)} \otimes e^{m\alpha}$. In it e^{α} has weight 1, $e^{-\alpha}$ has weight $2p-1$, and $e^{m\alpha}$ has weight $q_p(m)$.*

From the mathematics to the Lean statement

The instance has all nineteen fields of `VertexOperatorAlgebra` (Chapter 1); the quotation shows the ones that carry the content, and the ellipses mark the remaining fields, each a named lemma (`gradTrip_grading_mode`, `L0_gradTrip`, `translation_gradTrip`, `virasoro_gradTrip`, ...). The decisive points:

- `Y` is the *undeformed* lattice vertex map `YfullGen` of Chapter 6, Theorem 6.21: a background charge changes the stress tensor and the grading, not the operator product. So locality, vacuum and creation axioms are inherited verbatim.
- `grading k = gradTrip p k` collects the bigraded pieces `bigradα (w, β)` ($= \mathcal{F}_w \otimes e^{\beta}$) with $w + q_p(\beta) = k$ (`wtZP`); `gradTrip_eq` identifies it with the refined grading `gradingLatGenQ (latP p) (qrP p) k` of Chapter 6. Finite-dimensionality of each piece uses `qFinite_qrP` ($|m| \le q_p(m)$).
- `conformalVector` is ω_{λ_p}, and `tripletLatticeVOA_L` says that the Virasoro modes of the instance are exactly the deformed $L^{\lambda_p}_n$. The Virasoro relation (field `virasoro`) is proved with central charge $1 - 6(p-1)^2/p$ (`virasoro_gradTrip`), so the field `centralCharge` is not a free label.
- Grading axiom (VA1): the deformed weight differs from the undeformed one by $-\langle\lambda_p, \beta\rangle$, a linear function of the charge β; charge is additive under products, so the correction cancels in $\mathrm{wt}\, u + \mathrm{wt}\, v - n - 1$. Translation (VOA3): $L^{\lambda}_{-1} = L_{-1}$ because the correction $-(n+1)\lambda(n)$ vanishes at $n = -1$.

The three membership theorems are (18.3) as statements about the grading of the instance. The "`hp`" in `tripletLatticeVOA p hp` matters only through positive definiteness; at $p = 1$ the instance is the undeformed V_{A_1} ($\lambda_1 = 0$, $c = 1$).

Physical meaning

This is the free-field "Coulomb gas" of central charge $c_{1,p}$: one compact boson with background charge, compactified so that the long screening current e^{α} is a local field. All the logarithmic theories of this chapter live inside it as kernels of screening charges. Note that V_{L_p} itself is a perfectly rational lattice theory *as a VOA with its undeformed stress tensor*; it is the change of ω that makes the triplet subalgebra appear.

What the machine verified

Proved, unconditional (only `hp`). `#print axioms VOA.LatGen.Triplet.tripletLatticeVOA`: `[propext, Classical.choice, Quot.sound]`. No `VOA.pbw`.

18.4.2 The screening and the three generators

Definition 18.3 (Screening, F, H, E). Let L be an even positive-definite lattice, $\alpha \in L$, and λ a background charge. Put $Q = (e^{\alpha})_{(0)} = \mathrm{Res}_z\, Y(e^{\alpha}, z)$, and

$$F = e^{-\alpha}, \qquad H = QF, \qquad E = QH = Q^2F.$$

For $L = L_p$, $\alpha = \alpha_p$, these are the states `Ftrip p`, `Htrip p`, `Etrip p`, and ω_{λ_p} is `omegaTrip p`.

Files `VOA/Examples/TripletScreening.lean` (first block) and `VOA/Examples/TripletWp.lean` (second block).

```
noncomputable def Qscr (α : L.carrier) : End ℂ (LatModuleGen L) := mode (Yeαvec L α) 0

noncomputable def Fscr (α : L.carrier) : LatModuleGen L := latChargeGen L (-α)

noncomputable def Hscr (α : L.carrier) : LatModuleGen L := Qscr L α (Fscr L α)

noncomputable def Escr (α : L.carrier) : LatModuleGen L := Qscr L α (Hscr L α)
```

```
noncomputable def omegaTrip (p : ℕ) : LatModuleGen (latP p) :=
  BgA.omegaBg (latP p) (lamP p)

noncomputable def Ftrip (p : ℕ) : LatModuleGen (latP p) :=
  Screen.Fscr (latP p) (alphaP p)

noncomputable def Htrip (p : ℕ) : LatModuleGen (latP p) :=
  Screen.Hscr (latP p) (alphaP p)

noncomputable def Etrip (p : ℕ) : LatModuleGen (latP p) :=
  Screen.Escr (latP p) (alphaP p)
```

From the mathematics to the Lean statement

`Yeαvec L α` is the vertex operator of e^{α} written out as a normal-ordered exponential (`Qscr_eq_mode_YfullGen` proves it is the zero mode of the reconstructed `YfullGen`, so Q really is $(e^{\alpha})_{(0)}$ in the VOA V_{L_p}). In `TripletWpC2.lean` the same operator is re-presented as the generic screening of Chapter 5, Definition 5.28:

```
noncomputable def Qwp (p : ℕ) (hp : 1 ≤ p) : End ℂ (LatModuleGen (latP p)) :=
  Screening.screening (tripletLatticeVOA p hp) (latChargeGen (latP p) (alphaP p))
```

with `Qwp_eq_Qscr`. (Chapter 5 remarks that the triplet screening fits the generic definition only when $\lambda = 0$; that remark predates `tripletLatticeVOA`, and `Qwp` shows the fit is now exact.)

Trap / dead end

Naming: "short" versus "long" screening. `TripletScreening.lean` and `TripletWp.lean` call $Q = (e^{\alpha})_{(0)}$ the "short screening operator". In the literature (Adamović–Milas; FGST) the two screening momenta are α with $\langle\alpha,\alpha\rangle = 2p$ and $-\alpha/p$ with norm $2/p$; $e^{\alpha}_{(0)}$ is the *long* screening Q, and the short one $\widetilde{Q} = e^{-\alpha/p}_{(0)}$, which defines $W(p)$ as a kernel, does not act on V_{L_p} at all. `TripletWpC2.lean` uses the correct name. Docstring defect (documentation only); the mathematics is unaffected. The library never constructs $\widetilde{Q}$.

Physical meaning

$F = e^{-\alpha}$ is the vertex operator of the lowest charge in the triplet; applying the screening charge once and twice produces the neutral member H (a Schur polynomial in the boson oscillators, of charge 0) and the top member E (charge $+\alpha$). Because Q commutes with the deformed Virasoro algebra, all three have the same conformal weight; the three fields together with T are Kausch's W-algebra generators.

What the machine verified

Definitions.

Theorem 18.4 (Properties of the screening and the generators). *Let L be positive definite, $\alpha \in L$ with $\langle\alpha,\alpha\rangle = 2p$, $p \geq 1$.*

1. *If $\frac{1}{2}\langle\alpha,\alpha\rangle - \langle\lambda,\alpha\rangle = 1$ (i.e. e^{α} has deformed weight 1), then $[L_0^{\lambda}, Q] = 0$.*
2. *$H = \varepsilon(\alpha,-\alpha)\,S_{2p-1}(\alpha)\otimes e^{0}$, where $S_N(\alpha)$ is the N-th* vector Schur polynomial*: the polynomial in the oscillator (creation) variables $\alpha(-1), \alpha(-2), \ldots$ of the Fock space (Chapter 6, Definition 6.1) defined by the generating series*

$$\sum_{N\geq 0} S_N(\alpha)\, z^N = \exp\Big(\sum_{m\geq 1} \frac{\alpha(-m)}{m}\, z^m\Big), \tag{18.9}$$

   so $S_0 = 1$, $S_1 = \alpha(-1)$, $S_2 = \frac{1}{2}\alpha(-1)^2 + \frac{1}{2}\alpha(-2)$, $S_3 = \frac{1}{6}\alpha(-1)^3 + \frac{1}{2}\alpha(-1)\alpha(-2) + \frac{1}{3}\alpha(-3)$; and $S_N(\alpha) \neq 0$ for $\alpha \neq 0$, hence $H \neq 0$.
3. *$Q^3 F = 0$.*
4. *If moreover $\langle\lambda,\alpha\rangle = p - 1$, then F, H, E are L_0^{λ}-eigenvectors of eigenvalue $2p-1$.*

```

From the mathematics to the Lean statement

`LBG L lam 0` is L_0^λ (the `BgB` copy of `BgA.LBg`); the product $*$ of endomorphisms is composition, so the first statement is the commutation $L_0^\lambda Q = QL_0^\lambda$. Its hypothesis `hwt` is exactly "e^α has deformed weight one" and for L_p it is `triplet_wt_one` ($p-(p-1)=1$). `vSchur L α N` is the polynomial $S_N(\alpha)$ in the creation variables defined by $\sum_N S_N(\alpha)z^N = \exp\big(\sum_{m\geq 1}\frac{\alpha(-m)}{m}z^m\big)$ (Chapter 6); `latStateGen L q 0` is $q\otimes e^0$; `latticeCocycle` is the sign ε. The weight statement for H (`LBG_zero_Hscr`) is analogous. The general-L form is stronger than needed (the triplet uses $L=L_p$); there is no weakening. What the file does *not* prove is $E\neq 0$ (see Theorem 18.7 below for $p=2$).

Proof on paper. (1) On $q\otimes e^\gamma$ with $\deg q = d$, Q produces states of charge $\gamma+\alpha$ and Fock degree $d-1-\langle\alpha,\gamma\rangle$ (the operator $e^\alpha_{(0)}$ contains $z^{\langle\alpha,\gamma\rangle}$ and the coefficient of z^{-1} is extracted). The deformed weight changes by $(-1-\langle\alpha,\gamma\rangle)+\big(\frac12\langle\alpha+\gamma,\alpha+\gamma\rangle-\langle\lambda,\alpha+\gamma\rangle\big)-\big(\frac12\langle\gamma,\gamma\rangle-\langle\lambda,\gamma\rangle\big) = -1+\frac12\langle\alpha,\alpha\rangle-\langle\lambda,\alpha\rangle = 0$. (2) By the lattice vertex operator formula (Chapter 6), acting on the Fock vacuum $e^{-\alpha}$ only the creation half of $Y(e^\alpha,z)$ survives, and $Y(e^\alpha,z)e^{-\alpha} = \varepsilon(\alpha,-\alpha)z^{\langle\alpha,-\alpha\rangle}\exp\big(\sum_{m\geq1}\frac{\alpha(-m)}{m}z^m\big)e^0 = \varepsilon(\alpha,-\alpha)z^{-2p}\exp\big(\sum_{m\geq1}\frac{\alpha(-m)}{m}z^m\big)e^0$. By the generating series (18.9) this is $\varepsilon\sum_N S_N(\alpha)z^{N-2p}e^0$. Since $Q = e^\alpha_{(0)}$ is the coefficient of z^{-1}, we need $N-2p=-1$, i.e. $N=2p-1$, and $H = QF = \varepsilon\, S_{2p-1}(\alpha)e^0$. Non-vanishing of S_N: differentiating with respect to the variable $\alpha_b(-1)$ gives $\partial S_{N+1} = \alpha_b S_N$, so by induction $S_N\neq 0$ once some coordinate $\alpha_b\neq 0$. (3) Q preserves weight $2p-1$ and raises charge by α; Q^3F would have charge 2α, whose lowest weight is $q_p(2) = 2p+2 > 2p-1$, so it is zero (Fock degree -3). (4) $\operatorname{wt}F = \frac12\cdot 2p + (p-1) = 2p-1$, and Q preserves weight by (1). □

Physical meaning

(1) is the statement that a screening charge is a conformal invariant: the integral of a weight-one field commutes with L_0 (indeed with all L_n; the library proves the full primarity of E,H,F in Theorem 18.14). (3) says the screening string starting at F has length three: the triplet is a spin-one representation of the $\mathfrak{sl}_2$ generated by the screenings.

What the machine verified

All proved, unconditional. `#print axioms` for `LBG_zero_comm_Qscr`, `Hscr_ne_zero`, `Qscr_cube_Fscr`: `[propext, Classical.choice, Quot.sound]`.

18.4.3 The triplet algebra as a generated subalgebra

Definition 18.5 (The lattice triplet $W(p)$). $W(p)$ is the vertex operator subalgebra of V_{L_p} generated by $\{\omega_{\lambda_p}, E, H, F\}$, with the induced VOA structure.

File `VOA/Examples/TripletWp.lean`.

```
noncomputable def tripGens (p : ℕ) : Set (LatModuleGen (latP p)) :=
  {omegaTrip p, Etrip p, Htrip p, Ftrip p}

noncomputable def tripletW (p : ℕ) (hp : 1 ≤ p) : VOASubalgebra (tripletLatticeVOA p hp) :=
  VOASubalgebra.generated (tripletLatticeVOA p hp) (tripGens p)

noncomputable def tripletWVOA (p : ℕ) (hp : 1 ≤ p) :
    VertexOperatorAlgebra (tripletW p hp).carrier :=
  VOASubalgebra.generatedVOA (tripletLatticeVOA p hp) (tripGens p)
```

From the mathematics to the Lean statement

The carrier of `tripletWVOA p hp` is the subtype `(tripletW p hp).carrier` of V_{L_p}; its vertex operators, vacuum and conformal vector are the ambient ones (`tripletWVOA_Y_coe`, `tripletWVOA_vacuum_coe`, `tripletWVOA_conformalVector_coe`, all `rfl`). `VOASubalgebra.generated` is closure under *all* modes and homogeneous projections (Section 18.3); this is *weak* generation. It is *not* the definition (18.4) as a kernel, and it does not by itself say that $W(p)$ is *strongly* generated by the four states; the latter is a theorem of Adamović–Milas (Proposition 2.3) which the library proves at $p = 2$ (Theorem 18.15) and carries as a hypothesis for general p.

Is this the triplet algebra? Mathematically yes: by Adamović–Milas (2008, Prop. 2.3) the kernel $\ker \widetilde{Q}$ is strongly generated by ω, E, H, F, so it equals the subalgebra they generate. Formally, the library proves neither $\ker \widetilde{Q} \subseteq W(p)$ nor the converse — $\widetilde{Q}$ does not exist in the library. So every theorem about `tripletWVOA` is a theorem about the subalgebra generated by four explicit states; that this subalgebra is "the" triplet algebra is a citation.

Could it be degenerate? Three degeneracies would make the name misleading: $W(p) = 0$, $W(p) = V_{L_p}$, or $E = 0$. The library proves $W(p) \neq 0$ for all p (`tripletW_carrier_ne_bot`, via $H \neq 0$) and $\omega, H, F \neq 0$. The docstring lists $E \neq 0$ and $W(p) \neq V_{L_p}$ as open. At $p = 2$ both are settled by a Lean check outside the library (Theorem 18.7 and Remark 18.8); for $p \geq 3$ they remain open in Lean, although nothing proved depends on them (the relations below are true whether or not $E = 0$). At $p = 1$ the generators generate all of V_{L_1} (the docstring of `TripletWpC2.lean` records this), so the $p = 1$ instance is not a triplet algebra.

Physical meaning

$W(p)$ is the chiral algebra of the $(1, p)$ logarithmic minimal model: the symmetry algebra of the $c_{1,p}$ theory whose Virasoro representations are the logarithmic extensions of the first row of the Kac table. Its elements are the fields of the Coulomb gas that are "screened", i.e. that have well-defined correlators with the screening charge inserted.

What the machine verified

Definition; `#print axioms VOA.LatGen.Wp.tripletWVOA: [propext, Classical.choice, Quot.sound]`.

Theorem 18.6 (Central charge; non-degeneracy; consistency with the Abe model). *$W(p)$ has central charge $c_{1,p}$; it contains $\mathbf{1}, \omega, E, H, F$; it is nonzero; and at $p = 2$ its central charge equals that of* `SympFerm.tripletW2`.

File `VOA/Examples/TripletWp.lean`.

```
@[simp] theorem tripletW_centralCharge (p : ℕ) (hp : 1 ≤ p) :
    (tripletWVOA p hp).centralCharge = 1 - 6 * ((p : ℂ) - 1) ^ 2 / (p : ℂ) := rfl
```

```
theorem tripletW_carrier_ne_bot (p : ℕ) (hp : 1 ≤ p) :
    (tripletW p hp).carrier ≠ ⊥ := by

theorem omegaTrip_ne_zero (p : ℕ) (hp : 1 ≤ p) : omegaTrip p ≠ 0 := by

theorem tripletW_centralCharge_eq_tripletW2 (hp : 1 ≤ 2) :
    (tripletWVOA 2 hp).centralCharge = SympFerm.tripletW2.centralCharge := by
```

From the mathematics to the Lean statement

The central charge is `rfl`: a subalgebra keeps the ambient conformal vector. The last statement compares two numbers, $-2 = -2$; it is *not* an isomorphism and the library says so explicitly. `omegaTrip_ne_zero` is proved by observing that L_0 acts by 1 on $e^\alpha \neq 0$.

Physical meaning

Equality of central charges is the weakest possible consistency check between two free-field realizations of the same CFT (bosonic Coulomb gas and symplectic fermions); the real identification, due to Kausch, is a bosonization statement that the library does not formalise.

What the machine verified

Proved, unconditional; standard axioms only.

Theorem 18.7 ($E \neq 0$ and $W(2) \neq V_{L_2}$; Lean check outside the library)**.** *At $p = 2$, $E \neq 0$, and $e^\alpha \notin W(2)$; hence $W(2)$ is a proper subalgebra of V_{L_2}.*

Proof on paper. The library proves $F_{(3)}E = -48\,\varepsilon(\alpha,-\alpha)\varepsilon(-\alpha,\alpha)\,\omega$ (`Ftrip_three_Etrip_two_explicit`, Section 18.6); the right side is nonzero, so $E \neq 0$. The library also proves that $W(2)$ has no nonzero state of weight one (`eq_zero_of_mem_tripletW_two_and_grading_one`, Theorem 18.18); e^α is a nonzero state of weight one, so it is not in $W(2)$. □

Physical meaning

$E \neq 0$ says the top member of the screening triplet is a genuine field: the $\mathfrak{sl}_2$-string $F \mapsto H \mapsto E$ has full length three, as the name "triplet" requires. Properness says the chiral algebra is smaller than the free-field theory: the screening current e^α itself is not a symmetry generator.

What the machine verified

Checked in Lean against the library (the check is not part of this release); not a library theorem. The three statements depend on `[propext, Classical.choice, Quot.sound]`. These close, at $p = 2$, two items listed as "not proved" in the docstrings of `TripletWp.lean` and `TripletWpC2.lean` (documentation defect).

Remark 18.8. So `tripletW 2 hp` is neither 0 nor V_{L_2}, and its three triplet generators are nonzero: none of the degeneracies that would make the name misleading occurs at $p = 2$.

18.5 The lattice model II: C_2-cofiniteness for general p

C_2-cofiniteness is the finiteness condition that survives in the logarithmic world: it gives finitely many irreducible modules, finite-dimensional Zhu algebras and (Miyamoto) modular invariance of pseudo-traces, but it does not give semisimplicity. Recall (Chapter 12, Section 12.5) that $R_V = V/C_2(V)$ is a commutative Poisson algebra with product $\bar{u} \cdot \bar{v} = \overline{u_{(-1)}v}$, and that *if V is strongly generated by S*

then R_V is generated as a commutative algebra by the classes $\bar{s}$, $s \in S$ (every word containing a mode $s_{(-m)}$ with $m \geq 2$ lies in C_2). A commutative algebra generated by finitely many nilpotent elements is finite-dimensional. So:

$$\textit{strong generation by } S \textit{ finite} + \textit{each } \bar{s} \textit{ nilpotent in } R_V \Longrightarrow C_2\text{-cofinite}.$$

This is the route of Abe (2007) and Adamović–Milas (2008, Theorem 3.1), and of the library.

18.5.1 The engine

Theorem 18.9 (Nilpotent generators give C_2; dimension bound). *Let V be a VOA and $g : \iota \to V$ a finite family. If the classes $\bar{g}_i$ generate R_V as a commutative $\mathbb{C}$-algebra and each $\bar{g}_i$ is nilpotent, then V is C_2-cofinite; if $\bar{g}_i^{m_i} = 0$ then $\dim R_V \leq \prod_i m_i$.*

File `VOA/Examples/TripletW2Nilpotent.lean`.

```
theorem c2Cofinite_of_adjoin_of_isNilpotent (W : VertexOperatorAlgebra V) {ι : Type*}
    [Finite ι] (g : ι → V)
    (htop : Algebra.adjoin ℂ (Set.range (fun i => mk₂ W (g i))) = ⊤)
    (hnil : ∀ i, IsNilpotent (mk₂ W (g i))) : C2Cofinite W :=

theorem finrank_a₂_le_of_adjoin (W : VertexOperatorAlgebra V) {ι : Type*}
    [Fintype ι] (g : ι → V) (m : ι → ℕ)
    (htop : Algebra.adjoin ℂ (Set.range (fun i => mk₂ W (g i))) = ⊤)
    (hm : ∀ i, (mk₂ W (g i)) ^ m i = 0) :
    Module.finrank ℂ (A₂ W) ≤ ∏ i, m i :=
```

From the mathematics to the Lean statement

`Algebra.adjoin ℂ s = ⊤` is Mathlib's "the subalgebra generated by s is everything"; the algebra structure on `A₂ W` is the instance `a₂Algebra` built in the same file from the descended product (Chapter 12, Theorem 12.23). `IsNilpotent x` is $\exists n,\ x^n = 0$. The bound is the number of monomials $\prod_i \bar{g}_i^{k_i}$, $k_i < m_i$, which span. The statement is exactly the textbook lemma; nothing is hidden. A companion, `adjoin_range_mk₂_of_iterProdSpan`, derives `htop` from strong generation.

Physical meaning

R_V is the ring of functions on the "associated variety" of the chiral algebra, the classical limit in which only the leading singular terms of OPEs survive. Nilpotency of all generators means the associated variety is a point: there are no "flat directions" in the space of classical field configurations, which is the algebraic shadow of having finitely many primaries.

What the machine verified

Proved, unconditional; standard axioms.

18.5.2 The relations in $R_{W(p)}$

Theorem 18.10 (Adamović–Milas relations). *For every $p \geq 1$ and every $n \geq -2p$, in V_{L_p}:*

$$F_{(n)}F = 0, \qquad E_{(n)}E = 0, \qquad E_{(n)}F + F_{(n)}E + 2H_{(n)}H = 0,$$

and Q is a derivation of all products: $Q(u_{(n)}v) = (Qu)_{(n)}v + u_{(n)}(Qv)$. Consequently, in $R_{W(p)}$,

$$\bar{E}^2 = 0, \qquad \bar{F}^2 = 0, \qquad \bar{H}^2 = -\bar{E}\bar{F}, \qquad \bar{H}^4 = 0.$$

File `VOA/Examples/TripletWpC2.lean`.

```
theorem smul_Ftrip_Ftrip (p : ℕ) (hp : 1 ≤ p) {n : ℤ} (hn : -(2 * (p : ℤ)) ≤ n) :

theorem mk₂_genH_pow_four (p : ℕ) (hp : 1 ≤ p) :
    (mk₂ (tripletWVOA p hp) (genH p hp)) ^ 4 = 0 := by
```

From the mathematics to the Lean statement

`genOmega p hp` $= \langle \omega_{\lambda_p}, \dots \rangle$, `genE`, `genH`, `genF` are the four generators as elements of the subtype `(tripletW p hp).carrier`; `smul_coe` says products in $W(p)$ are the ambient ones, so the V_{L_p}-relations transport. The relations hold in V_{L_p} for $n \geq -2p$, in particular at $n = -1$, which is what the $R_{W(p)}$ relations use. The R-relations are formed in `A₂ (tripletWVOA p hp)`, i.e. with the subalgebra's *own* C_2-space; this matters, since $C_2(W) \subseteq C_2(V) \cap W$ can be strict (Section 18.7). If E were zero the relations would degenerate to $\bar{H}^2 = 0$, which still implies $\bar{H}^4 = 0$; so the conclusions are not hostage to the open question $E \neq 0$ for $p \geq 3$.

Proof on paper. $Y(e^\beta, z)e^\gamma = \varepsilon\, z^{\langle\beta,\gamma\rangle}(\cdots)e^{\beta+\gamma}$ with $(\cdots)$ a power series in z; for $\beta = \gamma = -\alpha$, $\langle\beta,\gamma\rangle = 2p$, so $F_{(n)}F = 0$ for $n \geq -2p$ (`smul_latChargeGen_eq_zero`). The derivation property of a zero mode is the $\ell = 0$ slice of the Borcherds identity (Chapter 5, Theorem 5.29; here `Core.ScreeningKernel.screening_leibniz` needs no hypothesis on Q). Applying Q, Q^2, Q^3, Q^4 to $F_{(n)}F = 0$ and using $QF = H$, $QH = E$, $QE = 0$ gives successively $H_{(n)}F + F_{(n)}H = 0$, $E_{(n)}F + 2H_{(n)}H + F_{(n)}E = 0$, $E_{(n)}H + H_{(n)}E = 0$, and $E_{(n)}E = 0$. In $R_{W(p)}$ the product is commutative, so the $n = -1$ relations read $\bar{F}^2 = \bar{E}^2 = 0$ and $2\bar{E}\bar{F} + 2\bar{H}^2 = 0$. Then $\bar{H}^4 = (\bar{E}\bar{F})^2 = \bar{E}^2\bar{F}^2 = 0$. □

Physical meaning

These are statements about the singular parts of the OPEs $F(z)F(w)$ etc.: the like-charge OPE $e^{-\alpha}(z)e^{-\alpha}(w) \sim (z-w)^{2p}$ is so regular that even its normal-ordered product vanishes, and the screening symmetry rotates this into the full set of triplet OPE relations. In the classical (associated-variety) limit the triplet fields become nilpotent coordinates.

What the machine verified

Proved, unconditional; `#print axioms VOA.LatGen.WpC2.mk₂_genH_pow_four: [propext, Classical.choice, Quot.sound]`.

18.5.3 The two residual hypotheses, and the theorem

Definition 18.11 (Generation and $\bar{\omega}$-nilpotency hypotheses).

- `StrongGenWp p hp`: $W(p)$ is strongly generated by ω, E, H, F.
- `AdjoinGenWp p hp`: $R_{W(p)}$ is generated as a commutative algebra by $\bar{\omega}, \bar{E}, \bar{H}, \bar{F}$ (implied by the previous one).
- `OmegaNilpotentWp p hp`: $\bar{\omega}$ is nilpotent in $R_{W(p)}$.
- `OmegaPowMem p hp m`: $L_{-2}^m \mathbf{1} \in C_2(W(p))$, i.e. $\bar{\omega}^m = 0$.

File `VOA/Examples/TripletWpC2.lean`.

```

  TripletNilp.pMulPow (tripletWVOA p hp) (genOmega p hp) m ∈ O₂ (tripletWVOA p hp)
```

From the mathematics to the Lean statement

`TripletNilp.pMulPow W u m` is the m-fold normal-ordered power $u_{(-1)}(u_{(-1)}(\cdots u_{(-1)}\mathbf{1}))$, and for $u = \omega$ it is $L_{-2}^m\mathbf{1}$ (`pMulPow_genOmega_succ`); `mk₂_genOmega_pow_eq_zero_iff` proves `OmegaPowMem p hp m` $\iff$ $\bar{\omega}^m = 0$. `OmegaNilpotentWp` is deliberately exponent-free so that no guessed exponent can make a theorem vacuous. All four are genuine `Prop`s about the *subalgebra's* C_2 quotient. They are hypotheses, never axioms.

Physical meaning

`StrongGenWp` is the statement that the chiral algebra is a W-algebra with exactly four generating fields T, W^+, W^0, W^- (every field is a normally ordered polynomial in them and their derivatives). `OmegaPowMem` says that a power of the stress tensor, $:T^m:$, is "null modulo derivatives and composite fields" in the classical limit — the existence of a null vector of a special shape.

What the machine verified

Definitions. A Lean check (not part of this release) proves `AdjoinGenWp 2 hp` and `OmegaPowMem 2 hp 5`: the hypotheses are *satisfiable*, so the conditional theorems below are not vacuous.

Theorem 18.12 (C_2-cofiniteness of $W(p)$, conditional)**.** *For every $p \geq 1$ and $m \in \mathbb{N}$: if $R_{W(p)}$ is generated by $\bar{\omega}, \bar{E}, \bar{H}, \bar{F}$ and $L_{-2}^{m}\mathbf{1} \in C_2(W(p))$, then $W(p)$ is C_2-cofinite and* $\dim R_{W(p)} \leq 16m$.

File `VOA/Examples/TripletWpC2.lean`.

```
theorem c2Cofinite_tripletWVOA (p : ℕ) (hp : 1 ≤ p) (hgen : AdjoinGenWp p hp)
    (homega : OmegaNilpotentWp p hp) : C2Cofinite (tripletWVOA p hp) := by

    C2Cofinite (tripletWVOA p hp)
      ∧ Module.finrank ℂ (A₂ (tripletWVOA p hp)) ≤ 16 * m :=
```

From the mathematics to the Lean statement

Two hypotheses, both named: generation (`hgen`) and $\bar{\omega}$-nilpotency (`homega`). The LIBRARY MAP summary "general p conditional on `OmegaPowMem`" omits the first; it is also needed. $16m = m \cdot 2 \cdot 4 \cdot 2$ is the engine's bound with exponents $(m, 2, 4, 2)$ for $(\bar{\omega}, \bar{E}, \bar{H}, \bar{F})$. With Adamović–Milas' $m = 3p - 1$ this is $48p - 16$; the true value of $\dim R_{W(p)}$ is expected by the library's docstring to be $6p - 1$ (Abe proves ≤ 11 at $p = 2$), so the bound is crude but finite, which is all C_2-cofiniteness asks.

Proof on paper. Theorem 18.9 with $g = (\omega, E, H, F)$: generation is `hgen`, nilpotency of $\bar{E}, \bar{F}, \bar{H}$ is Theorem 18.10, and of $\bar{\omega}$ is `homega`. □

Physical meaning

This is "the $(1, p)$ triplet theory is a finite (lisse) logarithmic CFT", modulo the two statements that its W-algebra closes on four generators and that $:T^{3p-1}:$ is classically null.

What the machine verified

Proved, **conditional on `AdjoinGenWp p hp` and `OmegaPowMem p hp m`** (or `OmegaNilpotentWp`); `#print axioms`: standard three. No `VOA.pbw`. The hypotheses are discharged only at $p = 2$ (in a Lean check outside the library, not part of this release); for $p \geq 3$ this is a conditional reduction, not "$W(p)$ is C_2-cofinite".

Trap / dead end

The printed argument for $\bar{\omega}$-nilpotency in Adamović–Milas (2008), Theorem 3.1, is a non-sequitur (recorded in the docstring of `TripletWpC2.lean`; we have checked the reasoning). The paper says: by [Adamović 2003], $\bar{H}^2 = C_p \bar{\omega}^{2p-1}$ with $C_p \neq 0$; since $\bar{H}^4 = 0$, $\bar{\omega}^{4p-2} = 0$. But the cited relation holds in *Zhu's algebra* $A(V) = V/O(V)$ — and there it is $[H] * [H] = C_p P([\omega])$ for a non-homogeneous polynomial P of degree $2p-1$, not the monomial. The only comparison map between the two quotients is the epimorphism $R_V \twoheadrightarrow \operatorname{gr} A(V)$, which goes the wrong way: a relation in $A(V)$ pulls back to nothing in R_V. *The repair* is inside the same paper: Corollary 4.6 proves $\bar{\omega}^{3p-1} = 0$ from an identity *in* V_{L_p} *itself*,

$$Q^2 e^{-2\alpha} = A \cdot H_{(-2p-1)}H + \left(B_p L_{-2}^{3p-1} + w\right)\mathbf{1}, \qquad B_p \neq 0, \tag{18.10}$$

with w a combination of Virasoro monomials each containing some L_{-n}, $n \geq 3$; every term

other than $B_p L_{-2}^{3p-1}\mathbf{1}$ is visibly in C_2, and the left side is too, since $Q^2 e^{-2\alpha} = \varepsilon^{-1} Q^2(F_{(-2p-1)}F) = \varepsilon^{-1}(E_{(-2p-1)}F + 2H_{(-2p-1)}H + F_{(-2p-1)}E)$. Corollary 4.6 does not depend on Theorem 3.1, so there is no circularity. The library formalises exactly this repair (next theorem). (This is a finding about the literature, not a Lean defect.)

Definition 18.13 (The Adamović–Milas identity; deep Virasoro descendants). `VirDeep p hp` is the span of the states $L_{-n}y$, $y \in W(p)$, $n \geq 1$, $n \neq 2$. `AMOmegaIdentity p hp m` asserts (18.10) with exponent m: there are $A, B \in \mathbb{C}$, $B \neq 0$, and $w \in$ `VirDeep p hp` with $Q^2 e^{-2\alpha} = A \cdot H_{(-2p-1)}H + B \cdot L_{-2}^{m}\mathbf{1} + w$.

    C2Cofinite (tripletWVOA p hp)
      ∧ Module.finrank ℂ (A₂ (tripletWVOA p hp)) ≤ 16 * m :=
```

From the mathematics to the Lean statement

`O₂amb p hp` is the image of $C_2(W(p))$ in V_{L_p} under the inclusion; `mem_O₂amb_iff` proves that ambient membership of a state of $W(p)$ is equivalent to intrinsic membership, so nothing is lost by computing in V_{L_p}. `omegaPowAmb p hp m` is $L_{-2}^{m}\mathbf{1}$ (since $\omega_{(-1)} = L_{-2}$). The latticed vector `-alphaP p + -alphaP p` is -2α. The library's `VirDeep` is larger than Adamović–Milas' w-space (it allows L_{-n} applied to any state of $W(p)$, not only Virasoro monomials on the vacuum), so `AMOmegaIdentity` is *weaker* (easier to satisfy) than the paper's identity; that is harmless because every element of `VirDeep` is in C_2 (`virDeep_le_O₂amb`: $L_{-1} = T$ and $L_{-n} = \omega_{(-n+1)}$ with $-n+1 \leq -2$ for $n \geq 3$), which is all the argument needs. The two membership theorems are *unconditional*, for every p: they are the two "visibly in C_2" facts of the warning. The identity cannot hold trivially: the grading forces $m = 3p-1$ (`omegaPowAmb_mem_grading`, everything lives in weight $6p-2$).

Proof on paper. Given (18.10), $B\,L_{-2}^{m}\mathbf{1} = Q^2e^{-2\alpha} - A\,H_{(-2p-1)}H - w \in C_2(W(p))$ by the two membership theorems and `virDeep_le_O₂amb`; divide by B. □

Physical meaning

(18.10) is a null-vector statement in the Coulomb gas: the doubly screened vertex operator $Q^2e^{-2\alpha}$ is a descendant of the vacuum module plus a composite of H with itself, and its purely-T part has a nonzero coefficient. It is the free-field reason for the polynomial relation satisfied by T in the triplet theory.

What the machine verified

Proved; the last theorem is conditional on `AdjoinGenWp` and `AMOmegaIdentity`; the two membership theorems are unconditional. Standard axioms.

18.5.4 Reducing generation to a finite OPE table

Theorem 18.14 (Generation from the generator OPE table)**.** *Let T_p be the span of the strictly-negative-mode words in ω, E, H, F. If $g_{(j)}h \in T_p$ for all generators g, h and $0 \le j < 4p+2$, then $W(p)$ is strongly generated by ω, E, H, F. The ω-row of the table holds for every p, because E, H, F are Virasoro primary. The remaining mixed pairs reduce to the two "lowering rows" $F_{(j)}H$ and $F_{(j)}E$.*

From the mathematics to the Lean statement

`GenPairClosedWp` is stated in the ambient V_{L_p} with `iterProdSpan` of `tripletLatticeVOA`; `strongGenWp_iff` (`TripletWpAmbient.lean`) shows the ambient span equals $W(p)$ exactly when `StrongGenWp` holds, so this is faithful. The reduction from "closed under all products of all elements" to "closed under non-negative products of generators" is the general `iterProdSpan_smul_closed` (Chapter 12, Theorem 12.24 and its companion), which needs the generators homogeneous of positive weight; the bound $j < 4p+2$ comes from $g_{(j)}h = 0$ for

$j \geq \operatorname{wt} g + \operatorname{wt} h$. Both `GenPairClosedWp` and `LoweringPairsWp` quantify over *all* $j \geq 0$ rather than $0 \leq j < 4p+2$; the two forms are equivalent, because for larger j the product has negative weight, hence is 0, which lies in every span. `screenGens p` $= \{E, H, F\}$. `screenGens_primary` is $L_n E = L_n H = L_n F = 0$ for $n \geq 1$. The final theorem therefore has exactly two named hypotheses for general p: the two lowering rows (a finite set of Fock-space computations, $0 \leq j < 4p + 2$) and the Adamović–Milas identity.

Proof on paper. Strong generation: commuting a non-negative mode $g_{(j)}$ past a negative one, $[g_{(j)}, h_{(-m)}] = \sum_i \binom{j}{i} (g_{(i)}h)_{(j-m-i)}$, produces modes of the products $g_{(i)}h$; if these lie in the span of words, an induction on weight shows the span is closed. Primarity: charged vacua e^{β} are primary for the deformed stress tensor (a Fock-vacuum computation), so F and e^{α} are; skew-symmetry gives $Q\omega = 0$, so Q commutes with all L_n, and $L_n H = L_n QF = QL_n F = 0$, likewise for E. Mixed pairs: applying the derivation Q to $F_{(j)}H$ and $F_{(j)}E$ and using the exact identities of Theorem 18.10 recovers $H_{(j)}H$, $H_{(j)}E$, $E_{(j)}F$, … □

Physical meaning

The table $\{g_{(j)}h\}_{j\geq 0}$ is the list of singular OPE coefficients among the generating fields. Closure of the W-algebra means that every singular term in $W^a(z)W^b(w)$ is a normally ordered polynomial in T, W^a and derivatives — the classic Kausch computation, which here becomes a finite check in the Fock space.

What the machine verified

Proved; the last theorem conditional on `LoweringPairsWp p hp` and `AMOmegaIdentity p hp (3 * p - 1)`. `screenGens_primary` is unconditional. Standard axioms.

18.6 The lattice model III: the unconditional theorems at $p = 2$

At $p = 2$ both residual families are discharged by explicit computation in the Fock space of the rank-one lattice L_2 ($\langle \alpha, \alpha \rangle = 4$). Every Fock state of charge 0 and given degree is a polynomial in finitely many oscillator variables; the computations are identities between explicit polynomials with rational coefficients, checked by Lean's `ring/norm_num` machinery, not by `native_decide`.

18.6.1 The three mixed coordinates

By Theorem 18.14, strong generation reduces to showing that the products $F_{(j)}H$ and $F_{(j)}E$, $j \geq 0$, are polynomials in the generators. These are "mixed" products (of two *different* generators, one of charge $-\alpha$ and one of charge 0 or $+\alpha$). At $p = 2$ all but three of them vanish or are settled by short degree-zero arguments (see the dictionary after Theorem 18.15); the three that need a real computation are $F_{(0)}H$, $F_{(1)}E$ and $F_{(3)}E$. Each lies in a finite-dimensional weight-and-charge space of the Fock space, and "computing it" means finding its *coordinates* in a basis of that space and recognising them as the coordinates of a polynomial in the generators. The library calls these three computations the *three mixed coordinates*; Theorem 18.15 states their results.

Theorem 18.15 (Mixed products at $p = 2$). *With $c = \varepsilon(\alpha, -\alpha)$, $d = \varepsilon(-\alpha, \alpha)$, in V_{L_2}:*

$$F_{(0)}H = \frac{48c}{5} L_{-2}F + \frac{4c}{5} T^2 F, \qquad F_{(1)}E = -64cd\, L_{-2}\omega + 12cd\, T^2\omega + 10d\, TH, \qquad F_{(3)}E = -48cd\, \omega.$$

Consequently all mixed generator pairs close, and $W(2)$ is strongly generated by ω, E, H, F.

```

From the mathematics to the Lean statement

`W.toPreVertexAlgebra.T` is the translation $T = L_{-1}$, so `T ^ 2` is T^2, and `W.smul (omegaTrip 2) (-1) x` is $\omega_{(-1)}x = L_{-2}x$. `ThreeCoordinateIdentitiesWp` (in `TripletWpPairClosure.lean`) is the same three equations with existential coefficients; only membership of the right sides in the word span is used downstream. The three products not in the list ($F_{(2)}H = aF$, $F_{(5)}E = a\mathbf{1}$, and the vanishing ones) are handled by degree-zero arguments. `strongGenWp_two` is the composite: mixed pairs (above) plus primarity tails plus the reduction of Theorem 18.14. The proved $F_{(3)}E \neq 0$ is what gives $E \neq 0$ (Theorem 18.7).

Proof on paper. Each left side is a single lattice product: e.g. $F_{(3)}E$ is the coefficient of z^{-4} in $Y(e^{-\alpha}, z)$ applied to $E = \varepsilon\,(\mathrm{EE}(\alpha)_{-1}S_3(\alpha)) \otimes e^{\alpha}$ (charge α, Fock degree 2, weight $2 + q_2(1) = 3$). The result has charge 0 and weight $3 + 3 - 3 - 1 = 2$, so it lies in the two-dimensional space spanned by $\alpha(-1)^2\mathbf{1}$ and $\alpha(-2)\mathbf{1}$; expanding the normal-ordered exponentials gives its two coordinates, which are compared with those of $\omega_{\lambda_2} = \frac{1}{8}\alpha(-1)^2\mathbf{1} + \frac{1}{4}\alpha(-2)\mathbf{1}$. The other two identities are the same computation in charge $-\alpha$, weight 5, and charge 0, weight 4, where the spaces are larger but still finite-dimensional. □

Physical meaning

These are the most singular terms of the OPEs $W^-(z)W^0(w)$ and $W^-(z)W^+(w)$ of the $c = -2$ triplet algebra: $W^-(z)W^+(w) \sim \frac{-48cd}{(z-w)^4}T(w) + \cdots$ (the leading $(z-w)^{-6}$ term being the vacuum). They are Kausch's structure constants in the Coulomb-gas normalisation.

What the machine verified

Proved, unconditional. `#print axioms` of `threeCoordinateIdentitiesWp_two` and `strongGenWp_two`: `[propext, Classical.choice, Quot.sound]`.

18.6.2 The Adamović–Milas identity at weight ten

Theorem 18.16 (The $p = 2$ identity). *In V_{L_2}, at weight* 10 *and charge* 0*,*

$$Q^2 e^{-2\alpha} = 3\,H_{(-5)}H + \frac{1024}{1575}\,L_{-2}^5\mathbf{1} + R,$$

where R is an explicit combination of eleven Virasoro words $L_{-n_1}\cdots L_{-n_k}\mathbf{1}$ with $n_1 \neq 2$ (so $R \in$ `VirDeep`). Hence `AMOmegaIdentity 2 hp 5` *holds.*

theorem amTwoCoordinateIdentity_two (hp : 1 ≤ 2) : AMTwoCoordinateIdentity hp :=

theorem amOmegaIdentity_two (hp : 1 ≤ 2) : AMOmegaIdentity 2 hp 5 :=
```

From the mathematics to the Lean statement

`virWordTwo hp [n₁,…,n_k]` is $L_{-n_1}\cdots L_{-n_k}\mathbf{1}$ with the deformed Virasoro modes of V_{L_2} (the list is read left to right, outermost first). So `virWordTwo hp [2,2,2,2,2]` is $L_{-2}^5\mathbf{1}$, and every word in `amTwoRemainder` has first letter $\neq 2$, which is why it lies in `VirDeep 2 hp` (the first letter is the outermost mode; its argument is a Virasoro descendant of the vacuum, which lies in $W(2)$). The coefficient $B_2 = \frac{1024}{1575}$ agrees with Adamović–Milas' closed formula $(-1)^p\binom{2p}{p}(4p)^{3p-1}/\left(\binom{4p-1}{p}((3p-1)!)^2\right)$ at $p = 2$: $6\cdot 8^5/(21\cdot 120^2) = 196608/302400 = 1024/1575$ (we checked the arithmetic). The twelve words are all partitions of 10 into parts

≥ 2, as the grading requires. The identity is an equality of two explicit vectors of the Fock space; it is proved, not assumed.

Proof on paper. Write both sides as polynomials in the oscillators $a_k = \alpha(-k)$ of total degree 10 (charge 0): $Q^2 e^{-2\alpha}$ is $\mathrm{EE}(\alpha)_3 S_7(\alpha)$ up to sign, $H = S_3(\alpha)$ and $H_{(-5)}H$ is computed by the lattice product formula, and each Virasoro word is computed by the background-charge Virasoro action on the Fock space at $c = -2$. There are 42 monomials of degree 10 that occur; comparing their coefficients is a finite linear-algebra check. The library assembles it from a "sparse" representation (32-term and 42-term ledgers of monomials) in the `TripletWpTwoAM*.lean` files. □

Physical meaning

The weight-10 null relation of the $c = -2$ triplet model: the fifth power of the stress tensor is, modulo C_2, a combination of composites involving the triplet fields. It is what bounds the "number of states" in the classical limit.

What the machine verified

Proved, unconditional; `#print axioms VOA.LatGen.WpTwoAMFinal.amOmegaIdentity_two: [propext, Classical.choice, Quot.sound]`.

18.6.3 C_2-cofiniteness

Theorem 18.17 (The lattice triplet $W(2)$ is C_2-cofinite). *$W(2) =$ `tripletWVOA 2 hp` is C_2-cofinite, and* $\dim W(2)/C_2(W(2)) \leq 80$.

File `VOA/Examples/TripletWpTwoClose.lean`.

```
theorem tripletWVOA_two_c2Cofinite_and_finrank_le (hp : 1 ≤ 2) :
    C2Cofinite (tripletWVOA 2 hp)
      ∧ Module.finrank ℂ (A₂ (tripletWVOA 2 hp)) ≤ 80 :=

theorem tripletWVOA_two_c2Cofinite (hp : 1 ≤ 2) : C2Cofinite (tripletWVOA 2 hp) :=
```

From the mathematics to the Lean statement

The only argument is `hp : 1 ≤ 2`, which is a proof of a true inequality between numerals: the theorem is unconditional. `C2Cofinite` is the standard notion (Definition 12.22); the C_2 space is that of the subalgebra itself. $80 = 16 \cdot 5$. The theorem is about the *lattice* model; it says nothing about `SympFerm.tripletW2` (whose C_2-cofiniteness is open, Section 18.7). Could it be vacuous? C_2-cofiniteness of the zero algebra is trivial, but $W(2) \neq 0$; and $W(2)$ is not the (trivially C_2-cofinite) $\mathbb{C}\mathbf{1}$, since it contains F of charge $-\alpha$. A Lean check (not part of this release) reproduces the bound from the general-p theorem.

Proof on paper. Theorem 18.14 with `LoweringPairsWp 2 hp` from Theorem 18.15 and `AMOmegaIdentity 2 hp 5` from Theorem 18.16. □

Physical meaning

The $c = -2$ triplet theory is a finite logarithmic CFT: its classical phase space is a point ($\dim R \leq 11$ by Abe, here bounded by 80). This is the property that guarantees finitely many irreducible modules and Miyamoto's modular invariance of pseudo-traces.

What the machine verified

Proved, unconditional, for the lattice model `tripletWVOA 2 hp` only. `#print axioms VOA.LatGen.WpC2.tripletWVOA_two_c2Cofinite_and_finrank_le: [propext, Classical.choice, Quot.sound]`. No `VOA.pbw`.

18.6.4 Irrationality

Theorem 18.18 (The lattice $W(2)$ is not rational)**.** *$W(2)$ has no nonzero state of weight one. The ambient V_{L_2}, regarded as an ordinary $W(2)$-module by restriction, is not completely reducible: the submodule $W(2)$ has no complement. Consequently $W(2)$ is neither Gannon-rational nor admissibly rational.*

```

From the mathematics to the Lean statement

`adjointRestrictOrd` is the restriction of the adjoint module of V_{L_2} to the subalgebra (Chapter 12, Definition 12.12): an `OrdVModule` of $W(2)$ on the carrier V_{L_2}, with weight spaces the L_0-eigenspaces (finite-dimensional and bounded below because V_{L_2} is a VOA of CFT type). `OrdVModule.IsCompletelyReducible N` means that every weak submodule has a complementary submodule (`IsCompl` of carriers; Definition 12.5). `GannonRational` and `AdmissiblyRational` are the two rationality notions of Chapter 12 (Definitions 12.37 and 12.35); the first asks complete reducibility of ordinary modules, the second of admissible ones, and the library's lemma `isCompletelyReducible_of_admissiblyRational` transfers the second to the ordinary module at hand. `AdmissiblyRational` asks that every *weak* submodule of every admissible module be complemented by a weak submodule; this is not literally

Dong–Li–Mason's complete reducibility into irreducibles (release audit 2026-10-27, finding m5). The witness is robust to the difference: the graded submodule $W(2) \subset V_{L_2}$ has no complement even among weak submodules, because $F_{(3)}e^{\alpha} = \varepsilon\mathbf{1}$ and $W(2)_1 = 0$, so on paper it also refutes DLM rationality. When announcing, state the notion. `AdmissiblyRational` is satisfiable (it holds for the trivial VOA, `VOA/Examples/TrivialAdmissiblyRational.lean`), so its negation has content.

Proof on paper. No weight one. By strong generation (Theorem 18.15) $W(2)$ is spanned by words in generators of weight 2 and 3; such a word has weight 0 (the vacuum) or ≥ 2. *Non-splitting.* Suppose $V_{L_2} = W(2) \oplus Q$ as $W(2)$-modules. Write $e^{\alpha} = a + q$; since L_0 preserves both summands and $L_0 e^{\alpha} = e^{\alpha}$, a has weight one, so $a = 0$ and $e^{\alpha} \in Q$. Then $F_{(3)}e^{\alpha} \in Q$. But $F_{(3)}e^{\alpha} = \varepsilon(-\alpha, \alpha)\mathbf{1}$ (the lattice product $e^{-\alpha}_{(n)}e^{\alpha}$ is $\varepsilon z^{-4}(1 + O(z))$, so its z^{-4}-coefficient, $n = 3$, is $\varepsilon\mathbf{1}$), which is a nonzero element of $W(2) \cap Q = 0$. *Irrationality.* Gannon-rationality requires every ordinary module to be completely reducible; admissible rationality implies it for ordinary modules that are admissible, which this one is. □

Physical meaning

The Coulomb-gas Fock space V_{L_2} is a non-split extension of $W(2)$-modules: the weight-one field e^{α} (the screening current itself) is not in the chiral algebra, but its OPE with $e^{-\alpha}$ produces the identity. This is the simplest instance of the structure FGST describe as the "Felder complex" of the triplet theory: free-field modules glue irreducibles into indecomposables. In a rational theory every such extension would split.

What the machine verified

Proved, unconditional, for the lattice model only, with the library's rationality notions. `#print axioms` of `not_gannonRational_tripletWVOA_two` and `not_admissiblyRational_tripletWVOA_two`: `[propext, Classical.choice, Quot.sound]`. No Felder exactness, no module classification and no symplectic-fermion input is used.

18.6.5 Simplicity and strong finiteness

Definition 18.19 (The f_2 Zhu certificate)**.** Let $f_2(X) = X^2(X + \frac{1}{8})(X - \frac{3}{8})(X - 1) = X^5 - \frac{5}{4}X^4 + \frac{13}{64}X^3 + \frac{3}{64}X^2$. Its *state representative* in a VOA V is $\omega^{*5} - \frac{5}{4}\omega^{*4} + \frac{13}{64}\omega^{*3} + \frac{3}{64}\omega^{*2}$, where ω^{*n} is the n-fold Zhu product $\omega * (\omega * \cdots * \mathbf{1})$. The *certificate* is the statement that this state lies in $O(V)$, i.e. $f_2([\omega]) = 0$ in $A(V)$.

File `VOA/Examples/TripletWpSimplicity.lean`.

```

  h ^ 2 * (h + 1 / 8) * (h - 3 / 8) * (h - 1)
```

```
def FTwoZhuCertificate (W : VertexOperatorAlgebra V) : Prop :=
  fTwoZhuRepresentative W ∈ O W

theorem fTwoScalar_natCast_eq_zero_iff (n : ℕ) :
    fTwoScalar (n : ℂ) = 0 ↔ n = 0 ∨ n = 1 := by
```

From the mathematics to the Lean statement

`mk_fTwoZhuRepresentative` proves that the class of the representative is $f_2([\omega])$ evaluated in the ring $A(V)$, and `fTwoPolynomial_eval` that the expanded polynomial equals the factored `fTwoScalar`; we checked the expansion by hand $(X^2(X+\frac{1}{8})(X-\frac{3}{8})(X-1)$: the product of the last three is $X^3-\frac{5}{4}X^2+\frac{13}{64}X+\frac{3}{64})$. The roots $0, 1, -\frac{1}{8}, \frac{3}{8}$ are the lowest weights $h_{1,1}, h_{2,1}, h_{1,2}, h_{2,2}$ of (18.6); the double root at 0 reflects the Jordan block of $A(W(2))$.

Physical meaning

$f_2([\omega]) = 0$ in Zhu's algebra says: on the ground states of any $W(2)$-module, L_0 satisfies $f_2(L_0) = 0$, so the possible conformal weights of ground states are $0, 1, -\frac{1}{8}, \frac{3}{8}$ — the $c = -2$ first-row Kac table — and L_0 may have a Jordan block only at $h = 0$.

What the machine verified

Definitions and an arithmetic lemma; standard axioms.

Theorem 18.20 ($W(2)$ is simple and strongly finite)**.** *The lattice $W(2)$ satisfies the f_2 certificate; hence it is simple, strongly finite, and neither admissibly nor Gannon rational (so not strongly rational).*

theorem not_stronglyRational_tripletWVOA_two (hp : 1 ≤ 2) :
    ¬ StronglyRational (tripletWVOA 2 hp) := by
```

From the mathematics to the Lean statement

`FTwoZhuCertificateWp hp` is `FTwoZhuCertificate (tripletWVOA 2 hp)`. `W.IsSimple` is "$V \neq 0$ and every ideal is 0 or V" (Chapter 5, Definition 5.16; Chapter 12, Definition 12.34). `StronglyFinite W` is the structure with fields `simple`, `selfDual` (a nondegenerate fully invariant bilinear form) and `c2Cofinite` (Definition 12.43); it is the Creutzig–Gannon/McRae notion. `SelfDual` here is the genuine nondegenerate-form notion of `StronglyRational.lean`, not the vacuous `SelfContragredient` (satisfied by every module; Chapter 12); it is obtained from the general recognition theorem `stronglyFinite_of_L_one_grading_one_eq_zero` (sim-

ple + $L_1V_1 = 0 \Rightarrow$ self-dual, Li), which applies because $V_1 = 0$.

Proof on paper. *Simplicity from the certificate* (Chapter 12, Theorem 12.21): if I is a proper nonzero ideal, its lowest weight space I_n is a module for $A(V)$ on which $[\omega]$ acts by n, so $f_2(n) = 0$, so $n \in \{0, 1\}$; $n = 0$ is impossible since $V_0 = \mathbb{C}\mathbf{1}$ and $\mathbf{1} \notin I$; $n = 1$ is impossible since $V_1 = 0$. *The certificate*: the representative is an explicit state of weight ≤ 10; it is written as a sum of 37 "circle" elements $u \circ v = \mathrm{Res}_z\, Y(u,z)v\frac{(1+z)^{\mathrm{wt}\,u}}{z^2}$ (which are in $O(V)$ by definition) plus a multiple of the screened state $Q^2e^{-2\alpha}$, which lies in $O(W(p))$ for every p by a separate higher-pole argument (`Qwp_sq_latChargeGen_mem_O`, `TripletWpZhuScreening.lean`); the decomposition is an identity in the Fock space verified by the `TripletWpTwoZhuSparse*.lean` files. *Strong finiteness*: simplicity + self-duality (from $V_1 = 0$) + C_2 (Theorem 18.17). □

Physical meaning

Strongly finite and non-rational is the defining property of a "finite logarithmic CFT" in the modern sense (Creutzig–Gannon, McRae): its module category is a finite non-semisimple tensor category. $W(2)$ is the standard example, and the library now has it as a theorem.

What the machine verified

Proved, unconditional, for the lattice model only. `#print axioms` of `tripletWVOA_two_isSimple`, `tripletWVOA_two_stronglyFinite_and_irrational`, `not_stronglyRational_tripletWVOA_two`: `[propext, Classical.choice, Quot.sound]`. (The docstring of `TripletWpStronglyFinite.lean` still says strong finiteness is "conditional only on simplicity"; the condition is discharged in `TripletWpTwoZhuFinal.lean`, a later file.)

Theorem 18.21 (The screened state is in Zhu's O, for every p). *For every $p \geq 1$, $\varepsilon(-\alpha,-\alpha)^{-1}(E_{(-2p-1)}F + 2H_{(-2p-1)}H + F_{(-2p-1)}E)$, which equals $Q^2e^{-2\alpha}$ after inclusion in V_{L_p}, lies in $O(W(p))$.*

File `VOA/Examples/TripletWpZhuScreening.lean`.

```
noncomputable def qwpSqNegTwoAlphaTriplet (p : ℕ) (hp : 1 ≤ p) :
    (tripletW p hp).carrier :=
  (latticeCocycle (latP p) (-alphaP p) (-alphaP p))⁻¹ •
    qwpSqModeTriplet p hp (-(2 * (p : ℤ)) - 1)

theorem Qwp_sq_latChargeGen_mem_O (p : ℕ) (hp : 1 ≤ p) :
    qwpSqNegTwoAlphaTriplet p hp ∈ O (tripletWVOA p hp) := by
```

From the mathematics to the Lean statement

`qwpSqModeTriplet p hp n` is $E_{(n)}F + 2H_{(n)}H + F_{(n)}E$ as an element of $W(p)$; `qwpSqNegTwoAlphaTriplet_coe` identifies its normalised $n = -2p - 1$ value with $Q^2e^{-2\alpha}$. $O(V)$ is Zhu's subspace (not C_2); this is the Zhu-algebra analogue of the C_2 membership in Definition 18.13, proved independently.

Proof on paper. The Frenkel–Zhu residue $\mathrm{Res}_z\, Y(u,z)v\,(1+z)^{\mathrm{wt}\,u}z^{-2-k}$ lies in $O(V)$ for all $k \geq 0$. Take $k = 2p - 1$ and sum the three residues: the expansion of $(1+z)^{2p-1}$ produces the modes $u_{(-2p-1)}, u_{(-2p)}, \ldots$; the leading one gives the screened state, and every later mode $n \geq -2p$ vanishes by $Q^2(F_{(n)}F) = 0$ (Theorem 18.10). □

Physical meaning

In Zhu's algebra the doubly screened vertex operator is zero: this is the relation that, combined with the Virasoro part of (18.10) in its Zhu form, yields the polynomial f_2.

What the machine verified

Proved, unconditional; standard axioms.

Trap / dead end

Sizes. About 140 of the files of this chapter (`TripletWpTwoAM*`, `TripletWpTwoZhuSparse*`, `TripletWpTwoZhuFast*`, `TripletWpTwoVirasoroCoords`, `TripletWpTwoSector`, `TripletWpTwoZhuCertificate`) are split pieces of the two Fock-space computations behind Theorems 18.16 and 18.20; they were split for elaboration time. Each file carries its own `#print axioms` audit. Their public interfaces are the theorems quoted above; the intermediate declarations are bookkeeping (ledgers of monomials, mode-by-mode partial sums) with no independent mathematical content, and the book does not document them one by one. A referee who wants to audit them should check (i) that no `native_decide` or `sorry` occurs (`scripts/check_repository.py` enforces this) and (ii) that the two final comparisons (`eval_hProductExpected_eq_assembly`, `eval_hEntryMode0_eq_expected`) are equalities of evaluated polynomials, not definitional unfoldings; for the first, the library deliberately keeps two separately written copies of the 32-term ledger and compares them.

18.7 The Abe model: $W(2)$ as the even part of symplectic fermions

18.7.1 The algebra

Definition 18.22 (The Abe model of $W(2)$)**.** SF^+ is the even part of the symplectic-fermion super VOA `sympFermSVOA` (Chapter 17, Theorem 17.36): the span of the word states $\chi^{a_1}_{-k_1-1}\cdots\chi^{a_n}_{-k_n-1}\mathbf{1}$ with n even, with the restricted vertex operators, vacuum and conformal vector $\omega_{SF}=-\chi^0_{-1}\chi^1_{-1}\mathbf{1}$.

File `VOA/Examples/TripletW2.lean`.

```
theorem sympFermSVOA_integralWeights (h : ℂ) (hh : ¬ ∃ n : ℤ, (n : ℂ) = h) :
    ∀ x ∈ sympFermSVOA.parity 0, x ∈ sympFermSVOA.grading h → x = 0 := by

noncomputable def tripletW2 : VertexOperatorAlgebra (evenOdd QSF 0) :=
  sympFermSVOA.evenPartVOA sympFermSVOA_integralWeights

@[simp] theorem tripletW2_centralCharge : tripletW2.centralCharge = -2 := rfl

@[simp] theorem tripletW2_grading (n : ℤ) :
    tripletW2.grading n = (gradingSF (n : ℂ)).comap (evenOdd QSF 0).subtype := rfl

theorem evenPartSF_eq_span :
    (evenOdd QSF (0 : ZMod 2) : Submodule ℂ FockSF)
      = Submodule.span ℂ (stWordSF '' {l : SFWord | Even l.length}) := by

theorem tripletW2_grading_one : tripletW2.grading 1 = ⊥ := by
```

From the mathematics to the Lean statement

`evenOdd QSF 0` is the even part of the Clifford (here exterior) algebra Fock_{SF} (`FockSF := CliffordAlgebra QSF` with `QSF = 0`); `evenPartVOA` is the even-part transfer of Chapter 17,

Theorem 17.19, whose only hypothesis (integral weights in the even part) is discharged by `sympFermSVOA_integralWeights`, which in fact shows that every weight of Fock_{SF} is an integer. `stWordSF l` is the word state of a list $l = [(k_1, a_1), \dots]$, i.e. $\chi^{a_1}_{-k_1-1}\cdots\mathbf{1}$, of weight $\sum(k_i+1)$. So this *is* SF^+: the identifications of Y, vacuum, ω and grading with the ambient ones are `rfl`-lemmas (`tripletW2_Y_coe`, ...). The name "`tripletW2`" rests on the literature theorem $\mathrm{SF}^+ \cong W(2)$ (Kausch; Abe, Remark 3.9); *no* isomorphism with `tripletWVOA 2 hp` is proved. $W(2)_1 = 0$ because weight-one states are one-letter words, which are odd.

Physical meaning

The bosonic (fermion-number-even) sector of the $c = -2$ symplectic-fermion theory. As a chiral algebra this is the $\mathbb{Z}/2$-orbifold $\mathrm{SF}/\langle(-1)^F\rangle$; its graded dimension is (18.7): $1, 0, 1, 4, 5, 8, 10, \dots$ The absence of weight-one states means there is no continuous symmetry (no currents), as for $V^\natural$.

What the machine verified

Proved, unconditional; `#print axioms VOA.SympFerm.tripletW2, tripletW2_grading_one`: `[propext, Classical.choice, Quot.sound]`.

18.7.2 Abe's generators

Definition 18.23 (ω, E, H, F in the Abe model). With $e = \chi^1_{-1}\mathbf{1}$, $f = \chi^0_{-1}\mathbf{1}$ (the normalisation for which $e_{(-1)}f = \omega_{SF}$), put $\omega = e_{(-1)}f$, $E = e_{(-2)}e$, $F = f_{(-2)}f$, $H = \frac{1}{2}(e_{(-2)}f + f_{(-2)}e)$. In word states, $E = \chi^1_{-2}\chi^1_{-1}\mathbf{1}$, $F = \chi^0_{-2}\chi^0_{-1}\mathbf{1}$, $H = \frac{1}{2}(\chi^1_{-2}\chi^0_{-1} + \chi^0_{-2}\chi^1_{-1})\mathbf{1}$.

File `VOA/Examples/TripletW2Gens.lean`.

theorem abeGens_linearIndependent :
```

```
    LinearIndependent ℂ ![abeOmega, abeE, abeH, abeF] := by

theorem abeE_eq_neg_Wminus : abeE = -Wminus := by
```

From the mathematics to the Lean statement

The word list `[(1, a), (0, b)]` is $\chi^a_{-2}\chi^b_{-1}\mathbf{1}$ (a letter (k,a) is χ^a_{-k-1}). The `_eq` lemmas identify the definitions with Abe's n-th products, using that the field of a one-letter word is the bare fermion field. Linear independence of the four (and of the four weight-3 states $\chi^a_{-2}\chi^b_{-1}\mathbf{1}$, `abeGen_linearIndependent`) is proved with an explicit dual pairing, so none of them is zero. `abeE_eq_neg_Wminus` and its siblings identify E, F, H (up to sign and $\frac{1}{2}$) with the triplet W^-, W^+, W^0 of `TripletTTNull.lean`, which are proved Virasoro primary (`LSF_one_WplusSF`, ...). Normalisation: the opposite labelling $e = \chi^0$ would give $e_{(-1)}f = -\omega_{SF}$; the file takes the one with $+$.

Physical meaning

ω is the stress tensor $:\chi^1\chi^0:$; E, H, F are the three symmetric bilinears $:\partial\chi^a\chi^b:$, the $W^{\pm,0}$ fields of weight 3; the antisymmetric bilinear is ∂T. They form an $\mathfrak{sl}_2$-triplet under the $\mathfrak{sp}(2) = \mathfrak{sl}_2$ rotating χ^0, χ^1.

What the machine verified

Proved, unconditional; standard axioms.

18.7.3 $\bar{\omega}^2 \neq 0$: no low-weight null vector

Theorem 18.24 ($\omega_{(-1)}\omega \notin C_2(W(2))$). *In the Abe model, $\bar{\omega}^2 \neq 0$ in $R_{W(2)}$; equivalently $:TT: = \omega_{(-1)}\omega$ is not in $C_2(W(2)) = L_{-1}W(2)_3$ at weight 4.*

File `VOA/Examples/TripletTTNull.lean`.

```
theorem omega_sq_not_mem_O₂ :
    poissonMul tripletW2 tripletW2.conformalVector tripletW2.conformalVector
      ∉ O₂ tripletW2 := by

theorem poissonMul_omega_omega_ne_zero_in_A₂ :
    mk₂ tripletW2 (poissonMul tripletW2 tripletW2.conformalVector
     ↪  tripletW2.conformalVector)
      ≠ 0 := by
```

From the mathematics to the Lean statement

`poissonMul W u v` $= u_{(-1)}v$. The statement is about the even part's own C_2; in the ambient symplectic fermions the corresponding membership is *true* ($\chi^0_{-2}\chi^1_{-2}\mathbf{1} = (\chi^0_{-1}\mathbf{1})_{(-2)}\chi^1_{-2}\mathbf{1}$), but the first factor is odd and so not available in $W(2)$.

Proof on paper. At weight 4, $C_2(W(2))_4$ is spanned by $u_{(-2)}v$ with $\mathrm{wt}\,u + \mathrm{wt}\,v = 3$; since $W(2)_1 = 0$ and $\mathbf{1}_{(-2)} = 0$, only $u_{(-2)}\mathbf{1} = Tu$, $u \in W(2)_3$, survive. In the five-dimensional weight-4 space with basis $e = \chi^0_{-2}\chi^1_{-2}\mathbf{1}$, $w_{ab} = \chi^a_{-1}\chi^b_{-3}\mathbf{1}$, one computes $TW^+ = 2w_{00}$, $TW^- = 2w_{11}$, $TW^0 = 2(w_{01} + w_{10})$, $T^2\omega = -2e + 2(w_{10} - w_{01})$ and $\omega_{(-1)}\omega = w_{10} - w_{01}$. The functional $F(e) = 2$, $F(w_{10}) = 1$, $F(w_{01}) = -1$, $F(w_{00}) = F(w_{11}) = 0$ kills the four translates and gives $F(\omega_{(-1)}\omega) = 2$. □

Physical meaning

There is no null vector at level 4 that kills $:TT:$ in the classical limit; the triplet theory is not "Virasoro-minimal-like" at low level. The relations that make $R_{W(2)}$ finite appear only at weight 6 and above.

What the machine verified

Proved, unconditional; `#print axioms VOA.SympFerm.omega_sq_not_mem_O₂`: standard three.

18.7.4 Abe's relations and nilpotency

Theorem 18.25 (Abe's C_2 relations in the Abe model). *In $R_{W(2)}$, with $\bar\omega, \bar E, \bar H, \bar F$ the classes of the generators:*

$$\bar E^2 = \bar F^2 = 0, \quad \bar E\bar H = \bar F\bar H = 0, \quad 2\bar H^2 + \bar E\bar F = 0, \quad 2\bar H^2 = \tfrac{16}{9}\bar\omega^3, \quad \bar H^4 = 0, \quad \bar\omega^6 = 0.$$

Abe's sharper $\bar\omega^5 = 0$ follows from his (unproved here) $\bar\omega^2\bar H = 0$.

File `VOA/Examples/TripletW2AbeRelations.lean`.

```

def OmegaPowFiveZero : Prop := wbar ^ 5 = 0

theorem omegaPowFive_of_omegaSqHbar (h : OmegaSqHbarZero) : OmegaPowFiveZero := by
```

From the mathematics to the Lean statement

The product $*$ on `A₂ tripletW2` is the commutative product induced by $u_{(-1)}v$ (`A₂_mul_mk`). The first two relations are proved in the stronger form $E_{(-1)}E = 0$ and $F_{(-1)}F = 0$ *exactly* in Fock_{SF}; the others are proved by computing both sides in the word basis and exhibiting the difference as an explicit element of $C_2(W(2))$ (translates, plus one generator $\omega_{(-2)}G^{10}$). `OmegaSqHbarZero` and `OmegaPowFiveZero` are open named `Prop`s, not assumed anywhere ex-

cept as explicit hypotheses. The coefficient $\frac{16}{9}$ is Abe's.

Proof on paper. E and F each live in one fermion flavour; $\chi^a\chi^a$ has no contraction (the symplectic form is antisymmetric), so $E_{(-1)}E$ is a four-letter word in one flavour of weight 6, which would need four distinct levels summing to 6 — impossible, the minimum is $1+2+3+4=10$. The mixed relations are explicit Wick computations at weights 6. Then $0=\bar{E}^2\bar{F}^2=(\bar{E}\bar{F})^2=4\bar{H}^4$, and $0=\bar{H}^4=(\frac{8}{9})^2\bar{\omega}^6$. □

Physical meaning

The weight-6 null relations of the $c=-2$ triplet theory in the classical limit: the triplet fields square to zero and their symmetric products are proportional to T^3. They make the associated scheme a fat point.

What the machine verified

Proved, unconditional; `#print axioms VOA.AbeRel.wbar_pow_six, Hbar_pow_four`: `[propext, Classical.choice, Quot.sound]`. Abe's weight-7 relations $\bar{\omega}^2\bar{E}=\bar{\omega}^2\bar{H}=\bar{\omega}^2\bar{F}=0$ and $\bar{\omega}^5=0$ are **not** proved; Abe himself states the underlying four-term formula without derivation (recorded in the file).

18.7.5 C_2-cofiniteness of the Abe model: the one remaining gate

Theorem 18.26 (C_2-cofiniteness of SF^+, conditional). *If $R_{W(2)}$ is generated as a commutative algebra by $\bar{\omega},\bar{E},\bar{H},\bar{F}$, then the Abe model is C_2-cofinite with* $\dim R_{W(2)}\le 96$. *Strong generation of $W(2)$ by ω,E,H,F implies this hypothesis. Alternatively, if $W(2)$ is spanned modulo C_2 by Abe's eleven states, it is C_2-cofinite.*

Files `VOA/Examples/TripletW2AbeAdjoin.lean`, `TripletW2Gens.lean`.

theorem c2Cofinite_of_abeSpanningEleven (h : AbeSpanningEleven) : C2Cofinite tripletW2 :=
↪ by
```

From the mathematics to the Lean statement

$96 = 6 \cdot 2 \cdot 4 \cdot 2$ from the exponents of Theorem 18.25. `abeOmegaPow n` is $L_{-2}^{n}\mathbf{1}$ and `abeMulOmega x` $= \omega_{(-1)}x$, so `abeSpanEleven` is Abe's $\{\mathbf{1}, \omega, \dots, \omega^4, E, \omega E, H, \omega H, F, \omega F\}$ (Abe, Prop. 3.11). All three hypotheses are statements about the *even part's own* C_2; none is proved. The library also records (and docstrings warn against) a tempting false shortcut: `SpanModO₂Abe` (ω, E, H, F span $W(2)$ modulo C_2) would give $\dim R \le 4$, contradicting the lower bound 9 below; it is named only so nobody tries to prove it.

Proof on paper. Theorem 18.9 with the nilpotency of Theorem 18.25. For the eleven-state form: a finite set spanning modulo C_2 gives $\dim R < \infty$ directly (`c2Cofinite_of_span_sup_O₂`). □

Physical meaning

What is missing is the classical-limit form of "$W(2)$ is a W-algebra with generators T, W^a" — the statement that is easy in the lattice model (Theorem 18.15) but requires, in the fermionic model, showing that every even fermion polynomial is a normally ordered polynomial in bilinears modulo C_2.

What the machine verified

Proved, **conditional on** `AbeQuotientGeneration` (resp. `AbeSpanningEleven`). `#print axioms`: standard three. `C2Cofinite tripletW2` itself is **open** in the library.

Theorem 18.27 (Further reductions of the Abe-model C_2 gap). *(a) V is C_2-cofinite iff $V_n \subseteq C_2(V)$ for all n large. (b) The Abe model is C_2-cofinite as soon as $\chi_{-2}^{a}v \in M + C_2(W(2))$ for all odd v, $a \in \{0,1\}$, and one finite-dimensional M. (c) Strong generation by ω and the four bilinears together with nilpotency of their classes gives C_2.*

Files `VOA/Examples/TripletW2C2.lean`, `TripletW2C2Direct.lean`, `TripletW2Nilpotent.lean`.

```
theorem C2Cofinite_iff_exists_grading_le_O₂ (W : VertexOperatorAlgebra ℙ) :

theorem c2Cofinite_tripletW2_of_nilpotent (hgen : StrongGenW2) (hnil : NilpotentGensW2) :
    C2Cofinite tripletW2 :=
```

From the mathematics to the Lean statement

`sfCre 1 a` $= \chi_{-2}^{a}\mathbf{1}$ as an element of the exterior algebra, so `sfCre 1 a ∗ v` is $\chi_{-2}^{a}v$; `oddSF` is the odd part; `O₂W2` is $C_2(W(2))$ pushed into Fock_{SF}. In (c), `genW2` is ω together with the four states $G^{ab} = \chi_{-2}^{a}\chi_{-1}^{b}\mathbf{1}$ (the antisymmetric combination is $T\omega$). (c) is superseded by Theorem 18.25 for the nilpotency half; its generation half `StrongGenW2` is open.

Trap / dead end

Recorded findings that bear on the attack (`TripletW2C2Direct.lean`, by weight counting): $\dim W(2)_w = 1, 0, 1, 4, 5, 8$ for $w = 0, \dots, 5$, and $C_2(W(2))_w$ has dimensions $0, 0, 0, 1, 4, 5$, so $\dim R_{W(2)} \geq 9$, with surviving classes $\mathbf{1}, \omega, W^a, \omega^2, \omega W^a$. Hence (i) there is no low-weight null vector that kills R to dimension $3p - 1 = 5$; (ii) the tempting "excess filtration" (every even state whose creation levels sum to ≥ 2 is in C_2) is false, since ω^2 has excess 2; (iii) the inclusion $C_2(W(2)) \subseteq C_2(\mathrm{SF}) \cap W(2)$ is strict already at weight 3 (the ambient C_2 contains all of $W(2)_3$, the even part's only $T\omega$), so the ambient result $\dim R_{\mathrm{SF}} \leq 4$ of Chapter 17 does *not* descend. These are paper calculations recorded in docstrings; only $\bar{\omega}^2 \neq 0$ (Theorem 18.24) is a Lean theorem.

Physical meaning

(a) says "finitely many classical states" is the same as "all sufficiently heavy states are composite modulo derivatives". (b) isolates the one fermionic computation still missing: that $\partial\chi^a$ times an odd state can be rewritten, modulo composites of *bosonic* fields, through finitely many states — the precise point where the orbifold SF^+ differs from SF.

What the machine verified

(a) proved unconditionally (a reformulation, for any VOA); (b) and (c) proved only **conditionally** on their displayed hypotheses, none of which is discharged. Standard axioms.

Index of the Abe-model C_2 reductions. Theorems 18.26 and 18.27 give several alternative routes to `C2Cofinite tripletW2`; none is discharged. Table 18.2 lists, for each theorem concluding C_2-cofiniteness of the Abe model, the hypotheses it takes. Any one of the open inputs in the last column would close the gap.

theorem	hypotheses	status of hypotheses
`c2Cofinite_tripletW2_of_abeQuotientGeneration` (also gives dim ≤ 96)	`AbeQuotientGeneration`	open
`abeQuotientGeneration_of_strongGenAbe` (feeds the row above)	`StrongGenAbe`	open
`c2Cofinite_of_abeSpanningEleven`	`AbeSpanningEleven`	open
`c2Cofinite_tripletW2_of_levelOne`	a finite-dimensional M and the level-one condition `h`	open
`c2Cofinite_tripletW2_of_nilpotent`	`StrongGenW2`, `NilpotentGensW2`	first open; for the second see Thm 18.25 and the dictionary above
`C2Cofinite_iff_exists_grading_le_O₂`	none (a reformulation, any VOA)	—

Table 18.2: The Abe-model C_2 reductions and their named hypotheses. All are `#print axioms`-clean (standard three axioms); `C2Cofinite tripletW2` itself is not proved.

18.7.6 Zhu's algebra and logarithmic modules

Definition 18.28 (ω-Jordan condition)**.** For a VOA V and $h \in \mathbb{C}$ let $\omega_h = [\omega] - h[\mathbf{1}] \in A(V)$. `OmegaJordanAt V h` is the statement $\omega_h \notin A(V)\,\omega_h^2$ (the left ideal generated by ω_h^2).

File `VOA/Examples/TripletW2Log.lean`.

```
noncomputable def omegaShift (h : ℂ) : A W :=
  mk W W.conformalVector - h • mk W W.vacuum

def OmegaJordanAt (W : VertexOperatorAlgebra 𝒱) (h : ℂ) : Prop :=
  omegaShift W h ∉
    zhuLeftMul W (Amul (zhuRingData_holds W) (omegaShift W h) (omegaShift W h))
```

From the mathematics to the Lean statement

`zhuLeftMul W x` is the left ideal $A(V)x$ (`mem_zhuLeftMul`); `Amul` is Zhu's product on $A(V)$. Since $[\omega]$ is central, the left ideal is two-sided. Equivalent forms, all proved: `omegaJordanAt_iff_exists_amod` ($\iff$ some $A(V)$-module has $\rho(\omega_h)^2 = 0 \neq \rho(\omega_h)$) and `omegaJordanAt_of_zhuMul` (it suffices to find $v \in V$ with $(\omega - h\mathbf{1}) * v \notin O(V)$ and $(\omega - h\mathbf{1}) * ((\omega - h\mathbf{1}) * v) \in O(V)$).

Physical meaning

$A(V)$ acts on ground states, $[\omega]$ by L_0; `OmegaJordanAt V h` says that L_0 can have a Jordan block of size two on a space of ground states of weight h. For $W(2)$ this is expected at $h = 0$ (the double root of f_2, Definition 18.19).

What the machine verified

Definition. **Not proved for any VOA and any** h in the library.

Theorem 18.29 (A logarithmic module from a Zhu-algebra Jordan block)**.** *Let V be a VOA with $A(V)$ and all $A_{n,0}(V)$ finite-dimensional. For every h there is a logarithmic module $M_h = M(U_h)$ (the Dong–Jiang induced module on $U_h = A(V)/A(V)\omega_h^2$) on which $L_0 = \rho([\omega]) + n$ on level n. If moreover the Dong–Jiang gate $A_{0,0}(V) = A(V)$ holds and* `OmegaJordanAt V h`*, then $L_0^{\mathrm{nil}} \neq 0$ on M_h: there are x, y of generalized weight h with $y \neq 0$ and $L_0 x = hx + y$. For the Abe model the two finiteness hypotheses follow from C_2-cofiniteness.*

    (∀ n : ℕ, FiniteDimensional ℂ (AnmFull tripletW2 n 0))
      ∧ FiniteDimensional ℂ (A tripletW2) :=
```

From the mathematics to the Lean statement

`AmMod W 0` is an $A_0(V) = A(V)$-module, `DJCarrier W U` and `DJPiece W U n` are the Dong–Jiang induced module $M(U) = \bigoplus_n A_{n,0}(V) \otimes_{A(V)} U$ and its level-n piece (Chapter 13, Definition 13.21); `DJAnnEqAn W 0` is the gate of Definition 13.20, which identifies $M(U)(0)$ with U (at project level it is discharged by the `BottomProjection` datum, which the theorem `VOA.pbw` supplies for every V; here it is carried as a hypothesis). `amModOmegaNil U h` is $\rho([\omega]) - h$ on U. `LogVModule` and its `L0nil`, `L0op`, `weight` (generalized eigenspaces) are Definition 12.8. `omegaJordanAMod W h` is the quotient $A(V)/A(V)\omega_h^2$; on it $(\rho(\omega_h))^2 = 0$ automatically, because $[\omega]$ is central. The Abe-model theorem therefore has four hypotheses (`hAnm`, `hA`, `hgate`, `hnd`), which amount to three substantive ones: finiteness (implied by C_2, itself open — the docstring of `TripletW2Log.lean` says that C_2 does *not* imply `hAnm` "in the form needed", but `tripletW2_zhuFiniteness_of_C2Cofinite` proves that it does: stale, documentation only), the gate, and `OmegaJordanAt tripletW2 h`.

Proof on paper. On $M(U)(n)$, $L_0([v] \otimes w) = [v] \otimes \rho([\omega])w + n[v] \otimes w$ (`djModeZero_omega_tmul`): the level-n collapse $[\omega *_0^n v] = [v *_0^n \omega] + n[v]$ in $A_{n,0}(V)$ moves ω onto U. So $(L_0 - h - n)^k = 1 \otimes (\rho([\omega]) - h)^k$, and finite-dimensional pieces lying in generalized eigenspaces give a `LogVModule`. If the bottom of $M(U)$ is U (the gate) and $\rho(\omega_h) \neq 0$ on U, then $L_0^{\mathrm{nil}} \neq 0$. On U_h, $\rho(\omega_h)[1] = \omega_h \neq 0$ exactly when $\omega_h \notin A(V)\omega_h^2$. □

Physical meaning

The "staggered" or logarithmic module of the $c = -2$ theory: inducing from a two-dimensional space of ground states on which L_0 is a Jordan block gives a module whose L_0 is non-diagonalisable — the $\mathcal{R}_0$ projective cover of the vacuum in the physics literature. The construction is algebraic; the only representation-theoretic input is that such a Jordan block exists in Zhu's algebra.

What the machine verified

Proved, **conditional** on four hypotheses: `hAnm`, `hA` (or C_2, itself open for the Abe model), `hgate` and `hnd`. Standard axioms, pbw-free. The key hypothesis `hnd : OmegaJordanAt tripletW2 h` literally asserts that $[\omega] - h$ is not semisimple in $A(V)$; the Jordan pair in the conclusion is a formal transcription of it, and it is proved for no VOA and no h. **No logarithmic module of any concrete VOA is constructed unconditionally** in the library; "$W(2)$ has a logarithmic module" is not a theorem of the library.

Theorem 18.30 (The obvious certificate cannot work)**.** *If $[\omega]$ acts on an $A(V)$-module by a scalar, the module has no Jordan vector; in particular the top level of any ordinary lowest-weight module never certifies* `OmegaJordanAt`.

File `VOA/Examples/ZhuTripletW2Alt.lean`.

```
def IsOmegaJordanVector (M : AMod W) (h : ℂ) (m : M.carrier) : Prop :=
  M.ρ (omegaShift W h) (M.ρ (omegaShift W h) m) = 0 ∧ M.ρ (omegaShift W h) m ≠ 0

theorem not_isOmegaJordanVector_lowestAMod {P : OrdVModule W Mod} {h₀ : ℂ}
    (hcw : IsLowestWeight P h₀) (h : ℂ) (x : (lowestAMod hcw).carrier) :
    ¬ IsOmegaJordanVector (lowestAMod hcw) h x :=
```

```
theorem omegaJordanAt_of_zhuMul {h : ℂ} (v : V)
    (hsq : zhuMul W (omegaSubV W h) (zhuMul W (omegaSubV W h) v) ∈ O W)
    (hne : zhuMul W (omegaSubV W h) v ∉ O W) :
    OmegaJordanAt W h := by
```

From the mathematics to the Lean statement

`lowestAMod hcw` is the $A(V)$-module on the lowest-weight space of an ordinary module (Chapter 12, Theorem 12.18); on it $[\omega]$ acts by h_0, so $\rho(\omega_h)$ is the scalar $h_0 - h$, which cannot be nonzero and square to zero. `omegaSubV W h` $= \omega - h\mathbf{1}$.

Physical meaning

Ordinary modules have diagonalisable L_0 on their ground states, so they cannot witness a Jordan block; a witness must come from a genuinely logarithmic source (projective covers, or a free-field module with a non-diagonal action). This is a no-go result for a natural but doomed strategy, not a statement about $W(2)$.

What the machine verified

Proved, unconditional; standard axioms. Also proved (`ZhuTripletW2.lean`): $A(W(2)) \neq 0$ (`tripletW2_one_ne_zero`), and the formulas $[\omega][v] = [\omega_{(-1)}v] - k[v]$ for $v \in V_k$ (`Amul_omega_mk`).

18.7.7 Irrationality of the Abe model, conditional on the literature

Theorem 18.31 ($A(W(2))$ is not semisimple; $W(2)$ is not rational — conditional)**.** *Assume: (C2) the Abe model is C_2-cofinite; (blocks) every Artin–Wedderburn decomposition of $A(W(2))$ has exactly four blocks; (five) the space of genus-one blocks of $W(2)$ has dimension ≥ 5. Then $A(W(2))$ is not semisimple. Alternatively, (blocks) together with* $\dim A(W(2)) = 11$ *implies the same. If moreover (Zhu) admissible rationality implies semisimplicity of $A(V)$, then $W(2)$ is not admissibly rational. (The hypothesis (Zhu) holds for every VOA:* `zhuAdmissibleSemisimple_holds`*, Chapter 12.)*

File `VOA/Examples/TripletIrrational.lean`.

  AdmissiblyRational W → letI := instRingA W; IsSemisimpleRing (A W)
```

(The last block is from `VOA/Modules/AdmissibleRationality.lean`.)

From the mathematics to the Lean statement

`instRingA`, `instAlgebraA` are the ring and algebra structures on $A(V)$ (Chapter 12, Theorem 12.17). `IsSemisimpleRing` is Mathlib's. `analyticBlocks W` is the space of analytic genus-one blocks (torus one-point functions satisfying Zhu's recursion; Chapter 15, Definition 15.17) and `restrictImGT` restricts to the upper half plane; its dimension is bounded above by $\dim \mathrm{SLF}(A(V))$, the space of symmetric linear functionals on $A(V)$, for every C_2-cofinite V (the Arike–Nagatomo bound, `Modularity/BlockBoundC2.lean`). For a semisimple algebra over $\mathbb{C}$ that dimension is the number of blocks. So the first theorem is: $4 < 5 \le \dim \mathcal{C}_1 \le \dim \mathrm{SLF}$, impossible if semisimple. Hypotheses, with the citations the file gives:

- `hC2`: Abe 2007, Thm. 3.9 — not proved in the library (Theorem 18.26).
- `hblocks`: Abe 2007, Thm. 4.2 ($W(2)$ has four simple modules) with Zhu's correspondence. *Note:* `WedderburnBlockCount ℂ A n` says only "*if* $A \cong \prod_i M_{d_i}(\mathbb{C})$ then $m = n$". For a non-semisimple A (which $A(W(2))$ is) no such isomorphism exists, so the hypothesis is *vacuously true*; it is therefore a true statement about the real $A(W(2))$, and assuming it is harmless. Its role is to fix the count in the hypothetical semisimple case.
- `hfive`: Arike–Nagatomo 2013, Thm. 6.3.2(4)–(5), the lower bound by explicit pseudo-trace construction (not their Thm. 6.3.4, which would be circular). The docstring flags that the library's block space differs from theirs in two conventions (equivalent on paper, not proved equivalent in Lean).
- `hdim`: Adamović–Milas 2011, $\dim A(W(p)) = 6p - 1$. `hfin` is implied by `hdim` (finrank $\neq 0$ forces finite dimension), so it is redundant (moderate, minor; the docstring acknowledges it).
- `hzhu`: Dong–Li–Mason 1998, Thm. 4.10(a). **Discharged**: `zhuAdmissibleSemisimple_holds` proves `ZhuAdmissibleSemisimple W` for every `W` (Chapter 12, Theorem 12.40, item 4).

Proof on paper. For a finite-dimensional semisimple algebra over $\mathbb{C}$, $A \cong \prod_{i=1}^{n} M_{d_i}(\mathbb{C})$, symmetric functionals are determined on $A/[A,A] \cong \mathbb{C}^n$, so $\dim \mathrm{SLF}(A) = n$ (`finrank_symmetricFunctionals_eq_of_wedderbu`
Combined with the bound $\dim \mathcal{C}_1 \le \dim \mathrm{SLF}(A(V))$ this gives $5 \le 4$. Route two: $\dim A = \sum d_i^2$ with four positive d_i, and 11 is not a sum of four positive squares ($1+1+1+1 = 4$, $4+1+1+1 = 7$, $4+4+1+1 = 10$, $4+4+4+1 = 13$, $9+1+1+1 = 12$). □

Physical meaning

The $c = -2$ theory has four irreducible representations but five independent torus amplitudes: the extra one is the pseudo-trace on the projective cover of the vacuum, whose modular transformation produces the τ-linear term in (18.8). A rational theory has as many torus

amplitudes as irreducibles.

What the machine verified

Proved, **conditional on** `hC2`, `hblocks`, `hfive`, `hzhu` (resp. `hfin`, `hblocks`, `hdim`, `hzhu`). `#print axioms`: standard three. `hzhu` is discharged by `zhuAdmissibleSemisimple_holds` (Chapter 12); `hC2` and `hfive` (resp. `hfin`, `hdim`) remain, together with `hblocks`, which is vacuously true for the non-semisimple $A(W(2))$ but is not discharged in Lean. So non-rationality of the Abe model is **conditional**, not proved. `¬ GannonRational tripletW2` is **not** proved for the Abe model (contrast Theorem 18.18, which is about the lattice model).

18.7.8 The modular route: a $\log q$ forbids rationality

Definition 18.32 (T-eigenfunctions, the log-free span, $\log q$ terms)**.** On functions $f : \mathbb{H} \to \mathbb{C}$ let $(Tf)(\tau) = f(\tau + 1)$. f is a *T-eigenfunction* with eigenvalue μ if $Tf = \mu f$. The *log-free span* is the $\mathbb{C}$-span of all T-eigenfunctions. f *has a log term* if $f = A + \tau B$ with A in the log-free span and $B \neq 0$ a T-eigenfunction with nonzero eigenvalue.

File `VOA/Examples/TripletLogModular.lean`.

```

    A ∈ logFreeSpan ∧ ν ≠ 0 ∧ IsTEigen ν B ∧ B ≠ 0 ∧ f = A + linTerm B

theorem linTerm_notMem_logFreeSpan {ν : ℂ} {B : UpperHalfPlane → ℂ} (hν : ν ≠ 0)
    (hB : IsTEigen ν B) (hB0 : B ≠ 0) : linTerm B ∉ logFreeSpan := by

theorem hasLogTerm_coe : HasLogTerm (fun τ : UpperHalfPlane => (τ : ℂ)) := by
```

From the mathematics to the Lean statement

`(1 : ℝ) +ᵥ τ` is $\tau + 1$ (the additive action of $\mathbb{R}$ on $\mathbb{H}$). The log-free span is a span, so A may mix eigenvalues — necessary, since in (18.8) $\chi_{-1/8}$ and $\chi_{3/8}$ have different T-eigenvalues. `hasLogTerm_coe` is a non-vacuity guard ($\tau = 0 + \tau \cdot 1$). Writing $\tau = \log q/2\pi i$, `linTerm B` is the $\log q$ term.

Proof on paper. Since $(T - \nu)(\tau B) = (\tau + 1)\nu B - \nu\tau B = \nu B$ and $(T - \nu)B = 0$, the operator T acts on $\mathrm{span}\{\tau B, B\}$ as $\nu + N$ with $N(\tau B) = \nu B \neq 0$, $N(B) = 0$; in particular τB and B are linearly independent. Suppose $\tau B = \sum_j c_j f_j$ with $Tf_j = \mu_j f_j$, and let P be the product of $(X - \mu)$ over the *distinct* μ_j, a polynomial without repeated roots. Then $P(T)$ kills the right side, while on the left $P(T)(\tau B) = P(\nu)\tau B + P'(\nu)N(\tau B) = P(\nu)\tau B + \nu P'(\nu)B$. Independence forces $P(\nu) = 0$ and (as $\nu \neq 0$) $P'(\nu) = 0$: a double root, a contradiction. □

Physical meaning

Characters of ordinary modules, $q^{h-c/24}\sum a_n q^n$, are T-eigenfunctions; any finite combination of them is log-free. A term $\tau B(\tau)$ is precisely what a non-diagonalisable L_0 produces in a pseudo-trace ($q^{L_0} = q^h e^{2\pi i\tau L_0^{\mathrm{nil}}}$). So "no $\log q$" is the modular shadow of "L_0 diagonalisable".

What the machine verified

Proved, unconditional; `#print axioms VOA.LogModular.linTerm_notMem_logFreeSpan`: standard three.

Theorem 18.33 (A $\log q$ in $S\chi_0$ refutes rationality — conditional)**.** *If Zhu's modularity theorem holds for $W(2)$ in the form "rational and C_2-cofinite $\Rightarrow$ the vacuum character belongs to a modular datum satisfying Zhu's analytic law", if $W(2)$ is C_2-cofinite, and if $\chi_0(S\tau)$ has a log term, then $W(2)$ is not admissibly rational. Similarly, a logarithmic module refutes rationality given "rational $\Rightarrow$ every logarithmic module is L_0-semisimple".*

```

From the mathematics to the Lean statement

`qEvalAt χ h τ` $= q^h\sum_{n\geq 0}\chi(h+n)q^n$ (Chapter 14); with $h = -c/24 = \frac{1}{12}$ and the graded dimension of the adjoint module, `vacChar tripletW2` is χ_0 of (18.7) as a function on $\mathbb{H}$ (`w2VacChar_low` checks its first two coefficients $1, 0$). `ModularData`, `ZhuModularityAnalytic` and `charOf` are Chapter 15, Definition 15.31: a finite family of *ordinary* irreducible modules whose characters transform under $SL_2(\mathbb{Z})$ by a matrix. Since every `charOf D i` is a T-eigenfunction (`charOf_isTEigen`), Zhu's law puts $\chi_0(S\tau)$ in the log-free span, contradicting `hlog`. The three hypotheses of the first theorem are all open in the library: `hzhu` would follow from the rational headline of Chapter 15 (`zhuModularity_canonical_of_C2Cofinite_admissiblyRational`) once the Abe model is proved simple, so that its vacuum character is one member of the canonical family; nei-

ther the simplicity nor the composition is in the library. `hC2` is Theorem 18.26, and `hlog` is the explicit transformation (18.8), which needs the product formula for the character (the library has no basis of the symplectic-fermion Fock space). `IsL0Semisimple` means `L0nil = 0`.

Physical meaning

The physicist's argument "rational theories have no $\log q$ in their modular transformations", formalised: in a rational theory the torus partition function lies in the span of characters of ordinary modules; the $c = -2$ vacuum character's S-transform contains $-\frac{i\tau}{2}\eta(\tau)^2$, which is not of that form.

What the machine verified

Proved, **conditional on** `hzhu`, `hC2`, `hlog` (resp. `hro` and the four inputs of Theorem 18.29); none is discharged. Standard axioms.

18.8 Pseudo-traces and logarithmic q-series

In a rational theory the torus one-point functions are traces $\mathrm{tr}_M o(v)q^{L_0-c/24}$ over the irreducible modules M. In a logarithmic theory two things break: L_0 is not diagonalisable, so q^{L_0} has polynomial dependence on τ; and traces over irreducibles no longer span the space of torus amplitudes. Miyamoto's answer (2004) is to take, for a projective module P with a large commutant algebra A, a symmetric linear functional φ on A and form the *pseudo-trace* tr_P^{φ}. The library formalises the algebraic core in its most general form (Arike's): the Hattori–Stallings trace.

18.8.1 Symmetric functionals and coordinate systems

Definition 18.34 (Symmetric functionals; commutator span)**.** For a K-algebra A, $\mathrm{SLF}(A) = \{\varphi : A \to K \text{ linear} \mid \varphi(ab) = \varphi(ba)\}$ and $[A,A] = \mathrm{span}_K\{ab - ba\}$. A symmetric functional is the same as a functional on $A/[A,A]$.

File `VOA/Modularity/SemisimpleTrace.lean` (assigned to Chapter 15; quoted here for self-containment).

```
def commSpan : Submodule K A := Submodule.span K {x : A | ∃ a b : A, x = a * b - b * a}

def symmetricFunctionals : Submodule K (A →ₗ[K] K) where
  carrier := {φ : A →ₗ[K] K | ∀ a b : A, φ (a * b) = φ (b * a)}
```

From the mathematics to the Lean statement

Literally the textbook definitions. `symmetricLift φ` (same file) is the induced map $A/[A,A] \to K$.

Physical meaning

Symmetric functionals on Zhu's algebra are the "torus amplitudes at the level of ground states"; for semisimple A they are combinations of traces of simple modules, and their number is the number of irreducibles.

What the machine verified

Definitions.

Definition 18.35 (Finite coordinate system; raw trace)**.** A *finite coordinate system* on a left A-module W is a family $(u_i, \alpha_i)_{i<n}$ with $u_i \in W$, $\alpha_i \in \mathrm{Hom}_A(W, A)$ and $\sum_i \alpha_i(w)u_i = w$ for all w. For $f \in \mathrm{End}_A(W)$ its *raw trace* is $\sum_i \alpha_i(f(u_i)) \in A$.

File `VOA/Modularity/PseudoTrace.lean`.

  /-- The coordinate functionals. -/
  coord : Fin card → (W →ₗ[A] A)
  /-- The reproducing identity. -/
  total : ∀ w : W, ∑ i, coord i w • gen i = w

theorem nonempty_of_finite_projective (A : Type*) [Ring A] (W : Type*) [AddCommGroup W]
    [Module A W] [Module.Finite A W] [Module.Projective A W] : Nonempty (FinCoords A W) :=
    ↪ by

def rawTrace (c : FinCoords A W) (f : Module.End A W) : A :=
  ∑ i, c.coord i (f (c.gen i))
```

From the mathematics to the Lean statement

A finite coordinate system is the dual-basis lemma: it exists exactly for finitely generated projective modules (`nonempty_of_finite_projective`; conversely `FinCoords.finite`, `FinCoords.projective`). This replaces the tensor product $W \otimes_A \mathrm{Hom}_A(W, A)$, which Mathlib lacks over noncommutative rings. Mathlib's modules are left modules; Miyamoto and Arike use right modules (a harmless side convention).

Physical meaning

A projective module over the commutant is the "multiplicity space" of a projective (logarithmic) VOA-module; the coordinate system plays the role of a basis in which the trace is taken.

What the machine verified

Definition and theorem, standard axioms.

18.8.2 The Hattori–Stallings trace and the pseudo-trace

Theorem 18.36 (Hattori–Stallings trace)**.** *For a finitely generated projective A-module W the class of the raw trace in $A/[A, A]$ is independent of the coordinate system, defining a K-linear $T_W : \mathrm{End}_A(W) \to A/[A, A]$, and $T_W(f \circ g) = T_X(g \circ f)$ for $g : W \to X$, $f : X \to W$.*

File `VOA/Modularity/PseudoTrace.lean`.

```
noncomputable def hattoriTrace : Module.End A W →ₗ[K] (A ⧸ commSpan K A) :=

theorem hattoriTrace_apply_of_coords (c : FinCoords A W) (f : Module.End A W) :
    hattoriTrace K A W f = (commSpan K A).mkQ (c.rawTrace f) := by

theorem hattoriTrace_comp_comm {X : Type*} [AddCommGroup X] [Module A X] [Module K X]
    [IsScalarTower K A X] [Module.Finite A X] [Module.Projective A X]
    (f : X →ₗ[A] W) (g : W →ₗ[A] X) :
    hattoriTrace K A W (f ∘ₗ g) = hattoriTrace K A X (g ∘ₗ f) := by
```

From the mathematics to the Lean statement

The section variables (not shown) are a field K, a K-algebra A, and W a finitely generated projective left A-module with compatible K-structure. `(commSpan K A).mkQ` is the quotient map to $A/[A,A]$. The theorem `hattoriTrace_apply_of_coords` says the trace can be computed in *any* coordinate system.

Proof on paper. For coordinate systems (u_i, α_i) on W and (v_j, β_j) on X: $\sum_i \alpha_i(fgu_i) = \sum_{i,j} \alpha_i(f(\beta_j(gu_i)v_j)) = \sum_{i,j} \beta_j(gu_i)\alpha_i(fv_j)$ and $\sum_j \beta_j(gfv_j) = \sum_{i,j} \alpha_i(fv_j)\beta_j(gu_i)$; the two sums differ by commutators. Taking $X = W$, $g = \mathrm{id}$ gives independence; one coordinate system gives cyclicity. □

Physical meaning

Cyclicity of the trace is what makes torus amplitudes well defined (the torus has no preferred starting point for the time evolution); the Hattori–Stallings trace is the most general cyclic trace on endomorphisms of projective modules.

What the machine verified

Proved, unconditional; standard axioms.

Theorem 18.37 (Pseudo-trace; it is the trace; it realises every symmetric functional). *For $\varphi \in \mathrm{SLF}(A)$ define $\mathrm{tr}_W^{\varphi} = \bar{\varphi} \circ T_W : \mathrm{End}_A(W) \to K$. Then tr_W^{φ} is a symmetric functional on $\mathrm{End}_A(W)$; for $A = K$, $\varphi = \mathrm{id}$, it is the ordinary trace; and on the regular module, $\mathrm{tr}_A^{\varphi}(x \mapsto xa) = \varphi(a)$, so $\varphi \mapsto \mathrm{tr}_A^{\varphi}$ is injective.*

File `VOA/Modularity/PseudoTrace.lean`.

```
noncomputable def pseudoTrace (φ : symmetricFunctionals K A) : Module.End A W →ₗ[K] K :=

theorem pseudoTrace_mem_symmetricFunctionals (φ : symmetricFunctionals K A) :
    pseudoTrace W φ ∈ symmetricFunctionals K (Module.End A W) := by

theorem pseudoTrace_idSymmetric_eq_trace (f : Module.End K W) :
    pseudoTrace W (idSymmetric K) f = LinearMap.trace K W f := by

theorem pseudoTrace_rightMulEnd (φ : symmetricFunctionals K A) (a : A) :
    pseudoTrace A φ (rightMulEnd a) = (φ : A →ₗ[K] K) a := by

theorem pseudoTraceMap_regular_injective :
    Function.Injective (pseudoTraceMap (K := K) (A := A) A) := by
```

From the mathematics to the Lean statement

`idSymmetric K` is the identity functional on K; `LinearMap.trace K W f` is Mathlib's trace of an endomorphism of a finite-dimensional space; `rightMulEnd a` is $x \mapsto xa$ (an A-linear map of the left regular module). The second statement is the decisive validation: on vector spaces the definition reduces to the trace, so it is not some other functional. This is Arike's definition (Arike 2010, §2), shown by him to agree with Miyamoto's basis-dependent Definition 3.6; that comparison is *not* formalised (not needed).

Proof on paper. Symmetry is cyclicity of T_W. For $A = K$ any basis is a coordinate system and the raw trace is the sum of diagonal entries. For the regular module take the coordinate system $(1, \mathrm{id})$: the raw trace of $x \mapsto xa$ is a. □

Physical meaning

Miyamoto's theorem (not formalised) says that for C_2-cofinite V the torus one-point functions are spanned by pseudo-traces $\mathrm{tr}^{\varphi}_{P}\, o(v)q^{L_0-c/24}$ over projective modules; the regular-module statement here is the algebraic fact that every symmetric functional on the commutant is realised.

What the machine verified

Proved, unconditional; `#print axioms VOA.pseudoTrace_idSymmetric_eq_trace, pseudoTrace_mem_symmetricFunctionals`: standard three.

18.8.3 Polynomial-valued q-series

Definition 18.38 (Logarithmic q-series; the pseudo-trace exponential polynomial)**.** A *logarithmic formal q-series* is a function from exponents $e \in \mathbb{C}$ to polynomials in τ. For a finite projective A-module P, endomorphisms S, N and a cutoff r,

$$\mathcal{P}_{\varphi}(S,N;r)(\tau) = \sum_{k<r} \frac{(2\pi i\tau)^k}{k!}\,\mathrm{tr}^{\varphi}_{P}(SN^k),$$

which for N nilpotent with $N^r = 0$ is $\mathrm{tr}^{\varphi}_{P}\big(S\,e^{2\pi i\tau N}\big)$.

File `VOA/Modularity/LogarithmicQSeries.lean`.

```
abbrev LogFormalQSeries := ℂ → Polynomial ℂ

noncomputable def logExpCoeff (k : ℕ) : ℂ :=
  (2 * (Real.pi : ℂ) * Complex.I) ^ k / (k.factorial : ℂ)

noncomputable def pseudoTraceExpPolynomial (phi : symmetricFunctionals ℂ A)
    (S N : Module.End A P) (r : ℕ) : Polynomial ℂ :=
  ∑ k ∈ Finset.range r,
    Polynomial.monomial k (logExpCoeff k * pseudoTrace P phi (S * N ^ k))

theorem pseudoTraceExpPolynomial_zero_eq_trace (S : Module.End ℂ P) :
    pseudoTraceExpPolynomial P (idSymmetric ℂ) S 0 1 =
      Polynomial.C (LinearMap.trace ℂ P S) := by
```

From the mathematics to the Lean statement

`Polynomial.monomial k c` is cX^k, with X standing for τ. The value at exponent e of a `LogFormalQSeries` is the coefficient polynomial of q^e, so the series is $\sum_e P_e(\tau)q^e$. `pseudoTraceExpPolynomial_stable` shows that once $N^r = 0$ the cutoff does not matter, and the last theorem that with $N = 0$, $A = \mathbb{C}$ one recovers the ordinary trace. The file states explicitly that it asserts no VOA origin, no recursion, no convergence and no modularity.

Physical meaning

On a generalized L_0-eigenspace of eigenvalue h, $q^{L_0} = q^h\, e^{2\pi i\tau L_0^{\mathrm{nil}}}$; the pseudo-trace of $o(v)q^{L_0}$ is therefore q^h times a polynomial in τ. These polynomial coefficients are the τ-linear (and higher) terms of the logarithmic torus amplitudes — the same terms that appear in (18.8).

What the machine verified

Proved; standard axioms.

18.8.4 The genus-one layer, on hypothetical commutant data

Definition 18.39 (Commutant data on a logarithmic module)**.** For a logarithmic module N of V and a $\mathbb{C}$-algebra A, *commutant data* consist of: A finite-dimensional; an A-module structure on every generalized weight space $N_{[\alpha]}$, finitely generated and projective; a symmetric functional φ on A; the requirement that every vertex-operator mode intertwines these A-actions; and an A-linear lift of each zero mode $o(v)$ to $N_{[\alpha]}$. From such data one forms the one-point function $S(v) = \sum_e \mathcal{P}_\varphi(o(v), L_0^{\mathrm{nil}}; r_\alpha)\, q^e$, $\alpha = e + c/24$.

File `VOA/Modularity/LogarithmicPseudoTraceRealization.lean`.

```

    pseudoTraceExpPolynomial (N.weight α) D.phi (D.zeroModeA α v)
      (D.nilpotentPiece α) (D.nilpotentCutoff α)
```

From the mathematics to the Lean statement

`N.weight α` is the generalized L_0-eigenspace of a `LogVModule` (Definition 12.8); `logOMod N v` is the zero mode $o(v)$ (the homogeneous component $v_{(\mathrm{wt}\, v-1)}$, extended linearly). `nilpotentPiece D α` is *derived*: it is $o(\omega) - \alpha$, i.e. L_0^{nil}, lifted; `nilpotentCutoff` is its nilpotency exponent. The structure has *no instance in the library* (it is used only in the three `LogarithmicPseudoTrace*.lean` files). It is not unsatisfiable: for any logarithmic module with finite-dimensional generalized weight spaces one can take $A = \mathbb{C}$, $\varphi = \mathrm{id}$ (every field is then automatic, since scalar multiplication commutes with linear maps), and $S(v)$ becomes the ordinary trace of $o(v)e^{2\pi i\tau L_0^{\mathrm{nil}}}$ (paper argument; not formalised). The interesting instances, with A the endomorphism algebra of a projective generator, come from the Huang–Miyamoto existence theorem, which is not in the library.

Physical meaning

A is the algebra of "hidden symmetries" of a projective module that commute with the chiral algebra (for $W(2)$ on the projective cover of the vacuum, a two-dimensional algebra $\mathbb{C}[\varepsilon]/\varepsilon^2$); pseudo-traces twisted by φ are the new torus amplitudes of the logarithmic theory.

What the machine verified

Definitions; standard axioms. **No instance**, hence no concrete application.

Theorem 18.40 (The cyclic block relations; the recursion bridge)**.** *For any commutant data, the one-point function S is linear in v, its vacuum value is the pseudo-character, $S(L_{[-1]}a) = 0$, and $S(a[0]b) = 0$ (Zhu's zero-mode relation, with square-bracket modes). If moreover the logarithmic $[-1]$-recursion* `LogPseudoTraceRecursionData` *holds, then S also satisfies the $[-2]$ relation and the logarithmic ω-recursion with $q\frac{d}{dq}$ acting on polynomial coefficients as $P_e \mapsto eP_e + (2\pi i)^{-1}P_e'$; i.e. S is a logarithmic formal genus-one block.*

Files `VOA/Modularity/LogarithmicPseudoTraceBlock.lean`, `LogarithmicPseudoTraceRecursion.lean`.

```
structure IsLogPseudoTraceCyclicBlock

theorem logPseudoTraceTwoPoint_conformalVector
    (D : LogPseudoTraceCommutantData N A) (v : V) :
    D.logPseudoTraceTwoPoint W.conformalVector v =
      logQDeriv (D.logPseudoTraceOnePoint v) +
        (W.centralCharge / 24) • D.logPseudoTraceOnePoint v := by

structure LogPseudoTraceRecursionData (D : LogPseudoTraceCommutantData N A) : Prop where
  zhu : ∀ (ka : ℕ), 1 ≤ ka → ∀ a ∈ W.grading (ka : ℤ), ∀ v : V,
    D.logPseudoTraceOnePointHom (vSqZ W a ka (-1) v) =
      D.logPseudoTraceTwoPoint a v +
        ∑ᶠ m : ℕ, logQConv (zhuG (m + 1))
          (D.logPseudoTraceOnePointHom
            (vSqZ W a ka (2 * (m + 1) - 1 : ℤ) v))
```

From the mathematics to the Lean statement

`Lsq W n` and `vSqZ W a k n b` are the square-bracket Virasoro modes $L_{[n]}$ and the square-bracket products $a[n]b$ of Chapter 15, Definition 15.7; `zhuG (m+1)` are Zhu's Eisenstein series G_{2m+2} and `logQConv` their convolution with q-coefficients (Definition 15.10). `logDerivativeScale` $= 2\pi i$. `logPseudoTraceTwoPoint a v` is the pseudo-trace of $o(a)o(v)q^{L_0}$. The ω-insertion formula is the logarithmic version of $\operatorname{tr} o(\omega)o(v)q^{L_0-c/24} = (q\frac{d}{dq} + \frac{c}{24})\operatorname{tr} o(v)q^{L_0-c/24}$: the extra $(2\pi i)^{-1}P'$ term is what differentiating $e^{2\pi i\tau L_0^{\mathrm{nil}}}$ produces. The recursion data is a hypothesis (one cross-weight identity), not proved for any D; the conclusion `IsLogPseudoTraceFormalBlock` is then a theorem (`isLogPseudoTraceFormalBlock`).

Proof on paper. Translation: $o(L_{[-1]}a) = 0$ is already true as an operator. Zero-mode relation: $o(a[0]b) = [o(a), o(b)]$ up to the L_0-shift, and pseudo-traces kill commutators, also when multiplied

by powers of L_0^{nil} which commute with zero modes (`pseudoTrace_commutator_mul_pow_eq_zero`). The ω-formula: $o(\omega) = L_0 = \alpha + L_0^{\mathrm{nil}}$ on $N_{[\alpha]}$, and $\frac{d}{d\tau}\sum_k \frac{(2\pi i\tau)^k}{k!}\mathrm{tr}(SN^k) = 2\pi i \sum_k \frac{(2\pi i\tau)^k}{k!}\mathrm{tr}(SN^{k+1})$. □

Physical meaning

These are the genus-one Ward identities for logarithmic torus amplitudes: invariance under translations on the torus, the zero-mode (commutator) relation, and the modular heat equation $\langle T\rangle_\tau \propto \partial_\tau$ — with the twist that ∂_τ now also hits the explicit τ-dependence of the pseudo-trace.

What the machine verified

Proved; the formal-block theorem conditional on `LogPseudoTraceRecursionData`. `#print axioms VOA.LogPseudoTraceCommutantData.isLogPseudoTraceCyclicBlock, isLogPseudoTraceFormalBlock`: standard three. Applies to no concrete VOA (no instance of the commutant data). No convergence, spanning or modularity is claimed.

18.9 The doublet algebra

18.9.1 The generators on an abstract lattice

Theorem 18.41 (Doublet generators). *Let L be positive definite, $g \in L$ with $2\langle g,g\rangle = p$ (so $\gamma = 2g$ has $\langle\gamma,\gamma\rangle = 2p$), and $\langle\lambda, g\rangle = \frac{p-1}{2}$. Put $Q = (e^{2g})_{(0)}$, $a^- = e^{-g}$, $a^+ = Qa^-$. Then $a^\pm$ have deformed weight $\frac{3p-2}{4}$, $a^+ \neq 0$, $Qa^+ = 0$, and e^{+g} has weight $\frac{2-p}{4}$, negative for $p > 2$.*

File `VOA/Examples/DoubletGenerators.lean`.

```
theorem LBG_zero_aMinus (hPos : L.PosDef) (lam : Fin (rank L) → ℂ) (g : L.carrier) (p : ℕ)
    (hgg : 2 * L.form g g = (p : ℤ)) (hlam : bgPair L lam g = ((p : ℂ) - 1) / 2) :
    LBG L lam 0 (aMinus L g) = ((3 * (p : ℂ) - 2) / 4) • aMinus L g := by

theorem LBG_zero_aPlus (hPos : L.PosDef) (lam : Fin (rank L) → ℂ) (g : L.carrier) (p : ℕ)
    (hgg : 2 * L.form g g = (p : ℤ)) (hlam : bgPair L lam g = ((p : ℂ) - 1) / 2) :
    LBG L lam 0 (aPlus L g) = ((3 * (p : ℂ) - 2) / 4) • aPlus L g := by

theorem aPlus_ne_zero (hPos : L.PosDef) (g : L.carrier) (p : ℕ) (hp : 1 ≤ p)
    (hgg : 2 * L.form g g = (p : ℤ)) : aPlus L g ≠ 0 := by

theorem Qdb_aPlus (g : L.carrier) (p : ℕ) (hp : 1 ≤ p) (hgg : 2 * L.form g g = (p : ℤ)) :
    Qdb L g (aPlus L g) = 0 := by

theorem LBG_zero_eG (hPos : L.PosDef) (lam : Fin (rank L) → ℂ) (g : L.carrier) (p : ℕ)
    (hgg : 2 * L.form g g = (p : ℤ)) (hlam : bgPair L lam g = ((p : ℂ) - 1) / 2) :
    LBG L lam 0 (latChargeGen L g) = ((2 - (p : ℂ)) / 4) • latChargeGen L g := by
```

From the mathematics to the Lean statement

`Qdb L g` = `Screen.Qscr L (g + g)`, `aMinus L g` $= e^{-g}$, `aPlus L g` $= Q\,e^{-g}$. The lattice is abstract: these are weight computations, true in any lattice satisfying the two hypotheses. Since the Gram form is integer-valued, $2\langle g,g\rangle = p$ forces p even (`p_even`). Weights: $\frac{1}{2}\cdot\frac{p}{2} + \frac{p-1}{2} = \frac{3p-2}{4}$ for e^{-g}, $\frac{p}{4} - \frac{p-1}{2} = \frac{2-p}{4}$ for e^{g}. $a^+ = \varepsilon\, S_{p-1}(2g)\otimes e^{g}$ (`aPlus_eq`), nonzero by `vSchur_ne_zero`.

Physical meaning

The doublet fields $a^{\pm}$ of Adamović–Milas: the "square roots" of the triplet, with half the charge. Their OPE $a^{+}(z)a^{-}(w)$ produces the triplet; the negative-weight state e^{g} shows that the ambient half-lattice theory is not of CFT type, so the doublet must be cut out carefully.

What the machine verified

Proved, unconditional; standard axioms.

18.9.2 The half lattice

Definition 18.42 (The half lattice $\frac{1}{2}L_p$)**.** `hlatP p` is the rank-one lattice $\mathbb{Z}g$ with $\langle mg, ng\rangle = \frac{p}{2}mn$ (natural-number division), and $q_H(m) = \frac{pm^2}{4} - \frac{(p-1)m}{2}$ is the deformed weight of e^{mg}.

File `VOA/Examples/DoubletHalfLattice.lean`.

```
noncomputable def hlatP (p : ℕ) : IntegralLattice where
  carrier := ℤ
  form := ((p / 2 : ℕ) : ℤ) • LinearMap.mul ℤ ℤ

noncomputable def qH (p : ℕ) (m : ℤ) : ℚ :=
  ((p : ℚ) * (m : ℚ) ^ 2) / 4 - (((p : ℚ) - 1) * (m : ℚ)) / 2

theorem hlatP_even_iff (p k : ℕ) (hp2 : 2 * k = p) : (hlatP p).Even ↔ 4 ∣ p := by

theorem not_posQuad_qrH (p k : ℕ) (hp2 : 2 * k = p) (hp : 2 < p) :
    ¬ PosQuad (hlatP p) (qrH p k hp2) := by

theorem qH_two_mul (p : ℕ) (m : ℤ) : qH p (2 * m) = ((Triplet.qZP p m : ℤ) : ℚ) := by
```

From the mathematics to the Lean statement

`p / 2` is natural-number division, so for odd p the form is $\lfloor p/2\rfloor mn$; every theorem that matters carries `hp2 : 2 * k = p`, so only even p is used. `qH_two_mul` shows the doubling $m \mapsto 2m$ embeds the triplet lattice L_p isometrically with $q_H(2m) = q_p(m)$, as it must. The half lattice is even iff $4 \mid p$; for $p \equiv 2 \bmod 4$ it is odd and its lattice vertex algebra is a super algebra, which the library cannot build from the bosonic `YfullGen`. `not_posQuad_qrH`: the refinement is not positive for $p > 2$ ($q_H(1) < 0$), but it is bounded below (`qH_bddBelow`).

Physical meaning

Halving the compactification radius doubles the charge lattice; the extra states $e^{\pm g}$ are the doublet's building blocks. For $4 \mid p$ they have half-integral weight but bosonic statistics (a spin–statistics violation), for $p \equiv 2 \bmod 4$ integral weight but fermionic statistics.

What the machine verified

Proved; standard axioms.

18.9.3 The doublet as a generated super subalgebra

Definition 18.43 (The doublet $\mathcal{A}(p)$)**.** For a super near-VOA W and states a^{-}, a^{+}, `doubletA W am ap` is the super subalgebra generated by $\{\omega, a^{-}, a^{+}\}$. A *deformed ambient* for (L, λ) is a super near-VOA on V_L whose L_0 is L_0^{λ}. The concrete doublet `doubletApC p h4 hp` is `doubletA` in the concrete ambient `ambientC p h4 hp` on the half lattice, for $4 \mid p$, with $a^{\pm}$ as above.

Files VOA/Examples/DoubletAp.lean, DoubletApConcrete.lean.

```
def doubletA (am ap : 𝒱) : SuperVOASubalgebra W :=
  SuperVOASubalgebra.generated W {W.conformalVector, am, ap}

structure DeformedAmbient (lam : Fin (rank L) → ℂ) where
  /-- The ambient super near-VOA on the half-lattice module. -/
  W : SuperNearVOA (LatModuleGen L)
  /-- Its Virasoro zero mode is the background-charge deformed one. -/
  L0_eq : W.L 0 = LBG L lam 0
```

```
noncomputable def ambientC (p : ℕ) (h4 : 4 ∣ p) (hp : 0 < p) :
    SuperNearVOA (LatModuleGen (latD p)) :=

noncomputable def doubletApC (p : ℕ) (h4 : 4 ∣ p) (hp : 0 < p) :
    SuperVOASubalgebra (ambientC p h4 hp) :=
  DoubletAp.doubletAp (deformedAmbientC p h4 hp) (gD p)
```

From the mathematics to the Lean statement

SuperNearVOA (Chapter 17, Definition 17.8) is a super vertex algebra with a conformal vector and a $\mathbb{C}$-grading but *without* positivity (bounded-belowness is a separate predicate BoundedBelow); this is forced here because the ambient has negative weights. latD p = hlatP p, gD p its generator; ambientC is built from the general super ambient of LatticeSuperAmbientB.lean (Chapter 17, Section 17.8.5) with background charge lamD p $= \frac{p-1}{p}$ g. DoubletAp.doubletAp da g is doubletA with $a^{\pm}$ of Theorem 18.41. In the abstract file DoubletAp.lean nothing is instantiated; the concrete file closes that gap for $4 \mid p$.

Physical meaning

$\mathcal{A}(p)$ is the chiral algebra generated by T and the doublet $a^{\pm}$; its charge-even part is $W(p)$. In the language of extensions, $\mathcal{A}(p)$ is a simple-current extension of $W(p)$ by its doublet module.

What the machine verified

Definitions; standard axioms.

Theorem 18.44 (What is proved about the concrete doublet). *For $4 \mid p$: $\mathcal{A}(p)$ is bounded below; its ambient is bounded below but not positive (it has the nonzero state e^g of negative weight); its central charge is $c_{1,p}$, that of $W(p)$; its parity is trivial, so $\mathcal{A}(p)_{\bar{0}} = \mathcal{A}(p)$; and the integrality hypothesis needed to form the even part as a bosonic VOA is false.*

File VOA/Examples/DoubletApConcrete.lean.

```

```

From the mathematics to the Lean statement

`hp : 0 < p` is passed as `1 ≤ p` to `tripletWVOA`; the central-charge comparison is again a comparison of numbers. The parity statement shows the super structure of the concrete ambient is trivial (everything even, because for $4 \mid p$ the half lattice is even and the ambient is a bosonic vertex algebra with half-integral weights). So the even-part construction `doubletAEvenVOA` of `DoubletAp.lean` — which would be the natural candidate for $W(p)$ inside $\mathcal{A}(p)$ — cannot be applied, and `hint_false_of_four_dvd` proves it. In the literature the relevant $\mathbb{Z}/2$ is the *charge parity* $e^{mg} \mapsto (-1)^m e^{mg}$, not the super parity; the library does not construct it.

Trap / dead end

What is not proved about the doublet (all recorded in the source): positivity of $\mathcal{A}(p)$ (equivalently $e^g \notin \mathcal{A}(p)$ — only reduced to exhibiting an intermediate subalgebra, `doubletA_positivity_of_subalgebra`); $\mathcal{A}(p)_{\bar{0}} \cong W(p)$ or any relation to `tripletWVOA`; anything at $p \equiv 2 \bmod 4$ (including $p = 2$, where $\mathcal{A}(2)$ should be the symplectic fermions); any representation theory. The concrete doublet is therefore, at present, a well-defined bounded-below subalgebra with the right central charge and nonzero generators, and nothing more. Is it degenerate? It contains $a^- \neq 0$ and $a^+ \neq 0$ (`aMinusC_ne_zero`, `aPlusC_ne_zero`) and $\omega \neq 0$, so it is not zero; whether it is a proper subalgebra is open.

Physical meaning

At $4 \mid p$ the doublet theory has bosonic fields of half-integral weight $(3p-2)/4$ (e.g. $\frac{5}{2}$ at $p = 4$): it is a vertex algebra but not a VOA in the $\mathbb{Z}$-graded sense, the same phenomenon as for the $\beta\gamma$ system at half-integral twist. Bounded-belowness, not positivity, is the right finiteness property for such an ambient.

What the machine verified

Proved, unconditional (only $4 \mid p$, $p > 0$); standard axioms. What is proved is only what is displayed: a *bounded-below* generated super near-VOA subalgebra exists for $4 \mid p$ (with the stated central charge, trivial parity and failing even-part hypothesis). It is **not** proved to be the doublet $\mathcal{A}(p)$ of the literature, nor that $\mathcal{A}(p)^{\text{even}} = W(p)$, and nothing exists for $4 \nmid p$.

18.10 The remaining files of this chapter

For completeness, the files not discussed theorem-by-theorem above, and what they contain.

- `TripletWpAmbient.lean`: besides Definition 18.13, the transport dictionary (`O₂amb`, `mem_O₂amb_iff`, `L_coe`), `strongGenWp_iff` and `SmulClosedWp` (strong generation $\iff$ the ambient word span is closed under all products), the lattice product `smul_latChargeGen_bottom` ($(e^\alpha)_{(-\langle\alpha,\beta\rangle-1)}e^\beta = \varepsilon(\alpha,\beta)e^{\alpha+\beta}$), and the weight bookkeeping forcing $m = 3p-1$.
- `TripletWpTwoSector.lean`, `TripletWpTwoVirasoroCoords.lean`: finite expansions of the charge dressing and of the weight-10 Virasoro words in Fock coordinates (no PBW: the Fock space is a polynomial ring with its monomial basis).

- `TripletWpTwoMixedAssembly.lean`, `TripletWpTwoMixedClose.lean`: assembly of Theorem 18.15.
- `TripletWpTwoAM{Assembly,Close,Coords,ExpectedSparse,Proof,Schur,Sparse*}.lean`: the pieces of Theorem 18.16.
- `TripletWpTwoZhu{Certificate,Fast*,Sparse*}.lean` (129 files, counting `TripletWpTwoZhuFinal.lean`): the pieces of the f_2 certificate (Theorem 18.20); `fTwoZhuRepresentative_eq_intrinsicCertificateRhs_of_sparse` is the interface.
- `TripletWpTwoFelderCarrier.lean`: charged Fock carriers for a future Felder-complex analysis; no exactness theorem.
- `TripletW2C2.lean`: the general criteria $C_2 \iff$ eventual vanishing modulo O_2 (Theorem 18.27(a)), Abe's Prop. 2.2 (strong generation $\Rightarrow$ ring generation), `vacuumGradeZero_of_VOA` (`VacuumGradeZero` holds for every VOA, so it is redundant wherever it is carried, for instance in the cusp theorems of Chapter 15), and Abe's Lemma 3.4 (`BW2_reduce`).
- `ZhuTripletW2.lean`: general Zhu-product calculus on homogeneous left factors (`zhuMul_of_mem_grading`: $u * v = \sum_{m \le k} \binom{k}{m} u_{(m-1)}v$), $[L_{-1}u] = -k[u]$, and the $W(2)$ specialisations.

18.11 Verification record

The following was run for this chapter at an earlier commit (not re-run for this edition), with the library's existing build products, on a scratch file importing the relevant modules (no full `lake build` was run for this chapter):

```
lake env lean -DmaxSynthPendingDepth=3 Axioms.lean
```

Output (abridged to the declaration names; every line reads `depends on axioms: [propext, Classical.choice, Quot.sound]`):

None of these depends on `VOA.pbw`. The Lean checks cited in this chapter (not part of this release) were compiled the same way and depend only on the same three axioms. A clean `#print axioms` does not report explicit hypotheses: every theorem marked "conditional" in this chapter is `#print axioms`-clean *and* conditional on the named `Prop` arguments listed in its status box.

Release audit 2026-10-27: RELEASE_AUDIT_L17_L18_L23.md. The independent release audit `Notes/Textbook/referee/RELEASE_AUDIT_L17_L18_L23.md` re-elaborated the headline statements of this chapter at an earlier commit (branch `deligne-lean`; `VOA/` unchanged since the audit's start; not re-run for this edition) from the existing build products, with `lake env lean -DmaxSynthPendingDepth=3` (`lake build` not run), re-ran `#print axioms` (standard three for `tripletLatticeVOA`, `tripletWVOA`, the $p = 2$ lattice theorems, `c2Cofinite_tripletWVOA`, `tripletW2`, `c2Cofinite_tripletW2_of_abeQuotientGeneration`, `tripletW2Log_jordan_pair`, both `not_admissiblyRational_tripletW2*` and `doubletApC_boundedBelow`), and recompiled the Lean checks cited in this chapter. Verdicts: *lattice $W(2)$: announceable with caveats* (lattice model only; state the rationality notions, findings M4, m5); *general p, the Abe model, the logarithmic module, the doublet and pseudo-traces: not announceable as theorems*, only as conditional reductions or constructions (M4, M5, m7, m8). This chapter's status boxes have been brought into line: every result on the Abe model, for general p, on the logarithmic module and on the doublet is marked conditional (with its hypotheses) or restricted to what is displayed. The audit also records (M7) that the aggregate build is not certified for the release commit and (m6) that `tripletW p` is the generated subalgebra, never proved equal to $\ker \widetilde{Q}$, with $E \neq 0$ and $W(p) \neq V_{L_p}$ proved only at $p = 2$, outside the library.

18.12 Recorded traps, dead ends and Lean defects

Trap / dead end

Two $W(2)$'s. `tripletWVOA 2 hp` (lattice) and `SympFerm.tripletW2` (Abe) live on different carrier types; no isomorphism, no homomorphism and no identification of their graded dimensions is proved. A theorem about one is not a theorem about the other. In particular "$W(2)$ is C_2-cofinite", "simple", "strongly finite", "not Gannon-rational" are proved for the lattice model only; "$A(W(2))$ is not semisimple" and "a logarithmic $W(2)$-module exists" are (conditionally) about the Abe model only. Constructing the isomorphism (bosonization of symplectic fermions) would transfer everything.

Trap / dead end

Dead ends recorded in the source (useful to anyone continuing): (i) Adamović–Milas' printed proof of $\bar{\omega}$-nilpotency (Section 18.5); (ii) $\bar{\omega}^2 = 0$ in $R_{W(2)}$ is false (Theorem 18.24); (iii) ω, E, H, F do *not* span $W(2)$ modulo C_2 (`SpanModO₂Abe` would give $\dim R \leq 4 < 9$); (iv) the ambient symplectic-fermion C_2 result does not descend to the even part; (v) the top level

of an ordinary module can never certify `OmegaJordanAt` (Theorem 18.30); (vi) "rational ⇒ $\operatorname{tr} L_0^{\mathrm{nil}} = 0$" is no obstruction ($L_0^{\mathrm{nil}}$ is nilpotent, so all its traces vanish anyway) — the reason pseudo-traces are needed; (vii) the doublet's even part cannot be formed by the super even-part construction for $4 \mid p$ (Theorem 18.44).

Trap / dead end

Lean defects found by this chapter:

1. (documentation only) `TripletWp.lean`, `TripletWpC2.lean` docstrings: "$E \neq 0$ not proved", "$W(p) \neq V_{L_p}$ not proved" are stale at $p = 2$ (Theorem 18.7).
2. (documentation only) `TripletScreening.lean`, `TripletWp.lean`: $Q = e^{\alpha}_{(0)}$ called the "short" screening; it is the long one.
3. (documentation only) `TripletWpPairClosure.lean` "What remains open" and `TripletWpStronglyFinite.lean` ("conditional on simplicity") are stale: the mixed coordinates, the AM identity and simplicity are proved in later files.
4. (documentation only) `TripletW2Log.lean`, carried hypothesis 2: says `hAnm` is not implied by C_2 in the form needed; `tripletW2_zhuFiniteness_of_C2Cofinite` proves that it is.
5. (moderate, minor) `tripletW2_not_isSemisimpleRing_A_of_finrank_eleven`, `not_admissiblyRational_tripletW2_of_finrank_eleven`: `hfin` is implied by `hdim`.
6. (moderate, harmless) `WedderburnBlockCount ℂ (A tripletW2) 4` is vacuously true for a non-semisimple algebra; the hypothesis `hblocks` therefore costs nothing but also carries no information about the real $A(W(2))$.
7. (open gap) `LogPseudoTraceCommutantData` has no instance; the logarithmic genus-one layer applies to no concrete VOA.
8. (open gap) The LIBRARY MAP summary "general p conditional on `OmegaPowMem`" omits the second hypothesis (`AdjoinGenWp`, or `LoweringPairsWp`); and `tripletW p hp` is never related to $\ker \widetilde{Q}$.
9. (documentation only) Chapter 5's remark that the triplet screening fits `Screening.screening` only at $\lambda = 0$ is superseded by `Qwp`.

18.13 Referee's checklist

Lean declaration	Intended meaning	Hypotheses	Check

Chapter 19

Graded unitarity and Lee–Yang

This chapter documents the release of the LeanVOA library named in the front matter. Every Lean quotation below is checked by `scripts/textbook/sync.py` to occur verbatim (up to whitespace and comments) in the source files of that release. Checks that were run at an earlier state of the library and not re-run for this edition are marked as such. By topic, the chapter covers: (1) sesquilinear forms, real structures and the graded-unitarity predicate; (2) the linear algebra of flags, leading minors and Schur complements; (3) the Virasoro VOAs, their real structures and the length-two positivity theorem; (4) the Lee–Yang model; (5) finite "Program B" certificates; (6) Drinfeld–Sokolov reduction; (7) weight-one positivity of affine $\mathfrak{sl}_2$ at level $-8/5$ (Section 19.12) and the abstract transfer of graded unitarity along graded isometric embeddings (Section 19.13); (8) the unconditional graded unitarity of the universal affine VOA $V^k(\mathfrak{sl}_2)$ for real $k < -2$ (Section 19.14); (9) two empty geometric files. An inverse Drinfeld–Sokolov programme (Adamović's free-field embedding of the boundary admissible $L_k(\mathfrak{sl}_2)$ into $L(c,0) \otimes \Pi(0)$) is under development and is not part of this release. By directory, the files covered are those assigned to this chapter in `Notes/Textbook/assignment.txt`: seven linear-algebra and structure files in `VOA/Core/` (`GradedUnitarity`, `FlagMinors`, `MinorPivots`, `HermitianSchur`, `RealStructure`, `RealSymmetricTwo`, `SesqFormTransport`), the example files in `VOA/Examples/` (the `LeeYang*` files, the `VirasoroLengthTwo*` files, the Virasoro real-structure and graded-unitarity files, the `InverseDS*` infrastructure files shipped with this release (free-field carriers and the general Virasoro Verma module used by Chapter 7; not otherwise documented here), the Drinfeld–Sokolov files `DSReductionSl2` and `DSMorphismSl2`, a handful of "Program B" finite certificates, `AffineSl2GradedUnitarityLow`, the twelve `AffineSl2BelowCritical*` files, and the stub `MoonshineModule`), and the two files of `VOA/Geometric/`.

What the chapter is about, in one paragraph. A vertex operator algebra (VOA) that arises from a four-dimensional $\mathcal{N} = 2$ superconformal field theory carries, besides its usual structure, a filtration (the "R-filtration") and a Hermitian form whose sign alternates with the filtration degree. Arabi Ardehali, Beem, Lemos and Rastelli (henceforth **ABLR**) call a VOA with such data *graded unitary*. The library formalises the ABLR datum (`GradedUnitaryAt`, `GradedUnitary`), repairs a defect that once made it refutable, reduces its nondegeneracy clause to leading principal minors of Gram matrices and proves the converse Sylvester criterion needed for the positivity clause, constructs real structures on the Virasoro VOAs, and proves the positivity clauses *through filtration degree two* for every boundary minimal model $M(2, 2n+1)$, unconditionally (`boundary_gradedUnitaryThroughTwo`). The full statement — Kaufmann's 1994 conjecture that $L(c_{2,2n+1}, 0)$ is graded unitary — is **not** proved and is not claimed. Around this core the chapter documents the Lee–Yang model $M(2,5)$ (its singular vector, its strong finiteness `leeYang_stronglyFinite`, its Zhu-algebra relation), the Drinfeld–Sokolov reduction of affine $\mathfrak{sl}_2$ (the arithmetic and the BRST differential; the cohomology is not built), and the weight-one Hermitian positivity of the currents of $V^{-8/5}(\mathfrak{sl}_2)$ (Section 19.12). The geometric files (geometric VOAs, chiral de Rham complex) contain no declarations at all. Finally, Section 19.14 documents the first theorem of the library that asserts

the full predicate `GradedUnitary` of a concrete VOA: `universal_gradedUnitary_belowCritical_unconditional` — for every real $k < -2$, $V^k(\mathfrak{sl}_2)$ with its normalised invariant form, the compact real structure and the current-length flag is graded unitary — proved with no hypothesis beyond $k < -2$, by a large-negative-level anchor, rigidity of layer signs along $(-\infty, -2)$, and a "no-wall" lemma.

Prerequisites and pointers. Generic Lean idioms (structures, `Submodule`, `finrank`, coercions ↑, ∃/∀) are explained in Chapter 1. The universal and simple Virasoro VOAs $V(c,0)$, $L(c,0)$, the canonical invariant form `canB/Bsimp`, creation words `negWordVir`, and the Kac determinant are in Chapter 7; the Lee–Yang rigidity theorem is in Chapter 8; affine $\mathfrak{sl}_2$ at level $-8/5$ is in Chapters 9 and 10; graded flags and good filtrations are in Chapter 11 (Definition 11.1); invariant forms are in Chapter 5 (Definition 5.48); C_2-cofiniteness and `StronglyFinite` are in Chapter 12 (Definitions 12.22 and 12.43); recall that V is C_2-cofinite when $V/C_2(V)$ is finite-dimensional, where $C_2(V)$ is the span of all $a_{(-2)}b$ with $a, b \in V$. Whenever a statement uses one of these notions we recall it in a sentence and point to the definition.

Trust model. Every headline of this chapter was checked with `#print axioms` (Section 19.16); all of them depend only on Lean's three standard axioms `propext`, `Classical.choice`, `Quot.sound`. None uses `VOA.pbw` (the PBW theorem of Chapter 3; formerly a project axiom, now a theorem). "Axiom-clean" does not mean "unconditional": many theorems below carry explicit hypotheses, and we name every one.

19.1 Unitarity: the standard notions and the graded one

19.1.1 Why physicists care about positivity

In quantum mechanics the space of states is a Hilbert space: the inner product $\langle\psi|\psi\rangle$ is a probability amplitude squared and must be positive. In a two-dimensional conformal field theory (CFT) on the plane, radial quantisation identifies states with local fields (the state–field correspondence $a \mapsto Y(a,z)$ of a VOA), and the inner product of the Hilbert space becomes a sesquilinear form on the space of states V for which the modes of the stress tensor satisfy $L_n^\dagger = L_{-n}$. Equivalently, in Euclidean signature, positivity is *reflection positivity* of correlation functions (Osterwalder–Schrader). A CFT whose state space has a positive-definite such form is called *unitary*.

Unitarity has dramatic consequences. For the Virasoro algebra alone, positivity of the vacuum module requires $c \geq 0$ (already at level two, $\|L_{-2}\mathbf{1}\|^2 = c/2$), and the work of Friedan, Qiu and Shenker (1984) and Goddard, Kent and Olive (1985–86) shows that the irreducible highest-weight representation $L(c,h)$ is unitary only for $c \geq 1$, $h \geq 0$, or for the *discrete series*

$$c = 1 - \frac{6}{m(m+1)}, \qquad m = 2, 3, 4, \ldots,$$

which are the minimal models $M(m, m+1)$ ($m = 3$: Ising, $c = 1/2$; $m = 4$: tricritical Ising, $c = 7/10$). Every other minimal model $M(p,q)$, $|p-q| \geq 2$, is non-unitary. The simplest such is the **Lee–Yang model** $M(2,5)$ with

$$c_{2,5} = 1 - \frac{6(2-5)^2}{2 \cdot 5} = -\frac{22}{5},$$

whose vacuum module already has $\|L_{-2}\mathbf{1}\|^2 = c/2 = -11/5 < 0$.

19.1.2 Unitary VOAs in the sense of Dong and Lin

Dong and Lin (2014) formalised the physicists' notion as follows. Let V be a VOA of CFT type with conformal vector ω.

Definition 19.1 (Unitary VOA; Dong–Lin 2014). A *unitary VOA* is a pair (V, ϕ) where $\phi : V \to V$ is an *anti-linear* involutive VOA automorphism (so $\phi(za) = \bar{z}\phi(a)$, $\phi(a_{(n)}b) = \phi(a)_{(n)}\phi(b)$, $\phi(\mathbf{1}) = \mathbf{1}$, $\phi(\omega) = \omega$, $\phi^2 = 1$), together with a *positive-definite* Hermitian form $(\cdot,\cdot)$ on V, linear in the first slot and anti-linear in the second, normalised by $(\mathbf{1},\mathbf{1}) = 1$, such that for all $a, u, v \in V$

$$\big(Y(e^{zL_1}(-z^{-2})^{L_0}a, z^{-1})u,\ v\big) = \big(u,\ Y(\phi(a), z)v\big).$$

Physical meaning

ϕ is the CPT-type anti-unitary symmetry that maps a field to its adjoint, and the displayed identity says $Y(a,z)^\dagger = Y(e^{\bar{z}L_1}(-\bar{z}^{-2})^{L_0}\phi(a), \bar{z}^{-1})$: the adjoint of a local field is again a local field, inserted at the image of z under inversion $z \mapsto 1/\bar{z}$. For $a = \omega$ it gives $L_n^\dagger = L_{-n}$. Positivity of $(\cdot,\cdot)$ is the Hilbert-space positivity of the CFT.

Ai and Lin (2017) extended this to vertex operator superalgebras (with a parity twist on the odd part), and Carpi, Kawahigashi, Longo and Weiner (CKLW, 2018) proved that, under an additional "strong locality" hypothesis, unitary VOAs are equivalent to conformal nets of von Neumann algebras on the circle. For Virasoro VOAs the classification is the one quoted above: $L(c,0)$ is a unitary VOA iff $c \geq 1$ or $c = 1 - 6/(m(m+1))$.

The library has no Dong–Lin unitarity

The library contains a structure `VOA.Unitary` in `VOA/Modules/Contragredient.lean`, but Chapter 12 (Proposition 12.31) shows it is **unsatisfiable** on every module of dimension ≥ 2 (it asks a $\mathbb{C}$-bilinear form to be "positive"; see the next subsection) and that its invariance clause is not the Dong–Lin one. It has no consumers. The positivity notion actually used in the library is the *graded* one of this chapter, which is a different notion (Remark 19.3 explains that, for Virasoro VOAs with ω in filtration degree one, the two are mutually exclusive).

19.1.3 Bilinear versus sesquilinear forms

A recurring point of this chapter is elementary but crucial. A VOA carries a canonical $\mathbb{C}$-*bilinear* invariant form $(\cdot|\cdot)$ (Chapter 5): it is $\mathbb{C}$-linear in *both* slots, and for the Virasoro VOA its Gram matrices are the Kac matrices of Chapter 7. A bilinear form cannot be positive on a complex vector space: if $(x|x) = r > 0$ then $(ix|ix) = i^2 r = -r < 0$. Positivity is a property of a *sesquilinear* form h, anti-linear in one slot, for which $h(ix, ix) = \bar{i}\, i\, h(x,x) = h(x,x)$. To pass from the bilinear form to a sesquilinear one, one needs an anti-linear map ρ and sets $h(a,b) = (\rho a|b)$. This is exactly what the Dong–Lin ϕ does, and exactly what the library's `RealStructure` (Section 19.3) does.

19.1.4 Graded unitarity: where it comes from

Beem, Lemos, Liendo, Peelaers, Rastelli and van Rees (2015) discovered that every four-dimensional $\mathcal{N} = 2$ superconformal field theory (SCFT) contains a protected subsector whose operator algebra is a VOA V, with $c_{2d} = -12\, c_{4d}$. Since $c_{4d} > 0$ in a unitary four-dimensional theory, $c_{2d} < 0$: these VOAs are *never* unitary in the sense of Dong–Lin. Nevertheless they inherit a shadow of four-dimensional unitarity. Each state of V comes from a four-dimensional operator with an $SU(2)_R$ charge R; the charge is not preserved by the VOA operations, but it defines an increasing filtration $G_0V \subseteq G_1V \subseteq \cdots$ (the *R-filtration*). The four-dimensional Hilbert-space inner product, transported to V, is a Hermitian form which on the associated graded pieces has sign $(-1)^R$. For the Virasoro VOA the conjectured R-filtration is the filtration by the number of Virasoro creation modes: $L_{-n_1}\cdots L_{-n_k}\mathbf{1}$ has filtration degree k.

Definition 19.2 (Graded unitarity, informal; ABLR, arXiv:2507.23781, Definition 2.2). A VOA V with an invariant bilinear form $(\cdot|\cdot)$ is *graded unitary* if it carries

(i) a grading compatible with an "R-parity" s;

(ii) an anti-linear VOA automorphism ρ with $\rho^2 = s$;

(iii) the sesquilinear form $(a, b) \mapsto (\rho a|b)$;

(iv) an increasing exhaustive filtration G_pV_n of each weight space V_n (a "good" filtration) on each step of which the form is nondegenerate;

(v) the orthogonal decomposition $G_pV_n = G_{p-1}V_n \oplus \mathcal{L}_p$, $\mathcal{L}_p = G_pV_n \cap (G_{p-1}V_n)^{\perp}$;

(vi) positivity of the twisted Hermitian form $(-1)^p(\rho a|b)$ on every layer $\mathcal{L}_p$.

Physical meaning

Clause (vi) says: a state of R-charge p (more precisely, the component of a state that is orthogonal to everything of lower charge) has four-dimensional norm of sign $(-1)^p$ when measured with the two-dimensional form. Graded unitarity is therefore a necessary condition for a VOA to be the chiral algebra of a unitary 4d $\mathcal{N} = 2$ SCFT, and a sharp tool to rule out candidate VOAs. The boundary minimal models $M(2, 2n + 1)$ are the chiral algebras of the Argyres–Douglas theories (A_1, A_{2n}) (Lee–Yang: (A_1, A_2)), so the conjecture that they are graded unitary — first formulated, in the language of signatures, by Kaufmann (1994) — is a consistency check of the SCFT/VOA dictionary.

Remark 19.3 (Graded unitarity and Dong–Lin unitarity are incompatible for Virasoro VOAs)**.** For $L(c, 0)$ with the length filtration, $\omega = L_{-2}\mathbf{1}$ spans the degree-one layer in weight two, so clause (vi) requires $-(\rho\omega|\omega) = -c/2 > 0$, i.e. $c < 0$; Dong–Lin unitarity requires $(\omega, \omega) = c/2 > 0$. Thus no Virasoro VOA with $c \neq 0$ is both. Graded unitarity is not a weakening of unitarity: it is a different positivity, adapted to $c < 0$.

The library's encoding of clauses (i)–(vi) is the subject of Sections 19.2–19.5.

19.2 Sesquilinear forms and positivity on a subspace

19.2.1 The defect that once made graded unitarity refutable

Theorem 19.4 (A bilinear form is never positive on a nonzero complex subspace)**.** *Let β be a $\mathbb{C}$-bilinear form on a complex vector space E and $S \leq E$ a complex subspace. If $\beta(x, x)$ is a positive real number for every nonzero $x \in S$, then $S = 0$.*

File `VOA/Core/GradedUnitarity.lean`.

```
theorem eq_bot_of_bilinear_pos (β : BilinForm ℂ E) (S : Submodule ℂ E)
    (hpos : ∀ x ∈ S, x ≠ 0 → ∃ r : ℝ, 0 < r ∧ β x x = (r : ℂ)) : S = ⊥ := by
```

From the mathematics to the Lean statement

`BilinForm ℂ E` is Mathlib's type of $\mathbb{C}$-bilinear forms $E \times E \to \mathbb{C}$ (a bilinear map, curried: `β x y`). `Submodule ℂ E` is a complex subspace; `S = ⊥` says it is the zero subspace. "$\beta(x, x)$ is a positive real" is spelled `∃ r : ℝ, 0 < r ∧ β x x = (r : ℂ)`, where `(r : ℂ)` is the real number r viewed as a complex number. The statement is exactly Theorem 19.4. It is not a VOA statement: it is kept in the library as a *recorded defect*, see the warning below.

Proof on paper. If $x \in S$ is nonzero with $\beta(x, x) = r > 0$, then $ix \in S$ is nonzero and $\beta(ix, ix) = i^2\beta(x, x) = -r < 0$, which is not a positive real. □

Physical meaning

A "probability" computed with a bilinear form changes sign when the state is multiplied by the phase i; a physical norm must be phase-invariant. This is why every positivity statement in quantum theory is about a Hermitian form.

What the machine verified

Proved; `#print axioms: [propext, Classical.choice, Quot.sound]`. The same theorem is discussed in Chapter 43 (Theorem 43.3).

Recorded defect, now repaired: the old clause (vi) was false for every VOA

An earlier version of `VOA/Core/GradedUnitarity.lean` stated clause (vi) as positivity of the $\mathbb{C}$-*bilinear* invariant form on the layers $\mathcal{L}_p$, via a predicate `IsPosOn (β : BilinForm ℂ E) (S : Submodule ℂ E)` of exactly the shape of the hypothesis of Theorem 19.4. By that theorem every layer would have to be zero, contradicting exhaustiveness on any nonzero weight space; so the old `GradedUnitary` and `VirGradedUnitary` were **provably false** for every VOA with $V_0 \neq 0$, while their docstrings called the conjecture "open". The repair, described in the file's §0 and checked below, is to state positivity for a *sesquilinear* form built from an anti-linear ρ (ABLR clause (iii)). Theorem 19.4 is kept as a theorem precisely so that the mistake cannot be reintroduced. ("ABLR" is Arabi Ardehali–Beem–Lemos–Rastelli, as the source files cite.)

19.2.2 Sesquilinear forms

Definition 19.5 (Sesquilinear form)**.** A *sesquilinear form* on a complex vector space E is a map $h : E \times E \to \mathbb{C}$ that is additive in each slot, conjugate-homogeneous in the first slot and homogeneous in the second: $h(za, b) = \bar{z}\, h(a, b)$, $h(a, zb) = z\, h(a, b)$.

File `VOA/Core/GradedUnitarity.lean`.

```
structure SesqForm (E : Type*) [AddCommGroup E] [Module ℂ E] where
  /-- The underlying function. -/
  toFun : E → E → ℂ
  /-- Additivity in the first slot. -/
  add_left : ∀ a a' b : E, toFun (a + a') b = toFun a b + toFun a' b
  /-- **Conjugate**-homogeneity in the first slot: `⟪z a, b⟫ = z̄ ⟪a,b⟫`. -/
  smul_left : ∀ (z : ℂ) (a b : E), toFun (z • a) b = (starRingEnd ℂ) z * toFun a b
  /-- Additivity in the second slot. -/
  add_right : ∀ a b b' : E, toFun a (b + b') = toFun a b + toFun a b'
  /-- ℂ-homogeneity in the second slot: `⟪a, z b⟫ = z ⟪a,b⟫`. -/
  smul_right : ∀ (z : ℂ) (a b : E), toFun a (z • b) = z * toFun a b
```

From the mathematics to the Lean statement

A Lean `structure` bundles a function `toFun` with proofs of its four laws. `starRingEnd ℂ` is complex conjugation $z \mapsto \bar{z}$ (Mathlib's name for the "star" ring endomorphism). `z • a` is scalar multiplication. A coercion (declared in the file) lets one write `h a b` for `h.toFun a b`. Convention: anti-linear in the *first* slot, as in ABLR's (2.30) and in physics ($\langle a|b\rangle$), the opposite of Dong–Lin's convention; this is a harmless relabelling.

What is not required. Hermitian symmetry $h(b, a) = \overline{h(a, b)}$ is *not* a field. The docstring says this is deliberate: positivity is stated as "$h(x, x)$ equals a positive real", which already asserts reality of the diagonal where it is needed. Since a sesquilinear form whose diagonal is real on a subspace is automatically Hermitian there (polarisation), nothing is lost for positivity statements; but the reader should know that `SesqForm` alone is the weaker notion.

Physical meaning

$h(a, b)$ is the transition amplitude $\langle a|b\rangle$ between two states. Anti-linearity in the bra is what makes $\langle a|a\rangle$ insensitive to the phase of a.

What the machine verified

A definition. The coercion and the lemmas `SesqForm.zero_left`, `zero_right`, `smul_self` are proved in the same file.

Theorem 19.6 (The obstruction disappears). *For every sesquilinear form h and vector x, $h(ix, ix) = h(x, x)$.*

File `VOA/Core/GradedUnitarity.lean`.

```
theorem I_smul_self (h : SesqForm E) (x : E) :
    h (Complex.I • x) (Complex.I • x) = h x x := by
```

From the mathematics to the Lean statement

`Complex.I` is i. The theorem is `SesqForm.I_smul_self`. Exactly the statement.

Proof on paper. $h(ix, ix) = \bar{i}\, i\, h(x, x) = |i|^2 h(x, x) = h(x, x)$. □

Physical meaning

Multiplying a state by a phase does not change its norm.

What the machine verified

Proved, axiom-clean (Section 19.16).

Definition 19.7 (Positivity on a subspace; the sign twist). A sesquilinear form h is *positive on* a subspace S if $h(x, x)$ is a positive real number for every nonzero $x \in S$. For $p \in \mathbb{N}$, the *signed form* of degree p is $(-1)^p h$.

File `VOA/Core/GradedUnitarity.lean`.

```
def IsPosOn (h : SesqForm E) (S : Submodule ℂ E) : Prop :=
  ∀ x ∈ S, x ≠ 0 → ∃ r : ℝ, 0 < r ∧ h x x = (r : ℂ)

def signedForm (h : SesqForm E) (p : ℕ) : SesqForm E where
  toFun a b := (-1 : ℂ) ^ p * h a b
  add_left a a' b := by rw [h.add_left]; ring
  smul_left z a b := by rw [h.smul_left]; ring
  add_right a b b' := by rw [h.add_right]; ring
  smul_right z a b := by rw [h.smul_right]; ring
```

From the mathematics to the Lean statement

`IsPosOn h S` is literally Definition 19.7; note it now takes a `SesqForm`, not a `BilinForm`, which is the repair of Warning 19.2.1. `signedForm h p` is the form $(a, b) \mapsto (-1)^p h(a, b)$; the four `by ...` lines are the proofs that it is again sesquilinear. The exponent is p, the filtration degree, matching ABLR's $\mathrm{sign}\langle O|O\rangle = (-1)^{R_O}$ (their eq. (3.16), Kaufmann's (4.4)) under the library's normalisation $(\mathbf{1}|\mathbf{1}) = +1$.

Could this be vacuous or refutable? The file contains three witnesses, all proved: `isPosOn_stdHerm_top` (the standard form $\bar{a}b$ on $\mathbb{C}$ is positive on all of $\mathbb{C}$, a nonzero sub-

space — so `IsPosOn` is satisfiable where the old predicate was not); `isPosOn_signedForm_stdHerm_zero` (the twist at $p = 0$ keeps it positive); and `not_isPosOn_signedForm_stdHerm_one` (at $p = 1$ the same form on the same subspace *fails*), so the predicate has teeth and the two parities impose opposite conditions. On the zero subspace it holds vacuously (`isPosOn_bot`); this is why later we check that the layers it is applied to are nonzero.

Physical meaning

`IsPosOn` is "all states in S have positive norm"; `signedForm` implements the $(-1)^R$ of the SCFT/VOA dictionary: in odd R-charge the two-dimensional form is the *negative* of the four-dimensional norm.

What the machine verified

Definitions; the witnesses `isPosOn_stdHerm_top`, `isPosOn_signedForm_stdHerm_zero`, `not_isPosOn_signedForm_stdHerm_one`, `isPosOn_I_smul` are proved and axiom-clean.

Theorem 19.8 (Positivity pulls back along injective maps). *Let $\iota : E \to F$ be an injective $\mathbb{C}$-linear map, h_F a sesquilinear form on F, and $h_E = \iota^* h_F$, i.e. $h_E(x, y) = h_F(\iota x, \iota y)$. If $(-1)^p h_F$ is positive on $\iota(S)$, then $(-1)^p h_E$ is positive on S.*

File `VOA/Core/SesqFormTransport.lean`.

```
def pullback (h : SesqForm F) (iota : E →ₗ[ℂ] F) : SesqForm E where
  toFun x y := h (iota x) (iota y)
  add_left x x' y := by rw [map_add, h.add_left]
  smul_left a x y := by rw [map_smul, h.smul_left]
  add_right x y y' := by rw [map_add, h.add_right]
  smul_right a x y := by rw [map_smul, h.smul_right]

theorem isPosOn_signedForm_of_eq_pullback {hE : SesqForm E} {hF : SesqForm F}
    {iota : E →ₗ[ℂ] F} (hiota : Function.Injective iota)
    (hcompat : hE = hF.pullback iota) {S : Submodule ℂ E} (p : ℕ)
    (hpos : IsPosOn (signedForm hF p) (S.map iota)) :
    IsPosOn (signedForm hE p) S :=
```

From the mathematics to the Lean statement

`E →ₗ[ℂ] F` is the type of $\mathbb{C}$-linear maps. `S.map iota` is the image subspace $\iota(S)$. `hcompat : hE = hF.pullback iota` says h_E *is* the pullback (an exact isometry). The theorem is `SesqForm.isPosOn_signedForm_of_eq_pullback`; it is exactly Theorem 19.8. Injectivity is needed: a nonzero x with $\iota x = 0$ would have $h_E(x, x) = 0$.

Proof on paper. For $0 \neq x \in S$, $\iota x \neq 0$ lies in $\iota(S)$, so $(-1)^p h_E(x, x) = (-1)^p h_F(\iota x, \iota x)$ is a positive real. □

Physical meaning

If a theory is realised inside a bigger one by an isometric embedding of state spaces (a free-field realisation, say), then positivity of norms in the bigger theory, restricted to the image, gives positivity in the smaller one. This is the engine of the transfer theorem of Section 19.13.

What the machine verified

Proved, axiom-clean. Also proved: `pullback_comp`, `pullback_signedForm`, `isPosOn_pullback`, `isPosOn_of_eq_pullback`.

19.3 Real structures

Definition 19.9 (Anti-linear automorphism with parity; ABLR clauses (i)–(ii))**.** A *real structure* on a VOA W (in the library's sense) consists of an additive map $\rho : V \to V$ such that $\rho(zv) = \bar{z}\rho(v)$, $\rho(u_{(n)}v) = \rho(u)_{(n)}\rho(v)$ for all $n \in \mathbb{Z}$, $\rho(\mathbf{1}) = \mathbf{1}$, $\rho(\omega) = \omega$, together with a function $s : \mathbb{Z} \to \mathbb{C}$ (the "R-parity") such that $\rho^2 = s(h)$ on the weight-h space.

File `VOA/Core/RealStructure.lean`.

```
structure RealStructure (W : VertexOperatorAlgebra 𝒱) where
  /-- The underlying additive map. -/
  rho : 𝒱 →+ 𝒱
  /-- **Anti-linearity**: `ρ(z·v) = z̄ ·ρ(v)`. -/
  antilinear : ∀ (z : ℂ) (v : 𝒱), rho (z • v) = (starRingEnd ℂ) z • rho v
  /-- **Vertex-algebra compatibility**: `ρ(u₍ₙ₎v) = ρ(u)₍ₙ₎ρ(v)` for every mode. -/
  map_smul : ∀ (u : 𝒱) (n : ℤ) (v : 𝒱), rho (W.smul u n v) = W.smul (rho u) n (rho v)
  /-- `ρ` fixes the vacuum. -/
  map_vacuum : rho W.vacuum = W.vacuum
  /-- `ρ` fixes the conformal vector. -/
  map_omega : rho W.conformalVector = W.conformalVector
  /-- ABLR's `R`-parity `s`, as a function of the conformal weight.  Carried as data. -/
  parity : ℤ → ℂ
  /-- **`ρ² = s`** on each weight space. -/
  sq : ∀ {h : ℤ} (v : 𝒱), v ∈ W.grading h → rho (rho v) = parity h • v
```

From the mathematics to the Lean statement

$\mathcal{V}$ `→+` $\mathcal{V}$ is an additive group homomorphism (not a linear map; anti-linearity is a separate field, a design choice explained in the file docstring). `W.smul u n v` is the n-th product $u_{(n)}v$ (Chapter 1). `W.grading h` is the weight-h space V_h. The structure is exactly Definition 19.9.

Comparison with Dong–Lin. With $s \equiv 1$ a `RealStructure` is precisely Dong–Lin's anti-linear involution ϕ (Definition 19.1). With general s it is ABLR's clause (ii) $\rho^2 = s$. The file's docstring records that ABLR's $s = (-1)^{h+d/2}$ was not checked against the source (the paper was not in the repository) and that therefore s is a free field; no theorem of the library depends on its value except through $s(n) \neq 0$ (Theorem 19.12). The Virasoro instances below all have $s \equiv 1$.

Not required: that ρ preserve weight spaces. It follows from $\rho(\omega) = \omega$ and `map_smul` (so $\rho L_0 = L_0\rho$, `RealStructure.rho_L`) together with anti-linearity and the reality of the L_0-eigenvalues.

Physical meaning

ρ is the anti-unitary "conjugation" that sends a field to its Hermitian conjugate up to the R-parity sign; for the Virasoro VOA it fixes every state $L_{-n_1} \cdots L_{-n_k}\mathbf{1}$ because the stress tensor is a Hermitian field with real OPE coefficients.

What the machine verified

A definition. `RealStructure.rho_L` ($\rho L_n = L_n\rho$) and `RealStructure.parity_eq_one_of_fixes` are proved in the same file. Instances: Virasoro, below.

Definition 19.10 (The sesquilinear form of clause (iii)). Given an invariant bilinear form B and a real structure ρ on W, set $h(a,b) = B(\rho a, b)$, and let h_n be its restriction to $V_n \times V_n$.

File `VOA/Core/GradedUnitarity.lean`.

```
def sesqForm (B : InvariantForm W) (R : RealStructure W) (a b : 𝒱) : ℂ := B.form (R.rho a)
 ↪ b

def gradedSesq (B : InvariantForm W) (R : RealStructure W) (n : ℤ) : SesqForm (W.grading n)
 ↪ where
```

From the mathematics to the Lean statement

`InvariantForm W` is the library's invariant bilinear form (Chapter 5, Definition 5.48); `B.form` is the underlying bilinear map. `gradedSesq B R n` bundles $(a,b) \mapsto B(\rho a, b)$ on the weight space `W.grading n` as a `SesqForm`; its four laws are proved from `R.antilinear` (we omit the four proof lines; the simp lemma `gradedSesq_apply` states `gradedSesq B R n a b = B.form (R.rho (a : 𝒱)) (b : 𝒱)`). On a set fixed by ρ the two forms agree: `sesqForm_eq_form_of_fixes` and `sesq_diag_eq_gradedForm`. This is why the library's *bilinear* Gram matrices (whose entries on Virasoro creation monomials are real) compute the *Hermitian* values of clause (vi).

Physical meaning

$h(a,b) = (\rho a|b)$ is the BPZ two-point function with the bra conjugated: the Hilbert-space inner product of radial quantisation.

What the machine verified

Definitions; homogeneity lemmas `sesqForm_smul_left`, `sesqForm_smul_right` proved.

19.4 The graded-unitarity predicate

19.4.1 Flags, layers, and the two clauses

Recall from Chapter 11 (Definition 11.1) that a `GradedFlag W` is a family of subspaces G_pV_n ($p \in \mathbb{N}$, $n \in \mathbb{Z}$), each inside V_n, increasing in p, exhausting V_n, with $G_0V_n = 0$ for $n > 0$ and $G_0V_0 = \mathbb{C}\mathbf{1}$. In Lean, `F.piece p n` is G_pV_n as a subspace of V, `F.pieceIn p n` is the same subspace viewed inside the finite-dimensional space V_n, and `F.pieceLT p n` is $G_{p-1}V_n$ (with $G_{-1} = 0$). The flag is *not* required to be compatible with the vertex operators (Chapter 11 records that the "good" clause `ModeCompatible` is a reconstruction and is never used here).

Definition 19.11 (Layers; clauses (iv) and (vi); graded unitarity). Let F be a graded flag, β a bilinear form and h a sesquilinear form on V_n.

1. The *layer* $\mathcal{L}_p = G_pV_n \cap (G_{p-1}V_n)^{\perp_\beta}$.
2. (F,β) is *layer-nondegenerate* at n if β restricted to every G_pV_n is nondegenerate.
3. (F,β,h) is *layer-positive* at n if $(-1)^p h$ is positive on $\mathcal{L}_p$ for every p.
4. *Graded unitarity at n* is the conjunction of 2 and 3. A VOA with invariant form B, real structure ρ and flag F is *graded unitary* if it is graded unitary at every n with $\beta = B|_{V_n}$ and $h = h_n$ of Definition 19.10.

File `VOA/Core/GradedUnitarity.lean`.

```

  ∀ n : ℤ, GradedUnitaryAt F n (LiRadical.gradedForm B n) (gradedSesq B R n)
```

From the mathematics to the Lean statement

Decoding. `⊓` is intersection of subspaces. `β.orthogonal S` is Mathlib's orthogonal complement $\{y : \beta(x,y) = 0\ \forall x \in S\}$ (for a reflexive form the side does not matter). `β.restrict S` is β on $S \times S$, and `.Nondegenerate` means the only $x \in S$ with $\beta(x,S) = 0$ is 0. `LiRadical.gradedForm B n` is B restricted to $V_n \times V_n$ (the level-n Gram form; `VOA/Core/InvariantFormRadical.lean`).

Clause by clause against ABLR. (i)–(ii): the `RealStructure` argument `R`. (iii): `gradedSesq B R n`. (iv): `LayerNondegenerate`. (v): *not an assumption*; it is derived from (iv) in Theorem 19.13. (vi): `LayerPositive`, for the *sesquilinear* form, with the twist $(-1)^p$.

Two forms in one definition. The layer is cut out by the *bilinear* β, positivity is for the *sesquilinear* h. This is legitimate when the steps are ρ-stable: Theorem 19.12 shows the two orthogonal complements coincide. For the Virasoro flag every step is ρ-stable for every real structure (Theorem 19.25).

What the definition does *not* pin down.

- *The flag is a free parameter.* `GradedUnitary B R F` is a statement about a given `F`. ABLR's flag is a specific one (the R-filtration); the library's `GradedFlag` does not even require compatibility with the vertex operators. See Warning 19.4.1.
- *ρ-stability of the steps* is not required (it holds in the Virasoro instance).
- *The R-parity s* plays no role in the predicate.

Physical meaning

$\mathcal{L}_p$ is the space of states of "exact R-charge p": the part of G_pV_n orthogonal to all states of lower charge. Clause (iv) says no state of charge $\le p$ is null with respect to all of charge $\le p$ (no accidental null states in a truncated sector); clause (vi) says the exact-charge-p states have four-dimensional norm sign $(-1)^p$.

What the machine verified

Definitions. The docstring stresses: "This is a predicate. No theorem in this repository asserts it of anything." That was accurate at the earlier state of the library against which this chapter was first written: `GradedUnitary` was then never proved for any VOA. At that snapshot, what was proved were reductions (below), the vacuum slice, and the truncated version through

degree two (Section 19.8). *Later addition:* in a later revision of the library the predicate is asserted, and proved unconditionally, for the universal affine VOA $V^k(\mathfrak{sl}_2)$ at every real $k < -2$ with a fixed (not free) flag (Theorem 19.49); the docstring sentence quoted above, still present at a pre-release build commit, is therefore stale.

The abstract predicate is only as meaningful as the flag supplied

Because `F` is an arbitrary `GradedFlag`, the bare statement "there is a flag F with `GradedUnitary B R F`" is nearly empty. *Paper argument (not machine-checked):* suppose B is nondegenerate on each V_n, $V_0 = \mathbb{C}\mathbf{1}$, and ρ is a real structure with $s \equiv 1$ for which h_n is Hermitian (as for the Virasoro VOAs below). For $n > 0$ choose the flag $G_1 V_n = N_n$, a maximal negative-definite subspace of h_n spanned by ρ-fixed vectors, and $G_p V_n = V_n$ for $p \geq 2$. Then $\mathcal{L}_1 = N_n$ is negative, $\mathcal{L}_2$ is the h_n-orthogonal complement of N_n, which is positive, and higher layers vanish; clause (iv) holds because h_n is nondegenerate on N_n and on V_n. So *every* such VOA — including unitary ones after a sign change, and non-unitary ones like Lee–Yang — is "graded unitary for some flag". The content of graded unitarity lies entirely in the choice of the flag. The library's Virasoro statement (`VirGradedUnitary`, Definition 19.20) correctly fixes the length flag, so it is not affected; but any future theorem of the form "$\exists F$, `GradedUnitary B R F`", or any transfer theorem whose flags are free, must be read with this in mind.

Theorem 19.12 (The two orthogonal complements agree on ρ-stable subspaces). *Let $S \leq V_n$ be ρ-stable ($\rho(S) \subseteq S$) and suppose $s(n) \neq 0$. Then $\{y : h_n(x,y) = 0\ \forall x \in S\} = \{y : B(x,y) = 0\ \forall x \in S\}$.*

File `VOA/Core/GradedUnitarity.lean`.

```
def RhoStableOn (R : RealStructure W) {n : ℤ} (S : Submodule ℂ (W.grading n)) : Prop :=
  ∀ x ∈ S, ∃ y ∈ S, (y : 𝒱) = R.rho (x : 𝒱)

theorem orthogonal_gradedSesq_eq (B : InvariantForm W) (R : RealStructure W) {n : ℤ}
    {S : Submodule ℂ (W.grading n)} (hS : RhoStableOn R S) (hp : R.parity n ≠ 0) :
    (gradedSesq B R n).orthogonal S = (LiRadical.gradedForm B n).orthogonal S := by
```

From the mathematics to the Lean statement

`RhoStableOn R S`: for every $x \in S$ the vector ρx (computed in V) lies in S. `SesqForm.orthogonal` is defined in the file with the convention "killed in the first slot", matching the bilinear convention. The statement is exactly Theorem 19.12.

Proof on paper. If $B(x,y) = 0$ for all $x \in S$ then $h(x,y) = B(\rho x, y) = 0$ since $\rho x \in S$. Conversely, if $h(z,y) = 0$ for all $z \in S$, take $z = \rho x$: $0 = B(\rho^2 x, y) = s(n)B(x,y)$, and $s(n) \neq 0$. □

Physical meaning

Whether one says "orthogonal" with the BPZ bilinear pairing or with the Hilbert-space inner product makes no difference on a sector closed under conjugation; so the "exact-charge" states are well defined independently of which form one uses.

What the machine verified

Proved, axiom-clean.

19.5 The layer reduction: clause (v) follows from clause (iv)

Theorem 19.13 (Gram–Schmidt along a nondegenerate flag). *Let V_n be finite-dimensional, β a reflexive bilinear form on V_n (i.e. $\beta(x,y)=0 \iff \beta(y,x)=0$), and assume clause (iv). Then for every p*

$$G_{p-1}V_n + \mathcal{L}_p = G_pV_n, \qquad G_{p-1}V_n \cap \mathcal{L}_p = 0, \qquad \dim G_{p-1}V_n + \dim \mathcal{L}_p = \dim G_pV_n,$$

the layers span V_n, and if $V_n \neq 0$ some layer is nonzero.

File `VOA/Core/GradedUnitarity.lean`.

```
theorem layerDecomposition [FiniteDimensional ℂ (W.grading n)] (href : β.IsRefl)
    (hnd : LayerNondegenerate F n β) (p : ℕ) :

theorem finrank_pieceLT_add_layer [FiniteDimensional ℂ (W.grading n)] (href : β.IsRefl)
    (hnd : LayerNondegenerate F n β) (p : ℕ) :
    finrank ℂ (F.pieceLT p n) + finrank ℂ (F.layer n β p) = finrank ℂ (F.pieceIn p n) :=

theorem iSup_layer_eq_top [FiniteDimensional ℂ (W.grading n)] (href : β.IsRefl)
    (hnd : LayerNondegenerate F n β) : (⨆ p : ℕ, F.layer n β p) = ⊤ := by

theorem exists_layer_ne_bot [FiniteDimensional ℂ (W.grading n)] (href : β.IsRefl)
    (hnd : LayerNondegenerate F n β) (hne : (⊤ : Submodule ℂ (W.grading n)) ≠ ⊥) :
    ∃ p : ℕ, F.layer n β p ≠ ⊥ := by
```

From the mathematics to the Lean statement

`⊔` is the sum of subspaces, `Disjoint` means zero intersection, `⨆ p` the span of all layers, `⊤` all of V_n. `[FiniteDimensional ℂ (W.grading n)]` is an instance argument (supplied automatically from the VOA axiom that weight spaces are finite-dimensional). `β.IsRefl` is reflexivity; for the canonical forms it follows from symmetry, which the library proves (`VirQuotForm.gradedForm_Bsimp_isRefl` for Virasoro). Exactly Theorem 19.13. The point of the theorem: ABLR's clause (v) is *not* an extra hypothesis once (iv) holds; and positivity cannot be satisfied vacuously by all layers being zero.

Proof on paper. If β is nondegenerate on $S = G_{p-1}V_n$ then $V_n = S \oplus S^{\perp}$ (standard linear algebra for a reflexive form on a finite-dimensional space). Intersecting with $T = G_pV_n \supseteq S$ gives $T = S \oplus (T \cap S^{\perp})$ by the modular law. Dimensions add. By induction on p each G_pV_n lies in the span of the layers, and by exhaustiveness so does V_n. If all layers were zero, V_n would be zero. □

Physical meaning

Gram–Schmidt orthogonalisation of states ordered by R-charge: the space of states is the orthogonal direct sum of the exact-charge sectors, and the number of states of exact charge p is the jump of the cumulative counts. Combined with a refined character (counting states by weight and length, Salazar's theorem cited in `AdmissiblePartitions`), this is what turns graded unitarity into the alternating-sum signature formula $\mathrm{sig} = \sum_r (-1)^r a_{N,r}$ studied numerically by the project.

What the machine verified

All four proved, axiom-clean; unconditional (the hypotheses are the clause-(iv) assumption and reflexivity, both explicit). `nondegenerate_restrict_bot` handles $p = 0$.

The next theorem is a *calibration check*, not a step of the positivity argument. Its job is to show that the repaired, sesquilinear encoding of clause (vi) is satisfiable on a nonzero layer of a genuine VOA — exactly what the old bilinear encoding could never achieve (Theorem 19.4). It is used once later, as the trivial layer $p = 0$ of the through-two theorem (Theorem 19.32); everything with mathematical content happens in layers $p \geq 1$.

Theorem 19.14 (The vacuum slice of clause (vi); calibration check). *For every VOA W with $B(\mathbf{1},\mathbf{1}) = 1$, every real structure, every flag and every form β on V_0, the twisted form $(-1)^0 h_0$ is positive on the bottom layer $\mathcal{L}_0 \subseteq V_0$, which equals $\mathbb{C}\mathbf{1}$; if $\mathbf{1} \neq 0$ this layer is nonzero.*

File `VOA/Core/GradedUnitarity.lean`.

```
theorem isPosOn_layer_zero_vacuum (B : InvariantForm W) (R : RealStructure W) (F :
↪  GradedFlag W)
    (β : BilinForm ℂ (W.grading 0)) (hn : B.Normalized) :
    IsPosOn (signedForm (gradedSesq B R 0) 0) (F.layer 0 β 0) := by

theorem layer_zero_ne_bot_and_isPosOn (B : InvariantForm W) (R : RealStructure W)
    (F : GradedFlag W) (β : BilinForm ℂ (W.grading 0)) (hn : B.Normalized)
    (hvac : W.vacuum ≠ 0) :
    F.layer 0 β 0 ≠ ⊥ ∧ IsPosOn (signedForm (gradedSesq B R 0) 0) (F.layer 0 β 0) :=
```

From the mathematics to the Lean statement

`B.Normalized` is $B(\mathbf{1},\mathbf{1}) = 1$ (`VOA/Core/BilinearForm.lean`). The bottom layer is `F.layer 0 β 0` $= G_0 V_0 = \mathbb{C}\mathbf{1}$ (a flag axiom). Exactly Theorem 19.14. Its role is calibration, not progress: it certifies that under the repaired encoding clause (vi) holds on a nonzero layer of a genuine VOA, where the old encoding was false, and that the sign $(-1)^0 = +1$ at $p = 0$ is consistent with $(\mathbf{1}|\mathbf{1}) = +1$ (`signedForm_gradedSesq_vacuum`, `pos_gradedSesq_vacuum`).

Proof on paper. $x = z\mathbf{1}$ gives $h(x,x) = B(\bar{z}\mathbf{1}, z\mathbf{1}) = |z|^2$. □

Physical meaning

The vacuum has norm one.

What the machine verified

Proved, axiom-clean, unconditional. The docstring warns that this "is not progress towards graded unitarity", which is the correct reading: the theorem certifies that, under the repaired sesquilinear encoding, clause (vi) holds on a nonzero layer of a genuine VOA (where the old bilinear encoding was impossible by Theorem 19.4). It is a consistency check of the definitions, not a step towards unconditional graded unitarity; the only later use is as the trivial layer $p = 0$ in Theorem 19.32.

19.6 The minors criterion

Clauses (iv) and (vi) are statements about subspaces. When the flag is the family of initial segments of an ordered basis $e_1, \dots, e_m$ of V_n, both become statements about the *leading principal minors* $D_k = \det(\beta(e_i, e_j))_{i,j \leq k}$ of the Gram matrix.

19.6.1 Clause (iv) and nonzero minors

Definition 19.15 (Leading principal submatrix; flags refining a basis). For an $m \times m$ matrix M and $k \le m$, $M_{\le k}$ is the top-left $k \times k$ block. A family of subspaces F_p *refines* the ordered basis e if there are integers $d_p \le m$ with $F_p = \mathrm{span}(e_1, \dots, e_{d_p})$.

File `VOA/Core/FlagMinors.lean`.

```
def leadingPrincipal (M : Matrix (Fin m) (Fin m) K) {k : ℕ} (hk : k ≤ m) :
    Matrix (Fin k) (Fin k) K :=
  M.submatrix (Fin.castLE hk) (Fin.castLE hk)

structure RefinesBasis (F : ℕ → Submodule K E) (e : Module.Basis (Fin m) K E) where
  /-- The dimension of the `p`-th step. -/
  dim : ℕ → ℕ
  /-- Each step dimension is at most the dimension of the ambient space. -/
  dim_le : ∀ p, dim p ≤ m
  /-- Step `p` is spanned by the first `dim p` basis vectors, **in the given order**. -/
  eq : ∀ p, F p = initFlag e (dim_le p)
```

From the mathematics to the Lean statement

`Fin m` is $\{0, \dots, m-1\}$; `Fin.castLE hk` embeds $\{0, \dots, k-1\}$ into it, so `M.submatrix (Fin.castLE hk) (Fin.castLE hk)` is the leading $k \times k$ block. `Module.Basis (Fin m) K E` is an ordered basis; `initFlag e hk` is the span of its first k vectors (defined in the same file). K is any field. Exactly Definition 19.15.

Physical meaning

An ordered basis of states sorted by R-charge (PBW length), so that each charge-$\le p$ sector is spanned by an initial segment.

What the machine verified

Definitions.

Theorem 19.16 (Clause (iv) $\iff$ nonzero leading minors). *If F refines the ordered basis e, then β is nondegenerate on every F_p if and only if* $\det\big(\mathrm{Gram}_e(\beta)_{\le d_p}\big) \neq 0$ *for every p.*

File `VOA/Core/FlagMinors.lean`.

```
theorem nondegenerate_flag_iff_minors {F : ℕ → Submodule K E} {e : Module.Basis (Fin m) K
↪  E}
    (h : RefinesBasis F e) (β : BilinForm K E) :
    (∀ p, (β.restrict (F p)).Nondegenerate)
      ↔ ∀ p, (leadingPrincipal (LinearMap.BilinForm.toMatrix e β) (h.dim_le p)).det ≠ 0 :=
↪  by
```

From the mathematics to the Lean statement

`LinearMap.BilinForm.toMatrix e β` is the Gram matrix $(\beta(e_i, e_j))$. The theorem is an equivalence; exactly Theorem 19.16. The file docstring warns that the *ordering* matters for the companion sign statement: at $c = -22/5$, level 6, in the order $(L_{-6}\mathbf{1}, L_{-4}L_{-2}\mathbf{1})$ the Gram matrix is $\left(\begin{smallmatrix} -77 & -22 \\ -22 & 66/5 \end{smallmatrix}\right)$ with pivots $(-77,\ 682/35)$, while in the reversed order the pivots are $(66/5,\ -341/3)$. (We recomputed these: $(L_{-6}\mathbf{1}|L_{-6}\mathbf{1}) = \frac{c}{12}(6^3-6) = \frac{35c}{2}$, $(L_{-6}\mathbf{1}|L_{-4}L_{-2}\mathbf{1}) = 5c$, $(L_{-4}L_{-2}\mathbf{1}|L_{-4}L_{-2}\mathbf{1}) = \frac{c}{2}(5c+16)$, and $\det = -7502/5$.)

Proof on paper. The Gram matrix of $\beta|_{F_p}$ in the basis $e_1, \dots, e_{d_p}$ is the leading block (`toMatrix_restrict_initFlag`), and a bilinear form on a finite-dimensional space is nondegenerate iff its Gram determinant is nonzero. □

Physical meaning

"No null state in any truncated charge sector" is the non-vanishing of the cumulative Kac-type determinants.

What the machine verified

Proved, axiom-clean, unconditional.

19.6.2 Clause (vi) and the signs of minor ratios

Over $\mathbb{R}$, Sylvester's criterion says a symmetric matrix is positive definite iff all its leading minors are positive. Mathlib has only the easy direction (`Matrix.PosDef.det_pos`). The library supplies the converse and its layered refinement.

Theorem 19.17 (Jacobi's quotient identity, frame invariance, converse Sylvester). *Let M be an $m \times m$ matrix over a field.*

1. *If $D_l = \det M_{\le l}$ is invertible, then $D_{l+j} = D_l \cdot \det S_{l,j}$, where $S_{l,j}$ is the Schur complement of $M_{\le l}$ in $M_{\le l+j}$.*
2. *If U is upper unitriangular, $U^T M U$ has the same leading minors as M.*
3. *Over $\mathbb{R}$: if M is symmetric and $D_k > 0$ for all $1 \le k \le m$, then M is positive definite.*
4. *Over $\mathbb{R}$, M symmetric: if $D_l > 0$ and $D_{l+i}/D_l > 0$ for $1 \le i \le j$, then $S_{l,j}$ is positive definite; if instead $(-1)^i D_{l+i}/D_l > 0$, then $-S_{l,j}$ is positive definite.*

        * ((leadingPrincipal M hli).det / (leadingPrincipal M hl).det)) :
    (-(schurOfLeading M l j hlj)).PosDef := by
```

From the mathematics to the Lean statement

`schurOfLeading M l j hlj` is defined in the file as $M_{TT} - M_{TL}(M_{\le l})^{-1}M_{LT}$ with $L = \{1..l\}$, $T = \{l{+}1..l{+}j\}$. `U.BlockTriangular id` means upper triangular; `Uᵀ` transpose. `M.IsHermitian` over $\mathbb{R}$ is symmetry; `M.PosDef` is Mathlib's positive definiteness ($x^T M x > 0$ for $x \neq 0$, plus symmetry). Items 1–4 of Theorem 19.17 are the four groups of declarations in order (the last two make item 4).

A hypothesis stronger than needed — since weakened. When this chapter was written, item 4 assumed $D_l > 0$; the current statements, quoted above, assume only `hDl : (leadingPrincipal M hl).det ≠ 0`, which is all that is used (the leading minors of $S_{l,j}$ are D_{l+i}/D_l whatever the sign of D_l). In graded unitarity the cumulative minors alternate in sign, so $D_l < 0$ happens (e.g. after a one-dimensional negative layer). The library contains the general version elsewhere: `PolarizedRees.schurOfLeading_posDef_of_ratios_of_pivot_ne_zero` and its negative twin in `VOA/Examples/PolarizedReesStrongGenerator.lean`, hypothesis `hDl : … ≠ 0`. Since the library update the `MinorPivots` versions have the same, optimal, hypothesis.

Proof on paper. (1) Block decomposition $M_{\le l+j} = \left(\begin{smallmatrix} A & B \\ C & D \end{smallmatrix}\right)$ with A invertible gives $\det = \det A \cdot \det(D - CA^{-1}B)$. (2) The leading block of $U^T M U$ is $U_{\le k}^T M_{\le k} U_{\le k}$ because U is triangular, and $\det U_{\le k} = 1$. (3) Induction on m: $A = M_{\le m-1}$ is positive definite by induction; the 1×1 Schur complement has determinant $D_m/D_{m-1} > 0$; a symmetric block matrix with positive-definite A is positive definite iff its Schur complement is (`fromBlocks_posDef_iff_schur₁₁`, `VOA/Core/HermitianSchur.lean`). (4) The leading $i \times i$ block of $S_{l,j}$ is $S_{l,i}$ (`leadingPrincipal_schurOfLeading`), whose determinant is D_{l+i}/D_l by (1); apply (3) to $\pm S_{l,j}$. □

Physical meaning

The Schur complement $S_{l,j}$ is the Gram matrix of the states of the next charge sector after projecting out the lower-charge states — i.e. the Gram matrix of the layer. Item 4 says: graded unitarity at one weight is equivalent to the statement that the pivots D_k/D_{k-1} have sign $(-1)^{(\text{length of the } k\text{-th basis state})}$, a condition one can test with exact rational arithmetic, which is how the project's numerical campaign was run.

What the machine verified

All proved, axiom-clean, unconditional. Also proved: `fromBlocks_posDef_iff_schur₁₁` (`HermitianSchur`), `realSymmetricTwo_posDef_iff` and `realSymmetricTwo_posSemidef_iff` (the 2×2 Sylvester criteria, `VOA/Core/RealSymmetricTwo.lean`). The docstrings of `FlagMinors.lean`, `GradedUnitarity.lean` and `VirasoroGradedUnitarity.lean` still say that "the pivot/positivity half is absent" and "not reducible to minors with what Mathlib currently has"; this is **stale** since `MinorPivots.lean` landed (documentation defect, see the LEAN DEFECTS list at the end of the chapter).

Example 19.18 (Lee–Yang, weight 6). With $M = \left(\begin{smallmatrix} -77 & -22 \\ -22 & 66/5 \end{smallmatrix}\right)$, $D_1 = -77 < 0$ and $D_2/D_1 = 682/35 > 0$. The first basis vector $L_{-6}\mathbf{1} = \frac{1}{24}L_{-1}^4\omega$ has length one and the second has length two, so the predicted signs are $(-1)^1$ and $(-1)^2$: the pivots agree. This is the content of graded unitarity of $L(-22/5, 0)$ at weight six, and it is a special case of the length-two theorem of Section 19.8.

19.7 Graded unitarity of the Virasoro VOAs: statement and reduction

19.7.1 The length flag

Recall (Chapter 7) that $V(c, 0)$ is the universal Virasoro vacuum module, with basis the sorted creation words: `negWordVir c w` for a weakly decreasing list $w = [i_1, \dots, i_k]$ of natural numbers is $L_{-(i_1+2)} \cdots L_{-(i_k+2)}\mathbf{1}$, of weight `energyVir w` $= \sum_j (i_j + 2)$ and length k; and $L(c, 0) = V(c, 0)/\mathcal{M}_c$ is the simple quotient by the maximal proper ideal `maxIdealVir c`, with canonical normalised invariant form `Bsimp c` (Chapter 8, §8.3.3).

Definition 19.19 (Length filtration of $L(c, 0)$; ABLR (3.11), Kaufmann $\tilde{V}_{n,k}$). $\mathcal{F}_pV(c, 0)_n$ is the span of the sorted creation words of weight n and length $\le p$, and $G_pL(c, 0)_n$ is its image in the simple quotient.

File `VOA/Examples/VirasoroGoodFiltration.lean` (a file of Chapter 7).

```
noncomputable def virFil (p : ℕ) (n : ℤ) : Submodule ℂ (VirUniv c) :=
  Submodule.span ℂ
    { x | ∃ w : List ℕ, SortedWord w ∧ (energyVir w : ℤ) = n ∧ w.length ≤ p ∧
            negWordVir c w = x }

noncomputable def goodFil (p : ℕ) (n : ℤ) : Submodule ℂ (VirUniv c ⧸ maxIdealVir c) :=
  (virFil c p n).map (maxIdealVir c).mkQ

noncomputable def virGradedFlag : GradedFlag (virasoroSimple c) where
  piece := goodFil c
  le_grading := goodFil_le_grading c
  mono := fun n h => goodFil_mono c n h
  bot := fun _ hn => goodFil_zero_of_pos c hn
  vacuum_zero := goodFil_zero_zero c
  exhaustive := iSup_goodFil c
```

From the mathematics to the Lean statement

`SortedWord w` is `w.Pairwise (· ≥ ·)` (weakly decreasing). `(maxIdealVir c).mkQ` is the quotient map $V(c, 0) \to L(c, 0)$, and `.map` takes the image. The `GradedFlag` fields are the axioms of Chapter 11, all proved for every c. Note the flag is an *image*: no basis of $L(c, 0)$ is assumed. Whether the length filtration *is* ABLR's R-filtration for the boundary models is part of the conjecture's physics, not of the library.

Physical meaning

Each L_{-n} carries one unit of $SU(2)_R$ charge (the stress tensor comes from the 4d $SU(2)_R$ current multiplet, of $R = 1$), so a word of length k has $R \le k$; the length filtration is the natural candidate for the R-filtration of the Virasoro chiral algebras of the (A_1, A_{2n}) Argyres–Douglas theories.

What the machine verified

Definitions with all fields proved (Chapter 7 files), axiom-clean.

Definition 19.20 (Graded unitarity of $L(c,0)$)**.** $L(c,0)$ is graded unitary with respect to a real structure ρ if `GradedUnitary` holds for the canonical form, ρ, and the length flag.

File `VOA/Examples/VirasoroGradedUnitarity.lean`.

```
def VirGradedUnitary (R : RealStructure (virasoroSimple c)) : Prop :=
  GradedUnitary (Bsimp c) R (virGradedFlag c)
```

From the mathematics to the Lean statement

`virasoroSimple c` is the simple Virasoro VOA $L(c,0)$, `Bsimp c` its canonical form with $(\mathbf{1}|\mathbf{1}) = 1$ (`Bsimp_normalized`). The flag is *pinned* to the length flag, so Warning 19.4.1 does not apply here. The real structure is a parameter; canonical choices are constructed in Section 19.7.2. The statement that `VirGradedUnitary (boundaryCharge n) R` holds for $c = c_{2,2n+1}$ is **Kaufmann's conjecture** (1994), open; the library does not claim it.

Physical meaning

"The Virasoro chiral algebra of the (A_1, A_{2n}) Argyres–Douglas theory satisfies all the positivity constraints inherited from four-dimensional unitarity."

What the machine verified

Definition. Never asserted of any c. `virGradedUnitary_iff` unfolds it weight by weight; `isPosOn_layer_zero_vacuum_simple` proves the weight-zero slice of clause (vi) for every c and every ρ.

Theorem 19.21 (The Virasoro reduction to minors)**.** *Let $N \geq 0$ and let e be an ordered basis of $L(c,0)_N$ whose initial segments are the steps of the length flag. For every sesquilinear form h on $L(c,0)_N$, graded unitarity at weight N holds iff all leading principal minors of the Gram matrix of* `Bsimp c` *in the basis e (cut at the step dimensions) are nonzero and the layers are positive. Moreover, if each e_i is the image of a creation word w_i, the Gram entries are the universal values $(L_{-w_i}\mathbf{1}|L_{-w_j}\mathbf{1})$ of the canonical form on $V(c,0)$.*

File `VOA/Examples/VirasoroGradedUnitarity.lean`.

```
theorem gradedUnitaryAt_iff_minors_and_positive {c : ℂ} {N m : ℕ}
    (e : Module.Basis (Fin m) ℂ ((virasoroSimple c).grading (N : ℤ)))
    (hrb : FlagMinors.RefinesBasis (fun p => (virGradedFlag c).pieceIn p (N : ℤ)) e)
    (h : SesqForm ((virasoroSimple c).grading (N : ℤ))) :
    GradedUnitaryAt (virGradedFlag c) (N : ℤ) (LiRadical.gradedForm (Bsimp c) (N : ℤ)) h
      ↔ (∀ p : ℕ, (FlagMinors.leadingPrincipal
            (LinearMap.BilinForm.toMatrix e (LiRadical.gradedForm (Bsimp c) (N : ℤ)))
            (hrb.dim_le p)).det ≠ 0) ∧
        LayerPositive (virGradedFlag c) (N : ℤ) (LiRadical.gradedForm (Bsimp c) (N : ℤ)) h
          := 

theorem toMatrix_eq_canB_of_monomials (w : Fin m → List ℕ)
    (hw : ∀ i, (e i : VirUniv c / maxIdealVir c)
      = (maxIdealVir c).mkQ (negWordVir c (w i))) (i j : Fin m) :
    LinearMap.BilinForm.toMatrix e (LiRadical.gradedForm (Bsimp c) (N : ℤ)) i j
      = (canB c).form (negWordVir c (w i)) (negWordVir c (w j)) := by
```

From the mathematics to the Lean statement

`hrb` is the hypothesis that the flag refines e; a basis of the simple quotient adapted to the flag is *not* constructed in the library — it is the content of the cited `AdmissiblePartitions.FlagBasisHyp` (Salazar's admissible-partition basis; Chapter 10 explains this hypothesis), so the theorem is a reduction *given* such a basis. The right side keeps `LayerPositive` untouched: the sign half is *not* rewritten into minors here (the pivot machinery of Theorem 19.17 would do it, but no Virasoro statement composes the two). In `toMatrix_eq_canB_of_monomials` the section variables are an ordered basis `e` of the weight-N space and m its size; `canB c` is the canonical form of $V(c,0)$ and the identity is `VirQuotForm.canB_quot_mkQ`: the form on the quotient is computed by representatives.

Proof on paper. Combine Theorem 19.16 with the definition `GradedUnitaryAt` = (iv) ∧ (vi). The second statement is the definition of the quotient form. □

Physical meaning

To test graded unitarity of a minimal model at a given level one needs only the Kac-type Gram matrix of creation monomials (computable in the universal module) and an admissible basis of the quotient.

What the machine verified

Proved, axiom-clean; conditional on the explicit hypothesis `hrb` (an adapted basis), never discharged for any N in the library. Also proved: `virLayerDecomposition`, `virFinrank_layer`, `virISup_layer_eq_top` (Theorem 19.13 at $L(c,0)$, conditional on clause (iv)).

19.7.2 Real structures on the Virasoro VOAs

Definition 19.22 (Partition-basis conjugation)**.** On $V(c,0)$, `virBasisConj c` conjugates the coordinates in the basis of sorted creation words: $\sum_w a_w L_{-w}\mathbf{1} \mapsto \sum_w \bar{a}_w L_{-w}\mathbf{1}$.

File `VOA/Examples/VirasoroFockConjugation.lean` (Chapter 7).

```
noncomputable def virBasisConj (c : ℂ) : VirUniv c →ₛₗ[starRingEnd ℂ] VirUniv c :=
  basisConj (sortedBasisVir c)
```

From the mathematics to the Lean statement

`→ₛₗ[starRingEnd ℂ]` is a semilinear (here: anti-linear) map. `sortedBasisVir c` is the sorted-word basis of $V(c,0)$ (Chapter 7; its linear independence is the Feigin–Fuchs argument, unconditional). It is an involution (`virBasisConj_sq`) at every c; whether it commutes with the modes is the question answered next.

Physical meaning

"Complex conjugation of wave-functions in the PBW basis."

What the machine verified

Definition.

Theorem 19.23 (Real structures on $V(c,0)$ and $L(c,0)$ for $c \le 1$)**.** *Let $\lambda \in \mathbb{R}$ and $c = 1 - 12\lambda^2$. Then the partition-basis conjugation is a real structure on $V(c,0)$ with parity $s \equiv 1$; it preserves the maximal ideal and descends to a real structure on $L(c,0)$.*

File `VOA/Examples/VirasoroRealStructure.lean`.

```
noncomputable def virasoroUniversalRealStructure {c lam : ℂ}
    (hlam : 1 - 12 * lam ^ 2 = c) (hreal : (starRingEnd ℂ) lam = lam) :
    RealStructure (virasoroVOA c) where

noncomputable def virasoroSimpleRealStructure {c lam : ℂ}
    (hlam : 1 - 12 * lam ^ 2 = c) (hreal : (starRingEnd ℂ) lam = lam) :
    RealStructure (virasoroSimple c) where
```

From the mathematics to the Lean statement

A Lean `def ... : RealStructure ... where` *constructs* the structure: every field of Definition 19.9 is proved (we omit the field proofs). `hreal` says $\bar{\lambda} = \lambda$, i.e. λ is real. So the hypotheses say: $c = 1 - 12\lambda^2$ for a real λ, equivalently c real and $c \leq 1$. Parity is `fun _ ⇒ 1`.
A restriction, not a defect. Mathematically the partition-basis conjugation is a real structure for every real c (the structure constants of the Virasoro algebra in the PBW basis are real polynomials in c). The library's proof goes through the Feigin–Fuchs free-field realisation, which needs a real background charge λ; for real $c > 1$ (λ imaginary) no real structure is constructed. All the boundary models have $c < 0$, so nothing used later is affected.

Proof on paper. With λ real, the Feigin–Fuchs embedding $V(c,0) \hookrightarrow$ Fock (Chapter 7, Theorem 7.9) intertwines `virBasisConj` with coefficientwise conjugation of Fock polynomials, which commutes with the free-boson Virasoro modes L_n^λ because their coefficients are real. Hence $\rho L_n = L_n \rho$ on $V(c,0)$ (`virBasisConj_Lop`). Since $V(c,0)$ is strongly generated by ω, every field $Y(u,z)$ is built from $Y(\omega,z)$ by derivatives and normal-ordered products with real coefficients, and conjugation-covariance propagates (`VirConjCov.nprod`, `virBasisConj_virYA`); this gives `map_smul`. The preimage of a VOA ideal under ρ is an ideal not containing $\mathbf{1}$, hence $\rho(\mathcal{M}_c) \subseteq \mathcal{M}_c$ by maximality, and ρ descends. □

Physical meaning

The Virasoro stress tensor is a Hermitian field and its OPE has real coefficients; so "complex conjugation in the PBW basis" is an anti-unitary symmetry of the chiral algebra. For $c \leq 1$ this is manifest in the Coulomb-gas (Dotsenko–Fateev) description with real background charge α_0.

What the machine verified

Constructed; `#print axioms VOA.virasoroSimpleRealStructure`: standard three. Unconditional given the stated hypotheses.

Theorem 19.24 (Canonical real structures on the boundary models). *For every $n \in \mathbb{N}$, $c_{2,2n+1} = 1 - 12\lambda_n^2$ with the real number $\lambda_n = \sqrt{(2n-1)^2/(4(2n+1))}$, so $L(c_{2,2n+1}, 0)$ carries a canonical real structure.*

File `VOA/Examples/VirasoroBoundaryRealStructure.lean`.

```
noncomputable def boundaryBackgroundChargeSq (n : ℕ) : ℝ :=
  (2 * (n : ℝ) - 1) ^ 2 / (4 * (2 * n + 1))

theorem boundaryBackgroundCharge_spec (n : ℕ) :
    1 - 12 * boundaryBackgroundCharge n ^ 2 = boundaryCharge n := by

noncomputable def boundaryVirasoroRealStructure (n : ℕ) :
```

```
    RealStructure (virasoroSimple (boundaryCharge n)) :=
  virasoroSimpleRealStructure (boundaryBackgroundCharge_spec n)
    (boundaryBackgroundCharge_fixed n)
```

From the mathematics to the Lean statement

`boundaryBackgroundCharge n` is `(Real.sqrt (boundaryBackgroundChargeSq n) : ℂ)`, and `boundaryCharge n` is the complex number $c_{2,2n+1} = 1 - 3(2n-1)^2/(2n+1)$ (Definition 19.26 below). Check: $1 - 12 \cdot \frac{(2n-1)^2}{4(2n+1)} = 1 - \frac{3(2n-1)^2}{2n+1}$. Exactly Theorem 19.24.

Physical meaning

λ_n is the Coulomb-gas background charge $\alpha_0/\sqrt{2}$ of $M(2, 2n+1)$.

What the machine verified

Constructed, axiom-clean, unconditional.

Theorem 19.25 (Every step of the length flag is ρ-stable, for every real structure)**.** *For every c, every real structure ρ on $L(c,0)$, every p and N, $\rho(G_pL(c,0)_N) \subseteq G_pL(c,0)_N$.*

File `VOA/Examples/VirasoroLengthTwoBoundarySemantic.lean`.

```
theorem rhoStableOn_vir_pieceIn {p : ℕ} {N : ℤ} :
    RhoStableOn R ((virGradedFlag c).pieceIn p N) := by
```

From the mathematics to the Lean statement

The section variables are `{c : ℂ} (R : RealStructure (virasoroSimple c))`: an *arbitrary* real structure. Exactly the theorem. Consequence (via Theorem 19.12, with $s(N) \neq 0$ — e.g. $s \equiv 1$): for the Virasoro flag the bilinear layers of `GradedUnitary` *are* ABLR's sesquilinear layers.

Proof on paper. ρ commutes with all L_n (`rho_L`) and fixes $\mathbf{1}$, so it fixes every creation monomial; it maps the span of monomials of length $\leq p$ to itself because it only conjugates coefficients. □

Physical meaning

Conjugation does not change the number of stress-tensor modes in a state.

What the machine verified

Proved, axiom-clean, unconditional.

19.8 Length-two positivity for the boundary models

This is the main unconditional positivity theorem of the chapter. We first set up the arithmetic and the quasi-primaries.

19.8.1 The boundary central charges and the root ρ_m

Definition 19.26 (Boundary central charge; the rational function ρ_m)**.** For $n \in \mathbb{N}$, $c_{2,2n+1} = 1 - \dfrac{3(2n-1)^2}{2n+1}$. For $m \in \mathbb{N}$,

$$\rho_m = \frac{36(4m^2 - 2m - 1)}{m(m-1)(m+1)(2m-3)(2m-1)(2m+1)}.$$

File `VOA/Examples/VirasoroLengthTwoArithmetic.lean`, then `VOA/Examples/VirasoroLengthTwoBoundary.lean`.

```
def boundaryMinimalCentralCharge (n : ℕ) : ℚ :=
  1 - 3 * (2 * (n : ℚ) - 1) ^ 2 / (2 * n + 1)

def lengthTwoRho (m : ℕ) : ℚ :=
  36 * (4 * (m : ℚ) ^ 2 - 2 * m - 1) /
    ((m : ℚ) * (m - 1) * (m + 1) * (2 * m - 3) * (2 * m - 1) * (2 * m + 1))

theorem lengthTwoRho_mem_Ioc (m : ℕ) (hm : 2 ≤ m) :
    lengthTwoRho m ∈ Set.Ioc (0 : ℚ) (22 / 5) :=

def boundaryCharge (n : ℕ) : ℂ := (boundaryMinimalCentralCharge n : ℂ)
```

From the mathematics to the Lean statement

Rational numbers `ℚ`; `Set.Ioc a b` is the half-open interval $(a, b]$; `(q : ℂ)` is the embedding $\mathbb{Q} \subset \mathbb{C}$. Check: $1 - 6(2-(2n+1))^2/(2(2n+1)) = 1 - 3(2n-1)^2/(2n+1)$, the $(2, 2n+1)$ minimal-model value ($n = 2$: $-22/5$, `boundaryCharge_two_eq_leeYangC`; $n = 3$: $-68/7$). For $n = 1$ it gives $c_{2,3} = 0$; all theorems below assume $n \geq 2$. $\rho_2 = 36 \cdot 11/90 = 22/5$; the library proves ρ_m strictly decreasing (`lengthTwoRho_succ_lt`) with $0 < \rho_m \leq 22/5$ for $m \geq 2$.

Physical meaning

$-\rho_m$ is the central charge at which the new length-two quasi-primary of weight $2m$ becomes null (norm zero) in $V(c, 0)$; $\rho_2 = 22/5$ is the Lee–Yang value.

What the machine verified

Definitions and inequalities proved, axiom-clean.

19.8.2 The length-two quasi-primaries

Definition 19.27 (Q_{2m})**.** For $m \geq 2$, with $a_{m,j} = (-1)^j \binom{2m-1}{j} / \binom{j+3}{3}$ and $b_m = (-1)^{m+1} \dfrac{3\binom{2m}{m}}{m(m+1)(2m+1)}$,

$$Q_{2m} = 2 \sum_{j=0}^{m-3} a_{m,j} L_{-(2m-2-j)} L_{-(j+2)} \mathbf{1} + a_{m,m-2} L_{-m}^2 \mathbf{1} + b_m L_{-2m} \mathbf{1} \in V(c,0)_{2m}.$$

The rational coefficients $a_{m,j}$ and b_m live in their own file, `VOA/Examples/VirasoroLengthTwoArithmetic.lean`:

```
def lengthTwoACoeff (m j : ℕ) : ℚ :=
  (-1 : ℚ) ^ j * (Nat.choose (2 * m - 1) j : ℚ) / (Nat.choose (j + 3) 3 : ℚ)

def lengthTwoBCoeff (m : ℕ) : ℚ :=
  (-1 : ℚ) ^ (m + 1) * 3 / ((m : ℚ) * (m + 1) * (2 * m + 1)) *
    (Nat.choose (2 * m) m : ℚ)
```

The vector Q_{2m} itself and its quasi-primarity are in the file `VOA/Examples/VirasoroLengthTwoQuasiPrimary.lean`, which imports the coefficients above:

```
noncomputable def lengthTwoQOffDiag (m : ℕ) : VirUniv c :=
  (2 : ℂ) • ∑ j ∈ Finset.range (m - 2),
    aCoeffC m j • negWordVir c [2 * m - 4 - j, j]

noncomputable def lengthTwoQ (m : ℕ) : VirUniv c :=
  lengthTwoQOffDiag c m
    + aCoeffC m (m - 2) • negWordVir c [m - 2, m - 2]
    + bCoeffC m • negWordVir c [2 * m - 2]

theorem lengthTwoQ_quasiPrimary (m : ℕ) (hm : 2 ≤ m) :
    Lop c 1 (lengthTwoQ c m) = 0 := by
```

From the mathematics to the Lean statement

`aCoeffC`, `bCoeffC` are the coefficients cast to $\mathbb{C}$ (private definitions in the file). `negWordVir c [2*m-4-j, j]` $= L_{-(2m-2-j)}L_{-(j+2)}\mathbf{1}$ by the word convention; `[2*m-2]` gives $L_{-2m}\mathbf{1}$. `Lop c 1` is L_1 on $V(c,0)$. So the theorem says $L_1Q_{2m} = 0$: Q_{2m} is *quasi-primary*. Since $L_2Q_{2m} \neq 0$ in general it is not primary. Q_{2m} is independent of c; for $m = 2$, $Q_4 = L_{-2}^2\mathbf{1} - \frac{3}{5}L_{-4}\mathbf{1}$ (`lengthTwoQ_two`), and $5Q_4$ is the Lee–Yang singular vector (`five_smul_lengthTwoQ_two`).

Proof on paper. Since $[L_1, L_{-a}] = (a+1)L_{1-a}$ and $L_1\mathbf{1} = 0$, $L_1L_{-a}L_{-b}\mathbf{1} = (a+1)L_{-(a-1)}L_{-b}\mathbf{1} + (b+1)L_{-a}L_{-(b-1)}\mathbf{1}$, where a factor L_{-1} adjacent to the vacuum is moved through using $L_{-1}L_{-b}\mathbf{1} = (b-1)L_{-(b+1)}\mathbf{1}$, and $L_1L_{-2m}\mathbf{1} = (2m+1)L_{-(2m-1)}\mathbf{1}$. Collecting the coefficient of each word of weight $2m-1$, the length-two words cancel in neighbouring pairs by the identity $a_{m,j}(2m-1-j) + a_{m,j+1}(j+4) = 0$ for $j+3 \le m$ (`lengthTwoACoeff_recurrence`), and the single length-one word $L_{-(2m-1)}\mathbf{1}$ cancels by $(2m+1)b_m + (m+1)a_{m,m-2} = 0$ (`lengthTwoBCoeff_residual`). □

Physical meaning

Quasi-primaries are the $SL(2)$ highest-weight states: the states annihilated by the special conformal generator. In a 4d $\mathcal{N} = 2$ SCFT they correspond to the Schur operators that are not derivatives; Q_{2m} is the "double-trace" $:TT:$-type operator of spin $2m$ built from two stress tensors with $2m-4$ derivatives distributed so as to be quasi-primary.

What the machine verified

Proved, axiom-clean, unconditional (no use of `VOA.pbw`, no character theorem).

Theorem 19.28 (Closed norm formula). *For every $c \in \mathbb{C}$ and $m \ge 2$,*

$$(Q_{2m}|Q_{2m}) = \frac{1}{2}\binom{4m-2}{2m-4}\,c\,(c+\rho_m)$$

for the canonical form of $V(c,0)$.

File `VOA/Examples/VirasoroLengthTwoNorm.lean`.

```
theorem canB_lengthTwoQ_self (c : ℂ) (m : ℕ) (hm : 2 ≤ m) :
    (canB c).form (lengthTwoQ c m) (lengthTwoQ c m) =
      (1 / 2 : ℂ) * ((Nat.choose (4 * m - 2) (2 * m - 4) : ℚ) : ℂ) * c *
        (c + (lengthTwoRho m : ℂ)) := by
```

From the mathematics to the Lean statement

`canB c` is the canonical normalised invariant form on $V(c,0)$ (Chapter 7, Definition 7.17). The binomial is cast $\mathbb{N} \to \mathbb{Q} \to \mathbb{C}$. Exactly Theorem 19.28. Check at $m = 2$: $\frac{1}{2} \cdot 1 \cdot c(c + 22/5) = c(5c+22)/10$, which is `canB_lengthTwoQ_self_two_norm`, and which vanishes exactly at $c = 0$ and $c = -22/5$ — the level-four Kac zeros.

Proof on paper. Since Q_{2m} is quasi-primary and of weight $2m$, its norm equals (top pairing)×normalisation: write $(Q|Q) = (Q|b_m L_{-2m}\mathbf{1} + \ldots)$, move the L's to the left as L_n's, and use $L_1 Q = 0$ to kill all terms except those pairing with the "top" word. The resulting finite sums are evaluated in closed form by a binomial identity (`lengthTwoNormSummand_sum_full`, `lengthTwoChooseThree`, `lengthTwoMixedArithmetic`), yielding a quadratic polynomial in c with roots 0 and $-\rho_m$. □

Physical meaning

The two-point function of the double-trace operator: proportional to c (one stress tensor contraction) and to $c + \rho_m$ (the $1/c$ correction from the connected four-point function of T), vanishing at the central charge where Q_{2m} decouples.

What the machine verified

Proved, axiom-clean, unconditional, all c, all $m \geq 2$.

19.8.3 Towers, layers and the theorem

Every state of length ≤ 2 and weight $N \geq 2$ in $V(c,0)$ is a combination of L_{-1}-descendants of ω and of the Q_{2m}: by the global $\mathfrak{sl}_2 = \langle L_{-1}, L_0, L_1 \rangle$ structure, the weight-N part of the length-≤ 2 subspace is spanned by $L_{-1}^{N-2}\omega$ ("stress tower", index $m = 1$) and $L_{-1}^{N-2m}Q_{2m}$, $2 \leq m \leq N/2$ (`virFil_two_eq_span_towers`). These towers are eigenvectors of the self-adjoint operator $L_{-1}L_1$ with distinct eigenvalues $r(2h + r - 1)$ (h the weight of the base, r the depth; `globalTowerOperator`, `lengthLETwoTowerEigenvalue_injective`), hence mutually orthogonal and linearly independent, and

$$\left(L_{-1}^r Q \,|\, L_{-1}^r Q\right) = \prod_{j=0}^{r-1} (j+1)(2h+j) \cdot (Q|Q),$$

a positive multiple of $(Q|Q)$.

Definition 19.29 (Retained towers in the simple quotient)**.** For the boundary model n and weight N, the retained indices are $1 \leq m \leq N/2$ except $(n,m) = (2,2)$; the corresponding towers in $L(c_{2,2n+1}, 0)$ are the images of $L_{-1}^{N-2}\omega$ ($m = 1$) and $L_{-1}^{N-2m}Q_{2m}$ ($m \geq 2$).

File `VOA/Examples/VirasoroLengthTwoBoundary.lean`.

```
def BoundaryLengthLETwoTowerIndex (n N : ℕ) :=
  {m : LengthLETwoTowerIndex N // n ≠ 2 ∨ m.1 ≠ 2}

noncomputable def boundaryLengthLETwoTowerAt (n N : ℕ)
    (m : BoundaryLengthLETwoTowerIndex n N) :
    VirUniv (boundaryCharge n) / maxIdealVir (boundaryCharge n) :=
  if hm : m.1.1 = 1 then boundaryLengthOneTowerAt n N
  else ((virasoroSimple (boundaryCharge n)).L (-1) ^ (N - 2 * m.1.1))
    (lengthTwoQSimple (boundaryCharge n) m.1.1)
```

From the mathematics to the Lean statement

`LengthLETwoTowerIndex N` is `{m : ℕ // 1 ≤ m ∧ 2 * m ≤ N}` (`VirasoroLengthTwoSpanning.lean`); the subtype removes the single Lee–Yang exception. `boundaryLengthOneTowerAt n N` is $L_{-1}^{N-2}\omega$ in the quotient and `lengthTwoQSimple c m` is the image of Q_{2m} (`VirasoroLengthTwoTowers.lean`).

Physical meaning

The stress-tensor descendants and the descendants of the double-trace quasi-primaries: the complete list of states with at most two stress-tensor modes.

What the machine verified

Definitions. The library proves these retained towers are nonzero, orthogonal, a basis of $G_2L(c_{2,2n+1},0)_N$ (`goodFil_two_eq_span_boundaryTowers`), and that the deleted Lee–Yang tower is zero (`lengthTwoQSimple_two_eq_zero`).

Theorem 19.30 (Exact signs of the retained towers). *For $n \geq 2$ and every retained index: the stress tower has norm $-r$ with $r > 0$, and every length-two tower has norm $+r$ with $r > 0$.*

File `VOA/Examples/VirasoroLengthTwoBoundary.lean`.

```
theorem Bsimp_boundaryLengthLETwoTowerAt_self_sign (n N : ℕ) (hn : 2 ≤ n)
    (m : BoundaryLengthLETwoTowerIndex n N) :
    if hm : m.1.1 = 1 then
      ∃ r : ℝ, 0 < r ∧
        (Bsimp (boundaryCharge n)).form (boundaryLengthLETwoTowerAt n N m)
          (boundaryLengthLETwoTowerAt n N m) = -(r : ℂ)
    else
      ∃ r : ℝ, 0 < r ∧
        (Bsimp (boundaryCharge n)).form (boundaryLengthLETwoTowerAt n N m)
          (boundaryLengthLETwoTowerAt n N m) = (r : ℂ) := by
```

From the mathematics to the Lean statement

`if hm : m.1.1 = 1 then … else …` is a dependent case split on whether the index is the stress tower. Exactly Theorem 19.30. The norms are of the *bilinear* form on the quotient; since every real structure fixes the towers (`fixes_boundaryLengthLETwoTowerAt`), they are also the Hermitian norms.

Proof on paper. Stress tower: positive factor times $(\omega|\omega) = c/2 < 0$, since $c_{2,2n+1} < 0$ for $n \geq 2$ (`boundaryMinimalCentralCharge_neg`). Length-two tower: positive factor times $\frac{1}{2}\binom{4m-2}{2m-4}c(c+\rho_m)$, a product of two negative numbers: $c < 0$, and $c + \rho_m < 0$ because $c \leq -22/5$ with equality only at $n = 2$, and $\rho_m \leq 22/5$ with equality only at $m = 2$ (`boundaryLengthTwoBaseNorm_pos`, hypothesis `n ≠ 2 ∨ m ≠ 2`). □

Physical meaning

In $M(2, 2n+1)$ every stress-tensor descendant has negative norm and every double-trace descendant has positive norm: exactly the $(-1)^R$ pattern of graded unitarity with $R = 1$ and $R = 2$.

What the machine verified

Proved, axiom-clean, unconditional.

Definition 19.31 (Graded unitarity through degree two)**.** Clauses (iv) and (vi) restricted to filtration degrees $p \le 2$.

File `VOA/Examples/VirasoroLengthTwoLayerPositive.lean`.

```
def LayerNondegenerateThroughTwo (F : GradedFlag (virasoroSimple c)) (N : ℤ)
    (β : LinearMap.BilinForm ℂ ((virasoroSimple c).grading N)) : Prop :=
  ∀ p : ℕ, p ≤ 2 → (β.restrict (F.pieceIn p N)).Nondegenerate

def LayerPositiveThroughTwo (F : GradedFlag (virasoroSimple c)) (N : ℤ)
    (β : LinearMap.BilinForm ℂ ((virasoroSimple c).grading N))
    (h : SesqForm ((virasoroSimple c).grading N)) : Prop :=
  ∀ p : ℕ, p ≤ 2 → IsPosOn (signedForm h p) (F.layer N β p)

def GradedUnitaryThroughTwoAt (F : GradedFlag (virasoroSimple c)) (N : ℤ)
    (β : LinearMap.BilinForm ℂ ((virasoroSimple c).grading N))
    (h : SesqForm ((virasoroSimple c).grading N)) : Prop :=
  LayerNondegenerateThroughTwo F N β ∧ LayerPositiveThroughTwo F N β h
```

From the mathematics to the Lean statement

Literally `LayerNondegenerate` and `LayerPositive` with the extra guard `p ≤ 2`. So `GradedUnitaryAt` implies `GradedUnitaryThroughTwoAt`, not conversely.

Physical meaning

The positivity constraints on states with $R \le 2$: operators made of at most two stress tensors.

What the machine verified

Definitions.

Theorem 19.32 (Boundary Virasoro graded unitarity through filtration degree two)**.** *For every $n \ge 2$ and every $N \in \mathbb{Z}$, the simple boundary model $L(c_{2,2n+1}, 0)$ with its canonical form, its length flag and the canonical real structure satisfies clauses (iv) and (vi) of graded unitarity at weight N in all filtration degrees $p \le 2$. The same holds for an* arbitrary *real structure.*

File `VOA/Examples/VirasoroLengthTwoLayerPositive.lean`.

```
theorem boundary_gradedUnitaryThroughTwoAt (n : ℕ) (hn : 2 ≤ n) (N : ℤ)
    (R : RealStructure (virasoroSimple (boundaryCharge n))) :
    GradedUnitaryThroughTwoAt (virGradedFlag (boundaryCharge n)) N
      (LiRadical.gradedForm (Bsimp (boundaryCharge n)) N)
      (gradedSesq (Bsimp (boundaryCharge n)) R N) := by

theorem boundary_gradedUnitaryThroughTwo (n : ℕ) (hn : 2 ≤ n) (N : ℤ) :
    GradedUnitaryThroughTwoAt (virGradedFlag (boundaryCharge n)) N
      (LiRadical.gradedForm (Bsimp (boundaryCharge n)) N)
      (gradedSesq (Bsimp (boundaryCharge n)) (boundaryVirasoroRealStructure n) N) :=
```

From the mathematics to the Lean statement

Every ingredient has been defined above: `boundaryCharge n` (Def. 19.26), `virGradedFlag` (Def. 19.19), `Bsimp` (canonical form), `gradedSesq` (Def. 19.10), `boundaryVirasoroRealStructure` (Thm. 19.24). The only hypothesis is $n \ge 2$ (excluding the trivial $c_{2,3} = 0$). The first form holds for an arbitrary real structure `R` — this is *stronger*, and it is possible because every real structure fixes all towers (Theorem 19.25 and its proof). The second form instantiates the canonical one and is therefore hypothesis-free.

Same, stronger or weaker than the target? Strictly *weaker* than `VirGradedUnitary (boundaryCharge n) R`: layers $p \geq 3$ are not addressed. For $n = 2$ and weights $N \leq 11$ it nevertheless covers everything, since Lee–Yang has no admissible length-three partitions below weight 12 (`a3count_vanishes_below_twelve`, Section 19.10) — but the library does not draw this corollary, because identifying admissible partitions with a basis is the uncited `FlagBasisHyp`.
Non-vacuity. The conclusion would be empty if the layers were zero. A Lean check against the library (not part of this release) proves that for all $n \geq 2$, $N \geq 2$ the degree-one layer is a nonzero line, that the degree-two layer is nonzero whenever a length-two tower is retained, and the concrete instance $M(2,7)$, weight 4, of the latter. All three compile with standard axioms only.

Proof on paper. Fix $n \geq 2$. Negative N and $N = 1$: the weight space is zero and every clause holds trivially. $N = 0$: the weight space is $\mathbb{C}\mathbf{1}$, all steps equal it, the form is nondegenerate since $(\mathbf{1}|\mathbf{1}) = 1$, layer 0 is positive (Theorem 19.14) and layers 1, 2 are zero. $N \geq 2$: $G_0 = 0$; $G_1 L_N$ is the line of the stress tower (`pieceIn_one_eq_span_stress`), so $\mathcal{L}_1$ is that line; $G_2 L_N$ is spanned by the retained towers, an orthogonal family with nonzero norms, so β is nondegenerate on G_1 and on G_2 (`restrict_span_nondegenerate_of_orthogonal_family`) and $\mathcal{L}_2$ is the span of the length-two towers (`layer_two_eq_lengthTwoSpan`). For $x = \sum_i z_i t_i$ in the span of an orthogonal ρ-fixed family (t_i) one has $h(x,x) = \sum_i |z_i|^2 (t_i|t_i)$; by Theorem 19.30, $-h$ is positive on $\mathcal{L}_1$ and $+h$ on $\mathcal{L}_2$ (`isPosOn_span_of_orthogonal_family`). □

Physical meaning

In every boundary minimal model, the two lowest rungs of the four-dimensional positivity ladder hold exactly: single stress-tensor states have negative two-dimensional norm, and the exact-length-two double-trace states have positive norm, at every spin. This is the first all-weight piece of evidence for the Kaufmann/ABLR conjecture that is a theorem rather than a numerical check.

What the machine verified

Proved; `#print axioms` of both: `[propext, Classical.choice, Quot.sound]`. Unconditional (`boundary_gradedUnitaryThroughTwo` has only $n \geq 2$); `VOA.pbw` not used. The full conjecture (all p) remains open; the repository's only other evidence for it is numerical (about 700 (n,N) pairs of the alternating-sum signature law, recorded in the project's internal records; *evidence, not proof*).

Example 19.33 (Lee–Yang at weight six, revisited)**.** At $n = 2$, $N = 6$ the retained towers are $m = 1$ ($L_{-1}^4\omega$) and $m = 3$ (Q_6); $m = 2$ is the deleted Q_4 (whose tower $L_{-1}^2 Q_4$ vanishes in the quotient). $\rho_3 = 36 \cdot 29/2520 = 29/70$, so $(Q_6|Q_6) = \frac{1}{2}\binom{10}{2} \cdot (-\frac{22}{5})(-\frac{22}{5} + \frac{29}{70}) = \frac{45}{2} \cdot \frac{22}{5} \cdot \frac{279}{70} > 0$, in agreement with the positive pivot 682/35 of Example 19.18. The two examples are two views of one computation: Example 19.18 reads the signs off the Gram-matrix minors (the minors criterion of Section 19.6), while this example reads them off the norms of the tower vectors that span the layers; their agreement is the layer decomposition at work.

Stale status lines in the Virasoro docstrings

In the earlier state of the library against which this chapter was first written, `VirasoroGradedUnitarity.lean` said "No `Core.RealStructure` is constructed on $L(c,0)$" and "No positivity statement is proved of anything". Both were already out of date then: real

structures are constructed (Theorem 19.23) and the through-two positivity theorem is proved (Theorem 19.32). The correct, still-true part is that the full `VirGradedUnitary` is never asserted. At a pre-release build commit the file header no longer contains these two sentences; it states that nothing in the repository proves graded unitarity of $L(c,0)$ and points to the through-two truncation `boundary_gradedUnitaryThroughTwo`.
The book does not repair docstrings: editing a `.lean` file (even a comment) changes the file's blob hash recorded in `manifest.json`, so docstring repairs are left to the library's maintainers. A reader of the Lean source should therefore trust the theorem statements quoted in this chapter, not the prose status lines in the file headers. This is a documentation-only defect, listed with the other stale docstrings in Section 19.17.

19.9 The Lee–Yang model

The Lee–Yang model is the boundary model $n = 2$, $M(2,5)$, $c = -22/5$. It is the testing ground of the whole graded-unitarity programme and the library proves a number of facts about it that are not about positivity: the derivation of its central charge from a singular vector, the level-four structure of its maximal ideal, its C_2-cofiniteness and strong finiteness, and the Zhu-algebra relation that pins its two lowest weights. Rigidity (every graded first-order deformation of $L(-22/5,0)$ is trivial) is Chapter 8, §8.7.2.

Physical meaning

The Yang–Lee edge singularity: the Ising model in an *imaginary* magnetic field ih has partition-function zeros (Lee–Yang zeros) on the imaginary h-axis; at the edge of their distribution the model is critical, and Cardy (1985) identified the critical theory with the $M(2,5)$ minimal model, a non-unitary CFT with one nontrivial primary φ of weight $h = -1/5$ (scaling dimension $-2/5$, so $\langle\varphi\varphi\rangle$ grows with distance — the hallmark of non-unitarity). In four dimensions, $L(-22/5,0)$ is the chiral algebra of the simplest Argyres–Douglas theory (A_1, A_2), which *is* unitary; graded unitarity is the reconciliation of these two facts.

19.9.1 The singular vector and the central charge

Theorem 19.34 (The Lee–Yang central charge is forced). *Let $c \in \mathbb{C}$. There is a nonzero vector $\alpha L_{-2}^2\mathbf{1} + \beta L_{-4}\mathbf{1} \in V(c,0)_4$ killed by L_1 and L_2 if and only if $c = -22/5$. At $c = -22/5$ one such vector is $s = 5L_{-2}^2\mathbf{1} - 3L_{-4}\mathbf{1}$.*

File `VOA/Examples/LeeYangSingular.lean`.

```
noncomputable def leeYangC : ℂ := -22 / 5

noncomputable def leeYangSingular : VirUniv leeYangC :=
  (5 : ℂ) • L2L2vac leeYangC + (-3 : ℂ) • L4vac leeYangC

theorem exists_level4_singular_iff (c : ℂ) :
    (∃ α β : ℂ, α • L2L2vac c + β • L4vac c ≠ 0
        ∧ Lop c 1 (α • L2L2vac c + β • L4vac c) = 0
        ∧ Lop c 2 (α • L2L2vac c + β • L4vac c) = 0)
      ↔ c = -22 / 5 := by
```

From the mathematics to the Lean statement

`L2L2vac c` $= L_{-2}L_{-2}\mathbf{1}$ and `L4vac c` $= L_{-4}\mathbf{1}$ in $V(c,0)$ (defined in the same file); `Lop c n` is the Virasoro mode L_n. Since $V(c,0)_4$ is spanned by these two vectors (`gradingVir_four`), the

left side says "$V(c,0)_4$ contains a nonzero singular vector". Exactly Theorem 19.34. (A vector killed by L_1, L_2 is killed by all L_n, $n > 0$: `Lop_pos_ann`.)

Proof on paper. $L_1 L_{-2}^2 \mathbf{1} = 3L_{-3}\mathbf{1}$, $L_1 L_{-4}\mathbf{1} = 5L_{-3}\mathbf{1}$, $L_2 L_{-2}^2 \mathbf{1} = (c+8)L_{-2}\mathbf{1}$, $L_2 L_{-4}\mathbf{1} = 6L_{-2}\mathbf{1}$. The linear system $3\alpha + 5\beta = 0$, $(c+8)\alpha + 6\beta = 0$ has a nonzero solution iff $18 - 5(c+8) = -(5c+22) = 0$; the solution is $(5, -3)$. □

Physical meaning

The central charge of the Yang–Lee CFT is not an input: it is the unique value at which the stress-tensor OPE closes with a null state at level four, the relation $:TT: \propto \partial^2 T$ that truncates the vacuum module. Cardy derived $c = -22/5$ from exactly this null vector.

What the machine verified

Proved, axiom-clean, unconditional.

Theorem 19.35 (Level four of the maximal ideal; non-simplicity of $V(-22/5, 0)$)**.** *The weight-four part of the maximal proper ideal of $V(-22/5, 0)$ is the line $\mathbb{C}s$; in particular $V(-22/5, 0)$ is not simple.*

Files `VOA/Examples/LeeYangKac.lean` and `VOA/Examples/LeeYangProper.lean`.

```
theorem maxIdealVir_leeYang_inf_grading_four :
    maxIdealVir leeYangC ⊓ gradingVir leeYangC 4 = Submodule.span ℂ {leeYangSingular} := by

theorem virasoroVOA_leeYang_not_isSimple : ¬ (virasoroVOA leeYangC).IsSimple :=
  not_isSimple_of_idealGen_proper leeYangSingular_ne_zero vacuum_notMem_idealGen
```

From the mathematics to the Lean statement

`gradingVir c 4` is the weight-four subspace of $V(c,0)$ (`VirasoroGrading.lean`); `maxIdealVir c` the maximal proper graded ideal; `(virasoroVOA c).IsSimple` the VOA simplicity predicate (Chapter 5). The second theorem's one-line proof term is informative: the ideal generated by s is proper because it does not contain the vacuum (all its states have weight ≥ 4, `four_le_leeYangEnergy`). The docstring of the first warns that it is a level-four statement only: the full description of $\mathcal{M}_{-22/5}$ (the ideal generated by s, which is the Rogers–Ramanujan character identity) is **not** proved.

Proof on paper. A vector of a proper ideal pairs to zero with everything under the invariant form (the form is $\mathbf{1}$-valued and the ideal misses $\mathbf{1}$), so $\mathcal{M} \cap V_4$ lies in the radical of the level-four Gram form; the library computes that radical to be $\mathbb{C}s$ (`radBil_shapForm_leeYang_eq_span`) and shows $s \in \mathcal{M}$. □

Physical meaning

The only null state at level four is s; in the Lee–Yang CFT the vacuum sector at weight four is one-dimensional ($\partial^2 T$ only).

What the machine verified

Both proved, axiom-clean, unconditional.

Two different level-four forms

`LeeYangKac.lean` computes the Gram matrix of the "top-mode" (Shapovalov) form $\langle a,b\rangle_4 = \varepsilon(a_{(7)}b)$ of `RigidBridge.shapForm` in the basis $(L^2_{-2}\mathbf{1}, L_{-4}\mathbf{1})$: `gram4_eq : gram4 c hvac = !![c ^ 2 / 2 + 40 * c, 63 * c; 63 * c, 105 * c]`, with `det_gram4 : (gram4 c hvac).det = 21 * (c ^ 2 * (5 * c + 22) / 2)`. This matrix is *not* 21 times the textbook contravariant Kac matrix $\left(\begin{smallmatrix} \frac{c}{2}(c+8) & 3c \\ 3c & 5c \end{smallmatrix}\right)$ (the $(1,1)$ entries differ by $-2c(5c+22)$), although the determinants agree up to the factor 21. The reason is that $L^2_{-2}\mathbf{1}$ is not quasi-primary, and $a_{(2k-1)}b$ equals the invariant pairing (up to $(-1)^k$) only for quasi-primary a. The file documents this correctly. The docstring of `shapForm` in `VOA/Core/RigidityBridge.lean` (Chapter 8), which says "This is the form whose Gram matrix is the level-k Kac matrix", is **inaccurate** in general (documentation defect).

19.9.2 C_2-cofiniteness and strong finiteness

Theorem 19.36 (Lee–Yang is strongly finite). *$L(-22/5,0)$ is C_2-cofinite, with $\dim L(-22/5,0)/C_2 \le 2$, and it is strongly finite (simple, self-dual and C_2-cofinite). If it is moreover admissibly rational (or regular), it is strongly rational.*

File `VOA/Examples/LeeYangC2.lean`.

```
theorem leeYang_c2Cofinite : C2Cofinite (virasoroSimple leeYangC) :=

theorem finrank_a₂_leeYang_le_two :
    Module.finrank ℂ (A₂ (virasoroSimple leeYangC)) ≤ 2 := by

theorem leeYang_stronglyFinite : StronglyFinite (virasoroSimple leeYangC) where
  simple := virasoroSimple_isSimple leeYangC
  selfDual := virasoroSimple_selfDual leeYangC
  c2Cofinite := leeYang_c2Cofinite

theorem leeYang_stronglyRational_of_admissiblyRational
    (h : AdmissiblyRational (virasoroSimple leeYangC)) :
    StronglyRational (virasoroSimple leeYangC) where
```

From the mathematics to the Lean statement

`C2Cofinite W` is `FiniteDimensional ℂ (A₂ W)`, where `A₂ W` is the quotient $V/C_2(V)$ (`VOA/Modules/C2Cofinite.lean`; the name `A₂` is *not* the second higher Zhu algebra, cf. Chapter 12). `StronglyFinite` is the structure of Chapter 12 (Definition 12.43): simple, self-dual, C_2-cofinite; the three fields are supplied explicitly in the quoted proof term, so the reader can see that simplicity and self-duality are the general Virasoro facts and only C_2-cofiniteness is specific. The last theorem has hypothesis `AdmissiblyRational`, which is **not** proved for Lee–Yang: rationality of $L(c_{p,q},0)$ (Wang 1993) is not in the library. Exactly Theorem 19.36.
Non-vacuity. `leeYang_conformalVector_ne_zero`: the VOA is not the trivial one.

Proof on paper. $L(c,0)$ is strongly generated by ω (every state is a combination of iterated products of ω, `virasoroSimple_iterProdSpan_conformalVector_eq_top`). In $R_V = V/C_2(V)$, $L_{-4}\mathbf{1} = \omega_{(-3)}\mathbf{1} \in C_2(V)$, so the relation $5L^2_{-2}\mathbf{1} - 3L_{-4}\mathbf{1} = 0$ becomes $5[\omega]^2 = 0$. A commutative algebra generated by one nilpotent element x with $x^2 = 0$ is spanned by $1, x$; the library's criterion `c2Cofinite_of_iterProdSpan_of_isNilpotent` (from the triplet files) turns this into $\dim R_V \le 2$. □

Physical meaning

$R_V = \mathbb{C}[x]/(x^2)$ is the coordinate ring of the *associated variety*, here a fat point: the Lee–Yang theory has no Higgs branch, as expected for the (A_1, A_2) Argyres–Douglas theory, and C_2-cofiniteness is the finiteness that underlies modularity of its two characters (the Rogers–Ramanujan functions).

What the machine verified

`leeYang_c2Cofinite`, `finrank_a₂_leeYang_le_two`, `leeYang_stronglyFinite`: proved, axiom-clean, unconditional. The `StronglyRational` corollaries are conditional on `AdmissiblyRational` or `Regular` (open in the library).

19.9.3 The Zhu-algebra relation

Theorem 19.37 (Lee–Yang lowest weights). *In Zhu's algebra $A(L(-22/5, 0))$ one has $5[\omega]^2 + [\omega] = 0$. Consequently, on any nonzero $A(V)$-module on which $[\omega]$ acts by a scalar h, $h \in \{0, -1/5\}$; every lowest-weight module has lowest weight 0 or $-1/5$.*

File `VOA/Examples/LeeYangZhu.lean`.

```
theorem leeYang_zhu_polynomial :
    (5 : ℂ) • Amul (zhuRingData_holds WLY) omegaA omegaA + omegaA = 0 := by

theorem omegaScalar_eq_zero_or_neg_one_fifth (U : AMod WLY) [Nontrivial U.carrier]
    {h : ℂ} (hU : U.OmegaScalar h) : h = 0 ∨ h = -(1 / 5 : ℂ) := by

theorem lowestWeight_eq_zero_or_neg_one_fifth (P : LWModule WLY) :
    P.h = 0 ∨ P.h = -(1 / 5 : ℂ) := by
```

From the mathematics to the Lean statement

`WLY` abbreviates `virasoroSimple leeYangC`; `omegaA` is the class $[\omega]$ in Zhu's algebra `A WLY`, `Amul` its product (Chapter 12, §12.4). `AMod` is a bundled $A(V)$-module, `OmegaScalar h` says $[\omega]$ acts as $h \cdot \mathrm{id}$, `LWModule` a lowest-weight module (Chapter 12). Exactly Theorem 19.37. Only the *necessary* condition is proved: that both weights 0 and $-1/5$ are realised (and that these are all irreducibles) is not.

Proof on paper. In Zhu's algebra $[(L_{-1} + L_0)a] = 0$, so $[L_{-1}a] = -\mathrm{wt}(a)[a]$; hence $[L_{-3}\mathbf{1}] = [L_{-1}\omega] = -2[\omega]$ and $[L_{-4}\mathbf{1}] = \frac{1}{2}[L_{-1}^2\omega] = 3[\omega]$ (`mk_mkQ_L4vac`); and $[L_{-2}^2\mathbf{1}] = [\omega_{(-1)}\omega] = [\omega] * [\omega] + 2[\omega]$ (`mk_mkQ_L2L2vac`, using $a * b = \sum_j \binom{\mathrm{wt}\,a}{j} a_{(j-1)}b$). So $0 = [s] = 5([\omega]^2 + 2[\omega]) - 9[\omega] = 5[\omega]^2 + [\omega]$, and on a module where $[\omega] = h$, $h(5h + 1) = 0$. □

Physical meaning

The two primaries of the Yang–Lee CFT: the identity ($h = 0$) and φ ($h = -1/5$). The negative weight is non-unitarity made visible.

What the machine verified

Proved, axiom-clean, unconditional. Also `admissibleBottomScalar_eq_zero_or_neg_one_fifth` for the bottom of any admissible module (with the extra hypotheses that the bottom is nonzero and L_0 acts by a scalar there, which the docstring states are not part of `AdmissibleModule`).

19.9.4 Other Lee–Yang files

`LeeYangGram.lean` computes level-four Gram entries at $c = -22/5$; `LeeYangRigidity.lean` instantiates the "rigidity bridge" of Chapter 8 at Lee–Yang, but only under an explicit undischarged hypothesis `hself` (`leeYangSingular_not_liftable`, `leeYang_F2_lt_F1`); the unconditional rigidity theorem is `VirDeformModes.leeYang_graded_rigidity` of Chapter 8.

Theorem 19.38 (Abstract Riccati tower; finite-dimensional core of a proposed length induction)**.** *Let $(Q_N, S_N, K_N)_{N\in\mathbb{N}}$ be real square matrices and $a_N > 0$, with lowering matrices $A_{N,i}$, such that for all N: Q_N is positive definite, K_N is positive semidefinite, $S_N = Q_N^{-1}K_NQ_N^{-1}$, $S_NQ_NS_N - a_NS_N = \sum_{i<N} A_{N,i}^T S_i A_{N,i}$, and either S_N is invertible or the $A_{N,i}$ have trivial joint kernel. Then every S_N is positive definite and $S_N - a_NQ_N^{-1}$ is positive semidefinite.*

File `VOA/Examples/LeeYangRiccatiReduction.lean`.

```
theorem tower_posDef (Q S K : ∀ N, Matrix (ι N) (ι N) ℝ) (a : ℕ → ℝ)
    (A : ∀ N, (i : Fin N) → Matrix (ι i) (ι N) ℝ)
    (hQ : ∀ N, (Q N).PosDef) (hK : ∀ N, (K N).PosSemidef)
    (hrec : ∀ N, S N = (Q N)⁻¹ * K N * (Q N)⁻¹)
    (hric : ∀ N, S N * Q N * S N - a N • S N = towerSource S A N)
    (ha : ∀ N, 0 < a N)
    (hker : ∀ N, IsUnit (S N) ∨ ∀ v : ι N → ℝ, (∀ i : Fin N, A N i *ᵥ v = 0) → v = 0) :
    ∀ N, (S N).PosDef ∧ (S N - a N • (Q N)⁻¹).PosSemidef := by
```

From the mathematics to the Lean statement

`towerSource S A N` $= \sum_{i<N} A_{N,i}^T S_i A_{N,i}$; `*ᵥ` is matrix–vector multiplication. Exactly Theorem 19.38. This is pure linear algebra: **no Lee–Yang matrix is shown to satisfy any hypothesis**. The file docstring says so ("the uniform inequality $K_N \geq 0$ is an open hypothesis, not a theorem, and this file must not be cited as a proof of graded unitarity"). Note also that the hypotheses `hK` and `hrec` already give $S_N \geq 0$; the content is the upgrade to definiteness and the Riccati margin.

Proof on paper. $S_N = Q_N^{-1}K_NQ_N^{-1} \geq 0$. By strong induction the right side of the Riccati identity is ≥ 0, and > 0 under the joint-kernel condition; a vector in the radical of S_N is then killed by the right side, contradiction. The margin: in the Q-whitened frame the eigenvalues λ of S satisfy $\lambda(\lambda + a) \geq 0$ with $\lambda > 0$, forcing $\lambda \geq$ the claimed bound. □

Physical meaning

A proposed proof strategy for all-length graded unitarity of Lee–Yang: positivity at length $r + 1$ is reconstructed from length r through a quadratic (Riccati) identity coming from the null vector. Only the matrix algebra is formalised.

What the machine verified

Proved, axiom-clean. Its hypotheses are not instantiated anywhere; it carries no VOA content.

19.10 Program B: finite certificates around the all-length problem

Six files record exact finite computations and interfaces produced by the project's attempt on the full Kaufmann conjecture ("Program B"). None of them proves a statement about a VOA beyond finite arithmetic; all are axiom-clean (some use `decide`, i.e. kernel evaluation, never `native_decide`). We list them with their headline and their honest scope.

Theorem 19.39 (Length-three counting and negative definiteness, weights 12–24). *(a) For $0 \le k < 33$, the number of Lee–Yang admissible length-three partitions of $k+12$ equals the number of partitions of k into at most three parts; there are none below weight 12. (b) The explicit rational "new-tower" blocks N_M at Lee–Yang weights $M = 12, \dots, 24$ are negative definite.*

File `VOA/Examples/LengthThreeQPFrame.lean`.

```
theorem a3count_eq_pLe3_shift :
    ∀ k ∈ List.range 33, a3count (k + 12) = pLe3 k := by decide

theorem negDef_w12 : ∀ x : ℚ, x ≠ 0 → n12_00 * x ^ 2 < 0 :=
```

From the mathematics to the Lean statement

`a3count n` counts triples $\ell_1 \ge \ell_2 + 2 \ge \ell_3 + 4$, $\ell_3 \ge 2$ with sum n (the Andrews–Gordon gap condition of $M(2,5)$; the Lean encoding enumerates (ℓ_2, ℓ_3) with $\ell_1 = n - \ell_2 - \ell_3$); `pLe3 k` counts partitions into ≤ 3 parts. `n12_00` is a rational *datum* (an output of an external Python engine), not derived in Lean from the Shapovalov form. The docstring is explicit: "the Lean file proves their internal identities and sign structure, not their provenance". That these counts are *dimensions* rests on the admissible-basis theorem, external.

Physical meaning

Evidence for the length-three rung of graded unitarity in Lee–Yang: the exact-length-three layers at weights 12–24 have the predicted sign $(-1)^3$, assuming the external matrices are correct.

What the machine verified

Proved by `decide`/`norm_num`, axiom-clean. **Numerical evidence encoded as data**, not a theorem about $L(-22/5, 0)$.

Theorem 19.40 (Weil parity at cutoff three). *For the thirteen balanced-tree channels of the enriched Lee–Yang fusion ring at cutoff three, the channel polynomials sum to $uv^7 + 5u^2v^6 + 6u^3v^5 + u^4v^4$, the recorded channel signs equal the Weil signs i^{p-q} of their bidegrees, and every class-uniform vacuum-anchored landing induces the "option (a)" twist.*

File `VOA/Examples/WeilPolarizedChannelParity.lean`.

```
theorem weil_polarized_twist_option_a :
    toMv (sumP (channels.map channelPoly))
        = X 0 * X 1 ^ 7 + C 5 * X 0 ^ 2 * X 1 ^ 6 + C 6 * X 0 ^ 3 * X 1 ^ 5
            + X 0 ^ 4 * X 1 ^ 4
      ∧ (∀ s : Sector,
          Xsign s = weil (sectorBidegree s) ∧ kappaSign s = weil (sectorBidegree s))
      ∧ (∀ L : Landing, IsUniformLanding L → (L.k0 : ℕ) % 2 = 0 →
          ∀ s : Sector, twist L s = optionA s)
      ∧ ∀ L : Landing, IsUniformLanding L → ¬ ∀ s : Sector, twist L s = optionC s :=
```

From the mathematics to the Lean statement

`toMv` interprets a list-encoded polynomial in Mathlib's `MvPolynomial (Fin 2) ℤ` ($X_0 = u$, $X_1 = v$). `Xsign`, `kappaSign`, `optionA`, `optionC` and the fusion weights `w` are **external data** (Godfard's enriched fusion ring, Dotsenko–Fateev channel norms), stated as definitions. What is proved is the finite combinatorics connecting them. The docstring's "Not claimed" list (no Hodge filtration on conformal blocks, no analytic magnitudes) is accurate.

Physical meaning

A heuristic Hodge-theoretic explanation of the graded-unitarity signs in terms of conformal blocks of the Lee–Yang fusion category; exploratory.

What the machine verified

Proved by `decide`, axiom-clean. Combinatorics on external data; no VOA content.

Theorem 19.41 (Minor signs from a congruence normal form). *Let S be a real symmetric $n\times n$ matrix, $d : \{1..n\} \to \mathbb{N}$, U upper unitriangular and G positive definite with $U^T S U = \mathrm{diag}((-1)^{d_i})\, G$. Then $(-1)^{\sum_{j<k} d_j} \det S_{\le k} > 0$ for all k, and every constant-degree layer Schur complement is $(-1)^r$-definite.*

File `VOA/Examples/PolarizedReesStrongGenerator.lean`.

```
theorem sign_det_leadingPrincipal_pos (Q : MinorPayload n) {k : ℕ}
    (hk : k ≤ n) :
    0 < (-1 : ℝ) ^ cumulativeDegree Q.d hk
        * (leadingPrincipal Q.S hk).det := by
```

From the mathematics to the Lean statement

`MinorPayload n` bundles S, d, U, G and the hypotheses (field `cross : Uᵀ * S * U = signDiag d * G`). The file's docstring makes an unusually honest "logical-distance disclosure": over $\mathbb{R}$ the field `cross` is *equivalent* to the conclusion (by LDL^T decomposition), so the theorem is a repackaging; all the difficulty lies in producing `cross` for a real model, which the file does not do. We agree with that assessment.

Physical meaning

The finite endgame of a proposed "polarised bi-Rees" proof: if a deformation argument produced the normal form, graded unitarity at that weight would follow.

What the machine verified

Proved, axiom-clean. Interface-level; the hypotheses are not produced for any VOA.

The remaining three files are interfaces:
`ScreenedReesInterface.lean` (a structure `ScreenedRees.Hypotheses` of filtration and Felder-descent conditions on a hypothetical screened map, plus the trivial transfer `isPosOn_of_metricTransport`: an injective map that pulls a positive form back to a positive multiple of the source form transfers positivity); `LogarithmicHeterotypicJet.lean` (first-order jets $f_0 + \epsilon f_1$ of linear maps and the Leibniz/Bockstein bookkeeping, pure algebra); `FreeFieldPiRFiltration.lean` (a combinatorial degree `rDegree` on free-field monomial labels, "number of derivatives of $\delta - \phi$ plus lattice charge", after Beem–Meneghelli–Rastelli). Their docstrings state their limits accurately.

19.11 Drinfeld–Sokolov reduction for $\mathfrak{sl}_2$

19.11.1 The idea

Quantum Hamiltonian (Drinfeld–Sokolov, DS) reduction produces W-algebras from affine Kac–Moody algebras by "gauging" a nilpotent subalgebra. For $\mathfrak{sl}_2$ at level k and the principal nilpotent f, one imposes the first-class constraint $e(z) = 1$ on the raising current. BRST-quantising it introduces

one pair of fermionic ghosts (b, c) and the BRST charge

$$Q = \oint c(z)\,\big(e(z)+1\big)\,dz, \qquad Q^2 = 0,$$

on the complex $V^k(\mathfrak{sl}_2) \otimes \mathrm{bc}$; the cohomology is the Virasoro VOA of central charge

$$c(k) = 13 - 6(k+2) - \frac{6}{k+2}.$$

Equivalently (Feigin–Frenkel), the reduction is the kernel of a screening operator $\oint e^{\alpha_+\phi}$ on a free boson with background charge. At admissible levels $k = -2 + p/q$, $c(k) = c_{p,q}$ and the simple quotient of the reduction is the minimal model (Arakawa). Physically the reduction is the passage from $SL(2)$ WZW models to Liouville/minimal models by gauging (Polyakov's $SL(2)$ gravity; Bershadsky–Ooguri).

Theorem 19.42 (DS arithmetic). *(a) For $p, q \neq 0$, $c(-2+p/q) = 1-6(p-q)^2/(pq)$. (b) For $k+2 \neq 0$, $c(k) = \frac{3k}{k+2} + (-2) - 12k \cdot \frac{1}{2}$, where $\frac{3k}{k+2}$ is the library's Sugawara central charge of $V^k(\mathfrak{sl}_2)$, -2 the library's bc central charge, and $\frac{1}{2} = \langle \rho^\vee, \rho^\vee \rangle$ computed from the library's Killing form.*

File `VOA/Examples/DSReductionSl2.lean`.

```
noncomputable def dsCentralCharge (k : ℂ) : ℂ := 13 - 6 * (k + 2) - 6 / (k + 2)

theorem dsCentralCharge_eq_minimalModel {p q : ℂ} (hp : p ≠ 0) (hq : q ≠ 0) :
    dsCentralCharge (-2 + p / q) = minimalModelCentralCharge p q := by

theorem dsCentralCharge_eq_affine_add_ghost (k : ℂ) (hk : k + 2 ≠ 0) :
    dsCentralCharge k
      = (AffineVOA.affineSl2VOA_closed k hk).centralCharge
        + Ghost.ghostCentralCharge 1 - 12 * k * rhoCheckNormSq := by
```

From the mathematics to the Lean statement

`minimalModelCentralCharge p q` $= 1 - 6(p-q)^2/(pq)$. `affineSl2VOA_closed k hk` is the universal affine VOA $V^k(\mathfrak{sl}_2)$ of Chapter 9, with central charge $3k/(k+2)$. `Ghost.ghostCentralCharge 1` is a *number* -2 (the library proves no Virasoro structure on the ghost system; Chapter 17); `rhoCheckNormSq` $= \kappa(h,h)/4 = 1/2$. So (b) is an arithmetic identity whose terms are tied to library objects; it is not a theorem that some BRST cohomology has that central charge (the docstring says so).

Proof on paper. Field arithmetic with $t = k+2$: $13 - 6t - 6/t = 3k/t - 2 - 6k$. □

Physical meaning

The ghost-number anomaly count: $c_W = c_{\mathrm{WZW}} + c_{\mathrm{ghosts}} - 12k|\rho^\vee|^2$, the last term coming from the improvement of the stress tensor needed to make the constraint $e = 1$ conformally invariant.

What the machine verified

Proved, axiom-clean. Arithmetic only.

Theorem 19.43 (The BRST charge squares to zero). *For $k+2 \neq 0$, the operator $Q = \sum_m (e+\mathbf{1})_{(m)} \otimes c_{(-1-m)}$ on $V^k(\mathfrak{sl}_2) \otimes \mathrm{bc}$ satisfies $Q^2 = 0$.*

File `VOA/Examples/DSReductionSl2.lean`.

```
noncomputable def dsQ (k : ℂ) (hk : k + 2 ≠ 0) :
    End ℂ (AffineVOA.WakModule k ⊗[ℂ] SympFerm.FockSF) :=
  TensorVA.rawCoeff (affSVA k hk) Ghost.bcGhostSVA (ePlusOne k) cGhost (-1)

theorem dsQ_mul_self (k : ℂ) (hk : k + 2 ≠ 0) : dsQ k hk * dsQ k hk = 0 :=
  rawCoeff_mul_self_eq_zero _ _ (coeffCommute_ePlusOne k hk) coeffAnticommute_cGhost (-1)
```

From the mathematics to the Lean statement

`WakModule k` is the carrier of $V^k(\mathfrak{sl}_2)$, `SympFerm.FockSF` the Fock carrier of the *bc* system `Ghost.bcGhostSVA` (Chapter 17), `affSVA` is V^k viewed as a super vertex algebra, `ePlusOne k` $= e_{(-1)}\mathbf{1} + \mathbf{1}$, `cGhost` the state c. `TensorVA.rawCoeff ... (-1)` is the z^{-1}-coefficient of $Y(e+\mathbf{1},z) \otimes Y(c,z)$, i.e. the zero mode of the tensor field (`dsQ_eq_mode_tenY`). The one-line proof term exhibits the two inputs: the coefficients of $Y(e+\mathbf{1},z)$ commute and those of $Y(c,z)$ anticommute.

Proof on paper. $Q^2 = \sum_{m,n} a_m b_{-1-m} a_n b_{-1-n}$ with $a_m a_n = a_n a_m$ ($[e_m, e_n] = 0$: no structure constant and $\kappa(e,e) = 0$) and $b_i b_j = -b_j b_i$ ($\{c_i, c_j\} = 0$); the swap $(m,n) \mapsto (n,m)$ negates the summand, so the sum vanishes. □

Physical meaning

Nilpotency of the BRST charge is gauge invariance of the constrained WZW model; the constant "+1" does not spoil it because it commutes with everything.

What the machine verified

Proved, axiom-clean, unconditional. **What is not done:** the BRST cohomology. `dsReductionSl2` takes as *input* a `BRST.BRSTComplex` whose differential is `dsQ`; none is constructed. Two obstructions are recorded: the super Leibniz rule `Q_deriv` is unavailable, and, as `DSMorphismSl2.lean` shows, `dsQ` splits into a weight-preserving half and a half that lowers weight by one (`dsQ_split`, `dsQlow_lowers_grading`), so the `Q_wt` axiom of `BRSTComplex` (Chapter 5, Definition 5.45) cannot hold for the naive grading — one needs the improved DS grading, which is not built.

Theorem 19.44 (The DS complex, the embedding, and the screening route). *(a) For $k+2 \neq 0$, $V^k(\mathfrak{sl}_2) \otimes \mathrm{bc}$ is a super vertex algebra and $x \mapsto x \otimes \mathbf{1}$ is an injective homomorphism of vertex superalgebras. (b) For $p \geq 1$ (level $k = p-2$), the kernel of the screening operator $(e^{\alpha})_{(0)}$ on the rank-one lattice VOA $V_{\sqrt{2p}\mathbb{Z}}$ with deformed conformal vector is a VOA of central charge $c(p-2)$, a proper subalgebra, and its inclusion is a VOA homomorphism.*

File `VOA/Examples/DSMorphismSl2.lean`.

```

theorem dsScreeningIncl_isVOAHom (p : ℕ) (hp : 1 ≤ p) :
    IsVOAHom (dsLatticeScreening p hp) (LatGen.Triplet.tripletLatticeVOA p hp)
      (dsScreeningIncl p hp) where
```

From the mathematics to the Lean statement

`TensorVA.tensorSVA` is the tensor product of Chapter 5 (Theorem 5.41); its hypothesis `TensorGradingHyp`, open there, is discharged here (`dsTensorGradingHyp`). `tripletLatticeVOA p hp` is the lattice VOA $V_{\sqrt{2p}\mathbb{Z}}$ with the background-charge conformal vector (Chapter 18); `dsScreeningState p` is e^{α}, $\alpha^2 = 2p$, of weight one; `Screening.screeningKernel` is Definition 5.30; `dsLevelOfP p` $= p - 2$; `IsVOAHom` preserves vacuum and all products. Note $c(p-2) = 1 - 6(p-1)^2/p = c_{1,p}$, the logarithmic $(1,p)$ central charge. **Not claimed:** that the screening kernel is the Virasoro VOA, nor anything at non-integer $k+2$ (Lee–Yang's $k = -8/5$ is out of reach of this route, since $\alpha^2 = 4/5$ is not an even integer). `RoutesAgreeSl2` (the Feigin–Frenkel comparison) is a `def : Prop`, unproved.

Proof on paper. (a) The tensor-product construction plus two graded-linear-algebra facts (independence of the convolution grading, via the weight operator; finite-dimensionality, since both factors are $\mathbb{N}$-graded). Injectivity: $\mathbf{1}_{bc} \neq 0$. (b) The kernel of a weight-one screening zero mode is a vertex subalgebra containing ω; its central charge is the ambient one, $1 - 12\lambda_p^2 = c(p-2)$; it is proper because $e^{-\alpha}$ is not annihilated ($(e^{\alpha})_{(0)}e^{-\alpha} \neq 0$). □

Physical meaning

(a) is the statement that the affine currents survive in the BRST complex as the ghost-number-zero, ghost-vacuum sector; (b) is the Feigin–Frenkel "free-field" description of the reduced theory at integral $k+2$, where the screening momenta are lattice vectors.

What the machine verified

All proved, axiom-clean, unconditional. The identification of either route with $L(c,0)$, and the Feigin–Frenkel theorem, are open.

19.12 Weight-one positivity of affine $\mathfrak{sl}_2$ at level $-8/5$

Before the all-level theorem of Section 19.14, the library records the first unconditional positivity fact on the affine side: at the boundary admissible level $k = -8/5$, whose simple quotient is the chiral algebra of the (A_1, D_5) Argyres–Douglas theory, the three weight-one current states of $V^{-8/5}(\mathfrak{sl}_2)$ have the graded-unitarity sign.

Theorem 19.45 (Weight-one Hermitian positivity at $k = -8/5$). *On the three weight-one current states of $V^{-8/5}(\mathfrak{sl}_2)$ the canonical invariant form is $(J^a|J^b) = \frac{8}{5}\kappa(a,b)$. With the compact conjugation $\theta(z_e, z_f, z_h) = (-\bar{z}_f, -\bar{z}_e, -\bar{z}_h)$, the signed form $-(\theta z|w)$ equals $\frac{8}{5}(\bar{z}_e w_e + \bar{z}_f w_f + 2\bar{z}_h w_h)$, which is positive definite.*

File `VOA/Examples/AffineSl2GradedUnitarityLow.lean`.

```
theorem canonicalForm85_currentState (a b : Fin 3) :
    canonicalForm85.form (currentState (-8 / 5 : ℂ) a)
```

```
      (currentState (-8 / 5 : ℂ) b) = (8 / 5 : ℂ) * kappa a b := by

theorem compactCurrentSignedForm85_eq_canonical (z w : CurrentCoords) :
    compactCurrentSignedForm85 z w =
      -canonicalForm85.form (currentCoordinates85 (compactCurrentConj z))
        (currentCoordinates85 w) := by

theorem compactCurrentSignedForm85_positive :
    IsPosOn compactCurrentSignedForm85 (τ : Submodule ℂ CurrentCoords) := by
```

From the mathematics to the Lean statement

`canonicalForm85` is the canonical normalised invariant form on $V^{-8/5}(\mathfrak{sl}_2)$; `currentState k a` is $J^a_{-1}\mathbf{1}$; `kappa a b` the Killing matrix in the Chevalley basis (e, f, h). `CurrentCoords` $= \mathbb{C}^3$, `currentCoordinates85 z` $= \sum_a z_a J^a_{-1}\mathbf{1}$, `compactCurrentConj` is θ. `compactCurrentSignedForm85` is *defined* by the displayed explicit formula; so the content is the identity with $-(\theta z|w)$ and the sign $\frac{8}{5} > 0$. The sign $+\frac{8}{5}$ (for $k < 0$) comes from the FHL convention $u_{(1)}v = -(u|v)\mathbf{1}$. **Scope:** θ is *not* a `RealStructure` on the VOA (the docstring says so: no mode covariance, no descent), and the statement concerns three vectors only.

Proof on paper. $J^a_{(1)}J^b_{-1}\mathbf{1} = k\kappa(a,b)\mathbf{1}$, so $(J^a|J^b) = -k\kappa(a,b) = \frac{8}{5}\kappa(a,b)$. Then $-(\theta z|w) = -\frac{8}{5}\sum \kappa_{ab}(\theta z)_a w_b$, and with $\kappa_{ef} = 1$, $\kappa_{hh} = 2$ this is the displayed sum of squares on the diagonal. □

Physical meaning

The currents of $L_{-8/5}(\mathfrak{sl}_2)$ — the flavour currents of the (A_1, D_5) Argyres–Douglas theory, whose $SU(2)$ flavour symmetry has $k_{4d} = -2k_{2d} = 16/5 > 0$ — have the graded-unitarity sign $(-1)^1$ at R-charge one: a 4d unitarity bound seen in 2d.

What the machine verified

Proved, axiom-clean, unconditional. Also `simpleCorrectedGoodFiltration85`: an unconditional good filtration on the simple quotient, induced from the corrected affine filtration.

19.13 Transfer of graded unitarity along isometric embeddings

This section records a piece of linear algebra about the graded-unitarity predicate that concerns no particular VOA: graded unitarity pulls back along an injective, weight-preserving, isometric and ρ-compatible linear map, provided the map is *orthogonally reducing*, i.e. compatible with the flags and with their orthogonal layers. It is the abstract input of the coset transfer of Chapter 28, which instantiates it through a filtered linear isomorphism (`LeeYangCosetTransferFiltered.lean`). The Lean file and namespace carry the prefix `InverseDS` for historical reasons; nothing in this section depends on the inverse Drinfeld–Sokolov programme.

Definition 19.46 (Graded isometric embedding; orthogonal reduction)**.** Given VOAs A, T with invariant forms and real structures, a *graded isometric embedding* is an injective linear $\iota : A \to T$ preserving weights, with $B_A(x,y) = B_T(\iota x, \iota y)$ and $\iota\rho_A = \rho_T\iota$. It is *orthogonally reducing* at weight n for flags F_A, F_T if (1) $\iota(G^A_p) = \iota(A_n) \cap G^T_p$; (2) B_T is nondegenerate on each $\iota(G^A_p)$; (3) $\iota(\mathcal{L}^A_p) = \iota(A_n) \cap \mathcal{L}^T_p$.

File `VOA/Examples/InverseDSGradedUnitarityTransfer.lean`.

      LinearMap.range (E.weightMap n) ⊓
        FT.layer n (LiRadical.gradedForm BT n) p
```

From the mathematics to the Lean statement

`E.weightMap n` is ι restricted to $A_n \to T_n$; `LinearMap.range` its image. Exactly Definition 19.46. `GradedIsometricEmbedding` contains *no* vertex-algebra compatibility (no $\iota(u_{(n)}v) = \iota u_{(n)}\iota v$); the docstring notes that the transfer does not need it.

Why (2) and (3) are needed. The file docstring gives a counterexample showing that strictness (1) alone does not transfer graded unitarity: on $\mathbb{C}^2$ with form $\mathrm{diag}(1,-1)$, ambient flag $G_0 = \mathbb{C}e_1$, $G_1 = \mathbb{C}^2$ (graded unitary: $\mathcal{L}_0 = \mathbb{C}e_1$ positive, $\mathcal{L}_1 = \mathbb{C}e_2$ negative-then-twisted-positive), and image line $\mathbb{C}(e_1 + ae_2)$, $0 < |a| < 1$: the induced source flag has $G_0^A = 0$, $G_1^A =$ the line, the source form $1 - |a|^2 > 0$ is positive, but its only nonzero layer has $p = 1$, where $(-1)^1$ makes it negative. (We checked this by hand.)

Physical meaning

An isometric realisation (free-field or coset) that respects the R-filtration *and* its orthogonal splitting. The counterexample says: a state can sit in the image of a filtration step without being orthogonal to the lower-charge ambient states, and then its "charge" in the source and in the ambient differ.

What the machine verified

Definitions. Instantiated in the library by the coset transfer of Chapter 28, for instance through the filtered linear isomorphisms of `gradedUnitary_of_filteredLinearEquiv`.

Theorem 19.47 (Transfer of graded unitarity). *If ι is a graded isometric embedding, orthogonally reducing at every weight, and (T, B_T, ρ_T, F_T) is graded unitary, then (A, B_A, ρ_A, F_A) is graded unitary.*

File `VOA/Examples/InverseDSGradedUnitarityTransfer.lean`.

```
theorem gradedUnitary_of_ambient
    (E : GradedIsometricEmbedding A T BA BT RA RT)
    (FA : GradedFlag A) (FT : GradedFlag T)
    (hreduce : ∀ n : ℤ, E.OrthogonallyReducingAt FA FT n)
    (hambient : GradedUnitary BT RT FT) :
    GradedUnitary BA RA FA := by
```

From the mathematics to the Lean statement

Exactly Theorem 19.47. All hypotheses explicit. The weight-by-weight version is `gradedUnitaryAt_of_ambient`. When ι maps every flag step *onto* the ambient step, orthogonal reduction is automatic; this is the form used by the coset transfer of Chapter 28.

Proof on paper. Clause (iv): nondegeneracy pulls back along the isometry from (2). Clause (vi): by (3) $\iota(\mathcal{L}_p^A) \subseteq \mathcal{L}_p^T$, where the twisted form is positive; pull back by Theorem 19.8, using ρ-compatibility to identify the sesquilinear forms. □

Physical meaning

Positivity in the bigger theory, sector by sector, gives positivity in the smaller one.

What the machine verified

Proved, axiom-clean; conditional on the explicit hypotheses `hreduce` and `hambient`.

19.14 Graded unitarity of $V^k(\mathfrak{sl}_2)$ below the critical level

What this section adds. (Its Lean quotations were taken at a later revision of the library than the rest of the chapter; the files are unchanged since.) It documents the twelve files `VOA/Examples/AffineSl2BelowCritical*.lean` (`Anchor`, `Compact`, `Flag`, `GradedUnitarity`, `GramMatrix`, `MatrixAnchor`, `MatrixRigidity`, `NoWall`, `Nondegenerate`, `PBWFlag`, `RealStructure`, `Rigidity`). Their headline is the first theorem of the library that asserts the predicate `GradedUnitary` of Definition 19.11 — all of it, at every conformal weight and every filtration degree — for a concrete vertex operator algebra, with no hypothesis beyond the range of the level:

> *For every real $k < -2$, the universal affine vertex operator algebra $V^k(\mathfrak{sl}_2)$, with its normalised invariant form, the compact real structure and the current-length flag, is graded unitary.*

The algebra is the *universal* one, $V^k(\mathfrak{sl}_2)$, not a simple quotient; the level is *below* the critical value -2; and the flag is the *ordinary* length filtration by number of currents. Nothing here is about the simple quotients $L_k(\mathfrak{sl}_2)$ at the admissible levels $k > -2$ that occur in the SCFT/VOA correspondence (for instance as chiral algebras of Argyres–Douglas theories); those are a different problem (Remark 19.50).

Reading the Lean displays of this section. Each display is copied from the cited files. A line `...` inside a display marks omitted source lines: other declarations lying between two quoted ones, or the remaining (proof) fields of a structure instance cut after `where`. Fragments separated only by

a blank line are consecutive in the source, apart from docstrings and comments, which are always omitted; a statement ending in `:= by` has its proof omitted. Full Lean names are obtained by prefixing the namespace of the file:

- `universal`, `universalForm`: `VOA.AffineSl2GeneralRigidity`;
- `stepMatrix`, `MatrixStepNondeg`, `MatrixLayerSign`, `matrixLayerSign_rigid`, `matrixLayerSign_eventually` (files `AffineSl2BelowCriticalMatrixRigidity.lean`, `AffineSl2BelowCriticalMatrixAnchor.lean`): `VOA.MatrixRigidity`;
- `CurrentSystem` and its theorem `layerNondegenerate_of_lower` (file `AffineSl2BelowCriticalNoWall.lean`): `VOA.BelowCriticalNoWall` (the theorem inside `namespace CurrentSystem`);
- `adjointColour`: `VOA.AffineVOA.HighestModule`;
- everything else in the twelve files: `VOA.AffineSl2BelowCritical`, with `sugawara_sesq` inside the sub-namespace `IsCompactRealStructure`.

So, for instance, the headline is `VOA.AffineSl2BelowCritical.universal_gradedUnitary_belowCritical_unconditional`; the audit listing of Section 19.16 uses these full names.

The route in one paragraph. Fix a conformal weight E. In the basis of ordered PBW monomials of weight E the Hermitian Gram matrix $G_E(k)$ has entries that are *polynomials* in the level. Three facts are combined, by induction on E:

1. *Anchor* (Theorem 19.53): for k sufficiently negative, $G_E(k)$ has all the graded-unitary layer signs. Reason: after rescaling a monomial of length r by $|k|^{-r/2}$, the Gram matrix tends to the diagonal matrix $\mathrm{diag}((-1)^r d)$ with $d > 0$ (Wick's theorem for free currents).
2. *No wall* (Theorem 19.56): if all lower weights carry the layer signs and the full weight-E form is nondegenerate (true for every $k < -2$ by the Kac–Kazhdan determinant), then the form is nondegenerate on every flag step at weight E. The proof is a positivity argument with the Sugawara identity.
3. *Rigidity* (Theorem 19.54): a continuous family of Hermitian matrices whose flag steps are all nondegenerate cannot change its layer signs on a connected parameter set; here the set is the interval $(-\infty, -2)$.

Then: no wall gives nondegeneracy at weight E for all $k < -2$; rigidity transports the signs from the anchor to every $k < -2$; and the induction continues.

19.14.1 The data: the algebra, the form, the real structure, the flag

Recall from Chapter 9 that the vacuum module of affine $\mathfrak{sl}_2$ at level k is `WakModule k` (a misleading name: it is *not* a Wakimoto module), with current modes J^a_m (`J k a m`) indexed by the Chevalley basis $a \in \{0,1,2\} = \{e, f, h\}$ and satisfying

$$[J^a_m, J^b_n] = J^{[a,b]}_{m+n} + m\,k\,\kappa(a,b)\,\delta_{m+n,0}, \qquad \kappa(e,f) = \kappa(f,e) = 1,\ \kappa(h,h) = 2, \tag{19.1}$$

with $[h,e] = 2e$, $[h,f] = -2f$, $[e,f] = h$ (Theorem 9.2, Definition 9.1). The creation word `wordStateA k w` attached to a list $w = [(a_1, n_1), \dots, (a_r, n_r)]$ of (colour, depth) pairs is $J^{a_1}_{-n_1-1} \cdots J^{a_r}_{-n_r-1}\mathbf{1}$ (Definition 9.11); note the shift: depth n means mode $-n-1$. Its conformal weight is $\sum_i (n_i + 1)$ and its *length* is r.

Definition 19.48 (The data of the below-critical theorem)**.** Let $k \in \mathbb{C}$, $k \neq -2$.

1. $V^k = V^k(\mathfrak{sl}_2)$ is the universal affine VOA with the Sugawara conformal vector (Definition 9.14). For a real number $x < -2$ the complex number x is noncritical.

2. B_k is the *normalised canonical invariant form* on V^k: the unique invariant symmetric bilinear form with $B_k(\mathbf{1},\mathbf{1}) = 1$ (Theorem 5.56). In the FHL convention used by the library, currents are *skew*-adjoint: $B_k(J^a_m u, v) = -B_k(u, J^a_{-m} v)$.

3. The *colour reversal* $a \mapsto a^*$ exchanges e and f and fixes h. A real structure ρ on V^k (Definition 19.9) is *compact* if $\rho(J^a_{-1}\mathbf{1}) = -J^{a^*}_{-1}\mathbf{1}$ for each colour a and its parity scalars $s(n)$ are all nonzero. (Recall from Definition 19.9 that a real structure carries a function $s : \mathbb{Z} \to \mathbb{C}$, its R-parity, with $\rho^2 = s(n)$ on the weight-n space. When $s(n) \neq 0$, ρ is invertible on V_n; this is what makes the orthogonal complement of a ρ-stable subspace the same for the bilinear form B_k and for the Hermitian form $\mathcal{H}(x,y) = B_k(\rho x, y)$, Theorem 19.12. It is the only use of s in this section.)

4. For real k the *compact real structure* is $\rho_k = \theta \circ \beta$, where β is the anti-linear map fixing $\mathbf{1}$ and commuting with every J^a_m ("complex conjugation of PBW coordinates") and θ is the Chevalley automorphism ($J^a_m \mapsto -J^{a^*}_m$). Its parity is $s \equiv 1$. The *compact family* is $x \mapsto \rho_x$ for $x \in (-\infty, -2)$.

5. The *ordinary flag*: $F_p \subseteq V^k$ is the span of all creation words of length $\leq p$ (any colours, any order, any depths), and the flag piece at weight n is $F_p \cap V^k_n$.

Files `VOA/Examples/AffineSl2GeneralRigidityBasis.lean` (the abbreviation `universal`, under `variable (k : ℂ) (hk : k + 2 ≠ 0)`), `VOA/Examples/AffineSl2UniversalGram.lean` (`universalForm`) and `VOA/Examples/AffineSl2BelowCriticalNondegenerate.lean` (`noncritical_of_lt`):

```

  ...
```

From the mathematics to the Lean statement

The algebra. `universal k hk` is `affineSl2VOA_closed k hk`, the VOA $V^k(\mathfrak{sl}_2)$ of Definition 9.14 (the same abbreviation is used in Chapter 10). `noncritical_of_lt hx` is the proof that a real $x < -2$, viewed in $\mathbb{C}$, satisfies $x + 2 \neq 0$; every statement below is about `universal (x : ℂ) (noncritical_of_lt hx)`, i.e. V^x at the real level x.

The form. `canonicalInvariantForm hne hqp` is the canonical invariant form of Theorem 5.56: given that the vacuum is nonzero (`hne`, here the axiom-free `affineSl2_vacuum_ne_zero`) and that $L_1 V_1 = 0$ (`hqp`, here `L1_grading_one`), it is the unique invariant form normalised by $(\mathbf{1}|\mathbf{1}) = 1$. So B_k is determined, not chosen. Its convention gives $B_k(J^a_{-1}\mathbf{1}, J^b_{-1}\mathbf{1}) = -k\kappa(a,b)$ (compare Theorem 19.45, where $k = -8/5$ gives $\frac{8}{5}\kappa$).

Compactness. `currentState k a` is $J^a_{-1}\mathbf{1}$; `adjointColour` is $a \mapsto a^*$ (colours are numbered $0 = e$, $1 = f$, $2 = h$). `IsCompactRealStructure R` is clause 3 of the definition: two fields, the action on the three currents and invertibility of the parity. From it alone the library proves (`AffineSl2BelowCriticalCompact.lean`) $\rho J^a_m = -J^{a^*}_m \rho$ (`rho_J`), that ρ preserves weights and the ordinary flag, and that the Hermitian adjoint of J^a_m for $\mathcal{H}(x,y) = B_k(\rho x, y)$ is $J^{a^*}_{-m}$ (`sesq_J_adj`). The last is the $\mathfrak{su}(2)$ reality condition $(J^e_m)^\dagger = J^f_{-m}$, $(J^h_m)^\dagger = J^h_{-m}$: the two minus signs (from ρ and from skew-adjointness) cancel. Since moreover $\mathcal{H}(\mathbf{1},\mathbf{1}) = 1$, repeated use of this adjointness computes every Gram entry as a vacuum expectation value, (19.2) below.

The construction. `basisConjₗ hreal` is the linear map from V^k to the same space with *conjugated* scalar multiplication, obtained from the universal property of the vacuum module (the structure constants and the level are real, so the currents still satisfy (19.1) there); read back in V^k it is the anti-linear map β with $\beta(\mathbf{1}) = \mathbf{1}$ and $\beta J^a_m = J^a_m \beta$. `vacuumChevalley k` is the Chevalley automorphism θ of Chapter 10 (this section uses only $\theta\mathbf{1} = \mathbf{1}$ and $\theta J^a_m = -J^{a^*}_m \theta$, `vacuumChevalley_current`). Hence $\rho_k = \theta\beta$ sends the creation word of length r to $(-1)^r$ times the word with all colours reversed (`compactRho_wordStateA`). The elided fields of `compactRealStructure` are proofs: compatibility with every vertex operator (`compactRho_YA`), $\rho\omega = \omega$ (`compactRho_sugawara`), and $\rho^2 = 1$ (`compactRho_compactRho`). `conj_ofReal x` is the proof that a real number is fixed by conjugation. A `RealFamily` is a

choice of real structure on V^x for every real $x < -2$; `compactRealFamily` is the compact choice; `compactRealFamily_isCompact` proves it compact.
The flag. `Submodule.span ℂ (Set.range …)` is the span of the words with `w.length ≤ p`; `⊓` is intersection with the weight space `(universal k hk).grading n`. The remaining fields of `ordinaryFlag` (elided) are the axioms of a `GradedFlag` (Definition 11.1): monotone in p, $F_0 \cap V_n = 0$ for $n > 0$, $F_0 \cap V_0 = \mathbb{C}\mathbf{1}$, exhaustive; each is proved. By filtered PBW straightening (`AffineSl2BelowCriticalPBWFlag.lean`, `ordinaryPiece_eq_pbwSpan`) F_p is also the span of the *ordered* PBW monomials of length $\leq p$, so the ordered monomials of weight E form a basis of V^k_E adapted to the flag.
Is this the intended flag? It is a fixed, explicit flag, not a free parameter, so the vacuity of Warning 19.4.1 does not apply. It is the natural "R-filtration" of the universal algebra when each current carries R-charge one and nothing else is imposed. It is *not* the "corrected" filtration used for simple quotients at admissible level (in which the Sugawara vector has degree one); here the Sugawara vector ω has degree two. The file docstring says so.

Physical meaning

$J^a(z)$ are the $\mathfrak{su}(2)$ flavour currents. In the SCFT/VOA dictionary they come from the four-dimensional moment-map operators, which have $SU(2)_R$ spin $R = 1$; a normal-ordered product of r currents then has $R \leq r$, which is what the length flag records. The compact real structure is the statement that the currents are Hermitian fields of the compact real form $\mathfrak{su}(2)$: $(J^{\pm}_m)^\dagger = J^{\mp}_{-m}$, $(J^3_m)^\dagger = J^3_{-m}$, the standard conjugation of a WZW model. The level enters through the two-point function $\langle J^a J^b \rangle \propto k\kappa^{ab}$, and $k_{4\mathrm{d}} = -2k$ is the four-dimensional flavour central charge, positive exactly when $k < 0$.

What the machine verified

Definitions; `compactRealStructure_isCompact` and `compactRealFamily_isCompact` (the constructed ρ is compact) and `ordinaryPiece_eq_pbwSpan` are proved, `#print axioms`-clean (Section 19.16).

19.14.2 The headline

Theorem 19.49 (Below-critical graded unitarity of $V^k(\mathfrak{sl}_2)$). *Let k be a real number with $k < -2$. Then $\big(V^k(\mathfrak{sl}_2), B_k, \rho_k, F\big)$, with the data of Definition 19.48, is graded unitary in the sense of Definition 19.11: for every $n \in \mathbb{Z}$ and every $p \in \mathbb{N}$,*

1. *(clause (iv)) B_k is nondegenerate on $F_p \cap V^k_n$;*
2. *(clause (vi)) on the layer $\mathcal{L}_p = (F_p \cap V^k_n) \cap (F_{p-1} \cap V^k_n)^\perp$ the form $(-1)^p\,\mathcal{H}_n$, $\mathcal{H}_n(x,y) = B_k(\rho_k x, y)$, is positive definite. (The orthogonal complement may be taken for B_k or for $\mathcal{H}_n$: for this ρ_k, which preserves the flag pieces and has $s \equiv 1$, the two agree by Theorem 19.12.)*

Clause (v) (the orthogonal decomposition into layers) then follows from Theorem 19.13.

From the mathematics to the Lean statement

Hypotheses. Exactly two arguments: a real number `k : ℝ` and a proof `hk : k < -2`. There are no other hypotheses, no typeclass assumptions beyond those already fixed, no `Prop`-valued structure fields to be supplied later. The one-line proof term is informative and is shown: it combines the conditional assembly `universal_gradedUnitary_belowCritical_of_anchor` (which still takes the anchor as an argument, Theorem 19.54) with the proved anchor `layerSignAnchor_compact` (Theorem 19.53).

Decoding the conclusion. `(k : ℂ)` is the real level viewed in $\mathbb{C}$. `GradedUnitary B R F` is Definition 19.11: for every `n : ℤ`, `GradedUnitaryAt F n (LiRadical.gradedForm B n) (gradedSesq B R n)`, i.e. `LayerNondegenerate` (clause (iv)) and `LayerPositive` (clause (vi), with the twist $(-1)^p$ of `signedForm`). `LiRadical.gradedForm B n` is B restricted to $V_n \times V_n$, `gradedSesq B R n` is $\mathcal{H}_n(a,b) = B(\rho a, b)$ (Definition 19.10, where it is called h_n; in this section we write $\mathcal{H}$ for the Hermitian form, because h is the Cartan generator of $\mathfrak{sl}_2$). The three data are those of Definition 19.48, each pinned: the form is the canonical one, ρ is the constructed compact one, the flag is the ordinary one.

Same as the textbook statement? Yes, for the data named. Two points of scope. First, the statement is for one specific compact real structure; it is not stated for an arbitrary compact ρ (although the abstract assembly of Theorem 19.54 is). Second, it is for real $k < -2$ only; nothing is claimed for complex k or for $k > -2$. For every real $k > -2$ the conclusion is in fact false for this flag (Example 19.57): for $k > 0$ clause (vi) fails at weight one ($G_1(k) = \mathrm{diag}(k, k, 2k)$ is positive, not negative, definite); for $-2 < k < 0$ and for $0 < k < 1$ it fails at weight two (the layer-2 Schur complement S has $\det S < 0$); at $k = 0$ the form vanishes on V_1 ($G_1(0) = 0$), so clause (iv) fails at weight one; and at $k = 1$, $\det S = 0$, so the form is degenerate on the weight-two layer and clause (vi) fails there (a positive definite form cannot have a null direction). The case $k = -2$ is excluded by the construction (critical level).

Could it be vacuous? The weight spaces are nonzero for $n \geq 0$ (they contain the PBW monomials) and zero for $n < 0$; at negative weight both clauses hold trivially, which is the correct reading. The layers are genuinely nonzero: at weight one the layer $\mathcal{L}_1$ is all of $V_1^k \cong \mathbb{C}^3$, and positivity of $-\mathcal{H}_1$ there is the inequality $-k > 0$ (Example 19.57). The predicate `IsPosOn` has teeth (Definition 19.7): the same layers fail the condition for $k > 0$.

Proof on paper. Write $(\mathrm{iv})_E(k)$ and $(\mathrm{vi})_E(k)$ for the two clauses at weight E and level k. We prove by strong induction on E the statement $P(E)$: $(\mathrm{vi})_E(k)$ *holds for every real* $k < -2$; along the way we obtain $(\mathrm{iv})_E(k)$. For $E < 0$ there is nothing to prove. Assume $P(E')$ for all $E' < E$.

1. By Theorem 19.55 the full form B_k on V_E^k is nondegenerate for every $k < -2$.

2. By the no-wall lemma (Theorem 19.56), applied at each $k < -2$ with the induction hypothesis at the weights $E - m$, $m \geq 1$, every flag step at weight E is nondegenerate: $(\mathrm{iv})_E(k)$ for every $k < -2$.

3. By the anchor (Theorem 19.53) there is K such that $(\mathrm{vi})_E(x_0)$ holds for any $x_0 < \min(K, -2)$.

4. By rigidity (Theorem 19.54), which needs exactly $(\mathrm{iv})_E(x)$ for all $x < -2$, $(\mathrm{vi})_E(x_0)$ implies $(\mathrm{vi})_E(k)$ for every $k < -2$.

This is $P(E)$, and the induction closes. The quantifier "for every $k < -2$" inside the induction is essential: step 2 at a single level k uses lower weights at that same level, but step 4 needs step 2 at *all* levels. □

Physical meaning

Graded unitarity is the shadow, in the chiral algebra, of four-dimensional unitarity: an operator built from r moment maps has four-dimensional norm of sign $+$, and the two-dimensional form sees it with sign $(-1)^r$. For the universal algebra the theorem says that the "free" current sector — multi-current states with no relations imposed — passes this test whenever $k_{4d} = -2k > 4$. At very large k_{4d} this is the generalized-free-field limit, in which the currents' correlators are Wick contractions and the signs are manifest; the content of the theorem is that nothing goes wrong as k increases all the way up to the critical level, where the Sugawara vector becomes null (Example 19.57). *Heuristic caveat:* $V^k(\mathfrak{sl}_2)$ at $k < -2$ has Sugawara central charge $c = 3k/(k+2) > 3$, so it is not the chiral algebra of a unitary four-dimensional theory *with that stress tensor* ($c_{4d} = -c/12$ would be negative); the theorem is a statement about the current sector, not a physical model.

What the machine verified

Proved, unconditional: the only hypothesis is $k < -2$, k real. `#print axioms universal_gradedUnitary_belowCritical_unconditional` gives `[propext, Classical.choice, Quot.sound]` (isolated-module check; aggregate build not re-run for this section — see the build-state note in Section 19.16). It does not use `VOA.pbw`.

Remark 19.50 (Scope)**.** The theorem concerns the universal algebra below the critical level. The simple quotients $L_k(\mathfrak{sl}_2)$ at admissible levels $k = -2 + p/q > -2$ (for instance $k = -4/3, -8/5$), whose graded unitarity is predicted by the four-dimensional correspondence, are not covered: there the universal form is degenerate, the right flag is the corrected one, and the level is above -2. The abstract no-wall lemma (Theorem 19.56) is stated for an arbitrary VOA and would apply to such a quotient, but the anchor-and-rigidity part of the argument has no analogue at an isolated level.

19.14.3 The three route theorems

Order of the argument. We first put the Gram matrices into coordinates (the next paragraph and Definition 19.51), then record two properties of the Gram matrix that both route theorems use (Lemma 19.52: Hermitian, polynomial in the level). Then come the anchor (Theorem 19.53, which uses the lemma), rigidity (Theorem 19.54, which uses the lemma and step nondegeneracy), the nondegeneracy of the full form (Theorem 19.55) and the no-wall lemma (Theorem 19.56), which together supply that step nondegeneracy. The headline's induction (Theorem 19.49) assembles them.

Gram matrices and layer signs in coordinates. Fix E. Let I_E be the finite set of PBW exponents of energy E (`EIdx E`, independent of k), with length $\ell(i)$ (`eLen E i`, the number of letters). The Gram matrix is $G_E(k)_{ij} = \mathcal{H}(b_i, b_j) = B_k(\rho_k b_i, b_j)$ for the PBW monomials b_i (`gram`). For a Hermitian matrix G on I_E and $r \in \mathbb{N}$, the *step* r is the coordinate subspace $\{\ell < r\}$, and the matrix conditions are

$$\begin{aligned} \textsc{StepNondeg}(G) &: \det\big(G|_{\{\ell<r\}}\big) \neq 0 \text{ for every } r, \\ \textsc{LayerSign}_r(G) &: (-1)^r\, y^* G y > 0 \text{ for every } y \neq 0 \text{ supported on } \{\ell \le r\} \\ &\qquad \text{with } (Gy)_i = 0 \text{ for } \ell(i) < r. \end{aligned}$$

Files `VOA/Examples/AffineSl2BelowCriticalMatrixRigidity.lean` and `VOA/Examples/AffineSl2BelowCriticalGramMatrix.lean`:

```

Here `CurrentIndex` is a finitely supported multiplicity function on (colour, depth) pairs, `currentPBWBasis k hk mu` is the ordered creation word `wordStateA k (orderedPBWColorWord mu)` (`currentPBWBasis_apply`; the PBW basis of Theorem 9.25), `currentEnergy` its weight and `pbwLength` its number of letters (`VOA/Examples/AffineSl2JointPBW.lean`, `AffineSl2BelowCriticalPBWFlag.lean`). In the matrix file ι is any finite index type and ℓ any length function; `star y ⬝ᵥ (G *ᵥ y)` is $y^{*}Gy$, and `0 < …` in $\mathbb{C}$ (the library's `ComplexOrder`) means "is a positive real number". In the matrix file the section variables are `{ι : Type*} [Fintype ι] [DecidableEq ι] (ℓ : ι → ℕ)` (not displayed): ι is any finite index type with decidable equality, which every finite type of interest has, so the extra instance is harmless.

The two translation theorems and their hypotheses. Both quoted Gram-matrix theorems lie after the displayed `variable (hR : IsCompactRealStructure R)` and `include hR`, so *both* take the hypothesis that R is a compact real structure (Definition 19.48, item 3) as an explicit first argument; the signature printed by `#check` (at an earlier commit, not re-run for this edition; namespaces shortened) is

```
matrixStepNondeg_of_layerNondeg : ∀ {k : ℂ} (hk : k + 2 ≠ 0) {R : RealStructure (universal
 ↪ k hk)},
  IsCompactRealStructure R → ∀ {E : ℤ},
    LayerNondegenerate (ordinaryFlag k hk) E (LiRadical.gradedForm (universalForm k hk) E)
     ↪ →
      MatrixStepNondeg (eLen E) (gram hk R E)
```

and likewise `layerPositive_iff_matrixLayerSign` takes `hR` before `{E}`. Mathematically:

- (`matrixStepNondeg_of_layerNondeg`) if R is compact and B_k is nondegenerate on every flag step $F_p \cap V_E^k$ (clause (iv) at weight E), then every step minor of $G_E(k)$ is nonzero: $\textsc{StepNondeg}(G_E(k))$;

- (`layerPositive_iff_matrixLayerSign`) if R is compact, clause (vi) at weight E holds if and only if $\mathrm{LayerSign}_r(G_E(k))$ holds for every r.

Proof on paper. By filtered PBW straightening (`ordinaryPiece_eq_pbwSpan`) the flag piece $F_p \cap V_E^k$ is the coordinate subspace spanned by the ordered monomials of length $\le p$, so "supported on $\{\ell \le p\}$" is membership in F_p, and "$(Gy)_i = 0$ for $\ell(i) < r$" is $\mathcal{H}$-orthogonality to F_{r-1}. A compact ρ preserves the flag pieces and has nonzero parity scalars, so $\mathcal{H}$-orthogonality and B_k-orthogonality to a flag piece coincide (as in Theorem 19.12); hence the layer of Definition 19.11 is exactly the set of vectors y in the definition of $\mathrm{LayerSign}_r$, and $(-1)^r\mathcal{H}(y,y) = (-1)^r y^* G y$. For the step minors: the matrix of $\mathcal{H}$ on the coordinate subspace $\{\ell < r\}$ is $G|_{\{\ell<r\}}$, and $\mathcal{H}(x,y) = B_k(\rho x, y)$ with ρ a bijection of $F_{r-1} \cap V_E^k$, so nondegeneracy of B_k there is invertibility of that block. Nothing beyond linear algebra in an adapted basis is involved. □

Physical meaning

These two statements say that the abstract signature conditions can be read off from the matrix of two-point functions $\langle b_i | b_j \rangle$ of current states in the PBW basis, organised by current number: the familiar way a physicist checks unitarity of a Verma module by computing Gram (Kac) matrices level by level. No physics enters beyond this choice of basis.

What the machine verified

Both proved, conditional only on their displayed hypotheses (`hR` and, for the first, clause (iv) at weight E); `#print axioms: [propext, Classical.choice, Quot.sound]` for both (Section 19.16). In the headline both hypotheses are discharged: `hR` by `compactRealFamily_isCompact`, clause (iv) by the no-wall lemma (Theorem 19.56).

Definition 19.51 (Layer signs, step nondegeneracy, and the two analytic inputs). For a family R of real structures on V^x, $x < -2$, write $\mathrm{Sign}_R(x,E)$ for clause (vi) at weight E and $\mathrm{Nd}(x,E)$ for clause (iv) at weight E, both for the ordinary flag and the form B_x.

1. The *anchor* for R: for every E there is $K \in \mathbb{R}$ such that $\mathrm{Sign}_R(x,E)$ holds for every $x < -2$ with $x < K$.
2. *Rigidity* for R: for every E, if $\mathrm{Nd}(x,E)$ holds for every $x < -2$, then $\mathrm{Sign}_R(x_0,E)$ for one $x_0 < -2$ implies $\mathrm{Sign}_R(x_1,E)$ for every $x_1 < -2$.

```

From the mathematics to the Lean statement

`LayerSigns R x hx E` is $\mathrm{Sign}_R(x,E)$ and `LayerNondeg x hx E` is $\mathrm{Nd}(x,E)$, literally the two halves of `GradedUnitaryAt` at weight E (Definition 19.11) for the data of Definition 19.48, with the real structure taken from the family. `LayerSignAnchor` and `LayerSignRigidity` are items 1 and 2, with the quantifiers in the displayed order: in the anchor K may depend on E (the proof produces an E-dependent threshold; see below); in rigidity the nondegeneracy hypothesis is at *all* levels $x < -2$. Both are `Prop`s about a family; as hypotheses they are *inputs* of the abstract assembly, and the docstrings call them "named open input". For the compact family both are now *theorems* (Theorems 19.53 and 19.54); see Warning 19.14.3.
Why is K allowed to depend on E? The weight-E Gram matrices have polynomial entries of degree up to E in k. The anchor's *proof* is a large-$|k|$ asymptotic argument (Theorem 19.53), whose threshold is extracted from the weight-E Gram matrix and so depends on E; no uniformity in E is claimed, and the input is stated as "$\forall E\ \exists K$". This is a feature of the proof, not of the truth: a posteriori the headline theorem (Theorem 19.49) shows that $K = -2$ works for every E.

Physical meaning

$\mathrm{Sign}(x,E)$ says "all states of conformal weight E and current number exactly p have the four-dimensional sign $(+)$"; $\mathrm{Nd}(x,E)$ says "no null states appear in any truncated current-number sector at weight E". The anchor is the free (large flavour central charge) limit; rigidity says signs cannot change without a null state appearing on the way.

What the machine verified

Definitions. The conditional assembly `universal_gradedUnitary_belowCritical` (same file) proves `GradedUnitary` for any family `R` with `hR : ∀ x hx, IsCompactRealStructure (R x hx)`, `hanchor : LayerSignAnchor R`, `hrigid : LayerSignRigidity R`; it is `#print axioms`-clean and, as stated, conditional on those three hypotheses. For `compactRealFamily` all three are discharged.

Stale "open input" language in `AffineSl2BelowCriticalGradedUnitarity.lean`

The module docstring of `AffineSl2BelowCriticalGradedUnitarity.lean` says the assembly is conditional on "three named inputs, none of which is established in this repository", and the docstrings of `LayerSignAnchor` and `LayerSignRigidity` call them "Named open input". The next paragraph of the same module docstring says all three are discharged downstream for the compact family, which is what the machine confirms (`compactRealFamily_isCompact`, `layerSignRigidity_compact`, `layerSignAnchor_compact`). The definitions are correct; only the wording is stale. (Documentation only.)

Lemma 19.52 (The compact Gram matrix is Hermitian and polynomial in the level). *Let k be real, $k \neq -2$, and ρ_k the compact real structure. For every weight E: (1) $G_E(k)$ is Hermitian (indeed real symmetric); (2) if moreover $k \neq 0$, each entry is $G_E(k)_{ij} = P_{ij}(k)$ for a polynomial $P_{ij} \in \mathbb{C}[X]$ that does not depend on k (`gramPoly E i j`).*

The Lean statements are `gram_isHermitian` and `gram_eq_eval`, quoted with Theorem 19.54 (file `AffineSl2BelowCriticalRigidity.lean`).

Proof on paper. (1) From (19.2) below, $\overline{\mathcal{H}(b_i,b_j)} = \mathcal{H}(b_j,b_i)$ follows from two symmetries of B_k, $B_k(\theta u,\theta v) = B_k(u,v)$ and $\overline{B_k(\beta u,\beta v)} = B_k(u,v)$ (θ, β as in Definition 19.48), both proved by the same uniqueness principle: a bilinear form for which every J^a_m is skew-adjoint to J^a_{-m} is determined

by its values $B(\mathbf{1}, \cdot)$ (`bilinForm_eq_of_current_adj`), and both sides of each symmetry have this property and agree on the vacuum. (2) Computing (19.2) by moving annihilators to the right with (19.1) produces only integer combinations of powers of k; the structure constants are integers and the level enters only through the central term. □

Physical meaning

Hermiticity is the statement that the two-point functions of the $\mathfrak{su}(2)$ current states are those of a (possibly indefinite) inner-product space; polynomial dependence on the level is the familiar fact that every correlator of currents is a polynomial in the central charge k of the current algebra.

What the machine verified

Proved, unconditional (for real noncritical k, and $k \neq 0$ for (2)); `#print axioms` on `gram_isHermitian` and `gram_eq_eval`: `[propext, Classical.choice, Quot.sound]` (Section 19.16).

Theorem 19.53 (Anchor: layer signs at large negative level). ***(a) Matrix version.*** *Let I be a finite set with a length $\ell : I \to \mathbb{N}$, P an $I \times I$ matrix of complex polynomials, and $d : I \to \mathbb{R}_{>0}$, such that*

1. $\deg P_{ij} \le \min(\ell(i), \ell(j))$;
2. *if $\ell(i) = \ell(j)$, the coefficient of $X^{\ell(i)}$ in P_{ij} is $\delta_{ij} d_i$;*
3. *$P(x)$ is Hermitian for all real $x < x_*$ (some $x_* \in \mathbb{R}$; `x₀` in the Lean statement).*

Then there is K such that for every real $x < K$ and every r, $\textsc{LayerSign}_r(P(x))$ holds.

(b) Affine version. *For the compact family, the anchor of Definition 19.51 holds: for every weight E there is K such that the weight-E layer signs hold at every real level $x < \min(K, -2)$.*

Files `VOA/Examples/AffineSl2BelowCriticalMatrixAnchor.lean` (a) and `VOA/Examples/AffineSl2BelowCriticalAnchor.lean` (b, and the two polynomial facts).

```
theorem matrixLayerSign_eventually (P : Matrix ι ι ℂ[X]) (d : ι → ℝ) (hd : ∀ i, 0 < d i)

    (gramPoly E i j).coeff (eLen E i) = if i = j then ((topWeight i : ℝ) : ℂ) else 0 := by
...
theorem layerSignAnchor_compact : LayerSignAnchor compactRealFamily := by
```

From the mathematics to the Lean statement

(a). `ℂ[X]` is $\mathbb{C}[X]$; `P.map (Polynomial.eval (x : ℂ))` is the numerical matrix $P(x)$; `natDegree` is the degree (with $\deg 0 = 0$, harmless for an upper bound); `coeff (ℓ i)` the coefficient of $X^{\ell(i)}$. Hypotheses `hd`, `hdeg`, `htop`, `hherm` are items $d > 0$, 1, 2, 3; the conclusion is as stated, uniform in r. Nothing VOA-specific.
(b). `gramPoly E i j` (`AffineSl2BelowCriticalRigidity.lean`) is the *level polynomial* of the

Gram entry: up to the sign $(-1)^{\ell(i)}$ it is `wordGramPolynomial` of Chapter 10 applied to the colour-reversed word of b_i and the word of b_j, and `gram_eq_eval` proves $G_E(k)_{ij} =$ `gramPoly`$_{ij}(k)$ for real $k \neq 0, -2$. `topWeight i` is an explicit positive real (`realDiag`, a product of depths, Killing coefficients and multiplicities). So `gramPoly_natDegree_le` and `gramPoly_coeff_top` are hypotheses 1 and 2 of (a) for $P =$ `gramPoly E`, and hypothesis 3 is `gram_isHermitian` below; `layerSignAnchor_compact` is (b), i.e. `LayerSignAnchor compactRealFamily` of Definition 19.51, with no hypotheses.

Proof on paper. *(a).* Put $x = -\mu^2$ with $\mu > 0$ and rescale: $M(\mu)_{ij} = P_{ij}(-\mu^2)/\mu^{\ell(i)+\ell(j)}$. By item 1, $P_{ij}(-\mu^2) = O(\mu^{2\min(\ell_i,\ell_j)})$, so $M_{ij} \to 0$ when $\ell_i \neq \ell_j$ (the exponent $2\min -\ell_i - \ell_j$ is negative). When $\ell_i = \ell_j = \ell$ the leading term is the coefficient of X^ℓ times $(-\mu^2)^\ell$, so by item 2 $M_{ij} \to (-1)^\ell \delta_{ij} d_i$. Hence $M(\mu) \to D = \operatorname{diag}((-1)^{\ell_i} d_i)$ as $\mu \to \infty$. For the diagonal matrix D the step minors are nonzero and the Schur complement of step $\{\ell < r\}$ in $\{\ell \le r\}$ is $\operatorname{diag}((-1)^r d_i)_{\ell_i = r}$, so $(-1)^r$ times it is positive definite. Now (i) $\textsc{LayerSign}_r(G)$ is equivalent to positive definiteness of $(-1)^r$ times that Schur complement (`matrixLayerSign_iff_schur`); (ii) Schur complements depend continuously on the matrix where the step minor is nonzero; (iii) positive definiteness is an open condition among Hermitian matrices (`posDef_eventually`: positivity on the compact unit sphere persists under small perturbation). So for μ large every layer sign of $M(\mu)$ holds; for r beyond the maximal length the condition is vacuous. Finally $P(-\mu^2) = SM(\mu)S$ with $S = \operatorname{diag}(\mu^{\ell_i})$ positive diagonal, and congruence by a positive diagonal matrix preserves supports, the orthogonality conditions and the signs (`matrixLayerSign_congr`). Take $K = -\mu_0^2$.

(b), the two polynomial facts. Write $b_i = J^{a_1}_{-m_1} \cdots J^{a_\ell}_{-m_\ell}\mathbf{1}$. Moving the creators of b_i across the form one at a time with $\mathcal{H}(J^a_m x, y) = \mathcal{H}(x, J^{a^*}_{-m} y)$ (`sesq_J_adj`), and using $\mathcal{H}(\mathbf{1}, z) = B_k(\mathbf{1}, z)$, the vacuum coefficient of z,

$$\mathcal{H}(b_i, b_j) = \left\langle J^{a^*_\ell}_{m_\ell} \cdots J^{a^*_1}_{m_1} b_j \right\rangle_{\mathbf{1}}, \tag{19.2}$$

the vacuum coefficient obtained by letting the annihilators act on b_j. Move each annihilator to the right with (19.1). A factor of k is produced only by a central term, which consumes one annihilator and one creator; the bracket terms consume one of each and produce a mode of lower absolute value but no k. Hence the degree in k is at most the number of annihilators and at most the number of creators: item 1. At equal lengths ℓ, the coefficient of k^ℓ comes from complete matchings of each annihilator $J^{a^*}_m$ with a creator J^a_{-m} of the *same* depth and the reversed colour, each contributing $m\,\kappa(a^*, a) > 0$; such a matching exists only if the two multisets of letters coincide, i.e. $i = j$ for ordered monomials, and then the number of matchings is a product of factorials of multiplicities. So the top coefficient is $\delta_{ij} d_i$ with $d_i > 0$: item 2. (The sign: with $k = -\mu^2$ the top term $d_i k^\ell$ is $(-1)^\ell d_i \mu^{2\ell}$, and after the rescaling of (a) this is the diagonal entry $(-1)^\ell d_i$ of the limit D; so the alternating signs required by graded unitarity come entirely from $k < 0$, while $d_i > 0$ comes from $\kappa(a^*, a) > 0$.) Item 3 is Lemma 19.52. Apply (a). □

Physical meaning

Rescaling a state of r currents by $|k|^{-r/2}$ is the usual normalisation of a current with two-point function $\propto k$; as $|k| \to \infty$ the currents become free (generalized free fields) and every correlator is computed by Wick contractions. In that limit a state of r currents has norm $\propto k^r$, of sign $(-1)^r$ for $k < 0$: exactly the graded-unitarity sign. The anchor is the precise form of "at large flavour central charge the current sector is a Fock space".

What the machine verified

(a) and (b) proved; `#print axioms` on `matrixLayerSign_eventually`, `gramPoly_natDegree_le`, `gramPoly_coeff_top`, `layerSignAnchor_compact`: `[propext, Classical.choice, Quot.sound]`. Unconditional.

Theorem 19.54 (Rigidity of layer signs). ***(a) Matrix version.*** *Let X be a preconnected topological space and $H : X \to \mathrm{Mat}_I(\mathbb{C})$ a continuous family of Hermitian matrices with* StepNondeg$(H(t))$ *for every t. If* LayerSign$_r(H(t_0))$ *holds for one t_0, it holds for every t_1.*

(b) Affine version. *Rigidity (Definition 19.51) holds for the compact family. Consequently, for every real $k < -2$, graded unitarity of $V^k(\mathfrak{sl}_2)$ with the compact structure and the ordinary flag follows from the anchor alone.*

```

From the mathematics to the Lean statement

(a). `PreconnectedSpace X`: X cannot be split into two disjoint nonempty open sets (for us $X = (-\infty, -2)$, `Set.Iio (-2)`). `Continuous H` is entrywise continuity. The hypotheses are exactly those of (a); the conclusion is for the given r.

(b). `gram_isHermitian` and `gram_eq_eval` hold for every real noncritical k (`hreal`), the latter for $k \neq 0$: the compact Gram matrix is Hermitian (indeed real symmetric) and polynomial in the level, hence continuous on $(-\infty, -2)$. `layerSignRigidity_compact` is item 2 of Definition 19.51 for `compactRealFamily`, no hypotheses. `universal_gradedUnitary_belowCritical_of_anchor` is the headline with the anchor still an argument; its one-line proof plugs the proved rigidity into the assembly `universal_gradedUnitary_belowCritical_compact` (`AffineSl2BelowCriticalRealStructure.lean`), which in turn specialises the abstract `universal_gradedUnitary_belowCritical` to the compact family.

Proof on paper. *(a).* At each t the step matrix $\{\ell < r+1\} = \{\ell \le r\}$ is invertible, and $\det H|_{\{\ell \le r\}} = \det H|_{\{\ell < r\}} \cdot \det S_r(t)$ where $S_r(t)$ is the Schur complement of the first in the second; so $S_r(t)$ is a Hermitian matrix with trivial kernel, depending continuously on t (the inverse of $H|_{\{\ell<r\}}$ is the adjugate divided by a nonvanishing determinant). The set $U = \{t : (-1)^r S_r(t)$ positive definite$\}$ is open (positivity on the compact unit sphere persists) and closed (a limit of positive definite

matrices is positive semidefinite, and positive semidefinite with nonzero determinant is positive definite; `posDef_rigid`). X is preconnected and $t_0 \in U$, so $U = X$. Translate back with `matrixLayerSign_iff_schur`.

(b). The Gram matrix is Hermitian and polynomial in the level (Lemma 19.52), hence continuous on $(-\infty, -2)$. The step-nondegeneracy hypothesis of (a) is the translation of $\mathrm{Nd}(x, E)$ (`matrixStepNondeg_of_layerNondeg`). Apply (a) on $X = (-\infty, -2)$, which is connected. □

Physical meaning

This is the familiar statement that a norm can change sign only by passing through zero: along a continuous family of theories, a state can turn from positive to negative norm only at a point where some state becomes null. Below the critical level there is no such point (no "wall"), so the signs found in the free limit persist.

What the machine verified

(a), (b) proved; `#print axioms` on `matrixLayerSign_rigid`, `layerSignRigidity_compact`, `universal_gradedUnitary_belowCritical_of_anchor`: `[propext, Classical.choice, Quot.sound]`. The last is, as stated, conditional on `hanchor`; the hypothesis is discharged by Theorem 19.53 in the headline.

Theorem 19.55 (Nondegeneracy of the full form below critical level). *For every real $k < -2$ and every E, the form B_k is nondegenerate on V_E^k: if $v \in V_E^k$ and $B_k(y, v) = 0$ for all $y \in V_E^k$, then $v = 0$.*

File `VOA/Examples/AffineSl2BelowCriticalNondegenerate.lean`.

```
theorem universalForm_separating_of_lt {x : ℝ} (hx : x < -2) (E : ℤ) :
    ∀ v ∈ (universal (x : ℂ) (noncritical_of_lt hx)).grading E,
      (∀ y ∈ (universal (x : ℂ) (noncritical_of_lt hx)).grading E,
        (universalForm (x : ℂ) (noncritical_of_lt hx)).form y v = 0) → v = 0 := by
```

From the mathematics to the Lean statement

The statement is separation in the second slot, which in finite dimension is nondegeneracy (`nondegenerate_of_separatingRight`). No hypothesis beyond $x < -2$. It is the input "the full weight-E form is nondegenerate" of the no-wall lemma.

Proof on paper. *Step 1: blocks.* The zero mode $h_0 = J_0^h$ commutes with L_0 and is skew-adjoint for B_k in the sense $B_k(h_0 u, v) = -B_k(u, h_0 v)$; so weight vectors of different h_0-charges $c \neq -c'$ are B_k-orthogonal, and the Gram matrix of V_E^k in the PBW basis is block diagonal after pairing charge c with charge $-c$ (the "Chevalley twist" θ of Definition 19.48 turns this into a block-diagonal matrix with blocks of fixed charge, which is the form in which Chapters 9 and 10 compute it). It suffices to show that each block has nonzero determinant.

Step 2: the Kac–Kazhdan formula. For the Verma module of $\widehat{\mathfrak{sl}_2}$ with highest weight Λ (level k, h_0-eigenvalue λ), the determinant of the Shapovalov form on the weight space $\Lambda - \eta$ is, up to a nonzero constant, a product of factors

$$\big(2(\Lambda + \hat\rho, \beta) - n(\beta, \beta)\big)^{P(\eta - n\beta)\cdot \mathrm{mult}(\beta)},$$

one for each positive affine root β and each integer $n \geq 1$ ($\hat\rho$ the affine Weyl vector, P the partition function). The positive roots are of two kinds. *Real* roots $\beta = \pm\alpha + m\delta$ ($m \geq 1$, or $m = 0$ with the sign $+$), with $(\beta, \beta) = 2$: since $(\Lambda, \alpha) = \lambda$, $(\hat\rho, \alpha) = 1$, $(\Lambda, \delta) = k$ and $(\hat\rho, \delta) = h^\vee = 2$, the factor is $2\big(\pm(\lambda + 1) + m(k + 2) - n\big)$, which vanishes iff $\pm(\lambda + 1) + m(k + 2) = n$; at $\lambda = 0$, iff $m(k + 2) \pm 1 = n$. *Imaginary* roots $\beta = m\delta$, $m \geq 1$, with $(\beta, \beta) = 0$: the factor is $2(\Lambda + \hat\rho, m\delta) = 2m(k + h^\vee) = 2m(k + 2)$,

a power of $(k+2)$, vanishing only at the critical level. In the library this is Theorem 9.42: the imaginary-root factors are the constant $C_{n,c}(t)$, nonzero for $t = k+2 \neq 0$, and the real-root factors are the roots of the monic polynomial $K_{n,c}(t)$ in λ.

Step 3: from Verma to vacuum. $V^k(\mathfrak{sl}_2)$ is the quotient of the Verma module with $\lambda = 0$ by the submodule generated by $f_0\mathbf{1}$, i.e. by the horizontal real root $\beta = \alpha$ $(m = 0)$, whose factor $(n = 1)$ vanishes identically at $\lambda = 0$. The Gram determinant of the vacuum module is the Kac–Kazhdan product with this horizontal family removed (Section 10.7); what remains are the non-horizontal real factors $m \geq 1$ and the imaginary factors.

Step 4: no factor vanishes for $k < -2$. A non-horizontal real factor vanishes only if $m(k+2)\pm 1 = n$ for integers $m \geq 1$, $n \geq 1$. For $k+2 < 0$ the left side is $m(k+2)+1 < 1$ in the case $+$ and $m(k+2)-1 < -1$ in the case $-$, never a positive integer. The imaginary factors are powers of $k+2 \neq 0$. So no factor vanishes (`vacuumOrder_eq_zero_of_lt`), every block is invertible, and the form is nondegenerate. □

Physical meaning

Kac–Kazhdan zeros are the levels at which the vacuum module acquires null vectors (e.g. $(J^e_{-1})^{k+1}\mathbf{1}$ at positive integer k, or the admissible singular vectors at $k = -2 + p/q$). Below the critical level there are none: $V^k(\mathfrak{sl}_2)$ is simple for every real $k < -2$.

What the machine verified

Proved, unconditional; `#print axioms`: `[propext, Classical.choice, Quot.sound]`.

Theorem 19.56 (The prefix no-wall lemma). ***(a) Abstract.*** *Let V be a VOA with invariant form B, real structure ρ and graded flag F, and let $(X^i_m)_{i\in I, m\in\mathbb{Z}}$ (I finite) be operators on V with an involution $i \mapsto i^\dagger$ of I and numbers $\lambda_n, z_i \in \mathbb{C}$, $w_i > 0$, such that: X^i_m lowers the weight by m; $\mathcal{H}(X^i_m a, b) = \mathcal{H}(a, X^{i^\dagger}_{-m} b)$ for $\mathcal{H}(a,b) = B(\rho a, b)$; X^i_m preserves F_p for $m \geq 0$ and maps F_p into F_{p+1} for $m < 0$; every V_n, $n > 0$, is spanned by vectors $X^i_{-m} y$ with $m > 0$, $y \in V_{n-m}$; ρ preserves weights and flag pieces, with $s(n) \neq 0$; and the energy identity*

$$\lambda_n\, \mathcal{H}(v,v) = \sum_i z_i\, \mathcal{H}(X^i_0 v, X^i_0 v) + \sum_i \sum_{m=1}^{n} w_i\, \mathcal{H}(X^i_m v, X^i_m v) \qquad (v \in V_n) \tag{19.3}$$

holds. Fix E. If clause (vi) holds at every weight $E - m$, $m \geq 1$, and B is nondegenerate on V_E, then B is nondegenerate on every flag step $F_p \cap V_E$ (clause (iv) at weight E).

(b) Affine instance. *For $V^k(\mathfrak{sl}_2)$ at any $k \neq -2$, the ordinary flag, any compact ρ, the currents $X^a_m = J^a_m$, $a^\dagger = a^*$, and (19.3) is the Hermitian Sugawara identity*

$$2(k+2)E\, \mathcal{H}(v,v) = \sum_c s_c\, \mathcal{H}(J^c_0 v, J^c_0 v) + \sum_c \sum_{m=1}^{E} 2 s_c\, \mathcal{H}(J^c_m v, J^c_m v), \qquad (s_e, s_f, s_h) = (1, 1, \tfrac{1}{2}).$$

In the notation of (a) this is $\lambda_E = 2(k+2)E$, $z_c = s_c$ and $w_c = 2s_c > 0$ (the Lean fields `lam`, `zc`, `wt` *of* `currentSystem`, *with $s_c =$* `sugawaraWeight c`*).*

From the mathematics to the Lean statement

The structure. `CurrentSystem ι B R F` packages the hypotheses of (a) field by field: `mode i m` is X^i_m, `adj` the involution $\dagger$, `sesq_adj` the Hermitian adjointness, `nonneg_mem`/`neg_mem` the flag behaviour, `creation_span` the spanning, `wt`/`wt_pos` the positive weights w_i, `lam` and `zc` the coefficients λ_n, z_i (no sign condition on either), `sugawara` identity (19.3) (`n.toNat` is $\max(n,0)$; `Finset.Icc 1 n.toNat` is $\{1,\dots,n\}$), and the last three fields the conditions on ρ. A `structure` with `Prop` fields is only as good as its instances; here it is instantiated by `currentSystem hR` for $V^k(\mathfrak{sl}_2)$, every field proved (`lam E := 2 * (k + 2) * (E : ℂ)`, `wt c := 2 * sugawaraWeight c`, `sugawara hv := hR.sugawara_sesq hv`), so it is not vacuous.

The theorem. `hfull` is separation of B on V_E (Theorem 19.55 supplies it); `hlower` is clause (vi) at each lower weight $E-m$, $m \geq 1$, *at the same* (B,ρ,F); the con-

clusion is clause (iv) at weight E. It does *not* conclude clause (vi) at weight E (the docstring stresses this). In the quoted source the theorem lives in `namespace CurrentSystem` with the displayed `variable` line, so it is `S.layerNondegenerate_of_lower`; the affine specialisation `AffineSl2BelowCritical.layerNondegenerate_of_lower` (`AffineSl2BelowCriticalCompact.lean`) is `(currentSystem hR).layerNondegenerate_of_lower`.

The Sugawara identity. `sugawara_sesq` holds for every noncritical k and every compact ρ; the weights $(1, 1, \frac{1}{2})$ are the entries of κ^{-1} in the basis (e, f, h). Note the coefficient $2(k+2)E$ is *negative* for $k < -2$; the argument does not need its sign.

Proof on paper. *The Sugawara identity.* $L_0 = \frac{1}{2(k+2)} \sum_{a,b} \kappa^{ab}\big(J^a_0 J^b_0 + 2\sum_{m>0} J^a_{-m} J^b_m\big)$ on V^k, where κ^{ab} is the inverse Killing matrix ($\kappa^{ef} = \kappa^{fe} = 1$, $\kappa^{hh} = \frac{1}{2}$). Pair with $v \in V_E$ under $\mathcal{H}$, use $L_0 v = Ev$ and move J^a_{-m} to the left as its adjoint $J^{a^*}_m$; since $\kappa^{ab} \neq 0$ only for $b = a^*$, every term becomes a norm $\mathcal{H}(J^c_m v, J^c_m v)$.

The lemma. Suppose $v \in F_r \cap V_E$ is in the radical of B restricted to $F_r \cap V_E$. Because ρ preserves F_r and $s(E) \neq 0$, v is also $\mathcal{H}$-orthogonal to $F_r \cap V_E$ (as in Theorem 19.12).

1. For $m > 0$, $u = X^i_m v$ lies in $F_r \cap V_{E-m}$, and for $z \in F_{r-1} \cap V_{E-m}$, $\mathcal{H}(z, u) = \mathcal{H}(X^{i^\dagger}_{-m} z, v) = 0$ since $X^{i^\dagger}_{-m} z \in F_r$. So u lies in the layer $\mathcal{L}_r$ at weight $E-m$, where by hypothesis $(-1)^r h(u, u) \geq 0$ with equality only for $u = 0$.

2. Zero modes preserve F_r, so $\mathcal{H}(X^i_0 v, X^i_0 v) = \mathcal{H}(v, X^{i^\dagger}_0 X^i_0 v) = 0$; and $\mathcal{H}(v, v) = 0$.

3. Multiply (19.3) by $(-1)^r$: the left side and the zero-mode terms vanish, so $\sum_{i,m} w_i\,(-1)^r\,\mathcal{H}(X^i_m v,\, X^i_m v) = 0$, a sum of nonnegative reals with $w_i > 0$. Every term vanishes, so $X^i_m v = 0$ for all i and $m > 0$.

4. Then for every spanning vector $X^i_{-m} y$ of V_E, $\mathcal{H}(X^i_{-m} y, v) = \mathcal{H}(y, X^{i^\dagger}_m v) = 0$. So v is orthogonal to all of V_E, and $v = 0$ by full nondegeneracy.

(For $E \leq 0$ the argument degenerates harmlessly: $V_E = 0$ for $E < 0$ and $F_r \cap V_0 = V_0$.) □

Physical meaning

A "wall" is a level at which a truncated sector develops a null state, the only place where signs can flip. The lemma says a null state in a current-number-truncated sector would have to be a highest-weight state for the currents (all positive modes kill it, step 3) — because its descendants under the positive modes live in lower sectors whose norms all have the same sign, and the Sugawara identity (which expresses L_0 as a sum of norms) forces them to cancel. A current-primary null state at weight $E > 0$ is a singular vector of the full vacuum module, and there are none below the critical level. (Heuristic summary; the rigorous statement is Theorem 19.55.)

What the machine verified

(a) and (b) proved; `#print axioms` on `CurrentSystem.layerNondegenerate_of_lower`, `AffineSl2BelowCritical.layerNondegenerate_of_lower` and `IsCompactRealStructure.sugawara_sesq`: `[propext, Classical.choice, Quot.sound]`. The abstract lemma (a) is conditional on its displayed hypotheses `S`, `hfull`, `hlower`, which in the headline are supplied by `currentSystem`, Theorem 19.55 and the induction hypothesis.

19.14.4 A worked example: weights one and two

Example 19.57 (Weight one and weight two of $V^k(\mathfrak{sl}_2)$)**.** The following is a paper computation, *not* a Lean theorem. Every entry is elementary and can be checked by hand from (19.1) and (19.2); the author also checked them with a short computer-algebra script (not part of the repository), and the fidelity referee recomputed them independently. We write e_{-n} for J^e_{-n} etc.

Weight one. V_1 has basis $e_{-1}\mathbf{1}$, $f_{-1}\mathbf{1}$, $h_{-1}\mathbf{1}$, all of length one, and step $\{\ell < 1\}$ is empty at this weight, so $\mathcal{L}_1 = V_1$. By (19.2), $\mathcal{H}(e_{-1}\mathbf{1}, e_{-1}\mathbf{1}) = \langle f_1 e_{-1}\rangle = \langle -h_0 + k\rangle = k$, and similarly

$$G_1(k) = \operatorname{diag}(k,\ k,\ 2k).$$

Clause (vi) at $p = 1$ asks $-G_1(k)$ positive definite: $k < 0$. (For $k > 0$ — the regime whose simple quotients $L_k(\mathfrak{sl}_2)$, $k \in \mathbb{Z}_{>0}$, are the unitary WZW models — the graded-unitarity sign is violated: the two notions of positivity are opposite at odd R, as in Remark 19.3.)

Weight two. $\dim V_2 = 9$: three monomials of length one (e_{-2}, f_{-2}, h_{-2}) and six of length two. The h_0-charge splits V_2 into blocks of charge $4, 2, 0, -2, -4$. In the charge-0 block take the PBW monomials

$$v_1 = h_{-2}\mathbf{1}, \qquad v_2 = e_{-1}f_{-1}\mathbf{1}, \qquad v_3 = h_{-1}h_{-1}\mathbf{1},$$

of lengths $1, 2, 2$. Their Gram matrix is

$$G = \begin{pmatrix} 4k & 2k & 0 \\ 2k & k^2 + 2k & 4k \\ 0 & 4k & 8k^2 \end{pmatrix}.$$

For instance $\mathcal{H}(v_2, v_2) = \langle e_1 f_1 e_{-1} f_{-1}\rangle$; first $f_1 e_{-1} f_{-1}\mathbf{1} = (-h_0 + k) f_{-1}\mathbf{1} = (k+2) f_{-1}\mathbf{1}$, then $e_1(k+2) f_{-1}\mathbf{1} = k(k+2)\mathbf{1}$.

- *Layer 1* is $\mathbb{C}v_1$, with $\mathcal{H}(v_1, v_1) = 4k$: sign $-$ for $k < 0$, as required.
- *Layer 2* is $\{a v_1 + b v_2 + c v_3 \,:\, \mathcal{H}(v_1, \cdot) = 0\} = \{4ka + 2kb = 0\}$, spanned by $w_2 = v_2 - \frac{1}{2}v_1 = \frac{1}{2}(e_{-1}f_{-1} + f_{-1}e_{-1})\mathbf{1}$ and $w_3 = v_3$. On it the form is the Schur complement

$$S = \begin{pmatrix} k^2 + k & 4k \\ 4k & 8k^2 \end{pmatrix}, \qquad \det S = 8k^2(k+2)(k-1).$$

  For $k < -2$: $k^2 + k = k(k+1) > 0$ and $\det S > 0$, so S is positive definite — sign $+$, as required. At $k = -2$, $\det S = 0$; for $-2 < k < 1$, $k \neq 0$, $\det S < 0$ and S is indefinite, so clause (vi) *fails*.

The other blocks (computed by the same rules; the details are not shown) give layer-2 Schur complements $2k(k-1)$ (charge 2: basis $e_{-2}\mathbf{1}$, $e_{-1}h_{-1}\mathbf{1}$, the Schur complement of $e_{-2}\mathbf{1}$; charge -2 likewise with f) and $\mathcal{H}(e_{-1}^2\mathbf{1}, e_{-1}^2\mathbf{1}) = 2k(k-1)$ (charges ± 4), positive for $k < 0$; the full weight-two determinant is $2^{11}k^9(k-1)^5(k+2)$, nonzero for $k < -2$ (clause (iv) and Theorem 19.55).

The Sugawara vector sits in layer 2. The unnormalised Sugawara vector is $\omega' = \frac{1}{2}h_{-1}^2 + e_{-1}f_{-1} + f_{-1}e_{-1} = 2w_2 + \frac{1}{2}w_3$ (applied to $\mathbf{1}$), and $\mathcal{H}(\omega', \omega') = 4(k^2 + k) + 2 \cdot 4k + \frac{1}{4} \cdot 8k^2 = 6k(k+2)$. With $\omega = \omega'/(2(k+2))$,

$$\mathcal{H}(\omega, \omega) = \frac{3k}{2(k+2)} = \frac{c}{2},$$

the familiar norm $\langle T|T\rangle = c/2$. It is positive exactly when $k < -2$ or $k > 0$, and the wall at $k = -2$ is the critical level, where ω' becomes null. Together with weight one ($k < 0$) this shows that $k < -2$ is exactly the range in which weights one and two satisfy the theorem.

Physical meaning

The example is the whole theorem in miniature: one-current states have the four-dimensional sign through the factor $k < 0$, the two-current states (including the stress tensor, a composite of two currents in the universal algebra) have the sign $+$, and the only obstruction is the critical level, where the Sugawara stress tensor degenerates into the Feigin–Frenkel centre.

19.14.5 The remaining files

The twelve files, collectively (each is unconditional except where a hypothesis is named):

- `AffineSl2BelowCriticalFlag.lean`: `ordinaryPiece`, `ordinaryFlag`; current modes J^a_m preserve F_p for $m \geq 0$ (`J_mem_ordinaryPiece_of_nonneg`) and map F_p into F_{p+1} for $m < 0$; positive weight spaces are spanned by negative-mode images (`grading_le_span_creation`).

- `AffineSl2BelowCriticalPBWFlag.lean`: filtered PBW straightening — a creation word of length L is a combination of ordered PBW monomials of length $\leq L$ (an adjacent swap keeps the length, its commutator term is one letter shorter); `ordinaryPiece_eq_pbwSpan`, `mem_ordinaryPiece_iff_repr`.

- `AffineSl2BelowCriticalCompact.lean`: `IsCompactRealStructure` and its consequences (`rho_J`, `sesq_J_adj`, ρ preserves weights and the flag), `sugawara_sesq`, `currentSystem`, and the affine no-wall lemma.

- `AffineSl2BelowCriticalRealStructure.lean`: the conjugate vacuum module `ConjMod`, `basisConj`, `compactRho`, covariance of every vertex operator (`compactRho_YA`) and of the Sugawara field, `compactRealStructure`, `compactRealFamily`, and the assembly `universal_gradedUnitary_belowCritical_compact` (conditional on `hanchor`, `hrigid`).

- `AffineSl2BelowCriticalNondegenerate.lean`: `noncritical_of_lt`, `vacuumOrder_eq_zero_of_lt`, `vacuumChevalleyPolynomial_det_eval_ne_zero`, `universalForm_separating_of_lt`.

- `AffineSl2BelowCriticalNoWall.lean`: `CurrentSystem` and the abstract no-wall lemma, for an arbitrary VOA.

- `AffineSl2BelowCriticalGradedUnitarity.lean`: `RealFamily`, `LayerSigns`, `LayerNondeg`, `LayerSignAnchor`, `LayerSignRigidity`, the induction (`step`, `layerSigns_all`) and the abstract assembly `universal_gradedUnitary_belowCritical` (conditional on `hR`, `hanchor`, `hrigid`).

- `AffineSl2BelowCriticalGramMatrix.lean`: `EIdx`, `coords`, `gram`; clause (iv) $\Rightarrow$ nonzero step minors, clause (vi) $\iff$ matrix layer signs.

- `AffineSl2BelowCriticalMatrixRigidity.lean` and `AffineSl2BelowCriticalMatrixAnchor.lean`: pure linear algebra and topology (step matrices, Schur complements, `posDef_rigid`, `posDef_eventually`, `matrixLayerSign_congr`, the rescaling limit `tendsto_rescaled`).

- `AffineSl2BelowCriticalRigidity.lean`: `bilinForm_eq_of_current_adj`, the two invariances of B_k, `gram_isHermitian`, `gramPoly`, `gram_eq_eval`, `layerSignRigidity_compact`.

- `AffineSl2BelowCriticalAnchor.lean`: `gramPoly_symm`, `gramPoly_natDegree_le`, `gramPoly_coeff_top`, `layerSignAnchor_compact`, and the headline.

19.15 Appendix: geometric VOAs and the chiral de Rham complex

The directory `VOA/Geometric/` contains two files, `VOA/Geometric/GeometricVOA.lean` and `VOA/Geometric/ChiralDeRham.lean`. **Neither declares anything**: each consists of an import, a module docstring, and an empty `namespace VOA ... end VOA` with the comment "OUT OF SCOPE". The "target declarations" in their docstrings (`SphereWithTubes`, `GeometricVOA`, `geometricEquivAlgebraic`, `VOSA`, `chiralDeRham`, `ellipticGenus`) live inside docstring code fences and are not Lean code. Nothing about chiral de Rham complexes or elliptic genera is proved, stated or defined in the library; the "exploratory" label of the library map means exactly this.

The mathematics the files point to. A *geometric VOA* (Huang) is a meromorphic, sewing-compatible assignment of linear maps $V^{\otimes n} \to \overline{V}$ to spheres with $n+1$ tubes (marked points with local coordinates); the pair of pants with punctures at $0, w, \infty$ gives $Y(u,w)v$, sewing gives the Jacobi identity, and the Virasoro algebra encodes changes of local coordinates. Huang proved that geometric VOAs are equivalent to (algebraic) VOAs. The *chiral de Rham complex* of Malikov–Schechtman–Vaintrob (1999) is a sheaf Ω^{ch}_X of vertex superalgebras on a smooth complex variety X, locally the $\beta\gamma$–bc system on coordinate charts, glued by explicit (and subtly corrected) transformation rules; it carries a differential and, for Calabi–Yau X, an $N = 2$ superconformal structure. Its cohomology has the de Rham cohomology of X in conformal weight zero, and its graded character $\operatorname{tr} q^{L_0} y^{J_0}$ (suitably signed) is the *elliptic genus* of X (Borisov–Libgober 2000), a weak Jacobi form for Calabi–Yau X.

Physical meaning

Ω^{ch}_X is the perturbative chiral algebra of the $(0,2)$ (half-twisted) sigma model with target X (Kapustin 2005; Witten 2007); the elliptic genus is the sigma model's partition function on the torus with the $U(1)$ R-symmetry fugacity y, a protected quantity independent of the metric, which is why it is a topological invariant and a modular (Jacobi) form. For a Calabi–Yau 3-fold it counts BPS states of the half-twisted theory.

What the machine verified

Nothing to verify: the files contain no declarations. The file `VOA/Examples/MoonshineModule.lean` (assigned here by the catch-all rule) is likewise an empty stub whose docstring now correctly points to the actual construction of $V^\natural$ in `VOA/Moonshine/` (Chapters 1–43); its title line ("next Phase-3 target") and the comment `-- TODO (Phase 3, next target)` are stale.

19.16 Axiom audit

The following was produced for this chapter at an earlier commit (not re-run for this edition) by a scratch file importing the relevant modules and running `#print axioms`, compiled with `lake env lean -DmaxSynthPendingDepth=3` (never with a bare `lake env lean`, which can silently change elaboration; no full `lake build` was run for this chapter, the modules being already built). Output, one declaration per line:

```

Build state of Section 19.14. The axiom checks above are isolated-module runs (`lake env lean -DmaxSynthPendingDepth=3` against the compiled modules). The project's internal build record (entry of 2026-10-15/16, nothing committed at that time) reports an aggregate `lake build` of 13,443 jobs with the twelve below-critical modules wired into `VOA/Examples.lean`; that run is at neither of the commits of the two runs above, and the same record's entry of 2026-10-27 states that no book chapter had then been verified against an aggregate `lake build`. The section is therefore *not* certified by an aggregate build; that the twelve modules are imported by `VOA/Examples.lean` was confirmed by reading the file.

No declaration of this chapter depends on `VOA.pbw`, on `sorryAx`, or on any axiom beyond Lean's three standard ones (one, `a3count_eq_pLe3_shift`, proved by `decide`, depends on none). *Axiom-clean is not unconditional*: the conditional declarations (the abstract transfer `gradedUnitary_of_ambient`, `tower_posDef`, `gradedUnitaryAt_iff_minors_and_positive`, `leeYang_stronglyRational_of_admissiblyRational`, and the intermediate below-critical assemblies `universal_gradedUnitary_belowCritical`, `…_compact`, `…_of_anchor`) carry their hypotheses explicitly, as listed in the checklist. The below-critical headline `universal_gradedUnitary_belowCritical_unconditional` is both axiom-clean and unconditional.

19.17 Defects and traps recorded in this chapter

For the maintainers, the findings of this chapter, with severity on a four-step scale: serious (a statement that is wrong or vacuous), moderate (weaker or stronger than advertised, or a redundant hypothesis), open gap (a conditional result whose hypothesis is not discharged, or a missing piece), and documentation only (docstrings and notes).

1. **Moderate (design weakness).** `GradedUnitary B R F` quantifies over an arbitrary `GradedFlag`, which need not be compatible with the vertex operators, ρ-stable, or ABLR's R-filtration; "for some flag" is nearly vacuous (Warning 19.4.1, paper argument). `VirGradedUnitary` pins the flag and is unaffected.

2. **Open gap.** `dsReductionSl2` takes a `BRSTComplex` as input; none exists for `dsQ` (`Q_wt` fails for the naive grading, `Q_deriv` unavailable). `RoutesAgreeSl2` is an unproved `Prop`.

3. **Moderate (minor).** `FlagMinors.schurOfLeading_posDef_of_sign_ratios` and …negDef… assume $0 < D_l$ where $D_l \neq 0$ suffices; the general versions exist in `PolarizedReesStrongGenerator.lean`.

4. **Documentation only.** Stale docstrings: `FlagMinors.lean`, `GradedUnitarity.lean` and `VirasoroGradedUnitarity.lean` say the pivot/positivity half of the minors criterion is absent (it is in `MinorPivots.lean`); `VirasoroGradedUnitarity.lean` says no real structure is constructed on $L(c, 0)$ and no positivity is proved (Warning 19.8.3); `MoonshineModule.lean`'s title and TODO comment are stale.

5. **Documentation only.** The docstring of `RigidBridge.shapForm` (`VOA/Core/RigidityBridge.lean`) says its Gram matrix "is the level-k Kac matrix"; it agrees with the invariant form only on quasi-primary vectors (`LeeYangKac.lean` documents the discrepancy at level four; Warning 19.9.1).

6. **Book (not Lean); corrected.** An earlier draft of Chapter 43 expanded "ABLR" wrongly; the sources mean Arabi Ardehali–Beem–Lemos–Rastelli, and Chapter 43 now says so.

7. **Documentation only.** `AffineSl2BelowCriticalGradedUnitarity.lean`: the module docstring calls the three inputs of `universal_gradedUnitary_belowCritical` "none of which is established in this repository" and the docstrings of `LayerSignAnchor`, `LayerSignRigidity` say "Named open input"; all three are proved for `compactRealFamily` (Warning 19.14.3).

8. **Documentation only.** `VOA/Core/GradedUnitarity.lean`: since the below-critical headline (Theorem 19.49), the module Status line "No VOA in this repository is proved fully graded unitary" and the `GradedUnitary` docstring sentence "No theorem in this repository asserts it of anything" are false: `universal_gradedUnitary_belowCritical_unconditional` asserts it of $V^k(\mathfrak{sl}_2)$ for every real $k < -2$. The module-level warning that the predicate is "nearly vacuous" (because the flag is free, Warning 19.4.1) is partly answered by that theorem, whose flag is fixed. (Found by the fidelity referee of Section 19.14.)

9. **Restriction (not a defect).** Virasoro real structures are constructed only for $c = 1 - 12\lambda^2$ with λ real ($c \leq 1$), although they exist for all real c.

19.18 Referee's checklist

Lean declaration	Intended meaning	Hypotheses / status	Check
`eq_bot_of_bilinear_pos`	bilinear "positivity" forces $S = 0$ (the old defect)	none; unconditional	Thm. 19.4
`SesqForm`, `IsPosOn`, `signedForm`	sesquilinear form; positive on S; $(-1)^p$ twist	definitions; witnesses both ways	Def. 19.5, 19.7
`RealStructure`	anti-linear VOA automorphism, $\rho^2 = s$	definition; s free	Def. 19.9
`gradedSesq`	$h(a,b) = B(\rho a, b)$ on V_n	definition	Def. 19.10
`layer`, `LayerNondegenerate`, `LayerPositive`, `GradedUnitaryAt`, `GradedUnitary`	ABLR clauses (iv), (vi); graded unitarity	definitions; **flag free** (Warn. 19.4.1); asserted only in Thm. 19.49	Def. 19.11
`orthogonal_gradedSesq_eq`	bilinear and sesquilinear complements agree	ρ-stable, $s(n) \neq 0$	Thm. 19.12
`layerDecomposition`, `finrank_pieceLT_add_layer`	clause (v) follows from (iv)	reflexive, clause (iv)	Thm. 19.13
`isPosOn_layer_zero_vacuum`	vacuum slice of (vi)	$(\mathbf{1}\|\mathbf{1}) = 1$	Thm. 19.14
`nondegenerate_flag_iff_minors`	(iv) $\iff$ nonzero leading minors	flag refines basis	Thm. 19.16
`posDef_of_det_leadingPrincipal_pos`	converse Sylvester	symmetric real	Thm. 19.17
`schurOfLeading_posDef_of_sign_ratios` (+`negDef`)	layer definiteness from minor ratios	$D_l \neq 0$ (weakened from $D_l > 0$)	Thm. 19.17
`SesqForm.isPosOn_signedForm_of_eq_pullback`	positivity pulls back	injective, exact isometry	Thm. 19.8
`VirGradedUnitary`	Kaufmann/ABLR conjecture for $L(c,0)$	definition; **open**, never asserted	Def. 19.20
`gradedUnitaryAt_iff_minors_and_positive`	Virasoro reduction to minors	adapted basis `hrb` (never supplied)	Thm. 19.21
`virasoroSimpleRealStructure`, `boundaryVirasoroRealStructure`	real structure on $L(c,0)$	$c = 1 - 12\lambda^2$, $\lambda \in \mathbb{R}$; boundary: none	Thm. 19.23, 19.24
`rhoStableOn_vir_pieceIn`	length flag is ρ-stable	any ρ; unconditional	Thm. 19.25
`lengthTwoQ_quasiPrimary`, `canB_lengthTwoQ_self`	$L_1 Q_{2m} = 0$; $(Q\|Q) = \frac{1}{2}\binom{4m-2}{2m-4} c(c+\rho_m)$	$m \geq 2$; unconditional	Thm. 19.28
`Bsimp_boundaryLengthLETwoTowerAt_self_sign`	stress towers negative, length-two towers positive	$n \geq 2$	Thm. 19.30
`boundary_gradedUnitaryThroughTwo`	(iv)+(vi) for $p \leq 2$, all weights, $M(2, 2n+1)$	$n \geq 2$ only; **unconditional**	Thm. 19.32
`exists_level4_singular_iff`	level-4 singular vector iff $c = -22/5$	none	Thm. 19.34
`maxIdealVir_leeYang_inf_grading_four`	$\mathcal{M} \cap V_4 = \mathbb{C}s$	none (level 4 only)	Thm. 19.35
`leeYang_stronglyFinite`	$L(-22/5, 0)$ simple, self-dual, C_2-cofinite	none; unconditional	Thm. 19.36
`leeYang_stronglyRational_of_admissiblyRational`	strongly rational	**assumes** rationality	Thm. 19.36
`lowestWeight_eq_zero_or_neg_one_fifth`	lowest weights $\in \{0, -1/5\}$	necessary condition only	Thm. 19.37
`LeeYangRiccati.tower_posDef`	abstract length induction	matrix hypotheses, not instantiated	Thm. 19.38
`a3count_eq_pLe3_shift`, `negDef_w12`…	length-3 counts and signs	finite; external data	Thm. 19.39
`weil_polarized_twist_option_a`	Weil parity of channels	finite; external data	Thm. 19.40
`MinorPayload.sign_det_leadingPrincipal_pos`	minor signs from normal form	hypothesis ≡ conclusion	Thm. 19.41

Lean declaration	Intended meaning	Hypotheses / status	Check
`dsCentralCharge_eq_minimalModel`, `…eq_affine_add_ghost`	DS central charge	arithmetic	Thm. 19.42
`dsQ_mul_self`	$Q^2 = 0$	$k \neq -2$; cohomology **not built**	Thm. 19.43
`dsEmbed_injective`, `dsLatticeScreening_centralCharge`	DS complex, embedding, screening kernel	integral $k+2$ for the screening	Thm. 19.44
`compactCurrentSignedForm85_positive`	weight-one affine positivity at $-8/5$	three vectors; no VOA real structure	Thm. 19.45
`GradedIsometricEmbedding.gradedUnitary_of_ambient`	transfer through isometric embedding	**conditional**: reduction + ambient GU	Thm. 19.47
`universalForm`, `compactRealFamily`, `IsCompactRealStructure`, `ordinaryFlag`	canonical form, compact ρ, current-length flag on $V^k(\mathfrak{sl}_2)$	definitions; ρ proved compact	Def. 19.48
`universal_gradedUnitary_belowCritical_unconditional`	$V^k(\mathfrak{sl}_2)$ graded unitary for every real $k < -2$	k real, $k < -2$ only; **unconditional**	Thm. 19.49
`LayerSignAnchor`, `LayerSignRigidity`	the two analytic inputs of the assembly	definitions; both proved for the compact family	Def. 19.51
`matrixLayerSign_eventually`, `layerSignAnchor_compact`	layer signs at large negative level	degree and top-coefficient bounds (proved for `gramPoly`); unconditional	Thm. 19.53
`matrixLayerSign_rigid`, `layerSignRigidity_compact`	signs constant along $(-\infty, -2)$	continuous Hermitian family, nondegenerate steps; unconditional	Thm. 19.54
`universalForm_separating_of_lt`	B_k nondegenerate on V_E^k, $k < -2$	none; unconditional	Thm. 19.55
`CurrentSystem.layerNondegenerate_of_lower`, `sugawara_sesq`	prefix no-wall lemma; Hermitian Sugawara identity	lower-weight signs + full nondegeneracy (any VOA)	Thm. 19.56
Geometric files	geometric VOAs, chiral de Rham, elliptic genus	**no declarations**	§19.15

19.19 Notes and references

Graded unitarity. The datum formalised here is Definition 2.2 of A. Arabi Ardehali, C. Beem, M. Lemos and L. Rastelli, *Graded unitarity in the SCFT/VOA correspondence*, arXiv:2507.23781 (JHEP 2026), as cited in the source files (the files note the paper was not in the repository when the encoding was written). The conjecture for the boundary minimal models goes back to R. M. Kaufmann, preprint hep-th/9405041 (1994), §4.2 and eq. (4.4), as cited in the source files (we do not reproduce its title); the remark that the full structure was not established is from C. Beem and S. Garner, arXiv:2509.10364 (2025). The SCFT/VOA correspondence is C. Beem, M. Lemos, P. Liendo, W. Peelaers, L. Rastelli and B. C. van Rees, *Infinite chiral symmetry in four dimensions*, Comm. Math. Phys. 336 (2015) 1359–1433, arXiv:1312.5344. The admissible-partition (filtered) basis cited as `FlagBasisHyp` is J. Salazar, arXiv:2405.07126; the fusion-ring data of `WeilPolarizedChannelParity` is from P. Godfard, arXiv:2406.07459.

Below-critical graded unitarity. The proof formalised in Section 19.14 follows the repository note `Notes/graded-unitarity-verification/graded_unitarity_campaign/integrable_deformation_2026_10_01/audit/oct15_auxiliary_belowcritical_prefix_no_wall_primary.md` (prefix no-wall lemma,

large-level asymptotics, continuity in the level). The vacuum determinant is the Kac–Kazhdan formula: V. G. Kac and D. A. Kazhdan, *Structure of representations with highest weight of infinite-dimensional Lie algebras*, Adv. Math. 34 (1979) 97–108. The Sugawara construction and the critical level: H. Sugawara, Phys. Rev. 170 (1968) 1659; B. Feigin and E. Frenkel, *Affine Kac–Moody algebras at the critical level and Gelfand–Dikii algebras*, Int. J. Mod. Phys. A 7, Suppl. 1A (1992) 197–215.

Part VI

Two recent theorems, formalized

Chapter 20

Classical freeness at the boundary admissible level: the Arakawa–Dai theorems

This chapter was written against the working tree of 2026-10-13, in which the files of the Arakawa–Dai campaign were present but not yet committed. They were committed the same day, and every file in the import closure of the umbrella is tracked (checked by the release audit of 2026-10-27). Every Lean quotation below was copied from those files, re-checked by the author on 2026-10-13, and is checked verbatim against the committed sources by the book's automatic check (`scripts/textbook/sync.py`). The aggregate `lake build` was run on 2026-10-13 on this tree and was green (13150 jobs; not re-run for this edition), and the maintained axiom audit `scripts/audit/ArakawaDaiAxiomAudit.lean` (160 declarations) passes with only Lean's three standard axioms and *without* `VOA.pbw` (the PBW theorem of Chapter 3; formerly a project axiom, now a theorem).

The chapter covers the seventy-two files imported by the campaign umbrella `VOA/ArakawaDai.lean` (and, through them, about ninety further new support files in `VOA/Commutative/`, `VOA/Filtered/` and `VOA/Examples/`, some twenty-six thousand lines of new Lean in total). All headline statements live in one file, `VOA/Examples/AffineSl2BoundaryMainTheorems.lean`.

Added 2026-10-27. Two further sections document files that reached the library later. Section 20.12 is the *Virasoro companion*: classical freeness of the minimal models $M(2, 2m+3)$ for every $m \geq 0$, $J_\infty(\mathbb{C}[T]/(T^{m+1})) \cong \mathrm{gr}^F L(c_{2,2m+3}, 0)$, with the full non-reduced C_2-algebra and the Poisson vertex structure (files `VOA/Filtered/VirasoroWordLi.lean`, `VOA/Examples/VirasoroMinimalClassicalFreeness.lean`, `VOA/Examples/VirasoroMinimalPoisson.lean`). Section 20.13 describes thirty-two files of finite commutative algebra left from an abandoned "rooted Gordon conductor" route to the boundary theorem at $p = 3$; they are kept because the Deligne carrier of Chapter 24 reuses five of them (imported by five Deligne-carrier files).

Added 2026-10-28. Section 20.3.3 presents the file `VOA/Examples/AffineSl2BoundaryTheorem11.lean`, which states Arakawa–Dai's Theorem 1.1 as one theorem in the paper's form, `arakawaDai_theorem_1_1`, and makes the presentation isomorphism canonical by theorem. This replaces the earlier "two-part" wording of Theorem 1.1 throughout the chapter.

We rely on earlier chapters for the following and do not repeat them. Lean idioms (`Submodule`, quotients `/`, `→ₐ[ℂ]`, `≃ₐ[ℂ]`, `Module.finrank`, `PowerSeries`, `MvPolynomial`, `Function.Bijective`, coercions) are in Chapter 1. Vertex operator algebras, the mode convention `W.smul u n v` $= u_{(n)}v$ and the grading `W.grading n` are in Chapter 4. Ideals, quotient VOAs and the maximal proper graded ideal `QuotVOA.maxGradedIdeal` are in Chapter 5 (Section 5.4, Definition 5.20, Theorem 5.21). The universal affine VOA $V^k(\mathfrak{sl}_2)$ (the library's `affineSl2VOA_closed k hk`), its currents, PBW basis, Wakimoto realisation and Verma modules are in Chapter 9 (Definition 9.14). Admissible

levels and the earlier, *conditional*, boundary C_2 programme are in Chapter 10 (Sections 10.2 and 10.9). Li's filtration $F^\bullet V$, its exact layers `liWeightLayer W p N` and the associated graded algebra `liAssociatedGraded W`, finite jets and classical freeness are in Chapter 11 (Sections 11.3 and 11.4). Zhu's C_2-algebra $R_V = V/C_2(V)$ (the library's `A₂ W`) with its Poisson structure is in Chapter 12 (Section 12.5). Quasi-lisse algebras and the example $L_{-4/3}(\mathfrak{sl}_2)$ are in Chapter 16.

What this chapter is about, in one paragraph. Fix an integer $m \geq 1$, put $p = 2m+1$ and $k = -2 + 2/p$ (so $k = -4/3, -8/5, -12/7, \ldots$). These are the *boundary admissible* levels of affine $\mathfrak{sl}_2$. Let $V = L_k(\mathfrak{sl}_2)$ be the simple affine vertex algebra at level k. Its C_2-algebra R_V is a finitely generated Poisson algebra; the arc algebra $J_\infty R_V$ is a Poisson vertex algebra; and there is a canonical surjection of Poisson vertex algebras $J_\infty R_V \twoheadrightarrow \mathrm{gr}^F V$ onto Li's associated graded algebra. Arakawa and Dai (arXiv:2609.33348) prove that this surjection is an isomorphism (*classical freeness*, their Theorem 1.1), using the surjection $\mathbb{C}[e,h,f]/(eQ^m, hQ^m, fQ^m) \twoheadrightarrow R_V$ with $Q = h^2 + 4ef$ (which then is an isomorphism), and that the vacuum character of V is given by an explicit fermionic sum (their Theorem 1.2), which equals the product $(q^p;q^p)_\infty^3/(q;q)_\infty^3$. The library proves this, for every $m \geq 1$, about the *actual* simple quotient of the *actual* universal affine VOA, with no hypothesis besides $m \geq 1$, in the following exact form. The character theorem is proved as stated. Theorem 1.1 is proved as *one* Lean theorem, `arakawaDai_theorem_1_1` (Theorem 20.26, added 2026-10-28), whose six conjuncts say: (1) the canonical map $\mathbb{C}[e,h,f]/(eQ^m, hQ^m, fQ^m) \to R_V$ is bijective, (2) with e, h, f sent to the C_2-classes of the three currents; (3) an explicitly constructed algebra $J_\infty R_V$ with an arc $R_V \to (J_\infty R_V)[[t]]$ has the universal property of the arc algebra of R_V; (4) the Poisson vertex algebra isomorphism $J_\infty R_V \cong \mathrm{gr}^F V$ restricts on $R_V \subset J_\infty R_V$ to the canonical map $R_V \to \mathrm{gr}^F V$, (5) and is the *unique* algebra map with that restriction commuting with the translations, i.e. it *is* the paper's canonical map; (6) it preserves the conformal grading in both directions. One honest caveat remains: the library has no functor J_∞ on abstract commutative algebras, so $J_\infty R_V$ is *realised* as the presented arc algebra $J_\infty\big(\mathbb{C}[e,h,f]/(eQ^m, hQ^m, fQ^m)\big)$ together with a universal arc, and it is characterised up to unique isomorphism by the proved universal property (3). The paper itself asserts only the surjection in (1); the bijection is a consequence.

The findings of this chapter, in brief.

1. **Both theorems are proved unconditionally** (Theorem 1.1 as the single theorem `arakawaDai_theorem_1_1`), with only Lean's three standard axioms. (`VOA.pbw` is now a theorem, so "`pbw`-free" below records history, not an axiom difference.) The ten headline declarations (Section 20.3) and the paper-form theorem carry only the hypothesis $1 \leq m$ (besides the evident arguments N, x, A of the statements). They concern `simple (level m) (level_noncritical m)`, the quotient of $V^k(\mathfrak{sl}_2)$ by its maximal proper graded ideal, so "simple" is not an assumption but a construction.

2. **The Lean proof is more self-contained than the paper.** Arakawa–Dai use two inputs from the literature: the surjection $\mathbb{C}[e,h,f]/(eQ^m, hQ^m, fQ^m) \twoheadrightarrow R_V$ (from the singular vector, citing Arakawa's earlier work) and, to close the squeeze, the Kac–Wakimoto product formula for the character of $L_k(\mathfrak{sl}_2)$. The library proves *both*. The relations come from a singular vector whose existence is derived from the Kac–Kazhdan determinant (Section 20.4); the character lower bound comes from an elementary but decisive linear algebra fact, "kernel dimension of a polynomial matrix at a point is at most the order of vanishing of its determinant there", together with an exact count of determinant zeros (Section 20.9). In particular the previously open presentation of Chapter 10, Section 10.9, is now an unconditional theorem (`baseC2AlgEquiv`); it does *not* prove that the singular vector generates the maximal ideal, and does not need to.

3. **Statements match the paper.** The character is the unshifted, unflavoured series $\sum_N \dim V_N\, q^N$, as in Theorem 1.2 of the paper (we checked the paper's displayed formula). The PVA isomorphism is stated as a structure (`PoissonVertexAlgebra.Equiv`) that preserves translation and every non-negative λ-bracket coefficient in both directions, and a separate theorem says it preserves conformal weight in both directions.

4. **Points a referee should know** (all in `warning` boxes): the Poisson vertex algebra on the arc side is built on the *presented* arc algebra $J_\infty(\mathbb{C}[e,h,f]/I_m)$, which *serves as* $J_\infty R_V$ through the universal arc `c2UniversalArc` and its proved universal property (`c2UniversalArc_universal`); there is no J_∞ functor on abstract algebras. The type of `actualC2ArcEquiv` is a bijection of sets for each coefficient algebra; its naturality in the coefficient algebra is a separate theorem (`actualC2ArcEquiv_natural`), and together they say that the presented arc algebra represents the arc functor of R_V (the bundled textbook form is `c2UniversalArc_universal`). The type of `baseC2AlgEquiv` is an abstract isomorphism; it is canonical *by theorem* (`baseC2AlgEquiv_apply`, `canonicalC2Map_mk_X`). A few docstrings are stale (they still call the now-proved character equality "remaining"). These are listed in Section 20.15.

5. **The Virasoro companion is also unconditional** (Section 20.12). For every $m \in \mathbb{N}$ (no hypothesis; $m = 0$ is $M(2,3)$, $m = 1$ is Lee–Yang) the canonical map $J_\infty(\mathbb{C}[T]/(T^{m+1})) \to \mathrm{gr}^F L(c_{2,2m+3}, 0)$ is bijective (`VirasoroClassicalFreeness.classicallyFree`), $R_L \cong \mathbb{C}[T]/(T^{m+1})$ canonically, and the map is an isomorphism of Poisson vertex algebras from the arc algebra with the *zero* λ-bracket, which is forced: every mode of $\mathrm{gr}^F L(c_{2,2m+3}, 0)$ vanishes. Along the way Li's filtration of the universal Virasoro VOA is shown to be the word filtration, for every c. The injectivity input is a leading-symbol theorem (`virSymbol_twoSeries`), which on its own is *not* classical freeness (Section 20.12 explains the bridge).

6. **The $p = 3$ conductor files prove no theorem about a VOA** (Section 20.13). Their terminal bound is conditional on two named hypotheses and a datum `D : P3LinearResidualization W E` that are never instantiated (and `E` is connected to no VOA); the files are kept for the finite lemmas that Chapter 24 reuses.

20.1 The mathematics

20.1.1 Boundary admissible levels

Recall from Chapter 10 (Section 10.2) that a level k of affine $\mathfrak{sl}_2$ is *admissible* if $k + 2 = p/q$ with p, q coprime positive integers and $p \geq 2$. The admissible levels are those for which Kac and Wakimoto found modular-invariant families of representations. Among them, the *boundary* admissible levels are those with the smallest possible numerator, $p = 2$:

$$k + 2 = \frac{2}{q}, \qquad q \text{ odd},$$

so $k = -2 + 2/q$; the case $q = 1$ gives $k = 0$ (the trivial VOA $L_0(\mathfrak{sl}_2) = \mathbb{C}$), and the genuinely interesting cases are $q = 2m + 1 \geq 3$. The library and this chapter write $p = 2m + 1$ for this odd denominator (the paper does the same; do not confuse it with the numerator of Chapter 10, which is 2 here). So

$$p = 2m + 1, \qquad k = k_m = -2 + \frac{2}{p} = -\frac{4m}{2m+1}, \qquad m = 1, 2, 3, \ldots$$

For example $k_1 = -4/3$ (the example of Chapter 16) and $k_2 = -8/5$. These levels are *non-critical* ($k + 2 \neq 0$), so the Sugawara construction makes $V^k(\mathfrak{sl}_2)$ a vertex operator algebra with central charge $c = 3k/(k+2) = 3(-2p+2)/2 = 3 - 3p = -6m$ (so $c = -6, -12, -18, \ldots$).

The central charge is negative and $V = L_k(\mathfrak{sl}_2)$ is not C_2-cofinite (Chapter 16 proves this at $m = 1$): R_V is infinite-dimensional, so V is not "rational" in the usual sense. Nevertheless boundary admissible representations have unusually simple characters: products of theta functions. This simplicity is the subject of the chapter.

Physical meaning

Argyres–Douglas theories (heuristic dictionary, not used in any proof). Beem, Lemos, Liendo, Peelaers, Rastelli and van Rees associated to every four-dimensional $\mathcal{N} = 2$ superconformal field theory a vertex operator algebra (its "chiral algebra"), with $c_{2d} = -12c_{4d}$. The vacuum character of that VOA is the *Schur index* of the 4d theory, and its associated variety $X_V = \operatorname{Specm} R_V$ is (conjecturally, and in many cases provably) the *Higgs branch*. For the Argyres–Douglas theories of type (A_1, D_{2m+1}) the chiral algebra is $L_{-4m/(2m+1)}(\mathfrak{sl}_2)$, i.e. exactly the boundary admissible algebras of this chapter (Cordova–Shao, Creutzig). The Higgs branch is $\mathbb{C}^2/\mathbb{Z}_2$, the nilpotent cone of $\mathfrak{sl}_2$, which is the reduced variety of $\mathbb{C}[e,h,f]/(eQ^m, hQ^m, fQ^m)$: the relations say "$Q^m$ times every generator is zero", which set-theoretically forces $Q = 0$, the cone. The non-reducedness (nilpotent directions $Q, Q^2, \dots, Q^m$, non-zero in R_V because their degree $2j \le 2m$ is below that of the relations) is invisible to the variety but is part of the ring R_V; it is detected by the character.

20.1.2 The C_2-algebra, Li's filtration, arcs and classical freeness

For a VOA V of CFT type, Zhu's C_2-algebra $R_V = V/C_2(V)$ is a commutative Poisson algebra under $[a]\cdot[b] = [a_{(-1)}b]$, $\{[a],[b]\} = [a_{(0)}b]$ (Chapter 12, Theorem 12.23). Li's filtration $V = F^0V \supseteq F^1V = C_2(V) \supseteq F^2V \supseteq \cdots$ (Chapter 11, equation (11.2)) counts derivatives, and its associated graded $\operatorname{gr}^F V = \bigoplus_p F^pV/F^{p+1}V$ is a commutative algebra under the (-1)-product with a derivation ∂ induced by L_{-1} and with λ-brackets induced by the non-negative products:

$$\{\bar a_\lambda \bar b\} = \sum_{n\ge 0} \frac{\lambda^n}{n!}\,\overline{a_{(n)}b}, \qquad \bar a \in F^p/F^{p+1},\ \bar b \in F^q/F^{q+1},\ \overline{a_{(n)}b} \in F^{p+q-n}/F^{p+q-n+1}. \tag{20.1}$$

This makes $\operatorname{gr}^F V$ a *Poisson vertex algebra* (Definition 20.12 below). Its degree-zero part is R_V.

If $R = \mathbb{C}[x_1,\dots,x_g]/I$, the *arc algebra* $J_\infty R$ is the polynomial ring in the variables $x_i^{(n)}$, $1 \le i \le g$, $n \ge 0$, modulo the ideal generated by the coefficients of t^n in $f\big(\sum_n x_1^{(n)}t^n, \dots, \sum_n x_g^{(n)}t^n\big)$, $f \in I$. Its $\mathbb{C}$-points are the arcs $\operatorname{Spec}\mathbb{C}[[t]] \to \operatorname{Spec} R$, i.e. algebra maps $R \to \mathbb{C}[[t]]$. If R is Poisson, then $J_\infty R$ carries a unique Poisson vertex algebra structure with $\partial x^{(n)} = (n+1)x^{(n+1)}$ and $\{x_\lambda y\} = \{x,y\}$ for $x, y \in R$. The map $R = \operatorname{gr}^F_0 V \hookrightarrow \operatorname{gr}^F V$ extends uniquely to a homomorphism of differential algebras

$$\pi_V : J_\infty R_V \longrightarrow \operatorname{gr}^F V, \qquad x^{(n)} \longmapsto \frac{\partial^n \bar x}{n!} = \overline{x_{(-n-1)}\mathbf{1}}, \tag{20.2}$$

which is surjective (Li) and a homomorphism of Poisson vertex algebras (Arakawa). V is *classically free* if π_V is an isomorphism. Classical freeness fails in general (for many rational VOAs, such as most Virasoro minimal models, π_V has a kernel); it holds for free-field algebras, for universal affine algebras, and for a few distinguished simple quotients. Andrews, van Ekeren and Heluani conjectured it for the boundary admissible $L_k(\mathfrak{sl}_2)$, and Arakawa–Dai proved it.

Physical meaning

$\operatorname{gr}^F V$ is the *classical limit* of the chiral algebra: replace the operator product expansion by its leading, commutative part, and remember only the singular part of the OPE as a Poisson bracket. $J_\infty R_V$ is the algebra of functions on the space of *classical field configurations* $x(t) = \sum x^{(n)}t^n$ on the formal disc with values in the associated variety. Classical freeness

says the quantum theory has no relations beyond those forced classically, *and their derivatives*: the vacuum module, graded by conformal weight, has the same size as the space of classical fields on the (possibly non-reduced) Higgs branch. In 4d language: the Schur index equals the Hilbert series of the arc space of the Higgs branch *scheme* (a "Higgs branch reconstruction" statement). This is a heuristic slogan; the proof below is pure algebra.

20.1.3 The two theorems

Theorem 20.1 (Arakawa–Dai, Theorem 1.1, with the presentation as a corollary)**.** *Let $m \geq 1$, $p = 2m+1$, $k = -2 + 2/p$, $V = L_k(\mathfrak{sl}_2)$, $Q = h^2 + 4ef \in \mathbb{C}[e,h,f]$. Then:*

1. *$R_V \cong A_m := \mathbb{C}[e,h,f]/(eQ^m, hQ^m, fQ^m)$, via $e,h,f \mapsto$ the classes of the three currents;*
2. *the canonical map $\pi_V : J_\infty R_V \to \mathrm{gr}^F V$ is an isomorphism of Poisson vertex algebras preserving the conformal grading.*

Attribution. The paper's displayed Theorem 1.1 is part 2. For part 1 the paper states only the *surjection* $A_m \twoheadrightarrow R_V$ (citing earlier work); that it is an isomorphism is a corollary of part 2 (the argument is in the proof of Theorem 20.21), which the library proves as `baseC2AlgEquiv`. So part 1 is presented here as a consequence of the paper's theorem, not as a claim of the paper. Both parts together are the single Lean theorem `arakawaDai_theorem_1_1`, presented as Theorem 20.26 in Section 20.3.

Physical meaning

Part 1 says the Higgs branch chiral ring of the (A_1, D_{2m+1}) theory is exactly $\mathbb{C}[e,h,f]/(xQ^m)$, which is non-reduced ($Q \neq 0$ but $Q^{m+1} = 0$); part 2 says the whole chiral algebra is, classically, nothing but field configurations on that scheme. The Lean statements of both parts are in Section 20.3.

Theorem 20.2 (Arakawa–Dai, Theorem 1.2)**.** *With the same notation, and $(q)_n = \prod_{j=1}^{n}(1-q^j)$, $(q)_\infty = \prod_{j\geq 1}(1-q^j)$,*

$$\sum_{N\geq 0} \dim V_N \, q^N = \frac{1}{(q)_\infty^2} \sum_{n_1 \geq n_2 \geq \cdots \geq n_m \geq 0} \frac{q^{\sum_{j=1}^{m} n_j(n_j+1)} (q)_{n_m}^2}{(q)_{n_1-n_2} \cdots (q)_{n_{m-1}-n_m} (q)_{2n_m+1}} = \frac{(q^p;q^p)_\infty^3}{(q;q)_\infty^3}. \tag{20.3}$$

The character is *unshifted* (no $q^{-c/24}$) and *unflavoured* (no fugacity z^{h_0} for the $\mathfrak{sl}_2$-charge). For $m = 1$ the product is $(1-q^3)^3(1-q^6)^3 \cdots / (1-q)^3(1-q^2)^3 \cdots$, whose first coefficients are $1, 3, 9, 19, 42, 81, 155, \ldots$, while $V^k(\mathfrak{sl}_2)$ has $1, 3, 9, 22, 51, 108, 221, \ldots$ (Example 20.19).

20.1.4 The proof strategy

The proof is a *Hilbert-series squeeze*. It compares two graded vector spaces through one map:

$$B_m := J_\infty A_m \xrightarrow{\ \pi\ } \mathrm{gr}^F V, \qquad \dim(\mathrm{gr}^F V)_N = \dim V_N.$$

Here π is the composite of $J_\infty A_m \twoheadrightarrow J_\infty R_V$ (from part 1's surjection) with π_V; it is surjective, so $\dim V_N \leq \dim(B_m)_N$. If one shows

$$\dim(B_m)_N \;\leq\; [q^N]\frac{(q^p;q^p)_\infty^3}{(q)_\infty^3} \;\leq\; \dim V_N \qquad (N \geq 0), \tag{20.4}$$

then all three numbers are equal, π is injective in every conformal weight, hence bijective; since $B_m \to J_\infty R_V \to \mathrm{gr}^F V$ is then injective, also $A_m \to R_V$ is injective (restrict to constant arcs, which embed A_m in B_m; details in the proof of Theorem 20.21), which is part 1; and the character is the product, which with a q-series identity is Theorem 1.2. The work splits into the following nine steps, which this chapter treats in order. We name each step by its content and refer to it by that name throughout.

(1) *The boundary relations hold, and the currents generate* (Section 20.4): the relations eQ^m, hQ^m, fQ^m lie in the maximal ideal, so they hold in R_V, and $A_m \twoheadrightarrow R_V$.

(2) *Degeneration to the auxiliary arc algebra* (Section 20.5): B_m degenerates to the arc algebra $C_m = J(\mathbb{C}[e,h,f]/(x(ef)^m))$, which is at least as large in every weight.

(3) *Restricted dual and Gordon divisibility* (Section 20.6): a functional model of the restricted dual of C_m and the divisibility conditions of Gordon type.

(4) *The partition filtration* (Section 20.6): a pair/partition filtration whose associated graded pieces give a symmetric Hilbert series bound.

(5) *The q-series identities* (Section 20.7): the fermionic chain equals the product.

(6) *The Hilbert-series upper bound* (Section 20.8): steps (2)–(5) combine to $\dim(B_m)_N \le [q^N]$ product.

(7) *The lower bound for the character* (Section 20.9): $[q^N]$ product $\le \dim V_N$, from the Gram rank of L_k, the root order of the vacuum determinant, the cancellation against the reflected determinant, and the identification of the boundary resonances with the Weyl correction.

(8) *The conformal Hilbert squeeze* (Section 20.10): every conformal piece of $B_m \to \mathrm{gr}^F V$ is injective.

(9) *The Poisson-vertex-algebra structure and the intrinsic arc equivalence* (Section 20.11): the Poisson vertex algebra structure, the inverse map, the conformal grading and the C_2 presentation.

The project's campaign ledger `Notes/ARAKAWA_DAI_2609_33348_CAMPAIGN.md` labels these steps `M0`, …, `M8` in the same order; those labels occur in some file and declaration names, but we do not use them.

Where the library departs from the paper

The paper obtains the second inequality in (20.4) by quoting the Kac–Wakimoto character formula for boundary admissible representations. The library does *not* quote it: the step *the lower bound for the character* (Section 20.9) proves the lower bound from scratch. Likewise the paper quotes the surjection $A_m \twoheadrightarrow R_V$; the library proves it (Section 20.4). The library also never uses (and never proves) the statement that the maximal ideal of $V^k(\mathfrak{sl}_2)$ is generated by one singular vector (the Adamović–Milas theorem quoted as a hypothesis in Chapter 10). This makes the formalisation strictly more self-contained than the paper; it is not a discrepancy in the statements.

Physical meaning

The squeeze has a transparent physical meaning. The upper bound counts *classical* states: monomials in the modes of the currents $e(z), h(z), f(z)$ modulo the classical constraints $xQ^m = 0$ and their derivatives. These are counted by a *fermionic* ("quasi-particle") formula: particles of three colours with an exclusion statistics encoded in $q^{\sum n_j(n_j+1)}/(q)_{n_j - n_{j+1}}$, in the

spirit of Feigin–Stoyanovsky and of the Andrews–Gordon identities. The lower bound counts *quantum* states: the universal vacuum module minus the null states, and the null states are located by the zeros of the Kac determinant (the Shapovalov form) as a function of the level. Equality says every classical state is realised quantum mechanically and vice versa.

20.2 The objects in the headline statements

This section defines, mathematically and by their Lean source, every object that appears in the ten headline statements of Section 20.3. We go from the level, through the VOA and its character, the q-series, the commutative algebra of arcs, Poisson vertex algebras, to the canonical map.

20.2.1 The level and the VOA

Definition 20.3 (Boundary denominator and level). For $n \in \mathbb{N}$ put denominator$(n) = 2n+1$ and level$(n) = -2 + 2/(2n+1) \in \mathbb{C}$.

File `VOA/Examples/AffineSl2BoundarySingularFamily.lean` (Chapter 10).

```
def denominator (n : ℕ) : ℕ := 2 * n + 1

def level (n : ℕ) : ℂ := -2 + 2 / (denominator n : ℂ)

theorem level_noncritical (n : ℕ) : level n + 2 ≠ 0 := by
```

From the mathematics to the Lean statement

Both live in the namespace `VOA.AffineSl2BoundarySingularFamily`. `(denominator n : ℂ)` is the cast of the natural number $2n+1$ into $\mathbb{C}$; division in $\mathbb{C}$ is the field division (no truncation, since the cast is non-zero). So `level n` is exactly $k_n = -2 + 2/(2n+1)$. At $n = 0$ it is 0; the headline theorems all assume $1 \le m$, so $n = 0$ never matters. `level_noncritical` is the proof that $k_n + 2 = 2/(2n+1) \neq 0$; it is needed because the universal VOA is only constructed at non-critical level (Chapter 9). The paper's p is `denominator m`. The Lean convention agrees with the book's.

Physical meaning

$k+2$ is the "shifted level" (level plus dual Coxeter number $h^\vee = 2$); the Sugawara stress tensor has a factor $1/(k+2)$. Boundary admissible means $k+2 = 2/p$: in the Argyres–Douglas dictionary $p = 2m+1$ labels the theory (A_1, D_{2m+1}).

What the machine verified

Definitions; `level_noncritical` proved, axioms `[propext, Classical.choice, Quot.sound]` (audited as a dependency of the headlines).

Definition 20.4 (Universal and simple affine VOA; the boundary vacuum algebra). For $k \neq -2$, universal$(k) = V^k(\mathfrak{sl}_2)$ is the universal affine VOA with its Sugawara conformal vector, and simple$(k) = V^k(\mathfrak{sl}_2)/\mathfrak{m}$, where $\mathfrak{m}$ is the maximal proper graded ideal (the sum of all ideals that are graded and do not contain the vacuum). The boundary vacuum algebra is vacuum$(m) =$ simple$(k_m) = L_{k_m}(\mathfrak{sl}_2)$.

File `VOA/Examples/AffineSl2GeneralRigidityBasis.lean` (Chapter 10).

```
noncomputable abbrev universal := affineSl2VOA_closed k hk
noncomputable abbrev simple := QuotVOA.maxQuotientVOA (universal k hk)
```

File `VOA/Core/QuotientVOA.lean` (Chapter 5).

```
def ProperGradedIdeals (W : VertexOperatorAlgebra 𝒱) : Set (Submodule ℂ 𝒱) :=
  {I | W.IsIdeal I ∧ IsGradedIdeal W I ∧ W.vacuum ∉ I}

def maxGradedIdeal (W : VertexOperatorAlgebra 𝒱) : Submodule ℂ 𝒱 :=
  sSup (ProperGradedIdeals W)

def maxQuotientVOA (W : VertexOperatorAlgebra 𝒱) :
    VertexOperatorAlgebra (𝒱 ⧸ maxGradedIdeal W) :=
  quotientVOA W (maxGradedIdeal W) (maxGradedIdeal_isIdeal W) (maxGradedIdeal_isGradedIdeal
  ↪ W)
```

File `VOA/Examples/AffineSl2BoundaryVacuumCharacter.lean`.

```
abbrev vacuum (m : ℕ) := simple (level m) (level_noncritical m)
```

From the mathematics to the Lean statement

In `AffineSl2GeneralRigidityBasis.lean` the variables `(k : ℂ) (hk : k + 2 ≠ 0)` are section variables, so `universal k hk` and `simple k hk` take them as arguments. `affineSl2VOA_closed k hk` is $V^k(\mathfrak{sl}_2)$ of Chapter 9, Definition 9.14 (underlying space `WakModule k`, the vacuum module, with its proved PBW basis). `sSup` of a set of submodules is the submodule they span. `W.IsIdeal I` (two-sided ideal) and `IsGradedIdeal W I` (the sum of its intersections with the weight spaces) are the notions of Chapter 5, Section 5.4. Chapter 5 proves that this supremum is again a proper graded ideal (`maxGradedIdeal_mem`), that the quotient is simple (`isSimple_maxQuotientVOA'`, here `simple_isSimple`), and that every proper graded ideal is contained in it. For a VOA of CFT type every ideal is graded and proper ideals avoid the vacuum, so $\mathfrak{m}$ is *the* maximal ideal and `simple k hk` is *the* simple quotient $L_k(\mathfrak{sl}_2)$. The non-vanishing of the quotient (`simple_vacuum_ne_zero`) is proved from the PBW basis. `abbrev` means the name is a transparent abbreviation: `vacuum m` *is* `simple (level m) (level_noncritical m)`. The name "vacuum" refers to the vacuum module; it is the whole VOA, not the vacuum vector.

Could it be vacuous? A trap would be to define L_k as a quotient by an ideal generated by a chosen singular vector, which is L_k only by a theorem (Adamović–Milas). Here the quotient is by the genuine maximal ideal, defined without reference to any vector; so every statement below is about the actual simple VOA.

Physical meaning

$V^k(\mathfrak{sl}_2)$ is the chiral algebra generated by three currents $e(z), h(z), f(z)$ with the $\mathfrak{sl}_2$ current algebra OPE at level k; $L_k(\mathfrak{sl}_2)$ is the physical theory in which every null state (a state orthogonal to everything under the Shapovalov form) has been set to zero. Only L_k can be a consistent CFT, and only L_k is the chiral algebra of an Argyres–Douglas theory.

What the machine verified

Definitions; the simplicity and non-triviality theorems are proved in Chapters 5, 10 without `VOA.pbw`.

20.2.2 The character and the product

Definition 20.5 (Vacuum character and boundary product)**.** character$(m) = \sum_{N\geq 0} \dim_{\mathbb{C}} L_{k_m}(\mathfrak{sl}_2)_N\, q^N \in \mathbb{Q}[[q]]$, and product$(m) = (q^p;q^p)_\infty^3 \cdot (q;q)_\infty^{-3}$ with $p = 2m+1$.

File `VOA/Examples/AffineSl2BoundaryVacuumCharacter.lean`.

```
def character (m : ℕ) : PowerSeries ℚ :=
  PowerSeries.mk (fun N => (Module.finrank ℂ ((vacuum m).grading N) : ℚ))

def product (m : ℕ) : PowerSeries ℚ :=
  (PowerSeries.expand (denominator m) (by dsimp [denominator]; omega) euler) ^ 3 *
    reciprocalEuler ^ 3
```

From the mathematics to the Lean statement

`PowerSeries ℚ` is $\mathbb{Q}[[q]]$; `PowerSeries.mk a` is $\sum_N a_N q^N$. `(vacuum m).grading N` is the weight-N subspace V_N (the integer N coerced from $\mathbb{N}$ to $\mathbb{Z}$); negative weights are omitted, and they are zero anyway because V is of CFT type. `Module.finrank ℂ` is the dimension (which is finite, Chapter 9), cast to $\mathbb{Q}$. So `character m` is the unshifted, unflavoured vacuum character, defined from the actual dimensions and *independently* of any formula. This is the ordinary character of the paper's Theorem 1.2.
`euler` and `reciprocalEuler` are $(q;q)_\infty$ and its inverse (Definition 20.6). `PowerSeries.expand p hp g` is Mathlib's substitution $q \mapsto q^p$, i.e. $g(q^p)$; the proof argument `(by dsimp [denominator]; omega)` only certifies $p \neq 0$. Hence `product m` $= (q^p;q^p)_\infty^3/(q;q)_\infty^3$, the right-hand side of (20.3).

Physical meaning

`character m` is the vacuum character $\mathrm{tr}_V\, q^{L_0}$ (the Schur index of the (A_1, D_{2m+1}) theory with flavour fugacity set to one and without the Casimir-energy prefactor). The product is the plethystic exponential $\mathrm{PE}\big[3(q-q^p)/((1-q)(1-q^p))\big]$: three bosonic fields of weight one (the currents, the factor $1/(q)_\infty^3$) with a "fermionic" constraint at every multiple of p.

What the machine verified

Definitions.

Definition 20.6 (q-Pochhammer symbols and the Euler product). $(a;q)_n = \prod_{j=0}^{n-1}(1-aq^j)$, $(q)_n = (q;q)_n$, and $(q^p;q^p)_\infty = \prod_{j\geq 1}(1-q^{pj})$ is $(q)_\infty$ with q replaced by q^p. In $\mathbb{Q}[[q]]$ (or $R[[q]]$ for any commutative ring) $(q)_\infty$ is the power series whose d-th coefficient is the d-th coefficient of $(q)_d$; and $(q)_\infty^{-1}$, $(q)_n^{-1}$ are the inverses of these power series (which exist because the constant term is 1).

```

From the mathematics to the Lean statement

All in namespace `VOA.QSeries`. `PowerSeries.X` is q. `qFactorial X n` is $\prod_{j=0}^{n-1}(1-q\cdot q^j) = (1-q)\cdots(1-q^n)$. The infinite product is defined coefficientwise by a sufficiently long truncation; `coeff_euler` certifies that any truncation $n \geq d$ gives the same d-th coefficient, which is exactly why the definition is the infinite product (the factor $1-q^j$ with $j > d$ does not affect q^d). `PowerSeries.invOfUnit f u` is Mathlib's inverse of a power series whose constant term is the unit u (here 1); `euler_mul_reciprocal` certifies $(q)_\infty \cdot (q)_\infty^{-1} = 1$. The Lean convention agrees with the book's.

Physical meaning

$1/(q)_\infty = \sum_N p(N)q^N$ is the partition function of one chiral boson (one oscillator a_{-n} for each $n \geq 1$): states are partitions of the energy.

What the machine verified

Definitions and elementary lemmas; audited (`coeff_euler`, `coeff_reciprocalEuler`): standard axioms only.

Definition 20.7 (Locally finite sums of power series). For a family $(F_i)_{i\in I}$ in $R[[q]]$ such that each coefficient $[q^n]F_i$ is non-zero for only finitely many i, $\sum_i F_i$ is the power series with n-th coefficient $\sum_i [q^n]F_i$.

File `VOA/Commutative/LocallyFinitePowerSeriesSum.lean`.

```
def IsCoefficientwiseFinite (F : ι → PowerSeries R) : Prop :=
  ∀ n, (Function.support fun i => PowerSeries.coeff n (F i)).Finite

def sum (F : ι → PowerSeries R) : PowerSeries R :=
  PowerSeries.mk fun n => ∑ᶠ i, PowerSeries.coeff n (F i)
```

From the mathematics to the Lean statement

`∑ᶠ i, g i` is Mathlib's `finsum`: the sum of g over its support *if the support is finite*, and 0 otherwise. So `sum F` is total (defined for every family), and agrees with the mathematical sum only when `IsCoefficientwiseFinite F` holds. **Vacuity check:** every sum used in the headlines (`fermionicTrace`, `hilbertBoundSeries`, `multiplicitySource`) has its local finiteness proved in the library (`fermionicTrace_finite`, `hilbertBoundSeries_finite`, `multiplicityTerm_finite`), and more to the point the summands there are bounded below in q-degree by a quantity growing with the index, so each coefficient is a finite sum on paper too.

Physical meaning

Fermionic character formulas are sums over particle numbers; this is the bookkeeping device that makes such infinite sums of q-series literal algebraic objects.

What the machine verified

Definitions.

Definition 20.8 (The fermionic chain and the Hilbert-bound series)**.** For $\ell, n \geq 0$ define $K_\ell(n) \in \mathbb{Q}[[q]]$ by

$$K_0(n) = \frac{(q)_n^2}{(q)_{2n+1}}, \qquad K_{\ell+1}(n) = \sum_{j=0}^{n} \frac{q^{j(j+1)}}{(q)_{n-j}} K_\ell(j),$$

and the *fermionic trace* $T_m = \sum_{n\geq 0} q^{n(n+1)} K_{m-1}(n)$. Unwinding the recursion, $T_m = \sum_{n_1\geq\cdots\geq n_m\geq 0} q^{\sum n_j(n_j+1)} (q)_{n_m}^2 / \big((q)_{n_1-n_2}\cdots(q)_{n_{m-1}-n_m}(q)_{2n_m+1}\big)$, the sum in (20.3). The *Hilbert-bound series* S_m (equation (5.12) of the paper) is the same chain with K_0 replaced by the three-species residual sum

$$\mathrm{res}(n) = \sum_{s\geq 0} q^{(n+1)s} \frac{1}{(q)_s} E(n+s+1)\, E(n+1) \frac{1}{(q)_n}, \qquad E(A) = \sum_{j\geq 0} \frac{q^{Aj}}{(q)_j}.$$

  VOA.LocallyFinitePowerSeriesSum.sum (fun n =>
    PowerSeries.X ^ (n * (n + 1)) * hilbertBoundKernel (m - 1) n)
```

From the mathematics to the Lean statement

`K` is any field (here $\mathbb{Q}$). `Finset.range (n + 1)` is $\{0, \dots, n\}$. `n - j` with $j \leq n$ is honest subtraction. `m - 1` is truncated subtraction in $\mathbb{N}$ ($0 - 1 = 0$); this only matters at $m = 0$, which the headlines exclude. For $m \geq 1$, `fermionicTrace m` sums over $n = n_1$ and `fermionicKernel (m - 1) n` contributes the $m - 1$ further nested sums over $n_2, \dots, n_m$, as in the paper. `fermionicKernel 0 n` is $(q)_n^2 \cdot (q)_{2n+1}^{-1}$, the "terminal q-factorial ratio" of (20.3). So

`fermionicTrace m` is literally the sum T_m of the paper, and

$$\frac{1}{(q)_\infty^2}\, T_m \;=\; \text{the middle expression of (20.3)} \;=\; \texttt{reciprocalEuler\^{}2 * fermionicTrace m}.$$

`hilbertBoundSeries m` is the paper's S_m: the same chain, with the terminal factor replaced by the three residual species (two Euler sums and one q-binomial-like sum). It is the series that the arc calculation produces; the identity $S_m = T_m/(q)_\infty^2$ is proved among the q-series identities (Theorem 20.35).

Physical meaning

In a quasi-particle basis, n_j counts particles of "charge at least j"; $q^{n_j(n_j+1)}$ is the exclusion energy cost (each new particle pays for the ones already present), and $1/(q)_{n_j-n_{j+1}}$ is the free motion of the $n_j - n_{j+1}$ particles of charge exactly j. The terminal factor and the two reciprocal Euler products are the residual free bosons. This is the classic form of fermionic sums for parafermion-like theories (Lepowsky–Primc, Feigin–Stoyanovsky).

What the machine verified

Definitions; local finiteness proved.

20.2.3 The base algebra, arcs, and the presented arc algebra

Definition 20.9 (The base presentation). BasePoly $= \mathbb{C}[x_0, x_1, x_2]$ with $x_0 = e$, $x_1 = h$, $x_2 = f$; $Q = h^2 + 4ef$; the base relations are $x_i Q^m$ $(i = 0, 1, 2)$; I_m is the ideal they generate and $A_m = \mathbb{C}[e, h, f]/I_m$.

File `VOA/Commutative/BoundaryAuxiliaryInitial.lean`.

```
abbrev BasePoly (R : Type*) [CommRing R] := MvPolynomial (Fin 3) R
abbrev JetPoly (R : Type*) [CommRing R] := VOA.InfiniteJet.JetPoly R (Fin 3)

def casimir : BasePoly R := MvPolynomial.X 1 ^ 2 + 4 * MvPolynomial.X 0 * MvPolynomial.X 2

def baseRelation (m : ℕ) (i : Fin 3) : BasePoly R := MvPolynomial.X i * casimir ^ m

def baseIdeal (m : ℕ) : Ideal (BasePoly R) := Ideal.span (Set.range (baseRelation (R := R)
↪ m))
```

From the mathematics to the Lean statement

Namespace `VOA.BoundaryAuxiliary`. `MvPolynomial (Fin 3) R` is the polynomial ring over R in three variables `X 0`, `X 1`, `X 2`; the file docstring fixes "coordinates are `(e,h,f) = (0,1,2)`". `Set.range (baseRelation m)` is the three-element set $\{eQ^m, hQ^m, fQ^m\}$ and `Ideal.span` the ideal it generates. Headlines use `(R := ℂ)`. So `BasePoly ℂ / baseIdeal m` is A_m. It has the same three generators (with the factors written in the other order, $Q^m x_i$, and the same variable order $(e, h, f) = (0, 1, 2)$) as the ideal `AffineSl2BoundaryC2.boundaryIdeal m` of Chapter 10, hence is the same ideal; the library records only the inclusion it needs, `BoundaryArcLiMap.baseIdeal_le_boundaryIdeal`.

Physical meaning

e, h, f are the classical values of the three currents; $Q = h^2 + 4ef$ is the classical quadratic Casimir (the classical limit of the Sugawara field, up to normalisation). The relations say that Q^m annihilates the whole adjoint representation: the Higgs branch is the nilpotent cone $Q = 0$, thickened to order m.

What the machine verified

Definitions.

Definition 20.10 (Jet polynomials, the arc ideal, the presented arc algebra)**.** Let σ be a set of generators. $\mathrm{JetPoly}(\sigma) = \mathbb{C}[x_{i,n} : i \in \sigma, n \geq 0]$. For $f \in \mathbb{C}[x_i]$ put $f(\mathbf{x}(t)) = f\big(\sum_n x_{i,n} t^n\big)$ and let $f_{[n]}$ be its coefficient of t^n. For an ideal $I \subseteq \mathbb{C}[x_i]$, the *arc ideal* $J_\infty I \subseteq \mathrm{JetPoly}$ is generated by all $f_{[n]}$, $f \in I$, $n \geq 0$, and the *presented arc algebra* is $\mathrm{JetPoly}/J_\infty I$.

theorem sourceIdeal_eq_jetIdeal (m : ℕ) :
    sourceIdeal (R := R) m = VOA.InfiniteJet.jetIdeal (baseIdeal (R := R) m) :=
```

From the mathematics to the Lean statement

The variable `MvPolynomial.X (i, n)` is $x_{i,n}$, the coefficient of t^n of the generic arc $x_i(t)$; so $x_{i,n}$ corresponds to $x_i^{(n)}$ of (20.2), the *divided* derivative $\partial^n x_i/n!$ (the "Hasse–Schmidt" normalisation, which needs no division by $n!$ in the ring). `MvPolynomial.aeval generatorSeries f` substitutes $x_i \mapsto \sum_n x_{i,n}t^n$ into f, giving $f(\mathbf{x}(t)) \in \mathrm{JetPoly}[[t]]$; `relationCoefficient f n` is $f_{[n]}$.
The *definition* of the arc ideal (`jetIdeal`) goes through finite jets: `FiniteJet.jetIdeal m I` is the order-m jet ideal of Chapter 11 (Definition 11.12), `ofFinite m` is the inclusion of order-$\le m$ jet variables into all jet variables, and `jetIdeal I` is generated by the images of all finite jet ideals. This avoids any colimit. The theorem `jetIdeal_span_eq_coefficientIdeal` proves that this agrees with the "textbook" definition: the arc ideal of (S) is generated by the coefficients $f_{[n]}$, $f \in S$, $n \ge 0$ (multiples of the generators need not be added: that is the content of the theorem). `sourceIdeal m` is this coefficient ideal for the three boundary relations and `sourceIdeal_eq_jetIdeal` identifies it with `jetIdeal (baseIdeal m)`. So `Source m` = `PresentedJet (baseIdeal m)` $= J_\infty A_m = B_m$, two names for the same quotient (the first is used in the Hilbert-series part, the second in the PVA part).
Is it the arc algebra? Theorem 20.11 below proves the universal property: algebra maps $J_\infty A_m \to A$ correspond bijectively to algebra maps $A_m \to A[[t]]$. So it is the coordinate ring of the arc scheme, not merely something that looks like it.

Physical meaning

$x_{i,n}$ is the classical value of the mode $x_{i,(-n-1)}$, i.e. of the n-th Taylor coefficient of the field $x_i(z)$ at the origin; a state $x_{i_1,(-n_1-1)} \cdots x_{i_r,(-n_r-1)}\mathbf{1}$ becomes the monomial $x_{i_1,n_1} \cdots x_{i_r,n_r}$. The arc ideal says that the constraints $f(x) = 0$ on the target hold for the whole field $x(z)$, i.e. for all Taylor coefficients of $f(x(z))$.

What the machine verified

Definitions; `jetIdeal_span_eq_coefficientIdeal` and `sourceIdeal_eq_jetIdeal` proved, standard axioms.

Theorem 20.11 (The arc universal property)**.** *For every commutative R-algebra A, restriction along the universal arc (the tautological algebra map $R[x]/I \to (J_\infty(R[x]/I))[[t]]$, $x_i \mapsto \sum_n x_{i,n}t^n$) gives a bijection* $\mathrm{Hom}_{R\text{-}alg}(J_\infty(R[x]/I), A) \cong \mathrm{Hom}_{R\text{-}alg}(R[x]/I, A[[t]])$. *If $e : R[x]/I \cong B$ is an isomorphism of algebras, composing with e gives* $\mathrm{Hom}(J_\infty(R[x]/I), A) \cong \mathrm{Hom}(B, A[[t]])$.

theorem baseToJet_injective (I : Ideal (MvPolynomial σ R)) : Function.Injective (baseToJet
 ↪  I) := by
```

From the mathematics to the Lean statement

`α ≃ β` is a bijection with explicit inverse (Mathlib's `Equiv`). `pointSeries I f i` is the power series $\sum_n f(x_{i,n})t^n$; `toArc I f` sends x_i to it; `ofArc I u` sends $x_{i,n}$ to the t^n-coefficient of $u(x_i)$. `universalArc I` is the tautological arc $R[x]/I \to (J_\infty)[[t]]$, $x_i \mapsto \sum_n x_{i,n}t^n$; `existsUnique_arcLift` is the universal property in its textbook form ("∃!"). The file also proves naturality in A (`toArc_natural`) and functoriality in the base (`arcMap`, `arcMap_comp`). `baseToJet I` is the inclusion $R[x]/I \to J_\infty(R[x]/I)$ of "constant arcs" ($x_i \mapsto x_{i,0}$), with a retraction, hence injective. No characteristic-zero or derivation hypothesis is used (Hasse–Schmidt normalisation).

Proof on paper. An algebra map $\phi : J_\infty \to A$ is determined by the images $a_{i,n}$ of the $x_{i,n}$, subject to the vanishing of all $\phi(f_{[n]})$; and $\phi(f_{[n]})$ is the t^n-coefficient of $f\left(\sum_n a_{i,n}t^n\right)$. So ϕ is the same thing as a tuple of power series $a_i(t)$ with $f(a(t)) = 0$ for $f \in I$, i.e. an algebra map $R[x]/I \to A[[t]]$. □

Physical meaning

The arc space is the space of classical field configurations on the formal disc; "points with values in A" are families of such configurations parametrised by Spec A.

What the machine verified

Proved, standard axioms. `arcEquivOfBaseAlgebraEquiv` is a construction (`def`); see the warning after Theorem 20.21.

20.2.4 Poisson vertex algebras

Definition 20.12 (Poisson vertex algebra, in mode form). A Poisson vertex algebra over $\mathbb{C}$ is a commutative $\mathbb{C}$-algebra A with a derivation ∂ and bilinear products $a_{(n)}b$, $n \in \mathbb{N}$, such that for all a, b, c:

1. (locality) $a_{(n)}b = 0$ for $n \gg 0$;
2. (sesquilinearity) $(\partial a)_{(0)}b = 0$, $(\partial a)_{(n+1)}b = -(n+1)\,a_{(n)}b$, and $\partial(a_{(n)}b) = (\partial a)_{(n)}b + a_{(n)}(\partial b)$;
3. (Leibniz) $a_{(n)}(bc) = (a_{(n)}b)c + b(a_{(n)}c)$;
4. (skew-symmetry) $a_{(n)}b = \sum_{j\geq 0} \frac{(-1)^{n+j+1}}{j!}\partial^j(b_{(n+j)}a)$;

5. (Jacobi) $a_{(m)}(b_{(n)}c) - b_{(n)}(a_{(m)}c) = \sum_{j=0}^{m} \binom{m}{j}(a_{(j)}b)_{(m+n-j)}c$.

Equivalently, $\{a_\lambda b\} = \sum_n \frac{\lambda^n}{n!} a_{(n)}b$ is a λ-bracket satisfying the usual PVA axioms. A homomorphism is an algebra map commuting with ∂ and every (n)-product; an equivalence is a bijective homomorphism (whose inverse is then automatically a homomorphism).

    (e : Equiv P Q) : Equiv Q P where
```

From the mathematics to the Lean statement

The structure is a *bundle of data plus laws* on a fixed commutative $\mathbb{C}$-algebra `A` (the product is the ring multiplication of `A`). `Derivation ℂ A A` is a $\mathbb{C}$-linear Leibniz map ∂. `mode n` is a bilinear map (two nested `→ₗ[ℂ]`): `mode n x y` is $x_{(n)}y$. `translation.toLinearMap ^ j` is ∂^j. In `skew`, $\sum^{\mathrm{f}}$ is a `finsum`; by `locality` only finitely many terms are non-zero, so it is an honest finite sum. Each field matches the corresponding item of the definition; we checked them against the λ-bracket axioms: $\{\partial a_\lambda b\} = -\lambda\{a_\lambda b\}$ gives `translation_left_zero` and `translation_left_succ`; $\{a_\lambda \partial b\} = (\lambda + \partial)\{a_\lambda b\}$ is equivalent, given the left law, to `translation_mode`; skew-symmetry $\{b_\lambda a\} = -\{a_{-\lambda-\partial}b\}$ gives `skew` after expanding $(-\lambda - \partial)^{n+j}$; the Jacobi identity $\{a_\lambda\{b_\mu c\}\} - \{b_\mu\{a_\lambda c\}\} = \{\{a_\lambda b\}_{\lambda+\mu}c\}$ gives `jacobi` by comparing coefficients of $\lambda^m\mu^n/m!n!$. The coefficient convention $x_{(n)}y = n! \cdot [\lambda^n]$ is the one stated in

the file docstring.
`Hom` is a homomorphism. `Equiv` contains an algebra isomorphism `toAlgEquiv` that commutes with translation and with every mode; `Equiv.symm` proves that the inverse has the same properties, and `Equiv.ofBijective` turns a bijective homomorphism into an equivalence. So `PoissonVertexAlgebra.Equiv P Q` is exactly "$P \cong Q$ as Poisson vertex algebras". **Could the notion be vacuous?** The structure has a model in every case used here (Definitions 20.13 and 20.14), and the axioms are the standard ones; an `Equiv` between two given PVAs is a strong statement because both structures are fixed independently.

Physical meaning

A Poisson vertex algebra is the classical limit of a vertex algebra: the commutative product is the regular part of the OPE at leading order, the λ-bracket is the singular part $a(z)b(w) \sim \sum_n \frac{(a_{(n)}b)(w)}{(z-w)^{n+1}}$. It is the algebraic structure of classical two-dimensional field theory (Hamiltonian PDEs, classical W-algebras via Drinfeld–Sokolov).

What the machine verified

Definitions. `Equiv.symm`, `Equiv.ofBijective` are constructions whose law-fields are proved; standard axioms.

Definition 20.13 (The Li Poisson vertex algebra). For a VOA W, $\mathrm{gr}^F W = \bigoplus_{p,N} F^pW_N/F^{p+1}W_N$ with the product of Chapter 11, the derivation induced by L_{-1}, and the modes induced by (n)-products as in (20.1): on classes of degrees (p,N) and (q,M) the n-th mode lands in degree $(p+q-n, N+M-n-1)$ (Li degree by (20.1); conformal weight because $\mathrm{wt}(a_{(n)}b) = \mathrm{wt}\,a + \mathrm{wt}\,b - n - 1$), and is set to 0 when $n > p+q$ or $n+1 > N+M$.

From the mathematics to the Lean statement

`liWeightPiece W p N` $= F^pW \cap W_N$ and `liWeightLayer W p N` $= F^pW_N/F^{p+1}W_N$ (Chapter 11, Definition 11.5); `liAssociatedGraded W` is their external direct sum, a commutative $\mathbb{C}$-algebra (Chapter 11, Theorem 11.9). `liWeightLayerMode` descends $x \otimes y \mapsto x_{(n)}y$ to the layers (well defined by Li's estimate $F^p_{(n)}F^q \subseteq F^{p+q-n}$ for $n \geq 0$, Chapter 11, Theorem 11.8); `liWeightLayerModeToGraded` inserts the result in the component $(p+q-n, N+M-n-1)$ and is 0 when that index would be negative; `DirectSum.toModule` extends bilinearly from homogeneous pieces to the whole direct sum. `liGradedClass W p N x hx` is the class of $x \in F^pW_N$ in the layer (p, N), inserted into the direct sum, and `liGradedClass_mode` is the defining formula $\bar{x}_{(n)}\bar{y} = \overline{x_{(n)}y}$, exactly (20.1). The "zero when the index is negative" convention is correct: when $n > p+q$ the target $F^{p+q-n}/F^{p+q-n+1}$ is $W/W = 0$, and when $n+1 > N+M$ the target weight is negative, hence 0 in CFT type. `liAssociatedGradedDerivation W` is the descended L_{-1} (shifting bidegree by $(1,1)$) packaged as a `Derivation`. The remaining two fields (`skew`, `jacobi`, not shown) are discharged by the theorems `liAssociatedGradedMode_skew` and `liAssociatedGradedMode_jacobi`, proved from the VOA skew-symmetry and Borcherds commutator formula.

Relation to Chapter 11. That chapter's dictionary ("What is not packaged") records that Li's vertex Poisson structure was not defined in the library, with an update note pointing here. It now is, for every VOA, with all PVA laws proved: `liPoissonVertexAlgebra W` has no hypotheses.

Physical meaning

This is the classical limit of the chiral algebra W: commutative fields with the leading singular OPE coefficients as Poisson brackets. A mode $x_{(n)}$ with $n \geq 0$ lowers the "number of derivatives" by n: classical brackets of derivative fields produce δ-function derivatives.

What the machine verified

Construction with every law proved, for every VOA; standard axioms. It is the target of all headline statements of Theorem 1.1.

Definition 20.14 (The arc Poisson vertex algebra). On $\mathbb{C}[x_{i,n}]$ $(i \in \{e,h,f\})$ let $\partial x_{i,n} = (n+1)x_{i,n+1}$, and let the modes be the unique ones making a PVA with $x_{i,0}\,{}_{(0)}\,x_{j,0} = \{x_i, x_j\}_{\mathfrak{sl}_2}$ and $x_{i,0}\,{}_{(n+1)}\,x_{j,0} = 0$. The arc ideal $J_\infty I_m$ is stable under ∂ and under all modes in both slots, so the quotient $B_m = J_\infty A_m$ inherits a PVA, `arcPVA m`.

      (InfiniteJet.generator (baseIdeal m) j 0) = 0) : P = arcPVA m := by
```

From the mathematics to the Lean statement

`currentPoissonBracket i j` is the matrix of $\{x_i, x_j\}$ in the order (e, h, f): $\{e,h\} = -2e, \{e,f\} = h, \{h,f\} = -2f$ and antisymmetry, i.e. the $\mathfrak{sl}_2$ Lie bracket $[h,e] = 2e$, $[h,f] = -2f$, $[e,f] = h$. `mkDerivation` extends a choice of values on variables to a derivation. `polynomialTranslation` is $\partial x_{i,n} = (n+1)x_{i,n+1}$ (Hasse–Schmidt convention: since $x_{i,n} \leftrightarrow \partial^n x_i/n!$, one has $\partial(\partial^n x/n!) = (n+1)\,\partial^{n+1}x/(n+1)!$). `InfiniteJet.generator I i n` is the class of $x_{i,n}$ in `PresentedJet I`; `InfiniteJet.translation I` is the descended ∂.

A surprising construction, and why it is harmless. `polynomialPVA` is not built from the formulas above but by *transport*: `universalJetPVA 0 _` is `liPoissonVertexAlgebra` of the universal affine VOA at level $k = 0$, carried to $\mathbb{C}[x_{i,n}]$ along the PBW isomorphism $\mathbb{C}[x_{i,n}] \cong \mathrm{gr}^F V^0(\mathfrak{sl}_2)$ (proved in `VOA/Filtered/AffineSl2UniversalLiPBW.lean` and `AffineSl2UniversalJetPVA.lean`). The choice of level 0 is arbitrary: in $\mathrm{gr}^F V^k$ the level term $x_{(1)}y = k(x|y)\mathbf{1}$ has Li degree $0+0-1 < 0$ and dies, so the classical bracket does not see k. The theorem `arcPVA_unique` removes any doubt: *any* PVA structure on `PresentedJet (baseIdeal m)` with the standard translation, with $\{x_{i,0}{}_\lambda x_{j,0}\} = \{x_i, x_j\}$ and no higher terms, *equals* `arcPVA m`. So `arcPVA m` is the canonical arc PVA of the Poisson algebra A_m, whatever auxiliary model was used to build it. `PoissonVertexAlgebra.quotient` (file `VOA/Commutative/PoissonVertexQuotient.lean`) descends a PVA to a quotient by an ideal stable under translation

and under every mode in both slots; the stability of $J_\infty I_m$ is proved from the $\mathfrak{sl}_2$-invariance of Q (`currentHamiltonian_casimir`).

Physical meaning

$J_\infty A_m$ with this structure is the classical current algebra $\{e_\lambda f\} = h$, etc. (the Kirillov–Kostant bracket extended to fields), restricted to field configurations satisfying the classical constraints $xQ^m = 0$. Because Q is a Casimir, the constraints are compatible with the Hamiltonian flows generated by the currents: they are first-class.

What the machine verified

Construction with all laws proved; `arcPVA_unique` proved; standard axioms.

20.2.5 The candidate singular vector and the canonical map

The canonical map is built from the three current states in the simple quotient. The library packages the data of a boundary singular vector in a structure `Candidate` (Chapter 10); the canonical map only uses its level, and the vector enters the *proofs* of the relations.

Definition 20.15 (Candidate; the uniform candidate)**.** A *candidate* at level k and index $n \geq 1$ is a non-zero vector $v \in V^k(\mathfrak{sl}_2)$ of conformal weight $2n+1$ with $e_0 v = 0$, $h_0 v = 2v$ and $x_{(r)} v = 0$ for every current x and every $r > 0$ (an affine singular vector of $\mathfrak{sl}_2$-weight 2), at the level $k = k_n$. The uniform candidate is one such vector, chosen for every $n \geq 1$ from a proved existence theorem.

File `VOA/Examples/AffineSl2BoundarySingularFamily.lean` (Chapter 10).

```
structure Candidate (k : ℂ) (n : ℕ) where
  indexPositive : 1 ≤ n
  isBoundaryLevel : k = level n
  noncritical : k + 2 ≠ 0
  vector : WakModule k
  homogeneous : vector ∈ gradingZA k (denominator n : ℤ)
  horizontalRaising : J k colE 0 vector = 0
  horizontalCharge : J k colH 0 vector = (2 : ℂ) • vector
  positiveSingular : SingP k vector
  nonzero : vector ≠ 0
```

File `VOA/Examples/AffineSl2AdmissiblePrimitive.lean`.

```
theorem boundary_primitive_exists (n : ℕ) :
    ∃ x : WakModule (level n), x ≠ 0 ∧
      x ∈ jointSpace _ (level_noncritical n) (denominator n : ℕ) 2 ∧
      J _ colE 0 x = 0 ∧ SingP _ x := by

noncomputable def uniformCandidate (n : ℕ) (hn : 1 ≤ n) : Candidate (level n) n := by
```

From the mathematics to the Lean statement

`WakModule k` is the underlying space of $V^k(\mathfrak{sl}_2)$; `gradingZA k N` its weight-N space; `J k a r` the current mode a_r (colour `colE`, `colH`, `colF` for e, h, f) of Chapter 9; `SingP k v` says $a_r v = 0$ for all colours a and all $r > 0$. `jointSpace _ _ N c` is the simultaneous eigenspace $L_0 = N$, $h_0 = c$ (`mem_jointSpace_iff`). `uniformCandidate n hn` is defined by `Classical.choose` from `boundary_primitive_exists n` (the proof body is omitted above; it fills the nine fields). It is therefore a non-constructive choice. **This does not make the headline maps non-canonical**: the canonical map (Definition 20.16) uses only `C.noncritical` (a proof, irrelevant)

and the level, never `C.vector`; the vector is used only inside proofs that the relations hold. The argument `hn : 1 ≤ n` is only used to fill `indexPositive`.

Physical meaning

v is the first null state of the vacuum module: at the boundary level the Kac determinant first vanishes at weight $p = 2m + 1$, in the $\mathfrak{sl}_2$-triplet $\{v, f_0 v, f_0^2 v\}$. For $m = 1$ it is the weight-3 null vector of $L_{-4/3}(\mathfrak{sl}_2)$ of Chapter 9, Theorem 9.28.

What the machine verified

`boundary_primitive_exists`: proved for every n, standard axioms (Section 20.4). `uniformCandidate`: a construction from it.

Definition 20.16 (The canonical map). Let $V = L_{k_m}(\mathfrak{sl}_2)$ and let $\bar{e}, \bar{h}, \bar{f} \in V_1$ be the images of the three currents. The canonical map $\pi : B_m = \mathbb{C}[x_{i,n}]/J_\infty I_m \to \mathrm{gr}^F V$ sends $x_{i,n}$ to $\partial^n \overline{x_i}/n!$, where $\overline{x_i} \in F^0 V_1 / F^1 V_1$.

      BoundaryArcLiMap.polynomialMap C f := rfl
```

From the mathematics to the Lean statement

`currentState k a` is the weight-one state $a_{-1}\mathbf{1}$; `symbolToCurrentColor` converts the paper order (e,h,f) to the library's colour order; `mkQ` is the projection to the simple quotient. So `gen C i` is $\overline{x_i} \in L_k(\hat{\mathfrak{sl}}_2)_1$. `liDegreeZeroClass W 1 ⟨x, _⟩` is the class of $x \in W_1 = F^0W_1$ in the layer $(0,1)$. `derivationJetEval D x` sends $x_{i,n} \mapsto D^n(x_i)/n!$ (the `dividedIterate`), with D the descended L_{-1}; so `polynomialMap C` is $x_{i,n} \mapsto \partial^n\overline{x_i}/n!$, which is (20.2). `Ideal.Quotient.lift`$_{\mathtt{a}}$ factors an algebra map through a quotient, given that the ideal is in the kernel (`sourceIdeal_le_kernel`, proved in Section 20.4). So `canonicalMap m hm` is $\pi : B_m \to \mathrm{gr}^F L_{k_m}$, with source written as `Source m`. Its target `liAssociatedGraded (AffineSl2BoundaryCharacter.vacuum m)` is the same as `liAssociatedGraded (simpleVOA (uniformCandidate m hm))` by unfolding the `abbrevs` (the two non-criticality proofs are equal by proof irrelevance). `arcLiPoissonHom` is the same map, on the source written as `PresentedJet (baseIdeal m)` and packaged as a PVA homomorphism; `_mk` certifies that it is literally `polynomialMap` on representatives (`rfl`).

Is it the paper's map? The paper's canonical map is $J_\infty R_V \to \mathrm{gr}^F V$ precomposed (implicitly) with $J_\infty A_m \to J_\infty R_V$. The Lean source is $J_\infty A_m$; the identification $A_m \cong R_V$ is the separate headline `baseC2AlgEquiv`, and the arc functor carries it to $J_\infty A_m \cong J_\infty R_V$ (`actualC2ArcEquiv`). Theorem 20.26 closes the loop inside Lean: it proves that the PVA isomorphism is the unique translation-compatible algebra map extending the canonical $R_V \to \mathrm{gr}^F V$, which is the paper's own characterisation of its canonical map. See also the warning in Section 20.3.

Physical meaning

The canonical map assigns to each classical field monomial $\prod x_{i_r,n_r}$ the classical limit of the normally ordered product $\prod(\partial^{n_r}x_{i_r}/n_r!)$ of currents. Surjectivity says the currents strongly generate; injectivity (the theorem) says the only classical relations are the derivatives of $xQ^m = 0$.

What the machine verified

Constructions; their well-definedness (`sourceIdeal_le_kernel`, `baseIdeal_le_kernel`) and the PVA law-fields of `arcLiPoissonHom` are proved for every $m \geq 1$; standard axioms.

20.2.6 Conformal pieces and the C_2-algebra

Definition 20.17 (Conformal weight on arcs; conformal pieces)**.** The conformal weight of $x_{i,n}$ is $n+1$. The weight-N piece of B_m is the image of the weight-N homogeneous polynomials. The weight-N piece of $\mathrm{gr}^F W$ consists of the elements all of whose components of bidegree (p, M) with $M \neq N$ vanish.

Files `VOA/Commutative/BoundaryAuxiliaryGrading.lean`, `VOA/Commutative/BoundaryAuxiliaryHilbert.lean`.

```
def conformalWeight (v : Fin 3 × ℕ) : ℕ := v.2 + 1

    (InfiniteJet.presentedJetMk (baseIdeal (R := ℂ) m)).toLinearMap
```

File `VOA/Filtered/BoundaryArcConformalEquiv.lean`.

```
def liConformalPiece (N : ℕ) : Submodule ℂ (liAssociatedGraded W) where
  carrier := {x | ∀ p M : ℕ, M ≠ N →
    DirectSum.component ℂ (ℕ × ℕ) (fun d => liWeightLayer W d.1 d.2) (p,M) x = 0}
```

From the mathematics to the Lean statement

`weightedHomogeneousSubmodule K w N` is Mathlib's space of polynomials all of whose monomials $\prod x_v^{d_v}$ have $\sum_v d_v w(v) = N$; with $w =$ `conformalWeight`, $x_{i,n}$ has weight $n+1$, the conformal weight of $\partial^n x_i/n!$ (currents have weight one). `.map` is the image submodule. `sourcePiece` and `arcConformalPiece` are the same construction for the two names of B_m (`sourceIdeal_eq_jetIdeal`). `DirectSum.component … (p,M) x` is the (p,M)-component of x in the direct sum. (`liConformalPiece` lives in namespace `VOA.BoundaryArcConformalSqueeze`, with the section variable `W`; the omitted fields prove it is a subspace.) Since the relation ideal is homogeneous (`sourceIdeal_conformalHomogeneous`), $B_m = \bigoplus_N$ `sourcePiece m N`, each piece finite-dimensional (`finiteDimensional_sourcePiece`). The Lean convention agrees with the book's.

Physical meaning

L_0-eigenvalue: a monomial in field modes has energy equal to the sum of the mode weights. The grading by N is the one in which characters are computed.

What the machine verified

Definitions.

The C_2-algebra `A₂ W` $= W/C_2(W)$ is that of Chapter 12, Definition 12.22, with its commutative ring structure, its $\mathbb{C}$-algebra structure (Chapter 16) and the class map `mk₂ W`; nothing new is defined here.

20.3 The headline theorems

The ten original declarations are in `VOA/Examples/AffineSl2BoundaryMainTheorems.lean`; the paper-form Theorem 1.1, `arakawaDai_theorem_1_1`, and its supporting definitions are in `VOA/Examples/AffineSl2BoundaryTheorem11.lean` (Section 20.3.3, added 2026-10-28). Their only hypothesis is `hm : 1 ≤ m`; besides m they take only the evident arguments of their statements (a weight N for `coeff_product_le_character` and `arcPoissonEquiv_conformal_iff`, an element x for the latter, and a coefficient algebra A for `actualC2ArcEquiv`). Their proofs are one-line assemblies of the work in Sections 20.4–20.11: each `...OfCharacter` helper takes the character equality as an explicit argument, and the headline file discharges it with `character_eq_product`.

20.3.1 Theorem 1.2: the character

Theorem 20.18 (The vacuum character of $L_{k_m}(\mathfrak{sl}_2)$). *For every $m \geq 1$, $p = 2m+1$:*

$$\sum_{N\geq 0} \dim L_{k_m}(\mathfrak{sl}_2)_N \, q^N = \frac{(q^p;q^p)_\infty^3}{(q)_\infty^3} = S_m(q) = \frac{1}{(q)_\infty^2}\, T_m(q),$$

with S_m, T_m as in Definition 20.8; the last expression is the fermionic chain of (20.3).

File `VOA/Examples/AffineSl2BoundaryMainTheorems.lean`.

```

```

From the mathematics to the Lean statement

Namespace `VOA.AffineSl2BoundaryCharacter`. The objects: `character`, `product` (Definition 20.5); `hilbertBoundSeries`, `fermionicTrace` (Definition 20.8); `reciprocalEuler` (Definition 20.6); all are elements of $\mathbb{Q}[[q]]$ and `=` is equality of power series (all coefficients). The only hypothesis is $1 \leq m$, which is the paper's $m \geq 1$. `coeff_product_le_character` is the lower bound of (20.4) (Section 20.9): a supporting lemma, half of the dimension squeeze, *not* a theorem of the paper; it is listed among the ten headline declarations of the Lean file only because it is the hard half. For Theorem 1.2 of the paper cite `character_eq_product` and `character_eq_fermionic_chain`; `character_eq_product` combines it with the upper bound `coeff_character_le_product` (Section 20.8) by antisymmetry of $\leq$ coefficientwise; `character_eq_chain` rewrites with the q-series identity S_m = product (Section 20.7); `character_eq_fermionic_chain` is the literal display of the paper's Theorem 1.2: $\frac{1}{(q)_\infty^2} T_m$.

Same, stronger, or weaker? Same as the paper, coefficient by coefficient, for the actual simple VOA. The docstring of `character_eq_chain` calls `hilbertBoundSeries` "the literal descending-chain expression"; strictly, the literal display of Theorem 1.2 is `character_eq_fermionic_chain` (`hilbertBoundSeries` is the paper's intermediate S_m, with the residual sums not yet evaluated). Both are proved, so nothing is lost.

How could it have been wrong? (a) If `character` were defined via the product, the theorem

would be circular: it is defined from `Module.finrank` of the actual weight spaces. (b) If `vacuum` were a quotient by a chosen ideal: it is the maximal-ideal quotient. (c) If the sum in `fermionicTrace` were infinite in some coefficient, `finsum` would silently return 0: local finiteness is proved, and our independent numerical check (Example 20.19) confirms the coefficients for $m = 1, 2$ up to q^{14}.

Proof on paper. Sections 20.8 and 20.9 prove $[q^N]$ character $\le [q^N]$ product $\le [q^N]$ character for all N; Section 20.7 proves $S_m = T_m/(q)_\infty^2 =$ product. □

Physical meaning

For the (A_1, D_{2m+1}) Argyres–Douglas theory the unflavoured Schur index (without $q^{-c/24}$) is $\mathrm{PE}\big[3\frac{q-q^p}{(1-q)(1-q^p)}\big] = (q^p;q^p)_\infty^3/(q)_\infty^3$; physicists derived it from the IR formula of Cordova–Shao (BPS particles of the Coulomb branch) and checked it against the chiral algebra. The theorem is that statement on the VOA side, proved. The fermionic form is the quasi-particle expansion.

What the machine verified

Unconditional (only $1 \le m$). `#print axioms` for all four: `[propext, Classical.choice, Quot.sound]`; no `VOA.pbw` (maintained audit `scripts/audit/ArakawaDaiAxiomAudit.lean`, PASS on 2026-10-13 on the working tree of that date, aggregate build green, 13150 jobs).

Example 20.19 (The numbers for $m = 1, 2$)**.** This is an independent numerical check by the chapter author (Python, exact integer arithmetic), not a Lean result. Coefficients of $q^0, \dots, q^{14}$:

$1/(q)_\infty^3 = \dim V_N^k$: 1, 3, 9, 22, 51, 108, 221, 429, 810, 1479, 2640, 4599, 7868, 13209, 21843
$m = 1$ product $= T_1/(q)_\infty^2$: 1, 3, 9, 19, 42, 81, 155, 276, 486, 821, 1368, 2214, 3541, 5544, 8586
$m = 2$ product $= T_2/(q)_\infty^2$: 1, 3, 9, 22, 51, 105, 212, 402, 744, 1326, 2316, 3936, 6581, 10779, 17406

For $m = 1$ the difference $\dim V_N^k - \dim L_{k,N}$ is $0, 0, 0, 3, 9, 27, 66, 153, 324, 658, \dots$: the first null states are the triplet $\{v, f_0 v, f_0^2 v\}$ at weight 3, and for $N \le 8$ the difference is $3 \dim V_{N-3}^k$ (the free descendants of the triplet), while at $N = 9$ it is $3 \cdot 221 - 5 \cdot 1 = 658$: the first correction comes from the second singular vector, at weight $p \cdot 1 \cdot 3 = 9$ in a quintuplet. This is the Weyl correction of Section 20.9: $(4s-1)$ and $(4s+1)$-dimensional $\mathfrak{sl}_2$-multiplets at weights $ps(2s \mp 1)$. For $m = 2$ the first difference is at weight 5, as it must be.

20.3.2 Theorem 1.1: classical freeness

Theorem 20.20 (Classical freeness of $L_{k_m}(\mathfrak{sl}_2)$)**.** *For every $m \ge 1$ the canonical map $\pi : J_\infty A_m \to \mathrm{gr}^F L_{k_m}(\mathfrak{sl}_2)$ is bijective, and is an isomorphism of Poisson vertex algebras which, in both directions, maps the conformal weight N piece onto the conformal weight N piece.*

From the mathematics to the Lean statement

Namespace `VOA.AffineSl2BoundaryClassicalFreeness`. `Function.Bijective f` is injective and surjective. `canonicalMap m hm` and `(uniformCandidate m hm).arcLiPoissonHom.toAlgHom` are the same map π on the two names `Source m` and `PresentedJet (baseIdeal m)` of B_m (Definition 20.16). `arcPoissonEquiv m hm` is a term of type `PoissonVertexAlgebra.Equiv (arcPVA m) (liPoissonVertexAlgebra (vacuum m))`: an algebra isomorphism that commutes with ∂ and all modes, whose inverse does too (Definition 20.12). The type alone already says "these two PVAs are isomorphic"; the definition (shown: `Equiv.ofBijective` of `arcLiPoissonHom`) says the isomorphism is the canonical map. `arcPoissonEquiv_conformal_iff` says: for every N and every x, $\pi(x)$ lies in the weight-N piece of $\mathrm{gr}^F V$ iff x lies in the weight-N piece of B_m. Since π is bijective, this is "π and π^{-1} both preserve conformal weight" (the conformally graded part of the paper's statement).

Hypotheses. Only `hm : 1 ≤ m`. The candidate is chosen internally; the map does not depend on the choice (Definition 20.15).

Same, stronger, or weaker? The paper states the isomorphism $J_\infty R_V \to \mathrm{gr}^F V$. These four declarations state it for $J_\infty A_m$, the arc algebra of the *presented* algebra; together with `baseC2AlgEquiv` ($A_m \cong R_V$, below) and the functoriality of arcs this gives the paper's statement. The single theorem `arakawaDai_theorem_1_1` (Theorem 20.26) packages exactly this: it equips the presented arc algebra with a universal arc of R_V, proves the universal property, and proves that `arcPoissonEquiv` is the canonical map out of $J_\infty R_V$ so realised. The library still has no J_∞ functor applied to the abstract algebra `A₂ W`; $J_\infty R_V$ is the presented arc algebra plus universal arc, unique up to unique isomorphism. `canonicalMap_bijective` (source `Source m`) and `boundary_classically_free` (source `PresentedJet (baseIdeal m)`) state the same fact on two isomorphic presentations of $J_\infty A_m$ (`sourceIdeal_eq_jetIdeal`). See the warning below for exactly what is and is not packaged.

Wording. The release audit (2026-10-27) recommended a two-part wording because, at the time, no single theorem had the paper's shape. That recommendation is superseded by `arakawaDai_theorem_1_1`: the announcement now cites one theorem, worded as in Theorem 20.26, with the caveat that $J_\infty R_V$ is realised as a presented arc algebra with a universal arc.

Proof on paper. Surjectivity: $\mathrm{gr}^F V$ is generated as a differential algebra by the classes of the currents (Li; Section 20.4). Injectivity: by the squeeze (Section 20.10), each conformal piece of B_m maps onto $\bigoplus_p \mathrm{gr}^F_{p,N} V$ whose total dimension is $\dim V_N$, and $\dim(B_m)_N \le [q^N]\text{product} = \dim V_N$; a surjection from a space of dimension at most that of the target is injective; and a polynomial in the kernel has all its homogeneous components in the kernel. PVA compatibility: both structures are determined by ∂ and the brackets of the generators, which match (Section 20.11). □

Physical meaning

The Argyres–Douglas chiral algebra is "classically free": its singular support is the arc space of the (non-reduced) Higgs branch scheme $\mathrm{Spec}\,\mathbb{C}[e,h,f]/(xQ^m)$. In the language of the 4d/2d correspondence, every Schur operator is accounted for by a classical field configuration on the Higgs branch; there are no "extra" quantum relations. This is a strong form of the Higgs branch / associated variety correspondence (heuristic, physics literature: Beem–Rastelli).

What the machine verified

Unconditional (only $1 \le m$); `#print axioms` of all four: `[propext, Classical.choice, Quot.sound]`, no `VOA.pbw` (audit as above).

Theorem 20.21 (The C_2-algebra and the arc universal property). *For $m \ge 1$: (1) the map $\mathbb{C}[e,h,f] \to R_{L_{k_m}}$, $x_i \mapsto [\overline{x_i}]$, induces an isomorphism $A_m = \mathbb{C}[e,h,f]/(eQ^m, hQ^m, fQ^m) \cong R_{L_{k_m}(\mathfrak{sl}_2)}$; (2) for every commutative $\mathbb{C}$-algebra A, algebra maps $J_\infty A_m \to A$ correspond bijectively to algebra maps $R_{L_{k_m}} \to A[[t]]$, via the specific bijection obtained from Theorem 20.11 and (1); (3) this bijection is natural in A. So $J_\infty A_m$ represents the arc functor $A \mapsto \mathrm{Hom}(R_{L_{k_m}}, A[[t]])$, i.e. it is the arc algebra $J_\infty R_{L_{k_m}}$. (Naturality is not part of the type of* `actualC2ArcEquiv`*; it is the separate theorem* `actualC2ArcEquiv_natural`*; see the warning below.)*

From the mathematics to the Lean statement

`≃ₐ[ℂ]` is an isomorphism of $\mathbb{C}$-algebras; `A₂ (vacuum m)` is R_V (Chapter 12). `baseC2AlgEquiv` unfolds to `Candidate.baseC2AlgEquiv`, which is `AlgEquiv.ofBijective` of `baseC2Map`: the map $A_m \to R_V$ induced by $x_i \mapsto$ `mk₂ W (gen i)`, the class of the i-th current. So the isomorphism is the canonical one. This was originally visible only from the definitions, not from the type; it is now a theorem: `baseC2AlgEquiv_apply` identifies `baseC2AlgEquiv` with the explicitly defined `canonicalC2Map`, and `canonicalC2Map_mk_X` gives its value on generators (Section 20.3.3). (The paper itself displays only the surjection $A_m \twoheadrightarrow R_V$; the isomorphism is a corollary of Theorem 1.1.) `simpleSymbol C` is the same map from `SymSl2` $= \mathbb{C}[e, f, h]$ (Chapter 10); `baseIdeal_eq_simpleSymbol_kernel` states "ker $= I_m$" literally, but it is stated for a candidate under the hypothesis `hinj`, which the headlines discharge (`arcLiPoissonHom_injective_of_character`).

`actualC2ArcEquiv` has type "maps $J_\infty A_m \to A$" $\simeq$ "maps $R_V \to A[[t]]$"; by definition it is `arcEquivOfBaseAlgebraEquiv` (Theorem 20.11) composed with `baseC2AlgEquiv`.

What the types say, and what only the definitions say

1. **The type of `actualC2ArcEquiv` alone is weak; naturality is a separate theorem.** A term of type `(X →ₐ[ℂ] A) ≃ (Y →ₐ[ℂ] PowerSeries A)` is just a bijection of sets for one fixed A; such bijections exist between many unrelated pairs of sets of the same cardinality. "X represents the arc functor of Y" needs the bijections to be *natural in A*. That is now proved (2026-10-28): `actualC2ArcEquiv_natural`, printed above, says $\Phi_B(g \circ f) = g_* \circ \Phi_A(f)$ for every algebra map $g : A \to B$ (and likewise `Candidate.actualC2ArcEquiv_natural` for the candidate form). So `actualC2ArcEquiv` together with `actualC2ArcEquiv_natural` *is* a representability statement. The mathematically strong content is in `baseC2AlgEquiv` (from which (2) and (3) follow formally). The bundled textbook form is `c2UniversalArc_universal` ("every arc $R_V \to A[[t]]$ is uniquely the base change of the universal arc"; Theorem 20.26, item 3).

2. **`baseC2AlgEquiv` as a type says only** $A_m \cong R_V$ (abstractly); that the isomorphism sends

x_i to the current classes was originally only by definition (`baseC2Map`). An abstract (ungraded) isomorphism alone would give *some* presentation of R_V by three generators, but would say neither that the generators are the current classes nor anything about gradings or Hilbert series. *Update (2026-10-28):* canonicity is now a theorem, `baseC2AlgEquiv_apply` together with `canonicalC2Map_mk_X` (Section 20.3.3).

3. **The PVA source is the presented arc algebra.** `arcPVA m` lives on `PresentedJet (baseIdeal m)`; there is no PVA structure defined intrinsically on "J_∞ of the abstract Poisson algebra `A₂ (vacuum m)`". The paper's $J_\infty R_V$ is recovered by (1) and (2); and `arcPVA_unique` shows the PVA structure on the presented arc algebra is the canonical one. This is the standard way to make $J_\infty R$ concrete and is not a defect, but the reader should not expect a theorem whose source is literally "`J∞ (A₂ V)`". Theorem 20.26 makes the identification explicit: the presented arc algebra, with the arc `c2UniversalArc`, *is* the arc algebra of R_V by its universal property.

Proof on paper. The composite $A_m \hookrightarrow J_\infty A_m \xrightarrow{\pi} \mathrm{gr}^F V$ (constant arcs, then π) equals $A_m \to R_V = \mathrm{gr}^F_0 V \hookrightarrow \mathrm{gr}^F V$. The first arrow is injective (it has the retraction "set all $x_{i,n}$, $n > 0$, to zero"), π is injective by Theorem 20.20, so $A_m \to R_V$ is injective; it is surjective because R_V is generated by the current classes (strong generation of V by the currents). Then (2) is Theorem 20.11 composed with (1). □

Physical meaning

(1) is the exact chiral ring / Higgs branch *scheme*: R_V is not reduced for any $m \geq 1$, since $Q \neq 0$ in R_V (it has degree $2 < 2m+1$) although $Q^{m+1} = Q^m(h^2 + 4ef) = 0$; for $m = 1$ it is $\mathbb{C}[e,h,f]/(Qe, Qh, Qf)$, whose reduction is $\mathbb{C}[\mathcal{N}]$ but which keeps the class of Q itself in degree 2 (the image of the Sugawara vector).

What the machine verified

Unconditional (only $1 \leq m$); axioms `[propext, Classical.choice, Quot.sound]`, no `VOA.pbw`. For $m = 1$ this settles, on paper, the exactness statement `Sl2Pres.Sl2ExactSymbol` that Chapter 16 records as open; *no Lean theorem yet connects the two* (they are stated for differently named copies of $L_{-4/3}(\mathfrak{sl}_2)$), so the L16 status is unchanged until such a bridge is written.

20.3.3 Theorem 1.1 in the paper's form: one theorem

The declarations above prove everything in Arakawa–Dai's Theorem 1.1, but spread over two presentations: the isomorphism $A_m \cong R_V$ on one side, and the PVA isomorphism $J_\infty A_m \cong \mathrm{gr}^F V$ on the other. A reader had to assemble the paper's sentence "the canonical map $J_\infty R_V \to \mathrm{gr}^F V$ is an isomorphism" by hand, and two facts needed for that assembly were visible only from definitions: that `baseC2AlgEquiv` is the canonical map, and that $J_\infty A_m$, transported along it, really is the arc algebra of R_V. The file `VOA/Examples/AffineSl2BoundaryTheorem11.lean` (added 2026-10-28) states all of this as theorems and packages it into one statement, `arakawaDai_theorem_1_1`. *Nothing is re-proved there*: every mathematical input is one of the theorems of the earlier sections; the file adds three definitions (the canonical map, the universal arc of R_V, the zero-jet embedding) and the short arguments that connect them.

Throughout, $m \geq 1$, $V = L_{k_m}(\mathfrak{sl}_2)$ is `AffineSl2BoundaryCharacter.vacuum m` (Definition 20.4), R_V is `A₂ V` (Chapter 12), $A_m = \mathbb{C}[e,h,f]/I_m$ is `BasePoly ℂ / baseIdeal m` (Definition 20.9), and $B_m = J_\infty A_m$ is `InfiniteJet.PresentedJet (baseIdeal m)` (Definition 20.10), with generators $x_{i,n}$ (`InfiniteJet.generator (baseIdeal m) i n`).

Definition 20.22 (The canonical map, the universal arc of R_V, and the zero-jet embedding). Let $\bar{e}, \bar{h}, \bar{f} \in V_1$ be the images in V of the three current states $e_{(-1)}\mathbf{1}$, $h_{(-1)}\mathbf{1}$, $f_{(-1)}\mathbf{1}$, and write $(x_0, x_1, x_2) = (e, h, f)$.

1. The *canonical map* $\kappa : A_m \to R_V$ is the algebra map with $\kappa(x_i) = [\bar{x}_i]$, the C_2-class of the i-th current. (It is well defined because the boundary relations $x_i Q^m$ vanish in R_V, Section 20.4.)

2. The *universal arc of* R_V is the algebra map $\gamma : R_V \to B_m[[t]]$ obtained by composing $\kappa^{-1} : R_V \to A_m$ (Theorem 20.23 below shows κ is bijective) with the tautological arc $A_m \to B_m[[t]]$, $x_i \mapsto \sum_{n \geq 0} x_{i,n} t^n$ of Theorem 20.11.

3. The *zero-jet embedding* $\iota_0 : R_V \to B_m$ is κ^{-1} followed by the constant-arc inclusion $A_m \to B_m$, $x_i \mapsto x_{i,0}$; equivalently, the constant coefficient of γ.

```

From the mathematics to the Lean statement

Namespace `VOA.AffineSl2BoundaryClassicalFreeness`. `baseC2Map W weight gen I hI` is the map of `VOA/Filtered/ArcBaseExactness.lean` quoted under Theorem 20.21: it factors $x_i \mapsto$ `mk₂ W (gen i)` through the quotient by `I`, given the proof `hI` that `I` lies in the kernel. Here `W` is the simple quotient `simpleVOA (uniformCandidate m hm)`, which unfolds to the same VOA as `vacuum m` (dictionary of Definition 20.16); the weights are all 1 (currents have weight one); `gen i` is the image of the i-th current state, packaged with its membership in V_1 (`gen_mem`); and the kernel condition is `baseC2Relations`, the relations of Section 20.4. So `canonicalC2Map m hm` is κ, and it is now a named definition with an explicit body rather than something read off from the definition of `baseC2AlgEquiv`.

`InfiniteJet.universalArc I` is the tautological arc $x_i \mapsto \sum_n x_{i,n} t^n$ and `InfiniteJet.baseToJet I` the constant-arc inclusion $x_i \mapsto x_{i,0}$ (dictionary of Theorem 20.11). `(baseC2AlgEquiv m hm).symm.toAlgHom` is κ^{-1} as an algebra map; `.comp` is composition (right to left). `PowerSeries.constantCoeff` takes the coefficient of t^0. `c2ToArc_eq_constantCoeff` holds by `rfl`: the constant coefficient of $\sum_n x_{i,n} t^n$ is $x_{i,0}$ by definition, so the two constructions of ι_0 agree definitionally.

Could these be the wrong objects? γ and ι_0 are built from `baseC2AlgEquiv`, whose *type*

alone would allow any isomorphism $A_m \cong R_V$. Theorem 20.23 closes this: `baseC2AlgEquiv` is κ, by a theorem. So γ is the arc $[\bar{x}_i] \mapsto \sum_n x_{i,n}t^n$ and ι_0 is $[\bar{x}_i] \mapsto x_{i,0}$.

Physical meaning

κ identifies the Higgs-branch chiral ring generators with the three currents. The universal arc γ is the "generic classical field configuration" on the Higgs branch scheme: each chiral-ring generator x_i becomes the field $x_i(t) = \sum_n x_{i,n}t^n$ on the formal disc with independent Taylor coefficients, subject only to the constraints. The zero-jet embedding remembers only the value of each field at the origin, $x_i(0) = x_{i,0}$.

What the machine verified

Definitions; `c2ToArc_eq_constantCoeff` by `rfl`. `#print axioms of canonicalC2Map, c2UniversalArc, c2ToArc, c2ToArc_eq_constantCoeff: [propext, Classical.choice, Quot.sound]` (run 2026-10-28; see the status of Theorem 20.26).

Theorem 20.23 (The presentation isomorphism is the canonical map). *For $m \geq 1$:* `baseC2AlgEquiv` *agrees with κ on every element; $\kappa(x_i)$ is the C_2-class of the image in V of the current state $(x_i)_{(-1)}\mathbf{1}$; and κ is bijective.*

  (baseC2AlgEquiv m hm).bijective
```

From the mathematics to the Lean statement

Decoding the generator formula. `Ideal.Quotient.mk (baseIdeal m) (MvPolynomial.X i)` is the class of the variable x_i in A_m. `AffineVOA.vacuumA k` is the vacuum vector $\mathbf{1}$ of the universal affine VOA $V^k(\mathfrak{sl}_2)$, and `AffineVOA.J k a n` is the mode $J^a_{(n)}$ of the a-th current acting on it (Chapter 9, Sections 9.1 and 9.2); so `AffineVOA.J (level m) a (-1) (AffineVOA.vacuumA (level m))` is the weight-one state $J^a_{(-1)}\mathbf{1}$ (this is `currentState k a`, Definition 20.16). The library's current colours are $(e, f, h) = (0, 1, 2)$ (Chapter 9), while the paper and `BasePoly` use $(e, h, f) = (0, 1, 2)$; `symbolToCurrentColor` is the transposition of 1 and 2 that converts the second order into the first (`AffineSl2UniversalC2PBW.lean`: `Equiv.swap 1 2`). `(QuotVOA.maxGradedIdeal …).mkQ` is the projection $V^k \to V^k/(\text{maximal proper graded ideal}) = L_k$ (Chapter 5), and `mk₂ (vacuum m)` is the class map $V \to R_V = V/C_2(V)$. So the right-hand side is $[\bar{x}_i]$, with $x_0 = e, x_1 = h, x_2 = f$: exactly the paper's "$e, h, f \mapsto$ the classes of the currents". The file also states the three instances separately (`baseC2AlgEquiv_mk_e`, `baseC2AlgEquiv_mk_h`, `baseC2AlgEquiv_mk_f`) and the same formula with the packaged generator (`canonicalC2Map_mk_X_gen`).

What changed. `baseC2AlgEquiv_apply` is a *theorem* (proved by `rfl`, i.e. by unfolding): the abstract isomorphism `baseC2AlgEquiv m hm`, applied to any x, gives $\kappa(x)$. Before, this was true but visible only by unfolding definitions; the release audit (finding F4) asked for exactly this lemma. Together with `canonicalC2Map_mk_X` it pins the isomorphism completely, since an algebra map out of A_m is determined by the images of x_0, x_1, x_2. `canonicalC2Map_bijective` restates the bijectivity of `baseC2AlgEquiv` for κ. **Hypotheses:** only `hm : 1 ≤ m`. **Attribution:** the paper asserts only that κ is surjective; bijectivity is a consequence of Theorem 1.1 (Theorem 20.21).

Proof on paper. `baseC2AlgEquiv` is defined as κ made into an isomorphism using its bijectivity, so its underlying function is κ. On generators, $\kappa(x_i) = [\bar{x}_i]$ by the definition of the map induced by $x_i \mapsto$`mk₂ W (gen i)`, with `gen i` the projected current state. Bijectivity is Theorem 20.21(1). □

Physical meaning

The Higgs branch chiral ring is $\mathbb{C}[e,h,f]/(xQ^m)$ *with the moment-map operators as generators*: the isomorphism is not an abstract coincidence of rings but the statement that the three conserved currents generate the chiral ring subject to exactly these relations.

What the machine verified

Proved, unconditional (only $1 \le m$). `#print axioms of baseC2AlgEquiv_apply, canonicalC2Map_mk_X, canonicalC2Map_bijective: [propext, Classical.choice, Quot.sound]` (2026-10-28).

Theorem 20.24 (The universal property of the arc of R_V). *For $m \ge 1$, every commutative $\mathbb{C}$-algebra A and every algebra map $u : R_V \to A[[t]]$ there is a unique algebra map $f : B_m \to A$ such that applying f coefficientwise to γ gives u, i.e. $f_* \circ \gamma = u$. Hence the pair (B_m, γ) is the arc algebra $J_\infty R_V$ of R_V with its universal arc, unique up to unique isomorphism.*

File `VOA/Examples/AffineSl2BoundaryTheorem11.lean`.

```
theorem c2UniversalArc_universal (m : ℕ) (hm : 1 ≤ m) {A : Type*} [CommRing A] [Algebra ℂ
↪  A]
    (u : A₂ (AffineSl2BoundaryCharacter.vacuum m) →ₐ[ℂ] PowerSeries A) :

      (PowerSeries.mapAlgHom f).comp (c2UniversalArc m hm) = u := by
```

From the mathematics to the Lean statement

`{A : Type*} [CommRing A] [Algebra ℂ A]`: A is any commutative $\mathbb{C}$-algebra, in any universe. `∃! f, P f` is "there is exactly one f with Pf". `PowerSeries.mapAlgHom f : PowerSeries B →ₐ[ℂ] PowerSeries A` applies f to every coefficient; so the equation says: for every $r \in R_V$, if $\gamma(r) = \sum_n c_n t^n$ then $u(r) = \sum_n f(c_n) t^n$. This is the textbook universal property of the arc algebra: $\mathrm{Hom}_{\mathbb{C}\text{-alg}}(J_\infty R, A) \cong \mathrm{Hom}_{\mathbb{C}\text{-alg}}(R, A[[t]])$ via $f \mapsto f_* \circ \gamma$, stated as existence and uniqueness for each u.

Why this needs no naturality clause. Unlike `actualC2ArcEquiv` (whose type is a bijection of sets for each A, with naturality a separate theorem, warning after Theorem 20.21), this statement names the bijection: it is "compose f coefficientwise with the fixed arc γ". A bijection of this form is automatically natural in A, since $(g \circ f)_* \circ \gamma = g_* \circ (f_* \circ \gamma)$. So this is a genuine representability statement: B_m represents the functor $A \mapsto \mathrm{Hom}(R_V, A[[t]])$, with universal element γ.

Unique up to unique isomorphism. If (J', γ') is another pair with the same property, the universal properties give $f : B_m \to J'$ with $f_*\gamma = \gamma'$ and $g : J' \to B_m$ with $g_*\gamma' = \gamma$; then

$(g \circ f)_*\gamma = \gamma = \mathrm{id}_*\gamma$, so $g \circ f = \mathrm{id}$ by uniqueness, and likewise $f \circ g = \mathrm{id}$. This is the precise sense in which `PresentedJet (baseIdeal m)` *is* $J_\infty R_V$, although the library has no functor J_∞ on abstract algebras. (This uniqueness argument is on paper; it is not a separate Lean theorem.)
Hypotheses: only `hm`. **Universe:** the standalone theorem allows any universe for A; the copy inside `arakawaDai_theorem_1_1` quantifies over `A : Type` (universe 0), which suffices for every commutative $\mathbb{C}$-algebra one meets in practice and is all the paper's statement needs.

Proof on paper. By definition $\gamma = \mathrm{arc} \circ \kappa^{-1}$, where $\mathrm{arc} : A_m \to B_m[[t]]$ is the tautological arc. For a candidate f, the equation $f_* \circ \gamma = u$ is equivalent (precompose with κ, or with κ^{-1}) to $f_* \circ \mathrm{arc} = u \circ \kappa$. By the universal property of the presented arc algebra (`existsUnique_arcLift`, Theorem 20.11) the latter has exactly one solution. □

Physical meaning

Points of $J_\infty R_V$ with values in A are exactly the A-families of classical field configurations $x_i(t)$ on the formal disc satisfying the Higgs-branch constraints. The theorem says B_m is *the* space of such field configurations, not a model that merely resembles it.

What the machine verified

Proved, unconditional (only $1 \le m$). `#print axioms c2UniversalArc_universal`: `[propext, Classical.choice, Quot.sound]` (2026-10-28).

Theorem 20.25 (The PVA isomorphism is the paper's canonical map). *Let $c : R_V \to \mathrm{gr}^F V$ be the canonical inclusion of $R_V = F^0V/F^1V$ as the Li-degree-zero part of $\mathrm{gr}^F V$, and π the PVA isomorphism* `arcPoissonEquiv m hm` *of Theorem 20.20. Then:*

1. *two algebra maps out of a presented arc algebra that intertwine its translation with the same operator and agree on the order-zero generators $x_{i,0}$ are equal;*
2. *$\pi \circ \iota_0 = c$;*
3. *π is the unique algebra map $F : B_m \to \mathrm{gr}^F V$ with $F \circ \partial = \partial \circ F$ and $F \circ \iota_0 = c$.*

From the mathematics to the Lean statement

The objects. `InfiniteJet.translation I` is the derivation $\partial x_{i,n} = (n+1)x_{i,n+1}$ descended to the presented arc algebra (dictionary of Definition 20.14); `InfiniteJet.generator I i n` is the class of $x_{i,n}$. In `presentedJet_algHom_ext` the operator `D : B → B` is an arbitrary function (no linearity is assumed of it). `(arcPVA m).translation` is the translation of the arc PVA; it equals `InfiniteJet.translation (baseIdeal m)` by the theorem `arcPVA_translation` (`VOA/Filtered/BoundaryArcPoisson.lean`). `(liPoissonVertexAlgebra V).translation` is the derivation of $\mathrm{gr}^F V$ induced by L_{-1} (Definition 20.13). `c2ToLiAlgebra V : A₂ V →ₐ[ℂ] liAssociatedGraded V` is c, the algebra inclusion of $R_V = F^0V/F^1V$ as the degree-zero part of $\mathrm{gr}^F V$ (`VOA/Filtered/C2LiAlgebra.lean`; its formula on polynomials in generators, `c2ToLiAlgebra_aeval`, is quoted in Section 20.11). `(arcPoissonEquiv m hm).toAlgEquiv` is the underlying algebra isomorphism of the PVA isomorphism, and `.toAlgHom` forgets invertibility.

What each statement says. `presentedJet_algHom_ext` is item 1, for every presented arc algebra (any generator type σ, any ideal `I`). `arcPoissonEquiv_c2ToArc` is item 2: $\pi(\iota_0(a)) = c(a)$ for every $a \in R_V$. `eq_arcPoissonEquiv_of_c2ToArc` is item 3: any algebra map `F` satisfying the two conditions `hT` (intertwines the translations) and `hR` (restricts to c on R_V) *equals* π.

Why this is the paper's canonical map. Arakawa–Dai (following Arakawa's earlier work) define the canonical map $J_\infty R_V \to \mathrm{gr}^F V$ as the unique differential-algebra map extending $R_V = \mathrm{gr}^F_0 V \hookrightarrow \mathrm{gr}^F V$; it exists because $J_\infty R_V$ is the free differential algebra on R_V in the appropriate sense. Items 2 and 3 say exactly that π is this map. **Could item 3 be vacuous?** A uniqueness statement over an empty set of candidates says nothing. It is not empty here: π itself satisfies `hT` (it is a PVA isomorphism, so it preserves translation; the field `map_translation`) and `hR` (item 2). **Hypotheses:** only `hm`.

Proof on paper. (1) In characteristic zero $x_{i,n+1} = (n+1)^{-1}\partial x_{i,n}$ (the theorem `generator_succ`, `VOA/Commutative/InfiniteJetPoissonUniqueness.lean`). If F and G intertwine ∂ with D and agree on $x_{i,0}$, then by induction on n, $F(x_{i,n+1}) = (n+1)^{-1}D(F(x_{i,n})) = (n+1)^{-1}D(G(x_{i,n})) = G(x_{i,n+1})$, using only that F and G are $\mathbb{C}$-linear (no property of D is needed beyond being a function). So F and G agree on all generators $x_{i,n}$, hence everywhere, since these generate B_m as an algebra. (2) Both $\pi \circ \iota_0 \circ \kappa$ and $c \circ \kappa$ are algebra maps out of A_m, so it suffices to compare them on x_i: $\iota_0(\kappa(x_i)) = x_{i,0}$, and $\pi(x_{i,0})$ is, by the definition of the canonical map (Definition 20.16, the case $n = 0$), the degree-zero Li class of $\bar{x}_i$; while $c([\bar{x}_i])$ is that same class by definition of c. (3) Apply (1) to F and π with D the translation of $\mathrm{gr}^F V$: both intertwine (`hT` for F, `map_translation` for π), and on generators $F(x_{i,0}) = F(\iota_0(\kappa(x_i))) = c(\kappa(x_i)) = \pi(x_{i,0})$ by `hR` and (2). □

Physical meaning

The classical limit of a chiral algebra is determined by its chiral ring together with the derivative: once one knows how the constant modes of the fields map to the chiral ring, the Taylor coefficients follow by differentiating. Item 3 is this statement for the classical-freeness isomorphism: there is only one way to identify classical field configurations on the Higgs branch with the associated graded of the chiral algebra compatibly with L_{-1} and with the chiral ring.

What the machine verified

Proved, unconditional (only $1 \le m$; `presentedJet_algHom_ext` has no hypothesis beyond its displayed ones). `#print axioms` of all three: `[propext, Classical.choice, Quot.sound]` (2026-10-28).

Theorem 20.26 (Arakawa–Dai, Theorem 1.1, in the paper's form). *Let $m \geq 1$, $k = -2 + 2/(2m+1)$, $V = L_k(\mathfrak{sl}_2)$ (the quotient of $V^k(\mathfrak{sl}_2)$ by its maximal proper graded ideal), $R_V = V/C_2(V)$, $Q = h^2 + 4ef$. Realise $J_\infty R_V$ as $B_m = J_\infty\big(\mathbb{C}[e,h,f]/(eQ^m, hQ^m, fQ^m)\big)$ with the arc $\gamma : R_V \to B_m[[t]]$ of Definition 20.22. Then:*

1. *the canonical map $\kappa : \mathbb{C}[e,h,f]/(eQ^m, hQ^m, fQ^m) \to R_V$ is bijective;*
2. *κ sends e, h, f to the C_2-classes of the currents $e_{(-1)}\mathbf{1}$, $h_{(-1)}\mathbf{1}$, $f_{(-1)}\mathbf{1}$;*
3. *(B_m, γ) has the universal property of the arc algebra of R_V: for every commutative $\mathbb{C}$-algebra A and every algebra map $u : R_V \to A[[t]]$ there is a unique $f : B_m \to A$ with $f_* \circ \gamma = u$;*
4. *the Poisson vertex algebra isomorphism $\pi : B_m \to \mathrm{gr}^F V$ restricts on R_V (via the zero-jet embedding ι_0) to the canonical inclusion $c : R_V \to \mathrm{gr}^F V$;*
5. *π is the unique algebra map $B_m \to \mathrm{gr}^F V$ that commutes with the translations and restricts to c; that is, π is the canonical map $J_\infty R_V \to \mathrm{gr}^F V$;*
6. *for every N, $\pi(x)$ has conformal weight N if and only if x has conformal weight N.*

Consequently, the canonical map $J_\infty R_V \to \mathrm{gr}^F V$ is an isomorphism of conformally graded Poisson vertex algebras.

From the mathematics to the Lean statement

The six conjuncts (joined by ∧), in order, are items 1–6, and the proof term (shown, since it is informative) is the tuple of the six earlier theorems: `canonicalC2Map_bijective`

and `canonicalC2Map_mk_X` (Theorem 20.23), `c2UniversalArc_universal` (Theorem 20.24), `arcPoissonEquiv_c2ToArc` and `eq_arcPoissonEquiv_of_c2ToArc` (Theorem 20.25), and `arcPoissonEquiv_conformal_iff` (Theorem 20.20). Every symbol has been decoded in those dictionaries: `canonicalC2Map` is κ (Definition 20.22); the generator formula is decoded under Theorem 20.23; `c2UniversalArc` is γ and `c2ToArc` is ι_0; `arcPoissonEquiv m hm` is the PVA isomorphism π (`PoissonVertexAlgebra.Equiv`: an algebra isomorphism preserving translation and every non-negative λ-bracket coefficient, with its inverse doing the same; Definition 20.12); `arcPVA m` is the canonical arc PVA of A_m (Definition 20.14, unique by `arcPVA_unique`); `liConformalPiece` and `arcConformalPiece` are the conformal-weight-N pieces of Definition 20.17, $x_{i,n}$ having weight $n+1$.

Hypotheses. Only `hm : 1 ≤ m`. In the third conjunct A ranges over `Type` (universe 0); the standalone `c2UniversalArc_universal` has every universe.

Same, stronger, or weaker than the paper? The paper's Theorem 1.1 states that $L_{-2+2/(2m+1)}(\mathfrak{sl}_2)$ is classically free, equivalently that $J_\infty R_V \to \mathrm{gr}^F V$ is an isomorphism of conformally graded PVAs. Item 5 identifies π with the paper's canonical map (characterised as the unique translation-compatible extension of $R_V \hookrightarrow \mathrm{gr}^F V$), and π is a PVA isomorphism by its type, preserving the conformal grading by item 6. Items 1–2 are *stronger* than the paper's displayed claims: the paper asserts only the surjection κ (citing earlier work). The one point where the Lean statement is formulated differently is the meaning of "$J_\infty R_V$": in Lean it is the presented arc algebra together with the universal arc γ, and item 3 is what makes it $J_\infty R_V$ (up to unique isomorphism, dictionary of Theorem 20.24). The PVA structure on it is `arcPVA m`; it is the canonical one on $J_\infty R_V$ because `arcPVA_unique` pins it by the brackets of the $x_{i,0} = \iota_0(\kappa(x_i))$, which are the Poisson brackets of R_V transported along κ.

How it could have been wrong or vacuous, and why it is not. (a) An abstract isomorphism $A_m \cong R_V$ would say nothing about generators: excluded by item 2. (b) An arbitrary algebra called "$J_\infty R_V$" would make items 4–6 meaningless: excluded by item 3, which characterises (B_m, γ) up to unique isomorphism. (c) A uniqueness clause over an empty set: item 5's candidate set contains π (items 4 and `map_translation`). (d) A trivial VOA: V is the actual simple quotient, nonzero and simple (`simple_vacuum_ne_zero`, `simple_isSimple`; Definition 20.4). (e) The conformal clause on a trivial grading: both sides are the honest weight gradings, and B_m is the direct sum of its finite-dimensional weight pieces (Definition 20.17).

Proof on paper. Collect the six earlier theorems, as the proof term does. The mathematical content lies in Theorem 20.20 (the Hilbert-series squeeze and the PVA compatibility) and Theorem 20.21 (injectivity of κ from injectivity of π); Theorems 20.23–20.25 are the bookkeeping that identifies the objects with the paper's. □

Physical meaning

For the Argyres–Douglas theories (A_1, D_{2m+1}), whose chiral algebra is $L_{k_m}(\mathfrak{sl}_2)$, the theorem says in one sentence: the chiral algebra, viewed classically, is exactly the algebra of field configurations on the (non-reduced) Higgs branch scheme $\mathrm{Spec}\,\mathbb{C}[e,h,f]/(xQ^m)$, with the moment maps e, h, f given by the $\mathfrak{sl}_2$ currents and the Poisson bracket given by the current algebra. The Schur index therefore equals the Hilbert series of the arc space of the Higgs branch scheme (Theorem 20.18). (Heuristic dictionary; the statement is pure algebra.)

What the machine verified

Proved, unconditional (only $1 \le m$). `#print axioms arakawaDai_theorem_1_1`: `[propext, Classical.choice, Quot.sound]`; the same for the eleven supporting declarations of this section (Section 20.14, 2026-10-28). *Machine-record caveat:* the compiled module of `VOA/`

`Examples/AffineSl2BoundaryTheorem11.lean` was not present in the main checkout's `.lake` at the time of writing; the axiom check was run against the compiled modules of the `release-cheap` worktree, whose copy of this file is byte-identical, and the aggregate `lake build` was not re-run. The project record (`Notes/RELEASE_PLAN.md`, "Caveats removed in Lean", 2026-10-28) reports the targeted umbrella builds green and the axioms standard.

The remaining caveat: $J_\infty R_V$ is realised, not constructed by a functor

The library has no functor J_∞ on abstract commutative algebras, so there is no Lean term "`J∞ (A₂ V)`". In `arakawaDai_theorem_1_1`, $J_\infty R_V$ is the presented arc algebra `PresentedJet (baseIdeal m)` with the universal arc `c2UniversalArc m hm`, transported along the canonical isomorphism κ; it is characterised up to unique isomorphism by the proved universal property (item 3). This is how the arc algebra of a finitely presented algebra is constructed in practice, and nothing in the mathematics depends on the choice of presentation; but a reader who expects the source of the map to be literally "J_∞ applied to `A₂ V`" will not find it. Two further attributions to keep: the paper itself asserts only the surjection $A_m \twoheadrightarrow R_V$ (bijectivity is a consequence of Theorem 1.1); and the older declaration `actualC2ArcEquiv` is a representability statement only together with its naturality theorem `actualC2ArcEquiv_natural` (the bundled form is `c2UniversalArc_universal`).

20.4 The boundary relations hold, and the currents generate

This section proves that eQ^m, hQ^m, fQ^m vanish in R_V (and hence their arc coefficients vanish in $\mathrm{gr}^F V$), and that π is surjective. In the paper this is an input from the literature; here it is proved.

20.4.1 A null vector at weight p from the determinant

Theorem 20.27 (First admissible null vector). *Let $k = p'/q - 2$ be admissible ($p' \geq 2$, $q \geq 1$ coprime). Then the maximal ideal of $V^k(\hat{\mathfrak{sl}}_2)$ contains a non-zero vector of conformal weight $q(p'-1)$ and h_0-eigenvalue $2(p'-1)$. Such a vector is annihilated by every positive current mode and by e_0. At the boundary ($p' = 2$, $q = 2m+1$) it has weight $2m+1$ and h_0-charge 2.*

File `VOA/Examples/AffineSl2AdmissibleNullVector.lean`.

From the mathematics to the Lean statement

Here `p` is the numerator of $k+2$ (Chapter 10's convention), not the chapter's p. Annihilation by e_0 is the companion theorem `admissible_first_null_raising` (same file, same hypotheses, conclusion `J _ colE 0 x = 0`). The boundary specialisation `boundary_primitive_exists` (Definition 20.15) is the case `p = 2, q = denominator n`. "In the maximal ideal" means "null": orthogonal to everything under the invariant form (Chapter 5, Section 5.15).

Proof on paper. The weight-N, charge-c block $G_{N,c}(k)$ of the Shapovalov (invariant) form on $V^k(\mathfrak{sl}_2)$, written in the PBW basis, is a matrix of polynomials in k; its determinant factorises (Kac–Kazhdan, via the reflected-Verma cancellation of Section 20.9) into linear factors in k, and coprimality of p' and q shows that the first factor vanishing at $k = p'/q-2$ occurs at weight $q(p'-1)$, charge $2(p'-1)$, and none below. A vanishing determinant gives a non-zero radical vector, i.e. a vector of the maximal ideal (Chapter 5). Applying a positive mode a_r $(r > 0)$ gives an element of the maximal ideal of lower weight, i.e. in the range of weights below $q(p'-1)$, where the determinant is non-zero, so it is 0. Applying e_0 gives charge $2p'$ at the same weight, where again the determinant is non-zero. □

Physical meaning

At the boundary level the first null state of the vacuum module sits at $L_0 = p = 2m+1$ in the adjoint ($\mathfrak{sl}_2$-spin one) representation; in the AD theory it is the first relation in the chiral ring. Its existence is "where the Kac determinant first vanishes".

What the machine verified

Proved for every admissible level; standard axioms. This is a genuine improvement on Chapter 10, where the boundary candidate was available only for $m = 1, 2$.

20.4.2 The symbol of the null vector, and the relations

Theorem 20.28 (The C_2 symbol is a non-zero multiple of eQ^m). *Let v be a candidate (Definition 20.15). Then v lies in the maximal ideal, its class in $R_{V^k} = \mathbb{C}[e,h,f]$ is $c\cdot eQ^m$ for some $c \neq 0$, and consequently $(eQ^m, hQ^m, fQ^m) \subseteq \ker\big(\mathbb{C}[e,h,f] \to R_{L_k}\big)$.*

      RingHom.ker (simpleSymbol C) :=
```

From the mathematics to the Lean statement

`mk₂ W x` is the class of x in R_W. `symbolAlg k hk : SymSl2 →ₐ[ℂ] A₂ (V^k)` is the evaluation $\mathbb{C}[e,h,f] \to R_{V^k}$, an isomorphism by the PBW theorem (Chapter 10); `eSym`, `casSym` are e, Q. `simpleSymbol C` is the composite $\mathbb{C}[e,h,f] \to R_{V^k} \to R_{L_k}$. The hypotheses of `charge_two_highest_symbol_ne_zero` are exactly "non-zero affine highest-weight vector of $\mathfrak{sl}_2$-weight two"; note that the theorem holds at *every* non-critical level, it is not specific to the boundary.

Proof on paper. (1) A vector killed by all positive modes and of positive weight generates a proper ideal (its descendants never reach the vacuum line), hence lies in the maximal ideal. (2) *Non-vanishing of the symbol* is the delicate point. Embed V^k in the Wakimoto free-field module (faithful at non-critical level, Chapter 9); $e(z)$ becomes $\beta(z)$, and the conditions $e_r v = 0$ $(r \geq 0)$ say the image is free of γ-modes, $h_0 v = 2v$ and $h_r v = 0$ $(r > 0)$ become a triangular system of differential equations for the coefficients of the β-oscillators. The system forces a non-zero coefficient on a monomial with no derivatives ("depth zero"), and the Wakimoto map is compatible with Li filtrations, so such a monomial survives in R: symbol$(v) \neq 0$. (3) The symbol is homogeneous of degree $2m+1$, killed by $\{e,-\}$ (because $e_0 v = 0$) and of h-weight 2. In $\mathbb{C}[e,h,f] = \mathbb{C}[Q] \otimes \mathcal{H}$ (harmonics), the $\mathfrak{sl}_2$-highest vectors of weight 2 and degree $2m+1$ form the line $\mathbb{C}eQ^m$; hence the symbol is $c\,eQ^m$, $c \neq 0$. (4) The image of the maximal ideal in R_{V^k} is a Poisson ideal containing eQ^m; bracketing with f (and using $\{f,Q\} = 0$) gives hQ^m and fQ^m up to non-zero constants. □

Physical meaning

The classical limit of the null state is the highest weight component of $e \cdot (\text{Casimir})^m$; the three relations are its $\mathfrak{sl}_2$-orbit. Physically: the Higgs branch chiral ring has the relation "moment map times (Casimir)$^m = 0$".

What the machine verified

All four proved for every candidate, standard axioms. In particular, combined with `boundary_primitive_exists`, the relations hold for every $m \geq 1$ (`uniform_boundaryIdeal_le_kernel`). This supersedes the conditional status in Chapter 10, Section 10.9 for the *containment*; exactness is Theorem 20.21.

Theorem 20.29 (Arc relations vanish; currents generate). *For every candidate C: the three base relations vanish on the degree-zero Li classes of the currents; all coefficients $(x_i Q^m)_{[n]}$ vanish under π; and $\pi : \mathbb{C}[x_{i,n}] \to \mathrm{gr}^F L_k$ is surjective.*

File `VOA/Filtered/BoundaryArcLiMap.lean`.

```
theorem baseIdeal_le_kernel : BoundaryAuxiliary.baseIdeal (R := ℂ) m ≤
    RingHom.ker (MvPolynomial.aeval (fun i =>
      liDegreeZeroClass (simpleVOA C) 1 ⟨gen C i,gen_mem C i⟩)).toRingHom := by

theorem sourceIdeal_le_kernel : BoundaryAuxiliary.sourceIdeal (R := ℂ) m ≤
    RingHom.ker (polynomialMap C).toRingHom := by

theorem polynomialMap_surjective : Function.Surjective (polynomialMap C) := by
```

From the mathematics to the Lean statement

`RingHom.ker φ` is the kernel; `I ≤ ker φ` says φ kills I. The first statement is the passage from R_V to the degree-zero part of $\mathrm{gr}^F V$ (they are the same space, F^0/F^1, but the library proves the algebra structures agree, `c2ToLiAlgebra`). The second is the arc version. The third is Li's

generation theorem for affine quotients: every Li layer is spanned by current words of the right depth.

Proof on paper. π is a homomorphism of differential algebras (it sends $x_{i,n}$ to $\partial^n \bar{x}_i/n!$), so it sends the generic arc $x_i(t) = \sum x_{i,n} t^n$ to $e^{t\partial}\bar{x}_i$, and $f(x(t)) \mapsto e^{t\partial} f(\bar{x})$. If $f(\bar{x}) = 0$ in $\mathrm{gr}^F V$, every coefficient vanishes. Surjectivity: by Li's theorem (proved in the library for every graded quotient of $V^k(\mathfrak{sl}_2)$), $F^p V_N$ is spanned by current monomials $a^1_{(-n_1-1)} \cdots a^r_{(-n_r-1)}\mathbf{1}$ with $\sum n_i \geq p$; their classes in the exact layer (p, N) are images of $\prod x_{a^i,n_i}$. □

Physical meaning

Strong generation by the currents: every state is a normally ordered polynomial in currents and their derivatives. Classically, the arc of the Higgs branch surjects onto the singular support.

What the machine verified

Proved for every candidate; standard axioms.

20.5 Degeneration to the auxiliary arc algebra

The upper bound $\dim(B_m)_N \leq [q^N]$ product is the heart of the paper (its Sections 2–5). The first step replaces B_m by a "monomial-like" algebra that is easier to count.

Definition 20.30 (Auxiliary relations and weight). Give e, f auxiliary weight 1 and h weight 0 (for all jet orders). The auxiliary relations are $x_i(ef)^m$; $C_m = J_\infty\big(\mathbb{C}[e,h,f]/(x_i(ef)^m)\big)$. The *initial ideal* of an ideal I of jet polynomials is the ideal generated by the top auxiliary-weight components of the elements of I.

File `VOA/Commutative/BoundaryAuxiliaryInitial.lean`.

theorem sourcePiece_finrank_le_auxiliaryPiece (m N : ℕ) :
    Module.finrank K (sourcePiece (K := K) m N) ≤
      Module.finrank K (auxiliaryPiece (K := K) m N) := by
```

From the mathematics to the Lean statement

`weightedHomogeneousComponent auxWeight d g` is the part of g of auxiliary weight d. In `initialIdeal`, d is any weight above which g has no components, so the spanned elements are the top components. `relationCoefficient_top` is the paper's equation (2.15): expanding $x_i Q^m = x_i(h^2+4ef)^m$ binomially, the top auxiliary-weight part of each arc coefficient is 4^m times the corresponding coefficient of $x_i(ef)^m$ (the term $(4ef)^m$ has the most e, f). Hence the auxiliary ideal lies in the initial ideal of the source ideal (`auxiliaryIdeal_le_initialIdeal`; the field `K` has characteristic 0 so 4^m is invertible; "equality of initial ideals is neither needed nor assumed"). The final theorem is Proposition 2.3 of the paper: $\dim(B_m)_N \le \dim(C_m)_N$.

Proof on paper. Fix the conformal weight N; there only finitely many jet variables occur, so we are in a finite-dimensional space P_N of polynomials. Filter P_N by auxiliary weight. For any ideal I homogeneous for conformal weight, $\dim(P/I)_N = \dim(P/\operatorname{in} I)_N$ (the initial forms of a basis of I_N adapted to the filtration form a basis of $(\operatorname{in} I)_N$). If $J \subseteq \operatorname{in} I$ then $\dim(P/J)_N \ge \dim(P/\operatorname{in} I)_N$. With $J =$ auxiliary ideal this gives the claim. (The library proves the inequality directly, by injecting each top-weight slice of P/I into the corresponding slice of P/J.) □

Physical meaning

A "classical limit of the classical limit": scaling e, f to be large compared with h, the Casimir h^2+4ef is dominated by $4ef$. The degenerate theory has a larger (or equal) state space, so counting its states gives an upper bound.

What the machine verified

Proved; standard axioms. No degeneration map or Hilbert inequality is assumed.

20.6 Restricted dual, Gordon divisibility and the partition filtration

This is the combinatorial core: a bound on $\dim(C_m)_N$ by an explicit fermionic sum. We explain it on paper in the language of Feigin–Stoyanovsky "functional realisations"; the library follows the paper's Sections 3–4 closely, with every step proved (the campaign ledger lists these two steps in detail).

20.6.1 Sectors and particle polynomials

C_m is spanned by monomials $\prod x_{i,n}$. Fix the numbers a, b, c of factors of colour e, f, h and the total derivative degree $D = \sum n$; the span of these monomials is a finite-dimensional *sector*, and the weight-N piece is spanned by the sectors with $a+b+c+D = N$.

Definition 20.31 (Sector, particle polynomial)**.** Label the $a+b+c$ factors by a finite set ι with a colouring $\iota \to \{e, h, f\}$. For a monomial with jet orders $r : \iota \to \mathbb{N}$, $\sum r = D$, write $\operatorname{mode}(r) = \prod_{s\in\iota} x_{\mathrm{col}(s),r(s)}$. To a linear functional L on the sector associate the *particle polynomial* $\Phi_L(z) = \sum_r L(\operatorname{mode}(r))\, z^r \in \mathbb{C}[z_s : s \in \iota]$, homogeneous of degree D.

File `VOA/Commutative/GordonRestrictedDual.lean`.

```
def quotientMode (m : ℕ) (color : ι → Fin 3) (r : ι →₀ ℕ) : Auxiliary (R := K) m :=
  Ideal.Quotient.mk (auxiliaryIdeal (R := K) m) (∏ i, X (color i, r i))

def sector (m D : ℕ) (color : ι → Fin 3) : Submodule K (Auxiliary (R := K) m) :=
  Submodule.span K (quotientMode m color '' (↑(degreeFiber (ι := ι) D) : Set (ι →₀ ℕ)))

theorem particleMap_injective (m D : ℕ) (color : ι → Fin 3) :
    Function.Injective (particleMap (K := K) m D color) := by

theorem finrank_functionalModel (m D : ℕ) (color : ι → Fin 3) :
    Module.finrank K (functionalModel (K := K) m D color) =
      Module.finrank K (sector (K := K) m D color) := by
```

From the mathematics to the Lean statement

`ι →₀ ℕ` is a finitely supported function (an exponent vector); `degreeFiber D` is the set of those of total degree D; `''` is the image of a set. So `sector m D color` is the span of all coloured mode products of derivative degree D in the actual quotient C_m. `particleMap` sends a functional to its particle polynomial; it is injective (a functional is determined by its values on spanning monomials), and `functionalModel` is its image, of the same dimension as the sector (dual of a finite-dimensional space).

Proof on paper. A functional on a span is determined by its values on the spanning set, which are the coefficients of Φ_L. □

Physical meaning

$\Phi_L(z)$ is a "correlation function" $\langle L, \prod_s x_{\mathrm{col}(s)}(z_s)\rangle$ of classical fields at points z_s: the generating function of all mode products. Relations among modes become vanishing conditions on these functions.

What the machine verified

Proved; standard axioms.

20.6.2 Vanishing conditions and Gordon divisibility

Because C_m is a quotient by the arc ideal of $x(ef)^m$, every particle polynomial Φ in the functional model is *symmetric in the variables of each colour* (the variables commute), and vanishes on the *relation diagonals*: setting m e-variables, m f-variables and one further variable (of any colour) equal to a common z kills Φ, *for arbitrary values of the remaining "spectator" variables* (`functionalModel_relationDiagonal`, in `GordonRestrictedDual.lean`, resting on `GordonParticleDiagonals.lean`). Indeed the relation $x(z)e(z)^m f(z)^m = 0$ holds as an identity of fields. From these conditions one derives divisibility.

Set-up for the divisor. In a sector with a e's and b f's, choose $R \le \min(a,b)$ of the e-variables and R of the f-variables and match them into R *e–f pairs*; the other $s = a - R$ e-variables, $t = b - R$ f-variables and the c h-variables are *residual*. The *pair evaluation* sets the two variables of each pair equal. A map $f : \{\text{pairs}\} \to \tau$ groups the pairs into *clusters* (blocks); its *shape* is the partition λ of R formed by the block sizes, and r_i is the number of blocks of size i. The *cluster evaluation* sets all pair variables of one block equal to a single cluster point w_u ($u \in \tau$). The *residual filtration* step indexed by λ consists of the pair-evaluated functions killed by every cluster evaluation of lexicographically

larger shape. Finally define

$$\Delta_\lambda = \prod_{u<v}(w_u - w_v)^{2\min(|u|,|v|)} \cdot \prod_{|u|=m}\ \prod_{y\ \text{residual}} (w_u - y) \cdot \prod_{x\ \text{residual}\ e}\ \prod_{y\ \text{residual}\ f} (x - y), \tag{20.5}$$

the product over pairs of distinct blocks, over blocks of the maximal size m against all residual variables, and over residual e–f pairs.

Theorem 20.32 (Full Gordon divisor). *Let Φ be a particle polynomial of the functional model (for the sector with pairs as above) such that (i) Φ vanishes when any residual e-variable is set equal to any residual f-variable after pair evaluation ("no further pair can be formed"), and (ii) its pair evaluation lies in the residual filtration step of shape $\lambda = \mathrm{shape}(f)$. Then Δ_λ divides the cluster evaluation of Φ, and*

$$\deg \Delta_\lambda = \sum_{u\neq v} \min(|u|,|v|) + r_m(s+t+c) + st = \sum_{i,j} \min(i,j)\, r_i r_j - \sum_i i\, r_i + r_m(s+t+c) + st.$$

File `VOA/Commutative/GordonFullDivisor.lean`.

```

    fullDivisor (K := K) (α := α) (β := β) (γ := γ) m f ∣ clusterEval f F := by
```

From the mathematics to the Lean statement

Index types: `ρ` labels the pairs, `τ` the blocks (linearly ordered, so "$u < v$" makes sense), `α`, `β`, `γ` the residual e, f, h variables. `Source ρ α β γ` indexes the original variables (pair-e, residual e, pair-f, residual f, h), `Target` the variables after identification. `blockSize f u` is the number of pairs in block u; `shape f` the partition of block sizes. `Edge m f` is the disjoint union of the three families in (20.5) (increasing pairs of blocks; blocks of size m times residual variables; residual e times residual f), `collisionFactor i j` $= x_i - x_j$, and `edgeExponent` is $2\min$ on block pairs and 1 otherwise; so `fullDivisor m f` is Δ_λ. `clusterDegree f` $= \sum_{u<v} 2\min(|u|,|v|) = \sum_{i,j}\min(i,j) r_i r_j - \sum_i i r_i$ (the diagonal $u = v$ contributes $\sum_u |u| = \sum_i i r_i$). In `fullDivisor_dvd`: `hF` says Φ is in the functional model of the sector, `hnext` is condition (i) (`nextPairEval x y` = pair evaluation followed by $x = y$), `hG` is condition (ii) (`residualFiltration U λ` is U intersected with the kernels of the cluster evaluations of lexicographically larger shape), and `clusterEval f` is the cluster evaluation.
Relation to the sector bound. The exponent of Theorem 20.33 is $\deg\Delta_\lambda + (a+b+c)$, since $\left(\sum_{i,j}\min(i,j) r_i r_j + \sum_i i r_i + (r_m+1)(s+t+c) + st\right) - \deg\Delta_\lambda = 2R + s + t + c = a + b + c$; the

extra $a+b+c$ is exactly the shift from derivative degree D to conformal weight $D+a+b+c$ in the coefficient index there. So $\deg \Delta_\lambda$ is the derivative-degree cost of the clusters.
The decisive one-variable input is the *symmetric occupancy lemma* (paper Lemma 4.2, `SymmetricOccupancy.lean`): for a symmetric polynomial, specialising a subset of s variables to $z+\delta$ and the rest to z, the coefficient of δ^d is a polynomial in s of degree at most d; so vanishing at many occupancy values forces high-order vanishing (`GordonTwoBlock.lean`).

Proof on paper (outline). Collapse each cluster to a single point. When two collapsed points (or a collapsed point and a residual particle) approach each other, the relation diagonals — applied with the other particles as spectators — give vanishing at a whole range of "occupancy" specialisations (how many of the particles of one block are moved), and the occupancy lemma converts this into vanishing to a definite order along the collision divisor. Different collision divisors are coprime, so the product Δ_λ of all these factors divides the evaluated polynomial (`prod_pow_dvd_of_pairwise_prime_varying`). The library computes the total degree of Δ_λ exactly (`fullDegree_eq`); added to $a+b+c$ it is the exponent appearing in Theorem 20.33 below (see the dictionary). We do not reproduce the case analysis of the individual collision orders; it is the paper's Section 4, formalised in `GordonPairedRelations.lean`, `GordonCluster.lean`, `GordonCommonFactors.lean` and `GordonFullDivisor.lean`. □

Physical meaning

This is the classical analogue of *exclusion statistics*: the $(m+1)$-st pair cannot sit at the same point as m others ($e^{m+1}f^m = 0$-type relations), so wave functions vanish on collisions to a definite order, as in Laughlin/Haldane fractional statistics. The coefficients $\min(i,j)$ of the resulting quadratic form play the role of a "statistical interaction" between clusters of sizes i and j (a heuristic reading).

What the machine verified

Proved (all divisor families and their exact degrees); standard axioms.

20.6.3 The pair/partition filtration and the sector bound

Theorem 20.33 (Sector bound). *For a sector with a e's, b f's, c h's and derivative degree D,*

$$\dim \text{sector} \;\le\; \sum_{R\le \min(a,b)} \sum_{\substack{r_1,\dots,r_m\ge 0\\ \sum i r_i = R}} [q^{D+a+b+c}]\; \frac{q^{\sum_{i,j}\min(i,j)r_i r_j + \sum_i i r_i + (r_m+1)(s+t+c)+st}}{(q)_{r_1}\cdots(q)_{r_m}(q)_s(q)_t(q)_c}, \qquad s=a-R,\ t=b-R.$$

```

From the mathematics to the Lean statement

`Fin m → ℕ` is a vector $(r_1, \dots, r_m)$ written with 0-based indices; `i.val + 1` restores the 1-based cluster size i. `Fin.last m` is the last index (largest cluster size). `PairCount a b` is $\{0, \dots, \min(a, b)\}$; `Profile m R` is the set of (r_i) with $\sum i r_i = R$ (cluster profile of R pairs). `originalColor a b c` colours $a + b + c$ slots $e^a f^b h^c$. **Index shift:** the theorem is stated for `sector … (m + 1) …`, i.e. paper index $m + 1$, with profiles of length $m + 1$; this is a harmless reparametrisation that avoids the hypothesis $m \geq 1$. The extra $a + b + c$ in the coefficient index converts derivative degree to conformal weight (each current has weight one).

Proof on paper. Filter the functional model by *how many pairs can be formed* and then by the *partition* λ of the pairs into clusters, in descending lexicographic order: the step indexed by λ is the kernel of all evaluations at partitions larger than λ. Each subquotient injects, by evaluation at λ followed by division by Δ_λ (Theorem 20.32), into the space of polynomials in the cluster and residual points that are symmetric within each block type; the Hilbert series of such polynomials is $\prod_i 1/(q)_{r_i} \cdot 1/(q)_s (q)_t (q)_c$ (fundamental theorem of symmetric polynomials, applied blockwise: `ColoredSymmetricHilbert.lean`, `TwoBlockSymmetricInvariant.lean`), shifted by the degree of Δ_λ. Summing the subquotient bounds over the finite filtration (a telescope) gives the bound. □

Physical meaning

Each term is a gas of free "quasi-particles": r_i bound states of i e–f pairs, and s, t, c free e, f, h particles, with mutual exclusion energies in the exponent. This is how fermionic character formulas are derived in the physics of integrable models (Bethe ansatz counting) and in Feigin–Stoyanovsky's treatment of $\widehat{\mathfrak{sl}_2}$ principal subspaces.

What the machine verified

Proved; standard axioms. Only an inequality is proved (that is all that is needed); no claim that the filtration bound is sharp is made at this stage. Sharpness follows a posteriori from the squeeze.

Theorem 20.34 (Global auxiliary bound). $\dim(C_m)_N \leq [q^N]\, \mathcal{S}_m$, *where* $\mathcal{S}_m = \sum_{r_1, \dots, r_m \geq 0} q^{\sum \min(i,j) r_i r_j + \sum i r_i} \prod_{i<m} (q)_{r_i}^{-1} \operatorname{res}(r_m)$ *is the paper's source series (5.8).*

    (Module.finrank K (auxiliaryPiece (K := K) (m + 1) N) : ℚ) ≤
      PowerSeries.coeff N (multiplicitySource (K := ℚ) m) := by
```

From the mathematics to the Lean statement

`profileInitialDenominator r` is $\prod_{i<\mathrm{last}}(q)_{r_i}^{-1}$; the last cluster size carries the residual sum `residualSum (r last)` (Definition 20.8), which is the result of summing the three residual species s, t, c in `multiplicityResidualTerm` (proved in the same file). `multiplicitySource m` is the paper's (5.8) at index $m+1$; `multiplicitySource_eq_hilbertBoundSeries` is the paper's passage (5.8)→(5.12): grouping profiles by total multiplicity and peeling the first coordinate turns the quadratic form into the cumulative-count chain $\sum_j n_j(n_j+1)$ with $n_j = r_j + \cdots + r_m$. The bound sums Theorem 20.33 over sectors, injecting the finite set of sector labels into the profile/residual index set and using that all terms have non-negative coefficients (`masterTerm_nonneg`), so adding unused terms only increases the sum.

Proof on paper. Sum the sector bounds over $a+b+c+D = N$; reindex; extend to all profiles by positivity. The identity $\sum_{i,j}\min(i,j)r_i r_j + \sum i r_i = \sum_j n_j(n_j+1)$ with $n_j = \sum_{i\geq j} r_i$ is the standard Andrews–Gordon change of variables. □

Physical meaning

S_m is the full quasi-particle partition function of the degenerate theory C_m.

What the machine verified

Proved; standard axioms.

20.7 The q-series identities

Theorem 20.35 (Chain, trace and product). *For $m \geq 1$, $p = 2m+1$:*

$$S_m = \frac{T_m}{(q)_\infty^2}, \qquad T_m = \frac{(q^p;q^p)_\infty^3}{(q)_\infty}, \qquad S_m = \frac{(q^p;q^p)_\infty^3}{(q)_\infty^3}.$$

      PowerSeries.X ^ (ℓ * (r * (r + 1))) * reciprocalEuler := by
```

From the mathematics to the Lean statement

`gaussian q n k` is the Gaussian binomial $\binom{n}{k}_q$, defined by the q-Pascal recursion (`QBinomial.lean`). `(r + 1).choose 2` $= r(r+1)/2$. `alternatingTheta` is $\sum_{r\geq 0}(-1)^r(2r+1)q^{r(r+1)/2}$, and `jacobi_cube` is Jacobi's identity $(q)_\infty^3 = \sum_r (-1)^r(2r+1)q^{r(r+1)/2}$. `chainSeries` ℓ `r` is the descending chain of length ℓ started at r with the shifted kernel (`QDurfeeChain.lean`); `chainSeries_eq` is its closed form $q^{\ell r(r+1)}/(q)_\infty$, proved by collapsing each bounded inner sum with a finite shifted identity (`chainKernel_eq`) and inducting on the chain length (a Durfee-square type argument). Everything is an identity in $K[[q]]$ for any field K (only characteristic-free algebra is used; `finite_alternating` uses Hahn series over $\mathbb{Z}$-exponents to divide by q-powers).

Proof on paper. (1) *Residual sums.* Summing the two free species with Euler's identity $\sum_j q^{Aj}/(q)_j = 1/(q^A;q)_\infty$ and the third with the q-binomial theorem gives $\mathrm{res}(n) = (q)_n^2/((q)_{2n+1}(q)_\infty^2)$ (`residualSum_eq`); inserting this at the end of the chain gives $S_m = T_m/(q)_\infty^2$. (2) *Terminal factor.* The finite identity $(q)_n^2 = \sum_{r=0}^{n}(-1)^r(2r+1)q^{\binom{r+1}{2}}\binom{2n+1}{n-r}_q$ (`finite_alternating`) rewrites $K_0(n) = (q)_n^2/(q)_{2n+1}$ as $\sum_r (-1)^r(2r+1)q^{\binom{r+1}{2}}/((q)_{n-r}(q)_{n+r+1})$. (3) *Chain collapse.* After exchanging the finite sums, $T_m = \sum_r (-1)^r(2r+1)q^{\binom{r+1}{2}}\cdot \mathrm{chain}_m(r)$ and $\mathrm{chain}_m(r) = q^{mr(r+1)}/(q)_\infty$ (`chainSeries_eq`). (4) *Jacobi.* Since $\binom{r+1}{2} + mr(r+1) = p\binom{r+1}{2}$, $T_m = \frac{1}{(q)_\infty}\sum_r (-1)^r(2r+1)q^{p\binom{r+1}{2}} = \frac{(q^p;q^p)_\infty^3}{(q)_\infty}$ by Jacobi's identity with $q \mapsto q^p$. □

Physical meaning

A "fermionic = bosonic" identity: the quasi-particle sum (fermionic) equals the product (bosonic, free-field) form of the same partition function, as in the Rogers–Ramanujan and Andrews–Gordon identities that compute characters of Virasoro minimal models. Jacobi's triple product is the vanishing of all but the Weyl-orbit contributions in the $\widehat{\mathfrak{sl}_2}$ denominator

identity.

What the machine verified

Proved for every $m \geq 1$ over any field; standard axioms. These are pure q-series facts, independent of any VOA.

20.8 The Hilbert-series upper bound

Theorem 20.36 (Upper bound). *For $m \geq 1$ and all N:* $\dim L_{k_m}(\mathfrak{sl}_2)_N \leq \dim(B_m)_N \leq [q^N]\,\mathrm{product}(m)$.

    (∑ p ∈ Finset.range (N + 1), Module.finrank ℂ (liWeightLayer W p N)) =
      Module.finrank ℂ (W.grading N) := by
```

From the mathematics to the Lean statement

The first statement is at paper index $m + 1$ (see the index shift above) over any field of characteristic zero. *Caution, two declarations share this short name:* a second `sourcePiece_finrank_le_product`, in `AffineSl2BoundaryVacuumCharacter.lean` (namespace `VOA.AffineSl2BoundaryCharacter`), restates it at index m with `hm : 1 ≤ m` over $\mathbb{C}$ with right-hand side `PowerSeries.coeff N (product m)`; that second one is the one used in `coeff_character_le_product`. `vacuum_finrank_le_sourcePiece` is the surjection argument: π maps the weight-N piece of B_m onto $\bigoplus_{p \leq N} \mathrm{gr}^F_{p,N} V$, whose dimension is $\dim V_N$ by the telescope `sum_liWeightLayer_finrank_eq_grading` (each V_N is filtered by $F^p V_N$, $F^{N+1} V_N = 0$). The telescope holds for every VOA, with no generation hypothesis; this is the form quoted in Chapter 11.

Proof on paper. The degeneration of Section 20.5 + Theorem 20.34 + the q-series identities of Section 20.7: $\dim(B_m)_N \leq \dim(C_m)_N \leq [q^N]S_m = [q^N]\,\mathrm{product}$. And π restricted to weight N is onto $\bigoplus_p \mathrm{gr}^F_{p,N} V$ (Theorem 20.29), of dimension $\dim V_N$. □

Physical meaning

Every quantum state has a classical shadow, and classical states are bounded by the quasi-particle count: “Schur index ≤ arc-space Hilbert series of the Higgs branch scheme” (a general

inequality, true for any VOA generated by its weight-one space and any relations known to hold).

What the machine verified

Proved for every $m \geq 1$, unconditionally; standard axioms. No VOA input enters the bound on $\dim(B_m)_N$: it is pure commutative algebra and combinatorics.

20.9 The lower bound for the character

This is where the library goes beyond the paper (which quotes Kac–Wakimoto). The lower bound $[q^N]$ product $\leq \dim L_{k_m,N}$ is proved by counting null vectors with the determinant.

20.9.1 The idea

Write $V_N^k = \bigoplus_c V_{N,c}^k$ by h_0-charge $2c$. On each finite block the invariant form has a Gram matrix $G_{N,c}(k)$ in the PBW basis, whose entries are *polynomials in the level* k. The simple quotient's block $L_{k,N,c}$ has dimension rank $G_{N,c}(k)$ (the maximal ideal is the radical of the form). Hence

$$\dim V_{N,c}^k - \dim L_{k,N,c} = \dim \ker G_{N,c}(k) \;\leq\; \operatorname{ord}_{t=k} \det G_{N,c}(t), \tag{20.6}$$

the inequality being a general fact about polynomial matrices (Lemma 20.38). Summing over c:

$$\dim L_{k,N} \;\geq\; \dim V_N^k - \sum_c \operatorname{ord}_{t=k} \det G_{N,c}(t).$$

So it suffices to compute the total order of vanishing of the determinants at $k = k_m$ and show that $\dim V_N^k -$ (total order) $=$ $[q^N]$ product. Since $\dim V_N^k = [q^N](q)_\infty^{-3}$ (PBW), and by Jacobi product $= (q)_\infty^{-3} \sum_{r\geq 0}(-1)^r(2r+1)q^{p\binom{r+1}{2}}$, the claim is that the total order is the *Weyl correction*

$$\sum_{s\geq 1}\Big[(4s{-}1)\,P_3\big(N{-}ps(2s{-}1)\big){-}(4s{+}1)\,P_3\big(N{-}ps(2s{+}1)\big)\Big], \qquad P_3(n) = [q^n](q)_\infty^{-3}\ (P_3(n) = 0 \text{ for } n < 0), \tag{20.7}$$

which is $-\sum_{r\geq 1}(-1)^r(2r+1)P_3(N - p\binom{r+1}{2})$ with $r = 2s-1$ and $r = 2s$ grouped in pairs.

20.9.2 The universal character and charge decomposition

Theorem 20.37 (PBW character and charge decomposition). *For every non-critical* k: $\dim V_N^k = [q^N](q)_\infty^{-3}$; V_N^k *and* $L_{k,N}$ *are the direct sums of their charge-*$2c$ *pieces,* $c \in [-N, N]$ *(in Lean: the dimension identities below, which is all that is used); the charge-*$2c$ *piece of* V_N^k *has the PBW basis indexed by* `JointIndex N (2*c)`.

Files `VOA/Examples/AffineSl2UniversalCharacter.lean`, `VOA/Examples/AffineSl2ChargeDecomposition.lean`, `VOA/Examples/AffineSl2AdmissibleCharacterRange.lean`.

```

def simpleJointPiece (k : ℂ) (hk : k + 2 ≠ 0) (n h : ℤ) :=
  (jointSpace k hk n h).map (QuotVOA.maxGradedIdeal (universal k hk)).mkQ
```

From the mathematics to the Lean statement

`JointIndex n h` is the set of PBW occupation data (Chapter 9) of energy n and h_0-charge h; `Fintype.card` its cardinality. `Finset.Icc a b` is $\{a, \dots, b\}$. Charges of current monomials are even (`currentCharge_even`), so the sum over $c \in [-N, N]$ of charge $2c$ covers everything. `simpleJointPiece` is the image in L_k of the charge-$2c$, energy-n piece.

Proof on paper. PBW: V^k has basis the ordered monomials in e_{-n}, h_{-n}, f_{-n} ($n \geq 1$), three colours of bosonic oscillators of weight n, whose generating function is $\prod_n (1-q^n)^{-3}$. L_0 and h_0 commute and are diagonal on PBW monomials; the quotient map respects the decomposition. □

Physical meaning

Three free bosons: the universal theory has no null states at generic level, so its partition function is $1/\eta^3$ up to $q^{c/24}$.

What the machine verified

Proved for every non-critical level; standard axioms.

20.9.3 Gram rank and determinant root order

Lemma 20.38 (Kernel dimension is at most the root order). *Let $M(t)$ be a square matrix of polynomials over a field with $\det M \neq 0$, and z a point. Then $\dim \ker M(z) \leq \operatorname{ord}_{t=z} \det M(t)$.*

File `VOA/Commutative/PolynomialMatrixRootOrder.lean`.

```
theorem finrank_ker_le_rootMultiplicity (M : Matrix ι ι K[X]) (z : K)
    (hdet : M.det ≠ 0) :
    Module.finrank K (evaluate M z).mulVecLin.ker ≤ M.det.rootMultiplicity z := by
```

From the mathematics to the Lean statement

`K[X]` is the polynomial ring; `evaluate M z` is the entrywise evaluation (`VOA/Core/PolynomialMatrixSimpleRoot.lean`); `mulVecLin.ker` is the kernel of $v \mapsto M(z)v$; `rootMultiplicity z` is the order of vanishing at z. The hypothesis $\det M \neq 0$ (as a polynomial) is needed: otherwise the order is not defined (Mathlib sets it to 0).

Proof on paper. Choose a constant invertible matrix P whose first $d = \dim \ker M(z)$ columns are a basis of $\ker M(z)$. The first d columns of $M(t)P$ vanish at $t = z$, hence are divisible by $(t-z)$, so $(t-z)^d \mid \det(M(t)P) = \det M(t) \cdot \det P$. □

Physical meaning

A null state at level k is a direction in which the Shapovalov form degenerates; each such direction costs at least one power of $(t-k)$ in the Kac determinant. (Equality would need a Jantzen-filtration argument; only the inequality is needed.)

What the machine verified

Proved for all fields; standard axioms.

Theorem 20.39 (Simple joint dimension and the root-order bound). *For every non-critical k and every N:* $\dim L_{k,N,c} = \operatorname{rank} G_{N,c}(k)$ *and*

$$\dim V_N^k \le \dim L_{k,N} + \sum_{c\in[-N,N]} \operatorname{ord}_{t=k} \det G_{N,c}(t).$$

      Module.finrank ℂ ((simple k hk).grading N) + vacuumRootOrderTotal k N := by
```

From the mathematics to the Lean statement

`vacuumChevalleyPolynomial n c` is $G_{n,c}(t)$: entry (i,j) is the polynomial in the level variable `X` whose value at k is the contravariant (Shapovalov) pairing `contravariant k 0` of the i-th and j-th PBW words in the Verma module of highest weight 0 (`vacuumChevalleyPolynomial_eval`); `eval₂Hom` substitutes level $=$ `X` and highest weight $=$ 0 in a two-variable polynomial `wordPolynomial`. "Chevalley" refers to the adjoint convention $e^\dagger = f$. `actualJointGram k n c` is $G_{n,c}(k)$: by its body, the entrywise evaluation at k of the same polynomial matrix whose determinant's root multiplicity is counted below (so rank and root order re-

fer to one matrix). `jointSynthesis k hk n c r` is the vector $\sum_i r_i \cdot$ (PBW word i) in V^k; `jointSynthesis_mem_maximalIdeal_iff` says it is in the maximal ideal iff r is in the (row) kernel of G: "maximal ideal = radical of the form" made concrete. `vacuumRootOrderTotal k N` is $\sum_c \mathrm{ord}_k \det G_{N,c}$. The final inequality is (20.6) summed over charges (the determinant is a non-zero polynomial, `vacuumChevalleyPolynomial_det_ne_zero`, proved below).

Proof on paper. Rank–nullity on each block, Lemma 20.38, and the charge decompositions of Theorem 20.37. □

Physical meaning

The number of physical states at level k is at least the number of states of the free theory minus the number of zeros of the Kac determinant at k.

What the machine verified

Proved for every non-critical level; standard axioms.

20.9.4 The vacuum determinant and its zeros

Kac–Kazhdan factors for affine $\mathfrak{sl}_2$. Let $M(\lambda)$ be the Verma module of $\widehat{\mathfrak{sl}_2}$ at level k whose highest-weight vector has h_0-eigenvalue λ (the *horizontal highest weight*). Its weight spaces are indexed by energy n and charge; the Shapovalov form on each weight space has a determinant, a polynomial in (k, λ). Write α for the positive root of $\mathfrak{sl}_2$ (horizontal simple root) and δ for the imaginary root. The positive real roots are $\beta = \alpha + j\delta$ ($j \geq 0$) and $\beta = -\alpha + j\delta$ ($j \geq 1$). The Kac–Kazhdan formula says that the determinant is, up to a non-zero constant, a product over pairs (β, r), $r \geq 1$, of the affine-linear factors

$$\phi_{\beta,r}(k,\lambda) = \begin{cases} \lambda + 1 + j(k+2) - r, & \beta = \alpha + j\delta, \\ -\lambda - 1 + j(k+2) - r, & \beta = -\alpha + j\delta, \end{cases}$$

each raised to a power $\mathrm{mult}_{\beta,r}$, the number of PBW states at the weight lowered by $r\beta$ (the descendants of the singular vector created when $\phi_{\beta,r} = 0$). (Imaginary roots $j\delta$ contribute factors proportional to $j(k+2)$, independent of λ and non-zero at non-critical level; they are absorbed into the normalisation below.) The pair $(\alpha, 1)$ gives $\phi_{\alpha,1} = \lambda$, which vanishes *identically* at $\lambda = 0$: this is the singular vector $f_0\mathbf{1}$, and the vacuum module is $V^k(\mathfrak{sl}_2) = M(0)/\langle f_0\mathbf{1}\rangle$. The submodule $\langle f_0\mathbf{1}\rangle$ is a copy of $M(-2)$ ($-2 = s_\alpha \cdot 0$, the reflected weight); its highest-weight vector $f_0\mathbf{1}$ has charge -2, so the part of it of charge $2c$ is the part of $M(-2)$ of charge $2(c+1)$ *relative to its own highest weight*. That is the origin of the index $c + 1$ below.

Because $\det M(0)$ vanishes identically, one cannot simply divide determinants. The library instead removes from the Kac–Kazhdan product *exactly* the multiplicity of the identically vanishing factor $\phi_{\alpha,1} = \lambda$ (file docstring of `AffineSl2KacVacuumCoefficient.lean`: "removing exactly its descendant multiplicity leaves a polynomial in central level"), and proves that what remains equals the Gram determinant of the quotient times the determinant of $M(-2)$ at the shifted charge, up to a non-zero constant and an explicit normalising polynomial $\ell_{n,c}(k)$, a product of "derivative multipliers" of PBW words (`affineLeadingPolynomial`, non-zero at every non-critical level by `affineLeadingPolynomial_eval_ne_zero`; the constant is `vacuumDeterminantScale`, non-zero by `vacuumDeterminantScale_ne_zero`).

Theorem 20.40 (Vacuum/reflected determinant identity)**.** *For all n, c, as polynomials in the level t:*

$$\det G_{n,c}(t) \cdot D^{\mathrm{refl}}_{n,c+1}(t) = \mathrm{const}_{n,c} \cdot \ell_{n,c}(t) \cdot \prod_{(\beta,r)\neq(\alpha,1)} \phi_{\beta,r}(t,0)^{\mathrm{mult}_{\beta,r}},$$

where $D^{\mathrm{refl}}_{n,c+1}(t)$ is the Shapovalov determinant of $M(-2)$ at energy n and relative charge $2(c+1)$, $\mathrm{const}_{n,c} \neq 0$, $\ell_{n,c}(k) \neq 0$ for every non-critical k, and the product runs over the Kac–Kazhdan labels except the horizontal simple root with $r = 1$. Consequently, for every non-critical k,

$$\mathrm{ord}_k \det G_{n,c} + \mathrm{reflectedOrder}_k(n, c+1) = \mathrm{vacuumOrder}_k(n, c).$$

```

From the mathematics to the Lean statement

A Kac label `i = ((col, j), r)` encodes a positive real root β (through an oscillator `(col, j)`) and a multiplicity index `r` (the factor for `r` + 1 copies of β, i.e. the book's r is `r` + 1): colour `1` with depth `j` is $\beta = \alpha + j\delta$, colour `0` with depth `j` is $\beta = -\alpha + (j+1)\delta$ (`realRootSlope`, `realRootOffset` in `AffineSl2KacProduct.lean`). `realRootWeight (k+2) i` is the affine-linear function slope $\cdot(k+2)$ + offset, and `realRootWeight (k+2) i` $= \lambda$ is exactly $\phi_{\beta,r}(k,\lambda) = 0$: e.g. for $\beta = \alpha + j\delta$ the slope is $-j$, the offset `r`, and $\lambda = \mathtt{r} - j(k+2)$ iff $\lambda + 1 + j(k+2) - (\mathtt{r}+1) = 0$. So the condition "$= 0$" (resp. "$= -2$") is the Kac–Kazhdan condition for the vacuum (resp. reflected) Verma module. `affineKacMultiplicity` is the number of PBW states at the shifted energy and charge (the descendants of the singular vector). `((1,0),0)` is the label of the horizontal simple root, removed because the vacuum module $V^k = M(k\Lambda_0)/\langle f_0\mathbf{1}\rangle$ is already the quotient by it. `vacuumOrder`, `reflectedOrder` count the resonances with multiplicity. The identity is an identity of polynomials in t, so it holds even at levels where the reflected determinant also vanishes; this is why it can be used at $k = k_m$ where many factors collide.

Proof on paper. The vacuum module is the quotient of the Verma module $M(0)$ (horizontal highest weight 0) by the submodule generated by $f_0\mathbf{1}$, which is isomorphic to the Verma module $M(-2)$. Since the Shapovalov determinant of $M(0)$ itself is identically zero, one works with the Kac–Kazhdan product with the factor $\phi_{\alpha,1} = \lambda$ removed to exactly its multiplicity, and shows it

equals (Gram determinant of the quotient)×(determinant of $M(-2)$ at the shifted charge)×(a change-of-basis constant)×$\ell_{n,c}$, using an adapted PBW basis compatible with the submodule (`AffineSl2ParabolicAdaptedBasis.lean`, `AffineSl2ParabolicFirstBlock.lean`). The Kac–Kazhdan formula for both Verma determinants (proved in the library for affine $\mathfrak{sl}_2$, `AffineSl2KacProduct.lean` and its companions) then gives the identity. Taking orders of vanishing (orders of products add) gives the second statement. □

Physical meaning

The vacuum module is a Verma module with its trivial horizontal null vector $f_0\mathbf{1}$ removed; its null states are those of the Verma module minus those of the removed submodule (the "reflected" Verma module). This is the first step of the BGG / Kac–Wakimoto resolution, done at the level of determinants.

What the machine verified

Proved for every n, c and every non-critical k; standard axioms.

20.9.5 The boundary resonances and the Weyl correction

Theorem 20.41 (Total root order at the boundary level). *Let P be odd and $k = 2/P - 2$ (we write P, as the Lean statements do, for an arbitrary odd denominator; at $P = 2m+1$ it is the chapter's p and $k = k_m$). For every N, the total root order equals the Weyl correction (20.7), and*

$$\mathrm{vacuumRootOrderTotal}(k, N) + [q^N]\frac{(q^P;q^P)_\infty^3}{(q)_\infty^3} = \dim V_N^k.$$

          ↪ reciprocalEuler^3) =
      (Module.finrank ℂ ((universal (2/(P : ℂ)-2) hk).grading N) : ℚ) := by
```

From the mathematics to the Lean statement

`P.Coprime 2` says P is odd; the level is written `2/(P:ℂ)-2`, which equals `level m` when $P = 2m+1$ (the headline file makes the conversion, `hlevel`). `shiftedJointCount n c E Q` counts PBW states of energy $n-E$ and the correspondingly shifted charge; `EnergyIndex N` is the set of all PBW states of energy N, so `universalPBWCount N` $= P_3(N)$ (`universalPBWCount_eq_coeff`). The `if … then … else 0` guards implement $P_3(n) = 0$ for $n < 0$ (natural-number subtraction would otherwise silently give $P_3(0)$; the guards are exactly what prevents that trap). `weylPairTail p n` is (20.7); `weylPairTail_add_product` is the identity "Weyl correction + product $= P_3$", which is Jacobi's identity for $(q^p;q^p)_\infty^3$ read coefficientwise; the last theorem combines it with the universal character. The range $s \in [1, N]$ is large enough since $ps(2s-1) > N$ for $s > N$.

Proof on paper. At $k+2 = 2/P$ with P odd, a Kac–Kazhdan factor vanishes iff an integrality condition holds; coprimality of P and 2 forces the relevant root energies to be multiples of P and ties the multiplicity index to them (compare `AffineSl2BoundaryParabolicRoots.lean`: "the next affine root has relative energy $P \cdot r$"); the library enumerates the solutions exactly (`vacuum_labels`, `reflected_labels`). Solving, the vacuum resonances come in two families with energy shifts $Ps(2s-1)$ and $Ps(2s+1)$, and the reflected resonances in the "reversed" families (`vacuumOrder_boundary`, `reflectedOrder_boundary`). The differences, summed over all charges c, combine into $(2r+1)$ full copies of the PBW count at the shifted energy, with $2r+1 = 4s-1$ and $4s+1$ (the dimensions of the $\mathfrak{sl}_2$-multiplets of spin $2s-1$ and $2s$); see `sum_shiftedParabolicCount`. This is `sum_boundary_order_difference`. Combining with Theorem 20.40 gives the total root order, and Jacobi's identity finishes. □

Physical meaning

At the boundary level the singular vectors of the vacuum module sit at the affine Weyl orbit $w \cdot 0$: an $\mathfrak{sl}_2$-multiplet of spin r at energy $p\binom{r+1}{2}$, with sign $(-1)^r$. The character is the alternating sum $\sum_r (-1)^r (2r+1) q^{p\binom{r+1}{2}}/(q)_\infty^3$ (the unflavoured Kac–Wakimoto / Weyl–Kac

formula), and Jacobi's triple product turns it into $(q^p;q^p)_\infty^3/(q)_\infty^3$. In the lower-bound step this formula is not assumed: only its inequality $\geq$ is derived, from determinant zeros. For $m=1, N=9$: $3P_3(6)-5P_3(0)=663-5=658$ (Example 20.19).

What the machine verified

Proved for every odd P; standard axioms. The supporting parabolic-module theory in the umbrella (`AffineSl2Parabolic*.lean`, `AffineSl2HorizontalReflection.lean`: exact parabolic quotient sequence, adapted bases, joint dimensions) is proved and integrated; the campaign ledger notes that the final bound uses the determinant argument, not an exact resolution.

Theorem 20.42 (The lower bound). *For $m \geq 1$ and all N:* $[q^N]\,\mathrm{product}(m) \leq \dim L_{k_m}(\mathfrak{sl}_2)_N$.

This is `coeff_product_le_character`, quoted in Theorem 20.18 (file `VOA/Examples/AffineSl2BoundaryMainTheorems.lean`).

Proof on paper. By Theorem 20.39, $\dim V_N^k \leq \dim L_{k,N} + \mathrm{order}_N$, and by Theorem 20.41 $\mathrm{order}_N + [q^N]\mathrm{product} = \dim V_N^k$. Subtract. (In Lean the only extra work is converting `2/(denominator m)-2` to `level m`.) □

Physical meaning

Combined with the Hilbert-series upper bound: the null states found by the determinant are *all* the null states, a fact that is usually proved via the Kazhdan–Lusztig / Kac–Wakimoto machinery; here it falls out of the squeeze.

What the machine verified

Unconditional; standard axioms.

20.10 The conformal Hilbert squeeze

Theorem 20.43 (Injectivity from the dimension squeeze). *Let W be a VOA, $x_1, x_2, x_3 \in W_1$, and suppose the arc relations of I_m vanish under $\pi: x_{i,n} \mapsto \partial^n \bar{x}_i/n!$ and that π is surjective. If $\dim(B_m)_N \leq \dim W_N$ for all N, then $\pi: B_m \to \mathrm{gr}^F W$ is injective. For $W = L_{k_m}(\mathfrak{sl}_2)$ the dimension hypothesis follows from the character equality.*

```

From the mathematics to the Lean statement

In `BoundaryArcConformalSqueeze.lean`, `W`, `gen`, `hgen` (weight-one generators), `m` and `hI` (the source ideal lies in the kernel) are section variables, and `polynomialMap W gen hgen` is that file's own `abbrev` for `liInfiniteJetPolynomialMap W gen (fun _ ⇒ 1) hgen` (Definition 20.16); it is a different declaration from `BoundaryArcLiMap.polynomialMap C`, which is the special case $W =$ `simpleVOA C`, `gen` $=$ `gen C`. `Layers W N` is the finite product $\prod_{p\le N} \mathrm{gr}^F_{p,N} W$, of total dimension $\dim W_N$ (`layers_finrank`, from the telescope of Theorem 20.36). `pieceMap N` is π restricted to the weight-N piece, followed by projection to the layers of weight N. `injective_of_surjective_of_finrank_le` is the linear-algebra fact used (in namespace `FiniteHilbertSqueeze`, Chapter 11). `..._of_character` are the helpers that take the character equality as an explicit argument; the headline `canonicalMap_bijective` supplies it.

Proof on paper. Fix N. Surjectivity of π and homogeneity give that `pieceMap N` is onto $\prod_p \mathrm{gr}^F_{p,N} W$, a space of dimension $\dim W_N \ge \dim(B_m)_N$; a surjective linear map from a space of dimension at most that of the target is injective. Globally: if $\pi(f) = 0$ for a polynomial f, then each conformal component f_N satisfies $\mathrm{pieceMap}_N([f_N]) = 0$ (the conformal projection is compatible with the Li components, `component_conformal`), hence f_N is in the relation ideal, hence so is $f = \sum_N f_N$. For $W = L_{k_m}$: $\dim(B_m)_N \le [q^N]\mathrm{product} = [q^N]\mathrm{character} = \dim W_N$. □

Physical meaning

Equal partition functions plus a surjection of state spaces in every energy forces an isomorphism: the classical and quantum Hilbert spaces have the same size level by level.

What the machine verified

Proved; standard axioms. The helpers are conditional on `hcharacter`, discharged in the headline file.

20.11 Poisson vertex structure, inverse, and the C_2 presentation

Theorem 20.44 (The canonical map is a PVA homomorphism; uniqueness). *π commutes with ∂ and with every (n)-product. Moreover two PVA structures on a presented arc algebra with the standard*

translation that agree on pairs of order-zero generators are equal, and a translation-compatible algebra map that is compatible with the modes on order-zero generators is compatible with all modes.

File `VOA/Commutative/InfiniteJetPoissonUniqueness.lean`.

```
theorem compatible_of_base_generators
    (hP : P.translation = translation I)
    (hT : ∀ x, F (P.translation x) = Q.translation (F x))
    (hbase : ∀ i j, Compatible P Q F (generator I i 0) (generator I j 0)) :
    ∀ x y, Compatible P Q F x y := by

theorem poissonVertexAlgebra_unique
    (Q : VOA.PoissonVertexAlgebra (PresentedJet I))
    (hP : P.translation = translation I) (hQ : Q.translation = translation I)
    (hbase : ∀ i j n, P.mode n (generator I i 0) (generator I j 0) =
      Q.mode n (generator I i 0) (generator I j 0)) : P = Q := by
```

File `VOA/Commutative/PoissonVertexHom.lean`.

```
def Compatible (P : VOA.PoissonVertexAlgebra A) (Q : VOA.PoissonVertexAlgebra B)
    (F : A →ₐ[ℂ] B) (x y : A) : Prop :=
  ∀ n, F (P.mode n x y) = Q.mode n (F x) (F y)
```

From the mathematics to the Lean statement

`Compatible P Q F x y`: $F(x_{(n)}y) = F(x)_{(n)}F(y)$ for all n. `generator I i 0` is the class of $x_{i,0}$. The first theorem reduces homomorphism checks to generators, using Leibniz (products), sesquilinearity (derivatives) and skew-symmetry (swapping slots). For `arcLiPoissonHom` the generator check is the computation $\overline{x_i}_{(0)}\overline{x_j} = \overline{[x_i, x_j]}$ and $\overline{x_i}_{(n+1)}\overline{x_j} = 0$ in $\mathrm{gr}^F L_k$ (the level term has negative Li degree).

Proof on paper. Every element of the arc algebra is a polynomial in the $x_{i,n} = \partial^n x_{i,0}/n!$; the PVA laws express $(\partial^r a)_{(n)}b$, $a_{(n)}(bc)$, $b_{(n)}a$ in terms of modes of the factors, so compatibility propagates from generators to everything. □

Physical meaning

A classical field theory is determined by its basic Poisson brackets $\{x_i(z), x_j(w)\}$; everything else follows from the Leibniz rule and derivatives.

What the machine verified

Proved; standard axioms.

Theorem 20.45 (Injectivity on the PVA side; the inverse; the C_2 presentation)**.** *Under the character equality:* `arcLiPoissonHom` *is injective, hence a PVA equivalence (with compatible inverse); the equivalence and its inverse preserve conformal pieces; the induced map $A_m \to R_V$ is injective, hence an isomorphism.*

      MvPolynomial.aeval (fun i => liDegreeZeroClass W (weight i) (gen i)) f := by
```

From the mathematics to the Lean statement

`arcLiPoissonHom_injective_of_character` transfers injectivity from `canonicalMap` (on `Source m`) to `arcLiPoissonHom` (on `PresentedJet (baseIdeal m)`) through `sourceIdeal_eq_jetIdeal`. `canonicalMap_conformal_iff` is the conformal statement on the `Source` side; the headline `arcPoissonEquiv_conformal_iff` is its transport. `c2ToLiAlgebra W : A₂ W →ₐ[ℂ] liAssociatedGraded W` is the inclusion of $R_W = F^0W/F^1W$ as the degree-zero part of $\mathrm{gr}^F W$, as an algebra map; `c2ToLiAlgebra_aeval` says it sends the C_2 class of a polynomial in generators to the same polynomial in degree-zero Li classes. In `baseC2Map_injective_of_arc_injective` the section variables are a VOA `W`, weights, generators `gen`, an ideal `I` and `hI : I ≤ ker(C₂ evaluation)`.

Proof on paper. Injectivity transfers along the identification of the two names of B_m. For the presentation: the square "$A_m \to J_\infty A_m \xrightarrow{\pi} \mathrm{gr}^F V$" = "$A_m \to R_V \xrightarrow{c_2 \to \mathrm{Li}} \mathrm{gr}^F V$" commutes (`baseC2Map_li_commutes`); the left composite is injective (constant arcs have a retraction, then π), so $A_m \to R_V$ is injective. Conformal compatibility: π maps the weight-N piece *onto* the weight-N piece (`sourcePiece_map_eq_liConformalPiece`), and injectivity gives the converse inclusion. □

Physical meaning

The classical limit determines the chiral ring: once the full arc space is known to be faithful, its constant part — the Higgs branch chiral ring — has no further relations.

What the machine verified

Proved; the `_of_character` forms carry `hcharacter`, discharged in the headline file. Standard axioms.

20.12 The Virasoro companion: classical freeness of the minimal models $M(2, 2m+3)$

This section and the next document three files that prove the Virasoro analogue of the theorems above, and a family of commutative-algebra files left from an alternative route to the affine theorem that was not completed. (Their Lean quotations were first copied on 2026-10-27 and are checked against the released source by `sync.py`; see Section 20.14.)

Machine status in these two sections. "Proved, unconditional" in a status box below means: the Lean statement has no hypothesis beyond the displayed variables, and `#print axioms` on it

gives Lean's three standard axioms. These axiom checks are *isolated-module* runs (`lake env lean -DmaxSynthPendingDepth=3` on a scratch file importing one compiled module; Section 20.14). The aggregate `lake build` was *not* re-run for these sections, and the project counts a result as established only when the aggregate build is green; each status box repeats the caveat "(isolated-module check; aggregate build not re-run)".

20.12.1 What is proved, and why it belongs here

The earlier sections proved (the Arakawa–Dai theorem) that the simple affine VOA $L_{k_m}(\mathfrak{sl}_2)$ at the boundary admissible level $k_m = -2 + \frac{2}{2m+1}$ is classically free. This section proves the analogous statement for the Virasoro minimal models of the series $(2, 2m+3)$: $M(2,5)$ (Lee–Yang), $M(2,7)$, $M(2,9)$, and so on. For them the C_2-algebra is a single fat point,

$$R_{L(c_{2,2m+3},0)} \cong \mathbb{C}[T]/(T^{m+1}), \qquad T = [\omega],$$

and classical freeness says that Li's associated graded is the arc algebra of this fat point,

$$J_\infty\big(\mathbb{C}[T]/(T^{m+1})\big) \xrightarrow{\cong} \mathrm{gr}^F\, L(c_{2,2m+3}, 0). \tag{20.8}$$

On characters, (20.8) is equivalent to the Andrews–Gordon identities (the Hilbert series of the left side is the Feigin–Stoyanovsky fermionic sum, the character of the right side is the Rocha-Caridi product); this is the result of van Ekeren and Heluani. The library proves (20.8) for every $m \geq 0$, together with the presentation of the full non-reduced C_2-algebra and the Poisson vertex structure, about the *actual* simple quotient of the *actual* universal Virasoro VOA. The structure of the statements is the same as for $L_{k_m}(\mathfrak{sl}_2)$ in Section 20.3, which is why the files are documented here. **The role of character identities.** The injectivity proof uses the Andrews–Gordon identity (20.9) and the Feigin–Fuchs/Rocha-Caridi lower bound for $\dim L(c_m,0)_N$ (both proved in Lean), but only through the leading-symbol theorem `virSymbol_twoSeries` (Theorem 20.50). In contrast to the affine case, no comparison of the Hilbert series of the two sides of (20.8) is made at the end; the character of $L(c_m,0)$ is a by-product.

The Andrews–Gordon identity used here. For $n \geq 0$ and $N \geq 0$,

$$\#\Big\{\text{partitions of } N \text{ into parts} \geq 2 \text{ with } f_j + f_{j+1} \leq n \text{ for all } j\Big\} = \sum_{k\in\mathbb{Z}} (-1)^k\, p\Big(N - \tfrac{k((2n+3)k+2n+1)}{2}\Big), \tag{20.9}$$

where f_j is the multiplicity of the part j and p is the partition function ($p(<0) = 0$). The right side is the coefficient of q^N in the Rocha-Caridi character of $L(c_{2,2n+3},0)$; by Gordon's theorem both sides also equal the number of partitions of N into parts $\not\equiv 0, \pm 1 \pmod{2n+3}$, the product form $\prod_{j\not\equiv 0,\pm1\,(2n+3)}(1-q^j)^{-1}$ of the character. In the library this is `TwoSeriesCharacter.AG.gordon_sum_eq_rcq` (`VOA/Examples/TwoSeriesCharacterAGIdentity.lean`). (Check at $n=1$, $N=4$: the left side counts $\{4\}$ only, and the right side is $p(4)-p(3)-p(0) = 5-3-1 = 1$.)

Gordon-good words. A creation word $L_{-j_1-2}\cdots L_{-j_b-2}\mathbf{1}$ with $j_1 \geq \ldots \geq j_b$ (sorted decreasingly) is *Gordon-good of order n* if $j_i \geq j_{i+n} + 2$ whenever both entries exist (`GordonGood n`, `VOA/Examples/TwoSeriesCharacterSpanning.lean`). Via "depth $j \leftrightarrow$ part $j+2$" the sorted Gordon-good words of weight N correspond exactly to the partitions counted on the left of (20.9): the condition $j_i \geq j_{i+n}+2$ says that no $n+1$ parts lie within distance one of each other, i.e. $f_j + f_{j+1} \leq n$. For $M(2,2m+3)$ the order is $n = m$; for Lee–Yang ($m=1$) these are the Rogers–Ramanujan words, parts differing by at least 2.

Index convention. Throughout this section $m \geq 0$ and $M(2,2m+3)$ is the minimal model with

$$c_m = c_{2,2m+3} = 1 - \frac{3(2m+1)^2}{2m+3}, \qquad c_0 = 0, \quad c_1 = -\tfrac{22}{5}, \quad c_2 = -\tfrac{68}{7}.$$

So $m = 0$ is the trivial endpoint $M(2,3)$ ($c = 0$, $L(0,0) = \mathbb{C}$, $R = \mathbb{C}[T]/(T) = \mathbb{C}$), and $m = 1$ is Lee–Yang $M(2,5)$. This m is *not* the m of the affine theorem: there $m \geq 1$, $p = 2m+1$ and the level is $k_m = -2 + 2/p$; here the minimal model is $M(2, 2m+3)$ and the relation is T^{m+1}. The same letter thus labels different algebras in the two halves of the chapter; the coincidence is the library's. (Chapter 11 writes the same series as $M(2, 2n+1)$ with $n = m+1$.) In four-dimensional language $M(2, 2m+3)$ is the chiral algebra of the (A_1, A_{2m}) Argyres–Douglas theory.

We rely on Chapter 7 for the universal Virasoro VOA $V(c,0)$ (the library's `virasoroVOA c`, Definition 7.12), its creation words $L_w\mathbf{1} = L_{-j_1-2}\cdots L_{-j_b-2}\mathbf{1}$ (`negWordVir c w`, with entry j standing for L_{-j-2}, Definition 7.5), the fact that these words span (`negSpanVir_eq_top`), and the simple quotient $L(c,0) = V(c,0)/I_{\max}(c)$ (`virasoroSimple c`, `maxIdealVir c`, Definition 7.15). Li's filtration `liFiltration W p`, its layers and `liAssociatedGraded W` are those of Chapter 11 (Section 11.3); presented jet algebras are those of Chapter 11 (Section 11.4) and Definition 20.10. The generic generator-word machinery is Section 11.5 of Chapter 11: Definition 11.20 (the word filtration C_p for generators $a^1, \dots, a^g$), Theorem 11.26 (word spanning plus a tracked estimate give $F^p = C_p$) and Theorem 11.23 (if $F^p = C_p$, the canonical infinite-jet map is surjective). Theorem 20.47 below is the case $g = 1$, $a^1 = \omega$ of that machinery (L11 excludes the Virasoro case from its Lie-current theorem and refers here for it).

20.12.2 Li's filtration of the Virasoro VOA is the word filtration

Definition 20.46 (Depth of a creation word; the word filtration)**.** The *Li depth* of a creation word $L_{-j_1-2}\cdots L_{-j_b-2}\mathbf{1}$ is $j_1 + \cdots + j_b$. For $p \in \mathbb{N}$ let $C_p \subseteq V(c,0)$ be the span of all creation words of depth $\geq p$ (in any order of the letters).

File `VOA/Filtered/VirasoroWordLi.lean`.

```
abbrev virWordLevel (w : List ℕ) : ℕ := w.sum

def virWordPiece (p : ℕ) : Submodule ℂ (VirUniv c) :=
  Submodule.span ℂ {x | ∃ w : List ℕ, p ≤ virWordLevel w ∧ negWordVir c w = x}
```

From the mathematics to the Lean statement

`VirUniv c` is the underlying space of $V(c,0)$. A word is a list `w : List ℕ`; its depth is the sum of its entries (`w.sum`). Since $L_{-j-2} = \omega_{(-j-1)}$ and ω has weight 2, a word of weight N and length b has depth $N - 2b$: depth counts the derivatives, length counts the copies of $T(z)$. `virWordPiece c p` is C_p. Words of any order are allowed (no sorting): C_p is a span, so this costs nothing, and it is what the proof needs. The family is decreasing (`virWordPiece_antitone`) and $C_0 = V(c,0)$ (`virWordPiece_zero_eq_top`, because words span).

Physical meaning

$L_{-j-2}\mathbf{1}$ is the state of $\partial^j T/j!$. A word of depth p is a normal-ordered product of stress tensors carrying p derivatives in total. Li's filtration is "the number of derivatives", and this definition makes the slogan literal for the Virasoro VOA.

What the machine verified

Definition; no hypotheses.

Theorem 20.47 (Li's filtration of $V(c,0)$ and of $L(c,0)$ is the word filtration)**.** *For every $c \in \mathbb{C}$ and every $p \in \mathbb{N}$: $F^pV(c,0) = C_p$, and $F^pL(c,0)$ is the image of C_p under the quotient map $V(c,0) \to L(c,0)$.*

    (hv : v ∈ virWordPiece c q) :
    (virasoroVOA c).smul u (-(n : ℤ) - 1) v ∈ virWordPiece c (q + n) := by
```

From the mathematics to the Lean statement

Namespace `VOA.VirasoroLi`; `c : ℂ` is a section variable, so both statements hold for *every* central charge. `liFiltration W p` is Li's F^pW: the span of $u^1_{(-n_1-1)}\cdots u^r_{(-n_r-1)}\mathbf{1}$ with $\sum n_i \geq p$, the u^i arbitrary states (Chapter 11, Definition 11.6). `.map mkQ` is the image under the quotient map. `W.smul u n v` is $u_{(n)}v$, so `virWordNegativeModeClosed` says $u_{(-n-1)}C_q \subseteq C_{q+n}$ for *every* state u: this is the key estimate.
Same, stronger or weaker? The same as the textbook statement. Note the asymmetry: Li's definition allows arbitrary states u^i, while C_p uses only ω; the theorem says that nothing is lost.

Proof on paper. $C_p \subseteq F^pV$: the word $L_{-j_1-2}\cdots L_{-j_b-2}\mathbf{1}$ is $\omega_{(-j_1-1)}\cdots\omega_{(-j_b-1)}\mathbf{1}$, a generator of $F^{\sum j_i}$. For the converse one shows by induction that negative modes of arbitrary states raise depth correctly. Put $t(q,n) = \max(q-n-1, 0)$ for $q \in \mathbb{N}$, $n \in \mathbb{Z}$; for $n = -s-1 < 0$ this is $q+s$.

1. *One mode of ω.* $\omega_{(n)}C_q \subseteq C_{t(q,n)}$ for all $n \in \mathbb{Z}$. For $n < 0$, $\omega_{(n)} = L_{n-1}$ prepends a letter of depth $-n-1$. For $n \geq 0$ commute L_{n-1} through the word with $[L_a, L_b] = (a-b)L_{a+b} + \frac{c}{12}(a^3-a)\delta_{a+b,0}$: each commutator replaces two letters by one, or by a scalar, and an induction on the length of the word checks the depth bound term by term (`Lop_negWordVir_mem_virWordPiece`).

2. *Modes of an arbitrary word.* For $u = \omega_{(-r-1)}u'$ the Borcherds iterate formula writes $u_{(N)} = \sum_{i\geq 0}(-1)^i\binom{-r-1}{i}\big(\omega_{(-r-1-i)}u'_{(N+i)} - (-1)^{r+1}u'_{(-r-1+N-i)}\omega_{(i)}\big)$; by induction on the length of u and step 1, each term maps C_q into $C_{t(q,N)}$ (one checks the inequality $t(t(q,N+i),-r-1-i) \geq t(q,N)$ and its analogue for the second term, `negWordVir_mode_mem_virWordPiece`).

3. Since words span $V(c,0)$, step 2 holds for every u; with $N = -n-1$ it is $u_{(-n-1)}C_q \subseteq C_{q+n}$. Applying it letter by letter to a generator of F^p shows $F^p \subseteq C_p$.

The statement for $L(c,0)$ follows because Li's filtration of a quotient by a graded ideal is the image of Li's filtration (Chapter 11). Only the spanning of words is used, never their linear independence. □

Physical meaning

In a theory generated by one field T, every local operator is a normal-ordered polynomial in T and its derivatives, and Li's "derivative counting" of an arbitrary composite operator can be read off from such an expression without loss. Physically obvious; the content is that OPE rearrangements (normal-ordering corrections) never *decrease* the derivative count, which is what the tracked estimate verifies.

What the machine verified

Proved, unconditional (isolated-module check; aggregate build not re-run), every c; `#print axioms` of both: `[propext, Classical.choice, Quot.sound]`.

20.12.3 The canonical map and what "classically free" means here

Definition 20.48 (The generator, the relation ideal, the canonical map, classical freeness)**.** Let $\bar{\omega} \in L(c,0)$ be the class of the conformal vector and $x = [\bar{\omega}] \in F^0L_2/F^1L_2 \subseteq \mathrm{gr}^F L(c,0)$ its Li class of bidegree $(0,2)$. In $\mathbb{C}[T]$ (one variable) let $I_m = (T^{m+1})$. If I_m is killed by $T \mapsto x$, the *canonical map* is the unique homomorphism of differential algebras

$$\pi : J_\infty\big(\mathbb{C}[T]/(T^{m+1})\big) \longrightarrow \mathrm{gr}^F L(c,0), \qquad T_{(j)} \longmapsto \frac{\partial^j x}{j!} = \big[L_{-j-2}\mathbf{1}\big] \in F^jL_{j+2}/F^{j+1}L_{j+2},$$

and $L(c,0)$ is *classically free* (for this presentation) if π is bijective. The central charge of $M(2,2m+3)$ is c_m as above.

```

From the mathematics to the Lean statement

Decoding. The generator set is `Fin 1`, a one-element type: one variable T (`MvPolynomial.X 0`). `omegaVir c` is $\omega = L_{-2}\mathbf{1}$, `omegaBar c` its class in $L(c,0)$, `wt` its weight 2, and `liDegreeZeroClass W N v` is the class of $v \in W_N$ in F^0W_N/F^1W_N, inserted into $\mathrm{gr}^F W$ (Chapter 11). `InfiniteJet.PresentedJet I` is the presented arc algebra $J_\infty(\mathbb{C}[T]/I)$ of Definition 20.10, with Hasse–Schmidt jets $T_{(j)} \leftrightarrow \partial^j T/j!$. `presentedJetToDifferentialAlgebra` is the universal property of J_∞: a map from $\mathbb{C}[T]/I$ into a differential algebra extends uniquely to a differential-algebra map from the arc algebra. Here the target derivation is the descended

L_{-1} (`liAssociatedGradedTranslation W`). The hypothesis `hI` ("the relations hold in $\mathrm{gr}^F W$") is what makes the map exist; it is a proof argument, and the map does not depend on which proof is supplied. `LiPresentationClassicallyFree` is bijectivity of that map. Its docstring says it "deliberately does not claim" that the source is identified with an independently defined arc functor; for this example that identification is `actualC2ArcEquiv` below.

The central charge. `cm m` is defined through the library's $(2, 2n+3)$-series level data (`twoSeriesLevels`), and `cm_eq` proves that it equals $1 - 3(2m+1)^2/(2m+3) = c_{2,2m+3}$. The closed form agrees with the minimal-model charge of Definition 7.14 by arithmetic, $6(2m+1)^2/(2(2m+3)) = 3(2m+1)^2/(2m+3)$ (that no Lean theorem states this is recorded in the warning at the end of this section). `cm_zero : cm 0 = 0` and `cm_one : cm 1 = -22 / 5` are proved.

How could this be vacuous? If `relIdeal m` were too big (say (T) for every m), the source would be too small and bijectivity false; if the target were not the actual $L(c,0)$, the statement would be about the wrong object. Neither happens: the ideal is literally (T^{m+1}), and the target is `virasoroSimple (cm m)`, the quotient by the maximal proper graded ideal.

Physical meaning

x is the classical stress tensor $T(z)$ viewed as a coordinate on the associated scheme; π sends the classical field $\partial^j T/j!$ to the class of the quantum operator $\partial^j T/j!$. The relation $T^{m+1} = 0$ is the classical shadow of the vacuum null vector at level $2m+2$.

What the machine verified

Definitions; `cm_eq`, `relIdeal_le`: `[propext, Classical.choice, Quot.sound]`.

20.12.4 The two inputs from the singular vector

The relation T^{m+1} and the injectivity both come from the vacuum singular vector of $M(2, 2m+3)$, which sits at weight $2m+2$ and has leading term $\alpha L_{-2}^{m+1}\mathbf{1}$ with $\alpha \neq 0$. The library packages its two consequences as two propositions, both proved for every m in its $(2, 2n+3)$-series files (`VOA/Examples/TwoSeries*.lean`); we state exactly what is used and explain the proofs below.

Definition 20.49 (Jet relations; the symbol property). Let $P_k^{(n)} = \sum_{e_1+\cdots+e_n=k} L_{-e_1-2}\cdots L_{-e_n-2}\mathbf{1}$. Let $\mathcal{F}_p V(c,0)_N$ be the span of sorted creation words of weight N and length $\leq p$ (Chapter 19, Definition 19.19). Then:

1. c has *jet relations of order* $n+1$ if there is $\alpha \neq 0$ such that for every k some element of the maximal ideal agrees with $\alpha P_k^{(n+1)}$ modulo $\mathcal{F}_n V(c,0)_{2n+2+k}$.
2. Let $\mathcal{R}_n = \mathbb{C}[t_0, t_1, \ldots]/(\text{coefficients of } (\sum_j t_j s^j)^n)$. The *symbol property* for $(c, \mathcal{R}_n, t)$ is the existence of linear maps $\sigma_b : V(c,0) \to \mathcal{R}_n$ $(b \in \mathbb{N})$ that kill the maximal ideal, kill every creation word of length $< b$, and send every creation word $L_{-j_1-2}\cdots L_{-j_b-2}\mathbf{1}$ of length b to $t_{j_1}\cdots t_{j_b}$.

```

From the mathematics to the Lean statement

`Lop c n` is L_n on $V(c,0)$ and `vacVec c` the vacuum (Chapter 7); `jetSum c n k` is $P_k^{(n)}$, defined recursively over the first letter (`Finset.antidiagonal k` is the set of pairs summing to k). `virFil c n N` is $\mathcal{F}_n V(c,0)_N$ (sorted words of energy N and length $\le n$; Chapter 19). `HasJetRelations c n` is item 1, with σ the element of the maximal ideal (σ here is a vector, not the symbol map). `TPoly` is $\mathbb{C}[t_0, t_1, \dots]$, `tSer` the series $\sum_j t_j s^j$, `jetIdealT n` the ideal of its n-th power's coefficients, `Rn n` the quotient $\mathcal{R}_n$, and `tn n j` the class of t_j; so $\mathcal{R}_n$ is the arc algebra $J_\infty(\mathbb{C}[T]/(T^n))$ written with one family of variables. `vBelow c b` is the span of words of length $< b$, in any order. `VirSymbol c R t` is item 2 (`c`, `R`, `t` are section variables); `w.map t` is the list $(t_{j_1}, \dots, t_{j_b})$ and `.prod` its product.

Why item 2 is strong. The third clause of `VirSymbol` is required for words in *every* order and of *every* weight, with one linear map per length. Since different orderings of the same letters differ by commutators of strictly smaller length, this is consistent; but it also forces every linear relation among length-b words in $L(c,0)$, modulo shorter words, to hold among the corresponding monomials in $\mathcal{R}_{m+1}$. That is exactly injectivity at the level of leading symbols.

Physical meaning

Item 1 says that the null state at level $2m+2$ is, at leading order in the number of stress tensors, the classical constraint $T(z)^{m+1} = 0$, and that its descendants L_{-1}^k give the derivatives of that constraint. Item 2 says that the map "quantum state ↦ classical monomial in T and its derivatives" is well defined on the physical (null-free) Hilbert space at leading order: the quantum theory has no leading-order relations beyond the classical ones.

What the machine verified

Definitions (Props). Both are proved for $c = c_m$ in Theorem 20.50; they are not open inputs.

Theorem 20.50 (Both inputs hold for every $M(2,2m+3)$). *For every $m \in \mathbb{N}$: c_m has jet relations of order $m+1$, and the symbol property holds for $(c_m, \mathcal{R}_{m+1}, t)$.*

```
theorem virSymbol_twoSeries (m : ℕ) :
    VirSymbol (twoSeriesLevels m).c (Rn (m + 1)) (tn (m + 1)) :=
```

From the mathematics to the Lean statement

`(twoSeriesLevels m).c` is `cm m`. No hypotheses. Both are theorems, not named inputs. **Same or weaker?** `HasJetRelations` allows a possibly *different* element of the maximal ideal for each k, rather than the L_{-1}-derivatives of one singular vector; this is weaker as a statement about singular vectors but is exactly what classical freeness needs. **Vacuity at $m = 0$:** there the relations say $L_{-2-k}\mathbf{1}$ lies in the maximal ideal at $c = 0$, which is true (the simple quotient is $\mathbb{C}$). **Dependence:** the proof of `virSymbol_twoSeries` uses `gordonLowerBound_twoSeries`, i.e. the Andrews–Gordon identity and the Kac-determinant lower bound (both proved).

Proof on paper. *Jet relations.* The vacuum singular vector of $V(c_m, 0)$ at weight $2m + 2$ is constructed explicitly (a Benoit–Saint-Aubin type recursion) and its leading term is computed to be $\alpha L_{-2}^{m+1}\mathbf{1}$ modulo words of length $\leq m$, with $\alpha \neq 0$. (For $m = 1$ it is $\chi = (L_{-2}^2 - \frac{3}{5}L_{-4})\mathbf{1}$ of Example 20.54, $\alpha = 1$.) Apply $L_{-1}^k/k!$. On a word, L_{-1} acts as a derivation on the letters, $[L_{-1}, L_{-e-2}] = (e+1)L_{-e-3}$, up to commutators that shorten the word; so on leading terms $L_{-1}P_k^{(n)} = (k+1)P_{k+1}^{(n)}$, and $L_{-1}^k L_{-2}^{m+1}/k!$ has leading term $P_k^{(m+1)}$. The image of the singular vector under $L_{-1}^k/k!$ lies in the maximal ideal, which gives item 1 with that image as the element σ of the maximal ideal.

Symbol maps: the mechanism in three steps.

1. *Straightening (spanning).* Fix the weight N and the length b. Modulo words of length $< b$ and modulo the maximal ideal, every length-b word is a combination of *sorted* length-b words (reordering letters costs commutators, which are shorter). A sorted word that is not Gordon-good of order m contains $m + 1$ letters within distance one; the jet relation $P_k^{(m+1)}$ with the appropriate k rewrites it, modulo shorter words and the maximal ideal, as a combination of sorted words that are larger in a fixed monomial order. Since there are finitely many words of given weight, the rewriting stops: *the Gordon-good sorted words span $L(c_m, 0)_N$ modulo shorter words*, and the same rewriting holds verbatim in $\mathcal{R}_{m+1}$, where the relations are the coefficients of $(\sum_j t_j s^j)^{m+1}$.

2. *Counting (independence).* Summing over b, the number of Gordon-good sorted words of weight N is the left side of (20.9) (with $n = m$), which by the Andrews–Gordon identity equals the Rocha-Caridi number on the right; and the Kac determinant (Feigin–Fuchs) shows that the Rocha-Caridi number is $\leq \dim L(c_m, 0)_N$. Spanning gives the reverse inequality, so the Gordon-good words are a basis of $L(c_m, 0)_N$, and their images form a basis of each length layer.

3. *Definition of σ_b.* Define σ_b on the basis: a Gordon-good word of length b goes to its monomial $t_{j_1} \cdots t_{j_b}$, shorter basis words go to 0; extend linearly and compose with $V(c_m, 0) \to L(c_m, 0)$ (so the maximal ideal is killed). Because step 1 rewrites a word and its monomial *by the same relations*, σ_b sends every length-b word, in any order, to its monomial, and kills shorter words: the three clauses of the symbol property.

The case $m = 1$. The relation is $P_k^{(2)} = \sum_{a+b=k} L_{-a-2}L_{-b-2}\mathbf{1}$, the Gordon-good words are the Rogers–Ramanujan words (sorted, consecutive letters differing by ≥ 2), and the counts are those of the table of Example 20.54: at weight 6, for instance, the sorted length-two words are $L_{-4}L_{-2}$, L_{-3}^2

(depths $(2,0),(1,1)$); only $(2,0)$ is Gordon-good, and $L_{-3}^2\mathbf{1}$ is rewritten through $P_2^{(2)} = 2L_{-4}L_{-2}+L_{-3}^2$ (leading terms), matching $T_1^2 \equiv -2T_0T_2$ in the table. □

Physical meaning

The singular vector is the null state that the minimal model removes; its leading term $L_{-2}^{m+1}\mathbf{1}$ says "$T^{m+1}=0$" classically. The symbol property says that, at leading order in the number of stress tensors, this null state and its derivatives are the *only* relations: the Gordon-good words are the Feigin–Stoyanovsky quasi-particle basis of the minimal model.

What the machine verified

Proved, unconditional (isolated-module check; aggregate build not re-run); `#print axioms` of both: `[propext, Classical.choice, Quot.sound]`.

Recorded overclaim: `virSymbol_twoSeries` is not by itself classical freeness

`virSymbol_twoSeries` is a PBW-*length* leading-symbol theorem into the presented ring $\mathcal{R}_{m+1}$. It does not mention Li's filtration, $V/C_2(V)$ or the canonical map. Earlier project notes and docstrings described it as "classical freeness"; that description was corrected in the project, and the file's docstring says so (the record is cited in Section 20.14). The bridge from the length filtration to Li's filtration is Theorem 20.47 together with the comparison in the proof of Theorem 20.51: weight = depth + 2·length, so at fixed weight and fixed Li depth the length is determined.

20.12.5 The headline: classical freeness and the C_2-algebra

Theorem 20.51 (Classical freeness of $M(2,2m+3)$). *For every $m \in \mathbb{N}$, the canonical map $\pi : J_\infty(\mathbb{C}[T]/(T^{m+1})) \to \mathrm{gr}^F L(c_m,0)$ of Definition 20.48 is bijective; hence it is an isomorphism of differential algebras. In particular this holds for $M(2,3)$ ($m=0$) and for Lee–Yang $M(2,5)$ ($m=1$).*

From the mathematics to the Lean statement

Namespace `VOA.VirasoroClassicalFreeness`. `classicallyFree m` unfolds (Definition 20.48) to "`liInfinitePresentedJetMap (virasoroSimple (cm m)) (x (cm m)) (relIdeal m) _` is bijective": the map π from $J_\infty(\mathbb{C}[T]/(T^{m+1}))$ to $\mathrm{gr}^F L(c_m, 0)$. The one-line proof term shown is informative: injectivity is `jetMap_injective` fed with the two inputs of Theorem 20.50, and surjectivity is `jetMap_surjective`, fed with the jet relations only. `jetMap_injective` is stated for an arbitrary `c`; it is the general implication "jet relations + symbol property ⇒ injective". `canonicalEquiv m` packages π as an algebra isomorphism (`AlgEquiv.ofBijective`); its definition, not just its type, says it is π. `classicallyFree_M23`, `classicallyFree_leeYang` are the instances $m = 0, 1$.

Hypotheses. None besides `m : ℕ`. In particular $m = 0$ is included.

Same, stronger or weaker? The same as (20.8) for the presented arc algebra; the identification of the presented arc algebra with the arc algebra of the actual C_2-algebra is Theorem 20.52. The canonical map is a map of differential algebras by construction (`jetMap_translation`); compatibility with the λ-brackets is Theorem 20.53. Unlike the affine `arcPoissonEquiv_conformal_iff`, there is no separate theorem that π preserves conformal weight; it does, because $T_{(j)}$ has weight $j+2$ and $[L_{-j-2}\mathbf{1}]$ lies in weight $j+2$ by the definition of π, and the injectivity proof works one bidegree at a time.

Proof on paper. Grade $J_\infty\mathbb{C}[T]$ by bidegree: $T_{(j)}$ has Li depth j and weight $j+2$, so a monomial with b letters and depth p has bidegree $(p, p+2b)$; π preserves bidegree, where $\mathrm{gr}^F L$ is bigraded by $(p, N) \mapsto F^pL_N/F^{p+1}L_N$.

The relations hold. In $R_L = F^0L/F^1L$ the class $[\omega]^{m+1}$ is the class of $L_{-2}^{m+1}\mathbf{1}$ (`mk₂_replicate`). By the jet relation with $k = 0$, $\alpha L_{-2}^{m+1}\mathbf{1}$ is congruent, modulo the maximal ideal, to a combination of sorted words of weight $2m+2$ and length $\le m$; such words have depth $(2m+2) - 2 \cdot \text{length} \ge 2$, so they lie in C_1, whose image is $F^1L = C_2(L)$ by Theorem 20.47 and Li's $F^1 = C_2$. Hence $[\omega]^{m+1} = 0$ in R_L (`mk₂_omegaBar_pow_eq_zero`), so $T^{m+1} \mapsto 0$ in $\mathrm{gr}_0^F L$, and π is defined.

Surjective. This is Theorem 11.23(4) for the single generator ω, whose hypothesis is Theorem 20.47; directly: by Theorem 20.47, F^pL_N is spanned by images of words of depth $\ge p$; so the layer $F^pL_N/F^{p+1}L_N$ is spanned by classes of words of depth exactly p. The class of $L_{-j_1-2}\cdots L_{-j_b-2}\mathbf{1}$ in that layer is the product $\prod_i \partial^{j_i}x/j_i! = \pi(T_{(j_1)}\cdots T_{(j_b)})$ (the generic statement "a word's Li class is the product of the divided derivatives of its letters" is in Chapter 11). Hence π is onto every layer.

Injective. Let h be a jet polynomial with $\pi(h) = 0$. Its bihomogeneous components are also killed (the target is a direct sum over bidegrees), so assume h has bidegree (p, N). If $N - p$ is odd, $h = 0$ (no monomials). Otherwise $N = p + 2b$ and every monomial of h has b letters; let $v \in V(c, 0)_N$ be the same combination of the corresponding words. Then $\pi(h) = 0$ says $[v] \in F^{p+1}L$, i.e. $v = y + z$ with z in the maximal ideal and $y \in C_{p+1}$ (Theorem 20.47). Project to weight N (the maximal ideal is graded): the weight-N part of y is a combination of words of weight N and depth $\ge p+1$, hence of length $\le b-1$ (weight = depth + 2·length). Apply the symbol map σ_b: it kills z and the shorter words, so $\sigma_b(v) = 0$. But $\sigma_b(v)$ is h read in $\mathcal{R}_{m+1}$, with $T_{(j)} \mapsto t_j$. So the image of h in $\mathcal{R}_{m+1} = J_\infty(\mathbb{C}[T]/(T^{m+1}))$ is zero; that is, h lies in the jet ideal (the comparison map $J_\infty\mathbb{C}[T] \to \mathcal{R}_{m+1}$, `psi`, has kernel inside the jet ideal of (T^{m+1}), `mem_jetIdeal_of_psi_eq_zero`). □

Physical meaning

In the (A_1, A_{2m}) Argyres–Douglas theories, whose chiral algebras are exactly $M(2, 2m + 3)$ (Beem–Lemos–Liendo–Peelaers–Rastelli–van Rees; Cordova–Shao), the Higgs branch is a point but the Higgs branch *scheme* $\operatorname{Spec} \mathbb{C}[T]/(T^{m+1})$ is a fat point. In the heuristic dictionary between the two sides, classical freeness says that the Schur index (the vacuum character) is the Hilbert series of the space of classical stress-tensor configurations $T(z)$ with $T(z)^{m+1} = 0$. On characters, this is the sum side of the Andrews–Gordon identity: the classical counting of such configurations is the Feigin–Stoyanovsky fermionic formula.

What the machine verified

Proved, unconditional (isolated-module check; aggregate build not re-run) (no hypothesis; every $m \in \mathbb{N}$). `#print axioms` of `classicallyFree`, `classicallyFree_M23`, `classicallyFree_leeYang`, `canonicalEquiv`, `jetMap_injective`: `[propext, Classical.choice, Quot.sound]` (run 2026-10-27, Section 20.14).

Theorem 20.52 (The full non-reduced C_2-algebra of $M(2, 2m + 3)$; arcs). *For every $m \in \mathbb{N}$: (1) $T \mapsto [\bar\omega]$ induces an isomorphism $\mathbb{C}[T]/(T^{m+1}) \cong R_{L(c_m,0)}$; in particular $[\omega]^{m+1} = 0$ in $R_{L(c_m,0)}$; (2) for every commutative $\mathbb{C}$-algebra A there is a bijection between algebra maps $J_\infty(\mathbb{C}[T]/(T^{m+1})) \to A$ and algebra maps $R_{L(c_m,0)} \to A[[t]]$, namely the one obtained from (1) and the arc universal property (Theorem 20.11). In words, (2) says that the presented arc algebra $J_\infty(\mathbb{C}[T]/(T^{m+1}))$ is the arc algebra of the actual C_2-algebra $R_{L(c_m,0)}$, so Theorem 20.51 identifies $\operatorname{gr}^F L(c_m, 0)$ with the arc algebra of $R_{L(c_m,0)}$ itself.*

From the mathematics to the Lean statement

`A₂ W` is $R_W = W/C_2(W)$ and `mk₂ W` the class map (Chapter 12). `baseC2AlgEquiv m` is, by its definition, `baseC2AlgEquiv_of_arc_injective` applied to the generator $[\bar\omega]$: this is the same generic construction used for the affine `baseC2AlgEquiv` (Theorem 20.45), i.e. `AlgEquiv.ofBijective` of the canonical map $\mathbb{C}[T]/(T^{m+1}) \to R_L$, $T \mapsto [\bar\omega]$. Its inputs are visible in the printed body: the relation holds in R_L (`relIdeal_le_c2`, from `mk₂_omegaBar_pow_eq_zero`), the arc map is injective (`(classicallyFree m).1`), and R_L is generated by $[\bar\omega]$ (`aeval_c2_surjective`). `actualC2ArcEquiv` is `arcEquivOfBaseAlgebraEquiv`

(Theorem 20.11) composed with it.
What the types say. Exactly as for the affine headlines (warning after Theorem 20.21): the type of `baseC2AlgEquiv` says only "abstractly isomorphic"; that the isomorphism sends T to $[\omega]$ is in its definition. The type of `actualC2ArcEquiv` is a bijection of sets for each A; its naturality in A is the separate theorem `VirasoroClassicalFreeness.actualC2ArcEquiv_natural`, printed above, so the presented jet algebra represents the arc functor of R_L. The definitions are the canonical ones.

Proof on paper. R_L is generated by $[\omega]$: words of positive depth lie in $F^1 = C_2$, and a word of depth 0 is $L^b_{-2}\mathbf{1}$, whose class is $[\omega]^b$. The relation holds (proof of Theorem 20.51). Injectivity of $\mathbb{C}[T]/(T^{m+1}) \to R_L$: it is the restriction of the injective π to constant arcs (Li degree 0), and constant arcs embed in J_∞. Then (2) is Theorem 20.11. □

Physical meaning

$R_{M(2,2m+3)} = \mathbb{C}[T]/(T^{m+1})$ is the chiral ring of the (A_1, A_{2m}) theory restricted to the Higgs-branch sector: the powers $T, T^2, \dots, T^m$ of the stress tensor survive as nilpotent elements, although the associated variety is a single point (the VOA is lisse). The physics term is "non-reduced Higgs branch".

What the machine verified

Proved, unconditional (isolated-module check; aggregate build not re-run); `mk₂_omegaBar_pow_eq_zero` carries the hypothesis `hJ`, discharged by `hasJetRelations m` in the headlines. `#print axioms` of all three: `[propext, Classical.choice, Quot.sound]`.

20.12.6 The Poisson vertex structure: the bracket is forced to vanish

Theorem 20.53 (Classical freeness as Poisson vertex algebras). *Let $J_\infty(\mathbb{C}[T]/(T^{m+1}))$ carry the jet derivation and the* zero *λ-bracket. For every $m \in \mathbb{N}$ the canonical map π is an isomorphism of Poisson vertex algebras onto $\mathrm{gr}^F L(c_m, 0)$ with its Li Poisson vertex structure (Definition 20.13). Consequently all (n)-products $(n \geq 0)$ of $\mathrm{gr}^F L(c_m, 0)$ vanish.*

```

From the mathematics to the Lean statement

`zeroPVA A T` is the Poisson vertex algebra (Definition 20.12) with translation `T` and every mode equal to `0`; the remaining fields (locality, sesquilinearity, Leibniz, skew-symmetry, Jacobi; not shown) are then trivial and are discharged by `rfl` or `simp`. `VirasoroClassicalFreeness.arcPVA m` (not to be confused with the affine `arcPVA m` of Definition 20.14) is `zeroPVA` on the presented arc algebra with the jet derivation $\partial T_{(j)} = (j+1)T_{(j+1)}$. `mode_x_x`: every mode of the Li class of ω with itself is zero, for every c. `arcPoissonEquiv m` is, by its definition, the canonical map π (`arcLiPoissonHom`, a PVA homomorphism) made into an equivalence by `classicallyFree`. `liPoissonVertexAlgebra_mode_eq_zero`: all modes of $\mathrm{gr}^F L(c_m, 0)$ vanish, for all a, b.

Is the zero bracket the right one? The textbook arc PVA of a Poisson algebra R has $\{x_\lambda y\} = \{x, y\}$ for $x, y \in R$. Here $R = R_L = \mathbb{C}[T]/(T^{m+1})$ with Zhu's bracket $\{[a],[b]\} = [a_{(0)}b]$, and $\{[\omega],[\omega]\} = [L_{-3}\mathbf{1}] = 0$ because $L_{-3}\mathbf{1} = \omega_{(0)}\omega \in C_2$. So the Poisson bracket of R_L is zero and the textbook arc PVA *is* `zeroPVA`. The theorem is therefore not a choice of convention: `arcPoissonEquiv` is an isomorphism with an independently defined target (`liPoissonVertexAlgebra`), and its existence forces the Li structure to be zero, which `liPoissonVertexAlgebra_mode_eq_zero` states outright. There is no analogue of the affine `arcPVA_unique` because the source structure is written down explicitly.

Proof on paper. On generators: $x_{(0)}x$ is the degree-$(0+0-0)$ class of $\omega_{(0)}\omega = L_{-1}\omega = L_{-3}\mathbf{1}$, which lies in F^1, so it is 0 in F^0/F^1; for $n \geq 1$, $x_{(n)}x$ would have Li degree $0+0-n < 0$, so it is 0 by definition (Definition 20.13). A homomorphism of differential algebras from an arc algebra into a PVA is a PVA homomorphism as soon as it matches the brackets of the generators (the "generator test" `poissonVertexHomOfBaseGenerators`, the same tool as in the affine case); both sides give zero. Bijectivity is Theorem 20.51; transporting the zero modes of the source along the isomorphism gives the vanishing of all modes of the target. There is also a one-line parity argument: in $\mathrm{gr}^F L \cong J_\infty(\mathbb{C}[T]/(T^{m+1}))$ the bidegrees (p, N) that occur all have $N-p$ even, while the n-th mode maps bidegrees $(p,N), (q,M)$ to $(p+q-n, N+M-n-1)$, whose difference $(N-p)+(M-q)-1$ is odd. □

Physical meaning

Recall the grading rule: the n-th Li product maps bidegrees (p,N) and (q,M) (Li depth, weight) to $(p+q-n,\ N+M-n-1)$. The TT OPE, $T(z)T(w) \sim \frac{c/2}{(z-w)^4} + \frac{2T(w)}{(z-w)^2} + \frac{\partial T(w)}{z-w}$, has no classical shadow in Li's grading: the central term and the $2T$ term lower the derivative count below zero, and the ∂T term has one derivative more than the leading order. So the classical limit of a minimal model in this sense is a purely commutative, purely kinematic object: the fat point and its arcs. This differs from the affine case, where the current algebra bracket $\{e_\lambda f\} = h$ survives.

What the machine verified

Proved, unconditional (isolated-module check; aggregate build not re-run); `#print axioms` of `zeroPVA`, `mode_x_x`, `arcPoissonEquiv`, `liPoissonVertexAlgebra_mode_eq_zero`: `[propext, Classical.choice, Quot.sound]`.

20.12.7 A worked example: Lee–Yang at low weight

Example 20.54 ($m = 1$: $J_\infty(\mathbb{C}[T]/(T^2))$ against $L(-\frac{22}{5}, 0)$)**.** Write T_j for $T_{(j)}$ (Li depth j, weight $j+2$) and $Q_k = \sum_{a+b=k} T_a T_b$ for the jet relations of T^2: $Q_0 = T_0^2$, $Q_1 = 2T_0T_1$, $Q_2 = 2T_0T_2 + T_1^2$, $Q_3 = 2T_0T_3 + 2T_1T_2$, $Q_4 = 2T_0T_4 + 2T_1T_3 + T_2^2$. The relation ideal in weight N is spanned by the

products μQ_k with μ a monomial of weight $N-k-4$. A monomial with b letters and weight N has depth $p = N - 2b$. Counting, at each weight N, monomials minus independent relations, sorted by b:

N	$b=1$ (depth $N-2$)	$b=2$ (depth $N-4$)	total
0	1 (the empty monomial)		1
1	–	–	0
2	T_0	–	1
3	T_1	–	1
4	T_2	$T_0^2 = Q_0 = 0$	1
5	T_3	$T_0T_1 = \frac{1}{2}Q_1 = 0$	1
6	T_4	$T_1^2 \equiv -2T_0T_2$ (one class)	2
7	T_5	$T_1T_2 \equiv -T_0T_3$ (one class)	2
8	T_6	T_0T_4, T_1T_3, T_2^2 modulo Q_4 (two classes)	3

Monomials with $b \geq 3$ vanish for $N \leq 8$: at $N=6$, $T_0^3 = T_0Q_0$; at $N=7$, $T_0^2T_1 = T_1Q_0$; at $N=8$, $T_0^2T_2 = T_2Q_0$, $T_0T_1^2 = \frac{1}{2}T_1Q_1$ and $T_0^4 = T_0^2Q_0$. The totals $1,0,1,1,1,1,2,2,3$ for $N=0,\dots,8$ are the coefficients of the Rogers–Ramanujan product $\prod_{n\geq 0}\big((1-q^{5n+2})(1-q^{5n+3})\big)^{-1}$, which is the vacuum character of the Lee–Yang model; so they are the dimensions of $L(-\frac{22}{5},0)_N$, as Theorem 20.51 predicts.

On the VOA side the relation $T_0^2 = 0$ is the vacuum null vector at weight 4: for $c = -\frac{22}{5}$,

$$\chi = \big(L_{-2}^2 - \tfrac{3}{5}L_{-4}\big)\mathbf{1}$$

is annihilated by L_1 and L_2 (indeed $L_1\chi = (3-3)L_{-3}\mathbf{1}$ and $L_2\chi = (8+c-\frac{18}{5})L_{-2}\mathbf{1}$, and $8+c = \frac{18}{5}$ exactly when $c = -\frac{22}{5}$). In $L(c,0)$ this gives $L_{-2}^2\mathbf{1} = \frac{3}{5}L_{-4}\mathbf{1} \in F^2$, so $[\omega]^2 = 0$ in $R_L = F^0/F^1$: the depth-0 class of $L_{-2}^2\mathbf{1}$ dies, which is $T_0^2 = 0$. Its leading term is $\alpha L_{-2}^2\mathbf{1}$ with $\alpha = 1$, the $m=1$ case of Definition 20.49. The class $T_2 \mapsto [L_{-4}\mathbf{1}]$ in depth 2 survives, which is the weight-4 state of the table. At weight 6 the two surviving classes are $[L_{-6}\mathbf{1}]$ (depth 4) and $[L_{-3}^2\mathbf{1}]$ (depth 2); the universal module has the four states $L_{-6}, L_{-4}L_{-2}, L_{-3}^2, L_{-2}^3$ and the null vectors $L_{-2}\chi$ and $L_{-1}^2\chi$ remove two.

20.12.8 Comparison with the affine headlines, and a recorded dead end

Points a referee should know about the Virasoro companion

1. **Same type-level caveats as the affine case.** `baseC2AlgEquiv` and `actualC2ArcEquiv` are canonical by definition, not by type; naturality of `actualC2ArcEquiv` in A is proved separately (`VirasoroClassicalFreeness.actualC2ArcEquiv_natural`). The source of every statement is the presented arc algebra `PresentedJet (relIdeal m)`.

2. **The central charge is reached through the two-series level data.** `cm m` is `(twoSeriesLevels m).c`, and only the closed form `cm_eq` connects it to $c_{2,2m+3}$; there is no theorem `cm m = minimalCentralCharge 2 (2 * m + 3)` (Definition 7.14). Harmless (the closed forms agree), but a reader who searches for the minimal-model constant will not find it used.

3. **No conformal-weight statement and no explicit character corollary.** The affine file states `arcPoissonEquiv_conformal_iff`; the Virasoro file does not state the analogous fact, nor the resulting identity "character of $L(c_m,0)$ = Hilbert series of $J_\infty(\mathbb{C}[T]/(T^{m+1}))$". Both follow from the bidegree-preserving construction, but they are

not Lean theorems in these files.

4. **Dead end.** An earlier generic surjectivity criterion assumed $V = \mathrm{span}(\text{generators} \cup \{\mathbf{1}\}) + C_2(V)$ (the hypothesis `hdec`); it fails for $M(2, 2m+3)$ with $m \geq 2$, because $[\omega]^2 \neq 0$ in $R_V = \mathbb{C}[T]/(T^{m+1})$. The full account is the warning at the end of Section 11.5 (Chapter 11). The route that works is word spanning of Li's filtration (Theorem 20.47).

20.13 The boundary-affine $p = 3$ particle and conductor model

20.13.1 What these files are, and what they are not

Thirty-two files of finite commutative algebra and combinatorics in `VOA/Commutative/` remain from a route to the upper bound at the first boundary level $p = 3$ ($m = 1$, $k = -4/3$) that was not completed: a "rooted Gordon conductor" argument in the functional (particle-polynomial) model of Feigin–Stoyanovsky type, pursued before the argument of Sections 20.5–20.6 was formalised. They are in the library, and in this chapter, for one reason: five files of the Deligne carrier (Chapter 24) import five of them: `DeligneAuxiliaryCollision` imports `RootedGordonConductorDivisibility`; `DeligneAuxiliaryDegree` imports `P3ConductorDegree`; `QuadraticTwoPointCarrier` imports `CollisionCommonFactors`; `QuadraticJetCoefficientPairing` imports `ModeParticlePairing`; and `QuadraticCurrentCoefficientReindexing` imports `ModeParticlePolynomial`. The other twenty-seven are reached only inside the cluster, or not at all.

The $p = 3$ route is incomplete and superseded; nothing in this chapter's headlines uses it

None of the headline theorems of this chapter (Section 20.3) depends on these files; the boundary theorem is proved by the Gordon/partition-filtration argument of Section 20.6. The $p = 3$ route itself was never completed in Lean. Its terminal statement, `P3ConeCarrierInterface.P3LinearResidualization.finrank_le_expectedDim`, is a fixed-sector dimension bound that takes three uninstantiated arguments: a datum `D : P3LinearResidualization W E` (two conductor factorisations, a compatibility field and an injectivity field; its only constructor `ofDivisibility` is never applied, and the coefficient space `E` is an arbitrary type connected to no vertex algebra), `P3QuadraticConeCarrierIdentification` (the compatible residual window is isomorphic to the quadratic-cone carrier of Dumanski–Feigin) and `DumanskiFeiginP3GradedDimensionHypothesis` (that carrier has the expected finite dimension, an external theorem). None is instantiated anywhere in the library, and `E`, `D` are never constructed from the restricted dual of a VOA. (The file's docstring speaks of "two remaining inputs"; the statement has three.) Several file docstrings say explicitly that they do not construct a cone carrier, a common-factor theorem, a Hilbert series, or classical freeness (`P3FunctionalModel.lean`). Read the files as a library of finite lemmas, not as a proof.

The model, on paper (a summary). This paragraph summarises the construction that the files were written for; none of its details is needed for the three theorems presented below, which are self-contained statements about polynomials. The reader may take it as motivation only. The underlying idea is the Feigin–Stoyanovsky *functional realisation*: a state built from N field modes is paired with a polynomial in N variables (the "positions" of the N particles), so that the restricted dual of a graded piece of a commutative differential algebra becomes a space of polynomials, and each relation of the algebra becomes a vanishing condition when some variables collide. A *species* is the field a particle comes from; variables of the same species are interchangeable, so the polynomials are symmetric within each species; and the "derivative degree" is the total degree. At $p = 3$ normalise the cone equation as $Q = XZ - Y^2$ (with X, Y, Z the three currents) and introduce an auxiliary field $S(z) = \sum_{r \geq 1} S_r z^r$ standing for z times the Casimir field. The auxiliary

differential algebra is $\mathrm{DAlg}(X,Y,Z,S)/(Q,\ XS,\ YS,\ ZS,\ S^2)$. Its restricted dual in a sector with a,b,c,d particles of species X,Y,Z,S and fixed derivative degree is realised by polynomials in labelled variables $x_1..x_a,\ y_1..y_b,\ z_1..z_c,\ s_1..s_d$, symmetric within each species. The relations become conditions on these polynomials: divisibility by every s_α (since S_0 is absent), vanishing when two S particles coincide, vanishing when an S particle meets a current particle, and the coupled condition "F_{XZ} on $x=z=t$ equals F_{YY} on $y_1=y_2=t$". (Here $\mathrm{DAlg}(X,Y,Z,S)$ is the free commutative differential algebra on four fields, and ξ_i runs over all current variables x,y,z.) For instance, with $d=1$ and one current particle ($a+b+c=1$, say one x), a polynomial $F(x,s)$ must be divisible by s and vanish at $s=x$; so $s(s-x)$ divides F, of degree $2=dN$. In general the first three conditions force the common factor

$$C_{N,d}=\prod_{\alpha} s_\alpha\cdot\prod_{\alpha<\beta}(s_\alpha-s_\beta)^2\cdot\prod_{\alpha,i}(s_\alpha-\xi_i),\qquad \deg C_{N,d}=d+d(d-1)+(a+b+c)d=dN,\ (20.10)$$

where $N=a+b+c+d$. The plan was to divide by $C_{N,d}$ and identify the residual with a known carrier. The Lean files prove the finite algebra of this plan. We present individually the three results that Chapter 24 reuses, and the rest collectively.

20.13.2 Collision factors

Definition 20.55 (Collision factor, collision map, transposition; increasing pairs)**.** For a field K and variables $(x_i)_{i\in I}$: the *collision factor* of i,j is x_i-x_j; the *collision map* $K[x_I]\to K[x_{I\setminus\{i\}}]$ substitutes $x_i:=x_j$ ($j\neq i$); the *transposition* swaps x_i and x_j. For a linearly ordered I, an *increasing pair* is (i,j) with $i<j$, and the Vandermonde is $\prod_{i<j}(x_i-x_j)$.

File `VOA/Commutative/CollisionCommonFactors.lean`.

```
def collisionFactor (i j : I) : MvPolynomial I K :=
  X i - X j

def collisionMap (i j : I) (hji : j ≠ i) :
    MvPolynomial I K →ₐ[K] MvPolynomial {a : I // a ≠ i} K :=
  MvPolynomial.rename (collisionIndex i j hji)

def swapVariables (i j : I) : MvPolynomial I K →ₐ[K] MvPolynomial I K :=
  MvPolynomial.rename (Equiv.swap i j)

abbrev IncreasingPair (I : Type v) [LinearOrder I] :=
  {ij : I × I // ij.1 < ij.2}

def vandermonde : MvPolynomial I K :=
  ∏ ij : IncreasingPair I,
    collisionFactor (K := K) ij.1.1 ij.1.2
```

From the mathematics to the Lean statement

`MvPolynomial I K` is $K[x_i : i\in I]$ and `X i` the variable x_i. `rename f` substitutes $x_a\mapsto x_{f(a)}$. `collisionIndex i j hji` sends i to j and every other a to itself, landing in the subtype `{a : I // a ≠ i}` of indices other than i; so `collisionMap` is $x_i:=x_j$ with x_i removed from the variable set. `Equiv.swap i j` is the transposition. `IncreasingPair I` is the subtype of pairs with first entry smaller.

Physical meaning

In a functional realisation, the labelled variables are positions of quasi-particles, and a collision $x_i=x_j$ is two particles at the same point. "Vanishing at a collision" is the functional form of

an OPE relation ("this normal-ordered product is null").

What the machine verified

Definitions.

Theorem 20.56 (Collision divisibility; square factors from symmetry)**.** *Let K be a field and $p \in K[x_I]$, $i \neq j$.*

1. *$x_i - x_j$ divides p iff p vanishes after the substitution $x_i := x_j$.*
2. *$x_i - x_j$ is prime, and for two different unordered pairs the collision factors do not divide each other.*
3. *If $\operatorname{char} K = 0$, p is symmetric under $x_i \leftrightarrow x_j$, and p vanishes on $x_i = x_j$, then $(x_i - x_j)^2$ divides p.*
4. *If $\operatorname{char} K = 0$ and p is symmetric under every transposition and vanishes on every diagonal, the square of the Vandermonde divides p.*

```

From the mathematics to the Lean statement

Namespace `VOA.CollisionCommonFactors`; `K` a field and `I` a type with decidable equality (section variables); the Vandermonde statement also needs `[Fintype I] [LinearOrder I]`. `a ∣ b` is divisibility, `Prime` the Mathlib notion of a prime element. The hypotheses `hdirect`, `hreverse` say $\{c, d\} \neq \{a, b\}$ as unordered pairs. `[CharZero K]` is needed in items 3–4 and is used exactly once, to cancel a factor 2. These are exactly the textbook statements.

Proof on paper. (1) Isolate x_i: $K[x_I] = A[x_i]$ with $A = K[x_{I\setminus i}]$; the substitution is evaluation at $x_j \in A$, and $X - a$ divides $f \in A[X]$ iff $f(a) = 0$. (2) $x_i - x_j$ corresponds to $X - x_j$, prime in $A[X]$. Two

collision factors for different unordered pairs are not associates: under the substitution $x_a := x_b$, which kills $x_a - x_b$, the factor $x_c - x_d$ becomes a *nonzero* polynomial (because $\{c,d\} \neq \{a,b\}$, it is $x_c - x_d$ with at most one index renamed, and the two indices remain different); an associate of $x_a - x_b$ would be killed too. (3) Write $p = (x_i - x_j)q$. Swapping gives $p = -(x_i - x_j)\,\mathrm{swap}(q)$, so q is antisymmetric; on the diagonal $q = -q$, so $2q|_{x_i = x_j} = 0$ and q vanishes there; apply (1) to q. (4) Each squared factor divides p by (3); they are pairwise non-associated primes in a UFD, so their product divides p. The library notes that the right tool is non-association of primes, not comaximality of the principal ideals, which would be false. □

Physical meaning

Item 3 is the familiar fact that for identical bosons a relation forcing a wave function to vanish at coincident points forces a *double* zero: symmetric functions vanish to even order on diagonals. Item 4 is, heuristically, the origin of the $\Delta(s)^2$ in quasi-particle character formulas, the $q^{d(d-1)}$-type shifts.

What the machine verified

Proved, unconditional (isolated-module check; aggregate build not re-run) (the hypotheses are the statement's own); `#print axioms` of all five: `[propext, Classical.choice, Quot.sound]`. `CollisionCommonFactors` is one of the five modules reused by Chapter 24 (opening of this section).

20.13.3 The rooted Gordon conductor and prime-power assembly

Colours, slots, roots (motivation; the Lean statements below are purely about polynomials). In the functional model of Gordon-type relations (Feigin–Stoyanovsky), the basic objects are *quasi-particles of colour c*: a quasi-particle of colour c stands for c coincident modes of the same current (a cluster of size c). A *colour profile* is a function $\rho : \{0, \dots, n-1\} \to \mathbb{N}$, read as "$\rho(j)$ quasi-particles of colour j"; the set of *slots* is the set of pairs (j,k) with $k < \rho(j)$, one variable x_i per slot i, and c_i denotes the colour of slot i. The relations of the algebra translate into two kinds of vanishing for the dual polynomials: at the *root* $x_i = 0$ to order c_i (the "rooted" condition, coming from the absence of the lowest modes) and on each collision $x_i = x_j$ to order $2\min(c_i, c_j)$ (Gordon's difference condition between clusters). The *rooted Gordon conductor* is the product of all these forced factors. The $p = 3$ conductor $C_{N,d}$ of (20.10) has the same shape for the S particles among themselves (each behaves as a slot of colour one: root order 1, pair order $2\min(1,1) = 2$), but its current–S factors have order 1, so it is an analogue, not a special case.

Theorem 20.57 (Product of separated prime powers; the rooted Gordon conductor divides)**.** *(1) In a cancellative commutative monoid with zero, if f_a ($a \in s$, s finite) are primes no two of which divide each other, and $f_a^{e_a} \mid p$ for each a, then $\prod_a f_a^{e_a} \mid p$. (2) For a colour profile ρ with slots i of colour c_i, the rooted Gordon conductor $\delta_\rho = \prod_i x_i^{c_i} \prod_{i<j} (x_i - x_j)^{2\min(c_i,c_j)}$ divides every polynomial that is divisible by each displayed prime power.*

        (2 * min (slotColor ij.1.1) (slotColor ij.1.2)) ∣ p) :
    rootedGordonConductor (K := K) rho ∣ p := by
```

From the mathematics to the Lean statement

`ColoredSlots rho` is the set of pairs (j,k) with $j < n$ and $k < \rho(j)$: $\rho(j)$ slots of colour j, and `slotColor` reads off j. `rootedGordonRootFactor` is $\prod_i x_i^{c_i}$ and `rootedGordonPairFactor` is $\prod_{i<j}(x_i - x_j)^{2\min(c_i,c_j)}$ (definitions in the same file). The order on slots used to orient pairs is an arbitrary enumeration (a local instance); this is harmless, since each pair factor carries the even exponent $2\min(c_i,c_j)$, so reversing a pair does not change the product. `IsCancelMulZero M` is cancellation of nonzero factors; polynomial rings over a field qualify. The separation hypothesis of the general lemma is discharged inside the conductor theorem (`rootedGordonPrimeFactor_separate`). `rootedGordonConductor_ne_zero` (same file) proves $\delta_\rho \neq 0$.

Proof on paper. (1) Induction on s: if $f_a^{e_a} q = p$ and $f_b^{e_b} \mid p$ for $b \neq a$, then $f_b^{e_b} \mid q$: the prime f_b does not divide f_a, hence (a prime dividing a power divides the base) does not divide $f_a^{e_a}$, so all the factors f_b of $p = f_a^{e_a} q$ must come from q. (2) The displayed factors are primes (x_i, and $x_i - x_j$ by Theorem 20.56), pairwise non-associated; apply (1). □

Physical meaning

Gordon's "difference-two at distance k" conditions become, in the functional model, prescribed orders of vanishing where quasi-particles of given colours collide: two quasi-particles of colours c_i, c_j repel with a zero of order $2\min(c_i,c_j)$ (heuristic picture). The conductor collects all these zeros; dividing it out is the functional form of the shift in a fermionic character (heuristic).

What the machine verified

Proved, unconditional (isolated-module check; aggregate build not re-run); axioms `[propext, Classical.choice, Quot.sound]` (also `rootedGordonConductor_ne_zero`). The general lemma (1) is reused by Chapter 24 (`DeligneAuxiliaryCollision`).

20.13.4 The degree of the $p = 3$ conductor

Theorem 20.58 (The weighted-degree count of the $p = 3$ conductor)**.** *The number of increasing pairs in* $\{0, \dots, d-1\}$ *is* $\binom{d}{2}$*, and the counting function* `p3ConductorWeightedDegree` *(root weight plus collision multiplicities) of the labelled conductor* (20.10) *in multidegree* (a, b, c, d) *equals* $d(a+b+c+d)$*.*

    ∑ i : ConductorCollisionIndex a b c d, conductorCollisionMultiplicity i
```

File `VOA/Commutative/P3ConductorDegree.lean`.

```
theorem card_increasingPair_fin (d : ℕ) :
    Fintype.card (IncreasingPair (Fin d)) = d.choose 2 := by

theorem p3ConductorWeightedDegree_eq (a b c d : ℕ) :
    p3ConductorWeightedDegree a b c d = d * (a + b + c + d) := by
```

From the mathematics to the Lean statement

`BoundaryCurrentLabel a b c` is the disjoint union $\mathrm{Fin}\,a \sqcup \mathrm{Fin}\,b \sqcup \mathrm{Fin}\,c$ of current labels; `ConductorCollisionIndex` indexes the collision factors of (20.10): S–S pairs (multiplicity 2) and current–S pairs (multiplicity 1). `SpeciesLabel (boundaryMultiplicity a b c d)` is the set of all $a + b + c + d$ labelled particles; `speciesShiftExponent … boundarySpeciesShift` is the exponent vector with 1 on each S label and 0 on currents (the monomial $\prod_\alpha s_\alpha$), and `Finsupp.weight particleWeightOne` its total degree, which is d (`weight_boundarySpeciesShift`). So `p3ConductorWeightedDegree` is $d + 2\binom{d}{2} + (a + b + c)d$ written as a sum over the factors, and the theorem evaluates it. The definition counts factors and does not mention the polynomial. That the conductor polynomial `p3CommonFactor` is weighted-homogeneous of this degree is the separate theorem `p3CommonFactor_isWeightedHomogeneous` (`P3ResidualWindowPreservation.lean`, not quoted here); "has degree exactly dN" would also need the conductor to be nonzero, which that theorem does not state. So the theorem printed here is the arithmetic of the count, and the title promises no more.

Proof on paper. Increasing pairs in a d-element ordered set are 2-subsets, so there are $\binom{d}{2}$ (the library goes through off-diagonal points of the symmetric square). Then $d + 2\binom{d}{2} + (a + b + c)d = d + d(d-1) + (a + b + c)d = d(a + b + c + d)$. □

Physical meaning

dN is the total "energy shift" that the d auxiliary particles cost in a sector with N particles: each S particle repels every other particle once (and other S particles twice) and cannot sit at

the origin. In a fermionic formula this is the exponent of q multiplying the free part of the sector.

What the machine verified

Proved, unconditional (isolated-module check; aggregate build not re-run); axioms `[propext, Classical.choice, Quot.sound]`. `card_increasingPair_fin` is reused by Chapter 24 (`DeligneAuxiliaryDegree`).

20.13.5 The remaining files, collectively

All of the following are finite statements about labelled polynomials, finite sets and group actions, with no hypothesis beyond those displayed in each statement; none mentions a vertex algebra. Every file's docstring states what it does *not* prove.

Files	What is proved, in words	Used by L24
`ModeParticlePairing`, `ModeParticlePolynomial`, `MultispeciesParticlePolynomial`	The dictionary of the functional model: monomials in field modes are paired with symmetric polynomials in particle positions, the pairing is perfect (a duality), and it is compatible with taking several species at once.	first two
`AuxiliaryIdealOrthogonal`	The relations $S^n = 0, A \cdot S^n = 0$ and $XZ = Y^2$ translate, under that duality, into the vanishing (resp. agreement) conditions on diagonals listed in "The model, on paper".	–
`BoundaryTypedSubstitution`, `BoundaryCoefficientFiber`, `BoundaryCollisionDivisibility`	How the coupled cone condition "F_{XZ} on $x = z$ equals F_{YY} on $y_1 = y_2$" is expressed by substitutions of variables; it yields an *equality* of two restrictions, not a vanishing, so no factor of the conductor is deduced from it.	–
`P3RestrictedDualCommonFactor`, `P3AuxiliaryCollisionBridge`, `P3CommonFactorInvariant`, `P3CommonFactorSourceInvariant`, `P3BoundaryRootEquiv`, `P3InvariantPolynomialRealization`	The conductor $C_{N,d}$ divides every polynomial satisfying the collision vanishings; it and the quotients by it are symmetric under relabelling particles of one species; bookkeeping of labels.	–
`P3ResidualWindowPreservation`, `P3ResidualConeBridge`, `P3ConeCarrierInterface`, `P3FunctionalModel`	Dividing by the conductor lowers the degree by its degree and keeps the symmetry and the cone condition; the conditional dimension bound `finrank_le_expectedDim` (three uninstantiated arguments; see the warning above).	–
`RootedMatching`, `RootedProfile`, `RootedTypedProfile`, `RootedIncidence`, `RootedIncidenceAction`, `RootedIncidenceOrbit`, `RootedLeafRelabeling`, `RootedSourceRelabeling`, `RootedGordonConductor`	Finite combinatorics of how particles can coincide (which particles sit at the same point, and with which colours), and the statement that two such coincidence patterns with the same colour counts differ only by a relabelling of particles.	–
`RootedGordonConductorDivisibility`	Theorem 20.57.	yes
`CollisionCommonFactors`	Theorem 20.56.	yes
`P3ConductorDegree`	Theorem 20.58.	yes

Files	What is proved, in words	Used by L24
`OrbitSectionAssembly`, `OrbitEvaluationDescent`, `LiteralSubstitutionNewton`	Generic tools: a symmetric family of linear maps has a symmetric common kernel; a function constant on fibres factors through the quotient; a count of exponent vectors with restricted support.	–

Physical meaning

Collectively: the functional (quasi-particle) model of the $p = 3$ auxiliary algebra, in which states are dual to symmetric polynomials in particle positions and OPE relations become vanishing conditions at collisions. The intended physics output, never reached in Lean by this route, was the fermionic character of $L_{-4/3}(\mathfrak{sl}_2)$, which Section 20.7 obtains by the Gordon route.

What the machine verified

No file declares an axiom or contains `sorry` or `native_decide` (text search of the 32 files). The `#print axioms` spot checks above are isolated-module runs on `P3ConductorDegree` and `RootedGordonConductorDivisibility`, all `[propext, Classical.choice, Quot.sound]`; aggregate build not re-run (Section 20.14). The route's terminal bound is conditional on three uninstantiated arguments (the datum `D` and two named hypotheses; see the warning at the head of this section) and is not used by any headline.

20.14 Verification record

What the machine confirmed (2026-10-13; not re-run for this edition). On the working tree of that date, before the campaign files were committed:

```
lake build                                  # aggregate: green, 13150 jobs
lake build VOA.ArakawaDai                   # umbrella: green (ledger: 4,513 jobs)
scripts/audit/ArakawaDaiAxiomAudit.lean     # 160 declarations: PASS, zero discrepancies
  headline axioms: [propext, Classical.choice, Quot.sound]   (no VOA.pbw)
```

The audit file lists, among others, all ten headline declarations, the `...OfCharacter` helpers, and the supporting q-series, Gordon, determinant and PVA lemmas. The campaign ledger also records a repository check: all Lean files reachable, no new axiom, no `sorry`/`admit`/`native_decide`.

What this chapter's author checked by hand. (1) Every `leancode` block above was compared with the working-tree source (a script replicating `sync.py`'s verbatim-chunk test against the working tree, including untracked files). (2) The paper's displayed Theorem 1.2 (arXiv:2609.33348v1) is the unshifted, unflavoured character; Lean's `character` is the same. (3) The PVA axioms in `PoissonVertexAlgebra` were compared with the λ-bracket axioms (Definition 20.12). (4) Coefficients of both sides of Theorem 1.2 for $m = 1, 2$, $N \leq 14$ (Example 20.19).

Sections 20.12 and 20.13 (2026-10-27; not re-run for this edition). The aggregate `lake build` was *not* re-run for these sections. The author ran, from the repository root, on the existing compiled modules, one scratch file per module with `lake env lean -DmaxSynthPendingDepth=3`:

```
import VOA.Examples.VirasoroMinimalPoisson      # 18 declarations
import VOA.Commutative.P3ConductorDegree        # 7 declarations
import VOA.Commutative.RootedGordonConductorDivisibility   # 3 declarations
  every one: [propext, Classical.choice, Quot.sound]
```

The 18 Virasoro declarations are `liFiltration_eq_virWordPiece`, `simpleLiFiltration_eq_virWordPiece`, `classicallyFree`, `classicallyFree_M23`, `classicallyFree_leeYang`, `canonicalEquiv`, `baseC2AlgEquiv`, `actualC2ArcEquiv`, `cm_eq`, `cm_one`, `jetMap_injective`, `mk₂_omegaBar_pow_eq_zero`, `arcPoissonEquiv`, `liPoissonVertexAlgebra_mode_eq_zero`, `mode_x_x`, `virSymbol_twoSeries`, `twoSeries_hasJetRelations_all`, `zeroPVA`. The project's internal build record of 2026-10-25 reports green targeted builds of the Virasoro files (9707 jobs) and of `VOA.ArakawaDai VOA.Examples` (10562 jobs), and a 38-declaration axiom probe with the same three axioms (not re-run for this chapter). Every new `leancode` block was checked verbatim by `sync.py check`. The same record (2026-10-25, the classical-freeness audit) is where the description of `virSymbol_twoSeries` as "classical freeness" was corrected.

Referee revision (an earlier commit; not re-run for this edition). The fidelity referee could not load the Virasoro modules (a missing `.olean`); at a later commit the compiled modules were present, and the reviser re-ran, with the same command on one scratch file importing `VOA/Examples/VirasoroMinimalPoisson.lean`:

```

(line breaks of the output joined). The aggregate `lake build` was again not run.

Theorem 1.1 in the paper's form (2026-10-28; not re-run for this edition). The new file `VOA/Examples/AffineSl2BoundaryTheorem11.lean` (Section 20.3.3) is committed, but its compiled module was *missing* from the main checkout's `.lake` (no `lake build` was run for this revision). The reviser therefore ran `lake env lean -DmaxSynthPendingDepth=3` on a scratch file importing `VOA.Examples.AffineSl2BoundaryTheorem11` from the root of the `release-cheap` worktree, whose compiled modules include it (built 2026-10-27) and whose copy of the file is byte-identical to the main checkout's (`cmp`). Output (line breaks joined; peak RSS 3.7 GB):

```

The build record for this file is the project's (`Notes/RELEASE_PLAN.md`, "Caveats removed in Lean", 2026-10-28: merged from `release-cheap`, umbrellas green, axioms standard). The aggregate `lake build` of the release commit is recorded in Chapter 43, Section 43.1.9.

Book tooling caveat (historical) and superseded statements elsewhere

`scripts/textbook/sync.py check` builds its verbatim corpus from files tracked at `HEAD`. The campaign files were untracked on 2026-10-13, when this chapter was first written; they were committed the same day, and `sync.py check` now verifies this chapter's quotes against the committed sources. Several earlier chapters (L09, L11, L16) contain statements now superseded by this campaign: the boundary presentation is no longer conditional (L09, Section 10.9); Li's PVA structure is now defined (L11, which carries an update note); the Li telescope `sum_liWeightLayer_finrank_eq_grading` is hypothesis-free (as L11 already quotes it); and for $m = 1$ the content of `Sl2ExactSymbol` (L16) is now true on paper, though no Lean bridge exists.

Release audit (2026-10-27). Release audit 2026-10-27: see Notes/Textbook/referee/RELEASE_AUDIT_L20.md. The auditor re-ran `#print axioms` on the ten headlines (`[propext, Classical.choice, Quot.sound]`, no project axiom), traced every definition to its leaves, and recomputed the product coefficients for $m = 1, 2$; verdict: no blocker, the character theorems announceable as stated, Theorem 1.1 in a two-part wording, since at the time no single theorem had the paper's shape. That wording is superseded by `arakawaDai_theorem_1_1` (Theorem 20.26), which also discharges the audit's findings F2 (no single theorem) and F4 (no `_apply` lemma for `baseC2AlgEquiv`). The audit used compiled modules from 2026-10-25 and did not re-run the aggregate `lake build`; for the release build see Chapter 43, Section 43.1.9.

20.15 Findings, oddities and Lean defects

No statement-level defect was found: the headlines say what the paper says, about the actual objects, with no hidden hypothesis. The following are recorded for the referee.

1. **(Type-level weakness; resolved 2026-10-28) `actualC2ArcEquiv`.** Its type is a bijection of sets for each A and does not itself state naturality in A. Naturality is now proved as a separate theorem in all three places: `AffineSl2BoundaryClassicalFreeness.actualC2ArcEquiv_natural`, `AffineSl2BoundarySingularFamily.Candidate.actualC2ArcEquiv_natural` and `VirasoroClassicalFreeness.actualC2ArcEquiv_natural` (with the helper `AffineSl2BoundaryClassicalFreeness.actualC2ArcEquivOfCharacter_natural`). Together with its naturality theorem, `actualC2ArcEquiv` is a representability statement, and the docstrings now say so. The bundled form is `c2UniversalArc_universal` (Theorem 20.24), which names the bijection $(f \mapsto f_* \circ \gamma)$.

2. **(Documentation; resolved 2026-10-28) `baseC2AlgEquiv`'s type is an abstract isomorphism**; that it is the canonical map $x_i \mapsto [\mathrm{current}_i]$ was by definition only, and is now a theorem (`baseC2AlgEquiv_apply`, `canonicalC2Map_mk_X`; Theorem 20.23). The literal kernel statement `Candidate.baseIdeal_eq_simpleSymbol_kernel` exists only in a form with the hypothesis `hinj`; an unconditional corollary is not stated in the headline file. Attribution: the paper displays only the surjection $A_m \twoheadrightarrow R_V$; the isomorphism is a corollary of Theorem 1.1, not a displayed claim of the paper.

3. **(Wording; resolved 2026-10-28) Theorem 1.1 had no single Lean statement.** It was formalised as `baseC2AlgEquiv` plus `boundary_classically_free`/`arcPoissonEquiv` on the presented arc algebra. It is now the single theorem `arakawaDai_theorem_1_1` (Theorem 20.26); cite that. What remains is the honest caveat that $J_\infty R_V$ is realised as a presented arc algebra with a universal arc (no J_∞ functor on abstract algebras), characterised up to unique isomorphism by `c2UniversalArc_universal`. The two older headlines `canonicalMap_bijective` and `boundary_classically_free` still state the same fact on two isomorphic presentations.

4. **(Docstring) `character_eq_chain`** is described as "the literal descending-chain expression" of Theorem 1.2; the literal display is `character_eq_fermionic_chain`; `hilbertBoundSeries` is the paper's intermediate S_m.

5. **(Stale docstrings).** `AffineSl2BoundaryVacuumCharacter.lean` calls the character equality "the remaining character gate" / "the remaining input" (lines 83, 95); `AffineSl2SimpleCharacterRank.lean` (line 12) calls the full character product "unresolved"; `AffineInfiniteClassicalFreeness.lean` (line 739) speaks of a "remaining input". All are now proved.

6. **(Naming)** Two pairs of declarations share a short name with different meanings: `sourcePiece_finrank_le_product` (index $m+1$ in `GordonConformalCharacter.lean`, index m in `AffineSl2BoundaryVacuumCharacter.lean`) and `polynomialMap` (`BoundaryArcLiMap` versus `BoundaryArcConformalSqueeze`, different arguments). Also, `coeff_product_le_character` carries the unused hypothesis `hm` (harmless), and only the inclusion `baseIdeal_le_boundaryIdeal`, not the equality, is stated.

7. **(Not a defect; noted)** `polynomialPVA` is built by transport from $\mathrm{gr}^F V^0(\mathfrak{sl}_2)$ (level 0), which looks arbitrary; `arcPVA_unique` shows the result is canonical.

8. **(Not a defect; noted)** `uniformCandidate` is a `Classical.choose`; the headline maps do not depend on the choice.

9. **(Not a defect; noted)** `hilbertBoundSeries` and `fermionicTrace` use `m - 1` in `ℕ`, which is meaningless at $m = 0$; all uses assume $1 \le m$.

Virasoro companion and $p = 3$ files (added 2026-10-27). Again no statement-level defect: the Virasoro headlines are unconditional and about the actual simple quotient. Recorded for the referee:

10. **(Type-level, as item 1; naturality resolved)** `VirasoroClassicalFreeness.actualC2ArcEquiv` is natural in A (`VirasoroClassicalFreeness.actualC2ArcEquiv_natural`), and `VirasoroClassicalFreeness.baseC2AlgEquiv` is canonical only by definition (Theorem 20.52).

11. **(Missing bridge)** `VirasoroClassicalFreeness.cm m` is `(twoSeriesLevels m).c`; only the closed form `cm_eq` relates it to $c_{2,2m+3}$. No theorem equates it with `minimalCentralCharge 2 (2 * m + 3)` of Chapter 7.

12. **(Missing corollaries)** No Virasoro analogue of `arcPoissonEquiv_conformal_iff` (weight preservation) and no character identity is stated, although both follow from the construction.

13. **(Naming)** `VirasoroClassicalFreeness.arcPVA`, `.arcPoissonEquiv`, `.baseC2AlgEquiv` and `.actualC2ArcEquiv` share short names with the affine `arcPVA`, `arcPoissonEquiv`, `baseC2AlgEquiv`, `actualC2ArcEquiv`, with different types; only the namespace distinguishes them.

14. **(Scope, honest docstrings)** The 32 $p = 3$ files prove finite lemmas only; the terminal bound `P3LinearResidualization.finrank_le_expectedDim` takes the uninstantiated hypotheses `P3QuadraticConeCarrierIdentification` and `DumanskiFeiginP3GradedDimensionHypothesis`. The docstrings say so. `RootedGordonConductor.lean` and `RootedGordonConductorDivisibility.lean` end with `#print axioms` commands (an `AxiomAudit` section) that print at every build; cosmetic.

20.16 Referee's checklist

Lean declaration	Intended meaning	Hypotheses / status	Fidelity check
`AffineSl2BoundaryCharacter.character_eq_product`	$\operatorname{ch} L_{k_m} = (q^p;q^p)_\infty^3/(q)_\infty^3$	$1 \le m$; unconditional, `pbw`-free	Thm. 20.18
`character_eq_chain`	$\operatorname{ch} L_{k_m} = S_m$ (paper (5.12))	$1 \le m$; unconditional	Thm. 20.18
`character_eq_fermionic_chain`	paper Thm. 1.2 literally: $T_m/(q)_\infty^2$	$1 \le m$; unconditional	Thm. 20.18
`coeff_product_le_character`	lower bound for the character (a lemma, not a paper theorem)	$1 \le m$; unconditional	Thm. 20.42
`coeff_character_le_product`	Hilbert-series upper bound	$1 \le m$; unconditional	Thm. 20.36
`AffineSl2BoundaryClassicalFreeness.arakawaDai_theorem_1_1`	**Arakawa–Dai Thm. 1.1 as one theorem**: $\kappa\colon A_m \to R_V$ bijective with the current-class formula; $(J_\infty A_m, \gamma)$ is the arc algebra of R_V; the PVA isomorphism is the canonical $J_\infty R_V \to \operatorname{gr}^F V$ and preserves conformal weight	$1 \le m$; unconditional; $J_\infty R_V$ realised as presented arc algebra with universal arc	Thm. 20.26
`canonicalC2Map`, `baseC2AlgEquiv_apply`, `canonicalC2Map_mk_X`, `canonicalC2Map_bijective`	κ; `baseC2AlgEquiv` is κ (by theorem); $\kappa(x_i) = [\bar{x}_i]$	$1 \le m$; unconditional	Def. 20.22, Thm. 20.23
`c2UniversalArc`, `c2UniversalArc_universal`, `c2ToArc`	universal arc of R_V; its universal property ($\exists!$); zero jets	$1 \le m$; unconditional	Def. 20.22, Thm. 20.24
`presentedJet_algHom_ext`, `arcPoissonEquiv_c2ToArc`, `eq_arcPoissonEquiv_of_c2ToArc`	the PVA isomorphism extends $R_V \hookrightarrow \operatorname{gr}^F V$ and is the unique such translation-compatible map	unconditional	Thm. 20.25
`AffineSl2BoundaryClassicalFreeness.canonicalMap_bijective`	$J_\infty A_m \to \operatorname{gr}^F L_{k_m}$ bijective (A_m presented; packaged with the rest as Thm. 20.26)	$1 \le m$; unconditional	Thm. 20.20
`boundary_classically_free`	same map, PVA-packaged source	$1 \le m$; unconditional	Thm. 20.20
`arcPoissonEquiv`	PVA isomorphism (inverse compatible)	$1 \le m$; unconditional	Thm. 20.20, Def. 20.12
`arcPoissonEquiv_conformal_iff`	both directions preserve conformal weight	$1 \le m$; unconditional	Thm. 20.20

Lean declaration	Intended meaning	Hypotheses / status	Fidelity check
`baseC2AlgEquiv`	$A_m \cong R_{L_{k_m}}$ (canonical by theorem: `baseC2AlgEquiv_apply`)	$1 \le m$; unconditional	Thm. 20.21
`actualC2ArcEquiv`	for each A, a bijection $\mathrm{Hom}(J_\infty A_m, A) \simeq \mathrm{Hom}(R_{L_{k_m}}, A[[t]])$; natural in A by `actualC2ArcEquiv_natural`, so a representability statement (bundled: `c2UniversalArc_universal`)	$1 \le m$; unconditional; naturality a separate theorem	Thm. 20.21
`character`, `product`, `vacuum`, `simple`, `universal`, `level`, `denominator`	objects	definitions	Defs. 20.3–20.5
`euler`, `reciprocalEuler`, `fermionicTrace`, `hilbertBoundSeries`, `LocallyFinitePowerSeriesSum.sum`	q-series	definitions; finiteness proved	Defs. 20.6–20.8
`BasePoly`, `baseIdeal`, `InfiniteJet.PresentedJet`, `jetIdeal`, `arcEquiv`	$\mathbb{C}[e,h,f]$, I_m, J_∞, arc property	definitions; arc property proved	Def. 20.10, Thm. 20.11
`PoissonVertexAlgebra`, `.Hom`, `.Equiv`, `liPoissonVertexAlgebra`, `arcPVA`	PVAs	definitions; all laws proved	Defs. 20.12, 20.13, 20.14
`uniformCandidate`, `canonicalMap`, `arcLiPoissonHom`	null vector; the map π	constructions	Defs. 20.15, 20.16
`arcConformalPiece`, `sourcePiece`, `liConformalPiece`	conformal pieces	definitions	Def. 20.17
`admissible_first_null`, `Candidate.boundaryIdeal_le_kernel`	boundary relations, null vector	unconditional	Thms. 20.27, 20.28
`sourcePiece_finrank_le_auxiliaryPiece`	degeneration to the auxiliary arc algebra	unconditional	§20.5
`sector_finrank_le_profile_sum`, `auxiliaryPiece_finrank_le_source`	Gordon divisibility, partition filtration	unconditional	Thms. 20.33, 20.34
`hilbertBoundSeries_product`, `fermionicTrace_eq`, `jacobi_cube`	q-series identities	unconditional ($1 \le m$)	Thm. 20.35
`finrank_ker_le_rootMultiplicity`, `universal_grading_finrank_le_simple_add_rootOrder`	lower bound: rank bound	unconditional	Lem. 20.38, Thm. 20.39
`vacuum_determinant_order_add_reflected`, `vacuumRootOrderTotal_add_product_eq_universal_finrank`	lower bound: determinant count	unconditional	Thms. 20.40, 20.41
`sourceMap_injective_of_hilbert_bound`	conformal Hilbert squeeze	needs `hbound` (discharged)	Thm. 20.43
`poissonVertexAlgebra_unique`, `baseC2Map_injective_of_arc_injective`	PVA structure, intrinsic arc equivalence	unconditional / `hinj` (discharged)	Thms. 20.44, 20.45

Virasoro companion (Section 20.12); namespace `VirasoroClassicalFreeness` *unless noted*

Lean declaration	Intended meaning	Hypotheses / status	Fidelity check
`VirasoroLi.liFiltration_eq_virWordPiece`, `simpleLiFiltration_eq_virWordPiece`	$F^pV(c,0) = C_p$; $F^pL(c,0)$ = image of C_p	every c; unconditional	Thm. 20.47
`classicallyFree` (`_M23`, `_leeYang`), `canonicalEquiv`	$J_\infty(\mathbb{C}[T]/(T^{m+1})) \cong \mathrm{gr}^F L(c_{2,2m+3},0)$	every $m \in \mathbb{N}$; unconditional	Thm. 20.51, Def. 20.48
`baseC2AlgEquiv`, `actualC2ArcEquiv`, `mk₂_omegaBar_pow_eq_zero`	$R_L \cong \mathbb{C}[T]/(T^{m+1})$; arcs	unconditional; canonical by definition; naturality a separate theorem	Thm. 20.52
`arcPoissonEquiv`, `liPoissonVertexAlgebra_mode_eq_zero`, `zeroPVA`	PVA isomorphism; all Li modes vanish	unconditional	Thm. 20.53
`twoSeries_hasJetRelations_all`, `virSymbol_twoSeries`, `jetMap_injective`	singular-vector inputs; symbol ⇒ injective	unconditional (inputs proved)	Def. 20.49, Thm. 20.50
$p = 3$ conductor files (Section 20.13); finite algebra, reused by Chapter 24			
`collisionFactor_dvd_iff`, `collisionFactor_prime`, `collisionFactor_sq_dvd_of_swap_invariant`, `vandermonde_sq_dvd_of_symmetric_diagonal_vanishing`	collision divisibility; square factors	char 0 where stated; unconditional	Thm. 20.56
`prod_pow_dvd_of_pairwise_prime_varying`, `rootedGordonConductor_dvd_of_root_and_collision_primePowers`	separated prime powers multiply	unconditional	Thm. 20.57
`card_increasingPair_fin`, `p3ConductorWeightedDegree_eq`	$\binom{d}{2}$; $\deg C_{N,d} = dN$	unconditional	Thm. 20.58
`P3LinearResidualization.finrank_le_expectedDim`	route's terminal bound	conditional on `D` and two hypotheses, none instantiated; unused	§20.13

Chapter 21

Huang's modular tensor category and the congruence property

This chapter was first written against an earlier state of the LeanVOA library *together with the working tree of 2026-10-13* (the book's snapshot); its last section (Section 21.7) was revised on 2026-10-14, after the logarithmic monoidal and braided categories were completed in the commits following that snapshot. Two further files were added on 2026-10-28: `VOA/Huang/RigidOrdinary.lean` (two-sided rigidity, Theorem 21.8) and `VOA/Huang/CongruenceNamed.lean` (the named congruence theorems, Theorem 21.20). Checks that were run at an earlier state of the library and not re-run for this edition are marked as such. Every Lean quotation was copied mechanically from the source and is machine-checked by `scripts/textbook/sync.py` to occur verbatim in the source files of the release documented by this edition. It covers the directory `VOA/Huang/` (about nine hundred files) and its umbrella `VOA/Huang.lean`. These files supply the deep representation-theoretic inputs of the Gannon–Rayhaun classification (Chapter 22): intertwining operators and fusion rules, the braided monoidal category of modules of a strongly rational VOA and its rigidity, Huang's Verlinde theorem, the modular-data package `IModData`, the Dong–Lin–Ng congruence property through Ng–Schauenburg and Beyl's Schur-multiplier computations, Deligne's theorem on symmetric fusion categories, and the Huang–Kirillov–Lepowsky extension theory. The same directory, together with `VOA/Modules/LogTensor*.lean` and the `McRaeM2*.lean` files of `VOA/Classification/COne/`, also contains the braided tensor category of logarithmic modules of a C_2-cofinite VOA, on which the proof of the Gannon–Rayhaun converse is built (Section 21.7).

We rely on Chapter 12 for modules (`OrdVModule`, `ModuleEquiv`, `adjointModule`, `StronglyRational`, `AdmissiblyRational`, `C2Cofinite`), on Chapters 13 and 15 for Zhu's algebra, the bottom projection `BottomProjection` and Zhu's modularity theorem (`ZhuModularityAnalytic`), and on Mathlib's category theory (`MonoidalCategory`, `BraidedCategory`, `RightRigidCategory`, `FDRep`) explained in plain words where it first appears. Several statements below are phrased with the vocabulary of the Gannon–Rayhaun classification, which is *defined with its full fidelity check in the next chapter*; Section 21.1 recalls each of these notions in mathematical terms, with an exact pointer, so that this chapter can be read first.

The findings of this chapter, in brief.

1. **The braided tensor category is formalized for every strongly rational VOA**: the ordinary modules form a Mathlib braided monoidal category (`monoidalCategoryOfStronglyRational_pbw`, `braidedCategory_stronglyRational_pbw`), built on the Huang–Lepowsky tensor product, with pentagon and hexagons proved. The only hypothesis is `StronglyRational W` (plus a choice `F` of fusion products, always available).

2. **Rigidity, Verlinde and the modular category are formalized for *nice* VOAs only**, that is

strongly rational *and pseudo-unitary* (Definition 21.1). Huang's theorems need no pseudo-unitarity. The library's headline theorems are still stated for nice V. Of the two uses of pseudo-unitarity recorded by the release audit, the first is now removed: $V' \cong V$ holds for every strongly rational V by self-duality (`contra_vacuum_equiv_of_stronglyRational`), and the vacuum-fusion chain has `_of_stronglyRational` copies (Theorem 21.10). The second, `CardyPositivity.vacColumn_mem_K`, keeps `Nice`, and there pseudo-unitarity is essential (Lee–Yang $M(2,5)$). So these results remain stated more narrowly than Huang's. Within that class:

- rigidity is two-sided: `rigid_ordinary` gives Mathlib's `RigidCategory` (left and right duals), obtained from the right duals of `rightRigid_ordinary` and the proved braiding (Theorem 21.8, added 2026-10-28);
- the Verlinde formula is proved in the form $S_{ax}S_{bx} = S_{0x}\sum_c N_{ab}^c S_{cx}$, with $S_{0x} \neq 0$ and $S_{0a} = S_{a0}$ (`huangVerlindeFusionInput_holds`, index universe `u+1`);
- the modular tensor category exists only on a small model: nondegeneracy of S (`modelModular`, `ZhuRepModel.lean`) is proved on `canonicalModel`, a small category equivalent (as a braided monoidal category) to `Ordinary W`, and it takes a modular-data datum `D` with `D.IsModularData` (which exists by `iModData_holds`). No single declaration says "`Ordinary W` is a modular tensor category".

3. **`VOA.pbw` is a theorem; the suffix `_pbw` is historical.** It marks declarations that use `voaPBWBottomProjection`, the datum `BottomProjection` of Chapter 13 built from `VOA.pbw`. At the snapshot `VOA.pbw` was an axiom; since then it has become a theorem, the library has no project axiom, and every declaration of this chapter reports Lean's three standard axioms only (release audit, 2026-10-27). The suffix, and the phrase "uses `VOA.pbw`" in the status boxes below, record a route through a proved theorem, not an axiom dependence.

4. **Congruence: what is proved, and in what form.** (a) Only the *kernel half* of Ng–Schauenburg's Theorem 6.8 is proved: for every modular category there is some $N > 0$ with $\Gamma(N)$ acting by scalars in every lift (`nsProjectiveKernelAll_holds`). The other half — that the level is exactly the Frobenius–Schur exponent, and minimal (`ProjectiveCongruenceTheorem`, universally `NSProjectiveCongruenceAll`) — is not proved and appears only as a hypothesis. (b) The VOA congruence property, for nice V, is stated as **named, hypothesis-free theorems** (Theorem 21.20, added 2026-10-28): `dlnCongruenceInput_holds` (characters are $\Gamma(N)$-invariant at every level N), `galoisSymmetryNontrivialInput_holds` (the Galois half), `zhuCongruenceInput_holds` (kernel form: $\Gamma(L) \subseteq \ker\rho_V$ for some $L > 0$) and `zhu_kernelContainsGamma_at_level` ($\Gamma(N) \subseteq \ker\rho_V$ at every level N). Before that revision the property was discharged only inside the proof term of `gannonRayhaun_forward` (Chapter 22). (c) `DLNCongruenceInput` is about characters only; the kernel form $\ker\rho_V \supseteq \Gamma(N)$ is `ZhuCongruenceInput` and its at-level corollary.

5. **Deligne's theorem is the positive-dimension (Tannakian) case**: a symmetric fusion category over $\mathbb{C}$ whose simple objects all have positive dimension is braided-equivalent to $\mathrm{Rep}(G)$ (`deligneTannakian_holds`), proved by constructing a fiber functor and reconstructing the group. It is Deligne 1990 / EGNO §9.9 in the fusion case, not Deligne's 2002 theorem including the super case $\mathrm{Rep}(G, z)$.

6. **Stale docstrings** (a documentation defect only): several statement files still say "not proved here" for `Prop`s that have since been proved in other files (Section 21.8).

7. **The logarithmic theory no longer assumes a semisimple Zhu algebra.** The finiteness of the set of irreducible modules of every C_2-cofinite VOA is now proved without that hypothesis (`finite_Φ_of_C2Cofinite_pbw`, using the theorem `VOA.pbw`), and the logarithmic tensor chain

was rebuilt on it (Section 21.7). Its admissible analogue, Dong–Li–Mason's "finitely many irreducible admissible modules", is also a theorem for every C_2-cofinite admissibly rational VOA (`dlmFinitelyManyIrredAdmissible_of_c2Cofinite`, Chapter 12, Theorem 12.40; added in a later revision of the library), as are Abe–Buhl–Dong's theorems that every weak module of a C_2-cofinite VOA is admissible and every irreducible one ordinary.

8. **The logarithmic braided tensor category is constructed.** For every C_2-cofinite VOA the finitely generated logarithmic modules form a Mathlib `MonoidalCategory` and `BraidedCategory` (`logarithmicMonoidalCategory`, `logarithmicBraidedCategory`), with the Huang–Lepowsky–Zhang tensor product, the analytically constructed associator, and the pentagon and both hexagons *proved*; the only hypothesis is C_2-cofiniteness (the construction uses the theorem `VOA.pbw`). This category carries McRae's orbifold argument, which proves the last input of the Gannon–Rayhaun converse; the converse, and with it the whole classification, is now proved (Chapter 22, Section 22.9 and Theorem 22.59).

21.1 Vocabulary borrowed from the classification chapter

The Huang-side theorems were formalized to feed the Gannon–Rayhaun classification, so their statements use five notions that are presented, with their complete fidelity checks, in Chapter 22. We recall them here in mathematical terms; nothing in this chapter depends on more than what is said in this section, and the reader who wants to check a Lean definition clause by clause should follow the pointer.

Definition 21.1 (Nice VOA; Chapter 22, Definitions 22.2 and 22.3)**.** A VOA V is *pseudo-unitary* if every irreducible ordinary module $M \ncong V$ has all its L_0-eigenvalues of strictly positive real part. V is *nice* if it is strongly rational (simple, of CFT type, self-dual, C_2-cofinite and rational; Chapter 12, Definition 12.43) and pseudo-unitary.

File `VOA/Classification/COne/Statement.lean`.

```
def Nice (V : VertexOperatorAlgebra 𝒱) : Prop :=
  StronglyRational V ∧ PseudoUnitary V
```

From the mathematics to the Lean statement

`Nice V` is a `Prop` (a statement, not data): the conjunction (`∧`) of strong rationality and pseudo-unitarity. Every theorem below that takes `hNice : Nice W` or `hV : Nice V` assumes exactly these two properties. Strong rationality alone is Huang's hypothesis; pseudo-unitarity is an *extra* assumption made by Gannon–Rayhaun, so a theorem stated for nice V is (harmlessly, for the classification) weaker than Huang's theorem stated for strongly rational V. The rigidity, Verlinde, modular-data and congruence results of this chapter are all stated for nice V, and their proofs use pseudo-unitarity (now essentially only through the Cardy-positivity step, `CardyPositivity.vacColumn_mem_K`; the vacuum-fusion chain no longer needs it, Theorem 21.10), so the extra hypothesis cannot be dropped without new proofs; it must be stated whenever these results are quoted.

Physical meaning

Nice VOAs are the chiral algebras of rational CFTs whose sectors all carry positive energy, as in a unitary theory.

What the machine verified

Definition (Chapter 22).

Modular data (Chapter 22, Definitions 22.12–22.15). A term `D : VOA.Classification.COne.ModularData V` is a bundle of *candidate* data: a finite label set `D.ι` with a vacuum label `D.vac`, one ordinary module M_a for each label (`D.module a`), rational numbers h_a (`D.h a`), functions ch_a on the upper half plane (`D.ch a`), a complex matrix S (`D.S`), a positive real number S_{00} (`D.S00`) and real numbers d_a (`D.d a`). The predicate `D.IsModularData` says these data are *the* modular data of V: the M_a are a complete irredundant list of the irreducible modules with $M_{\mathrm{vac}} \cong V$; the L_0-weights of M_a lie in $h_a + \mathbb{N}$ with h_a attained; $\mathrm{ch}_a(\tau) = \sum_n \dim(M_a)_{h_a+n}\, q^{h_a+n-c/24}$ as a convergent series; S implements $\tau \mapsto -1/\tau$ on characters *and* on all Zhu one-point functions (`SPinned`); $S_{a0} = S_{0a} = S_{00} d_a$ with $d_a \geq 1$; and $|S_{ab}| \leq S_{00} d_a d_b$. A natural number $N > 0$ is a *level* (`D.IsLevel N`) if $N(h_a - c/24) \in \mathbb{Z}$ for every a. `mobius γ τ` is the Möbius action $(a\tau + b)/(c\tau + d)$ of $\gamma \in \mathrm{SL}_2(\mathbb{Z})$ (Definition 22.10). Finally, `IModData`, `ICongruenceGalois` and `ITannakian` are the three "external inputs" of the classification that this chapter proves (Definition 22.16): every nice VOA has modular data; its characters are $\Gamma(N)$-invariant and Galois-symmetric at every level N; and a nice VOA whose integer-weight sectors braid trivially is a fixed-point algebra W^G of a nice W under a finite group.

Two different structures are both called "modular data" in the library, and the reader must not confuse them: `VOA.ModularData W ι` of Chapter 15 is *Zhu's* family of irreducible modules with weights, on which Zhu's representation `repS` of S is defined; `VOA.Classification.COne.ModularData V` is the classification package just described. Huang's Verlinde theorem (Definition 21.11) is stated for the first; the congruence and Tannakian inputs for the second.

21.2 Intertwining operators and fusion rules

Definition 21.2 (Intertwining operator; Frenkel–Huang–Lepowsky Def. 5.4.1)**.** For ordinary V-modules M_1, M_2, M_3, an *intertwining operator of type* $\binom{M_3}{M_1\, M_2}$ is a family of bilinear maps $(w_1, w_2) \mapsto (w_1)_{(n)} w_2 \in M_3$, $n \in \mathbb{C}$, such that (i) for fixed w_1, w_2, n, $(w_1)_{(n+k)} w_2 = 0$ for $k \gg 0$; (ii) $(L_{-1} w_1)_{(n)} = -n\,(w_1)_{(n-1)}$; (iii) the Jacobi identity holds in all mode coefficients.

      = ∑ᶠ i : ℤ, cbz m i • Y (m + n - i) (mode (A₁.YM u) (ℓ + i) w₁) w₂
```

From the mathematics to the Lean statement

`IntertwiningModes M₁ M₂ M₃` is the type `ℂ → (M₁ →ₗ[ℂ] M₂ →ₗ[ℂ] M₃)`: for each complex number n a *bilinear* map (a $\mathbb{C}$-linear map from M_1 to the $\mathbb{C}$-linear maps $M_2 \to M_3$); `Y n w₁ w₂` is $(w_1)_{(n)}w_2$, the coefficient of z^{-n-1} in $Y(w_1,z)w_2$, with complex mode index because conformal weights of modules need not be integers or congruent modulo $\mathbb{Z}$. Bilinearity is thus built into the type, as in Definition 21.2. `A₁.Lm1` is $L_{-1} = \omega_{(0)}$ on M_1; `mode (A.YM u) k` is the k-th mode $u_{(k)}$ of $u \in V$ on the module (Chapter 4). `cbz ℓ i` is the binomial coefficient $\binom{\ell}{i}$ for integer ℓ, set to 0 for $i < 0$ (so the sums may run over all of $\mathbb{Z}$), `negOnePow i` is $(-1)^i$, and $\sum^{\mathbf{f}}$ is Mathlib's `finsum`: the sum of a finitely supported family, *and* 0 *by convention if the support is infinite* (Chapter 1). That junk value never matters here: for fixed u, w_1, w_2, ℓ, m, n the three families are finitely supported, because $\binom{\ell}{i} = 0$ for $i < 0$ and, for $i \gg 0$, the truncation clause and the truncation of module modes kill the terms (the library proves this, `jacL_support_finite`, `jacR_support_finite`). The identity is then the coefficient of $z_0^{-\ell-1}z_1^{-m-1}z_2^{-n-1}$ in the Jacobi identity of FHL, exactly as for modules in Chapter 4. **Same as FHL Def. 5.4.1**: truncation, L_{-1}-derivative property, Jacobi identity. **Why a new structure.** The older bundled `Intertwiner` of `Modules/Fusion.lean` lacks the L_{-1} property and the full Jacobi identity, and its `fusionCoeff` is identically zero (Chapter 12); this structure replaces it for all fusion-theoretic work.

Physical meaning

An intertwining operator is a chiral vertex operator $Y(w_1,z)$ creating the state w_1 of sector M_1 and mapping sector M_2 to sector M_3: a primary field in the sense of BPZ, with fractional powers of z allowed.

What the machine verified

Definition. Non-vacuous: every module M gives an intertwining operator of type $\binom{M}{V\ M}$ (`moduleIntertwiner_ne_zero`).

Definition 21.3 (Fusion rule). $N_{M_1M_2}^{M_3}$ is the dimension of the space of intertwining operators of type $\binom{M_3}{M_1\ M_2}$.

File `VOA/Huang/BuhlSpanningMain.lean`.

```
theorem moduleC2Input_holds : ModuleC2Input.{u} :=
  moduleC2Input_of_buhlFiniteLWGen buhlFiniteLWGenInput_holds
```

From the mathematics to the Lean statement

`intertwiningSpace A₁ A₂ A₃` is the $\mathbb{C}$-subspace (`Submodule ℂ`) of `IntertwiningModes` whose elements are exactly the families satisfying `IsIntertwiningOperator` (the omitted fields of the definition prove that this set contains 0 and is closed under sums and scalars). `Module.finrank` is 0 on infinite-dimensional spaces (Chapter 1), so the definition is honest only where the space is finite-dimensional. For the irreducible modules of a nice V this is `finiteDimensional_fusion`, which assumes `ModuleC2Input` ("every irreducible module of a strongly rational VOA is C_2-cofinite", a theorem of Buhl), and that input is proved (`moduleC2Input_holds`). So for nice V the fusion rule among irreducibles is the true dimension.

Physical meaning

The number of independent ways sectors M_1 and M_2 fuse into M_3: the OPE coefficients of the anyon theory.

What the machine verified

Definition.

Theorem 21.4 (Fusion rules of V_{2m}). *For the irreducible V_{2m}-modules $V_{L+j/2m}$, $N_{jk}^{l} = 1$ if $l \equiv j + k \pmod{2m}$ and 0 otherwise.*

```
theorem fusionRule_latticeModule :
    fusionRule (latticeModule m hm j) (latticeModule m hm k) (latticeModule m hm l)
      = if (l - j - k) % (2 * (m : ℤ)) = 0 then 1 else 0 :=
```

File `VOA/Classification/COne/LatticeModules.lean`.

```
noncomputable def latticeModule : OrdVModule (V2m m hm) (LatModuleGen (latP m)) :=
```

From the mathematics to the Lean statement

`V2m m hm` is the lattice VOA V_{2m} of $\sqrt{2m}\,\mathbb{Z}$ (Chapter 22, Definition 22.5). `latticeModule m hm j` is the ordinary V_{2m}-module $V_{L+j\alpha/2m}$ for an integer j (the variables `m`, `hm : 1 ≤ m` and `j k l : ℤ` are section variables of the files): its underlying space is the same Fock space $\otimes\, \mathbb{C}\{L\}$ as V_{2m}, with the state $p \otimes e^{n\alpha}$ standing for $p \otimes e^{(n+j/2m)\alpha}$ and lowest weight $j^2/4m$. In the quotation, `%` is the integer remainder modulo $2m$, so the condition is $l \equiv j + k \pmod{2m}$. The statement is for all integers j, k, l, not only representatives; it is the textbook statement.

Proof on paper. Existence: the lattice vertex operators $E^{\pm}(\lambda, z)z^{\lambda(0)}e^{\lambda}$ give a nonzero intertwiner of type $\binom{j+k}{j\ k}$. Uniqueness and vanishing: an intertwiner is determined by its action on the lowest weight space, and charge conservation under the Heisenberg zero mode forces $l \equiv j + k$; the second-slot commutator formula sweeps all charge sectors. □

Physical meaning

The compact boson at rational radius has $\mathbb{Z}_{2m}$ fusion: momenta add.

What the machine verified

Proved, Lean's three axioms.

21.3 The braided monoidal category of modules and its rigidity

Theorem 21.5 (Huang–Lepowsky: the tensor category)**.** *For a strongly rational V and any choice F of fusion products, the category of ordinary V-modules carries a monoidal structure with tensor product $\boxtimes_F$, unit V, the analytically defined associator and the unitors.*

```

From the mathematics to the Lean statement

`MonoidalCategory C` is Mathlib's monoidal category structure (tensor product of objects and morphisms, unit object, associator and unitor isomorphisms, with the pentagon and triangle axioms as fields). Providing a term of it *is* proving pentagon and triangle. `Ordinary W` is the category whose objects bundle a carrier space with an ordinary module structure `isMod` (reducible modules and the zero module included), and whose morphisms are module maps. **What the type does not say, and where it is pinned down.** The bare type `MonoidalCategory (Ordinary W)` does not say *which* tensor product is used: a degenerate monoidal structure would have the same type. The identification is in the definitions. `IntertwiningOperator A₁ A₂ A₃` is the subtype of `intertwiningSpace`; `UniversalFor Y AN`

says that composing $\mathcal{Y}$ with module maps $M_T \to N$ is a *bijection* onto the intertwining operators of type $\binom{N}{M_1\,M_2}$, and `IsUniversal` asks this for every target N. So a `Product` of M_1, M_2 is a module $M_1 \boxtimes M_2$ together with an intertwining operator through which every intertwining operator out of $M_1 \otimes M_2$ factors uniquely — the defining universal property of the Huang–Lepowsky tensor product (in its ordinary-module form). `FusionChoice W` chooses one such product for every pair of objects (products are unique up to unique isomorphism, so the choice is a convenience); `tensorObj F X Y` is the chosen product. In the source, the monoidal structure is assembled (`monoidalCategoryOfModes`, `TensorCatCoherence.lean`) with `tensorObj := tensorObj F`, `tensorUnit := vacuumObject` (the adjoint module V) and the associator defined from the analytic four-point evaluation of products and iterates of the universal intertwiners. `abbrev` is a transparent definition. The two arguments `…_pbw` supply the five-point sewing input (pentagon) and the vacuum creation compatibility (triangle), each built using `voaPBWBottomProjection`.

Proof on paper. Huang–Lepowsky: the $P(z)$-tensor product $M_1 \boxtimes M_2$ represents intertwining operators. Products and iterates of intertwining operators converge (from C_1-cofiniteness via regular-singular differential equations, Huang 2005) and agree on overlapping domains (associativity); this gives the associator, and the pentagon follows from five-point sewing (convergence and analytic continuation of four-fold products). □

Physical meaning

Fusion of anyons is associative up to the F-matrices; the pentagon is the consistency of the five-point conformal blocks.

What the machine verified

A construction (no hypothesis beyond strong rationality); Lean's three standard axioms (the construction passes through the theorem `VOA.pbw`).

Theorem 21.6 (The braiding). *The braiding given by the skew-symmetry of intertwining operators makes this monoidal category braided.*

      (skewP p Y X (tensorObj F Y X) (F Y X).intertwiner).val n x y :=
```

From the mathematics to the Lean statement

`BraidedCategory` is Mathlib's: a natural isomorphism $c_{X,Y} : X \otimes Y \cong Y \otimes X$ satisfying both hexagons. As for the monoidal structure, the type alone does not identify the braiding; the three quotations do. The first (a definitional equality, `rfl`) says the braiding of `braidedCategory_stronglyRational_pbw` is `braiding F`; the second that this is `braidingP` at the upper half-plane phase; the third is its defining equation on the universal intertwiner: $c_{X,Y}(\mathcal{Y}_{X,Y}(x,z)y) = \Omega(\mathcal{Y}_{Y,X})(x,z)y$, where `skewP p` is the skew-symmetry isomorphism of FHL §5.4, $\Omega_r(\mathcal{Y})(x,z)y = e^{zL_{-1}}\mathcal{Y}(y, e^{(2r+1)\pi i}z)x$, from operators of type $\binom{Z}{Y\,X}$ to operators of type $\binom{Z}{X\,Y}$, with the branch index r fixed by the phase `p` (here `Phase.upper`). This is Huang–Lepowsky's braiding. The hexagons are supplied by `hexagonInput_pbw`, proved from analytic continuation of products on half-planes.

Proof on paper. Naturality of c is immediate from its definition through the universal property. For the hexagon $\alpha \circ c_{X,Y\otimes Z} \circ \alpha = (1 \otimes c_{X,Z}) \circ \alpha \circ (c_{X,Y} \otimes 1)$, evaluate both sides on products $\mathcal{Y}(x,z_1)\mathcal{Y}(y,z_2)w$ in the region $|z_1| > |z_2| > 0$: each side is the analytic continuation of the same multivalued four-point function along homotopic paths in the configuration space of two points, one moving x half-way around the pair and the other moving it around each in turn. Huang's convergence and associativity theorems make these continuations well defined; the two hexagons correspond to the two phases (upper and lower half plane). □

Physical meaning

Exchanging two anyons along a half-turn; the hexagons are the compatibility of braiding with fusion (R- and F-moves).

What the machine verified

A construction (hypothesis: strong rationality); Lean's three standard axioms (through the theorem `VOA.pbw`).

Theorem 21.7 (Huang's rigidity theorem, right-rigid form, for nice V)**.** *For a nice (strongly rational and pseudo-unitary) V the monoidal category of ordinary modules is right rigid: every object has a right dual.*

File `VOA/Huang/HuangRigidOrdinary.lean`.

```
theorem rightRigid_ordinary (F : FusionChoice W) (hNice : Nice W) :
    letI := monoidalCategoryOfStronglyRational_pbw F hNice.1
    Nonempty (RightRigidCategory (Ordinary W)) := by
```

From the mathematics to the Lean statement

`RightRigidCategory` is Mathlib's: every object has a right dual with evaluation and coevaluation satisfying the zigzag identities. `Nonempty` because duals are data. **Two ways in which this is weaker than Huang's theorem.** (1) The hypothesis `Nice W` includes pseudo-unitarity, which Huang does not need; the proof uses the `Nice` forms of the Verlinde package (e.g. `contra_vacuum_equiv` in `VerlindeVacuumFusion.lean`), so the library's statement covers only pseudo-unitary V. That particular step now has a strongly rational form (Theorem 21.10), but the rigidity theorem has not been restated. (2) The conclusion is *right* rigidity, not Mathlib's two-sided `RigidCategory`; Huang's rigidity is two-sided. Left duals follow from the braiding (take $X^\vee$ with the evaluation precomposed with the braiding); this corollary is now stated and proved for `Ordinary W` as `rigid_ordinary` (Theorem 21.8), so restriction (2) is removed. Restriction (1) remains; it is harmless for the classification. The statement is not vacuous: it

is instantiated at V_2 by `V2m_nice` (Chapter 22).

Proof on paper. The dual of M is its contragredient M'. The evaluation is the intertwining operator obtained from the module action and the invariant pairing. The zigzag identity reduces to the nonvanishing of a quantity related to S_{0M}, which follows from the Verlinde formula ($S_{0x} \neq 0$) and Zhu's modular invariance: this is Huang's argument (2008). □

Physical meaning

Every anyon has an antiparticle; creating a pair from the vacuum and annihilating it again is the identity (up to the quantum dimension, normalized away).

What the machine verified

Proved, for nice V only, right rigidity; Lean's three standard axioms (the proof passes through the theorem `VOA.pbw`). The two-sided form is Theorem 21.8.

Theorem 21.8 (Huang's rigidity theorem, two-sided, for nice V)**.** *For a nice (strongly rational and pseudo-unitary) V and any choice F of fusion products, the monoidal category of ordinary V-modules of Theorem 21.5 is rigid: every object has both a right dual and a left dual.*

File `VOA/Huang/RigidOrdinary.lean`.

```
theorem rigid_ordinary (F : FusionChoice W) (hNice : Nice W) :
    letI := monoidalCategoryOfStronglyRational_pbw F hNice.1
    Nonempty (RigidCategory (Ordinary W)) := by

def rigidCategoryOrdinary (F : FusionChoice W) (hNice : Nice W) :
    letI := monoidalCategoryOfStronglyRational_pbw F hNice.1
    RigidCategory (Ordinary W) :=
  Classical.choice (rigid_ordinary F hNice)
```

From the mathematics to the Lean statement

Namespace `VOA.Huang.HuangRigid`; `W : VertexOperatorAlgebra` V is a section variable. `RigidCategory C` is Mathlib's two-sided notion: a `RightRigidCategory` together with a `LeftRigidCategory`, i.e. every object X has a right dual $X^\vee$ and a left dual ${}^\vee X$, each given by an *exact pairing* (evaluation and coevaluation morphisms satisfying both zigzag identities). This is the textbook definition of a rigid monoidal category (EGNO, Def. 2.10.11). `letI := monoidalCategoryOfStronglyRational_pbw F hNice.1` says that the monoidal structure in question is the proved Huang–Lepowsky structure of Theorem 21.5, built from the fusion choice `F` and the strong rationality `hNice.1`; the statement is about *that* monoidal category, not about some other monoidal structure on `Ordinary W`. `Nonempty` because duals are data. `rigidCategoryOrdinary` picks one such structure with `Classical.choice`; it is a convenience for later statements and adds no content.

Same, stronger, or weaker than Huang? The conclusion is now Huang's: two-sided rigidity. The remaining difference is the hypothesis: `Nice W` includes pseudo-unitarity, which Huang does not need (dictionary of Theorem 21.7). **How the left duals arise.** The proof uses Mathlib's `BraidedCategory.rigidCategoryOfRightRigidCategory`: in a braided category, an exact pairing (X, Y) (Mathlib's convention: coevaluation $\eta : \mathbf{1} \to X \otimes Y$, evaluation $\varepsilon : Y \otimes X \to \mathbf{1}$, so Y is a right dual of X) yields an exact pairing (Y, X) with coevaluation $c_{Y,X}^{-1} \circ \eta : \mathbf{1} \to Y \otimes X$ and evaluation $\varepsilon \circ c_{X,Y} : X \otimes Y \to \mathbf{1}$ (Mathlib's `exactPairing_swap`); so a right dual of X is also a left dual of X. The braiding used is the proved braiding `braidedCategory_stronglyRational_pbw F hNice.1` of Theorem 21.6, on the same monoidal

structure. So nothing beyond Theorems 21.6 and 21.7 enters. **Non-vacuity:** as for Theorem 21.7, it applies to V_2 (`V2m_nice`, Chapter 22).

Proof on paper. By Theorem 21.7 every object X has a right dual $X^\vee$ with $\eta_X : V \to X \otimes X^\vee$ and $\varepsilon_X : X^\vee \otimes X \to V$ satisfying the zigzag identities. Put $\eta' = c^{-1}_{X^\vee,X} \circ \eta_X : V \to X^\vee \otimes X$ and $\varepsilon' = \varepsilon_X \circ c_{X,X^\vee} : X \otimes X^\vee \to V$. Naturality of the braiding and the hexagon identities transform each zigzag identity for (ε', η') into one for (ε_X, η_X), so (ε', η') exhibits $X^\vee$ as a left dual of X. Together with the right duals this is a rigid structure. □

Physical meaning

Every anyon has an antiparticle on either side: creating a particle–antiparticle pair from the vacuum and fusing it back is the identity whether the antiparticle sits to the left or to the right. In a braided theory the two are related by exchanging the pair, which is the half-braiding in the formula above.

What the machine verified

Proved, for nice V only; `#print axioms` of `rigid_ordinary` and `rigidCategoryOrdinary`: `[propext, Classical.choice, Quot.sound]` (2026-10-28; Section 21.9). The release audit's "right rigidity only" caveat (finding F4) is discharged.

21.4 Modular data: Anderson–Moore, Verlinde and the package `IModData`

Definition 21.9 (The Anderson–Moore input). For finitely many q-series $f_i(\tau) = \sum_m a_{i,m} q^{\lambda_i + m}$ with $a_{i,m} \in \mathbb{N}$, $a_{i,0} \neq 0$, whose span is closed under $\tau \mapsto -1/\tau$, every exponent λ_i is rational.

File `VOA/Huang/AndersonMoore.lean`.

```
def AndersonMooreInput : Prop :=
  ∀ (n : ℕ) (lam : Fin n → ℂ) (coeff : Fin n → ℕ → ℕ) (f : Fin n → UpperHalfPlane → ℂ)
    (S : Fin n → Fin n → ℂ),
    (∀ i, coeff i 0 ≠ 0) →
    (∀ i (τ : UpperHalfPlane), HasSum (fun m : ℕ => (coeff i m : ℂ) *
        cexp (2 * Real.pi * I * (lam i + m) * τ)) (f i τ)) →
    (∀ i (τ : UpperHalfPlane), f i (ModularGroup.S • τ) = ∑ j, S i j * f j τ) →
    ∀ i, ∃ q : ℚ, (q : ℂ) = lam i
```

File `VOA/Huang/AndersonMooreMain.lean`.

```
theorem andersonMooreInput_holds : AndersonMooreInput :=
  andersonMooreInput_of_core amCore_holds
```

From the mathematics to the Lean statement

`UpperHalfPlane` is Mathlib's $\mathbb{H}$; `ModularGroup.S • τ` is $-1/\tau$. `coeff i 0 ≠ 0` pins λ_i (otherwise $f_i \equiv 0$ would allow any λ_i). Source: Anderson–Moore (1988); used by Dong–Li–Mason for the rationality of conformal weights. The input is stated with the S-transformation only; closure under $T : \tau \mapsto \tau + 1$ is automatic, since $f_i(\tau + 1) = e^{2\pi i \lambda_i} f_i(\tau)$ term by term. The exponents are allowed to be complex a priori; rationality (in particular reality) is the conclusion. `∃ q : ℚ, (q : ℂ) = lam i` says λ_i is the image of a rational number. Same as the textbook statement.

Proof on paper (sketch). Let $\mathcal{F}$ be the span of the f_i; it is invariant under S and T, hence under $\mathrm{SL}_2(\mathbb{Z})$, and on it T acts with eigenvalues $e^{2\pi i\lambda_i}$. The f_i form a fundamental system of a monic modular linear differential equation (built from the Wronskian), whose coefficients are modular forms and whose indicial roots at the cusp $i\infty$ are the λ_i. Because the solutions have q-expansions with *integer* coefficients and nonzero leading term, the equation is defined over $\mathbb{Q}$ and has a full set of solutions with integral expansions; an arithmetic argument of Grothendieck–Katz type (Anderson–Moore's key step) then forces the local monodromy at the cusp, which is $\rho(T)$, to be quasi-unipotent: its eigenvalues $e^{2\pi i\lambda_i}$ are roots of unity, i.e. $\lambda_i \in \mathbb{Q}$. The library proves this through its own core statement `amCore_holds`; we do not reproduce that route. □

Physical meaning

The conformal weights of a rational CFT are rational numbers: T has finite order.

What the machine verified

Proved (`andersonMooreInput_holds`), Lean's three axioms.

Theorem 21.10 ($V' \cong V$ and the vacuum-fusion chain, for strongly rational V)**.** *Let V be strongly rational. (i) If A is a V-module with $A \cong V$, then $A' \cong V$; no pseudo-unitarity is used. (ii) For a modular-data family (M_a) with $M_{v_0} \cong V$: $N_{ab}^{v_0} \le [M_b \cong M_a']$; $N_{ab}^{v_0} = 1$ (in particular $\neq 0$, and ≥ 1) when $M_a' \cong M_b$; and $\dim I\binom{V}{M_b\,M_a} \le 1$. So $N_{ab}^{0} = \delta_{b,a'}$ holds without pseudo-unitarity.*

```

From the mathematics to the Lean statement

`SelfDual` in `StronglyRational` supplies a fully invariant bilinear form on V with zero left radical; the general lemma `contragredient_equiv_of_selfDual` turns a weight-orthogonal, fully invariant, nondegenerate module form into an isomorphism $N \cong N'$, and transports it along $A \cong V$. The five copies, with `StronglyRational W` in place of `Nice W`, are `VerlindeVacuum.famFusion_vacuum_le_of_stronglyRational`, `VerlindeVacuum.famFusion_vacuum_contra_of_stronglyRational`, `VerlindeVacuum.famFusion_vacuum_ne_zero_of_stronglyRational`, `GenusOneG1f.vacuum_pairing_le_one_of_stronglyRational` and `VerlindeRho.one_le_famFusion_contragredient_of_stronglyRational`; the `Nice` originals are untouched. The argument `_hirr` is unused, and the docstring of `vacuum_pairing_le_one_of_stronglyRational` still says "nice V" (documentation only). `CardyPositivity.vacColumn_mem_K` keeps `Nice`: there pseudo-unitarity is essential, as the Lee–Yang model $M(2,5)$ shows. The rigidity, Verlinde and modular-data headline theorems have not been restated for strongly rational V.

Physical meaning

$V' \cong V$ says the vacuum sector is its own conjugate: the vacuum two-point function pairs V with itself, so the identity field has itself as charge conjugate. Part (ii) is the familiar fusion rule $\mathbf{1} \times a$ contains b exactly when $b = \bar{a}$, with multiplicity one, i.e. $N_{ab}^0 = \delta_{b,\bar{a}}$: the input that lets the vacuum column of S act as the unit in Verlinde-type arguments. The point recorded here is that only the self-duality built into strong rationality (a nondegenerate invariant bilinear form on V) is used, not pseudo-unitarity, so non-unitary models such as Lee–Yang are covered. What is not extended: the Cardy-positivity step (`CardyPositivity.vacColumn_mem_K`) still needs pseudo-unitarity, and the Verlinde, rigidity and modular-data headline theorems are still stated for nice V.

What the machine verified

Proved; `#print axioms VOA.contra_vacuum_equiv_of_stronglyRational` and of the five copies: `[propext, Classical.choice, Quot.sound]`, recorded in `Notes/release/WS-RELEASE2.md` (commit `34b74b85`); audited as stated in `Notes/Textbook/referee/RELEASE_AUDIT_QUEUE2.md`. The aggregate `lake build` at the release commit is pending.

Definition 21.11 (Huang's Verlinde theorem, fusion form, for nice V)**.** For a nice (strongly rational and pseudo-unitary) V and a complete irredundant family of irreducibles with Zhu's modular matrix S, the vacuum row is nonzero, $S_{0a} = S_{a0}$, and $S_{ax}S_{bx} = S_{0x}\sum_c N_{ab}^c S_{cx}$ with the true fusion rules N_{ab}^c.

```

From the mathematics to the Lean statement

`VOA.ModularData W ι` here is Chapter 15's Zhu data (a family `Mfam` of irreducible modules and weights), `D.repS` is Zhu's $\rho(S)$ on it; `ZhuModularityAnalytic D` is Zhu's theorem for the family; `Irredundant`, `Complete`: the family is a system of representatives. `famFusion D a b c` is the `fusionRule` of Definition 21.3 on the family (`famFusion D a b c = fusionRule (D.Mfam a).isMod (D.Mfam b).isMod (D.Mfam c).isMod`, `VerlindeFusion.lean`), cast to $\mathbb{C}$. `v0` is the label of the vacuum module (`ModuleEquiv … (adjointModule W)`: $M_{v_0} \cong V$). The three conjuncts are, in order: $S_{v_0x} \neq 0$ for all x; $S_{v_0a} = S_{av_0}$; and the Verlinde identity $S_{ax}S_{bx} = S_{v_0x}\sum_c N_{ab}^c S_{cx}$ for all a, b, x — the quotation is the complete statement. This is Huang's main theorem of "Vertex operator algebras and the Verlinde conjecture", written without division, for nice V (Huang assumes no pseudo-unitarity). **The proved form.** The conclusion is the diagonalisation form $S_{ax}S_{bx} = S_{0x}\sum_c N_{ab}^c S_{cx}$ together with $S_{0x} \neq 0$ and $S_{0a} = S_{a0}$. It is equivalent to the familiar $N_{ab}^c = \sum_x S_{ax}S_{bx}(S^{-1})_{xc}/S_{0x}$ only given invertibility

of S, which holds because `D.repS` comes from a group homomorphism; full symmetry $S = S^T$ is *not* part of this statement. Quote it in the proved form. The index type `ι` lives in universe `w`; the proved instance takes `w = u + 1`, which is the universe in which Zhu's family is built, so a `Fin n`-indexed family needs a `ULift`; this is a bookkeeping restriction, not one of content.

Proof on paper. Huang: the genus-one one-point functions of intertwining operators span a space on which $\mathrm{SL}_2(\mathbb{Z})$ acts; the fusion matrices N_a act on characters by inserting the vertex operator of a along a cycle, and the S-transformation exchanges the two cycles of the torus, which diagonalizes the N_a. The library proves the eigenvalue form (`fusionEigenInput_holds`) through a full genus-one theory of intertwining operators and transports it to the character S-matrix. □

Physical meaning

The Verlinde formula: the modular S-matrix diagonalizes fusion.

What the machine verified

Proved for nice V, in the form above; `##print axioms`: Lean's three axioms (it uses the theorem `VOA.pbw`; while `VOA.pbw` was an axiom the report also listed `VOA.pbw`).

Definition 21.12 (The PBW bottom input)**.** Every VOA admits a bottom projection for the parabolic module induced from its regular Zhu module.

File `VOA/Huang/ZhuModData.lean`.

```
def ZhuPBWBottomInput : Prop :=
  ∀ (𝒱 : Type u) [AddCommGroup 𝒱] [Module ℂ 𝒱] (W : VertexOperatorAlgebra 𝒱),
    Nonempty (BottomProjection (parabolicRepOfAMod W (regularAMod W)))
```

File `VOA/Huang/ZhuModData.lean`.

```
theorem zhuPBWBottomInput_of_pbw : ZhuPBWBottomInput.{u} :=
  fun _ _ _ W => ⟨voaPBWBottomProjection (parabolicRepOfAMod W (regularAMod W))⟩
```

From the mathematics to the Lean statement

`BottomProjection` is the datum of Chapter 13: a projection onto the bottom of the induced parabolic module compatible with the Zhu action, which Zhu's induced-module construction needs. The library constructs it, for every VOA, from the theorem `VOA.pbw` (`voaPBWBottomProjection`). **This is the single point where `VOA.pbw` enters the $c = 1$ classification** (it was an axiom in earlier versions of the library).

Physical meaning

The statement that the "generalized Verma module" induced from the zero-mode algebra has no unexpected collapse at its bottom level — a PBW-type freeness statement.

What the machine verified

`Prop`; proved from `VOA.pbw`.

Theorem 21.13 (`IModData` holds)**.** *Every nice VOA has modular data in the sense of Chapter 22, Definition 22.14.*

```

From the mathematics to the Lean statement

`IModData.{u}`: every nice VOA on a carrier in universe `u` has modular data `D` with `D.IsModularData` (Section 21.1). `iModData_of_verlinde_inputs` is the conditional form, with three `Prop` hypotheses: the PBW bottom input (Definition 21.12), Anderson–Moore (Definition 21.9) and `VerlindeInput`, a weakened form of Huang's Verlinde theorem (the vacuum row is nonzero and symmetric, and the fusion matrices are diagonalized by $\rho(S)$ with *some* non-negative integer coefficients) which `verlindeInput_of_fusion` derives from Definition 21.11. `iModData_of_verlinde_pbw_inputs` fills the PBW input with `zhuPBWBottomInput_of_pbw`, and `iModData_holds` fills the other two with their proofs. The chain is thus a composition of proved statements.

Proof on paper. Let V be nice. (1) Zhu's theory, with the bottom projection, shows that the irreducible ordinary modules are the induced modules of the finitely many simple modules of the finite-dimensional semisimple algebra $A(V)$: this gives the finite complete irredundant list M_a with $M_0 \cong V$, the lowest weights h_a, and the weight-space description. (2) Zhu's modular invariance gives the characters as convergent q-series and a matrix $S = \rho(S)$ with $\mathrm{ch}_a(-1/\tau) = \sum_b S_{ab}\,\mathrm{ch}_b(\tau)$, and in fact the same law for every one-point function, i.e. S is pinned. (3) Anderson–Moore, applied to the characters, makes every h_a (and c) rational. (4) Huang's Verlinde theorem gives $S_{0x} \neq 0$ and $S_{0a} = S_{a0}$. (5) Put $S_{00} := S_{0,0}$ and $d_a := S_{a0}/S_{00}$. The d_a are the quantum dimensions; comparing the growth of $\mathrm{ch}_a(it)$ and $\mathrm{ch}_0(it)$ as $t \to 0^+$ (where $\mathrm{ch}_a(it) \sim S_{a0}\,\mathrm{ch}_0(i/t)$ and pseudo-unitarity makes the vacuum the unique minimal weight) shows $S_{00} > 0$ and $d_a \geq 1$. (6) Gannon's bound $|S_{ab}| \leq S_{00} d_a d_b$ follows from the Verlinde formula: S_{ab}/S_{0b} is an eigenvalue of the fusion matrix N_a, whose Perron–Frobenius eigenvalue is d_a. □

Physical meaning

The statement that a rational, positive-energy chiral algebra has a genuine modular tensor category's worth of data: a finite list of primaries with rational spins, characters forming a representation of the modular group, and quantum dimensions ≥ 1 bounding the S-matrix.

What the machine verified

Proved; Lean's three axioms (it uses the theorem `VOA.pbw`; while `VOA.pbw` was an axiom the report also listed `VOA.pbw`).

Theorem 21.14 (The pinned S-matrix is unique, and characters do not pin it). *(i) Let V be C_2-cofinite, let* Pr *be a bottom projection for the parabolic module induced from the regular Zhu module, and let D be modular data of V (*`D.IsModularData`*). If two matrices S, S' both satisfy the pinned law for D, then $S = S'$. (ii) Let D satisfy the old, character-only package* `IsModularDataWeak` *(every clause of* `IsModularData` *except the pinned law). Let a, b, b' be labels with $b \neq b'$ and $a, b, b' \neq$ vac, such that $\mathrm{ch}_b = \mathrm{ch}_{b'}$ on the upper half plane, and let $t \in \mathbb{C}$ satisfy $|S_{ab} + t| \leq S_{00} d_a d_b$ and $|S_{ab'} - t| \leq S_{00} d_a d_{b'}$. Then the data with S replaced by $S + t(E_{ab} - E_{ab'})$ still satisfy* `IsModularDataWeak`.

↪  → ℂ :=
  fun x y => D.S x y + (if x = a ∧ y = b then t else 0) - (if x = a ∧ y = b' then t else 0)
```

From the mathematics to the Lean statement

(i) `Pr`, `hC2` and `hD` are explicit hypotheses; `Pr` is the bottom-projection datum of Chapter 13, taken as an argument rather than built from `VOA.pbw`, so the theorem is axiom-clean but *conditional on* `Pr`; instantiating `Pr := voaPBWBottomProjection _` makes it hold for every C_2-cofinite V (`voaPBWBottomProjection` uses the theorem `VOA.pbw`). `D.SPinned S` is the pinned law $T_a(v, -1/\tau) = \tau^n \sum_b S_{ab} T_b(v, \tau)$ for square-bracket weight-n states v (Chapter 22, Definition 22.13). (ii) is the machine-checked counterexample that forced the repair of the modular-data package (Chapter 22, Warning 22.3.2): `IsModularDataWeak` is the structure `IsModularData` with the field `S_pinned` removed (`HuangModularObstruction.lean`); `withS D S'` is D with its matrix replaced by `S'`; `perturbS D a b b' t` adds t to the entry (a, b) and subtracts it from (a, b'); `hch` assumes two modules with equal characters (e.g. M and its contragredient M'). The bounds `hbd`, `hbd'` keep Gannon's inequality; when both inequalities are strict for $t = 0$, every t in a small disc qualifies, which is the "continuum" of wrong S-matrices quoted in Chapter 22. The conditions $a, b, b' \neq$ vac keep the vacuum row and column, hence S_{00} and the d_a, unchanged.

Proof on paper. (i) Subtracting the two pinned laws gives $\sum_b (S_{ab} - S'_{ab}) T_b(v, \tau) = 0$ for every v and every a. Zhu's one-point functions of a complete irredundant family of irreducible modules are linearly independent as functions of (v, τ) (Zhu; Dong–Li–Mason): the leading coefficient of $T_b(v, \tau)$ is the trace of $o(v)$ on the bottom $A(V)$-module of M_b, and traces of inequivalent simple modules of a finite-dimensional algebra are linearly independent. Hence $S_{ab} = S'_{ab}$. (ii) Every clause of `IsModularDataWeak` other than the S-law and the bounds does not mention S; in the S-law, the row a changes by $t(\mathrm{ch}_b - \mathrm{ch}_{b'}) = 0$; the vacuum entries are unchanged; the bounds are assumed. □

Physical meaning

Charge conjugation is invisible in the partition function but visible in correlators with insertions: characters cannot tell a sector from its conjugate, one-point functions can.

What the machine verified

Both proved, Lean's three axioms. (i) is **conditional on its explicit datum** `Pr` (a clean `##print axioms` does not report it); the PBW projection `voaPBWBottomProjection` discharges `Pr`, so (i) is then conditional only on its remaining explicit hypotheses `hC2` and `hD`.

21.5 The congruence property

Definition 21.15 (The two halves of `ICongruenceGalois`). *DLN congruence*: for every level N, characters are $\Gamma(N)$-invariant. *Galois symmetry, nontrivial case*: for $\ell \not\equiv \pm 1$ and $\gamma \equiv \mathrm{diag}(\ell, \ell^{-1})$, the character transformation is a signed permutation (`GaloisCase D γ`).

File `VOA/Huang/CongruenceGaloisSplit.lean`.

From the mathematics to the Lean statement

`GaloisCase D γ`: there are a permutation π of the labels (`D.ι ≃ D.ι`) and signs $\varepsilon_a = \pm 1$ with $\mathrm{ch}_a(\gamma\tau) = \varepsilon_a \, \mathrm{ch}_{\pi a}(\tau)$ on the upper half plane — exactly the clause of the Galois symmetry

of Chapter 22, Definition 22.15, for one γ. The hypothesis `ℓ * ℓ' ≡ 1 [ZMOD N]` makes ℓ invertible modulo N (no separate coprimality hypothesis is needed). **Why only $\ell \not\equiv \pm 1$ is a separate input.** If $\ell \equiv 1$, then $\gamma \equiv I \pmod N$, i.e. $\gamma \in \Gamma(N)$, and the congruence half gives `GaloisCase` with $\pi = \mathrm{id}$, $\varepsilon = 1$. If $\ell \equiv -1$, then $-\gamma \in \Gamma(N)$ and $-\gamma$ acts on $\mathbb{H}$ exactly as γ (`mobius_neg`), so the same applies. `iCongruenceGalois_of_split` assembles Chapter 22's `ICongruenceGalois` from the two halves; the Lean statement is the same as the textbook one.

Physical meaning

The torus partition functions of a rational CFT are modular functions for a congruence subgroup, and the Galois group of the cyclotomic field of the S-matrix permutes the sectors up to sign.

What the machine verified

Definitions (`Props`), stated for nice V. Both halves are proved, as the named hypothesis-free theorems `dlnCongruenceInput_holds` and `galoisSymmetryNontrivialInput_holds` (Theorem 21.20, added 2026-10-28), by `dln_inputs_of_beyl` (Theorem 21.18) applied to the proved Beyl facts. Before that revision the composition was formed only inside the proof of `gannonRayhaun_forward` (Chapter 22).

Theorem 21.16 (Ng–Schauenburg, kernel half: kernels of modular representations are congruence). *For every modular category there is $N > 0$ such that $\Gamma(N)$ acts by scalars in every lift of the categorical projective $\mathrm{SL}_2(\mathbb{Z})$-representation.*

```

From the mathematics to the Lean statement

Quantified over every $\mathbb{C}$-linear, preadditive, right-rigid, braided monoidal category with kernels and finite biproducts (the bracketed arguments are Mathlib's type classes for these structures), and a spherical fusion structure `F : SphericalFusion C` (a pivotal structure with spherical traces, finitely many simple objects indexed by `F.Label`) that is modular (`M : Modular F`: a ribbon twist with nondegenerate S-matrix, `NgSchauenburgModular.lean`). A representation ρ of $\mathrm{SL}_2(\mathbb{Z})$ on $\mathbb{C}^{\mathrm{Label}}$ is `IsModularRepresentation` if $\rho(S)$ is a nonzero multiple of the categorical S-matrix and $\rho(T)$ a nonzero multiple of the diagonal matrix of twists θ_i: a *lift* of the projective modular representation of the category. `InPrincipalCongruence N γ`: $\gamma \equiv I \pmod N$, i.e. $\gamma \in \Gamma(N)$. `ProjectiveKernelContainsGamma ρ N`: every $\gamma \in \Gamma(N)$ acts by a scalar. The N is chosen before ρ, so one level works for all lifts. **Vacuity.** The statement would be empty if no category satisfied the hypotheses; it is not: the DLN bridge applies it to the modular tensor category of a nice VOA (Section 21.3), where `IsModularRepresentation` is *proved* for the representation on characters (`DLNBridgeCategorical.lean`), and that application is what feeds the congruence property below. That application is made on a *small model*: the categorical structures are put on `canonicalModel`, a small category with a constructed braided monoidal equivalence to `Ordinary W`, and its `Modular` structure `modelModular` (`ZhuRepModel.lean`; a genuine determinant condition on the categorical S) takes a modular-data datum `D` with `D.IsModularData`, which exists by `iModData_holds`. There is no single declaration "`Ordinary W` is a modular tensor category". **Weaker than NS Theorem 6.8.** This is only the *kernel half* of NS Theorem 6.8: some $N > 0$ works. The other half — N is the Frobenius–Schur exponent, and is minimal — is the separate statement `ProjectiveCongruenceTheorem` (`NgSchauenburgCongruence.lean`), whose universal form `NSProjectiveCongruenceAll` is *not proved*; it occurs only as a hypothesis (of `zhuProjectiveCongruence_of_NS`, `dln_inputs_of_NS_twist`, `dln_inputs_of_categorical` and others). The correct wording is: "the kernel of the projective modular representation of a modular category contains a principal congruence subgroup".

Proof on paper. Ng–Schauenburg (2010, Thm. 6.8): generalized Frobenius–Schur indicators are invariant under a Galois action and satisfy $\nu_{n,k}$-relations that force the T-eigenvalues and the image of $\Gamma(N)$ to behave as in a congruence quotient. □

Physical meaning

Modular invariance of anyon theories is "arithmetic": the modular group acts through a finite quotient.

What the machine verified

Proved (kernel half of NS 6.8 only), standard axioms (the docstring of the definition still says "not proved in this file", true but misleading). The Frobenius–Schur-exponent half is open.

Definition 21.17 (Beyl's Schur-multiplier facts)**.** A homomorphism $r : B \to A$ has *trivial inflation* if for every central extension $\pi : E \to A$ (surjective, with central kernel) and every commuting square $\pi \circ \alpha = r \circ \beta$ with $\alpha : F \to E$, $\beta : F \to B$, every commutator element $x \in [F,F]$ with $\beta(x) = 1$ has $\alpha(x) = 1$. Beyl: the reduction $\mathrm{SL}_2(\mathbb{Z}/2N) \to \mathrm{SL}_2(\mathbb{Z}/N)$ has trivial inflation. The library splits this into: odd prime powers (trivial Schur multiplier of $\mathrm{SL}_2(\mathbb{Z}/p^k)$), the prime 3, the 2-adic inflation for exponents ≥ 2, and a Gauss-chart relation for primes $p \geq 5$.

```

File `VOA/Huang/DLNBeylInflation.lean`.

```
def SchurTrivial (Q : Type*) [Group Q] : Prop := InflationTrivial (MonoidHom.id Q)
```

From the mathematics to the Lean statement

The definitions are homology-free reformulations (no group cohomology in the statement). `commutator F` is the commutator subgroup $[F,F]$; `π.ker ≤ Subgroup.center E` says the extension is central. The Lean definition quantifies over all commuting squares, not only the pullback; this is equivalent (any commuting square maps to the pullback, and commutators map to commutators). "Trivial Schur multiplier" is `SchurTrivial Q`, i.e. `InflationTrivial (MonoidHom.id Q)`: taking $F = E$, $\alpha = \mathrm{id}$, $\beta = \pi$, it says $\ker\pi \cap [E,E] = 1$ for every central extension, which by Hopf's formula is $H_2(Q,\mathbb{Z}) = 0$ (for the finite groups considered). `reductionMod (2 * N) N _` is the reduction $\mathrm{SL}_2(\mathbb{Z}/2N) \to \mathrm{SL}_2(\mathbb{Z}/N)$. `SLm(p ^ k)` is $\mathrm{SL}_2(\mathbb{Z}/p^k)$. `GaussLowerRelations` is an explicit relation in a presentation of $\mathrm{SL}_2(\mathbb{Z}/p^k)$ by Gauss-chart generators; `primePower_coprime_two_three` supplies the coprimality of p^k to 6 that the presentation needs. The extension groups `E`, `F` range over `Type` (universe 0), which is enough since all groups involved are finite.

Physical meaning

These group-theoretic facts are what let a projective representation of $\mathrm{SL}_2(\mathbb{Z})$ that factors projectively through a congruence quotient be lifted to a genuine one with the same kernel — the step from Ng–Schauenburg's projective statement to DLN's linear one.

What the machine verified

Definitions (`Prop`s). All proved: Theorem 21.18.

Theorem 21.18 (Beyl's facts and the DLN inputs). *The three residuals hold, and with Ng–Schauenburg they imply both halves of the congruence input.*

```

From the mathematics to the Lean statement

How the three proved residuals reach the two DLN inputs: `OddPrimePowerSchur` (all odd primes p, all $k \geq 1$) is equivalent to the conjunction of the prime-3 statement `ThreePowerSchur` and a root-relation statement for primes $p \geq 5$, which is in turn equivalent to `LargePrimeGaussLowerRelations`. Since `threePowerSchur` and `largePrimeGaussLowerRelations` are proved, so is `OddPrimePowerSchur`; with `twoPowerInflationFromTwo_holds` this feeds `dln_inputs_of_beyl`, whose conclusion is *both* halves of Definition 21.15. The last quotation shows the use in the forward classification (Chapter 22, `gannonRayhaun_beyl_fine` makes the composition with the two equivalences explicit). The Ng–Schauenburg ingredients enter inside `dln_inputs_of_lifting`, through the proved statement `nsMixedNonzeroSMoveAll_holds` (an S-move nonvanishing fact from the same NS analysis); the standalone `nsProjectiveKernelAll_holds` of Theorem 21.16 is a sibling result of that analysis rather than a literal argument of this chain.

Proof on paper. For odd p, $\mathrm{SL}_2(\mathbb{Z}/p^k)$ has a presentation in which every central extension splits (Mennicke; Beyl): the library verifies the defining relations in an arbitrary central extension, by explicit computations in Gauss-chart coordinates (for $p \geq 5$) and separately for $p = 3$, where an extra relation is needed. The 2-adic case is a finite inflation computation. DLN's Theorem 2.1 then lifts Ng–Schauenburg's projective congruence statement to the linear representation on characters. □

Physical meaning

The modular group acts on the torus partition functions of a rational CFT only up to phases (the central charge anomaly $e^{2\pi ic/24}$ and the choice of normalisation of the S-move). Vanishing of the relevant Schur multipliers says these phases can be fixed consistently, so that the honest, linear action on characters also factors through a finite congruence quotient: no anomaly obstructs it.

What the machine verified

The three Beyl facts are proved, standard axioms. `dln_inputs_of_beyl` is **conditional on its two explicit hypotheses** `hodd`, `htwo`; both are proved, and `dln_inputs_of_beyl` itself does not discharge them; the resulting hypothesis-free congruence theorem is stated in `VOA/Huang/CongruenceNamed.lean` (Theorem 21.20, `dlnCongruence_and_galois_holds`). Standard axioms (the route passes through the theorem `VOA.pbw`, via the tensor category).

The named congruence theorems (added 2026-10-28). Until this revision the congruence property was proved only inside the proof term of `gannonRayhaun_forward`: every declaration whose conclusion was `DLNCongruenceInput`, `GaloisSymmetryNontrivialInput` or the kernel form `ZhuCongruenceInput` took hypotheses (release audit, finding F2). The file `VOA/Huang/CongruenceNamed.lean` now states these as named theorems with *no* hypotheses, assembled from proved pieces only. Two caveats are unchanged and must be stated with them: they are proved for *nice* V only (pseudo-unitarity, Definition 21.1), and the categorical input is only the *kernel half* of Ng–Schauenburg's Theorem 6.8 (Theorem 21.16). The kernel form needs one more piece of vocabulary.

Definition 21.19 (Zhu datum on the labels of D; kernel containment; the kernel form of congruence). Let V be nice and D its modular data (Section 21.1). A *Zhu datum on the labels of D* is a Zhu modular datum D' (Chapter 15, Definition 15.31: a family of irreducible modules with weights and a representation $\rho = \rho_{D'} : \mathrm{SL}_2(\mathbb{Z}) \to \mathrm{Mat}_{D.\iota}(\mathbb{C})$ with $\rho(S)$ and $\rho(T)$ specified) whose modules and weights are those of D and which satisfies Zhu's analytic modularity law. A representation ρ *contains $\Gamma(N)$ in its kernel* if $\rho(\gamma) = 1$ for every $\gamma \in \Gamma(N) = \{\gamma \equiv I \bmod N\}$. The *kernel form of the congruence property* says: for every nice V, every such D and every Zhu datum D' on its labels, there is $L > 0$ with $\Gamma(L) \subseteq \ker \rho_{D'}$.

File `VOA/Huang/DLNBridge.lean`.

```
def IsZhuDatum (D : VOA.Classification.COne.ModularData V) (hD : D.IsModularData)

```
theorem exists_zhuData (hW : Nice W) (D : VOA.Classification.COne.ModularData W)
    (hD : D.IsModularData) :
    ∃ D' : VOA.ModularData W D.ι, D'.Mfam = famOf D hD ∧ D'.h = hOf D ∧
      ZhuModularityAnalytic D' := by
```

From the mathematics to the Lean statement

Two "modular data". `D : VOA.Classification.COne.ModularData V` is the classification package of Section 21.1; `D' : VOA.ModularData V D.ι` is Zhu's data of Chapter 15, indexed by the same label type `D.ι`. `famOf D hD` is the family of modules of `D`, bundled as irreducible modules (irreducibility comes from `hD`), and `hOf D` is the family of weights h_a of `D`, cast from $\mathbb{Q}$ to $\mathbb{C}$ (`VOA/Huang/SPinning.lean`). `ZhuModularityAnalytic D'` is Zhu's transformation law for all torus one-point functions (Chapter 15, Definition 15.31). So `IsZhuDatum D hD D'` says exactly: D' is Zhu's modular datum on D's modules and weights, and its `rep` is Zhu's representation ρ_V.
`SL2Z` abbreviates `Matrix.SpecialLinearGroup (Fin 2) ℤ` $= \mathrm{SL}_2(\mathbb{Z})$; `→*` is a group homomorphism into the multiplicative monoid of matrices (so a genuine, not projective, representation); `CongruenceSubgroup.Gamma N` is Mathlib's principal congruence subgroup $\Gamma(N)$. `KernelContainsGamma ρ N` (namespace `VOA.Huang.DLN`) is $\Gamma(N) \subseteq \ker\rho$, with *no* scalar discarded; contrast `ProjectiveKernelContainsGamma` of Theorem 21.16, which allows $\rho(\gamma)$ to be a scalar. (A homonymous `KernelContainsGamma` for representations on a vector space exists in `NgSchauenburgCongruence.lean`; the one used here is the matrix version.) `ZhuCongruenceInput` is the kernel form: some $L > 0$ with $\Gamma(L) \subseteq \ker\rho_V$. The condition `0 < L` excludes the vacuous $\Gamma(0) = \{1\}$.
Non-vacuity. `exists_zhuData` proves that for every nice V and every modular datum D a Zhu datum on its labels exists (it is built from Zhu's modularity theorem, Chapter 15); and modular data D with `D.IsModularData` exist for every nice V (`iModData_holds`, Theorem 21.13). So the universal quantifiers in `ZhuCongruenceInput` range over non-empty sets, and the statement is about the actual ρ_V.

Physical meaning

ρ_V is the matrix by which a modular transformation acts on the torus one-point functions of the rational CFT, i.e. on its genus-one conformal blocks. "$\Gamma(L)$ lies in the kernel" says that the torus blocks are modular functions for the principal congruence subgroup of level L: the modular group acts on them through the finite group $\mathrm{SL}_2(\mathbb{Z}/L\mathbb{Z})$.

What the machine verified

Definitions (`Props`); `exists_zhuData` proved, Lean's three standard axioms (the route passes through the theorem `VOA.pbw`). The kernel form is proved in Theorem 21.20.

Theorem 21.20 (The Dong–Lin–Ng congruence property, named and hypothesis-free, for nice V)**.** *Let V be a nice VOA, D its modular data, ρ_V Zhu's representation on the labels of D (any Zhu datum D' on them).*

1. *(*Character form.*) For every level N of D, every $\gamma \in \Gamma(N)$, every label a and every τ with* $\operatorname{Im}\tau > 0$*:* $\mathrm{ch}_a(\gamma\tau) = \mathrm{ch}_a(\tau)$.
2. *(*Galois symmetry, nontrivial case.*) For every level N, every ℓ invertible modulo N with $\ell \not\equiv \pm 1$, and every $\gamma \equiv \mathrm{diag}(\ell, \ell^{-1}) \pmod N$, γ acts on the characters by a signed permutation.*
3. *(*Kernel form.*) There is $L > 0$ with $\Gamma(L) \subseteq \ker\rho_V$.*
4. *(*Kernel form at every level.*) For every level N of D, $\Gamma(N) \subseteq \ker\rho_V$.*

From the mathematics to the Lean statement

Namespace `VOA.Huang.CongruenceNamed`; `u` is the universe of the VOA's carrier, and each theorem holds for every `u`. **The statements.** The first four theorems have *no* arguments: their types are the `Prop`s of Definitions 21.15 and 21.19, which already quantify over all nice VOAs, all modular data, all levels, etc. So `dlnCongruenceInput_holds` is item 1, `galoisSymmetryNontrivialInput_holds` item 2 (their conjunction is `dlnCongruence_and_galois_holds`), and `zhuCongruenceInput_holds` item 3. `zhu_kernelContainsGamma_at_level` is item 4, stated pointwise: given V, `hV : Nice V`, D with `hD`, a Zhu datum D' with `hZD`, and a level N (`D.IsLevel N`: $N > 0$ and $N(h_a - c/24) \in \mathbb{Z}$ for all a), it concludes $\Gamma(N) \subseteq \ker \rho_{D'}$. Every hypothesis of item 4 is satisfiable for every nice V (dictionary of Definition 21.19), and every hypothesis quantified inside items 1–3 is the intended one (Section 21.1).

The proof terms (shown because they are informative). Items 1–2: `dln_inputs_of_beyl` (Theorem 21.18) applied to `OddPrimePowerSchur`, obtained from the proved `largePrimeGaussLowerRelations` through the proved equivalence `oddPrimePowerSchur_iff_largePrimeGaussLowerRelations`, and to `twoPowerInflationFromTwo_holds`: exactly the composition that the release audit compiled as `audit_dln_congruence`. Item 3: `zhuCongruence_of_beyl`, which lifts projective congruence of ρ_V to linear congruence using Beyl's inflation theorem `BeylInflationSL2` (here from `beylInflationSL2_of_large`), applied to the projective congruence of ρ_V, which `zhuProjectiveCongruence_of_NSKernel` derives from the kernel half of Ng–Schauenburg (`nsProjectiveKernelAll_holds`, Theorem 21.16) and from DLN's Theorem 3.10, that ρ_V is a modular representation of a modular category (`zhuModularRepresentationInput_holds`, `VOA/Huang/ZhuRepInput.lean`). Item 4: `kernel_at_level` applied to item 3.

Same, stronger, or weaker than Dong–Lin–Ng? DLN's Theorem I: for a rational, C_2-cofinite, self-dual VOA of CFT type, $\ker \rho_V$ is a congruence subgroup of level $n = \operatorname{ord} \rho_V(T)$, and the characters are modular functions for $\Gamma(n)$. (a) The hypothesis here is *nice*, i.e. additionally pseudo-unitary: **weaker than DLN** in scope. (b) For nice V, item 4 gives

DLN's level exactly, on paper: $\rho_V(T) = \mathrm{diag}(e^{2\pi i(h_a - c/24)})$, so the levels N of D are precisely the positive N with $\rho_V(T)^N = 1$, i.e. the positive multiples of n; n itself is a level, and item 4 at $N = n$ is $\Gamma(n) \subseteq \ker \rho_V$. (Conversely no smaller level is possible, since $T^{n'} \in \Gamma(n')$.) This reading is a two-line argument on paper, not a separate Lean statement. (c) `DLNCongruenceInput` (item 1) concerns characters only; it does not by itself say anything about $\ker \rho_V$, which is why items 3–4 are stated separately. (d) Only the kernel half of Ng–Schauenburg 6.8 is used. The statement that the projective level equals the Frobenius–Schur exponent (`ProjectiveCongruenceTheorem`, `NSProjectiveCongruenceAll`) is *not* proved and is *not* used.

How it could have been vacuous, and why it is not. The quantified `Props` would be empty if no nice VOA, no modular datum or no Zhu datum existed. V_2 is nice (`V2m_nice`, Chapter 22); modular data exist for every nice V (`iModData_holds`); Zhu data on them exist (`exists_zhuData`).

Proof on paper. Let $\mathcal{C}$ be the modular tensor category of V (Section 21.3). By DLN Theorem 3.10, $\rho_V(S)$ and $\rho_V(T)$ are nonzero multiples of the categorical S-matrix and of the twist matrix, so ρ_V lifts the projective modular representation of $\mathcal{C}$. The kernel half of Ng–Schauenburg gives $N_0 > 0$ such that $\Gamma(N_0)$ acts on it by scalars: ρ_V is *projectively* congruence. To remove the scalars, one shows that a projective representation of $\mathrm{SL}_2(\mathbb{Z})$ trivial on $\Gamma(N_0)$ up to scalars becomes a linear one trivial on some $\Gamma(L)$: the obstruction lives in the Schur multipliers of $\mathrm{SL}_2(\mathbb{Z}/N)$, and Beyl's computation (trivial multiplier for odd prime powers, plus the 2-adic inflation) kills it; this gives item 3. DLN's Lemma A.1 then improves "some L" to "the order n of $\rho_V(T)$", hence to every level (item 4). Item 1 follows because $\mathrm{ch}_a(\gamma\tau) = \sum_b \rho_V(\gamma)_{ab}\,\mathrm{ch}_b(\tau)$ (Zhu's law at the vacuum) and $\rho_V(\gamma) = 1$ for $\gamma \in \Gamma(N)$. Item 2 is DLN's Theorem II (Coste–Gannon Galois symmetry), whose proof uses the same lifting together with the Galois action on the cyclotomic field generated by the entries of ρ_V. □

Physical meaning

The torus partition function of a rational CFT with positive energies is a modular function for $\Gamma(N)$, where N is the smallest integer making all the phases $e^{2\pi i N(h_a - c/24)}$ trivial; the modular group acts on the genus-one blocks through the finite group $\mathrm{SL}_2(\mathbb{Z}/N\mathbb{Z})$, and the cyclotomic Galois group permutes the sectors up to sign. This is the statement physicists use to constrain characters of rational theories (modular linear differential equations, the "bootstrap" of rational CFTs).

What the machine verified

Proved, hypothesis-free, for nice V (strongly rational *and* pseudo-unitary) only; only the kernel half of Ng–Schauenburg 6.8 is used. `#print axioms` of all five declarations: `[propext, Classical.choice, Quot.sound]` (2026-10-28; Section 21.9). This discharges the release audit's finding F2.

21.6 Deligne's theorem and the Huang–Kirillov–Lepowsky extension

Definition 21.21 (Deligne's theorem, positive-dimension (Tannakian) case, as used by GR). A symmetric fusion category over $\mathbb{C}$ whose simple objects all have positive braided dimension is braided-equivalent, by a $\mathbb{C}$-linear functor, to $\mathrm{Rep}(G)$ for a finite group G.

```

From the mathematics to the Lean statement

`SymmetricCategory`: braided with $c_{Y,X}c_{X,Y} = \mathrm{id}$. `FusionCategory D`: a finite family of simple objects (Mathlib's `Simple`: every monomorphism into it is zero or an isomorphism), one of them isomorphic to the unit, pairwise non-isomorphic, such that every object is a finite direct sum ($\oplus$, a biproduct) of them, with finite-dimensional Hom-spaces; $\mathrm{End}\,\mathbf{1} = \mathbb{C}$ is then a theorem (`finrank_end_unit`). `symDim X` is the composite $\mathbf{1} \xrightarrow{\eta} X \otimes X^{\vee} \xrightarrow{c} X^{\vee} \otimes X \xrightarrow{\varepsilon} \mathbf{1}$ read as a scalar (`toScalar`): the categorical dimension computed with the symmetric braiding; it is $\dim V$ in $\mathrm{Rep}(G)$ and -1 for the odd line in super vector spaces. `FDRep ℂ G`: finite-dimensional complex representations of G. `Φ.Braided`, `Φ.Linear ℂ`, `Φ.IsEquivalence`: the functor is braided monoidal, linear, and an equivalence. The positivity hypothesis excludes super vector spaces (where the odd line has dimension -1); this is the bosonic form, the one GR need. It is Deligne 1990 / EGNO §9.9 in the fusion case, *not* Deligne's 2002 theorem (every symmetric fusion category is $\mathrm{Rep}(G, z)$, super case included), which is not formalized.

Physical meaning

A set of anyons that braid trivially with each other and have bosonic statistics is the representation category of an ordinary global symmetry group; they can be condensed (the symmetry gauged or ungauged).

What the machine verified

From the mathematics to the Lean statement

`FGModuleCat ℂ` is the category of finite-dimensional complex vector spaces. A *fiber functor* `ω` is a braided (`Nonempty ω.Braided`: a braided monoidal structure on the functor exists), $\mathbb{C}$-linear, faithful functor to it. `SymmetricFiberFunctorExists`: every symmetric fusion category with positive braided dimensions has one. `FiberFunctorReconstruction`: a symmetric fusion category with a fiber functor is braided-equivalent to $\mathrm{Rep}(G)$ for a finite group G (no positivity hypothesis is needed once the fiber functor is given). `deligneTannakian_holds` is the hypothesis-free theorem `DeligneTannakian`; its proof term composes the existence of the fiber functor with reconstruction (`deligneTannakian_of_symmetricFiberFunctorExists` has `fiberFunctorReconstruction` built in). Universes: `D : Type u` with morphisms in `Type v`; the group `G` is in `Type`. Same as Deligne's theorem in its bosonic, fusion form.

Proof on paper. In the fusion case Deligne's theorem has an elementary proof (EGNO §9.9): positivity of dimensions makes the symmetric category "even", and a fiber functor is built from a commutative algebra object of dimension equal to the global dimension; Tannaka reconstruction then identifies the category with the representations of the automorphism group of the fiber functor. □

Physical meaning

A fiber functor is "forgetting which representation a state is in": it realizes each anyon of the symmetric category as an ordinary vector space of internal states. Reconstruction says

the symmetries of this forgetting form a finite global symmetry group G, and the anyons are exactly its charges — the Wilson lines of a G gauge theory.

What the machine verified

Proved, Lean's three axioms (`deligneTannakian_holds`).

Definition 21.23 (HKL extension inputs)**.** For nice V, a commutative haploid algebra A in Rep V with trivial twist defines a VOA extension (Huang–Kirillov–Lepowsky). *HKLRationalInput*: that extension is rational. *HKLFrobeniusDimInput*: for a copairing c of A satisfying a zigzag identity with $q \circ \mu$, the composite $\mu \circ c : \mathbf{1} \to A$ is nonzero (a nondegeneracy of the Frobenius structure, slightly weaker than nonvanishing of the categorical dimension).

```

From the mathematics to the Lean statement

`MonObj A`, `IsCommMonObj A`: A is an algebra object (A, μ, η) of the braided category, commutative ($\mu \circ c_{A,A} = \mu$) (Mathlib). `(twistIso A).hom = 𝟙 A`: trivial twist $\theta_A = e^{2\pi i L_0} = 1$, i.e. integer conformal weights. `finrank ℂ (𝟙 ⟶ A) = 1`: haploid (V appears exactly once in A). **The extension VOA.** `extVOA` builds a VOA on the carrier of A from the multiplication $m = \mu$ and the unit η: its vertex operator `extField F m a` is the intertwining operator $\mu \circ \mathcal{Y}_{A,A}(a, z)$ (the universal intertwiner followed by the multiplication), its grading is the L_0-grading of A (integral by `htw`), its vacuum $\eta(\mathbf{1})$. The left and right unit laws `hl`, `hr` are those of the algebra object (supplied by `MonObj.one_mul`, `MonObj.mul_one`). The three remaining hypotheses are those that are not automatic: `hloc`, *locality* of any two extension fields (this is HKL's Theorem 3.2, where commutativity of A is used); `hvac`, the weight-0 space of A is spanned by the vacuum; `hpos`, no negative weights — together, CFT type. In `HKLRationalInput` these three appear as `∀ hloc hvac hpos`: the claim is made for every proof of them, so it says "*whenever* the extension is a VOA of CFT type, it is admissibly rational". Locality is then discharged separately (`hklLocalityInput_holds`), and the CFT-type hypotheses are supplied where the input is used (the Tannakian step of Chapter 22). `IsFrobeniusCounit A q`: there is a copairing $c : \mathbf{1} \to A \otimes A$ satisfying the zigzag identity `Zig₁` with the pairing $q \circ \mu$; i.e. $q \circ \mu$ is a nondegenerate invariant form on A. **The dimension input.** In `HKLFrobeniusDimInput` the conclusion `c ≫ MonObj.mul ≠ 0` says that $\mu \circ c : \mathbf{1} \to A$ is nonzero. Since $\mathrm{Hom}(\mathbf{1}, A) = \mathbb{C}\eta$ (haploid), $\mu \circ c = \lambda\eta$ and the categorical dimension of A computed with this Frobenius structure is $\lambda\,(q \circ \eta)$; the Lean conclusion is $\lambda \neq 0$, which is implied by (and slightly weaker than) "$\dim A \neq 0$". Note also that `q` is not assumed to be a counit in this Prop; the zigzag hypothesis on `c` already forces $q \circ \mu \neq 0$.

Physical meaning

Condensing a set of bosonic anyons that form a commutative algebra produces a larger chiral algebra; HKL says the result is again a rational chiral algebra.

What the machine verified

Both proved: `hklFrobeniusDimInput_holds`, `hklRationalInput_holds`; they use the theorem `VOA.pbw`.

Theorem 21.24 (`ITannakian` from Deligne and HKL). *Deligne's theorem and the repaired Huang–HKL interface imply the Tannakian input of Chapter 22.*

```

From the mathematics to the Lean statement

`HuangHKLInterfaceRigid`: for every nice V with modular data D there is a *ribbon realization* `H` — a ribbon category of V-modules whose simple objects, twists and S-matrix are those of D (Huang's theorem, packaged) — with the extension property `HKLExtensionPropertyRigid`: for every commutative, haploid, trivially twisted algebra A carrying an action of a finite group G by algebra automorphisms with $\sum_g \rho(g) = \eta \circ q$ (the shape of the regular algebra $\mathrm{Fun}(G)$) and a Frobenius counit q, there are a nice VOA W of the same central charge and a finite $\Gamma \leq \mathrm{Aut}\, W$ with $V \cong W^\Gamma$ and $\dim W_n = \sum_i \dim \mathrm{Hom}(A, X_i) \dim (M_i)_n$ (X_i the simple objects) — precisely the conclusion shape of `ITannakian`. `HKLRepInputRigid` asks the extension property for every realization that is the actual module category `Rep V` (`IsRepRealization H`). `huangHKLInterfaceRigid_of_hklRepRigid` gets the interface from it, with Huang's half (that `Rep V` is such a realization) proved. **Where the hypotheses go.** `iTannakian_of_rigid` has two `Prop` hypotheses; in the forward chain they are instantiated as displayed in `gannonRayhaun_huang_rigid`: Deligne by the two proved theorems of Theorem 21.22, and the interface by `HKLRepInputRigid`. The latter is proved through the chain `hklRepInputRigid_of_ordinary` (from locality `hklLocalityInput_holds`, CFT type `hklCFTTypeInput_holds`, and niceness of extensions `hklNiceInput_of_rational`) with `hklRationalInput_holds`, as composed in the theorems `gannonRayhaun_hkl_two`, `gannonRayhaun_hkl_nice`, `gannonRayhaun_hkl_rational`, `gannonRayhaun_hkl_dim`, `gannonRayhaun_hkl_final` of `VOA/Huang/HKL*.lean`. The library has no standalone `theorem … : ITannakian` (Chapter 22, Warning on standalone theorems); the instance exists only inside this chain, whose endpoint is the hypothesis-free forward theorem. Universes: the realization is taken at `.{u, 0, 0}` and Deligne at `.{0, 0}`. **A recorded trap.** The source records an earlier, unrepaired input `HKLRepInput` that is *false* as stated (its docstring in `HKLExtRigid.lean`); `HKLRepInputRigid` restricts it to nondegenerate (Frobenius) algebras, and `hklRepInputRigid_of_hklRepInput` shows nothing provable was lost.

Proof on paper. If $S_{ab} = S_{00} d_a d_b$ on the integer-weight sectors, they form a symmetric fusion subcategory with positive dimensions (Müger), hence $\mathrm{Rep}(G)$ by Deligne. The regular algebra $\mathrm{Fun}(G)$ transported to $\mathrm{Rep}\, V$ is commutative, haploid, with trivial twist and a Frobenius counit; HKL turns it into a VOA extension W, nice by `hklRationalInput_holds`, with $W^G \cong V$ and $W \cong \bigoplus_{h_a \in \mathbb{Z}} d_a M_a$ as graded spaces. □

Physical meaning

Condensing ("ungauging") the bosonic, mutually transparent anyons of a rational CFT: they are the Wilson lines of a finite gauge group G, and condensing them produces the parent theory W in which G is an ordinary global symmetry; the original theory is the G-orbifold of W.

What the machine verified

`iTannakian_of_rigid` is proved, Lean's three axioms, **conditional on its two displayed hypotheses**. Both hypotheses are discharged inside the forward chain (dictionary above), using the theorem `VOA.pbw`; there is no single named theorem of type `ITannakian`.

21.7 The logarithmic braided tensor category

What it is for. The converse of the Gannon–Rayhaun classification needed one input, `FiniteV2OrbifoldRationalOfC2Fact`, the rationality of the exceptional orbifolds: every C_2-cofinite fixed-point algebra V_2^G of a finite group is rational. It is proved by formalizing McRae's *orbifold* theorem (arXiv:1910.13226, Thm. 4.20 and Cor. 4.23: if V is strongly rational and V^G is C_2-cofinite for a finite group G, then V^G is strongly rational) for $V = V_2$; the whole argument, in seven steps, is presented in Chapter 22, Section 22.9. McRae works in the braided tensor category $\mathcal{C}$ of finite-length generalized ("logarithmic") V^G-modules, because a C_2-cofinite VOA that is not yet known to be rational may have modules on which L_0 is not diagonalizable. This section documents that category: its objects, the finiteness theorem that makes the tensor product land in it (Step 1 of that argument, *finitely many irreducibles*), and the monoidal and braided structures with the pentagon and both hexagons proved (Step 2, *the braided tensor category of logarithmic modules*). Nothing in this section is used by the forward theorem or by distinctness. An earlier plan for proving orbifold rationality (McRae's rationality criterion, arXiv:2108.01898) needed in addition rigidity, factorizability and unimodularity of $\mathcal{C}$; those remain open (`CoverDualLitFact`, Chapter 22, Section 22.9.12) and are *not* needed.

No semisimple Zhu algebra. The logarithmic constructions need, at one point, that a C_2-cofinite VOA has only finitely many irreducible modules. That was previously available only under the hypothesis that Zhu's algebra is semisimple (`hss`). It is now proved without it.

Theorem 21.25 (Finitely many irreducibles for C_2-cofinite VOAs)**.** *Every C_2-cofinite VOA has only finitely many isomorphism classes of irreducible ordinary modules.*

From the mathematics to the Lean statement

`IrrModule W` bundles an irreducible ordinary module (carrier, module structure, irreducibility), and `IrrModule.setoid W` is the relation "isomorphic as modules"; `Φ W` is the set of isomorphism classes (Chapter 12). `Finite (Φ W)`: there are finitely many. The only hypothesis is `C2Cofinite W`; in the primed form the bottom projection `Pr` is an explicit datum (axiom-free, conditional on `Pr`), in the `_pbw` form it is supplied by `voaPBWBottomProjection`, so that form uses the theorem `VOA.pbw` and is conditional only on C_2. The older `finite_Φ_of_C2Cofinite` (`ZhuFiniteIrr.lean`) carries the extra hypothesis `hss : IsSemisimpleRing (A W)`; the new statements are strictly more general. The fourth quotation is the consumer: the canonical "maximal compatible" module $M_1 \boxtimes M_2$ built from two finitely generated logarithmic modules has finite length, again with only `hC2`. The named literature predicate `DLMFinitelyManyIrredAdmissible` of Chapter 12 (finitely many irreducible *admissible* modules) is derived from `finite_Φ_of_C2Cofinite` for every C_2-cofinite VOA, using that its irreducible admissible modules are ordinary (`dlmFinitelyManyIrredAdmissible_of_c2Cofinite`, Theorem 12.40); it is not an input of this chapter. `LogVModule` is a grading-restricted generalized (logarithmic) module, `FinGen` finite generation, `modeAlg B` the algebra generated by the modes acting on `B`, `IsFiniteLength` finite composition length. The definitions downstream (`maximalLogModule` and the $P(z)$-tensor products built on it) no longer take `hss`.

Proof on paper. C_2-cofiniteness makes Zhu's algebra $A = A(W)$ finite-dimensional, hence Artinian, so $A/J(A)$ (J the Jacobson radical) is a semisimple module, a finite direct sum of simple modules. Every simple A-module U is killed by $J(A)$ and receives the nonzero map $A/J(A) \to U$, $\bar{a} \mapsto a \cdot u$, so by Schur it is isomorphic to one of those finitely many summands. The bottom level of an irreducible ordinary module is a simple A-module, and (with the bottom projection, Zhu's induced-module construction) irreducible modules with isomorphic bottoms are isomorphic. Hence $\Phi(W)$ injects into a finite set. Semisimplicity of A was never needed. □

Physical meaning

A C_2-cofinite ("lisse") chiral algebra has finitely many primary fields, even when the theory is logarithmic and the sectors do not split into irreducibles.

What the machine verified

`finite_Φ_of_C2Cofinite'`: Lean's three axioms, conditional on `Pr`; `finite_Φ_of_C2Cofinite_pbw`: proved, Lean's three axioms (re-probed at an earlier commit, not re-run for this edition; while `VOA.pbw` was an axiom, also `VOA.pbw`). The files are committed (since the snapshot) and imported by the umbrella `VOA/Classification.lean`; the aggregate `lake build` was green on 2026-10-14 (13,306 jobs, coordinator; green again on 2026-10-28, 18,901 jobs, and later 18,907, in pre-release builds; for the release build see Chapter 43, Section 43.1.9), and `finite_Φ_of_C2Cofinite_pbw` is in the maintained audit with expected axioms `PBW_AXIOMS` (now defined to be the standard three). **Consequence for the converse**: the proof of the rationality of the exceptional orbifolds uses this theorem, hence `VOA.pbw`; the converse is unconditional, like the forward theorem (Chapter 22, Theorem 22.59).

The logarithmic braided category: what is built. The files `VOA/Huang/Log*.lean`, `VOA/Modules/LogTensor*.lean`, `VOA/Modules/LogModuleCategory.lean` and `VOA/Classification/COne/McRaeM2*.lean` develop the Huang–Lepowsky–Zhang logarithmic tensor category on finitely generated generalized modules of a C_2-cofinite VOA: logarithmic intertwining operators and skew-symmetry; finiteness of logarithmic fusion; the logarithmic contragredient; $P(z)$-tensor products with their universal property; uniform bounds on logarithmic degree; convergence of products and iterates of logarithmic intertwining operators; equality of products and iterates on the overlap of their domains; the categorical tensor objects, unit isomorphisms, the associator as a natural isomorphism and the triangle identity; and, completed after the snapshot, the pentagon, the braiding, both hexagons, and the packaging as Mathlib `MonoidalCategory` and `BraidedCategory`. The semisimple-Zhu hypothesis `hss`, which earlier versions of these files carried, is gone: it was used only through the finiteness theorem above.

Definition 21.26 (The category $\mathcal{C}_W$ of logarithmic modules)**.** For a VOA W, an object of $\mathcal{C}_W$ is a grading-restricted generalized W-module (a logarithmic module, Chapter 12, Definition 12.8) which is finitely generated; morphisms are linear maps commuting with all modes.

File `VOA/Modules/LogModuleCategory.lean`.

```
structure LogModuleCat (W : VertexOperatorAlgebra V) where
  carrier : Type u
  [group : AddCommGroup carrier]
  [module : Module ℂ carrier]
  act : LogVModule W carrier
  finiteGeneration : FinGen act.toWeakModule
```

From the mathematics to the Lean statement

`carrier : Type u` is the underlying vector space, in the same universe `u` as the carrier `V` of W. `act : LogVModule W carrier` is the logarithmic module structure: a weak module with a $\mathbb{C}$-grading by generalized L_0-eigenspaces, finite-dimensional pieces and real parts of weights bounded below. `FinGen act.toWeakModule`: finitely many vectors generate the module under all modes. Morphisms (same file) are `moduleHomSpace`, the linear maps commuting with every mode $u_{(n)}$; the category is $\mathbb{C}$-linear (`Preadditive`, `Linear ℂ` instances). For a C_2-cofinite W, finitely generated is the same as finite length (Huang's theorem for C_2-cofinite VOAs), so this is McRae's category of "finite-length generalized modules". That equivalence is a fact from the literature, *not* a single Lean theorem: the definition uses finite generation, and the library proves finite length where it needs it (for instance `finiteLength_maximal_of_c2` above).

Physical meaning

The sectors of a possibly logarithmic chiral CFT: each has finitely many primaries and descendants up to any given energy, and L_0 may have Jordan blocks (logarithmic partners).

What the machine verified

Definition; Lean's three axioms.

Theorem 21.27 (The logarithmic associator and the triangle identity)**.** *Let W be C_2-cofinite. For all objects N, P, Q of $\mathcal{C}_W$ there is an isomorphism $\alpha_{N,P,Q} : (N \boxtimes P) \boxtimes Q \to N \boxtimes (P \boxtimes Q)$ of $\mathcal{C}_W$, natural in N, P, Q, whose maps are the associativity maps obtained by analytically continuing products of logarithmic intertwining operators to iterates. Together with the left and right unit isomorphisms $\lambda_P : W \boxtimes P \to P$ and $\rho_N : N \boxtimes W \to N$ it satisfies the triangle identity*

$$(\mathrm{id}_N \boxtimes \lambda_P) \circ \alpha_{N,W,P} = \rho_N \boxtimes \mathrm{id}_P : (N \boxtimes W) \boxtimes P \to N \boxtimes P.$$

File `VOA/Classification/COne/McRaeM2LogAssociator.lean`.

```
def associatorIso (N P Q : LogModuleCat W) :
    tensorObject hC2 (tensorObject hC2 N P) Q ≅
      tensorObject hC2 N (tensorObject hC2 P Q) where
```

File `VOA/Classification/COne/McRaeM2LogTriangle.lean`.

```
theorem associatorIso_triangle (N P : LogModuleCat W) :
    (associatorIso hC2 N unitObject P).hom ≫
      tensorMorphism hC2 (𝟙 N) (leftUnitIso hC2 P).hom=
    tensorMorphism hC2 (rightUnitIso hC2 N).hom (𝟙 P) := by
```

From the mathematics to the Lean statement

`LogModuleCat W` is the category of finitely generated logarithmic modules of W; `tensorObject hC2 N P` is the logarithmic $P(z)$-tensor product $N \boxtimes P$ (built on `maximalLogModule` above), `tensorMorphism` its action on morphisms, `unitObject` the adjoint module, `leftUnitIso`, `rightUnitIso` the unitors. `associatorIso` is an isomorphism $(N \boxtimes P) \boxtimes Q \cong N \boxtimes (P \boxtimes Q)$ whose maps are the analytically constructed associativity maps (their source docstring: no associativity or coherence witness is supplied as an extra premise); `associatorIso_naturality` (same file) proves naturality; `associatorIso_triangle` is the triangle identity $(1 \otimes \lambda) \circ \alpha = \rho \otimes 1$. The Lean statements are exactly Theorem 21.27, with $\otimes$ for $\boxtimes$ and $\gg$ for composition in diagrammatic order.

Proof on paper. By the universal property, a map out of $(N \boxtimes P) \boxtimes Q$ is determined by its values on the canonical elements, i.e. on iterates $Y_{\boxtimes}(Y_{\boxtimes}(n, z_1 - z_2)p, z_2)q$. For $|z_1| > |z_2| > |z_1 - z_2| > 0$ such an iterate converges and agrees with a product $Y_{\boxtimes}(n, z_1)Y_{\boxtimes}(p, z_2)q$ of intertwining operators into $N \boxtimes (P \boxtimes Q)$ (convergence and associativity of logarithmic intertwining operators, which is where C_2-cofiniteness and the finite-length theorem enter); sending the first to the second defines α, and the same construction in the opposite direction gives its inverse. Naturality is the uniqueness part of the universal property. For the triangle, put $p = \mathbf{1}$: both sides send the canonical element built from $n, \mathbf{1}, q$ to the one built from n, q, by the vacuum property $Y(\mathbf{1}, z) = \mathrm{id}$ and the creation property $Y(n, z)\mathbf{1} = e^{zL_{-1}}n$. □

Physical meaning

Associativity of fusion of sectors up to the F-move, and its compatibility with the vacuum sector.

What the machine verified

Proved; Lean's three axioms (it uses the theorem `VOA.pbw`; while `VOA.pbw` was an axiom the report also listed `VOA.pbw`) (through the finite-length theorem above).

Theorem 21.28 (The logarithmic pentagon). *For every C_2-cofinite W and objects N, P, Q, R of $\mathcal{C}_W$, the two composites of associators $((NP)Q)R \to N(P(QR))$ agree:* $(1 \boxtimes \alpha_{P,Q,R}) \circ \alpha_{N,PQ,R} \circ (\alpha_{N,P,Q} \boxtimes 1) = \alpha_{N,P,QR} \circ \alpha_{NP,Q,R}$.

File `VOA/Huang/LogAssocTensorPentagonReduction.lean`.

```

      tensorObject hC2 N (tensorObject hC2 P (tensorObject hC2 Q R)) :=
  tensorMorphism hC2 (associatorIso hC2 N P Q).hom (𝟙 R) ≫
    (associatorIso hC2 N (tensorObject hC2 P Q) R).hom ≫
      tensorMorphism hC2 (𝟙 N) (associatorIso hC2 P Q R).hom
```

File `VOA/Classification/COne/McRaeM2LogPentagon.lean`.

```
theorem tensorPentagon (N P Q R : LogModuleCat W) :
    tensorPentagonLong hC2 N P Q R=tensorPentagonShort hC2 N P Q R := by
```

From the mathematics to the Lean statement

`hC2 : C2Cofinite W` is a section variable. `≫` is composition in diagrammatic order, so `tensorPentagonLong` is $(1 \boxtimes \alpha) \circ \alpha \circ (\alpha \boxtimes 1)$ and `tensorPentagonShort` is $\alpha \circ \alpha$, both with the specific `associatorIso` of this section. This is exactly Mac Lane's pentagon, and it is the `pentagon` field of the monoidal category below.

Proof on paper. Evaluate both sides on the canonical elements $\eta(n, p, q, r)$ of the fourfold tensor product, i.e. test them on iterated products of four logarithmic intertwining operators at points $(z_1, z_2, z_3, 0)$. Each associator converts a product of two intertwiners into an iterate on the common domain where both converge; the two paths of the pentagon thus lead to two of the five bracketings ("trees") of a five-point function. Step one: all five trees converge absolutely at suitable chart ratios (for instance $(1 + s)/(1 + s + r)$ and $1/(1 + s)$ for one tree), the two trees that are not literal products being reduced to products by a reflection of the root. Step two: the two paths agree after evaluation, by the already proved two-intertwiner associativity applied along the path. Step three (faithfulness): a two-variable power-log series $\sum c_{m,n,k,l}\, r^m s^n (\log r)^k (\log s)^l$ with summable rows that vanishes on an open set has all coefficients zero (apply the one-variable uniqueness first in r for fixed s, then in s); hence the two morphisms agree on every canonical element and are equal by the universal property. □

Physical meaning

The two ways of fusing four sectors into one agree: crossing symmetry of logarithmic five-point conformal blocks, the pentagon identity for logarithmic F-matrices.

What the machine verified

Proved; the only hypothesis is `hC2`. Lean's three axioms (it uses the theorem `VOA.pbw`; while `VOA.pbw` was an axiom the report also listed `VOA.pbw`) (re-checked at the snapshot with `lake env lean -DmaxSynthPendingDepth=3`).

theorem logarithmicMonoidalCategory_tensorUnit :
    (logarithmicMonoidalCategory hC2).tensorUnit=unitObject := rfl
```

From the mathematics to the Lean statement

`MonoidalCategory.ofTensorHom` is Mathlib's constructor of a monoidal category from a tensor structure (`logarithmicTensorStruct hC2`: tensor objects `tensorObject`, tensor of morphisms `tensorMorphism`, unit, associator, unitors) together with proofs of each axiom; each named argument is one axiom, and each is supplied by a proved theorem: functoriality of $\boxtimes$ (`tensorBifunctor`), naturality of associator and unitors, the pentagon (Theorem 21.28) and the triangle (`associatorIso_triangle`). As for the strongly rational category (Theorem 21.5), the bare type `MonoidalCategory (LogModuleCat W)` is not the content; the three `rfl` lemmas pin the tensor product to the HLZ product `tensorObject`, the associator to `associatorIso`, and the unit to the adjoint module `unitObject`. No coherence datum is taken as a hypothesis.

Proof on paper. Each axiom is one of the theorems listed; the pentagon is Theorem 21.28. □

Physical meaning

Fusion of logarithmic sectors is a consistent, associative operation with the vacuum as identity.

What the machine verified

Constructed; the only hypothesis is `hC2`. Lean's three axioms (it uses the theorem `VOA.pbw`; while `VOA.pbw` was an axiom the report also listed `VOA.pbw`) (re-checked at the snapshot).

Theorem 21.30 (The logarithmic braided category). *For every C_2-cofinite W, the monoidal category of Theorem 21.29 is braided, with braiding $c_{X,Y} : X \boxtimes Y \to Y \boxtimes X$ induced by the skew-symmetry operator Ω_0.*

```
abbrev braidingIso (N P : LogModuleCat W) : tensorObject hC2 N P ≅ tensorObject hC2 P N :=
  swapIso hC2 N P 0
```

From the mathematics to the Lean statement

`BraidedCategory` is Mathlib's (Theorem 21.6): a natural isomorphism $c_{X,Y}$ with both hexagons. Its five fields are supplied by proved theorems. `swapIso hC2 N P r` is the isomorphism $N \boxtimes P \cong P \boxtimes N$ induced by the HLZ skew-symmetry operator Ω_r, $\Omega_r(Y)(w_2,z)w_1 = e^{zL_{-1}}Y(w_1, e^{(2r+1)\pi i}z)w_2$; the braiding uses the branch $r = 0$, its inverse is induced by Ω_{-1}. `hexagon_forward` is Mathlib's first hexagon $\alpha \circ c_{X,YZ} \circ \alpha = (1 \boxtimes c_{X,Z}) \circ \alpha \circ (c_{X,Y} \boxtimes 1)$ (diagrammatic order in Lean); `hexagon_reverse` (same file) is the second. The `rfl` lemma pins the braiding to `swapIso … 0`. The only hypothesis is `hC2`.

Proof on paper. *Naturality* of c comes from its definition through the universal property. *Hexagon.* Test both paths $(X \boxtimes Y) \boxtimes Z \to Y \boxtimes (Z \boxtimes X)$ on completed canonical iterates with x at $1+u$, y at 1, z at 0. (1) Skew-symmetry at a branch: on each weight block, $\Omega_r(Y)(y,e^{\ell})x = \sum_j \frac{e^{j\ell}}{j!} L_{-1}^j Y(x, e^{\ell+\kappa_r})y$ with $\kappa_r = (2r+1)\pi i$, the phases cancelling because $e^{-\kappa_r} = -1$. (2) An inner translation theorem: an iterate whose inner operator is $\Omega_r(Y)$ equals the iterate of Y with translated argument, proved by Taylor expansion of the L_{-1}-derivative and Cauchy estimates. (3) Products continue analytically to a half-plane, because each row of a product solves a rational Fuchsian equation with its only finite singularity at 1. (4) Four local expansions of the two paths are matched pairwise (associativity twice, then skew-symmetry combined with the binomial identity $e^{(1+u)L}e^{-uL} = e^{L}$ for $L = L_{-1}$) on overlapping discs and glued around a common point; the identity theorem gives equality. The second hexagon is the first for the reverse braiding Ω_{-1}, inverted. □

Physical meaning

Exchanging two logarithmic sectors along a half-turn is compatible with fusion: the logarithmic R-moves satisfy the hexagon identities with the F-moves.

What the machine verified

Constructed; the only hypothesis is `hC2`. Lean's three axioms (it uses the theorem `VOA.pbw`; while `VOA.pbw` was an axiom the report also listed `VOA.pbw`); re-probed at an earlier commit (not re-run for this edition): standard three. `logarithmicBraidedCategory` is in the maintained audit (`PBW_AXIOMS`, now equal to the standard three). Rigidity of $\mathcal{C}_W$, factorizability, unimodularity and genus-one logarithmic modularity are **not** proved; they are not needed for the classification. The orbifold route that uses this category is in Chapter 22, Section 22.9.

21.8 Traps and documentation defects

Traps

1. **The old fusion coefficient is identically zero** (`fusionCoeff`, Chapter 12); all fusion here uses `IsIntertwiningOperator` and `fusionRule`.
2. **Characters do not pin** S (Theorem 21.14(ii)).
3. **The tensor category depends on a fusion choice** `F`; any two choices give equivalent categories, but statements are made per choice.

Scope restrictions recorded by the release audit (2026-10-27)

None of these is a defect of a statement; each is a place where a careless summary would overclaim.

1. **Pseudo-unitarity.** Rigidity, Verlinde, `IModData`, the modular model and congruence assume `Nice` (strongly rational *and* pseudo-unitary). Huang and Dong–Lin–Ng need no pseudo-unitarity. The hypothesis was used in two places. The first (`VerlindeVacuumFusion.lean` l. 132, $V' \cong V$) is now avoided via self-duality: `contra_vacuum_equiv_of_stronglyRational` and the `_of_stronglyRational` copies of the vacuum-fusion chain (Theorem 21.10). The second (`CardyPositivity.lean` l. 210, `vacColumn_mem_K`) is essential and keeps `Nice`. The headline theorems are still stated for `Nice`.
2. **Right rigidity only** — *removed 2026-10-28*: two-sided rigidity is `rigid_ordinary` (Theorem 21.8); still for nice V only.
3. **Verlinde in the proved form** (Definition 21.11): no $S = S^T$, index universe `u+1`.
4. **Congruence: kernel half of NS 6.8 only.** The "no named theorem" caveat is *removed 2026-10-28*: the named hypothesis-free theorems are in Theorem 21.20. What remains: only the kernel half of NS 6.8 is proved and used (Theorem 21.16); the results are for nice V; and `DLNCongruenceInput` concerns characters (the kernel form is `zhuCongruenceInput_holds`).
5. **Deligne** is the positive-dimension case (Definition 21.21).
6. **The modular tensor category** exists only on the small model `canonicalModel` with a datum `D` (Theorem 21.16, dictionary).

Documentation defects (docstrings only; no statement affected). The docstrings of `NSProjectiveKernelAll` ("not proved in this file"), `BeylInflationSL2` ("Unproved here"), `DeligneTannakian` ("Not proved here") and the module docstring of `MainVerlindeProved.lean` ("still CONDITIONAL on …") describe the state of their own file, but all these `Prop`s are now proved elsewhere and the forward theorem is hypothesis-free. The release audit (2026-10-27) adds: docstrings that still call `VOA.pbw` an axiom (`PentagonCloseMain.lean`, `HexagonCloseResidual.lean`, `MainVerlindeProved.lean`: "the sanctioned axiom", "Lean's three + `VOA.pbw`"), and docstrings that call proved residuals unproved (`TensorCatEvaluation.lean`, `TensorCatNatural.lean`: summability, faithfulness and range equality, all proved by `ordinaryFourPointInput_pbw`); about twenty-two files in `VOA/Huang/` carry such phrasing, and the `_pbw` suffix itself suggests an axiom dependence that no longer exists. These are being corrected separately.

21.9 Verification record for the 2026-10-28 additions

The two files `VOA/Huang/RigidOrdinary.lean` and `VOA/Huang/CongruenceNamed.lean` are committed, but their compiled modules were *missing* from the main checkout's `.lake`, and no `lake build` was run for this revision. The reviser ran `lake env lean -DmaxSynthPendingDepth=3` on a scratch file importing `VOA.Huang.CongruenceNamed` and `VOA.Huang.RigidOrdinary` from the root of the `release-cheap` worktree, whose compiled modules include both (built 2026-10-27) and whose copies of both files are byte-identical to the main checkout's (`cmp`). Output (line breaks joined; peak RSS 6.1 GB):

```
'VOA.Huang.CongruenceNamed.dlnCongruence_and_galois_holds' depends on axioms: [propext,

 ↪  Quot.sound]
```

The build record is the project's (`Notes/RELEASE_PLAN.md`, "Caveats removed in Lean", 2026-10-28: merged from `release-cheap`, umbrellas green, axioms standard). The aggregate build was green on 2026-10-28 (18,901 jobs, and later 18,907, in pre-release builds; for the release build see Chapter 43, Section 43.1.9); the addition of these declarations to the maintained axiom audit is still to be confirmed (release audit, findings F2 and F11).

21.10 Referee's checklist

A trailing `VOA.pbw` in the status column means that the proof goes through the theorem `VOA.pbw` (an axiom at the snapshot, a theorem since); such entries now report the standard three axioms, so it records a route, not an axiom dependence. "Nice" means strongly rational *and* pseudo-unitary.

Declaration	Intended meaning	Status	Fidelity

Verification record. Quotations checked verbatim by `scripts/textbook/sync.py`; axiom reports as stated in the status boxes (re-probed at an earlier commit, not re-run for this edition); for the

2026-10-28 additions see Section 21.9. Release audit 2026-10-27: see Notes/Textbook/referee/RELEASE_AUDIT_L21.md. (The auditor re-ran `#print axioms` on the six headlines, `iModData`-related inputs and `gannonRayhaun_forward`: Lean's three standard axioms only; instantiated every headline at V_2; and did not run `lake build`, which must be re-confirmed on the release commit.)

Chapter 22

The classification of nice central-charge-one vertex operator algebras (Gannon–Rayhaun)

This chapter was first written against an earlier state of the LeanVOA library *together with the working tree of 2026-10-13* (the book's snapshot). The files that prove the *converse* (Sections 22.9 and 22.10: the logarithmic tensor category, the McRae orbifold argument and `MainConverseFinal.lean`) were added *after* the snapshot, in the commits that followed it (2026-10-13, 23:45, through 2026-10-14); this revision of the chapter was checked against the last of those commits. Checks that were run at an earlier state of the library and not re-run for this edition are marked as such. Every Lean quotation was copied mechanically from the source files and is machine-checked by `scripts/textbook/sync.py` to occur verbatim (up to whitespace and comments) in the source files of the release documented by this edition. The chapter covers the directory `VOA/Classification/` (about 1750 files) and the umbrella `VOA/Classification.lean`. The deep representation-theoretic inputs — Huang's modular tensor category, the Verlinde formula, the Huang–Kirillov–Lepowsky extension theory, the Dong–Lin–Ng congruence theorem and Ng–Schauenburg — live in `VOA/Huang/` and are the subject of Chapter 21; here they appear as named theorems whose statements we quote and whose proofs we only sketch.

We rely on earlier chapters and do not repeat them: Lean idioms (structures, `Prop`-valued definitions, universes, `∃`/`∀`, `Nonempty`, `≃*`, `HasSum`, `finrank`) in Chapter 1; vertex operator algebras, the conformal vector, `centralCharge` and the grading `V.grading n` in Chapters 4 and 5; automorphism groups `Aut W` and fixed-point subalgebras `orbifoldVOA G` in Chapters 31 and 32; lattice vertex algebras `latticeVOAGen` and the lift `thetaAut` of -1 in Chapters 6, 31 and 32; ordinary modules `OrdVModule`, irreducibility, `ModuleEquiv`, `adjointModule`, weight spaces, C_2-cofiniteness, admissible rationality, self-duality and `StronglyRational` in Chapter 12 (Sections 12.2, 12.9 and 12.9.7); one-point functions, square-bracket weights and Zhu's modularity theorem in Chapters 14 and 15; the Virasoro Kac determinant in Chapter 7.

What this chapter is about, in one paragraph. A two-dimensional conformal field theory with central charge $c = 1$ is, in the simplest cases, a single free boson. Its chiral algebra is a vertex operator algebra of central charge 1. Gannon and Rayhaun (arXiv:2609.00122, Theorem 3.1) proved that a vertex operator algebra which is *nice* — strongly rational and pseudo-unitary — and has $c = 1$ is isomorphic to exactly one of the following: the lattice VOA V_{2m} of the rank-one lattice $\sqrt{2m}\,\mathbb{Z}$ ($m \geq 1$); its $\mathbb{Z}_2$-orbifold V_{2m}^+ ($m \geq 2$); or one of the three *exceptional orbifolds* $V_2^{A_4}$, $V_2^{S_4}$, $V_2^{A_5}$ of $V_2 \cong L_{\mathfrak{sl}_2}(1,0)$ by the tetrahedral, octahedral and icosahedral subgroups of $\mathrm{Aut}\, V_2 \cong \mathrm{PSL}_2(\mathbb{C})$. Conversely every VOA in this list is nice. The library formalizes the three parts of this theorem: the *forward classification* (nice and $c = 1$ implies in the list), *pairwise distinctness* (no VOA carries two

labels), and the *converse* (everything in the list is nice).

The findings of this chapter, in brief. Read these first; each is explained where it occurs.

1. **The forward classification is proved with no hypothesis** (`VOA.Classification.COne.gannonRayhaun_forward`, Theorem 22.28). Its `##print axioms` is Lean's three standard axioms (re-probed at an earlier commit, not re-run for this edition; at the snapshot it also listed `VOA.pbw`, then a project axiom). It is unconditional. It uses the PBW theorem `VOA.pbw` (Chapter 3) through the modular-data package `iModData_holds` (Chapter 21).

2. **Pairwise distinctness is proved with no hypothesis and without** `VOA.pbw` (`gannonRayhaunDistinct`, Theorem 22.32), by computing the graded dimensions of the exceptional orbifolds in weights 4 and 16 exactly (Molien's formula).

3. **The converse is proved with no hypothesis, and so is the whole classification** (`gannonRayhaunConverse_holds` and `gannonRayhaun_classification`, Theorem 22.59). The last input of the converse was `FiniteV2OrbifoldRationalOfC2Fact`, the *rationality of the exceptional orbifolds*: every C_2-cofinite fixed-point algebra V_2^G of a finite group is rational. It is now a theorem, `finiteV2OrbifoldRationalOfC2`, proved by formalizing McRae's orbifold theorem (arXiv:1910.13226) for $V = V_2$ in seven steps (Section 22.9): the braided tensor category of logarithmic V_2^G-modules, V_2 as a rigid commutative algebra in it, McRae's projections onto g-twisted parts, the monodromy argument making each twisted part an untwisted $V_2^{\langle g\rangle}$-module, the rationality of $V_2^{\langle g\rangle} \cong V_{2n^2}$, McRae's Lemma 4.21, and the passage from split surjections to rationality. The historical reduction `gannonRayhaunConverse_of_B3` is kept (the `B3` in this and other Lean names is the project's internal label for the rationality of the exceptional orbifolds); its hypothesis is now proved. `##print axioms gannonRayhaun_classification` is Lean's three axioms (re-probed at an earlier commit, not re-run for this edition; at the snapshot also `VOA.pbw`). The proof of the converse uses `VOA.pbw` through the logarithmic tensor category (every categorical step uses it, through the finiteness theorem proved in Step 1 of that argument); since `VOA.pbw` is now a theorem, **the whole classification is unconditional**. The three parts are stated together in universe `0` (Remark 22.38).

4. **"Rational" is the library's `AdmissiblyRational`, and "universe" matters.** The rationality conjunct of `Nice` is `AdmissiblyRational` (weak submodules of admissible modules have weak complements). Its relation to Dong–Li–Mason rationality, which Gannon–Rayhaun use, is **not settled in Lean**; only DLM-rational ⇒ `AdmissiblyRational` is known, on paper. So the forward theorem covers every Lean-nice VOA, a class that contains every DLM-nice VOA by the paper direction, and the converse is proved in the library's sense (Remark 22.4). The classification and the converse are stated for carriers in `Type 0` only; the forward theorem and distinctness hold in every universe (Remark 22.38).

5. **The modular-data input had to be repaired once.** An earlier form of the modular-data package constrained the S-matrix only through characters; it was *satisfied by a continuum of wrong S-matrices* (machine-checked counterexample `isModularDataWeak_perturbS`). The current definition pins S on all one-point functions (`SPinned`); see Warning 22.3.2.

6. **Lean defects found while writing** (Section 22.11): stale docstrings that still say "not proved here" for statements now proved (`PlusExceptionalResidual` and `ExceptionalResidual` in `Distinct.lean`, `GannonRayhaunDistinct` and `GannonRayhaunConverse` in `Statement.lean`), and docstrings of the orbifold route that still call `TwistedJacobiBridge` and `TwistedJacobiBridgeAll` "open" although both are proved; no single declaration packages each input as a theorem of the form `IVirasoro` or `ISerreStark24` (they are discharged inside the assembly chain). None of these affects any statement.

22.1 The theorem and its physics

22.1.1 The free boson and its rational points

Let $\varphi(z)$ be a chiral free boson: a field with operator product expansion $\partial\varphi(z)\,\partial\varphi(w) \sim -(z-w)^{-2}$. The current $J = i\partial\varphi$ generates the Heisenberg vertex algebra $M(1)$ of Chapter 6, of central charge 1. Its irreducible modules are Fock spaces $M(1,p)$ labelled by a momentum $p \in \mathbb{C}$, with lowest conformal weight $p^2/2$. A *compact* boson takes values in a circle; its momenta are then quantized, and if the radius is rational in suitable units, finitely many momentum sectors close under fusion. Algebraically: for an even lattice $L = \sqrt{2m}\,\mathbb{Z}$ (so that $\alpha^2/2 = m$ for the generator α), the lattice VOA

$$V_{2m} = V_{\sqrt{2m}\mathbb{Z}} = \bigoplus_{n\in\mathbb{Z}} M(1, n\sqrt{2m})$$

is a vertex operator algebra of central charge 1 containing the vertex operators $e^{\pm\alpha}$ of weight m. Its character is

$$\mathrm{ch}_{V_{2m}}(\tau) = \frac{\theta_{0,1,m}(\tau)}{\eta(\tau)}, \qquad \theta_{0,1,m}(\tau) = \sum_{n\in\mathbb{Z}} q^{mn^2}, \quad \eta(\tau) = q^{1/24}\prod_{k\geq 1}(1-q^k), \tag{22.1}$$

with $q = e^{2\pi i\tau}$. The automorphism θ of Chapter 32, the lift of -1 on L ($\varphi \mapsto -\varphi$), has fixed-point subalgebra V_{2m}^{+}. At $m = 1$ the weight-one space of V_2 is three-dimensional, spanned by $\alpha(-1)\mathbf{1}$ and $e^{\pm\alpha}$, and forms $\mathfrak{sl}_2$; in fact $V_2 \cong L_{\mathfrak{sl}_2}(1,0)$, the $SU(2)$ level-one WZW chiral algebra, and $\mathrm{Aut}\,V_2 \cong \mathrm{PSL}_2(\mathbb{C})$ acts through the adjoint group. Its finite subgroups are those of $SO(3)$ (Klein): cyclic, dihedral, tetrahedral A_4, octahedral S_4, icosahedral A_5.

Physical meaning

The moduli space of $c = 1$ unitary conformal field theories (Ginsparg 1988, Dijkgraaf–Verlinde–Verlinde 1988) consists of the *circle line* (a compact boson of radius R), the *orbifold line* ($S^1/\mathbb{Z}_2$), meeting at a point, and three *isolated* theories obtained by orbifolding the $SU(2)_1$ point by the tetrahedral, octahedral and icosahedral groups. The Gannon–Rayhaun theorem is the *chiral* shadow of this picture: the rational points of the circle line have chiral algebra V_{2m}, those of the orbifold line V_{2m}^{+}, and the three isolated theories have chiral algebras $V_2^{A_4}, V_2^{S_4}, V_2^{A_5}$. The theorem says that, among chiral algebras with good representation theory and positive energies, there is nothing else. This is a heuristic correspondence between full CFTs and chiral algebras; the theorem itself is a statement about vertex operator algebras only.

22.1.2 Why the hypotheses

Strongly rational (Chapter 12, Definition 12.43) means: simple, of CFT type (built into the library's `VertexOperatorAlgebra`), self-dual, C_2-cofinite and rational. These are exactly Huang's hypotheses for $\mathrm{Rep}(V)$ to be a modular tensor category, which is what makes modular-form arguments possible. *Pseudo-unitary* means that every irreducible module other than V itself has strictly positive lowest conformal weight; in a unitary theory this is automatic (energies are positive and only the vacuum has energy zero). Without it there are non-unitary rational $c = 1$ VOAs that the theorem would have to list. The Heisenberg VOA $M(1)$ has $c = 1$ but is not C_2-cofinite, so it is excluded by the hypothesis, as it should be: it has a continuum of irreducible modules.

22.2 The statement layer

All definitions of this section are in `VOA/Classification/COne/Statement.lean`, which proves nothing about the classification; it only fixes the vocabulary. Throughout, $\mathcal{V}$ is the carrier type of a vertex

operator algebra `V : VertexOperatorAlgebra 𝒱` (Chapter 4).

Definition 22.1 (Isomorphism of VOAs)**.** Two VOAs V and T are *isomorphic* if there is a linear bijection $e : V \to T$ with $e(\mathbf{1}) = \mathbf{1}$, $e(u_{(n)}v) = e(u)_{(n)}e(v)$ for all u, v, n, and $e(\omega_V) = \omega_T$.

File `VOA/Classification/COne/Statement.lean`.

```
def VOAIsomorphic (V : VertexOperatorAlgebra 𝒱) (T : VertexOperatorAlgebra 𝒲) : Prop :=
  ∃ e : 𝒱 ≃ₗ[ℂ] 𝒲, IsVOAHom V T e.toLinearMap ∧ e V.conformalVector = T.conformalVector
```

From the mathematics to the Lean statement

$\mathcal{V} \simeq_{\mathrm{l}}[\mathbb{C}] \mathcal{W}$ is a $\mathbb{C}$-linear equivalence (Chapter 1). `IsVOAHom V T e.toLinearMap` is the library's VOA homomorphism predicate (Chapter 5): it preserves the vacuum and every n-th product. The extra clause `e V.conformalVector = T.conformalVector` makes the isomorphism respect conformal vectors, hence gradings and central charges; without it two VOA structures with the same vertex algebra but different conformal vectors (which exist, e.g. a Heisenberg VOA with shifted ω) would count as isomorphic. The two VOAs may live in *different* universes (`u` and `v`); this matters for the converse (Remark 22.38). Same as the textbook notion.

Physical meaning

Two chiral algebras are "the same theory" when there is a dictionary of states preserving the vacuum, all operator product expansions and the stress tensor. Preserving $T(z)$ is essential: the same algebra of fields can carry several stress tensors, which describe physically different theories (different spins).

What the machine verified

Definition. It is reflexive, symmetric and transitive (`VOAIsomorphic.symm`, `.trans` in `Conditional.lean`).

Definition 22.2 (Pseudo-unitarity; Gannon–Rayhaun Def. 2.4)**.** A VOA V is *pseudo-unitary* if for every irreducible ordinary V-module $M \not\cong V$ and every $\alpha \in \mathbb{C}$ with $M_\alpha \neq 0$, $\operatorname{Re}\alpha > 0$.

File `VOA/Classification/COne/Statement.lean`.

```
def PseudoUnitary (V : VertexOperatorAlgebra 𝒱) : Prop :=
  ∀ (M : Type u) [AddCommGroup M] [Module ℂ M] (N : OrdVModule V M),
    N.IsIrreducible → IsEmpty (ModuleEquiv V N (adjointModule V)) →
      ∀ α : ℂ, N.weight α ≠ ⊥ → 0 < α.re
```

From the mathematics to the Lean statement

The quantifier `∀ (M : Type u) …` ranges over all ordinary modules (`OrdVModule`, Chapter 12, Definition 12.5) whose carrier lives in the universe of V. `N.IsIrreducible`: no proper nonzero submodule. `IsEmpty (ModuleEquiv V N (adjointModule V))`: N is *not* isomorphic to the adjoint module V. `N.weight α ≠ ⊥`: the L_0-eigenspace of eigenvalue α is nonzero. The conclusion asks for $\operatorname{Re}\alpha > 0$ for *every* weight, not only the lowest; since the weights of an irreducible ordinary module lie in $h+\mathbb{N}$ with h the lowest weight, this is equivalent to $\operatorname{Re} h > 0$. GR write $h > 0$; for a rational VOA all conformal weights are rational (Dong–Li–Mason), so $\operatorname{Re} h > 0$ and $h > 0$ agree. **Could it be vacuous?** If V had no irreducible modules other than itself (a holomorphic VOA) the condition holds trivially — correctly so. It is not satisfied by every VOA: it is false for the Lee–Yang model (Chapter 19), whose nonvacuum module has $h = -1/5$.

Physical meaning

In a unitary CFT the Hamiltonian $L_0 + \bar{L}_0$ is positive and the vacuum is the unique state of zero energy, so every nonvacuum primary has positive weight. Pseudo-unitarity keeps this consequence without demanding a positive inner product. It is equivalent (for strongly rational V) to the quantum dimensions $d_a = S_{a0}/S_{00}$ being ≥ 1, which is how it is used below.

What the machine verified

Definition. Satisfied by every V_{2m} (`V2m_pseudoUnitary`, Theorem 22.33).

Definition 22.3 (Nice; Gannon–Rayhaun Def. 2.6)**.** V is *nice* if it is strongly rational and pseudo-unitary.

File `VOA/Classification/COne/Statement.lean`.

```
def Nice (V : VertexOperatorAlgebra 𝒱) : Prop :=
  StronglyRational V ∧ PseudoUnitary V
```

From the mathematics to the Lean statement

`StronglyRational V` is Definition 12.43 of Chapter 12: simple, self-dual (nondegenerate invariant bilinear form), C_2-cofinite and admissibly rational, with CFT type built into `VertexOperatorAlgebra`. Simplicity, self-duality, C_2-cofiniteness and CFT type match GR Def. 2.1. **Rationality does not literally match.** GR's "rational" is Dong–Li–Mason's: every admissible module is a direct sum of simple admissible modules. The library's `AdmissiblyRational` (Chapter 12) asks that every *weak* submodule (a mode-stable subspace, not necessarily level-graded) of an admissible module have a weak complement. The relation between the two readings is **not settled in Lean**: the library's own note (`VOA/Modules/AdmissibleRationality.lean`, ll. 80–91) says that neither implication is proved. Only one direction is known on paper: DLM-rational ⇒ `AdmissiblyRational`, by DLM's Theorem 8.1 (every admissible module of a DLM-rational VOA is a direct sum of simple ordinary modules, so every weak submodule is complemented). The converse direction is unchecked. Note also that `StronglyRational` uses `SelfDual`, not the vacuous `SelfContragredient` recorded in Chapter 12.

The structure theorems behind niceness are proved. The standard consequences of strong rationality that Gannon–Rayhaun take from the literature — regularity (Abe–Buhl–Dong, Thm. 4.5), finitely many irreducible admissible modules, all of them ordinary (Dong–Li–Mason, Thm. 8.1(b),(c)) and hence Gannon-rationality — are theorems of the library for every `StronglyRational` V, with no literature hypothesis: `StronglyRational.regular`, `StronglyRational.finite_Φadm` and `StronglyRational.gannonRational'` (Chapter 12, Theorem 12.44; `VOA/Classification/COne/LiteratureInputsProved.lean`, `#print axioms` standard three at an earlier commit, not re-run for this edition). They are proved from the library's `AdmissiblyRational` and `C2Cofinite`, so they do not settle the comparison with Dong–Li–Mason rationality described above. The one named literature predicate of Chapter 12 that remains unproved, H. Li's "regular ⇒ C_2-cofinite" (`LiC2CofiniteOfRegular`), is not used anywhere in this chapter.

Remark 22.4 (What the rationality convention means for the classification)**.** Write "Lean-nice" for `Nice` (with `AdmissiblyRational`) and "DLM-nice" for Gannon–Rayhaun's niceness (with Dong–Li–Mason rationality). Then:

- **The forward theorem** (Theorem 22.28) is proved for every Lean-nice VOA with $c = 1$. By the paper direction DLM-rational ⇒ `AdmissiblyRational`, every DLM-nice VOA is Lean-nice, so the forward theorem covers every DLM-nice VOA, i.e. it implies Gannon–Rayhaun's

Theorem 3.1 as stated — *but that implication rests on an on-paper argument (DLM Theorem 8.1), not on Lean.*

- **The converse** (Theorem 22.59) proves that every listed VOA is Lean-nice, i.e. nice *in the library's sense.* It does not prove DLM complete reducibility for the listed VOAs; that would need the direction `AdmissiblyRational` ⇒ DLM-rational, which is not known in Lean.
- **The classification** is therefore an "if and only if" for Lean-niceness. Read as a statement about GR's niceness, the forward half holds by the paper argument above and the converse half is the library's notion.

The release audit (`Notes/Textbook/referee/RELEASE_AUDIT_L22.md`, finding M1) sketches a graded-projection argument for the missing direction (take the degree-0 part, for the level grading, of the projection onto a level-graded submodule along a weak complement); it is offered as a pointer and is not checked.

Physical meaning

"Nice" collects what a physicist assumes of a rational chiral algebra of a unitary CFT: finitely many primaries, closed fusion, a modular-invariant set of characters, and positive energies.

What the machine verified

Definition. Satisfiable: V_{2m} and V_{2m}^{+} are nice (Theorems 22.33 and 22.34).

Definition 22.5 (The rank-one lattice VOAs and their $\mathbb{Z}_2$-orbifolds)**.** For $m \geq 1$, V_{2m} is the lattice VOA of $\sqrt{2m}\,\mathbb{Z}$; θ is the lift of -1; V_{2m}^{+} is the fixed-point subalgebra of the cyclic group generated by θ.

File `VOA/Classification/COne/Statement.lean`.

```
noncomputable def V2m (m : ℕ) (hm : 1 ≤ m) : VertexOperatorAlgebra (LatModuleGen (latP m))
 ↪  :=
  latticeVOAGen (latP m) (latP_even m) (latP_posDef m hm)
```

File `VOA/Classification/COne/Statement.lean`.

```
noncomputable def thetaV2m (m : ℕ) (hm : 1 ≤ m) : Aut (V2m m hm) :=
  thetaAut (latP m) (latP_even m) (latP_posDef m hm)
```

File `VOA/Classification/COne/Statement.lean`.

```
noncomputable def V2mPlus (m : ℕ) (hm : 1 ≤ m) :=
  orbifoldVOA (Subgroup.zpowers (thetaV2m m hm))
```

From the mathematics to the Lean statement

`latP m` is the rank-one lattice $\mathbb{Z}$ with bilinear form $\langle x, y\rangle = 2m\,xy$, i.e. $\sqrt{2m}\,\mathbb{Z}$; `latP_even m` and `latP_posDef m hm` certify that it is even and positive definite (the latter needs $m \geq 1$). `latticeVOAGen` is the general lattice VOA construction of Chapter 6; `thetaAut` the lift of -1 (Chapter 32); `Subgroup.zpowers g` the cyclic subgroup $\langle g\rangle$; `orbifoldVOA G` the fixed-point VOA W^G (Chapter 32). The hypothesis `hm : 1 ≤ m` is part of the data, so V_0 is never formed.

Physical meaning

V_{2m} is the chiral algebra of the compact boson at the rational radius where the momentum lattice is $\sqrt{2m}\mathbb{Z}$; V_{2m}^{+} is the chiral algebra of the corresponding point on the orbifold line,

obtained by gauging $\varphi \mapsto -\varphi$.

What the machine verified

Definitions. Simplicity, self-duality, C_2-cofiniteness and rationality of V_{2m} are proved (`V2m_stronglyRational`); so is niceness of V_{2m}^+ (Section 22.8).

Definition 22.6 (Exceptional orbifolds and the list). *V is a V_2-orbifold of type H* if $V \cong V_2^G$ for some subgroup $G \leq \mathrm{Aut}\, V_2$ isomorphic to the group H. *V is in the $c = 1$ list* if it is isomorphic to some V_{2m} ($m \geq 1$), or to some V_{2m}^+ ($m \geq 2$), or is a V_2-orbifold of type A_4, S_4 or A_5.

```

From the mathematics to the Lean statement

`V2m 1 le_rfl` is V_2 (`le_rfl : 1 ≤ 1`). `Nonempty (G ≃* H)`: there is a group isomorphism from the subgroup G (coerced to a type) to H. `alternatingGroup (Fin 4)` is A_4, `Equiv.Perm (Fin 4)` is S_4, `alternatingGroup (Fin 5)` is A_5. The orbifolds are stated *existentially*: *some* subgroup isomorphic to A_4. All such subgroups of $\mathrm{PSL}_2(\mathbb{C})$ are conjugate, so the orbifold does not depend on the choice. The forward theorem and distinctness do not need this conjugacy (distinctness works for *every* such subgroup); the library does prove it for A_4 and S_4 (`OrbC2d.tetrahedralConjugacy`, `OrbC2d.octahedralConjugacy`), where it is used in the converse. The side condition $m \geq 2$ for V_{2m}^+ is GR's: $V_2^+ \cong V_8$ is already in the first family. **Could the exceptional clauses be vacuous?** If no subgroup of $\mathrm{Aut}\, V_2$ were isomorphic to A_5, the clause would be empty. It is not: `exists_A4_subgroup`, `exists_S4_subgroup` and `exists_A5_subgroup` (Theorem 22.7) construct them.

Physical meaning

The three exceptional theories are gaugings of the $SU(2)_1$ WZW model by the finite subgroups of the global $SO(3)$ symmetry that are *not* contained in a $U(1)$ or its normalizer — the binary polyhedral groups modulo the centre. Gauging a $U(1)$ subgroup's finite cyclic or dihedral subgroup moves along the circle or orbifold line instead.

What the machine verified

Definitions; all five clauses are inhabited (Theorem 22.7).

Theorem 22.7 (The exceptional subgroups exist). *$\mathrm{Aut}\, V_2$ contains subgroups isomorphic to A_4, S_4 and A_5.*

File `VOA/Classification/COne/V2Automorphisms.lean`.

```
theorem exists_S4_subgroup :
    ∃ G : Subgroup (Aut (V2m 1 le_rfl)), Nonempty (G ≃* Equiv.Perm (Fin 4)) :=
```

File `VOA/Classification/COne/V2Automorphisms.lean`.

```
theorem exists_A4_subgroup :
    ∃ G : Subgroup (Aut (V2m 1 le_rfl)), Nonempty (G ≃* alternatingGroup (Fin 4)) :=
```

File `VOA/Classification/COne/V2Icosahedral.lean`.

```
theorem exists_A5_subgroup :
    ∃ G : Subgroup (Aut (V2m 1 le_rfl)), Nonempty (G ≃* alternatingGroup (Fin 5)) :=
```

From the mathematics to the Lean statement

The statements say exactly "there is a subgroup G with $G \cong H$". The witnesses are images of explicit injective homomorphisms `octHom : Perm (Fin 4) →* Aut V₂` and `icoHom`, built from the $\mathfrak{sl}_2$ action on V_2: S_4 acts through rotations of the octahedron, A_5 through the icosahedral rotations written with $\sqrt{5}$.

Proof on paper. V_2 contains the currents $h = \alpha(-1)\mathbf{1}$, $e = e^{\alpha}$, $f = e^{-\alpha}$ (up to a cocycle sign), and $\exp(\operatorname{ad} x_{(0)})$ for $x \in (V_2)_1$ is an automorphism. These generate a copy of $\mathrm{PSL}_2(\mathbb{C})$ acting on $(V_2)_1 \cong \mathfrak{sl}_2$ by the adjoint action. A finite rotation group $H \leq SO(3)$ lifts to $\mathrm{PSL}_2(\mathbb{C})$ through $SO(3) \cong \mathrm{PSU}(2)$; writing generators as explicit matrices (the icosahedral ones involve the golden ratio) gives a homomorphism $H \to \operatorname{Aut} V_2$, and injectivity follows because its action on the weight-one space is the faithful adjoint action. □

Physical meaning

These are the global symmetries of the $SU(2)_1$ theory that one can gauge to reach the isolated points of the $c = 1$ moduli space.

What the machine verified

Proved, `##print axioms`-clean (Lean's three).

Definition 22.8 (The forward statement). *Gannon–Rayhaun Theorem 3.1, forward direction*: every nice VOA of central charge 1 is in the list.

File `VOA/Classification/COne/Statement.lean`.

```
def GannonRayhaunStatement : Prop :=
  ∀ (𝒱 : Type u) [AddCommGroup 𝒱] [Module ℂ 𝒱] (V : VertexOperatorAlgebra 𝒱),
    Nice V → V.centralCharge = 1 → InCOneList V
```

From the mathematics to the Lean statement

A `Prop`: the claim is quantified over every carrier type $\mathcal{V}$ in a fixed universe `u`, every additive group and $\mathbb{C}$-module structure on it, and every VOA structure. The theorem `gannonRayhaun_forward : GannonRayhaunStatement.{u}` is universe-polymorphic, so it holds in every universe. Note that `V.centralCharge = 1` is a hypothesis *in addition* to niceness. Same as GR, with "rational" read as `AdmissiblyRational` (Remark 22.4).

Physical meaning

"Every rational unitary chiral algebra with $c = 1$ is a free boson at a rational point, its $\mathbb{Z}_2$ orbifold, or one of three exceptional gaugings of $SU(2)_1$."

What the machine verified

Proved without hypotheses, unconditional (it uses the theorem `VOA.pbw`; Theorem 22.28).

Definition 22.9 (Labels, distinctness and converse). The labels are lat(m), plus(m), tetra, octa, icosa; V has label l if it is isomorphic to the corresponding VOA (with the side conditions $m \geq 1$, resp. $m \geq 2$). *Distinctness*: a VOA has at most one label. *Converse*: every VOA in the list is nice and has central charge 1.

File `VOA/Classification/COne/Statement.lean`.

```
inductive COneLabel
  | lat (m : ℕ)
  | plus (m : ℕ)
  | tetra
  | octa
  | icosa
  deriving DecidableEq
```

File `VOA/Classification/COne/Statement.lean`.

```
def HasCOneLabel (V : VertexOperatorAlgebra 𝒱) : COneLabel → Prop
  | .lat m => ∃ hm : 1 ≤ m, VOAIsomorphic V (V2m m hm)
  | .plus m => ∃ hm : 1 ≤ m, 2 ≤ m ∧ VOAIsomorphic V (V2mPlus m hm)
  | .tetra => IsV2Orbifold V (alternatingGroup (Fin 4))
  | .octa => IsV2Orbifold V (Equiv.Perm (Fin 4))
  | .icosa => IsV2Orbifold V (alternatingGroup (Fin 5))
```

File `VOA/Classification/COne/Statement.lean`.

```
def GannonRayhaunDistinct : Prop :=
  ∀ (𝒱 : Type u) [AddCommGroup 𝒱] [Module ℂ 𝒱] (V : VertexOperatorAlgebra 𝒱) (l l' :
  ↪ COneLabel),
    HasCOneLabel V l → HasCOneLabel V l' → l = l'
```

File `VOA/Classification/COne/Statement.lean`.

```
def GannonRayhaunConverse : Prop :=
  ∀ (𝒱 : Type u) [AddCommGroup 𝒱] [Module ℂ 𝒱] (V : VertexOperatorAlgebra 𝒱),
    InCOneList V → Nice V ∧ V.centralCharge = 1
```

From the mathematics to the Lean statement

`HasCOneLabel V (.lat m)` unfolds to `∃ hm : 1 ≤ m, VOAIsomorphic V (V2m m hm)`: the side condition is *inside* the predicate, so an "invalid" label such as lat(0) is never realized. `inCOneList_iff_exists_label` proves InCOneList $V \iff \exists l$, HasCOneLabel $V\, l$. **Distinctness** quantifies over all V and pairs of labels and concludes `l = l'`; in particular it says $V_{2m} \ncong V_{2m'}$ for $m \neq m'$, $V_{2m} \ncong V_{2m'}^{+}$, and that the three exceptional orbifolds are pairwise non-isomorphic and not isomorphic to any lattice or plus VOA. Together with the forward theorem it gives GR's "exactly one". **The converse** includes $c = 1$ in its conclusion.

Physical meaning

Distinctness says the listed theories are genuinely different chiral algebras (different spectra); the converse says each of them is a legitimate rational unitary chiral algebra.

What the machine verified

Definitions. Distinctness is proved (Theorem 22.32); the converse is proved with no hypothesis, in universe `0`, using the theorem `VOA.pbw` (Theorem 22.59).

22.3 Modular data and the seven external inputs

The proof of Gannon and Rayhaun is a modular-forms argument resting on several large published theorems. The library's strategy, fixed early in the project, was: *first* state each published theorem as a named `Prop` at its natural generality, prove the classification *conditionally* on these (Section 22.5), and *then* discharge each `Prop` by an actual proof (Section 22.6). All inputs are in `VOA/Classification/COne/Inputs.lean`. We present them in full, because the referee must agree that each is a true theorem; if one were false (or too strong), the conditional theorem would be vacuous.

22.3.1 Shared vocabulary

Definition 22.10 (Möbius action, θ-type forms). $\gamma = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \mathrm{SL}_2(\mathbb{Z})$ acts on $\mathbb{C}$ by $\gamma\tau = (a\tau + b)/(c\tau + d)$. A function f on the upper half plane $\mathbb{H}$ is a *holomorphic θ-type modular form of weight $\frac{1}{2}$ for $\Gamma_1(N)$* if it is holomorphic on $\mathbb{H}$, transforms like $\theta(\tau) = \sum_n q^{n^2}$ under $\Gamma_1(N)$, i.e. $f(\gamma\tau)/f(\tau) = \theta(\gamma\tau)/\theta(\tau)$, and $|(c\tau + d)^{-1/2} f(\gamma\tau)|$ is bounded on $\mathrm{Im}\,\tau \geq 1$ for every $\gamma \in \mathrm{SL}_2(\mathbb{Z})$ (holomorphy at all cusps).

File `VOA/Classification/COne/Inputs.lean`.

```
def mobius (γ : Matrix.SpecialLinearGroup (Fin 2) ℤ) (τ : ℂ) : ℂ :=
  ((γ 0 0 : ℂ) * τ + γ 0 1) / ((γ 1 0 : ℂ) * τ + γ 1 1)
```

File `VOA/Classification/COne/Inputs.lean`.

```
def thetaRef (τ : ℂ) : ℂ := rankOneTheta 0 1 1 τ
```

File `VOA/Classification/COne/Inputs.lean`.

```
structure IsThetaTypeForm (N : ℕ) (f : ℂ → ℂ) : Prop where
  holo : DifferentiableOn ℂ f {τ : ℂ | 0 < τ.im}
  multiplier : ∀ γ ∈ CongruenceSubgroup.Gamma1 N, ∀ τ : ℂ, 0 < τ.im →
    f (mobius γ τ) * thetaRef τ = thetaRef (mobius γ τ) * f τ
  cusps : ∀ γ : Matrix.SpecialLinearGroup (Fin 2) ℤ, ∃ C : ℝ, ∀ τ : ℂ, 1 ≤ τ.im →
    ‖f (mobius γ τ)‖ ≤ C * ‖(γ 1 0 : ℂ) * τ + γ 1 1‖ ^ (1 / 2 : ℝ)
```

From the mathematics to the Lean statement

`Matrix.SpecialLinearGroup (Fin 2) ℤ` is $\mathrm{SL}_2(\mathbb{Z})$, with entries `γ 0 0`$= a$, `γ 0 1`$= b$, `γ 1 0`$= c$, `γ 1 1`$= d$. Functions on $\mathbb{H}$ are encoded as functions $\mathbb{C} \to \mathbb{C}$ constrained only where `0 < τ.im`. The multiplier condition is *cross-multiplied* ($f(\gamma\tau)\theta(\tau) = \theta(\gamma\tau)f(\tau)$), which avoids dividing by θ (it has no zeros on $\mathbb{H}$, so the two forms are equivalent). The cusp condition is a growth bound $\|f(\gamma\tau)\| \leq C|c\tau+d|^{1/2}$; for a form with this multiplier, it is exactly the absence of negative powers in the Puiseux q-expansion at the cusp $\gamma(i\infty)$. `CongruenceSubgroup.Gamma1 N` is Mathlib's $\Gamma_1(N)$. `rankOneTheta` is Definition 22.17 below.

Physical meaning

Weight-$\frac{1}{2}$ forms are the characters of a single chiral boson times η: the η removes the oscillator

contribution, leaving the theta function that counts momentum states.

What the machine verified

Definitions.

Definition 22.11 (Graded dimension and Euler's function as formal series). $\mathrm{vac}_V = \sum_{n\geq 0} \dim V_n \, q^n \in \mathbb{Z}[[q]]$ and $\prod_{n\geq 1}(1-q^n) \in \mathbb{Z}[[q]]$.

File `VOA/Classification/COne/Inputs.lean`.

```
def vacuumSeries {𝒱 : Type u} [AddCommGroup 𝒱] [Module ℂ 𝒱] (V : VertexOperatorAlgebra 𝒱) :
    PowerSeries ℤ :=
  PowerSeries.mk fun n => (finrank ℂ (V.grading n) : ℤ)
```

File `VOA/Classification/COne/Inputs.lean`.

```
def eulerSeries : PowerSeries ℤ :=
  PowerSeries.mk fun N =>
    PowerSeries.coeff N (∏ n ∈ Finset.range N, (1 - PowerSeries.X ^ (n + 1) : PowerSeries
    ↪ ℤ))
```

From the mathematics to the Lean statement

`PowerSeries.mk f` is the series with coefficients $f(n)$; `PowerSeries.coeff N` extracts the N-th coefficient. The infinite product is defined coefficientwise by the finite product over $n < N$ — correct, because factors $1-q^{n+1}$ with $n+1 > N$ do not affect the coefficient of q^N. These are formal series: the link to analytic characters is always an explicit `HasSum` (next definition).

Physical meaning

vac_V counts states of the chiral algebra by energy; $\prod(1-q^n)^{-1}$ counts the oscillator states of one free boson, so the product $\prod(1-q^n)\cdot\mathrm{vac}_V$ "removes one boson".

What the machine verified

Definitions.

22.3.2 Modular data

Definition 22.12 (Candidate modular data). Candidate modular data for V consist of a finite index set I with a vacuum label 0, a V-module M_a for each $a \in I$, rational numbers h_a, functions ch_a on $\mathbb{H}$, a matrix $S \in \mathbb{C}^{I\times I}$, a real number S_{00} and real numbers d_a. No properties are imposed.

File `VOA/Classification/COne/Inputs.lean`.

```
structure ModularData {𝒱 : Type u} [AddCommGroup 𝒱] [Module ℂ 𝒱]
    (V : VertexOperatorAlgebra 𝒱) where
  ι : Type
  [instFintype : Fintype ι]
  [instDecEq : DecidableEq ι]
  vac : ι
  carrier : ι → Type u
  [instACG : ∀ a, AddCommGroup (carrier a)]
  [instMod : ∀ a, Module ℂ (carrier a)]
  module : ∀ a, OrdVModule V (carrier a)
  h : ι → ℚ
```

```
  ch : ι → ℂ → ℂ
  S : ι → ι → ℂ
  S00 : ℝ
  d : ι → ℝ
```

From the mathematics to the Lean statement

A Lean `structure` bundles data. `ι : Type` with `[Fintype ι] [DecidableEq ι]` is a finite label set; `carrier a : Type u` is the underlying space of the a-th module, in the universe of V; `module a : OrdVModule V (carrier a)` is the module structure. Everything else is plain data; `IsModularData` below says which data are *the* modular data of V.

Physical meaning

The modular data of a rational CFT: the list of primaries, their conformal weights, their characters, and the modular S-matrix that implements $\tau \mapsto -1/\tau$ (exchange of space and time on the torus).

What the machine verified

Definition.

Definition 22.13 (The trace function and S-pinning)**.** For a label a and a state v, $T_a(v,\tau) = \operatorname{tr}_{M_a} o(v)\, q^{L_0 - c/24}$ (Zhu's one-point function). S is *pinned* if for every square-bracket-homogeneous v of weight n, $T_a(v,-1/\tau) = \tau^n \sum_b S_{ab} T_b(v,\tau)$.

File `VOA/Classification/COne/Inputs.lean`.

```
def trace (D : ModularData V) (a : D.ι) (v : 𝒱) (τ : UpperHalfPlane) : ℂ :=
  qEvalAt (onePoint (D.module a) v) ((D.h a : ℂ) - V.centralCharge / 24) τ
```

File `VOA/Classification/COne/Inputs.lean`.

```
def SPinned (D : ModularData V) (S : D.ι → D.ι → ℂ) : Prop :=
  ∀ (n : ℕ) (v : 𝒱), v ∈ sqWeightSpace V (n : ℂ) → ∀ (a : D.ι) (τ : UpperHalfPlane),
    D.trace a v (ModularGroup.S • τ) = (τ : ℂ) ^ n * ∑ b, S a b * D.trace b v τ
```

From the mathematics to the Lean statement

`onePoint (D.module a) v` is the formal one-point series $\sum_n \operatorname{tr}_{(M_a)_{h_a+n}} o(v)\, q^n$ and `qEvalAt … s τ` evaluates $q^s \sum c_n q^n$ at $q = e^{2\pi i\tau}$ (Chapter 14); the shift $s = h_a - c/24$ restores the $q^{L_0-c/24}$. `sqWeightSpace V n` is the weight-n space for Zhu's square-bracket $L[0]$ (Chapter 15); `ModularGroup.S • τ` is $-1/\tau$. This is Zhu's theorem (Zhu 1996, (5.3.18a)) at $\gamma = S$.

The S-matrix is not determined by characters

The first version of the modular-data package required only the character law $\mathrm{ch}_a(-1/\tau) = \sum_b S_{ab}\,\mathrm{ch}_b(\tau)$. Characters do not separate a module from its contragredient ($\mathrm{ch}_M = \mathrm{ch}_{M'}$), so the matrix S was not determined: the library proved that a whole continuum of perturbed S-matrices satisfied the old package (`VOA.Huang.HuangModular.isModularDataWeak_perturbS`). Since several later steps read off properties of S, an input satisfied by wrong S-matrices is dangerous. The repaired definition adds `S_pinned`, and `VOA.Huang.SPinning.S_unique_of_pinned` proves that a pinned S is unique, because one-point functions of inequivalent irreducibles are linearly independent.

Physical meaning

Characters are partition functions without insertions; one-point functions are torus amplitudes with one operator inserted. The S-matrix is defined by the modular transformation of all torus amplitudes, and only the insertions distinguish a sector from its charge conjugate.

What the machine verified

Definitions. The uniqueness theorem is proved (Chapter 21).

Definition 22.14 (Modular data of a nice VOA)**.** The candidate data are *the modular data of* V if: (classification) each M_a is irreducible, every irreducible ordinary module is isomorphic to exactly one M_a, and $M_0 \cong V$; (grading) the weights of M_a lie in $h_a + \mathbb{N}$, h_a is attained, $h_0 = 0$; (characters) $\mathrm{ch}_a(\tau) = \sum_n \dim(M_a)_{h_a+n}\, q^{h_a+n-c/24}$, a convergent sum, and the vacuum character is $\sum_n \dim V_n\, q^{n-c/24}$; ($S$) the character law and the pinned law; (pseudo-unitarity) the real number S_{00} is positive and equals the matrix entry $S_{\mathrm{vac,vac}}$, $S_{a0} = S_{0a} = S_{00} d_a$ with $d_a \geq 1$; (Gannon's bound) $|S_{ab}| \leq S_{00} d_a d_b$.

File `VOA/Classification/COne/Inputs.lean`.

```
structure IsModularData (D : ModularData V) : Prop where
  irred : ∀ a, (D.module a).IsIrreducible
  exhaust : ∀ (M : Type u) [AddCommGroup M] [Module ℂ M] (N : OrdVModule V M),

  S_bound : ∀ a b, ‖D.S a b‖ ≤ D.S00 * D.d a * D.d b
```

From the mathematics to the Lean statement

Each field is one clause of the mathematical definition. `cexp (2 * Real.pi * I * (…) * τ)` is $q^{(\cdots)}$. `HasSum f x` is unconditional convergence of $\sum_n f(n)$ to x (Chapter 1), so `char` says the character is an honest convergent series of *actual* graded dimensions — this is what prevents the package from being satisfied by arbitrary functions. `S_vac_left`, `S_vac_right` and `d_ge_one` encode pseudo-unitarity in its categorical form: $d_a = S_{a0}/S_{00} \geq 1$ are the Frobenius–Perron dimensions. `S_bound` is Gannon (2005), (4.2a), quoted as GR (2.35). **Stronger or weaker?** This is the standard package of GR §2.1. It contains nothing specific to $c = 1$. **Vacuity:** every clause constrains the actual modules of V; the package is satisfiable (it holds for every nice V by `iModData_holds`, Chapter 21).

Physical meaning

A rational CFT's torus partition functions form a finite-dimensional representation of $\mathrm{SL}_2(\mathbb{Z})$. The entries S_{a0}/S_{00} are the quantum dimensions: asymptotic ratios of the number of states in sector a and in the vacuum sector at high energy. Pseudo-unitarity makes them ≥ 1, as for the dimensions of representations of a group.

What the machine verified

Definition; satisfied by every nice VOA, proved using the theorem `VOA.pbw` (`iModData_holds`).

Definition 22.15 (Level and Galois symmetry). $N > 0$ is a *level* if $N(h_a - c/24) \in \mathbb{Z}$ for all a. The data are *Galois-symmetric at level N* if for all ℓ, ℓ' with $\ell\ell' \equiv 1 \pmod N$ and every $\gamma \equiv \mathrm{diag}(\ell, \ell') \pmod N$ there are a permutation π of the labels and signs $\varepsilon_a = \pm 1$ with $\mathrm{ch}_a(\gamma\tau) = \varepsilon_a \, \mathrm{ch}_{\pi a}(\tau)$.

File `VOA/Classification/COne/Inputs.lean`.

```
def IsLevel (D : ModularData V) (N : ℕ) : Prop :=
  0 < N ∧ ∀ a, ∃ k : ℤ, (N : ℂ) * ((D.h a : ℂ) - V.centralCharge / 24) = k
```

File `VOA/Classification/COne/Inputs.lean`.

```
def GaloisSymmetric (D : ModularData V) (N : ℕ) : Prop :=
  ∀ ℓ ℓ' : ℤ, ℓ * ℓ' ≡ 1 [ZMOD N] → ∀ γ : Matrix.SpecialLinearGroup (Fin 2) ℤ,
    γ 0 0 ≡ ℓ [ZMOD N] → γ 1 1 ≡ ℓ' [ZMOD N] → γ 0 1 ≡ 0 [ZMOD N] → γ 1 0 ≡ 0 [ZMOD N] →
    ∃ (π : D.ι ≃ D.ι) (ε : D.ι → ℂ), (∀ a, ε a = 1 ∨ ε a = -1) ∧
      ∀ a (τ : ℂ), 0 < τ.im → D.ch a (mobius γ τ) = ε a * D.ch (π a) τ
```

From the mathematics to the Lean statement

`[ZMOD N]` is congruence of integers modulo N. The conductor C_V of GR is the least level; every level is a multiple of it, so stating things "for every level" is equivalent to "at the conductor".

Physical meaning

$q^{h_a - c/24}$ is N-periodic in τ exactly when N is a level, so T^N acts trivially. Galois symmetry is the statement that the modular representation is defined over a cyclotomic field and the Galois group acts on the S-matrix by signed permutations (Coste–Gannon).

What the machine verified

Definitions.

22.3.3 The seven inputs

Definition 22.16 (The seven external inputs).

1. **IModData**: every nice VOA has modular data (Zhu, Dong–Li–Mason, Huang, Gannon).
2. **ICongruenceGalois**: for every level N, the characters are $\Gamma(N)$-invariant and Galois symmetric (Dong–Lin–Ng 2015; Coste–Gannon; Ng–Schauenburg).
3. **ISerreStark**: for $4 \mid N$, every holomorphic θ-type weight-$\frac{1}{2}$ form for $\Gamma_1(N)$ is a finite combination of theta series $\theta_{n_0,r,t}$ with $4tr^2 \mid N$ (Serre–Stark 1977). The library uses only levels divisible by 24 (**ISerreStark24**).
4. **IVirasoro**: for $c = 1$, $\prod(1-q^n)\cdot \mathrm{vac}_V = \sum_h A_h \, \eta\chi_h$ with multiplicities $A_h \in \mathbb{N}$, $A_0 = 1$ (Kac; Feigin–Fuchs).

5. **ITannakian**: if $S_{ab} = S_{00} d_a d_b$ on integer-weight labels, then $V \cong W^G$ for a nice W of the same central charge and a finite $G \le \mathrm{Aut}\, W$, with $\dim W_n = \sum_{h_a \in \mathbb{Z}} d_a \dim (M_a)_n$ (GR Props. 2.13, 2.17: Müger, Deligne, Kirillov–Ostrik, Huang–Kirillov–Lepowsky).

6. **IDongMason**: a nice $c = 1$ VOA W with $W_1 \neq 0$ is some V_{2m} (Dong–Mason 2004).

7. **IEnumeration**: V_{2m}^G is in the list for every finite $G \le \mathrm{Aut}\, V_{2m}$ (GR Prop. C.4).

From the mathematics to the Lean statement

Each input is a `def … : Prop`, never an `axiom`. Nothing is assumed by declaring them; the conditional theorem takes them as explicit hypotheses. We check each against its source.

- `IModData`: quantified over every nice V in universe `u`; the conclusion is the existence of modular data in the sense of Definition 22.14. Natural generality, no $c = 1$.
- `ICongruenceGalois`: for every nice V, every modular data `D` of V (not a chosen one) and every level, (1) $\Gamma(N)$-invariance of *all* characters, (2) Galois symmetry. This is DLN Theorem I plus the Coste–Gannon/Ng–Schauenburg Galois action.
- `ISerreStark24`: a statement about modular forms only; the triple `p = (n₀, r, t)` encodes $\theta_{n_0,r,t}$, and `4 * p.2.2 * p.2.1 ^ 2 | N` is $4tr^2 \mid N$. Serre–Stark's basis $\theta_{\psi,t} = \sum \psi(n) q^{tn^2}$ is a combination of these. The library also states the version for $4 \mid N$ (`ISerreStark`) and proves `iSerreStark24_of_iSerreStark`.
- `IVirasoro`: the hypothesis `V.vacuum ≠ 0` excludes the zero space, for which $A_0 = 1$ would be false. `etaVirasoroSum A` is $\sum_h A_h \eta\chi_h$ with GR's $c = 1$ Virasoro characters (Definition 22.19). It holds for every $c = 1$ VOA, rational or not, so it carries no classification content by itself.
- `ITannakian`: the hypothesis is the factorization of S on integer-weight labels; the conclusion produces W, G with `Nice W`, `Finite G`, equal central charges, `V ≅ W^G`, and the graded dimension formula. **Flag**: this is a GR proposition assembled from several published results, not a single published theorem. It is stated at the generality of GR §2.2 (any nice V).
- `IDongMason`: Dong–Mason Theorems 1 and 3 (the weight-one Lie algebra is reductive of rank $\leq \tilde{c}$, with equality iff W is a lattice VOA), with the elementary steps $\tilde{c} = c = 1$ (pseudo-unitarity) and "rank-one even lattices are $\sqrt{2m}\mathbb{Z}$" folded in.
- `IEnumeration`: GR Prop. C.4 — finite subgroups of Aut $V_2 \cong \mathrm{PSL}_2(\mathbb{C})$ and of Aut $V_{2m} \cong \mathbb{C}^\times \rtimes \mathbb{Z}_2$ ($m \geq 2$), plus $V_{2m}^{\mathbb{Z}_n} \cong V_{2mn^2}$ and $V_{2m}^{D_{2n}} \cong V_{2mn^2}^{+}$. **Flag**: assembled.

Could the conditional theorem be vacuous? Only if some input were false. Each is a true published theorem (or a GR proposition assembled from them), and — more decisively — *each has since been proved in Lean* (Section 22.6), so the question is settled by the machine.

Physical meaning

The inputs are the standard toolkit of rational CFT: modular invariance of torus amplitudes (Zhu), the modular tensor category of anyons (Huang), the congruence property (the representation of $\mathrm{SL}_2(\mathbb{Z})$ factors through a finite quotient), the theta-series description of one-boson partition functions (Serre–Stark), the Virasoro decomposition of the vacuum module, the gauging/ungauging correspondence (Tannakian reconstruction: a symmetric subcategory of anyons with trivial spins is Rep G and can be condensed), and the fact that a rank-one current algebra at $c = 1$ is a lattice boson.

What the machine verified

Definitions (`Props`). All seven are now theorems of the library, see Section 22.6: `IModData` (using the theorem `VOA.pbw`), `IEnumeration` and the Serre–Stark and Virasoro inputs with Lean's three axioms only.

22.4 The paper's own lemmas

The new mathematics of Gannon–Rayhaun §3 is formalized directly, as four lemmas: the S-transformation of the rank-one theta functions, the positivity of the theta weights (GR Lemma 3.11), the uniqueness of the surviving theta weight (GR Prop. 3.12), and the Tannakian squeeze (GR Theorem 2.18). They are stated in elementary terms (theta functions, finite sums, power series), so the referee can check them without any VOA theory.

22.4.1 The rank-one theta functions and their S-transformation

Definition 22.17 (Rank-one theta functions; GR (3.9)). For $n_0, r \in \mathbb{Z}$ and $t > 0$, $\theta_{n_0,r,t}(\tau) = \sum_{n \equiv n_0\ (r)} q^{tn^2} = \sum_{m \in \mathbb{Z}} e^{2\pi i t(n_0+rm)^2\tau}$.

File `VOA/Classification/COne/RankOneTheta.lean`.

```
def rankOneThetaTerm (n₀ r : ℤ) (t : ℝ) (τ : ℂ) (m : ℤ) : ℂ :=
  cexp (2 * π * I * t * ((n₀ + r * m : ℤ) : ℂ) ^ 2 * τ)
```

File `VOA/Classification/COne/RankOneTheta.lean`.

```
def rankOneTheta (n₀ r : ℤ) (t : ℝ) (τ : ℂ) : ℂ :=
  ∑' m : ℤ, rankOneThetaTerm n₀ r t τ m
```

From the mathematics to the Lean statement

`∑' m : ℤ` is Mathlib's `tsum`: the sum if it converges unconditionally, and 0 otherwise (the junk-value convention of Chapter 1). For $\operatorname{Im}\tau > 0$ and $t > 0$ the series converges absolutely (Gaussian decay), so the junk value never occurs where the theorems use it; the library also proves `rankOneTheta_eq_jacobiTheta₂`, identifying it with Mathlib's two-variable Jacobi theta function, which settles convergence. The parameter t is a real number in the definition and a natural number in all uses.

Physical meaning

$\theta_{n_0,r,t}/\eta$ is the character of the momentum sector $n_0 + r\mathbb{Z}$ of a compact boson: each momentum n contributes q^{tn^2} (its L_0 eigenvalue) times the oscillator partition function $1/\eta$.

What the machine verified

Definition.

Theorem 22.18 (S-transformation of $\theta_{n_0,r,t}$; GR (3.15)). *For $r \neq 0$, $t > 0$, $\operatorname{Im}\tau > 0$: $\theta_{n_0,r,t}(-1/\tau) = \big(-i\tau/(2tr^2)\big)^{1/2}\,\vartheta\big(n_0/r,\ \tau/(2tr^2)\big)$, with $\vartheta(z,\tau) = \sum_n e^{2\pi i n z + \pi i n^2 \tau}$.*

File `VOA/Classification/COne/RankOneTheta.lean`.

```
theorem rankOneTheta_S (n₀ : ℤ) {r : ℤ} (hr : r ≠ 0) {t : ℝ} (ht : 0 < t) {τ : ℂ}
    (hτ : 0 < τ.im) :
    rankOneTheta n₀ r t (-1 / τ) =
      (-I * (τ / (2 * t * (r : ℂ) ^ 2))) ^ (1 / 2 : ℂ) *
        jacobiTheta₂ ((n₀ : ℂ) / r) (τ / (2 * t * (r : ℂ) ^ 2)) :=
```

From the mathematics to the Lean statement

`jacobiTheta₂ z τ` is Mathlib's $\sum_n \exp(2\pi i n z + \pi i n^2 \tau)$; `(…) ^ (1 / 2 : ℂ)` is the principal branch of the square root, the correct one since $-i\tau/(2tr^2)$ has positive real part on $\mathbb{H}$. The

library derives the forms used later (`rankOneTheta_S_residues`, `rankOneTheta_zero_one_S`) by expanding the right-hand side over residues.

Proof on paper. Poisson summation: write $\theta_{n_0,r,t}(\tau) = \sum_m g(m)$ with $g(x) = e^{2\pi i t(n_0+rx)^2\tau}$, whose Fourier transform is again a Gaussian. Equivalently, apply Jacobi's transformation formula $\vartheta(z/\tau, -1/\tau) = (-i\tau)^{1/2} e^{\pi i z^2/\tau}\vartheta(z,\tau)$ (in Mathlib) after completing the square. □

Physical meaning

Exchanging space and time on the torus turns a sum over momenta into a sum over windings; this is the T-duality-like Poisson resummation of the free boson partition function.

What the machine verified

Proved, Lean's three axioms.

22.4.2 Virasoro multiplicities and positivity of the theta weights

Definition 22.19 (The $c = 1$ Virasoro characters; GR (3.4)–(3.7)). At $c = 1$ the irreducible Virasoro module $L(1,h)$ with $h \in \mathbb{N}$ has $\eta\chi_h = q^h - q^{(\sqrt{h}+1)^2}$ if h is a perfect square, and $\eta\chi_h = q^h$ otherwise (up to the common factor $q^{-1/24}$). For multiplicities $A : \mathbb{N} \to \mathbb{N}$, $\sum_h A_h\,\eta\chi_h$ is the formal series whose N-th coefficient is the finite sum over $h \le N$.

File `VOA/Classification/COne/WeightPositivity.lean`.

```
def etaVirasoroSum (A : ℕ → ℕ) : PowerSeries ℤ :=
  mk fun N => ∑ h ∈ range (N + 1), (A h : ℤ) * coeff N (etaVirasoroChar h)
```

From the mathematics to the Lean statement

`etaVirasoroChar h` is $\eta\chi_h$ as an integer power series (defined just above in the same file); `coeff_etaVirasoroChar_of_lt` proves that its coefficients below q^h vanish, which justifies truncating the infinite sum at $h \le N$. Only integer h occur because the weights of a VOA are integers; at $c = 1$ the degenerate weights are $h = \mu^2/4$, and for integer h only integer $\mu/2$ occur.

Physical meaning

At $c = 1$ the vacuum module of any chiral algebra decomposes into Virasoro representations; the degenerate ones ($h = j^2$) have a null vector at level $2j+1$, which is why their characters lose the term $q^{(j+1)^2}$. These are the $SU(2)$ spin-j multiplets of the free boson at the self-dual radius.

What the machine verified

Definition.

Theorem 22.20 (GR Lemma 3.11: the theta weights are non-negative). *Suppose a power series F equals $\sum_h A_h\eta\chi_h$ with $A_h \in \mathbb{N}$, $A_0 = 1$, and also $F = \sum_{t\in T}\sum_{j \bmod r_t} a_t(j)\,\theta_{j,r_t,t}$ with all t square-free. Then for each $t \in T$, $w_t := (r_t\sqrt{2t})^{-1}\sum_j a_t(j)$ is a non-negative real number.*

File `VOA/Classification/COne/WeightPositivity.lean`.

```
theorem theta_weight_nonneg (F : PowerSeries ℂ) (A : ℕ → ℕ) (hA0 : A 0 = 1)
    (hVir : F = map (Int.castRingHom ℂ) (etaVirasoroSum A))
    (T : Finset ℕ) (hT : ∀ t ∈ T, Squarefree t) (r : ℕ → ℕ) [∀ t, NeZero (r t)]
    (a : (t : ℕ) → ZMod (r t) → ℂ)
    (hθ : F = ∑ t ∈ T, ∑ j : ZMod (r t), a t j • map (Int.castRingHom ℂ) (thetaSeries (r t)
     ↪ j t))
    {t : ℕ} (ht : t ∈ T) :
    ∃ x : ℝ, 0 ≤ x ∧
      (1 / ((r t : ℂ) * (Real.sqrt (2 * t) : ℂ))) * ∑ j : ZMod (r t), a t j = x :=
```

From the mathematics to the Lean statement

`map (Int.castRingHom ℂ)` views an integer series as a complex series; `thetaSeries (r t) j t` is the formal q-expansion of $\theta_{j,r_t,t}$; `a t j • …` is scalar multiplication. `[∀ t, NeZero (r t)]` says every modulus is nonzero (so `ZMod (r t)` is finite). The conclusion `∃ x : ℝ, 0 ≤ x ∧ … = x` says the complex number w_t is real and ≥ 0. Hypotheses are exactly GR's.

Proof on paper. Compare coefficients at q^{tn^2} with t square-free. By Definition 22.19, the coefficient of $q^{(n+1)^2}$ in $\sum A_h \eta\chi_h$ is $A_{(n+1)^2} - A_{n^2}$, and the coefficient of a non-square N is $A_N \geq 0$. On the theta side, the coefficient of q^{tn^2} collects $a_t(j)$ for $j \equiv \pm n$. Summing over a full period of n and using $A \geq 0$ (and $A_0 = 1$ for the telescoping square terms when $t = 1$) gives $\sum_j a_t(j)$ as half a sum of non-negative integers. □

Physical meaning

The total weight w_t of the momentum lattice $\sqrt{2t}\mathbb{Z}$ in the vacuum character is a count of Virasoro primaries, hence non-negative.

What the machine verified

Proved, Lean's three axioms.

22.4.3 Uniqueness of the surviving theta weight

Theorem 22.21 (GR Prop. 3.12, arithmetic core). *Let $8 \mid C$, T a finite set of square-free t with $4t \mid C$, $w_t \geq 0$ with $\sum_t w_t = S_{00} > 0$, and suppose $\left|\sum_t \left(\frac{2t}{\ell}\right) w_t\right| \geq S_{00}$ for every ℓ coprime to C. Then exactly one w_t is nonzero.*

File `VOA/Classification/COne/ModularDataLemmas.lean`.

```
theorem existsUnique_weight_ne_zero {C : ℕ} (hC0 : C ≠ 0) (hC8 : 8 ∣ C) (T : Finset ℕ)
    (hT : ∀ t ∈ T, Squarefree t ∧ 4 * t ∣ C) (w : ℕ → ℝ) (hw : ∀ t ∈ T, 0 ≤ w t) {S₀₀ : ℝ}
    (hS₀₀ : 0 < S₀₀) (hsum : ∑ t ∈ T, w t = S₀₀)
    (hbound : ∀ ℓ : ℕ, ℓ.Coprime C →
      S₀₀ ≤ |∑ t ∈ T, (jacobiSym (2 * (t : ℤ)) ℓ : ℝ) * w t|) :
    ∃! t, t ∈ T ∧ w t ≠ 0 :=
```

From the mathematics to the Lean statement

`jacobiSym (2 * t) ℓ` is the Jacobi symbol $\left(\frac{2t}{\ell}\right) \in \{-1, 0, 1\}$; `ℓ.Coprime C` is $\gcd(\ell, C) = 1$. `∃! t, t ∈ T ∧ w t ≠ 0`: there is a unique such t. GR assume $24 \mid C$; the theorem needs only $8 \mid C$, so it is slightly *stronger*.

Proof on paper. Suppose $w_{t_1}, w_{t_2} > 0$ for $t_1 \neq t_2$. Since they are square-free and distinct, $2t_1$ and $2t_2$ differ as square classes, so by quadratic reciprocity and the Chinese remainder theorem there is ℓ

coprime to C with $\left(\frac{2t_1}{\ell}\right) = 1$ and $\left(\frac{2t_2}{\ell}\right) = -1$. Then $|\sum_t (\frac{2t}{\ell}) w_t| < \sum_t w_t = S_{00}$, since the two terms partially cancel, contradicting the bound. No Dirichlet theorem is needed. □

Physical meaning

The Galois symmetry of the modular data acts on the momentum sectors by Jacobi symbols. A mixture of two different radii would be broken by some Galois conjugation, while unitarity-type bounds forbid that.

What the machine verified

Proved, Lean's three axioms.

22.4.4 The Tannakian squeeze

Theorem 22.22 (GR Theorem 2.18, matrix part). *Let S be a finite matrix with vacuum label 0, $d_a > 0$, $d_0 = 1$, $S_{a0} = S_{00} d_a$, $|S_{ab}| \le S_{00} d_a d_b$, and positive functions $\mathrm{ch}_b(t)$ with $e^{-2\pi t c/24}\,\mathrm{ch}_0(t) \to 1$ and $e^{-2\pi t c/24}\,\mathrm{ch}_b(t) \to 0$ for $b \neq 0$. If $\sum_b \big(D S_{00} d_b - \sum_a d_a S_{ab}\big)\,\mathrm{ch}_b(t) = 0$ for all $t > 0$, then $D = \sum_a d_a^2$ and $S_{ab} = S_{00} d_a d_b$ for all a, b.*

File `VOA/Classification/COne/ModularDataLemmas.lean`.

```
theorem tannakian_squeeze {ι : Type*} [Fintype ι] (i₀ : ι) (S : ι → ι → ℂ)
    (d : ι → ℝ) (S₀₀ c : ℝ) (D : ℂ) (ch : ι → ℝ → ℝ)
    (hd : ∀ a, 0 < d a) (hd₀ : d i₀ = 1) (hS₀₀ : 0 < S₀₀)
    (hSa0 : ∀ a, S a i₀ = S₀₀ * d a)
    (hbound : ∀ a b, ‖S a b‖ ≤ S₀₀ * d a * d b)
    (hch : ∀ b, ∀ t, 0 < t → 0 < ch b t)
    (hlead₀ : Tendsto (fun t => Real.exp (-(2 * Real.pi * t * c / 24)) * ch i₀ t) atTop (𝓝
    ↪ 1))
    (hlead : ∀ b, b ≠ i₀ →
      Tendsto (fun t => Real.exp (-(2 * Real.pi * t * c / 24)) * ch b t) atTop (𝓝 0))
    (hid : ∀ t, 0 < t →
      ∑ b, (D * S₀₀ * d b - ∑ a, d a * S a b) * (ch b t : ℂ) = 0) :
    D = ((∑ a, d a ^ 2 : ℝ) : ℂ) ∧ ∀ a b, S a b = S₀₀ * d a * d b :=
```

From the mathematics to the Lean statement

`Tendsto f atTop (𝓝 x)`: $f(t) \to x$ as $t \to \infty$. The identity `hid` is GR (2.33) evaluated at $\tau = it$. The S-matrix need not be symmetric or unitary — the theorem is slightly *more general* than GR's.

Proof on paper. Multiply the identity by $e^{-2\pi t c/24}$ and let $t \to \infty$: only the vacuum survives, so its coefficient vanishes, $D S_{00} = \sum_a d_a S_{a0} = S_{00} \sum_a d_a^2$, i.e. $D = \sum d_a^2$. Then each coefficient $D S_{00} d_b - \sum_a d_a S_{ab} \ge D S_{00} d_b - \sum_a d_a \cdot S_{00} d_a d_b = 0$ by the bound, and a positive combination of positive functions vanishing identically forces each coefficient to vanish, and equality in the bound for every a: $S_{ab} = S_{00} d_a d_b$. □

Physical meaning

$S_{ab} = S_{00} d_a d_b$ says the braiding among these anyons is trivial (they are bosons that braid trivially): the subcategory is symmetric, so by Deligne it is $\mathrm{Rep}\, G$ and the anyons can be condensed (the symmetry "ungauged").

What the machine verified

Proved, Lean's three axioms.

22.4.5 The theta Galois law

Definition 22.23 (The theta Galois law; GR Prop. 3.8, (3.18)). For $24 \mid M$, $4tr^2 \mid M$, ℓ coprime to M, $\ell\ell' \equiv 1$ and $\gamma \equiv \mathrm{diag}(\ell, \ell') \pmod M$: $\theta_{n_0,r,t}(\gamma\tau)\,\eta(\tau) = \left(\frac{2t}{\ell}\right)\theta_{\ell n_0,r,t}(\tau)\,\eta(\gamma\tau)$.

File `VOA/Classification/COne/GapsPaper.lean`.

```
def ThetaGaloisLaw : Prop :=
  ∀ (n₀ : ℤ) (r t M : ℕ), 0 < r → 0 < t → 4 * t * r ^ 2 ∣ M → 24 ∣ M →
    ∀ ℓ : ℕ, ℓ.Coprime M → ∀ ℓ' : ℤ, (ℓ : ℤ) * ℓ' ≡ 1 [ZMOD M] →
    ∀ γ : Matrix.SpecialLinearGroup (Fin 2) ℤ,
      γ 0 0 ≡ ℓ [ZMOD M] → γ 1 1 ≡ ℓ' [ZMOD M] → γ 0 1 ≡ 0 [ZMOD M] → γ 1 0 ≡ 0 [ZMOD M] →
      ∀ τ : ℂ, 0 < τ.im →
        rankOneTheta n₀ r t (mobius γ τ) * ModularForm.eta τ =
          (jacobiSym (2 * (t : ℤ)) ℓ : ℂ) * rankOneTheta ((ℓ : ℤ) * n₀) r t τ *
            ModularForm.eta (mobius γ τ)
```

From the mathematics to the Lean statement

Cross-multiplied, again, to avoid dividing by η. `ModularForm.eta` is Mathlib's Dedekind η. For $\ell = 1$ this is the $\Gamma(M)$-invariance of θ/η. The docstring records a numerical check and, importantly, that the plausible variant with $\ell^{-1}n_0$ in place of ℓn_0 is *false* for $r = 7$.

Physical meaning

The lattice boson's characters transform under the congruence quotient by the Weil representation, in which diagonal matrices act by Jacobi symbols and by scaling the momentum label.

What the machine verified

A `Prop`, **proved**: `thetaGaloisLaw : ThetaGaloisLaw` in `VOA/Classification/COne/WeilKernel.lean`, through the Weil representation and Gauss's sign theorem (`WeilGalois.gaussG_one`).

22.5 The conditional theorem

22.5.1 Four gaps

Besides the seven published inputs, the first conditional proof named four *gaps*: steps of GR §3 or of classical analysis that were true but not yet formalized. They are recorded here because they are hypotheses of the conditional theorem; all four are now proved.

Definition 22.24 (The four gaps). (i) **GapQExpansion**: uniqueness of q-expansions on $\mathbb{H}$; multiplication of a q-series by η corresponds to the formal product with Euler's series; the q-expansion of $\theta_{j,r,t}$. (ii) **GapLemma37** (GR Lemma 3.7): for nice $c = 1$ V with $\Gamma(N)$-invariant characters, $F_V = \eta \cdot \mathrm{ch}_V$ is a holomorphic θ-type weight-$\frac{1}{2}$ form for $\Gamma_1(N)$. (iii) **GapThetaReduction** (GR (3.13)): a combination of $\theta_{n_0,r,t}$ can be rewritten with square-free t and one modulus R_t per t. (iv) **GapGaloisBound** (GR (3.31)–(3.35)): under Galois symmetry, $|\sum_t \left(\frac{2t}{\ell}\right) w_t| \geq S_{00}$ for every ℓ coprime to N.

            ((1 / ((R t : ℂ) * (Real.sqrt (2 * t) : ℂ))) * ∑ j : ZMod (R t), a t j)‖
```

From the mathematics to the Lean statement

ℕ+ is the type of positive natural numbers, so `R t : ℕ+` is a positive modulus. `Squarefree t` is Mathlib's square-freeness. In `GapGaloisBound` the quantity `(1 / ((R t : ℂ) * (Real.sqrt (2 * t) : ℂ))) * ∑ j : ZMod (R t), a t j` is the weight w_t of Theorem 22.20, and the conclusion (the last two lines of the quotation) is the bound $S_{00} \le |\sum_t (\frac{2t}{\ell}) w_t|$, exactly GR

(3.35).

Physical meaning

(ii) is the statement that the vacuum character of a $c = 1$ theory times η behaves like a one-boson theta function under the congruence subgroup; (iv) is the modular-invariance consistency of the Galois action with positivity of quantum dimensions.

What the machine verified

`Props`. All proved: `gapQExpansion`, `gapThetaReduction` (in `GapsClassical.lean`), and `gapLemma37_of_thetaGaloisLaw`, `gapGaloisBound_of_thetaGaloisLaw` (in `GapsPaper.lean`) together with `thetaGaloisLaw`.

22.5.2 The last step and the conditional theorem

Theorem 22.25 (Orbifold transport). *If $W \cong W'$ and $G \leq \operatorname{Aut} W$, then the conjugate subgroup $G' \leq \operatorname{Aut} W'$ satisfies $G \cong G'$ and $W^G \cong W'^{G'}$.*

File `VOA/Classification/COne/Conditional.lean`.

```
theorem orbifold_transport {W : VertexOperatorAlgebra 𝒱} {W' : VertexOperatorAlgebra 𝒲}
    (h : VOAIsomorphic W W') (G : Subgroup (Aut W)) :
    ∃ G' : Subgroup (Aut W'), Nonempty (G ≃* G') ∧
      VOAIsomorphic (orbifoldVOA G) (orbifoldVOA G') :=
```

From the mathematics to the Lean statement

The conjugate subgroup is the image of G under $g \mapsto ege^{-1}$, where $e : W \to W'$ is the isomorphism.

Proof on paper. e maps G-fixed vectors bijectively to eGe^{-1}-fixed vectors and preserves products, vacuum and ω. □

Physical meaning

Gauging the same symmetry of the same theory, described in two different bases, gives the same gauged theory.

What the machine verified

Proved, Lean's three axioms.

Theorem 22.26 (The last step of GR's proof). *Assume* IDongMason *and* IEnumeration. *If $V \cong W^G$ with W nice, $c = 1$, $W_1 \neq 0$ and G finite, then V is in the list.*

File `VOA/Classification/COne/Conditional.lean`.

```
theorem inCOneList_of_extension (hDM : IDongMason.{w}) (hEn : IEnumeration)
    {𝒱 : Type v} [AddCommGroup 𝒱] [Module ℂ 𝒱] {V : VertexOperatorAlgebra 𝒱}
    {𝒲 : Type w} [AddCommGroup 𝒲] [Module ℂ 𝒲] {W : VertexOperatorAlgebra 𝒲}
    (G : Subgroup (Aut W)) (hG : Finite G) (hW : Nice W) (hc : W.centralCharge = 1)
    (h1 : finrank ℂ (W.grading 1) ≠ 0) (hV : VOAIsomorphic V (orbifoldVOA G)) :
    InCOneList V :=
```

Proof on paper. Dong–Mason gives $W \cong V_{2m}$; transport moves G to $G' \leq \mathrm{Aut}\, V_{2m}$ with $W^G \cong V_{2m}^{G'}$; the enumeration puts $V_{2m}^{G'}$ in the list, and the list is closed under isomorphism (`inCOneList_of_iso`). □

Physical meaning

Every nice $c = 1$ theory is a gauging of a free boson at a rational radius by a finite symmetry group.

What the machine verified

Proved, conditional on the two displayed inputs; Lean's three axioms.

Theorem 22.27 (Gannon–Rayhaun Theorem 3.1, forward, conditionally)**.** *The seven inputs and the four gaps imply the forward classification.*

File `VOA/Classification/COne/Conditional.lean`.

```
theorem gannonRayhaun_of_inputs

    (hEn : IEnumeration)
    (g37 : GapLemma37.{u}) (gRed : GapThetaReduction) (gQ : GapQExpansion)
    (gGal : GapGaloisBound.{u}) :
    GannonRayhaunStatement.{u} := by
```

From the mathematics to the Lean statement

A theorem with eleven `Prop` hypotheses and conclusion `GannonRayhaunStatement.{u}`; all inputs are taken in the same universe `u`.

Proof on paper, following GR §3. Let V be nice with $c = 1$, with modular data D (IModData) and a level N divisible by 24.

1. *The character is a theta-type form.* The characters are $\Gamma(N)$-invariant (ICongruenceGalois), so $F_V = \eta\ \mathrm{ch}_V$ is a holomorphic θ-type form of weight $\frac{1}{2}$ for $\Gamma_1(N)$ (GapLemma37): η supplies the multiplier of θ on $\Gamma(24)$, T-invariance comes from integrality of the weights of V, and holomorphy at the cusps from the S-law and $h_a \geq 0$.

2. *Serre–Stark.* Hence $F_V = \sum_{t \in T} \sum_{j \bmod R_t} a_t(j)\, \theta_{j,R_t,t}$ with t square-free (ISerreStark24, GapThetaReduction).

3. *Lemma 3.10.* Apply S and project onto integer powers of q (an average over the translations T^k). By the S-transformation of the theta functions (Theorem 22.18) and the S-law, the projection of $\mathrm{ch}_V(-1/\tau)$ is a combination of the characters of the integer-weight modules, with coefficients $S_{0a} = S_{00} d_a$, and on the theta side it is a combination of the $\theta_{0,1,t}$:

$$\sum_{h_a \in \mathbb{Z}} d_a\ \mathrm{ch}_a(\tau) = \frac{1}{S_{00}\,\eta(\tau)} \sum_{t \in T} w_t\, \theta_{0,1,t}(\tau),$$

   with w_t as in Theorem 22.20.

4. *Lemma 3.11 and the weight sum.* IVirasoro and the positivity of the theta weights (Theorem 22.20) give $w_t \geq 0$; comparing leading terms gives $\sum_t w_t = S_{00}$.

5. *Prop. 3.12.* The Galois bound (GapGaloisBound) and the uniqueness of the surviving theta weight (Theorem 22.21) leave exactly one $t_\star$, so $\sum_{h_a \in \mathbb{Z}} d_a\, \mathrm{ch}_a = \theta_{0,1,t_\star}/\eta$ — the character of $V_{2t_\star}$.

6. *Theorem 2.18.* This vacuum identity, the theta S-transformation and the Tannakian squeeze (Theorem 22.22) give $S_{ab} = S_{00} d_a d_b$ on integer-weight labels.

7. *Tannakian step.* ITannakian produces a nice W with $V \cong W^G$, G finite, and $\dim W_n = \sum_{h_a \in \mathbb{Z}} d_a \dim(M_a)_n$, i.e. $\mathrm{ch}_W = \theta_{0,1,t_\star}/\eta$, so $\dim W_1 \geq 1$.

8. *Last step.* Theorem 22.26.

□

Physical meaning

The argument reads: the $c = 1$ theory's integer-spin anyons, weighted by quantum dimension, have exactly the partition function of a single compact boson; Galois symmetry forbids a superposition of radii; so the integer-spin anyons form a gaugeable Rep G, condensing them gives a theory with a current, hence a free boson at a rational radius, and the original theory is its G-gauging.

What the machine verified

Proved, `##print axioms` = `[propext, Classical.choice, Quot.sound]` (machine-checked on 2026-10-13). **Conditional** on the eleven displayed hypotheses.

22.6 Discharging the inputs: the unconditional forward theorem

22.6.1 How the discharge is organized

The conditional theorem was followed by a chain of theorems, each replacing one hypothesis by a proof or by finer hypotheses (files `Main*.lean`, `SerreStark*.lean`, `QExp*.lean` in `VOA/Classification/COne/`, and `HKL*.lean`, `DLN*.lean`, `NS*.lean` in `VOA/Huang/`). The chain ends at a hypothesis-free theorem. We list what discharges each hypothesis; the deep inputs are explained in Chapter 21.

Hypothesis	Discharged by
`GapQExpansion`	`gapQExpansion` (Mathlib power-series uniqueness, Euler product, theta regrouping).
`GapThetaReduction`	`gapThetaReduction` (reindexing of theta series).
`GapLemma37`, `GapGaloisBound`	`paperGaps_of_thetaGaloisLaw` with `thetaGaloisLaw` (Weil representation, `weilKernelLaw`, Gauss sums).
`ISerreStark24`	`SSHecke.iSerreStark24_of_boundedCoeff_of_levelBox` with `SSHecke.serreStarkBoundedCoeff24_holds` and `SSHecke.serreStarkLevelBox24`: a proof of Serre–Stark at levels $24 \mid N$ via Hecke operators, a Fricke involution and the q-expansion principle in weight two (`SSHecke.qExpPrinciple24Away_two`).
`IVirasoro`	`iVirasoro_of_composition` with `virLocalCompositionSeries` (weight-by-weight Jordan–Hölder for positive-energy Virasoro modules) and `virC1DegenerateCharacters_holds` (Feigin–Fuchs at $c = 1$ via a radical-level bound).
`IDongMason`	`iDongMason_of_modData`: trivial Heisenberg commutant from the modular data, then `heisLatticeReconstruction` (a VOA containing a rank-one Heisenberg with trivial commutant is a lattice VOA).

`IEnumeration`	`iEnumeration`: classification of finite subgroups of $SO(3)$ (`FiniteRotation.classification`), $\mathrm{Aut}\,V_2$ and $\mathrm{Aut}\,V_{2m}$, and the orbifold identifications.
`IModData`	`VOA.Huang.HKLRational.iModData_holds`: Zhu, Anderson–Moore, Huang's Verlinde theorem (Chapter 21); uses `VOA.pbw` (a theorem).
`ICongruenceGalois`	`iCongruenceGalois_of_split` with the Dong–Lin–Ng inputs, obtained from the Ng–Schauenburg congruence theorem `nsProjectiveKernelAll_holds` and Beyl's Schur-multiplier facts for $\mathrm{SL}_2(\mathbb{Z}/p^k)$: `threePowerSchur`, `twoPowerInflationFromTwo_holds`, `largePrimeGaussLowerRelations` (Chapter 21).
`ITannakian`	`iTannakian_of_rigid` with Deligne's theorem (`symmetricFiberFunctorExists_holds`, `fiberFunctorReconstruction`) and the Huang–Kirillov–Lepowsky extension theory (`hklRationalInput_holds`, `hklLocalityInput_holds`; Chapter 21).

Not every input has a standalone theorem

For `IVirasoro`, `ISerreStark24`, `ICongruenceGalois` and `ITannakian` the library contains no declaration of the literal form `theorem … : IVirasoro`; the corresponding instances are built inside the assembly chain (e.g. `gannonRayhaun_of_iTannakian` builds the Serre–Stark instance with a `let`). This is harmless: the chain ends in a theorem with *no* hypotheses, so every input it consumed has been proved. A referee who wants a named statement can read off the composition from the table.

22.6.2 The discharging theorems quoted

We quote the statements that close the analytic and arithmetic inputs; the Huang-side ones are quoted in Chapter 21.

```

From the mathematics to the Lean statement

The statements are exactly "the named `Prop` holds" (or, for the two reduction theorems, "these proved `Prop`s imply that one"). The bodies shown in one line (`:= by`, `where`) are the start of proofs that the book does not reproduce. `iModData_holds` is shown with its proof term because it is informative: it is a composition of Anderson–Moore (`andersonMooreInput_holds`) and Huang's Verlinde theorem (`huangVerlindeFusionInput_holds`), through `iModData_of_verlinde_pbw_inputs`, whose name records the dependence on `VOA.pbw`.

Physical meaning

Each line closes one of the classical pillars of rational CFT used by Gannon and Rayhaun: Serre–Stark (one-boson partition functions), Feigin–Fuchs (the $c = 1$ Virasoro spectrum), Dong–Mason (currents make a boson), Klein's classification of rotation groups, and Huang's modular tensor category.

What the machine verified

All proved. Lean's three axioms (re-probed: `iModData_holds` included); `iModData_holds` (and `iDongMason_of_modData` when instantiated with it) uses the theorem `VOA.pbw`.

22.6.3 The forward theorem

Theorem 22.28 (Gannon–Rayhaun Theorem 3.1, forward direction). *Every nice vertex operator algebra of central charge* 1 *is isomorphic to some* V_{2m} *(*$m \geq 1$*), some* V_{2m}^+ *(*$m \geq 2$*), or a fixed-point algebra* V_2^G *with* $G \cong A_4$, S_4 *or* A_5.

File `VOA/Classification/COne/MainUnconditional.lean`.

```
theorem gannonRayhaun_forward : GannonRayhaunStatement.{u} :=
  gannonRayhaun_beyl_large VOA.Huang.DLNSchur.largePrimeGaussLowerRelations
```

From the mathematics to the Lean statement

No hypotheses. The proof term is a composition: `gannonRayhaun_beyl_large` is the forward theorem conditional on the single large-prime Schur residual `LargePrimeGaussLowerRelations`, and `largePrimeGaussLowerRelations` proves it. The preceding layers are `gannonRayhaun_beyl_fine` (three Beyl residuals), `gannonRayhaun_beyl`, `gannonRayhaun_hkl_qexp`, `gannonRayhaun_hkl_final`, `gannonRayhaun_hkl_dim`, ..., back to `gannonRayhaun_of_iTannakian` and `gannonRayhaun_current_gauss`, which instantiates the conditional theorem of Section 22.5. The theorem is universe-polymorphic.

Proof on paper. Theorem 22.27 with every hypothesis discharged as in the table. □

Physical meaning

Any rational, positive-energy chiral algebra at $c = 1$ is a free boson at a rational radius, its $\mathbb{Z}_2$ orbifold, or one of the three exceptional gaugings of $SU(2)_1$.

What the machine verified

Proved with no hypotheses. `##print axioms gannonRayhaun_forward` (re-probed at an earlier commit, not re-run for this edition; on 2026-10-13, when `VOA.pbw` was an axiom, the list also contained `VOA.pbw`):

```
'VOA.Classification.COne.gannonRayhaun_forward' depends on axioms:
  [propext, Classical.choice, Quot.sound]
```

So it is unconditional; it uses the PBW theorem `VOA.pbw` (Chapter 3). It is also recorded in the maintained audit `scripts/audit/ClassificationCOneAxiomAudit.lean` with expected axioms `PBW_AXIOMS` (since `VOA.pbw` became a theorem, `PBW_AXIOMS` is the standard three); the audit passed on 2026-10-13 (844 declarations).

22.7 Pairwise distinctness

Most pairs of labels are separated by easy invariants: $\dim V_1$ ($= 1$ for V_{2m} with $m \geq 2$, 3 for V_2, 0 for V_{2m}^+ and the exceptional orbifolds), the weight of the first primary, the number of irreducible modules. The two hard cases, isolated in `VOA/Classification/COne/Distinct.lean`, are: V_{2m}^+ with $m \geq 4$ against the exceptional orbifolds, and the three exceptional orbifolds among themselves.

Definition 22.29 (The two residuals). **PlusExceptionalResidual**: no VOA is both V_{2m}^+ ($m \geq 4$) and an exceptional orbifold. **ExceptionalResidual**: no VOA carries two different exceptional labels.

File `VOA/Classification/COne/Distinct.lean`.

```
def PlusExceptionalResidual : Prop :=
  ∀ (𝒱 : Type u) [AddCommGroup 𝒱] [Module ℂ 𝒱] (V : VertexOperatorAlgebra 𝒱) (m : ℕ)
    (l : COneLabel), 4 ≤ m → l.IsExceptional → HasCOneLabel V (.plus m) → HasCOneLabel V l
     ↪  → False
```

File `VOA/Classification/COne/Distinct.lean`.

```
def ExceptionalResidual : Prop :=
  ∀ (𝒱 : Type u) [AddCommGroup 𝒱] [Module ℂ 𝒱] (V : VertexOperatorAlgebra 𝒱) (l l' :
   ↪  COneLabel),
    l.IsExceptional → l'.IsExceptional → HasCOneLabel V l → HasCOneLabel V l' → l = l'
```

From the mathematics to the Lean statement

`l.IsExceptional` says $l \in \{\text{tetra}, \text{octa}, \text{icosa}\}$. Concluding `False` from two labels is "these cannot both hold".

Physical meaning

The question is whether two differently constructed gaugings of $SU(2)_1$ could secretly be the same theory. Their spectra of states differ, which decides it.

What the machine verified

`Prop`s, both proved below. The docstrings of both still say "not proved here"; they are proved in `DistinctResiduals.lean` (Section 22.11).

Theorem 22.30 (Molien's formula for orbifold dimensions). *For a VOA W and a finite $G \le \mathrm{Aut}\, W$, $|G| \dim (W^G)_n = \sum_{g \in G} \mathrm{tr}(g | W_n)$.*

File `VOA/Classification/COne/DistinctResiduals.lean`.

```
theorem card_mul_finrank_orbifold (G : Subgroup (Aut W)) [Fintype G] (n : ℤ)
    [FiniteDimensional ℂ (W.grading n)] :
    (Fintype.card G : ℂ) * finrank ℂ ((orbifoldVOA G).grading n)
      = ∑ g : G, LinearMap.trace ℂ _ (autRes W n g) :=
```

From the mathematics to the Lean statement

`autRes W n g` is the restriction of g to W_n; `LinearMap.trace ℂ _` its trace. The left side is a complex number; the formula is the averaging (Reynolds) projection.

Proof on paper. $P = |G|^{-1} \sum_g g$ is a projection of W_n onto $(W_n)^G = (W^G)_n$; the trace of a projection is the dimension of its image. □

Physical meaning

The number of gauge-invariant states is the average over the group of the twisted traces — the untwisted-sector part of the orbifold partition function.

What the machine verified

Proved, Lean's three axioms.

Theorem 22.31 (Torus traces on V_2). *For the torus element g_u ($u \in \mathbb{C}^\times$) acting on the charge-k sector by u^k, $\mathrm{tr}(g_u | (V_2)_n) = \sum_{w^2 \le n} u^w\, p(n - w^2)$, where p is the partition function.*

File `VOA/Classification/COne/DistinctResiduals.lean`.

```
theorem trace_charU (n : ℕ) (u : ℂˣ) :
    haveI := (V1).finrank (n : ℤ)
    LinearMap.trace ℂ _ (autRes V1 n (charU 1 le_rfl u)) = torusTrace n u := by
```

From the mathematics to the Lean statement

`V1` is V_2 (a local notation in `DistinctResiduals.lean` for `latticeVOAGen (latP 1) (latP_even 1) (latP_posDef 1 le_rfl)`, the unfolding of `V2m 1 le_rfl`); `haveI := (V1).finrank (n : ℤ)` only registers that $(V_2)_n$ is finite-dimensional, so that the trace is the usual one (Mathlib's `LinearMap.trace` is 0 on infinite-dimensional spaces). `charU 1 le_rfl u` is the automorphism of V_2 acting by u^k on $e^{k\alpha} \otimes M(1)$; `autRes V1 n g` its restriction to $(V_2)_n$; `torusTrace n u` is the right-hand side $\sum_{w^2 \le n} u^w p(n-w^2)$. Every finite-order automorphism of V_2 is conjugate to some g_u (`exists_conj_charU`), so these traces suffice.

Proof on paper. $(V_2)_n = \bigoplus_w e^{w\alpha} \otimes M(1)_{n-w^2}$ and $\dim M(1)_k = p(k)$; g_u is the scalar u^w on the w-th summand. □

Physical meaning

A rotation about a fixed axis of $SU(2)$ acts on the states of momentum w by the phase u^w; the trace is the partition function with a $U(1)$ chemical potential.

What the machine verified

Proved, Lean's three axioms.

Theorem 22.32 (Pairwise distinctness). *A VOA carries at most one label of the list.*

File `VOA/Classification/COne/DistinctResiduals.lean`.

```
theorem plusExceptionalResidual : PlusExceptionalResidual.{u} := by
```

File `VOA/Classification/COne/DistinctResiduals.lean`.

```
theorem exceptionalResidual : ExceptionalResidual.{u} := by
```

File `VOA/Classification/COne/DistinctResiduals.lean`.

```
theorem gannonRayhaunDistinct : GannonRayhaunDistinct.{u} :=
  gannonRayhaunDistinct_of_residuals plusExceptionalResidual exceptionalResidual
```

From the mathematics to the Lean statement

Universe-polymorphic and hypothesis-free. Together with Theorem 22.28 it gives GR's "isomorphic to *exactly* one".

Proof on paper. With Molien and the torus traces, and the element counts by order of A_4, S_4, A_5 ((1, 3, 8, 0, 0), (1, 9, 8, 6, 0), (1, 15, 20, 0, 24) for orders $1, \dots, 5$), one computes exactly

$$\dim(V_2^G)_4 = p(4) - p(3) = 2, \qquad \dim(V_2^G)_{16} = p(16) - p(15) + \begin{cases} p(7) & G \cong A_4 \\ p(0) & G \cong S_4 \\ 0 & G \cong A_5 \end{cases}$$

(70, 56, 55). Since $p(7) = 15 \ge 2 > p(0) = 1 > 0$, the three are pairwise different (`exceptionalResidual`). For V_{2m}^+ with $m \ge 4$ one finds $\dim(V_{2m}^+)_4 = e + [m = 4]$ with e the number of partitions of 4 into an even number of parts, while $p(4) - p(3) = e + o - 3$ with $o \le 2$ the odd count; equality is impossible (`plusExceptionalResidual`). The easy pairs are handled in `Distinct.lean`. The weight-16 numbers were also checked independently by a spin decomposition $\sum_j (p(n-j^2) - p(n-(j+1)^2)) \dim(\text{spin } j)^G$, which is an independent consistency check, not part of the proof. □

Physical meaning

The tetrahedral, octahedral and icosahedral gaugings keep different numbers of $SU(2)$-invariant combinations of spin-j states (the first difference is at spin 3 and 4); counting gauge-invariant states at energy 16 distinguishes them.

What the machine verified

Proved with no hypotheses. `##print axioms gannonRayhaunDistinct` (machine-checked 2026-10-13): `[propext, Classical.choice, Quot.sound]` — no `VOA.pbw`.

22.8 The converse

The converse says every VOA in the list is nice and has $c = 1$. For V_{2m} and V_{2m}^+ this is proved directly; for the three exceptional orbifolds the proof needs four facts (Definition 22.35): the C_2-cofiniteness of $V_2^{A_4}$ and $V_2^{S_4}$, Xu's icosahedral relations (which give the C_2-cofiniteness of $V_2^{A_5}$), and the positivity of the conformal weights of the exceptional orbifolds are explicit computations (this section); the rationality of the exceptional orbifolds — more precisely, of every C_2-cofinite orbifold of V_2 by a finite group — is a theorem of McRae whose formalization occupies Section 22.9. All four are proved, and the assembled converse is Theorem 22.59.

22.8.1 The lattice and plus families

Theorem 22.33 (V_{2m} is nice). *For every $m \geq 1$, V_{2m} is strongly rational and pseudo-unitary.*

File `VOA/Classification/COne/LatticeStronglyRational.lean`.

```
theorem V2m_stronglyRational (m : ℕ) (hm : 1 ≤ m) : StronglyRational (V2m m hm) :=
```

File `VOA/Classification/COne/LatticeNice.lean`.

```
theorem V2m_pseudoUnitary : PseudoUnitary (V2m m hm) :=
```

File `VOA/Classification/COne/LatticeNice.lean`.

```
theorem V2m_nice : Nice (V2m m hm) := ⟨V2m_stronglyRational m hm, V2m_pseudoUnitary m hm⟩
```

From the mathematics to the Lean statement

`V2m_pseudoUnitary` and `V2m_nice` are stated inside a section with variables `(m : ℕ) (hm : 1 ≤ m)`, so they hold for every $m \geq 1$.

Proof on paper. Simplicity and self-duality come from the nondegenerate invariant form of a positive-definite lattice VOA; C_2-cofiniteness from the Fock-space description (the C_2 quotient is spanned by finitely many classes of e^{β} and $\alpha(-1)^k$); rationality (Dong; Dong–Li–Mason) from a Stone–von Neumann decomposition of every admissible module into $M(1) \otimes \Omega$, semisimplicity of $h(0)$ on Ω and the classification of irreducibles $V_{L+j/(2m)\alpha}$, j mod $2m$. Pseudo-unitarity: the irreducible modules not isomorphic to V_{2m} are $V_{L+\lambda_j}$ with $0 < |j| \leq m$, of lowest weight $j^2/(4m) > 0$. □

Physical meaning

The compact boson at a rational radius has $2m$ primaries of weights $j^2/4m$, all positive except the vacuum.

What the machine verified

Proved unconditionally, Lean's three axioms.

Theorem 22.34 (V_{2m}^+ is nice). *For every $m \geq 1$, V_{2m}^+ is nice.*

File `VOA/Classification/COne/MainConverse.lean`.

```
theorem V2mPlus_nice (m : ℕ) (hm : 1 ≤ m) : Nice (V2mPlus m hm) :=
  nice_V2mPlus_of_rational_pseudoUnitary v2mPlusRationalFactGe2_holds
    v2mPlusPseudoUnitaryFactGe2_holds m hm
```

Proof on paper. C_2-cofiniteness by an explicit strong-generation argument; pseudo-unitarity from the known list of irreducible V_{2m}^+-modules (Dong–Nagatomo) and their weights; rationality ($m \geq 2$) by a uniform version of Abe's splitting argument. For $m = 1$, $V_2^+ \cong V_8$ reduces to Theorem 22.33. □

Physical meaning

The points of the orbifold line are unitary rational CFTs.

What the machine verified

Proved unconditionally, Lean's three axioms (machine-checked 2026-10-13).

22.8.2 The exceptional orbifolds: the four inputs

Definition 22.35 (The four exceptional inputs). **(a) C_2-cofiniteness of $V_2^{A_4}$ and $V_2^{S_4}$**: V_2^G is C_2-cofinite for $G \cong A_4, S_4$ (Miyamoto's solvable-orbifold theorem, specialized). **(b) Xu's icosahedral relations**: for $G \cong A_5$ there are a weight-36 vector $X \in V_2^G$ and nonzero couplings c_0, c_6 such that, in the C_2-algebra, the classes $D^n\mathbf{1}$, D^nX ($D =$ the action of L_{-2}) span, and two explicit linear relations hold among $D^{37}\mathbf{1}, D^{19}X$ and $D^{38}\mathbf{1}, D^{20}X$ with Xu's integer coefficients. **(c) Positivity of the conformal weights of the exceptional orbifolds**: if an exceptional orbifold is strongly rational, it is pseudo-unitary. **(d) Rationality of the exceptional orbifolds**: for every finite $G \leq \mathrm{Aut}\, V_2$, if V_2^G is C_2-cofinite then it is rational (McRae, arXiv:1910.13226, Cor. 4.23).

The project's internal roadmap called these four facts `B2`, `B4`, `B5` and `B3` respectively; those labels survive in some Lean names (for instance `gannonRayhaunConverse_of_B3`, `MainConverseB4.lean`), but are not used in the prose of this book.

```

From the mathematics to the Lean statement

`(orbifold G).carrier` is the subspace of fixed vectors; `mk₂ W` the projection to the C_2-algebra $R_W = W/C_2(W)$; `exceptionalConformalEnd W` the endomorphism of R_W induced by L_{-2}; `xuU37`, `xuV19`, `xuU38`, `xuV20` are Xu's integers. The `Submodule.span … = ⊤` clause says R_W is spanned by the two L_{-2}-strings, which with the two relations makes R_W finite-dimensional. `IsExceptionalV2Group G` is the disjunction $G \cong A_4 \vee G \cong S_4 \vee G \cong A_5$. In Theorem 22.36 below, `A₂ W` is the same C_2-algebra $R_W = W/C_2(W)$, so `Module.finrank ℂ (A₂ (orbifoldVOA G)) ≤ 58` bounds its dimension. `[Finite G]` in `FiniteV2OrbifoldRationalOfC2Fact` quantifies over *all* finite subgroups — more than the converse needs (only the three exceptional ones), but this is McRae's theorem at its natural generality, and it is true. **Stronger than needed, not stronger than the literature.**

Physical meaning

Facts (a) and (b) say the exceptional gauged theories have finitely many "classical" states modulo derivatives (lisse); fact (d) says lisse orbifolds of rational theories are rational (gauging a finite symmetry of a rational theory gives a rational theory); fact (c) says gauging keeps energies positive (twisted sectors have positive weight).

What the machine verified

(a) C_2-cofiniteness of $V_2^{A_4}, V_2^{S_4}$: **proved** (`solvableExceptionalOrbifoldC2Fact_holds`). (b) Xu's relations: **proved** (`xuIcosahedralPoissonRelations_holds`). (c) Positivity of the conformal weights: **proved** (`OrbIcoZ.exceptionalOrbifoldPositiveWeightsFact_holds`). (d) Rationality: **proved** (`finiteV2OrbifoldRationalOfC2`, Theorem 22.54; it was the last open input of the converse until 2026-10-14).

Theorem 22.36 (C_2-cofiniteness and positivity for the exceptional orbifolds). *The three facts (a), (b), (c) of Definition 22.35 hold. In particular every V_2^G with $G \cong A_5$ is C_2-cofinite with* $\dim R_{V_2^G} \le 58$.

theorem exceptionalOrbifoldPositiveWeightsFact_holds :
    ExceptionalOrbifoldPositiveWeightsFact :=
```

Proof on paper. (a) C_2-cofiniteness of $V_2^{A_4}$ and $V_2^{S_4}$. For A_4 and S_4 the library proves the needed nilpotence of L_{-2} on the C_2-algebra directly: a spanning set of V_2^G by Virasoro descendants of finitely many primaries (from invariant theory of the binary polyhedral group acting on the charge sectors), and explicit relations (Dong–Jiang type) giving $D^{25} = 0$ in the octahedral case. A recorded trap: a constant printed in the source paper is wrong; the relation used is the corrected one (Section 22.11). *(b) Xu's icosahedral relations.* Xu's relations are established in the actual VOA: a generic Ward-identity solution over a family of Fock modules is specialized to $c = 1$, resonant pivots are cancelled by exact jet arithmetic, and the four actual coefficients are identified with nonzero ground couplings times Xu's values. *(c) Positivity of the conformal weights.* Positivity of the conformal weights of all irreducible modules of the exceptional orbifolds is reduced to finite Zhu-algebra certificates (level-13 mode computations, exact determinant factorizations with strictly positive roots). □

Physical meaning

These are the hard, explicit computations behind the statement "the exceptional $c = 1$ theories are lisse and unitary-like". The icosahedral case is the hardest because A_5 is not solvable, so Miyamoto's theorem does not apply.

What the machine verified

Proved unconditionally. `##print axioms`: Lean's three (maintained audit, 2026-10-13).

Theorem 22.37 (The converse from orbifold rationality; historical reduction)**.** *If the rationality of the exceptional orbifolds (fact (d) of Definition 22.35) holds, every VOA in the list (with carrier in universe* 0*) is nice and has central charge* 1*.*

File `VOA/Classification/COne/MainConverseB4.lean`.

```
theorem gannonRayhaunConverse_of_B3 (hRat : FiniteV2OrbifoldRationalOfC2Fact) :
    GannonRayhaunConverse.{0} :=
  gannonRayhaunConverse_of_B3_B4 xuIcosahedralPoissonRelations_holds hRat
```

From the mathematics to the Lean statement

One explicit hypothesis, `hRat : FiniteV2OrbifoldRationalOfC2Fact`. Conclusion `GannonRayhaunConverse.{0}`: the converse for carriers in `Type 0`. This was, until 2026-10-14, the form in which the library stated the converse. The hypothesis is now a theorem (`finiteV2OrbifoldRationalOfC2`, Theorem 22.54), so the reduction is kept as a step of the proof, not as a residual.

Remark 22.38 (Universe)**.** The converse is stated at universe `0` only, while the forward theorem and distinctness hold in every universe. Every VOA of the list has a model on a `Type 0` carrier (V_{2m} lives there), so nothing is lost mathematically; but a listed VOA built on a carrier in a higher universe is not covered by the Lean statement, and the library does not prove a universe-transfer lemma for `Nice` (whose `PseudoUnitary` clause quantifies over modules in the universe of V). A referee should read the converse as "every listed VOA built on a `Type 0` carrier is nice". The restriction comes from the proof, not from the mathematics: a VOA in the list is compared, through an isomorphism, with one of the concrete models V_{2m}, V_{2m}^+, V_2^G, all built on `Type 0` carriers, and niceness is transported along that isomorphism, which the library does only between carriers in the same universe. The final theorem (Section 22.10) therefore states all three parts at universe `0`.

Proof on paper. Write V with a label. Lattice: Theorem 22.33 and transport of niceness along isomorphisms. Plus: Theorem 22.34. Exceptional: simplicity, self-duality, $c = 1$ and $V_1 = 0$ come from the orbifold structure; C_2-cofiniteness from fact (a) or from Xu's relations (b); rationality from C_2-cofiniteness by fact (d); pseudo-unitarity by the positivity of the conformal weights (c). □

Physical meaning

Once one knows that gauging a finite symmetry of $SU(2)_1$ yields a rational theory (Section 22.9), the whole list consists of rational unitary-like chiral algebras: the only thing the reduction still needs from outside is the absence of logarithmic sectors in the three exceptional gaugings.

What the machine verified

Proved, `##print axioms` = `[propext, Classical.choice, Quot.sound]` (machine-checked 2026-10-13). Conditional on `FiniteV2OrbifoldRationalOfC2Fact`, **which is now proved** (Theorem 22.54). Composing the two gives the unconditional converse `gannonRayhaunConverse_holds` (Theorem 22.59); note that the composition uses the theorem `VOA.pbw` through the proof of orbifold rationality, although this reduction step alone does not.

22.9 Rationality of the orbifolds of V_2: McRae's orbifold theorem

This section proves the rationality of the exceptional orbifolds, fact (d) of Definition 22.35, in its general form: *for every finite group G of automorphisms of V_2 such that V_2^G is C_2-cofinite, V_2^G is rational*. It was the last open input of the converse. The route is McRae's theorem on compact orbifolds (arXiv:1910.13226, Theorem 4.20 and Corollary 4.23), specialized to $V = V_2$:

> *If V is strongly rational, G is a finite group of automorphisms of V, and V^G is C_2-cofinite, then V^G is strongly rational.*

The library formalizes the argument in seven steps, listed with their titles in Section 22.9.1 and referred to below as Step 1, ..., Step 7. Several of them are proved for an arbitrary ambient VOA, some only for V_2; the dependence on V_2 enters at exactly one point, Step 5 (twisted parts are modules for the cyclic orbifolds), through the fact that every cyclic orbifold $V_2^{\langle g\rangle}$ is a lattice VOA and hence rational. We first explain the shape of the argument, then go through the steps.

22.9.1 The plan, and the notation

Notation. Throughout, V is the ambient VOA (for us $V = V_2$), $G \leq \operatorname{Aut} V$ is a finite subgroup, and V^G is the fixed-point subalgebra (`orbifoldVOA G`, Chapter 32). The reader should note a clash with the Lean names: in the Lean files of this section the *ambient VOA* is called `W` and its *carrier type* is called `V`, so `orbifoldVOA G` is our V^G. We write $\mathcal{C}$ for the category of finitely generated grading-restricted generalized ("logarithmic") V^G-modules, `LogModuleCat (orbifoldVOA G)` (Chapter 21, Definition 21.26); $\boxtimes$ for the Huang–Lepowsky–Zhang tensor product in $\mathcal{C}$; $\mathbf{1} = V^G$ for its unit; α, λ, ρ for associator and unitors; $c_{X,Y} : X \boxtimes Y \to Y \boxtimes X$ for the braiding; and $M_{X,Y} = c_{Y,X} \circ c_{X,Y}$ for the *monodromy* (double braiding).

The idea. Rationality of V^G means that every (admissible) V^G-module is a direct sum of irreducibles. The danger, for a C_2-cofinite VOA, is *logarithmic* modules: indecomposable modules on which L_0 has Jordan blocks, which are extensions of irreducibles that do not split. McRae's insight is that every V^G-module Y can be "lifted" to a V-module in a generalized sense, namely the *induced*

module $V \boxtimes Y$, and that such generalized V-modules are controlled by honest *twisted* V-modules, which, for a rational V, are well behaved. In more detail, the seven steps, with the titles by which we refer to them, are:

Step 1. *Finitely many irreducibles.* Every C_2-cofinite VOA has finitely many irreducible modules, without assuming that its Zhu algebra is semisimple; this finiteness theorem is needed to construct $\boxtimes$ on finite-length modules.

Step 2. *The braided tensor category of logarithmic modules.* Build the braided monoidal category $\mathcal{C}$ of logarithmic V^G-modules: the pentagon, the braiding and the hexagons.

Step 3. *The ambient VOA as a commutative algebra.* Show that V itself, viewed as a V^G-module, is an object of $\mathcal{C}$ and a *commutative algebra* in it: the vertex operator of V is a V^G-intertwining operator of type $\binom{V}{V\,V}$, hence a morphism $\mu : V \boxtimes V \to V$, which is associative and commutative. Left modules for this algebra are "generalized V-modules" (they may be twisted).

Step 4. *Projections onto twisted parts.* Show that every module X for the algebra V splits, by explicit idempotents π_g ($g \in G$), into parts $\pi_g X$ on which the monodromy of V around X acts by g: the *g-twisted parts* (McRae's Theorem 3.3). The idempotents are built from a *coevaluation* $\tilde{\iota} : \mathbf{1} \to V \boxtimes V$, which exists because V is a rigid self-dual object of dimension $|G|$, proved here by Galois descent. We split this step in three: *Step 4a*, the Dong–Li–Mason Schur–Weyl duality, which supplies the finiteness and density inputs; *Step 4b*, rigidity and self-duality of V by Galois descent; *Step 4c*, McRae's projections π_g onto the twisted parts.

Step 5. *Twisted parts are modules for the cyclic orbifolds.* On a g-twisted part, the elements of V fixed by g have trivial monodromy, so their vertex operators have integral powers and no logarithms (*Step 5a*); they satisfy the Jacobi identity (*Step 5b*, the "Jacobi bridge"), so $\pi_g X$ is an honest module for the cyclic orbifold $V^{\langle g\rangle}$. For $V = V_2$, $V_2^{\langle g\rangle}$ is a lattice VOA V_{2n^2}, hence rational (*Step 5c*). So every surjection of V-modules splits V^G-linearly on each twisted part, and hence on the whole module (*Step 5d*).

Step 6. *Every surjection splits (McRae's Lemma 4.21).* From Step 5 applied to induced modules $V \boxtimes Y$, every surjection in $\mathcal{C}$ splits.

Step 7. *Split surjections imply rationality.* A C_2-cofinite VOA all of whose surjections in $\mathcal{C}$ split is rational.

The Lean files and some Lean names carry the project's internal labels for these steps, `O1`, ..., `O7` (with sub-steps such as `O4b`, `O5b`); for instance `McRaeO1FinitePhi.lean` belongs to Step 1 and the namespace `McRaeO5b` to Step 5b. The label `On` always means Step n, and the label `M2` in `McRaeM2LogBraided.lean` is left over from the internal labels of the earlier, abandoned route (Section 22.9.12); that file belongs to Step 2. We use the step numbers only.

The argument never needs the rigidity of $\mathcal{C}$ itself, modular invariance of logarithmic characters, factorizability, or the semisimplicity of Zhu's algebra of V^G — the inputs of the earlier, abandoned route (Section 22.9.12). That is why it could be completed.

Where `VOA.pbw` enters. The construction of $\boxtimes$ uses the finiteness theorem of Step 1 in its `_pbw` form, so every statement below that mentions the tensor category uses the theorem `VOA.pbw`. The purely algebraic or analytic steps (Schur–Weyl duality, the abstract projection theorem, the residue identity, the rationality of cyclic orbifolds, splitting ⇒ rationality) do not. The status boxes record which is which, from the project's audit logs. For this revision the `##print axioms` of every headline quoted below was re-run against the built tree at an earlier commit (with `lake env lean -DmaxSynthPendingDepth=3`, the audit-safe invocation; not repeated for this edition), and agrees with those logs; the final theorems were in addition machine-checked by the coordinator on 2026-10-14 (Section 22.10).

The physical picture of the whole argument. Gauging a finite symmetry G of a rational CFT produces a theory whose sectors are labelled by a twist $g \in G$ (the boundary condition of the fields around the insertion point) and by a representation of the centralizer. The untwisted sector decomposes V under G; the g-twisted sectors are the g-twisted modules of V. McRae's argument is the precise mathematical version of the statement "every sector of the gauged theory comes from a twisted sector of the parent theory". The parent theory $SU(2)_1$ (V_2) is rational, and each of its twisted sectors, seen through the cyclic subgroup $\langle g \rangle$, is a sector of a compact boson at a rational radius; so no logarithmic sector can appear in the gauged theory.

22.9.2 Step 1: finitely many irreducibles, without a semisimple Zhu algebra

Theorem 22.39 (Step 1: finitely many irreducibles)**.** *Every C_2-cofinite VOA has finitely many isomorphism classes of irreducible ordinary modules.*

File `VOA/Classification/COne/McRaeO1FinitePhi.lean`.

```
theorem finite_Φ_of_C2Cofinite_pbw (hC2 : C2Cofinite W) : Finite (Φ W) :=
  finite_Φ_of_C2Cofinite' (voaPBWBottomProjection (parabolicRepOfAMod W (regularAMod W)))
   ↪ hC2
```

From the mathematics to the Lean statement

`Φ W` is the type of isomorphism classes of irreducible ordinary W-modules, `Finite` says it is finite. The only hypothesis is `C2Cofinite W`. The proof term shows how `VOA.pbw` enters: the bottom projection of Zhu's induced module is supplied by `voaPBWBottomProjection`. The full fidelity check, the `Pr`-hypothesis primed form and the consumer `finiteLength_maximal_of_c2` are in Chapter 21, Theorem 21.25.

Proof on paper. Zhu's algebra $A(W)$ is finite-dimensional, hence Artinian; $A/J(A)$ is semisimple with finitely many simple summands; every simple A-module is killed by $J(A)$, so it is one of these; bottom levels of irreducible modules are simple A-modules and determine the module. (Chapter 21.) □

Physical meaning

A lisse chiral algebra has finitely many primary fields, logarithmic or not; this is what makes the fusion of finite-length modules land in finite-length modules.

What the machine verified

Proved; Lean's three axioms (it uses the theorem `VOA.pbw`; while `VOA.pbw` was an axiom the report also listed `VOA.pbw`) (audit log of Step 1). It removed the hypothesis `hss` (semisimple Zhu algebra) from the whole logarithmic tensor chain.

22.9.3 Step 2: the braided tensor category of logarithmic modules

Theorem 22.40 (Step 2: braided tensor category; Huang–Lepowsky–Zhang)**.** *For every C_2-cofinite VOA W, the category of finitely generated logarithmic W-modules, with the Huang–Lepowsky–Zhang tensor product, the vacuum module as unit, the analytically constructed associator, the unitors and the braiding induced by skew-symmetry, is a braided monoidal category.*

File `VOA/Classification/COne/McRaeM2LogBraided.lean`.

```
theorem nonempty_logarithmicBraidedCategory (hC2 : C2Cofinite W) :
    Nonempty (@BraidedCategory (LogModuleCat W) _ (logarithmicMonoidalCategory hC2)) :=
  ⟨logarithmicBraidedCategory hC2⟩
```

From the mathematics to the Lean statement

The two structures `logarithmicMonoidalCategory hC2` and `logarithmicBraidedCategory hC2` are quoted in full, with their fidelity checks, in Chapter 21, Theorems 21.29 and 21.30. The point a referee should check is that the bare type `BraidedCategory (LogModuleCat W)` is not the content: any category admits trivial monoidal structures. The content is that the *specific* structures are the intended ones, which the library pins down by definitional lemmas proved by `rfl`: the tensor object is `tensorObject hC2 N P` (the HLZ $P(z)$-tensor product), the associator is `associatorIso`, the unit is the adjoint module, and the braiding is `swapIso hC2 X Y 0`, induced by the skew-symmetry operator Ω_0. Every later step uses these structures through the local instances `letI := logarithmicMonoidalCategory hC2` and `letI := logarithmicBraidedCategory hC2`.

Proof on paper. See Chapter 21, Section 21.7: the pentagon is the equality of the two ways of associating a product of four intertwining operators, proved by showing that all five bracketings converge on a common domain, agree there by repeated use of the associativity of two intertwiners, and that a two-variable power-log series which vanishes on an open set has zero coefficients. The hexagons combine associativity with the skew-symmetry operator $\Omega_0(\mathcal{Y})(w_2,z)w_1 = e^{zL_{-1}}\mathcal{Y}(w_1,e^{\pi i}z)w_2$, which turns an intertwining operator of type $\binom{W_3}{W_1\ W_2}$ into one of type $\binom{W_3}{W_2\ W_1}$ and induces the braiding, using analytic continuation of products to a half-plane and the gluing of four local expansions around a common point. □

Physical meaning

Fusion of sectors of a logarithmic CFT is associative up to F-moves and commutative up to R-moves; the pentagon and hexagons are the consistency of four- and five-point conformal blocks. Here they are proved for logarithmic blocks, which carry powers of $\log z$.

What the machine verified

Proved; the only hypothesis is `C2Cofinite W`; Lean's three axioms (it uses the theorem `VOA.pbw`; while `VOA.pbw` was an axiom the report also listed `VOA.pbw`) (audit logs of the two halves of Step 2, monoidal and braided).

22.9.4 Step 3: the ambient VOA as a commutative algebra

Definition 22.41 (The object V of $\mathcal{C}$). Let V be a VOA, $G \le \mathrm{Aut}\,V$, and assume V is finitely generated as a weak V^G-module. Then V, with the V^G-action by restriction of its own vertex operator, is an object of $\mathcal{C}$.

File `VOA/Classification/COne/McRaeO3Object.lean`.

```
def vObj (hfg : FinGen (orbifold G).adjointRestrict) : LogModuleCat (orbifoldVOA G) :=
  LogModuleCat.of (ambientLog G) hfg
```

File `VOA/Classification/COne/McRaeO3Object.lean`.

```
abbrev ambientLog : LogVModule (orbifoldVOA G) V := (orbifold G).adjointRestrictOrd.toLog
```

From the mathematics to the Lean statement

`(orbifold G).adjointRestrict` is the adjoint module of the ambient VOA restricted to the subalgebra V^G; `FinGen` says it is finitely generated (finitely many vectors whose V^G-submodule is everything). `ambientLog G` views this restriction as a logarithmic module (Chapter 12, Definition 12.8); its grading is the ambient L_0-grading, so L_0 acts semisimply. `LogModuleCat.of`

bundles a logarithmic module with a proof of finite generation into an object of $\mathcal{C}$. The hypothesis `hfg` is discharged for V_2 in Step 4a (`V2m_orbifold_finGen`, Section 22.9.1).

Physical meaning

The parent theory's chiral algebra, decomposed into sectors of the gauged theory: the untwisted sector of the orbifold, before projection onto invariants.

What the machine verified

Definition. Lean's three axioms.

Theorem 22.42 (Step 3: V is a haploid commutative algebra in $\mathcal{C}$). *Let $G \le \mathrm{Aut}\, V$ be finite, with V^G C_2-cofinite and V finitely generated over V^G, and V nonzero. There are morphisms $\mu : V \boxtimes V \to V$ (induced by the vertex operator of V), $\iota : \mathbf{1} \to V$ (the inclusion $V^G \subset V$), $\varepsilon : V \to \mathbf{1}$ (the average $\frac{1}{|G|}\sum_g g$) and, for $g \in G$, $g : V \to V$, such that (V, μ, ι) is a commutative monoid object of the braided category $\mathcal{C}$;* $\dim \mathrm{Hom}(\mathbf{1}, V) = 1$ *("haploid"); each g is an algebra automorphism; and $\varepsilon \circ \iota = \mathrm{id}$, while $\iota \circ \varepsilon$ is the average over G:*

$$\mu \circ c_{V,V} = \mu, \qquad \varepsilon \circ \iota = \mathrm{id}_{\mathbf{1}}, \qquad \iota \circ \varepsilon = \frac{1}{|G|}\sum_{g \in G} g.$$

From the mathematics to the Lean statement

The section variables are `(G : Subgroup (Aut W)) (hfg : FinGen (orbifold G).adjointRestrict) (hC2 : C2Cofinite (orbifoldVOA G))`. `monObj G hfg hC2` is a Mathlib `MonObj` (monoid object: `one`, `mul` with unit and associativity laws) on `vObj G hfg`, whose `one` is `unitHom` (ι) and whose `mul` is `mulHom` (μ), both by `rfl` (`monObj_one`, `monObj_mul`). `IsCommMonObj` says `(β_ V V).hom ≫ mul = mul` for the braiding of `logarithmicBraidedCategory`. `𝟙_ C` is the monoidal unit, `⟶` the morphism type, so the second clause is $\dim_{\mathbb{C}} \mathrm{Hom}_{\mathcal{C}}(\mathbf{1}, V) = 1$. `autHom G hfg g` is g acting on V as a morphism of $\mathcal{C}$ (it is V^G-linear because V^G is fixed by g), and `IsMonHom` says it preserves unit and multiplication. `counitHom` is the Reynolds average ε; in the last clause $\bullet$ is scalar multiplication of morphisms. `[Nontrivial V]` excludes the zero carrier (needed for haploidy); `[Fintype G]` gives $|G|$. The statement is the commutative-algebra part of McRae's Assumption 3.1. Could it hold for a wrong μ? No: `mulHom` is defined (`mulHom`, `McRaeO3Algebra.lean`) as the morphism out of $V \boxtimes V$ corresponding, by the universal property of $\boxtimes$, to the vertex operator of V itself (`vertexIntertwiner G`).

Proof on paper. The product. For $u \in V^G$ and $a, b \in V$, the Jacobi identity of V for the triple (u, a, b) says precisely that $Y_V(\cdot, z)$ is an intertwining operator of type $\binom{V}{V\,V}$ for the algebra V^G; it has integral

powers and no logarithms. The universal property of $V \boxtimes V$ turns it into μ. *Commutativity.* The braiding is induced by Ω_0: $\Omega_0(\mathcal{Y})(a,z)b = e^{zL_{-1}}\mathcal{Y}(b,e^{\pi i}z)a$. For $\mathcal{Y} = Y_V$ the skew-symmetry of a VOA, $Y(a,z)b = e^{zL_{-1}}Y(b,-z)a$, and the fact that $e^{\pi i(n+1)} = (-1)^{n+1}$ for integral n, give $\Omega_0(Y_V) = Y_V$, i.e. $\mu \circ c_{V,V} = \mu$. *Associativity.* Testing $\mu \circ (\mu \boxtimes 1)$ and $\mu \circ (1 \boxtimes \mu) \circ \alpha$ on the canonical elements of the triple tensor product turns them into the iterate $Y_V(Y_V(a,z_1-z_2)b,z_2)c$ and the product $Y_V(a,z_1)Y_V(b,z_2)c$; these agree on the common domain by the associativity of V (the Jacobi identity of V, summed into a convergent series at a complex point). *Unit laws* are creation and the vacuum property. *Haploid.* A V^G-module map $f : V^G \to V$ is determined by $f(\mathbf{1})$, which has weight 0, and $V_0 = \mathbb{C}\mathbf{1}$ (the library's VOAs are of CFT type); so f is a multiple of ι. *Counit.* The average $\varepsilon(a) = \frac{1}{|G|}\sum_g ga$ lands in V^G and is V^G-linear; it fixes V^G. □

Physical meaning

In the gauged theory, the parent chiral algebra V becomes a "condensable algebra" of the orbifold's sectors: its fields close under fusion with trivial self-braiding (locality of the parent theory), and the vacuum appears exactly once. Undoing the gauging is condensing this algebra.

What the machine verified

Proved, conditional on the displayed hypotheses `hfg`, `hC2` (both discharged for V_2: `hfg` by Step 4a, `hC2` in the application by the C_2-cofiniteness facts (a) and (b) of Definition 22.35). Lean's three axioms (it uses the theorem `VOA.pbw`; while `VOA.pbw` was an axiom the report also listed `VOA.pbw`), inherited from the tensor category (audit log of Step 3). Right exactness of $V \boxtimes -$ is proved in the concrete form `tensorMorphism_epi` (if q is surjective, $1 \boxtimes q$ is an epimorphism), which is what Step 6 uses.

22.9.5 Step 4a: Schur–Weyl duality and finite generation

Definition 22.43 (Dong–Li–Mason Schur–Weyl duality). For a simple VOA V and finite $G \leq \mathrm{Aut}\,V$, and each irreducible representation E of G, let $M_E = \mathrm{Hom}_G(E,V)$ (the multiplicity space). DLM duality says: $M_E \neq 0$; M_E is an irreducible V^G-module; and $M_E, M_{E'}$ are inequivalent for $E \ncong E'$. Hence $V = \bigoplus_E E \otimes M_E$ with the M_E pairwise distinct irreducible V^G-modules.

From the mathematics to the Lean statement

`multSpace G σ` is the subspace of linear maps $\varphi : E \to V$ with $g(\varphi(x)) = \varphi(\sigma(g)x)$, i.e. $\mathrm{Hom}_G(E, V)$ (with $V = \bigoplus_n V_n$ the algebraic direct sum, so this is DLM's $\bigoplus_n \mathrm{Hom}_G(E, V_n)$). V^G acts on it by post-composition with modes, $\varphi \mapsto u_{(n)} \circ \varphi$ (`modeOp W u n`). Clause one: $M_E \neq 0$. Clause two: every subspace stable under all these modes (`ModeStable`) is 0 or all, i.e. M_E is irreducible. Clause three: every V^G-mode-commuting linear map $M_E \to M_{E'}$ with $E \not\cong E'$ (`IsEmpty (σ.Equiv σ')`) is zero (Schur form of "inequivalent"). Irreducible representations are quantified over all finite-dimensional E in `Type`, which covers every isomorphism class. `FinGen (orbifold G).adjointRestrict`: V is finitely generated as a weak V^G-module, the field that `vObj` requires. The decomposition $V = \bigoplus_E E \otimes M_E$ as a direct sum is *not* formalized (it would need a finite list of representatives of the irreducibles of G); only the three clauses and finite generation are.

Proof on paper. Density. V is a simple module over the algebra generated by its modes; by Schur and $V_0 = \mathbb{C}\mathbf{1}$ its commutant is $\mathbb{C}$, so by the Jacobson density theorem the modes act densely. *Dedekind's lemma for automorphisms:* if $\sum_g (y_g)_{(n)}\, g(w) = 0$ for all n and all w, then all $y_g = 0$; this uses an annihilator-stability lemma (the vanishing persists after inserting further modes, by the Jacobi identity) and simplicity. *Averaging.* If a sum $\sum_i f_i \circ \chi_i$ of mode-algebra elements composed with G-equivariant maps is itself G-equivariant, averaging over G rewrites it with modes of G-invariant vectors, i.e. of V^G. These three facts give non-vanishing, irreducibility (any nonzero $\varphi \in M_E$ generates M_E under V^G) and inequivalence (a nonzero intertwiner would have a graph which is a V^G-stable subspace of $M_{E\oplus E'}$ not of product form). *Finite generation.* Apply the same density and Dedekind arguments to the regular representation $\mathbb{C}^G$: finitely many orbit maps $g \mapsto g(b_j)$ already separate, so finitely many vectors b_j generate V over V^G. □

Physical meaning

The untwisted sector of the gauged theory decomposes the parent chiral algebra by G-charge: each irreducible charge E comes with its own primary family M_E, every charge occurs, and different charges give different sectors. This is the "Schur–Weyl" or "charge–sector" duality familiar from orbifold CFT.

What the machine verified

Proved: `dlmSchurWeyl_holds` and `V2m_orbifold_finGen` use Lean's three axioms only, no `VOA.pbw` (Step 4a audit log).

22.9.6 Step 4b: V is rigid and self-dual of dimension $|G|$: Galois descent

Theorem 22.44 (Step 4b: rigidity and self-duality; McRae Assumption 3.1, rigidity and dimension)**.** *In the setting of Theorem 22.42, with V simple, there is a morphism $\tilde{\iota} : \mathbf{1} \to V \boxtimes V$ such that $(V,\ \mathrm{ev} = \varepsilon \circ \mu,\ \tilde{\iota})$ satisfies both zigzag identities (so V is a rigid, self-dual object of $\mathcal{C}$), and $\mu \circ \tilde{\iota} = |G|\, \iota$; in particular $\varepsilon \circ \mu \circ \tilde{\iota} = |G| \cdot \mathrm{id}_{\mathbf{1}}$, i.e. $\dim V = |G|$.*

      (ρ_ _).hom ≫ (λ_ _).inv ∧
    coev ≫ mulHom G hfg hC2 = (Fintype.card G : ℂ) • unitHom G hfg := by
```

From the mathematics to the Lean statement

Section variables: `G`, `hfg`, `hC2` as before, plus `[Fintype G] [DecidableEq G] (hW : W.IsSimple)`. Mathlib's notation: `f ▷ X` is $f \boxtimes \mathrm{id}_X$, `X ◁ f` is $\mathrm{id}_X \boxtimes f$, `α_`, `λ_`, `ρ_` the associator and unitors, `≫` composition in diagrammatic order (first left, then right). The first conjunct is the zigzag $(\mathrm{id}_V \boxtimes \mathrm{ev}) \circ \alpha \circ (\tilde{\iota} \boxtimes \mathrm{id}_V) = \rho^{-1} \circ \lambda$, the second the other zigzag, with $\mathrm{ev} = \varepsilon \circ \mu$ (`mulHom ≫ counitHom`); together they say $(V, \mathrm{ev}, \tilde{\iota})$ is an exact pairing, Mathlib's `ExactPairing V V` (`vObjExactPairing`). The third is the dimension condition. This is exactly the rigidity-and-dimension part of McRae's Assumption 3.1. It does *not* say $\mathcal{C}$ is rigid — only the object V is — and McRae's argument needs no more. The V_2 instance `V2m_rigidity_dimension` (same file) discharges `hfg` and `hW`.

Proof on paper: Galois descent. McRae proves this with Kirillov's functor $\mathrm{Rep}\, G \to \mathcal{C}$; the library uses instead the Chase–Harrison–Rosenberg argument for Galois extensions of commutative rings, which is shorter. For $g \in G$ put

$$\psi_g = \mu \circ (\mathrm{id} \boxtimes g) : V \boxtimes V \to V, \qquad a \boxtimes b \mapsto a \cdot g(b).$$

Part (i) (abstract, in any $\mathbb{C}$-linear monoidal category). Suppose $\tilde{\iota}$ satisfies the *Galois condition* $\psi_g \circ \tilde{\iota} = |G|\, \delta_{g,1}\, \iota$. Write symbolically $\tilde{\iota} = \sum_i x_i \boxtimes y_i$. Then for $a \in V$,

$$\sum_i x_i\, \varepsilon(y_i a) = \frac{1}{|G|} \sum_i \sum_g x_i\, g(y_i)\, g(a) = \frac{1}{|G|} \sum_g \Big(\sum_i x_i g(y_i) \Big) g(a) = \frac{1}{|G|}\, |G|\, a = a,$$

using $\iota\varepsilon = \frac{1}{|G|} \sum_g g$, that each g is an algebra map, and associativity and commutativity. This is the first zigzag; the second is symmetric; and $\mu \circ \tilde{\iota} = \sum_i x_i y_i = |G| \iota$ is the case $g = 1$. In the library this computation is carried out with morphisms (`GaloisData.exactPairing`), the step "$\sum_h a\, h(bc) \otimes d = \sum_y a \otimes y(b\, \psi_{y^{-1}}(c \otimes d))$" being the one identity that needs care. *Part (ii) (surjectivity).* Write $a \boxtimes_n b \in V \boxtimes V$ for the coefficient of z^{-n-1} in the canonical intertwining operator $Y_{\boxtimes}(a, z)b$ (no logarithms occur here, because the vertex operator of V has none). There is $w' \in V \boxtimes V$ with $\psi_g(w') = \delta_{g,1}\mathbf{1}$: by the density and Dedekind arguments of Step 4a, every function $\mathbb{C}^G \to V$ is a combination of $a_{(n)} \circ$ (orbit map of b), and $\psi_g(a \boxtimes_n b) = a_{(n)} g(b)$. *Part (iii) (injectivity).* The joint map $\Psi = (\psi_g)_g$ is injective on $V \boxtimes V$ (an identity of part (i) evaluated on canonical elements). *Part (iv).* Define $\tilde{\iota}(u) = u_{(-1)}(|G| w')$. That this is a V^G-module map is checked after composing with each ψ_g and transported back by injectivity; then $\psi_g \circ \tilde{\iota} = |G| \delta_{g,1} \iota$, and part (i) applies. □

Physical meaning

$\dim V = |G|$ is the statement that the parent theory, seen as a sector of the gauged theory, has quantum dimension $|G|$: gauging G divides the "number of states" by $|G|$, and the parent algebra is self-conjugate. The Galois condition says that the fusion $V \times V$ contains the vacuum once for each group element, which is the classical statement $V \otimes_{V^G} V \cong \bigoplus_{g \in G} V$ of Galois theory.

What the machine verified

Proved, conditional on the displayed hypotheses (for V_2 only `hC2` remains). Lean's three axioms (it uses the theorem `VOA.pbw`; while `VOA.pbw` was an axiom the report also listed `VOA.pbw`), inherited from the tensor category; the abstract Galois-descent lemmas use Lean's three only (Step 4b audit log). McRae's Lemma 3.8 (haploid + rigid + dim $= |G| \Rightarrow$ Galois condition) is not formalized and not needed: the Galois condition is proved directly (`coevHom_psi`).

22.9.7 Step 4c: McRae's Theorem 3.3, projections onto twisted parts

Definition 22.45 (Modules, monodromy, twisted). In a braided monoidal category, let (A, m, u) be an algebra. A *left A-module* is (X, a) with $a : A \otimes X \to X$ satisfying $a \circ (u \otimes 1) = \lambda$ and $a \circ (m \otimes 1) = a \circ (1 \otimes a) \circ \alpha$. The *monodromy* is $M_{X,Y} = c_{Y,X} \circ c_{X,Y}$. For an automorphism φ of A, the module is *φ-twisted* if $a \circ (\varphi \otimes 1) \circ M_{A,X} = a$. Finally, *McRae's Assumption 3.1* on a commutative algebra A with an action of a finite group G by algebra automorphisms $g : A \to A$ is the list: A is associative, unital and commutative; a counit $e : A \to \mathbf{1}$ with $u \circ e = \frac{1}{|G|} \sum_g g$; and a coevaluation $\tilde{\iota} : \mathbf{1} \to A \otimes A$ with $m \circ (1 \otimes g) \circ \tilde{\iota} = |G|\, \delta_{g,1}\, u$ for every g (the Galois condition, established in the proof of Theorem 22.44 as `coevHom_psi`). In Lean these are the structures `GaloisData` and `McRaeData` quoted below.

From the mathematics to the Lean statement

`C` is any category with `[MonoidalCategory C] [BraidedCategory C]` (and, for `McRaeData`, $\mathbb{C}$-linear structure); `β_` is the braiding. The module axioms are Mathlib's `ModObj` axioms (`isLeftModule_of_modObj`). Note the direction of composition: `monodromy A X ≫ φ ▷ X ≫ a = a` reads $a \circ (\varphi \otimes 1) \circ M_{A,X} = a$, McRae's Definition 2.3. `GaloisData` lists the algebra axioms, that G acts by algebra automorphisms (`act_mul`: $m \circ (g \otimes g) = g \circ m$; `unit_act`; invertibility), and that `e ≫ u` is the average. `McRaeData` adds commutativity, that `act` is a group action (`act_comp`: `act (g * h) = act h ≫ act g`, i.e. $\mathrm{act}(gh) = \mathrm{act}(g) \circ \mathrm{act}(h)$, an ordinary left action written in diagrammatic order), and the Galois condition `coev_psi`: $m \circ (1 \otimes g) \circ \tilde{\imath} = |G| \delta_{g,1} u$. For $\mathcal{C}$ and $A = V$ all fields are supplied by Steps 3 and 4b (`mcraeData`, `McRaeO4cInstance.lean`). Every field is a true property of the intended data, so the structure is satisfiable and not vacuous.

Physical meaning

A module of the condensed algebra V is a sector of the parent theory possibly with a twisted boundary condition: the monodromy $M_{A,X}$ is the effect of carrying a parent field once around the sector's insertion point, and "φ-twisted" says that this effect is the symmetry φ — exactly a φ-twisted sector.

What the machine verified

Definitions. Lean's three axioms.

Theorem 22.46 (Step 4c: projections onto twisted parts; McRae Theorem 3.3, projection form)**.** *Under McRae's Assumption 3.1 (`McRaeData`), every left A-module (X, a) carries module endomorphisms π_g ($g \in G$) that are orthogonal idempotents summing to the identity, and the image of π_g is g-twisted:*

$$a \circ (1 \otimes \pi_g) = \pi_g \circ a, \quad a \circ (g \otimes 1) \circ M_{A,X} \circ (1 \otimes \pi_g) = a \circ (1 \otimes \pi_g), \quad \pi_g \pi_h = \delta_{g,h} \pi_g, \quad \sum_g \pi_g = \mathrm{id}_X.$$

In particular this holds for $A = V_2$ in $\mathcal{C}$, for every finite $G \leq \mathrm{Aut}\, V_2$ with V_2^G C_2-cofinite.

```

From the mathematics to the Lean statement

In `theorem_3_3` the data are section variables: `(D : McRaeData A m u e G act coev)` and a module `(hX : IsLeftModule m u a)`. Clause one: π_g is a module map. Clause two: on the image of π_g the action is `act g`-twisted (the twisted condition precomposed with $1 \otimes \pi_g$, which is how one says "the image is twisted" without forming the image). Clauses three and four: a complete family of orthogonal idempotents. **Weaker in form than McRae's statement, same in content:** McRae states $X \cong \bigoplus_g X_g$ with X_g g-twisted; the library gives the idempotents, because $\mathcal{C}$ has no images or biproducts as Lean instances. Given the idempotents, the decomposition is formal; and Steps 5–6 consume π_g directly. Also proved: naturality of π_g in module maps (`proj_natural`) and that there are no nonzero module maps between a g_1-twisted and a g_2-twisted module for $g_1 \neq g_2$ (`twisted_hom_eq_zero_orbifold`). In `V2m_theorem_3_3`, `V2mObj G` is `vObj` for V_2 and the only hypothesis left is `hC2`.

Proof on paper. Write $\theta_g = a \circ (g \otimes 1) \circ M_{A,X} : A \otimes X \to X$ ("act after twisting by g and carrying around X"). McRae's projection is

$$\pi_g = \frac{1}{|G|}\, a \circ (1 \otimes \theta_g) \circ \alpha \circ (\tilde{\iota} \otimes 1) \circ \lambda^{-1}, \qquad \text{symbolically} \quad \pi_g(x) = \frac{1}{|G|} \sum_i x_i \cdot \theta_g(y_i \otimes x).$$

Sum. $\sum_g \theta_g(y \otimes x)$ involves $\sum_g g(y) = |G|\,\iota\varepsilon(y)$, and the monodromy of the unit is trivial, so $\sum_g \pi_g(x) = \sum_i x_i \varepsilon(y_i) \cdot x = x$ by the zigzag identities of Step 4b. *Module map.* The Casimir element $\tilde{\iota}$ commutes with the action up to the braiding: $\sum_i a x_i \otimes y_i$ and $\sum_i x_i \otimes y_i a$ agree after multiplication (McRae's Lemma 3.7; proved from the zigzag identities of Step 4b), which, with the associativity of the monodromy action $M \circ a$ (a consequence of the pure-braid relation $\sigma_2^2\sigma_1\sigma_2^2\sigma_1 = \sigma_2\sigma_1^2\sigma_2\sigma_1^2$ and commutativity), gives that π_g commutes with a and that its image is g-twisted. *Orthogonality.* On the image of π_h one has $(1 \otimes \pi_h) \circ \theta_g$ expressed through $\theta_{h^{-1}g}$; a trace lemma using the Galois condition $\sum_i x_i g(y_i) = |G|\delta_{g,1}$ (McRae's Lemmas 3.6 and 3.8) then gives $\pi_h \pi_g = \delta_{g,h}\pi_h$. □

Physical meaning

Every sector of the parent theory that is compatible with the condensed algebra decomposes uniquely into twisted sectors, one for each group element: the projection π_g is the "twist-g projector" of orbifold CFT, built from the operator that inserts the parent algebra and averages over the symmetry.

What the machine verified

`theorem_3_3`: proved, Lean's three axioms (pure category theory). `V2m_theorem_3_3`: proved, conditional on `hC2`; Lean's three axioms (it uses the theorem `VOA.pbw`; while `VOA.pbw` was an axiom the report also listed `VOA.pbw`) (audit log of Step 4c).

22.9.8 Step 5: a twisted part is an untwisted module of the cyclic orbifold

This step is where the analysis of logarithmic intertwining operators meets the categorical structure, and where the specific VOA V_2 enters. Fix a left V-module (X, a) in $\mathcal{C}$ and $g \in G$, and let p be a module endomorphism of X whose image is g-twisted (for instance $p = \pi_g$). The action $a : V \boxtimes X \to X$ corresponds, by the universal property of $\boxtimes$, to a logarithmic intertwining operator of type $\binom{X}{V\,X}$ over V^G,

$$\mathcal{Y}_a(v,z)x = \sum_{n \in \mathbb{C}} \sum_{k \geq 0} v_{(n;k)}x \; z^{-n-1}(\log z)^k,$$

written `actY hC2 a` in Lean (`actY a = a ∘ 𝒴_⊠`, `McRaeO5Twisted.lean`; the mode `(actY hC2 a).1 n k v x` is $v_{(n;k)}x$, the coefficient of $z^{-n-1}(\log z)^k$).

Step 5a: monodromy kills logarithms and non-integral powers. The braiding is Ω_0, and $\Omega_0 \circ \Omega_0$ is the operator that continues $\mathcal{Y}$ once around $z = 0$: $z \mapsto e^{2\pi i} z$, which multiplies z^{-n-1} by $e^{-2\pi i(n+1)}$ and replaces $\log z$ by $\log z + 2\pi i$. On modes,

$$\big(\Omega_0\Omega_0\mathcal{Y}\big)_{(n;k)} = e^{-2\pi i(n+1)} \sum_{j\geq k} \binom{j}{k} (2\pi i)^{j-k} \mathcal{Y}_{(n;j)}.$$

If $v \in V$ is fixed by g, the twisted condition on the image of p says that this monodromy acts trivially on $\mathcal{Y}_a(v,z)$ restricted to $p(X)$. A family of modes fixed by this unipotent-times-phase operator must have $e^{-2\pi i(n+1)} = 1$ (so $n \in \mathbb{Z}$) and no component with $k \geq 1$ (the top logarithmic power would be multiplied by 1 but the next one would pick up $2\pi i$ times it). Hence, on $p(X)$, *the vertex operators of g-fixed vectors have integral powers and no logarithms* (`twisted_modes`).

Step 5b: the Jacobi identity (the "Jacobi bridge"). To make $p(X)$ a module for the cyclic orbifold $V^{\langle g\rangle}$ (the g-fixed vectors of V), one needs the Jacobi identity for these integral, log-free modes. This is a named `Prop`.

Definition 22.47 (The twisted Jacobi bridge)**.** For all left V-modules (X, a) in $\mathcal{C}$, all $g \in G$, all module endomorphisms p with g-twisted image, all g-fixed $u, v \in V$, all $x \in X$ and all $\ell, m, n \in \mathbb{Z}$, the modes $w_{(k)} := w_{(k;0)}$ of $\mathcal{Y}_a$ satisfy on $p(x)$ the Jacobi (Borcherds) identity

$$\sum_{i\geq 0} (-1)^i \binom{\ell}{i} \Big(u_{(\ell+m-i)} v_{(n+i)} - (-1)^\ell \, v_{(\ell+n-i)} u_{(m+i)} \Big) p(x) = \sum_{i\geq 0} \binom{m}{i} \big(u_{(\ell+i)} v\big)_{(m+n-i)} p(x).$$

```

From the mathematics to the Lean statement

Section variables `G`, `hfg`, `hC2` as in Step 3. The two hypotheses on `p` are "module map" (`a ≫ p = V ◁ p ≫ a`) and "g-twisted image" (the twisted condition of Definition 22.45 precomposed with $1 \boxtimes p$). `p.1` is the underlying linear map, `(g : Aut W) u = u` says u is g-fixed. `negOnePow i` is $(-1)^i$; `cbz ℓ i` is the binomial coefficient $\binom{\ell}{i}$ for $i \geq 0$ (any integer ℓ, the generalized binomial coefficient) and 0 for $i < 0$, so the sums over $i \in \mathbb{Z}$ are the sums over $i \geq 0$; $\sum^{\mathrm{f}}$ is a sum with finitely many nonzero terms (the truncation property makes the sums finite). `(actY hC2 a).1 ((k : ℤ) : ℂ) 0` is the mode $(\cdot)_{(k;0)}$ at an *integral* index with *no* logarithm; `W.smul u (ℓ + i) v` is $u_{(\ell+i)}v$ computed in the ambient VOA. So the display is exactly the Borcherds identity in the form of Chapter 4. The statement quantifies over *all* such data and is therefore strong; a referee should note that it is about the integral log-free modes only, which by Step 5a

are all the modes that act on $p(X)$ for g-fixed vectors. (Its docstring still says "open"; it is proved, Theorem 22.48; Section 22.11.)

Physical meaning

In a g-twisted sector, the parent fields invariant under g are single-valued around the insertion point, and their operator product expansions close; the Jacobi identity is the statement that these OPEs are associative and local, so that the twisted sector is an ordinary sector of the smaller gauged theory $V^{\langle g\rangle}$.

What the machine verified

Definition. It was the last open `Prop` of the converse until 2026-10-14; now proved (Theorem 22.48).

Theorem 22.48 (Step 5b: the Jacobi bridge holds). *For every VOA V, every subgroup $G \leq \mathrm{Aut}\, V$ (finite or not), every proof of finite generation and of C_2-cofiniteness of V^G, the twisted Jacobi bridge holds.*

    (a ℓ : ℤ) : resInf a ℓ s - resZero a ℓ t = resOne a ℓ q := by
```

From the mathematics to the Lean statement

`twistedJacobiBridge_holds` has no hypotheses beyond the parameters of the `Prop`; in particular neither simplicity of V nor finiteness of G is assumed. In `residue_of_glue`: Ψ is holomorphic on $\mathbb{C}\setminus\{0,1\}$ (`DifferentiableAt ℂ`); it has three Laurent expansions, $\sum_n s_n\zeta^n$ for $|\zeta|>1$ with $s_n=0$ for $n>n_0$ (a pole at ∞ of finite order), $\sum_n t_n\zeta^n$ for $0<|\zeta|<1$ with $t_n=0$ for $n<n_1$, and $\sum_m q_m r^m$ in $r=\zeta-1$ for $0<|r|<1$ with $q_m=0$ for $m<m_1$. `resInf a ℓ s`, `resZero a ℓ t`, `resOne a ℓ q` are the coefficients of ζ^{-1} (resp. r^{-1}) of $\zeta^a(\zeta-1)^\ell\Psi$ in the three expansions (`McRaeO5bResidue.lean`; e.g. `resOne a ℓ q` $=\sum_j \binom{a}{j} q_{-1-\ell-j}$). The conclusion is the residue theorem on the Riemann sphere, $\mathrm{Res}_\infty+\mathrm{Res}_0+\mathrm{Res}_1=0$, in the sign conventions of the Jacobi identity.

Proof on paper. Fix (X,a), g, p, g-fixed homogeneous u,v, a vector $x=p(x')$ in the image of p with x' of generalized weight c, a linear functional f on X, and an integer D, the *index line*: in every term below the two mode indices add up to D (for instance $(-n-1)+(D+n+1)=D$), so each channel is a single sequence indexed by one integer. (For the Jacobi identity with parameters ℓ,m,n one takes $D=\ell+m+n$; the modes are the integral, log-free modes $w_{(k)}=w_{(k;0)}$ of Y_a, and in the iterate $u_{(-m-1)}v$ is the product in V.) Consider three *channels*, all functions of one complex variable ζ (u inserted at ζ, v at 1, x at 0), each single-valued by Step 5a:

channel	series	domain
product	$\sum_n s_n\zeta^n,\ s_n = f\big(u_{(-n-1)}v_{(D+n+1)}x\big)$	$\lvert\zeta\rvert > 1$
reversed product	$\sum_n t_n\zeta^n,\ t_n = f\big(v_{(D+n+1)}u_{(-n-1)}x\big)$	$0 < \lvert\zeta\rvert < 1$
iterate	$\sum_m q_m(\zeta-1)^m,\ q_m = f\big((u_{(-m-1)}v)_{(D+m+1)}x\big)$	$0 < \lvert\zeta-1\rvert < 1$

(The intervals below are intervals of real ζ.) *Product = iterate* on $(1, 3/2)$: this is the module axiom $a \circ (\mu \boxtimes 1) = a \circ (1 \boxtimes a) \circ \alpha$ tested on canonical elements; it is the converse direction of the associativity proof of Step 3. *Reversed product = iterate* on $(1/2, 1)$: here the commutativity of the algebra enters — skew-symmetry $\Omega_0(Y_V) = Y_V$, an inner translation theorem for the iterate, and the module axiom at scale ζ. *Gluing.* The product row satisfies a rational Fuchsian differential equation with its only finite singularity at 1, so it continues analytically to $\mathbb{C} \setminus [1, \infty)$ in $1/\zeta$; with the other two channels and the identity theorem on convex pieces this produces one function Ψ holomorphic on $\mathbb{C} \setminus \{0, 1\}$ with the three expansions. *Residues.* Since the pole at 1 has finite order N, $(\zeta-1)^N\Psi$ is bounded near 1, and a Liouville argument shows Ψ is a Laurent polynomial divided by $(\zeta-1)^N$; uniqueness of Laurent coefficients identifies s, t, q with the binomial expansions of that rational function at ∞, 0, 1, and the residue theorem (a Vandermonde-convolution identity for binomial coefficients) gives `resInf - resZero = resOne`. Choosing the exponents $a = m$ and ℓ (the a of `residue_of_glue`, not the action) and $D = \ell + m + n$ turns this into f applied to the Jacobi identity for homogeneous data; since f is arbitrary, the identity itself holds; additivity (in x along generalized L_0-eigenspaces, in u, v along the grading of $V^{\langle g\rangle}$) gives the general case. This is the classical derivation of the Jacobi identity from rationality, commutativity and associativity of correlation functions (Frenkel–Lepowsky–Meurman, Frenkel–Huang–Lepowsky), carried out on a twisted part. □

Physical meaning

The three channels are the three operator-product limits of one chiral three-point function $\langle f, u(\zeta)\,v(1)\,x(0)\rangle$: u near infinity, near 0, near v. Crossing symmetry says they are one meromorphic function on the sphere, and the Jacobi identity is the statement that the residues of $\zeta^a(\zeta-1)^\ell$ times this function sum to zero.

What the machine verified

`twistedJacobiBridge_holds`: proved, no hypotheses; Lean's three axioms (re-probed at an earlier commit, not re-run for this edition; while `VOA.pbw` was an axiom the report also listed `VOA.pbw`; every VOA-side lemma uses the theorem `VOA.pbw` through the tensor category). It is in the maintained audit (`scripts/audit/ClassificationCOneAxiomAudit.lean`) with expected axioms `PBW_AXIOMS` (now the standard three). `residue_of_glue`: proved, Lean's three axioms (audit log of Step 5b).

Step 5c: the cyclic orbifolds of V_2 are rational.

Theorem 22.49 (Step 5c: the cyclic orbifolds of V_2 are rational)**.** *For every automorphism g of V_2 of finite order, $V_2^{\langle g\rangle}$ is (admissibly) rational.*

File `VOA/Classification/COne/McRaeO5Cyclic.lean`.

```
theorem V2m_cyclic_admissiblyRational (g : Aut (V2m 1 le_rfl)) (hg : IsOfFinOrder g) :
    AdmissiblyRational (orbifoldVOA (Subgroup.zpowers g)) :=
```

From the mathematics to the Lean statement

`IsOfFinOrder g`: $g^n = 1$ for some $n \geq 1$. `Subgroup.zpowers g` is the cyclic group $\langle g\rangle$. `AdmissiblyRational` (Chapter 12) says that in every admissible module every weak sub-

module has a weak complement. This is the library's rationality convention, whose relation to Dong–Li–Mason rationality is not settled in Lean (Remark 22.4); so the theorem is "$V_2^{\langle g\rangle}$ is admissibly rational", not literally "DLM-rational".

Proof on paper. Aut $V_2 \cong \mathrm{PSL}_2(\mathbb{C})$; an element of finite order is semisimple, hence conjugate to an element of the maximal torus $\{e^{2\pi i\, t\, \beta(0)}\}$ of Aut $V_{\sqrt{2}\mathbb{Z}}$ (β the generator of the lattice, $\beta^2 = 2$). A torus element of order n acts on the charge-k sector $M(1) \otimes e^{k\beta}$ by ζ^k for a primitive n-th root of unity ζ, and trivially on the Heisenberg part. Conjugate subgroups have isomorphic fixed-point algebras, and the fixed points of the torus element are the sectors with $n \mid k$, i.e. the lattice VOA of $n\sqrt{2}\mathbb{Z}$:

$$V_2^{\langle g\rangle} \;\cong\; V_{\sqrt{2n^2}\,\mathbb{Z}} = V_{2n^2}.$$

Rank-one positive-definite even lattice VOAs are rational (Theorem 22.33), and rationality is transported along isomorphisms. □

Physical meaning

Gauging a cyclic $\mathbb{Z}_n$ subgroup of the $SU(2)$ symmetry of the self-dual boson moves it along the circle line to the rational radius corresponding to V_{2n^2}: a compact boson, again rational. This is the single place where the specific parent theory matters.

What the machine verified

Proved; Lean's three axioms (audit log of Step 5).

Step 5d: sections on twisted parts. Combining Steps 5a, 5b and 5c: on each π_g-part of a V_2-module, the modes of $V_2^{\langle g\rangle}$ satisfy the Jacobi identity, the module is admissible (its generalized L_0-eigenspaces span and its spectrum is bounded below by that of X), so by Step 5c it is completely reducible. Hence a surjective V_2-module map restricted to the g-parts has a $V_2^{\langle g\rangle}$-linear section, which is in particular V_2^G-linear.

Theorem 22.50 (Step 5d: surjections of V_2-modules split V_2^G-linearly). *Let $G \le \mathrm{Aut}\, V_2$ be finite with V_2^G C_2-cofinite, and assume the bridge. If $f : X_1 \to X_2$ is a surjective map of left V_2-modules in $\mathcal{C}$, there is a morphism $s : X_2 \to X_1$ of $\mathcal{C}$ (a V_2^G-module map) with $f \circ s = \mathrm{id}$.*

File `VOA/Classification/COne/McRaeO5Main.lean`.

```
theorem V2m_exists_section (G : Subgroup (Aut (V2m 1 le_rfl))) [Fintype G] [DecidableEq G]
    (hC2 : C2Cofinite (orbifoldVOA G))

    letI := logarithmicMonoidalCategory hC2
    letI := logarithmicBraidedCategory hC2
    ∀ (X₁ X₂ : LogModuleCat (orbifoldVOA G)) (a₁ : V2mObj G ⊗ X₁ ⟶ X₁)
      (a₂ : V2mObj G ⊗ X₂ ⟶ X₂),
      IsLeftModule (mulHom G (VOA.Huang.SchurWeyl.V2m_orbifold_finGen G) hC2)
        (unitHom G (VOA.Huang.SchurWeyl.V2m_orbifold_finGen G)) a₁ →
      IsLeftModule (mulHom G (VOA.Huang.SchurWeyl.V2m_orbifold_finGen G) hC2)
        (unitHom G (VOA.Huang.SchurWeyl.V2m_orbifold_finGen G)) a₂ →
      ∀ f : X₁ ⟶ X₂, IsModuleHom a₁ a₂ f → Function.Surjective f.1 →
        ∃ s : X₂ ⟶ X₁, s ≫ f = 𝟙 X₂ :=
```

From the mathematics to the Lean statement

`IsModuleHom a₁ a₂ f` is $f \circ a_1 = a_2 \circ (1 \boxtimes f)$; `Function.Surjective f.1`: the underlying linear map is onto. The conclusion `s ≫ f = 𝟙 X₂` is $f \circ s = \mathrm{id}$. **Note:** s is only a morphism of $\mathcal{C}$, not a V_2-module map; that is all Step 6 needs. The hypothesis `hB` is now discharged by Theorem 22.48. The section is $s = \sum_g s_g \circ \pi_g$ with s_g the section on the g-part (`V2m_exists_twisted_section`).

Physical meaning

A short exact sequence of sectors of the parent theory (with all twists allowed) always splits as a sequence of sectors of the gauged theory: no logarithmic gluing survives on any twisted sector, because each is a sector of a rational compact boson.

What the machine verified

Proved, conditional on `hC2` and `hB`; `hB` is now proved. Lean's three axioms (it uses the theorem `VOA.pbw`; while `VOA.pbw` was an axiom the report also listed `VOA.pbw`) (audit log of Step 5).

22.9.9 Step 6: McRae's Lemma 4.21, every surjection in $\mathcal{C}$ splits

Theorem 22.51 (Step 6: every surjection splits; McRae Lemma 4.21 for V_2)**.** *Let $G \leq \mathrm{Aut}\, V_2$ be finite with V_2^G C_2-cofinite. Every morphism $f : Y_1 \to Y_2$ of $\mathcal{C}$ whose underlying map is surjective has a section σ, $f \circ \sigma = \mathrm{id}_{Y_2}$.*

File `VOA/Classification/COne/McRaeO6Main.lean`.

```
theorem V2m_lemma_4_21 (G : Subgroup (Aut (V2m 1 le_rfl))) [Fintype G] [DecidableEq G]
    (hC2 : C2Cofinite (orbifoldVOA G))
    (hB : TwistedJacobiBridge G (VOA.Huang.SchurWeyl.V2m_orbifold_finGen G) hC2) :
    ∀ {Y₁ Y₂ : LogModuleCat (orbifoldVOA G)} (f : Y₁ → Y₂), Function.Surjective f.1 →
      ∃ σ : Y₂ → Y₁, σ ≫ f = 𝟙 Y₂ :=
```

From the mathematics to the Lean statement

Now Y_1, Y_2 are arbitrary objects of $\mathcal{C}$ (no V_2-action), and σ is a morphism of $\mathcal{C}$. The hypothesis `hB` is discharged by Theorem 22.48. Every epimorphism of $\mathcal{C}$ has surjective underlying map (`surjective_of_epi`, which needed quotient objects in $\mathcal{C}$, `McRaeO6Quotient.lean`), so the hypothesis "surjective" is the categorical "epi".

Proof on paper. Induce: $V \boxtimes f : V \boxtimes Y_1 \to V \boxtimes Y_2$ is a map of left V-modules (action $(\mu \boxtimes 1) \circ \alpha^{-1}$), and it is an epimorphism (right exactness, Step 3), hence surjective. By Step 5 there is a $\mathcal{C}$-morphism s with $(V \boxtimes f) \circ s = \mathrm{id}$. Put

$$\sigma = \lambda \circ (\varepsilon \boxtimes 1) \circ s \circ (\iota \boxtimes 1) \circ \lambda^{-1} : Y_2 \to Y_1.$$

Then, by naturality of λ and the interchange law, $f \circ \sigma = \lambda \circ (\varepsilon \boxtimes 1) \circ (V \boxtimes f) \circ s \circ (\iota \boxtimes 1) \circ \lambda^{-1} = \lambda \circ ((\varepsilon \circ \iota) \boxtimes 1) \circ \lambda^{-1} = \mathrm{id}$, since $\varepsilon \circ \iota = \mathrm{id}$. This works in any monoidal category (`section_of_whisker`). □

Physical meaning

Every sector of the gauged theory is a summand of an induced sector ("fuse with the parent algebra and project back by averaging"), and induced sectors split by Step 5; so the gauged theory has no logarithmic extensions among its sectors.

What the machine verified

Proved, conditional on `hC2`, `hB` (now proved). Lean's three axioms (it uses the theorem `VOA.pbw`; while `VOA.pbw` was an axiom the report also listed `VOA.pbw`) (O67 audit log).

22.9.10 Step 7: split surjections imply rationality, and the rationality of the orbifolds

Theorem 22.52 (Step 7: split surjections imply rationality, general form). *Let W be a C_2-cofinite VOA such that every surjective morphism of $\mathcal{C}_W$ = `LogModuleCat W` has a section. Then W is admissibly rational.*

File `VOA/Classification/COne/McRaeO7Main.lean`.

```
def SurjectionsSplit (W : VertexOperatorAlgebra V) : Prop :=
  ∀ {Y₁ Y₂ : LogModuleCat W} (f : Y₁ → Y₂), Function.Surjective f.1 →
    ∃ σ : Y₂ → Y₁, σ ≫ f = 𝟙 Y₂
```

File `VOA/Classification/COne/McRaeO7Main.lean`.

```
theorem admissiblyRational_of_surjectionsSplit (hC2 : C2Cofinite W) (hs : SurjectionsSplit
↪  W) :
    AdmissiblyRational W := by
```

From the mathematics to the Lean statement

`SurjectionsSplit W` quantifies over objects of $\mathcal{C}_W$ only, i.e. finitely generated logarithmic modules; the conclusion `AdmissiblyRational W` is about *all* admissible modules (Chapter 12), so the theorem is a genuine passage from a finite-length statement to complete reducibility in general. No semisimplicity of Zhu's algebra and no positive-energy hypothesis is used.

Proof on paper. Let X be a weak module with a simple submodule P and simple quotient X/P. Then X has length 2, hence (by C_2-cofiniteness) is a finitely generated logarithmic module, an object N of $\mathcal{C}_W$; the quotient $N \to N/P$ is surjective, so it has a section σ, and $\sigma(N/P)$ is a complement of P. So every extension of a simple module by a simple module splits. The rest is a lattice-theoretic induction that the library already had from the proof of rationality of V_{2m}^+: for a C_2-cofinite VOA, every two-step interval $a < b < c$ in the submodule lattice of a weak module can be reduced, through its "factor bottoms" (lowest-weight pieces of the simple factors, which exist by C_2-cofiniteness), to a module of length two, which splits; so every two-step interval has a relative complement. A module in which all two-step intervals of all cyclic submodules split is semisimple (`semisimple_of_generalized_cyclic_splitting`). Hence every admissible module is completely reducible. □

Physical meaning

A lisse chiral algebra is rational as soon as no two primaries can be glued into a logarithmic pair: logarithmic partners always appear first in extensions of length two.

What the machine verified

Proved; Lean's three axioms, no `VOA.pbw` (O67 audit log).

Theorem 22.53 (Step 7 for V_2: orbifold rationality from the Jacobi bridge). *If the bridge holds for every finite $G \leq \mathrm{Aut}\, V_2$ with V_2^G C_2-cofinite, then the rationality of the exceptional orbifolds (fact (d)) holds, and the converse of the classification holds.*

    GannonRayhaunConverse.{0} :=
  gannonRayhaunConverse_of_B3 (finiteV2OrbifoldRationalOfC2_of_bridge hB)
```

From the mathematics to the Lean statement

TwistedJacobiBridgeAll is the bridge of Definition 22.47 for every finite $G \leq \mathrm{Aut}\, V_2$ with C_2-cofinite V_2^G. The second theorem is Theorem 22.51 followed by Theorem 22.52; the third is the historical reduction Theorem 22.37 applied to it. (The docstrings of TwistedJacobiBridgeAll and of the file still call it "open"; it is proved, Theorem 22.54.)

Physical meaning

Gauging any finite symmetry of $SU(2)_1$ with a lisse result gives a rational theory — provided twisted sectors behave as sectors of the cyclic orbifolds, which is the content of the bridge.

What the machine verified

Proved, conditional on hB, which is now proved. Lean's three axioms (it uses the theorem VOA.pbw; while VOA.pbw was an axiom the report also listed VOA.pbw) (O67 audit log).

Theorem 22.54 (Rationality of the orbifolds of V_2: McRae's Corollary 4.23). *For every finite subgroup $G \leq \mathrm{Aut}\, V_2$ with V_2^G C_2-cofinite, V_2^G is admissibly rational.*

File VOA/Classification/COne/MainConverseFinal.lean.

```

  intro G _ hC2
  exact McRaeO5b.twistedJacobiBridge_holds G _ hC2
```

File VOA/Classification/COne/MainConverseFinal.lean.

```
theorem finiteV2OrbifoldRationalOfC2 : FiniteV2OrbifoldRationalOfC2Fact :=
  McRaeO7.finiteV2OrbifoldRationalOfC2_of_bridge twistedJacobiBridgeAll_holds
```

From the mathematics to the Lean statement

FiniteV2OrbifoldRationalOfC2Fact is Definition 22.35: ∀ (G : Subgroup (Aut (V2m 1 le_rfl))) [Finite G], C2Cofinite (orbifoldVOA G) → AdmissiblyRational (orbifoldVOA G). The theorem has no hypotheses. It is the statement at its natural generality (all finite subgroups), not only the three exceptional ones the converse consumes. Its conclusion is admissible rationality, which is the rationality clause of StronglyRational; the other clauses of niceness of the exceptional orbifolds are supplied by the converse reduction (Theorem 22.37).

Proof on paper. Steps 1–7 above: the Jacobi bridge (Step 5b) for every such G, then Step 7 for V_2. □

Physical meaning

Every lisse gauging of a finite symmetry of the $SU(2)_1$ WZW model (the self-dual compact boson) is a rational CFT.

What the machine verified

Proved with no hypotheses. `##print axioms`: Lean's three (re-probed at an earlier commit, not re-run for this edition); on 2026-10-14, when `VOA.pbw` was an axiom, the coordinator machine-checked Lean's three plus `VOA.pbw` (aggregate `lake build` then green, 13,306 jobs; green again on 2026-10-28, 18,901 jobs, and later 18,907, in pre-release builds; for the release build see Chapter 43, Section 43.1.9), recorded in the maintained audit with expected axioms `PBW_AXIOMS` (now the standard three) (`run_axiom_audits.py` passes, 5,890 reports, of which 854 for `ClassificationCOne`).

22.9.11 Narrowing orbifold rationality to the exceptional groups (historical)

Before the proof of orbifold rationality was found, the library isolated the part of it that the converse consumes. These statements are proved and remain in the library; with orbifold rationality proved, their hypotheses are all discharged.

Theorem 22.55 (The converse needs orbifold rationality only at the exceptional groups)**.** *Orbifold rationality (fact (d) of Definition 22.35) implies its restriction to $G \cong A_4, S_4, A_5$; and facts (a), (b), (c) together with that restriction imply the converse.*

File `VOA/Classification/COne/OrbRat2Reduction.lean`.

```
def ExceptionalV2OrbifoldRationalOfC2 : Prop :=
  ∀ G : Subgroup (Aut (V2m 1 le_rfl)), IsExceptionalV2Group G →
    C2Cofinite (orbifoldVOA G) → AdmissiblyRational (orbifoldVOA G)
```

File `VOA/Classification/COne/OrbRat2Reduction.lean`.

```
theorem exceptionalV2OrbifoldRationalOfC2_of_finite (h : FiniteV2OrbifoldRationalOfC2Fact)
 ↪  :
    ExceptionalV2OrbifoldRationalOfC2 := by
```

File `VOA/Classification/COne/OrbRat2Reduction.lean`.

```
theorem gannonRayhaunConverse_of_narrowed (hSolv : SolvableExceptionalOrbifoldC2Fact)
    (hXu : XuIcosahedralPoissonRelations) (hRat : ExceptionalV2OrbifoldRationalOfC2)
    (hPU : ExceptionalOrbifoldPositiveWeightsFact) : GannonRayhaunConverse.{0} := by
```

From the mathematics to the Lean statement

`ExceptionalV2OrbifoldRationalOfC2` is `FiniteV2OrbifoldRationalOfC2Fact` with the quantifier over finite subgroups replaced by one over the exceptional subgroups (`IsExceptionalV2Group G`, Definition 22.35; finiteness is then automatic). The first theorem shows it is *no stronger* than fact (d). The second takes four `Prop`s: facts (a) and (b), the narrowed fact (d), and fact (c). All four are now proved (Theorems 22.36 and 22.54, the narrowed form by `exceptionalV2OrbifoldRationalOfC2_of_bridge`). The same file splits the narrowed statement further into single concrete models, $(V_8^+)^{\mathbb{Z}/3}$ and $(V_2^{A_4})^{\mathbb{Z}/2}$, and an icosahedral statement (`gannonRayhaunConverse_of_models`); that split is no longer needed.

Physical meaning

Only the three exceptional gaugings of $SU(2)_1$ appear in the $c = 1$ list; the general theorem is more than the classification needs.

What the machine verified

Proved; `##print axioms` of both theorems is Lean's three (re-checked for this revision; not listed in the maintained audit). All hypotheses of `gannonRayhaunConverse_of_narrowed` are now proved (the rationality input uses the theorem `VOA.pbw`).

22.9.12 The earlier route, abandoned

The first plan for proving orbifold rationality followed McRae's rationality criterion (arXiv:2108.01898): for a C_2-cofinite W with semisimple Zhu algebra, rationality is equivalent to every simple module S having a projective cover whose socle is S itself. Its formal pieces remain in the library. They are recorded here because they are proved statements that a reader will meet, and because their open input is *not* an input of the classification.

Definition 22.56 (McRae covers)**.** A *McRae cover* of a simple weak module S is a finite-length projective weak module P with a surjection $P \to S$ with superfluous kernel and an embedding $S \hookrightarrow P$ which is the essential socle. `McRaeCoverFact W`: every simple weak W-module has one.

File `VOA/Classification/COne/OrbMcRaeCover.lean`.

```
def McRaeCoverFact (W : VertexOperatorAlgebra 𝒱) : Prop :=
  ∀ {X : Type u} [AddCommGroup X] [Module ℂ X] (B : WeakModule W X),
    IsSimpleModule (modeAlg B) X → Nonempty (McRaeCover B)
```

File `VOA/Classification/COne/OrbMcRaeCover.lean`.

```
theorem mcRaeCoverFact_iff_admissiblyRational (hC2 : C2Cofinite W)
    (hss : letI := instRingA W; IsSemisimpleRing (VOA.A W)) :
    McRaeCoverFact W ↔ AdmissiblyRational W :=
```

From the mathematics to the Lean statement

`WeakModule W X`, `modeAlg B` (the associative algebra generated by the modes acting on X, whose submodules are the W-submodules) and `IsSimpleModule` are Chapter 12's weak modules in ring-theoretic form. `letI := instRingA W` installs the ring structure of Zhu's algebra `VOA.A W`, and `IsSemisimpleRing (VOA.A W)` says it is semisimple. The equivalence says that, for C_2-cofinite W with semisimple Zhu algebra, *rationality is exactly the existence of McRae covers*: nothing is lost by the reduction. At the time the route was pursued, the hypothesis `hss` was *not* available for $V_2^{S_4}$ and $V_2^{A_5}$ (for $V_2^{A_4}$ the library proves $A(V_2^{A_4}) \cong \mathbb{C}^{21}$), which is one reason the route was abandoned. Today `hss` for these orbifolds follows by composing two proved theorems: orbifold rationality `finiteV2OrbifoldRationalOfC2` (Theorem 22.54, applied to their proved C_2-cofiniteness) and Zhu's semisimplicity theorem `zhuAdmissibleSemisimple_holds` (Chapter 12, Theorem 12.40). The composition is not a named declaration of the library, and it is useless for this route, which was meant to *prove* rationality: `hss` obtained from rationality makes the criterion circular.

What the machine verified

The equivalence is proved (Lean's three axioms; maintained audit). `McRaeCoverFact` for the exceptional orbifolds is not proved in the library, and **not needed**: orbifold rationality is proved along the orbifold route (Theorem 22.54).

Physical meaning

In a logarithmic (non-semisimple) theory, simple modules have projective covers that glue several sectors together (Jordan blocks of L_0). A McRae cover whose socle is the simple module itself can only be the module itself when Zhu's algebra is semisimple, which is how the criterion detects that no logarithmic sector exists.

Theorem 22.57 (Huang's projective covers exist; first step of McRae's criterion)**.** *For every C_2-cofinite W, every simple weak module has a projective cover in the category of finite-length weak modules (Huang 2009).*

File `VOA/Classification/COne/OrbMcRaeMain.lean`.

```
def HuangCoverFact (W : VertexOperatorAlgebra 𝒱) : Prop :=
  ∀ {X : Type u} [AddCommGroup X] [Module ℂ X] (B : WeakModule W X),
    IsSimpleModule (modeAlg B) X → Nonempty (HuangCover B)
```

File `VOA/Classification/COne/McRaeM1Main.lean`.

```
theorem huangCoverFact_of_c2 (hC2 : C2Cofinite W) : HuangCoverFact W :=
```

From the mathematics to the Lean statement

`HuangCover B` packages a finite-length projective weak module with a surjection onto B with superfluous kernel (the projective cover in Huang's sense); `HuangCoverFact W` says every simple weak module has one. The only hypothesis of the theorem is C_2-cofiniteness.

Physical meaning

A lisse chiral algebra, even a logarithmic one, has for each primary a "largest indecomposable sector built on it" (its projective cover), the object in which all logarithmic partners of that primary are glued together.

What the machine verified

Proved, Lean's three axioms (maintained audit).

Definition 22.58 (The categorical input of the earlier route)**.** `CoverDualLitFact`: the contragredient of the projective cover of the contragredient of S is the projective cover of S ($P_{S'} \cong P_S$), McRae (2108.01898) Prop. 5.14 via Etingof–Nikshych–Ostrik unimodularity of a factorizable finite tensor category.

File `VOA/Classification/COne/McRaeM2Main.lean`.

```
def CoverDualLitFact (hC2 : C2Cofinite W) : Prop :=
  ∀ {X : Type u} [AddCommGroup X] [Module ℂ X] (B : WeakModule W X)
    (hB : IsSimpleModule (modeAlg B) X), ∀ C : HuangCover B,
    ∃ D : HuangCover (contra (gwOfFiniteLength hC2 B (finiteLength_of_simple
     ↪ hB))).toWeakModule,
      ∃ e : (contra (gwOfFiniteLength hC2 D.BP D.finiteLength)).toWeakModule.Hom C.BP,
        Function.Bijective e.toLinearMap
```

From the mathematics to the Lean statement

`contra` is the contragredient module, `gwOfFiniteLength` views a finite-length weak module as a generalized weight module so the contragredient is defined; `D.BP` is the projective object of the cover `D`; the bijective module map `e` is the isomorphism $P_{S'} \cong P_S$.

`unimodularSocleFact_of_coverDualLit` turns this into the socle statement, and with Theorem 22.57 into McRae covers.

Physical meaning

Conjugating (charge conjugation) a logarithmic projective sector and taking the conjugate of its top gives back the same projective sector: a symmetry of logarithmic CFTs whose chiral algebra has a non-degenerate (factorizable) braiding.

What the machine verified

Open, and **not an input of the classification** (orbifold rationality is proved without it, Theorem 22.54). It is a named `Prop`, not proved and not an axiom. Proving it would require the rigid, factorizable logarithmic tensor category of W with unimodularity, plus semisimplicity of the Zhu algebras of $V_2^{S_4}$, $V_2^{A_5}$ to conclude.

22.10 The classification, complete

Theorem 22.59 (Gannon–Rayhaun Theorem 3.1 and Proposition 3.2, with the library's rationality convention). *A vertex operator algebra (with carrier in universe* 0*) is nice ("rational" read as* `AdmissiblyRational`*, Remark 22.4) and has central charge* 1 *if and only if it is isomorphic to one of* V_{2m} $(m \geq 1)$, V_{2m}^{+} $(m \geq 2)$, $V_2^{A_4}$, $V_2^{S_4}$, $V_2^{A_5}$*; and it is isomorphic to exactly one of them.*

File `VOA/Classification/COne/MainConverseFinal.lean`.

```
theorem gannonRayhaunConverse_holds : GannonRayhaunConverse.{0} :=
  McRaeO7.gannonRayhaunConverse_of_bridge twistedJacobiBridgeAll_holds
```

File `VOA/Classification/COne/MainConverseFinal.lean`.

```
theorem gannonRayhaun_classification :
    GannonRayhaunStatement.{0} ∧ GannonRayhaunDistinct.{0} ∧ GannonRayhaunConverse.{0} :=
  ⟨gannonRayhaun_forward, gannonRayhaunDistinct, gannonRayhaunConverse_holds⟩
```

From the mathematics to the Lean statement

No hypotheses. The three conjuncts are the three `Prop`s of Section 22.2: `GannonRayhaunStatement` (Definition 22.8: nice and $c = 1 \Rightarrow$ `InCOneList`), `GannonRayhaunDistinct` and `GannonRayhaunConverse` (Definition 22.9). Together: "nice with $c = 1$" $\iff$ "in the list", and the label is unique, which is GR's "isomorphic to exactly one of". The proof term is the triple of Theorems 22.28, 22.32 and `gannonRayhaunConverse_holds`; the last is the reduction of Theorem 22.53 applied to the proved bridge (Theorem 22.54). The statement definitions are unchanged since the snapshot (they were not modified to make the proof go through). **Universes.** The suffix `.{0}` instantiates the universe parameter of each `Prop` at `0`: the quantifier "for every VOA" ranges over VOAs whose carrier is in `Type 0`. The forward theorem `gannonRayhaun_forward : GannonRayhaunStatement.{u}` and distinctness `gannonRayhaunDistinct : GannonRayhaunDistinct.{u}` hold separately in *every* universe; only the converse is proved at universe `0` (Remark 22.38), so the conjunction is stated there. Mathematically nothing is lost: every VOA of the list has a model on a `Type 0` carrier. **Rationality.** "Nice" is the library's `Nice`, whose rationality conjunct is `AdmissiblyRational`; its relation to Dong–Li–Mason rationality is not settled in Lean (Remark 22.4). So this is GR's theorem exactly for Lean-niceness; for GR's own niceness the forward half follows by the on-paper implication DLM-rational $\Rightarrow$ `AdmissiblyRational`, and the converse half

is proved in the library's sense only. The library's rationality and pseudo-unitarity also quantify modules only in the universe of V: harmless for the forward direction (it weakens a hypothesis), formally weaker for the converse.

Proof on paper. Forward: Section 22.6. Distinctness: Section 22.7. Converse: V_{2m} and V_{2m}^{+} are nice (Theorems 22.33, 22.34); the exceptional orbifolds are simple, self-dual, of CFT type with $c = 1$ and $V_1 = 0$ by their orbifold structure, C_2-cofinite by facts (a) and (b) of Definition 22.35, rational by orbifold rationality (Section 22.9), and pseudo-unitary by the positivity of the conformal weights (Theorem 22.37). □

Physical meaning

The rational, positive-energy chiral algebras at $c = 1$ are exactly: the compact boson at the rational radii, its $\mathbb{Z}_2$-orbifold, and the three gaugings of the $SU(2)_1$ WZW model by the tetrahedral, octahedral and icosahedral groups $A_4, S_4, A_5 \subset \mathrm{SO}(3)$ (the images of the binary polyhedral subgroups of $SU(2)$) — the chiral version of Ginsparg's picture of the $c = 1$ moduli space, with its three isolated points — and these are pairwise different theories.

What the machine verified

Proved with no hypotheses. Machine-checked by the coordinator on 2026-10-14: aggregate `lake build` then green (13,306 jobs; green again on 2026-10-28, 18,901 jobs, and later 18,907, in pre-release builds; for the release build see Chapter 43, Section 43.1.9), with axiom list `[propext, Classical.choice, Quot.sound, VOA.pbw]` while `VOA.pbw` was an axiom; re-probed at an earlier commit, not re-run for this edition:

```
'VOA.Classification.COne.gannonRayhaun_classification' depends on axioms:
  [propext, Classical.choice, Quot.sound]
```

and the maintained audit (`run_axiom_audits.py`: 5,890 reports, 854 for `ClassificationCOne`) passes, listing `gannonRayhaun_classification`, `gannonRayhaunConverse_holds`, `finiteV2OrbifoldRationalOfC2`, `twistedJacobiBridgeAll_holds` and `McRaeO5b.twistedJacobiBridge_holds` with expected axioms `PBW_AXIOMS` (now the standard three). So the classification is **unconditional**. Distinctness alone does not use `VOA.pbw`; the forward theorem uses the theorem `VOA.pbw` through the modular-data package, the converse through the logarithmic tensor category.

22.11 Recorded traps, dead ends and Lean defects

Traps and dead ends of the $c = 1$ campaign

1. **Characters do not pin the S-matrix** (Warning 22.3.2): the first modular-data package admitted a continuum of S-matrices (`isModularDataWeak_perturbS`); repaired by `SPinned`.

2. **The theta Galois law with $\ell^{-1}n_0$ instead of ℓn_0** is false (fails for $r = 7$); the correct form is Definition 22.23.

3. **A printed constant in Dong–Jiang is wrong.** The weight-20 constant of Dong–Jiang's Lemma 4.4, transcribed as `OrbC2f.CubicSeedRemainders`, is *false* (`OrbC2h.not_cubicSeedRemainders`; the true coefficient is $-447232/169744575$). The existential relation `TetrahedralDongJiangRelations` is nevertheless true, by rescaling

(`OrbC2h.tetrahedralDongJiangRelations`), and the C_2 argument survives.

4. **Library-wide defects that touch the campaign** (Chapter 12): the old `fusionCoeff` is identically zero (replaced by `fusionCoeffFHL`), the old bilinear `Unitary` is unsatisfiable in dimension ≥ 2 (replaced by `UnitaryVOADL`), `SelfContragredient` is vacuous. None of these is used by the classification statements, which use `SelfDual` and the repaired notions.

5. **A clean axiom audit is not a proof of a hypothesis.** `gannonRayhaunConverse_of_B3` has a clean `##print axioms` (Lean's three) but takes orbifold rationality as an argument; until 2026-10-14 that was the only form of the converse, and it was correctly reported as conditional. The hypothesis is now proved (Theorem 22.54).

6. **Proving the hypothesis changed the axiom footprint.** The conditional converse was free of `VOA.pbw`; the proved converse `gannonRayhaunConverse_holds` is not. Every categorical step of the proof of orbifold rationality (Steps 2–6) works in the logarithmic tensor category, whose construction uses `VOA.pbw` (through the finite-length theorem that rests on Step 1); only the algebraic and analytic steps (Schur–Weyl duality, the abstract projection theorem, the residue identity, cyclic-orbifold rationality, Step 7 in general) are free of it. So the converse moved from "`VOA.pbw`-free but conditional" to "unconditional relative to `VOA.pbw`", like the forward theorem. Since then `VOA.pbw` has become a theorem, so the footprint is again the standard three axioms and the converse is unconditional outright.

7. **The earlier route to orbifold rationality stalled on inputs the final route avoids** (Section 22.9.12): McRae's rationality criterion needs semisimplicity of the Zhu algebras of $V_2^{S_4}$, $V_2^{A_5}$ (not proved independently of rationality; it now follows *from* orbifold rationality by Zhu's semisimplicity theorem, which is circular for this route; Definition 22.56) and `CoverDualLitFact`, which needs rigidity, factorizability and unimodularity of the logarithmic category (not proved). The orbifold route needs rigidity of the single object V_2 only, which Galois descent gives directly.

Lean defects found while writing this chapter. All are documentation defects only (wrong or stale docstrings; no statement is affected):

1. `VOA/Classification/COne/Distinct.lean`: the docstrings of `PlusExceptionalResidual` and `ExceptionalResidual` say "true by GR Thm. 3.1; not proved here". Both are proved (`plusExceptionalResidual`, `exceptionalResidual`, `DistinctResiduals.lean`).

2. `VOA/Classification/COne/Statement.lean`: the docstrings of `GannonRayhaunDistinct`, `GannonRayhaunConverse` and `GannonRayhaunStatement` say "Not proved here". True of that file, but a reader may take it as a status; all three are now proved (`gannonRayhaunDistinct`, `gannonRayhaun_forward`, `gannonRayhaunConverse_holds`).

3. `VOA/Classification/COne/McRaeO5Main.lean`: the docstring of `TwistedJacobiBridge` is headed "O5 (b), the analytic bridge (open)" ("O5 (b)" is the internal label of Step 5b) and says the conversion to formal identities "is not done". It is proved (`McRaeO5b.twistedJacobiBridge_holds`).

4. `VOA/Classification/COne/McRaeO7Main.lean`: the module docstring and the docstring of `TwistedJacobiBridgeAll` call it "(open)"; it is proved (`twistedJacobiBridgeAll_holds`, `MainConverseFinal.lean`).

5. `VOA/Classification/COne/ExceptionalOrbifoldNice.lean`: the docstring before `SolvableExceptionalOrbifoldC2Fact` says "the analytic orbifold theorem [is] not

proved here"; true of that file, but the theorem (orbifold rationality) is now proved (`finiteV2OrbifoldRationalOfC2`).

6. `VOA/Classification/COne/McRaeO5Split.lean`: the module docstring describes part (b), `TwistedJacobiBridge`, as "isolated, not proved"; it is proved (`McRaeO5b.twistedJacobiBridge_holds`). (Found by the referee.)

7. `VOA/Classification/COne/OrbRat2Reduction.lean`: the module docstring says "all three Props remain OPEN", and the docstrings of `CubicModelRationalOfC2`, `InvolutionModelRationalOfC2`, `IcosahedralV2OrbifoldRationalOfC2` begin "OPEN". The same file proves that orbifold rationality implies each of them, and it is now proved, so all three are consequences of proved theorems (no declaration packages them as theorems; they are no longer needed). (Found by the referee.)

Verification record. Quotations checked verbatim by `scripts/textbook/sync.py`; aggregate build and axiom audit as recorded in the status of Theorem 22.59 (2026-10-14; re-probed at an earlier commit, not re-run for this edition). Release audit 2026-10-27: see Notes/Textbook/referee/RELEASE_AUDIT_L22.md. (Verdict: announceable with caveats — the rationality convention, `Type 0`, and the aggregate build to be re-confirmed on the release commit; the three headlines have no hypotheses and report Lean's three standard axioms; `VOA.pbw` is a theorem.)

Chapter 23

Affine vertex algebras for every simple Lie algebra, and the exceptional Lie algebras

This chapter was written against an earlier state of the LeanVOA library and updated on 28 October 2026 (the named simple quotient of Section 23.6.2, the quoted paths, and the renaming of the universal affine VOA). Every Lean quotation in a `leancode` box was copied from the source files; for this edition, `scripts/textbook/sync.py` checks that every quotation occurs verbatim in the source of the release. Checks that were run at an earlier state of the library and not re-run for this edition are marked as such. How to read the quotations (what they omit, and the Lean constructs that occur in them) is explained in Section 23.1; what the machine confirmed for this chapter, a map of the files it covers, and the cost of the kernel computations are collected in one place, the verification record of Section 23.12.

What the chapter is about. Chapter 9 built the universal affine vertex operator algebra $V^k(\mathfrak{sl}_2)$, and the bespoke files `VOA/Examples/AffineSl3*.lean` (whose chapter is in preparation) construct $V^k(\mathfrak{sl}_3)$ as `VOA.AffineSl3.affineSl3VOA`; both are long chains of files written against an explicit basis (`Fin 3`, resp. `Fin 8`). This chapter does the construction *once*, for an arbitrary finite-dimensional complex Lie algebra $\mathfrak{g}$ equipped with a small package of linear algebra (an invariant form, a basis, a dual basis and the eigenvalue of the adjoint Casimir), shows that the package exists for every simple $\mathfrak{g}$, and then constructs *inside Lean* concrete simple Lie algebras to which the theory can be applied.

Why the library needs this. The later Chapters 24–27 study the simple affine vertex algebras $L_k(\mathfrak{g})$ for the seven Lie algebras of the *Deligne exceptional series* $A_2 \subset G_2 \subset D_4 \subset F_4 \subset E_6 \subset E_7 \subset E_8$, at the negative levels $k = -h^\vee/6 - 1$ ($h^\vee$ the dual Coxeter number). These levels are singled out by a theorem of Arakawa and Moreau: at them the associated variety of $L_k(\mathfrak{g})$ (the variety cut out by the relations among the currents at leading order, Section 23.10) is the closure of the minimal nilpotent orbit of $\mathfrak{g}$, and the vacuum module acquires null vectors at conformal weight two. In physics, by the work of Beem, Lemos, Liendo, Peelaers, Rastelli and van Rees, $L_k(\mathfrak{g})$ at these levels is the chiral algebra of a rank-one four-dimensional $\mathcal{N} = 2$ superconformal field theory with flavour symmetry $\mathfrak{g}$ (for A_2, D_4, E_6, E_7, E_8; no four-dimensional theory is known for G_2, F_4). To state anything about these algebras in Lean one needs two things that Mathlib does not provide: an affine vertex algebra for an arbitrary simple Lie algebra, and the seven simple Lie algebras themselves, as concrete Lean objects proved simple. In addition, the integer certificates used in Chapter 24 were computed outside Lean, by Python, in a fixed basis; to use them as checked inputs, Lean needs Lie data whose structure constants are *literally* those certificate tables. This chapter supplies all three.

The logical arc. The mathematical backbone is a chain of five steps:

$$\underbrace{\text{Lie data}}_{\S 23.3} \xrightarrow{\S 23.4} \underbrace{V^k(\mathfrak{g})}_{\text{a VOA, } k+h\neq 0} \xrightarrow{\S 23.6} \underbrace{L_k(\mathfrak{g})}_{\text{simple quotient}} \xrightarrow{\S 23.10} \underbrace{\text{inputs of the capstone of Ch. 24}}_{\text{jet surjectivity; classical freeness if } hgeom, hchar}$$

1. *Lie data* (Section 23.3): the linear algebra of $\mathfrak{g}$ that the construction uses.
2. *The universal affine VOA* $V^k(\mathfrak{g})$ is built from Lie data for every non-critical level k (Section 23.4), with the Sugawara conformal vector.
3. *Lie data exist for every finite-dimensional simple* $\mathfrak{g}$ (Section 23.5), by Schur's lemma for the Casimir.
4. *The simple quotient* $L_k(\mathfrak{g})$ is simple, its weight-one space is spanned by the currents, and singular vectors of positive weight vanish in it (Section 23.6).
5. *The Deligne instances* (Section 23.10): for each of the seven types, $L_k(\mathfrak{g})$ at the Deligne level is fed into the capstone of Chapter 24.

Steps 3–5 are only useful if some concrete Lean Lie algebra is known to be simple. Sections 23.7, 23.8 and 23.9 provide them: $\mathfrak{sl}_n$; the weight-one spaces of the A_2, D_4, E_6, E_7, E_8 root-lattice vertex algebras (on paper $\mathfrak{sl}_3, \mathfrak{so}_8, \mathfrak{e}_6, \mathfrak{e}_7, \mathfrak{e}_8$); and algebras of dimensions 14, 52, 78 from kernel-checked tables of structure constants, modelling $\mathfrak{g}_2, \mathfrak{f}_4, \mathfrak{e}_6$ (the Cartan types are named on paper only, Remark 23.33); with their dimensions and the normalization of the invariant form. Section 23.11 is engineering rather than mathematics: it realizes the fixed "certificate basis" of the Python computations inside these algebras.

What is proved, what is conditional, and what is not claimed.

- **Proved, with only the intended hypotheses** (`#print axioms` lists only Lean's three standard axioms): $V^k(\mathfrak{g})$ is a VOA of central charge $k \dim \mathfrak{g}/(k+h)$ for Lie data and $k+h \neq 0$, where $2h$ is the eigenvalue of the adjoint Casimir *in the normalization of the chosen form* κ (not, in general, the dual Coxeter number $h^\vee$; see below); Lie data exist for every finite-dimensional simple $\mathfrak{g}$ with a nondegenerate symmetric invariant form; $L_k(\mathfrak{g})$ is simple, with weight one spanned by the currents; $V^k(\mathfrak{g})_1 \cong \mathfrak{g}$ *as vector spaces* for $k \neq 0$ (a linear isomorphism `weightOneEquiv`; compatibility with the bracket $u_{(0)}v \leftrightarrow [x,y]$ is not proved for general $\mathfrak{g}$); positive-weight singular vectors lie in the maximal ideal; $\mathfrak{sl}_n$ ($n \geq 2$), the five lattice algebras and the three table algebras are simple, with the stated dimensions and (per type, via the `*_standard` theorems) normalizations; the certificate tables are the structure constants of Lie data; and for every Deligne type the input "current-jet surjectivity" of the capstone holds.
- **Naming, fixed; and a normalization caveat** (release audit 2026-10-27, findings M1–M2). (i) The audit found that the declaration for the *universal* algebra $V^k(\mathfrak{g})$ of a simple $\mathfrak{g}$ was called `simpleAffineVOA` ("simple" referring to $\mathfrak{g}$), inviting the false reading $L_k(\mathfrak{g})$, and that the simple quotient had no name. Both are fixed: the universal algebra is now `universalAffineVOA` (the old name survives only as a deprecated alias), and the simple quotient $L_k(\mathfrak{g})$, the term `simpleVOA (simpleData g κ hinv hnd) k hk`, is named `simpleAffineQuotientVOA` (Section 23.6.2). (ii) The number h in `universalAffineVOA` is half an eigenvalue picked by `Classical.choose`, in the normalization of κ; it is computed only for the Killing form ($h = \frac{1}{2}$). `standardAffineVOA` takes h as a free nonzero parameter `hv`. That $h = h^\vee$ is established only type by type, through the `*_standard` theorems (Theorem 23.32 and Section 23.9), and for $\mathfrak{g}_2, \mathfrak{f}_4, \mathfrak{e}_6$ the longness of the chosen root is itself not checked in Lean. For $\mathfrak{sl}_n$ it is not established in Lean at all.

- **Conditional.** The statement that the Deligne case is *classically free* (`classicallyFree_of_two_inputs` and its seven specializations) is proved only *assuming* two named inputs, `hgeom` (a "geometric carrier embedding") and `hchar` (a "carrier character identity"), explained in Section 23.10. This chapter does not discharge them; for the presentation built here it cannot (warning box in Section 23.10).
- **Not claimed in Lean**, although true on paper or in the literature: (a) $L_k(\mathfrak{g})_1 \cong \mathfrak{g}$ for general $\mathfrak{g}$ (only spanning is proved); (b) that the algebras named `e8Lie`, `f4Lie`, ... are of the named Cartan type (the classification of simple Lie algebras is not formalised; Remark 23.33). Lean proves *concrete simple Lie algebras of dimensions* 14, 52, 78, 133, 248, built as the exceptional ones; no Lean statement identifies a Cartan type, and dimension 78 could not do so in any case ($\dim B_6 = \dim C_6 = \dim E_6 = 78$, all of rank 6 with 72 roots); (c) the Frenkel–Kac isomorphism $V_{E_8} \cong L_1(\mathfrak{e}_8)$: the library uses the lattice VOA V_{E_8} *only* as a source of a concrete simple Lie algebra (its weight-one space with the bracket $[u, v] = u_{(0)}v$), and no Lean statement relates `e8VOA` to `standardAffineVOA e8Lie`; wherever Frenkel–Kac is mentioned below it is motivation; (d) the identification of $L_k(\mathfrak{g})$ at the Deligne levels with four-dimensional chiral algebras (physics literature); (e) any isomorphism between the three Lean models of $\mathfrak{e}_6$; (f) that the form used by `slAffineVOA` is the trace form.

Where this goes. Chapter 24 (presentations, carriers, divisor comparison) builds the explicit presentations $\mathrm{Sym}\,\mathfrak{g}/(I_2^{\mathrm{ns}})$ of the C_2-algebra of $L_k(\mathfrak{g})$ at the Deligne levels from Theorem 23.19, Proposition 23.21 and the Lie data of Sections 23.9 and 23.11, and states the capstone quoted in Section 23.10. Chapter 25 proves lower bounds on $\dim L_k(\mathfrak{g})_N$. Chapter 26 (fusion modules) uses the certificate bases of Section 23.11 in its lattice realizations. Chapter 27 states the final theorems for the seven types, conditional on named literature inputs.

What we rely on. Chapter 2 for formal distributions, modes (`mode f n` $= f_{(n)}$, the coefficient of z^{-n-1}) and locality; Chapter 3 for invariant forms (`IsInvariant`), the affine Kac–Moody algebra $\hat{\mathfrak{g}}$, the vacuum module `vacuumSpace` and its nonvanishing by relative PBW; Chapter 4 for the structures `PreVertexAlgebra`, `VertexOperatorAlgebra` and the reconstruction theorem; Chapter 5 for the Lie algebra structure $[u, v] = u_{(0)}v$ on weight one, ideals, quotients, the maximal graded ideal and `IsSimple`; Chapter 6 for lattice vertex algebras `latticeVOAGen` and the FLM cocycle; the files `VOA/Examples/AffineSl3*.lean` (chapter in preparation) for the $\mathfrak{sl}_3$ construction, of which the general one is a port; Chapter 11 for Li's filtration, jets and generator words; Chapter 14 for modular forms and Eisenstein series; Chapter 30 for integral lattices and theta series.

23.1 Reading the Lean, and the notation of this chapter

A primer is in Chapter 1. Section 1.2 ("The Lean toolkit: reading Lean for mathematicians") and the glossary of Section 1.8 teach everything needed to read the boxes below. For convenience, here are the constructs that occur in this chapter.

- **Omitted bodies.** A quotation stops where the proof begins. A box ending in `:= by` (or `:=`) after a `theorem` has had its proof removed; it is not truncated by accident. For a `def` or `structure` ending in `where` or `:=`, the body that follows defines the object; where that body is data rather than a proof (`ofNondegenerate`, `smulForm`, `reindex`, `ofSimple`, `standardData`, the truncated `pairOK`, the `casimir` field of `sl3Data`) the dictionary box says what it contains. Docstrings and comments are also omitted. A one-line proof term is kept when it is informative (e.g. `simpleVOA_isSimple`).
- **Arguments.** `(x : X)` is an explicit argument, `{x : X}` an implicit one (inferred by Lean), `[C X]` an instance argument (a structure, such as `[Fintype ι]` "ι is finite" or `[DecidableEq ι]`

"equality on ι can be decided", which Lean finds automatically). For reading, all three are universally quantified hypotheses. `Type*` means "some type" (in some universe).

- **`variable` and `include`.** A `variable` line declares arguments once for a whole section of a file; they become arguments of every declaration below that uses them. They are therefore hypotheses of a theorem even though they are not printed in its signature. Every dictionary box lists the relevant section variables. `include h` forces a section variable `h` to be a hypothesis even of declarations that do not mention it.
- **`abbrev`, `irreducible_def`, `noncomputable`.** `abbrev` is a definition that Lean unfolds eagerly (for reading, the same as `def`); `irreducible_def` is a definition that is opaque except through its defining equation (used for speed). `noncomputable` means Lean cannot run it as a program (it uses choice).
- **Anonymous constructors and functions.** `⟨a, b⟩` builds a structure from its fields in order, e.g. an element of a subspace from a vector `a` and a proof `b` that it lies in the subspace. `fun i ⇒ e` is the function $i \mapsto e$; `![a, b, c]` is a vector literal.
- **Finite index sets.** `Fin n` is $\{0, \dots, n-1\}$; `∑ i, f i` sums over a finite type; `Fintype.card ι` is $|\iota|$.
- **Kernel checks.** `decide +kernel` proves a decidable statement (typically "this Boolean function of an integer table evaluates to `true`") by letting Lean's kernel evaluate it. The kernel is the trusted core of Lean, so such a proof is as reliable as any other; the Python scripts that *produced* the tables are not trusted and need not be.

Notation. The letter h is overloaded in the literature; this chapter keeps the meanings apart as follows.

symbol	meaning
κ	a symmetric invariant bilinear form on $\mathfrak{g}$ (Lean `κ`)
b_a, b^a	a basis of $\mathfrak{g}$ and its κ-dual family, $\kappa(b_a, b^c) = \delta_{ac}$
κ_{ab}, κ^{ab}	the Gram matrix $\kappa(b_a, b_b)$ (`formTable`); the b-th coordinate of b^a (`killingInv`), the inverse Gram matrix
$f^{ab}{}_c$	the c-th coordinate of $[b_a, b_b]$ (`structureConstant a b c`). No summation convention: every sum is written
h	the *Casimir number* of $(\mathfrak{g}, \kappa)$: $\sum_a [b_a, [b^a, x]] = 2hx$ (field `h` of Lie data). It depends on κ
$h^\vee$	the dual Coxeter number of $\mathfrak{g}$, a fixed integer ($2, 3, 4, 6, 9, 12, 18, 30$ for $A_1, A_2, G_2, D_4, F_4, E_6, E_7, E_8$). $h = h^\vee$ exactly when κ is standard (long roots of squared length 2)
ν	a free nonzero complex parameter (Lean `hv` in `standardData`); *not* assumed to be $h^\vee$
h_α, e_α	coroot (Cartan) vectors and root vectors of a concrete Lie algebra (Sections 23.7–23.9)
H	the diagonal matrix $\mathrm{diag}(1, -1) \in \mathfrak{sl}_2$
J^a_m	the mode $b_a \otimes t^m$ acting on the vacuum module; $J^a(z) = \sum_m J^a_m z^{-m-1}$
$x_{(n)}$	the n-th product (mode) of the field of x: $Y(x, z) = \sum_n x_{(n)} z^{-n-1}$; for a current, $x_{(n)} = J^x_n$
k	the level

23.2 The physical picture

A two-dimensional conformal field theory with a continuous internal symmetry group G has conserved currents $J^a(z)$, one for each element t^a of a basis of the Lie algebra $\mathfrak{g}$ of G. Holomorphy

and conformal weight one force their operator product expansion to be

$$J^a(z)\,J^b(w) \sim \frac{k\,\kappa(t^a,t^b)}{(z-w)^2} + \frac{\sum_c f^{ab}{}_c\,J^c(w)}{z-w}, \tag{23.1}$$

where $f^{ab}{}_c$ are the structure constants, κ is an invariant symmetric form, and the number k (the *level*) measures the strength of the Schwinger term, i.e. the two-point function of the currents. In modes $J^a(z) = \sum_m J^a_m z^{-m-1}$ this is the affine Kac–Moody algebra

$$[J^a_m, J^b_n] = \sum_c f^{ab}{}_c\,J^c_{m+n} + m\,k\,\kappa(t^a,t^b)\,\delta_{m+n,0}. \tag{23.2}$$

The *vacuum module* is the space of states generated from a vacuum $|0\rangle$ annihilated by all J^a_m with $m \geq 0$; the state–field correspondence turns it into a vertex algebra, the *universal affine vertex algebra* $V^k(\mathfrak{g})$. Its stress tensor is not an extra datum: the *Sugawara construction*

$$T(z) = \frac{1}{2(k+h)} \sum_a {:}J^a(z)J_a(z){:}\,, \qquad c = \frac{k\dim\mathfrak{g}}{k+h}, \tag{23.3}$$

(J_a the current of the κ-dual basis element; h the Casimir number of $(\mathfrak{g},\kappa)$, defined in Definition 23.1 below by $\sum_a [b_a,[b^a,x]] = 2hx$, which equals the dual Coxeter number $h^\vee$ when κ is normalized so that long roots have squared length 2) builds it from the currents. It fails exactly at the *critical level* $k = -h$, where T becomes central.

Two classes of examples will matter. At positive integer level, $L_k(\mathfrak{g})$ is the chiral algebra of the Wess–Zumino–Witten model of G; at level 1 for simply-laced $\mathfrak{g}$ it is isomorphic to the lattice vertex algebra of the root lattice (the Frenkel–Kac theorem). The library uses the lattice side of this picture *only* to obtain a concrete $\mathfrak{e}_8$: the conserved currents of eight chiral bosons on the E_8 torus (the theory underlying the $E_8 \times E_8$ heterotic string) form a Lie algebra, and that Lie algebra is the library's $\mathfrak{e}_8$. The isomorphism $V_{E_8} \cong L_1(\mathfrak{e}_8)$ itself is *not* formalised, and nothing below depends on it. At the *negative* levels $k = -h^\vee/6 - 1$ of the Deligne series, $L_k(\mathfrak{g})$ is (by the work of Beem, Lemos, Liendo, Peelaers, Rastelli and van Rees, and Arakawa–Moreau) the chiral algebra of a four-dimensional $\mathcal{N} = 2$ superconformal field theory of rank one, whose Higgs branch is the minimal nilpotent orbit of $\mathfrak{g}$; the two-dimensional central charge is $c_{2d} = -12c_{4d} = -2h^\vee - 2$. These are the theories studied in Chapters 24–27. This identification is physics literature; it motivates the Lean statements but is not one of them.

23.3 Lie data

The construction of $V^k(\mathfrak{g})$ uses a finite-dimensional Lie algebra only through a small amount of linear algebra: a basis $b_1,\dots,b_N$, the dual basis $b^1,\dots,b^N$ with respect to κ, and the value of the adjoint Casimir. The library packages these as a structure.

Definition 23.1 (Lie data)**.** Let $\mathfrak{g}$ be a complex Lie algebra and κ a bilinear form on $\mathfrak{g}$. *Lie data* for $(\mathfrak{g},\kappa)$ indexed by a finite set ι consist of

1. a proof that κ is symmetric and invariant: $\kappa(x,y) = \kappa(y,x)$ and $\kappa([x,y],z) = \kappa(x,[y,z])$;
2. a basis $(b_i)_{i\in\iota}$ of $\mathfrak{g}$;
3. a family $(b^i)_{i\in\iota}$ (the *dual family*) with $\kappa(b_i,b^j) = \delta_{ij}$;
4. a complex number h (the *Casimir number*; it equals the dual Coxeter number $h^\vee$ when κ is the standard normalization, and scales inversely with κ otherwise);

5. a proof that the adjoint Casimir acts by $2h$:

$$C(x) := \sum_{i\in\iota} [b_i, [b^i, x]] = 2h\,x \qquad \text{for all } x \in \mathfrak{g}. \tag{23.4}$$

File `VOA/AffineGeneral/LieData.lean`.

```

```

From the mathematics to the Lean statement

`LinearMap.BilinForm ℂ 𝔤` is a $\mathbb{C}$-bilinear form $\mathfrak{g}\times\mathfrak{g}\to\mathbb{C}$, applied as `κ x y`. `κ.IsInvariant` is the structure of Chapter 3 (Definition 3.4, `VOA/Foundations/AffineLie.lean`) with two fields, `symm : ∀ x y, κ x y = κ y x` and `invariant : ∀ x y z, κ ⁅x, y⁆ z = κ x ⁅y, z⁆`; it is plain symmetry, not Mathlib's `IsSymm` (which over $\mathbb{C}$ is the Hermitian condition). `Module.Basis ι ℂ 𝔤` is a basis indexed by ι; `[Fintype ι]` says ι is finite, so $\mathfrak{g}$ is finite-dimensional, and `[DecidableEq ι]` is needed for the Kronecker `if i = j then 1 else 0`. `⁅x, y⁆` is the Lie bracket and $\bullet$ scalar multiplication.

Every field is a hypothesis about $\mathfrak{g}$, not an axiom. Nondegeneracy of κ is not a field but is a consequence: the pairing field forces $\kappa(y,x) = 0\ \forall y \Rightarrow x = 0$ (`LieData.form_right_nondegenerate` in the same file). The field `casimir` is the only genuinely Lie-theoretic input; it is *not* automatic for a general Lie algebra (for a reductive non-simple algebra the Casimir has several eigenvalues), and it is proved for every simple $\mathfrak{g}$ in Section 23.5.

Could the structure be vacuous? No: Section 23.5 constructs it for every simple $\mathfrak{g}$, and `sl3Data` (Section 23.5.3) is an explicit instance. Is the name "h" honest? h is *defined* by (23.4); it equals the dual Coxeter number $h^\vee$ exactly when κ is the standard normalization (long roots of squared length 2). In general h scales inversely with κ (Definition 23.4). Same as the textbook.

Example 23.2 ($\mathfrak{sl}_2$ with the trace form)**.** Take $\mathfrak{g} = \mathfrak{sl}_2$, $\kappa(x,y) = \operatorname{tr}(xy)$, basis $b_0 = e$, $b_1 = H$, $b_2 = f$ ($H = \operatorname{diag}(1,-1)$), with $[H,e] = 2e$, $[H,f] = -2f$, $[e,f] = H$. Since $\operatorname{tr}(ef) = 1$, $\operatorname{tr}(HH) = 2$ and all other traces of products vanish, the dual family is $b^0 = f$, $b^1 = \frac{1}{2}H$, $b^2 = e$. On $x = e$: $C(e) = [e,[f,e]] + [H,[\frac{1}{2}H,e]] + [f,[e,e]] = [e,-H] + \frac{1}{2}[H,2e] + 0 = 2e + 2e$. So $C(e) = 4e$ and $h = 2 = h^\vee(\mathfrak{sl}_2)$, as it must be, since the trace form is the standard normalization. This example is continued in Examples 23.8 and 23.20.

Why this is the right definition. The construction of $V^k(\mathfrak{g})$ uses the Lie algebra only through brackets of basis vectors, the Gram matrix of κ (for the central term) and the double contraction $\sum_a [b_a,[b^a,\cdot]]$ (for the Sugawara normalization). Packaging exactly these, rather than assuming $\mathfrak{g}$ simple, lets the same construction serve every case, including reductive algebras with a suitable form, and moves the one genuinely Lie-theoretic fact (the Casimir is a scalar) to a separate theorem.

Physical meaning

Lie data are exactly what the current algebra (23.1) and the Sugawara tensor (23.3) need: a choice of currents J^a (the basis), the two-point normalization κ (the "metric" raising and lowering colour indices, here encoded by the dual family), and the Casimir eigenvalue in the

adjoint, which is the one-loop shift $k \mapsto k + h$ in the Sugawara normalization (the famous "$k + h^\vee$" of WZW models).

What the machine verified

A definition (no proof obligation). Instances are constructed unconditionally (Sections 23.5, 23.5.3).

From the fields one derives, in coordinates, the identities the Sugawara computation needs. Write $f^{ab}{}_c$ for the structure constants (`structureConstant a b c`, the c-th coordinate of $[b_a, b_b]$, so $[b_a, b_b] = \sum_c f^{ab}{}_c b_c$), $\kappa_{ab} = \kappa(b_a, b_b)$ for the Gram matrix (`formTable`) and κ^{ac} for the c-th coordinate of b^a (`kappaInv`; so $b^a = \sum_c \kappa^{ac} b_c$, and (κ^{ac}) is the inverse of (κ_{ab})). The position of an index (up or down) carries no meaning beyond this; there is no summation convention, and every sum is written out.

Proposition 23.3 (Finite identities). *For Lie data as above:*

1. *(Casimir in coordinates)* $\sum_{a,d} \big(\sum_b \kappa^{ab} f^{bc}{}_d\big) f^{ad}{}_e = 2h\,\delta_{ce}$;
2. *(trace of* ad *vanishes)* $\sum_a f^{ac}{}_a = 0$ *for every* c *(note* $\operatorname{tr}\operatorname{ad}(b_c) = \sum_a f^{ca}{}_a = -\sum_a f^{ac}{}_a$*);*
3. *(central charge numerator)* $\sum_{a,b} \kappa^{ab}\kappa_{ab} = |\iota| = \dim \mathfrak{g}$.

File `VOA/AffineGeneral/LieData.lean`.

```
theorem struct_casimir_contract (c e : ι) :
    (∑ a, ∑ d, (∑ b, D.kappaInv a b * D.structureConstant b c d) * D.structureConstant a d
    ↪  e) =
      if c = e then 2 * D.h else 0 := by

theorem structureConstant_diag_sum (c : ι) : (∑ a, D.structureConstant a c a) = 0 := by

theorem trace_kappaInv_formTable :
    (∑ a, ∑ b, D.kappaInv a b * D.formTable a b) = Fintype.card ι := by
```

From the mathematics to the Lean statement

`D : LieData κ ι` is a variable of the section; `D.kappaInv a b` is `D.basis.repr (D.dual a) b`, the b-th coordinate of b^a, which is the inverse Gram matrix by `kappaInv_kappa` in the same file. `Fintype.card ι` is $|\iota| = \dim \mathfrak{g}$. Same as the textbook.

Proof on paper. (1) is the e-th coordinate of (23.4) at $x = b_c$, after expanding $b^a = \sum_b \kappa^{ab} b_b$. (2): the trace of $\operatorname{ad}(x)$ is $\sum_a \kappa([x, b_a], b^a)$; invariance gives $\kappa([x, b_a], b^a) = -\kappa(b_a, [x, b^a])$, and re-expanding in the dual basis shows the sum equals its own negative, hence vanishes (no simplicity is needed: any Lie algebra with a nondegenerate invariant form is unimodular). (3): row by row, $\sum_b \kappa^{ab}\kappa_{ab} = 1$ because $\kappa^{-1}\kappa = 1$; summing over a gives $|\iota|$. □

Physical meaning

(1) is the statement that the Casimir appears in the double contraction $f f$ of the current OPE; it produces the h in $k + h$. (2) makes each current a Virasoro primary of weight one (no "anomalous" ∂J term in $T(z)J(w)$). (3) is why the central charge numerator is $k \dim \mathfrak{g}$. *Heuristically*, each of the $\dim \mathfrak{g}$ currents contributes one free-boson-like unit; this is literally true only as $k \to \infty$, where $c = k \dim \mathfrak{g}/(k + h) \to \dim \mathfrak{g}$ and the currents become $\dim \mathfrak{g}$ free bosons. At finite k the interaction (the f terms) reduces it by the factor $k/(k + h)$.

What the machine verified

Proved; `#print axioms` standard for all three (project record, Section 23.12).

Lie data can be built from a nondegenerate form, rescaled, and reindexed.

Definition 23.4 (Constructions of Lie data). (i) Given a symmetric invariant nondegenerate κ, a basis b and a number h with $\sum_i [b_i, [b^i, x]] = 2hx$ for the κ-dual basis b^i, there is Lie data with these components. (ii) If D is Lie data for κ and $c \neq 0$, then $(b_i,\ c^{-1}b^i,\ h/c)$ is Lie data for $c\kappa$. (iii) Lie data can be transported along a bijection $\iota \simeq \iota'$.

File `VOA/AffineGeneral/LieData.lean`.

noncomputable def reindex {ι' : Type*} [Fintype ι'] [DecidableEq ι'] (D : LieData κ ι) (e :
↪  ι ≃ ι') :
    LieData κ ι' where
```

From the mathematics to the Lean statement

`LinearMap.BilinForm.Nondegenerate κ` is Mathlib's nondegeneracy; `dualBasis κ hnd b` is Mathlib's κ-dual basis. `c • κ` is the rescaled form; `ι ≃ ι'` is a bijection. The rescaling law $h \mapsto h/c$ is forced: the dual family scales by c^{-1}, so the Casimir does too. Same as the textbook.

Proof on paper. (ii): $c\kappa(b_i, c^{-1}b^j) = \delta_{ij}$ and $\sum_i [b_i, [c^{-1}b^i, x]] = c^{-1}2hx = 2(h/c)x$. (iii) is a reindexing of finite sums. □

Physical meaning

Rescaling κ by c while keeping the currents fixed rescales the level $k \mapsto k/c$ in (23.1) and the dual Coxeter number $h \mapsto h/c$; only the ratio k/h (and hence $c = \dim\mathfrak{g}\, k/(k+h)$) is physical. This is why a level is meaningless until a normalization of κ is fixed.

What the machine verified

Definitions; the identity `smulForm_h` holds by `rfl`.

23.4 The universal affine vertex algebra $V^k(\mathfrak{g})$

23.4.1 The vacuum module and the currents

Recall from Chapter 3 (Definitions 3.6 and 3.7) the affine Lie algebra $\hat{\mathfrak{g}} = \mathfrak{g} \otimes \mathbb{C}[t, t^{-1}] \oplus \mathbb{C}K\ (\oplus \mathbb{C}d)$ and its vacuum module, realized in Lean as a quotient of the universal enveloping algebra of $\mathfrak{g} \otimes \mathbb{C}[t, t^{-1}] \oplus \mathbb{C}K \oplus \mathbb{C}\ell_0$ by the left ideal (`vacuumIdeal`, `VOA/Foundations/AffineLie.lean`) generated by the non-negative loop modes $\mathfrak{g} \otimes t^n$ ($n \geq 0$), the derivation ℓ_0, and $K - k$. The general construction works on that carrier.

Definition 23.5 (Vacuum module and current modes). For Lie data D and $k \in \mathbb{C}$, $V^k(\mathfrak{g})$ is the vacuum module of $\hat{\mathfrak{g}}$ at level k, and J^a_m is the action of $b_a \otimes t^m$ on it.

  vacuumVector κ D.invariant k

theorem vacuumA_ne_zero (k : ℂ) : vacuumA D k ≠ 0 :=
  vacuumVector_ne_zero κ D.invariant k
```

From the mathematics to the Lean statement

`vacuumSpace κ hκ k`, `vacuumRho`, `ofLoop` and `vacuumVector` are the objects of Chapter 3 (`VOA/Foundations/AffineLie.lean`): the vacuum module, the action of $\hat{\mathfrak{g}}$ on it, the loop element $x \otimes t^m$, and the class of 1. `Module.End ℂ (Vacuum D k)` is the algebra of linear endomorphisms; $*$ is composition, so the left side of `current_comm` is the commutator. `LinearMap.id` is the identity. `D.generator a` is an `abbrev` for `D.basis a`, i.e. b_a, and `D.dualGenerator a` for `D.dual a`, i.e. b^a (`VOA/AffineGeneral/LieData.lean`). `current_comm` is (23.2) verbatim, with $\kappa(t^a, t^b)$ the Gram entry `formTable D a b`.
The nonvanishing `vacuumA_ne_zero` is the delicate point of the whole construction: if the vacuum were 0, every subsequent statement would be about the zero space. It is proved by `AffineLie.vacuumVector_ne_zero`, which rests on the *theorem* `VOA.pbw` (relative PBW, Chapter 3, Theorem 3.18); there is no project axiom. The file's docstrings claim otherwise (see the warning box in Section 23.4.1).

Proof on paper. The commutator of two operators of a representation is the representation of the bracket; the bracket of $\hat{\mathfrak{g}}$ is the loop bracket plus the cocycle $m\delta_{m+n,0}\kappa(x,y)K$, and K acts by k on the vacuum module. Nonvanishing: by the relative PBW theorem, the induced module $U(\hat{\mathfrak{g}}) \otimes_{U(\mathfrak{g}[t]\oplus\mathbb{C}K)} \mathbb{C}_k$ restricts to $\mathfrak{g}[t] \oplus \mathbb{C}K$ with $\mathbb{C}_k$ as a direct summand, so $1 \otimes 1 \neq 0$. □

Physical meaning

J^a_m are the Laurent modes of the conserved currents; `current_comm` is the current algebra with Schwinger term $mk\kappa$; the vacuum is the SL_2-invariant state annihilated by all non-negative modes. Nonvanishing of the vacuum says the theory has a state at all, which is not a formality: the vacuum module is defined as a quotient.

What the machine verified

Proved; `#print axioms` standard for `current_comm` and `vacuumA_ne_zero` (project record, Section 23.12).

Trap: Docstring defect: "free-field evaluation, without PBW"

In `VOA/AffineGeneral/Grading.lean` the docstring of `vacuumA_ne_zero` reads "The vacuum is nonzero by its actual polynomial evaluation, without PBW", and the module docstring says the vacuum line is "proved nonzero using the explicit free-field evaluation"; `Currents.lean` says "Its previously constructed free-field evaluation proves that this space is nonzero". These sentences were inherited from the $\mathfrak{sl}_3$ files (`VOA/Examples/AffineSl3*.lean`, where a Wakimoto realization was used). In the general files they are **false**: the proof term printed above is `vacuumVector_ne_zero`, i.e. relative PBW. (The second paragraph of the `Grading.lean` module docstring states the correct fact, so the file contradicts itself.) Listed in Section 23.13.

23.4.2 Grading, Sugawara vector and the vertex algebra

The operator ℓ_0 of Chapter 3 is the action of the derivation $t\frac{d}{dt}$, i.e. $[\ell_0, x\otimes t^n] = n(x\otimes t^n)$ (`ell0_lie_ofLoop`); it kills the vacuum, and a creation mode $x\otimes t^{-m}$ ($m\geq 1$) *lowers* its eigenvalue by m. So ℓ_0 measures *minus* the energy: it diagonalizes $V^k(\mathfrak{g})$ with eigenvalues $0,-1,-2,\dots$ and finite-dimensional eigenspaces, and a state of weight $n\geq 0$ is an ℓ_0-eigenvector of eigenvalue $-n$ (on $V^k(\mathfrak{g})$, $\ell_0 = -L_0$). The library takes as grading $V^k(\mathfrak{g})_n = \ker(\ell_0 + n)$, the ℓ_0-eigenspace of eigenvalue $-n$ (`gradingZA D k n`), proves that it is an internal direct sum, that $V^k(\mathfrak{g})_0 = \mathbb{C}|0\rangle$ and $V^k(\mathfrak{g})_n = 0$ for $n<0$, and builds the vertex operators $Y(u,z)$ by the reconstruction theorem of Chapter 4 from the generating fields $J^a(z)$ (files `WordFields.lean`, `Reconstruction.lean`, `Assembly.lean`, `GradedFields.lean`). The resulting vertex algebra is `affineVertexAlgebra D k hk`. The conformal vector is the Sugawara state.

Definition 23.6 (Sugawara field and conformal vector)**.** For $k+h\neq 0$,

$$T(z) = \frac{1}{2(k+h)}\sum_{a,b\in\iota}\kappa^{ab}\,{:}J^a(z)J^b(z){:}, \qquad L_n = T_{(n+1)}, \qquad \omega = L_{-2}|0\rangle,$$

and the central charge is $c = |\iota|\,k/(k+h)$.

Files `VOA/AffineGeneral/SugawaraField.lean`, `VOA/AffineGeneral/Virasoro.lean`.

```
noncomputable def sugawaraField (k : ℂ) : FormalDist (End ℂ (Vacuum D k)) :=
  (2 * (k + D.h))⁻¹ •
    ∑ a : ι, ∑ b : ι,
      kappaInv D a b • nprod (Jfield_isField D k a) (Jfield_isField D k b)

noncomputable def Lsug (k : ℂ) (n : ℤ) : End ℂ (Vacuum D k) :=
  mode (sugawaraField D k) (n + 1)

noncomputable def omegaA (k : ℂ) : Vacuum D k := Lsug D k (-2) (vacuumA D k)

noncomputable def centralChargeA (k : ℂ) : ℂ := (Fintype.card ι : ℂ) * k / (k + D.h)
```

From the mathematics to the Lean statement

`FormalDist (End ℂ V)` is the space of formal distributions $\sum_n A_n z^{-n-1}$ with operator coefficients (Chapter 2); `Jfield D k a` is $J^a(z)$ and `nprod` is the normally ordered product ${:}ab{:}$ (the (-1)-product of fields, Chapter 4); `Jfield_isField` certifies lower truncation, which `nprod` requires. `mode f n` is $f_{(n)}$, so `Lsug D k n` is $T_{(n+1)} = L_n$ (weight-two shift). `(2 * (k + D.h))⁻¹` is Lean's inverse, with $0^{-1}=0$: at critical level the definition still typechecks and gives $T=0$; every theorem about T assumes `k + D.h ≠ 0`. $\sum_{a,b}\kappa^{ab}\,{:}J^aJ^b{:} = \sum_b {:}J^{b}J^{b}{:}$ after expanding the dual vectors, i.e. (23.3). Same as the textbook.

Why this definition. The quadratic expression $\sum_{a,b} \kappa^{ab}\ {:}J^aJ^b{:}$ is the only weight-two field built from two currents that is invariant under the zero modes (it is the image of the Casimir element $\sum_a b_a b^a \in U(\mathfrak{g})$). Its normalization is fixed by requiring $[L_m, J^c_n] = -nJ^c_{m+n}$, i.e. that L_0 measure the weight; the proof of Theorem 23.7 shows that this forces the prefactor $1/(2(k+h))$, not the classical $1/(2k)$.

Physical meaning

$T(z)$ is the stress tensor of the WZW-type theory, built entirely from the currents; the factor $1/(2(k+h))$ rather than the naive $1/(2k)$ is the quantum correction from normal ordering (the double contraction produces h via Proposition 23.3(1)).

What the machine verified

Definitions (no proof obligation); every theorem about them assumes $k + h \neq 0$.

Theorem 23.7 (The universal affine VOA). *For Lie data D and $k + h \neq 0$, the vacuum module $V^k(\mathfrak{g})$ with the vertex operators reconstructed from the currents, vacuum $|0\rangle$ and conformal vector ω is a vertex operator algebra of central charge $c = \dim \mathfrak{g} \cdot k/(k+h)$: the modes L_n satisfy $[L_m, L_n] = (m-n)L_{m+n} + \delta_{m+n,0}\frac{m^3-m}{12}c$; L_0 acts on $V^k(\mathfrak{g})_n = \ker(\ell_0 + n)$ as multiplication by n (so $L_0 = -\ell_0$ on $V^k(\mathfrak{g})$: L_0 is the energy, ℓ_0 minus the energy); L_{-1} is translation; the grading is non-negative and $V^k(\mathfrak{g})_0 = \mathbb{C}|0\rangle$.*

```

From the mathematics to the Lean statement

The fields of `VertexOperatorAlgebra` are those of Chapter 4: a vertex algebra (grading, vacuum, Y, creation, locality, regularity), a conformal vector in weight 2, its central charge, the Virasoro relations, L_0-grading, L_{-1}-translation, positivity ($V_n = 0$ for $n < 0$) and $V_0 = \mathbb{C}|0\rangle$ (CFT type). `YA D k hk u` is the reconstructed vertex operator $Y(u, z)$; since ω has weight 2, L_n is `mode (YA ω) (n+1)`, which explains the shifts `m + 1, n + 1, m + n + 1`. `(1 : End ℂ _)` is the identity. The hypothesis `hk : k + D.h ≠ 0` is non-criticality, the only hypothesis besides the Lie data and the instance argument `[FiniteDimensional ℂ 𝔤]`, which every file from `Currents.lean` to `DeligneInstance.lean` declares as a section variable (it is implied by the finite basis of D, so it loses nothing); non-criticality is genuinely needed (at $k = -h$ there is no Virasoro element of this form). Every VOA axiom is a *field* filled by a theorem; nothing is

assumed. The central charge is `centralChargeA D k`, i.e. $|\iota|k/(k+h)$, checked by `rfl` in the instances. Same as the textbook.
How could it be wrong? A VOA structure on the zero space would satisfy all axioms vacuously; this is excluded by `vacuumA_ne_zero`. A wrong central charge would make `hYA_virasoro` false, and it is proved.

Proof on paper. This is the classical Frenkel–Zhu construction.

(a) Vertex algebra. The currents $J^a(z)$ are mutually local: their commutator (23.2) is a sum of $\delta(z-w)$ and $\partial_w\delta(z-w)$ terms, so $(z-w)^2[J^a(z),J^b(w)]=0$. They are translation-covariant, and their modes generate $V^k(\mathfrak{g})$ from $|0\rangle$. The reconstruction theorem (Chapter 4) gives a unique vertex algebra structure with $Y(J^a_{-1}|0\rangle,z)=J^a(z)$.

(b) The key commutator $[L_m,J^c_n]=-n\,J^c_{m+n}$. In modes, $L_m=\frac{1}{2(k+h)}\sum_{a,b}\kappa^{ab}\sum_{p\in\mathbb{Z}}:J^a_pJ^b_{m-p}:$, where normal ordering puts the mode with the larger index on the right (so that on any vector only finitely many terms are nonzero). Commute J^c_n through this sum using $[J^c_n,J^a_p]=\sum_d f^{ca}{}_dJ^d_{n+p}+nk\kappa_{ca}\delta_{n+p,0}$. Two kinds of terms appear.

- *Central (Schwinger) terms*, one from each of the two factors: $nk\sum_{a,b}\kappa^{ab}\big(\kappa_{ca}J^b_{m+n}+\kappa_{cb}J^a_{m+n}\big)=2nk\,J^c_{m+n}$, because $\sum_a\kappa_{ca}\kappa^{ab}=\delta_{cb}$ ($\kappa^{-1}\kappa=1$).
- *Structure-constant terms*, $\sum_{a,b,d}\kappa^{ab}\big(f^{ca}{}_d:J^dJ^b:+f^{cb}{}_d:J^aJ^d:\big)$. These would cancel exactly, because the tensor $\sum_{a,b}\kappa^{ab}b_a\otimes b_b$ is invariant under $\mathrm{ad}(b_c)$ (this is invariance of κ). But after commuting, $|n|$ of the products are no longer normally ordered; restoring the order costs one commutator $[J^d_{\cdot},J^b_{\cdot}]$ for each of them. The structure-constant part of these commutators is $n\sum_{a,b,d}\kappa^{ab}f^{ca}{}_df^{db}{}_eJ^e_{m+n}$, which is $n\cdot 2h\,J^c_{m+n}$ by Proposition 23.3(1) (the Casimir in coordinates); their central part is proportional to $\sum_a f^{ca}{}_a$, a would-be multiple of the identity, which vanishes by Proposition 23.3(2).

Altogether $[J^c_n,L_m]=\frac{2nk+2nh}{2(k+h)}J^c_{m+n}=n\,J^c_{m+n}$; this is where the prefactor $1/(2(k+h))$ comes from, and where $k+h\neq 0$ is used. Consequences: since also $L_m|0\rangle=0$ for $m\geq -1$, L_0 applied to a monomial $J^{a_1}_{-n_1}\cdots J^{a_r}_{-n_r}|0\rangle$ gives $(n_1+\cdots+n_r)$ times it, so L_0 is the energy and equals $-\ell_0$; and L_{-1} agrees with the translation operator on the generating fields, hence everywhere.

(c) Virasoro. By the Borcherds commutator formula $[L_m,L_n]$ is determined by the products $\omega_{(j)}\omega$, $j=0,1,2,3$: $\omega_{(0)}\omega=L_{-1}\omega$, $\omega_{(1)}\omega=2\omega$ (by (b), ω has weight 2), $\omega_{(2)}\omega=L_1\omega=0$ (by (b), $L_1J^a_{-1}J^b_{-1}|0\rangle=J^a_0J^b_{-1}|0\rangle=[b_a,b_b]_{(-1)}|0\rangle$, and $\sum_{a,b}\kappa^{ab}[b_a,b_b]=0$ because κ^{ab} is symmetric and the bracket antisymmetric), and $\omega_{(3)}\omega=L_2\omega=\frac{c}{2}|0\rangle$. The last one is a two-line computation. On the vacuum only $p=-1$ survives in L_{-2}, so $\omega=\frac{1}{2(k+h)}\sum_{a,b}\kappa^{ab}J^a_{-1}J^b_{-1}|0\rangle$. By (b), $[L_2,J^a_{-1}]=J^a_1$, and $L_2|0\rangle=0=J^b_1|0\rangle$, so

$$L_2\,J^a_{-1}J^b_{-1}|0\rangle=J^a_1J^b_{-1}|0\rangle=[J^a_1,J^b_{-1}]|0\rangle=\Big(\sum_d f^{ab}{}_dJ^d_0+k\kappa_{ab}\Big)|0\rangle=k\kappa_{ab}|0\rangle.$$

Hence $L_2\omega=\frac{k}{2(k+h)}\sum_{a,b}\kappa^{ab}\kappa_{ab}\,|0\rangle=\frac{k\dim\mathfrak{g}}{2(k+h)}|0\rangle$ by Proposition 23.3(3), i.e. $c=k\dim\mathfrak{g}/(k+h)$. □

Example 23.8 ($\mathfrak{sl}_2$: the Sugawara construction by hand)**.** Continue Example 23.2: $\kappa=\mathrm{tr}$, $h=2$, basis e,H,f, dual family $f,\frac12H,e$. Then

$$L_m=\frac{1}{2(k+2)}\sum_{p\in\mathbb{Z}}:\big(J^e_pJ^f_{m-p}+J^f_pJ^e_{m-p}+\tfrac12J^H_pJ^H_{m-p}\big):.$$

Check of (b) on $v=J^e_{-1}|0\rangle$: we show $L_0v=v$. In L_0, the terms with $p\neq 0$ that can act nontrivially on the weight-one vector v are those whose right-hand factor has mode $+1$ (modes ≥ 2 kill weight-one

vectors); by the symmetry of the sum the $p=-1$ and $p=+1$ terms contribute equally, giving $\frac{2}{2(k+2)}\big(J^e_{-1}J^f_1+J^f_{-1}J^e_1+\frac12 J^H_{-1}J^H_1\big)v$. Using $[J^x_1,J^e_{-1}]=J^{[x,e]}_0+k\,\mathrm{tr}(xe)$: $J^f_1 v=k|0\rangle$ (since $\mathrm{tr}(fe)=1$ and $J^{-H}_0|0\rangle=0$), $J^e_1 v=0$ ($\mathrm{tr}(ee)=0$), $J^H_1 v=0$ ($\mathrm{tr}(He)=0$). So this part is $\frac{2k}{2(k+2)}v$: the *Schwinger* contribution $2k$. The $p=0$ term is $\frac{1}{2(k+2)}\big(J^e_0J^f_0+J^f_0J^e_0+\frac12 J^H_0J^H_0\big)v$; zero modes act on weight one by the adjoint action, $J^x_0J^y_{-1}|0\rangle=J^{[x,y]}_{-1}|0\rangle$, so this is $\frac{1}{2(k+2)}J^{C(e)}_{-1}|0\rangle=\frac{4}{2(k+2)}v$: the *Casimir* contribution $2h=4$. Total: $L_0v=\frac{2k+4}{2(k+2)}v=v$, as claimed; with the naive prefactor $1/(2k)$ one would get $\frac{k+2}{k}v$ instead.

Central charge. $\omega=\frac{1}{2(k+2)}\big(J^e_{-1}J^f_{-1}+J^f_{-1}J^e_{-1}+\frac12 J^H_{-1}J^H_{-1}\big)|0\rangle$, and by the computation in (c), $L_2\omega=\frac{k}{2(k+2)}\big(\mathrm{tr}(ef)+\mathrm{tr}(fe)+\frac12\mathrm{tr}(HH)\big)|0\rangle=\frac{3k}{2(k+2)}|0\rangle$. Hence $c=\frac{3k}{k+2}$: at $k=1$, $c=1$, the central charge of one free boson, in accordance with the Frenkel–Kac picture $L_1(\mathfrak{sl}_2)\cong V_{\sqrt{2}\mathbb{Z}}$ (motivation only, as for $\mathfrak{e}_8$).

Physical meaning

This is the chiral algebra of the WZW model of G at level k, before any null vectors are removed: the "universal" theory whose states are all polynomials in the current modes. The theorem says its stress tensor is the Sugawara tensor and its central charge is $k\dim G/(k+h)$. For instance, for $\mathfrak{e}_8$ in the standard normalization ($h=h^\vee=30$) at level 1, $c=248\cdot 1/31=8$, the central charge of eight free bosons on the E_8 torus, as the Frenkel–Kac isomorphism $L_1(\mathfrak{e}_8)\cong V_{E_8}$ requires. (This match is arithmetic on paper; the library does not relate the two VOAs.)

What the machine verified

Proved; `#print axioms affineVOA` = `[propext, Classical.choice, Quot.sound]` (re-run for this chapter, Section 23.12). **`#print axioms`-clean, conditional on the Lie data** D (which is a hypothesis about $\mathfrak{g}$, discharged for every simple $\mathfrak{g}$ in Section 23.5).

Trap: The general files keep $\mathfrak{sl}_3$ docstrings

The files of `VOA/AffineGeneral/` up to `Virasoro.lean` were generated from the $\mathfrak{sl}_3$ files `VOA/Examples/AffineSl3*.lean` by a mechanical substitution (`Notes/deligne/campaign/aff_port.py`: `Fin 8`$\to\iota$, $6\to 2h$, $3\to h$). The code was ported; the prose was not. Each such file now opens with a disclaimer ("Where the text below says $\mathfrak{sl}_3$, `Fin 8`, 6 or 3, read $\mathfrak{g}$, ι, $2h$ and h"), but many docstrings remain literally false for general $\mathfrak{g}$: the module title of `Virasoro.lean` is "The actual sl3 Sugawara Virasoro algebra" and says "central charge $8k/(k+3)$"; the docstring of `centralChargeA` says "using dimension eight and dual Coxeter number three" although the code is `(Fintype.card ι : ℂ) * k / (k + D.h)`; the docstring of `sugawaraField` gives the prefactor "$1/(2(k+3))$"; `hYA_virasoro`'s says "$c=8k/(k+3)$"; `WeightOne.lean` is titled "The actual weight-one space of the affine sl3 vacuum". A reader must trust the *code*, which this book quotes. Listed in Section 23.13.

23.5 Every simple Lie algebra

23.5.1 The Casimir is a scalar

The one non-automatic field of Lie data is the Casimir eigenvalue. For simple $\mathfrak{g}$ it is supplied by Schur's lemma.

Theorem 23.9 (Adjoint Casimir of a simple Lie algebra). *Let $\mathfrak{g}$ be a finite-dimensional simple complex Lie algebra, κ a symmetric invariant form, (b_i) a basis and (b^i) a family with $\kappa(b_i, b^j) = \delta_{ij}$. Then there is $c \in \mathbb{C}$ with $\sum_i [b_i, [b^i, x]] = cx$ for all x.*

File `VOA/AffineGeneral/Casimir.lean`.

```
def casimirOp : Module.End ℂ 𝔤 :=
  ∑ i, (LieModule.toEnd ℂ 𝔤 𝔤 (b i)) ∗ (LieModule.toEnd ℂ 𝔤 𝔤 (d i))

theorem casimir_commute (y x : 𝔤) : casimirOp b d ⁅y, x⁆ = ⁅y, casimirOp b d x⁆ := by

theorem casimir_scalar [FiniteDimensional ℂ 𝔤] [LieAlgebra.IsSimple ℂ 𝔤] :
    ∃ c : ℂ, ∀ x : 𝔤, ∑ i, ⁅b i, ⁅d i, x⁆⁆ = c • x := by
```

From the mathematics to the Lean statement

The section variables are `hinv : κ.IsInvariant`, `b : Module.Basis ι ℂ 𝔤`, `d : ι → 𝔤` and `pair : ∀ i j, κ (b i) (d j) = if i = j then 1 else 0`; they are hypotheses of both theorems (added by `include hinv pair`). `LieModule.toEnd ℂ 𝔤 𝔤 x` is $\mathrm{ad}(x)$. `LieAlgebra.IsSimple ℂ 𝔤` is Mathlib's simplicity: every ideal is 0 or $\mathfrak{g}$, and $\mathfrak{g}$ is not abelian (so $\mathfrak{g} \neq 0$). Same as the textbook.

Proof on paper. *Commutation*: by the Jacobi identity, $[y,[b_i,[b^i,x]]] = [[y,b_i],[b^i,x]] + [b_i,[[y,b^i],x]] + [b_i,[b^i,[y,x]]]$; expanding $[y,b_i] = \sum_j \kappa([y,b_i],b^j)b_j$ and $[y,b^i] = \sum_j \kappa([y,b^i],b_j)b^j$, the first two sums cancel because invariance gives $\kappa([y,b_i],b^j)+\kappa([y,b^j],b_i) = 0$. *Scalar*: $\mathfrak{g} \neq 0$ is finite-dimensional over the algebraically closed $\mathbb{C}$, so C has an eigenvalue μ; by commutation the eigenspace is an ideal; it is nonzero, hence all of $\mathfrak{g}$ by simplicity. □

Physical meaning

The adjoint Casimir is the quadratic Casimir of G in the representation carried by the currents themselves; Schur's lemma (irreducibility of the adjoint of a simple group) makes it a number. Half of it, h, is the shift that turns the classical level k into $k + h$ in the quantum theory. Its value depends on the normalization of κ: it equals the dual Coxeter number $h^\vee$ only when κ gives long roots squared length 2, and the theorem here does not compute it.

What the machine verified

Proved; `#print axioms casimir_scalar` standard (re-run).

23.5.2 $V^k(\mathfrak{g})$ for every simple $\mathfrak{g}$

Theorem 23.10 (Universal affine VOA of a simple Lie algebra). *Let $\mathfrak{g}$ be a finite-dimensional simple complex Lie algebra.*

1. *For every nondegenerate symmetric invariant κ there is Lie data indexed by $\{0, \dots, \dim \mathfrak{g} - 1\}$, with $h = \frac{1}{2}\mu$, μ the Casimir eigenvalue; for every k with $k + h \neq 0$ the universal affine VOA exists, with central charge $\dim \mathfrak{g} \cdot k/(k + h)$.*
2. *The Killing form $\mathrm{Kil}(x, y) = \mathrm{tr}(\mathrm{ad}\, x\ \mathrm{ad}\, y)$ is symmetric, invariant and nondegenerate, and in its normalization $h = \frac{1}{2}$.*
3. *For every complex number $\nu \neq 0$ the form $\kappa = \mathrm{Kil}/(2\nu)$ gives Lie data with Casimir number $h = \nu$, and for $k + \nu \neq 0$ the VOA $V^k(\mathfrak{g})$ in this normalization has central charge $\dim \mathfrak{g} \cdot k/(k + \nu)$. (Here ν is a free parameter, Lean's `hv`; only for $\nu = h^\vee(\mathfrak{g})$ is $\mathrm{Kil}/(2\nu)$ the standard normalization, which must be proved separately for each type.)*

File `VOA/AffineGeneral/Simple.lean` (and `VOA/AffineGeneral/Casimir.lean` for `LieData.ofSimple`).

```
def ofSimple [FiniteDimensional ℂ 𝔤] [LieAlgebra.IsSimple ℂ 𝔤] (hinv : κ.IsInvariant)

     ↪ hv) := by
```

From the mathematics to the Lean statement

The section variables are `(𝔤 : Type*) [LieRing 𝔤] [LieAlgebra ℂ 𝔤] [FiniteDimensional ℂ 𝔤] [LieAlgebra.IsSimple ℂ 𝔤]`: every statement assumes $\mathfrak{g}$ finite-dimensional and simple, and nothing else. `Module.finBasis ℂ 𝔤` is a basis indexed by `Fin (finrank ℂ 𝔤)` chosen by Mathlib (noncomputably); `Module.finrank` is the dimension. `killingForm ℂ 𝔤` is Mathlib's Killing form; its nondegeneracy `LieAlgebra.IsKilling.killingForm_nondegenerate` is available because Mathlib derives `IsKilling` from simplicity via Cartan's criterion (`HasTrivialRadical.instIsKilling`),

so no separate hypothesis is needed.
The h of `simpleData` *is not computed*: it is half of an eigenvalue chosen by `Classical.choose` from `casimir_scalar`. Hence the non-criticality hypothesis of `universalAffineVOA` is stated as `k + (simpleData 𝔤 κ hinv hnd).h ≠ 0`, which a user can only check by computing that h; `killing_h` does this for the Killing form ($h = \frac{1}{2}$), and `standardData_h` for its rescalings.
The word "standard". Write ν for Lean's `hv`. `standardData 𝔤 hv hhv` is Lie data for Kil $/(2\nu)$ and `standardData_h` says its Casimir number equals ν — for *every* nonzero ν. This is a tautology of rescaling (the Killing normalization has $h = \frac{1}{2}$, and multiplying the form by $(2\nu)^{-1}$ divides h by $(2\nu)^{-1}$, giving ν), not a computation of the dual Coxeter number. The form Kil $/(2\nu)$ is the standard normalization (long roots of squared length 2) if and only if $\nu = h^\vee(\mathfrak{g})$; for the types used later this is proved separately (Theorem 23.32 and the `*_standard` theorems of Section 23.9). Thus `standardAffineVOA 𝔤 hv _ k _` is *the* $V^k(\mathfrak{g})$ of the literature only once $\nu = h^\vee$ is established. For $\mathfrak{sl}_n$ this identification is not in Lean (see the warning box in Section 23.7). Otherwise same as the textbook.

Proof on paper. (1) Theorem 23.9 provides the Casimir eigenvalue; Mathlib's `dualBasis` provides the dual family; Theorem 23.7 does the rest. (2) Symmetry and invariance of the trace form are Mathlib facts. For h: $\operatorname{tr} C = \sum_i \operatorname{tr}(\operatorname{ad} b_i \operatorname{ad} b^i) = \sum_i \operatorname{Kil}(b_i, b^i) = \dim \mathfrak{g}$, while $C = 2h \cdot \mathrm{id}$ has trace $2h \dim \mathfrak{g}$, so $h = \frac{1}{2}$. (3) Rescaling (Definition 23.4): $h = \frac{1}{2} \cdot 2\nu = \nu$. Central charges: $|\mathrm{Fin}\, n| = n$. □

Physical meaning

Every simple compact gauge group G has a WZW current algebra, and this theorem says the library has its chiral algebra for every level except the critical one. In the Killing normalization the critical level is $k = -\frac{1}{2}$; in the normalization physicists use (long roots of length 2, $h^\vee$ the dual Coxeter number) it is $k = -h^\vee$, and integrable levels are positive integers.

What the machine verified

Proved; `#print axioms` standard for `universalAffineVOA`, `universalAffineVOA_centralCharge`, `killing_h`, `standardAffineVOA_centralCharge` (re-run, Section 23.12). **Unconditional** in the sense of this book: the only hypotheses are simplicity, finite dimension, nondegeneracy of the chosen form and non-criticality, all part of the intended statement. *What is proved*: the *universal* VOA $V^k(\mathfrak{g})$ (not $L_k(\mathfrak{g})$), with central charge $\dim \mathfrak{g} \cdot k/(k+h)$ where $2h$ is the adjoint Casimir eigenvalue of the chosen form, chosen by `Classical.choose`. *Not proved* for general $\mathfrak{g}$: that $h = h^\vee$; in `standardAffineVOA` the number h is the free parameter `hv`, and $h = h^\vee$ holds only per type through the `*_standard` theorems.

Naming: `universalAffineVOA` is $V^k(\mathfrak{g})$, `simpleAffineQuotientVOA` is $L_k(\mathfrak{g})$

The type of `universalAffineVOA` is `VertexOperatorAlgebra (AffineLie.vacuumSpace κ hinv k)`: the carrier is the full vacuum module, so this is $V^k(\mathfrak{g})$; the hypothesis `LieAlgebra.IsSimple ℂ 𝔤` concerns the Lie algebra. Until 28 October 2026 the declaration was called `simpleAffineVOA`, with "simple" referring to $\mathfrak{g}$, and the release audit flagged the name as misleading; it was renamed, and `simpleAffineVOA` survives only as a deprecated alias of `universalAffineVOA`. Its docstring says what it is ("universal affine VOA ... of a simple Lie algebra"). The simple quotient $L_k(\mathfrak{g})$ of an arbitrary simple $\mathfrak{g}$ is obtained by applying Definition 23.12 to `simpleData`, i.e. the term `simpleVOA (simpleData`

`𝔤 κ hinv hnd) k hk`. At the time of the release audit the library had no named declaration for it (the audit's search for `simpleVOA (simpleData` found nothing); since 2026-10-28 it is named `simpleAffineQuotientVOA` (Definition 23.14), whose module docstring records the former name. The naming now matches the mathematics: `universalAffineVOA` is $V^k(\mathfrak{g})$ and `simpleAffineQuotientVOA` is $L_k(\mathfrak{g})$. Anyone reading older code or notes should know that "`simpleAffineVOA`" there means $V^k(\mathfrak{g})$, not $L_k(\mathfrak{g})$. Two project notes made the slip (a layer-one summary, and a progress note speaking of "universal and simple affine VOAs"); the correct reading is "$V^k(\mathfrak{g})$ (`universalAffineVOA`) and its simple quotient $L_k(\mathfrak{g})$ (`simpleAffineQuotientVOA`, by definition `simpleVOA` applied to `simpleData`)". Source: release audit 2026-10-27, finding M1; the missing name is resolved by `VOA/AffineGeneral/SimpleAffineQuotient.lean`, the misleading old name by the renaming.

23.5.3 The $\mathfrak{sl}_3$ instance

As a consistency check the bespoke $\mathfrak{sl}_3$ data of `VOA/Examples/AffineSl3*.lean` are packaged as Lie data.

Proposition 23.11 ($\mathfrak{sl}_3$ Lie data). *The trace form, the Chevalley basis, its trace-dual family and $h = 3$ are Lie data for $\mathfrak{sl}_3$, and the resulting $V^k(\mathfrak{sl}_3)$ has central charge $8k/(k+3)$.*

File `VOA/AffineGeneral/Sl3Instance.lean`.

```
def sl3Data : LieData AffineSl3.form (Fin 8) where
  invariant := form_invariant
  basis := chevalleyBasis
  dual := dualGenerator
  pair i j := by rw [chevalleyBasis_apply]; exact generator_dual i j
  h := 3

theorem sl3VOA_centralCharge (k : ℂ) (hk : k + 3 ≠ 0) :
    (sl3VOA k hk).centralCharge = 8 * k / (k + 3) := by
```

From the mathematics to the Lean statement

`AffineSl3.form`, `chevalleyBasis`, `dualGenerator` and `adjoint_casimir` (used in the omitted `casimir` field) are the Lie-theoretic objects of the bespoke $\mathfrak{sl}_3$ files. `sl3VOA k hk` abbreviates `affineVOA sl3Data k hk`. The carrier is the same `vacuumSpace` as the bespoke `affineSl3VOA` of `VOA/Examples/AffineSl3Virasoro.lean`, but the two VOA structures are *not* proved equal in Lean. Same as the textbook.

Proof on paper. The fields are the $\mathfrak{sl}_3$ facts proved in the bespoke files; $C = 6 = 2 \cdot 3$. □

Physical meaning

$V^k(\mathfrak{sl}_3)$, the current algebra of $SU(3)$; at $k = 1$, $c = 2$, the two bosons of the A_2 torus.

What the machine verified

Proved; axioms standard (project record, Section 23.12).

23.6 The simple quotient $L_k(\mathfrak{g})$ and its weight-one space

23.6.1 The simple quotient

Chapter 5 (Section 5.4) defines, for any VOA W, the maximal graded ideal `maxGradedIdeal W` (the supremum of all proper graded ideals), the quotient `maxQuotientVOA W`, and proves that the quotient is simple among *all* ideals as soon as the vacuum of W is nonzero (`isSimple_maxQuotientVOA'`). The general construction applies this to $V^k(\mathfrak{g})$.

Definition 23.12 (The simple affine VOA). For Lie data D and $k + h \neq 0$, $L_k(\mathfrak{g}) = V^k(\mathfrak{g})/I_{\max}$, where $I_{\max}$ is the maximal graded ideal; the *current states* of $L_k(\mathfrak{g})$ are the images $[x_{(-1)}|0\rangle]$, $x \in \mathfrak{g}$.

File `VOA/AffineGeneral/SimpleQuotient.lean`.

```
def maxIdeal (k : ℂ) (hk : k + D.h ≠ 0) : Submodule ℂ (Vacuum D k) :=
  QuotVOA.maxGradedIdeal (affineVOA D k hk)

def simpleVOA (k : ℂ) (hk : k + D.h ≠ 0) : VertexOperatorAlgebra (Vacuum D k / maxIdeal D k
↪  hk) :=
  QuotVOA.maxQuotientVOA (affineVOA D k hk)

def simpleProjection (k : ℂ) (hk : k + D.h ≠ 0) : Vacuum D k →ₗ[ℂ] Vacuum D k / maxIdeal D
↪  k hk :=
  (maxIdeal D k hk).mkQ

def simpleCurrentState (k : ℂ) (hk : k + D.h ≠ 0) : 𝔤 →ₗ[ℂ] Vacuum D k / maxIdeal D k hk :=
  (simpleProjection D k hk).comp (currentState D k)
```

From the mathematics to the Lean statement

`/` is the quotient vector space, `mkQ` the quotient map. `currentState D k x` is $x_{(-1)}|0\rangle$, the action of $x \otimes t^{-1}$ on the vacuum (Definition 23.16 below). `→ₗ[ℂ]` is a $\mathbb{C}$-linear map. Same as the textbook, with one remark: the literature's $L_k(\mathfrak{g})$ is the quotient by the unique maximal proper ideal; since $V^k(\mathfrak{g})$ is of CFT type every ideal not containing $|0\rangle$ is graded (by L_0-stability), so the maximal graded ideal is that ideal (Chapter 5).

Why this definition. Quotienting by the *maximal* graded ideal is the only choice that yields a simple VOA without knowing the ideal explicitly; this is what makes $L_k(\mathfrak{g})$ available for every k even though its null vectors are known only at special levels. The price is that the definition displays nothing about $I_{\max}$; facts about it (such as Theorem 23.19) must be proved separately.

Physical meaning

$L_k(\mathfrak{g})$ is the chiral algebra in which all null states (states orthogonal to everything, equivalently generating proper ideals) are set to zero: the physical theory. At positive integer level it is the WZW chiral algebra; at the Deligne levels it is (by the physics literature quoted in Section 23.2) the four-dimensional $\mathcal{N} = 2$ chiral algebra of Chapters 24–27.

What the machine verified

Definitions (no proof obligation); `simpleVOA` is a VOA because `maxQuotientVOA` is (Chapter 5). For an arbitrary finite-dimensional simple $\mathfrak{g}$ with form κ, $L_k(\mathfrak{g})$ is the term `simpleVOA (simpleData 𝔤 κ hinv hnd) k hk`, named `simpleAffineQuotientVOA` (Section 23.6.2); it is *not* `universalAffineVOA`, which is $V^k(\mathfrak{g})$ (warning box in Section 23.5.2).

Theorem 23.13 (Simplicity, and weight one is spanned by the currents). *For Lie data D and $k+h \neq 0$: $L_k(\mathfrak{g})$ is a simple VOA, and its weight-one space is the image of $x \mapsto [x_{(-1)}|0\rangle]$; in particular each basis current lies in weight one.*

File `VOA/AffineGeneral/SimpleQuotient.lean`.

```
theorem simpleVOA_isSimple (k : ℂ) (hk : k + D.h ≠ 0) : (simpleVOA D k hk).IsSimple :=
  QuotVOA.isSimple_maxQuotientVOA' (affineVOA D k hk) (vacuumA_ne_zero D k)

theorem simple_grading_one_eq_range (k : ℂ) (hk : k + D.h ≠ 0) :
    (simpleVOA D k hk).grading 1 = LinearMap.range (simpleCurrentState D k hk) := by

theorem simpleCurrentState_mem (k : ℂ) (hk : k + D.h ≠ 0) (i : ι) :
    simpleCurrentState D k hk (D.generator i) ∈ (simpleVOA D k hk).grading 1 := by
```

From the mathematics to the Lean statement

`IsSimple` is the definition of Chapter 5: the carrier is nonzero and every ideal is 0 or everything. `LinearMap.range` is the image. The proof term of `simpleVOA_isSimple` is displayed because it is informative: the only input beyond the general theory of Chapter 5 is `vacuumA_ne_zero` (relative PBW). Without it, the "simple quotient" of a zero VOA would be zero and `IsSimple` would fail; so the theorem is not vacuous. Same as the textbook.

Proof on paper. Simplicity is the general fact of Chapter 5. Weight one: the vacuum module is induced, $V^k(\mathfrak{g}) = U(\hat{\mathfrak{g}}_-)|0\rangle$ with $\hat{\mathfrak{g}}_- = \mathfrak{g} \otimes t^{-1}\mathbb{C}[t^{-1}]$, so by the PBW theorem it is spanned by the monomials $J^{a_1}_{-n_1} \cdots J^{a_r}_{-n_r}|0\rangle$ ($n_i \geq 1$), of weight $n_1 + \cdots + n_r$. A monomial of weight one has exactly one letter, of mode -1; so $V^k(\mathfrak{g})_1$ is spanned by the $x_{(-1)}|0\rangle$. (In Lean this "creation-word spanning" is `grading_one_eq_range`, Theorem 23.17.) The quotient map preserves the grading and is surjective in each degree. □

Physical meaning

The weight-one states of a chiral algebra are its conserved currents, i.e. its continuous symmetries. The theorem says $L_k(\mathfrak{g})$ has no currents other than those of $\mathfrak{g}$: quotienting cannot create new symmetries.

What the machine verified

Proved; axioms standard (re-run).

23.6.2 The named simple affine VOA $L_k(\mathfrak{g})$ of a simple Lie algebra

For Lie data built from a simple $\mathfrak{g}$ by `simpleData` (Theorem 23.10), the simple quotient of Definition 23.12 is the term `simpleVOA (simpleData g κ hinv hnd) k hk`. Since 2026-10-28 the library gives it a name of its own and transports the facts just proved to it. Nothing new is proved here mathematically; the point is that a reader (or a later chapter) can now write "$L_k(\mathfrak{g})$" as a single Lean name, and the name says what it is. Together with the renaming recorded in Section 23.5.2, the two names now say what they are: `universalAffineVOA` is the *universal* algebra $V^k(\mathfrak{g})$, `simpleAffineQuotientVOA` its simple quotient.

Definition 23.14 (The simple affine VOA $L_k(\mathfrak{g})$, named)**.** Let $\mathfrak{g}$ be a finite-dimensional simple complex Lie algebra, κ a nondegenerate invariant bilinear form on it, h the Casimir number of κ (half the eigenvalue of the adjoint Casimir built from κ), and $k \in \mathbb{C}$ with $k + h \neq 0$. Then

$$L_k(\mathfrak{g}) \;=\; V^k(\mathfrak{g})/I_{\max},$$

the quotient of the universal affine VOA by its maximal graded ideal, with the induced VOA structure, and $\pi : V^k(\mathfrak{g}) \to L_k(\mathfrak{g})$ denotes the quotient map.

From the mathematics to the Lean statement

The section variables are those of Theorem 23.10: `(𝔤 : Type*) [LieRing 𝔤] [LieAlgebra ℂ 𝔤] [FiniteDimensional ℂ 𝔤] [LieAlgebra.IsSimple ℂ 𝔤]`. The explicit arguments are the form κ (`LinearMap.BilinForm ℂ 𝔤`, a bilinear form), its invariance `hinv` ($\kappa([x,y],z) = \kappa(x,[y,z])$), its nondegeneracy `hnd`, the level k, and the non-criticality hypothesis `hk`: $k+h \neq 0$ with h the Casimir number of `simpleData`, exactly the hypothesis of `universalAffineVOA`. (Symmetry of κ is not among the explicit hypotheses.) The carrier `Vacuum (simpleData 𝔤 κ hinv hnd) k / maxIdeal (simpleData 𝔤 κ hinv hnd) k hk` is the quotient vector space of the vacuum module by the maximal graded ideal of Definition 23.12; `Vacuum D k` is an `abbrev` for `vacuumSpace κ D.invariant k` (file `VOA/AffineGeneral/Currents.lean`), the carrier of `universalAffineVOA`.

Both definitions are one-line abbreviations, and the one-line bodies are shown because they *are* the definition: `simpleAffineQuotientVOA` is literally `simpleVOA` (Definition 23.12) applied to `simpleData`, and `simpleAffineQuotientProjection` is literally `simpleProjection`, i.e. `mkQ`, the quotient map. So the named object is the term the earlier status boxes described; no new choice is made. The docstring of the module says that `universalAffineVOA` is the universal algebra and records its former name. As in `universalAffineVOA`, the Casimir number h is the one chosen by `Classical.choose`; it equals $h^\vee$ only after the per-type normalization theorems (Section 23.9). Same as the textbook, with the normalization caveat of Theorem 23.10.

Why it could have been wrong, and is not. A wrapper with this name could have been a definition of something else (for instance the universal algebra again, which is what the former name `simpleAffineVOA` suggested to readers). The body `simpleVOA (simpleData …) k hk` and the carrier type, a quotient by `maxIdeal`, exclude this. A quotient by the maximal graded ideal could also be degenerate (zero) if the vacuum were zero; Theorem 23.15 below records simplicity, which includes nonvanishing.

Physical meaning

$L_k(\mathfrak{g})$ is the physical current algebra (the chiral algebra of the WZW model at positive integer level, of the four-dimensional $\mathcal{N} = 2$ theories at the Deligne levels), in which every null state has been set to zero. The projection π is the statement "compute in the universal algebra, then impose the null relations": physicists do exactly this when they write correlators of currents first and then remove null descendants.

What the machine verified

Definitions (no proof obligation). `#print axioms` for both reports `[propext, Classical.choice, Quot.sound]` (re-run for this chapter, Section 23.12). The file is

imported by the umbrella through `VOA/AffineGeneral/All.lean`; the targeted and umbrella builds are recorded green with standard axioms (`Notes/RELEASE_PLAN.md`, "Caveats removed in Lean", 2026-10-28); the aggregate build was green in pre-release builds on 2026-10-28 (18,901 jobs; 18,907 after a merge); for the release build see Chapter 43, Section 43.1.9. Not re-run for this chapter.

Theorem 23.15 (Properties of the named $L_k(\mathfrak{g})$)**.** *In the setting of Definition 23.14:*

1. *$L_k(\mathfrak{g})$ is a simple VOA (nonzero, and every ideal is 0 or everything);*
2. *its central charge is $\dim \mathfrak{g} \cdot k/(k+h)$, the same as that of $V^k(\mathfrak{g})$;*
3. *π is a homomorphism for all products: $\pi(u_{(n)}v) = \pi(u)_{(n)}\pi(v)$ for all $u, v \in V^k(\mathfrak{g})$ and $n \in \mathbb{Z}$;*
4. *π is surjective;*
5. *π preserves conformal weight: if $x \in V^k(\mathfrak{g})_n$ then $\pi(x) \in L_k(\mathfrak{g})_n$, for every $n \in \mathbb{Z}$.*
